#1 Androgens in glioblastoma: effect of testosterone on the maintenance of glioma stem-like cells.
Juan Carlos Quintero-Gallegos[1], Karina Hernandez-Ortega[2], Martha Robles-Flores[3], Nestor Fabian Diaz[4], Ignacio Camacho-Arroyo[1]

[1]Unidad de Investigacion en Reproduccion Humana, Instituto Nacional de Perinatologia- Facultad de Quimica, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico,[2]Departamento de Biologia, Facultad de Quimica, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico,[3]Departamento de Bioquimica, Facultad de Medicina, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico,[4]Departamento de Fisiologia y Desarrollo Celular, Instituto Nacional de Perinatologia, Mexico City, Mexico

Glioblastoma is the most common and lethal primary malignant tumor of the central nervous system, with a prevalence 1.6 times more frequent in men than in women, suggesting that sex hormones such as androgens play an important role in tumor progression. Poor prognosis has been associated with the presence of cancer stem cells that in glioblastoma are known as glioma stem cells. There is evidence that patients with glioblastoma have a higher serum concentration of testosterone, as well as a higher expression of the androgen receptor. In addition, the use of androgen receptor antagonists reduces the percentage of cancer stem cells. However, the role of testosterone in regulating stemness is unknown. In this study we analyzed the role of testosterone (100 nM) in processes associated with stem cell maintenance in the human glioblastoma cell lines U251 and T98G. Analyzing the presence of the androgen receptor, a higher expression was found in stem cell-enriched suspension cultures compared to monolayer cultures. The sequences of the stemness-associated genes PROM1, SOX2 and NES presented androgen response elements in their promoter regions. Consistently, testosterone increased the expression of these genes in stem cell-enriched cultures. Additionally, the self-renewal was evaluated by neurosphere generation assays, finding that testosterone favored the generation of primary and secondary neurospheres. Taken together, these results suggest that testosterone regulates the growth of cancer stem cells present in human glioblastoma by promoting the expression of stemness-associated genes as well as their self-renewal.

#100 L1CAM(CD171) can be highly expressed in many tumor types but lacks strong associations with tumor phenotype.

Seyma Buyucek[1], Magali Lurati[1], Katharina Moller[1], Florian Viehweger[1], Ria Schlichter[1], Anne Menz[1], Andreas M Luebke[1], Viktor Reiswich[1], Martina Kluth[1], Elena Bady[1], Lisa Hornsteiner[1], Claudia Hube-Magg[1], Andrea Hinsch[1], Florian Lutz[1], Soren Weidemann[1], Frank Jacobsen[1], David Dum[1], Christian Bernreuther[1], Patrick Lebok[1], Guido Sauter[1], Andreas H Marx[2], Ronald Simon[1], Christoph Fraune[1], Natalia Gorbokon[1], Eike Burandt[3], Sarah Minner[1], Stefan Steurer[1], Till S Clauditz[3], Till Krech[1], Viktoria Chirico[1], **Maximilian Lennartz**[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Academic Hospital Fuerth, Fuerth, Germany,[3]Miamedes Health Group, Hamburg, Germany

The cell adhesions molecule L1 (CD171; L1CAM) was initially characterized as an essential protein for neural development but subsequent studies have pinpointed towards a critical role in cancer. Because of its expression in only few normal tissues and its membranous nature L1CAM is a promising drug target. To better comprehend the role of L1CAM expression in different cancer types, a tissue microarray containing 20,079 samples from 135 different tumor entities and 608 samples of 76 different normal tissue types was analyzed. A membranous L1CAM staining was found in 1175 (9.1%) of the 12888 interpretable tumor samples, including 301 (2.3%) with weak, 569 (4.4%) with moderate, and 305 (2.4%) with strong positivity. A total of 73 of 135 tumor entities showed L1CAM expression in at least one case, and 36 tumor categories included at least one case with strong L1CAM staining. The frequency of L1CAM positivity was particularly high in several subtypes of neural and neuroendocrine neoplasms (11.1-100%), endometrium carcinoma (15.4-54.8%), ovarian cancer (22.0-44.6%), cervical adenocarcinoma (27.3%), malignant melanoma (25.3-31.0%), malignant mesothelioma (20.0-29.2%), adenocarcinomas of the gastrointestinal and the biliopancreatic tractus (9.1-18.9%), and in advanced urothelial tumors (13.0-18.2%). In urinary bladder cancer, there was a significant association between L1CAM expression and invasive tumor growth (pTa vs. pT2-4, $p<0.0001$). In colorectal adenocarcinoma, L1CAM positivity was linked to left-sided tumor location and microsatellite instability. However, L1CAM staining was unrelated to tumor phenotype in muscle-invasive urothelial carcinoma, clear cell and papillary renal cell carcinoma, serous high-grade carcinoma of the ovary, endometrioid endometrium carcinoma, gastric adenocarcinoma, and in pancreatic adenocarcinoma. It is concluded that many different tumor entities could benefit from L1CAM targeting drugs once these should provide sufficiently safe and efficient. However, L1CAM expression does not appear to confer an aggressive phenotype to affected cancer cells.

#1000 Impact of *GSTP1 Ile105Val* genetic polymorphism on cervical cancer risk among Bangladeshi female population.

Md. Mustafizur Rahman[1], Md Mehedi Hasan[1], Abdur Rahman Munna[1], Amir Hossain[2]

[1]Pharmacy Discipline, Khulna University, Khulna, Bangladesh,[2]Department of Pharmacy, Dhaka International University, Dhaka, Bangladesh

Background and aim: Worldwide, cervical cancer is both the fourth-most common cause of cancer and the fourth-most common cause of death from cancer in women. Approximately 90% of deaths from cervical cancer occurred in low- and middle-income countries. Glutathione S-transferase P1 (GSTP1) is a xenobiotic metabolizing (detoxifying) enzyme. Studies have suggested that GSTP1 genetic polymorphism in exon 5 (Ile105Val, *GSTP1 A313G*) may play important role in determining susceptibility to cervical cancer, though the data have often been inconsistent.

Objective: This study aimed to investigate the association of the *GSTP1* Ile105Val polymorphism with the prevalence and risk of cervical cancer in Bangladeshi females. We also aimed at finding any correlation between demographic variables and polymorphic genotypes in cervical cancer patients.

Materials and Methods: Polymerase chain reaction (PCR) followed by restriction fragment length polymorphism (RFLP) were performed to genotype GSTP1 polymorphism (Ile105Val). Genomic DNA was isolated from venous blood collected from 117 pathologically diagnosed squamous cell cervical cancer patients and 150 healthy females.

Results: The homozygous variant (G/G) genotypes and heterozygous plus variant (A/G+G/G) genotypes showed 3.17 fold (OR= 3.1746, 95% CI= 1.037 to 9.7187, p=0.043) and 1.71 fold (OR= 1.7143, 95% CI= 1.0425 to 2.8189, p=0.0337) increased risk of cervical cancer when compared to homozygous wild type (A/A) genotypes, respectively. The allele frequency distribution of A and G in cases and controls also associated with increased cervical cancer risk (OR= 1.677, 95% CI= 1.1129 to 2.5271) and the result is statistically significant ($p<0.05$). However, there was no significant combined effects of demographic variables ($p>0.05$) and *GSTP1* genotypes in cancer development.

Conclusion: *GSTP1*genetic polymorphism (Ile105Val) could influence susceptibility to cervical cancer among Bangladeshi women.

#1001 Leveraging Electronic Health Records to examine the real-world rates of cancer genetics referrals in a Singapore healthcare cluster.

Jonathan Jian Hao Soon[1], Jianglei Wu[1], Nur Diana Binte Ishak[1], See Wei Qiang[2], Hing Pong Matthew Che[2], Michael Dorosan[2], Jeanette Yuen[1], Andrea Wan Ling Tan[1], Marcus Eng Hock Ong[2], Sean Shao Wei Lam[2], Hwee Lin Wee[3], Jianbang Chiang[1], Joanne Ngeow[1]

[1]Cancer Genetics Service, National Cancer Centre Singapore, Singapore, Singapore,[2]Health Services and Systems Research, Duke-NUS Medical School, Singapore, Singapore,[3]Saw Swee Hock School of Public Health, National University of Singapore, Singapore, Singapore

Identifying patients with hereditary cancer syndromes through genetics referral enhances early detection and reduces healthcare costs. Despite potential benefits, genetics referral rates globally, including Singapore, remain low. This study investigates the real-world rates of genetics referrals in eligible cancer patients at Singapore's largest healthcare cluster using Electronic Health Records. Referral criteria for genetics referrals were based on international guidelines. The institution's data repository was queried for eligible patients with relevant diagnosis codes from 2017 to 2021. We assessed genetics clinic attendance among eligible patients to evaluate referral rates. Variations in referral rates over time were analyzed using linear regression and two-tailed t-test. Of the 10080 patients eligible for a genetics referral, 17.1% (1719) were referred to a cancer genetics clinic. Breast, ovarian, colorectal, and endometrial cancers accounted for 42.9%, 33.5%, 11.3%, and 8.6% of referrals, respectively. Other tumor types accounted for 3.7% of referrals. Referral rates for suspected Hereditary Breast and Ovarian Cancer syndrome (HBOC)-related cancers were higher (19.7%) than referrals for suspected Lynch syndrome (12.2%). Among HBOC referrals, women (20.7%) were more likely to be referred than males (7.8%). From 2017 to 2021, the referral rates among eligible patients steadily increased from 11.6% (483/4174) in 2017 to 23.6% (403/1705) in 2021, an increase of 12%, p=0.005. From 2017 to 2021, we found an increase in referral rates for HBOC (12.8% to 28.6 %, p= 0.005) but not for Lynch syndrome-related indications (8% to 12.6%, p=NS). The increase in referral rates for suspected HBOC in women was more significant than in men (p=0.03) This study found lower referral rates for Lynch syndrome than HBOC, and identified a gender discrepancy, with men with HBOC being less likely to be referred. Efforts to increase referral rates should include raising clinician awareness and electronically identifying suspected cases, especially for male breast cancer and Lynch Syndrome.

#1002 BRCA2, ATM, and POT1 genes mutations in Chilean hereditary gastric cancer families.

Graciela Adriana Molina Fuentes[1], Ana Patricia Estrada-Florez[2], Paul Lott[2], Osvaldo Torres[3], Cedric Adelsdorfer[4], Alejandro H Corvalan[5], Luis Carvajal-Carmona[2]

[1]Escuela de Medicina. Facultad de Ciencias de la Salud, Universidad Autonoma de Chile, Santiago, Chile,[2]Genome Center and Department of Biochemistry and Molecular Medicine, School of Medicine, University of California Davis, Davis, CA,[3]Servicio de Cirugia. Equipo Cirugia Digestiva Alta, Hospital Regional Dr. Guillermo Grant Benavente de Concepcion, Concepcion, Chile,[4]Servicio de Cirugia, Hospital Dr. Gustavo Fricke de Vina del Mar, Vina del Mar, Chile,[5]Departamento de Hematologia y Oncologia., Pontificia Universidad Catolica de Chile and Advanced Center for Chronic Diseases, Santiago, Chile

The purpose of this study is to describe Chilean families having hereditary Gastric Cancer (GC) presenting pathogenic mutations in BRCA 2 (c.4740_4741dup NP_000050.3:p.Glu1581fs), ATM (c.3381_3384del NP_000042.3:p.Gln1128fs) and Protector of Telomers 1 (POT1, 1087C>T:p.Arg363Ter) genes. Only one hereditary diffuse GC (HDGC) Chilean family with a pathogenic *CDH1* mutation has been reported, suggesting a low frequency of pathogenic mutation detection in this population. Whole exome sequencing (WES) was performed using the Agilent SureSelect Human All Exome V7 kit and sequenced in a NovaSeq6000 (Illumina, Inc.) S4 150PE aiming 100x. Alignment and variant calling were performed using Illumina Dragen v3.8. Variant calls were re-calibrated using GATK v4 variant recalibration and annotated with Illumina Nirvana and Annovar. Genotypification of the index patient and their family was performed using KASP-PCR. The index patient having a BRCA2 mutation had metastatic HDGC and his mother had asynchronous breast cancer and GC. The family presenting an ATM gene mutation had three GC-affected subjects, the index patient, and both parents. The index patient of the family having a POT1 mutation presented a CG at 47 yr., and two of her children died of CG at 24 yr. All families show an incomplete penetrance and variable expressivity. We are searching for the second hit in the index patient´s tumor samples. This is the first report of a POT1 gene mutation detected in a hereditary GC. POT1 belongs to the shelterin complex that protects telomeres. This mutation affects the binding to the shelterin complex, and it was previously reported in colorectal cancer. #1003 Cascade genetic testing for hereditary cancer syndromes in Algerian population: pathways to precision medicine.

Farid Cherbal[1], Chiraz Mehemmai[1], Mouchira Saadi[1], Djamel-Eddine Seddik[1], Hassen Mahfouf[2], Wassila Benbrahim[3], Mohammed Oukkal[4]

[1]Molecular Genetics Team, LBCM-Tamayouz, Faculty of Biological Sci, USTHB, Algiers, Algeria,[2]Mohamed El Kolli Public Hospital, Academic Medical Oncology Services, Rouiba, School. of Medecine, University of Algiers-1, Algiers, Algeria,[3]Medical Oncology Services, Center Anti Cancer Batna, University Batna2 Chahid Mostefa Ben Boulaid, Batna, Algeria,[4]Clinic of Medical Oncology Amine Zirout, University Hospital of Beni-Messous, School of Medicine, University. of Algiers-1, Algiers, Algeria

Background: Cascade genetic testing helps to identify at risk relatives within hereditary cancer syndromes families with a known germline pathogenic variant in cancer predisposition genes (CPG). The detection of high-risk germline CPG variants in index cases and relatives makes available cancer prevention and precision medicine, respectively. To date, in Algeria, there is a limited access in clinical genetic services, mainly due to the costs and the availability of genetic testing. Here, we report cascade genetic testing in at risk relatives within hereditary breast and ovarian cancer syndrome (HBOC), Lynch syndrome (LS) and familial adenomatous polyposis syndrome (FAP) families, respectively.

Material and Methods: Our study included 7 HBOC families, 4 LS families and 3 FAP families. We screened 34 high risk relatives using PCR-Sanger sequencing for the following CPG germline pathogenic variants: c.181T>G, c.798_799delTT, c.2125-2126insA, c.5332+1G>A in *BRCA1* gene, c.1310_1313delAAGA, c.8940delA in *BRCA2*gene, c.1546C>T in *MLH1* gene, c.1605dupA, c.2544dupA and c.3584delT in *APC* gene, respectively.

Results: We detected *BRCA1* c.181T>G in the brother of the index case. *BRCA1* c.798_799delTT has been detected in the sister of the index case. *BRCA1* c..2125_2126insA has been detected in two unrelated families and it has been identified in 4 relatives in the first family and 4 relatives in the second family, respectively. In the first family, the sister, the father, the paternal aunt and her son have been tested positive for the variant. The father and the cousin of the index case were disease free. In the second family, the father, the paternal aunt and two brothers of the index case have been tested positive for the variant and were disease free. *BRCA1* c.5332+1G>A has been detected in 2 relatives. *BRCA2* c.1310_1313delAAGA has been detected in the sister and the father of the proband, while *BRCA2* c.8940delA has been identified in the mother and the sister of the proband. Interestingly, the mother was disease free at age 78 years in this family. For LS, *MLH1* c.1546C>T detected in 3 related families has been identified in 9 relatives in the first family, 2 relatives in the second family and 3 relatives in the third family. In the third family, *MLH1* c.1546C>T has been detected in both parents (mother and father) and in one brother. Interestingly, in this family, a young female sister (not tested) developed glioblastoma and died at age 4 years. As obligate carrier, we can conclude that the young sister developed a CMMRD syndrome. In regard to FAP syndrome, *APC* c.1605dupA has been detected in 3 sisters and one brother of the proband, *APC* c.2544dupA has been detected in one relative and *APC* c.3784delT has been identified in two relatives, respectively.

Conclusion: Cascade genetic testing in Algerian population will help to implement strategies to reduce the risk of cancer in families, promote public health and precision medicine.

#1004 Genome-wide analysis of the interaction between physical activity and genetic susceptibility on colorectal cancer incidence: A nested case-control study in the UK Biobank.

Sooyoung Cho[1], Aesun Shin[2]

[1]Genomic Medicine Institute, Medical Research Center, Seoul, Korea, Republic of,[2]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Colorectal cancer (CRC) risk is influenced by a complex interplay between genetic predisposition and lifestyle factors, such as physical activity (PA). To investigate potential gene-environment interactions, we conducted a genome-wide interaction study (GWIS) using data from the UK Biobank (proposal #94695).

Methods: Participants with prior cancer diagnoses, missing genotyping data, missing PA data, or missing covariates (e.g., deprivation index, BMI, smoking, alcohol) were excluded. Genotyping data underwent stringent quality control with thresholds set for minor allele frequency (MAF > 0.03), genotyping call rate (> 99%), and Hardy-Weinberg equilibrium ($p > 1 \times 10^{-6}$). After exclusions, 325,858 participants with the required covariates were included as the base population. From this cohort, 3,607 CRC cases were matched to 14,155 controls using a 1:4 incidence density matching approach based on sex, age at recruitment (±5 years), and follow-up duration (±6 months). PA was categorized based on whether participants met the World Health Organization guidelines: engaging in at least 150 minutes of moderate-intensity activity or 75 minutes of vigorous-intensity activity per week. Conditional logistic regression models were used to evaluate SNP × PA interactions, adjusting for BMI, smoking, alcohol consumption, deprivation index, the first ten genetic principal components, and batch effects. Interaction p-values ($P_{interaction}$) were derived from the statistical significance of the SNP × PA interaction term in the model.

Results: After quality control, 402,069 SNPs were retained for analysis. We could not find any SNPs that met the genome-wide significance threshold of $p < 1 \times 10^{-7}$. However, seven SNPs met the suggestive significance threshold of $p < 1 \times 10^{-5}$, including rs6791309 ($P_{interaction} = 1.20 \times 10^{-6}$), which had the lowest interaction p-value, and rs6770805 (3.65×10^{-6}), which is located within the *ADCY5* gene. Other suggestive variants were identified in genes such as *KCNIP4*, *CDH18* and *LOC124904472*.

Conclusions: This GWIS identified SNPs with suggestive evidence of interaction with PA in relation to CRC risk, although no variants achieved genome-wide significance. Variants in genes such as *ADCY5, KCNIP4*, *CDH18* and *LOC124904472* highlight loci that may contribute to CRC risk through gene-environment interactions. Further replication studies and functional analyses are necessary to validate these findings and uncover the underlying biological mechanisms.

#1005 Germline-somatic interactions in non-small cell lung cancer (NSCLC) patients from Latin America.

Freitas[15], NIRVANA team, Ricardo Armisen[2]

[1]Centro de Oncologia de Precision, Universidad Mayor, Santiago, Chile,[2]Centro Genetica y Genomica, Instituto de Ciencias e Innovacion en Medicina, Facultad de Medicina, Universidad del Desarrollo, Santiago, Chile,[3]CORFO Center of Excellence in Precision Medicine, Pfizer, Santiago, Chile,[4]Departamento de Oncologia Basico Clinica, Facultad de Medicina, Universidad de Chile, Santiago, Chile,[5]Advanced Center for Chronic Diseases and Department of Hematology and Oncology, Pontificia Universidad Catolica de Chile, Santiago, Chile,[6]National Institute of Health, NIDCR, Bethesda, MD,[7]Centro de Oncologia de Precision, Centro de Investigacion Clinica Bradford Hill, Santiago, Chile,[8]Instituto Nacional del Torax, Santiago, Chile,[9]Department of Pathology, Hospital Clinico Regional de Concepcion Dr. Guillermo Grant Benavente, Santiago, Chile,[10]Departamento de Salud Publica, Facultad de Medicina, Universidad Catolica del Norte, Antofagasta, Chile,[11]Departamento de Ciencias Biomedicas, Facultad de Medicina, Universidad Catolica del Norte, Antofagasta, Chile,[12]Servicio de Oncologia, Departamento de Medicina Interna, Hospital Clinico de la Universidad de Chile, Santiago, Chile,[13]Hospital de Puerto Montt, Puerto Montt, Chile,[14]Centro de Genomica y Bioinformatica, Universidad Mayor, Santiago, Chile,[15]Laboratory of Medical Genomics, A. C. Camargo Cancer Center, Sao Paulo, Brazil

Motivation: Tumors of non-small cell lung cancer (NSCLC) patients are heterogeneous entities. Genomic landscapes are influenced by genetic constitution, environmental exposures and the complex interaction between the two. In particular, it has been reported that germline variability specific to Latin American (LA) populations play an important role modulating the presence of acquired somatic alterations in *EGFR* and *KRAS,* two of the most clinically relevant actionable genes for lung cancer (LC). The influence of these specific genetic differences appears to be independent of smoking status, a key exogenous agent also known to influence LC genomic heterogeneity. However, LA patients are strikingly diverse and further studies are needed to better understand the influence of germline-somatic interaction on tumor variability across populations with different patterns of environmental exposures.

Methodology: The population derived from the study protocol *Characterization and Validation of Molecular Diagnostic Technologies for LC Patients from Chile, Brazil, and Peru* (clinicaltrials.gov NCT03220230). The recruitment period was July 2015 to October 2018 and encompassed 37 centers. From NSCLC samples, genomics profiles were assessed using the Oncomine Focus Assay (OFA), with QC-approved assays obtained for 1864 subjects. Relevant covariates were interrogated at enrollment. In the absence of matched normal tissue samples, an in-house algorithm was developed to distinguish germline from somatic variation. Descriptive statistics, Principal Component Analyses (PCA) and logistic regression were used to evaluate germline-somatic interactions.

Results and Conclusions: The in-house algorithm detected 738 unique germline variants and 6636 unique somatic alterations. The majority of the germline variants (80.8%, n=597) are reported in other populations with a Minor Allele Frequency (MAF) ≥ 1%; only a minority (19.1%, n=141) report a MAF either <1% or unknown. These rare germline variants are present in 98 study participants (5.3%) and are more common in the group of Chilean smoker patients with adenocarcinoma and advanced disease, and without a personal and family history of cancer (FHC). Statistical significance was found for cancer stage (stage IV: 80.8% [n=63] vs. 70.8% [n=823], p-value<0.05) and FHC (positive: 20.5% [n=16] vs. 31.9% [n=371], p-value<0.05). Regarding the relationship between germline and somatic alterations, we found a positive association for *EGFR*, *PIK3CA*, *ALK*, *FGFR4* and *ERBB2* and a negative association for the remaining genes (n=46). These findings provide novel insights into the influence of inherited genetic variability on the clinical presentation and somatic landscape of an underrepresented population. Identification of the underlying germline alleles can improve our understanding of the affected biological pathways for the subset of LCs driven by these alterations.

#1006 Local genetic ancestry among breast cancer rare mutation carriers from Lima, Peru.

Luqi Wang[1], Xiaosong Huang[1], Paul Lott[1], Elad Ziv[2], Susan L. Neuhausen[3], Tatiana Vidaurre[4], Laura Fejerman[1]

[1]University of California Davis, Davis, CA,[2]University of California San Francisco, San Francisco, CA,[3]City of Hope Comprehensive Cancer Center, Duarte, CA,[4]Instituto Nacional de Enfermedades Neoplasicas, Lima, Peru

Genetic predisposition to breast cancer is understudied in populations of high Indigenous American (IA) genetic ancestry. This gap in knowledge can lead to lack of equity in risk assessment and prediction. This study aimed to identify pathogenic/likely pathogenic (P/LP) variants and variants of unknown significance (VUS) in known cancer susceptibility genes in women with breast cancer from Lima, Peru, and test their ancestry-specificity. Whole exome sequencing was performed on 40 susceptibility genes in 1,364 women from the Peruvian Genomics of Breast Cancer (PEGEN-BC) study. Variants were called by GATK HaplotypeCaller and annotated by ANNOVAR with the ClinVar database (v20240611). Global ancestry proportions (Indigenous American, European, African, and East Asian) were estimated using the program Admixture (v1.3.0, k = 4), and local ancestry inference was performed with RFMix v2 to determine the ancestral origins of specific chromosomal segments at each locus of identified variants. Among the 1,364 individuals analyzed, 135 (9.90%) carried P/LP variants, including 128 with one variant and 7 with two. The most frequently affected genes were *BRCA1* (29/142, 20.42%), *BRCA2* (24/142, 16.90%), *ATM* (20/142, 14.08%), *PALB2* (18/142, 12.68%), and *CHEK2* (14/142, 9.86%). VUSs were identified in 679 individuals (49.78%), with 503 carrying one VUS and 176 carrying multiple VUSs (2 to 5). The most commonly affected genes with VUSs were *BARD1* (189/888, 28.28%), *NF1* (96/888, 10.81%), *ATM* (67/888, 7.55%), and *BRIP1* (43/888, 4.84%). Seven P/LP variants showed significant differences between the observed and expected ancestry of haplotypes when comparing IA to all other ancestries, with four of these variants located in *BRCA1*. Additionally, 36 VUSs exhibited significant differences in ancestry distribution, with *CDH1* harboring the most variants (5), followed by *CHEK2* and *MSH6* (3 each). For all P/LP variants with a significant difference between the observed and expected haplotypes of IA and other ancestries, the observed frequency of IA haplotypes was lower than expected, whereas the observed frequency of haplotypes from other ancestries was higher than expected. A similar trend was observed for VUSs, except for three mutations where the observed IA haplotype frequency was higher than expected and the frequency of other haplotypes was lower than expected. Our findings suggest that population admixture influences the distribution of P/LP variants and VUSs in Latin American populations. The occurrence of breast cancer in these populations may be partly influenced by the infusion of non-IA haplotypes harboring risk associated variants to the local genomes.

#1007 Screening pathogenic germline variants in prostate cancer predisposition genes in an ethnically diverse cohort of unselected prostate cancer patients.

Introduction: There is limited data on the heritability of PrCa in Brazil, a country with a miscegenated ethnic composition. We enrolled participants in a case-control study aimed at calibrating a polygenic risk score. We now present preliminary results of 557 PrCa patients whose samples were analyzed using whole genome sequencing (WGS). We estimate genetic ancestry and assess the prevalence of pathogenic genetic variants (PGVs) in PrCa-related genes.

Methods: We included unselected PrCa patients. Previously we performed in silico random downsampling of WGS data initially at 30x depth to 15x, using samples from 3 Brazilian people, to estimate percentages of variant similarities and rare variants missed due to lower coverage. Only high-quality, rare variants (≤ 1% in population databases), likely functional (exonic or splicing regions) were considered, excluding chromosomes X, Y, and mitochondrial DNA. Sequencing at 15x depth identified 94.2% to 97.1% of heterozygous variants detected at 30x, with a mean expected variant loss of 4.3%. Subsequently, we performed WGS at 15x depth on 557 samples of PrCa patients using Illumina technology. We screened data for germline mutations in a panel of 16 genes (including *HOXB13*) associated with high/moderate risk for PrCa. Ancestry admixture proportions were also estimated.

Results: A total of 557 PrCa patients were included. The median age at diagnosis was 64.6 years (41—90y). Self-reported skin color consisted of White (44.8%), Brown (37.4%), and Black (13.2%). Most patients were diagnosed with clinical stages II (32.8%) and III (43.1%), and ISUP grades 2 (40.2%) and 3 (22.9%). There was significant ancestry admixture, with predominant EUR genetic composition (61.4%), followed by AFR (24.6%), INDIG (7.7%), Asian (1.6%), and Middle Eastern (4.7%). PGVs in high/moderate risk genes for PrCa were identified in 29 out of 557 patients (5.2%), including *BRCA2* (n=8), *CHEK2* (n=5), *ATM*, *BRCA1*, *BRIP1*, *MLH1*, *PALB2*, *PMS2* (n=2 each), and *MSH2*, *MSH6*, *NBN*, *RAD51C*, and *TP53* (n=1 each). One patient carried PGVs in both *PALB2* and *TP53*. Variants included 9 frameshift, 4 splice site, and 17 missense mutations. All these variants will be confirmed in subsequent evaluations.

Conclusion: In a predominantly mixed-population setting, WGS at 15x depth appears appropriate for screening high-risk variants. Although there is a small chance (~5%) of missing rare PGVs or detecting false positives, from a population perspective, downsampling seems to be acceptable, comparing the benefits of sequencing at 15x twice the number of samples than 30x. Preliminary data suggest that the prevalence of PGVs in high/moderate-risk genes in PrCa patients is similar to other populations worldwide. The PGV spectrum identified is consistent with those described in Brazilian cancer patients. Supported by CNPQ

#1008 Genetic predisposition to breast cancer in Senegal: mutations of the *BRCA*1 and *BRCA2* genes.

Jean Pascal Demba Diop

Universite Cheikh Anta Diop de Dakar, Dakar, Senegal

Background: *BRCA1* and *BRCA2* are the most incriminated genes in inherited breast and ovarian cancers. Several pathogenic variants of these genes conferring genetic predisposition have been described in different populations but rarely in subsaharan Africa. The objectives of this study were to identify pathogenic variants of the *BRCA* genes involved in hereditary breast cancer in Senegal and to search for a founder effect.

Methods: We recruited after free informed consent, 46 unrelated index cases diagnosed with breast cancer and each having a family history, a control population of 90 healthy women and 80 women diagnosed with sporadic breast cancer and 36 patients diagnosed without a known family history of breast cancer at under 50 years All *BRCA1* and *BRCA2* exons were Sanger sequenced for the first 15 index cases recruited. For the following 31 index cases and healthy relatives and controls, the recurrent pathogenic variant of *BRCA1* identified in the first group was genotyped by PCR. To search for a founder effect of the recurrent pathogenic variant of *BRCA1*, haplotype analysis of 7 microsatellites encompassing the gene was performed in 10 selected index cases with the pathogenic variant and 15 unrelated healthy controls. Mutation age was estimated using the following equation: $G = \log\delta / \log(1 - \theta)$.

Results: Mutation screening identified a recurrent duplication of 10 nucleotides c.815_824dupAGCCATGTGG, (p.Thr276Alafs) of *BRCA1*, in 26 index. Allelic frequency was estimated at 28, 26% compared to sporadic breast cancer cases (5%) healthy controls (0.55%) The variant was also found in 8 out of 36 patients diagnosed without a known family history of breast cancer at under 50 years of age (allelic frequency estimated at 11.11%) Haplotype analysis showed a shared haplotype encompassing approximately 400 kb. Estimation of the age of the pathogenic variant suggested that it occurred approximatively 1400 years ago and confirm a West African origin. The variant was also detected in healthy relatives of selected families. The genotyping method is now available as a first screening test in women at risk. For *BRCA2* gene, a novel pathogenic variant, c.5219 T >133 G; p.(Leu1740Ter) was identified in a proband from a consanguineous family along with three sisters and one daughter of the index case.

Conclusion: Our study identified a founder pathogenic variant of *BRCA1* predisposing to breast cancer and enabled the establishment of an affordable genetic test as a mean of prevention for Senegalese women at risk. We will screen for the variant *BRCA1*: c.815_824dup in Senegalese patient diagnosed with breast, ovarian, prostate and pancreatic cancers.

Keywords: Hereditary Breast Cancer, *BRCA1, BRCA2*, pathogenic variant, Senegal.

#1009 DNA methylation-predicted plasma proteins and risk of colorectal cancer recurrence: Findings from the ColoCare Study.

Alicia Richards[1], Esther Jean-Baptiste[1], Timothy Barrow[2], Sheetal Hardikar[3], Biljana Gigic[4], Jane Figueiredo[5], Christopher Li[6], David Shibata[7], Adetunji T. Toriola[8], Doratha A. Byrd[1], Cornelia M. Ulrich[3], Paul Stewart[1], Erin M. Siegel[1], **Jacob K. Kresovich**[1]

[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]University of Essex, Essex, United Kingdom,[3]Huntsman Cancer Institute, Salt Lake City, UT,[4]Heidelberg University Hospital, Heidelberg, Germany,[5]Cedars-Sinai Medical Center, Los Angeles, CA,[6]Fred Hutchinson Cancer Center, Seattle, WA,[7]University of Tennessee Health Science Center, Memphis, TN,[8]Washington University School of Medicine, St. Louis, MO

Introduction: DNA methylation (DNAm)-based predictors of individual proteins (e.g., C-reactive Protein, Interleukin-6) show better predictive performance for various health outcomes compared to direct measurements. This improved performance may be due to the higher reliability and temporal stability of DNAm profiles than direct protein measurements. Building on these findings, a library of 109 DNAm-predicted plasma proteins, called “Protein EpiScores,” was developed using paired plasma proteomic and blood DNAm data from thousands of individuals. Initial studies of Protein EpiScores identified associations with CRC risk, suggesting their potential as novel biomarkers for CRC prediction and as indicators of mechanisms underlying CRC development. Here, we extend the investigation of Protein EpiScores to cancer survivorship by investigating their associations with risk of recurrence and all-cause mortality in newly diagnosed CRC patients.

Methods: The ColoCare Study is an international, multi-center, prospective cohort of newly diagnosed CRC patients. For this study, we selected a nested case-control sample of 137 patients enrolled at Moffitt Cancer Center, matching recurrence cases 1:3 to recurrence-free controls by age, sex, body mass index, stage, and follow-up time. Pre-treatment whole blood DNA methylation profiles were assayed and used to calculate 109 Protein EpiScores. Logistic regression models, adjusted for matching factors and tumor location, estimated odds ratios (ORs) for associations between each Protein EpiScore (per 1-standard deviation [SD] increase) and risks of CRC recurrence and all-cause mortality.

Results: Patients had a mean age of 62.7 years at diagnosis (SD= 13), with a majority being male (57%), overweight (78%), and White (90%). During follow-up, 35 (25%) patients experienced disease recurrence, and 47 (34%) died. Sixteen Protein EpiScores were associated with CRC recurrence risk (HRs ranging from 0.55 to 1.88; all $P< 0.05$). These included six Protein EpiScores designed to predict proteins related to immune response and inflammation (CCL11, PIGR, CCL17, MMP12, OSM, PAPPA), with all showing positive associations except for PAPPA. Ten Protein EpiScores were positively associated with all-cause mortality (all $P< 0.05$), including five immune response and inflammation Protein EpiScores (OSM, S100A12, CCL22, PIGR, S100A9).

Conclusions: Multiple Protein EpiScores measured in pre-treatment blood samples were associated with CRC recurrence risk and mortality. Many of these Protein EpiScores were designed to predict proteins involved in immune response and inflammation, suggesting that changes in peripheral immunity contribute to disease progression.

#101 KPNA2 promotes the progression of lung adenocarcinoma.

Seongran Cho[1], Inyoung Cheon[1], Seoree Kim[2], Yoon Ho Ko[3], Young-Ho Ahn[1]

[1]Ewha Womans University, Seoul, Korea, Republic of,[2]The Catholic University of Korea, Bucheon, Korea, Republic of,[3]The Catholic University of Korea, Seoul, Korea, Republic of

KPNA2 (Importin α1) is a nuclear transporter that mediates the nuclear import of proteins, such as transcription factors and nuclear proteins. Previous studies have highlighted KPNA2 as an important factor influencing CAF activity, prompting us to explore its role and mechanisms in the migration, invasion, and metastasis of lung cancer cells. Immunohistochemistry on tumor samples from lung cancer patients revealed that higher expression of KPNA2 was linked to poorer survival outcomes. To further investigate its function, we used shRNAs to knock down KPNA2 in human and mouse lung cancer cells. This led to a reduction in cancer cell migration, invasion, and metastasis. In contrast, overexpressing KPNA2 enhanced cancer cell migration and invasion. RNA sequencing analysis showed that KPNA2 regulates focal adhesion and NF-κB signaling pathways. Additionally, protein microarray analysis identified Golgi-associated and RNA-associated proteins as potential KPNA2-binding partners, which require further study. These results indicate that KPNA2 plays a crucial role in promoting cancer cell migration, invasion, and metastasis, making it a promising therapeutic target in lung adenocarcinoma.

#1011 Transposable element patterns across genetic ancestries in prostate cancer patients.

Nicholas Korvink, Lucas Ueta, Hannah Park, Vinay Kumar, Farah Rahmatpanah

Pathology and Laboratory Medicine, University of California, Irvine, Irvine, CA

Introduction: Prostate cancer (PCa) is a significant burden to American men with African ancestry (AA). The mechanism of how ancestry contributes to aggressive PCa in AA patients is not well understood. We have identified a difference between races in endogenous retroviruses (ERVs) expression. In prostate and cervical cancer, we have demonstrated that ERV expression signatures are useful for identifying patients at the greatest risk of disease progression. There is consistency in mortality rates for black men in the US, Caribbean, and Sub-Saharan Africa suggesting that shared ancestry is a common risk factor. Using ERVcaller we investigated polymorphic transposon elements (TE) and ERV insertions unique to tumor cells compared to normal blood in prostate cancer patients of African (AF) and European ancestry (EU).
Method: ERVcaller software detects retrotransposons including Alu, LINE1, SVA, and HERV-K types using whole genome sequencing (WGS). We gathered publicly available WGS data (FASTQ files) from the European Nucleotide Archive (SRA accession SRP119289). These were derived from paired blood and tumor samples from 6 AF and 9 EU PCa patients. We processed this data with ERVcaller, revealing TE insertions present in each patient sample (i.e., blood or tumor). We identified tumor-exclusive and blood-exclusive insertions by excluding overlapping TE insertions between tumor and blood samples. These insertions were then analyzed for differences using a T-test in R Studio.
Results: Statistical analysis revealed significant differences in the number of TE insertions in the tumors of AF patients (mean = 50.00) compared to their EU (mean = 31.89) counterparts (p-value < 0.0038). In addition, we found no significant differences in TE insertions in blood samples of AF patients (mean = 35.50) relative to EU patients (mean = 32.78; p-value > 0.56), suggesting that this differential insertion pattern is isolated to the affected tumor region.
Conclusion: ERVs have previously demonstrated important roles in the development of various diseases. Our findings demonstrate significant variations in TE insertions in tumors of PCa patients across genetic ancestries.

#1012 Investigating genetic and transcriptomic drivers of endometrial cancer disparities in Black/African American women.

Danyelle Paine[1], Yuxin Jin[1], Javier Arias-Stella III[2], David Craig[1], John Carpten[1]

[1]Integrative Translational Science, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Department of Pathology, The City of Hope, Duarte, CA

Endometrial cancer (EC) is the sixth most common gynecological malignancy globally, with an increasing incidence over the last two decades. Black/African American (BAA) women are disproportionately affected, experiencing higher rates of high-grade EC and associated mortality compared to Non-Hispanic White (NHW) women. These disparities likely result from complex interactions between social determinants and biological factors. Notably, BAA women are 2-3 times more likely to be diagnosed with aggressive, high-grade EC and have significantly higher mortality rates, underscoring an urgent need to address this disparity. Uterine EC disparities arise from intricate tumor microenvironments characterized by cellular niches with distinct genotypes, phenotypes, and spatial transcriptomic landscapes. In estrogen-dependent EC tumorigenesis, the endometrium undergoes unregulated proliferation, progressing from normal tissue to atypical hyperplasia and ultimately carcinoma. The heterogeneity of EC tumors presents challenges for therapeutic targeting, contributing to poor outcomes. This study investigates the genetic and transcriptomic features within the tumor microenvironment of BAA EC patients to uncover drivers of these disparities. Our cohort includes primary, metastatic, and normal uterine tissues classified as uterine endometrial adenocarcinoma, along with two serous papillary carcinoma cases of varying tumor grades. RNA-sequencing analysis revealed differential gene expression enriched in pathways related to cell proliferation, epithelial-to-mesenchymal transition (EMT), DNA damage response, and immune modulation. Preliminary whole-exome sequencing (WES) data implicate both established and potentially novel mutations in genes associated with cell cycle regulation, angiogenesis, chromatin remodeling, and cell signaling. Paired WES analysis identified somatic variants and copy number alterations in key genes, correlating with known EC-driven genetic alterations documented in the literature. Spatial transcriptomics is being applied to characterize gene signatures across cellular neighborhoods within the tumor microenvironment. This approach elucidates the spatial architecture and cellular niches driving immune modulation and tumor progression. By integrating genomic and spatial transcriptomic data, we aim to provide a comprehensive understanding of the tumor microenvironment in BAA EC patients. This study represents a significant step toward identifying genetic and transcriptomic drivers of EC disparities in BAA women, with the goal of informing the development of improved diagnostic and therapeutic strategies to reduce these inequities.

#1014 Detection of reportable germline *BAP1* mutations in patients with uveal melanoma.

Amy C. Schefler[1], Julia Litvinov[2], Jason Maarsing[2], Kasia Wozny[2], Olga Zolochevska[2]

[1]Retina Consultants of Texas, Houston, TX,[2]Castle Biosciences, Inc., Friendswood, TX

Purpose: The reported rate of pathogenic germline mutations in the *BAP1* gene range from 2% in unselected population to up to 50% in patients with familial uveal melanoma (UM) and are associated with an increased risk of developing *BAP1*-Tumor Predisposition Syndrome (TPDS)-related cancers. The primary objective of this study was to determine more accurately the rate of germline *BAP1* mutations in a clinically representative sample population of UM patients with a known somatic mutation in *BAP1,* using clinically available 7-gene UM next-generation sequencing (NGS) panel DecisionDx-UM*Seq*.

Methods: Blood and buccal swab samples were prospectively collected from 45 adult participants (median age at diagnosis 63 y.o., range 35-92) at a single center under an IRB-approved protocol. All participants had a prior diagnosis of primary UM and had at least one reportable *BAP1* mutation previously identified in their tumors. Both samples (blood and buccal swab) were analyzed using the DecisionDx-UM*Seq* test. Results of all 3 assays (tumor, blood, and buccal swab) were analyzed for the presence of *BAP1* mutations.

Results: All reportable germline mutations detected in blood and buccal swab samples were previously identified in the primary tumor samples by DecisionDx-UM*Seq,* with 100% concordance in mutation calls between blood and swab samples and allele frequencies (AFs) within a 5% range. Out of 45 samples analyzed, 11 (24.4%) had reportable germline mutations classified as either Variants of Uncertain Significance (VUS) or pathogenic according to the ClinVar database. The remaining 34 samples had no reportable germline mutations. When comparing the AFs of *BAP1* mutations in blood and buccal swab to those in tumor samples, 4/11 (36.4%) had matching AFs, while 7/11 (63.6%) exhibited higher AFs in the tumor samples than in blood or buccal swabs. Among the detected mutations, four were classified as pathogenic and seven as VUS. Tumors in this cohort tended to be large, consistent with a high-risk molecular profile, with an average diameter of 14.5±3.53 mm and average tumor thickness of 6.14±3.48 mm.

Conclusions: The DecisionDx-UM*Seq* panel accurately identified reportable germline *BAP1* mutations in both buccal swab and blood samples from patients with previously reported somatic *BAP1* mutations. A quarter of patients in this cohort had a reportable germline mutation, including patients without a family history suggestive of typical *BAP1*-TPDS cancers, thus indicating that the rate of *BAP1* germline mutations may be higher in this cohort than reported elsewhere. This study supports the routine implementation of the DecisionDx-UM*Seq* panel for *BAP1* germline testing in all patients with a somatic *BAP1* mutation, enabling improved critical clinical decision-making and genetic counseling for patients and family members at risk of *BAP1*-related TPDS.

#1015 Real-world evaluation of androgen receptor (AR) ligand-binding domain (LBD) mutations in Chinese patients with metastatic castration-resistant prostate cancer (mCRPC).

Y. Chen[1], B. Dong[1], D. Li[1], Y. Xiao[1], J. Markensohn[2], E. Dettman[3], C. Pena[2], **X. Liu**[4];
[1]MSD R&D (China) Co., Ltd., Beijing, China, [2]Merck Sharp & Dohme LLC, Rahway, NJ, [3]Merck Sharp & Dohme LLC, North Wales, PA, [4]Merck & Co., Inc, Rahway, NJ

Purpose: While AR LBD mutations have been extensively studied in Caucasian populations, there is a lack of research in Chinese populations. This study aimed to investigate the prevalence of AR LBD activated mutations in Chinese mCRPC patients using real-world databases.
Methods: This observational study analyzed two databases of Chinese mCRPC patients. The Gloriousmed database included 2,030 patients with circulating-tumor DNA (ctDNA) collected between 2016-2023 and tested using Gloriousmed's Pushengtai (86 genes) /Qianxianan panel (693 genes), while the Geneseeq database included 91 patients with tissue and/or ctDNA collected between 2020-2022 and tested using Geneseeq Prime panel (425 genes). Activated AR LBD mutation and other prostate driver mutations were assessed in patients with novel hormonal agents (NHA) treatment information.
Results: In Gloriousmed's ctDNA database, 633 (31.2%) were NHA-naïve (not received any NHA treatment), and 1,397 (68.8%) were NHA-treated (undergone NHA treatment before sample collection). The prevalence of AR LBD mutations in NHA-treated patients (20.5%, 287/1397) was significantly higher than that in NHA-naïve patients (15.2%, 96/633) (Fisher test P=0.004). Regarding specific activated point mutations in the AR LBD, W742C (7.74%) and W742L (6.32%) were the two most common mutations in NHA-naïve populations, and significantly higher prevalence of L702H (5.44% vs 2.37%) and T878A (9.45% vs 3.48%) mutations were found in NHA-treated patients compared to NHA-naïve patients (Fisher test P<0.01).. In Geneseeq database, 21 (23.1%) subjects were NHA-naïve, while 70 (76.9%) were NHA-treated. The prevalence of AR LBD mutations in ctDNA was numerically higher in NHA-treated (21.3%, 13/61) than in NHA-naïve patients (5%, 1/20) (Fisher test P=0.17). Notably, the prevalence of AR LBD mutations in ctDNA was significantly higher than that in tissue (14/81 vs. 3/57, Fisher test P=0.04).
Conclusions: This study found consistent prevalence of AR LBD activated mutations (20.5% and 21.3%) in ctDNA from Chinese mCRPC patients after NHA treatment using two real-world datasets. Higher prevalence of AR LBD mutations was observed in NHA-treated patients compared to NHA-naïve patients and in ctDNA compared to tissue samples. Different patterns of specific AR LBD mutations were also identified in NHA-naïve and NHA-treated patients. These findings provide valuable insights into the overall prevalence of AR LBD mutations, as well as specific point mutations frequency that potentially associated with different treatment in real-world datasets of Chinese mCRPC patients.

#1016 Reduction of social disparities in clinical cancer feature prediction via somatic evolutionary embedding of mutational data.

Nic Fisk[1], Jeffrey P. Townsend[2]

[1]Cell and Molecular Biology, University of Rhode Island, Kingston, RI,[2]Biostatistics, Yale School of Public Health, New Haven, CT

Whole exome and whole genome sequencing (WES/WGS) of tumors provide rich repositories of information towards understanding the etiology of various cancer and how best to prevent and intervene in its progression. Studies utilizing these technologies, however, notably skew towards the inclusion of patients from white and well-resourced backgrounds. Considerable and ongoing effort has gone into reducing the disparate representation of WES/WGS data from diverse and global populations in the collective digital tumor corpus; however, the rapid development and deployment of machine learning models for cancer has not paused in wait of data reflective of the populace. This dissonance has resulted in imbalanced and, in an absolute sense, small WES/WGS data being used by increasingly complex machine learning models. Targeted sequencing panels, such as those hosted by AACR Project GENIE, are still skewed in a relative sense, but contain many more samples from all populations due to their routine clinical deployment and comparatively inexpensive. However, panel sequencing data is fundamentally limited in the amount of information captured. It is incumbent, then, to maximize the information that can be derived from WES/WGS data as it applies to somatic mutations assayed in these abundant targeted sequencing panels.

As cancer is ultimately a disease of somatic evolution, with even social and germline contributors to cancer often actualized via somatic mutation, impact scores—derived from observed evolutionary conservation over extended organismal timescales—are frequently used to contextualize somatic mutations for input into predictive machine learning models. We show that cancer effect size, a disease-specific, empirical measure of evolutionary benefit conferred to the tumor by a mutation, matches or outperforms impact measures to this end across a wide range of clinical features of cancer. Further, we apply a transfer learning approach to leverage the feature importance discovered by the cancer effect size annotated WES/WGS models to train models using targeted panel data. We find this embedding to not only improve the performance on predictive tasks overall, but also that it disproportionately improves performance for underrepresented groups. Lastly, we show that, while improvements to models and clever embedding of data undoubtedly can reduce disparities in model performance, the simple inclusion of samples from more diverse, representative individuals reduces that disparity more effectively.

#1017 Causal attribution in Korean cancer patients who underwent genetic testing: What caused my cancer?.

M.-C. Kang[1], M.-A. Jang[2], S.-Y. Park[1], S.-Y. Jung[1], S. Lee[1], J.-K. Kim[1], B. Park[3], S.-Y. Kong[1];
[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of, [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [3]Hanyang University College of Medicine, Seoul, Korea, Republic of

Introduction: Perception of patient's causal attribution is crucial for developing effective prevention strategies and improving overall health management approaches. Causal attributions of cancer patients have been well investigated in Western populations, while relatively few studies have conducted on East Asian populations. This study aimed to explore the perceptions of causal attributions among Korean cancer patients who underwent genetic testing.
Methods: Patients who met the criteria of hereditary cancer underwent germline genetic testing were recruited at the National Cancer Center in Korea between July 2023 and October 2024 (CRIS No. KCT0009460). Causal attributions were assessed through an open-ended item included in the Korean version of the Brief Illness Perception Questionnaire (BIPQ-K): "Please list in rank-order the three most important factors that you believe caused your illness." Responses were considered valid if they answered more than once in the three factors.
Results: Of the 958 cancer patients analyzed (97.9% female; mean age±SD, 52.7±9.9 years), breast cancer (531, 55.4%), ovarian cancer (390, 40.7%), other types of cancer (51, 5.3%), and multiple organ cancers (80, 8.4%) were included. First cancer diagnosis age less than the age of 40 were 194 (20.3%) patients and family history of cancer within second-degree relatives were observed in 748 (78.1%) patients. Their genetic testing results frequency were as following: pathogenic variants (PV), 196 (20.5%); variants of uncertain significance (VUS), 357 (37.3%); benign variants (BV), 405 (42.3%). The top five perceived risk factors were stress (718, 74.9%), dietary habits (385, 40.2%), genetics or family history (177, 18.5%), lack of weight management (167, 17.4%), and sleep habits (152, 15.9%). In the PV group, genetics or family history was reported more frequently compared to the VUS and BV groups (39.3% vs. 13.1%; $p<0.001$).
Conclusion: Korean cancer patients tended to overattribute stress as a cause of cancer than Western population, and this tendency was similar in PV group. Additionally, 10 respondents attributed their cancer to COVID-19 or COVID-19 vaccination, reflecting the influence of health anxieties during the COVID-19 pandemic period. The association between clinical and demographic characteristics and causal attributions will be analyzed. This work was supported by the grant of the Korean Cancer Survivors Healthcare R&D Project through the National Cancer Center, funded by the Ministry of Health & Welfare, Republic of Korea (Grant No. RS-2023-CC139201).

#1018 Genetic landscape and functional exploration of kidney cancer predisposition in cross-ancestral populations.

H. Dai, X. Chu, H. Du, S. Yang, Y. Yao, X. Yu, Y. Zhao, Z. Lyu, W. Wang, C. Sheng, H. Zheng, F. Song, F. Song, M. Li, K. Chen; Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

The genetic architecture of renal cell carcinoma (RCC) has not been fully characterized, particularly in Asian populations. Here, we conducted a genome-wide association study (GWAS) of 4,692 RCC patients and 10,116 controls of Chinese ancestry, extending to a multi-ancestry cohort totaling 879,498 participants. Our approach unveiled 10 novel RCC-associated loci and a Chinese-specific locus at 12p13.33 with genome-wide significance. Utilizing GWAS results and cross-ancestry expression quantitative trait loci (eQTLs), we achieved a refined identification of RCC-related candidate causal variants and genes. These findings were substantiated through CRISPR-based screenings and multiplexed single-cell perturbations. Functionally, we established a novel association between rs28684409 and the oncogene RPL4 at the complex genetic locus 15q22.31. This top-down genetic study of RCC underscores the utility of integrating cross-ancestry GWASs, QTLs, and functional screens to deeply elucidate complex diseases and identify potential therapeutic targets.

#1019 HRD status and biallelic loss of BRCA1/2 in breast cancer patients with germline BRCA1/2 mutation assessed by whole genome sequencing.

Ji Soo Park[1], Jeongsoo Won[2], Tae Yong Kweon[3], Sangwoo Kim[2], Hyung Seok Park[4]

[1]Hereditary Cancer Clinic, Cancer Prevention Center, Yonsei Cancer Center, Seoul, Korea, Republic of,[2]Department of Biomedical Systems Informatics, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Robot Mastectomy, Hereditary Breast and Ovarian Cancer Syndrome, & Translational Research (PROHBOT), Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Department of Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Beyond the properties of hereditary cancers with *BRCA1* and *BRCA2* mutations, the concept of BRCAness is used to predict hypersensitivity to PARP inhibitors by synthetic lethality. In addition to detecting deleterious mutation in homologous recombination (HR) - related genes and genomic instability score (GIS), the application of a mutational signature has been tried using whole genome sequencing (WGS). Although a BRCA-associated cancer arose in the heterozygous carrier with germline likely pathogenic/ likely pathogenic variant (PGVs) in *BRCA1/2* (g*BRCA1/2* mutant) had generally been considered as be in HRD status, some BRCA-associated cancer with g*BRCA1/2* mutation were classified into homologous recombination proficient (HRP) status by HRD assays. In this study, we tried to investigate the discordance in aspects of assay tools and bi-allelicity.

Methods: We collected WGS data from prospectively enrolled clinical database (N=18) and public database (TCGA, N=37) of g*BRCA1/2* mutant breast cancer patients. We compared the HRD status analyzed using HRDetect, CHORD, and HRD score (calculated by GIS) method, and investigated the association with biallelic or monoallelic alteration.

Results: Of all the 55 WGS data from the clinical and public database, 39 (71 %), 39 (71 %), 44 (80 %) were predicted to be HRD by HRD score, CHORD, and HRDetect, respectively. HRDetect showed 94.9 % positive percent agreement (PPA) and 56.3 % negative percent agreement (NPA) to CHORD, and HRDscore showed 86.4 % PPA and 90.9 % NPA to HRDetect. Most biallelic losses of *BRCA1/2* were identified in the tumor with germline mutation and LOH of wild type allele (40 of 43, 93.0%). For the HRD assay using HRDetect, 43 tumors with biallelic loss in *BRCA1/2* showed significant correlation with HRD compared to those with monoallelic loss in *BRCA1/2* (p value < 0.0001).

Conclusions: Even among the g*BRCA1/2* mutant breast cancers, HRD status showed some discordance according to the prediction tools and biallelic loss in *BRCA1/2* genes. Clinical utility of HRD tumors with biallelic loss in *BRCA1/2* need to be further investigated.

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#102 Identifying predictors of liver metastasis in small cell lung cancer using gene expression profiling.

George Chrisafis[1], Mohit Arora[2], Nobuyuki Takahashi[3], Anish Thomas[2]

[1]Internal Medicine, University of Michigan Medical School, Ann Arbor, MI,[2]National Cancer Institute, Bethesda, MD,[3]National Cancer Center Hospital East, Kashiwa, Japan

Small cell lung cancer (SCLC) is a highly aggressive, treatment-resistant form of lung cancer which carries an exceptionally poor prognosis. Patients with SCLC often present at an advanced stage due to the propensity of SCLC for early metastasis, with common sites including the brain, liver, adrenal glands, and bone. Liver metastasis has been identified as an independent prognostic factor for unfavorable response to chemotherapy, but specific steps in the liver metastatic cascade are yet to be described. Here, we seek to better characterize SCLC liver metastases by analyzing gene expression data from cell lines and patient biopsy samples. We analyzed data published in MetMap (Jin et al., 2020), which estimated organ-specific 'metastatic potential' of a variety of cell lines from the Cancer Cell Line Encyclopedia (CCLE). Gene set enrichment analysis revealed that SCLC cell lines with high liver metastatic potential exhibit significant positive enrichment of MYC signaling, oxidative phosphorylation, and Wnt/Beta-catenin signaling with negative enrichment of TNF-alpha signaling, inflammatory response, interferon response, and epithelial-to-mesenchymal transition. This pattern appears unique to SCLC cells compared with liver metastatic non-small cell lung cancer and colorectal cancer cells. Genes with differentially higher expression in SCLC lines with high liver metastatic potential were also found to play roles in embryonic organ and lung development. Cell lines with low liver metastatic potential exhibited increased expression of genes involved in pathways related to natural killer (NK) cell mediated immunity, suggesting the important role for innate immunity in preventing liver metastasis. This observation was confirmed in multiple datasets of SCLC patient biopsies, with higher expression of NK cell activating genes associated with a more favorable prognosis. Additionally, chromosome 3p deletion was more frequently observed in liver metastatic cell lines, and in primary patient tumors, the presence of a 3p deletion (plus 5q non-deletion) was associated with the presence of liver metastasis. Genes and pathways identified by this analysis, following experimental validation, could serve as potential therapeutic targets to predict and disrupt the liver metastatic cascade.

#1020 A cancer patient survival study facilitated by an integrated enrichment workflow streamlined DNA and RNA sequencing of biopsy samples.

Junhua Zhao, Benjamin J. Krajacich, Kevin Green, Xiaodong Qi, Shawn Levy

Element Biosciences, Inc., San Diego, CA

RNA sequencing provides valuable insights into gene expression alterations in response to drug-treatments, mutations, and gene fusions in cancer research. Combined analyses of RNA transcript variations and comprehensive genomic sequencing allows for cross-validation of somatic mutations, improvement of accuracy and clinical sensitivity, and understanding of the mutation effects on gene expression, yielding essential transcriptomic/genomic data that inform individual patient's responses to therapeutic interventions. However, challenges in sample and library preparation, along with the complexity of conducting multiple target enrichments for RNA and DNA samples, often are costly and time consuming. In this research study, we employed the novel integrated target capture technology, Trinity^{TM}, to simultaneously capture both RNA and DNA libraries in a single hybridization reaction, thereby streamlining the process and reducing overall costs. This optimized workflow significantly decreases sample-to-answer time below 21 hours, with 1 hour hybridization time and direct loading onto sequencing instrument. This improvement contrasts drastically to traditional multi-day procedures. Using this new approach, we processed matched DNA and RNA sequencing of blood and formalin-fixed paraffin-embedded (FFPE) tissue biopsy samples from eight prostate cancer patients collected pre- and post-intervention for treatment. As a result, the assay showed ~ 10% higher mean target coverage at equivalent read depths compared to data generated from the same samples processed using conventional target capture workflow. Additionally, the coverage depth for Indels was significantly better and generated >0.99 Indel F1 scores with the exome panel in the benchmarking data of reference genome NA12878. Similarly, the RNA data obtained in the study increased sequencing efficiency and generated more usable RNA seq data than traditional bulk-RNA sequencing. We performed a comprehensive evaluation on intervention effect for treatment in both expression changes and mutation profiling and showed the feasibility to apply this assay to larger sample sizes. In summary, using Trinity^{TM} for combined DNA/RNA hybrid capture workflow leads to a rapid, cost-effective workflow to simultaneously unlock both DNA and RNA biomarker insights. This advancement could accelerate multi-omic studies and contribute to research that could help the design of targeted therapies, ultimately benefiting the precision of cancer treatment.

#1021 Predictors of receipt of guideline-concordant chemotherapy among ovarian cancer patients in the Kaiser Permanente Research on Ovarian Cancer Survival (KPROCS) Study.

Elisa V. Bandera[1], Lindsay J. Collin[2], Valerie S. Lee[3], Juraj Kavecansky[4], Farzin Khosrow-Khavar[5], Scarlett L. Gomez[6], Jennifer A. Doherty[7], Lawrence H. Kushi[3]

[1]Rutgers Cancer Institute, New Brunswick, NJ,[2]Emory Univesity, Atlanta, GA,[3]Kaiser Permanente Northern California, Pleasanton, CA,[4]Kaiser Permanente Northern California, Antioch, CA,[5]Rutgers University, New Brunswick, NJ,[6]University of California at San Francisco, San Francisco, CA,[7]Huntsman Cancer Institute, Salt Lake City, UT

Background: Ovarian cancer is the fifth leading cause of cancer death among women in the US. Standard of care for ovarian cancer includes cytoreduction followed by paclitaxel-based chemotherapy. Herein, we aimed to assess patient-level factors affecting receipt of guideline concordant chemotherapy among patients diagnosed with epithelial ovarian cancer in an integrated health system.
Methods: This preliminary analysis included 5,327 patients in the ongoing Kaiser Permanente Research on Ovarian Cancer Survival (KPROCS) Cohort Study, who were diagnosed with epithelial ovarian cancer (2000-2022) and treated at Kaiser Permanente Northern California. Women were included if they were ≥18 years at diagnosis, resided in California, and received chemotherapy. Treatment and other sociodemographic and clinical information, including specific chemotherapy agents and whether neoadjuvant treatment was given were ascertained from electronic health records, and assessed for concordance against National Comprehensive Cancer Network guidelines that were in place at the time of treatment and as appropriate for clinical characteristics such as stage, grade, histotype, and comorbidities. We used logistic regression to compute odds ratios (ORs) and 95% confidence intervals (95%CI) to estimate associations of demographic and clinical characteristics with receipt of guideline concordant chemotherapy, in multivariable models including age, stage, histotype, and Charlson Comorbidity Index (CCI).
Results: We included 3,472 Non-Hispanic White (NHW) women, 297 Non-Hispanic Black (NHB) women, 771 Asian American and Pacific Islander (AAPI) women, 696 Hispanic women, and 91 women of other racial and ethnic groups. Overall, 48% of patients received guideline concordant care. In multivariable-adjusted models, NHB individuals were less likely to receive guideline care compared with NHW individuals (OR=0.76, 95%CI: 0.58-0.99), whereas AAPI individuals were more likely to receive guideline care (OR=1.13, 95%CI: 0.95-1.35) and Hispanic individuals were equally likely (OR=1.04, 95%CI: 0.87-1.24). Women were less likely to receive guideline-concordant chemotherapy if they were older (>70 vs. <50 years, OR=0.63, 95%CI: 0.52-0.78), had higher CCI (CCI 3+ vs CCI=0, OR=0.56, 95%CI: 0.46-0.68), later stage at diagnosis (Stage IV vs Stage 1; OR=0.40, 95%CI: 0.33-0.48), were diagnosed with histotype of carcinoma not otherwise specified vs. endometrioid (OR=0.28, 95%CI: 0.22-0.38), or had high body mass index (≥40 vs <25 kg/m^2; OR=0.58, 95%CI:0.44-0.77).
Conclusions: We found that in a managed care setting, ovarian cancer treatment disparities persisted across racial and ethnic groups, and those with higher comorbidity, later stage at diagnosis, and greater obesity were less likely to receive guideline-concordant care.

#1022 Tumor-associated microbiome association with colorectal cancer-specific mortality in a racially and ethnic diverse patient population.

C. E. Thomas[1], N. C. Lorona[2], S. D. LaBrie[1], K. R. Curtis[1], H. Yin[1], N. Ma[1], T. Randolph[1], C. Qu[1], J. Huyghe[1], S. Thomas[1], L. Hsu[1], A. L. Koehne[1], S. Nayemi[1], H. Ammar[1], O. Kahsai[1], D. Redwood[3], C. I. Li[1], L. Li[4], U. Peters[1], J. C. Figueiredo[2], T. K. Thomas[3], A. I. Phipps[1], M. A. J. Hullar[1];

[1]Fred Hutchinson Cancer Center, Seattle, WA, [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]Alaska Native Tribal Health Consortium, Anchorage, AK, [4]Ochsner Health System, New Orleans, LA

Background: The tumor-associated microbiome is an important component of the tumor microenvironment implicated in colorectal cancer (CRC) prognosis. However, it remains unclear which phyla or genera are associated with CRC-specific mortality, particularly in understudied racial and ethnic patient populations.

Methods: We included 382 patients with CRC (90 African American, 95 Alaska Native, 71 Hispanic, and 126 non-Hispanic White) from the Translational Research Program in Colorectal Cancer Disparities (TRPCD). We conducted V_4 16S rRNA gene sequencing of genomic DNA extracted from formalin-fixed paraffin embedded (FFPE) tumor tissue. Sequences were processed bioinformatically in QIIME 2.0 to classify the relative abundance of different bacterial genera and phyla in tumor tissue. All batches include positive, no template and tumor sample block wax controls that are extracted and sequenced and from which contaminants are identified and removed via bioinformatics. Patients who died of CRC were matched to patients who did not die of CRC by age, sex, tumor site, tumor stage, year at diagnosis, and racial and ethnic group. We used unconditional logistic regression to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the association between positivity (non-zero/zero) of phyla or genera with CRC-specific mortality, adjusted for all matching factors. As a sensitivity analysis, we also examined associations comparing those with high levels of a phyla or genera (among those non-zero, at or above the median) versus those with no such bacteria detected, or zero.

Results: After 16S rRNA gene sequencing, 8 phyla and 48 genera were available for analysis. No phyla or genera were statistically significantly associated with CRC-specific mortality status after accounting for multiple testing. The strongest associations were for the genera Enterococcus, where positivity was inversely associated with CRC-specific mortality [OR positive versus zero (95% CI) = 0.52 (0.30, 0.87)], and the genera Cloacibacterium, where positivity was associated with greater odds of CRC-specific mortality [OR positive versus zero (95% CI) = 2.40 (1.14, 5.16)]. Comparing high levels to zero, the strongest association was for the genera Leptotrichia, where high levels were associated with greater odds of CRC-specific mortality [OR high versus zero (95% CI) = 2.60 (1.24, 5.54)].

Conclusions: While no phyla or genera were statistically significantly associated with CRC-specific mortality after accounting for multiple testing, there are several genera that have strong associations and warrant further investigation. This work may be useful identifying pathogens or protective agents that impact CRC-specific mortality in understudied populations.

PREVENTION / EARLY DETECTION / INTERCEPTION: Behavioral Sciences and Prevention, Screening, and Early Detection Poster Session

#1026 Multi-modal liquid biopsy analysis of early-stage breast cancer patients.

Kaylee J. Kamalanathan[1], Alec Horrmann[1], Nathaniel R. Bristow[1], Yash Travadi[1], Kevin Mallery[1], Catalina Galeano-Garces[1], Song Yi Bae[1], Alexa Hesch[1], Grant Schaap[1], Yuliya Olimpiadi[2], Sarah Pederson[2], Jiarong Hong[1], Justin Drake[1], Jayant Parthasarathy[1], Badrinath R. Konety[1]

[1]Astrin Biosciences, Inc., Saint Paul, MN,[2]Allina Health Cancer Institute, Minneapolis, MN

The 5-year breast cancer survival rate in the United States is 91% overall with a 99% survival rate for localized disease. Early detection via mammograms has largely been responsible for the success of finding breast cancer early; however, mammograms have drastically decreased effectiveness in women with dense breasts tissue which is approximately half of the US population. To better serve these women, an alternative screening method is necessary. Astrin Biosciences has developed a multi-modal liquid biopsy-based alternative for breast cancer screening in this population.

Recent literature demonstrates that cancer cells disseminate into blood vessels even at early stages. These early-stage cells are a potential source of late recurrence and therapy resistance but have strong potential benefit in early detection as well as provide opportunities to determine possibly curative interventions. Although these cell assays have a huge potential benefit, they generally leave some to be desired as far as sensitivity due to the rarity of these cells with less than 10 cells per 10 mL blood tube from circulation. To overcome this limitation, Astin's algorithm pairs our AI-empowered proprietary holographic imaging platform with plasma proteomics. This pairing provides increased sensitivity over a cell-based assay alone while maintaining the ability to detect disseminating cells for further analysis in patients with enough cells present.

This combined technology was evaluated in a cohort of more than 100 newly diagnosed early-stage breast cancer patients (Stage 0, 1, and 2). Blood samples were collected prior to initiation of therapy and the plasma and cell fractions were separated. Proteomic analysis was performed on the plasma sample while Astrin's holographic imaging platform combined with in-flow protein marker expression was used to analyze the samples for circulating tumor cells. Preliminary data from this study demonstrates evidence of early dissemination detectable in the majority of breast cancer patients. GSEA analysis of protein expression revealed well known pathways associated with cancer biology. Astrin Biosciences' combined assay has the ability to detect cancer in women with dense breast, increasing the likelihood cancer is detected early in this population.

#1027 A multicenter clinical performance evaluation of a liquid biopsy for earlier brain cancer detection.

James M. Cameron[1], Georgios Antoniou[1], Paul Brennan[2], Holly Butler[1], David Eustace[1], Asgeir Jakola[3], Michael Jenkinson[4], Senada Koljenovic[5], Alan Lazarus[1], Ryan Mathew[6], David Palmer[1], Isaac Phang[7], Alexandra Sala[1], Tobias Weiss[8], Matthew Baker[1]

[1]Dxcover Ltd., Glasgow, United Kingdom,[2]University of Edinburgh, Edinburgh, United Kingdom,[3]University of Gothenburg - The Sahlgrenska Academy, Gothenburg, Sweden,[4]The Walton Centre, Liverpool, United Kingdom,[5]University Hospital Antwerp, Antwerp, Belgium,[6]Leeds Teaching Hospitals, Leeds, United Kingdom,[7]Royal Preston Hospital, Preston, United Kingdom,[8]Universitatsspital Zürich, Zurich, Switzerland

Diagnostic delays impact the quality of life and survival of patients with brain cancer. Currently, with no blood test to assist them, clinicians must make their referral decision based on symptoms. Existing symptom-based referral guidelines inadequately stratify patients for brain imaging based on suspicion of cancer. A simple, rapid liquid biopsy placed in a primary care setting would enable more efficient triage of patients with non-specific symptoms related to brain cancer.

The Dxcover® Liquid Biopsy is a rapid multi-omic liquid biopsy that interrogates a blood sample with infrared radiation and produces a distinctive signature that represents the whole biomolecular profile of the sample, and is sensitive to the hallmarks of brain cancer. The nature of the technology also allows for the diagnostic models to be tailored towards higher sensitivity (or specificity) depending on clinical priorities and international healthcare markets. In initial feasibility studies, we recruited 988 patients prospectively with non-specific symptoms associated with a brain tumor, and the algorithm detected 96% of the patients with brain tumors and 100% of glioblastomas (GBM), when tuned for greater sensitivity.

EMBRACE is a prospective, observational, multicenter study, currently recruiting patients across seven sites in the United Kingdom, Belgium, Sweden and Switzerland. The study duration is 24 months and will recruit a minimum of 2200 participants by the end of 2024. The target population is comprised of patients presenting to primary care with non-specific symptoms that are associated with brain cancer, such as headache and new onset neurological defect. The primary objective is to determine the clinical performance of the liquid biopsy for patients with brain cancer, in terms of diagnostic sensitivity and specificity. The test performance will be determined by comparing the liquid biopsy result to diagnostic imaging. The results of the EMBRACE study will be shared for the first time at the meeting.

Earlier and expeditious diagnoses in these patients are crucial to reduce the morbidities and mortalities associated with brain cancer. This simple, non-invasive liquid biopsy would facilitate the triage of brain tumor patients for rapid imaging.

#1028 Evaluating amplitude modulated radiofrequency electromagnetic fields as a cancer screening modality.

Callum T. McGrath[1], Hugo Jimenez[2], **Boris C. Pasche**[2]

[1]Wake Forest University School of Medicine, Winston Salem, NC,[2]Department of Oncology, Wayne State University School of Medicine, Detroit, MI

Background: Tumor-specific Amplitude Modulation Radiofrequency Electromagnetic Fields (AM RF EMF) have been identified in over 15 different tumor types. Tumor specific frequencies were identified by exposing patients with a known diagnosis of cancer to an AM RF EMF frequency sweep ranging from 0.1 Hz to 150 kHz. Frequencies that elicited an increase in pulse amplitude were registered as tumor-specific frequencies. We hypothesized that this mechanism could be used to screen for cancer, in which patients with an unknown diagnosis are exposed to previously identified tumor-specific frequencies and monitored for any change in hemodynamics.
Methods: 17 patients with biopsy-proven hepatocellular carcinoma (HCC), 14 patients with biopsy-proven breast cancer (BC), and 31 healthy controls were recruited for the study and had their systolic blood pressure (sBP), diastolic blood pressure (dBP), pulse pressure (PP), cardiac output (CO), heart rate (HR) R-R interval (RRI), stroke volume (SV), and total peripheral resistance (TPR) measured while exposed to random (non-tumor-specific) AM RF EMF, HCC-specific AM RF EMF, and BC-specific AM RF EMF. Patient data was then used to train a one-dimensional convolutional neural network (1D CNN) to classify each dataset as control, HCC, or BC.
Results: Overall accuracy for the model was 81.17%. AUC for the ROC curve for control, HCC, and BC was 0.91, 0.96, and 0.96 respectively.
Conclusion: Our model demonstrates that AM RF EMF has the potential to be used as a cancer screening modality. Further studies will need to be performed with larger cohorts to validate the findings of this study and to improve the accuracy of the model. Additionally, future studies should investigate the potential for AM RF EMF-based screening for pancreatic cancer, as tumor-specific frequencies have previously been identified for the malady.

#1029 Prevalence of mammographically dense breasts in Guam.

Reina Faye P. Evangelista[1], Louis Jane B. Dulana[1], **Rodney Teria**[1], Su Bin Jin[1], Gian Paras[1], Rose Grino[2], John Shepherd[3], Grazyna Badowski[1]

[1]University of Guam, Mangilao, Guam,[2]FHP Health Center, Tamuning, Guam,[3]University of Hawai'i Cancer Center, Honolulu, HI

Background: Breast cancer is the most diagnosed cancer among women in Guam. Mammographic breast density is a critical factor in assessing breast cancer risk and the effectiveness of screening. Guam's female population is diverse, comprising CHamoru (37.3%), Filipino (26.3%), Mixed (9.5%), White (7.1%), Chuukese (7%), and other Pacific Islander and Asian ethnicities. Understanding breast density patterns among these groups is essential for developing tailored public health strategies. However, specific data on the distribution of breast density among women in Guam is currently lacking. This study, conducted through the Hawai'i and Pacific Islands Mammography Registry (HIPIMR), addresses this gap by estimating the prevalence of dense breasts among women in Guam aged 40 years and older.

Methods: The mammographic breast density distribution by age and body mass index (BMI) was determined using data from 1,940 mammograms conducted at the FHP Health Center in Guam between October 2023 and September 2024 for women aged 40 and older (N = 1,920). These breast density distributions were applied to age- and BMI-specific counts of the female population in Guam, derived from the 2020 Guam Census and the Guam Behavioral Risk Factor Surveillance System (BRFSS), to estimate the number of women with dense breasts. Ethnic variations in breast density distributions were examined using a chi-square test. Results: Among the 1,920 women analyzed, breast density was categorized as BI-RADS A (9.2%), BI-RADS B (19.2%), BI-RADS C (17.2%), and BI-RADS D (54.1%). BMI distribution included under/normal weight (27.2%), overweight (26.7%), obese (31.2%), and cases with missing BMI data (14.9%). Filipino (81.1%) and Asian (84.0%) women had significantly higher combined proportions of dense breasts compared to CHamoru (63.6%) and Micronesian (52%) women ($P < 0.001$).Overall, 74.8% (95% CI: 74.3%-75.3%) of women aged 40-74 in Guam were classified as having heterogeneously or extremely dense breasts with the prevalence inversely associated with age and BMI. Based on the age and BMI distribution of Guam's female population, an estimated 22,185 (95% CI: 22,043-22,340) women aged 40-74 have heterogeneously or extremely dense breasts, with women aged 40-49 accounting for 82.5% of this group.

Conclusion: The prevalence of dense breasts among women in Guam is high (74.8%) compared to approximately 43% in the U.S., with Filipino and Asian populations showing the highest proportions. These findings underscore the need for breast density notification policies and enhanced access to supplemental screening for high-risk groups to improve early detection in Guam's diverse population.

Acknowledgement: This research was funded by the National Cancer Institute: The University of Guam/University of Hawaii Cancer Center Partnership to Advance Cancer Health Equity, Grant U54CA143728 (University of Guam, YCP)/Grant U54CA143727 (University of Hawaii Cancer Center).

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#103 Syndecan-1 Is a key mediator of entosis and cellular competition in pancreatic cancer.

Kara Li[1], Shigeaki Umeda[2], Chenyang Li[3], Rajya Kappagantula[4], Christine A. Iacobuzio-Donahue[4], Wantong Yao[1]

[1]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[2]Donahue-Zuckerman Research Center, Memorial Sloan Kettering Cancer Center, New York, NY,[3]MD Anderson Cancer Center, Houston, TX,[4]Donahue-Zuckerman Research Center, Memorial Sloane Kettering Cancer Center, New York, NY

Entosis, a form of cell-in-cell (CIC) structure formation where one cell invades and becomes internalized by another, has long been observed in various malignancies and is considered a critical cellular process in cancer progression, with potential impacts on tumor heterogeneity, survival, and metastasis. Syndecan-1 (SDC1), a transmembrane proteoglycan involved in cell adhesion and communication, plays a pivotal role in these processes, yet its specific function in entosis within pancreatic ductal adenocarcinoma (PDAC) remains underexplored. This study aimed to investigate whether SDC1 facilitates entosis in PDAC cells and to assess its impact on tumor aggressiveness and patient outcomes. Using immunohistochemistry, flow cytometry, and entosis assays, our findings reveal that SDC1 prominently localizes at cell-cell contact points, facilitating stable intercellular adhesion and promoting entotic activity. Knockdown experiments reveal that reduced SDC1 expression significantly diminishes CIC formation, implicating SDC1 as a critical mediator of this process. Analysis of clinical samples revealed that high SDC1 expression correlates with increased entotic activity in PDAC tumors and is associated with decreased patient survival. These results suggest that SDC1-mediated entosis enhances tumor aggressiveness by contributing to cellular competition and heterogeneity. Our study sheds light on the critical role of SDC1 in promoting CIC formation and cancer progression, highlighting its potential as a therapeutic target to disrupt entotic mechanisms in PDAC.

PREVENTION / EARLY DETECTION / INTERCEPTION: Behavioral Sciences and Prevention, Screening, and Early Detection Poster Session

#1030 Effects of clearing heat and removing phlegm prescription on inhibiting proliferation and secreted protein expression of human esophageal carcinoma cells.

Fuchun Si[1], Gao Si[2], Xuejie Song[1]

[1]Hunan University of Chinese Medicine, Henan, China,[2]Peking University Third Hospital, Beijing, China

Background: Esophageal carcinoma(EC) is the sixth most common cause of cancer death worldwide. It is still a key problem to find early diagnostic targets and effective treatment medicine in the study of EC. This study aims to screen out serum differentially expressed proteins from EC patients, and explore the inhibitory effects of Clearing Heat and Removing Phlegm prescription(CHRF) on the proliferation of EC cells and serum secretory proteins expression.
Methods: Serum samples of 21 EC patients and 7 healthy normal people were collected. Raybiotech AAH BLG-1 protein chip and data analysis software were used to profile serum differentially expressed proteins of EC. CHRF was developed in our previous research for the treatment of EC. Effects of CHRF on the proliferation, cell cycle and screened serum secretory protein expression of four EC cell lines EC-1, Eca109, EC9706, TE-1 were investigated by MTT assay, flow cytometry assay and Western blot analysis.
Results: 37 differentially expressed proteins were screened out from EC patients compared with the normal control group, among which 22 were significantly up-regulated, 17 were significantly down-regulated. These differential expression proteins mainly involved in cytokine-cytokine receptor interaction, PI3K-Akt signaling pathway, Jak-STAT signaling pathway, chemokine signaling pathway, which have the function of promoting tumor development, tumor growth, angiogenesis, growth and development of tissue. 22 up-regulated serum secretory proteins were selected to detect in four EC cells and observe the inhibitory effects of CHRF. CHRF could obviously inhibit the proliferation of EC-1, EC9706, Eca109 and TE-1 cells in dose-dependent and time-dependent manner. IC50 values of CHRF for EC9706, Eca109, TE-1 and EC-1 were 33.31μg/ml, 20.70μg/ml, 21.93μg/ml, 33.47μg/ml respectively. CHRF induced G2/M phase arrest in all four EC cells. MMP1, MMP14, OPG, FBLN5, PECAM-1 proteins were expressed in all four EC cells and down-regulated by CHRF.
Conclusion: Serum secretory proteins MMP1, MMP14, OPG, FBLN5, PECAM-1 were significantly up-regulated in esophageal cancer cells, which could be considered as the potential markers for EC diagnosis; the inhibitory effects of CHRF on the proliferation of Eca109, EC9706, TE-1 and EC-1 cells have relationship with down-regulating MMP1, MMP14, OPG, FBLN5 and PECAM-1 protein expression, which not only provides new basis for the in-depth study of EC pathogenesis, but also provides foundation for the further study of new traditional Chinese medicine prescriptions for EC treatment.

#1031 Cervical cancer awareness program in Rio Grande Valley (RGV) colonias: empowering communities through our cervical cancer prevention action network (CCPAN) program.

Swati Mohan[1], Bhupendra B. Srivastava[1], Murali M. Yallapu[2], Subhash C. Chauhan[2]

[1]School of Integrative Biological and Chemical Sciences, The University of Texas Rio Grande Valley, Edinburg, TX,[2]School of Medicine, The University of Texas Rio Grande Valley, Edinburg, TX

Cervical cancer remains a significant health challenge, particularly in underserved communities of US-Mexico trans-border Rio Grande Valley (RGV) region. This region represents remarkably higher cervical cancer health disparities. Thus, to improve awareness about cervical cancer in the RGV Colonias by providing crucial evidence-based information on the prevention, early detection, and available clinical resources is utmost desirable in this RGV region. Towards this, we have established a unique cervical cancer prevention action network (CCPAN) program to cater to this need of the community. Our approach towards the awareness of cervical cancer through community engagement and by explaining what cervical cancer is, its risk factors, symptoms, importance of Human Papillomavirus (HPV) vaccination, and right dose schedule of HPV vaccination in our visits to underserved Hispanic population of RGV Colonias. We also explain etiology and progression of HPV infection through our small dramatic representation, videos and cartoons. Additionally, we provide information to the residents of Colonia about the importance of regular Pap tests and HPV tests in early detection of cervical cancer. Moreover, we also provide patients navigation information to local clinics and healthcare facilities that offer cervical cancer, HPV screenings and HPV vaccinations. We encourage people to get vaccinated, get screened, and spread the word at grass root level in the communities. Through our CCPAN program, we are also developing a database regarding Demographics, Knowledge and Awareness, Screening and Prevention, Attitudes and Beliefs, and Awareness of Local Resources. So far, the data that we have collected is alarming and is very different compared to nationwide data. Our collected data from RGV colonias suggest that communities have very limited information related to cervical cancer (30%), causes of cervical cancer (5%), awareness of HPV vaccine (30%) and timely receiving of HPV vaccine (30%). This situation appears alarming and RGV colonias communities required urgent community support to reduce cervical cancer health disparities in the region. We believe that our unique CCPAN program has very high potential to educate and empower the RGV colonias communities to take proactive steps in preventing cervical cancer, that can ultimately lead to reduce cervical cancer health disparities in the RGV.

#1032 Knowledge, attitude and practices regarding human papillomavirus (HPV) and HPV vaccination among medical undergraduate students in Delhi: A cross-sectional study.

Srishty Srishty[1], Rajesh Kumar[1], Bratati Banerjee[1], Amod Laxmikant Borle[1], Aseem Aseem[2]

[1]Department of Community Medicine, Maulana Azad Medical College, New Delhi, India,[2]University of Illinois Chicago, Chicago, IL

Introduction: Human papillomavirus (HPV), a prevalent sexually transmitted infection, is a leading cause of cervical cancer, with high-risk strains such as HPV 16 and 18 contributing significantly to disease burden. Globally, cervical cancer is the fourth most common cancer in women, while in India, it ranks third, with an incidence rate of 18.3% (123,907 cases) and a mortality rate of 9.1% (GLOBOCAN, 2020). Previous studies have highlighted significant gaps in knowledge, attitudes, and practices related to HPV and its vaccine. Furthermore, evidence indicates that targeted educational interventions can significantly enhance vaccine uptake and empower students to serve as effective advocates for vaccination.

Objectives: This study aims to assess medical undergraduate students' knowledge about HPV and its vaccine, their vaccination status, and their attitudes towards HPV vaccination.

Methodology: A cross-sectional study was performed at a medical college attached to a tertiary care hospital (Maulana Azad Medical College), Delhi, India. A total of 415 medical undergraduate students were enrolled via systematic random sampling. These participants were interviewed using a self-designed, pretested, semi-structured questionnaire including sections on sociodemographic data, knowledge about HPV and its vaccination, attitude toward the vaccine and actual vaccination practices among the study participants. Data was collected using Epicollect5 software. Data analysis was done using SAS software. Associations using Chi-square test ($p<0.05$).

Results: The mean age of participants was 21 years (SD = 1.74), ranging from 18 to 27 years. Of the 415 participants, 46.5% (n = 193) were female, and 53.5% (n = 222) were male, with most from an upper-middle socioeconomic background. The mean knowledge scores for HPV vaccination and cervical cancer were 10.77 (SD = 4.10) out of 20 and 12.28 (SD = 3.47) out of 25, respectively. While two-thirds demonstrated adequate knowledge about cervical cancer, awareness of its causal link to HPV was limited. The mean attitude score was 41.59 (SD = 4.93) out of 50, reflecting a generally positive outlook, though concerns about side effects, cost, and cultural acceptance persisted. Only 12.5% (n = 52) were vaccinated, with lack of awareness, cost, and perceived lack of need as key barriers. Notably, 60% expressed willingness to vaccinate if provided at subsidized rates or through university health programs.

Conclusion: The study highlights both opportunities and challenges in promoting HPV vaccination among medical undergraduates in Delhi. Despite positive knowledge and attitudes, vaccination uptake was low. Most students expressed willingness to vaccinate if offered at a subsidized cost or through accessible programs, suggesting cost-effective strategies and institutional support could improve coverage.

#1035 Western lifestyle leads to obesity and cancer via a common factor FTO.

Dong Wu, Ying Qing, Keith Leung, Meiling Chen, Zhicong Zhao, Yangchan Li, Li Han, Wei Li, Zhenhua Chen, Chao Shen, Yuan Che, Tingting Tang, Kitty Wang, Lillian Sau, Zhaoxu Xu, Xiaolan Deng, Jianjun Chen

Department of Systems Biology and Center for RNA Biology and Therapeutics, Beckman Research Institute of City of Hope, Duarte, CA

FTO, the first identified RNA N^6-methyladenosine (m^6A) demethylase, has been reported by our group to play an oncogenic role in acute myeloid leukemia (AML) and by others in various solid tumors, including colorectal and liver cancers. Additionally, FTO was the first gene identified through genome-wide association studies (GWAS) to be associated with obesity risk, with evidence linking elevated FTO expression to increased food intake and obesity development. While obesity is a recognized risk factor for cancer, whether FTO serves as a shared factor driving both obesity and cancer remains unclear. To address this knowledge gap, we employed *in vivo* mouse models with Fto expression manipulated through genetic knockout or pharmacological inhibition to investigate its respective roles in tumorigenesis and obesity. In an ENU-treated spontaneous tumor model, we confirmed that *Fto*-WT mice showed greater susceptibility to tumorigenesis than *Fto*-KO mice. When fed a Western diet high in sugar and fat, *Fto*-KO mice exhibited resistance to diet-induced obesity compared to *Fto*-WT mice. Similar protective effects against diet-induced obesity were observed in models treated with CS1, a potent small-molecule FTO inhibitor developed by our group. To explore the interplay between obesity and cancer, we established combined obesity-tumor models. Western diet-fed obese mice were either treated with ENU to induce spontaneous tumors or transplanted with MC-38 cells. In both scenarios, CS1 treatment simultaneously reduced obesity and tumorigenesis significantly. Mechanistically, FTO inhibition partially reversed Western diet-induced alterations in immune cell populations, indicating an immune-modulatory role for FTO in the pathogenesis of obesity and cancer. Together, our findings identify FTO as a common factor in the development of obesity and tumor and highlight the potential of targeting FTO for the simultaneous prevention and intervention of these conditions.

#1036 Gender differences in recruitment, retention, and preliminary outcomes in a nutrition education program for Latino families.

Melissa Gaviria[1], Bharat Narang[1], Ashley M. Rodriguez[1], Jessica Llamozas[1], Frankie J. Gonzalez[2], Robert Payano[1], Jocelyn Galindo Viayra[1], Luis E. Banegas Ruiz[1], Alexandra Burgos[3], Josana Tonda[1], Vanessa Lucero Cruz[1], Francesca Gany[1], Jennifer Leng[1]

[1]Immigrant Health and Cancer Disparities Service, Memorial Sloan Kettering Cancer Center, New York, NY,[2]City College of New York/CUNY School of Medicine, New York, NY,[3]The University of Texas at Austin, Austin, TX

Background/Objective: Latinos experience a disproportionately high prevalence of obesity and its associated increased risks for cardiovascular disease and certain cancers compared to non-Hispanic whites. Family-centered lifestyle interventions must engage both men and women to increase nutrition knowledge, better distribute care responsibilities, and increase support for parents and caregivers in Latino communities. This study assesses gender differences in recruitment, retention, and preliminary outcomes in Family COMIDA, a pilot community-engaged culturally and linguistically tailored nutrition education program for Latino families.
Methods: Outreach for participation in Family COMIDA was conducted among Latino adults visiting the New York City Mexican Consulate's 'Ventanillas de Salud' (Health Windows) program. Eligible adults were Spanish-speaking, overweight or obese (BMI ≥ 25 kg/m^2), and were the primary caregivers for at least 1 child < 18. Participants received written and digital educational materials. We measured weight and administered the California Health Interview Survey (to assess self-reported dietary behaviors) at baseline and 3 months. We assessed gender differences in recruitment (eligible individuals who consented to participate); retention (participants who completed the 3-month follow-up); and preliminary outcomes (changes in weight and self-reported dietary behaviors).
Results: A total of 76 individuals were interested in participation, among whom 74 completed the eligibility screener (77% women, 23% men). Among them, 65 were eligible, and 51 enrolled (80% (41/51) of women and 71% (10/14) of men). Mean age was 44 (SD 7.3), and 51% had a primary school education or less. 80% of men and 37% of women were employed. At month 3, the retention rate was 98% for women and 60% for men. Mean weight loss among men was 6.1 lbs (SD 6.3), and 5.4 lbs (SD 5.9) among women. Men showed greater improvements in dietary behaviors in many categories, including fruit (+28% men, +15% women), ice cream (-12% men, -8% women), and fried food (-59% men, -35% women) consumption.
Conclusion: Recruitment rates were similar for men and women, with men demonstrating greater weight loss and more substantial dietary behavior improvements in several categories. However, fewer men completed the eligibility screener, and retention rates were lower for men, suggesting barriers to male participation. To address barriers to recruitment and retention of Latino men, outreach efforts should include tailoring to Latino men (e.g., scheduling health promotion/outreach events specifically for fathers, adjusting recruitment hours to after-work and weekends to accommodate job demands), and partnering with Hispanic-serving faith- and community-based organizations to highlight the value of participation to Latino men and encourage engagement with all family members.

#1037 Deep learning-derived dietary patterns and gastric cancer risk in women: A large-scale prospective cohort study.

Hyobin Lee[1], Dongseok Heo[2], Sukhong Min[1], Sinyoung Cho[1], Bongwon Suh[3], Daehee Kang[1]

[1]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Interdisciplinary Program in Artificial Intelligence, Seoul National University Graduate School, Seoul, Korea, Republic of,[3]Department of Intelligence and Information, Seoul National University, Seoul, Korea, Republic of

Background & Aims: Machine learning can address limitations of principal components analysis by capturing nonlinear relationships, enhancing dietary pattern identification. This study aimed to identify dietary patterns using deep learning and cluster analysis and to assess their association with gastric cancer incidence in a prospective cohort study.
Methods: Data were obtained from participants of the large-scale prospective cohort study, Health Examinees-Gem (HEXA-G) study, with baseline surveys conducted between 2004 and 2013. Cancer diagnosis information was retrieved from the Korea Central Cancer Registry up to December 31, 2018. The final analysis included 84,725 women. Dietary intake was assessed using a validated semiquantitative food frequency questionnaire at baseline. Dimensionality reduction was performed using an autoencoder, followed by k-means clustering. The optimal cluster number was determined using the silhouette coefficient. Multivariable Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for gastric cancer risk associated with the dietary patterns.
Results: Ten dietary patterns were identified: ‘Common’, ‘Low calorie’, ‘Rice’, ‘High calorie’, ‘Traditional’, ‘Dairy’, ‘Meat’, ‘Processed’, 'Noodles' and ‘Salty’ patterns. A total of 558 cases of gastric cancer were identified during median 9.4 years of follow-up. Compared to the ‘High calorie’ pattern (reference), the ‘Noodles’ (HR 1.97, 95% CI 1.05-3.70), and ‘Low calorie’ (HR 1.91, 95% CI 1.23-2.97) were associated with higher incidence of gastric cancer after adjusting for potential confounders. When stratified by age, ‘Salty’ pattern was associated with 4.34 times higher risk of gastric cancer (HR 4.34, 95% CI 1.49-12.60) among participants aged 40-49.
Conclusion: Our results suggest that relative to the ‘High calorie’ pattern, the ‘Noodles’, ‘Low calorie’, and ‘Salty’ patterns are associated with increased risk of gastric cancer among Korean women. While Helicobacter pylori infection—a major risk factor for gastric cancer—was not accounted for in this study, our findings highlight the importance of dietary interventions to reduce high-risk patterns, such as salty or noodle-based diets, to lower the risk of gastric cancer.

#1038 Examining racial disparities in the context of food security, poverty, and allostatic load.

Jennifer M. Crook[1], Eunkyung Lee[2], Rui Xie[3], Ladda Thiamwong[1], Victoria Loerzel[1]

[1]Nursing, University of Central Florida, Orlando, FL,[2]Health Sciences, University of Central Florida, Orlando, FL,[3]Statistics and Data Science, University of Central Florida, Orlando, FL

Intro: Disparities in cancer incidence and mortality remain a complex and elusive problem with diet well-studied as a contributing factor. However, it is unclear the impact of food and nutritional security on cancer risk. To fully appreciate nutritional inequities of both food insecurity (FI) and poverty within cancer, there remains a need to more closely examine racial/ethnic disparities in chronic inflammatory indicators of allostatic load. We have previously identified nutritional discrepancies between dietary intake report and plasma nutritional and inflammatory statuses. This study aimed to more clearly identify racial/ethnic disparities within FI, poverty, and allostatic load to develop targeted public health nutritional cancer interventions.
Methods: The Vitamin/Mineral and Inflammatory Correlations To Understand Chronic Stress in the U.S.: The VICTUS Study is a cross-sectional study utilizing data from the 2017/2018 National Health and Nutrition Examination Surveys (NHANES) as a representative sample of U.S. adults. Subjective survey data was interrogated with objective laboratory analyses to observe associations between demographic, socioeconomic, health behaviors, nutrition status, and biomarkers of allostatic load (defined as systolic and diastolic blood pressure, body mass index, glucose, albumin, creatinine, HDL, LDL, triglycerides, hs-CRP, red cell distribution width, and cholesterol) to identify racial/ethnic disparities. Pearson's chi-square, correlation, and ANOVA models were constructed.
Results: From 3083 participants, 38.2% other Hispanic, 37.3% multi-racial, 35.2% Mexican American, and 26.4% non-Hispanic Black adults reported FI, while only 22.5% non-Hispanic White and 5.8% of Asian adults did. Allostatic load and inflammatory biomarkers of SBP, DBP, BMI, HDL, tri, RDW, hs-CRP, alb, creat, ($p<0.001$), and chol ($p<0.05$) exhibited significant racial/ethnic disparities. When surveying poverty, Mexican American ($p < 0.001$), multi-racial ($p < 0.01$), NH Black and other Hispanic ($p < 0.05$) exhibited increased rates when compared to NH White participants. There were also clear racial/ethnic disparities between FI report and plasma nutritional status with significant deficient and inadequate statuses seen in the following micronutrients B, C, D ($p < 0.001$), E ($p < 0.01$), Na, and Ca ($p < 0.05$).
Discussion: This study found clear racial/ethnic disparities in FI, poverty, nutritional status, and inflammatory indicators of acute and chronic inflammation (allostatic load). Also identified were incongruences between self-reported FI and plasma nutritional status of many micronutrients with significant associations with race/ethnicity suggesting that current FI assessment may neither be adequately identifying nor intervening in those at highest risk of chronic inflammatory conditions contributing to increased cancer risk.

#1039 Bridging gaps in cancer care: Utilizing large language models for accessible dietary recommendations.

J. A. Logan[1], N. L. Simone[1], S. Sadhu[1], C. Hazlewood[1], S. Burke[1], H. Nourzadeh[1], Y. Vinogradskiy[1], W. Choi[1], A. P. Dicker[1], M. Denton[2], C. Black[2], C. Ciaverelli[2], J. Stulb[2], A. Leader[1];

[1]Sidney Kimmel Medical College, Philadelphia, PA, [2]Thomas Jefferson University Hospitals, Philadelphia, PA

Background: Weight management is directly linked to cancer recurrence and survival; however, oncology nutritional counseling is not typically covered by insurance, creating a disparity among patients without nutritional education and easy food access. Novel ways of imparting personalized nutrition advice are imperative to address this issue. Large language models offer a promising and sustainable path toward dietary advice tailored to individual needs.

Objective: This study aimed to assess the capacity of large language models to offer personalized dietary advice to patients with breast cancer.

Methods: Thirty-one prompt templates were designed to evaluate the dietary recommendations generated by ChatGPT and Gemini with variations within eight categorical variables, including cancer stage, comorbidity, location, culture, age, dietary guideline, budget, and store. Seven prompts were selected for response from four board-certified dietitians. The responses were then evaluated based on qualitative observations of the large language model-generated grocery lists and meal plans and a quantitative comparison of the calories and macronutrients of large language model- and dietitian-generated meal plans to the Acceptable Macronutrient Distribution Ranges and United States Department of Agriculture daily calorie standards.

Results: Large language models generated personalized grocery lists and meal plans, adapting to location, culture, and budget, but not age, disease stage, comorbidities, or dietary guidelines. Gemini provided more comprehensive responses, including visuals and specific prices. While dietitian-generated diets offered more adherent total daily calorie contents to the United States Department of Agriculture's estimated calorie needs, ChatGPT and Gemini offered more adherent macronutrient ratios to the Acceptable Macronutrient Distribution Range.

Conclusions: Large language models can provide personalized dietary advice to cancer patients who may lack access to this care. Recommendations apply to patients with variable food access, socioeconomic means, and cultural preferences and can be a tool to increase health equity.

#1040 Voices of resilience: Analysing #MetastaticBreastCancer content on TikTok.

N. Morena[1], **C. Herman**[1], J. Schneidman[1], E. Belzile[2], A. N. Meguerditchian[2];
[1]McGill University, Montreal, QC, Canada, [2]St Mary's Research Centre, Montreal, QC, Canada

INTRODUCTION:
Young women with metastatic breast cancer (YWMBC) have unique biopsychosocial challenges, for which they often turn to social media for information and support. The aim of this study is to understand YWMBC engagement on TikTok and analyze content about MBC.
METHODS:
Videos tagged with #metastaticbreastcancer on TikTok were collected in 07/24. Reviewers gathered video characteristics: username, user profile, caption, length, date posted, number of followers, likes, views, shares, comments, and presence of sponsorship. Creator demographics were noted. Explanations, communication style, themes, and topics discussed were assessed. Spearman's correlation coefficient was calculated between variables.
RESULTS:
336 English language TikToks were included. Most videos (41%) were posted in 2024, 97% were from individuals. 1% included sponsorship. Average video length was 1:46 minutes. 161 used music. Mean follower number was 61,927 (SD 350,900). Mean number of views, likes, and comments was 209,882 (SD 625,961), 15,541 (SD 134,070), and 622 (SD 3899), respectively. The majority of videos were filmed at home (56%), specifically in the bedroom. 21% were filmed in a hospital setting. Average age at diagnosis was 31.4 years old (SD 4.3). Emotion was explicitly present in 24% of videos. Topics discussed included: daily life with MBC (70%), diagnosis (42%), treatment options (38% systemic, 26% surgery and 16% radiation). Themes are addressed in Table 1. Most relevant correlations for engagement (likes, views) included display of surgical scars, explicit expression of emotions, and diagnosis story. Predictors specific to more comments included fear of recurrence, grief and motherhood.
CONCLUSION:
TikToks from YWMBC present personal narratives of the daily experience of MBC. They are minimally sponsored and generate higher engagement when personal content/emotions are displayed. They may represent a journaling equivalent and could potentially have a beneficial effect on patients.
Table 1 :

Themes	**N (%)**
General experience of treatment	175 (52.2)
Path to diagnosis	166 (49.4)
Side effects (fatigue, nausea, etc)	91 (27.1)
Motherhood	69 (20.5)
Appearance	68 (20.2)
Mental health	61 (18.2)
Treatment choices	54 (16.1)
Spousal relationship	49 (14.6)
Fear of recurrence	37 (11.0)
Family relationship	29 (8.6)
Grief	22 (6.5)
Fertility	15 (4.5)
Social commentary	12 (3.6)
Treatment toxicity	12 (3.6)
Preparing for end of life	9 (2.7)
Sexuality	3 (0.9)

#1041 Active interception to modulate the systemic cancer-permissive microenvironment and reduce cancer incidence in companion dogs with elevated cancer risk.

Ashley J. Schulte[1], Rose Dicovitsky[2], Taylor A. DePauw[1], Amber L. Winter[2], Kathleen L. Stuebner[1], Andrea Chehadeh[2], Sara Pracht[2], Antonella Borgatti[2], Ali Khammanivong[1], Mitzi Lewellen[1], Lauren E. Burt[1], Daniel A. Vallera[1], Michael S. Henson[2], Erin B. Dickerson[1], Christopher Ober[2], Kari L. Anderson[2], Esther Nell[2], Aaron L. Sarver[1], Gary R. Cutter[3], Jaime F. Modiano[1]

[1]University of Minnesota, Minneapolis, MN,[2]University of Minnesota, St. Paul, MN,[3]University of Alabama at Birmingham, Birmingham, AL

Companion dogs have a lifetime cancer risk similar to that of humans. This excess risk, as compared to what is seen in other species, seems to be due to our recent success in outliving our evolutionarily adapted lifespan. For cancers to develop, a cancer-permissive environment must be present, which may exist months or even years before a tumor becomes detectable. We have developed the Shine On Suspicion (SOS) test, a flow cytometry based test to detect these changes that lead to a cancer-permissive environment. To make this test actionable, we combined it with a novel agent for cancer interception (secondary prevention) called eBAT. eBAT is a bispecific ligand targeted toxin consisting of truncated, deimmunized *Pseudomonas* exotoxin fused to epidermal growth factor (EGF) and the amino terminal fragment of urokinase. This drug was designed to use epidermal growth factor receptors (EGFR) and urokinase-type plasminogen receptors (uPAR) as baits to deliver the lethal toxin into the cells, rather than disrupting receptor signaling. eBAT has self-limiting, well-tolerated side effects and is safe enough for administration to otherwise healthy individuals. To date, eBAT has been administered to 11 healthy dogs that were determined to have elevated cancer risk based on the SOS test, with only 1 of the 11 dogs developing cancer more than 2 years after treatment. A hazard ratio calculated with a 95% confidence interval shows that dogs receiving eBAT interception had nearly 4 times reduction in risk of a cancer diagnosis compared to controls. Ongoing research aims to explore the identity and function of niche-forming cells to improve cancer prevention strategies and their applicability to humans.

#1042 MAGE-A3 and PD-L1 protein co-expression in lung cancer a look at the immune cells' tumor microenvironment.

Aimee Icaza Galarza[1], Rachel M. Gonzalez[1], YiChen Guo[1], Dehe Kong[1], Bailey Gilmore[1], Tianli Qu[1], Alex Strom[1], Zhaoying Guo[1], Qi Ren[2], Xiaomin Hu[2], Ranran Zhang[2], Zhaohui Wu[2], Jessi Chen[1], Xuan Liu[1], Wei Fu[1]

[1]Immunology, OriGene Technologies, Inc., Rockville, MD,[2]Immunology, OriGene Wuxi Biotechnology Co., Wuxi, China

This lab's previous studies highlight the co-expression of PD-L1 (CD274) and MAGE-A3/A4 in non-small cell lung cancer (NSCLC) and squamous cell lung cancer, with around 50% of the screened tumors exhibiting this co-expression. Additionally, this study also identified MAGE-A3/A4 as a secreted protein using CytoSections. A sandwich ELISA was developed for MAGE-A3/A4 and demonstrated that serum levels of MAGE-A3 protein were significantly elevated in lung cancer patients compared to matched controls. This statistically significant difference suggests that MAGE-A3 could serve as a valuable biomarker for lung cancer diagnosis and prognosis. Such findings may also provide insights into the tumor microenvironment and the immune evasion mechanisms facilitated by PD-L1 and MAGE-A3 co-expression, potentially guiding the development of targeted therapies or combination strategies in the treatment of lung cancer. In this study, the lung cancers were screened with CD1C, CD163, CD20, CD31, CD3E, CD4, CD68, CD8A, FOXP3 immune markers previously evaluated with PD-L1 to characterize the tumor micro-environment where PDL1 and MAGE-A3 protein are co-expressed versus when only MAGE-A3 is expressed in lung cancer. MAGE-A3 was detected on positive CD3e and suggesting a role in regulating immune response. This study offers insights into the tumor microenvironment, a new view of immune escape in lung cancer, and the potential of MAGE-A3 as a diagnostic/prognostic biomarker and therapeutic target, particularly in combination with immune checkpoint inhibitors.

#1043 Efficacy and mechanistic insights of Shengyang Qushi Decoction in managing surufatinib-associated diarrhea.

Huangying Tan, Shaobo Hu

Integrative Oncology, China-Japan Friendship Hospital, Beijing, China

Background: Surufatinib, a novel TKI targeting VEGFRs, FGFR1, and CSF1R, treats advanced neuroendocrine tumors but often causes diarrhea, which impairs patients' health and anti-tumor efficacy. We've successfully established a rat model of surufatinib-induced diarrhea. This study aims to investigate Shengyang Qushi Decoction's mechanism in treating this diarrhea, focusing on intestinal mucosal barrier and inflammation, for clinical application.

Methods: Sixty male rats were randomly assigned to five groups after a 3-day acclimation period: control, model, low-dose decoction (12g/kg), high-dose decoction (24g/kg), and positive control (Loperamide 0.36mg/kg) group. Except for the control group, all received oral administration of surufatinib at a dose of 110 mg/kg, followed by corresponding treatment after 12 hours. We monitored body weight, general condition and assessed diarrhea. Histological changes in the colon were evaluated. ELISA measured plasma diamine oxidase (DAO) and D-lactate levels, as well as serum inflammatory cytokines (TNF-α, IL-1β, IL-6). Western blotting assessed the expression of tight junction proteins, inflammatory cytokines (TNF-α, IL-1β), and key proteins in the NF-κB pathway (IKK-α, IκB-α, NF-κB p65) in colon tissue.

Results: Rats in the high-dose decoction group had slower weight gain than the control but more than other groups, with improved physical appearance and activity levels, and food and water intake similar to the control. Diarrhea rates were 50%, 17%, and 42% in the low-dose decoction, high-dose decoction, and positive control groups, respectively. Hematoxylin-eosin staining revealed intact colonic structure in the control group with orderly mucosal epithelia and no abnormalities. In the high-dose decoction group showed intact colon mucosa with minimal inflammation and no congestion or edema. DAO levels were not significantly different among groups, but D-lactate levels were significantly higher in the model group ($P < 0.01$) ,and decreased after intervention, most notably in the high-dose decoction group. After drug intervention, the colonic tight junction proteins increased, most notably in the high-dose decoction group ($P < 0.01$ vs. model). Serum TNF-α, IL-1β, and IL-6 levels declined, with the high-dose decoction group showing the greatest reduction ($P < 0.01$). And the colon's TNF-α and IL-1β proteins followed the same trend ($P < 0.01$). Western blotting showed reduced expression of phosphorylated NF-κB pathway proteins (p-IKK-α, p-IκB-α, p-p65) after intervention, with the high-dose decoction group showing the greatest decrease ($P < 0.01$).

Conclusions: Animal experiments confirm Shengyang Qushi Decoction's efficacy in treating surufatinib-induced diarrhea. It mitigates colonic tight junction damage, reduces mucosal permeability, inhibits NF-κB signaling pathway activation, and alleviates colonic inflammation.

#1044 Patient acceptability of human papillomavirus (HPV) self-sampling for cervical cancer screening to reach under-screened women who present to the emergency department.

Sara Heinert[1], Ronald Ikechi[2], Eileen Hsieh[3], Neha Maddali[3], Rufine Kendra Soh[3], Yugledys Hoyos[4], Giana Oelkers[4], Camille Grullon[4], Maya Iglesias[3], Pamela Ohman-Strickland[5], Jonathan McCoy[1], Christine Ramdin[2], Racquel Kelly Kohler[6]

[1]Department of Emergency Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ,[2]Department of Emergency Medicine, Rutgers New Jersey Medical School, Newark, NJ,[3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ,[4]Rutgers University, New Brunswick, NJ,[5]Department of Biostatistics and Epidemiology, Rutgers School of Public Health, Piscataway, NJ,[6]Rutgers Cancer Institute, New Brunswick, NJ

Despite advancements in cervical cancer screening, treatment, and preventive measures, marked disparities exist among vulnerable populations. While several factors contribute to disparities, over half of cervical cancer cases are diagnosed in women who rarely or never screen. Emergency departments (EDs) tend to serve in a safety net capacity for underserved patients and thus can be an effective site to reach patients overdue for cancer screening. HPV self-sampling, where women use a swab to collect their own cervicovaginal sample, has similar accuracy to clinician-collected samples, has recently been FDA approved, and addresses barriers to screening. However, the optimal kit distribution strategy remains unknown. ED-based in-person distribution with same-day return of self-sampling kits has the potential to alleviate issues of prior trials mailing kits to women's homes. As a first step to implementing such a program, we surveyed women eligible for cervical cancer screening in two large EDs who presented with non-critical conditions to determine patient acceptability and preferences for HPV self-sampling in the ED. We conducted 118 surveys. Average participant age was 44 years (SD=10), 9% were Asian, 31% were Black, and 35% were Hispanic. Over half (55%) of participants had private insurance, 23% had Medicaid, 18% had no insurance; 28% had no primary care doctor. Fourteen percent of participants were overdue for cervical cancer screening (last Pap was >3 years ago or their Pap/HPV co-test was >5 years ago). Most participants (88% overall, 87% of overdue women) said they were willing to use a HPV self-sampling kit if it was offered acutely in the ED, and 89% overall and 87% of overdue women were confident in their ability to collect their sample correctly. The most prevalent concerns of using the kit were: that the test was not done right (50%) and not knowing how to perform the test (31%). Most women (71% overall, 80% overdue) said they would feel comfortable using the self-sampling kit in an ED bathroom. Of all women not comfortable, the most common reason was that it was a public place/no privacy (27%). When given the choice, 36% of all women would prefer to self-sample in the ED bathroom, 34% would prefer to take the kit home to complete and mail it back, and 30% would prefer collection by a physician or nurse. Preference for collection in an ED bathroom was higher (47%) for overdue women. Our survey showed strong patient acceptability of HPV self-sampling in the ED. Our next step is to conduct a pilot trial implementing HPV self-sampling kit distribution in the ED and navigation to follow-up care to improve cervical cancer screening access. Participants' most prevalent concern of not performing the test correctly suggests that education and instructions for self-sampling prior to use will be an important component to successful roll-out.

#1047 Addressing data disparity in pre-clinical research using a generative approach.

Oleksandr Narykov, Alexander Partin, Yitan Zhu, Priyanka Vasanthakumari, Thomas Brettin, Varuni Sastry, Rick L. Stevens

Argonne National Laboratory, Lemont, IL

Anti-cancer drug response prediction is of paramount importance to drug development and patient treatment design. However, publicly available drug screening datasets on cell lines and patient-derived organoids or xenografts contain highly unbalanced information with most experiments corresponding to non-responsive drug and tumor combinations. While previous research explored augmenting tumor gene expression for cancer type classification, we target a more challenging problem - a guided generation of the responder genetic makeup for specified drugs and sample populations. To tackle this task, we employ a combination of cutting-edge artificial intelligence techniques - consistency models (CM), biology-informed dynamic neural networks (NN), contrastive learning (CL), and transformers. Recent work from OpenAI has addressed the convergence and speed limitation of generative adversarial networks (GAN) by introducing CMs, a novel class of generative models. This development provides a framework for generating synthetic cell line data under complex, biologically relevant conditions for subsequent analysis and optimization. We have modified the CM architecture for the efficient, one-shot generation of RNA-Seq samples. However, the raw outputs of the model mimic the original data distribution and produce unbalanced responder and non-responder data. We employ CL between RNA-seq samples and compounds to guide the model to a desirable outcome. This component integrates hierarchical biological knowledge from the KEGG database with convolutional filters to achieve parameter efficiency and transformer-based encoding of drugs to match responders' genetic makeup with the corresponding drug to which it is susceptible. Unlike traditional fixed architectures, RNA-Seq encoder adaptively modifies its topology based on biological relationships in the data and leverages BRITE hierarchical relationships to guide the formation of neural connections in a biologically-informed manner. The proposed method allows for the generation of responder data that can be conditioned on both selected drugs and RNA-Seq samples to produce data with specific traits of demographics of interest. We apply popular clustering algorithms on a combination of real-world data and synthetic samples generated by our model. Multiple metrics, including adjusted random score, adjusted mutual information, and homogeneity score, are used for examining the mixing of real-world and synthetic data. The results demonstrate that ground truth and augmented data are nearly indistinguishable.

#1048 Unraveling cancer disparities in African Americans: Socioeconomic, healthcare, and environmental contributions in UChicago and Baylor catchment areas.

Ahmed Fadiel, Fadiel A.1, Fadel S. 1, Oluyomi A. 2, Rosales O. 2, Eichenbaum K.3, Abbasi M., Elbialy A., Odunsi K1, Saleh Fadel, Kunle Odunsi

University of Chicago, Chicago, IL

Background: Cancer incidence rates are disproportionately high among African Americans for several cancers, including breast and prostate cancer. Reasons for these disparities may take root from a complex set of social, economic, and environmental factors. This study examines disparities in cancer incidence among African Americans between the University of Chicago and Baylor College of Medicine catchment areas, focusing on identifying modifiable factors.
Methods: Data were obtained from SEER, CDC WONDER, ACS, and Policy Map. We used our intelligent Catchment Analysis Tool, or iCAT, to examine the incidence of cancers with demographic, socioeconomic, and healthcare utilization variables, environmental factors, pollution, and water quality. iCAT helped precisely delineate catchment areas to analyze referral patterns of hospitals and population density. Statistical analysis using multivariate logistic regression and spatial analysis enabled us to identify clusters of disparities. Data visualizations were developed to illustrate relationships, including geographic heatmaps and scatter plots.
Results: Our findings demonstrated that cancer incidence rates were dependent on socioeconomic and environmental inequalities, with distinct differences in patterns at U. Chicago and Baylor catchment areas. Communities characterized by higher poverty levels, lower educational attainment, and limited access to healthcare showed increased cancer incidence rates. Environmental factors, especially air quality, further accentuated these disparities.
Conclusions: The findings underscore the urgent need for multilevel interventions to target socioeconomic inequities, improve healthcare access, and reduce environmental risks to decrease the cancer burden among African Americans. This study provides a basis for working toward tailored public health strategies in the U. Chicago and Baylor catchment areas, contributing to health equity and improved cancer outcomes.

#1049 Advancing health equity in oncology through AI, GIS, and data-driven tools.

Ahmed Fadiel, Fadiel A.1, Fadel S. 1, Butt W. 1, Eichenbaum, KD.2 Abbasi M. 1, Elbialy A. 1, and Odunsi K. 1, Kunle Odunsi, Saleh Fadel

University of Chicago, Chicago, IL

Cancer outcomes are influenced by geographic, socioeconomic, and environmental factors, especially in rural and underserved urban areas. Such regions often lack appropriate screening and specialized care, leading to late-stage diagnoses and poor overall outcomes. Key socioeconomic determinants influencing disparities in cancer care include income, education, environmental conditions, insurance status, and geographic proximity to qualified healthcare providers. To address these inequities, sophisticated tools are needed to identify high-risk areas and to improve resource allocation. To address this need, we developed the Intelligent Cancer Catchment Area Tool (iCAT), a GIS-enabled platform enhanced by artificial intelligence (AI). iCAT integrates public health sources and health systems data to generate a comprehensive, geographically diverse analysis of cancer disparities. On this platform, mapping capabilities are analyzed with advanced statistics and machine learning algorithms to derive actionable insights into cancer social and environmental drivers of gaps in healthcare. Two recent module additions to iCAT are 1. integration of authoritative datasets, including SEER, CDC, and other trusted sources, and 2. advanced preprocessing, in which LLMs are used to clean data and handle confounders. We have improved the analytics package to enable univariate and multivariate analyses to find more complex relationships among the variables. We are adding AI-assisted literature matching to help formulate and suggest evidence-based research questions. Future directions for iCAT include quantum-enhanced predictive modeling, real-time analytics with biometric data from wearable devices, and hyper-localized risk assessment using augmented reality visualizations. We also plan to incorporate blockchain for data security and AI-driven optimization algorithms that guarantee privacy while enhancing intervention planning. We are developing iCAT as a tool for healthcare providers, policymakers, and researchers to make evidence-based decisions. With further development, we anticipate use cases ranging from deploying mobile screening units to culturally adapted educational programs and forming policy reforms. This new approach is a key milestone toward eliminating health disparities and redefinition of equitable cancer care. "

#105 Netrin-1 activates Yap1 to promote pancreatic cancer metastasis and mutant Kras-independence.

Chris R. Harris, Muhammad Sadeqi Nezhad, Shubhrika Jain, Wade Narrow, Darren R. Carpizo

University of Rochester Medical Center, Rochester, NY

Although pancreatic ductal adenocarcinoma (PDAC) is only the 10th most common cancer, it is the 3rd leading cause of cancer deaths due to its high incidence of metastasis. In patient samples, PDAC metastasis associates with expression of the secreted protein Netrin-1, and indeed metastasis of pancreatic adenocarcinomas in mouse models is sharply reduced upon genetic or pharmacological ablation of Ntn1 signaling. Upon binding to its Unc5b receptor, Ntn1 activates the survival factor Yap1, which then promotes resistance to anoikis, which is a key trait of metastatic tumors. But metastatic PDACs are not the only expressers of Ntn1: indeed, primary pancreatic tumors can also derepress Ntn1 if selected to grow in the absence of mutant Kras. These $Kras^{mut}$-independent tumors become dependent upon activation of Yap1 by Ntn1/Unc5b signaling, and suggest that patients with pancreatic cancer may benefit from combined pharmacological targeting of mutant Kras and Ntn1.

#1050 Geographic disparities in the incidence of breast and prostate cancers among African Americans: A comparative analysis between the UChicago and Baylor catchment areas.

Ahmed Fadiel, Fadiel A.1, Fadel S. 1, Oluyomi A. 2, Rosales O. 2, Eichenbaum K.D. 3, Abbasi M. 1, Elbialy A. 1, an, kunle Odunsi, Saleh Fadel

University of Chicago, Chicago, IL

Background: Cancer disparities continue to be a significant challenge for public health across the nation, especially among African Americans. Causes include socioeconomic factors, environmental conditions, and limited healthcare access. We are exploring data-driven studies of geographic disparities in the incidence rates for breast and prostate cancers across African American populations in catchment areas around the University of Chicago and Baylor College of Medicine.
Methods: Catchment areas were identified using our intelligent Catchment Analysis Tool, or iCAT, to map physical boundaries, referral patterns, distances, and population densities. Data were extracted from the SEER Program, CDC WONDER, and the American Community Survey (ACS). The variables analyzed included cancer incidence rates, demographic and socioeconomic factors, healthcare access and utilization, and environmental exposures, including air pollution and water quality. Chi-square tests, t-tests, logistic regression, and multivariate analysis were also performed to identify key drivers of disparities. The results were displayed on geographic maps, charts, and graphs, highlighting spatial clusters and relationships between cancer incidence and contributing factors.
Results: Our preliminary findings indicate large disparities in cancer incidence rates between the two catchment areas. We investigate associations between socioeconomic inequality, healthcare access, and environmental exposures. African Americans living in areas of the lowest socioeconomic status and decreased healthcare access demonstrated higher incidence rates.
Conclusions: This study can catalyze a focus on systemic inequity in socioeconomic conditions, healthcare accessibility, and environmental quality that influence cancer disparities among African Americans. These findings suggest actionable insights toward targeted interventions and policymaking within the UChicago and Baylor catchment areas.

#1051 Predicting stroke as a cause of death in Black cancer patients using ensemble machine learning models.

Raghad Wesamah Alrawashdeh[1], Nour Wesamah Alrawashdeh[2]

[1]Yarmouk University, Irbid, Jordan,[2]Jordan University of Science and Technology, Irbid, Jordan

Objective: No studies have sought to identify the risk factors associated with cerebrovascular diseases (CVD) as a cause of death in black cancer patients. This study aimed to use advanced machine learning techniques to predict CVD mortality in Black cancer patients and to identify significant risk factors.
Methods: We utilized The Surveillance, Epidemiology, and End Results 17 registry to predict CVD as a cause of death in Black cancer patients from January 1, 2000, to December 31, 2020. Various machine learning models were employed, including Random Forest, Logistic Regression, XGBoost, LightGBM, and Gradient Boosting. The dataset included features such as age, sex, cancer type, year of diagnosis, and treatment modalities including adjuvant chemotherapy, adjuvant radiotherapy, adjuvant chemoradiotherapy, surgery alone, primary chemotherapy, primary radiotherapy, primary chemoradiotherapy, and no treatment. Data preprocessing involved cleaning, feature selection, and 80-20 stratified train-test splitting. The models were combined into a voting ensemble to leverage their strengths. The performance of each model was evaluated using metrics including accuracy, AUC (macro, micro, weighted), precision, recall, and F1 scores. Feature importance was analyzed to identify the most contributing variables in predicting CVD.
Results: A total of 292,680 black cancer patients were included, with a mean age of 57.36 ± 13.68 years. The cohort comprised 152,991 males (52.27%) and 139,689 females (47.73%). Among them, 5,874 patients (2.01%) died from cerebrovascular diseases, while 286,806 patients are alive. The voting ensemble model achieved an accuracy of 0.98, with an AUC macro of 0.88, AUC micro of 0.99, and AUC weighted of 0.88. The average precision scores were 0.64 (macro), 0.99 (micro), and 0.98 (weighted). The F1 scores were 0.64 (macro), 0.98 (micro), and 0.97 (weighted). The precision scores were 0.78 (macro), 0.98 (micro), and 0.97 (weighted). Significant predictors of CVD included an earlier year of diagnosis (with patients diagnosed earlier in the study period from 2000 to 2020 having a higher risk of CVD), older age, lack of any cancer treatment, and specific cancer types (notably gastrointestinal and male genital cancers).
Conclusions: Our findings suggest that the voting ensemble machine learning model can effectively predict stroke mortality in black cancer patients, with high accuracy and robust performance metrics.

#1052 Integrating geographical and socioeconomic data with genomic information for enhanced prediction of cancer risk using large language models and knowledge graphs.

Ofek Mendel[1], **Michael S. Sinclair**[2], Kathleen M. Jagodnik[2], Till Krenz[2], Erin Kobetz[2], Beronica A. Ocasio[2], Jeronimo Pissinis[2], Vasileios Stathias[2], Alon Bartal[1], Stephan Schurer[2]

[1]The School of Business Administration, Bar-Ilan University, Ramat Gan, Israel,[2]Sylvester Comprehensive Cancer Center, University of Miami, Miami, FL

Cancer remains a leading cause of mortality worldwide, with risk and survival outcomes influenced by a complex interplay of genetic, environmental, and socioeconomic factors. Traditional cancer risk prediction models often focus on genetic, lifestyle, and family history factors but frequently overlook the critical roles of geographical location and social determinants of health (SDoH). This study introduces a novel approach that integrates diverse multimodal datasets—including environmental exposures, healthcare access, socioeconomic conditions, and genomic data—within a geographic framework to develop more comprehensive and spatially contextualized cancer risk prediction and survival models. First, we developed a data model to integrate the various data modalities. We leverage our internal Sylvester Data Portal Informatics Platform to manage and map the various data types and metadata. Using the GPT-4o Large Language Model, we identified entities and their relationships from semi-structured and unstructured data sources, and used them to construct a multimodal knowledge graph (KG). Our KG comprises 700,000+ nodes spanning 32 entity types (e.g., genes, 5 cancer types) and 2.134 million edges/links across 107 relationship types (e.g., has_genotype, from_race, from_sex). Graph Neural Networks (GNNs) were then trained on this KG to predict cancer risk and survival outcomes based on demographic factors, location, and tumor genetics. Querying our KG using Graph Retrieval Augmented Generation (GraphRAG) and predicting links using our trained GNN, we uncovered novel insights into the relationships among genetics, demographics, environmental exposures, and cancer statistics, highlighting potential complex gene-environment interactions that contribute to cancer risk and survival disparities, and suggesting directions for future research to reduce cancer risk and improve health outcomes.

#1053 Cellular heterogeneity and stress response in lung tumors: understanding cancer disparities through spatial transcriptomics.

Sabrina Akter[1], Aiman Soliman[2], Zeynep Madak-Erdogan[1], Sage J. Kim[3]

[1]Food Science & Human Nutrition, University of Illinois at Urbana-Champaign, Urbana, IL,[2]National Center for Supercomputing Applications, University of Illinois at Urbana-Champaign, Urbana, IL,[3]School of Public Health, University of Illinois Chicago, Chicago, IL

Background: Despite having lower smoking rates, Black men have a higher incidence of lung cancer. Previously, we showed that social stressors, such as neighborhood violent crime, may influence tumor biology through stress response pathways. In this study, we investigated the relationship between neighborhood violent crime rates and glucocorticoid biosynthesis in lung tumors. Specifically, we examined how cell populations change in tumor regions with high glucocorticoid metabolism and receptor activity.
Methods: We analyzed spatial transcriptomic data from 15 lung tumor samples. Pathway activity and cell type associations were examined using gene set co-regulation analysis (GESECA). We computed univariate and bivariate local Moran's I to assess spatial co-localization at $p < 0.05$. To validate these spatial associations, we performed unsupervised cell-type deconvolution using STdeconvolve and applied spatial interpolation to enhance the resolution of cell-type distributions.
Results: We identified a positive correlation between neighborhood violent crime rates and glucocorticoid biosynthesis pathway activity ($p < 0.05$). Several epithelial cell types, including adventitial fibroblasts, basal cells, club cells, and mesothelial cells, were significantly associated with glucocorticoid biosynthesis-enriched regions in lung tumor samples from high-crime neighborhoods. Cell type deconvolution and spatial interpolation confirmed localized clustering of these epithelial cells within glucocorticoid biosynthesis-active regions at high resolution.
Conclusions: Our findings suggest that social stressors, such as neighborhood violent crime, may contribute to lung cancer disparities by influencing tumor development through stress-induced pathways. This study highlights the importance of understanding cellular heterogeneity within the tumor microenvironment, which could inform targeted cancer prevention and control interventions.

#1054 A combined genome-wide-association and admixture analysis of prostate cancer risk in men of African ancestry in the *All of Us* Research Program.

William Letsou, David Mushiyev, Daniel Galvin Gusmano

New York Institute of Technology, Old Westbury, NY

Men of African ancestry are known to suffer increased rates of prostate cancer incidence and mortality. While many studies have identified common variants that are specific to, or at elevated frequency in African populations, the genetic basis of this healthcare disparity remains to be fully worked out. Admixture analysis is a computational tool for identifying local genetic ancestry across individual genomes, and is potentially useful for detecting shared, disease-associated haplotypes in populations, such as African Americans, who derive from multiple ancestry groups. Our hypothesis was that genome-wide admixture mapping could be used as a proxy for a genome-wide linkage scan in *unrelated* individuals, so that a direct comparison of the loci implicated by genome-wide association studies (GWAS) and linkage analysis could be made. To this end, we conducted a case-control GWAS, and a cases-only admixture mapping in 8,957 men at least fifty years-old of African ancestry (578 cases, 8,379 controls) in the *All of Us* Research Program. In total, we tested 5,856,945 common polymorphisms and indels (MAF ≥ 0.05), and found a genome-wide significant variant rs73705708 ($P = 8.8 \times 10^{-13}$) at the previously implicated 8q24 locus. We then conducted admixture analysis using RFMix v. 2.0, with phased input being supplied by Beagle v. 5.4, and detected a statistically significant increase in local European ancestry ($Z < -6$) in the 14q23 region near the *GPHN* gene, as well as a statistically significant increase in local African ancestry ($Z > 4$) near the HLA region at 6p22; neither region was implicated by the GWAS. And although we observed a nominally significant peak ($Z > 3$) as expected in the 8q24 region, we overall found little correlation ($R^2 = 0.0003$) between GWAS *P*-value and admixture Z-score in our cohort. These results support the hypothesis that regions of the genome inherited from a common ancestral population represent a distinct set of risk loci to those identified by GWAS, and suggest that the genetic basis of prostate cancer risk and disparities may have additional unidentified contributions. The authors of this study gratefully acknowledge *All of Us* participants for their contributions, without whom this research would not have been possible, and the National Institutes of Health's *All of Us* Research Program, for making available the participant data examined in this study. All data used in this study came from *All of Us* Research Program's Controlled Tier Dataset v. 7, available to authorized users on the Researcher Workbench.

#1055 Inclusion of large genomics databases in disease modeling improves outcomes across ancestral populations.

Leslie A. Smith[1], Franco Krepel[1], James A. Cahill[2], Ji-Hyun Lee[3], Kiley Graim[1]

[1]Department of Computer & Information Science & Engineering, University of Florida, Gainesville, FL,[2]Environmental Engineering Sciences Department, University of Florida, Gainesville, FL,[3]Department of Biostatistics, University of Florida, Gainesville, FL

Rapid advancements in genomic sequencing technologies have revolutionized the study and treatment of human diseases. Even with the wealth of genomic information available, successful application of developed treatments is often limited to the human populations represented in the original study, suggesting that these studies are overfitting to their data and thus limiting scientific understanding of complex traits and diseases. Human populations have developed population-specific variants in response to evolutionary changes as a result of human migrations and other stressors which can impact disease occurrence and outcome. Lack of sufficient sampling for equal representation of this variation in disease studies has led to disparate outcomes and treatments. While obtaining a representative study population for a disease is often unrealistic, equitable machine learning approaches can bridge the gap. Here, we demonstrate an equitable machine learning approach, PhyloFrame, showing that the inclusion of publicly available genomic resources in disease modeling methods can force machine learning and artificial intelligence models to be more robust to data distribution shifts caused by unequal sampling of human populations, thereby increasing model generalizability. We demonstrate PhyloFrame's utility across several diseases at high risk of ancestral bias, which we identified via an analysis of heritable disease signatures. We first perform statistical enrichment of ancestry-specific alleles within existing disease signatures for Mendelian disorders by calculating variant frequency enrichment for each of the populations in gnomADv4.1 and the 1000 Genomes Project. After identifying the diseases at highest risk for ancestral bias, we apply our PhyloFrame method to RNA-seq datasets from those diseases and contrast PhyloFrame's performance in each ancestry group to a comparable benchmark model that does not incorporate equitable machine learning techniques. Our results demonstrate that incorporating publicly available genomic data into disease modeling methods improves outcomes for all. Growing resources for publicly available large-scale genomic databases provide unprecedented opportunities to understand disease. Resulting analysis of variation across human populations is a powerful approach to supplement disease models. Here we demonstrate how to incorporate this information into disease modeling, and show it is a unique and feasible approach to advancing equity in precision medicine.

#1056 Exploring the impact of ancestry on metabolic dysregulation in lung adenocarcinoma: Implications for racial health inequities and targeted therapeutics.

Benecia A. Jackson, Yuxin Jin, Yonatan Amzaleg, Angel Perez Hunt, Nikita Jinna, Dan Raz, Loretta Erhunmwunsee, John Carpten, Aaron Neely

City of Hope National Medical Center, Duarte, CA

Introduction. The occurrence of lung adenocarcinoma (LUAD) is approximately 68.3 per capita for Black men and 61.5 per capita for White men, reflecting an 11% higher rate in the former. Black patients experience a poorer prognosis and significantly higher mortality rates compared to their White counterparts. *Purpose.* Understanding the genetic and molecular foundations that underly racial health inequities is essential for developing comprehensive interventions and advancing more precise therapeutic modalities for diverse patient populations. Single Nucleotide Polymorphisms (SNPs) can influence oncogenic transformation and may be associated with distinct molecular landscapes in tumors and adjacent TME. Furthermore, ancestry may play a pivotal role in shaping individual susceptibility and risk for mitochondrial dysfunction and ensuing oncogenic transformation.
Methods. We employed germline VCFs for ancestry analysis of 36 LUAD patients (18 Black and 18 White) from the ORIEN data set, while genotype data from the 1000 Genomes Project phase 3, grouped by super population served as reference. Oncoplots were generated using a combination of patients' somatic VCF and metadata from ORIEN. Regression analysis adjusting for age, staging, and gender was performed to determine association between ancestry and gene mutations. Global admixture was estimated using STRUCTURE v2.3.4 with k=5, NUMREPS=2000, and BURNIN=50000. VCFs were subset and merged by 1126 ancestry-informative markers (AIMs) and converted to STRUCTURE format with PLINK. PCA was conducted using R. Local ancestry analysis was performed with LAMP-LD v1.3 using a window length of 50 SNPs and 20 states, based on 20,803 SNPs. Results were visualized with ggplot2 in R.
Results. In Black patients, admixture analysis showed predominant AFR genetic similarity with varying proportions of EUR, AMR and SAS similarity. Local ancestry analysis using LAMPLD reveals admixture across different regions of the genome illustrating the variation in ancestral contributions within and between individuals of the same cohort and compared to counterparts in other populations. Mutations in ACADVL, HK2, SREBF1, COX6L, BID, POLG2, SLC2A2, SLC22A5, and ACKR1 are associated with AFR status >/= 0.5. Mutations in ACADSB, HK3, PPARGC1A are associated with AFR status < 0.5.
Conclusions. Mutations in metabolic and mitochondrial genes emerged as being highly enriched in LUAD patients with high relative to low African genetic ancestry, suggesting opportunities for improved risk-prediction and therapeutic targeting in this subpopulation.

#1057 Addressing challenges in integrating dietary factors into machine learning models for gastrointestinal cancer prediction in South Korean cohort.

Daina Baublyte, Jeonghee Lee, Madhawa Gunathilake, **Jeongseon Kim**

National Cancer Center - Korea, Goyang-si, Korea, Republic of

Introduction: Dietary factors are integral to cancer etiology but are underrepresented in predictive models for gastrointestinal (GI) cancer risk. Challenges such as limited availability and variability of dietary intake data hinder the development of effective machine learning (ML) models. This study investigates these challenges and develops practical solutions to enhance the integration of dietary data into GI cancer risk prediction using a South Korean cohort.
Methods: We analyzed data from the Cancer Screenee Cohort, following 7,862 adults (158 GI cancer cases and 7,704 controls) over 16 years. Dietary data were collected using a validated food frequency questionnaire (FFQ), supplemented by clinical biomarkers and anthropometric measurements. ML models—logistic regression, random forests, gradient boosting machines, and support vector machines—were trained and evaluated using precision and F1 scores, focusing on predicting the minority class (GI cancer cases). A tailored data sampling and model training strategy was developed to address class imbalance and improve predictive performance.
Results: Initial ML models faced performance challenges due to class imbalance and limited sample size, achieving zero precision for the case class and strong performance only for control class (control precision = 0.98). The proposed sampling and model training strategy enhanced minority-class predictions achieving a case class prediction precision of 0.78—a 78% improvement—while maintaining an overall F1 score of 0.75, reflecting a strong balance between overall model precision and recall.
Conclusions: This study highlights the challenges of incorporating dietary factors into GI cancer prediction and underscores the importance of tailored approaches to address class imbalance in ML models. The proposed strategy substantially improved predictions for the minority class, offering practical insights for enhancing GI cancer screening and prevention through data-driven methods. Future work could explore incorporating additional dietary factors and testing the approach in larger populations to further validate its applicability.

#1058 The prediction of positive prostate biopsies in men is significantly enhanced when PVT1 Exon 4A is combined with serum Prostate Specific Antigen (PSA)..

Tinovimba L. Hove[1], Rachel E. Sexton[2], Michael Liss[3], Robin Leach[3], Emmanuel Asante-Asamani[1], Olorunseun O. Ogunwobi[2]

[1]Clarkson University, Potsdam, NY,[2]Michigan State University, East Lansing, MI,[3]University of Texas Health, San Antonio, TX

Prostate cancer (PCa) remains a significant public health challenge, ranking as the second leading cause of cancer-related deaths among men in the United States. Current diagnostic approaches, predominantly centered on prostate-specific antigen (PSA) testing, often lead to overdiagnosis and unnecessary biopsies. The long nonprotein coding gene, PVT1 (plasmacytoma variant translocation 1), has shown promise as a biomarker, being upregulated in PCa and associated with disease progression and metastasis. This study investigates the potential of incorporating PVT1 biomarkers to improve diagnostic accuracy for PCa detection, focusing on both the general population and men of African ancestry, who are disproportionately impacted by PCa incidence and mortality.

A total of 144 serum samples were analyzed, with 72 samples from men diagnosed with PCa and 72 from men without cancer. Serum levels of PVT1 Exons 4A, 4B, and 9 were quantified using digital PCR. Multiple logistic regression models were developed to predict cancer status based on PSA alone, PVT1 biomarkers alone, and combinations of PSA with PVT1 biomarkers. Model performance was assessed using stratified k-fold cross-validation, with comparisons made using likelihood ratio tests, and z-tests for statistical significance.

The results show that combining PSA with PVT1 Exon 4A improves specificity in predicting cancer status in the general population from 0.45 to 0.54 while maintaining sensitivity at 0.81. Within the subpopulation of men of African Ancestry, PVT1 Exon 4A alone achieves an accuracy of 0.75 with a sensitivity of 1.0 and specificity of 0.5 compared to PSA alone which had an accuracy of 0.38, sensitivity of 0.5 and specificity of 0.25.

This study underscores the potential clinical utility of integrating PVT1 biomarkers into prostate cancer screening programs. The inclusion of Exon 4A enhanced PSA-based prediction by addressing its limitations in overdiagnosis and unnecessary biopsies, providing a balanced improvement in diagnostic performance. By improving the accuracy of PCa detection while reducing the burden of overdiagnosis, this approach provides significant value for healthcare providers, diagnostic laboratories, and insurers aiming to enhance early detection and equitable screening outcomes.

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#106 Growth-associated protein 43 (GAP-43): the link to Ewing sarcoma bone metastasis.
Tyler Biermann[1], Nicholas Cohen[2], Yasmine Wazni[3], Stefano Vicini[4], Jason Tilan[2], Joanna Kitlinska[1]

[1]Department of Biochemistry and Molecular & Cellular Biology, Georgetown University Medical Center, Washington, DC,[2]Department of Human Science, Georgetown University School of Health, Washington, DC,[3]Department of Global Health, Georgetown University School of Health, Washington, DC,[4]Department of Pharmacology & Physiology, Georgetown University Medical Center, Washington, DC

Ewing Sarcoma (ES) is an aggressive pediatric tumor that arises in bone or soft tissues. ES bone metastases do not respond well to routine therapies and their frequency markedly increases upon disease recurrence, which results in a lower survival rate in patients with osseous metastases as compared to those with pulmonary dissemination. Our previous studies have determined that ES bone metastasis is initiated by hypoxia in the primary tumor site, which leads to the formation of polyploid tumor cells, the progeny of which, named HYP-4n cells, exhibit high levels of chromosomal instability. These cells metastasize almost exclusively to bone and are less sensitive to cytostatic agents. In this study, we demonstrate that HYP-4n cells exhibit an upregulation in several neuronal proteins, specifically growth-associated protein 43 (GAP-43), a membrane protein promoting axon growth in neurons and formation of microtubes connecting glioblastoma cells into invasive and therapy-resistant cellular network. Similar phenotype characterized by the presence of microtube-like cell-cell connections was also observed in ES HYP-4n cells. GAP-43 immunostaining in HYP-4n cells revealed a punctuated pattern along the protrusions that is similar to its localization in neurons. Western Blot analysis performed on HYP-4n cells revealed a membranous localization of GAP-43, which was not detectable in their normoxic diploid counterparts. The functional role of the GAP-43-positive protrusions in connecting HYP-4n cells was confirmed by the gap-junction permeable dye transfer between the cells and ion transfer detected by a patch clamp assay. DAPI staining also displayed nuclear fragments within the protrusions, suggesting the transfer of genetic material. The suppression of GAP-43 expression via siRNA was further shown to inhibit HYP-4n cell migration measured via transwell assay. In immunostained ES xenografts, GAP-43 expression was shown in HYP-4n primary and osseous metastatic tumors, with the highest membranous expression in the ES cells on the invading edge of the tumors. A similar pattern of expression of GAP-43 was noted in the human samples of ES bone metastases. This study indicates that GAP-43 is active in the membrane in HYP-4n cells and drives the formation of microtube networks promoting cell invasion. Further studies are required to prove directly the role of GAP-43 in ES bone metastasis and chemoresistance.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Database Resources Poster Session

#1061 Post-doctoral fellow.

kang-lin Hsieh, Sankar Maity, Ganiraju Manya, Bradley Broom, Christopher Logothetis, Patrick Pilie

The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Prostate cancer research spans genetics, proteomics, metabolomics, cell signaling, and tumor microenvironment domains. While this data is valuable, integrating clinical and basic research findings presents challenges. The Prostate Cancer Cartography Initiative (PCCI) offers a unified data model for efficient research across clinical, co-clinical, and mechanistic studies. The data model divides cases into anatomic and biological groups, facilitating cross-domain knowledge translation and hypothesis generation through efficient data integration.
Materials & Methods: Our database incorporates data from 972 patients across three complementary sources: TCGA (primary prostate cancer), SU2C (metastatic patients), and MDA trials (intermediate-risk prostate cancer). For reproducibility and data consistency, we use NF core pipelines to harmonize data and derive copy loss, Single Nucleotide Variants/Insertions/Deletions (SNV & Indel), and gene expression. After analyzing this information, we group patients based on clinical information such as Gleason scores or genomic information such as copy loss and SNV/Indel to evaluate how these conditions affect gene expression and pathways.
Results: In our initial work, we focused on TCGA patients with Gleason scores, categorizing them into three groups (3+3, 3+4/4+3, and 8 or higher). We further subdivided each category based on genetic alterations: patients with no copy loss, patients with at least one copy loss, and patients with Single Nucleotide Variants or Insertions/Deletions (SNV & Indel). We analyzed key genes including TP53 across these subgroups. Our initial results showed that medium-risk patients (Gleason scores 3+4/4+3) had significantly lower TP53 gene expression when they had both copy loss and SNV & Indel. Patients with SNV & Indel alone also showed lower TP53 gene expression, though this finding was not statistically significant ($p = 0.06$). High-risk patients (Gleason scores 8 or higher) demonstrated similar patterns. When analyzing how copy loss or SNV & Indel affect genes near TP53, we found reduced expression in nearby genes—ALOX15B (logFC: -1.0153, $p<0.001$), TMEM220 (logFC: -0.719, $p<0.001$), and MYO1C (logFC: -0.348, $p<0.001$)—in patients with TP53 copy loss or SNV & Indel. This pattern was confirmed in both medium-risk and high-risk groups. In our pathway analysis, including AD-target and homologous recombination pathways, patients without TP53 copy loss or SNV & Indel showed higher Enrichment Scores.
Discussion: The PCCI provides a platform to integrate these data and generate hypotheses. Our results show that genetic alterations—such as copy loss and SNV & Indel—affect not only the TP53 but also nearby genes ALOX15B, TMEM220, and MYO1C. Notably, ALOX15B and MYO1C are tumor suppressor genes, which raises the question of how TP53 alteration leads to network changes in tumor suppressor genes. These findings further demonstrate the necessity of PCCI in facilitating hypothesis generation.

#1062 Cancer Complexity Knowledge Portal: a centralized web portal for finding cancer related data, software tools, and other resources.

Orion Banks, Ashley Clayton, Aditi Gopalan, Amber Nelson, Stockard Simon, Verena Chung, Amy Heiser, Jay Hodgson, Aditya Nath, Adam Hindman, Milen Nikolov, Adam Taylor, James Eddy, Susheel Varma, Jineta Banerjee

Sage Bionetworks, Seattle, WA

Applying artificial intelligence (AI) and machine learning (ML) techniques to biomedical problems is predicated on access to clean, high-quality data and reusable software tools. Data and tool repositories offer a vital infrastructure for centralizing, storing, and sharing such resources with the global research community of cross-disciplinary scientists. The Cancer Complexity Knowledge Portal (CCKP) is a NIH-listed domain-specific repository that makes oncology data findable and accessible. The CCKP is developed and maintained by the Multi-Consortia Coordinating (MC^2) Center, led by Sage Bionetworks. The MC^2 Center supports resource coordination among six cancer-focused interdisciplinary research consortia funded by the National Cancer Institute (NCI). Through this work, the CCKP has emerged as a significant repository for oncology data and tool sharing.

To define the metadata standards for sharing resources on the CCKP, we host data models for various data modalities including genomics and imaging, and are developing new models for emerging multimodal data types like spatial transcriptomics. The data models undergo iterative development based on emerging community needs, with versioned releases maintained in a public GitHub repository. These data models power established data management tools developed by Sage Bionetworks, including the Schematic Python package and Data Curator App, to support annotation of data according to FAIR standards. The data models are designed to help researchers link research outputs (e.g., publications, datasets), thus helping the CCKP synthesize and highlight the activities and outputs of the NCI-funded cancer research programs in a meaningful way. The CCKP provides search and filtering capability to accelerate discovery and collaboration in the cancer research community. As of November 2024, the portal hosts curated information on 3,786 publications, 904 datasets, and 292 computational tools emerging from over 140 research grants. Our data models also incorporate elements of the Cancer Research Data Commons (CRDC) Data Hub data model to support integration and reuse of datasets within the CRDC ecosystem.

The recent advances in computational oncology showcase the strength of secondary use of research data and highlight an unmet need to ensure that data and tools available through repositories are reliable, and reusable. We are engaging with scientists, clinicians, and patient advocates, and leveraging user-centered design approaches and structured data models to make cancer data and tools more findable, accessible, and reusable. These ongoing improvements of the portal aim to increase its usability, bringing experimental labs generating data and computational labs using data closer together, to fuel the iterative cycle of scientific discovery.

#1063 CellMap: a comprehensive human single cell gene expression reference for automated cell annotation and cancer cell-of-origin analysis.

Yuping Zhang, Gabriel Cruz, Hanbyul Cho, Chandan Kumar-Sinha, Rahul Mannan, Jin Chen, Xuhong Cao, Saravana M. Dhanasekaran, Arul M. Chinnaiyan

University of Michigan, Ann Arbor, MI

In single-cell transcriptomic analysis, accurate cell type annotation forms the essential basis for all downstream analysis and data interpretation. While time consuming manual annotation requires extensive prior knowledge, available automated cell annotation tools lack a unified, curated human cell reference to ensure successful identification of all cell types present in any given dataset. To fill in the gap we create “CellMap” a comprehensive single cell gene expression reference database of known cell types across most human tissues by compiling, curating and integrating single cell datasets from multiple sources including Human Protein Atlas, Tabula Sapiens, ArrayExpress and GEO. CellMap contains 151 different celltypes/states including 94 epithelial, 31 brain, 4 from soft tissues, 8 stromal and 15 major immune celltypes from 42 human tissues. Projecting pseudo-bulk profiles of the 151 celltypes into 2-dimensional UMAP revealed major clusters of cells from the nervous system, respiratory system, gastrointestinal tract, proximal digestive system, female tissues and endocrine tissues. Immune cells and stromal cells are generally clustered together regardless of their tissue origin. We also curated about 200 immune cell phenotypes from the ImmGen database for fine-tuning annotation of immune cell subpopulations. Importantly by combining CellMap and the SingleR algorithm, we successfully identified the cell lineage of the tumor and minor cell types originated from the biopsy site of a breast cancer metastatic sample; the latter were left unannotated with reference derived from breast tissue or misclassified using Human Primary Cell Atlas. In addition, CellMap allowed us to identify highly specific tissue markers and cell type markers. Based on 1241 identified marker genes, we trained a random forest model to predict cancer types using 80% of the TCGA tumor samples of each cancer type (n = 7160) and tested on a 20% hold-out testing set (n = 1774), achieving a median of 95.4% accuracy across cancer types. Cancer types with low accuracy include esophageal carcinoma (mostly mis-classified as head and neck squamous cell carcinoma) and rectum adenocarcinoma (mostly mis-classified as colon adenocarcinoma). The misclassification could be explained by the high similarity between these cancer types in terms of cell-of-origin.

Finally a webportal for exploring celltypes in CellMap and an open-source R-package for automated cell annotation of single cell data and cell lineage prediction for bulk RNA-seq data were developed. This work provides valuable resources for conducting single-cell analysis and cancer cell-of-origin analysis. Additionally, it helps identify closely related cell types across tissue types, which is particularly useful since diseases originating from related cell types may share similar therapeutic targets.

#1064 Cancer data aggregator: a new cancer data discovery tool.

Amanda Charbonneau[1], Arthur Brady[1], Tanner Coon[2], Rachel Kutner[3], Surya Saha[4], Katherine Thayer[3], Alexander Baumann[3], Todd Phil[5], Henry Schaefer[5], Heather Creasy[6], Jack DiGiovanna[4], David Pot[1], Bing-Xing Huo[3]

[1]General Dynamics Information Technology, Inc. (GDIT), Rockville, MD,[2]Blue Halo, Arlington, VA,[3]Broad Institute, Boston, MA,[4]Velsera, Boston, MA,[5]Frederick National Laboratory, Rockville, MD,[6]National Cancer Institute, Bethesda, MD

Cancer research data is generated and managed in silos. Data repositories frequently use different models and vocabularies to describe their data holdings, and many specialize in certain data types, necessitating that data from a large integrative project be spread across several repositories. For researchers who want to reuse existing cancer data, just navigating this ecosystem of repositories, formats and models can be overwhelming. The Cancer Data Aggregator (CDA) is a new free National Cancer Institute (NCI) service that aims to increase the discoverability of cancer datasets by making them searchable from a common interface, using a single model and vocabulary. We combine metadata for thousands of studies hosted at multiple data repositories across the NCI, and make that metadata available for search from a unified database, so researchers can more easily find and reuse existing cancer research data.

The CDA ensures that researchers can find what they're looking for using a single set of search terms by thoroughly cleaning, harmonizing, and cross-referencing the study metadata. This allows researchers to find subjects that have participated in multiple studies, discover data from a disease that was originally described in different ways at each repository, or compile all the data from a large consortium project like CPTAC - no matter how fragmented it ended up.

With the CDA, one set of search terms can return results from data repositories including the Genomic Data Commons, the Proteomic Data Commons, the Imaging Data Commons, Cancer Data Services, and the Integrated Canine Data Commons. Results are displayed in a simple table format (tsv) that is compatible with all standard spreadsheet apps (Excel, Google sheets, Numbers, etc) or loaded directly for analysis in a Jupyter notebook. Results include relevant clinical, phenotypic, genotypic values and provenance details, as well as information about where data files can be downloaded from using the GA4GH DRS API.

The Cancer Data Aggregator publishes a new release at the end of each month, and only publishes public data. This ensures that all researchers can use the CDA anonymously without any special privileges, and can always expect data to be up to date. Non-computational users can search the CDA using fill-in-the-blank style queries, while power users can create software for custom searches using our Python library. Visit https://cda.readthedocs.io/ to get started.

#1065 Exploring differential gene expression in head and neck squamous cell carcinoma using TCGA data.

Donghoon Shin[1], Ji Hyung Hong[2]

[1]MetroWest Medical Center, Framingham, MA,[2]Division of Medical Oncology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of

Introduction: The prognosis for head and neck squamous cell carcinoma (HNSCC) has shown limited advancements, and our understanding of how gene expression relates to patient outcomes remains unclear. With advancements in bioinformatics, the characterization of molecular abnormalities and the identification of prognostic signatures have become increasingly important for risk stratification, survival prediction, and treatment management of HNSCC patients. However, due to its lower prevalence, challenges remain in utilizing genetic markers to better understand prognosis. In this study, we performed a differential gene expression analysis (DEGs) to identify genes associated with overall survival.
Methods: RNA sequencing data from TCGA, including gene expression profiles and clinical information (tumor stage, overall survival), were analyzed to identify DEGs in HNSCC. DEGs associated with overall survival were identified using the R package DESeq2, and an integrated prognostic signature was developed. Kaplan-Meier survival analysis and log-rank tests were used to evaluate the prognostic value of DEGs, stratifying patients into high- and low-risk groups based on expression levels. A multivariate Cox regression analysis was performed to calculate the hazard ratios (HRs) for each gene, which were then used to construct a risk score.
Results: RNA expression data from 521 HNSCC patients were obtained from the TCGA database, comprising 111 early-stage (stage I, II) and 410 advanced-stage (stage III, IV) patients. DEG analysis comparing early-stage and advanced-stage tumors identified 51 genes, including 45 upregulated and 6 downregulated genes. Among these 51 genes, patients were stratified into high- and low-expression groups for each of the genes based on median expression levels. Kaplan-Meier survival analysis revealed that three genes—BRDT ($p = 0.0870$), ZFP42 ($p = 0.0213$), and FDCSP ($p = 0.0343$)—were significantly associated with overall survival. The HRs obtained from the multivariate Cox regression model are as follows: BRDT (HR = 1.51, 95% CI: 1.11-2.06, $p = 0.009$), ZFP42 (HR = 1.43, 95% CI: 1.05-1.94, $p = 0.022$), and FDCSP (HR = 0.72, 95% CI: 0.53-0.98, $p = 0.035$).
Conclusions: The study identified a novel 3-gene signature that can stratify HNSCC patients into distinct risk groups based on overall survival. Through DEG analysis, key genes linked to the prognosis of HNSCC were identified, providing valuable insights into the prognostic factors of the disease.

#1066 OncoKB^{TM}, MSK's precision oncology knowledge base: 2024 updates.

Moriah H. Nissan, Sarah P. Suehnholz, Hongxin Zhang, Ritika Kundra, Calvin Lu, Amanda Dhaneshwar, Nicole Fernandez, Kelly Cavender, Benjamin Preiser, John Konecny, Kseniya Petrova, Mark Ewalt, Maria E. Arcila, Marc Ladanyi, Michael F. Berger, Anoop Balakrishnan-Rema, Aijazuddin Syed, A. Rose Brannon, Ahmet Dogan, Diana Mandelker, Zsofia Stadler, Alexander Drilon, David B. Solit, Ross Levine, Nikolaus Schultz, Debyani Chakravarty

Memorial Sloan Kettering Cancer Center, New York, NY

OncoKB, Memorial Sloan Kettering Cancer Center's (MSK) precision oncology knowledge base, contains evidence-based information about the oncogenic effect and therapeutic implications of somatic alterations in cancer. OncoKB currently includes annotation for >8000 alterations in 900 cancer-associated genes and is the only somatic cancer variant database partially recognized by the US-FDA. OncoKB supports variant interpretation in the cBioPortal for Cancer Genomics, is used to annotate >17,000 MSK patient sequencing reports annually and is publicly available through its website (www.oncokb.org). Access to OncoKB, including its web-based API, is freely available to users in an academic setting, while users from commercial and hospital settings require a fee-based license. OncoKB's Therapeutic Levels of Evidence system classifies variants based on tumor type-specific sensitivity or resistance to targeted therapies. To date, OncoKB includes 53 Level 1 genes as well as MSI-H and TMB-H (included in the FDA drug label), 7 Level 2 genes (included in professional guidelines), 14 Level 3A genes (predictive of response in well-powered clinical studies), 10 Level 4 genes (predictive of response based on compelling biological evidence), and 12 R1/R2 resistance genes. In 2024, OncoKB updated its content to include notable precision oncology drug development changes. OncoKB promoted BRAF fusions to Level 1 following inclusion as patient eligibility criteria in the FDA drug label for tovorafenib (low-grade glioma). Additionally, OncoKB included KRAS G12C in colorectal cancer and IDH1 mutations in myelodysplastic syndromes as Level 1 following FDA approval of adagrasib + cetuximab and ivosidenib, respectively. NCCN guidelines for colorectal cancer and small bowel cancer listed immune-checkpoint inhibitors for tumors harboring POLE or POLD1 oncogenic exonuclease domain missense mutations, making them Level 2 in these indications. Lastly, novel biomarkers including FBXW7 and PPP2R1A alterations (endometrial and ovarian cancer), SMARCA4 mutations (non-small cell lung cancer and esophageal adenocarcinoma) and MTAP deletions (all solid tumors) were included in OncoKB based on compelling preclinical and emerging clinical evidence in association with lunresertib + camonsertib, PRT3789, and AMG193 and MRTX1719, respectively. In sum, 17 novel clinically actionable biomarkers (Levels 1-4) and 26 follow-on precision oncology therapies for existing leveled biomarkers were added to OncoKB in 2024. Additionally in 2024, OncoKB prepared to incorporate germline variants into the knowledge base, a feature expected to be publicly available in 2025. OncoKB also implemented major software updates to support data integration into the EPIC platform. Future OncoKB efforts are focused on whole genome/exome curation, inclusion of biomarkers for non-NGS-based precision oncology therapies, and the development of a clinical trial matching system.

#1067 The ISB Cancer Gateway in the Cloud (ISB-CGC): access, explore and analyze large-scale cancer data through the Google Cloud.

Fabian Seidl[1], Lauren Hagen[2], Jacob Wilson[1], Boris Aguilar[2], Deena Bleich[1], Lauren Wolfe[2], Poojitha Gundluru[1], Suzanne Paquette[2], Elaine Lee[2], Danna Huffman[1], William Longabaugh[2], David Pot[1]

[1]GDIT, Rockville, MD,[2]ISB, Seattle, WA

Rapid growth of cancer data in recent decades has made data discovery and wrangling difficult for the average cancer research lab. Our mission at the ISB Cancer Gateway in the Cloud (ISB-CGC), part of the NCI's Cancer Research Data Commons ecosystem, is to democratize access to large cancer datasets. Funded by the NCI, we have performed ETL processes on data from GDC and PDC projects such as TCGA, TARGET, and CPTAC. We generated hundreds of publicly available BigQuery tables containing data such as mutations, gene expression, and protein abundance, which enable data analysis in the cloud via SQL. BigQuery analyses are inexpensive and rapid even when scaled to petabyte sized inputs, for example in one analysis 6.6 billion correlations were computed in 2.5 hours with a total cost of about one dollar. These data can also be accessed affordably from Google Cloud VMs where researchers can develop analysis pipelines in Python, R, and workflow languages. We will also highlight recently improved accessibility to the Mitelman Database, added and expanded HTAN single cell data and notebook selections, and updates to our BigQuery Table Search tool.

#1068 Navigating next-generation pre-clinical models of drug discovery & development with RNA-seq.

A. P. Singh[1], R. R. Khairi[1], A. L. Reese[2], J. Kirkland[2], J. Duncan[2], N. Wax[2], R. Marlow[2], S. King[2], A. Fernandes[2], J. L. Jacobs[1]; [1]American Type Culture Collection, Gaithersburg, MD, [2]American Type Culture Collection, Manassas, VA

Cell models paired with curated gene expression data are vital for preclinical research. Transcriptomic data from traceable, authenticated cell lines streamline hypothesis development and experimental design while illuminating underlying biological mechanisms. In cancer research, these models have notably identified therapeutic targets and biomarkers. To advance cancer research, ATCC® sequenced the transcriptomes of 141 immune cancer cell lines, accessible through ATCC Cell Line Land, encompassing various hematopoietic lineages. This effort provided insights into gene expression patterns, revealing potential biomarkers and gene regulatory networks tailored to specific cell lines. Utilizing this data, we conducted a comparative analysis, pinpointing genes and pathways governing cellular traits. This informed our evaluation of therapeutic molecules like the Curcumin analog EF-24. Our analysis of EF-24's effects on leukemia cell lines K562 (ATCC® CCL-243™, HL-60 (ATCC® CCL-240™), THP-1 (ATCC® TIB-202™), Kasumi-1 (ATCC® CRL-2724™) demonstrated increased cell death post-treatment. EF-24 activated pathways associated with cell survival and death regulation, notably impacting STAT1-induced cell death, and enhancing innate immune system genes. This research offers a detailed understanding of EF-24's molecular actions in tumors, emphasizing the significance of STAT1 signaling in its antitumorigenic effects. The profound impact of EF-24 on inducing cell death across multiple leukemia cell lines underscores its potential as a therapeutic agent. By elucidating its specific molecular actions and highlighting the pivotal role of STAT1 signaling, this study not only deepens our comprehension of EF-24's mechanisms but also underscores its promising value in targeted antitumorigenic strategies.

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#107 Galectin-1 plays a critical role in normal and neoplastic mammary gland morphogenesis and metastatic spreading in breast cancer.

Magali Berton, Ramiro Perrotta, Tomas Dalotto-Moreno, Mahmoud D. Yamil, Sabrina Gatto, Rosa Morales, Gabriel A. Rabinovich, Mariana Salatino

IBYME-CONICET (Institute of Biology and Experimental Medicine), Buenos Aires, Argentina

Galectins are a family of glycan-binding proteins that regulate neoplastic transformation, angiogenesis, cell adhesion and tumor-immune escape. Galectin-1 (Gal-1), a prototype member of this family, binds to multiple *N*-acetyllactosamine units in N- and O-glycans on cell surface glycoproteins. Biologically, Gal-1 plays a key role in the creation of an immunosuppressed tumor microenvironment (TME) by acting as a negative regulator of the immune response, fostering tumor immune-escape, stimulating an invasive, stem-like phenotype and enhancing metastasis in several tumors. In this work we focus on the relevance of the Gal-1-glycan axis in the TME, metastatic progression and antitumor immune response, and we aim to address the role that Gal-1 plays in normal and transformed mammary gland development. First, we observed that C57BL/6 female mice deficient for Gal-1 (*Lgals1*$^{-/-}$ KO) have an impaired mammary branch morphogenesis in response to progesterone stimulus as compared to their C57BL/6 WT counterparts. To tackle the mechanism underlying this deficiency in mammary branching, we performed cell sorting based on surface markers (EpCAM and CD49f)to categorize the isolated mammary cells from C57BL/6 WT and C57BL/6 Lgals*1*$^{-/-}$ KO mice into four main populations: luminal (EpCAM^{high}-CD49f^{low}), basal (EpCAM^{low}-CD49f^{med}), stromal (EpCAM^{neg}-CD49f^{neg}), and mammary stem cells (MaSC) (EpCAM^{low}-CD49f^{high}). Each population's purity was evaluated by Real Time PCR (qPCR) using specific markers (PR, ER, Vim, a-SMA, Nanog) and we observed that *Lgals1*$^{-/-}$ KO mice present a decreased percentage of luminal and MaSC cells (Spectral CyTEK) in comparison to the Gal-1 sufficient strain, which may contribute to the reduced branching. To then analyze the role of Gal-1 in mammary tumorigenesis and metastasis, we developed a MMTV-PyMT transgenic mouse model WT or KO for Gal-1 (*lgals1*$^{-/-}$).Using this novel experimental model, we observed that that PyMT-Gal1-KO mice present a delay in tumor burden and a longer tumor-free survival time, with an overall lower number of transformed ducts in the mammary gland and reduced lung metastasis, alongside a reduced mammary gland branching morphogenesis. Our findings highlight the relevance of Gal-1 in regulating normal mammary gland morphogenesis and assert its critical role in metastatic spreading in breast cancer. From a therapeutical point of view, Gal-1 can be considered as a promising target in metastatic breast cancer.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Database Resources Poster Session

#1070 siderGrimoire: a database of retroCNVs in human tumors and populations.

Thiago Luiz Araujo Miller, Helena Beatriz da Conceicao, Pedro Alexandre Favoretto Galante

Sirio-Libanes Hospital Brazil, Sao Paulo, Brazil

Background: Retrocopies, also known as processed pseudogenes, are structural variations resulting from the duplication of protein-coding genes via the reverse transcription of their mature messenger RNA by the LINE-1 enzymatic machinery. These retrocopies can be fixed, present in all genomes of a given species, or unfixed—classified here as retroCNVs—when they are polymorphic, either germline or somatic. While fixed retrocopies have been extensively studied, the understanding of retroCNVs remains limited due to the lack of specialized bioinformatics tools for their detection and annotation in DNA sequencing data, as well as curated databases to share findings with the scientific community.
Objective: To address this gap, we developed the sideRETRO, a robust computational tool for the identification and annotation of retroCNVs in whole-genome and exome sequencing data. The results of this tool will be made accessible through siderGrimoire, an online, curated database integrating retroCNVs from human populations and cancer samples.
Methods: The sideRETRO pipeline, published in Bioinformatics, offers a dedicated approach to detecting non-fixed retroCNVs. Using datasets from the 1000 Genomes Project and The Cancer Genome Atlas (TCGA), siderGrimoire curates retroCNVs across human populations and tumor samples, providing detailed annotations and a user-friendly interface.
Results: Initial analyses reveal a comprehensive landscape of retroCNVs, uncovering their prevalence and patterns of events in diverse human populations and cancer types. This resource bridges a critical gap in the availability of retroCNV-specific data for the research community.
Conclusion: The siderGrimoire database represents a significant advancement in retroCNV research, providing a valuable tool for studying the role of retrocopies in genetic variation and cancer biology. By integrating large-scale data from key genomic projects, this platform enables new insights into the genomic impacts of retroCNVs, fostering further exploration in human genetics and oncology.

#1071 Online resources from the Allen Institute for Immunology: longitudinal profiling of multiple myeloma treatment and the Human Immune System Explorer platform.

Lucas Graybuck[1], Christian M. La France[1], Nicole Howard[1], Jessica Liang[1], Autumn Kelsey[1], Lauren Y. Okada[1], Zachary J. Thomson[1], Aishwarya Chander[1], Patrick I. McGrath[1], Love Tätting[2], Yudong D. He[1], Emma L. Kuan[1], Marla C. Glass[1], Samir Rachid Zaim[1], Palak C. Genge[1], Medbh A. Dillon[1], Cole G. Phalen[1], Peter J. Wittig[1], Alexander T. Heubeck[1], Julian Reading[1], Charles R. Roll[1], Veronica Hernandez[1], Vaishnavi Parthasarathy[1], Tyanna J. Stuckey[1], Blessing Musgrove[1], Elliott Swanson[1], Morgan D. A. [1]Allen Institute for Immunology, Seattle, WA,[2]Department of Haematology in Linkoping and Department of Biomedical and Clinical Sciences, Linkoping University, Linkoping, Sweden,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA,[5]Sylvester Comprehensive Cancer Center, Miami, FL

The Allen Institute for Immunology was founded in 2018 to deeply profile the human immune system in health and disease. As part of our mission to understand how the immune system changes over time in the setting of oncology, we recruited a cohort of patients at diagnosis for multiple myeloma (MM), and followed these subjects throughout induction therapy, autologous stem cell transplant, and after transplant recovery. We sampled the same subjects longitudinally, then performed immune profiling using scRNA-seq on peripheral blood cells, CITE-seq on bone marrow cells, multiple high-dimensional flow cytometry panels, plasma and bone marrow interstitial fluid (BMIF) proteomics, and clinical lab tests. To process, analyze, and distribute this data, we developed the Human Immune System Explorer (HISE) platform, a flexible, scalable, cloud-based framework to enable storage, interactive analysis, visualization, and generation of Certificates of Reproducibility that enable inspection and replay of any step of an analysis workflow. We joined our robust, large-scale analytical platform to public-facing tools, scientific context, and data releases, which now include interactive visualization tools for exploring the effects of MM treatment in detail. We invite oncologists, immunologists, and clinicians to explore this resource and our expanding library of immunology data, insights, and tools at https://explore.allenimmunology.org/.

#1072 MOSAIC Window: Spatial intra-tumoral heterogeneity characterization through large-scale spatial and single-nuclei multi-omics profiling.

The MOSAIC Consortium (Owkin, FR; Charite, DE; CHUV, CH; GR, FR; UKER, DE; UPMC, USA), **Presenter: Caroline Hoffmann**

Owkin, PARIS, France

INTRODUCTION- MOSAIC (Multi-Omics Spatial Atlas in Cancer) is a multicenter clinical omics study aimed at deciphering cancer biology. We systematically profile thousands of cancer samples, focusing on spatial transcriptomics and single-nuclei RNA sequencing (snRNAseq) data across multiple tumor types.Here, we present the MOSAIC Window initiative, our first open science dataset. This multi-omics dataset can be leveraged to explore tumor heterogeneity and biomarker discovery within the tumor microenvironment (TME).
METHODS- The MOSAIC Window dataset includes 60 samples from patients with Muscle Invasive Bladder Cancer (n = 15), Ovarian cancer (n = 15), Diffuse-large B-cell Lymphoma, Mesothelioma and Glioblastoma (n = 10 each).Each sample underwent Visium spatial transcriptomics, Chromium Flex snRNAseq, bulk RNAseq, whole-exome sequencing, and hematoxylin-eosin histology scans. We collected extensive clinical information, including age; gender; BMI; risk factors; cancer treatments; clinical, pathological and molecular information; and progression-free and overall survival.We applied strict quality control metrics in each data modality which we are reporting. Tumor heterogeneity was measured using snRNAseq and spatial transcriptomics integration. First, scANVI method was used on snRNAseq data to identify and annotate sub-populations cells from the TME. For cancer cell population, shared nearest neighbour (SNN) modularity optimization based clustering algorithm was used to separate clusters of cancer cell sub-populations. Differential expression analysis was used between these sub-populations to generate references. Then, cell type deconvolution was performed using cell2location and the references generated from snRNAseq data.
RESULTS- The analysis of the spatial distribution of sub-population of cancer cells revealed distinct sub-populations of cancer cells, corresponding to different molecular sub-clones and/or TME cell composition (niches). Our computational approach highlighted significant variability in intra-tumoral heterogeneity across cancer types and patients. Samples ranged from having a single homogeneous niche to multiple distinct niches, each characterized by specific malignant cell subtypes and their associated TME, highlighting the interplay between these two compartments, which we are detailing and quantifying. These results provide important insights into potential mechanisms of treatment resistance, biomarker discovery, patient subgroup identification, and potential combination treatment strategies.
CONCLUSION- The open science MOSAIC Window dataset demonstrates how integrating spatial and single-nuclei data provides key insights understanding of intra- and inter-patient tumor heterogeneity, paving the way for novel therapeutic strategies. Data is accessible on demand on EGA.

#1074 CTCFDB: a systematic framework and comprehensive data resource for CTCF binding in the human genome.

Shengyuan Wang, Zhenjia Wang, Grant Atwood, Yanbin Xu, Chongzhi Zang

Department of Genome Sciences, University of Virginia, Charlottesville, VA

CCTCC-binding factor (CTCF), a highly conserved zinc finger protein, plays a crucial role in the three-dimensional (3D) genome organization by mediating DNA loops and topologically associating domains (TADs). Variations in CTCF binding across different cell types can lead to changes in cell type-specific chromatin conformation, altering gene expression and contributing to diseases such as cancer. Despite its importance, an up-to-date and comprehensive database for human CTCF binding sites has been lacking. To fill this gap, we developed CTCFDB, a curated data resource encompassing 2,251 high-quality CTCF ChIP-seq datasets from NCBI GEO across 344 human cell types. We identified 510,675 high-confidence CTCF binding sites in the human genome. Among those, 22,722 were charactered as constitutive binding sites that are conserved across cell types. Using binding profiles across high-confidence CTCF binding sites, we performed unsupervised clustering analyses on all samples and found that the majority of cell types were clustered together, indicating cell type-specific binding patterns. Besides, we characterized 65,697 cell type-specific gained and 18,990 lost CTCF sites by focusing on individual union sites, further demonstrating the cell type specificity of CTCF binding. CTCFDB, with its systematic approach and user-friendly interface, provides an invaluable resource for advancing research on 3D genomics and gene regulation. This framework can be extended to generate similar data resources for other DNA-associating proteins, facilitating broader insights into functional genomics and cancer research.

#1075 Piloting NTRK fusion-specific oncogenicity guidelines - lessons learned.

Jason Saliba[1], Shivani Golem[2], Arpad Danos[1], Laura B. Corson[3], Elan Hahn[4], Morteza Seifi[5], Emma G. Sullivan[6], Jan Clement A. Santiago[7], Valentina Nardi[8], Theodore W. Laetsch[9], Marilyn M. Li[9], Obi L. Griffith[1], Malachi Griffith[1], Gordana Raca[10], Larissa V. Furtado[11], Alanna J. Church[12], Angshumoy Roy[13]

[1]Washington University School of Medicine, St. Louis, MO,[2]University of Kansas Medical Center, Kansas City, KS,[3]Oncology Consultant, Boston, MA,[4]Mount Sinai Hospital and the University of Toronto, Toronto, ON, Canada,[5]University of Wisconsin-Madison, Madison, WI,[6]Michael G. DeGroote School of Medicine, Hamilton, ON, Canada,[7]University of Washington, Seattle, WA,[8]Massachusetts General Hospital and Harvard Medical School, Boston, MA,[9]Children's Hospital of Philadelphia and University of Pennsylvania, Philadelphia, PA,[10]Children's Hospital Los Angeles, Los Angeles, CA,[11]St. Jude Children's Research Hospital, Memphis, TN,[12]Boston Children's Hospital and Harvard Medical School, Boston, MA,[13]Baylor College of Medicine and Texas Children's Hospital, Houston, TX

Gene fusions involving neurotrophic receptor tyrosine kinase genes (NTRK1, NTRK2, & NTRK3) are well-established oncogenic drivers and serve as critical diagnostic and therapeutic markers in cancer. Interpreting their clinical significance is a high priority given FDA approval of TRK inhibitors; however, this remains challenging due to the rapid pace of fusion discovery, the diversity of fusion partners and tumor types, inconsistent and incomplete reporting of fusion data elements, and the lack of standardized fusion-specific classification guidelines. The Clinical Genome Resource (ClinGen) NTRK Fusions Somatic Cancer Variant Curation Expert Panel (SC-VCEP) is addressing these challenges and creating a publicly available resource of high-quality clinically significant NTRK fusion classifications in the Clinical Interpretation of Variants in Cancer (CIViC; civicdb.org) knowledgebase to support patient care.
Our NTRK fusion-specific oncogenicity guidelines (approved April 2022) classify NTRK fusions as Oncogenic, Likely Oncogenic, Fusion of Unknown Significance (FUS), or Benign based on four categories: Fusion Gene Structure (orientation/breakpoints/reading frame), Cancer Association (number of unique cases), Clinical Validity (response to targeted inhibitors), and Functional Status (pathway activation or expression). Piloting our guidelines on a range of common to rare NTRK fusions found in cancers resulted in 12 Oncogenic Assertions (6 Oncogenic, 1 Likely Oncogenic, 2 FUS, 3 Benign), 5 Diagnostic Assertions covering 3 cancers, and 10 Predictive Assertions supporting sensitivity to FDA approved TRK inhibitors, larotrectinib or entrectinib. This pilot introduced several modifications to our oncogenicity guidance including: 1) reducing case numbers required to reach cancer association or clinical validity due to the rarity of reported NTRK-positive tumors; 2) further clarifying NTRK fusion structure, e.g., both gene partners must contribute to the fusion protein sequence; 3) requiring fusions to be reported in the published literature as databases may lack vetting; 4) expanding our NTRK-associated tumor list as more tumors are screened for the presence of NTRK fusions; 5) strengthening Benign support by requiring the confirmed lack of both RNA and protein fusion expression. This process was a valuable step in enhancing the consistency and clarity of the ClinGen NTRK SC-VCEP fusion-specific oncogenicity guidelines to aid their widespread adoption. Future efforts will focus on the Oncogenic classification of the over 80 known NTRK fusions found in cancers and their distribution to the public through the CIViC knowledgebase.

#1076 Sharing data from the Human Tumor Atlas Network through standards, infrastructure, and community engagement.

I. de Bruijn[1], M. Nikolov[2], C. Lau[3], A. Clayton[2], D. L. Gibbs[3], E. Mitraka[2], **D. Y. Pozhidayeva**[3], A. Lash[4], S. Sumer[1], J. Altreuter[4], K. Anton[5], M. DeFelice[2], X. Li[1], A. Lisman[1], W. J. R. Longabaugh[3], J. Muhlich[6], S. Santagata[6], S. Nandakumar[1], P. K. Sorger[6], C. Suver[2], X. Doan[2], J. Guinney[2], N. Schultz[1], A. J. Taylor[2], V. Thorsson[3], E. Cerami[4], J. A. Eddy[2];

[1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Sage Bionetworks, Seattle, WA, [3]Institute for Systems Biology, Seattle, WA, [4]Dana-Farber Cancer Institute, Boston, MA, [5]University of North Carolina at Chapel Hill, Chapel Hill, NC, [6]Harvard Medical School, Boston, MA

In September 2018, the National Cancer Institute (NCI) launched the first phase of the Human Tumor Atlas Network (HTAN) under the U.S. Cancer Moonshot program with the goal of generating three-dimensional molecular and spatial atlases of diverse human tumors and characterizing crucial transitions in cancer progression and treatment. With over 30 assay types including sequencing, imaging, and spatial transcriptomics spanning 58 cancers across 21 organ types, HTAN has delivered a substantial resource to the broader cancer research community and become the basis for a multitude of publications. Although HTAN is similar to previous large cancer data sharing efforts, new and unique challenges have emerged. First, each HTAN atlas consists of a unique collection of data focused on answering different hypotheses regarding cancer progression. Second, many of the experimental assays used within HTAN—particularly spatial profiling assays—are cutting-edge, requiring their own custom bioinformatics pipelines to perform analyses. Third, HTAN is focused on understanding temporal changes in cancer, and the HTAN data model must therefore be capable of capturing longitudinal clinical/phenotype and profiling data. Fourth, the multi-modal nature of HTAN data requires multiple visualization and data access resources, each of which must be tailored to individual data types or end-users.

To address the unique challenges of HTAN data, the network supports a dedicated Data Coordinating Center (DCC) which is currently managed by personnel from four institutions: Dana-Farber Cancer Institute, Sage Bionetworks, Memorial Sloan Kettering Cancer Center, and the Institute for Systems Biology. The DCC develops infrastructure and tools to ingest, curate, explore, and share these data in a findable, accessible, interoperable, and reusable (FAIR) manner. To this end, the DCC manages the HTAN Data Portal, which provides community access to the atlases and enables filtering of released atlas data based on metadata fields, and pointers to data availability. Additionally, the DCC leads community-driven metadata schema development through a Request for Comments (RFC) process. These activities are critical to ensuring that the wealth of data generated by HTAN is available for use by the broader scientific community. As we transition into the second phase, we describe insights from HTAN phase I, the multiple ways users can access HTAN data and metadata, the associated data standards, the enabling technical infrastructure and governance approaches underlying the DCC, and how community engagement is maintained throughout.

#1077 Visualization and analysis of cancer genomics data using UCSC Xena.

Mary Goldman[1], Brian Craft[1], Cally Lin[2], Jingchun Zhu[1]

[1]UC Santa Cruz Genomics Institute, Santa Cruz, CA,[2]Stanford University, Stanford, CA

UCSC Xena (http://xena.ucsc.edu/) is a web-based visual integration and exploration tool for both bulk and single-cell multi-omic data, and associated clinical and phenotypic annotations. Researchers can easily view and explore public data, their own private data (bulk only), or both using the Xena Browser. Private data are kept on the researcher's computer and are never uploaded to our public servers. We support Mac, Windows, and Linux.

Questions Xena can help you answer:

* Is overexpression of this gene associated with survival differences?
* What genes are differentially expressed between these two groups of samples?
* What is the relationship between mutation, copy number, expression, etc for this gene?

Xena visualizes seminal cancer genomics datasets from TCGA, the Pan-Cancer Atlas, GDC (a complete update from 2024, including new data from CPTAC3 and HCMI), PCAWG, ICGC, and more; a total of more than 1500 datasets across 50 cancer types. We support virtually any type of functional genomics data: SNPs, INDELs, copy number variation, gene expression, ATAC-seq, DNA methylation, exon-, transcript-, miRNA-, lncRNA-expression and structural variants. We also support clinical data such as phenotype information, subtype classifications and biomarkers. All of our data is available for download via python or R APIs, or using our URL links.

Our signature Visual Spreadsheet view shows multiple data types side-by-side enabling discovery of correlations across and within genes and genomic regions. We also have dynamic Kaplan-Meier survival analysis, powerful filtering and subgrouping, differential gene expression analysis, GSEA, charts, statistical analyses, genomic signatures, and the ability to generate URLs to live views.

We now visualize single-cell data, primarily gene, transcript, and protein expression, from spatially-resolved and disassociated single cell datasets. Using Xena, researchers can visualize 2D or 3D embedding views, such as tSNE and UMAP as well as the spatial imaging views, such as H&E, multiplex immunofluorescence, and co-registration of both. Crucially, we overlay genomic data — such as gene and protein expression, genomic signature scores, cell annotations, and label transfer information — on top of these images dynamically. We support a diverse range of data modalities ranging from 10x Chromium and Smartseq2 platforms for scRNA-seq and 10x scATAC-seq, to spatial transcriptomics platforms of Visium, Visium HD, Xenium, CosMx, and MERFISH/Vizgen, to imaging proteomics such as t-CycIF, CODEX, and MIBI-TOF. We showcase data from the HTAN data portal.

If you use us please cite our publication in Nature Biotechnology: https://www.nature.com/articles/s41587-020-0546-8

#1078 Enhancing reusability and adoption of cancer research tools: Development of the Cancer Complexity Toolkit.

Aditi Gopalan[1], Brad Macdonald[1], James Eddy[2], Thomas Yu[1], Susheel Varma[1], Jineta Banerjee[1], Jineta Banerjee[1]

[1]Sage Bionetworks, Seattle, WA,[2]ARPA-H, Bethesda, MD

The Cancer Complexity Knowledge Portal (CCKP) is an open-access data repository that stores and shares resources from multiple cancer research programs. Maintained by Sage Bionetworks, in collaboration with The Multi-Consortia Coordinating (MC2) Center, which supports six NCI Division of Cancer Biology (DCB) funded programs made up of interdisciplinary communities of scientists, the CCKP centralizes access to cancer research tools and data, improving their discoverability and reuse.Reusing tools has proven to be challenging for various reasons. Therefore, we aim to enhance the reusability of the tools available on CCKP. To achieve this, we are designing and implementing a Cancer Complexity Toolkit to validate tool reusability and increase their adoption. Building on existing efforts to curate tools generated by the cancer research community, the 'Cancer Complexity Toolkit' aims to achieve three key objectives: (1) enhancing the discovery and reuse of cancer research tools through rich metadata and standardized evaluation frameworks, (2) creating a catalog of cancer research-focused tools to improve accessibility and confidence in their use, and (3) enabling standardized reporting and validation of tool functionality. Ultimately, we aim to provide a robust platform for discovering, validating, and integrating computational tools in cancer research.To achieve these goals, we are (1) refining a standardized schema to capture metadata on tool parameters and usage, (2) building infrastructure for automated checks to assess documentation, test coverage, and community metrics, and (3) developing tool cards to display relevant metrics and metadata, helping researchers select the right tools and allowing developers to highlight their tools' impact.In Phase 1, we refined the tool metadata schema and developed a Python-based testing infrastructure to check for documentation, testing files, and deployment on non-native Linux environments. We selected ten tools from the CCKP for initial testing, generating logs that assess their reusability.

#1079 L2S2: Chemical perturbation and CRISPR KO LINCS L1000 signature search engine.

G. B. Marino, J. E. Evangelista, D. J. B. Clarke, A. Ma'ayan;
Icahn School of Medicine at Mount Sinai, New York, NY

The Library of Integrated Network-Based Cellular Signatures (LINCS) Common Fund program was established to construct a reference database of human cancer cell lines responses to diverse multi-omics and phenotypic perturbations. As part of the LINCS initiative, 248 cell lines were profiled with the L1000 transcriptomics assay to measure the response to 33,621 small molecules and 7,508 single gene CRISPR knockouts (KOs). From this massive dataset, we computed sets of up- and down-regulated genes. These gene sets are served for search by the LINCS L1000 Signature Search (L2S2) platform. L2S2 provides instant results when searching across over 1.678 million chemical perturbations and CRISPR KO signatures. The platform includes filters for FDA-approved drugs and signature directionality. With the L2S2 search engine, users can identify small molecules and single gene CRISPR KOs that produce gene expression profiles similar or opposite to their submitted gene sets. Significant CRISPR KO signatures can reveal potential driver genes and drug targets. Similarly, approved drugs and preclinical small molecule signatures that might reverse or mimic a desired expression pattern can provide hypotheses for preclinical experimental validation studies. L2S2 also includes a consensus search feature which ranks specific perturbations across cellular contexts, time points, and concentrations. L2S2 was systematically applied to the CPTAC3 cohort to prioritize potential targets, approved drugs, and preclinical compounds for all previously identified multi-omic cancer cohort subtypes. Overall, L2S2 provides cancer researchers with a powerful tool to further understand and personalize treatments for cancer subtypes. L2S2 is available from: https://l2s2.maayanlab.cloud.

#1080 Transforming cancer genomics research: A platform for integrated exploration of COSMIC resources.

Helder Pedro, Zbyslaw Sondka

Wellcome Sanger Institute, Cambridge, United Kingdom

The Catalogue of Somatic Mutations in Cancer (COSMIC) is a vital resource for cancer genomics, offering extensive data on somatic mutations, cell lines, and mutation signatures. While the existing COSMIC dataset provides wealth of diverse, high-quality information, accessing and fully utilising it requires significant processing and expertise in data analysis. To address this, we are developing a new suite of tools to enhance COSMIC data integration, usability and exploration.The Cell Line Explorer serves as a starting point for this suite, enabling users to easily access and analyse COSMIC data related to specific cell lines. This tool integrates genetic variants with annotations and reference datasets, providing dynamic insights into clinical significance. Beyond the cell lines mutation catalogue, the platform connects to key COSMIC resources, including the Cancer Gene Census, Actionability, Cancer Mutation Census, Mutational Signatures, and COSMIC3D. This integration allows users to derive deeper insights, and easily correlate mutation data with functional impact and potential clinical significance.The tools are designed for flexibility and scalability, meeting the needs of diverse users, from computational researchers, clinicians seeking actionable insights, educators incorporating bioinformatics into their teaching, and individuals with limited bioinformatics expertise who require intuitive solutions.With its intuitive interface and robust integration of COSMIC resources, this platform lowers the barriers to access and streamline complex analyses, providing researchers with powerful tools to explore and analyse cancer genomic data at unprecedented depth.

#1081 Sylvester Data Portal: Streamlined access to standardized clinicogenomic data.

Jeronimo I. Pissinis, Oliver Mazariegos, Marcin Pilarczyk, Michael S. Sinclair, Lukas Rupprecht, Caty Chung, Franklin Sotolongo, Gabriel Lichtenstein, Kathleen M. Jagodnik, Joanita Figueredo, Pearl Seo, Carlos J. Obregon, Marcin Blicharz, Piotr Smol, Michal Pyrkosz, Mateusz Jura, Vasileios Stathias, Stephan Schurer

SCCC-Data Science, Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

The Sylvester Data Portal (SDP), developed at the University of Miami (UM) Sylvester Comprehensive Cancer Center, is an advanced multi-omics platform that streamlines the management of real-world and research data. SDP facilitates the standardization and integration of data from major genomic profiling vendors, including Caris Life Sciences, Foundation Medicine, and NeoGenomics. SDP utilizes an event-driven ETL pipeline to process, validate, and standardize genomic reports (XML, PDF) and files (FASTQ, BAM, VCF, TSV) from Whole Exome Sequencing (WES), Targeted Sequencing (TS), and Whole Transcriptome Sequencing (WTS) tests. Metadata are harmonized into a unified format, enabling cross-vendor and cross-test-type queries. The platform also supports the preparation of data and metadata for submission to the AACR Project GENIE.A LIMS-like module within SDP is operationally integrated with data generation at the Onco-Genomics Shared Resource (OGSR). This module tracks sequencing workflows, performs automated quality control (QC), and manages the release of high-quality datasets to users, including their secure long-term storage. These functionalities enhance the reliability and accessibility of sequencing data for translational research. SDP also supports interactive data exploration and analysis.The platform enables containerized and reproducible bioinformatics workflows, supporting tasks like demultiplexing, as well as single-cell and bulk RNA-seq analyses. Future functionalities will include handling additional data types such as ATAC-seq and ChIP-seq, alongside integrated DNA analysis of germline and somatic variants.To ensure secure and tailored access to clinical data, SDP provides three user interfaces: (1) The Clinical Dashboard offers aggregated patient statistics, such as demographics and summaries of available data; (2) The Clinical Browser grants access to de-identified subject-level data upon institutional approval; and (3) Clinical Collections include PHI and NGS data, accessible after IRB and Data Broker approval. These interfaces facilitate data sharing within the Sylvester community, advancing translational research while adhering to data governance and regulatory policies.

#1082 A comprehensive platform for stage-specific analysis of colon cancer: integrating transcriptomic and clinical data for biomarker discovery.

Aron Baratha, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

Introduction: Understanding the molecular mechanisms underlying stage-specific colon cancer progression is essential for identifying biomarkers and developing effective therapies.
Aim: To address this need, we extended our previously established comprehensive database with stage-specific clinical and transcriptomic data. The new updated database was employed to mine stage-specific patterns and explore functional trends across stage-stratified colon cancer cohorts.
Methods: We used data from GEO (gene arrays), TCGA, and GTEx (RNA-seq) databases. A total of 1,926 colon cancer samples from gene chip studies were manually curated from GEO, and RNA-seq data comprising 469 samples were included from TCGA. To identify differentially expressed genes across stages, we first performed ANOVA tests, adjusting p-values using the Benjamini-Hochberg method with a cutoff of 0.01. Effect size was then estimated using the eta squared approach, applying a moderate effect size threshold of 0.06.
Results: Stage-specific data were incorporated into our previously established colon cancer dataset, including 37 (array) and 75 (RNAseq) Stage I samples, 291 (array) and 176 (RNAseq) Stage II samples, 197 (array) and 128 (RNAseq) Stage III samples, and 123 (array) and 64 (RNAseq) Stage IV samples. The expanded dataset facilitates a detailed investigation of gene expression changes across colon cancer stages, uncovering stage-dependent molecular signatures. We utilized the integrated database to uncover genes with consistent expression change across tumor progression. We identified 94 stage-specific genes with significant differential expression and at least a moderate effect size. These genes were primarily associated with transcription and phosphorylation. Among them, *COG5* (pAdj = 8.17E-09), *AMMECR1* (pAdj = 9.76E-10), and *SOWAHC* (pAdj = 8.51E-10) showed the most consistent differences across stages. The new integrated platform with all transcriptomic and clinical data is accessible at www.tnmplot.com
Conclusion: Our enriched platform provides a powerful resource for the comprehensive exploration of stage-stratified colon cancer data, offering valuable insights into cancer biology and supporting biomarker discovery.

#1083 T cell receptor-associated genes as biomarkers of survival in anti-PD-1 treated cancer patients.

Szonja Anna Kovacs, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

Background: Immune checkpoint inhibitors (ICIs) aim to restore T-cell function in the tumor microenvironment, but predicting patient response remains challenging. T-cell abundance and T-cell receptor (TCR) signaling are critical for the effectiveness of ICI therapies. While PD-L1 expression is a commonly used biomarker, its predictive accuracy is inconsistent. Exploring alternative biomarkers could improve response prediction and patient outcomes.
Methods: We integrated multiple gene expression cohorts from cancer patients treated with immune checkpoint inhibitors (anti-PD-1, anti-PD-L1, and anti-CTLA-4). Corresponding clinical annotation data were incorporated for survival and biomarker studies. Survival analysis was performed using Cox regression, and Gene Ontology (GO) enrichment analysis was conducted on both pre-treatment (samples taken before ICI therapy) and on-treatment (samples collected during or after therapy) groups. Published survival data were excluded if no progression or death occurred, and follow-up ended within 12 months.
Results: The complete database includes 1,297 patients with relapse-free survival data and 1,554 patients with overall survival (OS) data. Patients with higher expression of genes associated with the CD4+ or CD8+ T-cell lineage commitment pathway (GO:0043369) demonstrated improved OS. Notably, elevated expression of T-cell receptor beta constant 2 (TRBC2; HR=0.38, log-rank P=1E-03, FDR=5%), Cluster of Differentiation 247 (CD247; HR=0.37, log-rank P=1.7E-03, FDR=5%), and Cluster of Differentiation 3E (CD3E; HR=0.35, log-rank P=1.4E-03, FDR=5%) correlated with better OS after anti-PD-1 therapy. To determine whether these findings reflect a pre-existing immune-infiltrated tumor microenvironment or an immune system boost induced by anti-PD-1 therapy, we also analyzed pre-treatment samples. Higher expression of TRBC2 (HR=0.49, log-rank P=4.4E-05, FDR=1%), CD247 (HR=0.49, log-rank P=4.9E-07, FDR=1%), and CD3E (HR=0.42, log-rank P=9.5E-07, FDR=1%) in pre-treatment samples were also associated with better survival. PD-L1 (CD274) expression is a commonly used but controversial biomarker for ICI therapy. Patients with high PD-L1 expression before anti-PD-1 treatment showed better relapse-free survival (HR=0.61, log-rank P=4.1E-10, FDR=1%) and overall survival (HR=0.61, log-rank P=5.6E-04, FDR=5%). These results demonstrate that, as expected, an already immunologically "hot" tumor predicts a better response and, consequently, improved survival with anti-PD-1 immunotherapy. The complete ICI cohort was integrated into our established web platform (www.kmplot.com) to enable independent future biomarker discovery.
Conclusions: T-cell receptor complex-associated genes, such as TRBC2, CD247, and CD3E, are robust predictors of survival both before and after anti-PD-1 therapy.

#1084 Analyzing artificial intelligence (AI) Resources for Cancer Research Data Programs.

Juergen Klenk[1], Dina Mikdadi[1], Bhavani Singh[1], **Chelsea Owens**[1], Eric Barner[1], Ross Campbell[1], Mary Sears[1], Ina Felau[2], Erika Kim[2], Tanja Davidsen[2]

[1]Deloitte Consulting LLC, Rosslyn, VA,[2]Data Ecosystems Branch, National Cancer Institute, Rockville, MD

Purpose: The National Cancer Institute's (NCI) Cancer Research Data Commons (CRDC) supports the cancer research community by providing cloud-based, secure storage and analytic tools for multiple cancer data types (e.g., genomic, proteomic, imaging, and clinical trial data). CRDC is beginning to integrate artificial intelligence (AI) solutions, such as using AI to annotate medical images and making AI models and resources available for cancer researchers. As AI policies emerge, CRDC must track relevant guidelines to determine how AI can safely and compliantly unlock value for researchers.
Methods: CRDC conducted a landscape analysis to inform CRDC of potential AI risks and policies across three branches of the Federal government and international agencies. CRDC identified and analyzed policies from organizations focused on AI risk mitigation measures, general AI guidance, and AI strategy as relates to federal health agencies.
Results: The following policies have the most implications for CRDC. In the Executive Branch, the Executive Order on Safe, Secure, and Trustworthy AI mandates federal agencies to ensure AI safety and trustworthiness. The National Institute for Standards and Technology developed AI evaluation criteria, risk assessments, and tools to help assess AI models. CRDC can follow this mandate and use the tools to begin developing an AI strategy. In the Legislative Branch, the Senate AI Working Group and House AI Task Force are starting to discuss specific AI legislation. Although legislation hasn't passed, CRDC should track legislative updates that could impact CRDC compliance. In the Judicial Branch, the Supreme Court overturned the Chevron Deference. Although not directly related to AI, the decision could affect how CRDC interprets and acts upon AI guidance. Internationally, European countries developed accountability frameworks, evaluation criteria, tools, and risk assessments to identify roles and responsibilities and help assess AI models. While NCI is not obligated to follow European AI policies, these artifacts can inform CRDC in developing an AI strategy.
Conclusion: AI policies continue to emerge and evolve. As guidance is solidified, it is important that CRDC continues to monitor and analyze requirements to mitigate risks and ensure responsible use of AI in cancer research. This ongoing analysis will inform CRDC, enhance trust within their user community, increase timely access to cancer data analytical tools, and contribute to the advancement of cancer therapies.

#1085 Analyzing economic storage solutions for cancer research data.

Juergen Klenk[1], **Dina Mikdadi**[1], Bhavani Singh[1], Chelsea Owens[1], Eric Barner[1], Ross Campbell[1], Mary Sears[1], Ina Felau[2], Michael Warfe[2], Erika Kim[3], Tanja Davidsen[2]

[1]Deloitte Consulting LLP, Arlington, VA,[2]Data Ecosystems Branch, National Cancer Institute, Rockville, MD,[3]National Cancer Institute, Rockville, MD

Purpose: The National Cancer Institute's (NCI) Cancer Research Data Commons (CRDC) is a cloud-based data ecosystem that allows researchers to share and access clinical, genomic, proteomic, and imaging data. CRDC currently houses more than 10 petabytes (PB) of data (predominantly genomic). The volume of genomic data in CRDC has more than doubled since 2022 from 3.7 PB to 8.8 PB. To address the escalating data storage costs, CRDC must identify economic genomic data storage/compression strategies to achieve long-term sustainability.

Methods: To evaluate the impact of genomic compression algorithms and cloud storage solutions, a data compression and storage pilot study was conducted based on two CRDC data sources:185GB from 1000 Genomes Project, and 151GB from the Integrated Canine Data Commons (ICDC). Four compression algorithms - PetaGene, CRAM, PigZ, and Genozip - were chosen based on their current use within the cancer research community. The study consisted of three parts:

Compression-Only: four compression algorithms were evaluated for efficiency and cost-effectiveness

Cloud Storage+Compression: compressed data were placed in various AWS S3 storage tiers including AWS Intelligent-Tiering (Assumption: no monitoring and automation costs for intelligent tiering)

AWS HealthOmics: a range of possible storage costs were based on two scenarios- (1) data accessed monthly, and (2) data never accessed. (Assumptions: 4 gigabases per gigabyte, no egress costs when moving data off HealthOmics, each genome is downloaded in 500 parts generating 500 GET API calls)

Results: Of the four algorithms tested, PetaGene performed best on both datasets. For 1000 Genomes data, PetaGene compressed data by 76% in ~70 minutes for a one-time cost of $2.86. For ICDC data, PetaGene compressed data by 83% in ~63 minutes for $2.57.

It is broadly accepted that tiered storage yields cost savings. When compressed data was placed in tiered storage, yet more savings were realized. For both datasets, the most cost-effective strategy was S3 Intelligent-Tiering of PetaGene compressed data. The annual cost for PetaGene compressed data stored in intelligent tiering ranges from $2.10 - $6.90 (ICDC) and $3.70 - $12.14 (1000 Genomes).

The annual cost to store data in AWS HealthOmics is $11.15 - $41.82 (ICDC) and $13.66 - $51.23 (1000 Genomes) for data accessed monthly.

Conclusion: Significant cost savings can be achieved using effective genomic data compression tools paired with intelligent tiering storage solutions. There were two main limitations. Data license costs of compression algorithms were not studied, and while the frequency of data access should be considered for real world application, this was not part of the scope of this study. Both these factors will need to be considered as CRDC selects strategies to mitigate cost and inform overall infrastructure.

#1086 Introducing the Florida Cancer Research (FL CARES) Network and the Platform for Accelerating Collaborative Computational Cancer Research (PAC3R).

Michael Sinclair[1], Carlos Obregon[1], Caty Chung[1], Dusica Vidovic[1], Lukas Rupprecht[1], Jeronimo Pissinis[1], Marcin Pilarczyk[1], Franklin Sotolongo[1], Kathleen M. Jagodnik[1], Till Krenz[1], Umamaheswari Natarajan[2], Erin Kobetz[1], Mondal M. Ananda[3], Ling Cen[4], Xuefeng Wang[4], Appu Rathinavelu[2], Stuart Chalk[5], Jiang Bian[6], Ji-Hyun Lee[6], Qianqian Song[6], Vasileios Stathias[1], **Stephan C. Schurer**[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Nova Southeastern University, Fort Lauderdale, FL,[3]Florida International University, Miami, FL,[4]Moffitt Cancer Center, Tampa, FL,[5]University of North Florida, Jacksonville, FL,[6]University of Florida, Gainesville, FL

Florida ranks second in cancer burden in the United States. The Florida CAncer RESearch (FL CARES) Network (https://floridacancernetwork.org/) is a statewide collaboration dedicated to advancing cancer research and improving patient outcomes through education, collaborative research initiatives, and a focus on reducing health disparities by leveraging advanced computational approaches. Funded by the State of Florida Bankhead-Coley Cancer Research Program, FL CARES comprises six research organizations, including Florida's three NCI-designated Cancer Centers. The Network has established a collaborative research consortium with unified policies, coordinated data and metadata standards, and diverse datasets. It incorporates tools like SCAN360, developed at Sylvester Comprehensive Cancer Center, to explore the impact of social determinants of health and environmental factors on cancer outcomes across Florida communities. To further collaborative computational research, FL CARES is developing the Platform for Accelerating Collaborative Computational Cancer Research (PAC3R). This advanced informatics system enables FAIR (findable, accessible, interoperable, reusable) data management, including standardization, harmonization, and integration of multimodal cancer datasets. PAC3R facilitates secure data sharing, scalable bioinformatics tools' deployment, and collaborative analyses across the Network. Built on the Sylvester Data Portal (https://sdp.miami.edu/), a cloud-based multi-omics platform managing clinicogenomic and research data, PAC3R integrates diverse datasets such as transcriptional perturbation signatures, cell sensitivity data, small molecule interactions, and large-scale genomics from The Cancer Genome Atlas (TCGA) and Clinical Proteomic Tumor Analysis Consortium (CPTAC).

#1087 The evolving landscape of cancer transcriptomics data.

Valentin Bernu, Helia Brull Corretger, Charles Lescure, **Abdelkader Behdenna**, Julien Haziza, Clemence Petit, Akpeli Nordor

Epigene Labs, Paris, France

Secondary analysis of omic datasets holds great potential in accelerating precision oncology research and drug development. Yet, scientists lack efficient tools to assess the scope and volume of those datasets. Data heterogeneity and limited browsing features of public databases make it challenging to efficiently search for relevant datasets based on specific criteria, such as experimental designs. We introduce the latest iteration of our solution to map and navigate public databases.

Our solution extracts and preprocesses clinical data that serves as input for our classification models, which range from rule-based algorithms developed in collaboration with domain experts to large language models. We categorize datasets by cancer type, treatment modality, sequencing resolution, cell line identity, mutational status, and drug information. This iteration introduces models for predicting mutation and drug-related data and continuously updates mappings for existing models—cancer type, technology, and treatment—by incorporating new entries. Additionally, this version integrates two databases, namely “Gene Expression Omnibus” or “GEO” and ArrayExpress, and includes a dashboard that allows querying and visualization of the automatically tagged datasets.

We identified 24,131 cancer-related, patient-derived omic datasets from GEO. Our models estimate the following:

- Cancer types: the 5 most frequent indications (breast cancer, brain cancer, non-small cell lung cancer, acute myeloid leukemia, colorectal cancer) constitute about 60% of datasets.
- Technology: RNA-Seq accounts for 29% of datasets, with an estimation of 24% being single-cell and 76% bulk RNA-Seq. RNA-Seq has become the dominant technology: in 2012, the number of microarray studies published that year outnumbered RNA-Seq studies 10:1; by 2023, RNA-Seq studies published annually had overtaken microarray studies by a comparable margin. Today, the total volume of accumulated studies for each approach is nearly equal.
- Treatment: approximately 25% of datasets include treatment information; post-treatment samples are estimated to represent 15%.
- Mutations: information is available in 26% of datasets. Notably, 26% of colorectal cancer datasets contain mutation information, of which 35% report KRAS mutations.
- Drugs: information related to antineoplastic agents is found in 11% of GEO cancer datasets.

The analysis of ArrayExpress found 16,255 cancer-related datasets, 77% of which also exist on GEO.

Our unified data mapping approach streamlines the identification and querying of datasets across multiple public databases. Additionally, it uncovers otherwise hard-to-detect information and reveals meaningful trends, thereby providing researchers with valuable insights for conducting informed secondary data analyses.

#1088 LiverSCA 2.0: An enhanced and comprehensive cell atlas of human hepatocellular carcinoma, intrahepatic cholangiocarcinoma and metabolic dysfunction-associated steatotic liver disease/steatohepatitis.

Fanhong Zeng, Renwen Long, Tina Suoangbaj, Irene Oi-Lin Ng, Daniel Wai-Hung Ho

The University of Hong Kong, Hong Kong, China

Hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (ICC) are two distinct types of primary liver cancer (PLC) characterized by a considerable degree of cellular and molecular heterogeneity. We recently developed a web-based cell atlas called LiverSCA with a user-friendly interface, comprehensive functionality, and a complete set of analytical pipelines. In the previous version, LiverSCA includes 40 subjects (35 HCC patients with various etiological risk factors and five healthy controls) with a total cell count of more than 140,000 cells. It facilitates the exploration of gene expression patterns, cellular composition, and intercellular communication in the liver and PLC tumor microenvironment, aiming to help researchers discover new mechanistic insights into the complex tumor microenvironment of HCC. To further enhance the comprehensiveness of LiverSCA, we have expanded its catalog with additional datasets of different phenotypes/subtypes of liver and PLC, such as intrahepatic cholangiocarcinoma (ICC) and metabolic dysfunction-associated fatty liver disease/steatosis (MASLD/MASH). The current enhanced version of the LiverSCA cell atlas contains six phenotypes (normal, HBV-HCC, HCV-HCC, non-viral HCC, ICC, and MASH), encompassing 63 patients and more than 248,000 cells. In addition, we have incorporated a comparative visualization method that allows users to simultaneously examine and compare gene expression levels between two different phenotypes. We are committed to the continued development of LiverSCA to narrow the knowledge gap between different research fields and accelerate knowledge transfer in the scientific community. We envision that it will become a valuable resource that supports researchers to conveniently study the cellular and molecular landscape of the liver and PLCs. In addition, as scRNA-seq technology is still rapidly evolving, more features, such as spatial transcriptomics and multimodal omics, will be considered in future updates.

#1089 Developing subtype-specific pediatric cancer molecular targets by aggregating diverse genomic data resources to the pediatric cancer (PeCan) knowledge base portal.

David B. Finkelstein, Delaram Rahbarinia, Ramzi Alsallaq, Stephanie Sandor, Michael Macias, Jian Wang, Sue Qiu, Brian Curran, Michael Edmonson, Andrew Thrasher, Jobin Sunny, James Madson, Scott Foy, Brent Orr, Mark R. Wilkinson, Clay McLeod, Michael Rusch, Xiaotu Ma, **Jinghui Zhang**

Computational Biology, St. Jude Children's Research Hospital, Memphis, TN

Knowledge about molecular targets for pediatric cancer has accelerated exponentially in recent years thanks to the increased application of multi-omics profiling in both research and clinical settings. The efficacy of genomic-based clinical interventions may depend on whether observed genomic abnormalities are fundamental to the pathogenesis of a specific cancer subtype. At present such information is limited in pediatric cancer due to the rapid evolution of subtype discovery and classification as well as disease heterogeneity owing to the presence of many rare cancer types. To develop a comprehensive resource of molecular targets in pediatric cancer subtypes, we have integrated somatic variants in pediatric cancer samples (n=~5,500) currently hosted in PeCan Portal (https://pecan.stjude.cloud/) with those (n=~1,400) profiled by NCI's Childhood Cancer Data Initiative (CCDI) molecular characterization program. To leverage the recently developed WHO CNS5 classification of CNS tumors, we reclassified 2,167 relevant samples based on molecular drivers and histology as a major update to our pediatric cancer ontology definitions, which have recently become a shared standard in the CCDI community. To determine driver genes in disease pathways relevant to specific cancer types, we analyzed the pathogenicity of SNVs and indels, CNVs, SVs and gene fusions and integrated the findings with driver genes reported in 176 publications. A total of 469 distinct driver genes were mapped to 40 pathways across the 22 major pediatric cancer types, which include 3 types of hematological malignancies (HM), 10 types of CNS tumor and 9 types of solid tumor (ST). Pathways with driver genes disrupted across the broad spectrum of cancer types include cell cycle, chromatin remodeling, PI-3K, RAS signaling and telomere maintenance. By contrast the vast majority (>90%) of the transcription factors (TF) are lineage-specific— among the 128 TF genes identified as driver genes, only 11 affect multiple lineages. These include *MYC/MYCN* which affect HM, ST and CNS tumors; *ERG*, *EWSR1*, *FLI1* and *WT1* which affect HM and ST; and *KLF4*, *MED12*, *MN1*, *MYB* and *TCF4* which affect CNS and HM. These results highlight the importance of developing an infrastructure for exploring mutation prevalence in driver genes and pathways at the cancer subtype level, which will be supported in the upcoming release of the PeCan portal. This, coupled with new features for dynamic exploration of mutational signatures, global expression maps and gene-level transcription across the cancer subtype classification tree, will greatly expand our knowledge of molecular targets and vulnerabilities in pediatric cancer, paving the way for novel therapeutic advancements

#1090 Multiomic analysis of Taiwanese NSCLC: insights from a predominantly non-smoking cohort.

Hsu-Ching Huang[1], Samira Masoudi[2], Daniel Halmos[3], Chien-jung Huang[4], Yu-Chao Wang[4], Yi-Chen Yeh[5], Yung-Hung Luo[1], Han-Shui Hsu[6], Yuh-Min Chen[7], Chun-Ku Chen[8], Sandip Patel[9], Albert Hsiao[10]

[1]Division of Thoracic Oncology, Department of Chest Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,[2]Halıcıoğlu Data Science Institute, University of California, San Diego, San Diego, CA,[3]Bioinformatics and Systems Biology Graduate Program, University of California, San Diego, San Diego, CA,[4]Institute of Bioinformatics, National Yang Ming Chiao Tung University, Taipei, Taiwan,[5]Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,[6]Division of Thoracic Surgery, Department of Surgery, Taipei Veterans General Hospital, Taipei, Taiwan,[7]Department of Chest Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,[8]Division of Cardiopulmonary Radiology, Department of Radiology, Taipei Veterans General Hospital, Taipei, Taiwan,[9]Center for Personalized Cancer Therapy, Division of Hematology and Oncology, UC San Diego Moores Cancer Center, San Diego, CA,[10]Department of Radiology, University of California, San Diego, San Diego, CA

Introduction: We curated multiomic data including whole exome sequencing (WES) and high-resolution chest CT from patients diagnosed with NSCLC, and evaluated the potential for a multitask deep learning algorithm to predict tumor mutational status and WES signatures from CT.

Materials and Methods: Taipei Veterans General Hospital (TVGH) initiated a multi-omic databank integrating clinical, radiological, pathological, and genomic data from NSCLC patients. A predefined pipeline identified INDEL and SNP mutations with high or moderate impact using Ensembl Variant Effect Predictor (VEP). PCA reduced dimensionality of the WES binary data, and t-SNE was used for clustering and visualization. Chest CT was performed using scanners with ≥ 20 detector rows, at end-inspiration with 120 kV, automated exposure control, and a 50 cm field of view. Patients were split 80% for training and 20% for validation. 3D CT image data centered on lesions were rotated, resampled and cropped. A 3D ResNet-18 network, pre-trained on Kinetics-400, was used for predicting common NSCLC mutations (EGFR, TP53), and the first and second principal component coefficients.

Results: A total of 317 patients were included, with 74% non-smokers.(Table 1) Of 109 LDCT detected nodules, only 27 were from smokers. PCA of 12,023 gene mutations identified five principal components. t-SNE visualized the clustered distribution of the top three genes with the highest weights: EGFR, TP53, and RBM10, along with tumor mutation burden (TMB) and EGFR co-mutation status. Performance of the deep learning algorithm in the validation set (n=63) showed: EGFR mutation prediction: AUROC 71%, PPV 71%; TP53 mutation prediction: AUROC 76%, NPV 94%, sensitivity 0.84, specificity 0.72.Pearson correlation for prediction of the coefficients of the genetic signature principal components from CT images were 0.37 and 0.47.

Conclusion: Deep learning algorithms can infer genetic mutation signatures from CT radiologic features. Further optimization is needed.

Understanding unique cancer tumor phenotypes is critical in determining disease progression, drug response, and clinical outcomes. Tumor cell-specific total mRNA expression (TmS) which quantifies total mRNA content within tumor cells, has been shown as a robust biomarker to unravel genetic makeup of tumors and their surrounding environments. Currently, quantifying TmS from transcriptomic data is time consuming and resource intensive. Moreover, the unavailability of matched DNA/RNAseq data with clinical annotations limits the translation of TmS to clinical settings. Machine learning (ML) is powerful to create blackbox models that utilize raw high-dimensional omic data to predict clinical outcomes. In this work, we propose TmSNet, TmS prediction by ensemble Network. It is an ML framework that extracts cancer-type-specific gene expression, methylation, and miRNA profiles from 14 cancer types in TCGA cohort (Train =70%, test =30%) to predict TmS. For each cancer type, we extracted relevant features with an ensemble feature extractor block, using random forest (RF), gradient boosting (GB), lasso, and elastic net (EN) models. The extracted features from each model were used to train an ensemble of ML models consisting of variational auto encoder (VAE), model agnostic meta learning (MAML), support vector machine (SVM), and multi-layer perceptron (MLP). TmSNet achieved strong predictive performance across all cancer types (Table 1). Our findings suggest that TmSNet effectively predicts TmS from limited data, with strong performance and limited overfitting. The predicted TmS values from TmSNet successfully stratifies patient survival within early and late-stage cancer. This can serve as a valuable prognostic tool for multi-omic analyses in cancer, with implications for tumor phenotyping, cancer screening, and therapeutic intervention.

No.	Cancer Type	Root Mean Squared Error (RMSE) (average = 0.14)	Feature Extraction Model	Prediction Model
1.	Bladder urothelial carcinoma (n=337)	0.15	Lasso	VAE

#1096 Estimating risk factors and predicting various cancer types using integrated real-world data: An AI-based approach.

Md Ashad Alam[1], Nick Duesbery[1], Daniel Fort[2]

[1]Ochsner Health System, New Orleans, LA,[2]Ochsner Health Systerm, New Orleans, LA

Cancer remains a critical global health issue with numerous risk factors. However, comprehensive large-scale studies in the United States, particularly those examining cancer-related medical conditions, are limited. This study aims to develop AI-driven precision medicine algorithms by integrating data from electronic health records (EHR) to identify patients at elevated risk for various cancers, using age-, gender-, race-, and area deprivation index (ADI)-stratified data. By employing disease, demographic, and ADI data as covariates, we apply interpretable machine learning models to uncover insights into cancer risk factors. We explored eight machine and deep learning algorithms including logistic regression (LR) and random forest (RF) using 1,229 truncated unique ICD-10-CM codes (selected through related risk analysis) as binary features across a total pool of 1.6 million patients with 5-fold cross-validation. First, we applied both LR and RF methods for all patients. Using LR, we observed that conditions such as nicotine dependence, irregular menstruation, and urinary disorders were highly associated with subsequent cancer diagnoses, while acute pharyngitis and cardiac murmurs were associated with a decreased risk, achieving an overall accuracy of 86%. RF further identified conditions, including acute pharyngitis, nicotine dependence, and other soft tissue disorders with high predictive value, achieving 96% training accuracy and 86% test accuracy. Finally, eight machine and deep learning algorithms were evaluated on various sample sizes, ranging from 200 to 20,000, assessing accuracy, precision, recall, F1 score, ROC AUC, and MCC. Notably, RF accuracy increased from 69% to 78%, and ROC AUC from 79% to 86% as sample size grew, underscoring the model's robustness with larger datasets. Our findings contribute to early cancer detection and provide insights into disease progression. This comprehensive analysis has the potential to improve early detection, diagnostic pathways, and understanding of the pathological processes underlying cancer worldwide, as well as highlight variable performance across methodologies on this kind of data.

#1097 Tumor purity (TP) as a predictive biomarker for adjuvant radiotherapy (ART) in stage IIIAN2 non-small cell lung cancer (NSCLC): An ancillary analysis of Lung ART-IFCT 0503.

Wael Salem Zrafi[1], Victor Albarran-Artahona[2], Maria-Rosa Ghigna[3], Nicolas Signolle[4], Nathalie Cozic[5], Filippo Gustavo Dall'Olio[2], Julien Adam[6], Ludovic Lacroix[7], Cecile Le Pechoux[8], Antonin Levy[8], Daniel Gautheret[9], Benjamin Besse[2]

[1]Department of Biostatistics and Bioinformatics, Gustave Roussy, Villejuif, France,[2]Department of Medical Oncology, Gustave Roussy, Villejuif, France,[3]Department of Pathology, Gustave Roussy, Villejuif, France,[4]UMS AMMICa PETRA, CNRS UAR3655/ INSERM US23, Gustave Roussy, Villejuif, France,[5]Department of Biostatistics, Gustave Roussy, Villejuif, France,[6]INSERM U1186, Gustave Roussy, Villejuif, France,[7]Biopath department, Gustave Roussy, Villejuif, France,[8]Department of Radiation Oncology, Gustave Roussy, Villejuif, France,[9]I2BC, Universite Paris-Saclay, CNRS, Gif sur Yvette, France

BACKGROUND: TP is defined as the proportion of cancer cells in the tumor tissue and serves as a key characteristic of the tumor microenvironment .ESTIMATE algorithm infers TP on samples using gene expression. Its association with the effects of radiotherapy has not yet been explored.
METHODS: In the Lung ART trial (NCT00410683), 501 patients (pts) with completely resected stage IIIN2 NSCLC (AJCC 7th), were randomized to ART or observation (Obs). (Neo)adjuvant chemotherapy was permitted. RNA libraries were successfully extracted from 285 FFPE surgical primary, captured using SureSelect XT HS2 RNA Agilent kit, paired-end sequencing was conducted. Molecular barcode (MBC) was preprocessed using AGeNT tools and quantification was achieved using Kallisto. Gene level TPM quantification was used for TP estimation, then assessed as a prognostic and predictive biomarker using uni and multivariable Cox and Kaplan-Meier analyses.
RESULTS: Among the 285 pts, 141 (49.5%) received ART. Clinical baseline characteristics were well balanced between ART and Obs arms, 61 years as a median age, 30-31% female, 77-83% of non-squamous histology respectively. TP was higher in the ART arm (0.65) Vs (0.63) in Obs p=0.006. TP was positively associated with cancer cell percentage assessed by pathologist on Hematoxylin and Eosin (HE) slides (rho 0.23, p 7.2e-5). Higher TP was significantly associated with lower T cells infiltrate, $CD3^+$ and $CD8^+$ cell density on IHC (rho -0.52, -0.45 respectively $p < 2e-16$, p 1.1e-14). Higher TP was associated with higher necrosis percentage if not exceeding 50% of the slide (rho 0.3 p 4.2e-6). No significant drop in TP was found after neoadjuvant treatment. Patients with high TP, according to the median value in each arm, had worse overall survival (OS) and disease-free survival (DFS) with a median OS of 48.5 vs. 106.5 months (m) for low TP patients (p=0.0008) and median DFS of 18.4 Vs 48 m (p=0.017). The predictive role of TP was amplified in the ART arm, with median OS of 38.9 m (high TP) vs not reached (low TP; p=0.0017) and median DFS of 24 (high TP) vs 58.7 m (low TP; p=0.044). A multivariable cox model showed a significant interaction between TP and ART (HR 71.3 for OS p=0.04 and 33 for DFS p=0.07).
CONCLUSIONS: Our results show that higher TP is significantly associated with poorer outcomes in Stage IIIAN2 NSCLC. ART may have better efficacy in tumors with lower TP. TP is a potential new predictive biomarker for ART. Confirmatory studies are needed.

#1098 Combining random projection and stacking learning for NSCLC subtype classification based on transcriptomic data.

X. Wu, J. Wang, S. Wan;
University of Nebraska Medical Center, Omaha, NE

Lung cancer is the leading cause of cancer-related death and the second most diagnosed cancer worldwide. Non-small cell lung carcinoma (NSCLC), the predominant type of lung cancer, presents diverse pathological features and cellular heterogeneity. As the two major NSCLC subtypes, lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC) differ in their cells of origin and exhibit distinct disease progression, which, however, are difficult to distinguish solely based on conventional experimental methods like histological examination. Previous studies indicated that predicting subtypes based on transcriptomic profiles is a feasible and promising method. However, existing computational approaches may not fully capture information from transcriptomics data, and they are not effective in dealing with high dimensionality data. To address these concerns, we present a novel method called RPSLearner that combines Random Projection (RP) with Stacking Learning, to efficiently aggregate diverse information from base models for accurate identification of NSCLC subtypes. Specifically, we applied multiple RPs to reduce the dimensionality of transcriptomic profiles, which were then combined to capture diverse feature information. RP could efficiently reduce the dimensionality of the high-dimensional omics data while preserving distances between data points. Subsequently, the dimension-reduced feature vectors were classified by ten machine learning base models, which were further integrated by a stacking meta-learner. The stacking strategy combines the prediction results from various base models using a multi-layer perceptron (MLP) to boost the prediction performance. Experimental results based on 1,333 lung cancer patient samples from The Cancer Genome Atlas Program (TCGA) database suggested that RPSLearner significantly outperformed existing state-of-the-art methods. We further benchmarked RPSLearner against different cases including using only base classifiers, ensemble random projection with classifiers, and score ensemble methods, and demonstrated that RPSLearner achieved the best performance across multiple metrics including accuracy, AUC and F1-score. We believe that RPSLearner has direct positive impacts on downstream lung cancer risk stratification and tailored treatment design. We also expect that RPSLearner can be customized and extensible to identify subtypes of other types of cancer.

#1099 Leveraging RNA-seq for breast cancer survival analysis and risk stratification.

P. Naseri-Nosar, Z. Eftekhari, C. Wong;
City of Hope National Medical Center, Duarte, CA

Advancements in breast cancer treatment have significantly improved patient survival rates; however, the increasing incidence and stratified mortality risks underscore the critical need for Precision Medicine and Artificial Intelligence (AI) tools to provide clinicians with more accurate assessments of patient status. In this study, we analyzed solid tumor RNA-seq data from over 1,800 breast cancer patients treated at the City of Hope National Medical Center. We employed both supervised and unsupervised machine learning methodologies to develop models aimed at improving the understanding and prediction of patient survival outcomes.

Unsupervised clustering of RNA-seq data revealed that, despite conventional clinical groupings (HR+/ER+, HER2+, HR+/HER2+, and TNEG), breast cancer patients may segregate into distinct subgroups with statistically significant differences in survival rates. Notably, HR+/ER+ patients, typically associated with better survival outcomes, were observed to cluster alongside high-risk TNEG patients, challenging conventional survival expectations.

Building on these insights, we developed two classes of predictive survival models: (i) binary classifiers to predict survival beyond specific time thresholds (e.g., 3- and 5-year survival) and (ii) probabilistic survival models that estimate survival probabilities for clinician-specified timeframes. Evaluation on a 10% hold-out test set demonstrated strong model performance. The top-performing 3-year survival model achieved AUC's of 0.88 and 0.84 for the ROC and Precision-Recall curves, respectively, while the 5-year survival model reported elevated AUC's exceeding 0.95 and 0.98. Furthermore, the probabilistic survival model achieved a robust concordance index (C-index) of 0.83.

Our findings, in their current form, may equip clinicians with data-driven solutions to support more accurate diagnoses and better-informed personalized treatment planning. Further integration of these models with EMR data may provide deeper insights into the biological and clinical factors underlying the observed survival disparities among breast cancer patients. These insights could inform both improvements to current clinical practices and the development of novel therapeutic approaches.

#11 Overexpression of midasin drives cancer stem cell dynamics in *ESR1* mutant breast cancer.

Mounika Pamukuntla[1], Manasa Kotina[1], Bipika Banjara[1], Afia Ohemeng[1], Alicia Hudson[1], A. Michael Davidson[1], Jullian Pope[2], Selina Darlin-Reed[1], Simak Ali[3], Syreeta L. Tilghman[1]

[1]Basic Pharmaceutical Sciences, Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL,[2]Departemnt of Biological Sciences, Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL,[3]Department of Surgery and Cancer, Imperial College Of London, London, United Kingdom

While most cases of estrogen receptor-positive (ER+) breast cancer initially respond to endocrine therapy, many women acquire resistance. Two major hurdles hampering the response of metastatic breast cancer patients to endocrine therapy is constitutively active somatic mutations in the ER ligand binding domain (LBD) and the presence of cancer stem cells (CSCs). We previously identified midasin, a novel ribosomal protein, which was significantly overexpressed in letrozole-resistant MCF-7 cells enriched with CSCs. However, the consequences of midasin (MDN1) expression, stemness, and *ESR1* mutations are unclear. We hypothesize that *ESR1* mutations along with MDN1 cooperate to alter the microenvironment and position breast cancer cells for a survival advantage through increased stemness. Here, the objective is to evaluate the significance of midasin inhibition on CSCs formation in MCF-7 cells with *ESR1* LBD point mutations. RNA-Seq studies were conducted in MCF-7 parental cells (MCF-7^{LUC}) and cells containing ESR1 LBD point mutations (MCF-7^{Y537S} and MCF-7^{D538G}) and MDN1 levels were similar. Western blots were conducted and MCF-7^{D538G} cells expressed the highest level of MDN1 followed by MCF-7^{Y537S} and MCF-7^{LUC}. ER levels were highest in the MCF-7^{D538G} followed by the MCF-7^{LUC} and MCF-7^{Y537S}. Viability studies were performed using 1-12 µM ribozinoindole-2 (Rbin-2) (ie., midasin inhibitor) and while all cells were responsive, the MCF-7^{LUC} and MCF-7^{D538G} cells were more sensitive. After 48 hours of Rbin-2 treatment MDN1 protein expression was decreased in all cell lines. Wound healing assays were conducted and the MCF-7^{D538G} cells were the most migratory followed by the MCF-7^{LUC} and MCF-7^{Y537S} (ie., motility was inhibited by 48-55%). As there is a functional link between stemness and motility, mammosphere formation assay were performed. Interestingly, the MCF-7^{D538G} cells formedlarge, dense spheres with an average length of (480.3 ± 7.4 µm), followed bythe MCF-7^{Y537S} which formed large and hollow spheres (435.7 ± 0.52 µm),and the MCF-7^{LUC} cells which formed small, dense spheres (372. ± 2.7µm). Rbin-2 treatment induced a 57%decrease in MCF-7^{LUC} mammosphere formation, while the *ESR1*mutant mammospheres disintegrated, and sizes ranged from (101.8 ± 1.52 - 112.5 ±2.2 µm). Western blot studies were conducted in the mammospheres, and both MCF-7^{D538G} and MCF-7^{LUC} cells were $CD44^{high}/CD24^{low}$ and the MCF-7^{Y537S} cells were $CD44^{low}/CD24^{low}$. The cells were treated with Rbin-2 and CD44 expression was decreased while CD24 was unaltered. Likewise Rbin-2 treatment inhibited the mammosphere expression of MDN1 by 69-86%. Based on the preliminary results, higher levels of midasin and ER are associated with denser mammosphere that exhibit more stemness as indicated by the $CD44^{high}/CD24^{low}$ profile. Together, this may contribute to the highly migratory phenotype and survival advantaged which may be reversed by targeting midasin.

Butusova[2], Patrick Clayton[2], Francesca Paradiso[2], Sheila Yong[2], Alexander Bagaev[2], Lauren Byers[1], John Heymach[1], **Carl M. Gay**[1]

[1]Department of Thoracic/Head & Neck Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX,[2]BostonGene, Corp., Waltham, MA

Introduction: Small cell lung cancer (SCLC) exhibits significant molecular and clinical heterogeneity, leading to suboptimal clinical outcomes. To improve patient stratification and treatment selection, Gay et al. (2021) developed a transcriptional classification system that identified four distinct subtypes: SCLC-A (ASCL1), N (NEUROD1), P (POU2F3), and I (Inflamed). In particular, SCLC-I showed higher frequency of an inflamed gene signature than SCLC-A, N, and P, along with longer duration of response to immunotherapy when added to chemotherapy (e.g., IMpower133 and CASPIAN). However, the SCLC subtype clustering methods used in the original analyses by Gay et al. are not ideal for patient selection and stratification. While Heeke et al. (2024) created a bioinformatics tool for assigning individual patient samples to specific SCLC transcriptional subtypes, its implementation in a clinically applicable assay is still challenging. To address this unmet clinical need, we enhanced the bioinformatics classification approach by creating a machine learning SCLC transcriptional classifier for assigning individual patient tumor samples to subtypes A, N, P, and I.
Methods: In total, 167 RNA-seq samples from George et al. (2015) and Heeke et al. (2024) were used as ground truth and split into training (n=125) and tuning (n=42) sets. Our classifier consisted of three hierarchy-arranged gradient boosting binary models, each trained to distinguish between specific SCLC transcriptomic patterns. The first model distinguished between SCLC-P and non-P (SCLC-A, I, and N), the second between SCLC-I and A plus N, and the third between SCLC-A and N. Obtained probabilities of these six pre-subtypes (two from each model) were harmonized to generate four final probabilities, one for each SCLC subtype, the sum of which equaled one. The classifier was evaluated on the tuning set and then tested on a metacohort of 271 publicly available SCLC samples. The expression profile of classified samples was compared to samples of corresponding subtypes in the tuning set. Gene expression-based tumor microenvironment (TME) classification (Immune-enriched fibrotic [IE/F], Immune-enriched non-fibrotic [IE], Immune desert [ID], and Fibrotic [F]; Bagaev et al. 2021) was also applied to the SCLC metacohort.
Results: The SCLC classifier achieved 0.86 sensitivity and 0.95 specificity on the tuning set. For the evaluation samples, the classifier revealed gene expression patterns that were consistent with those in the tuning set. SCLC subtypes were also associated with specific TME subtypes (Chi-squared, $p = 1.14e-07$). SCLC-I correlated with IE (Pearson correlation, $p = 1.5e-15$) and IE/F TMEs ($p = 0.004$), while SCLC-A and N correlated with the ID TME ($p = 0.005$ and 0.001 respectively).
Conclusion: The proposed transcriptomic tool for subtyping and target expression will be applied to stratify patients across treatment arms in an upcoming clinical trial.

#1102 Integrated (epi)genomic atlas for identification of biomarkers in pediatric gliomas.

Devishi Kesar, Michaela Kristina Keck, Robert J. Autry, David T. W. Jones

DKFZ, Heidelberg, Germany

Pediatric gliomas are a heterogeneous group of brain tumors that affect children and adolescents. Despite recent advances in understanding the genetic and molecular underpinnings of these tumors, the precise mechanisms driving their pathogenesis remain elusive. Thus, we comprehensively investigated the regulatory landscape of pediatric gliomas, focusing on the identification of super enhancer regions and novel transcription factors implicated in the development and progression of both low and high grade gliomas. Using chromatin immunoprecipitation sequencing (ChIP-Seq) data we identified super-enhancer regions, which are key regulators of gene expression and to potentially identify novel enhancer hijacking events that have been shown to be important in oncogenic signaling. By leveraging a large dataset of pediatric gliomas omics data, we systematically identified how these super enhancer regions are associated with specific glioma subtypes. Furthermore, to gain a comprehensive understanding of the molecular landscape of pediatric gliomas, integrating ChIP-Seq data with multi-omic datasets, including RNA-Seq and copy number alterations, revealed key driver genes and pathways. This integrative approach allowed us to uncover potential driver genes and signaling pathways associated with pediatric gliomas. These findings offer a comprehensive view of the regulatory mechanisms in pediatric gliomas, highlighting potential biomarkers and therapeutic targets for personalized treatment approaches.

#1103 Multi-modal machine learning identifies predictive biomarkers of response to neoadjuvant axitinib in renal cell carcinoma with venous tumor thrombus.

Rebecca Wray[1], Hania Paverd[1], Ines Machado[1], Johanna Barbieri[1], Farhana Easita[1], Abigail R. Edwards[1], Ferdia A. Gallagher[1], Iosif A. Mendichovszky[1], Thomas J. Mitchell[1], Maike De La Roche[1], Jacqueline D. Shields[2], Stephan Ursprung[1], Lauren Wallis[1], Anne Y. Warren[1], Sarah J. Welsh[3], Mireia Crispin-Ortuzar[1], Grant D. Stewart[1], James O. Jones[1]

[1]University of Cambridge, Cambridge, United Kingdom,[2]University of Nottingham, Nottingham, United Kingdom,[3]Royal Devon University Healthcare NHS Foundation Trust, Devon, United Kingdom

Venous tumor thrombus (VTT) is present in 10-15% patients with renal cell carcinoma (RCC), where the primary tumor invades the renal vein and inferior vena cava, increasing the morbidity and mortality of curative surgery. Neoadjuvant anti-angiogenic therapies have shown potential to reduce VTT length and improve nephrectomy success rates. The NAXIVA trial, a phase II study of neoadjuvant axitinib in 20 RCC patients with VTT, demonstrated that 35% of patients experienced significant downstaging of VTT. However, the biological mechanisms driving response or resistance in the remaining 65% are unclear. Machine learning has the potential to uncover mechanistic relationships between features in these patients and guide biomarker discovery for early response.In this study, we present a predictive machine learning framework based on multi-modal integration of digital pathology, flow cytometry and plasma cytokine profiling, using tissue and blood samples from the NAXIVA trial. A machine learning model incorporating recursive feature elimination and logistic regression with stochastic gradient descent was developed to predict response. To avoid overfitting, a leave-one-out nested cross validation approach was used for 20 iterations, leaving one patient out at a time and training the model on the remaining 19 patients. Two separate model ensembles were produced, using baseline features (N=62) and features from both baseline and two weeks post-treatment initiation (N=69) respectively. We used a statistical consensus approach to identify key predictive factors.The baseline model achieved an AUC of 0.868, identifying tissue microvessel density, plasma IL-12p70 and plasma CCL17 as key predictive factors. Responding patients had lower plasma IL-12p70, lower CCL17 and higher microvessel density than non-responding patients. Bulk RNA-seq data from pre-treatment tumor biopsies revealed elevated *IL-12R* expression in non-responders. Incorporating features post-treatment initiation improved model performance (AUC = 0.945), with fold changes in PlGF and sTie-2, alongside baseline IL-12p70 and CCL17, emerging as key predictors. Responders showed greater PlGF and sTie-2 induction following treatment onset.In conclusion, our machine learning framework accurately predicts response to neoadjuvant axitinib in RCC patients with VTT. The high microvessel density and growth factor induction in responders suggests they exhibit an “angiogenic” phenotype (clusters 1/2 from IMmotion151), while higher cytokine levels in non-responders suggest an “immunogenic” phenotype (cluster 4). Early changes in PlGF and sTie-2 may serve as actionable biomarkers for patient stratification. Further validation in independent datasets is essential to facilitate clinical integration and improve personalized treatment strategies for RCC patients with VTT.

#1104 Identifying pancreatic cancer subtypes by a novel meta-learning model.

Nick Boos Peterson, Mengtao Sun, Jieqiong Wang, **Shibiao Wan**

University of Nebraska Medical Center, Omaha, NE

Due to the difficulty of both early diagnosis and treatment, pancreatic cancer (PC) is the third leading cause of cancer related deaths in the United States and is projected to become the second by 2030. As a heterogeneous disease, PC can be divided into four main subtypes, with each having differing molecular pathways, survival rates, and responses to therapy. Traditional wet lab approaches to identify PC subtypes, such as histopathological studies or molecular profiling, are costly, laborious, and time-consuming. Previous studies indicate that predicting PC subtypes based on transcriptomic profiling is a feasible and promising method. However, these methods are unable to capture the full complexity of the data and may lead to biased and unstable results. To this end, we present a novel meta-learning algorithm for PC subtype identification based on RNA-seq data only. Specifically, after some basic gene filtering and preprocessing, the transcriptome-based feature vectors were classified by multiple base machine learning (ML) classifiers like logistic regression, linear support vector machine (SVM), and radial basis function (RBF) SVM, whose outputs were then combined with the initial filtered feature vectors to constitute a new set of ensemble feature vectors for a meta-learning model. Our meta-learning model could learn and leverage the diversity of different base classifiers to boost the prediction performance beyond any single ML model. Results based on 100 times leave-one-out cross validation tests on a dataset with 96 PC patients demonstrated that our proposed method could achieve an average AUC of 0.99, which was significantly better than existing state-of-the-art methods. In addition, our meta-learning model remarkably outperformed each individual base classifier, demonstrating that our model could combine diverse results from multiple base classifiers to boost the ensemble performance. We expect that our method will provide a complementary way to characterize different PC subtypes, bringing positive impacts on downstream pancreatic cancer risk stratification and tailored treatment design. Additionally, we believe our meta-learning model can also be extensible to identify subtypes of other types of cancer.

#1105 Development of an in-house methodology to analyze large clinical cancer biomarkers datasets.

Tariq Arshad, Nikhil Wilkins, Gilles Tapolsky, Mike Gazda

Bexion Pharmaceuticals, Inc, San Ramon, CA

Background: BXQ-350 is a novel biologic that modulates sphingolipid metabolism. BXQ-350 is currently being investigated in several clinical studies. Multiple biomarker samples are collected in the course of these studies to support clinical development and illustrate the mechanism of action, support patient selection, and associate response with trends. The resulting large data set associated with these different biomarkers requires an analytical tool to process the data. To meet those ends, Bexion Pharmaceuticals developed an in-house analytical method to perform analysis on these data points. The platform performs data wrangling, processing, calculations, and produces statistical and graphical outputs from multiple different input sources.

Methods: The analytical methodology was developed using Python v3.13 and open-source modules. Windows Excel files are used for the input and are formatted in Excel to be properly read. The outputs are statistical Excel files and graphical visualization of the data.

Analytical Methodology 1. Import Excel file and create a pandas dataframe object 2. Merge dataframes based on patient identification 3. Perform data wrangling on the merged dataframe Create or update a MySQL table if applicable 4. Process the data and perform calculations, including QC samples incorporated in each analysis 5. Perform statistical analysis of QC samples to determine which changes would be statistically significant 6. Perform a second round of processing and calculations on data that passed QC 7. Group and separate data for output handling 8. Create graphs and tables

Results: The analytical methodology was designed to analyze any type of biomarker data set, allowing the comparison of results across biomarkers and supporting analysis of potential correlations. Serial analysis can compare trends in biomarkers results and clinical outcome(s). In addition, statistics are derived for both individual patients and groups to stratify the data.

Conclusion: Large biomarker data sets are collected in the course of clinical studies to support clinical development. Furthermore, such analyses can support understanding the mechanism of action and guide patient selection. The method developed allows for flexible and granular analysis of biomarkers and correlative analysis across different groups of biomarkers or individual patients and groups of patients

#1106 RNA-based risk model for nasopharyngeal carcinoma distant metastasis.

Zhaozheng Hou[1], Ping Feng[2], Kazi Anisha Islam[1], Songran Liu[1], Ying Wang[2], Yingpei Zhang[1], Michael King-yung Chung[1], Ngar-Woon Kam[1], Zi-Lu Huang[2], Victor Ho-Fun Lee[1], Anne WM Lee[1], Dora LW Kwong[1], Wai-Tong Ng[1], Yun-Fei Xia[2], Wei Dai[1]

[1]University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong,[2]Sun Yat-sen University Cancer Centre, Guangzhou, China

Background: With advancements in the treatment of nasopharyngeal carcinoma (NPC), the five-year relative survival rate for patients has the potential to reach upwards of 90%. However, patients who develop distant metastases after receiving primary treatment suffer from a significantly reduced survival rate.
Method: We analyzed bulk-RNA sequencing of primary NPC biopsies and clinical characteristics from 177 patients across multiple centers. We established a prediction model for distant metastasis and patient stratification in NPC. Patients diagnosed with NPC at four Hong Kong hospitals (Queen Mary, Queen Elizabeth, Princess Margaret, and Pamela Youde Nethersole Eastern Hospitals) and at Sun Yat-sen University Cancer Center in Guangzhou were selected. Metastatic NPC (MET-NPC) patients were defined as those who developed distant metastasis within three years after standard treatment, while other patients were grouped into non-metastatic NPC (nonMET-NPC). We evaluated the prediction accuracy using the area under the curve (AUC) index with two-way cross-cohort validation and applied Pareto optimization to select the final models. Histological analysis was applied to evaluate the number of Tertiary Lymphoid Structures (TLS) formation in NPC clinical tissues.
Results: Our RNA-based risk score for NPC distant metastasis prediction significantly improved the AUC to 90.4% when combined with a model based on known and identified prognostic clinical parameters including TNM stage, body-mass-index, and plasma EBV DNA level. Pathway-level analysis indicated that the benefit of the proposed risk score might derive from its correlation with the development and activities of B cells and T helper 17 (Th17) cells in the tumor microenvironment, which are highly linked to TLS formation. Multiplex IHC staining further confirmed that the number of TLS was highly correlated with the RNA-based risk score and this number was significantly reduced in MET-NPC.
Conclusions: This study effectively improves the accuracy of NPC metastasis prediction and introduces a new perspective for understanding and forecasting metastasis. We highlighted the potential association of immunosuppression characterized by dysregulated B cell and Th17 function, along with reduced TLS formation, with metastasis. This encourages future studies on understanding how NPC interacts with its tumor immune microenvironment to contribute to metastasis.

R. China, Science and Technology Program of Guangdong Province in China (2021A0505110010).

#1107 Feature selection and machine learning strategies optimize an affordable molecular assay for cholangiocarcinoma subtype.

Ellen Larson, Erik Jessen, Dong-Gi Mun, Jennifer Tomlinson, Amro Abdelrahman, Danielle Carlson, Hojjat Salehinejad, Rory Smoot

Mayo Clinic, Rochester, MN

Background: Cholangiocarcinoma is a molecularly heterogenous cancer arising from the biliary epithelium. Individual omic techniques have identified clinically relevant, targetable subtypes but most tumors have no targetable alterations based on exome or transcriptomic evaluation. Integrated multiomics approaches incorporating transcriptomic, proteomic, and phosphoproteomic characterization provide deeper understanding and identify non-mutated, activated pathways that can be targeted. To optimize the potential clinical utility of these approaches, minimal classifier features must be defined.
Methods: Approximately 60,000 RNA, protein, and phosphoprotein features were extracted from 35 cholangiocarcinomas treated at the primary US study site. 206 patients treated and profiled at an institution in China were also included. Using the Multiomics Factor Analysis clustering method, patients were sorted into 3 distinct molecular profiles. Important molecular features were selected using competing feature selection (FS) methods: Boruta, RreliefF, variable selection using random forests (RF), recursive factor elimination (RFE), median decrease accuracy in RF, and Concrete Autoencoders. Machine learning classification prediction models including Extreme Gradient Boosting, gradient-boosted trees, multinomial logit, and support vector machine (SVM) were tested on each FS. Each combination of FS and predictive model was tested with 10 replicates of 10-fold cross-validation of a randomly-selected balanced test set and an oversampled, balanced training subset. Accuracy, F1 score, AUC, precision, and recall were assessed for each FS and predictive model combination. A custom function of physical assay cost and classification accuracy was optimized to find the best assay. KEGG pathway overrepresentation analysis was used to analyze feature subsets.
Results: A consistent set of 50 important RNA and protein features was identified, including previously reported prognostic factors, like SpryD4 protein expression, as well as previously unreported pathway surrogates, such as Slc2A2 or Pipox protein. Pathway overrepresentation analysis found insulin signaling and resistance and amino acid biosynthesis/metabolism pathways were overrepresented in the discriminative feature set. The gradient-boosted trees algorithm combined with the RFE FS method had the best performance, with a multiclass macro average (±sd) cross-validation accuracy 89% (±6%), F1 score 89% (±8%), AUC 0.98 (±0.02), precision 90% (±10%), recall 89% (±6%).
Conclusions: Feature selection methods and predictive machine learning models work synchronously to develop accurate molecular subtype assays based on just 50 protein and RNA levels. This strategy has the potential to make molecular subtyping for cholangiocarcinoma and other molecularly complex cancers fast and widely available.

#1108 Tissue and circulating DNA methylation profiling can recapitulate SCLC heterogeneity to enable identification of new biomarkers of clinical relevance.

Siyu Liu[1], Mingchao Xie[1], Alexandra Clipson[2], Simon Pearce[2], Brychan Manry[3], Steven Criscione[1], Megan Callahan[1], Priti Chugh[1], Annabel Peachey[2], Ana Ortega-Franco[2], Steven Hill[2], Florent Mouliere[2], Dominic Rothwell[2], James Hadfield[4], Caroline Dive[2], Yashaswi Shrestha[3]

[1]AstraZeneca, Waltham, MA,[2]University of Manchester, Manchester, United Kingdom,[3]AstraZeneca, Gaithersburg, MD,[4]AstraZeneca, Cambridge, United Kingdom

Background: Small-cell lung cancer (SCLC), an aggressive lung cancer type, presents challenges in management due to limited treatment options. In the CASPIAN study (NCT03043872) assessing durvalumab (D) ± tremelimumab (T) and platinum-based chemotherapy in extensive-stage SCLC, improved survival with D + chemotherapy was revealed. Ongoing research exploring SCLC subtypes, treatment responses, epigenetic modifications like DNA methylation, and association with treatment outcomes, is offering insights into tailored treatment and disease progression. Recent studies highlighted the promise of liquid biopsies for sensitive detection and molecular subtyping of SCLC, but the lack of a comprehensive investigation comparing matched tissue and liquid biopsy in SCLC limits a thorough assessment of their effectiveness.

Methods: DNA was extracted from 175 FFPE samples in CASPIAN and TWIST methylome panel analysis, which covers 3.98M CpG sites, was performed to characterize their methylation profiles at promoters and CpG islands. DNA methylation patterns were compared with corresponding RNA-seq gene expression data, and association of methylation with somatic alterations and expression of key SCLC genes was evaluated. A total of 146 CASPIAN serum samples were used to capture ctDNA methylation profiles with T7-MBD-seq methodology.

Results: We uncovered 4 major tissue methylation-based clusters through unsupervised clustering of the top 5% most variable promoter methylation regions. Three clusters were enriched with neuroendocrine (NE) features while one was non-NE driven. Notably, these clusters showed high correlation with RNA-based subtypes and offered distinct insights into clinical outcomes. By integrating promoter methylation levels with other multi-omics datasets, we revealed biological features of each subtype and discovered novel methylation biomarkers, such as ZNF717 and REC8, which were negatively associated with corresponding gene expressions, suggesting that methylation-based profiling could enhance and even expand the current heterogeneity characterization. Other than tissue methylation, ctDNA tumor fractions predicted using copy number alterations served as a prognostic signature for patient outcomes in SCLC. High concordance between ctDNA and tissue methylation provided more confidence in personalized treatment opportunities based on SCLC heterogeneity for this otherwise difficult-to-treat malignancy.

Conclusions: Tissue methylation-based heterogeneity can reveal clinically relevant biomarkers for SCLC, and these clusters are crucial for understanding disease mechanisms and enabling personalized treatment. Additionally, liquid biopsies offer a non-invasive method for subtyping SCLC, potentially improving personalized treatment feasibility.

#1109 BN2 subtype of diffuse large B-cell lymphoma is characterized by distinct alternative splicing.

Sanyeowool An[1], Ja Min Byun[2], Youngil Koh[2], Sung-Soo Yoon[2]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic of

Diffuse large B-cell lymphoma (DLBCL) is a heterogeneous cancer with unique genetic subtypes and clinical profiles. Alternative splicing (AS) is pivotal in regulating cellular growth, tissue invasion, disease progression, and immune evasion in cancer. However, its specific contributions and associations with the molecular subtypes of DLBCL, remain inadequately characterized.Using RNA sequencing (RNA-Seq) and whole-exome sequencing (WES) data from 620 DLBCL patients, we analyzed splicing activity across genetic subtypes classified by the LymphGen algorithm. Splicing-related pathways were assessed using mean z-scores calculated from normalized expression values ($\log_2$(TPM + 0.01)). rMATS was used to quantify splicing events in terms of percent spliced in (PSI) values by comparing each subtype with the combined group of all other subtypes. Notably, splicing-related pathways showed relative activation in the BN2 subtype compared to other subtypes, suggesting a distinct role for splicing dysregulation in its molecular phenotype. Principal component analysis (PCA) of PSI values across all AS events further highlighted BN2's distinct molecular profile, with BN2 samples forming a separated cluster from other subtypes. These findings suggest that splicing dysregulation in the BN2 subtype, defined by translocations in *BCL6*, a well-established transcriptional regulator, may potentiate the downstream effects of disrupted transcriptional control.rMATS analysis revealed significant splicing alterations in RPLP0 (retained introns), *ACTG1* (alternative 5' splice sites and retained introns), *ACTB* (retained introns), and *CD74* (skipped exons), highlighting disruptions in ribosomal stability, cytoskeletal organization, and immune regulation (P-value < 0.05). Differential Transcript Usage (DTU) analysis further validated that isoform-level changes in BN2 corresponded to significant events identified by rMATS. Splicing alterations in *RPLP0*, a ribosomal stability regulator, suggest potential impairments in protein synthesis and cellular homeostasis, while dysregulation of *ACTB* and *ACTG1*, critical cytoskeletal proteins, may enhance cellular motility and invasiveness. These housekeeping genes showed disease-specific splicing in BN2, highlighting their biomarker potential and role in pathogenesis. Similarly, *CD74*, which plays a key role in antigen presentation and immune modulation, showed splicing changes that may contribute to the unique molecular and immune characteristics of BN2.By integrating pathway analyses, PCA, and splicing data, this study highlights BN2-specific molecular vulnerabilities and provides insights into the development of splicing-targeted therapeutic interventions. Future research should focus on validating these findings in preclinical models to evaluate their potential as diagnostic markers or therapeutic targets in DLBCL.

#111 Detection of clonal hematopoietic APOBEC3-mediated splicing deregulation.

Inge van der Werf[1], Jane Isquith[1], Emma Klacking[1], Jessica Pham[1], Thomas Whisenant[2], Ludmil Alexandrov[3], Catriona Jamieson[1]

[1]Division of Regenerative Medicine, Department of Medicine, Sanford Stem Cell Institute, University of California San Diego, La Jolla, CA,[2]Center for Computational Biology and Bioinformatics, University of California San Diego, La Jolla, CA,[3]Department of Cellular and Molecular Medicine and Department of Bioengineering, University of California San Diego, La Jolla, CA

Myeloproliferative neoplasms (MPNs) are clonal hematopoietic stem cell (HSC)-derived disorders that often arise as a result of JAK2/STAT3 signal activating mutations. In the setting of microenvironmental inflammatory cytokines, MPNs also acquire splicing alterations that are associated with progression to rapidly lethal secondary acute myeloid leukemia (sAML) (reviewed in *Jamieson, Weisman. NEJM. 2023*). By performing whole genome and RNA sequencing analyses of MPN hematopoietic stem and progenitor populations (HSPCs), we discovered that inflammatory cytokine inducible APOBEC3C upregulation was associated with IL6ST and ADAR1p150 splice isoform overexpressing progenitor proliferation and progression to sAML (*Jiang⋯Jamieson. Cell Reports. 2021*). Thus, we sought to investigate the role of APOBEC3 activation as a driver of clonal hematopoietic progenitor splicing deregulation and propagation.

We cloned human APOBEC3 family genes into pCDH lentiviral vectors and transduced cord blood derived immunomagnetic bead selected $CD34^+$ cells with APOBEC3A, B, C, D, G or H, or pCDH lentiviral backbone controls for whole genome and whole transcriptome analyses. Additionally, CD34+ cells derived from aged normal bone marrow (ABM), collected according to IRB approved protocols, were transduced with APOBEC3C for whole genome and whole transcriptome analyses, coupled with functional assays to assess the effects of APOBEC3 overexpression on RNA splicing and editing deregulation.

Following lentiviral APOBEC3B, APOBEC3C, and APOBEC3G transduction of $CD34^+$ cells, gene set enrichment analysis (GSEA) revealed splicing pathway alterations. Significantly altered APOBEC3-responsive pathways involved genes crucial for hematopoiesis, including ZRSR2, U2AF1, and SRSF2. Additional analysis of RNA sequencing data of CD34+ HSPCs derived from aged normal bone marrow overexpressing APOBEC3C, and CD34+ HSPCs derived from MPNs further confirmed these splicing pathway alterations and revealed a correlation with APOBEC expression levels. Moreover, we observed that lentiviral APOBEC3C wild-type overexpression in ABM-derived CD34+ cells resulted in differential exon usage using splicing reporter assays. Together, these results suggest that detection of APOBEC3-mediated splicing deregulation may inform the development of diagnostic and therapeutic strategies aimed at preventing splicing-mediated MPN progression.

#1110 Longitudinal and multi-regional analysis of cancer phenotypes in hepatocellular carcinoma and intrahepatic cholangiocarcinoma.

Javier Villela Castrejon[1], Dongya Jia[2], Jason T. George[3]

[1]Department of Translational Medical Sciences, Texas A&M University, Houston, TX,[2]Immunodynamics Group, Laboratory of Integrative Cancer Immunology, Center for Cancer Research, National Cancer Institute, Bethesda, MD,[3]Department of Biomedical Engineering, Texas A&M University, Houston, TX

Cancer cells exhibit abnormal metabolic behavior, a feature that allows cancer cells to utilize different metabolic pathways and substrates (such as glucose, fatty acids, and glutamine) to fulfill their energy and biosynthetic requirements. This study aims to explore the spatial and temporal variations in cancer phenotypes in hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (iCCA) using single-cell RNA sequencing data.
We utilized single-cell RNA sequencing data from the Sequential NCI-CLARITY cohort (GSE229772). Tumor biopsies were collected longitudinally. We also used the Multi-Regional Cohort (GSE189903), where single cells were isolated from multiple regions (tumor cores, borders, and adjacent normal tissues). Gene signatures in the anabolic and catabolic axis were applied to classify cells into four distinct metabolic clusters: O, W, W/O, and Q. To predict metabolic fluxome and variations, we used FLUXestimator, an online platform that implements single cell flux estimation analysis (scFEA). This unsupervised approach uses a neural network architecture to estimate reaction rates from transcriptomics data. Additionally, pathway enrichment analysis was conducted to corroborate our findings.
Our analysis identified the four distinct metabolic clusters across both cohorts. Briefly, the O cluster is characterized by high oxidative phosphorylation and is associated with better clinical outcomes. The W cluster is defined by high glycolytic activity and is linked to aggressive tumor behavior. The W/O cluster represents a hybrid state with both high glycolytic and oxidative activities, contributing to metabolic flexibility and tumor aggressiveness. The Q cluster relies heavily on glutamine metabolism and is associated with poor prognosis and drug resistance. Normal liver cells were predominantly grouped into the O cluster, with hepatocytes displaying low HIF1, AMPK, and MYC activity, indicative of normal metabolic function. Similarly, border cancer cells were conformed in a distinct cluster, characterized by a low HIF1 score, but a higher AMPK score. Temporal analysis from the Sequential NCI-CLARITY cohort revealed dynamic changes in the distribution of these clusters over time, reflecting the evolution of cancer phenotypes. FLUXestimator predictions and pathway enrichment analysis indicated significant changes in metabolic pathways, supporting the observed phenotypic shifts. This approach validates our comprehensive network model and suggests a method for developing new metabolic networks for cancer modeling based on key features observed during cancer progression.
This study reveals metabolic diversity in HCC and iCCA tumors, identifying clusters linked to tumor progression stages. These phenotypic traits may serve as a potential biomarker for better clinical outcomes.

#1112 Gene expression characteristics of EBV-positive smooth muscle tumors compared to EBV-positive NPC and LELC.

Harold Yu Chung Chan[1], Yi Ren[1], Teo Wei Keat[1], Joseph W. Foley[1], Loh Kwok Seng[1], Raymond KY Tsang[1], Han Shuting[2], Jain Amit[2], Toh Han Chong[2], Joshua K. Tay[1], Victor Lee[1]

[1]National University Hospital Singapore, Singapore, Singapore,[2]National Cancer Centre Singapore, Singapore, Singapore

Background: EBV SMTs are rare stromal malignancies associated with immunosuppression. Despite diversity in their anatomical location and clinical presentation, EBV SMTs likely share common pathways of EBV-driven tumorigenesis. We aim to evaluate the gene expression characteristics of EBV SMTs and compare them with EBV-negative sarcomas and other EBV-positive tumors such as nasopharyngeal carcinoma (NPC) and lymphoepithelial-like carcinoma (LELC).

Methodology: Formalin-fixed paraffin embedded (FFPE) tissue sections were obtained from patients with EBV SMTs, non EBV-SMTs and NPC tumors treated at the National University Hospital, Singapore. FFPE sections for LELC tumors were retrieved from the National Cancer Centre, Singapore. To ensure histological purity, laser-capture microdissection (LCM) was performed for tumor epithelial regions for each tumor specimen. Gene expression libraries were prepared using a specialized mRNA-Seq technique optimized for tiny amounts of FFPE material, followed by next generation sequencing. Differential gene expression analysis and geneset enrichment analysis was performed.

Results: Our preliminary cohort comprised 230 gene expression libraries, including 9 EBV SMT, 16 EBV-negative sarcoma, 161 NPC and 44 LELC libraries. Principal component analysis showed distinct clustering of EBV SMTs separate from EBV-negative sarcomas. EBV SMTs also clustered distinctly when compared to NPC and LELC tumors. Compared to EBV-negative sarcomas, EBV SMTs were enriched for immune genes including CD40 (TNF receptor found on antigen presenting cells, p-adj = 1.33e-13) and MHC Class II genes (HLA-DQA1, HLADQA2, p-adj < 0.005 for both). In contrast, pathways involved in epithelial mesenchymal transition (NES = -1.57, p-adj = 0.0429) were enriched in EBV-negative sarcomas. Although EBV SMTs were more inflamed than their EBV-negative counterparts, we observed that NPC and LELC tumors were further enriched for inflammatory processes compared to EBV SMTs. Biological processes that were upregulated in NPC and LELC tumors included neutrophil chemotaxis (NES = 1.46, p-adj = 0.0325 and antimicrobial humoral immune response mediated by antimicrobial peptide (NES = 1.63 , p-adj = 0.0317). Deconvolution of immune cell types with ESTIMATE, showed that NPC and LELC tumors had the highest immune cell score, followed by EBV SMTs and EBV-negative sarcomas (median score = 656, 595 and 329 respectively, p = 0.006).

Conclusion: Immune processes, including antigen presentation, are enriched in EBV SMTs compared to EBV-negative sarcomas. However, the extent of inflammation appears limited compared to other EBV-positive cancers. Our current work includes expanding our cohort of EBV SMTs for genomic profiling and identifying potential vulnerabilities for targeted treatment.

#1115 PM-AI agent: A conversational artificial intelligence system for precision medicine and advancing health equity through integrative clinical, genomic and social determinants of health data analysis.

Enrique I. Velazquez-Villarreal[1], Ei-Wen Yang[2]

[1]Integrative Translational Sciences, City of Hope Comprehensive Cancer Ctr., Duarte, CA,[2]Polyagent, San Francisco, CA

Introduction: The integration of clinical, genomic, and social determinants of health (SDoH) data is essential for advancing precision medicine. However, significant challenges remain due to the complexity of cancer research workflows, the technical expertise required, and the pressing need to address cancer health disparities. To overcome these barriers, we developed the Precision Medicine AI Agent (PM-AI)—an innovative conversational AI system that enables users to conduct integrative data analyses through natural language inquiries.
Methods: PM-AI leverages large language models (LLMs) to convert user instructions into executable code and autonomously analyze local stored datasets. The system performs advanced tasks such as subset comparisons, clinical prevalence studies using odds ratio tests, and survival analyses that provide survival curves and hazard ratios. Additionally, PM-AI delivers detailed analytic reports with actionable insights to support decision-making. To validate its utility, PM-AI was applied to a case-control study using data from TCGA and cBioPortal (including the AACR GENIE dataset). The study examined RAS mutations and their impact on the response to FOLFOX (folinic acid, 5-fluorouracil, and oxaliplatin) in colorectal cancer patients. Notably, the analysis incorporated race, ethnicity, and SDoH data, adhering to NASEM recommendations for population descriptors in genomics research, ensuring equitable and representative insights.
Results: PM-AI successfully compared FOLFOX-treated patients with or without RAS mutations and revealed a significant difference in progression-free survival. The result show that KRAS mutations predict a poorer response to FOLFOX and an increased risk of recurrence. These findings were consistent with those reported in the literature, validating PM-AI's independent analytical capabilities.
Conclusion: The development of PM-AI represents a transformative advancement in precision medicine research, addressing key challenges in the integration of clinical, genomic, population-specific variables (race, ethnicity, etc.), and SDoH, into analytical pipelines. By eliminating the need for programming, PM-AI bridges domain expertise with autonomous workflows, empowering researchers across disciplines. Its versatility in handling cross-domain datasets highlights its adaptability to diverse precision medicine applications. Overall, PM-AI ensures equitable and actionable insights, positioning this advance AI system as a scalable tool for advancing precision medicine and promoting health equity in cancer research.

#1116 AI framework for imputing genome-wide somatic mutations in pan-cancer targeted sequencing data for biomarker discovery.

Amirsaman Ashtari, Mohammad Shahrokh Esfahani

Stanford University, Palo Alto, CA

Background: Tumor genotyping via high-throughput sequencing has revolutionized our understanding of various cancer types. The genotyping of tumor biopsies or liquid biopsies has now become an integral part of clinical routines to survey tumors and to identify potential markers for treatment management. This has led to the development of many assays that are either commercially or institutionally available for such testing, where they often target less than 0.5% of the entire genome, focusing on known and recurrent genes for cancer-specific panels, pan-cancer solid tumor panels, or heme panels targeting blood cancers. This enrichment of certain regions has allowed us to find mutations that occur at lower allele fractions. Nonetheless, this approach results in missing hundreds or even thousands of potential mutations, some of which could be potential biomarkers for prognostic or predictive models, or even potential targets for future drug developments. Here, we hypothesize that an artificial intelligence (AI) framework can aid us in unraveling the complex interactions between mutations and thereby impute the off-target space.
Methods: Here, we introduce SPARK (Somatic mutation Prediction via Artificial intelligence for Rapid discovery and Knowledge translation), an algorithm for imputing missing genomic loci in existing genomic panels. SPARK relies on the assumption that there is a latent space in which mutations co-occur or are mutually exclusive across multiple malignancies. This AI-based framework utilizes other data modalities (e.g., gene expression) to train a unified model for solid tumors. During training, we use somatic mutations and RNA expression data, and then employ another network to transfer knowledge, enabling us to take only a small number of mutations from any sequencing panel and impute the rest.
Results: We used genotyping and RNA expression data from TCGA across multiple carcinomas to train the model (n>2000 samples). This pre-trained model is then fine-tuned for each panel for further optimization. To evaluate model performance, we focused on the genes present on the MSK-IMPACT panels obtained from the GENIE Project v16. We found a number of genes that occur with over 1% frequency across multiple carcinomas in TCGA but were not covered by the MSK-IMPACT panels. We then aimed to impute these genes and achieved a precision ranging from 60% to 100% for a minority of genes (e.g., ETV4 and ETV5). The precision was much lower (less than 10%) for many genes, suggesting that those mutations are likely not functional and do not show any strong complex association with the genes in the panel. As the next step, we plan to apply this model to the entire set of samples from the GENIE Project and impute the genes that showed acceptable precision in our TCGA analysis. This larger imputed dataset will enable us to find potential biomarkers from a large number of samples in the GENIE Project.

#1117 cBioPortal for cancer genomics.

Ino de Bruijn[1], Tali Mazor[2], Rima AlHamad[1], Calla Chennault[1], Corey Dubin[3], Jeremy Easton-Marks[2], Zhaoyuan Fu[2], Benjamin Gross[1], Charles Haynes[4], David M. [1]Memorial Sloan Kettering Cancer Center, New York City, NY,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Caris Life Sciences, Irving, TX,[4]Children's Hospital of Philadelphia, Philadelphia, PA,[5]Princess Margaret Cancer Centre, Toronto, ON, Canada,[6]The Hyve, Utrecht, Netherlands,[7]Bilkent University, Ankara, Turkey,[8]Harvard Medical School, Boston, MA

cBioPortal for Cancer Genomics is a widely used platform for exploratory, interactive visualization and analysis of large-scale clinico-genomic datasets. cBioPortal provides a range of visualizations and analyses including interactive cohort exploration, OncoPrints, mutation “lollipop” plots, survival analysis, alteration enrichment analysis, and detailed patient-level visualizations. cBioPortal also integrates variant annotations from a variety of sources to facilitate interpretation.

The public cBioPortal (https://www.cbioportal.org) is accessed by >40,000 unique visitors each month and hosts data from >460 studies. All data is also available in the cBioPortal Datahub: https://github.com/cBioPortal/datahub. In 2024 we added 76 new studies (~30,000 samples), including data from the NCI Genomic Data Commons. In addition, >94 instances of cBioPortal are installed at academic institutions and companies worldwide.

cBioPortal partners with AACR Project GENIE to provide access to the GENIE cohort in a dedicated instance (https://genie.cbioportal.org). Users can explore the full GENIE cohort of >229,000 clinically sequenced samples from 19 institutions, as well as cohorts with comprehensive clinical annotations including response, outcome, and treatment history, from the GENIE Biopharma Collaborative (BPC). BPC cohorts for NSCLC (~2,000 samples) and colorectal cancer (~1,500 samples) are available, with more to come.

The past year has brought a variety of enhancements to cBioPortal. A new data type selector on the home page enables users to find studies with specific types of data. The interactive cohort exploration has new ways to explore data with the addition of gene-specific charts to summarize the types of mutations in a gene and the integration of the Plots tab for customizable graphs of any two data attributes. The OncoPrint can now display per group alteration frequency based on any categorical attribute. Variant interpretation is enhanced with the integration of AlphaMissense as a novel annotation source and an update to the latest MutationAssessor data. The patient page also has new visualizations, including mutational signatures and the integration of Chromoscope to visualize structural variations.

We also made significant changes to the backend code to improve both the developer and user experience. The backend code was repackaged and upgraded to simplify and improve the development process. In addition, we are working on switching to an Online Analytical Processing (OLAP) database which will bring significant performance improvements.

cBioPortal is open source: https://github.com/cBioPortal. Development is a collaborative effort among groups at Memorial Sloan Kettering Cancer Center, Dana-Farber Cancer Institute, Children’s Hospital of Philadelphia, Princess Margaret Cancer Centre, Caris Life Sciences, Bilkent University, SE4BIO and The Hyve. We welcome open source contributions from others in the cancer research community.

#1118 The GENIE BPC BRCA Cohort: a real-world repository of standardized clinical and genomic data for young patients with breast cancer.

Evan Seffar[1], Brooke Mastrogiacomo[1], Alex Paynter[2], Protiva Rahman[3], Jesus Fuentes Antras[4], Sonya A. Reid[5], Nikolaus Schultz[1], Michael J. Hassett[6], Ben Park[5], Shawn Sweeney[7], Walid K. Chatila[1], Pedram Razavi[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Sage Bionetworks, Seattle, WA,[3]Vanderbilt University Medical Center, Nashville, TN,[4]Princess Margaret Cancer Centre, Toronto, ON, Canada,[5]Vanderbilt-Ingram Cancer Center, Nashville, TN,[6]Dana-Farber Cancer Institute, Boston, MA,[7]American Association for Cancer Research, Philadelphia, PA

Purpose: The first comprehensive analysis of the detailed clinico-genomic landscape of the breast cancer (BC) cohort of the American Association for Cancer Research (AACR) Project Genomics Evidence Neoplasia Information Exchange (GENIE) Biopharma Collaborative (BPC).

Methods: We analyzed 1,045 BC patients treated at three GENIE-participating institutions. Breast cancer patients in the GENIE registry aged 18-56 at sequencing and with tumor(s) sequenced between 2013 and 2018 were randomly chosen for curation using the PRISSMM framework. Sites of distant metastasis were captured from imaging and pathology reports. A previously published cohort of older patients was used as a point of comparison in identifying age-related differences. Overall survival (OS) was estimated for patients with advanced disease.

Results: Clinical and genomic features were compared across the four subtypes HR+/ HER2 - (N=660), HR+/HER2+ (N=138), HR-/HER2+ (N= 74), and TNBC (n = 173). The age distribution was similar across subtypes, HR+/HER2+ had the highest percentage of patients ages 18-39 (HR+/HER2-: 28%, HR+/HER2+: 39%, TNBC: 33%, HR-/HER2+ 35%). The most frequently altered genes in the cohort were TP53 (HR+/HER2-: 33%, HR+/HER2+: 58%, TNBC: 95%, HR-/HER2+ 80%), PIK3CA (HR+/HER2-: 35%, HR+/HER2+: 33%, TNBC: 8%, HR-/HER2+ 15%), and ERBB2 (HR+/HER2-: 3%, HR+/HER2+: 71%, TNBC: 2%, HR-/HER2+ 84%).

Analysis of patients with metastatic disease (n=818) revealed robust associations with OS and TP53 (HR = 1.87, SF = 100%), ERBB2 amplification (HR = 0.61, SF = 98%), MYC (HR = 1.09, SF = 52%), FGFR2 (HR=0.89, SF = 49.3%), MAP3K1 (HR = 0.94, SF = 35%), DDR2 (HR = 1.09, SF = 33%) and ESR1 (HR=1.07, SF = 32.7%).

In a comparison of older and younger patients with HR+/HER2- subtype, we found that mutations in TP53 (18-39: 35% vs >60: 22%), GATA3 (18-39: 21% vs >60: 10%), and MAP2K4 (18-39: 10% vs >60: 4%) were significantly ($q<0.1$) more prevalent among younger patients. Conversely, PIK3CA (18-39: 31% v >60: 48%), CDH1 (18-39: 3% v >60: 21%), and MAP3K1 (18-39: 5% v >60: 12%) showed higher alteration rates in seniors. These trends were consistent at pathway level with higher alteration of p53 (18-39: 44% vs >60: 29%) and PI3K (18-39: 46% vs >60: 62%).

In patients with any distant metastases, we calculated the metastatic burden, or the number of distant metastases reported in key sites of interest. Patients with a history of adrenal

Metastasis had a higher metastatic burden (49/61, 80.3% with at least 4 distinct sites recorded) than those with no adrenal metastasis recorded (326/764, 42.6% with at least 4 distinct sites recorded).

Conclusions: The GENIE BPC cohort provides a comprehensive clinico-genomic dataset enriched with younger patients with BC, providing a valuable source to improve our understanding of age-related clinical and genomic characteristics and their impact on real-world patient outcomes.

#1119 SoMatt: A foundation model for the tumor genome.

David Andreas Arredondo[1], Ala Jararweh[1], Luis Tafoya[2], Avinash Sahu[1]

[1]University of New Mexico Health Sciences Ctr., Albuquerque, NM,[2]University of New Mexico, Albuquerque, NM

Somatic mutations in cancer cells can lead to diverse phenotypic consequences due to variations in mutation types and locations within the same gene. Interactions between mutations across different genes further contribute to tumor heterogeneity, affecting pathology, phenotype, and clinical outcomes. Current computational methods often treat all mutations within a gene as functionally equivalent and overlook combinatorial effects between genes. Additionally, the diversity of sequencing platforms and gene panels poses significant challenges for integrative genomic analysis across datasets.

Here, we introduce Somatic Attention (SoMatt), a foundation model for tumor genomes that leverages self-attention mechanisms to model interactions among mutations within a tumor. Trained on 167,335 tumors from 149,831 unique cancer patients from AACR Project GENIE, SoMatt generates comprehensive tumor embeddings suitable for various downstream tasks. The model addresses three critical challenges in tumor genome analysis: (a) distinguishing the effects of different mutations within the same gene, (b) capturing complex interactions among multiple mutations within a tumor, and (c) integrating data from diverse targeted mutation panels without requiring uniformity.

We demonstrate that SoMatt accurately predicts patient survival outcomes, achieving a concordance index (C-index) of 0.76 across 90 cancer types, and classifies cancer types with an accuracy of 59%, outperforming baseline models in both tasks. Notably, SoMatt also enables patient stratification beyond traditional subtyping methods by identifying previously unrecognized, molecularly defined patient subgroups with significantly different outcomes, suggesting a novel approach to cancer subtype classification based on tumor molecular profiles.

SoMatt produce a robust and scalable framework for comprehensive modeling of tumor genomes, addressing key challenges in cancer genomics and advancing the potential for precision oncology.

#112 ROR1 drives tumor-initiating cells in pancreatic cancer.

Masaya Yamazaki, Takatsugu Ishimoto

Japanese Foundation for Cancer Research, Tokyo, Japan

Tumor-initiating cells are key players in driving chemoresistance and metastasis, making them promising targets for cancer therapy. However, the identity of tumor-imitating cells and molecular mechanisms underlying their capacity in human pancreatic ductal adenocarcinoma (PDAC) remains unclear. To address this, we conducted single-cell RNA sequencing and functional studies in human PDAC xenografts to identify targetable tumor-initiating cells. We found that a subpopulation characterized by a partial epithelial-mesenchymal transition (EMT)-like signature and high expression of receptor tyrosine kinase-like orphan receptor 1 (ROR1) serves as the origin of intratumor heterogeneity in PDAC. Functional analyses demonstrated that ROR1^{high} cells have high tumorigenicity and ROR1 promotes tumor growth, relapse following chemotherapy, and metastasis. We also showed that ROR1 prevents PDAC progression. Mechanistically, ROR1 activates the E2F transcriptional network via c-Myc, accelerating tumor cell hyperproliferation by inducing Aurora kinase B (AURKB). Moreover, epigenomic analyses revealed that *ROR1* expression is flexibly controlled by the enhancer through the YAP/BRD4 axis. Targeting this pathway with a BET inhibitor effectively downregulated *ROR1* expression and suppressed PDAC organoid growth. Collectively, our findings implicate ROR1^{high} cells as tumor-initiating cells in PDAC and illuminate the therapeutic potential of ROR1 as a promising strategy for PDAC.

#1120 Baseline biomarker analyses of patients with chemorefractory *KRAS* G12C-mutated metastatic colorectal cancer (mCRC) from the phase 3 CodeBreaK 300 study.

M. Fakih[1], Y. Katlinskaya[2], Y. Kuboki[3], E. Chan[2], A. Anderson[2], A. Hindoyan[2], A. Pati[4], A. Reddy[4], L. Salvatore[5];
[1]City of Hope Comprehensive Cancer Center, Duarte, CA, [2]Amgen, Thousand Oaks, CA, [3]National Cancer Center Hospital East, Kashiwa, Japan, [4]Amgen, San Francisco, CA, [5]Universita Cattolica del Sacro Cuore; Comprehensive Cancer Center, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy

Background: The genetic landscape of CRC tumors may influence responses to targeted therapies. In CodeBreaK 300 (NCT05198934), sotorasib (soto) 960 mg plus panitumumab (pani) showed significant improvement in progression-free survival (PFS) compared with trifluridine/tipiracil (T/T) or regorafenib (rego) (hazard ratio, 0.48 [95% CI, 0.30-0.78]; $P = 0.005$) in patients with chemorefractory *KRAS* G12C-mutated mCRC. Here, we evaluated baseline genetic co-occurring alterations and their impact on the efficacy of soto plus pani in CodeBreaK 300.
Methods: Study procedures and eligibility criteria have been previously reported. Next-generation sequencing was performed on baseline tumor and plasma circulating tumor DNA (ctDNA) samples with Tempus xT and Guardant Infinity platforms, respectively. Biomarker status was correlated with clinical outcomes.
Results: A total of 140 available tumor samples and 154 plasma samples were examined. The prevalence of individual gene alterations was similar between arms for both tumor and ctDNA assessments The most common pathogenic KRAS G12C co-alterations occurred in *APC* (82.1%), *TP53* (72.1%), *SMAD4* (23.6%), and *PIK3CA* (17.9%) in tumor samples and in *TP53* (73.4%), *APC* (65.5%), *DNMT3A* (39%), *TET2* (22.8%), and *SMAD4* (21.4%) in plasma samples. An exploratory analysis to determine associations between baseline molecular alterations with ≥10% prevalence and clinical outcomes showed that TGF-β pathway mutations were associated with shorter overall survival and time to progression (TTP) and *TP53* mutation status was associated with shorter TTP. Among the most prevalent co-alterations, clinical benefit with soto 960 mg plus pani vs T/T or rego was observed irrespective of biomarker subgroup. A hypothesis-driven analysis indicated that alterations in *ARID1A* in a few patients were associated with shorter PFS. In patients receiving soto 960 mg plus pani, median PFS was 2.07 months (95% CI, 1.84-3.84; n = 3) for those with *ARID1A* alterations and 5.78 months (95% CI, 4.24-7.59; n = 49) for those without.
Conclusion: Genetic alteration rates in CodeBreaK 300 were similar across all treatment arms and comparable to those observed in CodeBreaK 100 and 101 and *KRAS* G12C+ cases in AACR Genie BPC v1.1. Soto 960 mg plus pani demonstrated consistent clinical benefits compared with T/T or rego across various molecularly defined subgroups. While no additional strong biomarkers associated with response were identified, this study supported the potential association of *ARID1A* alterations with shorter PFS as previously reported in CodeBreaK 101. However, the overall low prevalence of pathogenic *ARID1A* alterations largely limited the interpretation of these findings.

#1121 Pan-cancer prevalence of unusual MTAP alterations: data from the AACR GENIE database.

Mohamed A. Gouda, Camila B. Xavier, Carlos Torrado, Pooja A. Shah, Kunal Rai, Natalie Vokes, Omar Alhalabi, Mark T. Bedford, Jianjun Gao, Nazanin K. Majd, Jenny Li, Milind Javle, Funda Meric-Bernstam, Jordi Rodon

The University of Texas MD Anderson Cancer Center, Houston, TX

Background: PRMT5 inhibitors has shown promising clinical activity in MTAP deficient tumors. Ongoing studies focus on tumors with homozygous *MTAP* deletions; but that doesn't span the whole spectrum of MTAP dysfunctional tumors. Herein, we tried to characterize the pan-cancer prevalence of *MTAP* oncogenic alterations.

Methods: We used the AACR GENIE database v.16.1 to extract data on the prevalence of *MTAP* alterations across different tumor types. OncoKB was used to obtain data on functional significance.

Results: We reviewed data from 214,475 samples obtained from 184,980 patients. Structural variants, mutations, and copy number alterations in *MTAP* were profiled in 55,021, 58,144, and 57,382 samples across different cancers; respetively. A total of 46 *MTAP* fusions were identified; all were likely oncogenic per OncoKB including 12 with level 4 alterations. The most common fusions were *MTAP* intragenic, *MTAP*::*CDKN2A*, and *MTAP*::*CDKN2B* fusions. The highest rates of *MTAP* structural variants were observed in CNS cancers (0.4%; n=1), gastrointestinal neuroendocrine tumor (0.3%; n=1), hepatobiliary cancer (0.2%; n=3), melanoma (0.2%; n=3), and glioma (0.1%; n=5). A total of 356 *MTAP* mutations were identified; including 82 that were likely oncogenic per OncoKB. The most common mutations that were annotated as likely oncogenic were *MTAP* A191Rfs*6, *MTAP* X231_splice, and *MTAP* X116_splice. The highest rates of *MTAP* mutations were observed in endometrial cancer (1.6%; n=36), small bowel cancer (1.6%; n=3), non-melanoma skin cancer, (1.5%; n=6), colorectal cancer (1.2%; n=72), and bladder cancer (1%; n=20). The highest rates of *MTAP* homozygous deletions were observed in glioma (24.6%; n=899), blastic plasmacytoid dendritic cell neoplasm (23.1%; n=3), nerve sheath tumor (18.3%; n=28), mesothelioma (17.7%; n=79), and bladder cancer (16.9%; n=350) (Table 1).

Conclusions: The spectrum of *MTAP* alterations expands beyond *MTAP* deletions; and could be explored in clinical trials targeting *MTAP* loss.

MTAP deletions			**MTAP mutations MTAP structural variants**					
Disease	**%**	**N**	**Disease**	**%**	**Disease**	**%**	**N**	**N**
Glioma	24.6%	899	Endometrial Cancer	1.6%	CNS Cancer	0.4%	1	1

Cancer of Unknown Primary	8.2%	185	Uterine Sarcoma	0.7%	Soft Tissue Sarcoma	0.1%	2	2

#1122 Pan-cancer clinical and molecular landscape of MTAP deletion in nationwide and international comprehensive genomic data.

Hiroaki Ikushima, Kousuke Watanabe, Aya Shinozaki-Ushiku, Katsutoshi Oda, Hidenori Kage

University of Tokyo, Tokyo, Japan

Methylthioadenosine phosphorylase (MTAP) deletion in cancer cells induces vulnerability to protein arginine methyltransferase 5 (PRMT5) inhibition, offering a synthetic lethal target. Early-phase clinical trials have shown promising efficacy of PRMT5 inhibitors in MTAP-deleted tumors, but the full spectrum of patients with MTAP-deleted tumors and their molecular characteristics remain unclear. We report a pan-cancer landscape of MTAP-deleted tumors using comprehensive genomic profiling (CGP) data of 51,828 cases in the Center for Cancer Genomics and Advanced Therapeutics (C-CAT), covering 99.7% patients who underwent CGP in Japan. Findings were validated using TCGA (n = 9,896) and GENIE (n = 178,034) data. MTAP deletion was observed in 9.6% of the C-CAT cohort, 8.9% of TCGA, and 6.6% of GENIE. A machine learning prediction model using pre-CGP clinical data, combined with SHapley Additive exPlanations (SHAP) analysis, identified clinical factors associated with MTAP deletion: sex, age, cancer type, and time intervals from cancer diagnosis to CGP. In C-CAT, MTAP-deleted patients were predominantly male (56.0% vs 47.8%, $p < 0.0001$) and slightly older (mean: 62.4 vs 59.8 years, $p < 0.0001$). MTAP deletion rates were high in pleura (33.1%), bladder/urinary tract (23.8%), brain (19.0%), pancreas (18.4%), biliary tract (15.6%), and lung (14.3%) cancers, but low in prostate (1.2%), bowel (1.7%), cervix (3.6%), uterus (4.0%), ovary/fallopian tube (4.3%), and breast (4.9%) cancers. The TCGA and GENIE cohorts showed similar trends, indicating the broad applicability of therapeutic strategies targeting MTAP deletion across different demographic groups. MTAP-deleted tumors demonstrated a shorter time to standard therapy failure in pan-cancer C-CAT data (median: 380.0 vs 567.0 days, HR: 1.34 [1.30-1.38], $p < 0.0001$) and worse overall survival in TCGA (median: 26.7 vs 93.0 months, HR: 2.36 [2.14-2.61], $p < 0.0001$).

Comprehensive molecular analyses revealed that CDKN2A/B loss was an almost necessary, but not sufficient, condition for MTAP deletion. MTAP deletion was more frequent in KRAS-mutant pancreatic cancer (19.8% vs 8.9%), suggesting a cooperative role of MTAP and KRAS and synergistic effects of PRMT5 and KRAS inhibitors. MTAP deletion was less common in RB1-mutated tumors across multiple cancer types, including pancreatic (7.6% vs 18.7%), lung (2.5% vs 16.1%), and biliary (5.4% vs 16.0%) cancers. In lung adenocarcinoma, MTAP deletion was found in 22.8% of EGFR-mutated tumors, 25.0% of ALK-translocated tumors, and 20.8% of ROS1-translocated tumors, indicating that MTAP deletion is not mutually exclusive with druggable mutations and that PRMT5 inhibitors might benefit patients with known driver mutations.

Our findings define the characteristics of MTAP-deleted cancers, providing a basis for refinement and expansion of synthetic lethal strategies in precision oncology.

#1123 Comprehensive molecular characterization reveals hallmarks and therapeutic insights of collecting duct carcinoma.

Xiaofan Lu[1], Wenxuan Cheng[1], Nassim Tawanaie Pour Sedehi[1], Li Xu[1], Xiaoping Su[2], Roger Mouawad[3], Nizar M. Tannir[4], Gabriel G. Malouf[1]

[1]Department of Cancer and Functional Genomics, IGBMC - Univ. of Strasbourg, Illkirch-Graffenstaden, France,[2]Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Medical Oncology, Groupe Hospitalier Pitie-Salpetriere, Paris, France,[4]Department of Genitourinary Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Collecting duct carcinoma (CDC) is a rare and aggressive subtype of renal carcinoma, posing significant challenges in diagnosis and treatment. Current treatment relies on platinum-based chemotherapy, yet clinical outcomes remain poor. While targeted therapies and immune checkpoint inhibitors (ICIs) show promise in clear-cell renal cell carcinoma (ccRCC), they have not been evaluated in CDC, and their efficacy remains speculative. This underscores a pressing need for personalized treatment approaches, driven by an in-depth molecular understanding of the disease.

Experimental Design: We conducted a comprehensive molecular characterization of 22 CDC cases using whole-exome sequencing, RNA-seq, and DNA methylation profiling. Renal medullary carcinoma, ccRCC, type 2 papillary RCC, and chromophobe RCC were included as comparators. To verify mutations of interest, we retrieved 25 CDC samples from GENIE (v15.0). We also assessed the association of genomic alterations with response to ICIs using data from the BIONIKK trial (NCT02960906) and the published CheckMate (-009, -010, -025) trials.

Results: We identified frequent mutations in *NF2* (20%), *LZTR1* (20%), and *SMARCB1* (10%), all located on chromosome 22q, along with 22q copy number loss (52%). Mutations in *NF2*, *SAV1*, and *WWC1*—key components of the Hippo signaling pathway—were observed, implicating its disruption (33%) and leading to overexpression of the YAP signature. Notably, a mutually exclusive pattern between DNA damage-related (DDR) mutations (33%) and 22q loss was observed. Transcriptomic analysis highlighted a cell cycle and immune cell enrichment signature in CDC, distinct from other RCC comparators. TME deconvolution revealed two CDC phenotypes tightly associated with genomic alterations. The immune-hot CDC was characterized by enrichment of CD8 T cells, B cells, and tertiary lymphoid structure signatures, and was enriched in DDR mutations. In contrast, the immune-cold CDC was marked by 22q loss and overexpression of the YAP signature. Furthermore, post-hoc analyses using BIONIKK and CheckMate data demonstrated that combining 22q loss and DDR mutations improves the precision of ICI response predictions. We also found a correlation between 22q loss and a CpG Island Methylator Phenotype (CIMP) pattern in CDC, which resembles the aggressive, immune-evasive CIMP subgroup observed in type 2 papillary RCC.

Conclusions: Our comprehensive characterization broadens the molecular understanding of CDC, revealing actionable vulnerabilities such as DDR mutations for immunotherapy and YAP activation for targeted interventions. These findings redefine CDC's therapeutic possibilities, offering a roadmap for precision oncology in this rare malignancy.

#1124 Mining the Kras-p53 mutational interface for synthetic lethality (SL) in pancreatic adenocarcinoma (PA).

Nishanth Thalambedu[1], Nadia Safar[2], Ahmad Mazin M. Safar[1]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Beth Israel Deaconess Medical Center, Boston, MA

Kras activating mutations are frequent in cancer but are insufficient alone for full malignant transformation. Mutations in the tumor suppressor (TSG) p53 cooperate with mutant Kras and permit full display of oncogenic Ras, both in clinical cases and in experimental models of Kras tumorigenesis. Interestingly, p53 mutations almost never fully abrogate its function, suggesting to us a possible essential role for the (either directly or indirectly) retained transcriptional targets within the p53 network. The phenomenon of oncogene addiction may be the result of this rigid but sufficient TSG output providing adaptations to constant oncogene signaling. It is also plausible that each mutation might provide different adaptations and therefore be differentially selected for in various cases. Drugging the dependency on this adaptation machinery provides an opportunity for SL sparing normal cells. This approach is especially valuable given the limited therapeutic impact of available Kras inhibitors (in scope or in potency). We have shown that specific mutations in p53 with their unique transcriptional lesions cooperate with various Kras mutants in tissue-specific manner. In this work we provide a broader and comparative assessment in PA. We hypothesize that frequency of the top 8 p53 mutational hotspots in PA is non-random with recurring comparable frequencies across independent public datasets (project GENIE, MSK and TCGA). Our work included 4 Kras PA mutants.
Results: Table reports on the frequency of respective mutational pairs.
Conclusion: The available cases in TCGA were limited in number. In the 2 more comprehensive datasets, the frequency of certain pairs between Kras and p53 is remarkably close suggesting a mechanistic justification. For SL considerations, therefore, one needs to examine the transcriptional spectra within defined pairs of Kras-p53 to nominate the appropriate genes for multiplexed gene editing experiments and inform drug discovery.

#1125 Analysis of the Genie database for TC-NER deficient cancers sensitive to ITX-0121.

Michael J. Kelner

UC San Diego, La Jolla, CA

Cells possess a complex DNA damage response (DDR) system, to prevent detrimental mutations from accumulating and being passed on. The genes encoding various DDR components are frequently mutated in cancer cells and provide a potential site for therapeutic intervention. DNA damaging agents, with one exception, are repaired by the global genome repair (GG-NER). The one exception are Illudofulvenes, which hide from the GG-NER and can only be repaired by the transcriptional-coupled repair (TC-NER) pathway. Many cancers are deficient in the TC-NER pathway and cannot properly repair DNA damage. In TC-NER deficient cancer cells the TC-NER polymerase complex becomes blocked by the illudofulvene ITX-0121, disengages from DNA, and the irreversible process of apoptosis. These cancers are 10-fold more sensitive to ITX-0121 than are cancer cells with a functional TC-NER pathway. In contrast, non-replicating or normal cells are minimally affected by and this is reflected in the lack of systemic toxicity in humans administered an illudofulvene. Analysis of the GENIE Database indicates the incidence of TC-NER deficient cancers in solid tumors is ~13%, and includes all major histological classifications (or ~175,000 new patients annually). The highest incidence of TC-NER gene mutations/deletions was for the ERCC2 and ERCC5 genes with an incidence of 2.1% for each. Surprisingly, many patients with an ERCC2 or ERCC5 mutation had a second mutation in another ERCC gene (often ERCC6). The ERCC8 gene has the lowest incidence (0.4%) and the ERCC1 gene had the second lowest incidence of mutations (0.5%), but 65% of ERCC1 mutations were associated with a mutation in another ERCC gene. Based on studies involving double knockouts of TC-NER genes, these cancers have a 20-fold increase in sensitivity to ITX-0121. Histological classifications of cancers with the highest incidence of TC-NER deficiency (>25%) in the GENIE database included bladder, colorectal, endometrial, ovarian, and melanoma. In contrast, bone, renal, and thyroid cancers had a relatively low incidence of <8%. We developed a companion diagnostic to identify TC-NER deficient patients based on this data. Based on prior studies, we believe the MTD of ITX-0121 in humans to be >1.2 mg/kg, but only 0.4 mg/kg will be sufficient for clinical efficacy in TC-NER deficient cancers. Hence, despite administering a cytotoxic agent, one will treat TC-NER deficient cancer patients at a non-toxic dose. Toxicity (if it occurs) should be limited to transient thrombocytopenia based on prior studies. In summary, we are utilizing a Precision Medicine approach to develop a drug for an indication defined by a specific molecular alteration across cancer types, which in this case is the presence of TC-NER deficiency as identified by monoallelic mutations in specific genes coding for proteins in the TC-NER pathway.

#1126 CLSP-1025, a first-in-class precision T cell engager for the treatment of p53 mutant cancers.

M. F. Maloney[1], J. X. Caushi[1], A. R. Andrews[1], J. B. Bingham[1], R. Copeland[1], L. Cullen[1], J. DeSander[1], S. Devens[1], V. S. Dobrev[1], A. Ford[1], A. S. Gizzi[1], L. C. Harshman[1], G. A. Kingsbury[1], K. Krapfl[1], D. Orlando[2], J. Shepherd[1], M. Curtis Siok[1], C. Souza[1], K. L. Stokes[1], S. A. Underwood[1], V. Suri[1], **K. McEachern**[1];

[1]Clasp Therapeutics, Inc., Cambridge, MA, [2]Orlando Data Science, LLC, Cambridge, MA

Oncogenic driver mutations in p53 occur frequently in cancer. T cell engagers that specifically target tumor cells harboring p53 mutations have the potential to enable durable efficacy while sparing normal tissue. CLSP-1025 leverages this specificity by targeting tumors that express the p53 R175H mutant protein in HLA-A*02:01 positive patients. The preclinical characterization provides a foundation for advancing CLSP-1025 to a first-in-human (FIH) study.

CLSP-1025 is a half-life extended single-chain diabody IgG4 Fc fusion protein that binds to the $p53(R175H)_{168\text{-}176}$ peptide presented by HLA-A*02:01 on cancer cells and to CD3ε on T cells with nM affinity. Preclinical studies show that CLSP-1025 induces potent and targeted T cell activation (EC_{50} = 0.8 nM), leading to effective tumor cell killing in vitro (EC_{90} = 10 nM) and regression of KMS-26 tumor xenografts in vivo.

The safety assessment of CLSP-1025 included various in vitro and ex vivo assays using human cells and tissues. CLSP-1025 did not show significant reactivity towards any non-target HLA-A*02:01-presented human proteome derived peptide. In an evaluation of cross-reactivity to other HLA alleles, CLSP-1025 cross reacted with 8 of 264 HLA alleles tested and patients with these alleles will be excluded in the FIH study. In a tissue cross-reactivity study, CLSP-1025 demonstrated no off-target binding to the 39 normal human tissues tested. Additionally, assays with human whole blood and PBMCs revealed no significant CLSP-1025-dependent T-cell activation, cytokine production, or platelet activation.

To define the addressable patient population, genomic data was analyzed from over 180,000 tumor samples (AACR Project GENIE Consortium, v16.1) to determine the frequency of the p53 R175H mutation. Overall, the mutation was present in 2% of patient samples, with gastrointestinal cancers having the highest frequencies: colorectal (6.3%), pancreatic (4.3%), and esophageal (4.9%). Gynecological cancers also showed notable frequencies, with ovarian at 2.8% and endometrial at 2.4%. The population frequency of HLA-A*02:01 in the US is ~41% (Gragert 2013).

A mechanistically based, CLSP-1025-specific quantitative systems pharmacology (QSP) model incorporating target binding affinities, CD3 receptor occupancy, in vitro pharmacodynamics, and in vivo rodent PK profiles was developed to predict an efficacious dose range to inform the FIH study. The model predicted a terminal half-life for CLSP-1025 of approximately 16 days and the potential for tumor regression at target peptide-HLA densities as low as 2 molecules/cell.

Clinical evaluation of CLSP-1025 will be initiated in early 2025 in the GUARDIAN-101 study, a FIH dose escalation and expansion trial to evaluate the safety, pharmacokinetics, pharmacodynamics, and preliminary antitumor activity of CLSP-1025 in HLA-A*02:01 positive patients with advanced solid tumors harboring the p53 R175H mutation.

#1127 Differences in the clinical and genomic landscape in young onset (YO) gastroesophageal cancer (GEC): an analysis from AACR Project GENIE.

Ronan Andrew McLaughlin, Yvonne Bach, Esraa Mahmoud, Nadia Ghazali, Sheeraz Ali, Harry Harvey, Zac Coyne, Ekaterina Kosyachkova, Carly Barron, Hiroko Aoyama, Sokaina Akhtar, Raymond Jang, Eric Chen, Kevin Wang, Lucy Ma, Sangeetha Kalimuthu, Aruz Mesci, Rebecca Wong, Elliot Wakeam, Jonathan Yeung, Philippe Bedard, Elena Elimova

UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Although GEC is most common in the elderly population, there is a rising incidence of YO GEC defined as occurring in patients ≤50 years of age. The clinical and genomic differences between YO and older onset disease remain unclear. We aim to comprehensively explore the clinical and genomic landscape of YO GEC and compare with older onset disease (>50 years) to elucidate potential molecular differences between the two age groups that may guide therapeutic approaches in the future.
Methods: Data from the Association for Cancer Research Project Genomics Evidence Neoplasia Information Exchange (AACR-GENIE) registry (version 16.1 for somatic mutation analysis and version 13.1 for survival analysis) to study patients diagnosed with GEC was queried. Patients with GEC were stratified by age at time of tumor sequencing. cBioPortal was used to analyze the differences in genetic mutation frequencies and differences were examined using chi-squared test. Overall survival (OS) between the groups was calculated using the Kaplan Meir method.
Results: The AACR-GENIE registry included 5933 samples from 5553 patients; 892 (16%) patients were ≤50 years old and 4661 (84%) were >50 years old. This cohort includes patients across all stages of disease. 64% were male in YO group versus 73% in group > 50 years. 11% of patients in YO group were of Asian race compared with 6% in older group. The older onset group demonstrated a significantly higher gene altered frequency ($p<0.001$). At a sample level analysis, significant genomic alterations between both age cohorts were identified in 21 genes. In particular, there were only two genes, CDH1 ($p<0.001$) and CCNE1 ($p<0.001$), found to be significantly observed more frequently in YO patients compared with the older onset group. These mutations have been associated with hereditary gastric cancer syndromes, aggressive disease and poorer survival. Amongst the 19 genes significantly observed more frequently in the older onset group was the hereditary APC gene $p<0.001$ and TP53 (<0.001). Potentially targetable markers such as CDKN2A ($p<0.001$), KRAS ($p<0.001$), FGF4 ($p<0.001$), and FGFR3 ($p<0.001$) were also significantly observed more frequently in patients >50 years old. In the earlier analysis of GENIE (Version 13.1) with 2874 patients median OS (all stages) in YO GEC was 37 months (26.6-59.5) versus 28.9 months (26.3- 32.5) (95% CI) in older onset patients, however this was not significant ($p=0.057$).
Conclusions: The GENIE analysis provides a comprehensive landscape of the clinical and genomic data in patients with YO and older onset GEC. Fewer somatic alterations were observed in YO GEC. Further exploration of these results and updated survival are vital to better understand the biological mechanisms and differences observed and to pinpoint potential biomarkers for diagnostic assays and personalized therapy.

#1128 Comprehensive multi-omics analysis of colorectal cancer tumors in diverse populations.

Brigette Waldrup[1], Francisco G. Carranza[1], Yuxin Jin[1], Yonatan Amzaleg[1], Mackenzie Postel[2], David W. Craig[1], John D. Carpten[1], Boudoir Salhia[3], Charite N. Ricker[4], Julie O. Culver[5], Carmen E. Chavez[5], Mariana C. Stern[6], Lourdes Baezconde-Garbanati[6], Heinz-Josef Lenz[4], Enrique I. Velazquez-Villarreal[1]

[1]Integrative Translational Sciences, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA,[3]Translational Genomics, University of Southern California, Keck School of Medicine, Los Angeles, CA,[4]Medical Oncology, University of Southern California Keck School of Medicine, Los Angeles, CA,[5]University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA,[6]Population and Public Health Sciences, University of Southern California Keck School of Medicine, Los Angeles, CA

Introduction: Colorectal cancer is a leading contributor to cancer-related mortality and health disparities within the Hispanic and Latino community. To uncover the biological and genetic factors underlying these inequities, we conducted an analysis of key colorectal cancer molecular characteristics, focusing on somatic alterations, gene expression and genetic similarity (NASEM's term for genetic ancestry).
Methods: As part of the Cancer Moonshot PE-CGS network, we obtained and performed a comprehensive genome-scale analysis of 131 primary CRC Tumor/Normal samples within the Hispanic and Latino population from the Los Angeles area. For comparison, we analyzed 3,920 Non-Hispanic White (NHW) samples obtained from public databases, including AACR-GENIE. Our methodology included DNA exome sequencing to evaluate somatic mutations, somatic copy number alterations, and genetic similarity, as well as RNA sequencing to investigate differential gene expression, cellular pathways, and gene fusions. Insights from Hispanic and Latino samples were systematically compared with those derived from NHW cohorts. In alignment with the NASEM report and terminology, we adhered to best practices for the use of race, ethnicity, genetic ancestry, and other population descriptors in genetics and genomics research.
Results: Our analysis revealed distinct genetic similarity patterns, with a notable prevalence of Peruvian-from-Lima-like (1KG-PEL-like) genetic similarity, as defined by the 1000 Genomes Project. These patterns correlated with microsatellite stability (MSI) status, age at diagnosis, and tumor location. Significant mutations were identified in key colorectal cancer genes, including APC, TP53, and KRAS. Comparative analyses highlighted CRC-related genes with significant differences between Hispanic and Latino samples and NHW cohorts. Drug-targetable amplifications were also identified, while gene fusion analyses uncovered targetable genes such as ALK, FGFR1, RAF1, and PTPRK. Notably, PTPRK was observed in samples with the highest 1KG-PEL-like genetic similarity proportions.
Conclusion: This study advances the molecular profiling of colorectal cancer in Hispanics and Latinos, addressing an underrepresented population in cancer research. As one of the first Cancer Moonshot projects focused on CRC in Hispanics and Latinos with a substantial sample size and among the pioneering efforts to utilize multi-omics for molecular characterization, it sets a significant precedent. Genetic similarity is identified as a critical factor in colorectal carcinogenesis, providing essential insights into the biological drivers of cancer health disparities. By establishing a comprehensive framework for analyzing this underserved group, this research lays the groundwork for future studies, fostering advancements in precision medicine and supporting the development of tailored therapeutic strategies.

#1129 Interrogating the molecular profile of pancreatic cancer tumors in Hispanics living in Puerto Rico.

Ingrid M. Montes-Rodriguez, Veroushka Ballester-Vargas, Sol Perez-Martir, Hilamaris Centeno-Girona, Marcia Cruz-Correa, Julie Dutil

University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Pancreatic adenocarcinoma (PDAC) is projected to become the second leading cause of cancer-related death in the U.S. by 2040. With a low survival rate at advanced stages and an increasing number of patients, PDAC poses a significant public health challenge. The five-year survival rate for localized PDAC is 44%, but it drops to 15% for regional and just 3% for distant disease. There are clear disparities in PDAC outcomes based on race and ethnicity; however, published data often lack racial and ethnic diversity, particularly regarding non-black minority groups like Hispanics. To address this gap, we evaluated the mutational profiles of PDAC tumors from 48 Hispanic patients living in Puerto Rico (PRH) who underwent next-generation sequencing (NGS) testing between 2015 and 2020. Data were provided by the Precision Oncology Alliance (POA) using the CARIS Life Sciences NGS platform. We estimated the prevalence of somatic mutations in PRH PDAC tumors and compared these profiles with those from the TCGA Pan-Cancer Atlas and the AACR Project GENIE, both accessible via the cBioPortal for Cancer Genomics. Notable differences were observed when compared to TCGA and GENIE. For instance, PRH samples exhibited higher mutational frequencies of *BRCA1/2*, which are actionable genes that could make these patients candidates for targeted therapies such as PARP inhibitors. Additionally, elevated frequencies of mutations in *ARID1A* and *TP53* in PRH suggest a distinct mutational landscape not typically represented in non-Hispanic populations. These findings underscore the need for population-specific molecular profiling to uncover optimal targeted therapeutic approaches for Hispanic patients.

#113 Decoding developmental programs driving tumorigenesis and immunotherapy resistance in triple-negative breast cancer.

Rachel Gleyzer[1], Farnaz Khameneh[1], Zhen Qi[1], Wubing Zhang[1], Chloe B. Steen[1], Minji Kang[1], Maya Maalouf[2], Melanis Ghadimi[2], Makenna Lindsey[2], Sally Bobo[1], Thomas J. Lomis[2], Frederick M. Dirbas[1], Michael F. Clarke[1], Aaron M. Newman[1]

[1]Stanford University School of Medicine, Palo Alto, CA,[2]Valley Presbyterian Hospital, Van Nuys, CA

Background: Triple-negative breast cancer (TNBC), defined by a lack of hormone receptors and lack of HER2 amplification, is the deadliest subtype of breast cancer. TNBC kills 1 in 3 patients and while promising new drugs based on PARP inhibition and anti-PD1 immunotherapy can extend survival in selected patients, 30-40% of patients relapse or fail therapy. Increasing evidence suggests that TNBC tumors harbor stem-like tumorigenic cancer cells with high plasticity, capable of replenishing cancer cell populations and linked to adverse outcomes. Unfortunately, the phenotypic diversity, microenvironmental contexture, and functional significance of these cells remain poorly understood and available marker genes are not specific, precluding rational drug development.
Methods: We created a multimodal single-cell RNA-seq atlas of 80 TNBC patients, including clinical covariates such as BRCA1/2 mutations, race/ethnicity, and prior treatment status. We then defined differentiation-associated malignant cell states using a novel interpretable deep learning approach for determining single-cell potency. We subsequently interrogated geospatial features, including localized microenvironments of less differentiated malignant cells, and linked them to immune checkpoint inhibitor (ICI) response.
Results: Our quantitative analysis shows that TNBC is enriched in cancer cells with high developmental potency as compared to other breast cancer subtypes, consistent with its aggressive phenotype. Critically, we observed a strong association between enrichment of high potency cells and resistance to ICI treatment across human and mouse bulk expression data, both within TNBC and across other cancer types, a finding that we experimentally validated in a murine model of TNBC. In scRNA-seq and spatial transcriptomics data, we defined striking relationships between less differentiated cancer cells and context-dependent T cell states indicative of strong immunosuppressive capability. In line with this, we found that knockout of genes associated with immature cancer cells promotes TNBC cell killing by T cells in a co-culture CRISPR screen. Ongoing experiments include perturbations of novel therapeutic targets emerging from this work, with the goal of improving immunotherapy responses and ultimately extending patient survival.
Conclusion: We anticipate that our approach will expand our understanding of developmental landscapes in TNBC and lead to new opportunities for developing targeted drugs in this devastating disease.

#1130 Race and sex differences in TP53 mutation in head and neck cancer.

Nosayaba Osazuwa-Peters, May Z. Gao, Tammara L. Watts, Rong Jiang

Duke University School of Medicine, Durham, NC

Importance: Head and neck cancer (HNC) is one of the most disparate cancers, with the Black vs. White survival difference being the third worst survival gap of all cancers. It is also a male-dominated cancer, with up to 75% of new cases in males. There remains several gaps in our understanding of the genetic basis for race and sex disparity in HNC, including paucity in characterizing differences in common genetic mutations in HNC, such as TP53 mutations.
Objective: To characterize the genetic differences in HNC by race and sex through 1) examining prevalence of TP53 mutation by race, and 2) differences in mutation by sex.
Design: Retrospective cohort study.
Setting: The AACR GENIE consortium level v17.4 dataset for patients with confirmed diagnosis of HNC, independent of HPV status.
Main Outcomes and Measures: First, we estimated the rate of TP53 mutation in our HNC cohort (n = 2,352). We also estimated relative risk (RR) for TP53 mutation by race, and then adjusted age, and sex. We also estimated differences in TP53 mutation by sex, reporting false discovery (q-value) rate as appropriate. Finally, we estimated adjusted hazard ratio for mortality for TP53, adjusting for clinical and nonclinical variables in the model.
Results: In the entire cohort, the rate of TP53 mutation was 48.7%. However, there were only 109 patients in our cohort of 2,352 patients that self-identified as Black patients, and among these, 60 (55.1%) had TP53 mutation. After adjusting for age and sex, compared to White patients, we found aRR for TP53 = 1.17 for Black patients (95% CI: 0.98, 1.39), and for other minority race and ethnic groups together aRR = 1.17 (95% CI: 1.06, 1.29). By sex, we found a significantly higher prevalence of mutant TP53 in female vs. males patients (57.8% vs. 45.3%, q-value <0.0001). TP53 mutation was associated with significantly increased hazard of mortality (aHR = 1.58; 95% CI: 1.30, 1.91).
Conclusion and Relevance: TP53 mutation is very common in HNC, and about one out of every two patients with HNC may have a TP53 mutation based on our results. There may be differences in TP53 mutations in HNC by race and sex, an important finding given the mortality implications of TP53 mutations in HNC.

#1131 Comprehensive genomic profiling in osteosarcoma: Insights from Japanese cohorts and the AACR Project GENIE.

Suehara Yoshiyuki[1], Rina Kitada[1], Masachika Ikegami[1], Satoshi Kamio[1], Koichi Ogura[2], Shintaro Iwata[2], Eisuke Kobayashi[2], Akira Kawai[2], Shinji Khosaka[1]

[1]National Cancer Center Research Institute, Tokyo, Japan,[2]National Cancer Center Hospital, Tokyo, Japan

Background: Osteosarcoma (OS), the most common primary malignant bone tumor, presents challenges in treatment, especially in metastatic or recurrent cases. Genomic profiling may offer novel therapeutic approaches by identifying actionable mutations. This study utilizes data from the Japanese Center for Cancer Genomics and Advanced Therapeutics (C-CAT) and AACR Project GENIE, comparing findings with the MSK-IMPACT dataset to understand differences in genomic landscapes and identify clinically actionable alterations.
Methods: We analyzed 223 high-grade OS samples from the C-CAT database, comparing findings to the GENIE cohort and MSK-IMPACT data. Tumor DNA sequencing was performed using FoundationOne® CDx and OncoGuide™ NCC Oncopanel. Genomic alterations were categorized by levels A-F per Cancer Knowledge Database (CKDB) and compared with public databases (cBioPortal).
Results: In the C-CAT cohort, 42.2% of samples had actionable mutations (CKDB Levels A-C), including two NTRK fusions (0.9%), one TMB-high case (0.4%), and recurrent ERBB, CDK4, PTEN, and PDGFRA gene alterations. Co-occurring KIT, KDR, and PDGFRA amplifications were observed at 4q12 in 3.6% of cases, while VEGFA and CCND3 co-amplifications at 6p12-21 occurred in 14.8% of cases, suggesting multi-kinase inhibitors as potential treatments. Differences from the MSK-IMPACT dataset (Suehara Y et al, Clin Cancer Res. 2019 25(21):6346-6356), where mutually exclusive amplifications were more pronounced, highlight the genetic diversity between Japanese and U.S. cohorts. Analysis with GENIE and MSK-IMPACT indicates a lower incidence of mutually exclusive alterations in the Japanese cohort.
Conclusions: Targetable alterations were present in 42.2% of Japanese OS cases, with a distinct genomic profile compared to U.S. cohorts. Amplifications in 4q12 and 6p12-21, which may be treatable with multi-kinase inhibitors, were found in both datasets, yet mutual exclusivity patterns varied. This study underscores the potential of precision oncology in OS, encouraging continued exploration of genomic data in diverse populations to expand treatment options.

#1132 Quantifying selection intensity of driver genes in primary and metastatic thyroid cancer.

Moein Rajaei, Andrew Ju, Jeffrey P. Townsend

Yale University, New Haven, CT

The mutational profiles of primary and metastatic thyroid cancer (THCA) have been identified by comparing genetic alterations between the two stages, using mutation prevalence and *P* values to identify significant differences. However, these metrics do not quantify the cancer effects of variants. In this study, we quantified somatic selection on variants and genes using exome and targeted sequencing data from 2,145 primary and 1,374 metastatic tumors, derived from previous studies as well as GENIE, and TCGA databases, utilizing cancereffectsizeR to measure the cancer effects of new mutations. Comparisons of trinucleotide mutation profile revealed a relatively similar mutational landscape between primary and metastatic THCA, with notable differences such as GTG → GAG, TTG → TCG, and ATG → ACG mutations, which were more prevalent in metastatic tissues. While it is shown that *TERT* genetic alterations are more frequent in metastatic papillary thyroid carcinomas (PTCs) compared to primary PTCs, our analysis showed that the strength of somatic selection on *TERT* coding mutations was lower during the span from primary to metastatic THCA than during the span from thyroid organogenesis to primary THCA. Conversely, *RET* mutations, which is also shown to be more prevalent in metastatic tumors, were highly selected during the progression from primary to metastatic THCA, in comparison from organogenesis to primary THCA, aligning with the broader spectrum of *RET* mutations observed in metastatic medullary thyroid carcinoma. Furthermore, the selection intensity for mutations in genes such as *BRAF*, *NRAS*, *TP53*, *ATM*, *KMT2D*, *KMT2C*, *NF1*, *NF2*, *PTEN*, and *NKX2-1* was higher during the transition from organogenesis to primary THCA compared to the progression from primary to metastatic THCA. In conclusion, our application of cancer effect size analyses revealed that the strengths of selection on mutations vary dynamically across the trajectories from organogenesis to primary THCA and from primary to metastatic THCA. We identified key genes driving THCA initiation and progression, providing a quantitative understanding of the evolutionary trajectory of mutations in this disease. These insights shed light on the determinants of THCA pathogenesis and metastasis and hold potential to inform future precision treatment strategies.

#1133 Molecular evolution patterns in primary versus recurrent adult gliomas: A multi-institutional study from Project GENIE.

Abhishek Bhattacharya, Anand Kornepati

Internal Medicine, NYU Langone Health, New York, NY

Introduction: Gliomas are the most common primary malignant brain tumors in adults, with high recurrence rates despite multimodal treatment. While previous multi-institutional genomic studies have revealed molecular differences between primary and recurrent tumors, the AACR Project GENIE dataset provides another valuable resource to investigate these distinctions.
Methods: We analyzed 8,959 adult glioma cases from Project GENIE v16.1 (2024), selecting cases with complete mutation and copy number alteration (CNA) data. Tumors were stratified by Isocitrate dehydrogenase (IDH) mutation status, as IDH-wildtype and IDH-mutant gliomas have distinct molecular profiles and patterns of progression. The IDH-mutant cohort (n=2,635) comprised 79.9% primary tumors (n=2,097) and 20.1% recurrent tumors (n=538). The IDH-wildtype cohort (n=5,885) included 89.8% primary tumors (n=5,290) and 10.2% recurrent tumors (n=595). We examined the top 10 mutated somatic genes and compared mutational frequencies and copy number variations between primary and recurrent tumors using Fisher's exact test with Benjamini-Hochberg correction.
Results: In IDH-mutant gliomas, recurrent tumors showed increased mutations across multiple genes, particularly in KMT2D (7.8% to 20.6%, OR 3.06, $p<0.001$), NF1 (5.25% to 13.8%, OR 2.79, $p<0.001$) and NOTCH1 (12.4% to 23.6%, OR 2.18, $p<0.001$). In IDH-wildtype gliomas, the most notable changes were observed in CIC (21.65% to 32.71%, OR 2.12, $p<0.001$) and SMARCA4 (6.82% to 13.75%, OR 2.36, $p<0.001$). Oncogenic drivers like TP53 ($p>0.05$) and PTEN ($p>0.05$) maintained stable mutation frequencies between primary and recurrent tumors in both IDH cohorts. Copy number alterations for all examined genes showed no significant differences between primary and recurrent tumors in either IDH group.
Conclusion: Analysis of this large real-world dataset reveals molecular evolution patterns that align with previous observations, particularly in the stability of copy number alterations in driver genes between primary and recurrent tumors across both IDH groups. Similarly, oncogenic drivers like TP53 and PTEN maintained stable mutation frequencies, indicating preservation of critical growth-promoting pathways during glioma progression. Recurrent IDH-mutant tumors showed high mutational variance in chromatin regulators like KMT2D as well as developmental pathway gene NOTCH1. Recurrent IDH-wildtype gliomas showed more modest increases in mutational frequencies compared to primary counterparts, indicating less selective pressure from treatment in these more aggressive tumors. While the unbalanced distribution of primary versus recurrent samples and potential sampling biases inherent in real-world data limit the generalizability of these findings, these patterns may inform future therapies. Further validation in independent cohorts is warranted.

#114 Unraveling the origin of Ewing sarcoma using zebrafish transgenic models.

Elena Vasileva[1], Claire Arata[2], Gage Crump[1], James Amatruda[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Keck School of Medicine, University of Southern California, Los Angeles, CA

Ewing sarcoma (ES) is a pediatric cancer of bones and soft tissues with enigmatic origin. Ewing sarcoma cells are characterized by the presence of a driver fusion oncogene, most frequently *EWSR1-FLI1*. Previous reports have suggested that bone-marrow mesenchyme or/and neural crest cells may serve as potential cells of origin for Ewing sarcoma. These hypotheses have never been tested in vivo, largely due to the absence of a representative mouse model as the EWSR1-FLI1 fusion causes severe developmental toxicity in most cell types. To address these questions, we developed a stable zebrafish transgenic model enabling tissue-specific expression of the human EWSR1-FLI1 oncofusion in neural crest cells (Vasileva et al., 2024). Using this model, we demonstrated that expression of human EWSR1-FLI1 oncofusion in neural crest cells can lead to their transformation and the development of tumors in vivo. Single-cell analysis of tumor initiation shows that EWSR1::FLI1 reprograms neural crest-derived cells to a mesoderm-like state, strikingly resulting in ectopic fins formation throughout the body. EWSR1-FLI1 hindered the normal differentiation of neural crest cells into glial and neuronal lineages. Instead, EWSR1-FLI1 strongly reprogrammed neural crest cells by hijacking developmental enhancers and upregulating the expression of mesodermal regulators, including the key mesodermal regulator tbxta (Brachyury or T) transcription factor. *tbxta/TBXT* expression was maintained in subset of zebrafish and human Ewing sarcomas. Our model provides a mechanism by which a neural crest cell lineage can be transformed to Ewing sarcoma, a malignancy with predominant mesenchymal features. Taken together, these findings show how a single mutation profoundly alters embryonic cell fate decisions reprogramming neural crest cells to a mesoderm-like state to initiate a devastating childhood cancer.

#115 S-adenosyl-methionine (SAM) synthesis protects ovarian cancer from chemotherapy induced DNA damage and contributes to cancer stem cell enrichment.

Shu Zhang[1], Tara X. Metcalfe[1], Zhen Fu[2], Christiane Hassel[1], Heather M. O'Hagan[1], Kenneth P. Nephew[1]

[1]Indiana University Bloomington, Bloomington, IN,[2]Van Andel Institute, Grand Rapids, MI

High-grade serous ovarian cancer (HGSOC) is a deadly gynecological malignancy characterized by tumor recurrence and chemoresistance to first-line therapies, including platinum (Pt)-based chemotherapy, and Pt-induced increase in OC stem cells (OCSCs). Methionine (Met) has been shown to maintain CSC phenotypes, but its role in Pt-enriched OCSCs remains unclear. HGSOC cell lines were sorted using FACS into OCSCs and non-CSCs. Expression of methionine adenosyltransferase 2A (MAT2A), the enzyme converting Met to S-adenosyl-methionine (SAM), was higher ($p<0.01$) in OCSCs compared to non-CSCs. Supplementation of extracellular SAM (50μM) increased ($p<0.05$) the percentage of OCSCs, whereas inhibiting MAT2A by siRNA knockdown or the activity inhibitor prevented ($p<0.05$) the cisplatin (IC50, 16hr) induced increase in both OCSCs population and spheroid formation, demonstrating the importance of SAM biosynthesis in OCSC enrichment. The combination of cisplatin and siMAT2A also enhanced ($p<0.01$) DNA damage and apoptotic cell death compared to cisplatin. Mechanistically, siMAT2A inhibited ($p<0.05$) proteins involved in the DNA damage response and repair, including yH2Ax, ATM, ATR, Chk1 and FANCD2. MAT2A knockdown also suppressed ($p<0.05$) the cisplatin-induced upregulation of cyclin E/CDK2 which increased the percentage of cells by-passing the cell cycle checkpoint for DNA repair. Furthermore, siMAT2A increased ($p<0.05$) the binding of SAM sensor protein BMT2 on GATOR1, the negative regulatory complex of mTORC1, attenuating p70-S6 kinase and potentially contributing to downregulate cyclin E. Notably, the effects of siMAT2A were independent of the status of Met salvage enzyme methylthioadenosine phosphorylase. As SAM is a universal methyl donor for various methylation processes and given the established link between OCSC enrichment and aberrant DNA methylation, we used Infinium MethylationEPIC array v2.0 BeadChip to investigate genome-wide changes in DNA methylation using HGSOC cell line OVCAR3 treated with vehicle (control), cisplatin (15μM, 16hr) and/or siMAT2A (48hr). DNA methylation analysis identified differential methylated regions (DMRs) between three comparisons. Cisplatin alone increased ($p<0.05$) hypermethylated DMRs compared to the control. The combination of cisplatin and siMAT2A resulted in an increased ($p<0.05$) hypomethylated DMRs compared to cisplatin only, demonstrating a critical role of SAM synthesis in cisplatin-altered DNA methylation patterns. Enrichment analysis identified genes associated with stemness, differentiation, and cell death in the combination. Collectively, our study demonstrates a new role of SAM synthesis in Pt-induced DNA damage repair and OCSCs enrichment, providing a potential therapeutic target for improving chemotherapy outcomes and preventing OCSC enrichment in ovarian cancer.

#116 CD73$^+$cancer-associated fibroblasts augment cancer stemness and drug resistance in hepatocellular carcinoma through adenosine accumulation.

Hui Hai Yang, Carmen Oi Ning Leung, **Terence Kin-Wah Lee**

Hong Kong Polytechnic University, Hong Kong, Hong Kong

Background: Hepatocellular carcinoma (HCC) exhibits significant therapeutic resistance due to its high cancer stemness, which is strongly influenced by the tumor microenvironment (TME). Extracellular adenosine (eAdo), a critical metabolic regulator within the TME, is primarily generated from extracellular ATP via the enzymatic activity of CD73 (NT5E), which is highly expressed in cancer-associated fibroblasts (CAFs). In our pilot study, we found that the CAF populations marked by CD73 were drastically induced in a lenvatinib-resistant immune-competent mouse HCC model. Based on this data, we hypothesize that CD73$^+$ CAFs confer cancer stemness-driven drug resistance via eAdo accumulation in the TME. **Methodology:** Liquid chromatography-mass spectrometry (LC-MS) was used to quantify adenosine levels, whereas flow cytometry was used to assess stemness-related surface markers. Tumor-initiating frequencies were evaluated using a limiting dilution assay, and CRISPR-Cas9-mediated CD73 knockdown in CAFs, the precursors of CAFs, was employed to validate CD73's functional role. Western blot analysis was conducted to investigate the pathway activation.**Results:** Our results showed that CD73 is a functional marker of CAFs, and its overexpression is significantly correlated with poor prognosis of HCC patients. LC-MS detected a significant amount of adenosine in CAFs when compared with HCC cells, while a notable reduction in adenosine levels was observed in the conditioned medium (CM) of CD73-knockout CAFs. Interestingly, ATP-supplemented CM of CAF augments the cancer stemness of HCC cells, while its effect is offset upon CD73 knockout in CAFs. Echoed to this finding, adenosine treatment (10 μM) exerted similar effects, confirming the critical role of CD73 in CAF-driven cancer stemness via adenosine accumulation. Mechanistic studies have demonstrated that adenosine promotes stemness through activation of the A2AR/AKT/mTOR signaling pathway in HCC cells. **Conclusion**: This study establishes that CD73$^+$ CAFs drive HCC stemness and drug resistance by modulating the TME through eAdo accumulation. Targeting CD73 and its downstream signaling pathways represents a promising therapeutic strategy to overcome drug resistance which potentially opens a new therapeutic avenue for HCC treatment.

#119 A multipotent PROX1+ tumor stem/progenitor cell population emerges during intestinal tumorigenesis and mediates radioresistance in CRC.

Pauliina Kallio[1], Cinzia Bessone[1], Fatemeh Seyednasrollah[1], Jefim Brodkin[1], Marika Lassila[1], Jenny Hogstrom[2], Alejandra Gonzalez-Loyola[3], Tatiana V. Petrova[4], Caj Haglund[1], Kari Alitalo[1]

[1]University of Helsinki, Helsinki, Finland,[2]Cancer Research Institute, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA,[3]Aragon Health Institute of Research IISA, University of Zaragoza, Zaragoza, Spain,[4]Department of Oncology, University of Lausanne, Lausanne, Switzerland

Colorectal carcinoma (CRC) progression is associated with an increase in PROX1+ tumor cells, which exhibit features of CRC stem cells and contribute to metastasis. Here, we aimed to provide a better understanding to the function of PROX1+ cells in CRC, investigating their progeny and their role in therapy resistance. PROX1+ cells in intestinal adenomas of ApcMin/+ mice expressed intestinal epithelial and CRC stem cell markers, and cells with high PROX1 expression could both self-renew tumor stem/progenitor cells and contribute to differentiated tumor cells. Most PROX1-lineage traced tumor cells were stem/progenitor cells, which can supply cells to multiple intestinal tumor cell lineages, whereas most lineage-traced LGR5+ tumor cells were enterocytes, indicating that PROX1+ and LGR5+ tumor stem cells have distinct differentiation programs. Although the PROX1+ tumor cells proliferated slower than PROX1- cells, irradiation increased the proportion of PROX1+ cells in human CRC cell lines, patient-derived organoids, and tumor xenografts. Furthermore, transcripts related to DNA damage repair (DDR) were enriched in PROX1+ vs. PROX1- cells in adenomas and in CRC tumor cells from patients. Experiments with PROX1 silencing and overexpression indicated that PROX1 expression enhances CRC cell colony formation following irradiation. PROX1 interacted with DDR proteins, including components of non-homologous end-joining (NHEJ) and base excision repair, and inhibition of NHEJ repair led to a decreased proportion of PROX1+ cells following irradiation. In conclusion, PROX1+ cells are irradiation-resistant tumor stem/progenitor cells capable of self-renewal and differentiation. DDR inhibitors could represent a strategy to target the treatment-resistant PROX1+ tumor stem cells.

#12 Deciphering the role of oncogenic integrin alpha 6B in aged mouse mammary epithelial cells.

Thangarajeswari Mohan, Morgana McLaughlin, Jacob Mackay, Luzhe Sun

UT Health Science Center at San Antonio, San Antonio, TX

Breast cancer (BC) is the most diagnosed cancer in women with aging being the major risk factor. According to American Cancer Society (2024), an estimation of 310,720 invasive BC and about 56,500 cases of DCIS diagnosed among women in the USA, and the women die from BC are likely among age groups of 70 or older. Our previous report demonstrated that aging was associated with an increased number of basal epithelial cells (CD49f^{hi}CD24^{low}) and reduced luminal epithelial cells (CD49f^{low}CD24^{hi}) in mice. The CD49f (Integrin α6), a cell surface marker of mammary stem cells (MaSc), is enriched in the basal cell population of the mammary gland (MG). These cells have oligo-lineage differentiation potential, especially when transplanted into the cleared mammary fat pad (CFP). Integrin α6 has two variants with a different cytoplasmic domain, produced *via* alternative splicing (Isoforms: α6A & α6B). Recent scientific evidence suggests that α6B produced in transformed mammary cell lines was oncogenic. Previous studies from us and others showed CD49f^{hi} aberrant stem cell-like cells in the luminal epithelium display more hyperplastic duct in the old mice, as well as tumor adjacent normal tissue from women with breast cancer. The mechanism underlying the expansion of CD49f^{hi} cells during aging is unclear. It could be due to the proliferation of basal cells, or trans-differentiation of luminal cells. Henceforward, this study examines changes in the CD49f expression (and its isoforms) in the basal and luminal cell populations with aging in mice, hypothesizing that luminal cell attains basal cell signature by expressing more CD49f that contributes to hyperplasia in the aged mammary glands. To explore this hypothesis, we evaluated the gene and protein expression of Integrin α6 isoforms (α6A & α6B) across basal and luminal populations in FVB/NJ and C57Bl/6 aging mice using RT-PCR and Western blotting. Mammary cells were gated and sorted in FACS and used for RNA and protein studies. Our results revealed that aged basal and luminal cells express higher levels of ITGA6B mRNA transcript compared to ITGA6A in both the mice stains. Cell cycle analysis was performed using Hoechst to evaluate the cell cycle phase of each population using flow cytometry. The results showed that luminal cells from aged mice have a higher fraction of G2/M phase cells than those from young mice, suggesting an increased cell cycle in the aged luminal cells, which may be due to increased Integrin α6B. We are currently developing a method to measure Integrin α6B protein levels in young and aged mouse mammary luminal and basal cells. Our study provides the first evidence that aged CD49f^{hi} cells, particularly those expressing α6B exhibit increased cell proliferation potential, revealing a potential target for breast cancer prevention.

#120 Developing a novel intra-portal stem cell hydrogel carrier system for enhancing liver remnant hypertrophy and improving surgical eligibility for hepatocellular carcinoma: preclinical assessment in a murine model of portal vein blockade.

Dominic Karl M. Bolinas, Allan John R. Barcena, Archana Mishra, Marvin R. Bernardino, Steven Y. Huang, Marites P. Melancon

The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Hepatocellular carcinoma (HCC) is definitively treated with surgical resection of the affected lobe. However, 32% of patients are ineligible due to insufficient future liver remnant, which increases the risk of post-hepatectomy liver failure. To address this, portal vein blockade with mesenchymal stem cell (MSC) augmentation is used to induce pre-operative liver hypertrophy. However, 20-30% of patients fail to achieve adequate growth due to the rapid washout of MSCs from the liver. Therefore, we pioneered the use of hydrogels as stem cell carrier systems to enhance the retention, survival, and efficacy of MSCs in the liver to maximize hypertrophy.
Materials and Methods: MSCs were loaded in 1.5% sodium alginate solution and cross-linked with $CaCl_2$ to form hydrogels. The biocompatibility of the hydrogels and the release of MSCs were evaluated for 2 weeks. For in vivo modeling, portal vein blockade was achieved via left portal vein ligation (PVL) in cirrhotic Sprague-Dawley rats, effectively cutting off circulation into the ipsilateral lobe. The treatment groups ($n \geq 4$) are untreated control, PVL (surgery only), PVL+MSC (surgery with intraportal $1x\ 10^6$ MSCs injection), and PVL+MSC+hydrogel (surgery with intraportal injection of hydrogel carrier system loaded with 1×10^6 MSCs). The treatment effect was monitored using CT volumetry and liver tests. After two weeks, the animals were sacrificed and livers were collected for liver growth calculation, collagen staining, and MSC immunostaining. Statistical significance is defined as $p<0.05$.
Results: The hydrogel carrier system showed excellent biocompatibility by maintaining high MSC viability (89.0 ± 3.0 %) for 2 weeks. The system demonstrated an initial burst release over 7 days (64.6 ± 4.5%) followed by a more gradual release up to 2 weeks (87.0 ± 2.0%), which is ideal for the controlled delivery of therapeutic MSCs. On CT volumetry, PVL+MSC+hydrogel showed the highest liver growth among the treatment groups at 79.61% from baseline. Furthermore, PVL+MSC+hydrogel improved serum liver markers, such as AST, ALP, and ALT, compared to the PVL and PVL+MSC. On collagen staining, PVL+MSC+hydrogel revealed the highest reduction in fibrosis at 27.4%. Lastly, MSC retention with the alginate hydrogel carrier system in the liver remnant was 41.8% higher than PVL+MSC.
Conclusion: We successfully developed a stem cell hydrogel carrier system with ideal physicochemical and biological properties. The cell-loaded carrier system allowed the improvement of the structure and function of the liver. This is crucial for sustaining therapeutic and regenerative effects of MSCs for liver hypertrophy. Adapting this technology will enhance future liver remnant growth and thus, improve survivability among patients with HCC.

#121 Iqgap3 and Myc interaction regulates damaged stomach repair and early gastric carcinogenesis.

Junichi Matsuo[1], Mitsuhiro Shimura[1], Jungwon Lee[1], Linda S. H. Chuang[1], Wei Peng Yong[2], Yoshiaki Ito[1]

[1]Cancer Science Institute of Singapore, National University of Singapore (NUS), Singapore, Singapore,[2]National University Cancer Institute, National University Health System, Singapore, Singapore

The gastrointestinal tract is frequently subjected to tissue damage caused by various environmental stressors. Adult stem cells conduct tissue repair through regenerative programs with striking parallels to carcinogenesis, implying that dysregulated repair mechanisms initiate cancer development. Previously, we identified Iqgap3 as a marker of rapidly proliferating stem cells within the isthmus of gastric glands, a region essential for maintaining tissue homeostasis. Following tissue injury, we observed upregulation of Iqgap3 expression and activation of Myc signaling pathways, particularly within the fully differentiated chief cell population. Given that Myc is a major oncoprotein, our findings implicate Iqgap3 as a critical mediator in the stomach repair process and carcinogenesis. To understand how the role of Iqgap3 in tissue repair may be hijacked for carcinogenesis, we developed a conditional knockout (cKO) mouse model that attenuates Iqgap3 expression in gastric epithelial cells. Tissue damage and Iqgap3 deletion were induced by high-dose tamoxifen (HDT) treatment. Iqgap3-cKO mice were markedly compromised in tissue repair, exhibiting reduced cellular proliferation and chief cell population even one month after tissue injury. Transcriptomic analyses revealed that Iqgap3 deficiency suppressed the Myc signaling pathway and stem cell activity in the stomach, indicating a causal link between Iqgap3 and Myc during tissue regeneration. Furthermore, Iqgap3 depletion in oncogenic KrasG12D-induced metaplasia mouse model and KrasG12D-induction with Apc-depleted dysplasia mouse model protected against formation of metaplasia and dysplasia. Mechanistically, Iqgap3 deficiency led to reduced expression of neoplastic factors, such as CD44, Aqp5 and Trop2. Interestingly, Myc phosphorylation was attenuated in Iqgap3-cKO mice. We further showed that Iqgap3 directly interacted with Myc, which reinforces a role of Iqgap3 in enhancing Myc activity. Our findings highlight the critical roles of the Iqgap3-Myc axis in the regulation of stem cell activity, gastric tissue regeneration and precancerous metaplasia and dysplasia development. These insights provide a mechanistic framework for understanding the intersection of tissue repair and early carcinogenic processes.

#122 Novel role of SLC22A3 in serotonin transport and subsequent regulation of the pancreatic cancer stemness machinery.

Nivedeta Krishna Kumar, Bhuvaneshwari Seshadri, Venkatesh Varadharaj, Neelanjana Gayen, Palanisamy Nallasamy, Zahraa Wajih I. Alsafwani, Kirtana Arikath, Annant Bir Kaur, Surinder K. Batra, Moorthy P. Ponnusamy

Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE

Cancer stem cells (CSCs) are a small subpopulation within tumors that possess self-renewal and differentiation capabilities, driving tumor recurrence, therapy resistance, disease aggressiveness, and metastasis. In pancreatic cancer (PC), the mechanisms governing CSC self-renewal remain poorly understood, despite their critical role in malignancy. Emerging evidence indicates that normal embryonic and adult progenitor stem cells share molecular characteristics with CSCs, suggesting that early pluripotency programs may be reactivated during oncogenesis, contributing to cancer aggressiveness. In this study, we investigated novel stemness regulators that drive CSC self-renewal in PC. By performing computational analyses of gene signatures shared between embryonic stem cells, CSCs, and PC cells using publicly available datasets, we identified several putative stemness-associated genes, including SLC22A3/OCT3. Our results reveal that SLC22A3/OCT3 is highly expressed in CSC sub-type population and pancreatic tumor tissues and organoids derived from Kras; PdxCre (KC) and Kras; p53; PdxCre (KPC) mouse models, while its expression is minimal or absent in normal pancreatic tissues. Functional studies demonstrated that knockdown (KD) of SLC22A3/OCT3 in PC cell lines significantly reduced spheroid size in serum-free 3D cultures, indicating a decline in the CSC population. Flow cytometry further confirmed a marked reduction in the side population (SP) fraction in SLC22A3/OCT3 KD clones compared to controls. *In vivo*, SLC22A3/OCT3 depletion led to reduced tumor burden and impaired oncogenic dedifferentiation, a hallmark of CSCs in PC. SLC22A3/OCT3, a transmembrane transporter, facilitates the uptake and efflux of organic cations, including monoamine neurotransmitters such as serotonin, dopamine, and norepinephrine. Interestingly, serotonin supplementation increased stemness potential in PC cells, but this effect was absent in SLC22A3/OCT3 KD clones, implicating serotonin transport as a key mechanism in CSC regulation. Mechanistically, we propose that SLC22A3/OCT3 regulates serotonin transport in pancreatic CSCs, activating downstream pathways that enhance transcription factor binding and upregulate self-renewal and pluripotency-related genes. This process may involve serotonin-mediated epigenetic modifications, including serotonylation, to maintain CSC stemness and drive pancreatic tumor aggressiveness. Our findings highlight SLC22A3/OCT3 as a critical regulator of serotonin-driven stemness in PC. Understanding its role in CSC biology may provide novel insights into pancreatic cancer pathogenesis and open avenues for the development of targeted therapies aimed at disrupting CSC-mediated tumor progression.

#123 Induced natural killer cells: A next-generation platform for allogeneic immune cell therapies.

H.-S. Kim, J. Kim, B. Seol, J. Choi, J.-Y. lee, **Y. Cho**;
Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

Background: Natural Killer (NK) cells hold significant promise for effective and safe allogeneic immune cell therapies, primarily due to their ability to selectively target and eliminate cancer and other abnormal cells. Key advantages, including off-the-shelf availability and a low risk of graft-versus-host disease, cytokine release syndrome, and immune effector cell-associated neurotoxicity syndrome, make them ideal candidate for immunotherapy. However, conventional NK cell sources derived from blood or stem/progenitor cells face challenges such as high heterogeneity, limited scalability, and high production costs, underscoring the need for innovative and robust NK cell sources.

Methods: We previously developed induced NK (iNK) cells *via* OSKM transcription factor-mediated direct reprogramming as an alternative allogeneic NK cell source. To explore their therapeutic potential, we compared the phenotypic and functional characteristics of iNK cells, including receptor expression, cytotoxicity, degranulation, cytokine production, and antibody-dependent cellular cytotoxicity (ADCC), with those of control NK cells (PBMC-NK cells and NK-92). Furthermore, CRISPR/Cas9 screening was performed on pancreatic cancer (PC) cells using a human whole-genome dual-gRNA knockout library to identify genes critical for NK cell-mediated targeting and killing.

Results: iNK cells demonstrated high purity ($CD56^+CD16^+$, 93.1±3.4%) and homogeneity, along with elevated expression of activating receptors (CD69, NKG2D, DNAM-1) and natural cytotoxicity receptors (NKp30, NKp44, and NKp46) while showing reduced KIR expression (2DL1, 2DL2 and 3DL1) compared to control NK cells. Functionally, iNK cells displayed robust cytotoxicity against a broad range of human solid cancers, including PC, through cytokine secretion (IFN-γ, granzyme B, and TNF-α), CD107a degranulation, and ADCC. CRISPR/Cas9 screening identified 500 depleted genes in PC cells, with key targets such as EIF2AK3, PRKAA1, IRAK3, and NEK2, validated as contributors to NK cell-mediated cytotoxicity.

Conclusions: iNK cells represent a scalable and homogeneous alternative to conventional NK cell sources, overcoming limitations such as donor dependency, variability, and production inefficiencies. With their enhanced cytotoxic potential and the identification of key gene targets critical for NK cell-mediated killing, induced NK cells provide a robust and promising platform for the development of “off-the-shelf” allogeneic immunotherapies.

#124 Cell state regulation in early colorectal cancer through transcription factor and chromatin action.

Sweta Sharma, Alireza Lorzadeh, George Ye, Unmesh Jadhav

Department of Stem Cell Biology and Regenerative Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA

Colorectal cancer (CRC) is the second leading cause of cancer-related deaths in the United States, despite established treatment options and knowledge of causal mutations. CRC involves significant rewiring of cellular chromatin alongside mutational accumulation, which fuel aberrant cancer transcriptional programs. Many developmental gene regulatory mechanisms are also activated during early tumorigenesis. However, details of molecular controls in early tumor development and evolution are not fully understood. Mutations in tumor suppressor APC gene are essential for cancer initiation in the majority (>70%) of CRC patients. We ablated Apc in the mouse gastrointestinal stem cells resulting in their transformation leading to adenoma formation. We purified the transformed epithelial cells in adenoma using FACS and performed single nuclei ATAC and RNA sequencing to generate paired chromatin accessibility and transcriptional profiles using 10X genomics single cell multiome (scMultiome-seq) platform. By profiling the expression of known intestinal cell markers and comparing adenoma cells to wild type cells, we identified cell Apc-null cell populations with transcriptomic and chromatin landscape distinct from those of the wild-type cells. We identified differentially accessible genomic regions among wild-type and adenoma cells, the majority of which were located outside of gene promoters. This suggested changes in the cis-regulatory gene enhancer circuits potentially through altered transcription factor activity. MOTIF analysis using the differentially accessible peaks in adenoma cells revealed significant enrichment of several development specific transcription factors (TFs), including Sox17 and Foxa2. Such reappearance of developmental TFs in early adenomas may drive formation of unique cell states and cancer progression. Interestingly, immunostaining for Sox17 at various stages of adenoma development revealed heterogeneous enrichment within adenomas suggesting its involvement in early adenoma evolution. By profiling the histone modifications and transcription factor binding through chromatin immunoprecipitation sequencing, Sox17 directly binds to uniquely accessible enhancers in adenoma cells and promotes the activation of genes associated with cell-cell adhesion and migration. Our results using single-cell transcriptomic and epigenomic approaches reveal novel cell states formed during the birth and early growth of adenomas and how transformed cells utilize transcription factor activity to alter the cellular enhancer landscape as well as cellular properties during tumor evolution.

#125 Targeting colorectal cancer stem cells through GUCY2C expression.

Jess Kopenhaver, Scott A. Waldman, Adam E. Snook, Trevor Baybutt, Lara Cheslow, Ross Staudt, Jasmine Alvarez

Thomas Jefferson University, Philadelphia, PA

The intestinal cell surface receptor GUCY2C is universally over-expressed by colorectal tumors. Loss of expression of the intestinal hormones regulating GUCY2C silences this signaling pathway which dysregulates the cell cycle and DNA damage repair contributing to intestinal tumorigenesis. Thus, reconstituting GUCY2C activity with oral hormone replacement is being explored in clinical trials as a novel chemoprevention approach for colorectal cancer (CRC). Moreover, GUCY2C is being explored in clinical trials as an immunotherapeutic target reflecting its universal over-expression by metastatic CRC tumors. Here, we explore the expression and activity of GUCY2C in tumor stem cells (SCs) to define its potential as a therapeutic target to prevent therapeutic escape and recurrence in colorectal cancer. CRC-SCs were isolated from a library of patient-derived xenografts (PDXs) and in vitro cell lines by flow cytometry using aldehyde dehydrogenase (ALDH) activity and EpCAM expression. The $ALDH^{HI}EpCAM^{HI}$ CRC-SC fraction comprised ~1-10% of bulk tumor cells, and expressed the cardinal features of cancer SCs, including non-adherent tumor sphere and colony formation in vitro and tumor formation in immunodeficient mice compared to $ALDH^{LO}EpCAM^{HI}$ differentiated tumor cells. $ALDH^{HI}EpCAM^{+}$ SCs universally express GUCY2C mRNA and protein, and expression levels are positively correlated to bulk PDX tumors of origin. GUCY2C is expressed on the surface of $ALDH^{HI}EpCAM^{+}$ SCs, which respond to the GUCY2C agonist linaclotide (*Linzess™*) by producing and secreting cyclic (c)GMP. Unexpectedly, $ALDH^{HI}EpCAM^{+}$ SC are hyper-responsive to linaclotide, and their hormone-induced cGMP accumulation is 5- to 10-fold greater than $ALDH^{LOW}EpCAM^{HI}$ differentiated tumor cells. Universal expression, with amplified signaling, in CRC-SCs suggest that GUCY2C might be utilized as a therapeutic target. Indeed, linaclotide induces a durable block of proliferation in, and expansion of, $ALDH^{HI}EpCAM^{+}$ SCs, quantified by colony formation and expression of Ki67 in vitro. Similarly, $ALDH^{HI}EpCAM^{+}$ CRC-SCs are completely eliminated by GUCY2C-targeted chimeric antigen receptor (CAR) T cells in vitro. Taken together, these observations suggest that, beyond bulk tumor cells, GUCYC may have dual utilities as a therapeutic target in CRC-SCs. Thus, amplified GUCY2C signaling could be activated by agonists, like linaclotide, to suppress SC persistence and resistance to chemotherapy and potentially shift them to a differentiated phenotype susceptible to treatment. Moreover, metastatic CRC-SCs could be eliminated by GUCY2C-targeted immunotherapies, like CAR T cells, to prevent tumor persistence and recurrence.

#126 Targeting PAR1 in an aggressive blood cancer: A novel strategy to eradicate leukemic stem cells.

Nunki Hassan, Kaitlyn Trajcevski, Jenny Wang

University of Sydney, Camperdown, Australia

Acute Myeloid Leukemia (AML) remains a challenging hematologic malignancy with poor prognosis due to the persistence of therapy-resistant leukemic stem cells (LSCs). Current therapeutic strategies often fail to completely eradicate LSCs, leading to relapse. One promising therapeutic target is protease-activated receptor 1 (PAR1), a G-protein-coupled receptor selectively expressed in LSCs. Our research investigates the potential of targeting PAR1 to eliminate LSCs and improve treatment outcomes in AML. High PAR1 expression in a cohort of AML patients had a reduced overall survival (n=163, P<0.001). Lentiviral transduction of PAR1 knockdown and overexpression in mouse LSCs was established. PAR1 and its downstream gene and protein targets were validated utilising RT-qPCR and Western blot, respectively. PAR1 function was assessed with knockdown and PAR1 inhibitor treatment independently, which concurrently reduced colony formation, increased apoptosis, induced cell differentiation, and decreased expression of key self-renewal targets (i.e., ß-catenin and transcriptional factor Tcf7L2) and Gα subunits in LSCs. PAR1 overexpression in pre-LSCs was consistent with knockdown studies, demonstrating significantly increased colony formation and increased expression of key self-renewal genes (i.e. *Tcf7l2*, *Ccnd1*). PAR1 inhibitor showcased a dose and time-dependent early and late-stage apoptosis in LSCs, while in parallel reduced self-renewal signature markers and increased pro-apoptotic markers (i.e., cleaved caspase 3, Txnip). Murine models included intravenous transplantation of LSCs and pre-LSCs to evaluate PAR1 function *in vivo*. Overexpression of PAR1 in pre-LSC accelerated leukemogenesis compared to controls *in vivo*. Murine models demonstrated a marked reduction in leukemic burden in PAR1 knockdown mice, with prolonged survival compared to controls further enhancing LSC eradication and mitigating relapse *in vivo*. This innovative study is the first to establish PAR1 as a critical regulator of LSC self-renewal and survival, offering a potential breakthrough in AML therapy. These findings support the clinical development of PAR1 inhibitors as a next-generation treatment in eradicating LSCs, with the potential to overcome current therapeutic limitations and reduce relapse rates in AML patients, ultimately uniting cancer biology and therapeutic innovation.

#13 A disease-linked mutant reveals a critical N-terminal influence of SOX2 on translation.

Meric Ataman[1], Nitish Mittal[1], Hui Wang[2], Sergiy Velychko[3], Tata Nageswara Rao[4], Jordan Loliger[5], Jonas Lotscher[5], Sarah Roffeis[5], Christoph Hess[6], Hans R. Scholer[7], Ed Hurt[8], Matthias P. Wymann[5], Mihaela Zavolan[1], Claudia Lengerke[9], **Thorsten Schaefer**[5]

[1]University of Basel, Biozentrum, Basel, Switzerland,[2]Shanghai University of Medicine and Health Sciences, Shanghai, China,[3]Harvard Medical School, Department of Genetics, Boston, MA,[4]Cantonal Hospital St. Gallen, Medical Research Center & University of Bern, Institute of Pharmacology, St. Gallen/Bern, Switzerland,[5]University of Basel & University Hospital Basel, Department of Biomedicine, Basel, Switzerland,[6]University of Basel & University Hospital Basel, Department of Biomedicine & University of Cambridge, Department of Medicine, CITIID, Cambridge, United Kingdom,[7]Max Planck Institute for Molecular Biomedicine, Munster, Germany,[8]University of Heidelberg, Biochemistry Center Heidelberg, Heidelberg, Germany,[9]University Hospital Tubingen, Internal Medicine II, Tubingen, Germany

Changes in cell fate are primarily attributed to the spatio-temporal influence of transcription factors, but the ultimate level of expression control remains translation. Some transcription factors (such as YB-1, RfaH and Bicoid) play complementary roles in translation, and we have recently reported that also the pluripotency-inducing transcription factor SOX2 has ribosomal affinity and modulates transcript selection (*Schaefer et al., Cell Reports 2024*). Although this post-transcriptional layer of regulation mainly reflects SOX2‘s C-terminal influence in the cytosol, we here present evidence for a further involvement also of N-terminal SOX2 in translation.
Ribosomal affinity within N-terminal parts of SOX2 first showed in domain separation analyses in breast cancer-derived cell lines. However, although SOX2 fragments (1-119) and (1-179) co-sedimented with 60S ribosomes in sucrose density gradients, they imposed no translational fingerprint in polysome profiles as otherwise seen for full-length or C-terminal SOX2. Nonetheless, the synthesis of bulk protein (indicated by OPP incorporation into nascent polypeptides) did change and hundreds of mRNAs experienced a translational regulation upon SOX2 N-terminus induction. Among these, 65 differentially regulated factors stood out as co-regulated by full-length or N-terminal SOX2, but unaltered or counter-regulated in SOX2 C-terminus induced cells. Overrepresentation analyses within STRING and TISSUES databases indicated a preferential expression in the reproductive tract for 35 of these hits, and also under more stringent inclusion criteria, a functional assignment to the reactomes mitosis and reproduction was reconfirmed. In phenotypic correlation, we indeed noted a co-regulation of cell growth in full-length or N-terminus induced T47D and MDA-MB468 reporter cells, while the C-terminus recapitulated the proliferation rate of control cells. Real-life evidence for a SOX2 N-terminal contribution to translation, however, came from a disease-linked human mutant, SOX2(L97P), originally identified in the context of eye development. When expressed in reporter cells the L97P mutation severely impaired 60S binding, so that neither the polysome profile nor the phosphorylation status of RPS6 changed as otherwise seen for wild-type SOX2.
Our study highlights that, despite decades of preceding research, the protein biochemistry of even key pluripotency factors remains underexplored and still holds unforeseen learning. In summary, we present here extended evidence for a translational significance of SOX2 that (i) involves N-terminal contributions, (ii) arises in physical contact with ribosomes, and (iii) takes influence on cell proliferation. A better understanding of the underlying molecular principles may thus pave the way to a targeted control of cell division, selectively in SOX2-driven reprogramming and cancer.

#130 Matrix remodeling promotes macrophage recruitment in breast cancer.

Ioannis K. Zervantonakis, Youngbin Cho

University of Pittsburgh, Pittsburgh, PA

A high number of tumor-associated macrophages (TAM) in breast tumors is associated with poor patient outcomes. Furthermore, activation of myosin II, a key cytoskeletal regulator, has been identified as a predictor of distant metastasis in triple negative breast cancer (TNBC). However, the relationship between myosin II activation in TNBC cancer cells and macrophage motility remains poorly understood. Here we employed a novel 3D microfluidic model of tumor-macrophage co-culture to study macrophage infiltration toward cancer cells with high spatiotemporal resolution and evaluation of extracellular matrix remodeling. Using a panel of TNBC cell lines we found that cancer cells with higher macrophage recruitment potential in a 3D matrix exhibited higher levels of myosin II activity. We found that macrophage infiltration was higher in decellurized extracellular matrices seeded with the high-macrophage recruiting cancer cell line EMT6 compared to the low-macrophage recruiting cancer cells E0771. Functional contractility analysis using traction microscopy revealed that EMT6 exerted higher matrix displacements compared to E0771 that could be suppressed by pharmacologically blocking myosin II in cancer cells or genetic silencing of the myosin regulatory light polypeptide 9. Consistent with these suppressive effects of targeting actomyosin contractility on matrix remodeling we also found that macrophage recruitment was reduced. These studies reveal the critical role of cancer cell-driven matrix remodeling in promoting macrophage infiltration that can be therapeutically targeted to revere the establishment of a macrophage-rich pro-tumorigenic tumor microenvironment.

#131 PDAC tumor growth suppression by targeting the CD49b collagen receptor through modulating the CD8$^+$ T cell infiltration.

Ibrahim R. Eissa, Motaz Qadan, Sonia Cohen, Genevieve M. Boland, Tatyana Sharova, Kenneth K. Tanabe

Surgery Department, Gastrointestinal & Oncologic Surgery Division, Massachusetts General Hospital /Harvard Medical School, Boston, MA

Background:Pancreatic ductal adenocarcinoma (PDAC) has a desmoplastic extracellular matrix enriched with collagen type I (COL1) and poor CD8$^+$ tumor-infiltrating lymphocyte (TIL) infiltration. CD49b, a key collagen receptor, has been implicated in PDAC progression, but its role in immune exclusion remains unclear.
Objective: This study investigates the functional role of CD49b in modulating anti-tumor immune responses and collagen architecture in PDAC, while exploring its therapeutic potential against PDAC. Methods: Collagen receptors expression in PDAC was analyzed using flow cytometry on treatment-naïve human PDAC samples, Western blotting on PDAC cell lines including KPC cell lines, immunofluorescence on both human and mouse specimens, and analysis of single-cell RNA sequencing (scRNA-seq) on KPC models and human PDAC sample databases. The ITGA2 (CD49b) receptor was knocked out in KPC and Pan02 cells using CRISPR-Cas9. Tumor growth was evaluated in immunocompetent and immunodeficient mouse models, with or without CD8+ T cell depletion. Tumor-infiltrating lymphocytes (TILs) were assessed using FACs, and downstream signaling pathways were analyzed using RNA sequencing and Western blotting. Collagen fiber alignment was evaluated using CT-FIRE. Functional experiments included FAK overexpression to rescue signaling in CD49b-knockout models. Additionally, the consequence of blocking CD49b in vivo was examined.
Results: CD49b was selectively expressed in PDAC cancer cells in both mouse and human specimens. Loss of CD49b impaired tumor adhesion to collagen and significantly suppressed tumor growth in an immunocompetent model by increasing activated intratumoral CD8$^+$ T cell infiltration. Experimental depletion of CD8$^+$ T cells abrogated tumor suppression in CD49b-deficient tumors, demonstrating the importance of CD8$^+$ T cells in the anti-tumor response. Regarding affected signaling pathways, CD49b loss disrupted focal adhesion kinase (FAK) and pFAK signaling, increased CXCL10 chemokine expression, and altered collagen fiber alignment, creating a microenvironment permissive to immune infiltration. A negative correlation between CD49b expression and CD8$^+$ T cell infiltration was observed between the tumor core and edge. FAK overexpression restored tumor growth in CD49b-deficient tumors. Furthermore, vatelizumab, a CD49b-blocking antibody, effectively inhibited PDAC-collagen adhesion and reduced tumor growth in hCD49b-expressing KPC tumor.
Conclusion: This study reveals CD49b as a potent mediator of immune exclusion and collagen remodeling in PDAC and highlights its role in modulating FAK signaling and collagen alignment. Targeting CD49b , such as with vatelizumab, represents a novel and promising approach to overcome immune resistance and improve therapeutic efficacy in PDAC.

#132 Collagen I triggers a GCN2-mediated integrated stress response to promote cancer cell survival.

Mark Ellie De Boton Alonzo[1], Ethan Jadon Subel[2], Hongbo (Beth) Gao[2], Stephen QR Wong[2], Yung Hsing Huang[2], David Chang[2], Grace Wong[2], Mustafa Karabicici[3], Sung Yun Jung[4], Fotis Nikolos[2], Keith Syson Chan[2]

[1]Graduate School of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Department of Urology, Houston Methodist Research Institute, Houston, TX,[3]Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA,[4]Baylor College of Medicine, Houston, TX

Bladder cancer (BLCA) is the 6th most commonly diagnosed cancer in the US. Despite recent advances, BLCA has a high recurrence rate. Increased deposition of the extracellular matrix Collagen I (Col I) is a hallmark of cancer progression and correlates with poor patient survival in BLCA. Recent studies have showcased the dynamic nature of Col I, which signals key pro-tumoral processes like immune evasion and metastasis. Interestingly, Col I limits nutrient access and oxygen to adjacent tumors in the tumor microenvironment. Cancer cells adapt to disadvantageous conditions by activating pathways such as the integrated stress response (ISR) to downregulate mRNA translation to promote survival. High activity of ISR and its related proteins in cancer cells also increase chemoresistance, dormancy and metastasis. How Col I plays a role in activating pro-survival ISR in BLCA remains to be investigated. In this study, we describe the direct role of Col I in exploiting ISR in BLCA, increasing its tumorigenic capacity. We uncover that Col I rapidly downregulates global mRNA translation by inducing ISR, while promoting spheroid size *in vitro* and tumor growth *in vivo*. Mechanistically, Col I induces intracellular amino acid deprivation thereby activating GCN2, an important amino acid sensor and a key kinase mediating ISR. Inhibition of GCN2 and subsequent ISR activity is an effective therapeutic target in multiple cancer types. Here, we show pharmaceutical inhibition of GCN2 disrupts ISR, rescuing translation while decreasing Col I-induced spheroid and tumor growth. Clinically, analysis of the TCGA BLCA dataset reveal both high expression of ISR-associated genes and a high GCN2-mediated signaling pathway score correlate with poor overall survival. GCN2 and ISR pathway scores also correlate with high Col I expression, further indicating their involvement in promoting BLCA tumorigenesis. These findings unravel a novel mechanism by which Col I utilizes the ISR pathway to promote BLCA tumorigenesis and provides a potential therapeutic targets for BLCA patients in the future.

#133 From waste to nutrient: ammonia's recycling by fibroblasts to sustain collagen production.

Julien Guillard, Shan Cao, Marta Storl-Desmond, Brandon Faubert, Simon Schworer

Section of Hematology/Oncology, Department of Medicine, Biological Sciences Division, The University of Chicago, Chicago, IL

Collagen and other extracellular matrix (ECM) proteins are highly abundant in tumors, including pancreatic and breast cancers, and are involved in tumor progression and therapy resistance. Given its amino acid composition, collagen production imposes unique biosynthetic demands on cancer-associated fibroblasts (CAFs), particularly a high need for proline. Understanding how CAFs meet the metabolic requirements for collagen synthesis could provide opportunities to modulate ECM production in cancer. CAFs synthesize proline from glutamine; however, glutamine and other nutrients are often depleted in poorly perfused tumors. How CAFs maintain collagen synthesis under such nutrient-limiting conditions remains unclear, and addressing this question may reveal unique metabolic vulnerabilities in cancer. Previous work from our laboratory showed that CAFs recycle extracellular lactate as an alternative carbon source to sustain non-essential amino acid (NEAA) biosynthesis for collagen production. However, NEAA synthesis also requires nitrogen, and how CAFs fulfill the nitrogen demands for NEAA synthesis under nutrient limitations remains poorly understood. To address this gap, this study aims to identify the nitrogen source used by CAFs for collagen production. To define the nitrogen source for collagen synthesis, we performed metabolic tracing of potential nitrogen donors using fibroblasts stimulated to deposit ECM in the presence of 15N-labeled nutrients. Stable isotope tracing with GC-MS was used to quantify 15N-labeled hydroxyproline in the decellularized and hydrolyzed ECM. We further used CRISPR/Cas9 to delete rate-limiting enzymes to elucidate the pathways involved. Our findings indicate that ammonia, a waste product of cellular metabolism, is recycled for NEAA biosynthesis. Ammonia’s contribution to collagen was dependent on the concentrations of glutamine and ammonia, and could rise to up to 50% of nitrogen in ECM hydroxyproline. All tested fibroblast cell lines exhibited similar ammonia-derived nitrogen labeling. Through genetic and chemical inhibition, we identified glutamate dehydrogenase (GDH) as a key enzyme in ammonia recycling via reductive amination. In conclusion, ammonia, a waste product of cancer metabolism, can be recycled by CAFs to sustain collagen production. This discovery highlights the metabolic plasticity of fibroblasts to maintain ECM synthesis under nutrient-limited conditions and offers new avenues for targeting adaptive pathways to reduce CAF-mediated pro-tumoral effects.

#134 Integrating spatial transcriptomics and second harmonic generation imaging of collagen identifies genes associated with discoidin domain receptor 1 and collagen alignment in colorectal cancer.

Maxwell Stuart Hamilton[1], Harsimran Kaur[2], Alan J. Simmons[2], Ken S. Lau[2], Ambra Pozzi[3], Robery J. Coffey[3]

[1]Cancer Biology, Vanderbilt University, Nashville, TN,[2]Vanderbilt University, Nashville, TN,[3]Vanderbilt University Medical Center, Nashville, TN

Immune checkpoint blockade (ICB) has been shown to be an effective treatment for colorectal cancers (CRCs) highly infiltrated by $CD8^+$ T cells. However, there is a paucity of $CD8^+$ T-cell infiltration in the majority of CRCs. Tumors with highly aligned collagen fibers have been shown to have reduced $CD8^+$ T-cell infiltration. We previously identified a four-gene signature associated with T-cell exclusion in CRC. One of the genes, Transforming Growth Factor Beta Induced (TGFBi), is known to be involved in extracellular matrix regulation. Another, Discoidin Domain Receptor 1 (DDR1), promotes collagen fiber alignment in breast cancer. To determine if TGFBi and DDR1 are associated with collagen alignment in CRC, as well as to identify additional genes involved in collagen alignment, we have developed a method to spatially resolve collagen fiber alignment and integrate it with spatial transcriptomics. To do this, 30 µm thick CRC sections are imaged using a Nikon AX multiphoton microscope by second harmonic generation imaging, which permits label-free imaging of collagen fibers. Spatial heatmaps of the collagen alignment are generated from the resulting images. Spatial transcriptomics is performed on a serial tumor section using the Visium v2 platform and the gene expression matrix is integrated with the collagen alignment heatmap data. As proof-of-principle, two CRC tumors have been analyzed using this method. Highly aligned regions were found to be associated with expression of genes involved in extracellular matrix organization, keloidal collagen and specific fibroblast subtypes. The genes that correlate with collagen alignment will be confirmed at the protein level by multiplexed immunofluorescence on serial sections. This method will provide a rich dataset permitting elucidation of the complex interactions between T-cell exclusion, gene expression and collagen fiber alignment and may support the discovery of new strategies to overcome immune exclusion in CRC.

#135 Myosin 10 suppresses integrin α6β4 expression and drives invasive force generation in Non-small cell lung cancer leader cells.

Raaven Goffe[1], Maia Vierengel[2], Hiroaki Ogasawara[2], Henry Claussen[3], Robert A. Arthur[3], Khalid Salaita[2], Adam I. Marcus[4]

[1]Emory University School of Medicine, Atlanta, GA,[2]Department of Chemistry, Emory University, Atlanta, GA,[3]Emory Integrated Computational Core, Emory University, Atlanta, GA,[4]Winship Cancer Institute, Atlanta, GA

A major contributor to lung cancer mortality is the late stage at which it is diagnosed. Currently, 5-year survival rates for persons with regional and distant lung cancer metastasis at diagnosis are 29.7% and 4.7%, respectively, compared to 56.3% for persons with localized (non-metastatic) disease. Identifying and therapeutically targeting drivers of lung cancer metastasis can improve overall survival, but few models exist where subpopulations with stable high and low invasive potentials can be easily and reliably isolated. Previous work from our group isolated two stable subpopulations from the H1299 Non-Small Cell Lung Cancer (NSCLC) cell line, highly invasive cells at the front of a pack termed Leaders, and significantly less invasive cells that trail behind termed Followers. H1299 Leaders and Followers have heterogenous transcriptional profiles, biomarkers, genomic methylation patterns, metabolic states, and morphologies. H1299 Leaders express high levels of Myosin 10 (MYO10), an actin-bound myosin motor protein that functions in filopodia and drives collective invasion. To investigate how *MYO10* contributes to Leader cell biology and invasion, we generated MYO10 knockout single-cell derived Leader clones utilizing CRISPR-Cas9. Three (3) $MYO10^{-/-}$ knockout and two (2) $MYO10^{+/+}$ wildtype single-cell derived clones were generated suggesting that *MYO10* is not essential for Leader cell survival. In validated clones, WST-8 assays confirmed that proliferation was slightly decreased in $MYO10^{-/-}$ clones relative to their $MYO10^{+/+}$ controls. Bulk RNA sequencing demonstrated distinct transcriptional profiles of $MYO10^{-/-}$ and $MYO10^{+/+}$ clones with gene set enrichment analysis revealing activation of extracellular matrix and external encapsulating structure pathways in $MYO10^{-/-}$ clones relative to controls. Western blot of integrin subunits showed increased expression of α6 and β4 subunits with decreased β3 expression in MYO10 knockout clones. Further, DNA-based tension gauge tether (TGT) probes were used to assess cell spread area and force generation, functional readouts of integrin activity. Of note, $MYO10^{-/-}$ clones demonstrate dramatically reduced cell area and tension forces when compared to $MYO10^{+/+}$ clones. Taken together, these data suggest MYO10 supports integrin-based adhesion and force generation in Leader clones which likely contributes to the highly invasive H1299 Leader cell phenotype. This works serves as a foundation for future studies which aim to elucidate MYO10-dependent mechanisms that drive metastasis in NSCLC.

#136 Discerning the role of the extracellular matrix on epithelial-to-mesenchymal transition and invasiveness of glioblastoma multiforme using a xeno-free 3D hydrogel system.

Alejandra Ferrer Diaz, John Huang

TheWell Bioscience, Monmouth Junction, NJ

The invasive nature of cancer, driven by epithelial-to-mesenchymal transition (EMT), is a critical process influenced by external cues from the tumor microenvironment, such as extracellular matrix (ECM) composition. The ECM primes cells for EMT and metastasis, making it a key topic in understanding disease progression. For example, in glioblastoma multiforme (GBM), a grade IV astrocytoma and the most aggressive brain malignancy, EMT contributes to the highly invasive behavior of tumor cells, limiting patient survival to less than five years. Thus, developing *in vitro* models that can accurately examine how the ECM contributes to GBM invasiveness and survival is vital. Currently, most *in vitro* studies evaluating cell invasion and EMT are conducted in two-dimensions (2D), disregarding the microenvironment's complexity and the ECM role in such processes. The limited case studies on three-dimensional (3D) cancer invasion and EMT models heavily rely on animal-based ECM, such as Matrigel or collagen. These matrices, due to their inherent instability, introduce variability, compromise experimental consistency, and make it challenging to draw robust conclusions. In this study, we use the synthetic and biofunctional VitroGel® system to evaluate cell invasion and EMT in 3D GBM models. The fully characterized VitroGel system allow us to study the effect of the mechanical strength and biochemical composition of the ECM on cell invasion and EMT. In this study, GBM spheroids were formed in an ultra-low attachment plate, and hydrogels functionalized with ligands such as RGD peptides, matrix metalloproteinases, collagen-mimetic peptides, and others were gently added to the cultures to evaluate their role in cell invasion and EMT. The findings showed that the functional ligands stimulate spheroid invasion and promote EMT, evidenced by the rapid proliferation of the spheroid and engulfment of the matrix, resulting in the formation of tumoroid-like structures. Furthermore, we evaluated whether the mechanical strength of the ECM affects spheroid invasion and EMT by adjusting the stiffness of the matrix. Indeed, we showed that less stiff matrices propel spheroid invasion and EMT, indicating that the physical properties of the ECM influence migration. Overall, this study demonstrated that using the xeno-free 3D hydrogel system is an excellent approach to evaluate cancer invasiveness and EMT, and a promising tool for drug-screening applications.

#137 Type XII collagen is elevated in serum from patients with solid tumors: A non-invasive biomarker of activated fibroblasts.

Marina Crespo-Bravo[1], Annika Hettich[1], Jeppe Thorlacius-Ussing[1], Thomas R. Cox[2], Morten A. Karsdal[1], Nicholas Willumsen[1]

[1]Nordic Bioscience, Herlev, Denmark,[2]Garvan Institute of Medical Research, Darlinghurst, Australia

Background: The tumor microenvironment (TME) and extracellular matrix (ECM) are critical to tumor progression and treatment outcomes. Collagens, the main ECM components, influence cell signaling, migration, and tumor invasion. Type XII collagen is essential for type I collagen assembly and stabilizes the ECM. It is predominantly produced by cancer-associated fibroblasts (CAFs), and its upregulation is linked to poor survival in several cancers. This study developed and validated an ELISA to measure circulating type XII collagen as a potential cancer biomarker.
Methods: A monoclonal antibody targeting the C-terminal of type XII collagen was used to develop a competitive ELISA (nordicPRO-C12) for detecting type XII collagen fragments in serum from cancer patients (n=230) and healthy controls (n=33). Type XII collagen expression was also assessed by Western blot in supernatants and lysates from CAFs and normal fibroblasts (NFs) derived from pancreas, lung, colon, and breast tissues, under both TGFβ-stimulated and non-stimulated conditions.
Results: The nordicPRO-C12 assay showed high specificity and robustness, detecting significantly elevated serum PRO-C12 levels in patients with prostate, breast, melanoma, lung, gastric, pancreatic, head and neck, and colorectal cancers ($p < 0.005$ for all). The assay effectively distinguished cancer patients from healthy controls, with high AUROCs for breast (0.95), prostate (0.92), lung (0.92), gastric (0.88), melanoma (0.83), pancreatic (0.80), and head and neck cancers (0.76). These findings were supported by COL12A1 expression data from TCGA and GTEx. Western blot analysis confirmed increased type XII collagen expression in both CAFs and NFs after TGFβ stimulation, highlighting TGFβ's role in ECM remodeling and type XII collagen regulation in cancer and normal microenvironments.
Conclusion: This study highlights PRO-C12 as a promising non-invasive biomarker for cancer detection and monitoring. The ability to quantify type XII collagen fragments provides insights into cancer progression. While these results are encouraging, further studies are required to validate PRO-C12's diagnostic and prognostic potential across cancers, potentially expanding its application to clinical practice.

#138 Lysyl oxidases suppress pancreatic cancer progression by inhibiting focal adhesion kinase signaling.

Lijuan Sun[1], Jean Albrengues[2], John E. Wilkinson[3], Sarah L. Dallas[4], Valerie M. Weaver[5], Mikala Egeblad[1], Mario A. Shields[6]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[3]University of Michigan Medical School, Ann Arbor, MI,[4]University of Missouri-Kansas City, Kansas City, MO,[5]University of California, San Francisco, San Francisco, CA,[6]Stony Brook University Renaissance School of Medicine, Stony Brook, NY

Lysyl oxidases crosslink type I collagen to promote fibrosis and cancer progression in mouse mammary tumor models. Pancreatic ductal adenocarcinomas (PDACs) are highly fibrotic and contain abundant type I collagen with elevated expression of lysyl oxidases. Indeed, inhibition of lysyl oxidases constitute an attractive anti-tumor therapeutic strategy, with several reported preclinical studies demonstrating efficacy at reducing PDAC fibrosis and progression. Yet, lysyl oxidase was first described as an anti-oncogene through its effect of directly suppressing cell transformation by mutant Ras which is present in around 90% of human pancreatic tumors. These prior studies highlight the dual functions, anti-ras and pro-fibrotic, of lysyl oxidases in pancreatic cancer. As a result, clinical trials targeting lysyl oxidase in cancers have demonstrated limited efficacy. Here we examined the effects of perturbation of lysyl oxidase activity or expression using syngeneic orthotopic transplantation models expressing mutant Ras and intravital imaging. Unexpectedly, genetic or pharmacological inhibition of lysyl oxidases increased invasion along collagen fibers and distant metastasis. Furthermore, inhibition of lysyl oxidases promoted focal adhesion kinase (FAK) activity which was required for metastasis. We found that mutant Kras status dictated lysyl oxidase-mediated suppression on FAK signaling in both mouse and human pancreatic cancer cells. These results suggest that the effect of lysyl oxidase on metastasis are dependent on signaling from Ras and FAK. These results strongly caution against inhibiting lysyl oxidases for cancers driven by mutant Ras.

#139 The nutrient-dictated ECM regulates cancer cell growth via the itga2-FAK-YAP axis.

Kristof Turan, Julien Guillard, Simon Schwoerer

University of Chicago, Chicago, IL

Pancreatic ductal adenocarcinoma (PDAC) is the third leading cause of cancer-related deaths in the United States. PDAC tumors are characterized by a dense desmoplastic stroma and altered nutrient availability that promote aggressive cancer cell behavior. A collagen-rich extracellular matrix (ECM) produced by cancer-associated fibroblasts (CAFs) is a key feature of PDAC's stroma and associated with tumor progression and therapy resistance. How altered nutrient availability and ECM production are integrated to modulate PDAC cell biology is not well understood. To address this gap, we develop a spheroid outgrowth assay on ECM produced by CAFs under altered availability of glutamine, an amino acid shown to be depleted in PDAC. We find that glutamine availability dictates the composition of CAF-derived ECM. The glutamine-dictated ECM differentially modulates PDAC cell behavior, with ECM produced under high glutamine (HQ) availability restraining PDAC cell growth but promoting PDAC cell migration. We link these phenotypes to collagen I abundance, which is depleted in ECM produced under low glutamine (LQ) availability. Mechanistically, we find that increased stiffness of HQ ECM underlies its growth restraining properties, while its activation of focal adhesion kinase (FAK) signaling in PDAC cells supports migration. Specifically, collagen I in HQ ECM binds to integrin α2 (Itga2), activating FAK and downstream YAP/TAZ signaling, both of which are required for PDAC cell migration. In contrast, LQ ECM fails to activate YAP/TAZ signaling in PDAC cells. Activation of YAP/TAZ signaling alone was sufficient to rescue PDAC cell migration on LQ ECM. These findings demonstrate that tumor nutrient availability alters ECM composition, which modulates PDAC biology via Itga2-FAK-YAP signaling.

#14 Molecular drivers of lineage bias in TP53-mutant therapy-related acute leukemias.

Diren Arda Karaoglu[1], Ibrahim Aldoss[2], Ann-Kathrin Eisfeld[3], Madina Sukhanova[4], Yasmin Abaza[4], Peng Wang[1], Melissa Tjota[1], Jeremy Segal[1], Angela Lager[1], Carrie Fitzpatrick[1], Jason Xiaojun Cheng[1], Sandeep Gurbuxani[1], Girish Venkataraman[1], Anand Ashwin Patel[1], Adam S. Duvall[1], Michael W Drazer[1], Todd C Knepper[5], Daniel A. Arber[1], Toyosi Odenike[1], Richard A. Larson[1], Guido Marcucci[6], Bijal D Shah[7], Wendy Stock[1], Caner Saygin[1]

[1]The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL,[2]Department of Hematology & Hematopoietic Cell Transplantation, City of Hope, Duarte, Duarte, CA,[3]The Ohio State University, Columbus, OH,[4]Northwestern University, Chicago, IL,[5]H Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[6]City of Hope Medical Center and Beckman Research Institute, Duarte, CA,[7]University of South Florida Morsani College of Medicine, Tampa, FL

Clonal hematopoiesis (CH) is a precursor for acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL). Therapy-related (tr-) leukemias are long-term complications of genotoxic therapies for cancer or autoimmune disease. They often present with a myeloid phenotype, but a subset of patients (pts) may develop tr-ALL. Molecular mechanisms driving the lineage bias of tr-leukemogenesis originating from CH are unknown.We studied 345 tr-MN and 217 tr-ALL pts from six centers in North America. Multiple myeloma (MM) was the most common antecedent malignancy in tr-ALL (25% of pts), and only 4% of tr-MN pts had MM ($p< 0.01$). 33% of tr-MN pts had complex karyotype, 24% of tr-ALL pts had low hypodiploidy. Other most frequent genetic abnormalities had similar frequencies between tr-MN vs tr-ALL, including mutations in *TP53* (30% vs 33%), *DNMT3A* (16% vs 11%), and *KMT2A*-rearrangements (8% vs 15%). Given the overlap for common genetic drivers in tr-MN vs tr-ALL, we focused on the most frequent subtype of *TP53*-mutant (*TP53*-m) tr-leukemias. We hypothesized that *TP53*-m CH progresses to tr-AML vs tr-ALL via divergent molecular pathways.To elucidate the molecular differences between tr-*TP53*-m leukemias, we performed scRNA-seq of bone marrows from healthy individuals (n=4), *TP53*-m CH (n= 3), *TP53*-m tr-AML (n= 7) and *TP53*-m tr-ALL (n= 6). A total of 120,726 cells were analyzed. We compared gene signatures and transcription factor (TF) activities of hematopoietic stem cells (HSCs) vs leukemic blasts. In GSEA, *TP53*-m HSCs from CH were enriched in fat metabolism pathways (i.e., fatty acid, arachidonic acid, peroxisomal lipid metabolism) when compared to *TP53*-wild type HSCs from healthy individuals. These metabolic pathways were further enriched in *TP53*-m AML blasts when compared to CH and healthy stem cells, suggesting a switch in energy metabolism associated with myeloid lineage commitment. AML blasts also had high NLRP3-inflammasome and tumor necrosis factor (TNF) signaling. AML blasts showed higher TF activity of GATA2, CEBPA, LMO2 and KAT6A, which may indicate a block in myeloid differentiation and altered chromatin remodeling. ALL blasts showed increased activity of transcription factors involved in NF-κB signaling, including NFKB, RELA, JUN and AP1 that may promote cell survival and resistance to apoptosis.In interactome analysis, *TP53*-m AML blasts were characterized by their integrin cell surface interactions, including ITGA5 interaction with CD40LG on T cells, and ITGAV interaction with TGF-β secreted from CD8+ T, NK, and Treg cells. In *TP53*-m ALL, upregulated TNFα response resulted in increased HLA antigen expression.Collectively, tr-AML and tr-ALL have overlapping genetic characteristics, dominated by *TP53*-m and aneuploidy. Our data identified key molecular pathways associated with myeloid vs lymphoid bias of leukemogenesis.

#140 Profiling ECM biomarkers PRO-C3 and PRO-C5 in plasma from patients with esophagogastric cancer.

Eleonora Moroncini[1], Andrea Ponzetta[2], Magnus Nilsson[2], Fredrik Klevebro[2], Rebecca Maltez de Sousa[2], Nora Noren[2], Morten Karsdal[1], Nicholas Willumsen[1]

[1]Nordic Bioscience, Copenhagen, Denmark,[2]Karolinska Institute, Stockholm, Sweden

Background: Esophagogastric cancer encompasses malignancies of the esophagus, esophagogastric junction, and stomach. These cancers involve distinct regions of the esophagus and gastroesophageal junction (GEJ) and exhibit unique clinicopathologic, histologic, and mutational features. The major constituents of the tumor microenvironment (TME) are besides the tumor cells themselves, cancer associated fibroblasts (CAFs), stromal cells and the extracellular matrix (ECM). CAFs synthesize excess amounts of collagens leading to a fibrotic TME with poor response to anti-cancer treatment; it was previously found that among other types of collagens COL3A1 and COL5A1 are expressed in most of activated CAFs. The aim of this study was to investigate the relevance of non-invasive serological biomarkers of type III collagen synthesis (PRO-C3) and type V collagen synthesis (PRO-C5) in patients with GEAC and ESCC.
Methods: Levels of PRO-C3 and PRO-C5 were measured non-invasively using competitive enzyme-linked immunosorbent assays in EDTA Plasma from patients diagnosed with esophageal squamous cell carcinoma (ESCC) (n=27), gastroesophageal adenocarcinoma (GEAC) (n=165) and compared to healthy controls (n=20). Blood samples were obtained during biopsy, and the biomarker measurements reflect baseline levels. PRO-C3 and PRO-C5 levels in patients with GEAC and ESCC were assessed according to disease stage, treatment type and resection status.
Results: Circulating PRO-C3 levels were significantly elevated in both GEAC ($p = 0.0025$) and ESCC ($p = 0.0022$), while PRO-C5 levels were markedly increased in both subtypes (GEAC: $p = 0.0012$; ESCC: $p = 0.0002$). PRO-C5 levels were higher in ESCC compared to GEAC ($p = 0.0023$), whereas PRO-C3 levels were similar between the two ($p = 0.441$). Stratifying by treatment intention showed no significant differences in PRO-C3 or PRO-C5 levels in ESCC patients receiving curative or palliative care. In GEAC, PRO-C5 levels were higher in palliative treatment patients ($p = 0.01$). For resection status, neither PRO-C3 nor PRO-C5 levels varied significantly in GEAC. In ESCC, PRO-C3 levels were elevated in non-resected samples ($p = 0.002$). Stratification by cancer stage revealed significant increases in PRO-C5 levels in GEAC patients at Stage III ($p = 0.002$) and Stage IV ($p = 0.004$).
Conclusion: The non-invasive fibrosis-associated biomarkers PRO-C3 and PRO-C5, indicative of type III and type V collagen synthesis mediated by activated CAFs, are elevated in patients with ESCC and GEAC. These biomarkers show promise as non-invasive tools for stratifying and monitoring patients across different subtypes of esophagogastric cancer.

#141 Utilizing multiplex imaging to characterize the extracellular matrix in cancer.

Anton Villamejor, Joseph Lownik, Ben Falk, Larry Milshteyn, Akil Merchant

Cedars-Sinai Medical Center, Los Angeles, CA

The tumor microenvironment (TME) is known to be an essential component in the response to multiple therapeutics, including immunotherapies. The TME is comprised of the tumor itself, infiltrating immune cells, and the extracellular matrix (ECM). ECM has been shown to play a critical role in tumorigenesis, affect the efficacy of certain treatments, and regulate anti-tumor immunity. However, methods to study ECM have typically been limited to single-marker studies or have used dissociated methods which lose spatial context. Additionally, fluorescence-based approaches to study the ECM are challenging due to the auto-fluorescence properties of multiple ECM components. We chose to utilize the multiplex capabilities of Imaging Mass Cytometry (IMC) for its ability to detect up to 40 different proteins via metal-tagging and absence of auto-fluorescence. We selected and validated 40 markers which we believe play an integral role in ECM, including structural proteins as well as immune markers and metabolic enzymes. This 40-plex panel was validated using a tissue microarray (TMA) comprised of various healthy and diseased tissue samples such as Lung, Colon, Breast, Prostate, Kidney, and Liver and their respective tumor counterparts. After staining, our results underwent rigorous analysis through a multi-step image comparison of our staining results to those in the current literature, ensuring our staining was specific. We found significant differences in the protein expression of various ECM markers between the healthy tissue and their tumor counterpart. We found structural variations of multiple ECM proteins between the normal tissue and tumor tissue. However, the expression patterns of these ECM elements were not uniform between tumor types, with overexpression of HAPLN1 in breast cancer while decreased in colon cancer. The included immune markers allow for spatial studies to examine the role of ECM in regulating immune responses, such as CD8+ T-cell infiltration. Additionally, we found that tumors from non-small cell lung cancer (NSCLC) patients exhibit significant ECM heterogeneity. We used a patch-based analysis approach to examine the ECM phenotypes of a cohort of 35 NSCLC patients. Preliminary assessment demonstrates unique clusters of ECM phenotypes have a utility for predicting patient outcomes. Further analysis of this cohort will be presented. Overall, we present a highly-multiplexed IMC panel which allows for detailed assessment of the ECM.

#142 Integrin α6β4 upregulates IDO1 expression and decreases IFNγ-mediated T cell growth in ER-negative breast cancer.

Parvanee Karimpour[1], Oscar Hanson[2], Andrew Elliott[3], Min Chen[4], Kathleen O'Connor[1]

[1]Molecular & Cellular Biochemistry, University of Kentucky, Lexington, KY,[2]Chemistry, Berea College, Berea, KY,[3]Markey Comprehensive Cancer Center, University of Kentucky, Lexington, KY,[4]Toxicology & Cancer Biology, University of Kentucky, Lexington, KY

The kynurenine metabolic pathway degrades tryptophan into immunosuppressive metabolites following pro-inflammatory cytokine stimulation and is upregulated in ER-negative (ER(-)) breast cancers, where it is associated with a worse prognosis. The laminin receptor integrin α6β4 is expressed in a majority of hormone receptor negative breast cancers, where it is known to promote an aggressive phenotype by regulating cellular signaling and epigenetics. Here, we seek to identify how integrin α6β4 regulates the IFNγ-mediated induction of the first kynurenine pathway enzyme, IDO1, and its impact on immunosuppression in ER(-) breast cancer. Integrin β4 only pairs with integrin α6; thus, expression of the β4 subunit is representative of integrin α6β4 when integrin α6 is expressed. We demonstrate that stable expression of integrin β4 in BT549 cells regulates IDO1 expression by altering methylation of the IDO1 promoter and gene body compared to empty vector (EV) control, which resulted in increased IDO1 expression determined using high throughput sequencing, qPCR, and immunoblot analyses. Likewise, knockdown of integrin β4 by shRNA or knockout by CRISPR in HCC1806 and HCC1954 cells decreased IDO1 expression. Gene set enrichment analysis demonstrated an increased IFNγ response in BT549 cells expressing integrin β4 compared to EV control. Moreover, using the TCGA Breast Invasive Carcinoma dataset, we show that expression of IFNγ, a known inducer of IDO1, is positively associated with IDO1 expression in breast cancer. Upon IFNγ stimulation, the expression of integrin β4 resulted in a more dramatic upregulation of IDO1 at the mRNA and protein level, which was accompanied by alterations in STAT signaling. Furthermore, integrin α6β4 signaling significantly increased secretion of the immunosuppressive metabolite kynurenine following IFNγ stimulation, effects which were abrogated by pharmacologic IDO1 inhibition. Using conditioned media transfer onto Jurkat cells, we show that conditioned media from integrin β4-expressing cells stimulated with IFNγ significantly reduced T cell growth compared to media from IFNγ stimulated EV cells or unstimulated β4 cells. In summary, our data suggest that integrin α6β4 increases IDO1 induction in ER(-) breast cancer cells, amplifies kynurenine secretion, and suppresses T cell growth in the presence of the inflammatory cytokine IFNγ. This study suggests a novel role of integrin α6β4 in limiting T cell-mediated antitumor immunity and highlights the need to elucidate the detailed mechanisms governing integrin α6β4-mediated immunosuppression in ER(-) breast cancers.

#143 Cilengitide sensitivity is predicted by overall integrin expression in breast cancer.

Nomeda Girnius[1], Aylin Z. Henstridge[1], Benjamin Marks[1], Jeffrey K. Yu[1], G. Kenneth Gray[1], Chris Sander[1], Ioannis Zervantonakis[2], **Augustin Luna**[3]

[1]Harvard Medical School, Boston, MA,[2]University of Pittsburgh, Pittsburgh, PA,[3]National Institutes of Health, Bethesda, MD

Background: Treatment options for triple-negative breast cancer (TNBC) are limited and patients face a poor prognosis. Here, we sought to identify drugs that target TNBC vulnerabilities and understand the biology underlying these responses. We analyzed the Broad Institute DepMap to identify recurrent TNBC vulnerabilities and performed a 45-compound screen on vulnerability-related pathways on a set of up to 8 TNBC cell lines. We identified a subset of cell lines with an ITGAV vulnerability and a differential sensitivity to cilengitide, an integrin inhibitor targeting ITGAV:ITGB3 and ITGAV:ITGB5. Next, we sought to understand cilengitide resistance and response biomarkers. Clinical trials targeting integrins continue enrolling patients, necessitating an understanding of how these drugs affect tumors.

Methods: We combined in vitro assays with computational approaches to systematically explore the differential sensitivity to cilengitide and resistance mechanisms. We tested an additional pan-ITGAV inhibitor (GLPG0187) to determine how generalizable our findings on cilengitide sensitivity might be to integrin inhibition. ITGB4, ITGA3, and ITGA6 knockdown experiments assessed the importance of integrin monomers in cell attachment during cilengitide treatment. Also, we explored the role of extracellular matrix (ECM) proteins in cilengitide response by performing cell replating experiments and by culturing on collagen, fibronectin, or laminin coated plates.

Results: We discovered that cell-derived ECM modulates cilengitide sensitivity and exogenous fibronectin addition conferred resistance to all sensitive TNBC cell lines, though fibronectin expression did not correlate with sensitivity. Instead, elevated overall integrin protein levels, not specific integrins, in TNBC cells positively correlated with resistance. This suggested that high pan-integrin expression promotes cilengitide resistance. Thus, we tested cilengitide in six luminal breast cancer cell lines (which have low integrin levels); all were sensitive. Also, pan-ITGAV inhibitor, GLPG0187, showed the same sensitivity profile across our TNBC cell lines, suggesting our findings apply to other integrin inhibitors.

Conclusions: Integrin inhibitors are appealing candidates to pursue as anti-cancer drugs because they are generally well-tolerated, but their efficacy is mixed, possibly due to the absence of predictive markers. Cilengitide induces death in breast cancer cells with low integrin abundance, where complementary ECM promotes survival. Thus, integrin inhibition in breast cancer warrants further study.

#144 A bispecific integrin α5β1/αv antibody downregulates c-myc/E2F and TGF-β signaling and induces immunological control of basal-type prostate cancer cells.

R. Joshi[1], M. Zhou[1], J. Lin[1], C. Morrissey[2], K. Hu[1], A. Poltorak[3], P. Mathew[1];
[1]Tufts Medical Center, Boston, MA, [2]University of Washington, Seattle, WA, [3]Tufts University, Boston, MA

Background: Prior studies demonstrated that integrin α5β1 and αv crosstalk in chemotaxis and clonogenic survival of prostate cancer cells is abrogated by a bispecific α5β1/αv antibody (BsAbα5β1/αv), which uniquely induces internalization and lysosomal degradation of target integrins (Joshi, MCR 2020). We hypothesized that the BsAbα5β1/αv would inactivate pathological signaling pathways which would be validated in the control of tumor xenografts *in vivo* and in correlative studies from patient samples.
Methods and Results: In basal-type prostate cancer (BTPC) cells, the BsAbα5β1/αv uniquely abrogated nuclear localization of YAP, active β-catenin, FAK and EGFR, compared to monospecific integrin α5β1 and αv antibodies (MsAbs), individually or combined. Dual integrin αv and α5 knockdown alone phenocopied the BsAbα5β1/αv effect. *In vivo,* clonogenic survival of BTPC cells (PC-3, DU-145) was eliminated by the BsAbα5β1/αv in nude mice, with complete regressions in up to 50% of established xenografts, associated with mononuclear infiltration. Tumor response and survival with BsAbα5β1/αv-treatment was superior to MsAbs, individually or combined. *In vitro*, RNA-seq of BsAb-treated BTPC cells revealed control of c-myc/E2F and EMT signaling with upregulation of Type I/II interferon pathways. Concordantly, multiplex ELISA of BsAb-treated BTPC supernatants showed induction of CXCL10 and CCL5 cytokines, with influx of natural killer (NK) cells, monocytes and macrophages into BsAb-treated xenografts confirmed by flow cytometry. Tumor control by the BsAbα5β1/αv was abrogated by NK cell depletion, highlighting their critical role. In a rapid autopsy TMA of metastatic castration-resistant prostate cancer (CRPC), integrin αv was highly expressed in osseous and non-osseous metastases and co-expressed with integrin α5 in bone metastases, osteoblasts and endothelial cells. Relevant to the osteoblastic phenotype of metastatic prostate cancer, the BsAbα5β1/αv strongly downregulated osteogenic differentiation of human bone marrow-derived mesenchymal stromal cells, superior to individual MsAbs. RNA-seq from rapid autopsy samples correlated integrin αv expression with c-myc/E2F signaling, consistent with data from SU2C CRPC and DKFZ early-onset prostate cancer cohorts.
Conclusions: The BsAbα5β1/αv represents a novel therapeutic strategy to reprogram multiple hallmark pathological pathways including c-myc/E2F, TGF-β and EMT. It induces immunologic control of basal-type prostate cancers which are a paradigm of stem-like treatment resistance and immune evasion. Further translational development of the BsAbα5β1/αv therapeutic strategy in prostate cancer is warranted.

#145 Engineered hydrogel platform reveals integrin-ECM mechanisms and therapeutic targets in esophageal adenocarcinoma.

Daniel E. Garcia, Esha A. Uddin, Noriyuki Nishiwaki, Yasuto Tomita, Joel T. Gabre, Hiroshi Nakagawa, **Ricardo Cruz-Acuna**

Columbia University Irving Medical Center, New York, NY

INTRODUCTION: Esophageal adenocarcinoma (EAC) is an aggressive cancer with poor prognosis, partly due to its complex interaction with the extracellular matrix (ECM), which influences disease progression and therapy resistance. However, the underlying ECM-driven mechanisms of EAC growth and therapeutic resistance remain unknown. Traditional *in vitro* models are limited by their use of cancer cell lines and lack of 3D cellular interactions. To address this gap, we developed a bioengineered hydrogel system integrated with patient-derived 3D organoids (PDOs) to better replicate the native ECM environment in EAC.

METHODS: We engineered a hyaluronic acid (HA)-based hydrogel with tunable physicochemical properties to support the culture of EAC PDOs. To study ECM component-specific influences on EAC mechanobiology, we tethered individual adhesive peptides corresponding to key ECM components onto the hydrogel backbone: RGD (fibronectin), GFOGER (collagen), and YIGSR, AG73, or IKVAV (laminin). By independently varying the type and density of each peptide, we examined their effects on PDO growth, proliferation, and therapeutic resistance. Additionally, we conducted inhibition studies using integrin-targeting small molecule inhibitors to explore the role of integrin-mediated adhesion in sensitizing PDOs to chemotherapy.

RESULTS: Among the five adhesive peptides tested, RGD had the most significant effect on PDO formation, growth, and proliferation. Transcriptional and protein analyses revealed elevated expression of integrin αv, integrin β1, and Yap in PDOs cultured in NorHA-RGD hydrogels compared to other peptides. These findings were validated in EAC patient tissue samples. Additional experiments demonstrated a concentration-dependent effect of RGD on PDO growth and Yap activation, mirroring the increased fibronectin deposition observed in EAC tissue. Treatment with cilengitide, an αvβ3 integrin inhibitor, in RGD-modified hydrogels significantly reduced PDO formation, and enhanced the sensitivity of PDOs to standard chemotherapy.

CONCLUSION: This study establishes an engineered biomaterial platform that recapitulates key ECM biochemical properties, providing a foundation for pre-clinical drug testing and mechanistic studies. Our data indicate that αvβ3 integrin-mediated adhesion is critical for EAC PDO growth and activation of oncogenic pathways. The efficacy of cilengitide within this model suggests that targeting fibronectin-integrin αvβ3 interactions could be a viable therapeutic strategy for EAC when combined with chemotherapy. Ongoing work will extend this platform to *in vivo* models to investigate chemoresistance mechanisms and characterize αvβ3+ cancer stem cell populations.

#146 Studying the effect of compressive solid stress on macrophage phenotype and function in the context of glioblastoma.

Alice Burchett, Hao Chen, Scott Howard, Meenal Datta

University of Notre Dame, Notre Dame, IN

Glioblastoma (GBM) is one of the most aggressive forms of brain cancer, with an overall survival of less than two years. One barrier to therapeutic efficacy is the extremely immunosuppressive GBM tumor microenvironment (TME). Myeloid cells, such as macrophages, accumulate in GBM tumors and can comprise up to half of the tumor bulk. Macrophage phenotype typically ranges from pro-inflammatory (M1-like) to anti-inflammatory (M2-like). In GBM, they adopt a pathological, pro-tumor phenotype that thwarts anti-tumor immune responses. The GBM TME also features solid stress, which arises as the tumor expands and presses against the surrounding tissue. As residents of the tumor, macrophages therefore experience chronic compression. Here, we utilize 2D and 3D models to interrogate the macrophage response to and contribution to solid stress as seen in GBM.

Murine macrophages were seeded in a cell culture insert and compression was applied with a 3D printed weight. An agarose cushion between the cells and the weight served as a media reservoir and prevented direct contact between the cells and the rigid weight. We measured the resulting changes in metabolic state, gene expression, nitric oxide production, phagocytosis, and influence on GBM cell proliferation. Using fluorescence lifetime imaging, we found that compression caused an increase in average cell fluorescence lifetime, indicating a shift towards increased oxidative phosphorylation. This is consistent with an M2-like, or anti-inflammatory phenotype. However, compressed macrophages also produced significantly more nitric oxide, a hallmark of pro-inflammatory macrophage function. Compressed macrophages upregulated both nitric oxide synthase and arginase-1, markers of canonically pro- and anti-inflammatory phenotype, respectively. They also had increased phagocytosis of microbeads. These results suggest that chronic compression results in a more complex phenotype than is represented on the traditional pro- and anti-inflammatory axis. Macrophages can also generate de novo solid stress in a confining 3-D hydrogel, with stress generation and phenotype responsive to physical and biochemical cues. This indicates that there may be reciprocal regulation between solid stress and macrophage phenotype in GBM, representing a promising therapeutic target to alleviate pathological solid stress and immunosuppression.

Macrophages in GBM tumors also display elements of classical pro- and anti-inflammatory phenotypes. These results suggest that mechanical compression alone, independent from tumor-derived biochemical cues, may contribute to this pathological phenotype. Future work will elucidate targetable pathways involved in the macrophage response to chronic solid stress, with the aim of normalizing the tumor immune microenvironment to improve the efficacy of the natural or engineered anti-tumor immune response.

#15 Midasin is required for mammosphere stability in Letrozole resistant breast cancer.

Bipika Banjara[1], Mounika Pamukuntla[1], Manasa Kotina[1], Afia Ohemeng[1], Alicia Hudson[1], Selina Darling-Reed[1], Jillian L. Pope[2], Michael Davidson[1], Syreeta L. Tilghman[1]

[1]Pharmacy and Pharmaceutical Sciences, Florida Agricultural and Mechanical University Foundation, Inc., Tallahassee, FL,[2]Biological Sciences, Florida Agricultural and Mechanical University Foundation, Inc., Tallahassee, FL

While aromatase inhibitors (AI) (i.e., Letrozole) are first-line therapy for postmenopausal women with hormone dependent breast cancer, long-term treatment leads to resistance accompanied by the emergence of breast cancer stem cells (CSCs). Previously, our lab demonstrated that midasin, a novel chaperone protein involved in ribosomal biogenesis was increased 35-fold in the letrozole-resistant mammospheres and high levels of midasin was associated with increased relapse free survival in endocrine resistant breast tumors. Here, we hypothesize that elevated midasin expression poises AI-resistant cells for increased stemness, proliferation, and metastasis. To this end, we cultured AI-sensitive (AC-1) and AI-resistant (LTLT-Ca) cells two- and three dimensionally to study the consequences of midasin alteration on cellular behavior by utilizing a midasin inhibitor (i.e., ribozinoindole-2). Although results from proliferation assays indicate that 1-18 μM Rbin-2 treatment caused a 35-60% reduction in cell proliferation, the AC-1 cells were more sensitive. Similar results were observed when colony formation assays were performed. Overall, the LTLT-Ca cells expressed higher levels of midasin compared to the AC-1 cells, and 18μM Rbin-2 treatment reduced midasin expression in both cell lines. To understand the impact of midasin on the biology of endocrine resistance, epithelial to mesenchymal markers were examined and compared to AC-1 cells, LTLT-Ca cells expressed 3-fold higher levels of N-cadherin which were reduced by Rbin-2 treatment. Although the LTLT-Ca exhibited more mesenchymal properties and were more migratory, Rbin-2 treatment caused a similar dose-dependent decrease in wound healing in both cell lines. Interestingly, when mammosphere formation assays were conducted, Rbin-2 treatment induced mammosphere disintegration in both cell lines. When AC-1 and LTLT-Ca cells were treated with 18 μM Rbin-2, the AC-1 spheres were denser and larger (41.73 μm) while the LTLT-Ca spheres were hollow and smaller (5.80 μm), suggesting that midasin is required for stemness. LTLT-Ca mammospheres exhibited higher levels of N-cadherin and vimentin that were decreased with Rbin-2 treatment. Taken together, these changes suggest that increased midasin expression induces an EMT-like state which may in part be responsible for the mammosphere integrity, and enhanced migration which ultimately aids in maintenance of endocrine resistance. Midasin inhibition reverses this phenotype and may provide a novel strategy to target certain endocrine resistant breast tumors.

The combination of spatial metabolomics and spatial transcriptomics can reveal powerful connections between gene expression and metabolism in heterogeneous tissues. However, section-to-section variability can convolute data integration. We present a novel approach, termed Desium, which integrates spatial metabolomics by Desorption Electrospray Ionization Mass Spectrometry Imaging (DESI-MSI) and Visium Spatial Transcriptomics (VST) on the same tissue section. This work demonstrates that DESI-MSI does not significantly impact RNA quality, enabling robust analysis of gene-metabolite relationships in human breast and lung cancer tissues. The Desium workflow involves sequentially performing DESI-MSI at 100 µm spatial resolution, hematoxylin and eosin (H&E) staining, and VST CytAssist analyses on the same tissue section. We applied this workflow to six human cancer tissues (3 breast, 3 lung) and analyzed a serial section of two samples (1 breast, 1 lung) with standard VST CytAssist as a control. H&E and VST data were automatically aligned, while DESI-MSI and H&E data were coregistered manually using nonrigid registration. The MSI data was then converted into VST spot coordinates using a Gaussian granularity matching algorithm. Pearson correlation scores were calculated for each tissue to link gene expression and metabolite abundances. Comparing sequencing results between Desium and the standard VST protocol using UMI counts/gene, we found a correlation coefficient of 1 for both lung and breast samples, indicating minimal impact of DESI-MSI on gene expression measurements. Across all samples, we identified 15,111 transcript-metabolite correlations from 1,136 transcripts and 439 metabolites, with correlation scores above 0.5 or below -0.5. Notably, we observed a 0.82 correlation between glycerophosphorylethanolamine and XBP1 in breast cancer and a 0.77 correlation between phosphatidylglycerol PG 22:6_22:5 and MSLN in lung cancer. Our study demonstrates that Desium enables unambiguous spatial correlations between metabolites and RNA transcripts, uncovering novel relationships and unique patterns of intratumor heterogeneity not evident through histologic analysis. These findings suggest that Desium could serve as a powerful tool to explore the gene expression-metabolic phenotype relationships within the complex tumor microenvironment.

#151 Spatial patterns of APOBEC mutagenesis in the tumor microenvironment of Asian breast cancer.

Z. Tan[1], Y. Wu[2], Z. Neo[2], M. Lau[2], S. Chang[3], J. Yeong[2], S.-H. Teo[1], J. Pan[1];
[1]Cancer Research Malaysia, Subang Jaya, Malaysia, [2]Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [3]Universiti Malaya, Wilayah Persekutuan Kuala Lumpur, Malaysia

A common germline polymorphism in chromosome 22 involves the deletion of a large portion of the *APOBEC3B* gene that results in an *APOBEC3A-B* hybrid transcript. The hybrid transcript increases *APOBEC3A* activity and therefore increases APOBEC-associated mutagenesis, which is a common and important mutational signature in cancers. This deletion polymorphism is found with higher prevalence in Asians and is associated with increased risk of breast cancer in Asian women, as well as development of hypermutated cancers with greater immune cell infiltration. We used Stereo-seq spatial transcriptomics to study the relationship between *APOBEC3B* germline deletion, APOBEC mutagenesis, and the tumor immune microenvironment in Asian breast cancers with *APOBEC3B* germline deletion (carriers, either $A3B^{del/del}$ or $A3B^{del/WT}$), and compared them to non-carriers. To study APOBEC mutagenesis, we constructed new bioinformatics pipelines to conduct variant calling and neoantigen prediction from Stereo-seq data whilst retaining spatial information. Unsupervised neighborhood clustering and cell type deconvolution revealed that the carriers have overall higher immune infiltration into the tumor compared to non-carriers. Somatic C>T mutations, the hallmark of APOBEC mutagenesis, were more prevalent in $A3B^{del/del}$ tumors. One sample showed a high overlap between somatic YTCA mutations, which are associated with *APOBEC3A* activity, and cancer associated fibroblasts (CAFs). Neoantigens originating from somatic mutations, specifically those arising from C>T mutations, were also more prevalent in $A3B^{del/del}$ tumors, but relatively few neoantigens arose from TCA or YTCA mutations. Our data suggest that biologically meaningful spatial resolution of APOBEC-associated somatic variants and neoantigens in tumor samples is possible using Stereo-seq technology.

#153 High-resolution profiling of the tumor microenvironment with spatial ecotypes.

W. Zhang[1], E. L. Brown[1], A. Usmani[2], N. Earland[2], H. Jeon[1], I. Alahi[3], N. P. Semenkovich[4], J. C. Schwab[1], C. B. Steen[5], C. M. Sachs[2], B. Gungoren[6], F. Qaium[7], P. K. Harris[2], J. Mudd[2], Q. Cai[8], A. Bacchiocchi[9], R. C. Fields[2], M. Sznol[9], R. Halaban[9], D. Y. Chen[2], A. A. Chaudhuri[7], A. M. Newman[1];

[1]Stanford University, Palo Alto, CA, [2]Washington University School of Medicine, St. Louis, MO, [3]Washington University, St. Louis, MO, [4]Medical College of Wisconsin, Milwaukee, WI, [5]Oslo University Hospital Institute of Clinical Medicine, Oslo, Norway, [6]California Institute of Technology, Pasadena, CA, [7]Mayo Clinic, Rochester, MN, [8]Peking University, Beijing, China, [9]Yale University, New Haven, CT

Background: Multicellular programs in the tumor microenvironment (TME) drive cancer pathogenesis and response to therapy but remain challenging to identify and profile clinically. Here, we present Spatial EcoTyper, a multimodal machine learning framework for large-scale profiling of spatially dependent cell states and multicellular ecosystems, termed spatial ecotypes (SEs).

Methods and Findings: By integrating five million single-cell and spot-level spatial transcriptomes from 10 diverse human neoplasms, including carcinomas and melanomas, we identified a rich tapestry of conserved regional plasticity across nine TME cell types. We then applied Spatial EcoTyper to deeply dissect these data, revealing nine novel SEs with broad conservation - each with unique biology, TME cell states, geospatial features, and clinical outcome associations. SEs were linked to specific biogeographic domains, including the tumor core, margin, and adjacent stroma, and were remarkably well-validated in 235 held-out tumor samples profiled by either single-cell RNA sequencing, sequencing-based spatial transcriptomics (10x Visium), or high-resolution imaging-based spatial transcriptomics (Vizgen MERSCOPE and NanoString CosMx). By deconvolving SEs from over 1,200 bulk tumor RNA-seq profiles, we discovered striking associations between SE levels and response to immune checkpoint inhibitors (ICIs), outperforming nearly 40 potential correlates of ICI response, including previously described signatures of tertiary lymphoid structures and tumor tissue PD-L1 expression. Notably, baseline levels of a proinflammatory SE - localized to the tumor core and defined by a hub of unique T cell, macrophage, fibroblast, and endothelial cell states - strongly forecasted ICI benefit, while another SE - localized to the tumor margin and defined by myofibroblast and hypoxia-associated endothelial cell states - portended ICI resistance.

Conclusion: Our data reveal fundamental units of TME organization and demonstrate a platform for large-scale profiling of spatial cellular ecosystems in any tissue, with implications for improved forecasting of immunotherapy response and the development of novel therapeutic strategies.

#154 Single-cell spatial transcriptomics unravels cell states and ecosystems associated with clinical response to immunotherapy.

Ziena Abdulrahman[1], Roderick C. Slieker[1], Daniel McGuire[2], Marij J.P. Welters[1], Mariette I.E. van Poelgeest[1], Sjoerd H. van der Burg[1]

[1]Leiden University Medical Center (LUMC), Leiden, Netherlands,[2]Nanostring Technologies, Seattle, WA

The tumor microenvironment (TME) is a highly dynamic and complex ecosystem, where the diversity of cell types, their functional states, and spatial interactions determine responses to immunotherapy. Despite its critical role, the precise mechanisms through which these factors influence clinical outcomes remain poorly understood. In this study, we leveraged single-cell spatial transcriptomics to systematically dissect the TME and identify determinants of immunotherapeutic response in vulvar high-grade squamous intraepithelial lesions (vHSIL).

We analyzed 20 treatment-naïve vHSIL lesions, stratified based on clinical response to tumor-specific peptide vaccination into: complete responders (CR, 100% lesion clearance, n=6), partial responders (PR, >50% lesion clearance, n=7), and non-responders (NR, <50% lesion clearance, n=7). Using a 1000-gene panel, we mapped over 274,000 single cells *in situ*, revealing 18 cell clusters that were further delineated into 99 distinct non-epithelial cell states. Validation against public single-cell transcriptomic datasets confirmed the broader relevance of these findings across tumor types.

Our findings demonstrated profound heterogeneity within the TME across response groups. Notably, CR lesions exhibited a significantly higher ratio of immune-supportive to immune-suppressive cells compared to PR and NR lesions—a pattern mirrored in other solid tumors following neoadjuvant checkpoint blockade therapy (anti-PD1, anti-PDL1, anti-CTLA4). Key immune populations enriched in CR lesions included CD4+CD161+ effector T cells and chemotactic CD4+ and CD8+ T cells, implicating these populations as critical drivers of favorable therapeutic outcomes. Conversely, PR lesions were characterized by increased proportions of T helper 2 cells and CCL18-expressing macrophages, which are associated with the recruitment of type 2 T cells and regulatory T cells. NR lesions displayed preferential infiltration with immunosuppressive fibroblasts. Distinct spatial immune ecosystems further defined response groups: type 1 effector cells dominated interactions in CR lesions, type 2 cells were prominently interacting in PR lesions, while NR lesions lacked organized immune cell interactions.

Thus, these findings emphasize the dual importance of cellular composition and spatial organization in steering response to immunotherapy. By elucidating the mechanisms underlying clinical responses to immunotherapeutic vaccination, this study provides actionable insights to advance precision immunotherapy.

#155 Spatial analysis of tumor-immune-stromal cellular phenotypes and microenvironments in pancreatic cancer.

Noor Shakfa[1], Ferris Nowlan[2], Elizabeth Sunnucks[1], Sibyl Drissler[2], Tiak Ju Tan[3], Chengxin Yu[2], Jennifer L. Gorman[1], Michael J. Geuenich[2], Sheng-Ben Liang[4], Edward L. Y. Chen[1], Golnaz Abazari[2], Barbara Gruenwald[5], Ayelet Borgida[6], Cassandra J. Wong[7], Brendon Seale[7], Zhen Yuan Lin[7], Miralem Mrkonjic[8], Julie M. Wilson[9], Kieran R. Campbell[2], Anne-Claude Gringas[1], Grianne M. O'Kane[9], Faiyaz Notta[9], Steven Gallinger[10], Hartland W. Jackson[1]

[1]Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada,[2]Molecular Genetics, University of Toronto, Toronto, ON, Canada,[3]Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada,[4]UHN Program in BioSpecimen Sciences, University Health Network, Toronto, ON, Canada,[5]Tumor Heterogeneity and Translational Systems Biology, West German Cancer Center, Essen, Germany,[6]Medical Oncology and Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada,[7]NBCC Proteomics Facility, Mount Sinai Hospital, Toronto, ON, Canada,[8]Department of Pathology and Laboratory Medicine, Mount Sinai Hospital, Toronto, ON, Canada,[9]PanCuRx Translational Research Initiative, Ontario Institute for Cancer Research, Toronto, ON, Canada,[10]Hepatobiliary/Pancreatic Surgery, University Health Network, Toronto, ON, Canada

Pancreatic ductal adenocarcinoma (PDAC) is notoriously resistant or refractory to both modern and conventional therapies. These tumors are characterized by heterogeneous malignant epithelial lesions and immune cells embedded within a highly dense and complex stroma. The unique, multi-compartmental tumor microenvironment (TME) —encompassing diverse lineages such as fibroblasts, mural cells, endothelial cells, lymphoid and myeloid populations, cancer cells, and a rich extracellular matrix—indicates the presence of intricate cellular networks that drive tumor progression. Efforts to profile and therapeutically target specific compartments or cellular phenotypes have often led to unintended adverse effects on neighboring cells and their microenvironments, compromising drug efficacy. To identify vulnerabilities in these interactions and precisely quantify intra- and inter-tumoral spatial heterogeneity, we utilized single-cell RNA sequencing data from eight distinct datasets to design separate custom multiplexed histopathology panels for imaging mass cytometry against tumor, immune, and stromal targets. Three serial sections of a tissue microarray containing 4 cores from 221 patients on each were stained with compartment-specific panels. Cell segmentation and clustering of 7.9 million cells in our dataset revealed 104 unique cell types, their functional states along with biophysical responses. We identified the presence of multiple epithelial subtypes within a single patient, along with single-compartment cellular organization and phenotypes associated with patient outcomes. Advanced image alignment using pixel classification and image transformation across serial sections enabled integration of TME-wide information, defining reproducible microenvironments neighboring malignant ducts. These microenvironments demonstrated immune and stromal patterns closely associated with specific epithelial phenotypes, carrying significant prognostic implications. Laser capture microdissection combined with mass spectrometry provided deeper insights into the biological processes within our microenvironments. We further identified associations between our microenvironments with bulk-RNAseq and specific genomic aberrations. These findings contribute to a nuanced understanding of the TME in PDAC and highlight the therapeutic potential in addressing this complexity to overcome the challenges in treating patients with PDAC.

#156 Tumor microenvironment profiling of multiplexed images in head and neck cancer reveals spatial features associated with immunotherapy response.

Ettai Markovits[1], James Monkman[2], Aaron Kilgallon[2], Thazin Nwe Aung[3], David Rimm[3], Arutha Kulasinghe[2]

[1]Nucleai, Tel Aviv, Israel,[2]Frazer Institute, Faculty of Medicine, The University of Queensland, Brisbane, Australia,[3]Department of Pathology, Yale University School of Medicine, New Haven, CT

Introduction: Current objective response rates of recurrent or metastatic head and neck squamous cell carcinoma (RM HNSCC) to immune checkpoint inhibition (ICI) remain less than 20%, highlighting the innate variability of patient tumors that preclude their immunogenic clearance. Such outcomes in HNSCC have driven the exploration of the immune and tumor centric properties that drive such refractory responses to ICIs. This study expands on this knowledge base by leveraging highly multiplexed imaging combined with a deep learning cell type classification pipeline to comprehensively evaluate the spatial properties of tumor and immune cells associated with ICI response.

Methods: 65 RM HNSCC pre-ICI biopsies on tissue microarrays were imaged using highly multiplexed immunofluorescence performed on the Akoya PhenoCycler platform. Cell type classification was performed using a deep learning platform developed by Nucleai. Marker positivity was used to further assign cell type functional states. Supervised spatial clustering and tumor cell density contours were used to define tissue regions in TMA cores. Cell frequencies, tumor-immune cell ratios and cell-cell interactions were computed within these regions as input for tests against clinical correlates.

Results: 95,000 tumor cells and 76,000 immune cells were phenotyped for both functional and metabolic states. Macrophages and CD4 T cells were the most abundant immune cell types in the cohort, with both CD4 and CD8 T cells demonstrating highly $OXPHOS^+$ metabolically active states. Univariate analysis for progression free survival indicated CD8 T cells in tumor regions were associated with better PFS, while CD4 Tregs expressing ICOS in stromal regions correlated with poorer PFS. Interestingly, both B cells and Granulocytes at the tumor-stroma interface correlated with poorer PFS. Furthermore, the interaction between tumor cells and highly metabolically active fibroblasts within tumor regions was also associated with poorer PFS.

Conclusions and future directions: Our study interrogated spatial compartments in HNSCC tissues for cellular features that may predict response to ICI therapy. Such approaches are limited by the provision of sufficient cells to derive meaningful biology. Future aims for this study include deep learning methods to contrast tissue subgraphs to identify regions that differ significantly between patients, and thereby provide novel insights into the relevant spatial communities that drive cancer immunotherapy responses in patient biopsies.

#157 Exploratory analysis of tumor microenvironment using scRNA, scTCR, and spatial transcriptomics in salivary gland cancer with surgical sample after neoadjuvant immuno-chemotherapy.

Hyunsu Kim[1], Sehhoon Park[1], Jin Woo Oh[2], Soohyun Hwang[2], Jinyoung Kim[1], Eun-hye Kim[3], Nayeon Choi[3], Junhun Cho[4], Hyun-Ae Jung[1], Dongryul Oh[5], Se-Hoon Lee[1], Yong Chan Ahn[5], Han-Sin Jeong[3], Chang Ho Ahn[2], Chan-Young Ock[2], Myung-Ju Ahn[1]

[1]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Korea, Republic of,[2]Lunit, Seoul, Korea, Republic of,[3]Department of Otorhinolaryngology-Head and Neck Surgery, Samsung Medical Center, Seoul, Korea, Republic of,[4]Department of Pathology and Translational Genomics, Samsung Medical Center, Seoul, Korea, Republic of,[5]Department of Radiation Oncology, Samsung Medical Center, Seoul, Korea, Republic of

Background: High-grade resectable salivary gland cancer (SGC) is a rare malignancy, with surgery as the standard primary treatment. However, patients with high-grade histology face a significant risk of regional and distant metastasis, often leading to treatment failure. As part of the ONO-4538-X78 clinical trial, three cycles of neoadjuvant nivolumab combined with cytotoxic chemotherapy were administered prior to surgery. This study aimed to conduct exploratory biomarker analyses using surgical samples to investigate tumor microenvironment (TME) changes after neoadjuvant immunotherapy.
Methods: Single-cell RNA sequencing (scRNA-seq) and single-cell T cell receptor (TCR) sequencing were performed on 17 samples from 14 SGC patients, including 3 adjacent normal tissues, 2 pre-treatment biopsies, and 12 post-treatment surgical specimens. Additionally, spatial transcriptomics (Xenium) and histological analyses (H&E via Lunit SCOPE IO) were conducted on 16 post-treatment surgical samples. Responders were defined as patients exhibiting ≤10% viable tumor in surgical specimens.
Results: scRNA-seq analysis identified 32,489 T and NK cells, which were subclustered to reveal cell types associated with treatment response. Non-responders exhibited a predominance of CD4+ memory T cells, while responders demonstrated enrichment of CD8+ dysfunctional T cells and CD8+ memory T cells. Despite statistical insignificance of increased CD8+ T cell subtypes in responders, accompanied by elevated TCR clonality and reduced TCR diversity, suggestive of clonal expansion. Myeloid cell analysis revealed a predominance of tumor-associated macrophages in non-responders, while responders were enriched in dendritic cells and neutrophils. Morphological profiling via Lunit SCOPE IO identified endothelial cells, fibroblasts, lymphocytes, macrophages, tumor cells, and other cell types. Integration of scRNA annotations with Xenium data validated gene expression patterns and identified detailed subtypes. In cancer regions, responders exhibited significantly higher densities of "other" cell populations, predominantly myeloid and stromal cells, including monocyte-derived macrophages, neutrophils, and smooth muscle cells.
Conclusions: This study employed an integrative approach combining scRNA-seq, Xenium spatial transcriptomics, and advanced morphological profiling to characterize the TME and its association with neoadjuvant therapy response in SGC. This multi-modal methodology provided enhanced resolution, enabling the identification of distinct cellular compositions and spatial patterns in cancer areas that differed between responders and non-responders. These findings offer valuable insights into the mechanisms of neoadjuvant therapy and may inform future therapeutic strategies for SGC.

#158 Spatial heterogeneity of tumor cell states in primary cutaneous melanoma.

Tuulia Vallius[1], Yingxiao Shi[1], Edward Novikov[1], Ajit Nirmal Johnson[2], Roxanne Pelletier[1], Shishir Pant[1], Zoltan Maliga[1], David Liu[3], Guihong Wan[4], Yevgeniy Semenov[4], Christine Lian[5], George Murphy[5], Sandro Santagata[5], Peter Sorger[6]

[1]Harvard Medical School, Boston, MA,[2]Department of Dermatology, Brigham and Women's Hospital, Boston, MA,[3]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Department of Dermatology, Massachusetts General Hospital, Boston, MA,[5]Department of Pathology, Brigham and Women's Hospital, Boston, MA,[6]Department of Systems Biology, Harvard Medical School, Boston, MA

Cutaneous melanoma develops from precursor cells that progress to melanoma *in situ* (MIS) and eventually to invasive disease. In metastatic tumors, cells switch from a melanocytic to an undifferentiated, and neural crest (NC)-like state, which is associated with metastasis and therapeutic resistance. However, it is unclear whether these cell states or gene expression changes occur at the premetastatic stage or if they are associated with features of the local tumor microenvironment (TME). We analyzed a cohort of 62 patients with primary cutaneous melanoma (stages 0-III), using cyclic multiplex immunofluorescence imaging (CyCIF), and spatial transcriptomics to assess the molecular and TME changes that occur during the transitions from normal to precursor lesions, MIS and invasive melanoma. The loss of MART1 was associated with increased NGFR expression and elevated proliferation (KI67) in thicker tumors compared to thin (<1mm) lesions. Various tumor cell states coexisted in close proximity within early-stage, untreated melanomas. These tumor states were not arranged by depth of invasion but were associated with specific immune and stromal cell niches. Using CyCIF, we quantified the spatial heterogeneity of tumor cell states at whole-slide, microregion, and single-cell levels by calculating spatial entropy. We found that samples with a range of spatial entropy values contained *both* regions of high and low local neighborhood Shannon entropy at the single cell level. High spatial heterogeneity at the protein level was associated with enrichment of interferon gamma and alpha pathway transcripts. We also identified that transcriptomic heterogeneity within a single primary melanoma sample could be just as varied as across the entire cohort, with microregions showing distinct morphologic and spatial features. To understand the gene expression changes leading to intratumoral heterogeneity, we applied a self-organizing map to the spatial transcriptomic data to determine a developmental trajectory from melanocytic atypia to invasion. We discovered that tumor cells in invasive regions followed two developmental branches, characterized by epithelial-to-mesenchymal transition, angiogenesis, interferon response pathways, and dedifferentiation signatures. These developmental branches also showed differences in the local TME composition and the depth of invasion. Our multi-omic analyses reveal that a spectrum of tumor states exists even in early-stage primary cutaneous melanomas, suggesting an association between these tumor states and TME niches.

#159 Spatial multimodal understanding of disease heterogeneity and aggressiveness in renal cell carcinoma.

Yize Li[1], Wagma Caravan[1], Yuwei Zhang[1], Andrew Houston[1], Siqi Chen[1], Chia-Kuei Mo[1], Preet Lal[1], Xiangwei Fang[1], Xiyi Wei[1], Ruiyang Liu[1], Ilya Strunilin[1], Yizhe Song[1], Song Cao[1], Cody Weimholt[1], Hui Zhang[2], Feng Chen[1], Li Ding[1]

[1]Washington University in St. Louis, St. Louis, MO,[2]Johns Hopkins University, Baltimore, MD

Renal cell carcinomas (RCC) are highly heterogeneous and aggressive cancers with diverse histological subtypes, molecular profiles, tumor microenvironments (TMEs), and clinical behaviors. Intratumoral heterogeneity (ITH), a hallmark of RCC, arises from distinct subclones within the same tumor that vary histopathologically and molecularly. To elucidate the biological mechanisms underlying RCC tumorigenesis at single-cell resolution, we examined 155 tumor specimens from 78 cases, encompassing clear cell RCC (ccRCC), papillary RCC (pRCC), chromophobe RCC (chRCC), and rare subtypes. We utilized 80 single-nucleus RNA sequencing (snRNA-seq) and 55 single-nucleus ATAC sequencing (snATAC-seq) datasets alongside advanced spatial biology techniques, including 27 Xenium In Situ, 12 Visium spatial transcriptomics (ST), and 7 co-detection by indexing (CODEX) samples. The connection of matched bulk proteogenomic data, clinical annotations, and histopathological evaluations from H&E staining further enhanced our spatial multimodal investigation. From single-nucleus sequencing of over half a million nuclei, we identified specific transcriptional programs and chromatin accessibility patterns among RCC subtypes, including HIF pathway dysregulation in ccRCC and MET pathway activation in pRCC. We also identified markers and constructed signature scores for rare but high-grade phenotypes, such as the aggressive rhabdoid and sarcomatoid features in ccRCC. Spatial analyses confirmed the utility of these feature-associated signatures for detection, quantification, and potential therapeutic targeting. Furthermore, we characterized the spatial organization and tumor-TME interactions, providing critical insights into spatially diverse ITH in RCC. Notably, a Grade-4 ccRCC sample exhibited three distinct tumor subclones and regions of necrosis characterized by Xenium, CODEX, and Visium profiling. Among these, a rhabdoid-associated subclone showed tumor-intrinsic signatures of elevated cell cycle activity and epithelial-mesenchymal transition (EMT), distinguishing it from conventional ccRCC subclones and indicating higher metastatic potential. We further revealed a unique macrophage subpopulation closely interacting with the rhabdoid subclone, forming an immunosuppressive niche that likely contributes to immune evasion, resistance to immunotherapies, and disease recurrence. Collectively, our spatial multimodal findings delineate the molecular signatures and mechanisms underlying RCC heterogeneity and aggressive features. By linking spatially distinct subclones to tumor progression and therapeutic resistance, this study provides valuable insights for developing personalized and effective therapeutic strategies to improve outcomes for RCC patients.

#16 Differential stemness properties in bone marrow-derived mesenchymal stem cells from healthy subjects and from patients with acute myeloid leukemia.

Souraya Ismail[1], Fouad Al Feghali[2], Rana Abdel-Samad[3], Abdullah A. Shaito[4], Hiba El Hajj[5], Carine Deleuze-Masquefa[6], Pierre-Antoine Bonnet[6], Marwan El-Sabban[7], **Jessica Saliba**[8]

[1]Biology, Lebanese University, Fanar, Lebanon,[2]Medical Laboratory Sciences, University of Balamand, Sin el Fil, Lebanon,[3]Biology, Saint Mary's College, South Bend,, IN,[4]5Biomedical Research Center and Department of Biomedical Sciences at College of Health Sciences, Qatar University, Doha, Qatar,[5]Experimental Pathology, Immunology and Microbiology, American University of Beirut, Beirut, Lebanon,[6]Institute of Biomolecules Max Mousseron (IBMM), Balard Chemistry Unit, Montpellier University, Montpellier, France,[7]Anatomy, Cell Biology and Physiological Sciences, American University of Beirut, Beirut, Lebanon,[8]Public Health, University of Balamand, Sin el Fil, Lebanon

Study purpose: The imidazoquinoxaline EAPB0503, an imiquimod analogue, exhibits immunomodulatory and anti-cancer properties against several blood malignancies, including acute myeloid leukemia (AML). The bone marrow (BM) niche plays a pivotal role in normal hematopoiesis and in leukemogenesis. To characterize the molecular potency of EAPB0503 in AML, we compared its effect on the expression profile of genes involved in the function and differentiation potential of BM-derived mesenchymal stem cells (BM-MSCs) from a healthy subject and a patient with AML.
Experimental procedures: Transcriptional levels of stemness markers and genes potentially relevant to niche function were evaluated by quantitative real-time polymerase chain reaction in BM-MSCs isolated from BM aspirates of subjects undergoing BM analysis and exposed to EAPB0503. Differentiation potential was assessed in BM-MSCs exposed to EAPB0503 and induced into osteogenic differentiation using a mixture of dexamethasone, ascorbic acid and β-glycerophosphate (DAG). A colorimetric assay was used to detect early-stage osteogenic differentiation by evaluating alkaline phosphatase (ALP) activity.
Summary of results: EAPB0503 treatment induced a differential expression of functionally important marker genes between BM-MSCs from the healthy subject and the patient with AML. As such, levels of Connexin 43 (*GJA1*) decreased in healthy BM-MSCs and increased in AML-derived BM-MSCs following treatment with EAPB0503. In contrast, transcriptional levels of multi-drug resistance 1 (*MDR1* or *ABCB1*) markedly increased in healthy BM-MSCs and remained stable in AML-derived BM-MSCs. Vascular Endothelial Growth Factor (*VEGF*) and N-cadherin (*CDH2*) transcriptional levels increased in AML-derived BM-MSCs, with modest changes in healthy MSCs. In addition, AML-derived BM-MSCs do not seem to respond to differentiation signals in a manner similar to healthy BM-MSCs, as shown by ALP activity.
Conclusions: These preliminary findings underscore the differential transcriptional profile in BM-MSCs derived from a healthy subject or a patient with AML. Importantly, a differential gene expression profile was also obtained in response to the therapeutic drug EAPB0503. Our preliminary findings implicate the BM niche in AML leukemogenesis and response to drugs.

Alfa

Noetik, South San Francisco, CA

Targeting the right patient population with any given therapeutic agent largely remains an unsolved problem, and successes in pre-clinical models often do not translate into positive outcomes for patients. Recent advances in multi-omics spatial profiling have highlighted the diversity of tumor microenvironment compositions and architectures across patients. Our deepened understanding of human disease also further demonstrates that the handful of pre-clinical models used for a large proportion of pre-clinical studies seldom recapitulate human biology and are unreliable predictors of clinical success.
To bridge the gap between pre-clinical models of disease and human biology, we developed a high throughput in vivo platform that can reproduce in mice the diversity of tumor phenotypes seen in patients. Our platform leverages Perturb-map, a spatial functional genomics technology compatible with high content multimodal phenotyping of 100s of tumor clones (and their associated genetic perturbations) in the same animal. A key feature of Perturb-map is that genetic perturbations can be identified by reading a protein barcode using multiplex imaging, a scalable read out. Our current custom imaging pipeline can analyze the impact of 100+ genetic perturbations - and the equivalent of 1,000s of individual tumors - in a few weeks, while simultaneously profiling the tumor microenvironment.
To date, we have used this platform to generate a dataset encompassing 600+ genetic perturbations (CRISPR KO) in a mouse model of NSCLC (KRASG12D Tp53-/-). For each perturbation, >50 tumors are profiled at baseline, and in the context of immune checkpoint blockade. We have found that, unlike mouse models traditionally used for discovery, our in vivo dataset reproduces a broad spectrum of patient immunotypes, including T cell deserts, highly infiltrated tumors, and more specific profiles of immune infiltration. Moreover, we have identified genetic perturbations that drive the establishment of these immunotypes. For example, loss of STK11 in the mouse tumors lead to a local increase in neutrophil infiltration, a feature that is also associated with STK11 mutations in the patient population. Among the 600+ genetic perturbations, we also identify specific genes that promote local inflammation or tumor immunoediting, and therefore constitute potential therapeutic targets.
Altogether, we have demonstrated that our ability to scale up in vivo experimentation using Perturb-map addresses current limitations in drug development, as we can (i) generate at scale models that better reflect the various facets of human tumor biology and (ii) perform target evaluation at a high throughput without compromising phenotypic readouts.

#161 High-resolution spatial proteomics characterizes colorectal cancer consensus molecular subtypes.

Batuhan Kisakol[1], Anna Matveeva[1], Sanghee Cho[2], Mohammedreza Azimi[1], Andreas U. Lindner[1], Manuela Salvucci[1], Elizabeth McDonough[2], Joanna Fay[3], Tony O'Grady[3], Niamh McCawley[4], John P. Burke[4], Deborah McNamara[4], John Graf[2], Simon McDade[5], Daniel B. Longley[5], Fiona Ginty[2], Jochen H. M. Prehn[1]

[1]Department of Physiology and Medical Physics & RCSI Centre for Systems Medicine, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[2]GE Healtcare, Niskayuna, NY,[3]Department of Pathology, Beaumont Hospital, Dublin, Ireland,[4]Department of Colorectal Surgery, Beaumont Hospital, Dublin, Ireland,[5]School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, United Kingdom

Background: Identification of the consensus molecular subtypes (CMS) opened significant potential for understanding the tumor biology and intertumoral heterogeneity of colorectal cancer (CRC). Molecular subtyping in CRC traditionally relies on bulk transcriptomics. However, single-cell transcriptomics studies have shown that CRC tumors may be composed of tumor cells displaying different CMS traits, suggesting additional intratumoral heterogeneity.
Methods: To investigate intratumoral heterogeneity at protein level, we constructed tissue microarrays using tumor cores from 222 CRC patients. Arrays were stained and imaged with Cell DIVE multiplexed immunofluorescence (MxIF) imaging using 54 selected protein markers, ranging from cell identity markers to cancer hallmark proteins of metabolism, proliferation, cell death and differentiation. RNA sequencing data and CMS classification were also available for all patients. After segmentation of tumor, stromal and immune cells, we investigated intratumoral heterogeneity within CMS subtypes using spatially resolved single-cell protein profiling (>2 million cells). We compared cell types, their spatial organization and their expression of cancer hallmark-related proteins in CMS 1-4 subtypes.
Results: We revealed tissue atlases illustrating the cell types/states, spatial heterogeneity, cellular neighborhoods, cellular network, and single-cell protein profiles of CMS tumors. CMS1 tumors had more $CD3^+$, $CD8^+$, and $PD1^+$ immune cells that were found in the epithelial layer more frequently than in the other subtypes. CMS1 was also associated with higher levels of metabolic reprogramming markers such as upregulated glycolysis. CMS2 showed immune segregation, reactive stroma patterns, and higher levels of apoptotic and proliferative signaling proteins. CMS3 exhibited tightly clustered cancer cells with high RIP3 and low FLIP levels, suggesting a pro-inflammatory microenvironment driven by intense cell-cell interactions and stromal hubs. CMS4 displayed stromal-centric and immune-evasive tumors characterized by decreased HLA-1 levels and regulatory T cell exclusion from epithelium.
Conclusion: We present the first spatial atlas of CRC tumors with regard to their molecular subtypes at single-cell protein resolution and demonstrate new spatial aspects of tumor structures in CRC.

#162 Mapping the complex interplay between vasculogenic mimicry and immune response in lung cancer using digital spatial profiling.

Chun-Hui Lee[1], Chun-Hua Hung[2], Shu-Hsien Wang[3], Wei-Pang Chung[1], Yu-Min Yeh[1], Peng-Chan Lin[1], Wu-Chou Su[1]

[1]Department of Oncology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan,[2]Department of Bioengineering, College of Engineering, National Cheng Kung University, Tainan, Taiwan,[3]Department of Pathology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan

Background: Vasculogenic mimicry (VM) represents an alternative vascularization mechanism contributing to cancer progression and treatment resistance. Despite its clinical significance, the spatial and molecular relationships between VM networks and immune components remain poorly characterized in non-small cell lung cancer (NSCLC).
Methods: We conducted a comprehensive spatial analysis of treatment-naïve, surgically resectable advanced non-small cell lung cancer (NSCLC) specimens (n=4), encompassing both EGFR-mutant and wild-type variants. High-dimensional spatial phenotyping was performed using PhenoCycler-Fusion multiplexed immunofluorescence technology, enabling precise visualization and quantification of vasculogenic mimicry (VM) architectures and immune cell infiltrates at subcellular resolution. Complementary molecular characterization of discrete tumor microenvironmental regions was achieved through GeoMx Digital Spatial Profiling platform. Spatial transcriptomics analysis was subsequently employed to validate primary observations and elucidate region-specific transcriptional signatures.
Results: Through high-dimensional spatial analysis, we identified a previously undescribed vessel-like population characterized by CD31-VEGFR1+PanCK+ expression, representing vasculogenic mimicry (VM) structures in non-small cell lung cancer (NSCLC). Comprehensive spatial mapping revealed distinct topographical relationships between VM networks and immune cell populations, including CD4+ and CD8+ T lymphocytes, as well as functionally diverse macrophage subsets (CD68+, CD206+, iNOS+, and HLA-DR+). Molecular characterization through digital spatial profiling demonstrated enhanced transcriptional heterogeneity at the tumor margin, with significant enrichment of pathways involved in extracellular matrix (ECM) organization and hypoxia response (FDR < 0.01). Integration of spatial transcriptomics with an established 70-gene VM signature revealed a core set of 10 genes operating at the intersection of VM and ECM remodeling programs. This gene module, predominantly expressed at the tumor-stromal interface, represents a previously unrecognized regulatory hub coordinating VM formation through ECM modification.
Conclusions: Our integrated analysis reveals a novel VM phenotype in NSCLC and identifies a core gene signature linking VM formation to ECM remodeling at the invasive front. These findings provide new insights into tumor-stromal-immune interactions and suggest potential therapeutic strategies targeting the VM-ECM-immune axis.

#163 Spatiotemporal multi-omics uncover tumor ecosystem dynamics driving metastatic colonization.

Liang Wu[1], Yu Zhong[1], Shang liu[1], Zefan Zhang[2], Chunqing Wang[3], Yunfan Sun[2], Jia Fan[2], Jian Zhou[2], Xun Xu[4]

[1]BGI Research, Chongqing, China,[2]Department of Liver Surgery, Liver Cancer Institute, Zhongshan Hospital, Fudan University, Shanghai, China,[3]College of Life Sciences, University of Chinese Academy of Sciences, Beijing, China,[4]BGI Research, Shenzhen, China

The mechanisms underlying the interaction between disseminated tumor cells (DTCs) and their tissue microenvironment during metastasis colonization are poorly understood. We integrated multimodal single-cell and spatial profiling from liver cancer mouse models and human metastases to track the spatiotemporal dynamics of DTCs and their microenvironments across nine sequential time points from single-cell seeding until overt lung metastasis. We identified a residual population of quiescent *Phgdh*^{high} DTCs that survive initial innate immune clearance and become transiently enriched in micrometastases. These cells shape an immune-scarce microenvironment through PHGDH-dependent, H3K27me3-mediated epigenetic silencing of chemokine transcription, promoting metastatic expansion. *Cx3cr1*^{high} interstitial macrophages were also found to be transiently enriched before DTCs expansion, creating an immune-privileged niche for metastatic outgrowth by recruiting immunosuppressive cells. Inactivating the Phgdh-H3K27me3 axis in DTCs or depleting interstitial macrophages restored immune surveillance and inhibited metastatic colonization. These findings provide new therapeutic concepts for developing micrometastasis-targeting regimens.

#164 Heterogeneous dormant breast cancer cells leverage bone marrow cell plasticity at the single-cell level to drive metastasis initiation.

Noriko Gotoh

Cancer Research Institute and Institute for Frontier Science Initiative, Kanazawa University, Kanazawa, Japan

Breast cancer remains a leading cause of cancer-related deaths among women worldwide, largely due to the high risk of recurrence and metastasis in HER2-negative and hormone receptor-negative triple-negative breast cancer (TNBC) patients. While bone metastasis is common, the molecular mechanisms driving its initiation remain poorly understood. We recently identified a subpopulation of cancer stem cells (CSCs) with ancestral features, marked by the FXYD domain-containing ion transport regulator 3 (FXYD3), a Na+/K+ pump component. These “ancestor-like CSCs” persist in breast tissues during neoadjuvant chemotherapy (NAC), linking them to drug-tolerant persisters (DTPs) and positioning them as critical therapeutic targets for preventing local recurrence (Li M, Gotoh N et al., J Clin Invest, 2023). Despite this, the mechanisms underlying DTP dormancy in the bone marrow and their transformation into bone metastasis-initiating cells remain unclear. Given the stromal richness of TNBC tissues, we explored interactions between cancer-associated fibroblasts (CAFs) and breast cancer cells using a co-culture system. Single-cell analysis revealed a strong upregulation of granulocyte colony-stimulating factor (GCSF) in co-cultured CAFs. Notably, we identified FXYD3+ and GCSF receptor-positive cancer cells as a distinct subpopulation of CSCs with bone metastasis initiation potential. To investigate the temporal-spatial dynamics of bone metastasis initiation, we performed single-cell RNA sequencing (10x Genomics) and multiplex immunofluorescent imaging (PhenoCycler) using metastatic bone marrow from the patient-derived xenograft (PDX) models. These analyses revealed how bone metastasis-initiating CSCs exploit the plasticity of bone marrow cells—particularly hematopoietic and mesenchymal stem cells—to establish a CSC niche at the single-cell level. Our findings provide critical insights into the mechanisms of recurrence and metastasis in breast cancer, offering novel therapeutic opportunities to target ancestor-like CSCs and prevent disease progression.

#165 Spatially resolved mechanostress effects on tumor microenvironments: Tumor cells and fibroblasts in focus.

Wooseok Kim[1], Hyunseok Kim[1], Minki Kim[2], Zhangxian Lan[3], Hyung-Soon Park[2], Mi Ryung Roh[4], Joon Kim[1], Jong-Eun Park[1]

[1]Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[2]Department of Mechanical Engineering, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of,[3]Oral Cancer Research Institute, College of Dentistry, Yonsei University, Seoul, Korea, Republic of,[4]Department of Dermatology, Yonsei University College of Medicine, Seoul, Korea, Republic of

Tumorigenesis is influenced by various environmental factors, including growth-induced solid stress and fluid pressure, both of which are key drivers of tumor progression and resistance to therapy. While certain tumors arise in regions exposed to significant weight-pressure, how macroscopic mechanostress affects the tumor microenvironment remains largely unclear. In this study, we showed that macroscopic mechanostress disrupts nuclear envelope integrity. Single-cell RNA sequencing data demonstrated that the macroscopic pressure shows changes in gene expression within tumor microenvironment cells and reshaped fibroblast subtypes.In spatial transcriptomics, using a distance-based tumor border detection model, we can determine spatially resolved fine layers of tumor margin and peritumor regions. We found an increased proportion of fibroblasts, especially Lrrc15-positive myofibroblasts, located in peritumor region facing the tumor border. We also showed upregulated metastasis signature and immune inhibitory signature indicating that mechanostress-driven transcriptional changes promote metastasis and resistance to immunotherapy. Using a mouse plantar melanoma model, we found that exogenous mechanostress, mimicked by genetic disruption of the nuclear lamina, induces nuclear envelope rupture in melanoma cells and increases the number of Lrrc15-positive myofibroblasts. Interestingly, these myofibroblasts further contribute to nuclear envelope rupture in melanoma cells, creating a feedback loop. Together, our findings highlight a critical role for mechanostress in cancer progression, driven by nuclear envelope damage and shifts in tumor-stromal interactions.

#166 Spatial subtypes and cellular interactions of cancer-associated fibroblasts revealed by single-cell spatial omics.

Yunhe Liu[1], Ansam Sinjab[1], Jimin Min[1], Guangchun Han[1], Francesca Paradiso[1], Yuanyuan Zhang[1], Yang Liu[1], Ruiping Wang[1], Guangsheng Pei[1], Kyung Serk Cho[1], Enyu Dai[1], Akshay Basi[1], Jared K. Burks[1], Kimal I. Rajapakshe[1], Yanshuo Chu[1], Jiahui Jiang[1], Daiwei Zhang[2], Xinmiao Yan[1], Paola A. Guerrero[1], Alejandra Serrano[1], Mingyao Li[2], Tae Hyun Hwang[3], Andrew Futreal[1], Jaffer A. Ajani[1], Luisa M Solis Soto[1], Amir A. Jazaeri[1], Humam Kadara[1], Anirban Maitra[1], Linghua Wang[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]University of Pennsylvania Perelman School of Medicine, Pennsylvania, PA,[3]Department of Artificial Intelligence and Informatics, Mayo Clinic Rochester, Rochester, MN

Background: Cancer-associated fibroblasts (CAFs) are a highly diverse cell population that plays a crucial role in shaping the tumor microenvironment (TME). Their spatial interactions within the TME remain to be systematically characterized, and the factors driving their phenotypic heterogeneity are not yet fully understood. Recent advancements in single-cell spatial transcriptomics technologies and cell segmentation approaches enable the precise measurement of thousands of transcripts at subcellular resolution. Combined with innovative bioinformatics, these advancements have unlocked unprecedented opportunities for in-depth characterization of CAFs and their interactions within the TME.

Methods: We conducted a comprehensive spatial transcriptomic analysis of CAFs across 8 cancer types, using the CosMx and MERSCOPE platforms to profile nearly 6 million cells as part of our discovery cohorts. We developed a novel computational method to spatially cluster CAF subpopulations and defined four distinct spatial CAF subtypes. We further examined their phenotypic differences, spatial niche organization, and interactions with neighboring cells. Additionally, we investigated the influence of CAF subtypes on immune cell phenotypes and infiltration levels. To validate our findings, we employed multiple spatial platforms, including Visium, Xenium, COMET, CODEX, and IMC, to ensure reproducibility across diverse technologies. Moreover, we performed correlative studies in large-cohorts with rich clinical data to evaluate the clinical significance of these CAF subtypes.

Results: Our approach provided an unprecedented high-resolution examination of the spatial phenotypes of CAFs in large, complex tissues, uncovering novel insights. We comprehensively characterized CAFs across various solid tumor types and identified four conserved spatial CAF subtypes. These subtypes are characterized by distinct cell organizational patterns, neighboring cell compositions, interaction networks, and transcriptomic features. Moreover, they demonstrate significant correlations with the abundance, distribution, and phenotypes of tumor-infiltrating immune cells, as well as associations with tumor histopathological features and clinical outcomes.

Conclusions: Our study provides a pan-cancer, high-resolution characterization of CAF spatial organization and interactions in solid tumors and identified conserved spatial CAF subtypes linked to distinct organizational patterns. Our findings reveal that the transcriptomic states and phenotypes of CAFs are significantly shaped by their interactions with neighboring cancer and immune cells. Beyond offering novel insights into the spatial heterogeneity of CAFs, this work paves the way for developing strategies to effectively target and modulate CAFs for therapeutic benefit.

#167 Novel spatial tagging of single nuclei spatializes single-cell ATAC-seq and V(D)J sequencing with gene expression for tumor microenvironment analysis.

Wanxin Wang, Julie Wilhelmy, Christina Chang, Christina Fan

Research and Development, Curio Bioscience, Palo Alto, CA

Advances in single-cell multiomic technologies such as RNA-seq, ATAC-seq, or V(D)J sequencing have enriched our understanding of tumor gene expression, chromatin accessibility, and immune receptor diversity, but they fall short in capturing the critical spatial context of cells within the tumor microenvironment (TME). This limitation hinders our understanding of how tumor cells organize and interact with surrounding cells during tumor progression, metastasis, and treatment response. Existing spatial methods, whether microscopy- or sequencing-based, primarily focus on gene or protein expression only. Additionally, they often lack true single-cell resolution, requiring computationally involved cell segmentation or deconvolution, and offer limited molecular complexity. To address this gap, Curio Trekker single-cell spatial mapping kit, based on Slide-tags technology, provides a paradigm-shifting solution by transforming single-cell sequencing assays into spatially resolved single-cell data. Curio Trekker spatially labels individual cells within a tissue section by releasing the DNA barcodes from a spatially indexed bead array surface into nearby nuclei. The spatially tagged nuclei are then dissociated from the array and processed on conventional single-cell sequencing assays and platforms. The technique expands spatial measurement beyond gene expression alone, enabling spatial multiomic analyses such as chromatin and V(D)J profiling. Moreover, given the spatial measurements are at true single-cell resolution, the resulting datasets are easier to analyze and interpret. In this study, we applied Curio Trekker to existing single-nuclei (sn) ATACseq and sn-V(D)J assays combined with gene expression to spatially analyze human melanoma fresh frozen tissues. These previously unattainable combinations enable the simultaneous spatial exploration of gene expression and epigenetic regulation within the spatial context of tumors and the mapping of immune receptor clones within TME. Joint unsupervised clustering on sn-RNAseq and sn-ATACseq data identified spatially defined tumor, stromal, immune, and vasculature cell types driven by both transcriptomic and epigenetic signatures. These cell types were further classified spatially into tumor zones and tumor-free areas, determined by their spatial locations and CNV profiles. We linked tumor-zone-specific transcriptional factors with accessible chromatin domains and binding motifs. Tumor-stromal interactions were inferred within their native spatial context using spatially aware ligand-receptor analysis. V(D)J and immune composition analysis revealed spatial distribution of different T cell clones. Our findings demonstrate the potential of Curio Trekker to advance oncology and immunotherapy by providing a comprehensive spatial view of tumor ecosystems.

#168 Genomic heterogeneity drives distinct infiltration patterns in glioblastoma.

Dylan Harwood[1], Sara Blaabjerg Artzi[1], Vilde Pedersen[1], Alessio Locallo[1], Maya Jeje Schuang Lu[1], David Scheie[2], Anne Dorte Schou Noroxe[2], Nadine Margaretha Hammouda[1], Ulrik Lassen[2], Joachim Lutken Weischenfeldt[1], Bjarne Winther Kristensen[1]

[1]University of Copenhagen, Copenhagen, Denmark,[2]Rigshospitalet, Copenhagen, Denmark

Glioblastoma is the most common and malignant type of primary brain cancer with a median patient survival of only 15 months. Tumors are typically categorized into three molecular subtypes—proneural, classical, and mesenchymal—each linked to specific genomic and microenvironmental factors. However, the functional and clinical implications of these subtypes remain poorly understood. Standard treatment involves surgical resection followed by chemotherapy and radiotherapy. Despite this, malignant cells have already at the time point of diagnosis infiltrated healthy brain tissue, driving tumor recurrence. Infiltrating cells have been found to maintain high proliferative rates while invading the brain (termed “go-and-grow”) but have also been shown be non-proliferative (termed “go-or-grow”). Here, we perform computational analyses on transcriptomic data from over 600 patients, supplemented with genomic data, to investigate infiltration patterns in glioblastoma tumors. We identify a proliferative astrocytic state strongly associated with the classical subtype and EGFR amplification and distinct from a non-proliferative astrocytic state. Further analysis showed subtype-specific infiltrative patterns between the tumor core and adjacent brain tissue. To validate these findings, we performed single-cell spatial transcriptomics on patient samples, revealing that classical tumors exhibit a “go-or-grow” phenotype, where core regions are proliferative and infiltrative regions are dormant. In contrast, proneural tumors maintain consistent malignant states and proliferation rates, reflecting a “go-and-grow” phenotype. These findings indicate a direct relationship between the genomic status of glioblastoma tumors and the transcriptomic profiles of their infiltrating malignant cells. Together, our study provides insights into genomically-driven infiltration patterns in proneural and classical glioblastomas, with potential implications for clinical treatment.

#169 Tumor heterogeneity and differential pathway activation in melanoma: insights from spatial profiling of AXL and NGFR upregulated regions.

Mark Woodnorth, Giuseppe Tarantino, Anne Zaremba, Tuulia Vallius, Florian Rambow, Lisa Zimmer, Antje Sucker, Elisabeth Livingstone, Eva Hadaschik, Roxanne Pelletier, Yingxiao Shi, Mariana Lopez, Samira Makhzami, Christine Lian, George Murphy, Genevieve Boland, Peter Sorger, Dirk Schadendorf, David Liu

Dana-Farber Cancer Institute, Boston, MA

Tumor heterogeneity remains an obstacle in the treatment of melanoma, with unique tumor microenvironments contributing to therapy resistance and differential tumor growth. Dedifferentiated melanoma states have been associated with resistance to targeted and immunotherapy. AXL and NGFR are dedifferentiation markers linked to these states; however, the mechanisms by which they interact or result in distinct tumor programs remain unclear. Both AXL and NGFR have been linked to therapy resistance. AXL has been associated with cell survival, proliferation and immune suppression and NGFR with tumor progression, invasion, metastasis and therapy resistance. Understanding these interactions is critical for identifying therapeutic strategies and improving patient outcomes. In a melanoma patient with longitudinal tumor samples, we used highly multiplexed cyclic immunofluorescence (CyCIF) and matched H&E to study the tumor and immune states associated with progression. Spatial transcriptomic profiling was performed using GeoMX on selected regions of interest to further study tumor states characterized by different morphology and proteomic differentiation markers. In the primary and in-transit metastasis, we observed intratumoral heterogeneity, with histologically distinct tumor nodules. CyCIF of the in-transit sample showed upregulation of AXL in one nodule and NGFR in the other. The NGFR nodule was characterized by densely packed tumor cells, while the AXL nodule featured an inner cleft region encased by dense peripheral tumor cells. In the NGFR nodule, differential expression analysis (DEA) revealed upregulation of EPAS1, HIF1A, ERBB3 and VEGFA suggesting hypoxic stress, cell signaling, active angiogenesis and cell migration. Transcription factor analysis (TFA) showed upregulation of HDGF, TGFB1I1, HOXA7, IRF6 and SRSF2, TFs associated with proliferation, differentiation and increased translational activity. Downregulated HIP2K and PAWR suggest apoptosis inhibition, further facilitating tumor survival and expansion. In the AXL nodule, DEA revealed increased CDKN1A, indicating stress response and altered cell cycle regulation. Gene set enrichment analysis (GSEA) highlighted WNT and Hedgehog signaling, hormonal responses (e.g., estrogen signaling), and metabolic alterations (bile acid metabolism, myogenesis). EMT upregulation suggested a mesenchymal-like phenotype associated with resistance. TFA showed elevated KLF8 and TGFB1I1 driving EMT and metastasis, while SRSF2, HSF4, CXXC1, and NR1H2 suggested stress resilience, apoptosis regulation, and ER stress mitigation. Distinct signaling in AXL and NGFR regions suggests NGFR drives metabolic activity and proliferation, while AXL promotes resilience via stress and hormonal signaling. These findings offer insights into therapies targeting melanoma heterogeneity and resistance.

#17 hiPSCs-derived *PTEN* deletion suppresses cardiomyocyte differentiation and beating.

Thang Huu Nguyen[1], Chaeyong Jung[2], Sang Wook Park[3], Seung-Rock Lee[1]

[1]Department of Biochemistry, Department of Biomedical Sciences, Chonnam National University Medical School, Gwangju, Korea, Republic of,[2]Department of Anatomy, Chonnam National University Medical School, Gwangju, Korea, Republic of,[3]Department of Oral Biochemistry, School of Dentistry, Chonnam National University, Gwangju, Korea, Republic of

Human-induced pluripotent stem cells (hiPSCs) have been increasingly used for cardiac tissue engineering and cell-based therapies for heart regeneration because they possess self-renewal capability *in vitro* and can differentiate into most cardiovascular cell types, including cardiomyocytes. The phosphatase and tensin homolog deleted on chromosome 10 (PTEN) is a potent tumor suppressor frequently being deficient in human cancer. It is also important for cardiac functions and embryonic development since the loss of *PTEN* induced embryonic lethality; however, the underlying mechanisms are not fully understood. Here, to understand the function of PTEN in cardiomyocyte differentiation, we generated *PTEN* deletion in hiPSCs by using CRISPR/Cas9 system. *PTEN* ablation suppressed cardiomyocyte differentiation, which was shown by decreases in cardiac markers *cTNT* and *Myh6* compared with *PTEN* WT. Immunofluorescence staining and flow cytometry analysis using α-actinin and cTNT supported the suppression of cardiomyocyte differentiation induced by $PTEN^{-/-}$ hiPSCs. q-PCR analysis was performed using representative markers for differentiation steps including mesoderm, cardiac mesoderm, cardiac progenitor, and cardiomyocyte. $PTEN^{-/-}$ hiPSC decreased mesoderm markers (*Brachyury, Dkk1, Fox C1*) on the 2nd day of differentiation, suggesting that PTEN is important for early cardiac differentiation. Western blot analysis revealed that Gsk3β and mTOR phosphorylation levels were increased due to an activation of Akt, which may involve $PTEN^{-/-}$-induced mesoderm abnormality. In addition, PTEN deletion also inhibited cardiac beating capability, which may explain $PTEN^{-/-}$-induced embryonic lethality.

#170 A novel protease-free workflow for spatial multiomics analysis of the tumor microenvironment in breast cancer.
Patrick Savickas

HistoWiz, Brooklyn, NY, NY

Introduction: Spatial multiomics is revolutionizing our understanding of the tumor microenvironment (TME) by enabling simultaneous analysis of multiple analytes within their tissue context. Combining in situ hybridization with immunofluorescence enables detection of key RNA and protein markers, together, on the same section. However, traditional ISH protocols that use enzyme-based pretreatment were incompatible with certain IHC/IF antibodies. Here, we present a novel protease-free workflow for a spatial multiomics panel, applied to human breast cancer samples, to investigate the interplay between immune cell infiltration and tumor cell signaling.
Methods: Formalin-fixed paraffin-embedded (FFPE) breast cancer tissue sections underwent a protease-free staining protocol. The panel comprised three protein markers: CD3 (all T cells), CD8 (cytotoxic T cells), and PanCK (tumor cells). The RNAscope™ Multiomic LS in situ hybridization (ISH) assay was employed to detect IFNG (T cell activation), CXCL9 (chemokine produced by tumor cells), and CXCR3 (receptor for CXCL9 on CD8+ T cells). Spatial analysis algorithms were used to quantify co-expression and proximity of these markers.
Results: Our protease-free workflow enabled simultaneous visualization of protein and RNA targets with high sensitivity and specificity. Preliminary data demonstrate distinct spatial patterns of immune cell infiltration and activation within the breast TME. We observed correlations between IFNG expression in CD8+ T cells and CXCL9 expression in PanCK+ tumor cells, suggesting a potential mechanism of T cell recruitment and activation.
Conclusions: This novel protease-free spatial multiomics panel provides a powerful tool for dissecting the complex interactions between tumor cells and the immune system in breast cancer. By preserving both protein and RNA integrity, this approach offers valuable insights into the spatial organization of the TME and may identify novel therapeutic targets and biomarkers.

#171 A novel single-cell level approach integrating artificial intelligence (AI)-powered histomorphology labeling and spatial transcriptomics enables biomarker identification of treatment-resistance in salivary gland cancer (SGC).

[1]Oncology, Lunit Inc., Seoul, Korea, Republic of,[2]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Korea, Republic of,[3]Department of Pathology and Translational Genomics, Samsung Medical Center, Seoul, Korea, Republic of,[4]Department of Otorhinolaryngology-Head and Neck Surgery, Samsung Medical Center, Seoul, Korea, Republic of

Introduction

We integrated H&E-AI analysis and spatial transcriptomics (ST) to provide a synergistic analysis of tumor microenvironments (TME) beyond each technology alone. In this study, we focused on SGC, which encompasses several rare tumor types with unmet need.

Methods

We developed an integrated analysis pipeline to combine cell- and tissue-level morphological information from H&E-AI (Lunit SCOPE IO, AI-powered H&E image analyzer) and gene expression profiles from ST (10x Genomics Xenium). We then analyzed 12 tumor samples provided by 10x Genomics for validation and, as a test set, 16 surgically resected SGC including 11 salivary duct carcinoma (SDC) treated with neoadjuvant nivolumab and cetuximab.

Results

We first reciprocally validated H&E-AI and ST by confirming that ST captures well established cell-specific gene expression that corresponds to AI-predicted cell types (EPCAM, VWF, and TRAC mark carcinoma cells, endothelial cells, and lymphocytes with F1 = 0.88, 0.81, and 0.72, respectively). In the test SGC cohort (total 915,215 cells), we identified 20 cell type groups with distinct gene expression patterns. Due to high gene expression heterogeneity among putative tumor cell subtypes, ST based tumor cell detection using reference gene expression profiles was insufficient and required complementary morphological analysis from H&E-AI, which identified 10 groups as tumor cell subtypes harboring diverse morphologies (mean nuclear size per subtype: 27.14 - 40.92 μm^2). Two patients with SDC had the same dominant tumor subtype (largest nucleus size, HER2/FOXA1/GATA3 positive), yet exhibited discordant responses to neoadjuvant therapy. Tumor cells from the SDC patient with recurrence (SDCw/Rec), compared to those from the SDC patient without recurrence (SDCw/oRec), exhibited upregulation of genes associated with immune evasion or epithelial-to-mesenchymal transition (EMT) such as MYC, TNC, and JUN (174%, 197%, 77% higher). Moreover, SDCw/Rec also had significantly fewer tumor-infiltrating lymphocytes (TIL) than SDCw/oRec (515 vs. 2,306 /mm^2). Interestingly, the proportion of TIL with CXCL9 expression was far lower in SDCw/Rec [19.7% (1,636/8,312)] compared to SDCw/oRec [67.0% (25,658/38,267)].

Conclusion

An integrated ST and H&E-AI analysis allowed parallel transcriptomic and subcellular-level histomorphologic characterization of individual cells from tumor specimens at the micron scale, providing a highly visualizable solution for discovering novel resistance mechanisms. Based on this novel approach, we reported a SDC pair discrepant for recurrence after neoadjuvant therapy, where the recurred case exhibited 1) high intrinsic tumor signatures of EMT and immune evasion and 2) a low level of TILs along with low CXCL9 expression in each TIL.

#172 Spatial profiling of stage III melanoma microenvironment reveals tertiary lymphoid structures as markers of long-term outcomes.

Angel Guan[1], Xinyu Bai[1], Nurudeen A. Adegoke[1], Shila Ghazanfar[2], Nigel G. Maher[1], Alexander M. Menzies[1], Ines Pires da Silva[1], Richard A. Scolyer[1], Georgina V. Long[1], James S. Wilmott[1], Camelia Quek[1]

[1]Melanoma Institute Australia, The University of Sydney, Sydney, Australia,[2]School of Mathematics and Statistics, The University of Sydney, Sydney, Australia

The recent neoadjuvant anti-PD-1 and anti-CTLA4 therapy, such as the PRADO trial (NCT02977052), has shown a high pathological response rate in many melanoma patients. In resectable macroscopic stage III melanoma, PRADO achieved a 72% pathological response rate. However, recurrence remains a challenge, and the biological mechanisms behind durable responses are unclear. Tertiary lymphoid structures (TLSs), immune sites that enhance antigen presentation, cytokine signaling, and antibody release, are present in several cancers, including melanoma. Their role in the efficacy of neoadjuvant therapy, however, is not fully understood. This study quantifies and characterizes TLS formation in melanoma patients treated in the neoadjuvant setting. Using the most recent data with a median follow-up of 55 months, 17 patients involved in this study were grouped into non-recurrence (n=11) and recurrence (n=6) groups. We performed 41-plex PhenoCycler Fusion imaging on 26 formalin-fixed, paraffin-embedded patient index lymph node samples from the PRADO cohort, including 17 baseline samples and nine Week 6 post-treatment samples. Among these, eight patients had paired baseline and Week 6 samples. Bioinformatic analysis was used to quantify cells, characterize TLS molecular features, and analyze interactions within the tumor microenvironment (TME) associated with recurrence-free survival (RFS). The presence of TLSs—consisting of B cells, CD4+ and CD8+ T cells, myeloid cells, and vessels—in baseline samples was associated with longer RFS ($p = 0.0498$). At Week 6, TLSs were present in 4 out of 5 non-recurrence patient samples and 1 out of 4 recurrence patient samples. Moreover, the TLSs in the recurrence patient were relatively less mature than those in non-recurrence patients. These findings indicate mature TLS presence at 6 weeks post-treatment may be associated with durable outcomes, and quantification of TLSs is underway. Notably, TLSs were observed in some matched baseline and Week 6 samples in non-recurrence patients. The structural organization of immune cells at baseline compared to Week 6 demonstrates patterns of increased immune activation, where the early TLSs evolved into more mature-like structures with increased immune cell diversity. Molecular profiling of these immune structures is underway to characterize the TME changes associated with neoadjuvant treatment and to identify features of durable immune protection in patients with prolonged RFS. This 41-plex spatial imaging study highlights the immune-responsive features of TLSs in melanoma, shedding light on their mechanisms of promoting durable responses to neoadjuvant therapy and providing a foundation for future translational research.

#173 Advancements in 3D high-multiplex imaging using the stellaris confocal platform.

L. Alvarez, I. Steinmetz, T. Straka, F. Hecht, M. J. Roberti

Leica Microsystems GmbH, Mannheim, Germany

In cancer immunology research, evaluating tissue changes and cell interactions is crucial for identifying specific cell types, assessing the activation status of immune cells, monitoring the expression of certain proteins and genetic markers, and characterizing the tumor microenvironment. Traditional imaging techniques often fall short in providing comprehensive spatial and functional insights due to their limitations in multiplexing and three-dimensional (3D) analysis. Here, we introduce an innovative high-multiplexing workflow on the STELLARIS confocal platform, utilizing a new functionality called SpectraPlex for advanced 3D imaging (Kunz L., et al. Nat. Methods, 2024). SpectraPlex significantly enhances the capabilities of spatial biology by streamlining the steps from panel creation to image acquisition and unmixing through advanced unmixing algorithms. In addition to the traditional single references and semi-blind unmixing for 15-plex experiments, we introduce a “group” approach that allows users to generate 15 references using only 3 samples, thereby saving preparation and imaging time and preserving a larger amount of samples for experimental steps. This workflow was validated on a cancer model where murine pancreatic ductal adenocarcinoma cells (KPC-4662) were injected into C57Bl/6 mice and allowed to grow for three weeks. Tumor tissues were harvested, fixed, and processed into 70-µm-thick sections for imaging. A 15-plex panel, including markers for T cells (CD4, CD8), B cells (B220), myeloid cells (CD11b, MHC II, CD11c), and other functional and structural markers (TCF1, FoxP3, PD1, Ki67, α-SMA, MHC I, E-cadherin, Tenascin C, CD31), was used to visualize the resulting tumor infiltration. High-resolution 3D imaging was performed on a STELLARIS confocal system, capturing comprehensive spatial information and enabling the identification of immune cell subtypes, functional states, and structural markers within the tumor microenvironment. All 15 markers were present and imaged in a single acquisition, allowing further probing in areas of interest. We also demonstrate how this general approach is easily adapted to investigate the immune landscape of murine lymph nodes (Roberti M. J., et al, Nat. Methods, 2024). The implementation of the 3D high-multiplexing workflow on the STELLARIS confocal platform represents a significant advancement in the ability to interrogate the tumor microenvironment in detail. The SpectraPlex toolbox not only streamlines the imaging process but also ensures high data quality and reliability, setting a new standard for future spatial biology research in cancer.

#174 Multimodal mass spectrometry imaging of immune cell glycosylation across three immunosuppressive tumor microenvironments.

Lyndsay E. A. Young[1], Caroline G. Kittrell[1], Kameisha Rashford[1], Grace Grimsley[1], David N. Lewin[2], Anand S. Mehta[1], Peggi M. Angel[1], Kristin Wallace[3], Richard R. Drake[1]

[1]Pharmacology and Immunology, The Medical University of South Carolina (MUSC), Charleston, SC,[2]Pathology and Laboratory Medicine, The Medical University of South Carolina (MUSC), Charleston, SC,[3]Public Health Sciences, The Medical University of South Carolina (MUSC), Charleston, SC

Glycosylation is essential for the development, trafficking, and activation of the immune system. The complex interaction between the immune system and tumor cells within the tumor microenvironment is crucial to understand cancer progression and improve therapeutic interventions. Immunotherapy is an emerging tool in cancer treatment, showing promise across various malignancies, however; its effectiveness in solid tumors remains limited and inconsistent. Colorectal carcinoma (CRC) has demonstrated enhanced sensitivity to immunotherapy, particularly in cases with high microsatellite instability or mismatch repair deficiency. In contrast, the immune cold prostate (PCa) and pancreatic ductal adenocarcinoma (PDAC) cancers are typically less responsive to immunotherapy due to an immunosuppressive tumor microenvironment. Emerging evidence for the role of N-glycosylation modulating activity in the tumor microenvironment suggests it could be an indicator of response to immunotherapy. We aimed to establish spatial profiles of immune cells surrounding and within tumor tissues of CRC, PCa, and PDAC using Matrix-Assisted Laser Desorption-Ionization Mass Spectrometry Imaging (MALDI-MSI) for N-glycomic profiling and MALDI-immunohistochemistry to identify the cellular compositions of the tumor microenvironment. Utilizing 73 tissue samples collected from patients with varying stages of CRC, PCa, and PDAC, our lab has characterized the N-linked glycan profile of over 250 immune cell clusters within and surrounding these tumors. Using an established photocleavable-mass tagged antibody panel (CD20, CD3, CD8, CD44, CD11b, CD68) we broadly characterized the immune microenvironment. In CRC, we identified immune clusters of CD20+ B cells and CD3/CD44+ T cells distinctive and predictive with signature profiles of bisecting and branched N-glycans. In PCa and PDAC, we identified a similar cellular makeup for the immune clusters as seen in CRC; however, high mannose and core fucosylated N-glycans were more prevalent within and surrounding these tumors. Additionally, N-glycan signatures varied depending on spatial proximity to the tumor in PCa and PDAC tissues. Our innovative, two dimensional approach provides critical insights into the cellular composition and metabolic complexity of the tumor microenvironment. Importantly, establishing a cellular and metabolic profile of the tumor immune microenvironment may offer valuable indicators of immunotherapy effectiveness, paving the way for improved personalized medicine.

#175 Characterising head and neck tumour microenvironment using high plex spatial omics technologies and analyses.

Chin Wee Tan[1], Naomi Berrell[2], Meg L. Donovan[2], James Monkman[3], Habib Sadeghirad[3], Vahid Yaghoubi Naei[3], Jinjin Chen[1], Alyssa Rossenbloom[4], Shilah Bonnett[4], Mark Conner[4], Brian Filanoski[4], Christine Kang[4], Joseph M. Beechem[4], John F. Fraser[2], Catherine Barnett[3], Rahul Ladwa[5], Brett G. M. Hughes[3], **Arutha Kulasinghe**[3]

[1]The Walter & Eliza Hall Institute of Medical Research (WEHI), Melbourne, Australia,[2]Wesley Research Institute, Brisbane, Australia,[3]The University of Queensland, Brisbane, Australia,[4]Nanostring Technologies, a Bruker company, Seattle, WA,[5]Princess Alexandra Hospital, Brisbane, Australia

Head and neck squamous cell carcinoma (HNSCC) is the cancer of different parts of the head and neck region originating from epithelial cells of the mucosal layer. Globally, it is the 7th most common cancer with over 89 thousand new cases each year. Its prognosis has not changed significantly in recent years despite improvements in treatments options like immunotherapy, radiotherapy (RT), chemotherapy (CT) and surgery. Using the latest spatial omics technologies and approaches, this work aims to develop a better insight of the tumour microenvironment (TME), particularly the association with typical clinical endpoints including Disease-Free Survival (DFS) and Overall Survival (OS). In this study, we utilised the latest ultra-high plex (580-proteins) spatial protein technology (GeoMx Immuno-Oncology Proteome Atlas, IPA) and full transcriptome profiling (18,000 transcripts, Whole Transcriptome Atlas, WTA) from Bruker Spatial Biology (Nanostring Technologies) to analysed 84 mucosal HNSCC patient specimens collected during resection. Each patient tissue sample was subdivided into tumour and stromal regions prior to digital spatial profiling. Patients had either underwent CT and/or RT and samples were stratified as either tumour or stromal regions before processing. Till this end, results suggest that patient DFS and OS were associates with anatomical locality and stages of the tumour. We uncovered unique protein and transcript features that's associated with either DFS and/or OS. We validated these findings (specifically CD34 and CD44) using an independent approach (i.e. single-cell proteomics using PhenoCycler-Fusion from Akoya Biosciences) and uncovered cell types associated with patient survival by applying cell type deconvolution on transcript data. This study demonstrated an integrated analysis workflow using high plex proteomics and transcriptomics profiling data for uncovering markers of clinical significance in mucosal HNSCC.

#176 Simultaneous spatial characterisation of copy number change and immune cell profiling using DNA FISH and multiplexed immunofluorescence.

Eleanor M. O'Roberts[1], Pranauti Panshikar[1], Xiaoze Li-Wang[2], Quentin Verron[2], Shahrzad Shirazi Fard[3], Magda Bienko[2], Charlotte Stadler[1]

[1]KTH, Department of Protein Science, SciLifeLab, Stockholm, Sweden,[2]Department of Molecular, Tumor and Cell Biology, Karolinska Institutet, Stockholm, Sweden,[3]Department of Women's and Children's Health, Karolinska Institutet, Stockholm, Sweden

Background: Recent advances in spatial characterization of protein expression has greatly improved our understanding of tissue architecture, cell-cell interactions and their function. In this work, we aim to further improve cell characterization by combining the detection of DNA and proteins in the same sample in an automated and cyclic manner. Single molecule DNA FISH can identify cells with genetic aberrations linked to different tumor types or aggressiveness, however as a stand-alone method this technique lacks spatial context. We set out to use the microfluidic Phenocycler-Fusion platform from Akoya Biosciences to detect single molecule DNA FISH signals, as well as multiplexed protein detection, in order to gain multiple layers of spatial information from one sample and the possibility to explore clonal heterogeneity within tumor sections.
Methods: The Phenocycler-Fusion involves the use of antibodies conjugated to oligonucleotide barcodes. In each cycle, the microfluidics instrument adds up to three reporters labelled with distinct fluorophores (AF488/AF750, Atto550, AF647), these are complementary to individual barcodes. The fluorophores are then imaged and the reporters are eluted ready for the next round of reporter addition, imaging and elution. Our integrated workflow for detecting DNA and protein involves hybridization of primary DNA FISH probes downstream of antibody staining before the sample is loaded onto the Phenocycler-Fusion instrument for cyclic addition of secondary fluorescent DNA FISH probes and reporters. The data is processed so that images from each cycle are collated into a single image meaning that DNA and protein signals can be spatially analyzed simultaneously.
Results: The protocol was developed using fixed cells to identify the optimal conditions for combined DNA and protein detection and we successfully executed the same protocol in fresh frozen tissue sections. We have obtained proof of concept data illustrating the possibility of imaging chromosomal regions simultaneously with immune cell and structural markers such as CD45, pan-cytokeratin and Ki67. We have also shown that DNA targets can be detected across imaging cycles along with protein detection and thereby demonstrate the multiplexing capacity of our integrated protocol on the Phenocycler-Fusion platform in a fully automated manner. The combined method can be optimized and applied to various cancer samples to investigate the tumor microenvironment along with chromosomal aberrations or copy number variations of specific genes. Overall, these promising results show the possibility of using a commercially available system for detecting multiplexed DNA and protein simultaneously across a large imaging area.

#177 Increasing throughput of high-quality spatial biology data via low magnification, high NA scanning on the CellScape platform.

J Spencer Schwarz[1], Charles E. Jackson[1], Kayla E. Cashion[1], Mathew H. Ingalls[1], Brian J. Lane[1], Joseph Lownik[2], **Oliver Braubach**[1]

[1]Bruker Spatial Biology, St. Louis, MO,[2]Cedars-Sinai Medical Center, Los Angeles, CA

The etiology of solid tumor formation is diverse and complex, and studies that better incorporate diversity in sample selection will result in more robust patient stratification and treatment. This reasoning applies to spatial biology studies as well, but increasing sample diversity can quickly lead to added technical challenges, more cost, and more time to data. There is then an obvious benefit to any innovation that increases the throughput of sample processing without unacceptable degradation in data quality. The CellScape™ Precise Spatial Proteomics platform offers spatial resolution at 182 nm/pixel while sampling 0.815 mm^2 per field of view (FOV). This provides a balance of speed and resolution optimal for many applications. However, there are use cases where fast collection is more important than high resolution. To serve these, we explored fitting the CellScape with a primary 10x 0.45 NA objective. The instrument can then collect 3.18 mm^2 of sample area per FOV, quickly scanning through large specimens such as whole embryo mounts, resection biopsies, and tissue micro arrays (TMAs). Combining this large scanning area with the CellScape whole-slide imaging chamber (WSIC) tissue window of 44 mm x 16 mm provides a very efficient workflow for gathering multiplexed immunofluorescence (mIF) data on large area samples. Here we provide data describing the efficiency and data quality of such a system. We found that a complete tonsil resection measuring >57 mm2 can be captured in less than 20 FOVs. And that a single FOV can capture an entire 1.6 mm diameter core without cropping. Further maximization of scanning efficiency was provided by a modification to the typical spatial biology imaging workflow. During TMA scanning, replacing grid-based scanning, we place each FOV at the center of each core to avoid any unnecessary scanning of blank area or double-scanning of single cores. We deployed a 40-plex assay on a 96-core TMA grid using a combination of large-FOV, high-numerical-aperture scanning and on-center FOV placement. We assessed the time required to process the samples from archived FFPE TMA block to image collection and found that using the WSIC and the CellScape platform optimized the mIF assay for rapid data collection. Importantly, we also illustrated the preservation of high-quality imaging data provided by a digital sampling rate of 364 nm per pixel, maintaining compatibility with downstream data analysis pipelines including image segmentation, cell phenotyping, and cellular neighborhood assignment. When speed outweighs resolution, the increased efficiency demonstrated here applies to most mIF spatial biology applications. Large area samples require less FOVs to capture. Small area samples can be batched on the same slide. And small, single samples can be captured without image stitching. All these examples benefit from efficient placement of large FOVs.

#178 Automating a spatial profiling workflow to explore the effects of hypoxia in the tumor microenvironment in head and neck cancer.

Kyla Teplitz[1], David Mason[2], **Regan Baird**[3], Kelly Hunter[4], Joana Campos[4], Jill Brooks[5]

[1]Bruker Spatial Biology, Seattle, WA,[2]Visiopharm, Horslom, Denmark,[3]Visiopharm, Arvada, CO,[4]Propath UK, Hereford, United Kingdom,[5]University of Birmingham, Birmingham, United Kingdom

Background: Head and neck cancer (HNC) encompasses a diverse group of malignancies originating from the mucosal surfaces of the upper aerodigestive tract. The tumor microenvironment (TME) in HNC is marked by immune cells, stromal cells, and extracellular matrix components. Hypoxia, a key feature of the TME, drives tumor growth, invasion, and metastasis by modulating gene expression related to angiogenesis, cell survival, and metabolism. Understanding the interplay between hypoxia and immune infiltrates in the TME is essential for developing new therapeutic strategies for HNC. While whole transcriptome analysis via digital spatial profiling is a powerful method for probing the TME, it is time-consuming for large cohorts. Automating the profiling workflow can reduce hands-on time and selection bias in regions of interest (ROIs), facilitating the exploration of large cohorts to identify mechanisms of action, potential drug targets, and biomarkers.
Methods: We developed an optimized spatial multi-omic workflow for high-throughput spatial analysis using the GeoMx® Digital Spatial Profiler (DSP) with the Whole Transcriptome Atlas (WTA) and immunofluorescent morphology markers: SYTO82 (nuclei), CAIX (hypoxia), pan-cytokeratin (epithelium), and CD3 (T-cells). AI-based analysis (Oncotopix® Discovery) of serial section H&E and GeoMx IF images was employed to identify ROIs for GeoMx collection. Immune hot and cold selections were based on leukocyte density, while tumor/stromal interface selections focused on epithelial areas. Areas of illumination (AOI) were chosen using concentric CAIX expression gradients. Integrated analysis of digital images and the whole transcriptome was conducted to assess the TME compartments.
Results: Automated ROI placement based on tumor/stroma, hypoxia, and immune infiltration, along with AI/Deep Learning-based AOI segmentation, reduced AOI selection time and improved tissue compartment enrichment accuracy across samples and tissue types. The development of hypoxia gradient-based AOI selection enabled a strategy not possible with standard DSP software. Cell phenotyping using IF morphology scans supervised cell deconvolution. DSP results showed strong correlation with patient outcomes.
Conclusions: This study demonstrates that ROI-based spatial analyses can effectively explore the impact of hypoxia on immune infiltration in HNC. Automated AI-based ROI selection offers an unbiased, reproducible method for sampling relevant tumor subtypes based on hypoxia and immune infiltrate criteria. This approach provides a standardized, automated method for selecting ROIs and segmenting AOIs across diverse tissue types and pathological subtypes, enhancing throughput.

#179 Spatial and multiomics analysis reveals immune interactions as key drivers of immunotherapy outcomes in melanoma patients with in-transit metastases.

X. Bai[1], C. Quek[1], G. Al-Eryani[2], S. Ramkomuth[2], L. Baldwin[2], J. Tian[1], N. A. Adegoke[1], I. A. Vergara[1], F. Newell[3], K. Harvey[4], J. Reeves[2], A. J. Spillane[1], N. Waddell[3], S. N. Lo[1], A. M. Menzies[1], I. P. da Silva[1], U. Palendira[1], G. V. Long[1], R. A. Scolyer[1], A. Swarbrick[2], J. S. Wilmott[1];

[1]Melanoma Institute Australia, The University of Sydney, Sydney, Australia, [2]Garvan Institute of Medical Research, University of New South Wales, Sydney, Australia, [3]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [4]Garvan Institute of Medical Research, Sydney, Australia

Background: In-transit metastasis (ITM) of melanoma occurs between the primary tumor and draining lymph nodes. ITM can be managed by by adjuvant immunotherapy after resection, or immunotherapy alone when unresectable. Nevertheless, nearly half of ITM patients are resistant, which constitutes a clinical challenge. Multiomic spatial profiling offers insights into features influencing immunotherapy response, but the tumor microenvironment (TME) and biological determinants of ITM remain poorly defined. This study aims to characterize molecular and spatial TME attributes in ITM patients to improve understanding of immunotherapy response and resistance.
Methods: Fifty-four samples from ITM patients treated with immunotherapy were collected at pre-treatment (PRE) and progression (PROG). Patients with a complete or partial response in the advanced setting, or recurrence-free survival over 12 months in the adjuvant setting, were classified as "responsive," and others as "resistant". Single-cell sequencing and 40-marker imaging were conducted on 18 matched tumor dissociates and FFPE samples at PRE (n=3 resistant, n=5 responsive) and PROG (n=10). Whole genome sequencing on 12 fresh frozen samples (n=4 resistant, n=8 responsive at PRE) were used to identify somatic variants.
Results: While regional immune cell proportions were broadly similar across response groups, PRE responders showed increased intra- and peri-tumoral T cells, and surprisingly, reduced CD141+ dendritic cells (cDC1s) compared to resistant patients (P=0.024). K-means clustering identified 7 spatially resolved cellular neighborhoods (CNs) across all ITMs with heterogeneous cellular constitution; nevertheless, lymphocyte-enriched CNs were more dispersed in PRE responders and interacted with other immune and tumor CNs, while remaining peripheral in PRE resistant tumors. Despite having a lower DC density, pairwise interaction analysis highlighted significant interactions between cDC1s and CD14+ macrophages in PRE responders, and between macrophages and IDO1+ CD4+ T cells or Granzyme B+ CD8+ T cells ($P<0.05$, log2 fold change>0.2), suggesting enhanced macrophage-driven local T cell stimulation in the absence of DCs. Single-cell transcriptomics analysis comfirmed the reduced proportion of cDC1s in PRE responders compared to resistant ITM (P=0.006). Genomic profiling revealed *EREG* mutations exclusively in resistant ITMs, which has been linked to immunoregulationand tumor invasion through the EGFR pathway. Ongoing analysis explores interactions among DCs, macrophages, T cells, B cells, melanocytes, and endothelial cells to elucidate TME dynamics associated with immunotherapy outcomes.
Conclusion: These findings deepen our understanding of tumor-immune interactions in ITM patients and inform personalized immunotherapy approaches tailored to their unique TME.

#18 Fisetin effectively inhibits cancer stem cell properties in pancreatic ductal adenocarcinoma.

Anjali Aggarwal[1], Vinit Sharma[1], Rajesh Gupta[2], Mayank Sharma[1], Ankita Semwal[1]

[1]Anatomy, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[2]Surgical Gastroenterology, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Introduction: Cancer stem cells (CSCs) are crucial in the aggressiveness and chemoresistance of pancreatic ductal adenocarcinoma (PDAC). Targeting CSCs is essential for effective treatment and preventing relapse. Fisetin, a natural flavonoid, has demonstrated anticancer, anti-inflammatory, and antioxidant properties. This study investigates the anti-CSC effects of fisetin in PDAC.
Methods: CSCs were isolated from Panc-1 cells and explant cultures of PDAC tissue using fluorescence-activated cell sorting (FACS) with specific surface markers (CD44, CD24, CD133, CD326/ESA). The isolated CSCs were treated with various doses of fisetin for 24 and 48 hours, and the half-maximal inhibitory concentration (IC50) was determined using the MTT assay. The effects of fisetin on colony formation, cell cycle, apoptosis, migration, invasion , and sphere formation were evaluated. Additionally, the expression of epithelial-mesenchymal transition (EMT) markers and stemness markers was assessed at both gene and protein levels. The molecular mechanisms underlying the anti-CSC effects of fisetin were investigated through mRNA sequencing, followed by validation using ELISA.
Results: Fisetin significantly reduced viability and colony formation of CSCs in a dose- and time-dependent manner. The apoptotic cells increased from 2.06% in untreated to 50.9% in fisetin-treated CSCs. This was further supported by enhanced expression of apoptosis markers Bid and Bcl-2 in fisetin-treated CSCs. Migration capacity was significantly reduced, with the wound closure area increasing from 1.18% to 29.5%. Fisetin also induced cell cycle arrest, with a notable increase in the percentage of cells in the G2 and S phases. The size of tumor spheroids was significantly reduced after treatment. Additionally, fisetin elevated the expression of the epithelial marker E-cadherin and reduced the level of the mesenchymal marker N-cadherin. The expression of transcription factors SOX2 and OCT4, which are associated with the maintenance of CSCs, was decreased. Reactive oxygen species (ROS) levels in CSCs were significantly reduced. Fisetin treatment led to the downregulation of genes involved in inflammatory signalling pathways, including BCL2A1 (NF-κB target gene), CXCL1, CXCL8, CX3CL1, and CCL2. KEGG pathway analysis showed that the NF-κB and cytokine-cytokine receptor signalling pathways were significantly downregulated following fisetin treatment. ELISA further confirmed the significant downregulation of NF-κB p65 signaling ($p = 0.013$) in fisetin-treated CSCs.
Conclusion: Fisetin effectively targets and inhibits CSCs in PDAC, modulating key markers of epithelial-mesenchymal transition and stemness, while downregulating NF-κB signaling. These results support the need for further validation in in vivo models.

#183 High-content screening reveals kinase regulators of Dvl2 phase separation in Wnt signaling: Implications for targeted cancer therapy.

Antonia Schubert[1], Florian Heigwer[1], Christian Scheeder[1], Oksana Voloshanenko[1], Dominique Kranz[1], Thilo Miersch[1], Barbara Schmitt[1], Melanie Kuhse[1], Franziska Ragaller[1], Nadine Winkler[1], Anastasija Paneva[1], Daniel Gimenes[2], Diana Ordonez-Rueda[2], Jennifer Schwarz[3], Frank Stein[3], Dirk Jager[4], Ulrike Engel[5], Michael Boutros[1]

[1]Signaling and Functional Genomics, DKFZ German Cancer Research Center, Heidelberg, Germany,[2]Flow Cytometry Core Facility, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany,[3]Proteomics Core Facility, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany,[4]Medical Oncology, National Center for Tumor Diseases (NCT), University Hospital Heidelberg, Heidelberg, Germany,[5]Nikon Imaging Center (NIC), BioQuant and Centre for Organismal Studies (COS), Heidelberg, Germany

Wnt signaling controls cell proliferation, differentiation, and migration, with critical roles in diseases such as cancer. It was proposed that Wnt signaling relies on the formation of dynamic biomolecular condensates, such as the “signalosome” and the “destruction complex”, with a potential to modify the spatial and temporal regulation of signaling outcomes. To investigate the role of phase separation in Wnt signaling, we generated a cell line with endogenously tagged Dvl2, a central Wnt scaffolding protein, using the mEos3.2 fluorophore. Applying live-cell and single-molecule localization microscopy, we could demonstrate that Dvl2 forms condensates at the centrosome in a Wnt- and cell-cycle-dependent manner in HEK293T cells (Schubert et al. PNAS, 2022).
Here, we used image-enabled cell sorting to separate cell pools based on these endogenous Dvl2 condensates, followed by temporal and phosphoproteomic analysis to further understand their functional significance. Condensate-positive cells were enriched with proteins associated with planar cell polarity (PCP) Wnt signaling and proteins of the G2/M cell cycle phase were differentially phosphorylated, suggesting distinct signaling and cell-cycle states.
We then conducted a high-throughput, image-based screen of more than 600 kinase inhibitors to identify modulators of Dvl2 condensate dynamics. Several kinases influenced Dvl2 phase separation, revealing a correlation of condensate formation and canonical Wnt signaling activation. Notably, a candidate inhibitor disrupted both Dvl2 condensates and Wnt signaling, affecting cell division, most likely through microtubule regulation. Further phosphoproteomic and chemical-genetic interaction analysis applying CRISPR/Cas9 targeting the Wnt scaffolds APC, Axin1, and MCC, alongside kinase inhibition, revealed distinct roles for these scaffolds in condensate regulation and, interestingly, pathway outcomes.
This work underscores the regulatory complexity of Wnt condensates, highlighting post-translational modifications, cellular context, and scaffold roles in Wnt signaling. Our study introduces a high-content screening approach to intracellularly study phase-separated systems. Targeting condensates may represent a novel therapeutic strategy in cancers with aberrant Wnt signaling.

#184 PHF6-LEO1 axis depletion drives aggressive colorectal cancer through WNT activation and metabolic reprogramming with therapeutic implications.

Su Chan Park[1], Shinae Park[2], Ji-Yeon Lee[1], Taehan Yoon[1], So Hyun Kwon[1], Jung-Shin Lee[2], Eun Jung Park[3], Ji Min Lee[1]

[1]Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of,[2]Department of Molecular Bioscience, College of Biomedical Science, Kangwon National University, Chuncheon, Korea, Republic of,[3]Department of Colon and Rectal Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Colorectal cancer (CRC) progression is closely linked to alterations in key signaling pathways and metabolic reprogramming. The WNT signaling pathway plays a critical role in regulating cell development and proliferation, and its abnormal activation is a hallmark of CRC. Plant Homeodomain 6 (PHF6), a chromatin-associated factor, is known for its roles in clonal hematopoiesis, ribosome biogenesis, DNA repair, and aging, and is frequently mutated in lymphoid cancers and leukemia. In this study, RNA-seq and ATAC-seq were conducted to investigate the function of PHF6, we identified PHF6 as a novel regulator of the WNT signaling pathway. We found that PHF6 depletion activate WNT signaling and proliferation of colon cancer cells. In the AOM/DSS model, PHF6 knockout mice exhibited larger polyp formation compared to wild type mice, with polyps extending into the proximal region. Proximal CRC is more prevalent and aggressive and has distinct genetic features compared to distal CRC. Alterations in proximal CRC include the PIK3CA mutation and CpG island methylator phenotype (CIMP)-high frequency, the development of CIMP is followed by global gene expression alteration and metabolic changes. However, the molecular mechanisms of this type of cancer are not fully understood. We observed a reduced levels of LEO1, the transcriptional elongation partner of PHF6 within the PAF1 complex, in the proximal region of PHF6 KO mice. We identified LEO1 and SETD1A as epigenetic regulators of lipid homeostasis in colon cancer cells and patient samples with matched normal. Dysregulation of lipid metabolism in cancer cells impacts tumor initiation, progression, and metastasis. LEO1 KO cells exhibited reduced expression and activation of SREBP1, a master regulator of lipid metabolism, under glucose starvation. These effects were further enhanced by SETD1A knockdown. LEO1 was found to localize to the nucleus and is required for the nuclear localization of SETD1A under nutrient stress. These cells showed an altered cell cycle, resulting in reduced proliferation but increased metastatic potential. These findings suggest that the PHF6-LEO1 axis plays a crucial role in the regional development and metastasis, underscoring its importance in advancing our understanding of tumor biology and guiding targeted therapy development.

#185 Alternative NF-kB inhibits MAPK activity to promote quiescence and drug resistance in ovarian cancer.

Cecilia Gallo, Mikella Robinson, Jacqueline Lara, Omar Lujano Olazaba, Carrie D. House

Biology, San Diego State University, San Diego, CA

Ovarian Cancer (OC) is the most lethal gynecological malignancy in the United States and despite good initial response to chemotherapy, approximately 80% of late-stage patients relapse. Recent studies suggest that a subpopulation of tumor cells with stem-like characteristics, called Cancer Stem-like Cells (CSCs), resist treatment and drive recurrence. Several signaling pathways, including MAPK and NF-kB, are known for their roles in tumor initiation, disease progression, and drug resistance in ovarian cancer. We previously showed that the canonical NF-kB factor, RelA, primarily promotes proliferation, while the non-canonical NF-kB factor, RelB, promotes quiescence. Additionally, activation of MAPK/ERK has been implicated in proliferation of ovarian cancer cells. NF-kB and MAPK signaling cascades are both critical for OC progression, although their precise roles in maintaining CSCs remain unclear. Our preliminary data showed that knockdown (KD) of RelB in vivo following chemotherapy did not decrease growth of residual tumors, whereas KD of RelA or inhibition of MAPK alone reduced growth of residual tumors. However, combining RelB KD with MAPK inhibition reduced growth of residual tumors comparable to RelA KD or MAPK inhibition alone. Therefore, we hypothesize that RelB supports quiescence in CSCs by downregulating MAPK activity. Western Blot analysis indicated increased MAPK activity in the absence of RelB in two high grade serous ovarian cancer (HGSOC) cell lines. Moreover, in vitro cell cycle studies revealed an increase in the percentage of CSCs in the S phase following RelB KD and combining RelB KD with MAPK inhibition rescued this phenotype. Taken together, our findings suggest that RelB downregulates MAPK activity to support quiescence in ovarian CSCs. Ongoing studies are investigating the expression of S phase specific cyclins in the absence of RelB to further elucidate mechanisms of proliferation and cell cycle progression regulated by RelB and MAPK. Additionally, immunohistochemistry (IHC) analysis using tissues derived from control, RelB KD, and RelB KD with MAPK inhibition tumors will be used to evaluate changes in NF-kB, MAPK and cell cycle proteins in residual and regrown tumors. This work reveals novel mechanisms of how RelB supports drug resistance in ovarian CSCs and information gleaned from this study could inform future therapeutic studies.

#186 Tumor cell-intrinsic STAT2 signaling contributes to mitochondrial energetics in colorectal cancer.

J. Canar[1], S. Fossati[1], M. Slifker[2], A. M. Gamero[1];
[1]Temple Univ. Lewis Katz School of Medicine, Philadelphia, PA, [2]Fox Chase Cancer Center, Philadelphia, PA

Colorectal cancer (CRC) is the 3rd most common cancer type in the US, with an alarming increase in incidence rates in young adults that is preventable when detected early. Identifying the molecular culprits involved in promoting CRC is urgently needed to design novel therapeutic interventions to combat this disease. Signal transducer and activator of transcription 2 (STAT2) is a key transcription factor that uniquely mediates the antitumor effects of type I and III interferons (IFNs), a family of pleiotropic cytokines, by activating the transcription of genes involved in restricting tumor growth. Much of what is known about STAT2 is in the context of IFN signaling. Yet, the precise function of STAT2 in cancer is understudied. New evidence shows that STAT2 has opposing biological effects in cancer. We and others have reported that STAT2 inhibits tumor cell proliferation and induces apoptosis in response to IFNs. Conversely, our new data finds that STAT2 promotes tumor growth in pre-clinical models of CRC (spontaneous and tumor xenografts) by a mechanism that is still unidentified. To begin to elucidate the pro-tumorigenic effects of STAT2, we analyzed the human colon adenocarcinoma TCGA datasets for an association with overall survival and alterations in transcriptional signatures between high and low STAT2 expression levels. First, we found a correlation between high STAT2 levels and poor survival. Second, out of the 42 hallmark gene set pathways significantly enriched, oxidative phosphorylation (OXPHOS) was strikingly downregulated in STAT2-high tumors. We performed mitochondrial and glycolysis stress tests to determine changes in cellular energetics between parental and STAT2 deficient (STAT2KO) human HCT116 colon adenocarcinoma cells. Compared to parental tumor cells, STAT2 KO tumor cells had lower glycolytic capacity but increased maximal respiration and spare respiratory capacity. We next assessed the role of STAT2 in mitochondrial homeostasis because loss of STAT2 had been previously reported to interfere with mitochondrial fission. We determined by western blot analysis the activation status of Dynamin-related protein-1 (Drp1), a key protein that regulates mitochondrial fission. We found impaired activation of Drp1 in STAT2 KO tumor cells. Drp1 phosphorylation was reduced at activatory serine 616 and increased at inhibitory serine 627. Overall, our findings are first to indicate that STAT2 in CRC may be involved in disrupting mitochondrial respiration and favoring glycolysis, a hallmark of cancer, to promote CRC. This paves the way for determining whether the tumor promoting effects of STAT2 are dictated at the mitochondrial level by disrupting OXPHOS and whether this is occurring independently of IFN signaling. Studies are ongoing to determine whether other components of mitochondrial fission and kinases involved in Drp1 activation are also regulated by STAT2.

#187 STAT1 and GBP1 promote proliferation in postpartum breast epithelium by downregulating cyclin-dependent kinase inhibitors: implications for increased postpartum breast cancer risk.

Joshua Ogony[1], Melody Stallings-Mann[1], Sarah McLaughlin[2], Mark Sherman[3], **Derek C. Radisky**[1]

[1]Department of Cancer Biology, Mayo Clinic Florida, Jacksonville, FL,[2]Department of Surgery, Mayo Clinic Florida, Jacksonville, FL,[3]Department of Quantitative Health Sciences, Mayo Clinic Florida, Jacksonville, FL

Background: Postpartum breast cancer (PPBC) is associated with increased morbidity and mortality among women within 5 to 10 years following childbirth. The postpartum breast undergoes involution, involving tissue remodeling and immune cell infiltration, potentially creating a pro-tumorigenic microenvironment. The molecular mechanisms underlying this elevated risk remain poorly understood. In this study, we compared normal breast tissue samples and human mammary epithelial cells (HMECs) from postpartum women to those from age- and BMI-matched nulliparous women to elucidate potential molecular contributors to PPBC risk.
Methods: Transcriptomic profiling was performed on RNA extracted from FFPE normal breast tissues using the NanoString IO 360 and BC 360 platforms to examine gene expression in nulliparous and postpartum women under 45 years of age. HMECs were isolated from organoids derived from breast tissue samples and used for next-generation sequencing and knockdown experiments targeting STAT1 and GBP1. Gene set enrichment analysis (GSEA) was applied to NanoString and RNA-seq datasets to identify differentially enriched genes between postpartum and nulliparous women.
Results: Transcriptomic analysis revealed significant upregulation of interferon-stimulated genes, including STAT1 and GBP1, in postpartum breast tissues, consistent with increased immune responses during involution. NanoString data showed that markers of cell proliferation, such as Ki67, STAT1, and GBP1, were significantly higher in samples from parous compared to nulliparous women ($p < 0.05$). GSEA revealed that cell cycle-promoting genes (GBP1, cyclins, CDKs) were upregulated, while cyclin-dependent kinase inhibitors (CDKNs) were downregulated in postpartum breast tissues. Immunohistochemistry confirmed significantly higher expression of Ki67, STAT1, and GBP1 in postpartum versus nulliparous breast tissues ($p < 0.0001$). Silencing STAT1 and GBP1 in HMECs resulted in decreased cell proliferation, G1 cell cycle arrest, and increased expression of CDKN1A and CDKN1C.
Conclusion: These findings suggest that STAT1 and GBP1 promote proliferation in postpartum breast epithelial cells by downregulating cyclin-dependent kinase inhibitors, potentially contributing to the increased risk of PPBC. Targeting these pathways may offer novel strategies for mitigating postpartum breast cancer risk.

#188 Phosphorylation of StarD10 advances alcohol induced breast cancer progression.

M. Dagar, A. Floris, Y. Lim, S. Chandla, M. Justo, N. Mavila, K. Ramani, M. Tomasi;
Cedars-Sinai Medical Center, Los Angeles, CA

Introduction: Breast cancer is the second most common cancer among women, and excessive alcohol consumption is a well-established risk factor for various cancers, including breast cancer. Even moderate alcohol consumption (one drink per day) increases breast cancer risk by 10% compared to non-drinking women. The STAR-related lipid transfer domain-containing protein 10 (StarD10), a phosphoprotein, is overexpressed in 35-40% of primary human breast cancers and interacts with the ErbB2 signalling pathway. Our recent studies demonstrated that ethanol administration promotes StarD10 dephosphorylation and increases its activity, as well as enhances ErbB2 expression, which is strongly correlated with increased cell malignancy and aggressiveness. However, the precise role of StarD10 as a subcellular lipid transporter in the regulation of ErbB2 signalling remains unclear. This study aimed to elucidate ethanol-induced changes in StarD10 activity, with the inhibition of its phosphorylation being a potential target for mitigating alcohol-induced breast cancer progression.

Materials and Methods: To identify specific phosphorylation sites, phospho-peptide mapping of StarD10 from MCF-7 and SKBR-3 cells was performed. The identified phosphorylation site in StarD10 was further validated by western blot and co-immunoprecipitation studies. A lipid overlay assay was performed to assess StarD10 binding to phospholipids.

Results: Phospho-peptide mapping identified threonine 288 (T288) as a specific phosphorylation site, regulated by casein kinase 1α (CK1α). Silencing CK1α blocked StarD10 phosphorylation, mimicking the dephosphorylation effects induced by ethanol. Lipid overlay assay demonstrated that StarD10 binds to a range of phospholipids. We found the interaction of StarD10 with PI(3)P, PI(4)P, PI(5)P, $PI(3,4)P_2$, $PI(3,5)P_2$, $PI(4,5)P_2$, $PI(3,4,5)P_2$ in both MCF-7 and SKBR-3 cells. PP2A and PP1, serine/threonine phosphatases regulate protein function by dephosphorylation impacting in several critical cellular pathways. We found that treatment with okadaic acid (a PP2A inhibitor) and calyculin A (a PP1/PP2A inhibitor) blocked ethanol-induced StarD10 dephosphorylation in both MCF-7 and SKBR-3 cells. Also, this treatment inhibited the membrane fluidity as compared to ethanol. It suggests a regulatory role of PP1/PP2A in the StarD10 function.

Conclusions: The role of phosphorylated StarD10 in alcohol-induced breast cancer progression is mediated by the phosphorylation of T288 by CK1α. PP1/PP2A acts as a positive regulator of StarD10 activity, further implicating these phosphatases in the progression of ethanol-induced breast cancer.

#189 The role of DEPTOR in promoting breast cancer initiation and progression.

A. Nam, B. Xiao, V. Sanguin-Gendreau, D. Zuo, W. J. Muller;
McGill Univ. Goodman Cancer Ctr., Montreal, QC, Canada

Breast cancer is one of the most common malignancies in the world, with 2.3 million women diagnosed in 2022. It is largely driven by dysregulation of cellular signaling pathways such as mTOR, which, as a key regulator of cellular growth, is frequently hyperactivated in many cancers. Despite evidence implicating mTOR as a promising target for anti-cancer therapies, many inhibitors in clinical trials yield unfavorable outputs, largely due to its complex regulatory mechanisms that are yet fully understood. DEPTOR, a recently identified direct inhibitor of mTOR, has thus become an intriguing focus of study. Interestingly, while many tumors exhibit high mTOR activity and, as expected, also show low DEPTOR expression, paradoxically, high DEPTOR levels in several cancers corresponds with the worst prognoses for patients. These observations point to dual roles for this protein, and unknown pro-tumor functions that are potentially independent of mTOR. Our work aims to expand our understanding of the functions and interacting partners of DEPTOR, and characterize its role in breast cancer, about which knowledge is currently lacking. In a mouse model of luminal B breast cancer, we observe a severe defect in early mammary cell expansion, delay in tumor onset, and reduction in tumor penetrance upon genetic ablation of DEPTOR, indicating DEPTOR acts in an oncogenic capacity in this system. However, these results are not accompanied by a significant change in activity of major mTOR effectors, and gene expression profiles indicate changes in factors related to transcription and chromatin accessibility but not translation, despite the latter being largely modulated by mTOR to drive cell growth. Additionally, while the innate proliferative ability of early DEPTOR-deficient mammary cancer cells appears unchanged, their immune microenvironment (TIME) is altered to favour an anti-tumor immune response. Thus, we will investigate how DEPTOR-dependent transcriptional regulation may reprogram the TIME to influence tumor initiation and progression. Considering mTOR’s ubiquity in cancer, elucidating the activities of a core regulatory component such as DEPTOR will provide important insights for its therapeutic targeting. Further, by investigating DEPTOR’s mTOR-independent roles, this work will highlight the scope of a poorly understood but widely acting player in cancer and its potential as a novel therapeutic target.

#19 ACTL6A promotes the progression of prostate cancer by modulating GLI1 expression in the Hedgehog signaling pathway.
L.-H. Cheng, K. Tsai;
Taipei Medical University, Taipei, Taiwan

The disruption of tissue organization is a major contributing factor to the malignant transformation of glandular epithelium, including prostate glands. Three-dimensional organotypic cultures have facilitated the discovery of molecular mechanisms underlying malignant progression. Using a robotic-assisted MicroWestern Array-based proteomics screening, we identified that the protein abundance level of the chromatin remodeling factor ACTL6A is upregulated in disorganized prostate epithelial organoids. We showed that ACTL6A critically regulates prostate glandular morphogenesis as its overexpression led to glrandular transformation. Consistent with this finding, ACTL6A expression is higher in human prostate cancer compared to normal prostate tissue and is associated with poor clinical prognosis. At the functional level, tthe knockdown of *ACTL6A* expression in PCa cells attenuated stemness and tumorigenesis *in vitro* and PCa progression in an orthotopic mouse tumor model. Intriguingly, screening of development-associated signaling pathways identified the Hedgehog (Hh) pathway, whose activity and the target genes were reduced by the loss of *ACTL6A* expression in PCa cells. Further mechanistic and molecular studies revealed that ACTL6A regulates the protein abundance level of GLI1, the key transcriptional factor in Hh-pathway, PCa cells by disabling its ubiquitin-dependent proteosomal degradation. Our study thus illuminated a novel oncogenic mechanism mediated by the ACTL6A-GLI1-Hh signaling axis in PCa, which may have diagnostic and therapeutic implications.

#190 Effects of bisphenol compounds on gene expression and cellular outcomes in MDA-MB-231 breast cancer cells mediated via the G protein-coupled estrogen receptor.

Norman R. Estes, Cameron Sheeler, Olivia Merriam

University of Alabama at Birmingham, Birmingham, AL

Bisphenol A (BPA) is used in the manufacturing of various consumer products such as plastic bottles, epoxy resins in food cans, thermal printed paper, and dental sealants. BPA has been identified as an endocrine disruptor due to its ability to mimic estrogen by activating estrogen receptor signaling pathways and regulating estrogen-responsive genes through a classical estrogen receptor-mediated pathway. Concerningly, BPA is linked to health risks, such as hormone-dependent cancers, metabolic diseases, and developmental defects. What remains unclear is the effect BPA and BPA alternatives have on gene expression and cellular outcomes via interaction with a membrane-bound estrogen receptor that functions as a G protein-coupled receptor (GPER). MDA-MB-231 triple-negative breast cancer cells (TNBC) express GPER but lack the classical estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). These studies seek to determine if BPA or alternatives, functioning through GPER, differentially affect gene expression, cell proliferation, and cell migration through GPER. Preliminary studies using total RNA sequencing (RNA-Seq) identified differential gene expression patterns in cells treated with BPA or 17β -estradiol including changes in cancer-related pathways, CREB signaling, and G-protein coupled receptor-mediated pathways. Cell migration assays performed in MDA-MB-231 cells treated with BPA, BPB, BPC, or 17β -estradiol suggest that treatment with these compounds differentially affects migration, with the highest degree of migration being induced by BPC. These studies indicate that BPA and BPA alternatives differentially affect gene expression and cell migration in triple negative MDA-MB-231 breast cancer cells and exposure to these compounds may affect therapeutic outcomes in TNBC patients. Future studies will seek to clarify the role of select genes and related pathways as identified through RNA-Seq analysis in TNBC cells treated with BPA or BPA alternatives in order to clarify the role of GPER-mediated signaling in TNBC cells.

#191 Functional role of chromosome 1q loci on breast cancer progression.

A. Bera[1], E. Russ[1], H. Hu[2], C. D. Shriver[3], **M. Srivastava**[1];
[1]Uniformed Services University of the Health Sciences, Bethesda, MD, [2]Chan Soon-Shiong Institute of Molecular Medicine, Windber, PA, [3]Murtha Cancer Center, Walter Reed National Military Medical Center, Bethesda, MD

Several studies have identified differential expression at various loci on the long arm of chromosome 1 (1q) as the most frequent cytogenetic abnormalities associated with human breast carcinoma. To investigate the impact of genetic alterations on chromosome 1q, we analyzed data from over thirteen thousand human breast tumors (n=13,146 samples; corresponding to 12,229 patients across 30 studies) using cBioPortal, which included comprehensive datasets like The Cancer Genome Atlas(TCGA). Our findings revealed that eight genes exhibit significant copy number alterations (12-15%), predominantly amplifications. These genes include *TRIM67* (1q42.2, 14%), *DISC1* (1q42.2, 14%), *REN* (1q32.1, 15%), *DNM3* (1q24.3, 12%), *ATP1B1* (1q24.2,12%), *VSIG8* (1q23.2, 14%), *SPTA1* (1q23.1, 14%) and *MUC1* (1q22, 14%). In contrast, analysis across more than 100,000 samples from over 35 different cancers (n=105,424samples; 101,597 patients across 226 studies) showed that these genes have much lower alteration frequencies, approximately 3%. Besides, these genes also exhibited notably low expression levels at both RNA and protein levels in normal breast tissues. We further explored the clinical relevance of these genes, examining their roles in breast cancer prognosis and survival outcomes. Our mutual exclusivity and co-occurrence analyses revealed distinct patterns of genetic interplay, indicating a probable collective gain-of-function that drives breast cancer progression. Specifically,TP53 was found to co-occur with *MUC1, SPTA1,* and *VSIG8,* while *REN* exhibited mutual exclusivity. The driver gene *PIK3CA* co-occurred with *DISC1, TRIM67*, and *REN*, whereas *ERBB2* showed co-occurrence with all eight genes. These findings suggest a complex network of genetic interactions that may underlie invasive and metastatic breast cancer phenotypes.

Additionally, we observed that some of the above mentioned gene products (proteins) including *REN* (Renin) are detectable in serum, suggesting potential as biomarkers for recurrence or prognosis. Our ongoing studies are focused on validating these proteins as diagnostic and therapeutic targets. Collectively, this study underscores the importance of multi-locus evaluation on chromosome 1q, which could pave the way for novel diagnostic and therapeutic strategies in breast cancer management.

#192 Honokiol effectively induces apoptosis by targeting the hedgehog signaling pathways in breast cancer.

Santosh K. Singh, Rajesh Singh

Microbiology, Biochemistry & Immunology, Morehouse School of Medicine, Atlanta, GA

Breast cancer (BrCa) is a heterogeneous and deadly cancer affecting women, involving various pathways regulating the growth and proliferation of cancer cells. Upon diagnosis, BrCa is typically treated according to the molecular subtypes such as estrogen receptor (ER), progesterone receptor (PR), or human epidermal growth factor receptor 2 (HER2). In recent years, chemotherapy and targeted therapy have improved the 5-year survival rate for patients with receptor-positive BrCa. However, the patients diagnosed with triple-negative breast cancer (TNBC) remain unsatisfactory. The existing therapies, such as chemotherapy, cause drug resistance, toxicity, and relapse. Therefore, identifying the alternative approach and molecular targets responsible for BrCa development is crucial for improved therapy. One such target is Sonic Hedgehog (Shh) signaling molecules, which have been linked to the activation of several pathways important for developing BrCa. Shh is a critical component of the Hedgehog (Hh) pathway known for cell differentiation and tissue development. In this study, we investigated the effect of Honokiol (HNK), a dietary photochemical isolated from the *Magnolia officinalis* tree, on inhibiting the progression of TNBC cells (MDA MB231, MDA MB468) and inducing apoptosis *via* the Shh signaling pathway. HNK possesses potent anti-angiogenic, anti-microbial, anti-inflammatory, and antitumoral activities against aggressive cancers, including BrCa. However, the effect of HNK in targeting Hh signaling in TNBC cells remains limited. To determine the IC50 values of HNK, an MTT assay was performed for different time intervals with various concentrations (5-100μM). HNK cytotoxicity was estimated using live/ dead cell assay, scratch assay, and clonogenic assays. The expression of Hh signaling molecules and apoptotic markers were quantitated with real-time PCR and western blot assay, and an immunofluorescence assay was performed to observe the Shh expression in both cell lines. Our results indicate that HNK led to lower cell viability at 48 hours of treatment compared to control. The flow cytometric analysis showed that HNK enhanced the apoptosis of TNBC cells. Furthermore, HNK increased the expression of cell cycle inhibitor p21WAF1/CIP1, which induces cell cycle arrest by controlling the downstream molecules, CDK4 and cyclin D1. Additionally, HNK suppresses the expression of NF-kB and Hh molecules (Shh, Gli1, and Ptch1) in both TNBC cells. These findings suggest that HNK may directly affect the Shh signaling pathway by interfering with NF-κB crosstalk activity, thereby preventing the communication between tumor cells and surrounding tissue. The migration assay further supported these results. Overall findings indicate a promising role of HNK in targeting the Shh pathway in TNBC type of breast cancer, which could improve the understanding for further translational research.

#193 Notch pathway activation predicts poor prognosis in combined hepatocellular carcinoma-cholangiocarcinoma.

Seokhwi Kim[1], Chan Mo Yang[2], Jaehong Lim[3], Ara Ko[3], Taebum Lee[4], Young-Bae Kim[1], Dakeun Lee[1]

[1]Department of Pathology, Ajou University School of Medicine, Suwon, Korea, Republic of,[2]Department of Biomedical Science, Ajou University Graduate School of Medicine, Suwon, Korea, Republic of,[3]Ajou University School of Medicine, Suwon, Korea, Republic of,[4]Lunit, Seoul, Korea, Republic of

Background: Combined hepatocellular carcinoma and cholangiocarcinoma (cHCC-CCC) is a distinct type of tumor that differs from both hepatocellular carcinoma (HCC) and cholangiocarcinoma (CCC). Although the involvement of the Notch signaling pathway in its development is recognized, its role in clinical specimens has not been extensively studied.
Methods: We analyzed surgically resected specimens from 38 HCCs, 32 CCCs, and 42 cHCC-CCCs obtained between 2017 and 2023 at Ajou University Hospital. The expression levels of the HCC marker Glypican-3, the CCC markers CK7 and CK19, and the hepatobiliary progenitor cell markers CK19, EpCAM, and CD13 were investigated through immunohistochemistry (IHC). The expression of Notch receptor subtypes (Notch1-4) and the downstream transcription factors Hes5 and Ascl1 were analyzed using qRT-PCR. Additionally, NOTCH1 and Hes5 protein expression levels were evaluated via IHC.
Results: Compared to HCC, cHCC-CCC exhibited reduced expression of Glypican-3 (p<0.0001) and increased expression of CK7 (p<0.0001), CK19 (p<0.0001), and EpCAM (p<0.0001). When compared to CCC, cHCC-CCC displayed significantly elevated levels of Glypican-3 (p<0.0001) and CD13 (p<0.0001). Among the four Notch receptor subtypes, the mRNA level of Notch1 was preferentially elevated in cHCC-CCC compared to HCC or CCC. Similarly, the mRNA expression levels of Hes5 and Ascl1 were higher in cHCC-CCC than in HCC (p=0.0920 for Hes5; p=0.5453 for Ascl1) and CCC (p=0.0586 for Hes5; p=0.0759 for Ascl1). Higher NOTCH1 protein expression was observed in cHCC-CCC compared to HCC (mean H-score: 43.9 vs. 24.0, p<0.01) and CCC (mean H-score: 43.9 vs. 29.4, p<0.05). Similarly, Hes5 expression in cHCC-CCC was substantially greater than in HCC (mean H-score: 52.7 vs. 8.6, p<0.001). A scatter plot analysis of NOTCH1 and Hes5 expression levels in cHCC-CCC revealed three distinct subgroups based on their expression profiles. Group 1 (n=28) was characterized by low levels of NOTCH1 expression (Notch-inactivated). Group 2 (n=5) exhibited elevated expression of both NOTCH1 and its downstream target (Notch-responsive). Group 3 (n=8) demonstrated high NOTCH1 expression but very low levels of Hes5 expression (Notch-non-responsive). Survival analysis indicated that Group 1 and Group 3 cHCC-CCCs had overall survival and progression-free survival (PFS) rates similar to those of HCCs. In contrast, Group 2 (Notch-responsive subtype) exhibited a significantly worse PFS (hazard ratio [HR] 7.708 [95% confidence interval (CI) 0.7807-76.11], p=0.0002), which was comparable to the PFS of CCC (HR 5.355 [95% CI 2.376-12.10], p<0.0001).
Conclusion: The Notch signaling pathway is differentially expressed in cHCC-CCC. Tumors with activated Notch signaling components are associated with poorer prognostic outcomes within the cHCC-CCC cohort.

#194 Angiopoietin-like 4 induces proliferation and migration of head and neck squamous cell carcinoma cells via p38 kinase and NRP1/ABL1/PXN pathway.

Ajay Kumar

Oncology and Diagnostic Sciences, University of Maryland, Baltimore, Baltimore, MD

Background: The molecular mechanisms in which angiopoietin-like 4 (ANGPTL4), a pluripotent protein implicated in cancer development, contribute to head and neck squamous cell carcinoma (HNSCC) growth and dissemination are unclear.
Methods: We analyzed ANGPTL4 expression in human normal oral keratinocytes (NOKs), dysplastic oral keratinocytes (DOKs), oral leukoplakia cells (LEUK1), and HNSCC cell lines, HN13, HN6, HN4, HN12, and CAL27, as well as in tissue biopsies from patients with oral dysplasia, and primary and metastatic HNSCC. We further examined the contribution of ANGPTL4 cancer progression in an HNSCC orthotopic floor-of-mouth tumors model and upstream and downstream signaling pathways linking ANGPTL4 to cancer cell proliferation and migration.
Results: ANGPTL4 expression was upregulated in premalignant DOKs and HNSCC cell lines compared to NOKs as well as in tissue biopsies from patients with oral dysplasia, and primary and metastatic HNSCC. Downregulation of ANGPTL4 expression inhibited primary and metastatic cancer growth in an HNSCC orthotopic tumor model. Interestingly, ANGPTL4 binding to the neuropilin 1 (NRP1) receptor led to phosphorylation of the focal adhesion protein, paxillin (PXN), and tumor cell migration; this was dependent on the tyrosine kinase ABL1. Further, we examined theextracellular signaling associated with ANGPTL4 expression in HNSCC. Intriguingly, amphiregulin (AREG), an epidermal growth factor receptor ligand, induced ANGPTL4 expression in NOKs and DOKs. AREG-induced activation of cell proliferation was dependent on ANGPTL4. We show that the proliferative potential of AREG in HNSCC is, in part, mediated by ANGPTL4. We also observed a role for p38 MAPK as an important downstream effector for the pro-tumorigenic effects ofANGPTL4 and an upregulation of a wide array of proliferative, proangiogenic, and proinflammatory factors upon treatment of NOKs with this adipokine. This suggests that ANGPTL4 may induce HNSCC tumorigenesis through both autocrine and paracrine pathways.
Conclusion: Our findings identify novel opportunities for the development of therapies targeting the ANGPTL4-induced signaling pathways for the treatment of patients with HNSCC.

#195 The transmembrane mucin MUC1 modulates MAPK signaling dynamics in pancreatic cancer cells.

Seth Thesing, **Ryan Lee Hanson**

Biology and Microbiology, South Dakota State University, Brookings, SD

The transmembrane mucin MUC1 plays several roles in the progression of pancreatic ductal adenocarcinoma (PDAC) and is associated with aggressive disease. One function of MUC1 is the regulation of intracellular signal transduction through association with transmembrane receptors like EGFR and Src. While multiple studies have shown that MUC1 can potentiate signaling mitogen activated protein kinases, such as ERK, it's unclear how dynamic this process is in PDAC. Previous studies examining ERK signaling have shown that dynamics can play a major role in the overall response to cells to growth factor signaling. To examine the influence of MUC1 on dynamic signal transduction we established cell lines expressing fluorescent biosensors of mitogen activated protein kinase activity (ERK, JNK, and p38) using cell lines derived from either wildtype KPC tumors or MUC1 knockout tumors. Morphologically, MUC1 expressing KPC cells appeared more mesenchymal consistent with MUC1's roles in mediating migration and invasion of tumor cells. By comparison, MUC1 knockout cells readily formed monolayers with epithelial morphology. Using time-lapse fluorescence microscopy, we examined whether these cells also exhibited differences in MAPK signaling over time and in response to EGF stimulation. At baseline, KPC wildtype cells showed sustained ERK activation consistent with constitutive activation via K-Ras G12D. In comparison, MUC1 KO cells while still exhibiting high levels of ERK activity would also undergo periodic pulses of on and off states suggesting that MUC1 contributes to sustained ERK activation in tumor cells. EGF stimulation was capable of inducing ERK activation in both KPC wildtype and MUC1 KO cells, but as before KPC wildtype cells exhibited sustained activation while MUC1 KO cells pulsed. Given the high constitutive ERK activity in KPC wildtype cells we hypothesized these cells may be more reliant on ERK activation to survive. Interestingly, while treatment with 25 nM trametinib had a stronger inhibitory effect on MUC1 knockout cells, viability assays suggest that MEK inhibition reduces KPC wildtype growth more strongly than in MUC1 KO cells. These findings suggest that the sustained ERK signaling promoted by MUC1 expression may make tumor cells more reliant on ERK signaling and more prone to MEK inhibition.

#196 Acetylcholine enhances HIF-1α expression in pancreatic cancer cells under hypoxia through nAchR-α7/PDPK1/YAP signaling pathway.

Y. Cho, E.-T. Oh, H. Kim, H. Park;
Inha University College of Medicine, Incheon, Korea, Republic of

The pancreas has a high distribution of the autonomic nervous system. The role of the autonomic nervous system in pancreatic ductal adenocarcinoma development has been addressed in recent studies. HIF-1 regulates the expression of genes involved in angiogenesis, metastasis, tumor growth, chemoresistance and radioresistance, underscoring the growing interest in targeting HIF-1 for cancer control. In this study, we investigated the molecular mechanisms underlying the neurotransmitter acetylcholine-enhanced HIF-1α expression in pancreatic cancer cells under hypoxia, leading to the growth of pancreatic cancer organoids. In vitro assays showed that, under hypoxic conditions, acetylcholine caused a concentration-dependent increase in nAChR-α7-mediated HIF-1α expression, enhancing expression of its target genes in pancreatic cancer cells. We further found that acetylcholine increased HIF-1α protein stability in pancreatic cancer cells under hypoxic conditions. This effect was mediated by PDPK1/YAP signaling pathway, as evidenced by the fact that acetylcholine-induced enhancement of HIF-1α expression was blocked by siRNA-mediated knockdown of PDPK1/YAP signaling pathway. Consistent with these findings, an investigation of the relationship between nAChR-α7 and clinicopathological features in pancreatic cancer patients using publicly available datasets showed that high levels of nAChR-α7 are correlated with a poorer prognosis in pancreatic cancer patients. Subsequently, nAChR-α7 specific inhibitor α-bungarotoxin efficiently inhibited the acetylcholine-induced increase of growth of pancreatic cancer organoids under hypoxia. Collectively, these findings identify novel mechanisms by which acetylcholine enhances HIF-1α expression through PDPK1/YAP signaling pathway and provide further evidence that HIF-1α is a potential anticancer target in acetylcholine-associated pancreatic cancer.

#197 Effects of three nucleoside reverse transcriptase inhibitor analogs on Stat3, NFκB, and JNK/c-Jun signaling in bone metastatic prostate cancer.

Wishrawana Sarathi Ratnayake, Luke Lajmi, Sloan Breedy, Aaron Todman, Karimeh Hagani, Kirpal Bisht, Mildred Acevedo-Duncan

Chemistry, University of South Florida, Tampa, FL

Bone metastatic prostate cancer (BMPC) is the primary cause of fatality in patients with prostate cancer, and there is currently no effective treatment available. The role of the bone microenvironment in this process has led to an increased focus on the interactions between cancer cells and the bone microenvironment, particularly with osteoblasts. Our study delved into the mechanisms of interactions between prostate cancer cells (DU-145 and PC-3) and the hFOB 1.19 osteoblast cell line. We are investigating the broader effects of three different nucleoside reverse transcriptase inhibitor (NRTI) analogs, namely KBMD-E, KBMD-G, and KBMD-H, for their potential development as anti-cancer drugs. Our previous findings indicated that aPKC-ι and ζ play a role in the progression and metastasis of prostate cancer and that NRTI analogs were capable of inducing apoptosis and pyroptosis in DU-145 and PC-3 cells while showing less pronounced effects on the hFOB.1.19 cell line. Our findings revealed that osteoblasts play a crucial role in helping prostate cells thrive in the bone microenvironment by producing chemokines that promote metastasis. Current data suggested that all three NRTI analogs negatively affect three oncogenic pathways, Stat3, NFκB, and JNK/c-Jun pathways, thereby inducing apoptosis and diminishing metastatic stimulating signals in DU-145 and PC-3. Transcription factors Stat3, c-Jun, and NFκB seem to be critical in establishing the prostate cancer cells in bones. Also, data suggested that these three pathways work in tandem. Data shows that KBMD-E/G/H upregulated interleukin (IL)-18 while downregulating IL-8 and IL-6. KBMD-E/G/H can be used to disrupt critical steps of these metastatic cascades of prostate cancer cells, which can be targeted to develop customized, tailored therapies for bone metastatic prostate cancer, which merit further research.

#199 Clinicopathological significance of stromal enzymes lysyl oxidase like 1, 3, and 4 in gastric cancer.

H. Kasashima, Y. Fukui, I. Omori, Z. Wang, S. Ozawa, T. Ishidate, K. Yonemitsu, Y. Seki, Y. Miki, M. Yoshii, T. Fukuoka, T. Tamura, M. Shibutani, T. Toyokawa, S. Lee, M. Yashiro, K. Maeda;
Osaka Metropolitan University, Osaka, Japan

[Background and Objective]
The Lysyl oxidase (LOX) family comprises enzymes that physiologically participate in the cross-linking of extracellular matrix components such as collagen and elastin, thereby playing roles in cell differentiation and tissue formation. In the tumor microenvironment, LOX is known to contribute to the remodeling of the cancer stroma and to influence cancer cell metastasis and differentiation. Our previous studies have reported associations between LOX, LOX-like (LOXL)2, and prognosis in gastric cancer. In this study, we investigated the clinicopathological significance of LOXL1, 3, and 4 in gastric cancer through immunohistochemical staining.
[Methods]
Immunohistochemical staining was performed to analyze the relationship between LOXL1, LOXL3, LOXL4 expression and the clinicopathological characteristics of 597 gastric cancer patients. Additionally, the influence of TGF-β on the expression of LOXL1, LOXL3, and LOXL4 was examined in vitro using diffuse-type gastric cancer cell lines (OCUM-2M, OCUM-12, KATO-III), gastric cancer lymph node metastatic cell lines (OCUM-2MLN), and gastric cancer peritoneal dissemination cell lines (OCUM-2MD3).
[Results]
LOXL1, LOXL3, and LOXL4 expression was significantly associated with T-factor, lymph node metastasis, lymphatic invasion, and venous invasion. LOXL1 expression was more common in the intestinal-type histological subtype ($p < 0.001$). Gastric cancer patients positive for LOXL1, LOXL3, or LOXL4 had a lower overall survival rate compared to negative patients ($p < 0.001$ for each). In vitro analysis revealed that LOXL1 mRNA expression was significantly higher in gastric cancer cell lines compared to lymph node metastatic and peritoneal dissemination cell lines, while LOXL3 and LOXL4 were significantly more expressed in metastatic and peritoneal dissemination cell lines. Western blot analysis showed similar results. When TGF-β was added to the gastric cancer cell lines, LOXL1 expression decreased, while LOXL3 and LOXL4 expression increased.
[Discussion]
The expression of LOXL1, LOXL3, and LOXL4 in gastric cancer is suggested to be associated with distant metastasis and poorer prognosis. TGF-β may influence the expression of LOXL1, LOXL3, and LOXL4 and potentially correlate with histological subtypes of gastric cancer.

#2 CAV1-ITGA3 axis attenuates cancer stemness in a preclinical murine model of triple-negative breast cancer.

Naveen Chintala Ramulu[1], Shilpa Thota[1], Rizwana Begum[1], Dhirendra Pratap Singh[2], Biplov Sapkota[1], Dayanidhi Raman[3], Joseph Francis[1]

[1]Comparative Biomedical Sciences, Louisiana State University, Baton Rouge, LA,[2]Krannert Cardiovascular Research Center, Indiana University School of Medicine, Indianapolis, IN,[3]Cell & Cancer Biology, University of Toledo, Toledo, OH

Triple-negative breast cancer (TNBC) is a notoriously aggressive phenotype with enhanced metastatic and relapse potential. Caveolin-1 (CAV1), a structural component of caveolae is linked to multiple processes involved in primary tumor progression and metastasis. Notably, an upregulation of CAV1 expression level enhances the metastatic capability of TNBC. Previous findings from our lab have demonstrated that CRISPR/Cas9-mediated knockout (KO) of CAV1 mitigates BC metastasis to the lungs in a 4T1 mouse model of mammary carcinoma via integrin alpha 3 (ITGA3) dysregulation. Breast cancer is a heterogenous disease with cancer stem-like cells of high plasticity that recapitulate the primary tumor at a distant metastatic site, CAV1-KO 4T1 cells may likely have an impact on regulation of cancer stemness. In order to investigate this, we evaluated one of the cancer stemness markers, ALDH1A1; pluripotency transcription factors (SOX2, OCT4 and NANOG); and drug efflux transporters (ABCB1, ABCC1, and ABCG2). In support of our hypothesis, data from *in vitro* CAV1-KO cells and the *in vivo* CAV1-KO tumors demonstrated a significant downregulation of cancer stemness parameters as compared to control tumors. Based on these findings, we conclude that CAV1-KO may regulate cancer stemness in a 4T1 mouse model of TNBC. Isolation of breast cancer stem cells (BCSCs) based on ALDH1 activity, morphological characterization, and 3D-functional assays will further solidify the role of CAV1 in cancer stemness and its invasive potential. Overall, we identified a novel role for CAV1 in regulating cancer stemness. CAV1-based targeted therapy has tremendous potential to augment treatment outcomes for TNBC.
Keywords: Triple-negative breast cancer, Caveolin-1, and breast cancer stem-like cells.

#200 Role of transforming growth factor beta signaling in mediating cancer-stromal interaction and its inhibition by apigenin in ovarian cancer.

Hyunjin Seo, Soo-Jung Lee, Somin Lee, **Youngjoo Kwon**

Ewha Womans University, Seoul, Korea, Republic of

Tumor microenvironment (TME) plays crucial roles in regulating tumor progression. Fibroblasts as predominant component in the TME have shown to promote growth of cancer cells. Transforming growth factor beta (TGF-β) regulates many cellular functions, including cell growth, differentiation, and apoptosis in a context-dependent manner. Growing evidence suggests that TGF-β mediates interaction between cancer cells and their associated fibroblasts (CAFs) to facilitate malignant progression. Polyphenols are widely present in plant-based foods and have diverse health promoting effects via modulating multiple cellular signaling pathways in various cell types. The present study investigated if growth-stimulating tumor-stromal interaction is mediated by TGF-β derived from ovarian CAFs and if food polyphenols inhibit this interaction. Ovarian cancer cells, OVCAR3 and OVCAR4, were cultured in conditioned media (CM) derived from CAFs (CAF-CON) in the presence and absence of SB525334 (an inhibitor of TGF-β receptor 1) to test the involvement of TGF-β in CAF-CON-induced cell growth. Effects of mitogen-activated protein kinase and AKT pathways on TGF-β signaling pathways were examined using their specific inhibitors. Various food polyphenols (5 μM) were treated to CAFs while preparing CM and evaluated their effects on TGF-β1 secretion and cancer cell growth induced by CAFs. Further, the effect of apigenin (API), the most effective compound, on TGF-β signaling pathway was evaluated using immunoblotting. OVCAR3 cells were transplanted into SCID mice. Once tumors were palpable, mice were either treated with vehicle control (VEH) or API (2.5 mg/kg bw/day) by oral gavage while concentrated CAF-CON, CM derived from API-treated CAFs (CAF-API), or phosphate buffered saline were injected onto formed tumors. Treatment with SB525334 effectively inhibited CAF-CON-induced growth increase in both OVCAR3 and OVCAR4 cells. Notably, inhibition of p38 activity suppressed CAF-CON-induced activation of Smad3 and AKT in ovarian cancer cells, suggesting that p38 activation induced by CAF-CON enhances TGF-β1 and AKT signaling pathways. Among various CM obtained from CAFs treated with diverse polyphenols, CAF-API exhibited the greatest inhibitory effect on cell proliferation in both OVCAR3 and OVCAR4 cells (> 50% reduction relative to CAF-CON) and the lowest TGF-β1 levels (<40% reduction relative to CAF-CON). Smad activation was induced in the presence of CAF-CON, whereas it was reduced in CAF-API. OVCAR3-derived tumor growth was significantly increased by treatment with CAF-CON (40% relative to VEH) but not with CAF-API or CAF-CON with simultaneous oral administration of API. Therefore, the present study suggests that TGF-β1 contributes to interplay between ovarian cancer cells and their stroma, and API can inhibit this interaction.

#201 Enhanced motility of cancer-associated fibroblasts is mediated by HIF-1α signaling in the lung tumor microenvironment.

Jihye Park[1], Sieun Lee[1], Jonathan M. Kurie[2], Young-Ho Ahn[1]

[1]Department of Molecular Medicine, Ewha Womans University College of Medicine, Seoul, Korea, Republic of,[2]Department of Thoracic/Head and Neck Medical Oncology, University of Texas MD Anderson Cancer Center, Houston, TX

Cancer-associated fibroblasts (CAFs) are key contributors to promote cancer progression in the lung tumor microenvironment via interactions with cancer cells and other cell types. In a 3-D culture system, we classified CAFs into two subgroups based on their motility, motile and static CAFs, and isolated these subgroups using the photoconvertible fluorescent protein Dendra2. RNA sequencing and subsequent analyses revealed the upregulation of hypoxia- and glycolysis-related genes in motile CAFs. Activation of HIF-1α increased CAF motility in both mono- and co-culture systems. Knockdown of HIF-1α downstream genes, ALDOA and LDHA, reduced CAF motility. Interestingly, HIF-1α activity and CAF motility were heightened when co-cultured with mesenchymal-like lung cancer cells. Mass spectrometry analysis identified ceruloplasmin (CP) as a secretory protein derived from mesenchymal-like lung cancer cells. Knockdown of CP in mesenchymal-like lung cancer cells attenuated CAF motility in co-culture systems and lung tumor metastasis in a mouse model. Collectively, these findings demonstrated that CAF motility is regulated by HIF-1α signaling, which is modulated by lung cancer cell-derived CP.

#203 TCF12 regulates PD-L1 expression through TGF-beta signaling and modulates the immune microenvironment in micropapillary lung cancer.

Yifei Liu[1], Ting Wang[2], Tingting Bian[1], Jia Feng[1], Qiushi Lin[3], Xiaoqun Dong[3]

[1]Affiliated Hospital of Nantong University, Nantong, China,[2]Radiation Oncology, The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Zhengzhou, China,[3]Precision Health Program, College of Human Medicine, Michigan State University, Lansing, MI

Background: The prognosis of lung adenocarcinoma (LUAD) is strongly influenced by its histologic growth patterns, with the micropapillary component (MPC) being a poor prognostic indicator. However, the molecular mechanisms driving the poor prognosis of the MP subtype remain unclear, particularly regarding spatial transcriptomic (ST) insights.
Methods: Spatial transcriptomics (10X Genomics) was performed on 4 LUAD cases to map gene expression. Targeted next-generation sequencing (NGS) on 72 LUAD samples evaluated genetic alterations. The roles of TCF12 and its regulation via the TGF-β pathway were explored through in vitro and in vivo studies, including CCK-8 assays for cell proliferation, Transwell migration and invasion assays, and sphere formation assays to assess tumorigenic potential. Western blotting and PCR were used to analyze protein and gene expression levels, respectively. Immunohistochemistry of 160 LUAD samples validated TCF12 and PD-L1 expression correlations. Furthermore, mouse xenograft tumor models were employed to verify the effects of TCF12 on tumor growth and its interaction with the TGF-β pathway and PD-L1 expression in vivo.
Results: The first spatial transcriptomic map of LUAD revealed significant spatial heterogeneity, with the MP pattern strongly linked to TGF-β signaling and immune responses. TCF12 was highly expressed in MP regions, activating TGF-β signaling and upregulating PD-L1 expression. Functional assays demonstrated that TCF12 overexpression promoted proliferation, invasion, and angiogenesis in LUAD, which were suppressed by TGF-βRI kinase inhibition. In animal models, dual inhibition of TGF-β and PD-L1 significantly reduced tumor growth in TCF12-overexpressing tumors compared to single-drug and control groups. Immunohistochemistry showed that increased TCF12 expression correlated with poor survival, lymph node metastasis, and MP pattern presence.
Conclusions: TCF12 drives PD-L1 expression via TGF-β signaling, fostering an immunosuppressive microenvironment in LUAD. Dual inhibition of TGF-β and PD-L1 restores immune function, offering a promising strategy for MP-LUAD precision therapy.
Keywords: TCF12, Spatial transcriptomics, TGF-β signaling, PD-L1, Lung adenocarcinoma, Micropapillary component

#204 Targeting tumor-stroma interactions: Prognostic and therapeutic implications of the ACVR1-BMP7 axis in colorectal cancer.

Norikatsu Miyoshi[1], Shinya Kato[2], Shiki Fujino[2], Soichiro Minami[2], Rie Mizumoto[2], Rie Hayashi[2], Kengo Haruma[2]

[1]Gastroenterological Surgery, Osaka University, Osaka, Japan,[2]Innovative Oncology Research and Regenerative Medicine, Osaka International Cancer Institute, Osaka, Japan

The tumor microenvironment plays a critical role in colorectal cancer (CRC) progression, with stromal signatures closely linked to poor prognoses and resistance to chemotherapy. These stromal factors significantly influence tumor dynamics, promoting progression, relapse, and overall worse outcomes. Among these, cancer-associated fibroblasts (CAFs) have gained attention due to their heterogeneity and functional contributions to the tumor microenvironment. Although single-cell analysis has identified distinct CAF subpopulations, molecular-targeted therapies against CAFs remain lacking, highlighting a critical clinical need. To address this, the study utilized organoid culture methods replicating CRC histological architecture. Two-dimensional organoids (2DO) provided a novel platform to study tumor-stromal interactions, facilitating the investigation of cancer-fibroblast crosstalk. The focus was on signaling pathways, specifically the interplay between Activin receptor type I (ACVR1) in fibroblasts and Bone morphogenetic protein 7 (BMP7) in cancer cells, as potential therapeutic targets. Using single-cell analysis and patient-derived models, the study examined the prognostic significance of ACVR1 and BMP7 expression in CRC, especially in stage II patients. Single-cell RNA sequencing identified fibroblast subpopulations, revealing a previously unexplored BMP7-ACVR1 signaling axis. High BMP7 and ACVR1 expression levels were significantly associated with poorer disease-free survival (DFS) and overall survival (OS), emphasizing their prognostic value. Clinical data from stage II patients supported this finding, linking elevated BMP7 and ACVR1 levels to adverse outcomes. The functional role of the BMP7-ACVR1 axis was validated with a 2DO-based mouse xenograft model, which reflected the stromal heterogeneity of human CRC tumors. Tumor growth was significantly inhibited by administering an ACVR1 inhibitor during 2DO-mouse stromal cell co-culture, highlighting the therapeutic potential of targeting ACVR1. This underscores the critical role of CAFs in tumor progression and their potential as therapeutic targets. In conclusion, the study identifies ACVR1 as a promising therapeutic target regulating CAF proliferation, influencing tumor growth and patient outcomes. The prognostic significance of BMP7 and ACVR1 further underscores their potential as biomarkers in stage II CRC.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Comprehensive Multiomic Profiling of Chromatin Dynamics, DNA Methylation, and Tumor Microenvironments

#207 snNOMeHiC: joint profiling of 3D genome, DNA methylation, and chromatin accessibility from the same nuclei at flash-frozen tissue and primary tumor sample.

Hailu Fu[1], Jiayan Ma[1], Eric Tong[1], Mark Youngblood[2], Harrshavasan Congivaram[2], Mateo Gomez[1], Juan Wang[1], Feng Yue[1], Li Wang[1], Yaping Liu[1]

[1]Department of Biochemistry and Molecular Genetics, Northwestern University - Chicago, Chicago, IL,[2]Department of Neurological Surgery, Northwestern University - Chicago, Chicago, IL

Epigenetic marks, including DNA methylation, chromatin accessibility, and three-dimensional (3D) genome organization, play instrumental roles in gene regulation in mammals. Gene activation or repression potential, however, cannot be entirely predicted by looking at a single modality. Accurate predictive models require multiple modalities simultaneously. We previously developed single-cell Methyl-HiC technology to jointly profile DNA methylation and 3D genome from the same cells. Further, we incorporated an additional footprint of GpC methyltransferase activity (i.e., chromatin accessibility) into the assay, named NOMe-HiC, but at the bulk level. Here, we extended NOMe-HiC technology to the single-cell level to enable the joint profiling of the 3D genome, DNA methylation, and chromatin accessibility from the same nuclei. We performed snNOMe-HiC at IMR-90 cell lines and found high concordance across all three modalities with the bulk NOMe-HiC by pooling the single cells. We further prepared a mixture of GM12878 and IMR-90 cells and processed the cell mixture with snNOMe-HiC. snNOMe-HiC can distinguish the two cell types using each of the three epigenetic features, respectively. To benchmark the performance of snNOMe-HiC at flash-frozen heterogeneous tissues, we generated snNOMe-HiC data from ~2000 nuclei at flash-frozen mice cortex. We identified all the major known cell types in the previous studies across three modalities and showed reproducible results across replicates. Finally, we applied snNOMe-HiC to a primary meningioma sample. We identified previously known copy number alterations in tumor-related cell clusters and found concordant changes of epigenetic heterogeneity across cell populations, which can potentially reveal the crosstalk between genetics and multiple epigenetic marks during the clonal evolution in cancer progression. In summary, snNOMe-HiC is a robust technology that can profile three epigenetic modalities and genetic aberrations in the same nuclei from flash-frozen tissues and primary tumors.

#208 Epigenomic characterization of keratinocyte carcinomas in xeroderma pigmentosum.

Bea Riebesehl[1], Lea S. Beensen[1], Felix Bormann[2], Wilfried Roth[3], Carlos F. M. Menck[4], Thomas G. Hofmann[3], Frank Lyko[1], **Manuel Rodriguez Paredes**[1]

[1]German Cancer Research Center, Heidelberg, Germany,[2]Bioinformatics.Expert UG, Berlin, Germany,[3]Johannes Gutenberg University, Mainz, Germany,[4]University of Sao Paulo, Sao Paulo, Brazil

Keratinocyte carcinomas (KCs), comprising basal cell carcinoma (BCC) and cutaneous squamous cell carcinoma (cSCC), arise in the epidermis due to chronic exposure to solar ultraviolet (UV) radiation. KCs account for 99% of skin neoplasms and represent the most prevalent form of cancer worldwide. DNA methylation, an epigenetic modification of CpG dinucleotides, modulates gene expression, thereby defining cell identity and mediating cellular responses to external stimuli. Aging and environmental stressors, including UV radiation, progressively alter epidermal methylomes, thus influencing KC development and progression. Xeroderma pigmentosum (XP) is a rare genetic disorder characterized by mutations in genes of major cellular response mechanisms to UV-induced DNA damage, such as the nucleotide excision repair (NER) system or the translesion synthesis (TLS) DNA polymerase η. Consequently, XP patients exhibit a more than 10,000-fold increase in KC incidence, with tumors potentially manifesting as early as childhood. Epigenomic analysis of tumors derived from XP patients could provide valuable insights into the deregulation of DNA methylation in KC tumorigenesis, thereby contributing to the development of novel antitumor therapies for both XP patients and the broader population. Here, we used *Infinium* MethylationEPIC BeadChips to assess the DNA methylation status of 30 epidermal samples from XP patients with mutations in the *XPC* and *POLH* genes, representing roughly 50% of all XP cases and significantly impacted by KCs. Our sample set comprised BCC and cSCC tumors, non-tumorous epidermis, and actinic keratosis (AK), a precancerous lesion that frequently progresses to cSCC. DNA methylation analysis of XP samples clearly distinguished between BCC and cSCC tumors, whereas non-tumorous epidermis unexpectedly clustered with AK samples, reflecting substantial methylome dysregulation that is consistent with the heightened risk of KC development in XP patients. In line with this, further examination of non-tumorous XP methylomes relative to non-XP counterparts revealed features indicative of premature aging, including significant erosion of DNA methylation profiles and increased mitotic rates. Analysis of XP-derived BCC and cSCC methylation profiles also identified a higher frequency of copy number variation (CNV) events and a potential bias towards an epidermal stem cell (EpSC)-like cell-of-origin in cSCC tumors. These findings may suggest an elevated aggressiveness of XP tumors, which we now aim to verify using cellular models of KC deficient in key XP genes.

#209 Differentially expressed genes associated with disease-specific chromatin changes in oral cancer have a significant correlation with overall survival.

Diane Terry[1], Andrey Loginov[1], Jennifer Coleman[2], Amy Plotkin[2], Ashley Johnson[2], Carol Robles[2], Joshua Lubek[3], Donita Dyalram[3], Kyle Hatten[3], Daria Gaykalova[4]

[1]University of Maryland School of Medicine, Baltimore, MD,[2]Pathology and Biorepository Shared Service, Marlene & Stewart Greenebaum Comprehensive Cancer Center, University of Maryland Medical Center, Baltimore, MD,[3]Otorhinolaryngology, Head and Neck Surgery, Marlene & Stewart Greenebaum Comprehensive Cancer Center, University of Maryland Medical Center, Baltimore, MD,[4]IGS, University of Maryland School of Medicine, Baltimore, MD

Globally, there are ~400,000 Oral Squamous Cell Carcinoma (OSCC) cases diagnosed each year and ~200,000 deaths. The 5-year survival rate for OSCC is only ~50%, and this has not improved in decades. In other cancers, recent studies have shown that chromatin structure changes, impacting gene regulatory regions known as enhancers, can play a key role in gene expression dysregulation. Enhancers, with their transcription factor binding sites, attract transcription factors that, along with coactivators, assemble the transcription machinery. Super-enhancers, dense clusters of enhancers, amplify this assembly. The addition of coactivators like histone acetyltransferases and methyltransferases remodels chromatin, affecting DNA accessibility. Research has not been done using primary OSCC tissues. I propose that in OSCC, specific aberrations in chromatin organization lead to alterations in gene expression associated with cancer. Furthermore, I hypothesize that these chromatin anomalies are not random but concentrated at certain genomic loci, which act as 'hotspots' for regulatory disruption. Chromatin immunoprecipitation sequencing (ChIP-seq) for the active enhancer marker H3K27ac was performed using 20 pairs of OSCC-tongue patient matched tumor and normal tissues. From the H3K27ac ChIP-seq data, disease-specific enhancers and super-enhancers, which are present either only in tumor or normal chromatin, were identified. There were 22,336 “hot spots” found where the disease-specific change is in more than one patient. To identify differentially expressed genes (DEGs) regulated by those (super)enhancers, RNA extracted from these tissues was submitted for sequencing (RNA-seq) and analyzed. DEGs that are within the regulatory range of disease-specific enhancers and super-enhancers were identified and evaluated for their impact on OSCC. Tumor-specific enhancers cause upregulation of the target gene, whereas normal-specific enhancers that are absent in the tumor are associated with a gene downregulated in the tumor. Many DEGs in the regulatory range of disease-specific enhancers and super-enhancers were found to have a significant association with overall survival. Such elucidation of the role of chromatin structural alterations in OSCC paves the way for a deeper comprehension of gene expression dysregulation and heralds a new frontier in the development of innovative therapeutic strategies.

#210 Direct multiomic mapping of chromatin proteins and DNA methylation.

Jen Spengler[1], Bryan J. Venters[1], Vishnu U. Sunitha Kumary[1], Allison Hickman[1], Anup Vaidya[1], Jonathan M. Burg[1], Louise Williams[2], Louise Williams[2], Chaithanya Ponnaluri[2], Pierre-Olivier Esteve[2], Issac Meek[2], Sriharsa Pradhan[2], Zu-Wen Sun[1], Martis W. Cowles[1], Michael-Christopher Keogh[1]

[1]Epicypher, Durham, NC,[2]New England Biolabs, Ipswich, MA

DNA methylation (DNAme) is a class of epigenetic marks that includes the methylation of cytosine residues (5mC) within CpG islands. In addition to well characterized roles regulating gene expression, imprinting, and silencing parasitic DNA elements, misregulation of DNAme is implicated in multiple cancers. Evidence is emerging that DNAme is not an independent epigenetic mark but rather closely linked to chromatin proteins. However, examining the relationships between DNAme and chromatin proteins is hampered by correlative analyses that cannot establish a direct mechanistic link. Furthermore, the traditional approach to measure DNAme relies upon harsh bisulfite chemical conversion, which introduces DNA breaks and systemic biases. To address these limitations, we developed CUT&RUN-EM: an ultra-sensitive multiomic technology that integrates EpiCypher's CUT&RUN genomic mapping with New England Biolab's Enzymatic Methyl-seq (EM-seq). Together, these technologies permit high-resolution, simultaneous profiling of chromatin proteins and DNAme, enabling direct interrogation of the complex molecular crosstalk between these genomic features. To quantify the capabilities and limitations of the assay, we tested CUT&RUN-EM across chromatin proteins and cell lines. We show that CUT&RUN-EM is highly reproducible, specific, sensitive, and efficient, requiring as few as 5 million short-read sequences per reaction (10-100x less than whole-genome DNAme sequencing). The advent of CUT&RUN-EM will enable detailed interrogation of the cancer epigenome, providing insights into new therapeutic targets.

#211 Epstein-Barr virus (EBV)–human host chromatin interactions rearrange spatial DNA genome organisation and hijack KDM5B to distant metastasis proneness in EBV-associated nasopharyngeal carcinoma (NPC).

Lai Shun Dittman Chung[1], Zhaozheng Hou[1], Ying Wang[2], Kazi Anisha Islam[1], Songran Liu[1], Jiayan Liu[3], Larry Ka-Yue Chow[1], Cyrus Pakk-Ting Chak[1], Yingpei Zhang[1], Lanqi Gong[1], Karl Kui-Wai Cheng[1], Zhuoyou Yu[1], Ping Feng[4], Zilu Huang[4], Roger Kai-Cheong Ngan[1], Xinyuan Guan[1], Wai-Tong Ng[1], Zhonghua Liu[5], Anna Chi-Man Tsang[1], Dora Lai-Wan Kwong[1], Annie Wing-Mui Lee[1], Victor Ho-Fun Lee[1], Honglin Chen[3], Yunfei Xia[4], Wei Dai[1]

[1]Department of Clinical Oncology, School of Clinical Medicine, LKS Faculty of Medicine, Hong Kong, Hong Kong,[2]Department of Radiation Oncology, Sun Yat-sen University Cancer Centre, Guangzhou, PR China, Guangzhou, China,[3]Department of Microbiology, University of Hong Kong, Hong Kong (SAR), PR China, Hong Kong, Hong Kong,[4]Department of Radiation Oncology, Sun Yat-sen University Cancer Centre, Guangzhou, PR China, Hong Kong, Hong Kong,[5]Department of Biostatistics, Columbia University, New York, NY, USA., Hong Kong, NY

Introduction: Epstein-Barr virus (EBV), the first identified human DNA tumour virus, has been detected in nasopharyngeal carcinoma (NPC) over 40 years and over 90% of NPC is strongly associated with EBV infection in the endemic regions. However, the detailed roles of EBV in NPC pathogenesis and disease progression remain inconclusive. We hypothesise that EBV–human chromatin interactions induce the spatial reorganisation of compartments and chromatin loops facilitating NPC tumour progression.
Methods: Chromosome conformation capture sequencing (Hi-C), transposase-accessible chromatin with sequencing (ATAC-seq), and Cleavage Under Targets and Release Using Nuclease with sequencing (CUT&RUN-seq) were performed in EBV-positive (EBV+) and EBV-negative NPC cell lines, EBV+ patient-derived xenografts (PDXs) and EBV+ clinical samples, followed by single-cell RNA sequencing (scRNA-seq), GeoMx Digital Spatial Profiler, and Spatial Molecular Imaging platform using the clinical samples. To evaluate the clinical impact of the high-order epigenomic changes associated with EBV, whole exome sequencing (WES) and bulk RNA sequencing (RNA-seq) were conducted for NPC biopsies in the multi-center multi-omics study.
Results: EBV modulates 3D human genome by cross-species chromatin interactions. Two paired NPC cell lines demonstrated EBV infection causes 3D genome reorganisation. The PDXs and one clinical sample showed distinctive compartmentalisation compared to normal epithelial (NPE) cells. We discovered that the EBV episomes could tether to the human genome through EBV-interacting regions (EBVIRs), particularly related to inactive-to-active compartment transition. These regions have shown an increase in H3K27-acetylation, suggesting enhancer infestation by the EBV-host chromatin interactions, resulting in aberrant upregulation of KDM5B and its targets (EBVIR-enhancer-KDM5B signature). The spatial transcriptome data revealed that the cancer cells with higher expression of EBV latent genes had increased EBVIR-enahncer-KDM5B signature with metastatic potential. Similarly, the bulk RNA-seq data indicated this signature was highly associated with development of distant metastasis in two independent patient cohorts. The combination of KDM5B pathway activity with plasma EBV DNA level at baseline or after treatment suggests this can be a promising predictor of metastatic risk, achieving AUC = 0.77 and AUC = 0.82, respectively.
Conclusion: EBV, as episomes, tethers to the human genome to reorganise 3D genome and epigenome. Through this mechanism, it regulates cancer-related genes and promotes distant metastasis in NPC. Our discovery of EBVIR-enhancer-KDM5B signature can be used as a promising metastatic predictor in the future.

#212 Disruption of the menin-MLL complex impedes HCC maintenance and increases sensitivity to NF-Y loss.

Margarita M. Dzama, Peyton C. Kuhlers, Jesse R. Raab

UNC Chapel Hill, Chapel Hill, NC

Most patients with hepatocellular carcinoma (HCC) are diagnosed at advanced stages, and there are only a few moderately effective systemic therapies available. Despite the decreased mortality rate for most cancer types over the last decade, liver cancer, with HCC being the prevailing type (~90%), showed an increase, making this disease the third most common cancer-related cause of death. Since ~50% liver cancer samples carry mutations in epigenetic modifiers and the imbalance in the transcriptional landscape can be potentially restored using epigenetic drugs, we focused on identifying new therapeutic targets of HCC among chromatin modifiers and understanding their role in HCC maintenance. Using our epigenome-focused CRISPR library of 6000 gRNAs targeting 737 chromatin-related genes, we performed screenings in two- (2D) and three-dimensional (3D) cultures using multiple HCC cell lines (HLF and PLC/PRF5). Our screen identified several potential new targets essential for HCC survival, including several core subunits of the H3K4me3-mediating menin-MLL complex (*MEN1*, *ASH2L*, *KMT2A*). We validated HCC dependency on these targets by performing a negative selection CRISPR/Cas9 competitive growth assay in HLF and PLC/PRF5 cell lines. Moreover, treatment of HCC cell lines with the next-generation menin inhibitor SNDX5613 in 2D and 3D settings revealed a dose-dependent reduction in cell proliferation. We assessed the changes in the chromatin binding profile of menin (*MEN1*) and MLL (*KMT2A*) as well as changes in H3K4me3 levels upon treatment with 5μM SNDX5613 by CUT&RUN. While menin peaks showed a ~90% reduction upon treatment, MLL and H3K4me3 peaks exhibited a ~3- and ~2-fold reduction, respectively. Next, we evaluated transcriptional changes associated with disrupting the menin-MLL complex by performing RNA sequencing of HCC cells following either *MEN1* gene knockout or treatment with 5μM SNDX5613. Integrated CUT&RUN and RNA-seq data revealed genes involved in the PI3K/AKT signaling pathway, whose independent knockouts affected HCC survival. ATAC sequencing of HLF cells treated with 5μM SNDX5613 revealed a connection between closed genomic sites and loss of menin-MLL complex binding, while newly accessible chromatin was enriched for NF-Y transcriptional factor motifs and were independent of menin binding. Loss of *NFYA* or *NFYB* significantly affected cell growth, supporting their role in HCC survival. The combined *NFYB* knockout and SNDX5613 treatment showed a significantly decreased HCC cell proliferation compared to a single menin inhibition. We propose inhibition of the menin-MLL interaction disrupts HCC homeostasis through changes in the expression of direct target genes within the PI3K/AKT pathway and alters chromatin accessibility, creating sensitivity to *NFYB* gene loss. We believe targeting core subunits of the menin-MLL complex represents an appealing therapeutic strategy for HCC treatment.

#213 Epigenomic dissection of histology-specific drivers of testicular germ cell tumors.

Esme Wheeler[1], Alok K. Tewari[1], Anis A. Hamid[2], Henry Long[1], Christopher Sweeney[1], Myles Brown[1], Eliezer Van Allen[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Memorial Sloan Kettering Cancer Center, New York, NY

Outcomes of testicular germ cell tumors (TGCT), which are the most common malignancies in adolescents and young adult males, are paradoxical; although highly curable with platinum based chemotherapy, testicular cancer is also the cause of the highest number of years of life lost of any adult malignancy. Major barriers to research aiming to uncover novel therapeutic approaches for chemotherapy-resistant TGCTs include its relatively low incidence, histologic diversity (seminoma vs multiple non-seminoma histologies), and the rarity of tissue biopsies in the metastatic setting. As epigenomic alterations play a key role in germ cell development, and there is a paucity of genomic alterations associated with the initiation and development of therapeutic resistance in TGCT, we hypothesized that epigenomic analysis integrated with transcriptomics in a cohort of pre- and post-treatment TGCTs may reveal novel targetable pathways in TGCT. We collected a cohort of 24 TGCT patients with multiple pre- and post-treatment formalin fixed paraffin embedded (FFPE) tissue, and macrodissected histology-specific tumor foci from surrounding stroma. This tissue was subjected to chromatin-immunoprecipitation (ChIP-seq) of the H3K27Ac enhancer chromatin mark and transcriptional profiling (RNA-seq). Histology-specific cell lines were subjected to the same molecular assays. As an initial analysis, we compared differential enhancer marks (ChIP-seq peaks) and transcripts between specific histologies to identify putative drivers of tumor phenotype and tested the function of these candidate drivers in cell lines. Of 52 histology-specific foci dissected from FFPE slides, we generated matched H3K27Ac and RNA data from 19 samples, H3K27Ac data only from 15 samples including two choriocarcinomas, and RNA only data from 3 samples. Principal component analysis demonstrated that epigenomic and transcriptomic profiles clustered by histology rather than by patient. Superenhancer and motif analysis of enhancer marks suggested various histology-specific transcriptional drivers including POU5F1 and NANOG in EC and SEM, E2F in SEM, AP-1 in TER, the HNF and WNT factors in YST, and GRHL2 in choriocarcinoma. A CRISPR-knockout screen in EC cells in the presence of cisplatin and etoposide indicated that POU5F1 and NANOG promote chemotherapy sensitivity in EC cells. Integrated chromatin and transcriptional analyses suggested multiple potential up- and down-stream effectors of WNT signaling in YST, including multiple extracellular matrix proteins. Collectively, our chromatin, transcriptomic and CRISPR assays in TGCT samples have nominated multiple histology-specific drivers of tumor phenotype. Further analysis of pre- vs post- treatment samples and broader validation of these findings is ongoing.

#214 Chromatin profiling from formalin-fixed paraffin-embedded samples for precision oncology.

Ellen N. Weinzapfel[1], Alysha E. Simmons[1], Eva Brill[1], Vishnu U. Sunitha Kumary[1], Eva Oswald[2], Georg Kuales[2], Julia B. Schueler[2], Martis W. Cowles[1], Bryan J. Venters[1], Michael-Christopher Keogh[1]

[1]EpiCypher, Durham, NC,[2]Charles River Laboratories, Inc., Freiburg, Germany

As the oncology field moves towards a precision medicine model of patient care, understanding and profiling the epigenetic landscape is increasingly important. Gene expression and cell function are regulated by epigenomic features, including histone post-translational modifications (PTMs), transcription factors, and other chromatin proteins. Mapping the location of these features provides a powerful approach to study chromatin mechanisms driving disease and can be leveraged for biomarker and drug development.

Formalin-fixed paraffin-embedded (FFPE) tissues banked from cancer clinical trials could be a rich resource for retrospective biomarker studies, due to their association with drug response and disease progression data. However, using FFPE tissues for chromatin mapping assays has been technically challenging for multiple reasons. For instance, the heavy cross-linking conditions make FFPE samples unsuitable for chromatin accessibility profiling (ATAC-seq), while the small amounts of chromatin extracted from FFPE tissues make standard epigenomic mapping assays (ChIP-seq) impractical. Combined, these difficulties have precluded widespread application of FFPE tissues for epigenomics research.

To better leverage chromatin profiling for translational research, we are developing a modified CUT&Tag workflow that is compatible with FFPE samples (CUT&Tag-FFPE). CUT&Tag (Cleavage Under Targets and Tagmentation) is an immunotethering-based strategy that uses pAG-Tn5 to selectively cleave and ligate sequencing adapters at antibody-bound chromatin. The entire assay takes place in intact cells or nuclei bound to a solid support, enabling a highly streamlined, 2-day workflow. Compared to ChIP-seq, CUT&Tag requires 10-1,000X fewer cells, 5-10X reduced sequencing reads, and is scalable for large studies. The improved sensitivity of CUT&Tag makes it an attractive technique in fields limited by cell number, particularly preclinical research studies.

Here, we will discuss optimization of upstream sample processing steps for efficient extraction of nuclei from heavily fixed cells and FFPE tissue. We have applied these modifications to successfully map RNA polymerase II (RNAPII) in heavily fixed cell lines, resulting in high quality chromatin profiles comparable to native controls. We are currently applying this workflow to map RNA Pol II in FFPE liver tissue samples. Future work will be done to validate additional chromatin targets using matched FFPE and fresh frozen tissue samples from various tissues. In parallel, we are optimizing workflows to pair with downstream single cell and spatial platforms to expand the impact of this technology. We envision that CUT&Tag-FFPE, and the associated automated assay service we are developing for large scale clinical trials, will accelerate the discovery of epigenetic drug targets and biomarkers to advance precision medicine.

#215 A novel framework for deciphering 3D genome structure in colorectal cancer.

Amin Nooranikhojasteh, Jakob Zerbs, Ghazaleh Tavallaee, Elias Orouji

Princess Margaret Cancer Centre, University Health Network (UHN), Toronto, ON, Canada

Background: The spatial organization of chromatin is a fundamental determinant of epigenomic landscape which is widely investigated using high-throughput chromosome conformation capture (HiC) technique. To address challenges associated with the resolution and variability of HiC technique, we applied a novel workflow, HiC-ECC (HiC Enhance, Compare, and Call). This approach not only enhances HiC data quality but also enables the identification of biologically significant chromatin interactions and genome structural features. By integrating advanced computational tools with a focus on colorectal cancer (CRC) biology, this study sheds light on the 3D genome architecture of CRC organoids and its implications for patient stratification and therapeutic targeting.
Methods: We applied the HiC-ECC workflow to a cohort of 15 patient-derived CRC organoid models, including samples derived from primary tumors and metastatic sites in the lung and liver. The workflow involved initial data preprocessing to generate high-quality chromatin contact matrices and ensure rigorous quality control. To enhance the resolution of HiC datasets, we utilized deep learning-based methods, enabling more accurate identification of chromatin interactions. Comparative analyses were conducted to identify differential chromatin interaction patterns and conserved structural features across the cohort. Chromatin architecture was further characterized by delineating topologically associating domains (TADs) and clustering them to reveal common and sample-specific interaction networks, offering insights into the hierarchical organization of 3D genome structures.
Results: Our analysis revealed four distinct subtypes of CRC organoids based on their 3D genome architecture, revealing a novel approach to interrogate heterogeneity within CRC. This subtyping was driven by differential chromatin interaction patterns and structural features, including unique TADs and conserved regulatory elements. Comparative analysis highlighted subtype-specific chromatin interaction networks, suggesting distinct epigenomic landscapes that correlate with tumor progression and metastatic potential.
Conclusion: This study enhances our understanding of CRC epigenomics and lays the groundwork for integrating chromatin architecture into patient stratification and precision therapy.

#216 CRISPR screen validates RIC-seq revealed eRNA-uaRNA interactions and transcriptome changes in gastric cancer.

Xiangnan Zhang, Yanxin Yao, Hongji Dai, Wei Wang, **Kexin Chen**, Ben Liu

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Introduction: Enhancer RNA (eRNA) is generated by the transcription of activated enhancers and belongs to non-coding RNA, regulating epigenetic activities and significantly affecting the transcription and activating target genes. We use RIC-seq (RNA in situ conformation sequencing) to simultaneously identify RNA-RNA interactions and loop structure between enhancers and promoters in the genome. RIC-seq also characterizes hubRNAs, which are transcribed from motifs similar to hubs that interact with globally distinct RNA fragments and transcriptionally robust and structurally conserved.

Methods: We performed RIC-seq analysis of GC cell lines and normal gastric mucosa cell lines to capture RNA high-level structures, and identify sites of molecular enhancer RNA-uaRNA (promoter region transcribed RNAs) interactions and annotation information at the cellular in situ level. Several CRISPR libraries, including CRISPRa/i and CRISPR-Cas13 libraries were designed to validate these interactions in two GC cell lines. CROP-seq was used to identify transcriptome-level expression patterns generated from eRNA or uaRNA changes.

Results: Based on RIC-seq, we identified direct or RBP-mediated indirect RNA-RNA proximity interactions and global enhancer-promoter loops among GC chromatin structure and specific spatial contacts. We found 88,696 significant pairs of RNA-RNA interactions in the GC cell line, while 96,990 significant pairs in the normal gastric mucosa cell line. Then, 831 pairs of RNA-RNA interactions and 146 eRNA-uaRNA interactions showed significantly differential expression between such two cell lines. All hubRNAs matched by RIC-seq were categorized and demonstrated that hubRNAs were mainly concentrated in protein-coding RNAs, antisense RNAs, and lincRNAs. From all these differentially expressed interactions, we constructed CRISPRa/i libraries using 10 relatively high expressed eRNAs and 116 target genes corresponding to uaRNAs respectively. Three hubRNAs and thirty-eight eRNAs were selected to construct CRISPR-Cas13 library for further validation of interested interactions. We found and validated eRNAs and target genes which were significantly related to GC cell proliferation, and resistance of target genes of 5-Fluorouracil (5-FU) and Oxaliplatin (Oxa). Through CROP-seq, we obtained transcriptome changes at the single-cell level caused by changes in target genes, further revealing the mechanisms underlying the influence of eRNA-uaRNA interactions on transcriptional regulation.

Conclusion: We explored the mechanism of enhancer-promoter interactions by capturing all direct eRNA-uaRNA pairs in GC obtained by RIC-seq, and validation by CRISPR library screen combined with CROP-seq, yielding potential biomarkers and therapeutic targets in GC treatment.

#217 Analysis of chromatin accessibility profiling reveals epigenetic features of azacitidine response in high-risk myelodysplastic syndrome.

Dayoung Kim[1], Silvia Park[2], Yoo Jin Kim[2], Ryan Corces[3], Seung Woo Cho[1]

[1]Ulsan National Institute of Science & Technology, Ulsan, Korea, Republic of,[2]Department of Hematology, Seoul St. Mary's Hematology Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[3]Gladstone Institute of Neurological Disease, San Francisco, CA

Azacitidine, a hypomethylating agent, is currently represented as initial therapy in most cases of high-risk myelodysplastic syndromes (MDS), yet only 40-60% of patients achieve therapeutic response. Non-responders face poor outcomes and disease progression to secondary acute myeloid leukemia. To improve treatment outcomes, understanding the pre-treatment molecular determinants of azacitidine response is critical. Despite the fundamental role of epigenetic regulation and cellular composition in MDS, the complex interplay between epigenetic regulation and therapeutic response has not been investigated. Here, we analyzed chromatin accessibility landscapes of 23 high-risk MDS patients before getting azacitidine, using Assay for Transposase-Accessible Chromatin using sequencing (ATAC-seq). We identified 1,940 distinct chromatin accessibility features strongly associated with azacitidine response, suggesting gene regulatory elements like enhancers as key determinants of it. Also, non-responders exhibited significant myeloid lineage commitment, while responders showed elevated accessibility in regions governing immune activation and T cell differentiation pathways. Notably, T cell subsets of non-responders displayed distinct chromatin states associated with impaired cellular differentiation compared to responders and healthy donors. This study first establishes chromatin accessibility features as potential biomarkers for azacitidine response in high-risk MDS and provides novel insights for personalized treatment optimization.

#218 Long-read nanopore sequencing in pursuit of complete methylation profiling of Hungarian colorectal cancer patients.

Kristof R. Rada, Nikolett Szakallas, Barbara Kinga Bartak, Alexandra Kalmar, Istvan Takacs, Bela Molnar

Semmelweis University, Budapest, Hungary

Introduction: Variations of the epigenetic landscape are the hallmark of many pathologies, including cancer. We investigated the Hungarian colorectal cancer cohort *via* Oxford Nanopore's long-read whole-genome sequencing (WGS) platform to provide for the first time a genome-spanning methylation report of the country. A prominent benefit of the method is native, and so, bias-free detection of modified or alternative nucleotides.

Aims & Methods: We selected 136 tissue biopsy, resection, normal adjacent tissue (NAT) and peripheral buffy coat (BC) samples from patients of Semmelweis University, to represent the range of pathological progression: healthy - adenoma (AD) - carcinoma (CRC). After thorough quality control by fragment length analysis (Tape Station), WGS was carried out on Nanopore's PromethION platform in simplex basecalling mode. Bioinformatic analysis utilized the Nanopore software package, Dorado basecaller and our custom scripts. We focused on methylation and hydroxymethylation of cytosine residues as the most abundant form of epigenetic marks.

Results: Coverage is 19.3x (±0.13), with an average read length and precision of 4.3 (±0.16) kb and 98% (±0.01), respectively; median PHRED is 16.03 (±1.18) and N50 is 7807 (±2262). Average GC ratio is 47% (±7%), island-mapped CpG sites show 69% (±5%) average methylation, of which 5hmC accounts for 5.68% (±1.88%), showing significant variations between groups: from 71% (healthy individuals), average methylation drops by 4.1% (AD, $p=0.013$), 8.8% (CRC, $p=0.007$), and 12.9% (resection, $p<0.001$) in solid tumors; by 0.1% (AD) and 2.5% (CRC) in buffy coats (not significant); and by 2.7% (CRC, $p=0.01$), and 4.6% (resection, $p<0.001$) in NAT samples. Solid samples always show significant hypomethylation compared to buffy coats. Contrasting this, 5hmC reveals a different pattern: it is relatively stable in solid samples and buffy coats, but rises by 47% (CRC, $p<0.001$) and 56% (resection, $p<0.001$) in normal adjacent tissues. When matching the tumor and healthy tissue of the same patient, we also see significant hypomethylation: 5mC decreases by 7% (±2.1%, $p=0.005$), and 5hmC by 31.4% (±3.9%, $p<0.001$) with very few exceptions.

Conclusion: long-read WGS is a strong tool for studying methylation in solid and liquid samples of colorectal cancer patients, revealing marked differences between solid and liquid samples, and also between tumor and healthy tissue. We corroborated the general cytosine hypomethylation associated with cancer, while also observing new trends in hydroxymethylation.

#219 Uncovering synergistic and antagonistic interactions in epigenetic therapeutics using perturb-seq.

Changde Cheng, Rui Lu, Sajesan Aryal, Doug A. Welsch

University of Alabama at Birmingham, Birmingham, AL

Acute myeloid leukemia (AML) is a heterogeneous malignancy characterized by genetic and epigenetic dysregulation, including aberrant activity of chromatin modifiers. The complex interactions among these modifiers and regulators in AML pathogenesis remain poorly understood, posing significant challenges to developing effective combination therapies. To address this, we used Perturb-seq, a CRISPR-based single-cell transcriptomics approach, to profile 16 key genes from the Menin-MLL, Polycomb, and histone acetyltransferase (HAT) complexes in the MOLM-13 AML cell line. We developed a machine learning framework called Composer, which predicts the combinatorial effects of perturbations by analyzing their impact on the transcriptome. We identified cooperative regulation of oncogenic pathways by Menin-MLL and KAT6A, while PRC1 components, such as PCGF1, were found to antagonize DOT1L activity. These predictions were validated using bulk RNA-seq and experiments combining perturbations through small molecule inhibitors and gene knockouts, demonstrating that dual inhibition of Menin-MLL and KAT6A, or DOT1L and KAT6A, significantly reduced AML cell viability. This study underscores the power of combining AI with single-cell Perturb-seq to provide novel insight into the epigenetic landscape of AML and identify promising therapeutic targets to overcome treatment resistance.

#22 Engineering KRAS-mutant-organoids from pancreatic ductal adenocarcinoma for advanced drug screening applications *in-vitro* and *in-vivo*.

A. Savadipour, K. Tummala, E. Park, V. Vidimar, M. Veling, M. Buchanan, E. Muise, G. Hebert, B. Long, N. Solban;
Merck & Co., Inc., Boston, MA

Background: Organoids are powerful tumor models for cancer research surpassing 2D-cultures in maintaining tumor heterogeneity and genetic fidelity. However, working with organoids encounters challenges in imaging, drug-screening, and in-vivo efficacy studies, due to their structural complexity. Additionally, the absence of other relevant cell types including cancer-associated-fibroblasts (CAFs) and immune cells, limits their ability to fully recapitulate the tumor-microenvironment (TME). To overcome these limitations, we developed GFP- or RFP-expressing KRAS-mutant-PDAC-organoids for efficient in-vitro and in-vivo drug-screening in mono- and co-culture systems.
Methods: We developed KRAS-mutant-PDAC-organoids that overexpress GFP or RFP using lentiviral-transduction. The growth and gene expression profile of these engineered organoid lines were compared to the parental line using Incucyte, DRUG-seq, and immunoblotting. These modifications enabled in-vitro mechanistic studies and drug sensitivity assays via confocal-microscopy and cell viability assays, as well as in-vivo quantification of tumor growth, drug-response, and gene expression.
Results: Antibiotic-sensitivity assays showed that 10 µM of antibiotic induces complete cell death within 5 days. Based on this, we stably overexpressed GFP or RFP in organoid lines, with strong GFP and RFP signals confirmed through microscopy. Optimizing culture conditions revealed that the addition of growth-factors (EGF and FGF) is crucial in initial phases of growth, though they can be removed later for drug-screening without impacting the organoids growth curve. This is important for accurate drug-screening, particularly for growth-factor pathway inhibitors. Further, we compared the growth rates and protein expression of the engineered organoids to their parental lines and observed no substantial differences. In high-throughput drug screening, we tested the effects of chemotherapy drugs (Gemcitabine and SN38) on organoids at varying seeding densities. While lentiviral transduction did not significantly affect the IC50 values, increasing the number of cells significantly raised the IC50 values (e.g., IC50 for Gemcitabine increased from 6-70 nM with 1k cells to 32-517 nM with 5k cells).
Conclusion: We successfully engineered KRAS-mutant-PDAC-organoids, which will serve as invaluable tools for in-vitro and in vivo efficacy experiments. Engineered organoids will simplify detection in co-culture systems and eliminate the need for additional staining. Future studies will focus on evaluating the growth and gene expression of engineered lines in-vivo compared to their parental lines. Additionally, these novel co-culture systems are being used to investigate the effects of novel KRAS inhibitors on organoid growth in-vitro and in-vivo.

#220 Early methylome-level alterations in colorectal adenocarcinoma.

Dalma Muller, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

Introduction: Methylation-based biomarkers represent a promising tool for early tumor detection in colorectal cancer. Genome-wide methylation analysis of large cohorts is an effective way of for the discovery of new biomarker candidates. For such purposes, Illumina arrays are today the most popular sources of methylation data.
Purpose: We aimed to analyze the methylation pattern differences between different groups, especially those involved in normal-adenoma and adenoma-adenocarcinoma transition. In order to enable straightforward exploration of the database we also aimed to establish an interactive web-based platform.
Methods: Raw files of 2,356 samples, out of which 1,273 were from normal mucosa, 815 from adenocarcinoma, and 258 from precancerous adenoma tissues were processed in R using the *minfi* and the *watermelon* libraries. The dataset contains data from both Illumina HumanMethylation450K and EPIC microarray platforms, which were analyzed separately. Based on a matrix of β-values, methylated regions and CpG loci were identified using Kruskal-Wallis-test complemented with ROC analysis. For data visualization we created www.epigenplot.com, a web platform designed for the comprehensive analysis of our database.
Results: When compared to normal tissues, the average methylation of both adenoma and adenocarcinoma samples was significantly lower in both HM450K and EPIC arrays (Kruskal-Wallis, $p<0.001$). The majority of the significant ($\Delta\beta >= 0.2$, $p < 0.001$) methylation changes discovered in adenocarcinomas were already detectable in adenoma tissues. This occurred more often for hyper- than hypomethylation (HM450K: 80.5% and 78.58%; EPIC: 79% and 41%, respectively). Out of 75 genes previously proposed in the literature as CRC biomarker candidates, 49 and 45 (HM450K and EPIC) were significantly differentially methylated in adenocarcinoma tissues. Notably, for all these genes, the change was already present in adenoma tissues. When the difference between normal and adenocarcinoma tissues was analyzed, the methylation of the first exon of the *C1orf70* gene reached the highest AUC 0.98 at both platforms. For this region, the AUC for normal and adenoma tissues was 0.97 in HM450K and 0.99 in the EPIC dataset.
Conclusions: Alternations of the methylome are early events of tumorigenesis. The changes detected by methylation-based biomarkers are already present in precancerous lesions. Our web tool can be utilized for the discovery and validation of biomarkers suitable the early detection of CRC using genome-wide data.

#221 Investigating sex disparities in bladder cancer using carcinogen induced bladder cancer mouse model.

Bhavisha Doshi[1], Eduardo Cortes[2], Bryan M. Gillard[3], Ellen Karasik[1], Norbert Sule[4], Barbara A. Foster[1], Jianmin Wang[5], Wendy J. Huss[6], Anna Woloszynska[1]

[1]Pharmacology & Therapeutics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Biostatistics & Bioinformatics, Roswell Park Comprehensive Cancer Center, University at Buffalo, Buffalo, NY,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Pathology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[5]Biostatistics & Bioinformatics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[6]Dermatology, Roswell Park Comprehensive Cancer Center, Buffalo, NY

DNA methylation plays a crucial role in regulating gene expression; thereby influencing tumor growth, progression, and response to treatment in muscle-invasive bladder cancer (MIBC). Intriguingly, methylation patterns may also underlie the pronounced sex disparities in MIBC incidence and outcomes; where men show a fourfold higher incidence rate. Still, female patients face higher risks of progression, recurrence, and mortality. Despite substantial documentation of DNA methylation patterns in patient tumors, translating these findings into actionable treatments requires reliable preclinical models that recapitulate the human methylation landscape. Such models offer a controlled environment to explore methylation-driven gene expression changes and evaluate potential therapeutic approaches that are otherwise challenging in clinical settings. Our research focuses on the BBN (N-butyl-N-(4-hydroxybutyl) nitrosamine)-induced bladder cancer mouse model. The BBN model mimics the histological and mutational features of human MIBC. We investigated whether the BBN induced bladder cancer model recapitulates the DNA methylation patterns found in clinical bladder cancer, and the use of the model to shed light on methylation-driven shifts in gene expression and pathways. By employing methylation arrays and RNA sequencing, we systematically compared DNA methylation profiles and gene expression patterns in MIBC tumors between BBN-induced mouse bladder tumors and human clinical samples. We identified 4,250 common differentially methylated genes (DMGs) and 512 shared differentially expressed genes (DEGs) between human and BBN-induced mouse tumors. Notably, 280 sex-specific DMGs and four conserved sex-specific DEGs, including XIST, KDM5D, UTY, and DDX3Y, were identified, highlighting the ability of the BBN model to demonstrate sex-based epigenetic characteristics observed in human MIBC. Pathway analysis revealed that genes associated with mTOR signaling were hypomethylated and upregulated in male tumors. While the EMT pathway was upregulated in female tumors across both species. These findings confirm that the BBN model not only recapitulates the methylation patterns of human MIBC but can also serve as a valuable tool to investigate sex-specific methylation mechanisms in disease progression. The BBN model shows significant promise for advancing MIBC biology and guiding the development of sex-specific, methylation-targeted therapies. This abstract was reviewed and refined using AI-based tools to check grammar and improve clarity.

#222 Unraveling tumor progression in breast cancer: The impact of differential DNA methylation.

N. Jayaswal, A. N. Tegge;
Virginia Tech Carilion School Of Medicine, Roanoke, VA

Breast cancer affects over 300,000 Americans annually, with 42,780 deaths projected in 2024. DNA methylation, an epigenetic modification, has been associated with breast cancer progression (e.g., BRCA1 gene promoter hypermethylation). We hypothesize that we can identify differentially methylated CpG sites linked to cancer progression, thereby revealing the biological functions and pathways involved in tumor progression.We used DNA methylation data characterizing over 487,000 CpG sites from 1,032 female breast cancer patients in the Cancer Genome Atlas. CpG methylation was quantified using M values for more accurate homoscedastic statistical analysis. To focus on CpG sites with high methylation variability, sites were filtered by removing those whose variance in the tumor samples were lower than the normal tissue sample. Differential methylation across cancer stages was determined using an analysis of variance (ANOVA; $p \leq 1\times10\text{-}4$). Statistically significant differentially methylated CpG sites were annotated to genes, and these genes were used to perform functional enrichment analysis in DAVID.We identified 473 CpG sites with significant differential methylation across cancer stages that were annotated to 556 genes. Functional enrichment analysis revealed seven significantly enriched pathways, including non-small cell lung cancer (NSCLC; hsa05223, adj. $p = 0.0027$), gastric acid secretion (hsa04971, adj. $p = 0.0032$), insulin signaling (hsa04910, adj. $p = 0.0066$), aldosterone synthesis and secretion (hsa04925, adj. $p = 0.0070$), viral myocarditis (hsa05416, adj. $p = 0.0090$), long-term potentiation (hsa04720, adj. $p = 0.0090$), and propanoate metabolism (hsa00640, adj. $p = 0.0091$). In the NSCLC pathway, five genes were identified: KRAS, a well-known oncogene promoting cell proliferation; ERBB2 (HER2), driving aggressive HER2-positive breast cancer growth; FHIT, a tumor suppressor gene regulating apoptosis and cell cycle; CASP9, a pro-apoptotic tumor suppressor; and RARB, a tumor suppressor regulating cell growth and differentiation. Methylation differences related to tumor progression have been documented in the literature for several of these genes. Our study identified significant CpG sites and corresponding genes associated with breast cancer progression via differential methylation analysis. These results provide valuable insights into the biological mechanisms driving cancer progression and highlight the potential of DNA methylation as predictive biomarkers. Further research is needed to validate and expand these findings, and to explore their clinical implications in breast cancer surveillance and therapeutic interventions.

#223 Evaluating the therapeutic potential of MDM2 inhibitor RG-7388 and epigenetic modulator CM-272 in cisplatin-resistant ovarian cancer.

Fatimah AlssamaniI[1], Umamaheswari Natarajan[2], Shyam Jaganathan[2], Appu Rathinavelu[2]

[1]Rumbaugh-Goodwin Institute for cancer research, Barry & Judy Silverman Collage of Pharmacy, College of Clinical Pharmacy, King Faisal University, Nova Southeastern University, Fort Lauderdale, FL,[2]Rumbaugh-Goodwin Institute for cancer research, Barry & Judy Silverman Collage of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL

Ovarian cancer (OC) is the deadliest gynecological malignancy, often presenting late diagnosis and exhibiting treatment resistance, partly due to dysregulation of the crucial tumor suppressor p53. The oncoprotein MDM2 also negatively regulates p53, and therefore, MDM2 specific inhibitors may offer potential therapeutic avenues through reactivation of p53 and reversing adverse epigenetic modifications causing growth or resistance. In this study, we investigated the therapeutic potential of the MDM2 inhibitor RG-7388, chemotherapeutic agent cisplatin, and the epigenetic modulator CM-272 in cisplatin-resistant A2780cis ovarian cancer cells. We first characterized the growth kinetics of cisplatin sensitive and resistant A2780 cell lines, which confirmed significantly longer doubling times in the resistant cells (approximately 35 hours versus 20 hours in sensitive cells). Treatment efficacy was evaluated through cell viability and cell death assays, along with the expression levels of DNMT1 and EZH2, which are key epigenetic regulators. Treatment of A2780cis cells with RG-7388 demonstrated significant anti-cancer activity, by reducing live cell populations by 42-48% through increased cell death. Despite resistance, qRT-PCR analysis revealed that both cisplatin and CM-272 treatments significantly suppressed DNMT1 expression by 96%A2780cis cells. Western blot analysis also confirmed that both RG-7388 and cisplatin reduced DNMT1 protein levels in A2780cis cells along with the most pronounced reduction of DNMT1 after CM-272 treatment. Notably, CM-272 significantly decreased the levels of EZH2 also while RG-7388 did not impact the EZH2 protein levels. Interestingly, treatments with RG-7388 and CM-272 drug combinations showed varied effects, while maintaining strong inhibition of PARP. Overall, our findings suggest that the MDM2 inhibitor RG-7388 could be a promising therapeutic agent for cisplatin-resistant ovarian cancer, particularly because of its ability to modulateepigenetic regulators like DNMT1. However, the complex interplay between cell survival and epigenetic regulation in drug resistant cells warrant further investigation to optimize the outcomes of combination treatment strategies. #224 Methyl-CpG-binding domain protein 2 (Mbd2) as a therapeutic target in breast cancer.

Olivia Dumas[1], Niaz Mahmood[2], Ani Arakelian[2], Moshe Szyf[3], Shafaat Rabbani[4]

[1]Department of Physiology, McGill University, Montreal, QC, Canada,[2]Department of Medicine, McGill University, Montreal, QC, Canada,[3]HKG Epitherapeutics, Shatin, N.T., Hong Kong,[4]Department of Physiology & Department of Medicine, McGill University, Montreal, QC, Canada

Abnormal DNA methylation is frequently observed in the cancer epigenome, rendering it a prime target for pharmacological manipulation. Methyl-CpG-binding domain protein 2 (Mbd2), a reader of DNA methylation, has been shown to be strongly linked to various malignancies, including breast cancer, establishing *Mbd2* as a viable and effective therapeutic target. Our previous studies have demonstrated that genetic deletion of *Mbd2* significantly reduces primary breast tumor growth and lung metastasis in a well-established transgenic mouse model of breast cancer. In the current study, we examined the effect of pharmacological inhibition of *Mbd2* on breast cancer progression and metastasis to non skeletal and skeletal sites. Several small-molecule inhibitors for *Mbd2* have been described, and among these, KCC-07 was shown to significantly reduce medulloblastoma *in vitro* and *in vivo*. Treatment of mouse luminal B breast cancer cell lines (PyMT-R221A, E0071) with KCC-07 resulted in a time- and dose-dependent decrease in tumor cell proliferation and reduced the invasiveness of the cells *in vitro*. These results were recapitulated *in vivo*, where PyMT-R221A cells inoculated via mammary fat pad (m.f.p) and intra-tibial (i.t) routes into female FVB mice and treated with vehicle alone or KCC-07 (100.0 mg/kg) 3QW via the intraperitoneal route for three weeks showed a decrease in tumor volume and skeletal metastasis. Further immunohistochemical analyses of the tumor tissues using markers of tumor proliferation (Ki67), angiogenesis (CD31), and bone resorption (TRAP), as well as any potential side effects on animal toxicity and global transcriptomic changes of the PyMT-R221A cells induced by treatment with KCC-07, will be presented and discussed. In other studies, PyMT-R221A cells were treated with the most effective dose of *Mbd2* siRNA and KCC-07 (40μM) and cellular RNA from control and experimental groups was extracted and subjected to RNA-seq analysis, which is now being analyzed and validated in depth. Results from these analyses will identify key *Mbd2*-mediated signaling pathways and genes that play an important role in breast cancer. Taken together, the results of this study will provide mechanistic insights into the therapeutic potential of targeting *Mbd2* with KCC-07 to block breast cancer growth and metastasis in a preclinical setting. These findings could be highly valuable for the future evaluation of selective inhibitors of *Mbd2* to treat breast cancer patients.

#225 Single Cell DNA methylomes from multiple tissues demonstrate tissue heterogeneity and target enrichment as a driver of read utility.

Austin Holmes, Camden Jansen, Eric Pu, Sanika Khare, Dominic Skinner, Bryce Alves, Jerushah Thomas, Dmitry Pokholok, Felix Schlesinger

Scale Biosciences, Inc., San Diego, CA

Comparative analysis of single cell gene expression technologies is helpful in choosing a platform that fits experimental needs. However, emerging single cell (sc) technologies, like scDNA methylation, are currently unavailable across platforms and are unable to benefit from such analysis. Rather than comparing the performance of one tissue across multiple technologies, here we present one technology and a comparative analysis across multiple tissues, and sequencing read depths, with target enrichment. We integrate bulk-DNA methylation with single cell and transform methylation data to gene level metrics on par with current technologies. These datasets give guidelines on how to maximize the data per cell without excessive sequencing, allowing experiments to scale up. Single cell DNA methylation adds value to current genetic and epigenetic modalities as an orthogonal dataset that further characterizes functional genomics. Scale Bio offers a kitted platform for library generation and analysis of thousands of single cell methylomes. DNA methylation from bulk samples has been widely demonstrated to be a gene regulatory mechanism in health and disease, however large-scale single cell datasets are limited. At the onset of new technologies sequencing depth and cell number often exceed requirements for the most basic single cell analyses such as cell clustering, cell annotation and calling differentially methylated regions. At these high read depths and high cell # per sample, sample multiplexing in a biologically relevant way becomes difficult. We investigated six single cell methylomes (solid tumor, blood tumor, young PBMCs, old PBMCs, human brain and mouse brain) generated with Scale Bio scMet kit. For the tumor samples, we conducted copy number variation analysis alongside down-sampled read depth and cell number. For all samples, we cross compared cell clustering and cell annotation/recovery at various sequencing depths and cell number demonstrating that brain tissue tolerates much lower read depths. Each of these libraries were further enriched using the Twist Human methylome panel, demonstrating that an enrichment of regulatory regions allows for even lower read depths while maintaining a high number of significant DMRs. Lastly, we generated a bulk-DNA methylation library from the blood tumor sample to overlap with the most differentially methylated regions resolved at the single cell, revealing the limitations of bulk DNA compared to single cell. In conclusion these datasets and analyses conclude that tissue heterogeneity and the enrichment of known differentially methylated regions is a critical factor when considering sequencing depth required and the cell number per sample. However, emerging single cell methylomes continue to fine tune known DNA regulatory elements as well as facilitate discovery of de novo DNA methylation events at the single cell level.

#226 Methylation specific silencing of miR-9 is associated with an epithelial-mesenchymal transition (EMT) phenotype in laryngeal squamous cell carcinoma.

Christina Gobin, Matthew Chang, Marie Gauthier, Chayil C. Lattimore, Michael Kladde, Kristianna Fredenburg

University of Florida, Gainesville, FL

Background: Advanced stage laryngeal squamous cell carcinoma (LSCC) carries one of the highest mortality rates of all head and neck cancers. We previously demonstrated that low miR-9 expression impacts invasiveness and resistance to cisplatin in advanced stage LSCC. Here, we seek to further elucidate how low miR-9 influences LSCC pathogenesis.
Methods: Gene expression and clinicopathologic data were obtained for 116 LSCC patients from The Cancer Genome Atlas (TCGA) and used to evaluate predictors of LSCC overall survival. A simple logistic regression combined with a Receiver Operating Characteristic (ROC) curve was used to determine a cutoff for categorizing LSCC patients into low and high miR-9 expression groups. A panel of epithelial-mesenchymal transition (EMT) related genes (MAP1B, DOCK10, FGFR1, FGF1, ZEB1, VCAN, WNT5A, SRGN, THEM30B, CDH1 and EGFR) and methylated miR-9 transcripts were assessed between low and high miR-9 expressing LSCC patients via Principal Component Analysis. *In vitro* validation of an EMT phenotype and miR-9 promoter hypermethylation was performed using four advanced stage LSCC cell lines with variable miR-9 expression. Cell line EMT gene expression was evaluated via RNA sequencing and validated by qPCR. Methylation and chromatin accessibility of the three miR-9 promoter regions were quantified in each LSCC cell line through PacBio sequencing. Low miR-9 expressing cell lines were treated with the global demethylating agent, 5-Azacytidine (0μM, 0.1μM, 0.5μM and 1μM), and differences in EMT-related gene expression were assessed via qPCR.
Results: Low miR-9 and methylation of miR-9 were found to be significant predictors of poor LSCC survival ($p < 0.05$). Gene signatures representing a high EMT phenotype and high methylated miR-9 status were identified as unique classifiers of low compared with high miR-9 expressing LSCC patients. Differential expression of EMT related genes was detected in low compared with high miR-9 expressing cell lines; low miR-9 cell lines had significantly higher baseline expression of MAP1B, DOCK10, FGFR1, FGF1, and ZEB1 (>2-fold, $p < 0.0001$) and significantly lower baseline expression of CDH1 and EGFR (>2-fold, $p < 0.0001$). Low miR-9 expressing cell lines also had significantly greater methylation of miR-9 promoter regions ($p < 0.0001$) as well as significantly fewer chromatin accessibility sites open for miR-9 transcription ($p < 0.0001$). Global demethylation treatment of the low miR-9 expressing cell lines dose dependently restored miR-9 expression (>2-fold, $p < 0.0001$) and resulted in inverse expression of MAP1B, DOCK10, FGFR1, FGF1, ZEB1, CDH1 and EGFR at the 1μM dose (>2-fold, $p < 0.0001$).
Conclusion: Our findings indicate that methylation specific silencing of miR-9 may be a mechanism that yields a high EMT phenotype, predictive of poor overall survival in LSCC.

#227 How arsenic and particulate matter affect epigenetic gene regulation and cancer: bridging the gap between the environment and health: a review.

Bianca Ehling

Olentangy Orange High School, Lewis Center, OH

There are numerous environmental factors that influence epigenetic gene regulation and can thus lead to the development of cancer. Two of these factors include metals and air pollutants. This review examines how arsenic and particulate matter affect epigenetic gene regulation and can lead to cancer. It is important to continue to learn about and understand these mechanisms in a preventative effort to reduce the risk of developing cancer, especially since wildfires are projected to increase in frequency, and they are a source of particulate matter (PM). Arsenic is widespread in the environment and it can be present in PM as well. The references for this review were collected by conducting database searches (PubMed and ScienceDirect) using keywords such as metals, air pollutants, epigenetics, and cancer. Arsenic has been found to be associated with DNA demethylation and the formation of malignancies in vitro in rats, which could possibly be due to the universal methyl group donor (SAM) methylating arsenic and thus having limited availability to methylate DNA and histones. Arsenic can also promote the creation of reactive oxygen species that can damage DNA and hinder its ability to be methylated. Arsenic can lead to the methylation-induced transcriptional silencing of tumor-suppressor genes, as well. In addition, the presence of arsenic is associated with the methylation of transposable elements, which is correlated with colon cancer. Arsenic can also lead to the activation of certain histone kinases, which can potentially demethylate certain histones and eventually lead to proto-oncogenes being induced. Arsenic has also been found to induce the “marking” of certain silent genes, to the point where they are not yet activated, but have the ability to be quickly activated. In addition, since alternative splicing of RNA (specifically, which parts of the RNA will become exons) is dependent on DNA methylation and histone modifications, exposure to arsenic could disrupt normal RNA alternative splicing patterns. Arsenic has also been found to potentially alter miRNA expression. PM can potentially contribute to DNA hypermethylation and thus the onset of lung cancer. The alteration of DNA methylation has also been associated with dysregulation of apoptosis. PM has been found to potentially decrease the expression of histone demethylase, which may lead to increased methylation of histone modifications. PM can also potentially suppress the expression of tumor suppressor miRNAs, enabling lung cancer to develop. Since environmental factors can often be confounding variables, especially when the exposome is taken into account, it is often difficult to discern which environmental factor is causing which epigenetic effect. To combat this, data science methods could be implemented in future research endeavors.

#228 Loss of *TET2* and *TET3* mediated DNA demethylation drives intestinal tumor formation.

Oliver Gilliam[1], Ihab Ansari[2], Nikolaos Georgakopoulos[1], Manuel Mastel[1], Rene Jackstadt[1], Sebastian Belle[3], Yehudit Bergman[2], Frank Lyko[1]

[1]German Cancer Research Center, Heidelberg, Germany,[2]Department of Developmental Biology and Cancer Research, Institute for Medical Research Israel-Canada, Hebrew University Medical School, Jerusalem, Israel,[3]Department of Medicine II, University Medical Center Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany

Non-mutational epigenetic reprogramming is a widely recognized hallmark of cancer, which emphasizes the relevance of epigenetic modifications for cancer development. The discovery of the CpG island methylator phenotype in colorectal cancer (CRC) and promotor hypermethylation of tumor suppressor genes further raised the interest in DNA methylation changes during tumor development. However, despite decades of cancer epigenetics research, our understanding of the function of aberrant DNA methylation remains limited. Thus, new models are needed to study the link between global DNA methylation changes and tumorigenesis. The Ten-eleven translocator (*TET)* enzymes are critical mediators of active demethylation by oxidizing the C^5-methylcytosine, thereby playing a vital role in regulating DNA methylation. Here, we report an intestinal epithelium-specific *TET2/3* double knockout (dko) mouse model, which shows invasive adenocarcinomas in the small intestine at high penetrance. We performed a detailed DNA methylation analysis and identified enhancers as the main target of hypermethylation in the tumors. Additionally, we observed substantial overlap in methylation patterns with the fetal developmental stage of the mouse intestine. Subsequent analysis also revealed a fetal gene expression signature and activation of *YAP1* signaling, suggesting oncofetal reprogramming. Since fetal reprogramming is enriched in the serrated route to colorectal cancer, we compared our model with models of the classical (*APC*) and serrated (*BRAF*- and *KRAS*-derived) route of CRC. We found similar methylation patterns between the *TET2/3* dko tumors and *BRAF*- and *KRAS*-derived tumors. To investigate the clinical relevance of our findings, we collected human small bowel adenomas and integrated their methylation profiles with available datasets of colorectal adenomas and carcinomas. We observed notable similarities between adenomas of the small bowel and serrated adenomas of the colon. This finding further confirms the similarities between our *TET*-deficient mouse model and the serrated route to colorectal cancer and suggests that non-mutational *TET* deficiency could be an important driver of intestinal cancer.

#229 Oncogenic cell growth linked with hypermethylation of CpG sites within the p53 pathway, and its effects on subgroups.

Roy Khalife, Ethan Grebler, **Anthony Magliocco**

Protean BioDiagnostics Inc, Orlando, FL

Methylation of tumor-suppressor genes is a recognized oncogenic mechanism. This study focuses on determining the extent of CpG site methylation within genes of the p53 pathway and assessing how patient sex influences these methylation patterns, which could aid in cancer identification through p53 pathway methylation analysis. Given that mutations in p53 occur in over half of all human cancers, their pro-apoptotic properties are vital for halting unchecked cell growth. We analyzed the methylation status of p53-regulated transcriptional target genes using FFPE samples from various primary brain cancers. Methylation data, generated using the Infinium MethylationEPIC v2.0 array, was visualized through heat maps. Among all samples, the most hypermethylated genes (m-value >2) were identified in descending order as SFN, CASP9, TP53, APAF1, GTSE1, TSC2, and SESN3. Interestingly, TSC2 and SESN3 did not exhibit hypermethylation in male samples, suggesting potential sex-specific epigenetic regulation. The observed trend of hypermethylation—exceeding 80% CpG site methylation—within key inhibitory, apoptotic, and repair genes underscores their silencing and involvement in tumor development. Additionally, the absence of hypermethylation in canonical TP53 targets such as WAF1/p21 highlights the need for further investigation into pathway-specific methylation patterns, potentially uncovering alternative or complementary mechanisms of tumor suppression evasion.

#233 Targeting Rho GTPases RAC1 and CDC42 in advanced prostate cancer cells.

Wilfred Fonseca Ferrer[1], Valeria Torres Matos[2], Carolina Restrepo Soto[3], Jessica Colon Gonzalez[4], Suranganie Dharmawardhane Flanagan[4], Cornelis P. Vlaar Stoop[5], Carlos Joel Diaz Osterman[6]

[1]School of Pharmacy, UPR - Medical Sciences Campus, San Juan, Puerto Rico,[2]Biology, UPR - Rio Piedras Campus, San Juan, Puerto Rico,[3]Mathematics, UPR - Rio Piedras Campus, San Juan, Puerto Rico,[4]Biochemistry, UPR - Medical Sciences Campus, San Juan, Puerto Rico,[5]UPR - Molecular Sciences Center, San Juan, Puerto Rico,[6]Clinical and Translational Research, UPR - Comprehensive Cancer Center, San Juan, Puerto Rico

BACKGROUND: The androgen receptor (AR) plays a central role in the development and progression of prostate cancer. Standard treatment for advanced prostate cancer targets the AR using androgen deprivation therapy. Despite initial responses, patients eventually progress to androgen-independent disease with metastasis, raising the need for novel treatment options. GTPases regulate many metastasis-associated processes, including cell division, cell growth, cell migration, and cell adhesion. Novel inhibitors for GTPases are currently being evaluated for efficacy in metastatic breast cancer. However, little is known about their utility for other hormone-dependent cancers such as prostate cancer. We hypothesize that Rho GTPase inhibitor efficacy will vary between prostate cancer cell models based on AR expression status and metastatic potential. This study aims to determine the efficacy of nine compounds targeting the GTPase pathway in the setting of AR-positive compared to AR-negative prostate cancer cells. METHODS: AR-positive (LNCaP, 22rv1) and AR-negative (PC3, DU145) prostate cancer cell lines were used to evaluate the efficacy of nine novel Rho GTPase inhibitors. MTT viability assays were performed following exposure of cells to 0-100μM compound for 72 hours. Migration assays were performed using sublethal doses of select compounds for 3-5 days. Intracellular expression of Rho GTPase-associated proteins was evaluated using Western blot. RESULTS: Of the compounds analyzed, six had an IC50 in the nanomolar range. The most effective compound overall was CPV-337 (IC50: 6.5-108.6nM). AR-negative cell lines exhibited a higher sensitivity to EHOP-097 and MBQ-168 than AR-positive cell lines. Proteins associated with mechanotransduction were elevated in AR-negative compared to AR-positive cells. CONCLUSION: Our study demonstrates a central role for Rho GTPases in prostate cancer metastatic potential in the context of AR independence.
ACKNOWLEDGEMENTS: These studies were supported by start-up funds provided to C.J.D.O. by the University of Puerto Rico Comprehensive Cancer Center in San Juan, Puerto Rico.

#234 $G\alpha_i2$ induces cell migration in prostate cancer cells in the absence of rac1 activation.

Rarnice Johnson[1], Silvia Caggia[2], Shafiq Khan[1]

[1]Biological Sciences, Clark Atlanta University, Atlanta, GA,[2]Department of microbiology and immunology, University of Miami, Miami, FL

Prostate cancers can grow slowly and are confined to the prostate gland; However, metastatic prostate cancers are aggressive and can spread quickly. $G\alpha_i2$ is a heterotrimeric G protein subunit and its essential for cell migration in prostate cancer cells, in response to both oxytocin and EGF, acting via GPCR and PTKR, respectively. The Rho family of GTPases includes RhoA, Rac1 and Cdc42, these are intracellular protein that regulate cell migration. In the previous studies we seen that the knockdown of $G\alpha_i2$ reduces cell migration and lamellipodia formation at leading edge of PC3 cell overexpressing constitutively active Rac1, therefore $G\alpha_i2$ may be involved in the regulation of cell motility and lamellipodia formation at a step which is independent or downstream of Rac1 activation. We hypothesize that $G\alpha_i2$ is required for the activation of the downstream proteins of Rac1 leading to lamellipodia formation at the leading edge of migrating cells. We overexpressed constitutively active form of Gαi2 (Gαi2-Q205L) in PC3 parental cell lines. The result showed that when PC3 cells are transfected with Gαi2-Q205L the migration rate in these cells is significantly increased. In the parallel experiment we used a specific Gαi2 inhibitor, which resulted in attenuation of Giα2-Q205L effects on cell migration in PC3 cells. Furthermore, Rac1 inhibitor did not block increased cell migration in PC3 cells overexpressing constitutively active Gαi2. We studied $G\alpha_i2$ effects on proteins activated by Rac1, specifically Wave2 and Arp 2/3. We transfected PC3 empty vector and PC3 Rac1 constitutively active stable cells with control siRNA or Gαi2 siRNA to knockdown endogenous Gαi2 expression. The western blot analysis showed Rac1 dependent activation of Wave2 and Arp 2/3 are impaired in the absence of Gαi2. We conclude activated Gαi2 plays a crucial role in cell migration in prostate cancer cells which is independent of Rac1 activation.

#235 Targeting NOS sensitizes the NRAS-mutant melanomas to MEK inhibition and induces immunogenic cell death.

Jyoti Srivastava, Vipin Kumar Yadav, Rachel V. Jimenez, Bin Fang, Alvaro de Mingo Pulido, John M. Koomen, Kenneth Y. Tsai, Keiran SM Smalley, Paulo C. Rodriguez, Sanjay Premi

H. Lee Moffitt Cancer Center, Tampa, FL

Background: Activating NRAS mutations occur in 15-25% of melanomas; however, this subtype is highly aggressive and refractory to existing therapeutic approaches. Consequently, the identification of novel molecular mechanisms is of critical clinical importance. Melanomas harbor hyperactive nitric oxide synthases (NOS) that strongly correlate with poor prognosis. Here, we investigated the role of nitrosylation, a nitric oxide-induced posttranslational modification, in regulating the oncogenic MEK/ERK signaling pathway and Immunogenic Cell Death (ICD) in NRAS-mutant melanomas.
Methods: We employed various cellular and mouse models to investigate the effect of combinatorial inhibition of NOS and MEK in NRAS-mutant melanomas. We also profiled global nitrosylation by mass-spectrometry and validated the nitrosylation status of various MEK-ERK regulators and ICD markers using Biotin-switch method. Using site-directed mutagenesis, we characterized potential nitrosylation sites on the MEK and ERK proteins. Additionally, we characterized the nitrosylated forms of potential regulators of ICD andanti-melanoma immunity using cell-based assays and immunogenic mouse models. The immunomodulatory role of nitrosylation was further characterized using the dendritic cells(DCs): CD8+ T-cell cocultures.
Results: By inhibiting nitrosylation, we sensitized the NRAS-mutant melanomas to MEK inhibitors. We observed a strong correlation between global de-nitrosylation of MEK-ERK cascade proteins, and that of death-associated molecular patterns (DAMPs) which induce ICD.We also identified potential nitrosylation sites on MEK and ERK proteins with a pivotal role in melanoma cell proliferation. Further, we observed elevated nitrosylation and induction of oncogenic proteins upon MEKi acquired resistance, which was abrogated upon NOS inhibition. Using an immunocompetent mouse model, we demonstrated marked restriction of tumor growth in Nras-mutant melanoma upon inhibition of nitrosylation and MEK. Both *in vivo* and *in vitro* models showed extracellular release of ICD hallmark DAMPs, such as calreticulin, phospho-eIF2α, and HMGB1, which is a pre-requisite for ICD induction. This release triggered the activation of dendritic cells, leading to the proliferation and activation of a functional CD8+ T-cell repertoire in the tumor microenvironment.
Conclusions: We conclude that nitrosylation hyperactivates the MEK-ERK pathway and suppresses the anti-melanoma immune response, thereby promoting tumor progression and Meki resistance. Inhibiting nitrosylation not only enhances MEKi efficacy but also induces ICD. Further investigations on underlying mechanism(s) will identify novel therapeutic vulnerabilities against the yet untreatable, NRAS-mutant melanoma.

#236 Selective inhibition of NRAS-GTP in cancer models with small molecule NEOS-223.

Harish Potu[1], **Sara A. Little**[1], Stephanie Fedorchak[1], Sumathi Chittamuru[1], Timothy M. Murphy[1], Sarah Di Croce[1], Melanie George[1], Jeremy Harvey[2], Neil Rory McFarlane[2], Piet Christiaens[3], Timothy Fisher[1], Laxman S. Desai[1]

[1]NeoSome Life Sciences, Boston, MA,[2]KU Leuven, Leuven, MA,[3]Silverbridge Consulting, Heverlee, MA

NRAS is one of the second most mutated RAS oncogene followed by KRAS in cancer, and efforts to target directly inhibit its function have been continuing for years. Strategies targeting oncogenic RAS pathway include direct and indirect approaches. However, despite aggressive efforts in recent years, there are no clinical or on the market that directly target NRAS and inhibit its aberrant function in various cancers. The recent success of KRAS G12C inhibitors has demonstrated clinical efficacy in patients and approved for the treatment of non-small cell lung cancer. Despite the promising success of targeting KRAS, there remains no available inhibitor that targets NRAS alone. In pursuit of NRAS inhibition and we have developed a small molecule potent selective non-covalent inhibitor that inhibits NRAS-GTPase activity of both mutant and wild type of NRAS while sparing KRAS and HRAS. Our molecular dynamics simulation studies reveal the structural basis of inhibitor binding at the switch II pocket in NRAS. NEOS-223 demonstrated potent activity against cancer models with NRAS Q61K and inhibited cancer growth. Treatment with NEOS-223 led to tumor growth blockage and well tolerated in diverse RAS-addicted preclinical cancer models. NEOS-223 has a greater synergistic effect on inhibition of cell proliferation combined with specific targeted inhibitors such as gefitinib (EGFR), sotorasib (KRAS G12C), vemurafenib (BRAF V600E) and MRTX1133 (KRAS G12D) correlating with stronger suppression of EGFR-RAS-MAPK signaling. Resistance to KRAS inhibitors (G12C, G12D) seemed to be driven by EGFR mediated upregulation of wild type RAS activity. Feedback reactivation of adaptive RAS family members including NRAS (WT) occurs following KRAS inhibition, a key mediator of resistance. Co-targeting with NEOS-223 abrogates the EGFR-mediated feedback NRAS reactivation enhancing the antitumor effects improving the efficacy in KRAS mutant tumors with KRAS inhibition and similar effects were also observed in BRAF mutant colon cancer with inhibition of NRAS with NEOS-223 plus vemurafenib. Our study highlights the feasibility of developing NRAS selective inhibitor for therapeutic efforts and these results suggest that NRAS plus KRAS to be a promising strategy for treating both EGFR and RAS mutant tumors. Overall, these data provide important mechanistic insight to guide therapeutic strategies targeting NRAS mutant, dependent and resistance tumors.

#237 Species-specific role of RAS in malignant transformation.

Nikhil Gupta[1], Milla Majaniemi[1], Otto Kauko[1], Tero Aittokallio[1], Vera Gorbunova[2], Jukka Westermarck[1]

[1]University of Turku, Turku, Finland,[2]University of Rochester, Rochester, NY

Malignant transformation is a complex, multi-step process driven by the interplay between oncogene activation and tumor suppressor inhibition. The role of RAS in this process has been shown to exhibit striking species-specific differences. In mouse cells, RAS can effectively induce transformation with the inhibition of a single tumor suppressor. However, in human cells, RAS-driven transformation uniquely requires the inhibition of Protein Phosphatase 2A (PP2A). Despite over 20 years of investigation, the molecular explanation for this radical difference remains elusive. To address this fundamental gap in understanding, we performed a comprehensive phosphoproteogenomics analysis comparing mouse and human cells overexpressing oncogenic RAS.Transcriptomics, proteomics, and phosphoproteomics analyses revealed remarkably significant intra- and interspecies heterogeneity, highlighting the profound species-specific differences in RAS-induced signaling. Strikingly, while mTOR, CDK4-E2F1, and MYC signaling pathways were robustly activated by RAS in mouse cells, these activations were notably absent in human cell models. However, co-inhibition of the tumor suppressor phosphatase PP2A rendered human cells permissive to RAS-induced malignant transformation and restored pathway activities overlapping with RAS-only transformed mouse cells. Intriguingly, our findings suggest that RAS overexpression in human cells opposes phosphosignaling and pathway-targeted therapy responses, a phenomenon absent in mouse cells. This highlights a unique buffering role for RAS against transformation in human cells. Moreover, whereas RAS induced substantial signaling pathway connectivity in mouse cells, similar connectivity in human cells was observed only upon PP2A co-inhibition.Collectively, these findings reveal that, unlike in immortalized mouse cells, RAS signaling in human cells acts as a buffer against transformation unless PP2A is inhibited. This underscores the inadequacy of mouse models in representing RAS-driven signaling and transformation in human cells. Our results highlight the need for human cancer models to revolutionize the cancer therapies.

#239 RCZY-690 and RCZY-680: Novel, highly potent, and orally bioavailable, tri-complex pan RAS-MULTI(ON) inhibitors with distinctive oral pharmacokinetic profiles, exhibiting broad anti-tumor activities in CDX models.

Celia X.-J. Chen, Lin Wang, Yu Bai, Xiaohong Liu, Qiaoni You, Jianming Bao

Rongchang Pharmaceuticals, Ltd., Shanghai, China

Alterations in RAS proteins, including KRAS, HRAS, and NRAS, are common in cancer. KRAS mutations drive 85% of RAS-driven cancers, including lethal types like pancreatic ductal adenocarcinoma (PDAC), non-small-cell lung cancer (NSCLC), and colorectal cancer (CRC). These mutations impair GTP hydrolysis, locking RAS in an active GTP-bound state that promotes unchecked cell proliferation and survival. Although KRAS G12C inhibitors like sotorasib and adagrasib show promise for NSCLC, resistance develops rapidly, and effective therapies are still lacking for over 85% of RAS-driven or RAS-amplified cancers.
Herein, we report RCZY-690 and RCZY-680 as novel and potent tri-complex RAS-MULTI(ON) inhibitors. These compounds form a tri-complex with active GTP-bound RAS proteins and cyclophilin A (CyPA) through a RAS-targeting strategy pioneered by Revolution Medicine. This approach, exemplified by the lead compound RMC-6236, has shown promise in KRAS-mutant PDAC and NSCLC patients in phase 1 study. RCZY-690 and RCZY-680 demonstrated high binding affinity to CyPA, as confirmed by surface plasmon resonance assays, and potent nanomolar EC_{50} values for binding to CyPA and KRAS mutants (G12C, G12V, G12D) in HTRF assays. Both compounds achieved potent IC_{50} values in disrupting interactions between NRAS, HRAS, and various KRAS subtypes (e.g., G12C, G12D, G12V, G12R, G12S, G13C, G61L) with the CRAF-RAS binding domain, as determined by HTRF. Their efficacy in blocking the RAS/RAF/MAPK pathway was demonstrated by sub-nanomolar IC_{50} values for suppressing p-ERK in cancer cell lines with diverse RAS mutations, including HPAC and Capan-2. CellTiter-Glo assays further revealed sub-nanomolar IC_{50} values for cellular cytotoxicity across multiple RAS-mutant human cancer cell lines. As expected, RCZY-690 and RCZY-680 were inactive in BRAF V600E-mutated and RAS-independent cancer cell lines. Both compounds exhibited favorable in vitro ADME properties. They have excellent and yet distinctive oral pharmacokinetic profiles across multiple species. At tolerable doses, oral administration of RCZY-690 and RCZY-680 showed potent anti-tumor efficacy in a KRAS G12D-mutant HPAC pancreatic xenograft model, with sustained inhibition of intratumoral p-ERK and DUSP6 levels. The superior anti-tumor efficacy may be attributed to their highly potent cellular cytotoxicity, long mouse half-lives (10.1 h and 4.8 h, respectively), and high oral exposure levels. In conclusion, RCZY-690 and RCZY-680 are tri-complex pan RAS-MULTI(ON) inhibitors with best-in-class clinical potential for treating RAS-driven solid tumors.

TUMOR BIOLOGY: Human and PDX Models 1

#24 Influence of culture conditions and donor material on phenotypic features of PDX-derived breast cancer tumoroid lines.
Ellen Klaproth[1], Julia Thiel[2], Jannik Scherer[1], Meng Dong[2], Kanstantsin Lashuk[1], **Julia B. Schueler**[1]

[1]Charles River Laboratories, Inc., Freiburg, Germany,[2]Dr. Margarete Fischer-Bosch-Institute of Clinical Pharmacology and University of Tubingen, Stuttgart, Germany

Introduction: Breast cancer is one of the most common and deadly cancers among women, highlighting the need for reliable in vitro models to study tumor biology and assess therapeutic strategies. In this project, we established and characterized three breast cancer tumoroid lines (two triple negative and one HER2+), derived from patient-derived xenograft models as a robust in vitro system for cancer research: MAXFHER 2500, MAXFT 583 and MAXFTN 2988. The tumoroids were maintained under various conditions, including long-term culture, cryopreservation, and suspension adaptation, to evaluate their morphological stability and functional fidelity over time. They were characterized by histology, multiplex IHC and QuantiGene analysis. To evaluate predictivity for preclinical in vivo as well as clinical outcomes, four standard of care compounds were evaluated in the HER2 positive breast cancer model MAXFHER 2500 and compared to in vivo data of the corresponding PDX. To be able to determine tumor growth as well as efficacy of test compounds an automated image analysis script was developed to quantify tumoroid growth.
Results: The three lines showed very similar expression levels of Ki67, Her2 (both IHC) and histological architecture as compared to the donor PDX and the donor patient. The expression levels of Estrogen as well as Progestogen receptor, EpCAM and Cytokeratin 18 were comparable in the tumoroid lines and the PDX as confirmed by multiplex IHC. The different culture techniques, dome (high Matrigel concentration) vs suspension method (low Matrigel concentration) did not influence the expression of the above-mentioned markers or the histological structure of the tumoroids. It was possible to create tumoroid lines from fresh PDX as well as from viably frozen material. Cisplatin was highly active in all three tested culture conditions with IC50 values ranging from 2.9 - 9.6 µM. In contrast, the sensitivity towards Oxaliplatin was influenced by the culture conditions with IC50s ranging from 8.2 - 94.6 µM. Gemcitabine and Cisplatin efficacy in vitro was predictive for antitumoral activity in vivo. However, Paclitaxel was inactive in vitro but showed some efficacy in vivo. Discussion: Overall, this study demonstrates that tumoroid lines derived from PDX models retain key tumor characteristics, making them a valuable tool for cancer research. Although the breast cancer tumoroid lines preserved morphological and functional features under various conditions there were indications that some culture conditions do influence the sensitivity towards anticancer treatment. The observed variability underscores the importance of carefully selecting and optimizing culture conditions to maintain the predictive value of PDX derived tumoroids for breast cancer drug development.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Growth Factors, Receptors, and GTPase Signaling

#240 Study of MUC16/ERBB axis in pancreatic cancer.

Amina Baniya, Michael (Tony) A. Hollingsworth

University of Nebraska Medical Center, Omaha, NE

Pancreatic cancer is the third leading cause of cancer-related deaths due to its poor prognosis and highly malignant nature. About 65% of pancreatic cancer cases express the biomarker CA125, encoded by the *MUC16* gene. MUC16 is a member of mucin family of glycoproteins known to line epithelial cells for protection and lubrication and is overexpressed in several cancer types including pancreatic cancer, often linked with enhanced disease progression, metastasis, and reduced patient survival. MUC16 has a large extracellular domain containing unstructured N-terminal domain and variable number tandem repeat domain with SEA domain, and short carboxy terminal domain. TR1.2 is a recombinant peptide containing SEA domain 5. Circulating levels of MUC16/CA125 has been used as a biomarker to monitor adenocarcinoma for decades. In serum, CA125 sizes range from 200-2000 kDa and contain SEA domains. However, functional roles of CA125/MUC16 have not been elucidated. We present evidence that in addition to serving as a biomarker, circulating MUC16 has pro-tumorigenic activities by engaging ERBB receptors. We hypothesize that isoforms of MUC16 engage ErbB3 receptors, enhancing ERBB2-EGFR heterodimerization upon ligand binding to redirect oncogenic signaling in pancreatic cancer, with concomitant activation of downstream signaling cascades that include Akt. We evaluated the influence of MUC16 (TR1.2) on ErbB receptor activation, and its capacity to activate downstream signaling pathways using pancreatic cell line models. We used alphafold3 to model the binding of TR1.2 to different ERBB receptors. We found that in serum starved conditions, TR1.2 induced a transient, yet significant downregulation of ERBB3 phosphorylation, accompanied by a slight reduction in ERBB2 phosphorylation, with no observable changes in EGFR phosphorylation in time- and dose- dependent manner. By 15 hours, phosphorylation levels returned to baseline, indicating the transient changes in serum-starved conditions. In contrast, in the presence of serum-containing media, we found significant increases in ERBB2 and EGFR phosphorylation after 15 hours treatment. Alphafold3 predicted that TR1.2 binds to domain 1 of ERBB3 causing conformational changes leading to blocking of dimerization. Together, our results suggest that TR1.2 directly binds to ERBB3 to enforce a monomer conformation. This in turn allows ERBB2 to preferentially heterodimerize with EGFR in the presence of EGF-type ligands in complete media, thereby enhancing downstream oncogenic signaling through AKT. Our future directions include validation of binding of TR1.2 to ERBB3 receptor and investing the activation of alternative pathways (such as MAPK) in pancreatic cancer cell line-based models. Understanding the biological activity of MUC16 and its cleaved product (CA125) provide insight into the role of MUC16 in the autocrine setting, the tumor microenvironment and at distant organ sites to influence the metastatic niche.

#241 Clec4f is expressed in a subset of PDAC metaplastic neuroendocrine cells and alters tumor cell growth.

Bailey A. Bye[1], R. McKinnon Walsh[1], Austin E. Eades[1], Kathleen E. DelGiorno[2], Michael N. VanSaun[1]

[1]Department of Cancer Biology, University of Kansas Medical Center, Kansas City, KS,[2]Department of Cell and Developmental Biology, Vanderbilt University, Nashville, TN

Pancreatic ductal adenocarcinoma (PDAC) is a deadly disease with a 5-year survival rate of just 13%. Poor survival is due in part to late detection, as well as resistance to current standard-of-care therapeutics. PDAC tumorigenesis is a result of exocrine cell metaplasia: when stressed, acinar cells transdifferentiate to form metaplastic ducts in a process called acinar-to-ductal metaplasia (ADM). ADM is normally protective, but if metaplastic ductal cells develop a mutation in the proto-oncogene *Kras*, they can become trapped in the transdifferentiated state and form neoplastic lesions (PanINs), which can eventually develop into PDAC. Metaplastic ducts contain a myriad of cell types, including metaplastic neuroendocrine cells, which have been shown to promote neoplastic growth and PDAC tumorigenesis. In a subset of metaplastic neuroendocrine cells, we have identified upregulation of carbohydrate receptor Clec4f. In humans, Clec4f is upregulated in PDAC tumors compared to normal pancreas and correlates with poor prognosis when elevated in early stage disease. While Clec4f's function in mice has been primarily associated with glycan recognition for antigen clearance by mouse liver macrophages, its function in PDAC tumor cells is unknown. Since we have identified Clec4f expression in a discrete subpopulation of pancreatic epithelial cells associated with early stage disease, we hypothesize that Clec4f plays a novel role in regulating PDAC tumorigenesis in response to binding glycans in the tumor microenvironment. Ectopic overexpression of Clec4f (Clec4f-oe) in murine PDAC cells revealed prominent reduction of classically mitogenic pathways including MAPK (via phosphorylated ERK) and PI3K (via phosphorylated AKT) as well as elevated levels of phosphorylated c-Myc (S62), which has been shown to play a role in regulating ductal-to-neuroendocrine lineage plasticity and therapeutic resistance. Clec4f-oe also preliminarily protected PDAC tumor cells from cell death via Gemcitabine or a D-galactose-based senescence model. In accordance with other studies in macrophages, Clec4f expression in PDAC tumor cells appears to be niche dependent. We found that, in Clec4f-oe tumor cells, incubation with galactose stabilizes Clec4f expression and Clec4f-associated signaling alterations. These data suggest that carbohydrate binding by Clec4f alters growth and plasticity phenotypes in PDAC tumor cells. Future experiments will investigate the intracellular binding partners for Clec4f to interrogate its signaling function in metaplastic neuroendocrine cells in early PDAC.

#242 Differential activation of TAM receptors by Gas6 and protein S.

Ziren Wang, Samhita Bapat, Varsha Gadiyar, Christopher Varsanyi, Rachael Pulica, Trevor Frederick, Ahmed Aquib, Raymond Birge

Rutgers Graduate School of Biomedical Sciences, Newark, NJ

Tyro-3, Axl, and Mertk (abbreviated TAM receptors) comprise a homologous family of type I receptor tyrosine kinases (RTKs) have been shown to have increasingly important roles for both homeostasis, particularly for anti-inflammation and the resolution of inflammation. While previous studies have shown that TAM receptors are differentially expressed on immune cells, surprisingly much less is currently known about the differential functional activities and expression of the major TAM ligands, Growth Arrest Factor-specific gene 6 (Gas6) and Protein S (Pros1), particularly whether they have overlapping or distinct biochemical and cellular functions, and how they regulate the interplay between inflammation and coagulation. To evaluate the functions of Gas6 and Pros1, we first cloned and expressed human proteins for testing on TAM-IFNgR1 reporter cell lines. While both Gas6 and Pros1 require post-translational gamma-carboxylation of their Gla domains for biological activity and binding to phosphatidylserine (PS), they possess differential capacity to bind soluble Axl and C4BP. Moreover, both Gas6 and Pros1 require the 4 tandem EGF-like domains for their activity, and both appear to require extracellular protein disulfide isomerase activity for receptor activation. Taken together, we have identified a novel mechanism for TAM activation by Gas6 and Pros1, as well as both overlapping and non-overlapping activities with respect to ligand-dependent receptor activation. These results have potential implications in both cancer and inflammation.

#243 FLT4, a novel regulator of renal cell carcinoma progression.

Djazia Haferssas[1], Nathalie Henley[2], Jonatan Barrera Chimal[2], Casimiro Gerarduzzi[1]

[1]Pharmacology and Physiology, University of Montreal, Montreal, QC, Canada,[2]Centre de Recherche de l'hopital Maisonneuve Rosemont, Montreal, QC, Canada

Background: Clear Cell Renal Cell Carcinoma (ccRCC) is one of the ten most frequently diagnosed malignancies worldwide and constitutes 2-3% of all adult cancers. Disruption of p53 function, a critical tumor suppressor, plays a pivotal role in cancer development and resistance to chemotherapy. While p53 gene mutations are rare in ccRCC, these tumors often resist DNA-damage- based therapies, suggesting alternative mechanisms suppressing wild-type p53 in ccRCC. Therefore, reactivating this pathway represents a potential therapeutic strategy. p53 is tightly regulated by MDM2 and MDMX which are frequently elevated in ccRCC patients. However, the molecular mechanisms underlying MDM2/MDMX-mediated p53 regulation in ccRCC remain unclear. Our study identified the Receptor Tyrosine Kinase FLT4 as a novel regulator of MDM2/MDMX and p53 activity. Notably, both FLT4 and its ligand, VEGFC, are overexpressed in ccRCC patients.
Hypothesis: We propose that FLT4 activation increases the stability of the MDM2/MDMX complex, resulting in p53 inactivation and promoting ccRCC tumorigenesis.
Methods: 1) We analyzed Bulk and single cell RNAseq data of ccRCC patients from the Cancer Genome Atlas (TCGA) to assess the expression of FLT4 and VEGFC. 2) The ccRCC cell lines ACHN and Caki-2 were used for *in vitro* experiments, including VEGFC treatment for functional assays (proliferation, migration, and survival) and MDM2/MDMX/p53 protein analysis. 3) ACHN and Caki-2 cells were transduced with Luciferase and FLT4 and injected into immunodeficient NOD/SCID mice to study tumor development and metastasis using *In vivo* Imaging System (IVIS).
Results: FLT4 and VEGFC are overexpressed in ccRCC patients and correlate with cancer progression and poor survival. In addition, FLT4 activation promotes proliferation and migration both *in vitro* and *in vivo* and reduces the chemosensitivity of ccRCC cells mainly through the modulation of p53 levels. Mechanistically, FLT4 activation decreases p53 stability and activity by increasing MDM2/MDMX levels through post-translational modifications.
Conclusion: Aberrant FLT4 signaling drives ccRCC progression by suppressing p53 through the upregulation of its negative regulators MDM2 and MDMX. These findings highlight FLT4 as a potential target for restoring p53 activity and improving ccRCC outcomes.

#244 Identification of proteins in the oncogenic FLT3-ITD signaling pathway using the APEX2 system.

O. Tatli[1], M. E. Jakobsson[2], G. Mitsa[2], J. U. Kazi[3], **L. Ronnstrand**[3];
[1]Istanbul Medeniyet University, Istanbul, Turkey, [2]Acrivon AB, Lund, Sweden, [3]Lund University Faculty of Medicine, Lund, Sweden

The FLT3-ITD oncogenic mutation is commonly found in acute myeloid leukemia (AML) and correlated with a poor prognosis. In order to identify proteins within the FLT3-ITD pathway, we employed the engineered ascorbate peroxidase 2 system (APEX2). Monoclonal Ba/F3 cells stably expressing the APEX2-FLT3-ITD fusion protein were incubated with biotin-phenol and treated with H_2O_2, enabling the APEX2 enzyme to catalyze the biotinylation of proteins in close proximity to FLT3-ITD. Given that quizartinib, an FLT3 inhibitor, alters the localization of FLT3-ITD protein to the cell surface, a quizartinib-treated group was used to mimic wild-type FLT3 and designated as pseudo-wild-type FLT3. Biotinylated proteins were selectively enriched using streptavidin beads to obtain proximity proteome of FLT3-ITD. Enriched proteins were analyzed by state-of-the-art data independent acquisition (DIA) liquid chromatography-mass spectrometry (LC-MS/MS), uncovering differential associations between wild-type and oncogenic FLT3-ITD. After quantitation by mass spectrometry, the proteins were classified by KEGG enrichment analysis. Interestingly, the protein export group (mmu03060) was enriched in only FLT3-ITD protein interactors. Given that activation of differential signaling cascades relies upon the subcellular localization of FLT3, this set of proteins suggests a possible nuclear localization of FLT3. Upon categorizing the identified proteins based on their molecular function, a significant number of FLT3-ITD interactor proteins were found to be engaged in nuclear events, supporting that FLT3-ITD protein is translocated to the nucleus. Subsequently, we grouped the identified FLT3-ITD interactors based on the domains that they harbor. We selected some specific candidates of particular interest for validation by reciprocal co-immunoprecipitation (co-IP) assays. Protein kinases CDK5 and CHEK1, small GTP binding protein GSPT1, and the nuclear export protein XPO1 were tested for their interaction with FLT3-ITD. Plasmids encoding these proteins with a C-terminal FLAG-tag were co-transfected into human kidney cells with FLT3-ITD. Of these, CDK5 displayed a robust interaction with FLT3-ITD in reciprocal co-IP experiments. Besides, the CDK5 interaction of FLT3-ITD was significantly greater than that of wild-type FLT3. Thereof, we surveyed the phosphorylation dependence of FLT3/CDK5 interaction by suppressing FLT3 phosphorylation in both wild-type FLT3 and oncogenic FLT3-ITD. The inhibition of FLT3 kinase activity with quizartinib drastically reduced CDK5 interaction, revealing that CDK5/FLT3 interaction is dependent of FLT3 phosphorylation. To summarize, we leveraged exploratory proteomics to uncover a panel of candidate FLT3-ITD effectors based on their association or proximity with FLT3-ITD. Future studies will investigate the role of these proteins in FLT3-ITD-induced transformation.

#245 Preclinical development of HDM2020, a novel ADC targeting FGFR2b, in gastric cancer (GC) and squamous non-small cell lung cancer (sq-NSCLC) xenograft models.

Tingyang Wang, Liubin Guo, Kuan Lu, Hao Pan, Yang Chen, Zhaoxing Yu, Yayun Zhao, Shengxing Zhao, Qingli We, Ruizhe Wang, Yan Xia, Hongwen Li, Dongzhou Jeffrey Liu

Huadong Medicine Co., Ltd., Hangzhou, China

Introduction: FGFR2b is a novel protein biomarker detected by IHC with the overexpression rate of ~30% (any 2+/3+) in gastric or gastroesophageal junction cancer(GC/GEJC) patients, and among those patients ~40% are not eligible for currently approved targeted therapies (HER2, PD-L1, MMR and CLDN18.2)[1]. HDM2020 is a topoisomerase Inhibitor based DAR8 ADC developed using a novel Ab targeted against FGFR2b, which has the potential to treat FGFR2b overexpressing tumor with reasonable safety window[2].
Methods: *In vivo* cell line (CDX) and patient derived xenograft (PDX) models were conducted to validate the therapeutic potential of HDM2020 against GC and sq-NSCLC. FGFR2b expression were detected by IHC using various tumor paraffin sections.
Results: Combination of HDM2020 and avastin or paclitaxel demonstrated a synergistic effect in GC CDX model. Single-agent therapeutic activity of HDM2020 was demonstrated in two FGFR2b-positive GC PDX models with TP53 or BCOR gene mutation and at least 1st line chemotherapy. At a dose of 10mg/kg, the maximum tumor growth inhibition rate were 98% and 99%. In FGFR2b middle expressed sq-NSCLC PDX model, complete response was observed at single dose of 10mg/kg. The minimum effective doses were between 2.5-3mg/kg in above three models. FGFR2b is overexpressed in GC, sq-NSCLC, TNBC and may other tumor types.
Conclusion: Based on the clinical validation of FGFR2b in GC and signs of early preclinical activity in sq-NSCLC with significant unmet need, HDM2020 might has promising efficacy in these indications. HDM2020 is expected to enter clinical development in 2025.

#246 Innovative use of a fluorescent probe and 3D spheroids to study A3 adenosine receptor-targeted compounds in cancer cell lines.

Katerina Jecmenova, Alzběta Srovnalova, Marian Hajduch, Petr Dzubak

Palacky University in Olomouc, Olomouc, Czech Republic

Introduction: The A3 adenosine receptor (A3AR) is a promising cancer therapy targeted due to its role in tumor progression, immune regulation, and apoptosis. Its selective expression in tumors like the liver and pancreas makes it ideal for therapies with minimal off-target effects. However, live-cell imaging techniques to study A3AR, including receptor expression, membrane localization, and interactions with AR modulators, are limited. Here, we present CELT-228, an A3AR-specific fluorescent probe, as a tool for visualization and functional analysis in live cells and 3D spheroid cultures. This method also enables competitive binding assays to identify and validate new A3AR agonists and antagonists.
Material and methods: The reporter cell line ES-012-A, overexpressing A3AR, was treated with the CELT-228 (Celtarys, Spain) and imaged via spinning disc confocal microscopy (Yokogawa CV7000). Fluorescent signal localization and intensity were analyzed using Signal Image Artist (Revity). Competitive binding assays using CELT-228 were developed for High Content Screening (HCS) of newly synthesized nucleoside-based compounds and for studying A3AR interactions in cancer cell lines of diverse origins. Additionally, CELT-228 staining was applied to 3D spheroids from Hep-3B cells to investigate receptor localization under varying microenvironmental conditions.
Results: In 2D and 3D models, CELT-228 predominantly localized to cell membranes of reporter and cancer cell lines. Competitive assays showed that new compounds bind to the orthosteric site, competing effectively with CELT-228. In 3D spheroids, staining revealed A3AR distribution across different regions, including cell membranes and intracellular compartments. A3AR expression patterns varied in hypoxic, nutrient-deprived, and proliferative regions, providing insights into microenvironmental influences on A3AR regulation.
Conclusion: CELT-228 is a versatile tool for studying A3AR in 2D and 3D models, enabling receptor localization, competitive binding assays, and receptor mapping in spheroids. This approach holds great potential for A3AR-targeted drug discovery and advancing cancer therapies.
Supported by the MEYS Czech Republic: CZ-OPENSCREEN (LM2023052), EATRIS-CZ (LM2023053), SALVAGE (811100711/37), National Institute for Cancer Research (Program EXCELES, ID Project No. LX22NPO5102) and IGA_LF_2024_038.

#247 Investigating the impact of HER4 mutations on intracellular signalling pathways.

Denis M. Collins[1], Marta Valenti[2], Johanna Gaubatz[1], Birgit Bossenmaier[3], Bryan Hennessy[4], John Crown[5]

[1]Dublin City University, Dublin, Ireland,[2]Cancer Biotherapeutics Research Group, Life Sciences Institute, School of Biotechnology, Dublin City University, Dublin, Ireland,[3]Bossenmaier Consulting, Munich, Germany,[4]Department of Medical Oncology, Beaumont Hospital, Dublin, Ireland,[5]Department of Medical Oncology, Saint Vincent's University Hospital, Dublin, Ireland

Background: HER4 is the least studied member of the HER/ErbB receptor tyrosine kinase family that also includes EGFR, HER2 and HER3. HER4 is frequently mutated in skin, lung and gastro-intestinal tumours but there are limited data on the impact of HER4 point mutations (MUTs) on intracellular signalling pathways. This study identifies 8 HER4 point MUTs (2 extracellular domain (ECD) and 6 intracellular domain (ICD)) and utilises plasmid-based overexpression to assess the impact of the HER4 point MUTs on intracellular signalling pathways in HEK293 cells.

Methods: 8 HER4 point MUTs were identified using publicly available Catalogue Of Somatic Mutations in Cancer (COSMIC) data and Provean/SIFT analysis. 4 HER4 MUTs were deemed deleterious/damaging and 4 MUTs were classified as neutral or tolerated. MUT1 (p.E202D) and 2 (p.P224R) are ECD, MUT3-8 (p.T1036I, p.Y1242C, p.H1245N, p.S1246R, p.L1247M, p.H1255N) are ICD. Mutant primers were designed and constructed (Sigma Aldrich). Site-directed mutagenesis (QuikChange Lightning kit) was carried out using the pRK5 HER4 wild-type (WT) plasmid as template creating 8 HER4 MUT plasmids. Sequences were validated (SequiServe). HEK293 cells were transfected (Fugene) with either empty vector, GFP control, WT HER4 or the HER4 MUT plasmids. Transfection was confirmed by Western blot. Plasmid transfected HEK293 protein lysates were analysed in biological triplicate by reverse phase protein array (RPPA) to determine the levels of 50 total proteins and 34 phospho-proteins (n= 84 targets). Increases or decreases in protein levels were determined as significant ($p<0.05$, Student's t test) vs appropriate control, WT HER4 vs. empty vector or MUT HER4 vs WT HER4.

Results: HEK293 cells express WT EGFR and negligible levels of HER3 and HER4. Total EGFR levels were unchanged in response to WT HER4 transfection but EGFR phosphorylation at Y992 ($p=0.01$), and Y1068 ($p<0.001$) increased 15-fold and 2-fold, respectively. Total and phosphorylated Akt (S473 and T308) and MAPK-ERK1/2 (T202/Y204) were not impacted by WT HER4 transfection. Overexpression of WT HER4 resulted in increased levels of phosphorylated p38 MAPK (T180/Y182) ($p=0.04$), Src (Y416) ($p<0.001$) and STAT3 (Y705) ($p<0.001$). The 8 HER4 MUTs assessed had no impact on the activity or total expression of EGFR, Akt and Stat3. MUT2 decreased phosphorylated MAPK-ERK1/2 ($p=0.01$) and total p38 MAPK levels ($p=0.04$). MUT4 decreased phosphorylated MAPK-ERK1/2 levels ($p<0.001$). MUT6 decreased total p38 MAPK levels ($p=0.03$) and increased phosphorylated Src levels ($p=0.01$). MUT7 decreased levels of total MAPK-ERK1/2 ($p=0.03$) and total p38 MAPK ($p<0.001$).

Conclusions: WT HER4 activates EGFR and downstream signaling through p38 MAPK, Src and STAT3. The HER MUTs investigated affected MAPK-ERK1/2, p38 MAPK and Src signaling pathways, suggesting phenotypic impact that supports a role in tumorigenesis.

#248 Dissecting therapeutic mechanisms in EGFR and HER2 signaling pathways using Lumit cellular immunoassays.
Matthew R. Swiatnicki, Mindy Lin, Hicham Zegzouti

Promega Corporation, Fitchburg, WI

Due to the importance of aberrant receptor tyrosine kinase (RTK) regulation in many cancers, we sought to employ the Lumit Immunoassay Cellular System (Lumit ICS) in order to characterize signaling nodes within important RTK signaling pathways. Lumit ICS is a homogenous immunoassay for detecting targets of interest in cellular lysate. Phosphorylated or total protein can be detected in as little as two hours with a simple add and read format. In this study, we generated several Lumit assays to explore whether Lumit was capable of teasing out mechanistic differences between various drug treatment modalities. These assays include p-EGFR, p-HER2, p-cMET, and various downstream nodes such as p-AKT and p-H2AX. In *EGFR* WT cell lines, we observed increased phosphorylation of EGFR when treating cells with the ligand, EGF. This increased phosphorylation was inhibited with both small molecule inhibitors, such as erlotinib, and monoclonal antibodies, such as cetuximab. However, in mutant *EGFR* cell lines that have a level of basal EGFR phosphorylation, only small molecule inhibitors could completely inhibit EGFR phosphorylation. Cetuximab was only capable of inhibiting EGFR phosphorylation stemming from extracellular stimulation (EGF) and not basal p-EGFR. Within the *HER2* overexpressed cell line BT474, we detected a high level of basal HER2 phosphorylation. This increased phosphorylation could be inhibited by the small molecule inhibitor CP-724714. However, when treating BT474 cells with monoclonal therapies such as trastuzumab and pertuzumab, we saw a robust increase in HER2 phosphorylation at early timepoints and a more modest increase at longer treatment timepoints. We also noted differences in other cell signaling nodes when treating HER2 overexpressing cells with varying treatment modalities. When treating cells with the antibody drug conjugate (ADC) DS-8201a, we noted increased HER2 phosphorylation, as well as increased phosphorylation of the DNA damage response (DDR) mark, p-H2AX. Increased p-H2AX was not seen when treating the same cell line with trastuzumab. An increase in DNA damage response with DS-8201a treatment fits within the context of DS-8201a delivering a topoisomerase inhibitor as its payload. Finally, we noted a loss of AKT phosphorylation when treating BT474 cells with trastuzumab, but not DS-8201a. While we have yet to explore the reason for this difference in AKT phosphorylation, this result highlights the divergent effects of varying treatment modalities on downstream signaling. Overall, these data exemplify the complexity of cell signaling pathway inhibition and demonstrate Lumit ICS as being an assay capable of teasing out some of that complexity.

#249 EGFR activation reverses gastrin suppression by MENIN by inducing its nuclear export.

Uloma B. Elvis-Offiah[1], Suzann Duan[2], Sulaiman Sheriff[2], Juanita L. Merchant[3]

[1]Program in Cancer Biology, University of Arizona, Tucson, AZ,[2]Department of Medicine, Division of Gastroenterology, University of Arizona College of Medicine, University of Arizona, Tucson, AZ,[3]Program in Cancer Biology; Department of Medicine, Division of Gastroenterology, University of Arizona, Tucson, AZ

Introduction: Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) are rapidly increasing malignancies in the US. They are strongly associated with loss-of-function mutations in the *Multiple Endocrine Neoplasia type 1 (MEN1)* gene which encodes the tumor suppressor MENIN. Gastrinomas secrete excess gastrin, representing the most malignant subtype of sporadic or hereditary GEP-NETs. Although MENIN epigenetically inhibits *gastrin* gene expression, ligand-receptor activation inducing *GASTRIN* removes MENIN suppression. However, the mechanism by which MENIN suppression is alleviated remains poorly defined. Exon 10 encodes all three nuclear localization signals (NLSs) of MENIN within its C-terminal domain. Moreover, NLS1 harbors a phosphorylation motif for protein kinase B, which mediates epidermal growth factor receptor (EGFR) signaling. Since MEN1-gastrinomas predominantly arise within the submucosal Brunner's glands rich in pro-proliferative EGFR ligands like epiregulin (EREG), we hypothesized that EGFR activation induces *GASTRIN* by reducing nuclear MENIN.

Methods: We subcloned wild-type (WT) *MENIN* cDNA and the sequential C-terminal deletions into pcDNA carrying the FLAG epitope and validated with sequencing. Regulation of endogenous *GASTRIN* mRNA was determined after transfection of MENIN vectors into two human gastric cancer cell lines—AGS and KATOIII. The effect of EGFR signaling on MENIN's subcellular localization, stability, and repression of the gastrin gene was determined by immunoblotting, subcellular fractionation, immunofluorescent staining, and RT-qPCR.

Results: WT MENIN and constructs retaining 2 or 3 nuclear localization signals (NLSs) suppressed 50% of *GASTRIN* expression under basal conditions. Moreover, deleting all three NLSs abolished MENIN suppression. EREG treatment induced *GASTRIN* in the absence of the presence of WT or MENIN without 1-2 NLS. However, no induction of GASTRIN was observed with all 3 NLSs deleted. Constructs lacking all 3 NLSs exhibited reduced protein expression, which was reversed by the proteasome inhibitor MG132, suggesting decreased protein stability. NLS-deficient MENIN was highly localized to the cytoplasm whereas WT MENIN and deletions with >1 NLSs were distributed between the nucleus and cytoplasm under basal conditions. However, EREG treatment induced their cytoplasmic translocation, suggesting that EGFR signaling blocks MENIN's nuclear localization.

Conclusion: EGFR activation induces *GASTRIN* gene expression by preventing nuclear import which requires the C-terminal NLSs.

#250 TMEM97/sigma 2 receptor increases androgen receptor activities to regulate prostate cancer cell growth and sensitivity to castration therapy.

Daotai Nie, Xiangwei Fang, Yuanqin Zhang, Jiuhui Wang

Southern Illinois University School of Medicine, Springfield, IL

Prostate cancer is one of the most common cancers in men. Suppression of androgen receptor (AR) activity by androgen depletion or direct AR antagonist treatment, although initially effective, leads to emergence of castration-resistant prostate cancer. Sigma 2 receptor (σ2R) has been implicated in carcinogenesis including prostate cancers. Its molecular identity remained elusive until 2017 that transmembrane protein 97 (TMEM97) was identified as the *bona fide* sigma 2 receptor. Here we report that TMEM97/σ2R expression was elevated in prostate tumors of higher malignancy and advanced stages, and was associated with reduced survival of prostate cancer patients. Via in-vitro studies, increased expression of TMEM97 enhanced prostate cancer cell proliferation, clonogenicity, and resistance to enzalutamide. Knockdown of σ2R expression reduced prostate cancer cell growth and clonogenicity, and sensitized LNCaP and castration resistant 22Rv1 cells towards enzalutamide. There was a positive correlation between TMEM97 and AR expressions in prostate tumors. Knockdown of σ2R expression reduced the protein levels of AR and its AR-V7 variant under hormone deprivation condition. Decreased TMEM97 expression also downregulated AR activities as evidenced by reduced expression of AR target genes. PB-28, a known σ2R agonist, can stimulate AR target genes expressions while antagonist decreased them. SM21, a σ2R antagonist, presented synergism when combined with enzalutamide in the treatment of prostate cancer cells. Our findings suggest a potential approach targeting TMEM97/σ2R to reduce castration resistance.

#251 Resistance to androgen receptor pathway inhibitors is mediated by a pro-survival stress response converging on altered mitochondrial energetics.

Shibjyoti Debnath[1], Kathryn Ware[1], Bea Thomas[1], Kelsey H Fisher Wellman[2], Andrew Armstrong[1], Jason Somarelli[1]

[1]Duke University, Durham, NC,[2]East Carolina University, Greenville, NC

Purpose: The current front-line therapies for men with metastatic prostate cancer are novel androgen receptor pathway inhibitors (ARPIs), such as abiraterone acetate or enzalutamide, which target the androgen receptor (AR) pathway. These therapies significantly prolong overall survival; however, acquired resistance to these drugs is common over several years. Therefore, there is a major unmet clinical need to identify mechanisms of resistance and innovative therapies to treat this therapy-resistant, metastatic disease.
Experimental Procedures: To identify common molecular mechanisms of acquired ARPI resistance we developed a panel of three enzalutamide-resistant (enzaR) cell lines, LNCaP-enzaR, CS2-enzaR, and LN95-enzaR, by chronic, long-term exposure to increasing doses of enzalutamide. Analysis of the genome, transcriptome and phospho-proteome of enzaR prostate cancer cell lines were evaluated by comparative genomic hybridization (aCGH), RNA-seq and reverse phase phospho-protein arrays. Oxygen consumption rate was measured by Seahorse assays. To decipher the correlation between stress response and ATP hydrolysis, we have utilized small molecule p38 inhibitor (SB203580) to test if p38 is related to ATP hydrolysis and validated the result by western blot. The functional role ATPIF1 was deciphered by ATPIF1 siRNA transfection in LNCaP cells.
Results: Our genomic and functional studies have pinpointed a pro-survival cellular stress response as convergently activated during the acquisition of AR-dependent enzalutamide resistance. This pro-survival stress response leads to induction of metabolic quiescence and activation of p38/MAPK signaling, which triggers reversal of mitochondrial ATP synthase. Instead of canonical “forward” ATP synthase activity to generate ATP, the ATP synthase runs in “reverse”, hydrolyzing ATP to maintain a proton gradient across the mitochondrial membrane and permit survival. These features create collateral sensitivity to organic cations that target non-canonical polarization of the mitochondrial membrane that is critical to cellular persistence. In short, our findings support the hypothesis that AR inhibition induces a pro-survival response characterized by mitochondrial energetic changes that can be targeted as novel treatments for AR therapy-resistant prostate cancer.
Conclusion: We have discovered non-canonical ATP synthase reversal as a key targetable mechanism by which cancer cells maintain mitochondrial polarization in the face of therapy-induced resource depletion to sustain cell survival. Future studies are aimed at clinical translation of novel agents to target these persister populations.

#252 IRS2-driven modulation of PI3K/AKT signaling and tumorigenesis in estrogen receptor-positive breast cancer.

Seonmin Lee[1], Ju Hee Kim[2], Han-Byoel Lee[3], Wonshik Han[3]

[1]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of,[2]Biomedical Research Institute, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of

Introduction
Insulin receptor substrate 2 (IRS2) is a critical adaptor protein mediating intracellular signaling pathways downstream of insulin and insulin-like growth factor 1 (IGF1) receptors. Through its involvement in the PI3K/AKT signaling cascade, IRS2 regulates key processes essential for tumor growth and progression. While high IRS2 expression is linked to tumor progression, low IRS2 expression is associated with poorer overall survival, particularly in estrogen receptor-positive (ER+) breast cancer. However, the underlying mechanisms remain unclear, prompting this investigation into the role of IRS2 in ER+ breast cancer.
Method
IRS2 expression levels and overall survival across subtypes were analyzed using TCGA and METABRIC public data. IRS2 expression levels were analyzed by Western blot and qRT-PCR. In the ER+ MCF7 cell line, IRS2 knockdown was performed using shRNA, and its effects on tumor cell proliferation, migration, and invasion were assessed via MTT, wound healing and transwell assays. To examine the impact of IRS2 on the IGF1 pathway, cells were treated with IGF1, and Western blot was used to analyze alterations in PI3K/AKT signaling and EMT marker expression following IRS2 knockdown. Tumorigenesis and metastasis were studied using fat pad and tail vein injections in NOD.SCID mice.
Results
Analysis of METABRIC and TCGA patient data revealed that in the Luminal A subtype, lower IRS2 expression correlated with poorer overall survival. Among the 12 breast cancer cell lines, the ER+ MCF7 cell line, which exhibited relatively high IRS2 expression, was selected for shRNA knockdown experiments. IRS2 knockdown resulted in reduced cell proliferation, migration, and invasion. Time-dependent IGF1 treatment revealed reduced p-AKT levels following IRS2 knockdown, demonstrating suppression of IGF1-mediated PI3K/AKT signaling. EMT marker analysis revealed reduced expression of mesenchymal markers associated with cancer metastasis. Animal experiments suggested a potential reduction in tumorigenesis and metastasis; however, results were inconclusive and required further validation.
Conclusion
Our findings demonstrate that IRS2 knockdown reduces proliferation, migration, and invasion, emphasizing its critical role in tumor cell functions. IRS2 depletion also suppressed IGF1-induced activation of the PI3K/AKT pathway and downregulated mesenchymal EMT markers, highlighting its role in cancer progression and metastasis. However, the significant correlation between low IRS2 expression and poorer patient outcomes underscores the need for further investigation into its clinical implications.

#253 Diet induced insulin resistance is due to induction of expression of tumor suppressor pten.

Radha Mukherjee, Priya Pancholi, Malvika Sharma, Hilla Solomon, Merna N. Timaul, Vladimir Markov, Elisa de Stanchina de Stanchina, Kiran Vanaja, Neal Rosen

Memorial Sloan Kettering Cancer Center, New York, NY

The PI3K/AKT/mTOR pathway is a key regulator of insulin and metabolic homeostasis, proliferation, growth, and apoptosis. While AKT regulates key processes like glucose uptake, mTOR is a master regulator of cap-dependent translation through its substrates S6K and 4E-BP. This pathway also plays a key role in tumorigenesis- with high incidence of activating mutations in the oncogene *PIK3CA* and loss of function alterations of tumor suppressor and lipid phosphatase *PTEN*. **Most recently our work led to the discovery that the translation of PTEN lipid phosphatase, is regulated by PI3K-mTOR regulated cap dependent translation, constituting a feedback loop.** Pharmacologic inhibition by PI3K inhibitors reduces PTEN protein leading to a rebound in PI3K signaling that reduces the efficacy of the PI3K inhibitors. Insulin resistance is a condition which arises due to inadequate response of the PI3K/AKT signaling to insulin, demanding increasing amount of insulin to elicit the same degree of AKT activation. Onset of insulin resistance is closely associated with a variety metabolic aberrations like type 2 diabetes, obesity and liver steatosis. Insulin resistance and Type 2 Diabetes are characterized by hyperinsulinemia, hyperglycemia with severe cases ending up in insulin deficiency due to pancreatic beta cell exhaustion. There is also a strong association of insulin resistance and increased risk of developing cancer and resistance to cancer therapy especially in breast and endometrial cancers that are mutant for PI3K/PTEN. Currently, little is known about the early kinetics and molecular changes in PI3K/AKT signaling that may allow for the reduced insulin action and therefore progression of insulin resistance. We speculated that insulin resistance is due to insulin dependent induction of its negative regulator PTEN protein that prevent further increases in PI3K signaling. Here we show that in a diet induced model of obesity and insulin resistance, mouse fed on high fat diet, PTEN levels are increased in fat, muscle and liver tissues. Onset of hyperinsulinemia and PTEN induction in tissue is followed by hyperglycemia, hepatic steatosis and severe glucose intolerance. Treatment with a PTEN phosphatase inhibitor prevents and reverses these phenotypes, whereas an mTORC1 kinase inhibitor reverse all but the hepatic steatosis. These data suggest that induction of PTEN by increasing levels of insulin elevates feedback inhibition of the pathway to a point where downstream PI3K signaling is reduced and hyperglycemia ensues. PTEN induction is thus necessary for insulin resistance and the type 2 diabetes phenotype and a potential therapeutic target. This was accompanied by a significant increase in weight, hyperinsulinemia, hyperglycemia, insulin resistance and liver lipidosis. Inhibition of PTEN activity or its translation by inhibiting mTOR, both prevented and reversed the development of insulin resistance and obesity phenotypes

MGH/Harvard Medical School, Boston, MA

E3 ubiquitin ligases mediating turnover of proteins engaged in cancer progression point to key regulatory nodes. To uncover modifiers of metastatic competency, we conducted an *in vivo* genome-wide CRISPR-inactivation screen using cultured breast circulating tumor cells, following intravascular seeding and lung colonization. We identified *HECTD4,* a previously uncharacterized gene encoding a conserved potential HECT domain-containing ubiquitin transferase, as a potent tumor suppressor. We show that purified HECTD4 mediates ubiquitin conjugation *in vitro,* and proteomic studies combined with ubiquitin remnant profiling identify a major degradation target as the prostaglandin synthetic enzyme cyclooxygenase-2 (COX-2; *PTGS2*). In addition to COX-2 itself, HECTD4 targets its regulatory kinase MKK7. In breast cancer models, HECTD4 expression is induced as cells lose adherence to the matrix, and its depletion massively increases COX-2 expression, enhancing anchorage-independent proliferation and tumorigenesis. Genetic or pharmacologic suppression of COX-2 reverses the pro-tumorigenic phenotype of *HECTD4*-depleted cells. Thus, *HECTD4* encodes an E3 ubiquitin ligase that downregulates COX-2 suppressing anchorage-independence in epithelial cancer cells.

#258 RUNDC1 is required for p53-mediated tumor suppression.

Atul Ranjan[1], Elizabeth Thoenen[1], Mrinalini Bhosale[1], Dipesh Thapa[2], Alejandro Parrales[1], Tomoo Iwakuma[1]

[1]Division of Hematology & Oncology, Department of Pediatrics, Children's Mercy Research Institute, Kansas City, MO,[2]Department of Cancer Biology, The University of Kansas Medical Center, Kansas City, KS

The tumor suppressor p53 is a transcription factor whose downstream target genes are involved in the regulation of the cell cycle and apoptosis, thus leading to tumor suppression. In many cancers, wild-type p53 activity is inhibited. Small molecule inhibitors of MDM2 (a negative regulator of p53), like Nutlin-3a which activates p53 by binding to MDM2, induce tumor suppression. Although p53-dependent tumor suppression is well studied, crucial factors required for the efficacy of p53-activating agents remain unknown. Toward this goal, we conducted a human whole-genome lentiviral shRNA screening in wild-type p53 carrying cells treated with Nutlin-3a. We identified RUNDC1 (Run domain containing 1) as one of crucial factors that were required for Nutlin-3a-mediated inhibition of colony formation in a p53-dependent manner. RUNDC1 is a poorly characterized protein, and its role in cancer is still unknown. Here, we demonstrated that downregulation of RUNDC1 attenuated p53-mediated cell cycle arrest. As a mechanism, RUNDC1 bound to p53 and enhanced p53's binding to the p53-responsive elements in the promoter regions of p53 target genes. Our study, for the first time, reveals the biological function of RUNDC1, and its functional association with p53, suggesting the possibility that RUNDC1 contributes to p53-mediated tumor suppression.

#259 Germline p53 R181 mutants and DNA binding cooperativity in tumorigenesis.

R. Moses[1], A. Indeglia[2], A. S. Levine[3], R. Hausler[1], G. Kelly[1], S. A. Miller[4], M. Heller[1], A. N. Le[5], W. Kohlmann[6], A. Naumer[6], J. Vagher[6], S. H. Cahill[3], L. D. Maese[6], J. Karanicolas[4], J. E. Garber[3], M. E. Murphy[7], K. N. Maxwell[1];
[1]University of Pennsylvania, Philadelphia, PA, [2]Harvard University, Boston, MA, [3]Dana-Farber Cancer Institute, Boston, MA, [4]Fox Chase Cancer Center, Philadelphia, PA, [5]Philadelphia College of Osteopathic Medicine, Philadelphia, PA, [6]Huntsman Cancer Institute, Salt Lake City, UT, [7]Wistar Institute, Philadelphia, PA

TP53 is the most frequently mutated gene in cancer, and its encoded protein p53 has many tumor-suppressive functions. There are several different classes of mutant p53 acquired in human cancer and inherited in cancer-prone families with Li-Fraumeni Syndrome, where individuals have an 80-90% increased risk of cancer. These include structural mutations that are generally misfolded (R175H), DNA contact mutations (R273H); and oligomerization mutations (A347D). A new class of variants called “cooperativity” mutations affect the binding of the p53 tetramer to DNA via disruption of a salt bridge formed by the negatively charged glutamic acid (E) 180 residue of one p53 monomer and the positively charged arginine (R) 181 residue of another. p53 cooperativity mutations at the R181 residue (R181H and R181C) have been increasingly identified in cancer-prone families undergoing genetic testing; however, the mechanism by which these variants disrupt p53 tumor suppression in humans is not understood. We show that R181H and R181C have significantly diminished ability to transactivate a curated set of ~300 known p53 target genes in CRISPR knock-in colorectal and breast cancer cell lines. This loss of transactivation ability is not explained by defects in p53 structure or oligomerization, but through reduced cooperative binding to p53 target sites on DNA as determined by fluorescence polarization and chromatin-immunoprecipitation experiments. Interestingly, we observe residual apoptotic activity in R181H and R181C mutant cells upon DNA damage, despite the poor transcriptional activation of p53’s proapoptotic targets. We observe increased p53 at the mitochondria for transcription-independent apoptosis in R181-mutant cells. Understanding the tumor suppressive activities that are lost versus retained will guide the definition of the pathogenicity of R181 variants, which account for 5000 cancer cases per year in the United States.

TUMOR BIOLOGY: Human and PDX Models 1
Poster Session

#26 Developing PDX derived organoid models for efficacy evaluation of anticancer therapies.
W. Zhang, X. Zhao, Y. Chang, Y. Jiang, F. Jia, Z. Sun, J. Li, X. Zhang, X. Yan, Q. Zhou, D. Zhang, Y. Guan, X. Mei, F. Yan, C. Zhao, J. Liao, Z. Liu, Q. Mei, J. Zhang, Y. He, X. Zhang, J. Zhang, W. Sun, B. Cao;
Shanghai Medicilon Inc., Shanghai, China

BACKGROUND AND PURPOSE: Developing the most fitting models that best reflect real patient tumor system is crucial for advancing cancer mechanistic research and mediating drug discovery. Patient derived xenograft (PDX) models can accurately reflect cancer responses to therapies, thus being recognized as a gold standard in oncology drug development. However, PDX models can be labor intensive, time-consuming and costly. Cancer organoid is 3D infinitesimal derived from cancer stem cells, which can faithfully recapitulate genetic profile, mutational landscape, phenotypic and histo-pathological features and responses to therapies of patient tumors. Organoids derived from PDX tumors, namely PDXOs, are suitable for in vitro anticancer drug efficacy evaluation, forming good combinations with their in vivo PDX counterparts. This work aims to develop PDXO models from our PDX biobank for anti-cancer drug efficacy evaluation uses.
EXPERIMENTAL APPROACH: PDXOs were developed using Matrigel dome embedding approach with fresh cell digests from PDX tumor tissues. The model development included continuous expansion for >3 passages followed with cryopreservation and downstream analysis. Each model was assessed using bright field imaging (BFI) and H&E staining. Whole exome sequencing (WES) and mRNAseq were used to assess the genetic status. Immunocytochemical staining (ICC) and flow cytometry were used to assess the biomarker expression. CellTiter-Glo (CTG) assay and LDH release assay were used for drug efficacy evaluation.
KEY RESULTS: By 2024-Oct, we have established >20 PDXOs, covering different cancer types, including colon cancer, gastric cancer, pancreatic cancer, lung cancer, liver cancer, etc. We have shown that the exonic mutational status and drug response behavior of PDX and PDXO counterparts were consistent, and CTG assay and BFI were suitable for drug efficacy evaluation of PDXOs. We have also shown that PDXOs with particular protein expression features were suitable for evaluating the corresponding targeted therapies. Moreover, co-culture with PBMCs or other immune cells could be used to assess the anti-cancer efficacy of immune therapies on PDXOs.
CONCLUSIONS AND IMPLICATIONS: Our work illustrates the significant potential and value of PDXO models in assessing various kinds of anti-cancer therapies. An integrated platform combining PDX and PDXO models will advance cancer pharmacological research and drug discovery.

#260 PDCD10 regulates Wnt activation-induced intestinal adenoma formation by promoting Wnt dependent stem cell function.

Trisha Mondal[1], Sneha Kesaraju[1], Li Dong[1], Alex Ellerstein[1], Tong-Chuan He[2], Evgeny Izumchenko[3], Christopher R. Weber[1], Le Shen[1]

[1]Department of Pathology, The University of Chicago, Chicago, IL,[2]Department of Orthopedic Surgery and Rehabilitation Medicine, The University of Chicago, Chicago, IL,[3]Section of Hematology and Oncology, Department of Medicine, The University of Chicago, Chicago, IL

The goal of this study is to understand how PDCD10 regulates early steps of tumor development by using genetically modified mice and organoids.

BACKGROUND: Programmed cell death 10 (PDCD10) is an adaptor protein critical for vascular development. Germline loss of function mutations of PDCD10 cause familial cerebral cavernous malformation. While some studies show that upregulated PDCD10 increases cancer aggressiveness, others show that the loss of PDCD10 promotes tumor progression. Given these conflicting reports, the role PDCD10 plays in tumorigenesis and cancer aggressiveness remains largely elusive. Furthermore, as most of the previous studies were performed using established 2D adapted tumor cell lines, how PDCD10 affects the early stages of tumorigenesis has not yet been investigated. In this study, we aimed to delineate how PDCD10 expression affects early stage of tumor development in the intestine using genetically modified mice.

METHODS: Intestinal stem cell (ISC) and intestinal epithelial cell (IEC) specific *Pdcd10* deletion mice were generated by crossing *Olfm4-EGFP-CreERT2* and *Vil-CreERT2* mice with *Pdcd10*floxed mice, respectively. *Ctnnb1* (β-catenin encoding gene) exon 3 floxed mice were crossed with these mice to induce Wnt activation. IEC organoids from these mice were generated and characterized. Histological and molecular analyses were performed using samples obtained from mice and organoids.

RESULTS: Tamoxifen-induced Wnt activation in *Olfm4-EGFP-CreERT2 Ctnnb1* exon 3 floxed mice caused progressive weight loss, leading to animal death. These changes were limited by *Pdcd10* deletion. Histological assessment revealed that while Wnt activation induced significant adenoma formation, particularly in proximal small intestine, very limited adenoma was present in Wnt activated mice with *Pdcd10* deletion in ISCs. Lineage tracing studies using mice with tamoxifen-induced IEC specific *Pdcd10* deletion showed that *Pdcd10* deletion reduced ISC function. This ISC defect was associated with reduced expression of intestinal stem cell markers, including *Lgr5*, *Olfm4*, and *Lrig1*, along with decreased expression of *Axin2* and other Wnt signaling marker genes. Studies using IEC organoids derived from *Pdcd10* floxed mice indicated that 4-hydroxytamoxifen-induced *Pdcd10* deletion limited organoid growth, and reduced ISC marker and Wnt signaling marker gene expression. Induced Wnt activation in organoids by CHIR99021 rescued *Pdcd10* deletion-induced organoid growth defect, and lineage tracing studies showed that *Ctnnb1* exon 3 deletion reverses ISC defects in *Pdcd10* deleted mice.

CONCLUSION: PDCD10 is required for optimal Wnt signaling to maintain ISC function and participates in Wnt-induced intestinal adenoma formation. These results demonstrate that targeting PDCD10 function and related signaling pathways may serve as therapeutic targets to limit cancer progression.

#261 Blocking AKT2 downregulates SOX9/Notch signaling inhibiting PTEN-null driven liver tumorigenesis.

Qi Tang, Jingyu Chen, Guo Zhang, Ielyzaveta Slarve, Ni Zeng, Lina He, Diala Alhousari, Phillip Nguyen, Shunan Hu, Shefali Chopra, Liyun Yuan, Bangyan L. Stiles

USC - University of Southern California, Los Angeles, CA

Primary liver cancer, including hepatocellular carcinoma (HCC) and Cholangiocarcinoma (CCA), arise from the neoplastic transformation of hepatocytes and cholangiocytes in the liver. Their association with liver cancer stem-like cell (LCSC) makers presents a more aggressive behavior and high lethal rate. PTEN is a tumor suppressor gene that negatively regulates the PI3K/AKT pathway. Downregulation of *Pten* is observed in up to 70% of the cases in CCA and 50% of the cases in HCC. In mouse models lacking PTEN, CCA develops in 100% of the mice at 12 months of age regardless of whether the whole liver cells (LiPTEN, $Pten^{loxP/loxP}$; Alb-Cre^{+}), hepatocytes-only (HpPTEN, $Pten^{loxP/loxP}$; $R26R^{YFP}$; AAV8-TBG-Cre), or cholangiocytes-only (ChoPten, $Pten^{loxP/loxP;}$ $R26R^{YFP}$; SOX9-$Cre^{ERT)}$ are targeted. Treatment of these mice with DDC at 3 months to obstruct the bile duct leads to an earlier CCA oncogenesis at 6 months of age. Using YFP to follow the lineage of tumor cells in the HpPTEN and ChoPTEN mice, we found that PTEN loss allows for transdifferentiation from cholangiocytes to hepatocytes or vice versa. To explore the mechanism for how PTEN regulates cell fate, we focused on SOX9, a transcription factor that plays a critical role in embryonic development and is believed to be the downstream target of NOTCH signaling. Hyperactivation of the SOX9 and NOTCH signaling are observed at the tumor stage of all the PTEN loss mouse models. We showed that knocking down SOX9 with siRNA reduced the sphere-forming ability of liver cells established from the mice mentioned above, indicating SOX9 promotes LCSC proliferation and sustains the tumorigenic potential of these liver cells. Gain-of-function assays of the Notch signaling through exposure to Jag1 ligand-coated extracellular matrix or transfection of Notch intracellular domain (NICD) both induced the expression of SOX9 significantly. The treatment of *Pten*-deleted mice with DAPT to inhibit NOTCH signaling showed concurrently decreased expression of Notch target Hes1 and SOX9. We also addressed the roles of AKTs in this PTEN-regulated CCA development. Our data show that deletion of *Akt2* in the LiPTEN mice (LiPTEN-A2, $Akt2^{loxP/loxP}$; $Pten^{loxP/loxP}$; Alb-Cre^{+}) significantly attenuates tumor development. Compared with the LiPTEN mice, loss of AKT2 in LiPTEN-A2 mice robustly and significantly reduces the expression of SOX9/NOTCH signaling and manifests a bile duct malformation at 12 months of age. Together, this finding suggests NOTCH activation regulates SOX9 and collaborates with PTEN loss to drive liver cancer progression, and inhibiting AKT2 specifically can block HCC-CCA formation through SOX9/NOTCH downregulation.

#262 APOBEC4, a novel regulator of p53-dependent cell cycle arrest, senescence, and apoptosis.

Dipesh Thapa[1], Atul Ranjan[2], Elizabeth Thoenen[2], Alejandro Parrales[2], Shigeto Nishikawa[3], Jay Vivian[2], Tomoo Iwakuma[2]

[1]Department of Cancer Biology, The University of Kansas Medical Center, Kansas City, KS,[2]Department of Pediatrics, Children's Mercy Research Institute - Kansas City, Kansas City, MO,[3]Department of Thoracic Oncology, Kyoto University, Kyoto, Japan

Introduction: The tumor suppressor protein p53 (p53) is a transcription factor that can transactivate downstream target genes like *p21, PUMA, NOXA, BAX,* and *GADD45a* to cause cell cycle arrest, senescence, apoptosis, and other biological processes. However, its function is frequently compromised in tumorigenesis, with approximately half of human cancers harboring mutations in the TP53 gene. Notably, even in cases retaining wild-type p53 (wtp53), it gets degraded or inhibited through various mechanisms, including, the overexpression of its E3 ubiquitin ligase MDM2. MDM2 antagonists such as Nutlin-3a are promising strategies to restore p53 function and suppress tumor growth. However, the factors/biomarkers regulating the efficacy of MDM2 antagonists and p53-mediated tumor suppression remain unclear. Identifying such factors and understanding their functions are important to develop optimal therapeutic strategies targeting p53.

Experimental procedures: Through a human whole-genome shRNA library screen, we attempted to identify factors regulating p53-mediated tumor suppression by treating osteosarcoma U2OS cells with an MDM2 antagonist. This screening and subsequent validation identified APOBEC4 as a factor that is required for p53-mediated suppression of colony formation following Nultin-3a treatment.

Summary of data: Knocking down *APOBEC4* mitigated Nutlin-3a-induced activation of p53 as a transcription factor, as well as p53-mediated cell cycle arrest and apoptosis in multiple p53-proficient cancer cells. Cellular senescence induced by H_2O_2 was also reduced upon APOBEC4 knockdown. Moreover, APOBEC4 overexpression enhanced x-ray irradiation-induced apoptosis in a manner dependent on p53.

Conclusion: Our data suggest that APOBEC4 is a novel regulator required for p53-dependent cell cycle arrest, cellular senescence, and apoptosis.

#263 Histone hypoacetylation of CD9 mediates differentiation arrest and immune evasion in pediatric acute myeloid leukemia.

Yaqun Xu[1], Kathy Yuen Yee Chan[1], Qiwei Sun[1], Yixuan Wu[1], Siu Ping Fok[1], Qi Zhao[2], Gernot Schabbauer[3], Kam Tong Leung[1]

[1]The Chinese University of Hong Kong, Shatin, NT, Hong Kong,[2]University of Macau, Taipa, Macao,[3]Medical University Vienna, Vienna, Austria

Acute myeloid leukemia (AML) is an aggressive hematologic malignancy characterized by impaired terminal differentiation. Despite intensive treatment regimes, the clinical outcomes remain suboptimal. Here, we report a new mechanism involving the tetraspanin protein CD9 in orchestrating differentiation arrest and immune escape in pediatric AML.

The expression of CD9 on blasts of AML patients (12.5%, n=115) was significantly lower than those of ALL patients (93.6%, n=343, $P<0.0001$) or hematopoietic stem cells from normal bone marrow donors (48.4%, n=22, $P=0.004$). Among AML cases, 43 patients (37.4%) were CD9+, with 5-year event-free survival rate significantly higher than CD9- patients (58.1% *vs*. 38.3%, $P=0.040$).

A marked decrease of H3K9/27Ac occupancy in the *CD9* locus was observed in AML than in ALL cells, which strongly correlated with CD9 repression ($r=0.585$-0.719, $P<0.01$). Exposure of CD9- AML to the HDAC inhibitor panobinostat significantly elevated CD9 mRNA and protein level, restored histone acetylation marks, and suppressed myeloblast proliferation *ex vivo* (median IC50: 21.4 nM). Compound library screen with a collection of 896 epigenetic agents confirmed focal hypoacetylation as the key driver of CD9 silencing. Enforced CD9 expression in MV4-11 cells significantly suppressed proliferation and colony formation. NOD/SCID mice transplanted with CD9+ cells exhibited reduced leukemic load, prolonged survival duration ($P<0.001$), and a marked regression of extramedullary sarcoma.

RNA-seq of 114 pediatric AML revealed decreased stemness and increased monocyte gene signatures in CD9+ samples. Concordantly, we observed a profound up-regulation of CD9 with the appearance of lineage markers (CD14, CD36, CD86, CD115, CD300e) in monocytic-supportive *ex vivo* culture. The gain of CD9 in primary myeloblasts (n=13) consistently augmented monocytic markers. Transcriptional network analysis revealed CD9+ AML exhibited enhanced antigen processing and presentation. Confirmatory overexpression of CD9 promoted basal and IFNγ-induced MHC-I/II expression through JAK2/STAT5 axis. Interestingly, CD9 physically bound to MHC-I/II and formed an immune complex on the membrane. In NSG mice, co-transplantation of human PBMCs mounted an effective immunity against CD9+ but not CD9- AML, concomitant with a robust BM infiltration of GZMB+ cytotoxic T cells as revealed by single-cell transcriptomics and CyTOF deep T cell profiling. Importantly, panobinostat priming rejuvenates immune sensitization via CD9 transcriptional activation in humanized mice, resulting in robust leukemia clearance.

Taken together, our data provided molecular, cellular and clinical evidence showing CD9 as a key driver intertwining monocytic differentiation and immune recognition in pediatric AML, and inspired a new combinatorial epigenetic/immunotherapy for this rare but aggressive malignancy.

#264 The E3 ubiquitin ligase WWP2 regulates stability of the chromatin remodeler ARID1B.

Pradipta Hore, Sandipkumar Bambhaniya, **Murali Dharan Bashyam**

Ctr. for DNA Fingerprinting & Diagnostics (CDFD), Hyderabad, India

The Switch/sucrose-non-fermentable (SWI/SNF; also known as BRG1 associated factors (BAF)) chromatin remodeling complex functions to slide/evict nucleosomes thus making DNA available for multiple DNA-protein interactions to facilitate cardinal nuclear processes. Work during past two decades has revealed the cardinal role of the BAF complex in modulating tumorigenesis. ARID1B, a well-known tumor suppressor and a key subunit of the cBAF complex, is frequently mutated across various cancer types. Although the downregulation of *ARID1B* transcript levels has been observed in many cancers, our knowledge about the regulation of ARID1B at the protein level remains meagre. Here, using BioGRID (Biological General Repository for Interaction Datasets) and PDC (Proteomic Data Commons) datasets, multiple ubiquitination sites were predicted to be localized at the C-terminal end of ARID1B. We performed affinity purification followed by mass spectrometry for ARID1B and further mined previously published ARID1B interactome to identify a comprehensive list of potential ARID1B interactors that included several hitherto unidentified proteins. More importantly, this analysis identified WWP1 and WWP2, well characterized E3 ubiquitin ligases, as interacting partners of ARID1B. Interestingly, WWP2 is known to modulate levels of BAF155, another SWI/SNF subunit, via poly-ubiquitination mediated proteasomal degradation. We confirmed the interaction of ARID1B with both WWP1 and WWP2 through bi-directional pull down-immunoblotting assays. Domain mapping of the interaction is currently underway. Ectopic expression of WWP2 resulted in significant downregulation of ARID1B levels. Further, cycloheximide chase assay revealed that wild-type (but not catalytically inactive) WWP2 modulates ARID1B protein stability. Specifically, WWP2 facilitates the K48-linked ubiquitination of ARID1B, leading to the latter's subsequent proteasomal degradation. Interestingly, silencing WWP2 expression results in a decrease in ubiquitination and a subsequent increase in endogenous ARID1B protein levels. Our preliminary observations suggest that ARID1B protein level varies during cell cycle progression. Work is currently underway to determine a possible oncogenic function of WWP2 via downregulation of ARID1B mediated tumor suppression. Our results therefore highlight a novel mechanism of post-translational regulation of ARID1B, which may have implications in the regulation of ARID1B-mediated tumor suppression and cell cycle progression. Given the recent interest to target BAF complex as a therapeutic option in many cancers, our results on regulation of ARID1B protein stability form a foundation for development of possible targeted therapy in cancer.

#265 NF1 is a novel MAP that modulates microtubule damage repair: rediscovering a tumor suppressor.

Neurofibromin 1 (NF1) is a tumor suppressor widely mutated across several cancers and primarily recognized as a GTPase-activating protein (GAP) that inhibits RAS signaling. Other potential functions have been suggested but still not fully explored, due to its large size and complex domain structure. It remains unclear whether somatic mutations in NF1 can be used to inform clinical decision-making. We previously showed that NF1 plays a novel RAS-independent role in microtubule damage repair in response to the microtubule destabilizing drug Mertansine (DM1), the payload in the commonly used Antibody-Drug Conjugate T-DM1. We showed that NF1 exhibits biochemical properties of a *bona fide* Microtubule-Associated Protein (MAP) and specifically enhances microtubule (MT) repair, a recently discovered phenomenon whose regulation remains poorly characterized. A key unresolved question is whether the MT-repairing function is dependent or uncoupled from the GAP activity; this requires the development of novel methods to quantify MT damage *in vitro* and *in vivo*. We developed a novel analysis method to systematically identify and quantify areas of decreased tubulin intensity in MT stabilized *in vitro* in conditions known to lead to intratubular damage, using TIRF microscopy. Our method allowed us to asses MT repair as the amount of free-tubulin incorporation spatially overlapping with damaged sites. DM1 increased the number of intra-lattice discontinuities and abolished repair of damaged sites. This was rescued by the addition of NF1, which led to a strong increase in the fraction of repaired MTs, with or without DM1.To further confirm the role of NF1 in modulating DM1-dependent microtubule damage, we quantified tubulin staining patterns by high-resolution immunofluorescence (MT length, mean staining intensity and other derived parameters) in HER2+ breast cancer cell lines, in which we managed to obtain, for the first time, stable expression of WT NF1 in a KO background by lentiviral transduction. NF1 ablation or rescue did not lead to visible differences in MT signal in the absence of treatment. Upon addition of DM1, MTs were significantly shorter and more damaged in NF1 KO cells; this was completely rescued by WT NF1 re-expression. This system allows to directly measure the activity of NF1 or its mutants on MT damage, allowing the quantification of structure-function relationships in a relevant cellular system. We generated a collection of NF1 mutants, selected based on clinical associations and prior literature, that impact various domains of NF1, either affecting its GAP activity, its MT binding or its structural stability. Preliminary results suggest that GAP and MT-repairing activity can be partially but not entirely uncoupled. We speculate that some effects of NF1 somatic loss in cancer may be revisited as due to MT dysfunction and not to altered RAS signaling. Funded by Next Generation EU- PNRR-MAD-2022-12376934

#266 Androgen regulated ECD overexpression promotes prostate cancer tumorigenesis through increased glycolysis.

Mohsin Raza[1], **Asher Rajkumar Rajan**[1], Benjamin B. Kennedy[1], Timothy E. Reznicek[1], Farshid Oruji[1], Sameer Mirza[1], M Jordan Rowley[1], Glen Kristiansen[2], Bhopal C. Mohapatra[1], Hamid Band[3], Vimla Band[1]

[1]Genetics Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Institute for Pathology, University Hospital "Carl-Gustav-Carus", University of Technology, Dresden, Institute for Pathology, University Hospital "Carl-Gustav-Carus", University of Technology, Dresden, Fetscherstrasse 74, Germany,[3]Fred & Pamela Buffett Cancer Center, University of Nebraska Medical Center, Omaha, NE

Introduction: Prostate cancer (PC) is the most diagnosed cancer in males. Androgen receptor (AR) signaling is essential for PC progression. ECD (Ecdysoneless) protein participates in cell cycle progression and cell survival and is overexpressed in non-PC cancers. Current study explored the role and function of ECD in PC progression.
Methods: TCGA Prostate Adenocarcinoma database was used to assess correlation between ECD and AR expression, and ECD's expression in PC dataset. Bioinformatic analysis was performed to predict androgen response elements in the ECD promoter. Chromatin immunoprecipitation (ChIP) and Promoter-Luciferase assays were used to assess AR recruitment to the ECD promoter. ECD was overexpressed, as well as crispr knocked out in hormone-dependent LNCaP and hormone-independent C4-2B PC cell lines. RNA-seq analysis was performed to assess transcriptomics changes in ECD-overexpressing (ECD-OE) tumors. RNA immunoprecipitation (RIP) was performed to assess ECD protein association to RNAs. Glucose uptake, and glycolytic rates assays were carried out to assess glycolysis.
Results: ECD is overexpressed in PC patients' tissues as compared to hyperplasia prostate samples, and ECD overexpression is associated with short patient survival. A significant positive correlation was observed between ECD and AR expression. Consensus androgen response elements in the ECD promoter showed androgen dependent recruitment of AR to the ECD promoter by ChIP assay. Luciferase assays showed androgen-dependent increase in ECD-luciferase activity. ECD overexpression and knockout in both LNCaP and C4-2B PC cell lines showed enhanced and decreased oncogenic traits, respectively. *In vivo* mice xenograft experiments showed ECD overexpression in LNCaP led to a significant increase in tumorigenesis. RNA-seq showed ECD overexpression led to increased levels of key glycolytic genes, which was confirmed by qRT-PCR. RIP assay revealed that ECD associates with the mRNA of these key glycolytic genes and enhances their stability. Functionally, ECD overexpressing PC cells showed higher glucose uptake and glycolytic rates, as compared to vector cells.
Conclusion: Overall, our results demonstrate a novel role for androgen-regulated ECD overexpression in PC tumorigenesis through direct binding and stabilization of mRNAs of key glycolytic genes.

#267 ECD co-operates with ERBB2 to promote tumorigenesis through upregulation of unfolded protein response and glycolysis.

Benjamin B. Kennedy[1], **Mohsin Raza**[1], Sameer Mirza[1], Asher Rajkumar Rajan[1], Farshid Oruji[1], Matthew M. Storck[2], Subodh M. Lele[3], Timothy E. Reznicek[1], Lusheng Li[1], M. Jordan Rowley[1], Shibiao Wan[1], Bhopal C. Mohapatra[1], Hamid Band[2], Vimla Band[1]

[1]Department of Genetics, Cell Biology, and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, NE,[3]Department of Pathology, Microbiology, and Immunology, University of Nebraska Medical Center, Omaha, NE

Introduction: The mammalian ortholog of the Drosophila ecdysoneless (ECD) protein regulates cell cycle progression and cell survival. ECD levels are overexpressed in breast cancer (BC), and its overexpression correlates with poor prognosis and short patient survival, particularly in ERBB2-positive BC. This study explores the cooperative oncogenic mechanisms of ECD and ERBB2 to enhance cancer progression.

Methods: We generated immortal human mammary immortalized epithelial cell lines (hMECs) overexpressing ECD, ERBB2, or both. Additionally, we developed transgenic mice overexpressing ECD and/or ERBB2 (huHER2) in mammary epithelium under the control of the MMTV promoter (*ECD; HER2*Tg) to elucidate the co-oncogenic role and mechanisms underlying this cooperation.

Results: hMECs co-expressing ECD and ERBB2 demonstrated a significant increase in *in vitro* oncogenic traits as compared to cells expressing either ECD or ERBB2. Similarly, while *huHER2*Tg mice developed more homogenous solid nodular carcinomas, double transgenic mice (*ECD; huHER2*Tg) developed heterogenous and histologically aggressive mammary tumors with basal-like phenotype and epithelial mesenchymal transition (EMT) features, resembling tumors seen in *ECD*Tg mice. RNA sequencing revealed significant upregulation of two major oncogenic pathways, unfolded protein response (UPR) and glycolysis in ECD+ERBB2 expressing cells as compared to ECD or ERBB2 overexpressing hMECs. Consistently, transcriptomic profile of *ECD; huHER2*Tg tumors also demonstrated upregulation of glycolysis and UPR pathways. RNA immunoprecipitation assays showed ECD associates to mRNAs of three key glycolytic enzymes (LDHA, PKM2, and HK2) and the major UPR-regulated gene GRP78. This association resulted in increased mRNA stability, leading to higher expression of these genes in ECD+ERBB2-expressing cells. Consequently, ECD+ERBB2-overexpressing cells exhibited higher glucose uptake, and a higher glycolytic rate compared to cells overexpressing either ECD or ERBB2 alone.

Conclusions: Our findings support a co-oncogenic role of ECD and ERBB2 in ERBB2-driven BC oncogenesis by enhancing two major oncogenic pathways, UPR and glycolysis.

#268 Ryanodine receptor-1 upregulation alters organellar calcium signaling, modulates gene expression and contributes to ovarian cancer development.

Chi-Lam Au-Yeung[1], Kay-Pong Yip[2], Wan-Yee Tang[3], Samuel C. Mok[1], James S.K. Sham[4]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of South Florida, Tampa, FL,[3]University of Pittsburg, Pittsburg, PA,[4]Johns Hopkins University School of Medicine, Baltimore, MD

Ca^{2+} signaling plays crucial roles in cancer development through Ca^{2+}-dependent regulation of gene transcription. However, specific changes of Ca^{2+} signaling in HGSOC are unclear. Analysis of RNAseq data from TCGA and GEO database and our patient samples identified ryanodine receptor 1 (RYR1) over-expression was associated with poor survival of HGSOC patients. RYR1 expression was also markedly higher in several HGSOC cell lines compared to normal human control cells. To examine Ca^{2+} signaling in HGSOC cells, cytosolic, nucleoplasmic, and mitochondrial [Ca^{2+}] were monitored by confocal imaging of Ca^{2+} fluorescence dyes and organelle specific Ca^{2+} biosenors. Resting cytosolic [Ca^{2+}] and $[Ca^{2+}]_{nucleus}$ was significantly elevated. Ca^{2+} signals triggered by the RYR-agonist 4-chloro-m-cresol (4-cmc) in cytosol, nucleus, and mitochondria were significantly higher in OVCA432 cells compared to the control HOSE cells. The elevated resting [Ca^{2+}] and the 4-cmc-induced Ca^{2+} signals in various intracellular compartments were reduced to the control level by RYR1-shRNA in OVCA432 cells. Gene Set Enrichment Analysis of RNAseq data revealed that RYR1 silencing suppressed gene sets related to mitochondrial proteins, mitochondrial membrane potential, fatty acid metabolism and oxidoreductase activity, as well as activated gene sets related to histone 4 lysine acetyltransferase, H2A ubiquitination and protein localization to chromatin, suggesting RYR1 in HGSOC cells plays important roles in modulating mitochondrial functions and epigenetic regulation of gene expression. Furthermore, shRNA knockdown or inhibition of RYR1 with the RYR1 blocker dantrolene suppressed HGSOC proliferation and migration, and significant reduced OC tumor evaluated by bioluminescence and tumor weight in OVCA432 cells injected athymic nude mice These observations are the first direct evidence that RYR1 alters cytosolic, nucleoplasmic and mitochondrial Ca^{2+} signaling in HGSOC cells, and these changes may contribute to the malignant phenotype for HGSOC development.

#269 TRPM8 as a testosterone receptor: Exploring its role in prostate cancer and male behavior.

Erick Benjamin Saldes[1], Alexandra Erdmier[1], Jai Velpula[2], Benny Tom[1], Timothy E. Koeltzow[3], Don Vander Griend[4], Swapna Asuthkar[1]

[1]University of Illinois College of Medicine (Peoria), Peoria, IL,[2]Pringle Robotics, Peoria, IL,[3]Department of Psychology, Bradley University, Peoria, IL,[4]University of Illinois at Chicago, Chicago, IL

The transient receptor potential melastatin 8 (TRPM8) channel has emerged as a critical mediator of testosterone signaling in prostate cancer (PC), influencing both tumor progression and sexually dimorphic behaviors. Our research expands upon TRPM8's role as a testosterone receptor, facilitating calcium influx that modulates cell proliferation and apoptosis in PC cells. Notably, TRPM8 mRNA is overexpressed in androgen-dependent benign PC tumors, but exhibits decreased expression in metastatic tumors, indicating a potential tumor-suppressive function in early-stage PC. This suggests that TRPM8 may serve as a biomarker for disease progression and a therapeutic target in androgen-regulated PC. Moreover, our findings suggest that TRPM8 is involved in sexually dimorphic behavioral responses, particularly in the context of age-dependent testosterone’s effects on male physiology. The absence of TRPM8 has been shown to result in significant alterations in male-specific behaviors, highlighting its role in mediating testosterone's influence on male reproductive and territorial behaviors. The male TRPM8 knock out (TRPM8 KO) mice showed increased serum testosterone when compared to wild type. Together, increased testosterone in the male TRPM8 KO mice is associated with aberrant anxiety and depression-like behavioral responses. This data position TRPM8 as a promising therapeutic target in PC and a key player in the regulation of male-specific behaviors. Further studies are warranted to elucidate the mechanisms by which TRPM8 influences both cancer progression and sexually dimorphic behaviors, particularly in the context of androgen signaling.

TUMOR BIOLOGY: Human and PDX Models 1

#27 Orthotopic tumor models using luciferized patient-derived organoids for investigating EGFR-MAPK pathway inhibition in colorectal and pancreatic cancer.

K. S. Tummala, M. Chalishazar, M. Angagaw, A. Savadipour, Q. Yan, C. Long, M. Buchanan, P. N. Lalagkas, E. Muise, L. Chen, K. Cheng, E. Park, J. Piesvaux, E. Leccese, B. Long, N. Solban;
Merck & Co., Inc, Boston, MA

The EGFR-MAPK signaling pathway is frequently activated in cancers, particularly due to KRAS gain-of-function mutations. Certain types, such as pancreatic ductal adenocarcinoma (PDAC) with KRAS mutations and cholangiocarcinoma with FGFR2 fusions, show dependency on EGFR. Recent studies demonstrate promising outcomes in metastatic colorectal cancer by combining an irreversible $KRAS^{G12C}$ inhibitor with an EGFR inhibitor. To explore therapeutic benefits across tumor types, we analyzed the expression of EGFR and co-receptors (ERBB) in TCGA samples and CCLE models with different KRAS mutations. We also verified the reliance on ERBB receptors using DepMap data.
Patient-derived organoid (PDO) models from PDAC, colorectal cancer (CRC), and CRC liver metastases were utilized to develop orthotopic tumor models. These PDO lines were characterized through mutational profiling, cell signaling analysis, RNA-sequencing, and whole exome sequencing, providing insights into their molecular features. Higher EGFR expression levels at both protein and RNA levels were observed in specific CRC PDO models, consistent in in-vitro PDO models and in-vivo PDO-derived Xenograft (PDOX) tissues from subcutaneous implantation in immunocompromised mice.
Additionally, the PDO models were evaluated for sensitivity to standard of care (SOC) drugs and EGFR inhibitors, revealing EGFR expression-independent and tumor type-dependent sensitivities (e.g., Afatinib IC50: PDAC (128nM+/-123) vs CRC (2776nM+/-3099)). Surface expression levels of ERBBs were measured in in-vivo PDOX tissues to assess the comparative use case for targeting the EGFR pathway via inhibition or antibody-drug conjugate (ADC) molecules.
Furthermore, we generated and validated stable tumoroid models expressing firefly luciferase in PDOs derived from primary CRC, CRC metastasis to the liver, and primary PDAC. To further validate the potential for in-vivo models, orthotopic tumor models were established in immunocompromised mice for each PDO line, monitoring tumor burden using bioluminescence imaging. Correlation with MRI and ultrasound imaging was conducted for PDAC and liver tumor burden, respectively, with significant correlation observed.
Overall, this study aims to enhance understanding of tumor biology and response to treatment through the development and validation of PDO-based orthotopic models, with future work involving validation of EGFR inhibitors targeting the pathway and ADCs based on ERBBs targeting tumor cells expressing these proteins. In vivo luciferase reactivation in our models will allow us to dissect the mechanisms of resistance to these agents using physiologically relevant tumor models and single-cell RNA-sequencing analysis.

#271 BMH-21, an RNA polymerase I inhibitor provides a novel mechanism to target Δp53 and R248Wp53 driven pancreatic cancers.

Mudassier Ahmad[1], Sahir Sultan Alvi[1], Haider Ahsan[1], Carlos Perez[1], Andrew Massey[2], Vivek Kashyap[1], Neeraj Chauhan[1], Emmanuel Anning[1], Manish Tripathi[1], Dae Joon Kim[1], Nirakar Sahoo[3], Tamer Oraby[4], Mohammad Moshahid Khan[5], Manu Sebastian[6], Subhash C. Chauhan[1], Bilal Bin Hafeez[1]

[1]University of Texas Rio Grande Valley, McAllen, TX,[2]National Institute of Biomedical Imaging and Bioengineering, Section on Mechanobiology, Bethesda, MD,[3]School of Integrative Biological and Chemical Sciences, University of Texas Rio Grande Valley, Edinburg, TX,[4]School of Mathematical and Statistical Sciences, University of Texas Rio Grande Valley, McAllen, TX,[5]Department of Neurology, College of Medicine, UTHSC, Memphis, TN,[6]Department of Veterinary Medicine & Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX

p53 mutations occur in 50-75 % of pancreatic cancer cases. p53 mutations promote the protein turnover and increase the dependence of cancer cells on ribosome biogenesis as compared to normal cells. We report that BMH-21, which is an RNA Polymerase I inhibitor can be used to inhibit the growth of Δp53 (truncated p53) and R248Wp53 driven pancreatic cancers. Our studies show that BMH-21 induced degradation of RPA194 (a catalytic subunit of RNA Polymerase I) has a very less cytotoxic effect on normal human pancreatic ductal epithelial cells. The p53 mutations in PanCa cells were found to play an important role in the recruitment of catalytic subunits of RNA polymerase I (RPA194 and RPA135) on ribosomal DNA (rDNA). BMH-21 decreases the recruitment of RPA194 on rDNA in Capan-2 cells that express p53 wild type and recruitment of both RPA194 and RPA135 on rDNA in MIA PaCa-2 cells that express R248W p53. We found that p53 wild type (WT) and mutant p53 physically interact with both the catalytic subunits of RNA polymerase I. BMH-21 induced degradation of RPA194 was found to expose Δp53 and R248Wp53 for ubiquitination. No ubiquitination of p53 WT was observed in BMH-21 treated Capan-2 cells. RNA polymerase inhibitors induce nucleolar stress that promotes p53 expression. BMH-21 induced ubiquitination of p53 prevents increases in expression of Δp53 and R248Wp53p53 which restricts the role of mutant p53s in the proliferation of PanCa cells. BMH-21 treatment reduces the growth of orthotopic xenograft pancreatic tumors in athymic nude mice with no observed toxicity. These findings suggest that BMH-21 is a promising therapeutic agent for treatment of PanCa.

#272 Loss of Rab25 and associated mechanisms in cancerous transformation of melanocytes.

Samikshya Kandel, Krishna Rao

Southern Illinois University School of Medicine, Springfield, IL

Background: Rab25 is a member of RAS protein superfamily of small GTPases that belong to RAB11 subfamily located on 1q22 of chromosome. It is generally expressed by epithelial cells and its expression level varies by tissue types. From our previous research, Rab25 has been shown to be a significant player in moderating transformation of human mammary epithelial cells, as its loss promotes cellular transformation particularly in presence of RAS mutation. Rab25 is an ambiguous protein in cancer research as its role is cancer type dependent and remains unknown in melanoma. There is deep deletion of Rab25 in a section of melanomas (only~3% profiled) in databases like the Cancer Genome Atlas and Cbioportal. Additionally, Rab25 shares a common consensus motif with the binding site of mutant H-RAS, Q61L. NRAS is mutated in 80% of RAS activated melanomas. Therefore, we are investigating the role of Rab25 loss in the development of NRAS mutant melanoma.

Objectives: To study the status of Rab25 and its role in the transformation of melanocytes, we screened for Rab25 expression and protein level in different melanoma cell lines. We further did immunohistochemistry to examine the Rab25 expression in biopsy-proven melanoma sections. To uncover the function of Rab25, we overexpressed Rab25 in NRAS mutant melanoma cell lines and knocked down Rab25 in non-tumorigenic immortalized melanocytes. Further, we will use liposomal encapsulation technique to deliver a six-peptide sequence intracellularly to target NRAS.

Results: There was significant loss of Rab25 in mRNA and protein level in melanoma cell lines. Rab25 is found in normal skin tissues but was significantly lost in melanoma sections and associated with reduced survival. NRAS mutant human melanoma cells transduced with Rab25 showed reduced proliferation, migration tendency, and loss of anchorage-independence growth as compared to control cell lines. Additionally, knockdown of Rab25 in non-cancerous immortalized human melanocytes showed resulted in enhanced proliferative behavior and gain of anchorage-independent growth in soft agar colony formation assay.

Conclusion: These observations suggest that Rab25 loss results in gain of migratory potential, anchorage-independent growth, and enhanced proliferation potential which are requisite events in melanoma-genesis. Further studies on associated functional proteins of Rab GTPase family will be conducted to strengthen this data.

#273 Decipher actionable tumor suppressor defects in prostate cancer for precision medicine.

F. Chen, **D. Zhao**;
UT MD Anderson Cancer Center, Houston, TX

Chromatin remodeling proteins contribute to DNA replication, transcription, repair, and recombination. The chromodomain helicase DNA-binding (CHD) family of remodelers plays crucial roles in embryonic development, neurogenesis, and carcinogenesis. As the founding member, CHD1 is capable of assembling nucleosomes, remodeling chromatin structure, and regulating gene transcription. Dysregulation of CHD1 at genetic, epigenetic, and post-translational levels is common in prostate cancer and other malignancies. Through interacting with different genetic alterations, CHD1 possesses the capabilities to exert oncogenic or tumor-suppressive functions in context-dependent manners. In the past decade, my study uncovered the novel cell-intrinsic and -extrinsic roles of CHD1 during prostate cancer development, progression, and therapy resistance (*Nature 2017, Cancer Discover 2020, Cancer Research 2022, Nature Cancer 2024*). Cancer genome studies have uncovered a unique subtype of prostate cancer characterized by speckle-type BTB/POZ protein (SPOP) mutations, which stabilize AR and its co-activators and have been associated with prolonged responses to androgen deprivation therapies and favorable prognoses. Loss of CHD1 frequently co-occurs with SPOP mutations; however, how concurrent CHD1 loss impacts SPOP-mutated prostate cancer remains unclear. Most recently, by generating the first-in-the-field genetically engineered mouse models, we provided genetic evidence supporting that CHD1 loss accelerates SPOP-mutated prostate cancer progression and confers resistance to castration in this context. We uncover a non-canonical epigenetic function of CHD1 and demonstrate that CHD1 reprograms lipid metabolism by governing SREBPs. CHD1 loss-induced lipid reprogramming supplies intratumoral androgen biosynthesis and retains AR transcriptional activity in SPOP-mutated prostate tumors upon castration. Furthermore, the mechanistic studies facilitate the development of a novel biomarker-driven combinatorial therapy for castration-resistant prostate cancer harboring CHD1 loss and SPOP mutations. These findings advance our understanding of an emerging prostate cancer subtype and mechanism of action and provide novel therapeutic strategies for men with advanced prostate cancer.

#274 Resistance to VEGFR inhibitors converges from molecular diversity in angiosarcoma cells.

Eslenur Nipa, Donghee Lee, Sun Hee Choi, Jong Hyuk Kim

Small Animal Clinical Science, University of Florida, Gainesville, FL

Angiosarcomas are aggressive soft tissue sarcomas that form malignant endothelium. Standard care treatment for angiosarcoma patients includes surgery, radiation, and chemotherapy, but outcomes remain poor, especially in unresectable or metastatic cases. These endothelial malignancies activate angiogenic and vascular pathways, implying VEGF/VEGFR and Tie2 signaling as key drivers of tumor progression. However, therapeutic antibodies, such as bevacizumab (Avastin), and chemical inhibitors targeting VEGF pathways have shown limited clinical benefits in angiosarcomas. The molecular mechanisms that establish resistance to VEGF inhibition in angiosarcomas are virtually unknown. In this study, we used five human angiosarcoma cell lines - KU-CAS3, KU-CAS5, HAMON, ISO-HAS-B, and AS5 - for functional characterization. We first determined cell surface expression of four endothelial markers: CD31, neurophilin-1, VEGFR2, and Tie2. Our flow cytometry data revealed that CD31 expression was markedly elevated in nearly 100% of cells in four of the five angiosarcoma cell lines, with the exception of AS5, which showed 26.1% expression. Neurophilin-1 expression varied across the cell lines: 5.6% in KU-CAS3, 11.8% in AS5, 31.1% in ISO-HAS-B, 60.0% in HAMON, and 99.7% in KU-CAS5. We also found that three cell lines - HAMON (95.2%), KU-CAS3 (72.6%) and KU-CAS5 (92.7%) - showed high expression of VEGFR2, while two cell lines - ISO-HAS-B (14.0%) and AS5 (14.8%) - exhibited low expression. The expression levels of Tie2 were abundant, ranging from 74.8% to 96.4% in four cell lines, with modest expression in AS5 (47.8%). Then, we examined cellular response to VEGFR2 (Regorafenib, Sorafenib) and Tie2 inhibitors (Rebastinib, Pexmetinib) using cell growth inhibition assays. All five angiosarcoma cell lines exhibited IC50 values higher than 1 uM against both VEGFR2 inhibitors, Regorafenib and Sorafenib, except for KU-CAS5, which showed an IC50 of 0.44 uM. Both Tie2 inhibitors, Rebastinib and Pexmetinib, were also ineffective in decreasing cell proliferation in most of the cell lines, with two exceptions showing submicromolar IC50 values of 0.91 uM and 0.25 uM in KU-CAS3 and AS5, respectively. In summary, our data revealed that the robust expression of endothelial and vascular markers in angiosarcoma cells indicates a conserved endothelial phenotype under in vitro conditions. However, none of the cell lines exhibited significant sensitivity to VEGFR and Tie2 inhibitors in terms of clinical potential. It demonstrates broad resistance to VEGFR2 and Tie2 inhibition, independent of VEGFR2 and Tie2 expression in angiosarcoma cells. Furthermore, our results suggest angiosarcoma cells establish a functional convergence that potentiates the signaling activation of VEGF and Tie2 pathways, despite their molecular divergence. Our ongoing work aims to explore the molecular mechanisms promoting resistance to VEGF and Tie2 inhibitors.

#275 Increased expression levels of *KISS1* in IDCC breast cancer induced by melatonin treatment.

Kelly P. Ferreira, Bruna C. Almeida, Edmund C. Baracat, **Katia C. Carvalho**

University of Sao Paulo, Faculty of Medicine, Sao Paulo, Brazil

Introduction: Tumor suppressors encode proteins commonly expressed in non-cancer cells that avoid abnormal events that culminate to neoplasms development. In a deregulated expression case, they are useful as biomarkers for pathological stages or tumor progression. *KISS1* (*KiSS-1 metastasis suppressor*), is a known metastatic suppressor and its expression is commonly downregulated in the metastatic tumors of various origins, including breast cancer. In this context, some researches showed that melatonin (Mel) can improve survival rates, suggesting that its application may be a tool for therapeutic use in some breast tumors. Thereby, we aimed to identify mRNA levels of *KISS1* in invasive ductal carcinoma cells (IDCC) with metastasis in pleural effusion (MCF7) treated with Mel and compare with MCF7 non-treated cells (CC).

Methods: MCF7 (ER+) cell line was cultured with RPMI 1640 (Sigma-Aldrich, Germany), with 10% fetal bovine serum (FBS - Gibco, USA) treated with activated charcoal, inactivated, sodium bicarbonate, pyruvic acid and antibiotics as recommended by ATCC and subsequently treated with 3000 µM Mel. After treatment the RNA was extracted using mirVana miRNA Isolation Kit (Ambion, USA) and then, purity and concentration of total RNA were accessed. The Reverse transcription synthesis was performed using High-Capacity cDNA Reverse Transcription Kit (ThermoFisher Scientific, Lithuania). Expression profile of 91 mRNA, including *KISS1* and, 5 housekeeping mRNAs was performed by TaqMan Array Plates using Real-Time PCR (Applied Biosystems, USA). Data analysis was obtained by ExpressionSuit Software v1.3 (ThermoFisher Scientific).

Results: The concentration of melatonin tested in MCF7 cells (ER+) from metastasis showed, a significant increase of mRNA *KISS1* expression levels when compared to the levels presented in MCF7 cells that did not receive melatonin treatment (control cell - CC).

Conclusion: Melatonin treatment was able to increase the expression of *KISS1* in MCF7 cells, indicating that its use may bring benefits associated to an improved prognosis for similar tumors. Further studies are ongoing to confirm and expand our results.

#279 Unraveling biological differences of high grade serous ovarian cancer subtypes by metabolomics.

Zhanjun Hou[1], Madelyn Brzezinski[1], Carrie O'Connor[1], Xun Bao[1], Ayesha B. Alvero[2], Radhika Gogoi[1], Ramandeep Rattan[3], Gil Mor[2], Jing Li[1], Aleem Gangjee[4], Larry H. Matherly[1]

[1]Barbara Ann Karmanos Cancer Institute, Detroit, MI,[2]Wayne State University School of Medicine, Detroit, MI,[3]Henry Ford Cancer Institute and Henry Ford Health System, Detroit, MI,[4]Duquesne University Division of Medicinal Chemistry, Pittsburgh, PA

Epithelial ovarian cancer (EOC) accounts for ~90% of ovarian cancers and continues to be a deadly disease. High grade serous ovarian cancer (HGSOC) is the most common subtype of EOC. PARP inhibitors (PARPis) are important drugs for treating recurrent ovarian cancer post-platinum-based chemotherapy and recently this has been applied to first-line maintenance treatment after chemotherapy. Meta-analysis suggested that PARPis are most effective for patients with *Brca* mutations. Studies also suggested better efficacy of PARPis in HGSOC patients with *Brca2* mutations than patients with *Brca1* mutations. However, only ~15-20% of HGSOC tumors carry germline *Brca1* or *Brca2* mutations and somatic mutations are found in ~8% of cases. In addition, the increasing use of PARPis for treating HGSOC has raised concerns about PARPi resistance in clinical practice. Clearly, there is an urgent need to identify new metabolic vulnerabilities in HGSOC in general, and in *Brca1*/*Brca2* mutant subtypes in particular, that can be targeted alone, or in combination with existing medications including PARPis. The ID8 HGSOC model is the most widely used transplantable mouse syngeneic model of ovarian cancer. ID8 variants including single (*Trp53*$^{-/-}$) or double (*Trp53*$^{-/-}$/*Brca1*$^{-/-}$ or *Trp53*$^{-/-}$/*Brca2*$^{-/-}$) gene deletions recapulate characteristics of human HGSOC subtypes including the expected patterns of sensitivity to cisplatin and PARPis (i.e., olaparib). Our previous studies showed that in primary patient specimens [including normal ovary (n=8) and HGSOC (n=40)], transcripts for one-carbon (C1) genes in mitochondria (*SLC25A32*, *SHMT2*, *MTHFD2*, *MTHFD1L*) and in cytosol (*GARFTase*, *AICARFTase*) increased significantly over normal ovaries. We performed untargeted metabolomics studies (~2000 metabolites) with the aforementioned ID8 sublines. The results showed significant quantitative differences between wild-type ID8 and ID8/*Trp53*$^{-/-}$, ID8/*Trp53*$^{-/-}$/*Brca1*$^{-/-}$ or ID8/*Trp53*$^{-/-}$/*Brca2*$^{-/-}$ cells, as well as between ID8/*Trp53*$^{-/-}$/*Brca1*$^{-/-}$ and ID8/*Trp53*$^{-/-}$/*Brca2*$^{-/-}$ cells, involving C1 metabolism including metabolites of glycine, serine, threonine, cysteine, methionine, pyrimidines and purines. Targeted metabolomics and flux analysis with [^{13}C (U)]serine and LC-MS/MS revealed enhanced mitochondrial C1 flux in the ID8 variants, reflected in levels of total serine and serine isotopomers (ID8 > ID8/*Trp53*$^{-/-}$ = ID8/*Trp53*$^{-/-}$/*Brca1*$^{-/-}$ > ID8/*Trp53*$^{-/-}$/*Brca2*$^{-/-}$). C1 flux from [^{13}C (U)]serine in the cytosol was also significantly elevated in ID8 variants, reflected in a dramatic decrease of glycinamide ribonucleotide (GAR) (M+0, M+2) in *de novo* purine biosynthesis compared to wild-type ID8 cells. Collectively, our results suggest that C1 metabolism in both the mitochondria and cytosol is a bona fide metabolic vulnerability in HGSOC that can be therapeutically exploited.

#28 Novel organoid-based exploration reveals the role of LMTK3/FADS2 signaling in metastatic breast cancer progression in cats and humans.

H. Yamamoto[1], M. Elbadawy[2], T. Usui[3], K. Sasaki[3];

[1]Haru Yamamoto (Individual), Fuchu, Japan, [2]University of Georgia, Athens, GA, [3]Tokyo University of Agriculture and Technology, Fuchu, Japan

Cat breast cancer (CBC) is the third most common type of feline neoplasm. It constitutes approximately 17% of feline tumors, with an estimated annual incidence of between 13 and 25/100,000 cats. CBC shares similar histology, genetics, behavior, and clinicopathological characteristics with human BC. Despite advancements in human breast cancer (BC) treatment, outcomes in human and veterinary medicine remain suboptimal. Spontaneously developed BC in CBC is highly malignant, intractable, and has the potential to become a valuable translational model for human metastatic BC (HBC). We developed primary CBC organoids and analyzed their morphology, gene expression patterns, and response to anti-cancer drugs. CBC organoids recapitulated the structure and behavior of tumor cells, exhibiting diverse hormone receptor expressions and tumorigenic potential. Moreover, varying sensitivities to chemotherapies and targeted drugs were evident across CBC organoid lines. Furthermore, LMTK3 was significantly upregulated in CBC organoids compared to normal organoids. Further, LMTK3/FADS2 pathway was revealed to be implicated in progression and metastasis by influencing cell proliferation, invasion, and apoptosis of CBC organoids. Cell viability of human BC organoids was also prevented by treatment of LMTK3 inhibitor. Survival time of human BC patients with high co-expression of LMTK3 and FADS2 was shorter than that with low co-expression. These findings highlight the importance of LMTK3/FADS2 pathway in BC progression and indicate that companion animal cancer organoid research can model HBC.

#280 ALDH2 knockout dysregulates arginine and proline metabolism in SK-BR-3 breast cancer cells.

Ming Zhao[1], Blake R. Rushing[2], Zhikun Ma[1], Rachel A. Coble[2], Amanda B. Parris[1], Sergey Krupenko[2], Susan J. Sumner[2], **Xiaohe Yang**[1]

[1]BBRI and Department of Biological and Biomedical Sciences, North Carolina Central University, Kannapolis, NC,[2]Department of Nutrition and Nutrition Research Institute, UNC Chapel Hill, Kannapolis, NC

Aldehyde dehydrogenase 2 (ALDH2) mitigates cellular stress by detoxifying reactive aldehydes produced during alcohol exposure and endogenous metabolic processes. The ALDH2*2 variant, prevalent in East Asian populations, has decreased catalytic activity, which is linked to an increased risk of cancer and other diseases. While the effects of ALDH2 deficiency on cellular stress responses are well documented, the specific metabolic dysregulations arising from this deficiency require further investigation. To explore the impact of ALDH2 deficiency on metabolism and cellular stress in breast cancer, we generated the ALDH2 knockout subline of the SKBR-3 cell line (SKBR-3/ADKO) using CRISPR/Cas9 technology. Our findings indicate that ALDH2 knockout leads to heightened cellular stress, evidenced by elevated levels of 8-OHdG, reactive oxygen species (ROS), and malondialdehyde (MDA). Untargeted metabolomic analysis of SKBR-3 and SKBR-3/ADKO cells using Ultra High Performance Liquid Chromatography/High Resolution Mass Spectrometry assigned a total of 5,033 metabolites, with 615 metabolites being significantly different (fold change ≥ 2, p-value < 0.05) between the two cell lines. The Mummichog approach has identified six key metabolic pathways altered upon ALDH2 knockout, including: arginine biosynthesis; D-amino acid metabolism; arginine and proline metabolism; alanine, aspartate and glutamate metabolism; pentose and glucuronate interconversions; pantothenate and CoA biosynthesis. The most significantly dysregulated pathway in response to the ALDH2 loss was arginine and proline metabolism, which is an integral pathway to redox homeostasis, ROS production, and cellular stress responses. Our study provides a novel insight into the role of ALDH2 in cancer metabolism, which might have a broader implication for cancer biology.

#281 Plasma metabolomic profiling identifies novel biomarkers for gastric cancer diagnosis and prognosis.

Zun Li, Xiangnan Zhang, Yanxin Yao, Yubei Huang, Zhangyan Lv, Hongji Dai, **Kexin Chen**, Ben Liu

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Gastric cancer (GC) remains a significant global health challenge, representing the fifth leading cause of cancer-related mortality. Altered metabolism plays a crucial role in GC development and progression. This study aimed to identify plasma metabolic biomarkers for improved GC diagnosis and prognosis prediction. We performed untargeted metabolomic profiling of plasma samples from 105 GC patients and 120 healthy controls using ultra-performance liquid chromatography coupled with tandem mass spectrometry (UPLC-MS/MS). Following rigorous quality control, orthogonal partial least squares discriminant analysis (OPLS-DA) identified 562 differentially abundant metabolites between groups. Pathway enrichment analysis revealed significant alterations in metabolic pathways associated with amino acid metabolism, lipid metabolism, and hormone signaling. Machine learning algorithms were employed to develop diagnostic and prognostic models based on these differentially abundant metabolites. A four-metabolite diagnostic model achieved high sensitivity (0.86) and specificity (0.95) in an independent validation cohort, significantly outperforming conventional protein-based diagnostic markers. Furthermore, our prognostic model demonstrated superior performance compared to established clinical parameters, effectively stratifying patients into distinct risk groups for personalized therapeutic strategies. This comprehensive metabolomic analysis provides novel insights into the metabolic landscape of GC and identifies promising biomarkers for improved clinical management.

#282 Pre-diagnostic circulating metabolites and risk of overall, intermediate-risk, high-risk and lethal prostate cancer: a systematic review andmeta-analysis of untargeted metabolomic studies.

Harriett Fuller, Orietta P. Agasaro, Burcu F. Darst

Fred Hutchinson Cancer Center, Seattle, WA

Prostate cancer (PCa) is the 2nd most common cancer in men. Metabolomic dysregulation is expected to contribute to PCa pathogenesis; however, pre-diagnostic evidence of metabolite-PCa associations has not been quantitatively aggregated. This study aimed to quantitatively assess metabolite-PCa associations, compare these associations between distinct PCa outcomes, and evaluate sources of bias in PCa metabolomic epidemiology studies. We conducted a systematic review (October 17th, 2024) and meta-analysis to identify pre-diagnostic untargeted serum metabolomic studies of PCa risk. Restricted maximum likelihood (REML) was used to conduct meta-analyses to quantify associations between metabolites and risk of overall PCa, low- to intermediate-risk PCa, high- to very high-risk PCa and lethal PCa, as defined by the NCCN. Statistical significance was defined as FDR-adjusted P< 0.05. Enrichment analyses were conducted to identify biologically relevant pathways. The DrugBank Pharmaco-metabolomics database was used to determine whether identified metabolites are drug modifiable. Thirteen predominantly European ancestry studies were identified (10,467 cases/10,833 controls) and 602 metabolite biomarker associations were meta-analyzed. Three, three, eleven and nineteen metabolites were significantly associated with risk of overall, low- to intermediate-risk, high- to very high-risk and lethal PCa, respectively. No metabolite was significantly associated with >1 PCa outcome; however, 12 metabolites were nominally associated (P<0.05) with >1 outcome. Effect sizes between metabolites associations with overall and high- to very high-risk PCa were significantly correlated when considering all 144 metabolites (r=0.19, P=0.023) and 10 metabolites nominally associated with both outcomes (r=0.87, P=0.001). Metabolite effects associated with lethal PCa risk were largely distinct from other outcomes. Metabolites significantly associated with risk of high- to very high-risk PCa were significantly enriched for lipids (P=0.03). Using DrugBank, we found that levels of 11 significant metabolites are drug modifiable. Key sources of bias identified included the selective reporting of results, inconsistent metabolite naming, limited adjustment for fasting status and limited diversity, which could impact the generalizability of findings. In conclusion, pre-diagnostic levels of 36 circulating metabolites were associated with PCa risk, 30 of which were associated with high- to very high-risk or lethal PCa. The metabolomic profile of lethal PCa risk was largely distinct from other PCa outcomes. Future work is needed to further investigate how pre-diagnostic metabolite profiles differ by PCa aggressiveness and to evaluate the role of identified metabolites as PCa biomarkers across populations.

#283 Cholesterol($C_{27}H_{46}O$)identified by metabolomics enhance lipid raft composition for cell proliferation in epithelial ovarian cancer.

Hitomi Sakaguchi-Mukaida, Kosuke Hiramatsu, Tatsuo Masuda, Mamoru Kakuda, Satoshi Nakagawa, Tadashi Iwamiya, Shinya Matsuzaki, Yutaka Ueda

Osaka University, Suita, Japan

Objective: We previously reported that lipoprotein promoted cell proliferation of epithelial ovarian cancer (EOC) cells in vitro. Moreover, we demonstrated High-Fat Diet (HFD) strongly promoted the tumor growth of EOC in vivo and HFD mouse serum promoted cell proliferation in vitro. These results suggest that lipid molecules derived from HFD contribute to cell proliferation of EOC. In this study, we aimed to identify the lipid molecules in HFD mouse serum which contribute to cell proliferation of EOC cells by metabolomics and figure out the function of the lipid molecule.
Methods: We obtained serum of HFD and normal diet (ND) fed mouse and performed metabolomics to identify the lipid molecules which contribute to cell proliferation of EOC. In vitro, we validated that lipid molecules in HFD mouse serum promote the cell proliferation and analyzed which signaling pathway was activated. In vivo, we evaluated the effect of lipid molecules-rich diet in tumor growth. We also evaluate the association of lipid molecules and lipid rafts in EOC cells.
Results: HFD significantly promoted the tumor growth EOC in vivo ($p < 0.05$), and HFD mouse serum also promoted cell proliferation of EOC cells in vitro ($p < 0.05$). Metabolomics showed obvious different metabolic profiles of HFD and ND mouse serum (non-tumor bearing). Partial least squares-discriminant analysis revealed that cholesterol ($C_{27}H_{46}O$) ranked highest as the lipid molecule in HFD mouse serum. In vitro, cholesterol significantly promoted cell proliferation ($p < 0.05$) via Akt/mTOR signaling pathway. Moreover, we demonstrated that cholesterol-rich diet promoted the tumor growth of EOC ($p < 0.05$). Finally, we evaluated that lipid raft inhibitor blocked cholesterol induced cell proliferation ($p < 0.05$).
Conclusions: Cholesterol ($C_{27}H_{46}O$) uptake lead to the cell proliferation of epithelial ovarian cancer via stimulation Akt/mTOR signaling pathway following lipid raft.

#285 Integration of serum and tumor metabolomics reveals distinct metabolic profiles in early onset colorectal cancer.

D. Vadehra[1], S. Rosario[1], T. J. Brown[2], H.- . Hsaio[1], S. Mukherjee[1];
[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]UTSW Simmons Comprehensive Cancer Center, Dallas, TX

Introduction: Early onset colorectal cancer (EOCRC) is rising at an alarming rate and is increasingly recognized as a distinct clinical entity from average onset (AO) CRC. However, the molecular underpinnings remain largely unknown. We found key differences at the transcriptomic level that highlighted the enrichment of several metabolic pathways that are distinct in the EOCRC (<50 years old) compared to the AOCRC population, prompting further study of the association between age of onset and role of metabolomics. To this end, we sought to highlight differences in the metabolic profile of EOCRC patients compared to AOCRC.
Methods: Banked serum samples from the Roswell Park Data Bank and biorepository were obtained from EOCRC (n=25) and AOCRC (n=25) patients, as well as age-matched non-disease (n=10) populations. Further, matched tumor samples from AOCRC (n=25) and EOCRC (n=25) were obtained. Comprehensive metabolomics via mass spectrometry was conducted on both the serum and matched tumors. Metabolite abundances from serum and tumors were assessed independently. Abundances were log2 transformed to achieve a normal distribution. Prior to differential metabolite abundance, patient data were assessed for outliers and necessary co-variates (e.g., sex, race, etc.). Differential abundance was assessed via the generation of linear mixed models and analyses of variances with $p \leq 0.05$ set for statistical significance.
Results: Samples were well-matched at baseline for relevant demographics aside from age. When integrating serum and tumor metabolites, after adjusting for biological sex, there were eight significantly altered metabolites. These were primarily lipids, including phosphatidylcholines, lysophosphatidylcholines, sphingolipids, and ceramides. All of these were increased in AOCRC compared to EOCRC. Conversely, hypoxanthine and hexosylceramides were found to be increased in the EOCRC compared to AOCRC. Further, we observed significant differences in metabolite expression by biological sex, with AO female tumor samples also enriched for lipids like phosphatidylcholine, sphingolipids, and ceramides, as compared to AO males.
Conclusion: Metabolomics assessment of CRC patients demonstrated significant differences in metabolite concentrations between EOCRC and AOCRC patients in both serum and tumor samples. Further, these differences were strongly correlated with patients' sex, suggesting a biological influence of sex on CRC pathogenesis. Altogether, these results imply a distinct metabolic phenotype among the EOCRC population. Given the reported role of hypoxanthine and hexosylceramides in CRC metastasis, further studies should investigate their influence on clinical outcomes and treatment response.

#286 Metabolic alterations in skeletal muscle and serum of tumor-bearing cachectic mice.

Kuo-Chu Lai

Department of Physiology and Pharmacology, College of Medicine, Chang Gung University, Taoyuan, Taiwan

Cancer cachexia, a multifactorial syndrome characterized by systemic inflammation, high energy expenditure, and progressive skeletal muscle loss, poses a significant challenge in cancer management due to limited therapeutic options. Understanding the metabolic shifts associated with cachexia-related muscle wasting could provide critical insights into identifying potential biomarkers and therapeutic targets. In this study, we conducted targeted metabolomics to investigate metabolic alterations in the skeletal muscle and serum of tumor-bearing cachectic mice. To facilitate a comprehensive analysis, skeletal muscle samples from non-cachectic tumor-bearing mice were included to explore metabolic changes associated with tumor growth and its progression to cachexia. We found that tumor-bearing, non-cachectic muscles exhibited significantly higher levels of glucose-6-phosphate (G6P), fructose-6-phosphate with glucose-1-phosphate (F6P + G1P), glyceraldehyde-3-phosphate (G3P), glycerol-3-phosphate (Glycerol-3P), and phosphoenolpyruvate (PEP) compared to control muscles. However, no significant differences were observed between non-cachectic muscles and cachectic muscles. These findings indicate that increased glycolysis is more critical for tumor growth than for the progression to cachexia. Amino acids such as asparagine, alanine, and serine were significantly increased in cachectic muscle. Compared to non-cachectic muscle, levels of 2-hydroxyglutarate (2-HG) and CoA were decreased in cachectic skeletal muscle. Notably, alterations in 2-HG and CoA were consistent between muscle and serum, highlighting their potential as systemic biomarkers. These results reveal key metabolic alterations in skeletal muscle and serum associated with cancer cachexia, offering novel insights into the pathogenesis of muscle wasting and providing potential avenues for biomarker discovery and therapeutic intervention.

#287 Circulating metabolites associated with response to immune checkpoint blockade in melanoma.

Nazli Dizman, Iqbal Mahmud, Julie Simon, Elizabeth Sirmans, Hussein A. Tawbi, Jeffrey Gershenwald, Michael Davies, Nadim Ajami, Carrie Daniel-MacDougall, Jennifer Wargo, Philip Lorenzi, Jennifer McQuade

UT MD Anderson Cancer Center, Houston, TX

Introduction: Metabolism plays a crucial role in tumor microenvironment dynamics and may influence response to immune checkpoint blockade (ICB). We examined the relationship between the serum metabolomic and lipidomic profiles and outcomes with ICBs in melanoma.

Methods: Patients with melanoma initiating standard of care anti-PD1-based ICB therapy with neoadjuvant or palliative intent were prospectively enrolled. Clinical characteristics were abstracted and survival and objective response using RECIST 1.1 were assessed. Patients with complete or partial response were classified as the response (R), and the remainder as the non-response (NR) cohort. Baseline serum metabolome profiling was conducted at the University of Texas MD Anderson metabolomics core using high-resolution mass spectrometry to assess global lipids and semi-targeted metabolites using in-house standard metabolite library and compared between R and NR.

Results: A total of 67 patients (median age 61 years, 70% male) were included. The majority (67%) received ICB for stage IV disease while 34% were treated in the neoadjuvant setting. The most common ICB regimen was anti-PD-1 and anti-CTLA4 combination (55.2%), followed by anti-PD-1 and anti-LAG3 combination (35.8%). Overall objective response rate was 52.5%. A total of 1,161 lipid metabolites and 120 semi-targeted metabolites were identified and analyzed. Global metabolite profiles of the R and NR cohorts suggested up-regulation of pentose phosphate pathway metabolites and downstream nucleotide precursors in the R cohort. Global lipidome profile demonstrated similarities between groups, although a degree of clustering effect by response status was observed in principal component analysis (data will be presented). In the R cohort, differentially overrepresented lipid classes included plasma membrane lipids ($p<0.001$, false detection rate [FDR] q-value=0.004) and inflammation-associated lipids such as sphingolipids ($p<0.005$, $q=0.006$), diacylceramides ($p=0.001$, $q=0.008$), diradylglycerols ($p=0.003$, $q=0.016$), diacylglycerols ($p<0.001$ $q=0.004$), and sphingosine-containing lipids ($p=0.003$, $q=0.017$). Additionally, polyunsaturated fatty acid (PUFA)-containing lipids in general were down-regulated ($p<0.001$, $q<0.001$), with notable down-regulation of PUFA-enriched triacylglycerides (TAGs) such as TAG 52:7, TAG 50:5, TAG 54:7, TAG 56:9, TAG 50:4, TAG 54:8 ($p<0.005$, $q<0.05$).

Conclusion: Distinct lipid class differences were observed between R and NR to ICB in melanoma. Together, these observations prompt the hypothesis that melanomas that are highly responsive to immunotherapy may efflux metabolites representing up-regulated nucleotide synthesis and dysregulated lipid metabolism representing a highly inflammatory state and potentially up-regulated autophagy.

#288 Metabolic profiling of MEKi-treated fusion-negative rhabdomyosarcoma cell lines suggests a role for glutamine antagonism as a preclinical therapeutic approach.

Konstantinos Flamourakis, Lior Levy, Jingdong Tan, Kathryn M. Lemberg

Johns Hopkins University School of Medicine, Baltimore, MD

Improved genetic characterization of rhabdomyosarcoma (RMS) subtypes, including PAX3/PAX7 fusion-negative RMS (FN-RMS) with RAS pathway mutations [1], has led to hope for individualized treatments with fewer side effects than conventional chemotherapy. Understanding the metabolic vulnerabilities of RMS remains an area with room for improvement. We hypothesized that determining the metabolic effects of RAS pathway inhibition in RAS-active RMS could inform new therapeutic combinations. We performed polar metabolomic profiling comparing trametinib and DMSO-treated FN-RMS cell lines, including two cell types with RAS mutations (SMS-CTR and RD) and one with an FGFR1 amplification (RMS-YM). Although inhibition of phospho-ERK was observed after 6 hours of treatment with trametinib in cells, limited effects on polar metabolites were observed at this time point. Following 24h of trametinib treatment, we observed alterations in purine and pyrimidine metabolism, amino acid metabolism, and central carbon metabolism. Based on these findings and our prior research on metabolic vulnerabilities other RAS-active sarcomas [2], we investigated RMS cell dependence on glutamine, the most abundant amino acid in serum and a crucial metabolic contributor of nitrogen and carbon substrates to these pathways [3]. FN-RMS cell lines demonstrated reduced colony formation in media with low glutamine. The clinical glutamine antagonist, DRP-104 [4], inhibited the growth of RAS-RMS cells with IC50 values in the low micromolar range. We investigated the effects of DRP-104 on markers of tumor growth, DNA damage, and cell death by western blotting. As our own and other data support a role for MEKi and glutamine antagonism in RAS-active tumor models [5], future investigations will seek to combine DRP-104 with trametinib in cell-based and in vivo RAS-RMS models.

#29 The utilization of patient-derived organoids as a platform for drug screening: Chemotherapy, targeted therapy, and immunotherapy.

N.-G. Lee, M. Park, S.-E. Park, H.-A. Kim, S.-y. Lee, J. Rheey, **J.-Y. Park**;
Gradiant Bioconvergence, Seoul, Korea, Republic of

Cancer is one of a leading cause of mortality worldwide, with current treatments facing limitations such as drug resistance and relapse. To address these issues, the use of advanced in vitro models, such as patient-derived organoids (PDOs), is crucial. Unlike conventional 2D cultures, PDOs closely resemble the biological characteristics of tumors, thereby allowing the prediction of responses to drugs and supporting personalized therapies. Gradiant Bioconvergence (GBCC) has established a biobank comprising over 800 PDOs derived from tissue or metastatic samples of patients with lung, colorectal, gastric, pancreatic, and ovarian cancers. The biobank also includes NGS datasets of genomics and transcriptomics, as well as clinical information, including treatment history, and autologous peripheral blood mononuclear cells (PBMCs) or tumor infiltrating lymphocytes (TILs). PDOs are highly effective models for evaluating drug efficacy in vitro, capable of predicting clinical drug responses and providing valuable insights for the development of new therapeutics. GBCC has developed two distinct organoid-based drug screening platforms for evaluating various cancer therapies. The first drug screening platform employs organoids alone to evaluate anti-cancer drugs, including chemotherapy and targeted therapy. Additionally, the platform is capable of supporting mono or combination drug screenings. Of note, lung PDOs with driver mutations, such as EGFR and KRAS, demonstrated responsiveness to targeted drugs, with results that aligned with the patient's treatment history. Antibody-drug conjugates (ADCs), including Trastuzumab Deruxtecan (T-DXd), exhibited sensitivity in HER2-overexpressing gastric cancer organoids and lung cancer organoids with HER2 mutations. To evaluate immune checkpoint inhibitors (ICIs), the GBCC has developed a second drug screening platform using autologous T cell co-culture with organoid models. Flow cytometry was employed to ascertain organoid viability and cytokine release by T cells, thereby confirming that the viability of cancer organoids was reduced in the presence of ICIs. The results demonstrate that our organoid-based drug screening platforms can be utilized to assess drug responsiveness, thus representing a valuable tool for the preclinical evaluation of drugs, and supporting the advancement of precision medicine and the discovery of new anti-cancer drugs.

#293 DNMT1 promotes escape from chemotherapy-induced senescence in acute myeloid leukemia.

Manna Ahmed[1], Dharmendra Kashyap[1], Hannah Kim[2], **Cihangir Duy**[1]

[1]Fox Chase Cancer Center, Philadelphia, PA,[2]Temple University, Philadelphia, PA

In addition to inducing cell death, chemotherapy can trigger cellular senescence in cancers as a side effect that is typically viewed beneficial for hindering cancer progression. However, acute myeloid leukemia (AML) cells can evade chemotherapy-induced senescence (CIS), leading to therapy failure and disease recurrence. To reduce the risk of AML recurrence, we investigated the mechanisms underlying CIS escape in AML that remain largely elusive. To achieve this, we developed an *ex vivo* AML recurrence model using primary patient-derived AML cells following exposure to chemotherapy (Ara-C). To minimize potential confounding effects caused by genetic heterogeneity, we utilized single-cell-expanded monoclonal AML populations. These populations were analyzed following CIS escape through integrative transcriptome and DNA methylome profiling. Our analyses revealed that, beside random DNA methylation changes, AML clones gained gene-specific promoter DNA hypermethylation sites associated with transcriptional silencing after CIS escape. This gained transcriptional silencing was conserved across five genetically independent AML specimens, suggesting a shared mechanism underlying AML recurrence after CIS. Using CRISPR-based epigenome-editing tools, we demonstrated that these acquired promoter DNA hypermethylation sites enhanced the survival fitness of AML cells during CIS. To identify the DNA methyltransferase (DNMT) responsible for this epigenetic silencing, we conducted knockdown experiments and identified DNMT1 as the key mediator. Both genetic and pharmacological inhibition of DNMT1 effectively blocked AML cells from escaping CIS. Overall, targeting DNMT1 disrupted CIS escape in AML cells, offering a therapeutic strategy to mitigate the risk of relapse driven by senescence-like leukemia cells.

#294 TFEB nuclear persistence predicts sensitivity to lysosomal inhibition in therapy-induced senescent thyroid cancer cells.
Beatrice Mazzoleni, Mara Mazzoni, Angela Greco

Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy

Therapy-induced senescence (TIS), is a potential outcome of anti-cancer treatments, characterized by a stable cell cycle arrest. However, it is now widely accepted that this process acts as a double-edged sword: in facts, senescent cells are active drivers of cancer relapse, aggressiveness and metastasis, through the release of various pro-inflammatory factors, and the ability to resume proliferation. Therefore, selectively targeting TIS cells, a strategy named one-two punch approach, is crucial to avoid their harmful effects. To this purpose, identifying targetable characteristics of TIS cells is essential for the development of new senotherapeutics. One of the peculiarities of senescent cells is the expansion of the lysosomal compartment. To assess whether lysosomes may be a valid target for new senotherapies, we employed as a TIS model different cell lines of anaplastic thyroid cancer, an aggressive and untreatable type of tumor, undergoing senescence upon either CDK4/6 inhibitor Palbociclib or ionizing radiation treatment. Senescence induction and lysosomal expansion were assessed by a multi-marker approach, comprising β-gal assay, γH2AX nuclear foci quantification, p21 and HMGA2 expression levels, and lysosomal staining. Our findings indicated that the response to TIS varied among cell lines regarding lysosomal content increase. Although the autophagic flux, that relies on lysosomes, was elevated across all cell lines, its functionality was line-specific, as evidenced by differential p62 protein turnover. Targeting autophagy with the lysosomal inhibitor Chloroquine exhibited a senolytic effect only on senescent cells with an expanded lysosomal compartment and functional autophagy. Conversely, the lysosome-sparing autophagy inhibitor LY294002 did not replicate these results, suggesting that the senolytic effect is ascribable to lysosomal rather than autophagy inhibition. To further explore the differential expansion of the lysosomal compartment, we analyzed the localization of TFEB, the master regulator of lysosomal biogenesis, following TIS induction, through immunofluorescence. Six days after treatment, TFEB maintained a nuclear localization exclusively in the cell line with functional autophagy. Interestingly, this was associated with significantly lower protein levels of Exportin-1, an export receptor responsible for TFEB nuclear extrusion.
Our results indicate that lysosomes represent a promising target for developing new senotherapeutics, but TFEB's ability to enter and persist at the nuclear level appears to be crucial in determining this sensitivity. Understanding the molecular differences underlying the varying functionality of the lysosomal biogenesis machinery, often defective in cancer, may pave the way for the future introduction of this one-two punch approach in the clinical setting.

#295 Induction of senescent cancer associated fibroblasts promotes cancer cell growth.

Shengliang Zhang, Lanlan Zhou, Leiqing Zhang, Wafik S. El-Deiry

Brown University, Providence, RI

Cancer associated fibroblasts (CAF) are heterogenous and plastic population in the tumor microenvironment (TME), and each of the CAF subtypes plays a different role in cancer progression and suppression. Chemotherapy can induce CAF senescence, and cell senescence has been known to promote tumor growth and drug resistance. To investigate the role and molecular mechanism of the senescent CAF to promote tumor growth, we set up methods to induce CAF senescence by Chemotherapy or Radiation therapy using two gastrointestinal CAF cell lines CK4520 and CK8612. The flow cytometry showed around 40% of the cells with beta-gal staining in both CK8612 and CK4520 by the Etoposide (40 uM) treatment, and around 80-90% of the cells with beta-gal staining by the X-ray (20 Gy) treatment in both CK8612 and CK4520. Western blot assay showed an increase in p21 and p53 at protein level, and a decrease in Lamin B1 at the protein level in both CK8612 and CK4520 by the X-ray treatment. The cytokine profiling showed an increase in IL6, IL8, and CXCL2 and other factors related to senescence in CK4520 cells treated with X-ray and Etoposide. These results indicate the CAF senescence. In addition, the cytokine profiling also showed the different senescence-associated secretory phenotype (SASP) in CK4520 cells between X-ray and Etoposide treatment, and the different SASP also observed between CK4520 and CK8612 upon the X-ray treatment. To determine if the senescent CAF promotes tumor growth, we generated the conditioned medium using the senescent CK4520. Cancer cells cultured with the conditioned medium showed an increase in cell viability in different cancer cell lines. These results suggest that SASP of the senescent CAF promotes cancer cell growth.

#296 Identification of novel senolytic targets and development of conditionally active biologic-based-drug conjugates for targeted senescence-associated secretory phenotype elimination *in vivo*.

Jian Chen, Jing Wang, Haizheng Liu, Gerhard Frey, Cathy Chang, William J. Boyle, Jay M. Short

R&D, BioAtla, Inc., San Diego, CA

Elimination of senescent cells has been reported to improve normal and pathological changes associated with aging and cancer in mice. However, most senolytic agents inhibit anti-apoptotic pathways that do not differentiate between hyper-inflamed senescence-associated secretory phenotype (SASP) cells from relatively non-inflamed, valuable functional senescent cells, leading to off-target effects in normal tissues. Conditionally Active Biologics (CAB) technology is a proprietary platform unique in its ability to be selectively active in the context of diseased, acidic tissues (*e.g.* inflamed tissue and tumor microenvironment), but not in alkaline normal tissues. The aberrant accumulation of senescent cells in aged and cancerous tissue triggers increasing inflammatory signaling through SASP, promoting aging and tumor progression. Since these cells have an acidic surface environment, similar to cancer cells, we explored whether CAB technology allows selective removal of senescent cells in SASP-associated microenvironments. In addition, to complement this selectivity, we identified more specific senolytic targets to further reduce side effects and increase the efficiency of senescence cell removal and SASP reduction. In this study we identified several novel senescence-specific surface antigens as senolytic targets both i*n vitro* and *in vivo*. For the *in vivo* studies, we developed several fibrosis models in mice, including unilateral ureteral obstruction (UUO) in kidneys, bleomycin- or silica-induced pulmonary fibrosis in lung, high-fat diet (HFD)+CCl4-induced non-alcoholic steatohepatitis (NASH) in liver, and isoproterenol-induced cardiac fibrosis. We confirmed that the novel senescence-specific antigens we identified in our *in vitro* system are highly expressed in fibrotic tissues with newly induced senescent cells and associated with inflammation in *in vivo* models. Furthermore, these antigens were co-expressed with senescence makers SA-β-Gal, GL13, p16 and p21. Finally, we developed duocarmycin-based CAB-antibody drug conjugates (CAB-ADC) to study whether CAB-ADC reduces senescent cell occurrence *in vivo*. Mice treated with CAB-ADC targeting novel senescence-specific antigens showed a significant reduction of inflammatory cells infiltrated in kidneys compared to mice treated with benchmark and isotype ADCs. Thus, the CAB antibody-based therapeutic is a promising strategy for senescent cell removal in an inflammatory microenvironment using these newly identified senescence-associated targets. In conclusion, CAB technology provides a new generation of biologics with an increased safety margin and therapeutic index, selectively targeting acidic senescence cells and SASP in cancer and age-related diseases.

#297 Targeting splicing factor SF3B4 induces cancer cell senescence by elevating p21 mRNA levels.

Donghee Kang, Hyun Jung Hwang, Min-Ji Kim, Jae-Seon Lee

Inha University College of Medicine, Incheon, Korea, Republic of

SF3B4, a component of U2 snRNP complex, is amplified in various cancers and contributes to cancer cell proliferation, migration and invasion by regulating alternative gene splicing. Despite its potential significance, the mechanisms by which SF3B4 regulates nonsense-mediated mRNA decay (NMD) and cancer cell senescence remain poorly understood. In this study, we reveal a novel regulatory role of SF3B4 in the regulation of cancer cell senescence by targeting *p21* mRNA. Depletion of SF3B4 leads to reduced cancer cell proliferation, increased SA-β-Gal positivity, and elevated p21 expression independent of p53, ultimately inducing cellular senescence. Mechanistically, SF3B4 directly binds to the 3'UTR of *p21* mRNA, negatively regulating its stability. We demonstrate that SF3B4 plays a crucial role in recruiting key components of the NMD pathway, such as UPF1, MAGOH and RNPS1, to promote the degradation of *p21* mRNA. Depletion of SF3B4 disrupted the association of NMD factors from the 3'UTR of *p21* mRNA. Taken together, our results reveal a novel regulatory role in which SF3B4 collaborates with NMD factors to regulate *p21* mRNA stability and cancer cell senescence.

#298 Senescence-associated gene expression in head and neck cancer in TCGA samples.

Sanjana Arji, Beverly R. Wuertz, Frank G. Ondrey

Otolaryngology, University of Minnesota-Twin Cities, Minneapolis, MN

Introduction: Senescent cells in tumors constitute an important cell population that may be both anti- and pro-tumorigenic. Head and neck cancer (HNC) is associated with treatment resistance, recurrence, and decreased survival rates that are somewhat stagnant. We examined the TCGA for differences in senescence-associated genes using various parameters.
Methods: 83 established HNC senescence-associated genes were examined in the TCGA Pancancer Atlas dataset via CBioPortal. mRNA expression (RSEM; Batch normalized from Illumina HiSeq_RNASeqV2) for each of the genes of interest was examined. Demographic information, disease stage, and HPV subtype data were also collected. Student's t-tests were conducted using RStudio's *tidyverse* package to determine statistically differentially expressed genes ($p < 0.05$). Then, Gene Ontology, through DAVID Bioinformatics, was conducted on the set of statistically significant genes found from each comparison to determine overexpressed pathways and adjusted p-values post-Benjamini-Hochberg correction ($q < 0.05$).
Results: Considering HPV Status: 65/83 of the tested genes statistically differed between HPV+ and HPV-. Out of the 65 significant genes, 6 were related to peptidyl-serine phosphorylation: TOP1, NEK6, LATS2, MAPK1, MAP4K1, TGFBR1($p = 4.3E-5$; $q = 1.7E-2$), 5 were related to the G1/S transition of the mitotic cell cycle: CCND1, CDK6, CDKN1A, EZH2, LATS2 ($p = 2.7E-5$; $q = 1.7E-2$), and 5 were related to canonical WNT signaling pathway: YAP1, CAV1, LATS1, PTEN, SIAH1($p = 1.7e-4$; $q = 3.5E-2$). Considering Caucasian vs African American, HSPA5 ($p=0.02$), NEK6 ($p = 0.0163$), and SMURF1 ($p = 0.0015$) were all found to be statistically significant. SMURF1 and HSPA5 were found to negatively regulate the TGF-beta receptor signaling pathway ($p = 1.3e-2$; $q = 7.6e-1$). Considering 1st vs 4th quartile age: SERPINE1 ($p = 0.00301$), POU5F1 ($p = 0.0063$) and CDKN2A ($p = 0.0653$) were differentially expressed. No overexpressed pathways were noted in the Gene Ontology Biological Process Analysis. Considering tumor stage: AREG ($p=0.01405$), GAPDH ($p = 0.01475$), PSMB5 ($p = 0.04848$), LIMA1 ($p = 0.04709$), EHF ($p = 0.03858$), and DPY30 ($p = 0.003711$) were found to be differentially expressed. However, no overexpressed pathways were found in Gene Ontology Biological Process Analysis.
Conclusions: We identified various statistically different senescence-associated markers between various parameters in our analysis of TCGA-associated data. Furthermore, four overexpressed pathways were identified through gene ontology of statistically significant genes between HPV status and race. Identifying these pathways and genes may help better understand variations in HNC presentation and create more definitive senescent markers to determine prognosis based on these parameters. Further analysis of the genes with higher stringency thresholds and consideration of epigenetic factors must be done to solidify the findings.

#299 Characterization of a senescence phenotype induced by advanced glycation end products in prostate cancer.

Luisa Bacca[1], Tarek Hallal[2], Carole Luthold[3], Nadia Boufaied[4], Francois Bordeleau[3], David Labbe[5]

[1]Experimental Medicine, McGill University, Montreal, QC, Canada,[2]Department of Anatomy and Cell Biology, McGill University, Montreal, QC, Canada,[3]Departement de biologie moleculaire, de biochimie medicale et de pathologie, Universite Laval, Quebec City, QC, Canada,[4]Cancer Research Program, Research Institute of the McGill University Health Centre, Montreal, QC, Canada,[5]Department of Surgery, McGill University, Montreal, QC, Canada

Prostate cancer (PCa) represents a worldwide leading cause of cancer-related mortality in men. Diabetes is also a highly prevalent and a rapidly growing pathology. Intriguingly, diabetes is associated with decreasing PCa incidence, and at the same time, it is linked to increased mortality rates for men already afflicted by the disease. A plausible mediator causing this effect are Advanced Glycation End Products (AGEs), products of the Maillard reaction, occurring between sugars and proteins at body temperature. AGEs, known to be elevated in diabetic patients, have been reported to increase the Extracellular Matrix (ECM) stiffness via ECM-crosslinking, potentially explaining the tumor-promoting effects of diabetes in cancer progression. Nonetheless, the protective role of diabetes in prostate cancer is not yet fully understood. Interestingly, we demonstrated that AGEs, produced by mixing sugars and an abundant circulating protein in the blood decreased PCa cell proliferation *in vitro* in a dose-dependent and irreversible manner across a panel of human PCa cell lines. Importantly, through transcriptomic analysis, we found that AGEs-mediated cell proliferation blocking correlate with a senescence transcriptional signature. Accordingly, treatment with AGEs lead to increased beta-galactosidase activity, a hallmark of senescence, and to the upregulation of senescent markers linked to cell cycle arrest ($p21^{WAF1/Cip1}$) and pro-inflammatory cytokines (IL-8) at the transcriptional and translational levels. We also confirmed the expression of the senescence-associated secretory phenotype (SASP, *e.g.*, IL, CXCL, CCL) in AGEs-treated PCa cells. Finally, our validation of key transcriptomics analysis confirmed the upregulation of HMOX1, an enzyme reported to be induced during cellular senescence, upon AGEs treatment. Altogether, our results suggest that AGEs-mediated senescence could underlie the lower incidence of PCa among diabetic patients. This sets the stage for combination treatments between AGEs and senolytics, drugs that selectively target and induce cell death in senescent cells, as a novel therapeutic strategy in PCa.

#3 TIP60 modulates colorectal cancer stemness through cd44 expression.

Mohammad Asad, Sudhakar Jha

Physiological Sciences, Oklahoma State University, Stillwater, OK

Objective: To identify the functional role of TIP60 in regulating colorectal cancer (CRC) stemness.
Materials and Methods: The HCT116 CRC cell lines were cultured in DMEM (high glucose) supplemented with 10% FBS. ShRNA-mediated depletion of TIP60 was generated using lentiviral vectors. To confirm TIP60 knockdown efficiency and CD44 expression levels, qPCR analyses were performed. For the colony formation assay, 1000 cells of HCT116 ShLuc control and ShTIP60 were seeded in 6-well plates and incubated for 11 days. For immunofluorescence staining, cells were grown on cover slips, fixed with 100% methanol for 20 minutes, and blocked with 3% BSA. They were then incubated with E-cadherin primary antibody at a 1:500 dilution and secondary antibody Alexa Fluor-488 at a 1:1000 dilution. Cells were mounted with Vectashield mounting medium containing DAPI. Spheroid culture was conducted in 96-well ultra-low attachment plates, with 100 cells of HCT116 ShLuc control and ShTIP60 seeded in each well and incubated for 7 days. The 3D invasion assay was performed in 96-well ultra-low round-bottom plates supplemented with 3D basement membrane extract (BME) invasion matrix.
Findings: This study uncovered the pivotal role of HIV Tat-interactive protein (TIP60) in regulating CRC stemness. TIP60 depletion resulted in a significant decrease in cellular proliferation, highlighting the importance of TIP60 in CRC growth. Furthermore, TIP60 depletion altered colony formation, transitioning from densely packed formations to scattered spindle networks implying its involvement in the epithelial-mesenchymal transition (EMT). 3D culture models demonstrated that TIP60 is essential for spheroids formation, emphasizing its significance in promoting cancer stemness. TIP60-depleted cells exhibited enhanced invasion in a 3D BME invasion matrix, accentuating its crucial contribution to cellular invasiveness. Furthermore, we have identified that TIP60 undergoes liquid-liquid phase separation (LLPS). TIP60 harbors an intrinsically disordered region (IDR), which is essential for inducing LLPS in CRC. We have also discovered that TIP60 IDR regulates CRC stemness and EMT in CRC. In addition, the reduction of TIP60 was linked to a decrease in the expression of CD44, which is a crucial indicator for cancer stem cells (CSCs). Significantly, CD44 overexpression reinstated the efficiency of spheroid formation and reversed the EMT phenotype.
Conclusions and Clinical Implications: Our findings suggest that TIP60 has CSC characteristics in CRC, and targeting TIP60 will offer a novel therapeutic approach against colorectal cancer stem cells.

#30 Establishment of a chemical carcinogen-induced bladder cancer model using healthy canine bladder organoids.

Yuko Nagashima, Haru Yamamoto, Mohamed Elbadawy, Amira Abugomaa, Tatsuya Usui, Kazuaki Sasaki

Tokyo University of Agriculture and Technology, Tokyo, Japan

Background Canine bladder cancer (BC) accounts for approximately 2% of all spontaneous canine cancers, and the majority (over 90%) of these are moderate to highly invasive bladder cancers. In terms of biological behavior, canine BC is said to be similar to the cytological and molecular characteristics of human muscle-invasive BC, especially high-grade invasive transitional cell carcinoma. In recent years, cancer research in dogs has been used to define genetic and environmental risks and evaluate prevention and treatment approaches that will benefit not only dogs but also humans. An organoid is a miniaturized and simplified version of an organ produced ex vivo in three dimensions, mimicking the key functional, structural, and biological complexity of the actual organ. Organoids are attracting attention as complementary models to traditional animal models, and are often used in human and animal cancer research. In the current study, we developed a carcinogen-induced BC organoid model using organoids generated from healthy canine bladder tissue.
Materials and methods Canine normal bladder organoids (CNBOs) were established using bladder epithelial cells collected using a urinary catheter from a healthy beagle dog in a non-invasive manner. The CNBOs were treated with 1 μM 2-Acetylaminofluorene (2-AAF), a known bladder carcinogen, and then transplanted subcutaneously into immunodeficient mice. As a result, a mass was formed, confirmed to be a benign bladder tumor (canine bladder benign tumor: CBB) by histopathological analysis. When organoids were developed again from CBB (CBBO) and transplanted under the skin of immunodeficient mice, the tumor was reformed. The re-formed tumor was confirmed to be BC (Canine bladder carcinoma: CBC), and organoids were created from CBC (CBCO), and comparative analysis was conducted on CNBO, CBBO, and CBCO.
Results The expression of CK5 and UPK3A, was confirmed in CNBO, CBBO, and CBCO. In addition, observations using electron microscopy revealed findings suggestive of a normal bladder in CNBO and findings suggestive of a malignant tumor in CBCO. RNA sequencing analysis showed significant differences in gene expression in CNBO, CBBO, and CBCO. Gene set enrichment analysis revealed that the epithelial-mesenchymal transition pathway was enhanced in CBCO compared to CNBO. CNBO showed high cell proliferation in cell proliferation assays. The anti-cancer drug sensitivity test showed different sensitivities to treatment with vinblastine, mitoxantrone, carboplatin, and lapatinib.
Discussions In this study, chemical carcinogen-induced canine BC organoids were generated by treating CNBO with bladder carcinogen (2-AAF) and transplanting it into mice twice. In the future, we plan to perform cancer-related gene mutation analysis and proteomic analysis of CNBO, CBBO, and CBCO to clarify further the detailed molecular mechanisms of carcinogenesis.

#300 Senescence and secreted factors: implication of DNA damage response pathways.

Jordan Desmul, Nicolas Malaquin, Francis Rodier

CRCHUM, Montreal, QC, Canada

Introduction Senescence is a tumor-suppressive mechanism characterized by a halt in cellular proliferation. It can be triggered by various genotoxic sources, such as exposure to ionizing radiation during anticancer therapies to prevent the proliferation of cells with DNA damage. These cells adopt a senescence-associated secretory phenotype (SASP), which consists of hundreds of molecules, including cytokines, chemokines, and other pro-inflammatory factors. These secretions have beneficial anti-proliferative effects. However, their long-term accumulation can lead to detrimental outcomes, such as aging and tumorigenesis, driven by chronic inflammation. The senescence mechanism develops progressively in multiple steps over several days following genotoxic stress. In our model of irradiation-induced senescence (IR-10Gy) in human fibroblasts (BJ, HCA2), IR activates DNA damage response (DDR) pathways. These cells enter senescence 7 to 10 days post-exposure and develop their SASP. It is well established that there is a link between DDR activation and SASP induction. The genetic depletion of key DDR players (ATM, CHK2, NBS1) results in SASP suppression. However, the timing of these processes does not coincide. While DDR pathways are activated within minutes of DNA damage, the SASP takes several days to develop. Thus, the mechanism by which DDR influences SASP activation remains poorly understood. We identified a late non-canonical branch of the DDR (ncDDR) that appears to activate several days after the initial stress and is associated with the late pro-inflammatory SASP. In contrast, the canonical DDR pathway seems responsible for early non-inflammatory secretions. These findings suggest that the composition of senescent cell secretions evolves over time.
Objective: We hypothesize that during the multi-step process of senescence establishment, the composition of the SASP evolves based on the activation or deactivation of DDR pathways. Modulating DDR activation through irradiation or genetic/pharmacological approaches will allow us to understand its impact on SASP. Our objective is to determine how the activation of different DDR pathways drives SASP induction and how these pathways influence its composition over time.
Results: We irradiated fibroblasts with increasing doses of irradiation (10, 20, 40, 80 Gy) to sustain a high level of canonical DDR activation. At day 10 post-IR, we observed: • a dose-dependent decrease in the number of cells with genomic instability, • an almost complete suppression of the pro-inflammatory factor IL-6, • a significant increase in the secretion of GDF15, another SASP factor. Interestingly, these results were reversed when analyzing the secretome 24 hours post-irradiation. In conclusion, increased DDR activation induced a significant increase in various components of the early SASP and demonstrated distinct regulation between the early and late SASP.

#301 PARP inhibitor-induced senescent fibroblasts enhance prostate cancer cell proliferation and suppress NK cell-mediated cytotoxicity.

Introduction: Prostate cancer (PCa) is a leading cause of cancer-related morbidity and mortality in men. Despite initial tumor response to androgen deprivation therapy (ADT), most patients with PCa progress to a castrate-resistant disease state. Therapy-induced cellular senescence modulates the tumor microenvironment (TME) through the senescence-associated secretory phenotype (SASP), contributing to tumor growth, progression, and treatment resistance. We have demonstrated increased patient serum levels of SASP-related cytokines following treatment with ADT (Schwermann, AACR 2024). We investigated the ability of PARP inhibitors (PARPi) to induce senescence of fibroblasts and its impact on the proliferation of PCa cell lines and NK cell-mediated cytotoxicity.
Methods: Senescence of fibroblasts (IMR-90) was induced by treatment with etoposide (40uM), olaparib (15uM), and talazoparib (20uM) for 3 weeks. The senescent population was stained with the SPiDER-Gal live cell marker and sorted (BD FACS Aria). Cytokines (SASP) from senescent fibroblasts were characterized using bead-based multiplex assay (Luminex® xMAP®). Senescent fibroblasts were co-cultured with PCa cell lines (LNCaP, DU145, 22Rv1, PC3) in a 10:1 ratio over 12 days. The growth rate of PCa cells was assessed by colony assay formation. Senescent fibroblasts were co-cultured with NK cells (1:30 ratio) over 5 days. The NK proliferation status and cytotoxic markers were analyzed by flow cytometry. NK cells exposed to senescent fibroblasts were incubated with fluorescently labeled PCa cells.
Results: PCa cell lines displayed increased proliferation when co-cultured with senescent fibroblasts (PC3+IMR-90 [C] = 59.6±4.72, PC3+etoposide treated IMR-90 [T1]=111.7±10.6, PC3+olaparib treated IMR-90 [T2]=97±11.3, $p<0.005$, LNCaP+[C]=16.67±5.6, LNCaP+[T1]=86.33±5.1, LNCaP +[T2]=65.3±8.3, $p<0.001$). Senescent fibroblasts induced by etoposide, olaparib, and talazoparib displayed an increased secretion of the SASP IL-6, IL-8, IL-1, IL-15, CCL2, CCL3, and CCL20. NK cells exhibited a lower proliferation rate when co-cultured with senescent fibroblasts (Ki67% [C]:71.6±3.5, [T1]: 26.3±5.1, [T2]: 41.5±3.5, $p<0.002$) and reduced IFN-γ secretion ([C]:32±4, [T1]: 26±3.1, [T2]: 29±6.5, $p=0.32$). NK cells co-cultured with senescent fibroblasts also exhibited reduced killing of PCa cells (tumor-NK cell ratio 10:1 and 20:1).
Conclusions: Etoposide and PARPi-induced senescent fibroblasts displayed increased SASP production and promoted the proliferation of PCa cells in vitro. These senescent fibroblasts also limited NK cell proliferation and reduced their cytotoxicity. Future experiments will investigate the impact of therapy-induced senescent fibroblasts *in vivo* growth of PCa tumors.

#302 Study of treatment-induced senescence in head and neck squamous cell carcinoma according to HPV status.

Karim Bouhjar[1], Carine Michiels[2], Francis Rodier[1]

[1]CrCHUM, ICM, University of Montreal, Montreal, QC, Canada,[2]URBC, Narilis, University of Namur, Namur, Belgium

Introduction: Head and neck cancer (HNC) is the sixth most common cancer worldwide, with an incidence of approximately 600,000 new cases each year. Within this type of cancer, two main categories should be distinguished: HPV-negative and HPV-positive tumors. In this context, the tumorigenesis process differs, and the prognosis associated with each subtype is variable. Despite this difference, the therapeutic management of patients is identical. The aim of this research project is to demonstrate that this management should take HPV status into account and that the associated treatments must be adapted accordingly. Indeed, preliminary results show that depending on the HPV status, the response to treatments induces either a pro-apoptotic or pro-senescence response. This research project therefore investigates the biological and molecular mechanisms by which the HPV status influences cell fate decisions following treatment.

Materials and Methods: Different characteristics of senescent cells have been assessed; morphology, positivity for SA-β-gal, SASP expression, cell cycle assessment and proliferation. The preliminary results suggest an induction of cellular senescence in most of the cell lines following treatment. Following this, a new aspect of the thesis has been recently opened through a mass spectrometry approach. In parallel, HPV-negative cell lines expressing key viral factors are currently being generated to create a more relevant model, combined with the use of patient tissues that will be analyzed by multiplexed immunofluorescence.

Discussion: The first results have fully characterized the induction of the senescent phenotype following treatment, depending on HPV status, in head and neck cancer cell lines. The unbiased proteomic approach will help to identify promising candidates involved in this senescence induction according to HPV status. Simultaneously, access to the CrCHUM biobank will allow testing of the various hypotheses in situ.

#303 Discovery of autophagy-inhibiting compounds as a novel class of senolytics.

Martin Mistrik, Matthew Lacey, Lucie Beresova, Alzbeta Srovnalova, Josef Srovnal, Petr Dzubak, Marian Hajduch

Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky Univer, Palacky University in Olomouc, Olomouc, Czech Republic

Introduction: Senolytics are compounds capable of selectively eliminating senescent cells, holding promise for therapies targeting age-related diseases and cancer. To identify novel senolytic agents, we screened a chemical library using cellular models of replicative senescence induced by replication stress. This screen yielded several hits, including MCOPPB, a known nociceptin receptor agonist. Subsequent in vivo studies in a murine model confirmed the potent senolytic activity of MCOPPB. Surprisingly, further investigations revealed that this activity was independent of nociceptin receptor signaling, suggesting an off-target mechanism. Methods: To explore the underlying mechanism, we performed a cell-painting assay, which phenotypically links compounds based on their cellular effects. MCOPPB clustered closely with another senolytic hit from the screen, Daurisolin, a natural autophagy inhibitor. Autophagy inhibition by MCOPPB was validated through assays measuring LC3 accumulation and other markers. Additional studies with known autophagy inhibitors, including Dauricin and Chloroquine, demonstrated both senolytic activity and clustering with MCOPPB in the cell-painting assay.
Results: Our findings establish autophagy inhibition as the common mechanism of senolytic action for this newly identified class of compounds. MCOPPB, Daurisolin, and related inhibitors displayed consistent phenotypes in cell-painting assays and induced selective clearance of senescent cells. The clustering of these compounds in phenotypic assays provides a powerful approach for identifying senolytics with similar mechanisms of action.
Conclusion: This study highlights autophagy inhibition as a novel senolytic mechanism and identifies a unique chemical cluster of autophagy-inhibiting senolytic compounds. These insights could drive the development of targeted therapies for conditions associated with cellular senescence.

#304 Profiling the acute effects of androgen receptor inhibition in hormone-sensitive prostate cancer.

Julian Brandariz[1], Lara de Llobet Cucalon[1], Daniel Aguilar[1], Andrei Salca[1], Victor Esquefa[1], Youhao Chen[1], Gisela Mir[1], Anna Oliveira[1], Irene Casanova-Salas[1], Alba Escriche[1], Manuel Jara Espejo[2], Jose Alberto Lopez-Dominguez[3], Victoria Cid[4], Marco Piva[4], Maria Abad[1], Francisco Martinez-Jimenez[2], Raquel Perez-Lopez[1], Manuel Serrano[5], Arkaitz Carracedo[4], Nicolas Herranz[1], Joaquin Mateo[1]

[1]Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain,[2]Systems Oncology Program, Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain,[3]Instituto de Biologia Molecular y Celular del Cancer and Centro de Investigacion del Cancer of Salamanca, University of Salamanca-CSIC, Campus Unamuno s/n, 37007, Salamanca, Spain,[4]Translational Prostate Cancer Research Laboratory, CIC bioGUNE-Basurto, Biobizkaia Health Research Institute, Barakaldo, Bizkaia, Spain,[5]Institute for Research in Biomedicine (IRB Barcelona), Barcelona, Spain

Introduction: Metastatic prostate cancer (mPC) is driven by androgen signaling. Standard treatment involves androgen-deprivation therapy (ADT) and androgen receptor (AR) inhibitors (e.g. enzalutamide), but resistance eventually arises, leading to metastatic castration-resistant prostate cancer (mCRPC). This study investigated the acute effects of AR inhibition in hormone-sensitive mPC to identify therapeutic targets to prevent resistance.

Methods: We analyzed RNAseq before and after 3 or 6 months of AR inhibition from two neoadjuvant enzalutamide clinical trials in PC (NCT03297385, *n=39*; NCT02430480, *n=37*) using Hallmark pathways, and with a focus on senescence and senescence associated secretory phenotype (SASP) signatures. *In vitro*, we treated human (LNCaP, VCaP, LAPC4) and murine (Myc-CaP, *Pten*$^{pc-/-}$*Lkb1*$^{pc-/-}$) mPC cells with enzalutamide and we assessed proliferation (CCK8, BrdU), viability (AnnexinV/PI), cell cycle distribution, SAβGAL activity, cyclin-dependent kinase (CDK) inhibitors, and RNAseq. We derived an RNA hormonal therapy-induced senescence (HTIS) signature from LNCaP cells treated with enzalutamide for 2 days vs 2 weeks or 6 weeks. ssGSEA analysis assigned a senescence score to patient samples for clinical outcome correlations. *In vivo*, HTIS was validated in LNCaP and mPC patient-derived xenografts (PDX) models using SAβGAL activity, Ki67 (proliferation), p16/p21, and RNAseq.

Results: Upon enzalutamide, GSEA analysis of patient samples (NCT03297385, NCT02430480) revealed downregulated Hallmark gene sets linked to proliferation/AR signaling, and upregulated pathways related to protein secretion, inflammation, TNFα-NFκB, and IL6-JAK-STAT3 signaling. Senescence and SASP signatures were enriched in post-enzalutamide biopsies. *In vitro,* AR inhibition in LNCaP, VCaP, LAPC4, Myc-CaP and *Pten*$^{pc-/-}$*Lkb1*$^{pc-/-}$ induced G_0/G_1 proliferation arrest without affecting cell viability, alongside senescence features such as increased SAβGAL activity, and upregulation of p16/p21 and SASP genes. HTIS signature from LNCaP cells, which incorporated downregulated genes linked to proliferation and upregulated genes linked to inflammation was validated *in vivo*, where castration or enzalutamide in LNCaP xenografts and PDXs tumors resulted in decreased proliferation (Ki67), increased SAβGAL activity, upregulation of p16 or p21, and enrichment for senescence and SASP signatures. Last, patients from the NCT03297385 dataset with high HTIS signature scores showed greater correlation with other senescence signatures and lower rates of biochemical relapse (high = 28% (7/25); mid = 42.9% (3/7); low = 85.7% (6/7)).

Conclusions: We demonstrate that AR inhibition induces a senescent phenotype in hormone-naïve prostate cancer models, including PDXs. RNAseq of patient biopsies suggest this adaptive phenotype is present also in patients and has prognostic implications.

Liver senescence involves the gradual deterioration of hepatic cell function and reduction of regenerative capacity due to aging, chronic liver disease, and cancer. To elucidate the role of liver senescence in aging and cancer, we employed single-cell sequencing, spatial omics, and imaging approaches, collectively over 100 assays, to characterize 43 normal liver samples from a cohort of 95 donors, across ages and selected based on histology and clinical data. We conducted similar assays on samples from 24 patients with colorectal cancer metastasis in the liver. Our study identified CDKN1A+ senescent cells across four liver-resident cell types, namely hepatocytes, fibroblasts, cholangiocytes, and liver sinusoidal endothelial cells, with their prevalence significantly associated with age or liver disease. We observed distinct senescent populations in fibrotic compared to aged livers, indicating differential mechanisms of senescence in these conditions. Fibrosis was related to the expansion of a specific niche residing in portal triads and fibrous septae including immune cells and senescent fibroblasts, which exhibited abundant and strong cellular interactions. Notably, chemotherapy exacerbated senescence, increasing the number of senescent hepatocytes by five-fold compared to aging alone, while the effect of cancer itself was moderate. Other cell types affected by chemotherapy included liver sinusoidal endothelial cells and stellate cells, while CDKN1A+ portal fibroblasts and cholangiocytes were not affected as much. Cancer appeared to induce senescence in nearby hepatocytes, whereas chemotherapy severely affected more distant normal liver tissue. Cancer patients also demonstrated unique populations of CDKN2A+ hepatocytes and cholangiocytes with a distinct secretory phenotype. Senescent cells in liver shared core features, such as AP-1, NFkB activity, SERPINE1, CCL2, COL4A secretion, and anti-apoptotic protein expression, offering new insights into the cellular and molecular mechanisms underlying liver senescence. These findings underscore the complexity and heterogeneity of liver senescence and may have implications for our understanding of liver health and disease.

#309 Adding nadunolimab to chemotherapy or antibody drug-conjugates (ADCs) may improve antitumor efficacy and counteract peripheral neuropathy.

Samuel Le Sourd[1], Rocio Garcia-Carbonero[2], Sandrine Hiret[3], **Elin Jaensson Gyllenback**[4], Camilla Rydberg Millrud[4], Lars Thorsson[4], Svetlana Shatunova[5], Irina Vetter[5], Hana Starobova[5], David Liberg[4]

[1]Centre Eugene Marquis, Rennes, France,[2]12 Oct Hospital, Madrid, Spain,[3]Institut de Cancerologie de l'Ouest ICO, Saint-Herblain, France,[4]Cantargia AB, Lund, Sweden,[5]The University of Queensland, Institute for Molecular Bioscience, Saint Lucia, Australia

Background: Nadunolimab, a fully humanized ADCC-enhanced, monoclonal IgG1 antibody targets IL-1 receptor accessory protein (IL1RAP) and blocks IL-1 signaling. In pts, nadunolimab with standard chemotherapies showed good safety and promising efficacy. In 73 advanced pancreatic ductal carcinoma (PDAC) pts, combination with nab-paclitaxel and gemcitabine showed 33% ORR and 13.2mo OS, with 48% ORR and 14.2mo OS in the IL1RAP-high subgroup. In 40 1st or 2nd line non-small cell lung cancer pts, combination with platinum-doublet showed 55% ORR and 13.7mo OS, with 91% ORR and 26.7mo OS in the 2nd line non-squamous subgroup. Interestingly, in addition to promising anti-tumor effects, a significantly delayed onset and reduced incidence of nab-paclitaxel/gemcitabine-related chemotherapy-induced peripheral neuropathy (CIPN) were observed in pts receiving higher doses of nadunolimab compared to lower doses (36% vs 60%). CIPN is a neuroinflammatory side effect driven by immune activation and cytokine release such as IL-1 that limits treatment and severely impairs quality of life. Building on these promising findings, our aim was to further investigate nadunolimab's additional potential in mitigating neuropathies associated with chemotherapy and ADCs.
Methods: The potential neuroprotective effect of nadunolimab was analyzed in two clinical trials: one involving 14 pts with 8 different cancer indications treated with FOLFOX and nadunolimab at 1 mg/kg (n=7) or 0.5 mg/kg (n=7), and another involving 18 PDAC pts treated with FOLFIRINOX and nadunolimab at doses of 0.5 mg/kg (n=8), 1 mg/kg (n=3), 1.5 mg/kg (n=4), and 2.5 mg/kg (n=3). In mice, neuropathy was induced by vincristine, nab-paclitaxel, nab-paclitaxel plus gemcitabine, or ADC payloads. The effects of nadunolimab surrogate antibody (10 mg/kg) on neuropathy were evaluated using electronic von Frey apparatus, parallel rod floor apparatus, and grip strength meter. Tissue samples were analyzed for inflammatory markers and immune cell infiltration.
Results: We observed a lower incidence of any-grade FOLFOX-induced CIPN in the 1 mg/kg nadunolimab dose group compared to the 0.5 mg/kg dose group (43% vs 100%) and a significantly longer time to onset (median not estimable vs 4 days; HR=0.15, p=0.0004). Similar trends were observed for FOLFIRINOX-induced CIPN in PDAC pts. In mice, CIPN was linked to infiltration of myeloid cells and inflammatory cytokines in dorsal root ganglia. Co-administration of the nadunolimab surrogate completely abrogated CIPN. Ongoing studies aim to confirm the effects of the nadunolimab surrogate on ADC payload-induced neuropathy.
Conclusion: Overall, our current findings in conjunction with previous results, suggest that nadunolimab may not only offer anti-tumor benefits but also protection against the neuro-inflammatory component driving chemotherapy- and ADC-induced neuropathy.

Immunotherapy has emerged as a promising cancer treatment strategy, including approaches such as immune checkpoint inhibitors (ICIs), cytokine-based therapies, chimeric antigen receptor (CAR) T-cell therapies, oncolytic viruses, cancer vaccines, and combination treatments. ICIs and CAR-T-cells have revolutionized cancer therapy, significantly enhancing the treatment landscape for a variety of cancers. However, despite encouraging results in preclinical models, translating novel therapies into clinical success remains challenging. Traditional rodent models, which have long been fundamental in cancer research, have limitations in mimicking human immune responses. To address these challenges, humanized mouse models have recently emerged as a critical tool. These models incorporate human immune components, providing a more accurate representation of how human immune systems interact with tumors. In this study, we explored the differences in the longitudinal dynamics of human immune cell populations across two distinct humanization mouse models. One model was generated using CD34+ hematopoietic stem cells (HSC) derived from cord blood donors, while the other was created by injecting human PBMCs. The PBMC-based model included characterization of several different PBMC donors, whereas the CD34+ HSC-based model involved evaluation of distinct stem cell donors across various CDX models.Our findings reveal dynamic changes in immune cell composition and behavior in humanized mouse models. In CD34+ HSC-humanized mice, the overall amount of human CD45+ cells in peripheral mouse blood declines over time including a shift of immune cell populations. B cells are initially predominant but decrease as the T cell compartment increases. In PBMC-humanized mice, the proportion of human immune cells in the circulation starts low (1-3% of total CD45+ cells) but increases significantly over time, reaching up to 70%, depending on the donor. These human immune cells are mainly comprised of T cells, whereas other hematopoietic compartments, like B cells or Monocytes are quickly lost.
In both humanized mouse models, PBMC and CD34+ HSC, expression of the activation marker PD-1 on T cells increases over time. Notably, the CD4:CD8 T cell ratio, as well as overall numbers, are different for each model.Based on our studies tumor characteristics, rather than the type of PBMC or stem cell donor, are the primary drivers of immune cell infiltration. We found that tumor-specific factorsare key in shaping immune responses. This highlights the critical role of intrinsic tumor properties in modulating the immune microenvironment and influencing therapeutic outcomes.
These results provide valuable insights into the selection of appropriate humanized models and can inform experimental timing for testing novel immuno-oncology therapies. This may ultimately lead to more personalized and effective cancer treatment strategies.

#310 Deciphering the molecular basis for pan-HLA recognition of divarasib-modified pMHCs by newly discovered hit-to-lead antibody AETX-R302.

Lorenzo Maso, Weifeng Liu, Angelina Pizzo, Sarah Mosure, Matthew Southard, Lauren Stopfer, Samantha Sze, Diamond Mensah, Sergio Rodriguez, Anusha Keerthi, Sean Toenjes, Brian Vash, Paul Da Silva Jardine, Rajesh Chopra, Christoph Rader

Aethon Therapeutics, Long Island City, NY

The practicality of combining targeted therapies using covalent inhibitors of driver oncoproteins with specifically engineered antibodies to selectively kill drug-resistant cancer cells was recently demonstrated (Hattori, Maso et al., *Cancer Discov* 2023; Maso et al., *PNAS* 2024). Covalent inhibitors, once bound to their intracellular targets, can survive proteasomal degradation and are subsequently presented by class I MHCs as tumor-specific synthetic neoantigens. Companion antibodies of high specificity and affinity are then generated to selectively recognize these hapten-peptide MHCs (hapten-pMHCs), exploiting the high dissimilarity of hapten-pMHCs from MHCs presenting self-peptides. Therefore, combining the benefits of both targeted and immune therapy, overcomes their weaknesses as monotherapy. The potential of exploiting synthetic neoantigens is well demonstrated by antibody AETX-R114, which recognizes multiple hapten-peptides (sotorasib-conjugated $KRAS^{G12C}$ peptides) presented by different HLAs. When reformatted as a T cell engager (TCE), AETX-R114 potently and selectively kills sotorasib-resistant $KRAS^{G12C}$ cancer cells expressing different HLAs upon sotorasib treatment *in vitro* and *in vivo*. However, its high-affinity hapten-pMHCs cross reactivity, and related cancer cell killing, is restricted to hapten-peptides presented by HLAs belonging to the same HLA superfamily. Here we present the discovery and structural characterization of hit-to-lead antibody AETX-R302, which was raised against hapten-pMHCs presenting divarasib-conjugated $KRAS^{G12C}$ peptides (diva-pMHCs). AETX-R302 reveals specific, high affinity (K_D ranging between 0.78 and 2.75 nM), and pan-HLA recognition of diva-pMHCs across HLAs A*02 (A2 supertype) and A*03/A*11 (A3 supertype), with minimal free drug competition (IC_{50} >30 μM), demonstrating that antibodies developed through this platform can effectively break down the supertype barrier while maintaining MHC-restricted recognition. High-resolution cryo-EM structures of AETX-R302 in complex with diva-pMHCs revealed an epitope that involves all three components of the synthetic neoantigen (HLA, hapten, and peptide), exemplifying the three-layer specificity that can be achieved with such antibodies. Its unique binding geometry enables the recognition of HLA residues that are almost completely conserved among HLAs A*02, A*03, and A*11, while allowing a comparable recognition of the hapten when presented by different $KRAS^{G12C}$-derived peptides. Collectively, the cryo-EM structures explain AETX-R302's unprecedented A2/A3 supertype cross-reactivity and its high specificity and affinity. This information will be exploited to develop TCEs that engage tumor-specific synthetic neoantigen targets with pan-HLA recognition.

#311 Long-term tumor growth inhibition and extended survival with TD001, a novel optimized PSMA-targeting ADC, in PSMA-expressing CRPC CDX castrated mouse models.

Daniela Impellizzieri[1], Elisa Storelli[1], Atik Balla[1], Simone Mosole[1], Cristina Dongilli[1], Federico Jauk[1], Roberta Frapolli[2], Lavinia Morosi[3], Maurizio D'Incalci[3], Jemila Houacine[4], Morris Rosenberg[4], Mohamed Bekradda[4], Esteban Cvitkovic[4], **Carlo V. Catapano**[1]

[1]Institute of Oncology Research (IOR), Bellinzona, Switzerland,[2]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy,[3]IRCCS Humanitas Research Hospital, Milan, Italy,[4]T.O.A.D. Oncology SA, Geneva, Switzerland

Patients with metastatic castration-resistant prostate cancer (mCRPC) who progress on androgen deprivation therapy (ADT) have limited therapeutic options. Prostate-specific membrane antigen (PSMA) is a type II transmembrane glycoprotein highly expressed in mCRPC and is a validated target for precision medicine approaches. TD001 is a novel antibody-drug conjugate (ADC) composed of a deimmunized anti-PSMA IgG1 monoclonal antibody (HuJ591) conjugated to a highly stable protease-cleavable topoisomerase I inhibitor (exatecan) proprietary linker-payload (LD038) with a drug-to-antibody ratio (DAR) of 8. TD001 was evaluated in vivo in human cell line-derived xenograft (CDX) models with high PSMA expression (LNCaP-abl; ~10^4 ligands/cell) or intermediate/heterogeneous PSMA expression (22Rv1; ~10^2-10^4 ligands/cell) in castrated NRG mice, and in the high PSMA-expressing (~10^5 ligands/cell) patient-derived xenograft (PDX) model C5 in non-castrated NRG mice. Of note, PSMA expression increased upon castration in both CDX models, mimicking the clinical condition of the target patient population. After single IV administration across a wide range of doses (up to 20 mg/kg), TD001 achieved dose-dependent, potent tumor growth inhibition (TGI) not only in the high-PSMA LNCaP-abl CDX and C5 PDX models but also in the intermediate-PSMA 22Rv1 CDX model. Rapid responses and high TGI (>90%) after a single administration at optimal doses were seen across all models. Upon tumor regrowth, PSMA expression was unchanged between treated and vehicle control groups, indicating no impact on target expression. Recurrent tumors remained similarly responsive to rechallenge with TD001. Of note, fractionation of a single TD001 dose into 2 or 3 doses administered every 10 days resulted in persistent tumor regression (TGI ≥90% for 60-70 days) and extended survival compared to the equivalent higher single dose. TD001 was well tolerated with no body weight loss or other signs of toxicity, nor mortality at all doses after single and repeated dosing regimens. Alternative dosing schedules, dose response, and tumor/plasma ratio result in a 2-3 fold increase in therapeutic index (TGI ≥90% for up to 60 days). TD001 appears as a best-in-class anti-PSMA ADC with its novel linker-payload (LD038) and exhibits potent antitumor activity in preclinical models with a broad range of PSMA expression, representing a highly promising treatment for PSMA-expressing CRPC patients. The efficacy of TD001 in preclinical in vivo castrated CDX and PDX models supports further investigation in clinical settings.

#3116 High-definition spatial transcriptomics reveals microenvironment features associated with resistance to anti-PD1 therapies in lung cancer.

Corinne Ramos, Sandra Delebecq, Richard Ruez, Victor Senechal

R&D, Aliri, Lille, France

Introduction: Primary resistance to immune checkpoint inhibitors (anti PD1) presents a significant hurdle in lung cancer treatment. Tumor microenvironment (TME) features, particularly within the immune compartment, are central to shaping therapeutic response. This study employs high-definition spatial transcriptomics to identify biomarkers and mechanisms underlying resistance.
Methods: Formalin-fixed, paraffin-embedded (FFPE) lung cancer tissues from patients resistant to anti PD1 therapies were analyzed using the Visium HD spatial transcriptomics platform. Unsupervised clustering of spatial transcriptomics data was performed to identify distinct gene expression patterns within the immune compartment. Tissue morphology was integrated with gene expression profiles to map spatial heterogeneity.
Results: Our in-depth analysis of lung cancer tumor samples, utilizing high-throughput spatial transcriptomics and multiplexed immunohistofluorescence (IHF), revealed that primary resistance to PD1 PDL1 therapies is associated with a distinct tumor microenvironment. Unsupervised clustering of spatial transcriptomics data identified clear groupings that differentiated responders from resistant patients, based on immune compartment gene expression profiles. This analysis highlighted a suppression of immune-activating pathways and enrichment of immunosuppressive signals in resistant tumors, particularly within peritumoral regions. These findings underscore the pivotal role of the tumor microenvironment in modulating the likelihood of response to PD-1 blockade.
Conclusion: This study underscores the transformative potential of high-definition, single-cell scale spatial transcriptomics in revealing microenvironmental features associated with primary resistance to PD1 therapies in lung cancer. By enabling precise spatial evaluation of the tumor microenvironment, the identified biomarkers offer a robust foundation for developing predictive tools and personalizing immunotherapy strategies for improved patient outcomes.

#312 Comprehensive characterization of DT-7012, a differentiated CCR8-depleting antibody for the treatment of solid tumors.

Helene Lelievre, Melanie Frauli, Maria Dolores Garcia Fernandez, Dounia Chraa, Luc Baron, Aurelie Janvier, Iseulys Richert, Solene Rose, Katia Saulnier, Malaury Schappler, Christel Franchet, Orphee Blanchard, Thibaut Brugat, Stephan Schann, **Nathalie Lenne**

Domain Therapeutics, Illkirch-Strasbourg, France

Background: CCR8 is a chemokine G-protein coupled receptor predominantly expressed on tumor-resident regulatory T cells (Tregs), which suppress anti-tumor immunity. DT-7012 is a highly differentiated, fully humanized monoclonal antibody designed to deplete CCR8+ Tregs through Fc-mediated mechanisms, including antibody-dependent cellular cytotoxicity (ADCC) and phagocytosis (ADCP). This study aimed to characterize the binding properties, effector functions, and Treg-depleting activity of DT-7012 to support its clinical development, planned for early 2025.
Methods: Binding assays: The binding affinity of DT-7012 to human CCR8 was assessed using flow cytometry on a variety of CCR8-expressing cell lines and native Tregs. Specificity against native circulating immune cells as well as membrane and secreted targets have been investigated. Functional assays: ADCC and ADCP activities were evaluated using gene reporter assays or various target:effector killing assays. Treg depletion: Ex vivo studies were conducted using blood samples from patients with non-small cell lung cancer (NSCLC) to quantify DT-7012-mediated depletion of CCR8+ Tregs.Results: DT-7012 displayed high-affinity binding to human CCR8 and selectively recognized CCR8 without cross-reactivity to other targets including chemokine receptors. In vitro, DT-7012 induced robust ADCC and ADCP activities on all tested CCR8-expressing cells, including in presence of CCL1. Ex vivo treatment with DT-7012 resulted in significant depletion of CCR8+ Tregs from NSCLC patient samples without affecting other immune cell populations. Together, these results demonstrate the high potency and selectivity of DT-7012. Preliminary safety studies confirmed the good tolerability of DT-7012 in rat and monkey. Additional data are ongoing and will be presented.
Conclusions: DT-7012 exhibits high-affinity binding to CCR8, potent Fc-mediated effector functions, and selective depletion of CCR8+ Tregs in NSCLC patient samples as well as a good safety profile. These findings highlight the therapeutic potential of DT-7012 as a novel strategy to enhance anti-tumor immunity and support its upcoming clinical development.

#313 Discovery of novel CXCR4 targeting compounds with antitumor activity in preclinical models of diffuse large B-cell lymphoma.

Miranda Fernandez-Serrano[1], Nuria Profitos-Peleja[1], Judith Camalo-Vila[2], Miquel Martinez-Asensio[2], Jordi Teixido[2], Jose I. Borrell[2], Albert Gibert[2], Raimon Puig de la Bellacasa[2], Roger Estrada-Tejedor[2], Gael Roue[1]

[1]Josep Carreras Leukaemia Research Institute, Badalona (Barcelona), Spain,[2]Pharmaceutical Chemistry Group, IQS School of Engineering, Ramon Llull University, Barcelona, Spain

The constitutive activation of CXC motif chemokine receptor 4 (CXCR4) is strongly implicated in tumor progression, metastasis, invasion, and chemotherapy resistance. In diffuse large B-cell lymphoma (DLBCL), the most common subtype of mature B-cell non-Hodgkin lymphoma, CXCR4 activation is associated with poor prognosis. Previous attempts to target CXCR4 in this disease using tetraamine-based inhibitors (CXCR4-i) have been limited by suboptimal pharmacological properties. Using structure-based drug design, we identified novel CXCR4-i candidates with potential anti-lymphoma activity. A library of 31 highly pure compounds was synthesized and evaluated for cytotoxicity in DLBCL cell lines via the MTT assay. Four compounds showed concentration-dependent antiproliferative effects, with 46-59% and 57-96% inhibition at 30 μM and 50 μM, respectively. The most potent compound, IQS-022, achieved up to 96% viability reduction at 50 μM, with an IC_{50} of 45.5 μM at 24 hours across seven DLBCL cell lines representing the ABC and GCB subtypes. In an immunocompetent chicken chorioallantoic membrane (CAM) DLBCL xenograft model, 50 μM IQS-022 reduced tumor area by 36.5% and decreased tumor B-cell infiltration in the heart and bone marrow by 54.7% and 74.2%, respectively. However, treatment led to >30% embryo weight loss, indicating limited selectivity, as corroborated by off-target effects in human peripheral blood mononuclear cells (PBMCs). To address this limitation, five new tetraamine derivatives were synthesized. Among these, IQS-036 demonstrated similar potency (IC_{50} = 38.14 μM at 24 hours) but significantly improved selectivity, reducing DLBCL cell viability by 52% at 30 μM while sparing PBMCs (10% viability reduction). Flow cytometry revealed that 94-97% of DLBCL cells underwent apoptosis after 24-hour exposure to 50 μM IQS-036, whereas the standard CXCR4-i, Plerixafor, showed minimal apoptogenic effects. IQS-036 exhibited concentration-dependent CXCR4 occupancy (64% at 20 μM) and decreased sensitivity in CRISPR-engineered NALM6-$CXCR4^{KO}$ cells compared to wild-type counterparts. In vivo, 30 μM IQS-036 inhibited tumor growth by 42% in NALM6-$CXCR4^{WT}$ xenografts without systemic toxicity, whereas CXCR4-knockout tumors were unresponsive. These findings establish CXCR4 as a viable therapeutic target in DLBCL and identify IQS-036 as a potent, selective, and specific CXCR4 inhibitor with significant antitumor activity in lymphoid neoplasms.

#314 Improved tumor penetration and cytotoxic payload release with TD001, a novel PSMA-targeting ADC with optimized linker-payload composition, in PSMA-expressing CRPC CDX castrated mouse models.

Daniela Impellizzieri[1], Elisa Storelli[1], Atik Balla[1], Simone Mosole[1], Cristina Dongilli[1], Federico Jauk[1], Roberta Frapolli[2], Lavinia Morosi[3], Maurizio D'Incalci[3], Jemila Houacine[4], Morris Rosenberg[4], Berangere Deleglise[4], Esteban Cvitkovic[4], Carlo V. Catapano[1]

[1]Institute of Oncology Research (IOR), Bellinzona, Switzerland,[2]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy,[3]IRCCS Humanitas Research Hospital, Milan, Italy,[4]T.O.A.D. Oncology SA, Geneva, Switzerland

Prostate-specific membrane antigen (PSMA), a type II transmembrane glycoprotein belonging to the folate receptor family, is highly expressed in metastatic castration-resistant prostate cancer (mCRPC), and increases following androgen deprivation therapy (ADT). PSMA is a validated diagnostic and therapeutic target for radioligands and antibody-drug conjugates (ADCs). TD001 is a novel ADC composed of a deimmunized anti-PSMA IgG1 monoclonal antibody (HuJ591) conjugated to a highly stable protease-cleavable proprietary linker and the potent Topo I inhibitor exatecan payload. The LD038 linker-payload leverages exatecan's ability to stabilize Topo I-DNA complexes and induce DNA damage and cell death. We tested TD001 in 2D and 3D cell cultures and in vivo in human CRPC xenograft models with different levels of PSMA expression. We evaluated cell internalization, payload release, and drug activity by flow cytometry, immunohistochemistry, and immunofluorescence microscopy. Free payload levels were measured 24 h post treatment in plasma and tumors by LC-MS/MS. TD001 showed efficient binding and rapid internalization within 1-3 h followed by lysosomal localization and payload release in PSMA-expressing cells. Due to the quick and effective payload release, TD001 exhibited selective and potent activity with the induction of Topo I-mediated DNA damage (gamma-H2AX) and apoptosis (cleaved caspase 3). TD001 had no effect on PSMA-negative cells. This was supported by 3D cell culture models, which demonstrated rapid diffusion into the extracellular matrix, and rapid internalization of TD001 into PSMA-expressing tumor cells. TD001 was evaluated in vivo in three CRPC xenograft models with different PSMA expression patterns: the high/homogenous (~10^4 ligands/cell) PSMA-expressing LNCaP-abl cell line-derived xenograft (CDX) castrated mouse model, the intermediate/heterogeneous (~10^2-10^4 ligands/cell) PSMA-expressing 22Rv1 CDX castrated mouse model, and the AR-positive, high/homogenous (~10^5 ligands/cell)-PSMA-expressing patient-derived xenograft (PDX) C5 mouse model. The LD038 linker-payload in TD001 resulted in high free payload release within tumor tissue, triggering DNA damage, cell death, and growth arrest. Notably, tumor uptake and a very high tumor/plasma ratio (70-100 fold) of exatecan were similar 24 h after IV administration in all three in vivo models despite substantial differences in PSMA expression and heterogeneity. These findings highlight the ability of TD001 to deliver effectively and selectively the payload exatecan to PSMA-positive prostate tumors, resulting in potent antitumor activity in different CRPC models, including those with intermediate and heterogenous PSMA expression.

#315 Dose-response and tumor size at time of treatment with TD001, a novel ADC against PSMA, drive potent tumor growth inhibition in a CRPC CDX castrated mouse model.

Roberta Frapolli[1], Ezia Bello[1], Marina Meroni[1], Daniela Impellizzieri[2], Elisa Storelli[2], Carlo V. Catapano[2], Lavinia Morosi[3], Maurizio D'Incalci[3], Jemila Houacine[4], Esteban Cvitkovic[4]

[1]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy,[2]Institute of Oncology Research (IOR), Bellinzona, Switzerland,[3]IRCCS Humanitas Research Hospital, Milan, Italy,[4]T.O.A.D Oncology SA, Geneva, Switzerland

Prostate-specific membrane antigen (PSMA), a type II transmembrane glycoprotein belonging to the folate receptor family, is highly expressed in metastatic castrate-resistant prostate cancer (CRPC), and increases following androgen deprivation therapy. TD001 is a novel antibody-drug conjugate (ADC) composed of a deimmunized anti-PSMA IgG1 monoclonal antibody (HuJ591), which binds to the extracellular domain of PSMA, conjugated to a proprietary cleavable topoisomerase I inhibitor exatecan linker-payload (LD038), with a drug-to-antibody ratio (DAR) of 8. Flow cytometry and immunofluorescence microscopy show TD001 is internalized and cleaved rapidly, colocalizing with lysosomes in PSMA-expressing tumor cells. TD001 (10-20 mg/kg IV) was evaluated in a human CRPC cell line-derived xenograft (CDX) model, LNCaP-abl with high PSMA expression, in castrated NSG mice, with a range of tumor sizes (from 150 to 700 mm3) at the time of treatment. TD001 gave dose-dependent and sustained potent activity (tumor growth inhibition [TGI] >80%) with single dosing. Sustained inhibition of regrowth for 20 days was observed after TD001 10 mg/kg even in large tumors up to 400 mm^3. Strong antitumoral activity of a single dose of TD001 10 mg/kg was also observed even in tumors >400 mm^3 at the time of treatment. Tumor regrowth was faster in larger tumors (mean volume ~300-400 mm3) compared to smaller tumors (mean volume ~200 mm3). PSMA expression was unchanged in tumor regrowth between treated and vehicle control in the CDX castrated mouse model after treatment with TD001 up to 20 mg/kg, indicating no impact on target expression. Fractionation of a single TD001 dose into 2 or 3 doses administered every 10 days resulted in a 2-3 fold higher therapeutic index (TGI >90%) compared to the equivalent higher single isodose. No mortality or weight loss was reported. Pharmacokinetics/pharmacodynamic correlations of TD001 are described separately. TD001 appears as a best-in-class anti-PSMA Topo I inhibitor ADC (exatecan payload), and exhibited potent and sustained antitumor activity, including in large tumors, and represents a promising new treatment for PSMA-expressing CRPC patients.

#316 Translational studies of HDM2012, a novel topoisomerase inhibitor ADC targeting MUC17, in patient derived GC, CRC, PDAC tumor models.

Qinyu Shu, zhaofeng qin, Shengxing Zhao, Yang Chen, Kuan Lu, Qian Zhang, Liubin Guo, Qingli Wei, Hao Pan, **Yan Xia**, Hongwen Li, Dongzhou Jeffery Liu

Huadong Medicine Co., Ltd., Hangzhou, China

Introduction: Mucin-17 (MUC17) is a transmembrane glycoprotein, expressed on the apical membrane of normal gastrointestinal mucosal epithelial cells, play important roles in preventing infection at mucosal surfaces[1-2]. MUC17 is a promising target for ADC development due to its highly expressed in gastric, colon and pancreatic cancers, but limit normal organs expression.
Methods: HDM2012 is a MUC17 targeting ADC, consisting of a topoisomerase inhibitor via a cleavable liker with average drug antibody ratio (DAR) 8. The efficacy and safety of HDM2012 was tested in patient derived xenograft (PDX) models and monkeys, respectively.
Results: HDM2012 showed target dependent anti-tumor activity and by-stander effect in vitro. HDM2012 exhibits good efficacy in PDX and CDX models. In gastric PDX models, HDM2012 demonstrated dose dependent efficacy, with TGI (tumor growth inhibition) value of 82-93%, regardless of prior Ironitecan and Top-I ADC treatment. In heavily pre-treated colon cancer PDX models, HDM2012 induced prolonged tumor regression, with TGI value of 94.6%. Furthermore, in MUC17 low expression pancreatic PDX models, HDM2012 could induce sustained tumor regression, with TGI value of 91.5%. In exploratory toxicology study, HDM2012 is well tolerated by cynomolgus monkeys at 45 mpk.
Conclusion: Here, we reporting a novel ADC product HDM2012 targeting MUC17, is a potential therapeutic approach for MUC17 positive GC, CRC, PDAC cancer treatment. All the experiment data indicated HDM2012 may be a promising candidate for GI cancer treatment.

#317 Discovery of HDM2017, a CDH17-targeting ADC for colorectal cancers.

Chen Lin, **Yan Xia**, Liubin Guo, Yang Chen, Tingyang Wang, Kuan Lu, Hao Pan, Yayun Zhao, Jie Fang, Hongwen Li, Dongzhou Jeffery Liu

Huadong Medicine Co., Ltd., Hangzhou, China

Introduction: Cadherin 17 (CDH17) is a cell-to-cell adhesion protein that is a member of the cadherin superfamily. CDH17 is frequently overexpressed in colorectal cancer (CRC), gastric cancer (GC) and pancreas cancer (PC)1. HDM2017 ADC comprises a human monoclonal antibody specifically targeting CDH17 and chemically conjugated to CPT-derivative payloads. HDM2017 is undergoing IND-enabling studies.
Methods: In vitro and in vivo preclinical studies were conducted in the discovery of HDM2017 against gastrointestinal cancers. Initial investigations on plasma stability were performed. Exploratory toxicity assessments were carried out in cynomolgus monkeys and rats.
Results: HDM2017 demonstrates excellent cell binding activities with CRC and GC cells, with an EC50 ranging between 0.1-1.0nM. Additionally, HDM2017 exhibits strong target-mediated internalization activities, achieving an internalization efficiency of 43-75%. The HDM2017 ADC displays potent expression-dependent in vitro anti-tumor activity in a range of CDH17 expressing tumor cell lines. Treatment with HDM2017 ADC resulted in significant inhibition of tumor growth in xenograft models of CDH17+ human CRC (71~97% TGI) and GC (71~90% TGI). HDM2017 ADC exhibited excellent stability in human, monkey, and rat plasma with a drug shedding rate below 0.5%. Toxicity studies primarily revealed payload-related toxicity profile, which supports further development of the ADC molecule. Analysis using CDH17 IHC assay on patient tissues showed detectable expression of CDH17 in 90% (29/29) cases of colorectal cancer, 70% (7/10) cases of gastric cancer and 65% (13/20) cases of pancreas cancer.
Conclusion: HDM2017ADC exhibited potent cytotoxicity in vitro and in vivo anti-tumor activity in various gastrointestinal cancer models. The preclinical activity and safety profile warrants further clinical development with biomarker strategy. Overall, the preclinical data presented here suggests that HDM2017 ADC has the potential to provide clinical benefit to gastrointestinal cancer patients.

#318 Optimal free exatecan payload tumor/plasma ratio of TD001, a new ADC against PSMA, in CRPC CDX mouse models.

Lavinia Morosi[1], Daniela Impellizzieri[2], Roberta Frapolli[3], Elisa Storelli[2], Atik Balla[2], Carlo V. Catapano[2], Jemila Houacine[4], Esteban Cvitkovic[4], **Maurizio D'Incalci**[1]

[1]IRCCS Humanitas Research Hospital, Milan, Italy,[2]Institute of Oncology Research (IOR), Bellinzona, Switzerland,[3]Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy,[4]T.O.A.D. Oncology SA, Geneva, Switzerland

Prostate-specific membrane antigen (PSMA), a type II transmembrane glycoprotein folate receptor, is highly expressed in metastatic castrate-resistant prostate cancer (CRPC) and expression increases following androgen deprivation therapy. TD001 is a novel antibody-drug conjugate (ADC) composed of a deimmunized anti-PSMA IgG1 monoclonal antibody (HuJ591), conjugated to a highly stable, protease-cleavable proprietary Topo I inhibitor exatecan linker-payload (LD038), with a drug-to-antibody ratio (DAR) of 8. Free payload and total ADC were evaluated in mouse plasma, tumor, and liver, after TD001 10 mg/kg IV (which has potent antitumor activity in vivo) in 2 human CRPC cell line-derived xenograft (CDX) models, LNCaP-abl (high PSMA expression ~10^4 ligands/cell) and 22Rv1 (intermediate/heterogeneous PSMA ~10^2-10^4 ligands/cell) in castrated NRG/NSG mice. The TD001 PK profile was characterized across a wide temporal span post treatment, in LNCaP-abl (5 min to 10 days) and 22Rv1 (2 h to 6 days). The PK/PD profile of a range of doses (3-20 mg/kg) was characterized in both models. Dose proportional free exatecan concentrations were observed in tumor and plasma, and a consistently high tumor/plasma (T/P) ratio (~70-100 fold) was seen in both tumor models across the range of TD001 doses tested. Potent tumor growth inhibition (TGI) was dose dependent up to 20 mg/kg. PK/PD and the high therapeutic index with different dosing schedules are presented separately. Free exatecan was detected in tumors 5 min post treatment in LNCaP-abl. Free exatecan concentrations were approximately 80x higher in tumor compared to plasma 2 h post treatment, and at least 100x higher from 6 h to 6 days post treatment, showing rapid and high distribution of TD001 to the targeted tumor tissue regardless of PSMA expression levels. The concentration of total ADC (assuming constant DAR 8) was ~200 µg/mL (5 min post treatment), remained high for up to 6 days post treatment, while decreasing gradually from 24 h allowing for prolonged tumor exposure to TD001. The high and prolonged T/P ratio supports the excellent therapeutic index observed in TGI studies in both CDX castrated mice models, with TGI >90% and good tolerance (described separately). Of note, exatecan plasma levels rapidly declined under 0.5 ng/mL (from 24 h) and were under the limit of quantification (0.1 ng/mL) 10 days post treatment, preventing systemic toxicity. No free exatecan accumulation was observed after repeat dosing (described separately). TD001 effectively and preferentially delivers the potent exatecan payload to tumor tissue, with minimal systemic exposure, contributing to an excellent therapeutic index and strong antitumor activity in multiple CRPC models with high or intermediate PSMA expression. Our preclinical PK data support clinical development of TD001 in PSMA-expressing CRPC patients.

#319 Testing of trispecific antibodies for treating multiple myeloma using the Membrane Proteome Array.

Lewis Joe Stafford, J. Tabb Sullivan, Carmen T, Navia, Amelia M. Snyder, Diana M. Norden, Benjamin J. Doranz

Integral Molecular, Philadelphia, PA

Background: Assessment of off-target antibody reactivity is a regulatory requirement prior to clinical development; however, conventional screening methods are frequently ineffective in screening newer therapeutic modalities including multispecifics and CAR-T cell therapies. This presents an issue for T-cell engaging therapeutics that require exquisite specificity, as even minimal cross-reactivity could result in non-target cell killing accompanied by serious or even life-threatening consequences.
Methods: We developed the Membrane Proteome Array (MPA)—containing 6,000 human proteins—as a comprehensive approach to identify off-target protein interactions. The MPA is a cell-based protein array that assesses binding interactions in native, unfixed cells, allowing for quantitative and high sensitivity detection using flow cytometry. The MPA has been used to test specificity of over 1000 therapeutic molecules, including conventional MAbs and newer biotherapeutic modalities, including scFv, VH/VHH, and bispecific molecules, as well as other protein modalities.
Results: We used the MPA to evaluate the specificity of several multispecific antibody candidates targeting the G protein-coupled receptor GPRC5D, a promising target for multiple myeloma. Here we tested a panel of GPRC5D bispecifics using a CD3 targeting arm, as well as trispecific antibodies targeting GPRC5D, BCMA, and CD3. The MPA was successfully able to assess specificity of these molecules, showing compatibility with screening trispecifics. As a result, lead candidates devoid of cross-reactivity were identified for further development. The MPA has also been used to rapidly evaluate the specificity of novel CAR-T cell therapies for cancer and autoimmunity.
Conclusions: The MPA is compatible with screening of multispecifics, has been used for lead selection, and has been used in numerous successful regulatory applications for antibody-based therapies. The MPA is currently being developed as an FDA-qualified Drug Development Tool.

#32 Efficacy and tolerability of a enantiomer of Edelfosine (S-CP201) in pancreatic cancer PDX models as a single agent and in combination with approved drugs in clinical use.

Michael Ahrweiler, Wolfgang Meyer, Axel Zander, Daniel Perrissoud

RDP Pharma AG, Romanshorn, Switzerland

The anticancer alkylphospholipid Edelfosine incorporates into cell membrane lipid rafts, inducing apoptosis via CD95 and inhibiting AKT3/PI3K, phospholipase C, and protein kinase C. It disrupts cholesterol and phosphatidylcholine metabolism, and has antiangiogenic and antimetastatic effects. It's preferentially taken up by malignant cells, showed efficacy in xenografts (including metastatic breast and prostate cancer), and phase 2 trials across tumors. The main adverse events were reversible, dose-dependent gastrointestinal toxicity. Due to PK and PD advantages of Edelfosine's S-enantiomer (S-CP201), further development has focused on S-CP201. Inter alia its efficacy was tested in patient-derived xenograft (PDX) pancreatic cancer models in immunodeficient mice. Initial testing used NSG mice with s.c. implanted PNX0001 pancreatic cancer PDX cells. Treatment groups included S-CP201, R-CP201 (20 mg/kg p.o. each; given for 5 days/week over 3 w.), Gemcitabine (Gem.;) (50 mg/kg i.p., 3 d./w. over 3 w.), and vehicle. S-CP201, R-CP201, and Gem. showed tumor growth inhibition (TGI) of 57%, 33%, and 40%, respectively, with all mice on active treatment surviving the treatment period. Treatments were well tolerated. In a similar study, Gem. and S-CP201 were combined. Three groups of mice were allocated: 5 mg/kg p.o. for S-CP201 plus i.p. Gem.; 20 mg/kg S-CP201 plus i.p. Gem.; Gem. doses see above; vehicle; 3 w. treatment. The 20 mg/kg combination group exhibited the best TGI (85%), equal to stable disease in patients. The tolerability of the active groups was comparable. The antitumor efficacy of S-CP201 (20 mg/kg p.o. over 3 w.) was assessed when given in triple combination with Gem. and albumin-bound Paclitaxel in clinically relevant doses with a TGI of 67% (matching partial response in patients), compared to 57% for Gem. and albumin-bound Paclitaxel. Additional studies with S-CP201 (20 mg/kg daily p.o. over 3 w.) and Gem. (240 mg/kg, 1x/w. over 3 w.) testing 9 pancreatic adenocarcinoma PDX models in NMRI mice showed limited efficacy for S-CP201 alone, with modest activity in PAXF2141 and PAXF2146 (tumor/control ratio [T/C] ~57%). Gem. alone was modestly effective only in PAXF2196 (T/C ~50%). Combination therapy achieved borderline efficacy (T/C 51%-59%) in models PAXF2141, PAXF2146, and PAXF1986, and significant TGI in PAXF1900, PAXF2196, and PAXF2116, with T/C values of 31%, 35%, and 47% ($p<0.05$). PAXF2141, PAXF2146, and PAXF2116 harbor Ras mutations: (G12R, G12V, G12R respectively). Weight loss was minor but rose in 4 combination groups. Survival rates stayed high across all models. These results support clinical trials of S-CP201 as an effective combination partner for Gem. and/or albumin-bound Paclitaxel in pancreatic adenocarcinoma, including in patients with tumors containing mutated Ras. An IND enabling data package is underway.

#320 CRISPR-mediated glypican-3 genome editing via ultra-large porous silica nanoparticles in hepatocellular carcinoma therapy.

S. Lee[1], S. Lee[2], H. Lee[2], S. Kim[3], D.-H. Kim[1];

[1]Feinberg School of Medicine, Northwestern University, Chicago, IL, [2]Korea Institute of Science and Technology (KIST), Seoul, Korea, Republic of, [3]Gyeongsang National University, Jinju, Korea, Republic of

Purpose: We aim to develop non-viral nanocarriers to deliver ribonucleoproteins (RNP) targeting Glypican-3 (GPC3) and investigate the biological and immunological therapeutic effects from CRISPR-Cas9 GPC3 gene editing in hepatocellular carcinoma (HCC).
Methods: Ultra-large porous silica nanoparticles (ULSN) were synthesized following established methods, with morphology confirmed via electron microscopy. ULSN-loaded Cas9-RNP was characterized using Zetasizer NS90, and RNP content measured by NanoDrop and BCA assays (ThermoFisher). *In vitro* experiments were performed on HepG2 (HB-8065, ATCC) and Hepa1-6 (CRL-1830, ATCC) cells. Gene deletion was assessed via RT-PCR, deep sequencing (Illumina MiniSeq), and cell viability. Western blotting analyzed key signaling pathways. *In vivo* GPC3 genome editing was evaluated in Hepa1-6 orthotopic HCC models (C57BL6, male, 6-7 weeks) using T7E1 assay and T cell infiltration analysis. GPC3 targeting therapeutic effects were compared with Codrituzumab (anti-GPC3) treatment in HepG2-bearing HCC models (Balb/c, male, 6-7 weeks) by measuring tumor volume, immunohistology (H&E, Ki67, and GPC3), serum GPC3, and T cell populations from tumor-draining lymph nodes using flow cytometry (BD).
Results: ULSN exhibited a size of 300 nm, pore size of 22.86 nm, and surface area of 525.9 m^2/g as determined by TEM and BET analyses. Its ultra-large pores allowed a 27% loading capacity for Cas9-RNP, with a loading efficiency of 98% for both sgRNA and Cas9, compared to 48% and 52% for Lipofectamine (commercial control), respectively. In HepG2 cells, GPC3 deletion showed 67% reduction in RT-PCR, 15% indel frequency (vs. 3% for Lipofectamine), and reduced cell viability (55% vs. 94%). To analyze the molecular effects of GPC3 gene, Wnt and Hippo/YAP signaling were examined. Western blotting revealed downregulation of Wnt signaling (lower level of Wnt, p-LRP, and β-catenin), upregulation of Hippo signaling through increased LATS phosphorylation, and decreased YAP phosphorylation, potentially inhibiting tumor cell proliferation. In orthotopic HCC models, ULSN showed targeted accumulation in liver tissues, successfully achieving GPC3 deletion with complete tumor regression 14 days post-procedure. Tumor cell death led to enhanced $CD4^+$ and $CD8^+$ T cell infiltration, alongside a decrease in regulatory T cells. Additionally, ULSN-mediated GPC3 gene editing outperformed Codrituzumab (GPC3 blockade) by reducing tumor establishment, Ki67 and GPC3 expression levels in tumor cells.
Conclusions: ULSN presents strong potential as a non-viral delivery system for CRISPR-Cas9 RNP targeting GPC3 in HCC, offering improved gene delivery efficiency over lipid-based nanomaterials. This approach not only enhances tumor growth suppression, but also promotes T cell infiltration, ensuring effective and lasting therapeutic outcomes through GPC3 deletion.

#321 BTE-EN1, a novel acting heterobifunctional compound inhibiting bone destruction by established prostate cancer bone metastasis.

Fangfang Qiao[1], Ryan Gordon[2], Abhinandan Pattanayak[3], Katelyn O'Neill[1], Weining Chen[1], Prathap R. Mukthapuram[1], Amar Natarajan[1], Raymond Bergan[1]

[1]Eppley Institute for Research in Cancer and Allied Diseases, University of Nebraska Medical Center, Omaha, NE,[2]Division of Hematology/Oncology, Knight Cancer Institute, Oregon Health & Science University, Portland, NE,[3]Oregon Health & Science University, Portland, OR

Bone destruction by prostate cancer (PCa) metastasis is a major cause of morbidity and mortality. In order to destroy bone, PCa and bone cells stimulate each other in a process that requires their coordinated movement within bone itself. To therapeutically inhibit this process, we synthesized the first-in-class heterobifunctional compound, BTE-EN1. One group is a selective inhibitor of cancer cell motility, discovered by us (Nature Communications 2018). It is chemically coupled to a bisphosphonate group, which binds to bone mineral and enables targeted delivery of the therapeutic to bone-destructive lesions. We sought to test whether BTE-EN1 would be active against well-established bone-destructive PCa metastasis and to evaluate its potential as a therapeutic.

We used the state-of-the-art caudal artery injection model to selectively deposit human PCa cells into the long bones of the leg in mice and let them grow for two weeks, thus emulating the scenario of established disease in patients. We then began weekly administration of BTE-EN1 for six weeks, quantified bone destruction by CT imaging and demonstrated a significant decrease in bone destruction by 62%, compared to control. In a separate study, BTE-EN1 treatment prior to intra-cardiac injection of PCa cells led to dose-dependent significant prolongation of life, a finding not seen with bisphosphonate and denosumab therapies. Comprehensive in vitro studies demonstrate that BTE-EN1 retains the cellular and molecular pharmacologic and pharmacodynamic properties of its two functional groups. BTE-EN1 exhibited no toxicity when mice were treated at a dose 4000-fold higher than that showing efficacy and lacked toxicity in the NCI-60 cell line panel screen. Additional studies supporting translation to the clinic include non-interference with therapy used to treat advanced PCa, as well as inhibition of cell motility across a panel of human cancer cell types associated with bone destruction.

In conclusion, BTE-EN1 is a first-in-class highly active heterobifunctional compound that inhibits bone destruction in established PCa bone metastasis and is well tolerated. Our data strongly suggests that BTE-EN1 has high potential for translation into humans and constitutes a novel therapeutic strategy.

#322 Nonclinical characterization of the secondary mechanisms of action of PF-08046054 (PDL1V), a novel vedotin ADC directed to PD-L1 that selectively depletes tumor cells without depleting healthy immune cells.

Megan Atkins Ramirez, Midori Clarke, Steven Jin, Ellie Moskovitz, Andres Forero-Torres, Garrett Cornelison

Pfizer Oncology, Bothell, WA

PDL1V is a novel vedotin antibody drug-conjugate (ADC) currently in Phase I clinical development for advanced solid tumors as a monotherapy or in combination with pembrolizumab (NCT05208762). The primary mechanism of action (MOA) of PDL1V is direct cytotoxicity to PD-L1-expressing tumor cells via the intracellular delivery of MMAE. While PD-L1 is an established checkpoint protein, pharmacokinetic data suggest steric checkpoint inhibition by PDL1V may be limited by the dose and schedule being evaluated in the clinic. Here, we characterized additional antitumor MOAs of PDL1V, including bystander killing and immunogenic cell death (ICD), and evaluated the effects of PDL1V on immune cells.

PDL1V is potently cytotoxic to a variety of PD-L1-positive cancer cell lines *in vitro.* Using a flow cytometry-based viability assay, we showed that PDL1V also drives dose-dependent bystander effect-based cytotoxicity of PD-L1-negative tumor cells when co-cultured with PD-L1-positive tumor cells. ICD, a regulated activation of immune cell recruitment to the TME, is caused by tumor cell release of damage-associated molecular patterns (DAMPs) such as cell surface chaperone calreticulin (CRT), extracellular adenosine triphosphate (eATP), and High Mobility Group Box 1 protein (HMGB1). PD-L1-positive cancer cells treated with PDL1V *in vitro* released all three DAMPs, suggesting that targeted delivery of the MMAE payload drives induction of ICD.

As an immune checkpoint protein, PD-L1 is expressed on antigen presenting cells and T cells. Depletion of these cells could affect the tolerability of PDL1V as a monotherapy, or limit efficacy in combination with anti-PD-1 therapies. To investigate the potential for immune cell depletion, macrophages, CD4+ T cells, and CD8+ T cells were evaluated in an *in vitro* fluorescence-based cytotoxicity assay. PDL1V had minimal cytotoxic activity across all three cell-types, despite expression of PD-L1. These data support PDL1V as selectively cytotoxic to PD-L1-positive and negative cancer cells of the tumor microenvironment, and not cytotoxic to PD-L1-positive immune cells involved in natural antitumor immunity. Since T cell-driven antitumor immunity is a key driver for the efficacy of PD-(L)1 blockade, these data suggest PDL1V is a promising combination partner with anti-PD-1 immunotherapies such as pembrolizumab. Future studies will evaluate the effects of PDL1V on immunosuppressive cells, including regulatory T cells and myeloid derived suppressor cells, and the pharmacodynamic effects of PDL1V in syngeneic mouse xenograft models.

Ethics Approval: All procedures performed on animals were in accordance with regulations and established guidelines and were reviewed and approved by an Institutional Animal Care and Use Committee or through an ethical review process.

#323 Preclinical evaluation of SDV2102, a novel PSMA-targeting DAR1 ADC for mCRPC treatment.

Damien Dattler, Fabian Schlimpen, Constantin Semenchenko, Oleksandr Koniev, **Sergii Kolodych**

Syndivia, Strasbourg, France

Metastatic castration-resistant prostate cancer (mCRPC) presents a significant therapeutic challenge due to limited treatment options. Prostate-specific membrane antigen (PSMA) is overexpressed in mCRPC tumors, making it a viable target for antibody-drug conjugates (ADCs). We developed SDV2102, a novel PSMA-targeting ADC designed to enhance tumor penetration and efficacy. SDV2102 utilizes a novel anti-PSMA antibody, D10, selected for its superior antigen-binding properties. The D10 antibody is conjugated with monomethyl auristatin E (MMAE), a tubulin-binding cytotoxic agent to which mCRPC tumors are inherently more sensitive than to topoisomerase I inhibitors. Notably, SDV2102 has a drug-to-antibody ratio (DAR) of 1, allowing for higher dosing and increased efficacy without proportional increases in systemic toxicity, thereby improving the therapeutic index. In vivo efficacy was assessed using the C4-2 cell-derived xenograft (CDX) model, characterized by high PSMA expression. SDV2102 demonstrated significantly greater anti-tumor efficacy than classical DAR4 ADCs constructed with either the generic J591 antibody or the D10 antibody when administered at equivalent doses of MMAE. Additionally, SDV2102 showed potent activity in patient-derived xenograft (PDX) models with low to moderate PSMA expression levels, with some tumors expressing as few as 25,000 receptors per cell. This indicates that SDV2102 may be effective across a spectrum of PSMA expression in mCRPC tumors. Pharmacokinetic studies in rats revealed that SDV2102 has a favorable profile, closely mirroring that of the unconjugated D10 antibody, suggesting maintained antibody-like characteristics in circulation. Dose-response studies in the C4-2 model identified a minimum effective dose of 2.5 mg/kg. Toxicology studies in non-human primates showed no major toxicities at doses up to 24 mg/kg, with the maximum tolerated dose (MTD) not reached, indicating a wide therapeutic window. SDV2102 achieved a therapeutic index of 38, representing a substantial safety margin. These preclinical results support the advancement of SDV2102 into clinical trials as a promising therapeutic candidate for the treatment of mCRPC.

#324 PF-08052666 (SGN-MesoC2; HBM9033), a first-in-class topoisomerase 1 inhibitor-based ADC targeting MSLN, demonstrates potent antitumor activity in preclinical models of ovarian, lung, and colorectal cancers.

Garrett L. Cornelison[1], Meihong Zhang[2], Cui Nie[2], Guangbei Zhu[2]

[1]Pfizer Oncology, Bothell, WA,[2]Nona Biosciences, Natick, MA

Mesothelin (MSLN) is a cell surface molecule that is expressed in its mature form as a 40 kDa protein anchored to the cell membrane through a glycosylphosphatidylinositol linkage. While its expression is limited in normal tissues, MSLN is overexpressed in numerous solid tumors, including ovarian, pancreatic, endometrial, lung and colorectal cancers. Since its discovery, MSLN has been a target of interest for the development of anti-tumor therapeutics across a variety of modalities, including antibodies, CAR-T, and multiple antibody-drug conjugates (ADCs). To-date, anti-MSLN ADCs have focused on the delivery of anti-tubulin payloads, including DM4, MMAE, and tubulysin. While these ADCs have had manageable safety profiles in the clinic, efficacy has been modest. Here we present the nonclinical characterization of PF-08052666 (SGN-MesoC2; HBM9033), a first-in-class topoisomerase 1 inhibitor (TOP1i)-based ADC targeting MSLN. PF-08052666 has been designed to overcome the shortcomings of the previous generation of anti-MSLN ADCs through a novel antibody, differentiated payload, and a higher drug-to-antibody ratio (DAR). PF-08052666 consists of a human IgG1 monoclonal antibody conjugated to a potent camptothecin-based TOP1i payload with a protease cleavable linker at an average DAR of 8. *In vitro*, PF-08052666 drives direct cytotoxicity through delivery of payload to MSLN-positive cells, bystander killing activity on co-cultured MSLN-negative cells, and retains cytotoxicity in the presence of physiologically relevant concentrations of soluble MSLN. *In vivo*, PF-08052666 outperformed a DM4-based anti-MSLN benchmark ADC in cell-line and patient-derived xenograft models across various tumor types, including ovarian, lung, and colorectal cancers. PF-08052666 also outperformed the DM4-based anti-MSLN benchmark ADC in heterogenous xenograft models consisting of ad-mixed MSLN-positive and MSLN-negative cells, demonstrating the increased bystander activity of the TOP1i-based payload of PF-08052666. These data support the ongoing first-in-human phase 1 clinical trial of PF-08052666 in patients with advanced solid tumors, which is currently enrolling (NCT06466187).
Note: All procedures performed on animals were in accordance with regulations and established guidelines and were reviewed and approved by an Institutional Animal Care and Use Committee or through an ethical review process.

#325 Innovative approach in evaluating gap junction functionality using co-cultured spheroids.

Tomas Lugo, Annelise Nguyen, Stephanie Myers

Texas Tech University, Lubbock, TX

In recent years, significant advancements were made in colorectal cancer research, particularly in understanding the role of gap junctions in cancer development and progression. However, challenges persisted in effectively evaluating gap junction functionality within 3D structures without disrupting spheroids or relying on dye-addition methods to the media, which often had limitations. To address these issues, we developed an innovative method for microinjecting dye into a single cell within a multicellular spheroid, enabling real-time analysis of gap junction functionality in living cells. Building on this approach, we aimed to create a more physiologically relevant tumor microenvironment by co-culturing spheroids with fibroblast cells. This setup better replicated the complexity of in-vivo conditions. To further enhance our analysis, we fixed these spheroids at various time points and used immunohistochemistry (IHC) to evaluate dye penetration into the spheroid core. The experimental method involved co-culturing fibroblasts (CCD-112CoN) with colorectal cancer epithelial cells (Caco2, SW620, SW480, or HT-29) in a CelVivo Clinostar reactor to produce spheroids larger than 300 µm in diameter. These spheroids were then microinjected using an Eppendorf FemtoJet 4i Microinjector with a dye mixture containing Texas Red (high molecular weight, 40,000 Da) and Lucifer Yellow (low molecular weight) to assess gap junction activity using a Leica confocal microscope. Additionally, we examined gap junction proteins using an immunofluorescence assay between co-cultured and single-cell cultured spheroids. The results indicated that microinjection was a reliable method for evaluating gap junction functionality within spheroids. Notably, different stages of colorectal cancer modulated dye absorption and transfer, with SW620 spheroids exhibiting lower transfer through cells, while HT-29 spheroids showed increased dye transfer between cells. Furthermore, co-cultured spheroids demonstrated enhanced dye transfer compared to single-cell-type spheroids of the same type. There was an increase in connexin 43 expression based on immunofluorescence in Caco2 with CCD-112CoN spheroids compared to Caco2 and CCD-112CoN single-cell cultures. In conclusion, to our knowledge, this study introduced a novel approach to measuring gap junction activity for spheroids. Furthermore, it highlighted the significant role fibroblasts may play in influencing gap junction dynamics in colorectal cancer cells within complex 3D structures.

#326 Chemotherapies change the NRF2 levels and impact the differentiation and growth of human high grade serous ovarian cancer.

Chelsea Katz[1], Helen Toma[1], Yaas Azmoudeh[2], Nasrine Bendjilali[3], Huseyin Karaduman[4], Hadi Shojaei[5], Gord Zhu[5], Lauren Krill[6], Chu Christina[6], David P. Warshal[6], Yemin Wang[7], Samera Hamad[1]

[1]Surgery Department, Cooper University Health Care, Camden, NJ,[2]Cooper Medical School of Rowan University, Camden, NJ,[3]College of Science and Mathematics, Rowan University, Glassboro, NJ,[4]North Carolina State University, Raleigh, NC,[5]Department of Pathology and Laboratory Medicine, Cooper University Health Care, Camden, NJ,[6]MD Anderson Cancer Center at Cooper, Camden, NJ,[7]Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada

NRF2, an antioxidant gene and anti-inflammatory pathway, is altered in about 50% of high grade serous ovarian cancer (HGSOC), the most aggressive type of ovarian cancer. NRF2 is implicated in the resistance to chemotherapies in several types of cancers. We aimed to understand if treatment with carboplatin or paclitaxel impacts the levels of NRF2 and if that changes the differentiation, growth, and metastasis of HGSOC. We used OVCAR8, a human HGSOC cell line with a basal level of NRF2, and induced overexpression of NRF2 using pIND20 system with $NRF2^{E79Q}$ mutation (one of the most common mutations of NRF2 found in human tumors). Our results showed high growth and invasion in high-NRF2 tumor cells compared to low-NRF2 tumor cells with and without chemotherapies. Treatment with carboplatin inhibits the levels of NRF2 in low-and high-NRF2 versions of OVCAR8. Carboplatin also inhibits the MYC, P63, and CD274 (PD-L1) protein levels, and the epithelial to mesenchymal transition (EMT) pathway (Vimentin). Additionally, in high-NRF2 tumor cells, paclitaxel increases the levels of NRF2, MYC, CD274 (PD-L1), and Vimentin, and decreases the levels of P63. In contrast, low-NRF2 tumor cells treated with paclitaxel show decreased MYC, CD274 (PD-L1) and Vimentin and increased P63. These changes impact the growth and metastasis (by scratch test) of OVCAR8. We found that carboplatin inhibits the growth and invasion while paclitaxel increases the growth and invasion in the high-NRF2 version of OVCAR8. These studies show that carboplatin might be a good option as a single treatment compared to paclitaxel. In addition to the increase in NRF2 and differentiation markers that support the tumor cell growth, paclitaxel also increased the PD-L1 protein levels in high-NRF2 tumor cells which might enhance the efficacy of anti-PDL1. Therefore, combination immunotherapy (anti-PDL1) with paclitaxel may have therapeutic benefit in patients with high-NRF2 HGSOC.

#328 A novel human-like asparaginase - indication expansion made possible.

Amanda M. Schalk[1], Maaike Van Trimpont[2], Ying Su[1], Ashley De Loera[1], Alyssa Garcia[1], Tim Lammens[2], Steven Goossens[2], Arnon Lavie[1]

[1]University of Illinois College of Med. at Chicago, Chicago, IL,[2]Cancer Research Institute Ghent (CRIG), Ghent, Belgium

L-asparaginase (ASNase) has been a cornerstone of pediatric acute lymphoblastic leukemia (ALL) treatment since the 1970s, leveraging a unique mechanism that exploits the metabolic vulnerability of leukemic cells. Cancer cells deficient in asparagine synthetase (ASNS), which rely on blood asparagine, are starved when ASNase depletes asparagine in the bloodstream. While this approach is effective in ALL, preclinical studies suggest that ASNase could also target other ASNS-deficient ($ASNS^{low}$) cancers, including acute myeloid leukemia (AML) and subsets of solid tumors like liver and colorectal cancers. However, the severe toxicity of existing ASNase formulations, largely due to off-target glutaminase activity and immunogenicity, has limited its broader clinical application. To overcome these barriers, we developed a novel human-like mammalian ASNase designed to minimize immunogenicity and eliminate glutaminase-driven toxicity while maintaining high specificity for asparagine. This engineered ASNase demonstrated robust in vitro and in vivo efficacy against both T-cell and B-cell ALL. Notably, it also showed potent activity as a monotherapy in AML, eradicating tumor cells in blood and bone marrow. Beyond blood cancers, this ASNase displayed significant anti-tumor effects against a CRISPR/CAS-9-engineered melanoma model with genetic loss of ASNS and a hepatocellular carcinoma model with low endogenous ASNS expression, achieving durable tumor suppression. This demonstrates that for $ASNS^{low}$ tumors the glutaminase activity is not required for efficacy. Crucially, the novel ASNase was well tolerated in animal studies, enabling prolonged asparagine depletion—an essential factor for its striking anti-cancer effects. With its enhanced safety profile and specificity, this humanized ASNase represents a transformative advancement, extending the benefits of metabolic tumor starvation to a broader range of cancers. Its predictable mechanism of action, guided by biomarkers of $ASNS^{low}$ status, positions it as a promising therapeutic breakthrough for targeting diverse malignancies. The authors used GPT-4.o in order to rephrase certain sentences. After using this tool or service, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

#329 Proliferative inhibition of pancreatic cancer cells treated with pancreatic cancer - specific amplitude-modulated radiofrequency electromagnetic fields.

Hugo Jimenez[1], Callum McGrath[2], Liyue Zhang[1], Grayson Barker[1], Allan M. Johansen[2], Janaka S. S. Liyanage[1], Mohammed N. Al Hallack[1], Anthony F. Shields[1], Wasif Saif[1], Husain Y. Khan[1], Amro Aboukameel[1], Hafiz Uddin[1], Sahar F. Bannoura[1], Ramzi M. Mohammad[1], Alexandre Barbault[3], Carl F. Blackman[1], Ravi K. Paluri[4], Asfar Azmi[1], Boris Pasche[1]

[1]Oncology, Wayne State University School of Medicine / Karmanos Cancer Institute, Detroit, MI,[2]Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC,[3]TheraBionic GmbH, Ettlingen, Germany,[4]Medicine, Atrium Health Wake Forest Baptist Hospital, Winston-Salem, NC

Background: Pancreatic ductal adenocarcinoma (PDAC) is the fourth leading cause of cancer-related mortality, and about 50% of PDC patients present with metastatic disease. Despite advances in systemic therapy, the prognosis for PDC is dismal, with a five-year overall survival (OS) for metastatic PDC of about 5%. The most used regimens for advanced pancreatic cancer include gemcitabine/nab-paclitaxel (Gem/NabP) and FOLFIRINOX, with the recent addition of NALIRIFOX. All these regimens result in median survival rates under one year. Amplitude-modulated 27.12 MHz radiofrequency electromagnetic fields (AM RF EMF) delivered via a spoon-shaped antenna placed on the patient's tongue results in shrinkage of the primary and metastatic tumors in patients with cancer. The mechanism by which AM RF EMF have direct antiproliferative effect has been found to be dependent on the influx of extracellular Ca2+ into the cancer cell via Cav3.2 (gene name CACNA1H) T-type voltage gated calcium channel. Here we present, for the first time, data showing that Pancreatic cancer-specific AM RF EMF (PancMF) is effective in pancreatic cancer cells.
Methods: MIAPaCa-2 and PANC-1 cell lines were exposed either to no treatment (SHAM) to PancMF three hours per day for seven days total. Cell lines were exposed using systems replicating human exposure levels and treatment duration. Ethosuximide (Ethos), a pan t-type voltage gated calcium channel (VGCC) blocker was used to inhibit the effects of PancMF. In vitro experiments, (proliferation) Tritiated Thymidine incorporation and (stemness) tumor sphere formation were performed. ANOVA and Two-tailed Student's t-test were used for comparison.
Results: Panc1 cell line: Proliferation was inhibited 38.51% by PancMF treatment (p-value: <0.0001) but in the presence of ethosuximide PancMF proliferation inhibition was blocked (p-value: 0.9897). Stemness was inhibited 41.02% by PancMF treatment (p-value < 0.0001). MiaPaca2 cell line: Proliferation was inhibited 20.67% by PancMF treatment (p-value: 0.0208) but in the presence of ethosuximide PancMF proliferation inhibition was blocked (p-value: 0.8933). Stemness was inhibited 26.54% by PancMF treatment (p-value < 0.0001).
Conclusions: Proliferation and Stemness of Panc1 and MiaPaca2 cell were inhibited following PancMF treatment, however, the presence of ethosuximide blocked the anti-proliferative effects of PancMF. Results indicate that the t-type VGCC mediates the anti-proliferative effect. This results trend with previously published data showing that Cav3.2 is the bioantenna and mediator for tumor-specific AM RF EMF treatment.

#33 Development of a humanized mouse model for γδT cells.

Lydia Blot[1], Lopes Joaquim[1], Emerson Serres[1], Vanessa Croize[1], Herve Barret[1], Pauline Rettman[1], Clement Barjon[2], Dorothee Bourges[1], Antoine Lhermitte[1], Valeria Fantin[3], **Sukhvinder Sidhu**[1], Loreley Calvet[1]

[1]Oncology, Sanofi, Vitry sur Seine, France,[2]Oncology, Servier, Saclay, France,[3]Oncology, Sanofi, cambridge, MA

Unconventional T cells such as gamma delta (γδ) T cells have garnered significant interest in cancer immunotherapy due to their potent anti-tumor properties including strong cytotoxic capabilities in hematological malignancies and their ability to recognize a broad range of tumor antigens independent of the classical major histocompatibility complex (MHC) molecules. Given the interest in engaging these immune cell populations in cancer therapy, we established a new in vivo humanized mouse model through the adoptive transfer of human γδT cells to support this emerging area of therapeutic interest. This model was created by transplanting γδT cells sorted from PBMC donors into Fc-resolv huIL15 NOG (functional knock-out of murine Fcγ receptors to minimize the confounding impact of mouse immune cells) mice, genetically engineered to express human IL-15. We demonstrate that various γδT cell populations, including Vδ1 and Vδ2, can be successfully maintained over a long period of time, preserving the expression of critical functional biomarkers such as NKG2D, CD69 or CD16, under various engraftment conditions. Additionally, we showed that hu γδT cells display functional engagement in vivo, achieving high efficacy with epcoritamab (CD20-CD3 Ab) against disseminated tumors in the hu γδT cell adoptive transfer mouse model.

#330 Treatment of fibrolamellar carcinoma with hepatocellular carcinoma -specific amplitude-modulated radiofrequency electromagnetic fields.

Hugo Jimenez[1], Liyue Zhang[1], Grayson Barker[1], Callum McGrath[2], Allan M. Johansen[2], Janaka S. S. Liyanage[1], Mohammed N. Al Hallak[1], Anthony F. Shields[1], Wasif Saif[1], Husian Y. Khan[1], Amro aboukameel[1], Hafiz Uddin[1], Sahar F. Bannoura[1], Ramzi Mohammad[1], Sean Ronnekleiv-Kelly[3], Alexandre Barbault[4], Carl F. Blackman[1], Asfar Azmi[1], Boris Pasche[1]

[1]Oncology, Wayne State University School of Medicine / Karmanos Cancer Institute, Detroit, MI,[2]Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC,[3]Surgery, University of Wisconsin - Madison, Detroit, WI,[4]TheraBionic GmbH, Ettlingen, Germany

Background: Amplitude-modulated 27.12 MHz radiofrequency electromagnetic fields (AM RF EMF) delivered via a spoon-shaped antenna placed on the patient's tongue result in shrinkage of the primary and metastatic tumors in patients with advanced hepatocellular carcinoma (HCC). The mechanism by which AM RF EMF has a direct antiproliferative effect has been found to be dependent on the influx of extracellular Ca^{2+} into the cancer cell via $Ca_V3.2$ (gene name CACNA1H) T-type voltage-gated calcium channel. Fibrolamellar Carcinoma (FLC), a rare subtype of HCC, has few options available for treatment. Here we present, for the first time, data showing that HCC-specific AM RF EMF (HCCMF) are effective in FLC.
Methods: HepG2 is an HCC cell line and H33 ($HepG2^{DNAJB1\text{-}PRKACA}$) was generated by using the HepG2 cell line and generating the *DNAJB1-PRKACA* gene fusion at the native locus (CRISPR-based 400kbp excision). Cells either received no treatment (SHAM) or were exposed to HCCMF three hours per day for seven days total. HepG2 and H33 cells were exposed using systems replicating human exposure levels and treatment duration. *In vitro* experiments (colony formation and tumor sphere formation) with HepG2 and H33 cells were performed. Two-tailed Student's t-test was used for statistical comparison.
Results: Proliferation (colony formation assay) of HepG2 and H33 is inhibited by 37.54% (p-value: 0.0023, N=6) and 27.08% (p-value: 0.0006, N=6), respectively. Stemness (tumor sphere formation assay) of HepG2 and H33 is inhibited by 33.17% (p-value < 0.0001, N=8 SHAM and N=7 HCCMF) and 43.95% (p-value< 0.0001, N=7 SHAM and N=8 HCCMF), respectively.
Conclusions: Proliferation and stemness of the HepG2 and H33 [HepG2 (DNAJB1-PRKACA)] cell lines were inhibited following HCCMF treatment. Results show the presence of the FLC fusion protein (DNAJB1-PRKACA) does not inhibit the potential of HCCMF as a novel systemic targeted therapy for FLC. This proof-of-principle data shows significant potential for the treatment of FLC.

#334 proPBD-ADCs: optimization of therapeutic potential of ADCs based on capped PBD payload with attenuated potency.

Anette Sommer, Remon van Geel, Sander van Berkel, Elias Post, Jorin Hoogenboom, Floris van Delft

Synaffix - A Lonza company, Oss, Netherlands

Antibody-drug conjugates (ADCs) with pyrrolobenzodiazepine (PBD) dimer payloads have been explored preclinically and several PBD-based ADCs entered clinical trials. PBD dimers produce highly cytotoxic DNA crosslinks and thus have a mode-of-action differentiated from microtubule inhibitors, TOPO1 inhibitors and other DNA targeting warheads. In April 2021, the FDA approved the first PBD-based ADC, the CD19 targeting loncastuximab tesirine, for treatment of adult patients with relapsed or refractory large B-cell lymphoma, including DLBCL, after 2 or more lines of therapy. However, loncastuximab tesirine carries safety warnings - for example for effusion and edema, myelosuppression, and cutaneous reactions.
While PBD-based ADCs show efficacy in the clinic, they belong to a highly potent payload class with IC50 values on human cancer cell lines in the picomolar range. In fact, the ultrapotent character of the vast majority of PBD-based ADCs has highly limited the administration at clinically suitable dosing regimens. Therefore, increasing the therapeutic dose and at the same time improving the therapeutic windows of PBD-based ADCs will be key for the next generation of PBD-ADCs.
Although conjugation of linker-payload to the antibody is typically based on random conjugation to cysteine or lysine, we have shown that the native glycan of monoclonal antibodies is a privileged site for attachment of cytotoxic payloads[1] (GlycoConnect® technology), while the therapeutic index is further elevated by a highly polar spacer technology (HydraSpace®)[2]. Complemented by a broad choice of payloads with various mode-of-action (toxSYN® platform), these joint technologies have been applied in multiple clinical programs up to phase 3.
Our strategy to optimize the therapeutic potential of PBD-ADCs that incorporate GlycoConnect® and HydraSpace® technology further, is two-fold: (a) apply PBD dimer payload with reduced potency versus common clinical structures and (b) incorporate a pro-drug concept (proPBD-ADC) by shielding the PBD payload by a capping structure that is stable in circulation but at the same time conditionally released by tumor-associated proteases or under reducing conditions.
Data from efficacy studies with HER2-proPBD-ADCs in CDX tumor bearing mouse models will be shared, as well as tolerability studies performed both in rats and in the chicken egg chorioallantoic membrane (CAM) model. The data suggest that different cap structures of proPBD-ADCs, as well as the use of a PBD structure with attenuated potency, have a differential impact on efficacy and tolerability.

#337 Highly potent, bispecific ADCs by application of clinical stage GlycoConnect® technology to bYlok® antibodies.

Floris van Delft, Lianne Lelieveldt, Jasper van de Sande, Anette Sommer

Synaffix - A Lonza company, Oss, Netherlands

Bispecific antibodies (bsAbs), with the ability to bind selectively to two different tumor-associated antigens in concerted fashion, have been increasingly successful for the treatment of cancer patients, delivering increased therapeutic potency compared to traditional mAbs, whilst also contributing to a reduction in the development of clinical resistance. Unfortunately, production of bsAbs is often plagued by HC-LC mispairing or by reduced titers, binding affinity, thermal stability or immunogenicity. Recently, we demonstrated that bsAbs generated using Lonza's bYlok® modification display a high percentage (>95%) of correct HC-LC pairing and can be purified to high levels using standard downstream purification (https://www.lonza.com/biologics/expression-technologies/bYlok).

Another increasing successful modality for anti-cancer therapy is the antibody-drug conjugate (ADC). Although typically based on random conjugation to cysteine or lysine, we have shown that the native glycan of monoclonal antibodies is a privileged site for attachment of cytotoxic payloads[1], while the therapeutic index is further elevated by a highly polar spacer technology (HydraSpace®)[2]. Complemented by a broad choice of payloads with various mode-of-action (toxSYN® platform), these joint technologies have been applied in multiple clinical programs up to phase 3 (see: https://synaffix.com/partnered-pipeline/).

Here we will demonstrate how bYlok® and GlycoConnect® technology are seamlessly combined to generate bispecific ADCs (bsADCs) with high yield and purity. Various bsADCs, featuring cytotoxic payloads with multiple MOA, including topoisomerase 1 inhibitors and tubulin binders, were fully analytically characterized and functionally evaluated, showing compelling tumor regression in multiple in vivo xenograft models. Combination of the technologies was further expanded to provide first-in-class bispecific ADCs with dual mode-of-action (dual warhead bsADCs).

#338 Innovative strategy for enhancing the reach of HER3 antibody-drug conjugates: A novel drug combination approach.

Kathryn E. Vanderlaag, Anukriti Dhar, Arisa Paul, Molly I. Volkman, Erik M. Werner, Transon V. Nguyen, Kamran A. Ali

Eigen Therapeutics Inc., Redwood City, CA

Antibody-drug conjugates (ADC) and radioligand therapies (RLT) have emerged as promising treatment modalities for various cancers. In recent years, there have been numerous approvals of ADCs and RLTs by regulatory agencies, highlighting their clinical success. Despite their success, they still suffer from a common challenge: tumor heterogeneity. Tumor heterogeneity limits not only the patient response, but also the eligible patient population for these therapies. To address this challenge, we have developed a high throughput screening platform to identify small molecule “priming” agents that selectively upregulate tumor antigens in cancer, but not in normal cells. We have demonstrated that by increasing expression of target antigens on cancer cells, priming agents sensitize tumors to ADCs and can thus improve their efficacy and therapeutic window. Our priming screens thus far included evaluating priming agents for HER3, B7-H4, FR-A, TROP2, HER2, NECTIN-4, and CD123. Additionally, DLL3, c-MET, and SSTR2 are scheduled for early next year.

Our lead program focuses on HER3, where we have utilized our library to identify priming agents that upregulate HER3 cell surface expression by 2-3 fold across breast and ovarian cancer cell lines, demonstrating potential for indication-agnostic applications. Mechanistic validation has been achieved through the use of multiple inhibitors within the same pathway, which exhibit similar priming effects. Notably, HER3 upregulation is cancer-selective, with expression levels remaining low in normal cells. Ongoing experiments aim to further elucidate the underlying mechanism, and we have initiated medicinal chemistry efforts to advance this program.

Utilizing a priming approach in conjunction with an ADC or radiopharmaceutical offers three distinct advantages that lead to best-in-class or first-in-class therapies:

1. Patient Population Expansion: The priming approach enables the treatment of a broader range of cancer patients by overcoming tumor heterogeneity.
2. Reduced Toxicity: The ability to lower the dose of the ADC or radiopharmaceutical while maintaining efficacy reduces the risk of adverse effects and enhances patient safety.
3. Improved Durability of Responses: By addressing tumor heterogeneity, the priming approach enhances the durability of patient responses, leading to longer-lasting remissions.

By leveraging the potential of ADC and RLT (radioligand therapy), the priming approach opens up new avenues for more effective and personalized cancer treatments.

#339 Development of ^{212}Pb-based Radio-DARPin therapy (RDT) for the treatment of mesothelin (MSLN)-positive solid tumors.

Stephan Wullschleger[1], Amal Saidi[2], Delphine Buffet[1], Tania Stallons[2], Stefanie Riesenberg[1], Amy Wong[2], Maria Paladino[1], Federico Rojas[2], Mischa Muller[1], Christel Herzog[1], Justin Walter[1], Denis Villemagne[1], Yvonne Kaufmann[1], Nicole Pina[1], Henri Fernandez[1], Tamara Lekishvili[1], Eleni Tselempi[1], Jacqueline Blunschi[1], Liridon Abduli[1], Chloe Iss[1], Amelie Croset[1], Clara Domke[1], Aaron Schatzmann[2], Anne Goubier[1], Julien Torgue[2], Daniel Steiner[1]

[1]Molecular Partners, Zurich-Schlieren, Switzerland,[2]Orano Med LLC, Plano, TX

Radioligand therapies have emerged as promising treatment modality for certain cancers. This therapeutic approach relies on a suitable tumor-targeting moiety labelled with a radioactive payload to allow the delivery of the radionuclide to cancer cells with high specificity. Due to its expression profile in tumor vs healthy tissues, MSLN is an attractive protein for targeted therapies. MSLN is a GPI-anchored membrane protein which is overexpressed in many tumor types, including ovarian cancer and pancreatic adenocarcinoma. Therapeutic approaches targeting MSLN have encountered obstacles due to the high levels of its proteolytically cleaved soluble form (sMSLN), which can sequester anti-MSLN therapeutics and potentially diminish their efficacy. To circumvent this caveat, we sought to generate a Designed Ankyrin Repeat Protein (DARPin) that binds to a membrane proximal epitope of MSLN and therefore avoids binding to sMSLN. Thanks to their small size and high affinity, DARPins are ideal vectors for targeted radiotherapies, dubbed as Radio-DARPin therapies (RDT). As radioactive payload we used ^{212}Pb, an alpha particle-emitting radionuclide with a short half-life and a favorable decay profile which allows high energy deposition on tumor in a short time frame. Herein we report for the first time the development and initial preclinical characterization of our anti-MSLN ^{212}Pb-RDT approach. *In vitro* assays revealed that the membrane proximal MSLN targeting DARPin specifically interacts with MSLN expressed on cancer cells with high affinity, and cell binding was not affected by the presence of sMSLN. The DARPin was then labelled with ^{212}Pb and its preclinical pharmacokinetic and biodistribution profile was evaluated in MSLN-expressing xenograft tumor models. In these tumor bearing mice, the anti-MSLN ^{212}Pb Radio-DARPin demonstrated substantial uptake into MSLN-positive tumors, while other organs only showed limited accumulation. We designed an approach to specifically target MSLN expressed on cancer cells employing DARPin technology combined with ^{212}Pb. Our early preclinical results indicative of a favorable biodistribution profile of the ^{212}Pb labelled MSLN DARPin motivate further development of this RDT for the treatment of patients with MSLN-positive solid tumors.

#34 From fluid to function: Leveraging ascites to build orthotopic ovarian cancer models.

Cheryl Davis, Melissa Tran, Helen Ketteringham, Corrine Silvio, Ben Hoerner, Marcus Josey, Victoria Caruso, Kathleen Hutchinson, Dawn Lusk, Chris Holding, Shorena Nadaraia-Hoke

Reaction Biology Corporation, Hummelstown, PA

Often referred to as the “silent killer”, ovarian cancer poses significant challenges due to its asymptomatic nature and lack of reliable early detection methods, leading to late-stage diagnoses in over 70% of cases. As the eighth most common cancer among women worldwide, robust translational models for preclinical testing of ovarian cancer are essential. Unfortunately, the limited availability of orthotopic in vivo models presents a significant challenge in accurately replicating ovarian cancer for research purposes. By harnessing the ascitic nature of two well-established ovarian adenocarcinoma cell lines, we have successfully generated robust orthotopic ovarian in vivo models, which we can now offer as a valuable platform for preclinical research. Both our intra-peritoneal and intra-bursal models exhibit predictable growth patterns, thus contributing to the advancement of ovarian cancer treatments by enabling the exploration of tumor biology, drug resistance mechanisms, and therapeutic efficacy. The innovative models presented here are powerful tools for investigating tumor biology and advancing preclinical drug development, with the ultimate goal of improving therapeutic outcomes for patients with ovarian cancer.

#340 GenSci139, a highly differentiated EGFR×HER2 bispecific ADC, for the treatment of multiple solid tumors.

Xiaojuan Chai, Fu Li, Hongmei Xie, Yuting Lu, Nan Li, Hanxi Yu, Li Tong, Weiming He, Wenqiang Zhai, Fanglong Yang, John L. Xu

GeneScience Pharmaceutical Co., Ltd., Shanghai, China

Background: Enhertu®/DS-8201, a HER2-directed ADC, has been used for the treatment of multiple tumor types, including HER2-positive and HER2-low breast cancer, HER2-mutant NSCLC, HER2-positive gastric cancer, etc. Despite Enhertu's success as a breakthrough therapy, significant unmet need remains in the HER2-low settings and in the occurrence of secondary resistance. Dual targeting of EGFR and HER2 represents a promising approach to the treatment of HER2-low patients and to overcoming drug resistance, as they are both oncogenic drivers and widely co-expressed. We developed GenSci139, an EGFR×HER2 bispecific ADC with a highly stable but cleavable linker and a potent topoisomerase 1 inhibitor payload, using our proprietary platform technologies. Preclinical studies are underway to evaluate the potential of GenSci139 as a novel targeted therapy across multiple solid tumor types.

Methods: GenSci139's plasma stability, *in vitro* cellular binding, internalization, cytotoxicity, and bystander effect, and blocking activity of GenSci139 or its parental bispecific antibody on EGFR/HER2 signaling in a number of human cancer cell lines were characterized. *In vivo* anti-tumor activity of GenSci139 was evaluated in a number of human cancer CDX models in mice. In addition, the ability of GenSci139 to induce immunogenic cell death (ICD) in tumor cell cultures was assessed.

Results: GenSci139 showed much better *in vitro* plasma stability than DS-8201, suggesting a favorable PK and safety profile. GenSci139 exhibited stronger *in vitro* tumor cell binding and internalization activities than DS-8201 and potent direct cytotoxicity and bystander killing effect in tumor cell lines. The parental bispecific antibody of GenSci139 inhibited EGF-induced signaling and cell proliferation in tumor cell culture. GenSci139 demonstrated superior *in vivo* anti-tumor efficacy *versus* DS-8201 in a number of CDX models in mice. In addition, GenSci139 was shown to induce hallmarks of ICD in tumor cells, providing a complementary anti-tumor mechanism when in a combination therapy regimen with immune checkpoint inhibitors.

Conclusion: These data suggest the potential of GenSci139 as a novel and effective therapy across a variety of tumor types, including urothelial cancer, lung cancer, gastric cancer, colorectal cancer, ovarian cancer, breast cancer, etc., and support its further evaluation in IND-enabling studies.

#341 VBC108: a first-in-class CDH17/CLDN18.2 targeted bispecific antibody drug conjugate (ADC) to overcome tumor heterogeneity of gastrointestinal cancers (GC, PADC, CRC, etc.).

Wei (Vivian) Wang[1], Lingyu Guan[2], Man Xu[1], Qun Yin[1], Chen Dong[1], Jing Li[1]

[1]VelaVigo (Hong Kong) Limited, Pudong, China,[2]VelaVigo (Shanghai) Limited, Pudong, China

CLDN18.2 is a promising target for GI cancer therapy, with various modalities under clinical evaluation. However, these therapies face challenges due to the heterogeneous expression of CLDN18.2, leading to inconsistent efficacy and the need of patient stratification, as observed with Zolbetuximab, AZD0901 and IBI343. Besides, these treatments may induce drug resistance by downregulating CLDN18.2. Recently, CDH17 (Cadherin 17) has emerged as a novel target for biologics, often overexpressed in GI cancers. But in normal tissues, it remains inaccessible as it is hidden within the tight junctions of intestinal epithelial cells, which makes it a favorable target for cancer therapy. More importantly, systematic analysis of expression data reveals high co-expression or complementary expression of CDH17 with CLDN18.2 in GI cancers, with no co-expression in other major organs. This discovery presents an opportunity for a bispecific anti-CDH17/CLDN18.2 therapy, potentially addressing the limitation of targeting CLDN18.2 alone. VBC108 is a bispecific ADC designed to target both CDH17 and CLDN18.2 with TOPO1i payload. The unique design maximizes efficacy while minimizing safety risks. VBC108 distinguishes itself from other CLDN18.2-targeting therapies through the following features. VBC108 targets both CDH17 and CLDN18.2, potentially overcoming tumor heterogeneity and covering over 80% of gastric and 50% of pancreatic cancers without CLDN18.2 IHC selection. It has high affinity to CDH17 and CLDN18.2, enhanced binding avidity, internalization and cytotoxicity. Moreover, it has a strong bystander effect to help further overcome the heterogeneity of tumor antigen expression. In CDH17 single-positive CDX models, which represent clinical scenarios lacking targeted therapies, VBC108 exhibited strong efficacy, whereas AZD0901 did not inhibit tumor growth at all. In CDH17/CLDN18.2 double-positive CDX models, representing clinical scenarios with target expression heterogeneity, VBC108 further showed its superiority. In CLDN18.2 single-positive CDX models, reflecting clinical scenarios with available CLDN18.2-targeted therapies, VBC108 demonstrated comparable efficacy with different payload mechanisms. In the PDX (GC, PADC, CRC) studies, especially in the GC model with low to medium expression of CDH17/CLDN18.2, it achieved a 100% CR. Furthermore, preliminary toxicity studies in Cyno-monkeys showed good tolerability with repeated doses. VBC108 also exhibited excellent developability in a comprehensive developability assessment (DA) test, making it a strong candidate for further CMC development. In summary, VBC108, with its unique design, shows the potential as a first-in-class ADC for GI cancer and supports the advancement to clinical trials.

#342 First-in-class click chemistry-based pre-targeting of CEACAM5 tumor antigen selectively activates an MMAE payload at tumors.

George Coricor, Masa Aleckovic, Sangeetha Srinivasan, Jesse McFarland, Stefanie Wagner, Nathan A. Yee, Tri-Hung Nguyen, Michael Zakharain, Travis Biechele, Jose M. Mejia Oneto

Shasqi, San Francisco, CA

Targeted delivery technologies (ADC, TRT, etc.) are commonly dose-limited by off-target toxicities. Less than 1% of the dose is delivered to the tumor while the remainder follows the normal catabolic elimination route of the antigen-binder resulting in significant normal tissue exposure and toxicity. A pre-targeting approach such as Shasqi's Click Activated Protodrugs Against Cancer (CAPAC®) technology, that separates the antigen-binder from the payload and reunites them only at the antigen is needed to overcome this limitation. CAPAC utilizes in-vivo click chemistry to selectively and rapidly reunite antigen-binders and payloads. Here we present preclinical data on a clickable CEACAM5 antigen-binder and a clickable monomethyl auristatin E (MMAE) payload or protodrug. We synthesized a clickable binder for CEACAM5 consisting of fragment antibodies covalently conjugated with the activating agent. The microtubule-disruptor, MMAE, was chemically attenuated with *trans*-cyclooctene to develop the protodrug, SQP22 (clickable payload). Both the clickable binder and protodrug were tested individually *in vitro*, with or without cells. They are currently being tested *in vivo*, individually or together, for efficacy and tolerability in naive tumor-free or tumor bearing CEACAM5-expressing cell-derived xenograft (CDX) rodent models. SQP22 showed a high level of attenuation (up to ~700x) in cytotoxicity assays *in vitro* compared to the active payload and cleared rapidly *in vivo*, both important features of CAPAC protodrugs. Additionally, the drug metabolism and pharmacokinetic characterization showed a favorable drug profile for SQP22, supporting its further development as a clinical agent of the CAPAC platform. The CEACAM5-targeted Fab has a binding affinity (KD) of 0.046 nM and a strong binding potency of 0.78 nM (EC50) to a CEACAM5-expressing cell line. Efficacy data from gastric and pancreatic CDX models shows that the clickable binder with SQP22 significantly improves tumor growth inhibition over a clickable non-binding isotype control with SQP22 and other negative controls. Tolerability studies in rats at various dose levels are ongoing. We have developed a novel, first-in-class, CEACAM5 clickable binder that can selectively activate an MMAE payload using click chemistry-based pre-targeting. Our results show that the protodrug and the clickable binder have favorable characteristics. Moreover, efficacy data indicate a meaningful benefit in cancer CDX models over negative controls. These data support the continued development of CEACAM5 clickable binder in combination with MMAE clickable payload for the treatment of CEACAM5 expressing cancers.

#343 GenSci143, a novel B7-H3×PSMA bispecific and potential best-in-class ADC, for the treatment of metastatic castration-resistant prostate cancer.

Yao Xu, **Fu Li**, Zhiyu Cui, Hongmei Xie, Wei Yan, Yan Li, Weiming He, Wenqiang Zhai, Fanglong Yang, John L. Xu

GeneScience Pharmaceutical Co., Ltd., Shanghai, China

Background: PCa is the most common cancer among men worldwide. Once patients have progressed to castration resistance, treatment options become scarce, leaving a substantial unmet need in the mCRPC settings. Both B7-H3 and PSMA are tumor-associated antigens that exhibit high levels of expression in PCa, and dual targeting of them with a single agent represents a promising therapeutic approach to the treatment of mCRPC. We developed GenSci143, a novel B7-H3×PSMA-directed bispecific ADC comprised of a bispecific antibody against B7-H3 and PSMA, a highly stable but cleavable linker, and a potent topoisomerase 1 inhibitor payload. Potential of GenSci143 as a novel targeted cancer therapy is currently evaluated in preclinical studies.

Methods: Membrane expression of B7-H3 and PSMA in tissue microarrays of PCa biopsies was examined by immunohistochemistry analysis. Cell surface levels of B7-H3 and PSMA in PCa cell lines were quantified by flow cytometry using Quantibrite beads. Binding affinity of GenSci143 to B7-H3- and/or PSMA-expressing tumor cells was also determined using flow cytometry. To assess internalization, cells were treated with pHrodo^{TM}-labelled antibodies, and fluorescence intensity was recorded. *In vitro* cytotoxic effect of GenSci143 on PCa cell lines was evaluated using a Luminescent Cell Viability assay. *In vivo* anti-tumor activity of GenSci143 was assessed in CDX models of PCa and compared to that of the DS-7300 and ARX517 analogs.

Results: B7-H3 and PSMA were highly co-expressed in PCa tissues (N=102), lending strong support to our dual-targeting therapeutic approach for mCRPC. GenSci143 showed strong *in vitro* binding, internalization, and cytotoxicity in tumor cells expressing either B7-H3 or PSMA or both TAAs. In human CDX models of PCa in mice, GenSci143 effectively induced tumor regression across different expression levels of B7-H3 and PSMA and demonstrated superior anti-tumor efficacy *versus* the DS-7300 and ARX517 analogs. Moreover, GenSci143 showed much better *in vitro* plasma stability than DS-7300. Following intravenous injection at 10 mg/kg in cynomolgus monkeys, GenSci143 exhibited a favorable pharmacokinetic profile, with serum concentration of free payload lower than 1.0 ng/mL at any time examined. In a pilot non-GLP repeat dose toxicity study in cynomolgus monkeys, GenSci143 was well tolerated, demonstrating a significantly higher therapeutic index than DS-7300 based on PK-PD modeling and simulation.

Conclusion: These results suggest that GenSci143 has the potential to become an effective therapeutic option for mCRPC patients and support its further evaluation in IND-enabling studies.

#344 IBI3014, a TROP2xPD-L1 bi-specific ADC integrating ADC killing with checkpoint blockade within one molecule, exhibits promising efficacy and safety in preclinical models.

Xiguang Zhang, Yanping Jin, Jinchang Lu, Ninghuan Li, Zhihai Wu, Min Wu, Yan Bian, Fenggen Fu, Weiwei Wu, Shuaixiang Zhou, Huizhong Xiong

Innovent Biologics (Suzhou) Co. Ltd, Jiangsu, China

Antibody-drug conjugates (ADCs) have emerged as a distinguished class of anticancer therapeutics. ADCs targeting Trophoblast Cell Surface Antigen 2 (TROP2) have shown efficacy in treating various epithelial tumors, such as non-small cell lung cancer (NSCLC) and triple-negative breast cancer (TNBC). Programmed Death Ligand 1 (PD-L1) serves as both an immune checkpoint and a tumor-associated antigen (TAA), commonly overexpressed in diverse tumor types. Growing evidence showed that ADCs can increase the efficacy of immunotherapeutic agents by multiple mechanisms, such as induction of immunogenic cell death, dendritic cell maturation, increase of T cell infiltration and expression of immune-regulatory proteins including PD-L1 and MHC. Both preclinical and early clinical studies suggest that ADCs and immunotherapy are promising combination options for tumor treatment. IBI3014 is an innovative TROP2 and PD-L1 dual-targeting ADC, comprising a humanized bispecific antibody linked to a novel DNA topoisomerase I inhibitor, NT1, via a cleavable linker. *In vitro* studies demonstrated the unconjugated bispecific antibody of IBI3014 has potent internalization activity potent immune checkpoint blocking activity. IBI3014 demonstrated superior cytotoxicity to benchmark and parental ADCs across several cell line-derived xenograft (CDX) models with different TROP2 and PD-L1 expression pattern, offering broader tumor type coverage. IBI3014 showed acceptable stability profile in mice and monkeys and can be well tolerated in monkeys with a highest non-severely toxic dose (HNSTD) of 50 mg/kg. Conclusion: IBI3014 represents a first-in-class bispecific ADC that integrates targeted cytotoxicity with checkpoint blockade within a single molecule. This dual mechanism of action not only enhances therapeutic efficacy but also maintains a favorable safety profile, which provides a promising approach for cancer therapy.

#345 Trop2 and B7H4 bi-specific ADC with improved efficacy and safety for gynecologic cancers.

Jing Chen, Chenjuan Zhu, Chenchen Zhu, Zhongmin Liu, Min Wu, Weiwei Wu, Junjie Deng, Yi Wang, **Xiguang Zhang**, Yiming Li

Innovent Biologics (Suzhou) Co. Ltd, Jiangsu, China

The effectiveness of Antibody-Drug Conjugates (ADCs) is closely associated with the level of tumor antigen expression and the administered drug dose, as observed in both preclinical and clinical settings. Trop2-targeted ADCs represent a promising therapeutic approach for various solid tumors; however, their efficacy is constrained by the expression levels of Trop2 and the off-tumor, on-target toxicity. To address these limitations, we have developed a bi-specific ADC that targets both Trop2 and B7H4, aiming to increase the overall tumor antigen expression level, and reduce the off-tumor toxicity associated with Trop2 by incorporating a single-arm Trop2 antibody and employing a less toxic Topoi NT3 linker payload in the ADC. Our research has confirmed the co-expression of Trop2 and B7H4 on tumor cells in Triple Negative Breast Cancer, ovarian cancer, and endometrial cancer, while not on normal mucosal epithelial cells. This co-expression profile supports the use of our bi-specific approach to improve cancer targeting efficiency while minimizing toxicity to normal tissues. In vitro studies demonstrate that our bi-specific Trop2/B7H4 ADC (IBI3022) exhibits superior cytotoxicity in HT29 cells overexpressing Trop2 and B7H4 compared to mono-specific ADC benchmarks targeting Trop2 or B7H4. Additionally, IBI3022 shows comparable efficacy to B7H4 ADC in B7H4-positive HCC1569 cells and to Trop2 ADC IBI130 in Trop2-positive BxPC3 and HCC1954 cells. In vivo, IBI3022 demonstrates enhanced tumor suppression compared to mono-specific ADC benchmarks in various tumor models with differing levels of Trop2 and B7H4 expression, including MDA-MB-468, HT29-Trop2-B7H4, HCC1806, JIMT1, and NUGC4. The half-life of IBI3022 in mice is 113 hours, supporting its sustained in vivo efficacy. The developability profile of IBI3022 is favorable, and notably, it is well-tolerated in cynomolgus macaques at doses up to 50 mg/kg. Overall, IBI3022 represents a promising bi-specific ADC for the treatment of gynecologic cancers, offering improved efficacy and safety profiles.

#346 MP0712, the first anti-DLL3 212Pb radio-DARPin (RDT) candidate for targeted radiotherapy of small cell lung cancer (SCLC).

Amelie Croset[1], Amal Saidi[2], Francesca Malvezzi[1], Tania Stallons[2], Madlaina Mettier[1], Amy Wong[2], Jitka Rantanen[1], Federico Rojas[2], Stephan Wullschleger[1], Eleni Tselempi[1], Yvonne Kaufmann[1], Tamar Lekishvili[1], Stefanie Riesenberg[1], Nicole Pina[1], Jacqueline Blunschi[1], Liridon Abduli[1], Christian Reichen[1], Christian Lizak[1], Aaron Schatzmann[2], Anne Goubier[1], Julien Torgue[2], Daniel Steiner[1]

[1]Molecular Partners AG, Zurich-Schlieren, Switzerland,[2]Orano Med LLC, Plano, TX

Radioligand therapy has shown strong clinical potential for the treatment of certain neuroendocrine and prostate tumors. Nevertheless, effective strategies in various cancer types are currently restricted by the lack of appropriate targeting agents for suitable tumor-associated antigens. Not expressed in healthy tissue, DLL3 is one of these promising targets highly upregulated in SCLC and other high-grade neuroendocrine tumors. Herein we present preclinical results of our DLL3-targeting 212Pb-based Radio-DARPin Therapeutic (RDT) combining the advantages of a small protein-based delivery vector and the short-lived alpha particle-emitting radioisotope 212Pb. Designed Ankyrin Repeat Proteins (DARPins) are a class of binding proteins with high specificity and affinity that can be generated against a broad range of tumor targets. Leveraging the learnings from our DARPin platform optimization allowed us to achieve efficient tumor uptake and penetration, while limiting exposure of healthy tissues. Our Radio-DARPin platform was optimized to effectively reduce DARPin uptake to kidneys, a major drawback of all small-size polypeptide vectors. This can be addressed by engineering the DARPin scaffold surface in conjunction with half-life extension (HLE) through serum albumin binding. 212Pb is a radioisotope with a short half-life of 11h and a favorable decay chain, allowing high energy deposition on tumor in a short time frame. By combining 212Pb with a HLE anti-DLL3 DARPin candidate, we aimed to generate a targeted RDT with high efficacy and a favorable safety profile. After several screening rounds of anti-DLL3-binding DARPins combined with HLE in mice, MP0712 was selected as lead candidate for further development. This molecule showed specific binding to lung cancer cells in vitro (~2nM on NCI-H82 ± HSA) and high affinity to human DLL3 (0.2nM by Surface Plasmon Resonance). MP0712 biodistributions were assessed in different mouse xenograft tumor models, matching clinically relevant DLL3 expression levels or overexpression of DLL3, and reached tumor:kidney ratios >2. Double xenografted mouse models showed selective uptake in DLL3-expressing tumors compared with tumors not expressing DLL3, confirming high target specificity of MP0712. The anti-tumor activity of MP0712 in different mouse xenograft tumor models showed promising efficacy. MP0712 led to tumor stabilization and significant effects on tumor versus necrotic tissue. In NCI-H82 tumors, median survival duration increased up to 3-fold with MP0317 compared with the buffer control. MP0712 also showed a favorable safety profile in vivo up to 30µCi. These preclinical results support our 212Pb-based RDT against DLL3 as a promising treatment option for SCLC, with encouraging in vivo antitumor activity and a good safety profile for our first DLL3-targeting 212Pb-RDT candidate for further development into the clinic.

#347 Novel EGFR x cMET bispecific ADC GQ1033 and DLL3-ADC GQ1030 demonstrated promising therapeutic efficacy in preclinical studies.

Sipeng Li, Yajun Sun, Meijun Xiong, Chong Liu, Yanwen Feng, Zengyan Mu, Xinju Gao, Yu Han, Paul H. Song, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: Lung cancer is the leading cause of cancer deaths globally, with NSCLC comprising around 85% and SCLC about 15%. Several tyrosine kinase inhibitors (TKIs) have been approved for NSCLC. However, TKIs favor the emergence of resistant cells, ultimately resulting in tumor relapse. EGFR and cMET are co-expressed oncoproteins, with cMET playing a pivotal role in resistance to EGFR TKI in NSCLC. SCLC commonly develops disease relapse and resistance following first-line platinum-based chemotherapy, leading to a poor 5-year overall survival of below 7%. DLL3, an inhibitory Notch ligand, is selectively expressed on the surface of SCLC cells and represents a validated therapeutic target.

Methods: Traditional ADC discovery relies on rational design, which often limits diversity and may exclude promising candidates due to the complexity of ADCs. Existing conjugation technologies are not well-suited for diversity-oriented synthesis (DOS), as they involve multi-step processes, low versatility, and inconsistent quality. Our proprietary enzymatic site-specific conjugation platforms, iGDC™ and iLDC™, enable high-throughput synthesis of diverse ADC libraries. Using the platforms, we created a broad ADC library targeting EGFR x cMET and DLL3, combining antibodies with various formats, different linkers, and payloads like MMAE, Eribulin, Exatecan, Lurbinectedin, and TopoIx. The resulting ADCs were rigorously evaluated using in vitro cytotoxicity assays and in vivo PDX subclinical trials. Through this process, we developed GQ1033 and GQ1030, next-generation ADCs specifically targeting EGFR x cMET and DLL3, respectively.

Results: GQ1033 showed potent cytotoxicity in the HCC827 cell line and complete tumor regression at a single 4 mg/kg dose in the NCI-H1975 CDX model. In an osimertinib-resistant NSCLC PDX trial, involving ~10 models with diverse EGFR/cMET expression levels, GQ1033 demonstrated robust antitumor activity with an overall ORR of ~70%. GQ1030 displayed strong cytotoxicity in DLL3-positive cancer cell lines, with no off-target effects in DLL3-negative cells. In vivo, GQ1030 exhibited robust antitumor activity in the SHP-77 CDX model at a single dose of 2.5 mg/kg. In a PDX trial involving over 10 SCLC models randomly chosen without consideration of DLL3 expression, GQ1030 demonstrated best-in-class potential with an ORR of ~80%. The selected lead ADCs did not necessarily possess the highest antibody affinities or the most potent payloads. Furthermore, ADCs with higher DARs did not consistently demonstrate significant efficacy advantages.

Conclusions: GQ1033 and GQ1030, developed through high-throughput screening leveraging our iGDC™ and iLDC™ platforms, have demonstrated encouraging efficacy in preclinical studies, suggesting a broader therapeutic index. These next-gen ADCs hold potential as innovative treatments for lung cancers.

#348 Development of an anti-TF ADC with a potentially improved therapeutic index.

Xiaodong Xiao[1], Zhidi Pan[2], Zhangyi Song[1], Haiyang Yin[2], Hua Jiang[1], Yueqing Xie[1], Jianwei Zhu[1]

[1]Jecho Laboratories, Frederick, MD,[2]Jecho Institute, Shanghai, China

Tissue factor (TF) plays important roles in the hemostasis process. Through forming complex with factor (F) VII/VIIa, TF helps to initiate the blood coagulation process that protects vital organs from excessive bleeding. Under pathological conditions TF could also be involved in thrombosis. Furthermore, TF has functions beyond hemostasis such as signaling. TF is involved in many aspects of cancer transformation such as aberrant signaling, metastasis, and tumor angiogenesis. TF has been found to overexpress in multiple cancers including cervical, pancreatic, lung, head and neck, and prostate cancers, etc. Therapeutics targeting TF has achieved success with most notably the recent approval of Tisotumab Vedotin against cervical cancer. We report here the early phase development of an anti-TF ADC. Our in-house phage display library was employed to isolate a panel of fully human anti-TF antibodies. They vary in binding epitope and affinity allowing the opportunity to evaluate the optimum combination of both to achieve superior efficacy and safety. We found that the binding epitope plays a significant role in the antibody-mediated internalization, whereas within the same binding bin, antibody affinity and internalization may not have a direct correlation. One such antibody, 1E11, has a similar epitope to Tisotumab. It has a modest binding affinity (KD=68 nM) compared to other internal candidates as well as Tisotumab, yet it displayed similar or superior internalization efficiency and ADC mediated cell killing against multiple TF positive cell lines *in vitro*. In several CDX *in vivo* models tested so far, 1E11 based ADC showed comparable or superior activities to Tisotumab carrying the same linker/payload. Significantly, while Tisotumab displayed significant disruption of TF/factor VII interaction, a potential cause for excessive bleeding observed in clinics using Tisotumab Vedotin, 1E11 showed little or no such activities. These highly relevant function and safety features of 1E11-based ADC plus its excellent developability profile suggest that it is a promising candidate for further development into various ADC based therapeutics either used alone or in combination with other therapeutics.

#349 GenSci140, a potential best-in-class FRα-directed biparatopic ADC, for the treatment of platinum-resistant ovarian cancer.

Meihan Li, Fu Li, Yingying Sun, Qiuru Che, Na Dong, Li Tong, Weiming He, Wenqiang Zhai, Peng Qi, Min Zhang, Fanglong Yang, John L. Xu

GeneScience Pharmaceutical Co., Ltd., Changchun, China

Background: Folate receptor alpha (FRα) is a GPI-anchored cell-surface glycoprotein overexpressed in a variety of solid tumors, including ovarian cancer, non-small cell lung cancer (NSCLC), triple-negative breast cancer (TNBC), and endometrial cancer. It exhibits limited expression in normal tissues, making it an ideal target for the development of cancer therapy. IMGN853/ELAHERE^{TM}, a FRα-directed ADC, has been approved for platinum-resistant epithelial ovarian cancer (PROC) patients with high levels of FRα expression. Despite this advancement, it is estimated that around 60% of PROC patients with medium to low FRα expression do not benefit from this therapy. In addition, occurrence of ocular toxicity has been reported in approximately 40% of patients treated with ELAHERE^{TM}. In order to address unmet need in broader patient populations and to minimize toxicity, we developed GenSci140, a novel FRα-directed biparatopic ADC with a potent Topo1 inhibitor payload and a stable but cleavable linker at the drug-to-antibody ratio (DAR) of 6.
Materials and Methods: A novel FRα-directed biparatopic antibody was constructed from a monoclonal antibody and a VHH domain antibody to bind with high and low affinity, respectively, to two distinct epitopes on the tumor antigen, and used to generate GenSci140 with our proprietary linker-payload technology. *In vitro* tumor cell binding and internalization of GenSci140 were characterized by flow cytometry; cytotoxicity and bystander killing activity were assessed in Cell Titer-Glo assay and in luciferase assay, respectively. *In vivo* anti-tumor efficacy of GenSci140 was assessed in human cancer cell line-derived xenograft (CDX) models in mice, and pharmacokinetic and toxicology profiles were evaluated in cynomolgus monkeys.
Results: GenSci140 exhibited significantly stronger *in vitro* tumor cell binding and more efficient internalization than IMGN853. GenSci140 displayed potent cytotoxicity in FRα-positive tumor cells and effective bystander killing of FRα-negative cells in a FRα^{+}/FRα^{-} tumor cell co-culture system. GenSci140 demonstrated superior *in vivo* anti-tumor efficacy compared to ELAHERE^{TM} and IMGN151 (competitor's next-generation FRα-directed biparatopic ADC product) across a variety of CDX models including ovarian cancer, NSCLC, and TNBC, irrespective of their FRα expression levels. Furthermore, GenSci140 featured a favorable pharmacokinetic profile and was well-tolerated in a non-GLP repeat dose toxicity study in NHPs.
Conclusion: These data suggest that GenSci140 could be a more effective and safer treatment option than the current standard of care for 2L PROC, potentially addressing the unmet need of patients with varying levels of FRα expression. Therapeutic potential of this molecule is currently further evaluated in IND-enabling studies.

#35 Hydrogel-based microwell chip for improved organoid culture and on-chip imaging.
Thi Kim Ngan Ngo, Ting-Yuan Tu

Department of biomedical engineering, National Cheng Kung University, Tainan, Taiwan

Organoids have become essential tools for modeling complex biological systems, driving significant advancements in drug screening, cancer research, and regenerative medicine. However, traditional dome-shaped organoid culture methods come with notable limitations. These include variability in organoid size, structural heterogeneity, and difficulties in achieving high-resolution imaging due to overlapping positions and artifacts from the surrounding extracellular matrix (ECM). Such issues often hinder the reproducibility and precision of experimental outcomes, especially in long-term culture settings. To overcome these challenges, we developed a hydrogel-based microwell chip designed to standardize organoid culture and enhance imaging quality. The chip contains a grid of 100 microwells, each optimized to support the formation of up to 100 uniform spheroids or organoids. It is designed with a main microwell channel along with two inlet and outlet channels for hydrogel injection, which can be connected to a pump to enable dynamic culture conditions. Using this system, we successfully generated uniform spheroids from various cancer cell lines and consistent mouse intestinal organoids that retained characteristics comparable to those produced with the dome-shaped method. Importantly, the optimized size of the microwells reduces the volume of culture medium and cell suspension required, offering a more cost-effective and resource-efficient solution. This efficiency is particularly advantageous for drug screening, large-scale studies, or research involving precious samples, such as patient-derived organoids. Another notable advantage of our microwell chip is its compatibility with high-quality, live on-chip imaging throughout the culture period. This capability is essential for real-time studies of dynamic processes in organoid models, such as tissue morphogenesis, drug responses, and disease progression. Furthermore, the chip's glass-bottom design, combined with a thin hydrogel layer, facilitates confocal imaging either with the hydrogel in place or after it has been dissolved. Overall, our hydrogel-based microwell chip represents a robust and versatile platform that not only standardizes organoid culture but also improves the quality of imaging and data collection. By enhancing reproducibility, efficiency, and throughput, this technology holds promise for applications in precision medicine, drug testing, cancer research, and beyond.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Biochemical Modulators of Cancer / Differentiation Therapeutic Strategies

Introduction: Phenotypic plasticity, or the ability of cancer cells to switch between cell states, is a hallmark of cancer. Cancer cells can hijack normal developmental pathways and push cells to a more proliferative, plastic cell state similar to those found in early development. To identify therapeutic targets driving tumor plasticity, we utilized our proprietary AI-ML platform to create a high resolution atlas of normal human development. Tumors were mapped to the atlas to identify the genes driving their oncogenic cell state. Our platform identified KAT2A, a lysine acetyltransferase, as a key driver in neuroendocrine prostate cancer (NEPC). Additionally in castration resistant prostate cancer (CRPC), elevated expression of KAT2A has been reported in patients with high grade disease or biochemical recurrence and is associated with poor clinical survival. Literature has demonstrated that shKAT2A can modify resistance to anti-androgens and suggests that KAT2A can play a role in the localization of androgen receptor (AR). Our studies investigate the opportunity for targeting KAT2A in treatment refractory prostate cancer (NEPC and CRPC).
Methods: To pharmacologically target KAT2A, and its paralog KAT2B, we developed AUTX-703, a novel, potent and orally bioavailable heterobifunctional protein degrader. The effects of AUTX-703 on cellular differentiation and growth inhibition were evaluated in NEPC cell lines and patient derived organoids models. The effects of AUTX-703 on AR localization and signaling were also evaluated in cell lines resistant to anti-androgens.
Results: Treatment of the NEPC cell line, LASCPC01 and two NEPC organoid models with AUTX-703 degraded KAT2A and KAT2B, induced differentiation toward an epithelial cell state and inhibited growth, in vitro. In AR positive treatment refractory prostate adenocarcinoma models, AUTX-703 alone or in combination with anti-androgens reduced cell growth, decreased levels of nuclear AR, and decreased levels of AR and Myc signaling. Unlike anti-androgen treatment which shifted cells toward a more stem-like state, treatment with AUTX-703 alone or in combination with anti-androgens shifted cells towards a more differentiated epithelial cell state.
Conclusion: Our studies validate KAT2A and KAT2B as key drivers of tumor cell state plasticity. Degradation of KAT2A and KAT2B with AUTX-703 induces a more differentiated cell state and inhibits growth in NEPC and CRPC models. These data support progression of AUTX-703 into clinical development for NEPC and targeting KAT2A and KAT2B in the treatment of anti-androgen resistant prostate cancer.

#351 Preclinical development of MHB009C: A novel anti-B7-H4 ADC with a potent topoisomerase I inhibitor.

L. Zhu, B. Liu, Y. Chen, X. Meng, A. Li, L. Liu, Z. Yao, Y. Wang, X. Weng, X. Zhu, Y. Liu, S. Zhou, J. Shi, **G. Cao**;
Minghui Pharmaceutical, Hangzhou, China

B7-H4, a member of B7 family, is a transmembrane protein that inhibits T cell immunity. It is overexpressed in various malignancies, including breast, ovarian, and endometrial cancers, as well as cholangiocarcinoma, where it has been associated with tumor progression and poor patient outcomes. Antibody-drug conjugates (ADC) targeting B7-H4 have demonstrated promising clinical activity. Here, we present the development and preclinical characterization of MHB009C, a novel B7-H4 ADC.

MHB009C comprises a human IgG1 antibody against B7-H4, conjugated to the SuperTopoi™ payload, a novel DNA topoisomerase I inhibitor that is 3~5 times more potent than DXd, with a drug-antibody ratio of ~4.0. Fc function was silenced to minimize nonspecific ADC uptake, and the linker was designed to enhance hydrophilicity and prevent the retro-Michael reaction, improving plasma stability. MHB009C demonstrated strong binding affinity to B7-H4 and was efficiently internalized by SK-BR-3 cells. It exhibited potent cytotoxicity in B7-H4-positive breast cancer cell lines and showed significant antitumor activity in an MX-1 breast cancer xenograft model. GLP study in monkeys revealed a favorable safety profile with no off-target toxicities, and the highest non-severely toxic dose (HNSTD) was determined to be 30 mg/kg Q3W, the maximum dose tested.

In conclusion, MHB009C demonstrated potent anti-tumor activity both *in vitro* and *in vivo*, along with a favorable safety profile, supporting further clinical development.

#352 Preclinical development of MHB042C: A next-generation anti-c-Met ADC conjugating VHH-Fc fusion protein with a novel topoisomerase I inhibitor.

Bo Liu, Liyuan Zhu, Yile Chen, Xiang Meng, Ao Li, Li Liu, Zhili Yao, Yan Wang, Xialian Weng, Xuefeng Zhu, Yang Liu, Shiyu Zhou, Junwei Shi, **Guoqing Cao**

Minghui Pharmaceutical, Hangzhou, China

c-MET, a receptor tyrosine kinase encoded by the MET proto-oncogene, is widely expressed in various solid tumors. Antibody-drug conjugates (ADC) targeting c-Met have shown promising clinical activity in patients with high c-MET expression, yet the therapeutic benefit remains limited for those with moderate or low expression levels. Here, we present the development and preclinical characterization of MHB042C, a next-generation anti-c-Met ADC.

Unlike conventional monoclonal antibody (mAb), MHB042C utilizes a humanized VHH targeting c-Met, fused with human IgG1 Fc to deliver the cytotoxic payload. The smaller VHH-Fc fusion protein offers higher potential for tumor tissue penetration compared to traditional mAb. This unique configuration streamlines the conjugation process, achieving a uniform drug-to-antibody ratio (DAR) of 4. Additionally, Fc function was silenced to minimize nonspecific ADC uptake. The payload, SuperTopoi^{TM}, a novel DNA topoisomerase I inhibitor, was 3 to 5 times more potent than DXd. The linker was designed to enhance hydrophilicity and to resist the retro-Michael reaction, thereby improving plasma stability. In preclinical assays, MHB042C demonstrated stronger cellular binding than competitor antibodies, reaching an internalization rate of approximately 60% in Hs746t cells within one hour. MHB042C exhibited potent cytotoxicity across c-Met-positive cancer cell lines and showed marked antitumor activity in an EBC-1 Squamous NSCLC xenograft model. GLP study in monkeys revealed a favorable safety profile with no off-target toxicities. The highest non-severely toxic dose (HNSTD) was determined to be 15 mg/kg Q3W, the maximum dose tested.

In conclusion, MHB042C demonstrated potent antitumor activity both *in vitro* and *in vivo*, along with a favorable safety profile, supporting advancement to clinical development.

#353 Preclinical development of MHB048C: A novel anti-PSMA ADC with a potent topoisomerase I inhibitor.

Yile Chen, Ao Li, Bo Liu, Liyuan Zhu, Xiang Meng, Zhili Yao, Yan Wang, Xialian Weng, Xuefeng Zhu, Shiyu Zhou, Junwei Shi, **Guoqing Cao**

Minghui Pharmaceutical, Hangzhou, China

Prostate-specific membrane antigen (PSMA), a type II transmembrane glycoprotein, is highly and specifically expressed in prostate cancer while showing limited expression in normal tissues. The FDA's approval of (177) Lu-PSMA-617 has validated PSMA as a therapeutic target for treating metastatic castration-resistant prostate cancer (mCRPC). Here, we present the development and preclinical characterization of MHB048C, a novel PSMA specific antibody-drug conjugate (ADC).

MHB048C comprises a human IgG1 antibody against PSMA, conjugated to the SuperTopoi^{TM} payload, a novel DNA topoisomerase I inhibitor that is 3~5 times more potent than DXd. The drug-antibody ratio is approximately 4.0. Fc function was silenced to minimize nonspecific ADC uptake, and the linker was designed to enhance hydrophilicity and prevent the retro-Michael reaction, improving plasma stability. The antibody preferentially binds to the PSMA dimer rather than the monomer, as only dimers display the native conformation. MHB048C showed strong binding affinity in protein and cell-level assays and was efficiently internalized by LNCaP cells, reaching an internalization rate of ~70% within 1 hour. It exhibited potent cytotoxicity in PSMA-positive prostate cancer cell lines with varying PSMA expression levels and demonstrated significant antitumor activity in an LNCaP FGC prostate cancer xenograft model. In GLP monkey studies, MHB048C exhibited a favorable safety profile with no off-target toxicities. The highest non-severely toxic dose (HNSTD) was determined to be 45 mg/kg Q3W, the maximum dose tested.

In conclusion, MHB048C demonstrated potent anti-tumor activity both in vitro and in vivo, along with a favorable safety profile, supporting advancement to clinical development.

[1]Acrivon Therapeutics Inc., Watertown, MA,[2]Acrivon AB, Medicon Village, Lund, Sweden,[3]Active Motif, Carlsbad, CA

Introduction: WEE1 and PKMYT1 are essential kinases that safeguard genomic integrity by regulating CDK1 and CDK2. ACR-2316 is a potent, selective WEE1/PKMYT1 inhibitor rationally designed using Acrivon's Predictive Precision Proteomics (AP3) platform. ACR-2316 was uniquely designed, optimized, and advanced from initial lead to first-in-human dosing in < 15 months by AP3 to deliver complete tumor regression and pro-apoptotic tumor cell death through potent activation of CDK1, CDK2, and, importantly, PLK1. Here, we leveraged AP3-based global differential phosphoproteomic profiling and computational analyses to map and quantify the ACR-2316-regulated CDK1/2 and PLK1 substrates for unbiased understanding of drug action.
Results: AP3-based data-independent acquisition mass spectrometry was conducted using human cancer cells treated with vehicle or ACR-2316, -/+ CDK1 or CDK2 inhibition. Kinase activity inference analyzed by AP3 machine learning leveraging curated kinase-substrate relationships revealed that ACR-2316 strongly activated CDK1 and CDK2 followed by mitotic and DNA damage response kinases. We quantified hundreds of CDK1 and CDK2 substrates, regulated by ACR-2316, associated with S-phase DNA replication and replicative stress (CDK2) and with G2/M phase mitotic chromosome re-organization and segregation (CDK1). Multiparametric flow cytometry confirmed that ACR-2316 triggers DNA damage, premature mitosis, and S/G2-M cell cycle arrest. CellTiter-Glo and live cell imaging assays demonstrated robust inhibition of cell proliferation and potent cell death across human cancer cell lines. Inhibition of CDK1 or CDK2 partially rescued these phenotypes, confirming on-target mechanism of action identified through AP3. Chromatin immunoprecipitation sequencing showed unique intronic regions were susceptible to ACR-2316-induced double strand breaks. Finally, multiplexed immunofluorescence for alpha-tubulin and DNA revealed a large ACR-2316-induced increase in the number of mitotic aberrations in human cancer cells compared to vehicle control, and inhibition of only WEE1 or PKMYT1.
Conclusions: The unique capabilities of our generative AI-driven AP3 platform used to rationally design ACR-2316 enabled a comprehensive analysis of ACR-2316-regulated CDK1/2-and PLK1-induced pathways underlying its differentiated, potent anticancer activity, as demonstrated in head:head preclinical studies against clinical benchmark inhibitors. ACR-2316 has advanced into the clinic ahead of schedule uniquely enabled by AP3 and is currently in a Phase 1 clinical trial in subjects with AP3-selected advanced solid tumors. Acrivon anticipates reporting initial ACR-2316 clinical Phase 1 data second half of 2025.

#358 INK4A/B as predictive biomarkers for enhanced efficacy of dual WEE1 and PKMYT1 inhibition in CDK4/6 inhibitor-resistant breast cancer.

Mei-Kuang Chen[1], Xiaoting Jiang[1], Xiayu Rao[2], Tuyen Bui[1], Yan Wang[1], Jing Wang[2], Grace DeAlessandro[1], Nicole L. Massoumi[1], Rachel Y. Kim[1], Roanna A. Debler[1], Serena Kim[1], Kelly K. Hunt[3], Felicia Gray[4], Shaoxian Sun[4], Khandan Keyomarsi[1]

[1]Experimental Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Schrodinger, Inc., New York, NY

Purpose: Although CDK4/6 inhibitors combined with endocrine therapy represent the standard of care for ER+/HER2- advanced breast cancer, resistance inevitably develops in a significant subset of patients, limiting effective treatment options. Similarly, patients with triple-negative breast cancer (TNBC) lacking BRCA mutations face an absence of targeted therapeutic strategies. These challenges underscore the urgent need for biomarker-driven targeted therapies in approximately 30% of breast cancer patients. Both CDK4/6 inhibitor-resistant (CDK4/6i-R) breast cancer and TNBC exhibit increased replication stress and cell cycle dysregulation, suggesting potential sensitivity to interventions targeting G2/M transition regulation by kinases like WEE1 and PKMYT1. Prior findings show that WEE1 and PKMYT1 inhibition disrupts TNBC cell survival by forcing cell cycle progression without adequate DNA repair and chromosome segregation. Our findings further indicate that WEE1 or PKMYT1 inhibition can effectively suppress CDK4/6i-R tumor growth. Additionally, PKMYT1 upregulation mediates resistance to WEE1 inhibition, suggesting that dual WEE1/PKMYT1 inhibition may provide synergistic tumor suppression in CDK4/6i-R and TNBC contexts. This study aimed to identify predictive biomarkers of response to WEE1/PKMYT1 dual inhibition while maintaining manageable toxicity.
Results: Evaluating WEE1 inhibitors (adavosertib or azenosertib) in combination with the PKMYT1 inhibitor (lunresertib) across CDK4/6i-R and TNBC models, including patient-derived xenografts (PDXs) and organoids, demonstrated significant tumor suppression, with the novel dual WEE1/PKMYT1 inhibitor SGR-3515 showing comparable efficacy. RNA sequencing analysis revealed a positive association between high INK4B (p15) expression and robust treatment response, while baseline expression data from the Cancer Cell Line Encyclopedia indicated a positive correlation between both INK4A (p16) and INK4B expression and responsiveness to dual WEE1/PKMYT1 inhibition across ER-positive and TNBC subtypes. Notably, forced overexpression of INK4B sensitized cells to dual inhibition, whereas INK4B knockdown increased resistance, underscoring its pivotal role in therapeutic response. Higher baseline levels of INK4A and INK4B in CDK4/6i-R and TNBC PDX models further correlated with improved treatment outcomes.
Conclusion: Dual inhibition of WEE1 and PKMYT1 presents a compelling therapeutic strategy for CDK4/6i-R breast cancer and TNBC. Elevated baseline levels of INK4A and INK4B are strongly associated with enhanced treatment responses, highlighting their potential as predictive biomarkers for selecting patients likely to benefit from WEE1/PKMYT1 dual inhibition therapy.

#359 Rb loss-related DNA damage repair deficiency mediates the synthetically lethal effect of ATR/PKMYT1 co-inhibition in TNBC and CDK4/6i-resistant ER+ breast cancer.

X.-T. Jiang, M.-K. Chen, J. Lee, X. Rao, J. Wang, K. Hunt, K. Keyomarsi;
The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: This study explores the therapeutic potential of dual ATR and PKMYT1 inhibition for treatment-resistant breast cancers, particularly triple-negative breast cancer (TNBC) and ER-positive breast cancer resistant to cyclin-dependent kinase 4/6 inhibitors (CDK4/6i). By investigating the synthetic lethality of ATR/PKMYT1 co-inhibition, we aimed to identify biomarkers predictive of treatment response, specifically examining Rb status and its effect on DNA damage repair mechanisms.
Methods: The study tested the combination of ATR inhibitor (RP3500) and PKMYT1 inhibitor (RP6306) in TNBC and ER-positive parental and palbociclib-resistant breast cancer cell lines, as well as in patient-derived xenograft (PDX) models. RNA sequencing (RNAseq), reverse phase protein array (RPPA) analyses, and western blot were employed to evaluate treatment efficacy, synergy, and biomarkers associated with response, particularly focusing on Rb1 expression.
Results: In vitro, both TNBC and palbociclib-resistant breast cancer cells—characterized by higher replicative stress—showed heightened dependency on ATR and PKMYT1 pathways. ATR inhibition disrupted DNA replication, while PKMYT1 inhibition induced premature mitosis, collectively leading to increased DNA damage and apoptosis in these models. In vivo, the combination treatment produced significant anti-tumor effects in TNBC and palbociclib-resistant PDX models. The loss of Rb strongly predicted treatment response; Rb-deficient cell lines (MCF-7 palbociclib-resistant, BT-549, and MB-436) and PDX models (PR4-T141 and TNBC2-BCX070) demonstrated pronounced apoptosis and tumor regression. Conversely, Rb-proficient MCF-7 parental cells, MB-231 and MB453 were less responsive. Rb1 re-expression in sensitive BT-549 cells mitigated apoptosis under the combination treatment, while Rb1 knockdown in MB-231 and MCF-7 cells increased sensitivity to the therapy. Comparative RNAseq and RPPA analyses showed diminished DNA damage repair activity in Rb-deficient cell lines and PDX models compared to Rb-proficient models, suggesting an Rb-dependent regulation of various DNA damage repair pathways. This was further supported by neutral comet assays in the MB-231 parental and Rb1 knockdown cell lines, which demonstrated longer DNA double stranded-break repair times with Rb1 knockdown.
Conclusions: ATR and PKMYT1 co-inhibition is a promising therapeutic strategy for TNBC and CDK4/6i-resistant breast cancer. The synthetic lethality of this combination is enhanced in Rb-deficient models, where Rb1 loss impairs DNA damage repair capabilities, amplifying the anti-tumor effects.

#36 A patient-centered approach to 3D *in vitro* modeling of pancreatic ductal adenocarcinoma.
Jade Vipond Cotter, Katie Reindl

Biological Sciences, North Dakota State Univ., Fargo, ND

Matrigel® is the most commonly used hydrogel product for developing and testing 3-D *in vitro* pancreatic ductal adenocarcinoma (PDAC) models; however, its composition is not reflective of the ECM content of most PDAC tumors. To remedy this pitfall, we have developed a novel approach for generating patient-derived 3D tumor organoids grown in customized hydrogels that better reflect their original tumor tissue. Using surgically resected original patient tissue, we measured the relative area covered by the major ECM constituents in PDAC: collagens I, III, IV, and laminin via IHC. Cells collected from PDX-propagated patient tissues were then embedded in the custom hydrogel comprised of ECM proteins in concentration that mirrored the original patient tissue. Organoids will then be monitored for size and rate of proliferation via MTT assay. Finally, to ensure transmembrane interactions with the customized hydrogel, expression of integrins α1, α2, α6, which bind the aforementioned hydrogel components, will be measured via IHC. We anticipate organoids grown in these custom hydrogels will demonstrate a greater likelihood of successful model development and higher growth rate than those grown in Matrigel®. Additionally, we expect organoids grown by this method will show increased expression of integrins α1, α2, and α6. These results provide preliminary evidence that the composition of the hydrogel used to generate 3D *in vitro* models may have an impact on their phenotypic expression. Further development and characterization of these models could result in better reflection of *in vivo* conditions in preclinical therapy testing.

Advancing effective cancer therapies requires innovative approaches to better understand complex biological interactions. PKMYT1, a crucial regulator of the cell cycle involved in the G2/M transition through inhibitory phosphorylation of CDK1, has emerged as a promising therapeutic target. Inactivation of PKMYT1 is synthetically lethal in tumor cells with genomic alterations leading to high replication stress, such as CCNE1 amplification, which is frequently found in high-grade serous ovarian, uterine, and gastro-esophageal cancers. In this report, we present a series of potent PKMYT1 inhibitors, emphasizing their pharmacokinetic profiles and anti-tumor activities, characterized as either single agents or in combination. Furthermore, we explored the potential of combination therapy using these profiled PKMYT1 inhibitors. We hypothesized that inhibition of the DNA damage response kinase ATR and its downstream pathway may further enhance the tumor cytotoxicity of PKMYT1 inhibitors. Preclinical validation of this hypothesis demonstrated that combining PKMYT1 inhibitors with ATR inhibitors, such as prexasertib and RP-3500, resulted in enhanced antitumor activity in CCNE1-amplified cancer models. Additionally, we observed synergistic effects when combining PKMYT1 inhibitors with standard-of-care chemotherapies that induce DNA damage, such as gemcitabine and hydroxyurea. We also identified novel synergistic partners from library screening, featuring GSK3B inhibitors. These findings were confirmed in cell lines, organoid models, and in vivo CDX models, highlighting the potential of PKMYT1 inhibitors as part of combination therapy strategies. In conclusion, our study underscores the therapeutic potential of selective PKMYT1 inhibitors in CCNE1-amplified cancers and provides a strong rationale for their combination with ATR inhibitors and DNA-damaging chemotherapies. These findings support the continued development and clinical evaluation of PKMYT1 inhibitors as a novel approach to cancer treatment.

#361 Allosteric ClpP agonist ONC206 alters mitochondrial metabolism, stress response, chromatin accessibility and cell cycle to elicit apoptosis in pheochromocytoma.

Varun V. Prabhu, Cristina Maranto, Andrew Lee, Scott Foster, Joshua E. Allen

Chimerix, Inc., Durham, NC

Dordaviprone (ONC201), an allosteric caseinolytic protease P (ClpP) agonist and dopamine receptor D2/3 (DRD2/3) antagonist, has demonstrated durable responses in recurrent H3 K27M-mutant glioma patients. ONC206, a derivative of dordaviprone with nanomolar potency for DRD2/3 and ClpP, is in Phase I trials. Dordaviprone demonstrated responses in patients with neuroendocrine pheochromocytoma-paraganglioma (PC-PG) including tumors with SDHB/FH loss-of-function driver mutations. We characterized ClpP binding, in vitro efficacy, comparison to standard of care (SOC) treatments, downstream signaling and response determinants for ONC206 in PC. Co-crystallization with ClpP that assembles as a tetradecameric complex revealed an allosteric ligand interaction with distinctions in the ONC206-ClpP resolved crystal structure relative to the dordaviprone-bound or apo complex, including an increase in the resolved pore size and decreased complex height. ONC206 was more potent than dordaviprone in cell-free human ClpP casein/peptide degradation assays. Accordingly, PC lines (hPheo1, PC12, MPC10) exhibited increased nanomolar sensitivity to ONC206 (~6 fold) relative to dordaviprone in cell viability assays. ONC206 induced dose- and time-dependent apoptosis in PC but not fibroblast (HFF-1, MRC-5) cells as measured with caspase Glo and/or annexin V assays. ONC206 generally required a shorter duration of exposure (~24h) and induced enhanced apoptosis in PC cell lines relative to dordaviprone at therapeutically relevant concentrations. ONC206 also demonstrated superior cell viability inhibition and apoptosis induction in PC cell lines relative to temozolomide and sunitinib at equivalent concentrations. CRISPR-mediated SDHB or FH knockout hPheo1 cells were equally sensitive to ONC206 as parental cells. Unlike DRD2, CRISPR-mediated ClpP knockout in hPheo1 cells impaired ONC206 sensitivity. Proteomics indicated inhibition of mitochondrial metabolism including OXPHOS and TCA cycle in hPheo1 cells. Accordingly, metabolomics revealed ONC206 elevated α-ketoglutaric acid, 2-hydroxyglutaric acid and reduced succinic acid, fumaric acid in a ClpP-dependent manner in hPheo1 cells. Consistent with epigenetic regulation by metabolites, ATACseq revealed ONC206 altered chromatin accessibility in hPheo1 cells. RNAseq demonstrated ONC206 upregulated stress response, apoptosis and downregulated cell cycle, metabolism-related pathways in hPheo1 cells. Accordingly, western blot showed ONC206 downregulated mitochondrial proteins (ClpX, SDHB), neuroendocrine markers (tyrosine hydroxylase, enolase-2, synaptophysin) and upregulated stress response (ATF4) in hPheo1 cells. Thus, ONC206 is a potent novel agent that is superior to SOC and dordaviprone that have shown clinical activity in PC-PG.

#362 Prevention of centrosome clustering by targeting the motor protein X: A promising therapeutic strategy for small cell lung cancer.

N. Nakagawa[1], M. Tokunaga[1], M. Ka[1], T. Iida[1], T. Ando[1], A. Kunita[1], K. Watanabe[1], Y. Ohta[2], X. Liu[3], E. Dmitrovsky[3], H. Kage[1], M. Kawakami[1];

[1]Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Research Hospital, Institute of Medical Science, University of Tokyo, Tokyo, Japan, [3]Frederick National Laboratory for Cancer Research, Frederick, MD

Cancer cells often have more than two centrosomes (centrosome amplification). This is a cancer hallmark. Cancer cells cluster supernumerary centrosomes during mitosis so that they can undergo bipolar mitosis, similar to normal cells. We previously reported that inhibition of centrosome clustering by CDK2 antagonism in non-small lung cell cancer caused multipolar cell division and apoptotic death, termed anaphase catastrophe. Anaphase catastrophe preferentially affects cancer cells, sparing normal cells with two centrosomes. This therapeutic window implicates triggering anaphase catastrophe as a promising antineoplastic pathway. Motor protein X is reported to affect centrosome clustering but is not essential in normal cells. Small cell lung cancer (SCLC) has p53 inactivation and a poor prognosis with limited therapeutic options. Loss of p53 function disrupts the cell cycle checkpoint and is associated with centrosome amplification. We hypothesized that SCLC is vulnerable to mitotic abnormalities, including anaphase catastrophe. We explore here protein X as a novel therapeutic target that triggers anaphase catastrophe and apoptosis in SCLC. In vitro studies of multiple SCLC cell lines were performed. Immunofluorescence staining of pericentrin revealed higher frequency of centrosome amplification in SCLC than in normal human bronchial epithelial (NHBE) cells. Immunoblotting indicated that motor protein X was over-expressed in SCLC cells compared to NHBE cells. Functional analyses of protein X was done using siRNAs, CRISPR-Cas9 system, and a specific inhibitor. Protein X inhibition reduced cell proliferation and triggered apoptosis in the examined SCLC cell lines. In NHBE cells with infrequent centrosome amplification, these effects were rarely observed. To elucidate the mechanism for these antineoplastic effects, the mitotic status of SCLC cells was studied by staining for α-tubulin, pericentrin, and DAPI. Cells with clustered supernumerary centrosomes were statistically significantly decreased, while the number of multipolar mitotic cells were statistically significantly increased upon protein X inhibition. This indicated that targeting the protein X produced anaphase catastrophe in SCLC cells. We confirmed and extended these in vitro findings to the in vivo setting. The protein X inhibitor statistically significantly suppressed the growth of NCI-H146 tumor xenografts in mice. Pericentrin staining of resected treated xenografts revealed that the protein X inhibitor antagonized clustering of supernumerary centrosomes and led to multipolar mitosis in vivo. Taken together, prevention of supernumerary centrosome clustering by targeting the motor protein X is an attractive therapeutic strategy for SCLC.

#363 Exploiting Rb-deficiency: Dual inhibition of TRIP13 and Aurora A as a path to mitotic catastrophe.

Lacin Yapindi[1], Soma Ghosh[1], Li Shen[2], Jing Wang[2], Faye M. Johnson[1]

[1]Thoracic/Head & Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX

Deregulation of the Rb pathway is found in approximately one-third of all solid tumors. Despite the high prevalence, there are still no clinically established therapies selectively targeting Rb-deficient cancers. Therefore, understanding how Rb function loss can be leveraged is crucial for developing novel, biomarker-driven, targeted therapeutic strategies. We and others have previously shown that Rb-deficient cancer cells depend on Aurora A kinases to bypass the primed spindle assembly checkpoint (SAC) and survive due to overexpression of the mitotic checkpoint protein Mad2. Thyroid hormone receptor interactor 13 (TRIP13) is a mitotic checkpoint modulatory protein that catalyzes the ATP-dependent conformational conversion of Mad2 to promote SAC silencing. Our previous research demonstrated that the combination of Aurora A inhibition using specific inhibitor alisertib and TRIP13 depletion induced synthetic lethality selectively in Rb-deficient cancer cells where the combination induced mitotic catastrophe. The combination also significantly increased the number of mitotic cells with an abnormal mitotic morphology by causing mitotic spindle defects and abnormalities in chromosomal alignment. Additionally, the combination led to prominent G2/M arrest in Rb-deficient cancer cells, while it only transiently delayed cell cycle progression in Rb-proficient cancer cells. Our live-cell imaging experiments using three Rb-deficient cell line models (HeLa, UMSCC47, ME180) showed that the combination induces marked prolonged arrest in mitosis and results in mitotic cell death. Furthermore, using auxin-inducible degron system and siRNA-mediated protein depletion, we showed that TRIP13 plays a modulatory role in mitotic exit as its depletion induced transient mitotic arrest and enhanced alisertib-induced lethality by further extending the mitotic arrest. Since mitotic catastrophe can cause DNA damage and this damage can be sensed by the inducers of immunogenic cell death (ICD), we also tested the effect of the combination on DNA damage and ICD. The combination caused marked DNA damage in mitotic Rb-deficient cancer cells, as measured by the increased γH2AX protein levels and tail-length using the neutral comet assay. Similarly, it increased the protein levels of ICD potentiators, cGAS and cleaved-gasdermin E. The mitotic entry was shown to be pivotal to the lethal effects of the combination, since the inhibition of mitotic entry with concurrent CDK1 inhibitor, RO-3306, prevented apoptosis and DNA damage, as determined by APO-DIRECT assay and immunoblotting. This is the first study to elucidate the mechanism behind the synthetic lethality of TRIP13 and Aurora A in Rb-deficient cancer cells. These findings may provide important insight into how to rationally design novel therapeutic strategies targeting mitotic regulators by harnessing the therapeutic vulnerability of Rb-deficient cancer cells.

#364 Oxaliplatin and 5-fluorouracil cause therapy-induced senescence in low-grade serous ovarian cancer cells.

Rewati Prakash[1], Alicia A. Goyeneche[2], Edith Zorychta[3], Shuk On Annie Leung[4], Lucy Gilbert[4], Carlos Telleria[1]

[1]Pathology, McGill University, Montreal, QC, Canada,[2]Research Institute of the McGill University Health Centre, Montreal, QC, Canada,[3]McGill University, Montreal, QC, Canada,[4]Gynecologic-oncology, Research Institute of the McGill University Health Centre, Montreal, QC, Canada

A critical concern with managing low-grade serous ovarian cancer (LGSOC) is the lack of response to standard carboplatin-paclitaxel chemotherapy; less than 30% of patients respond to such initial chemotherapy. Oxaliplatin (OXP) and 5-Fluorouracil (5-FU) combination treatment is a standard treatment regimen against colorectal cancer (CRC); however, it could be repurposed for use against LGSOC. p53 wildtype CRC tumours have been shown to respond better to OXP & 5-FU suggesting that LGSOC, which is well-characterized to also be p53 wildtype, would also respond effectively to this treatment. Consequently, in this study, we utilized three LGSOC cell lines: VOA6406, VOA7681, and VOA1056. We determined the cytotoxic effects of treatment with OXP & 5-FU; viability, proliferation, clonogenic capacity, and drug-withdrawal recovery were assessed. Results showed a dramatic decrease in cell proliferation in the short-and-long term, without a reduction in cell viability. This effect was confirmed further by measuring Ki67, a marker of cell proliferation; OXP & 5-FU-treated cells showed a significant reduction in Ki67 labelling. The persistence in viability alongside the reduced cell proliferation in cells treated with OXP & 5-FU led us to hypothesize that this drug combination induces senescence in LGSOC cells. A critical aspect of senescence is the arrest of the cell cycle. A propidium iodide-based cell cycle assay, along with western blotting to measure expression of p53, p21, and pRb, demonstrated that the LGSOC cells treated with OXP & 5-FU were arresting at the G1-S phase. Morphology alterations and lysosomal swelling were measured via expression of senescence-associated β-galactosidase (SA-β-gal); OXP & 5-FU-treated LGSOC cells demonstrated a marked increase in SA-β-gal as well as a distinct flattening of cell morphology. Consistent with hallmarks of senescence, anti-apoptotic proteins Bcl-2 and Mcl-1, were elevated upon treatment with OXP & 5-FU. A compelling increase in reactive oxygen species (ROS) production, as well as an elevated expression of caveolin-1, suggest a senescence-induction pathway dependent on oxidative stress. The use of a known ROS quencher, α-tocopherol, confirmed this pathway, as it partially rescued the senescence phenotype induced by OXP & 5-FU. The use of OXP & 5-FU to induce senescence in LGSOC shows promise as an alternate treatment option for this rare disease. We will further study if facilitating a “one-two punch theory” could be used against LGSOC, whereby OXP & 5-FU induces senescence, which could be subsequently “cleared” by a senolytic drug.

#365 A dual mechanism of sensitivity to PLK4 inhibition by RP-1664 in neuroblastoma.

Isabel Soria-Bretones[1], Matias Casas-Selves[1], Elliot Goodfellow[1], Ariya Shiwram[1], Nancy Laterreur[1], Li Li[1], Cathy Carron[1], Julian Bowlan[2], Hyeyeon Kim[1], Danielle Henry[1], Alejandro Alvarez-Quilon[1], Frederic Vallee[1], Artur Veloso[2], Jordan T. F. Young[1], Stephen J. Morris[1], C. Gary Marshall[2], **Michal Zimmermann**[1]

[1]Repare Therapeutics Inc., St. Laurent, QC, Canada,[2]Repare Therapeutics Inc., Cambridge, MA

Introduction:

High-risk neuroblastoma (HRNB) is a pediatric tumor with poor prognosis and limited treatment options. Recently, a novel therapeutic hypothesis for HRNB was proposed based on synthetic lethality between inhibition of polo-like kinase 4 (PLK4) and high expression of *TRIM37* - a gene encoded on chromosome 17q, whose gain is among the most frequent genomic alterations in HRNB[1,2]. This synthetic lethality depends on PLK4 inhibition-driven loss of centrioles, which in *TRIM37*-overexpressing tumor cells disrupts mitotic spindle assembly, and causes cell death through mitotic delay and p53 activation. Interestingly, partial PLK4 inactivation by low doses of pharmacological inhibitors is known to have an opposite effect on centrioles - increasing their number[3]. Here we report that both centriole amplification and centriole loss contribute to an exquisite sensitivity of HRNB models to RP-1664, a first-in-class selective and orally available inhibitor of PLK4.

Methods:

RP-1664 sensitivity and cellular consequences of PLK4 inhibition were evaluated in a panel of HRNB cell lines and normal immortalized cells with or without *TRIM37* overexpression and functional *TP53*. To that end, cell growth assays, immunofluorescence, immunoblotting and live cell imaging were used. CRISPR/Cas9 genomic screening was employed to map genes modulating RP-1664 sensitivity. RP-1664 *in vivo* efficacy was assessed in HRNB mouse xenograft models.

Results:

RP-1664 induced expected phenotypes of PLK4 inhibition in human cells, including an increase in PLK4 protein level, p53/p21 activation, centriole amplification at lower concentrations, and centriole loss at higher concentrations. HRNB cell lines showed general hypersensitivity to RP-1664, including at concentrations leading to centriole amplification. While sensitivity at higher RP-1664 concentrations depended on *TRIM37* and *TP53*, and was associated with a delay in mitosis, sensitivity at lower concentrations was *TRIM37*- and *TP53*-independent. CRISPR screens and live cell imaging after low-dose RP-1664 treatment revealed that HRNB cells, unlike normal immortalized cells, were unable to compensate for excess centrioles by their inactivation or clustering, and succumbed to multipolar mitoses. *In vivo*, RP-1664 showed robust efficacy at well tolerated doses in HRNB models and at plasma exposures consistent with centriole amplification.

Conclusion:

HRNB cell models are hypersensitive to centriole amplification induced by low levels of PLK4 inhibition as well as to centriole loss at higher PLK4 inhibitor levels, warranting the investigation of RP-1664 in clinical trials with neuroblastoma patients.

#366 CDK7 inhibition as a synthetic lethal strategy in Rb-deficient ER+/HER2- breast cancer and sarcoma cells resistant to CDK4/6 inhibitors.

Rezvan Esmaeili[1], Tuyen N Bui[1], Tuyen Duong Thanh Nguyen[1], Jim Joseph[2], Fred Aswad[2], Kelly K Hunt[3], Elena Fonfria[4], Khandan Keyomarsi[1]

[1]Department of Experimental Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Apeiron Therapeutics, Burlingame, CA,[3]Department of Breast Surgical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Recursion, Oxford, United Kingdom

Purpose: Resistance to CDK4/6 inhibitors (CDK4/6i) presents a significant barrier in the treatment of ER+/HER2-breast cancers, affecting approximately 50%-60% of patients initially responsive to therapy. Moreover, soft tissue sarcomas (STS), representing over 13,000 new cases annually in the U.S. alone, are frequently characterized by Rb pathway disruption and have poor survival outcomes due to limited therapeutic options. Given the role of CDK7 as an upstream regulator of CDK2, and emerging evidence that Rb deficient cells are sensitive to CDK7 inhibition, we hypothesize that the novel CDK7 inhibitor REC-617may act as a synthetic lethal agent in Rb-deficient, CDK4/6i-resistant cancer models. This study aims to evaluate the efficacy of REC-617 in both ER+/HER2-breast cancer and STS cell lines, especially within Rb-deficient contexts, as a therapeutic strategy for overcoming resistance and broadening targeted treatment options.

Methods: CDK4/6i-resistant cell lines were generated by progressively exposing MCF7 breast cancer cells to increasing concentrations of palbociclib (1.2-4.8 µmol/L), ribociclib (1.2-4.8 µmol/L), and abemaciclib (0.5 and 1 µmol/L). CRISPR-Cas9 technology was used to create Rb-deficient models in resistant cells to assess REC-617's impact. Syngeneic and non-syngeneic sarcoma cell lines with differential Rb status were also treated to evaluate the drug's broader applicability in Rb-deficient cancers. Cell cycle progression, apoptosis, and toxicity were analyzed, and Western blotting was performed to monitor changes in cell cycle proteins, DNA damage markers, and signaling pathways.

Results: REC-617 induced a marked G2 phase arrest and increased apoptosis in CDK4/6i-resistant MCF7 breast cancer cells compared to parental cells. This effect correlated with decreases in CDK1 and CDC25C and an increase in cyclin B1, confirming G2/M arrest. DNA damage response was heightened, as shown by elevated γH2AX levels, while Rb and p53BP1 levels were diminished. Notably, both Rb-deficient CRISPR-engineered breast cancer cells and Rb-deficient sarcoma models exhibited heightened sensitivity to REC-617 compared to their Rb-intact counterparts. This increased susceptibility was consistently observed across palbociclib-, abemaciclib-, and palbociclib-resistant cells, further validating the relevance of Rb status in CDK7-targeted responses.

Conclusion: These findings demonstrate that CDK7 inhibition via REC-617 offers a potent synthetic lethal approach in Rb-deficient, CDK4/6i-resistant ER+/HER2-breast cancer and soft tissue sarcomas. Reduced Rb expression may be predictive of the level of response to REC-617, thus providing a targeted treatment option for overcoming resistance in both cancer types and addressing a critical need in resistant ER+/HER2-breast cancers and soft tissue sarcomas.

#367 Temporal dynamics of the senescence-associated secretory phenotype triggered by CDK4/6 inhibitor or doxorubicin treatment in liposarcoma.

Joanna Lan Hing Yeung[1], Justin Rendleman[1], Nicole Pagane[1], Irene Duba[1], Andrew Scortea[1], Lauren Anderson[1], Ria Hosuru[1], Bat Ider Tumenbayar[1], Andrew Koff[2], Viviana Risca[1]

[1]The Rockefeller University, New York, NY,[2]Memorial Sloan Kettering Cancer Centre, New York, NY

Liposarcoma is a rare cancer that frequently exhibits amplification of the cyclin-dependent kinase CDK4 gene. CDK4/6 inhibitors (CDK4/6i) represent a promising targeted therapy to halt proliferation in these tumors, particularly when therapeutic options are limited, and surgical resection is no longer viable. CDK4/6 inhibition can result in either reversible or irreversible exit from the cell cycle (quiescence or senescence, respectively), but the mechanisms driving these outcomes remain unclear. Since CDK4/6 inhibitors appear to induce cell cycle arrest without causing extensive DNA damage, we hypothesize that the senescence-associated secretory phenotype (SASP)—a collection of secreted proinflammatory molecules—induced by CDK4/6i differs significantly from the SASP triggered by cytotoxic chemotherapeutics such as doxorubicin. To investigate this, we characterized differences in SASP gene expression and its upstream regulators using RNA-seq and ATAC-seq in a 28 day time-course study of a patient-derived liposarcoma cell line responsive to both drugs. Our findings reveal that extracellular matrix (ECM) genes are upregulated early in CDK4/6i treatment, a response largely absent in doxorubicin-treated cells. Many of these ECM genes are previously identified SASP components, suggesting a CDK4/6i-specific SASP module. We identified the Hippo pathway regulator TEAD as a key player in shaping this response. Pharmacological inhibition of TEAD suppresses the upregulation of key SASP genes, *ANGPTL4* and *IGFBP3*, which are more strongly induced by CDK4/6i compared to doxorubicin. While the SASP profiles differ between drugs early in treatment, we observe emergence of a shared SASP signature characterized by NF-κB signaling at later time points. This is indicated by upregulation of NF-κB target genes and enrichment of NF-κB motifs in the regions with increased chromatin accessibility under both drugs. In both cases, we detect increased nuclear localization of p65, a subunit of NF-κB, confirming NF-κB activation. Furthermore, addition of an NF-κB inhibitor suppresses the upregulation of NF-κB target SASP genes in both treatments. These results highlight how the composition of therapy-induced SASP evolves over time and contains both common and treatment-specific modules. We also demonstrate that NF-κB activity contributes to shaping part of the CDK4/6i-induced senescence response, addressing an area of ongoing debate in the field. Our study provides new insights into how cancer therapies regulate the SASP profile, with implications for understanding the effects of therapy-induced senescence on the tumor microenvironment.

#368 Unique breast cancer CDX panels for KAT6, ER, and CDK4/6.

Tianyu Pang, Haiting Dai, Ziwei Li, Wenbo Du, **Wen-Jen Yu**

ICE Bioscience INC, Beijing, China

Estrogen receptor-positive (ER+) breast cancer accounts for approximately 75% of all breast cancers. Over-expression of lysine acetyltransferase 6A (KAT6A), a histone acetyltransferase (HAT), shared a proportion of 10-15% in breast cancer patients and increased the tumor growth through binding the promoter region to enhance ER expression level. Inhibitors of KAT6A were thought to be anti-tumorigenic by deregulation of ER expression. In addition, the cyclin-dependent kinases 4/6-cyclinD-Rb (CDK4/6-cyclinD-Rb) pathway is very important and crucial for ER downstream signaling in ER+ breast cancers. To accelerate the discovery of anti-ER+ breast cancer drugs through KAT6A and CDK4/6 pathways, we generated four specific CDX models which cover the most popular ER+/KAT6A cell lines (BT-474, ZR-75-1) and ER+/ CDK4/6 cell lines (MCF-7, HCC1428) and revealed the efficacy of KAT6A inhibitor (PF-9363), CDK4/6 inhibitor (Palbociclib), or ER inhibitor (Fulvestrant) on these breast CDX models. The in vivo MOA of these inhibitors were also evaluated by Western Blotting and pathological examination.

#369 A novel class of multitarget small molecule PI3K-CDK4/6-CDK9-AURAKA/B inhibitor harnesses Warburg effect against non-small cell lung cancer.

Anna V. Ivanina Foureau, Cody C. McHale, Hailey L. Dryden, Krishnaiah Maddeboina, David M. Foureau, Fei Guo, Donald L. Durden, Kathryn F. Mileham

Levine Cancer Institute, Charlotte, NC

Introduction: *In silico* designed novel multitarget small molecule PI3K-CDK4/6-CDK9-AURKA/B inhibitor LCI139 is nanomolar potent against NSCLC cells of mixed histologic and mutational backgrounds. We previously established that higher NSCLC cells metabolic activity promotes LCI139 potency. Here, we describe how LCI139 harnesses the Warburg effect to induce synthetic lethality in NSCLC.
Methods: LCI139-sensitive (NCI-H1703) and resistant (NCI-H1781) human NSCLC cells, identified from prior IC_{50} experiments, were treated with LCI139 (0.25 and 0.5μM) or single agent inhibitors PI3Ki (BKM120), CDK4/6i (Ribociclib), CDK9i (AZD4573), and AURKAi (Alisertib). Apoptosis and senescence were measured by flow cytometry (Annexin V/7-AAD or β-gal). Mitochondrial respiration and mitochondrial complexes activity was measured with Clark-type electrode. Target inhibition, glycolysis and OXPHOS enzymes, AMPK-FoxO3 signaling, Bcl2-family proteins, and caspase expression/activation were evaluated by Western blot and qRT-PCR on whole cellular extract or isolated mitochondria.
Results: LCI139 induced caspase-dependent apoptosis in sensitive H1703 cells by promoting Cas8 activation, BIM expression, Bax-Bak complex formation, mitochondrial fission and apoptosome formation (Cas9). In resistant H1781 cells, LCI139 promoted cellular senescence by inducing mitochondrial respiration and oxidative stress (ROS-forming complexes I-III activity), while repressing caspase activation. Bioenergetic stress sensor AMP-activated protein kinase (AMPK) and downstream forkhead box O3 transcription factor (FOXO3) signaling played a key role in LCI139 response. Upon treatment of H1703 sensitive cells, pAMPK levels increased and FoxO3 was expressed/stabilized, leading to subsequent pro-apoptotic Cas8/BIM expression. Compared with H1781 resistant cells, H1703 cells had greater baseline glycolytic activity and mitochondrial respiration. Consequently, LCI139 profoundly disrupted both glycolytic-ATP (glucose uptake [Glut1] and catabolism [PFK, LDH] reduction), and OXPHOS-ATP production (mitochondrial complexes I-IV loss) in H1703 sensitive but not H1781 resistant cells. Single target inhibition experiments showed that the metabolic stress response to LCI139 was primarily driven by PI3Ki and CDK4/6i warheads and promoted both Cas8 and BIM. Inhibition of CDK9 alone was a potent inducer of subsequent Cas8 activation and, together with AURKAi, promoted cellular apoptosis in H1703 sensitive cells
Conclusions: Multitarget inhibitor, LCI139 is uniquely designed to harness the Warburg effect to induce synthetic lethality in glycolysis-reliant NSCLC by 1) inducing metabolic stress (pAMPK), 2) lowering the threshold to metabolic stress response (FoxO3 stabilization), and 3) enhancing caspase-dependent cell death non-canonical Cas8 activation.

TUMOR BIOLOGY: Human and PDX Models 1
Poster Session

#37 Characterization of cervical cancer patient derived organoid.

Rui Wang, Dalissa Negron-Figueroa, Xiaogang Wu, Bo Jiang, Barrett C. Lawson, Timothy A. Harris, Maura Gillison, Lauren Colbert

UT MD Anderson Cancer Center, Houston, TX

Background: HPV-related cervical cancers pose challenges in murine models due to human-specific viral carcinogenesis. Patient-derived organoids (PDOs) enable to incorporate extracellular matrix and tumor microenvironment, and mirror human tumor features.
Methods: Tumor and adjacent tissues were sampled via cytobrushes and resections, and then dissociated, and purified using a Lymphoprep gradient. One million cells were used for scRNA sequencing, while the rest formed PDOs. Baseline tumor and buccal swabs served as genomic controls. PDO identity was validated through immunofluorescent staining, bulk RNA sequencing, and whole exome sequencing (WES). Cell viability assays assessed PDO responses to bacterial metabolites, radiation, and chemotherapy.
Results: We established five PDO lines from cervical squamous cell carcinoma (CSCC) and cervical adenocarcinoma (CAC), including one normal PDO from CAC-adjacent tissue. Two primary cell lines were also developed: one from CAC and one from CSCC. Early cultures showed differential KI67 staining: CAC1101, CAC1446, and normal PDOs were positive, while CAC1237 and CSCC1188 were negative. Later cultures showed KI67 positivity across all lines. P63 staining was positive in early CAC1101, CAC1446-adjacent normal, and CSCC1188 PDOs but became negative in late CSCC1188. Only CAC1101 PDOs were PAX8-positive, and PAS staining was observed in all CAC-derived PDOs, including CAC1446-adjacent normal. Somatic mutation analysis revealed 22-46 mutations across most samples, except for Day-14 CAC1101 PDOs, which had 536 mutations. Day-21 CAC1101 PDOs showed 32.6%-54.5% similarity to their tumor swab. CSCC1188 samples exhibited consistent similarity with their tumor swabs (25.9%-40.0%) and within PDOs (37.0%-64.0%). Germline mutation analysis showed 1,045-1,918 mutations in most samples, except for Day-14 CAC1101 PDOs, which had 38 mutations. CSCC1188 samples showed higher similarity with their buccal swabs (71.3%-74.0%) and within PDOs (70.4%-78.4%) compared to CAC1101. Comparison of RNA sequencing data of CAC1101 and CSCC1188 showed samples from same patient sharing similar profiles. Cell viability assays indicated that bacterial metabolites increased resistance to radiation and cisplatin in CSCC1188-derived primary cells but had no effect on CAC1237-derived cells.
Conclusion: We developed a workflow for generating and expanding PDOs from surgical and non-invasive cytobrush samples while preserving tumor characteristics. PDOs recapitulated the features of their original tumors, offering insights into tumor-microenvironment interactions and variable responses to chemoradiation therapy.

#370 Resistance to sotorasib does not confer resistance to adagrasib: Why?.

Atish Ranjan Mohanty[1], Baiyi Quan[2], Supriyo Bhattacharya[1], Dana Do[1], Sravani Ramisetty[1], Tsui-Fen Chou[3], John Orban[4], Prakash Kulkarni[1], Ravi Salgia[1]

[1]City of Hope National Medical Center, Monrovia, CA,[2]Proteome Exploration Laboratory, California Institute of Technology, Pasadena, CA,[3]California Institute of Technology, Monrovia, CA,[4]University of Maryland, Baltimore, MD

Introduction: KRAS mutations are among the most common gain-of-function alterations, found in approximately 30% of lung adenocarcinomas. These mutations primarily occur at codon 12, leading to amino acid substitutions that impair KRAS's intrinsic GTPase activity, rendering the oncoprotein constitutively active. For decades, KRAS was considered "undruggable" due to the absence of a suitable drug-binding pocket. This paradigm shifted with the development of sotorasib, a covalent inhibitor that irreversibly binds to a cysteine residue, locking KRAS in its inactive GDP-bound state. Despite this breakthrough, the CodeBreaK 100 Phase I/II clinical trial revealed that the objective response rate to sotorasib was only 36%, with a median progression-free survival (PFS) of 7.6 months. These findings underscore that 64% of patients with advanced NSCLC exhibited innate resistance to sotorasib and those who responded eventually developed acquired resistance. Thus, in this study, we aim to explore the mechanisms of sotorasib resistance and evaluate the response of resistant cells to adagrasib using proteomic data.
Methods: KRAS G12C NSCLC cell lines were screened for sotorasib sensitivity, and isogenic-resistant lines were developed through incremental exposure. These lines were tested for adagrasib sensitivity. Proteomic changes in parental and resistant cells, untreated or after treatment, were analyzed via mass spectrometry.
Results: Incremental sotorasib treatment of sensitive cells generated isogenic resistant lines capable of tolerating sotorasib concentrations up to 20 μM. Exome analysis of resistant cells revealed no acquired driver mutations, which could be correlated with sotorasib resistance. However, these cells exhibited increased expression of ITGB4 and WNT2, leading to activation of PI3K/Akt and Wnt/β-catenin signaling pathways, as confirmed by western blot analysis. Proteomic profiling identified an upregulation of proteins involved in biological processes like cell adhesion and signal transduction, consistent with the activation of ITGB4 and Wnt signaling. Notably, adagrasib treatment significantly suppressed these biological processes and activated metabolic processes. Live-cell imaging and cell cycle analysis further demonstrated that adagrasib induced a more robust cell cycle arrest than sotorasib.
Conclusion: This study concludes that sotorasib resistance can arise through the activation of alternative signaling pathways, underscoring the adaptability of biological networks in cancer cells. However, this non-genetic resistance mechanism to sotorasib does not confer cross-resistance to adagrasib, indicating that the fitness acquired by cancer cells to tolerate sotorasib is ineffective against adagrasib. These findings suggest that patients who progress on sotorasib treatment may still benefit from adagrasib, highlighting its therapeutic potential in overcoming resistance.

#371 Co-existent *PIK3CA* and *ARID1A* mutations lead to enhanced sensitivity to PI3K inhibition through PUMA induction by FOXO3a and p53/p21.

Shirsa Udgata, Jordan N. Stoecker, Xingqi Shen, Cheri A. Pasch, Dustin A. Deming

University of Wisconsin-Madison, Madison, WI

Background: *PIK3CA* (PK) mutations occur in ~18% of colorectal cancer (CRC) cases. However, an effective means to target these cancers in clinic remains a challenge. Co-alterations in *PIK3CA* and *ARID1A* (AD) occur in ~1% of all cancer cases. The Z1F arm of the NCI MATCH clinical trial demonstrated an improved response rate for the pan-PI3K inhibitor, copanlisib (cop) in subjects with PK and AD mutant cancers. Recent studies have shown that cop treatment leads to p53 independent induction of PUMA by FOXO3a in CRC cell lines. Furthermore, ARID1A is suspected to regulate the levels of p53/p21 and c-MYC, which are important for the induction of apoptosis. Here we further evaluate this potential mechanism of action.

Methods: AD was knocked out from human 2D CRC cells SW48 and SW48$^{PIK3CA\text{-}H1047R}$ (SW48PK) using CRISPR as previously described (SW48AD; SW48PKAD). Flow cytometry (FC) was performed for apoptosis (Annexin V and PI) after 48 hours of cop treatment at 10nM and 50nM (PI3K and MTOR IC_{50} respectively). Western blot (WB) was performed after cop treatment for 6 hours and 24 hours to determine the protein levels of the anti-apoptotic protein MCL-1, pro-apoptotic protein PUMA, and proteins that activate PUMA (FOXO3a, p53, p21 and c-MYC).

Results: An increase in apoptosis was observed in SW48PKAD cells compared to SW48PK with 50nM cop treatments for 48 hours ($p=0.02$). MCL-1 protein expression at baseline was lower in SW48PKAD compared to SW48PK cells. This also decreased significantly by 6 hours with cop ($p<0.05$). PUMA expression was significantly increased in SW48PKAD after 6 hours cop 10nM ($p<0.05$) and 50nM ($p<0.005$) compared to SW48PK, where there was a delayed increase in PUMA levels by 24 hours (50nM; $p<0.005$). FOXO3a was significantly increased in SW48PKAD at 6 hours (10 and 50nM; $p<0.005$), indicating the potential for the induction of PUMA to be secondary to FOXO3a. Among FOXO3a targets, c-MYC showed no difference in its expression but there was higher expression of p53 in SW48PKAD compared to SW48PK without cop which significantly decreased after 24 hours of cop at 50nM ($p<0.005$). p21, which is present downstream of p53 and helps induce apoptosis in both p53-dependent and independent manners, was also highly expressed without cop and decreased after 24 hours in SW48PKAD compared to SW48PK ($p<0.005$).

Conclusions: Co-alterations in *PIK3CA* and *ARID1A* lead to enhanced sensitivity to PI3K inhibition through PUMA induction by FOXO3a due to aberrant expression of p53/p21 caused by ARID1A loss. Further validation studies are underway utilizing PK and AD altered patient-derived cancer organoids.

#372 Loss of *RB1* sensitizes *TP53*-mutated cancer cells to WEE1 inhibition by azenosertib.

Daehwan Kim, Olivier Harismendy, Catherine Lee, Erika Cabrera, Danielle Jandial, Doris Kim, Mark R. Lackner, Jianhui Ma

Zentalis Pharmaceuticals, San Diego, CA

The retinoblastoma protein 1 (RB1), encoded by *RB1* gene, plays a critical role in regulating the G1 to S-phase transition of the cell cycle through its interaction with the E2F family of transcription factors. In addition, RB1 has been shown to directly regulate DNA damage response and apoptosis. Loss of RB1 function, predominately via gene deletion, occurs frequently in various human cancers, with the highest prevalence in small cell lung cancer (almost ubiquitous) and basal-like breast cancer (up to 72%). *RB1* loss is often associated with aggressive phenotypes, especially in cancers that harbor concurrent *TP53* mutations. In *TP53* mutated cancer cells, further loss of *RB1* can drive uncontrolled entry into S phase, leading to increased replication stress and DNA damage. WEE1 kinase regulates essential cell cycle checkpoints, preventing premature mitosis and allowing time for DNA repair. Therefore, we hypothesized that loss of *RB1* would sensitize *TP53*-mutant cancer cells to the selective WEE1 inhibitor azenosertib. We tested this hypothesis using small cell lung cancer (SCLC) and triple-negative breast cancer (TNBC) models. In *TP53*-mutant SCLC (N=9) and TNBC (N=3) cell lines, concurrent *RB1* loss increased sensitivity to azenosertib, as evidenced by greater cell growth inhibition compared to cells with wild-type *RB1* (median GR_{max} = -0.23 vs -0.81, 0.01 vs -0.55, respectively). Knockdown of *RB1* in *RB1* wild-type DMS53 (SCLC) and MDA-MB-231 (TNBC) cell lines sensitized them to azenosertib (GR_{max} = -0.47 vs -0.94, -0.02 vs -0.5, respectively). Downstream signaling analysis revealed that azenosertib treatment induced higher levels of DNA damage and apoptosis, as shown by the significant increase in γH2AX and cleaved-Caspase 3 levels in *RB1* knockdown cells compared to control cells. Conversely, overexpression of *RB1* in *RB1*-null cell lines significantly desensitized the cells to azenosertib with GR_{max} increased from -0.81 to -0.45 in NCI-H1048 (SCLC), and from -0.63 to -0.34 in MDA-MB-468 (TNBC), respectively. Consistently, *RB1* overexpressed cells demonstrated lower levels of DNA damage and apoptosis after azenosertib treatment. In xenograft models, azenosertib demonstrated enhanced tumor growth inhibition (TGI) in models with both *TP53* and *RB1* loss (NCI-H146 [SCLC]: 90%, MDA-MB-468 [TNBC], 87%) compared to those with *TP53* mutation alone (DMS53 [SCLC]: 49%, MDA-MB-231 [TNBC] 50%). Together, our data demonstrates loss of *RB1* sensitizes *TP53*-mutant cancer cells to WEE1 inhibition in multiple models of SCLC and TNBC, suggesting *RB1* loss can be used as a predictive marker to identify *TP53*-mutated patients of these cancers who are likely to benefit from WEE1 inhibition by azenosertib.

#373 Comparison of the anti-cancer mechanism of tolfenamic acid and its copper (II) complex.

Hayden Flume[1], Riva Sarkar[2], Tanaya Washington[3], Ethan Schroeder[3], Sakariyau A. Waheed[3], Kaylin L. Thomas[3], Stephen Beebe[3], Riyaz Basha[1], Alvin Holder[3], Umesh T. Sankpal[1]

[1]Texas College of Osteopathic Medicine, University of North Texas Health Science Ctr., Fort Worth, TX,[2]George Mason University, Fairfax, VA,[3]Old Dominion University, Norfolk, VA

Tolfenamic acid (TA), a non-steroidal anti-inflammatory drug, has demonstrated anti-cancer properties across multiple cancer models including prostate, pancreatic, ovarian, colon, leukemia, lung, and medulloblastoma. Studies have identified potential targets of TA including transcription factors Sp1, Sp3 and Sp4, anti-apoptotic proteins survivin and Bcl2, anti-angiogenic protein VEGF, and NFkB gene products. These interactions result in inhibition of cell proliferation, induction of apoptosis, and suppression of tumor growth in mouse models. To enhance the efficacy of TA, a novel copper (II) complex of TA ($[Cu(TA)_2(bpy)]$, bpy = 2,2'-bipyridine, Cu(II)-TA) was synthesized. Cell viability assays revealed that Cu(II)-TA exhibited greater anti-proliferative activity than TA, as indicated by lower IC_{50} values. However, the mechanism underlying this increased activity remains unclear. In this study, we compared the mechanism of action of TA and Cu(II)-TA in medulloblastoma cells. The anti-proliferative activity of the two compounds was assessed using a cell viability assay and the apoptotic activity was evaluated by caspase 3/7 activity assay. Cell cycle effects were analyzed by flow cytometry and DNA damage was assessed by measuring levels of phospho-H2AX using western blot and immunofluorescence microscopy. Consistent with previous findings, we observed increased anti-proliferative effects with Cu(II)-TA compared to TA in medulloblastoma cells. This enhanced activity was accompanied by increased apoptosis as indicated by higher caspase 3/7 activity. Cell cycle analysis by flow cytometry revealed distinct profiles for the inhibitors. TA treatment resulted in increased G2/M population, while Cu(II)-TA did not show a prominent or dose-dependent increase with treatment. Interestingly, TA induced greater DNA damage than Cu(II)-TA as indicated by increased phospho-H2AX levels detected by western blotting and immunofluorescence staining. These findings suggest that while Cu(II) enhances the anti-proliferative activity of TA, the underlying mechanisms differ, likely involving distinct proteins and pathways.

#374 OMX-0407 - A spectrum selective kinase inhibitor shows preclinical efficacy in RCC as well as sarcomas.

Ilona Petra Maser, Carolin Strobl, Bettina Bauer, Andreas Schirmer, Moritz Zulley, Carmen Amerhauser, Marisa Stebegg-Wagner, Tiantom Jarutat, Hannes Loferer, Stefan Bissinger

iOmx Therapeutics AG, Martinsried/Planegg, Germany

OMX-0407 is an orally available spectrum-selective kinase inhibitor targeting key oncology-relevant tyrosine kinases and the salt-inducible kinase family. OMX-0407 offers a dual mode of action (MoA) in cancer by inducing cell cycle arrest in tumor cells and sensitizing the tumor environment to immune cell-mediated tumor cell killing. It is being developed as first-in-class treatment for solid tumor indications with high unmet medical need.

Key oncogenic signaling pathways of tyrosine kinases drive cancer progression by regulating cell cycle and growth signaling cascades. Dysregulation of these kinases, such as platelet-derived growth factor receptors, Eph receptors, and Src family kinases, contributes to cancer progression and therapy resistance. OMX-0407 effectively disrupts these processes through potent inhibition of these kinases and their downstream signaling cascades. A comprehensive viability screen of over 380 human cancer cell lines revealed a selective anti-tumor activity across a subset of cancers, including in renal cell carcinomas (RCC) and sarcomas.

Pharmacodynamics studies via phospho-proteomics, Simple-Western or functional kinase activity assays revealed that OMX-0407 induces a G1 cell cycle arrest, accompanied by dose-dependent downregulation of cell cycle-associated proteins and kinase signaling pathways. These effects have been confirmed across in vitro cell line studies, in vivo cell line-derived models or even patient-derived xenograft models.

Besides its direct effect on tumor cells, OMX-0407 is repolarizing the tumor microenvironment by reducing immunosuppressive regulatory T cells in the tumor bed and shifting toward a pro-inflammatory state. This dual MoA contributes to the potent anti-tumor effects in various syngeneic animal studies. In a human patient-derived xenograft of epithelioid angiosarcoma (AS), derived from a 9-year-old patient, OMX-0407 demonstrated remarkable dose-dependent anti-tumor efficacy as a single agent. The strong anti-tumor efficacy, with tumor reduction in individual animals, was associated with dose-dependent downregulation of phosphoproteins and significant inactivation of key OMX-0407 regulated signaling pathways on kinase level. Clinical data from a patient, diagnosed with secondary radiation-induced AS, resistant to prior lines of chemotherapy, demonstrated that OMX-0407 was well tolerated and achieved a complete response at doses of up to 60 mg twice daily, which remains ongoing at 14 month.

These findings support OMX-0407 as a promising first-in-class therapeutic candidate for the treatment of AS and RCC, with a dual mechanism combining direct anti-tumor effects with repolarization of an immunosuppressive tumor microenvironment. As of September 2024, Ph1b expansion cohorts of the first-in-human trial (NCT05826600) were initiated for patients with unresectable or metastatic AS or clear cell RCC.

#375 Cancer cells may utilize centrosome amplification to promote survival as a response to chemotherapeutic stress.

Madison M. Purkerson, Sarah R. Amend, Kenneth J. Pienta

Johns Hopkins University School of Medicine, Baltimore, MD

Therapy resistance is one of the most common underlying causes of poor prognosis in cancer patients, ultimately driving fatal outcome. We have previously demonstrated that following chemotherapeutic stress, a subset of cancer cells undergo a mitotic skip and enter an endocycle, causing whole-genome duplication without division. This endocycling cell state is resistant to cytotoxic therapies and thus is an actuator of therapy resistance. Cells in the endocycling state eventually undergo depolyploidization and repopulate the tumor, observed clinically as a recurrence. A common feature of cancers is centrosome amplification (CA) that includes aberrations in centrosome number (>2 centrosomes/cell), size, shape, and/or positioning. Our preliminary data has shown that endocycling cancer cells exhibit CA following treatment across multiple types of chemotherapies. Based upon this data, we hypothesize that studying centrosome dynamics and abnormalities presents a window into better understanding endocycle biology and this novel mechanism of therapy resistance.We have found that the population of prostate cancer and breast cancer cells possessing CA following treatment with LD50 dose of cisplatin or docetaxel increased as a function of recovery time to over 95% by day 10, with nearly all cells clustering extra centrosomes together. Of note, the number of mitotic skips an endocycling cell undergoes has not been found to be associated with the number of centrosomes the cell has. PLK4 is a kinase essential for centriole duplication and its overexpression causes CA. Immunofluorescence analysis has revealed that endocycling cancer cells exhibit an increase in PLK4 protein expression. Endocycling cancer cells also exhibit increased protein expression of KIFC1, a mediator of centrosome clustering. Both PLK4 and KIFC1 protein expression have been found to positively correlate with DNA content. We hypothesize that endocycling cells may use clustered, supernumerary centrosomes as platforms to locally concentrate signaling molecules, lowering the activation threshold for downstream effectors. Published data from bioID proteomics of centrosomal proteins has revealed an enormous unexplored protein landscape around these organelles. Because of this, CA may be a critical mechanism for endocycling cancer cells to survive and maintain this resistant cell state.

#376 Characterization of PARP inhibitor response in prostate tumor cells reveals drug tolerant persistent phenotype.

Akshaya Karthikeyan, Love A. Moore, Bryan Correa Gonzalez, Anamitra Bhaumik, Ethan Sandoval, Alan P. Lombard

UCD School of Medicine & Medical Science, Davis, CA

Background: PARP inhibitors (PARPi) have improved management of prostate cancer, but acquired resistance and progression remain inevitable. Understanding treatment failure will improve outcomes. Drug tolerant persistence (DTP) is characterized by a small population of tumor cells which survive treatment through transient acquisition of insensitivity. DTP cells are not intrinsically resistant but may slowly proliferate, allowing for mutation accumulation, development of resistance, and progression. DTP cells may also increase mutability, further driving this process. Characterization of drug tolerant persistence and mechanisms enabling a DTP state under PARP inhibition remain poorly understood in prostate cancer.

Methods: Viability assays determined efficacious doses of olaparib and rucaparib in PARPi sensitive C4-2B metastatic castration-resistant prostate cancer cells and the C4-2B abiraterone-resistant derivative cells, AbiR. Phase contrast microscopy, western blots, beta-galactosidase activity assays, and flow cytometry characterized response to olaparib and rucaparib. RNA-seq determined the transcriptomic profile of PARPi DTP cells.

Results: C4-2B and AbiR response to olaparib and rucaparib is heterogeneous, characterized by cell death and cytostasis. Despite prolonged exposure to high dose PARPi, we observe a small minority of cells which persist, display varying altered morphologies, and altered cell cycle dynamics. While most of these cells appear arrested, we consistently note the presence of a subset which form colonies. C4-2B and AbiR cells exposed to high PARPi dosing for 9 days followed by drug holiday regain normal, parental cell morphology and become re-sensitized to treatment in line with acquisition of a DTP phenotype. RNA-seq reveals transcriptomic characteristics of drug tolerant persistence including evidence for increased mutability, altered metabolism including fatty acid metabolism and lysosomal activity, altered inflammatory signaling, and cell identity changes.

Conclusions: Our data suggest that transient, drug tolerant persistence may mediate survival of a minority of tumor cells via modulating metabolic and immune-associated pathways. Overtime, these persisters may acquire resistance and fuel progression due to increased mutability via down-regulation of DNA repair mechanisms. Future efforts will characterize this phenotype further and investigate vulnerabilities that target survivors to improve treatment efficacy.

#378 Nicotine replacement therapy may interfere with cisplatin efficacy and promote tumor progression.

Gautham Chengizkhan[1], Vengatesh Ganapathy[1], Mayilvanan Chinnaiyan[1], Lurdes Queimado[2]

[1]Department of Otolaryngology - Head and Neck Surgery, University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Dept. of Otolaryngology-Head & Neck Surgery, Cell Biology, TSET Health Promotion Research Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: Smoking during cancer treatment is associated with significant risks, including treatment failure, metastasis, recurrence, and reduced quality of life. Continued smoking during therapy remains the strongest adverse predictor of survival in cancer patients. Nicotine replacement therapy (NRT) is commonly used to manage cravings in cancer patients undergoing treatment. Although nicotine has been proposed to promote cellular proliferation and tumor progression, the impact of NRT during cisplatin treatment has not been investigated.
Methods: Human oral cancer cell lines (WSU-HN6 and WSU-HN30) were subjected to various treatment combinations to explore the effects of NRT on cisplatin efficacy. Cells were first exposed to nicotine (10, 20, or 40 ng/mL, consistent with plasma concentrations) for 48 hours, followed by treatment with cisplatin at its 50% inhibitory concentration (IC50) in the presence or absence of nicotine for an additional 48 hours. Then, cell viability was assessed using the MTT assay, and clonogenic survival of single cells was evaluated. Controls included exposure to nicotine only, cisplatin only, and mainstream cigarette smoke. Additionally, cells were exposed to varying concentrations of nicotine, treated with cisplatin, and then fixed with 70% ethanol, and analyzed by flow cytometry for cell cycle progression. Statistical significance between groups was determined using Student's t-test.
Results: Cisplatin treatment of cancer cells exposed to nicotine at concentrations similar to those observed in the plasma of individuals undergoing NRT, resulted in a significant decrease in cell viability but did not achieve the anticipated 50% reduction observed with cisplatin treatment alone. To explore this further, cells were exposed to nicotine for 48 hours, followed by cisplatin treatment for an additional 48 hours in the presence or absence of nicotine. The presence of nicotine during cisplatin treatment significantly impaired the efficacy of cisplatin to induce cancer cell death in a concentration-dependent manner. The nicotine presence during cisplatin treatment also altered cell cycle progression and increased clonogenic survival in both oral cancer cell lines.
Conclusion: This study shows that nicotine, even at very lower concentrations, significantly impairs the efficacy of cisplatin, as evidenced by increased cell viability and altered cell cycle progression and increases clonogenic survival in both oral cancer cell lines. These findings pinpoint the potential of NRT to compromise cancer treatment outcomes by interfering with the cytotoxic effects of cisplatin and increasing the number of cancer cells able to proliferate indefinitely. Addressing nicotine exposure during cancer therapy is critical for improving treatment efficacy and patient outcomes.

#38 Augmenting drug responses to PARP inhibitors in high grade serous cancer with inhibitors of the anti-apoptotic protein Bcl-XL.

Alla Buzina, Wiebke Schormann, Lilian Gien, Helen MacKay, **David W. Andrews**

Sunnybrook Health Sciences Centre, Toronto, ON, Canada

While most patients with high grade serous ovarian cancer (HGSC) respond to platinum-based chemotherapy, the response is rarely durable and recurrence almost inevitable. A characteristic of HGSC is defective DNA repair. A class of drugs called PARP inhibitors (PARPi) exploit this vulnerability and have proven useful in delaying recurrence. However, resistance is inevitable. In models of HGSC a protein that frequently confers resistance is called Bcl-xL, a member of the Bcl-2 family of proteins that prevent apoptosis. If treating the patients with a PARPi makes cancer cells dependent on Bcl-xL then adding an inhibitor of Bcl-xL to their treatment might overcome resistance to Olaparib and cause the cancer cells to die.
To test this, we have initiated companion studies for a clinical trial in which patients that have had a recurrence after receiving platinum-based therapy will first be treated with the PARPi Olaparib and then, an inhibitor of Bcl-xL, Navitoclax, will be added to their course of treatment. Navitoclax has a well-known on-target side effect of thrombocytopenia. We show that with continuous dosing of Navitoclax, platelet counts recover and are maintained. Our preliminary data from the first few patients enrolled in the trial suggest that the combination is well tolerated and for several participants there was a reduction in tumor burden. However, Bcl-xL is only one of the five known inhibitors of apoptosis. To identify which women will benefit most from adding Navitoclax to their treatment we need a biomarker(s).
Our hypothesis is that patient derived organoids can be used as a pragmatic way to identify for patient cohorts which Bcl-2 protein inhibitor will synergize with a PARPi to optimize treatment.
By combining novel methods for cell aggregation and hydrogel based synthetic ECM supports we can reproducibly generate HGSC patient-specific tumor organoids models in weeks with greater than 90% success. Organoids grown 384 well format are stained with novel non-toxic dyes enabling live cell painting of chemoresponses to drugs alone and in combination with drugs targeting anti-apoptotic proteins. Our data suggest that this approach captures the inherent heterogeneity of the disease, albeit local to the sampled site. We are employing deep learning AI algorithms to enable automated analyses of 3D confocal image stacks of organoids to infer drug responses that will be compared to patient responses in ongoing clinical trials.

#382 TRX-214-1002, An antibody drug conjugate (ADC) targeting CD33 with a novel GSPT1 molecular glue for treatment of acute myeloid leukemia.

H. Lee, S. Kim, D. Kim, S. Choi, J. Lee, S. Lee, E. Choi, S. Park, K. Chun, K. Lee;
Therapex, Seoul, Korea, Republic of

Several promising therapies for acute myeloid leukemia (AML) targeting specific genetic and epigenetic mutations have been reported. However, there remains a critical need for novel therapies with higher efficacy and favorable safety profiles particularly for patients with poor-risk cytogenetic features, such as TP53 mutation, or those with relapsed and refractory AML. G1 to S phase transition 1 (GSPT1) is a small GTPase that interacts with eRF1, the translation termination factor, to facilitate the process of translation termination. GSPT1 has been well known to play a critical role in the proliferation of AML and MYC-driven lung cancer. Recently, molecular glue degraders (MGDs) targeting GSPT1 have emerged as a new class of cancer therapies and have shown early promise in clinical trials for AML. However, clinical development of GSPT1 MGDs, such as CC-885 and CC-90009, has been hampered by off-target toxicities. To improve both target specificity and the therapeutic window, we discovered TRX-214-1002, a CD33-targeting ADC that used the same monoclonal antibody (mAb) as Mylotarg, conjugated with a novel proprietary GSPT1 MGD as the payload. The *in vitro* and *in vivo* pharmacology of TRX-214-1002 were compared with ORM-6151 (another GSPT1 MG degrader-based CD33 ADC) and Mylotarg. TRX-214-1002 demonstrated superior and sustained degradability against GSPT1 compared to ORM-6151, and it exhibited potent anti-leukemic activity with picomolar GI_{50} values in TP53 or FLT3 mutated AML cell lines. Importantly, it highly spared CD33-negative leukemia cell and human PBMC, with an *in vitro* therapeutic index greater than 100-fold. We also observed that TRX-214-1002 significantly upregulated integrated stress response markers (ATF4, CHOP, ATF3) and impaired neo-protein synthesis, consistent with apoptosis induction. Interestingly, TRX-214-1002 maintained potent anti-leukemic activity even in venetoclax-resistant HL-60 cells and in drug-resistant milieu derived from bone marrow stromal HS-5 cells. Furthermore, a single 1 mg/kg dose of TRX-214-1002 completely regressed tumors in MV4-11 and HL-60 xenograft models without tumor regrowth until day 42, whereas the ORM-6151-treated group led to transient tumor regression. Pharmacodynamic studies in the HL-60 tumor model showed dose-dependent degradation of GSPT1. In addition, we estimated that the minimum therapeutically effective dose was less than single 1 mg/kg in a disseminated tumor model. Collectively, TRX-214-1002 highlighted the noticeable GSPT1 degradability and enhanced antileukemic activity, particularly in TP53 mutated and venetoclax-resistant AML cell lines, along with significant antitumor activity superior to competitor ADCs. Our preclinical data suggest that TRX-214-1002 has the high potential to provide a novel treatment strategy for CD33 positive relapse/refractory AML patients.

#383 Discovery of potent, selective, and orally bioavailable GSPT1 molecular glue degraders (MGDs) for the treatment of MYC-driven tumors.

Zhimin Zhang, Min Chen, Cancan Cai, Li Teng, Sirui Liu, Yujie Chang, Xinxin Jin, Xiaohua Zhang, **Dongzhou Liu**

Huadong Medicine Co.,Ltd, Hangzhou, China

Background: MYC is a well-recognized proto-oncogene, which is mutated and overexpressed in various tumors. However, MYC is challenging to target due to its disordered structure and nuclear localization. There is a significant unmet clinical need for the effective treatments for MYC-driven tumors. G1 to S phase transition 1 (GSPT1) is a translation termination factor regulating protein expression. GSPT1 is involved in many biological processes, including the regulation of cell proliferation, migration, growth cycle and apoptosis. MYC-driven tumors are highly dependent on protein translation to sustain their growth, creating a reliance on the GSPT1 activity. Recent studies have shown that molecular glue degraders (MGDs) targeting GSPT1 affect protein synthesis, thus interfering with the expression of MYC and its downstream target genes. Therefore, GSPT1 is a potential therapeutic target for MYC-driven tumors.
Results: Through a comprehensive artificial intelligence-driven drug design and structure-based approach, we designed and synthesized a series of GSPT1 degraders. The most potent degrader effectively degrades GSPT1 proteins in the MDA-MB-468 cells in a dose-dependent manner and achieves a DC_{50} value of less than 2 nM. The maximum degradation (D_{max}) value observed is >95%. The degradation of GSPT1 induced the associated downregulation of MYC (EC_{50}<10 nM), resulting in preferential anti-proliferative activity in MYC-driven cancer cells with IC_{50} values of 3.28 nM in MDA-MB-468 cells and 0.82 nM in NCI-H1155 cell lines. PK studies revealed low clearance, high plasma exposure, and oral bioavailability in mice. Furthermore, the MGD induced robust and statistically significant tumor growth inhibition (TGI) in the NCI-H1155 and MDA-MB-468 Xenograft Models, with TGI values of 99.57% and 97.93%, respectively.
Conclusion: A novel, selective, potent oral GSPT1 degrader was discovered and demonstrated robust anti-tumor activity in mouse xenograft tumor models as a single agent. Collectively, we have identified novel GSPT1 MGDs as promising candidates for the treatment of MYC-driven tumors.

#384 IPS-06061, a novel TPD molecular glue degrader targeting KRAS G12D.

Incheol Kang[1], Seungoh Seo[2], Seong Hyeok Cho[1]

[1]InnoPharmaScreen/Hoseo University, Incheon, Korea, Republic of,[2]InnoPharmaScreen, Incheon, Korea, Republic of

We have discovered a novel KRAS G12D-degrading Molecular Glue using IPS's cutting-edge ProGlu AI-based drug discovery platform and PPIExplorer, an IPS-Chip based Proteomics technology. ProGlu accurately predicts PPI between E3 ligase and KRAS G12D through MD simulation, enabling de novo design of MG degraders. One such degrader, namely IPS-06061, was successfully synthesized and confirmed a strong anti-tumor efficacy using a xenograft animal model. These data demonstrate that KRAS MG will be a promising new therapeutic modality for the treatment of PDA, CRC, and NSCLC.

#385 Discovery of OST08267, an orally available PDE3A-SLFN12 molecular glue for the treatment of gastrointestinal stromal tumors with tyrosine kinase inhibitors (TKIs) resistance.

F. Wu, L. Deng, Z. Ma, Z. Lu, G. Deng;
Open Source Therapeutics, Suzhou, China

Gastrointestinal stromal tumor (GIST) is the critically mesenchymal malignancy inhabiting the GI tract, which crucially induced by receptor tyrosine kinase (KIT) gene mutation. Although the tyrosine kinase inhibitors (TKIs), such as imatinib has prolonged survival significantly, the intrinsic and acquired resistance still disturbed more than 20% patients. Therefore, significant unmet medical remains needed. phosphodiesterase 3A (PDE3A)- Schlafen family member 12 (SLFN12) molecular glue is a novel anti-tumor targeted drug, mainly by mediating the formation of a complex between PDE3A and SLFN12, ultimately leading to the tumor apoptosis. In this study, we present OST08267, an orally available PDE3A-SLFN12 molecular glue tailored from the FDA-approved PDE3A inhibitor. Our transcriptional profiling of over 2,000 patient samples revealed high expression levels of PDE3A and SLFN12 in GIST tumors, suggesting that GIST is a promising indication for this treatment with a high responsive rate of up to 60%. In vitro, OST08267 demonstrated significant anti-tumor activity, irrespective of KIT mutation status by testing against multiple GIST patient-derived organoids. In vivo, OST08267 causes dose-dependent regression of tumor volume in the GIST patient-derived xenograft (PDX) model with imatinib resistance, with 4 mg/kg/day dose resulting in deeper and durable tumor regressions that were maintained for at least a month even after the dosing had discontinued.Moreover, OST08267 exhibited favorable pharmacokinetic and toxicity properties. These promising preclinical results strongly support the potential of OST08267 to address unmet needs in GIST treatment, justifying its further clinical development.

#386 High CRBN expression in neuroendocrine cancer creates a vulnerability to GSPT1 molecular glue degraders: Target indication selection for CYRS1542 development.

Jaewoo Park[1], **Min Sung Joo**[2], JaeYung Lee[2], Eun-Jung Kim[2], Dong Hyuk Ki[2], Hunmi Choi[2], Wooseok Han[2], Keon Wook Kang[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Cyrus Therapeutics, Seoul, Korea, Republic of

Multiple companies have been developing GSPT1-targeted molecular glue degraders (MGDs) for neuroendocrine (NE) cancers, a rare and aggressive cancer type. CYRS1542, a potent and orally bioavailable GSPT1 MGD with a superior therapeutic index, was identified and derived from CYRS381 (originally known as SJ6986) in our previous work (Joo et al., AACR 2024). In this study, we investigated the mechanistic basis of GSPT1 MGD sensitivity in NE cancers, using CYRS381 as a tool compound to assess selective susceptibilities. We found that CYRS381-induced GSPT1 degradation was selectively effective in the NE cancers with high CRBN expression, while the non-NE cancers with a low level of CRBN showed limited response. NE cancer cells positive for NE markers exhibited both higher CRBN expression and greater sensitivity to CYRS381, showing rapid GSPT1 degradation upon GSPT1 MGD treatment compared to non-NE cancer cells. Further analysis of TCGA and DepMap expression data revealed a significant positive correlation between high CRBN levels and NE characteristics, whereas GSPT1 levels showed no such correlation. Consistently, overexpressing CRBN in non-NE cancer cells increased sensitivity to GSPT1 MGD, and introducing NE-driving factors in non-NE cancer cells elevated CRBN expression, further enhancing the response to GSPT1 MGD. Finally, CYRS1542 demonstrated effects similar to CYRS381 in comparable experiments, further supporting the selection of NE cancers as the lead indication for its clinical trials. Overall, these findings highlight CRBN as a key determinant of GSPT1 MGD efficacy and underscore the potential of CYRS1542 as a targeted therapeutic option for aggressive NE cancers.

#387 Preclinical biological screening and evaluation of KRAS molecular glues.

Zhaoxia Yin, Lili Chai, Xian Wu, Tao Li, Xiaojian Wang, **Tj (Tiejun) Bing**

ICE Bioscience, Inc., Beijing, China

The KRAS protein is a signal transduction molecule associated with various types of cancer. Due to its high mutation rate and key role in tumor development, KRAS has become an important target for anti-cancer drug development. Activating mutations in KRAS, such as KRASG12C, are prevalent in about one-third of all human cancers and significantly contribute to tumor initiation, progression, and resistance to therapy. In recent years, with the continuous deepening of research related to KRAS, a new therapeutic strategy targeting the KRAS protein has been discovered, known as KRAS molecular glue. KRAS molecular glue specifically binds to particular mutation sites on the KRAS protein, such as the G12C mutation, thereby preventing its interaction with downstream signaling molecules and inhibiting the proliferation and survival of tumor cells.

In this context, we have developed a comprehensive screening and evaluation platform for KRAS molecular glue, covering studies from in vitro to in vivo. The platform includes a series of assays at both the biochemical and cellular levels. It utilizes biochemical and biophysical methods for the screening of POI binders, detection of KRAS(ON)/CypA/cRAF binary complexes, and KRAS(ON)/CypA ternary complexes, among others. Cell-based functional assays such as 3D cell proliferation and detection of ERK phosphorylation, a marker related to signaling pathways, are also included. Additionally, we offer p-ERK panel and 2D/3D cell panel including pan KRAS cell panel, KRAS G12D cell panel, KRAS G12C cell panel, KRAS G12V cell panel, pan NRAS cell panel and pan HRAS cell panel tests for KRAS molecular glue, and we can also supply KRAS G12C mutation-resistant cell lines for related testing. Of course, it also includes the efficacy assessment of the CDX model in vivo. Overall, we provide a comprehensive platform for the screening and evaluation of KRAS molecular glue, offering a scientific basis for the clinical application of KRAS molecular glue.

#388 HZ-V068, an oral, highly potent pan-Ras molecular glue inhibitor demonstrated robust potency in pancreatic ductal adenocarcinoma and colorectal cancer models.

Yizhe Wu, Jiangfeng Xie, Jinglai Huang, Xinglu Zhou

HealZen Therapeutics Co., Ltd., Hangzhou, China

Introduction: Ras oncogenes are frequently mutated in approximately 30% of all human cancers, which drive tumor growth and metastasis. The current approved Kras-targeted drugs are Kras G12C inhibitors. However, Kras G12C is only prevalent in part of lung cancer. Most of common mutations in pancreatic ductal adenocarcinoma (PDAC) or colorectal cancers (CRC) including Kras G12D, G12V, G12R are still lack of approved drugs. RMC6236, a next generation of novel pan-Ras^{Multi}(on) inhibitor which functions as molecular glue to form binary complex with CYPA and Ras^{Multi} and sterically blocks Ras binding to effectors, has been validated as a superior strategy targeting Ras in clinical study. Given GTP-bound RAS proteins as a promising new approach to enhance clinical benefits, we have developed a novel oral available pan-Ras molecular glue——HZ-V068 based on in-house Rational Molecular Glue Design Platform, which exhibits significantly binding affinity to CYPA, enriched tumor exposure and prolonged Ras inhibition. HZ-V068 has been validated as a promising pre-clinical candidate for further clinical development.

Results: 1. In biochemical assays, HZ-V068 more potently disrupted the binding of $KRAS^{Mut}$(On) to BRAF in a CypA-dependent manner. 2. HZ-V068 suppressed the growth of $Kras^{Multi}$-BaF3 cell-line covering various mutation types (G12C/D/V/R, G13C/D, Q61K, A146V) at picomolar level. Moreover, HZ-V068 demonstrated 5-10 folds stronger potency in $Kras^{Multi}$-addicted cancer cell lines compared to RMC-6236. 3. In a single-dose PK/PD study, HZ-V068 demonstrated rapid and more sustained intratumoral pERK inhibition, improved bioavailability, and enhanced tumor distribution. 4. In multiple KrasMulti-driven PDAC or CRC CDX models, oral administration of HZ-V068 results in robust tumor regression at lower doses, demonstrating efficacy that is significantly superior to that of RMC6236

Conclusion: In summary, HZ-V068 is a promising targeted therapeutic option for PDAC and CRC. Based on these promising results, we are advancing HZ-V068 into clinical study.

#389 GFH276: A molecular glue panRAS(on) inhibitor with broad spectrum anti-tumor activities.

Feng Yan, Jichen Zhao, Jingyang Zhang, Hongcan Ren, Siyuan Le, Fusheng Zhou, Jiong Lan, Qiang Lu

GenFleet Therapeutics, Shanghai, China

KRAS is the most frequently mutated oncogene but had long been considered to be undruggable until the approval of the first KRAS G12C inhibitor Sotorasib for NSCLC treatment in 2021. However, the clinical performance of Sotorasib and other SIIP-based KRAS inhibitors is hindered by their susceptibility to adaptive resistance and rapidly emerging, diverse acquired resistance. Therefore, developing a novel RAS inhibitor being able to overcome the above limitations holds the potential of making the most of RAS-targeted therapies. Here we report the characterization of a preclinical candidate molecular glue panRAS(on) inhibitor- GFH276, designed to target multiple RAS mutants of active, GTP-bound state by recruiting intracellular cyclophilin A (CypA) protein. In biochemical assays, GFH276 disrupted the binding of GMPPNP-bound KRAS G12C, G12D or G12V mutants or wild type KRAS, HRAS or NRAS proteins to RAF1 in a CypA-dependent manner. In cellular assays, GFH276 suppressed phosphor-ERK1/2 (p-ERK) level in KRAS G12C, G12D and G12V-mutated cells with IC50s < 1 nM, and demonstrated potent tumor-suppressive effect in a panel of cell lines carrying different KRAS (G12A, G12C, G12V, G12R, G12S, G13D or Q61K), NRAS (G12D) or HRAS (Q61H) mutations, with IC50s of 0.07-73 nM. In addition, GFH276 was also active in tumor cell lines carrying EGFR or FGFR2/3 alterations but showed no activity in cell lines carrying mutations on downstream BRAF component. In KRAS-mutated xenograft models, oral administration of GFH276 elicited rapid and deep inhibition on p-ERK level in tumor tissues, demonstrated dose-dependent anti-tumor activity and induced tumor regression at dose level as low as 1 mg/kg QD. Compared to SIIP-based KRAS G12C inhibitors Sotorasib, Adagrasib and Divarasib, GFH276 was not susceptible to upstream RTK-reactivation by EGF stimulation and remained effective against cell lines carrying second KRAS mutations or RTK alterations or with induced resistance to Sotorasib. GFH276 showed no off-target activity in 72-kinase selectivity and SafetyScreen44 panel tests. GFH276 showed high bioavailability in mice, rats and dogs (39%-113%). Taken together, GFH276 represents a new generation of RAS inhibitors that are superior to the mainstream SIIP-based KRAS inhibitors in overcoming adaptive and acquired resistance. GFH276 demonstrated strong therapeutic activities in tumors with activating RAS and RTK alterations. Encouraged by these promising results, we are advancing GFH276 into the Phase 1 clinical trial by conducting IND-enabling studies and the IND submission is planned in Q2 2025.

#39 Digital pathology foundation models enable accurate tumor organoid classification.

Adi Orlyanchik[1], Matteo Sacco[1], James Dolezal[2], Joseph Kainov[1], Piao Zhao[1], Mohammed Aziz Khan[1], Marina Garassino[1], Marc Bissonnette[1], Le Shen[1], Alexander T. Pearson[1], Christopher Weber[1]

[1]BSD, The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL,[2]Geisinger Cancer Institute, Danville, PA

This study develops an efficient and accurate pipeline for classifying tumor-derived organoid candidates as benign or malignant, addressing challenges posed by organoid culture and advancing personalized medicine applications.
Background: Tumor-derived organoids replicate tumor architecture and molecular features, providing controlled environments to study tumor behavior and therapeutic responses. A key challenge in using organoid models is classifying cellular aggregates as benign or malignant. Benign cells in a tumor source can sometimes outcompete malignant tumor cells in culture, misrepresenting the tumor's characteristics. Also, histological characterization of organoids is challenging due to the absence of histologic clues from tissue organization. Current approaches, such as genomic sequencing, effectively resolve such uncertainties but are costly and time-intensive.
Hypothesis: We hypothesized that a deep learning (DL) based computational image analysis classification pipeline could improve the accuracy and efficiency of distinguishing organoids as benign or malignant.
Methods: We developed a novel pipeline to enhance organoid classification methods using ML. Our pipeline was developed and validated on H&E-stained slides obtained from organoids derived from 17 colorectal cancer patients (26 slides: 11 tumor, 15 normal) with various degrees of differentiation and paired normal controls. Ground truth data were established using a comprehensive genomic profiling panel to confirm that tumor organoids matched primary tumor features and, for tumors with high microsatellite instability, mismatch repair protein status. We first trained a segmentation model using a Human-in-the-Loop approach for precise identification of regions of interest. We extracted non overlapping 256x256 tiles at 20x magnification. We used the UNI foundation model to extract (k=1024) relevant features from each tile. We fitted Linear Discriminant Analysis (LDA) models on the UNI feature vectors using leave-one-patient-out cross validation according to patients. Each slide's final classification score was determined by averaging the LDA scores across all tiles from that slide.
Results: The LDA classifier achieved 92.3% accuracy and AUROC of 0.964 (0.907-1.000), matching gastrointestinal pathologist performance. Additionally, we visualized the UNI feature vectors through UMAP plots. Plot evaluation demonstrates distinct clustering of unsupervised features into tumor and normal groups.
Conclusions: These findings demonstrate the feasibility of coupling organoids with DL methods to facilitate organoid classification. Our approach offers an efficient new strategy for studying organoid morphology and advancing organoid models. Adaptations of this model are expected to be valuable in understanding organoid responses to various therapies, paving the way for improved personalized cancer care.

#390 ERAS-0015 is a pan-RAS molecular glue with best-in-class potential in RAS mutant solid tumors.

Erin D. Lew, Alexei Brooun, Justine Lam, Joanne Oh, Taylor Sullivan, Corine Holub, Jae Hyun Bae, Bingzhen Lin, Brian Qua, Alex Stromitis, Sarah M. Griffith, Andrea Shen, Dawei Xuan, Robert F. Shoemaker

Erasca, Inc., San Diego, CA

As a key node of the canonical RTK-RAS-MAPK signaling cascade, the RAS family of GTPases plays an essential role in numerous physiological processes including cellular proliferation, migration, survival, and immune cell activation. However, under pathological conditions, oncogenic RAS mutations, particularly in hotspot codons 12, 13, and 61, affect RAS intrinsic hydrolysis and/or GEF-mediated exchange resulting in a shift from GDP-bound to GTP-bound RAS. This shift to the GTP-bound RAS state leads to recruitment of effector proteins through the RAS-binding domains (RBDs) and ultimately leads to prolonged intracellular activation and modulation of the tumor microenvironment (TME).
ERAS-0015 is a pan-RAS molecular glue with best-in-class potential designed to target RAS in the GTP-bound state and shut down cellular signaling mediated by both mutant and wild-type RAS. ERAS-0015 exhibited 3-7-fold more potent inhibition of cellular proliferation relative to RMC-6236, a RAS molecular glue comparator, across multiple RAS mutant cell lines harboring G12X/G13X/Q61X mutations. ERAS-0015's roughly 8-20-fold higher binding affinity to cyclophilin A (CYPA) is thought to contribute to its higher *in vitro* cellular potency as well as favorable ADME and PK properties resulting in a longer residence time and greater exposure in tumor tissues as compared to RMC-6236. These favorable properties enabled ERAS-0015 to achieve comparable tumor growth inhibition (TGI) relative to RMC-6236 at $1/8^{th}$-$1/10^{th}$ the dose across multiple KRAS mutant CDX models irrespective of histology or specific mutation.
ERAS-0015 demonstrated promising preclinical activity across multiple RAS mutant models supporting IND filing in 1H 2025.

#391 Pharmacological suppression of neuroblastoma growth via RBM39 degradation by the molecular glue PPI-011.

Yu Cao[1], Qilei Han[1], Penxuan Ren[1], Bin Zhang[2], Lin Wang[1], Xianglei Zhang[1], Lei Zhou[3], Song Feng[3], **James X. Rong**[3], Lianghe Mei[2], Kai Li[4], Fang Bai[1]

[1]School of Life Science and Technology, and Shanghai Institute for Advanced Immunochemical Studies, ShanghaiTech University, Shanghai, China,[2]Suzhou Institute of Drug Innovation, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Suzhou, China,[3]Peak Perform Innova Co., Ltd., Shanghai, China,[4]Department of Pediatric Surgery, Children's Hospital of Fudan University, Shanghai, China

High-risk neuroblastoma, often driven by the amplification or overexpression of MYC family oncogenes (*MYCN* and *MYC*), remains a significant cause of pediatric cancer mortality, contributing to 15% of tumor-related deaths in children. Despite multimodal treatment approaches, prognosis remains poor, underscoring an urgent need for new therapies. The current study targets the degradation of RBM39, an RNA splicing factor linked to splicing irregularities in MYC-driven tumors. We identified PPI-011, a proprietary molecular glue, using an AI-assisted integrated drug design platform. Demonstrated by the Time-Resolved Förster's Resonance Energy Transfer recruitment assay, PPI-011 promotes the formation of the ternary complex involving RBM39 and DDB1-DCAF15, a substrate adaptor in the RBX-CUL4-DDA1-DDB1-DCAF15 E3 ligase. PPI-011 induced dose-dependent degradation of RBM39 across multiple neuroblastoma cell lines, a mechanism confirmed by the inhibitory effects of a neddylation blocker and DCAF15 knockout, validating CUL4-DCAF15-mediated proteasomal degradation as the underlying pathway. RBM39 degradation resulted in splicing changes in multiple genes, including CDK4 and PEX3, and led to cancer cell death. Preliminary pharmacokinetic studies indicated that PPI-011 possessed good PK profiles, with oral bioavailability of ~100% and high exposure. In vivo, daily oral administration of PPI-011 (15 mg/kg) suppressed tumor growth by 90% ($P < 0.001$ vs. vehicle) in IMR-32 neuroblastoma xenografts in balb/c nude mice, with almost complete tumor elimination at 30 and 50 mg/kg within 28 days, and no associated weight loss at any dose. The suppressed tumor growth was associated with decreased RBM39 protein in the xenografts. Notably, tumor suppression at 50 mg/kg was sustained for 72 days even after treatment discontinued. Similarly, PPI-011 significantly ($P < 0.001$ vs. vehicle) inhibited the growth of LAN-5 xenografts, another neuroblastoma model, at doses of 3, 10, and 30 mg/kg in a dose-dependent manner. In a patient-derived xenograft model, using cells from a chemotherapy-relapsed neuroblastoma, PPI-011 achieved 88% tumor suppression ($P < 0.001$ vs. vehicle) at 30 mg/kg, and complete tumor clearance at 90 mg/kg within 21 days. Furthermore, PPI-011 has no apparent safety liabilities, supported by in vitro genetic toxicology and hERG assays, warranting further in vivo toxicological analysis. Our findings demonstrate that PPI-011, developed through an innovative drug design platform targeting previously undruggable targets, effectively inhibits neuroblastoma growth by inducing RBM39 degradation. This suggests PPI-011 as a promising new therapeutic strategy for MYC-driven malignancies, including neuroblastoma.

#392 Pyrimethamine inhibits NRF2^{Mut} in esophageal squamous cell carcinoma as a molecular glue.

Zhaohui Xiong[1], Chorlada Paiboonrungruang[1], Boopathi Subramaniyan[2], Candice Bui-Linh[1], Yahui Li[2], Huan Li[2], Francis Spitz[2], Xiaoxin Chen[1]

[1]Coriell Institute for Medical Research, Camden, NJ,[2]Cooper University Health Care, Camden, NJ

Esophageal squamous cell carcinoma (ESCC) is a deadly disease and one of the most aggressive cancers of the gastrointestinal tract. As a master transcription factor regulating the stress response, nuclear factor erythroid 2-related factor 2 (NRF2) is often mutated and becomes hyperactive, and thus causes chemo-radioresistance and poor survival in human ESCC. In our previous study, we have identified pyrimethamine (PYR) as an NRF2 inhibitor using a small molecule screening, and further validated it as an inhibitor of NRF2 expression in *NRF2^{Mut}* ESCC cells *in vitro* and *Nrf2^{E79Q}*-driven esophageal phenotype in mice. As a result, PYR has moved into a Phase I window of opportunity trial (NCT05678348). This study is aimed to investigate the molecular and phenotypic consequences of NRF2 hyperactivation in ESCC, and elucidate the mechanism of action of PYR. We first generated isogenic human ESCC cells through CRISPR-Cas9 knockout for comparison with its parental cells. RNAseq and Western blotting showed that NRF2^{Mut} overexpression downreulated the expression of squamous differential markers and upregulated the expression of proliferation markers, while NRF2^{WT} overexpression showed different patterns. Flow cytometry and live cell imaging further showed that NRF2 activation modulated cell cycle distribution and proliferation, but not apoptosis of human ESCC cells. PYR increased chemosensitivity and radiosensitivity in *NRF2^{Mut}* ESCC cells. Co-immunoprecipitation (Co-IP) and proximity ligation assay (PLA) suggested that PYR promoted NRF2-KEAP1 binding as a molecular glue in *NRF2^{Mut}* ESCC cells, but not in *NRF2^{WT}* ESCC cells. In summary, NRF2 hyperactivation differentially modulated squamous differentiation and cell proliferation in *NRF2^{Mut}* and *NRF2^{WT}* ESCC cells. PYR enhanced chemo-radiosensitivity by acting as a molecular glue specifically in *NRF2^{Mut}* ESCC cells, supporting PYR as a novel therapy for *NRF2^{Mut}* ESCC.

#393 Discovery of novel, potent and orally active GSPT1 molecular glue degraders.

Chi-Chung Chan, Chun-Sing Li, Lihong Hu, Wenxi Li, Zhenzhen Zhu, Shuhui Chen

Prospect Therapeutics, Shanghai, China

Molecular glue degrader (MGD) is an emerging therapeutic strategy offering an exciting alternative to traditional small molecules exploring new target space. These small molecules interact with the ubiquitin-proteasome system (UPS) to promote degradation of protein of interest (POI), especially those considered to be challenging targets (e.g., GSPT1, VAV1, WIZ, BCL6, STAT6, IKZFs). In fact, clinical proof of concept has been obtained with immunomodulatory drugs such as thalidomide, lenalidomide and pomalidomide, which degrade IKZF1/IKZF3. GSPT1 (G1 to S phase transition protein 1) is a challenging POI engaged in regulation of cell cycle progression at the G1-S transition and in mRNA translation termination, playing a key role in cancer progression. Recently, encouraging results have been obtained with different modalities targeting GSPT1. GSPT1 degrader antibody conjugates are now in clinical trials for breast cancer (ORM-5029) and AML (BMS-986497/ORM-6151). Of interest, an orally active GSPT1 degrader (MRT-2359) is in Phase 2 trial for MYC-driven tumors including NSCLC and SCLC, with 2 PR, 1 SD in six biomarker positive patients (September 2024). Safety profile at this stage supports further clinical development. Preclinically, MRT-2359 is a potent GSPT1 degrader with nanomolar *in vitro* IC50 and oral bioavailability of ~50%. It shows anti-tumor activity in NSCLC xenograft model starting at 1 mg/kg PO, QD. These encouraging results have prompted us to explore a series of GSPT1 MGDs.

In the present study, we describe the discovery of a series of novel, potent and orally active GSPT1 MGD targeting tumors with high GSPT1 expression. In the BT-747 human breast cancer cell assay, IC50s for serval compounds are between 5 - 50 nM, in the same range as that of MRT-2359 and other comparators in the same assay. Significant GSPT1 protein degradation of these compounds is observed showing on-target mechanism of action, without affecting protein degradation in a panel of proteins. A representative compound in the series shows a promising pharmacokinetic profile (PO at 3 mg/kg; IV at 1 mg/kg) with an oral bioavailability of 55 %, Cmax of 0.78 μM, t1/2 of 2.3 hour and Vdss of 1.82 L/kg in mouse. This compound demonstrates *in vivo* efficacy in CDX model with a favorable profile comparable to that of MRT-2359. In summary, a series of orally active GSPT1 degraders have been discovered with preclinical profile suitable for further development to manage cancers with high GSPT1 expression.

#394 Bridged proteolysis targeting chimera (PROTAC) enables degradation of the cyclin D undruggable protein.

Y. Zhong[1], Y. Xiong[1], H. Yim[1], X. Yang[1], K.-S. Park[1], L. Xie[2], P. Poulikakos[1], X. Chen[2], J. Liu[1], J. Jin[1];
[1]Icahn School of Medicine at Mount Sinai, New York City, NY, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Proteolysis targeting chimeras (PROTACs) are attractive therapeutic modalities for degrading disease-causing proteins. While significant progress has been made in developing PROTACs for various protein targets, current small-molecule PROTAC approaches cannot target undruggable proteins lacking small-molecule binders. To overcome this limitation, we present a novel PROTAC approach, termed bridged PROTAC. This approach utilizes a small-molecule binder of the target protein's binding partner to recruit the protein complex into proximity with an E3 ubiquitin ligase, enabling the degradation of the target undruggable protein. Applying this bridged PROTAC strategy, we discovered MS28, the first-in-class degrader of cyclin D1. MS28 effectively degraded cyclin D1 prior to CDK4/6 and with superior degradation potency through recruiting the CDK4/6-cyclin D1 complex to the von Hippel-Lindau (VHL) E3 ligase. MS28 suppressed the proliferation of lung and breast cancer cells more effectively than CDK4/6 inhibitor and degraders. Notably, while triple negative breast cancer (TNBC) cell lines were mostly insensitive to CDK4/6 inhibitor and degrader treatment, they exhibited potent sensitivity to MS28. RNA-sequencing analysis revealed that while MS28 and CDK4/6 inhibitor and degrader shared downregulated genes associated with cell cycle regulation and DNA replication, MS28 upregulated a unique set of genes such as those involved in the unfolded protein response and endoplasmic reticulum stress pathway. Altogether, the bridged PROTAC strategy could provide a generalizable platform for targeting undruggable proteins, thereby offering invaluable chemical tools for the study of these proteins, and potentially delivering greater therapeutic efficacy than small-molecule inhibitors or degraders targeting alternative components within the signaling pathway.

#395 Triamterene and Asinex 1 target DLG and ETGE mutants of NRF2 in esophageal squamous cell carcinoma.

Zachary A. Ladd[1], Candice Bui-Linh[2], Chorlada Paiboonrungruang[2], Boopathi Subramaniyan[3], Zhaohui Xiong[2], Tao Gao[3], Haining Wang[4], Francis Spitz[3], Xiaoxin Chen[3]

[1]Cooper Medical School of Rowan University (CMSRU), Camden, NJ,[2]Coriell Institute for Medical Research, Camden, NJ,[3]Surgery, Cooper University Health Care, Camden, NJ,[4]Insilico Medicine, Cambridge, MA

Introduction: NRF2 is a master transcription factor that regulates oxidative stress response. Esophageal squamous cell carcinoma (ESCC) frequently harbors gain-of-function NRF2 mutations that cause NRF2 overexpression, drive chemo- and radio-resistance, and lead to poor survival in human patients. NRF2 interacts with KEAP1's Kelch domain through the DLG (Trp^{24}-Leu^{30}) and ETGE (Leu^{76}-Leu^{84}) motifs, which are mutation hotspots in human ESCC. Hence, there is a need to develop targeted therapies against $NRF2^{Mut}$-ESCC carrying DLG or ETGE mutations, without inhibiting $NRF2^{WT}$. Our previous study has validated two FDA-approved drugs (Pyrimethamine and Mitoxantrone) as $NRF2^{Mut}$inhibitors in human ESCC cells and a genetically modified murine model (*Redox Biology 2023; 67:102901*). This study aims to further identify inhibitors that target DLG and ETGE mutants of NRF2 in ESCC.

Methods: The effects of Triamterene (FDA-approved diuretic) and Asinex 1 (novel compound) on NRF2 expression, half-life, and ubiquitination were examined in $NRF2^{W24C}$-KYSE70, $NRF2^{D77V}$-KYSE180, $NRF2^{D29H}$-TE14, $NRF2^{G81S}$-OE21, $NRF2^{WT}$-KYSE450, and $KEAP1^{Null}$-KYSE450 cells. Proximity ligation assay (PLA) was performed to investigate the KEAP1-NRF2 interaction. Seven Triamterene analogues were synthesized for a structure-activity relationship study.

Results: Both Triamterene and Asinex 1 displayed dose- and time-dependent inhibitory effects on $NRF2^{W24C}$ and $NRF2^{D77V}$ expression, respectively, with limited cytotoxicity. Both compounds did not impact $NRF2^{WT}$ expression in $NRF2^{WT}$-KYSE450 and $KEAP1^{Null}$-KYSE450 cells, indicating their selective inhibition of $NRF2^{Mut}$. Triamterene and Asinex 1 significantly reduced the half-life and enhanced ubiquitination of $NRF2^{W24C}$ and $NRF2^{D77V}$, respectively. In addition, Triamterene and Asinex 1 significantly inhibited the expression of $NRF2^{D29H}$ in TE14 cells and $NRF2^{G81S}$ in OE21 cells, respectively. PLA showed a significant increase in KEAP1-$NRF2^{W24C}$ interaction by Triamterene. The structure-activity relationship study and computer modeling suggested that Triamterene binds KEAP1 (in particular Arg^{415}), thus modifies the conformation of Kelch domain to fit DLG^{W24C}.

Conclusion: Triamterene and Asinex 1 inhibit $NRF2^{Mut}$ in ESCC cells with specificity for DLG mutants and ETGE mutants, respectively. Both compounds are being further investigated for their mechanisms of action as molecular glues and efficacy in genetically modified mice carrying DLG and ETGE mutations.

#396 Discovery of SHR3591, a highly potent and orally bioavailable AR PROTAC for the treatment of prostate cancer.

Minqiang Jia, Limin Zhang, Fanglong Yang, Gang Chen, Shouli Zhao, Weimin Wang, Jiangtao Chi, Wei Peng, Luona Wang, Huishuang Miao, Zhibin Xu, Yuchang Mao, Xun Li, Yi Mao, Shuyu Cai, Jun Feng, Min Hu, Xin Li, Feng He

Shanghai Hengrui Pharmaceutical CO., LTD., Shanghai, China

Prostate cancer is the second most common cancer in men after lung cancer. Androgen receptor (AR) signaling plays a key role in the development and progression of prostate cancer. A number of AR-centered therapies have been developed for the treatment of prostate cancer, such as CYP17A1 inhibitor abiraterone, which blocks the androgen synthesis pathway, and a series of second-generation AR antagonists. Unfortunately, resistance mechanisms to these AR-signaling targeted agents usually develop within 18 months of treatment, including AR amplification, various ligand-binding domain (LBD) mutations and splicing variants. However, AR signaling still plays an important role in these resistant settings. Therefore, it's urgent to develop new therapeutic strategies targeting AR, particularly for the treatment of metastatic castration-resistant prostate cancer (mCRPC). To meet this challenge, proteolysis-targeting chimera (PROTAC) technology provides a possible solution. We disclose herein SHR3591 as an orally bioavailable AR PROTAC for the treatment of prostate cancer, which is potent in degrading both AR wildtype and LBD mutations.SHR3591 demonstrated nanomolar AR degradation activities in both LNCaP (DC_{50}: 7.9 nM) and AR-amplified VCaP cells (DC_{50}: 7.5 nM). To our delight, SHR3591 also degraded various clinically relevant AR mutants, including H875Y, T878A, W742L, F877L and M896V with single-digit nanomolar potency. One of the most common mutant L702H could also be degraded efficiently with a DC_{50} value less than 20 nM. Meanwhile, no obvious degradation of neosubstrates of common CRBN binders, such as IKZF1, IKZF3 or GSPT1, were observed (DC_{50}>10000 nM), displaying good selectivity. The *in vivo* PD experiment was carried out in castrated male mice harboring VCaP tumors with 10 mg/kg of SHR3591 treatment (po, qd×3). Over 90% of AR proteins were degraded by SHR3591 treatment. Furthermore, in a VCaP xenograft model, SHR3591 showed robust anti-tumor activity in a dose-dependent manner, leading to tumor regression (TGI > 130%) at as low as 3 mg/kg (po, qd), without obvious influences in mouse body weight during 25 days of treatment. Additionally, SHR3591 also displayed favorable pharmacokinetic profiles across preclinical species with oral bioavailability more than 20%. In conclusion, SHR3591 has been developed as a highly potent and orally bioavailable AR PROTAC, exhibiting superior AR degradation activities and good selectivity *in vitro*. SHR3591 could efficiently degrade AR WT and clinically relevant mutants including L702H. Furthermore, SHR3591 displayed excellent PD effect and robust tumor inhibition activity *in vivo*. SHR3591 showed favorable pharmacokinetic profiles across different preclinical species as well. SHR3591 has advanced into phase1/1b clinical studies in patients with mCRPC.

#397 Combinatorial use of VHL and KEAP1-based PROTACs reveals unexpected synergy and hook effect relief.

Sehbanul Islam[1], Haihong Jin[2], Dong Liu[2], Dan Lu[2], Yunkai Zhang[2], Renxu Chang[1], Joel Austin[2], Thomas Beer[3], Hsin-Yao Tang[3], Lan Huang[2], James Tonra[2], Luca Busino[1]

Proteolysis-targeting chimeras (PROTACs) are bifunctional molecules bridging a target protein with an E3 ubiquitin ligase, promoting its ubiquitylation and degradation. Unlike traditional inhibitors, PROTACs exploit transient interactions, enabling the selective degradation of "undruggable" proteins, thereby expanding the landscape of druggable targets. However, PROTACs are not without limitations. The "hook effect"—a phenomenon where high PROTAC concentrations reduce efficacy due to inactive binary complex formation—compromises their clinical utility. Additionally, single PROTACs may fail to achieve complete degradation due to insufficient polyubiquitination or suboptimal E3 ligase recruitment, limiting their therapeutic efficacy. These challenges highlight the need for strategies to enhance PROTAC performance and so therapeutic applicability. In this study, we introduce a novel dual-PROTAC strategy that recruits two distinct E3 ligases, such as KEAP1 and VHL, to cooperatively degrade KRAS(G12D) and Androgen Receptor (AR). Our data demonstrate that combining KEAP1- and VHL-recruiting PROTACs synergistically enhances target degradation, reduces the required dosing, and minimizes off-target effects. Notably, KEAP1 recruitment offers the unique advantage to favour polyubiquitin chains elongation, thereby improving proteasomal recognition. In conclusion, dual-targeting approach represents a promising avenue for optimizing PROTAC-based therapeutics.

#398 Systematic identification and translation of novel targeted protein degradation mechanisms.

Christian Dillon

PhoreMost Limited, Pampisford, United Kingdom

The rise of Targeted Protein Degradation (TPD) is rapidly changing perceptions about therapeutic target druggability and drug design. However, the majority of degraders in clinical and preclinical development rely on the recruitment of a single E3 ligase, Cereblon, highlighting a pressing need to identify and translate novel mechanisms. Moreover, the discovery of molecular glue degraders is hampered by the prevailing serendipitous nature of their discovery. To unlock the potential of this modality we have developed proprietary cell-based screening platforms, SITESEEKER® and GlueSEEKER™, to uncover novel TPD mechanisms. These technologies exploit vast libraries of computationally-derived coded peptide fragments within the context of a pooled degradation-based phenotypic screen. Specifically, SITESEEKER® screens have identified a cache of degrader mechanisms that rely on hijacking components of the UPS machinery. GlueSEEKER™ utilizes peptide libraries to create a diverse suite of surface-edited E3 ligases to systematically explore neo-substrate degradation across a variety of E3 ligases and Proteins-of-Interest (POI).PhoreMost is progressing a pipeline of monovalent and heterobifunctional oncology degrader programmes arising from its platforms. We describe a novel set of small molecule heterobifunctional degraders that operate via an E3 ligase distinct from Cereblon or VHL-based PROTACs. Mechanistically, these degraders function via a CUL1-SKP1 SCF complex FBOX substrate receptor and demonstrate potential for enhanced cancer-selective degradation of POIs. Finally, we uncover neomorphic interactions revealed by GlueSEEKER™ that provide translational insights for the degradation of both precedented and unprecedented substrates of the E3 ligase, Cereblon.

#399 Targeted protein degradation of the androgen receptor by ARCC-4 and ARD-2128: proteomic and therapeutic potential in AR-driven cancers.

Elsa Liu[1], Judy Fu[1], Lori Fan[1], Luciano Galdieri[2], Justin Lipner[2], Steven Garner[2], Brogan Epkins[2], Emily Schultz[2], Daria Clucas[2], Kaitlyne Powers[2], Julie Chung[1], Ian Huang[1], Pei Ching Cheng[1], Phil Lin[1], Alastair J. King[2], ChunYao Lee[1]

[1]Eurofins Discovery, New Taipei City, Taiwan,[2]Eurofins Discovery, St. Charles, MO

Background: The androgen receptor (AR) plays a central role in the progression of prostate cancer, where AR signaling drives tumor cell growth and survival. Current treatment strategies, including androgen deprivation therapy and AR antagonists like enzalutamide, aim to reduce AR activation. However, resistance often develops partly due to compensatory upregulation of the AR protein. Targeted protein degradation (TPD) represents an alternative strategy to overcome the limitations of traditional therapies by degrading the AR protein rather than merely inhibiting its function.

Methods: This study investigated the AR-targeting degraders, ARCC-4 and ARD-2128, and their effects on AR nuclear translocation and transactivation in AR-expressed CHO-K1 cells. Additionally, *in vitro* efficacy was evaluated in cell proliferation assays, notably using the LNCaP clone FGC prostate cancer cell line. Proteomic analysis was conducted to examine global protein profiles and signaling pathways impacted by each degrader.

Results: ARCC-4 and ARD-2128, which act via distinct E3 ligase pathways (VHL and CRBN, respectively), demonstrated significant AR degradation, with ARD-2128 achieving greater potency in reducing AR nuclear translocation and transactivation. Both degraders showed lower GI_{50} values and greater efficacy in suppressing cell proliferation in LNCaP clone FGC cells when compared with enzalutamide. Additionally, proteomic analysis highlighted distinct molecular signatures associated with each degrader, revealing differential effects on AR network proteins and broader signaling pathways.

Conclusion: The potent growth inhibition observed with ARCC-4 and ARD-2128, as compared with enzalutamide, underscores the therapeutic potential of TPD in AR-driven cancers. These findings also potentially support TPD as a robust approach for overcoming resistance mechanisms associated with AR-targeted therapies. Broader profiling using the OncoPanel® platform would further demonstrate the therapeutic potential and selectivity of AR degraders such as ARCC-4 and ARD-2128. Investigation in additional prostate and breast cancer cell lines with diverse nuclear hormone receptor expression would be particularly relevant and may offer insights into the application of AR-targeted degradation across different cancer types, potentially leading to more effective treatment options.

#4 Vitamin D blocks platinum-induced ovarian cancer stem cell plasticity.

Tara X. Metcalfe[1], Sophie Xanders[2], Shu Zhang[3], Christiane Hassel[4], Heather M. O'Hagan[1], Kenneth P. Nephew[5]

[1]School of Medicine, Indiana University, Bloomington, IN,[2]Jesse H. and Beulah Chanley Cox Scholars Program, Indiana University, Bloomington, IN,[3]Biology, Indiana University, Bloomington, IN,[4]Flow Cytometry Core Facility, Indiana University, Bloomington, IN,[5]Melvin and Bren Simon Comprehensive Cancer Center, Indiana University, Indianapolis, IN

Most women diagnosed with late-stage high grade serous ovarian cancer (HGSOC) develop recurrent, platinum-resistant tumors. Ovarian cancer stem cells (OCSCs) are hypothesized to contribute to the emergence of these tumors. CSCs reside in a plastic state, with the ability to convert between non-CSC to CSC. This process of dedifferentiation is thought to continue during tumor development and chemotherapeutic agents such as platinum can exaggerate CSC plasticity. However, the underlying mechanism has not been established. Furthermore, how platinum transforms non-OCSCs into OCSCs to contribute to this subpopulation of cells remains unclear. To examine OCSC plasticity, aldehyde dehydrogenase (ALDH; functional marker) and fluorescence activated cell sorting were used to isolate OCSCs (ALDH+) and non-OCSCs (ALDH-) from HGSOC cell lines, OVCAR5 and OVCAR3. To determine if platinum induced conversion of non-OCSC to OCSC, ALDH- cells were cultured for 3-10 days after sorting. At timepoints examined, ALDH- cells remained ALDH-, (>99% were ALDH- after 10 days). ALDH- cells were then treated with cisplatin (OVCAR5: 12μM,16h, OVCAR3: 15μM 16h), and the percent of ALDH+ cells was measured using flow cytometry. Treatment of cisplatin resulted in conversion of approximately 4% and 10% of ALDH- cells into ALDH+ cells ($p<0.05$) in OVCAR5 and OVCAR3 cells, respectively. Furthermore, converted OCSCs displayed increased ($p<0.05$) expression of stemness genes (BMI1, NANOG, OCT4, SOX2) and spheroid formation compared to parental ALDH+, demonstrating that platinum induced the observed differences in the stemness phenotype. With the goal of targeting key genes and pathways to inhibit platinum-induced OCSC conversion, RNA-sequencing was performed on ALDH- and ALDH+ cells before and after cisplatin treatment. Vitamin D receptor (VDR)/retinoid x receptor (RXR) activation was a major pathway in the platinum-induced converted OCSC transcriptome, which was of interest because VDR signaling plays a role in differentiation, and its key binding partner, RXR and retinoic acid receptor (RAR) are linked to stemness. To determine the effect of vitamin D on OCSC conversion, ALDH- cells were treated with vitamin D for 24h (OVCAR5: 34nM, OVCAR3: 56nM) and/or cisplatin and the ALDH activity was measured with flow cytometry. Vitamin D treatment in combination with cisplatin significantly decreased the platinum-induced percent of converting cells ($p<0.05$). Additionally, vitamin D treatment decreased expression of stemness genes and spheroid formation in both whole cell and sorted cell populations. Currently, we are further investigating the relationship between cisplatin, RAR/RXR signaling and stemness. Collectively, these results demonstrate a role for VDR signaling in platinum-induced OCSC conversionproviding further support for the development targeted therapies to block the persistence of OCSCs and ultimately reduce patient mortality.

#40 Organoid models of ovarian clear cell carcinoma for evaluating therapeutic sensitivity.

Clare E. Padrick[1], Magdalena Zielinska[1], Minh Ha[1], Aisha L. Saldanha[1], Cam Anh Tran[1], Brendan Shay[2], Daohong Zhou[3], Kristopher A. Sarosiek[4], Cloud P. Paweletz[1], Ursula A. Matulonis[2], Joyce F. Liu[2], **Elena V. Ivanova**[1], Elizabeth H. Stover[2]

[1]Belfer Center for Applied Cancer Science, Dana-Farber Cancer Institute, Boston, MA,[2]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Biochemistry & Structural Biology, U.T. Health San Antonio, San Antonio, TX,[4]Environmental Health, Harvard School of Public Health, Boston, MA

Ovarian clear cell carcinoma (OCCC) is a rare subtype of ovarian cancer, often resistant to platinum-based chemotherapy. OCCC is characterized by ARID1A mutations, PI3K and RAS/MAPK pathway alterations, and activation of the HIF signaling pathway. We and others showed that OCCC are sensitive to inhibition of BCL-XL, a pro-survival protein in the intrinsic pathway of apoptosis. Patient-derived models of OCCC could potentially accelerate pre-clinical testing of therapeutics in this difficult-to-treat cancer, but relatively few patient-derived organoid (PDO) or xenograft models of OCCC have been reported. We describe the establishment and propagation of two PDO models of OCCC. Patient 1 had recurrent OCCC with PIK3CA mutation and HER2 amplification. Patient 2 had recurrent OCCC with CDKN2A/B deletion. Both patients underwent secondary cytoreductive surgery for recurrent disease. Fresh tissue was collected under IRB-approved protocols and tumor cells were plated in Matrigel and formed PDOs. Patient 1 OCCC cells have been propagated for over 35 passages, and patient 2 cells for 9 passages to date. Immunohistochemistry to confirm fidelity to the original tumor is in progress. As a proof-of-concept for evaluating therapeutics in OCCC PDOs, we used a 3D microfluidic device (AIM Biotech) to evaluate drug responses in patient 1 PDO. PDO cells were seeded in the microfluidic device and expanded for one week, treated with drugs within the device, then stained at day 6 with fluorescence markers for live (TMRM, Thermo Fisher), apoptotic (CellEvent Caspase-3/7, Thermo Fisher), and dead (DRAQ7, CST) cells. Quantitative imaging was performed to determine the cell area positive for each marker. The OCCC PDO was treated with standard-of-care chemotherapies carboplatin and paclitaxel; BCL-XL inhibitor A1331852 (Selleckchem); a novel BCL-XL PROTAC degrader DT2216 (Dialectic Therapeutics); or combinations of the BCL-XL inhibitor/degrader with paclitaxel. Treatment with A1331852 or DT2216 induced apoptosis and death in the OCCC PDO cells compared to control. While paclitaxel alone also induced some cell death, the combination of DT2216 (1μM) and paclitaxel (500nM) was highly potent, resulting in elimination of almost all the OCCC cells (Bliss synergy score 0.28±0.08, p=0.013). These data suggest that BCL-XL inhibition/degradation combined with paclitaxel may be a promising treatment strategy for OCCC. Our study also demonstrates the successful establishment of OCCC PDOs and application of a microfluidic device for evaluating novel therapeutic strategies in ovarian cancer.

#400 Preclinical development of TQB3019: A potent and selective oral BTK degrader leveraging the OAPD® platform to overcome acquired resistance mutations.

Jing Ren, Jinan Wang, Sheng Xu, Jin Liu, Ying Zhang, Xiaojin Wang, Baomin Liu, Wei Shi, Hongjiang Xu, Ling Yang, Wei Zhao, Xiquan Zhang

Chia Tai Tianqing Pharmaceutical Group Co., Ltd., Nanjing, China

Background: Bruton's tyrosine kinase (BTK) is a clinically validated target for the treatment of hematological malignancies. Small molecule inhibitors targeting BTK have been used in the clinic to manage B-cell malignancies. However, the emergence of BTK mutations, such as BTK C481S, ect., can lead to drug resistance to both covalent and non-covalent inhibitors. To address the acquired resistance mutation issues, here we report TQB3019, a novel BTK degrader, discovered using Chia Tai Tianqing's proprietary Platform for Orally Available Protein Degrader (OAPD®).

Result: TQB3019, a highly potent oral BTK degrader, induced robust BTK degradation with a DC_{50} of less than 0.1 nM and D_{max} of greater than 95% in DLBCL cell line OCI-LY10 at 6 hours. Proteomics studies revealed excellent degradation selectivity, then no Ikaros and Aiolos degradation was further confirmed in OCI-LY10 cells and human T cells. TQB3019 also exhibited efficient degradation kinetics in cells harboring both wild-type and C481S mutation, achieving 80% of BTK degradation within 2 hours at 10 nM. Importantly, TQB3019 induced strong cell proliferation inhibition in cells carrying wild-type BTK (IC_{50} of sub-nanomolar range) and BTK C481S mutation (IC_{50} of single-digit nanomolar range). TQB3019 exhibits favorable kinase selectivity of BTK over EGFR, and did not degrade EGFR in lung cancer cell line A431. Unlike covalent inhibitor ibrutinib, TQB3019 also demonstrated improved selectivity for BTK over TEC. TQB3019 using a novel designed CRBN ligand showed over 14-fold higher binding affinity to CRBN protein compared to pomalidomide. Additionally, TQB3019 showed weak inhibition of hERG and cytochrome P450 activities (CYPs) (hERG IC_{50} >30 μM and CYPs IC_{50} >10 μM). TQB3019 demonstrated promising metabolic stability *in vivo* with a mean residence time (MRT) of over 10 hours in dogs, and exhibited good oral bioavailability in both rodents and dogs. Furthermore, oral administration of TQB3019 led to dose-dependent tumor growth inhibition (TGI>95% at 15mg/kg) even complete tumor regression (30mg/kg) in a BTK wild-type TMD8 xenograft tumor model, without significant weight loss.

Conclusion: Developed using Chia Tai Tianqing's OAPD® platform, TQB3019 is an orally available BTK degrader with promising potency, superior selectivity, and favorable pharmacological properties. With IND (Investigational New Drug) application forthcoming, TQB3019 represents a promising therapeutic candidate to address resistance challenges associated with traditional BTK inhibitors.

#401 HDBNJ3049: A novel EGFR-targeting PROTAC to overcome C797S-mediated osimertinib resistance in NSCLC.

Mohammad Hassan Baig[1], Yun Seong Jo[1], Sagar Dattatraya Nale[2], Chang Joong Kim[2], Tae Hwan Park[2], Ju Han Bok[3], Dong Min Kim[3], Ji Min Park[3], Hye Mi Kim[3], Jae June Dong[1], Byoung Gon Moon[3]

[1]Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]BNJ Biopharma Inc., Incheon, Korea, Republic of,[3]Handok Inc., Seoul, Korea, Republic of

The emergence of C797S-driven Osimertinib resistance represents a major hurdle in the treatment of non-small cell lung cancer (NSCLC). This study presents a novel series of proteolysis-targeting chimeras (PROTACs) designed to overcome resistance by potently and selectively degrading EGFR mutants, including the C797S variant. These next-generation EGFR PROTACs demonstrated significant anti-proliferative activity across a broad spectrum of EGFR mutations, achieving subnanomolar potency in cellular proliferation and protein degradation assays alike. Notably, these compounds effectively targeted not only C797S mutants but also other clinically relevant mutations such as Exon19Del and L858R/T790M variants. The lead candidate, HDBNJ3049, exhibited superior activity across all tested EGFR mutant cell lines, including potent growth inhibition of C797S-mutant Ba/F3, and H1975 cells (GI_{50} as low as 17 nM and 50 nM for L858R/T790M/C797S Ba/F3 and H1975, respectively), and robust degradation of Del19/T790M/C797S mutant EGFR (DC_{50}: 13 nM, D_{max}: 98%). *In vivo* pharmacokinetic and pharmacodynamic studies further validated the therapeutic potential of HDBNJ3049, establishing it as a highly promising lead candidate for overcoming osimertinib resistance in NSCLC and offering new hope for patients with limited treatment options.

#402 BCL6 degrader with novel CRBN ligand demonstrates promising selectivity and preclinical efficacy alone or in combination with BCL2 inhibitor.

Jun Xu, Yangguang Li, Ju Wang, Pingmin Tang, Yuting Liao, Chen Zhang, Pangke Yan

Haisco Pharmaceutical Group Co Ltd., Chengdu, China

The B-cell lymphoma 6 (BCL6) transcription repressor, a protooncogene particularly significant in diffuse large B-cell lymphoma (DLBCL), is known to confer survival, protection, and maintenance of lymphoma cells. Its expression in normal B cells is crucial for the initiation and sustenance of germinal centers (GC). Somatic mutations of the BCL6 gene, including chromosomal translocations, have been linked to the deregulation of BCL6 expression, contributing to a subset of aggressive double- and triple-hit lymphomas with poor outcomes with conventional therapy. Addressing this critical clinical need, we have developed HSK47977, a highly specific, potent, and orally bioavailable BCL6 protein degrader with a novel CRBN ligand. Unlike traditional IMiDs, this new CRBN ligand alone had no IMiD activity and barely induced protein degradation in PBMC cells. Meanwhile, HSK47977 baring this ligand has shown remarkable in vitro and in vivo efficacy across multiple pre-clinical DLBCL models. HSK47977 achieves over 90% BCL6 degradation at 10 nM and a DC50 of less than 1 nM in the OCI-Ly1 model. Time-course studies revealed that over 90% BCL6 degradation was achieved within 1 hour and sustained up to 24 hours. Meanwhile, HSK47977 minimally induced the degradation of first-generation IMIDs targets, including GSPT1, SALL4, CK1α, Aiolos, and Ikaros, suggesting its safety profile. The optimization of the CRBN ligand has also significantly bolstered the pharmacokinetic (PK) profile of HSK47977, endowing it with impressive oral bioavailability and enhanced in vivo exposure following oral administration. In addition to this, we have devised a mechanism-based combination strategy aimed at amplifying the therapeutic potency of HSK47977. Given that BCL6 functions as a transcriptional repressor, the degradation of BCL6 could potentially upregulate the expression of the anti-apoptotic protein BCL2, providing the rational for combined inhibition of both. Indeed, we proved that the synergistic effects of of HSK47977 and a BCL2 inhibitor was achieved in both in vitro and in vivo. This combination therapy demonstrated that a minimal dose of HSK47977, when paired with a BCL2 inhibitor, was adequate to elicit tumor regression in CDX models. In summary, these findings underscore HSK47977 as a potent and orally bioavailable BCL6 degrader, distinguished by its novel CRBN ligand. Moreover, the strategic combination with a BCL2 inhibitor is poised to significantly augment the therapeutic efficacy, offering a promising approach for the treatment of diffuse large B-cell lymphoma.

#403 Characterization of PROTACs for targeting tissue transglutaminase 2 (TG2) in cancer.

Andres Felipe Valdivia[1], Purav Vagadia[2], Natalia Masnica[3], Joshua Li Zhu[2], Vanessa Hernandez[4], Ana Maria Isac[4], Gary Schiltz[2], Daniela Matei[4]

[1]Medicine, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Department of Chemistry, Northwestern Univ., Evanston, IL,[3]Northwestern Univ., Evanston, IL,[4]OBY/GYN, Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Introduction: Tissue transglutaminase (TG2) is a multifunctional enzyme involved in the interaction between fibronectin and integrins, as well as in GTP hydrolysis. TG2 is upregulated and active in several cancers, including ovarian cancer (OC). Due to its multifunctional nature and involvement in various processes that promote cancer progression, targeting TG2 therapeutically has proven challenging. Here, we explore the development of PROteolysis TArgeting Chimeras (PROTACs) against TG2 as a strategy to induce protein degradation and target TG2 in cancer.

Materials and Methods: OVCAR5 or SKOV3 OC cells expressing TG2 were treated with different concentrations of PROTACs for 6 or 24 hours. TG2 expression was measured via Western blot (WB) and TG2 activity was assessed by using an enzymatic activity assay. PROTACs that induced TG2 degradation were further validated through reverse phase protein array (RPPA) analysis, adhesion assays, migration assays, and in-vivo omentum adhesion assays.

Results: Over 50 compounds were screened. WB analysis showed significant ($p < 0.05$) degradation of TG2 using three PROTACs: P74, P404, and P405, in both SKOV3 and OVCAR5 cells at 24 hours of treatment, without decreased cell viability ($p < 0.05$). Degradation was stable at 48 hours. Migration and adhesion assays revealed that PROTACs reduced both adhesion and migration capabilities of the cells at 24 hours ($p < 0.005$). Additionally, PROTACs reduced the enzymatic activity of TG2, demonstrating the ability to disrupt other TG2 functions ($p < 0.001$). MG132 treatment prevented PROTAC induced degradation of TG2 showing that the degradation is proteasome dependent. ($p < 0.05$). Reverse phase proteomic analysis (RPPA) of P74-treated cells identified 136 differentially expressed proteins, including a reduction in TG2 and an increase in VHL expression. The most affected pathways in PROTAC-treated cells included cell adhesion, the PI3K/AKT pathway, and others (FDR < 0.05, fold change < 0.5). PROTACs P74 and P405 also reduced in vivo adhesion of OVCAR5 cells to the omentum in an intraperitoneal omental colonization assay ($p < 0.05$).

Conclusion: Treatment of OC cells with PROTACs P74, P404, and P405 significantly reduced TG2 expression levels, disrupted migration and adhesion, and impaired TG2 enzymatic activity. Furthermore, PROTACs reduced cell adhesion in-vivo, highlighting their potential as therapeutic agents

#404 Mechanistic characterization of selective monovalent direct degraders of SMARCA2.

Julia Toth, Gregory Parker, Geoffray Leriche, Tayor Kampert, Aleksandar Jamborcic, Gabrielle Blanco, Kenneth Steadman, Duc Tran, Shu You, Luis Lopez, Farhana Barmare, Kyohei Hayashi, Gang Liu, Alex Campos, Meg McCarrick, Kevin Freeman-Cook, Peggy Thompson

Plexium, San Diego, CA

SMARCA2 and SMARCA4 are essential, redundant, catalytic subunits of the multi-subunit BRG1/BRM-associated factor (BAF) complex. This complex regulates gene expression and DNA repair through chromatin remodeling activity. The paralogues SMARCA2 and SMARCA4 bind acetylated histones through their highly conserved bromodomains and alter DNA-histone contacts using ATP-dependent helicase activity. Recently, mutations in specific components of the BAF complex have been identified. Of great interest are loss of function mutations in SMARCA4, found in 5-7% of all human cancers and occur with high prevalence (~10%) in non-small cell lung cancer (NSCLC), making these SMARCA4-deficient tumor cells highly dependent on SMARCA2 for viability. This synthetic lethal relationship may provide a unique opportunity for SMARCA2-selective degraders to block the growth of SMARCA4 deficient tumors, while sparing normal tissues. To enable degrader discovery, we focused our efforts on a monovalent direct degrader approach, where small molecules are designed to bind the target protein and induce its degradation through the recruitment of an E3 ligase complex. Initial screening hits from distinct chemical series were optimized to produce potent and selective SMARCA2 degraders. Co-treatment with a proteasome inhibitor confirmed that degradation was mediated via the ubiquitin proteasome system (UPS), and a UPS-focused CRISPR screen identified the E3 ligase responsible for compound-induced degradation of SMARCA2. Cell based protein-protein interaction (PPI) studies advanced our understanding of compound-mediated E3 ligase recruitment and provided mechanistic insights into the observed selectivity for SMARCA2 over SMARCA4. Ternary complex dynamics were further investigated *in vitro* via surface plasmon resonance (SPR) studies. Using a combination of co-immunoprecipitation, mass spectrometry, and point mutant studies, specific amino acids that are required for compound-induced PPI and subsequent degradation of SMARCA2 were identified. Collectively, these results highlight the discovery and characterization of novel small molecule monovalent direct degraders of SMARCA2. The detailed description of the degradation mechanism presented here provides critical insights into an efficient approach to eliminating pathogenic proteins through targeted protein degradation.

#405 Discovery of GLR203101, a selective and orally bioavailable PROTAC of SMARCA2 for the treatment of SMARCA4 mutant tumors.

Xiaoguang Li, Siyu Gu, Yongzheng Ding, Jing Cheng, Kanghua Wang, Weiwei Yu, Wenmin Chen, **Fuming Xu**

Gan & Lee Pharmaceuticals, Beijing, China

The SWI/SNF (mammalian SWItch/Sucrose Non-Fermentable) helicase SMARCA4 is frequently mutated in cancer. Its inactivation results in a cellular dependence on its paralog, SMARCA2, for survival. Therefore, SMARCA2 constitutes an attractive therapeutic synthetic lethality target. However, the co-deletion of Smarca2 and Smarca4 in adult mice was lethal, highlighting the necessity for designing molecules that target SMARCA2 selectively. This objective is rather challenging due to the high homology of SMARCA2/4. Few SMARCA2 selective compounds have entered clinical trials, including PROTAC molecule PRT-3789 administered by intravenous injection in phase 2 clinical trials.

Herein, we report the discovery of a selective and orally bioavailable SMARCA2 PROTAC degrader, GLR203101. Notably, our lead compound GLR203101 possesses a favorable molecular weight (< 650), contributing to excellent physical and chemical properties. GLR203101 exhibited robust degradation of SMARCA2 (DC_{50} < 10 nM, D_{max} > 80%) over SMARCA4 (D_{max} < 10%) in Hela cell line using HiBiT assay. The degradation selectivity was also validated by western blot in several SMARCA4 wild-type cell lines, including Hela, MV-4-11, LNCaP and SW1573. GLR203101 also selectively inhibited the viability of SMARCA4-deficient cancer cells with low nanomolar IC_{50} values, showing >1000-fold selectivity over SMARCA4 wild-type cell lines. In addition, GLR203101 exhibited favorable PK properties with high exposure and moderate oral bioavailability in mice and SD rats. After 24 hours of oral administration of GLR203101, a robust degradation of SMARCA2 while sparing SMARCA4 was observed in transplanted tumors in the xenograft model. GLR203101 is being evaluated as a preclinical candidate.

#406 Targeting NSD2 aberrations in hematological malignancies with a potent and selective NSD2 PROTAC degrader.

Yihan Liu[1], Abhijit Parolia[1], Lianchao Liu[2], Tongchen He[1], Yuanyuan Qiao[1], Sanjana Eyunni[1], Jie Luo[1], Zhen Wang[2], Arul Chinnaiyan[1], Ke Ding[2]

[1]Michigan Center for Translational Pathology, University of Michigan, Ann Arbor, MI,[2]Shanghai Institute of Organic Chemistry, Shanghai, China

Nuclear receptor-binding SET domain-containing 2 (NSD2) is a methyltransferase that predominantly catalyzes the dimethylation of lysine 36 on histone 3 (H3K36me2). It has been implicated as an oncogene, with a hotspot gain-of-function mutation frequently identified in B-cell acute lymphoblastic leukemia (B-ALL) and chromosomal translocations involving NSD2 reported in approximately 20% of multiple myeloma cases. Despite its clinical significance, existing NSD2 inhibitors suffer from low activity or inferior selectivity, and none can simultaneously remove the methyltransferase activity and chromatin binding function of NSD2. To address these limitations, we developed LLC0424, a novel NSD2 degrader engineered using proteolysis-targeting chimera (PROTAC) technology based on a PWWP1 domain binder. LLC0424 demonstrated potent degradation of NSD2 protein in acute lymphoblastic leukemia (ALL) RPMI-8402 cells, with a DC50 value of 20 nM and a Dmax value of 96%. TMT quantitative proteomics confirmed LLC0424's high selectivity for NSD2, underscoring its specificity. Intravenous or intraperitoneal administration of LLC0424 achieved robust NSD2 degradation in vivo, validating its systemic effectiveness. In B-ALL cells harboring the NSD2 point mutation, LLC0424 treatment led to sustained downregulation of H3K36me2, a critical epigenetic mark associated with NSD2 activity. Additionally, LLC0424 exhibited cytotoxicity in ALL cell lines with NSD2 mutations, inhibiting cell growth and reducing colony formation capacity. Overall, these findings highlight the therapeutic potential of NSD2 degradation as a novel strategy to target cancers driven by NSD2 aberrations.

#407 Development of an integrated multi-modal platform for comprehensive analysis of targeted protein degraders in a drug discovery setting.

Magdalena Kieltyka[1], Maciej Olszewski[2], Marta Smejda[2], Kamila Zaremba[2], Katarzyna Nosek[2], Magdalena Malik[2], Katarzyna Szafran[2]

[1]Selvita Inc, Boston, MA,[2]Selvita SA, Krakow, Poland

With growth in the area of targeted protein degradation (TPD), there has been increasing interest in the development of analytical platforms which can facilitate efficient drug discovery processes. We provide a fully developed high throughput analytical platform to study and optimize protein degrader candidates in a comprehensive manner. Our platform consists of multiple orthogonal technologies that generate major mechanistic information and help advance TPD drugs rapidly through the preclinical development stages. Our platform is based on a well-defined degrader development strategy using advanced technologies and automated processes. Major analytical features include: • Binding and binary complex formation: assessment of warheads. Monitoring target protein binding interactions in both cell free and cellular systems, using surface plasmon resonance (SPR), isothermal titration calorimetry (ITC) and NanoBRET, respectively. • Ternary complex formation evaluation: assessment of degrader-induced protein-protein interactions in both cell free and cell-based systems, using homogeneous time-resolved fluorescence (HTRF) and NanoBRET respectively. • Cellular degradation profiling via a variety of methods, including automated capillary Western blotting, HiBiT and High Content Screening, enabling precise quantification of degradation kinetics and efficacy. • Proteome-wide specificity assessment using mass spectrometry. In our integrated data processing pipeline, we correlate physicochemical properties with degradation efficiency, to support SAR analysis and enhance the rational optimization of degraders. The platform has been proven to work across multiple E3 ligase systems, including CRBN, VHL and other tissue-specific ligases, thus supporting a wide range of TPD programs. Comparative case studies from several client-based programs exemplify the versatility of our platform and its capability to generate comprehensive data for effective decision making. Notably, we achieved high concordance between orthogonal methods. Modular design of the platform enables its segmentation to fit the needs of the clients' individual specifications whilst retaining standardized work procedures for effective delivery of the project. This comprehensive analytical strategy addresses the challenges of TPD drug discovery and provides the scalability and reliability required for contract research organizations supporting multiple concurrent programs.

#408 CETSA-based evaluation of non-degraded PROTAC targets.

Tomas Friman, Tuomas Tolvanen, Alexey Chernobrovkin, **Daniel Martinez Molina**

Pelago Bioscience AB, Solna, Sweden

Protein degradation is a non-classical modality with the potential to tackle therapeutically interesting proteins, even those previously deemed undruggable. The molecular effect that a productive interaction between target proteins and a bifunctional degrader/PROTAC can easily be monitored by measuring protein degradation. However, not all proteins that bind degraders are in fact degraded, which suggests that not all effects of PROTACs are based on the degradation of targets, but also the effects of traditional binary protein - ligand interactions. The Cellular Thermal Shift Assay (CETSA) is a powerful technology for identifying the interactions between compounds and their cognate protein targets. Coupling CETSA with mass spectrometric (MS) readout allows for profiling of binding selectivity of both the warhead that binds the protein of interest (POI) but also to investigate the selectivity for different PROTAC scaffolds. CETSA can be carried out in both lysates and intact cells, always without the need to modify the compound, the proteins or the cellular environment. In a typical CETSA workflow we can address both the degradation profile of proteins in the proteome that is accessible by MS, and also provide insights into the binding of the degrader to both the E3 ligase and the POI. This allows us to identify any disconnect between degradation and binding of degrader as well as to follow the downstream cellular and molecular effects. Here we will exemplify how CETSA can be applied in deconvoluting protein binding of a CDK9 targeting PROTAC: THAL SNS 032, which is composed of the cereblon (E3-ligase) binder Thalidomide and the CDK (POI) binder SNS 032. THAL SNS 032 induces degradation of the annotated target CDK9 and its associated protein Cyclin-T1, but target engagement can also be observed for additional proteins, including other kinases. In turn, the non-productive interactions from a degradation point of view can still result in biological effects, as exemplified here where GSK3A and GSK3B as well as their downstream substrate FOXK1 are thermally shifted but not degraded by the PROTAC. The effects on the GSK3 - FOXK1 signaling axis would have been missed if only protein degradation had been considered. By combining mass spectrometric data from CETSA experiments with degradation readouts it is possible to correlate cellular target engagement potencies with degradation efficiency and importantly, also identify any drug - protein binding that do not result in degradation

#409 Targeted degradation of FAK and PYK2 in cancer.

Christina C. Kuismi[1], Yuan Jiang[2], Baishan Jiang[2], Behnam Nabet[1]

[1]Human Biology, Fred Hutchinson Cancer Center, Seattle, WA,[2]Department of Radiation and Medical Oncology, Medical Research Institute, Zhongnan Hospital, Wuhan University, Wuhan, China

Focal adhesion kinase (FAK) and its paralog proline-rich tyrosine kinase 2 (PYK2) are non-receptor kinases that are critical in the initiation, progression, and metastasis of several cancers, including triple-negative breast cancer and pancreatic ductal adenocarcinoma. FAK and PYK2 are overexpressed in these cancers and have diverse activities in the cell, including functioning as kinases, serving as scaffolding proteins, and regulating transcriptional programs. Consequently, they have emerged as important drug targets in cancer. Despite the critical need to advance novel therapeutic approaches in triple-negative breast cancer and pancreatic ductal adenocarcinoma to improve survival rates, the development of selective agents to target FAK or PYK2 in isolation has remained challenging. In this study, we hypothesized that abolishing all functions of FAK and/or PYK2 using targeted degradation approaches would be advantageous over small molecule kinase inhibitors. Building on our prior work to develop FAK-selective heterobifunctional degraders known as PROTACs, we endeavored on a campaign to develop PYK2-selective and FAK/PYK2-dual targeting PROTACs. We synthesized a series of PROTACs that engage FAK and/or PYK2 and recruit an E3 ubiquitin ligase to achieve target protein degradation. These compounds, which vary in their kinase binding warheads, linkers, and E3 ubiquitin ligase binders, were evaluated through assays to measure target engagement in cells, protein levels using immunoblotting, selectivity using quantitative proteomics, and impact on phenotypes including 3D-spheroid viability and cell migration. This pipeline led to the identification of potent (< 250 nM) and selective degraders of PYK2 and FAK/PYK2 that rapidly (< 2 hours) diminish protein levels. These PROTACs require the ubiquitin-proteasome machinery to achieve degradation and display proteome-wide selectivity towards the intended kinases. In pancreatic cancer and breast cancer cell lines, degradation of both FAK/PYK2 led to significant reductions in 3D-spheroid viability and migration. These effects were improved compared to FAK or PYK2 inhibition or degradation in isolation. In addition, targeted destruction of FAK, PYK2, or FAK/PYK2 led to substantially improved reductions in 3D-spheroid viability and migration compared to kinase inhibition, highlighting the importance of disabling the enzymatic and non-enzymatic roles of FAK and PYK2. Together, our work establishes a chemical toolbox to degrade FAK, PYK2, or FAK/PYK2 to uncover FAK and PYK2 shared and distinct roles and advances targeted degradation of these kinases as a potential therapeutic approach in cancer.

#41 Generation and multiomic profiling of a*APC/TP53*double knockout normal colon organoid.

Younghee Choi, Eunju Kim, Jihyun Park, Sang-Hyun Song, Tae-You Kim

Seoul National University, Jongno-gu, Korea, Republic of

Colorectal cancer frequently arises from early tumorigenic events driven by mutations in the APC and TP53 genes. To elucidate mechanisms underlying early colon tumorigenesis, we established normal colon organoids with APC and TP53 double knockouts (DKO). Through integrated multi-omics analyses, including RNA-seq, ATAC-seq, methylation-seq, and H3K27ac ChIP-seq, we identified significant upregulation of the KIT gene in DKO organoids compared to controls. Subsequent KIT knockout generated APC/TP53/KIT triple knockout (TKO) organoids, which exhibited markedly reduced migratory capacity and Ki-67 tumor intensity, highlighting a pivotal role for KIT in early tumorigenic processes. Proteomic analysis further revealed that GSK3β phosphorylation was significantly reduced in TKO organoids compared to DKO organoids, suggesting a mechanistic link between KIT expression and downstream signaling pathways critical for early tumor progression. Notably, treatment with the KIT inhibitor imatinib phenocopied the effects of KIT knockout, reinforcing KIT's role as a driver of early colon tumorigenesis. These findings provide critical insights into the molecular mechanisms of early tumorigenesis in APC and TP53 mutant contexts, identifying KIT as a promising therapeutic target for intervention in early-stage colorectal cancer.

#410 The BTK degrader BGB-16673 shows anti-tumor activity in marginal zone lymphoma models.

Alberto J. Arribas, Elisa Civanelli, Camilla Scalise, Luciano Cascione, Andrea Rinaldi, Davide Rossi, Emanuele Zucca, Francesco Bertoni

IOR - Institute of Oncology Research, Bellinzona, Switzerland

Introduction. Targeting the B cell receptor (BCR) signaling with BTK and PI3K inhibitors is efficacious in treating patients with lymphoid tumors, including marginal zone lymphoma (MZL). Unfortunately, resistance occurs, indicating the need for combinations and novel approaches. BGB-16673 is a first-in-class cereblon-mediated BTK degrader currently in phase 1 for refractory/relapsed B cell lymphoma patients, including MZL. Here, we assessed BGB-16673 in MZL models as a single agent to provide the rationale for future trials in MZL patients.
Methods. Effect on cell viability was assessed by MTT assay after 5 days of exposure to increasing concentrations of compounds or DMSO (control) in MZL cell lines and in cell lines with secondary resistance to idelalisib (n.=2), copanlisib (n.=1), ibrutinib (n.=2), and copanlisib/venetoclax. Analyses included apoptosis and cell cycle analysis by flow cytometry, immunoblotting, and RNA-Seq.
Results. Six MZL cell lines (SSK41, Karpas1718, VL51, HC1, HAIRM, and ESKOL) were treated with the BTK degrader BGB-16673 at a concentration of up to 10μM. The BTK degrader was very active in 2 models (SSK41, IC50=0.1 nM; Karpas1718, 1.7 nM). VL51 achieved a maximal reduction in proliferation of 25% at 10 nM. Less than 20% of the reduction was observed in HC1, HAIRM and ESKOL. The activity of BGB-16673 did not differ from the BTK inhibitor zanubrutinib and, accordingly, was limited in cells resistant to ibrutinib (n.=2), idelalisib (n.=2), copanlisib (n.=1), and copanlisib/venetoclax (n.=2). BGB-16673 induced apoptosis and cell cycle arrest in sensitive Karpas1718 and SSK41. It importantly inhibited p-BTK(Tyr223) and decreased total BTK protein levels in all six cell lines. RNA-Seq was performed on Karpas1718 exposed to BGB-16673, zanubrutinib or DMSO. Both molecules down-regulated the BCR-TLR-NF-κB signaling pathway, MYC target genes, and upregulated genes involved in DNA damage. Oxidative phosphorylation, commonly associated with resistance to multiple therapies, was repressed by BGB-16673 but upregulated by zanubrutinib.
Conclusions. Its ability to degrade BTK protein and its antitumor activity position the BTK degrader BGB-16673 as a promising candidate for further development in MZL patients.

#411 Selective degradation of SMARCA2 and dual degradation of SMARCA2 and SMARCA4 has strong antitumor activity in marginal zone lymphoma (MZL).

Alberto J. Arribas[1], Eleonora Cannas[1], Stefano Pileri[2], Davide Rossi[1], Diane Heiser[3], Francesco Bertoni[1]

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland,[2]Division of Diagnostic Haematopathology, European Institute of Oncology, Milan, Italy,[3]Prelude Therapeutics Inc, Wilmington, DE

Background: The SWI/SNF chromatin remodeling complex is crucial for normal B cell development. Its importance is underlined by the occurrence of somatic mutations in genes coding for subunits of the complex, such as ARID1A and SMARCA4, in lymphomas. PRT3789 is a novel bifunctional small molecule containing a SMARCA2-bromodomain binder linked to a VHL E3 ubiquitin ligase-binding moiety, with preclinical activity in SMARCA4-deficient cancer cells but not SMARCA4 wt cells. PRT3789 is currently in phase 1 as a single agent or in combination with docetaxel for patients with solid tumors with loss of SMARCA4. Here, we assessed the antitumor activity of the SMARCA2 degrader PRT3789 and a novel dual SMARCA2/4 degrader in MZL preclinical models, including derivatives with acquired resistance to BTK, PI3K, and BCL2 inhibitors.
Methods: VL51, Karpas1718, SSK41, ESKOL, HC1, HAIRM and derivatives with resistance to targeted agents obtained by long drug exposure (3 from VL51, 1 from Karpas1718 and SSK41) were exposed to increasing concentrations of the compounds or DMSO, as control. Anti-proliferative activity was assessed by MTT assay after 6 days of exposure. Cell cycle and apoptosis assays were performed.
Results: Antitumor activity was seen in the nM range with both compounds. PRT3789 had a median IC50 of 13.27 nM (95%CI, 3.91-41.19). The dual SMARCA2/4 degrader was more active, with a median IC50 of 0.93 nM (95%CI, 0.18-1.92). The activity was maintained in cells with acquired resistance to BTK, PI3K, and BCL2 inhibitors. None of the models had mutations in the coding regions of ARID1A or SMARCA4.Adding individual degraders to the BTK inhibitor ibrutinib, the PI3Kδ inhibitor idelalisib, or to the combination of the PI3K inhibitor copanlisib with the BCL2 inhibitor venetoclax led to additivity/synergism. Adding a low concentration of the degraders (1-10nM) overcame resistance to either copanlisib/venetoclax, ibrutinib, or idelalisib. Adding the dual SMARCA2/4 degrader increased copanlisib/venetoclax efficacy in resistant SSK41 and was strongly synergistic in resistant VL51. Adding PRT3789 enhanced copanlisib/venetoclax and ibrutinib potencies and idelalisib efficacy in the corresponding resistant cells. When we exposed Karpas1718 and SSK41 to the two degraders as single agents or in combination with ibrutinib, we observed that the addition of the compounds improved the cytotoxic activity of ibrutinib in both cell lines by inducing apoptosis.
Conclusions: The single SMARCA2 degrader PRT3789 and the dual SMARCA2/4 degrader showed strong dose-dependent cytotoxic activity in MZL cells, showing activity in the low nM range. Both compounds induced apoptosis as single agents and improved the activity of a BTK inhibitor in the two cell lines tested. Interestingly, the antitumor activity was maintained in MZL cell lines with acquired resistance to BTK, PI3K, and BCL2 inhibitors.

#415 Metformin sensitizes non-small cell lung cancer to CDK4/6 inhibitor treatment by reducing lysosomal trapping.

Yaqi Liu[1], Yalei Wang[1], Ni Zhang[1], Haijuan Xiong[1], Lipan Zhao[1], Jiping Xie[2], Xiaofeng Duan[3], Dongsheng Yue[2], **Shuo Qie**[1]

[1]Department of Pathology, Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China,[2]Department of Lung Cancer, Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China,[3]Department of Minimally Invasive Esophageal Surgery, Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Hyperactivation of cyclin D1-CDK4/6 signaling is correlated with tumour metastasis, and poor prognosis in patients with non-small cell lung cancer (NSCLC), suggesting the therapeutical potential of targeting CDK4/6 to treat NSCLC. Our preliminary data suggest CDK4/6 inhibitors are sequestered in lysosomes in NSCLC cells, a phenomenon termed lysosomal trapping that is correlated with intrinsic resistance. It's promising to search for new compounds that could be co-administered with CDK4/6 inhibitors to reduce lysosomal trapping, hence enhancing the sensitivity of NSCLC cells. Here, we find metformin reduces the activity of lysosomal pathway through genome-wise analyses; in accordance, metformin efficiently reduces lysosomal trapping of CDK4/6 inhibitors in NSCLC cells. Biologically, metformin enhances the suppressing effects of CDK4/6 inhibitors on cell cycle progression, cell proliferation, and colony formation. Mechanistically, metformin suppresses lysosomal trapping by: 1) reducing translocation of TFEB into nuclei that leads to decreased lysosome biogenesis, and 2) disrupting lysosomal acidic environment through reduced V-ATPase activity and decreased interaction between LAMP1/LAMP2 and TMEM175. Clinically, combined treatment with metformin and CDK4/6 inhibitors significantly retards the growth of mouse xenografts and tumour cell organoids. Taken together, our study provides a new mechanistic dimension on utilizing metformin to treat NSCLC by reducing lysosomal trapping, therefore, increasing cellular sensitivity to CDK4/6 inhibitors.

#416 Spatial transcriptomic analysis of breast cancer patients with early and late progression of disease after endocrine and CDK4/6 treatments: deconvoluting the tumor microenvironment.

Sunil S. Badve[1], Shihan Liu[2], Madhubanti Basu[3], Chiao-Wang Sun[3], Shanrun Liu[3], Jian Hu[4], **Yesim Gokmen-Polar**[1]

[1]Pathology and Laboratory Medicine; Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA,[2]Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, GA,[3]Flow Cytometry and Single Cell Core Facility, University of Alabama at Birmingham, Birmingham, AL,[4]Department of Human Genetics, Emory University School of Medicine, Atlanta, GA

Background: Cyclin-dependent kinase inhibitors, CDK4/6i, have been one of the most significant practice-changing advancements for the estrogen receptor positive (ER+) breast cancer therapy in the recent decade. However, no molecular biomarkers are successful in predicting sensitivity/resistance to CDK4/6 inhibitors in clinical trials. It is believed that the heterogeneity of the tumor microenvironment (TME) plays a key role in resistance and metastasis. Deconvolution of TME in CDK4/6 treated samples may provide novel tumor-specific strategies to overcome resistance and reduce mortality in ER+ breast cancer.
Methods: Samples of primary tumors from patients treated for metastatic ER+ breast cancer with CDK4/6 inhibitors were identified from the database of Emory University hospital. Archival FFPE sections were analyzed using 10X CytAssist-enabled Visium Spatial transcriptomics using the UAB Flow Cytometry and Single Cell Core Facility. IRIS and cell type deconvolution analyses were performed to identify TME parameters (immune markers and cell types) associated with time to progression on CDK4/6i.
Results: The analysis was performed on 10 patients who were all treated with Palbociclib and endocrine therapy. The early time to progression (<6 months; n=6) exhibited differential cellular phenotypes (Tumor, Stroma, and Immune Cells) in comparison to late time of progression (>30 months; n=4). The study revealed that both B cells, and CD4+ and CD8+ T cells, are present in significantly higher proportions in the progression of the <6 months group, suggesting a role for immune-related mechanisms in the development of resistance. In addition to lymphocytes, cancer-associated fibroblasts (CAFs) were more prominent in early progression cases suggesting the involvement of tumor microenvironment. Additional confirmatory analyses are on-going.
Conclusion: Deconvolution of the TME using spatial transcriptomics will be a powerful tool for understanding the tumor heterogeneity. Better understanding of the cellular interactions could provide novel strategies to prevent CDK4/6 inhibitor resistance.

#417 Identification of novel inhibitors of the deubiquitinase USP14 for targeting cisplatin-resistant ovarian carcinoma.

C. Corno[1], D. Russo[2], F. Pignotti[3], F. De Giorgi[2], I. Penna[2], F. Saccoliti[2], M. Costantino[1], L. Mirra[1], P. Pettinari[1], N. Perta[3], C. M. Ciniselli[1], P. Pratesi[1], R. Scarpelli[2], F. Bertozzi[2], P. Verderio[1], G. L. Beretta[1], D. Di Marino[3], T. Bandiera[2], **P. Perego**[1];
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy, [2]Istituto Italiano di Tecnologia, Genoa, Italy, [3]Polytechnic University of Marche, Ancona, Italy

Deubiquitinases (DUBs) including the proteasome-associated USP14 have emerged as drug targets in cancer and may contribute to drug resistance. Since DUBs are deregulated in ovarian carcinoma, the disease management may benefit from novel inhibitor development. The aim of this study was to identify novel USP14 inhibitors (USP14i) to test in preclinical ovarian cancer models. Cellular pharmacology approaches were employed to examine USP14 role in cisplatin-sensitive and resistant cells. An assay for compound screening, previously developed by Lee and colleagues (PMID: 23788557), was optimized using Ub-Rho110-G. Molecular docking was used to evaluate the best ligand interaction of putative inhibitors. In 134 specimens representative of the frequency occurrence of the histological ovarian carcinoma subtypes, USP14 mRNA levels were associated with tumor grade. Exogenous over-expression of USP14 increased survival upon cisplatin exposure in cisplatin-resistant IGROV-1/Pt1 cells, but not in cisplatin-sensitive IGROV-1 cells, supporting a role for this DUB in the cisplatin-resistant phenotype. Knockdown of USP14 in IGROV-1/Pt1 cells by small-interfering RNA transfection impaired cell aggressive features such as proliferative, migratory and invasive abilities; sensitization to cisplatin was evident in IGROV-1/Pt1 but not in IGROV-1 cells, suggesting that USP14 acts on resistance-relevant substrates. A diversity set of 1056 small molecules from a library of ca. 11,000 compounds was screened. Setting a relatively low threshold of inhibition of USP14 activity, 5 initial hits were identified. The most interesting compound, referred to as Cpd1, displayed an IC_{50} of 18.4 μM. As Cpd1 represents a novel chemical class of USP14i, a docking protocol targeting the USP domain of USP14 was employed to identify its potential binding modes (BMs). Molecular dynamics simulations were then performed using the best docking results to assess the stability of the identified BMs and evaluate the interactions between Cpd1 and USP14. The simulations revealed excellent stability for two BMs and provided insights into the interaction mechanism. In cells expressing a proteasome sensor vector, Cpd1 displayed proteasome inhibiting activity, also evident in intact cells by active-site direct labeling with HA Ub-vinyl sulfone. The identified hit represents a new chemical class of USP14i and is a starting point for future chemical optimization aiming at identifying more potent compounds. In conclusion, USP14 appears to be a relevant and druggable target in ovarian carcinoma.

#418 Modelling PARP inhibitor resistance using CRISPR/Cas9 genome engineering in a PARP inhibitor-sensitive organoid model identified by organoid panel screening.

Lenno Krenning[1], Dorrith Verstegen[1], Irene Drosou[1], **Marten Hornsveld**[1], Mariusz Madej[1], Hester Bange[1], Peter van Schaik[1], Ludovic Bourre[2], Marrit Putker[1]

[1]Crown Bioscience Netherlands B.V., Leiden, Netherlands,[2]Crown Bioscience, San Diego, CA

Background: Inhibition of poly(ADP-ribose)polymerase (PARP) is synthetically lethal in cells with impaired homologous recombination (HR) DNA repair Hence, PARP-inhibitors (PARPi) are used to treat tumors with disruptive mutations in HR factors. However, both pre-existing and acquired resistance mechanisms limit the clinical success of PARPi, highlighting the need to develop new drugs and/or treatment strategies.

Methods: PARPi efficacy was tested in a CellTiterGlo (CTG)-based OrganoidXplore™ organoid screening panel of 50 organoid models, spanning 7 cancer indications, including models with mutations in HR genes. CRISPR/Cas9-based genome editing was used to knock-out SLFN11 in an originally PARPi-sensitive organoid model, to mimic clinical PARPi resistance. Lastly, isogenic pairs of PARPi sensitive and resistant organoids were used in drug efficacy studies to assess treatment efficacy of multiple therapies.

Results: The OrganoidXplore panel screening captured the heterogeneous response to talazoparib that is also observed in patients. 19 models demonstrated sensitivity to talazoparib (IC_{50}s <1 µM), including models carrying inactivating mutations in HR genes (BRCA1, BRCA2 and RAD51C). However, not all models that carry mutations in HR genes displayed PARPi sensitivity and not all sensitive organoid models carry mutations in known HR genes, stressing the importance of *in vitro* efficacy testing. Inactivating mutations into SLFN11, a well-known clinical biomarker for PARPi and chemotherapy response, was introduced in one of the most PARPi-sensitive models, using CRISPR/Cas9. The isogenic SLFN11 wild-type and knockout pair were used to assess single agent sensitivity to talazoparib, and the chemotherapeutic drugs etoposide, doxorubicin and camptothecin (the parent compound to irinotecan and topotecan), and found that SLFN11 loss causes resistance to all tested agents.

Conclusion: *In vitro* organoid screening successfully identified PARPi-sensitive organoid models containing known and unknown mechanisms of PARPi sensitivity. Further investigation is required to determine the sensitivity of certain models, as they may bear novel biomarkers of PARPi sensitivity, or possess unknown intrinsic resistance mechanisms. Furthermore, CRISPR/Cas-mediated genome editing can be used to establish isogenic organoid pairs that can subsequently be used for single agent as well as combination therapy efficacy testing *in vitro*.

#419 Chromosomal instability and oncogene dosage variations underlying KRAS G12C inhibition therapy resistance in lung cancer.

Dingcheng Gao[1], Yingzhuo Liu[1], Yi Ban[2]

[1]Weill Cornell Medicine, New York, NY,[2]NYU, New York, NY

KRAS G12C inhibitors (G12Ci), including the FDA-approved Sotorasib and Adagrasib, represent a significant advancement in targeted cancer therapies. As their use in non-small cell lung cancer patients expands, addressing the pervasive challenge of drug resistance is critical. Resistance mechanisms can be innate, acquired, or both, often coexisting within complex scenarios. Recent studies have highlighted various resistance mechanisms to G12Ci, such as oncogene amplification, activation of alternative signaling pathways, additional mutations in KRAS or its associated networks, and adaptive processes like epithelial-to-mesenchymal transition. Identifying the primary drivers and predominant mechanisms of resistance is crucial for developing effective countermeasures. To tackle these challenges, we developed Oligo-CALL, an innovative cellular barcoding technology that employs antisense oligonucleotide-inducible CRISPRa for lineage labeling. This technique allows for precise clonal tracking and the retrospective isolation of clones. Using Oligo-CALL, we analyzed tumor clonal heterogeneity and traced the evolution of resistance in lung cancer cells treated with G12Ci. Treatment with Sotorasib resulted in reduced clonal diversity, indicative of strong selective pressure. Similar clonal compositions across different replicates suggest that intrinsic mechanisms significantly contribute to G12Ci resistance. Notably, about 30% of resistant clones showed increased expression of the Kras G12C allele, primarily due to genomic gains, pointing to chromosomal instability (CIN) as a key factor in resistance development. Comprehensive analyses including fluorescent karyotyping, whole-genome, and transcriptome sequencing of isolated tumor clone pairs, revealed extensive genomic complexity and increased heterogeneity under G12Ci treatment. Resistant clones exhibited specific increases in copy number variations, chromosomal structure variations, and additional single nucleotide mutations, further underscoring CIN as a driving force behind G12Ci resistance. Clones that underwent drug treatment displayed higher CIN scores compared to their treatment-naïve counterparts. Intriguingly, cells resistant to G12Ci demonstrated increased sensitivity to PARP inhibitors, suggesting that targeting DNA repair pathways could induce synthetic lethality, offering a potential strategy to overcome resistance in lung cancer cells.

TUMOR BIOLOGY: Human and PDX Models 1

#42 Non-small cell lung cancer (NSCLC) patient derived xenograft organoids (PDX-O) as a model for testing novel therapeutic approaches.

Maia G. Clare, Robert B. Cameron, Nia G. Hammond, Massar Alsamraae, Brandon Faubert

The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL

Despite advances in therapy and early screening, non-small cell lung cancer (NSCLC) remains responsible for the most cancer-related deaths worldwide. There is an urgent need to elucidate the drivers of NSCLC progression to develop better treatment options, but these efforts are often limited by a lack of clinically relevant model systems. To address this need, we developed a series of patient-derived xenografts (PDX) from a clinical study of tumor metabolism. We confirmed that these models retain the genetic, metabolic, and metastatic phenotypes of the patient tumor. Furthermore, we developed patient-derived organoids (PDOs) from these systems by growing and passaging PDX cells in Matrigel droplets with the ThermoFisher OncoPro System. Preliminary validation studies have revealed these organoids have expected morphology, high viability, and maintenance of NSCLC expression markers. We have used these novel model systems to identify heterogeneous metabolic phenotypes and identify targetable vulnerabilities. Specifically, we have used a drug screening approach to combine metabolic inhibitors with standard of care chemotherapies to evaluate combinatorial treatment strategies in NSCLC by cancer cell death. In summary, we have developed a bedside-to-bench approach of identifying patient-relevant tumor biology, in tractable, testable systems, and we use these models to identify novel therapeutic approaches in NSCLC.

[1]Wellcome Sanger Institute, Hinxton, United Kingdom,[2]GSK, Upper Providence, PA, US 19426, PA,[3]GSK, Cambridge, MA, US 02139, MA,[4]Babraham Institute, Babraham Institute, Cambridge, UK., United Kingdom,[5]Candiolo Cancer Institute, 10060 Candiolo, Torino,, Italy,[6]Instituto Superior Tecnico (IST), Universidade de Lisboa, 1049-001 Lisboa, Portugal, United Kingdom

Werner helicase inhibitors (WRNi) are in clinical development for treating patients with microsatellite-unstable (MSI) tumors characterized by defective DNA mismatch repair. Here, we investigate the impact of cancer cell evolutionary adaptation on WRN pharmacological inhibition with implications for understanding drug selectivity and potential clinical resistance. Coupling genome-wide CRISPR screens with WRN gene knockout, no suppressors of WRN dependency were identified, underscoring WRN's essential non-redundant function in MSI cells. Pharmacogenomic screens pinpointed modulators of WRNi sensitivity, including SMARCAL1, linking it to WRN-MSI synthetic lethality. Semi-saturation mutagenesis of WRN and prolonged drug treatment identified on-target WRN mutations driving acquired resistance to multiple WRNi in vitro and in vivo. Specific resistance mutations induce cross-resistance to WRN inhibitors, whereas others preserve sensitivity to alternative WRNi. Our work guides next-generation strategies for targeting MSI cancers, enabling cross-resistance studies to evaluate current and novel WRNi efficacy and informing future clinical trial design.

#421 Targeting WEE1 enhances the antitumor effect of *KRAS* mutated non-small cell lung cancer harboring *TP53* mutations.

K. Fukuda[1], S. Takeuchi[1], S. Sato[1], S. Arai[2], S. Nanjo[3], H. Taniguchi[1], S. Yano[3];
[1]Kanazawa University Cancer Research Institute, Kanazawa-shi, Japan, [2]Kanazawa University Nano Life Science institute, Kanazawa-shi, Japan, [3]Kanazawa University Department of Respiratory Medicine, Faculty of Medicine, Institute of Medical, Pharmaceutical, and Health Sciences, Kanazawa-shi, Japan

While *KRAS*-G12C inhibitors are clinically approved, the efficacy of sotorasib alone remains limited due to challenges such as co-mutations, intrinsic resistance, and acquired resistance. Overcoming these barriers requires innovative strategies to enhance apoptosis in *KRAS*-mutant non-small cell lung cancer (NSCLC).

To identify genes whose loss induces apoptosis in *KRAS*-mutant NSCLC, we performed a CRISPR-knockout screen using a crRNA library targeting 746 protein kinase genes. This high-throughput approach identified WEE1 as a critical kinase whose inhibition significantly enhances apoptosis. Drug screening with a custom library of 432 kinase inhibitors also validated WEE1, CHK1, and CDK inhibitors as effective, with WEE1 emerging as the most potent target, particularly in *TP53*-mutant cells.

WEE1's primary role is to prevent cells with damaged DNA from entering mitosis by regulating the cell cycle through DNA damage checkpoints. Mechanistic analyses revealed that WEE1 inhibition accelerates the G2/M transition and markedly reduces the expression of CHK2 and Rad51, two critical regulators of the DNA damage response (DDR) pathway. This indicates that WEE1 operates upstream of the DDR pathway, playing a crucial role in DNA repair and cell cycle regulation in *KRAS*-mutant NSCLC cells.

To further evaluate therapeutic potential, we investigated the combined effects of sotorasib and WEE1 inhibitors. Combined treatment significantly suppressed cell viability and enhanced c-caspase-3/7 activity in both sotorasib-sensitive and sotorasib-resistant cells. Multidimensional two-drug synergy assays revealed Bliss scores of 11.105 for H358 (sotorasib-sensitive) and 11.226 for H2122 (sotorasib-resistant) cells, indicating a potent synergistic effect across different resistance profiles. In patient-derived xenograft (PDX) models established from a patient with KRAS-G12C mutation and primary resistance to sotorasib, the combination of sotorasib and the WEE1 inhibitor, ZN-c3, resulted in near-complete tumor regression. This effect was consistently observed across four in vivo models, highlighting the translational potential of this combination therapy.

Our findings highlight WEE1 inhibition as a promising therapeutic strategy for *KRAS*-mutant NSCLC with *TP53* mutations. This approach provides a foundation for future clinical investigations to overcome initial resistance to KRAS-G12C inhibitors and improve outcomes for patients with *KRAS*-mutant NSCLC.

#422 Aurora kinase A inhibition overcome adaptive resistance to KRAS G12C inhibitor by replication stress-induced genomic instability and mitotic cell death.

C. Li[1], V. Nangia[2], C. J. Graser[3], J. Chang[4], A. Nimbalkar[1], M. U. Syed[1], M. Vieira[1], Y. Shen[1], S. Altschuler[4], L. Wu[4], F. Michor[3], S. L. Spencer[2], A. N. Hata[1];

[1]Harvard Medical School/Massachusetts General Hospital, Boston, MA, [2]University of Colorado, Boulder, CO, [3]Dana-Farber Cancer Institute, Boston, MA, [4]University of California San Francisco, San Francisco, CA

Cancer cells develop drug-tolerant states, enabling them to evade therapies. In response to KRAS G12C inhibitors (G12Ci), non-small cell lung cancer (NSCLC) cells harboring KRAS mutations sustain a drug-tolerant phenotype through the activation of aurora kinase A (AURKA). AURKA phosphorylates c-Raf, thereby sustaining KRAS signaling under G12Ci treatment. However, the molecular mechanism by which G12Ci treatment induces dependency on AURKA remains poorly understood, and there is currently a lack of molecular biomarkers that predict sensitivity to combined G12Ci and AURKA inhibitor (AURKAi) therapy. We show that the selective AURKAi (LSN3321213) induces mitotic catastrophe and subsequent cell death in NSCLC cells resistant to the G12Ci (LY3499446). Machine learning-based single-cell image tracking revealed that G12Ci-treated cancer cells overcome G1 arrest-induced apoptosis. When treated with AURKAi, these cells undergo mitotic stalling and subsequent mitotic slippage, allowing them to evade cell death. In contrast, simultaneous treatment with both inhibitors results in catastrophic mitotic cell death. G12Ci induces DNA damage as a result of replication stress, leading to increased apoptotic priming during mitosis, which may shift the cellular response towards mitotic catastrophe rather than slippage. Approximately 40% of genetic alterations in NSCLC are associated with replication stress, including MYC amplification. Our findings indicate that MYC amplification is associated with enhanced synergy between G12Ci and AURKAi in NSCLC. Furthermore, induction of CMYC expression in CMYC wild-type cell lines leads to mitotic catastrophe in response to G12Ci + AURKAi, suggesting that CMYC induces replication stress, thereby promoting a dependency on AURKAi. This study reveals a novel relationship between replication stress-induced genomic instability and mitotic defects in KRAS G12C NSCLC and identifies MYC amplification as a potential biomarker for guiding the selection of combined G12Ci and AURKAi therapy in patients with KRAS mutations and MYC amplification.

#423 CDK2 activation mediates response of acute myeloid leukemia to CHK1, ATR and WEE1 inhibitors.

Annapoorna Venkatachalam, Husheng Ding, Nicole Vincelette, Cordelia McGehee, Kevin Peterson, Paula Schneider, Cristina Correia, Hu Li, Scott Kaufmann

Mayo Clinic, Rochester, MN

Background: Replication checkpoint modulators (RCMs), including inhibitors of CHK1, ATR, and WEE1, have been widely studied for their ability to inhibit cell cycle checkpoints and enhance the toxicity of agents that stall replication forks. In preclinical studies each of these inhibitors also demonstrates notable activity as a single agent against relapsed/refractory acute myeloid leukemia (R/R AML). In particular, our prior study (PMID: 33414171) demonstrated that several myeloid cell lines underwent cell death at nanomolar concentrations, with a median IC_{50} of 9 nM irrespective of the *TP53* status. Examination of pathways involved in RCM-induced leukemia cell killing demonstrated that CHK1 inhibition induces CDC25A upregulation accompanied by activation of a death program that involves a CDK2-initiated 10- to 50-fold upregulation of TNFα and downstream engagement of the extrinsic apoptotic pathway. Here we have comprehensively characterized the processes that occur between the interruption of replication checkpoints and leukemic cell death in these sensitive cells versus cells selected for RCM resistance.
Methods: Using the CHK1 inhibitors MK8776 and prexasertib, ATR inhibitors berzosertib and ceralasertib, and WEE1 inhibitor adavosertib as paradigm drugs, we examined signaling in two AML cell lines, U937 and THP.1, that were selected for CHK1 inhibitor resistance, examined cross-resistance patterns, and assessed the biochemical basis for leukemic cell death. Changes in gene expression and signaling induced by RCMs were analyzed in isogenic pairs using RNA sequencing, flow cytometry and immunoblotting.
Results: In contrast to parental U937 and THP.1 cells, CHK1 inhibitor-selected U937 and THP.1 cell exhibited a lack of TNFα mRNA induction and did not undergo cell death in response to multiple CHK1 inhibitors. RNA sequencing of CHK1 inhibitor-selected AML lines revealed an almost complete absence of induction of CDK2-activated genes following prexasertib treatment. Interestingly, unlike solid tumors, AML cell lines that were resistant to CHK1 inhibitors exhibited hypersensitivity to WEE1 or ATR inhibition. Further studies demonstrated that CHK1 inhibitor response was varied in primary AML samples, with 50% of primary AML specimens resistant to CHK1i monotherapy, again without any relationship to *TP53* status. The common features among sensitive vs. resistant leukemias was the successful inhibition of CDK2 phosphorylation and the associated induction of TNFα.
Conclusions: Our findings reveals critical new insights into the factors that influence the response to CHK1 inhibitors in AML. Importantly, we found no evidence of cross-resistance to inhibitors of other replication checkpoint proteins, enabling alternative options.

#424 Chromosomal instability leads to EGFR-TKI refractoriness via cGAS-STING activation in EGFR-mutated non-small cell lung cancer.

K. Yonesaka[1], T. Kurosaki[1], J. Tanizaki[1], H. Kawakami[1], K. Tanaka[1], O. Maenishi[1], S. Takamura[1], K. Sakai[1], Y. Chiba[1], T. Teramura[1], H. Goto[2], E. Otsuka[2], H. Okida[2], M. Funabashi[2], Y. Hashimoto[2], K. Hirotani[3], Y. Kamai[3], T. Kagari[2], K. Nishio[1], K. Kakimi[1], H. Hayashi[1]; [1]Kindai University, Faculty of Medicine, Osaka, Japan, [2]Daiichi Sankyo Co., Ltd., Tokyo, Japan, [3]Daiichi Sankyo Co.; Ltd., Tokyo, Japan

Background: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are a standard therapy for EGFR-mutated non-small cell lung cancer (NSCLC); however, their efficacy is inconsistent. Tumor inflammation is observed in subpopulations of EGFR-mutated NSCLC tumors, which potentially influence the efficacy of anti-cancer agents. Chromosomal instability (CIN) is a trigger of tumor inflammation in malignancies. CIN causes accumulation of cytoplasmic DNA, which subsequently activates cGAS-STING signaling, resulting in tumor inflammation. However, it is unclear whether CIN affects susceptibility to EGFR-TKIs.
Materials and methods: The current study was based on the genomic and transcriptomic analyses of 67 tissue samples obtained from patients with EGFR-mutated NSCLC before EGFR-TKI treatment (n = 32) and after the acquisition of EGFR-TKI resistance (n = 35). RNA-Seq data were analyzed using the CIBERSORTx, GenePattern for ssGSEA, Carcinoma EcoTyper, and Tumor Immune Dysfunction and Exclusion (TIDE). The CIN score was calculated as previously reported (S. L. Carter et al. Nat. Genet. 2006), using the mean of the normalized gene expression data for the 70 genes comprising the signature.
Results: CIN is associated with poor outcomes of EGFR-TKI treatment in patients with EGFR-mutated NSCLC (CIN-low group vs CIN-high group; median PFS 16.7 vs. 11.0 months, HR 3.274, p = 0.005). Transcriptomic analysis revealed that cGAS-STING signaling is enhanced and the innate immune response is prominent in chromosomally unstable cancers. Consistently, EGFR-mutated H1975dnMCAK cells, which frequently underwent chromosomal mis-segregation, demonstrated a refractoriness to EGFR-TKI osimertinib compared to control cells in vitro growth inhibition assay (IC50 values; 6 vs 0.005 μM, respectively). H1975dnMCAK cells showed an activated signaling of cGAS-STING and an increase of its downstream IL-6. Several protumor signaling, including IL-6 and NF-κB, was activated in chromosomally unstable EGFR-mutated NSCLC tumor. Finally, chromosomally unstable H1975dnMCAK cells showed enhanced epithelial-mesenchymal transition (EMT) and blockade of cGAS-STING-TBK1 signaling reversed EMT, and consequently restored susceptibility to EGFR-TKIs both in vitro and in vivo.
Conclusion: These results suggest that CIN may induce EGFR-TKI refractoriness via cGAS-STING activation in EGFR-mutated NSCLC. Furthermore, cGAS-STING-TBK1 inhibitors, in combination with EGFR-TKIs, represent a rational therapeutic strategy that should be evaluated in patients with CIN-induced EGFR-TKI resistant NSCLC.

#425 Overcoming PARP inhibitor resistance in triple-negative breast cancer models through olaparib and RAD51 inhibition with TGF-beta 2 downregulation.

TaeYeong Kim[1], Jeong Dong Lee[2], Won-Ji Ryu[3], Cheol-Hwa Hong[3], Hyun Myoung Yun[3], Yumi Hwang[3], Hyunju Han[3], Gun Min Kim[3], Joohyuk Sohn[3], Min Hwan Kim[3]

[1]Internal medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Biomedical Research Institute, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Recent studies have shown that RAD51 involves resistance to the PARP inhibitor in triple-negative breast cancer (TNBC) cells with *BRCA1* mutations. RAD51 protein has been reported to be recruited to the double-stranded DNA cleavage site to form homo-polymeric filaments that function as templates for double strand break repair. This study aimed to characterize the mechanisms of PARP inhibitor resistance and the therapeutic relevance of RAD51 using a *BRCA1*-mutant triple-negative breast cancer (TNBC) patient-derived xenograft (PDX) model.

Method: We used three PDX models derived from tumor tissues of TNBC patients with *BRCA1* c.5339T>C(L1780P) and c3627 dupA mutation, as well as wild-type *BRCA1* status. We administered Olaparib (PARP inhibitor), RI-1 (RAD51 inhibitor), and their combination for 6 weeks to PDX models for tumor growth assay. After 6 weeks, tumor tissues (n=3, each) was collected and subjected to RNA sequencing and RAD51 immunohistochemistry (IHC) staining. To investigate the role of TGF-β in RAD51-mediated resistance, we assessed TGF-β2 expression levels after RAD51 inhibitor treatment. We also established acquired Olaparib resistance model by chronic drug treatment in TNBC cell lines with mutant BRCA1 (L1780P) stable transfection. Combination treatment of RI-1 and LY2109761 (TGF-β receptor inhibitor) was performed in these Olaparib-resistant TNBC cells.

Results: In the three TNBC PDX models, *BRCA1* c.5339T>C model showed sensitivity to Olaparib treatment, while *BRCA1* wild-type and *BRCA1* L1780P-mutant PDX models showed resistance to Olaparib treatment. Notably, combination treatment with RI-1 and Olaparib synergistically inhibited growth of *BRCA1* wild-type and L1780P mutant PDX model. In the IHC assay of tumor tissues, we observed that RAD51 expression was downregulated in tumors after PARP and RAD51 inhibitor combination treatment. RNA sequencing analysis of tumors identified TGFB2 as downregulated in the RAD51 inhibitor-treated tumors, suggesting TGF-β2 suppression may involves overcoming Olaparib resistance mechanisms. We subsequently found RI-1 and LY2109761 combination treatment induces upregulation of P53 protein expression and decreased RAD51 expression in BRCA1-mutant TNBC cells. RI-1 and LY2109761 combination treatment also decreased cell growth Olaparib-resistant TNBC cells.

Conclusion: RAD51 and PARP combinatory inhibition effectively overcomes Olaparib resistance in BRCA1-mutatnt and wild-type TNBC PDX models. RAD51 inhibition decreased expression of TGF-β2 in TNBC tumors, suggesting targeting RAD51 and TGF-β2 may be a potential therapeutic strategy to overcome Olaparib resistance in triple-negative breast cancer.

#426 Dual CDK4/6 and CDK7 inhibition: A synergistic strategy to overcome resistance and enhance anti-tumor immunity in breast cancer.

Sungsoo Kim, Eugene Son, Haram Park, Minah Kim, **Hee Won Yang**

Columbia University Irving Medical Center, New York, NY

Cyclin-dependent kinase 4/6 inhibitors (CDK4/6i) have significantly improved outcomes for patients with hormone receptor-positive (HR^+) breast cancer. However, resistance to CDK4/6i limits their long-term efficacy, and their monotherapy has shown limited impact in triple-negative breast cancer (TNBC). Here, we present a novel therapeutic strategy combining CDK4/6i and CDK7 inhibitors (CDK7i) to address these limitations. Using a comprehensive suite of approaches—including live-cell imaging, RNA sequencing, and preclinical tumor models—we demonstrate the efficacy of this combination in overcoming drug resistance and enhancing anti-tumor immunity.Kinetic analyses revealed that CDK7i primarily suppresses RNA polymerase II-mediated transcription, a key driver of CDK4/6i resistance. Mechanistically, CDK7i prevents E2F activity amplification following retinoblastoma protein (Rb) degradation, a critical step in the development of resistance. Consequently, combining CDK4/6i and CDK7i synergistically suppresses E2F-driven transcriptional programs, resulting in robust inhibition of tumor proliferation in both HR^+ and TNBC models.In vivo studies using syngeneic and patient-derived xenograft organoid models showed that this combination therapy not only suppresses tumor growth but also reprograms the tumor microenvironment (TME). RNA sequencing of treated tumors revealed upregulation of immune response pathways, including IFN-γ and TNF-α signaling, and increased expression of cytokines such as Cxcl9, Cxcl10, and Ciita. Flow cytometry and immunohistochemistry further confirmed enhanced infiltration of $CD8^+$ T cells and natural killer cells into the TME, accompanied by a reduction in immunosuppressive macrophages. These changes collectively amplify anti-tumor immunity, providing an additional therapeutic benefit.This dual CDK4/6 and CDK7 inhibition approach represents a promising first-line strategy for TNBC and a second-line option for HR+ breast cancer resistant to CDK4/6i and endocrine therapy. These findings not only provide a strong rationale for advancing CDK7i into clinical trials but also highlight the therapeutic potential of targeting transcriptional regulation to overcome resistance in breast cancer.

#427 Genome-wide CRISPR knockout screen identifies novel determinant of PARP inhibitor resistance in small-cell lung cancer.

Jiaqi Xiong[1], Mansi Aparnathi[1], Tony Yu[1], Lifang Song[1], Jonathan St-Germain[1], Brian Raught[1], Troy Ketela[1], Sami Ul Haq[2], Vivek Philip[1], Benjamin Lok[1]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]Schulich School of Medicine & Dentistry, London, ON, Canada

Introduction: Small cell lung cancer (SCLC) is an aggressive tumor with poor prognosis. The standard-of-care treatment (chemotherapy +/- radiation) has seen little advancement over three decades, apart from the addition of immunotherapy for extensive-stage patients. PARP inhibitors (PARPi) have emerged as a promising therapeutic option in SCLC; however, their clinical application remains challenging due to variable patient responses. The biological determinants of PARPi response in SCLC are not fully understood. This study aims to identify novel biological factors that predict PARPi response in SCLC.

Methods: A genome-wide CRISPR-Cas9 knockout (KO) screen was conducted in the SBC-5 SCLC cell line using the Toronto Knockout v1 (TKOv1) library with PARPi olaparib (5 μM) as the selection pressure. Cells were collected on days 25 and 35 for genomic sequencing to determine sgRNA enrichment. Isogenic *FBXO11* and *LacZ* (negative control) KO cell lines were generated, and cell viability was assessed after 7-day PARPi (olaparib, talazoparib) treatment. Immunofluorescence staining of γH2AX foci was performed in isogenic *FBXO11* KO SBC-5 cells after 24hr talazoparib (100 nM) treatment. Proximity-dependent biotin labeling combined with LC-MS protein identification (BioID) was performed in FlpIn HEK293 cells expressing BirA*-FBXO11 fusion protein. KEGG pathway analysis of putative interactors was performed to examine enrichment of relevant biological pathways. Protein-protein interaction was assessed using proximity ligation assays (PLA). LC-MS-based global proteomic profiling was conducted in isogenic *FBXO11* KO SBC-5 cells (+/- olaparib), and gene ontology (GO) analysis was performed to identify differentially regulated pathways.

Results: The genome-wide CRISPR-Cas9 KO screen revealed that *FBXO11* loss provides a survival advantage under stringent PARPi selection. *FBXO11* KO resulted in a 2- to 20-fold increase in the IC50 of olaparib and talazoparib in three SCLC cell lines (NCI-H196, SBC-5, NCI-H69). *FBXO11* KO cells exhibited fewer γH2AX foci after PARPi treatment compared to LacZ KO ($p < 0.0001$). BioID of FBXO11 identified putative protein interactors from a pre-mRNA splicing complex (XAB2, ISY1, AQR). PLA showed a significantly reduced interaction between XAB2 and AQR in *FBXO11* KO cells ($p < 0.0001$), suggesting that FBXO11 affects pre-mRNA splicing complex formation. GO analysis of global proteomics showed an upregulation of pathways involved in apoptosis, mRNA splicing, and spliceosomal complex assembly after olaparib treatment exclusively in *LacZ* KO cells, but not *FBXO11* KO cells, which may explain the differential response to PARPi.

Conclusion: We identified a novel gene, *FBXO11*, whose loss results in PARPi resistance in SCLC cell lines. BioID of FBXO11 and global proteomic profiling suggests that pre-mRNA splicing may play a role in mediating drug resistance.

#428 Low cellular pH promotes survival in CDK4/6 inhibitor resistant ER+ breast cancer.

Erin R. Scheidemann, **Ayesha N. Shajahan-Haq**

Oncology, Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Cyclin dependent kinase 4 and 6 inhibitors (CDK4/6i) are part of standard of care therapy in combination with antiestrogens for the treatment of metastatic estrogen receptor positive (ER+) breast cancer. However, resistance to CDK4/6i is prevalent and advanced metastatic ER+ breast cancer remains incurable. Beside inhibiting the cell cycle, CDK4/6i are known to induce accumulation of lysosomes in sensitive cells but the role of lysosomes in CDK4/6i resistance remains elusive. Recently, we have shown that CDK4/6i resistant breast cancer cells gain metastatic potential relative to sensitive cells and this is potentially due to deregulated lysosomes. We have shown that all three CDK4/6i induce rapid cellular acidification in sensitive cells, which suggests a role of cellular pH in CDK4/6i-mediated cell death. Particularly, in abemaciclib resistant cells, intracellular pH is lower (pH=6.9) than that of sensitive cells (pH=7.4). Therefore, we hypothesize that a lower pH in CDK4/6i resistant cells promotes survival and this pathway can be leveraged to target resistance. Interestingly, protein levels of carbonic anhydrase IX (CA9), an important regulator of cellular pH, are significantly elevated in resistant cells. Increased CA9 levels correlate with impaired overall survival in breast and other cancers. Small molecule inhibitor of CA9, S4 or the clinical-grade drug SLC-0111, inhibits growth and invasive potential in resistant cells when combined with CDK4/6i plus an antiestrogen. CDK4/6-induced cellular acidity correlated with increased levels of hypoxia-inducible factor 2-alpha (HIF2α) protein in sensitive cells. Moreover, basal HIF2α was increased in resistant cells compared with sensitive cells. Furthermore, knockdown of HIF2α reduces CA9 protein expression and inhibits proliferation in resistant cells. Thus, our study highlights the role of the modulation of pH homeostasis as a mechanism for CDK4/6i resistant breast cancer and identifies CA9 and HIF2α as novel targets in treating advanced ER+ breast cancer.

#429 Targeting translesion synthesis to sensitize ovarian cancer cells to PARP inhibitor treatment.

Na Li, Qianyun Ge, Yajing Yang, Linzhou Wang, Xiaoli Zhang, Junran Zhang, Zaibo Li, Floor Backes, Qi-En Wang

The Ohio State University, Columbus, OH

BRCA-deficient tumor cells, characterized by defective homologous recombination (HR) repair, show high sensitivity to poly (ADP-ribose) polymerase inhibitors (PARPi). The mechanism is that PARPi blocks PARP and traps them at DNA damage sites (PARP-DNA complex), inducing replication fork stalling, leading to cancer cell death with BRCA mutation due to the accumulation of unrepaired DNA double-strand breaks. At present, PARP inhibitors have been widely used to treat ovarian cancer patients with deficient HR. However, like other chemotherapy agents, many patients acquire PARPi resistance. Replication fork protection is a key mechanism driving resistance to PARPi. Translesion synthesis (TLS) is an error-prone DNA damage tolerance pathway that can help cancer cells bypass DNA lesions and rescue replication fork stalling with Y-family DNA polymerases. Thus, we hypothesized that enhanced TLS enables BRCA-mutated ovarian cancer cells to overcome PARPi treatment via bypassing PARP-DNA complexes, and rescuing stalled replication forks, eventually leading to BRCA secondary mutations and partial restoration of HR function. To test this hypothesis, we first confirmed that PARPi can promote TLS activity by increasing the expression of monoubiquitinated PCNA in BRCA-mutated ovarian cancer cells. In addition, replication fork stalling has been observed following treatment with PARP inhibitors, as demonstrated by DNA fiber assays. Blocking TLS by knocking down REV1 exacerbates replication fork stalling, highlighting the interplay between PARPi treatment and TLS pathways. To further investigate the role of TLS polymerases, we individually knocked down TLS polymerases and evaluated their effects. Knocking down POLH (encode Polη), exacerbated Olaparib-induced replication fork stalling, irrespective of BRCA status. Functional analyses revealed that POLH knockdown sensitized BRCA-mutated cells to Olaparib but had no significant effect on BRCA wild-type cells. Next, we utilized a newly developed ChIP-based assay to assess TLS efficiency. We demonstrated that TLS inhibition through knocking down POLH or using a TLS inhibitor JH-RE-06 impairs DNA replication across Olaparib-induced PARP1-DNA complexes. Furthermore, JH-RE-06 sensitized HR-deficient ovarian cancer cell lines and patient-derived organoids to Olaparib in vitro. It also enhanced the efficacy of Olaparib in vivo, both in NSG mice bearing human BRCA1-mutated ovarian cancer cells and C57BL/6 mice with murine ovarian cancer cells harboring $P53^{-/-}$ and $BRCA1^{-/-}$ genotypes. In summary, our findings reveal that TLS facilitates replication fork recovery by enabling DNA replication across PARPi-induced PARP-DNA complexes, with Polη playing a key role. Importantly, JH-RE-06 represents a promising strategy to enhance the therapeutic sensitivity of HR-deficient ovarian cancer cells to PARP inhibitors like Olaparib.

#43 Establishment and characterization of prostate adenocarcinoma XPDX models from naïve and pretreated patients.

Johnnie Flores[1], Alyssa Simonson[1], Anna Stackpole[1], Jennifer Garcia[1], Shaquille Johnson[1], Pedro Cesenes[1], Mia Lopez[1], Peter Forofontov[1], Lisa Gonzales[1], Garrett Mercer[1], Amarissa Rojas[1], Nehal Lakhani[2], Emiliano Calvo[3], Andrew Cunningham[1], Michael J. Wick[1]

[1]XenoSTART, San Antonio, TX,[2]START Midwest, Grand Rapids, MI,[3]START Madrid, Madrid, Spain

Background: Preclinical models of prostate adenocarcinoma (PAC) are challenging to develop and maintain. We previously reported (AACR2022/ENA2023) the successful establishment and characterization of four parental and three conditioned prostate adenocarcinoma models in intact immunodeficient male mice. Using this experience, we have expanded our platform with six additional PAC models designated ST6084, ST6838, ST7482, ST7695, STF1159 and STM344. These models were characterized for receptor expression, genomic alterations, and in vivo drug sensitivity to relevant therapies.
Methods: XPDX models representing prostate cancer were established from primary (ST6084, ST6838, ST7695, STF1159) or metastatic (ST7482, STM344) samples implanted into intact CB-17 SCID mice. Resulting models were passaged serially and further developed in both intact and castrated mice until growth stabilization. Resulting models were characterized using genomic analysis, including WES and RNA_{seq}, receptor expression, and in vivo drug sensitivity studies. For in vivo studies, docetaxel, abiraterone and enzalutamide were evaluated at standard treatment regimens. Study endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a %T/C of ≤ 20% versus control was considered sensitive. Tumor regression (%T/C<0%) versus Day 0 tumor volume was also reported.
Results: Most models lacked AR or PSMA staining but ST6838 and STM344 were positive for AR-V7. Genomic characterization identified KDM6A loss in ST7482, a model from a patient post-apalutamide. An ATM aberration was present in both ST7482 and STM344, the latter derived from a patient post-chemo and targeted therapies including a five-month response on an ATR inhibitor. No tested models were sensitive to abiraterone or enzalutamide (%T/C>20%) and only ST7482 was sensitive to docetaxel.
Conclusion: We have established and characterized an expanded panel of PAC XPDX models. These models can be utilized as a valuable tool in better understanding prostate cancer and in developing novel therapies for drug-resistant patients.

#430 Therapeutic benefits of maintaining CDK4/6 inhibitors and incorporating CDK2 inhibitors beyond progression in breast cancer.

Jessica Armand, Sungsoo Kim, Kibum Kim, Eugene Son, Minah Kim, Hee Won Yang

Pathology and Cell Biology, Columbia University Irving Medical Center, New York City, NY

The combination of CDK4/6 inhibitors (CDK4/6i) and endocrine therapy has revolutionized treatment for hormone receptor-positive (HR+) metastatic breast cancer. However, the emergence of resistance in most patients often leads to treatment discontinuation with no consensus on effective second-line therapies. The therapeutic benefits of maintaining CDK4/6i or incorporating CDK2 inhibitors (CDK2i) after disease progression remain unclear. Here, we demonstrate that sustained CDK4/6i therapy, either alone or combined with CDK2i, significantly suppresses the growth of drug-resistant HR+ breast cancer. Continued CDK4/6i treatment induces a noncanonical pathway for retinoblastoma protein (Rb) inactivation via post-translational degradation, resulting in diminished E2F activity and delayed G1 progression. Importantly, our data highlight that CDK2i should be combined with CDK4/6i to effectively suppress CDK2 activity and overcome resistance. We also identify cyclin E overexpression as a key driver of resistance to CDK4/6 and CDK2 inhibition. These findings provide crucial insights into overcoming resistance in HR+ breast cancer, supporting the continued use of CDK4/6i and the strategic incorporation of CDK2i to improve therapeutic outcomes.

#431 Novel WRN drug resistant CDX models.

Haiting Dai, Tiejun Bing, Huayi Qu, Huawei Pan, **Wen-Jen Yu**

ICE Bioscience INC, Beijing, China

Microsatellite Instability (MSI) is a condition characterized by the presence of mutations in microsatellite regions of DNA. This can lead to the accumulation of mutations in microsatellite regions, resulting in genomic instability and happened in various cancer types. Werner helicase (WRN) plays an important role in highly MSI (MSI-H) cancer cells and cause synthetic lethality when WRN was inhibited or knockout. Few WRN inhibitor like HRO761 and VVD-214 were revealed effectively killing the MSI-H cancer cells such as human colorectal cell lines HCT116 and SW48. In this study, to face the new unmet need that WRN inhibitors anti-cancer drugs may occurred, a WRN inhibitor resistant cell line against HRO761 and VVD-214 were established through the combination drug tolerance in vivo and in vitro was established. The drug resistant tumor tissues were collected after the in vivo drug resistance appeared as regrowth of tumors under 20 mg/kg HRO761 and 5 mg/kg VVD-214 treatment and dissected for primary cell culture to get the drug resistant cell line by escalating drug concentrations in vitro. The WRN inhibitors resistant cell lines were genotype and phenotype checked by STR and IC50 of cell growth when reached the drug resistant index more than 5 times of that of parental cells and indicated that different WRN inhibitors resistant HCT116 cell lines were successfully established and helpful for the discovery of anti-cancer drugs targeted on resistant to WRN inhibitors.

#432 Evolution of drug tolerance and resistance to endocrine therapy and CDK4/6 inhibitors in ER+ breast cancer.

Justin Rendleman[1], Matthew Pressler[1], Joanna Yeung[1], Lauren Anderson[1], Arnold Ou[1], Junyue Cao[1], Andrew Koff[2], Sarat Chandarlapaty[2], Viviana Risca[1]

[1]The Rockefeller University, New York, NY,[2]Memorial Sloan Kettering Cancer Center, New York, NY

Inhibitors of CDK4/6 kinases provide a significant clinical benefit among estrogen receptor positive (ER+) breast cancer patients with advanced disease when combined with endocrine therapies (e.g., fulvestrant, letrozole). However, drug resistance to this combination therapy arises in many individuals. Some drivers have been defined that are responsible for a fraction of refractory disease, but for >50% of cases, the underlying cause of disease progression remains unknown. While inducing cell death in cancer cells is an ideal drug outcome, growing evidence indicates CDK4/6 inhibitors (CDK4/6i) can contribute to disease management by forcing cancer cells into permanent cell cycle arrest through a process known as geroconversion. We hypothesize that acquired resistance can arise from cells that are drug-tolerant and fail to complete geroconverstion, instead only entering a state of quiescence for a limited time before returning to proliferation.

Here we investigate the molecular networks and their regulators that are responsible for differential outcomes in combined hormone and CDK4/6i treatment, and the synergistic effects of these drugs on geroconversion in ER+ breast cancer models. Employing a combination of bulk and single-cell RNA- and ATAC-seq, we have generated temporal maps of the transcriptional evolution of underlying regulator networks that cultivate a resistant state in MCF7 ER+ breast cancer cells. We validated our top findings in patient tumor samples and propose targets for novel therapeutic approaches.

Our phenotypic and bulk sequencing assays displayed synergistic effects between drugs, resulting in a more rapid repression of cell cycle genes in combined therapy during early timepoints (<5 day), as well as a more durable suppression of S-phase entry at later time points (>15 days). By applying sci-RNA-seq we identified gene expression patterns that are specific to these drug-tolerant subpopulations, which we have validated at the protein level. Interestingly, we found that endocrine therapy imposed a distinct chromatin and transcriptional landscape detectable as early as 9 days of treatment which persisted through 40 days of treatment. Activated genes included cell surface proteins that could distinguish this drug-tolerant population and demarcate the bottleneck period between initial response and inevitable progression.

Our evidence suggests that while endocrine therapy alone can induce both apoptosis and senescence, the additional layer of proliferative suppression afforded by CDK4/6i further delays the evolution and expansion of endocrine resistant cells that emerge. Future directions aim to validate our putative biomarkers of drug resistance using 3D patient-derived organoid models, *in vivo* xenografts, and additional patient clinical data to assess the robustness of the drug resistance signatures we have identified.

#433 Clarification and overcoming the resistance mechanisms to inotuzumab ozogamicin and ponatinib in B-ALL.

N. Ida[1], M. Okura[2], N. Hosono[1], T. Yamauchi[1];
[1]University of Fukui Hospital, Fukui, Japan, [2]Dokkyo Medical University Saitama Medical Center, Saitama, Japan

[Introduction] Recently, the prognosis of B-cell acute lymphoblastic leukemia (B-ALL) has significantly improved with the appearance of novel drugs, including inotuzumab ozogamicin (IO) and ponatinib. IO is an anti-CD22 antibody conjugated with calicheamicin and highly effective for B-ALL. Ponatinib, a third-generation tyrosine kinase inhibitor for Philadelphia chromosome (Ph)-positive ALL. The acquisition of resistance to these latest drugs is a major clinical hurdle. In the previous study, we showed that the addition of polyadenosine diphosphate-ribose polymerase (PARP) inhibitors synergistically enhanced the cytotoxicity of IO via the inhibition of the leukemic DNA damage repair mechanism. The present research attempted to clarify and overcome the resistance mechanism to IO and ponatinib using newly established drug-resistant cell lines.
[Method] Gene expression were analyzed using DNA microarray. Protein expression was analyzed by western blotting. Quantitation of DNA damage and repair was measured using the alkaline comet assay. Additional aberrations of Ph were examined by G-banding and FISH analysis. *BCR::ABL* point mutations were analyzed by direct sequencing.
[Results] We successfully established 6 IO-resistant cell lines that were 60-fold more resistant to IO than the parental cell line. All 6 cell lines were also resistant to apoptosis. In resistant cells, DNA microarray showed that *ABCB1* gene encoding p-gp, drug efflux pump, was overexpressed, and western blotting revealed the overexpression of p-gp protein. The combination of IO and a p-gp inhibitor, PSC-833, decreased the IC_{50} values of IO by 90% and increased apoptosis. Alkaline comet assay revealed increased DNA damage in the combination. When combined with IO and PARP inhibitors, olaparib and talazoparib, increased the IO sensitivity of resistant cell lines by 50 to 90%. The triple combination of p-gp inhibitor, PARP inhibitors and IO improved the IO sensitivity to the same level as the parental cell line. The alkaline comet assay indicated DNA damage observed at 1 hour after administration of IO and restored after 6 hours. However, in the triple combination, DNA damage that was observed 1 hour more increased after 6 hours. In the ponatinib-resistant cell line, the IC_{50} value of the ponatinib was 100-fold higher than in the parental cell line. No additional chromosomal abnormalities other than Ph were detected in G-banding in the ponatinib-resistant cell line. The *BCR::ABL* breakpoint was the same , and no point mutations were detected in parental and resistant cell lines. DNA microarray showed that *JAK2* expression was upregulated in resistant cell line.
[Conclusion] The present study indicated that inhibition of drug efflux and DNA damage repair overcame the resistance to IO in Ph-negative B-ALL. Moreover, *JAK2* might be the therapeutic target to overcome the resistance to ponatinib in Ph-positive B-ALL.

#434 Synergistic suppression of gemcitabine resistance in PDAC by targeting STAT3 and ABCB11.

Tai-Lin Chen[1], Chi-Wei Chen[2]

[1]Department of Post-Baccalaureate Medicine, National Chung Hsing University, Taichung, Taiwan,[2]Department of Biology, Appalachian State University, Boone, NC

Gemcitabine resistance is a critical challenge in treating pancreatic ductal adenocarcinoma (PDAC). STAT3 is implicated in tumor progression and chemotherapy resistance. This study investigates the role of STAT3 in gemcitabine-resistant PDAC and evaluates the potential of a STAT3 inhibitor (napabucasin) to enhance gemcitabine efficacy. Gemcitabine-resistant PDAC cells were developed via long-term in vitro culture and in vivo xenograft models. The expression of STAT3 and its phosphorylated form (p-STAT3) was analyzed in resistant cells. Cytotoxicity assays evaluated the sensitivity of resistant and non-resistant PDAC cells to gemcitabine, napabucasin, and an EGFR inhibitor (gefitinib). RNA sequencing revealed upregulation of ABCB11, correlating with p-STAT3 levels, suggesting STAT3-driven multidrug resistance. Combination therapies were assessed in vitro using colony formation assays and in vivo using a PDAC xenograft mouse model treated with gemcitabine, napabucasin, and/or the ABCB11 inhibitor glibenclamide. Gemcitabine-resistant PDAC cells (BxPC3-GR and BxPC3-T1-GR) exhibited elevated STAT3 and p-STAT3 levels. Cytotoxicity assays demonstrated resistance to gemcitabine and gefitinib but increased sensitivity to napabucasin. Combination treatment with gemcitabine and napabucasin significantly suppressed colony formation in vitro. In vivo, combining gemcitabine with napabucasin and glibenclamide led to significant tumor growth inhibition in gemcitabine-resistant PDAC xenografts. The combination of gemcitabine, napabucasin, and glibenclamide synergistically suppresses tumor growth in resistant models, highlighting a potential therapeutic strategy to overcome gemcitabine resistance. Further studies are warranted to optimize combination therapies for clinical application.

#435 JAK/STAT1-interferon-ISGylation networks in breast cancer resistance to inhibitors of FOXM1 and CDK4/6.

Benita S. Katzenellenbogen[1], Yvonne Ziegler[1], Sandeep Kumar[1], Blake N. Plotner[1], Carlos M. Saeh[1], Grace O. Pento[1], Sung Hoon Kim[1], Rachel Schiff[2], John A. Katzenellenbogen[1]

[1]University of Illinois at Urbana-Champaign, Urbana, IL,[2]Baylor College of Medicine, Houston, TX

Resistance to targeted therapies often develops in advanced estrogen receptor (ER)-positive breast cancer, but the mechanisms underlying this resistance are still not fully known. We show that ER-positive FOXM1 inhibitor resistant cells and CDK4/6 inhibitor (Palbociclib and Abemaciclib) resistant cells all exhibit an increased JAK/STAT1-interferon responsive gene and protein signaling network with elevated interferon stimulated gene15 (ISG15). ISG15 protein is present as high intracellular free ISG15 and also as increased ISGylated protein conjugates that can be markedly reduced by treatment of resistant cells with the JAK1/2 inhibitor ruxolitinib. Likewise, resistant cells contain increased levels of ubiquitin-like conjugating enzymes HERC5 and HERC6 and ubiquitin ligases (e.g., UBE2L6) known to facilitate the transfer of ISG15 onto cell proteins. Notably, elevated ISG15 and elevated HERC5 and HERC6 are all associated with poorer relapse-free and overall patient survival. Breast cancer cells resistant to the CDK4/6 inhibitors Palbo or Abema, which are often used in first line treatment of patients with HR-positive breast cancer, and cells resistant to FOXM1 inhibitor show some similarities in the ISGylated protein patterns. However, there are also some differences observed in these patterns between Palbo and Abema and FOXM1 inhibitor (NB73) resistant cells. Upregulation of this STAT1-interferon-ISGylation network in ER-positive breast cancers displaying resistance to three different drugs suggests it may be centrally involved in supporting the drug-resistant state. Importantly, Palbo and Abema resistant cells and organoids can still be effectively growth inhibited by FOXM1 inhibitor NB73, and likewise, FOXM1 inhibitor resistant cells and organoids are sensitive to suppression of viability by Palbo or Abema. This suggests that sequential treatment approaches might be effective in overcoming resistance and enabling the suppression of these drug-resistant cancers.(Supported by Breast Cancer Research Foundation grant BCRF-083 and NIH R01CA220284 to BSK and BCRF grant BCRF-145 to RS)

#436 NRF2 activity impairs the efficacy of sotorasib in human KRAS-mutant lung adenocarcinoma.

T. Hess[1], Hansa Joshi[1], Yaas Azmoudeh[2], Gord Zhu[3], Francis Spitz[1], David Shersher[1], Samera Hamad[2]

[1]Surgery, Cooper Medical School of Rowan University (CMSRU), Camden, NJ,[2]Cooper Medical School of Rowan University (CMSRU), Camden, NJ,[3]Pathology, Cooper Medical School of Rowan University (CMSRU), Camden, NJ

Lung cancer continues to be the leading cause of cancer-related mortality in the United States, with lung adenocarcinoma (LUAD) representing the most common histological subtype. Clinical evidence has demonstrated that tumor plasticity—, the transformation between lung cancer subtypes—, plays a crucial role in the development of resistance to chemotherapy and targeted therapies. Hyperactivation of NRF2, a transcription factor that normally protects cells from oxidative damage, is implicated in the resistance to various types of therapies including chemotherapies and targeted therapies. This study aimed to identify if NRF2 induces the resistance to carboplatin, and/or to sotorasib, a targeted therapy of KRAS-mutant LUAD, through histological transformation. We used KRAS-mutant human lung adenocarcinoma cell lines, high $NRF2^{WT}$-A549, and H358 with $NRF2^{E79Q}$ activating mutation. Our results show that treatment of high-NRF2 LUAD cell lines with sotorasib induces the transformation to neuroendocrine tumors (NE) and augments the NRF2 levels in vitro. Further, this transformation increased the growth and invasion of the transformed tumor cells. Interestingly, the low-NRF2 version of H358 (without $NRF2^{E79Q}$ activating mutation) did not have these changes. Further, LUAD cell lines had good responses to carboplatin with and without NRF2 activation. This NRF2-treatment interaction study shows that carboplatin might be a good option in NRF2-high LUAD with KRAS mutation and that targeting NRF2 in $NRF2^{high}$ LUAD tumors could enhance the efficacy of sotorasib and prevent the transformation after treatment. Current studies in our lab are testing these changes in vivo using immunodeficient mice.

#44 PDX-derived cellular models for pharmacological screening and functional studies.

Lea Sinayen[1], Enora Le Ven[1], Emilie Indersie[1], Ester Morgado[2], Laurent Pouyet[2], Francois Romagne[2], **Olivier Deas**[1]

[1]XenTech, Evry-Courcouronnes, France,[2]MImAbs, Marseille, France

Despite substantial advancements in understanding the biology and genetics of cancer, the development of effective therapies is hindered by the lack of adequate experimental models that replicate the genetic diversity of this disease. Patient-derived xenografts (PDXs) have become the gold standard in preclinical oncology for the evaluation of new anticancer drug candidates. The faithful reproduction of patients' cancer features, and the ability to generate models that recapitulate the genetic heterogeneity of the patient population, confer PDXs with a critical added value in the preclinical field. Over the past 15 years, we have generated and characterized a collection of over 200 PDXs from various solid tumors that accurately reproduce the histological and molecular heterogeneity of original tumors. This panel has enabled the preclinical validation of several anticancer drugs that are now used in the clinic. Although an indispensable tool for conducting preclinical studies, the use of in vivo PDX systems for large-scale screening during early drug discovery is restricted by ethical, economic, and throughput limitations that limit the number of drug candidates tested. To address this challenge, we have developed a panel of PDX-derived cells (PDXDCs) that we propose as a time- and cost-effective, medium-throughput screening tool to profile the anticancer activity of early test compounds. To date, over 50 PDXDCs from various indications such as breast, prostate, lung, and several others have been generated and tested for their in vitro response to standard of care, targeted anticancer agents, and immunotherapies, used as monotherapy or in combination to study potential synergistic effects. PDXDCs were obtained from dissociated PDX tumors cultured under various media and matrix conditions. They were characterized by comparison with the parental PDX through short tandem repeat (STR) profiling prior to establishing a master bank. PDXDC RNA and exome sequencing data faithfully match the parental PDX features, and by modulating experimental parameters, such as 2D or 3D growth conditions, drug exposure duration, and endpoint readouts, we could phenocopy in vitro the corresponding PDXs' sensitivities to drug candidates. These results support our PDXDCs panel as a valuable in vitro tool for drug screening to help selecting drug candidates for further in vivo validation, as well as the most appropriate in vivo PDX models to use.

#440 Dual epigenetic targeting of hepatocellular carcinoma.

Kyounghyun Kim, Ponmari Guruvaiya

University of Arkansas for Medical Sciences, Little Rock, AR

Despite advancements in medical treatment, hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality globally. Combination therapies involving multiple targeted agents are increasingly recognized as effective strategies to improve treatment outcomes and overcome the limitations of single-agent therapies. While single-target approaches have shown specificity and potency, they face challenges such as drug resistance, limited pharmacokinetics, and patient adherence. Given the complex nature of HCC, targeting multiple molecular pathways through combination strategies holds promise for more robust therapeutic outcomes. Epigenetic therapies offer a distinct advantage in treating HCC by targeting reversible modifications to reprogram aberrant gene expression and address tumor heterogeneity. These therapies can enhance the efficacy of existing treatments, overcome resistance mechanisms, selectively target cancer cells, and modulate the immune microenvironment, making them a promising avenue for improving HCC outcomes.
EZH2 (Enhancer of Zeste Homolog 2) is a histone methyltransferase that catalyzes the trimethylation of histone H3 at lysine 27 (H3K27me3), leading to the silencing of tumor suppressor genes and the promotion of stem cell-like features. LSD1 (Lysine-specific demethylase 1) is a histone demethylase that modulates gene expression to promote tumor progression, cancer stemness, drug resistance, and epithelial-mesenchymal transition (EMT). These epigenetic enzymes form a corepressor complex to inhibit tumor suppressor gene expression. Both EZH2 and LSD1 are overexpressed in HCC and are strongly associated with poor clinical outcomes. Patients with high expression levels of both EZH2 and LSD1 exhibit the poorest survival, suggesting that dual inhibition of these enzymes may offer a more effective therapeutic strategy than monotherapy in HCC.
Dual inhibition of EZH2 and LSD1 using GSK126 (an EZH2 inhibitor) and SP2509 (an LSD1 inhibitor) more effectively suppresses liver cancer cell proliferation compared to single-agent treatments. This combination reduces cell proliferation markers, including PCNA and Cyclin D1, and is associated with enhanced programmed cell death. Additionally, we observed decreased cell migration, invasion potential, cancer stem cell characteristics, and drug resistance. Gene Set Enrichment Analysis (GSEA) revealed that high expression of either EZH2 or LSD1 is linked to crucial processes such as cell proliferation, migration, invasion, cancer stemness, and EMT, reinforcing the potential of dual epigenetic targeting. Although EZH2 and LSD1 inhibitors are currently undergoing clinical trials for various cancers, their combination has not yet been explored in HCC. Therefore, evaluating this dual epigenetic therapy for HCC treatment represents a promising direction for future research with immediate translational potential.

#441 Evaluation of the effects of MDM2 inhibitor and epigenetic modifiers in combination with AURKB inhibitors for treating lung cancer.

Neha Tumati[1], Umamaheswari Natarajan[2], Shyam Sundar Jaganathan[3], Appu Rathinavelu[4]

[1]Rumbaugh-Goodwin Institute for Cancer Research, Farquhar Honors College, Halmos College of Arts and Science, Nova Southeastern University, Fort Lauderdale, FL,[2]Rumbaugh-Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Farquhar Honors College, Halmos College of Arts and Science, Nova Southeastern University, Fort Lauderdale, FL,[3]Rumbaugh-Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL,[4]Rumbaugh-Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Farquhar Honors College, Nova Southeastern University, Fort Lauderdale, FL

Lung cancer remains one of the leading causes of cancer-related deaths globally, primarily due to its aggressive nature, high metastatic potential and resistance to treatment. It is classified into two main subtypes: non-small cell lung cancer (NSCLC), which accounts for approximately 85% of cases, and small cell lung cancer (SCLC), making up the remaining 15%. Despite significant advances in early detection and treatment, lung cancer continues to pose a major challenge because of its resistance to therapy and its ability to metastasize rapidly. A promising avenue for more effective treatments lies in understanding the molecular mechanisms that can trigger lung cancer progression. Specifically, Aurora kinase B (AURKB) has emerged as an important oncogenic protein involved in regulating cell cycle progression, and its dysregulation is implicated in various cancers, including lung cancer. The interaction of AURKB with MDM2 is of interest due to its potential role in tumor progression and resistance to chemotherapy. In this study, we aimed to explore the relationship between AURKB and MDM2 in lung cancer cells, to determine where and how these proteins interact to support cancer growth. We also examined the anti-cancer effects of RG-7388, SAHA, CM-272, and Barasertib (an AURKB inhibitor), in modulating cell cycle regulation. Our results demonstrate that inhibition of AURKB induces cell cycle arrest and apoptosis in lung cancer cells. Additionally, treatment with RG-7388 activates the p53 pathway, leading to upregulation of p21 and subsequent cell cycle arrest and cell death. Interestingly, SAHA and CM272 both exhibited inhibitory effects on tumor growth by modulating AURKB through other regulatory proteins. Western blot and Immunofluorescence analysis of A549 and H460 cells after drug treatments, revealed differential responses of protein involved in cell cycle regulation, Cell Death, and epigenetic alterations. Interestingly, treatment of A549 and H460 cells with RG-7388, CM-272, and SAHA) led to upregulation of p53, p21, p27, ALDH1A1, PARP, BAX, Caspases 3, and Caspases 7. On the other hand, MDM2, AURKB, CDC25C, Cyclin A, Cyclin D, CDK4, CDK6, BCl-XL, and XIAP levels were downregulated after above mentioned treatments. Our findings confirm that AURKB levels can be down-regulated by using the combination of MDM2 inhibitors and epigenetic regulators such as SAHA and CM-272. However, the therapeutic efficiency of these combinations needs to be verified using *in vivo* experimental models.

#442 Dual KAT6/7 inhibition disrupts epigenetic programs that promote tumor evolution and adaptive drug resistance.

Manav Gupta, Pranav Gupta, Scott R. Tyler, Nour Ghaddar, Steven L. Spivak, Zabrisky Roland, Katelyn N. Lukas, Ivan G. Shabalin, Jonathon S. Ryan, Carl Schultz, Daniel M. Walden, Santosh Keshipeddy, Muzaffar Alam, Daniel Severance, Anjali Bisaria, Kelly S. Tego, Parker Y. Jameson, Mason J. Appel, Brittany Cruzan, Jay Prakash Jain, Michael E. Dalziel, Sunjay Sethi, Rebeca Choy, Richard Zang, Xin Linghu, Yuchen Bai, Peter Teriete, Diana M. Munoz, Christian R. Frey, Claire L. Neilan, Josh Taygerly, Jacob Burch-Konda, Paul A. Barsanti, Michael A. White, Brian T. Jones

Ideaya Biosciences, South San Francisco, CA

The formation of cancer and responsiveness to therapy is governed by a constantly evolving balance between somatic variation and dynamic epigenetic regulation. This evolution has been recognized as a significant obstacle confronting the development of durable cancer therapies. Thus, targeting epigenetic reprogramming in human cancers is a key focus for the design of new drugs to potentially deliver robust and durable anti-tumor activity. Lysine acetyltransferases (KATs) are a promising class of epigenetic targets that operate within interchangeable multi-subunit complexes to regulate cell cycle, pluripotency and lineage determination. Within this class, KAT6A and KAT7 have been recognized as mechanistically intertwined modulators of stem cell identity and lineage commitment through partially overlapping control of chromatin organization specified by histone H3 acetylation of lysine 23 (H3K23) and lysine 14 (H3K14). We noted multiple lines of orthogonal genetic evidence for a “paralog” relationship between these enzymes to support cancer cell autonomous survival in lineage-enriched subsets of the CCLE associated with predictive molecular features. These observations prompted evaluation of concomitant inhibition of KAT6A and KAT7 as a therapeutic approach in biomarker-defined patient populations. Here, we report an equipotent KAT6/KAT7 dual inhibitor with high selectivity versus the structurally similar KAT family members KAT5 and KAT8. We observed synergistic impact on cell viability and pharmacodynamic (PD) modulation of H3K23/H3K14 acetylation in biomarker positive breast, lung, and esophageal cancers with dual KAT6/7 inhibition versus selective inhibition of KAT6 or KAT7. *In vitro* transcriptomic evaluation of dual KAT6/7 drug effects in ER+ metastatic breast cancer models recapitulated convergent paralog behavior observed using genetic suppression with RNAi. Quantitative transcriptomic and epigenomic profiling of cancer cell responses to dual KAT6/7 inhibition confirmed downregulation of gene expression programs supporting lineage specification, stemness, and WNT signaling. *In vivo* efficacy studies in 8p11-amplified breast and lung xenografts confirmed enhanced tumor growth inhibition and PD modulation responses for dual KAT6/7 versus selective KAT6 inhibition. Notably, dual KAT6/7 inhibition also promoted improved durable and stable anti-tumor responses in endocrine therapy resistant and ESR1-mutant breast cancer patient derived xenografts that could not be achieved with selective KAT6 inhibition alone. Taken together, these observations support evaluation of dual KAT6/7 inhibition in biomarker-selected patient populations.

#443 Targeting therapeutic vulnerabilities mediated by epigenetic reprogramming in ARID1A and ARID1B dual-deficient gynecologic cancers.

Rebecca Ho, Bengul Gokbayrak, Eunice Li, Shary Chen, Emma Guo, Chae Young Shin, David Huntsman, Nathan Lack, Yemin Wang

University of British Columbia, Vancouver, BC, Canada

Background: Dedifferentiated carcinoma of the uterus and the ovary (DDEC collectively) are rare gynecologic cancers made of low-grade differentiated adenocarcinoma of the uterus or ovary juxtaposed against undifferentiated carcinoma. The two components are clonally related, and previous studies have suggested that loss of various switch/sucrose non-fermentable (SWI/SNF) proteins may contribute to the transformation of differentiated cancer cells to an undifferentiated state. Specifically, a third of all DDECs have co-inactivation of cBAF-specific subunits ARID1A and ARID1B. cBAF is one of the three major SWI/SNF complex subfamilies, and loss of ARID1A/B disrupts the chromatin remodeling function of cBAF. We hypothesize that epigenetic reprogramming in response to loss of cBAF activity will alter residual SWI/SNF complex assembly, creating vulnerabilities in DDEC that will allow for novel therapeutic opportunities. **Methods:** We generated an isogenic cell line with ARID1A/B dual loss to narrow down vulnerabilities in dual-deficient cells. Using this isogenic pair, we conducted a drop-out screen using EPIKOL, a CRISPR knockout library targeting epigenetic modifiers and cofactors. To validate the results, we genomically depleted and treated cells with small molecules to inhibit protein function. Additionally, to further understand the changes in SWI/SNF complex assembly when cBAF is lost, we conducted density gradient sedimentation assays with nuclear protein extracts isolated from the isogenic cell line pair. Finally, SWI/SNF inhibitors were added to bona fide ARID1A/B dual-deficient dedifferentiated carcinoma of the uterus and the ovary cell lines and xenografted tumors to test the generalizability of our findings. **Results:** EPIKOL screening identified that ARID1B-dependent, ARID1A-deficient cancer cells have increased reliance on ARID2 and PBRM1, two PBAF-specific subunits, upon ARID1B deletion. When *ARID2* and *PBRM1* were knocked out in ARID1A proficient and ARID1A/B dual-deficient cells, the latter had significant growth impairment. Furthermore, when treating the isogenic cell line pair with SWI/SNF inhibitors, we also noted increased sensitivity in the dual-deficient cell line. Moreover, we observed a shift towards PBAF assembly in the cells with ARID1A/B dual-loss, further supporting an increased dependency on the remaining SWI/SNF complexes in dual-deficient cells. Finally, we observed increased sensitivities towards SWI/SNF subunit inhibitors in other ARID1A/B dual-deficient ovarian and endometrial cancer cell lines and their xenografted tumors. **Conclusion:** ARID1A/B dual-deficient cancer cells have an increased reliance on the remaining SWI/SNF complexes for survival, thus highlighting a novel therapeutic option for DDEC with ARID1A/B dual loss.

#444 ASXL1 mutations in AML are associated with a distinct epigenetic state that results in vulnerabilities to epigenetic-targeted agents.

Christopher P. Mill[1], Warren C. Fiskus[1], Christine E. Birdwell[1], John A. Davis[1], Kaberia Das[1], Hanxi Hou[1], Surbhi Sharma[1], Koji Sasaki[1], Sanam Loghavi[1], Tapan M. Kadia[1], Naval Daver[1], Courtney D. DiNardo[1], Lu Wang[2], Kapil N. Bhalla[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Northwestern University, Chicago, IL

ASXL1 is frequently mutated in myeloid malignancies, often causing a stabilization of ASXL1 and the polycomb-repressive deubiquitinase (PR-DUB) complex, that results in a global reduction in H2AK119Ub and increased mRNA transcription. Poorer prognosis of AML with mutant (mt) ASXL1 creates an unmet need to identify and test novel therapies for this AML sub-type. We generated two knock-in (KI) models of the clinically relevant mtASXL1 Y591* into the AML cell lines OCI-AML3 and UCSD-AML1. Notably, ASXL1/BAP1 stabilization caused an increased expression of c-Myc at both the RNA and protein level. We observed via ChIP-Seq reduced H2AK119Ub at H3K27Ac-marked chromatin on Wnt/β-catenin stem cell pathway genes that resulted in increased mRNA expression of FZD5, TCF7L2, and WNT5A. KI of mtASXL1 in OCI-AML3 cells also increased G0/G1 with a concomitant reduction in S and G2/M phases of the cell-cycle. RNA-Seq analysis showed reduced expression of the REACTOME cell-cycle mitotic gene-set, associated with depletion of E2F1, AURKA/B, and PLK1 mRNA. A CRISPR screen in parental and KI cells revealed SPI1, CDK9, and EP300 among the top dependencies specific to mtASXL1 AML. Notably, compared to parental cells, OCIAML3 ASXL1 Y591* cells exhibited reduced sensitivity to standard anti-AML, chemotherapeutic agents, including cytarabine, etoposide and daunorubicin. Our findings confirm the previously published discovery that the presence of mtASXL1 confers an increased sensitivity to BETi inhibitors, e.g., pelabresib or birabresib. These cells were also more sensitive to other epigenetically targeted agents, including HATi (GNE-781 or CBP-IN-1), CDK8/19 mediator kinase inhibitor (SEL120-34A/RVU120) and the dual HAT/BETi (NEO2734/EP31670). Treatment with NEO2734 reduced the permissive chromatin marks especially on c-Myc and SPI1 super enhancers. There was also a significant reduction in mRNA and protein expressions of c-Myc, c-Myb, and PU.1. RNA-seq and mass-spectrometric analyses revealed that treatment with NEO2734 negatively enriched gene sets of c-Myc targets, rRNA processing, mRNA splicing, and translation. Treatment with SEL120 globally reduced active chromatin marks in the mtASXL1 expressing AML cells. This was associated with reduced protein expression of BAP1, pSTAT1 (S727), pSTAT5 (S726), MEIS1 and HOXA9, exclusively in mtASXL1 expressing cells. Co-treatment with pelabresib and NEO2734 or SEL120 and NEO2734 synergistically induced apoptosis in mtASXL1-expressing cells. Importantly, in the NSG mice engrafted with OCIAML3 ASXL1 Y591*, monotherapy with NEO2734, pelabresib or SEL120 significantly reduced AML burden. Collectively these findings highlight previously uncharacterized biologic effects of the presence of mtASXL1 and support the rationale for further evaluating AML therapies incorporating BETi, HAT-BETi or mediator-kinase inhibitor.

#445 Epigenetic modification induced by DNMTs inhibitor enhances apoptosis through p21 pathway in neuroblastoma cells.

Arun Jagarlamudi[1], Nicolas Tapia Stoll[1], Shyam Sundar Jaganathan[2], Umamaheswari Natarajan[3], Appu Rathinavelu[2]

[1]Rumbaugh-Goodwin Institute for Cancer Research, Halmos College of Arts and Sciences, Nova Southeastern University, Fort Lauderdale, FL,[2]Rumbaugh-Goodwin Institute for Cancer Research, Barry & Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL,[3]Rumbaugh-Goodwin Institute for Cancer Research, Barry & Judy Silverman College of Pharmacy, Halmos College of Arts and Sciences, Nova Southeastern University, Fort Lauderdale, FL

Introduction: Neuroblastoma, a prevalent and aggressive pediatric cancer, poses significant treatment challenges due to its aggressive nature, rapid proliferation, and tumor heterogeneity, particularly in high-risk cases. While genetic mutations and chromosomal abnormalities play a key role in the development and progression of neuroblastoma, there is growing evidence to confirm that epigenetic changes are equally important in influencing tumor behavior, treatment responses, and patient outcomes. Emerging evidence indicates that the DNMTs inhibitor (CM-272) may facilitate cell cycle arrest and induce apoptosis by modulating critical regulatory pathways. Therefore, our hypothesis is that CM-272 treatment could lead to apoptosis mediated cell death in SK-N-SH neuroblastoma cells through the upregulation of p21 transcription.
Methods: To test our hypothesis, SK-N-SH cells were treated with 2 μM of CM-272 with untreated cells serving as control. Cell viability was evaluated using the Trypan Blue Dye Exclusion (TBDE) assay. Both qRT-PCR and western blot analyses were conducted to assess the expression levels of cell cycle, apoptotic, and epigenetic markers such as p53, p21, PARP, BAX, BCL-XL and DNMT1. The RT^2 Profiler PCR array method was used for determining the expression profile of the cell cycle pathway genes.
Results: Our study results confirmed that SK-N-SH cells treated with CM-272 undergo increased cell death. Consistent with our hypothesis, we observed an increase and decrease in BAX, BCL-XL levels, respectively, suggesting that DNMT1 inhibition might have facilitated the induction of apoptosis through a p21-driven mechanism.
Conclusion: Our results highlight the potential use of CM-272 to induce apoptosis in SK-N-SH cells through p21 upregulation and an increase in BAX levels. Furthermore, our findings suggest that targeting DNMT1 may offer an alternative pathway for inducing cell death through elevation of p21 in neuroblastoma that may have p53 mutations. If validated in further studies, DNMTs-targeted therapies could represent a significant advancement in developing new treatments for aggressive cancers.

#446 Embryonic ectoderm development protein (EED) inhibitor APG-5918 exhibits potent antitumor activity and synergizes with androgen receptor (AR) inhibitor enzalutamide in preclinical prostate cancer (PCa) models.

Yan Yin[1], Zhiyan Liang[2], Baisong Li[1], Yun Yang[1], Dajun Yang[1], Yifan Zhai[1]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: Frequent PRC2 dysregulation in PCa is associated with poor prognosis. As a core PRC2 component, EED is essential for histone methyltransferase activity. The potential antitumor effects of APG-5918 in combination with enzalutamide were evaluated in PCa models.

Methods: Human AR-dependent LNCaP and AR-independent castration-resistant C4-2B and 22Rv1 PCa cell lines were used for *in vitro* antiproliferation assays. Cell viability was assessed using CellTiter-Glo® luminescent assay. Subcutaneous LNCaP cell-derived xenograft (CDX) and 22Rv1 CDX models in castrated nude mice were established to evaluate *in vivo* antitumor effects.

Results: APG-5918 showed superior inhibitory effects on cellular proliferation *in vitro,* with IC_{50} values of 10.16 nM in LNCaP, 26.32 nM in C4-2B, and 70.32 nM in 22RV1 cells after 14-day continuous treatment. APG-5918 appeared to be more potent than two EZH2 inhibitors (tazemetostat, PF-06821497) and EED inhibitor ORIC-944 under the same experimental condition. APG-5918 in combination with enzalutamide synergistically suppressed cellular proliferation. APG-5918 induced dose-dependent cell cycle arrest in LNCaP and C4-2B cells, increasing the proportion of cells in G0/G1 phase while decreasing those in S- and G2/M-phase by flow cytometry. Combining enzalutamide with APG-5918 deepened G0/G1 cell cycle arrest. In the LNCaP CDX model, APG-5918 100 mg/kg administered orally once daily for 28 days exerted significant antitumor activity (T/C = 40.78%; $p < 0.001$ vs. vehicle), whereas enzalutamide 20 mg/kg showed limited antitumor activity (T/C = 81.56%). In the 22Rv1 CDX model, APG-5918 100 mg/kg or 50 mg/kg had superior antitumor activity, with T/C values of 41.57% ($p < 0.001$ vs. vehicle) and 33.78% ($p < 0.001$ vs. vehicle), respectively, whereas enzalutamide 30 mg/kg for 41 days had minimal antitumor effects (T/C = 87.03%). No significant differences in body weight changes were observed between treatment and vehicle groups (all p values > 0.1 vs. vehicle), indicating a favorable safety profile. Western blot analysis showed that APG-5918 downregulated key on-target pharmacodynamic markers (e.g., H3K27me3, EED, EZH2, SUZ12) and AR pathway proteins. APG-5918 also suppressed oncogenic driver ERG, DNA methylation factors (UHRF1, DNMT1), and antiapoptotic protein MCL-1, and reduced levels of pRb, CDK4, and cyclin D1—crucial mediators of cell cycle regulation. APG-5918 combined with enzalutamide further enhanced the downregulation of PRC2 components, AR pathway proteins, cell cycle regulators, oncogenic drivers, and DNA methylation factors.

Conclusions: APG-5918 alone or in combination with enzalutamide exhibited antitumor activity in preclinical PCa models, supporting EED inhibition (± AR antagonists) as a therapeutic strategy for PCa.

#447 Preclinical development and characterization of IACS-16559, a dual bromodomain inhibitor of CBP/EP300, and its potential in AML subtypes.

Ciro Zanca, Michael Soth, Ajay Saw, Uttara Saran, Guang Gao, Jason Gay, Ningping Feng, Christopher Bristow, Joseph Marszalek, Kunal Rai, Virginia Giuliani, Tim Heffernan

UT MD Anderson Cancer Center, Houston, TX

Paralogs CBP and EP300 are transcriptional co-regulators, with a mechanism of action involving regulation of chromatin accessibility, direct acetylation of master transcriptional factors and bridging enhancers to activated promoters. They possess both reader and writer of the histone code due to the bromodomain and histone acetyltransferase domain, respectively. Aberrant transcription in cancer can occur at multiple stages, contributing to proliferation, therapeutic resistance, and escape from induced cell death, making it a good target for therapeutic intervention. Clinical validation of bromodomain inhibition of paralogs CBP and EP300 is undergoing in multiple clinical trials, including both hematological diseases and solid tumors, using EP31670, CCS1477 and TT125-802, while selective CBP or EP300 inhibition is being explored preclinically. We recently developed a dual bromodomain inhibitor for CBP and EP300, IACS-16559 with selectivity over BRD4, pharmacokinetic properties showing low clearances, high oral exposures and predicted QD dosing in human. IACS-16559 toxicity profile in rats and dogs was in line with previous reports for dual CBP/EP300 bromodomain inhibition. Repeat dose studies in rats and dogs of IACS-16559 was tolerated, with dose-dependent changes affecting bone marrow and lymphoid tissues, testes, GI tract at high doses. All the toxicology findings were reversable once the drug treatment is discontinued, and the animals allowed to recover. Given the potential for anticancer activity mediated by dual CBP/EP300 inhibition, we evaluated the response in selected subtypes of AML, both *in vitro* and *in vivo*. Single agent inhibition prolongs survival of the mice bearing orthotopic leukemia xenografts driven by several alterations, such as AML1-ETO, MLL-AF9, NPM1c, RUNX1mut. Mechanistically, CBP/EP300 dual inhibition caused disruption of the MYC and MYB oncogenic network in multiple models, required for the AML proliferation. Interestingly, the combination of IACS-16559 and MLL-Menin inhibition demonstrated synergistic effects *in vivo* with the OCI-AML3 (NPM1c) model, significantly prolonging the survival of experimental animals. However, in contrast, long-term treatment in the MLL-AF9 (MOLM14) model resulted in antagonistic effects. These findings underscore the complexities of combinatorial therapeutic development and emphasize the critical need for careful selection of robust therapeutic combinations and consideration of the genetic background in the target disease.

#449 Small molecular inhibitors of PRC1 demonstrate potent activity in acute leukemia models.

SeRa Park, Yiwu Yao, Sydney Musser, Miranda Simes, Haiqing He, Hongzhi Miao, Alyssa Winkler, Trupta Purohit, Xiaotian Zhang, Jolanta Grembecka, Tomasz Cierpicki

University of Michigan, Ann Arbor, MI

Background: Polycomb repressive complex 1 (PRC1) is an epigenetic regulatory complex that monoubiquitinates H2A on lysine 119 and is involved in gene regulation and development, resulting in the repression of target genes important for cellular identity, stemness and differentiation. Activity of PRC1 is maintained by E3 ligases RING1A or RING1B. Recent studies implicate RING1B in various cancers and highlights the importance of PRC1 function in the maintenance and proliferation of leukemic stem cells. This demonstrated that PRC1 has role in acute leukemias, supporting the need to develop PRC1 inhibitors. Therefore, development of potent small molecule inhibitors targeting PRC1 can provide novel therapeutic new approach for leukemia treatment.
Results: We have developed potent PRC1 inhibitors represented by our lead compound RB-231. We found that treatment with RB-231 induces potent anti-proliferative effects on cell growth at mid-nanomolar concentrations in multiple acute leukemia cell lines. Analysis of H2A ubiquitination using Western Blots have shown that activity of RB-231 is correlated with global reduction of H2Aub levels. Profiling of gene expression in various AML and ALL cell lines demonstrates de-repression of many genes. Through mechanistic studies using Cut&Run, we validated decrease in H2Aub signal at multiple gene loci, including CDKN1A. We performed Flow cytometry to verify apoptosis and cell differentiation in AML cells. These studies revealed that RB-231 treatment induces cellular differentiation as well as apoptosis in leukemia cells. We also tested the activity of RB-231 in primary AML patient samples. Treatment with RB-231 decreased colony formation in patient samples and induced morphological changes, suggesting differentiation of these cells from leukemic blasts to more mature hematopoietic cells. We also evaluated the activity of RB-231 in normal human CD34+ bone marrow cells to confirm no toxicity. We assessed efficacy of RB-231 *in vivo* using MV4;11, Jurkat and Reh xenografts. Treatment with PRC1 inhibitor resulted in pronounced reduction of leukemia burden and increase in survival. In accompanying pharmacodynamics PD experiments, RB-231 showed reduced leukemia hCD45+ blast level in blood, bone marrow and spleen compared to the vehicle control, and increased CDKN1A expression.
Conclusion: We developed a first- in class inhibitor directly targeting the E3 ligase activity of PRC1. Treatment with our PRC1 inhibitors in leukemic cells elicits an anti-proliferative effect, blocks ubiquitination of H2A, and results in the de-repression of many genes repressed by PRC1. Our data suggests that multiple subtypes of acute leukemia are sensitive to inhibition of PRC1. Furthermore, this study demonstrated that RB-231 is potent PRC1 inhibitor suitable for evaluation *in vitro* and *in vivo* models of acute leukemia.

#45 PDX technology transfer: NCI cancer center to HBCU.

Teni O. Akin-Olugbemi (equal contribution)[1], De'llaijah Lucas (equal contribution)[2], Romell Stone[1], Esther Frimpong[1], Raviteja Bulusu[1], Hernan Flores-Rozas[1], Edward Agyare[1], Tanise Jackson[1], Renee Reams[1], Seth Ablordeppey[1], Brooke Hensel[3], Jose Trevino[4], Steven J. Hughes[2], Han Song[2], Christina Gobin[2], Bodour Salhia[5], Paul Okunieff[2], Kristianna Fredenburg[2], John M. Allen[3], Bereket Mochona[1], Diana J. Wilkie[2]

[1]Florida A&M University, Tallahassee, FL,[2]University of Florida, Gainesville, FL,[3]University of Florida, Orlando, FL,[4]Virginia Commonwealth University, Richmond, VA,[5]University of Southern California, Los Angeles, CA

We profile a technology transfer process between two partnering research institutions and the early outcomes. The Partnerships to Advance Cancer Health Equity (PACHE) program seeks to increase cancer research at HBCUs via collaborations with NCI-designated cancer centers. One such partnership, the Florida-California Cancer Research Education and Engagement (CaRE^2) Health Equity Center, completed a series of studies with Patient Derived Xenograft (PDX) models to test novel compounds and delivery systems as treatment for pancreatic cancer. PDX models involve the implantation of human tumor tissues into immune incompetent mice for studies that mirror the human context. Few pancreatic cancer PDX models exist for Black patients, at high risk for pancreatic cancer incidence and mortality. For early studies, the cancer center Tissue Modeling & Drug Development Core (TMDDC) shipped the PDX models to the HBCU after implantation in the 25 mice needed for each study. To increase research capacity at the HBCU after these successful studies, the HBCU investigators, students, and a veterinarian were trained at the cancer center lab to implant the PDX tumor tissue in immune incompetent mice. The TMDDC shipped frozen PDX tumor tissue from a Black male patient to the HBCU, which the veterinarian implanted in 3 mice (Generation 1; Gen1). Tumor growth occurred in 1 of 3 mice (33%). The Gen1 tumor is now being expanded by implantation into 5 additional mice (Gen2) for future implantation in the 25 mice (Gen3) that are needed for the planned studies. The TMDDC shipped tissue from a Black female patient's PDX tumor to the HBCU for replication of Gen1-3 procedures. In support of 2 CaRE^2 projects, the 50 mice (25 from a Black male, 25 from a Black female) with the Gen3 PDX tumors will be used at the HBCU to (1) test effects of a modified gemcitabine compound delivered by nanotechnology, and (2) test a cfDNA biomarker of tumor response. Two postbaccalaureate trainees (1 at cancer center, 1 at HBCU) worked with the TMDDC at each institution as part of the technology transfer from the cancer center to the HBCU. The trainees' important contribution to the technology transfer process involved documentation of the standard operating procedures for receiving the PDX tissues, implementing the expansion Gen1-3 steps for research at the HBCU, and building a well-annotated, living repository of pancreatic PDX tissues at the HBCU for ongoing cancer health disparities research studies and for training of the HBCU graduate students in the use of these technologies. This successful technology transfer enables cutting edge training for the HBCU students and facilitates their success as they enter the cancer health disparities research workforce. Furthermore, this project demonstrates the hallmark of a successful PACHE partnership, specifically the complementary collaboration among the CaRE^2 Projects, Research Education Core, TMDDC, and Administrative Core to enable this technology transfer to the HBCU.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Epigenetic Targets

#450 Discovery of a highly potent KAT6 Inhibitor for potential treatment of advanced, metastatic and refractory ER+Her2- breast cancers.

Congcong Cai, Shiya Zhu, Linjun Wang, Shu Cai, Hongkun Li, Min Wen, Mingxin Qian, Shifeng Liu, **Bin Shi**, Hancheng Zhang

Hangzhou Innogate Pharma Co., Ltd, Hangzhou, China

Frequent genomic alteration of KAT6A and KAT6B have been found in a variety of cancer types. Histone acetyltransferases (HAT) KAT6A and KAT6B can acetylate lysine residues of histone H3 (including H3K23), leading to a relaxing state of chromatin and active transcription of genes regulating cell cycle, cellular senescence, and tissue development; to name a few, genes encoding ER (estrogen receptor), Myc, and Cyclin D1. Inhibition of these processes exerts an anti-tumor effect in many cancer types. We, Innogate Pharma (Innogate), have discovered a novel and highly potent series of small molecule KAT6 inhibitors with strong in vitro potency and robust in vivo anti-tumor efficacy.
Innogate's KAT6 preclinical candidate compound (PCC) exerts single digit nM IC_{50} activities against KAT6A/6B enzymes with good selectivity over KAT5, KAT7, KAT8. The molecule also demonstrated anti-proliferation activity at sub-nM IC_{50} in ZR-75-1 and T47D. We also tested enzyme kinetics and found the molecule have favorable binding profile to KAT6A in a fast-on-slow-off manner. The PCC molecule can be converted to salts with potential advantages in CMC development and showed a favorable solubility profile independent of GI pH variation. In ER+Her2-breast cancer ZR-75-1 xenograft models, the molecule at 0.3 mg/kg /PO/QD for 28 days leads to significant tumor growth inhibition and regression with TGI 129% at the termination day 28. Furthermore, in a fulvestrant resistant, ER+HER2- breast cancer PDX model, the molecule displayed excellent anti-tumor efficacy at 10 mg/kg /PO/QD, with tumors completely disappeared on day 22 and without safety issues observed, while the positive control compound still had palpable tumors on termination day 28 at the same dose. In other preclinical studies, the molecule holds good in vitro ADME properties and PK profiles in mice, rats and beagle dogs, favoring a potential once daily oral dose regime in the future clinical setting. The molecule also exhibited good in vitro safety profile in hERG and well tolerated in rodent study. Collectively, these results provide preclinical evidence that our PCC molecule could be a superior KAT6A/6B inhibitor to treat patients with advanced, metastatic, refractory, fulvestrant-sensitive or-resistant, ER+Her2- breast cancers.

#451 Superior preclinical efficacy of BRG1/BRM inhibitor combined with BET inhibitor or decitabine against MECOM-rearranged AML.

Warren C. Fiskus[1], Christopher P. Mill[1], Jessica Piel[2], Murphy Hentemann[2], Christine E. Birdwell[1], Kaberi Das[1], Hanxi Hou[1], John A. Davis[1], Surbhi Sharma[1], Tapan M. Kadia[1], Naval Daver[1], Sanam Loghavi[1], Courtney D. DiNardo[1], Kapil N. Bhalla[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Foghorn Therapeutics, Cambridge, MA

AML with MECOM rearrangement (r) involving chromosome 3q26.2, specifically inv(3)(q21q26.2) or a translocation t(3;3)(q21;q26.2), accounts for approximately 1% of newly diagnosed AML. They involve aberrant relocation of the distal GATA2 hematopoietic enhancer with MYB binding sites, leading to EVI1 overexpression from the MDS1-EVI1 complex (MECOM) locus. EVI1 is a transcriptional regulator that plays a role in proliferation, differentiation and maintenance of the AML stem cell-like phenotype. In MECOM-r AML, due to the GATA2 haplo-insufficiency with overexpression and increased activity of EVI1, AML stem/progenitor cells exhibit aggressive proliferation, are therapy refractory and display poor overall survival. Therefore, there is an unmet need to develop and test novel targeted therapies to improve outcomes in AML with MECOM-r and EVI1 overexpression. BRG1 (SMARCA4) and BRM (SMARCA2) are the core ATPases within the chromatin remodeling BAF complexes that regulate gene transcription. FHD-286 is a potent, selective, first in the class inhibitor of BRG1/BRM in clinical development as an AML therapy. Our present studies demonstrate that exposure to FHD-286 (10 to 100 nM) for 4 to 7 days induced CD11b expression with morphologic features of differentiation leading to loss of viability in AML cell lines and patient-derived (PD) AML cells with MECOM-r. FHD-286 treatment caused whole-genome, concordant, up- or down-regulations in H3K27Ac ChIP-Seq peaks and the RNA-Seq-determined mRNA expressions of specific loci, including significant reduction in the gene-sets of MYC targets and repression of EVI1. Immunoblot analysis showed that FHD-286 treatment reduced EVI1 protein expression. Additionally, mass spectrometry on MECOM-r AML cells treated with FHD-286 showed log2 fold-reductions in EVI1, c-Myc, CD44, c-KIT, CD93, CDK4 and PLK1 protein levels. In mass cytometry-determined, phenotypically defined AML stem/progenitor cells, FHD-286 treatment also reduced EVI1 expression. Co-treatment with FHD-286 and decitabine, BET inhibitor (OTX015), or HAT inhibitor GNE-781 exerted synergistic in vitro lethality against MECOM-r AML cell lines and PD AML cells (Delta synergy scores > 5 by the ZIP method). Finally, as compared to treatment with each drug alone or vehicle control, in PD xenograft (PDX) models of AML cells with MECOM-r, co-treatment with FHD-286 and decitabine or OTX015 significantly reduced AML burden and improved overall survival of the NSG mice, without inducing significant toxicity. Taken together, these findings highlight the promise of FHD-286 treatment alone and in rational combinations in exerting significant anti-AML efficacy against cellular models of AML, especially those with MECOM-r and EVI1 overexpression.

#452 ORIC-944, a PRC2 inhibitor with best-in-class properties, restores luminal features and restricts adaptation in prostate cancer models, conferring synergy with AR pathway inhibitors.

Anneleen Daemen, Alexandr Pankov, Natalie Yuen, Amber Wang, Livia Ulicna, Xi Chen, Frank L. Duong, Jason E. Long, Robert Warne, Lori S. Friedman, **Melissa R. Junttila**

ORIC Pharmaceuticals, Inc., South San Francisco, CA

Polycomb repressive complex 2 (PRC2) silences transcription by tri-methylating histone H3 at lysine 27 (H3K27me3), regulating cell growth and differentiation. The EED subunit is required for chromatin recruitment and histone methyltransferase activity. PRC2 dysregulation is linked to poor prostate cancer prognosis, promotes lineage plasticity and therapeutic resistance. Combining androgen receptor pathway inhibitors (ARPI) with PRC2 inhibitors may overcome or prevent resistance, with clinical trials showing promise in metastatic castration-resistant prostate cancer. First-generation PRC2 inhibitors exhibit poor drug properties and short half-lives, requiring at least twice daily dosing at high doses. ORIC-944 is a second-generation allosteric inhibitor of PRC2 that binds EED and exemplifies best-in-class drug properties including potency, solubility, and ADME/PK, with half-life supporting once daily dosing. The mechanism of PRC2 in prostate cancer lineage plasticity was explored with RNA-seq, H3K27me3 ChIP-seq, and ATAC-seq data from in vitro and in vivo studies of ORIC-944 as a single agent and combined with ARPI. No evidence for a non-canonical EZH2 role was found comparing EZH2 and EED inhibitors by RNAseq. ORIC-944 or EZH2 inhibition led to robust PRC2 inhibition, luminal state transition, and increased AR signaling in a spectrum of AR-positive in vivo prostate cancer models. In vivo kinetic studies revealed that luminal cell state transition and increased AR signaling are early events induced by ORIC-944. The luminal cell state acquired with PRC2 inhibition was confirmed by IHC, and is highly dependent on AR signaling in vivo, indicative of a functionally relevant cell state. Continuous ORIC-944 administration was necessary to maintain the luminal state and antitumor efficacy. Surprisingly, analysis of chromatin revealed that ORIC-944 specifically restricts accessibility to lineage-associated transcription factors known to impart cellular plasticity in prostate cancer. This plasticity-restricted luminal state conferred by PRC2 inhibition is dependent on AR, leading to antitumor activity either in the hormone-depleted context or in the setting of ARPI combination. Together these data indicate that ORIC-944 reinforces a luminal cell state and, notably, restricts access to plasticity genes leading to a highly AR-dependent state in prostate models. This mechanism supports the observed preclinical synergy between PRC2 inhibition and ARPI combination in both ARPI-sensitive and ARPI-resistant settings. These results position ORIC-944 as a potential best-in-class PRC2 inhibitor that blocks prostate tumor adaptation, restores luminal features, and sensitizes tumors to ARPI. A phase 1b trial of ORIC-944 in combination with ARPIs is ongoing in metastatic prostate cancer (NCT05413421).

#453 Discovery of potent, selective, and orally bioavailable small molecule inhibitors of YTHDC1 for the treatment of MYC-driven cancers.

Richard C. Centore[1], Mark Charles[2], Mansi Arora[1], Marius Rebmann[2], Jerome Cattin[2], Xuejing Yang[3], Emily Batchelor[3], Matthew Watson[2], Nagakumar Bharatham[2], Prathima Radhakrishanan[1], Alex Howarth[2], Seema Qamar[2], Laura Andraghetti[2], Martin Kulander[2], Tuomas Knowles[2], Michael G. Kharas[3], **Shilpi Arora**[1]

[1]Transition Bio, Watertown, MA,[2]Transition Bio, Cambridge, United Kingdom,[3]Memorial Sloan Kettering Cancer Center, New York, NY

The MYC family of oncogenes (including c-MYC, L-MYC, and N-MYC) has been considered one of the most sought-after drug targets in oncology. These transcription factors are critical cancer drivers but have remained difficult to drug directly with small molecules; thus, alternative approaches to regulate MYC expression or activity are of high interest. We have previously demonstrated that MYC family members are regulated by YTHDC1. In AML cells, *MYC* mRNA is post-transcriptionally modified with methylation of adenosine at the N6 position (m^6A), and m^6A-marked *MYC* transcripts localize within phase-separated assemblies, termed biomolecular condensates, with the m^6A reader, YTHDC1. YTHDC1 condensates regulate m^6A-marked *MYC* and other oncogenic transcripts and promote cancer cell proliferation including in MYC-driven AML and small cell lung cancer (SCLC). Here, we describe the identification of YTHDC1 inhibitors optimized utilizing structure-based drug design (SBDD). This series of inhibitors occupies the RNA binding pocket of YTHDC1 and disrupts its interaction with m^6A-RNA at nanomolar potencies in biochemical and cellular assays. The inhibitors are selective for YTHDC1 over other YTH family members and selectively dissolve YTHDC1 condensates over other condensate systems. Profiling in broader kinase and safety panels also suggests that these YTHDC1 inhibitors are selective with a favorable *in vitro* safety profile. Our lead molecule is drug-like, orally bioavailable, has suitable ADME properties and is well-tolerated *in vivo*. In *MYC*- and *MYCL*-driven AML and SCLC cells, respectively, we demonstrate the presence of YTHDC1 condensates, which are abrogated by YTHDC1 inhibition. Consistent with the genetic perturbation of YTHDC1, pharmacologic inhibition of YTHDC1 reduces MYC expression and results in anti-proliferative and pro-apoptotic phenotypes. Induction of myeloid differentiation markers is also observed in AML cells upon YTHDC1 inhibition. We evaluate the effects of YTHDC1 inhibition on primary patient AML samples. In addition, we demonstrated no impact on normal CD34+ progenitor cells. YTHDC1 inhibition results in *in vivo* efficacy at well-tolerated doses in multiple AML and SCLC xenograft models. Further, we demonstrate a dose-dependent PK/PD/efficacy relationship, suggesting on-target YTHDC1 activity through suppression of the MYC pathway. Thus, our data demonstrate that targeting YTHDC1 condensates represents a novel approach to the treatment of MYC-driven tumors.

#454 Leveraging cell cycle to enhance differentiation therapy in acute myeloid leukemia.

Riccardo Valzelli[1], Kourosh Hayatigolkhatmi[1], Amir Hosseini[2], Elena Ceccacci[1], Giorgia Parodi[3], Angela Bachi[4], Saverio Minucci[1]

[1]European Institute of Oncology (IEO), Milan, Italy,[2]Ludwig Institute for Cancer Research, Oxford, United Kingdom,[3]Cogentech, Milan, Italy,[4]IFOM ETS - The AIRC Institute of Molecular Oncology, Milan, Italy

Acute myeloid leukemia (AML) is a highly heterogeneous hematological malignancy characterized by diverse genetic and epigenetic aberrations, making therapeutic interventions particularly challenging. We have identified a novel combination therapy that leverages differences in cell cycle dynamics to induce AML cell differentiation, and found AML cells which were highly sensitive to inhibitors of the histone demethylase LSD1/KDM1A depending on their cell cycle profile. Here, we aim at identifying other potential epigenetic vulnerabilities of AML cell lines exposed to the treatment with different CDK inhibitors. Given the heterogeneity of the epigenetic aberrations found in AML, targeting additional chromatin regulators could improve the clinical applicability of this combination therapy. Thus, we started an in vitro CRISPR-screening approach, targeting over 600 chromatin-related genes. Following optimization of Cas9-expressing clones and evaluation of knockout (KO) efficiency, we confirmed that the best-performing clone retained phenotypic consistency with parental cells under combination therapy. Preliminary data validated the effectiveness of our screening platform, as sgRNAs targeting LSD1 recapitulated the phenotype observed with CDK inhibitors treatment, thereby demonstrating the feasibility of the approach. In parallel, we investigated the molecular link between cell cycle manipulation and chromatin remodeling. We conducted a nuclear phospho-proteomics experiment on cells treated with CDK inhibitors. This analysis identified differential phosphorylation of several proteins, which are currently under investigation. Additionally, gene ontology analysis revealed enrichment in pathways regulating RNA metabolism, transcription, and DNA damage response. By integrating cell cycle modulation with epigenetic targeting, our work offers new insights into AML differentiation therapy, with the potential to improve therapeutic outcomes in diverse AML subtypes.

#455 Targeting CARM1- expressing ovarian cancers with HSP-70 inhibitors.

S. Kumari, S. Gupta, A. Jamil, S. Karakashev;
Temple Univ. Lewis Katz School of Medicine, Philadelphia, PA

Epithelial ovarian cancer (EOC) is the leading cause of gynecological cancer-related deaths in the United States, characterized by its genetic heterogeneity and the urgent need to develop novel therapeutic strategies in a personalized manner. Coactivator-associated arginine methyltransferase 1 (CARM1) is an enzyme responsible for post-translational modifications of protein substrates on arginine residues. CARM1 is often overexpressed and functions as an oncogene in several cancer types. Notably, high-grade serous ovarian carcinoma (HGSOC) exhibits the highest rates of CARM1 amplification, with approximately 20% of cases showing overexpression, which correlates with poor survival outcomes in EOC patients. This study aimed to identify potential therapeutic targets for EOC cells with CARM1 amplification. We conducted an unbiased evaluation of a custom set of 27 small-molecule inhibitors to identify agents selectively effective against CARM1-expressing EOC cells, leading to the identification of the HSP-70 inhibitor AP-4-139B as the most potent candidate. HSP-70 is a crucial part of the protein folding machinery, and its levels are upregulated in multiple types of cancer and serve as a substrate for CARM1 enzymatic activity; however, the implications of HSP-70 modification by CARM1 remain unclear. The CRISPR-Cas9-based knockout technology was employed to analyze the effect of CARM1 knockout on cell proliferation in EOC cells, which demonstrated that CARM1 knockout significantly slowed cell growth in EOC cells. Synthetic lethality of CARM1-expressing cells upon HSP-70 inhibition by AP-4-139B was validated in both the ovarian cancer cell model system and the xenograft model. Mechanistically, AP-4-139B treatment induced apoptotic cell death in CARM1-high EOC cells through activation of the apoptotic pathway as analyzed by cell proliferation assay, apoptotic assay, and immunoblotting of apoptotic markers. Our findings indicate that CARM1-high cells are selectively sensitive to HSP-70 inhibitors as a single agent. HSP-70 inhibition alone will be sufficient to induce apoptosis and inhibit tumor growth in a CARM1-dependent manner *ex vivo* and *in vivo*. Thus, these findings will have far-reaching implications for developing personalized therapeutic strategies based on CARM1 amplification. The therapeutic and mechanistic rationale for targeted therapy on patients with CARM1 high EOC who are most likely to benefit from HSP-70 inhibitor treatment.

#456 An ultrahigh throughput phenotypic screening platform to discover novel inhibitors of methyl transferases.

Nathan G. Hedrick, Maina Ndungu, Ivy Nai-Jung Hung, Devin K. Porter, Elliot Imler, Gopi Chandran RaviChandran, Aurelien Lauerre, Chris M. Glinkerman, Martin Smrcina, Mark R. Hansen, Allan Nojadera, Alexandra Cole, Cindy Huynh, Michael Miller, Dmitri rozanov, Logan Van Meter, Nicholas Sm-Soon, Steven Brown, Yi Zhang, **Vikas K. Goel**

Zafrens Inc., San Diego, CA

Discovering drug-like molecules for hard-to-target proteins remains a significant challenge. Methyltransferases (DNA, RNA, and protein) are among such targets. At Zafrens, we have developed an ultra-high-throughput discovery platform that leverages large arrays of isolated nano-wells and single-bead-single-compound DNA-encoded library (DELs) to uncover target-specific inhibitory impacts on cells. Using a combination of next-generation sequencing and spatially indexed optical imaging of biomarkers and cell paint probes, we successfully linked transcriptomic signatures and phenotypic responses to a combinatorial chemical library of over 15,000 compounds, achieving approximately fivefold hit coverage. Incorporation of known inhibitors of a methyltransferase into the chemical library revealed that both transcriptome-driven clustering and machine learning-driven linkage of compound SMILES with cell phenotype could successfully identify reproducible signatures that were aligned well with public databases, including expected methyltransferase-dependent genes such as MTF1. The robustness and consistency of our platform have allowed us to identify several novel compounds that mirrored the transcriptomic and phenotypic profiles of the control compounds. Subsequent biochemical assays confirmed that many of these were bona fide inhibitors of the target methyltransferase. Among these, ZF165 emerged as a promising candidate due to its high hit frequency across multiple screens and across two cell lines. ZF165 was then resynthesized and further validated by both immunofluorescence- and western blot analyses for its impact on biomarker responses. Bulk transcriptomic mRNA sequencing analysis confirmed common profiles between ZF165 and a control methyltransferase inhibitor. Furthermore, ZF165 demonstrated initial anti-tumor cell activity with a potency comparable to known pre-clinical compounds, further supporting its potential as a lead molecule. With ZF165 as the new series lead, we designed a secondary DEL library featuring novel warheads and improved physicochemical properties. The secondary library, ZEL29, was synthesized and screened, yielding new hits as additional (or) providing SAR, with enhanced potency and better drug-like properties relative to ZF165. These results support the utility of our platform in both the initial hit discovery and subsequent hit optimization toward lead compounds. Validation-design cycles for lead optimization are currently ongoing. By coupling this powerful screening platform with robust data analytics, we aim to revolutionize the discovery of novel therapeutics to address other challenging drug targets.

#457 QLS1304, a highly potent and selective KAT6A/B inhibitor treating $ER^{+}HER2^{-}$ breast cancer.

Yuxing Zhang, Chundao Yang, Huijie Guo, Changliang He, Lan Zhang, Ling Li, Mengmeng Zhang, Xuejian Zheng, Ping Chen, Dong Yang, Dongdong Wu, Guqin Shi, Daqing Sun, Wenyuan Qian, Weimei Sun, Weikang Tao

Shanghai Qilu Pharmaceutical Research and Development Center Ltd., Shanghai, China

KAT6A and KAT6B, members of the MYST family of lysine acetyltransferases, are implicated in estrogen receptor-positive (ER+) breast cancer. KAT6A amplification occurs in about 10% of these patients, linking to overexpression and poorer outcomes. KAT6B is known to be functionally redundant with KAT6A in regulating levels of H3K23Ac, although its specific role in ER+HER2- breast cancer is not well understood. The simultaneous inhibition of KAT6A and KAT6B may lead to a more profound suppression of histone acetylation. Thus, the development of a dual inhibitor targeting KAT6A and KAT6B has been aggressively pursued, with the goal to offer an effective therapeutic solution for patients with ER+ breast cancer. QLS1304 is a highly potent and selective inhibitor of KAT6A/B (KAT6A Ki: 0.2 nM, KAT6B Ki: 0.4 nM; and >200-fold selectivity over KAT5/KAT7/KAT8). H3K23 acetylation was dose-dependently inhibited in ER+HER2- breast cancer cell lines, while ER expression was only suppressed in KAT6A-high cells. QLS1304 demonstrates strong in vitro and in vivo efficacy in multiple ER+HER2- breast cancer CDX models, either as a single agent or in various combinations with current standard therapies. Notably, QLS1304 has demonstrated efficacy in an ESR1 mutant ER+HER2- PDX model derived from a patient resistant to SoC. QLS1304 also exhibits desirable drug-like properties with an excellent pharmacokinetics profile across different animal species, and preclinical safety assessment also indicates a wide therapeutic window. Collectively, QLS1304 appears to be a promising candidate for the treatment of ER+HER2- breast cancer given its efficacy in both SoC-sensitive and SoC-resistant models. Moving it forward into clinical trials is warranted both as single agent and combining with other therapies.

#459 Discovery and proteomic characterization of a novel KAT6A/B inhibitor.

Gali Arad[1], Avital Hay-Koren[1], Sagie Brodsky[1], Andrew Morley[2], Iris Alchanati[1], Galina Otonin[1], Yonatan Katzenelenbogen[1], Barr Tivon[1], Alon Shtrikman[1], Dimitri Kovalerchik[1], Anjana Shenoy[1], Katharina Lange[1], Nitzan Simchi[1], Eran Seger[1], Kirill Pevzner[1]

[1]Protai, Ramat Gan, Israel,[2]O2H Discovery, Cambridge, United Kingdom

Lysine histone acetyltransferase 6 (KAT6A/B) is a MYST family member of histone acetyltransferases (HATs), known to regulate gene expression by acetylation of both histone and non-histone substrates. KAT6A/B is a promising cancer drug target, specifically in estrogen receptor positive (ER+) breast cancer, but anti-cancer activity in other cancer indications has also been shown, suggesting a potential benefit for wider patient populations. Despite antitumor activity observed in clinical trials, KAT6i inhibitors are also reported to cause several high grade adverse events, including dysgeusia, neutropenia, and anemia, in some cases leading to treatment discontinuation. The efficacy alongside tolerability profiles of KAT6i reflects the need for improved therapeutic window by developing cleaner, more selective drugs; as well as by identification of additional responsive populations.

By applying computational and medicinal chemistry approaches we discovered a novel, highly potent inhibitor of KAT6A/B, demonstrating anti-tumor activity using both in-vitro cell viability assays and tumor growth inhibition in xenograft models. We combined drug sensitivity with basal and perturbational proteomics data of cancer cell lines, in order to provide a mechanistic explanation of KAT6A/Bi mode of action. Proteomic analysis of KAT6i sensitive and resistant cell lines highlighted several candidates for KAT6 predictive biomarker and shed light on the proteome-wide effects of KAT6 inhibition. In summary, these results support KAT6i drug development both within and outside ER+ breast cancer, as well as optimization of more selective KAT6 inhibitors to improve tolerability and therapeutic window.

#46 Alternative lengthening of telomeres in patient-derived xenograft models of soft tissue sarcomas with complex genomic profile.

Agnieszka Wozniak[1], Nicola Biondi[2], Kimberly Verbeeck[1], Oliver Bechter[3], Priya Chudasama[2], Patrick Schoffski[3]

[1]Laboratory of Experimental Oncology, KU Leuven, Leuven, Belgium,[2]Precision Sarcoma Research Group, German Cancer Research Center, Heidelberg, Germany,[3]Department of General Medical Oncology, University Hospitals Leuven, Leuven, Belgium

Background: Cancer cells require telomere maintenance mechanisms (TMM) to achieve replicative immortality. About 85% of cancers utilize telomerase-mediated elongation of telomeres, and 15% of cancers use alternative lengthening of telomeres (ALT). In sarcoma ALT positivity (ALT+) is observed in 10-80% of samples, mainly in tumors with high genomic instability. They are characterized by the presence of extra-chromosomal telomeric repeats called C-circles and frequent loss of function of chromatin remodeling proteins alpha-thalassemia/mental retardation syndrome X-linked (ATRX) and/or death domain-associated protein (DAXX). To expand the utility of patient-derived xenografts (PDX) to therapeutic approaches targeting ALT pathway we aimed to characterize the type of TMM and related characteristics in PDX of sarcoma with high genomic instability.
Methods: Out of 92 established and well-characterized PDX from 27 subtypes of soft tissue sarcoma (STS) from our XenoSarc panel 22 models with complex genomic profile were selected for the analysis: 7 models of leiomyosarcoma (LMS), 6 of dedifferentiated liposarcoma (DDLPS), 4 of undifferentiated pleomorphic sarcoma (UPS) and myxofibrosarcoma (MFS), and 1 model of high grade sarcoma not otherwise specified (HG). The level of C-circles as an ALT surogate marker was quantified based on detection of products of rolling circle amplification of C-circles by Phi-polymerase. Samples with C-circle levels ≥ 0.1 were classified as ALT+. Expression levels of ATRX and DAXX were evaluated using immunohistochemistry (IHC) and low coverage whole genome sequencing (lcWGS) was performed to compare potential differences in genomic landscapes of ALT+ and ALT- PDX models.
Results: C-circle analysis revealed 14 out of 22 PDX models analyzed to be ALT+ (63%), including 5/7 LMS, 2/6 DDLPS, 4/4 UPS, 2/4 MFS, and 1/1 HG models. Out of 14 ALT+ models, loss of ATRX and DAXX expression was detected in 9 and 2 PDXs, respectively. High quality lcWGS data were successfully generated, which are currently being analyzed to detect differences between ALT+ and ALT- PDX, and will be integrated with IHC results.
Conclusion: We documented a high prevalence of ALT+ in STS PDX models with complex genomic profile. An on-going molecular characterization of these models will further support genotype-specific evaluation of TMM-associated characteristics of PDXs, such as telomeric features, will add to the validity of these ALT+ models. We consider our PDX models an appropriate platform to study candidate drugs that can target ALT pathway in STS.

#461 A screening platform to target intrinsically disordered regions (IDRs) of chromatin factors in disease.

Laura Hsieh, Philamer Calses, Muryam Gourdet

TippingPoint Biosciences, Inc., San Francisco, CA

Aberrant chromatin is expanding as a new class of disease and resistance driver for multiple disease pathologies. While billions of dollars have been poured into drugging chromatin regulatory factors, the toxicity of previous approaches limits potential and promise. Conventional drug discovery strategies have focused on targeting only the stable interfaces of chromatin regulators. However, the specific regulation of chromatin function occurs in large part from the unstructured intrinsically disordered regions (IDRs). IDRs help specify the functionality of structured domains and play a critical role in regulating both physiological and disease-driving multi-protein assemblies. TippingPoint Biosciences has developed a first-of-a-kind screening platform that now enables targeting of IDRs in chromatin proteins by exploiting unique inter-molecular interfaces only found in disease driving chromatin states. TippingPoint's approach should increase specificity, reduce toxicity and be less susceptible to drug resistance. To validate our drug discovery approach we are focusing our efforts on developing novel small molecule therapeutics for a rare pediatric brain tumor, Diffuse Intrinsic Pontine Glioma (DIPG), a disease driven by a very specific chromatin mutation that is difficult to target using conventional approaches. DIPG is driven by the H3.3 K27M mutation. Recognition of H3.3K27M by Polycomb Repressive Complex (PRC2), renders PRC2 inactive leading to a reduction in global H3K27me3. As a result, there are increased levels of H3K27ac and altered gene expression. Using our platform we generated a synthetic DIPG chromatin state, mimicking the stabilized interactions between PRC2-H3.3K27M chromatin IDRs. We successfully screened thousands of molecules against the DIPG chromatin state and identified molecules that disrupted PRC2 and H3K27M IDR interactions. These small molecule hits partially restored H3K27me3 levels, reduced H3K27ac levels, and decreased oligodendrocyte transcription factor 2 (OLIG2) expression in DIPG cell-lines to promote differentiation. These results successfully show that our platform can identify small molecules that uniquely target aberrant chromatin to rescue disease pathology.

#462 TNG456 is a next-generation, brain-penetrant, MTA-cooperative PRMT5 inhibitor for the treatment of solid tumors with MTAP loss.

Kimberly J. Briggs, Alice Tsai, Minjie Zhang, Wenhai Zhang, Alan Huang, Jannik N. Andersen, Kevin M. Cottrell

Tango Therapeutics, Boston, MA

MTAP deletions occur in 10-15% of all human cancers, providing one of the largest precision oncology patient populations. MTA-cooperative PRMT5 inhibitors leverage the well-characterized synthetic lethal relationship between PRMT5 inhibition and MTAP deletion. TNG908, TNG462, AMG 193, BMS-986504, and AZD3470 are clinical-stage MTA-cooperative PRMT5 inhibitors for the treatment of solid tumors with MTAP loss, though only TNG908 and AMG 193 are reported to be brain-penetrant. TNG456 is a next-generation, highly potent and selective MTA-cooperative PRMT5 inhibitor designed for patients with MTAP-null cancers including gliomas and other tumors which frequently metastasize to the brain, such as NSCLC. In vitro, TNG456 is 55X selective for MTAP-null cancer cell lines over isogenic MTAP WT cell lines (compared to 15X for TNG908) and has marked selectivity for MTAP-null cancer cell lines independent of lineage in a large, diverse cell line panel. TNG456 is brain-penetrant in preclinical species with a Kpuu range of 0.5-1.1 in non-human primates and dogs. Oral administration of TNG456 drives dose-dependent antitumor activity including durable tumor regressions and complete responses in multiple cell line- and patient-derived xenograft models. With enhanced potency and selectivity for MTAP-null cancer cells, and strong preclinical evidence of brain-penetrance, TNG456 has the potential for broad clinical activity in MTAP-null solid tumors including gliomas and CNS metastases.

#463 Preclinical evaluation of CNS drug penetration of a novel series of MTA-cooperative PRMT5 inhibitors including TNG456.

Alice Tsai, Charles B. Davis, Kimberly J. Briggs, Kevin M. Cottrell, John P. Maxwell, Adam S. Crystsal, Ellen Hooper, Jannik N. Andersen

Tango Therapeutics, Boston, MA

Treatment of brain tumors and brain metastases remains a significant unmet medical need. This is especially true for high-grade gliomas, where up to 50% of cases exhibit loss of MTAP, creating a dependency on PRMT5 and a susceptibility to MTA-cooperative PRMT5 inhibitors. For preclinical drug discovery, the accurate prediction of drug exposure in the human CNS compartment is therefore of critical importance. This study evaluates the utility of preclinical models, specifically the monkey cerebrospinal fluid (CSF) model, alongside the physicochemical properties of compounds, including permeability and efflux characteristics, to predict free brain drug exposure in humans. The non-terminal monkey CSF model permits assessment of CNS penetration with minimal invasiveness. Complementary to this, as part of the 14-day terminal dose range finding toxicology studies, brain tissues were collected at necropsy to verify and correlate predicted brain penetration with actual exposure levels. Our findings demonstrate a strong correlation between CSF concentrations in the monkey model and free brain drug exposure, suggesting that incorporating these datapoints, in addition to optimizing permeability and efflux properties, enhances the reliability of CNS drug delivery predictions. This research highlights the importance of integrating non-terminal preclinical models and physicochemical analysis to improve the safety and efficacy of CNS-targeted therapeutics. In addition, utility of rodent terminal brain drug exposure models and the importance of deriving unbound free brain drug exposures will be discussed.

#464 Discovery and development of IST-477, a selective KAT6A histone acetyl transferase inhibitor and characterization of its anti-tumor efficacy in ER+ HER2- breast cancer and other tumor indications.

Roopa Rai[1], M.v. Sreedhara[2], Samir K. Pawar[3], Rahul R. Nagawade[3], Krishna A. Putta[2], Mahaboobi Jaleel[2], Jianhong Wang[1], Alison L. Hannah[1], **Leslie J. Holsinger**[1]

[1]Isosterix, Inc., San Carlos, CA,[2]Biology, Sai Life Sciences Limited, Medchal-Malkajgiri District Telangana, India,[3]Discovery Chemistry, Sai Life Sciences Limited, Medchal-Malkajgiri District Telangana, India

KAT6A and its paralog KAT6B are histone acetyltransferases (HATs) which direct chromatin structural rearrangement and subsequent changes in gene transcription through acetylation of histones, primarily specific lysine residues on histone H3. Dysregulation of this epigenetic target is known to drive gene expression and tumorigenic progression in cancers and is commonly amplified at the genomic level and/or overexpressed in a number of solid tumors. An inhibitor of KAT6A and KAT6B, PF-07248144, has entered phase 2 clinical studies with durable partial responses reported in estrogen-receptor positive (ER+) HER2- breast cancer patients who had progressed on a prior endocrine therapy and CDK4/6 inhibitor (Mukohara et al, 2024, Nature Medicine 30:2242). In addition to estrogen receptor expression, transcriptional regulation of other pathways involved in tumorigenesis is known to involve KAT6A, expanding the potential for KAT6A inhibitors to be used in other indications.

Isosterix has developed a series of structurally diverse small molecule KAT6 inhibitors which are potent and selective for the KAT6A paralog. Potency directed to the KAT6A paralog is believed to offer the potential for reduced off-target toxicity. Lead optimization led to a clinical development candidate IST-477, which has entered IND-enabling studies. IST-477 inhibits KAT6A-mediated histone acetylation in a variety of tumor cell lines. It reduces cell proliferation and is additive when treated in combination with CDK4/6 inhibition. Excellent anti-tumor potency has been achieved in ER+ HER2- CDx and PDx breast cancer models with this KAT6A-selective inhibitor. IST-477 has high aqueous solubility, good PK properties, including %F>50 in mice/rats/dogs with an estimated clearance of 0.26 mL/min/kg and half-life of 10.2 hours in humans, predicted by multi-species allometric scaling. Early repeat-dose toxicology studies indicate excellent tolerability.

Efficacy of IST-477 in pharmacology models outside of breast cancer support clinical investigation of this therapeutic in other indications. IST-477 demonstrates single-agent efficacy in a number of solid tumor models including an ovarian CDx and an esophageal PDx tumor model. Pharmacologic efficacy of this targeted therapeutic will be discussed with an analysis of the relationship to KAT6A and 6B expression in these models. All IND-enabling studies to support clinical progression of IST-477 are planned for completion in mid-2025.

#467 Programmable transcription factors as protein adjuvants for cancer immunotherapy.
Nicholas Truex

University of South Carolina, Columbia, SC

Immunotherapies are transforming clinical oncology by exploiting immune pathways to improve cancer treatment outcomes and provide long-term remission. Anticancer immune pathways are typically activated with dose regimens of antibodies, engineered cytokines, salt or oil emulsions, oligonucleotides, or lipid nanoparticles, which ultimately induce transcription and translation of interferon-stimulated genes that instruct the immune system to respond to tumors. These and other molecular adjuvants are widely used to stimulate broad inflammatory signals but are also associated with abnormal cytokine expression levels and tissue toxicity. To address the challenge of nonspecific activation and to improve antitumor immunity, our group is developing artificial transcription factor (ATF) proteins as a generalizable technology platform to target and control specific immune signaling pathways. This presentation will describe the design and characterization of these ATF proteins, including biophysical, biological, and antitumor properties, and demonstrate their therapeutic potential as gene- and protein-based adjuvants for cancer immunotherapy.

#468 A novel gene therapy approach for treating prostate cancer through the overexpression of mutant androgen receptor.
S.-h. Jeong, S. Hong, H. Yuk, C. Kwak;
Seoul National University, Seoul, Korea, Republic of

Prostate cancer is the second most common cancer in men and one of the leading cause of cancer related death. In metastatic prostate cancer androgen deprivation therapy (ADT) is the main treatment strategy. However within one to two years it progresses into castration resistant prostate cancer (CRPC) through various mechanisms including androgen receptor (AR) mutations and splicing variants. In this study we produced non-functioning AR gene incorporated into plasmid vector enabling constant amplification in mammalian cells. The reconstructed plasmid was encapsulated within PLGA nanoparticle which harboring PSMA antibody on its surfaces through PEGylation. The therapeutic effect of non-functioning AR amplification was evaluated in this study We developed AR gene sequence with 3 base pair deletion in DNA binding domain which confers non-functioning AR. The mutated AR was incorporated into plasmid vector under CMV promotor which enables constant amplification of non-functioning AR in mammalian cells. To enhance the delivery of the reconstructed plasmid to prostate cancer cells, PLGA nanoparticle was utilized. PLGA nanoparticle was PEGlyated with PSMA antibody on its surfaces. The reconstructed plasmid was contained in PSMA-PLGA nanoparticle (mAR-PSMA-PLGA). Prostate cancer celling 22Rv1 was used for the experiment and enzalutamide resistant 22Rv1 (EnzR-22Rv1) was produced through serial treatment of enzalutamide on 22Rv1 cells. Xenograft prostate cancer model was developed using nude mice and treatment effect was evaluated We confirmed the specificity of PSMA-PLGA nanoparticle on prostate cancer cells. When LNCaP prostate cancer cells were co-cultured myoblast cells, GFP producing PSMA-PLGA nanoparticle was treated. Only LNCaP cells were positive for GFP signal which means that PSMA-PLGA nanoparticle attaches to prostate cancer cells specifically. 22Rv1 cells were treated with mAR-PSMA-PLGA and showed constantly enhanced non-functioning AR production without activating subsequent genes including IGF1 and PSA. The mAR-PSMA-PLGA also suppressed proliferation of 22Rv1 and EnzR-22Rv1 cells. Furthermore in xenograft model using EnzR-22Rv1, mAR-PSMA-PLGA reduced tumor growth significantly and reversed enzalutamide resistance showing synergistic effect with enzalutamide treatment. PSMA-PLGA nanoparticle system efficiently deliver reconstructed plasmid in vitro and in vivo which enabling targeted gene therapy. Amplification of non-functioning AR using mAR-PSMA-PLGA significantly suppress tumor growth and diminishes enzalutamide resistance.

#469 Bladder cancer gene therapy via Nectin-4-targeted PLGA nanoparticles delivering CRISPR/Cas9 for double-strand break induction.

Seung-hwan Jeong, Seokbong Hong, Hyeong Dong Yuk, Cheol Kwak

Urology, Seoul National University, Seoul, Korea, Republic of

Nectin-4-targeted antibody-drug conjugates (ADCs) linked with monomethyl auristatin E (MMAE) have revolutionized the treatment paradigm for metastatic bladder cancer. In combination with pembrolizumab, this therapy has doubled overall survival compared to conventional platinum-based chemotherapy. However, challenges such as drug toxicity and the accumulation of resistance to MMAE limit its therapeutic potential. In this study, we introduce a novel Nectin-4-targeted gene therapy strategy employing the CRISPR/Cas9 system. This advanced gene-editing tool, known for its precise induction of double-strand DNA breaks, was adapted to create over 50 random double-strand breaks (referred to as MT50) in target cells, leading to apoptotic cell death. To address the critical challenge of delivering gene-editing tools efficiently and specifically to cancer cells, we developed a highly efficient nucleic acid encapsulation system with poly(lactic-co-glycolic acid) (PLGA) nanoparticle. This platform demonstrated high nucleic acid encapsulation efficiency, exceeding 60% for plasmids (~1 kb) and 80% for shorter RNAs, such as siRNA. The system was further optimized for encapsulating CRISPR/Cas9 components, including guide RNA (gRNA) and Cas9 mRNA. The T24 bladder cancer cell line, characterized by high Nectin-4 expression, was used as the experimental model. In vitro experiments demonstrated that MT50 delivery via Nectin-4-conjugated PLGA nanoparticles inhibited cellular proliferation by over 70%. In vivo, the nanoparticles were administered systemically through intraperitoneal injection into a murine model bearing T24 bladder cancer tumors. Tumor volume decreased by 70% following MT50 treatment, with significant downregulation of Nectin-4 expression observed in treated tumors compared to controls. While this experiment was conducted in immunocompromised mice, precluding the assessment of immunogenic cell death or synergistic effects with immune checkpoint inhibitors, we anticipate enhanced anti-tumor efficacy in immunocompetent models. Specifically, combining MT50 treatment with immune checkpoint inhibitors is expected to amplify therapeutic outcomes. This study highlights the successful development of a Nectin-4-targeted PLGA nanoparticle system capable of efficiently encapsulating and delivering CRISPR/Cas9 components to bladder cancer cells. The MT50 delivery system demonstrated significant anti-tumor effects both in vitro and in vivo, offering a promising alternative to MMAE-linked ADCs. By circumventing cumulative resistance and leveraging the precision of gene editing, this approach has the potential to redefine bladder cancer therapeutics.

#47 Optimizing in vivo establishment of hormone receptor-positive breast cancer patient-derived xenografts for therapeutic assessment.

Abigail M. Fielder, Manohar Ratnam, Lisa Polin, Julie Boerner, Seongho Kim, Kristen Purrington

Oncology, Wayne State University School of Medicine, Detroit, MI

Patient-derived xenograft (PDX) models are invaluable tools for studying the heterogeneity of primary human tumors and preclinical drug responses. However, traditional PDX models for estrogen receptor-positive (ER+) breast cancer face notable challenges. These models involve implanting tumor tissue into mice with the aim of achieving tumor "engraftment," a process that typically requires 2 to 6 months and often longer for the tumor to grow to a size adequate for passaging. This extended timeframe, combined with the relatively indolent and less aggressive nature of hormone receptor-positive (HR+) breast cancers, results in lower success rates for tumor engraftment and passage. Additionally, these slow-growing tumors are prone to clonal selection during long-term growth, further reducing the utility of traditional PDX models for timely therapeutic studies. To address these challenges, we developed a streamlined PDX model optimized for HR+ breast cancer. Tumors were resected from deidentified patients at Karmanos Cancer Institute meeting specific eligibility criteria: ER or PR-positive, HER2-negative, and no prior neoadjuvant or endocrine therapy. Tumor specimens were aseptically implanted into the mammary fat pads of female SCID mice, which were supplemented with slow-release estradiol pellets to maintain estrogen levels. Tumor growth was monitored using caliper measurements, and tumor presence and vascularization were confirmed at 14 days post-implantation using Susceptibility Weighted Imaging (SWI). Following confirmation of tumor establishment, mice were randomized into two groups: a Tamoxifen-treated cohort (100 mg/kg orally for three days) and an untreated control group. Tumors were subsequently harvested for molecular and histological analyses. Our preliminary findings indicate that tumor engraftment and vascularization can be reliably achieved within two weeks, supporting the feasibility of this approach for time-sensitive therapeutic studies. Importantly, tumors remained present following treatment, providing adequate samples for downstream analyses after the experiment. This model circumvents many limitations of traditional PDX systems, including slow tumor growth and clonal selection, while providing a practical platform for studying endocrine therapy responses in HR+ breast cancer. By minimizing reliance on long-term engraftment and optimizing conditions for short-term assessment, this refined system holds promise for advancing translational research and improving preclinical evaluations of HR+ breast cancer therapies.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Gene and Vector-Based Therapy

#470 Appropriateness of long-term culture of patient-derived tumor organoid for colorectal cancer modeling through genetic and phenotypic profiling.

Jaemin Cho[1], Eun Ah Jung[2], Hyowon Hong[3], Sang Joon Byun[4], Sung Wook Bae[5], Inchul Seo[6], Jumgsook Ha[7], Hyewon Lee[1], Shin Kim[1]

[1]Pathology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[2]Anatomy, Keimyung University School of Medicine, Daegu, Korea, Republic of,[3]Research Affairs, Keimyung University School of Medicine, Daegu, Korea, Republic of,[4]radiation omcology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[5]colorectal surgery, Keimyung University School of Medicine, Daegu, Korea, Republic of,[6]immune, Keimyung University School of Medicine, Daegu, Korea, Republic of,[7]Laboratory Medicine, Keimyung University School of Medicine, Daegu, Korea, Republic of

Background and Objective: Colorectal cancer (CRC) is one of the leading causes of cancer-related morbidity and mortality worldwide, requiring effective disease models to study its progression and develop novel therapeutics. This study aimed to establish a long-term patient-derived tumor organoid (PDO) model and evaluate its suitability for colorectal cancer modeling through comprehensive genetic, morphological, and molecular analyses.
Methods: PDOs were cultured for 1, 3, and 6 months to mimic the progression of CRC. Chromosomal instability was assessed using karyotyping, and morphological changes were evaluated through hematoxylin and eosin (H&E) staining and bright-field imaging. Immunofluorescence staining was performed for the colorectal stem cell marker LGR5 and the epithelial differentiation marker CDX2, which is specifically expressed in the small intestine and colon epithelium and plays a key role in epithelial growth and differentiation. Temporal changes in genetic instability, structural characteristics, and marker expression were analyzed to validate the model.
Results: Karyotyping revealed a progressive increase in chromosomal instability across the 1-, 3-, and 6-month PDOs, consistent with CRC-associated genetic alterations. Morphological analysis using H&E staining and bright-field imaging demonstrated gradual structural changes, with the 6-month PDOs displaying histological features characteristic of CRC. Immunofluorescence staining showed a decline in LGR5 expression over time, reflecting reduced stemness in advanced stages, while CDX2 expression was maintained across all time points, indicating its critical role in epithelial differentiation during cancer progression.
Conclusion:The long-term PDO-based model successfully recapitulates the genetic, morphological, and molecular hallmarks of colorectal cancer progression. This model captures key transitions, including chromosomal instability, structural alterations, and dynamic marker expression, while retaining essential epithelial markers like CDX2. These findings underscore the potential of PDOs as a robust in vitro platform for studying colorectal cancer development and progression and advancing therapeutic research.

#471 CRISPR-Cas9 as a novel cancer gene therapy approach against pancreatic cancers.

Selina Shiqing K. Teh, Akhil Kotwal, Kirsten Bowland, Alexis Bennett, Eitan Halper-Stromberg, Laura Morsberger, Sarah Wheelan, Nicholas J. Roberts, Chien-Fu Hung, Michael Goldstein, Ying S. Zou, James R. Eshleman

Johns Hopkins University School of Medicine, Baltimore, MD

Pancreatic cancer (PC) is the third leading cause of cancer deaths in US with a 5-year survival rate of 13%. Most patients are diagnosed at advanced stages, and conventional treatments remain ineffective and highly toxic to these patients as both chemotherapy and radiation affect normal, healthy cells, leading to adverse side effects. We have adapted CRISPR-Cas9 as a cancer-specific killing strategy that spares normal cells. CRISPR-Cas9 is a molecular scissor that induces DNA double strand breaks (DSBs) at its targeted genomic locations. We use CRISPR-Cas9 to target the subset of somatic mutations that create protospacer adjacent motifs (PAMs). Using *S. pyogenes* Cas9 that recognizes a 5'-NGG-3' PAM, we identified somatic single base substitutions (SBSs) that give rise to novel PAMs (e.g. NCG→NGG), and use the upstream sequence to design sgRNAs for cancer-targeting. We have discovered that ~13% of SBSs in PC form novel PAMs, and these cancer-specific sgRNAs exhibited on-target activity and lack of off-target events. Notably, while examining WGS data from rapid autopsy samples, we found that 90% of PAMs were maintained among primary carcinomas and metastases. Using multi-target sgRNAs targeting 2-16 sites in the non-coding regions of human genome, we demonstrate a dose-response relationship in which >10 target sites are required to achieve >99% cell elimination. Moreover, we established that simultaneous induction of multiple DSBs by CRISPR-Cas9 causes extreme chromosomal instability that ultimately leads to cell death. We detected massive chromosomal aberrations, including dicentrics, ring chromosomes, and polyploidization. Surprisingly, CRISPR-Cas9-induced DSBs are significantly more cytotoxic in PCs than a comparable number of radiation-induced DSBs, in which the number of DSBs required to achieve equitoxic effects was ~3 times higher for radiation than CRISPR-Cas9. Finally, we have developed a pipeline to screen for the most toxic sgRNAs in a given PC for selective killing. Using our PAM-based approach, we identified >100 Panc10.05-specific sgRNAs that have no off-target activity at 0- and 1-mismatch sites. We cloned them into lentiviral vectors and transduced in bulk, followed by NGS to discover sgRNAs that decreased in representation in the targeted cell line but not in the controls. We selected the top sgRNAs that have 100% variant allele frequency (VAF), cloned 4 of them into a multi-sgRNA expression vector, and transduced it into co-cultures consisting of two PC cell lines. Greater than 85% selective reduction of the targeted cell line was detected. Then, we selected nine top sgRNAs, transduced them as a pool into Panc10.05 cell line, and injected these cells into athymic, nude mice for tumor growth. We observed >90% tumor growth inhibition with these cancer-specific sgRNAs. Overall, our study highlights the therapeutic potential of CRISPR-Cas9 as an anti-cancer strategy and supports the genetic targeting of PCs.

#472 A simple, rapid, and robust bioluminescent assay for detecting anti-AAV neutralizing antibodies in serum samples.

Morten Seirup, Trish Hoang, **Jeff Nelson**, Brock Binkowski, Marjeta Urh

Promega, Madison, WI

Adeno-associated viruses (AAVs) are widely used as vectors in gene therapy, including for the delivery of therapeutic genes in cancer treatments. In the context of cancer therapeutics, AAVs can be engineered to deliver tumor-suppressing genes or immune-modulating factors directly to cancer cells, enhancing the efficacy of immunotherapy and oncolytic strategies. However, these treatments can be compromised by pre-existing neutralizing antibodies (NAbs) in human serum. To address the need for a sensitive and efficient screening method, we present a novel cell-based transduction inhibition (TI) assay using NanoLuc luciferase, an engineered enzyme known for its high brightness and stability. This assay enables rapid and sensitive detection of NAb activity, utilizing low multiplicities of infection (MOI: 100-10,000) and incubation times as short as 4 hours. Our workflow employs a straightforward add-mix-read format with a luminescent detection reagent, facilitating luminescence measurements with high reproducibility and minimal hands-on time. The assay's ability to tolerate high serum concentrations, allowing dilutions as low as 1:3, significantly enhances sensitivity for detecting neutralizing activity. Comparative analysis with firefly luciferase demonstrated that NanoLuc produces over 700-fold brighter signals, providing superior detection at lower MOIs. We validated the assay using HEK293 cells, achieving consistent intra-assay variability (%CV <18%) and precise neutralizing dose (ND50) determinations in a 3-fold dilution series of 60 human serum samples. Single-dilution screening highlighted the impact of serum dilution on hit rates, while robust 4-parameter logistic (4PL) curve fitting enabled reliable ND50 determinations for 28 of the tested samples. The assay’s simplicity, high sensitivity, and rapid turnaround make it an invaluable tool for the preclinical and clinical evaluation of NAbs against AAV serotypes, thereby supporting patient eligibility assessments and therapeutic development. These findings underscore the NanoLuc-based assay as a transformative solution for advancing AAV-based gene therapy, particularly in the realm of cancer therapeutics, where precise and rapid NAb screening is crucial for successful treatment outcomes.

#473 Inhibition of SUMOylation reverses T-cell metabolic exhaustion in large B-cell lymphoma.

Joseph Lownik, Larry Milshteyn, Anton Villamejor, Akil Merchant

Cedars-Sinai Medical Center, Los Angeles, CA

Immune based therapies for large B cell lymphoma (LBCL) have transformed our approach to this disease. Therapies such as CD3 bispecific T cell engagers and chimeric antigen receptor (CAR) T cells, have diverse mechanisms of action, yet they all depend on activation of T cells to affect an anti-cancer response. While the often-dramatic responses seen to immune therapies have captured wide-spread attention, the majority of patients treated with immune based therapies for relapsed lymphoma will not achieve long term cure, and poor T cell function is a common mechanism for treatment failure. Several seminal studies have identified T-cell metabolic reprogramming as a key mechanism behind T-cell exhaustion. Mechanisms to reverse metabolic exhaustion and reinvigorate T-cells has been shown to lead to increased anti-tumor responses. Small ubiquitin-like modifiers (SUMO) proteins regulate a variety of cellular processes in tumor and immune cells. Inhibitors of SUMOylation (SUMOi) have shown anti-tumor activity in a CD8 T-cell dependent manner, however, the mechanism behind this T-cell dependence is unknown.

We show that a novel covalent SUMOi, SB-4826 leads to a robust anti-tumor response which is dependent on CD8+ T-cells in lymphoma. Using single cell metabolic studies, we demonstrate that SUMOi increases the metabolic rate, glycolytic dependency and proliferative capacity of tumor infiltrating PD1+ CD8+ T cells. We further show that SUMOylation is increased following T-cell activation, and exhausted CD8+ TILs have the highest levels of total SUMOylation of T-cell subsets. We validate these findings of increased SUMOylation in CD8+ TILs in human lymphoma samples. In a CD19 CAR T-cell model, we show that pulse treatment of CAR T-cells with SUMOi leads to enhanced anti-lymphoma activity in vitro.

Using a mass-spectroscopy/immunoprecipitation approach, we identified more than 1,000 proteins which are SUMOylated in T-cells. We found that multiple T-cell transcriptional regulators, including TBET, LEF1 and TCF1 are all SUMOylated either during a resting or activation state in CD8+ T-cells. Together, these findings suggest a novel role for SUMOylation in regulating T-cell effector activation and exhaustion, by modulating metabolic state likely through the regulation of key transcriptional T-cell programs.

#474 IL-12 immunotherapy using a novel gene delivery platform for RNA payloads achieves effective antitumor responses without systemic toxicity in an aggressive CT26 murine cancer model.

Laura Strauss[1], Carli Jones Burns[1], Akihito Inagaki[1], Stephanie Lees[2], Noriyuki Kasahara[3], Cecilia Roh[2], Robert G. Johnson[1]

[1]Pre-Clinical Immuno-Oncology, GenVivo, Inc., San Marino, CA,[2]R&D, GenVivo, Inc., San Marino, CA,[3]Brain Tumor Center, UCSF, San Francisco, CA

Background: IL-12 exhibits potent anti-tumor properties, which enhance cytolytic activity and tumor infiltration of natural killer (NK) cells and cytotoxic T lymphocytes (CTLs) and activates Th-1-type immune responses [1-2]. However, systemic administration of recombinant IL-12 protein is still a challenge due to serious toxicity resulting from interferon (IFN)-γ overproduction [3-5]. Viral and non-viral vectors for IL-12 gene therapy represent an alternative therapeutic strategy, which can be combined with pro-drug activated cancer killing gene therapy approaches. Combined gene delivery of IL-12 and herpes simplex virus thymidine kinase (HSV-TK) significantly boosts anti-tumor efficacy in animal studies and has been shown to be safe in human clinical studies when administered intratumorally [6-12]. Here we present a novel gene therapy approach for *in vivo* gene delivery of IL-12 combined with an enhanced gain of function-variant of HSV-TK (v-eTK).

Methods: Non-replicating retrovectors encoding murine IL-12 only (mGEN1018, encoding both p35 and p40 subunits, as described previously [13-14], or in combination with v-eTK (mGEN1013), were administered intratumorally or systemically to a subcutaneous tumor model of CT26 murine colorectal cancer in syngeneic BALB/c mice. Mice receiving mGEN1013 were subsequently treated with Ganciclovir (GCV) pro-drug. General health and body weight as well as tumor growth and survival were monitored over time, and immunophenotyping of peripheral blood, spleen, and tumor-infiltrating immune cells was performed.

Results: Our data show that in subcutaneous CT26 tumor models, intratumoral and systemic gene delivery of IL-12 by the mGEN1018 vector induces both local and systemic anti-tumor immune responses primarily by stimulating production of IFN-γ from NK cells and CTLs. Gene delivery of IL-12 in combination with v-eTK by the mGEN1013 vector followed by GCV pro-drug showed enhanced tumor growth inhibition and increased survival compared to untreated controls. Systemic anti-tumor effects of IL-12 gene therapy were not associated with visible signs of toxicity or significant body weight loss.

Conclusion: Gene delivery of v-eTK followed by GCV treatment results in tumor cell lysis and exposure of tumor antigens, while simultaneously, IL-12 gene delivery enhances anti-tumor immune responses though upregulation of inflammatory cytokines. These results show the potential of mGEN1013 as a novel RNA payload delivery platform for combined GCV pro-drug and more effective tumor-localized IL-12 immunotherapy without systemic toxicity.

#475 Autophagy inhibition enhances the antitumor effect of p53-armed oncolytic virotherapy against pancreatic cancer.

Yosuke Takahashi[1], Hiroshi Tazawa[1], Satoru Kikuchi[1], Shinji Kuroda[1], Yasuo Urata[2], Shunsuke Kagawa[1], Toshiyoshi Fujiwara[1]

[1]Gastroenterological Surgery, Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan,[2]Oncolys BioPharma, Inc., Tokyo, Japan

Background: Autophagy is a survival mechanism that transports intracellular materials to lysosomes for degradation to provide energy or macromolecular precursors in response to cellular stresses such as hypoxia or starvation. Pancreatic ductal adenocarcinoma (PDAC) is characterized by high levels of autophagy, which plays a crucial role for cancer survival. Recently, autophagy has been shown to promote immune evasion by lysosomal degradation of MHC-1 expression and has been proposed as a therapeutic target in combination with immunotherapy. We have previously developed OBP-702, a tumor-specific replication-competent oncolytic adenovirus expressing the p53 tumor suppressor gene and demonstrated that OBP-702 exhibited direct cytotoxicity via p53-mediated induction of apoptosis and indirect immune activation via p53-mediated enhancement of immunogenic cell death (ICD). In this study, we examined the therapeutic potential of autophagy inhibition on the cytotoxicity and ICD of OBP-702 and MHC-I expression in PDAC cells.
Methods: Murine PDAC cell line PAN02 was used in this study. The cytotoxic activity of autophagy inhibitor, chloroquine (CQ), and OBP-702 in monotherapy and combination therapy was analyzed using XTT assay. The combination index was calculated using CalcuSyn software. The apoptosis-inducing effect of CQ and OBP-702 in monotherapy and combination therapy was analyzed using apoptosis assay. The effect of CQ on virus-induced cell death and the molecular mechanism were investigated by Western blot analysis. The levels of extracellular ATP as ICD marker were analyzed following OBP-702 infection with or without CQ using ELISA assay. We further analyzed whether CQ enhances the expression level of MHC-1 by FACS analysis.
Results: CQ and OBP-702 suppressed the viability of PAN02 cells in a dose-dependent manner. The calculation of combination index demonstrated that combination of CQ and OBP-702 showed profound synergistic effect, in which CQ enhanced the apoptosis-inducing effect of OBP-702. Moreover, CQ increased the levels of extracellular ATP followed by OBP-702 infection, suggesting that CQ enhances OBP-702-mediated ICD induction. CQ also increased the expression level of MHC-I on PAN02 cells.
Conclusions: Our data suggest that autophagy inhibition by CQ enhances the induction of apoptosis and ICD by OBP-702 and the level of MHC-I expression on PDAC cells, probably promoting the antitumor immune responses against PDAC cells. Therefore, we are currently evaluating the combined effect of CQ and OBP-702 using the syngeneic PAN02 subcutaneous tumor models.

#476 *In vivo* CD47-mediated targeted oligonucleotide delivery for endolysosomal escape in cancer treatment.

M. Jo[1], Y. Jeong[1], Y. Kim[2], S. Song[2], H. Joo[3], Y. Choi[2], I. Lee[2], M. Kwon[1], G. Kim[2], I.-S. Kim[3], G.-H. Nam[1];
[1]Korea University, Seoul, Korea, Republic of, [2]SHIFTBIO INC., Seoul, Korea, Republic of, [3]KU-KIST Graduate School of Converging Science and Technology, Korea University, Seoul, Korea, Republic of

Therapeutic oligonucleotides, such as small interfering RNAs (siRNAs) and antisense oligonucleotides (ASOs), hold promise for suppressing pathogenic genes, including mutated KRAS, a key driver in many cancers. However, their systemic administration is challenged by rapid degradation and poor cellular uptake. Existing delivery systems, like lipid nanoparticles, face limitations in safety, extrahepatic delivery, and evading endolysosomal degradation. To address these limitations, we developed and evaluated an extracellular vesicle (EV)-based delivery platform for CD47-mediated oligonucleotide delivery *in vivo*. EVs, known for their biocompatibility, were engineered to display the SIRPα membrane protein on their surface, creating CD47-targeting SIRPα-EVs (S-EVs). These S-EVs were designed to preferentially accumulate in CD47-overexpressing pathological tissues, such as inflamed and tumor sites, as confirmed by *in vivo* imaging systems, flow cytometry, and intravital live imaging. To ensure consistent oligonucleotide encapsulation and batch-to-batch stability, we employed a cholesterol-based exogenous loading technique. Mechanistically, S-EVs entered target cells through CD47-mediated endocytosis, bypassing endolysosomal degradation and delivering oligonucleotides efficiently. Our results demonstrated that S-EVs accumulated selectively in CD47 overexpressing tissues and delivered oligonucleotides more efficiently than lipid-based transfection reagents or naïve EVs, significantly enhancing therapeutic efficacy. When administered systemically in an LPS-induced inflammatory model, S-EVs loaded with NLRP3-ASOs effectively reduced inflammation, outperforming naïve EVs. In a KRAS-mutated tumor model, KRAS siRNA-loaded S-EVs (siKRAS-S-EVs) suppressed KRAS expression in tumor tissues and increased $CD8^+$ T cell infiltration into the tumor microenvironment, demonstrating significant antitumor effects. When combined with PD-1 blockade therapy, siKRAS-S-EVs led to substantial survival improvements, with 60% of treated animals achieving complete tumor remission. These findings emphasize the advantages of CD47-mediated EV delivery, enabling selective targeting of pathological tissues and efficient intracellular delivery of therapeutic oligonucleotides by bypassing endolysosomal degradation. This study highlights the potential of EV-based CD47-mediated delivery platforms as next-generation systems for treating cancers and other CD47-overexpressing diseases, addressing the limitations of current therapeutic approaches.

#477 The Nanoprimer: Overcoming the liver challenge to increase the efficacy of IV-administered biologic therapies.

matthieu Germain, Julie Devalliere, Laurence Poul, Maxime Bergere, Francis Mpambani, Andromeda Savari

Nanobiotix, Paris, France

Despite progress in the design of therapies administered by intravenous (IV) route, the liver remains one of the main challenges for treatment delivery. The hepatic clearance is responsible for the low delivery of treatment to the target site and the limited efficacy outcome. Moreover, the unintended liver distribution could cause harmful side effects. Curadigm's innovative Nanoprimer technology aims to shift the balance of therapeutic agents' bioavailability and toxicity. The platform is designed to decrease therapeutic agents' liver trapping, to increase their systemic bioavailability for optimal accumulation in target tissues. This technology has the potential to redefine the benefit/risk ratio of drugs, improving their clinical outcomes and treatment value. The Nanoprimer is an engineered, biocompatible liposome that transiently and specifically occupies the liver clearance pathways responsible for sub-optimal therapeutic bioavailability. The Nanoprimer is administered just before the treatment. By interacting specifically with the receptors of the mononuclear phagocytic system cells, the Nanoprimer enables a temporary reduction of the drug clearance. Multiple proofs of concept were realized, showing the ability of the Nanoprimer to improve the efficacy of different natures of treatments including nanomedicines such as irinotecan-loaded liposomes and nucleic acid-loaded lipid nanoparticles in various therapeutic areas. Evaluation of the Nanoprimer has now been extended to biologic therapies: - Protein-based therapy: E. Coli asparaginase is used to treat Acute Lymphoblastic Leukemia (ALL). This protein depletes asparagine from the blood leading to tumor cell death since they are not able to synthetize this amino acid contrary to healthy cells. Bioavailability evaluation performed on a mouse model showed that the Nanoprimer increases by 3-fold the systemic bioavailability of the asparaginase. Adding the Nanoprimer in ALL treatments could allow a decrease of the number of asparaginase injections, potentially reducing the related toxicity for the same efficacy. - Oncolytic viruses: The use of oncolytic viruses by IV route is highly limited by the liver that removes up to 90% of the administered dose. In a collaborative study, we evaluated the impact of the Nanoprimer on the biodistribution of a herpes simplex virus-1 in a mouse model xenografted with a B-16 tumor model. The addition of the Nanoprimer led to a 10-fold increase in the viral copy number in the tumor, opening perspectives for cancer treatment by IV route administered oncolytic viruses. Altogether these data demonstrate that the ubiquitous mode of action of the Nanoprimer allows its application to a broad spectrum of drugs ranging from nanomedicine to biologic therapies.

#478 Engineering viruses for the next generation targeted cancer therapy.

Ikeda Trashi[1], Jeremiah Gassensmith[2]

[1]University of Texas at Dallas, Richardson, TX,[2]University of Texas at Dallas, Richardson, TX

The development of targeted therapies, including monoclonal antibodies, CAR-T cells, nanobodies, and combination treatments, has significantly advanced cancer management, particularly for HER2-positive tumors. Despite these advancements, challenges such as instability, high toxicity, immune responses, rapid clearance, drug resistance, and exorbitant manufacturing costs persist. A major contributor to these costs is the reliance on mammalian cell systems for production. Additionally, minimizing off-target effects remains a critical concern for targeted therapies.

In this study, we engineered virus-like particles (VLPs) to selectively target HER2-positive tumors with minimal off-target effects. These VLPs were further designed to carry genetically expressed RNA interference (RNAi) systems for in situ gene silencing. Cryo-electron microscopy (Cryo-EM) was employed to characterize the functionalization of the VLP exterior and verify the packaging of the RNAi cargo. This novel single-cell approach combines targeted tumor homing with siRNA delivery, enabling simultaneous tumor targeting and silencing of the PDL1 gene. The multivalent nature of VLPs allows for the incorporation of multiple peptides, enhancing tumor affinity and specificity. With a size of approximately 35 nm, VLPs exhibit favorable pharmacokinetics, including reduced clearance and effective tumor homing. A key advantage of our approach is the ability to express VLPs in Escherichia coli systems, significantly reducing production costs compared to traditional mammalian cell-based systems, making the therapy more accessible.

Our findings demonstrate that intravenously administered HER2-targeting VLPs achieve high specificity and affinity for HER2-positive tumors. Once localized, the VLPs penetrate deeply into tumor tissue, delivering RNAi cargo to silence PDL1 expression. Light sheet microscopy will be used to visualize tumor architecture in three dimensions to further investigate tumor penetration, offering a more comprehensive view than traditional cryosections. By inhibiting tumor growth and recruiting immune cells, this approach offers a dual mechanism of action: direct tumor suppression and enhanced immune-mediated clearance. Furthermore, VLPs provide unique advantages such as efficient cell penetration, scalable production, and robust cargo delivery, positioning them as a promising platform for cost-effective and effective cancer therapies.

#479 Engineering LNP formulations for mRNA delivery to macrophages.

Yasir A. Alshehry, Raneem R. Aldaqqa, Matthew E. Fernandez, Asma M. Al-Terawi, Douglas H. Sweet, Sandro R.P. da Rocha

Department of Pharmaceutics and Center for Pharmaceutical Engineering and Sciences, Virginia Commonwealth University - VCU, Richmond, VA

Macrophages play a pivotal role in the microenvironment of solid tumors, contributing to cancer progression and metastases through various functions. mRNA technologies may afford opportunities to reprogram these cells towards an anti-tumorigenic phenotype for therapeutic interventions in cancer. This study focuses on optimizing lipid nanoparticle (LNP) formulations for mRNA delivery to macrophages. We first investigated the impact of six ionizable lipids, three helper lipids, and two sterols on the transfection efficiency of mRNA-LNPs in RAW264.7 macrophages in vitro. Among the ionizable lipids, SM-102 demonstrated the highest reporter protein expression, significantly outperforming other lipids except ALC-0315, with the ranking as follows: SM-102 > ALC-0315 = OF-C4-Deg-Lin > CL1 > cKK-E12 > MC3. For helper lipids, DOPE yielded higher protein expression compared to DSPC and 9A1P9, though the difference was not statistically significant relative to DSPC. Among the sterols tested, increasing the proportion of β-sitosterol in β-sitosterol:cholesterol mixtures resulted in a corresponding increase in protein expression. The formulation comprising SM-102, DOPE, and β-sitosterol emerged as the top candidate, surpassing formulations prepared with the same composition as commercially available LNPs, with a 700-fold and 250-fold increase in reporter luciferase (Fluc) and eGFP expression, respectively. We also evaluated the extent of particle internalization, which did not correlate with protein production. Our analysis revealed that nearly 100% of macrophages took up the LNPs with the optimum formulation within 4 hours, with the peak in protein expression observed at 24 hours post-transfection. To extend these findings, the optimum formulation was tested on murine bone marrow-derived monocytes differentiated into M0 [F4/80+], M1-like [F4/80+CD80+CD206-], and M2-like [F4/80+CD206+CD80-] macrophages, as well as RAW264.7 cells polarized into these same subtypes. The results confirmed the superior transfection efficiency of the optimum formulation across all tested phenotypes. To evaluate in vivo performance, we quantified the bioluminescence expression of Fluc mRNA in BALB/c mice following an intraperitoneal injection of 0.5 µg of the mRNA-loaded LNPs. Bioluminescence was measured 6 hours post-injection for whole-body imaging and organs *ex vivo*. The optimum formulation demonstrated efficient mRNA delivery without any observed toxicity. Organ distribution studies indicated accumulation of the LNPs in the liver and spleen. Overall, our findings demonstrate the significant effect of LNP formulation on its ability to transfect macrophages, achieving efficient transfection in M0, M1-like, and M2-like macrophage subtypes *in vitro* and effective mRNA expression *in vivo*. These results highlight the potential of optimized LNPs to advance macrophage-targeted mRNA therapies for the treatment of solid tumors.

TUMOR BIOLOGY: Human and PDX Models 1

#48 Enhanced patient derived xenotransplantation of TP53 mutant and splicing factor mutant acute myeloid leukemia in super immunodeficient NOG-EXL mice.

Tanmoy Sarkar[1], Sarah Skuli[1], Nicolas Skuli[1], Martin Keogh[1], Anthony Secreto[1], Moriah Jacobson[2], Martin Carroll[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]Taconic Biosciences, Inc., Rensselaer, NY

Xenotransplantation of acute myeloid leukemia (AML) cells is an established model for preclinical development and understanding of AML biology. AML xenotransplantation has been well characterized in highly immunocompromised NSG mice, but time to engraftment in this strain is often prolonged and some AML types engraft poorly. In particular, we have found that TP53 mutant AML and splicing factor mutant AML engraft poorly in NSG mice. Alternative mouse models are NSG-SGM3 (SGM3) and NOG-EXL mice, which combine severe immunodeficiency with transgenic expression of human myeloid stimulatory cytokines. However, the SGM3 strain is prone to highly variable time to and level of engraftment as well as spontaneous animal death. To address these concerns, we compared AML primary sample engraftment in the NSG, SGM3, and NOG-EXL. First, we studied overall survival in SGM3 mice compared to NOG-EXL mice engrafted with 4 separate AML's (n=5 per cohort). Consistent with previous results, 25% of SGM3 mice engrafted with AML became ill and required sacrifice approximately 5 weeks after injection. This did not correlate with the level of AML engraftment. In contrast, only one NOG-EXL mouse became ill during 12 weeks of observation. We next studied relative engraftment in all 3 strains of five TP53 mutant AML samples that had either previously not engrafted or engrafted poorly in NSG mice. We aspirated bone marrow on all mice five weeks after injection. Level of engraftment across strains varied from not detectable in NSG mice to over 80% in NOG-EXL and SGM3 mice. Mice were observed until symptoms of leukemia engraftment developed (42 to 77 days) at which time mice were sacrificed and analyzed for leukemic burden by measuring huCD45+huCD33+ cells in bone marrow and spleen. Interestingly, bone marrow burden increased in NSG mice over time although total mouse leukemic burden in NSG mice was consistently lower than in the SGM3 and NOG-EXL mice. Comparing leukemic burden in NOG-EXL to SGM3 mice showed a modestly higher leukemic burden in NOG-EXL at time of sacrifice. Human CD45+ and human CD33+ cell expression, as assessed by flow cytometry, were higher in SGM3 and NOG-EXL compared to NSG mice. We also found that splicing factor mutant AML engrafted poorly in NSG mice, and preliminary analysis suggests similar results with shorter time to engraftment and higher levels of engraftment in NOG-EXL and SGM3 mice. Again, no early deaths were seen in the NOG-EXL strain. Overall, these results support the hypothesis that the NOG-EXL strain is an improved strain for use in AML xenotransplantation compared to NSG and NSG-SGM3, with enhanced levels of engraftment without spontaneous mortality. Data on relative response to cytotoxic and venetoclax therapies is ongoing.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Gene and Vector-Based Therapy

#480 An engineered bacterial delivery platform, BacID, selectively delivers activated Caspase-3 into the cytoplasm of cancer cells, eliminating tumors and reducing metastatic burden.

Vishnu Raman[1], Christopher L. Hall[1], Victoria E. Wetherby[1], Neil S. Forbes[2], Nele Van Dessel[1]

[1]Ernest Pharmaceuticals, Hadley, MA,[2]University of Massachusetts, Amherst, Amherst, MA

Most cytotoxic therapies, either administered as a compound or incorporated as cargo into a targeted platform (nanoparticles, antibody drug conjugates etc.), only become effective after reaching the intended target inside the tumor cell cytoplasm. Intracellular targeting faces multiple challenges, including tumor-specific receptor-binding, crossing the cell membrane, and endosomal escape into the cytoplasm. Each of these limitations reduce tumor accumulation while increasing systemic toxicity of the drug. Here, we have created a clinically-ready, non-pathogenic strain of bacteria, BacID, that accumulates and grows exponentially in tumors. The bacteria have a 5,000-fold selectivity for tumors over healthy organs and enter into cancer cells without requiring any tumor-specific receptor engagement. Once intracellular, BacID lyse and deliver a cytotoxic payload into the cytoplasm. The resulting cell death creates an immunostimulatory microenvironment that facilitates tumor clearance. The BacID strain is engineered to be safe by attenuating the external lipopolysaccharide layer, flagella expression and utilizing the intracellular lysis system that enables both delivery inside cancer cells and autonomous clearance after treatment. The bacteria is well tolerated after systemic administration in mice. To target liver cancer and metastases, The BacID strain was engineered to deliver activated Caspase-3 (EBT-002) to cancer cells. After systemic administration, the bacteria colonize tumors and rapidly clear from healthy organs. Three days after injection, bacterial concentrations in tumors peak. At this point, aspirin is administered to activate expression of flagella and the type 3 secretion system, which triggers the BacID strain to invade cancer cells. After invasion, the bacteria enter a modified endosome within the cell, lyse, and deliver the activated Caspase-3 payload into the cytoplasm, inducing cell death. Delivery of Caspase-3 with BacID enables tumor clearance, in part, by activating a 12-fold increase in intratumoral innate immunity, followed by an adaptive immune response. EBT-002 also targets and eliminates liver and lung metastases of breast cancer as small as 100 µm in diameter. After systemic administration, EBT-002 reduces lung metastatic burden by over 80% compared to a standard-of-care chemotherapeutic regimen. The BacID platform enables delivery of several biological therapies selectively inside tumor cells due to the natural tumor tropism of the platform. Moreover, the BacID strain can express and deliver DNA, RNA and protein-based therapies into tumor cells without any need for tumor-specific receptor engagement due to the natural cell invasion mechanisms inherent to the platform. These qualities make the BacID platform a universal delivery vehicle to treat solid tumors.

#481 Development of a rapid method for the detection of neutralizing antibodies in sera of primates for viral gene therapy stratification.

Gregor Sommerkamp, Eva M. Egenter, Katharina Schaich, Daniel Feger, Sebastian Dempe, Jan E. Ehlert

Reaction Biology Europe GmbH, Freiburg, Germany

Gene therapeutical intervention using viral vectors is becoming increasingly relevant for the treatment of various diseases, including cancer. A critical factor for a successful viral therapy is that the patient has not previously developed neutralizing antibodies to the respective viral serotype in the context of a naturally occurring anti-infection immune response. Such antibodies would impose the risk to neutralize and thus jeopardize the intended therapeutic response. This is especially relevant in therapies with adeno-associated virus (AAV), as immunity against AAV-serotypes is very common. We here report on the development and validation of a straightforward method to functionally detect neutralizing antibodies in primate sera, employing a transduction method on a human cell line using AAVs of different serotype coding for an easily detectable transgene. The reported methodology will be helpful for the stratification of primates and patients exploiting their sera for the prevalence of neutralizing antibodies prior to the initiation of the AAV treatment. In addition, our assay has the potential to be applied to other viral treatment strategies also.

#483 RNA-missplicing dependent nucleic acid therapeutics for SF3B1-mutant cancers.

Benjamin G. Dubner[1], Jian Xiang Peng[2], Rebecca Foerstch[3], In-Young Choi[1], Panagiotis Tsakiroglou[1], Ilias Sinanidis[1], Fatemeh Rajaii[4], Ben Park[5], Jonathan Ling[6], William Dalton[1]

[1]Hematologic Malignancies, Johns Hopkins University School of Medicine, Baltimore, MD,[2]Duke University, Durham, NC,[3]Oregon Health & Sciences University, Portland, OR,[4]Ophthalmology, Johns Hopkins University School of Medicine, Baltimore, MD,[5]Vanderbilt School of Medicine, Nashville, TN,[6]Pathology, Johns Hopkins University School of Medicine, Baltimore, MD

Cancer therapies face the challenge of specificity-limiting toxicity to normal cells and maximizing it in malignant ones. The last two decades have seen significant advancements in therapeutics that increase specificity; however, these remain elusive for the many cancerous aberrations that affect nonenzymatic, intracellular proteins.

One such protein, SF3B1, mediates branch point selection in pre-mRNA splicing as part of the U2snRNP complex. Its mutation in various cancers-from hematologic malignancies to pancreatic carcinomas-creates conserved missplicing events, including alternative 3' splice acceptors, exon exclusion/inclusion, and intron retention. Here, we sought to create nucleic acid therapeutics that leverage missplicing to express targetable or intrinsically toxic cargo in SF3B1-mutant cancers.

We previously reported a highly specific missplicing event caused by mutant SF3B1: the inclusion of a cryptic exon in the UBA1 gene. Using a fragment containing this exon, we engineered a plasmid to switch between dsRed with canonical splicing and eGFP with cryptic splicing. We also created a splicing dependent iCaspase9 plasmid that induced mutant-specific cell death with transient transfection. However, when using more clinically relevant delivery with viral vectors, we discovered that expression was too low to produce a significant effect. We therefore engineered more efficient and potent plasmids that could induce toxicity even with low expression.

We first tested a variety of constitutive promoters driving expression of our fluorescent switch. Across separate transient transfections in triplicate, flow cytometry consistently showed that the promoter from human elongation factor 1 alpha (EF1a) resulted in the highest ratio of cryptic to canonical fluorescence.

In isogenic acute myeloid leukemia (K562) and uveal melanoma (Mel202) models, we further optimized plasmids with our synthetic UBA1 gene fragment and CD19 or diphtheria toxin A subunit (DTA) cargo. For CD19, we created a fusion of the CD44 signal peptide and CD19 extracellular domain that demonstrated high specificity for SF3B1-mutant clones through anti-CD19 staining and flow cytometry. For DTA, our plasmid with an attenuated version of the toxin induced statistically significant, highly mutant-specific cell death, both through transient transfection and delivery with adeno-associated viral (AAV) vectors.

Using the cryptic exon inclusion event from UBA1, we have selectively killed SF3B1-mutant cells in 2 distinct isogenic cell models *in vitro*. Next, we hope to further optimize plasmid delivery and splicing specificity, especially *in vivo*. While recent literature has shown the efficacy of a different cryptic intron inclusion event in inducing SF3B1 mutant-specific death, our approach may result in greater splicing specificity. Combined, our results underscore the promise of mutant-SF3B1-targeting nucleic acid therapies.

#484 Mechanisms of synergy between TGF-beta inhibitor and IL12 expression from the systemically deliverable clinical oncolytic immunotherapy VET3-TGI.

Steve Thorne

Kalivir Immunotherapeutics LLC, Pittsburgh, PA

Oncolytic vaccinia virus therapies actively recruit T-cells towards the tumor microenvironment. These can be combined with IL-12 expression to help enhance the immune response by stimulating Th1 cells. However, IL-12 mediated induction of IFN-gamma was also found to increase TGF-beta signaling within the tumor microenvironment.TGF-beta mediated resistance is one of the major mechanisms of immune suppression utilized across multiple solid tumor types. Blockade of TGF-beta (TGFBi) will therefore likely improve response to immunotherapy. Combining TGF-beta inhibition with IL-12 expression can maximize therapeutic benefits through simultaneously reducing immunosuppression and enhancing anti-tumor immune response. Current studies describe a vaccinia-based immunotherapy, VET3-TGI, combining enhanced systemic virus delivery to tumors and locally expressed IL-12 and TGFBi within the tumor microenvironment, for efficient control of multiple tumor models. *In vivo* mouse studies demonstrated potent therapeutic activity, including many CRs, even at doses several logs below equivalent clinical doses after systemic (intravenous) delivery. In addition, toxicity studies demonstrated the safety of VET3-TGI in mouse models. This data led to the selection of VET3-TGI as a lead clinical candidate and clinical testing has begun.

#485 Using the Celigo™ Image Cytometer for effectively screening rAAV gene delivery methods.

Mackenzie Pierce, **Yongyang Huang**, Bo Lin

Revvity Health Sciences, Inc., Lawrence, MA

To develop effective rAAV gene delivery vectors, scientists need to consider multiple elements, such as the promoter, insertion location, genetic target, and target gene to name a few. Green fluorescent protein (GFP), or other detection markers are often used to measure vector transduction and gene expression efficiency. Transduced GFP samples can be analyzed using fluorescent microscopy and flow cytometry, however, both methods can be quite time consuming, labor intensive, and lack high-throughput capabilities to kinetically monitor gene expression. In this work, we developed and employed the Celigo™ Image Cytometer to screen different gene delivery vectors by comparing GFP expression level in SupT1 cells at 24-, 48-, 72-, and 96-hours following transduction. Using the Celigo™ we were able to monitor transient and integrated GFP expression amongst multiple gene delivery vectors. For transient expression monitoring, SB-P-AA-101-07 displayed stronger expression levels at 24- and 48-hours. For integrated expression monitoring, both plasmid and rAAV with integration element exhibited over ~90%+ GFP transduction efficiency by 96-hours. In summary, the Celigo™ may prove useful for researchers developing and screening gene delivery vectors in a high throughput manner.

Note: SB-P-AA-101-07 (from Revvity Health Sciences, Inc.) is for research use only. Not for use in diagnostic procedures.

#486 Intratumor gene therapy designed to induce both local and systemic tumor directed immune responses.

Richard Heller[1], Loree C. Heller[1], Jody Synowiec[1], Julie Singh[1], Alex Otten[2], Mark J. Jaroszeski[2]

[1]USF Health Morsani College of Medicine, Tampa, FL,[2]Medical Engineering, University of South Florida, Tampa, FL

Immune checkpoint inhibitors (ICIs) have provided a major breakthrough for the treatment of multiple cancer types. While there have been significant clinical benefits, the therapy has been limited by both primary and acquired resistance. The immune state of the tumor microenvironment (TME) can play a significant role in ICI effectiveness. Modifying the TME to increase lymphocytic infiltrate and/or increasing expression of checkpoints can improve ICI efficacy. Multiple studies have been initiated to modify the TME to enhance the effectiveness of ICIs. We previously demonstrated that the intratumor delivery of a plasmid encoding interleukin-12 (pIL-12) resulted in a significant increase in T effector cells and a reduction in T regulatory cells and myeloid derived suppressor cells within the TME, inducing a robust systemic immune response when combined with ICIs. The key to make this an effective therapy is to deliver these agents in a manner that has minimal adverse and off target effects while still inducing the desired response. We have designed a novel approach to efficiently deliver multiple plasmids directly to solid tumors. The rationale was based on the premise that by performing intratumor delivery, stimulation would be directed against the specific antigens within the TME to produce an effective local response while stimulating a systemic response, resulting in an abscopal effect. This delivery utilizes a next generation electrotransfer device that enables the use of significantly reduced voltages and includes a means to monitor when successful delivery has occurred. We tested this concept in the B16.F10 mouse melanoma model. Intratumor delivery of pIL-12 resulted in effective control of the treated tumor in over 90% of the mice and generated resistance to challenge. To fully test this approach, we next evaluated a combination therapy delivering both pIL-12 combined with a plasmid encoding a PD1 peptide, an alternative form of checkpoint inhibitor. The therapy was tested in a multi-tumor model which included a subcutaneous tumor and intraperitoneal injection of tumor cells. The plasmids were delivered to the subcutaneous tumor; tumors generated by intraperitoneal injection were untreated. Peritoneal tumor growth was not affected by single plasmid delivery or when both plasmids were delivered using other delivery approaches or older electrotransfer technology. However, this new therapy induced complete regression of the subcutaneous tumor and blockage of peritoneal tumor growth as assessed via in vivo imaging. Work is ongoing to translate this approach to clinical evaluation.

[1]Biometric Research Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Rockville, MD,[2]Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD,[3]Biological Testing Branch, Developmental Therapeutics Program, National Cancer Institute at Frederick, Frederick, MD,[4]Advanced Development Research Directorate, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD,[5]Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD,[6]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD

Rare tumors are unique cancers that often present distinct biological behaviors and treatment responses. Researchers face significant challenges in the study of those tumors due to limited patient samples, lack of comprehensive genomic data, and difficulties in establishing appropriate preclinical models for effective drug testing. The identification of effective drug combinations for cancer treatment remains a major challenge, largely due to tumor heterogeneity and variable therapeutic responses. ATR is a key kinase involved in the DNA damage response. The combination of ATR inhibitors with temozolomide (TMZ) [ATRi+TMZ] enhances the cytotoxic effects of TMZ by targeting DNA damage response pathways, particularly in cancer cells with impaired DNA repair mechanisms, offering a promising therapeutic strategy for tumors resistant to conventional treatments. This study utilized gene expression profiling of 38 rare tumor patient-derived xenograft (PDX) models available in the NCI Patient-Derived Models Repository (PDMR) (https://pdmr.cancer.gov) to identify potential biomarkers that predict responses to TMZ combined with either of two ATR inhibitors, i.e., AZD6738 (Ceralasertib) and BAY1895344 (Elimusertib). We conducted comprehensive analyses including gene expression correlation with response, network interaction and gene set enrichment analysis. Our study revealed that lower MGMT expression (i.e., $MGMT^{low}$, normalized count <50) in PDX models was associated with sensitivity to ATRi+TMZ combination therapy as expected; 3/4 and 4/4 $MGMT^{low}$ models were sensitive to AZD6738+TMZ and BAY1895344+TMZ combination, respectively. However, $MGMT^{high}$ status did not necessarily denote resistance; a portion of $MGMT^{high}$ models were also sensitive to the ATRi+TMZ combinations. In $MGMT^{high}$ PDXs, network analysis and GSEA revealed that ATRi+TMZ sensitive models had significant ($p<0.001$) enrichment of highly expressed DNA replication genes such as MCM2 compared to resistant models. Moreover, elevated MCM2 expression was associated with sensitivity to ATRi+TMZ: 8/8 and 7/9 $MGMT^{high}/MCM2^{high}$ models were sensitive to AZD6738+TMZ and BAY1895344+TMZ, respectively. Correspondingly, 14/18 and 24/24 $MGMT^{high}/MCM2^{low}$ PDX models were resistant to AZD6738+TMZ and BAY1895344+TMZ, respectively. We used mass spectrometry-based proteomics data from a subset of rare tumor models in our RNAseq-based dataset to validate the MGMT/MCM2 expression association with ATRi+TMZ response, confirming a similar trend. Our findings revealed distinct expression signatures associated with favorable responses to two ATR inhibitors when individually combined with TMZ, highlighting candidate markers that could guide treatment decisions. Additional validation in a larger study would establish the potential utility of these candidate genes for patient selection in clinical trials.

#49 Genetic, genomic, and pharmacologic characterization of a new cohort of ancestrally diverse patient-derived xenograft models of cancer.

Nina M. Dashti-Gibson, Amy L. Olex, Katarzyna M. Tyc, Carson J. Walker, Oniya M. Smith, Rachel K. Myrick, Bin Hu, Praveen Bhoopathi, Madhavi Puchalapalli, Li Wang, Yue Zhang, Brydon P. G. Wall, Valentina Robila, Mikhail G. Dozmorov, Jinze Liu, Jennifer E. Koblinski, Jose G. Trevino, J. Chuck Harrell

Virginia Commonwealth University, Richmond, VA

Introduction: Patient derived xenografts (PDX) are important preclinical models of cancer as they faithfully recapitulate many aspects of human tumors. Currently, models derived from patients of non-European genetic ancestry are underrepresented, limiting the potential of precision medicine advancements to equitably improve patient outcomes. The United for Health Equity Living PDX Program (U4HELPP) seeks to address this need by generating new PDX models representative of the diverse population served by the VCU Health System. This study aims to 1) characterize the histologic, genomic, and transcriptomic features of a new cohort of ancestrally diverse PDX models of breast, pancreatic, colon, and lung cancer, and 2) identify drug sensitivities and response markers that will be targeted in ongoing studies utilizing these models.
Methods: Tumor fragments were implanted in the bilateral mammary glands or subcutaneous flank of NSG mice, and growth rates were defined. Tissue was fixed and embedded for histological staining to identify the cancer type and subtype. Whole genome and bulk RNA sequencing were performed to assess the mutational profile, genetic ancestry, and global transcriptomic landscape. Single cell RNA sequencing was utilized to capture the transcriptomic heterogeneity within each model. Finally, high throughput drug screening with the NCI NExT Oncology Interrogation Tools Set of 555 agents was performed in vitro to assess the drug sensitivities of each PDX.
Results: Whole genome sequencing and bulk RNA sequencing positively identified distinct genetic ancestries within the cohort. Histopathologic analysis revealed a rare metaplastic breast carcinoma, and immunohistochemical staining stratified breast cancer models into estrogen receptor positive and triple negative subtypes. Bulk RNA sequencing was used to subtype pancreatic ductal adenocarcinoma models as basal-like, classical, or intermediate, and single-cell RNA sequencing confirmed the presence of mixed subtype populations within these samples. High throughput drug screening identified sensitivities that correlated with mutations detected through whole genome sequencing; overall, several classes of drugs including proteasome and cyclin-dependent kinase inhibitors were found to be highly cytotoxic in all cancer types tested.
Conclusion: This study integrates multiple modalities to characterize the histological features, molecular signatures, and cellular heterogeneity of this new cohort of PDXs, which will provide researchers with extensive data on which to base future studies utilizing these models. Furthermore, it identifies promising therapeutic agents and explores genomic markers of drug sensitivity which could be used to predict patient response to novel treatments.

#491 Molecular correlates of drug response to identify novel therapeutic combinations in triple-negative breast cancer.

Nathan M. Merrill, Hamadi Madhi, Nathalie Vandecan, Athena Apfel, Habib Serhan, Peter J. Ulintz, Liwei Bao, Xu Cheng, Aki Morikawa, Matthew B. Soellner, Sofia D. Merajver

University of Michigan, Ann Arbor, MI

TNBC accounts for 10-20% of total breast cancer cases in the US and is more aggressive, higher grade, and has a poorer prognosis than other forms of breast cancer. TNBC is more likely to metastasize within 3-5 years than other forms of breast cancer and there is an urgent need to effectively implement precision medicine to improve outcomes for patients with TNBC, beyond unranked lists of drugs that may affect pathways related to genomic alterations. To this end, we have developed a precision-medicine-platform (PMP) to identify robust predictors of drug response in TNBC. We assembled a panel of 35 TNBC models that were screened with a curated library of 359 compounds comprising a broad array of approved and experimental small-molecule inhibitors. Additionally, we completed multiomic characterization (DNA sequencing, RNA sequencing, RNA targeted panels, and Reverse Phase Protein Array, RPPA) of passage-matched material. Integrating drug response readouts with molecular characterization allowed us to identify statistically significant molecular correlates of response to therapy. Further, co-targeting correlating pathways has proven to be a reliable method to identify robust synergistic combinations. Following screening, we prioritized 35 drugs on the basis of their activity and variance of response, identifying significant molecular correlates of drug response for 27 prioritized compounds. Grouping together chemotherapeutic agents, we were able to identify a signature of response generalized to chemotherapeutics. From our molecular correlate signatures, we identified a robust and novel correlation between combretastatin A4 (CA4) response and expression of EGFR at both the RNA and protein levels. Combining CA4 and EGFR inhibitors resulted in robust synergy in cell lines, *ex vivo* patient-derived xenograft models, and patient-derived organoid models. We finally validated this synergy using *in vivo* models of TNBC. Moving forward, we are working to evaluate the CA4 and EGFR inhibitor combination using additional *in vivo* models of TNBC. In conclusion, our PMP has allowed us to identify molecular correlates of response to therapy. Leveraging these molecular correlations, we identified robust novel combinations. This strategy will be critical in helping to translate precision-medicine to the clinic for patients with TNBC. Moreover, our strategy could allow us to revive repurposing strategies that previously failed clinical trials by pairing the right patients with the right drug and combination.

#493 Cingulin plays a role in PDAC organoid polarity and subtype.

Mariaelena Nabors, Sandra Zarmer, Yi Xu, Jen Jen Yeh

University of North Carolina at Chapel Hill, Chapel Hill, NC

Pancreatic ductal adenocarcinoma (PDAC) is one of the deadliest cancers with a dismal five-year survival rate of 12.5%. Our lab previously identified two transcriptomic PDAC tumor subtypes, termed basal-like and classical. Basal-like tumors are more aggressive while classical tumors have a better prognosis and are more sensitive to chemotherapy. However, many of the biological differences and drivers of the two subtypes remain unknown. We defined the proteomic landscape of PDAC tumors and found that classical tumors are enriched for cell polarity processes compared to basal-like tumors, and that one of the significantly enriched polarity proteins in classical PDAC tumors was cingulin (CGN). Classical organoids recapitulate the well-differentiated architecture of classical PDAC with well-organized hollow lumens. We found that CGN is required for the well-differentiated architecture of classical PDAC organoids and overexpression of CGN is sufficient to drive basal-like organoids to a more well-differentiated state. Additionally, overexpression of CGN in basal-like cell lines decreased invasion. Our results indicate CGN plays a role in PDAC organoid polarity, subtype, and aggression and further study could increase our understanding of the biological differences between PDAC subtypes.

#494 Identifying vulnerabilities in basal-like pancreatic adenocarcinoma (PDAC).

Sandra Zarmer, Ian McCabe, Jen Jen Yeh

UNC Chapel Hill, Chapel Hill, NC

Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal disease, with a 5-year survival of only 12.5%. There are two transcriptomic PDAC tumor subtypes: classical and basal-like. Basal-like PDAC is associated with worse patient outcomes and does not respond to the standard-of-care chemotherapeutic regimen FOLFIRINOX; new therapeutic strategies effective in basal-like PDAC are needed. To identify essential targets in basal-like PDAC, we designed a CRISPR library targeting 394 highly expressed basal-like exemplar genes and performed the screen basal-like cell lines derived from PDAC patient-derived xenograft (PDX) tumors. We found 46% of the library genes were essential (181/394, $p<0.05$), with the top Reactome pathways represented by essential genes being polo-like kinase mediated events, cell cycle checkpoints, formation of the cornified envelope, and Type I hemidesmosome assembly. Of 8 top lethal genes, 7 were validated. One of these validated targets was integrin subunit alpha 3 (ITGA3). Integrins are cell surface receptors that interact with extracellular matrix proteins, the cytoskeleton, as well as downstream effectors important in cancer signaling. ITGA3 was required for colony formation in basal-like PDX-derived cell lines. In basal-like organoids, shRNA knockdown of ITGA3 reduced growth compared to classical organoids. We report promising targets for basal-like PDAC that may play a role in subtype-specific biology and therapeutic response.

#496 Clinical, biologic, and immunogenic characteristics of gastro-esophageal cancers (GEC) harboring *CLDN18::ARHGAP* fusions.

Axel Grothey[1], Amber Fifield[2], Kieran Sweeney[2], Heinz-Josef Lenz[3], Matthew Oberley[2], Sanjay Goel[4], Shuanzeng Wei[5], Andrew Elliott[2], Bradley Somer[1]

[1]The West Clinic, Memphis, TN,[2]Caris Life Sciences, Irving, TX,[3]USC Norris Cancer Center, Los Angeles, CA,[4]Rutgers Cancer Institute, New Brunswick, NJ,[5]Fox Chase Cancer Center, Philadelphia, PA

Background: Claudin 18.2 (*CLDN18.2*) overexpression has recently emerged as a therapeutic target in advanced gastro-esophageal cancer (GEC). *CLDN18::ARHGAP* fusions are pathognomonic for GEC, but their biologic relevance in this malignancy is poorly understood. We analyzed the correlation of *CLDN18::ARHGAP* fusions with other molecular parameters, tumor microenvironment (TME) parameters, patient characteristics, and outcomes data in a large clinico-genomic database.

Methods: DNA and RNA (whole transcriptome) sequencing was performed for patient tumor samples submitted to Caris Life Sciences. *CLDN18::ARHGAP* fusions were identified from RNA transcripts. PD-L1 (28-8) and CLDN18 (43-14A) protein levels were determined by immunohistochemistry (IHC). TMB-High (TMB-H) was defined as ≥10 mutations/Mb. Significance was tested using Mann-Whitney, Fisher's Exact, or Chi-squared tests with multiple comparisons correction applied as appropriate. TME cell fractions were estimated by RNA deconvolution using quanTIseq. Real-world overall survival (OS) and nivolumab time on treatment (ToT) were obtained from insurance claims data and calculated from collection date to time of last contact and first of nivolumab to last of nivolumab, respectively; associated hazard ratios (HR) and p-values were calculated using the Cox proportional hazard model.

Results: Among 4430 GEC tumors, 262 tumors (6.1%) harbored a *CLDN18::ARHGAP* fusion, primarily *CLDN18::ARHGAP26* (N=226). Patients with fusion+ tumors were younger (median age: 58 vs 66 years, p<0.0001) and more frequently female (64.1% vs 41.1%, p<0.0001). Fusion+ tumors had more frequent *HER2* (9.7% vs 3.4%, p<0.0001) and *HER3* (10.5% vs 3.8% p<0.0001) mutations and less frequent *RHOA* (0% vs 7.5%, p=0.0009), *CDH1*(3.9% vs 20.4%, p<0.0001), and *KRAS* (2.7% vs 10.0%, p=0.0033) mutations. Fusion+ tumors had a lower prevalence of the IO-related biomarkers TMB-H (4.8% vs 13.9%, p=0.0030), dMMR/MSI-H (3.9% vs 9.5%, p=0.0416), and PD-L1+ (12.5% vs 32.5%, p=0.0001), lower infiltration of CD8+ T cells (0% vs 0.2%, p=0.0016) and M1 macrophages (3.0% vs 3.9%, p<0.0001), and higher infiltration of M2 macrophages (5.4% vs 3.9%, p<0.0001). Using either standard (≥2+, ≥75%) or reduced (≥2+, ≥40%) IHC cut-offs, fusion+ tumors were more frequently CLDN18 IHC+ than fusion- tumors (79.5% vs 47.9%, p<0.0001 and 86.4% vs 54.5%, p<0.0001, respectively). Comparing fusion+ vs fusion- cancers, there was no significant difference in median OS (15.6 vs 13.6 months; HR=0.892, p=0.1986) or nivolumab ToT (7.4 vs 4.8 months, HR=0.751, p=0.1359).

Conclusions: *CLDN18::ARHGAP* fusions characterize GECs with distinct clinical and biologic features that suggest lower immunogenicity. Fusions were positively correlated with a higher CLDN18 protein expression

#497 Real world experience of Aspyre Lung (Tissue) LDT: Simplified genomic profiling.

Elizabeth Gillon-Zhang[1], Eleanor Gray[2], Ryan Evans[1], Julia Brown[1], Candace King[1], Katherine Knudsen[1], Ethan Clark[1], Mary Beth Rossi[1], Cory Kiser[1], Amanda Green[1], Honey V. Reddi[1], Barnaby Balmforth[2], **Jeffrey Gregg**[1], Wendy Levin[1], Shari Brown[1]

[1]Biofidelity Inc, Morrisville, NC,[2]Biofidelity Ltd, Cambridge, United Kingdom

Aspyre Clinical Test for Lung (Tissue) tests lung FFPE and blood samples for actionable biomarkers across 11 genes and 114 variants associated with NSCLC (*ALK*, *BRAF*, *EGFR*, *ERBB2*, *KRAS*, *MET*, *RET*, *ROS1*, *NTRK1*/*2*/*3*). The assay uses standard PCR equipment and interrogates RNA and DNA directly for clinically actionable alterations in a cost effective and rapid manner. We present results from the initial cohort of clinical samples sent to Biofidelity Inc. Laboratory (a CAP/CLIA site). De-identified demographic and clinical data were obtained, and collated alongside laboratory data. Clinical sample and internal laboratory processing characteristics analyzed included biopsy type, pathology diagnosis, tumor content, % necrosis, number of slides used, turnaround time (TAT), variant(s) identified, and assay validity. Samples that did not meet all validated requirements were also analyzed separately. 113 clinical samples were analyzed. At the time of data cut-off, mean patient age was 65.9 yrs (range 38-94 yrs), 58 Male, 55 Female, mean tumor content 46% (range 0-95%), mean necrosis 5% (range 0-80%), 15 were resections, 18 FNA, 35 CNB, 4 cytology, 19 cryobiopsies, 11 transbronchial biopsies, 11 unknown. 92% of samples were processed within 2 business days, with an average of 5.7 slides (cut at 5 µm) used (median 4). 64 samples were adenocarcinoma/ adenosquamous, 24 samples were squamous cell carcinoma, 1 spindle cell carcinoma, 7 NSCLC, 1 small cell carcinoma and 16 not known or no pathology report. Overall, 49 samples were positive for a variant, and 64 had no variant identified. Variants included SNV in *BRAF*, *EGFR*, and *KRAS*, *EGFR* exon 19 deletions and exon 20 insertions, *MET* exon 14 skipping and gene fusions. Aspyre Clinical Test for Lung has a high assay success rate and proven rapid 2-day TAT. This makes it suitable as a first-line testing option, or for samples that are scant, of low quality, or fail next-generation sequencing (NGS) quality control, and can provide a large fraction of NSCLC patients with actionable biomarker information. The Aspyre assay is uniquely suited to inform patient decisions using very small samples that are not otherwise amenable to comprehensive genomic profiling by NGS. Aspyre Clinical Test for Lung simplified genomic profiling is transformative for cancer care management, and enables more patients with NSCLC to benefit from more effective and better tolerated targeted therapies.

#498 In melanoma, disruption of the NF1/SPRED1 RAS inactivating complex cooperates with mutant KIT necessitating combined KIT and MEK inhibition to suppress tumor growth.

M. Tee[1], J. Yang[1], J. Ma[1], M. Wang[1], D. Schadendorf[2], B. C. Bastian[1], **I. Yeh**[1];
[1]UCSF - University of California San Francisco, San Francisco, CA, [2]University Hospital Essen and German Cancer Consortium (DKTK), Essen, Germany

We previously identified concurrent loss of function mutations of either *NF1* or *SPRED1* with activating mutations in *KIT* in primary acral and mucosal melanomas. We hypothesized the positive selection for NF1 or SPRED1 inactivation in the context of KIT mutations reflects a functional cooperation that may impact response to therapy targeting KIT. We find that contrary to each of the alterations alone, combined loss of either NF1 or SPRED1 in the presence of mutant KIT transforms immortalized mouse melanocytes. Because loss of NF1 and SPRED1 each activates RAS acting downstream of KIT, it could subvert the effect of KIT inhibitors. In patient-derived melanoma cell lines with KIT mutations and loss of NF1 or SPRED1, combination treatment with a KIT inhibitor (imatinib or avapritinib) and a MEK inhibitor (trametinib) acted synergistically. Combined KIT and MEK inhibition also reduced tumor growth and prolonged survival of mice xenografted with KIT-mutant melanoma cell lines. Our findings suggest that combination therapy with KIT and MEK inhibitors would be beneficial for melanoma patients with activating KIT mutations and concomitant loss of function NF1/SPRED1 mutations.

#499 Spatial RNA sequencing supports programmed death ligand 2 (PD-L2) as a potential immunotherapy target in high grade serous ovarian carcinoma (HGSOC).

Elise Yates[1], Cailin O'Connell[2], Yin Zheng[3], Hong Zhao[4], Aparna Kamat[5], Biana Godin[6]

[1]Obstetrics and Gynecology, Houston Methodist Hospital, Houston, TX,[2]Texas A&M University School of Engineering Medicine, College Station, TX,[3]Biomedical Infromatics Service Core, Houston Methodist Research Institute, Houston, TX,[4]Advanced Cellular and Tissue Microscopy Core, Houston Methodist Research Institute, Houston, TX,[5]Gynecology Oncology, Houston Methodist Hospital, Houston, TX,[6]Department of Nanomedicine, Department of Ob/Gyn and Cancer Center, Houston Methodist Research Institute, Houston, TX

Currently available PD-1 and PD-L1 immune checkpoint inhibitors have shown limited success in HGSOC. There is increasing evidence for the significance of PD-L2, a PD-1 ligand expressed by antigen presenting cells (APC), and mainly by tumor associated M2 macrophages (CD163+), as a key player in the HGSOC immune microenvironment. Here we aimed to utilize the GeoMx Digital Spatial Profiling system to evaluate the presence of PD-L2 and APC in HGSOC across clinical stages and in normal adjacent tissue (NAT)
GeoMx spatial sequencing protocols were applied to HGSOC tumor microarrays (TMA) of different stages and whole transcriptome (RNA) was quantified using Illumina next generation sequencing (NGS). 47 cores were analyzed, including NAT (n=8), local (IA-IB, n=8), regional (IC-IIC, n=17), and distant HGSOC (IIIA+, n=14). The data was then imported into the GeoMx analysis pipeline and Q3 normalized data was used to perform immune deconvolution analysis. GeoMx SpatialDecon was used to estimate the abundance of immune cells using whole transcriptome analysis RNA expression as a proxy for cell type. Differences across stages were analyzed using a linear mixed model with BH multiple test correction and adjusted for region of interest (ROI) to account for inter-patient heterogeneity. A Kaplan-Meier plot of PD-L2 (PDCD1-LG2) progressionfree survival outcomes for all histologic subtypes of ovarian cancer (OvCa) was also created using kmplot.com.
Results: Expression of M2-macrophage marker CD163 and PD-L2 were significantly increased in the stroma among all stages of HGSOC compared to NAT (P=<0.05) Generic macrophage marker CD68 was increased in local and distant stages. PD-1 (CD274) was not significantly different from NAT in the stroma among any stage of HGSOC. However, PD-1 expression was found to be increased in the NAT epithelium group when compared to local HGSOC epithelium. A Kaplan-Meier plot of PD-L2 expression in all subtypes and treatment pathways of OvCa demonstrated that high expressors have a much lower progression free survival versus low expressors (HR=1.41, p = 0.0022).
We found that macrophages are increasingly present in the HGSOC stroma across stages. Additionally, CD163 expression is increased versus NAT, demonstrating the importance of the M2-like macrophage phenotype in OvCa progression. Interestingly, we found that PD-L2, but not PD-L1 transcription, is significantly increased in the stroma of all stages of HGSOC versus NAT stroma. These findings were supported by a Kaplan-Meier plot of PD-L2 expression in all OvCa subtypes showing that the prognosis (progression-free survival) is poorer in high PD-L2 expressors. Therefore, PD-L2 serves as a potential immunotherapy marker for HGSOC. Future efforts should investigate the impact of PD-L2 expression on the success of anti-PD-1 therapies and the role of PD-L2 as a potential immunotherapy target.

#5 Noncanonical NF-kB and notch signaling activity supports ovarian cancer stem-like cells following chemotherapy.

Gregory J. Jordan, Cecilia Gallo, Mikella Robinson, Omar Lujano-Olazaba, Carrie D. House

San Diego State University, San Diego, CA

In the United States, ovarian cancer is the most lethal gynecological malignancy and the fifth most lethal cancer for those at risk. Although patients typically respond well to initial chemotherapy treatments, approximately 80% of patients will relapse with chemotherapy-resistant disease. Studies suggest a subpopulation of ovarian cancer cells, termed cancer stem-like cells (CSCs), can resist chemotherapy and repopulate tumors following treatment. The mechanisms enabling these cells to survive chemotherapy and re-establish heterogeneous tumors are unclear but likely involve activation of multiple survival and developmental pathways. Our previous work shows that the noncanonical NF-κB transcription factor, RelB, supports ovarian CSCs, and our preliminary data suggests RelB regulates the expression of Notch pathway genes. Notably, Notch is upregulated in patient-matched tumors following chemotherapy relative to pre-treatment samples. We hypothesize that RelB-mediated upregulation of Notch signaling is required to maintain CSCs and facilitate tumor regrowth after chemotherapy. To test this hypothesis, we first used qRT-PCR and western blot to assess the expression of different Notch receptors and ligands under spheroid-forming 3D culture conditions relative to monolayer 2D conditions. We observed increased expression of most Notch genes in 3D conditions. Interestingly, in sorted CD117+ CSCs, Notch receptor expression (Notch 1 and Notch 3) was maintained, while expression of Notch ligands (DLL1 and DLL3) was reduced, and Jag2 expression was elevated relative to CD117- bulk tumor cells. Additionally, we observed a consistent increase in the Notch target gene *CDKN1A* in 3D growth conditions relative to 2D. To confirm and further assess Notch activity, we are currently using Notch reporter cells under various conditions, including spheroid culture, treatment with carboplatin and paclitaxel, RelB knockdown, and RelB activation. Our preliminary *in vitro* data suggests that RelB upregulates Notch signaling in CSCs to enhance stemness and tumor-initiation following chemotherapy treatment. These findings will be validated in an *in vivo* relapse model to assess the requirement for Notch signaling during relapse. This work highlights a novel collaboration between RelB and Notch activity in CSCs, which may guide the design of more effective therapeutic strategies to reduce relapse and improve survival outcomes for ovarian cancer patients.

TUMOR BIOLOGY: Human and PDX Models 1

#50 Development of paired enfortumab vedotin-resistant urothelial cancer models using organoid and PDX.

Claire Beraud[1], **Emilie Decaup**[1], Anne-Sophie Bajeot[2], Celine Rouget[1], Karine Rollet[1], Mathieu Roumiguie[2], Xavier Game[2], Philippe Lluel[1], Nadege Bidan[1]

[1]Urosphere SAS, Toulouse, France,[2]Toulouse Hospital, Toulouse, France

Nectin-4 has emerged as a promising target for antibody-drug conjugates (ADCs) due to its high expression in bladder cancer (BC) cells. Enfortumab vedotin (EV), an anti-Nectin-4 ADC conjugated with MMAE toxin, has demonstrated potent therapeutic activity, particularly in combination with pembrolizumab. However, resistance to EV presents a significant clinical challenge. This study aims to develop EV resistant models among Urosphere's biobank of BC patient-derived xenografts (PDX) and organoids for screening anti-Nectin-4 compounds and investigating mechanisms of resistance to EV. RNA sequencing/Affymetrix and immunohistochemistry (IHC) were performed to quantify Nectin-4 expression. Sixteen PDX models were treated with EV (4 mg/kg, twice) to evaluate antitumor activity. Two PDX models (coded as B521 and F659) highly responsive to EV were selected to generate acquired-resistant models. They were treated with repeated EV treatments until tumors no longer regressed. Subsequently, tumor fragments from both PDX models were implanted into new NMRI mice and treated with EV to validate the resistance acquisition. Starting from PDX tumors no longer responding to EV, organoid model was established and treated to EV from 0.003 up to 10 µg/mL for five days, followed by cell viability assessment using the CellTiter-Glo® 3D assay to confirm their resistance. Urosphere's PDX biobank encompasses diverse Nectin-4 expression profiles. EV efficacy *in vivo* was not strictly correlated with Nectin-4 expression. B521 did not acquire any resistance whereas F659 PDX model developed resistance after ~200 days of repeated administration. We established the corresponding organoids and we showed that IC50 and Emax were significantly different between sensitive and resistant models. Nectin-4 expression remained stable in resistant models (mRNA and protein levels), indicating that resistance was unrelated to target loss. Transcriptomic analyses highlighted several potential mechanisms, including the upregulation of efflux transporters such as MDR1 and MRP3, which may contribute to resistance. Urosphere's PDX and organoid biobank serves as a powerful platform for advancing research on Nectin-4-targeted therapies. From the F659 PDX model, we successfully developed paired *in vitro* and *in vivo* models resistant to EV. These novel models provide valuable tools for assessing innovative therapeutic approaches for resistant tumors. Additionally, the EV-resistant models underscore the potential role of ABC transporter upregulation in resistance mechanisms, offering critical insights for the development of alternative treatment strategies.

#500 A molecular comparison reveals distinct transcriptomic differences between uterine carcinosarcoma and papillary serous carcinoma distinguishable by DNA damage.

Kevin J. Lee[1], Tanvi Joshi[1], Sagar Chokshi[1], Mackenzie Cummings[1], Jennifer Scalici[2], Nathaniel Jones[1]

[1]Gynecologic Oncology, USA Health Mitchell Cancer Institute, Mobile, AL,[2]Gynecologic Oncology, Emory University School of Medicine, Atlanta, GA

Background: Uterine papillary serous carcinoma (UPSC) and uterine carcinosarcoma (UCS) are rare subtypes of endometrial cancer (EMCA) with poor prognosis. Both are high risk histotypes, though their distinct molecular and genomic profiles are undefined. Recent clinical trials such as RUBY, Keynote 775, DUO-E and NRG-GY018 have shown survival benefit in subsets of EMCA with mismatch repair deficiency (MMRd), however, small numbers of patients with UPSC and UCS were included. The role of MMRd or DNA damage & response (DDR) mechanisms in general are under-explored in these EMCA subtypes. We therefore sought to characterize the immune, inflammatory, and DNA damage profiles of UPSCs and UCSs to better define the role of immunotherapy (IO) in these tumors.
Methods: Total DNA damage was analyzed in 53 UPSC and 43 UCS FFPE samples collected at our institution using repair-assisted damage-detection (RADD). RNA was isolated from a subset of patients (n = 18/group) and expression (50 ng/per sample) was analyzed using the nCounter PanCancer IO 360 panel from Nanostring comprising 770 gene expression markers. Data was analyzed using the Rosalind Bioinformatics in conjunction with Nanostring's IO360 analysis team.
Results: We have previously shown a 3.6 fold decrease ($p<0.0001$) of unrepaired DNA damage between UCS samples compared to UPSC, suggesting greater DNA repair capacity in UCS than UPSC. Consistent with this data, transcriptional analysis revealed increased expression of DNA repair genes in UCS such as POLD1, MSH2, BRIP1, BIRC5, and CDK6, among others. Interestingly, decreased expression of DNA repair genes was noted in UPSC despite nearly 4 times the amount of unrepaired DNA damage. As expected, the immune system was activated in response to this increased DNA damage with higher levels of T cells, NK cells, IL-10, cytotoxic T cells, and Th1 cells. However, there was also increased expression of immune evasive genes such as PD-1, CD47, and VTCN1, among others. Additionally, expression of NK CD56dim was also upregulated, a known marker of immune exhaustion. This suggests DNA damage tolerance and immune exhaustion are hallmarks of UPSC.
Conclusions: We present here a detailed, treatment-oriented molecular comparison between two histologically distinct EMCA subtypes, UPSC and UCS. Assessment of unrepaired DNA damage and, by proxy, DNA repair capacity, gives context to the immune transcriptomic landscape. Our data suggests that the immune exhausted molecular landscape of UPSC is more amenable to IO than that of UCS, while the DNA repair-robust UCS may be more vulnerable to agents targeting DNA Damage repair such as PARP inhibitors. Further, our data suggests that estimation of DNA repair capacity via RADD may be as treatment informative as molecular sequencing.

#501 APC-loss as a potential biomarker for NT219 treatment in colorectal cancer (CRC).

Hadas Reuveni, Hava Ben David, Tomer Meirson

Purple Biotech Ltd., Rehovot, Israel

Background: NT219 is a small molecule dual inhibitor of STAT3 and insulin receptor substrate 1/2 (IRS), covalently binds to IRS1/2 leading to its degradation. IRS regulates PI3K/AKT and the β-catenin pathways. It was demonstrated that NT219 inhibits the IRS2-mediated β-Catenin signaling and synergizes with 5FU to suppress colorectal cancer (CRC) brain metastasis and increase survival. In an APC loss-driven CRC mouse model (CPC-APC), where IGF1R and IRS1/2 are upregulated, the dual inhibitor caused a substantial reduction in tumor burden and metastasis by affecting the tumor and the TME. Here we present the effect of NT219 in CRC patient-derived specimens and suggest upregulation of wnt/β-catenin or loss of its negative regulator APC as a potential biomarker for NT219 therapy.

Method: Six CRC ex vivo patient-derived tumor explants (PDEs), involving resected tumor fragments retaining TME native architecture, tumor heterogeneity and proliferative capacity were treated with NT219 and analyzed for efficacy. Genomic and transcriptomic analyses were performed on responding and non-responding biopsies to identify potential predictive biomarkers. Phospo-STAT3(Y705) immunohistochemistry assessed the immediate and sustained effects of NT219. Additional PDEs harboring TP53(D259Y), PIK3CA(E110del) gain-of-function, and APC(s1355fs*60) loss-of-function (LoF), were treated with NT219 w/wo TAS-102. A FOLFOX-resistant patient derived xenograft (PDX) with an APC R1450* LoF mutation received NT219 (60mg/kg, twice weekly) to detect tumor growth.

Results: CRC PDEs treated with NT219 showed >75% cell death in 2/6 (33%) samples. Genomic analysis identified APC(E1138fs) LoF mutation (1/2 responders, 0/4 non-responders) and CNV associated with the wnt/ β-catenin pathway (2/2 responders, 0/4 non-responders). Transcriptomic analysis showed differential patterns of genes associated with up-regulation of wnt/β-catenin pathways, such as WNT7A/10A and DDR2. Sustained inhibition of STAT3 phosphorylation was exclusive for responders. Genomic analysis of one biopsy pre vs post- NT219 treatment revealed the APC LoF mutation Y917fs in the pretreatment biopsy which was undetectable post-treatment, suggesting elimination of APC LoF cells. The anti-tumor activity was confirmed in a PDX CRC model harboring APC R1450* in which NT219 demonstrated a single agent sustained tumor growth inhibition (86%, p=0.001). NT219 with TAS-102, induced significant and synergistic cell death (91%) in TAS-102 resistant CRC PDE harboring APC (s1355fs*60) LoF.

Conclusion: The anti-tumor activity in CRC explants along with genomic and transcriptomic analysis propose that the response to NT219 is associated with enhanced wnt/β-catenin signaling or APC loss. The results suggest APC-loss as a potential biomarker for NT219 treatment in CRC.

#502 Exploring STEAP1 expression in prostate cancer cells in response to androgen deprivation and in small extracellular vesicles.

Candice L. Bizzaro[1], Camilla A. Bach[1], Ricardo A. Santos[1], Cecilia E. Verrillo[1], Nicole M. Naranjo[1], Ishan Chaudhari[1], Waleed Iqbal[2], Alessandro Fatatis[2], Ada G. Blidner[3], Gabriel A. Rabinovic[3], William Kevin Kelly[4], Lucia R. Languino[1]

[1]Department of Pharmacology, Physiology and Cancer Biology, Thomas Jefferson University, Philadelphia, PA,[2]Department of Pharmacology and Physiology, Drexel University, Philadelphia, PA,[3]Laboratory of Glycomedicine, Institute of Biology and Experimental Medicine, Buenos Aires, Argentina,[4]Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA

The Six Transmembrane Epithelial Antigen of the Prostate (STEAP1 and 2) metalloreductases are therapeutic targets for advanced PCa, and their expression has been linked to androgen receptor (AR) signaling; however, the regulatory mechanism and function of STEAP in PCa progression remains elusive. In this study, we explore how *in vitro* androgen modulation influences STEAP family expression in cell lines with varying reliance on androgen signaling. Our data show that in response to androgen deprivation, *STEAP1* and *STEAP2* exhibit elevated transcript levels, while *STEAP4* mirrors the expression profile of *KLK3* (Kallikrein Related Peptidase 3), showing reduced expression. Further, we found that an AR splice variant, AR-V7, which emerges in aggressive PCa, correlates with lower STEAP1 expression under androgen deprivation compared to full hormone conditions. Given their role in the exocytic pathway, we evaluated STEAP1 and STEAP2 expression profiles in hormone refractory PCa cells and their derived circulating small extracellular vesicles (sEVs). STEAP1, but not STEAP2, is upregulated in sEVs from AR-negative cells with low STEAP1 levels (DU145 and PC3) and AR-positive cells with higher STEAP1 levels (C4-2B). These results indicate selective packaging of STEAP1 in PCa cell sEVs, irrespective of AR status and cellular STEAP1 expression levels. We have previously shown that β1 integrins in the prostate tumor epithelium are necessary for sEVs to support anchorage-independent growth. Here, *ex vivo* analysis of circulating sEVs from genetically engineered mice carrying PCa show that STEAP1 is found in the sEV cargo, independent of β1 integrins. Our findings underscore the nuanced interplay between androgen signaling and STEAP1 expression and highlight the potential use of STEAP1 in sEVs as a biomarker in PCa to inform diagnostic and therapeutic strategies.

#503 Tracking evolution of transcriptional landscapes during colorectal cancer development and progression.

Sudhir B. Malla[1], Natalie Fisher[1], Raheleh Amirkhah[1], Joanne Edwards[2], Owen Sansom[3], Philip D. Dunne[1]

[1]Queen's University Belfast, Belfast, United Kingdom,[2]Wolfson Wohl Cancer Research Centre, School of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom,[3]Cancer Research UK Scotland Institute, Glasgow, United Kingdom

Colorectal cancer (CRC) has been classified into molecular subtypes using gene-level data from both bulk and single-cell RNA sequencing (scRNA-seq), leading to the development of the consensus molecular subtypes (CMS) and intrinsic CMS (iCMS). In addition to CRC studies, scRNA-seq and spatial transcriptomics characterization of human polyps, aligned with the conventional adenoma and serrated polyps, identified distinct driver mutations, cells-of-origin and iCMS traits associated with each polyp type. These gene-level transcriptional classification approaches were both strongly aligned to mutations underpinning the Vogelstein model of CRC development.

However, when viewed using pathway-level information, the most dominant mechanistic signaling cascades in CRC were completely independent of these same mutational drivers. Therefore, to deliver a holistic landscape-view of the tumor ecosystem, we proposed that pathway-level subtyping could offer a broader understanding of non-genetic phenotypic signaling in CRC, leading to more informative stratification and therapeutic decision-making.

Using this new approach in combination with bulk transcriptional data from n=1200+ tumors, alongside n=29,452 scRNA-seq profiles derived from murine organoids, and n=49,155 epithelial cells derived from n=63 human tumor samples, we identified three pathway-derived subtypes (PDS1-3), revealing previously overlooked changes in epithelial cell identities and phenotypic states. PDS2 represents tumors with stroma/immune-dense, regenerative stem-like features. PDS1 were associated with elevated MYC signaling, proliferation and canonical stem-cells with good prognosis, while PDS3 displayed a differentiated-like phenotype associated with reduced polycomb repressive complex 2 (PRC)-mediated gene repression and poorer prognosis.

The inverse relationship between MYC/PRC targets within PDS1/PDS3 tumors supported the development of stem maturation index, which was directly related to cellular entropy and differentiation status of colonic cells allowing our tumor data to be projected onto a Waddington's landscape. Given these associations with developmental patterns in established tumors, we next utilized the same pathway-level approach in combination with transcriptional data derived from n=2641 human polyps, where we observe that PDS traits can be established early in precancer development. Using a combination of trajectory analyzes, lineage identities and cellular phenotyping, these approaches have again revealed that, even in very early precancers, there is no association between Vogelstein-related mutational drivers and prominent phenotypic signaling cascades.

While work is ongoing, the use of pathway-level information provides a unique insight into the dynamic nature of phenotypic evolution across early-to-late stages of colorectal precancers and tumors.

#504 A comparative analysis of statistical and machine learning approaches to predict drug resistance based on synergistic genetic alterations.

R. Nair[1], N. R. Mistry[1], R. Khalife[2], A. M. Magliocco[2];
[1]University of Central Florida, Orlando, FL, [2]Protean BioDiagnostics, Orlando, FL

Introduction: This study evaluates the utility of a machine learning approach to predict drug resistance in breast cancer (BC), based on comparison to an automated statistical model, using data from cBioPortal.

Methods: Our *in silico* approach investigated the association between synergistic genetic alterations in BC and survival data with various treatments based on one study (TCGA, PanCancer Atlas 2018). A set of 491 commonly altered genes in cancer (based on TSO500) was analyzed for this study. We programmed a statistical model to automatically select pairs of genes whose alterations (mutations, structural variants/fusions, copy number alterations) correlated with significantly worse five-year overall survival (OS) upon synergistic alterations, compared to one gene alone ($p<0.05$; $HR\geq1$). The results were analyzed via subgroup analysis of six treatment groups according to cBioPortal (chemotherapy, ancillary, hormone, immunotherapy, radiation, other) to predict potential drug resistance if HR significantly changed based on treatment. We compared our results with a machine learning approach. The model first computed relevancy/attention scores on treatments based on order, duration and type. This allowed the model to consider chronological order and simultaneous treatment administration. We then fed this into a model that returned a classification score (probability of death before 60 months) with ~90% accuracy, and another model that returned a regression score (expected survival in months) score, with mean squared error<0.02.

Results: A statistical brute force approach tested each gene's influence on another, and each treatment category's influence on a gene pair. Permutations of pairs from the geneset (240590 total) were generated for each treatment; 570 corresponded with significantly worse OS ($HR\geq1$) with chemotherapy, 392 with hormone therapy, 124 with immunotherapy and 614 with radiation therapy. Less than five patients had ancillary or other treatment, preventing us from generating statistically significant results. Permutations were used since the order of genes matters during statistical analysis for alterations to one gene versus synergistic alterations. The machine learning approach yielded treatment rankings for each gene permutation based on the classification score. The latest test demonstrated that most gene permutations correspond with a high classification score with hormone therapy (48%), and most gene permutations correspond with worse total OS with chemotherapy (86%). Rankings show promise that some marked values from statistical analysis are shared with the machine learning model, but further work is needed to improve stability to make accurate predictions for survival outcomes.

Conclusion: Our findings suggest the possible utility of an automated approach to predict gene pairs that confer drug resistance in BC.

#505 Differences in gene expression across races in pediatric T-cell acute lymphoblastic leukemia (T-ALL).

Rishabh Gaur[1], Irina Pushel[2], Midhat Farooqi[2]

[1]University of Missouri-Kansas City School of Medicine, Kansas City, MO,[2]Children's Mercy Hospital, Kansas City, MO

T-cell acute lymphoblastic leukemia (T-ALL) is a malignancy of immature T-cells characterized by rapid proliferation of leukemic cells in the bone marrow and blood. Despite significant advancements in the understanding and treatment of B-cell acute lymphoblastic leukemia (B-ALL), T-ALL remains comparatively underexplored, with limited data on the underlying genomic alterations driving disease progression. T-ALL constitutes 12-15% of pediatric and adult ALL cases, with poorer outcomes than B-ALL. Understanding differential gene expression in T-ALL is critical, especially with respect to how these may differ across racial groups, as African Americans and Asians have been shown to have lower survival than Caucasians.

In this study, we analyzed RNA sequencing data from a cohort of pediatric T-ALL patients to identify differences in gene expression patterns between racial groups, specifically focusing on Caucasian, Asian, and African American patients. Using DESeq2, differential gene expression analysis was performed across racial categories. A total of 37 patients with genomic data were included, with expression counts normalized, and statistical significance was determined based on adjusted p-values <0.05. We also examined potential correlations between gene expression and clinical outcomes such as relapse status. Preliminary results identified several genes exhibiting significant differential expression between racial groups. 250 genes, mostly related to the adaptive immune system, were significantly differentially expressed in Caucasian vs African American patients. 261 genes, mostly related to homeostasis and cellular development, showed differential expression in Caucasian vs Asian patients. There was an overlap of 17 genes which were differentially expressed in all three races. Importantly, FAT1 was one of these 17 genes, as it is a gene that has previously been implicated in T-ALL but not studied with regard to differences in expression by race. Preliminary analyses also found differentially expressed genes between African American vs Asian and relapse vs non-relapse. Additional studies are ongoing to determine the specificity of all these genes to T-ALL and to compare the genes that were differentially expressed across various races to the genes differentially expressed across outcomes.

This study highlights the importance of examining racial differences in gene expression within T-ALL, a leukemia subtype that has not been extensively understood. The identification of race-specific gene expression profiles may provide insights into the biological mechanisms that contribute to differences in clinical outcomes and response to treatment. Future work will focus on validating these findings in larger, independent cohorts and exploring how these genetic differences may influence disease progression, ultimately reducing racial disparities in T-ALL survival.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Repurposing New and Existing Drugs for Cancer Treatment

#507 Nebivolol induces autophagy and inhibits cell proliferation in triple negative breast cancer.

Wangjia Cao[1], Tagari Samanta[2], Benny A. Kaipparettu[2], Meghana V. Trivedi[1]

[1]Department of Pharmacological & Pharmaceutical Sciences, University of Houston, Houston, TX,[2]Department of Molecular & Human Genetics, Baylor College of Medicine, Houston, TX

Background: Among various types of breast cancer (BC), triple negative BC (TNBC) has a high-risk of recurrence and poorer prognosis. Chemotherapy, which is associated with many acute and chronic toxicities, remains the primary treatment for TNBC. Despite aggressive therapy, about one-third of early-stage TNBC patients develop metastasis within 5 years of diagnosis and have a median survival of only 12 months. Therefore, identifying safe and effective novel treatment for TNBC is of utmost importance. Using 2 cell models, our group recently reported the repurposing potential of nebivolol (NEB) in TNBC cells. Here, we aimed to confirm the effects of NEB using a panel of 10 TNBC cell lines and identify its mechanism of action.
Methods: The half-maximal inhibitory concentrations of NEB (IC50) were determined across 10 cell lines by a concentration-response curve using non-linear regression analysis fitted to a 3-parameter logistic equation. MDA-MB-231 and SUM159 cells were chosen for subsequent experiments. RNA-seq followed by enrichment analysis using KEGG database and reverse phase protein array (RPPA) followed by two-way Analysis of Variance (ANOVA) with multiple comparisons were conducted to identify downstream pathways and target proteins impacted by NEB. To assess the effect on autophagy, lysosome formation, and cell proliferation, autophagy and lysosome fluorescent dyes and EdU proliferation assay were used, respectively, after treating the cells with various NEB concentrations. Fluorescent images from these experiments were imaged using a Nikon confocal microscope and analyzed in ImageJ. Differential expression of protein candidates from RPPA and autophagy related markers was confirmed using western blotting (WB). A p-value < 0.05 was considered statistically significant by student's t-test and one-way ANOVA, as appropriate.
Results: NEB inhibited the growth of all 10 TNBC cell lines in a concentration-dependent manner. The IC50 of NEB for TNBC cell lines ranged from 6.1 to 13.9 µM. Integrative RNA-seq analysis of both cell line models suggested significant upregulation of autophagy pathway (FDR < 0.05) after NEB treatment. NEB induced autophagy and lysosome formation in a concentration- and time-dependent manner, significantly inhibited cell proliferation, and significantly upregulated autophagy markers p62 and LC3B-II. In RPPA, DNMT3B and pTRAP220/MED1 were the most significantly downregulated proteins after NEB treatment in both cell lines (FDR < 0.05), which was further confirmed using WB.
Conclusion: NEB inhibits TNBC growth and proliferation and induces autophagy and lysosome formation by modulating key proteins. Ongoing studies include the analysis of NEB's effects on inducing apoptosis and its role in clonogenic and tumorigenic potential of TNBC cells.

#508 Triple negative breast cancer growth and immune responses to metronomic chemotherapy regimens with varied drugs and dosages.

Amanda I. Rakoski, Sarah Y. Neshat, Joshua C. Doloff

Biomedical Engineering, Johns Hopkins University, Baltimore, MD

Despite an increasing number of chemotherapy options, triple-negative breast cancer (TNBC) has arisen as the subtype that causes the most breast cancer mortality as it is not sensitive to drugs targeting estrogen, progesterone, and epidermal growth factor 1 receptors. The current standard of care for cancer, utilizing maximum tolerated dose with a following long break for patient recovery, has not been optimal as it causes temporary tumor regression. We propose utilizing metronomic dose scheduling where a reduced amount of drug is given on a schedule with intermittent drug-free breaks. Due to findings on the utility of metronomic chemotherapy against glioblastoma (JCD, et al. Molecular Cancer) where cyclical immune cell infiltrations have been seen, we are applying a similar 6-day schedule on aggressive TNBC mouse models to investigate if we can cause similar induction of antitumor immunity and tumor regression. For our experiments, 4T1 TNBC cells syngeneic to BALB/c mice were injected orthotopically into the right mammary fat pad. Once tumors were ~200 mm3, treatment was initiated. Various clinically relevant chemotherapies at doses shown in the literature to affect cancer growth were dissolved in vehicles and dispensed based on mouse body weight (mg/kg). Every 6 days, drug solutions were injected intraperitoneally (IP). We additionally injected 200 µg anti-PD1 (aPD1) IP starting at day -3 and every 6 days after that for chosen drugs at 100 mg/kg. Mice were sacrificed and tissues collected after 4 rounds of chemotherapy. Comparing six chemotherapies, we found no tumor regression, but tumor stasis was instead achieved in gemcitabine (GEM) and cyclophosphamide (CPA)-treated mice. After increasing GEM up to 150 mg/kg, CPA up to 200 mg/kg, and adding aPD1 to GEM and CPA at 100 mg/kg, the tumor volume still remained static vs. GEM and CPA at 100 mg/kg alone. To investigate local immune responses, qPCR was performed on bulk tumor tissues, measuring RNA expression of gene markers for immune cells. Immune trends comparing GEM and CPA varied based on drug mechanism of action. Anti-metabolite GEM caused more expression of markers associated with the innate immune system, seen with natural killer cell marker NKp46. Alkylating agent CPA-treated tumors experienced more favorable adaptive immune cell RNA expression such as increased CD8+ T cell marker CD8a and decreased FoxP3 marker seen in Tregs. Generally, decreased immune marker gene expression was seen when the mice were given higher doses compared to 100 mg/kg, suggesting dose-limiting immune cytotoxicity. aPD1 co-treated tumors also had increased immune marker expression but not enough to change tumor stasis to regression. Ultimately, these findings showcase that metronomic chemotherapy can bring upon immune cell responses, but drug dose and activation of immune cells need to be carefully considered for potential in achieving tumor regression.

#509 Synergistic inhibition of TNBC via enhancer of zeste homologue 2 (EZH2) inhibition and D1 receptor agonism.

Rajni Kant Shukla[1], Kate Ormiston[2], Gautam Sarathy[3], Shivani Dhekne[3], Sanjay Gupta[4], Daniel Stover[2], Christian Rolfo[2], **Eswar Shankar**[2]

[1]Cardiology, Oklahoma Health Science Center, Columbus, OK,[2]Internal Medicine, The Ohio State University Wexner Medical Ctr., Columbus, OH,[3]The Ohio State University Wexner Medical Ctr., Columbus, OH,[4]Urology, Case Western Reserve University School of Medicine, Columbus, OH

EZH2, a histone methyltransferase linked to poor outcomes in cancer, is overexpressed in triple-negative breast cancer (TNBC), disproportionately affecting African-American and Hispanic women. EZH2 regulates the tumor immune microenvironment (TIME) by inhibiting MHC-I antigen presentation, upregulating PD-L1, leading to reduced antitumor immune responses. Current EZH2 inhibitors target its catalytic activity; however, the development of resistance mechanisms in cancer cells frequently undermines their effectiveness. The neurotransmitter dopamine, through activation of its D1 receptor, promotes apoptosis and autophagy while suppressing cancer cell invasion. Dopamine D1 receptor signaling mitigates the immunosuppressive effects of myeloid-derived suppressor cells (MDSCs) on T cell proliferation and IFN-γ production. Using in silico approaches such as cryptic pocket identification, docking, and molecular dynamics (MD) simulations, initially we assessed the binding affinity of the DRD1 agonist to EZH2. Our in-silico analyses uncovered stable binding profiles, indicating novel interactions at previously uncharacterized sites within the CXC domain and the EED-binding region for both GSK126 and A77636. Next, we performed in vivo experiments combining GSK126 and A77636 to evaluate their effect on tumor growth and the TIME using an NSG mouse model. MDA-MB-231 cells were injected into the breast fat pads of 4-6-week-old female NSG mice. Once tumors were palpated, the mice were randomized into four groups: vehicle treatment, GSK126 (2 mg/kg), A77636 (50 mg/kg), and the combination of both, with treatments administered intraperitoneally for four weeks. Tumor growth was monitored throughout the treatment period, and at the termination, blood, tumor, and spleen were collected and processed into single-cell suspensions for high-dimensional flow cytometry analysis. GSK126 and A77636 treatment in combination significantly reduced tumor volume and decreased EZH2 expression in monocytes and neutrophils within the blood and tumor microenvironment and lowering the levels of pro-inflammatory cytokine IL-1β. In summary, this approach unveils new possibilities for treating TNBC by concurrently targeting EZH2 and DRD1 through a combinatorial strategy. #51 10 second classification of spontaneous lymphoma in patient-derived tumor xenograft models.
N.-A. Pham, L. A. Ye, J. Froment, A. Zarrine-Afsar;
University Health Network, Toronto, ON, Canada

Patient-derived tumor xenografts (PDX) propagated in immunodeficient murine hosts have become effective preclinical models used in drug development and biological studies. PDX models have been established across tumor types with varying degrees of success. A main factor of engraftment failure is formation of spontaneous lymphocytic growths that may occur in murine hosts at the implant site of the patient tumor fragments or serial PDX fragments. Continuous monitoring of fidelity of PDXs to their parent patient tumors is by histological slide review of collected tumors. Processing for histological reviews could range from several hours to days, thus lacking in real-time decision-making support for utility of specimens.
Method: Ambient Picosecond InfraRed Laser (PIRL) ablation soft ionization Mass Spectrometry (MS) was evaluated as a potential tool for rapid classification of spontaneous lymphocytic growth compared to PDX tumor growths. This method uses a 10-second sampling and analysis duration of 3 mm^3 tumor fragments.
Results: PIRL MS analyses across 5 common tumor types of pancreas, lung, colon, ovarian and head and neck with a total of 90 PDX specimens and 20 samples of H&E verified lymphocytic growths was used to train a Principal Component Analysis Linear Discriminate Analysis (PCA-LDA) model to discriminate lymphocytic growths from tumors. Cross-validation using a 20% leave-out test resulted in >94% accuracy for correctly classifying lymphocytic or tumor growths. To ensure the validity of this observation, a permutated version of this model with false annotation resulted in prediction accuracy of ~50% in a 20% leave-out cross-validation. A test set of 90 specimens comprised of 15 lymphomas and 75 tumours was blindly sampled and subjected to the aforementioned model for prediction of specimen type. This blind assessment resulted in 99% sensitivity and 99% specificity values for either of the lymphoma or tumor classes.
Conclusion: This proof-of-principle evaluation suggests that 10-second PIRL MS analysis is able to differentiate between lymphocytic and true tumor growths, further highlighting distinct mass to charge (*m/z*) values specific to each tissue type. PIRL-MS can therefore enable real-time decision-making with respect to the utility of PDX tissue collection for immediate downstream laboratory use, and to further minimize the cost associated with unintentional use of non-tumor outgrowths. The next steps involve determining the molecular identities of lymphoma classifying *m/z* values and to assess the PCA-LDA model's sensitivity to engrafts that contain both lymphocytic and cancer growths.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Repurposing New and Existing Drugs for Cancer Treatment

#510 Neurotransmitter receptor antagonists and metronomic chemotherapy: A promising novel approach for brain metastases in breast cancer.

Arianna Bandini[1], Paola Orlandi[1], Marta Banchi[1], Giulio Francia[2], Guido Bocci[1]

[1]Department of Translational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy,[2]Border Biomedical Research Center, University of Texas at El Paso, El Paso, TX

Brain metastases (BM) from breast cancer are a significant clinical issue with a poor prognosis. New therapies targeting the tumor microenvironment are promising. Various types of neurotransmitter (NT) receptors (e.g., glutamatergic, dopaminergic, serotoninergic receptors) are expressed on breast cancer (BC) cells, modulating cell proliferation, survival, and migration. We propose a novel approach for BM treatment using NT receptor antagonists in combination with metronomic chemotherapy (mCHEMO) - the frequent and regular administration of drug doses, for extended time, without breaks - to block the pro-tumoral interaction between cancer cells and the brain microenvironment, increasing therapeutic efficacy and reducing toxicity. The Kaplan-Meier plotter website was used to assess the impact of the NT receptor gene expression of our interest on overall survival (OS) in metastatic BC patients. Real-Time PCR assessed NT receptor gene expression in monolayer and spheroid cultures of MCF-7 (ER+), MDA-MB-231 (triple-negative), and MDA-MB-361 (HER2+) BC cell lines. Proliferation assays were performed on BC cell lines exposed to metronomic temozolomide (TMZ) and NT receptor antagonists (memantine, ML00253764, SB-269970, clozapine) for 144h daily treatments. The synergism of the concomitant combinations between low-dose TMZ and NT receptor antagonists was evaluated by the combination index method.The Kaplan-Meier analysis showed that a higher level of NT receptors expression is associated with worse OS rates in metastatic BC, particularly with elevated *GRIN1* and *MC4R*. Indeed, genes of NT receptors were highly expressed in BC cell lines. The MC4R antagonist ML00253764 was active on tumor cell lines with a strong antiproliferative effect on MDA-MB-231, showing IC_{50} value of 4.72 nM. The NMDA antagonist memantine was very effective on MDA-MB-361 with a concentration- and time-dependent effect (IC_{50} at 144h 168.1 nM), while the 5-HT_7 receptor antagonist SB-269970 showed encouraging antiproliferative results on MCF-7 (IC_{50} 9.61 nM). Metronomic TMZ decreased cell proliferation in tumor cell lines. The concomitant combinations of TMZ+ML00253764, TMZ+memantine, and TMZ+SB-269970 showed marked synergisms, notably on MDA-MB-361 cells. These findings build rational bases for the promising therapeutic approach, including NT receptor antagonists and metronomic TMZ, for breast cancer BM. Moreover, *in vitro* experiments demonstrated a key role of NT receptor on cell proliferation due to the activity of pharmacological antagonists alone or with mCHEMO. These results support further *in vitro* 3D investigation on multicellular spheroids and *in vivo* experiments on BM models to validate our pioneering therapeutic hypothesis, which could be easily translated into future clinical trials.

#511 Neratinib monotherapy in advanced non-small cell lung cancer with EGFR exon 18 mutations in China.

Wenfeng Fang[1], Ning Li[2], Runxiang Yang[3], Ying Cheng[4], Baogang Liu[5], Haiyong Wang[6], Lin Wu[7], Qiming Wang[8], **Steve Shen**[9]

[1]Sun Yat-sen University Cancer Center, Guangzhou, China,[2]Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China,[3]Yunan Cancer Hospital, Kunming, China,[4]Jilin Cancer Hospital, Changchun, China,[5]Harbin Medical University Cancer Hospital, Harbin, China,[6]Shandong Cancer Hospital, Changsha, China,[7]Hunan Cancer Hospital, Changsha, China,[8]Henan Cancer Hospital, Changsha, China,[9]Convalife (Shanghai) Co., Ltd., Shanghai, China

Background: In NSCLC patients, EGFR exon 18 mutations account for approximately 3-5% and are associated with a poor prognosis. In phase 2 SUMMIT global trial, 29 metastatic NSCLC patients with EGFR exon 18 mutations received neratinib monotherapy, having good result. The objective response rate (ORR) was 35%. However, only 1 (4.5%) Asian individual is enrolled in study. Therefore, there is an urgent need to explore the effect of neratinib monotherapy in Chinese NSCLC patients with EGFR exon 18 mutation.
Methods: Planned 14 patients with EGFR exon 18-mutated NSCLC who had failed first-line standard chemotherapy were enrolled in this study(NCT06029816) . The primary endpoint is the ORR by the investigator according to RECISTv1.1 and the secondary endpoints are DCR (Disease Control Rate), PFS (Progression-Free Survival).
Results: To date, 7 advanced NSCLC patients with exon 18 mutations after receiving Neratinib treatment following the failure of standard first-line therapy. The ORR is 42.9% (3 PR, 4 SD) and DCR is 100.0%. The common 1-2 grade treatment-related adverse events (AEs) occur in 82% of patients. 28.6% of patients have Diarrhea (CTCAE Grade 2) , and that can be managed after loperamide intervention within 3 days. To date, there have been no grade 4- 5 AEs in any of the patients.
Conclusion: Neratinib monotherapy has demonstrated tolerable safety and encouraging preliminary efficacy in NSCLC with EGFR exon 18 mutations. This study is expected to provide more treatment options for Chinese patients with NSCLC who have EGFR exon 18 mutations.

#512 Inhibition of ATR enhances the anticancer activity of ciclopirox in triple-negative breast cancer.

Bing Cheng[1], Chinedum Okafor[2], Jehan Abdulsattar[2], Bolin Liu[3], **Shile Huang**[4]

[1]Biochemistry and Molecular Biology, LSU Health Sciences Center - Shreveport, Shreveport, LA,[2]Pathology, LSU Health Sciences Center - Shreveport, Shreveport, LA,[3]LSU Health Sciences Center - New Orleans, New Orleans, LA,[4]LSU Health Sciences Center - Shreveport, Shreveport, LA

Triple-negative breast cancer (TNBC) is a deadly and difficult-to-treat cancer, partly due to drug resistance, which links to enhanced DNA damage response (DDR). Our previous studies have shown that ciclopirox olamine (CPX), an off-patent fungicide, inhibits cell proliferation and induces apoptosis of various tumor cells *in vitro* and *in vivo*. Mechanistically, this is partly associated with inhibition of the mTOR signaling in tumor cells. Meanwhile, CPX can induce DDR by activating the ATR-Chk1 pathway. AZD6738 (ATR inhibitor) is currently under clinical trials for treatment of solid tumors including TNBC. This study aimed at investigating whether AZD6738 can enhance the anticancer activity of CPX in TNBC. We found that AZD6738 potentiated CPX-induced inhibition of cell proliferation and induction of apoptosis in TNBC cells. CPX treatment decreased the levels of cyclins, CDKs and phospho-Rb and increased the levels of cleaved caspase-3 and γH2AX in TNBC cells, which could be strengthened by addition of AZD6738. In addition, we observed that the combined treatment with CPX/AZD6738 did not exhibit significant toxicity in nude mice, but inhibited tumor growth more potently than the single treatment with CPX or AZD6738 in MDA-MB-231 xenografts. The results indicate that inhibition of ATR with AZD6738 can potentiate the anticancer activity of CPX in TNBC cells *in vitro* and *in vivo*. Our finding suggests that combination of CPX and AZD6738 may represent a novel therapeutic approach for TNBC.

#514 Therapeutic potential of antidepressant amitriptyline in medulloblastoma.

Frank B. Wang[1], Prabhakar Pitta Venkata[1], Andrew Brenner[2], William Kelly[2], Gangadhara R. Sareddy[3], Manjeet K. Rao[1]

[1]Greehey Children's Cancer Research Institute - UT Health San Antonio, San Antonio, TX,[2]Mays Cancer Center - UT Health San Antonio, San Antonio, TX,[3]Department of Obstetrics & Gynecology, UT Health San Antonio, San Antonio, TX

Introduction: Medulloblastoma, the most common malignant brain tumor in children, primarily arises in the posterior fossa, predominantly affecting the cerebellum. Accounting for approximately 20% of all pediatric brain tumors, medulloblastoma has an annual incidence of about 500 cases in the United States, with a peak age of diagnosis between 5 and 7 years and a slight male predominance. Advances in genomic and epigenomic profiling have identified four distinct subgroups—WNT, Sonic Hedgehog (SHH), Group 3, and Group 4—each characterized by unique molecular features, patient demographics, and prognostic outcomes. Current treatment strategies, including surgical resection, craniospinal irradiation, and adjuvant chemotherapy, have improved survival rates; however, up to 40% of patients experience incurable recurrence or metastasis, the leading cause of mortality. Furthermore, survivors often endure debilitating long-term side effects from these aggressive therapies, underscoring the urgent need for more effective and less toxic therapeutic approaches.
Methods: To evaluate the anticancer activity of Amitriptyline, we utilized SHH (DAOY) and Group 3 (HDMB03, D556, D425) medulloblastoma cell lines. Cell viability, survival, and apoptosis were assessed through established functional assays. The impact of Amitriptyline on cancer stemness was investigated using sphere formation and extreme limiting dilution assays. Mechanistic studies were conducted through RNA sequencing, quantitative RT-PCR, and Western blot analysis to elucidate molecular pathways. The therapeutic potential of Amitriptyline was further validated in vivo using orthotopic xenograft mouse models of medulloblastoma.
Results: Amitriptyline treatment significantly inhibited cell viability, colony formation, and migratory capacity while promoting apoptosis in medulloblastoma cell lines. Additionally, Amitriptyline reduced the viability and sphere-forming ability of medulloblastoma stem cells, indicating a potent effect on cancer stemness. Notably, Amitriptyline enhanced the therapeutic efficacy of Vincristine in medulloblastoma cell lines. *In vivo* studies demonstrated that Amitriptyline treatment significantly prolonged survival in the orthotopic xenograft mouse model, with no sign of toxicity, highlighting its therapeutic potential.
Conclusion: Collectively, our findings suggest that Amitriptyline may serve as a viable therapeutic option for medulloblastoma, providing a basis for potential clinical application.

#515 Repurposing nebivolol with dasatinib and CPI-613: A synergistic strategy to combat triple-negative breast cancer.

Mikayla Skillman[1], Airong Li[1], Fatima Dagher[1], Diana Chow[1], Meghana Trivedi[2]

[1]Department of Pharmacological & Pharmaceutical Sciences, University of Houston, Houston, TX,[2]Department of Pharmacy Practice and Translational Research, University of Houston, Houston, TX

Triple-negative breast cancer (TNBC) is a relentless and aggressive disease, posing significant challenges due to its high recurrence rates and poor prognosis. Existing treatments, such as chemotherapy and radiation, often cause long-term side effects, and over half of patients experience relapse within a few years of diagnosis. This study investigates the novel approach of repurposing nebivolol (NEB), a beta-blocker with a well-established safety profile, in combination with dasatinib (DAS) or Devimistat (CPI) to potentially enhance anti-tumor efficacy in TNBC. Dasatinib targets multiple kinases involved in cancer cell proliferation and metastasis, while CPI-613 induces metabolic stress and apoptosis in cancer cells. We evaluated the cytotoxic effects of NEB, DAS, and CPI, both individually and in combination, across TNBC cell lines (MDA-MB-231, 4T1, BT-549) using MTT assays. IC_{50} values were determined, and optimal drug ratios were identified using the Chou-Talalay method and 3D surface plots. Drug ranges were selected below and above determined IC_{50} values and used in a two-system matrix design. Combination Index (CI) plots were generated to assess synergistic interactions. Additionally, a migration assay was performed to evaluate the effects of the combinations on cell migration. NEB, DAS, and CPI individually reduced cell viability with IC_{50} values of 6.3 µM, 76.4 nM, and 71.1 µM in MDA-MB-231 cells; 12.8 µM, 91.2 nM, and 41.4 µM in 4T1 cells; and 2.7 µM, 33.2 nM, and 24.8 µM in BT-549 cells. The NEB-DAS combination exhibited significant synergy in BT-549 cells, with a CI of 0.35 at 800 nM NEB and 3 nM DAS ($p < 0.002$ compared to each drug alone). Similarly, NEB-CPI demonstrated additive effects in BT-549 cells, with a CI of 1.0 at 800 nM NEB and 20 µM CPI ($p < 0.003$ compared to each drug alone). In MDA-MB-231 cells, the NEB (3 µM)-DAS (50 nM) combination showed significant synergy only with NEB ($p = 0.0007$, CI 0.85), while the NEB (3 µM) -CPI (15 µM) combination was synergistic compared to either drug alone ($p < 0.001$, CI 0.49). For 4T1 cells, NEB (6 µM) and CPI (20 µM) was significantly more potent compared to each drug alone ($p < 0.0001$, CI 0.32), and NEB (3 µM) and DAS (30 nM) was more potent compared to each drug alone ($p < 0.004$). Most combinations using Chou-Talalay had CI values predominantly below 1, confirming synergy. The migration assay indicated that NEB and CPI significantly reduced migration in MB-231 cells compared to either drug alone ($p < 0.03$). Interestingly, the NEB-DAS combination did not show a significant difference compared to DAS alone ($p=0.17$) but was more effective than NEB alone ($p = 0.0009$). These findings highlight the potential of NEB in combination with DAS or CPI as a promising therapeutic strategy for TNBC. Ongoing *in vivo* studies using a TNBC mouse model aim to validate these findings and further explore the clinical potential of these combinations to improve TNBC patient outcomes.

#516 SOX4 dictates gastric cancer progression by modulating the tumor immune microenvironment.

G. Zou[1], K. Yoshimura[2], Y. Fan[1], R. Wang[1], K. Yamashita[1], S. Shao[1], A. Scott[1], J. Jin[1], M. P. Pizzi[1], M. Silva[1], X. Yao[3], C. Brown[1], R. Waters[1], S. Song[3], L. Wang[1], S. Dhar[1], J. A. Ajani[1];

[1]UT MD Anderson Cancer Center, Houston, TX, [2]Hamamatsu University School of Medicine, Hamamatsu, Japan, [3]Coriell Institute for Medical Research, Camden, NJ

SOX4 upregulation is common in multiple tumors, yet its role in shaping the immune microenvironment of gastric adenocarcinoma (GAC) remains unclear. This study investigates the influence of SOX4 on GAC progression and immune modulation. Using single-cell RNA sequencing, patient-derived models, and functional analyses, we examined SOX4 expression and its target genes in GAC. SOX4 was found to be highly expressed in both primary and metastatic GAC tissues, correlating with poor prognosis. Knockdown of SOX4 in GAC cells reduced tumor growth, migration, and colony formation and suppressed metastasis. Furthermore, SOX4 depletion enhanced T-cell cytokine production and promoted M2-macrophage repolarization in cocultures with patient-derived PBMCs and U937 cells. Conversely, SOX4 overexpression reinforced these aggressive phenotypes. RNA-seq analysis of SOX4 wildtype and knockout cells led to the identification of six drugs that could mimic the effects of SOX4 deletion, with Cucurbitacin-I and Tunicamycin emerging as potent inhibitors of GAC cell growth in patient-derived models. These findings highlight SOX4's role in driving GAC progression and immune evasion, offering potential therapeutic avenues for targeting SOX4 in GAC treatment.

#517 YAP-TEAD-mediated tumor suppression and immune modulation of gastric adenocarcinoma by HSP90 inhibition.

K. Yoshimura[1], **G. Zou**[2], Y. Fan[2], K. Yamashita[2], J. Wu[2], R. Wang[2], S. Shao[2], A. Scott[2], J. Jin[2], M. Pizzi[2], X. Yao[2], C. Brown[2], L. Wang[2], L. Wang[2], Q. Gan[2], R. Waters[2], Y. Feng[2], S. Song[3], S. Dhar[2], J. Ajani[2];

[1]Hamamatsu University School of Medicine, Hamamatsu, Japan, [2]UT MD Anderson Cancer Center, Houston, TX, [3]Coriell Institute for Medical Research, Camden, NJ

Heat shock protein 90 (HSP90), a vital chaperone involved in the folding and stabilization of various cellular proteins, regulates key functions in many tumor cells. In the context of gastric adenocarcinoma (GAC), where HSP90's role remains largely unexplored, we aimed to investigate the significance of HSP90 inhibitor, AUY922, in regulating the YAP1/TEAD pathway and its association with the tumor immune microenvironment (TME). Our results showed that AUY922 effectively inhibited GAC aggressiveness in both the in-vitro and in-vivo models, induced apoptosis, and cell-cycle arrest. Various functional assays elucidated that AUY922 potently inhibited the expression and interaction among YAP1/TEAD and HSP90, evoking in down-regulation of target functional genes. AUY922 additionally altered the TME into an inflamed state with increased cytokine production in T-cells and inhibition of M2-polarization of tumor-associated macrophages, rendering it a favorable partner for immune checkpoint inhibition. Our findings highlighted the suggestion of targeting HSP90 in GAC therapy via down-regulating YAP1/TEAD signaling. Further, results suggest that AUY922's ability to reshape the GAC TME favoring the host sets the stage for a clinical trial that combines HSP90 and checkpoint inhibition, where HSP90 could serve as a biomarker for patient selection.

#518 Repurposing of pralatrexate in gastric cancer: Inducing cell death via SMO inhibition and GLI1 suppression.

Hyemi Yun[1], Bo Ram Kim[2], Bu Gyeom Kim[2], Dae Yeong Kim[2], Okhyeon Kim[1], Yoon Namgung[3], Jun Woo Bong[4], Sanghee Kang[4], Sun Il Lee[4], Sang Cheul Oh[2]

[1]Biomedical Sciences, Korea University College of Medicine, Seoul, Korea, Republic of,[2]Department of Oncology, Korea University Guro Hospital, Seoul, Korea, Republic of,[3]Division of Oncology/Hematology, Department of Internal Medicine, Korea University Guro Hospital, Seoul, Korea, Republic of,[4]Surgery, Korea University Guro Hospital, Seoul, Korea, Republic of

Gastric cancer (GC) is the fifth most common cancer and the fourth leading cause of cancer-related deaths worldwide. Currently, GC has serious drug resistance and side effects to existing treatments, and the development of new treatments is urgently needed. Abnormal activation of Hedgehog (Hh) signaling can promote the proliferation, metastasis, and drug resistance of GC cells and inhibit apoptosis. In gastrointestinal cancer, the expression of components of the Hh signaling pathway and their target genes are upregulated. Through TCGA analysis, we found that among the five types of digestive cancers: cholangial, colorectal, gastric, hepatocellular, and pancreatic, GC is most affected by Hh signaling. Pralatrexate is an FDA-approved drug originally used to treat relapsed or refractory peripheral T-cell lymphoma (PTCL). Research has been conducted on its anticancer efficacy in solid carcinomas such as Non-small cell lung cancer (NSCLC), but its efficacy in GC remains unexplored. In a previous study, screening results using an FDA-approved drug library showed that Pralatrexate inhibits GLI-dependent luciferase activity. In this study, we demonstrated that Pralatrexate canonically regulates Hh signaling by downregulating SMO. Structural predictions using AI modeling indicated that Pralatrexate binds to a site similar to the SMO antagonist ANTA-XV, distinct from Cyclopamine's binding pocket. It was confirmed that Pralatrexate causes degradation of SMO, and GLI1 was subsequently degraded by lysosome. This suppression of Hedgehog (Hh) signaling results in reduced cell proliferation and the induction of apoptosis. In summary, Pralatrexate canonically regulates Hh signaling by inhibiting SMO and suppressing GLI1, ultimately reducing cell proliferation and causing apoptosis in GC. Our findings uncover a novel anticancer mechanism of Pralatrexate in GC, providing a potential basis for its clinical application in GC therapy.

#519 CDK4/6 inhibitors and endocrine therapies induce senescence with drug- and cell line-specific vulnerabilities in ERα+ breast cancer.

Lena Batoon, Angelo J. Guilatco, Anna Detry, Xiyin Wang, Megan M. Weivoda, John R. Hawse

Mayo Clinic, Rochester, MN

Estrogen receptor alpha (ERα)-positive breast cancer accounts for up to 80% of cases. Despite advances in CDK4/6 inhibitors (CDK4/6i) and endocrine therapies, recurrence and late relapse remain significant challenges. Recurrence often arises from disseminated cancer cells that persist despite 5-10 years of systemic adjuvant treatment. While CDK4/6i and endocrine therapies induce prolonged growth arrest resembling senescence, they do not significantly kill cancer cells. Senescent/pseudo-senescent cancer cells are implicated in aggressive variant formation, recurrence, and metastasis. We explored eliminating breast cancer cells via senolysis while they are in therapy-induced senescent state to prevent their potential to escape, repopulate, or cause long-term adverse effects. Live-cell imaging of MCF7 and T47D cells treated with abemaciclib and endocrine therapies (endoxifen or estrogen deprivation to mimic aromatase inhibition) at clinically relevant concentrations for eight days demonstrated prolonged growth cessation and G1 cell cycle arrest even two weeks post-drug withdrawal. These cells displayed a senescence-like gene expression profile, with increased *CDKN2B* (p15), *CDKN1A* (p21), *BCL2*, reduced *KI67*, and increased *TGFβ* expression, a known Senescence-Associated Secretory Phenotype (SASP) factor linked to deep senescence. These results confirm effective senescence induction by various CDK4/6i and endocrine therapy combinations. Further analysis using established senescence markers (e.g., nuclear size, telomere-associated foci, satellite distension, and loss of nuclear HMGB1 and LaminB1) revealed unique senescence phenotypes across therapy combinations. Cell viability assays and live imaging of Caspase 3/7 activation demonstrated differential vulnerabilities of senescent/senescent-like ERα+ cancer cells (MCF7, T47D, UCD4, UCD12) to 13 senolytics (1 μM), including natural flavonoids and inhibitors targeting pro-survival factors, tyrosine kinases, and the Notch pathway. For example, MCF7 and UCD4 cells responded to MCL1i and RSL3, T47D to BCLXLi and RSL3, and UCD12 to BCLXLi and Navitoclax. Notably, senolytic cocktails (e.g., RSL3, GNF7, Venetoclax, Dasatinib) at reduced concentrations (0.25 μM each) effectively eliminated senescent/senescent-like ERα+ cancer cells across all cancer cell lines, achieving 100% elimination in T47D cells. Collectively, these findings demonstrate that despite variability in therapy-induced senescence, senolytic combinations effectively target senescent ERα+ cancer cells. This provides preliminary evidence for the potential integration of this strategy into standard breast cancer therapy with a goal to improve recurrence-free survival and increase the cure rates for ERα+ breast cancer patients. In vivo studies are underway to evaluate this strategy in preclinical models.

#520 Repurposing verteporfin: anti-metastatic properties associate with extracellular matrix modulation in osteosarcoma.

Danny Carreira[1], Anita K. Luu[1], Carey E. Dougan[2], Shelly R. Peyton[2], Geoffrey A. Wood[3], Brenda L. Coomber[1], Alicia M. Viloria-Petit[1]

[1]Biomedical Sciences, University of Guelph, Guelph, ON, Canada,[2]Chemical Engineering, University of Massachusetts Amherst, Amherst, MA,[3]Pathobiology, University of Guelph, Guelph, ON, Canada

Osteosarcoma (OS) is the most common primary bone cancer; 20% of OS patients present with metastasis at diagnosis, with more than 80% of those cases having spread to the lungs. Lack of treatments for metastatic disease leads to poor survival outcomes, making it imperative to find better therapies. Verteporfin (VP), a photosensitizer used for the treatment of age-related macular degeneration, targets the hippo signaling pathway via YAP1, while also inhibiting autophagy mediators through the formation of crosslinked oligomers, all without direct photoactivation. The purpose of this study was to assess VP's effect on OS lung colonization, biomechanical properties, and extracellular matrix modulation independent of photoactivation.

K7M2 OS cells or PBS were tail vein injected into BALB/c mice, and K7M2 injected mice were assigned to receive intraperitoneal 20 mg/kg VP or vehicle twice a week, starting at day 2 post-injection. Histological analysis of H&E and Masson's trichrome stained sections was performed using QuPath on lung tissue collected on days 4, 8, 16, and 24 to assess metastatic burden and collagen content, respectively. Biomechanical analysis was performed with a custom indenter setup on lung samples with and without lesions to measure tissue stiffness. Insoluble protein contents were analyzed via mass spectrometry. Subsequently, in-vitro analysis was performed in K7M2 cells following treatment with 0.09 μM, 1.5 μM, 7.5 μM VP or vehicle for 24 hours, controlling for light. Fibronectin (FN) and tumor-related FN isoform (EIIIA, EIIIB, and IIICS) levels were assessed at the mRNA level via RT-qPCR on cell and lung samples, and FN protein expression was analyzed through immunofluorescence microscopy of cultured K7M2 cells.

Histological analysis of day 24 lung samples highlighted a significant reduction in metastatic burden following VP treatment. Interestingly, stiffness was unchanged across day 4 and 24 in lung samples from vehicle-treated mice; however, VP treated samples showed a small yet significant increase. Collagen levels in metastases and stroma from vehicle and VP injected mice were unchanged throughout OS progression, though mass spectrometry identified FN enrichment in lung tissue from VP treated mice. FN mRNA levels were unchanged in cell lysates; conversely, lung samples highlighted reduced FN mRNA with metastasis, with VP restoring levels to that of normal lung. EIIIB FN was found to be decreased with metastasis, though largely variable with VP treatment. In cultured cells, FN protein expression increased parallel to VP concentration, with unchanged distribution. Results point towards VP effectively reducing OS metastasis to the lungs in parallel to increases in stiffness and FN expression. Further research on the role of the ECM, including FN and its isoforms, will further our understanding of the anti-metastatic properties of VP.

#521 Drug repurposing via ultra-high throughput 3D spheroids screening in rare cancer treatment.

M. G. Yonk[1], M. S. Tora[1], M. A. Lim[2], T. Federici[1], H. Fu[1], Y. Du[1], B. Yao[1], N. Boulis[1], K. Lei[1];
[1]Emory University School of Medicine, Atlanta, GA, [2]University of Illinois Urbana Champaign, Champaign, IL

Spinal cord gliomas (SCG) are rare cancers, and relevant pharmaceutical research and treatments are limited. While drug repurposing of FDA-approved compounds has shown promise for orphan diseases, its potential for SCG remains uncertain. Our research team has recently developed an SCG model in minipigs, offering anatomical, immunological, developmental, and genetic similarities to humans, which makes it an ideal model for translational precision medicine. In this study, we used a novel drug repurposing strategy using 3D spheroids from our recently established large animal SCG model as a case study. First, we established a miniaturized 3D cell culture platform for ultra-high-throughput screening (uHTS). After screening the FDA-approved and Bioactive compound library with minipig SCG 3D spheroids, Clofoctol, showed potential as a glioma treatment by targeting genes in the p53 pathway. Evaluation in a xenograft model demonstrated Clofoctol's ability to suppress tumor growth over a 10-day treatment period, followed by immunohistochemistry and RNA-seq. These findings suggested Clofoctol is a promising therapeutic for glioma treatment. Thus, our study shows the feasibility of 3D spheroids uHTS to expedite orphan disease research, providing a strategy for future drug repurposing for rare cancer patients.

#522 One drug- Two targets in osteosarcoma.

Marina Curcic, Sanjay K. Srivastava

Texas Tech University Health Sciences Center, Lubbock, TX

Osteosarcoma, the most common primary malignant bone tumor, mostly affects adolescents and older adults, with limited therapeutic advances leading to poor survival rates for metastatic or recurrent cases. Current treatments often fail due to high mutational burdens and chemoresistance, necessitating new targeted therapies. In this study, we investigated the potential of PCT, a kinase inhibitor recently approved for hematological malignancies, for its anticancer effect against osteosarcoma. Our comprehensive in vitro analysis demonstrated that PCT inhibits cell viability, induces apoptosis, and causes G2/M arrest in multiple osteosarcoma cells. Gene expression analysis indicated that at very low micromolar concentrations, PCT inhibits the expression of AXL, β-Catenin and key players of the pathway at protein and mRNA level. Molecular docking analysis indicated PCT's high binding affinity to AXL confirming our observations that PCT suppresses AXL/β-Catenin expression and transcriptional activity. Oral administration of PCT significantly reduced osteosarcoma tumor growth in murine models without any observable toxicity. The tumors of PCT treated mice exhibited inhibition of AXL and β-Catenin signalling axis and induction of apoptosis. Our findings suggest PCT as a dual inhibitor of AXL and β-catenin, directly affecting osteosarcoma progression. This research highlights PCT's potential as a targeted therapeutic for osteosarcoma, offering new avenues to improve outcomes for patients with this aggressive malignancy.

#523 Minnelide as a potential treatment strategy for CIC::DUX4 sarcoma.

MaKenna R. Browne[1], Peter G. Hendrickson[2], David G. Kirsch[3]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]Duke Universtiy, Durham, NC,[3]Radiation Medicine, UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: CIC::DUX4 Sarcoma (CDS) is driven by t(4;19) or t(10;19) chromosomal translocations and is associated with high rates of metastasis, chemoresistance, and poor outcomes. Previously classified as “Ewing-like sarcoma” due to overlapping morphological and immunobiological features, CDS differs from Ewing sarcoma in several key aspects: it rarely arises in bone, lacks the Ewing-defining ETS gene fusion, and has a more aggressive clinical course. Despite recent reclassification by the World Health Organization as its own entity, CDS patients are still treated with ineffective Ewing-based chemotherapies. This study evaluates the therapeutic potential of 160 compounds in human CDS cells, identifying Triptolide as a top candidate. Minnelide, the water-soluble prodrug of Triptolide, is currently undergoing Phase I/II trials for various cancers, including pancreatic and gastric cancer.

Methods: We conducted a viability drug screen on human CDS cells using a Tocriscreen compound library. The top hit, Triptolide, was subsequently validated using its water-soluble prodrug, Minnelide, which replicated the screen results. To investigate the mechanism of action, cells were treated for 72 hours at the IC_{50} concentration and processed for RNA sequencing. Finally, we modeled CDS by generating subcutaneous xenograft tumors in immunodeficient NSG mice. Mice were transplanted with CDS tumor-derived cells and treated with Minnelide (or vehicle control) once daily for 21 days. The drug doses (0.21 mg/kg and 0.27 mg/kg) were selected based on bioavailability data and maximum tolerability observed in Phase I/II clinical trials.

Results: Minnelide treatment decreased CDS cell viability and significantly reduced the growth of CIC::DUX4 sarcoma xenografts within 21 days. The Phase I clinical trial data indicates that the recommended starting dose for patients is 0.67 mg/m², which corresponds to a dosage of 0.21 mg/kg in mice. The average tumor volume of the 0.21 mg/kg Minnelide treatment group was significantly (two-way ANOVA, $P = 0.0001$) lower than that of the control group at day 21 post-treatment initiation. Moreover, drug treatment was not associated with any adverse side effects. RNA sequencing and western blot analysis of CDS cells treated with Minnelide revealed downregulation of many CIC::DUX4 target genes, such as ETV1/4/5 and DUSP6. These results suggest that Minnelide alters the CDS transcriptional program and could represent an efficacious treatment alternative.

Conclusion: Therapeutic advancements for CIC::DUX4 sarcoma have been limited to date, and there are currently no clinical trials available for CDS patients. Our findings demonstrate that Minnelide effectively reduces CDS cell viability and xenograft growth, while downregulating key CIC::DUX4 target genes. Given the role of CIC::DUX4 as a potent transcriptional activator, Minnelide's disruption of this activation may offer a promising therapeutic approach for CDS.

#524 An integrative approach to unveiling biomarkers and therapeutic targets identifies novel treatment strategy for advanced prostate cancer.

Shreya Shyam Sundar[1], Ephraim J. Gardner[1], Surendra Gulla[2], Remi Adelaiye-Ogala[2]

[1]Pharmacology, University at Buffalo, State University of New York, Buffalo, NY,[2]Department of Medicine, University at Buffalo, State University of New York, Buffalo, NY

Advanced prostate cancer (PCa) is one of the leading causes of cancer-related deaths in men in United states. Despite advances in treatment modalities, patients still develop resistance to treatment. Limited studies have focused on targeted therapeutic approach addressing the heterogeneity of the disease. However, a comprehensive multi-omics approach that integrates transcriptomic and proteomic profiles can discover pathways associated with the development of both primary and acquired resistance and remains a critical factor in identifying predictive markers of treatment efficacy to investigate new therapeutic options. In this study, we performed LC-MS/MS and downstream analysis in established patient derived xenograft (PDX) models of advanced castrated resistant PCa (CRPC) to detect protein abundance and enriched pathway. All terms and pathways with an FDR <0.05 after BH adjustment were used. To integrate and determine concordance, transcriptomic followed by enrichment pathway analysis was performed, revealing commonly enriched pathways at the proteomics and transcriptomics level. These data formed the bases for a biomarker-specified library of 100 FDA approved drugs for high throughput screening. Amongst all drugs tested, Trifluridine, previously FDA approved for viral eye infection and in combination with Tipiracil, approved for metastatic colorectal cancer, emerged as a promising candidate. Trifluridine in combination with enzalutamide, showed reduced cell proliferation in CRPC models. The potential of Trifluridine was further highlighted in CRPC cells exhibiting synergism when combined with PARP inhibitors. The synergistic impact of trifluridine alone or in combination will potentially enhance treatment efficacy in overcoming drug resistance by perhaps targeting the DNA repair mechanism. Therefore, our hypothesis is that repurposing Trifluridine alone or in combination with standard of care will be benefitable for treatment-resistant prostate cancers. Our current study has shown that changes in the proteomic landscape that are in concordance with changes at the transcriptomic level are associated with treatment resistance and can direct the best treatment option. This approach identified an FDA approved drug, trifluridine, that can be repurposed for treatment of CRPC, offering a promising treatment strategy for advanced disease. In summary, our studies highlight the unique benefits of using an integrative approach to unveil novel biomarkers and targets for enhanced therapeutic strategies for CRPC.

#525 From unbiased genetic screen to therapy: Combination of 5-ALA and artesunate for the treatment of primary glioblastoma multiforme.

Michael Orthofer[1], Marianna Rozsova[1], Ferdinand Baumgartner[1], Barabara Kiesel[2], Georg Widhalm[2], **Moritz Horn**[1], Josef M. Penninger[3]

[1]JLP Health GmbH, Vienna, Austria,[2]Medical University Vienna, Vienna, Austria,[3]Helmholtz Centre for Infection Research, Braunschweig, Germany

The natural compound Artemisinin and its derivative Artesunate are widely used anti-malarial drugs. Due to their cytotoxic activity, they have also been investigated as anti-cancer agents, while their precise mechanism of action and key host cell targets have remained largely elusive. Using an innovative forward genetic screening approach, we identified porphyrin biosynthesis as the critical pathway governing Artemisinin's cytotoxicity. Genetic or pharmacological modulation of porphyrin production, e.g. by supplementation of the porphyrin precursor 5-aminolevulinic acid (5-ALA), defines Artesunate's cytotoxicity in multiple eukaryotic cells, including human cancer cells. 5-ALA, a clinically approved photodynamic porphyrin enhancer, is used as a surgical fluorescence marker, which specifically labels tumorigenic brain areas due to differential uptake and metabolism. Combining Artesunate with 5-ALA therefore provides an additional level of selectivity towards malignant tissue. We translated the screening results into clinically relevant model systems of brain tumor development: glioblastoma models in engineered cerebral organoids, patient-derived brain tumor spheroids, and orthotopic xenograft models using freshly isolated patient cells. The 5-ALA-Artesunate combination showed a strong and selective antineoplastic activity in all three model systems. At AACR 2025 we will present a comprehensive preclinical data-package, including a new delivery system with animal pharmacokinetics and efficacy data, paving the way for the clinical application of this promising therapeutic approach.

#526 Leveraging germline genetics to predict the efficacy of repurposing approved cancer therapies for cancer prevention.

Chibuzor F. Ogamba[1], Elio Riboli[2], James Yarmolinsky[2], Philip C. Haycock[3], Ruth C. Travis[1], Karl Smith-Byrne[1]

[1]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom,[2]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, United Kingdom,[3]Bristol Population Health Science Institute, MRC Integrative Epidemiology Unit, University of Bristol, Bristol, United Kingdom

Background: The high costs and failure rates of drug development have hindered progress in new cancer therapies, driving interest in systematic drug repurposing. Recent studies suggest that genetic evidence can improve the success rate of drug development. We aimed to investigate the yield of germline genetics in recapitulating the efficacy of approved cancer therapies for preventing the same cancer.

Methods: We mapped 3,081 plasma protein cis-protein quantitative trait loci (pQTLs) from UK Biobank Olink and Iceland SomaLogic GWAS data to approved and currently marketed cancer drug information on the Open Targets Platform. Using publicly available GWAS summary statistics for 39 cancer subtypes, we performed cis-pQTL Mendelian randomization (MR) analyses to estimate the association between drug-target protein concentrations and corresponding cancer risk. Odds ratios (ORs) were oriented to the drug's action on the protein i.e., a drug inhibiting a risk-increasing protein would correspond to a reduced risk. Using our MR results, we evaluated the success of genetic evidence in repurposing cancer treatments for prevention, relative to the approval rate of new drugs progressing from phase 1 trials. We quantified this using the relative probability with 95% confidence intervals (CI) that a target-indication (T-I) pair approved for treatment will have genetic evidence for use in prevention (R(G)), using the ratio of the probability of a directionally consistent significant MR result (P(G)) to the probability of approval for pairs that completed phase 1 trials (P(D)). We tested the sensitivity of R(G) by cancer type and targeted pathways.

Results: Of the 298 cancer T-I pairs available for MR analyses, we found 49 significant protein-cancer associations representing 28/72 targets across 22/39 cancer subtypes. Of these, 36 were directionally congruent with the drug's action on the protein, representing 20/72 targets of 54/139 drugs across 19/39 cancer subtypes. MR-significance and directionality of T-I pairs did not differ significantly by the presence of a targeted somatic mutation in the protein. We estimated the relative probability (R(G)) that a T-I pair approved for treating cancer has genetic support for prevention to be 1.95 (95% CI: 1.46-2.60). R(G) was significantly higher for 8/18 cancers [pancreatic cancer (3.7, 1.1-12.1) to brain cancer (67.5, 18.6-244.6)], significantly lower for thyroid cancer, and not significantly different for 9/18 cancers. Furthermore, R(G) was significantly higher for T-I pairs mapped to 9/12 pathways, including extracellular matrix organization, transcription and signal transduction.

Conclusion: Our findings indicate that certain targets of existing cancer therapies may be repurposed for cancer prevention and demonstrate a potentially high yield in the utility of genetics in improving target identification for drug repurposing in cancer.

#527 Atovaquone upregulates PD-L1 expression via activation of the ATM/ATR DNA damage response pathway.

Sejal Tarun Sharma, Maria Virumbrales-Munoz, Mayra Betancourt Ponce, Lisa Barroilhet, Manish Patankar

Department of Obstetrics & Gynecology, University of Wisconsin-Madison, Madison, WI

Background: Ovarian cancer is one of the deadliest gynecological malignancies, typically diagnosed at an advanced stage complicating standard treatments and shows a need for new treatment options. Previously our lab has shown that atovaquone, a known anti-malarial drug, reduces ovarian cancer proliferation under *in vitro* and *in vivo* conditions. Atovaquone is a potent inhibitor of oxidative phosphorylation (OXPHOS) and as a result causes a significant increase in intracellular oxygen radicals. The oxidative stress mediated by atovaquone causes double strand DNA breaks. Here, we examine if the DNA damage by atovaquone leads to activation of the ATM/ATR pathway and, consequently, upregulate PD-L1. Increased PD-L1 expression in ovarian cancer patients after treatment with atovaquone will provide a rationale in combining atovaquone with anti -PDL1 therapy to enhance anti-tumor response and improve overall treatment outcome.

Methods: For all experiments, ovarian cancer cells (OVCAR-5 and ID8) were treated with atovaquone at IC50 concentrations (10-30 μM). DNA damage was assessed by staining with picogreen and monitoring the cells by fluorescent microscopy as well as 8-OHdG (marker of DNA damage due to oxidative stress) flow cytometry. Activation of the ATM/ATR pathway was evaluated by western blotting using cell lysates for the expression of phosphorylated ATM, ATR, CHK1, CHK2, JAK1, STAT1 and IRF1 proteins. Flow cytometry was used to monitor expression of PD-L1 on the tumor cells. In some experiments, the ATM/ATR inhibitor, AZD1056, was added to the media at 2.5 μM-5 μM concentration for 5 h prior to determining the effect of this treatment on PD-L1 expression.

Results: A 75% increase in abnormal nuclei with DNA damage was observed after 72 h treatment of OVCAR-5 and ID8 with atovaquone. Mild dysfunction in nuclear morphology was visible at the 24 h. Increase in expression of 8-OHdG was observed after atovaquone treatment confirming DNA damage. Exposure to atovaquone for 72 h resulted in significant upregulation of phosphorylated ATM, ATR, CHK1, CHK2, JAK1 and STAT1 proteins. Flow cytometry data demonstrated a (20-55%) increase in the level of PDL1 expression after 48h to 72 h atovaquone treatment in OVCAR 5 and ID8 cells. A (55-65%) increase in the number of both OVCAR 5 and ID8 cells expressing PDL1 expression was also observed. Inhibition of ATM/ATR signaling by pretreatment with AZD1056 reversed the level of increase in PDL1 expression in atovaquone treated OVCAR-5 and ID8 cells.

Conclusion: These findings underscores ATM/ATR pathway as a novel molecular mechanism of PDL1 upregulation in atovaquone-treated ovarian tumors. Thus, our next step is to investigate if combining atovaquone with anti-PD1/PDL1 therapy will be effective in *in vivo* models of ovarian cancer.

#529 Obatoclax, a safe BH3-mimetic, is noninferior to neurotoxic oxaliplatin when combined with adenovirus to treat colorectal carcinoma.

John Milburn Jessup[1], Sameer Tiwari[1], Ali Andalibi[2], Yungtao Wu[1]

[1]George Mason University, Manassas, VA,[2]Charles R. Drew University, Los Angeles, CA

Oxaliplatin (Ox) in an important inducer of Immunogenic Cell Death (ICD) that causes endoplasmic reticulum (ER) stress and externalizes Calreticulin (ectoCALR) to attract and activate immune cells agnostically. However, since OX is quite toxic, we hypothesize that Obatoclax (OB), a clinically safe BH3 mimetic, that causes ER stress through mitochondrial stress can replace OX in our vaccine model. Our model involves a single intralesional injection of 80 μM OX combined with an oncolytic chimeric Ad5/3-NP2.ADP (ADP) adenovirus into > 6 mm CT26 colorectal carcinomas (CRC) dwelling in BALB/c hosts for 14 or more days. Treatment causes 90% regression with 20% durable complete responses - without checkpoint blockade. Treatment is accompanied by a four-fold increase in intratumoral CD8+ T cells from 99% PD-1^{Hi}EOMES$^{Int\text{-}High}$in control tumor bearers to 79% PD-1^{Lo}EOMES^{Lo} or PD-1^{Lo}EOMES^{Int} CD8+ T cells in treated mice along with new *in vitro* cytotoxicity to CT26 cells and rejection of distant CT26 cells in survivors. We postulate that OB synergizes with ADP to increase ectoCALR, enhance viral infectivity and inhibit the growth of murine and human CRC *in vitro* that can be used *in vivo* as a vaccine. The approach used cytometry to quantify proliferation, CALR protein expression, viral production, autophagy and ER stress, and their response to inhibitors. In both murine CT26 and human Clone A (DLD-1) CRC cells, OB induces more ectoCALR than OX as a monotherapy within 2 hours at dosages equivalent to 50% of clinical Cmax for each agent. OB increased superoxide production with an EC50 50.2 nM in CT26 cells confirming mitochondrial stress. OB and OX both cause necroptosis in CT26 and Clone A cells which is critical for ICD. OB synergizes with ADP to inhibit growth *in vitro* in CT26 cells (OB alone IC50 1.1 nM, ADP IC50 for Multiplicity of Infection (MOI) 69.2 MOI which decreases to an IC50 of 0.3 MOI with OB at 1 nM). Similar synergy occurred with Clone A cells. Clone A was used In further studies for interaction with ADP because human adenovirus does not replicate in mouse cells. Both OB and OX activate PERK, increase DDIT3/CHOP expression, and enhance red/green fluorescence ratio (R/GFIR) in acridine orange staining. PERK (PERK-IN-2) and ER stress (4-phenylbutyric Acid) inhibitors decrease these responses and ectoCALR expression but increase proliferation of Clone A cells. Ecto-CALR expression with OB-ADP on Clone A cells was higher than that of Clone A cells after OX-ADP after three days *in vitro* with a similar growth inhibition. In summary, OB is an agent that rapidly initiates ICD and supports viral infectivity in CRC cells to achieve ICD with necroptosis and autophagy. OB-ADP treatment is noninferior to OX-AdV therapy *in vitro* for initiation of ICD. These results support using OB in an agnostic therapeutic vaccine *in vivo*, particularly due to its systemic injection capability.

#530 A personalized HGSC organoid platform for repurposing lysosomal death inducing drugs.

A. Skorda[1], B. S. Rasmussen[1], M. Lund Bay[1], D. Afedeva[2], A. Rossberg Lauridsen[1], Y. Li[2], E. Valkonen[3], A. Abdul-Al[1], M. Casasnovas Ventura[1], L. Fuso[1], J. Roca Arias[1], W. Senkowski[4], K. Wennerberg[4], O. Carpen[2], A. Virtanen[5], A. Lahtinen[2], J. Oikkonen[2], J. Hynninen[3], S. Hautaniemi[2], T. A. Kallunki[1];

[1]Danish Cancer Society, Copenhagen, Denmark, [2]University of Helsinki, Helsinki, Finland, [3]University of Turku, Turku, Finland, [4]Biotech Research and Innovation Centre, Copenhagen, Denmark, [5]University of Helsinki, Helsinki, Denmark

Introduction: Among the gynecological malignancies, the most prevalent and lethal is the high-grade serous ovarian cancer (HGSC), accounting for 70-80% of ovarian cancer mortality. Tumor evolution studies suggests that high molecular heterogeneity prevails long before treatment intervention, evincing that patients would not benefit from a universal treatment but would rather benefit personalized treatments. Here, we established a prospective HGSC patient-derived tumor organoid biobank, where we are testing lysosome-targeting FDA approved medicines, to evaluate their cytotoxicity as standard treatment alternatives and/or supplements.

Materials and Methods: HGSC patient tissues from various anatomical sites (multiregional) and different courses of treatment (longitudinal) were grown as long-term 3D tumor organoid cultures (PDOs). Relevant biomarker proteins were qualitative and quantitative evaluated via immunofluorescent labeling and drug profiling was studied via cytotoxicity assays, measurement of proliferative index and lysosomal membrane permeabilization using 3D high-throughput high-content imaging and image analysis. Genomic and transcriptomic data were derived from whole-genome sequencing, whole exome sequencing and RNA sequencing of the organoid cultures and corresponding parental tumors. PDX models were used for in vivo drug testing.

Results and Discussion:Organoids were established as self-renewable, robust cultures with stemness-like characteristics that mirrored the genomic profile of the parental tissue, thus being ideal model systems for preclinical studies. We identified a cohort of 22 samples derived from 17 patients and tested sensitivity towards clinically approved lysosomal-targeting drugs. Samples were categorized as sensitive or non-sensitive to the treatment and gene-expression analysis indicated a pathway possibly involved in the resistance mechanism of the non-sensitive group. Inhibition of this pathway enhanced the initially observed cytotoxicity. Treatment efficiently inhibited the growth of engrafted sensitive samples in vivo.

Conclusion: To maximize survival potential of HGSC patients, functional drug testing on patient-derived cancer models is essential. Here, our platform is a powerful tool to study a broad spectrum of alternative drug combinations to accordingly direct clinical decisions. It also gives the possibility to investigate intensively the mechanisms that lie behind the onset and the refractory of the HGSC.

#531 Treatment of pancreatic adenocarcinoma with omeprazole.

Karl N. Thomas[1], Rohit Singh[1], William E. Grizzle[2], Lacey R. McNally[1]

[1]OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]University of Alabama at Birmigham, Birmingham, AL

Background: Pancreatic adenocarcinoma (PADC) is associated with poor clinical outcomes that show resistance to apoptosis. Therefore, we explored an off-label use of Omeprazole to discover its effect on PADC. Our goal was to expose underlying cellular processes, namely autophagy, which are differentially regulated by Omeprazole to aid in treatment design and improve patient outcomes.
Methods: Freshly cultured S2VP10 and Panc1 cells were given 50uM and 500uM Omeprazole treatment for 4-hours. Neutral Red (NR), Acridine Orange (AO), and LysoTracker stains were used to assess viability and lysosomal activity. Immunocytochemistry (ICC) in S2VP10 and Suit2 Cells was used to examine the activity of proton-sensing ion channels ASIC1 and ASIC3 following 50uM Omeprazole treatment. For AO, LysoTracker, and ICC experiments, analysis of fluorescence was performed using Nikon NIS Elements to trace relevant regions and normalize to region area. Significance was determined using Kruskal-Wallis tests followed by pairwise Wilcoxon pos hoc tests. Differences were considered statistically significant at $p<0.05$.
Results: Following Omeprazole treatment, mean NR fluorescence decreased by 54.5% and 6.0% respectively for 500uM treatment of S2VP10 and Panc1 cells. AO staining of S2VP10 cells after 4-hour 500uM treatment showed a 58.2% increase in red fluorescence indicative of autophagosomes and lysosomes. This finding is supported by qualitative analysis of LysoTracker staining. Significantly increased ASIC1 and ASIC3 staining was observed for the 4-hour treatment groups compared to controls in S2VP10 and Suit2 cells lines.
Discussion: Our results show that Omeprazole, a proton pump inhibitor, has a significant effect on the proton compartmentalization within pancreatic cancer. Treatment of PDAC remains challenging due to its enhanced autophagy expression and low extracellular pH which enables cell survival despite nutrient deprivation. We have shown that use of proton inhibitors like Omeprazole disrupt autophagy and cytoprotective mechanisms. Exploiting this, may help to reduce chemoresistance in PDAC.

#532 Single-cell analysis reveals neuroblastoma heterogeneity and therapeutic opportunities.

Michele Tomanelli[1], Jennifer Hoti[1], Matteo Saettone[1], Daniele Reverberi[2], Adriana Bajetto[1], Tullio Florio[1], Aldo Pagano[2]

[1]University of Genoa, Genova, Italy,[2]IRCCS Policlinico San Martino, Genova, Italy

Neuroblastoma is the most common extracranial tumor found in neonatal patients, arising from neural crest cells. By utilizing specific Neuroblastoma cell lines, we have developed clones that express the non-coding RNA NDM29. These investigations have enabled the assessment of NDM29's role in tumor differentiation, identifying new therapeutic targets for controlling tumor malignancy. Further studies highlighted the presence of different cell subpopulations in this model by performing a single-cell sequencing analysis. These subpopulations were isolated with FACS analysis. The cellular heterogeneity characterizing this model reflects what is observed in patients. The gene expression of potential therapeutic targets identified in the heterogeneous model was evaluated in individual subpopulations. The individual subpopulations were pharmacologically treated by inhibiting some of these targets. These treatments revealed subpopulations that were either more sensitive or more resistant to specific inhibitors. By performing gene ontology analyses using sequencing data, we identified potential new pharmacological targets to enhance the mortality of even the resistant cells.

#533 Disruption of cholinergic signaling via inhibition of the M3 muscarinic acetylcholine receptor reduces glioblastoma stemness and enhances cell death.

Godwin Peasah-Darkwah[1], Ayanfeoluwa S. Kolawole[2], Tingting Huang[3], Grace M. Rosner[1], Johnathan D. Rodgers Gochicoa[4], Matthew C. Havrda[1], Kelli B. Pointer[3]

[1]Molecular and Cellular Biology, Dartmouth College, Hanover, NH,[2]Geisel School of Medicine, Hanover, NH,[3]Radiation Oncology and Applied Sciences, Dartmouth Cancer Center, Lebanon, NH,[4]Integrated Neuroscience, Dartmouth College, Hanover, NH

Background: Glioblastoma (GBM) is the most aggressive primary brain tumor in adults, with a median survival of less than two years despite treatment with surgery, chemotherapy, and radiation. Tumor recurrence, driven in part by treatment-resistant glioblastoma stem cells (GSCs), contributes to this poor prognosis. Understanding the mechanisms that promote GSC resistance may aid in developing targeted therapies. GBMs frequently occur in acetylcholine (ACh)-rich brain regions. ACh is a neurotransmitter responsible for cholinergic signaling through muscarinic acetylcholine receptors (mAChRs) and has been shown to regulate stemness in healthy oligodendrocyte progenitor cells. The M3 mAChR has also been shown to hold potential prognostic value in GBMs. Taken together, we investigated the role of ACh and the M3 mAChR in promoting GSC-like states and therapeutic resistance.
Methods: Human GBM LN-229 cells were cultured under stem-like conditions. CRISPR/Cas9 was used to generate an M3 mAChR knockout line. To assess the role of cholinergic signaling in promoting stemness, cell lines were treated with vehicle control or 3μM of carbachol, an ACh mimetic, and sphere formation assays and immunoblotting for stem-like markers (Nestin and CD44) were performed. To assess if M3 mAChR inhibition decreases stemness and tumor cell viability, cell lines were treated with benztropine (BZT; 1 μM and 3 μM), a muscarinic antagonist, and MTT assay for cell viability was performed. All experiments were performed in triplicates.
Results: Carbachol treatment increased the number of spheres compared to vehicle control (mean: 34 vs. 20, $p=0.0141$), as well as the sizes of the spheres (mean: 192 μM vs. 100 μM, $p<0.0001$). Immunoblotting after carbachol treatment increased protein expression of stemness markers and the M3 mAChR. The M3 mAChR knockout cell line demonstrated a decrease in cell viability after 48 hours of treatment compared to wildtype control ($p<0.0001$). Also, there was a decrease in protein expression of stemness markers in the M3 mAChR knockout cell line compared to wildtype control. Additionally, BZT treatment reduced cell viability compared to vehicle control in the MTT assay at 1 μM ($p<0.0001$) and 3 μM ($p<0.0001$).
Conclusion: ACh signaling via M3 mAChR promotes stemness in GBM and disruption of cholinergic signaling through knockout of the M3 receptor decreases stemness and tumor cell viability. Also, pharmacological inhibition of cholinergic signaling with a muscarinic antagonist such as BZT may be useful to target GSCs with the ultimate goal of improving patient outcomes.

#534 Sotorasib-resveratrol combination induces synergistic cytotoxicity by downregulating K-RAS signaling in K-RAS mutant lung cancer cell lines.

Pedro Barrios Bernal, Norma Hernandez-Pedro, Jose Lucio-Lozada, Eunice Romero-Nunez, Cesar Castillo-Ruiz, Brandon Lopez, Sandra Hernandez-Sanchez, Oscar Arrieta

Instituto Nacional de Cancerologia, Mexico, Mexico City, Mexico

Background: K-RAS mutations are the most frequent (35-50%) in patients with non-small cell lung cancer (NSCLC) who have a smoking history. These mutations promote cancer development through constitutive activation of poliferative signaling pathways, metabolic modifications and mechanisms of apoptosis evasion. Sotorasib is a covalent inhibitor targeting KRAS G12C; however, the primary challenge lies in acquired resistance. Resveratrol is a natural compound that promotes apoptosis and inhibits proliferation through the MAPK and Wnt/β-catenin pathways in cancer cells. Therefore, this project proposes using resveratrol as an adjuvant therapy to sotorasib in cell lines with KRAS mutations.
Methods: Dose-response curves were generated using MTT assays to determine the IC50 for sotorasib and the IC10 for resveratrol, in addition to determine the type of interaction between both drugs in the K-RAS mutant cell lines A549 (G12S) and H23 (G12C). Crystal violet assays were performed to measure the effect on cell proliferation. Mitochondrial membrane potential was assessed via flow cytometry. Finally, protein expression, activation, and inactivation were analyzed using western blot assays (K-RAS, BRAF, C-RAF, p-CRAF, GLUT1, GLUT3, HXK 1, AMPK and p-AMPK).
Results: Our results revealed a synergistic effect of the combined sotorasib-resveratrol treatment in the H23 cell line, while an additive or antagonic effect was observed in the A549 cell line. Cell proliferation assays demonstrated significant growth inhibition in both cell lines when treated with sotorasib alone or in combination with resveratrol. Additionally, mitochondrial matrix collapse was predominantly observed with the combined treatments. Western blot analysis showed strong inhibition of the K-RAS signaling pathway and glucose transporters (GLUTs), along with AMPK activation, particularly in treatments involving resveratrol. Furthermore, the induced cytotoxicity was linked to the inhibition of K-RAS signaling, GLUTs, Hexokinase 1, and AMPK reactivation.
Conclusions: The addition of resveratrol to sotorasib enhanced growth inhibition, independent of KRAS mutations, primarily through apoptotic mechanisms and the downregulation of the glucose metabolic pathway.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Reversal of Drug Resistance 1
Poster Session

#539 Secretory EMT fuels ERBB3 axis activation in resistance to EGFR inhibitors.

Alessandra Morselli[1], Donatella Romaniello[1], Chiara Miroglio[1], Martina Mazzeschi[1], Michela Sgarzi[1], Federica Pagano[1], Cinzia Girone[1], Francesca Ambrosi[1], William Kothalawala[2], Gyorffy Balazs[3], Andrea De Giglio[1], Michelangelo Fiorentino[1], Andrea Ardizzoni[1], Yosef Yarden[4], **Mattia Lauriola**[1]

[1]University of Bologna, Bologna, Italy,[2]Semmelweis University, Budapest, Hungary,[3]Dept. of Bioinformatics, Semmelweis University, Budapest, Hungary,[4]Weizmann Institute of Science, Rehovot, Israel

Non-small cell lung cancer (NSCLC) patients with activating EGFR mutations, such as exon 19 deletions (del746-750) and the L858R point mutation in exon 21, respond well to third-generation tyrosine kinase inhibitors (TKIs) like osimertinib. However, resistance inevitably emerges, limiting the long-term efficacy of these therapies. In this study, we investigated non-genomic mechanisms contributing to TKI resistance, focusing on the activation of bypass pathways that facilitate drug tolerance. These pathways enable drug tolerant persister cells to survive EGFR inhibition by exploiting alternative signaling routes. Among these, the upregulation of HER3 has been identified as a key mechanism. Clinical evidence has demonstrated the therapeutic potential of targeting HER3, notably with antibody-drug conjugates (ADCs) like patritumab deruxtecan. However, the precise molecular and cellular basis for HER3 dependency in NSCLC patients who progress on TKI therapy remains poorly understood. To address this gap, we employed a combination of immortalized and patient-derived cell lines, alongside advanced single-cell sequencing technologies, to elucidate the underlying biology. Our findings reveal that HER3 dependency post-TKI treatment is specifically enriched in pulmonary alveolar type I and II cells. This dependency is driven and maintained by paracrine signaling involving secreted factors, with neuregulin-1 (NRG1) playing a central role. NRG1 is primarily secreted by the tumor stroma and by cancer cells undergoing epithelial-to-mesenchymal transition (EMT) or dedifferentiation. Prolonged drug exposure further amplifies NRG1 secretion, which not only sustains HER3 activation but also promotes genetic and phenotypic plasticity. This is accompanied by EMT-associated morphological changes that enhance invasiveness and metastatic potential. Notably, our preclinical models demonstrated that the combination of an NRG1-neutralizing antibody with a dual EGFR blockade—achieved through a TKI and an anti-EGFR antibody—completely eradicated tumors in vivo. These results highlight the critical role of HER3 signaling and its interplay with the tumor microenvironment in mediating TKI resistance and suggest a compelling therapeutic strategy for overcoming resistance in NSCLC.

#54 Comparative preclinical antitumor assessment of 5FU versus anti-PD1 using in vivo imaging system in MC38 orthotopic tumor model.

Balaji Ramachandran, Ravindra Ghodke, Satheeshkumar Rajendiran, Bhanupranav Skanda, Krishnappa Haladasappa, Sachin Joshi

Pharmacology, Adgyl Lifesciences Private Limited, Bangalore, India

Immunotherapy has evolved as potential and practical therapeutic options for primary and metastatic tumors. Orthotopically implanted tumor models are clinically relevant and however growth monitoring of orthotopic tumor & assessing efficacy outcomes poses a practical challenge. Optical imaging by *In Vivo* Imaging System (IVIS) is a valuable method to monitor the real time progression of in vivo tumor growth without implying the need for interim termination during the study. In the present study, we have evaluated the preclinical efficacy of 5- Fluorouracil in combination with mouse anti-PD1 antibody in orthotopic MC38 model in immunocompetent mice. Subcutaneous tumor was generated in donor mice by inoculation of MC38 luciferase reporter cell line. Tumor fragments (~30mg) harvested from the donor mice were orthotopically implanted on the subserosal layer of cecum of C57BL/6 mice. Tumor growth was monitored twice weekly by IVIS optical imaging system. Mice were randomized based on total flux signal intensity (1-3 X 10^6 photons/second). Standalone & combination treatment was initiated with 5-FU; 25 mg/kg, i.p; Q2D and anti-PD-1 at 5 mg/kg, ip; Q4D x 4 doses. Total flux (photons/second), changes in body weight, clinicals signs, mortality were monitored twice weekly up to 2 weeks. At the end of the study, ex vivo bioluminescence signal intensity and tumor weights were recorded. In the current MC38 orthotopic tumor model, standalone treatment of anti-PD-1 and 5-FU resulted in moderate tumor regression. However, combination of 5-FU with anti-PD1 resulted in improved efficacy when compared with individual treatments which was evident from the reduction in signal intensity. In conclusion, evaluating efficacy of combinations treatment in preclinical orthotopic tumor models using IVIS imaging will be helpful tool for an accurate, non-invasive longitudinal monitoring of tumor growth over extended duration.

#540 AVJ16 alleviates ABCB1-mediated doxorubicin chemoresistance via IGF2BP1 inhibition.

Eveiyn Weng Yan Phoon, Kowit-Yu Chong

Division of Biotechnology, Graduate Institute of Biomedical Sciences, Chang Gung University, Taoyuan City, Taiwan

Background: The efficacy of chemotherapy is often compromised by multidrug resistance (MDR), driven by the overexpression of ATP-binding Cassette Sub-family B Member 1 (ABCB1). While ABCB1 inhibitors are urgently needed, toxicity and pharmacokinetic challenges have limited clinical progress. Dysregulation of N6-Methyladenosine (m^6A)—a key mRNA modification involved in gene regulation—is linked to chemoresistance, presenting a potential target to counteract ABCB1-mediated MDR.
Aim: To examine m^6A's role in ABCB1-driven chemoresistance in uterine sarcoma and breast cancer and evaluate alternative ABCB1 inhibitors.
Methods: RT-qPCR analysis identified *Insulin-like Growth Factor 2 mRNA-binding protein 1 (IGF2BP1)*—an m^6A reader—as the most upregulated m^6A regulator in MDR uterine sarcoma cells. Expression levels were validated in parental and MDR uterine sarcoma and breast cancer cells. GEO dataset of breast cancer patients treated with neoadjuvant chemotherapy was analyzed *in silico* to determine *IGF2BP1-ABCB1* correlation. Functional assays were performed to evaluate IGF2BP1 knockdown and inhibition effects by AVJ16 (an IGF2BP1 inhibitor) on ABCB1 expression and doxorubicin resistance. Additionally, 3-deazaadenosine (DAA), an m^6A inhibitor, was added to MDR cells with IGF2BP1 knockdown or AVJ16 treatment to confirm IGF2BP1's role in m^6A-dependent regulation of ABCB1 and chemoresistance.
Results: IGF2BP1 and ABCB1 were significantly upregulated in MDR uterine sarcoma and breast cancer cells. *In silico* analysis confirmed a positive correlation between *IGF2BP1* and *ABCB1* expression, linking IGF2BP1 to ABCB1-driven chemoresistance clinically. IGF2BP1 knockdown in MDR uterine sarcoma cells reduced ABCB1 expression and doxorubicin resistance, evidenced by lower cell viability and colony formation. Moreover, AVJ16 significantly decreased doxorubicin's half-maximal inhibitory concentration (IC_{50}) in MDR uterine sarcoma by downregulating ABCB1 expression. DAA, combined with IGF2BP1 knockdown or AVJ16, markedly enhanced doxorubicin sensitivity, supporting IGF2BP1's m^6A-dependent role in MDR.
Conclusion: IGF2BP1 is a novel m^6A-dependent regulator of ABCB1-driven chemoresistance. These findings highlight AVJ16 as a promising therapeutic candidate for overcoming ABCB1-driven MDR cancers.

#541 PARP and autophagy inhibition synergy in small cell lung cancer.

T. Yu, R. Barayan, L. Song, V. Venkatasubramanian, S. N. Nair, V. Philip, B. H. Lok;
Princess Margaret Cancer Centre, Toronto, ON, Canada

Purpose: Small cell lung cancer (SCLC) is a high-grade neuroendocrine carcinoma comprising 15% of lung cancers. First-line treatment with platinum and etoposide chemotherapy—and radiotherapy for limited stage disease—produces good initial response, but most patients suffer treatment-resistant relapse within 2 years. The median survival is under 10 months, with immunotherapy increasing this by about 2 months. This regimen has changed minimally in 3 decades, fueling a need for more effective therapies. Poly (ADP-ribose) polymerase (PARP) inhibitors (PARPi) effectively induce DNA damage in SCLC and have shown potential in this setting, but response is variable, so we aimed to identify mechanisms through which SCLC may be sensitized to PARPi therapy.
Methods: CRISPR dropout screens were conducted using the Toronto KnockOut v1 (TKOv1) CRISPR library in the SBC5 and H82 SCLC cell lines, with the PARPi, olaparib, as the selection pressure. DNA sequencing was performed at days 25 and 35 for SBC5 and days 28 and 39 for H82. Top hits were identified by gene dropout in the olaparib condition versus the control, with a false discovery rate (FDR) cutoff of 0.05. Gene ontology analysis was used to identify critical pathways. Stable shRNA knockdown cell lines were generated using lentiviral transduction and validated by Western blot. Cells were treated with olaparib and assayed for viability with CellTiter-Glo 2.0. In wild-type cell lines, therapeutic mTOR activation with MHY1485 was validated by Western blot and therapeutic autophagy inhibition with chloroquine (CQ) or GNS561 was validated by Western blot after 3 hours starvation in EBSS medium. Efficacy of autophagy inhibitors alone and in combination with PARPi was assayed by cell viability, and SynergyFinder+ was used to quantify synergism of the combination.
Results: CRISPR screening identified mTOR pathway regulators, including components of the TSC and GATOR1 complexes, and gene ontology analysis indicated downregulation of TOR signaling and upregulation of autophagy as key pathways which confer PARPi sensitivity when lost. *TSC1/2* knockdown cell lines exhibit reduced viability after PARPi treatment. MHY1485 treatment blocked autophagy as indicated by LC3B-II accumulation, but combination therapy with MHY1485 and olaparib was antagonistic due to proliferative effects of MHY1485. CQ or GNS561 treatment also blocked autophagy, and SCLC cell lines had varying sensitivity to these agents as monotherapies. Autophagy inhibition synergized with PARPi, sensitizing SCLC cell lines to PARPi therapy.
Conclusions: *TSC1/2* knockdown sensitizes SCLC cell lines to PARPi in concordance with our model that mTOR downregulation promotes autophagy and cell survival after PARPi therapy. While mTOR upregulation was antagonistic with PARPi and promoted cell growth, autophagy inhibitors were a superior therapeutic approach, synergizing with PARPi *in vitro*.

#542 Chronic gastroesophageal reflux promotes chemoresistance in esophageal adenocarcinoma through APE1-redox-dependent PRDX2 activation and ferroptosis inhibition.

Lei Chen[1], Heng Lu[1], Farah Ballout[1], Dunfa Peng[1], Zheng Chen[1], Jianwen Que[2], Oliver G. McDonald[1], Alexander Zaika[1], Wael El-Rifai[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Columbia University, New York, NY

Background: The incidence of esophageal adenocarcinoma (EAC) is rapidly increasing in Western countries. Most EACs originate from Barrett's esophagus (BE), a precancerous lesion initiated by chronic reflux of gastrointestinal contents, especially acidic bile salts (ABS). Several chemotherapeutics induce high reactive oxygen species (ROS) levels to eliminate tumor growth. Ferroptosis is a recently identified cell death mode triggered by ROS and subsequent lipid peroxidation. However, cancer cells develop adaptive abilities to recalibrate redox balance via hijacking the antioxidant systems, resulting in drug resistance. PRDX2 protein is a member of the peroxiredoxin family of antioxidant enzymes. We hypothesized that PRDX2 may be a critical mediator in redox-associated chemoresistance under reflux conditions.

Methods: We analyzed RNA sequencing data and public databases to unveil the aberrant overexpression and potential chemoresistance function of PRDX2 in EAC. To simulate both acute and chronic clinical conditions of gastroesophageal reflux disease (GERD) in vitro, we employed transient and repeated ABS exposure (rABS). EAC cells and 3D organotypic culture (OTC) served as platforms to explore the anti-ferroptosis function and regulatory mechanisms of PRDX2. Our initial findings were validated in patient-derived xenografts (PDX), and human EAC tissue microarrays (TMA).

Results: Aberrant expression of PRDX2 was detected in both human EAC tissues and cell lines exhibiting resistance to oxaliplatin treatment. Knockdown of PRDX2 impaired the recovery of EAC cells from ABS-induced ROS-dependent lipid peroxidation. Moreover, silencing PRDX2 sensitized the chemo-resistant EAC cells to oxaliplatin. Chromatin immunoprecipitation (ChIP) assay identified that NF-kB activated PRDX2 transcription by directly binding to its promoter region. We also found that APE1-redox-mediated NF-kB activation is crucial for ABS-induced PRDX2. We further discovered that PRDX2 contributes to chemoresistance by upregulating GPX4 and suppressing ferroptosis. Furthermore, immunofluorescent staining in the 3D model (OTC) and immunohistochemistry staining in human TMA confirmed co-overexpression of APE1 and PRDX2. In addition, APX2009, an APE1-redox-specific inhibitor, significantly sensitized EAC cells to oxaliplatin by inhibiting PRDX2 expression and inducing ferroptosis. Notably, we observed synergistic effects of the combination of Oxaliplatin and APX2009 in the xenografts derived from a chemo-resistant EAC cell line.

Conclusion: Our findings revealed a novel link between reflux-induced redox unbalance and ferroptosis-related chemoresistance in EAC via APE1/redox/NF-kB/PRDX2/GPX4 axis. Targeting PRDX2 by APE1-redox-specific inhibitors is a potential novel strategy for drug combination in refractory EAC.

#543 SF2523, a dual PI3K-BRD4 inhibitor, enhances KRAS (G12C) or EGFR (exon 19/21) mutant targeted inhibitors in non-small-cell lung cancer (NSCLC).

Baskaran Subramani[1], Patrick Joseph Conway[2], Kun Zhang[1], Guillermo A. Morales[3], Joseph R. Garlich[4], **Daruka Mahadevan**[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Keiser University, Palm Beach Garden, FL,[3]Innoventyx LLC, Baton Rouge, LA,[4]SignalRx, San Diego, CA

KRAS and EGFR mutations are common oncogenic drivers in NSCLC. Osimertinib is a first line therapy for EGFR exon 19 and 21 mutant NSCLC. Sotorasib and Adagrasib are a second line therapy for KRAS G12C mutant NSCLC. Single agent inhibitors targeting mutant EGFR or KRAS develop drug resistance leading to relapsed/refractory NSCLC. SF2523 is a dual PI3K-bromodomain-containing protein 4 (BRD4) small molecule inhibitor being evaluated to mitigate KRAS or EGFR inhibitor induced drug resistance. Co-inhibition of PI3K/BRD4 blocks MYC expression, activation and enhances MYC degradation leading to inhibition of cancer growth and metastasis. We investigated SF2523 in EGFR mutant (HCC2935 and HCC827) and KRAS mutant (NCI H2030 & NCI H23) NSCLC cells lines with single agent or combination with Osimertinib or Sotorasib for anti-tumor activity, respectively. SF2523 IC_{50} in EGFR mutated NSCLC cells ranged from 90-230nM, while in KRAS mutated NSCLC cells ranged from 144-217nM versus Buparlisib plus JQ1 in the µM range. SF2523 plus Osimertinib decreased the IC_{50} to 1.2-1.4nM and SF2523 plus Sotorasib 1.6-13nM, respectively. In contrast, combinations of SF2523 plus Nindetinib (VEGFR inhibitor) or Rapamycin (mTOR inhibitor) were additive in potency with EGFR and KRAS mutant NSCLC cell lines. In KRAS mutant NSCLC treatment with SF2523 or Sotorasib increased PTEN mRNA expression and the combination therapy was additive. In EGFR mutant NSCLC treatment with SF2523 or Osimertinib or in combination decreased MYC, PIK3CA and AKT1, respectively. In a SCID H2030 KRAS G12C mouse xenograft model, SF2523 at a dose of 150 mg/kg was well tolerated without weight loss with tumor growth inhibition of >60% at 6 weeks. In conclusion, our results demonstrate SF2523 is active alone and is synergistic with Osimertinib or Sotorasib in inhibiting EGFR or KRAS mutant NSCLC cell lines and is active as a single agent in a KRAS G12C mutated H2030 CDX NSCLC mouse model.

#545 RFX5 knockdown restores sensitivity to cellular cyclophosphamide in triple-negative breast cancer cell lines.

Elizabeth Katherine Molchan, Kathleen Streeks, Alyssa Ohaegbulam, Mohammed Gbadamosi

University of Florida, Gainesville, FL

Cyclophosphamide (CTX) is a widely used chemotherapeutic agent in breast cancer (BC) treatment regimens. Despite its frequent use, patient responses vary significantly. While several studies have identified clinically relevant genetic variants associated with CTX metabolism to phosphoramide mustard (PM)—the active cellular anti-tumor metabolite—the factors influencing sensitivity at the cellular level remain poorly characterized. We previously performed a genome-wide association study (GWAS) of lymphoblastoid cell lines identified the SNP rs12408401 as associated with PM resistance. Employing the 15-state chromatin prediction model, ChromHMM, and other *in silico* tools, we identified an association between this SNP and the disruption of a repressive CTCF binding domain in multiple tissue types, including breast. This leads to an upregulation of several nearby genes regulated by this motif, including *RFX5*. Analysis of TCGA BC patient data revealed that increased RFX5 expression correlates with reduced disease-free interval in breast cancer patients treated with CTX (HR = 5.32, P = 0.028), but not in other BC patients. *RFX5* is a transcription factor that typically regulates the expression of MHC II-related genes. However, *RFX5* has been reported to exhibit upregulation in several malignancies and off-target transcriptional activity. Herein, we aim to functionally validate the role of *RFX5* in mediating CTX resistance, hypothesizing that decreased *RFX5* expression will decrease drug resistance *in vitro*. To test this hypothesis, we achieved gene knockdown through the administration of silencing RNA (siRNA) targeting RFX5 then assessed sensitivity by treating cells with PM, determining cell viability to quantify IC_{50}. As determined by qPCR, knockdown of RFX5 expression in the cell line MDA-MB-468 resulted in a 91% reduction in RFX5 expression compared to cells treated with scrambled siRNA ($p = 0.004$). At a PM concentration of 0.4 mM, RFX5 knockdown cells showed significantly reduced viability compared to scramble control cells ($33.3 \pm 4.5\%$ vs. $49.6 \pm 5.4\%$; $p = 0.031$). Furthermore, there was a 15% reduction in the IC_{50} of knockdown cells compared to control cells (0.273 ± 0.016 mM versus 0.346 ± 0.020 mM; $P = 0.004$). Together, these results provide strong evidence that RFX5 significantly attenuates CTX resistance. This work aims to link SNP genotype, gene expression, and drug sensitivity to improve predictive models of patient response and support targeted therapies enhancing CTX efficacy. Ongoing studies aim to delineate the pathways mediating aberrant RFX5 activity and validate its role in PM sensitivity across additional TNBC cell lines, with a focus on using CRISPRi to investigate the impact of genetic variation on the regulation *RFX5* expression and *RFX5* target genes.

#546 A novel approach to treat relapsed/refractory acute myeloid leukemia by targeting nucleolin as an innovative and promising biomarker.

Jihyun Um[1], Kyung Jin Kim[1], Eun-Hye Huh[2], Eun Jung Shin[1], Yumi Ji[1], Sung Hwan Moon[1], Je-Hwan Lee[2], Soo Jin Lee[1]

[1]Aptabio Therapeutics Inc., Yongin, Korea, Republic of,[2]Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Acute myeloid leukemia (AML) is a rapidly growing cancer of abnormal white blood cells accompanied by various genetic alteranation. Cytarabine (Ara-C) and daunorubicin are treated as the standard first-line chemotherapy for AML but approximately 30% of the patients are refractory and more than 50% of them face a relapse because of resistance. Moreover, FLT3 inhibitors, the only targeted therapy for AML, can treat only 20% of patients and resistance develops within a few months. Therefore, there is a strong unmet to develop a next-generation targeted therapy to overcome resistance. Nucleolin (NCL) is a protein highly expressed and localized on the cell surface of cancer cells. In this study, we confirmed that NCL was highly expressed in various human AML cell lines and patient-derived bone marrow cells compared to normal cells. Furthermore, it was particularly overexpressed in drug-resistant AML cells and refractory/relapsed (R/R) AML patient-derived bone marrow cells. NCL is a promising target for cancer treatment as mentioned above, but to date, no therapy has been developed to specifically target NCL. APTA-16 is a first-in-class AML treatment that specifically targets NCL developed by aptamer-drug conjugation (APTA-DC) technology. APTA-16 showed an outstanding anti-leukemic activity in drug-resistant AML cells through NCL inhibition whereas standard chemotherapies showed no efficacy *in vitro* and *in vivo*. We also identified the resistance-overcoming mechanism of APTA-16 in terms of intracellular drug metabolism and biological signaling pathway. The alternative activies of equilibrative nucleoside transporter (ENT) and deoxycytidine kinase (dCK) are main mechanisms by which cancer cells acquire Ara-C resistance. APTA-16 can avoid this process by entering cells via NCL on the surface of AML cells. We also figured out that NCL-DNMT1-axis signaling pathway plays an important role in drug-resistant AML cells and APTA-16 treatment significantly regulated the pathway. Collectively, our findings show that NCL can be an innovative biomarker targeting entire population of R/R AML patients regardless of their genetic defects and APTA-16 has can be developed as the first innovative NCL-targeted therapy. Based on the excellent *ex vivo* results using patient-derived AML cells, successful clinical results are expected. GLP safety/toxicity studies of APTA-16 have been completed and orphan drug designation (ODD) was grantd by FDA in 2021.

#547 HPB-092: A novel FLT3 and IRAK4 dual inhibitor for the treatments of AML and MDS.

Suyue Wang[1], Lei Wu[2], Rui Yang[2], He Zhou[2], Bing Zhang[2], Wenyuan Xu[2], Michael Xiang[1], Camille Xiang[1], Brent Meadows[1], Jason Xiang[1]

[1]Polymed Biopharmaceuticals, Cambridge, MA,[2]Polymed Biopharmaceuticals, Hangzhou, China

Activating mutations in the Tyrosine kinase FLT3 occur in about 25% of acute myeloid leukemias (AML)[1] and selective FLT3 inhibitors are clinically effective and have been recently approved by FDA for patients with relapsed/refractory AML with FLT3 mutations. While effective, a significant challenge with current FLT3 inhibitors is the rapid development of resistance through mechanisms including additional FLT3 mutations, CYP3A4 upregulation, or adaptive resistance through activation of parallel signaling pathways. It has been recently shown that an important mechanism of adaptive resistance to FLT3 inhibitors involves activation via Interleukin-1 receptor-associated kinase 4 (IRAK4) pathway[2]. Concomitant inhibition of FLT3 and IRAK4 could, therefore, enhance efficacy and durability in FLT3 mutant AML. We have developed HPB-092, a highly selective, novel FLT3/IRAK4 dual inhibitor. In biochemical assays, HPB-092 demonstrated potent inhibitory activity against FLT3-ITD (IC50 = 0.24 nM), FLT3-D835Y (IC50 = 0.18 nM), and IRAK4 (IC50 = 3.1 nM). HPB-092 effectively inhibited the proliferation of MV4-11, a FLT3-ITD mutant cell line at IC50 = 6.5 nM, and displayed excellent kinase selectivity in the Eurofins ScanEDGE assay at 1 uM. HPB-092 did not inhibit CYP3A4 up to 50 uM or hERG at concentrations up to 10 uM. In mouse tumor xenograft models of FLT3 mutant leukemias (MV4-11 and MOLM-13 cells), HPB-092 exhibited dose dependent efficacy and regression of established tumors. A 28-day GLP-compliant toxicity study showed HPB-092 was well tolerated in rats (NOAEL: 75 mg/kg/day) and dogs (NOAEL: 24 mg/kg/day), with no test article-related genotoxicity or safety pharmacology findings. Compared to the approved FLT3 inhibitors gilteritinib and quizartinib, and the clinical-stage FLT3/IRAK4 dual inhibitor CA-4948, HPB-092 showed comparable or superior inhibitory potency against mutated forms of FLT3, improved IRAK4 inhibition, better selectivity, minimal inhibition of CYP3A4, no hERG activity, and an overall favorable safety profile, potentially benefiting a broader range of hematological malignancies. HPB-092 has received FDA clearance for a phase 1 dose-escalation and expansion study to assess its safety, tolerability, pharmacokinetics, pharmacodynamics, and preliminary efficacy in adult patients with relapsed or refractory AML, particularly those with FLT3 mutations and U2AF1 or SF3B1 mutations, at a leading cancer center in the US. 1https://pubmed.ncbi.nlm.nih.gov/31972687/ 2https://www.sciencedirect.com/science/article/pii/S0006497118618622

#548 Histone deacetylase inhibitor, Vorinostat, reverses EGFR-TKI resistance in lung adenocarcinoma via degradation of MET.

Choudhary Harsha[1], Yuan Liu[1], Whitney S. Brandt[1], Di He[1], Manendra B. Lankadasari[1], Stella Tsui[1], Nanruoyi Zhou[1], Brooke Mastrogiacomo[2], Tetsuhiko Asao[1], David R. Jones[1]

[1]Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Center for Molecular Oncology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: *Epidermal growth factor receptor* (*EGFR*) mutations occur in 15-50% of patients worldwide with lung adenocarcinoma (LUAD). While tyrosine kinase inhibitors (TKIs) that directly target activating *EGFR* mutations prolong the survival of these LUAD patients, most tumors inevitably develop acquired resistance to TKI therapy. The second most frequent cause of such acquired TKI resistance is the amplification of the *MET* oncogene, which occurs in about 20% of *EGFR*-mutated LUAD samples with acquired TKI resistance. Our prior study showed that Vorinostat (VS), a potent HDAC inhibitor, induced cell death in NSCLC cell lines, and its sensitivity was correlated with *MET* levels in these cells. Therefore, we hypothesize that VS can re-sensitize *EGFR*-mutant LUAD with *MET* amplification-induced acquired TKI resistance to TKI treatment.

Methods: The human LUAD cells HCC827 parental ($EGFR^{Exon19Del}$) and HCC827-R (Osimertinib resistant with *MET* amplification) were used to test our hypothesis. To confirm if VS induced cell death in a *MET*-dependent manner, we conducted cell viability assays in HCC827 and HCC827-R cells after treatment with escalating doses of VS. Next, to explore the mechanism(s) through which VS enhances MET-dependent cell death, we performed several experiments including 1) real-time RT-PCRs and western blots to discern if VS regulates the expression of MET at transcriptional or translational level; 2) cycloheximide chase assays to examine the impact of VS on MET protein stability; 3) treatment with RGFP109, a HDAC1/HDAC3 selective inhibitor, to specify which HDAC(s) may be involved in this process. Finally, cell viability assays and clonogenic assays were performed using HCC827 and HCC827-R cells treated with VS alone, Osimertinib alone, or both, to investigate if VS re-sensitizes TKI-resistant cells to the treatment of Osimertinib.

Results: Our results showed that VS inhibited the viability of both HCC827 and HCC827-R cells in a dose-dependent manner with an IC50 of ~3μM. Unexpectedly, VS failed to affect *MET* mRNA, but significantly reduced the protein level of MET, compared to DMSO treatment. Moreover, the treatment with VS induced MET protein degradation in a MET level-dependent manner. Treatment with RGFP109 also induced MET protein degradation, suggesting that HDAC1 and/or HDAC3 might be involved in VS induced MET degradation. Interestingly, we observed that VS rescued sensitivity to Osimertinib in both HCC827 cells pre-treated with HGF and HCC827-R cells.

Conclusion: Our study suggests that VS promotes cell death of LUAD cells with amplification of *MET* via inducing HDAC1/3-mediated MET protein degradation. In combination with Osimertinib, VS reverses the amplification of *MET*-induced TKI resistance in LUAD cells. This combination might be therapeutically exploitable to overcome acquired TKI resistance caused by *MET* amplification in NSCLC patients.

#549 Biologically informed machine learning for discovery of protein assemblies underlying cancer therapeutic resistance.

Oliver Priebe[1], Eric Ho[1], Fransisco Guedes[1], Chandni Khandwala[1], Eduardo Farias[1], Trey Ideker[2], Adam Yaari[1], Maxwell Sherman[1]

[1]Serinus Biosciences Inc., New York, NY,[2]University of California, San Diego, La Jolla, CA

Despite substantial advances in cancer therapeutics, the near inevitable emergence of treatment resistance limits overall survival of advanced cancer patients. Genomic drivers of intrinsic and acquired resistance are highly multifaceted. Extensive profiling of tumors has demonstrated that the disparate resistance driving alterations often converge onto shared cellular processes. Motivated by this observation, we developed an intrinsically interpretable, gradient descent-based algorithm to learn assemblies of physically and functionally interacting proteins that are jointly predictive of tumor sensitivity to chemical and genomic perturbations. Importantly – and unlike existing solutions – the model learns protein assemblies de novo during training rather than being limited to rigid gene sets from public databases or literature. By co-embedding experimentally derived PPI maps with sample-specific multi-omics, the model to identifies interacting proteins that predict perturbation response. Once identified, protein assemblies can be used as compound biomarkers, for new target identification, for drug-target deconvolution, and for combination design amongst other therapeutic applications.

We benchmarked the predictive accuracy of our method using a panel of 23 clinical oncology drugs and related genetic perturbations targeting multiple areas of cell biology, including Ras/Raf signaling, G1/S checkpoint control, and DNA damage response. Our single model, trained on all 23 perturbations, outperformed state-of-the-art methods optimized for each individual perturbation in a held-out response prediction task (Mean accuracy: Random Forest, 0.41; Elastic Net, 0.37; FCNN, 0.33; this work, 0.43, highest accuracy for 15/23 perturbations). Our method achieved increased predictive accuracy while providing interpretable importance statistics for the members of each protein assembly. To predict CDK4/6 inhibitor response, the model learned a G1/S checkpoint assembly including CDK4 ($P=1.4\times10^{-8}$), CDK6 ($P=4.5\times10^{-8}$), CCNE1 ($P=7.0\times10^{-15}$), and RB1 ($P=4.7\times10^{-17}$). To demonstrate the application of our method to target discovery, we performed a synthetic lethality screen in cell lines with high and low activation of a G2/M protein assembly predictive of Nutlin-3A response ($P=3.1\times10^{-34}$). As expected given p53's central role in the protein assembly ($P=3.6\times10^{-56}$), top hits included known TP53-driven lethalities including TP53BP1 ($P=2.8\times10^{-34}$) and USP28 ($P=2.8\times10^{-27}$). Moreover, we identified a synthetic dependency on FBXO42 ($P=5.2\times10^{-8}$) associated not only with TP53 loss-of-function but also with two other assembly members involved in apoptosis regulation.

These results demonstrate the potential for biologically informed machine learning models to discover protein assemblies that explain drug resistance and enable new therapeutic avenues.

#55 A claudin-1 near-infrared fluorescent antibody conjugate for in vivo primary and metastatic colorectal cancer detection.

Mark Primeaux[1], Ritika Gupta[1], Iram Fatima[1], Sumbal Talib[1], Aaron Mohs[1], Michael Bouvet[2], Punita Dhawan[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]University of California San Diego, San Diego, CA

Background: Claudins are a large family of tight junction (TJ) proteins being investigated as biomarkers and therapeutic targets in cancer. Their availability at the cell surface, tissue-specific expression, and upregulation in some carcinomas make them amenable to monoclonal antibody targeting. In addition, epitope masking within the intact TJs of healthy tissue limits off-target binding. Claudin-1 (CLDN1) is upregulated in colorectal cancer (CRC) and promotes therapy resistance and metastasis.
Significance of Problem: CRC is the second deadliest cancer in the United States. While localized CRC can be treated surgically and has a 5-year survival rate of 91.1%, the survival rate of metastatic CRC falls to 15.7%. Due to resistance to current systemic treatments, surgery is the only curative option for CRC. However, tumors recur after ~30% of curative surgeries for stage II or III CRC. The rate of positive surgical margins for CRC has been reported at 6.83% and is associated with poor prognosis and metastasis. Fluorescence-guided surgery using targeted near-infrared (NIR) dyes allows surgeons to more accurately identify tumor margins.
METHODS: scRNAseq was used to characterize CLDN1 expression in CRC tumors. A NIR fluorescent dye, IRDye800 NHS-Ester, was conjugated to an anti-CLDN1 mAb (1C5-D9, CLDN1-IR800) and an IgG isotype control (IgG-IR800). Specificity was evaluated using fluorescent microscopy and Western blot in CLDN1-overexpression and knockout cell lines. The antibody was then tested *in vivo* using CRC cell line xenograft, patient-derived organoid (PDO) xenograft, and orthotopic syngeneic mouse models. Animals were injected IV and imaged using the LI-COR Pearl Trilogy System at multiple time points post-injection. Finally, an *ex vivo* panel of PDOs representing different ethnic and mutational backgrounds was used to examine the conjugate's translation potential.
Results: CLDN1 is highly expressed in CRC tumor cells, with low levels in the healthy colon. CLDN1-IR800 showed specific binding and robust fluorescence in CLDN1-expressing CRC cells compared to non-expressing cell lines or IgG-800. *In vivo*, CLDN1-IR800 showed significantly higher signal in CLDN1-expressing CRC cell line and PDO xenografts when compared to CLDN1 knockout tumors or IgG-IR800-injected mice. Biodistribution upon necropsy showed a significantly higher signal in the tumor compared to other organs. In an orthotopic syngeneic mouse model, both primary and metastatic lesions were detectable. Finally, *ex vivo* imaging showed significant signal in a panel of PDOs with diverse mutational and racial backgrounds.
Conclusions: CLDN1's selective expression on CRC tumor cells makes it an ideal candidate for *in vivo* tumor detection. In this study, we demonstrate the translation potential in targeting CLDN1 for tumor detection using multiple *in vitro, in vivo*, and *ex vivo* models.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Reversal of Drug Resistance 1

#550 Patient-derived organoids as a screening platform to identify mechanisms of osimertinib resistance in non-small cell lung cancer.

Yifan Yu, Samir H. Barghout, Nikolina Radulovich, Geoffrey Liu, Ming Tsao

University Health Network, Toronto, ON, Canada

Background: Epidermal growth factor receptor (*EGFR*)-positive non-small cell lung cancer (NSCLC) represents a large subset of NSCLC, accounting for approximately 30% of cases. Despite the initial effectiveness of osimertinib, the frontline modality in *EGFR*-positive NSCLC, resistance remains a major therapeutic challenge. To address osimertinib resistance, preclinical models that accurately represent the complexity of tumor biology are needed. Patient- and xenograft-derived organoids (PDOs and XDOs) offer a promising option as they preserve the genetic and phenotypic characteristics of the original tumor, allowing for more clinically relevant studies. We developed a panel of *EGFR*-positive PDOs and XDOs with fully annotated molecular, genetic, clinical and treatment profiles, and will utilize them to investigate osimertinib resistance.
Method: To demonstrate the utility of these models as a screening platform to identify osimertinib resistance mechanisms, we conducted a pilot single-agent screen in 6 PDOs/XDOs using osimertinib and a panel of small-molecule inhibitors that target relevant targets in NSCLC including Aurora kinase B, CDK4/6, c-MET, ALK, RET, ROS1, MEK, and BRD4. Viability has been assessed by the ATP luminescence assay CellTiter-Glo. Subsequently, we performed a high-throughput combinatorial screen where 2 osimertinib resistant models (LPTO357 & LPTO362) were treated with osimertinib alone and in combination with a library of 1144 FDA-approved and investigational drugs.
Result: We identified several compounds that displayed efficacy and potency in osimertinib-resistant models. The c-MET inhibitor capmatinib was specifically potent in LPTO245 but not in other models. This finding was confirmed using savolitinib, another selective c-MET inhibitor, suggesting the observed effects were due to on-target c-MET inhibition. Using whole exome sequencing, we confirmed the presence of c-MET amplification in LPTO245. Additionally, we identified an inverse sensitivity correlation between osimertinib and the Aurora kinase B inhibitor AZD2811 across all 6 models (r = -0.64; p = 0.03). The following analysis of our RNAseq data has shown a positive correlation between AURKB RNA expression and osimertinib IC_{50} values in 9 PDOs/XDOs. These data corroborate previously reported role of c-MET and Aurora kinase B as osimertinib resistance mechanisms and demonstrate the utility of the platform. Subsequently, our high-throughput combinatorial screen has identified 125 hits that potentiate/synergize the action of osimertinib including drugs targeting topoisomerases, JAK, PLK1, and PI3K.
Conclusion: Our screening platform can provide novel biological insights into osimertinib resistance. Moreover, it can potentially identify drug combinations with immediate clinical utility in NSCLC, particularly with approved and clinical-grade drugs.

#551 The FOXC2 transcription factor inhibitor MC-1-F2 alters the chemosensitivity of B16-F10 melanoma cells.

B. F. Jenkins, K. M. Hargadon;
Hampden-Sydney College, Hampden-Sydney, VA

Melanoma, the most aggressive form of skin cancer, is highly resistant to diverse classes of chemotherapeutics. The FOXC2 transcription factor, which is dysregulated in many cancers, has been linked with drug resistance in cancers of epithelial origin. We have recently identified a role for FOXC2 in the progression of melanoma. To investigate whether FOXC2 contributes to chemoresistance in this cancer, we have evaluated B16-F10 melanoma cell susceptibility to diverse classes of chemotherapeutic agents following treatment with the FOXC2 inhibitor MC-1-F2. We report increased anti-tumor activity when MC-1-F2 is used in combination with 5-fluorouracil, doxorubicin-HCl, or gemcitabine, highlighting the potential of this inhibitor as a novel chemosensitizing anti-cancer agent.

#552 Fenretinide enhances trastuzumab efficacy in trastuzumab-resistant HER2+ breast cancer cell lines.

Debbie O'Reilly[1], John Crown[2], Denis M. Collins[1]

[1]School of Biotechnology, Dublin City University, Dublin, Ireland,[2]Department of Medical Oncology, St Vincent's University Hospital, Dublin, Ireland

Introduction: HER2-positive (HER2+) breast cancer (BC) treatments have significantly improved patient outcomes, but treatment resistance remains a critical challenge, often driven by breast cancer stem cells (BCSCs). These resilient cells evade targeted therapies, leading to disease relapse and progression. Fenretinide (Fen), a synthetic retinoic acid (RA) derivative, has shown promise in acute myeloid leukemia by promoting cellular differentiation. Given BCSCs' similarities to embryonic cells, RA-based approaches may induce BCSC differentiation, reducing their resistance to HER2-targeted therapies. This project aims to identify BCSC markers in resistant HER2+ BC cell lines and evaluate the effects of Fen induced differentiation.
Methods: RNA-Seq gene expression data was downloaded from CCLE and analysed using RStudio (R version 4.1.2). HER2+ BC cell lines with innate (HCC1569, HCC1954) or acquired (SKBR3-T, BT474-T) trastuzumab (Tras) resistance were studied. Acquired resistance was induced by continuous exposure to 10 ng/mL Tras for 6 months. Cells were treated with 1 µM Fen for 24 hours. qPCR analysis employed the comparative Ct method (ΔΔCt), expressed as fold change to control. Statistical significance was determined using the Student's t-test or one-way ANOVA with Dunnett's multiple comparison. Results are presented as the mean of biological triplicate experiments ± standard deviation.
Results: DepMap analysis showed enhanced CD44 expression in innate-resistant HCC1569 and HCC1954 compared to parental SKBR3 and BT474. qPCR confirmed significantly higher CD44 levels in HCC1569 than SKBR3 ($p = 0.0318$) and significantly lower CD24 levels in HCC1569 and HCC1954 compared to SKBR3 ($p = 0.008$ for both). Acquired-resistance models SKBR3-T and BT474-T exhibited reduced BCSC markers compared to their parental lines. Fen had no significant effect on the expression of BCSC markers in innate or acquired resistant cell lines. Fen significantly decreased colony formation (CFA) across all cell lines and enhanced the growth-inhibitory effect of Tras in the SKBR3-T cell line in a dose-dependent manner.
Conclusions: Preliminary findings indicate that Fen influences CFA in both innate and acquired Tras-resistant HER2+ BC cell lines and enhances Tras efficacy in acquired resistant SKBR3-T. However, its impact on BCSC markers is limited. Further investigation is needed to elucidate the role of Fen in overcoming Tras resistance mechanisms in HER2+ BC.

#553 Drp1 knockdown impairs mitophagy and sensitizes AML cells to venetoclax by inducing apoptosis.

Priyanka Sharma[1], Hiroki Akiyama[1], M. Anna Zal[2], Bing Z. Carter[1], Michael Andreeff[1], Gautam Borthakur[1]

[1]Department of Leukemia, UT MD Anderson Cancer Center, Houston, TX,[2]Epigenet & Mol Carcinogenesis, UT MD Anderson Cancer Center, Houston, TX

Background: Mitochondrial structural dynamic of fission and fusion impacts mitochondrial function as well as mitochondrial quality control by facilitating mitophagy and ROS mitigation. Mitophagy as well as the expression of DRP1, a dynamin related protein driving mitochondrial fission, are increased in acute myelogenous leukemia (AML) resistant to Bcl-2 inhibitor venetoclax. Our previous findings demonstrated that ERK1/2 inhibition reduced the phosphorylation of Drp1, a dynamin-like GTPase involved in mitochondrial fission, and overcame resistance to venetoclax in acute myeloid leukemia (AML). While Drp1-driven mitochondrial fission acts as a mitophagy checkpoint, the precise relationship between Drp1 and mitophagy is not fully elucidated in AML.
Methods: Effect of doxycycline induced Drp1 knock down on viable cell count and apoptosis in AML cells was determined by bead-based annexin-V assay. Mitochondrial length was assessed using super resolution imaging with OMX Blaze. Mitochondrial ROS levels, mitochondrial mass, LC3 lipidation (autophagosome maturation), mitophagy and autophagosome content were determined using flowcytometry.
Results: Mitochondrial fission driven by Drp1 acts as a mitophagic checkpoint to regulate mitochondrial quality. Drp1 overexpression in OCIAML3 cells resulted in smaller mitochondria and higher LC3 lipidation, while knockdown increased mitochondrial length with a decrease in autophagic vesicles and LC3B lipidation suggesting decreased autophagy. Conditional knockdown of Drp1 inhibited mitophagy ($p<0.0001$), as detected with flowcytometry using the mitophagy dye that detects mitochondrial acidification resulting from fusion of mitochondria to lysosomes. Additionally, Drp1 knockdown significantly increased mitochondrial ROS with no change in mitochondrial mass. Knockdown of Drp1 significantly inhibited the clonogenic potential of AML cells, leading to a marked reduction in colony formation compared to control cells supporting that mitochondrial fission, ROS mitigation and mitophagy are crucial for preserving the stem-like properties of leukemia stem cells in AML. Moreover, conditional knockdown of Drp1 sensitized OCIAML3 cells to venetoclax ($p<0.0001$) as well as Idarubicin ($p<0.0001$) as demonstrated by a reduction in viable cell count and an increase in apoptosis.
Conclusion: Drp1 knockdown reduces mitochondrial fission and mitophagy in AML cells and sensitizes AML cells to venetoclax. These results further elucidate the role of Drp1 in mitochondria and offer new mechanistic insights into the interplay between mitophagy and mitochondrial fission in AML, highlighting the potential therapeutic benefit of co-targeting Drp1 in venetoclax-based regimens to eliminate leukemia stem cells. Ongoing studies are investigating the molecular mechanisms and in vivo efficacy of Drp1 knockdown in AML.

#554 Nanoparticle enabled miR-205 restoration in docetaxel resistant prostate cancer.

Neeraj Chauhan, Eswara NHK Ghali, Rahul Tiwari, Iris Enriquez, Rajasekhar Baru, Subhash C. Chauhan, **Murali M. Yallapu**

University of Texas Rio Grande Valley, McAllen, TX

Background: Prostate cancer (PrCa) is the second most diagnosed malignancy and a leading cause of cancer-related death in men worldwide. Docetaxel (Dtxl)-based chemotherapy remains a cornerstone of treatment for PrCa. However, most patients develop resistance to Dtxl treatment, leaving limited therapeutic options. Although cabazitaxel offers a secondary line of therapy, it is associated with many severe adverse effects. Restoring miR-205, a tumor-suppressor microRNA frequently downregulated in PrCa, has emerged as a promising strategy to reverse Dtxl resistance and achieve tumor regression.
Methods: A novel nanoformulation (MNP-miR-205) was developed using iron oxide magnetic nanoparticles (MNPs) layered with polyethylene imine (PEI) polymer to deliver miR-205. The optimized nanoformulation of MNP-miR-205 was characterized by size, surface charge, biochemical properties using DLS, gel retardation, and biochemical analyses. Chemo-sensitizing and anti-cancerous effects of MNP-miR-205 were evaluated in Dtxl-resistant PrCa cell lines and corresponding xenograft mouse models. Biodistribution of the formulation was evaluated by incorporation of indocyanine green (ICG) dye to track tumor accumulation.
Results: The MNP-miR-205 nanoformulation demonstrated optimal particle size and zeta potential, ensuring efficient cancer cell delivery. Hemocompatibility studies confirmed its safety profile. The formulation achieved an excellent cellular uptake *via* endocytosis, by passing endosomal and lysosomal degradation pathways. In Dtxl resistant PrCa cells, MNP-miR-205 enhanced chemosensitivity to Dtxl, as evident by increased apoptosis, Caspase 3/7 activity, and reduced mitochondrial membrane potential. In vivo studies confirmed that MNP-miR-205 exhibited superior tumor accumulation, significantly reducing tumor volume and weight, and prolonging overall mice survival in xenograft mouse models.
Conclusion: This innovative MNP-miR-205 nanoformulation offers a groundbreaking theranostic approach to address Dtxl resistance in prostate cancer. By enhancing chemo-sensitization and providing a safer imaging platform, it holds significant potential to improve prostate cancer management.

#555 ERBB4 upregulation in a taxol-resistant triple-negative breast cancer cell line.

Ling-Huei Yih, Hsiao-Hui Kuo, Tsai-Ming Lu

Academia Sinica - Institute of Cellular & Organismic Biology, Taipei, Taiwan

Resistance to chemotherapy remains an unfavorable obstacle to effective cancer treatment. Although paclitaxel is one of commonly used chemotherapeutic agents in the treatment of triple-negative breast cancer (TNBC), resistance mechanisms are not fully understood. In this study, we found that ErbB2 Receptor Tyrosine Kinase 4 (ERBB4) was substantially upregulated in T50RN, a paclitaxel-resistant cell clone established from the human TNBC cell line MDA-MD-231. We thus aimed to explore whether and how ERBB4 may modulate T50RN cell resistance to paclitaxel. The T50RN cell was obtained by exposing human TNBC cell line MDA-MB-231 to stepwise escalating paclitaxel concentration from 0.5 to 50 nM and then the resistant cell line T50RN was selected and expanded. The IC50 of paclitaxel was 2 and >100 nM in MDA-MB-231 and T50RN cells respectively. Treatment of the cells with ERBB inhibitors, sfatinib, allitinib, or PF299804, in sub-lethal concentration only induced a small additive effect on paclitaxel cytotoxicity in MDA-MB-231 cells, but dramatically enhanced paclitaxel cytotoxicity in T50RN cells. Since only the expression of *ERBB4* was significantly upregulated in T50RN cells, the expression of *EGFR1* was equally high in MDA-MB-231 and T50RN cells, and *ERBB2* and *ERBB3* were low in both cells, *ERBB4* might play a critical role on the effect of the three ERBB inhibitors. In addition, the three inhibitors also significantly enhanced paclitaxel-induced spindle abnormalities in T50RN cells but had no effect in MDA-MB-231 cells. Depletion of ERBB4 with shRNA also significantly reduced the cell growth ability of T50RN but not MDA-MB-231 on soft agar. These results suggest that ERBB4 may play a critical role in paclitaxel resistance in T50RN cells. Further elucidation of how ERBB4 is induced in T50RN cells and how ERBB4 regulates cell resistance might provide leads to overcome paclitaxel resistance.

#556 The glucocorticoid axis serves as biomarkers for supraphysiological androgen therapy response in enzalutamide-resistant prostate cancer.

J. Li, Z. Liu, M. Sands, S. Adams, J. Lee, M. Wang, T. Walsh, M. Haerens, M. Li, L. Leon, A. Zablah;
University of Notre Dame, Notre Dame, IN

Next-generation androgen receptor (AR) antagonist, like enzalutamide (Enz) has revolutionized the treatment of castration-resistant prostate cancer (CRPC), the lethal form of the disease, by effectively suppressing the androgen axis. However, resistance to Enz eventually develops in nearly all patients. Recent studies indicate that increased glucocorticoid receptor (GR) expression contributes to Enz resistance. Our prior work in prostate cancer models and patient tissues suggests that Enz decreases 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2, inactivates cortisol) and increases hexose-6-phosphate dehydrogenase (H6PD, promotes cortisol production) expression in tumor, which then sustains high levels of cortisol, leading to overstimulation of GR and resistance to Enz. Collectively, the glucocorticoid axis, including GR expression level and cortisol concentration controlled by 11β-HSD2 and H6PD, plays a critical role in Enz-resistant CRPC. Studies suggest AR activation reduces GR expression in PC, and SPA counteracts glucocorticoid-induced muscle atrophy, indicating AR activation inhibits GR functions in various contexts. Patient and mouse studies show that supraphysiologic androgen (SPA) reverses Enz resistance, and ~30% of patients respond to SPA; however, we lack a biomarker that identifies which patients will respond. A clinical study revealed that Enz treatment increases serum cortisol by suppressing11β-HSD2 expression, which is correlated with patient blood pressure. Taking all these together, we hypothesized that SPA reverses Enz through attenuation of the GR pathway by affecting GR expression and cortisol level. By using qPCR, immunoblot, high-performance liquid chromatography, and live cell imaging analysis, we observed that SPA decreases GR expression, accelerates cortisol metabolism by decreasing H6PD and increasing 11β-HSD2, and suppresses glucocorticoid-induced cell growth in Enz-resistant prostate cancer cell lines. Next, to further test our hypothesis that the glucocorticoid axis and blood pressure can serve as biomarkers for SPA therapy response. We will first confirm our cell level findings with cell-derived and patient-derived xenograft studies, then by collaborating with physician scientists, we will further evaluate the biomarker roles of the glucocorticoid axis for SPA therapy response in Enz-resistant prostate cancer by analyzing serum cortisol, expression of GR, H6PD, and 11β-HSD2 in circulating tumor cells, and blood pressure of patients who have undergone SPA treatment. This research holds the promise of not only confirming and solidifying both SPA's clinical benefits and the GR pathway's clinical significance in Enz resistance but also setting the foundation for our goal of developing the first non-invasive biomarkers for SPA therapy in patients with disease resistant to Enz.

#557 A novel tumor targeted extracellular vesicle based iron nanoparticle delivery system to induce ferroptosis and overcome chemoresistance in lung cancer.

Anjugam Paramanantham, Rahmat Asfiya N/A, Akhil Srivastava

University of Missouri - Columbia, Columbia, MO

Introduction: Cisplatin (CDDP) and its analogs are widely used in lung cancer (LC) treatment. However, despite their effectiveness, advanced LC has a poor 5-year survival rate of less than 10% due to chemoresistance. This resistance is often driven by disrupting apoptosis, a key hallmark of cancer. Ferroptosis, an iron-dependent, non-apoptotic cell death pathway driven by lipid peroxidation, presents a promising alternative to bypass apoptotic resistance. In this study, we developed a novel, tumor-specific delivery system, ExoFeR^{TF}, based on extracellular vesicles (EVs) functionalized with transferrin (TF) and loaded with iron oxide nanoparticles (IONPs). This system is designed to target transferrin receptors on LC cells to induce ferroptosis, thereby overcoming chemoresistance in a targeted manner.

Methods: ExoFeR^{TF} was synthesized by loading IONPs into TF-decorated EVs derived from MRC-9 lung fibroblast cells. The structural and functional integrity of ExoFeR^{TF} was confirmed through physicochemical characterization. To assess its therapeutic efficacy in reversing chemoresistance, ExoFeR^{TF} was tested on CDDP-resistant LC cells, patient-derived tumoroids (PDTs), and circulating tumor cell (CTC)derived xenograft (cDXT) cells and xenograft mouse models. We evaluated cell viability, mitochondrial damage, glutathione (GSH) levels, and expression changes in key ferroptosis markers (xCT/SLC7A11, GPX4). Molecular mechanisms of ferroptosis induction were also explored. In vivo, ExoFeR^{TF} tumor targeting was confirmed in LC xenograft models using Magnetic Resonance Imaging and Prussian Blue staining.

Results: ExoFeR^{TF} demonstrated robust structural stability, targeted tumor localization, and effective induction of ferroptosis in CDDP-resistant LC cells, PDTs, cDXT cells and xerograph mouse models. Treatment with ExoFeR^{TF} led to mitochondrial disruption, GSH depletion, and downregulation of ferroptosis markers. Additionally, Nrf2, a key regulator of antioxidant responses and chemoresistance, was downregulated with reduced intracellular translocation in ExoFeR^{TF}-treated cells. Subsequent CDDP treatment further sensitized the cells, indicating a reversal of chemoresistance.

Conclusion: ExoFeR^{TF} offers a promising, tumor-targeted approach to overcoming chemoresistance in lung cancer by inducing ferroptosis, a non-apoptotic cell death mechanism. These findings support the potential of ExoFeR^{TF} as a novel therapeutic strategy for treating resistant lung cancer, providing a foundation for future clinical applications in combatting chemoresistant cancers.

#558 MUC1*-deruxtecan kills tumors that have acquired resistance to trastuzumab containing therapeutics.

Cynthia C. Bamdad, Benoit J. Smagghe, Scott T. Moe, Kevin R. Yi, Trevor J. Grant, Mark G. Carter, Daniel S. Miller, Michael J. Nash, Jacy P. Marquez, Natalie K. Miller, JacLeen S. S. Nash, Robert McDermot, Andrew K. Stewart

Minerva Biotechnologies, Waltham, MA

Purpose: To develop a treatment for HER2 positive patients whose tumors have stopped responding to Enhertu
Methods: HER2 positive BT474 breast cancer cells were induced to become Herceptin resistant (trastuzumab resistant) in vitro via prolonged exposure to sub-lethal levels of the drug. Analysis of the trastuzumab-resistant cells showed that they had greatly increased expression of MUC1*, known to have anti-apoptotic and pro-growth properties. Recall that MUC1* (muk 1 star) is a growth factor receptor created after cleavage and release of the N-terminal portion of MUC1. The targeting antibody, huMNC2, has already demonstrated safety and cancer selectivity in a 1st-in-human CAR-T clinical trial for treatment of metastatic breast cancers. MNC2 is an IgG1 antibody that only recognizes the conformational epitope created when MUC1 is cleaved by specific tumor-associated enzymes. Confocal microscopy and pHrodo show that MNC2 is rapidly and robustly internalized by the cancer cells. We conjugated MNC2 to deruxtecan to yield an MNC2-deruxtecan with a DAR of 7.4. Female NSG mice were xenografted with either BT474-wt cells or the trastuzumab-resistant cells, BT474-Res2. Tumors were allowed to engraft then treated with trastuzumab or MNC2-deruxtecan.
Results: Herceptin had little to no effect on BT474-Res2 implanted tumors. However, MNC2-deruxtecan potently killed the trastuzumab resistant tumors in a matter of weeks. MNC2 conjugated to other linker-payloads similarly killed the trastuzumab resistant tumors. Treated animals showed no obvious signs of toxicities.
Conclusions: Patients with HER2 positive breast cancers have benefitted greatly from the new ADC Enhertu (fam-trastuzumab deruxtecan). However, most patients, develop resistance to HER2-directed therapies and experience progressive disease leaving them with few treatment options. Here we've shown that HER2 positive breast cancer cells acquire resistance to trastuzumab by increasing expression of the powerful growth factor receptor MUC1*. These MUC1*-targeting ADCs offer an effective treatment for these patients. These data support a conclusion that a MUC1*-ADC is safe and could have high therapeutic value for patients who have stopped responding to Enhertu.

#559 Targeting MCL1 or SOS1 can overcome lenvatinib resistance in HCC.

Kevin Chau[1], Martina S. J. McDermott[2], Dennis J. Slamon[2]

[1]Medicine - Molecular and Medical Pharmacology, UCLA - University of California Los Angeles, Los Angeles, CA,[2]Medicine - Hematology Oncology, UCLA - University of California Los Angeles, Los Angeles, CA

Lenvatinib (LEN), a front-line treatment for advanced liver cancer, has a short benefit of 13.6 months median overall survival. Understanding how resistance emerges may provide insight into LEN-combined therapies that might boost its clinical efficacy. LEN-sensitive liver cell lines were conditioned with LEN in culture to establish this study's three LEN-resistant (LR) models. All LR models exhibited a stable right shift in the LEN dose-response curve. The LR models were cross-resistant to other FGFR inhibitors and expressed markers linked to cancer aggressiveness. Pro-apoptosis signals, induced by LEN treatment in Hep3B parental cells, were no longer induced in Hep3B LR cells. Compared to parental cells, Hep3B LR and JHH4 LR cells were no longer Annexin-V positive with LEN treatment, supporting their ability to evade apoptosis. A validated HTS method, using Cell-Titer Glo to measure the cell viability of Hep3B and JHH4 models tested across 440 small molecule inhibitors and LEN at a single concentration, identified nine synergistic combinations. Vetting these leads using a multidose titration assay showed synergy with LEN across all three LR models for two drugs: MRTX0902 targeting SOS1, an intracellular RTK signaling protein, and S63845 targeting MCL1, an anti-apoptosis protein. Multiple RTKs were upregulated in the LR models, thus making SOS1 an attractive target for blocking convergent signals. LEN treatment of parental models increased the expression of pAKT, pERK, and MCL1. LEN with S63845 in Hep3B parental cells reduced pAKT, pERK, and MCL1 and increased γ-H2AX. LEN with S63845 induced more apoptosis than either single agents in parental models or Hep3B LR cells. Enhanced apoptosis was not observed using MRTX0902 alone or with LEN. MRTX0902 alone reduced pAKT and pERK in Hep3B parental cells and was able to offset LEN's accumulation of these proteins in combination. We performed RNA-seq analysis of our model systems at baseline and with LEN treatment. LEN-treated parental cells exhibited a statistically significant increase in MCL1 and SOS1 transcripts. GSEA analysis of LEN-treated parental cells revealed positive MAPK pathway enrichment consistent with SOS1 function. It also identified negative enrichment of genes involved in DNA replication and G2M checkpoint, a p53-regulated process. This novel finding suggested that LEN induces genotoxic stress. Indeed, immunofluorescent foci staining of γ-H2AX increased with LEN treatment of parental Hep3B cells and remained elevated in Hep3B LR cells. Therefore, SOS1 and MCL1 may have a role in overcoming genotoxic stress induced by LEN. Overall, our research has generated multiple LR models and used them to identify resistance components. We also showed that targeting these components (SOS1 and MCL1) synergizes with LEN and inhibits cancer growth. These findings may become relevant patient treatments to extend patient survival against liver cancer.

#56 Multi-omic profiling of PSMA heterogeneity in prostate cancer liver metastases identifies new metabolomic targets.

Martin K. Bakht, Yasutaka Yamada, Sheng-Yu Ku, Anthony P. Belanger, Quang-De Nguyen, Himisha Beltran

Dana-Farber Cancer Institute, Boston, MA

Background: Prostate-specific membrane antigen (PSMA) is a metabolic enzyme involved in glutamate and folate pathways. Being a cell surface protein, PSMA serves as a theranostic target in castration-resistant prostate cancer (CRPC) with PSMA-radioligand therapy (PSMA-RLT). However, not all patients with PSMA-PET positive tumors respond to PSMA-RLT, partly due to heterogeneous expression of PSMA. We hypothesize that the metabolic features of the tumor microenvironment contribute to PSMA expression and function.
Methods: We profiled CRPC autopsy tumors from five patients and a series of orthotopic PSMA-positive metastatic CRPC models using mass spectrometry (MS), H3K27ac ChIP-seq, and spatial whole transcriptomics by Visium CytAssist platform.
Results: Spatial transcriptomic mapping indicated enrichment of amino acid transport and biosynthesis pathways in PSMA-suppressed liver metastases versus other sites of disease. Similarly, MS metabolomics revealed elevated levels of neutral amino acids, such as L-Leucine, in liver metastases. H3K27ac ChIP-seq showed that only liver metastatic tumors in the 22Rv1 CRPC model exhibited an H3K27ac peak at the SLC7A5 (LAT1) gene locus, correlating with low PSMA expression, not seen in primary tumors. A PSMA-suppressed 22Rv1 liver metastasis-derived cell line demonstrated sensitivity to LAT1 inhibition (V-9302), suggesting its potential as a therapeutic target.
Conclusions: Multi-omic profiling of patient tumors and prostate cancer models point to PSMA-suppression and heterogeneity in liver metastases associated with potentially targetable epigenetic and metabolomic alterations.

#560 Characterizing the role of TIAM1-Rac1 signaling in advanced prostate cancers.

James P. Maine, Masuda Sharifi, Shu Ning, Amy R. Leslie, Zachary A. Schaaf, Wei Lou, Allen C. Gao

Urologic Surgery, University of California, Davis, Davis, CA

Background: Roughly 20-30% of patients with castration-resistant prostate cancer (CRPC) will progress to neuroendocrine prostate cancer (NEPC) following treatment of androgen receptor signaling inhibitors (ARSIs) such as enzalutamide and abiraterone. NEPC is an aggressive, treatment-resistant form of prostate cancer (PCa) with an average survival time of ~7 months post-diagnosis. Poor understanding of acquired resistance mechanisms and disease progression prevents the development of efficacious treatments for advanced PCa (NEPC and CRPC). The Rac1-associated guanine nucleotide exchange factor TIAM1—identified as a novel neural lineage signature in enzalutamide-resistant PCa cells—promotes the survival of neuroendocrine small-cell lung cancer. Here, we interrogate how TIAM1 contributes to acquired resistance and disease progression in advanced PCa.
Methods: RNA-seq, GEO, and cBioPortal datasets were analyzed to assess the relationships between TIAM1 expression and enzalutamide treatment, patient survival, and androgen receptor dependency. Cell growth assays determined the effects of TIAM1-specific RNA interference and TIAM1 overexpression in CRPC and NEPC-like cell lines. TIAM1 expression was evaluated using real-time quantitative PCR.
Results: Analysis of publicly available datasets revealed patients and mice treated with enzalutamide showed increased TIAM1 mRNA expression and that high relative TIAM1 mRNA expression significantly correlated to poor disease-free survival. NEPC and NEPC-like cell lines exhibited higher average TIAM1 mRNA expression than CRPC cells. siRNA TIAM1 depletion in drug-resistant NEPC-like cells showed moderate re-sensitization to the ARSIs enzalutamide and abiraterone. Transient TIAM1 overexpression in CRPC cells conferred partial tolerance to enzalutamide compared to vehicle-treated cells.
Conclusions: These results establish the clinical relevancy of TIAM1 in PCa models. Long-term treatment with enzalutamide increased TIAM1 expression in patient and murine samples, possibly contributing to acquired resistance mechanisms as demonstrated by increased ARSI sensitivity upon TIAM1 depletion. Current efforts in our lab focus on elucidating the mechanistic contributions of the TIAM1-Rac1 axis in acquired ARSI resistance to facilitate synergistic treatment of advanced PCa.

#561 Targeting mTOR/S6 signaling reverses acquired resistance to MTRX849 in KRAS^{G12C}-mutant lung adenocarcinoma cell lines.

Athena M. Madrid[1], Gabriel Choi[1], Jenny J. Hong[2], Sahel Hazeghsa[1], Jenny Z. Zhang[3], Kenny Castro[1], Neil A. O'Brien[1], Dennis J. Slamon[1]

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]Chicago Medical School at the Rosalind Franklin University of Medicine and Science, North Chicago, IL,[3]Weill Cornell Graduate School of Medical Sciences, New York, NY

Background: *KRAS* is a commonly mutated oncogene long considered undruggable. Recent discoveries found compounds capable of binding to KRAS^{G12C} that inhibit KRAS-dependent signaling by locking the protein in its inactive state. However, clinical efficacy of these molecules has been limited by high rates of innate and acquired therapeutic resistance. Here, we developed cell line models of acquired resistance to the KRAS-G12C inhibitor MRTX849 (adagrasib) to study the mechanisms that underlie resistance which may help in the identification of novel therapeutic strategies to overcome resistance.

Materials and Methods: KRAS^{G12C}-mutant H358 and H1373 lung cancer cell lines were treated through long-term exposure of increasing doses of the MRTX849 to generate the resistant clones, H358-R and H1373-R. Antiproliferative IC50s were determined by treating cells with serially diluted drug for 6 days and cells were quantified using CellVista® at Day 1 and Day 6. Resistant cells were genotyped by PCR amplification. Changes in protein signaling were determined by immunoblotting and changes in mRNA signaling were measured using RNA-seq analysis.

Results: A 15-fold shift in IC50 was observed between H358-R and parental H358 (p-value = 0.029), and between H1373-R and parental H1373 (p-value = 0.022). Genotyping of the cell lines indicated that mutant *KRAS^{G12C}* was preserved in both resistant cell lines. RNA-seq analysis revealed a significant log-fold increase in *RPS6* expression between H358-R and parental cells treated with MRTX849 (p-value = 6.06E-6). Treatment with MRTX849 inhibited downstream signaling of ERK1/2 and RSK in both parental and resistant cell lines. However, signaling downstream of mTORC1 through pS6 only remained active in the presence of MRTX849 in the resistant cells. Treatment with the mTORC1 inhibitor, RAD001, induced partial inhibition of pS6 in the resistant cells, whereas combined treatment with MRTX849 and RAD001 induced complete and sustained inhibition of resistant pS6 signaling. Combination treatment with MRTX849 and RAD001 also produced significantly improved inhibition of proliferation in both the acquired resistant clones relative to treatment with either single agent alone; H358-R (p-value = 0.0099) and H1373-R (p-value = 0.018).

Discussion: In this study, we confirmed mTOR/S6 signaling as a potential escape pathway for KRAS-G12C inhibition. Targeting mTORC1 in combination with MRTX849 induced a sustained knockdown of S6-signaling and reversed resistance to MRTX849. Further genomic, transcriptomic and proteomic profiling of the generated resistant cell lines may identify additional mechanisms responsible for acquired KRAS-G12C resistance.

#562 Role of kinesin and Bcl-2 protein association in prostate cancer therapeutic resistance to taxane chemotherapy.

Maddison Archer[1], Hamam Said[2], Sudeh Izadmehr[1], Nabila Zaman[1], Prerna R. Nepali[1], Goutam Chakraborty[1], Matthew D. Galsky[1], Wei Yang[2], Natasha Kyprianou[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY,[2]Stony Brook University, Stony Brook, NY

Introduction: Therapeutic resistance to taxane chemotherapy remains a key contributor to lethality in patients with metastatic castration resistant prostate cancer (mCRPC). Understanding the mechanisms that drive therapeutic resistance is critical to reduce prostate cancer mortality. Our previous studies demonstrated overexpression of the mitotic spindle protein kinesin (HSET) and the anti-apoptotic Bcl-2 in taxane resistant human prostate cancer cells, C4-2BDR. This study aims to understand the contribution of Bcl-2 and kinesin protein interactions and their co-targeting by cabazitaxel (2nd line taxane chemotherapy) and kinesin inhibitor ispinesib, to overcome therapeutic resistance in prostate cancer.

Methods: Two prostate cancer cell lines were used, the LNCaP-Bcl-2 and the C4-2BDR. To investigate the role of Bcl-2 in resistance, LNCaP cells overexpressing Bcl-2 were treated with cabazitaxel and ispinesib as monotherapies and in combination. Treatment response was analyzed based on cell viability studies, and expression of HSET and Bcl-2 was assessed via Western blot. Immunoprecipitation of Bcl-2 was performed for proteomic analysis in C4-2BDR cells following cabazitaxel treatment. We subsequently evaluated the *in vivo* effect cabazitaxel in combination with ispinesib, on C4-2B xenograft growth and tumor evaluation by immunohistochemistry.

Results: Time course and dose response studies revealed that overexpression of Bcl-2 in LNCaP cells *in vitro* conferred resistance to both cabazitaxel and ispinesib as monotherapies. Transient increase in expression of HSET was observed, while Bcl-2 expression was unchanged by treatment. However, the association between HSET and Bcl-2 was targeted by cabazitaxel after 24 hours in both parental and LNCaP-Bcl-2 cells. Proteomic analysis of Bcl-2 binding partners in C4-2BDR cells, revealed upregulation of pathways involved in cytoskeleton remodeling, ribosomal and translation pathways, and cell adhesions in response to treatment. In C4-2B xenograft models, combination therapy of cabazitaxel and ispinesib reduced tumor growth, compared to each drug alone. Tumors treated with combination therapy exhibited higher E-cadherin, and reduced vimentin and HSET immunoreactivity compared to other treatments, suggesting EMT reversion towards an epithelial phenotype that correlated with response.

Conclusions: These studies suggest a functional Bcl-2 association with mitotic spindle protein, kinesin and proteins involved in cytoskeleton organization and remodeling, that might result in resistance to taxane chemotherapy. These findings are of therapeutic significance in identifying a potential targeting value of Bcl-2 association with HSET to increase the therapeutic vulnerability in advanced prostate tumors.

#563 AR-dependent castration-resistant prostate cancer relies on histone methyltransferase KMT2D for cell growth.

A. Bononi[1], P. Redford[2], W. Zhang[3], G. Cifelli[3], S. Kim[3], I. Gao[3], K. Werth[3], P. Carman[3], G. Valdes Garcia[3], Z. Taylor[3], R. Totoritis[3], J. Schneck[3], P. Bamborough[2], M. Queisser[2], G. Maundrill[2], D. Thomas[2], H. Tran[3], S. Varma[1], B. Mangatt[3], M. McCabe[3], B. Schwartz[1], K. Choi[1];

[1]GlaxoSmithKline, Cambridge, MA, [2]GlaxoSmithKline, Stevenage, United Kingdom, [3]GlaxoSmithKline, Upper Providence, PA

The KMT2D histone H3 lysine 4 (H3K4) methyltransferase plays critical roles in enhancer-regulated gene activation. It is a large multi-domain protein with its C-terminal SET domain being responsible for this activity. High KMT2D expression is associated with reduced patient survival in prostate cancer. Cancer Dependency Map data show a correlation between KMT2D gene dependency and FOXA1 expression in prostate cancer cell lines. FOXA1 is a major regulator of Androgen Receptor (AR) transcription and recent findings showed that KMT2D establishes the chromatin competency to recruit AR and for FOXA1 to activate AR-dependent transcription. Since FOXA1 is predicted to be poorly tractable, we aimed to target the more tractable KMT2D in FOXA1-overexpressing AR-dependent castration-resistant prostate cancer (CRPC). CRPC cell lines with high FOXA1 ($FOXA1^{high}$) and high AR (AR^{high}) and/or AR constitutively active splice variants, such as AR-V7 (AR-$V7^{+}$) were found to express high levels of KMT2D. KMT2D knockout (KO) reduced cell growth in these cells and in isogenic AR-$V7^{+}$ 22Rv1 cells lacking full length AR. Additionally, KMT2D KO modulated AR target genes as demonstrated by reduced PSA mRNA and increased mRNA for IGFBP3 and EFNB2. Inactivating SET domain mutations demonstrated that these effects were mediated by KMT2D's catalytic function thus supporting SET-domain inhibition as the desired target modality. This study highlights the potential of KMT2D as a therapeutic target for AR-dependent CRPC patients with constitutively active AR splice variants who have high unmet medical need due to AR variants being undruggable with currently available therapeutic agents.

#566 Preclinical and translational pharmacokinetic (PK) modeling of the self-assembling and disassembling (SADA) bispecific fusion protein CD38-SADA for first-in-human (FIH) pretargeted radioimmunotherapy (PRIT).

Brian H. Santich[1], Charlotte A. Russell[2], LinLin Wang[1], Maria During[2], Lionel Renaud[3], Matthias Machacek[3], Norman LaFrance[1]

[1]Y-mAbs Therapeutics, Inc., New York, NY,[2]Y-mAbs Therapeutics, A/S, Horsholm, Denmark,[3]LYO-X AG, Basel, Switzerland

Background: PRIT is designed to deliver tumor-targeted radiation while limiting exposure to healthy tissues. CD38-SADA binds CD38 and select radioisotopes chelated to tetraxetan (DOTA) and contains a p53-derived domain mediating the self-assembly of tetramers from monomers in a reversible, concentration-dependent manner. Preclinical studies have demonstrated dose-dependent anti-tumor efficacy of two-step CD38-SADA PRIT with ^{177}Lu-DOTA administered 48h after an initial CD38-SADA infusion. Here, we report preclinical PK models and human simulations that informed the FIH study design and dosing regimen.
Methods: Total plasma concentrations of CD38-SADA (not cross-reactive with mouse CD38) were measured in 2 repeat dose studies following administration on D1, 8, and 15 in transgenic mice expressing human CD38 (huCD38 tg) and in a single dose study in huCD38 tg and wild-type (WT) mice. A PK model with Michaelis-Menten approximation of target-mediated drug disposition (TMDD) was fitted to the combined data. The PK model also incorporated *in vitro* mass photometry estimates of the CD38-SADA tetramer: monomer equilibrium. The model was scaled for human PK simulations using body weight-based allometry and theoretical scaling coefficients. For TMDD scaling, 2 scenarios were simulated: 1) Same CD38-mediated elimination in human as estimated in huCD38 tg mice. 2) No CD38-mediated elimination, *i.e.*, the most conservative case resulting in the highest predicted CD38-SADA exposure.
Results: The mouse PK model adequately described the observed CD38-SADA plasma concentration-time profiles. C_{max} was dose-proportional, with faster elimination observed in huCD38 tg mice vs WT mice at low doses, consistent with TMDD through binding to CD38 receptors. CD38-SADA monomers and tetramers demonstrated parallel linear and CD38-mediated nonlinear elimination from the central compartment. Linear clearance of CD38-SADA monomers was approximately 20 times faster than CD38-SADA tetramers (CL_{mon} 1.21 vs CL_{tet} 0.058 mL/h). At the planned FIH starting dose of 3 mg/kg, the predicted exposure provided a sufficient toxicological margin with/without TMDD scaling: C_{max} = 57.68 vs 58.71 µg/mL; $AUC_{0\text{-}inf}$ = 1070 vs 3020 µg·h/mL, respectively. The predicted tetrameric prevalence was ≥90% at the C_{max} concentrations and >50% at total plasma CD38-SADA concentrations >1 µg/mL, which was predicted to last for 40 to 136 hours depending on the TMDD scaling scenario.
Conclusions: A 2-compartmental PK model with nonlinear CD38-mediated elimination of CD38-SADA described the observed total CD38-SADA plasma concentration-time in huCD38 tg mice. PK simulations supported the initial FIH dosing for trial NCT05994157, CD38-SADA/^{177}Lu-DOTA PRIT in patients with relapsed/refractory non-Hodgkin lymphoma.

#567 Effectiveness of [^{225}Ac]Ac-labeled anti-MUC-16 radioimmunconjugate against CA125 expressing pancreatic and ovarian cancer xenografts.

Emmanuel Nwangele[1], Hanan Babeker[2], Alyssar Monzer[2], Fabrice Ngoh Njotu[3], Jessica Pougoue Ketchemen[3], Alireza Doroudi[4], Florence-Anjong Tikum[4], Nikita Henning[4], Emina Torlakovic[5], Maruti Uppalapati[6], Humphrey Fonge[7]

[1]Faculte de pharmacie, CHU de Quebec - Universite Laval, Quebec, QC, Canada,[2]College of Medicine, University of Saskatchewan, Saskatoon, SK, Canada,[3]Faculte de pharmacie, CHU de Quebec-Universite Laval, Quebec, QC, Canada,[4]College of medicine, University of Saskatchewan, Saskatoon, SK, Canada,[5]Department of Pathology, Royal University Hospital, Saskatoon, SK, Canada,[6]Department of Pathology and Lab. Medicine, University of Saskatchewan, Saskatoon, SK, Canada,[7]Faculte de Pharmacie, Centre de Recherche du CHU de Quebec-Universite Laval, Quebec, QC, Canada

Purpose: Cancer biomarkers like CA125 (MUC-16) are targets for the selective delivery of toxic radiation and/or cytotoxic molecules to tumor loci. MUC-16 is overexpressed in 80% of epithelial ovarian cancer (EOC) and 65% of pancreatic ductal adenocarcinomas (PDAC). Prognosis of EOC and PDAC has remained poor with 5-year survival rate of between 30-50% and 15-20% for EOC & PDAC respectively, hence, the need for new treatment approaches. Our lab has developed a fully human monoclonal antibody (mAb) that binds specifically to MUC-16 and demonstrated the effectiveness of [^{89}Zr]Zr-DFO-MUC-16 as a PET imaging agent. Here, we have developed [^{225}Ac]Ac-Macropa-MUC-16 and investigated its effectiveness against CA125 expressing EOC and PDAC cell derived xenografts (CDX) and patient derived xenografts (PDX).

Method: The anti-MUC-16 mAb was conjugated to macrocyclic bifunctional chelator Macropa-NCS and radiolabeled with [^{225}Ac]$AcNO_3$ to produce [^{225}Ac]Ac-Macropa-MUC-16 radioimmunoconjugate (RIC). Quality control assays were conducted to evaluate the integrity of the antibody, stability of the RIC and binding to MUC-16. We developed MUC-16 positive PDAC CDX (SW1990) and PDX (medium MUC-16 expression) and EOC PDXs (high and low MUC-16 expression).Biodistribution studies of [^{225}Ac]Ac-Macropa-MUC-16 was performed in non-tumor bearing mice at different timepoints and used to project organ doses using OLINDA. Groups of tumor-bearing mice were treated using 2 x of 13 kBq of the RIC at day 0 and 10 and tumor growth was monitored. [^{225}Ac]Ac-Macropa-Rituximab was used as a control RIC.Additionally, safety of the RIC was assessed after administration of 1 or 2 doses of the agent to healthy mice followed by clinical chemistry, CBC and histopathology.

Results: 16.67% of CDX (SW1990) treated with 2 x 13 kBq of the RIC had complete remission (CR). The remaining 83.33 % in this group had tumor growth suppression for ≥ 50 days post treatment and never reached endpoint (≥ 1500 mm^3), while saline and control RIC groups reached end point by day 33.[^{225}Ac]Ac-Macropa-MUC-16 was very effective against high and medium MUC16 expressing PDAC and EOC PDXs, respectively heading to 100% CRs while median survival for control groups was 36 (PDAC) and 47 (EOC) days. The RIC was less effective at inhibiting EOC PDX with low MUC-16 expression. For this, the % tumor growth inhibition (% TGI) was 94.5±6.8% and 84.7±11% at the day 12 and 21, respectively. Although CBC & clinical chemistry show no safety issues, histopathological studies showed mild to moderate pathologies in the liver and spleen for mice exposed to 2 doses of 15 kBq of the RIC. .

Conclusion: [^{225}Ac]Ac-Macropa-MUC-16 is effective against MUC-16 expressing EOC and PDAC xenografts. The exciting therapeutic potential is however dependent on the expression level of MUC-16 and points to the significance of heterogeneity within and between tumor types in cancers.

#568 Click chemistry for theranostic approaches in triple negative breast cancer.

Cristina Simo, Shayla Shmuel, Alex Vanover, Patricia M. R. Pereira

Washington University School of Medicine in St. Louis, St. Louis, MO

Introduction: Immunotherapies are part of the rapidly expanding landscape of targeted cancer treatments, with market sizes reaching over $150 billion in 2024. However, further understanding of tumor biology is crucial to developing effective therapies that minimize resistance. *N*-linked glycosylation, a post-translational membrane modification, is well known for its critical role in tumor growth and resistance, its impact on antibody tumor accumulation, and its effect on tumor response to targeted therapies. Despite its significance, methods to image and target (theranostic approaches) *N*-glycosylation have still not been fully developed. In this study, we use biorthogonal (click) chemistry to visualize and target *N*-glycans on triple negative breast cancer (TNBC) and exploit them to enhance immunotherapy.

Methods: 4T1 TNBC cells were inoculated subcutaneously in Balb/c mice. Glycans visualization: Mice were administered intravenously with tetraacetyl-*N*-azidoacetylmannosamine (mannose-N_3; 40 mg/kg) or PBS (control) once daily for three consecutive days. At 24 h post the last injection, AZDye-680 DBCO (5 mg/kg) was intravenously injected. At 24 h post-AZDye-680 DBCO administration, the organs were harvested, scanned, homogenized, and lysed for fluorescence and protein measurements. Glycans targeting to enhance anti-PD-L1 antibody uptake: Mice were administered mannose-N_3 or PBS as described before. Mice were then intravenously injected with the anti-PD-L1 antibody avelumab radiolabeled with copper-64 [^{64}Cu]Cu-NOTA-avelumab-DBCO (6.7 MBq, 40 µg). Mice were imaged with positron emission tomography (PET) at 24 and 48 h.

Results: Glycans visualization: 4T1 tumors exhibit high levels of *N*-glycosylation as visualized through metabolic glycoengineering using a mannose-N_3 derivative and AZDye-680 DBCO fluorescent dye. First, mannose-N_3 is administered, introducing azide functional groups to cell-surface *N*-glycoproteins. Next, the AZDye-680 DBCO is administered, clicking with azide groups on the cancer cell's surface. When compared with PBS, we observed a 3.5-fold increase in tumor uptake in animals administered mannose-N_3. Glycans targeting to enhance anti-PD-L1 antibody uptake: Previous studies demonstrated that PD-L1 is highly *N*-glycosylated in cancer cells, affecting antibody accumulation in tumors. Using immuno-PET with [^{64}Cu]Cu-NOTA-avelumab-DBCO, we showed a 1.9-fold increase in avelumab accumulation in mannose-administered mice compared to PBS controls.

Conclusions: In this study, we applied click chemistry to not only visualize *N*-glycans within tumors but also to exploit their presence to enhance antibody therapy. Our ongoing studies are focused on using metabolic glycoengineering to enhance anti-PD-L1 and anti-PD-1 therapy in TNBC.

#57 Membrane-bound heat shock protein Hsp70 as a new target in oncology: from theory to practice.

Maxim Shevtsov[1], Natalia Yudintceva[2], Danila Bobkov[2], Ruslana Likhomanova[2], Anastasiya Nechaeva[2], Anastasiya Lukacheva[2], Natalia Mikhailova[2], Viacheslav Fedorov[2], Elena Oganesyan[2], Oleg Rozanov[2], Konstantin Samochernykh[3], Alexey Ulitin[3], Alexander Kim[3], Elena Mikhailova[2], Rustam Ziganshin[4], Emil Pitkin[5], Stephanie E. Combs[1]

[1]Klinikum rechts der Isar, Technical University of Munich, Munich, Germany,[2]Personalized Medicine Centre, Almazov National Medical Research Centre, St.Petersburg, Russian Federation,[3]Polenov Neurosurgical Institute, Almazov National Medical Research Centre, St.Petersburg, Russian Federation,[4]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry Russian Academy of Sciences (RAS), Moscow, Russian Federation,[5]Department of Statistics and Data Science, The Wharton School, University of Pennsylvania, Philadelphia, PA

Heat shock proteins (HSP), particularly 70 kDa heat shock protein (Hsp70), apart from their cytoplasmic localization in cancer cells, can be exposed on the surface of the plasma membrane. We report that the membrane-bound protein mHsp70 of malignant brain tumors is required for high migratory and invasive activity of cancer cells. Live-cell inverted confocal microscopy of adult and pediatric brain tumor samples (n=32) showed mHsp70 overexpression on the membrane, especially in the perifocal zone. Mass-spectrometry analysis of lipid rafts isolated from brain tumor cells confirmed the presence of the protein in HSP cluster (including representatives of other families such as HSP70, HSP90), which in turn, during interactome analysis, was associated with proteins involved in cell migration and invasion (i.e., Rac1, RhoC, myosin-9). Application of small-molecule inhibitors of HSP70 (JG-98, PES) led to a significant decrease in the invasive potential of cells isolated from a tumor sample of patients, which indicates the role of the chaperone in invasion. Moreover, the use of chaperone inhibitors in orthotopic brain tumors model in rodents significantly decreased tumor progression, which was accompanied by an increased overall survival. Data demonstrate that chaperone inhibitors, particularly JG-98, disrupt the function of mHsp70, thereby providing an opportunity to better understand the diverse functions of this protein and offer aid in the development of novel cancer therapies. Apart from chaperone inhibitors we developed mHsp70-targeted peptide that could efficiently cross the blood-brain barrier accumulating in the glioblastoma cells in vivo. Subsequently, in the orthotopic GL261 mice and C6 rat glioma, intravenous administration of the fluorescently labeled peptide resulted in the tumor retention of agent (further confirmed by histological studies) 24 hours following i.v. injection. Topical application of the mHsp70-targeted peptide (sprayed over the freshly dissected brain tissues) helped to delineate the tumors in glioma-bearing animals employing intraoperative fluorescent imaging system. In conclusion, peptide recognizing mHsp70 demonstrated high targeting properties which could be employed for the intraoperative visualization as well as for developing of a potential carrier for drug delivery.

[1]Cluster for Molecular Imaging, Cluster for Molecular Imaging, Copenhagen University Hospital - Rigshospitalet; University of Copenhagen; Minerva Imaging ApS, Copenhagen, Denmark,[2]Minerva Imaging ApS, Oelstykke, Denmark,[3]Department of Biomedical Sciences, Cluster for Molecular Imaging, Copenhagen University Hospital - Rigshospitalet; University of Copenhagen, Copenhagen, Denmark

Introduction: Targeted radionuclide therapy (TRT) is a unique treatment option allowing for *in vivo* imaging and delivery of lethal radiation directly and specifically to solid cancers. As TRT is generally well-tolerated with limited side effects, it holds a significant potential for use in combination with other therapies such as immunotherapy. However, preclinical assessment of this combinational pair has been limited by the lack of relevant animal models. To address this, we established a fully immunocompetent animal model bearing murine tumors expressing a human target making the model eligible for both TRT and immune checkpoint inhibitor (ICI) therapy. Subsequently, the model was used for evaluating the *in vivo* biodistribution, tolerability and efficacy of Tb-161 trastuzumab in combination with anti-PD-1 (aPD-1) therapy. In addition, whole-body immune status following therapy was evaluated with CD8 ImmunoPET with 89Zr-Df-IAB42M1-14 (ImaginAb) and tumor microenvironment was profiled by flow cytometry.
Methods: The murine EMT-6 breast cancer cell line was modified to express HER2 by lentiviral transduction with expression confirmed by flow cytometry. The engineered EMT-6-HER2 (1+) were implanted on Balb/c mice, which subsequently were included in a theranostic study receiving either vehicle, ^{161}Tb-Trastuzumab, aPD-1 or a combination of ^{161}Tb-Trastuzumab and aPD-1. SPECT/CT imaging was performed 72 and 168 hours post dosing of TRT single therapy to evaluate biodistribution. Eight days after treatment initiation, PET/CT imaging of CD8 T cells was performed 24 hours after injection 89Zr-Df-IAB42M1-14 (4 MBq, 0.2 MBq/µg) in all treatment groups. Autoradiography and IHC were performed on tumors to evaluate co-localization of target expression and compound accumulation.
Results: Animals were included with a tumor volume of 101.5 mm^3 (n=12-16/ group). ^{161}Tb-Trastuzumab SPECT/CT imaging showed high tumor uptake (>15 %ID/g) and limited uptake in non-target expressing organs. Animals receiving ^{161}Tb-Trastuzumab as a single therapy or in combination with aPD-1 had significantly smaller tumor volumes when compared to the vehicle control (Dunnett's, p=0.003) with the smallest tumor volume observed in the combinatory treatment group. PET/CT imaging of 89Zr-Df-IAB42M1-14 targeting CD8 T cells revealed tumor uptake of 5-10 %ID/g. Autoradiography and IHC confirmed tumor border T cell infiltration and subcellular overlay between HER2 target expression and Tb-161.
Conclusion: This study demonstrated an evaluation of the efficacy of TRT and ICI, both as single therapies and in combination in a relevant animal model. We furthermore confirmed targeting of ^{161}Tb-Trastuzumab *in vivo* and showed that the immune response and CD8 T cell infiltration could be monitored with PET/CT imaging in animals previously dosed with Tb-161 radiolabeled trastuzumab.

#571 Novel somatostatin receptor type 2 targeted radiopharmaceuticals with improved renal clearance and enhanced tumor retention relative to DOTATATE.

Nicole Bakas, Alain Noncovich, Andrew Hudson, Su-Tang Lo, Lea Nyiranshuti, Patrick Napier, Nicholas Smith, Steven Horton, Samantha Richardson, Terra Miller, Ron Deocareza, Katrina Salvador, Tarsicio Juarez, Charlotte Lorenz, Abhijit Bhat

RayzeBio, San Diego, CA

Introduction: Somatostatin receptor type 2 (SSTR2) is highly expressed on a majority of well-differentiated gastroenteropancreatic neuroendocrine tumors (GEP-NETs) and is also expressed in other solid tumors such as small-cell lung cancer (SCLC) and breast cancer, albeit with a lower prevalence. [^{177}Lu]Lu-DOTATATE is an eight amino acid peptide with high affinity for SSTR2 receptor used as a radiopharmaceutical therapy (RPT) for treatment of SSTR2 expressing solid tumors. One limitation of DOTATATE-based RPT is the uptake and extended retention of radiolabeled peptides in the proximal renal tubule cells, increasing the risk for radiation-induced nephropathy. The kidney retention of DOTATATE limits the administered radioactivity and effective radiation dose delivered to the tumors. We report the development of a novel SSTR2 targeted RPT agents, RYZ-SSAs, designed to have enhanced renal clearance and improved tumor exposure compared to [^{177}Lu]Lu-DOTATATE; thereby maximizing the therapeutic potential of SSTR2 RPT by effectively delivering higher radiation doses to tumors while minimizing renal exposure.

Methods: RYZ-SSAs are highly selective, potent SSTR2 agonists conjugated to a DOTA chelator, and capable of binding various radioisotopes. The binding affinity to the SSTR1-5 proteins, and the cell binding and internalization in SSTR2 expressing cell lines were determined by radioligand binding assays. Further evaluation by cAMP and b-arrestin recruitment assays were performed in SSTR2 overexpressing CHO cells. Biodistribution studies using SPECT imaging and *ex vivo* quantification, and efficacy were performed in SSTR2 expressing xenograft models.

Results: RYZ-SSAs show high binding affinity to human SSTR2, with sub-nanomolar SSTR2 Ki's and selectivity of >200-fold against SSTR1/3/4/5 isoforms. The IC50s and EC50s for RYZ-SSAs ranged from single digit nanomolar to sub-nanomolar. In *ex vivo* mouse biodistribution studies, [^{177}Lu]Lu-RYZ-SSAs were compared with [^{177}Lu]Lu-DOTATATE in a SSTR2 positive NSCLC xenograft. The tumor to kidney ratio based on the mTIACs were 2.1 for DOTATATE and 10.5 for RYZ-SSA1. RYZ-SSA1 demonstrated greater than two-fold increase in tumor retention, and two-fold decrease in renal exposure relative to DOTATATE. A single injection of [^{225}Ac]Ac-RYZ-SSA1 resulted in significant tumor growth inhibition in a NSCLC xenograft model with durable regression and prolonged survival. All treatments were well tolerated.

Conclusion: Preclinical *in vitro* and *in vivo* data demonstrate that RYZ-SSAs have an improved therapeutic window relative to [^{177}Lu]Lu-DOTATATE. RYZ-SSA1 has the potential to deliver higher radiation doses to tumors while sparing the kidneys without co-administration of amino acids, paving the way for a more effective and convenient RPT treatment regimen for SSTR2 expressing solid tumors.

#572 Development of a targeted copper theranostic to fibroblast activation protein (FAP) which shows high uptake and long-term retention at the tumor site.

Jaclyn L. Lange[1], Lachlan E. McInnes[1], Jessica Van Zuylekom[2], Benjamin Blyth[2], Stacey E. Rudd[3], Paul S. Donnelly[3], Aidan Ingham[4], Jason S. Lewis[4], **Matthew Harris**[1]

[1]Clarity Pharmaceuticals, Sydney, Australia,[2]Peter MacCallum Cancer Centre, Melbourne, Australia,[3]School of Chemistry and Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Melbourne, Australia,[4]Memorial Sloan Kettering Cancer Centre, New York, NY

Background and Purpose: Fibroblast Activation Protein (FAP), a membrane-bound enzyme and cell surface protein, is up-regulated in cancer-associated fibroblasts and is present in the tumor microenvironment across numerous cancers. There is low to no expression of FAP in healthy tissue. Targeted Copper Theranostics (TCTs) are radiopharmaceuticals that utilize copper-64 (Cu-64) for PET imaging and copper-67 (Cu-67) for therapy. Herein, we report preclinical evaluation of a mono- and bis-FAP targeting agent using Cu-64 in two FAP-positive tumor xenograft models. These agents enable the visualization of FAP as a potential pan-cancer imaging agent and therapy.

Methods: We evaluated the imaging characteristics of SAR-FAP and a dimer, SAR-bisFAP, which utilize the FAP inhibitor (UAMC1110) conjugated to a sarcophagine chelator (SAR). We tested the compounds in two xenograft models which have high expression levels of FAP: NSG mice bearing a SK-MEL-187 xenograft (a human-derived metastatic cell line); or athymic nude mice bearing a U87MG xenograft (a human-derived glioblastoma cell line). The mice were administered ~5 MBq of [^{64}Cu]Cu-SAR-FAP or [^{64}Cu]Cu-SAR-bisFAP and the biodistribution and tumor uptake assessed via microPET/CT imaging and *ex vivo* biodistribution at 1, 4 and 24 h post i.v. injection. A comparison study with [^{68}Ga]Ga-FAPi-46 along with blocking studies with FAPi-46 (an industry standard) were also completed.

Results: Imaging and an ex-vivo biodistribution study of the SK-MEL-187 xenograft NSG mice showed that both SAR-FAP tracers have specific binding to FAP-positive SK-MEL-187 tumors and higher uptake compared to ^{68}Ga-FAPi-46 at 1 h. Additionally, both SAR-FAP tracers show FAPi-46 blockable uptake, confirming the tracer is binding specifically to FAP. Overall, the [^{64}Cu]Cu-SAR-bisFAP has better retention at 24 h. In the U87MG xenografted athymic nude mice, the tumor uptake, as measured via ex vivo biodistribution for the [^{64}Cu]Cu-SAR-FAP tracer was consistent over 4 hours (4.8% IA/g) which thereafter decreased to 0.8% IA/g at 24 hours. We were again able to observe higher uptake and long retention in the tumor after 24 hours (6.2% IA/g) for the [^{64}Cu]Cu-SAR-bisFAP.

Conclusion: Imaging and biodistribution studies demonstrated high tumor-specific uptake for [^{64}Cu]Cu-SAR-FAP and [^{64}Cu]Cu-SAR-bisFAP tracers in the SK-MEL-187 and U87MG tumor xenograft mouse models. The uptake and 24-hour retention of the [^{64}Cu]Cu-SAR-bisFAP is very encouraging and indicates potential for therapeutic benefit with this tracer. Efficacy studies are underway to ascertain the therapeutic potential of [^{67}Cu]Cu-SAR-bisFAP as a TCT.

#573 Radioimmunotherapy using $^{64/67}$copper labelled trastuzumab in mice bearing HER2-positve xenografts as a model for breast cancer therapy.

Stacey E. Rudd[1], Jessica Van Zuylekom[2], Benjamin Blyth[2], **Matthew Harris**[3], Paul S. Donnelly[1]

[1]School of Chemistry and Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Melbourne, Australia, [2]Peter MacCallum Cancer Centre, Melbourne, Australia,[3]Clarity Pharmaceuticals, Sydney, Australia

Background and Purpose: Human epidermal growth factor receptor 2 (HER2) is overexpressed in several cancers including breast cancer. In the treatment of HER2 positive breast cancer, patients have shown significant improvements with trastuzumab therapy. Radioimmunotherapy (RIT) utilizes an antibody targeted to a receptor overexpressed on tumors to deliver radiation to the target. RIT utilizing trastuzumab could provide an additional treatment option for HER2+ breast cancer patients. We have produced the theranostic pair [^{64}Cu]Cu-MeCOSar-trastuzumab, for PET imaging, and [^{67}Cu]Cu-MeCOSar-trastuzumab, for therapy via beta emission, to evaluate this Targeted Copper Theranostic (TCT) approach as an effective radioimmunotherapy.

Methods: The MeCOSar chelator was conjugated to trastuzumab and subsequently radiolabeled with either copper-64 (Cu-64) or copper-67 (Cu-67). Proof of concept studies were performed using SKOV-3 tumor bearing mice, injected with one dose of [^{64}Cu]Cu-MeCOSar-trastuzumab or [^{67}Cu]Cu-MeCOSar-trastuzumab to compare biodistribution of the theranostic pair. Tumor uptake was assessed using PET/CT imaging and/or ex vivo biodistribution studies. In therapy studies, a single dose of saline, MeCOSar-trastuzumab, or [^{67}Cu]Cu-MeCOSar-trastuzumab was administered and endpoints assessed.

Results: [^{64}Cu]Cu-MeCOSar-trastuzumab and [^{67}Cu]Cu-MeCOSar-trastuzumab showed comparable high tumor-specific uptake in biodistribution studies, with tumor uptake at 48 hours of 61 ± 6 % IA/g for [^{64}Cu]Cu-MeCOSar-trastuzumab and 59 ± 7 % IA/g for [^{67}Cu]Cu-MeCOSar-trastuzumab. Mice treated with [^{67}Cu]Cu-MeCOSar-trastuzumab tolerated the treatment well with limited side effects or AEs. Treated mice also showed significant tumor growth inhibition and extended survival in a dose dependent manner compared with the control groups. The median survival was 32 days in the control groups and 102 days in the 9 MBq group.

Conclusion: These results show high tumor uptake for [^{64}Cu]Cu-MeCOSar-trastuzumab and [^{67}Cu]Cu-MeCOSar-trastuzumab with very similar biodistribution profiles at 48 hours in SKOV-3 xenograft model. [^{67}Cu]Cu-MeCOSar-trastuzumab demonstrated significant tumor growth inhibition compared to the control groups and effectively increased the survival of the treated group. This study demonstrates the potential of [^{67}Cu]Cu-MeCOSar-trastuzumab for clinical translation.

#574 Detection of tumor cell surface calreticulin after doxorubicin treatment using a novel radiolabeled nanobody.

Rachael Guenter[1], Yuvasri Golivi[1], Lucinda Hall[1], Amro Abdelrahman[2], Chloe La Prairie[3], Caleb Miller[1], Tejeshwar C. Rao[4], Danielle M. Carlson[5], Mark J. Truty[2], Benjamin Larimer[6], J. Bart Rose[1]

[1]Surgery, University of Alabama at Birmingham, Birmingham, AL,[2]Surgery, Mayo Clinic, Rochester, MN,[3]Pediatric Dentistry, University of Alabama at Birmingham, Birmingham, AL,[4]Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX,[5]Internal Medicine, Mayo Clinic, Rochester, MN,[6]Radiology, University of Alabama at Birmingham, Birmingham, AL

Background: Targeted agents, such as nanobodies, can be covalently linked to radionuclide chelators for theranostics. Nanobodies are single-domain immunoglobulin variable regions with a short blood half-lives and high specificity. Calreticulin (CALR) is endoplasmic reticular (ER) protein that translocates to the cell surface upon induction with certain agents, namely doxorubicin. We hypothesized surface CALR on tumors could be targeted using a novel nanobody after induction with doxorubicin.

Methods: Studies were conducted using *in vitro* and *in vivo* models of pancreatic ductal adenocarcinoma (PDAC). Surface CALR expression was determined by western blot on fractionated lysates, flow cytometry, or immunofluorescence (IF). Doxorubicin was administered by intraperitoneal injection to mouse models of PDAC. The anti-CALR nanobody was developed via the panning of a synthetic nanobody phage display library. The top CALR-binding nanobody was confirmed by ELISA, immunohistochemistry (IHC), and flow cytometry. For *in vivo* studies, the nanobody was conjugated with the chelator NOTA and radiolabeled with ^{64}Cu. PET images were acquired 1-hour after injection. Significance was determined using an independent t-test and p values < 0.05 were considered statistically significant.

Results: PDAC cells treated with doxorubicin showed peak surface CALR expression between 24 and 48 hours. Flow cytometry revealed that 61.7% of live PDAC cultured cells treated for 24 hours expressed surface CALR, compared to 2.2% in controls ($p < 0.001$). In a subcutaneous syngeneic PDAC mouse model, two doses of doxorubicin 48 hours apart significantly increased surface CALR, with 30.4% of live-cells expressing CALR in treated tumors versus 1.5% in controls ($p < 0.001$). Similarly, doxorubicin-treated tumors from a PDAC patient derived xenograft (PDX) model had a 6.7-fold increase in live-cells expressing surface CALR compared to controls ($p < 0.01$). IF confirmed a 1.4-fold increase in CALR expression in doxorubicin-treated tumors from the subcutaneous PDAC mouse model ($p < 0.01$) and a 1.7-fold increase in the PDAC PDX model ($p < 0.01$). Our anti-CALR nanobody has an apparent 37 nM affinity for recombinant CALR and successfully detected surface CALR by IHC and flow cytometry. *In vivo* PET imaging showed significant increased uptake of the ^{64}Cu-NOTA-nanobody in tumors from doxorubicin-treated mice over controls, with no significant changes in heart, kidney, or liver accumulation by PET quantification and flow cytometry ($p < 0.05$).

Conclusions: Systemic doxorubicin treatment induces CALR surface translocation in tumors that can be successfully targeted with a radiolabeled nanobody for PET imaging. Targeting chemotherapy-induced surface CALR using our radiolabeled nanobody could provide a theragnostic strategy for the detection and treatment of PDAC.

#575 ^{225}Ac-SSO110 as next-generation SSTR2 targeting radiopharmaceutical for small cell lung cancer.

Anika Jaekel, Prachi Desai, Manuel Sturzbecher-Hoehne, Dennis Mewis, Germo Gericke, Manfred Ruediger

Ariceum Therapeutics GmbH, Berlin, Germany

SSO110 (DOTA-JR11) is a somatostatin receptor 2 (SSTR2) antagonist currently under clinical development in small cell lung cancer (SCLC). SSO110 targets a higher number of SSTR2 binding sites and shows longer tumor retention than the SSTR2 agonist DOTATATE translating into higher anti-tumor efficacy of ^{177}Lu-SSO110 compared to ^{177}Lu-DOTATATE. The aim of this study was to identify the most potent radioisotope (^{225}Ac, ^{212}Pb, ^{161}Tb, ^{177}Lu) for SSO110 in comparison to DOTATATE to guide further clinical development. Balb/c or Swiss nude mice were engrafted with SSTR2-positive xenografts NCI-H69 (SCLC model) or AR42J (pancreatic cancer model). The therapeutic efficacy of ^{225}Ac, ^{161}Tb-, ^{212}Pb-, and ^{177}Lu-labelled SSO110 was compared to ^{225}Ac- and ^{161}Tb-labelled DOTATATE after single-dose intravenous injection. In the NCI-H69 SCLC model, 20 MBq ^{177}Lu-SSO110 and 21 kBq ^{225}Ac-SSO110 demonstrated significantly better anti-tumor efficacy than 42 kBq ^{225}Ac-DOTATATE, 20 MBq ^{161}Tb-DOTATATE, or 20 MBq ^{161}Tb-SSO110. Most remarkably, a single dose of only 30 kBq ^{225}Ac-SSO110 (human equivalent dose: 7.3 MBq) induced complete tumor remissions and long-term survival. Various doses of ^{212}Pb-SSO110 were less or equally effective than ^{177}Lu-SSO110. In contrast to treatment with ^{225}Ac-SSO110, no complete remissions were induced with ^{212}Pb-SSO110. In the AR42J model, 37 kBq ^{225}Ac-SSO110 induced tumor growth inhibition immediately after treatment and tumor volume remained low and constant leading to 100% survival of all animals. Histopathological assessment of the tumors showed a lower mitotic index, higher necrosis and a regressing phenotype of neoplastic cells in comparison to tumors from the vehicle group (median survival of 11 days). 37 kBq ^{225}Ac-DOTATATE could not control tumor growth and median survival was reached after 33 days. 20 MBq ^{161}Tb-SSO110 induced a slightly stronger tumor growth delay than 20 MBq ^{177}Lu-SSO110 (median survival 36 vs 30.5 days). All treatments were well-tolerated. The preclinical in vivo comparison demonstrates superior efficacy of SSO110 over DOTATATE across all isotopes tested (Lu-177, Ac-225, Tb-161). Our results highlight the exceptionally strong anti-tumor efficacy of ^{225}Ac-SSO110 in vivo even at low, single doses. Interestingly, ^{212}Pb-SSO110 was not superior to ^{177}Lu-SSO110 and ^{225}Ac-SSO110, most likely due to the long tumor half-life of SSO110 (>7 days) that matches better with the long-lived isotopes Ac-225 and Lu-177. ^{161}Tb-SSO110 demonstrated modestly better efficacy than ^{177}Lu-SSO110, but only in the AR42J model with high and homogenous target expression. Based on promising emerging clinical data from the LuSato1 study with ^{177}Lu-SSO110 and the outstanding preclinical activity of ^{225}Ac-SSO110, a global phase I/II clinical study with ^{225}Ac-SSO110 in patients with ES-SCLC or Merkel Cell Carcinoma on Immune-Checkpoint Inhibitor monotherapy is being initiated.

#576 Discovery of FL801, a B7-H3-targeting nanobody-based radioligand vector, using Clear-XTM linker technology.

Xiaozhu Wang, Ming-Jin Jheng, Pengyun Li, Dian Li, Yihu Xie, Biao Guo, Ruyi Hu, Fa Liu

Full-Life Technologies Limited, Shanghai, China

B7-H3, also known as CD276, is a type I transmembrane protein and a member of the B7 family, which includes immune checkpoints such as PD-L1. B7-H3 is over-expressed in multiple solid tumors including lung, esophageal, prostate and breast cancers. B7-H3 antibody-drug conjugates (ADCs) have demonstrated promising early clinical antitumor activity. In contrast to ADCs, radionuclide drug conjugates (RDCs) offer not only a different therapeutic approach but also allow tumor imaging. VHH (variable heavy domain of heavy chain) is a highly attractive binder modality, however, one persistent challenge of VHH-based RDCs is the low tumor uptake together with a high kidney uptake prohibiting its application in RDC therapy. Our Clear-X™ linker technology was developed to specifically address such therapeutically sub-optional biodistribution profiles that are nearly without exception shared by all VHHs and other similar-sized protein-based vectors such as affibodies and DARPins. Using Clear-X™, we developed our lead B7-H3 radioligand vector FL801. The binding affinity of FL801 was assessed in vitro. In the cell-based binding assays, FL801 exhibited specific B7-H3 binding with sub-nanomolar affinity. The radiolabeling of FL801 with ^{177}Lu resulted in radiochemical purities (RCP) of >98% and molar activities of 18.5 MBq/nmol. [^{177}Lu]Lu-FL801 was found to be stable in the formulation buffers at 4°C for 5 days. The in vivo biodistribution profile of [^{177}Lu]Lu-FL801 was characterized by SPECT/CT imaging and cut-and-count biodistribution studies in B7-H3-positive tumor-bearing mice. The SPECT/CT imaging of 11.1 MBq [^{177}Lu]Lu-FL801 revealed an intense tumor uptake that was significantly higher than in all normal organs at 24 and 72 hour. In the cut-and-count biodistribution studies, [^{177}Lu]Lu-FL801 demonstrated a therapeutically favorable profile including a tumor uptake of >30% ID/g and a tumor-to-kidney (T/K) ratio of >2.0 at 24 hour. This was a significant improvement over our starting-point VHH lead without Clear-X™ modification which exhibited a tumor uptake of 2.3% ID/g and a T/K ratio of <0.01 at 24 hour. In addition, the anti-tumor activity of [^{177}Lu]Lu-FL801was evaluated in the same model using a single dose of 11.1 MBq [^{177}Lu]Lu-FL801 per mice. It was found that the treatment was well tolerated, and all treated animals achieved a complete remission of the tumor. In summary, the preclinical data package collectively supports to proceed towards clinical studies of [^{177}Lu]Lu-FL801 as a potential therapeutic option for B7-H3 positive tumors. In addition, this work validated the effectiveness of Clear-X™ linker technology in optimizing VHH-RDCs, and we expect Clear-X™ is also applicable to other protein-based RDCs with similar molecular sizes.

#577 First-in-class Claudin 18.2 targeting radiopeptide, ^{64}Cu-PD-29875 and ^{177}Lu-PD-29875, exhibit promising theranostic potential in a pancreatic cancer xenograft model.

Shota Tsuchida[1], Yoshihide Mizukoshi[1], Shintaro Kato[1], Hiroko Inaba[1], Rie Komura[1], Miho Satake[2], Yuki Sato[2], Naoki Kanazawa[2], Hayato Yanagida[1], Hidetomo Kitamura[1], Kentaro Suzuki[2], Keisuke Matsuhara[2], Satoshi Matsushima[2], Masato Murakami[1]

[1]PeptiDream Inc., Kawasaki, Japan,[2]PDRadiopharma Inc., Sammu, Japan

Introduction: Claudin 18.2 (CLDN18.2) is one of the tight junction proteins essential for maintaining the gastric mucosal barrier, preventing gastric acid leakage through paracellular space. Although CLDN18.2 is physiologically expressed in gastric mucosal cells and restricted localization at tight junction, it is overexpressed and exposed on the surface of cancer cells in several tumor types, including pancreatic, esophageal, and gastric cancers, which indicates CLDN18.2 is attractive molecule for cancer targeting. PD-29875 is a novel macrocyclic peptide targeting CLDN18.2 and can be labeled with radionuclides such as cupper (^{64}Cu) and lutetium (^{177}Lu), which enables tumor-specific PET imaging and therapy. This study reports the theranostic potential of PD-29875 for a pancreatic cancer xenograft model.

Materials and Methods: PD-29875 was discovered using Peptide Discovery Platform System (PDPS), a proprietary screening system of PeptiDream. Binding affinity and CLDN18.2 selectivity of PD-29875 was measured by cell-based assay. For in vivo evaluation, we used a xenograft model in which BxPC3 (PDAC cell line) which overexpressed CLDN18.2 was subcutaneously transplanted into nude mice. To assess biodistribution, ^{64}Cu-PD-29875 or ^{177}Lu-PD-29875 was dosed to BxPC3 xenograft mice, and the percentage of injected dose in tumors and major organs was quantified by cut and count method. To evaluate whether PET imaging can detect tumors, ^{64}Cu-PD-29875 was dosed to BxPC3 xenograft mice and PET scanning was performed. For therapeutic experiment, ^{177}Lu-PD-29875 was dosed to BxPC3 xenograft mice and tumor volume and body weight were measured for 48 days after dosing.

Results: Cell-based assay revealed that ^{64}Cu-PD-29875 exhibit a strong binding to HEK293-hCLDN18.2 OE cell line, but not HEK293-hCLDN18.1 OE and parental HEK293 cell line, demonstrating that PD-29875 is selectively binding to hCLDN18.2. In *in vivo* biodistribution experiment, ^{64}Cu-PD-29875 and ^{177}Lu-PD-29875 showed a strong accumulation in the tumors and were still highly retained in the tumor at 24 hours after dosing, in contrast, accumulation in the normal stomach was markedly lower, suggesting PD-29875 distinguishes physiological and tumor-expressed CLDN18.2. In PET imaging, ^{64}Cu-PD-29875 clearly detected tumors, consistent with the biodistribution data. In therapeutic experiment, ^{177}Lu-PD-29875 was well tolerated and improved mouse overall survival compared with control animals for 62 days after transplantation, which suggests a robust tumor growth inhibition of ^{177}Lu-PD-29875 administration.

Conclusion: PD-29875 has preferable properties for imaging and therapy with radionuclides for theranostic use in CLDN18.2 expressing solid tumors including pancreatic cancer.

#578 ATNM-400 is a novel Actinium-225 antibody radioconjugate with strong efficacy in preclinical models of prostate cancer.

Denis Beckford, Sumit Mukherjee, Debbie Lewis, Jason Li, Dina Yang, Karina Peregrina, Amanda Chin, Le-Cun Xu, Monideepa Roy, **Adeela Kamal**

Actinium Pharmaceuticals, Inc., New York, NY

Introduction: In 2024, an estimated 299,010 new prostate cancer (PCa) cases will be diagnosed in the US, with 35,250 deaths. While PCa initially responds to androgen deprivation therapy (ADT), it often progresses to metastatic castration-resistant prostate cancer (mCRPC), a challenging condition with limited treatment options. Targeted radiotherapies like Pluvicto, a beta-emitting treatment targeting prostate-specific membrane antigen (PSMA), have shown promise but face limitations due to radiation properties and variability in PSMA expression. mCRPC is driven by persistent androgen receptor signaling and other pathways, often mediated by overexpressed cell surface receptors. We designed ATNM-400 against a target highly expressed in mCRPC that has been previously targeted with naked antibodies or antibody drug conjugates but have been ineffective clinically. Here, we tested ATNM-400, a first-in-class actinium-225 (Ac-225) antibody radioconjugate (ARC) in preclinical models of PCa with the hypothesis that targeted delivery of an alpha-emitter would offer stronger therapeutic potential than existing therapies to address a critical unmet need in mCRPC patients.
Methods: ATNM-400 was synthesized by conjugating ATNM400 antibody with p-SCN-Bn-DOTA, followed by radiolabeling with Ac-225. Binding affinity and internalization in PCa cell lines were evaluated using flow cytometry and radioactivity measurement. The biodistribution (BioD), pharmacokinetics (PK), and efficacy of ATNM-400 were tested in preclinical mouse models using 22Rv1 and DU145 PCa cell lines. The potential to overcome Pluvicto resistance in mCRPC was also studied both in vitro and in vivo.
Results: ATNM-400 demonstrated over 98% radiochemical purity and rapid internalization into PCa cells. Treatment of PCa cells with ATNM-400 demonstrated potent cytotoxic effects in a dose-dependent manner. In vivo BioD and PK studies in PCa models showed that ATNM-400 accumulated in tumors for up to 144 hours, with minimal accumulation in normal organs. Small animal SPECT/CT images in mouse xenograft models of PCa showed that Indium-111 radiolabeled ATNM400 selectively accumulated in tumors and cleared from healthy tissues. The radiation dose to organs, extrapolated from mouse dosimetry, suggested an acceptable safety profile. In vivo studies in multiple PCa models (22RV1 and DU145) using a single-dose of ATNM-400, showed a potent tumor growth inhibition of 68.5% at 20 µCi/kg and 99.8% at 40 µCi/kg, with all doses well tolerated. Also, ATNM-400 is being tested in Pluvicto-resistant PCa preclinical models, with results forthcoming.
Conclusions: ATNM-400 showed strong anti-tumor efficacy and a favorable safety profile in preclinical PCa models. These results highlight ATNM-400's potential as a transformative therapeutic option for PCa patients with unmet clinical needs.

#579 A novel nanobody-based radionuclide drug conjugate (RDC) platform through introducing a human serum albumin (HSA) binder by the intelligent ligase-dependent conjugation (iLDC) technology: an innovative and versatile approach for next-generation RDCs with enhanced pharmacokinetics and druggability.

Chong Liu, Sipeng Li, Zengyan Mu, Yajun Sun, Haibo He, Lili Shi, Paul Song, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: RDC has become an attractive strategy in cancer treatment, but still faces significant drawbacks due to poor tumor penetration and undesirable pharmacokinetics of the most used targeting carriers, such as peptides, small molecules and nanobodies. To address these limitations, we developed a robust and versatile nanobody-based RDC platform, that site-specifically conjugates an small molecular HSA binder into the nanobody-based RDC to improve its druggability by increasing its circulation half-life. The validation of the RDC platform is exemplified by ^{64}Cu/^{177}Lu-NBC-02, a theranostic anti-PSMA nanobody-based RDC.

Method: Using iLDC technology, a diverse and high-quality RDC library was generated by site-specifically conjugating various stable branch linkers containing different HSA binders and a DOTA into multiple anti-PSMA nanobodies with varying affinities, followed by labeling with ^{64}Cu and ^{177}Lu. Following the screening of those RDCs through PET imaging study and in vivo anti-tumor efficacy study, the theranostic anti-PSMA RDC, ^{64}Cu/^{177}Lu-NBC-02, was developed. Subsequently, an IIT study was conducted to confirm the distribution of ^{177}Lu-NBC-02in mCRPC patients.

Results: PET imaging studies performed in the LNCaP CDX model showed enhanced circulation half-life of ^{64}Cu-NBC-02, which resulted in a higher accumulation and retention over time in the tumor with a much higher tumor-to-background ratio. Remarkably, ^{177}Lu-NBC-02 demonstrated superior antitumor efficacy to ^{177}Lu-PSMA-617 (Pluvicto®) with complete tumor regression in all treated mice. In addition, ^{177}Lu-NBC-02 can reduce tumor volume significantly when the tumors became refractory to Pluvicto®. This demonstrated ^{177}Lu-NBC-02's potential to overcome resistance to Pluvicto®. An IIT study in several mCRPC patients injected with a single dose showed that ^{177}Lu- NBC-02 was well tolerated. SPECT images revealed longer blood circulation of ^{177}Lu- NBC-02 with much higher uptake in tumor lesions and lower uptake in salivary glands compared with published data of Pluvicto®.

Conclusion: The novel RDC platform combining iLDC technology with a unique HSA-binding linker-chelator design can generate ^{177}Lu-NBC-02 with an extended circulation half-life, higher tumor uptake and lower salivary gland uptake in both CDX model and mCRPC patients compared to Pluvicto®. The IND enabling of this potential BIC anti-PSMA RDC is underway for the exploration of therapeutic effects on the treatment of mCRPC. Furthermore, the applied strategy provides a promising next-generation platform for future RDC discovery which requires nanobody as a targeting carrier, hence significantly expanding promise beyond the current format.

TUMOR BIOLOGY: Imaging in Animal Models

#58 Subcutaneous tumor volume measurements: The method matters.

Katarzyna Urbańska, Irmina Przydatek, Agnieszka Drzał, Karina Adamowicz, Fabio dell'Aquila, Magdalena Chwalisz, Miłosz Gawenda, **Martyna Sniegocka**

Selvita S.A., Krakow, Poland

In preclinical studies, tumor volumes are important indicators of cancer progression and the response to therapy with selected drug candidates. The most common method of tumor volume assessment, due to its simplicity and cost-effectiveness, is measuring length, width, and height with a caliper, and calculating the volume using the ellipsoid formula. However, many tumors, even if inoculated by an experienced operator, show irregular shapes that deviate from the idealized ellipsoid volume which may lead to over- or underestimation of the actual tumor volume. In such cases, more specialized techniques like TumorImager® using structured light or ultrasound imaging can potentially be a better solution. The purpose of this study was to compare three different methods of tumor measurements: the caliper, the TumorImager®, and ultrasound imaging, and observe any correlation between the volumes obtained by each technique. CT26 and B16F10 cancer cells were inoculated subcutaneously on the flank of 6-week-old male mice (Balb/c and C57Bl6/J, respectively). Tumors were measured on days 8, 15 and 22 after cancer cell inoculation. Ultrasound, caliper and TumorImager® measurements were always performed by the same person to maintain replicability. The last measurements were performed on the day mouse sacrificed, and data collected was compared with the dissected tumor volume. Obtained tumor volumes were analyzed to compare the differences between the techniques used and determine the level of correlation between them. Our results showed that the measurements obtained with a caliper were similar to those based on an ultrasound 3D model. In this case, the biggest differences observed were of tumors significantly deviating from the ellipsoid shape. Measurements acquired with the TumorImager® differed significantly from those taken with calipers and ultrasound imaging. This study emphasizes the importance of choosing the right method of tumor measurement and understanding the differences between them. With an experienced operator, choosing either the caliper or ultrasound imaging is the right choice; the decision should be made based on information that needs to be obtained. Ultrasound imaging is the most informative method since it can be used, for example, to visualize the vascularity of the tumor. However, it has the greatest impact on animal welfare because the animals need to be anesthetized for the procedure. Moreover, it is important to acknowledge that the formula chosen for the study considers the tumor height, which is crucial in the case of tumors growing deeply into the animal's body. The TumorImager® does not record this height dimension and therefore the highest deviations in relation to ultrasound were observed. However, based on a correlation between the techniques deployed. we were able to find constant coefficients enabling the scaling of TumorImager® volumes to the true volume of a tumor.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Theranostics and Radiotheranostics
Poster Session

#580 ^{111}In/^{225}Ac-ABD320, a novel 5T4-targeted radiopharmaceutical with favorable tumor-to-normal tissue biodistribution and single-dose efficacy in preclinical cancer models.

E. S. Melese, E. Cummins, A. Mandel, L. Li, D. Namjoshi, M. Čučuk, N. Menon, B. Harbourne, P. Tao, B. McLeod, T. Osborne, A. Roman, K. Lassueur, A. McDonagh, M. Abrams, A. Judge, L. Janes, **I. Kulić**;
Abdera Therapeutics Inc., South San Francisco, CA

Radiopharmaceutical therapies offer a promising, targeted approach for treating cancers with limited options. The 5T4/trophoblast glycoprotein (encoded by *TPBG)* is an oncofetal cell surface antigen found on various cancer cells, including gastrointestinal, head and neck, and non-small cell lung cancers. 5T4 is associated with cancer stem cell properties, metastatic spread and poor clinical outcomes in cancer patients, while it is minimally expressed or absent in healthy adult tissue. Hence, 5T4 is an ideal target for tumor-directed radiotherapy, particularly since targeting 5T4 has no clear therapeutic benefit without a cytotoxic payload in preclinical models. ABD320, a humanized camelid heavy chain only antibody (VHH) fused to an engineered Fc with altered Fc-gamma and neonatal Fc receptor binding, uses a novel linker-chelator to deliver targeted ^{111}In and ^{225}Ac to 5T4 positive cancer cells. The ABD320 VHHFc binds human 5T4 with high affinity and specificity and is internalized by 5T4-expressing cancer cells. ABD320 is designed to minimize systemic and whole-body exposure through fast blood clearance and minimal normal tissue exposure. Tumor targeting was evaluated using ^{111}In-ABD320 in murine models bearing human xenografts. In the NCI-H1975 non-small cell lung cancer model, a single intravenous administration of ^{111}In-ABD320 was rapidly cleared from blood and normal tissues. Tumor accumulation peaked at 40% ID/g, despite low expression (29,000 receptors/cell) corresponding to high tumor to normal tissue exposure ratios (kidney 6, liver 11) assessed between 1 to 240 hours after ^{111}In-ABD320 administration. ABD320 was well tolerated when used to deliver 12 to 20 kBq of the therapeutic radionuclide ^{225}Ac to 5T4-expressing tumors. ^{225} Ac-ABD320 achieved significant tumor regression, suppression of regrowth and extension of survival. Within-mouse dosimetry estimates a tumor inferred dose of 50 to 80 Gy corresponding to efficacious doses of ^{225} Ac-ABD320. In conclusion, ABD320, which employs a novel VHH-binder and linker-chelator, selectively and preferentially delivers radionuclides to 5T4 expressing tumors, demonstrates potent anticancer activity and is a promising candidate for further development.

#581 Better together: Biparatopic [^{225}Ac]Ac-labeled anti-HER2 antibody-drug radioconjugates using two domain-specific antibodies for the treatment of trastuzumab and T-DM1 resistant HER2-positive breast cancer xenografts.

Jessica Pougoue Ketchemen[1], Alissar Monzer[2], Fabrice Ngoh Njotu[3], Hanan Babeker[2], Emmanuel Nwangele[3], Anjong Florence Tikum[2], Nikita Henning[2], Nava Hassani[2], Alireza Doroudi[2], Humphrey Fonge[1]

[1]CHU de Quebec - Universite Laval, Quebec, QC, Canada,[2]University of Saskatchewan, Saskatoon, SK, Canada,[3]Universite Laval, Quebec, QC, Canada

Purpose: HER2 is amplified and overexpressed in breast cancer (BC) and other cancers where it promotes proliferation and mediates resistance to targeted therapies. A combination of anti-HER2 trastuzumab and pertuzumab is approved for treatment.

Aim: To develop and evaluate a combination antibody-drug radioconjugates (ADRs) [^{225}Ac]Ac-Macropa-trastuzumab-PEG$_6$-DM1 ([^{225}Ac]Ac-Macropa-T-PEG$_6$-DM1) and [^{225}Ac]Ac-Macropa-pertuzumab-PEG$_6$-DM1 ([^{225}Ac]Ac-Macropa-P-PEG$_6$-DM1) against HER2-positive BC.

Experimental Design: Therapeutics [^{225}Ac]Ac-Macropa-T-PEG$_6$-DM1 and [^{225}Ac]Ac-Macropa-P-PEG$_6$-DM1 and their respective imaging pairs [^{89}Zr]Zr-DFO-trastuzumab-PEG$_6$-DM1 and [^{67}Cu]Cu-DOTA-pertuzumab-PEG$_6$-DM1 were developed and characterized. Biodistribution and toxicological evaluation of [^{225}Ac]Ac-Macropa-T-PEG$_6$-DM1 and [^{225}Ac]Ac-Macropa-P-PEG$_6$-DM1 were carried out in healthy female Balb/C mice. Dual microPET/SPECT/CT imaging and biodistribution using [^{89}Zr]Zr-DFO-T-PEG$_6$-DM1 and [^{67}Cu]Cu-DOTA-P-PEG$_6$-DM1 was performed in female athymic Balb/C nude mice bearing HCC1954 and JIMT-1 xenografts. Therapy was carried out using ADCs (T-PEG$_6$-DM1 + P-PEG$_6$-DM1) and ADRs ([^{225}Ac]Ac-Macropa-T-PEG$_6$-DM1 + [^{225}Ac]Ac-Macropa-P-PEG$_6$-DM1 = [^{225}Ac]Ac-Macropa-(T+P)-PEG$_6$-DM1) in athymic Balb/C nude mice bearing trastuzumab-resistant HCC1954 (high HER2 density) and T-DM1/trastuzumab-resistant JIMT-1 (medium HER2 density) tumors.

Results: Internalization in HCC1954 and JIMT-1 cells was HER2 density-dependent, with the highest total red object area values recorded with the ADC combination (T-ADC + P-ADC) compared with the single agents ($p < 0.0001$). Dual microPET/SPECT/CT imaging and biodistribution of [^{89}Zr]Zr-DFO-T-PEG$_6$-DM1 and [^{67}Cu]Cu-DOTA-P-PEG$_6$-DM1 showed very high tumor uptake in both HCC1954 and JIMT-1 xenografts with high tumor-non-target ratios. The combination of ADCs (T-ADC + P-ADC) and ADRs ([^{225}Ac]Ac-Macropa-(T+P)-PEG$_6$-DM1) administered separately in healthy Balb/C mice, 10 days apart was well tolerated biochemically and haematologically for 20 days (d). Compared with the individual agents, there was improved non-target clearance using the combined ADRs [^{225}Ac]Ac-Macropa-(T+P)-PEG$_6$-DM1. In HCC1954-tumor bearing mice, all treatment groups had complete remission (CR) after 29d and 22d for (T-PEG$_6$-DM1 + P-PEG$_6$-DM1) and ADRs ([^{225}Ac]Ac-Macropa-(T+P)-PEG$_6$-DM1) respectively. Interestingly, in JIMT-1 xenografts at 60d post treatment, no CR was observed for the ADCs group whereas in the ADRs group, the average tumor volume was 11.5 ± 4.4 mm^3 with 3/8 CRs.

Conclusion: [^{225}Ac]Ac-Macropa-(T+P)-PEG$_6$-DM1 is more potent than their respective combined ADCs against HER2-positive BC and warrants further evaluation.

#583 Preclinical development of [^{68}Ga]Ga/[^{225}Ac]Ac-FL-031 theranostic pair for the treatment of SSTR2-positive cancers.

Junyu Yang, Taishan Hu, Lanjiao Zhao, Yihu Xie, Juan Zhang, **Fa Liu**

Full-Life Technologies Limited, Shanghai, China

Somatostatin receptor 2 (SSTR2) is frequently overexpressed in solid tumors including neuroendocrine tumors (NETs) and small cell lung cancer (SCLC), making it a promising target for radionuclide drug conjugates (RDC) based cancer imaging and therapy. Gallium-68 and Lutetium-177 labeled somatostatin analogs [^{68}Ga]Ga/[^{177}Lu]Lu-DOTATATE, a theranostic pair, have been approved by FDA for detecting and treating gastroenteropancreatic (GEP)-NETs. Currently, [^{225}Ac]Ac-DOTATATE is under clinical development for the treatment of SSTR2-positive cancers. To further optimize the theranostic profile of SSTR2-targeting RDC, we have applied our proprietary UniRDC^{TM} platform technologies to discover FL-031, a novel and potentially next generation SSTR2-targeting RDC vector. We then evaluated the feasibility of PET/CT imaging with [^{68}Ga]Ga-FL-031, as well as the *in vivo* biodistribution and efficacy profiles of [^{225}Ac]Ac-FL-031 in SSTR2^{+} xenograft mouse models. The radiochemical purity (RCP) of radiolabeled FL-031 was determined by radio high-performance liquid chromatography (radio-HPLC). FL-031 was successfully labeled with ^{68}Ga and ^{225}Ac, achieving an RCP of over 98% and specific activities of 18.5 MBq/nmol and 185 kBq/nmol, respectively. Subsequently, PET/CT imaging and *in vivo* biodistribution as well as efficacy was conducted in SSTR2-expressing SCLC and NET tumor-xenograft models. After administration of 3.7 MBq [^{68}Ga]Ga -FL-031 in mice implanted with SCLC-21H SCLC xenografts, PET/CT images demonstrated intense tumor uptake which was significantly higher than in normal organs at 1- and 3-hour post-dosing. In the *in vivo* biodistribution study, [^{225}Ac]Ac-FL-031 showed high and durable tumor uptake in mice implanted with AR42J NET xenografts with fast clearance in normal organs. Importantly, in SSTR2^{+} xenograft models, [^{225}Ac]Ac-FL-031 exhibited significant anti-tumor activity at dose levels of 37 kBq or lower without notable changes in body weight and hematology parameters. In summary, [^{68}Ga]Ga-FL-031 PEC/CT proved suitable in detecting SSTR2-positive tumors in preclinical models. [^{225}Ac]Ac-FL-031 demonstrated a promising *in vivo* biodistribution profile and anti-tumor activity in SSTR2-expressing xenograft models. In conclusion, our data suggest that [^{68}Ga]Ga/[^{225}Ac]Ac-FL-031 is a promising theranostic pair for further development as a diagnostic imaging and RDC therapy for SSTR2-positive cancers.

#584 Preclinical efficacy and safety of [^{161}Tb]Tb-labeled anti-nectin-4 radioimmunoconjugate as theranostic against triple-negative breast cancer (TNBC) and non-small cell lung cancer (NSCLC).

Fabrice Ngoh Njotu[1], Hanan Babeker[2], Jessica Pougoue Ketchemen[1], Emmanuel Nwangele[1], Anjong Tikum[2], Nikita Henning[2], He Dong[2], Nava Hassani[2], Alissar Monzer[2], Dede Api Fon[1], Chrysantus Njobinkir Bimela[2], Therese Mercado[2], Franco Vizeacoumar[2], Dennis Elema[3], Michiel Van de Voorde[3], Maarten Ooms[3], Maruti Chandra Uppalapati[2], Humphrey Fonge[1]

[1]Pharmacy, Universite Laval, Quebec, QC, Canada,[2]University of Saskatchewan, Saskatoon, SK, Canada,[3]SCK CEN- Belgian Nuclear Research Center, Mol, Belgium

Purpose: Targeted radioligand therapy (RLT) and radioimmunotherapy (RIT) have emerged as effective and safe treatment modalities for metastatic cancers. Nectin-4 is a Ca^{2+}-independent immunoglobulin-like cell adhesion molecule. Aberrant expression of Nectin-4 is observed in many cancers notably TNBC and NSCLC. No RLT/RIT is approved/in advanced clinical development against TNBC and NSCLC. For the first time, we report the efficacy and safety of ^{161}Tb-labeled anti-Nectin-4 antibody ([^{161}Tb]Tb-DOTA-N4MU01) against Nectin-4 positive TNBC and NSCLC mouse models.

Procedures: Nectin-4-expressing mouse syngeneic cell lines for TNBC (4T1.$_{Nectin-4}$ and E0771.$_{Nectin-4}$) and NSCLC (LLC.$_{Nectin-4}$ and CMT167.$_{Nectin-4}$) were obtained by stable transduction or transfection. Nectin-4 expression and binding affinity of immunoconjugates were assessed by flow cytometry and radioligand binding assays, with internalization studied using live-cell imaging. Pharmacokinetics and safety of the radioligand were evaluated in healthy female Balb/C mice, with tumor uptake assessed by SPECT/CT and biodistribution in tumor-bearing mice. The efficacy of the radioligand was assessed in mouse xenograft models of Nectin-4-expressing human cell line, MDA-MB468, and mouse syngeneic cell lines 4T1.$_{Nectin-4}$ (immune checkpoint blockade therapy (ICBT) resistant), E0771.$_{Nectin-4}$, CMT167.$_{Nectin-4}$, and LLC.$_{Nectin-4}$.

Results: Nectin-4 expression on syngeneic cell lines was high. DOTA conjugation did not affect the internalization of N4MU01 *($p > 0.999$*) while immunoconjugates retained strong binding affinities to human Nectin-4 (≤ 11 nM). ^{161}Tb was stably chelated to DOTA-N4MU01 with yield and purity > 95 %. The clearance half-life of [^{161}Tb]Tb-DOTA-N4MU01 was 120 ± 20 h while a dose of 2x 5 MBq administered intravenously, and 7 d apart was well tolerated over 28 d. Tumor targeting was specific with tumor-to-muscle uptake ratios of 7.7 and 6.7 for CMT167.$_{Nectin-4}$ and 4T1.$_{Nectin-4}$ at 24 h post-injection. In 4T1.$_{Nectin-4}$ model, single dose radioligand at 2.5 MBq and 5 MBq and a repeated dose at 2x 5 MBq showed significant dose-dependent anti-tumor efficacy and survival (*$p \leq 0.0021$*) compared with saline and N4MU01 (25 µg), with 2x 5MBq of radioligand producing complete remission in 20 % of mice. Anti-PD-L1 ICBT had no anti-tumor effect (*$p = 1166$*) on this model. A dose of 2x 5 MBq of radioligand resulted in significant anti-tumor effects and survival compared with saline and N4MU01 (25 µg), in aggressive E0771.$_{Nectin-4}$ (*$p \leq 0.0316$*), CMT167.$_{Nectin-4}$ (*$p \leq 0.0236$*), LLC.$_{Nectin-4}$ (*$p \leq 0.0097$*), and MDA-MB-468 (*$p \leq 0.0.0017$*) xenograft models.

Conclusions: Our findings reveal the clinical potential of [^{161}Tb]Tb-DOTA-N4MU01 as an effective and safe theranostic against Nectin-4-expressing TNBC and NSCLC, even for patients who do not respond to ICBT

#585 Utilizing CAR T cell-derived exosomes for radiotheranostic applications.

Sarah Qureshy[1], Leah Gajecki[2], Darren Veach[2], Sang Gyu Lee[2], Irina Matei[3], Lukas Carter[4], David Lyden[3], David Scheinberg[1], Simone Krebs[5]

[1]Molecular Pharmacology Program, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Radiochemistry and Imaging Sciences Service, Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Departments of Pediatrics, Cell and Developmental Biology, Drukier Institute for Children's Health, Weill Cornell Medicine, New York, NY,[4]Department of Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Molecular Imaging and Therapy Service, Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY

Chimeric antigen receptor (CAR) T cell therapy is limited by antigen escape, poor solid tumor penetration, and an off-tumor toxicity profile. CAR T cell-derived exosomes have been shown to express the parental CAR construct, allowing tumor targeting but limited inherent anti-tumor effects alone. Further engineering CAR T cells to modify their exosome cargo, such as to bind anti-tumor drugs or radionuclides, may allow for the generation of novel targeted delivery vehicles for cancer therapy. We previously engineered humanized C825 (huC825), an anti-metal-DOTA-hapten single chain variable fragment (scfv), into multiple different constructs, one of which is the 4h11 CAR against MUC16/Cancer Antigen 125, developed by Brenjens lab at Memorial Sloan Kettering Cancer Center. We showed that huC825 allows for theranostic potential based on high-affinity binding to various chelated radionuclides, such as for alpha or beta particle-based radiotherapy or diagnostic imaging. We derived exosomes from 4h11 and huC825-4h11 CAR T cells, as well as untransduced T cells, and characterized them for CAR and huC825 expression using Western blot and radio thin layer chromatography (radio-TLC), respectively, as well as with direct stochastic optical reconstruction microscopy (dSTORM). We performed binding and cytotoxicity assays in vitro after radiolabeling and purifying the exosomes with size-exclusion chromatography (SEC), or using a pretargeted approach, with various chelated radiotracers. 4h11 and huC825-4h11 CAR T cell exosomes were reliably manufactured from parental CAR T cells with high transduction rates (80-95%). Western blot using CD81 and ALIX exosomal markers illustrates that 4h11 and huC825-4h11 CAR T cell exosomes and their parental CAR T cells are positive for the 4h11 CAR. dSTORM imaging shows huC825-4h11 exosomes are positive for both 4h11 and huC825. Radio-TLC illustrates that radionuclides chelated by Y-aminobenzyl-1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid, further referred to as aminobenzyl-DOTA (ABD), such as [^{161}Tb]Tb-ABD (therapeutic metal) or [^{177}Lu]Lu-ABD (diagnostic and therapeutic), exhibit significant binding to huC825-4h11 CAR T cell exosomes compared to controls. We optimized a method for radiolabeling huC825-4h11 exosomes and purifying the product with SEC using various DOTA-chelated radionuclides. In vitro radiotracer binding assays using SKOV3 human ovarian cancer cells overexpressing MUC16 illustrate that only huC825-4h11 CAR T cell-derived exosomes selectively bind both MUC16-expressing tumor cells and DOTA-chelated radionuclides. Our work illustrates the potential of huC825-4h11 CAR T cell-derived exosomes as delivery vehicles for radionuclides for imaging or targeted therapy. Their 50-160 nm size may allow better solid tumor penetration in vivo than current cellular treatment modalities. Future directions include in vivo imaging and radiotherapy studies.

#586 Combining advanced peptide screening methods to identify candidates for PDC/RDC/POC development.

Weiliang Xu, Jin Zhang

PepLib, Metuchen, NJ

Peptide-based therapeutics, including peptide-drug conjugates (PDCs), peptide-radionuclide conjugates (RDCs), and peptide oligonucleotides (POCs), are gaining recognition as highly promising targeted treatment options due to their exceptional specificity, low toxicity, and flexible pharmacokinetic profiles. To expedite the identification of effective peptide candidates, we have developed an advanced peptide discovery platform that combines Peptide Information Compression Technology (PICT), Disulfide-Rich Peptides (DRPs) phage display, animal toxin libraries, nano macrocyclic peptides, and virtual peptide libraries. This cutting-edge platform efficiently discovers multicyclic peptide hits with antibody-like binding affinity (sub-nM to pM), enhanced serum stability (lasting from hours to days), and bi-functional properties optimized to engage multiple receptor targets within a six-month timeframe. Our integrated screening approach employs high-throughput techniques to swiftly identify peptide leads that meet the stringent criteria required for PDC, RDC, and POC development. We have successfully discovered peptide leads with high binding affinity and endocytosis on over 40 targets, including tumor biomarkers such as FAP, Nectin-4, Trop2, GRPR, FGFR2, GPC3 and DLL3. The platform's combination of diverse peptide libraries and sophisticated computational modeling enhances the selection of candidates with superior binding affinities, structural stability, and functional adaptability. By leveraging these advanced screening technologies, we address the limitations of traditional peptide discovery methods, shortening development timelines and reducing the reliance on extensive medicinal chemistry optimization. Our findings illustrate that this platform significantly streamlines the discovery process for peptide-based therapeutics, establishing a powerful pipeline for the development of next-generation bi-functional peptides with broad applications in oncology, inflammation, and other therapeutic areas.

#588 Preclinical evaluation of a novel ^{212}Pb-based, PSMA-targeted radioligand, ^{212}Pb-ADVC001, for prostate cancer treatment.

Melissa E. Monterosso, Feifei Liu, Didier Boucher, Stelle Shakti, Kwong Ching Li, Aimee Horsfall, Saawan Kumar, Johannes Koehbach, Kevin Kuan, William Tieu, Stephen Rose, Anna Karmann, Gary Li, Simon Puttick, Thomas Kryza

AdvanCell Isotopes Pty Limited, Sydney, Australia

Introduction: PSMA-targeted radioligand therapy (RLT) with lutetium-177 (^{177}Lu), a beta-emitter, has been clinically proven to be efficacious for the treatment of prostate cancer (PC). Although emerging clinical data indicate that better efficacy can be achieved by alpha-emitters, the toxicities associated with actinium-225 (^{225}Ac) may limit its broad application especially in early lines of treatment. Lead-212 (^{212}Pb), is a promising isotope for alpha therapy with a high linear energy transfer, a half-life of 10.6 hours, and a simple decay scheme. These properties promote efficient targeting of PSMA+ PC cells while limiting off-target toxicities. ^{212}Pb-ADVC001 is a novel ^{212}Pb-based PSMA-targeted RLT currently in Phase Ib/IIa clinical trial (NCT05720130) for patients with metastatic castration-resistant prostate cancer (mCRPC).

Methods: The affinity of ADVC001 and ^{212}Pb-ADVC001 to PSMA was determined by SPR and radioligand-binding assays in PSMA+ PC cell lines. Cytotoxic activity was measured by cell viability and clonogenic assays. *In vivo* biodistribution and anti-tumor efficacy studies were performed in human-derived PC-bearing mice. The intrinsic molecular and cellular mechanisms associated with ^{212}Pb-ADVC001 mediated cell-death were assessed using transcriptomics and proteomics.

Results: ADVC001 binds human, mouse and rat PSMA with comparable nanomolar activities, and efficiently internalizes upon binding to PSMA+ PC cells. *In vitro*, ^{212}Pb-ADVC001 showed specific and potent cytotoxic activity against multiple PSMA+ human PC cell lines, while sparing PSMA- cells. *In vivo* biodistribution of ^{212}Pb-ADVC001 showed tumor uptake at 19.6, 20.9, 9.4 and 5.4 %ID/g at 1, 3, 24 and 48 h, respectively, with retention out to 72 h. High tumor uptake and fast renal clearance resulted in favorable tumor/kidney ratios. Minimal uptake was observed in other normal tissues. Single administration of ^{212}Pb-ADVC001 in PSMA+ PC xenografts led to dose-dependent anti-tumor response and significant survival benefit. Transcriptomic analysis of *in vitro* treated PC cells and proteomic analysis of tumors harvested longitudinally revealed multiple mechanisms of action involving DNA damage, cell cycle arrest and cell death, and immune response modulation.

Conclusion: Preclinical data demonstrated the potential of ^{212}Pb-ADVC001 for the treatment of patients with PSMA+ prostate cancer. Transcriptomic and proteomic analyses indicate multiple mechanisms of action collectively resulting in effective cancer therapy.

#59 CD4-targeted peptides: Discovery, *in vitro* characterization, and preclinical PET tracer evaluation in a humanized CD4 knock-in mouse model.

Anders Wilgaard Sinkjaer[1], Ida Vang Andersen[2], Anne Skovsbo Clausen[1], Line Bruhn Schneider Knudsen[1], Camilla Stavnsbjerg[1], Andreas Kjaer[1]

[1]Department of Clinical Physiology and Nuclear Medicine & Department of Biomedical Sciences, Copenhagen University Hospital - Rigshospitalet & University of Copenhagen, Copenhagen, Denmark,[2]University of Copenhagen, Copenhagen, Denmark

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment, but their efficacy can vary greatly among patients. This variation may be due to the level of immune infiltration in the tumor microenvironment. Immune surveillance, particularly of tumor-infiltrating leukocytes like CD4+ T-cells, can help predict ICI efficacy. This work presents the discovery and preclinical characterization of two CD4-targeted peptide PET tracers.
Methods: Peptide discovery was based on a peptide phage display biopanning, and selected peptides were commercially synthesized (>95% purity). The binding of all peptides to human CD4 (hCD4) was characterized using surface plasmon resonance (SPR) on a Biacore X100. Peptides exhibiting binding to hCD4 were also evaluated for binding to a negative control protein and select peptides to murine CD4 (mCD4). All SPR experiments were analyzed via reference and blank subtraction, and fitted to a 1:1 Langmuir model. The peptides' ability to interact with hCD4 was evaluated using a Sypro Orange thermal shift assay (TSA) on an MxPro3005 qPCR instrument, followed by determination of the midpoint temperature (T_m) via a Boltzmann fit. Peptides 11 (P11) and 17 (P17) underwent DOTA-conjugation (>95% purity) and radiolabeling with copper-64 (^{64}Cu) (>95% radiochemical purity) for *in vivo* PET/CT imaging of C57BL/6J hCD4 knock-in (KI) and control (wild-type) models on a Siemens Inveon PET/CT scanner. The mice were imaged at 1 and 3 hours post-injection (p.i.), and the PET signal of select organs was decay-corrected and quantified as percentage injected dose per gram (%ID/g). The spleen was the organ of interest due to its relatively high population of CD4+ T-cells.
Results: Twenty peptides were synthesized and tested on SPR. P11 and P17 showed selective hCD4 binding on SPR with affinities of K_D=0.96 µM and 2.39 µM, respectively. P11 induced a significant T_m shift (57.3±0.28°C, p<0.0001) and [^{64}Cu]Cu-DOTA-P11 PET/CT imaging showed high spleen uptake at 1 and 3 hours p.i. in both models. P11 binding to mCD4 was estimated to K_D =26.6 nM. [^{64}Cu]Cu-DOTA-P17 PET/CT imaging showed significantly higher spleen uptake (0.71±0.10 %ID/g, p<0.05) at 1 hour p.i. in the hCD4 KI model, but not at later time-points.
Conclusions: P11 bound hCD4 with nanomolar affinity, and a significant T_m increase suggests hCD4-P11 interaction. PET/CT imaging with [^{64}Cu]Cu-DOTA-P11 showed high spleen uptake in both models. This, and P11's nanomolar affinity towards mCD4 indicates cross-reactivity. For future work [^{64}Cu]Cu-DOTA-P11 needs to be evaluated in a different animal model not reliant on differences between hCD4 and mCD4, e.g., in a high and low expressing hCD4 xenograft flank tumor model. P17 bound hCD4 with low micromolar affinity. PET/CT imaging with [^{64}Cu]Cu-DOTA-P17 showed significantly higher uptake in the hCD4 KI spleen at 1 hour.

#590 Prostate specific membrane antigen targeted PRMT5 inhibition re-sensitizes cancer cells to radiation therapies.

Sagnik Sengupta, **Sudarsan Reddy Kasireddy**, Ramesh Mukkamala, Madduri Srinivasarao, Philip S. Low

Chemistry, Purdue University, West Lafayette, IN

Prostate cancer (PCa) is the second most common cause of cancer-related deaths in US men. Although treatment with the targeted radioligand therapy, ^{177}Lu-PSMA-617 (Pluvicto®) has significantly improved outcomes of patients who progress on androgen deprivation therapy, development of resistance to Pluvicto via upregulation of DNA damage repair enzymes has remained a major impediment to achievement of complete responses. To prevent emergence of this resistance, DNA damage repair inhibitors (DDRIs) have been explored with some success, however, their efficacies are limited by significant off-target toxicities. To avoid these toxicities, we have designed prostate specific membrane antigen (PSMA)-targeted DDRIs comprised of the same targeting ligand used in Pluvicto, but linked to a DDRI instead of a radionuclide. In the studies summarized here, we conjugate an inhibitor of protein arginine methyltransferase 5 (PRMT5), i.e. a master regulator of DNA damage repair that is overexpressed in response to ionizing radiation, to the small ligand PSMA-617, and examine its impact on the treatment of PCa tumor bearing mice with ^{177}Lu-Pluvicto.
Briefly, a releasable PSMA-targeted PRMT5 inhibitor (PSMA-PRMT5i) was synthesized and tested for its binding affinity and efficacy in PSMA-expressing LNCaP cells. PSMA-PRMT5i was found to bind PSMA on LNCaP cells in culture with high affinity (K_d = 1.5 nM) and significantly reduce their survival following exposure to 2Gy of beam radiation. Quantitative analysis of the radiation-induced DNA double-strand breaks showed that PSMA-PRMT5i increased the number of DNA double-strand breaks by a factor of two, even at the very low concentration of 1 nM, whereas non-targeted PRMT5 inhibitor had no impact at the same concentration. Finally, analysis of antitumor activity in LNCaP tumor bearing mice demonstrated that the targeted PSMA-PRMT5i reduced tumor growth by 90% when used in combination with ^{177}Lu-Pluvicto, whereas ^{177}Lu-Pluvicto alone suppressed tumor growth by only 50%. Not surprisingly, co-administration of PSMA-PRMT5i similarly increased the efficacy of beam radiation from 50% to 90% tumor suppression at the same concentration (10 nmol/mouse/day). Because no therapeutic benefit could be detected in mice treated with the same concentration of nontargeted PRMT5i, and since no loss in animal body weight was observed in any of the treatment groups, we conclude that low dose PSMA-PRMT5i can significantly improve radiation therapies outcomes with little or no accompanying toxicity.

#591 Exploration of immune effects of [^{177}Lu]Lu-PSMA therapy and rationale for combination with immunotherapy.

Y.-H. Dai, G. Dias, C. Kramer, K. A. Vallis;
University of Oxford, Oxford, United Kingdom

[^{177}Lu]Lu-PSMA therapy has emerged as a promising option for metastatic prostate cancer (PCa). Many ongoing trials are exploring the combination of [^{177}Lu]Lu-PSMA therapy with immunotherapy, highlighting the urgent need to identify potential biomarkers for this therapeutic approach. This study aims to investigate the immune effects of radionuclide therapy using [^{177}Lu]Lu-PSMA-I&T in PCa.We used the RM1-PGLS cell line (a murine PCa cell line with a castration-resistant phenotype, stably transfected with human PSMA) to establish a syngeneic mouse model. RM1-PGLS tumor-bearing male C57BL/6 mice were treated with either 60 MBq of [^{177}Lu]Lu-PSMA-I&T or 5 Gy of external beam radiotherapy (EBRT). Tumors were harvested on day 7 following treatment, and downstream profiling of immune responses was conducted using the NanoString Pancancer Immune panel.In vivo, immune responses were significantly activated on day 7, with 109 differentially expressed genes (DEGs) upregulated after [^{177}Lu]Lu-PSMA-I&T therapy (accounting for 98.2% of all DEGs). Single sample Gene Set Enrichment Analysis revealed that 24 immune-related pathways (curated from MSigDB) were activated compared to the untreated control. Further analysis also showed significantly higher estimated infiltrations of macrophages, neutrophils, and CD56dim NK cells.Among the observed changes, Cxcl10 emerged as the most significantly upregulated gene for both therapies ([^{177}Lu]Lu-PSMA-I&T: log2 fold change [FC] = 2.1, adjusted p = 0.0059; EBRT: log2FC = 2.3, adjusted p = 0.0025). Protein-protein interaction analysis revealed that Cxcl10 ranked among the top three genes with the highest number of interactions with other genes ([^{177}Lu]Lu-PSMA-I&T: 71 edges, top 1; EBRT: 124 edges, top 3), indicating its critical role in the immune response.To investigate whether RM1-PGLS cells can express and release Cxcl10, we treated the cells with 1.2 MBq/ml of [^{177}Lu]Lu-PSMA-I&T (equivalent to 5 Gy EBRT in vitro) and incubated them for 7 days, with the medium replaced every 2 days. Immunofluorescence images demonstrated a significant increase in Cxcl10 gene expression on day 7 ($p < 0.001$), while the Cxcl10 protein release peaked on day 2 ($p < 0.05$) but declined by days 4 and 6, showing no significant difference from baseline. These results suggest that RM1-PGLS cells can express and release Cxcl10 independent of immune cell involvement.Taken together, this study demonstrates that [^{177}Lu]Lu-PSMA-I&T therapy induces a significant immune response characterized by Cxcl10 upregulation and activation of multiple immune pathways. Further studies are warranted to validate the therapeutic potential of these combinations in enhancing anti-tumor immunity and improving clinical outcomes for patients with PCa.

#592 Theranostic ^{68}Ga/^{131}I compounds for PSMA targeted radioligand therapy.

Lars Hvass[1], Marcel Martin[2], Anne Clausen[1], Panagiota Iakovidou[2], Marius Muller[2], Umberto Battisti[2], Vladimir Shalgunov[1], Agustin Lenero[2], Nadia Pedersen[2], Sophie Stotz[1], Matthias Herth[2], Andreas Kjaer[1]

[1]University of Copenhagen and Rigshospitalet, Copenhagen, Denmark,[2]University of Copenhagen, Copenhagen, Denmark

Introduction: Prostate cancer is the most common cancer in men and continues to be a common cause of cancer related death. With progression to castration resistant metastatic prostate cancer, treatment options are scarce. Radioligand therapy has emerged as a successful treatment for these patients, significantly prolonging survival when other treatments fail. Thus far, approved PSMA targeting radiopharmaceuticals mainly use DOTA-based precursors to chelate gallium-68 for diagnosis and lutetium-177 for therapy. Here we suggest a gallium-68/iodine-131 theranostic pair as an alternative radiohalogenated treatment option.

Method: Four compounds based on a common urea PSMA binding motif with additional peptidic linkers were synthesized. These compounds are suitable for both radiohalogenation as well as radiometal labeling via DOTA-chelator(s). For comparative screening, all compounds were labelled with ^{68}Ga in >95% radiochemical purity. Subsequently, BALB/c nude mice carrying LNCaP xenografts were intravenously injected with 8-13 MBq of compound [1]-[4]. Mice were PET/CT scanned one and two hours after injection. After final scan, mice were euthanized and organs harvested for ex vivo biodistribution. Based on tumor and off-target accumulation, a lead compound is selected for iodine-131 labelling by dematallation to assess distribution and dosimetry.

Results: All compounds screened demonstrated favorable tumor uptake and fast clearance. Ex vivo Tumor, blood and kidney accumulation is presented in Table 1, alongside tumor- (T/B) and tumor-to-kidney (T/K) ratios. Notably, compound 3 demonstrated high tumor uptake similar to PSMA-617, as well as low renal retention and faster blood clearance.

Conclusion: Here we tested four different compounds in a mouse model of prostate cancer and identified compound 3 as lead candidate for further translational investigation using iodine-131.

#593 c-MET targeted theranostic Raptamers for early diagnosis of lung cancer.

Sougata Dey, Uksha Saini, Stephanie Vega, Secondra L. Holmes, Nancy Ward, Atul Varadhachary, Dev Chatterjee

Fannin, Houston, TX

Histological screening of tumor biopsies is the gold standard for identifying actionable biomarkers, but is invasive and non-representative, especially for patients with advanced or inaccessible tumors. Imaging with targeted positron emission tomography (PET) may provide a more complete view of the cancer and guide therapy. PET imaging, with a targeting ligand, is preferred for evaluating tumor avidity of new radiolabeled molecular entities. Raptamers (aptamers with amino acid-like functionality) combine attractive attributes of small molecules and monoclonal antibodies (mAbs) in targeted delivery of radionuclides. Like mAbs, Raptamers can provide low nM to pM binding affinities with very low off-rates. Unlike mAbs, they are smaller (with a potentially broader volume of distribution), are manufactured synthetically (less expensive and more consistency), and are more stable. Radionuclide-labeled Raptamers (Radiomers®) can be used for both imaging and therapeutics. We are developing a Radiomer to image, and potentially treat, c-Met over-expressing cancers with minimal off-target effects. c-Met protein is over-expressed in non-small cell lung cancer (NSCLC); with up to 70% in adenocarcinomas (ADCs) and 40% in squamous cell carcinomas (SCCs). Overexpression promotes tumor growth, angiogenesis, invasion and metastasis. The expression level of c-Met correlates with response to c-Met-targeted therapy. The discovery campaign identified multiple high-affinity Raptamers for c-Met, confirmed using biolayer interferometry, and a lead candidate was selected. For surrogate studies, we conjugated Raptamers with a fluorescent tag (Cy5) at the 5’ end. Cy5-Raptamers showed internalization into c-Met+ cells and accumulated, *in vivo*, in c-Met+ tumors in mice. Additional modifications on the 3’ end improved the biodistribution profile. We then optimized click chemistry reaction conditions to conjugate a DOTA chelator at the 5’ end of Raptamers with a high degree of reproducibility and purity. Stability tests confirmed *in vitro* integrity of the DOTA conjugates, followed by successful radiolabeling trials with ^{86}Ga and ^{177}Lu. The tests showed higher loading efficiency of Lu over Ga, but we were able to proceed with further studies using both isotopes. ^{177}Lu-Radiomers demonstrated cell surface binding and rapid clearance in mice. ^{177}Lu-Radiomers also showed promising biodistribution in tumor bearing mouse models. hese studies provide the first proof-of-concept data of Radiomers in targeted molecular imaging of cancer. Molecular imaging can potentially allow detection and monitoring of lung cancers with abnormal alterations of c-Met in real time. Also, Radiomers can focus radioactive decay to the vicinity of or within the tumor cells, leading to therapeutic options. In this way, Radiomers can potentially target any cell-surface neo-antigen and open up new diagnostic and therapeutic paradigms in cancer.

#594 Lintuzumab-Ac225 has potent mutation agnostic antileukemic activity in preclinical models of AML.

Amanda S. Chin[1], Rubin Jiao[2], Kevin J. H. Allen[2], Jason Li[1], Madhuri Vusirikala[1], Avinash Desai[1], Le-Cun Xu[1], Monideepa Roy[1], Mackenzie Malo[2], Denis Beckford-Vera[1], Ekaterina Dadachova[2], Adeela Kamal[1]

[1]Actinium Pharmaceuticals, Inc., New York, NY,[2]University of Saskatchewan, Saskatoon, SK, Canada

Introduction: Acute myeloid leukemia (AML) is a complex and aggressive blood cancer with a poor prognosis, driven by genetic mutations that complicate treatment and often lead to relapse. Lintuzumab-Ac225 is a promising investigational antibody radio-conjugate that targets CD33. The payload, actinium-225 (Ac-225) is an alpha particle-emitting radionuclide that causes lethal DNA damage. In clinical trials, lintuzumab-Ac225 had positive responses when combined with CLAG-M chemotherapy in relapsed/refractory AML patients, including those with high-risk features like venetoclax resistance and TP53 mutations. Here we tested the hypothesis that lintuzumab-Ac225 has anti-leukemic activity in AML cells regardless of mutations (FLT3, TP53, NPM1, and KMT2A). Also, we explored its potential as a single agent or in combination with other therapies to enhance the treatment response for AML.

Methods: Lintuzumab-Ac225 was made by conjugating lintuzumab with *p*-SCN-Bn-DOTA and subsequently radiolabeled with Ac-225. A flow cytometry viability assay was performed in vitro with test drugs to assess the response across genetically altered human AML cell lines (mutant *FLT3*, *KMT2A*: MV-4-11, MOLM-13 cells, mutant *NPM1*: OCI-AML3, and mutant *TP53*: Kasumi-1, HL-60 cells). FLT3 inhibitors (gilteritinib, quizartinib), KMT2A inhibitors (revumenib, ziftomenib) and azacitidine were evaluated as single agents and in combination with Lintuzumab-Ac225. The modulation of DNA damage markers in response to lintuzumab-Ac225 was analyzed by Western blots. The effect of lintuzumab-Ac225 on AML growth in vivo was investigated in subcutaneous MV-4-11 leukemia xenograft models.

Results: Treatment with lintuzumab-Ac225 showed a potent, dose-dependent decrease in leukemia cell viability in vitro, across all tested AML models, regardless of mutation status (FLT3, KMT2A, NPM1, TP53). IC50 values ranged from 0.5 to 5 nCi/mL, showing that lintuzumab-Ac225 induces cell death independent of these mutations. The treatment also triggered DNA damage and apoptosis in mutant cells, with increased phosphorylation of H2A.X and p21. While FLT3 inhibitors, KMT2A inhibitors, and azacitidine showed variable single-agent efficacy in mutation-carrying AML cells, combining these with lintuzumab-Ac225 in vitro enhanced their effects ($p<0.01$). In the MV-4-11 in vivo AML model, lintuzumab-Ac225 combined with FLT3 or KMT2A inhibitors significantly reduced tumor growth compared to monotherapy ($p<0.002$).

Conclusions: Lintuzumab-Ac225 shows broad anti-leukemic activity in AML cell lines, in a mutation (FLT3, KMT2A, NPM1, TP53) agnostic manner. It improves AML control in high-risk cases and enhances response durability when combined with standard of care treatments. These findings support its potential as a backbone therapy for relapsed/refractory AML, warranting further clinical evaluation.

#595 CMOS sensor-based micro-dosimetry for radiation theranostics: A novel approach.

Rao V. Papineni[1], Prem Saganti[2], Huichen Wang[2], Rahman M[2]

[1]University of Kansas Medical Center, Branford, CT,[2]Prarie View A & M University, Prarie View, TX

CMOS Sensor based micro-dosimetry allowing measuring radiation tracks at micron level by the track structure detector (TSD) have been established by us with 1.67 micron / pixel resolution. In radiation theranostics, individual organ dosimetry is critical for predicting absorbed doses to normal organs and target tissue in terms of therapeutic efficacy and toxicity reduction with radiopharmaceutical therapy. We designed and applied our well characterized micro dosimetry system utilizing a CMOS (complementary metal oxide)-based radiation Track Structure Detector (TSD) device to analyze radiation quality and quantity from different forms of radiation and radiopharmaceutical drugs. The TSD system allowed capturing and analyzing heavy ion tracks at cellular dimensions with a 1.67 microns per pixel resolution and more than 10 M pixels on a 0.6 cm x 0.4 cm sensor. Further towards individualized radiopharmaceutical treated patients, we propose Integrated Wearable Micro Dosimetry for Remote Monitoring-VASTRA. Here, we demonstrate the capability to objectively detect, measure, and spatially resolve the imaging radiation activity of radiopharmaceutical therapeutic radionuclides including 18F-FDG, TC99m and validates the VASTRA in a smart phantom. Consequently, the approach is capable to measure patient-specific temporal activity data in radiopharmaceutical therapy. As an integrated ergonomical wearable dosimetry, VASTRA in Post cancer treatment, has unique opportunities and a profound impact on the quality assurance in the cancer treatment.

#599 Oligomeric proanthocyanidins overcome Lenvatinib resistance by targeting ITGA3 and EGFR-AKT pathways in hepatocellular carcinoma.

Takayuki Noma[1], Yuan Li[1], Yuma Wada[2], Katsuki Miyazaki[2], Yuji Morine[2], Mitsuo Shimada[2], Ajay Goel[1]

[1]Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of The City of Hope, Monrovia, CA,[2]Department of Surgery, Tokushima University, Tokushima, Japan

Background: Hepatocellular carcinoma (HCC) is the third most common cancer worldwide and is often diagnosed at an advanced stage, with chemotherapy often being the treatment of choice. Lenvatinib, a multi-targeted tyrosine kinase inhibitor, is widely used as a first-line therapy for advanced HCC following the REFLECT trial, demonstrating its non-inferiority to Sorafenib in overall survival. Additionally, combination therapies with immune checkpoint inhibitors or transarterial chemoembolization have shown promising results, with clinical studies indicating improved overall survival compared to monotherapies. However, frequent resistance to Lenvatinib significantly limits its clinical efficacy, necessitating novel strategies to address this challenge. Various pathways have been reported for the mechanisms of Lenvatinib resistance, including activation of EGFR, changes in the immune microenvironment, and activation of tumor stem cells. Oligomeric proanthocyanidins (OPCs), natural polyphenols with broad-spectrum anticancer properties, may enhance Lenvatinib's efficacy by targeting these resistance pathways. This study aims to elucidate the mechanisms of Lenvatinib resistance and evaluate the potential of OPCs to overcome resistance in HCC.
Methods: Lenvatinib-resistant Huh-7 and PLC-PRF-5 cell lines were generated through long-term exposure to increasing concentrations of Lenvatinib. We performed a series of cell culture experiments to evaluate the synergistic anticancer effect of the combination of Lenvatinib and OPCs in Lenvatinib-resistant cell lines. By performing genome-wide transcriptomic profiling, we identified specific growth-signaling pathways targeted by the combined treatment and validated these findings in cell lines.
Results: The combination therapy of Lenvatinib and OPCs yielded promising results, significantly suppressing cell proliferation, invasion, and spheroid formation in Lenvatinib-resistant HCC cells. Transcriptomic analysis revealed that ITGA3 is a critical factor in Lenvatinib resistance, and its upregulation is associated with poor prognosis in HCC patients. Furthermore, high ITGA3 expression in resistant cells was found to promote activation of the EGFR-AKT pathway and enhance resistance to anoikis, contributing to Lenvatinib resistance. Molecular analyses demonstrated that this combination therapy effectively suppresses the ITGA3, EGFR-AKT pathway, thereby overcoming Lenvatinib resistance and supporting the promising results of this treatment.
Conclusion: This study identifies OPCs as a promising therapeutic agent for overcoming Lenvatinib resistance by targeting ITGA3 and the EGFR-AKT pathways. The results emphasize the potential benefits of combining OPCs with Lenvatinib to enhance therapeutic efficacy and improve outcomes in Lenvatinib-resistant HCC.

#6 Targeting eukaryotic elongation factor 2 kinase (eEF2K) to combat cancer stem cells and tumorigenesis in triple-negative breast cancer.

Ezgi Biltekin[1], Nermin Kahraman[1], Yasemin M.Akay[2], Gulperi Oktem[3], Metin Akay[2], Bulent Ozpolat[1]

[1]Department of Nanomedicine, Houston Methodist Research Institute, Houston, TX,[2]Department of Biomedical Engineering, University of Houston, Houston, TX,[3]Department of Histology, Ege University Faculty of Medicine, Izmir, Turkey

Breast cancer remains the most commonly diagnosed cancer and the second leading cause of cancer-related deaths among women. Triple-negative breast cancer (TNBC) accounts for 15-20% of all breast cancers, is a highly aggressive and lethal form of breast cancer (BC) and characterized by the lack of ER, PR, and HER2 receptor expression, early relapses, drug resistance, and the poorest survival outcomes among all BC subtypes. Currently, there are no effective targeted therapies for TNBC, highlighting the urgent need for novel treatment strategies. eEF2K is an atypical alpha kinase that has been shown to promote TNBC cell proliferation, migration, invasion, and tumor growth. We previously validated eEF2K for the first time as a potential molecular target in TNBC and demonstrated that genetic inhibition of eEF2K completely suppresses in vivo TNBC tumor growth in mice. Overall data suggests that eEF2K is a critical oncogenic driver of TNBC tumorigenesis. Cancer stem cells (CSCs), a small but specific group of cancer cells, play a significant role in relapses and resistance to therapeutics including chemo-drugs. CSCs initiate tumor formation, promote tumor growth and cause relapses with their self-renewal and self-proliferation properties. While TNBC is known for the high number of CSCs population, the role of eEF2K in CSCs is unknown. In this study, we report the critical role of eEF2K in TNBC CSCs survival and tumorigenesis and found that the inhibition of eEF2K by siRNA and a small molecule inhibitor that we developed dramatically suppressed CSCs growth, migration, invasion and spheroid formation as well as TNBC cell proliferation and tumor growth in mice multiple TNBC models. Conversely, eEF2K overexpression promoted sphere formation. Our Kaplan-Meier analysis of the Cancer Genome Atlas (TCGA) revealed that high expression of eEF2K and ALDH1a3, a stemness marker, is associated with shorter overall and relapse-free survival. We also found that eEF2K is highly overexpressed in the ALDH-positive TNBC stem cell population. Genetic knockdown and pharmacological inhibition of eEF2K significantly suppressed the expression of key stemness signaling molecules, including ALDH1a3, Notch1, and Notch2. Currently, we are targeting eEF2K in MDA-MB-231 and MDA-MB-436 TNBC orthotopic xenograft and 4T1 mouse mammary tumor models in syngeneic mice to further assess its impact on CSCs-driven tumorigenesis. Our findings suggest that eEF2K plays a pivotal role in promoting TNBC stemness through the modulation of key stemness pathways, including ALDH1a3, Notch1, and Notch2 and tumor growth. Targeting eEF2K may therefore be a promising therapeutic strategy to eradicate TNBC by targeting primary and CSCs populations.

#60 Nanoparticle delivery of cancer-activated DNA constructs for the diagnosis of liver tumors.

Nadege Morisot, Blaine McCarthy, Sushil Lathwal, Dariusz Wodziak, Suthara Ramachandran, Anderson Lee, Dang Dang, Blair Cain, Xiaobin Wu, Robby Chandra, Badriprasad Ananthanarayanan, David Suhy, Christine Peterson

Earli Inc., Redwood City, CA

Early detection of liver cancer has the potential to substantially improve survival rates. Yet, diagnosis of hepatocellular carcinoma (HCC) is hampered by poor sensitivity of traditional imaging techniques - such as ultrasound, CT, and MRI - which often miss small or atypical tumors, particularly in cirrhotic livers with altered anatomy. As a result, more than a third of early-stage HCCs are missed. Earli is addressing these limitations by developing a platform technology that utilizes LNP-delivered recombinant DNA constructs containing cancer-activated synthetic promoters driving the selective expression of proteins such as well defined epitopes for the imaging of tumors or cytokines that have therapeutic potential to treat the tumor. Although non-viral systems like lipid nanoparticles (LNPs) have proven effective for RNA delivery, DNA delivery to tumor cells remains challenging. Earli-derived LNP formulation FRM237 was used to encapsulate a recombinant DNA comprised of a non-specific CAG promoter to drive the expression of a firefly luciferase reporter and was evaluated by ex vivo bioluminescence imaging (BLI) in a subcutaneous Hep3B (liver adenocarcinoma) xenograft model. The FRM237 formulation produced high levels of expression and achieved BLI levels that were 5-fold higher than the same DNA formulated in a multi-component LNP used in a commercial siRNA product. More importantly, engineered LNP enabled 88-fold greater tumor-to-liver BLI ratio, revealing liver tumor tropism. Pharmacokinetic studies show a large increase in circulation LNP-delivered DNA vector copies were consistently 10-fold higher in serum as compared to the competitor formulation. Effective extrahepatic delivery and expression to HCC was further verified in an orthotopic liver xenograft model using a recombinant DNA driven by a synthetic promoter known to be highly active in liver cancer cells. Administered via IV injection to mice with Hep3B tumors, this product produced 96-fold higher expression from those malignant tissues as compared to naïve liver tissues. Likewise, immunohistochemistry (IHC) analyses revealed selective expression of the protein throughout the orthotopic Hep3B tumors with little or no corresponding staining in normal hepatocytes. Finally, intravenously dosed lead formulations were tolerated as evident by modest but transient body weight loss and clinical observations. Overall, our data collectively points to successful delivery of DNA to hepatic tumors via engineered LNP formulations following iv administration. When combined with cancer-activated expression of PET reporter genes and further validation in preclinical mouse models and toxicology studies, this represents a promising diagnostic imaging platform for early detection of liver cancer.

#600 Targeting STAT pathways with oridonin derivatives to suppress triple negative breast cancer.

Gabrielle Vontz[1], Jun Li[2], Zhipin Liang[1], Jia Zhou[2], Qiang Shen[1]

[1]Department of Interdisciplinary Oncology, LSU Health New Orleans, New Orleans, LA,[2]Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, LA

Breast cancer remains the most common cancer type and second leading cause of cancer related deaths among women in the U.S. Despite progress in detection, surveillance, and targeted therapies, aggressive subtypes like triple-negative breast cancer (TNBC), along with challenges such as drug resistance and disease recurrence, remain significant clinical hurdles. To address these unmet needs in TNBC treatment, our group has developed a series of oridonin-derived analogs (oridonalogs), including CYD0618. These analogs exhibit enhanced drug-like properties and significantly improved potency against various cancers in both *in vitro* and *in vivo* models. This study aims to characterize the mechanism of action of CYD0618 against TNBC cells. Our findings demonstrate that CYD0618 effectively reduces the proliferation of TNBC cells *in vitro* with IC_{50}s at the nanomolar level. Additionally, CYD0618 exhibits high potency against TNBC *in vivo*, significantly suppressing tumor growth and prolonging survival in a xenograft mouse model. Preliminary results reveal that CYD0618 inhibits activation of STAT3, a key transcription factor involved in proliferation, survival, and transformation of epithelial cells. Given that STAT3 is constitutively active in ~70% of human cancers, there has been a tremendous effort to develop STAT3 targeting therapies; however, none have achieved FDA approval. In addition to STAT3, our study shows that CYD0618 also suppresses other STAT family transcription factors. Compared to selective STAT3 degradation by PROTAC treatment, poly-STAT targeting by CYD0618 exhibits superior activity against TNBC cells. These findings identify CYD0618 as a novel poly-STAT inhibitor with promising activity against TNBC.

#601 Momordicine-I treatment reduces the triple negative breast cancer growth and alters the M2 phenotype of macrophages in tumor microenvironment.

R. A. Patel, E. T. Tran, K. Kesh, R. B. Ray;
Saint Louis University, St. Louis, MO

Triple negative breast cancer (TNBC) is an aggressive form of breast cancer with a worse prognosis. The goal of this study is to examine whether Momordicine-I (M-I), a key bioactive compound from *Momordica charantia*, displays an anti-cancer activity and the potential mechanism. We treated human and mouse TNBC cell lines, MDA-MB-231 and 4T1, with M-I in a dose-dependent manner for 48 hr. We observed a significant inhibition of cell growth. To understand the potential mechanism, we treated these cells with vehicle or M-I and cell lysates were prepared after 48 hr. We found that M-I inhibited pSTAT3, cyclinD1 and c-Myc expression in M-I treated cells. We next evaluated the anti-tumor efficacy of M-I in orthotopic breast cancer mouse model. MDA-MB-231 cells were implanted into the mammary fat pad of nude mice. Tumor bearing (~80 mm^3 in volume) mice were divided into two groups. One group received M-I (30 mg/kg/day) and the other group received vehicle as a control. Tumor volumes were significantly reduced in the M-I treated group compared to the control group. Our previous study showed that M-I treatment alters macrophage phenotype in a different cancer model. We next examined the status of tumor associated macrophages (TAMs) in TNBC tumors. TAMs are mainly considered M2-like macrophages, which plays a crucial role in mediating the interaction between tumor cells and the immune cells. To examine the specific TAM polarization *in vivo*, RNA from control and treated tumors was analyzed for macrophage polarization using specific primers. Since nude mice contain macrophages, we examined the status of *Arg1* and *IRF-4* (M2 *marker)* from the tumor treated with vehicle or M-I. We found a significant reduction in treated tumors. We also performed an *in vitro* experiment where conditioned media of 4T1 cells with or without M-I treatment were incubated with immortalized bone marrow derived mouse macrophages (iMac) cells and examined the expression of several macrophage markers. We observed that M-I treatment significantly reduced M2 phenotype of iMac cells. Co-culture experiment with or without M-I treated MDA-MB-231 cells with PMA treated THP-1 displayed downregulation of Arg1 and IL-10 expression. Our data demonstrates that M-I has potential as a candidate for TNBC therapy and inhibits the M2 polarization of macrophages. Further work is underway using 4T1 mouse model to understand M-I mediated tumor growth inhibition.

#602 Synergistic anti-tumor effects of andrographis and lactoferrin in colorectal cancer via modulation of AXIN2/Wnt/E-cadherin signaling pathway.

Yuan Li, Caiming Xu, Takayuki Noma, Ajay Goel

City of Hope Comprehensive Cancer Ctr., Duarte, CA

Background: Colorectal cancer (CRC) is one of the most common malignancies worldwide and 20-25% of patients experience metastatic colorectal cancer (mCRC) at initial diagnosis. However, the high mortality rates associated with mCRC are largely due to the inadequate efficacy of current treatments and the development of acquired resistance to conventional chemotherapy. Recent studies have indicated that Lactoferrin is frequently used as a drug transport carrier, enhancing drug absorption. Natural compounds like Andrographis offer cost-effective, multi-targeted treatments for tumors. Therefore, we hypothesize that Lactoferrin might serve as a transport carrier for Andrographis, improving its bioabsorption and in offering a more pronounced anticancer activity in CRC.
Methods: We conducted a series of in-vitro and in-vivo experiments to evaluate the synergistic anticancer effects of Lactoferrin and Andrographis in CRC. Furthermore, we performed a genomewide transcriptomic analysis to identified specific growth-signaling pathways targeted by the combined treatment and subsequently validated these findings in cell lines and patient-derived 3D organoids.
Results: The combined treatment with Lactoferrin and Andrographis exhibited excellent synergistic anti-tumor potential, affecting cell viability, proliferation, migration, and invasion in CRC cells. In CRC, metastasis commonly occurs through the epithelial-mesenchymal transition. This combination treatment exerted the most pronounced effects on β-catenin responsive transcription and E-cadherin promoter activity. Mechanistically, transcriptomic analysis revealed that the combined treatment resulted in the inhibition of AXIN2 which resulted in E-cadherin-mediated inhibition of Wnt signaling ([FC]: 3.46, $P < 0.005$). Additionally, we observed that the expression levels of AXIN2 were significantly higher in cancer vs. normal tissues ($P < 0.005$) in the TCGA dataset. Finally, in 3D organoid models, the combined treatment exhibited superior anti-cancer activity, significantly reducing both the number and size of organoids ($P < 0.05$). These findings highlight the therapeutic potential of targeting the AXIN2/Wnt/E-cadherin axis with Lactoferrin and Andrographis in CRC.
Conclusion: We present evidence that the synergistic anticancer effects of Lactoferrin and Andrographis in CRC are mediated through the AXIN2/Wnt/E-cadherin axis, highlighting their potential as a therapeutic strategy.

#603 Repurposing the plant-derived compound apigenin in anticancer and antiaging pipelines.

Y. Sun[1], H. Zhang[2], Q. Xu[1], R. Sun[3], J. L. Kirkland[4];

[1]Chinese Academy of Sciences, Shanghai, China, [2]Shanghai University of Traditional Chinese Medicine, Shanghai, China, [3]Bioduro-Sundia, Shanghai, China, [4]Cedars-Sinai Medical Center, Los Angeles, CA

Cellular senescence is a cell fate triggered by inherent or environmental stress and characterized by stable cell cycle arrest accompanied by a hypersecretory feature, termed as the senescence-associated secretory phenotype (SASP). Senescent cell burden increases with natural aging, functionally contributing to age-related organ dysfunction and multiple disorders including various malignancies. In this study, we performed a large scale screening of a natural product library for senotherapeutic candidates by assessing their effects on human senescent cells. Apigenin, a dietary flavonoid previously reported with antioxidant and anti-inflammatory activities, exhibited a prominent capacity in targeting senescent cells as a senomorphic agent. In senescent cells, apigenin blocks the interactions between ATM/p38 and HSPA8, thus preventing transition of the acute stress-associated phenotype (ASAP) towards the SASP. Mechanistically, apigenin targets peroxiredoxin 6 (PRDX6), an intracellular redox-active molecule, suppressing the iPLA2 activity of PRDX6 and disrupting downstream reactions underlying the SASP development. Without reversing cellular senescence, apigenin deprives cancer cells of malignancy acquired from senescent stromal cells in culture, while reducing chemoresistance upon combination with chemotherapy in anticancer regimens. In preclinical trials, apigenin administration improves physical function of animals prematurely aged after whole body irradiation, alleviating physical frailty and cognitive impairment. Overall, our study demonstrates the potential of exploiting a naturally derived compound with senomorphic capacity to achieve anticancer and geroprotective effects by modulating the SASP, thus providing a research platform for future exploration of novel natural agents against age-related pathologies, including but not limited to cancers.

#604 Punicic acid from pomegranate seed oil induces cytotoxicity and oxidative stress in MCF-7 breast cancer cells.

Braden Quitmeyer, Shelley A. Phelan

Fairfield University, Fairfield, CT

Punicic Acid is an omega-5 long chain saturated fatty acid found in abundance in the oil of pomegranate seeds. While already known to provide various health benefits from a dietary perspective, punicic acid (PA) has also been shown to be an anti-proliferation agent in various cancer cell lines such as colorectal cancer and breast cancer. In this study, we examined the effects of PA on the MCF-7 breast cancer cell line as compared to the non-cancerous MCF-10A breast epithelial cell line. We found that PA induces dose-dependent cytotoxicity on both lines, with higher cytotoxicity in MCF-10A cells at all concentrations. MCF-7 cells exhibited relatively strong resistance to PA at the 0.4 µg/ml concentration, but increased cytotoxicity at 2 and 10 µg/ml. By contrast, there was notable cell death at all three concentrations within the non-cancerous cell line. Examination of apoptosis confirmed its role in both cell line responses to punicic acid, with significantly higher levels of apoptosis in MCF-10A cells. In order to examine the antioxidant response to punicic acid, we used qPCR to measure the expression of the Peroxiredoxin gene family (Prdx1, Prdx2, Prdx3, Prdx4, Prdx5, and Prdx6) after 48 hours of punicic acid treatment in both lines. We observed significant induction of all six Prdx genes in MCF-7 cells, with over a 4-fold increase in Prdx1, Prdx2 and Prdx6 at the 10ug/ml concentration. Interestingly, MCF-10A cells exhibited considerably higher induction of all six Prdx mRNAs at 10 µg/ml, exceeding a 30-fold induction of Prdx1, Prdx2 and Prdx5. Current work in our lab is focused on determining the role of oxidative stress in the PA-induced cytotoxicity in MCF-7 cells. Our data suggests a dose-dependent increase in mitochondrial superoxide production after 48hrs of punicic acid treatment. Analysis of other ROS markers is ongoing. Together, our data provide important new insights into the mechanisms and cell-specific effects of punicic acid, and its potential preventative and treatment efficacy in breast cancer.

#606 Celastrol treatment induces apoptosis and modulates metabolic pathways in FLT3 - Positive acute myeloid leukemia cells.

Biba Vikas[1], Vasantharaja Raguraman[1], Shanid Mohiyuddin[1], Sofia Vega[1], Zhentian Lei[2], Gerhard Hildebrandt[1], Senthilnathan Palaniyandi[1]

[1]Ellis Fischel Cancer Center, University of Missouri - Columbia, Columbia, MO,[2]Metabolomics Center, University of Missouri - Columbia, Columbia, MO

Acute Myeloid Leukemia (AML) is a hematologic malignancy with poor prognosis. Historically, its treatment is associated with severe toxicity and mortality. Moreover, the success of chemotherapy is often hampered by drug resistance and relapse, affecting treatment response and long-term survival of patients. To find alternative drugs and targeted immunotherapies for AML remains an unmet need. Celastrol is a natural compound isolated from the medicinal plant *Tripterygium wilfordii Hook F*. It is a pentacyclic triterpenoid, that has shown therapeutical potential due to its anti-inflammatory and anti-cancer properties, yet the mechanism is poorly understood. In the present study, we demonstrate the cytotoxic effects of celastrol in FLT3 ITD mutated AML. Molecular docking studies confirmed celastrol's effective binding to the FLT3 protein, suggesting a potential targeted therapy. Cell viability and apoptosis were determined after celastrol treatment in MV-4-11 cells at varying concentrations, and cell viability was hampered in a dose-dependent manner with an IC_{50} value of 0.3μM. Next, Annexin V and PI staining were used to examine whether this inhibitory effect of celastrol on cell viability was related to the induction of apoptosis. Celastrol-induced cell apoptosis was demonstrated ranging from 75 to 78 % along with increased apoptotic markers like caspase 3, caspase 8, and caspase 9 expression, confirming its ability to trigger the apoptotic cascade through intrinsic and extrinsic pathways. Seahorse assay revealed that celastrol treatment significantly suppressed the maximal oxygen consumption rate (OCR) with minimal effect on basal respiration. Interestingly, combination treatment with celastrol and Giltertinib strongly suppressed maximal OCR. In addition, celastrol treatment affected the extracellular acidification rate (ECAR) in MV-4-11 cells showing a compensatory decrease in glycolysis. Furthermore, untargeted metabolomics showed 18 significantly changed metabolites with better variance between the vehicle and celastrol treatment as evidenced by principal component analysis (PCA). Pathway analysis revealed alterations in glutathione, lipid, and energy metabolism after celastrol treatment. This study demonstrated that celastrol treatment targets both glutathione and glycolysis metabolism which are crucial for cell survival and will potentially be a powerful strategy to induce a more selective, metabolically driven toxicity on FLT3-positive AML cells. The ongoing transcriptomics analysis and the in vivo experiments will delineate celastrol's potential role in treating AML.

#607 Andrographis and aronia berry extract synergistically exhibit anticancer effects in colorectal cancer by activating the p-YAP/PUMA signaling pathway.

Kainan Wang, Yuan Li, Caiming Xu, Ajay Goel

City of Hope Comprehensive Cancer Ctr., Monrovia, CA

Background: Colorectal cancer (CRC) is the third leading cause of cancer-related mortality worldwide, posing a persistent global health challenge. Despite advancements in current therapeutic strategies, the emergence of resistance highlights the urgent need for novel treatment approaches to overcome their limited efficacy. Among these, natural products have emerged as a promising resource due to their high efficacy, low toxicity, and potential for integration into dietary regimens. The antioxidant and anti-inflammatory properties of Andrographis (Andro) and Aronia berry extract (ABE) counteract cancer by neutralizing free radicals, reducing inflammation, and enhancing immune function. Herein, we hypothesize that their combined treatment may synergistically regulate multiple oncogenic pathways, leading to enhanced anti-cancer effects in CRC. Methods: The synergistic anticancer effects and mechanisms of Andro and ABE in CRC were evaluated through a combination of functional assays and genome-wide transcriptomic profiling. Clonogenic, cell viability, flow cytometry, and transwell migration assays were employed to assess their impact on cell proliferation, apoptosis, and metastatic potential. Transcriptomic analysis was performed to identify the key signaling pathways modulated by the combination treatment. Finally, these findings were validated using CRC patient-derived 3D organoids (PDOs). Results: The combined treatment with Andro and ABE exhibited synergistic anti-tumor effects in CRC cells by suppressing cell viability, proliferation, migration, and invasion. Transcriptomic profiling revealed a significant upregulation of PUMA expression (Andro vs. Control, log2Foldchange [FC]: 1.29, $P = 0.01$; ABE vs. Control, log2FC: 1.08, $P = 0.001$), which was associated with modulation of the Hippo-YAP pathway (Fold enrichment: 5.06, $P = 0.0009$). Mechanistically, Andro, and ABE synergistically promote YAP phosphorylation (p-YAP), which in turn enhances PUMA expression, thereby driving apoptosis in CRC cells, as confirmed by western blot, qRT-PCR, and flow cytometry analyses. These findings were validated in PDOs, which showed reduced size and number, and increased p-YAP activation and PUMA expression, underscoring the therapeutic potential of the combination treatment. Conclusion: In summary, our research provides strong evidence that the combination of Andro and ABE could be a potent and safe integrative approach for CRC treatment. The synergistic activation of the p-YAP/PUMA signaling pathway by these natural products induces apoptosis in CRC cells, offering a promising new direction for cancer treatment.

#609 Triptolide inhibits ovarian cancer growth by enhancing EZH2 degradation.

Yongxia Zhu[1], Qing Tang[2], Hongtao Xiao[1], Ningyu Wang[2]

[1]Department of Pharmacy, Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Chengdu, China,[2]School of Life Science and Engineering, Southwest Jiaotong University, Chengdu, China

Ovarian cancer is a lethal gynecological tumor, typically diagnosed at an advanced stage and associated with limited treatment options. The Enhancer of Zeste Homolog 2 (EZH2) is a crucial methyltransferase that serves as a catalytic subunit of the Polycomb Repressive Complex 2 (PRC2), alongside other core subunits (EED, SUZ12, and RbAp46/48). EZH2 contributes to ovarian cancer progression through both its catalytic and non-catalytic functions, making it a promising therapeutic target. Data from the TCGA database and the Human Protein Atlas indicate that EZH2 mRNA and protein levels are elevated in ovarian cancer tissues compared to normal ovary tissues, correlating with poor prognosis in patients. This provides a rationale for targeting EZH2 in ovarian cancer treatment. However, traditional EZH2 enzyme inhibitors only block its catalytic function and are ineffective against ovarian cancer driven by its non-catalytic functions. EZH2 degraders can effectively inhibit both functions. To identify phytochemicals that promote EZH2 degradation, we screened and identified 20 candidates that can directly or indirectly modulate EZH2 expression. Western blot analysis revealed that Triptolide (TPL, 1 μM) significantly degrades EZH2 protein. TPL is a diterpene compound extracted from the roots, leaves, flowers, and fruits of *Tripterygium wilfordii*, known for its anti-inflammatory and anti-tumor properties. However, its role in regulating EZH2 in ovarian cancer has not been previously reported. Our western blot results showed that TPL significantly degrades EZH2 and other core PRC2 subunits (EED and SUZ12) in a concentration-dependent manner, with a half-degradation concentration (DC_{50}) as low as 25 nM in the ovarian cancer cell line A2780. The degradation effect of TPL on EZH2 and PRC2 increased with longer exposure times. Further experiments indicated that TPL induces degradation of EZH2 or the PRC2 complex via the ubiquitin-proteasome pathway. A biotin-labeled TPL probe, Biotin-TPL, used in a pull-down assay, confirmed the interaction between TPL and EZH2. Additionally, TPL effectively inhibits the proliferation of ovarian cancer cells in a time- and concentration-dependent manner, with IC_{50} values in low nanomolar range. Colony formation and 3D cell spheroid formation assays demonstrated that TPL (3.7-33.3 nM) significantly reduces colony formation in A2780 and ES-2 ovarian cancer cells, as well as the formation of ovarian cancer 3D cell spheroids. RNA-seq data and subsequent validation experiments showed that TPL can inhibit signaling pathways regulated by EZH2's non-catalytic functions. Collectively, these findings suggest that TPL may inhibit ovarian cancer growth by degrading the EZH2/PRC2 complex and modulating the signaling pathways associated with EZH2's non-catalytic functions.

TUMOR BIOLOGY: Imaging in Animal Models
Poster Session

#61 Establishment of translational luciferase-based cancer models to evaluate antitumoral therapies.

Martin R. Ramos-Gonzalez[1], Nagabhishek S. Natesh[1], Satyanarayana Rachagani[2], James Amos-Landgraft[3], Haval Shirwan[4], Esma S. Yolcu[4], Jorge G. Gomez-Gutierrez[4]

[1]NextGen, University of Missouri - Columbia, Columbia, MO,[2]Veterinary Medicine and Surgery, University of Missouri - Columbia, Columbia, MO,[3]Veterinary Pathobiology, University of Missouri - Columbia, Columbia, MO,[4]Pediatrics, University of Missouri - Columbia, Columbia, MO

There is an increased need for translational cancer models in research that can serve as more clinically relevant platforms to better study how cancer develops, the formation of metastases, and for the evaluation of the efficacy of new antitumoral therapies. Orthotopic cancer models represent a valuable opportunity to better understand how cancer cells behave and produce tumors in their primary organs, as well as how the local microenvironment can affect the tumor development. However, studying a growing tumor inside of an animal's body carries several challenges, like the difficulty to accurately detect the tumor's presence or changes in size since its location is not always easily accessible. To address this situation, we developed luciferase-based cancer cell lines that can produce bioluminescence (BL) and when inoculated orthotopically, they produce solid tumors that can be detected in live animals, allowing for a more accurate model to evaluate antitumoral therapies. We stably transfected the triple negative breast cancer (TNBC) cell line from human origin HCC1937, and the murine cell line 4T1, as well as the murine lung cancer cell line TC-1 with a luciferase expressing plasmid. After transfection, the luciferase activity was tested *in vitro* and once confirmed these luciferase-expressing cell lines were inoculated orthotopically into synergic animals. We successfully established orthotopic BL tumors that could be detected by bioluminescence imaging (BLI), as well as the detection of distal metastases by this method. The signal from the tumors in vivo correlated with the signal detected from the ex vivo organs, confirming the high accuracy and sensitivity of the use of BL as a detection method for cancer models. Interestingly, we confirmed a change in phenotype after the plasmid internalization in the cell line HCC1937/luc2. This cell line modified its response to an oncolytic adenovirus virotherapy, downregulating its antiviral response and becoming more sensitive to be infected and killed by these viruses. This highlights the importance of confirming the desired phenotype of a cell line remains unaltered after a genetic modification, as in our case, a plasmid insertion. In our study, we offer clinically relevant bioluminescent orthotopic cancer models that can be used to accurately evaluate the efficacy of antitumoral therapies by the quantification of BL signal coming from live animals. This method facilitates the monitoring of the tumoral growth and the appearance of metastases, with the advantage of allowing for multiple readings over time on live animals to assess the efficacy of antitumoral therapies.

#610 Manzamine and mitragynine: investigation of beta carboline compounds from marine sponges and kratom leaves as ovarian cancer therapeutics.

Ashley Gabriel, Haifa Sahouri, Helen Fischer, Kimberly A. Gonzalez, Jihad Aburas, **Cai M. Roberts**

Midwestern Univ. - Downers Grove Campus, Downers Grove, IL

Epithelial ovarian cancer (EOC) is the leading cause of death among gynecologic cancers. Five-year survival rates hover around 35%, largely due to widely metastatic and drug-resistant recurrent disease. Prior studies in our laboratory and others have shown that tumor progression, as evidenced by epithelial to mesenchymal transition (EMT) and metastasis, can have a significant impact on the response of cancer cells to treatment. Tumor heterogeneity is a substantial barrier to effective therapy. For instance, stem-like cells can withstand treatment that eliminates faster-growing cells and have the potential to give rise to recurrence. Thus, novel therapies or drug combinations that can eliminate all subpopulations within a tumor are needed. Natural products have a long history in cancer treatment. Prior studies in the natural products space on anti-EMT drugs focused on the beta carboline molecule harmine and its derivatives. While these compounds have shown efficacy, translation of these compounds to the clinic is complicated by their hallucinogenic properties. Therefore, we sought alternatives with similar beta carboline moieties. In the present study, we investigated alkaloids from marine sponges *(Halicloa spp.)* and the kratom plant *(Mitragyna speciosa)* as potential therapeutics for EOC. We tested the kratom compound mitragynine, the marine compound manzamine A, and several of their derivatives and analogues, in multiple EOC cell lines. We found that mitragynine killed EOC cells with an IC50 of ~20 μM. The marine alkaloid manzamine A killed EOC cells with IC50 values in the low micromolar range. Each of these outperformed their respective analogues in cell survival assays. Importantly, both pre- and post-EMT cells, and models of primary and recurrent disease, all responded to manzamine treatment. Our findings also suggest an additive effect when manzamine therapy is combined with conventional chemotherapy. Additional work will be needed to fully elucidate the full mechanism of action of these compounds and whether inclusion of these alkaloids in treatment regimens will be effective in combating drug resistance. However, our results suggest that there is a place for these compounds in our arsenal for the deadliest gynecologic cancers.

#611 Actinobacteria from macroalgae as a source of new anti-lymphoma compounds.

Filippo Spriano[1], Alberto J. Arribas[1], Nikolai Bendik[1], Mariana Girao[2], Ines Ribeiro[2], Maria de Fatima Carvalho[2], Francesco Bertoni[1], Pedro Leao[2]

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland,[2]CIIMAR - Interdisciplinary Centre of Marine and Environmental Research, Matosinhos, Portugal

Background: Actinomycetota of the genus Streptomyces are well known to produce a wide range of secondary metabolites, many of which have already been developed into antibiotics, antifungals, anti-inflammatory compounds, and anticancer agents. They can be found in the marine environment, including the deep sea, and are frequently associated with marine organisms, such as macroalgae. We studied the anti-lymphoma activity of extracts from Actinomycetota isolated from several deep-sea samples and macroalgae species abundant along the Portuguese coast.
Methods: Organic extracts were made from 7-day cultures using a 1:1 (v/v) methanol:acetone mix. An LC-MS/MS-based dereplication was applied to the extracts presenting the most relevant properties, using GNPS to identify the ones putatively containing novel molecules. Cancer cell lines were treated with each extract for 72h followed by MTT.
Results: Actinomycetota strains were isolated from the tissues of 3 macroalgae species collected on the northern Portuguese coast (*Laminaria ochroleuca*, *Chondrus crispus, Codium tomentosum*) and from sediments, corals, and sponges from deep-sea regions. 147 extracts were tested (1 and 10 µg/ml) in marginal zone lymphoma (MZL) cell lines with acquired resistance to PI3K (n.=2), BTK (n.=1), and PI3K/BCL2 (n.=1) inhibitors and their parental counterparts (n.=2). 18 extracts gave broad-activity in at least 4/6 cell lines tested. Among those, we identified molecules present in more than 1 fraction, such as Apoptolidin A, known to have a cytotoxic effect in cancer cells. All extracts were MS tested to know the compositions of known molecules or analogs. Among the active extracts, we have identified some containing known molecules with unknown functions or unknown molecular entities with a broad anti-cancer effect. Twenty-three extracts showed different activity in parental and resistant cell lines. Thirty extracts with broad anti-cancer activity or different activity between parental and resistant were further validated in a larger dose-response curve. Seven were confirmed to have a higher activity in resistant than parental cells or broad antitumoral activity. Three extracts from seaweeds, M15 and M16 (from Streptomyces) and M28 (Verrucosispora sp) were selected for up-scaling culture and further fractionation in 13, 12, and 11 fractions, respectively. Activity was confirmed in some fractions at 10 µg/ml and for some M28-derived fractions at 1 µg/ml. M28 (containing no known compounds) and M15 showed a higher activity in resistant than parental models.
Conclusions: We identified Actinobacteria extracts with broad anti-lymphoma activity or showing increased activity in MZL cells with acquired resistance to FDA-approved compounds compared to parental cells. Some fractions were composed of new molecular entities, representing potential sources of novel therapeutic compounds.

#612 Antimicrobial peptides with antitumor activity against marginal zone lymphoma cell lines resistant to BTK, PI3K, and BCL2 inhibitors.

Filippo Spriano[1], Alberto J. Arribas[1], Fangwen Zhang[1], Maria Luisa Mangoni[2], Francesco Buonocore[3], Francesco Bertoni[1]

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland,[2]Department of Biochemical Sciences, Sapienza University of Rome, Laboratory Affiliated to Pasteur Italia-Fondazione Cenci Bolognetti, Rome, Italy,[3]Department for Innovation in Biological, Agrofood and Forest Systems, University of Tuscia, Viterbo, Italy

Background: Antimicrobial peptides (AMPs) are a class of small proteins produced by all living organisms, from prokaryotes to humans. In higher eukaryotes, AMPs contribute to the host's innate immunity, promptly responding against any pathogen. Due to their mechanism of action, represented mainly by their ability to bind and perturb microbial membranes, AMPs are being explored as novel agents against multidrug-resistant bacteria and anti-cancer agents. Natural peptides could be used as a scaffold to design new AMPs with improved effectiveness, stability, and selectivity. Marginal zone lymphoma (MZL) is an indolent yet incurable B-cell lymphoid tumor. Here, we assessed the antitumor activity of seven AMPs in MZL models with acquired resistance to FDA-approved BTK, PI3K, and BCL2 inhibitors.

Methods: Established human cell lines derived from MZL (VL51, Karpas1718) and derivatives with secondary resistance to targeted agents obtained by long drug exposure (n.=3 from VL51, n.=1 from Karpas1718 (Arribas et al, Haematologica 2022; Mol Cancer Ther 2024; ENA 2019; ENA 2020) were exposed to increasing concentrations of AMPs or DMSO, as control. Anti-proliferative activity was assessed by MTT assay after 72 hours of exposure.

Results: MZL cell lines were exposed to AMPs originating from Antarctic fishes (*Chionodraco hamatus*, *Trematomus bernacchii*; trematocines, n.=2; chionodracines, n.=1) and amphibians (temporins, n.=4;). Anti-proliferative activity was observed in parental MZL with two synthetic AMPs: a *Trematomus bernacchii* - derived trematocine mutant (Della Pelle et al, Antibiotics 2020), with IC50 values of 7.5 µM in VL51 and 10 µM in Karpas1718 and the *Rana temporaria* - derived Temporin L (Simmaco et al, Eur J Biochem 1996) with IC50 of 8 µM in VL51 and 15 µM in Karpas1718. Notably, the antiproliferative activity was maintained in all the derivative MZL cell lines with resistance to BTK, PI3K, and BCL2 inhibitors. At higher concentrations, also the other trematocine *(*Karpas1718 models) and all the temporins (VL51 and Karpas1718 models) had anti-proliferative activity (IC50 values 25-50 µM).

Conclusions: AMPs derived from Antarctic fishes and amphibians have in vitro anti-tumor activity in cell lines derived from MZL, including models with acquired resistance to BTK, PI3K, and BCL2 inhibitors. AMPs and their synthetic derivatives can provide novel anti-lymphoma agents with mechanisms of action deeply different from currently used drugs.

#613 Investigating cyclooxygenase isoforms as targets for anticancer compounds isolated from Tulbaghia violacea.

Zodwa Dlamini, Rodney Hull, Mohammed Alaouna

Pan African Cancer Research Institute (PACRI), University of Pretoria, Pretoria, South Africa

Introduction: The medicinal plant Tulbaghia violacea exhibits anticancer properties in triple-negative breast cancer (TNBC) cells, primarily through apoptosis induction. Transcriptomic analyses of treated TNBC cells highlighted altered expression of cyclooxygenase isoforms COX-1 and COX-2. COX-1, with anti-apoptotic properties, is associated with tumor progression, while COX-2, with pro-apoptotic properties, acts as a tumor suppressor.

Methods: Bioactive compounds derived from T. violacea were screened for their potential interaction with cyclooxygenase isoforms using molecular docking approaches. Protein structures for COX-1 (PDB: 6Y3C) and COX-2 (PDB: 5IKT) were retrieved from the Protein Data Bank. Ligand and protein preparation for sixteen compounds was conducted using the Schrödinger Suite. Standard precision (SP) docking was followed by MM-GBSA post-docking and extra precision (XP) docking to refine binding affinity predictions.

Results and Discussion: COX-2 demonstrated the highest average docking scores, indicating stronger binding affinity for the T. violacea-derived compounds. Comparative structural analysis revealed significant differences in binding site residues and global backbone structures between COX-1 and COX-2. SiteMap analysis identified the most druggable regions, with COX-2's larger binding pocket enabling higher binding affinity. Notably, the same compounds were capable of binding both isoforms, although with lower affinity for COX-1. These findings suggest that the anticancer activity of T. violacea compounds may be mediated by their preferential binding to COX-2, which is often upregulated in cancers.

Conclusion: This study highlights the potential of Tulbaghia violacea as a source of bioactive compounds targeting cyclooxygenase isoforms, particularly COX-2. The preferential binding to COX-2 aligns with its pro-apoptotic role and its upregulation in cancers, underscoring its relevance in cancer therapy. Further experimental validation is warranted to confirm these in silico findings and to explore the therapeutic potential of T. violacea-derived compounds.

#614 REPYR-SC1: Hemp extract exhibits potent inhibition of squamous cell carcinoma.

Joel Costoya, Sylvia S. Daunert, Sapna K. Deo, **Joaquin J. Jimenez**

Biochemistry and Molecular Biology, University of Miami Miller School of Medicine, Miami, FL

Squamous cell carcinoma (SCC) is the second most common form of skin cancer in the world, presenting in nearly 1 in 5 US adults by age 70 alongside basal cell carcinoma. Localized low- and high-risk SCC is treated with surgical techniques offering favorable prognoses with recurrence being unlikely. Therapies for non-operable metastatic SCC, such as chemotherapy, possess undesirable side effects, and have yet to achieve similar response rates to surgery. Investigation into pharmacological targeting of cancer using cannabinoids is ongoing, demonstrating pre-clinical efficacy in various cancer models. Additionally, cannabinoids are established immunomodulatory compounds, capable of shifting immune cell populations, regulating immune cell trafficking, and their migration. Our study aimed to investigate the immunomodulatory, and anti-neoplastic capacity of REPYR-SC, a novel hemp extract. SCC-15 cells were used to model SCC, HEKa epidermal keratinocytes were used as a non-cancerous peripheral tissue model, and CTLL-2 T lymphocytes to screen for immune reactivity. REPYR-SC1 was dosed at 0 (control), 0.1, 0.5, 1, and 5 µL/mL and incubated with SCC-15 or HEKa cells for 36 and 72 hours, meanwhile 24 and 48 hours for CTLL-2 cells all at 37°C under 5% CO_2 (initial cell density of 2.5 x 10^5 cells/mL). Cell counts were evaluated pre- and post-treatment with an automated cell counter, and cell viability was determined following treatment via trypan blue exclusion and morphological analysis. REPYR-SC1 induced a significant time- and dose-dependent reduction in proliferation and cell viability ($p<0.001$) in squamous cell carcinoma cell line SCC-15, as well as T lymphocytes. At a dose of 1 and 5 µL/mL at the 36- and 72-hour mark, 100% inhibition of proliferation was observed in SCC-15 cells and 25% at 5 µL/mL - 72 hours for HEKa cells. At a dose of 1 and 5 µL/mL at the 48-hour mark, 100% inhibition of proliferation was observed for CTLL-2 cells. These results support earlier evidence suggesting the immunomodulatory, and anti-neoplastic activity of cannabinoids. Further testing *in-vivo* is warranted, and the mechanism of action for REPYR-SC1 remains unknown. Nonetheless, cannabinoid-based compounds may still represent a novel chemotherapeutic modality with a favorable toxicity profile.

#616 TYK2: A novel therapeutic target in triple-negative breast cancer brain metastasis.

Jayshree Mishra[1], Priyam Kumar[2], Narendra Kumar[1]

[1]Pharmaceutical Sciences, Texas A&M University, Kingsville, TX,[2]University of Pennsylvania, Philadelphia, PA

Breast cancer (BC) is one of the deadliest cancers that affect 300,000 women annually where 15-25% are Triple negative in nature and spreads quickly to the brain causing brain metastasis (TNBC-BM). Triple-negative breast cancer (TNBC) is a heterogeneous disease characterized by lack of hormone receptor expression and is known for high rates of recurrence, distant metastases, and poor clinical outcomes. The 5-year survival rate for TNBC-BM is only 9%. Current standard of care to treat TNBC-BM include whole brain radiation therapy, surgery and chemotherapy which leads to sever side effects, high level of neurotoxicity, neurological complication that leads to low survival rate and low quality of life. Because of such a low survival rate, there is an unmet clinical need to treat these patients differently to decrease neurotoxicity, and TNBC-BM cell death. In our study, we identified and characterized novel therapeutic targets and targeted pharmacologic inhibitors of natural compound origin for the treatment of TNBC-BM. Our preliminary data suggest (1) overexpression of Tyk2 (JAK Family meber) gene in TNBC-BM compared to TNBC and TNBC lung metastasis using a PDX database. Overall Survival analysis of TNBC patients databases suggest that higher expression of Tyk2 gene and it's downstream signaling partner gene STAT5A. Tyk2 is overexpressed in the TNBC-BM metastatic brain sample and TNBC -BM specific cell line (BrM-831). Based on the published literature and our strong preliminary data, we hypothesize that over expression of Tyk2 promotes brain metastasis in TNBC cells through the activation of Tyk2-STA5A signaling pathway stimulating epithelial-to-mesenchymal transition, cell migration and invasion of TNBC cells, leading to tumorigenesis and metastasis in TNBC; Together, this study will demonstrate Tyk2 as a new target and Tyk2 targeted therapeutic agent will be capable of inhibiting TNBC-metastasis through blocking the activation of the Tyk2-/STAT5 molecular targets. In future, we plan to develop Tyk2 targeted drug compounds originated from natural products to treat TNBC-BM.

TUMOR BIOLOGY: Imaging in Animal Models
Poster Session

#62 Tumor targeted contrast agents for pancreatic adenocarcinoma.

Sylvana Knapp[1], Ryan Bynum[1], Molly McNally[1], William E. Grizzle[2], Lacey R. McNally[1]

[1]OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]University of Alabama at Birmigham, Birmingham, AL

Purpose: Pancreatic cancer has a low relative survival rate of only 12.8%, with surgical resection being an option for just 20% of patients. Achieving R0 resection is vital, as it forms the cornerstone of curative treatment strategies. pH low insertion peptides (pHLIPs), a novel class of targeted imaging agents, are being developed for use with multispectral optoacoustic imaging (MSOT) for potential clinical or intraoperative applications. However, existing pHLIPs have limitations in dynamic range and solubility. To address these issues, a new pHLIP variant, V7Phe, was designed to enhance both solubility and dynamic range for identifying the acidic tumor microenvironment in pancreatic cancer.
Methods: V7 and V7F peptides were synthesized using microwave chemistry, then removed from resin, lyophilized, and rehydrated. Conjugation with HiLyte 750 dye via maleimide chemistry was confirmed through spectroscopy. Pancreatic cancer cell lines S2VP10 and S2013 were treated with V7-750 and V7F-750 at pH 7.4 and pH 6.6. Probe uptake was assessed using near-infrared fluorescence imaging.
Results: V7F-750 demonstrated a significantly higher signal in vitro than V7-750 at both pH 7.4 and pH 6.6 ($p<0.01$). V7F-750 also exhibited greater signal in more acidic conditions ($p<0.01$). Although solubility was moderately improved, V7F-750 did not show an enhanced dynamic range compared to V7-750, with the ratio of signal at pH 6.6 to 7.4 being 1.19 for V7F-750 versus 1.39 for V7-750 ($p=0.21$) across both cell lines.
Conclusion: V7F-750 effectively targets the acidic tumor microenvironment, demonstrating improvements in peptide solubility

CLINICAL RESEARCH: Cancer Care for All: Innovations in Geriatric Oncology and Broadening Research Representation Poster Session

#620 Differences in fatigue, sleep disturbance, and quality of life in middle aged and older adults with cancer prior to cancer treatment.

David Asakitogum[1], Arsham Alamian[2], Victoria Loerzel[1]

[1]University of Central Florida, Orlando, FL,[2]University of Miami, Miami, FL

Introduction: Symptom burden and poor quality of life (QOL) are associated with cancer and its treatment. However, there is limited amount of research regarding age differences in common physical symptoms and QOL in adults with cancer prior to cancer treatment. Knowledge of age differences in common physical symptoms in these patients will inform clinical decision on pre-interventions. Therefore, the purposes of this study were to: 1) evaluate age differences in occurrence rates and severity ratings for fatigue, sleep disturbance, and QOL; 2) assess risk factors associated with the severity of each symptom and QOL outcomes.
Methods: Participants (n=111) were dichotomized into middle (50 - 64 years) and older (≥65 years) age groups. Participants completed the Symptom Representation Questionnaire and the European Organization for Research and Treatment of Cancer-Core 30 prior to cancer treatment. Differences in demographic and experiential characteristics, each symptom, and QOL outcomes were evaluated using parametric and non-parametric tests. Logistic procedures were used to identify risk factors associated with the severity of each symptom and QOL outcomes.
Results: Overall, the prevalence of moderate to severe fatigue were 13.51% and 26.12%, tired 21.62% and 40.54%, and sleep disturbance were 12.61% and 26.13% in the middle and older aged patients respectively, prior to the initiation of chemotherapy. Our findings indicate that compared to middle age, older patients experienced similar fatigue (2.67 Vs 3.04), sleep disturbance (1.98 Vs 2.03), and QOL scores (5.62 Vs 5.42) respectively prior to chemotherapy. Holding other variables constant: patients with trade and some college degrees were less likely (OR=0.095) to experience severe fatigue scores while those with cancer stage II-III were less likely (OR=0.129-0.083) to experience moderate fatigue. Compared to females, male patients were less likely (OR=0.166) to experience severe sleep disturbance while older aged were more likely (OR=5.492) to experience moderate sleep disturbance compared to middle age. Patients with breast cancer were more likely (OR=7.835) to experience excellent QOL compared to other cancers.
Conclusion: Approximately 4.50% and 9.01% of middle and 11.71% and 9.01% of older aged patients with cancer experienced severe fatigue and sleep disturbance respectively prior to cancer treatment. The study identified risk factors associated with severe fatigue and sleep disturbance. These findings have implications for oncology clinicians to assess symptoms and provide early intervention for these patients before commencement of cancer treatment so worsening of side effects can be minimized.

#621 Changes in the senescence biomarker p16INK4a among older adults with early breast cancer treated with and without chemotherapy and non-cancer controls.

Chaiyaporn C. Vatanatham[1], Jingran Ji[1], Canlan Sun[2], Marla D. Lipsyc-Sharf[1], Nikita V. Baclig[1], Yuliya A. Zektser[1], Ali Al Saleem[1], Joseph D. Olivera[1], Kelly S. Synold[1], Lauren R. Zelman[1], Hyman B. Muss[3], Mina S. Sedrak[1]

[1]University of California, Los Angeles, Los Angeles, CA,[2]City of Hope, Duarte, CA,[3]University of North Carolina at Chapel Hill, Los Angeles, CA

Background: Our group previously showed that $p16^{INK4a}$ (p16) expression, a biomarker of senescence (a fundamental process of aging), increases after adjuvant breast cancer chemo. However, no study has examined whether this increase in p16 is driven by cancer, chemo, or both. Here, we compare the change in p16 between older adults with early breast cancer who receive chemo, those who do not, and those without cancer.

Methods: We prospectively recruited 701 adults age ≥65 with stage I-III breast cancer (composed of three age-matched cohorts: 501 treated with chemo [BC chemo], 100 treated without chemo [BC control]), and 100 without cancer (NC control). Sociodemographic, functional, and clinical characteristics were collected at baseline. The p16 level in peripheral blood CD3+ T lymphocytes was obtained at two time points: ≤14 days pre-chemo (T1) and ≤30 days post-chemo (or at matched time points in the BC and NC control groups, T2). The primary endpoint was the mean Δp16 level from T1 to T2. Data was analyzed using descriptive statistics, t-tests, and analysis of variance (ANOVA).

Results: There were no differences in T1 age, race/ethnicity, education, comorbidities, or functional status across the three groups. At T1, there was no difference in mean p16 levels across the three groups (p=0.06) (Table). At T2, the BC chemo group had a significantly higher mean p16 level compared to the BC and NC control groups (p<0.01). The mean Δp16 levels from T1 to T2 were significantly different among the three groups (p=0.04). The BC chemo group had a 15% increase in mean Δp16 from T1 to T2 (p<0.01), while the BC and NC control groups had no significant change.

mean Δp16 Level from T1 to T2 (log_2 units)					0.04
No. of participants	199	67	68	334	
Mean (SD)	0.2 (0.81)	0.1 (0.87)	-0.1 (0.87)	0.1 (0.84)	
Median	0.1	0.1	0.0	0.1	
95% CI	(-0.6-1.0)	(-0.8-0.8)	(-1.1-0.8)	(-0.6-0.8)	

Conclusions: In a cohort of older adults with early breast cancer, the combination of breast cancer and chemo led to increases in p16 levels. Further independent validation of these findings is needed to understand the role of senescence in older adults with early breast cancer treated with chemo.

#622 Age-dependent changes in cell cycle dynamics and hematopoietic responses to chemotherapy.

Jianxing He[1], **Yue Pan**[1], Hao Liu[2], Ying Huang[1], Hongsheng Deng[1], Chao Yang[1], Qi Cai[1], Shan Xiong[1], Huiting Liu[1], Wenhua Liang[1]

[1]The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China,[2]Henan University, Henan, China

Background: Precision medicine emphasizes individualized cancer treatment, particularly for elderly lung cancer patients facing unique chemotherapy challenges. Age-related changes in cell cycle dynamics significantly influence therapeutic outcomes, yet their role in optimizing personalized therapies remains underexplored. This study investigates these age-related dynamics to inform personalized therapeutic strategies for elderly lung cancer patients.

Methods: Single-cell RNA sequencing data from 166 healthy individuals (aged 25-85 years) were analyzed to explore age-associated changes in cell cycle distribution, differentially expressed genes (DEGs), and enriched pathways. Young (9-11 weeks) and aged (17 months) mice received weekly cisplatin for four cycles. Peripheral blood and hematopoietic stem cells (HSCs) were monitored dynamically for cell cycle phases, DNA damage (γ-H2AX), and vascular leakiness using immunofluorescence. RNA sequencing of HSCs identified DEGs and enriched pathways after treatment cycles.

Results: Single-cell analysis revealed a linear decrease in S-phase proportions with age ($r=-0.681$, $p=0.0026$) and identified 28 DEGs, including PAXB-AS1, BABAM1, and DONSON, enriched in immune regulation and cell cycle pathways. In murine models, aged mice showed impaired immune recovery, with persistently higher neutrophil proportions (post-cycle 1: 14.75% vs. 6.1%, $p<0.05$) and lower lymphocyte proportions (post-cycle 1: 65.73% vs. 79.98%, post-cycle 4: 60.5% vs. 63.8%) compared to young mice. Moreover, aged mice exhibited delayed neutrophil recovery (Day 4 vs. Day 2), accompanied by persistent G1-phase arrest in HSCs (Day 4: 86% vs. 82%) and reduced G2/M-phase proportions (Day 4: 3% vs. 6%). RNA sequencing of aged HSCs further revealed significant enrichment in the DNA_DAMAGE_TELOMERE_STRESS_INDUCED_SENESCENCE pathway after four treatment cycles ($|NSE| = 1.98$, $p < 0.05$), a pattern absent in young mice. Finally, γ-H2AX flow cytometry confirmed increased DNA damage in aged HSCs, while immunofluorescence demonstrated heightened bone marrow vascular leakiness in aged mice.

Conclusion: Aging significantly alters cell cycle dynamics, hematopoietic recovery, and chemotherapy responses, highlighting the need to integrate cell cycle-based insights into personalized treatment strategies. These findings provide a foundation for future research on age-specific therapeutic interventions in lung cancer.

#623 Epigenetic age acceleration measures and chemotoxicity in older adults with early breast cancer.

Jingran Ji[1], Canlan Sun[2], Marla Lipsyc-Sharf[1], Nikita V. Baclig[1], Yulia A. Zektser[1], Ali Al Saleem[1], Joseph D. Olivera[1], Kelly S. Synold[1], Lauren R. Zelman[1], Alexandra M. Binder[3], Mina S. Sedrak[1]

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]City of Hope, Duarte, CA,[3]University of Hawaii, Honolulu, HI

Background: Older adults with early breast cancer can have very different risks of chemotoxicity despite similar chronological age. This heterogeneity may be due to differences in biological age. However, few studies have evaluated whether epigenetic indicators of biological age can stratify the risk of chemotoxicity in older adults with early breast cancer.
Methods: In a prospective multicenter study of 394 adults age >65 with stage I-III breast cancer treated with neo/adjuvant chemo, we analyzed DNA methylation patterns from peripheral blood to estimate epigenetic age acceleration (EAA) prior to chemo. We tested three generations of epigenetic age algorithms (1st gen: Horvath and Hannum; 2nd gen: PhenoAge and GrimAge; 3rd gen: DunedinPACE). We calculated EAA as the residual that results from regressing epigenetic age on chronological age. The primary endpoint was grade 2+ chemotoxicity (yes/no, yes defined as any grade 2+ toxicity attributed to chemo). Using multivariable logistic regression, we examined the association between EAA (analyzed as continuous and categorical [quartiles] variables) and grade 2+ chemotoxicity, adjusting for demographic, geriatric, and clinical covariates.
Results: The median (range) pre-treatment chronological age was 70 (65-85), 65% had stage II/III disease, 38% had anthracycline, and 75% received G-CSF prophylaxis. A total of 334 (84.8%) participants experienced a grade 2+ toxicity. After adjusting for age, cell composition, stage, race/ethnicity, education, regimen, organ function, and geriatric assessment variables, there was no significant association between the measures of EAA and grade 2+ chemotoxicity (Table).
Conclusions: In this cohort of older adults with early breast cancer, there was no significant association between pre-treatment EAA and grade 2+ chemotoxicity. Further research is needed to examine how measures of biological age can be translated to the clinical care of older patients with breast cancer.

	Multivariable Analysis*	
Measures of EAA	**OR (95% CI)**	**p-value**
Horvath		
Categorical (quartiles, Q4 vs. Q1)	1.35 (0.57-3.16)	0.50
Continuous (each one-year increase)	1.00 (0.94-1.07)	0.96
Hannum		
Categorical (quartiles, Q4 vs. Q1)	1.17 (0.50-2.78)	0.71
Continuous (each one-year increase)	1.00 (0.93-1.08)	0.98
PhenoAge		
Categorical (quartiles, Q4 vs. Q1)	1.41 (0.63-3.16)	0.40
Continuous (each one-year increase)	1.02 (0.96-1.08)	0.59
GrimAge		
Categorical (quartiles, Q4 vs. Q1)	1.12 (0.47-2.67)	0.81
Continuous (each one-year increase)	1.02 (0.94-1.11)	0.66
DunedinPACE		
Categorical (quartiles, Q4 vs. Q1)	1.29 (0.51-3.28)	0.59
Continuous (each one biologic year/chronologic year increase)	1.69 (0.10-28.70)	0.72
*Adjusted for age, cell composition, stage, race/ethnicity, education, regimen, organ function, and geriatric assessment variables.		

#625 Partnering with the community to evaluate policies that regulate cancer clinical trial practice at Henry Ford Health to make it accessible for the Black/African American community in Detroit.

Lisa Lange[1], Donna Harris[2], Martina Caldwell[1], Linda Kaljee[1], Ali Haythem[1], Sophia Chue[3], Valerie Ofori Aboah[1], Harriet Larrious-Lartey[1], Sylvester Antwi[1], Eleanor Walker[1], Dominique Bragg[1], Jorge Chinea[4], Danielle Nelson[1], Camille Romain[1], Denise White-Perkins[1], Evelyn M. Jiagge[1]

[1]Henry Ford Health System, Detroit, MI,[2]Grace Learning Center, Detroit, MI,[3]Caribbean Community Service Center, Detroit, MI,[4]The Center for Latino/a and Latin American Studies, Detroit, MI

Background: Within communities of color, traditional approaches to research have often not benefited and sometimes actually harmed the participants, resulting in a distrust of and reluctance to get involved in clinical trials. The participation of the Black/African American population in clinical trials is essential to develop globally applicable curative, life-extending, life-enhancing cancer therapies using patient centric approaches. The proposed project builds on our Participatory Action for Access to Clinical Trials (PAACT) project which focused on systemic, clinical, and community barriers to Black/African American participation in cancer clinical trials. The proposed project is designed to concurrently address health system policies and programs that affect community engagement, cancer clinical care, and clinical trials.

Method: We documented and assessed the current Henry Ford Health (HFH) policies that govern community engagement, cancer care, and cancer clinical research at Henry Ford Cancer Institute (HFCI). Six main levels of policies were assessed. These include: (1) Cancer clinical trial review processes to determine if the trials are scientifically sound and can be conducted at HFH; (2) Cancer Clinical and Translational Research Office (CCTRO); (3) Feasibility Review Committee (FRC); (4) Scientific Review Committee (SRC); (5) Research Administration; and, (6) Internal & External Institutional Review Boards (IRB). We then engaged with the project Steering Committee consisting of community stakeholders from ten community organizations, other community members, and HFH/HFCI leadership to evaluate the policies and make recommendations for the development of interventions to make the process more acceptable to Black/African American communities.

Results: The interventions that were recommended by the steering committee were put into six categories: (1) Seat at the Table: Valuing People Over the Project; (2) Enhanced Participant Recruitment Approaches; (3) Monitoring Racial/Ethnic Representation at Monthly Clinical Trial Review Meetings; (4) Patient-Centered Informed Consent; (5) Respectful Monetary Incentives for Clinical Trial Participants; (6) Recognition of Healthcare Providers' Time and Effort. We are in the process now of prioritizing and piloting these interventions at HFH.

Conclusion: To increase the participation of *Black/African Americans* in cancer clinical trials, we need to not only focus on patient and community level interventions *ideally,* but, there is the need to evaluate the institutional policies that make the process acceptable to the patients.

#626 Black/African American participation in cancer clinical trials: Healthcare professional perspectives.

Linda Kaljee[1], Sylvester Antwi[1], Doreen Dankerlui[1], Donna Harris[2], Barbara Israel[3], Denise White-Perkins[1], Valerie Ofori Aboah[1], Livingstone Aduse-Poku[4], Harriet Larrious-Lartey[1], Barbara Brush[3], Chris Coombe[3], La'Toshia Patman[5], Nayomi Cawthorne[6], Sophia Chue[7], Zachary Rowe[8], Cassandra Mills[1], Kurt Fernando[3], Gwendolyn Daniels[9], Eleanor Walker[1], Evelyn M. Jiagge[1]

[1]Henry Ford Health System, Detroit, MI,[2]Grace Learning Center, Detroit, MI,[3]University of Michigan, Ann Arbor, MI,[4]University of Florida, Gainesville, FL,[5]Our Wellness Hub, Detroit, MI,[6]Eastside Community Network, Detroit, MI,[7]Caribbean Community Service Center, Detroit, MI,[8]Friends of Parkside, Detroit, MI,[9]Institute for Population Health, Detroit, MI

Purpose: The purpose of this community-based participatory research (CBPR) was to identify barriers and facilitators to Black/African American engagement and inclusion in cancer clinical trials in the Detroit Metropolitan Area. This presentation focuses on data from healthcare professionals at Henry Ford Cancer Institute.
Design: The CBPR approach included the establishment of a Steering Committee composed of researchers, health professionals, and representatives of eight diverse organizations representing African American, African Caribbean, and Ghanaian communities. A qualitative methodology was employed to obtain contextual and experiential data. Fourteen healthcare professionals participated in individual interviews including physicians, surgeons, research nurses and navigators, clinical research coordinators, and cancer trial investigators. Interview guides were developed based on an extensive literature review. Interviews were audio recorded and transcribed. Data were coded and searches were conducted to identify themes within the coded data.
Outcomes: Data were categorized into six constructs: 1. disparities; 2. trust; 3. advantages and disadvantages to trial participation; 4. clinical and system challenges for physicians' trial engagement; 5. trial participant selection criteria; and 6. clinical trial recruitment protocols. Themes within disparities include inequitable access to healthcare and patient selection bias. Patient and community trust and distrust were discussed within historical and experiential abuses and neglect in Black/African American communities. Physicians perceived trial advantages to include access to new therapies and patient-internal rewards, e.g., contributing to wellbeing of future generations. Disadvantages included participants' financial, social, and psychological costs. Physician challenges included awareness of trials, time allocation, and systemic expectations of output. Selection criteria themes were focused on the internal procedures required to identify eligible patients and the barriers associated with trial sponsor requirements. Recruitment barriers included complex consenting procedures and resources to support informed patient decision-making. Study respondents provided recommendations to address barriers for both patients and healthcare providers.
Conclusions: Increasing diversity in clinical trials requires understanding barriers and facilitators at multiple levels including communities, patients and their families, healthcare professionals, health system leadership, and trial sponsors. Recognizing the experiences and perceptions of healthcare professionals is one step toward addressing the complex social environments in which cancer clinical trials reside. Recommendations from this study are being piloted.

#628 Enhancing data integrity in contact registries: Methods for preventing fraudulent enrollment.

Ileana Guzman[1], **Nazleen Del Rio**[1], Brooke Hensel[1], Eduardo Ibarra[2], Carolina Aristizabal[2], John Luque[3], Rosa Barahona[2], Diana Wilkie[4], Mariana C. Stern[2], Lourdes Baezconde-Garbanati[2], Sandra Suther[3], Fern Webb[5]

[1]University of Florida, Orlando, FL,[2]University of Southern California, Los Angeles, CA,[3]Florida A&M University, Tallahassee, FL,[4]University of Florida, Gainesville, FL,[5]University of Florida, Jacksonville, FL

Significant barriers to engaging underrepresented communities in cancer research are the limited access to information, misinformation, mistrust, and, at times, the absence of invitations to participate. Contact registries play a vital role in connecting community members with opportunities in cancer health research, they ensure that more people are informed and included in these efforts. With the use of contact registries, participants gain access to studies aligned with their interests; and have the freedom to choose to participate or not. While contact registries enable the large-scale recruitment of diverse participants, they also have a higher likelihood of attracting fraudulent enrollments. The likelihood drastically increases when an incentive is available upon enrollment. On July 2021 the Florida-California Cancer Research, Education, and Engagement (CaRE^2) Health Equity Center, Community Outreach Core (COC), developed a contact registry designed to engage Black/African American (B/AA) and/or Hispanic/Latinos/a (H/L) individuals in ongoing research studies conducted across our bicoastal center institutions which includes the Florida Agricultural & Mechanical University, the University of Florida, and the University of Southern California. Due to the increased challenges of internet-based recruitment, the study team has implemented methods to filter out fraudulent applications and confirm participant eligibility. The methods include 1) using a REDCap software feature (CAPTCHA) to prevent bots from enrolling, 2) individually reviewing each registry application for any errors, 3) checking for duplicate IP addresses, 4) Using external resources such as voter registration information, social media, and/or Google to verify identity information; and lastly, 5) calling each potential applicant and having them verify the information they provided. Each application is color-coded to identify whether it has been approved (green), denied (red), or pending (purple). Although internet-based recruitment poses a great risk to a study, it in turn provides a time and cost-effective option, allows for recruitment from multiple geographical areas, and facilitates the recruitment of a large number of participants. As of November 8th, 2024, 1,408 participants have enrolled in the registry, representing 70% of the 2,000 enrollment goal. Based on our experience with internet-based recruitment for contact registries, we recommend the following) Implement methods to verify applicant information 2) Utilize security features within the registry application. 3) Incorporate a phone screening process. 4) Consider leveraging external resources, such as Whitepages, for information verification. 5) Maintain detailed records of the verification process.

#629 Providing a safe space for our diverse vulnerable populations to talk about their health concerns across the continuum of cancer care: Lazarex Cancer Wellness HUB pop-up model.

Elena Nieves[1], Rosa Barahona[2], Marya Shegog[3], Dana Dornsife[3], **Lourdes A. Baezconde-Garbanati**[2]

[1]Norris Comprehensive Cancer Center, Keck School of Medicine of USC, Los Angeles, CA,[2]Keck School of Medicine of USC, Los Angeles, CA,[3]Lazarex Cancer Foundation, Danville, CA

Background: The Lazarex Cancer Foundation, in collaboration with USC established the Lazarex Cancer Wellness HUBs pop-up model to provide a welcoming and safe space embracing the cultural and unique cancer challenges of communities that we serve, our diverse populations. A major part of cancer health equity means providing a space representative of the people we serve so we meet them where they are while providing information in a culturally sensitive and language specific way. The HUB offers equitable access to cancer programs and support that could help achieve better results from prevention through treatment and survivorship.
Methods: Between Oct 2021 to July 2024 our HUB has conducted outreach in several YMCAs across LA County with other community-based organizations and churches. We supported community events such as Black Men's Wellness Day, Taste of Soul, and the San Gabriel Lunar Lantern Festival. A series of mindfulness workshops provide interventions that help develop emotional balance and find greater calm and control in the daily lives of those affected by cancer. Our speaker series, facilitated by scientists and invited guest speakers have provided community members with current scientific discoveries including robust overview of cancer, cancer treatment and opportunities available.
Results: Over 8,000+ individuals have received cancer information. Majority have identified as women (over 70%) representing different race/ethnicity designations. Most indicated some level of health insurance with about 50% having a government supported plan. About half shared they received a pre-high school or high school education. Moreover, over 2,000 community members have attended our speaker series that discussed topics such as Oral Care for Cancer Patients, At Your Cervix: How the Pap Smear Helps Prevent and Detect Cancer, LGBTQI+ Identity, Screening, and Risk Factors, and Liver and Hepatitis Cancer. 52 members attended mindfulness workshops that were engaged in mind-body health practices. Finally, a one-day in-person event where 92 community members attended and learned about "The Future in Cancer Therapy: From Participant Engagement to Scientific Discovery" brought together cancer research experts to immerse the community in knowledge.
Conclusion: We created a community outreach approach that allows to be present and visible in our diverse communities in LA County with information tailored culturally and locally. Education and connection to cancer support services are provided to help equip everyone in their cancer journey before, during and beyond. Information provided include cancer screening guidelines, the importance of diversity participation in cancer clinical trials, self or patient advocacy, and access to sources. The actions we are take allow us to help reduce cancer disparities.

TUMOR BIOLOGY: Imaging in Animal Models

#63 Orai1 regulates collagen secretion in pancreatic stellate cells and is enriched in fibrotic cancer-associated fibroblasts in PDAC.

Zoltan Petho[1], Ilka Neumann[1], Andrea Oeckinghaus[2], Albrecht Schwab[1], Rieke Schleinhege[1]

[1]Insitute of Physiology II, University of Munster, Munster, Germany,[2]Insitute of Molecular Tumor Biology, University of Munster, Munster, Germany

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is characterized by a desmoplastic stroma driven by pancreatic stellate cells (PSCs) and cancer-associated fibroblasts (CAFs). The Ca^{2+}-permeable ion channel ORAI1 is known to influence PSC proliferation and activation, but its role in collagen secretion and tumor fibrosis remains unclear.
Experimental Procedures: Using the PSC cell line PS-1, we developed and validated a high-throughput fibrosis assay based on the collagen-binding peptide CNA-35-tdTomato. Collagen secretion was assessed following treatment with transforming growth factor β1 (TGF-β1) and/or vitamin C, with ORAI1 inhibition achieved via siRNA or Synta-66. In vivo, Orai1 expression was examined by immunohistochemistry in the genetically engineered murine PDAC model KPfC ($Kras^{wt/LSL-G12D}$ $Tp53^{fl/+}$ $PDX1^{Cre+}$). The intracellular Ca^{2+} concentration was assessed with the fluorescent Ca^{2+} indicator Fura-2.
Results: TGF-β1 and vitamin C synergistically enhanced collagen deposition in PSCs, a process regulated by ORAI1. Vitamin C induced a significant rise in intracellular Ca^{2+} in PSCs, which was attenuated by the ORAI inhibitor Synta-66. ORAI1 expression was detected in αSMA^{+} CAFs in KPfC-derived PDAC tissue, with a higher prevalence in collagen-rich fibrotic tumor regions compared to non-fibrotic areas or non-tumorous tissue. In addition, vessel-lining endothelial cells also express ORAI1.
Conclusions: Our findings highlight ORAI1 as a regulator of collagen secretion in PSCs and reveal its enrichment in CAFs within fibrotic PDAC stroma, underscoring its potential role in PDAC-associated desmoplasia.

CLINICAL RESEARCH: Cancer Care for All: Innovations in Geriatric Oncology and Broadening Research Representation Poster Session

#630 Directly engaging participants in rare cancer research is feasible: the osteosarcoma and leiomyosarcoma projects.

Julia M. W. Wong[1], David Merrell[1], Eirian Siegal-Botti[1], Noorshifa Arssath[1], Carrie Cibulskis[1], Evelina Ceca[2], Alanna Church[3], Alex Wilson[1], Lorena Lazo De La Vega[2], Jill Stopfer[2], Ellen Sukharevsky[2], Nia Daley[2], Anusha Sharma[2], Sidney Benich[2], Zachary Kahn[2], Lauren Fisher[2], Parker Chastain[1], Brendan Reardon[2], Taisha Hendrickson[1], Colleen Nguyen[1], Melissa Chiumiento[1], Melissa Mirick[1], Noriela Elia[1], Priscilla Merriam[2], Eliezer Van Allen[2], Judy Garber[2], Riaz Gillani[2], Chandrajit Raut[4], Stacey Gabriel[1], Timothy Rebbeck[2], Jason L. Hornick[4], Jennifer Mack[2], Suzanne George[2], Diane Diehl[1], Gad Getz[1], Katherine A. Janeway[2]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Boston, MA,[3]Boston Children's Hospital, Boston, MA,[4]Brigham and Women's Hospital, Boston, MA

Background and Purpose: Osteosarcoma (OS) and Leiomyosarcoma (LMS) are sarcomas with complex genomes for which there has been limited progress in identifying new treatments and improving outcomes. While slow progress is partially due to insufficient genomic characterization, generating large genomic datasets has been challenging because these are rare cancers. The OS and LMS Projects use various approaches to directly engage pediatric and adult participants with OS and LMS in genomics research.
Methods: Working with patients and advocates at the design stage, we created websites (OSProject.org and LMSProject.org) where patients register and consent to participation. Any patient with OS or LMS living in the United States or Canada is eligible. Participant outreach approaches include partnership with advocacy organizations, webinars, social media posts, meeting presentations, stakeholder and physician engagement committees, and direct mailings. Blood and saliva are collected directly from consented participants by mail, archival FFPE tumor samples are obtained from pathology departments and medical records are requested from treating institutions. WES, WGS, DNA panel sequencing and RNASeq of tumor and germline (T/N) is performed. Results are shared with patient, advocacy, physician, and research communities in several ways. Individual participants receive a shared learning report describing the somatic variants identified in their tumor from T/N clinical WES and are offered clinical germline genetic testing and genetic counseling.
Results: The study outreach team has participated in or led a total of 33 online and in person events not including social media posts or stakeholder meetings. So far, in 26 months 515 LMS patients (ages 16-83y; median 55) and 145 OS patients (ages 7-74y; median 20) have consented. Thus far, 274 and 76 tumor samples and 555 and 127 germline samples have been obtained from LMS and OS consented participants, respectively. Analysis of the first 20 LMS participants with T/N WGS showed widespread alteration of TP53 (11 pts), RB1 (8 pts), and PTEN (16 pts), concordant with findings in past studies. Likewise, the first 7 OS pts with T/N WGS demonstrated inactivation of TP53 (4 pts) and RB1 (2 pts), as expected from past OS cohorts.
Conclusions: Using community partnerships and direct outreach to connect and engage with participants and a virtual consenting process for genomics research in rare cancers is feasible. It is possible to obtain germline samples directly from about half of participants and archival tumor samples from treating pathology departments for about one third of participants consented in direct-to-patient online genomics studies. We have been able to utilize archival tumor samples to identify, with T/N WES/WGS, expected genomic events in complex genome cancers. Recruitment and sequencing are ongoing.

#631 Building bridges between communities and cancer researchers through the CaRE^2 Health Equity Center Community Scientist Research Advocacy Program.

Carolina Aristizabal[1], Fern Webb[2], Sandra Suther[3], John Luque[3], Eduardo Ibarra[1], Nazleen Del Rio[2], Ileana Guzman[2], Brooke Hensel[2], Janet Rodriguez[1], Rosa Barahona[4], Mariana Stern[5], Lourdes A. Baezconde-Garbanati[4]

[1]University of Southern California, Los Angeles, CA,[2]University of Florida, Orlando, FL,[3]Florida Agricultural and Mechanical University, Tallahassee, FL,[4]Keck School of Medicine, University of Southern California, Los Angeles, CA,[5]University of Southern California Norris Comprehensive Cancer Center, Los Angeles, CA

Building healthy and trustworthy relationships between communities and researchers is essential for cancer research endeavors. Training community advocates in cancer research can increase capacity among community members to leverage networks, participate in research teams and/or boards, and increase knowledge and insights to I'm prove patient outcomes through increased participation in cancer research. The Florida-California Cancer Research Education and Engagement (CaRE^2) Health Equity Center designed a Community Scientist Research Advocacy (CSRA) program to inform, educate, and empower community members to become cancer research advocates. Our program was specifically tailored for Black/African American (B/AA) and Hispanic/Latino/a (H/L) adults living in Florida or California. Primary program objectives were to increase human capacity for cancer research advocacy and increase multi-directional communication between cancer advocates with cancer survivors, community members, academic scientists, and policy makers. The CSRA program was delivered over a 10-week period, with a hybrid model compromised of 90% virtual sessions via Zoom to allow for joint participation across the two coasts, and one in-person experiential lab day at each of our three institutions from our partnership. Didactic online learning sessions covered topics including cancers that disproportionately affect medically underserved populations, participation in clinical trials, genomics, social determinants of health, tissue donation/biorepository, and ethics in research studies. Participants completed pre- and post-surveys to assess knowledge, self-efficacy, and program satisfaction and evaluation; and they also completed a mentored advocacy project upon completion of the program. We provided simultaneous Spanish interpretation during all sessions, and materials were translated and provided in both English and Spanish. The 2024 CSRA cohort (N=18) included 12 females and 6 males; 11 were B/AA and 7 were H/L, 11 were from Florida and 7 were from California. Participants were required to attend at least 80% of sessions including one mandatory in-person lab visit activity; leading to a 100% program completion. When comparison pre- and post-attendance surveys, participants showed increases in knowledge (p-value = 0.007) and self-efficacy (p-value = 0.3). Program satisfaction and evaluation were rated as high. In summary, our program demonstrates the effectiveness of training community members to become cancer research advocates to help reduce the burden of inequities in cancer research and care. CSRA programs increase communication between scientists and communities to bring education and awareness about clinical studies and cancer research. Thus, promoting diverse participation in cancer studies, and eventually reducing cancer health disparities.

#635 Unraveling the potential of neogenin 1 in non-small cell lung cancer: A path toward innovative combination therapies.

Asmita Pandey[1], Shaoqiu Chen[2], Li Ma[2], Mayumi Jijiwa[2], Masaki Nasu[2], Vedbar Khadka[2], Yu Chen[2], Hua Yang[2], Sudhir Rai[2], Youping Deng[2]

[1]Department of Tropical Medicine, Medical Microbiology, and Pharmacology, John A. Burns School of Medicine University of Hawaii at Manoa, Honolulu, HI,[2]Department of Quantitative Health Sciences, Bioinformatics Core, John A. Burns School of Medicine University of Hawaii at Manoa, Honolulu, HI

Non-small cell lung cancer (NSCLC) has a poor survival rate due to delayed diagnosis and treatment resistance. Currently, immunotherapy has advanced the NSCLC treatment; however, only a small fraction of patients respond to the therapy, demanding the identification of novel biomarkers associated with resistance to develop new therapeutic strategies. Herein, we investigated the role of neogenin 1, a transmembrane protein that belongs to the immunoglobulin superfamily, in seven different human NSCLC cell lines and compared the expression with Jurkat T cell line and human peripheral blood mononuclear cell (PBMC)-derived CD3/CD28-activated CD8+ T cells using qPCR and western blot. We also performed the cell proliferation assay in adenocarcinoma (LUAD) and squamous cell carcinoma (LUSC) human cell lines after knockdown and overexpression of neogenin 1. We found that neogenin 1 was highly expressed in primary CD8+ T cells compared to the cancer cell lines, implying that genetic alteration of neogenin 1 might interfere more with CD8+ T cell effector function. We also discovered that both adenocarcinoma and squamous cell carcinoma cell proliferation ability were influenced by genetic alteration of neogenin 1. In addition, gene ontology enrichment analysis and KEGG pathway analysis indicated that neogenin 1 was involved in the TGF-beta signaling pathway, possibly suggesting that neogenin 1 might play a role in therapeutic resistance, including immunotherapy, in NSCLC. Correlation analysis in LUAD and LUSC in the TCGA dataset also revealed that neogenin 1 was positively correlated with a set of genes, such as IGF1R and USP8, associated with immunotherapy resistance. Further investigation of this potential gene *in vivo* will unfold its role in immunotherapy resistance in NSCLC, paving the way for developing novel and effective combinatorial therapeutic strategies targeting neogenin 1.

#636 ABT-863: The next generation anti-CCR8 immuno-oncology antibody therapeutic.

Pia Kuss, Karen Chiang, Alexander Alexandrov, Le Li, Riccardo Contu, Christopher Roth, Anke Kretz-Rommel, Mauro Mileni

Abilita Therapeutics, San Diego, CA

The chemokine receptor CCR8 has come into focus based on its upregulation on immune suppressive Tregs within the tumor microenvironment in a range of solid tumors, eg breast, colon, and lung cancers. This finding has spurred efforts to develop CCR8 targeting antibodies (mAbs) that can selectively target and deplete this Treg population to augment the antitumor immune response and the efficacy of cancer therapies, including checkpoint inhibitors. To date, the development of several clinical antibodies primarily focuses on the depletion of CCR8-expressing Tregs through enhanced Antibody Dependent Cellular Cytotoxicity and Antibody-Dependent Cellular Phagocytosis. While these antibodies have been reported to compete with CCL1, CCR8's endogenous ligand, the simple inhibition of the receptor, without a depletion mechanism, has failed to demonstrate tumor suppression in mouse models. Overall, the impact of CCR8 expression on the Treg phenotype and its involvement in cancer progression remains to be fully elucidated. Abilita Therapeutics has instead focused on maximizing the inhibition of CCR8 function by developing potent inverse agonists based on single domain heavy chain antibody (VHH) scaffolds that engage the receptor's orthosteric pocket in the transmembrane domain to inhibit both CCL1 agonism and ligand-independent signaling. Our development candidate ABT-863 was discovered using Abilita's proprietary Enabled Membrane Protein (EMP) platform. EMP technology was leveraged to generate a stabilized CCR8 variant, which was key to llama immunization, protein-based antibody selections, and affinity maturation of the humanized VHH. ABT-863 is formatted as a bivalent VHH-Fc fusion that demonstrates excellent affinity, selectivity, and an optimal developability profile. In preclinical studies using human CCR8 knock-in mice, ABT-863 demonstrated significant tumor growth inhibition in both the MC38 (murine colon carcinoma) and CMT167 (murine lung carcinoma) models. Remarkably, an Fc effector-null version of the antibody demonstrated efficacy in absence of Treg depleting activity, both as monotherapy or in synergy with anti-PD1, which contrasts with what others have reported. Because of its distinct pharmacology, this mechanism may offer more robust modulation of the TME and immune responses, potentially enhancing therapeutic efficacy, while avoiding unnecessary safety risks of depleting Tregs in healthy tissues or other CCR8-expressing cell types. In conclusion, ABT-863 is a differentiated first-in-class inverse agonist antibody with the potential to provide superior efficacy, improved safety and more favorable patient outcomes.

#637 Single-cell analysis of systemic immune response to sequential radiation and immune checkpoint blockade in metastatic colorectal cancers.

Joshua Brand[1], Sean G. Kraus[2], Michael Bassetti[3], Dustin A. Deming[2], Huy Q. Dinh[2]

[1]Department of Pathology and Laboratory Medicine, University of Wisconsin-Madison, Madison, WI,[2]Department of Oncology, University of Wisconsin-Madison, Madison, WI,[3]Department of Human Oncology, University of Wisconsin-Madison, Madison, WI

Immune checkpoint blockade (ICB) has shown significant clinical efficacy in mismatch repair deficient colorectal cancers (CRCs). However, an effective means to use these therapies for mismatch repair proficient (pMMR) CRC has yet to be developed. To enhance the efficacy of ICB for patients with oligometastatic pMMR CRC, we performed a clinical trial evaluating the sequential use of stereotactic body radiotherapy (SBRT), pembrolizumab, surgical resection, and then adjuvant pembrolizumab (NCT02837263). The primary endpoint of 1-year recurrence-free survival (1 yr RFS) was met in 60% of trial participants compared to a historical control of 50%. From this trial, 13 subjects could have blood samples collected for peripheral blood mononuclear cell isolation pretreatment and after operative management. We hypothesize that the systemic immune response changes upon combined treatment and is distinct between responders and non-responders. We performed scRNA-Seq on these samples to compare the circulating immune cell populations with clinical outcomes. Despite a small sample size, integrated bioinformatics analysis identified (i) pre-existing CD8+ T cells were observed with treatment response ($p = 0.031$) (ii) combined RT and ICB induces changes in myeloid cell phenotypes, including reduced pro-inflammatory monocytes ($p = 0.038$) and conventional cDC2 ($p = 0.030$) in subjects without recurrence and increasing pDCs ($p = 0.024$) in most patients. CD8+ T cells from those recurrence-free subjects showed terminally differentiated effector phenotypes, expressing *CX3CR1*, *GZMB*, and *KLRG1* before treatment. cDC2s expressed interferon activity markers, including *STAT1*, *IFI44*, and I*RF7,* that presented a more activated state. CD8+ T cell abundance remained stable, with no significant changes before and after treatment. In contrast, myeloid cells showed greater variability, reflecting unique polarization states through differences in cytokine (*CCL3*, *CXCL8*), interferon (*ISG15*, *IFI44*), and complement (*C1QA*, *C1QB*) associated genes. Future work will increase sample size in independent patient cohorts to elucidate the extent to which circulating phenotypes are also identified in tumors. Overall, this study demonstrates pre-existing T cell abundance and changes in myeloid cell phenotypes may be associated with clinical outcomes from combined immunotherapy, which have the potential to serve as predictive biomarkers for therapeutic response.

#638 Discovery of HX016-7, a novel PD-L1 x VEGF BsAb, as a new candidate treatment of solid tumors.

H. Ke[1], T. Yang[1], F. Peng[1], J. Li[1], C. Chen[1], S. Xiong[2], L. Zhang[1], F. Zhang[1], **H. Q. Li**[1];
[1]Hanx Bio, Hangzhou, China, [2]Crown Bioscience, Taicang, China

A first-in-class PD-L1xVEGF bispecific antibody (BsAb), BNT327/PM8002, has demonstrated promising efficacy in treating TNBC and NSCLC cancers in advance stage of clinical development, which prompted us to engineer a novel and potentially best-in-class (BIC) PD-L1xVEGF BsAb by using a validated anti-PD-L1 and a novel anti-VEGF (HX006, a novel VEGF mAb with more favor activity over Avastin) mAb sequences. HX016-7 has 2+2 IgG1 symmetric structure constructed by grafting the PD-L1 binding domain of PD-L1 mAb onto the N-terminus of HX006. HX016-7 binds with similarly affinity to PD-L1 recombinant protein with EC_{50} of 0.27nM (vs. 0.36nM by BNT327/PM8002) and to VEGF recombinant protein with EC_{50} of 0.094nM (vs. 0.063 by BNT327) in ELISA assay. It also binds similarly to the PD-L1 positive cell line as BNT327/PM8002 with comparable affinity. Reporter-based bioassay for PD1/PD-L1 blockade function demonstrated that HX016-7 has EC_{50} of 4.85 nM (vs. 5.13nM for BNT327/PM8002), while reporter-based bioassay for VEGF function demonstrated that HX016-7 has EC_{50} of 11.7nM (vs. 15.8nM for BNT327/PM8002). In a MC38-hPD-L1-hVEGF colorectal cancer syngeneic model implanted in hPD-1 humanized mice, HX016-7 was shown to have comparable anti-tumor activity as BNT327/PM8002, but stronger activity over HX006, which can be attributed to both PD-L1- and VEGF-targeting. In a subcutaneous A549 non-small-cell lung cancer (NSCLC) cell-derived xenograft model in immunocompromised mice, HX016-7 also showed slightly stronger anti-tumor activity over BNT327/PM8002, which can be attributed to anti-VEGF function. We believe these preclinical data warrants the candidacy of HX016-7 to be further developed for the treatment of solid tumors.

#639 Targeting TET3 potentiates an effective anti-tumor immune response after irradiation.

Sera Averbek, Stephen J. Kron

Ludwig Center for Metastasis Research and Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL

The benefits of radiotherapy (RT) have long been appreciated as limited by formation and repair of DNA double-strand breaks (DSBs) in tumor cells, but recent understanding has identified a key role for RT and DNA damage in promoting inflammation that drives anti-tumor immune response. While chromosomal DSBs indeed directly limit cancer cell survival and proliferation, RT-induced damage leads to cytosolic DNA that activates cGAS/STING/IRF3 signaling and drives IFNα/β expression, recruiting cytotoxic T and NK cells to shrink tumors. In turn, along with DSB repair, another determinant of RT resistance is rebound immunosuppression. Here, IFNγ released by the infiltrating lymphocytes activates JAK/STAT to induce interferon-stimulated genes (ISGs) including PD-L1 that can reduce tumor inflammation and restore growth. Though combining PD-1/PD-L1 blockade with RT is sufficient to block this adaptive response in mice, the lack of benefit to patients suggests the need to more broadly target immunosuppressive ISG expression. Targeting IFNγ signaling by blocking JAK/STAT may limit immunosuppressive ISG expression but will impair T and NK cytotoxicity. Looking downstream, blocking JAK/STAT-dependent ISG promoter CpG demethylation by Ten Eleven Translocation (TET) dioxygenase enzymes may prevent PD-L1 expression without affecting cytotoxicity. In this study, we disrupted TET activity with small-molecule inhibitors and CRISPR RNP knockouts (KO) to evaluate effects on radiation response *in vitro* and in tumors. As predicted, TET inhibitors blocked PD-L1 induction in irradiated CT26 murine colon carcinoma cells. Assaying TET1, 2 and/or 3 KO CT26 cells for PD-L1 induction identified TET3 as the critical mediator. TET3 KO cells also exhibited slower DSB repair after irradiation, associated with markedly increased ssDNA resection and cytosolic DNA. The irradiated TET3 KO cells also displayed enhanced IFNα/β expression, suggesting intact cGAS/STING/IRF3 signaling. While TET3 KO CT26 cells formed tumors in syngeneic BALB/c mice much like CT26 controls, RT produced greater NK cell infiltrates by one week and increased tumor elimination by two weeks. TET3 KO 4T1 mammary carcinoma cells formed orthotopic tumors in BALB/c mice but produced fewer lung metastases compared to controls. In conclusion, TET3 may offer an attractive, druggable target for radiosensitization by slowing DSB repair, enhancing tumor inflammation, and blocking immunosuppressive ISG expression.

#64 Depleting CD38 leads to an aggressive phenotype of multiple myeloma.

Michael Riley Dyer, Alexander Zheleznyak, Rui Tang, Julie Prior, Erin Teubner, Brad Manion, Mikhail Y. Berezin, Junwei Du, Julie O'Neal, Monica Shokeen

Radiology, Washington University School of Medicine in St. Louis, St. Louis, MO

Introduction: Multiple myeloma (MM), the second most common hematological cancer in the United States, is characterized by the proliferation of malignant clonal plasma cells within the bone marrow. Since the FDA approval of Daratumumab in 2015, CD38-targeted immunotherapies have significantly advanced the treatment of MM, improving patient response. However, due to the multifunctional role of CD38 in the complex bone microenvironment, its role in MM remains under investigation. This study examined the effect of modulating CD38 expression by using a CD38 knock-out (KO) clone of a human MM cell line xenografted into immunodeficient mice.
Methods: CRISPR/Cas9 gene editing was used to KO CD38 expression in the MM.1S human MM cell line, confirmed with RNA sequencing and flow cytometry. After tumor implantation in mice, bioluminescence imaging (BLI) monitored tumor burden. PET was performed using [^{18}F]-FDG to detect metabolic activity and [^{89}Zr]-Daratumumab to analyze human CD38 expression throughout the body. Post-PET tissue biodistribution and select bone autoradiography were performed to evaluate the specificity of tracer uptake. CT, dual-energy X-ray (DEXA), and immunohistochemistry were used to quantify changes in bone mineral density and osteolytic disease. The imaging results were corroborated with changes in blood composition and cytokine production in the microenvironment.
Results: After the cells were implanted into mice, BLI showed a significant tumor burden increase in CD38 KO MM models compared to WT MM models at 4 weeks. CT and DEXA imaging revealed that the KO mice had significantly decreased bone density, and similarly, planar X-ray imaging indicated severe myeloma bone disease characterized by cortical and trabecular osteolytic lesions in the femur and tibia. [^{89}Zr]-Daratumumab accumulated in the spine, femur, and tibia in WT MM mice, with minimal bone uptake in CD38 KO MM mice. [^{18}F]-FDG PET revealed an increased metabolic activity of CD38 KO MM, with an aggressive kinetic uptake of the tracer. Blood analysis indicated elevated markers of disease progression and renal dysfunction, with reduced leukocyte and thrombocyte production in CD38 KO MM xenografts. Cytokine profiling revealed altered levels of pro-inflammatory cytokines, including IL-6, RANKL, and VEGF-α in the bone microenvironment of MM with depleted CD38. RNA sequencing showed significant transcriptional changes in CD38 KO cells, particularly in cell adhesion and inflammatory pathways.
Conclusions: The findings underscore CD38's critical role in MM progression, where its depletion drives an aggressive phenotype marked by widespread metastasis, extensive bone degradation, renal involvement, and heightened immunosuppression. These results showcase the critical importance of CD38 expression levels and suggest a potential role for CD38 and related transcriptional changes in contributing to the aggressive phenotype of MM.

#640 Augmenting T-cell bispecific antibody therapy in AML through co-stimulatory agonists.

Anne-Sophie Neumann[1], Gerulf Hanel[1], Vesna Kramar[2], Christina Claus[2], Kieron White[1], Amelie Muth[1], Lis Winter[1], Monika Sponheimer[1], Giulia Rappa[1], Sebastian Theurich[1], Veit L. Bucklein[1], Pablo Umana[2], Christian Klein[3], Marion Subklewe[1]

[1]Department of Medicine III, University Hospital LMU Munich, Munich, Germany,[2]Pharmaceutical Research & Early Development, Roche Innovation Center Zurich, Schlieren, Switzerland,[3]Curie.Bio, Zurich, Switzerland

The classical two-signal model states that T-cell activation requires TCR/CD3 engagement (signal 1) and co-stimulation (signal 2) via e.g. CD28 or 4-1BB. T cell bispecific antibodies (TCBs) activate T cells solely through CD3 engagement, bypassing co-stimulatory pathways. However, the efficacy of TCB-mediated cytotoxicity against acute myeloid leukemia (AML) cells is determined by co-stimulatory and co-inhibitory ligands expressed on AML cells (Marcinek et al., 2023). Thus, we hypothesized that TCB-mediated T-cell responses could be enhanced by combination with targeted co-stimulation, particularly in AML cases lacking co-stimulatory ligands. Accordingly, we evaluated the combination of the AML-targeting Wilms tumor 1 (WT1)-TCB with co-stimulatory agonistic bispecific antibodies, targeting 4-1BBL or OX40 and fibroblast activation protein (FAP) expressed on bone marrow stromal cells.Efficacy of WT1-TCB + FAP-4-1BBL or FAP-OX40 was evaluated in co-culture assays with human AML cell lines or murine Ba/F3 cell lines expressing hu4-1BBL or huCD86, healthy donor T cells and an NIH-3T3 fibroblast cell line expressing FAP. In addition to short-term assays (4 days), we co-cultured cells over 28 days to address T-cell exhaustion in the context of continuous target antigen exposure. Lastly, we investigated the impact of co-stimulation in an *ex vivo* setting with primary AML cells (pAML). T-cell activation, phenotype, cytotoxicity, and metabolic fitness were assessed by MPFC, bulk RNA sequencing, and Seahorse assays. Addition of FAP-4-1BBL strongly enhanced WT1-TCB-mediated cytotoxicity against the AML cell line Set-2, which shows a low expression of co-stimulatory ligands. Although FAP-OX40 did not enhance cytotoxicity, it increased T-cell proliferation. T-cell responses against AML cell lines with high expression of co-stimulatory ligands (SKM-1, OCI-AML3, OCI-AML2) did not show any improvement by the combinatorial approaches. The results were confirmed in the murine Ba/F3 system, showing that especially the presence of hu4-1BBL on the cell surface cancels out the positive effect of the combinatorial approaches. Results could be validated using pAML samples. Importantly, considering the continuous application of TCBs in the clinics, long-term cultures over 28 days showed that adding FAP-4-1BBL or FAP-OX40 preserved T-cell function (proliferation, cytokine secretion, cytotoxicity, and metabolic fitness) over time compared to WT1-TCB alone. Improvements were again stronger and more durable for the combination with FAP-4-1BBL than with FAP-OX40. We conclude, that combining a WT1-targeting TCB with a 4-1BB agonist significantly enhanced T-cell activity against AML cell lines and primary AML samples. Notably, this positive immune modulation persisted in long-term cultures, counteracting T-cell exhaustion caused by continuous TCB stimulation.

#641 Identification of anti-tumoral neutrophil phenotypes induced by immunotherapies in head and neck cancer.

Anqi Gao[1], Amy Erbe-Gurel[1], Natalie B. Winn[1], Joel Matthews[1], Kaia N. Heimstreet[1], Wei Wang[2], Paul F. Lambert[1], Paul M. Sondel[1], Huy Q. Dinh[1]

[1]University of Wisconsin-Madison, Madison, WI,[2]Michigan State University, East Lansing, MI

Only ~20% of recurrent and metastatic head and neck squamous cell carcinoma (HNSCC) patients respond to immune-checkpoint blockade (ICB) therapy. A major roadblock is the immunosuppressive nature of the tumor microenvironment. Increased infiltration of neutrophils in blood and tumors of HNSCC patients is associated with worse prognosis and ICB therapy resistance. Depleting neutrophils, however, with or without ICB treatment, has not inhibited tumor growth in mice bearing syngeneic MOC2 tumors, which are phenotypically analogous to immunologically “cold”, aggressive HNSCC tumors. We hypothesize that this is due to the heterogeneity of tumor-infiltrated neutrophils with both pro- and anti-tumoral phenotypes. This study uses multi-omics single-cell profiling, combining RNA and protein, to identify pro- and anti-tumoral neutrophil states in MOC2 tumors treated with recently reported neutrophil-related therapies. Specifically, we tested anti-CD40 agonist, TNF-alpha, and both in combination with cetuximab, an anti-tumor antibody (designated Neutrophil Activating Therapy, NAT) that has been recently reported in other cancers. Cetuximab (an anti-EGFR mAb) was used for MOC2-huEGFR (M2h), an HNSCC cancer model transduced with human-EGFR. We found this treatment induced new neutrophil subsets, defined by scRNA-Seq bioinformatics analysis. One subset has recently reported interferon-stimulated phenotypes, which we found in the anti-CD40 alone, and NAT combinatorial treatment groups; these two groups also showed the best anti-tumor efficacy. Gene signature of this subset is also found in scRNA-Seq of infiltrating neutrophils in our previous K17-KO MOC2 model, which shows spontaneous tumor regression in the absence of therapy. In addition, we identified a neutrophil subset associated with migration-related transcription factors only in NAT and TNFa treatment groups, which might explain why NAT is superior to anti-CD40 alone. Our findings thus far demonstrate the presence of neutrophil heterogeneity, with some phenotypes associated with anti-tumor responses, including a potentially new phenotype, in a murine head and neck cancer model induced by a combination of immunotherapies. Ongoing and future work includes identifying specific synergistic mechanisms of the anti-tumoral neutrophil subpopulations induced by anti-CD40 and TNF-alpha treatment and if these phenotypes are also seen in ICB-treated HNSCC patients who respond to their therapy. We anticipate our characterization of anti-tumoral neutrophil phenotypes induced by NAT in M2h tumors may provide insights into how more effective immunotherapy regimens beyond ICB can be designed to confer tumor clearance and prolonged survival in patients with head and neck cancer.

#642 Peripheral immune cells associated with toxicity to ipilimumab plus nivolumab checkpoint blockade in patients with metastatic melanoma.

Jiajia Chen[1], Joanna Baginska[1], Giuseppe Tarantino[1], Kelly Burke[1], Elad Sharon[2], Anita Giobbie-Hurder[1], Jason L. Weirather[1], Michael Manos[1], Janice D. Russell[1], Ryan Brennick[1], Matthew Nazzaro[1], Emma Hathaway[1], Marta Holovatska[1], Claire Manuszak[1], Srinika Ranashinge[1], David Liu[1], F. Stephen Hodi[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]National Institutes of Health, Bethesda, MD

Background: Immune checkpoint blockade (ICB) has revolutionized clinical outcomes in melanoma. Compared with single ICB (aCTLA-4, aPD-1), combination ICB aCTLA-4 plus aPD-1 shows the highest response rate, with 50%-60% patients responding to treatment. However, it also has the highest toxicity rate, with about 50% patients developing high grade toxicity. Identifying circulating immune cells as biomarkers to predict toxicity could guide clinical decisions and shed light on potential mechanisms driving toxicity.
Methods: We identified and quantified circulating immune cells proportions using CyTOF (cytometry by Time-Of-Flight), measured cytokines using Luminex, and collected complete blood counts from 89 patients with metastatic melanoma treated with combination therapy. Samples were obtained from three points in time: pre-treatment, one month and approximately three months after treatment started. We then evaluated the association between circulating immune cells, cytokines, clinical labs values, and high grade toxicities (grade >=3 or grade 2 requiring treatment). We also investigated the co-occurrence patterns of toxicity at various organs systems, as well as the onset timing of different grades of toxicities.
Results: Most high grade toxicities occurred between 3 and 18 weeks after start of therapy, consistent with prior studies. Interestingly, we found a statistically significant mutual exclusivity of high grade lung and gastrointestinal toxicities (Fisher's exact, $p = 0.01$, OR = 0). In contrast to prior results, we found that in pre-treatment blood samples higher naïve T cells, lower central memory T cells (TCM) and effector memory T cells (TEM) are associated with development of high grades toxicities (MWW, $p = 0.002$, $p = 0.043$, $p = 0.009$). A greater increase in CD8+ TEMs from pre to post1 time points (MWW, $p = 0.047$), while a lower increase in basophils (MWW, $p = 0.030$), was associated with patients with high grade toxicities.
Conclusions: Collectively, our findings help gain more insights into the development of toxicities, and could ultimately guide the development of personalized strategies for toxicities prevention, surveillance, and mitigation in melanoma patients treated with combination immunotherapy.

#643 Efficacy and safety comparison of CAR-T and blinatumomab immunotherapy as bridge-to-transplant strategy in relapsed/refractory B cell acute lymphoblastic leukemia.

Wenyue Cao[1], Ningwen Li[2], Na Wang[2], Yang Cao[2]

[1]Texas A&M University, Houston, TX,[2]Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: B cell acute lymphoblastic leukemia (B-ALL) remains a therapeutic challenge despite advances. Hematopoietic stem cell transplantation (HSCT) provides a potential cure but is hindered by various limitations. Emerging immunotherapies, including chimeric antigen receptor T cell (CAR-T) therapy and Blinatumomab, have shown potential as bridging strategies to HSCT in relapsed/refractory (R/R) cases.
Methods: A retrospective study was conducted at Tongji Hospital from March 2017 to March 2023, involving 36 R/R B-ALL patients who underwent HSCT. Prior to transplantation, 27 patients received CD19/CD22 CAR-T therapy, while 9 received Blinatumomab. Outcomes assessed included the overall survival (OS), progression-free survival (PFS), graft-versus-host disease-free and relapse-free survival (GRFS), and non-relapse mortality (NRM) , with comparisons made between treatment groups. Hematopoietic reconstitution and transplant-related complications were also evaluated.
Results: The median follow-up time was 28.07 (range: 2.29-92.21) months. The 2-year OS, PFS, GRFS, and NRM of the entire cohort were 76.54%, 54.97%, 40.12%, and 9.93%, respectively. In the CAR-T and the Blinatumomab treatment group before transplantation, the 2-year OS was 73.89% and 88.89% (P=0.862), PFS, was 59.03% and 44.44% (P=0.501), GRFS was 47.86% and 13.89% (P=0.083), and NRM was 8.52% and 11.11% (P=0.713), respectively. Safety profiles were similar with no significant differences observed in hematopoietic reconstitution, infection, the incidence of grade II-IV acute graft-versus-host disease (GVHD) and chronic GVHD incidence between CAR-T and Blinatumomab groups.
Conclusion: CAR-T and Blinatumomab therapies demonstrate comparable safety and efficacy as bridging treatments to HSCT in patients with R/R B-ALL. Further studies are needed to optimize these treatment strategies.

#644 Cytokine-induced memory-like NK cells with tafasitamab show efficacy against B-cell acute lymphoblastic leukemia.

Dimitrios Filioglou, Geovana Leite, Helena Batatinha, Nina Santa-Cruz, Dan Davini, Richard Simpson, Emmanuel Katsanis

University of Arizona, Tucson, AZ

Introduction: While chimeric antigen receptor (CAR)-T cells can be effective in treating B-cell acute lymphoblastic leukemia (B-ALL), Natural Killer (NK) cell therapies are showing promise as an easier to manufacture product with potent activity in early studies. Cytokine-induced memory-like NK cells (CIMLNK) are generated by brief stimulation with the cytokines IL-12, IL-15, and IL-18 and demonstrate enhanced anti-cancer responses. Tafasitamab (TAFA) is an Fc-enhanced humanized anti-CD19 monoclonal antibody designed to enhance anti-tumor activity through antibody-derived cellular cytotoxicity (ADCC), a function primarily mediated by NK cells. Therefore, we hypothesized that combining TAFA with CIMLNK can augment responses against B-ALL.
Methods: NK cells were isolated from peripheral blood mononuclear cells (PBMCs) of healthy volunteers. For the generation of CIMLNK, NK cells were incubated overnight with IL-12, IL-15, and IL-18. For flow cytotoxicity assays, target cells (NALM-6, a B-ALL cell line) were co-incubated with the effectors (NK or CIMLNK) at 2.5:1 effector: target (E: T) ratio, with or without TAFA (1 µg/ml). Degranulation and IFN-γ release assays were performed to examine mechanistic differences between effector responses. CD16 blocking assays were done using a purified anti-CD16 mAb to assess the role of CD16 binding in TAFA-induced ADCC. In vivo, irradiated NSG mice received 1 x 10^4 Nalm6-luc intravenously (i.v.). The next day, 1 x 10^6 CIMLNK were injected i.v., with TAFA given at 0.3 - 0.5 mg/kg, i.v. or intraperitoneally (i.p.) respectively. Statistical analyses were performed using GraphPad Prism v10. P values of < 0.05 were considered significant.
Results: Cytotoxicity assays showed that CIMLNK + TAFA resulted in significantly higher killing of NALM6 compared with CIMLNK alone 84.4% vs 22.7%, (p=0.0005) and NK+TAFA 84.4% vs 38.3%, (p=0.0006). CIMLNK alone demonstrated significantly higher cytotoxicity against NALM6 compared to NK cells, 22.7% vs 1.2% (p=0.02). Cytotoxicity was not observed when TAFA was used alone. Mechanistically, we observed that combining TAFA with CIMLNK led to a significant increase in degranulation, 55.4% vs 13.3%, (p=0.02) and IFN-γ release, 26.7% vs 3.6%, (p=0.03) compared to CIMLNK monotherapy. Moreover, in the presence of TAFA, CIMLNK degranulated significantly more compared to unstimulated NK cells, 55.4% vs 27.7% (p=0.04). The addition of anti-CD16 mAb to CIMLNK abrogated TAFA-induced ADCC. In vivo, combining CIMLNK with TAFA resulted in a median survival of 35 days, which was significantly higher than that seen in untreated mice (28 days, p= 0.01), TAFA monotherapy (28 days, p= 0.003) and CIMLNK monotherapy (26.5 days, p=0.009).
Conclusion: The combination of CIMLNK and TAFA exerts synergistic effects against B-ALL both in vitro and in vivo.

#646 Unravelling the mechanisms of resistance and hyperprogression of renal medullary carcinoma to immune checkpoint therapy.

J. Qian[1], M. Soeung[2], X. Yan[1], K. Yu[1], C. Zanca[1], L. Zhang[1], Z. Chen[1], L. Perelli[1], J. Chen[1], R. S. Tidwell[1], H. Khan[1], F. Duan[1], M. Karki[1], R. He[1], C. N. Le[1], T. N. Lam[1], N. Bhattacharya[1], M. N. Williams[1], D. H. Peng[1], R. Shah[1], I.-L. Ho[1], N. Feng[1], N. M. Zacharias[1], R. A. Sheth[1], T. K. Bathala[1], P. Rao[1], N. C. Daw[1], D. N. Tripathi[3], C. L. Walker[4], R. Wang[1], M. Dang[1], E. Dai[1], F. Peng[1], Y. Liu[1], A. S. Jadhav[1], W. Lang[1], C. A. Arrechedera[1], L. Campos Clemente[1], H. Lu[1], C. L. Haymaker[1], I. I. Wistuba[1], A. [1]UT MD Anderson Cancer Center, Houston, TX, [2]Dana-Farber Cancer Institute, Boston, MA, [3]FDA, Silver Spring, MD, [4]Baylor College of Medicine, Houston, TX

Renal medullary carcinoma (RMC) is defined by the loss of the SMARCB1 tumor suppressor and represents one of the most aggressive kidney cancers, predominantly affecting young individuals of African descent with the sickle cell trait. RMC exhibits rapid progression, and poor response to standard therapies, with a median survival of only 13 months following diagnosis. In pursuit of more effective treatments, we launched two clinical trials specifically for patients with RMC evaluating anti-PD1 + anti-CTLA4 immune checkpoint therapy (ICT) with nivolumab + ipilimumab (ClinicalTrials.gov identifier: NCT03274258) and anti-PD1 + anti-LAG3 ICT using nivolumab + relatlimab (ClinicalTrials.gov identifier: NCT05347212). However, both trials were terminated early for futility due to resistance and hyperprogression by the established consensus Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 radiological criteria in Matos et al. Clin Cancer Res. 2020 (PMID: 31757877). Co-clinical experiments testing the same ICT regimens in our immunocompetent somatic mosaic genetically engineered mouse model (GEMM) of RMC demonstrated similar patterns of resistance and hyperprogression with ICT compared with IgG control. The combination of anti-PD1 with either anti-CTLA4 or anti-LAG3 significantly accelerated primary tumor progression and markedly increased metastatic burdens in the lung and liver of RMC mice. Comprehensive analyses, including longitudinally collected single-cell RNA sequencing from human RMC patient samples and RNA sequencing of GEMM RMC tumors revealed significant transcriptional reprogramming, enhanced tumor proliferation, activation of oncogenic pathways, and a shift toward myeloid-specific gene expression by RMC tumor cells in response to ICT. In our RMC mouse models, tumor cells have been engineered to express green fluorescent protein (GFP), enabling us to distinguish them from non-malignant mouse cells. Accordingly, multiplex immunofluorescence (mIF) revealed that tumor tissues from mice treated with ICT showed a significant increase of tumor cells co-expressing GFP and myeloid markers such as CD68, F4/80 and S100A9. Differential patterns of resistance and hyperprogression when RMC mice were treated with monotherapies targeting PD1, CTLA4, or LAG3. To counteract ICT-induced hyperprogression, we tested the CEBPB/p300 complex inhibitor IACS16898 which successfully induced tumor responses when combined with ICT in our RMC GEMM. IACS16898 treatment significantly reduced the expression of myeloid-associated markers on GFP+ tumor cells. Our study not only elucidates a novel mechanism of resistance and hyperprogression to PD1 plus either CTLA4 or LAG3 inhibition in SMARCB1-deficient cancers but also provides a foundation for targeting oncogenic and resistance pathways in RMC treated with distinct immunotherapy regimens.

#647 Intratumoral activation of anti-tumor CD4Th1 cells prior to neoadjuvant chemotherapy eradicate metastasis initiating cancer cells in breast cancer patients.

Ganesan Ramamoorthi[1], Marie Catherine Lee[2], Carly M. Farrell[2], Hyo S. Han[2], Caitlyn N. Balsay-Patel[2], Grace Spiegelhoff[1], Brian J. Czerniecki[2]

[1]Clinical Science and Immunology, Moffitt Cancer Center, Tampa, FL,[2]Department of Breast Oncology, Moffitt Cancer Center, Tampa, FL

Clinical overt metastases emerge from metastasis initiating cancer cells (MICs) disseminated during early tumor progression prior to clinical diagnosis of apparent primary breast cancer (BC). Targeting and inhibiting dissemination of MICs from early tumor lesions can be a potential therapeutic strategy to prevent late recurrence and metastasis in patients. Unfortunately, no such therapy currently exists that inhibits MIC dissemination and metastatic seeding in distant organs. Our recent findings support the critical contribution of intratumoral delivery of type 1 conventional dendritic cells (cDC1) in complete eradication of primary BC in patients. We demonstrated that intratumoral activation of anti-tumor CD4T helper 1 (CD4Th1) cells by tumor antigen targeting cDC1 limits MIC dissemination mechanisms independent of CD8 T cells in BC mouse models. Anti-tumor CD4Th1 cells also restored the loss of nuclear receptor subfamily 2 group F member 1 (NR2F1) in human epidermal growth factor receptor 2 (HER2)+ early tumor lesions, reducing dissemination of MICs. Moreover, CD4Th1 cytokine Interferon gamma inhibited dissemination of MICs from early lesions and primary tumors via the modulation of HER2/progesterone receptor/Wnt4/receptor activator of nuclear factor-κB ligand (RANKL) dissemination mechanisms. Most strikingly, we provide clinical evidence that intratumoral activation of anti-tumor CD4Th1 cells inhibited disseminating MIC phenotypes in the tumor lesion of BC patients. This was further corroborated by the decreased seeding of disseminated MICs in the bone marrow of BC patients treated with intratumoral cDC1 prior to any standard neoadjuvant chemotherapy (NACT) compared to patients treated with standard NACT or patients with no prior treatment. Single cell RNA sequencing (scRNA-seq) of isolated MICs (disseminated cancer cells; DCCs) from bone marrow of BC patients with no prior treatment revealed that these patient MICs were highly enriched for cytokeratin 10/13, heterogeneity, stemness and loss of MHC class II and displayed a unique transcriptome profile. Our ongoing clinical study is investigating isolated MICs from patients treated with intratumoral cDC1 and standard NACT at a single cell level by scRNA-seq. Collectively, these results provide a new strategy to selectively target and inhibit dissemination of MICs from the early tumor lesion and prevent overt metastasis in patients. This is also the first study to delineate the transcriptome profile of MICs (DCCs) from BC patients using scRNA-seq.

#648 Activity of BNT327/PM8002 (PD-L1 x VEGF-A bispecific antibody) in combination with BNT325/DB-1305 (TROP2 ADC) in solid tumors: Early preclinical and clinical evidence to support BNT327 + ADC combinations.

Emerging data suggest that IO-ADC combinations may lead to better patient outcomes. BNT327 (also known as PM8002) is an investigational anti-PD-L1 x VEGF-A bispecific antibody that has shown encouraging efficacy and tolerability across tumor types, including “cold” tumors not generally responsive to IO therapies (eg, low PD-L1 levels) (Wu J, SABCS 2024 PS3-08; Wu YL, ESMO 2024 1255MO). BNT325 (also known as DB-1305) is an investigational topoisomerase-I-inhibitor-based anti-TROP2 ADC that has so far shown manageable safety and encouraging early clinical activity (Rubinstein M, SGO 2025). The combination of BNT327 with BNT325 may allow for improved efficacy without compounding overlapping toxicities. The monotherapy safety profiles are characterized by low-grade proteinuria, hypertension, and elevated transaminases (BNT327; Guo Y, ASCO 2023 #414802) and stomatitis (BNT325; Marathe O, ESMO 2023 689P). Herein we provide evidence of early preclinical and clinical data to support the novel combination of an anti-PD-L1 x VEGF-A bispecific antibody with an ADC. Preclinical *in vivo* models testing the combination of BNT327 with BNT325 showed superior tumor growth inhibition (TGI) compared with each treatment alone. In a xenograft A375 + PBMC co-injection model (hTROP2^{+}A375 in B.NDG B2M KO plus mice), the combination of BNT325 (1 mg/kg Q2D*5) and BNT327 (20 mg/kg Q2D*2) had TGI of 111.3% vs. 33.6% for BNT325 or 78.2% for BNT327 alone. In a syngeneic hTROP2^{+}MC38 model, BNT325 (20 mg/kg QW*4) combined with a surrogate BNT327 (surBNT327, anti-mPD-L1 x mVEGF) showed TGI of 106.1% and 106.9% for surBNT327 (5 mg/kg Q2D*4 and 20 mg/kg Q2D*4, respectively) vs. 51.4% for BNT325 alone or 47.6% for surBNT327 (5 mg/kg) and 71.4% for surBNT327 (20 mg/kg) alone. In the clinic, as of Nov 21, 2024, 8 patients (breast cancer n=2, ovarian cancer n=2, other n=4) have received the combination of BNT327 and BNT325 in an ongoing first-in-human phase 1/2a study of patients with advanced solid tumors (NCT05438329). No DLTs were reported in the DLT-evaluable patients (first 6 patients). Stomatitis was reported in 6/8 patients (Grade 3 in 2 patients), which led to a dose reduction of BNT325 in 3 patients. There were no adverse events leading to dose discontinuation. Tumor response analyses and biomarker testing are ongoing. Overall BNT327 plus BNT325 demonstrated superior anti-tumor effects preclinically compared to each drug alone. Early clinical data showed successful dose escalation allowing enrollment to NSCLC, TNBC, ovarian, and cervical cancer expansion cohorts, with updated clinical data planned to be presented. Further evaluation is ongoing of BNT327 with ADCs against HER2 (BNT323/DB-1303), B7H3 (BNT324/DB-1311) and HER3 (BNT326/YL202), with a focus on tumors where early monotherapy efficacy has been observed with these ADCs.

#65 Real time imaging of the non-small cell lung cancer immune microenvironment modulation by low dose photodynamic therapy.

Damien N. Marie[1], Louis-Emmanuel Chriqui[1], Alexandros Sifis[1], Etienne Abdelnour[1], Michel Gonzalez[1], Thorsten Krueger[1], Johanna A. Joyce[2], Sabrina Cavin[1], Jean Y. Perentes[1]

[1]Lausanne University Hospital, Lausanne, Switzerland,[2]Department of Oncology, University of Lausanne, Lausanne, Switzerland

Immune checkpoint inhibitors (ICIs) have significantly improved the outcome of non-small cell lung cancers (NSCLCs). However, cancer response to ICIs occurs in a fraction of patients and correlates with the presence of tumor-infiltrating lymphocytes (TILs). Thus, methods to increase the presence of TILs within lung cancer are urgently needed. Previously, in a murine model of malignant pleural mesothelioma, we described a mechanism by which low dose photodynamic therapy (L-PDT) enhanced the vascular expression of E-selectin which favored TILs recruitment and improved tumor control. Here, we hypothesized that a similar mechanism existed in NSCLC and could be further potentiated by ICIs.
We developed a murine model with a chest window allowing real time imaging by two-photon microscopy of lung adenocarcinoma (LUAD, 344-SQ-GFP, $Kras^{G12D}$; $p53^{R172H\Delta G}$ mutant) growing in the lungs of C57BL/6-CD2-dsRed transgenic mice. We determined the impact of L-PDT±E-selectin blocking antibodies (EBA) on CD2+TILs recruitment over 30 days. In a separate experiment, we then assessed the impact of L-PDT±EBA on tumor growth, animal survival and spontaneous metastasis development. Finally, we characterized the LUAD immune microenvironment and TILs immune checkpoint expression 1 and 5 days after L-PDT by 16-colors flow cytometry.
L-PDT significantly enhanced the recruitment of CD2+TILs, with a significant increase observed at day 1, that lasted up to 20 days post-treatment compared to controls. L-PDT was significantly correlated with improved tumor control (-42%), a significant reduction in metastasis development (-50%) and an increase in animal survival (+26%) compared to the control group. Interestingly, this phenotype was abrogated to control levels when L-PDT was combined with EAB. Further analysis of the tumor immune microenvironment confirmed the recruitment of CD8+ T lymphocytes at both 1- and 5-days following L-PDT with increased PD-1 expression on their surface day 5 post-treatment compared to controls.
L-PDT triggers, through vascular E-Selectin, a durable infiltration of NSCLCs by TILs which provide better tumor control, impair metastasis development, and improve animal survival. The increased PD-1 levels on CD8-T cells following L-PDT suggest a favorable combination with PD1/PDL1 inhibitors.

#650 Enhancing antitumor immunity by inducing PANoptosis using a new generation of vesicular stomatitis virus.

F. Chen[1], L. Lang[2], S. Tang[1], F. Yang[1], N. F. Saba[1], M. Luo[3], **Y. Teng**[1];
[1]Emory University, Atlanta, GA, [2]Augusta University, Augusta, GA, [3]Georgia State University, Atlanta, GA

Despite significant advances, the limited therapeutic efficacy of virotherapy remains a major hurdle in the use of oncolytic viruses (OVs) for cancer treatment. To overcome this challenge, we integrated the SMAC/DIABLO gene into the genome of vesicular stomatitis virus (VSV) to create a new generation of VSV, termed VSV-S. In this study, we infected head and neck squamous cell carcinoma (HNSCC) cells and tumors with VSV-S to evaluate its therapeutic efficacy and underlying mechanisms. VSV-S exhibited significantly enhanced antitumor activity in HNSCC cells compared to the parental virus. It not only promoted cancer cell apoptosis through the overexpression of SMAC during VSV infection, but also induced PANoptosis (a combination of pyroptosis, apoptosis, and necroptosis) through the activation of caspase 3, gasdermin D and gasdermin E, and MLKL signaling pathways, which led to enhanced recruitment of CD8+ T cells to the tumor and eventually potentiated T cell-mediated antitumor immunity. In addition, VSV-S reduced PD-L1 levels in HNSCC cells and, when combined with anti-PD-1 antibody, produced a more potent antitumor effect than either treatment alone. These results provide valuable preclinical evidence to support the development of VSV-S-based antitumor therapies that could improve outcomes for patients with HNSCC.

#6509 Carcinogen withdrawal in the BBN induced mouse model of bladder cancer mimics cigarette smoking cessation in humans with decreased tumor progression.

Gabrielle Kennelley[1], Alexandra Pado[2], Rachel Sanyu[2], Norbert Sule[3], Craig Brackett[3], Barbara Foster[3], Wendy Huss[3]

[1]University of Pittsburgh Medical Center, Pittsburgh, PA,[2]University at Buffalo Jacobs School of Medicine and Biosciences, Buffalo, NY,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Field cancerization is associated with greater tumor mutational burden in bladder cancer. Mutations in TRP53 (p53) are early drivers of disease and correlate with tumor stage, grade, and a poor prognosis. In humans, cigarette smoking correlates with a greater frequency of p53 mutations. N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN) is a cigarette smoke-mimicking carcinogen that can be used to induce bladder cancer in rodent models. Mirroring real-world phenomena, BBN exposure induces p53 mutations and leads to more rapid tumor initiation and progression in male rodents. Male and female mice were exposed to 0.05% BBN in drinking water for 4, 12, or 20 weeks (wks). Bladder samples were collected immediately after BBN discontinuation or after a period of drinking untreated water. Pathology, proliferation, and mutant p53 expression were analyzed to investigate BBN-induced field cancerization in urothelium, urothelial carcinoma in situ (UCIS), and invasive urothelial carcinoma (iUC). Mice exposed to 4 wks of BBN had groups of proliferative and mutant p53 cells. A continuous basal proliferation pattern was more commonly seen in males compared to females (87% vs. 43%), and a single male progressed to UCIS. Interestingly, by 22 wks (18 wks untreated drinking water after 4 wks BBN), there was no longer detectable proliferation, mutp53 cells, or UCIS. Mice exposed to 12 wks of BBN progressed to UCIS or iUC (55% males vs. 33% females). Most bladders with UCIS had a continuous basal cell proliferation pattern with mutant p53. By 22 wks (10 wks untreated drinking water after 12 wks BBN), bladders with UCIS had limited continuous basal cell proliferation but retained mutant p53, and males had more iUC than females (38% vs. 14%). Additionally, by 52 wks (40 wks untreated drinking water after 12 wks BBN), males more often progressed to iUC compared to females (94% vs. 44%). By 78 wks (66 wks untreated drinking water after 12 wks BBN), 75% of females progressed to iUC. After 20 wks of BBN, all male mice progressed to iUC by 26 wks, whereas iUC development in female mice was delayed until 51 wks. BBN induces p53 mutations associated with the initiation and progression of murine bladder cancer. Data showing mutant p53 without development of UCIS or iUC in mice treated with BBN for 4 wks indicates field cancerization is not maintained after a short exposure to BBN. However, exposure to BBN for 12 wks induces iUC in most males, but less in females, and 20 wks of BBN exposure leads to more rapid iUC development in males than in females. This data mimics research in humans showing a reduced risk of bladder cancer development after cessation of cigarette smoking. The pattern of mutant p53 staining, particularly p53 mutations within proliferating cells, may also correlate with greater field cancerization and likelihood of UCIS and iUC development, particularly in those with a longer history of carcinogen exposure.

#651 Safety and efficacy of pembrolizumab plus personal dendritic cell vaccines in elderly patients with metastatic melanoma.

C. S. Nangia[1], K. L. Lopez[2], G. I. Nistor[2], **R. O. Dillman**[2];
[1]Hoag Hospital, Newport Beach, CA, [2]AIVITA Biomedical, Inc., Newport Beach, CA

Monoclonal antibodies targeting programmed death molecule-1 (anti-PD-1) are an effective immunotherapy for advanced melanoma. An investigational approach that has also produced encouraging long-term survival results in such patients is a patient-specific therapeutic vaccine consisting of autologous dendritic cells (DC) pulsed with autologous tumor antigens (ATA) from autologous tumor cells that are self-renewing in tissue culture. There is a strong rationale for combining these two immunotherapy approaches, but the first step is establishing that it is safe to give both therapies concurrently. Eligible patients had advanced melanoma with at least one resectable lesion and were intended to be treated with an anti-PD-1 monoclonal antibody. There was no upper age limit. Co-administration of anti-CTLA-4 antibody was not allowed. Surgically resected metastatic melanoma tissue was processed into cell suspension, then cultured in liquid media that favors stem cell survival and progenitor cell proliferation. Lysates of Irradiated tumor cells (ITC) were used as ATA. Peripheral blood mononuclear cells were collected by leukapheresis, enriched for monocytes (MC), and then immature DC were differentiated from MC by culturing with granulocyte-macrophage colony-stimulating-factor (GM-CSF) and interleukin-4. Antigen loading was accomplished by incubating DC with ITC lysate. During the 8 to 9 weeks while DC-ATA was being manufactured, patients received standard infusions of anti-PD-1. Over the next 24 weeks, anti-PD-1 was infused at standard intervals, and DC-ATA admixed in GM-CSF was injected s.c. at weeks 1, 2, 3, 8, 12, 16, 20, and 24. Patients were followed for acute, subacute, and chronic toxicity. Four patients (mean age 81.7 years) have been treated (NCT03743298). Three were treated with pembrolizumab. An 89-year-old female with recurrent stage 3 stopped treatment after five vaccine doses due to recurrent dermatologic toxicity that started during pembrolizumab and persisted during concurrent therapy. She remains recurrence-free 26 months after vaccine initiation. Two stage-4 patients received all 8 DC-ATA doses without toxicity. A 73-year-old female with stage 4b remains in complete remission 33 months after vaccine initiation. An 81-year-old male with stage 4b had a partial response, progressed after 6 months, but was still alive after 14 months. An 82-year-old male with stage 4c received pembrolizumab while DC-ATA was manufactured, then because of new brain metastases, received opdualag with DC-ATA. He had a partial response while receiving the eight vaccine doses but later progressed and died 10 months after vaccine initiation. In elderly patients with advanced melanoma, it appears that DC-ATA can be administered concurrently with anti-PD-1 without increased toxicity and with no decrease in efficacy. Additional testing of this combined immunotherapy is warranted.

#652 Exploring the therapeutic benefit of AVA-NP-695 with combination modalities in ICB refractory and rare cancers.

Borja Ruiz-Fernandez de Cordoba[1], Avijit Goswami[2], Sandeep Goyal[2], Kawaljit Singh[2], Princy Khurana[2], Alejandro Sweet-Cordero[3], **Aditya Kulkarni**[2]

[1]Department of Pediatric Oncology, University of California San Francisco, San Francisco, CA,[2]Avammune Therapeutics, Phoenixville, PA,[3]University of California San Francisco, San Francisco, CA

Background: Ectonucleotide pyrophosphatase/phosphodiesterase 1 (ENPP1) expression is associated with poor prognosis in many cancers. Previous studies identified ENPP1 as the primary hydrolase of extracellular cGAMP, that activates the anticancer STING pathway. High ENPP1 expression is found in several tumors, including human astrocyte tumors and triple-negative breast cancer (TNBC) cell lines, where it contributes to tumor progression and impedes T cell infiltration. By inhibiting cGAS-STING-mediated immune activation and producing adenosine, an immune suppressor that promotes cell migration, ENPP1 plays a critical role in tumor growth. Interestingly, surface and global proteome analyses identify ENPP1 as potential immunotherapeutic targets in case of rare cancers like sarcomas.

Methods: The inhibition potency of AVA-NP-695 was confirmed by 5'TMP and 2'2'-cGAMP enzymatic assays. Pharmacokinetic profile of AVA-NP-695 in Mice, Rats and Beagle Dogs and the human PK profile was predicted. The efficacy of AVA-NP-695 was demonstrated in 4T1 Tumor bearing BALB/c mice as monotherapy and in combination with anti-PD-L1, Olaparib and Paclitaxel. Finally, *in vivo* the effect of pharmacological inhibition of DDR with Olaparib in combination with AVA-NP-695 was assessed in OS models.

Results: We demonstrate that AVA-NP-695, a selective and potent small molecule ENPP1 inhibitor, exhibited no adverse effects in multiple safety studies in mice and beagle dogs. *In vivo* studies revealed that AVA-NP-695 (6 mg/kg BID) provided superior tumor growth inhibition and reduced metastasis compared to Olaparib and Anti-PD1 in a syngeneic 4T1 breast cancer mouse model. Additionally, AVA-NP-695 demonstrates tumor regression in both paratibial (OT) and metastatic (lung) models of Osteosarcoma (OS). AVA-NP-695 significant increase the cGAMP levels (~2-3 fold) as early as 6h post-treatment, without additional stimulation. A targeted pharmacological screen revealed synthetic lethality when combining AVA-NP-695 with Olaparib (PARPi) *in vitro* OS cell lines. This novel combination increased both intra- and extracellular cGAMP production. Additionally, the pharmacological inhibition of DDR with Olaparib in combination with AVA-NP-695 led to OS tumor regression and enhanced antitumor immune responses in both OT and metastatic contexts. Compassionate use of AVA-NP-695 showed > 80% tumor volume reduction in Canine patients.

Conclusions: The potent anti-tumor efficacy of AVA-NP-695 both as monotherapy and combination along with its safety profile provides a strong rationale for the therapeutic potential of AVA-NP-695 against solids tumors (breast cancer and Osteosarcoma). Our results uncover novel mechanistic vulnerabilities and suggest that treatment with AVA-NP-695 in combination may increase effectiveness in patients, thus preventing local and distant dissemination.

#653 Proved clinical benefit of low-dose anti-CTLA4 + anti-PD-1 immunotherapy versus mono anti-PD-1 therapy in patients unresectable or metastatic melanoma: Phase III OCTAVA trial.

Background: BCD-217-2/OCTAVA (NCT05732805) is an international, multi-center, randomized, double-blind, placebo-controlled phase III study conducted to access the efficacy and safety of prolgolimab+nurulimab (BCD-217) combination therapy with continued prolgolimab therapy compared to prolgolimab monotherapy as 1st line treatment for patients (pts) with unresectable or metastatic melanoma (un/mM). BCD-217 is a fixed-dose combination of nurulimab (aCTLA-4, 5 mg/ml) and prolgolimab (aPD-1, 15 mg/ml) was recently approved as the 1st line treatment for un/mM in Russia. Here we present the primary analysis of the study.

Methods: Pts with unresectable or metastatic cutaneous melanoma (IIIC-IVM1a-c) with treatment- *naïve* for unresectable/metastatic disease were randomized in 2 treatment arms: combination drug containing nurulimab (1 mg/kg) and prolgolimab (3 mg/kg) at a dose of 0.2 ml/kg Q3W during the first four blinded infusions (nuru+prolgo arm) and prolgo arm received prolgolimab monotherapy at a dose of 3 mg/kg Q3W during the first four blinded infusions. Then both arms received prolgolimab maintenance up to two years. The primary endpoint of the study was progression-free survival (PFS).

Results: 271 pts were randomized to nuru+prolgo (n=135) or prolgo monotherapy (n=136) arms. After the median of 15.8 mo follow-up the median PFS (mPFS) was 15.4 (10.3; ND) mo in the nuru+prolgo group and 10.8 (4.7; ND) mo in the prolgo monotherapy group (95% CI, HR 0.68 (0.482; 0.957), iRECIST). The mPFS benefit of nuru+prolgo arm compared to prolgo arm are maintained in RECIST 1.1 assessment: 9.9 mo vs 2.8 mo, respectively. ORR and DCR were also higher in NURU+PROLGO arm. mOS was not reached in both groups (95% CI, HR 0,88, (0.50; 1.55)). 12-mos OS was 84% in each arm. Grade 3-4 treatment-related AE were reported in 16.3% of pts in nuru+prolgo arm compared to 14.0% - prolgo arm. Immune-related AEs (irAE) of all grades were reported in 52.6% of cases in nuru+prolgo arm and 32.4% of cases - in prolgo arm (p 0.0007). Majority of them were mild. The proportion of gr.≥3 irAEs was 13.3% vs 5.9% in nuru+prolgo arm and prolgo arm, respectively (p 0.04). Treatment discontinuation due to AE was reported in 9.6% of cases for nuru+prolgo vs 4.4% of cases for prolgo arm.

Conclusions: OCTAVA trial resuts demonstrated that the fixed-dose combination of nurulimab + prolgolimab is significantly more effective than aPD-1 monotherapy without a serious deterioration of the safety profile in patients with metastatic or unresectable cutaneous melanoma as 1st line therapy.

#654 Transcriptomic analysis ofTGF-β-targeting oncolytic adenovirus and immune checkpoint inhibitor therapy in a triple-negative breast cancer mouse model.

N. Nhan[1], B. Filimon[1], H. Fowler[2], S. Ganesan[2], X. Wang[2], B. Brockstein[1], W. Xu[1];
[1]Northshore University Healthsystem, Evanston, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL

Immunotherapy has shown promise in cancer treatment, but resistance remains a major challenge. Combining therapies that target specific pathways, such as TGF-β signaling, can enhance the effectiveness of immune checkpoint inhibitors (ICIs). Our oncolytic adenovirus (OAd), mHAdLyp.sT, containing a TGF-β decoy to reverse immune resistance to ICI treatment and the LyP-1 peptide to enhance tumor targeting, has been shown to significantly enhance anti-tumor responses and reduced lung metastasis in a 4T1 triple negative breast cancer (TNBC) mouse model when systemically delivered in combination with anti-PD-1 and anti-CTLA-4 antibodies. We also showed previously that mHAdLyp.sT systemically primes an inflamed immune cell phenotype for ICI treatment by both flow cytometry and mass cytometry (CyTOF). In this study, we investigated how the mHAdLyp.sT-ICIs combination affects the expression of key genes in major signaling and immune regulatory pathways by RNA-seq analysis, both in tumors and systemically in the spleen, at the early response stage (day 16) and experiment terminal point (day 25) in the TNBC mouse model. In tumor, both ICIs and the mHAdLyp.sT-ICIs combination treatments significantly induced immune-related genes beneficial for anti-tumor effects compared to the untreated control group at both day 16 and day 25. However, at day 16, while ICI treatment significantly escalated the expression of several proinflammatory cytokines, such as IL-6, IL-10, and IL-11, which are known to potentiate tumor resistance to immunotherapy, mHAdLyp.sT-ICIs combination treatment did not trigger this response. In the spleen, all treatments exhibited slight effects on the immune response at day 16, while at day 25, mHAdLyp.sT-ICIs combination induced a strong response with extensive rescued changes across various crucial signaling pathways in tumor progression and metastasis, including those involved in TGF-β signaling, cell adhesion, migration, angiogenesis, extracellular matrix organization, cell differentiation, gene expression regulation, protein phosphorylation, inflammation, and apoptosis. Notably, mHAdLyp.sT-ICIs combination treatment more effectively inhibited immunosuppressive genes such as *Myd88* and *Ptgir* than ICI alone, confirming that TGF-β inhibition by mHAdLyp.sT enhanced anti-tumor immune responses and helped overcome ICI resistance. We are confident in advancing this new treatment option for TNBC and other metastatic cancers that are projected to be resistant to immunotherapy in a clinical setting.

#655 Spatiotemporally deciphering the response dynamics of micro-satellite stable rectal cancer to neoadjuvant short-course radiotherapy and PD-1 blockade.

J. Wang, Z. Zhang;
Fudan University Shanghai Cancer Center, Shanghai, China

Neoadjuvant chemoradiotherapy is the stand of care for patients with locally advanced rectal cancer (LARC). For microsatellite-stable (MSS) LARC patients, combining immune checkpoint inhibitors (ICIs) with radiotherapy has shown improved tumor regression, though the mechanisms behind tumor response remain unclear. Here, we analyzed 60 pre-, mid- and post-treatment tumor samples from 39 LARC patients in the TORCH clinical trial, utilizing single-cell sequencing and spatial transcriptomics to explore cell dynamics and their association with therapeutic efficacy. In well responders, combination therapy expanded the $CD8^+$ and $CD4^+$ memory T cell pool, which interacted with type 2 dendritic cells and clustered around non-malignant epithelial cells, forming part of tertiary lymphoid structures, as validated by spatial transcriptomics. In poor responders, the tumor microenvironment was enriched with immunosuppressive cells clustering around cancer-associated fibroblasts. This study uncovers mechanisms underlying the efficacy of radiotherapy combined with ICIs and provides valuable resources for identifying targets in MSS LARC patients.

#656 Enhanced therapeutic effect of combining denosumab with PD-1 inhibitor in advanced KRAS-mutated lung adenocarcinoma.

C. Liu, H. Li, S. Zheng, N. Sun, Y. Wang, **J. He**;
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Background: Previous studies have suggested that the combination of RANKL inhibitors and immune checkpoint inhibitors (ICIs) may potentiate the therapeutic response in lung adenocarcinoma, particularly in cases with KRAS mutations. The exact mechanisms and clinical validation of this combination therapy are yet to be fully understood.
Methods: We conducted a comprehensive analysis by integrating public datasets and retrospective clinical data to examine the relationship between RANKL alterations and the tumor immune microenvironment in KRAS-mutated lung adenocarcinoma. We also investigated the signaling pathways affected by RANKL manipulation in cancer cell lines and assessed the impact on macrophage function. A prospective clinical trial was carried out to evaluate the potential of the RANKL inhibitor combined with PD-1 inhibitor therapy.
Results: Our analysis revealed that the combination therapy of RANKL inhibitor with PD-1 inhibitor demonstrated improved outcomes in patients with KRAS-mutated lung adenocarcinoma. Transcriptomic data and immunohistochemical staining showed that RANKL was upregulated in these tumors, which was inversely associated with PD-L1 expression and the secretion of CXCL9, CXCL10, and CXCL11, leading to a decrease in $CD8^+$ T cell infiltration and a more immunosuppressive environment. We found that RANKL modulated PD-L1 levels via the PI3K/AKT pathway and reduced CD8+ T cell infiltration by decreasing the expression of CXCL9, CXCL10, and CXCL11. In a mouse model, KRAS-mutated lung adenocarcinoma treated with the combination therapy showed significant tumor growth inhibition compared to PD-1 inhibitor alone. Additionally, the combination therapy significantly enhanced macrophage and $CD8^+$ T cell recruitment. The DEMAND trial confirmed the superior therapeutic efficacy of this combination regimen in patients with KRAS-mutated lung adenocarcinoma.
Conclusion: Our study sheds light on the role of RANKL overexpression in promoting immunosuppression and ICI resistance in KRAS-mutated lung adenocarcinoma. Our results indicate that the combination of RANKL inhibitor and PD-1 inhibitor could be a promising therapeutic strategy for this patient subset.

#658 Triple-negative breast cancer sensitization to anti-metabolite chemotherapy utilizing PARP inhibiting olaparib.

Joshua C. Doloff, Amanda Rakoski, **Abigail Yoo**

Biomedical Engineering, Johns Hopkins University, Baltimore, MD

Triple Negative Breast Cancer (TNBC) is one of the most aggressive breast cancer subtypes as it grows faster than typical invasive carcinoma, leading to poor prognosis and an increased chance of recurrence. It lacks three key hormone receptors, estrogen, progesterone, and HER2 receptors, eliminating the efficacy of receptor-targeted therapies. The first line of treatment is the use of combination chemotherapies given at Maximum Tolerated Dosage (MTD) but this typically leads to higher toxicity and systemic side effects. We investigate Olaparib (OLA) and Gemcitabine (GEM) as a dual chemotherapy. OLA is an FDA-approved PARP inhibitor, facilitating single-stranded DNA breakage by preventing PARP from replacing excised nucleotides. GEM is an anti-metabolite that prevents cancerous cells from continuing mitosis and increasing apoptosis by taking the place of the nucleotide cytidine in the DNA during replication, leading to cell cycle arrest. We propose sensitizing TNBC to GEM by using OLA at lower doses than MTD while causing significant TNBC tumor cell death compared to the drug alone.We used EO771 cells (syngeneic to C57BL/6 mice) to evaluate GEM and OLA. Cells (100,000/well) were plated in 24-well plates and treated with 0, 10, or 30 nM GEM, OLA, or combinations thereof. Crystal violet staining was used to visualize viable cells, which were quantified by absorbance at 550 nm. RNA extracted from 500,000 cells/well in 6-well plates was analyzed via qPCR for stress and cytokine-related gene expression. GEM at 30 nM was more effective than at 10 nM, especially in combination with OLA (10 or 30 nM). Phase-contrast microscopy revealed significant cytotoxicity and cellular detachment with combined treatments, particularly GEM30/OLA10 and GEM30/OLA30. GEM 30/OLA 10 and GEM 30/OLA 30 showed the most significant cell death in response to combined chemotherapy. GEM 30/OLA 10 interestingly exhibited a slightly lower cell viability percentage than GEM 30/OLA 30. GEM30/OLA10 was the most effective combination tested, reducing TNF-α expression and cell viability while minimizing toxicity. The dual combinations suggest that GEM effectively disrupts DNA synthesis and drives single-stranded breakage. Future studies should include in vivo analyses of the tumor microenvironment, ELISAs for protein validation, and additional cell viability assays, such as MTT or XTT, to confirm these findings.

#659 Translational medicine studies of BR111, a biparatopic anti-ROR1 antibody drug conjugate for hematological and solid tumor treatment.

Qinqin Zhuang[1], Yan Sun[1], Lilv Fan[1], Qianqian Tao[1], Xiaobei Zhao[2], Jie Zhu[2], Zhenhua Wu[1], Lei Nie[1], Gang Chen[2], Haibin Wang[1]

[1]Bioray Pharmaceutical Ltd., Hangzhou, China,[2]Bioray Pharmaceutical Co., San Diego, CA

ROR1 is a type I transmembrane protein that belongs to the ROR family. It is a receptor for Wnt family signaling molecules Wnt5a, and plays a critical role in various cellular processes, such as cell proliferation, survival, and migration. Being an oncofetal protein, ROR1 exhibits limited expression in most normal tissues. However, it is abnormally expressed in various hematological and solid cancers, contributing to the development and progression of many types of cancer. Due to its overexpression in cancer, ROR1 presents as a highly attractive target for antibody-drug conjugate (ADC) therapy. The current clinical results of ROR1 ADCs have been promising in treating patients with relapsed and/or refractory (R/R) hematologic malignancies.

BR111 is anti-ROR1 ADC that consists of a biparatopic antibody, stably conjugated to an antimitotic agent. The biparatopic antibodies demonstrate superior binding affinity to ROR1-expressing cancer cells compared to single epitope antibodies. Notably, our unique and innovative conjugation platform CysX™, not only prevents payload detachment during circulation and reducing the off-target toxicity, but also enables a uniformed drug-to-antibody ratio (DAR) of 4.

Recent translational medicine studies showed that ROR1 is relatively highly expressed in the patients of many solid tumors including sarcoma, gastric cancer, TNBC, endometrial cancer, etc. And BR111 has demonstrated efficacy in *in vitro* and *in vivo* models of those indications. BR111 has also showed synergistic efficacy when combined with PD-1/L1 antibodies, SIRPα antibody and several chemotherapeutics. Studies have also shown that ROR1 levels increase while HER2 levels decrease in cell lines treated with DS-8201, and BR111 showed improved efficacy in DS-8201 resistant cell line as well as in combination with DS-8201. The promising outcome holds great potential as a therapeutic treatment for hematological and solid cancers, offering a better safety profile. BR111 has great potential in further clinical evaluations.

#660 Investigating the mechanism of the abscopal effect in combined IRE and anti-PD-1 therapy against PDAC.

Qizhen Cao[1], Yitao Tang[1], Nicholas A. Egan[2], Ping Pan[1], James P. Long[1], Huamin Wang[1], Jared K. Burks[1], Han Liang[1], Weiyi Peng[2], **Chun Li**[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Houston, Houston, TX

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is characterized by a high potential for metastatic dissemination, contributing to its poor 5-year survival. Irreversible electroporation (IRE) is an interventional technique that employs short, high-voltage electric pulses to induce cell death. This study was aimed at investigating the abscopal effect of combined IRE and anti-PD-1 therapy in the setting of liver metastasis and possible mechanisms action.

Methods: Female C57BL/6 mice were inoculated with murine Kras* PDAC cells in the pancreas and the liver. The primary tumor in the pancreas was treated with IRE while the distal liver metastasis was untreated by IRE. Following six intraperitoneal doses of anti-PD-1 (100 μg/100 μL/injection, administered every other day), all mice were euthanized 14 days after IRE. Both the IRE-treated pancreatic tumors and the liver metastases were collected for pathological analysis. Tumor tissue microarrays were prepared, and multiplex immunofluorescence staining was performed using the Lunaphore COMET™ system. Additionally, to evaluate the impact of IRE on macrophage phagocytosis of pancreatic tumor cells, macrophages were co-cultured with either control or IRE-treated CFSE-pre-stained pancreatic tumor cells, and phagocytosis effect was assessed using flow cytometry. To explore the impact of IRE on gene expression pathways, Kras* PDAC cells were treated with IRE (400 V, 20 pulses), and cells were collected 4 hours post-treatment. Total RNA was extracted for RNA sequencing analysis.

Results: Results from the PDAC liver metastasis mouse model demonstrated enhanced antitumor activity in both the IRE-treated pancreatic tumors and the untreated liver metastases following combined IRE and anti-PD-1 treatments. Multiplex immunofluorescence analysis of both tumor types revealed a significant accumulation of F4/80+ macrophages in the interface between necrotic tissue (caused by IRE) and viable tumor tissue. Additionally, CD8+GzmB+ T cells and B220+ B cells were significantly increased in the tumor tissues of mice treated with the combination of IRE and αPD-1. In vitro macrophage phagocytosis assays further demonstrated that macrophages were more effective at phagocytosing IRE-treated Kras* PDAC cells compared to untreated control cells. Moreover, RNA sequencing of KRAS* PDAC cells treated with IRE (400 V, 20 pulses) identified 908 differentially expressed genes (DEGs) (fold change > 2, FDR < 0.01) compared to untreated controls. Ingenuity Pathway Analysis revealed that these DEGs were associated with TNFα signaling via the NFκB pathway and IL6-JAK-STAT3 signaling, highlighting the expression of key inflammatory genes essential for immune responses.

Conclusions: These findings indicate that combining IRE with PD-1 blockade enhances a robust antitumor immune response, resulting in systemic antitumor activity and a strong abscopal effect.

#661 LAG-3 blockade enhances the anti-tumor efficacy of PD-1 blockade combined with radiotherapy in a syngeneic murine triple-negative breast cancer model.

Yoomin Kim[1], Seung Hyuck Jeon[2], Nawon Park[1], Seongmin Kim[1], In Ah Kim[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of

The anti-tumor efficacy of PD-1 blockade and local radiotherapy (RT) is often limited by diverse mechanisms that suppress $CD8^+$ T cell responses. Lymphocyte-activation gene 3 (LAG-3) is an inhibitory receptor expressed on exhausted $CD8^+$ T cells and regulatory T cells (Tregs), and its blockade has been shown to enhance the anti-tumor effects of PD-1 blockade. Therefore, we hypothesized that combining LAG-3 blockade with PD-1 blockade and local RT would overcome treatment resistance in triple-negative breast cancer (TNBC). Using the 4T1 syngeneic mouse TNBC model, we evaluated the anti-tumor effects and immune cell phenotypes following treatments with local RT, PD-1 blockade, and LAG-3 blockade. We found that the triple combination of local RT, PD-1 blockade, and LAG-3 blockade resulted in the greatest tumor growth delay in both irradiated (primary) and unirradiated (secondary) tumors, with a significant reduction in metastatic lung nodules. The proportion of tumor-infiltrating $CD8^+$ T cells increased with triple combination therapy while the proportion of Tregs decreased compared to the PD-1 + RT combination in both primary and secondary tumors. Consequently, the $CD8^+$ T cell to Treg ratio was highest in the triple combination group. The proportion of tumor-specific $CD8^+$ T cells increased following triple combination therapy not only in tumor microenvironment but also among splenic $CD8^+$ T cells. Interestingly, the proportions of $CD8^+$ T cells, as well as $CD4^+$ T cells, with an effector memory phenotype were most significantly elevated by the triple combination therapy. In tumor-draining lymph nodes, the proportion of conventional type 1 dendritic cells capable of antigen cross-presentation to $CD8^+$ T cells was increased by the triple combination therapy. These findings suggest that LAG-3 blockade enhances the therapeutic efficacy of local RT and PD-1 blockade by promoting T cell-mediated anti-tumor immune responses. This study highlights the potential of combining LAG-3 blockade with local RT and immune checkpoint inhibitors for the treatment of TNBC. (Work supported by grant from the National Research Foundation of Korea #2023R1A2C3003782)

#662 Clinical and biomarker analyses of SHR-1701 combined with famitinib in patients with previously treated advanced biliary tract cancer or pancreatic ductal adenocarcinoma: A phase II trial.

L. Yi, Z. Meng, J. Xie;
Fudan University Shanghai Cancer Center, Shanghai, China

Background: Advanced biliary tract cancer (BTC) and pancreatic ductal adenocarcinoma (PDAC) are aggressive malignancies with poor prognoses and limited treatment options. This first-in-class phase II study evaluated the efficacy and safety of SHR-1701, a bifunctional fusion protein targeting PD-L1 and TGF-β, combined with famitinib, a multi-targeted receptor tyrosine kinase inhibitor, in patients with advanced BTC or PDAC who failed previous standard treatment.
Methods: In this open-label, single-arm trial (ChiCTR2000037927), patients with advanced BTC or PDAC who had failed at least one line of prior therapy received SHR-1701 (30 mg/kg IV Q3W) plus famitinib (20 mg PO daily). The primary endpoint was objective response rate (ORR) per RECIST v1.1. Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety. Exploratory biomarker analyses were performed using RNA sequencing, multiplex immunohistochemistry, and machine learning.
Results: Among 51 patients (BTC, n=25; PDAC, n=20), the BTC cohort showed an ORR of 28% (including 2 complete responses [CRs]) and a DCR of 80%, with a median PFS of 5.1 months and a median OS of 16.0 months. In the PDAC cohort, the ORR was 15% (2 CRs), with a DCR of 60%, and the median PFS and OS were 2.1 and 5.3 months, respectively. Grade 3/4 treatment-related adverse events occurred in 29.4% of patients, with no grade 5 events reported. Primary tumor resection history, peripheral blood immunophenotype changes, and distinct immune-metabolic profiles were associated with treatment benefits, with the TGF-β trap function of SHR-1701 potentially sequestering TGFB1 that was elevated in responders. An immune/metabolism (I/M) score integrating six genes was developed as a predictive biomarker for immunotherapy response in multiple cohorts, allowing to identify patients most likely to benefit from this therapy regimen.
Conclusions: SHR-1701 plus famitinib showed promising efficacy and manageable toxicity in advanced BTC and PDAC, providing proof-of-concept for targeting PD-L1, TGF-β, and angiogenesis pathways simultaneously. The I/M score may help select patients most likely to benefit from this regimen.

#663 A novel combination immunotherapy for p53 mutant metastatic breast cancer leveraging vulnerabilities in the DNA damage response.

Andrei V. Bakin[1], Ashley Guo[1], Priyanka Rajan[1], Mohammed Alruwaili[1], Joseph Barbi[1], Scott I. Abrams[1], Thomas Melendy[2], Christos Fountzilas[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]The University at Buffalo, Buffalo, NY

Metastatic breast cancer (MBC) is a life-threatening disease with the lowest 5-year survival rates seen in patients with metastatic triple-negative breast cancer (TNBC). MBCs, including TNBCs, commonly carry mutations in the tumor suppressor p53. Mutant p53 (p53Mut) drives cancer progression and metastasis, in part, by promoting the accumulation of myeloid-derived suppressor cells (MDSCs) and tumor-associated macrophages (TAMs), major enforcers of immune suppression in the tumor microenvironment (TME). At present, there are no effective treatment options for p53mut MBC, while existing chemotherapy-based treatments exhibit low selectivity for p53mut status and frequent adverse side effects. To address this clinical challenge, we developed a novel therapeutic strategy for the selective targeting of p53mut tumors. This novel strategy employs two drugs, one acting as an inducer (TAS102) and the other as an amplifier (PARP inhibitor, PARPi), to achieve selective and potent damage to p53mut tumors. Thymidine nucleotide analogue TAS102 does not block DNA synthesis but activates post-replicative repair leading to DNA breaks, while PARPi blocks repair of these DNA lesions. Post-replicative DNA repair results in DNA breaks and G2-arrest in p53mut cells. In contrast, p53WT cells accumulate in G1-phase and efficiently remove thymidine analogues. Our two-drug strategy showed high efficacy, without adverse effects, in preclinical cancer models of MBC. In this study, we further investigated the impact of the two-drug TAS102-PARPi regimen on the immune landscape in preclinical models of metastatic TNBC. We observed that the TAS102-PARPi combination reduced tumor growth and metastases in the lungs and liver. The two-drug regimen reduced the levels of MDSCs and TAMs, increased the levels of lymphocytes in the TME, and promoted $CD8^+$ T cell-mediated anti-tumor activity that was abrogated by cell depletion. Immunophenotyping showed that the dual agent therapy increased the frequency of intra-tumoral $CD8^+$ T cells expressing the immune checkpoint receptors PD-1 and LAG3, suggesting that the regimen may cooperate with immunotherapies targeting these molecules. Indeed, combining the dual agent therapy with anti-PD-1 or anti-LAG3 antibodies showed a further reduction in tumor growth and metastases. Together, these results demonstrate that the two-drug TAS102-PARPi regimen can be combined with immune checkpoint blockade for effective treatment of MBC, and potentially other p53-mutant cancers, like colorectal and pancreatic cancers.

#664 Integrated scRNAseq and spatial transcriptomic analyses identify immune correlates of response to combined BRAF/MEK/PD-1 inhibition in metastatic colorectal cancer.

Hongcheng Yao[1], Alexander Tang[2], Ryan Corcoran[3], Nir Hacohen[3], Ilya Korsunsky[1], **Jonathan H. Chen**[4]

[1]Brigham and Women's Hospital, Boston, MA,[2]Broad Institute, Cambridge, MA,[3]Massachusetts General Hospital, Boston, MA,[4]Northwestern University - Feinberg School of Medicine, Chicago, IL

Background: Our clinical trial of combined BRAF, MEK, and PD-1 inhibition showed a 24% response rate in BRAF V600E mutant colorectal cancer (CRC) (PMID: 36702949). However, the mechanism underlying this response is unknown.
Methods: We analyzed 327,000 immune and stromal cells from 23 paired scRNAseq profiles of pre- and day 15 on-treatment tumor biopsies. Progression-free survival of 6 months or greater was defined as a clinical response. We performed hierarchical clustering on the scRNAseq data and tracked the TCR repertoire in tumor and blood. Spatial transcriptomic mRNA microscopy (Xenium) was run on 16 biopsies and single cell cluster assignments were mapped onto the microscopy image.
Results: Analysis of scRNAseq data revealed that responders had significant increases in CXCL10+ macrophages and MHCII+ and HOBIT+ CD8 T cells.
Prior analysis of the tumor epithelial cells showed that responders had inhibition of the MAPK pathway (consistent with BRAF/MEK blockade) and increased interferon-stimulated gene (ISG) scores. In contrast, the combination therapy induced more modest shifts in MAPK gene expression scores in immune cells. ISG scores increased across immune cells.
Integration of scRNAseq T cell clusters with TCR clones found a greater influx of new clones (as a fraction of all clones in the activated CD8 T cell clusters) on-treatment in mismatch repair proficient (MMRp) responders versus non-responders ($p=0.02$), with higher normalized counts per new clone in responders versus non-responders ($p=0.03$). Within the blood, TCRs from Tregs and activated CD8 T cells (identified based on scRNAseq signatures in tumor-infiltrating lymphocytes) displayed a burst at two weeks on-treatment but this clonotypic expansion diminished over the next couple of weeks.
Using spatial transcriptomic to localize the populations identified by scRNAseq, we found that SPP1+ macrophages and Tregs were diffusely distributed in tumor areas whereas CXCL10+ macrophages and CD8 T cells formed clusters near the tumor-stromal interface, consistent with tumor immunity hubs.
Conclusions: Altogether, our work suggests that MAPK inhibition in combination with PD1 blockade can induce anti-tumor immune T cell responses, even in MMRp CRC. However, our T cell clonal analysis and subsequent patient cancer progression indicate this response is not sustained. Future work will focus on developing ways to increase the durability of this response, possibly by therapeutically targeting immunity hubs.
Ethics approval: This study was approved by the DF/HCC IRB as protocol 18-144 (see ClinicalTrials.gov NCT03668431).

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Mechanisms of Oncogenesis and Tumor Suppression

#6663 DGAT1 inhibition enhances radiosensitivity in treatment-resistant cervical tumor cells.

Leahan E. Castillo, Marin Guthrie, Naoshad Muhammad, Naomi Msengi, Julie Schwarz

Department of Radiation Oncology, Washington University School of Medicine in St. Louis, ST. Louis, MO

Standard of care treatment for locally advanced cervical cancer has proven to be minimally effective in one third of patients, emphasizing the need for new treatment strategies. Previous research has found that the supplementation with unsaturated free fatty acids may improve tumor response to radiation therapy. Building on this finding, this study investigates if radiation resistant cervical cancers are dependent upon fatty acid metabolism activation of the PI3K pathway. The P13K pathway is responsible for promoting cellular growth, survival and metastasis, thus mutations in this pathway can predict radio-sensitization through the inhibition of DGAT1. DGAT1 is an enzyme involved in cancer cell proliferation and spread by promoting fatty acid metabolism and energy storage, therefore its inhibition can lead to severe oxidative stress, killing cervical cancer cells.
This study investigated the role of DGAT1 inhibition in enhancing radiosensitivity in cervical cancer cells using SiHa parental and SiHa PTEN-null cell lines. Cells were treated with the DGAT1 inhibitors Fenofibrate and A-922500, individually and in combination with radiation therapy (RT). Alamar Blue assays measured cell viability post-treatment, while Western blotting evaluated DGAT1 protein expression following radiation exposure and inhibitor treatment. Flow cytometry was used to quantify apoptosis and reactive oxygen species (ROS), including total, lipid, and mitochondrial ROS, across different treatment conditions. Additionally, colony-forming assays assessed the long-term impact of treatments on cell proliferation and survival.
Results showed that radiation upregulated DGAT1 expression, likely as a protective response to oxidative stress, and that inhibiting DGAT1 significantly decreased cell viability and increased apoptosis when combined with radiation, particularly in PTEN-null cells. These findings suggest that targeting DGAT1 disrupts lipid metabolism and enhances radiosensitivity in cervical cancer cells.
DGAT1 plays a critical role in protecting cervical cancer cells from oxidative damage and maintaining lipid homeostasis during radiation therapy. Inhibition of DGAT1 using Fenofibrate and A-922500 successfully sensitized both SiHa parental and SiHa PTEN-null cells to radiation, with a more pronounced effect observed in the PTEN-null cell line, which is associated with PI3K pathway activation and radio-resistance. These results highlight the therapeutic potential of targeting DGAT1 to overcome radio-resistance in cervical cancer, particularly in tumors with PI3K/Akt pathway activation. Future directions include testing DGAT1 inhibitors in other radioresistant cervical cancer models and conducting in vivo studies to further explore the clinical potential of this approach.

[1]Precede Biosciences, Inc., Boston, MA,[2]Emory University, Atlanta, GA,[3]OHSU, Portland, OR

Background
Accurate prediction of RNA transcript levels from circulating tumor DNA (ctDNA) offers a promising approach for dynamic noninvasive cancer biomarker characterization and longitudinal monitoring. By leveraging epigenomic signals proximal to individual genes, we developed transcript level machine learning prediction models for breast and prostate cancer using simulated plasma and validated them in patient plasma.
Methods and Results
In breast cancer, our models predicted a panel of 760 key breast cancer oncogenes and transcriptional drivers at simulated ctDNA fractions that capture approximately 45% of stage IV breast cancers profiled, enabling clinically relevant prediction of cancer gene transcription. These models are tuned to separate healthy plasma signal from cancer cells' contribution to the plasma. The panel is enriched for genes important for transcriptional regulatory identity and breast cancer subtypes, as well as targets for antibody drug conjugates (ADCs) and radio immune conjugates (RICs), including HER2, PSMA , Nectin-4, B7-H3, B7-H4, MET, and EGFR. Our models demonstrated direct applicability in patient plasma with orthogonal validation. For example, they accurately predicted prostate cancer PSA and PSMA PET SUVmean, as well as breast cancer HER2, ER, and PR status. Additionally in a cohort of patients with matched tissue RNA-seq there was a strong correlation between RNA-seq and plasma-based predictions. Further improvements were achieved with bespoke feature engineering and multi-gene aggregation. A PSMA predictor refined with locus-specific features improved performance at lower ctDNA fractions for predicting PSMA PET SUVmean. Similarly, a multi-gene DLL3 predictor in lung cancer reduced the ctDNA threshold from 4% to 1.9% by incorporating predicted expression of three highly correlated genes. In predicting ER+ IHC breast cancer, ESR1 transcript prediction alone performed well at 1% ctDNA (AUC=.78) but was significantly improved (AUC=.90) by incorporating predictions of transcription partners FOXA1 and GATA3.
Conclusions
Comprehensive epigenomic profiling enables accurate prediction of tumor-specific RNA transcription in cfDNA, even at low ctDNA levels. This approach enhances ADC target profiling and enables tumor transcriptional profiling in patients from blood. Expanding beyond proof-of-concept models promises improved predictive accuracy at lower tumor fractions and broader applications in diagnostics and therapeutic targeting.

#669 AmoyDx essential NGS panel (LC 10), one solution covering tumor tissue and plasma for detection of EGFR and cMET alterations in NSCLC.

[1]Janssen Research & Development, Shanghai, China,[2]Department of Oncology, The First Affiliated Hospital of Xiamen University, Xiamen, China,[3]Department of Pulmonary and Critical Care Medicine, The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China,[4]Department of Pathology, The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China,[5]Amoy Diagnostics Co., Ltd., Xiamen, China,[6]Janssen Research & Development, Beijing, China,[7]Janssen Research & Development, Raritan, NJ

Background: Approximately 50% of Asian non-small cell lung cancer (NSCLC) patients carry EGFR and MET alterations with available targeted therapies. LC10 was designed for detection of genetic alterations in 10 driver genes in NSCLC, using FFPE or plasma samples. Notably, current commercial testing systems often use different NGS platforms for tissue and plasma analysis, limiting direct comparability and sample accessibility. This study validates EGFR and cMET alteration detection in tissue and plasma samples using a unified NGS platform (LC10) and assesses its implications for treatment planning in NSCLC patients.
Methods: LC10 is used for detection of 10 lung cancer driver genes by using ddCapture® technology with increased recovery rate and capture specificity. The analytical validation utilized clinical samples with varying dilutions of specific mutations (EGFR ex20ins, common mutations and MET ex14 skipping) and 11 synthesized plasmids in HEK-293T cells with gradient concentrations of 3rd TKI acquired resistance mutations (muts), along with a total of 277 plasma and 163 tissue samples. During clinical validation stage, paired peripheral blood and tumor tissue samples collected from 316 NSCLC patients were analyzed. Both tissue and plasma samples were tested with an average sequencing depth of 10,000X. The recommended input for tissue DNA and plasma ctDNA is 50ng and 30ng respectively.
Results: LC10 showed competent performance in EGFR ex20ins, common muts, 3rd TKI resistance muts and MET ex14 skipping detection with LOD 1% in tissue and 0.3% in plasma analysis. Specifically, a total of 16 different EGFR ex20ins types were validated during analytical validation stage. Among the 316 NSCLC patients (median age: 59 years; 51.6% male), 80.1% were treatment-naïve, while 19.9% had relapsed with drug resistance. Patients from stage IIIB-IV comprised 37.3% of the cohort (n: 118). In these 118 stage IIIB-IV patients, 57 EGFR muts (19del: 21, L858R: 23, T790M: 7, exon20ins: 4, other: 2) and 1 MET ex14 skipping muts were detected in plasma, achieving an overall percent agreement (OPA) of 86.4% with tissue samples. Concordance by muts site was as follows: 19del: 94.9%, L858R: 91.5%, T790M: 94.1%, exon20ins: 100%, and MET exon 14 skipping: 98.3%. Among the 189 stage I-IIIA patients, 12 EGFR muts and 1 MET exon 14 skipping mut were detected in plasma with OPA of 60.31% compared to tissue. Considering the “non-shedding” nature of early-stage lung adenocarcinoma, this concordance rate is comparable to previous studies.
Conclusion: In advanced-NSCLC, plasma is a dependable source for guiding targeted therapies, capturing both primary driver muts and acquired resistance. Employing LC10 provides a one-stop platform for both tissue and plasma testing in NSCLC diagnosis and treatment, which enhances the precision of muts detection with broader sample accessibility.

#67 Deciphering the mechanisms underlying the pathophysiology and chemotherapy resistance in acute myeloid leukemia using intravital imaging and humanized NSGW41IL7 mouse.
R. Niavarani, X. Lei, M. Edson, E. Chen, S. Wang, R. DaCosta;
University Health Network, Toronto, ON, Canada

Introduction: Acute Myeloid Leukemia (AML) is an aggressive & highly heterogeneous malignancy that originates within the bone marrow (BM). A major challenge in treating AML is its resistance to therapy & high relapse rates, driven in part by changes AML induces in the BM microenvironment, promoting immune suppression & creating hypoxic conditions. However, the mechanisms behind therapeutic resistance in AML patients in the presence of hypoxic BM niche, are poorly understood.
Innovation & Clinical Impact: To address this knowledge gap, our study employs two pioneering methods: a humanized NSGW41IL7 mouse model engrafted with human AML cells & the femur window chamber (FWC) technique, enabling unprecedented real-time visualization of AML dynamics within BM. Using advanced intravital imaging, we are the first to observe the intricate, continuous interactions between AML cells & immune components, such as human gamma delta T cells, within the BM microenvironment. Furthermore, we are interested in using our new approach to investigate how standard chemotherapies impact AML cell survival & immune responses under hypoxic conditions over time. Ultimately, our findings will provide new insights into treatment resistance mechanisms & pave the way for innovative therapeutic strategies targeting the BM microenvironment, improving outcomes for AML patients.

#671 Development of a diagnostic antibody for CD24 targeted therapy.

Peng Chen[1], Jishun Chen[2], Min Deng[1], Rong Guo[1], Ming Song[1], Jay Mei[3], **Bing Hou**[3]

[1]Shanghai Antengene Corporation Limited, Shanghai, China,[2]Antengene (Hangzhou) Biologics Co., Ltd, Hangzhou, China,[3]Antengene Corporation, Shaoxing, China

Background: CD24 is a small yet extensively glycosylated glycosylphosphatidylinositol protein that is overexpressed in many tumor cells. Elevated CD24 levels typically indicate a poorer prognosis, as it facilitates malignant activity and confers resistance to chemotherapies. CD24 is also identified as a surface marker of cancer stem cells across multiple tumor types. It triggers an anti-phagocytic by binding to sialic-acid-binding Ig-like lectin 10 (Siglec10) on tumor-associated macrophages, thereby inhibiting the phagocytosis of tumor cells. CD24 has emerged as a promising therapeutic target for anti-cancer treatment. Several clinical trials are being conducted to evaluate the safety and efficacy of CD24-targeted therapies. Here, we developed and characterized an anti-CD24 diagnostic antibody to enhance the screening and selection of patients based on CD24 expression.
Methods: SJL mice were immunized with 5-10 million HEK293T-hCD24 cells by intraperitoneal injection. Screening and selection of positive hybridoma clones were conducted using ELISA and flow cytometry analysis. Potential immunohistochemistry (IHC) clones were screened by staining formalin-fixed, paraffin-embedded (FFPE) specimens of human normal esophageal tissue using Leica Bond III platforms. The accuracy assessment, sensitivity (selectivity), specificity, and assay precision were evaluated using the lead antibody. Various human tumor tissue microarrays (TMA), including but not limited to breast cancer, ovarian cancer, urothelial cancer, and small cell lung cancer, were evaluated using lead antibody through IHC staining for further validation.
Results: Monoclonal antibody clone ATG1144 binds to the hCD24 core peptide in ELISA with an EC50 of 0.06 nM. Distinct membrane staining on human normal esophageal tissue FFPE specimens can also be observed with IHC staining using ATG1144. For accuracy assessment, six CDX and twenty human specimens, comprising both positive and negative specimens (including solid tumors and B-cell non-Hodgkin lymphomas), were validated. Samples exhibiting high, medium, and low CD24 expression levels were evaluated for sensitivity and specificity, and the interpreted results aligned with the reference outcomes. FFPE tissues from three distinct patients were evaluated for assay precision assessment. The TMA IHC staining result revealed that 50-80% of patients with lung, breast, bladder, ovarian, or liver cancer have CD24 expression on tumor cell surface with low expression in the para-cancerous normal tissue.
Conclusion: ATG1144 specifically binds to human CD24 with high sensitivity as demonstrated by IHC staining. The development and validation of the method have been finalized using Leica Bond III platforms. These data suggest a potential diagnostic use of ATG1144 for identifying human CD24 + patients.

#672 Plasma levels of Endothelin-1 are increased in colorectal cancer patients versus benign disease patients.

C. S. Herath Mudiyanselage[1], Y.-R. Chen[1], N. Mitra[1], H. Miyagaki[2], E. Nilsson Sjolander[1], X. Yan[1], V. Cekic[1], R. L. Whelan[1]; [1]Lenox Hill Hospital, Northwell Health, New York, NY, [2]Otemae Hospital, Osaka, Japan

Introduction: Endothelin-1 (ET-1) belongs to the Endothelin family and exerts its effects via ETA and ETB receptor (ETAR, ETBR) activation. ET-1 is mainly produced by endothelial cells (EC); its receptors are found in EC and vascular smooth muscle cells. ET-1 increases HIF1α stability and results in transcription of VEGFA, VEGFC, and their receptors. ET-1 has anti-apoptotic effects and influences cell survival pathways, including PI3K-dependent AKT activation and NF-κB signaling that are implicated in tumor progression, migration, and metastatic growth. ETAR inhibition impedes tumor growth and promotes apoptosis. ET-1 is overexpressed in many colorectal cancers. Tumor-derived ET-1 modulates MMP's and urokinase-type plasminogen activator that facilitate ECM degradation and tumor cell liberation. ET-1 alone also promotes neovascularization. This study assesses and compares preoperative (PreOp) plasma ET-1 levels in colorectal cancer (CRC) and benign colon pathology (BCP) patients.

Method: CRC and BCP patients (pts.) undergoing elective colorectal resection who were enrolled in an IRB approved tissue/data bank for whom PreOp plasma samples were available were eligible for the study. Demographic and clinical data were collected. PreOp plasma samples were obtained and stored at -80°C. Plasma ET-1 levels (pg/ml) were determined in duplicate via ELISA in and results presented as median +95% CI. ET-1 expression was analyzed in matched CRC and adjacent normal mucosal tissue samples from a subgroup of CRC patients (n=23) via QRT-PCR. Immunohistochemistry (IHC) was performed on formalin-fixed tissue sections (tumor/normal pairs) as per protocol.

Results: A total of 116 CRC pts (68% colon, 32% rectal) and 112 BCD pts (adenoma 46%, diverticulitis 50%, other 4%) were studied. The CRC stage distribution was: Stage (Stg) 1, 30%; Stg 2, 31% Stg 3, 31%; and stg 4,8%. Median plasma ET-1 levels were higher in CRC (1.39, CI: 1.25, 1.56) compared to BCP patients (1.11, CI: 1.021, 1.21p<0.001). A non-significant (ns) increase in mean ET-1 levels were noted in STG IV vs STG I and STG II and STG III was found (30-37%) and the mean levels in rectal cancer patients was 21% higher than those found colon cancer pts. IHC validated the presence of ET-1 protein in CRC tumors relative to normal colon. Increased expression of ET-1 was seen in 39% of tested CRC samples (9/23).The AUC value for the ROC curve was 0.673 (sensitivity 53%, specificity 73%).

Conclusion: The median plasma level of ET-1 in CRC pts. was 26% greater than noted in BCP pts. Increased tumor expression of ET-1 mRNA was identified in 39% of pts. High expression in the tumor may contribute to the elevated plasma levels. The analysis of the ROC curve indicates that ET-1 could serve as a potential candidate for inclusion in a more comprehensive diagnostic panel with other proteins found to be elevated in CRC pts. Further investigation is necessary.

#673 Protein Plus BCT: Ensuring reliable protein biomarker analysis in liquid biopsies by minimizing pre-analytical variations.
Rachel M. Miller, Sama Mehta, Jing Li

Streck LLC.R, La Vista, NE

While plasma protein biomarkers show promise for cancer early detection, diagnosis, prognosis, and monitoring, pre-analytical variation can affect sample integrity and limit the reliability of proteomic analysis. Sample collection, storage, and processing conditions can alter the proteome through *ex vivo* blood cell activation and lysis, which releases proteins that can obscure relevant *in vivo* abundances. This can significantly impact cancer biomarkers, many of which are expressed in white blood cells and platelets. Here, we use both immunoassay- and LC-MS-based proteomics to show that Protein Plus BCT minimizes proteome alterations during whole blood storage and plasma processing. To this end, plasma was isolated using single and double spin protocols from blood collected into EDTA and Protein Plus BCT immediately after draw or after 3 days of storage at either 2 °C, room temperature (22 °C), 30 °C, or 37 °C. When samples were analyzed on the Ella platform for oncology-relevant biomarkers, including TGF-β (relevant in CRC), we observed that the abundance of TGF-β increased by 5- and 4.3-fold on day 3 compared to draw time in plasma isolated from EDTA using single and double spin protocols, respectively. Conversely, there were minimal changes in abundance for plasma isolated from Protein Plus BCT, with no more than 1.5-fold change from day 3 to draw time observed for either single or double-spin processing. When samples were prepared for bottom-up proteomic analysis, we noted 6 times more proteins were significantly elevated in abundance for single spin plasma at draw time for EDTA compared to Protein Plus BCT. This trend persisted after 3 days of whole blood storage, with 11 times more proteins being elevated in abundance for single spin plasma for EDTA compared to Protein Plus BCT, further demonstrating the ability of Protein Plus BCT to maintain proteome stability across diverse sample storage and handling conditions. Specifically, we saw that EDTA samples demonstrated at least a 3 Log_2 fold change increase in S100A8 concentration, a potential cancer biomarker, on day 3 relative to draw time levels regardless of sample processing (single vs double spin) or storage temperature (2 °C, 22 °C, 30 °C, or 37 °C), whereas we saw no increase in abundance in samples collected into Protein Plus BCT on day 3 except for samples stored at 37 °C, which showed a 0.5 Log_2 fold change increase. Taken together, these data indicate that Protein Plus BCT preserves sample integrity and minimizes changes to the proteome, relative to EDTA, by reducing the impact of extended storage, temperature variations, and sample handling on accurate analysis. This offers researchers and assay developers flexibility in sample transport, storage, and processing. Protein Plus BCT is for Research Use Only. Not for use in diagnostic procedures. Protein Plus BCT should only be used for research or the development of new assays.

#674 Functional characterization of SMARCA4 genomic variants.

Shivani Jagannathan Murali, Bharath Kumar karre, Cristina Ivan, Kelly Craven, Stephanie Williams, Shikha Mahajan, Asfetaw Abera, Chao Sima, David Spetzler, Milan Radovich, Heather O'neill, Ravi Chakra Turaga

Department of Precision Medicine, Target & Drug Discovery, Caris Life Sciences, Inc., Chandler, AZ

Purpose: This study aims to carry out a pan cancer analyses of SMARCA4 genomic variants, including fusions, protein truncating variants (PTVs) and non-truncating variants(non-PTVs). Histological correlation of genomic variants for SMARCA4 expression may help identify tumors deficient in SMARCA4, making them potential candidates for treatment with synthetically lethal SMARCA2 inhibitors.
Methods: We analyzed 350,413 samples from Caris Life Sciences for clinical molecular profiling at Caris Life Sciences via Caris MI Tumor Seek (Phoenix, AZ). Gene fusion detection was performed on mRNA from FFPE tumor samples using the Illumina NovaSeq platform. Fusions with ≥ 3 junction reads were reviewed for domain prediction, breakpoints, frame retention, and co-occurring alterations. WES data was also examined for pathogenic mutations to assess fusion oncogenicity. IHC for SMARCA4 (N-terminal & C-terminal) and SMARCA2 was conducted on FFPE sections from 35 patients with SMARCA4 variants, with staining scored by a board-certified pathologist.
Results: Pan-Cancer analysis of SMARCA4 alterations revealed that NSCLC (30.7%) cases harbored the largest percentage of mutations followed by the CRC (15%) and UTNE (10%). Further, analysis through IHC revealed that patients with PTVs such as nonsense and frameshift mutations, were typically characterized by shorter/ truncated SMARCA4 protein and exhibited complete loss of SMARCA4 expression through IHC, often accompanied by an increase in SMARCA2 expression by IHC. In contrast, patients with missense mutations (non-PTVs) retained SMARCA4 expression, with minimal changes in SMARCA2 staining. In cases with SMARCA4 fusions detected, IHC analysis revealed an ambiguous result with some fusions retaining expression of SMARCA4 protein and others that did not. Patient cases harboring SMARCA4 fusions that displayed loss of SMARCA4 and concordant increase in SMARCA2 staining, would make good candidates for SMARCA2 inhibitor treatment. WTS analyses also revealed a decrease in SMARAC4 expression in PTVs, but not in non-PTVs. Further, we noted that other prevalent co-occurring mutations included TP53(55.7%), KRAS(19.7%) and ARID1A(16.7%) to be the most prominent alterations in patients with SMARCA4 alterations. Patients with SMARCA4 PTVs had poor prognosis compared to those without SMARCA4 variants in the NSCLC and UTNE indication.
Conclusion: SMARCA4 mutations, including frameshift and nonsense mutations, are common in NSCLC, UTNE, and OSEC. These alterations, particularly PTVs, make SMARCA4-deficient tumors potential targets for SMARCA2 inhibitor therapy. Some cases with SMARCA4 fusions or missense mutations may also be eligible for treatment, but these should be assessed individually, considering co-occurring mutations, copy number amplifications and fusion partners. This will aid in refining patient selection and improving treatment outcomes using companion diagnostics.

#675 Performance of highly sensitive molecular biomarker for pancreatic cancer detection.

Sophia F. Fang, Neng Yang

Epi One, Inc., Brooklyn, NY

Background: Pancreatic cancer is one of the most lethal malignancies, with resection being the only potentially curative treatment. However, due to the absence of effective early detection or screening, most patients are diagnosed at an advanced stage with a five-year survival rate of only 3%. Several genetic mutation-based biomarkers are already in use for cancer diagnosis. Epigenetic alterations, recognized as early events in tumorigenesis, also play a critical role in cancer development. The integration of mutational and epigenetic biomarkers has significant potential to enhance the accuracy of diagnostic panels for early cancer detection. By applying advanced mathematical models to integrate multi-level genomic and epigenetic data, Epi One has identified highly accurate biomarker panel for the early detection of pancreatic cancer. We developed pancreaScout - a simple, cost-effective, and highly sensitive qPCR assay for detecting the biomarker panel associated with pancreatic cancer. In this report, we present the performance of pancreaScout for the biomarker panel in human tissue and blood samples.

Methods: Eighty-seven human primary tissue samples and 48 blood samples with IRB consent were collected DNA was extracted from human primary samples DNA underwent bisulfite conversion to enable methylation-specific analysis, with quantitative methylation-specific PCR (qMSP) performed to quantify DNA methylation levels. In parallel, quantitative PCR (qPCR) was conducted on untreated DNA to detect genetic mutations. qPCR data analysis was carried out to calculate scores, which reflect the levels of mutation and methylation in samples.

Results: Identification of a pancreatic cancer detection panel with two mutation- and four DNA methylation- biomarkers. Validation of the biomarker panel using qPCR in 87 tissue samples (65 pancreatic cancer patients and 22 adjacent normal controls) , achieving 87% sensitivity and 90% specificity. Validation of the biomarker panel using qPCR in 41 blood samples (including 41 pancreatic cancer patients and 7 normal individuals) and achieved 69% sensitivity and 100% specificity.

Conclusions: pancreaScout is a sensitive and specific diagnostic panel for pancreatic cancer detection for both tissue and blood samples. Compared to sequencing-based methods for early cancer detection, pancreaScout assay achieves comparable sensitivity in blood tests. The simplicity of pancreaScout adds significant value in the fight against pancreatic cancer.

#676 First in man microdose trial of [^{68}Ga]Ga-R54, CXCR4 targeted PET tracer: Comparison with [^{18}F]-FDG and proof of concept in lung cancer models.

Anna Maria Trotta[1], Luigi Portella[1], Michela Aurilio[1], Crescenzo D'Alterio[1], Francesco Manna[1], Costantina Maisto[1], Antonio Luciano[1], Giuseppe Palma[1], Gaetana Di Maiolo[1], Laura D'Ambrosio[1], Francesca Bruzzese[1], Roberta De Marino[1], Aureliana Esposito[1], Luigi Di Caterino[1], Valentina Vozza[1], Elena Sinopoli[1], Gianfranco De Feo[1], Francesco Perrone[1], Salvatore Di Maro[2], Secondo Lastoria[1], **Stefania Scala**[1]

[1]Istituto Nazionale Tumori - IRCCS G. Pascale, Naples, Italy,[2]Universita della Campania "L. Vanvitelli", Caserta, Italy

CXCR4 is overexpressed on the majority of haematological and solid cancers and correlates with metastatic features. CXCR4 is a potential imaging target for the accuracy of diagnosis, staging and predictive treatment efficacy. Despite the development of CXCR4 targeting PET tracers, the sensitivity and specificity toward solid tumors is modest. A new CXCR4-targeting PET tracer, [^{68}Ga]Ga-R54 (PCT/EP2020/087792) specifically accumulated in CXCR4-overexpressing tumors in *in vivo* murine models. Aim of the work is to extend the *in vivo* specificity and imaging efficacy of [^{68}Ga]Ga-R54 in lung cancer and to evaluate the [^{68}Ga]Ga-R54 in humans. Thus, PET/CT imaging and biodistribution was conducted on athymic mice bearing subcutaneous NCI-H69 (SCLC) and H460 (NSCLC) tumors. Biodistribution studies revealed high and specific tumour uptake in both H69 and H460 tumors s after 1 hour post injection (H69-tumor uptake: 12.2±1%ID/g; H460-tumor uptake: 2±0.4%ID/g) and rapid renal excretion. Competition with cold R54 reduced [^{68}Ga]Ga-R54 uptake by approximately 90% and 60% respectively showing CXCR4 specificity. Compared to [^{18}F]-FDG, [^{68}Ga]Ga-R54 showed significantly higher uptake in H69 tumors (12.2±1%ID/g vs 3.75±0.6%ID/g, $p<0.001$). Consistently, PET/CT scans clearly visualized tumors at 1 hour post tracer administration with significant reduction in accumulation due to cold R54. Accordingly, high CXCR4 expression was revealed in H69 human lung cancer cells. Thus, a Microdose clinical study (ICH M3(R2) CPMP/ICH/286/95 Chapter 7.1) was planned to identify Pharmacokinetics/ Pharmacodynamic properties of [^{68}Ga]Ga-R54 in metastatic/ advanced solid tumors. Toxicity and toxicokinetic as GLP-Extended single dose toxicity study in rats demonstrated non-evident toxicity induced by iv injection of 1000x the supposed clinical dose of [^{68}Ga]Ga-R54 at 2 and 14 days post-injection. A monocentric, nonrandomized, open label clinical trial with [^{68}Ga]Ga-R54 (R4-FOUR-PET - EU CT: 2024-513303-14-00) was recently approved on October 2024. R4-FOUR-PET will enrol 5 to 10 patients carrying CXCR4 expressing advanced cancers (breast, colon, lung, pancreas and ovarian) and will be conducted at the Nuclear Medicine of IRCCS-Pascale. Primary objective of the study is to evaluate pharmacokinetics and pharmacodynamics of a single microdose (<100µg) of [^{68}Ga]Ga-R54; comparison with [^{18}F]-FDG and correlation between SUVmax and CXCR4 IHC expression will be conducted. Patient’s enrolment is ongoing.

#677 H-score as a diagnostic tool in HER2 equivocal (IHC 2+) breast cancer.

Tasnem Alsebai[1], Muhammed Yaman Swied[1], Ricardo Cossyleon[2], Kathy Robinson[2], Kristin Delfino[1], John Gao[3], Krishna Rao[2]

[1]Southern Illinois University at School of Medicine, Springfield, IL,[2]Simmons Cancer Institute at Southern Illinois University, Springfield, IL,[3]Department of Pathology, Springfield Memorial Hospital, Springfield, IL

Introduction: Human epidermal growth factor 2 receptor (HER2) overexpression occurs in 15-20% of primary invasive breast cancers, significantly contributing to their aggressive nature and poor prognosis [1]. HER2 status is typically assessed using immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH). IHC results classified as 2+ are considered equivocal, leading to a reliance on FISH for confirmation. However, FISH is costlier and time-consuming, which can delay necessary treatment [2]. This study aims to assess the potential of the histochemical score (H-score), a quantitative measure derived from IHC staining and calculated using ImageJ software, as a reliable tool for classifying HER2 status in cases with equivocal IHC 2+ results. By investigating whether the H-score can accurately predict HER2 status, this study explores the possibility of reducing reliance on FISH for confirmation.
Methods: This retrospective study included adult patients (≥18 years) diagnosed with HER2 IHC 2+ breast cancer from January 2014 to December 2023. Demographic and pathologic data were collected from medical records, and diagnostic biopsy slides were reviewed. Images of IHC specimens were captured at ×10 magnification, standardized, and analyzed using ImageJ software. The H-score was calculated using mean staining intensity and stained area percentage. Binary logistic regression evaluated the predictive power of the continuous H-score on HER2 status by FISH.
Results: The mean H-score of 182 patients was 2.65, with HER2-positive cases showing a higher mean score (3.06) than HER2-negative cases (2.62). ROC analysis yielded an AUC of 0.668 (95% CI 0.523 to 0.812), indicating poor predictive accuracy. Moreover, when calculating the Youden index, the optimal H-score cutoff score (2.6007) provided moderate sensitivity (0.769) but limited specificity (0.580). These results suggest that while the H-score may provide some predictive value, it has limited accuracy for classifying HER2 status independently.
Summary: The H-score lacks accuracy to reliably distinguish HER2 status (positive from negative) in IHC 2+ cases. The moderate AUC and risk of false positives emphasize the need to continue using FISH analysis for confirmation. While moderately correlated with HER2 status, the H-score does not meet clinical precision standards, making FISH essential for accurate classification. Future research should aim to refine the H-score or identify new markers to improve predictive accuracy in equivocal cases.

#678 A 10-second lipidomic based approach to diagnose common spinal tumor types with picosecond infrared laser mass spectrometry.

Alexa Fiorante[1], Michael Woolman[1], David Munoz[2], Taira Kiyota[3], Lan Anna Ye[4], Yasamine Farahmand[5], Darah Vlaminck[1], Francis Talbot[4], Sunit Das[2], Gelareh Zadeh[4], Howard Ginsberg[2], Ahmed Aman[3], Arash Zarrine-Afsar[4]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Unity Health Toronto, Toronto, ON, Canada,[3]Ontario Institute for Cancer Research, Toronto, ON, Canada,[4]University Health Network, Toronto, ON, Canada,[5]University of Toronto, Toronto, ON, Canada

Intradural extramedullary spinal neoplasms account for ~40% of all diagnosed spinal tumors. Of that, meningioma and schwannoma are the most common. However, improving the surgical outcomes for these spinal neoplasms requires precise intraoperative diagnosis provided by highly trained neuropathologists. Through a retrospective study of n=257 patient specimens, we demonstrate that 10-second picosecond infrared laser mass spectrometry (PIRL-MS) can robustly and objectively diagnose commonly occurring spinal tumor types with the sensitivity and specificity values of (93±1)% and (97±2)%, respectively. This classification utilizes n=41 cellular lipids including phosphatidylcholines, sphingomyelins, phosphatidylethanolamines, and ceramides, whose identities were established using high-resolution tandem mass spectrometry. The identified lipids form a ‘molecular array’ for robust diagnosis of meningioma and schwannoma tumors by non-pathologists in a manner like genomic, transcriptomic, or methylomic arrays used to diagnose brain cancer types, albeit on a faster timescale of seconds as opposed to hours. Furthermore, when subjected to the presence of additional intradural extramedullary spinal tumor types in the differential diagnosis, the generalizability and robustness of the identified molecular array rendered correct classification even in the presence of data not seen previously by the model. PIRL-MS mediated pathology stratifies the resection risk such that complete removal of certain spinal neoplasms such as meningioma tumors with dural excision could be justified to improve the surgical outcomes. Thus, providing informed surgical care even in the absence of intraoperative consults, addressing the human resource limitations in settings that are understaffed in neuropathology. Here, the current state of PIRL-MS device development allows operation by anyone with basic laboratory skills.

#679 Orthogonal confirmation using the Pacbio®two step universal adapter amplicon protocol to validate a comprehensive genomic profiling assay for hematologic malignancies.

Grant Hogg[1], Kimberly A. Holden[1], John Howitt[2], Adib Shafi[1], Amanda Willliamson[2], Tong Liu[1], Helen Cao[1], Xiaojun Guan[1], Michael Mooney[2], Qian Zeng[3], Stan Letovsky[3], Li Cai[2], Eric A. Severson[2], Shakti Ramkissoon[2], Anjen Chenn[2], Marcia Eisenberg[4], Eyad Almasri[1], Taylor J. Jensen[1], Jonathan Williams[1]

[1]Oncology, Labcorp, San Diego, CA,[2]Oncology, Labcorp, Durham, NC,[3]Labcorp, Westborough, MA,[4]Labcorp, Burlington, NC

Next generation sequencing (NGS) using targeted panels is standard of care to aid diagnosis, prognosis and treatment selection for hematologic diseases such as acute myeloid leukemia. We have validated the Labcorp Pan-Heme NGS (LPH) panel that targets 141 clinically relevant genes to detect single nucleotide variants (SNVs), insertions/deletions (indels), *FLT3* internal tandem duplicates (*FLT3*-ITDs) and copy number aberrations (CNAs) in myeloid and lymphoid malignancies. In total, 677 samples were assessed including 315 clinical samples. Analytical sensitivity and specificity experiments estimated that the limit of detection (LoD) for the LPH panel was 3-5% variant allele frequency (VAF). Determining accuracy of SNV/indels in clinical samples requires an independent confirmation. Sanger is the gold standard but has a sensitivity of ~15% VAF. We developed and utilized a custom PacBio multiplexed two-step amplicon sequencing protocol using Sanger sequencing products as template. We determined it to be a sensitive, cost-effective and easily customizable approach to detect variants with VAF <15%. The LPH panel interrogates all coding exons of the 141 genes using a custom hybrid capture-based assay of genomic libraries from 250 ng blood or bone marrow genomic DNA followed by sequencing on Illumina® sequencers. For PacBio confirmation, M13 tagged amplicons with length ranging from 214-678bp were generated using 10-50 ng input DNA, amplified with asymmetric barcodes, and processed for PacBio HiFi sequencing on a Sequel II. PacBio variants were called using Mutect2 (GATK) and/or visual inspection of .bam files by Integrated Genome Viewer (IGV). A subset of variants was called using the PacBio Amplicon Analysis tool (pbAA). 217 amplicons from 126 unique clinical samples were assessed by PacBio with a VAF ranging from 3-100% and comprising 140 SNVs, 63 indels <25bp and 14 indels ≥ 25bp. Concordance between PacBio and the LPH panel was 84.8% (184/217) and 69.4% (66/95) for the subset of variants with VAF between 3-5%. 9 of 184 required pbAA analysis to make a final consensus call. 63 variants were assessed with PacBio by processing the same M13 amplicons previously taken through Sanger analysis. This "double-dip" approach showed an 96.7% agreement (59/61) between PacBio and Sanger. The 2 variants not in agreement had VAF <15%.The PacBio variant calls in this study were incorporated into the results of the LPH panel analytical validation as orthogonal information, yielding an overall PPA for SNVs/indels of 99.1% (1250/1272) and FDR of 0.8% (10/1260) using VAF thresholds of 3% for SNVs and 5% for indels. In conclusion, the PacBio amplicon protocol can utilize amplicons generated for Sanger sequencing with minimal additional wet lab processing offering a flexible approach to confirmation for variants below the threshold of Sanger sensitivity.

#68 Precision medicine in glioblastoma: cortical network disruptions, biomarker development, and multimodal therapeutic strategies.

Tenesha Connor, Frederick Bell, Macit Emre Lacin, Miguel Maldonado, Kemal Ozdemirli, Anthony Sloan, Justin Lathia, **Murat Yildirim**

Cleveland Clinic Lerner Research Institute, Cleveland, OH

Glioblastoma (GBM) is a highly aggressive brain tumor characterized by diffuse infiltration into surrounding brain tissue, disruption of neural circuitry, and interactions among neurons, astrocytes, and blood vessels. This infiltration leads to severe functional impairments, including neuronal hyperexcitability, cognitive deficits, and in some cases seizures. While substantial progress has been made in understanding GBM's molecular mechanisms, less is known about how tumor progression alters brain connectivity, neural oscillations, and behavior. Using advanced transgenic mouse models (e.g., GCaMP6s, GCaMP6f, jGCaMP8m, and Vgat-Cre-ChR2) and custom-built optical microscopes, we performed large-scale, high-speed neural recordings and manipulations across over 10 million neurons spanning 60 brain regions in vivo in pre-clinical GBM models. Our approach integrates deep learning tools for multimodal analysis of brain activity, pupil dynamics, and orofacial behaviors, supported by computational models optimized with quantum computing. Preliminary data reveals significant tumor-induced disruptions in neural and behavioral dynamics. Tumor growth in the mouse striatum is associated with increased pupil size, restricted gaze range, and reduced interhemispheric connectivity. Furthermore, oscillatory activity shows a striking shift, with decreases in delta power accompanied by increases in theta and alpha band power. These findings highlight GBM's capacity to disrupt normal neural rhythms and connectivity. Our work underscores the potential of using behavioral relevant parameters as a non-invasive biomarker for early detection of GBM-induced neural dysfunction. Future studies will focus on leveraging these insights to develop novel therapeutic strategies targeting tumor-induced disruptions in oscillatory activity. By integrating cutting-edge imaging technologies and computational methods, our findings have significant implications for improving early diagnosis and treatment outcomes for GBM patients.

[1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Department of Radiation Oncology, University of Toronto, Toronto, ON, Canada,[3]Infections and Cancer Epidemiology Division, German Cancer Research Center (DKFZ), Heidelberg, Germany,[4]Princess Margaret Cancer Centre, Toronto, ON, Canada,[5]Department of Otolaryngology-Head & Neck Surgery/Surgical Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada,[6]Division of Medical Oncology & Hematology, Princess Margaret Cancer Centre, Toronto, ON, Canada

Introduction: The incidence of human papillomavirus-positive (HPV+) oropharyngeal cancer (OPC) has increased rapidly, and HPV early antigen serology has been proposed as a scalable and cost-effective early detection test. HPV seropositivity can precede clinical presentation of OPC by several years, so additional surveillance procedures may be necessary to optimize early cancer detection. The potential for HPV circulating tumor DNA (ctDNA) to confirm a diagnosis of OPC in seropositive individuals is poorly understood. Here, we assess the relationship between HPV serology and HPV ctDNA with disease burden in a large cohort of HPV+ OPC.
Methods: We analyzed pre-treatment peripheral blood plasma from 262 patients with non-metastatic p16+ OPC treated with definitive (chemo)radiotherapy. A multiplex ELISA was used for serologic evidence of HPV proteins from 10 HPV genotypes, quantified by mean fluorescence intensity (MFI). Plasma HPV ctDNA was quantified by whole viral genome sequencing utilizing a custom HPV-targeted capture panel for 38 HPV genotypes. Gross tumor volume (GTV) was obtained from the sum of all target contours on computed tomography scans.
Results: Both assays identified HPV16 as the most prevalent genotype (84%), with results indicating a total of 4 and 6 HPV genotypes for serology and HPV ctDNA, respectively. HPV ctDNA results demonstrated higher sensitivity and lower cross-reactivity between HPV types compared with HPV serology results. Furthermore, HPV ctDNA but not HPV16 E6 antibody levels were positively associated with disease burden as determined by N-category (Table 1) and tumor volume (ctDNA vs GTV, r=0.48 p=6.4e-13; E6 vs GTV, r= -0.079 p=0.26).
Conclusion: This is the largest cohort to compare HPV serology and ctDNA results in OPC. These findings highlight the potential for ctDNA to augment future strategies for blood-based early detection of HPV+ OPC.
Table 1: Comparison of HPV16 E6 serology (MFI) and HPV ctDNA (log[copies/mL]).

#681 A novel approach of Claudin 18 immunohistochemistry testing demonstrated comparable performance and high concordance compared to Ventana 43-14A in gastric cancer.

Zhenghua Tang[1], peng cheng[2], Xin Liu[3], Huangbin Lu[1], Jingjing Xu[1], Yiling Cai[1], **Changbin Zhu**[2]

[1]Research and Development Department, Amoy Diagnostics Co., Ltd., Xiamen, China,[2]Translational Medicine Department, Amoy Diagnostics Co., Ltd., Xiamen, China,[3]BD Department, Amoy Diagnostics Co., Ltd., Xiamen, China

Background: Claudin(CLND)18 is a tight-junction molecule consisting two Isoforms:CLND18.1 and CLND18.2. Isofrom CLND18.2 is specificly expressed in gastric cancer. Zolbetuximab is the first CLDN18.2 therapeutic monoclonal antibody approved by FDA. VENTANA® CLND18(43-14A), a pan-CLND18 immunohistochemistry (IHC) testing, was approved as companion diagnostics simutanusly. Validation between different Claudin 18 IHC testing approaches could improve the convenience of diagnostics in clinical use.

Methods: A total of 68 gastric cancer samples were enrolled in this study. Expressing status of Claudin 18 was evaluated independently by two IHC approaches. AmoyDx CLDN18 (43-14A) assay was used as testing reagent and VENTANA® CLDN18 (43-14A) RxDx acts as reference reagent. Claudin 18 positive was defined as: tumor with staining intensity of 2+ or 3+(total) in ≥75% of tumor cell.

Results: Validtaion results was shown in Table 1. 21 positive cases and 47 negative cases were identified by two reagents. Standing for a 100%(84.54% - 100%) positive percent agreement (PPA), 100% (92.44% - 100%) negative percent agreement (NPA), and 100% (94.65% - 100%) overall percent agreement (OPA). Poisson distribution analysis of the proportion of cells with four staining intensities(3+, 2+, 1+ and 0) demostrated that the staining intensity of the two approaches was highly consistent ($R = 0.99$-1, $p < 2.26e^{-16}$). When the positive threshold was exploratively adjusted (2+/3+ cells ≥50%), high concordance was still maintained (PPA 100%, NPA 93.55%, OPA 97.06%, Table 1.) except 2 conflict samples, which were close to the exploratively threshold.

Conclusion: Two Claudin 18 testing approaches demonstrated high concordance. It has potential versatility in future clinical practice.

Concordance of two CLND18 testing approaches

2+/3+≥75%	Ventana CLDN18(43-14A)				2+/3+≥50%	Ventana CLDN18(43-14A)			
AmoyDx CLDN18 (43-14A)		Positive	Negative	Total	AmoyDx CLDN18 (43-14A)		Positive	Negative	Total
	Positive	21	0	21		Positive	37	2	39
	Negative	0	47	47		Negative	0	29	29
	Total	21	47	68		Total	37	31	68
PPA	100% (84.54% - 100%)				PPA	100% (90.59% - 100%)			
NPA	100% (92.44% - 100%)				NPA	93.55% (79.28% - 98.21%)			
OPA	100% (94.65% - 100%)				OPA	97.06% (89.90% - 99.19%)			

#682 PCDHGB10: a unique, sensitive, and specific serum cfDNA methylation biomarker for stomach adenocarcinoma diagnosis.

Donghong Zhang[1], Chaoyan Niu[2], Daoyu Yan[3], Ruo-Pan Huang[4]

[1]Donghong Zhang (Individual), Peachtree Corners, GA,[2]RayBiotech Guangzhou Co. Ltd, Guangzhou, China,[3]RayBiotech Guangzhou Co. Ltd., Guangzhou, China,[4]RayBiotech Life Inc, Peachtree Corners, GA

Serum cell-free DNA (cfDNA) methylation has demonstrated its potential in detecting and screening for multiple cancers, offering a critical window for identifying patients eligible for effective treatment. Our objective was to evaluate the efficacy of high methylation-sensitive restriction enzyme combined quantitative PCR (MSRE-qPCR) in identifying a serum cfDNA methylation biomarker for a spectrum of cancer types. We initially developed a 6-gene panel comprising 11 pan-cancer cell-differentially methylated regions across 15 prevalent cancer types, utilizing data from the TCGA methylome database (n = 6981). This panel was then validated using MSRE-qPCR on serum cfDNA samples from 825 participants, encompassing 632 cancer patients across 11 cancer types and 193 healthy controls, collected from multiple cancer centers in China. We assessed the specificity and sensitivity of the panel for diagnosing individual cancers at multiple sites, including the colorectum, esophagus, stomach, liver, lung, ovary, lymphoma, cervix, endometrium, nasopharynx, and pancreas. Among the 11 cancer types, stomach adenocarcinoma (STAD) demonstrated the highest sensitivity and specificity for DNA methylation-based diagnosis in real-world scenarios. PCDHGB10 methylation particularly stood out for STAD diagnosis, achieving a sensitivity of 93.16% and specificity of 88.24% in the training cohort, and 84.09% sensitivity and 96.67% specificity in the validation cohort. For early-stage (I and II) patients, PCDHGB10 sensitivity was 78.48%, rising to 86.89% in late-stage patients. In contrast, PCDHGB10 methylation showed suboptimal diagnostic performance (less than 65% sensitivity) in the other 10 cancer types. This extensive public database and clinical validation study underscores the role of PCDHGB10 methylation as a highly sensitive, specific, and distinctive serum cfDNA methylation biomarker for STAD diagnosis, with particular promise for early-stage detection.

#683 NaDC3: a potential tumor suppressor and biomarker in renal cell carcinoma.

Miswakumari Lad, Tianyu Yang, Karina Aguilar, Vinata Lokeshwar

Augusta University, Augusta, GA

Introduction and Objective: The five-year survival rate for patients with metastatic renal cell carcinoma (mRCC) is less than 10%, with the highest incidence found among African American males. Addressing racial disparities in renal cell carcinoma (RCC) are essential for the development of biomarkers and targeted therapies. NaDC3, a succinate/citrate transporter expressed in kidney epithelial cells, has not yet been studied in relation to any diseases. In our research, we assessed NaDC3 expression in both normal and RCC tissues and examined its correlation with clinical outcomes and racial disparities. Additionally, we investigated the biological functions and molecular signaling pathways influenced by NaDC3 in RCC cells.

Methods: Differences in gene expression in the matched normal and RCC tissues (n=6/category) was evaluated using microarray analysis; results were then validated by QPCR and immunoblotting in tissues from 83 patients (White=46; Hispanic=24; AA=13). VHL+ and VHL- RCC cells were stably transfected with a NaDC3 construct. Transfectants were assessed for cell proliferation, cell cycle, motility, succinate/citrate transport and reactive oxygen species (ROS) measurement assays under normoxic and hypoxic conditions. SDCT2 induction was evaluated following 5-azacytidine plus Trichostatin A treatment.

Results: NaDC3 was 63- and 100-fold downregulated in low- and high-stage RCC tissues respectively. QPCR validation showed 40-fold downregulation of NaDC3 in RCC tissues when compared to normal kidney ($P< 0.0001$). Downregulation was 40-fold in White and Hispanic patients, but 198-fold in AA patients ($P=0.0049$) and correlated with tumor stage and metastasis ($P=0.009$). Under hypoxic conditions, NaDC3 expression caused 3-4-fold inhibition of proliferation, cell-cycle, and motility in both VHL+ and VHL- cells ($P<0.01$); only VHL+ cells were inhibited under normoxia. NaDC3 expression induced ROS levels and succinate transport by >3-fold ($P<0.01$) and activated the p16INK4a-RB pathway and apoptosis (caspase-3 and PARP activation). NaDC3 expression was silenced in patient-derived primary cell lines from AA patients.

Conclusion: This is the first study on a functional biomarker in RCC, NaDC3, that is a possible novel tumor suppressor gene. NaDC3 loss promotes RCC growth and survival and inhibits cellular senescence, while its downregulation correlates with metastasis and racial disparity.

Support: 1R01CA227277-05A1; 1R01CA283699-01

#684 Multi-site external reproducibility of PD-L1 IHC 22C3 pharmDx performance on Dako Omnis and comparison to Autostainer Link 48 for head and neck squamous cell carcinoma using the Combined Positive Score.

Monika D. Polewski[1], Lining Hutchinson[1], Jianan Ren[2], Nichole LaPointe[2], Siena Tabuena-Frolli[2], Kurt Mathews[2], Gregory A. Cherryholmes[1]

[1]Global Clinical Affairs, Organization of the Chief Medical Officer, Agilent Technologies, Inc., Carpinteria, CA,[2]Research and Development, CDx, Agilent Technologies, Inc., Carpinteria, CA

Background: PD-L1 IHC 22C3 pharmDx is a diagnostic assay indicated as an aid in identifying biomarker PD-L1 expression levels for use on the Autostainer Link 48 (ASL48) platform for multiple indications. However, to date PD-L1 IHC 22C3 pharmDx on Dako Omnis platform has only been validated for non-small cell lung cancer. This study sought to demonstrate external reproducibility of PD-L1 IHC 22C3 pharmDx for head and neck squamous cell carcinoma (HNSCC) using Dako Omnis (Investigator Use Only/Performance Evaluation Only). This study also investigated the concordance of PD-L1 IHC 22C3 pharmDx on HNSCC on both ASL48 and Dako Omnis at external sites.

Methods: This study was a three-site, blinded, and randomized study of PD-L1 IHC 22C3 pharmDx on HNSCC specimens. To investigate inter-site and intra-site reproducibility, five replicate sets of pre-qualified unstained specimens were stained using Dako Omnis and evaluated at each of the three testing sites. For the inter-platform performance evaluation, pathologists at each of the three testing sites evaluated one set of HNSCC slides that was pre-stained using PD-L1 IHC 22C3 pharmDx on ASL48. Pathologists determined the PD-L1 expression level using a Combined Positive Score (CPS) at diagnostic cutoffs CPS ≥ 1 and CPS ≥ 20. The analytical agreements of the diagnostic outcome (positive/negative) were estimated by evaluating negative percent agreement (NPA), positive percent agreement (PPA), and overall percent agreement (OA) based on comparisons to the consensus diagnostic outcome with corresponding percentile bootstrap confidence intervals. The pre-determined acceptance criteria (AC) for all endpoints are that the lower-bound (LB) of a two-sided 95% confidence interval (CI) for NPA, PPA, and OA must meet or exceed 85.0%.

Results: The study met all AC for the CPS ≥ 1 and CPS ≥ 20 cutoffs. For CPS ≥ 1, the 95% CI LB of the inter-site reproducibility endpoints were 90.5% for NPA, 98.7% for PPA, and 95.0% for OA and intra-site reproducibility endpoints were 98.9% for NPA, 98.0% for PPA, and 98.5% for OA. For CPS ≥ 20, the 95% CI LB of the inter- site reproducibility endpoints were 87.7% for NPA, 91.1% for PPA, and 91.2% for OA and intra-site reproducibility endpoints were 92.7% for NPA, 95.8% for PPA, and 95.0% for OA. For CPS ≥ 1, the 95% CI LB of the inter-platform performance comparison endpoints were 96.0% for NPA, 98.7% for PPA, and 98.0% for OA. For CPS ≥ 20, the 95% CI LB of the inter-platform performance comparison endpoints were 90.6% for NPA, 94.2% for PPA, and 93.3% for OA.

Conclusions: This study demonstrates reproducibility of PD-L1 IHC 22C3 pharmDx (with Dako Omnis) in HNSCC specimens at the CPS ≥ 1 and CPS ≥ 20 cutoffs. The results of the inter-platform performance comparison study demonstrate concordance between ASL48 and Dako Omnis in HNSCC specimens at the CPS ≥ 1 and CPS ≥ 20 cutoffs.

#685 Integrative screening of DNA methylation markers enables early detection of hepatocellular carcinoma.

Hao Zhuang[1], Bo Wang[2], Yongmei Li[2]

[1]UC San Diego, San Diego, CA,[2]Tianjin Medical University, Tianjin, China

DNA methylation, a pivotal epigenetic modification regulating gene expression, has gained significant attention as a potential diagnostic biomarker for various cancers, including hepatocellular carcinoma (HCC). This study aimed to identify aberrant DNA methylation patterns and protein alterations using integrated methodologies and to develop a robust biomarker panel for blood-based early detection of HCC. Genome-wide methylation profiling was performed to identify hypermethylated CpG sites and genes that distinguish early-stage HCC from non-HCC tissues. Using four distinct strategies, 44 candidate marker genes were identified and subsequently assessed in combination with five protein markers in a cohort of 299 blood samples. Through 5-fold cross-validation, a panel comprising six methylation markers from four different groups achieved an area under the curve (AUC) of 0.938, outperforming panels derived from single-group markers. A final 6-marker panel, combining four methylation markers and two protein markers in a logistic regression (LR) model, was developed. This panel demonstrated a sensitivity of 92.2% at a specificity of 94.3% in the training set, and a sensitivity of 86.4% at a specificity of 97.8% in the validation set. Notably, the 6-marker panel showed superior sensitivity (75.0%) for detecting HCC at Barcelona Clinic Liver Cancer (BCLC) stages 0-A compared to alpha-fetoprotein (AFP) and des-gamma-carboxyprothrombin (DCP). A multi-group approach to selecting methylation markers outperformed single-group strategies. The developed 6-marker panel demonstrates excellent sensitivity and specificity, offering a promising tool for the early detection of HCC, particularly in its earliest stages.

#686 Retrospective analysis of estrogen receptor expression in prostatic neoplasms: Implications across age and racial groups.

Laura B. Pagan[1], Tingting Yang[2], Jinghe Mao[3], Xinchun Zhou[1]

[1]Pathology, The University of Mississippi Medical Center, Jackson, MS,[2]The First Hospital of Jilin University, Changchun, China,[3]Biology, Tougaloo College, Jackson, MS

Background: Prostate cancer (PCa) is the most common cancer in men in the United States, aside from non-melanoma skin cancer. The roles of estrogen receptor α (ERα) and estrogen Receptor β (ERβ) in PCa have not been fully elucidated yet. This study aims to evaluate the expression levels and localizations of ERα and ERβ in benign prostatic tissue (BPT) and PCa across different racial and age groups.
Methods: Immunohistochemistry (IHC) for ERα and ERβ was performed on tissue microarrays (TMA) containing 240 samples of BPT and PCa from Black and White individuals and age groups ≤60 and >60 years. The localization of the IHC signal for ERα and ERβ was determined in glandular and stromal regions. Expression levels of ERα and ERβ were quantified using an IHC score, calculated by multiplying the area score (percentage of stained cells: 0 for no staining, 1 for <10% staining, 2 for 10-50% staining, and 3 for >50% staining) by the intensity score (0 for no signal, 1 for weak, 2 for moderate, and 3 for strong staining). Statistical analysis was performed using Student's t-test; a p-value ≤0.05 was considered significant.
Results: In the entire population, the IHC scores for glandular ERα, stromal ERα, and glandular ERβ were lower in all PCa cases than in BPT, but a significant difference was only seen in glandular ERβ between PCa and BPT (3.43±2.3 vs. 4.86±2.8; p=0.0021). Interestingly, the IHC scores for all glandular ERα, stromal ERα, and glandular ERβ were significantly lower in metastatic PCa than in BPT (p=0.014, p=0.0001, and p=0.0035, respectively). While the entire population was stratified by race, there was no significant difference in IHC score for glandular ERα, stromal ERα, or glandular ERβ in both BPT and PCa between Black and white populations. While entire population was stratified by age, individuals with age >60 years had significantly lower IHC scores for glandular ERα (p=0.0023) and stromal ERα (p=0.03), but not for and glandular ERβ (p=0.1) in BPT; and significantly lower IHC score for stromal ERα (p=0.0036).
Conclusions: These findings suggest that ERα and ERβ could be potentially diagnostic and prognostic biomarkers for PCa. Declined expression levels of glandular ERα, stromal ERα, and glandular ERβ may correlate to the oncogenesis, progression and disparities in race and age PCa.

#687 Development of MAGE-A4 IHC 1F9 pharmDx for melanoma-associated antigen 4 (MAGE-A4) detection in FFPE synovial sarcoma specimens for afamitresgene autoleucel therapy.

Andrea N. Marquez[1], Siena Tabuena-Frolli[1], Sneha L. Koneru[1], Pedro Corona[1], Rose-Ann De Los Santos[1], Adrian Miranda[1], Kristopher Kersch[1], Eric Broxham[2], Regina Singson[2]

[1]Companion Dx, Life Sciences and Diagnostics Markets Group, Agilent Technologies, Inc., Carpinteria, CA, [2]Pathology, TOPA Diagnostics, Thousand Oaks, CA

Introduction: MAGE-A4 IHC 1F9 pharmDx is a qualitative immunohistochemistry assay developed as a companion diagnostic for afamitresgene autoleucel therapy to detect Melanoma-associated antigen 4 (MAGE-A4) expression in synovial sarcoma (SyS) specimens. The assay's analytical performance has been validated on the Autostainer Link 48 Platform using mouse monoclonal anti-MAGE-A4 antibody, clone OTI1F9, in formalin-fixed paraffin-embedded (FFPE) human synovial sarcoma (SyS). Squamous non-small cell lung carcinoma (sqNSCLC) specimens were used in the analytical performance evaluation to supplement sample size and support the use of sqNSCLC as a positive control due to the rarity of SyS. MAGE-A4 positivity was defined as nuclear and/or cytoplasmic staining in viable tumor cells and MAGE-A4 expression was determined using a Tumor Intensity Proportion Score (TIPS) algorithm. Analytical validation of the MAGE-A4 IHC 1F9 pharmDx assay included sensitivity, precision, and robustness testing of MAGE-A4 expression in SyS and sqNSCLC specimens based on the MAGE-A4 TIPS (≥ 2+) ≥ 75% cutoff.
Methods: Sensitivity determined if the assay could detect a range of MAGE-A4 expression levels in SyS and sqNSCLC specimens. Precision testing assessed variability in observers/run/instrument/operator/day/lot. Observer precision was evaluated by inter/intra-observer agreement. Robustness studies evaluated assay performance variability for target retrieval solution (pH, re-use, temperature and time), slide type, and tissue section thickness. SyS and sqNSCLC data were analyzed together using negative percent agreement (NPA), positive percent agreement (PPA), and overall agreement (OA) with two-sided 95% bootstrap confidence intervals (CIs) based on MAGE-A4 binary status (positive/negative) at the cutoff. The following acceptance criterion (AC) was applied: the lower bound (LB) of the two-sided 95% CI computed on percent agreement (NPA, PPA, and OA) ≥ 85%.
Results: MAGE-A4 IHC 1F9 pharmDx detected a dynamic range of staining levels in SyS and sqNSCLC. The prevalence of MAGE-A4-positive cases per cutoff in the commercially procured FFPE SyS specimens tested was 30.3%. MAGE-A4 IHC 1F9 pharmDx demonstrated acceptable performance characteristics (sensitivity, precision, robustness) and met all predefined AC. The NPA 95% CI LB for slide type was 83.9%, however, this result was due to lower-than-expected sample size since the NPA point estimate was 100%. The MAGE-A4 TIPS (≥ 2+) scoring algorithm is practical, transferrable, and reproducible per the assessment of inter/intra-observer percent agreement point estimates being >93%.
Conclusion: These studies demonstrated high analytical assay performance and observer scoring precision of the MAGE-A4 IHC 1F9 pharmDx assay in SyS and combined with sqNSCLC specimens at MAGE-A4 TIPS (≥ 2+) ≥ 75%.

#688 Characterization of microsatellite status in endometrial tumors using comprehensive genomic profiling via the PGDx elio tissue complete.

Darshan Shimoga Chandrashekar[1], Joao Lobo[2], Mehenaz Hanbazazh[3], Kanako Okamoto[1], Jennifer B. Jackson[4], Shuko Harada[1], Alexander C. Mackinnon[1]

[1]Pathology, University of Alabama at Birmingham, Birmingham, AL,[2]Portuguese Oncology Institute of Porto, Porto, Portugal,[3]University of Jeddah, Jeddah, Saudi Arabia,[4]Labcorp, Baltimore, MD

Background: Microsatellite instability (MSI) is a vital genomic biomarker in endometrial cancer (EC), playing a key role in guiding patient management decisions. Microsatellite status can be assessed using various methods, including immunohistochemistry (IHC), polymerase chain reaction (PCR), and next-generation sequencing (NGS). However, accurately determining microsatellite status in EC can be challenging due to the typically weak MSI phenotype observed in this cancer type. This study aims to enhance microsatellite analysis in EC by combining EC mutation profiling with MSI detection techniques into a unified analytical workflow.
Methods: We performed comprehensive genomic profiling on 43 EC samples using the PGDx elio™ tissue complete (ETC), an FDA-cleared NGS test targeting 505 solid tumor related genes. In addition to mutation profile, we obtained microsatellite status and tumor mutational burden for each case. Mismatch repair (MMR) status were also determined for all 43 ECs using IHC (MLH1, PMS2, MSH2 and MSH6). 'maftools' R package was utilized for data processing and visualization, while genomic classifier was developed using 'randomForest' R package.
Results: IHC analysis led to identification of 28 proficient MMR (pMMR) and 15 deficient MMR (dMMR) EC samples. We observed 100% (28/28) concordance for pMMR samples and 73.3% (11/15) concordance for dMMR samples between IHC analysis and NGS assay. Four discordant samples showed low TMB and low-grade instability in 68 mononucleotide tracts considered by NGS assay indicative of weak MSI phenotype. We also identified 15 genes (including *ERBB4, PTPRT, ARID1A, ARID1B*, and *BRD4*) significantly altered in dMMR samples compared to pMMR samples. Random forest classifier was developed considering 88 distinct parameters (including mutation profile of 15 genes, 5 clinicopathologic features and 68-mononucleotide tract status) for all EC samples.
Conclusion: We observed varying degrees of concordance (100% specificity and 73.3% sensitivity) between MSI status by NGS based ETC and MMR status by IHC in a cohort of EC. Targeted genomic profiling via ETC identified significantly altered genes in dMMR endometrial tumors and led to development of random forest classifier to predict MSI EC tumor [which showed AUC value of 0.875, 87.5% specificity and 100% sensitivity for test set]. Integration of mutational profiling with MSI detection can be leveraged to increase sensitivity for MSI detection on the ETC platform.

#69 Integrin $\alpha_V\beta_3$-targeted PET/CT for the assessment of bevacizumab therapy in patient-derived glioblastoma xenografts.

Anne Skovsbo Clausen[1], Ida Vang Andersen[1], Malene Martini Clausen[1], Aleena Azam[1], Julie van Krimpen Mortensen[1], Emilie Graae Lund[1], Thomas Haargaard Urup[2], Andreas Kjaer[1]

[1]Department of Clinical Physiology and Nuclear Medicine & Cluster for Molecular Imaging, University of Copenhagen & Rigshospitalet, Copenhagen, Denmark,[2]Department of Oncology, Rigshospitalet, Copenhagen, Denmark

Introduction: Glioblastoma continues to be the most aggressive type of brain cancer. Standard treatment includes surgical resection, concomitant chemoradiation therapy (CRT) with temozolomide (TMZ) followed by adjuvant TMZ (Stupp's regimen). Bevacizumab (BEV), a monoclonal antibody targeting vascular endothelial growth factor (VEGF) A, is approved for recurrent glioblastoma with no significant benefit in the total population of recurrent glioblastoma patients. However, responders to BEV experience clinical improvement and prolonged survival. Nevertheless, no predictive biomarker for treatment effect has been identified. This study evaluates tumor angiogenesis using [^{68}Ga]Ga-NODAGA-E[c(RGDyK)]$_2$ (RGD_2) PET/CT targeting integrin $\alpha_V\beta_3$ to predict response to BEV combined with conventional therapy in patient-derived xenograft (PDX) models with postoperative primary or recurrent glioblastoma, aiming to guide clinical patient selection.
Experimental procedures: Tumors from four patients with primary or recurrent glioblastoma were enrolled for preclinical efficacy evaluation in PDX models (PDX 1-4) to receive BEV monotherapy, Stupp's plus BEV, Stupp's alone, or saline. PDX patient tissue were selected based on clinical treatment regimen. PET/CT with RGD_2 was performed at baseline and post-therapy. To assess the correlation between treatment efficacy and tracer uptake, tumor uptake of RGD_2 was compared with survival outcomes. Immunohistochemistry (IHC) was used to assess glioblastoma and angiogenesis markers.
Results: PDX models with increased uptake of RGD_2 at baseline (PDX 1: 6.2±0.66 max%ID/g) showed better response rate to Stupp's plus BEV compared with PDX models with low uptake (PDX 3: 2.1±0.25 max%ID/g). PDX models of both primary (PDX 1) and recurrent (PDX 4) glioblastoma had better survival with Stupp's plus BEV therapy compared with BEV monotherapy, Stupp's, and saline. PDX 1 treated with Stupp's plus BEV had better survival with a median survival time of 70 days (95% CI: 63-77 days) compared with BEV monotherapy (p<0.0001), Stupp's (p<0.05), and controls (p<0.0001). Additionally, PDX 4 treated with Stupp's plus BEV had better survival with a median survival time of 49 days (95% CI: 42-56 days) compared with BEV monotherapy (p<0.0001), Stupp's (p=0.0009), and controls (p<0.0001). IHC showed upregulated angiogenesis markers (CD31, CD34, VEGF, and integrin $\alpha_v\beta_3$) in PDX tumors with high RGD_2uptake.
Conclusion: Our results indicate that RGD_2 can be used as a predictive biomarker for treatment response to BEV in PDX models of glioblastoma. Translationally, RGD_2 PET imaging could be used in clinical settings to predict responses to BEV combination therapy. Furthermore, our results support the investigation of BEV in clinical trials as part of first-line adjuvant therapy, potentially advancing its role in improving treatment outcomes in glioblastoma patients.

#690 Rethinking molecular analysis of gastric cancer: Insight into morphologic phenotype.

Harim Chun[1], Kwangil Yim[2], Sangjeong Ahn[3], Sung Hak Lee[1]

[1]Department of Hospital Pathology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[2]Department of Hospital Pathology, Uijeongbu St. Mary Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[3]Department of Pathology, Korea University Anam Hospital,, College of Medicine, Korea University, Seoul, Korea, Republic of

Introduction: Advanced gastric cancer (GC) is one of the most challenging malignancies, with high mortality rates and a lack of effective treatment strategies. Histomorphological features, termed ‘morphologic phenotypes’, predict therapeutic response, with lymphoepithelial carcinoma showing immunotherapy responsiveness while diffuse-type GC exhibits resistance to immunotherapy and targeted therapies such as HER2 and CLDN18 inhibitors. Despite these associations, comprehensive molecular understanding based on meticulous morphological assessments remains elusive. Herein, we aim to identify robust biomarkers and elucidate the molecular mechanisms underlying GC phenotypes, providing a more precise reflection of the spatial phenotype of GC.
Methods: TCGA stomach adenocarcinoma RNA-sequencing (n=412), WSIs (n=398), and clinical data were retrieved from the GDC Data Portal. Expert gastrointestinal pathologists reviewed H&E-stained WSIs for consensus morphological classifications. RNA-seq data were analyzed using DESeq2 for normalization and differential expression testing. Overall single-cell RNA sequencing (scRNA-seq) analysis was conducted using Seurat to validate findings at the cellular level. Functional analyses, including Gene Set Enrichment Analysis (GSEA) and Over-Representation Analysis (ORA), utilized the MSigDB Hallmark and Gene Ontology Biological Process databases to identify key pathways and biological processes.
Results: A total of 4,342 differentially expressed genes (DEGs) were identified, revealing novel distinctions between diffuse and intestinal GC subtypes. A calcium-dependent adhesion signature showed coordinated upregulation of *CDH2* and *ACTA2*, with *CDH1* downregulation in diffuse-type tumors. Notably, elevated *ACTA2* expression, a marker of *CAF*, suggested enhanced tumor-stromal interaction and potential therapy resistance mechanisms. Further analysis indicated that *CDH1* suppression could be attributed to somatic mutations or epigenetic regulation. Single-cell level transcriptome profiling revealed tumor heterogeneity, with distinct cell populations exhibiting unique molecular signatures in diffuse-type tumors. These findings highlight the *CDH2*/*CDH1* axis as a key determinant of aggressive tumor phenotypes in diffuse-type gastric cancer, offering potential therapeutic insights.
Conclusion: This study underscores the importance of standardized pathological annotations for uncovering phenotype-specific molecular biomarkers in GC. By integrating RNA-seq and scRNA-seq data, we highlighted the *CDH1*/*CDH2* adhesion axis as a critical determinant of diffuse-type tumor aggressiveness. These molecular insights emphasize the significance of phenotype-specific biomarker discovery and reveal potential mechanisms of therapy resistance, providing a foundation for novel therapeutic strategies and improved patient stratification.

#691 Decentralized pan-cancer tumor profiling: a comprehensive performance evaluation of the MSK-IMPACT® Assay with SOPHiA DDM™ .

Julien Pontis[1], Fuad Mohammad[1], Anjali Anjali[1], Yvan Wenger[1], Florian Klemm[1], Anita F. Bowman[2], Brian Houck-Loomis[2], Jacklyn Casanova-Murphy[2], A. Rose Brannon[2], Micheal F. Berger[2], Zhenyu Xu[1]

[1]SOPHiA GENETICS SA, Rolle, Switzerland,[2]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Molecular profiling of solid tumors through FFPE (Formalin-Fixed Paraffin-Embedded) tissue samples is crucial for personalized cancer treatment. MSK-IMPACT® (Memorial Sloan Kettering - Integrated Mutation Profiling of Actionable Cancer Targets) is a well-established, high-throughput genomic assay designed to identify known cancer-driving alterations in solid tumors from FFPE tissue samples. SOPHiA GENETICS is developing a decentralized version of this assay, integrating key features of MSK-IMPACT® including comprehensive genomic profiling, the utilization of hybrid capture-based next-generation sequencing, and the identification of actionable somatic mutations. This report presents the results from a performance evaluation study conducted during the development of this product.

Methods: A cohort of 167 FFPE solid tumor samples and matched normal tissue were collected from cancer patients and processed at MSKCC (Memorial Sloan Kettering Cancer Center) according to the validated standard operating procedures for MSK-IMPACT®, which involves DNA extraction, library preparation, hybrid capture targeting 505 actionable cancer genes, and sequencing on an Illumina platform. In parallel, SOPHiA GENETICS processed the same samples using proprietary enrichment techniques, and sequencing was performed on Illumina platforms. Somatic variants were identified using a robust bioinformatics pipeline, and the results were compared with those obtained by MSKCC to assess the accuracy of the decentralized “MSK-IMPACT® powered with SOPHiA DDM™” solution.

Results: A total of 1736 somatic mutations were detected, with variant allele fractions (VAF) as low as 1.1% and a median of 5 variants with coding impact per sample. The positive percent agreement (PPA) for all detected variants with the original MSK-IMPACT® assay is 99.3% for SNV/INDEL with a PPA >98% down to 2.5-6% VAF. Furthermore, PPA for CNVs is 94.6%, and overall percent agreement for MSI and TMB of 99.4% and 98.8%, respectively.

Conclusions: The findings affirm that the decentralized “MSK-IMPACT® powered with SOPHiA DDM™” solution delivers a high level of concordance with the established results by MSK-IMPACT®. Future studies are planned to further verify the analytical and clinical performance and to evaluate the utility in routine clinical practice. This solution equips laboratories with a premier, comprehensive testing capability that identifies SNV/INDEL, CNV, DNA fusion, and the critical immuno-oncology biomarkers TMB and MSI.

#692 Analytical validation of a tissue-free epigenomic assay for circulating tumor DNA (ctDNA)-based molecular residual disease (MRD) detection in early-stage cancer.

Katie Quinn, Amy Wilfert, Ranjani Lakshmin, Sai Chen, Albert Lee, Jun Zhao, Daniel Gaile, Yunpei Chang, Ruth McCole, Jordan Burke, Derek Dustin, Thereasa Rich, Jack Tung, Kristin Price, Darya Chudova

Guardant Health, Redwood City, CA

Introduction: Molecular residual disease (MRD) detection can offer valuable prognostic insights and guide personalized treatment decisions. High sensitivity and specificity are required for accurate MRD assessment, with most methods currently relying on tissue sequencing for informing MRD assay design. However, tissue testing can be logistically challenging and not all patients have accessible tissue. Here, we describe the analytical validation of Guardant Reveal for plasma-only, epigenomic-based detection and quantification of ctDNA in CRC, lung, and breast cancers.

Methods: Guardant Reveal evaluates signals in thousands of differentially methylated regions (DMRs) and classifies samples as ctDNA detected or not detected. Quantitative tumor fraction (TF) is estimated by normalizing selected cancer DMRs with matched control regions. Analytical sensitivity was assessed in titrations of cancer clinical samples and cell lines into non-cancer samples. Analytical specificity was assessed in samples from age-matched self-declared healthy donors. Qualitative precision was assessed in within- and between-batch replicates of ctDNA-positive and ctDNA-negative samples. Accuracy was assessed for concordance to a genomic and methylation-based reference assay.

Results: Analytical sensitivity studies determined the ≥ 95% limit of detection (LoD) for each cancer type to be down to an order of 10^{-5}-10^{-4} at both minimal (3-4ng) and typical (15ng) cfDNA input amounts. The analytical specificity (limit of blank) study using 102 age-matched healthy donor samples demonstrated 100% specificity (ctDNA negative results) for each cancer type caller. Within-batch and between-batch qualitative precision was 100% (81/81) for ctDNA-positive samples across cancer types, and 100% (36/36) for ctDNA-negative samples. In studies using titration replicates, TF demonstrated high quantitative precision and accuracy down to an order of 10^{-4}, a range which encompasses 97% of ctDNA-positive clinical MRD samples. Comparison of ctDNA detection to a reference method demonstrated ≥97% positive percent agreement (PPA), and ≥95% negative percent agreement (NPA) for 153 CRC, 92 lung cancer, and 96 breast cancer samples. All discordant samples were borderline to the detection threshold. TF demonstrated quantitative equivalence to the reference method across the range of TF.

Conclusions: Guardant Reveal demonstrated high analytical sensitivity, specificity, and TF quantitative precision in CRC, lung and breast cancer. This technology demonstrates the potential for ultra-sensitive and accurate MRD detection using a tissue-free assay, enabling precise monitoring for cancer recurrence.

#693 Comparative gene signature between NEPC and CRPC transcriptomics.

Srinivas V. Koduru, Mark Kidd, Abdel Halim

Wren Laboratories, LLC, Branford, CT

Introduction: Prostate cancer (PCa) is the most common cancer in men, with an estimated 299,010 new cases and 32,250 deaths projected in 2024. Approximately 1 in 8 men will be diagnosed with PCa, with the majority (60%) occurring in those aged 65 or older. Castration-resistant prostate cancer (CRPC) represents an advanced stage of PCa, with up to 30% of these cases classified as neuroendocrine prostate cancer (NEPC). Previous studies have demonstrated that DNA methylation, chromatin integrity, and transcriptional regulation play crucial roles in the development of treatment-resistant PCa. In this study, we aim to apply next-generation sequencing (NGS) to identify gene signatures regulated in CRPC and NEPC using whole blood samples from patients to discover circulating RNAs and their dysregulated pathways.

Methods: Whole blood samples were collected from NEPC (n=9), CRPC (n=5), and healthy controls (n=11). Total RNA was extracted using TRIzol and RNeasy kits, with quality control assessed via Bioanalyzer. RNA-seq was performed on a NovaSeq 6000 platform, and data were analyzed using PartekFlow with High Performance computing system (HPC) to identify differential gene expression patterns. Pathway analysis was conducted on the differentially expressed genes.

Results: RNA-seq analysis revealed significant differences in gene expression between NEPC, CRPC, and healthy controls. In total, 4,655 genes were found to be significantly differentially expressed (fold change >1; $P<0.05$) in NEPC, and 2,944 genes in CRPC. Notably, 28% of the statistically significant genes overlapped between NEPC and CRPC. Additionally, analysis of the Wren's PROSTest (27 genes) and NETest (55 genes) signatures identified 25 and 43 genes in NEPC, and 23 and 41 genes in CRPC, respectively, within the differentially expressed gene sets.

Conclusion: Our transcriptomic data reveal that NEPC and CRPC share approximately 28% of their gene signatures, with significant correlation to the PROSTest and NETest gene panels. This highlights the potential of these gene signatures as diagnostic tools in identifying and understanding the progression of advanced prostate cancer.

#694 Brush biopsy miRNA based oral squamous cell carcinoma detection and localization-overcoming barriers to classifier development.

Madeleine W. Fine[1], **Samira Cheruku**[1], Antonia Kolokythas[2], Ashleigh Weyh[3], Joel Schwartz[1], Beth Miloro[1], Guy R. Adami[1]

[1]Oral Medicine and Diagnostic Sciences, University of Illinois Chicago, Chicago, IL,[2]Oral and Maxillofacial Surgery, Vanderbilty University Medical Center, Memphis, TN,[3]Oral and Maxillofacial Surgery, University of Illinois Chicago, Chicago, IL

Cancers of the oral cavity arise from the surface tissues and, despite prominence of these sites, over 50% are not diagnosed until they are in advanced stage. Unfortunately, patients with advanced stage oral cancer have high mortality rates because treatments are usually not successful, complex and have high complication rates. Among the main reasons for delays in diagnosis of squamous cell carcinoma, which make up over 90% of oral cancers, is the resemblance of these lesions to benign lesions. Specifically, oral squamous cell carcinoma (OSCC) is often misdiagnosed as a benign process, most commonly benign leukoplakia (BL) or oral lichen planus (OLP) and is not interrogated for diagnosis confirmation. On the other extreme, patients with BL or OLP that have no malignant potential are subjected to unnecessary stress and surgical interventions when these lesions are mistaken as cancers. Unlike cancers of other organs, no screening protocols or non-invasive diagnostic tests are currently available to reliably detect these cancers early when treatments can save lives. We have developed a noninvasive brush-based tissue collection and miRNA (and not mRNA) analysis method that can differentiate OSCC from other mucosal lesions. This brush based sampling method showed 93% accuracy in differentiating OLP from OSCC based on the expression of as few as 6 miRNAs. We will report on the validation of this classifier with a set of 40 OSCC and OLP samples, and the training of a classifier to differentiate BL from OSCC with over 35 additional samples. We will also discuss the role of technical replicates and clinician calibration in efficient miRNA based classifier development.

#695 Relative importance between DNA methylation and mutation in nonmalignant tissue for cancer risk.

Harumi Yamada[1], Satoshi Yamashita[2], Yu-Yu Liu[1], Toshikazu Ushijima[1]

[1]Hoshi University, Tokyo, Japan,[2]Maebashi Institute of Technology, Maebashi, Japan

Cancer risk is correlated with the accumulation level of genetic (mutation) and epigenetic alterations (DNA methylation). Analysis of these alterations in nonmalignant tissue contributes to assessing cancer risk and to revealing environmental factors that induce the alterations. DNA methylation can be readily measured due to its high accumulation levels, while on the other hand, it is difficult to measure accumulation levels of mutations because of their rarity. To detect rare point mutations accurately and inexpensively, we developed a novel next generation sequencing (NGS) method, EcoSeq [Ueda, PNAS, 119:e2123241119, 2022]. Here, using EcoSeq, we aimed to evaluate the impact of DNA methylation and mutation for gastric cancer risk, and the mutational signatures of *H. pylori* (*HP*) infection, which is a mutagen for gastric cancer. Nonmalignant gastric mucosae were obtained from G1 (low risk; never infected with *HP*), G2 (intermediate; healthy people after *HP* eradication) and G3 (high; cancer patients after *HP* eradication). The mutation frequency was slightly increased by history of *HP* infection (p=<0.0001, G1vsG2), but not associated with cancer risk (p=0.50, G2vsG3). On the other hand, the DNA methylation level of *miR124a-3* was strongly correlated with cancer risk (p<0.0001, G1vsG2; 0.00069, G2vsG3). Mutational signatures of SBS39 were observed in G2 and G3. These results showed that DNA methylation was more useful for assessing gastric cancer risk than point mutation frequency, and suggested that SBS39 is due to *HP* infection.

#696 Shed Trop2 drives prostate cancer progression and Trop2 is a novel tissue prognostic biomarker and a candidate urinary marker for prostate cancer and bladder cancer.

Shiqin Liu

UCLA - University of California Los Angeles, Los Angeles, CA

Distinguishing indolent from clinically significant localized prostate cancer and treatment of metastatic prostate cancer are two major clinical challenges in prostate cancer. The development of novel predictive biomarkers will help with risk stratification, and influence clinical decision-making between treatment and active surveillance, leading to a decrease in over or under-treatment of patients with prostate cancer. Here, we report that Trop2, an oncogenic transmembrane surface protein, is a prognostic tissue biomarker for clinically significant prostate cancer by utilizing the Canary Prostate Cancer Tissue Microarray (CPCTA) cohort composed of over 1100 patients from a multi-institutional study. We demonstrate that higher Trop2 expression is correlated with worse clinical features and elevated Trop2 expression at radical prostatectomy predicts worse overall survival in men undergoing radical prostatectomy. Additionally, we detected shed Trop2 in urine from men with clinically significant prostate cancer and bladder cancer. We further define the functional role of shed Trop2 on metastasis in prostate cancer and identify that shed Trop2 increases cell migration, invasion, metastatic colonization, and spontaneous metastasis *in vitro* and *in vivo*. Proteomic profiling reveals that shed Trop2 modulates a set of proteins associated with invasion, migration, mTOR signaling, and epithelial-to-mesenchymal transition. Shed Trop2 binds to EGFR and results in the activation of the EGFR-PI3K-AKT-mTOR pathway in prostate cancer. Our study reveals a new function of shed Trop2 in driving prostate cancer progression and identifies Trop2 as a novel tissue prognostic biomarker and a candidate non-invasive marker for prostate cancer that could be used to optimize treatment decision-making.

#697 The role of salivary exosomal cargo as diagnostic biomarker for oral squamous cell carcinoma among South African population.

D. O. Temilola, M. Chetty;
University of the Western Cape, Bellville, South Africa

Introduction: Globally, oral cancer remains a non-communicable debilitating disease of major public health concerns in Africa and other low- and middle-income countries (LMICs). South Africa has the highest incidence and prevalence of oral cancer in Africa. More than 90% of all oral cancer are oral squamous cell carcinoma (OSCC). Factors such as the aggressive nature of the disease among Africans, late diagnosis, and access to and limited healthcare resources have contributed to the growing burden of OSCC in Africa and other LMICs. Exosomes play a major intercellular communication role due to their ability to transmit their cargo of proteins, nuclei acids, and lipids from one cell to another.
Aim: The study is focused at investigating the role of salivary exosome cargo as diagnostic biomarkers for OSCC in a South African population.
Methodology: Saliva samples were collected from 10 OSCC patients and 5 healthy individuals that consent to be part of the study. Exosomes were isolated from all saliva samples. Characterization of exosomes size and concentration was done using NanoSight NS300. Exosomes samples were also characterized using transmission electron microscope.
Results: Salivary exosomes from OSCC patients were found to significantly have higher concentration and size than those from healthy individuals. There are no significant differences in size and concentration of exosomes between male and female OSCC patients. ROC analysis showed a maximal sensitivity (100%) and specificity (80%) (AUC of 0.98) at cut-off of 1.99e+9 particles/ml.
Conclusion: Our study showed the potential uses of salivary exosomes morphological characteristic as diagnostic biomarker tool for OSCC.

#7 Lipid-driven oxidative phosphorylation fuels lymph node colonization by esophageal tumor cells.

Shanshan Li[1], Baifeng Zhang[2], Cuicui Huang[2], Yuying Zhao[1], Stephanie Ma[2], Xinyuan Guan[1]

[1]University of Hong Kong-Shenzhen Hospital, Shenzhen, China,[2]University of Hong Kong, Hong Kong, China

Lymph node (LN) metastasis is a pivotal step in the progression of esophageal squamous cell carcinoma (ESCC) and is associated with poor clinical outcomes. Despite its significance, the mechanisms underlying the early colonization of LNs by tumor cells remain insufficiently understood. In this study, we utilized a human xenograft model of spontaneous LN metastasis and performed single-cell RNA sequencing to analyze the transcriptomes of tumor cells from primary tumors and LN metastases. A rare subset of metastasis-initiating cells (MICs) with stem-like characteristics was identified as critical drivers of LN metastasis. These MICs exhibited a unique metabolic adaptation, relying on fatty acid oxidation (FAO)-driven oxidative phosphorylation (OXPHOS) to survive in the lipid-enriched LN microenvironment. Additionally, nuclear factor erythroid 2-related factor 2 (NRF2) was found to play a key role in maintaining redox balance and supporting the metabolic resilience of MICs during metastatic progression. This study underscores the importance of FAO-driven OXPHOS and NRF2-regulated redox homeostasis in LN metastasis and highlights these pathways as promising targets for therapeutic intervention in ESCC.

#70 Novel PSMA+ and FAP+ mouse models to support the development of novel molecular radiotherapy agents.

Sarah Belderbos, Peggy Provent, Solene Fernandez, Maeva Albanese, Marie Grunenwald, Florent Potvain, Kenny Herry, Didier Grillot, Nicolas Ancellin, **Eftychia Koumarianou**

Oncodesign Services, Dijon, France

To evaluate novel molecular radiotherapies preclinically, non-radiosensitive mouse models with optimal target expression levels that recapitulate the human tumor microenvironment are required. Within the past year Oncodesign Services has developed and validated such models for two targets: fibroblast activated protein (FAP) and prostate specific membrane antigen (PSMA), which are of high interest to the oncological and nuclear medicine community.
To assess novel FAP inhibitor (FAPi) tracers, we developed two FAP-overexpressing cell lines. First, HT-1080 human sarcoma (FAP-negative; 0.0% FAP+) and U87-MG human glioblastoma cells (low FAP-positive; 15.0% FAP+) were transduced using a lentiviral vector overexpressing FAP and ZsGreen (VectorBuilder, Neu-Isenburg, Germany). Immunohistochemistry and flow cytometry confirmed the expression of both markers in the transduced cells, with up to 63.4% and 96.0% of FAP-positive cells in the HT-1080-FAP and U87-MG-FAP cells, respectively. Next, Swiss Nude mice (Charles River, Ecully, France) were subcutaneous engrafted with either the FAP-overexpressing HT-1080 or U87-MG cell line. A slow homogeneous tumor growth (humane endpoint of 1500 mm^3 reached after 33-36 days) was noted with U87-MG-FAP tumors, while a faster and more heterogeneous tumor development was observed in mice bearing HT-1080-FAP tumors (humane endpoint reached after 14-18 days). Flow cytometry of the tumors *ex vivo* showed a higher expression of FAP in the U87-MG-FAP tumors (up to 81.5% FAP+ tumor cells) compared to HT-1080-FAP tumors (up to 61.5% FAP+ cells), as previously noted *in vitro*.
In parallel, our team also focused on developing additional models for the assessment of novel molecular radiotherapies targeting PSMA. Male BRGSF mice (GenOway, Lyon, France) were subcutaneously engrafted with either LnCaP C4.2 cells (50%/50% Matrigel) or 22RV1-Luc-mCherry cells. A special enrichment was put in place to allow group housing of the male mice. The growth of LnCaP C4.2 tumors was relatively quick but heterogenous (humane endpoint reached after 19-32 days) and accompanied by a body weight loss that reached 23.6% despite the use of an enriched diet. 22RV1-Luc-mCherry tumor growth was relatively homogeneous and tumor size surpassed the human endpoint of 1500 mm^3 after 29 days. Castration of the BRGSF mice before tumor cell engraftment delayed tumor growth by 3 to 11 days, depending on individual mice. Confirmation of PSMA expression or evaluation of PSMA tracers/molecular radiotherapy is foreseen in future projects.
In conclusion, we designed several new mouse models, which could aid in the development of novel imaging or molecular radiotherapy agents for both FAP and PSMA, two “hot” biomarkers in the field of oncology.

CLINICAL RESEARCH: Precision Medicine in Pediatric Cancer

#701 Understanding the genomic landscape of pediatric cancer predisposition.

Martha O'Brien[1], Robert J. Autry[1], Olaf Witt[2], David Jones[3], Stefan Pfister[1]

[1]Pediatric Neurooncology, Hopp Children's Cancer Center Heidelberg, Heidelberg, Germany,[2]CCU Pediatric Oncology, Hopp Children's Cancer Center Heidelberg, Heidelberg, Germany,[3]Pediatric Glioma Research, Hopp Children's Cancer Center Heidelberg, Heidelberg, Germany

Once thought to be rare, 10% of pediatric cancers can be attributed to mutations in known cancer predisposition genes (CPGs). However, given that many pediatric cancers occur sporadically without germline mutations in the ~114 known CPGs, it is plausible that previously unidentified mutations in novel genes and non-coding regions contribute to pediatric cancer development. This research aims to uncover novel germline mutations, to use somatic “second hits” to prioritize candidates for detailed multi-faceted analysis of downstream effects contributing to pediatric cancer predisposition and pathogenesis. Here we present an analysis of the largest pediatric burden testing cohort to date (>7,000 tumor/normal) of WGS, WES and RNAseq data to explore the genetic landscape of childhood cancers. First, we combined multiple rare-variant burden testing methods, such as TRAPD, SKAT-O, CoCoRV, RV-EXCALIBER, to identify novel germline variants associated with cancer at both within and across pediatric cancer entities. Putative CPGs were prioritized by detecting somatic second hits in tumors, leveraging multiple genomic data types (SNVs, indels, structural variants (SVs), and copy number variations (CNVs). The impact of germline mutations on the somatic landscape was explored by examining how these variants influence tumor mutational profiles, including co-occurring mutations and mutational signatures. Single-cell RNA sequencing data were interrogated when available for pediatric brain tumors and sarcomas to determine how the identified germline genes influence the cell-of-origin and its malignant transformation. We will assess whether these mutations can be observed early in development and their potential causative role in specific tumor types. The findings from our comprehensive approach will deepen our understanding of the interplay between germline and somatic mutations in cancer, enhancing risk prediction and guiding precision oncology efforts.

#702 Payor coverage for laboratory developed genomic testing, a looming challenge for pediatric precision cancer medicine.

Jennifer A. Oberg[1], Susan Hsiao[2], Mahesh Mansukhani[2], James H. Garvin[1], Darrell J. Yamashiro[3]

[1]Pediatrics, Columbia University Irving Medical Center, New York, NY,[2]Pathology and Cell Biology, Columbia University Irving Medical Center, New York, NY,[3]Pediatrics; Pathology and Cell Biology, Columbia University Irving Medical Center, New York, NY

Introduction: Although genomic testing may inform medical decision making for pediatric cancers, inconsistent coverage and variable payment by insurers has made routine utilization in clinical practice challenging. Payer's state insufficient evidence of clinical utility limits their evaluation of medical necessity for genomic testing. Adoption of changes to CPT coding may have furthered an uncertain reimbursement landscape for laboratories. A review of solid and CNS tumor cases sequenced through the Precision in Pediatric Sequencing (PIPseq) program at Columbia University Irving Medical Center (CUIMC) was conducted to describe clinical utility, coverage, and reimbursement for genomic testing.

Methods: Laboratory developed matched tumor-normal whole exome, tumor transcriptome, or 450+ targeted gene panel sequencing was performed in a CLIA-certified laboratory at CUIMC. Claims were submitted April 2014-October 2024 based on CPT coding Pre 2020 (stacked Tier 1/2 Molecular Pathology CPT codes) and Post 2020 (limited Genomic Sequencing Procedure (GSP) CPT codes). Carriers were categorized into commercial, managed government (managed Medicaid), and government (Medicaid) plans and linked to clinical utility, defined as an alteration of diagnostic, prognostic, or therapeutic significance, to demonstrate medical necessity of genomic testing. All costs were covered by PIPseq.

Results: Reimbursement/utility data were available for 226/303 tests; Pre 2020 (n=186), Post 2020 (n=40). Solid tumors (ST), n=135 (2020: Pre n=113, Post n=22); CNS tumors (CNS), n=91 (2020: Pre n=73, Post n=18). Clinical utility was demonstrated in 162 tests (72%): ST, n=87 (64%); CNS, n=75 (82%). RNAseq identified 43% of findings (ST, n=38). Findings of diagnostic (n=61: ST, n=39) or prognostic (n=54: CNS, n=31) significance were identified; 44 were denied coverage (ST, n=20) and 70 received partial coverage (ST, n=41) at an average rate of 57% of the service charge. Targetable alterations were identified in 49 patients; 25 received a matched targeted therapy (CNS, n=15), 8 were denied coverage (CNS, n=5) and 17 received partial coverage (CNS, n=10) at an average rate of 51% of the service charge. Medicaid did not provide coverage for testing (n=11). Commercial and managed government plans Pre 2020 (n=177) covered 42% of the service charge (median, 50%) whereas limited GSP codes Post 2020 (n=38) led to a 48% reduction in reimbursement with insurers covering 21% of the service charge (median, 0%) ($t(213)=3.58$, $p=.001$; $eta^2=.06$).

Conclusions: 72% of samples sequenced had a clinically impactful finding supporting the medical necessity of testing in pediatric solid and CNS tumors. Changes in CPT coding not reflected in updated payer coverage policies reduced insurance coverage by 48%. Revised reimbursement policies are needed to ensure equitable access to genomic testing that benefits most patients.

#703 Epigenome-wide analysis of DNA methylation mediators linking cancer treatments to cardiometabolic risks in survivors of childhood cancer.

Tiffany Eulalio[1], Yoonji Kim[1], Peggy Meng[1], Qian Dong[1], Noel-Marie Plonski[1], Heather Mulder[2], John Easton[2], Emily Walker[3], Geoffrey Neale[3], Deokumar Srivastava[4], Stephanie Dixon[5], Kirsten K. Ness[1], Melissa M. Hudson[5], Gregory T. Armstrong[1], Zhaoming Wang[1]

[1]Epidemiology and Cancer Control, St. Jude Children's Research Hospital, Memphis, TN,[2]Computational Biology, St. Jude Children's Research Hospital, Memphis, TN,[3]Hartwell Center, St. Jude Children's Research Hospital, Memphis, TN,[4]Biostatistics, St. Jude Children's Research Hospital, Memphis, TN,[5]Oncology, St. Jude Children's Research Hospital, Memphis, TN

Background: Cancer treatments engender the risk of long-term cardiometabolic and cardiac conditions among survivors of childhood cancer. However, the underlying biological mechanisms remain unclear. This study aimed to identify DNA methylation (DNAm) CpG sites associated with cardiometabolic risk factors (CMRFs) and adverse cardiac outcomes, and to assess if these DNAm CpG sites mediate associations between specific cancer treatments and these outcomes.

Methods: We included 3,044 survivors (median age at blood draw: 29.6 years) from the St. Jude Lifetime Cohort. Blood-derived DNA was profiled using the EPIC BeadChip. Associations between DNAm and seven clinically assessed outcomes were examined: five CMRFs (abnormal glucose metabolism, hypercholesterolemia, hypertriglyceridemia, hypertension, and obesity), and two cardiac outcomes (cardiomyopathy and myocardial infarction). Treatment-specific epigenome-wide association studies (EWAS) evaluated associations with 10 chemotherapeutic agents and four region-specific radiotherapies.

Results: EWAS identified 1,833 CpG sites associated with cardiometabolic outcomes ($p < 9x10^{-8}$), including obesity (N=1,709), abnormal glucose metabolism (N=141), and hypertriglyceridemia (N=134). A moderate number of CpG sites mapped to *CPT1A*, a key gene in fatty acid metabolism linked to metabolic disorders, with 23 outcome-CpG associations involving 7 unique CpG sites. Most (71%) outcome-associated CpG sites were also associated with cancer treatments, particularly chest- (N=610) and abdominal-radiotherapy (N=599), suggesting potential causal mediation for the treatment-related genotoxicity. Mediation analyses identified 386 CpG sites mediating treatment effects on cardiometabolic outcomes. Asparaginase treatment was significantly associated with abnormal glucose metabolism (Odds ratio [95% CI] = 1.09 [1.06-1.13]). Eighteen CpG sites collectively mediated 26.7% of this effect, with 14 previously implicated in type-2 diabetes. Similarly, alkylating agents were associated with hypertriglyceridemia (1.11 [1.07-1.14]) mediated by DNAm at 46 CpG sites; five independent CpG sites accounted for a substantial 79.8% of such mediation effect. Notably, 39 of these mediator CpG sites were previously associated with C-reactive protein (CRP) levels (two-sided Fisher's test, $p=2.2x10^{-30}$), suggesting potential DNAm-mediated inflammatory pathways connecting alkylating agents to triglyceride dysregulation.

Conclusion: Our findings suggest that DNAm changes may mediate the association between cancer treatments and cardiometabolic risks. These results implicate inflammatory and metabolic pathways in treatment-related adverse outcomes. These insights may inform risk stratification and targeted interventions to improve cardiometabolic and cardiac health in childhood cancer survivors.

#704 Primary versus delayed surgery in fibrolamellar carcinoma.

Paul M. Kent[1], Tomoaki Kato[2], Abhinar Humar[3], Oliver Fisher[4], Matthew Dixon[5], Christopher Seder[6], Tom Stockwell[7]

[1]Medical Director, FibroFighters, River Forest, IL,[2]Hepatobiliary Surgery and Transplant, New York Presbyterian - Columbia, New York, NY,[3]Hepatobiliary Surgery and Liver Transplant, University of Pittsburgh, Pittsburgh, PA,[4]Hepatobiliary Surgery, FibroFighters, St. George Hospital, Australia,[5]Hepatobiliary Surgery, Rush University Medical Center, Chicago, IL,[6]Thoracic Surgery, Rush University Medical Center, Chicago, IL,[7]CEO, FibroFighters, Temacula, CA

Background: Fibrolamellar carcinoma (FLC) is a rare, primary liver cancer of young adults without liver disease, distinct from hepatocellular carcinoma (HCC), usually presenting as advanced stage. FLC has been thought of as a "surgical disease." Because of a lack of data, and a legacy of FLC being mislabeled as “fibrolamellar HCC,” recommendations have been similar to HCC with upfront surgery considered for all new diagnosis and systemic therapy reserved for those deemed inoperable. Our foundation has assembled the largest collection of FLC cases to date. We reviewed surgery data in FLC stratified by stage and systemic therapy.
Methods: We report 216 cases of FLC from our own database and 24 from the medical literature that included: Information about demographics, surgery, systemic therapy, staging, time to relapse and overall survival. We defined “localized” as confined to the liver (AJCC stage 1), “regional” as regional lymph node involvement at surgery (AJCC stage 2 and 3), and “metastatic” (AJCC stage 4) as distant metastasis.
Results: Of 155 patients with initial surgery, 44 (28%) had adjuvant systemic therapy and 85 ‘unresectable’ patients had neo-adjuvant therapy converting 31 patients to have delayed surgery (36%). Relapses were nearly universal (89% at 5 years). There was 100% 10-year survival for localized disease, but frequent relapses nonetheless. Adjuvant therapy gave regional patients a survival advantage. Neo-adjuvant therapy benefited metastatic patients as well as providing as significant delay in time to relapse. Benefit to 54 metastatic patients who had neoadjuvant therapy but no surgery was also seen. [Table1]
Conclusion: Primary surgery for localized FLC offers excellent long-term control, but regional and metastatic FLC should be considered systemic diseases and systemic therapy before surgery should be considered before committing to initial resection. Neoadjuvant therapy can covert unresectable patients to resectable, and adjuvant therapy appears to benefit all non-localized patients.

Primary v. Delayed Surgery in FLC as a Function of Stage and Therapy

Stage	Number	Median Followup (months)	Median Overall Survival (years)	1 yr OS	3 yr OS	5 yr OS	10 yr OS	Median time to progression (months)	1 yr Freedom from Relapse	3 yr Freedom from Relapse	5 yr Freedom from Relapse	10 yr Freedom from Relapse

#706 Impact of symptom clusters on quality of life in pediatric cancer survivors after treatment completion.

Krishtee Napit[1], Don Coulter[1], Katrina Cordts[1], Daisy Dai[1], Evi Farazi[2], Shinobu Watanabe-Galloway[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]European University Cyprus, Nicosia, Cyprus

Background: The advancement in pediatric cancer treatment led to an increased five-year survival. Symptoms develop due to cancer and its treatment during the treatment phase, but they can persist even after treatment completion. Cancer patients experience multiple interrelated symptoms known as symptom clusters. Compared with a single symptom, symptom clusters synergistically affect quality of life (QoL). Limited studies in pediatric cancer have assessed the association between symptom clusters and quality of life, but none were assessed after the treatment completion.
Objective: To find the association between symptom clusters and QoL among pediatric cancer survivors after treatment completion.
Method: We conducted a cross-sectional study of 136 pediatric cancer survivors aged 10-25 who completed treatment within eight years from 2 major hospitals in Nebraska. We used a survey to collect data during their hospital visit, the validated Memorial Symptom Assessment Scale tool to collect information on symptoms, and the PedsQoL instrument to measure the quality of life. We used exploratory factor analysis to derive symptom clusters. We conducted a multiple linear regression model to find the association between symptom clusters and quality of life at a significance level with a p-value of less than 0.05 and an adjusted beta coefficient.
Results: The mean age was 14.91, the mean year since diagnosis and treatment completion was 4.66 and 3.05, respectively, and the mean number of symptoms was 6.06. Difficulty concentrating (48.53%), lack of energy (45.59%), and feeling drowsy (45.59%) were the most common symptoms. Around 80% of participants experienced more than one symptom. The mean overall quality of life score was 80.84, the psychosocial score was 79.84, and the physical score was 82.72 out of 100. The exploratory analysis derived four symptom clusters: Cluster 1: dry mouth, lack of energy, feeling drowsy, feeling irritable, and difficulty sleeping; Cluster 2: feeling nervous, worrying, feeling sad, and difficulty concentrating; Cluster 3: nausea and lack of appetite; and Cluster 4: pain, cough, numbness in hands/feet, dizziness and sweats. The multiple linear models were adjusted for possible confounders and sociodemographic and clinical characteristics. Cluster 1 (β= -4.74, 95% CI: 7.32, 2.15) and Cluster 2 (β= -3.39, 95% CI: 5.80, -0.98) were associated with lower overall quality of life. Cluster 1 (β= -3.96, 95% CI: -7.47, -0.44) was associated with lower physical quality of life. Cluster 1 (β= -5.15, 95% CI: -7.83, -2.47) and Cluster 2 (β= -4.64, 95% CI: -7.13, -2.14) were associated with lower psychosocial quality of life.
Conclusion: Even after treatment completion, symptom clusters are prevalent in pediatric cancer survivors. Among the four clusters identified, Cluster 1 and Cluster 2, which include mainly psychological symptoms, affect all dimensions of quality of life.

#708 Phase I clinical trial to target oxidative phosphorylation and CREB for children and young adults with relapsed or refractory AML.

K. Mark, N. Lacayo, **K. M. Sakamoto**;
Stanford University, Stanford, CA

The overall survival for pediatric AML is 60-70% and treatment includes intensive chemotherapy and stem cell transplantation, which are associated with significant morbidity and mortality. There are few therapies for relapsed/refractory pediatric AML. We previously demonstrated that the transcription factor CREB is overexpressed and activated in AML blasts and leads to increased proliferation and survival of AML cells. CREB overexpression was associated with an increased risk of relapse and decreased event-free survival in AML patients. Knockdown of CREB in mouse bone marrow transduction/transplantation assays did not affect engraftment of healthy hematopoietic stem or progenitor cells. Therefore, we hypothesized that CREB is a potential target for AML therapy.The CREB inhibitor, XX-650-23, disrupts CREB interaction with its binding partner, CBP/p300 (CREB Binding Protein), which is required for CREB function. Treatment of primary pediatric AML cells and xenograft mouse models demonstrated that XX-650-23 inhibits AML progress *in vitro* and *in vivo*. Since XX-650-23 is not a clinical candidate, we performed a virtual screen of FDA-approved drugs with known safety and pharmacokinetic profiles and similar structure to XX-650-23. Niclosamide is an orally bioavailable drug that was previously used to treat tapeworm in developing countries and is safe for both children and adults. We studied niclosamide in pediatric AML cells and pediatric AML xenograft mouse models. Niclosamide primarily acts through inhibition of oxidative phosphorylation and induces apoptosis of AML blast cells, including leukemia initiating cells, resulting in decreased progression and prolonged survival in mice. Combination of niclosamide and cytarabine showed synergistic effects with combination index of less than 1. Based on our preclinical data, a Phase I clinical trial was initiated for relapsed or refractory AML in children and young adults (clinicaltrials.gov, NCT05188170). The study is a single institution, open label, prospective, dose escalation study. The treatment is 2 weeks of oral niclosamide followed by 5 days of high dose cytarabine. Eligibility is between 2 and 30 years of age with relapsed or refractory AML. The primary objective is to identify and evaluate the safety for Phase 2 dose of niclosamide in combination with cytarabine for relapsed/refractory pediatric AML. The secondary objective is to determine the pharmacodynamic effects of niclosamide in AML cells. We are currently enrolling patients and at the first dose level have not observed any significant toxicities related to niclosamide. Preliminary data have demonstrated decreased AML blasts in the bone marrow. Our results suggest that repurposing niclosamide is potentially safe and effective for treatment of relapsed or refractory pediatric AML.

#709 Gut microbiome, physical activity and cognitive dysfunction among childhood brain tumor survivors.

Jinbing Bai[1], Anna Janss[1], Claire Mazewski[1], Hye In Noh[1], Maria C. Swartz[2], Lisa Ingerski[1], Grace Fong[3]

[1]Emory University, Atlanta, GA,[2]Department of Pediatrics-Research, University of Texas MD Anderson Cancer Center, Houston, TX,[3]Children's Healthcare of Atlanta, Atlanta, GA

Background: Childhood brain tumor survivors (BTS) experience a significant increase in cognitive dysfunction, adversely affecting educational attainment and quality of life. The biological mechanisms of cognitive dysfunction, particularly the gut microbiome (GM) and its function, are rarely studied in childhood BTS. Physical activity (PA) may mitigate cognitive dysfunction by reducing proinflammatory GM. Associations of GM with PA and cognitive dysfunction are unknown in childhood BTS. This study investigated associations of GM with PA and cognitive dysfunction in this population.

Methods: A prospective, observational study was conducted in 28 childhood BTS (60% female, 63% white, mean age 13.7 years) enrolled from Children's Healthcare of Atlanta. 16S rRNA V3V4 gene of fecal specimens was sequenced for GM. PA and cognitive function were self-reported by the Patient-Reported Outcomes Measurement Information System-PA and Cognitive Function scales; cognitive performance (working memory [WM] and processing speed [PS]) was tested by Wechsler Adult Intelligence Scale-IV (18-21 year) or Wechsler Intelligence Scales for Children-V (7-17 year). Chi-square test analyzed the relationship of PA with cognition; Mann-Whitney and PERMANOVA tests were used for diversity analysis, and general linear models for abundance analysis. Function of 16S bacterial communities were analyzed by Tax4fun2.

Results: Most survivors were diagnosed with medulloblastoma (71%) with surgery (98%) and radiotherapy (65%). 61% and 71% of survivors reported low PA and cognitive function (T-score<50); 31% reported low WM and 77% reported low PS. A higher PA indicated better self-report cognitive function (p=0.035). Survivors with normal PA and self-report cognitive function (T-score≥50) showed higher diversity than those with low PA (p=0.086), mild (p=0.026) and moderate (p=0.028) self-report cognitive dysfunction, respectively. Children with normal PA had lower abundance of proinflammatory genera *UBA1819* (p=0.016)*, Ruminococcus gnavus group* (p=0.016)*, Incertae sedis* (p=0.026)*, Alistipes* (p=0.026), but higher anti-inflammatory *Marvinbryantia* (p=0.005). Children with high normal self-report cognitive function had higher *Marvinbryantia* (p=0.007). Survivors with normal WM had lower *Ruminococcus gnavus group* (p=0.085) but higher *Ruminococcus gnavus group* (p=0.086) for normal PS. Fatty acid biosynthesis and vitamin metabolism were associated with PA, while glycan, lipid, and amino acid metabolisms were associated with cognitive dysfunction.

Conclusions: Low PA was associated with lower diversity and more proinflammatory taxa, which are linked with cognitive dysfunction. Promoting PA and anti-inflammatory GM may be useful strategies to improve cognitive function in childhood BTS. Future work is needed to study whether GM mediates the relationship of PA with cognitive dysfunction in a large cohort.

#71 Improving the pH-responsive peptide V3 for pancreatic cancer imaging and identification.

Emma Sanderson[1], Ryan C. Bynum[1], Tereza Husarova[2], Lacey R. McNally[1]

[1]OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]Military University Hospital Prague, Prague, Czech Republic

Introduction: Pancreatic cancer treatment with surgical resection or receptor-targeted therapies is complicated by the heavy vasculature of the organ and the heterogeneity of the tumors. Utilization of pH-responsive peptides in tandem with multispectral optoacoustic tomography may address these issues and offer a treatment solution. Although the V3 pH-responsive peptide has demonstrated its ability to target slightly acidic microenvironment, the V3 peptide struggles to identify highly acidic microenvironment like those found around pancreatic cancer cells. To overcome this limitation, we modified the V3 peptide's original sequence to make the V3-Pro and V3-ProFS variants and then tested the new variants' abilities to target the more acidic microenvironment that is characteristic of pancreatic cancer.
Methods: We designed modifications to the V3 peptide sequence, and the peptide variants were synthesized using the CEM Liberty Blue microwave technology. V3 and the new variants were conjugated to HiLyte Fluor 750 C2 maleimide dye to make the V3-750, V3-Pro-750, and V3-ProFS-750 imaging probes. S2VP10 pancreatic cancer cells were pretreated with 7.4, 6.8, and 6.6 pH media for 30 minutes, and then treated with the peptide imaging probes at 1 micromolar concentration for 1 hour. The cells were then washed with pH-specific PBS and imaged with the Odyssey LiCor near-infrared fluorescence machine. Cells were then scraped for multispectral optoacoustic tomography (MSOT). Scraped cells were loaded into tissue-like phantoms, then imaged with the MSOT software.
Results: The V3-Pro-750 and the V3-ProFS-750 treated S2VP10 cells featured significantly higher signal values in the 6.6 pH environment compared to the 7.4 pH environment ($p<0.01$). Fluorescent images of the V3-Pro-750 and V3-ProFS-750 treated S2VP10 cells featured higher signal values for the 6.6 pH and a larger contrast between 6.6 and 7.4 pHs as compared to fluorescent images of S2VP10 cells treated with V3-750 ($p<0.05$). MSOT data supported this trend, with the V3-Pro-750 and V3-ProFS-750 treated cells at 6.6 pH displaying the highest signal values and visual contrast.
Conclusion: Increased signal values for cells treated with the new V3-Pro-750 and V3-ProFS-750 imaging probes in both fluorescence and MSOT suggest that the modified sequences increased the dynamic range between the 6.6 pH and the 7.4 pH. These results point to the newly designed probes potentially being better suited to identify pancreatic cancer based on its acidic tumor microenvironment. The V3-ProFS-750 is especially appealing because of its increased water solubility and its contrast between the 6.6 and 7.4 pHs, making it promising for the clinical translatability of a pH-responsive peptide suited for targeting pancreatic cancers.

#710 Germline whole genome sequencing and nanopore long-read sequencing reveal high incidence of pathogenic variants in childhood cancer survivors with subsequent malignant neoplasms.

Eun Seop Seo, Ji Hwan Moon, Woong-Yang Park, Ji Won Lee

Samsung Medical Center, Seoul, Korea, Republic of

Background: Childhood cancer survivors with cancer-predisposing variants are at increased risk of developing subsequent malignant neoplasms (SMNs). Although panel sequencing is commonly used for diagnostics, its overall yield has been lower than expected.
Methods: From 1,435 pediatric solid tumor patients diagnosed or treated between 1994 and 2014, we previously identified 72 individuals who developed SMNs; germline DNA samples were available for 40 of them. Whole genome sequencing (WGS) was performed on these 40 survivors using Illumina sequencing to investigate deleterious germline variants in 205 known cancer predisposition genes (CPGs). We further assessed candidate structural variants with Oxford Nanopore long-read sequencing in 10 patients who showed no pathogenic variants but were highly suspicious for genetic predisposition.
Results: Pathogenic or likely pathogenic (P/LP) variants were identified in 18 patients (45%), with 11 patients (27%) carrying P/LP variants in known autosomal dominant CPGs. Excluding RB1, the incidence remained high at 32% (10 out of 31 patients). Patients with P/LP variants in known CPGs developed a second tumor at a significantly younger age ($P = 0.031$), more pronounced in autosomal dominant CPGs ($P = 0.008$). Excluding RB1 cases, patients with any P/LP variants were more likely to have a family history of cancer among second-degree relatives ($P = 0.034$). Nanopore long-read sequencing revealed pathogenic structural variants in two highly suspicious cases not identified by Illumina sequencing. Specifically, a structural variant in the MLH1 gene was discovered in a patient with colorectal cancer and microsatellite instability, leading to a Lynch syndrome diagnosis. Additionally, a structural variant was found in the RB1 gene of a patient with a family history of retinoblastoma.
Conclusions: Our study demonstrates a high incidence of pathogenic germline variants in childhood cancer survivors who develop SMNs. Integrating long-read sequencing technologies, such as Oxford Nanopore sequencing, enhances the detection of structural variants missed by traditional short-read WGS. These findings underscore the importance of comprehensive genomic profiling—including both short-read and long-read sequencing—in accurately identifying genetic predispositions in high-risk populations. Early identification of these variants can inform surveillance strategies and guide clinical management to improve patient outcomes.

#711 The Medulloblastoma Meta-Analysis Portal for integrative exploration of clinical and genomic data from 898 patients.

Xin Zhou, Karishma Gangwani, Congyu Lu, Sandeep Dhanda, Airen Peraza, Edgar Sioson, Gavriel Matt, Robin Paul, Jian Wang, Colleen Reilly, Alexander Acic, Kyle Smith, Tong Lin, Qian Li, Paul A. Northcott, Giles W. Robinson

St. Jude Children's Research Hospital, Memphis, TN

Medulloblastoma (MB) is one of the most malignant pediatric brain tumors. Molecularly, MB separates into four subgroups—WNT, SHH, Group 3 (G3), and Group 4 (G4)—each with unique clinical features and genetic profiles. WNT tumors have the best survival outcomes and low metastatic potential, whereas G3 tumors exhibit the highest malignancy and poorest outcomes. While WNT and SHH are highly distinct, G3 and G4 tumors are interrelated and when grouped together, these are referred to as G3/G4 tumors. These tumors are genetically complex, with a constellation of molecular features including *MYC/MYCN* amplifications, *OTX2* activation, *KBTBD4* mutations, and 8 molecular subgroupings complicating risk stratification. Multi-omics approaches, especially DNA methylation profiling, have advanced our understanding, but further exploration is needed to clarify the genetic heterogeneity of G3/G4 tumors.

To address this complexity, we developed the Medulloblastoma Meta-Analysis Portal, incorporating data from 898 patients across three major clinical trials (ACNS0331, ACNS0332, SJMB03) to facilitate cross-cohort data exploration. Our portal offers an array of robust tools for investigating genetic, cytogenetic, and clinical features of medulloblastoma, including custom variable creation, cohort filtering, integration of molecular data with tumor methylome t-SNE maps, and on the fly Cox regression. As a use case the portal enables the assessment of *MYC* amplification and isochromosome 17 cytogenetic association with progression-free survival of standard-risk G3/G4 tumors. This exercise reveals that *MYC* amplification is significantly associated with worse outcomes irrespective of isochromosome 17 status suggesting *MYC* amplification as the prognostic marker and justifying its inclusion as a high-risk feature in risk-stratification algorithms. In the second use case, we overlay mutation status on the methylome t-SNE map to reveal complex relationships between genetic alterations and DNA methylomic state. Given that *KBTBD4* is mutated with complex insertions in G3/G4 tumors we explored its relationship among G3/G4 subgroups. By manually reviewing and rescuing mutation calls, the portal uncovered novel mutation patterns associated with distinct methylome subgroups, as well as outlier cases. These findings emphasize the heterogeneity within G3/G4 subgroups and underscore the limitations of current classification methods, which may fail to capture nuanced genetic differences. In summary, the portal is a valuable resource for detailed exploration of medulloblastoma clinical features, methylomic classifications, and driver mutations that can inform both basic research and clinical decision-making. The portal will be freely available at https://proteinpaint.stjude.org/mbmeta.

#712 The genomic landscape of subsequent breast, meningioma, and thyroid neoplasms after treatment for childhood cancer: a report from the Childhood Cancer Survivor Study.

Samuel W. Brady[1], Michael A. Arnold[2], Mingjuan Wang[1], Ramzi Alsallaq[1], Li Dong[1], Mohammad A. Khan[1], Wentao Yang[1], Kayla L. Stratton[3], Wei Liu[1], Yan Chen[1], Emily Plyler[1], Jacob Steele[1], Brent B. Powers[1], David Rosenfeld[1], Michael N. Edmonson[1], Sasi Arunachalam[1], Heather L. Mulder[1], Deo Kumar Srivastava[1], Michael Rusch[1], Vikki Nolan[1], Aaron McDonald[1], Lucie Turcotte[4], Cindy Im[4], John Easton[1], Zhaoming Wang[1], Wendy Leisenring[3], Miriam Conces[5], Joseph P. Neglia[4], Yutaka Yasui[1], Smita Bhatia[6], Jinghui Zhang[1], Gregory T. Armstrong[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]University of Colorado, Anschutz Medical Campus, Aurora, CO,[3]Fred Hutchinson Cancer Center, Seattle, WA,[4]University of Minnesota, Minneapolis, MN,[5]Nationwide Children's Hospital, Columbus, OH,[6]University of Alabama at Birmingham, Birmingham, AL

While >85% of children with cancer will become five-year survivors, they are at substantially increased risk of developing subsequent neoplasms (SNs) in part due to DNA-damaging therapy. However, the effects of primary cancer therapy on the SN genomic landscape are unknown. We utilized biospecimens collected through the Childhood Cancer Survivor Study (CCSS) and employed whole-genome, exome, and RNA sequencing to analyze 199 SNs (median diagnosis age of 37.8 years, range 13.0-54.4) and matched germline tissue from 159 childhood cancer survivors, including 62 breast, 57 meningioma, and 42 thyroid SN patients. Overall, each SN type had similar somatic driver alterations to corresponding *de novo* cancers though at different frequencies, including increased frequency of kinase fusions and copy number alterations in thyroid SNs compared to *de novo* thyroid cancers. Meningioma and thyroid SNs had significantly elevated somatic single-nucleotide variant (SNV) and insertion-deletion (indel) burdens compared to *de novo* tumors from published cohorts such as The Cancer Genome Atlas, while breast SNs and *de novo* breast cancers had similar SNV and indel burdens. Prior treatment with nitrogen mustards, such as cyclophosphamide, was associated with increased levels of ubiquitous clock-like SNV mutational signature SBS5 in breast and meningioma SNs. We confirmed this association experimentally by treating cultured breast epithelial cells with an active cyclophosphamide metabolite followed by WGS, which revealed an SBS5-like signature induced by the treatment. In addition, we observed platinum-induced signatures SBS31 and SBS35 in 4 of 5 meningioma and thyroid SNs previously treated with platinum therapy, and identified and functionally validated *NF2* splice variants which were predicted to be platinum-induced in meningioma based on their occurrence at platinum signature hotspots. Driver alterations occurred evolutionarily early in most breast and thyroid SNs (12 of 14 multi-sample patients) as evidenced by their truncal status (detected in all samples at clonal variant allele fractions), while most meningioma patients (3 of 5) show intrapatient driver divergence, including a lack of shared mutations indicative of genetically independent tumors. Together, these results demonstrate the long-term impact of childhood cancer treatment on the genomes of SNs developing in adulthood, which may guide efforts to treat and prevent SNs.

#713 Utility of next generation sequencing multigene assay for comprehensive molecular profiling and targeted therapy in solid organ malignancies - An Indian experience.

R. Katara, A. Agarwal, D. K. Sharma, V. Kumar, S. S. Mohanty, A. Yadav, S. Sharma, M. Dixit, S. Arora, S. K. Mohanty;
CORE Diagnostics India, Gurgaon, India

Introduction: Next-generation sequencing (NGS) has paved its path and broaden its utility in oncology practice. The dependability, experiments, pipeline building, data annotation, and its interpretation, including the cost have significantly improved in the recent years making its application more universal. As a result, molecular pathology is now essential for making treatment decisions in clinical practice as predictive and prognostic tools. The need of the hour is to identify a reliable and cost effective comprehensive genomic panel which can aid in a) massive parallel sequencing and screening of multiple genes at the same time; b) identifying deleterious somatic aberrations; c) assessing baseline disease progression / recurrence and guidance to therapy; d) conclude druggable tumor specific somatic mutations. This study aims at the validation and implementation of a comprehensive NGS panel in solid tumors.
Methodology: A total of 243 patient samples (Females: 126, Males 117) were included. DNA and RNA were isolated from the tumor sample and subjected to target amplification using an optimized 161 gene panel (Oncomine Somatic 161 Gene Panel and Thermo Fischer Scientific Ion S5™ System). The NGS output sequences of the multigene assay were aligned to the human reference genome hg19 (GRCh37). The alignments and variant calling was done using the ION S5 torrent server. Variants were identified and interpreted using Ion Reporter Software.
Results: The DNA and RNA alterations were more prevalent between 51-60 years in females, while 61-70 years in males. Total positivity rate was found to be 66% in males and 79% in females. The most prevalent mutations observed amongst females were *TP53* (39% in lung cancers), *KRAS* (16% in lung cancers), *PIK3CA* (10% in breast cancers), *NRAS* (3% not specific to any particular cancer), *CTNNB1* (3% not specific to particular cancer) and *ATM* (3% in pancreas cancers) while male preponderance were observed with *EGFR* (7% in lung cancers), CNVs (6% in stomach cancers), *RB1* (3% in gall bladder cancers) and *BRAF* (3% in lung cancers).
Conclusions: The study is unique as it allows thorough genetic profile of individuals by examining 161 genes at the same time, eliminating the need for several tests. The assay aids clinicians in personalizing drug regimens by understanding tumorigenic pathways and timely management of the disease. Comprehensive genomic profiling improves the evaluation of moderate/low penetration genes that are frequently overlooked in clinical genetic settings, resulting in a direct influence on providing individuals with appropriate genetic counselling and clinical care
Keywords: NGS, 161 genes, Comprehensive molecular profiling

#716 Discovery of biomarkers of brain metastasis using Genomic Proximity Mapping (GPM) on formalin-fixed paraffin-embedded head and neck squamous cell carcinomas.

Emily Reister[1], Maika Malig[1], Mary Wood[1], Alexander Muratov[1], Ivan Liachko[1], **Stephen Eacker**[1], Ida Deichaite[2]

[1]Phase Genomics, Seattle, WA,[2]University of California, San Diego, San Diego, CA

Introduction: Head and neck squamous cell carcinoma (HNSCC) encompass a heterogenous classification of solid tumors that account for ~5% of the total new cancer cases globally. HNSCC presents as metastatic disease at estimated rates of 4-25%, most commonly in bone, liver and lung. Brain metastasis (BM) is uncommon and is particularly deadly. There is a need to better understand biomarkers that may presage brain metastasis in hopes of identifying those patients requiring aggressive treatment to head-off metastatic disease. Furthermore, identification of common biomarkers may elucidate therapeutic strategies to treat this disease. To compliment ongoing targeted sequencing efforts, we have applied high-resolution cytogenomic analysis using the genomic proximity mapping (GPM) platform, CytoTerra, to investigate chromosomal abnormalities associated with BM HNSCC.
Methods: GPM uses proximity ligation and short-read sequencing to detect alterations in genomic structure. This technology is compatible with formalin-fixed paraffin-embedded tissue samples because it uses formalin fixation to capture genomic proximity information. 15 µm molecular curls were used as inputs for library preparation from 2 primary tumors of BM HNSCC and 3 samples of non-BM HNSCC. Chromosomal abnormalities were detected using the cloud-based CytoTerra analytic platform which utilizes a suite of AI-based and bioinformatic tools.
Results: GPM libraries with sufficient QC statistics were generated from all five samples. Evaluation of HNSCC genomes revealed a wide array of structural alterations commonly observed in cancer, including balanced and unbalanced translocations, inversions, chromothripsis, deletions, duplications, and copy-neutral loss of heterozygosity. Notably structural rearrangements involving the *JAK1* and *EGFR* loci were observed in BM HNSCC samples. In addition we identified a novel *NRG1::FAM110B* fusion in one case of BM HNSCC. None of these rearrangement involved the disruption of the coding sequence of the gene and therefore would escape detection through standard panel sequencing. Non-BM HNSCC showed similar classes of chromosomal abnormalities and included a deletion of *KDM6A*. Variants identified in serial sampling of neighboring HNSCC lesions in non-BM HNSCC demonstrated a high degree of overlap, demonstrating reproducibility. Uniquely identified variants allow inferences on tumor evolution between the two lesions.
Conclusion: GPM with the CytoTerra next generation cytogenomic platform successfully identified chromosome abnormalities in FFPE HNSCC samples. BM HNSCC samples demonstrated structural alterations in known and targetable oncogenes suggesting that CytoTerra can be a useful tool for novel biomarker discovery in solid tumors, including HNSCC.

#717 Pan-cancer analysis of *TRIM37* copy-number and development of fit-for-screening in situ hybridization tools.

Background: Elevated TRIM37 protein levels, often driven by genomic copy number (CN) gains in cancer cells, lead to loss of the pericentriolar material during mitosis and increased dependence on PLK4-mediated centriole assembly. This synthetic lethal hypothesis is being tested in a phase I clinical trial evaluating the activity of the PLK4 inhibitor, RP-1664, in advanced solid tumors with *TRIM37* CN gains or overexpression (LIONS, NCT06232408). In support of this clinical study, we characterized *TRIM37* CN and RNA expression across a large genomic database and by imaging-based DNA and RNA in-situ hybridization.

Methods: Whole exomes and transcriptomes from >12,000 adult solid tumors were analyzed for *TRIM37* CN gain (CN > ploidy) or amplification (amp, CN ≥ ploidy + 2), respectively, or TRIM37 RNA expression (BostonGene^{TM}). Locus specific probes for fluorescence in-situ hybridization (FISH) were developed for *TRIM37* and centromere 17 (*CEP17*). TRIM37 RNA-ISH was developed using the RNAscope^{TM} system (ACD Bio^{TM}).

Results: Across adult solid tumors, *TRIM37* amps, were most frequent in breast (9%), lung adenocarcinoma (5%), and melanoma (5%). Using the lower cutoff inclusive of *TRIM37* gains, CN events were most often observed in urinary tract cancer (33%), lung adenocarcinoma (32.2%), breast cancer (26%), and squamous cell lung carcinoma (24.2%). *TRIM37* CN levels were correlated with TRIM37 RNA expression in all indications examined. *TRIM37* CN level was inversely correlated with segment length (coef -1.76, p-value = 6.1e-20). *ERBB2* (HER2) is located approximately 19 megabases (mb) from *TRIM37* and was often co-amplified, with 73% of *ERBB2* gain/amps also having *TRIM37* gain/amps. *TRIM37* focal amps (<5.6 mb) were enriched in samples with co-occurring *ERBB2* focal amps, even though these events were on different segments. HER2-enriched breast cancer had the highest percentage of focal *TRIM37* amps (56%) and high-level amps (≥ 5 copies; 60%). To identify TRIM37 high patients clinically, we developed RNA and DNA ISH assays. *TRIM37* DNA FISH ratio and ploidy corrected CN by NGS were strongly correlated (N=16, Pearson correlation = 0.89, p-value = $3.4x10^{-6}$). DNA FISH ratio was positively associated with RNA-ISH scores (Jonckheere-Terpstra test, P = 0.03), and of 16 *TRIM37* FISH positive DNA-FISH samples, 14 were scored 2-3+ (≥4 copies/cell), while 2, scored 1+ (1-3 copies per cell) by RNA-ISH.

Conclusions: A considerable population of adult solid tumors are TRIM37-high. Creation of fit-for-screening tools employing in-situ hybridization techniques may provide enhanced sensitivity for identification of patients with TRIM37-high tumors.

#718 The crucial role of SPARC during the transition from in situ to invasive breast cancer.

Breast carcinomas are classified as ductal carcinoma in situ (DCIS) or invasive carcinoma (IDC) depending on the degree of invasion. DCIS is generally found adjacent to IDC in the primary tumor and is considered a precursor of IDC. Still, it has not been possible to identify features that predict the progression to more advanced stages. We have previously demonstrated that MT1-MMP, a key membrane-associated metalloprotease (MMP), involved in the cleavage of the extracellular matrix is essential for the transition from in situ to invasive tumors using intraductal xenograft model (Lodillinsky, 2016; 2021). In this work, RNAseq analysis from MT1-MMPhigh cells from invasive tumors post-intraductal inoculation was compared against a set of human high-grade DCIS previously described (Abba, 2015). Secreted protein acidic and cysteine-rich (SPARC) emerges as a candidate gene in early breast cancer progression. By IHC, we observed an over-expression of SPARC in neoplastic cells compared to normal tissue from 2 different cohorts of patients with IDC and DCIS foci (PICBIM n=55 and Roffo n=34). In matched samples, SPARC levels were higher in IDC than DCIS tumors ($p<0,0001$) and correlated with MT1-MMP levels. SPARC-positive tumors were higher in high-grade and TNBC IDC tumors ($p=0,02$). In a metastatic cohort of patients (n=57), lymph node metastases did not express SPARC, suggesting its specific role in early breast cancer progression. In the murine cell LM38-LP, MT1-MMP mRNA level and degradative capacity were reduced in KO SPARC cells ($p<0,05$). STRING analysis showed a medium interaction score between SPARC and TGF-B1. LM38-LP cells were sensitive to TGF-B1 pathway regulation ($p<0,05$; $p<0,001$) and KO SPARC LM38-LP cells reduced pSMAD 2/3 ($p=0,003$). SB431542 (20ng/ml) decreased SPARC and MT1-MMP expression in LM38-LP and human MCF10DCIS.com cell lines ($p<0,001$). TGF-B1 (2ng/ml) increased the degradative capacity of LM38-LP whereas, SB431542 and Galunisertib (1µg/ml), reduced it ($p<0,001$; $p<0,05$). On migration assays, we observed that the inhibitory effect of SB431542 was lost in KO SPARC cells ($p<0,0001$). In vivo, Galunisertib (50mg/kg) reduced the proportion and tumor area of IDC ($p= 0,04$) in a new mouse intraductal syngeneic model. Moreover, high SPARC expression was positively correlated with both, TGF-β and TGFBR1 in a basal type of breast cancer collection supporting our findings. This study identifies SPARC as a driver of early tumor progression via a TGF-B1-dependent mechanism, suggesting TGFRI as a target for SPARC-positive patients.

#719 Clinical and molecular differences suggest different responses to immune checkpoint inhibitors in microsatellite-stable solid tumors with high tumor mutational burden.

Tarik Demir[1], Imran Nizamuddin[2], Katrina Dobinda[3], Ruohui Chen[3], Masha Kocherginsky[3], Peter Doukas[2], Neelima Katam[4], Carolyn Moloney[1], Devalingam Mahalingam[1]

[1]Division of Hematology and Oncology Developmental Therapeutics Institute, Northwestern University, Chicago, IL,[2]Division of Hematology and Oncology, Northwestern University, Chicago, IL,[3]Preventive Medicine; Feinberg School of Medicine, Northwestern University, Chicago, IL,[4]Northwestern University, Chicago, IL

Introduction: High tumor mutational burden (TMB) has shown promise in specific tumor types; however, its broad applicability across all solid tumors remains unclear. We aim to evaluate the outcomes of patients with advanced solid tumors exhibiting TMB ≥10 mutations per megabase (mut/Mb) who were treated with immune checkpoint inhibitors (ICIs) and to identify resistance mechanisms.
Methods: Patients who received treatment at the Northwestern University between January 2015 and December 2020 with ICIs and a TMB of ≥10 mut/Mb were identified through an Enterprise Data Warehouse grant and determined by next-generation sequencing. Tumors with microsatellite instability were excluded. Survival curves were calculated using the Kaplan-Meier method, and multivariate analyses were conducted to evaluate the impact of clinical variables on response, with significance defined as $p \leq 0.05$.
Results: 117 patients were enrolled, median age of 68 years, and 61% of the participants were male. The patient cohort was categorized into two distinct groups based on their sensitivity to ICI treatments: Group 1: ICI-sensitive (75%, 88/117 patients). Group 2: Non-ICI-sensitive (25%, 29 /117 patients). Upon evaluation of treatment efficacy (n=105), the overall response rate was recorded at 34%, with 14% of patients achieving a complete response (CR). The median progression-free survival and overall survival were 10.9 months and 29.9 months, respectively. Positive treatment responses were associated with a lack of prior exposure to systemic therapy (p=0.046), specific tumor types (p=0.009), absence of liver metastasis (p=0.015) across all group. Additionally, the presence of POLE mutations was associated with better outcomes (p=0.037), as well as a TMB of ≥15 mut/Mb in non-ICI-sensitive cancer group (p=0.012). However, PD-L1 status, specific ICI regimen, age, and sex did not demonstrate prognostic significance. Regarding genetic pathways, mutations in the TP53 pathway were significantly correlated with poorer treatment response (p=0.018). No significant differences were observed in the RTK/RAS, NRF2, PI3K, TGFβ, WNT, MYC, cell cycle, and Notch pathways. Furthermore, specific mutations in the TP53 ($p = 0.029$) and PIK3CA ($p = 0.033$) genes were linked to diminished responses. A trend was also noted suggesting ROS1 mutations may be associated with a poorer response (p=0.057).
Conclusion: Immunotherapy utilizing ICIs effectively treats TMB-H tumors, which typically demonstrate low CR rates. Enhanced therapeutic responses have been observed in patients who have not previously undergone systemic therapy, do not present with liver metastasis, and possess a TMB level of ≥15 mut/Mb. Mutations in the TP53 pathway are linked to a diminished response, while other pathways analyzed did not exhibit statistically significant differences in response rates.

#72 A case of immune therapy-refractory composite lymphoma: The complex interplay between two distinct tumors within a single spatial microenvironment.

Ashley K. Volaric, James Gerson, Karamatullah Danyal, Rangsinee Nusapan, Seth Frietze

Larner College of Medicine at The University of Vermont, Burlington, VT

Immune checkpoint (IC) therapy with anti-PD1 agents is typically used in treatment-refractory classic Hodgkin lymphoma (CHL). However, we present a rare case of composite classic Follicular lymphoma (cFL) and CHL whereby frontline use of anti-PD1 therapy (Nivolumab) in combination with standard AVD (Doxorubicin, Vinblastine, Dacarbazine) was clinically justified. We performed the Visium spatial transcriptomics assay to gain insight into the unique tumor cell characteristics and immune cell composition of the tumor microenvironment both pre- and post-IC therapy. Our case is a of a 44-year-old female who presented with fever, night sweats, and cervical lymphadenopathy. The patient underwent frontline IC combination therapy with single-agent Nivolumab and standard AVD. She showed nearly complete treatment response after 6 cycles. However, three months post-therapy, she developed new symptoms of fatigue, fever, and inguinal lymphadenopathy. Excisional biopsy of the inguinal lymph node showed recurrence of the cFL with no evidence of the previous CHL. The clinicopathologic findings suggest a primary treatment response of the CHL to IC combination therapy, but refractory response of the cFL. To understand the complex immune cell composition of this rare lymphoma, we performed the 10X Genomics Visium CytAssist assay on a representative tumor area from the formalin-fixed paraffin-embedded tissue block of the initial diagnostic biopsy. The data were analyzed using a bioinformatics workflow for cell deconvolution to identify cellular composition, ligand-receptor interaction analysis to study cell-cell communication, and spatial gene expression analysis to understand the disease context. Pathologic diagnosis of the lymph node excision showed a composite lymphoma comprised of cFL and CHL. Cytogenetic fluorescence *in situ* hybridization (FISH) study for *BCL2* rearrangement was negative. Our analysis revealed distinct transcriptomic profiles associated with cFL and CHL regions within the lymph node excision. We identified unique immune cell infiltration patterns with pronounced CD4(+) T-cell memory signatures in both cFL and CHL regions. We observed transitional zones between the two lymphomas characterized by a mixed expression profile with increased stromal and stem cell markers. Furthermore, we uncovered T-cell immunoregulatory and trafficking signals localized to the CHL and transitional zones, potentially influencing the surrounding tumor microenvironment. In conclusion, this study provides an unprecedented investigation into a rare case of composite lymphoma treated with frontline IC combination therapy through molecular and spatial profiling. Further analysis using the Visium assay is pending on the subsequent post-therapy tissue biopsy which may undoubtedly reveal underlying unique biologic relationships.

Introduction: While traditionally informed by tumor tissue origin and histopathology, advancements in next-generation sequencing (NGS) technology have catalyzed tumor-agnostic approaches which prioritize molecular alterations for personalized treatment. Here, we demonstrate the clinical utility of molecularly guided tumor-agnostic precision medicine in an Asian cohort, leveraging an Asian-centric NGS panel tailored to address the unique genetic landscape of the region.
Methods: 1,167 formalin-fixed paraffin-embedded tissue samples from 1,150 Asian cancer patients across >70 centers in 7 countries underwent real-world NGS testing using an Asian-centric pan-cancer hybrid-capture NGS panel (UNITED), profiling 572 cancer-related genes and 91 RNA fusion partners. Biomarkers were classified as actionable if therapeutic indications were FDA-approved, guideline-recommended, or supported by robust phase III clinical trials.
Results: The cohort encompassed 23 cancer types, with lung (17.7%), colorectal (12.8%), prostate (11.1%), and breast (8.6%) cancers accounting for 50.1% of the clinical volume. Actionable biomarkers were identified in 62.2% of samples, with *KRAS, EGFR,* and *PIK3CA* among the most frequently mutated genes. The likelihood of identifying ≥1 actionable mutation was highest in CNS tumors (83.6%), followed by lung cancer (81.2%), breast cancer (79%), and others. Among 27,552 somatic variants detected, 1,291 (4.7%) were potentially targetable by regulatory-approved therapies. Notably, ≥1 tumor-agnostic biomarker (including TMB-H, dMMR/MSI-H, *NTRK*/*RET* fusions, and *BRAF* V600E) was identified in every cancer type, detected in 98 samples (8.4%). This includes in 16.9% of lung tumors, 12.2% of tumors of unknown primary origin, 11.8% of endometrial tumors, and others. As expected, TMB was significantly associated with MSI ($p<0.0001$). *ERBB2* amplification, a potential surrogate marker for HER2 overexpression, was identified in 42 samples (3.6%) and was most frequently detected in breast tumors (15%), followed by endometrial tumors (11.8%), ovarian tumors (8.9%), and others. Homologous recombination deficiency (HRD) was observed in 407 samples (34.9%) and were present in about half of the tumors of the breast (50%), colon (49%), urothelium (47.1%), endometrium (47.1%) and lung (44%). Notably, HRD-positive tumors exhibited significantly higher TMB compared to HRD-negative tumors (median TMB 5.58 vs. 5.15, $p=0.0001$).
Conclusion: Leveraging an Asian-centric NGS panel, actionable molecular alterations were detected in 62.2% of Asian cancer patients. The high prevalence of actionable biomarkers, coupled with the detection of regulatory-approved tumor-agnostic markers, underscores the significance of comprehensive NGS testing in facilitating tumor-agnostic precision medicine in an Asian setting, thereby improving treatment strategies and patient outcomes.

#721 The role of NCAM1(CD56) in mediating venetoclax resistance.

Bernhard Alber, Tania Q. Vu, Bridget Robinson, Daniel Chandra, Jessica Mulkey, Yoko Kosaka, Evan Lind, Jeffrey W. Tyner, Jennifer N. Saultz

Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Background: NCAM1 (CD56) is a neural cell adhesion molecule that is expressed on immune cells including NK cells, T cells, dendric cells and monocytes. Acute myeloid leukemia (AML) patients also aberrantly express NCAM1 in around 30% of cases which may impact treatment response. Our group recently found that CD56 expression on myeloid blasts is associated with worse overall survival to treatment with the BCL2 inhibitor, Venetoclax (VEN), including VEN combined with hypomethylating agents or with the JAK inhibitor, Ruxolitinib. Within molecular prognostic risk score (mPRS) defined higher and intermediate- risk groups, CD56 positivity further stratified survival in addition to genetics. The functional role of CD56 in VEN resistance is unknown.

Methods: We used 2 different AML cell lines showing high and intermediate expression of CD56, MOLM14 and OCI-AML2 respectively. Utilizing CRISPR Cas9 gene editing technology we generated stable *NCAM1* knockouts. Multiparameter flow cytometry was used to access changes in surface CD56 expression. Ex-vivo drug sensitivity assays were performed on parental, *NCAM1* knockout, and non-targeting cells to investigate VEN response at baseline and upon *NCAM1* knockout. Western blot as well as single-cell imaging analysis were performed to elucidate changes in protein expression.

Results: VEN sensitivity is associated with relative CD56 expression in MOLM14 and OCI-AML2. MOLM14 cell with high CD56 expression are more resistant to VEN than OCI-AML2 showing intermediate expression. Additionally, upon acquisition of VEN resistance through long-term drug exposure, MOLM14 and OCI-AML2 increase expression of CD56, phospho-MAPK1/3 (pERK), and have a higher ratio of MCL1/BCL2. To understand the impact of genetic deletion, we utilized CRISPR Cas9 to knockout *NCAM1* in MOLM14 and OCI-AML2 and found that absence/or knockdown of CD56 sensitizes cells to VEN, as well as decreases protein levels of BCL2, pMAPK1/3, MCL1 and FGFR1. Of note, we saw no changes in surface markers associated with myeloid cell differentiation state (ie. CD11b, CD14, CD117) in our *NCAM1* knockout lines compared to non-targeted control.

Conclusions: Genetic deletion of CD56 sensitizes AML cells to VEN treatment and decreases pMAPK1/3 as well as BCL2 protein levels. CD56 signaling occurs through the PTK2/RAS/MAPK signaling pathway, however a direct regulatory role of CD56 on BCL2 expression has not yet been reported. Future therapeutics targeting CD56 may be able to improve response and survival in patients with CD56 positive AML particularly after VEN resistance. Further research to delineate the underlying mechanisms associated with CD56 and BCL2 family profiles are underway which may enhance current treatment approaches.

#722 Characterization and estimation of treatment response of immunotherapy-based total neoadjuvant therapy (iTNT) for microsatellite stable (MSS) locally advanced rectal cancer.

Yaqi Wang[1], Yang Xu[2], Fan Xia[1], Juefeng Wan[1], Lijun Shen[1], Yan Wang[1], Hui Zhang[1], Hairong Bao[2], **Haimeng Tang**[2], Qiuxiang Ou[2], Hua Bao[2], Yang Shao[2], Sanjun Cai[1], Xinxiang Li[1], Zhen Zhang[1]

[1]Fudan University Shanghai Cancer Center, Shanghai, China,[2]Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Total neoadjuvant therapy (TNT) combined with immunotherapy (iTNT) has shown promising results for locally advanced rectal cancer (LARC), especially in proficient mismatch repair (pMMR)/microsatellite stable (MSS) patients. However, traditional clinical approaches often fail to accurately forecast clinical outcomes, and reliable methods to predict treatment response and recurrence risk are essential for optimizing treatment strategies and maximizing organ preservation.

Methods: We analyzed clinical and genetic data from 63 patients in the TORCH clinical trial who received iTNT. Baseline tissue mutations, magnetic resonance tumor regression grade (mrTRG), and circulating tumor DNA (ctDNA) positivity at different time points were examined for their association with complete response (CR) and recurrence. Predictive models integrating these features were developed to assess their accuracy in distinguishing CR from non-CR patients. Prognostic features were analyzed using COX regression and Kaplan-Meier analyses.

Results: Baseline *SMAD4* mutation was significantly associated with poor response to iTNT (P=0.007), while post-treatment mrTRG (P<0.0001), tumor mutational burden (TMB) (P=0.03), and latest ctDNA status (P=0.03) also correlated with CR rates. Integration of post-treatment mrTRG, *SMAD4* mutation, TMB, and latest ctDNA status significantly improved CR prediction accuracy compared with mrTRG-only model (area under the curve (AUC) 0.92 vs 0.75, P=0.0098). Early prediction models incorporating middle-iTNT mrTRG and these genetic features showed superior accuracy to predict CR than mrTRG-only model (AUC 0.89 vs 0.76, P=0.047). Furthermore, ctDNA positivity at later time points and *SMAD4* mutations correlated with worse disease progression, including local recurrence and distant metastases.

Conclusion: Our findings highlight the predictive power of combining genetic and clinical features, particularly ctDNA and *SMAD4*mutation, for improving CR prediction and early recurrence risk stratification in iTNT-treated LARC. These models could guide more personalized treatment strategies, enabling early identification of patients requiring intensified therapy or nonoperative management.

#723 Tumor microenvironment and epithelial subtypes in nasopharyngeal carcinoma for precision oncology.

Wei Keat Teo[1], Yi Ren[1], Chee Yit Lim[1], Luvita Suryani[1], Joseph W. Foley[1], Bing Cheng Wu[2], Kwok Seng Loh[1], Raymond KY Tsang[1], Joshua K. Tay[1]

[1]Otolaryngology - Head & Neck Surgery, National University of Singapore (NUS), Singapore, Singapore,[2]Pathology, National University of Singapore (NUS), Singapore, Singapore

Nasopharyngeal carcinoma (NPC) is an Epstein-Barr virus (EBV)-associated epithelial malignancy endemic to Southeast Asia, Southern China, and the Middle East. Profiling the gene expression of NPC has been challenging due to its dense inflammatory microenvironment admixed with tumor epithelial cells, as well as limited tissue availability from small 4mm transnasal endoscopic biopsies. We performed laser-capture microdissection on a cohort of formalin-fixed paraffin-embedded (FFPE) biopsy samples obtained from NPC patients (n = 69) treated at the National University Health System Singapore and nasopharyngeal biopsies from healthy controls (n = 7). Primary, pretreatment tumors from patients who developed recurrent or metastatic disease (Group A) were compared with tumors from patients who remained healthy (Group B), matched for stage of disease. Tumor epithelial (TUM) and microenvironment (TME) regions were separately isolated. Gene expression libraries were prepared using a specialized mRNA-Seq technique optimized for tiny amounts of FFPE material, followed by next generation sequencing. Post-filtering, 330 gene expression libraries were analyzed, including 165 TUM, 134 TME, 4 dysplasia, 18 normal-adjacent and 9 normal libraries. Principal component analysis showed distinct clustering of epithelial and microenvironment gene expression libraries, confirming the purity of microdissection. Unsupervised k-means clustering revealed three distinct TME clusters (C1, C2, C3), which were also confirmed by silhouette analysis. Gene set enrichment analysis demonstrated significant enrichment of immune processes in C1, proliferative pathways in C2 and stromal processes in C3. Deconvolution of cell-type signatures with ESTIMATE showed that C1 had the highest immune score (1057, 129 and 733 respectively, $p < 2e-16$) while C2 had the highest tumor epithelial purity score (0.666, 0.852 and 0.715 respectively, $p = 3e-16$). C2 and C3 tumors had a higher recurrence rate compared to C1 (42.85%, 73.07% and 71.43% respectively, $p = 0.004$). Within the tumor epithelial compartment, Group A tumors were enriched for vascular endothelial growth factor signaling (NES = 1.55) and fibroblast growth factor receptor signaling (NES = 1.53), when compared to Group B. Consistent with our previous work interrogating receptor kinase signaling in NPC, FGF2 was significantly upregulated in Group A tumors (log2FC = 3.612). Microdissected gene expression profiling of FFPE patient biopsies identifies biomarkers and microenvironment subtypes important for prognosis and targeted treatment. VEGF and FGF pathway enrichment in high-risk tumors forms the basis of ongoing anti-VEGF clinical trials for NPC at our institution, with the potential of using a gene signature approach for patient selection.

#724 Target identification for antibody-drug-conjugate (ADC) therapy in biliary tract cancers (BTC).

Aruj Dhyani[1], Zeynep Tarcan[2], Joanne Chou[3], Rohit Thummalapalli[1], Walid Chatila[3], Sharanya Nag[4], Ezra Rosen[5], Sydney Bowker[6], Wungki Park[1], Elisa De Stanchina[7], Sarat Chandarlapaty[5], David Solit[4], William Jarnagin[8], Marinela Capanu[3], Eileen M O'Reilly[1], Ghassan K Abou-Alfa[1], Olca Basturk[9], James Harding[1]

[1]GI Oncology-Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Epidemiology-Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Human Oncology and Pathogenesis, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Breast Oncology-Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Research Facilities, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Department of anti-tumor assessment, Memorial Sloan Kettering Cancer Center, New York, NY,[8]Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[9]Pathology and laboratory medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Background: BTCs are an uncommon malignancy with poor prognosis. ADCs have efficacy in several solid tumors with antigen surface expression serving as a potential biomarker in some instances. Herein, we evaluate the protein expression and heterogeneity of ADC target antigens and their prognostic implications in BTC.
Methods: Utilizing an IRB-approved, retrospective biospecimen protocol, we constructed tissue microarrays (TMA) from resected, early staged intrahepatic cholangiocarcinoma (IHC), extrahepatic cholangiocarcinoma (EHC) and gallbladder cancer (GB). IHC for Nectin-4, TROP2, c-MET, CLDN18.2 was assessed. Positivity defined as ≥10% weakly stained tumor cells and quantified by H-score (intensity × percentage). HER2 IHC scored per standard colon criteria. Clinicopathological factors and outcomes were associated with ADC target expression.
Results: N=65 resected cases were selected (median age 72 years (range 36-92); 55% males, anatomical subtype 40% IHC, 43% EHC, 17% GB; 84% moderately differentiated adenocarcinoma. c-MET and TROP2 were expressed in 75% and 83% of cases with differential expression based on anatomic site (c-MET: IHC: 62%, EHC: 89% vs GB: 73%, p=0.049; TROP2: IHC: 65%, EHC: 93% vs GB: 100%, p=0.010, Table). HER2, CLDN18.2, and Nectin-4 were expressed in 7.7%, 46%, and 66% of cases, and did not differ based on anatomic site. Median RFS and OS were 20 (95%CI 10-NR) and 40 (95%CI 27-NR) months respectively and outcomes were not impacted by expression of HER2, Nectin-4, TROP2, c-MET, or CLDN18.2.
Conclusion: Modest to high expression of Nectin-4, TROP2, c-MET and CLDN18.2 was identified across BTC anatomic subtypes, suggesting a potential role for ADCs to these antigens in patients with BTC. Preclinical validation is ongoing in BTC patient derived xenografts with trastuzumab deruxtecan (HER2 sensitive and HER2 resistant models), enfortumab vendotin (Nectin-4 positive model), and sacituzumab govitecan and these results will be presented at the meeting.

The purpose of this study was to develop a predictor of response to treatment with daratumumab in multiple myeloma. Daratumumab has considerably improved outcomes for myeloma patients. However, the treatment is expensive and not all myeloma patients benefit from treatment. Therefore, a predictor of daratumumab benefit would focus on treating patients with high likelihood of responding, and avoid treating those who are unlikely to respond or benefit. Daratumumab is a monoclonal antibody that binds to CD38, causing apoptosis via antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cellular cytotoxicity (CDCC). ADCC requires the presence of natural killer cells, and can be measured in vitro with a calcein release assay using multiple myeloma cell lines in the presence of natural killer cells. Measuring the baseline gene expression in the cell lines makes it possible to identify mechanisms of resistance or sensitivity to daratumumab induced ADCC in vitro. We used published data of lysis of 19 multiple myeloma cell lines and B-cell non-Hodgkin's lymphoma cell lines in the presence of daratumumab and natural killer cells from peripheral blood mononuclear cells. Correlating the sensitivity to ADCC with the baseline gene expression of these cell lines, we identified 27 genes correlated to sensitivity and 26 genes correlated to resistance. Among these are genes previously associated with sensitivity to daratumumab, glucocorticoid response, the proteasome, natural killer cell resistance, nuclear transport, myeloma risk classification, and myeloma cancer drivers. The 53 genes collectively constitute a daratumumab drug response predictor (DRP), and a single score of predicted sensitivity to daratumumab can be calculated as the difference between the mean of the positively correlated genes and the mean of the negatively correlated genes. We used published single-cell RNAseq data from the KYDAR trial of multiple myeloma patients treated with daratumumab, carfilzomib, lenalidomide and dexamethasone, to test the 53 gene DRP on clinical samples. The KYDAR trial enrolled 41 newly diagnosed MM patients who either failed to respond, or experienced early relapse, after a bortezomib-containing induction regimen. Baseline single-cell RNA sequencing data and overall response information was available for 17 subjects. The overall response to treatment correlated with the DRP score: Pearson correlation coefficient 0.26 (95% CI 0.15 - 0.83). A cutoff can be applied to separate responding patients from nonresponding patients. These results provide proof-of-concept for an mRNA-based predictor of response in multiple myeloma that warrants further clinical validation in multiple myeloma. When combined with our previously published response signatures for other cancer treatments used in myeloma, a map of predicted sensitivities can be provided for each patient based on a bone marrow sample.

#726 Comprehensive genomic profiling of cell-free DNA and matched white blood cells improves accuracy of ctDNA molecular response in immunotherapy treated NSCLC.

Introduction: Assessment of molecular response (mR) to targeted and immunotherapies (IO) in solid cancer is an emerging clinical liquid biopsy application. Current approaches have demonstrated promising results but have predominately relied on tumor-informed strategies and small to intermediate-sized next generation sequencing (NGS) gene panels. Lack of tissue availability and emergence of comprehensive genomic profiling (CGP), however, limit the practicality of implementing these approaches in a clinical setting. Furthermore, biological signals from non-tumor derived alterations arising from clonal hematopoiesis (CH) may confound detection of tumor-specific alterations for therapy selection and longitudinal monitoring. To address these limitations, we evaluated the 521-gene PGDx elio™ plasma complete assay with an integrated matched white blood cell (WBC) analysis algorithm to longitudinally assess cell-free tumor DNA (ctDNA) through a baseline plasma-informed approach and correlate mR to radiographic response and outcomes.
Methods: Plasma from 57 patients with mNSCLC who received IO from 2017-2019 at Hospital del Mar had detectable pre-treatment ctDNA. Blood was collected prior to the start of therapy, early on-treatment (median 4 weeks) and longitudinally throughout clinical follow-up and disease progression. Germline and CH variants were identified and removed through matched WBC NGS analyses. mR was calculated as the percent change in mean variant allele frequency of the tumor-specific alterations assessed at the early on-treatment timepoint compared to the pre-treatment timepoint and then compared to radiographic response (RR) and overall survival (OS).
