Results: Thirty percent (17/57) of patients had a complete or partial radiographic response, with median follow up of >12 months. A tumor-specific genomic landscape analysis at baseline demonstrated associations between mR, recurrently mutated genes, and clinical outcomes. Removal of non-tumor derived cell-free DNA (cfDNA) variants improved characterization of mR and associations with radiographic and survival-based endpoints. A mR rate of 33% (19/57) was observed with a median OS of 53 months compared to 8.4 months for patients experiencing molecular progression at the early on-treatment timepoint (HR 4.8, 95% CI 2.2-10.2, $p<0.001$). Of all patients that survived ≤12 months after initiation of treatment, 85.7% (24/28) were categorized as experiencing molecular progression through early on-treatment cfDNA analyses.
Conclusions: CGP of cfDNA with integrated matched WBC analyses improves accuracy of mR and associations with RR and outcomes. This tumor-agnostic approach for assessment of genomic alterations at baseline and mR early on-treatment improves our ability to associate liquid biopsy-based biomarkers with patient and treatment-level outcomes.

#727 Association of baseline tumor and peripheral biomarker features with efficacy in metastatic castration-resistant prostate cancer patients treated with xaluritamig.

Benjamin E. Decato[1], Zhao Yang[1], Isabelita Vengco[2], Katherine Paweletz[2], Amrita Pati[2], Anita Reddy[2], Tara O'Donohue[1], Sheryl Treichel[2], **Kristen M. Smith**[2]

[1]Amgen Oncology, Thousand Oaks, CA,[2]Amgen Oncology, South San Francisco, CA

Xaluritamig, a novel STEAP1 x CD3 XmAb® 2+1 T-cell engager, is showing initial safety and efficacy in patients with metastatic castration-resistant prostate cancer (mCRPC). Here, we report on the association of baseline tumor and peripheral biomarker characteristics with efficacy in the first-in-human dose exploration trial. We examined STEAP1 target expression by immunohistochemistry in fresh and archival tumor biopsies, peripheral immune populations by multiparameter flow cytometry, and tumor somatic mutations via circulating tumor DNA (ctDNA) in plasma. STEAP1 was broadly expressed in mCRPC subjects with greater than 95% of tumor biopsies containing at least 1% STEAP1-positive tumor cells. STEAP1 expression was similar at various metastatic sites examined in the patient cohort and was not impacted by the number or types of prior therapies. Additionally, STEAP1 expression levels were not correlated with PSMA expression. Neither STEAP1 IHC intensity nor the percentage of STEAP1-positive tumor cells correlated with response to xaluritamig. Baseline peripheral immune cell populations and blood chemistry features may potentially associate with response. Patients who achieved a PSA50 response had lower neutrophil counts, neutrophil-to-lymphocyte ratio, and C-reactive protein than non-responding patients. The association between xaluritamig response and baseline tumor T cell infiltration is being assessed. Baseline somatic tumor mutations were determined by analysis of ctDNA. The distribution of somatic tumor mutations was consistent with published mCRPC mutational frequencies, with deleterious alterations in TP53, AR, PTEN and RB1 observed most frequently. Xaluritamig efficacy was observed in patients whose tumors carried these common mCRPC alterations, as well as in patients with detectable TMPRSS2:ERG fusions Taken together, these data suggest that xaluritamig has anti-tumor activity in a broad mCRPC patient population and provide support for enrolling patients with mCRPC in a Phase 3 study of xaluritamig (NCT06691984) regardless of STEAP1 expression levels or tumor mutational status.

#728 Identification of high-risk luminal early breast cancer patients based on a p53 signature.

Florian A. Buttner[1], Stefan Winter[1], Johanna V. Dahlen[2], Thomas E. Murdter[1], Reiner Hoppe[1], Peter Fritz[1], Patrick Danaher[3], Stephen F. Madden[4], Matthias Schwab[5], **Werner Schroth**[1]

[1]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology and University of Tuebingen, Stuttgart, Germany,[2]Medical Faculty, University of Tubingen, Tubingen, Germany,[3]Bruker Spatial Biology, Seattle, WA,[4]Data Science Center, School of Population Health, Royal College of Surgeons in Ireland, Dublin, Ireland,[5]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology and Departments of Clinical Pharmacology, Pharmacy and Biochemistry, University of Tuebingen, Stuttgart, Germany

Estrogen receptor (ER) positive luminal early breast cancer (BC) benefits from endocrine therapy based on the selective ER modulator tamoxifen (TAM) and aromatase inhibitors (AI). Yet, tumor recurrence occurs in up to one third of patients due to primary and secondary endocrine treatment resistance (ETR). The causes of primary ETR are not well defined by predictive tumor markers, however, *TP53* mutations have been linked with primary ETR in a preoperative short-term endocrine treatment study. We used a previously learned *TP53* mutation-predictive p53 score as part of the NanoString®BC360 mRNA expression panel to identify patients with p53 mutant-like status, and tested its applicability for the prediction of primary ETR in the adjuvant setting. In the TCGA BRCA cohort (N=1078), the p53 score distribution was analyzed for the presence of different subgroups using Gaussian finite mixture modeling. The same procedure was applied in breast cancer patients from the BreastMark database (N=1936) as an independent test of methodological and clinical validity. An ad-hoc binary classifier was trained to apply the cutoff identified in TCGA patients to patients of a prospectively collected, postmenopausal early breast cancer test cohort (IKP211) of hormone receptor-positive patients treated with TAM and/or AI (median follow up 6 years, N=632; DRKS00000605). Cluster modeling revealed that the p53 score distribution in the TCGA cohort is composed of two different patient groups: 363 patients (33.7%) with higher p53 scores were separated from the remaining patients with lower p53 scores. Likewise, the BreastMark cohort also showed two clusters with 419 patients (21.6%) forming the patient subgroup with high p53 scores. Cancer-specific survival (TCGA) and recurrence-free survival (BreastMark) were significantly shorter in p53-high patients of Luminal A subtype (P=0.0045 and P=0.04, respectively), with no significant differences observed in the remaining subtypes. When applying the binary classifier (mean AUC 0.95) on patients of the IKP211 test cohort, 14 patients (2.2%) were predicted as p53 mutant-like. This p53-positive patient group was strongly associated with higher recurrence or death rates in multivariate Cox regression (HR=3.3, 95% confidence interval 1.5-7.4; P=0.0037). As an independent verification, *TP53* amplicon sequencing of these patients confirmed a positive mutation status in all samples that passed quality control (N=11, 100%). We conclude that this p53-based division of Luminal A patients is useful to predict high-risk hormone receptor-positive early breast cancer patients with p53 mutations upfront, whose tumors likely show primary ETR and who are not sufficiently treated with endocrine agents.

#729 Applying novel transcriptomics-based markers to predict response to durvalumab and olaparib in mTNBC from histopathological slides.

Yaron Kinar[1], Gal Dinstag[1], Omer Tirosh[1], Doreen S. Ben-Zvi[1], SMMART Clinical Trials Program, **Tuvik Beker**[1], Aharonov Ranit[1], Gordon B. Mills[2]

[1]Pangea Biomed, Tel Aviv-Yafo, Israel,[2]Knight Cancer Institute, Portland, OR

Background: Transcriptomics-based predictors show great promise in identifying responders to immune checkpoint inhibitors (ICI) who are rejected by standard biomarkers like PD-L1. However, the reliance on gene-expression data makes these biomarkers less applicable in the clinic. On the other hand, H&E-stained slides are commonly available, so predicting response from slide scans could greatly improve accessibility. We have previously described DeepPT - a deep learning model to infer gene expression from H&E slides. Such a model could bridge that gap and allow clinicians to use transcriptomics-based biomarkers directly with H&E slides.
Methods: We tested two transcriptomics-based biomarkers of response to PD-1/PD-L1 inhibitors on a dataset of 21 mTNBC patients treated with olaparib and durvalumab. The first biomarker was derived using our published ENLIGHT platform, and the second is an XGBoost model on a curated set of 839 genes associated with ICI response, trained on 24 datasets with measured gene-expression and response data. We blindly applied the two models to the pre-treated tumor RNAseq data of the patient tumors, as well as to expression profiles inferred from their H&E slides using DeepPT. We also examined whether combining the scores from multiple slides per sample improves prediction. We then unblinded the outcomes and analyzed the model's ability to predict objective response (RECIST 1.1).
Results: Both models showed high predictivity in distinguishing responders (CR/PR) from non responders (SD/PD) when applied to RNAseq gene-expression profiles: AUC of 0.73 for the ENLIGHT model and 0.85 for the XGB model (Odds ratio for classification of 2.1 and 5.6, respectively). The performance on the gene-expression profiles that were inferred from a single H&E slide was also high - AUC of 0.82 for ENLIGHT and 0.83 for XGB (OR of 44 and 12). The performance of the XGB model improves when we average over all slides that correspond to a single patient (AUC of 0.85, OR of 16.7) while we observe no such improvement for ENLIGHT (AUC of 0.78, OR of 6.7). Interestingly, both models also distinguish stable from progressing disease within the nonresponders group.
Conclusion: We introduce a method to tackle the challenge of applying gene-expression based biomarkers for response to treatment by PD1/PDL1 inhibitors in the clinic. We do this by combining transcriptomics-based models and a deep-learning model for predicting gene-expression from H&E slides. We demonstrate that this method correctly predicts response on an external dataset, favorably comparing with direct application of the models to RNAseq data. This approach may be extended to additional drugs where transcriptomics-based biomarkers exist, and can be further improved by taking into consideration the differential predictivity of genes from H&E slides.

#73 Molecular characterization of senescence induced by PARPi in preclinical xenograft mouse models of ovarian cancer.

Sarah Saoudaoui, Nicolas Malaquin, Isabelle Clement, Tibila Kientega, Erwan Goy, Kim Leclerc-Desaulniers, Anne Marie Mes-Masson, Francis Rodier

CHUM Research Centre, Montreal, QC, Canada

Introduction: Ovarian cancer (OC) is amongst the most lethal cancers in Canada. High-grade serous ovarian cancer (HGSC) usually responds to initial therapy, however resistance to drugs often develops over time. We have described a new two-step OC combo-therapy: 1st, a PARP inhibitor is used to induce a senescence proliferation arrest in cancer cells followed by, 2nd, the induction of senolysis in senescent cancer cells using the Bcl-2 family inhibitor ABT263, which redirects senescent cells towards apoptosis. Our hypothesis is that therapy-induced senescence (TIS) could be beneficial in the clinic, but questions remain on its exact function in this context. Our objective is to characterize the spatiotemporal evolution of senescence during OC treatment using xenograft mouse models to define the senescence peak in tissues and optimize the targeting of senolysis approaches. Methods-results: We generate a tumor biobank consisting of OV1946, OV4453, TOV21G and MDAMB231 preclinical xenograft models treated with combinations of the PARP inhibitor Olaparib and ABT263. In all models, PARPi-ABT263 resulted in a significant reduction in tumor growth compared to each drug alone. To explore spatiotemporal cell fate decisions including senescence, a time course analysis was performed by gene expression analysis, SA-βgal staining and COMET multiplexing. COMET is an immunofluorescence technology that allows up to 40 molecular biomarkers (vasculature, epithelium, senescence phenotypes, DNA damage response) at single-cell resolution on paraffin embedded tumors. Conclusion: We propose that characterizing the cell fate decisions within the tumor including senescence can be used to improve drug administration patterns in combo therapies and reduce resistance. For example, this should refine targets and timing to improve chemotherapies that aim to manipulate senescence.

CLINICAL RESEARCH: Predictive Biomarkers 2

#730 Can we overcome the scarcity of data for building predictive models in cancer?.

Gal Dinstag, Yaron Kinar, Eden Maimon, **Tuvik Beker**, Ranit Aharonov

Pangea Biomed, Tel Aviv-Yafo, Israel

Background: A major aim in precision oncology is establishing predictive biomarkers to enable improved treatment matching for patients. mRNA expression is one of the most available and explored modalities to enable generation of such models. Several works have demonstrated that supervised learning using transcriptomic data can generate predictive biomarkers. However, the scarcity of datasets that couple mRNA with drug response severely limit this approach. In contrast, unsupervised models offer a potential for a broadly applicable approach to develop predictive markers. We have previously described ENLIGHT, an unsupervised approach that generates predictive biomarkers to virtually any targeted cancer drug without any drug-specific data requirements. Here, we perform a large-scale analysis, comparing the supervised and unsupervised approaches. We show that ENLIGHT is able to generate predictive markers on a far larger number of drugs than the supervised approach, and that for those drugs where a supervised approach is feasible, ENLIGHT's performance is comparable.
Methods: We established a list of the 114 approved targeted oncology drugs, and systematically searched for available training and validation data. For all 114 drugs, we generated an unsupervised biomarker using ENLIGHT. For drugs where more than one dataset was available, we trained and validated a logistic regression model with LASSO in a leave-one-dataset-out fashion, and compared its performance with ENLIGHT, which was not trained on any of the datasets. For drugs where only one dataset was available, we only tested ENLIGHT. We evaluated both methods by the odds ratio (OR) to respond at a score threshold that yields 50% sensitivity in each dataset. We then averaged these values across datasets to a single value for comparison.
Results: Of the 114 drugs tested, only 7 had more than one dataset with mRNA and objective responses available, to allow appropriate supervised training and validation. Thus, while we could generate ENLIGHT biomarkers for all 114 drugs, supervised methods allowed generation of a biomarker for only 7 drugs. We could test the ENLIGHT biomarkers for 17 drugs for which at least one dataset was available for validation, and found it was predictive (OR>1) in 16 of those. When focusing on the 7 drugs for which we could also generate supervised biomarkers, we found that ENLIGHT was roughly on par with the supervised models (aggregated OR of 2, p=0.003 on 6 datasets vs. aggregated OR of 2.52, p=0.0001 on all 7 datasets, respectively).
Conclusion: We demonstrate that ENLIGHT can overcome the inherent lack of data for generating predictive models for cancer drugs using a powerful unsupervised approach. While less than 10% of approved targeted cancer drugs have minimal data enabling generation of supervised models, ENLIGHT can generate predictive models for all the targeted drugs, and shows predictive value in almost all cases where validation data exists.

#731 Integrating ctDNA and FDG-PET dynamics to predict pathological response following neoadjuvant systemic therapy in stage III melanoma.

Wei Yen Chan[1], Li Zhou[2], Edward Hsiao[3], Jenny H. Lee[1], Ashleigh Stewart[1], Russell J. Diefenbach[1], George Au-Yeung[4], Maria Gonzalez[2], Andrew J. Spillane[2], Robyn P. M. Saw[2], Sydney Ch'Ng[2], Matteo Carlino[2], Richard A. Scolyer[2], Alexander M. Menzies[2], Georgina V. Long[2], Helen Rizos[1]

[1]Macquarie University, Sydney, Australia,[2]Melanoma Institute Australia, Sydney, Australia,[3]Royal North Shore Hospital, Sydney, Australia,[4]Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Neoadjuvant therapy followed by surgery is the current standard for stage III melanoma, but 60% of patients achieve a major pathological response (MPR) with good long-term outcomes. This raises the potential for modifying treatment strategies to identify patients who may safely omit surgery. Biomarkers such as circulating tumor DNA (ctDNA) and imaging modalities have shown promise in assessing therapeutic response, yet each has limitations when used independently. This study evaluates the relationship between ctDNA clearance and changes in fluorodeoxyglucose(FDG)-positron emission tomography(PET) SUVmax from pre-treatment to pre-surgery, to predict pathological response and the feasibility of non-surgical management in appropriately selected patients.
Methods: In the discovery cohort, plasma ctDNA levels and computed tomography (CT) RECIST data were retrospectively analyzed in stage III melanoma patients from the OpACIN-neo trial (N=9), where two doses of neoadjuvant combination immunotherapy was administered. For validation, FDG-PET SUVmax changes and ctDNA dynamics will be assessed in two trial cohorts: NeoTrio (N=45, pembrolizumab ± dabrafenib and trametinib) and NeoPele (N=20, pembrolizumab and Lenvatinib). PET responses will be categorized into complete metabolic response (CMR), near-CMR (SUVmax reduction >90%), partial metabolic response (PMR), stable metabolic disease (SMD), and progressive metabolic disease (PMD).
Results: In the OpACIN-neo cohort, 7/9 (78%) patients achieved ctDNA clearance pre-surgery and RECIST partial response, with five achieving MPR and two non-MPR. Two patients with persistent ctDNA pre-surgery, which cleared post-surgery, had RECIST stable disease (one achieved MPR and one non-MPR). None of these nine patients experienced clinical recurrence. Preliminary data from the validation cohort shows that all eight patients (8/33; 24%) with CMR or near CMR achieved MPR, while 5/6 (83%) patients with PMD were pathological non-responders. CT RECIST was useful in evaluating disease burden in the discovery cohort; however, PET imaging is expected to provide greater specificity and stronger correlation with pathological outcomes. Furthermore, ctDNA clearance has demonstrated potential in identifying patients who may avoid surgery and remain recurrence-free, highlighting the complementary value of both modalities.
Conclusion: Combining ctDNA dynamics with FDG-PET SUVmax changes can improve the prediction of pathological response to neoadjuvant therapy in stage III melanoma. This integrated approach could help identify patients who will achieve durable responses and can safely avoid surgery, supporting the development of more personalized treatment strategies.

#732 Targeting adenosine A2B receptor using PBF-1129 in treating patients with metastatic non-small cell lung cancer.

Ruohan Wu[1], Dwight Owen[1], Lai Wei[1], Mikhail Dikov[1], Shankar Suman[1], Joseph Amann[1], Shuxiao Guan[1], Po-Lan Su[1], Catherine Schweitzer[1], Michael B. Smith[1], Sarah Ferguson[1], Julio Castro[2], Daniel Spakowicz[1], Erin Bertino[1], Peter Shields[1], Kai He[1], Carolyn J. Presley[1], Gregory A. Otterson[1], William E. Carson[1], David P. Carbone[1]

[1]The Ohio State University Wexner Medical Center, Columbus, OH,[2]Palobiofarma, Barcelona, Spain

Background: Immunotherapy has improved lung cancer treatment drastically, but its effectiveness is limited by the immunosuppressive tumor microenvironment (TME). In the TME, adenosine accumulates from ATP breakdown by ectonucleotidases like CD39 and CD73, recruiting immunosuppressive cells such as Tregs and MDSCs. Adenosine regulates immune cell function by activating four cell surface receptors, with A2B being the only low-affinity receptor primarily triggered by high adenosine levels in cancer, which makes it a favorable drug target. We previously reported the results of a phase 1 dose escalation trial of PBF-1129, a first-in-class A2BAR inhibitor in patients with mNSCLC who progressed on chemotherapy and immune checkpoint inhibitors (ICI, NCT03274479). Patients received escalating doses of PBF-1129 orally daily (40 mg, 80 mg, 160 mg, 320 mg) until disease progression or intolerability. Primary objective was safety and tolerability, followed by PK, ORR, PFS, OS, and immunophenotyping analysis. Here we report correlative analysis of immunophenotyping of peripheral blood changes during treatment. Blood was collected before treatment started, after the first cycle of treatment, and after the second cycle/end of treatment. PBMC was isolated using ficoll gradient.

Results: 21 patients (9 female), median age 61 years (range 49-75) were enrolled, median line of therapy was 4th (range 3-6). As previously reported, no dose-limiting toxicities were observed at any dose level and no maximum tolerated dose was identified. Best response of stable disease was observed. Flow cytometry analysis revealed that the PD-1 exhaustion marker was downregulated in CD8+ T cells following one to two treatment cycles ($p=0.03^*$). Nonsignificant changes indicated a reduction in CD73 expression on various immune subpopulations, in addition to MDSCs and Tregs percentage reduction was observed in most patients. Conclusions: PBF-1129 was safe and tolerable in patients with heavily pretreated mNSCLC, although limited single-agent activity was observed. The treatment improved immune cell function by alleviating PD-1 levels in cytotoxic T cells.

#733 Development and characterization of a negative prediction algorithm for actionable mutations utilizing genomic and epigenomic profiling in cfDNA.

Andrew M. Gross, Katie Quinn, Leslie Bucheit, Jill Tsai, Aaron Hardin, Catalin Barbacioru, Martina Lefterova, Justin Odegaard, Darya Chudova

Guardant Health, Palo Alto, CA

Introduction: Despite success of genomic tumor characterization from plasma, one challenge of cell-free DNA (cfDNA) profiling is an inability to rule out the presence of actionable genomic mutations. This difficulty stems from the inability to assess if known drivers are absent or if the tumor level is insufficient for detection in the assay. Confident negative variant prediction could allow clinicians to expedite clinical action from cfDNA without waiting for tissue biopsy sequencing when no actionable alterations are identified. Here we leverage an assay which simultaneously profiles epigenomic and genomic signals to develop a negative prediction algorithm in advanced cancers.

Methods: We use epigenomic signals to quantify an unbiased tumor fraction (TF) estimate and overcome limitations of genomic-based TF estimation including limit of detection, clonal hematopoiesis, variable copy-number on mutant alleles, and ambiguity of germline/somatic mutation origin. Using population priors, epigenomic TF, and observation of mutant and non-mutant coverage over variants of interest, we developed an algorithm to predict post-test probability of the cfDNA sample harboring guideline recommended genomic biomarkers relevant for treatment selection. This algorithm is applied in multiple tissue-specific diagnostic settings including colorectal cancer where testing for RAS/RAF hotspot mutations and lung cancer where testing multiple biomarkers are needed for optimal therapy selection.

Results: In an analysis of 3775 de-identified advanced stage CRC samples, 1342 (36%) were found to have a reportable *RAS*/*RAF* mutation. Among the remaining samples, 38% had sufficient tumor fraction to confidently assess the sample as *RAS*/*RAF* variant negative (with >99% confidence), which expanded to 46% at >95% confidence. This indicates that the test can confidently assign *RAS*/*RAF* status to >65% of CRC plasma samples. Reasons why the remaining samples could not be confidently assessed as biomarker positive or negative included low tumor shedding (including 15% with nondetectable tumor), low genomic coverage over loci of interest, and mutant allele support below the confident call threshold. Finally, we compare the application of epigenomic TF against genomic tumor-fraction algorithms using either RAS hotspot or a broader subset of cancer mutations, and show the epigenomic method to be much more sensitive and precise for TF estimation than genomic-only methods.

Conclusions: An epigenomics-based approach to enable confident negative prediction may increase the utility of liquid biopsy and expedite clinical decision-making in advanced solid tumors with biomarker-informed treatment pathways. Next steps include characterization in diverse tissue types as well as clinical validation to link negative call status to variant status in tissue biopsies.

#734 Stratification based on PRAME gene expression shows inverse survival associations among histology subtypes in a first-line non-small cell lung cancer real-world cohort.

R. S. Patel, S. Franch-Exposito, P. A. Fields, S. Islam, C. Igartua;
Tempus AI, Inc., Chicago, IL

Background: PRAME (Preferentially Expressed Antigen in Melanoma) is an intracellular cancer-testis antigen over-expressed across solid tumor types. Elevated PRAME expression is associated with poor prognosis, particularly in lung cancer. Further, its selective expression in tumor cells and ability to induce robust T-cell-mediated immune responses make it a promising pan-cancer immunotherapy target. This study investigates the influence of histological subtypes on PRAME expression and its impact on outcome to immunotherapy in first line (1L) lung cancer patients.

Methods: We analyzed 4,519 non-small cell lung cancer patients from the Tempus de-identified real-world database. PRAME expression levels (quantified by the Tempus xR RNA-seq assay), were classified into high and low based on median expression. We included pre-treatment biopsy samples receiving immunotherapy (IO) and chemotherapy (chemo), as individual monotherapies or in combination in the 1L setting. We evaluated PRAME expression by histology, tumor purity and biopsy site using a linear model and compared real-world overall survival and progression-free survival for high versus low expressors in each histological subtype.

Results: PRAME expression displayed a bimodal distribution in both adenocarcinoma (n=3,213) and squamous (n=1,306) histologies, with a significant enrichment of high expressors in the squamous subtype (Chi square $p < 2.22 \times 10^{-16}$). The squamous group exhibited inferior rwOS and rwPFS compared to the adenocarcinoma group across all treatment groups (rwOS: IO+chemo: HR: 1.25, p<0.01, IO: HR: 1.63, p<0.01, chemo: HR: 1.31, p=0.02, rwPFS: IO+chemo: HR: 1.04, p=0.471, IO: HR: 1.13, p<0.01, chemo: HR: 0.88, p=0.297). Notably, high PRAME expressors in the squamous group correlated with improved overall survival only within the IO+chemo treatment group (HR: 1.28, p=0.027), while low PRAME expressors in the adenocarcinoma cohort demonstrated better survival outcomes compared to high expressors (HR: 0.79, p<0.01). PRAME expression was not significantly associated with outcome in the IO mono or chemo mono treatment groups. Similarly for rwPFS, high PRAME expression was only significantly associated with benefit in the IO+chemo group (HR: 0.81, p<0.01, IO: HR: 0.91, p=0.425, chemo: HR: 0.85, p=0.232).

Discussion: Our findings identify PRAME expression as a prognostic biomarker in lung cancer, with distinct implications based on histological context. High *PRAME* expressors may benefit from PRAME-targeted therapies combined with IO and chemo, highlighting the potential for personalized treatment strategies. These results emphasize the utility of PRAME expression in clinical treatment decisions and demonstrate the value of real-world data in identifying patients with unmet need.

#735 Immunologically active phenotype by gene expression profiling predicts clinical benefit from PD-1/PD-L1 inhibitors in a pancancer cohort.

Mehdi Lamkhioued[1], Foy Jean-Philippe[2], Aurelie Swalduz[1], Sandra Ortiz-Cuaran[1], Andy Karabajakian[1], Kim-Arthur Baffert[1], Lucas Michon[1], Adrien Buisson[1], Maurice Perol[1], Sylvie Lantuejoul[1], Loic Verlingue[1], Jerome Fayette[1], **Pierre Saintigny**[1]

[1]Ctr. Leon Berard, Lyon, France,[2]Sorbonne Universite, Hopital Pitie-Salpetriere, Paris, France

Background: Our team recently developed a scoring system called the HOT-score, derived from an unsupervised clustering analysis of 421 HPV-negative head and neck squamous cell carcinomas (HNSCC) from TCGA. The HOT-score is based on a 27-gene signature associated with cytotoxic CD8+ T cell activation, interferon-gamma signaling, and IDO1 expression. These genes were identified through differential expression analysis. The HOT-score is computed as an enrichment score (ES) using Gene Set Variation Analysis (GSVA), providing a bimodal ES distribution ranging from -1 to 1. Tumors are classified either as "hot" phenotypes (ES score > 0) or "cold" phenotypes (ES score < 0). We have previously shown an association between the HOT-score and “hot”/”cold” phenotypes with overall survival (OS) and progression-free survival (PFS) in retrospective cohorts of patients with HNSCC (n=102) and non-small cell lung cancer (NSCLC, n=82) treated with immune checkpoint blockade (ICB). Herein, we evaluated the HOT-score's association with clinical outcomes across a broader range of cancer types in the CRi-Atlas cohort.
Methods: We analyzed pre-treatment tumor samples from the CRi-Atlas cohort (available at https://cri-iatlas.org/) that included cancers for which ICB therapies are approved. Inclusion criteria required samples to have annotations for progression-free survival, overall survival, or response evaluation by RECIST criteria. Associations with survival outcomes were assessed using Cox proportional hazards modeling, and comparisons of HOT-scores by response categories were performed using the Wilcoxon test.
Results: The cohort consisted of 348 bladder carcinomas, 207 kidney clear cell carcinomas, 313 skin cutaneous melanomas, and 45 stomach adenocarcinomas. HOT-scores, analyzed as continuous variables, were significantly lower in patients with progressive disease compared to those with stable disease (P=3.6e-05), partial response (P=3.3e-07), and complete response (P=5.5e-07). HOT-scores were strongly associated with better survival outcomes, including progression-free survival (PFS; n=489, HR 0.67; 95% CI [0.53-0.85]) and overall survival (OS; n=913, HR 0.51; 95% CI [0.41-0.63]). Tumors with "hot" phenotypes exhibited improved survival outcomes compared to those with "cold" phenotypes, with PFS (HR 0.77; 95% CI [0.67-0.97]) and OS (HR 0.54; 95% CI [0.43-0.67]). Notably, in a multivariate analysis accounting for tumor types, both HOT-scores and "hot" phenotypes remained strongly associated with better PFS and OS (P<0.001).
Conclusion: The HOT-score is associated with favorable clinical outcomes, including PFS, OS, and RECIST response, across multiple cancer types. Prospective studies are needed to validate its utility for routine clinical implementation.

#736 Deep learning response score using baseline and 12-week RECIST chest CTs enhances overall survival (OS) prediction in advanced NSCLC: external validation in a trial with dostarlimab.

Background: Early response assessment and identification of patients (pts) with NSCLC likely to derive long-term benefit from immune checkpoint inhibitors (ICIs) are crucial for treatment planning and drug development.
Methods: We developed a deep learning pipeline using a large multi-institute real-world dataset to generate a serial CT response score (SerialCTRS) from paired pre-treatment and 12wk scans, estimating probability of 1y OS. External validation applied SerialCTRS to an expansion cohort of a single-arm phase 1 clinical trial of dostarlimab as ≥2L therapy for advanced NSCLC (GARNET [cohort E], NCT02715284). OS hazard ratios (HRs) of SerialCTRS were compared to tumor volume change derived from manual segmentations and 12 wk RECIST 1.1 overall response using the same input scans.
Results: Of 67 clinical trial pts, 49 were evaluable for all 3 models predicting OS. Matching group sizes to RECIST overall response, 13 pts (26%, the number with RECIST PD) had low probability of 1y OS (SerialCTRS 0.12-0.64), 21 pts (43%, number with SD) had medium probability (0.64-0.82), and 15 pts (31%, analogous to CR/PR) had high probability of 1y OS (0.83-0.90). HRs of adjacent categories predicting OS showed superior performance of SerialCTRS, especially for SD/medium vs CR/PR/high probability (HR 2.68 [95% CI 1.09-6.59]; Table). Continuous SerialCTRS predicted OS with a concordance index of 0.717 (0.733 in subset with RECIST 12 wk SD) and remained a significant predictor of OS in bivariable survival models controlling for known predictors of OS such as age, ECOG, stage at diagnosis (all n=54), and best overall response from previous therapy (n=49).
Conclusions: Deep learning-based SerialCTRS, without manual annotation, improved prediction of OS vs RECIST and tumor volume change in the NSCLC cohort of the GARNET trial.

SerialCTRS prediction of advanced NSCLC OS compared to 12 wk RECIST response and percentage change in tumor volume

	Concordanceindex	SD/medium (n=21) vsCR/PR/high (n=15)		PD/low (n=13) vsSD/medium (n=21)	
		HR[a] (95% CI)	p-value	HR[a] (95% CI)	p-value
RECIST 1.1	0.686	1.35(0.58–3.16)	0.49	10.87(3.49–33.92)	<0.001
% change in tumor volume	0.610(0.507[b])	0.93(0.40–2.16)	0.87	4.31(1.71–10.86)	0.002
SerialCTRS	0.717(0.733[b])	2.68(1.09–6.59)	0.03	7.83(2.88–21.30)	<0.001

[a]SerialCTRS and volume change categorized to match three RECIST response category proportions for like-to-like comparisons (low vs medium vs high probability of 1y OS corresponding to PD vs SD vs CR/PR). Unadjusted p-values from Wald test for pairwise comparisons in Cox proportional hazards model.[b]Concordance index for continuous marker (% change in tumor volume or SerialCTRS) predicting OS for participants with 12 wk RECIST response of SD

#737 Androgen receptor-indifferent prostate cancer in radical prostatectomy cases detected by single-cell image analysis.

Beatrice S. Knudsen[1], Wei Zhang[2], Mason Hovinga[1], Erika Egal[2], Chance Walker[1], Yosep Chong[3], Galaxy Yang[4], Michael R. Freeman[4], Yi Qiao[5]

[1]Pathology, University of Utah, Salt Lake City, UT,[2]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[3]Pathology, St. Mary Hospital, Seoul, Korea, Republic of,[4]Surgery, Cedars Sinai Medical Center, Los Angeles, CA,[5]Biomedical Informatics, University of Utah, Salt Lake City, UT

Rational: A subset of castration-resistant prostate cancer (CRPC) displays an androgen receptor indifferent (ARi) phenotype. In these cases, the nuclear AR fails to promote the expression of transcripts in the AR cistrome, such as KLK3/PSA. Because of the aberrant functionality of AR, the ARi PC may not respond efficiently to hormonal therapies. As the ARi phenotype has only been described in CRPC, we hypothesized that it might exist in primary PC, potentially providing an opportunity for early detection of treatment resistance.
Methods: 36 cases of pT3b prostate cancer with lymph node metastasis are displayed in 10 x 2mm cores per case on tissue microarrays. From each, we sampled 10 tumor regions including lymph node metastases, seminal vesicle and perineural invasion, extraprostatic extension, cribiform and non-cribifrom intraprostatic regions. TMA slides are stained with a multiplex panel of AR, PSA, Nkx3.1, PSMA, High molecular weight cytokeratin (HMW-CK, 34betaE12) and pan-cytokeratin (AE1/AE3) on the Leica Bond Rx and digitized using the Axioscan Z1. Manual annotations, cell and gland segmentation, and single cell protein expression measurements are conducted in QuPath. The clustering analysis is performed using CytoMap. Gene set enrichment analysis is used to determine the ARi phenotype in public RNA expression data sets. Significant differences are determined using T-statistics.
Results: Using normal prostate glands as a reference, we identified the intensity of nuclear AR that is sufficient for PSA expression. We used this threshold to find cancer regions with less than 30% PSA-positive cells despite adequate AR expression levels in more than 50% PC cells, indicative of the ARi phenotype. Five of 36 cases contained regions with an ARi phenotype in at least one of the TMA cores. Out of all ARi regions, 23.9% are in lymph node metastasis and 21.7% in seminal vesicle PC. Within PC cases, percentages of AR positive cancer cells in lymph nodes don't correlate with percentages at other PC locations, while percentages of AR-positive cells in seminal vesicle correlates with those in areas of extraprostatic extension or cribiform PC. Unsupervised k-means clustering using multiplex PC staining data reveals one of five clusters harboring most ARi TMA cores. The AR:PSA ratio is the most important variable for predicting the ARi phenotype, followed in importance by percentages of PSA, PSMA, Nkx3.1 and AR positive PC cells. Differential expression analysis of the TCGA-PRAD cohort cases confirms a subgroup of high AR and low KLK3/PSA cases with significant enrichment of the EMT hallmark gene expression signature, consistent with the ARi phenotype.
Conclusion: Single cell analysis of AR and PSA identifies PC regions with ARi characteristics in primary PC and lymph node metastases, possibly predicting primary resistance to first line PC treatment.

#738 Single-cell trajectories of metastatic urothelial cancer and individual patterns of resistance to immune checkpoint inhibitors.

Ronan Flippot[1], Amelie Roehrig[2], Julien Vibert[3], Nicolas Stransky[4], Luc Cabel[5], Kevin Mulder[6], Benjamin Besse[7], Claudio Nicotra[8], Maud Ngo Camus[3], Christophe Massard[3], Etienne Rouleau[9], Gerome Jules-Clement[10], Alicia Tran-Dien[10], Lambros Tselikas[11], Fabrice Andre[12], Jean-Yves Scoazec[9], Celine Vallot[2], Maud Kamal[12], Eric Letouze[2], Yohann Loriot[12]

[1]Medical Oncology / Immunomonitoring laboratory (CNRS 3655 - INSERM US23), Gustave Roussy, Villejuif, France,[2]One Biosciences, Paris, France,[3]Drug Development Department, Gustave Roussy, Villejuif, France,[4]Celsius Therapeutics, Villejuif, MA,[5]Institut Curie Paris, Paris, France,[6]INSERM UMR1015, Gustave Roussy, Villejuif, France,[7]INSERM U981, Gustave Roussy, Villejuif, France,[8]Drug Development epartment, Gustave Roussy, Villejuif, France,[9]Pathology, Gustave Roussy, Villejuif, France,[10]Bioinformatics Core Facility, Gustave Roussy, Villejuif, France,[11]Radiology, Gustave Roussy, Villejuif, France,[12]IHU PRISM, Gustave Roussy, Villejuif, France

Background. Immune checkpoint inhibitors (ICI) improve survival in patients with metastatic urothelial cancers (mUC) but most patients experience disease progression. The mechanisms driving this progression are mostly unknown. We longitudinally assessed mUC microenvironment at the single-cell level in ICI-treated patients to explore the determinants of the response and adaptive resistance mechanisms on therapy.

Methods. The prospective MATCH-R study (NCT02517892) included patients with mUC treated with single-agent PD-(L)1 inhibitors. Biopsies of metastatic sites were performed at baseline, on therapy and at progression for single-nuclei RNA sequencing (10X genomics, 5' v1.1). After stringent quality control and cell type annotation, we compared the proportions and transcriptomic signatures of tumor and immune cell subsets between responders and non-responders, and explored their evolution during treatment. Pseudobulk analyses were used to classify whole samples according to the consensus molecular classification (Kamoun et al. 2020).

Results. We enrolled 32 patients among whom eight (25%) achieved objective response (OR). All patients underwent biopsies at baseline, 6 (19%) on therapy, 17 (53%) at progression. Tumor cells showed high transcriptomic heterogeneity within the consensus groups, with the coexistence of basal and luminal cell states within the same samples. The proportion of basal cells at baseline, but not the basal sample classification, was associated with an increased OR (p=0.02). Immune features associated with resistance to ICI at baseline involved both myeloid and lymphoid compartments : within myeloid cells, an abundance of pro-tumoral HES1 macrophages and higher expression of immunosuppressive genes *CD163*, *MS4A4A* and *STAB1* ; within T cells, a higher proportion of exhausted CD8+ lymphocytes, and higher expression of immune checkpoint genes including *PDCD1.* Conversely, the baseline abundance of CD4+ naive T helpers was associated with improved OR. Longitudinal sampling showed potential adaptive resistance mechanisms at progression, including downregulation of HLA genes and IFN signaling in tumor cells ; shift from M1 to M2 macrophage polarization within myeloid cells; increased expression of immune checkpoints, downregulation of type-I interferon induced genes and cytotoxicity markers such as *GZMA* in T cells. Individual patient analyses have shown that these mechanisms may coexist with discrete patterns.

Conclusions. We identified potential mechanisms of resistance to ICI in patients with mUC related to both tumor and immune compartments, including specific T cell and macrophage subpopulations. Longitudinal assessments in patients show individual molecular patterns related to progression that may allow for dynamic and tailored therapeutic strategies.

#739 Patient-derived xenografts allow deconvolution and prediction of chemotherapy responses.

Introduction: Combination chemotherapy remains essential for clinical management of triple-negative breast cancer (TNBC), making it impossible to assess responses to multiple agents in a single patient. Herein, we conduct multi-omic analyses of TNBC patient-derived xenografts (PDXs) treated with single agent carboplatin and docetaxel, or the combination, to identify candidate mechanisms of resistance, as well as predictive biomarkers to individual treatments, and to develop therapeutic strategies to overcome resistance.
Methods: Genomic, transcriptomic, and proteomic profiles of baseline tumors from 50 TNBC PDXs were associated with responses to human equivalent doses of either single agent carboplatin, docetaxel, and the combination. Integration of external TNBC PDX and clinical datasets was performed using ComBat. Protein Marker Selection (ProMS) tool was used to integrate both RNA and protein data to select 5-10 RNA feature combinations for optimized prediction of chemotherapy response in a logistic regression model.
Results: Combination responses were generally no better than the best single agent, with enhanced response in only ~13% of PDX, and apparent antagonism in a comparable percentage. Single ome comparisons showed largely non-overlapping results between genes associated with single agent and combination treatment that validated in independent patient cohorts. Multi-omic analyses of PDXs identified agent-specific treatment-associated biomarkers and predictive biomarker combinations. Notably, integrating proteomic with mRNA data improved machine learning models that achieved AUROC performance of 0.85 to predict pathologic complete response to combination chemotherapy. These models await further evaluation in datasets that may become available, including data from the BEAUTY (NCT02022202), TBCRC 030 (NCT01982448), and RESPONSE (NCT05020860) clinical trials, or in future experimental settings using PDX/PDX organoids. In PDXs responsive to any treatment, several basal cytokeratins were among the top upregulated proteins compared to PDXs resistant to all treatments. KRT5 was validated by IHC in PDX tumors, achieving an AUROC of 0.83 for predicting responsiveness, indicating its potential as a future chemoresponse marker in TNBC. PDXs refractory to all treatments showed dysregulated mitochondrial function. Treatment with romidepsin, an HDAC inhibitor that targets this process indirectly, increased DNA damage, and enhanced carboplatin response, in a chemoresistant PDX model with high abundance of HDAC proteins.
Conclusion: Multi-omic characterization identifies molecular mechanisms and predictive biomarkers for stratifying TNBC tumors for single or combination chemotherapy treatments, suggests targeted therapies to augment chemotherapy response, and provides a valuable resource for researchers and clinicians.

#74 Hypoxia-fibrosis cycle in pancreatic tumor microenvironment: Implication for diagnosis and treatment.

Nai-Jung Chiang[1], Ya-Chin Hou[2], Jiun-I Lai[1], Lun-De Liao[3], Yan-Shen Shan[4]

[1]Department of Oncology, Taipei Veterans General Hospital, Taipei, Taiwan,[2]Institute of Clinical Medicine, College of Medicine, National Cheng Kung University, Tainan, Taiwan,[3]Institute of Biomedical Engineering and Nanomedicine, National Health Research Institutes, Miaoli, Taiwan,[4]Department of Surgery, National Cheng Kung University Hospital, Tainan, Taiwan

Pancreatic cancer (PC) is difficult to treat and has the lowest five-year survival rate across the world. PC are characterized by a dense fibrotic stroma composed of abundant cancer-associated fibroblasts (CAFs) and excessive extracellular matrix (ECM), which creates a pathological barrier that impedes drug delivery to tumors, leading to suboptimal treatment efficacy and resistance to current therapeutics. Like a vicious cycle, hypoxia-fibrosis cycle consists of dynamic cancer cell-CAF interactions. Currently, most clinical therapeutics aim at tumor cells while overlooking the surrounding tumor microenvironment (TME). The TME comprises all of the physiological and biochemical elements, including, but not limited to, the ECM, CAFs, cancer-associated immune cells, and the hypoxic and acidic environment. Therefore, we aim to investigate intratumor heterogeneity of PC and figure out the tumor- and TME-driven signaling by using multi-omics analysis. The data obtained from bulk and single-cell RNA sequencing, spatial transcriptomics, and tissue microarrays show that hypoxia levels were positively correlated with tumor fibrosis. Hypoxia-fibrosis cycle modulates PC progression and pro-tumoral inflammatory microenvironment, which was associated with activation of hypoxia, KRAS, mTORC1, and inflammatory response pathways. This cycle acts as a poor prognostic indicator in patients with PC. We also established a three-dimensional cell culture model mimicking cancer cell in hypoxia-fibrosis environment to validate the impacts of hypoxia-fibrosis cycle on promoting the malignant phenotype of PC cells. A dual-modality ultrasound (US) and photoacoustic (PA) real-time imaging system is demonstrated to assess tissue oxygen saturation dynamics as well as tumor fibrosis in an orthotopic PC mouse model with/without irinotecan or nanoliposomal irinotecan treatment and highlights the potential for evaluating the efficacy of cancer therapies in preclinical settings. Our work provides useful information for enhancing the effectiveness of current therapies and may have the potential to develop new precision medicines.

#740 Standardization and validation of CLDN18 antibodies for CLDN18.2 testing in pancreatic cancer: performance across antibodies and immunohistochemistry platforms.

Gudrun Baenfer, Ali Jason Saleh, Rolf Diezko, Riem Adjam, Hans-Ulrich Schildhaus, Matthias Kirchner, Josef Ruschoff, Michael Friedrich

Discovery Life Sciences Biomarker Services GmbH, Kassel, Germany

Background: Pancreatic cancer, with a 5-year survival rate of just 10%, is one of the most lethal cancers. Claudin 18.2 (CLDN18.2) is a promising therapeutic target under investigation. This study aims to standardize and validate CLDN18.2 IHC testing in pancreatic cancer by: (1) extending a gold-standard CLDN18 IHC method from gastric to pancreatic cancer, (2) validating two CLDN18 antibodies across three IHC platforms, and (3) assessing a CLDN18.2-specific antibody in pancreatic cancer samples.
Methods: The Ventana CLDN18 (43-14A) assay on the Benchmark Ultra platform served as reference standard. Results from CLDN18 antibodies—Abcam 43-14A and LSBio B16145—were evaluated on Benchmark Ultra, Dako AS Link48, and Leica BOND III. Sixty pancreatic cancer samples verified the Ventana assay with inter-rater agreement by two pathologists. Twenty samples reflecting the full CLDN18 expression level (0-100%), were used to validate the two CLDN18 antibodies on the three platforms. Concordance with the reference standard was calculated for system suitability and accuracy. Precision was evaluated with five samples. A sample was deemed CLDN18.2 positive if at least 75% of tumor cells showed ≥2+ membranous CLDN18 staining. In addition, ten samples were used to explore the performance of the CLDN18.2-specific Abcam EPR19202 antibody on the Benchmark Ultra platform using OptiView DAB IHC detection kits.
Results: The verification of the Ventana CLDN18 IHC Assay demonstrated its reliability and reproducibility in determining CLDN18.2 positivity in human pancreatic cancer samples, with an interrater agreement of 92%. This validation study showed that the Abcam 43-14A antibody outperformed the LSBio antibody in concordance analysis with the reference standard. The Benchmark Ultra platform provided the best results with strong, specific membranous CLDN18 staining and minimal background. The Leica platform performed the poorest, with strong cytoplasmic staining and lower specificity. The Dako platform was intermediate, more specific than Leica but weaker than the Benchmark Ultra. The Abcam EPR19202 antibody performed inadequately with OptiView; staining was faint, diffuse, non-specific with significant background, and poor membranous delineation.
Conclusions: This study reveals key variations in anti-CLDN18 antibodies and IHC platforms, crucial for assessing borderline cases at the cutoff used in clinical trials (≥75%, IHC 2+/3+). It underscores the need for selecting suitable antibodies and optimizing antibody-platform combinations for reliable results. The Abcam 43-14A antibody on the Benchmark Ultra platform performed comparably to the Ventana assay. By evaluating multiple combinations, the study helps standardize CLDN18.2 IHC testing, enhancing diagnostic accuracy and healthcare decision-making.

#741 Assessing overall survival relative to LORIS response prediction in patients receiving immunotherapy in a large community-based health system.

Cheryl P. Jones[1], McKenna Deaton[1], Bing Xu[1], **Rachel Elsey**[1], Crystal Hattum[1], Mason Arndt[1], Victoria Moe[2], Alex Mohama[3], Casey Williams[1], Tobias Meissner[1]

[1]Avera Cancer Institute, Sioux Falls, SD,[2]University of South Dakota, Sanford School of Medicine, Vermillion, SD,[3]Science and Behavior, University of Notre Dame, Notre Dame, IN

Purpose: The use of immune checkpoint inhibitors (ICI) has revolutionized outcomes in several cancers. Despite markers such as tumor mutational burden (TMB) and PD-L1 expression, predicting which patients will respond remains a challenge. Recently, a tool was developed using machine learning to predict clinical outcomes from ICI across cancer types known as LORIS (logistic regression-based immunotherapy-response score) that provides a probability of response from 0-100% based on six factors. LORIS values <27% were deemed 'unlikely to respond' and >70% were 'likely to respond' in the originating study. This project evaluates the association of LORIS scores to overall survival (OS) with the aim of understanding its utility in clinical-decision making in a community health-based cancer center.

Methods: We performed a retrospective analysis of 136 patients at the Avera Cancer Institute that received at least one dose of an ICI and possessed all components to calculate LORIS, including age, cancer type, previous therapy, albumin, blood neutrophil-to-lymphocyte ratio (NLR) and TMB, in addition to outcomes. LORIS values were calculated according to the most recent values available prior to initiation of therapy. The association between OS and LORIS was evaluated by Cox proportional hazards model. With no scores >70% in our population (the threshold for likely response), patients were categorized as 'unlikely to respond' or 'not unlikely to respond' based on a score of ≤27% or >27%, respectively, and assessed via Kaplan-Meier.

Results: The median age was 67 years (range 36-87) and 48.5% were female. Lung cancer represented 47% of patients, followed by 15.4% melanoma, 14.7% gynecologic cancer and less than 5 patients each with GI, GU, and head and neck cancers; the remaining were considered "other" per LORIS. The median TMB was 6.1, median albumin was 3.8, and median NLR was 3.8. In contrast to the original LORIS datasets where 72% of patients were previously treated, our population was greater at 84% indicating a more heavily pre-treated group. Only 20 patients (14.7%) had a LORIS ≥27%. The hazard ratio was 0.09 (95% confidence interval 0.017-0.51) and LORIS was statistically significant for impact on OS (p=0.006). The median OS for those unlikely to respond (n=116) was 13.7 mo (9.9 - 18.7) vs. not reached (NR) (15.9 - NR) for those not unlikely to respond (n=20).

Conclusion: Higher scores were associated with longer OS, confirming its ability to predict long-term outcomes. This was upheld despite having few patients with >27% scores and no patients >70%, possibly due to the greater portion that previously received systemic therapy. Future studies will need to address how LORIS can be applied to individual patient scenarios to support clinical decision-making.

#742 Development and evaluation of a non-invasive qPCR assay for sensitive detection of FGFR2/3 alterations in urine samples as a companion diagnostic for erdafitinib.

Meirong Zhang, Mingzhu Li, Yue Zhang, Hang Dong, Haoran Tang, Feng Xie, **Qing Xu**

Huidu Shanghai Medical Sciences, Ltd., Shanghai, China

Introduction: Fibroblast growth factor receptor (FGFR) alterations, including point mutations and gene fusions, play a pivotal role in various cancers, particularly urothelial carcinoma. Erdafitinib, an FDA-approved therapy for locally advanced or metastatic urothelial carcinoma with FGFR2/3 alterations, currently relies on tissue-based diagnostics, which are invasive and may not always be feasible. Non-invasive liquid biopsy approaches, such as qPCR assays using urine cell pellets (UCP), offer significant advantages in terms of patient convenience and safety while providing accurate detection of clinically relevant alterations.

Methods: We developed and evaluated the Predicine FGFR2/3 qPCR Kit, a real-time multiplex PCR assay designed to detect four FGFR3 mutations (R248C, S249C, G370C, Y373C) and five FGFR2/3 fusions (FGFR3-TACC3 V1/V3, FGFR3-BAIAP2L1, FGFR2-BICC1, FGFR2-CASP7) from urine DNA and RNA. The assay integrates proprietary buffers to preserve nucleic acids, allowing simultaneous detection of DNA mutations and RNA fusions. Analytical performance, including sensitivity, specificity, and accuracy, was assessed using gradient dilutions, known positive controls, and clinical urine samples. Detection thresholds were benchmarked against NGS and ddPCR.

Results: The assay demonstrated high sensitivity, detecting DNA variants at allele frequencies as low as 0.25% and RNA fusions at 6-7 copies. Specificity exceeded 98% across all tested alterations in healthy donor samples, and positive percentage agreement (PPA) exceeded 95% for FGFR3 mutations and FGFR2/3 fusions compared to NGS results. In a retrospective cohort of 60 clinical urine samples, mutation detection sensitivity reached 100% for most variants, except for FGFR3-S249C, while specificity ranged from 92% to 100%. UCP-derived nucleic acids enabled streamlined workflows with a single vial of urine. Mutation detection achieved a limit of 0.1% for DNA and 6.25 copies for RNA fusions.

Conclusion: The Predicine FGFR2/3 qPCR Kit offers a rapid, robust, and non-invasive solution for detecting FGFR alterations in urine samples. By providing high sensitivity, specificity, and efficiency, it represents a promising alternative to invasive tissue-based diagnostics for identifying patients eligible for FGFR-targeted therapies such as erdafitinib. These findings highlight its potential utility as a companion diagnostic, with further clinical validation planned to support its integration into routine molecular diagnostics.

#743 A prognostic model based on plasma proteomics for predicting immuno-chemotherapy outcomes in advanced non-small cell lung cancer.

Zhihuang Hu[1], **Jialei Wang**[1], Changbin Zhu[2], Xin Zhang[1], Shenglin Huang[3], Si Sun[1], Zhenhua Wu[1], Yao Zhang[1], Ying Lin[1], Jin Wang[2], Tao Hu[2], Zhan Huang[2], Hui Yu[1], Xinmin Zhao[1], Huijie Wang[1], Xianghua Wu[1]

[1]Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China; Institute of Thoracic Oncology, Fudan University, Shanghai, China,[2]Department of Medicine, Amoy Diagnostics Co., Ltd., Xiamen, China,[3]Shanghai Key Laboratory of Radiation Oncology, Fudan University Shanghai Cancer Center; Shanghai Key Laboratory of Medical Epigenetics, Institutes of Biomedical Sciences, Fudan University, Shanghai, China

Background: Predicting benefit from immune checkpoint inhibitors in advanced non-small cell lung cancer (aNSCLC) remains challenging. We developed a plasma proteomic model to evaluate immuno-chemotherapy (IC) outcomes.

Methods: Blood samples were collected prior to 1st-line IC for analysis of plasma proteins and peripheral blood mononuclear cells (PBMC) from 194 aNSCLC patients without *EGFR/ALK* mutations. The Olink Immuno-Oncology Panel was used to detect the soluble proteins in plasma, and transcriptome sequencing was conducted on PBMC.

Results: We optimized a prior prognostic model by incorporating a validation cohort and employing the Survival SVM method. This improved model, trained on plasma levels of eight proteins (CD27, TWEAK, CD8A, GZMH, IL6, PGF, TIE2, and TNFRSF12A), independently predicted overall survival (OS). Kaplan-Meier analysis validated significant differences in PFS and OS ($p < 0.001$, respectively). Repeated 10-fold cross-validation in the discovery cohort demonstrated model robustness, with stable predictive power for 12-month OS and PFS (AUCs: 0.86 and 0.68, respectively), which was further supported in the validation cohort (AUCs: 0.78 and 0.63, respectively). The model's independent prognostic value was further substantiated through Cox regression analyses (Table). Our model exceeded the performance of conventional PD-L1 TPS cutoff values of 1% or 50% in stratifying patient risk. Low-risk patients exhibited enriched memory B cells ($p < 0.05$), while high-risk patients showed an upregulation of angiogenesis-related proteins ($p < 0.05$), consistently observed across both cohorts. Validation of the eight proteins is ongoing using ELISA assays to further confirm their clinical utility.

Conclusion: We established and validated an optimized plasma protein-based prognostic model that identifies distinct immune phenotypes and provides critical insights into aNSCLC progression.

PFS and OS by Risk Groups in Discovery and Validation Cohorts

Cohort	Group	PFS/OS	HR (95% CI)	p value	mPFS/OS /(month) (95% CI)	p value
Discovery cohort	High risk vs. Low risk	PFS	4.09(2.28-7.34)	p<0.001	High risk: 5.1 (4.2–9.9) vs. Low risk: 14.8 (12.5–31.9)	p<0.001
		OS	8.33 (4.26-16.28)	p<0.001	High risk: 8 (5.5-13.3) vs. Low risk: 35.3 (28.7-NA)	p<0.001
Validation cohort	High risk vs. Low risk	PFS	2.35 (1.25-4.42)	p=0.008	High risk: 15.1 (7-NA) vs. Low risk: 21.5 (14.9-NA)	p=0.006
		OS	3.16 (1.54-6.47)	p=0.002	High risk: 15.5 (7.4-NA.0) vs. Low risk: NA (NA)	p<0.001
HR, Hazard Ratio; 95% CI, 95% Confidence Interval						

#744 Exploration of potential biomarkers associated with treatment outcomes in locally advanced esophageal squamous cell carcinoma patients receiving neoadjuvant nivolumab plus paclitaxel and cisplatin chemoradiotherapy.

Ta-Chen Huang[1], Jhe-Cyuan Guo[2], Chia-Chi Lin[1], Hung-Yang Kuo[1], Chien-Huai Chuang[2], Jason, Chia-Hsien Cheng[1], Feng-Ming Hsu[1], Jang-Ming Lee[1], Pei-Ming Huang[1], Chih-Hung Hsu[1]

[1]National Taiwan University Hospital, Taipei, Taiwan,[2]National Taiwan University Cancer Center, Taipei, Taiwan

Background: In a phase II trial (neo-NTP-CRT, NCT05130684), the efficacy of adding nivolumab to paclitaxel and cisplatin-based neoadjuvant chemoradiotherapy (CRT) was tested in patients with locally advanced esophageal squamous cell carcinoma (ESCC) (n=17). The study reported a pathological complete response (pCR) rate of 24%, a median relapse-free survival and overall survival (OS) of 8 and 16 months, respectively. We conducted this exploratory analysis to investigate the potential immune-related biomarkers.
Materials and Methods: Pretreatment endoscopy-biopsied tumor tissues were analyzed. Immunohistochemistry (IHC) was used to measure PD-L1 expression by clone SP142 (Ventana, Tucson, AZ, USA) on tumor cells (PD-L1-TC), immune cells (PD-L1-IC), and combined positive score (CPS), and to define mature tertiary lymphoid structure (mTLS) according to CD20 and CD23 expression (n=16). The expression of immune-related genes in ESCC tumor tissues was quantitated by PanCancer Immune Profiling and analyzed by nCounter® Analysis System (nanoString, Seattle, WA, USA) (n=12). 12-chemokine TLS signature was also analyzed. The association of PD-L1-TC, PD-L1-IC, CPS, mTLS, and TLS signature with pCR was examined by Chi-square test; the association with OS was examined by log rank test. The differences of various immune cells and immune-related functions between patients with and without pCR was investigated by t-test.
Results: pCR rate was significantly higher in the patients with positive PD-L1 TC (100% vs 18%, p=0.019), high PD-L1 IC (100% vs 18%, p=0.019), and CPS≥5 (100% vs 10%, p=0.0006), and trended to be higher in patients with mTLS (50% vs 14%, p=0.19) and higher 12-chemokine TLS signature (75% vs 17%, p=0.077). OS trended to be longer in patients with positive PD-L1 TC (median: not reached vs 15 months; HR: 0.24, p=0.05) and CPS≥5 (median: 26 vs 15 months; HR: 0.19, p=0.069), and patients with high PD-L1 IC had numerically longer OS (median: 25 vs 16 months; HR: 0.42, p=0.38). mTLS was not associated with OS (median: 25 vs 25 months; HR: 0.91, p=0.88); however, patients with higher 12-chemokine TLS signature had better OS (median: 25 vs 14 months; HR: 0.23, p=0.042). The analysis of immune-related gene expression revealed patients with pCR had significantly higher abundance of TILs, lower amounts of Treg, exhausted CD8 T cells, and macrophages. Significantly higher B cell function, cytotoxicity function, and Toll-like receptor function was found in tumors of pCR patients.
Conclusion: We found that PD-L1 expression and 12-chemokine TLS signature may be a potential predictor of the response to neoadjuvant nivolumab plus paclitaxel and cisplatin-based CRT. (grants: NCTRC200909, MOST 108-2314-B-002-076-MY3, MOHW 111-TDU-B-221-114006)

#745 Combining circulating inflammatory proteins and thymidine kinase activity to predict survival in melanoma patients receiving immune checkpoint inhibitors.

Suzanne Egyhazi Brage[1], Fernanda Costa Svedman[2], Mattias Bergqvist[3], Hildur Helgadottir[2]

[1]Karolinska Institutet, Stockholm, Sweden,[2]Karolinska University Hospital/Karolinska Institutet, Stockholm, Sweden,[3]Biovica, Uppsala, Sweden

Background: We have demonstrated that increased baseline levels of several inflammatory plasma proteins were associated with poorer clinical outcome in melanoma patients with metastatic cancer treated with immune checkpoint inhibitors (ICIs). Furthermore, the plasma levels and dynamics of thymidine kinase activity (TKa), which is involved in DNA synthesis and cell proliferation, have also been associated with treatment efficacy and patient outcome. The aim of our study was to explore the link between TKa, inflammation, and overall survival (OS) in ICI-treated melanoma patients.
Methods: Fifty-eight patients receiving single anti-PD1 therapy for metastatic disease were treated between 2015 and 2019. There were twenty-one patients with M1a disease, fifteen patients with M1b disease, sixteen patients with M1c disease and six patients with M1d disease. TKa levels were measured with the DiviTum® TKa assay (Biovica) and correlated to 80 inflammation proteins from the Olink® target 96 inflammation platform in pretreatment plasma samples using Qlucore Omics Explorer 3.9.
Results: A cut-off level of TKa at 60 Du/L has previously been determined in metastatic melanoma. Thirty-three out of 80 inflammation proteins were differentially expressed between low and high TKa groups (adjusted p-value<0.05), including IL8, CCL3, HGF and S100A12 which are also associated with shorter OS. We explored if the combination of the five unfavorable biomarkers TKa, IL8, CCL3, HGF and S100A12 could improve risk stratification for survival. When comparing Kaplan-Meier curves we observed a shorter median OS for patients with four-five or two-three markers elevated (10.2 or 18.8 months) compared with patients with one or no marker being elevated (not reached) (log-rank trend test p<0.0001). A pronounced gradual decrease in the proportion of alive patients was associated with an increasing number of unfavorable biomarkers. The five-year OS rates were 83%, 62%, 33% and 11% for the subgroup of patients with no, one, two-three or four-five elevated biomarkers, respectively.
Conclusions: This multi-biomarker panel could serve as a risk stratification tool for melanoma patients to predict survival after anti-PD1 therapy. Our findings demonstrate a complex interplay between cell proliferation and pro-tumorigenic inflammation. Further investigations are warranted to elucidate the underlying biology and if circulating TKa and inflammatory proteins can be utilized jointly as biomarkers for ICI efficacy.

CLINICAL RESEARCH: Spatial Proteomics and Transcriptomics 1
Poster Session

#749 Dynamic change in immune landscape among NSCLC patients who received neo-adjuvant PD-1 treatment.

Zheshen Han[1], Haoting Shi[2], Xue Wang[2], Yufei Wang[3], Ruixin Pan[2], Chao Hu[2], Qing Qu[2], Rong Cai[2]

[1]The University of Hong Kong, Hong Kong, Hong Kong,[2]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China,[3]Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Neoadjuvant immunotherapy in combination with chemotherapy has been approved for resectable lung squamous cell carcinoma (LUSC) patients. However, the dynamic protein changes in the local tumor microenvironment (TME) associated with treatment remains unclear. We sought to spatially profile the treatment-related protein landscape changes in LUSC.
Methods: A total of 11 LUSC patients who received 2 to 4 cycles of neoadjuvant PD-1 inhibitors in combination with chemotherapy (nab-paclitaxel and carboplatin) were recruited. Formalin-fixed paraffin-embedded (FFPE) pre-treatment lung biopsy and paired post-operative surgery samples were collected. To investigate the immune landscape change related to neoadjuvant immunotherapy, we utilized the GeoMx Digital Spatial Profiler (DSP) to spatially profile the expression of >570 proteins in tumor- (pan-CK+), immune- (CD45+), and cancer-associated fibroblast (CAF, a-SMA+) regions in pre- and post-treatment specimens. Differential expression analyses, and GSEA were performed.
Results: We found that active YAP1, BAX, and IRF3 in the tumor region, and CD11a, CXCR3, and CD34 in the immune region were upregulated after treatment, while Syndecan-1, Tuberin, and PAK1 in the immune region and MEK1, CD3G, and VEGFD in the CAF region were downregulated after treatment (all FDR < 0.05). GSEA highlighted that the neoadjuvant immunochemotherapy downregulated differentiation, HIF1, Insulin, and mTOR pathway (NES: -1.70, -1.76, -1.77, and -1.64, respectively) in immune and CAF regions (all adjusted P < 0.05). Findings suggested that neoadjuvant immunochemotherapy may improve oxygenation via the HIF1 pathway, induce metabolic stress and nutrient depletion via the mTOR and insulin pathways, promote dedifferentiation or epithelial-to-mesenchymal transition, as well as reduce immune evasion by modifying the tumor microenvironment. This study provides clues and preliminary evidence to further understand the treatment mechanism of neoadjuvant immunochemotherapy for LUSC.
Conclusion: In this spatial biology study, we found dynamic changes in proteins between pre- and post-neoadjuvant immunochemotherapy among LUSC patients. The dynamic changes revealed some potential impacts of NAT on LUSC, including improving oxygenation, reducing mTOR and insulin activity, and mitigating immune evasion. Understanding these mechanisms can guide the development of combination therapies to improve patient outcome.

#750 Exploring PD1/PDL1 interactions and macrophage-tumor barriers in head and neck cancer: A spatial approach to immunotherapy response.

V. Yaghoubi Naei[1], R. Tubelleza[2], J. Monkman[2], H. Sadeghirad[3], M. L. Donovan[4], T. Blick[2], A. Wicher[5], S. Bodbin[5], S. Basu[5], R. Stad[6], C. Barnett[7], K. O'Byrne[7], R. Ladwa[7], C. Cooper[7], M. Ebrahimi Warkiani[1], B. GM Hughes[8], **A. Kulasinghe**[2];
[1]University of Technology Sydney, Sydney, Australia, [2]The University of Queensland, Brisbane, Australia, [3]The University of Queensland, Brisbane, Brisbane, Australia, [4]Queensland Spatial Biology Centre, Brisbane, Australia, [5]Navinci Diagnostics, Uppsala, Sweden, [6]Akoya Biosciences, California, USA, California, CA, [7]The Princess Alexandra Hospital, Brisbane, Australia, [8]The Royal Brisbane and Women's Hospital, Brisbane, Australia

With nearly a million new cases expected, the global death rate from mucosal head and neck cancer is projected to reach around 50% in 2024. In the U.S., patients with localized tumors have a five-year survival rate of 50-60%. While immune checkpoint inhibitors (ICIs) have shown promise in extending survival, significant challenges remain, particularly the limited effectiveness of PD-1/PD-L1 blockade therapies. Since many studies have shown that PD-L1 protein expression alone may not be a reliable predictor of response to ICI therapy, understanding the spatial context of PD-1/PD-L1 interactions might be crucial for identifying immune evasion mechanisms and predicting responses to ICIs in head and neck cancer. To address this, we aimed to take a more comprehensive approach by mapping PD-1/PD-L1 interactions across n=35 mucosal head and neck squamous cell carcinoma (HNSCC) tissue samples collected before ICI treatment, using a combination of high-plex spatial proteomics and the *in situ* Navinci Proximity Ligation Assay (isPLA). Formalin-fixed, paraffin-embedded (FFPE) tissue samples were stained using multiplex immunofluorescence and the Navinci Diagnostics isPLA assay to detect PD-1/PD-L1 interactions. After incubation with primary anti-PD1 and anti-PD-L1 antibodies, secondary probes tagged with oligonucleotides were applied, enabling PLA to highlight the interactions through a ligation step and an amplification process to enhance the visibility of the protein interactions. Finally, a detection solution was applied to visualize the amplification product at the sites of PD1/PD-L1 interaction.We identified distinct spatial patterns of PD-1/PD-L1 interactions at the tumor-stroma interface, particularly in progressive disease (PD) patients, who exhibited dense layers of isPLA$^+$ macrophages, CD3e T cells, and tumor cells, suggesting an immunosuppressive barrier in this region. In contrast, complete response (CR) patients showed rare or absent barriers, with enriched immune cell aggregates, including B cells and T cells, near the tumor boundary. These findings were corroborated through neighborhood clustering analysis, revealing significant associations between isPLA$^+$ regions and poor prognosis.The spatially resolved nature of our analysis underscores the critical role of PD-1/PD-L1 interactions in shaping the tumor microenvironment (TME) and highlights their potential as predictive biomarkers for ICI therapy efficacy. Unlike methods that detect mere colocalization, isPLA technology enables us to detect true PD-1/PD-L1 interactions, which are more likely to affect immune suppression directly. Our study also emphasizes the need for further exploration of macrophage and T cell subtypes, as well as PD-1/PD-L1 interactions across tumor-stroma boundaries in various cancers to improve immunotherapy strategies.

#751 High-resolution and AI-enabled single-cell spatial transcriptomics and histopathology integrated to reveal tumor differentiation and immune exclusion in skin squamous cell carcinoma.

Patrick Danaher, **Michael Patrick**, Shanshan He, Liang Zhang, Stefan Rogers, Michael Rhodes, Haiyan Zhai, Joseph Beechem

Bruker Spatial Biology, Seattle, WA

Skin squamous cell carcinoma (SCC) is characterized by heterogeneity in differentiation states and immune exclusion within the tumor microenvironment (TME). Using the Bruker Spatial Biology CosMx® Whole Transcriptome (WTX) panel, which profiles approximately 19,000 genes at single-cell resolution, we examined spatial gene expression in FFPE SCC sections. Individual single cell boundaries were defined utilizing a trained AI cell segmentation model. H&E staining on the same tissue provided histopathological context, enabling the integration of molecular and morphological findings. Combining CosMx WTX data with H&E staining, downstream AI models could be used to further predict cell types and transcriptomic signatures directly from H&E images. FFPE SCC samples were subjected to CosMx WTX imaging to generate spatially resolved transcriptomic data. H&E staining, performed after CosMx WTX, was aligned with transcriptomic data using custom software. Histopathological analysis identified keratin pearls, invasive fronts, and stromal compartments. Bioinformatics mapped gene expression signatures of keratinization, immune exclusion, and extracellular matrix remodeling, providing a detailed view of tumor architecture. Thousands of genes were mapped with high resolution, allowing in-depth exploration of the SCC TME. Cell typing identified spatially distinct cancer subpopulations and their relationship with stromal and immune components. Ligand-receptor analysis revealed spatial patterns of cell-cell communication, while proximity analyses highlighted unique immune interactions. Macrophages near cancer cells showed increased transcription of specific genes compared to distant macrophages, suggesting spatially restricted tumor-immune signaling. Integration with H&E staining revealed molecular correlates of keratinization, immune exclusion, and invasive front dynamics, bridging histopathology with spatial transcriptomics. This integration offers the potential to train AI models that predict tumor cell types and molecular profiles directly from H&E images, enabling faster and more accessible analysis. This study integrates single-cell spatial transcriptomics with histopathological features to reveal the molecular mechanisms of tumor differentiation, immune evasion, and stromal remodeling in SCC. The combination of spatial transcriptomics and H&E images holds potential for future AI models that enable non-invasive, real-time tumor profiling, providing a foundation for therapeutic strategies targeting SCC progression and immune suppression.

#752 Hypoxia-driven spatial dynamics of epigenetic and transcriptional cell states in glioblastoma.

Phoebe Lombard, Mark Zaidi, Ronald Wu, Sheila Mansouri, Gelareh Zadeh, Bradly G. Wouters

UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Glioblastoma (GBM) is an aggressive disease with poor overall survival rates that have not substantially changed in decades. A key feature underlying the lack of therapeutic success in GBM is its inherent morphological and phenotypic diversity. To better understand intra-tumor heterogeneity, single cell sequencing studies have delineated core transcriptional states to characterize GBM cell phenotypes. This study investigates the role of hypoxia in driving the establishment and transformation of GBM cell state. To characterize the spatial organization of cell states relative to hypoxia, spatial transcriptomics (ST) was performed on samples from GBM patients administered pimonidazole prior to surgery as part of a clinical trial. By overlaying serial pimonidazole-stained sections with ST, we constructed a hypoxia gene signature to identify hypoxic regions in ST. Our ST data was integrated with public datasets to create the largest global GBM dataset. In this dataset, we identified novel, ST-specific states that represent recurring cellular phenotypes. We used geographically weighted models to assess hypoxia's spatial colocalization with previously defined cell states and our independently derived states. Finally, we investigated underlying mechanisms by which hypoxia may influence cell state using patient derived glioma stem cells (GSCs) cultured under hypoxic conditions. Using ATAC-seq, ChIP-seq, and bulk RNA-seq, we identified specific genes and chromatin regions differentially regulated under hypoxia. We find that hypoxia demonstrates remarkable spatial correlation with mesenchymal-like cell states, while states reminiscent of neural and glial lineages are notably absent in hypoxic regions. We also identify a leukocyte migratory phenotype strongly spatially correlated with hypoxia, which may indicate immune infiltration in these regions. Epigenetic profiling in GSCs identified specific genomic regions epigenetically regulated by hypoxia. Chromatin regions open under hypoxia with corresponding increased expression are enriched for known hypoxia-associated transcription factors. Conversely, chromatin regions closed and with corresponding decreased expression are enriched for neurodevelopment and differentiation transcription factors. These epigenetically regulated genes are strongly spatially correlated with hypoxic regions in patient ST data and are prognostic as a signature in data from TCGA. Together, our work demonstrates that hypoxia drives remodeling of the transcriptional and epigenetic landscape in GBM. In patients, hypoxia and genes epigenetically regulated under hypoxic conditions associate with specific GBM cell states, suggesting that hypoxia-driven epigenetic remodeling may contribute to these state phenotypes and, consequently, to malignant phenotypes in tumors.

#753 AI-powered deep visual proteomics (DVP) for early pancreatic cancer insights.

Jimin Min[1], Lisa Schweizer[2], Gijs Zonderland[2], Benson Chellakkan Selvanesan[1], Lukas Oldenburg[2], Michael A. Hollingsworth[3], Paul M. Grandgenett[3], Ishani Ummat[2], Maximilian T. Strauss[2], **Andreas Mund**[4], Anirban Maitra[1]

[1]Department of Translational Molecular Pathology, Sheikh Ahmed Center for Pancreatic Cancer Research, MD Anderson Cancer Center, Houston, TX,[2]OmicVision Biosciences, Copenhagen, Denmark,[3]The Eppley Institute for Research in Cancer and Allied Diseases, Fred & Pamela Buffet Cancer Center, University of Nebraska Medical Center, Omaha, NE,[4]Andreas Mund (Individual), Copenhagen, Denmark

Pancreatic ductal adenocarcinoma (PDAC), the most common form of pancreatic cancer, presents a formidable clinical challenge. Patients experience 70-80% post-resection mortality due to recurrence. Identifying aberrant molecular pathways and drivers of pre-cancer progression is an unmet area of importance for developing effective biomarkers and enabling early detection. Pancreatic intraepithelial neoplasia (PanINs) represent the key precursor to PDAC. While genomic and transcriptomic profiling of these lesions has been performed at depth, the deep proteomic profiles of these precursors remains largely unexplored. Deep Visual Proteomics (DVP) combines advanced microscopy, machine learning-based image analysis, automated laser microdissection, and high-sensitivity mass spectrometry to analyze specific cell populations while maintaining their spatial context within tissue samples. Here, we combine DVP with cutting-edge pathology foundation models trained on over 600,000 histopathological slides and data from more than 200,000+ patients, to systematically and precisely characterize key regions of interest (ROIs) in incidental panIN lesions in organ donor samples. We then employ our spatially-resolved mass-spectrometry based proteomics pipeline to compare these pancreatic precursor lesions, including acinar ductal metaplasia and regions of low- and high-grade PanINs, to normal healthy ducts. Hereby we developed the first comprehensive spatial proteomics maps of pancreatic precursor lesions. This AI-powered ROI classification, coupled with our advanced DVP platform, delivers unprecedented molecular insights. Our platform achieves remarkable proteomic depth, identifying ~6,000 proteins from ~100 phenotype-matched cells per sample, revealing stage-specific molecular signatures in PanIN lesions. This first-of-its-kind dataset enables the creation of detailed, phenotype-specific and spatially-resolved proteomic landscapes of PDAC progression. Our innovative approach reveals progressive activation of KRAS signaling across the PanIN-to-PDAC transition, corroborating key drivers of multistep carcinogenesis. Furthermore, we identify several promising biomarkers candidates, including targets that might form the basis for early detection and also provide unprecedented insights into targets for cancer interception. Combining the precision of AI-based pathology with the depth of DVP represents a paradigm shift in the toolkit to study PDAC progression, and generates novel molecular insights in panIN lesions that may enable meaningful intervention in pancreatic cancer.

#754 AI-powered spatial inference platform for qualifying ADCs and multispecific therapeutic targets.

Michael Mints[1], Ettai Markovits[1], Ron Elran[1], Shai Bookstein[1], Yuval Shachaf[1], Elad Amsalem[1], Mor Kenigsbuch[1], Jason W. Reeves[2], Ken Bloom[2], Oscar Puig[2]

[1]Nucleai, Tel Aviv, Israel,[2]Nucleai, Chicago, IL

Over the past two decades, genomic alterations have become important biomarkers for predicting response to targeted therapies; however, the emergence of immunotherapy, antibody-drug conjugates and multispecifics may require a different class of biomarkers that can quantify and localize drug targets within tumor and immune cells. Genomic testing frequently lacks correlation with protein expression, fails to capture membranous versus cytoplasmic localization, and has limited ability to decipher spatial interactions between targets. Multiplex immunofluorescence (mIF) is an established technology capable of quantifying and capturing the subcellular localization of dozens of proteins (>25 proteins per slide), enabling parallel assessment of a large number of drug targets. Here we describe a framework for leveraging high-plex spatial proteomics with an AI-driven platform to develop rational approaches for evaluating individual targets and combinations of targets within and across disease indications. We designed a 30-plex mIF panel to perform sequential immunofluorescence (seqIF™) on the COMET™ platform to profile known tumor antigens and targets (n = 18) currently in development along with the tumor microenvironment (TME), immune cells, and key signaling cascades (n = 12). We tested this panel on 217 samples (>1,700,000 cells) from lung (n = 90), gastric (n = 11), and colorectal (n = 68) cancers, as well as normal tissue specimens (n = 48, 22 sites). Utilizing Nucleai's deep-learning-based multiplex imaging analysis pipeline, we quantified the protein abundance, localization, and interactions among 9 different cell types. Tissue areas were divided into subregions and neighborhoods to characterize localization of these cell types to distinct areas including the tumor core (TC), tumor invasive margin interface (TIM), and stroma. We confirmed known drug targets with historical approvals in each of these indications, which validated that the pipeline was able to correctly identify key targets based on subcellular localization, spatial proximity analysis, and analysis of off-target cell type expression. We also identified potential combination partners for multi-specifics based on target colocalization, which were found to have reductions in off-target cell colocalization, as determined by protein expression in the right compartment and in the expected cell types. Nucleai's platform enables deep spatial proteomic profiling by deriving AI-driven insights for actionable characterization of protein interactions and patient heterogeneity across tissues. We demonstrate that this framework can aid in the prioritization and derisking of potential drug targets used by key classes of therapeutics currently in development.

#755 Identifying the molecular signature of infiltrating edge cells in glioblastoma as drivers of tumor invasion and recurrence.

Alyona Ivanova[1], Shamini Ayyadhury[2], Megan Wu[3], David G. Munoz[4], Trevor J. Pugh[5], Sunit Das[6]

[1]Institute of Medical Science, University of Toronto, Toronto, ON, Canada,[2]The Donnelly Centre, University of Toronto, Toronto, ON, Canada,[3]Brain Tumour Research Centre, The Hospital for Sick Children, Toronto, ON, Canada,[4]St. Michael's Hospital, Toronto, ON, Canada,[5]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[6]St.Michael's Hospital, Toronto, ON, Canada

Background: Glioblastoma (GBM) is the most common malignant brain tumor in adults. Despite extensive research, there haven't been remarkable gains in resolving the seeds of glioblastoma recurrence, and the outcomes for many patients suffering from this devastating disease remain poor. Complete tumor resection in GBM patients is not possible. Residual therapy-resistant cells drive tumor recurrence and infiltrative expansion. Our knowledge on GBM heterogeneity is mostly restricted to the surgically resectable tumor core, while the functional characterization of tumor cells at the infiltrating edge remains largely elusive due to the presence of normal functional brain tissue in the peritumoural lesion. Edge-derived cells exhibit larger capacity for infiltrative expansion and are the main drivers of treatment failure and tumor recurrence, making them action targets for novel treatment approaches.
Methods: To resolve the transcriptional heterogeneity of GBM within the spatial context, we profiled gene expression of tumor regions selected based on histological features ("edge", "core", and "infiltrating zone") obtained from 4 primary and 2 matched pairs of primary/recurrent IDH-WT GBM patients at single-cell resolution with Visium HD.
Results: We show that infiltrative cells are spatially segregated and are characterized by regionally shared distinct transcriptomic signatures which define their cell state and identity. We complement non-spatial leiden clustering approach with BANKSY spatial clustering to augment the features of each cell with both an average of the features of its spatial neighbors along with neighborhood feature gradients. Using pathologically annotated H&E images integrated with spatial gene expression, we identify patterns related to tissue structure and identify transcriptional programs that promote invasiveness and underly disease recurrence in GBM. To further characterize invasive cells at the normal brain-tumor boundary, we identify top spatially variable genes in this cell population using unsupervised cell phenotyping. Upregulated DEGs of tumor edge cells are significantly associated with chemical synaptic transmission, and nervous system development. These modules represent tumor cell hijacking of neuronal programs as described in the context of glioma-neuron synaptic communication and formation of neurite-like tumor microtubes. Upregulation of ion regulation transport at the tumor periphery indicates enhanced neuronal activity and excitability driving infiltrating growth.
Significance: Identifying biomarkers that are specific to malignant edge-derived cells may serve as new diagnostic feature that would help assess treatment response before or within early phases of therapy and allow for individual tailoring of the treatment plan to slow disease progression.

#756 Unveiling the spatial landscape of tumor and stroma heterogeneity in colorectal cancer with spatial transcriptomics and deep learning.

Jie Zhou[1], Todd B. Sheridan[2], Sergii Domanskyi[3], Stephanie L. Cowles[4], Sunghee Park[3], Ilham Putra[4], Olga Anczukow[1], Jeffrey H. Chuang[1], Jill C. Rubinstein[5]

[1]The Jackson Laboratory for Genomic Medicine, Farmington, CT;Department of Genetics and Genome Sciences, Farmington, CT,[2]The Jackson Laboratory for Genomic Medicine, Farmington, CT; Department of Pathology, Hartford hospital, Hartford, CT,[3]The Jackson Laboratory for Genomic Medicine, Farmington, CT,[4]Department of Pathology, Hartford hospital, Hartford, CT,[5]The Jackson Laboratory for Genomic Medicine, Farmington, CT; UCONN School of Medicine, Department of Surgery, Farmington, CT;Hartford HealthCare Cancer Institute at St. Vincent's Medical Center, Bridgeport, CT

Heterogeneity in colorectal cancer (CRC) manifests as inter- and intra-patient diversity in tumor and immune cell populations as well as varied patterns of tumor interaction with surrounding stroma. Spatial transcriptomics (ST) captures gene expression within the native spatial context of tissues, offering a high-resolution approach to dissect cancer molecular landscapes. Prior ST studies in CRC have been constrained by small sample sizes and tissue selection biases, reducing clinical relevance. Here we performed ST (10x Genomics Visium Spatial Gene Expression) on 40 retrospectively-collected CRC samples with available clinicopathological data (stages I-IV: 13, 8, 14, and 5 samples, respectively) and long-term clinical outcomes to define the molecular topography and spatial heterogeneity of tumors with their stromal context. Using ST data, we identified recurring spot-level (55-micron resolution) tumor and stromal sub-populations across the cohort, designating them as T1 (marker genes EPCAM, LGALS4, and FXYD3) and T2 (marker genes KRT8, KRT18, and KRT19) for tumor subtypes, and F1 (marker genes SPARC and LUM) and F2 (marker genes COL3A1 and PTGDS) for stromal subtypes. Comprehensive analysis of tumor/stromal pairs—including copy number variations (CNVs), cell type compositions, pathway activations, metabolic profiles, spatial distributions, and histological characteristics—revealed pathways enriched in T2 compared to T1, including epithelial-mesenchymal transition (EMT), angiogenesis, hypoxia response, TGF-beta signaling, and metabolic pathways supporting the energy and biosynthetic demands of aggressive tumor cells. We also identified recurrent spatially co-localized tumor and stromal sub-clonal pairs—T1&F2 and T2&F1—that consistently preserved their spatial architecture across samples. Notably, the prevalence of T1&F2 was significantly correlated with disease-specific survival (DSS) (log-rank test, p=0.05), highlighting the prognostic importance of tumor-microenvironment interactions. Using a transformer-based image feature encoder, we demonstrated that these clusters are morphologically distinguishable in hematoxylin and eosin (H&E)-stained images co-registered with the ST data, achieving an AUC (the Area Under the ROC Curve) of 0.84 for distinguishing T1 from T2 and an AUC of 0.75 for distinguishing F1 from F2. These clusters were also detected in H&E images from external datasets, including The Cancer Genome Atlas (TCGA, N=232) and an independent validation set (N=107). Deep learning models trained on TCGA data further revealed a trend where higher T2 prevalence or lower T1 prevalence correlated with shorter overall survival. This ST study establishes novel molecular subtypes and their spatial co-occurrence in CRC, linking spatial behaviors to clinically prognostic and H&E-based morphological characteristics.

#757 Decoding resistance: Spatial transcriptomics reveals tumor core and edge dynamics in high-risk cutaneous squamous cell carcinoma treated with neoadjuvant cemiplimab.

Ali Baghian[1], Hugo Lara-Martinez[2], Rania Bassiouni[3], Gino In[4], Homa Dadrastoussi[4], Paniz Zarand[4], Harley Wu[4], Kaijin Wu[4], Brittney K. DeClerck[4], Ashley Gochoco[1], Kevin Kelly[4]

[1]Beth Israel Deaconess Medical Center, Boston, MA,[2]MD Anderson Cancer Center, Houston, TX,[3]City of Hope, Duarte, CA,[4]Keck School of Medicine of USC, Los Angeles, CA

Introduction: Immune checkpoint inhibitor (ICI) therapies have redefined the treatment landscape of advanced cutaneous squamous cell carcinoma (CSCC). NeoPOWER is an ongoing, single-arm, phase II clinical trial studying the role of preoperative cemiplimab in patients with high risk/unresectable CSCC. Based on recent data, patients with CSCC who attain a pathologic complete response with neoadjuvant ICI have a 12-month disease free survival of 92%. Response rates to ICI; however, are approximately 50-60% and CSCC refractory to ICI is associated with an inferior survival, highlighting a need to stratify patients who are most likely to benefit from neoadjuvant cemiplimab. We employ Visium (v2, 10x genomics) to comprehensively analyze the CSCC tumor immune microenvironment of patients with divergent responses to immunotherapy.

Methods: We performed Visium spatial transcriptomics (ST) profiling on formalin fixed paraffin embedded biopsy samples from patients with high risk or unresectable CSCC treated with neoadjuvant cemiplimab. Nine patients were included and divided into two groups as defined by presence of residual disease (RD) or no residual disease (NRD). An integrated RD and NRD pre-treatment (pre-iRD/NRD) analysis (n = 8 samples) was performed to identify factors predictive of treatment response. Separately, an integrated RD pre-treatment and post treatment (iRD) analysis was explored to assess for mechanisms of treatment resistance (n = 7 samples). Gene expression data generated by Visium was imported and analyzed in Seurat.

Results: We observed that 2 distinct clusters identified as CSCC, histologically and transcriptionally, formed a substructure comprised of an outer and inner layer tumor edge (TE) and tumor core (TC), respectively. This association of spatial adjacency was visually evident in both pre-iRD/NRD and iRD groups. Comparative gene set enrichment analysis between pre-iRD/NRD showed alterations in KRAS signaling pathways and down-regulation of multiple immune response pathways, implying fundamental differences in the TC of both response groups. In contrast, comparisons of the iRD TC showed post-treatment enrichment of epithelial mesenchymal transition, hypoxia, and metabolic pathways. Post treatment TE was similarly enriched in EMT and hypoxia with down-regulation of immune response pathways. Alterations in immune cell proportions post-treatment were notable in the iRD group following ICI, as were differences in baseline B and T cell proportions in pre-iRD/NRD tumor clusters. Ligand receptor analysis highlighted key immune-inhibitory interactions within the TE and TC.

Conclusions: ST analysis of the pre- and post-treatment CSCC microenvironment captures tumor edge/core dynamics associated with different response outcomes.

#758 Spatial profiling of matched primary and recurrent glioblastoma samples reveals changes in cellular states and the immune microenvironment.

Sara Artzi[1], Marc N. Klausen[1], Dylan S. L. Harwood[1], Signe R. Michaelsen[1], Simone B. Maarup[2], Alessio Locallo[3], Nicolai S. Bager[1], Nadine M. Hammouda[1], Benedikte Hasselbalch[2], Ulrik Lassen[2], Joachim Weischenfeldt[3], Bjarne W. Kristensen[1]

[1]Department of Pathology, Rigshospitalet, Copenhagen University Hospital, Biotech Research and Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark,[2]Department of Oncology, Rigshospitalet, Copenhagen University Hospital, Copenhagen University Hospital, Copenhagen, Denmark,[3]The Finsen Laboratory, Rigshospitalet, Copenhagen, Biotech Research and Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark

Background: Glioblastoma (GBM), the most aggressive brain tumor, is treated with surgery, chemotherapy, and radiation, yet 90% recur within two years. PD-1 blockade improves outcomes in other cancers, but shows limited effect in GBM, likely due to tumor heterogeneity and an immunosuppressive microenvironment. This study aims to investigate post-treatment transcriptional changes in tumor cells and tumor-associated macrophages (TAMs) in matched primary and recurrent GBM, focusing on neoadjuvant PD-1 blockade.

Methods: We used the GeoMx Digital Spatial Profiler to spatially select and transcriptomically profile tumor cells ($SOX2^+$) and TAMs ($IBA1^+$). Gene expression changes between primary and recurrent GBMs were analyzed in 30 patients (26 IDHwt, 4 IDHm) with 20 paired primary samples. All patients received standard treatment, and 20 also received second-line nivolumab one week before recurrence surgery. Tumor purity was confirmed using InferCNV and cell signatures. Subsequently, differential expression and pathway enrichment analyses were performed to compare recurrent tumors treated with nivolumab to those untreated, as well as primary vs. recurrent tumors. We also evaluated Neftel signatures in matched tumors to assess treatment- and recurrence-associated malignant state changes.

Results: Principal component analysis of all samples revealed distinct transcriptional profiles between tumor cells and TAMs. Separate analyses showed clear differences in tumor cell and TAM segments based on tumor status (primary/recurrent), though no separation related to nivolumab treatment. Similarly, comparing nivolumab-treated recurrent tumors with untreated controls showed no significant changes in malignant states or gene expression in tumor cells or TAMs, consistent with the lack of clinical survival benefit.To investigate overall transcriptional changes induced by standard treatment, differential expression analysis comparing tumor cell segments in paired primary and recurrent tumors revealed few significant genes, likely reflecting high inter-patient variability driven by tumor heterogeneity. Unsupervised clustering of tumor cell segments identified a distinct cluster specific to recurrent tumors, with DEGs highlighting pathways linked to this particular tumor cell phenotype. In TAM segments, increased expression of checkpoint-related genes in recurrent tumors suggests TAM phenotype changes that may influence immune dynamics in the microenvironment.

Conclusion: Spatial profiling of matched primary and recurrent GBM samples reveals distinct transcriptional changes in both tumor cells and TAMs, reflecting the complex microenvironment of recurrent GBM. However, our findings point to a limited impact of neoadjuvant PD-1 blockade on transcriptional activity, highlighting ongoing challenges in targeting GBM with immunotherapy.

#759 Spatial transcriptomics identifies unique tumor and microenvironment pathomic programs that are associated with the lung premalignancy and adenocarcinoma continuum.

Yibo Dai[1], Fuduan Peng[1], Ansam Sinjab[1], Sujuan Yang[1], Minyue Chen[1], Warapen Treekitkarnmongkol[1], Lorena I. Gomez Bolanos[1], Tieling Zhou[1], Alejandra G. Serrano[1], Jianlong Liao[1], Guangsheng Pei[1], Yunhe Liu[1], Yang Liu[1], Jiahui Jiang[1], Kyung Serk Cho[1], Yanshuo Chu[1], Kai Yu[1], Ruiping Wang[1], Jiping Feng[1], Zahraa Rahal[1], Guangchun Han[1], Naoe Jimbo[2], Takuo Hayashi[3], Satsuki Kishikawa[3], Kazuya Takamochi[3], Akshay Basi[1], Avrum Spira[4], Steven Dubinett[5], Tomokazu Itoh[2], Takashi Yao[3], Kenji Suzuki[3], Luisa M. [1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Kobe University Hospital, Kobe, Japan,[3]Juntendo University Graduate School of Medicine, Tokyo, Japan,[4]Boston University, Boston, MA,[5]The University of California Los Angeles, Los Angeles, CA,[6]University of Pennsylvania, Philadelphia, PA,[7]Hiroshima University Hospital, Hiroshima, Japan

Background: Lung adenocarcinoma (LUAD) is one of the most prevalent and lethal cancer types worldwide. However, our understanding of the transition from normal-appearing tissue (NAT) to adenomatous lung premalignant lesions (aPMLs) and LUADs, particularly within a spatial context, remains limited. This study aims to address this gap by systemically analyzing the pathologic continuum of NAT > aPML > LUAD using spatial transcriptomics (ST).

Methods: High-resolution spatial profiling was conducted on 56 samples from 25 patients with paired aPMLs and LUADs using the Visium ST platform. Non-negative matrix factorization was conducted to identify transcriptional programs for each sample, following clustering analysis to define consensus metaprograms across the cohort. Additionally, spatial molecular imaging was performed on an expanded cohort of 188 cores arranged into eight tissue microarrays using the Xenium in situ platform with a customized lung cancer gene panel to establish a single-cell spatial atlas of the disease continuum and systemically investigate spatial organization, cellular neighborhoods and interactions.

Results: Eight distinct metaprograms (MP1~8) were identified, distinguishing stromal (MP2), myeloid (MP4), lymphoid (MP6), and epithelial (MP3, MP5) compartments. Additionally, metaprograms were identified for the lung capillary bed (MP7), stressed cellular state (MP8), and mosaic cellular patterns (MP1). These metaprograms correlated strongly with pathological annotations and captured fine tissue structures like lymphoid aggregates. LUADs and aPMLs showed distinct MP profiles, with MP3 and MP6 being highly abundant in LUADs, while MP1, MP4, MP5 and MP7 were more abundant in aPMLs. Specifically, we observed positive correlations between MP3 and MP6, as well as between MP4 and MP5 in sample distributions, indicating co-evolution of tumor and immune microenvironments during disease progression. Xenium data complemented these findings by revealing distinct compositions of microenvironmental cellular states and tumor neighborhood structures across aPML and LUAD lesions. A total of 44 cell states were defined. Specifically, NK cells were depleted in aPMLs and LUADs compared with NAT, accompanied by an enrichment of regulatory T cells and myofibroblastic cancer-associated fibroblasts (CAFs) in the latter. Additionally, pro-inflammatory cellular subsets, including *IL1B*$^{+}$ macrophages and *IL6*$^{+}$ inflammatory CAFs were more abundant in tumor neighborhoods of aPMLs compared to LUADs, potentially contributing to the pre-malignant to malignant transition.

Conclusions: This study offers a comprehensive molecular and cellular landscape of aPML and LUAD, laying a crucial foundation for future mechanistic studies aimed at early disease interception.

#760 Cell type resolved spatial proteomics defines the transition of precancerous fallopian tube lesions to invasive ovarian cancer.

Andreas Metousis[1], Hilary Kenny[2], Lisa Schweizer[1], Agnes Bilecz[2], Rahul Krishnan[3], Isabel Alcazar[2], Mallika Ravi[2], Aasa Shimizu[2], Sophia Steigerwald[1], Thierry Nordmann[1], Ricardo Lastra[4], Ernst Lengyel[2], Matthias Mann[1]

[1]Proteomics and signal transduction, Max Planck Institute of Biochemistry, Munich, Germany,[2]Obstetrics and Gynecology, University of Chicago, Chicago, IL,[3]Northwestern Medical Group, Orland Park, IL,[4]Pathology, University of Chicago, Chicago, IL

Serous epithelial ovarian cancer is the most common subtype of ovarian cancer, and it is thought to arise from dysplastic fallopian tube (FT) lesions. Depending on their histopathological characteristics and proliferative potential, precancerous lesions of the FT are categorized as p53 signatures, Serous Tubal Intraepithelial Lesions (STILs) or Serous Tubal Intraepithelial Carcinomas (STICs). In this study, we analyzed protein changes from precancerous lesions through invasive tumor development and metastasis to identify early molecular switches and druggable proteins for ovarian cancer treatment.

We assembled a cohort of 5 p53 signatures, 8 STILs, 5 STICs alone, and 7 STICs with concurrent HGSC and 4 matching omental metastases. We interrogated these samples using Deep Visual Proteomics, an innovative technology we recently developed for spatial and cell-type resolved mass spectrometry-based proteomics. Epithelial cells were segmented using deep learning and classified into normal, dysplastic precursor, tumor, and metastasis. We collected 100-150 cell epithelial cell shapes for each pathologic category and 250 cell shape equivalents of adjacent stroma using laser capture microdissection. The samples were analyzed on a Thermo Orbitrap Astral mass spectrometer coupled to an Evosep One.

Single injections of epithelial samples yielded a median of 6,562 proteins. The epithelial proteomics data validated that the secretory, and not the ciliated, epithelial FT cells are the origin of dysplastic FT lesions. While p53 signatures have at least 12 consecutively mutated cells lining the FT, they are almost identical to normal cells on the proteomic level. However, more than 2,000 proteins are differentially regulated in STIC vs normal secretory cells. Among these proteins, MARCKSL1 (cell motility and adhesion), WLS (Wnt signaling and cell proliferation), and PCNA (DNA repair and replication) are significantly enriched in STIC.

In the stroma, we detected a median of 5,072 proteins. Interestingly, the PCA plot for components 1 and 2 reveals that separating STICs, invasive tumors, and omental metastases is better accomplished using the stroma than the epithelium. Consistent with the epithelial data, the transition from normal to the histologic p53 signature stroma is not accompanied by any proteomic changes in our dataset. However, STIC stroma, when compared to normal, is characterized by a significant loss of most collagens but not COL8, which shows the opposite trend. A massive extracellular matrix (ECM) remodeling is observed in the entire STIC tumor microenvironment, with significant regulation of ECM proteins like VCAN and laminins.

In conclusion, our study provides a deep, cell-type resolved proteomics map of the transition of early FT lesions to invasive cancer and omental metastasis and identifies proteins with potential therapeutic or diagnostic implications.

#761 Shared and heterogeneous structural and transcriptional signatures of pre-cancerous cystic lesions in the development of PDAC.

Austin N. Southard-Smith, Reyka G. Jayasinghe, Andre L. N. Targino da Costa, Liang-I Kang, John M. Herndon, Jacqueline Mudd, Andrew Houston, Xiang Li, Michael C. Wendl, Faria A. Simin, Xiangwei Fang, Feng Chen, Koushik K. Das, Ryan C. Fields, Li Ding

Washington University School of Medicine in St. Louis, St. Louis, MO

Pancreatic ductal adenocarcinoma PDAC has been observed to arise in the context of diverse pre-cancerous cystic (intraductal papillary mucinous neoplasms (IPMN) and mucinous cystic neoplasms (MCNs)) and pre-cystic (pancreatic intraepithelial neoplasia (PanIN)) lesions in the clinic. While mouse models of PDAC and these precancerous lesions have existed for a decade, only recently has the transcriptional signature of dysplastic progression for one of these lesions (PanIN) been thoroughly characterized at single cell resolution. Utilizing a multimodal, spatial interrogation via Xenium and co-detection by indexing (CODEX) of PanIN (n=5), IPMNs (n=5), MCNs (n=2), and PDAC (n=5) at varying stages, we identify transcriptional signatures of each lesion at varying stages of progression and alterations of the pre-cancer microenvironment composition and structure. In doing so, we observed a conserved gastric metaplasia phenotype along the progression from PanIN to IPMN that is maintained in a subset of cells in higher grade and dual-subtype IPMNs. This phenotype is diminished in invasive PDAC. By contrast, MCN cyst epithelium and a small subset of PanIN cells lacked the expression of gastric markers and exhibited a more reactive ductal phenotype. Directly, adjacent to each of the pre-cancerous lesions we observed a thin layer of myCAF-like fibroblasts frequently interspersed with T cells that were otherwise excluded from the region surrounding invasive PDAC while the myCAF layer expanded. In the case of MCNs specifically this thin myCAF-like layer coincided with an ovarian-like expression signature alongside other markers. Our findings offer a high resolution window into the heterogeneity of PDAC precursor lesions, highlighting shared dysplastic expression and structural phenotypes along the progression towards invasive PDAC.

#762 Spatial transcriptomic characterization of uterine carcinosarcomas identifies MECOM as a tumor regulator.

Sanaa N. Borrego, Elizabeth Kertowidjojo, Yan Li, Agnes Bilecz, Bridget Rodig, Lucy Kelliher, Hilary Kenny, Ernst Lengyel, **Katherine C. Kurnit**

University of Chicago, Chicago, IL

Uterine carcinosarcoma is an aggressive subtype of endometrial cancer associated with poor patient outcomes. Less is known about the molecular features of this heterogeneous cancer, which is characterized by both epithelial and mesenchymal components. Our study aimed to use spatial transcriptomics to provide insights into its tumor biology. Spatial transcriptomics was performed using the NanoString DSP's GeoMx 1,800 Cancer Transcriptome Atlas. We evaluated 7 primary tumors, 5 of which had paired lymph node metastases. Planned comparisons were as follows: epithelial vs mesenchymal; epithelial vs stromal; mesenchymal vs stromal; primary vs metastatic tumor. In primary tumor, there was differential expression of cell-cell adhesion genes and keratins (both higher in epithelial), and epithelial-mesenchymal transition (EMT) genes and collagens (both higher in mesenchymal). The stroma had multiple immune genes upregulated, including genes relating to macrophage function, cytokine binding, and complement activation. To further investigate the immune findings, immunohistochemistry (IHC) from 4 cases showed inconsistent immune cell differences between the carcinoma and sarcoma compartments. In 3 of the 4 cases, CD3 (T cell) cells were higher in the carcinoma than in the sarcoma, and 2 of the 4 cases showed higher CD206 (M2 macrophage) in the sarcoma than the carcinoma compartments. Few differences in gene expression were noted between the primary and metastatic tumors. MECOM and SOX17, two stem cell genes found to be associated with more aggressive ovarian cancers, were both upregulated in the epithelial compartment relative to the mesenchymal or stromal compartments on transcriptomics. To further elucidate MECOM's role in uterine carcinosarcoma, we used in situ hybridization and confirmed differential MECOM RNA expression in the tumor compartments of two different uterine carcinosarcoma cases. This was paralleled by higher protein expression in the epithelial relative to the mesenchymal tumor compartments in 12 cases (IHC). Then, MECOM was knocked down in two uterine carcinosarcoma cell lines. While no differences in proliferation were noted, blocking MECOM led to lower expression of EMT-related proteins. These data suggest that MECOM may be linked to EMT characteristics within uterine carcinosarcoma. The immune characterization of uterine carcinosarcoma is likely complex given the inherent heterogeneity of these tumors, and should be further evaluated.

#763 Multimodal spatial-omics atlas of lung premalignancy and adenocarcinoma reveals tumor initiating interplay between alveolar progenitors and inflammation.

Fuduan Peng[1], Ansam Sinjab[1], Sujuan Yang[1], Yibo Dai[1], Minyue Chen[1], Warapen Treekitkarnmongkol[1], Tieling Zhou[1], Alejandra G. Serrano[1], Jianlong Liao[1], GuangSheng Pei[1], Yunhe Liu[1], Yang Liu[1], Jiahui Jiang[1], Kyung Serk Cho[1], Yanshuo Chu[1], Kai Yu[1], Ruiping Wang[1], Jiping Feng[1], Zahraa Rahal[1], Lorena I. Gomez Bolanos[1], Guangchun Han[1], Naoe Jimbo[2], Takuo Hayashi[3], Satsuki Kishikawa[3], Kazuya Takamochi[3], Akshay Basi[1], Avrum Spira[4], Steven Dubinett[5], Tomokazu Itoh[2], Takashi Yao[3], Kenji Suzuki[3], Luisa M. Solis[1], Stephen Swisher[1], Mingyao Li[6], Junya Fujimoto[7], Ignacio I. Wistuba[1], Jared Burks[1], Kadir Akdemir[1], Jeffrey Myers[1], Linghua Wang[1], Humam Kadara[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Kobe University hospital, Kobe, Japan,[3]Juntendo University Graduate School of Medicine, Tokyo, Japan,[4]Boston University, Boston, MA,[5]University of Califormia Los Angeles, Los Angeles, CA,[6]University of Pennsylvania, Philadelphia, PA,[7]Hiroshima University Hospital, Hiroshima, Japan

Background: The events mediating the transition of normal-appearing tissue (NAT) to adenomatous premalignant lesions (aPMLs) and minimally or locally invasive lung adenocarcinoma (LUAD) are very poorly narrated.

Methods: We analyzed matching NATs, aPMLs, and LUADs from 25 patients using integrative approaches including spatial transcriptomics (ST, n=56 tissues), single-cell RNA-sequencing of fixed cells (scFFPE-seq) from matched uninvolved NAT, aPMLs and LUADs (n = 75 tissues), and whole exome sequencing (WES, n=79). A subset of tissues was also analyzed by sequential immunofluorescence (seqIF, COMET) and subcellular spatial gene expression (Xenium, n=41).

Results: We performed multimodal spatial omics analysis of lung tissues along the NAT-aPML-LUAD continuum. After quality control, we retained and analyzed 477,283 spots by ST, 401,636 cells by scFFPE-seq, and more than 1.75 million cells by Xenium. Paired aPMLs and LUADs showed distinct spatial transcriptional patterns, lineage plasticity, and cell states. We derived nine metaprograms using scFFPE-seq data of epithelial cells, which showed robust alignment with sub-cell type and states from the ST data. Integrative analysis of ST and scFFPE-seq demarked metaprograms that denote alveolar type 1 (AT1) and type 2 (AT2), alveolar intermediate cell (AIC), and tumor cells in the cellular path to aPML and LUAD. Both LUAD and aPML regions highly expressed signatures of KRT8+ AICs (KACs), which denoted transitionary states between NATs and aPMLs or LUADs. Trajectory analysis demonstrated two alveolar transition paths, namely AT2-AIC-AT1 and AT2-KAC-lung tumors. In contrast to LUADs, early aPMLs and KAC-rich NAT expressed proinflammatory metaprograms, suggesting that interplay between KAC and inflammation is contextual and likely involved in tumor initiation in the peripheral lung. Spatial single-cell neighborhood analysis by Xenium platform concordantly showed that KACs were proximal to proinflammatory macrophages and cancer-associated fibroblasts (CAFs). Specifically, IL-1B+ proinflammatory macrophages and inflammatory CAFs were observed to be enriched in the neighborhood of tumor cells in aPMLs. Multimodal analysis of a tobacco lung carcinogenesis mouse model showed that KACs displayed increased NF-kB signaling and expression of the *Il1b* receptor *Il1r1*. Importantly, treatment with IL-1b or macrophage co-culture enhanced growth of KAC-enriched organoids, and IL-1b neutralization *in vivo* led to KAC regression.

Conclusions: We generated a multimodal spatial and single-cell atlas of the transition of normal tissue to aPML and LUAD. This comprehensive atlas uncovered critical interactions between tumor progenitors and inflammation that inspire initiation of lung lesions and inform of unique and targetable cellular states for early detection and interception of LUAD.

#764 Molecular diagnosis using spatial analysis of lung tumors with a history of pancreatic cancer.

Kosei Ishimura[1], Kazuhiko Shien[2], Shuta Tomida[3], Hidetaka Yamamoto[4], Hirofumi Inoue[5], Kazuya Hisamitsu[1], Ryota Fujiwara[1], Atsushi Matsuoka[1], Ryunosuke Fujii[1], Ryo Yoshichika[1], Tomohiro Higashihara[1], Naohiro Hayashi[1], Yuma Fukumoto[1], Kazuhiro Okada[1], Fumiaki Mukohara[1], Mao Yoshikawa[1], Ken Suzawa[2], Shinichi Toyooka[2]

[1]Thoracic, Breast and Endocrinological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[2]Thoracic, Breast and Endocrinological Surgery, Okayama University Hospital, Okayama, Japan,[3]Center for Comprehensive Genomic Medicine, Okayama University Hospital, Okayama, Japan,[4]Pathology (Tumor Pathology), Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[5]Okayama University Hospital, Okayama, Japan

Background: In pancreatic cancer (PC) patients, the lung is the third most common site of recurrence after the liver and peritoneum. Accurate histological diagnosis of lung tumors is essential for determining treatment strategies. However, pancreatic cancer lung metastases (PCLM) and invasive mucinous adenocarcinoma (IMA), a subtype of primary lung adenocarcinoma, share histopathological features, such as mucin-rich tall columnar epithelial cells growing in glandular or papillary structures with a lepidic growth pattern. Even with immunohistochemical markers like TTF-1 or CK20, differentiation remains challenging. This study aimed to identify molecular markers unique to PCLM and IMA using spatial multi-omics analysis.
Materials and Methods: We performed spatially resolved transcriptomics/proteomics on surgically resected lung tumor specimens obtained from patients with a history of PC. A total of nine patients were included: five diagnosed as possibly PCLM based on clinicopathological features and four with tumors difficult to distinguish between PCLM and primary lung IMA. Regions of interest (ROIs) were selected in each tumor component and the tumor microenvironment (TME). Gene and protein expression profiles were comprehensively analyzed using the GeoMx digital spatial profiler in each ROI. Additionally, primary PC specimens were analyzed in five cases where there were available, and three patients of primary lung IMA without a history of PC were included as controls.
Results: The median age of the nine patients with PC were 67 years (range: 54-80 years), with four males and five females. Histologically, all patients exhibited tall columnar epithelial cells with glandular or papillary structures. Among them, five patients had limited or sparse mucin, leading to a diagnosis of possibly PCLM, while the remaining four were challenging to distinguish. Spatial multi-omics analyses stratified the nine patients into subtypes, revealing distinct molecular signatures. Comparison with IMA-specific signatures identified molecular markers to aid in differentiating PCLM from primary lung IMA. Additionally, differences in gene/protein expression profiles, including within the TME, were observed between primary pancreatic tumors and lung metastases.
Conclusion: This study identified molecular markers that could distinguish PCLM from primary lung IMA despite their similar imaging and histological features. These findings suggest that spatial multi-omics analysis could be a valuable tool for improving the differential diagnosis of PCLM and IMA.

#765 Spatial transcriptomic profiling of normal breast tissue reveals potential mechanisms underlying increased breast cancer risk in Black women.

Camila Pacheco Erak[1], Nicole Cruz-Reyes[1], Pria Westerman[1], Joshua Ogony[1], Jean R. Clemenceau[2], Tae Hyun Hwang[2], Sarah McLaughlin[3], Derek Radisky[1]

[1]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[2]Department of Artificial Intelligence and Informatics, Mayo Clinic, Jacksonville, FL,[3]Department of Surgery, Mayo Clinic, Jacksonville, FL

Purpose: Black women are disproportionately affected by aggressive breast cancers compared to white women, suggesting underlying biological differences in normal breast tissue. This study aims to identify molecular disparities in normal breast tissue between premenopausal Black and white women that may contribute to increased breast cancer risk.
Experimental Procedures: Visium spatial transcriptomic analysis was performed on a pilot cohort of normal breast tissue samples from premenopausal Black and white women. Tissue sections were spatially profiled, and capture spots were classified based on predominant cell types: epithelial, stromal, or endothelial. Differential gene expression analysis between racial groups was conducted for each cell type classification. Multiplex immunofluorescence (mIF) was used to validate selected markers in the pilot cohort. Meta-analysis compared differentially expressed genes with published gene sets associated with breast cancer subtypes.
Results: Significant racial differences in gene expression profiles were identified in both epithelial and stromal spots. In epithelial spots, genes upregulated in Black women significantly overlapped with over 20 published gene sets associated with estrogen receptor-negative (ER–) breast cancer, including key genes involved in Wnt signaling inhibition (e.g., WIF1) and basal epithelial markers (e.g., KRT14, KRT15). This suggests alterations in pathways linked to more aggressive breast cancer phenotypes. In stromal spots, differentially expressed genes related to extracellular matrix remodeling and fibroblast activation (e.g., PI16, DPT, EFEMP1) were observed, indicating potential differences in stromal-epithelial interactions. Ongoing deconvolution and spatial analyses are being performed to further elucidate these findings. Preliminary mIF validation confirmed increased expression of PI16 in samples from Black women. Validation of additional markers is underway in a larger cohort of premenopausal Black and white women.
Conclusions: Spatial transcriptomic profiling of normal breast tissue reveals distinct molecular differences between Black and white women, particularly in pathways associated with aggressive breast cancer subtypes and stromal interactions. These findings suggest that inherent variations in the normal breast microenvironment may contribute to the increased risk and aggressiveness of breast cancer in Black women. Further validation and analysis may identify potential biomarkers for risk assessment and inform targeted prevention strategies.

#766 Spatial evaluation of tumor sialylation of N-linked glycans in prostate cancer tissues..

Kameisha Rashford[1], Caroline Kittrell[1], Bettina F. Drake[2], Ariana Ahmed[2], Aleksandra Klim[3], Eric Kim[3], Peggi Angel[1], Joseph E. Ippolito[4], Richard Drake[1]

[1]Immunology and Pharmacology, The Medical University of South Carolina (MUSC), Charleston, SC,[2]Institute of Public Health, Washington University, St.Louis, MO,[3]Division of Urology, Washington University, St.Louis, MO,[4]Department of Radiology, Washington University, St.Louis, MO

Aberrant sialylation is a common feature of prostate cancer. Sialylation is part of the co-translational glycosylation machinery, where sialic acids are enzymatically added to glycoproteins as a quality control mechanism to ensure proper protein folding and stability. However, in solid tumors like prostate cancer, this process becomes dysregulated, resulting in hypersialylation. Tumor cells exploit this alteration to mask their identity, evade immune detection, and promote aggressive tumor growth. In humans, α2,3 and α2,6 isomers of N-acetylneuraminic acid are the most abundant species detected in sialylated N-glycans. The presence of α2,6 sialylated glycans is a well-established marker for PCa aggressiveness, while α2,3 sialylation is a known feature of sialyl Lewis x/a tumor antigens. Distinguishing between these isomers is crucial due to their distinct chemical and biological properties, which can offer deeper insights into disease pathology, thus we used N-glycan mass spectrometry imaging to preserve histology and spatial distribution of both sialic acid isomeric species. In this study, we evaluated N-linked sialylated glycans in a large cohort of 381 primary prostatectomy samples in tissue microarray format. A double amidation chemical treatment to differentially add mass tags specific to each isomer was done, followed by matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI). This platform enabled high-resolution spatial analysis of α2,3 and α2,6 sialylated N-glycan isomers in each tumor core. Initial data grouping compared the intensities of 80 sialylated N-glycan isomers across Gleason scores G6 (n = 134), G7[3+4] (n = 181), and G7[4+3] (n = 66). Significant differences in the levels of specific N-glycans were determined between these groups, including upregulation of α2,3-linked tetra-antennary fucosylated glycans, downregulation of bi-antennary α2,3- and α2,6-linked species, and fluctuations in tri- and tetra-antennary glycans of both isomers, suggesting glycan remodeling with tumor advancement. Additional clinical data assessments are ongoing to evaluate sialylation differences associated with tumor stage, race, BMI, age, and other parameters. The combination of double amidation isomer tagging and MALDI-MSI provides a promising advancement in the differentiation and characterization of previously difficult-to-identify sialic acid isomers, enhancing potential applications in prostate cancer diagnostics.

#767 Discovering the geospatial framework in glioblastoma: Uncovering hotspots for glioma stem cell hide-out and their therapeutic implications.

[1]University of Toronto, Toronto, ON, Canada,[2]Qatar University, Qatar, Saudi Arabia,[3]The Hospital for Sick Children, Toronto, ON, Canada,[4]University of Calgary, Calgary, AB, Canada,[5]Princess Margaret Genomic Center, University Health Network, Toronto, ON, Canada,[6]Mount Sinai Hospital, Sinai Health, Toronto, ON, Canada,[7]The Author and Sonia Labatt Brain Tumor Research Centre, The Hospital for Sick Children, Toronto, ON, Canada,[8]Structural Genomics Consortium, Toronto, ON, Canada,[9]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Introduction : Glioblastoma or GBM is an aggressive brain cancer with a 5 year survival rate below 10 percent. Glioma stem cells or GSCs drive GBM formation, growth, and resistance. Previously, analysis of 17,601 phase contrast images from 15 GBM patients revealed that neurodevelopmental GSCs form smaller, uniform clusters, while mesenchymal and injury-response GSCs exhibit complex, irregular growth patterns. This new study examines the spatial distribution and local cellular niche of GSCs along a neurodevelopmental gradient in primary GBM. We develop a geospatial map of GSCs in relation to other cell-types, identifying community patterns of organization.

Methods : We profiled 14 primary, treatment-naive GBM tissue sections (5 micrometer thick) on a spatial transcriptomics platform (Xenium), utilizing a custom 414 gene panel to score the GSC, GBM and other cell signatures. We segmented cell boundaries using both Baysor and Proseg algorithms and performed hematoxylin-eosin (HE) staining of tissue sections post-Xenium run. We performed spatial clustering using SpaGCN and Banksy, followed by spatial distribution and spatial point pattern analysis (Ripley's, Moran's I).

Results : Across the 14 tissues, we segmented 5, 705, 825 cells and annotated each cell with a cell-type label using pre-defined gene sets. This resulted in 15.2 percent GSC-like cells, 9.0% oligodendrocytic-OPC-like, 8.7% astrocytic-mesenchymal-like, 6.7% neuronal-like, 15.0% immune, 7.1% endothelial, and the rest of the cells showing mixed signatures. In total we identified 110-140 spatial clusters, which we classified into 8 domains by grouping highly correlated spatial clusters using Pearson correlation.

All cell-types were differentially distributed both proportionally and spatially. Domains with highly correlated grouped clusters exhibited distinct spatial arrangements of cells as well. For instance, GSC-like cells were confined to unique spatial domains with specific geometric properties across cellular hierarchies. Likewise, immune and endothelial cells displayed enrichment in preferred domains, with some co-localized with GSC-enriched regions while others were devoid of these cell types. Therefore, we find that these geospatial topology maps could identify spatial enrichment patterns and distributional trends.

Conclusions : This study deciphers GBM's geospatial topology, where annotated cell-types are mapped to specific niches. Though the ultimate aim of the study will be to eliminate GSC-like cells in GBM, we posit that by revealing cell community patterns, we aim to shift therapeutic strategies from targeting single cells or molecules to biomarkers that address entire cell communities within which these GSCs are spatially and functionally connected to. This framework lays the groundwork for future biomarker discovery and therapeutic interventions in GBM.

#768 Decode the antibody-drug conjugate surfaceome in metastatic urothelial cancer (DECODE-ADC).

C. Kuppe[1], N. Klumper[2], O. Goni[1], P. Kie?ling[1], E. Scheidereit[1], S. Samiei[1], T. Buttner[2], F. Zengerling[3], N. Gaisa[3], C. Bolenz[3], M. Toma[2], S. Zschabitz[4], V. Grunwald[5], M. Holzel[2], M. Iyer[6], N. Kashikar[6], M. Eckstein[7];
[1]University Hospital RWTH Aachen, Aachen, Germany, [2]University Hospital Bonn, Bonn, Germany, [3]University Hospital Ulm, Ulm, Germany, [4]University Hospital Heidelberg, Heidelberg, Germany, [5]University Hospital Essen, Essen, Germany, [6]OMAPiX, Frederick, MD, [7]University Hospital Erlangen, Erlangen, Germany

Background: Antibody-drug conjugate (ADC) therapies like Enfortumab Vedotin (EV), targeting NECTIN4, are transforming cancer treatment, particularly for metastatic urothelial cancer (mUC). While single-agent EV and EV in combination with immunotherapy show promising results, long-term benefits are limited to a subset of patients, underscoring the challenges associated with its non-selective application. All-comer application of EV raises concerns about toxicity and cost, highlighting the necessity for more personalized approaches. ADCs targeting other tumor antigens, such as HER2, HER3 and EGFR, are in late-stage clinical development, emphasizing the importance of understanding spatial molecular target distributions in patient tissues. Spatial multi-omics and single cell technologies applicable to patient tissues like formalin fixed paraffin embedded tissue (FFPE) open the possibility to unlock these spatial molecular profiles which ultimately could be used to identify companion diagnostic biomarkers and providing valuable insights into tumor microenvironment heterogeneity to optimize treatment efficacy and minimize off-target effects.
Methods: The DECODE-ADC project integrates single-cell and spatial multi-omics data from FFPE tissues of EV-treated patients, encompassing matched pairs of primary tumors and metastatic biopsy from a cohort of 20 patients. Single-nucleus RNA sequencing and high-resolution spatial transcriptomics were used to profile various ADC targets with additional markers of the tumor microenvironment and drug resistance (over 5000 gene panels). To bridge translational gaps, we employed machine learning (ML) models, such as variational autoencoders, to predict molecular signatures from routine Hematoxylin and Eosin (H&E) stainings, enabling cost-effective clinical application.
Results: Using spatial single-cell multiomics, we identified novel spatial domains regulating ADC target expression and delineated tumor microenvironment-specific signals. Unique molecular signatures distinguished luminal from basal urothelial cancer subtypes, revealing conserved microdomains across metastatic sites. Importantly, machine learning models transferred high-resolution molecular insights to H&E images, enabling precise, scalable predictions of ADC target distribution.
Conclusions: DECODE-ADC provides unprecedented insights into the spatial dynamics of ADC targets within the tumor microenvironment of mUC. By integrating advanced molecular profiling with ML-driven predictions, this study advances our understanding of ADC target expression and establishes a pathway for rational biomarker selection Our findings propose a foundation for precise ADC biomarker development and stratification strategies to improve treatment ADC responses, which ultimately paves the way for ADC precision oncology.

#769 Spatial proteomics and transcriptomics reveal an altered immune cell landscape in bladder cancer patients unresponsive to BCG treatment.

Trine Strandgaard[1], Tine Ginnerup Andreasen[1], Tessa Jane Divita[1], Liina Salminen[1], Sean Houghton[2], Kasper Thorsen[1], Iver Nordentoft[1], Iyinyeoluwa Okulate[3], Alexander Schmitz[4], Soren Riis Paludan[4], John Sfakianos[3], Amir Horowitz[3], Jorgen Bjerggaard Jensen[1], Lars Dyrskjot[1]

[1]Aarhus University Hospital, Aarhus, Denmark,[2]Weill Cornell Medicine, New York, NY,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]Aarhus University, Aarhus, Denmark

Introduction: Patients with high-risk non-muscle invasive bladder cancer (NMIBC) are recommended treatment with Bacillus Calmette-Guérin (BCG). The therapeutic effect of BCG is highly dependent on the host immune system and the tumor microenvironment (TME). The cellular composition and the functional status of the TME have been shown to play crucial roles for treatment efficacy. However, much is still unknown regarding the cellular interactions and mechanisms of BCG. Using spatial proteomics and transcriptomics we investigated the immune cell landscape in a cohort of BCG treated patients.

Materials and methods: A total of 150 tumors from 105 patients with NMIBC treated with BCG were included on a tissue microarray (TMA). The TMA included paired pre- and post-BCG tumors. We analyzed the tumor tissue using Imaging Mass Cytometry (IMC; StandardBioTools) for simultaneous detection of 35 immune and tumor-related proteins at single cell resolution. Ilastik was used to generate probability maps and DeepCell Mesmer was used for cell segmentation. Markers were quantified for the mean intensity per cell. The GeoMX Digital Spatial Profiling (DSP) was used for spatial proteomics and transcriptomics profiling of tumor and stromal areas, targeting 63 protein targets and whole transcriptome amplification, respectively.

Results: After computing a neighborhood graph using the log normalised and z-scaled signal and embedding it using UMAP, leiden clustering was performed on 360,673 cells to detect communities of unique cell types by interrogating the presence of phenotypic markers. We identified major lineages such as macrophages, CD8 T cells, dendritic cells, natural killer (NK) cells and neutrophils in the TME of analyzed tumors. We observed more macrophages, CD4 T cells and CD8 T cells after BCG (p=0.02, p<0.001 and p=0.004, respectively) and similarly, we found enrichment of cellular neighborhoods composed of immune cells after treatment. Patients who progressed to muscle-invasive bladder cancer after BCG had higher numbers of CD4 T cells, CD8 T cells and NK cells prior to BCG (p=0.034, p=0.023 and p<0.001, respectively). Prolonged exposure to interferons has been associated with immune evasion and tumor cell proliferation. In concordance, we found high pretreatment expression of interferon signaling pathways in tumor regions from patients with a signature of CD8 T cell exhaustion after BCG using GeoMx DSP transcriptomic analysis.

Conclusion: The composition and functional status of the TME is associated with clinical and biological features such as immune cell abundance, CD8 T cell exhaustion, and progression. A greater understanding of the TME may help identify patients unresponsive to BCG and improve the understanding of biological differences in tumor development and aggressiveness ultimately improving patient outcomes.

#770 ccRCC metastasis rewires tumor microenvironment to increase immunosuppression and fibrosis.

Yufei Wang[1], Jae-Won Cho[2], Yasmin Nabil Laimon[2], Wenxin Xu[1], Aseman Bagheri Sheshdeh[2], Nithyassree Murugan[1], Hsien-Chi Yuan[1], Jon Wee[2], David Braun[3], Toni Choueiri[1], Catherine Wu[1], Sabina Signoretti[2], Gordon Freeman[1], Martin Hemberg[2], Wayne Marasco[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]Yale School of Medicine, New Haven, CT

Tumor progression and metastasis is driven by interplays between cancer cells and their surrounding tumor microenvironment (TME). Investigating the spatiotemporal transcriptomic profile of primary and metastatic tumors sheds light on how the differences in spatial architecture shape the TME and promote tumor metastasis. Here, we profiled three primary and three lung metastatic clear cell renal cell carcinoma (ccRCC) samples using the CosMx platform, which provides a 999-gene transcriptome with spatial coordinates. After cell segmentation and annotation, we further incorporate the cellular context and spatial information to identify niches by grouping the cells with similar neighboring cells. Cell-cell communication and architecture were analyzed to understand the spatial organization in primary and metastatic ccRCC. From niche analysis, 12 distinctive niches were identified, including cancer, stroma, alveolar, tertiary lymphoid structure (TLS), and mast niches, formed by 25 different cell types. Analyzing cancer niches, we found that the metastatic TME is much more immunosuppressive compared to the TME in primary ccRCC. There is a higher infiltration of exhausted T cells, Treg and M2-like macrophages in metastases. Moreover, the fibroblasts in metastases have higher expression of VEGF and metalloproteinases, which led to angiogenesis and worse prognosis. Architecture analysis showed that lung metastatic ccRCC cells, surrounded by a stromal barrier, are not directly interacting with tumor infiltrating leukocytes (TILs), whereas primary ccRCC cells interact more with TILs. Moreover, compared to the TLSs in primary ccRCC, the ones in metastases showed features of dysfunction, which was correlated with a worse prognosis. Our results show the impact of spatial architecture on primary and metastatic ccRCC, as well as the relation between spatial organization of the cellular context and cell-cell communication. In addition, it suggests that immune cells and cancer-associated fibroblasts (CAFs) are essential components of the ccRCC TME. Their interaction constitutes a major factor not only for tumor progression but also limiting therapy response in metastatic ccRCC.

#771 Spatiotemporal evolution of the tumor microenvironment predicts treatment response in phase II trial of neoadjuvant chemotherapy for resectable pancreatic cancer.

Choong-kun Lee[1], Changjin Hong[2], Ho Kyoung Hwang[3], Min Hwan Kim[1], Jean Rene Clemenceau[4], Seock-Jin Chung[4], Isabel Barnfather[4], Sumanth Reddy Nakkireddy[4], Jeong Hwan Park[5], Ji-Youn Sung[6], Minji Kim[4], Yooho Choi[4], Inyeop Jang[4], Sunho Park[4], Sung Hyun Kim[3], Chang Moo Kang[3], Hye Jin Choi[1], Tae Hyun Hwang[4]

[1]Division of Medical Oncology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]KURE.AI, Seoul, Korea, Republic of,[3]Department of Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Department of Artificial Intelligence and Informatics, Mayo Clinic, Jacksonville, FL,[5]Department of Pathology, SMG-SNU Boramae Medical Center, Seoul National University College of Medicine, Seoul, Korea, Republic of,[6]Department of Pathology, College of Medicine, Kyung Hee University hospital, Kyung Hee University, Seoul, Korea, Republic of

Background: Understanding the spatiotemporal dynamics of the tumor microenvironment (TME) during treatment is crucial for improving outcomes in pancreatic ductal adenocarcinoma (PDAC). This study presents a pre-planned spatiotemporal analysis from a phase II trial evaluating neoadjuvant mFOLFIRINOX in resectable PDAC, aimed at elucidating treatment resistance mechanisms and identifying predictive biomarkers.
Methods: This multi-institutional, single-arm phase II trial enrolled treatment-naïve patients with histologically confirmed resectable PDAC (NCT05066802) who underwent six cycles of neoadjuvant mFOLFIRINOX followed by surgery. The primary endpoint was the R0 resection rate. Matched pre-treatment tumor biopsies and post-treatment surgical specimens were analyzed from selected responders (R) and non-responders (NR) using high-resolution spatial transcriptomics (10X Genomics Visium). This approach enabled comprehensive mapping of TME evolution and treatment-induced changes.
Results: Between May 2020 and February 2022, 27 patients were enrolled. Of these, 24 patients underwent surgery after neoadjuvant treatment (resection rate: 88.9%), and 23 achieved R0 resection (85.2%), meeting the primary endpoint. However, 20 resected patients (83.3%) recurred. Spatiotemporal analysis was performed on matched samples from four R and four NR. In pre-treatment samples from NR group, clusters dominated by fibroblasts (enriched for ECM, EMT, and CAF phenotypes) and B cell subtypes were distinct compared to R group, which exhibited elevated antibody responses and robust T cell and macrophage activity. NR samples showed increased IgM expression but lacked corresponding Fc receptors, suggesting limited immune effector function. Post-treatment NR surgical specimens displayed elevated expression of MUC5AC and CEACAM6 in malignant ductal cells, alongside genes promoting tumor growth. Neoadjuvant mFOLFIRINOX increased fibroblast, while reducing immune cell components. NR tumors formed distinct "resistance niches" after chemotherapy, marked by ECM production, CAF activation, and RTK signaling. Conversely, R tumors showed enhanced epithelial organization with increased type-I hemidesmosome complexes facilitating epithelial adhesion to the basement membrane.
Conclusion: Three months of neoadjuvant mFOLFIRINOX was feasible and tolerable for resectable PDAC but associated with high recurrence rate, emphasizing the need for better patient selection. Spatiotemporal analysis revealed critical differences in TME dynamics according to treatment response, including the emergence of resistance niches and distinct pre-treatment spatial signatures. These findings support the integration of spatial biology into future pancreatic cancer trials to improve stratification and therapy.

#772 Spatial analysis of the DLBCL tumor microenvironment via the novel SignalStarTM multiplex immunohistochemistry assay.

Jennifer Ziello[1], Shuling Zhang[2], Derek Papalegis[1], Lily Vu[1], Gabriella Spang[1], Jean Loebelenz[1], Arvin Ruiz[3], Giorgio Inghirami[3], Sarah Klein[1]

[1]Cell Signaling Technology, Inc., Danvers, MA,[2]Visiopharm (Registered Trademark), Horsholm, Denmark,[3]New York Presbyterian Hospital Weill Cornell, New York, NY

Diffuse Large B-Cell Lymphoma (DLBCL) is the most common type of non-Hodgkin lymphoma, accounting for more than 18,000 cases each year within the United States. While roughly 60% of patients with DLBCL achieve durable remissions with existing chemotherapies, the prognosis of patients with refractory DLBCL is poor. The immune landscape of DLBCL is complex and further elucidation of the interplay between T cell activation and immunosuppression within the tumor microenvironment (TME) is necessary in order to better stratify patients and predict outcomes for therapy. This complexity, as well as the relevance of the spatial context of the various cell types within the TME necessitate the ability to simultaneously visualize biomarkers and phenotypic markers via multiplex immunohistochemical (mIHC) assays. Here, we construct a 12-plex SignalStar mIHC panel consisting of T cell phenotypic, activation and suppression markers in order to characterize the TME of FFPE DLBCL cores. We visualize immuno-oncology markers in the context of the tumor and myeloid cells, as defined by CD68. In this assay, all 12 antibodies are applied in one primary incubation, followed by the addition of a network of fluorescently-labeled oligonucleotides used to amplify the signal of 4 antibody-oligo conjugates across 3 rounds of imaging. Following amplification and imaging of the first 4 conjugates, the fluorescent signal was enzymatically removed and the process repeated for two more rounds. The three resulting images were then aligned using Visiopharm's Tissuealign^{TM} platoform. Quantitative analysis, including positive cell counts and marker co-localization, was conducted with Visiopharm's Phenoplex^{TM}. Biomarker expression patterns were also examined using Phenoplex^{TM}. Finally, we correlated these data with patient demographics, disease progression, and treatment responses. Our data demonstrate that the SignalStar mIHC assay is a powerful tool in the elucidation of the complex immunosuppressive TME, enabling researchers to better understand the responses to immunotherapeutic approaches and chemotherapy combination strategies.

#773 High-throughput in situ multiomic profiling of kidney, lung, colon, and breast cancer FFPE samples for profiling of tumor-immune interactions.

Kenneth H. Gouin, Michael Lawson, Andrew Pawlowski, Sabrina Shore, Yuji Ishitsuka, Daan Witters, Eli N. Glezer

Singular Genomics Systems Inc., San Diego, CA

Molecular level spatial profiling of tissue provides crucial insights into tumor biology and immunotherapeutic responses. The G4X Spatial Sequencer, our innovative platform, facilitates extensive translational studies by simultaneously detecting RNA transcripts, proteins, and H&E staining in FFPE tissues. Capable of imaging up to 40 cm^2 of tissue in a single run, it significantly enhances throughput compared to traditional methods and enables 3D reconstruction from serial sections in one run. We designed ~300-gene transcript panels for each of four tissue types: kidney, lung, colon, and breast, with an emphasis on immuno-oncology relevant targets. The panels share a common set of 150 immuno-oncology and 50 stromal genes. Each panel also includes a set of ~100 tissue-specific genes to profile cell types, cancer pathways and tumor microenvironment. We imaged gene and protein expression in 5-µm thick sections of human kidney, lung, colon, and breast, from both healthy and cancer FFPE tissue samples. Using a novel tissue transfer process, we arrayed multiple tissue sections in two formats: a large sample format (10 mm x 10 mm) with 10 sections/slide, and a small sample format (4.5 mm x 4.5 mm) with 32 sections/slide. Each slide was analyzed in three modalities (RNA, proteins, fluorescent H&E). Following antibody staining, probe binding and amplification of targets, images were acquired using 4-color SBS readout, followed by nuclear and cytoplasmic staining to generate a fluorescence-based H&E stain. In FFPE cancer samples and healthy controls, we detected an average of 50-200 transcripts/cell and 20-50 unique genes/cell, with the dynamic range extending to > 500 transcripts/cell. Using 6 rounds of priming, we achieved high transcript density profiling while maintaining a false discovery rate of ~1%. Strong correlation between single-cell transcript and protein expression profiles confirmed specificity of each modality. Comparison across serial sections showed strong concordance in expression profiles for both modalities, demonstrating robust reproducibility. We also show the assembly of serial sections to reconstruct a 3D tumor volume. Finally, we identified distinct tumor-associated cellular phenotypes and spatial neighborhoods using a novel multi-modal graph-based clustering method leveraging RNA, protein, morphology, and spatial information.

#774 Deciphering the biology of colorectal metastasis to the peritoneal surface.

Shahid Umar, Badal C. Roy, Amrita Mitra, Jill Haley, Harsh B. Pathak, Andrew K. Godwin, Luke V. Selby, Mazin Al-Kasspooles

General Surgery, University of Kansas Medical Center, Kansas City, KS

Background. Colorectal cancer (CRC) is the third most frequently diagnosed cancer with an annual incidence of 1.4 million new cases and 700,000 deaths worldwide. The high death toll of CRC patients is due to metastatic disease with liver being the preferred site of metastasis (LM), followed by lung and peritoneal metastasis (PM). Roughly 25% of CRC patients present with, or will eventually develop PM, and while survival for LM and lung metastasis has significantly improved over time, survival following PM remains poor. Mucinous and non-mucinous adenocarcinoma have different propensity to form PM or LM, and surprisingly little is known about the biology of CRC PM. Aims and

Objectives. To perform deep mapping using Nanostring's GeoMx Cancer Transcriptome Atlas assay to measure gene expression in resected normal colon (healthy) primary tumors (primary), LM, and PM samples collected from the KUMC Biospecimen Repository. Morphological staining using Pan-cytokeratin, CD45, & ELA2 was performed to identify epithelial tumor cells, immune cells, and neutrophils, respectively. Data processing and resulting DCC files were imported to the GeoMx DSP software for statistical analyses of the transcriptomic data using a linear mixed model.

Results. We performed spatial transcriptomic analysis on paired tissue samples (surgical tissue from primary and metastatic sites) from 4 patients with stage IV CRC. Our results unveiled diverse gene expression patterns across different PM and LM tumor sub-regions. Cluster analysis revealed significant differences in gene expression between specimen types. Specifically, in mucinous adenocarcinoma samples, *PKM*, *CEACAM6* and *LYZ* were upregulated in primary tumors while *ADH1A/B/C*, *Muc4* and *PCK1* were upregulated in healthy tissues. Interestingly, we also observed significant upregulation of *CEACAM6* and *SERPINA1* in PM vs primary tumor cells. In non-mucinous adenocarcinoma, *CEACAM6* and *H3C2/10* were upregulated in primary vs metastatic tissues. When comparing either primary or metastatic vs healthy stromal areas, *COL1A1* and *COL6A3* were significantly upregulated in primary and or metastatic regions hinting at extracellular matrix remodeling during PM. In LM, *CEACAM6*, *SLC1A5* and *CD74* were significantly upregulated when compared to PM, indicating an inflammatory role in LM. As neutrophil extracellular traps (NETs) promote metastasis, we discovered significant infiltration of ELA2+ neutrophils in the primary mucinous adenocarcinoma while ELA2+ cells were predominantly localized at the leading edge of the non-mucinous adenocarcinoma. These spatio-temporal relationships were further validated in the metastatic sites of the two CRC subtypes.

Conclusions. Mucinous vs non-mucinous adenocarcinomas differ in terms of their proclivity to metastasize to the peritoneal surfaces and that the differences could be attributed to the intra-tumoral vs leading edge distribution of ELA2+ neutrophils.

#776 Identifying gene expression patterns in intraductal carcinoma of the prostate using spatial gene expression analysis: Potential for new biomarkers and treatments.

R. Watanabe[1], H. Arai[1], M. Kurata[1], N. Miura[1], R. Kitazawa[2], T. Kikugawa[1], T. Saika[1];
[1]Ehime University Graduate School of Medicine, Toon, Japan, [2]Ehime University Hospital, Toon, Japan

Introduction and Objective: Intraductal carcinoma of the prostate (IDC-P) is a form of prostate cancer where abnormal cells grow inside the ducts and glands, while the outer basal cell layer stays intact. IDC-P is often linked to certain genetic changes, including TMPRSS2-ERG fusions, as well as mutations or deletions in key genes like TP53, RB1, and PTEN. Given these findings, NCCN guidelines advise early genetic testing for IDC-P patients. Correctly diagnosing IDC-P and applying this knowledge to tailor treatments is essential for improving patient outcomes.
Methods: We performed spatial gene expression analysis (using CytAssist Visium) on prostate cancer tissue samples with IDC-P. The goal was to identify gene abnormalities that could help in diagnosing IDC-P or serve as targets for future treatments. We analyzed how gene expression was distributed in IDC-P regions compared to other parts of prostate cancer tissue.
Results: Our analysis showed that IDC-P regions had a unique gene expression profile, distinct from other prostate cancer areas. Specific genes such as MUC6, MYO16, NPY, and KLK12 were highly expressed in IDC-P, and these genes are associated with more aggressive cancer behavior. Additionally, genes related to hypoxia like HIF1A, BNIP3L, PDK1, and POGLUT1 were highly upregulated in IDC-P areas. At the same time, markers for immune cells (CCR5, FCGR3A) and fibroblasts (CCL5, TRAC) were downregulated. This suggests that IDC-P may be more aggressive due to hypoxia and fewer immune and fibroblast cells in the tumor environment.
Conclusions: This study used spatial gene expression analysis to characterize IDC-P (Watanabe et al., IJMS 2024), providing valuable insights. However, this method also has some challenges, such as capturing signals from different cell types in the same spots, which makes it harder to distinguish between them. In future studies, combining spatial gene analysis with single-cell RNA sequencing or using more advanced techniques like Xenium could address these challenges. We are currently working on those studies and will be able to present the latest data on the day of the presentation. These approaches may help identify new diagnostic markers and lead to more personalized treatment options for patients with IDC-P.

#777 Revealing the transcriptional and proteomic spatial neighborhoods of early prostate cancer and the tumor microenvironment.

Anna Y. Lee[1], Megan Hopkins[1], Linda Liao[1], Vida Talebian[1], Tamara Jamaspishvili[2], David M. Berman[3], Melanie Spears[1], Jane Bayani[1]

[1]Diagnostic Development, Ontario Institute for Cancer Research, Toronto, ON, Canada,[2]Department of Pathology & Laboratory Medicine, SUNY Upstate Medical University, Syracuse, NY,[3]Department of Pathology & Molecular Medicine, Queen's University, Kingston, ON, Canada

Intermediate-risk prostate cancer (PCa) poses a challenge for treatment decisions, made more complex by its heterogeneous nature. Growing evidence highlights the critical role of the tumor microenvironment (TME), in cancer initiation, progression, and response to treatment, underscoring the importance of profiling cancer cells but also the TME within their spatial context. Here, we present single-cell *in situ* transcriptomic and spatial proteomics results from 300 intermediate-risk PCa prostatectomy samples. Multiple regions of the prostate, including regions of the index lesion, secondary lesions, regions of benign and normal were sampled then analyzed using Bruker's CosMx SMI platform for a 6000-plex RNA assay in a subset of patients; in addition to proteomic profiling using the GeoMx DSP platform. Clustering assigned cells into 15 cell types based on their transcriptional profiles. Each cell type was tested for significantly different proportions in tumor versus non-tumor samples. The cell type with the greatest bias had a 9-fold greater proportion in tumor samples (adjusted $P < 0.01$). ERG, largely associated with the TMPRSS2-ERG fusion in PCa, was most specifically expressed in cells of this type. Conversely, the cell type with the greatest bias towards non-tumor samples (3-fold greater proportion, adjusted $P < 0.01$) is characterized most specifically by the expression of MSMB, which encodes an immunoglobulin binding factor previously found to have decreased expression in PCa. Other evidence of intratumoral heterogeneity was found in samples that are not dominated by these stereotypical cell types. For example, a relatively higher-grade sample from an index tumor possessed high proportion of the tumor-dominant cell type whereas a relatively lower-grade sample from the same tumor did not. Similarly, the tumor and non-tumor samples arising from the same patient showed similar cell type composition, highlighting inter-patient heterogeneity. Moreover, we identified proteins with significantly different expression in tumor versus non-tumor samples. In the TME, EpCAM and CD56 were significantly overexpressed and underexpressed in tumor versus non-tumor regions, respectively (adjusted $P < 0.01$). In the epithelium, cleaved caspase-9, which initiates the caspase cascade leading to apoptosis, was the most significantly underexpressed protein in tumor samples (adjusted $P < 0.01$). However, the expression of the mRNA encoding caspase-9 is not highly correlated with the expression of cleaved caspase-9, highlighting the added benefit of protein expression profiling. Taken together, this multi-modal spatial analysis of multiple samples from the same PCa patients facilitates a detailed understanding of early PCa for biomarker discovery and pathways of therapeutic intervention.

#778 Profiling the immune landscape of CDK4/6 inhibitor intrinsic resistance among metastatic HR+ breast cancer.

Haoting Shi[1], Zheshen Han[2], Xue Wang[1], Yufei Wang[3], Chao Hu[1], Ruixin Pan[1], Xiaosong Chen[1], Qing Qu[1], Rong Cai[1], Kunwei Shen[1]

[1]Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China,[2]The University of Hong Kong, Hong Kong, Hong Kong,[3]Shanghai Jiao Tong University School of Medicine, Shanghai, China

Cyclin-dependent kinases 4/6 (CDK4/6) inhibitor is a standard-of-care for hormone receptor-positive/human epidermal growth factor receptor 2 negative metastases breast cancer (HR+/HER2- mBC), while substantial proportion of patients suffer from intrinsic resistance (IR), and the mechanism at the spatial level remains unclear. A total of 10 eligible HR+/HER2- mBC patients (age: median age 63, range 40-67 years) with liver metastases who underwent liver biopsies and received CDK4/6 inhibitor were included. The majority (N = 7, 70%) were of first-line treatment at metastatic disease settings and in combination with fulvestrant (N = 9, 90%). After a median follow-up of 22.2 months, four patients were determined as IR, with a median PFS of 4.2 months. We collected formalin-fixed paraffin-embedded samples from these patients and spatially profiled the expression of more than 570 proteins across tumor (panCK+), immune (CD45+), and cancer-associated fibroblast region (CAF, α-SMA+) regions, respectively using the GeoMx Digital Spatial Profiler (DSP) platform. The differentially expressed proteins (DEPs) were identified and GSEA analyses were performed. Elevated expression of MHC I proteins (HLA B7 and HLA E), extracellular matrix (ECM)-associated protein (FAK, Fibronectin, and Periostin), antioxidant-associated proteins (NQO1 and G6PD), and mucin-related proteins (Muc5AC and Muc1) were observed in tumor regions (all FDR < 0.05) among IR patients. Similarly, HLA B7, Fibronectin, MucAC5 and NQO1 were found to be overexpressed in CAF region. The proteins associated with the target of CDK4/6 inhibitor were down-regulated among IR patients [NF-kB p105, CK8 (phosphor S431), and Cyclin D1], suggesting that the IR could be partially explained by loss-of- drug-target. Meanwhile, downregulation of Caveolin-1 and CD63 were identified in CAF regions, while downregulation of HLA-DR and MHC II proteins were observed in immune regions. GSEA results showed that MHC I antigen presentation pathway was significantly upregulated in CAF regions (NES 1.87, FDR 0.016), while TGF-beta pathway and autophagy pathway were significantly downregulated in CAF regions (NES -1.77 [FDR 0.016] and -1.84 [FDR 0.040], respectively). These findings suggested that IR might be driven by the immune escape associated with CAFs. Our results showed that Bcl-2 expression in tumor region has the highest value in predicting IR (AUROC 0.989). Leveraging high-plex spatial proteomics data from HR+/HER2- mBC patients, the IR of CDK4/6 inhibitor might be associated with loss-of-target in tumor cells, immune escape driven by CAFs, and alterations in the ECM.

[1]Duke University Medical Center, Durham, NC,[2]University of Pittsburgh, Pittsburgh, PA,[3]University of North Carolina, Chapel Hill, NC

Small nucleolar RNAs (snoRNAs) are a class of ncRNAs that canonically guide post-transcriptional modifications, including 2'-*O*-methylation, on ribosomal RNA (rRNA) and small nuclear RNA (snRNA). While traditionally considered housekeeping genes, snoRNAs have increasingly been found to function in diverse physiologic and pathologic processes, including cancer. In an immune-competent murine model of triple negative breast cancer (TNBC) lymphatic metastasis, we identified the snoRNA Snord67 as one of the most upregulated noncoding RNAs in axillary LN (AxLN) tumors relative to mammary fat pad (MFP) tumors and lung metastases. Loss of Snord67 resulted in decreased colony formation and spheroid size in murine and human TNBC cell lines, and led to decreased lymph node tumor growth and decreased distant metastases in two immune-competent murine models of TNBC lymphatic dissemination. To determine the mechanism by which Snord67 promotes tumor growth and metastasis, we examined the impact of Snord67 on 2'-*O*-methylation, gene expression, and alternative splicing. Loss of Snord67 in TNBC cell lines led to decreased 2'-*O*-methylation at the C60 nucleotide (Cm60) in the core spliceosome component U6 snRNA. Re-introduction of wild-type Snord67 rescued Cm60 in U6 snRNA and rescued the colony formation and spheroid phenotypes of the Snord67 knockout cell lines. However, a mutant Snord67 incapable of guiding U6 Cm60 only partially rescued these *in vitro* phenotypes, suggesting that Snord67 promotes *in vitro* tumor cell growth at least in part by guiding Cm60 in U6 snRNA. We then performed RNA sequencing of Snord67 knockout and wild-type murine and human TNBC cell lines. We found that loss of Snord67 led to widespread changes in alternative splicing, consistent with its role in guiding 2'-*O*-methylation of the core spliceosome component U6. We further demonstrated that the inclusion of alternatively spliced cassette exons in *MYO18A* and *NFYA* was not only downregulated upon Snord67 knockout in a human TNBC cell line, but also positively correlated with Snord67 expression levels in primary breast tumors and lymph node metastases from breast cancer patients. Based on these results, we propose a model in which Snord67 guides U6 Cm60, which leads to a pro-metastatic alternative splicing program and thereby promotes lymph node tumor growth and distant metastasis.

#782 Mapping therapy-related clonal hematopoiesis across immune cell populations in long-term survivors of pediatric cancer by single-cell multi-omics profiling.

Sivaraman Natarajan, Nadezhda V. Terekhanova, Kohei Hagiwara, Bensheng Ju, Li Dong, Zhaoming Wang, Jinghui Zhang, John Easton

St. Jude Children's Research Hospital, Memphis, TN

Recently we and others reported high prevalence of clonal hematopoiesis (CH) in long-term survivors of pediatric cancers by performing ultra-deep panel sequencing of peripheral blood samples, a phenomena significantly associated with exposures to radiotherapy and chemotherapeutic agents. Motivated by a preliminary finding that a therapy-related *STAT3* CH mutations were highly enriched in T-cells of 3 Hodgkin's Lymphoma (HL) survivors, we initiated a systematic investigation to map the CH mutations across different immune cells populations. Blood samples of 108 survivors of 13 pediatric cancer types (4 hematological, 8 solid and 1 central nervous system (CNS) tumor types), known to harbor CH mutations discovered by prior bulk sample analysis, were selected for multi-omics single-cell profiling with Mission Bio Tapestri assay. For mutation screening, we designed a panel of 29 amplicons across 12 genes, covering 52 CH mutations detected in bulk samples. Amongst the 23 completed samples, we identified 99 mutations in CH-genes (*DNMT3A*, *STAT3*, *TP53*, *KRAS*, *TET2*, and *ASXL1*), and 67.7% of those were found in all cell types and the rest were present in at least two cell types. We discovered that a subset of CH mutations was enriched (FDR < 0.05) in certain cell types across several samples. For example, *STAT3* Y640F mutations were consistently enriched in CD8 T-cells in 6 out of 7 HL samples with a mean fold change of 18.5. *DNMT3A* mutations were enriched in cells from both myeloid (monocytes) and lymphoid (CD4/8 T-cells and NK-cells) lineages and affected samples from five cancer types. Specifically, we found that *DNMT3A* mutations were enriched in monocytes in 2 HL and 2 acute lymphoblastic leukemia (ALL) cases with an average fold change of 2.3; and in CD8 T-cells in 5 samples from Wilms tumor, soft tissue sarcoma, ALL, HL, and CNS with an average fold change of 4.9. *KRAS* L19F was found to be enriched in monocytes and NK-cells in an ALL sample. By contrast, we observed a uniform distribution of some *TP53* mutations across all cell types, suggesting that they confer comparable selective advantage across all immune cell types, consistent with the biological function of TP53 in cell cycle. To our knowledge, this is the first large-scale multi-omics single-cell profiling of CH mutations in long-term survivors of pediatric cancer. The differential clonal expansion in immune cell populations demonstrates the potential impact of CH mutations on immune cell dysfunction. This suggests that CH mutations may contribute to long-term adverse health outcomes related to the immune system in long-term survivors beyond the direct cause of secondary neoplasms, which will warrant future investigations using the valuable data resource established through this study.

#783 Estrogen Receptor Alpha (ERα) is critical for the maintenance of mitochondrial form and function in the prevention of anthracycline-induced cardiotoxicity.

T. K. King III, N. L. Yang, A. Singh, P. H. Tran, A. Ma, E. Yim, W. C. Tai, E. H. Yang, A. Hevener;
University of California Los Angeles, Los Angeles, CA

Cancer remains a leading cause of mortality in the United States, and women's cancer risk increases after menopause. Anthracyclines (e.g., doxorubicin) are widely used in cancer treatment but their therapeutic value is limited by anthracycline-induced cardiotoxicity (AIC), which can promote irreversible cardiac damage and heart failure. 17-β-estradiol protects against cardiac injury in ovariectomized rodents treated with anthracyclines, thus, we hypothesized that estrogen receptor (ER) α may play a role in safeguarding against AIC. Even without AIC, cardiomyocellular-specific deletion of ERα impairs mitochondrial form and function. This is accompanied by increased fibrosis and reduced cardiac ejection fraction, as determined by echocardiography. Transmission electron microscopy of hearts from ERα knockout mice revealed a marked reduction in mitochondrial cristae density. These cristae are essential structures of the inner mitochondrial membrane, serving as the primary sites for electron transport chain protein localization and oxidative metabolism required for ATP production. Microscopy findings were further supported by RNA sequencing, which indicated differences in the expression of transcripts associated with ATP biosynthesis, oxidative phosphorylation, and mitochondrial respiratory chain complex assembly in the hearts of ERα knockout mice compared to ERα-replete controls. Complementary analysis using Seahorse respirometry on frozen tissue demonstrated a marked reduction in complex I oxygen consumption in ERα knockout mice. With the phenotype observed in heart-specific ERα knockout mice, we hypothesized that doxorubicin-treated HL-1 cardiomyocytes lacking ERα would display increased cell death compared to control cells due to further impairment of mitochondrial function. Indeed, doxorubicin treatment induced a higher rate of cell death in ERα knockout cells vs. control. Key proteins involved in mitochondrial remodeling and mtDNA replication, including Mitofusin 1 (MFN1), Mitofusin 2 (MFN2), Optic Atrophy 1 (OPA1), Dynamin-Related Protein 1 (DRP1), DNA Polymerase Gamma (POLG), Mitochondrial Contact Site and Cristae Organizing System Subunit 25 (MIC25), and Peroxisome Proliferator-Activated Receptor Gamma Coactivator 1-Alpha (PGC1α), were significantly reduced in non-treated ERα knockout HL-1 cells compared to cells with ERα. Combining these findings with the observation that ERα overexpression enhances mitochondrial cristae density, the expression of key mitochondrial-related targets, and mtDNA copy number, our results collectively suggest that ERα is essential for mitochondrial function in the heart and could serve as a therapeutic target to protect against AIC.

#784 Cardiovascular disease mortality surpasses cancer mortality in patients with renal cell carcinoma: A U.S. population-based cohort study.

Zhengyi Deng, Minji Jung, Jinhui Li, Mingyi Li, Marvin E. Langston, Benjamin I. Chung

Stanford University School of Medicine, Stanford, CA

Background: Cardiovascular disease (CVD) is the leading cause of non-cancer death among patients diagnosed with renal cell cancer (RCC). There is limited evidence on how CVD and RCC death rates change over time since RCC diagnosis, and evidence on potential risk factors associated with short-term and long-term CVD and RCC deaths.
Methods: This population-based cohort study used data from the Surveillance, Epidemiology, and End Results Program (SEER, 2004-2020). We included adult patients (aged ≥18 years) diagnosed with a first malignant RCC from 2004 to 2019, who survived at least one year since their cancer diagnosis. Poisson regression with natural cubic spline was used to model the trends in RCC and CVD death rates over a 16-year follow-up period and to determine the crossover time where the two curves intersected. Fine and Gray competing risk models were implemented to evaluate time-dependent associations of sociodemographic and clinical characteristics with CVD and RCC deaths at 1, 5, 10, and 16 years of follow-up.
Results: Among 116,836 RCC patients, CVD death rate overtook RCC death rate at 13.7 (95% confidence interval: 12.0-15.4) years after cancer diagnosis. The crossover time occurred earlier in patients who were ≥75 years, female, unmarried, Non-Hispanic Black, or had a RCC of stage I, tumor size ≤7 cm, grade I, or chromophobe histology, compared to others (crossover time ranged from 3.0 to 9.0 years). In contrast, CVD death rate did not exceed RCC death rate in patients with a RCC of stage III/IV, tumor size >7cm, or those receiving chemotherapy/radiotherapy during the study period. Age, sex, and papillary histology were time-dependently associated with RCC deaths, and stage and grade were time-dependently associated with CVD deaths.
Conclusion: In RCC patients, CVD death became dominant over RCC death during survivorship, with patterns varying according to different sociodemographic and clinical characteristics. These findings underscore the need for integrated management strategies addressing both cancer and CVD in RCC patients.

#785 Epidemiology, clinical outcomes, and healthcare resource utilization in multiple myeloma patients with protein-energy malnutrition hospitalized for acute congestive heart failure: A comprehensive population-based analysis.

Adamsegd I. Gebremedhen[1], Abdu Mohammed[2], Mamdouh Souleymane[1], Michael Fatuyi[3], Malik Samardali[4], Kemnasom Nwanwene[5], Toni O. Pacioles[5]

[1]Internal Medicine, Marshall University Joan C. Edwards School of Medicine, Huntington, WV,[2]Internal Medicine, Trinity Health System, Steubenville, OH,[3]Cardiology, University of Wisconsin, Madison, WI,[4]Internal Medicine, St Elizabeth Youngstown Hospital, Youngstown, OH,[5]Hematology and Oncology, Marshall University Joan C. Edwards School of Medicine, Huntington, WV

Introduction Multiple myeloma (MM) is often associated with heart failure, which can result from a high- output state, light-chain cardiac amyloidosis, or treatments such as proteasome inhibitors. Common MM-associated complications like anemia can further exacerbate heart failure, leading to acute decompensation and increased rates of hospitalization. Protein-energy malnutrition (PEM) is common in MM patients and is linked to poorer outcomes and longer hospital stays in various cancers. However, the impact of PEM on MM patients with acute congestive heart failure (ACHF) has not been well studied. This research aims to explore how PEM affects in- hospital outcomes in MM patients with ACHF. Methods We identified adult patients with MM from the National Inpatient Sample who were admitted with ACHF as the principal diagnosis from 2018 to 2021, using ICD-10 codes. The cohort was categorized based on the presence or absence of PEM, and we applied complex sampling weights to ensure national representativeness. Our primary outcome was all-cause mortality, and we analyzed several secondary outcomes. We used multivariate regression models to evaluate outcome disparities between the groups, with statistical significance set at $p < 0.05$. Results We identified a total of 2,390 adults with MM who were admitted with a principal diagnosis of ACHF from 2018 to 2021. Among these, 395 patients (16.5%) had a concurrent diagnosis of PEM. The mortality rate was 5.2% in the entire cohort and 11.4% in the PEM group. The PEM group had a higher proportion of female patients (59.5% vs. 43.9%, p=0.01). Patients with PEM had higher odds of all-cause mortality, with an adjusted odds ratio (aOR) of 2.64 (95% confidence interval [CI] 1.07-6.48). They also had higher odds of experiencing acute kidney injury (aOR 1.86, 95% CI 1.05-3.30), requiring mechanical ventilation (aOR 15.17, 95% CI 1.98-116.22), experiencing cardiogenic shock (aOR 3.73, 95% CI 1.27-10.92), and needing vasopressor support (aOR 4.96, 95% CI 1.37-17.90). Furthermore, patients with PEM faced longer hospital stays (9.8 vs. 5.8 days), with an adjusted incidence rate ratio (aIRR) of 1.55 (95% CI 1.25-1.92), and higher hospitalization charges ($118,775 vs. $59,505), with an aIRR of 1.71 (95% CI 1.28-2.28). Conclusion Our study found that MM patients with PEM admitted for ACHF had significantly higher odds of all-cause mortality and other adverse clinical outcomes compared to those without PEM. In addition, these patients experienced longer hospital stays and higher hospitalization charges. These findings underscore the importance of addressing PEM in the management of MM patients with ACHF to improve clinical outcomes and reduce healthcare resource utilization.

#787 Multi-omics approach to delineate the mechanisms of doxorubicin-induced cardiotoxicity.

Mohamed S. Dabour[1], Ibrahim Y. Abdelgawad[1], Bushra Sadaf[1], Mary R. Daniel[1], Marianne K. O. Grant[1], Anne H. Blaes[2], Pamala A. Jacobson[1], Beshay N. Zordoky[1]

[1]Experimental and Clinical Pharmacology, University of Minnesota, College of Pharmacy, Minneapolis, MN,[2]Division of Hematology/Oncology/Transplantation, Medical School, University of Minnesota, College of Pharmacy, Minneapolis, MN

Introduction: Doxorubicin (DOX) is a highly effective chemotherapeutic agent utilized in the treatment of a wide variety of adult and pediatric malignancies. However, the clinical utility of DOX is limited by its cardiotoxicity. Mechanisms of DOX-induced cardiotoxicity are not fully elucidated, highlighting the need for comprehensive studies. Proteomic and transcriptomic analyses provide an unbiased platform to uncover the molecular pathways underlying drug-induced toxicity. *The objective* of the current work is to delineate the mechanisms of DOX-induced chronic cardiotoxicity in C57BL/6N mice using a multi-omics approach to identify key molecular pathways and potential therapeutic targets.

Methods: Five-week-old C57BL/6N mice were randomized to receive six weekly intraperitoneal injections of either DOX (4 mg/kg/week for 6 weeks) or saline. Three days following the last injection, cardiac function was assessed by trans-thoracic echocardiography. Cardiac proteomic profiling and RNA sequencing were performed using pulverized heart tissues to determine the underlying molecular mechanisms of DOX-induced cardiotoxicity. Identified differentially expressed proteins and genes were validated by western blotting and quantitative real-time PCR, respectively. Key protein biomarkers were measured in plasma samples from breast cancer patients treated with doxorubicin using ELISA. To contextualize our findings, we also compared our data with multiple publicly available proteomic and RNA-sequencing datasets.

Results and Conclusion: DOX treatment induced cardiac dysfunction, evidenced by reductions in left ventricular fraction and fractional shortening. Proteomic analysis of heart tissue identified key proteins related to cardiotoxicity, including serpina3n, thrombospondin-1, and epoxide hydroxylase 1, all of which were significantly upregulated. RNA sequencing revealed the upregulation of Nr1d1, Phlda3, sestrin2 (sesn2), lipocalin2 (Lcn2), and Trp53inp1, with a downregulation of apelin-1. Protein expressions of serpina3n, and thrombospondin-1 were confirmed by immunoblotting, and gene expressions of Nr1d1, Trp53inp1, sestrin2, epoxide hydroxylase 1, and apelin-1 were confirmed by real-time PCR. Integrative analysis of our proteomics, RNA sequencing and other publicly available datasets identified common molecular pathway involving Nr1d1-serpina3n, underscoring its potential role in DOX-induced cardiotoxicity. Furthermore, plasma levels of serpina3 were significantly elevated in breast cancer patients 24 hours after receiving DOX-based chemotherapy compared to baseline, highlighting translational relevance of these findings. In conclusion, our findings provide valuable insights into the molecular mechanisms underlying DOX-induced cardiotoxicity, which could inform future therapeutic strategies to mitigate its adverse effects.

#788 QT prolongation induced by CDK-4/6 inhibitors in breast cancer: A prospective cohort study utilizing 12-hour continuous ECG monitoring.

Chia-Lun Chang[1], Wan-Chen Hsieh[1], Wei-Wen Chang[2], Ping-Kun Hsiao[2], Mao-Chih Hsieh[2], Tzeon-Jye Chiou[1], Tzu-Yao Liao[1], H-Eugene Liu[1], Hsin-Hsien Yu[2], Chih-Hsin Lee[3]

[1]Hemato-oncology, Taipei Municipal Wanfang Hospital (Managed by Taipei University), Taipei City, Taiwan,[2]General surgery, Taipei Municipal Wanfang Hospital (Managed by Taipei University), Taipei City, Taiwan,[3]Pulmonary medicine, Taipei Municipal Wanfang Hospital (Managed by Taipei University), Taipei City, Taiwan

CDK 4/6 inhibitors improve survival in HR+ and HER2 breast cancer patients but carry risks of QT prolongation. Single ECG readings may be unreliable. This study assesses QT prolongation via 12-hour ECG monitoring for three CDK 4/6 inhibitors.
Methods: A prospective cohort study (Apr 2023-Aug 2024) included HR+, HER2- breast cancer patients receiving CDK 4/6 inhibitors. Exclusions were QTc >500 msec and persistent Af. Ribociclib/Palbociclib followed a 21/7 regimen; Abemaciclib was continuous. ECG monitoring occurred pre-treatment and on day 14 (Ribociclib/Palbociclib) or day 14 only (Abemaciclib). ECGs were recorded from 8 PM-8 AM and stored on the PCA 500 cloud. Drug blood concentrations were measured on day 8, with dose adjustments as needed.
Results: From July 16, 2023, to July 31, 2024, 33 patients were included: Ribociclib (N=19), Abemaciclib (N=9), and Palbociclib (N=5). Case 36 underwent testing at 600 and 400 mg Ribociclib due to QT prolongation.

- Ribociclib: Median baseline QTcF was 422 msec, rising to 431 msec (400 mg, N=7) and 440 msec (600 mg, N=13) post-treatment. QTcF Max >500 msec increased from 23% to 54% in the 600 mg group.
- Palbociclib: Median QTcF rose from 431 msec (washout) to 439 msec (100 mg, N=4) and decreased to 421 msec (125 mg, N=4). QTcF Max >500 msec rose from 20% to 40% post-treatment.
- Abemaciclib: Post-treatment QTcF medians were 425 msec (100 mg, N=1), 433 msec (150 mg, N=5), and 434 msec (alternative 150 mg, N=3). QTcF Max >500 msec increased to 56% post-treatment.

Conclusions: Ribociclib and Abemaciclib prolonged QTcF Max >500 msec, especially at higher doses. Palbociclib had less QT prolongation and reduced QTcF at 125 mg. 12-hour ECG monitoring underscores the need for closer cardiac safety measures.

Patient characteristic	Ribociclib 400mg	Ribociclib 600mg	Abemaciclib	Palbociclib

#789 The role of the cardio-splenic axis in doxorubicin-induced exacerbation of hypertension-associated cardiomyopathy.

MARY RAPHEL DANIEL[1], Benu George[1], Marianne K.O Grant[1], Korbyn J.V. Dahlquist[2], Christina D. Camell[2], Beshay N. Zordoky[1]

[1]Experimental and Clinical Pharmacology, University of Minnesota, College of Pharmacy, Minneapolis, MN,[2]Department of Biochemistry, Molecular Biology and Biophysics, University of Minnesota, Minneapolis, MN

Introduction: Doxorubicin (DOX), a commonly used chemotherapeutic agent in childhood cancers, is associated with significant cardiotoxic side. Hypertension is a known risk factor for heart failure in DOX-treated childhood cancer survivors. This study utilizes a "two-hit" mouse model, wherein juvenile DOX exposure amplifies adult-onset hypertension-associated cardiomyopathy. We hypothesize that hypertension mobilizes DOX-induced immunosenescent cells from the spleen to the heart via the cardio-splenic axis, contributing to cardiac dysfunction. The primary objective was to delineate the role of the cardio-splenic axis and CCR2+ immune cell recruitment in DOX/hypertension-induced cardiomyopathy.
Methods: Male C57BL/6N mice (5 weeks old) were treated with DOX (4 mg/kg/week) or saline for 3 weeks, followed by a 5-week recovery period. Subsequently, hypertension was induced with angiotensin II (ANG II; 1.4 mg/kg/day) or saline for 14 days. Cardiac function was assessed via echocardiography, and gene expression of inflammatory and immune recruitment markers in the heart and spleen was quantified using real-time PCR. Flow cytometry was performed to evaluate changes in splenic immune cell subpopulations, focusing on CCR2+ immune cells. To assess the functional role of CCR2, the effects of DOX/hypertension on cardiac function were assessed in CCR2 knockout mice.
Results: Low-dose DOX treatment alone did not cause significant cardiac dysfunction in young C57BL/6N mice. However, ANG II-induced hypertension markedly exacerbated cardiac dysfunction in DOX-treated mice, as evidenced by a significant reduction in cardiac output and a remarkable inflammatory/fibrotic remodeling. DOX treatment disrupted splenic immune cell populations, with an increase of CCR2+ immune cells. ANG II-induced hypertension further compounded this effect by causing splenic contraction in DOX-treated mice. ANG II-induced hypertension upregulated gene expression of CCR2 in the heart and reduced it in the spleen of DOX-treated mice, suggesting that CCR2+ cells were mobilized to the heart via the cardio-splenic axis. CCR2 knockout mice were protected against DOX/hypertension-induced cardiac dysfunction, as KO mice maintained cardiac output compared to wild-type mice, underscoring the critical role of CCR2-mediated innate immune responses in the observed cardiac dysfunction.
Conclusions: These findings demonstrate that DOX-induced CCR2+ immune alterations exacerbate hypertension-associated cardiomyopathy via the cardio-splenic axis. Our data suggest that hypertension mobilizes CCR2+ immune cells from the spleen to the heart, driving inflammatory responses and cardiac dysfunction. Genetic deletion of CCR2+ cells protects against these effects, highlighting CCR2 as a potential therapeutic target to mitigate DOX/hypertension-induced cardiac dysfunction.

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#79 Pax6 regulates stemness and enhances brain metastases in breast cancer.

Laiba Anwar[1], Asad Ur Rehman[1], Mohammad Abbas Ali Zaidi[1], Parvez Khan[1], Mahek Fatima[1], Md Arafat Khan[1], Aatiya Ahmad[1], Nivedeta Krishna Kumar[1], Moorthy P. Ponnusamy[1], Surinder K. Batra[1], Metin Uz[2], Juan Santamaria-Barria[1], Mohd Wasim Nasser[1]

[1]Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE,[2]Cleveland State University, Cleveland, OH

Brain metastasis (BrM) remains the most severe complication of breast cancer (BC), the most diagnosed cancer in females, associated with an abysmal prognosis. Our poor understanding of the molecular mechanisms driving the disease is one of the major reasons for the dearth of specific therapies. This highlights an urgent clinical need to decipher how BC cells form BrM. BCBrM is preceded by a period of dormancy, during which stem cell-like features of cancer cells may play a role in reactivating them to form metastatic lesions. Cancer stem cells, known as “brain tumor-initiating cells” contribute to tumor formation in the brain and could also lead to radio and chemoresistance in the treatment of brain metastases. We, therefore, conducted a bioinformatic analysis on publicly available transcriptomic datasets of matched primary and brain metastatic patient samples and found that Pax6, a transcription factor, was upregulated in the metastatic samples compared to the primary tumors. In tissue microarray (TMA) belonging to BrM patients, Pax6 expression was evident in the BrM lesions and nearly absent in normal brain tissue. Pax6 was found to be upregulated in BCBrM cell lines compared to primary BC cell lines. Pax6, a master regulator of transcription, essential for normal development of the eyes and central nervous system, has been implicated in cancer progression. Pax6 can promote proliferation, migration, and resistance to apoptosis. To delineate the essentiality of Pax6 in BCBrM, we performed CRISPR/Cas9-mediated Pax6 knockout (KO) in the BCBrM cell lines, which decreased proliferation, wound healing, and migration properties. Intracardiac injection of these Pax6 KO BCBrM cells into immunocompromised mice resulted in a significant reduction of brain metastatic tumor lesions compared to controls. Conversely, overexpression of Pax6 in primary BC cells induced a BrM-like phenotype, enhancing proliferation, migration, and wound healing. Since Pax6 regulates stem cell features we also found that Pax6 KO reduced the expression of stemness-promoting factors such as OCT4, NANOG, and KLF4. Further, to confirm the stemness features we found that in serum-free conditions, Pax6 KO cells significantly lacked mammosphere-forming abilities and side populations. These findings suggest that Pax6 mediates stemness in cancer cells and enhances the metastatic potential of BCBrM cells. Unraveling the role of Pax6 in BCBrM could potentially open new therapeutic avenues for the treatment of BCBrM patients which eventually will improve outcomes of these patients.

#790 Effect of heart failure on incidence rates of pneumonia, septic shock and overall mortality in patients with myelodysplastic syndrome.

Karnav Modi[1], **Himil Mahadevia**[1], Simran Chandra[1], Ibrahim Khamees[1], Parth Sharma[1], Deepthi Vodnala[2], Taiyeb Khumri[2]

[1]University of Missouri - Kansas City School of Medicine, Kansas City, MO,[2]Saint Luke's Hospital of Kansas City, Kansas City, MO

Introduction: Myelodysplastic syndromes (MDS) refer to disorders originating from clonal stem cells, marked by ineffective hemopoiesis and cytopenias. Patients with MDS have a higher incidence of cardiovascular mortality, with heart failure playing a significant role. This has been linked to persistent anemia, excess iron accumulation and a systemic inflammatory state. Patients with MDS have significantly higher rates of infectious events, with pneumonia (PNA) and sepsis being the most common infections. The influence of systolic heart failure (SHF) or diastolic heart failure (DHF) on the risk of infections in patients with MDS is unclear. We evaluated whether chronic SHF or DHF, as well as acute SHF or DHF in concomitance with MDS, affected the rates of PNA, septic shock and overall mortality.
Method: A retrospective study identified patients with MDS using specific ICD 10 codes (D46.9, D46A-C and D46.22) from the National Inpatient Sample 2019-2021. Patients with acute and chronic SHF or DHF were obtained using particular ICD 10 codes (I50.2 - I50.4). The incidence rates of PNA, septic shock and overall mortality were compared between MDS patients with each of these types of HFs versus those without any HF using multivariate logistic regression adjusting for demographic characteristics, hospital-related factors, and common comorbidities.
Results: A total of 223,975 patients were identified with MDS. Patients with MDS who had chronic SHF (n=11,505) showed increased rates of PNA (OR:1.4, $p<0.001$) and septic shock (OR: 1.4, $p <0.001$) but no significant difference in overall mortality ($p=0.603$) compared to those without any HF. Patients with MDS and acute SHF (n=12,560) had enhanced rates of PNA (OR: 1.4, $p<0.001$), septic shock (OR: 1.9, $p<0.001$), and overall mortality (OR:1.6, $p<0.001$) versus those without any HF. Patients with MDS and chronic DHF (n=18,990) had no difference in rates of PNA ($p=0.2$), septic shock ($p=0.16$), or overall mortality ($p=0.1$). Acute DHF (n=16,700) led to a greater incidence of PNA (OR: 1.5, $p<0.001$) and overall mortality (OR: 1.2, $p<0.001$), but no significant difference in the incidence of septic shock ($p=0.07$) in patients with MDS.
Conclusion: Acute SHF was associated with significantly elevated rates of PNA and septic shock in patients with MDS, whereas acute DHF was linked to an increased incidence of PNA. Chronic SHF demonstrated higher occurrences of both PNA and septic shock. Furthermore, acute SHF and DHF correlated with increased mortality rates. Consequently, fostering early collaboration between hematology specialists and those in cardio-oncology is essential for effectively managing patients who have both MDS and HF. This would enable the implementation of timely preventive measures and therapeutic interventions, leading to more comprehensive care strategies that may improve clinical outcomes for these patients.

#791 Increased aortic stiffening in premenopausal women and triple negative breast cancer patients: impact of biomarkers and breast cancer therapy- findings from the PREVENT Trial (WF-98213).

Lorraine N. Velez-Torres[1], Alexandra Thomas[2], Sarah Hatcher[2], Ralph B. D'Agostino[3], Nathaniel S. O'Conell[3], Carolyn J. Park[3], W. Gregory Hundley[1], Jennifer H. Jordan[1]

[1]Virginia Commonwealth University, Richmond, VA,[2]Duke University, Durham, NC,[3]Wake Forest University, Winston-Salem, NC

Background: Breast cancer (BC) systemic therapies have improved survival but are associated with cardiovascular (CV) risks, particularly in premenopausal women with hormone receptor-positive (HR+) BC under near-complete estrogen deprivation (NCED) and in those with triple-negative BC (TNBC) who may experience chemotherapy-induced menopause. This PREVENT Trial (NCT01988571) sub-analysis investigated the impact of BC treatment, menopausal status, and biomarkers on vascular stiffness over two years.
Methods: This randomized trial included 238 BC patients receiving either atorvastatin (40 mg/day) or placebo for two years (PREVENT Trial WF-98213 Wake Forest NCORP Research Base UG1CA189824, ECOG-ACRIN and Alliance). Aortic pulse wave velocity (PWV) and aortic distensibility (AoD), measured via cardiac magnetic resonance imaging (CMR), were assessed at baseline, 6 months, and 24 months as indicators of vascular stiffness. Longitudinal general linear mixed models adjusted for baseline values, hypertension, body mass index, BC subtype, menopausal status, and statin treatment group evaluated changes in vascular stiffness. Univariate adjustments were performed to assess the influence of biomarkers, including cholesterol, aldosterone, renin, IL-6, TNF-alpha, and CRP.
Results: Of 238 participants, 116 were premenopausal (65% HR+, 35% TNBC) and 122 postmenopausal (58% HR+, 42% TNBC). At baseline, PWV did not differ significantly between BC subtypes but by 24 months, TNBC patients exhibited significantly increased PWV ($p = 0.0298$). Premenopausal women, despite having lower baseline PWV, surpassed postmenopausal levels by 24 months. AoD declined significantly across all subgroups ($p < 0.05$), reflecting increased vascular stiffening. Preliminary analysis links biomarkers with vascular stiffness. In TNBC patients, every 1 ng/mL increase in renin is associated with a 0.18 $mmHg^{-1}$ AoD decrease at 6 months ($p=0.0343$). For IL-6, every 5 pg/mL increase is linked to a 0.145 $mmHg^{-1}$ AoD increase at 6 months and 0.192 $mmHg^{-1}$ at 24 months in TNBC and postmenopausal women ($p=0.0288$ and $p=0.0325$, respectively). For cholesterol, every 10 mg/dL rise in TNBC reduces AoD by 0.261 $mmHg^{-1}$, reflecting higher PWV ($p=0.0298$). Statin treatment did not mitigate aortic stiffening.
Conclusions: This study reveals that premenopausal and TNBC women undergoing anthracycline-based chemotherapy exhibit significant increases in vascular stiffness, highlighting their heightened CV risk. Biomarker interactions differed across subgroups, with renin and cholesterol linked to poorer vascular outcomes in TNBC patients, while IL-6 appeared to promote compensatory vascular remodeling in TNBC patients and postmenopausal women. Enhanced cardiac monitoring and targeted interventions may be essential for these high-risk populations.

#792 Immunoprotective effects of metformin against delayed doxorubicin-induced immune perturbation in C57BL/6 mice.

Ian J. Ahlberg[1], Mary R. Daniel[1], Benu George[1], Marianne K.O. Grant[1], Korbyn J.V. Dahlquist[2], Christina D. Camell[2], Beshay N. Zordoky[1]

[1]Department of Experimental and Clinical Pharmacology, University of Minnesota, Minneapolis, MN,[2]Institute on the Biology of Aging and Metabolism, University of Minnesota, Minneapolis, MN

Introduction: Chronic immunological perturbations that leave cancer survivors with a long list of sequelae, such as an increased risk of death due to infection, remain a major complication of traditional chemotherapy. This risk is particularly pronounced in childhood cancer survivors treated with doxorubicin (DOX), a well-known culprit of immunosuppressive activities that may linger for years following the cessation of chemotherapy. Metformin is a first-line drug against Type-2 Diabetes Mellitus and has recently entered the pharma-oncology limelight due to its senomorphic and immunoprotective properties. In this study, we determined the potential immunoprotective effects of metformin against delayed DOX-induced immune perturbation in a mouse model of childhood cancer survivors.
Methods: Five-week-old C57BL/6N mice were randomly assigned to four groups: Control, Metformin, DOX, and Metformin/DOX. DOX-treated mice received intraperitoneal injections with either DOX (4 mg/kg/week) or saline for three weeks. Metformin-treated mice were administered metformin (250 mg/kg/day) via drinking water. Metformin treatment began three days before the first DOX injection and was continued throughout and five weeks post DOX injections. Five weeks following the last dose of DOX, all mice were humanely euthanized in accordance with institutional guidelines. Blood and bone marrow samples were collected during the necroscopy and analyzed with a Flow Cytometer and a Hematological Analyzer to provide insight into individual immune cell populations.
Results: Metformin alleviated delayed DOX-induced perturbations in several immune subpopulations. In the innate immune system, metformin decreased neutrophil and monocyte frequency in the blood and bone marrow. However, metformin also ameliorated DOX-induced depletion of the $CCR2^+$ activated and $CD86^+$ invasive monocyte frequencies. In the adaptive immune system, metformin increased the frequency of lymphocytes, particularly B cells, in the blood. This trend is supported by the increased population of $Ki67^+$ proliferating B cells in the bone marrow across all stages of maturation.
Conclusion: DOX-induced lingering effects on immune cell populations were partially mitigated by metformin. Metformin improved the functionality of the attenuated monocyte population in the bone marrow and increased the frequency of B lymphocytes in the blood, which can be traced to the expanded population of proliferating B cells in the bone marrow. These results suggest metformin has dual effects on the immune system and may serve as a therapeutic option to mitigate chronic immune perturbations in childhood cancer survivors.

#793 Cardiometabolic risk factors among Puerto Rican men with prostate cancer.

Valeria Torres Matos[1], Katherine Carrero Figueroa[2], Noemi Santiago[3], Julie Dutil[4], William Roman Torreguitart[3], Carlos Joel Diaz Osterman[2]

[1]Biology, UPR - Rio Piedras Campus, San Juan, Puerto Rico,[2]UPR - Comprehensive Cancer Center, San Juan, Puerto Rico,[3]Puerto Rico Urology Group, Mayaguez, Puerto Rico,[4]Clinical and Translational Research, UPR - Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Cardiovascular and metabolic disorders are significant contributors to morbidity and mortality among men with prostate cancer. However, few studies characterize the association between cardiometabolic comorbidities and tumor risk in the post-operative space among high-risk groups. Like African American men, Puerto Rican men have a higher risk of developing and dying from prostate cancer than other racial and ethnic groups in the United States. As cardiovascular and metabolic risk factors are highly prevalent in Puerto Rico, we proposed to investigate coordinated risk evaluation of cardiometabolic and oncologic risk in this population. We hypothesized that a subset of cardiometabolic risk factors consistently correlate with clinically defined aggressive disease.
Methods: The Puerto Rico Urology Group (PRUG) is the largest group urology practice in Puerto Rico. It currently consists of ten urologists serving the Western, Southern, Central, and Metropolitan regions of Puerto Rico including the island municipalities of Vieques and Culebra. Our cohort (n=388) of patients underwent robotic assisted radical prostatectomy for prostate cancer between 2015 and 2022. Clinical data were extracted from consented patients' electronic health records with appropriate IRB approval (Ponce Research Institute IRB no. 2210121134, University of Puerto Rico Comprehensive Cancer Center IRB no. 2023-08-111). Post-surgical cancer of the prostate risk assessment (CAPRA-S) was used to stratify tumors and cardiometabolic risk factors were evaluated across tumor risk strata.
Results: The majority of study participants had low-risk tumors (238/388, 61.3%), with intermediate tumors accounting for 106/388 (27.3%), and high-risk tumors accounting for 44/388 (11.3%). Higher CAPRA-S score was significantly associated with greater tumor mass ($p<0.001$), presence of perineural invasion ($p<0.001$), and presence of hyperlipidemia ($p<0.001$).
Conclusion: The Puerto Rican population represents the second largest Hispanic/Latino subgroup in the United States and has disproportionately high rates of prostate cancer and cardiometabolic comorbidity. Our preliminary findings indicate that the coordinated evaluation of cancer risk in the context of high-risk disease may provide additional insights for clinicians managing prostate cancer among populations with high prevalence of these chronic diseases. These findings provide insights for ongoing studies to evaluate large, multi-institutional cohorts and identify molecular indicators of cardiometabolic risk predictive of prostate cancer aggressiveness among diverse populations.

[1]Cantor Center for Nursing Research, Dana-Farber Cancer Institute, Boston, MA,[2]University of Nebraska, Omaha, NE,[3]UT Health Houston, Houston, TX,[4]University of Florida College of Nursing, Gainsville, FL,[5]The University of Texas MD Anderson Cancer Center, Houston, TX,[6]Ohio State University, Columbus, OH,[7]Memorial Sloan Kettering Cancer Center, New York, NY,[8]Pack Health, A Quest Diagnostics Company, Birmingham, AL,[9]Montefiore Medical Center, Bronx, NY,[10]National Institute of Nursing Research, Bethesda, MD,[11]Rutgers School of Nursing, Newerk, NJ

Purpose: Wellness interventions are important for improving outcomes, including physical function (PF), in cancer survivors. The COACH study is a randomized, wait-list controlled trial assessing feasibility of a 6-month digital health coaching (DHC) program for individuals within one year of completing primary cancer therapy, and those with metastatic disease. Diverse patient-reported outcome (PRO), wearable, device, gut microbiome, and dietary data are collected up to once monthly from 675 individuals over 12 months. This interim analysis examined change in PF using the PROMIS Short Form v2.0-PF 10a.

Methods: The analysis included a pooled sample of participants who completed baseline and 6-month assessments as of November 2024. Descriptive statistics evaluated trends in physical function by age, sex, enrollment site, metastatic disease, and tumor and primary treatment type.

Summary Data: Among the 352 individuals enrolled across 7 study sites, 177 completed baseline and 6-month assessments to date. Mean age of participants was 59.7 (R 30-83, SD 11.8). Fourteen participants (8%) identified as Black or African American, 9 (5%) as Hispanic or Latino, 147 (83%) as non-Hispanic White, and 7 (4%) as other, including Asian, American Indian, or Alaskan Native. Mean PROMIS PF scores by analysis group are presented in Table 1.

Conclusions: An interim analysis of PF data demonstrated trending improvements across all groups from baseline to 6 months, except at one site enrolling only individuals with metastatic breast cancer, for whom mean difference is lower than in those with non-metastatic disease. Minimally important differences in PROMIS PF for individuals with advanced cancer is 4-6 points. At study completion (July 2026), a full analysis will be conducted to explore differences in PF by various patient characteristics, and if and how DHC may impact these trends over time.

#795 Acute and long-term effect of prepubertal chemotherapy on spermatogenesis, fertility and offspring health.

Meghali Joshi, Duane G. Pereira, Sonia de Assis

Department of Oncology, Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Early detection and treatment of childhood cancers have improved the cure and the survival rates for more than a decade. However, long-term survivors of childhood cancers can experience fertility problems because of chemotherapy treatment. This is a major problem particularly for young boys, for whom no fertility preservation treatment is yet established. Here, we have determined the acute and long-term effect of cyclophosphamide (an alkylating drug commonly used in childhood cancers) on the germ cell development, fertility and on the health of their subsequent generations. We treated the prepubertal mice with clinically relevant dose of either cyclophosphamide (low dose- 100mg/kg and high dose- 200mg/kg), and vehicle control (sterile PBS), respectively. Acute exposure to both low and high doses of cyclophosphamide led to morphological changes in the prepubertal testis. Moreover, prepubertal treatment had long-term effect as the sperm concentration and motility in adult mice decreased in a dose dependent manner. Infertility and sub-fertility were observed in males exposed to high, but not in low dose of cyclophosphamide as compared to control males. There was no difference in the litter size born to cyclophosphamide exposed fathers as compared to controls. However, there was a sex specific increase in the litter weights of the female offspring born to fathers exposed to high dose of cyclophosphamide as compared to controls. Additionally, a high male to female birth sex ratio was found in the litters born to cyclophosphamide exposed fathers as compared to controls, suggesting that the cyclophosphamide exposure may be impacting the paternal X chromosome. We also investigated the adverse effect of paternal cyclophosphamide exposure on the metabolic health of F1 offspring. Female, but not male offspring of fathers exposed to cyclophosphamide, developed severe insulin resistance compared to controls. We have previously shown that sperm small non-coding RNAs contribute to the intergenerational transmission of paternally acquired metabolic disorders. Using small RNA sequencing, we found alterations in the population of small non-coding RNAs in the sperm of cyclophosphamide exposed fathers as compared to controls suggesting that sperm small non-coding RNAs may contribute to the adverse effect of pre-pubertal cyclophosphamide exposure. Overall, our results demonstrate that exposure to clinically relevant dose of cyclophosphamide in prepubertal mice not only affects the reproductive health of exposed mice but could also affect the health of their off-spring by altering the sperm small non-coding RNAs.

#796 Incidence of depression and anxiety in kidney cancer survivors: A nationwide population-based cohort study.

M. Jung[1], M. Li[1], E. Choo[2], S. Lee[2], D. Spiegel[1], M. Baiocchi[1], Z. Deng[1], J. Li[1], M. E. Langston[1], M. L. Bondy[1], B. I. Chung[1]; [1]Stanford University School of Medicine, Stanford, CA, [2]Ajou University, Suwon, Korea, Republic of

Depression and anxiety are highly prevalent among kidney cancer survivors, yet limited evidence exists on their cumulative incidence following kidney cancer diagnosis and their associations with the diagnosis. We conducted a nationwide, population-based retrospective cohort study using the Korean National Health Insurance and Medical Checkup Linkage Database. Adults, over 20 years, diagnosed with kidney cancer from 2010 to 2020 were included, along with age- and sex-matched non-cancer comparators. Individuals with prior cancer, depression, or anxiety were excluded. We 1) quantified the empirical risk trajectories of depression and anxiety in kidney cancer survivors for up to five years post-diagnosis, and 2) estimated the time-dependent associations between kidney cancer diagnosis and the incidence of these conditions within three post-diagnosis intervals (0-1, 1-3, and 3-5 years) using inverse-probability weighted Cox regressions. Until five years post-diagnosis, survivors (n=24,310) consistently had a higher cumulative incidence of depression (2.8% vs 2.2%) and anxiety (3.3% vs 2.6%) compared with comparators (n=173,471). Additionally, survivors (n=16,049) had an increased hazard of depression (hazard ratio (HR)=1.92, 95% confidence interval (CI): 1.52-2.42) and anxiety (HR=1.63, 95% CI: 1.31-2.02) compared to comparators (n=100,782) within the first year. During the subsequent 1-3 years, the hazard of anxiety remained increased (HR=1.32, 95% CI: 1.07-1.62). In conclusion, kidney cancer survivors experienced a higher rate of depression and anxiety, especially in the early post-diagnosis period, compared to the non-cancer population. Our findings emphasize the need for proactive prevention and management of psychiatric disorders in kidney cancer patients.

#798 The genetic link between psychosocial stress and outcome in oral squamous cell carcinoma.

Minh Phuong Dong[1], Gary Yu[2], Michele Arambula[1], Bradley Aouizerat[3], Khanh Nguyen[1], Paul Walker[1], Carissa Thomas[4], Chi Viet[1]

[1]Loma Linda University, Loma Linda, CA,[2]Columbia University, New York, NY,[3]New York University, New York, NY,[4]University of Colorado, Boulder, CO

Psychological well-being predicts future physical health and mortality beyond its association with reduced stress and depression. Studies on psychological well-being in cancer have not evaluated the effect of psychosocial stressors on cancer outcomes. The objective of this study was to investigate the impact of psychosocial stressors and their resultant dysregulated genetic pathways on oral squamous cell carcinoma (OSCC) outcomes. This prospective multi-institutional study enrolled 173 OSCC patients to determine prior and current psychosocial stressors (using the Adverse Childhood Experience - ACE and Life Events Checklist - LEC-5), characterize cancer symptoms and quality of life disturbance (using the UCSF Oral Pain Questionnaire - UCSF-OPQ, modified Brief Pain Inventory - BPI, and EORTC-QLQC30 and H&N35), and collect flash-frozen cancer tissue for RNA-sequencing. Data was analyzed by a biostatistician using Pearson correlation, Student's t-test, one-way ANOVA, Kaplan Meier log-rank test and Cox hazard regression. Our cohort consisted of 99 males, 74 females; racial/ethnic composition included 118 White, 14 Asian, 12 Black, and 28 White-Hispanic. The mean age of the cohort was 64. Patients who had high cancer pain (UCSF-OPQ) had significantly greater physical and psychological interferences (modified BPI; $p<0.05$). Patients with worse pain also had disturbances in all 6 functional categories measured by EORTC-QLQC30, including physical functioning, role functioning, emotional functioning, cognitive function, social functioning, and global health status ($p<0.0001$). In terms of the effect of childhood or adult psychosocial stressors on cancer outcomes, patients with a high ACE or LEC-5 score had worse cancer symptoms (in all symptom scales including modified BPI, EORTC-QLQ, and H&N35) independent of their pathologic stage. A Cox hazard regression model showed that the H&N35 score (HR = 1.969, CI 95% [1.060 - 3.659]) was independent of pathologic stage (HR =1.808, CI 95% [1.244-2.628] and age (HR: 1.669, CI 95% [1.151-2.419]) in predicting survival. Analysis of RNA-seq data in flash-frozen cancer tissue of 50 OSCC patients showed that the extracellular matrix organization and the regulation of integrin-mediated signal pathways were dysregulated in patients with high pain levels. Additionally, patients with psychosocial stress exhibited high expression of genes such as *RLP6*, *RPL11*, and *RPL23*, which are known to play significant roles in lung and gastric cancer but not previously associated with OSCC. Enriched pathways in these patients included ribonucleoprotein complex biogenesis and regulation of p53-mediated signal transduction. Our results demonstrate that psychosocial stressors worsen cancer symptoms, which is independently associated with worse cancer outcomes and survival. We delineate the significant dysregulated pathways linking behavioral health to cancer outcomes.

#799 Comparing the efficacy of infliximab and vedolizumab in treating steroid-refractory immune checkpoint inhibitor-induced colitis.

Irene Li[1], Sandip P. Patel[2]

[1]School of Medicine, University of California San Diego, La Jolla, CA,[2]Moores Cancer Center, University of California San Diego, La Jolla, CA

Purpose: This study aims to evaluate the efficacy of infliximab and vedolizumab in managing corticosteroid-refractory immune checkpoint inhibitor (ICI)-induced colitis. Some patients receiving immunotherapies develop severe, grade 3+ ICI-induced colitis, which often requires second-line treatments such as biologics commonly used for irritable bowel disease. Although there is literature supporting the use of infliximab, limited data exist regarding the efficacy and specific use of vedolizumab for ICI-induced colitis.
Methods: A retrospective analysis was conducted on patients treated with either vedolizumab or infliximab alongside a checkpoint inhibitor over the past five years (March 1, 2019 - March 1, 2024). Patients included were treated with vedolizumab and received one of the following immunotherapies at UC San Diego: pembrolizumab, nivolumab, ipilimumab, atezolizumab, durvalumab, or cemiplimab. Patients treated with infliximab/vedolizumab for other indications, such as conventional irritable bowel syndrome, were excluded.
Results: The database search identified 16 patients on infliximab and 18 on vedolizumab. The final analysis included 9 patients in the infliximab group and 8 in the vedolizumab group. Most patients were white and had various types of cancer, predominantly at advanced stages (III or IV). Of the patients, 41% were receiving PD1-targeted immunotherapy at the onset of colitis symptoms. Patients received an average of 1.7 doses of infliximab (range: 1-8) and 3.5 doses of vedolizumab (range: 1-8). Among infliximab-treated patients, 66% received a single dose during hospitalization without further treatment, compared to 12.5% of vedolizumab-treated patients. Infliximab enabled 66% of patients to successfully complete a steroid taper, while vedolizumab had a success rate of 75% (Chi-square, $p = 0.70$). The average time on steroids was longer in the vedolizumab group (30.21 weeks) than in the infliximab group (17.97 weeks), though this difference was not statistically significant ($p = 0.80$). No significant differences were observed when results were stratified by sex (infliximab, $p = 0.40$; vedolizumab, $p = 0.21$) or type of immunotherapy (infliximab, $p = 0.96$; vedolizumab, $p = 0.21$).
Conclusion: Both infliximab and vedolizumab appear to be viable options for treating ICI-induced colitis, with most patients successfully completing a steroid taper. However, this study does not provide sufficient evidence of superior outcomes for either drug, although some patients responded well to treatment. Therefore, infliximab remains a reasonable first-line treatment for steroid-refractory ICI-induced colitis.

#8 Identifying the role of KIF20A in stemness and metastasis in hepatocellular carcinoma.

Liuxian Ban[1], Xiaona Fang[2], Shan Liu[3], Jie Luo[1], lanqi Gong[1], Hongyu Zhou[1], Beilei Liu[4], Jiao Huang[5], Nanzhou Yu[1], Yingchen Lyu[1], Licheng Tan[1], Qin Liu[1], Cuicui Huang[1], Xin-Yuan Guan[1]

[1]The University of Hong Kong, Hong Kong, China,[2]Sun Yat-sen University Cancer Center, Guang Zhou, China,[3]Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Sichuan, China,[4]City University of Hong Kong, Hong Kong, China,[5]Cutaneous Biology Research Center, Massachusetts General Hospital, Boston, MA

Hepatocellular carcinoma (HCC) is remarkable for its high recurrence and metastasis rate. According to the cancer stem cell (CSC) model, a small group of stem cells is capable of keeping self-renewal, initiating relapse and metastasis in tumors. However, the mechanism of CSCs in regulating HCC recurrence and metastasis awaits further investigation. We previously established an in vitro human hepatocyte differentiation model and defined four developmental stages: embryonic stem cell (ES), endoderm (EN), liver progenitor cell (LN) and premature hepatocyte (PH). Kinesin family member 20A (KIF20A) was found highly expressed in ES and EN stages while decreasing sharply in LP and PH stages. Besides, in an online GEO dataset, we regrouped single cells into the hepatocyte, stem-like HCC and HCC subclusters according to their expression profiles. KIF20A was spotted mostly in the stem-like HCC cluster with a low proportion, sharing the same expression pattern with CD133, suggesting its potential role in cancer stemness. Moreover, KIF20A expression was positively correlated with stemness markers CD133, Epcam, CK19, and MYCN in our clinical cDNA array. In the TCGA-LIHC dataset, KIF20A expressed higher in tumor tissues than normal counterparts, and related to shorter overall survival in patients. Functionally, KIF20A promoted cell proliferation, induced sorafenib resistance, increased sphere formation, and enhanced cell migration and invasion in vitro. In subcutaneous mouse models, liver orthotopic mouse models and hydrodynamic transfection mouse model of HCC, KIF20A fueled tumorigenicity and lung metastasis significantly. After mRNA sequencing of KIF20A knock-down cells, bioinformatic analysis suggested that KIF20A may modulate metastatic biological processes via the Hippo pathway. Western Bloting further confirmed the result of pathway changes in protein level. The underlying mechanism of how KIF20A interacts with Hippo pathway still needs further investigation. In conclusion, we provided new insights into the role of KIF20A in regulating stemness and metastasis in HCC. KIF20A might be a potential target for HCC treatment in the future.

#80 Integrin driven adhesion in ovarian cancer.

Nazia Bano[1], Isabelle Lewis[2], Malaika Amin[3], Eva M. Schmelz[2]

[1]Virginia Polytechnic Institute & State University, Blacksburg, VA,[2]Human Nutrition, Foods, and Exercise, Virginia Polytechnic Institute & State University, Blacksburg, VA,[3]Hollins University, Roanoke, VA, Roanoke, VA

Ovarian cancer is the fifth leading cause of cancer-related deaths in women due to late-stage diagnosis, reducing the survival rate to 30%. During dissemination, ovarian cancer cellsexfoliate from the primary tumor and aggregate to form spheroids in the peritoneal cavity. Peritonealaggregation enhances the survival of cancer cells by mitophagy, reduced metabolism, andproliferation. However, as spheroids adhere to secondary sites, mitochondrial function is restoredby mitobiogenesis, with increased metabolism and proliferation. These findings strongly suggest aswitch from mitophagy in spheroids to mitobiogenesis upon adhesion. However, the mechanism bywhich adhesion induces mitobiogenesis remains unknown. Therefore, our objective is to identifykey adhesion receptors, with a focus on integrins that activate adhesion and downstream signalingcascades. To investigate changes in integrin expression, we mimicked three major stages ofovarian cancer progression by developing adherent, spheroid, and adherent spheroid stages usingmouse ovarian surface epithelial (MOSE) cell lines. These represented the benign (MOSE-E) stage,as well as slow-developing (MOSE-L) and fast-developing (MOSE-LTIC*v*) disease in biologicallyrelevant conditions. We identified integrin and adhesion-related gene expression levels via RT-qPCR. Western blotting and confocal microscopy were used to observe protein expression andlocalization throughout ovarian cancer progression. Drug treatment was done to observe the effectof integrin inhibition on spheroid aggregation and adhesion to secondary sites. Our finding revealeddistinct expression changes of different integrins during aggregation and adhesion, as well asspecific changes of other adhesion molecules, ECM, and their regulators indicating specific rolesin metastatic dissemination and implantation. This was further confirmed with specific integrininhibitors that were effective in preventing aggregation and spheroid adhesion to secondary sitesindicating distinct roles of integrins during the metastatic stages. Overall, this project will aid inidentifying integrin and integrin drug targets to develop new metastatic treatments, ultimately aimingto reduce mortality in women with ovarian cancer.

Background: There is controversy over whether Granulocyte colony-stimulating factor (G-CSF) can be used within 24 h after chemotherapy. Efbemalenograstim α is a novel long-acting G-CSF approved by FDA in 2023. Guard-02 trial (ChiCTR2300078792) was to evaluate the efficacy and safety of efbemalenograstim α for prevention of chemotherapy-induced neutropenia (CIN) within 24 h after chemotherapy.
Methods: This was a prospective, multicenter, single-arm, two-stage clinical study. Breast cancer patients received chemotherapy with epirubicin (90 mg/m^2) and cyclophosphamide (600 mg/m^2) for 4 cycles were enrolled. If less than 9 cases of grade 3-4 neutropenia occurred in 16 patients in first stage, the toxicity was acceptable and more patients would be recruited in second stage. Patients received 20 mg efbemalenograstim α at 24±4 h (d2) after chemotherapy in first cycle and at 4±1 h (d1) after chemotherapy in subsequent cycles. The primary endpoint was incidence of grade 3-4 (ANC <1×10^9/L) neutropenia in cycle 1-2. The safety profile was evaluated.
Results: The incidence of grade 3-4 neutropenia in cycle 1-2 and cycle 1-4 of 16 patients (median age at 51 years, r.35-60) were 25.00% (90% CI: 9.03%-48.44%) and 31.25% (95% CI: 11.02%-58.66%), both lower than that in phase III trial using efbemalenograstim α at 48 ± 4 h (d3) after EC chemotherapy (NCT04174599, whose incidence of grade 3-4 neutropenia in cycle 1-2 and cycle 1-4 were 34.16% and 36.67%). Using efbemalenograstim α within 24 h after chemotherapy was safe, the most frequently adverse event (AE) related to study drug was muscle pain (6.25%). The incidences of AEs were low and no serious adverse event was related to study drug.
Conclusions: Using long-acting G-CSF on same-day of chemotherapy was as safe and effective as on d3 of chemotherapy in reducing CIN. In patients with daytime chemotherapy, efbemalenograstim α provides oncologists an alternative for simplifying management of CIN.

	Cycle 1-2	Cycle 1	Cycle 2	Cycle 3	Cycle 4	Cycle 1-4
The incidence of grade 3-4 neutropenia in each cycle (n/N, %)	4/16(25.00)	1/16 (6.25)	3/16 (18.75)	1/16 (6.25)	1/16 (6.25)	5/16 (31.25)

#801 Mechanism of oxaliplatin-induced cachexia: A transcriptional and physiological perspective.

Junwei Du[1], Rachel L. Mintz[2], Rachael Field[3], Leland C. Sudlow[1], John E. Morley[4], Jonathan R. Brestoff[3], Gwendalyn J. Randolph[3], **Mikhail Y. Berezin**[5]

[1]Radiology, Washington University In St. Louis, St. Louis, MO,[2]Department of Biomedical Engineering, Pathology and Immunology, Washington University In St. Louis, St. Louis, MO,[3]Pathology and Immunology, Washington University In St. Louis, St. Louis, MO,[4]Saint Louis University, St. Louis, MO,[5]Washington University In St. Louis, St. Louis, MO

Background: Cancer cachexia is a multifactorial, largely irreversible metabolic disorder characterized by skeletal muscle and adipose tissue depletion that is responsible for 20% of cancer-related deaths. Oxaliplatin, a chemotherapeutic agent commonly used to treat colorectal cancer and other malignancies, is associated with weight loss, muscle weaknesses, and metabolic dysregulation. Yet it is unknown whether oxaliplatin mediates these effects independently of cancer.
Methods: Non-tumor-bearing immunocompetent C57BL/6 mice were administered a human-equivalent dose of oxaliplatin over 8 weeks. Metabolic parameters were assessed using metabolic cages and EchoMRI, followed by post-mortem bulk RNA sequencing of muscle, adipose tissue, and the hypothalamus. The results were compared to data sets from cachexia models in cancer and fasting.
Results: Oxaliplatin induced significant weight loss (~12%), decreased lean mass, reduced food intake, decreased physical activity, and lowered core body temperature. Adipose tissue exhibited extensive transcriptional dysregulation, with over 2,000 differentially expressed genes (DEGs) affecting metabolic and inflammatory pathways. Muscles exhibited transcriptional evidence of atrophy, supported by histological images. Hypothalamic RNA-seq revealed dysregulated thermogenic and adipocytokine pathways and overexpression of neuropeptides such as neuropeptide Y (NPY), linking peripheral metabolic changes to central regulation. Comparisons with clinical and preclinical cancer and fasting models demonstrated overlapping yet distinct transcriptional signatures.
Conclusion: Our study demonstrates that oxaliplatin independently induces cachexia-like symptoms via transcriptional and metabolic disruptions peripherally in muscle, adipose tissue, and centrally in the hypothalamus. The findings point to the importance of identifying early cachexia diagnostic markers and targeted interventions to stop and reverse cachexia during oxaliplatin treatment.
Significance: Adipokines such as leptin and GDF15 may be potential biomarkers of oxaliplatin-induced cachexia, and the associated metabolic pathways could be targeted therapeutically to improve cancer patient outcomes.

#802 Utilization of emotional support services among breast cancer patients.

Ahmed Allibhai[1], Asiyah Allibhai[1], Zishan Allibhai[2]

[1]Holy Trinity School, Richmond Hill, ON, Canada,[2]Department of Radiation Oncology, Southlake Hospital/Princess Margaret Hospital, Newmarket, ON, Canada

Introduction: Breast cancer patients frequently experience significant psychological distress, with prevalence rates of anxiety and depression reaching as high as 50% in certain studies. This distress is linked to worse treatment adherence and outcomes. Additionally, a recent review demonstrated that psychological interventions in these patients have been found to improve quality of life, decrease distress, and may extend disease-free survival while reducing recurrence and mortality. Despite the benefits, mental health services remain underutilized in this population. This study examined the use of emotional support resources by breast cancer patients using data from a single-institution patient-reported outcomes registry.

Method: Data were collected from our institutional electronic medical records of breast cancer patients treated within the past year. Participants included those reporting moderate to severe symptoms (≥4) on the Edmonton Symptom Assessment Score (ESAS) for depression or anxiety. Utilization of emotional support resources, such as referrals to psychosocial interventions (Psychiatrists, Social Workers), was analyzed. Demographic, clinical, and geographic characteristics were compared between resource users and non-users using chi-square and z-tests.

Results: Among 340 participants with moderate or higher distress, 118 (35.1%) accessed psychosocial resources, such as counseling or support groups. Younger patients showed a trend toward higher utilization ($p=0.068$), and white participants were slightly more likely to use resources ($p=0.229$), though neither finding reached statistical significance. Travel time significantly impacted resource use, with shorter commutes (<30 mins) leading to greater engagement (43.5% vs. 21.7% for 30-60 mins and 12.5% for >60 mins, $p<0.001$). Furthermore, patients with higher ESAS scores, reflecting greater symptom burden, were significantly more likely to engage with support resources ($p<0.001$). Other characteristics, including gender ($p=0.51$) and disease stage ($p=0.432$) were not associated with differences in resource use.

Conclusions: This study highlights factors influencing the utilization of psychosocial support resources among breast cancer patients with moderate or greater distress. While age and race showed nonsignificant trends, travel time and symptom burden were significant predictors of engagement. Some patients may have declined additional referrals due to pre-existing support systems, indicating the need to assess these factors in future studies. Expanding access and addressing barriers through healthcare and advocacy partnerships remains essential. Further research could explore the use of psychosocial resources by patients with mild distress (ESAS scores 1-3).

#803 Elevated neuroinflammation in women with breast cancer: initial insights from [^{11}C]PBR28 PET/MR imaging.

Yehui Zhu[1], Natalie Swanson[1], Mehrbod Mohammadian[1], Jennifer Murphy[1], Minhae Kim[1], Ann Partridge[2], Marilyn Hammer[2], Robert Edwards[3], Kristin Schreiber[3], Marco Loggia[1]

[1]Massachusetts General Hospital, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Brigham and Women's Hospital, Boston, MA

Introduction: As breast cancer survivorship rises, addressing the long-term side effects of cancer and its treatment is crucial. Chemotherapy has been linked to neuroinflammation, leading to cognitive and neurological impairments. However, other treatments (e.g., surgery, endocrine therapy) or related conditions (e.g., pain, cancer progression) may impact neuroinflammation as well.
Methods: This cross-sectional study used Siemens 3T integrated positron emission tomography-magnetic resonance imaging (PET/MRI) with the radioligand [^{11}C]PBR28, which binds to the neuroinflammation marker 18kDa translocator protein (TSPO), to assess the extent and distribution of neuroinflammation in two age-matched cohorts of women with and without breast cancer. A T1-weighted volume (MEMPRAGE; voxel size = 1x1x1mm3) was acquired simultaneously and used for attenuation correction of PET data and spatial normalization to the MNI space. Standardized uptake values ratios (SUVR) were computed from 60-90 min post-[11C]PBR28 injection data, intensity normalized by whole brain signal, spatially smoothed (FWHM=8mm) and normalized to the MNI template. PET imaging data were analyzed and processed using FSL and FreeSurfer. A mixed effects ordinary least squares analysis, using a cluster-forming threshold of $z=2.3$ and a cluster size threshold of $p<0.05$ was conducted. Mean PET signal in the regional clusters was determined, and an exploratory comparison in neuroinflammation ([^{11}C]PBR28 signal) made between women with and without breast cancer, who did or did not receive chemotherapy (Mann-Whitney U test).
Results: Twelve breast cancer patients (age=63±9) and 6 matched healthy controls (age=57±10) were included in this analysis. Compared to healthy controls, breast cancer patients showed significant increased [^{11}C]PBR28 signal uptake in the middle cingulate cortex and underlying white matter ($SUVR_{BC}$=0.95±0.03, $SUVR_{HC}$=0.85±0.04). No significant differences were observed between women with (n=7) and without (n=5) chemotherapy (U=15.00, p=0.685).
Conclusions: These preliminary findings indicate increased neuroinflammation in breast cancer patients compared to age-matched controls, independent of chemotherapy. These preliminary findings suggest that cancer or other treatments may contribute to neuroinflammation. Larger studies with focused analysis of region(s) of interest are needed to confirm these results.

#804 Gut microbiota, health-promoting lifestyle behaviors, and symptoms of pain and fatigue in hematopoietic cell transplantation survivors.

Elham Samami[1], Angela Starkweather[2], Debra Lyon[1], Debra Kelly[3]

[1]University of Florida, Gainesville, FL,[2]School of Nursing, Rutgers Health, Newark, NJ,[3]Loewenberg College of Nursing, University of Memphis, Memphis, TN

Hematopoietic cell transplantation (HCT) is a critical treatment for hematological malignancies, but survivors often face long-term health challenges, including complications related to immune dysfunction, gut microbiota (GM) alterations, and physical symptoms. Recent research has highlighted the important role of health-promoting lifestyle behaviors (HPLBs), such as diet, physical activity, and stress management, in improving health outcomes among HCT survivors. This study is a post-transplant analysis (30 days) of 55 adults (> 18 years of age) from a longitudinal descriptive study of GM composition diversity using Chao, Shannon, and health-promoting lifestyle profile domains measured by the HPLPII that includes health responsibilities, physical activities, nutrition, spiritual growth, interpersonal relationships, and stress management. Pain and fatigue were measured using the Memorial Symptom Assessment Scale, GM was assessed using 16S ribosomal gene (V4 region) amplicons from Illumina MiSeq. Data analysis was performed with the Python 'pandas' package using robust Pearson correlations for finding linear correlations and production of 95% Credibility Intervals (CI) align with Canonical Correlation using scikit-learn library and Kernel Correlation using rbf_kernel function to find nonlinear associations with ($p<0.05$) significance level. The study sample was comprised of 77% white,19.3% African American or Black, and included 2.5% Hispanic ethnicity. The mean age of participants was 56.21 years + 14.67 years, participants were diagnosed with Lymphoma (46.2%), Leukemia (27.7%), Multiple Myeloma (16.80%) and Myelodysplastic syndrome (9.24%) and the majority received autologous HCT (39.16%). Both Canonical and Kernel correlations between health-promoting lifestyle scores, gut microbiota number of OTUs, and pain-related metrics showed moderate association with 0.60 and 0.4. Pearson correlation revealed a negative association between stress management domain and pain (r= -0.30) pain severity (r= -0.26), fatigue (r= -0.37), fatigue interference (r= -0.44) and negative association between physical activity and pain frequency (r= -0.4) and severity (r= -0.4) and fatigue (r= -0.21). The physical activity domain showed a positive correlation with the Chao index (r= 0.11) and the Shannon index (r= 0.14). The nutrition domain showed a positive association between Chao (r= 0.11) and Shannon (r= 0.07). Also, positive associations between pain frequency (r= 0.10), pain severity (r= 0.19), pain distress (r= 0.20) and the spiritual growth domain were identified. These findings highlight the potential of multi-domain lifestyle interventions in enhancing post-HCT recovery and improving gut microbiota diversity. Further research is warranted to confirm these associations and refine health promotion strategies for HCT survivors.

#805 Macrophages protect salivary glands from ionizing radiation.

Dimitri Scofield, Cristina Paz, Jasmine Robinson, Kwang Nickel, Randy Kimple

Human Oncology, University of Wisconsin-Madison, Madison, WI

Background: Radiation-induced xerostomia (RIX) is a common side-effect of radiation therapy in patients with head and neck cancer. Our group has previously demonstrated that MSC(M) injection into irradiated murine SMG tissue results in an improvement in salivary function and improvement in glandular health (% saliva in MSC v PBS groups). which corresponds to alterations in macrophages. Our clinical studies have demonstrated that MSC(M) injection into salivary glands is safe and effective. However, the full mechanism behind this effect remains unknown. We hypothesized that MSC(M)s in the SMG are affectingimpact tissue-resident macrophage activity and/or promotein macrophage traffickingg the influx of new macrophages to mediate improved salivary function. Here we test whether macrophages modulate the response to radiation in our mouse model of RIX and whether MSC(M)s can modulate salivary tissue resident macrophages.

Methods: Clodronate liposomes delivered via tail vein injection were used to deplete macrophages in C57/BL6 mice prior to irradiation treatment (15 Gy) of SMGs with 15 Gy. Saliva production was monitoredmonitored, and glands were collected for histology at 3-, 7-, and 60-days post-irradiation. Primary, marrow-derived MSCs (MSC(M)) from C57/B6 male mice were isolated, cultured, and characterized using the immune monitoring 48-plex Luminex assay to characterize the secretion profile of immunomodulatory chemokines.

Results: Macrophage depletion was confirmed via flow cytometry of mouse spleens. Clodronate-treated mice produced less saliva than control mice (92% vs 71% percent decrease respectively) consistent with a protective effect of macrophages. Secretome analysis of MSC(M) revealed a robust secretion profile with high levels of macrophage associated proteins including CCL2 (1527 pg/mL), CCL7 (332.18 pg/mL), CXCL1 (311.41 pg/mL), and CCL5 (157.62 pg/mL). These data suggest that MSC(M)s may have the capacity to modulate recruited and tissue-resident SMG macrophages. This is currently being tested.

Conclusions: Our data suggests a beneficial role of macrophages in the natural response to radiation in the murine SMG. Previous data from our lab demonstrates a benefit from MSC injection after RT-exposure, and our secretome analysis of these cells show the immunomodulatory capacity of our MSC line. Future experiments must be done evaluating the effectiveness of MSC injection in our immune depleted models to determine whether MSCs are directly impacting the macrophages in the radiation damaged gland.

#807 RSV vaccine hesitancy among southern rural veterans with cancer in the Arkansas-Louisiana-Texas (ArkLATX) region: The impact of vaccine fatigue.

P. A. Haddad[1], C. Barmer[2], M. Craig[2], S. Hudson[2], A. Gupta[2];

[1]LSUHSC-S, Feist-Weiller Cancer Ctr/Overton Brooks VAMC, Shreveport, LA, [2]Overton Brooks VAMC, Shreveport, LA

Background: Respiratory syncytial virus (RSV) is one of the leading causes of respiratory infections, particularly in immunocompromised older adults. The recently available RSV vaccines offer a tool to reduce the disease burden. However, despite the availability of effective vaccines, vaccine fatigue, a phenomenon characterized by declining enthusiasm and adherence to vaccination campaigns due to the perceived overload of immunization schedules, has emerged as a challenge for vaccine uptake. With the increasing number of recommended vaccines, particularly in the wake of COVID-19 and the influenza vaccination efforts, many patients may experience hesitation toward additional vaccines, including RSV. This quality improvement study aims to explore the prevalence of vaccine fatigue and its effects on the uptake of the RSV vaccine among ArkLATX veterans to identify potential strategies to address this growing concern.

Methods: Between 2023-2024, age-appropriate veterans from 3 Hematology-Oncology clinics at Overton Brooks VAMC were provided the CDC RSV vaccine pamphlet to read along with a provider discussion about the need, indication, and side effects. Afterward, the patients were offered the RSV vaccine. If they declined, they were asked about the reasons. Descriptive statistics, as well as the Chi-square test and logistic regression, were calculated to determine the impact of demographic factors on RSV vaccine uptake.

Results: The sample consisted of 200 veterans from Arkansas, Louisiana, and Texas. The median age was 74, with an age range of 54-93 years. Participants were 93% male, 53% White, 45% Black, and 2% Other. Ninety-one percent were COVID19 vaccinated with 62% receiving both. Thirty-seven percent of the participants declined the RSV vaccine (factoring in 4% RSV vaccine uptake conversion rate during the study period), and 7% received neither. The main reasons for declining were “did not want another shot” (53%), current illness/vaccine reactions (11%), and unknown reasons (36%). There were no statistical differences with respect to age, sex, race, or geography between those who received the RSV vaccine and those who declined. Those who were COVID-19 vaccinated were more likely to have received the RSV vaccine (Odds Ratio=2.4, p=0.02).

Conclusions: Our study reveals that the majority of ArkLATX veterans with cancer are willing to be vaccinated against RSV, though at a lesser rate than previously reported for the same group with the COVID-19 vaccine. The primary reason behind vaccine hesitancy was not wanting another vaccine injected, which was consistent with vaccine fatigue. Fortunately, no one voiced major concerns regarding vaccine safety or efficacy. The results suggest that targeted communication, consistent but not obtrusive reminders, simplifying access, and respecting the patient’s timing and mental readiness could improve uptake.

#808 Healthy dietary patterns and cancer survival: A cohort study.

Z. Bian, X. Xu, S. Zhou, X. Li, X. Wu;
Zhejiang University School of Medicine, Hangzhou, China

Introduction: Diet plays a crucial role in the management and recovery of cancer patients. Making appropriate dietary choices can help provide necessary nutrients, enhance the immune system, maintain energy levels, and promote recovery. To examine the associations of dietary scores for 9 healthy eating patterns with risk of all-cause and cancer mortality in cancer survivors.
Methods: A prospective cohort of cancer survivors (n = 4001; weighted number, 17548466) from the US National Health and Nutrition Examination Survey from 1999 to 2018. Participants were linked to mortality data from their interview and physical examination date through December 31, 2019.
The exposures were Alternative Healthy Eating Index-2010 (AHEI2010), Alternate Mediterranean Diet score (AMED), Dietary Approaches to Stop Hypertension score (DASH), Dietary inflammation index (DII), Healthy dietary score (HDS), Healthy eating index-2020 (HEI2020), Plant-based diet index (PDI), Healthful plant-based diet index (hPDI), and World Cancer Research Fund/American Institute for Cancer Research dietary score (WADS).
Main Outcomes were All-cause and cancer mortality.
Results: The final study sample included 4001 cancer survivors (mean [SD] baseline age,61.86[14.79] years; 2408 (66.37%) females; 2519(82.33) white individuals). During a total of 33130 person-years of follow-up, 1385 Participants died. Of note, when comparing the highest with the lowest tertiles, only AMED (HR (95% CI): 0.80 (0.65-0.98), P = 0.03), HEI2020 (HR (95% CI): 0.81 (0.68-0.96), P = 0.02), and hPDI (HR (95% CI): 0.84 (0.71-0.98), P = 0.03) were significantly associated with all-cause mortality. Also, higher levels of HEI2020 were associated with a lower risk of cancer mortality in cancer survivors (HR (95% CI): 0.70 (0.55-0.88), P = 0.003). All dietary scores had no nonlinear association with all-cause mortality. The inverse associations between these scores and risk of mortality were consistent in subgroups.
Conclusions: In this cohort study of a nationally representative sample of US cancer survivors, embracing a comprehensive and nutritionally balanced dietary pattern, as exemplified by HEI2020, holds tremendous value in promoting the well-being and recovery of cancer survivors.

#809 Food choices of patients with advanced cancer at start of early-phase combination trials with immune checkpoint blockade.

Goldy C. George, Hangil Lee, Sarina A. Piha-Paul, Ecaterina Dumbrava, Apostolia Tsimberidou, Siqing Fu, Grace Appleton, Laila Noor, Jordi Rodon, Timothy A. Yap, Funda Meric-Bernstam, David S. Hong

UT MD Anderson Cancer Center, Houston, TX

Purpose: We examined baseline diet and its association with outcomes and social determinants of health (SDoH) factors among patients (pts) enrolled in early-phase immune checkpoint blockade-included combination trials in a comprehensive cancer center.
Methods: Pts (ECOG 0-1) scheduled to begin an early-phase combination trial with immune checkpoint blockade were recruited into a prospective, longitudinal study design, and completed the validated Multifactor Dietary Screener (0-8, higher score = more frequent use of food during the past 30 days) prior to trial start. Clinical data were extracted from the EMR. Statistics included t-tests and Spearman correlations.
Results: Among 259 pts (52% male, 85% White, age=25-83y, BMI=14-46, median prior lines of treatment=3, 41% had ≥2 metastatic organ involvement), increased intakes of vegetables and whole grain breads were associated with longer trial duration ($P<0.029$ for each). Frequent use of nuts/ seeds was linked to prolonged overall survival ($P=0.014$), and beans to extended progression-free survival ($P=0.039$). Lower regular sugar desserts and white potatoes were associated with superior treatment response (CR / PR) ($P<0.005$ each). Males had bacon/ sausage, hot dogs, red meat, milk, and ice-cream more often than females, and fruits, green leafy vegetables, and other vegetables less often ($P<0.008$ each). White pts had milk and ice-cream more often, and lettuce and leafy vegetables less often than minority pts ($P<0.002$ each). Hispanic pts had beans ($P=0.024$) more often, and cheese, and other vegetables less often than non-Hispanic pts ($P<0.006$ each). Young adults (25y-39y) had pasta more often than older patients ($P=0.006$); pts >70y had shellfish and milk more often than younger pts ($P<0.028$ each). Higher BMI was linked to more frequent intakes of regular fat sausage or bacon, hot dogs, fried potatoes ($P<0.003$ each), and regular fat salad dressing or mayonnaise ($P=0.013$), less frequent intakes of fruit ($P<0.001$), and fewer years of education ($P=0.037$). Less education was associated with more frequent use of bacon/ sausage, doughnuts/ other baked desserts ($P<0.002$ each), regular fat salad dressing, and hot dogs ($P<0.016$ each), and less frequent intakes of whole grain breads, fruits, greens, other vegetables, nuts, yogurt ($P<0.004$ each), and fish ($P=0.013$).
Conclusions: Dietary food choices, increasingly recognized as impacting the hallmarks of cancer, may offer tangible interception of disease outcomes even during treatment in early-phase combination trials incorporating immune checkpoint blockade. Food preferences for pts in trials may be bidirectionally influenced by SDoH factors including educational attainment, gender, race/ ethnicity, and age, and as such, these factors need to be considered when developing wholesome individualized dietary prescriptions and dietary interventions for trial participants.

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#81 FOXN3 suppresses FUT5-mediated adhesion of metastatic ovarian cancer cells to mesothelial cells.

Siyu Zhou, Ayon Ahmed Hassan, Alice Sze Tsai Wong

School of Biological Science, The University of Hong Kong, Hong Kong, Hong Kong

Ovarian cancer is the most lethal gynecological malignancy primarily due to widespread peritoneal metastasis at diagnosis, posing significant treatment challenges. Our previous research has indicated that fucosyltransferase 5 (FUT5) is upregulated in metastatic ovarian cancer and is a key contributor to peritoneal metastatic colonization, which represents the initial rate-limiting step in metastasis. However, little is known about the regulation of FUT5. In this study, using a microfluidic chip model with ascitic fluid shear stress perfusion, we found that FUT5 is transcriptionally upregulated in ovarian cancer cells treated with ascitic shear stress, with no changes in degradation rates of FUT5 protein and transcript. Through a comprehensive analysis involving transcriptional factor prediction, biostatistics on TCGA database expression patterns, and sequence analysis using a metastatic cancer model, we identified Forkhead Box N3 (FOXN3) as a potential regulator of FUT5 transcription. Further investigation demonstrated that FOXN3 suppresses FUT5 expression by directly interacting with its promoter. Expression of FOXN3 suppresses tumor-mesothelial adhesion, which can be reversed by FUT5 overexpression. Together, these findings suggest that the FOXN3/FUT5-axis plays a crucial role in ovarian tumor-mesothelial interaction and could serve as a potential therapeutic target (This work is supported by HMRF08192286 and RGC SRFS2223-7S05).

CLINICAL RESEARCH: Targeted Therapies and Combinations 1
Poster Session

#813 *In vitro* and *in vivo* modelling of drug tolerance and minimal residual disease to discover effective therapeutic combination strategies for EGFR-mutated lung cancer.

Kristyna A. Gorospe[1], Ming Li[2], Arundhathi Arivajiagane[2], Nhu-An Pham[2], Roya Navab[2], Kelsie L. Thu[3], Ming-Sound Tsao[2]

[1]Laboratory Medicine and Pathology, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Research Tower, Toronto, ON, Canada,[3]Laboratory Medicine and Pathology, St. Michael's Hospital, Toronto, ON, Canada

Resistance to EGFR-targeted therapy is a major barrier to improving survival rates for non-small cell lung cancer (NSCLC) patients whose tumors have activating *EGFR* mutations. Resistance to EGFR tyrosine kinase inhibitors (TKIs) emerges from drug-tolerant persister cells (DTPs) that survive TKI therapy and manifest in patients as minimal residual disease, which inevitably drives fatal tumor recurrences. DTPs are a rare population of cancer cells in a reversible, slowly proliferating state that survives targeted therapy. Upon TKI withdrawal, they exit the DTP state to recommence rapid proliferation and aggressive tumor growth. Since DTPs provide a reservoir of surviving cells from which outright resistance driven by acquired genetic alterations arises, we hypothesize that discovering DTP survival mechanisms will inform vulnerabilities whose inhibition could enhance the efficacy of EGFR TKIs. However, such mechanisms are poorly understood in EGFR-mutant lung adenocarcinoma (LUAD). To address this knowledge gap, this study aims to generate robust *in vitro* and *in vivo* LUAD models of Osimertinib (Osi)-induced drug tolerance. Genetic and functional characterization of these models has the potential to identify mechanisms enabling drug tolerance that could be targeted to prevent TKI resistance from developing. To date, the response of 3 *EGFR*-mutant LUAD models to Osi treatment has been characterized both in vitro and in vivo [PC9, HCC4006, and 1 patient-derived xenograft (PDX)-derived cell line, X137CL]. Osi treatment of these cells increased apoptosis, but also arrested treated cells in G0-G1 phases of the cell cycle, consistent with the slow cycling nature of DTPs. Osi treatment of the xenografts formed by these lines induced strong tumor regressions and tumor replicates relapsed upon drug cessation, indicating these models are appropriate for studying DTPs *in vivo*. These models will be leveraged for molecular, functional, and pharmacological studies to identify shared and distinct mechanisms driving drug tolerance, in *in vitro* and *in vivo* conditions, including comparative single-cell transcriptomic profiling and pathway analysis. Candidate genes and pathways discovered will be functionally validated using CRISPR screens. Our comparative analyses of DTP versus untreated tumors will reveal novel interventions for preventing tumor relapse following TKI therapy in *EGFR*-mutant lung cancers.

#814 A novel small molecule prodrug activated inside cancer cells by a tumor associated enzyme for targeted chemotherapeutics in kidney cancer.

Ross A. Hamilton, Leniher C. Chibas, Uksha Saini, Stephanie Vega, Dev Chatterjee, Atul Varadhachary

Brimstalt Therapeutics, Houston, TX

Significance: Brimstalt Therapeutics is developing a small molecule drug for treatment of cancer patients with tumors that express the tumor associated enzyme (TAE), SULT1A1. The lead compound, BST-12, is a prodrug that is activated by SULT1A1, converting it into a potent non-specific alkylating agent resulting in targeted cancer cell death while leaving normal tissue unaffected. BST-12 belongs to a class of compounds called N-Benzyl Indole Carbinols (N-BICs). N-BICs have been previously identified as compounds that demonstrate potent antitumor effects once activated by SULT1A1, whose expression is both necessary and sufficient for activation. Kidney and renal pelvis cancer is the seventh most common cancer in the US, with an estimated 82,610 new cases and 14,390 deaths in 2024. Renal cell carcinoma (RCC) is the most frequent type of renal cancer; unfortunately, 33% of patients will experience relapse at metastatic sites and, consequently, have significantly poorer outcomes, highlighting the urgent need for novel therapeutic strategies. SULT1A1 is a metabolic sulfotransferase that is normally expressed in the liver, kidney, and GI tract, and either not expressed or expressed at low levels in other tissue types. However, SULT1A1 is a known inducer of carcinogenesis, considered a TAE that is over-expressed in about 8-15% of major cancers, including RCC, breast, and prostate, and its expression correlates with poorer patient prognosis. An IHC study on 233 tumors from 48 tissue types showed that in RCC, SULT1A1 levels were elevated and homogenously expressed; thus, RCC was selected for the initial indication for BST-12 testing.

Results: In preclinical studies, BST-12 demonstrates potent anticancer activity in SULT1A1+ RCC cells (A498 and Caki-1), with IC50s under 250 pM, but has no effect on SULT1A1- cells (ACHN and 786-0). Direct sulfonation assays using recombinant SULT1A1 protein supports the mechanism of action reported with N-BICs. Furthermore, BST-12 treated A498 and Caki-1 cells had increased phospho-H2A.X levels, a DNA-damage marker associated with non-specific alkylation, topoisomerase inhibitors, and ROS inducing agents. In vivo, BST-12 treatment in A498 CDX models rapidly eliminated established tumors. To assess toxicity, the organs (liver, kidney, GI tract), serum liver enzyme levels (AST, ALT), and body weights of male/female rats treated with BST-12 were evaluated and indicated BST-12 has a good tolerability profile.

Conclusions: The development of BST-12 has significant potential to improve survival / quality of life of SULT1A1+ RCC cancer patients. Although RCC is our primary target indication, the initial BST-12 proof-of-concept will support label expansion opportunities in other SULT1A1+ cancer types. Lastly, BST-12 has intriguing promise for bypassing any acquired resistance pathways associated with current standards of care.

#815 AZD5335, a folate receptor alpha-targeted ADC, enhances ovarian cancer treatment with bevacizumab, paclitaxel and/or carboplatin.

Jason J. Zoeller[1], Ravinder Tammali[1], Ana De Almeida[2], Shane Cronin[1], Nancy Lee[1], Alma Andoni[1], Claire Myers[1], Elaine Joseph[2], Michael Lehmann[1], Rebecca Sargeant[3], Ina Bisha[4], Simon Christ[4], Iris Dino[4], Xhenifer Guza[4], Jixin Wang[1], Lisa Godfrey[3], Roger Dodd[3], Neki Patel[5], Edward Rosfjord[1], Marco Gymnopoulos[1], Tim Brier[3], Sabina Cosulich[3], Elaine Hurt[1], Puja Sapra[1]

[1]AstraZeneca US, Gaithersburg, MD,[2]AstraZeneca US, Waltham, MA,[3]AstraZeneca UK, Cambridge, United Kingdom,[4]AstraZeneca GmbH, Munich, Germany,[5]AstraZeneca UK, London, United Kingdom

Elevated expression of folate receptor alpha (FRα) in various cancers, including epithelial ovarian cancer (EOC), highlights FRα as a potential target for the development of novel therapeutics to treat FRα-expressing tumor types. AZD5335, an FRα-targeting antibody conjugated to a topoisomerase 1 inhibitor (TOP1i) payload, is currently being investigated in the FONTANA Phase I/IIa clinical trial (NCT#05797168), either as a single agent or in combination with a PARP1-selective inhibitor (saruparib). Using an FRα-expressing EOC xenograft model (OV90), we evaluate additional AZD5335-relevant combined treatment strategies and report pre-clinical assessment of AZD5335 in combination with bevacizumab, paclitaxel and/or carboplatin. Compared to monotherapy treatment, we successfully demonstrate that combination treatments with AZD5335+bevacizumab, AZD5335+paclitaxel or AZD5335+carboplatin result in significant and durable anti-tumor responses. Using the same EOC xenograft model, we extended these studies to include AZD5335+bevacizumab plus either paclitaxel or carboplatin treatments and demonstrated that these triplet combos resulted in superior and durable anti-tumor activities. Combination data in a number of additional CDX/PDX will be presented. A series of in vitro studies will also define the ADC/SOC drug interactions and further delineate underlying mechanisms driving enhanced efficacy. These studies inform our ongoing clinical development of AZD5335 in ovarian cancer.

#816 Aurora kinase A inhibition overcomes tolerance to panHER inhibitors in HPV positive HNSCC.

Sebastian Cruz-Gomez[1], Jong Woo Lee[1], Julian Barrantes[1], Richard Ivey[2], Sara Savage[3], Pratima Chaurasia[1], Gunner Dickson[1], Dickson Adah[1], Bing Zhang[3], Amanda Paulovich[2], Barbara Burtness[1]

[1]Internal Medicine, Yale Cancer Center, New Haven, CT,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]Baylor College of Medicine, Houston, TX

The incidence of HPV-associated (HPV+) head and neck squamous cell carcinoma (HNSCC) has been increasing in recent decades. The EGFR inhibitor cetuximab (CTX) is less active in HPV+ than HPV- HNSCC. HPV oncoproteins E6 and E7 induce HER3 overexpression, and EGFR-HER3 heterodimer-driven survival signaling via PIK3, AKT and ERK1-2 contributes to resistance to cetuximab and the EGFR inhibitor erlotinib. We demonstrate that although panHER inhibitors afatinib and dacomitinib more effectively inhibit growth of HPV+ HNSCC cells than do erlotinib or cetuximab, adaptive signaling through the AURKA/PLK1 axis mediates resistance to panHER inhibitors. We hypothesized that combined panHER and AURKA inhibition would synergize to overcome persistence of HPV+ HNSCC. We find that HPV+ HSNCC cells UM-SCC47 and UPCI:SCC154 express both EGFR and HER3. Indeed, cell viability experiments and clonogenic survival assays demonstrate strong synergy between panHER and AURKA inhibitors, confirmed in xenografted tumor models treated with the second generation AURKA inhibitor VIC-1911 and dacomitinib. We then performed RNAseq and shotgun proteomics to understand the cellular mechanisms behind our combination. Dacomitinib had expected effects downregulating Hallmark G2M and EGFR phosphorylation targets, upregulating EMT markers and cell death markers. In contrast, addition of AURKA inhibition upregulated PLK1 and pPLK1 and cell death markers. These findings indicate that combination therapy with AURKA inhibition will mitigate the adaptability to EGFR and panHER inhibitors previously described for HPV+ HNSCC.

#817 A prospective, multi-center, phase IV study to evaluate safety and efficacy of Dr. Reddy's bevacizumab (DRL_BZ) in patients with solid tumors.

Narendra Maharaj[1], Ranjith K[1], Anand Eswaraiah[1], Pramod kumar Reddy[1], Gopichand M[2], Rajender Singh Arora[3], Krishna Chaithanya Puligundla[4], Ashok Kumar Diwan[5], Tanveer Mohibbhai Maksud[6]

[1]Dr. Reddy's Laboratories Ltd, Hyderabad, India,[2]HCG City Cancer Centre- A unit of Health Care Global Enterprises Limited, Vijaywada, India,[3]Sujan Surgical Cancer Hospital- Amravati Cancer Foundation, Amravati, India,[4]MNJ Institute of Oncology and Regional Cancer Center, Hyderabad, India,[5]Government Medical College, Nagpur, India,[6]Unique Hospital Multispecialty & Research Centre, Surat, India

Introduction: DRL_BZ is a biosimilar to the reference product, bevacizumab, and was approved in India and subsequently introduced in other markets for the use in various other solid tumors as single or combination therapy. This study was conducted as part of a post-marketing commitment to regulatory authority aimed to evaluate treatment safety (primary objective), and efficacy (secondary objective) in male and female patients with solid tumors.

Methods: In this prospective, single-arm, multicenter, Phase IV study (BZ-01-002), a total of 200 patients with median age 54.0 years were enrolled with the following indications: mCRC (n = 59); NSCLC (n = 41); epithelial ovarian cancer (n = 27), and cervical cancer (n = 73). Patients received DRL_BZ either with chemotherapy or as monotherapy and followed up to disease progression, unacceptable toxicity, or death due to any cause, or up to 6 months from first dose whichever occurs earlier.

Results: The overall median duration (days) of DRL_BZ treatment exposure for the enrolled patients was 151.5 (1.0 - 253) days. Of the 200 enrolled patients, 117 (58.5%) patients completed the study, while 83 (41.5%) patients were withdrawn from the study due to various reasons (majorly due to COVID-19 pandemic). Out of 454 TEAEs reported from 139 (69.5%) patients, 46 TEAEs in 25 (12.5%) patients were considered related to DRL_BZ administration. Thirteen (6.5%) TEAEs leading to permanent study drug discontinuation. A total of 13 SAEs in 12 (6%) patients were reported and four of them were related to study drug. As per mITT population, 153 patients were evaluable for efficacy, and the reported ORR was 23.1% (3/13) for 2-weekly mCRC patients, 25% (8/32) for 3-weekly mCRC patients, 45.7% (16/35) for NSCLC patients, 72.7% (16/22) for epithelial ovarian cancer patients, and 37.3% (19/51) for cervical cancer patients.

Conclusions: The safety profile of DRL_BZ, in terms of reported adverse events, in patients with solid tumors is comparable and consistent with the known safety profile of bevacizumab in literature. Overall, findings from this Phase IV study indicate that the safety and efficacy of DRL_BZ in patients with solid tumors is as per the approved prescribing information.

#818 A logic-gated chimeric antigen receptor T cell (CAR T) for post-transplant acute myeloid leukemia (AML) that distinguishes donor and recipient hematopoiesis.

D. Manry, B. L. Luna, A. G. Winters, A. D. Flynn, T. K. Gill, M. Mcelvain, A. Sima, J. Wang, A. Zampieri, M. Daris, J. Zhang, S. Martire, B. DiAndreth, C. Netirojjanakul, T. Tokatlian, A. Kamb, J. S. Welch;
A2 Biotherapeutics, Inc, Agoura Hills, CA

Background: AML relapse after a stem cell transplant is associated with dismal outcomes and no current FDA-approved therapeutic options. Cell therapy for AML has been challenging due to a lack of antigens distinguishing malignant from normal hematopoiesis, the potential for antigen escape due to intratumor antigen heterogeneity, and poor T cell function in lymphocytes from AML patients. To overcome these problems, we focus on opportunities in patients who have received human leukocyte antigen (HLA)-A*02 mismatched transplants. We have developed a Tmod HLA-A*02 NOT gate (blocker) that prevents CAR T killing of HLA-A*02 positive cells. In patients who are HLA-A*02 negative and receive an HLA-A*02 positive stem cell transplant, the blocker distinguishes tumor (HLA-A*02 negative) and normal (HLA-A*02 positive) hematopoiesis. A similar Tmod NOT gate has been safe in an ongoing solid tumor clinical trial (NCT05736731) (Grierson, et al. *SITC.* 2024). The blocker is paired with a dual CD33/CLL-1 activator to prevent antigen escape in donor-derived HLA-A*02 positive T cells to mitigate AML patient T-cell dysfunction. Additional blockers targeting HLA-A*03, etc can expand therapeutic opportunity to patients who have received other HLA-mismatch transplants.
Methods: CAR constructs were designed and screened in Jurkat and primary T cell assays. The 50% effective and inhibitory concentration (EC50 and IC50) results were compared to monospecific CAR constructs using benchmark activators based on single-chain variable fragments (scFvs) from M26 (CLL-1) and lintuzumab (CD33) using wild-type A*02-negative and A*02-positive engineered AML cell lines.
Results: 111 tandem CD33/CLL-1 activator CAR constructs were evaluated in Jurkat cells and 23 in conjunction with HLA-A*02 blocker. Six tandem constructs were prioritized for evaluation in primary T cells, identifying one (20I21-1A4 mBAAsh) with IC50 potency similar to monospecific CAR constructs, and selectivity observed between HLA-A*02 positive vs. HLA-A*02 negative cells. Selective protection also was observed in HLA-A*02 positive primary hematopoietic stem cells compared with CAR constructs without the blocker.
Conclusions: We have developed a cell therapy strategy to leverage HLA mismatched stem cell transplants using a Tmod HLA-A*02 blocker. This approach could be applied to patients who have relapsed after a mismatched transplant or integrated into a stem cell transplant to prevent relapse. Pre-clinical data of this design demonstrates selectivity between HLA-A*02 positive and HLA-A*02 negative cells, and dual antigen activity addresses antigen escape. Future studies will interrogate the impact of membrane-tethered cytokines to augment potency and xenografts studies to further define activity.

#819 Comparison of DNA+RNA-NGS and DNA-NGS for detecting targetable driver gene alterations in Chinese patients with advanced NSCLC.

Guohao Xia[1], Ping Liu[1], Lin Shi[1], Gao Ning[2], Ding Zhang[2]

[1]Medical Oncology, Jiangsu Cancer Hospital, Nanjing, China,[2]3D Biomedicine Science & Technology Co., Ltd., Shanghai, China

Background: Patients with advanced non-small cell lung cancer (NSCLC) require genetic testing to enable precision treatment. The conventional method for genetic testing is next-generation sequencing (NGS) using DNA templates (DNA-NGS). However, multiple studies have shown that DNA-NGS often fails to detect fusion mutations, while RNA-based NGS demonstrates superior detection rates for these alterations. This study evaluates the rate of targetable driver gene alterations (AGAs) in NSCLC patients using DNA+RNA-NGS compared to DNA-NGS in real-world settings, providing reliable evidence to support clinical practice.

Methods: This study included 143 Chinese patients with advanced untreated NSCLC from November 2022 to October 2024. Eighty patients underwent DNA-NGS testing, and 63 underwent DNA+RNA-NGS testing. In DNA+RNA-NGS, DNA and RNA were extracted from the same tissue specimens. RNA was reverse transcribed into complementary DNA (cDNA) and combined with DNA. Detection was performed in a single workflow, using DNA for single nucleotide variant (SNV) and insertion/deletion (indel) detection, while RNA was utilized for rearrangement detection.

Results: In the DNA+RNA-NGS cohort, the median age was 68 years (63.5% male), while in the DNA-NGS cohort, it was 64 years (67.5% male). The detection rate of AGAs was higher in the DNA+RNA-NGS cohort (55.6% vs. 45.0%, p=0.21), primarily due to increased detection of rearrangements (14.3% vs. 7.5%, p=0.21). SNV/indel detection rates showed no significant difference (41.3% vs. 37.5%, p=0.65). Among rearrangement AGAs, there were no significant differences in ALK (4.8% vs. 3.8%, p=0.76), RET (1.6% vs. 1.3%, p=0.86), and METex14 skipping (1.6% vs. 2.5%, p=0.71). However, the ROS1 rearrangement detection rate was significantly higher in the DNA+RNA-NGS cohort (6.3% vs. 0%, p=0.02), attributed to the sequence characteristics of the ROS1 gene, which contains two large repetitive fragments (L1PA8A and L1PA10) in intron 31 that DNA probes often miss. Similar challenges occur with NTRK1/2/3 rearrangements, especially at intron 11 and 12 breakpoints in NTRK3, which are hard to capture with DNA probes, leading to missed detections. However, due to the low incidence of NTRK rearrangements, no cases were found in either cohort. In total, 7 (ALK, n=2; ROS1, n=3; RET, n=1; METex14 skipping, n=1) and 3 (ALK, n=3) fusion-positive patients from the DNA+RNA-NGS and DNA-NGS cohorts, respectively, received targeted therapy, with all 10 achieving favorable clinical responses.

Conclusion: DNA+RNA-NGS enhances the detection rate of AGAs compared to DNA-NGS, particularly for rearrangement-related genes in patients with NSCLC. Patients with rearrangements identified by DNA+RNA-NGS who receive targeted therapy can experience significant clinical benefits, thereby improving precision diagnosis and treatment in NSCLC.

#820 Combined HDAC and ATM inhibition potentiates anticancer effects in glioblastoma preclinical models.

Susan J. Histed, Kaitlyn Chung, Gozde Uzunalli, Elizabeth Hayes, Kyria Kelley-Wolfe, Jordon Fakhoury, Tigran Margaryan, Sonam Patel, Nader Sanai, Artak Tovmasyan, An-Chi Tien, Shwetal Mehta

Ivy Brain Tumor Center at Barrow Neurological Institute, Phoenix, AZ

Background: Brain penetrant histone deacetylase inhibitors (HDACi) are promising radiosensitizing agents for glioblastoma (GBM). In addition to suppression of HDAC activity, the antiproliferative effect of HDACi includes downregulation of DNA damage repair (DDR) pathway and persistent DNA damage. Here, we evaluated synergistic effect of combining HDAC and DNA repair enzyme, ataxia telangiectasia mutated (ATM) inhibitors, quisinostat (QST) and AZD1390 to broaden therapeutic window for GBM treatment.
Methods: *In vitro* dose-response assays were performed in patient-derived xenograft (PDX)-derived glioma stem cells (GSCs) with both QST and AZD1390 with or without radiation treatment to assess synergy. Immunoblotting and immunofluorescence assays were performed for histone acetylation, DNA damage (pH2AX), pRAD50, pATM and cleaved caspase 3 to assess pharmacodynamic responses. Quantitative PCR analysis was performed to examine changes in gene expression of key DNA damage pathway genes.
Results: Combined treatment with QST and AZD1390 synergistically inhibit GBM growth across multiple GBM GSC models in combination with radiation. HDACi treatment dampens the DDR response pathway via suppression of key DDR pathway genes resulting in persistent unrepaired DNA damage.
Conclusions: Our data indicate that QST and AZD1390 act synergistically to radiosensitize GBM cells and increase the therapeutic window for treatment. *In vivo* experiments are under way to examine efficacy of this combination using orthotopic PDX GBM models.
Keywords: glioblastoma, ATM, HDAC, DNA damage repair

#821 A potent CDK7 inhibitor TY-2699a suppresses palbociclib-resistant breast cancer and has the potential for combination with chemotherapy or immunotherapy in solid tumors.

Shengli Dong*,#[1], Apeng Liang*,#[1], Shaoqing Chen*[1], Zhengfei Guo[1], Jian Zhu[1], Huan Wang[2], Jing-Lan Mu[2], Yakun Qi[2], Meihua Li[1], Kai Wang[1], Hongqiang Li[1], Xinlong Yang[1], Chao Zhou[1], Zhiyong He[1], Zhengzhou, Henan Niu[3], Mingyu Jiang[2], Xiugui Chen[2], Jun Li[3], Yusheng Wu[3]

[1]TYK Medicines, Inc., Changxing county, Huzhou City, China,[2]TYK Medicines, Inc. (Shanghai), Xuhui District, Shanghai, China,[3]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, Henan, China

Introduction: Development of an effective treatment strategy for CDK4 and CDK6 inhibitors (CDK4/6i)-resistan cancers has become an urgent unmet clinical need. CDK7 is a kinase at the core of transcription and also functions in regulating cell cycle progression. Recent studies have shown that CDK7 is a potential target to overcome CDK4/6i resistance. CDK7 overexpression has been identified in pancreatic cancer. High CDK7 expression blocked apoptosis of pancreatic cancer cells induced by nab-paclitaxel combined with gemcitabine. TY-2699a is a selective CDK7 inhibitor developed by TYK Medicines, Inc. Here we report that TY-2699a demonstrated superior efficacy as well as good tolerability and safety.

Results: TY-2699a was more than 80-, 66- and 86-fold more active than palbociclib in palbociclib-resistant stable cell lines of MCF7, T47D and HCC1428 cells, respectively. Consistent with the *in vitro* results, a 40 mg/kg dose of palbociclib almost completely failed to inhibit tumor growth in the xMCF-7/Palbo-R mouse model of breast cancer. TY-2699a at a dose of 6 mg/kg significantly inhibited tumor growth. The efficacy of CT-7001 monotherapy at a dose of 100 mg/kg was comparable to that of TY-2699a at a dose of 1 mg/kg, which only mildly inhibited tumor growth. Our efficacy data of TY-2669a provides a solid rationale for further evaluation of TY-2699a +/- fulvestrant in clinical HR+Her2- CDK4/6-resistant breast cancer patients. In addition, targeted inhibition of CDK7 not only enhanced the efficacy of paclitaxel or gemcitabine in pancreatic cancer cells, but also enhanced the *in vivo* efficacy of nab-paclitaxel, gemcitabine, and nab-paclitaxel in combination with gemcitabine in mouse pancreatic cancer tumor models. We initiated a phase I, multicenter, open-label study of TY-2699a administered orally to adult patients with locally advanced or metastatic solid tumors in 2023. In the single-agent dose escalation stage, TY-2699a showed better clinical safety than SY-5609 did. Most Adverse events were Grade 1 or 2. Adverse events assessed as grade 3 or 4 were a decrease in PLT, diarrhea, stomatitis, and anemia. We plan to enroll 40 subjects each cohort to evaluate the efficacy of TY-2699a combination treatment in ER+/Her2- breast cancers, pancreatic cancer, and nasopharyngeal carcinoma.

In summary, TY-2699a is a highly selective and potent CDK7 kinase inhibitor, The compound has potential wider therapeutic window than multiple CDK7 inhibitors that are active in the clinical development stages. TY-2699a has shown a manageable clinical safety profile. In addition to its use as monotherapy, TY-2699a has great potential for use as a combination therapy with chemotherapy or immunotherapy.

#822 Combination of carboplatin and CHK1 inhibition to overcome platinum resistance in high grade serous ovarian cancer.

Mackenzie Cummings[1], Jaden Williams[2], Jennifer Pierce[1], Nathaniel Jones[1], Kevin Lee[1]

[1]Gynecologic Oncology, USA Health Mitchell Cancer Institute, Mobile, AL,[2]USA Health Mitchell Cancer Institute, Mobile, AL

Platinum based chemotherapy is the most effective treatment for high grade serous ovarian cancer (HGSOC). Resistance in the recurrent setting is a poor prognostic indicator with few treatment options. CHK1 inhibitors have been studied in HGSOC in preclinical and early phase trials alone and in combination with cytotoxic chemotherapy, but have not been studied in combination with platinum to our knowledge. We used the CHK1 inhibitor, prexasertib, as a strategy to overcome platinum resistance by promoting cell cycle progression, limiting repair of platinum induced DNA damage. Sensitivity to carboplatin and prexasertib alone and in combination were measured in a panel of pre-clinical HGSOC cell lines. DNA damage was detected using the Repair Assisted Damage Detection method in untreated and treated cells for 24h with carboplatin and prexasertib alone and in combination. An enzymatic cocktail of UDG, FPG, T4PDG, Endo IV, Endo VIII, and AAG was used to extract DNA damaged lesions. Damaged lesions were labeled for detection with polymerase and a Digoxigenin labeled dUTP. Samples were stained for anti-DIG and anti-pCHK1 S317, imaged on a confocal microscope, and analyzed in Nikon Elements software. Expression of pCHK1 S317 was confirmed via Western Blot. A synergistic effect was observed in all cell lines with the combination of carboplatin and prexasertib. In ES2 cells, carboplatin alone resulted in 15.4% cell death and increased to 72.5% ($p<0.001$) and 86.8% ($p<0.0001$) with the addition of prexasertib 5nM and 10nM, respectively. In SKOV3 cells, carboplatin resulted in 38.2% cell death and increased to 80.0% ($p=0.0002$) and 86.6% ($p<0.0001$). In OvCar4 cells, carboplatin resulted in 53.2% cell death and increased to 90.6% ($p=0.0001$) and 92.4% ($p<0.0001$). In OV90 cells, carboplatin resulted in 25.3% cell death and increased to 56.6% ($p<0.0001$) and 60.1% ($p<0.0001$). In OvCar8 cells, carboplatin resulted in 29.3% cell death and increased to 91.9% ($p<0.0001$) and 95.4% ($p<0.0001$). DNA damage increased in ES2 cells with prexasertib 10 nM + carboplatin (1.4-fold increase, $p=0.03$), SKOV3 with prexasertib 5 nM + carboplatin (257.0-fold increase, $p=0.002$), OvCar4 with prexasertib 10 nM + carboplatin (1.4 fold increase, $p=0.03$) and OvCar8 with prexasertib 10 nM + carboplatin (2.0-fold increase, $p=0.0003$). There was no difference in DNA damage in OV90 cells. pCHK1 S317 was increased significantly in all 5 cell lines treated with combination therapy, consistent with known phosphorylation of CHK1 at S317 by ATR in response to DNA damage and inhibition of p-CHK1 auto-phosphorylation by prexasertib leading to inactivation. The CHK1 inhibitor, prexasertib, demonstrated a synergistic effect when used in combination with carboplatin, correlating with an expected increase in DNA damage and p-CHK1 S317. The use of CHK1 inhibitors with platinum may be a new treatment strategy in platinum resistant HGSOC.

#823 Combination therapy of HDAC inhibitors with HSP90 and TRAP1 targeting the hypoxia pathway in triple-negative breast cancer.

Golnaz Asaadi Tehrani[1], Becca Kubick[2], Andrew Gutierrez[3], Terin D'Amic[3], Hailey Sanders[3], Brian Blagg[3], Bradley Smith[3], Meenal Datta[1]

[1]Aerospace and Mechanical Engineering, University of Notre Dame, South Bend, IN,[2]Department of Biological Sciences, University of Notre Dame, South Bend, IN,[3]Department of Chemistry and Biochemistry, University of Notre Dame, South Bend, IN

Triple-negative breast cancer (TNBC) is one of the deadliest subtypes of breast cancer that more than 50% of cases present with hypoxia, which induces chemotherapy resistance and fuels treatment failure. While various therapies targeting components of the hypoxia signaling cascade have been identified, those focusing on specific targets often fail to produce lasting clinical responses. Therefore, there is a critical need for novel hypoxia inhibitors that combine potency, specificity, low toxicity, and favorable druggability. In this study, we evaluated the efficacy of novel drug combinations involving Heat Shock Protein 90 inhibitor (HSP90i) NDNB-25, Tumor Necrosis Factor Receptor-Associated Protein 1 inhibitor (TRAP1i) NDNT-34, and histone deacetylase inhibitors (HDACis) such as CAY10603, suberoylanilide hydroxamic acid (SAHA), and Valproic acid (VPA). The goal was to suppress the hypoxia pathway in TNBC and assess impacts on cell viability, metastasis, and hypoxia-related gene expression using 2D and 3D TNBC models. Our results demonstrated a strong synergistic effect of SAHA/NDNB-25 and SAHA/NDNT-34 combination therapies. Specifically, NDNB-25/SAHA combination significantly down-regulated *HIF1A* expression in 2D- cultures. While NDNB-25 and NDNT-34 mono-therapies only reduced *HIF2A* and *TRAP1* expression, the NDNB-25/NDNT-34 combination down-regulated *HIF1A*, *HIF2A*, *VEGFA*, *TRAP1*, and *HSP90* in 3D cultures. Moreover, the NDNB-25/NDNT-34 combination, at lower concentrations (250 nM and 5 µM), inhibited cell migration more effectively than mono-therapies at higher concentrations (500 nM and 10 µM). Fluorescent imaging revealed more distribution of hypoxia signals using a labeled hypoxia probe and the localization of TRAP1i, tagged with rhodamine B, in TNBC-derived mammospheres compared with luminal subtype. These findings suggest that combining epi-drugs and targeted therapies to modulate the hypoxia pathway could inform the development of innovative clinical strategies against TNBC.

#824 Comparative pharmacokinetics (PK) of targeted tissue factor tTF-NGR when intravenously applied alone or in combination with preceding trabectedin .

Christian Schwoppe, Caroline Brand, Kathrin Hessling, Heike Hintelmann, Andrew F. Berdel, Georg Lenz, Torsten Kessler, Manfred Fobker, Christoph Schliemann, **Wolfgang E. Berdel**

University of Munster, Muenster, Germany

Trabectedin is a treatment option for relapsed/refractory soft tissue sarcomas (STS). CD13 is a neutral aminopeptidase expressed on invasive endothelial cells (EC) such as in the tumor vasculature. CD13-targeted tissue factor (tTF-NGR) is a recombinant pro-coagulatory fusion protein with a molecular weight of 30381.98 g/mol which accumulates in the tumor vasculature leading to tumor vascular occlusion and tumor infarction. Giving both compounds in sequence could trap trabectedin inside tumors and increase its efficacy. *Vice versa* trabectedin optimizes activity of tTF-NGR by externalizing phosphatidylserine (PS) on the surface of EC. PK of safety patients treated at our hospital within a multicenter trial of a combination of trabectedin and tTF-NGR in advanced STS patients refractory to 1st line systemic therapy (TRABTRAP, EudraCT 2020-005858-21) were compared with PK from our phase I monotherapy study with tTF-NGR (EudraCT 2016-003042-85). We compared standard PK parameters for tTF-NGR at identical dose levels (1.0 to 3.0 mg/m²) from TRABTRAP and phase I within the same laboratory with identical methods and calculations. Although some PK differences between phase I and TRABTRAP were more pronounced at lower dose levels, global values such as Cmax, AUC, t1/2alpha, t1/2term, and Kel indicated an increased AUC with a delayed elimination of tTF-NGR when given after trabectedin. As tTF-NGR was always given daily, we measured the remaining tTF-NGR concentrations before subsequent applications and found significantly increased values in the combination protocol (1 mg/m^2: $p<0.0001$; 3 mg/m^2: $p<0.0002$) when compared with the phase I values, suggesting a possible accumulation of tTF-NGR which we did not observe with monotherapy. A specific way of tTF-NGR elimination in the vascular system is the internalization of the tTF-NGR:CD13 complex into EC. Using flow cytometry and fluorescence labeling with tTF-NGR and EC *in vitro*, expression of CD13 on EC was slightly diminished by trabectedin exposure. Also, tTF-NGR binding to CD13 ($p<0.01$) and internalization ($p=0.01$) decreased when tested on control and trabectedin-exposed EC. Both lead to more tTF-NGR molecules remaining in the circulation, explaining part of the delayed elimination. Further, we compared functionality of tTF-NGR in the plasma of patients from phase I and TRABTRAP. On the basis of equal protein amounts and without influence of confounders such as storage, the ability of factor VIIa:tTF-NGR:CD13 to activate factor X to Xa was higher when trabectedin was given to the patients before. Among possible explanations are the decreased liver protease levels after trabectedin, which could influence the functionality of tTF-NGR. In summary, these results explain why the Maximum Tolerated Dose level for tTF-NGR established in the TRABTRAP safety cohort is lower than the 3 mg/m^2 in the phase I study.

#825 Correlation of clinical and biomarker data in FGFR inhibitor failed metastatic cholangiocarcinoma patients with tumor response to tinengotinib.

Sarina A. Piha-Paul[1], Sanjay Goel[2], Chih-Yi Liao[3], Nashat Gabrail[4], Farshid Dayyani[5], Syed Kazmi[6], Sayeh Lavasani[7], Katie Hennessy[8], Hui Wang[9], Caixia Sun[9], Peng Peng[9], Jean Fan[8], Milind Javle[1]

[1]University of Texas MD Anderson Cancer Center, Houston, TX,[2]Rutgers Cancer Center Institute of New Jersey, New Brunswick, NJ,[3]The University of Chicago Medicine and Biological Sciences, Chicago, IL,[4]Gabrail Cancer Center Research, Canton, OH,[5]University of California, Irvine, Irvine, CA,[6]University of Texas Southwestern, Dallas, TX,[7]City of Hope National Medical Center, Duarte, CA,[8]TransThera Sciences (US), Inc., Gaithersburg, MD,[9]TransThera Sciences (Nanjing), Inc., Nanjing, China

Background: Cholangiocarcinoma (CCA) patients (pts) harboring FGFR fusions treated with FGFR inhibitors (FGFRi) have shown clinical benefit, but often have progression in 5- 7 months. Secondary polyclonal mutations in the FGFR2 kinase domain (KD) may be a mechanism for acquired resistance to FGFRi. Tinengotinib, a spectrum-selective multi-kinase inhibitor with unique binding properties to FGFR2, potently inhibited FGFR2 KD mutations in pre-clinical models and exhibited antitumor activity in CCA pts. Here we present two cases of CCA pts treated with tinengotinib in a phase Ib/II trial.

Methods: Biomarker samples were collected at baseline and C3D1 timepoints as an exploratory endpoint for pts receiving tinengotinib therapy. Efficacy was evaluated by RECIST v1.1. Tissue and blood samples were analyzed by FoundationOne® CDx and FoundationOne® Liquid CDx test, respectively, for FGFR alterations.

Results: Two CCA pts received oral tinengotinib 12mg once daily continuously for 28-day cycles and completed biomarker sampling at baseline and C3D1. Both pts were previously treated with chemotherapy and pemigatinib. Pt A is a 28yr female with CCA metastatic to liver and bone. Tinengotinib was initiated in August 2021. The pt achieved a partial response (PR) with tumor reductions of 29.2%, 36% and 41.6% at C3D1, C4D1 and C5D1, respectively. Pt A was treated for 210 days, discontinuing due to radiographic disease progression following a 17-day dose interruption for suspected grade 3 TSH increase. The progression-free survival (PFS) was 6.9 months. Baseline biomarker data showed presence of KD mutations including: E565G/A, N549H, K659M and I548T. At C3D1, E565G had reduced from 1.36% to 0.09%, and there was disappearance of all other FGFR2 KD mutations. Pt B is a 40yr female with CCA metastatic to liver, lung and lymph nodes. Tinengotinib was initiated in August 2021. The pt achieved a PR with tumor reductions of 23.4% and 48.6% at C3D1 and C5D1, respectively. Pt B was on treatment for 181 days and discontinued due to progression in non-target lesions at C6D1, following a 23-day dose interruption for unrelated grade 3 ALT increase. PFS was 5.9 months. Baseline biomarker data showed presence of KD mutations including: E565A/G/K, V564L/I/F, N549K/T

Conclusions: An inverse correlation between the presence of KD mutations and the response to tinengotinib treatment was observed in these two FGFRi relapsed/refractory metastatic CCA pts. This suggests tinengotinib may overcome acquired resistance to FGFRi in CCA pts. An ongoing randomized phase III study is investigating tinengotinib vs. chemotherapy in FGFRi refractory/relapsed CCA (NCT05948475). Clinical trial information: NCT04742959

#826 Combination of CDK4/6 and CDK2/4/6 inhibitors with novel biguanides for pancreatic cancer treatment.

Samantha A. Melendrez[1], Mario Morales Martinez[1], Eduardo Mauricio Gonzalez[1], Gang Deng[2], Timothy Donahue[3], Michael Jung[2], Jaydutt V. Vadgama[4], Richard Pietras[1], Diana C. Marquez-Garban[1]

[1]Department of Medicine, UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Chemistry and Biochemistry, UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA,[3]Division of Surgical Oncology, Department of Surgery, Department of Medical Pharmacology, UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA,[4]Department of Medicine, Charles Drew University of Medicine and Science, UCLA Jonsson Comprehensive Cancer Center, Los Angeles, CA

Pancreatic ductal adenocarcinomas (PDAC) is a leading cause of cancer mortality in the U.S. Men and women of African ancestry have the highest incidence and mortality rates as compared to other racial or ethnic groups. African American (AA) patients present at younger ages, with more advanced disease stage, and the least access to surgical and chemotherapeutic interventions. Risk factors include diabetes mellitus type 2 (DM2), obesity, tobacco use, age, race/ancestry, and genetic mutations. Cytotoxic chemotherapy remains a first-line treatment for many PDAC patients since current therapies are often ineffective, necessitating alternative strategies. KRAS is mutated in about 90% of PDAC cases and is essential for initiating and maintaining PDAC growth. Further, a second key genetic event in PDAC involves deletion or silencing of the CDKN2A tumor-suppressor gene that encodes p16INK4A which in turn inhibits cyclin-dependent kinases CDK4 and CDK6 and complements KRAS activation in promoting PDAC. Of note, independent epidemiologic reports show that DM2 patients treated with the biguanide, metformin, a common medication used to treat DM2, have a reduced risk of PDAC and improved survival rates among those who develop PDAC. The current study investigates the hypothesis that combination of new, more potent biguanide analogues with CDK 4/6 and CDK2/4/6 inhibitors could improve treatment outcomes for PDAC. Our work involved the assessment of a newly-designed biguanide analogue termed JD006, alone and combined with selected CDK 4/6 inhibitors (abemaciclib or ribociclib) or CDK2/4/6 inhibitor PF-0687300, on growth of human PDAC cells (Panc-1, Panc 02.03, CFPac-1) in vitro. Cell proliferation assays and immunoblot analyses were used to assess effects of treatments. Combined therapy with JD006 plus CDK 4/6 or CDK2/4/6 inhibitors significantly reduced PDAC cell proliferation ($P<0.01$); with evidence of an additive effect. Immunoblots revealed enhanced inhibition of cell cycle-related proteins and AKT/mTOR downstream signaling with combination treatment with JD006 and ribociclib, abemaciclib or PF-0687300. In conclusion, combinations of JD006 with CDK 4/6, CDK2/4/6 inhibitors appears to effectively target multiple molecular pathways, suggesting a potential new approach for PDAC treatment. Further studies are needed to compare response to treatment and molecular signatures in preclinical models from patients of different ancestry. Better understanding of these biological differences may help reduce health disparities in patients diagnosed with PDAC. #827 Correlation among early surrogate endpoints and survival in borderline-resectable pancreatic cancer: A trial-level meta-analysis.

Chanbormey Leatheng[1], Alexander Khamechand[1], Gabriel A. Brooks[2], Hirotaka Miyashita[2]

[1]Medicine, Dartmouth-Hitchcock, Lebanon, NH,[2]Oncology, Dartmouth-Hitchcock, Lebanon, NH

Background: Multiple endpoints are used as surrogates for overall survival (OS) in clinical trials for borderline resectable pancreatic cancer (BRPC), including the R0 resection rate. However, consensus is lacking regarding the validity of this and other surrogate endpoints. This study aims to assess the relationship between common surrogate endpoints and median OS (mOS).
Methods: We conducted a systematic review of PubMed and Web of Science to identify clinical trials investigating neoadjuvant treatment (surgery, chemotherapy, or radiation therapy) of BRPC. Eligible trials reported on OS and at least one surrogate endpoint (resection rate [RR], R0 resection rate [R0], 1-year OS [1yOS], and 2-year OS [2yOS]). We estimated the correlation of OS with each of the surrogate endpoints using both Spearman and Pearson coefficients (r). The confidence intervals (CI) of coefficients were estimated by 2,000 times of bootstrapping resampling. Weighted linear regressions with calculation of R-squared were utilized to estimate correlations adjusted for the sample size in each cohort.
Results: We identified 25 eligible clinical trials with 32 treatment cohorts. The range of mOS was 11 to 41 months, and the median mOS was 23.3 months. R0 and 2yOS were significantly correlated with mOS by the Spearman coefficient (r=0.51 [95% CI: 0.01-0.79] and r=0.74 [0.19-0.95], respectively) but RR and 1yOS were not. All early endpoints (RR, R0, 1yOS and 2yOS) were significantly correlated with mOS by the Pearson coefficient (r=0.49 [0.01-0.79], 0.58 [0.28-0.78], 0.75 [0.12-0.91] and 0.79 [0.43-0.92], respectively). Weighted liner regression revealed that RR, R0, 1yOS and 2yOS were significantly correlated with mOS (R-squared= 0.20, 0.32, 0.43 and 0.57, respectively with $p < 0.05$ for all).
Conclusions: This study demonstrated significant correlations between early surrogate endpoints and mOS in BRPC. However, the correlation between mOS and resection-related endpoints (RR and R0) was modest. These findings provide important context for selection and interpretation of surrogate endpoints in studies of BRPC.

#828 ANS03, a novel, orally bioavailable small-molecule type II ROS1/NTRK inhibitor, effectively overcomes clinically relevant ROS1/NTRK resistance mutations and exhibits potent antitumor activity in preclinical tumor models.

Gong Li[1], Alexander Drilon[2], Shengxiang Ren[3], Peilong Zhang[1], Xiangqiu Li[1], Linna Li[1], Ruiya Zhang[1], Wenli Lan[1], Di Han[1], Weizhe Xue[1], Peipei Yang[1], Shutan Liao[4], Kevin Schaab[5], **Brendan Putz**[6], Hepeng Shi[1]

[1]Shenzhen Avistone Biotechnology Co., Ltd, Beijing, China,[2]Memorial Sloan Kettering Cancer Center and Weill Cornell Medical College, New York, NY,[3]Department of Medical Oncology, Shanghai Pulmonary Hospital, Shanghai, China,[4]Avistone Biotechnology Ltd, Beijing, China, Beijing, China,[5]Avistone Biotech, Inc., Dover, DE,[6]Avistone Biotech, Inc., Raleigh, NC

Background: ROS1 and NTRK are critical driver genes for tumorigenesis and progression, and inhibitors targeted towards their tyrosine kinases (TKIs) are clinically proven anti-cancer agents. Although Type I ROS1/NTRK TKIs like Repotrectinib show clinical benefit, on-target resistance mutations inevitably develop. Hence there is an unmet clinical need for novel Type II ROS1/NTRK TKIs capable of overcoming on-target acquired resistance mutations.
Methods: A comprehensive panel of IND-enabling non-clinical studies was conducted to evaluate the mechanism of action, pharmacologic activity, pharmacokinetics, and the safety profile of ANS03.
Results: ANS03 is a novel Type II TKI targeting both ROS1 and NTRK. Unlike type I TKIs, which engage the active “DFG-in” conformation of the kinase, type II TKIs engage the inactive “DFG-out” conformation of the kinase and also extend into an adjacent allosteric pocket. As a result, ANS03 shows a broad and potent inhibitory spectrum for ROS1/NTRK drug-resistance mutations with $IC_{50's}$ ranging from 0.324 nM to 4.88 nM. In cellular systems, ANS03 showed outstanding antitumor effects against wild-type fusions and diverse acquired drug-resistance mutations, with $IC_{50's}$ ranging from 0.1 nM to 26 nM. For ROS1 SF mutations (G2032R, D2033N), ANS03 was 22.2x and 30.6x more active than Repotrectinib, respectively. ANS03 showed a 10^4x enhancement against ROS1 Cβ6 mutation (L2086F), a 52.5x enhancement against NTRK1 xDFG mutation (G667C), and a 104.4x enhancement against NTRK1 compound mutation (G595R-G667C) vs. Repotrectinib. ANS03 also had better activity against the ROS1 L2086F mutation when compared to both Repotrectinib and NVL-520. *In vivo*, ANS03 exhibited antitumor effects in BALB/c nude mouse subcutaneous xenotransplantation models that were as good- or better than- those of the ROS1/NTRK TKIs Repotrectinib or NVL-520. Notably, it achieved complete tumor regression in Ba/F3-ROS1-G2032R models at a dose of 10 mg/kg and triggered tumor regression in LU-01-0414 (ROS1 wild-type fusion) and KM12-Luc (NTRK wild-type fusion) models at a dose of 3 mg/kg. Moreover, ANS03 significantly improved the survival rates of tumor bearing mice in a dose-dependent manner. Concurrent pharmacokinetic (PK) studies in mice positively correlated plasma exposures of ANS03 to administered doses, with ANS03 showing favorable tumor distribution and detectable brain penetration.
Conclusion: Non-clinical studies of ANS03 showed it is a potent, orally bioavailable Type II ROS1/NTRK inhibitor with remarkable activity against various pathogenetic ROS1/NTRK alterations and with favorable absorption, distribution, pharmacokinetics, efficacy, and tolerability profiles *in vivo*. The compound will enter Phase 1 clinical development in the US and China soon.

#829 *ITGAV* is a targetable vulnerability in epithelial ovarian cancer.

Gilbert K. Salloum

Pathology, Beth Israel Deaconess Medical Center - Harvard Medical School, Boston, MA

Ovarian cancer is a lethal heterogenous disease that is typically diagnosed at late stages. In high-grade serous ovarian carcinoma (HGSOC), the most common subtype, PARP inhibitors and chemotherapy are standard of care. Although HGSOC patients are responsive to these therapies, resistance develops and patients invariably relapse. Alterations in genes within the phosphoinositide 3-kinase (PI3K) and AKT network are highly prevalent. Although specific PI3K and AKT small molecule inhibitors have been developed and clinically evaluated, to date none have been approved for clinical use in ovarian cancer patients. To identify collateral druggable vulnerabilities to AKT hyperactivation and develop novel combination therapies in HGSOC, we have performed a CRISPR-based genome-wide synthetic lethal screen. The goal is to identify genes that upon genetic knockout transform a cytostatic cellular response to PI3Ki/AKTi to a cytotoxic one. Using this platform, we have identified genes that regulate integrin signaling as a major mechanism of synthetic lethality against the PI3Ki pictilisib and the AKTi capivasertib. *ITGAV*, encoding the integrin subunit α_V, was a significant dropout against both kinase inhibitors. Pharmacological targeting of integrin α_V synergized with pictilisib and capivasertib to induce apoptotic cell death in multiple cell line models of ovarian cancer, as well as patient-derived organoids. Combined PI3K/AKT and integrin α_V inhibition induced DNA damage and cell cycle arrest. The mechanisms underlying induction of DNA damage and cell death in response to combination treatment are currently under investigation. The ultimate goal is to bring this combination treatment approach to HGSOC patients and shed new light on mechanisms of resistance to PI3K/AKT pathway inhibitors in ovarian cancer.

TUMOR BIOLOGY: Molecular Regulation of Metastasis

#83 Investigating the effect of SERPINB3 and STAT3 on invasion and metastasis in cervical cancer cells.
M. Campos Guerrero, **D. E. Hasanova**, L.-Y. Chen, L. Sherbansky, S. Markovina;
Washington University in St. Louis, Saint Louis, MO

Cervical cancer is the fourth most leading cause of cancer related deaths in women worldwide. Of the women treated for cervical cancer, nearly a third experience recurrence after initial treatment with chemotherapy and radiation. After recurrence, salvage rates are low, thus better treatment options must be developed.
One biomarker in cervical cancer is Squamous Cell Carcinoma Antigen 1, also known as SERPINB3. SERPINB3, a member of the serine protease inhibitor superfamily, has been found in elevated levels in patients with cervical cancer, and correlates with resistance to chemo and ionizing radiation. Signal Transducer and Activator of Transcription 3 (STAT3) activates signaling pathways that lead to tumor progression including cancer cell migration and metastasis.
In this project, we investigated how SERPINB3 and STAT3 correlate to cervical cancer cell migration and metastasis. Our hypothesis is that SERPINB3 interacts with STAT3 to increase metastasis of cervical cancer cells. To test this hypothesis, we used the genetically modified SW-756 cervical cancer cell line with and without SERPINB3 and performed transient transfection to knock down the STAT3 gene using silencing RNA (siRNA).
To analyze the knock down of STAT3, we used immunoblotting and quantitative polymerase chain reaction (qPCR) to determine whether the expression of the STAT3 protein and gene was silenced. To determine metastasis of the cells in vitro, we conducted a wound healing assay, in which a wound is generated in the middle of the tissue culture well, and the closure of the wound is monitored every 24 hours via microscopy. The images were analyzed using FIJI Image J Wound Healing Program.
In this project, we have minimized the expression of STAT3 in our cervical cancer cell lines. We noticed that when we decreased STAT3 expression, SERPINB3 levels had also decreased. This correlates with literature suggesting that STAT3 regulates SERPINB3 expression. The wound healing assays revealed that upon knocking down STAT3 in SERPINB3 knockout cells, cell migration had severely decreased compared to SERPINB3 control cell lines knocked down with STAT3. The knockdown will be optimized and results repeated along with pharmacologic inhibition of STAT signaling to determine the mechanism of B3 in migration and metastasis phenotypes. The future direction of this project is to identify the exact SERPINB3-STAT3 interaction that leads to invasion metastasis in cervical cancer. By doing this, we hope to determine different pathways that may lead to increased invasion and metastasis to develop better treatment options in cervical cancer.

CLINICAL RESEARCH: Targeted Therapies and Combinations 1

#830 Combined a B7-H3-targeting antibody-drug conjugate, 7MW3711, and PARP inhibitors synergistically potentiates the antitumor activity in B7-H3-positive cancers.

Xiaowei Cen[1], Peng Fang[2], Yueyue Yang[1], Dongan Yu[2], Yueqin Yao[1], Fei Mei[2], Xueying Li[1], Meng You[2], Yiyan Zhang[1], Long Yin[2], Xiaowei Sun[2], Xiaoding Tan[2], Wei Zhou[1], Hai Wu[1]

[1]Mabwell (Shanghai) Bioscience Co., Ltd., Shanghai, China,[2]Jiangsu Mabwell Health Pharmaceutical R&D Co., Ltd., Taizhou, China

Introduction: B7-H3, an attractive target for antibody drug conjugate, is overexpressed in multiple tumors. Overexpression of B7-H3 in tumor cells frequently correlates with fewer tumor-infiltrating lymphocytes, faster cancer progression, and poor clinical outcome in several malignancies. Preliminary evidence revealed PARP inhibitors (PARPi) and B7-H3-directed antibody-drug conjugate (ADC) as two practical approaches to overcome chemoresistance in solid cancers. Thus, synthetic lethality exploitation by an anti-B7-H3 ADC plus PARPi might be a promising strategy in solid tumor models. Here, we investigated the activity of 7MW3711, a B7-H3-directed ADC bearing a novel isomerase I inhibitor (TOP1i) payload, alone and in combination with PARPi, in preclinical models to evaluate the potential for future clinical application.
Method: 7MW3711 was evaluated in vitro and vivo efficacy with or without PARPi (Olaparib or AZD5305). In vitro, human cancer cell lines were treated with 7MW3711 and two PARPi to determine the effect on anti-proliferative effects, double-stranded DNA breaks, and cell-cycle arrest. In vivo, mice bearing ovarian and SCLC tumor xenografts were treated with the combination of 7MW3711 and PARPi.
Results: Evaluation of the drug resistance ability in cell lines expressing P-gp revealed 7MW3711 exhibited > 3-fold more potent than DS7300 (B7-H3-directed DXd ADC), indicating that 7MW3711 has a lower efflux efficiency in drug-resistant strains. 7MW3711 combined use of PARPi synergistically potentiated the inhibitory effects of 7MW3711 on the growth of B7-H3-positive cancer cells, inducing DNA damage and apoptosis. The highest level of double-stranded DNA breaks was observed in cells treated with combination which can be determined in the upregulation of γ-H2AX protein. Combination increased both G2/M phase-arrested cells and S-phase cells, reduced G1-phase, indicating that most proliferating cells were arrested. Combining 7MW3711 with olaparib or AZD5305 produced significant antitumor effects and survival benefit above that achieved with monotherapy in various B7-H3-positive solid tumor xenografts. Collectively, our results demonstrate the synergistic antitumor activity of combining 7MW3711 with PARPi, suggesting that DNA damage-repair inhibitors in combination with B7-H3-targeted ADCs is a promising approach for treating B7-H3-positive malignancies.
Conclusion: These data provide evidence for the potential utility of 7MW3711 combination with PARPi for treatment of B7-H3-expressing tumors and support the rationale for further clinical studies.

#831 CPT1A inhibition sensitizes diffuse large B-cell lymphoma to venetoclax treatment.

Sophia Steinlein[1], Heike Horn[1], Emma Attwood[1], Annette M. Staiger[2], Katrin S. Kurz[2], Andreas Rosenwald[3], German Ott[2], Claudia Kalla[1]

[1]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany,[2]Department of Clinical Pathology, Robert Bosch Hospital, Stuttgart, Germany,[3]Institute of Pathology, University of Wurzburg, Wurzburg, Germany

First-line immunochemotherapy fails to achieve a durable response in up to one third of patients with diffuse large B-cell lymphoma (DLBCL). Therapy resistance is mediated, in part, by ineffective elimination of B-cells protected by a metabolic tumor-stroma interaction. Carnitine palmitoyltransferase 1A (CPT1A), a component of the prognostic DLBCL-LAMI signature, plays a major role in transporting fatty acids - partly provided by stromal cells - into mitochondria to support B-cell metabolism. We investigated the CPT1A inhibitors ST1326 and perhexiline for their ability to eliminate lymphoma cells in the presence of stromal cells and the potential of sensitizing them to the therapeutic BCL2 inhibitor venetoclax.

CPT1A protein expression was evaluated in primary tumor specimens by immunohistochemistry using TMAs. CPT1A inhibitors and venetoclax (ABT-199) were tested on different pre-clinical models: (1) 15 DLBCL cell lines, (2) co-culture models of DLBCL cell lines and either stromal cell line HS-5 or primary DLBCL-cancer associated fibroblasts to evaluate the induction of B-cell death in a stromal environment, and (3) patient-derived DLBCL cells. Therapeutic efficacy was assessed using MTT cytotoxicity and CellTiter Glo 2.0 assays. Effects on lipid metabolism, molecular signaling and induction of cell death were investigated by oil red O staining, immunoblots and AnxV/TMRM flow cytometry, respectively.

CPT1A protein was expressed in 77% (67/87) of primary DLBCL (cytoplasmic staining, cut-off 20%). Both CPT1A inhibitors impaired the viability of lymphoma cells: perhexiline treatment was cytotoxic in 5/5 cell lines (IC50 = 5.5-7.5 μM), ST1326 in 10/15 cell lines (IC50 = 5-18 μM). Viability of normal fibroblasts was not affected by either drug. Perhexiline lost its cytotoxic effect against lymphoma cells when co-cultured with stromal cells. In contrast, ST1326 remained effective in killing DLBCL cells also in stromal environment. Suppression of fatty acid transport into mitochondria by ST1326 resulted in cytoplasmic lipid accumulation, suppression of anti-apoptotic Bcl-XL and phospho-AKT, and induction of apoptotic cell death. The combination of ST1326 with the BCL2 inhibitor venetoclax increased its cytotoxic efficacy. Three DLBCL cell lines that were BCL2-positive but resistant to venetoclax were sensitized by ST1326 to the BCL2 inhibitor, an effect that persisted in the presence of stromal cells. In patient-derived DLBCL models (partly from patients with poor response to standard immunochemotherapy), CPT1A inhibition impaired the viability of primary DLBCL cells and enhanced the antitumor activity of venetoclax.

Targeting fatty acid metabolism using ST1326 effectively eliminates lymphoma cells in the presence of stromal cells and increases significantly the efficacy of the BCL2-specific inhibitor venetoclax, thus providing a new candidate approach in the treatment of DLBCL.

#833 A novel anti-CEACAM6 heavy-chain antibody-drug conjugate for gastrointestinal cancer therapy.

Ming-Heng Wu, Yao-Tsung Tsai, Chee Voon Yap

International Ph.D. Program for Translational Science, Taipei Medical University, Taipei, Taiwan

Antibody-drug conjugates (ADCs) are "biological missiles" that utilize a chemical linker to connect monoclonal antibodies (mAbs) with cytotoxic drugs, which induces the precise killing of targeted tumor cells and causes the death of surrounding untargeted cancer cells through the bystander effect. However, current ADCs are too specific to certain cancer subtypes and not specific enough to accurately target a cancer-specific protein, which limits the therapeutic populations and induces unwanted side effects. We developed a heavy-chain antibody (HCAb) from a llama immune library, which recognizes glycosylated CEACAM6 (Carcinoembryonic antigen-related cell adhesion molecule 6), a broad-surface marker of epithelial-type cancers. The anti-CEACAM6 HCAb showed a higher affinity (KD: sub-nanomolar), better thermal stability, unique tissue penetration and epitope-recognition abilities compared to the conventional antibodies. The anti-CEACAM6 HCAb-drug conjugate (HCAb-ADC), which links the HCAb and tubulin inhibitors via hydrophilic linkers, specifically killed CEACAM6-expressing colorectal (CRC), lung, pancreas, and bile duct carcinoma cells at sub-nanomolar concentrations and had a better anti-cancer effect than current FDA-approved ADCs. In xenograft models, a single administration of HCAb-ADC completely abolished colorectal and pancreatic tumors. Notably, HCAb-ADC can effectively inhibit tumor growth even at very low doses (0.2 mg/Kg) and demonstrated a superior therapeutic effect over current therapeutic regimens. Meanwhile, it exhibited minimal toxicity to normal epithelial and peripheral blood mononuclear cells. In summary, the excellent anti-tumor activity across different epithelial cancers and minimal toxicity to normal tissues support the clinical development of the novel HCAb-ADC for treating multiple epithelial-type cancers, including CRC, lung, pancreatic, and bile duct carcinoma.

#834 *In vivo*, *ex vivo*, and *in vitro* (2D and 3D) tumor models: Uses, strengths and limitations.

B. A. Teicher[1], M. G. Hollingshead[1], N. P. Coussens[2], T. S. Dexheimer[2], T. E. Silvers[3], E. M. Jones[2], L. Rubinstein[1], J. H. Doroshow[4]; [1]National Cancer Institute, Rockville, MD, [2]Frederick National Lab for Cancer Research, Frederick, MD, [3]Frederick National Lab for Cancer Research, Freerick, MD, [4]National Cancer Institute, Bethesda, MD

Preclinical models are critical tools in the war on cancer, used in cancer biology & genetics research, drug/therapeutic discovery & development, and for identification of drugs & drug combinations for use to treat specific tumors & specific patients. Each preclinical model has strengths & limitations & varied endpoints. When driving an SAR, new compounds are compared with each other in solid tumor models & tumor growth delay is the endpoint assessed. To determine tumor-cell kill in vivo in syngeneic or xenograft tumors, ex vivo assays are used after in vivo drug administration. To assess inherent potency & potential depth of tumor cell kill, 3D in vitro models are used. The limitations of in vitro models include that prodrugs are non-functional, there is no normal tissue, & the dynamics of drug metabolism are missing. A major limitation of in vivo tumor models is that the mouse is an inbred host in a controlled environment making it difficult to predict toxicity in patients. It is possible to extrapolate response to a drug or drug combination from a 3D cell culture model to the same model grown as a solid tumor in a mouse. Optimized 3D culture models include tumor cells & normal cells such as endothelial & mesenchymal cells. The log-kill hypothesis holds that 90% kill of tumor cells is required for a partial response, while 99% kill is required for a complete response. The 138582-377-R Merkel cell (PDX) treated with cediranib (6 mg/kg) & erlotinib (90 mg/kg) Q5D for 3 wks resulted in 80% decrease in tumor vol compared with controls & 80% cytotoxicity in complex spheroids from the same tumor. The 712881-215-R penile squamous cell ca PDX achieved a brief disappearance of measurable tumor on a complex regimen of cediranib (6 mg/kg) & erlotinib (90 mg/kg), reaching a tumor vol 1% of the control tumor. In complex spheroids, exposure to the combination of cediranib & erlotinib produced 99% cytotoxicity. When the 138582-377-R Merkel cell PDX was exposed to entinostat (30 mg/kg) Q5D for 3 wks, an 86% decrease in tumor vol was achieved compared with the control tumor vol. Less than 90% cytotoxicity was achieved in the complex spheroids in the estimated clinical Cmax concentration range of entinostat. The combination of ipatasertib (60 mg/kg) & selumetinib (20 mg/kg) administered twice per day for 2-rounds of 10 days was less effective in the 171881-019-R breast ca PDX and the 845751-090-R head & neck squamous ca PDX than would be predicted by the complex spheroid studies. Funded in part by NCI Contract No. 75N91019D00024.

#835 A potent and selective small molecule inhibitor of CD38.

Jinwen Huang, Zhongyuan Li, Zeng Song, Yunli Liu, **Steve Shen**

Convalife (Shanghai) Co., Ltd., Shanghai, China

Background: CD38 is a multifunctional ectoenzyme involved in NAD metabolism and is highly expressed in various hematological malignancies, making it a critical therapeutic target in oncology. By depleting NAD and producing immunosuppressive metabolites such as adenosine, CD38 supports tumor growth and creates an immunosuppressive microenvironment. Compared to CD38 antibodies, small-molecule inhibitor offer advantages, including better tissue penetration, oral bioavailability, and cost-effectiveness. CD38 inhibition may restore NAD levels, reverse immunosuppression, and enhance antitumor immune responses, potentially synergizing with immune checkpoint inhibitors (ICIs), providing a promising strategy for cancer therapy.
Methods and Materials: Accelerated by the "Right 6D+AI" platform, AI-based screening and multi-angle evaluation were conducted on over 5,000 virtual molecules, yielding candidate molecule N066 with IC50 activity below 1 nM. To explore the therapeutic potential, oral administration of N066 in mice assessed dose-dependent effects on NAD+ elevation and ADPR reduction in tissues such as the spleen and liver. In syngeneic cancer models, CD38 protein expression was evaluated using immunohistochemistry (IHC) following ICI treatment. In mouse solid tumor models, N066 was administered as monotherapy or combined with ICIs.
Results: The small-molecule inhibited intracellular CD38 activity in cultured human primary T cells, increasing intracellular NAD+ levels. In mice, oral administration of the inhibitor resulted in a dose-dependent increase in NAD+ levels and a decrease in ADPR levels in tissues such as the spleen and liver. In syngeneic cancer models, monotherapy with the N066 showed antitumor activity correlated with changes in NAD+ and ADPR levels. In B16-F10 tumor-bearing mice, combining N066 with anti-PD-L1 therapy enhanced antitumor activity.
Conclusion: CD38 small-molecule inhibitors N066 demonstrates good antitumor activity, highlighting its therapeutic potential.

#836 A phase Ib/II study of PARPi Mefuparib Hydrochloride (CVL218) in combination with PD-1 inhibitor plus chemotherapy in metastatic or recurrent triple-negative breast cancer (TNBC).

Jian Zhang[1], Rujiao Liu[1], **Steve Shen**[2]

[1]Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China,[2]Convalife (Shanghai) Co., Ltd., Shanghai, China

Background: BRCA 1 and /or BRAC 2 mutation accounts for about 15% of all TNBC and remains poor outcomes. Mefuparib hydrochloride (CVL218) is a second generation in PARPi with low hematological toxicity and high ability to cross the blood-brain barrier. This study is to explore efficacy and safety of CVL218 combined with PD-1antibody and paclitaxel nanoparticle albumin-bound in patients with TNBC who have failed previous first-line treatment.
Methods: This open- labeled, phase Ib/II clinical study NCT06078670 explores efficacy and safety of three drugs combination . 500mg BID CVL218 was administered orally in combination with toripalimab 240 mg on Day 1 of every 21-day cycle and paclitaxel nanoparticle albumin-bound 125 mg/m^2 on Day 1 of every 21-day cycle. Patients in cohort A were advanced TNBC with either CPS ≥ 1 or HRD gene pathogenic variants.
Results: From July 2023 to 15 July 2024 data, 6 subjects were enrolled in Phase Ib and 5 subjects were enrolled in Phase II. In phase Ib, The RP2D of CVL218 was identified as 500 mg BID. The preliminary efficacy was perfomed every 6 weeks in the first half a year and then once every 12 weeks thereafter in both phase Ib and II by RECISTv 1.1. Among 11 patients, ORR was 72.7% (8 PR, 2 SD), and DCR (Disease Control Rate) was 90.9%. The most common Grade 3 or higher treatment-related AEs (TRAEs) were hepatic function injury (2.6%), adynamia (1.8%), creatinine increased (0.8%), neutrophils decreased (0.8%), white blood cell decreased (0.8%), exanthema (0.8%), and peripheral sensory nerve disorder (0.8%), No Grade 5 TRAE. A total of 9 treatment-related SAEs in 6 patients (54.5%) were observed, including 2 aspartate aminotransferase increased, 2 alanine aminotransferase increased, 1 creatinine increased, 1 liver function injury, 1 adynamia, 1 neutrophils decreased, 1 fever, and 1 ventricular premature beats. All these SAEs recovered after symptomatic treatment.
Conclusion:CVL218 combined with PD-1 antibody and chemotherapy appears to be well tolerated and has good preliminary efficacy in TNBC patients.

#837 A highly potent and selective small molecule TY-4028 for the targeted therapy of non-small cell lung cancer with EGFR exon 20 or HER2 exon20 insertion mutations.

Chengshan Niu*[1], Shengli Dong*[2], Shaoqing Chen[3], Zhongwei Guo[1], Huan Wang[3], Apeng Liang[2], Kaige Ji[1], Meihua Li[2], Bailu Zheng[3], Yanchao Zhao[1], Ming Wu[3], Mingyu Jiang[3], Xiugui Chen[3], Jun Li*[3], Yusheng Wu[3]

[1]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, Henan, China,[2]TYK Medicines, Inc., Changxing county, Huzhou City, China,[3]TYK Medicines, Inc. (Shanghai), Xuhui District, Shanghai, China

Introduction: Following EGFR exon 19del and EGFR L858R mutations, EGFR exon20 insertion mutations are the third most common type of EGFR mutations, representing up to 12% of all EGFR mutations. Approximately 2% of NSCLC patients bear hotspot mutations in HER2,and over 90% of these HER2 mutations are exon 20 insertion mutations. The FDA-approved 1st to 3rd targeted EGFR inhibitors failed to effectively treat NSCLC harboring constantly active EGFR exon20ins mutations in the clinic. To date, no small molecule targeted therapy has been approved by the FDA for the treatment of EGFR exon20ins in NSCLC. Furthermore, Antibody such as Amivantamab has difficulty penetrating the BBB, brain metastases presents a significant clinical challenge in lung cancer with EGFR exon20ins mutations. There is an urgent unmet medical need to develop targeted therapeutics against EGFR and Her2 exon20ins mutations.
Results: TY-4028 is a novel, potent, and orally available inhibitor targeting EGFR and Her2 exon20ins mutations. It is a highly potent covalent inhibitor with rapid absorption and clearance, which contributes to the decreased toxicity of covalent drugs. Preclinical studies have shown a good PK profile and manageable toxicity with TY-4028. TY-4028 showed remarkable efficacy in *in vitro* and *in vivo* models of EGFR exon20ins and HER2 exon20 Ins. The data showed that the efficacy of TY-4028 was similar to that of Mobocertinib(TAK-788)and better than that of Sunvozertinib (DZD9008), whereas the tolerance of TY-4028 was better than that of Mobocertinib in CDX mouse models. The B/P ratio (brain tissue AUC_{last}/plasma AUC_{last}) of SD rats was 1.63 and 1.04, respectively, suggesting that TY-4028 has good potential to cross the BBB.
Taken together, TY-4028 was fully developed by TYK Medicines, Inc., and the compound has great potential to meet the unmet medical needs of NSCLC patients with EGFR exon20ins mutation or HER2 exon20ins mutation. IND clearances of TY-4028 from the US FDA and CN NMPA has received.

#838 The novel eIF4A inhibitor synergizes potently with the XPO-1 inhibitor in T-cell lymphoma.

So-Young Seol[1], Chung Hyun Park[2], Soo Jeong Kim[2], Hyunsoo Cho[3], Jin Seok Kim[3], Yu Ri Kim[1]

[1]Department of Internal Medicine, Hematology, Gangnam Severance Hospital, Seoul, Korea, Republic of,[2]Department of Internal Medicine, Hematology, Yongin Severance Hospital, Yongin, Korea, Republic of,[3]Department of Internal Medicine, Hematology, Severance Hospital, Seoul, Korea, Republic of

Malignant lymphomas are categorized into B-cell and T-cell lymphomas. While treatment outcomes for B-cell lymphoma have significantly improved with targeted therapies and cellular treatments, T-cell lymphoma remains a therapeutic challenge due to the lack of standardized first-line treatments. Consequently, T-cell lymphoma exhibits lower remission rates, higher relapse rates, and poor overall prognosis. Although T-cell lymphomas account for only 15-20% of all malignant lymphomas, their incidence is notably higher in Asia compared to Western countries, making Korea an ideal location for research on this disease. Also, T-cell lymphoma (TCL) is an aggressive malignancy with poor prognosis, characterized by high relapse rates and limited therapeutic options. Novel therapeutic approaches are urgently needed to improve outcomes for patients with TCL. Previous studies have demonstrated the efficacy of eIF4A inhibitors in downregulating oncogenic protein synthesis and inducing cell death in various lymphoma models. We hypothesized that the combination of eIF4A inhibitor (CR-1-31-B) and XPO-1 inhibitor (Selinexor) would exhibit synergistic anti-lymphoma activity in TCL and have potential clinical applications. The anti-lymphoma effects of CR-1-31-B in combination with a XPO-1 inhibitor were evaluated in TCL cell lines using flow cytometry. Cell apoptosis assays were performed at increasing concentrations of CR-1-31-B and the XPO-1 inhibitor alone, as well as in combination, over 48 hours. To investigate the molecular mechanisms underlying the observed synergistic effects in TCL, RNA-seq profiling was conducted on cells treated with single agents and the combination therapy. Gene set enrichment analysis (GSEA) was performed to identify pathways involved in the combination's mechanism of action. CR-1-31-B and the XPO-1 inhibitor demonstrated concentration- and time-dependent cytotoxicity in TCL cell lines at low nanomolar concentrations. The combination of the eIF4A inhibitor and the XPO-1 inhibitor showed strong synergistic effects in all tested TCL cell lines ($p<0.0001$). RNA-seq profiling revealed that the transcriptional signature of the combination therapy was distinct from that of single-agent treatments. The combination of eIF4A inhibitor and XPO-1 inhibitor demonstrates potent anti-lymphoma activity in T-cell lymphoma. This novel combination represents a promising therapeutic strategy for patients with TCL, warranting further preclinical investigations and potential clinical translation.

#839 The clinical C/EBPβ antagonist peptide lucicebtide synergizes with molecularly targeted therapies in GBM.

Julia Diehl, Ricardo Ramirez, Mark Koester, Franco Abbate, Lila Ghamsari, Abi Vainstein-Haras, Barry J. Kappel, **Claudio Scuoppo**, Jim A. Rotolo

Sapience Therapeutics, Inc., Tarrytown, NY

Glioblastoma (GBM) is the most common and aggressive malignant brain tumor, with median overall survival (OS) following standard-of-care treatment of 15-18 months and 5-year survival of less than 10%. Despite extensive characterization of the genetic lesions driving GBM, there has been no improvement on the overall natural history of the disease, mostly due to the cellular and genetic heterogeneity of these tumors. CCAAT/Enhancer Binding Protein β (C/EBPβ) is a transcription factor identified as a master regulator of the mesenchymal transition in GBM. Lucicebtide (ST101) is a C/EBPβ antagonist peptide that was evaluated in a Phase 2 clinical study in patients with recurrent and newly diagnosed GBM (NCT04478279) and has shown durable responses in a subset of patients. We have previously demonstrated that lucicebtide anti-tumor activity is due to both direct cancer cell death and immune-activation within the tumor microenvironment. Here we investigated whether lucicebtide may synergize with targeted therapeutic strategies against genetic dependencies or immune checkpoints in GBM. We adopted a synthetic lethal CRISPR screen approach in which gain-of-function drivers that are mutated in more than 5% of GBM patients in publicly available datasets (*EGFR, PDGFRA, PI3KCA, MDM2, MDM4, CDK4)* were suppressed in the presence or absence of lucicebtide in three genetically characterized GBM lines. Our data identified that EGFR suppression by multiple independent sgRNAs was synthetic lethal in the presence of lucicebtide. We confirmed these findings by performing checkerboard assays of lucicebtide in combination with chemically distinct EGFR inhibitors, indicating that lucicebtide synergizes with EGFR inhibition (EGFRi) in GBM. We further characterized the mechanism of action of EGFRi-lucicebtide combination on known signal transducers of EGFR in the presence or absence of ST101. Finally, we explored the relationship between transcriptional signatures of C/EBPβ activity and EGFR mutational profile in publicly available GBM datasets, identifying potential genetic biomarkers for prediction of maximal efficacy of this combination. These studies demonstrate the potential of lucicebtide to enhance the activity of molecularly targeted therapeutics such as EGFRi that are typically not effective when used as monotherapies in GBM. Biomarker analysis utilizing GBM genetics and signatures of C/EBPβ activity was performed to identify potential target populations likely to benefit from ST101 combinations.

#84 Dimerization of MACC1: A newly identified feature and its role in cancer metastasis.

Malti Dumbani[1], Benedikt Kortum[1], Simona Kostova[1], Fabian Zincke[1], Alexandra Forrai[1], Dennis Kobelt[1], Wolfgang Walther[1], Erich Wanker[1], Oliver Daumke[1], Christoph Buhlheller[2], **Ulrike S. Stein**[1]

[1]Max Delbruck Center for Molecular Medicine, Berlin, Germany,[2]Medical University Graz, Graz, Austria

Cancer metastasis remains the most lethal characteristic of tumors mediating the majority of cancer-related deaths and continues to be a leading cause of mortality. Exemplified for colorectal cancer (CRC) metastasis results in around 0.9 million deaths annually worldwide. Identifying key molecules responsible for metastasis, understanding their biological functions and therapeutically targeting these molecules is therefore of tremendous value. Metastasis Associated in Colon Cancer 1 (MACC1), a gene first described in 2009, is such a key driver of metastatic processes, initiating cellular proliferation, migration, invasion, and metastasis in vivo. Since its discovery, the value of MACC1 as a prognostic biomarker has been confirmed and linked to poor overall outcome in more than 20 cancer types. Despite numerous studies identifying MACC1 as a promising target for solid cancer, little is known about the structural features of MACC1 protein and its oligomeric states. Therefore, we asked whether MACC1 can form protein complexes and if so, which region is critical for complexation/oligomerization. Using AlphaFold-Multimer, the MACC1 homodimer structure was predicted and the residues involved in dimerization were evaluated. The notion of MACC1 dimerization was validated further using bioluminescence resonance energy transfer (BRET) in HEK293 and HCT116 cell system. To our surprise, BRET revealed that MACC1 exists as homodimer in living cells. Further, we report that mutation of the predicted dimer interface residues Val212, Ile214 and Cys216 close to the N-terminus of MACC1 in the ZU5 domain hinders homodimerization and affects MACC1-mediated cell migration in vitro and metastasis formation in vivo. Taken together, these findings identify an important role of MACC1 dimers for the MACC1-mediated metastasis phenotype. We provide with this study a framework to better understand the MACC1 signaling landscape and to facilitate the rational development of novel therapies aiming at MACC1 oligomerization to intervene in MACC1-mediated metastasis.

#840 The ITCC-P4 consortium: Deep molecular characterization of pediatric cancer xenograft (PDX) models enable prediction of novel personalized combination treatment options for patients with childhood cancer.

D. Gurgen[1], A. Gopisetty[2], E.-M. Rief[2], A. Federico[3], D. A. Zwijnenburg[4], M. Kool[3], A. Saint-Charles[5], G. Schleiermacher[5], G. Vassal[2], J. J. B. Koster[4], S. M. Pfister[3], J. Hoffmann[1];

[1]Experimental Pharmacology and Oncology Berlin-Buch GmbH, Berlin, Germany, [2]ITCC-P4 gGmbH, Heidelberg, Germany, [3]Hopp Children's Cancer Center (KiTZ), Heidelberg, Germany, [4]University of Amsterdam, Amsterdam, Netherlands, [5]PSL Research University, Institut Curie Research Centre, Paris, France

Despite advances in the understanding of the pathogenesis of pediatric cancers, first line treatment of advanced, recurrent and metastatic childhood cancer still remains chemotherapy. Omics data unraveling the molecular pathogenesis together with overall low efficacy of targeted agents in preclinical trials so far did not improve the clinical outcomes of pediatric patients. The EU-IMI-2 funded, public-private partnership project “ITCC-Pediatric Preclinical Proof-of-Concept Platform” (ITCC-P4) has built a large repertoire of more than 400 pediatric patient-derived xenograft (PDX) models, including brain, neuroblastoma, soft tissue and other rare solid pediatric cancers. Tumor and PDX omics and in vivo data are stored and analized utilizing the ITCC-P4 R2 data base (https://r2.amc.nl). Our strategy aimed to utilize deep systems biology data from human tumors and corresponding PDX models to predict more effective drug and superior drug combination treatment of neuroblastoma (NB) and rhabdomyosarcoma (RS).

ITCC-P4 single mouse trial (SMT) screening in 27 PDX models from the NB and 24 RS cohort reveal overall low response rates for single targeted drugs including ALk, MDM2, CHEK, MEK kinase inhibitors and efficacy in 1 out of 3 chemotherapies only. Therefore, we conducted a SMT combination trial with already approved targeted cancer drugs in NB and RS PDX models (n=10 each), including major entity subtypes, e.g. high risk-, MYCN amplified NB and PAX3-Foxo fusion RS. In total, 10 drug combinations were compared to a control and single agent arm of up to four individual drugs. Except one drug combination, all doses and schedules were well tolerated in mice indicating absence of adverse side effects.

Interestingly, similar response pattern were observed in NB and RS PDX regardless of their molecular phenotype. However, the response to single agent treatment according to RECIST criteria was low with only 20% achieving stable disease (SD) or better. In contrast, when combining these less effective single agents, we observed an additive anti-tumoral effect with 40% of PDX models responding with SD or better. Most importantly, a significant and outperforming synergistic effect with 50% complete remission and 20% stable disease was achieved with simultaneous inhibition of ALK / BCl-2 or ALK / RAF signaling, which was observed in NB and RS to similar extend.

Taking together, deep molecular phenotyping together with our extensive *in vivo* PDX toolbox allows prediction and exploration of promising noval treatment options. Our results highlight the great potential of the ITCC-P4 portfolio and the close collaboration with internationally recognized pediatric oncologists and physicians, which enable personalized translation of specific combination treatments for childhood cancers in the near future.

#841 The preclinical pharmacokinetics and pharmacodynamics of AZD0022: A potent, oral KRAS^{G12D}-selective agent exhibiting oral bioavailability and KRAS pathway suppression in the GP2D xenograft model.

Kevin Beaumont[1], Sofia Guzzetti[1], Pablo Morentin-Gutierrez[1], Rhys D. O. Jones[1], Ken Grime[1], Carla Martins[1], Alex Koers[1], Alison Peter[1], Simon T. Barry[1], Susan Critchlow[1], Michele Moschetta[2], Michael Niedbala[3]

[1]DMPK, Oncology Targeted Discovery, AstraZeneca UK Limited, Cambridge, United Kingdom,[2]Early Oncology Clinical, AstraZeneca, Barcelona, Spain,[3]Early Oncology Programs Group, AstraZeneca, Waltham, MA

Objectives: AZD0022 is a small molecule selective inhibitor of KRAS^{G12D}. These studies investigate the preclinical PKPD relationships of AZD0022 to inform clinical development.

Methods: Measurement of plasma and tumor concentrations were completed using standard extraction techniques with quantitation by LC-MS/MS methods. Target modulation (pRSK inhibition) was assessed in Nude mice implanted with GP2D human tumors by Western blot.

Results: The preclinical PK properties of AZD0022 are defined by its physicochemistry (MW 614, extensive lipophilicity with log $D_{(7.4)}$ 2.5, dibasic with pKa values of 8.4 and 7.4). Oral administration studies suggest that AZD0022 is 30 to 70% absorbed from the gastrointestinal tract. AZD0022 exhibits extensive distribution into tissues. It also undergoes time-dependent partitioning into the red blood cell fraction of whole blood, suggesting that whole blood is the matrix that best represents the PK of the molecule. Blood clearance of AZD0022 was 8.2 and 8.6 mL/min/kg in mice and dogs, respectively. The measured Vss values based on blood were 10.8 and 20.4 L/kg, respectively. These characteristics suggest that in human, AZD0022 should be orally absorbed and exhibit a half-life consistent with once daily administration. In the GP2D model, single oral 150 mg/kg doses displayed prolonged plasma and tumour exposure. AZD0022 was estimated to be 18x more bound in tumour tissue than in plasma. Seven days of continuous 150mg/kg BID dosing resulted in up to approx. 75% pRSK inhibition. A dose range of 10, 50 and 150 mg/kg BID over 7 days displayed exposure-dependent pRSK modulation, with maximal of 75% pRSK inhibition. PKPD modelling suggested an unbound IC_{50} of 1.4 nM for pRSK inhibition.

Conclusions: The results presented here support the clinical development of AZD0022 which is currently being tested in a first in human Phase I/IIa study (ALAFOSS-01, NCT06599502)

#842 Early clinical outcomes of pembrolizumab plus neoadjuvant chemotherapy in early stage triple negative breast cancer in a Hispanic majority community.

Aymen Baig, **Erin C. Kaser**, Nico-al Paolo Gotera, Jay Parekh, Ranjit S. Banwait, Marcela Mazo Canola

The University of Texas Health Science Center At San Antonio, San Antonio, TX

Background: Triple-negative breast cancer (TNBC) accounts for 15% of breast cancers, and it has a poor prognosis with a five-year survival of 8 to 16% lower than that of hormone receptor-positive disease. There is a high prevalence of TNBC among Hispanics. In KEYNOTE-522 (KN522), a phase 3 trial, pembrolizumab plus neoadjuvant chemotherapy had been shown to be an effective option for pathological complete response (pCR) in early-stage TNBC as compared to neoadjuvant chemotherapy alone at the time of definitive surgery. While this treatment protocol showed promising data, immune checkpoint inhibitors such as pembrolizumab have been known to cause immune-related adverse effects (iRAEs) such as thyroiditis. There are limited studies on the efficacy of this treatment protocol and its adverse effects in Hispanic communities. Our study aims to present the relationship between pCR and immune-mediated thyroiditis in pembrolizumab plus neoadjuvant therapy for early-stage TNBC in a Hispanic-majority population in South Texas.
Methods: This is a retrospective analysis of patients with stage II or III TNBC at Mays Cancer Center in San Antonio, Texas between January 2020 to November 2024. This KN522 treatment protocol included neoadjuvant therapy with four cycles of pembrolizumab every 3 weeks plus paclitaxel and carboplatin. Patients then received four additional cycles of pembrolizumab and doxorubicin-cyclophosphamide or epirubicin-cyclophosphamide. At the 24-week mark, patients were assessed to see if they had successfully completed the KN522 protocol as planned. Patients were assessed for pCR at the time of definitive surgery. Outcomes include assessing for the development of immune-mediated thyroiditis. Statistical analysis to compare outcomes between Hispanics and non-Hispanics was performed using R v4.2.
Results: 66 patients were originally identified on review. 3 patients were excluded based on incomplete data. 63 patients were identified (68.3% Hispanic, 31.6% Non-Hispanic). At the time of definitive surgery, 55.6 % of patients had pCR (62.9% Hispanic, 37.1% Non-Hispanic) vs 44.4% with no pCR (75.0% Hispanic, 25.0% Non-Hispanic) with a p-value = 0.3. Comparing pCR and the development of immune-mediated thyroiditis, 14 patients with pCR (40%) vs 9 patients with no pCR (32.1%) developed immune-mediated thyroiditis with a p-value = 0.5.
Conclusion: There was no difference in pCR with pembrolizumab plus neoadjuvant chemotherapy between Hispanic and non-Hispanic populations. Furthermore, there was no difference in pCR between patients who developed immune-mediated thyroiditis or not. Our results were notable for occurring in a Hispanic majority population, but our study was limited by a small sample size. More studies are needed with a larger sample size to ascertain if there is a difference in outcomes between Hispanic vs non-Hispanic patients.

#845 Development of enhanced extracellular vesicle-based canine osteosarcoma cancer vaccines via metabolic labeling and click chemistry approach.

Yuan Liu[1], Yusheng Liu[1], Matthew R. Berry[2], Hua Wang[1]

[1]Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, Urbana, IL,[2]Department of Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL

Introduction: Osteosarcoma, characterized by its high metastatic potential, remains a prevalent bone malignancy in canines. Current therapeutic approaches, including amputation and chemotherapy, demonstrate limited efficacy and may compromise the patient's quality of life. This study explores a novel immunotherapeutic strategy utilizing metabolically labeled extracellular vesicles (EVs) conjugated with toll-like receptor (TLR) agonists as a potential cancer vaccine for canine osteosarcoma. The approach involves a facile and universal metabolic labeling technique to introduce azido groups onto the surface of mammalian cells, including cancer cells. Subsequently, nanosized EVs released from these cells inherit the azido groups, enabling conjugation with TLR agonists via click chemistry. Upon internalization by dendritic cells (DCs), the conjugated EVs are hypothesized to undergo lysis, facilitating antigen processing and presentation to effector T cells, while simultaneously activating DCs through TLR stimulation. This dual-action mechanism aims to promote a robust cytotoxic T lymphocyte (CTL) response against osteosarcoma cells.
Methods: In this study, peripheral blood mononuclear cells (PBMCs) were isolated from canine donor blood samples. CD14+ monocytes were subsequently purified using magnetic-activated cell sorting (MACS) with microbeads. The isolated monocytes were cultured for 6 days in the presence of human granulocyte-macrophage colony-stimulating factor (GM-CSF) and canine recombinant interleukin-4 (IL-4) to induce differentiation into monocyte-derived dendritic cells (moDCs). For the conjugation with EVs, a panel of toll-like receptor (TLR) agonists was selected, comprising imiquimod (TLR7 agonist), motolimod (TLR8 agonist), CpG oligodeoxynucleotides (TLR9 agonist), and polyinosinic:polycytidylic acid (poly(I:C), TLR3 agonist).
Results and Conclusion: The selected TLR agonists were successfully conjugated with EVs. Notably, EVs conjugated with imiquimod demonstrated significantly enhanced activation of moDCs compared to EVs alone, imiquimod alone, or a simple mixture of EVs and imiquimod. These findings suggest that the conjugation of TLR agonists, particularly imiquimod, with EVs may potentiate the immunostimulatory effects on moDCs. This approach shows promise for the development of a novel immunotherapeutic strategy against canine osteosarcoma. *In vivo* evaluation of the vaccine's efficacy is currently in preparation, which will provide crucial insights into its potential clinical application.

#846 Circular RNA based cancer vaccine encoding NY-ESO-1 is effective for the treatment of lung cancer.

S. Chen, **M. Qiu**;
Peking University People's Hospital, Beijing, China

Nucleic acid vaccines have undergone rapid development in recent years and are playing an increasingly prominent role in cancer therapy. Circular RNA (circRNA), with its unique closed-loop structure, extended protein expression half-life, enhanced stability, and simplified production process, represents a next-generation RNA carrier that offers significant advantages over traditional mRNA. In this study, we utilized our proprietary circRNA platform (NeoAna) to synthesize circRNA encoding NY-ESO-1, a highly immunogenic cancer-testis antigen expressed in various types of cancer, including lung cancer. This circRNA was delivered via lipid nanoparticles to develop a cancer vaccine. Our in vitro experiments demonstrated that circRNA encoding EGFP which was synthesized by NeoAna platform, achieved higher protein expression levels and prolonged expression duration in various cell lines compared to its mRNA counterpart. Moreover, NY-ESO-1 circRNA was found to effectively promote dendritic cell maturation, as well as T cell proliferation and activation in vitro. To assess the vaccine-induced anti-tumor immune responses, we collected spleens and lymph nodes from C57BL/6 mice following intramuscular vaccination. ELISpot assays and flow cytometry assays revealed that circRNA vaccine significantly increased the CD8/CD4 T cell ratio in these tissues, along with enhanced IFN-γ and TNF-α secretion by CD8+ and CD4+ T cells. Elevated NY-ESO-1-specific IgG antibody and IL-12 were confirmed by ELISA. In a murine lung cancer model established by subcutaneous injection of Lewis lung carcinoma cells overexpressing NY-ESO-1 into C57BL/6 mice, the circRNA vaccine demonstrated superior tumor suppression compared to an mRNA vaccine, with a higher proportion of antigen-specific T cells detected in peripheral blood. Additionally, histological examination of (H&E staining) and blood tests confirmed the safety of the circRNA vaccine for biological applications. In conclusion, our novel circRNA vaccine effectively activates anti-tumor immune responses and inhibits lung cancer progression, thereby providing a promising strategy for the clinical treatment of lung cancer.

#847 Small circular RNA for cancer immunotherapy.
Xiang Liu

Xiang Liu (Individual), Ann Arbor, MI

Introduction: Messenger RNA (mRNA) has emerged as a novel vaccine platform and has proven highly effective during the pandemic. This platform had also found application in the development of cancer vaccines. Despite the encouraging outcomes observed in early-phase clinical trials, certain concerns are still associated with current mRNA-based cancer vaccines such as limited stability, suboptimal tumor therapy potency and durability, and limited safety. Here, we report novel highly stable antigen-encoding small circular mRNA (circRNA) vaccines that elicit potent and durable T cell responses for robust tumor immunotherapy.
Method: Small circRNAs comprise minimal elements: codon-optimized peptide antigen-encoding RNA, a short IRES, and a Kozak consensus sequence that recruits ribosomes for peptide translation. Using MHC-I-restricted ovalbumin$_{257\text{-}264}$ (OVA$_{257\text{-}264}$ or SIINFEKL) as a model antigen, we prepared circRNA as follows: 1) circularizing 5'-phosphate-RNA using T4 RNA ligases and complementary 30-mer DNA splints, 2) removing linear/lariat RNA and DNA using DNase I and exonuclease T or RNase R, 3) purification to remove immunostimulatory small DNA/RNA fragments, enzymes, and nucleotides, and 4) verification by Sanger sequencing and gel electrophoresis.
Results: Compared to modified mRNA and current long circRNA, small circRNA shows superior stability, minimal protein kinase R activation, and low cytotoxicity. This allows small circRNA vaccines to sustain efficient antigen translation over an extended period while activating pattern recognition receptors for innate immunostimulation. Relative to several modified mRNAs, nanocarrier-delivered small circRNA vaccines show superior safety and elicit up to 10-fold antigen-specific T cells, accounting for 25%-75% total peripheral CD8+ T cells over 6 months in mice. circRNA vaccines are applicable for various major histocompatibility complex I/II-restricted tumor and viral (neo)antigens to elicit CD8+ and CD4+ T cell responses, in young adult and immunosenescentaged mice. In mice, mono-/multi-valent circRNA vaccines plus immune checkpoint blockade reduced tumor immunosuppression and eradicated multiple tumors, including B16F10, MC38, TC1, and immunotherapy-resistant BrafV600E melanoma. Overall, small circRNA vaccines represent a promising advancement in the field of tumor immunotherapy, offering optimal stability, safety, and the potential to generate potent and enduring immune responses against a variety of tumors.

#848 Preclinical development of the lipid nanoparticle-based mRNA vaccine with multiple natural T cell epitopes for pancreatic cancer.

Josephine Chang[1], Kevin Zheng[2], Yiming Li[3], Wanting Shan[4], **Lei Zheng**[4], Hai-Quan Mao[4], Juan Fu[4], Jiawei Zhou[4]

[1]Hampton Roads Academy, Newport News, VA,[2]Gilman School, Baltimore, MD,[3]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD,[4]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD

Background: Immunotherapy has recently emerged as a promising avenue in cancer treatment; however, its effectiveness on pancreatic ductal adenocarcinoma (PDAC) is hindered by the lack of effector T cells in the tumor microenvironment. One of the strategies to overcome the resistance of PDAC to immunotherapy involves identifying immunogenic tumor-associated and specific antigens for the development of personalized cancer vaccines. The mRNA platform has become an attractive platform for antigen presentation. The delivery of mRNA cancer vaccines via lipid nanoparticles (LNPs) enables intracellular delivery and controlled release of the payload, offering improved vaccine efficacy. However, mRNA vaccines presenting human T cell epitopes often lack a preclinical model for antitumor immune efficacy testing.
Methods: A syngeneic mouse model of PDACs was established by implanting KPC tumor cells into the livers by hemispleen surgery. mRNA vaccines expressing five 25-mer peptide regions were synthesized. Two mouse CD8+ T cell epitopes were predicted. Their MHC binding was tested by the T2 binding assay. CD8+ T cells specific for these two epitopes were examined by ELISpot assays and were quantified by ImmunoSpot ELISpot Reader to identify changes in IFN- secretion.
Results: Using mass spectrometry analysis, we successfully identified natural HLA class I and class II-binding epitopes in the neoplastic tissues of human PDACs. For the design of mRNA vaccine, we chose five 25-mer peptide regions that each contains both class I and class II epitopes punctuated by AAY and GPGPG linkers and followed by an MITD sequence, which all aim to improve the efficiency of antigen presentation to dendritic cells. Using NetMHC, we predicted H2Kb or H2Db-binding epitopes LYPFPLAL and SMVQMTFL, within these five human peptide regions. The T2 binding assay showed a lack of evident binding of both peptides to the T2-Kb or T2-Db cells. However, The ELISpot assay showed that LYPFPLAL, but not SMVQMTFL, can induce the IFN- expression from CD8+ T cells derived from splenocytes of the KPC tumor mice vaccinated by a peptide vaccine containing both peptides. Therefore, this result confirmed that LYPFPLAL is a mouse CD8+ T cell epitope and can be used to monitor antigen-specific CD8+ T cell response in response to the mRNA vaccine treatment in the syngeneic mouse model of PDACs.
Conclusions: Antitumor efficacy of our above-designed mRNA vaccine can be tested in the syngeneic mouse hemispleen model of KPC tumors. Mouse LYPFPLAL epitope-specific CD8+ T cell response can serve as a surrogate marker for the antitumor efficacy of this mRNA vaccine in mouse models for PDAC.

#85 Puf60 drives tumor progression and therapy resistance in head and neck squamous cell carcinoma.
Jung Je Park[1], Chae Dong Yim[2], Ji Hyun Seo[3], So Young Cheon[4]

[1]Otorhinolaryngology-head and neck surgery, Gyeongsang National University, Jinju, Korea, Republic of,[2]Otorhinolaryngology-head and neck surgery, Gyeongsang National University Hospital, Jinju, Korea, Republic of,[3]Gyeongsang National University, Jinju, Korea, Republic of,[4]Gyeongsang National University Hospital, Jinju, Korea, Republic of

Background: Head and neck squamous cell carcinoma (HNSCC) is a malignancy with high morbidity and mortality due to its invasive nature and frequent resistance to therapy. PUF60, a multifunctional RNA-binding protein, plays roles in transcription regulation and DNA repair, but its specific contributions to HNSCC pathogenesis remain unclear. This study investigates the role of PUF60 in tumor progression, oxidative stress responses, and resistance to therapeutic interventions.
Methods: HNSCC cell lines were employed to study the functional effects of PUF60 overexpression and knockdown. Cellular assays assessed invasion, migration, and apoptosis under standard conditions and in response to oxidative stress, cisplatin, and radiation. DNA damage was analyzed using flow cytometry and Western blotting, while immunoprecipitation and subcellular fractionation were performed to explore interactions between PUF60 and vital regulatory proteins such as PTEN and Sirt6.
Results: Overexpression of PUF60 significantly enhanced the invasive and migratory capabilities of HNSCC cells, while knockdown reduced these phenotypes. PUF60-overexpressing cells demonstrated resistance to cisplatin-induced apoptosis, accompanied by altered ROS production and decreased markers of DNA damage under oxidative stress. Radiation studies revealed a protective effect of PUF60, with reduced DNA damage and enhanced survival. Mechanistically, PUF60 modulated the subcellular localization of PTEN and interacted with Sirt6, highlighting its role in maintaining tumor cell viability under stress conditions.
Conclusion: PUF60 is a crucial driver of HNSCC progression and therapy resistance, promoting tumor cell invasiveness, modulating responses to oxidative and genotoxic stress, and facilitating survival under therapeutic pressure. Targeting PUF60 may offer a novel approach to overcoming resistance and improving treatment outcomes in HNSCC.

#850 Development of a systemic enveloped immunovirotherapy for targeting metastatic sites.

Yunyi Kang[1], **Duong Nguyen**[1], Trevor Smith[1], Stephanie Songco[1], Forrest Neuharth[1], Ivelina Minev[1], Karolin Streule[2], Selamawit Alemu[2], Lina Schulte[2], Thomas Herrmann[2], Boris Minev[1], Antonio Santidrian[1]

[1]Calidi biotherapeutics, San Diego, CA,[2]StemVac, Bernried, Germany

Background: Systemic virotherapies targeting directly all tumors are a promising form of cancer immunotherapy not only due to their tumor lytic characteristics but also because of their potential to transform tumor immune microenvironment, and targeted delivery of virus-encoded therapeutic payloads into tumors. Developing a platform for systemic delivery would provide a significant advantage in treating both primary tumors and any metastatic lesions. However, systemic administration of virotherapies may pose challenges of increased toxicity and reduced efficacy due to rapid virus clearance. In order to overcome these limitations, we have selected and developed a novel enveloped vaccinia virus platform by isolating a complement-resistant strain called Redtail vaccinia virus (RT). We have further engineered the backbone of the isolated strain to achieve tumor specific targeting and high therapeutic efficacy.
Methods: The RT backbone was genetically engineered by deleting multiple metabolic and immuno-modulatory genes. The replications of lead RT candidates were compared in vitro by xCELLigence real time cell analysis. In addition, therapeutic efficacy and toxicity profile of the candidate RT were monitored through in vivo imaging and clinical observation in both immunocompromised and immunocompetent mouse models.
Results: The newly developed and engineered RT demonstrated significant production of enveloped viruses with improved safety profile and enhanced therapeutic efficacy in metastatic lung cancer mouse models. In the immunodeficient nude mouse model, selected RT modification showed tumor specific targeting and preferential amplification in the tumors. In immunocompetent mouse model, RT lead candidate exhibited significant survival in circulations, tumor targeting, regression of primary and metastatic tumors with acceptable safety profile. In addition, drastic changes in tumor microenvironment were observed. Enveloped RT oncolytic immunotherapy increased cytotoxic T cell infiltration and decreased Tregs at the tumor sites, along with the release of proinflammatory cytokine, ultimately leading to tumor regression.
Conclusions: In summary, we have successfully developed a novel enveloped antitumor virotherepy that could be systemically delivered as a form of cancer immunotherapy in a safe manner.

#851 AdAPT-001 demonstrates potent oncolytic activity, high levels of TGFβ inhibition, and encouraging clinical activity in refractory sarcoma: update of the BETA-PRIME trial and preclinical correlates.

Chris Larson[1], Ana Sanchez[1], Farah Hedjran[1], Garett Soapes[1], Bryan Oronsky[1], Anthony P. Conley[2], Meaghan Stirn[1], Tony Reid[1]

[1]EpicentRx, Inc., La Jolla, CA,[2]MD Anderson Cancer Center, Houston, TX

Soft tissue sarcomas are an exceedingly rare and aggressive malignancy, occurring in about 5000 patients per year with an estimated median overall survival of around 12-18 months. Standard chemotherapy includes doxorubicin alone or with ifosfamide with high toxicity and low response rates. Other approved therapies in sarcoma are trabectedin, eribulin, and pazopanib, but their response rates are less than 10%. Immunotherapy trials have been largely disappointing. In the SARC028 phase 2 clinical trial, the PD-1 inhibitor, pembrolizumab, had limited activity except in undifferentiated pleomorphic sarcoma and liposarcoma. In the Phase 2 Alliance A091401 trial, the response to nivolumab was very low at only 5%, which led the investigators to arrive at a conclusion of medical futility, stating that, “Nivolumab alone does not warrant further study in an unselected sarcoma population given the limited efficacy”. AdAPT-001 is currently under investigation in a Phase 1/2 clinical trial for the treatment of advanced malignant solid tumor(s) for patients who have received all conventional therapies considered appropriate by Investigator. To date, of the 25 patients who received multiple doses of AdAPT-001 plus a checkpoint inhibitor, 14 of them were diagnosed with soft tissue sarcoma. Of these 14 patients, 69.2% (9/14 patients) reached a 3-month PFS and 35.7% (5/14) had an objective response. Most of these sarcomas had previously progressed on a PD-1 or PD-L1 inhibitor or were considered nonimmunogenic and, therefore, unsuitable for checkpoint inhibitor monotherapy. To date, the median PFS is 8.5 months. To further understand the activity of AdAPT-001 in sarcoma, we analyzed the lytic activity, TGFβ trap expression, and checkpoint expression patterns of sarcoma cell lines after infection. We demonstrate robust infection, replication, lysis and high-levels of TGFβ trap expression in sarcoma cell lines and objective responses, including pathologic complete responses, among patients who have progressed on chemotherapy and immunotherapy.

#852 A novel EGFR neoantigen-specific mRNA cancer vaccine demonstrates immunogenicity and anti-tumor efficacy in human.

Wenhua Liang[1], Bo Cheng[1], Jingshu Ma[2], Yan Wu[2], Liang Du[2], Peng Gao[2], Zhenxing Yang[2], Wenjie Song[2], Bo Ying[2], Jianxing He[1]

[1]Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, China,[2]Suzhou Abogen Biosciences Co., Ltd., Suzhou, China

Activating mutations in the epidermal growth factor receptor (EGFR) gene occur in 10-20% of Caucasian and 40% of Asian non-small cell lung cancer (NSCLC) patients. Predominant ones among these are in-frame deletions in exon 19 and the L858R point mutation in exon 21, which constitute 85-90% of all tyrosine kinase domain mutations. Although targeting these mutations has led to the early success of tyrosine kinase inhibitors, all patients eventually will develop resistance to treatment. Immunotherapy has been extensively explored in NSCLC patients in the recent years, but treatment outcome is still unsatisfying. As peptide-based neoantigens targeting EGFR mutations have demonstrated the potential of eliciting robust T cell responses against cancer cells, the combination of immune checkpoint inhibitor (ICI) and cancer vaccine has become a promising approach in fighting NSCLC. Here, we reported an mRNA-based cancer vaccine targeting mutated EGFR led to great anti-tumor efficacy in patients either in monotherapy or in combination of ICI. ABO2013 is an mRNA-based cancer vaccine targeting three most common EGFR mutations including exon 19 deletions, L858R, and T790M mutations. Mutation-specific T-cell responses induced by ABO2013 were initially tested using human PBMCs and transgenic mice expressing prevalent human HLA-A alleles, then anti-tumor efficacy was assessed in EGFR mutation-bearing mouse models. Intramuscular injection of ABO2013 elicited a robust adaptive T-cell response specifically targeting the three encoded EGFR mutations. The activated T cells demonstrated potent cytotoxic activity against tumor cells harboring the corresponding mutations, as evidenced by both *in vivo* and *in vitro* anti-tumor efficacy assessment. A first-in-human dose-escalation trial was conducted to further evaluate clinical safety and efficacy of ABO2013 in treating NSCLC patients (ChiCTR2300071001). Eligible participants include those carrying EGFR exon 19 deletions and/or L858R and/or T790M mutations. Participants must have also failed of standard of cares. Different doses of ABO2013 monotherapy or in combination with sintilimab 200mg were administered every 3 weeks to evaluate the safety, immunogenicity and antitumor efficacy. A total of 30 patients have been treated with either ABO2013 monotherapy (n=20) or in combination with sintilimab (n=10) by October 29, 2024. No dose-limiting toxicities or grade 3-4 TRAEs have been observed. Notably, robust neoantigen-specific immune responses were detected with patients achieving complete remission or partial response, respectively. ABO2013, as a monotherapy and in combination with sintilimab, has exhibited a favorable safety profile and a robust neoantigen-specific immune response and promising antitumor activity, warranting further investigation in EGFR-mutated NSCLC population.

#853 PDL1-PRAME dual antigen cancer vaccine inhibits melanoma growth in syngeneic mouse model and induces antigen-specific immune responses.

K.-T. Chan[1], H.-W. Chen[2], P.-H. Liang[3], Y.-Y. Lin[3], T. Zhang[1], M. Toh[1];

Preferentially expressed antigen in melanoma (PRAME) is a cancer/testis antigen frequently expressed in various types of cancer, especially in melanoma, and its overexpression is associated with aggressive tumor progression. PRAME-specific T-cells found in cancer patients recognize and specifically lyse cancer cells, positioning PRAME as a promising target for cancer immunotherapy. PDL1 represents one of the most important immune checkpoint antigens frequently overexpressed on tumor cells to suppress T-cell mediated anti-cancer immunity. Several anti-PDL1 antibodies have been approved for clinical use through passive immunization. We had developed PDL1-PRAME dual antigen cancer vaccines and reported their promising tumor growth inhibition effects against syngeneic mouse hepatocellular carcinoma in 2023. In the present study, anti-cancer efficacy of the PDL1-PRAME dual antigen cancer vaccine was evaluated in an aggressive mouse melanoma model. Subcutaneous administration of the cancer vaccine formulated with alum-CpG oligodeoxynucleotides (ODNs) prior to tumor implantation significantly inhibited tumor growth by 91.5% *(P<0.01)* and prolonged the median survival time from 23.5 days to 40.5 days *(P<0.01),* compared to adjuvant treated control. To further optimize the vaccine formulation, another *in vivo* study was conducted with the PDL1-PRAME vaccine protein formulated with different adjuvants, including a novel synthetic saponin based adjuvant IAS-01, to evaluate the vaccine-induced antigen-specific immune responses in C57BL/6 mice. IAS-01, developed by ImmunAdd, is a liposome-based adjuvant incorporating two potent immunostimulants, a fully synthetic monophosphoryl Lipid A and a fully synthetic truncated QS-21 analogue, IA-05, devoid of hemolytic toxicity. Both alum-CpG ODN and IAS-01 obviously enhanced the vaccine-induced T-cell response against PRAME and elevated the anti-PDL1 antibody response. In particular, the highest anti-PDL1 antibody response was found with the IAS-01 adjuvant, compared to all the other adjuvants tested. Our study highlighted the prospect of developing the PDL1-PRAME dual antigen cancer vaccine for cancer immunotherapy. The vaccine efficacy is being further optimized in terms of its protein structure, adjuvant formulation, and administration route for potential clinical testing.

#854 Targeting Irg1 expressed on macrophages in lymph nodes promotes response to mRNA cancer vaccines.

Chao Wan[1], Wenwen Wei[1], Xiao Yang[1], Yeshan Chen[1], Mengjie Che[1], You Qin[1], Qiao Li[2], Kunyu Yang[1]

mRNA cancer vaccines show great promise for tumor therapy, but their therapeutic efficacy is limited. Metabolites play critical roles in immunomodulation, however, their role in mRNA cancer vaccines remains unclear. Using metabolome analysis combined with single-cell RNA sequencing, we found that macrophage-derived itaconate increased markedly after ovalbumin-encoding mRNA-lipid nanoparticle (OVA-LNP) injection in activated ipsilateral lymph nodes compared to that in homeostatic contralateral lymph nodes. Depleting the immune-responsive gene 1(Irg1) in macrophages, which encodes the itaconate-production enzyme aconitate decarboxylase (ACOD1), improved the antigen presentation of dendritic cells and the functions of T cells. Knockdown of Irg1 using small interfering RNA (siRNA) combined with OVA mRNA in LNPs enhanced the therapeutic efficacy of mRNA vaccines alone or combined with an anti-programmed cell death-1 antibody. Taken together, our results reveal a link between itaconate and mRNA cancer vaccines, and suggest that targeting Irg1 via siRNA-LNP may be a promising strategy for improving the therapeutic efficacy of mRNA cancer vaccines.

#855 Dynamics of T cell and T cell receptor following mRNA-4157 (V940) plus pembrolizumab or pembrolizumab alone in resected melanoma from the mRNA-4157-P201 (KEYNOTE-942) trial.

Chiles Research Institute, Portland, OR,[8]Sarah Cannon Research Institute, Nashville, TN,[9]Melanoma Institute Australia, The University of Sydney, Royal North Shore and Mater Hospitals, Sydney, Australia,[10]The Angeles Clinic and Research Institute, a Cedars-Sinai affiliate, Los Angeles, CA,[11]UPMC Hillman Cancer Center, Pittsburgh, PA

Introduction: mRNA-4157 is a novel mRNA-based individualized neoantigen therapy (INT) designed to enhance endogenous antitumor T-cell responses by targeting unique patient-specific tumor mutations. In the phase 2 mRNA-4157-P201 (KEYNOTE-942) trial, patients with completely resected high-risk stage IIIB-IV melanoma receiving mRNA-4157 + pembrolizumab (pembro) showed prolonged recurrence-free survival (RFS) and distant metastasis-free survival (DMFS) versus those receiving pembro alone (Weber JS, et al. *Lancet* 2024). Here, we characterized the dynamics of T cell and T cell receptor (TCR) repertoire in peripheral blood following mRNA-4157 plus pembro or pembro alone.

Methods: Patients were randomized 2:1 to receive mRNA-4157 + pembro or pembro alone. Whole blood samples from longitudinal time points (baseline: pre-pembro & pre-INT; post-pembro & pre-INT; post-pembro & post-INT; and longer-term follow-up after completion of treatment; 116, 101, 108, and 79 patients respectively) were collected and TCR sequencing was performed. TCR beta chains were down sampled and normalized to the top 10k clones by rank sum unique molecular identifier. Shannon clonality was calculated on down sampled data. Differential clone abundance between screening and on-treatment samples was calculated by binomial test.

Results: Baseline TCR clonality was not associated with RFS of mRNA-4157 + pembro or pembro alone. However, longitudinal analysis of samples post-INT showed clonality was increased in 70% (55 out of 78) and 31% (12 out of 38) of the patients treated with mRNA-4157 + pembro and pembro alone, respectively. Analysis of clonotypes showed median number of novel expanded clonotypes after mRNA-4157 + pembro (n=78) and after pembro alone (n=38) was 38 and 22, respectively, suggesting that mRNA-4157 + pembro was associated with expansion of more novel clonotypes relative to pembro alone. Furthermore, among 78 patients in the mRNA-4157 + pembro arm, patients without recurrence (n=59) had median number of 40 novel expanded clonotypes while patients with recurrence (n=19) had median number of 16 novel expanded clonotypes. Additional analysis of neoantigen-specific T cells is ongoing and will be reported.

Conclusions: Expansion of novel T cell clonotypes in peripheral blood was observed to a greater extent after mRNA-4157 + pembro compared to pembro alone, and the degree of novel expansion was associated with RFS.

#856 Exploiting the molecular mimicry for preventive/therapeutic cancer vaccine development.

Maria Tagliamonte, Beatrice Cavalluzzo, Angela Mauriello, Concetta Ragone, Biancamaria Cembrola, Simona Mangano, **Luigi Buonaguro**

National Cancer Institute Pascale, Naples, Italy

Shared tumor antigens are needed for developing off-the-shelf preventive/therapeutic cancer vaccines. To this aim, shared mutated neoantigens (TSAs) cannot be exploited for highly prevalent tumors in the majority of worldwide cancer patients. Therefore, TAAs must be used, which may suffer from the potential immunological tolerance. Analogue peptides with improved antigenicity and immunogenicity, able to elicit a cross-reactive T cell response are needed. To this aim, non-self-antigens derived from microorganisms (MoAs) may be of great benefit. We will describe several examples of MoAs sharing sequence homology with TAAs (“molecular mimicry”), able to elicit a cross-reacting CD8+ T cell response. In particular, the homology to cancer testis TAA (e.g. MAGE-A1) allows to develop cancer vaccines useful for several tumor types, “one-vaccine-for-many-tumors”. In conclusion, non-self MoAs should be selected and included in preventive/therapeutic cancer vaccines with a more potent anti-tumor efficacy compared to those based on TAAs. This would allow the development of ready to be used “off-the-shelf” cancer vaccines for the global population of patients affected by one or more cancer types (Tagliamonte M, et al., Molecular mimicry and cancer vaccine development. Mol Cancer. 2023 Apr 26;22(1):75. doi: 10.1186/s12943-023-01776-0).

#857 Calcium enhances synthetic HPV long peptide vaccination-mediated anti-tumor immunity and improves tumor control.
Ming-Hung Hu

Johns Hopkins University, Baltimore, MD

Introduction: Transfection efficiency is a critical factor in the successful delivery of tumor vaccines. Intramuscular (IM) injection followed by electroporation is considered a superior approach compared to conventional IM injection alone. However, electroporation's clinical unavailability and feasibility present significant limitations. Calcium, a ubiquitous second messenger, plays a crucial role in regulating various cellular processes, including transcription and cell death. Calcium overload can increase cell membrane permeability, promote reactive oxygen species accumulation, and trigger cell necrosis, leading to the release of intracellular contents such as antigens and damage-associated molecular pattern molecules (DAMPs). Our hypothesis is that calcium administration, by effectively priming immune responses, could serve as a feasible therapeutic strategy to overcome these limitations in cancer vaccine delivery.
Method: The synthetic long-peptide vaccine utilized in this study, E7aa 43-62, comprises a synthetic peptide that mimics the 43-62 amino acid sequence of the HPV-16 E7 antigen. The long-peptide vaccines (20 μg) were administered to evaluate their anti-tumor effects in buccal TC-1 tumor-bearing C57BL/6 mice, with a total of three doses given at 7-day intervals. Vaccination was followed immediately by calcium administration or calcium electroporation. Calcium chloride solution (168 mM) was administered either subcutaneously or intratumorally. Electrical pulses were delivered using Tweezertrodes electrodes connected to a BTX electroporation generator (ECM830; BTX Harvard Apparatus). Eight pulses at 72 V were applied, each lasting 20 ms, with 200-ms intervals between pulses.
Results: In the current study, calcium administration was shown to enhance HPV long-peptide vaccination-mediated anti-tumor immunity. Specifically, calcium administration achieved tumor control and prolonged survival comparable to calcium electroporation, accompanied by elevated levels of serum E7-specific tetramer formation. Additionally, mice receiving calcium injections, either subcutaneously or intratumorally, exhibited improved tumor control and superior survival compared to vaccination alone. Cellular analysis revealed that calcium injection significantly increased the systemic E7-tetramer population. This robust and sustained immunological activation was not only effective against contralateral buccal tumors but also provided protection against TC-1 tumor re-challenge.
Conclusion: Our data demonstrate that calcium administration, either subcutaneously or intratumorally, enhances the anti-tumor immunity elicited by HPV long-peptide vaccination. This treatment effect is evidenced by controlled tumor growth and prolonged survival, accompanied by increased E7-specific tetramer formation.

#858 Development of next generation carbohydrate-based vaccines.

X. Huang;
Michigan State University, East Lansing, MI

The development of an effective vaccine construct against tumor associated carbohydrate antigens (TACAs) is an attractive approach towards cancer treatment and prevention. However, a significant challenge is that TACAs are only weakly immunogenic and direct administration of TACAs cannot elicit a powerful antibody response to protect the host from cancer development. In this presentation, we will present our strategies in engineering virus like particle bacteriophage Qβ to significantly enhance the immunogenicity of TACAs as potential anti-cancer vaccines. With its abilities to display antigens in a highly organized manner, Qβ can be a powerful carrier to deliver the antigen to the immune system and activate adaptive immunity. We have engineered Qβ to reduce the antibody responses against the carrier and incorporate T cell epitopes to induce a comprehensive immune response activating both humoral and cellular immunity. With the new Qβ carrier in hand, ganglioside GD2 has been explored as a representative antigen. Ganglioside GD2 is an appealing TACA due to its overexpression on many types of tumor cells. However, its low immunogenicity and the significant side effects observed with anti-GD2 antibodies present significant obstacles for vaccines. To overcome these, a new GD2 derivative bearing an *N*-acetamide (NHAc) at its non-reducing end neuraminic acid (9NHAc-GD2) has been designed to mimic the 9-*O*-acetylated-GD2 (9OAc-GD2), a GD2 based antigen with a restricted expression on tumor cells. 9NHAc-GD2 was synthesized efficiently via a chemoenzymatic method and subsequently conjugated with a powerful carrier bacteriophage Qβ. Mouse immunization with the Qβ-9NHAc-GD2 conjugate elicited strong and long-lasting IgG antibodies, which were highly selective toward 9NHAc-GD2 with little cross-recognition of GD2. Immunization of canines with Qβ-9NHAc-GD2 showed the construct was immunogenic in canines with little adverse effects, paving the way for future clinical translation to humans. Building on these results, we are further engineering the 9NHAc-GD2 antigen to improve its immunogenicity. Our latest efforts in designing new GD2 antigens and evaluating them in tumor models will be discussed.

#859 Novel oncolytic RNA viruses, IVX037 and IVX055, demonstrate potent antitumor activity.

Darren Shafren, Christine Lee, Jera Peters, Szun Tay, Chloe Evans, Min Quah

ImmVirX, Newcastle, Australia

Background: Oncolytic viruses have emerged as promising therapeutic agents to selectively target, infect and destroy cancer cells while synergizing with novel immunotherapies including Checkpoint inhibitors (CPI) and Chimeric Antigen Receptor (CAR) T- cells to increase anti-tumor efficacy. We developed two novel oncolytic non-enveloped RNA viruses, IVX037 and IVX055, using a proprietary receptor-focused bio-selection platform technology. IVX037 and IVX055 are small, single stranded RNA viruses, utilizing independent cell surface receptors to facilitate tumor targeting, cell entry and subsequent potent lytic replication. Intratumoral (i.t) IVX037 challenge of human microsatellite-stable colorectal cancer (MSS-CRC) xenografts increases expression of PD-L1 and mediates a widespread inflammation phenotype, suggested to allow increased migration of anti-tumor lymphocytes, elevation of cellular targets for immune checkpoint and cell-based anti-cancer therapies.

Methods: *In vitro* monolayer cultures of human cancers were challenged with various input multiplicities of IVX037 or IVX055 with lytic infection assessed by a XTT viability assay. For mouse models, immunocompromised mice (SCID or nu/nu) were seeded with single flank human tumor cell administrations. Following development of palpable tumors, IVX037 was administered via i.v or i.t routes. Calliper measurements were employed to assess tumor burden. Checkerboard titrations of IVX037 and a mesothelin targeted CAR-T were utilized to assess anti-tumor activity in monolayer cultures of human gastric cancer cells.

Results: IVX037 demonstrated potent oncolytic *in vitro* activity in human ovarian, gastric, and hepatocellular cancer (HCC) cell cultures. IVX055 induced rapid cell lysis in non-small cell lung, HCC and human bladder cancer *in vitro* cell preparations. Intratumoral and intravenous administration of IVX037 in human tumor xenograft models using immunocompromised mice were well tolerated and displayed potent anti-tumor activity against ovarian, gastric and HCC cancers. In reference, to cell-based therapies, preliminary *in vitro*combination studies with mesothelin-targeted CAR T-cells and IVX037 suggest enhanced tumor cell killing compared to that of either agent alone in a human gastric cancer cell culture model.

Conclusions: The promising preclinical anti-tumor activity of IVX037 and IVX055 against a wide range of human malignancies warrants further clinical evaluation in combination with novel immunotherapy strategies. To this end, IVX037 is currently being investigated in an ongoing Phase 1b combination trial with sintilimab (anti-PD-1) in patients with advanced MSS-CRC, gastroesophageal, and ovarian cancer (NCT05427487). Future plans for IVX055 include evaluation in combination with immune checkpoint therapy in patients with advanced non-small cell lung cancer (NSCLC) bearing metastatic liver disease.

#86 The role of truncated O-glycans in PDAC progression: Linking C1GALT1 loss to metabolic alterations.

Wyatt Petersen[1], Venkatesh Varadharaj[2], Zahraa I. Alsafwani[2], Surinder K. Batra[2], Moorthy P. Ponnusamy[2]

[1]Cancer Research, University of Nebraska Medical Center, Omaha, NE,[2]Biochemistry and Molecular Biology, University of Nebraska Medical Center, Omaha, NE

Pancreatic cancer (PC) remains one of the leading causes of cancer death, often advancing undetected until late stages. Aberrant O-glycosylation, including the expression of truncated carbohydrate antigens such as Tn and STn, is a hallmark of PC; however, the mechanisms linking these glycan alterations to tumor progression and metastasis are poorly understood. This study investigates the role of truncated O-glycans, driven by the loss of the O-glycosyltransferase core 1 synthase (C1GALT1), in promoting metabolic reprogramming and early metastatic dissemination in pancreatic cancer. C1GALT1 catalyzes the biosynthesis of mucin-type O-glycans, but its inactivity in PC leads to the accumulation of truncated glycans. Analysis of poorly differentiated human PC tissues revealed a significant loss of C1GALT1 expression. CRISPR/Cas9-mediated knockout (KO) of C1GALT1 in PC cell lines also results in increased Tn and STn glycan expression, enhanced tumorigenic potential, and increased metastatic capacity. Using genetically engineered mouse models (*C1galt1* KO with $Kras^{G12D/+}Trp53^{R172H/+}$ mutations), we observed early-onset and widespread metastasis, mirroring the heightened aggressiveness associated with C1GALT1 loss in pancreatic cancer. Transcriptomic profiling through RNA sequencing and pathway enrichment analysis in C1GALT1 KO PC cells revealed significant upregulation of cholesterol metabolism pathways, suggesting that the loss of C1GALT1 may drive metabolic changes to support the aggressive behavior of PC cells. Supporting this, functional assays demonstrate a significant increase in wound healing and migratory capacity of C1GALT1 KO cells compared to control PC cells, highlighting their enhanced motility and potential for metastasis. These findings underscore the role of C1GALT1 loss in driving aggressive tumor phenotypes, potentially through metabolic and functional adaptations that promote the need for further investigation. This work highlights a previously underexplored link between aberrant glycosylation and metabolic rewiring in pancreatic cancer. By elucidating the role of C1GALT1 loss in driving these processes, our findings provide novel insights into the mechanisms of tumor progression and identify potential vulnerabilities for therapeutic intervention. Targeting the interplay between glycosylation and metabolic pathways offers a promising avenue to disrupt the aggressive phenotype of pancreatic cancer.

#860 BCMA CAR-T cells releasing mutant CST6 ^{N137D} proteins further improve therapeutic effects in multiple myeloma.

Yamin Meng[1], Zijun Zhang[2], Yan Cheng[2], Hongwei Xu[2], Frits van Rhee[2], Guido Tricot[2], John D. Jr Shaughnessy[2], Fenghuang Zhan[2]

[1]University of Arkansas for Medical Sciences, Little Rock, AR,[2]Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR

Introduction: Multiple myeloma (MM) is a hematological malignancy characterized by the accumulation of abnormal monoclonal plasma cells and osteolytic bone disease. The latter is a key feature of MM, which is associated with worse clinical outcomes. We have found that high cystatin E/M (CST6) expression is linked to the absence of bone lytic lesions in human MM patients and CST6 suppresses the formation of osteolytic lesions by blocking osteoclast differentiation and function in MM. We have also developed the B cell maturation antigen (BCMA)- chimeric antigen receptor T cell secreting wild-type CST6 proteins (BCMA/CST6^{WT}), which specifically kill MM cells and suppress osteolytic lesions in MM mouse models. However, we also found that CST6^{WT} induced immunosuppression in MM, which is an unwanted effect of MM therapy. The objective of this study is to develop a BCMA-CAR-T engineering a mutant CST6, which still targets both MM cells and osteoclasts but without immunosuppressive function.
Materials and Methods: The different functional mutants of CST6 proteins were purified to test their effects on both osteoclastogenesis and immune cells. The proliferation assays and osteoclast formation assays were conducted to test the mutant CST6 function on immunosuppression and osteoclast formation. the BCMA/CST6 ^{N137D} CAR vector contained BCMA-scFv and the mutant CST6 ^{N137D} was constructed. A P2Aself-cleaving peptide was inserted between CAR and CST6 ^{N137D}. The CBA assays were employed to test the concentration of the cytokines. The ELISA assays were conducted to test the concentration of CST6 protein.
Results: We have generated 6 different CST6 mutants to determine the key domain(s) for the immunosuppressive effects of CST6. By determining $CD8^+$ cell proliferation and performing osteoclast formation assays, we have identified that the non-glycosylated CST6 ^{N137D} proteins lack an immunosuppressive function but maintain the suppressive function of osteoclastogenesis. We further developed the BCMA/CST6 ^{N137D} CAR-T cells releasing a mutant CST6 and found that the BCMA/CST6 ^{N137D} CAR-T cells significantly increased the expression of both IFN-γ and TNF- α cytokines compared with the BCMA-CAR-T cells and BCMA/CST6 ^{WT} -CAR-T cells. The BCMA/CST6^{N137D}CAR-T cells also had a stronger antitumor activity compared with the BCMA-CAR-T cells and BCMA/CST6 ^{WT} -CAR-T cells.
Conclusion: In this study, we have identified a CST6^{N137D} mutant, which could suppress osteoclast differentiation without immunosuppressive effects. Furthermore, we have also developed that the BCMA/CST6^{N137D} CAR-T cells may have a better therapeutic effect by targeting both tumor cells and osteoclasts but without suppression of cytotoxic T cell proliferation in MM.

#862 Dynamic hydrogel drug delivery systems for enhancing tertiary lymphoid structure formation and maturation.

W. Tang[1], C. Kuwentrai[2], M. J. Webber[3], Z. Ye[1], **J. Huang**[2];
[1]University of Hong Kong, Faculty of Dentistry, Pokfulam, Hong Kong, [2]University of Hong Kong, The - Li Ka Shing Faculty of Medicine, Pokfulam, Hong Kong, [3]University of Notre Dame, Notre Dame, IN

Introduction: Tertiary lymphoid structures (TLSs), also known as ectopic lymphoid structures, are organized lymphoid-like aggregates that can form within the tumor microenvironment. TLSs exhibit similar structural and functional characteristics to secondary lymphoid organs, such as lymph nodes, and are associated with improved cancer prognosis and enhanced immune responses, including immune checkpoint blockade (ICB) therapies. However, inducing mature TLSs remains a significant challenge. Our study aims to develop a dynamic hydrogel drug delivery system that stimulates the formation and maturation of TLSs.
Design: The study involved the synthesis of a hydrogel through supramolecular interactions between 4-(4-chlorophenyl)pyridine-modified hyaluronic acid (HA-CPP) and cucurbit[8]uril (CB[8]). The hydrogel was loaded with the cytokines CXCL13 and LIGHT or with liposomes encapsulating the mRNA coding for these two cytokines, and was injected into cancer-bearing mouse models. We assessed the effect of the hydrogel on TLS formation and maturation through immunofluorescence staining. We also investigated tumor growth and survival rates. Furthermore, we explored the combined effect of the hydrogel and anti-PD1 ICB therapy on tumor suppression and TLS formation.
Results and discussion: The study demonstrated that a single injection of the HA-CPP ⊂ CB[8] hydrogel containing CXCL13 and LIGHT effectively increased TLS density, facilitated TLS maturation, suppressed tumor growth, and extended survival in the intraperitoneal melanoma mouse model. Moreover, the combination of the hydrogel-based drug formulation and anti-PD1 ICB therapy resulted in increased tumor suppression, improved survival rates, and further strengthened TLS formation. Furthermore, although TLS formation in some solid tumor locations like subcutaneous areas was significantly suppressed compared to that in intraperitoneal areas, our mRNA-loaded hydrogel still effectively induced TLS and combated tumors in various subcutaneous tumor models, including melanoma, breast cancer, colon cancer, and pancreatic cancer. This effectiveness is likely due to the adaptability, high translational efficiency, and durable bioactivity of mRNA therapies.
Conclusion: The study concludes that the HA-CPP ⊂ CB[8] hydrogel-based drug formulation acts as an effective synthetic immune niche scaffold for promoting mature TLS formation within tumors. This approach provides a promising strategy for advancing tumor immunotherapy by enhancing the immune response against various cancers and improving the efficacy of ICB therapy.

#863 A novel SIRPA based FiCAR T cells therapy targeting TYRP1 to treat melanoma patients.

Henrik Paavilainen[1], Sakari Poysti[1], Veera Nikoskelainen[2], Marie Nyman[1], **Anil K. Thotakura**[1]

[1]Immuno-Oncology, Orion Corporation, Turku, Finland,[2]Protein and Antibody Engineering, Orion Corporation, Turku, Finland

Background: The first-generation immune checkpoint inhibitors anti-PD1/PDL1 and anti-CTLA-4 either alone or in combination have shown tremendous clinical success in BRAF wild type melanoma cancer patients. However, there is still a high unmet need as great proportion of melanoma patients relapsed after treatment with first generation immune checkpoint inhibitors and BRAF mutant patient relapsed after treatment BRAF inhibitors. Chimeric antigen receptor (CAR) expressing T cells have shown clinical success in hematological malignancies, recent studies have shown that CAR Ts cells were detected in circulation a decade after the first CD19 CART cell injection. Here, we generated a novel SIRPa based extracellular extension TYRP1 targeting CAR T cell, here onwards referred as TYRP1 FiCAR, that work independent of the tumor mutation burden and BRAF status. TYRP1 targeting FiCARs could be an alternative and attractive therapeutic strategy for treatment relapsed melanoma patients.

Methods & Results: A well-known anti-TYRP1 binder flanvotumab's scfv was inserted into FiCAR-structure containing CD28 and CD3zeta intra cellular signaling domain and those CAR T cells were studied for both in vitro and in vivo function. TYRP1 based FiCAR grew normally and good transduction rates with low vector copy numbers were achieved. In addition, upon co-culture of TYRP1 FiCAR T cells with tumor cells expressing TYRP1 a rapid and significant release of pro-inflammatory cytokines was detected. Moreover, killing of the target cells were observed by the TYRP1 FiCAR T cells. To study the in vivo functionality of the TYRP1 FiCAR-T cells, NSG mice were inoculated with melanoma cells subcutaneously. Three weeks after the inoculation mice were intravenously injected with a single dose of TYRP1 FiCAR T cells.

Discussion: The data presented here shows a proof-of-concept study for the FiCAR structure to work against TYRP1 antigen. TYRP1 FiCAR T cells upon co-culture with TYRP1 expressing tumor elicited a significant increase in effector cytokines production and has not shown any signs of tonic signaling. Additionally, TYRP1 FiCAR T cells were able to kill tumor cells efficiently reaching 100% maximal killing. In vivo, TYRP1 FiCAR T cells significantly delayed tumor growth. However, full regression of the tumors was not achieved in vivo. Collectively, the in vitro and in vivo data support further optimization of TYRP1 FiCAR T cells to treat melanoma patients refractory to immunotherapy and BRAF inhibitors.

#864 Novel innate immune receptor-based chimeric antigen receptors for *in vivo* programming of myeloid cells show potent anti-tumor activity in preclinical solid tumor models.

Yuxiao Wang[1], Neha Diwanji[1], Shannon Argueta[1], Junming Tong[2], Ewa Grudzien-Nogalska[1], Michael Gorgievski[1], Josephine D'Alessandro[1], Edward Cochran[1], Phillip Darcy[2], Jian Ding[1], Robert Hofmeister[1], Daniel Getts[1]

[1]Myeloid Therapeutics, Cambridge, MA,[2]Peter MacCallum Cancer Centre, Melbourne, Australia

Background: Chimeric antigen receptor (CAR) T cell therapy faces significant challenges in solid tumors due to the immunosuppressive tumor microenvironment (TME). Given their tumor-infiltrating capability, phagocytic activity, and ability to promote adaptive immune responses, CAR-engineered myeloid cells represent a promising therapeutic approach. Here we introduce a novel class of CARs designed for programming myeloid cells *in vivo*. These CARs comprise antibody binders against tumor antigens fused with truncated innate immune receptors CD89 or NKp44. Like their natural counterparts, activation of CD89 and NKp44-based CARs requires association with their cognate signal adapters FcRγ or DAP12, which are only expressed in myeloid/NK cells. Such segregation of antigen binding from cellular activation ensures immune cell-restricted CAR activity, minimizing off-target effects during *in vivo* administration.

Methods: The CAR constructs comprise a single-chain variable fragments (scFv) against HER2 or gp75, fused to truncated CD89 or NKp44. CAR mRNA was encapsulated in lipid nanoparticles (LNPs) to achieve *in vivo* programming. Coding sequences and 3' UTR of the mRNA were optimized for prolonged expression. *In vitro*, CAR expression and function were evaluated in a THP1 reporter cell line and primary monocytes. Anti-tumor efficacy of the CARs was assessed in a human HER2 (hHER2) transgenic mouse model and a syngeneic B16/F10 melanoma model, in which CAR mRNA/LNPs were administered intravenously.

Results: The CD89 or NKp44-based CARs were highly expressed in primary CD14+ monocytes for more than 7 days post electroporation. THP1 reporter cell assays demonstrated CAR-dependent activation of the NFκB pathway. Biochemical studies confirmed specific association and phosphorylation of FcRγ chain or DAP12 with CD89 or NKp44-based CARs, respectively. Transfection of human PBMCs with mRNA/LNP showed preferential CAR expression in myeloid cells. In the hHER2 transgenic mouse model bearing hHER2-MC38 tumors, intravenous administration of mRNA/LNPs encoding HER2-targeting CARs showed potent anti-tumor activity and prolonged survival. In the B16/F10 melanoma model, delivery of gp75-targeting CARs reduced tumor growth and increased $CD8^+$ T cell infiltration into tumors, indicative of TME remodeling toward an immunostimulatory state.

Conclusions: We demonstrated that CD89 and NKp44-based CARs achieve robust expression in myeloid cells. *In vivo* programmed CAR myeloid cells elicit potent anti-tumor activity and promote an T cell-mediated adaptive immune response in syngeneic mouse models. The CARs' reliance on endogenous signaling adaptors, combined with preferential mRNA/LNP uptake by myeloid cells, ensures immune cell-specific activity and provides an enhanced safety profile for *in vivo* myeloid cell engineering.

#865 Engineering a next-generation dual-knockout TIL product with AaCas12b nuclease editing.

Jingwei Sun[1], Yao Sheng[1], Hongwei Zhang[2], Xi Zhu[2], Jingman Wang[1], Ke Liu[1], Shin-Shay Tian[2], **Pin Wang**[3], Xiaoping Zhao[2], Yarong Liu[1]

[1]Grit Biotechnology, Shanghai, China,[2]Shanghai Vitalgen Biopharma, Shanghai, China,[3]USC - University of Southern California, Los Angeles, CA

Advancing cellular therapies, particularly allogeneic and functionally enhanced treatments using gene editing technologies, necessitates rigorous safety and quality assessments to ensure clinical success. Among CRISPR nucleases, Cas12b—a type V CRISPR enzyme—stands out for its high editing fidelity, owing to its stringent mismatch intolerance between single guide RNA (sgRNA) and target DNA, surpassing SpCas9 in precision. An engineered variant of Cas12b from *Alicyclobacillus acidiphilus*, termed AaCas12b^{Max}, has demonstrated exceptional on-target editing efficiency with minimal off-target activity, making it a promising tool for complex therapeutic gene editing. This study employed AaCas12b^{Max} to develop GT300, a next-generation tumor-infiltrating lymphocyte (TIL) product incorporating a dual-gene knockout. Candidate sgRNAs for the target genes were identified through *in silico* analysis to minimize genome-wide mismatches. Top-performing guides, validated in HEK293 cells and human PBMC T cells, were further evaluated in TIL products and compared with SpCas9-mediated editing. The AaCas12b^{Max} system achieved comparable knockout efficiency and target protein reduction to SpCas9, with functional evaluations showing similar cytotoxicity, cytokine secretion in vitro, and antitumor efficacy in a mouse PDX model using autologous TILs. Notably, TIL products edited with AaCas12b^{Max} exhibited 3-5 times greater expansion and enhanced viability during large-scale production compared to those edited with SpCas9. These cells demonstrated improved stemness, reduced exhaustion, and apoptosis, alongside superior expansion post-infusion in vivo, suggesting reduced genetic stress during editing. Comprehensive off-target and chromosomal translocation analyses using SITE-seq, GUIDE-seq, and PEM-seq, validated by Amp-seq and hybrid capture assays, confirmed a superior safety profile for AaCas12b^{Max}-edited GT300 compared to SpCas9. RNA-seq analyses at 6 and 24 hours post-electroporation revealed diminished activation of apoptosis and exhaustion pathways in AaCas12b^{Max}-edited TILs. In conclusion, GT300 edited with AaCas12b^{Max} demonstrated efficient gene editing, a superior safety profile, and significant improvements in cell expansion, viability, and fitness. A first-in-human clinical trial of GT300 is currently underway in China.

#866 Next-generation neoantigen vaccines powered by AI-assisted discovery and APC-targeted delivery platforms.

Jingwei Sun[1], Zhenjiang Liu[1], Ke Liu[1], Xi Zhu[2], Chenxi Hou[2], Hong Chen[2], Xu Wang[1], Jiahui Jin[1], Zhao Xu[1], Stephen Schoenberger[3], **Pin Wang**[4], Yarong Liu[1]

[1]Grit Biotechnology, Shanghai, China,[2]Shanghai Vitalgen Biopharma, Shanghai, China,[3]La Jolla Institute for Immunology, La Jolla, CA,[4]USC - University of Southern California, Los Angeles, CA

Neoantigen-based cancer vaccines have shown promising efficacy in recent clinical trials for treating solid tumors. However, traditional neoantigen prediction methods, which largely rely on HLA-peptide binding databases, often yield false-positive predictions, highlighting the need for more accurate strategies to identify truly immunogenic neoantigens. To address this, we developed *NEOVigator*, an advanced neoantigen discovery platform that combines an AI-driven algorithm with functional validation using tumor-specific T cells derived from autologous tumor-infiltrating lymphocytes (TILs) and peripheral blood mononuclear cells (PBMCs). The *NEOVigator* platform mimics the complete antigen presentation and T-cell response cascade by isolating and expanding autologous antigen-presenting cells (APCs) to evaluate neoantigen expression, processing, MHC binding, and presentation. Patient-derived TILs and PBMC T cells are then used to assess TCR recognition and T-cell responses to APC-presented antigens. Trained on experimentally validated immunogenic neoantigens, the AI algorithm achieves over 40% predictive accuracy across diverse solid tumor types. To enhance neoantigen delivery and maximize antitumor T-cell responses, we developed an APC-targeted lipid nanoparticle (LNP) system. This innovative mRNA delivery platform enables efficient, APC-specific targeting across multiple organs while minimizing off-target expression in non-immune cells, such as hepatocytes. Preclinical toxicology studies in multiple species have demonstrated favorable tolerability for both the ionizable lipid L52715 and the APC-targeted LNP formulation. Our lead neoantigen vaccine candidate, GT601, has successfully entered an investigator-initiated clinical trial in China, marking a major milestone in translating the *NEOVigator* platform into next-generation cancer immunotherapies.

#867 Multi-omic characterization of tumor microenvironment evolution in LBCL across treatment lines: Insights from Atlas classification and axicabtagene ciloleucel trials.

Michael D. Mattie[1], Regis Perbost[2], Aurelie Auguste[2], Alexia Papadopoulos[2], Jenny J. Kim[1], Ioana Kloos[1], Gayatri Tiwari[1], Justin Budka[1], Darawan Rinchai[1], **Simone Filosto**[1], Rhine Shen[1], Davide Bedognetti[1], Jerome Galon[3]

[1]Kite Pharma, Inc., Santa Monica, CA,[2]Veracyte, Inc., Marseille, France,[3]INSERM, Paris, France

Axicabtagene ciloleucel (axi-cel), an autologous anti-CD19 chimeric antigen receptor (CAR) T-cell therapy, was approved for patients with relapsed or refractory large B-cell lymphoma (LBCL) after two or more lines of systemic therapy (ZUMA-1, NCT02348216), as well as for those refractory to or relapsing within 12 months of first-line chemoimmunotherapy (ZUMA-7, NCT03391466). Recent molecular classifications of LBCL based on genetic factors shown to associate with response to R-CHOP and other chemo-immunotherapy based standard of care regimens have not been shown to associate with response to axi-cel in LBCL. Methods: To advance our understanding of the impact of tumor biology on response to axi-cel, we performed a detailed characterization of the tumor microenvironment (TME) using a multi-omic approach, integrating data from proteomics, transcriptomics and genomics offering a comprehensive view of biological systems, which we named Atlas. To construct the LBCL Atlas, we applied multiple technologies to 267 vendor-procured tumor samples from LBCL patients at diagnosis: (i) IHC panels, capturing spatial information at the protein and cellular level by counting and positioning cells of interest, (ii) Transcriptomics via RNA sequencing (RNA-seq) and Nanostring hybridization technology, (iii) Genomics, focusing on somatic mutation analysis through whole-exome sequencing (WES). Advanced mathematical and bioinformatics processing was employed to extract biological insights by combining both linear (multimodal factor analysis) and non-linear (self-organizing maps) methodologies. This effort resulted in a graphical representation of both complementary and overlapping signatures. Using samples with different prognostic outcomes and data from ZUMA-1 and ZUMA-7 axi-cel clinical trials, we further explored the evolution of the TME throughout disease progression and different lines of treatment. We focused on both adaptive immunity (lymphocytes, NK cells, etc.) and innate immunity (macrophages, MDSCs), examining the TME clusters defined by Atlas to characterize distinct tumor microenvironments. This Atlas provided an alternative to the cell-of-origin classification and other genetically based classifications of LBCL, based on TME. We will present evolutionary changes though lines of therapy to less favorable tumor microenvironments and, through the projection of clinical trial samples, demonstrate that the Atlas is a powerful tool for exploring mechanisms behind treatment response and disease progression. This includes the association of immune cell populations, such as T-cell and macrophage phenotypes and overall immune cell contexture within the TME, and other biomarkers with disease progression and treatment response.

#868 Platform for purifying serially cytotoxic T cells: advancing cell engineering and in vivo applications.

Eric Ferguson, John M. Beierle, **Behrad Azimi**

Narwhal Bio Inc., San Diego, CA

Current techniques for the enrichment of engineered T cells rely on surface markers that do not accurately capture a T cell's exhibited cytotoxicity, specificity for antigens, or its temporal state in the activation-exhaustion cycle. While microscopy-based methods have been developed to assay live T cells based on their interaction and cytotoxicity against antigen-presenting cells (APCs), no single technique can isolate serially cytotoxic T cells based on the frequency and the cytotoxic outcome of their interaction with specific APCs. The addition of an isolation step based on cell behavior is imperative for pooled screening for optimized engineering of T-cells as well as for the utilization of the enriched cells in vivo. Narwhal Bio Inc.'s A1 platform, an instrument, software, and reagent combination, seeks to overcome this challenge by in vitro cell identification, tagging, and downstream isolation of live cells based on behaviors assessed through microscopy. This live-cell-in, live-cell-out process could enable downstream applications like animal studies, further cell engineering, and multiomics drug and target discovery. We have applied this system to enrich CAR-T cells involved in repeated cytotoxic events. We assayed and tagged T cells based on their serial cytotoxicity in an APC co-culture in real time. We then isolated the tagged T cells, assessed their activation state using CD69 and CD25, and confirmed enrichment for the CAR representation in the more cytotoxic cell population. We assessed the potency of the enriched T cells after sorting, culture, and subsequent co-culture with APCs, showing >3x improvement in potency. Lastly, we illustrated how the process can be performed on the order of millions of cells in a day for various in vivo and in vitro downstream applications, including pooled screening of T-cell engineering and use in animal models.

#869 Distinct expansion, phenotype, function, and toxicity of cilta-cel vs. ide-cel CAR T cells in the real world.

Djordje Atanackovic[1], Tim Luetkens[2], Dina Schneider[3], Peirong Hu[3], Xu Wang[3], Amol C. Shetty[4], Luke Tallon[4], Imari Patel[1], Rohan Singh[1], Etse Gebru[1], Rediet Mulatu[1], Destiny Omili[1], Daniel Yamoah[1], Xiaoxuan Fan[1], Aerielle Matsangos[1], Patricia Lesho[1], Kenneth A. Dietze[2], Ariel A. Fromowitz[1], Kim Hankey[1], Saurabh Dahiya[5], Jean A. Yared[1], Nancy M. Hardy[1], Rima Koka[2], Michael E. Kallen[2], Ashraf Badros[1], Aaron P. Rapoport[1], Mehmet Kocoglu[1]

[1]University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD,[2]University of Maryland, Baltimore, MD,[3]Lentigen Technology Inc., Gaithersburg, MD,[4]University of Maryland Baltimore, Baltimore, MD,[5]Stanford University, Stanford, MD

Idecabtagene vicleucel (ide-cel) and ciltacabtagene autoleucel (cilta-cel) are approved chimeric antigen receptor T cell (CAR T) therapies for multiple myeloma. Unfortunately, most patients receiving these treatments will experience toxicities and/or relapse highlighting the need for optimizing CAR T strategies. We performed the first in-depth, comparative and prospective biomonitoring of patients (N=39) receiving cilta-cel or ide-cel in the real-world setting. Cilta-cel response rates were higher, although not statistically significant, and atypical neurotoxicities/infections were more frequent in the cilta-cel group. Peak circulating CAR T counts were significantly higher in cilta-cel patients, driven by a pronounced $CD4^+$ CAR T expansion, and correlated with depth of clinical response. The pronounced expansion of cilta-cel CAR T was associated with higher CAR expression and overexpression of CD27. The cilta-cel CAR T expansion was followed by a CAR-specific switch from proliferation-associated genes to genes/surface markers associated with effector/memory (EM) function. The comparably longer persistence of cilta-cell CAR T was associated with increased resistance to exhaustion and increased IL-7R expression; *in vitro* data showed persistent and antigen-independent activation and higher metabolic activity of cilta-cel vs. ide-cel CAR T. Among cilta-cel-treated patients experiencing atypical neurotoxicities, central nervous system (CNS)-infiltrating, effector-type cilta-cel CAR T presented a distinct inflammatory phenotypic/cytokine-expression profile. This first report of in-depth, comparative patient biomonitoring following real-world cilta-cel or ide-cel therapy highlights intrinsic biological differences between these BCMA-targeting CAR T products, potentially explaining differences in clinical activity and toxicity. Our findings may guide the optimization of cellular immunotherapy strategies in myeloma patients.

TUMOR BIOLOGY: Molecular Regulation of Metastasis

#87 Targeting POU5F1-expressing circulating tumor cells to prevent metastasis and recurrence in colorectal cancer.
S. Fujino, A. Ito, R. Hayashi, M. Yasui, M. Ohue, N. Miyoshi;
Osaka International Cancer Institute, Osaka, Japan

Background: Recurrence and metastasis following curative treatment remain significant challenges in colorectal cancer (CRC). Circulating tumor cells (CTCs) are pivotal in the dissemination of cancer, leading to distant metastases and eventual recurrence. Despite their importance, the cellular lineages driving these processes in CRC remain poorly defined. POU5F1, a transcription factor associated with stemness, is highly expressed in recurrent CRC tumors and is linked to poor prognosis and a high incidence of liver metastasis.
Methods: We developed a patient-derived cancer cell model, termed isolated tumor-derived cancer cells, cultured as two-dimensional organoids (2DOs). These 2DOs retain tumor heterogeneity and tumor microenvironment interactions, providing a robust platform for investigating treatment-resistant lineages. Using EGFP-reporter 2DOs, POU5F1-expressing cells were isolated and characterized through drug sensitivity assays, single-cell RNA sequencing, immunocytochemistry, and epigenetic analyses. Therapeutic studies were conducted to evaluate the efficacy of targeting key pathways.
Results: POU5F1-expressing cells were highly enriched in blood samples from relapsed CRC patients as CTCs. These cells exhibited cancer stem cell properties, including self-renewal and differentiation, and demonstrated a high capacity for liver metastasis in vivo. Single-cell RNA sequencing revealed that POU5F1-positive cells generate heterogeneous populations enriched in the Wnt signaling pathway. Immunocytochemistry confirmed the co-expression of POU5F1 and CTLA4, with epigenetic analysis showing demethylation at transcriptional start sites of both genes, implicating epigenetic regulation in their aggressiveness. The Wnt/β-catenin pathway inhibitor XAV939 effectively suppressed adhesion and survival of POU5F1-positive cells in vitro. Remarkably, early administration of XAV939 completely inhibited liver metastasis induced by these cells in vivo.
Conclusions: POU5F1-expressing cells are critical drivers of CRC metastasis and recurrence, exhibiting stem-like properties and treatment resistance. Their enrichment in Wnt signaling and CTLA4 expression identifies actionable therapeutic targets. Our findings highlight the potential of Wnt/β-catenin inhibitors like XAV939 to prevent CRC metastasis and recurrence, paving the way for improved therapeutic strategies in high-risk patients.

#870 Engineering of a novel Buddy-CAR system: CAR-NK cells expressing IL7/IL7Rα exhibit superior proliferation and anti-tumor responses while promoting trans-activation of the bystander T cells.

Andreia Maia, Mubin Tarannum, Sara Piccinelli, Mila Stanojevic, Maily Nhuyen, Grace Birch, Alaa Ali, Rizwan Romee

Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

Natural killer (NK) and chimeric antigen receptor (CAR) NK cells offer a promising platform for cellular immunotherapy. However, the immunosuppressive tumor microenvironment (TME), particularly in pancreatic cancer, negatively affects the efficacy of cell therapies. IL7 is an attractive cytokine to module TME as it promotes $CD4^+$ and $CD8^+$ T cell proliferation while maintaining them in a less differentiated state, improving metabolic profile, and preventing exhaustion. Mature NK cells are minimally responsive to IL7 as they lack the expression of IL7Rα. To overcome this, we engineered the Buddy-CAR system, consisting of CAR-NK cells expressing IL7Rα AND secreting IL7 to enhance the activation and proliferation of CAR-NK cells (cis-activation) and modulate the TME by activating the bystander tumor-infiltrating T cells. We designed three CAR constructs: (1) Mesothelin (MSLN)-CAR (M), (2) MSLN-CAR secreting IL7 (M7) and (3) MSLN-CAR expressing IL7Rα AND secreting IL7 (M7R). Peripheral blood-derived NK cells were transduced using Baboon lentivirus achieving a high transduction efficiency and IL7 secretion was assessed by ELISA. M7R cells exhibited a superior proliferation index of 1.9 versus 1.1 for M (p=0.03) on day 9 using CTV flow cytometry assay. M7R showed increased cytotoxicity against $MSLN^+$ ASPC1 cells, 61.4% vs 52.3% for M7 (p=0.712) and 49.8% for M7R (p=0.002) at a 2:1 ratio. In addition, M7R showed a 3.9-fold increased IFN-γ production versus M7 (0.9, p=0.0002) and M (1, p=0.0005). The incorporation of IL7Rα and IL7 also led to increased expression of NKp30, NKp46, pSTAT1 and pSTAT5. We then evaluated the Buddy-CAR system's ability to stimulate bystander T cells by co-culturing IL7-releasing CAR-NK cells (M7 and M7R) with donor-matched MSLN-CAR T cells for 9 days in a 1:1 ratio. In a CTV flow cytometry assay, CAR-T cells showed a higher percentage of cells in >G3 when co-cultured with M7 (26.3%, p=0.048) and M7R (27.6%, p=0.035), versus M (2.72%). Lastly, we assessed the impact of IL7 signaling in CAR NK cells *in vivo* by injecting $6x10^6$ of M7 and M7R cells into NGS-Tg (Hu-L15) mice intravenously. Mice injected with M7R showed a significantly higher percentage of human $CD45^+$ infiltrating cells in the bone marrow (47.6%, p=0.02), liver (66.7%, p<0.0001), and spleen (69.8%, p=0.03), two weeks post-injection compared to M7-NK cells (<3%), indicating superior trafficking and proliferation *in vivo*. Ongoing studies are evaluating tumor control and effects on T cell proliferation and trafficking of the Buddy-CAR system in a xenograft mouse model. The versatility of the Buddy-CAR system allows for targeting different antigens by modifying CAR specificity while also modulating the immunosuppressive TME, offering a powerful approach to significantly improve the efficacy of CAR-based therapies across diverse cancer types.

#871 Quality control aspects of cell therapy products.

Bettina A. Y. Meissburger, Julian S. Thimm, Stefan B. Eichmueller

D210 GMP & T cell therapy, German Cancer Research Center, Heidelberg, Germany

Quality control of cell therapy products is critical to ensure safety and efficacy of these advanced therapeutics. Cell therapy products are characterized by their complexity and variability due to the use of patient-individual living cells as the primary therapeutic agent. Consequently, QC processes must address several unique challenges and parameters. The QC process typically involves a combination of in-process controls and final product testing. In-process controls are essential to monitor critical manufacturing steps and ensure that the process remains within predefined parameters. Final product testing is conducted to confirm that the cell therapy product meets all established quality specifications before release. Key QC criteria for a T cell product include cell number and viability, identity, potency, as well as endotoxin, mycoplasma and microbiological testing. Analytical QC methods need to be extensively validated before routine use. The application of pre-validated QC kits simplifies the validation process while at the same time ensuring fast in-house QC testing. For endotoxin testing we have established a cartridge based testing methodology, which has been validated with the final cell product enabling rapid pre-release testing. Mycoplasm testing can be performed using a Ph.Eur. compliant TaqMan-based real-time qPCR method, which ensures fast and sensitive mycoplasm detection including a DNA extraction step from the cellular product. Pre-tested freeze-dryed antibody cocktails combined with automatic gating strategies ensure robust identity testing by flow cytometry analysis. Additionally, cell counting and viability testing can be integrated into this analysis, thus omitting additional counting methods. Due to the short product shelf-life of living cells, microbiological testing poses a challenge with classical culture methods. Post-release final results might be acceptable taking into account the advantage of direct application of living cells without additional freezing steps. Novel rapid testing methods will be a promising alternative in the future. Potency of the cell product is another challenge, which is often assessed by surrogate markers such as cytokines. In case of known target antigens, killing assays or ELISpot assays are possible. Additionally, multimer staining can test for MHC-antigen recognition of the cell product. In summary, robust QC systems are indispensable for the development and clinical application of cell therapy products, safeguarding patient health and advancing the field of regenerative medicine.

#872 High quality on-demand gene edited human primary T cells.

John Latimer, Daniel Orozco, Paolo Piazza, Alex Brown

EditCo Bio, Inc., Redwood City, CA

EditCo unveils a breakthrough in T cell engineering aimed at benefiting cancer research: a rapid platform delivering premium-quality edited human CD4+ and CD8+ T cells with unprecedented efficiency. The platform achieves knock-out efficiency greater than 80% in less than 2 weeks, with edited cell pools maintaining viability above 70% before cryopreservation. These cells can be thawed and expanded at least 30-fold over 14 days independent of TCR stimulation, with no loss in editing efficiency. The platform's versatility has been demonstrated across multiple unique gene targets critical to cancer research and diverse donor populations, ensuring broad applicability. Notably, edited CD4+ T cells retain robust functionality after cryo-recovery, producing IL2, IFNγ, and TNFα upon stimulation. Similarly, edited CD8+ T cells maintain their endogenous antigen-specific cytotoxic activity, successfully express lentiviral CAR-T constructs, and demonstrate bi-specific engager-mediated cell killing. This comprehensive validation establishes EditCo's platform as a versatile, high-performance solution for T cell editing, maintaining cellular integrity and functionality while delivering consistent results across multiple genetic targets and donor populations.

#873 2-deoxy-D-glucose sensitizes the antigen recognition of chimeric antigen receptor-expressing tumor-infiltrating lymphocytes toward hepatocellular carcinoma cells.

Mingyu Liu, Deping Han, Jean-Paul Thiery, **Xi Zhang**

Biosyngen Pte Ltd, Singapore, Singapore

Background: Tumor-infiltrating lymphocytes (TILs) are heterogeneous populations of lymphocytes residing in tumor tissues, comprising various T-cell clones with specificity towards tumor or viral antigens. TIL therapy has been recently approved for advanced melanoma treatment with high-dose interleukin-2 (IL-2) as a concomitant treatment. However, the accessibility of tumor tissues, the varied abundance and effectiveness of tumor-reactive T-cells, and the toxicity of IL-2 infusion limit the clinical application of TILs toward a broader range of tumor indications. To address the high individual variance, we have engineered TILs expressing chimeric antigen receptor (CAR) constructs targeting glycoproteins on the hepatocellular carcinoma (HCC) cell surface. However, heavy glycosylation of these glycoproteins may mask peptidic epitopes to single-chain antibodies. Previous studies have revealed that the glucose/mannose analog, 2-deoxy-D-glucose (2-DG) treatment of pancreatic cancer cells can disrupt the synthesis of N-glycan moieties on the cell surface and enhance CAR T-cell activity. 2-DG treatment of T cells augmented antitumor activity and cell surface retention of IL-2R of T cells. In this study, we investigated whether the anti-tumor function of CAR-TILs against HCC lines would also benefit from the 2-DG treatment.
Methods: TILs were isolated from fresh or cryopreserved tumor biopsy samples and stimulated with anti-CD3/CD28 antibodies. Thereafter, TILs were lentiviral transduced with Glypican 3 (GPC3) CAR and membrane bound-interleukins, expanded with γ-irradiated feeder cells in an optimized rapid expansion process (REP), and cryopreserved until use. Phenotypic analyses were performed by flow cytometry. HCC lines were pre-treated with or without 2-DG, and the antigen recognition by antibodies targeting GPC3, CD133, and CD44v6 was evaluated by flow cytometry. *In vitro* effector function was assessed by IFN-γ release (ELISA) and killing assay (Incucyte). The anti-tumor efficacy of CAR-TILs with or without 2-DG treatment was further assessed in the immunocompromised xenograft model.
Results: Pre-treatment of HCC cell lines with 2-DG (1~10 mM) enhanced the antibody recognition of GPC3 in a dose-dependent fashion while showing no improvement in mAb binding towards CD133/CD44v6. CAR-TILs showed enhanced killing and more IFNγ release towards 2-DG pre-treated $GPC3^+$ HCC lines. The synergistic effect of 2-DG with CAR-TILs was further validated in the immunocompromised murine model, and no apparent toxicity was observed. The proliferation and the CD4/CD8 ratio of CAR-TILs were not affected by 2-DG treatment.
Conclusion: 2-DG sensitized GPC3 antigen recognition, thus boosting CAR-TIL cytotoxic activity against $GPC3^+$ HCC cells. These data prompt further investigation before pursuing a combination therapy.

#877 Targeting pancreas cancer liver metastases with B7-H3 tri-specific killer engager and regional delivery of placental-derived NK cellular therapy.

M. Purl[1], T. Mukarrama[1], J. Kim[1], S. M. Cruz[1], J. S. Miller[2], M. Felices[2], W. J. Murphy[3], R. J. Canter[1], S. J. Judge[1];
[1]UC Davis Comprehensive Cancer Center, Sacramento, CA, [2]University of Minnesota Masonic Cancer Center, Minneapolis, MN, [3]UC Davis School of Medicine, Sacramento, CA

Introduction: Pancreatic cancer (PDAC) is a dismal disease characterized by early metastases to the liver and poor overall survival. The success of natural killer (NK) cell therapies for solid tumors has been limited in part due to inadequate cytotoxicity and homing to sites of disease. We set out to evaluate the function of placental-derived NK cells in combination with a tri-specific killer engager (TriKE) targeting B7-H3 with ability to engage CD16 and express IL-15, critical components for NK cytotoxicity against B7-H3-expressing PDAC cells. We also investigated the effect of regional delivery as a method to enhance liver engraftment with the goal of combining regionally delivered placenta NK cells with B7-H3 TriKE platform to treat pancreatic cancer liver metastases.
Materials and Methods: B7-H3 IHC staining was performed on 84 patient samples from resected PDAC to quantify expression on primary tumors. Human NK cells were isolated from human placenta and expanded ex vivo using the established K562.cl9mIL21 feeder line and IL-2. Phenotype was evaluated by flow cytometry and functional assessment by PANC-1 killing with or without B7-H3 TriKE. Nanoparticle labelled and unlabeled ex vivo activated NK cells were adoptively transferred into immunodeficient mice via either tail vein (IV) or portal vein (PV) injection and liver and spleen engraftment was assessed by ultrasound-guided photo-acoustic imaging and flow cytometry.
Results: B7-H3 (>1% expression) was detected on 76/84 (90%) primary resected PDAC samples and median H-score was 12 (range 0-132). In vitro, PANC-1 cells showed 99% expression of B7-H3. Ex vivo expanded placenta NK cells were >90% CD16 positive and showed cytotoxicity against PANC-1 cells after 4 and 8 hours at 10:1 effector-to-target ratio. Addition of B7-H3 TriKE enhanced cytotoxicity in placenta NK cells, at both time points (4 hr: 51.2% ±2.0 vs 27.7% ± 3.0, $P < 0.01$; 8 hr: 76.7% ± 2.6 vs 56.6% ± 2.1, $P < 0.01$). 24 hours after administration, in vivo imaging analysis showed a 2.7-fold higher signal from PV compared to IV in the liver. This was confirmed by flow cytometry with administration by PV having showed significantly higher liver engraftment compared to IV (human CD45 positivity 23.6% ± 7.6 vs 8.8% ± 4.5, $P = 0.03$), while spleen engraftment was minimal and not significantly different between PV and IV administration (0.7% ± 0.4 vs 0.3% ± 0.2).
Conclusion: B7-H3 is expressed on both primary human PDAC and the PANC-1 cell line representing a logical target for novel therapeutic strategies. Ex vivo expanded placenta NK cells demonstrate cytotoxicity against PDAC which is further enhanced through the B7-H3 TriKE. Regional delivery by portal venous administration results in increased liver engraftment and represents a viable and rational strategy for targeting PDAC liver metastases.

#878 Anti-MICA/B antibody promote anti-tumor activity of cytokine expanded tumor infiltrated natural killer (TINK) cells from canine sort tissue sarcomas.

Weiqing Jing[1], Himaly Shinglot[1], Juliana Ng[1], Milan Medd[1], Ali Zhang[1], abhilasha srivastava[1], Shay Bracha[2], Laura Selmic[2], Chelsea Tripp[3], Farres Obeidin[1], Jennifer Wu[4], Seth Pollack[1]

[1]Northwestern University, Chicago, IL,[2]Ohia State University, Columbus, OH,[3]Bridge Animal Referral Center,, Edmonds, WA,[4]Urology, Northwestern University, Chicago, IL

Background: Presence of tumor infiltrating NK (TINK) cells linked to prognosis in many solid tumors, but their function is often constrained by the adverse tumor microenvironment. Although promising antileukemia activity has been shown, the exploitation of adoptive NK cell therapy for solid tumor is still limited and unsatisfactory. Tumor MIC (MHC I chain related molecule) modulates TME and contributes NK cell dysfunction, here we study the role of anti-MICA/B antibody in TINK's function against sarcoma tumors. Because NK cells are prevalent in human Undifferentiated Pleomorphic Sarcomas (UPS), we sought the analogous canine soft tissue sarcomas (STS) as a readily available source to culture and perform intensive study on TINKs.
Methods: Canine TINK cells were expanded form canine sarcoma tumor specimens with IL-2. Human NK cells were expanded from PBMC of healthy donor with K652 feeder cells. In vitro cytotoxic assay against sarcoma was monitored by Incucyte system. Canine or human sarcoma xenograft mouse models were used to evaluate therapy effect of adoptive transferred NK cells, with or without anti-MIC Ab combinatory therapy.
Results: The percentage of CD5-NKp46+ and CD5dimCD8+NKp46+ NK cell within tumor infiltrating CD45 cells in canine STS is significantly higher compared with osteosarcoma and other types of tumors. Even with small STS tumor fragments for TIL expansion, more than 90% of the fragments were expanded sufficiently for analyses. Expanded lymphocytes were mostly NK cells (TINKs) which was confirmed with flow cytometry (NKp46+ CD5(dim) TCRαβ− TCRγδ− CD4− B220−CD1d−) and RNA sequencing. TINKs effectively kill autologous tumor cells and the NK-sensitive canine tumor cell line CTAC and result in a significantly increased expression of Granzyme B and Th1 cytokines (IFN-γ, TNF-α and GM-CSF) upon co-culturing with tumor cells. Although adoptively transferred TINK cells showed a significant inhibition in xenograft CTAC tumor growth, combinatory therapy with huB10G5 further significantly inhibited tumor growth. The anti-MIC antibody huB10G5 showed specific binding to canine sarcoma tumor cell lines, fresh processed tumor cells and tumor tissues. Similar to canine STS, NK infiltration in human UPS is significantly higher than in other types of sarcoma tumors. IHC demonstrated that MIC is broadly expressed in human UPS. Similarly, huB10G5 significantly enhanced the in vivo therapeutic effect of PBMC-expanded human NK cells against human sarcoma xenografts.
Conclusions: Our results demonstrated that functional TINKs can be efficiently expanded from canine sarcoma tumor tissue and demonstrated therapeutic potential in vivo allowing us to better model human disease. Anti-MIC treatment enhanced the efficacy of NK therapy in both canine and human sarcoma xenografts mouse models.

#879 Chemokine engineering significantly enhanced migration and tumor infiltration of *ex vivo*-expanded natural killer cells in osteosarcoma.

Shiori Eguchi[1], Wen Luo[1], Hai M. Hoang[1], Hongwen Zhu[1], Mitchell S. Cairo[2]

[1]Department of Pediatrics, New York Medical College, Valhalla, NY,[2]Department of Pediatrics, Medicine, Pathology, Microbiology and Immunology, Cell Biology and Anatomy, New York Medical College, Valhalla, NY

Metastatic and relapsed osteosarcoma (OS) has poor prognosis despite multiagent chemoradiotherapy. Novel therapies are urgently needed. Natural killer (NK) cells are highly cytotoxic to OS cells. Increased abundance of tumor infiltrating activated NK cells has been correlated with extended overall survival in OS. However, the OS tumor microenvironment (TME) impairs NK cell TME infiltration. We and others found that CXCR3, a receptor for CXCL9, -10, and -11, is highly expressed on *ex vivo*-expanded NK cells. We hypothesize that inducing OS cells to secrete CXCL9, -10, or -11 will enhance NK infiltration into the OS TME and improve outcomes. We expanded NK cells from PBMCs using K562-mbIL21-41BBL feeder cells in the presence of IL-2 (50 IU/mL) and confirmed high CXCR3 expression (98%) on expanded NK cells by flow cytometry. CXCL9, -10, or -11 cDNA was cloned into pMSCVneo to produce lentiviruses for infecting OS 143B cells. ELISA assay showed significantly increased secretion of CXCL9, -10, and -11 from CXCL9, -10, and -11 virus-infected 143B cells compared with wild-type (WT) cells (135.0 ± 51.3 vs. 1.7 ± 1.7 pg/mL, $p < 0.05$; 1165.4 ± 102.4 vs. 0.4 ± 0.4 pg/mL, $p < 0.01$; and 86.1 ± 10.5 vs. 0.0 ± 0.0 pg/mL, $p < 0.01$, respectively). Importantly, we observed significantly enhanced migration of expanded NK cells toward CXCL9, -10, or -11 conditioned media (CM) relative to WT CM (1.6 ± 0.1-fold, $p < 0.001$; 1.7 ± 0.1-fold, $p < 0.05$; and 1.5 ± 0.0-fold, $p < 0.001$, respectively) in transwell assays. Luciferase-based *in vitro* cytotoxicity assay showed that chemokine (CXCL9, -10, or -11)-secreting 143B cells were similarly if not more sensitive than WT cells to NK cells. To compare the migration of expanded NK cells towards WT and chemokine-secreting OS, we inoculated WT and chemokine-secreting 143B cells subcutaneously into separate flanks of the same NSG mice and administered luciferase-expressing human NK cells intraperitoneally after tumor establishment. IVIS imaging of the mice showed significantly enhanced NK migration toward CXCL9, -10, or -11-secreting tumors compared with WT tumors (2.0 ± 0.3-fold, $p < 0.05$; 2.0 ± 0.2-fold, $p < 0.05$; and 2.1 ± 0.1-fold, $p < 0.01$, respectively). To evaluate NK cell tumor infiltration, we injected human NK cells with an IL-15 agonist, NKTR-255, and harvested and dissociated tumors 5-7 days after NK injection for flow cytometry analysis. Intriguingly, we found significantly increased number of human $CD45^+$ cells in CXCL9, -10, or -11-secreting tumors compared with WT tumors (2.4 ± 0.2-fold, $p < 0.05$; 11.3 ± 2.8-fold, $p < 0.05$; and 4.7 ± 1.2-fold, $p < 0.05$, respectively). Our *in vitro* and *in vivo* data demonstrated that secretion of CXCL9, -10, and -11 from OS significantly enhanced NK migration and NK infiltration into the OS TME. We are actively investigating the *in vivo* anti-tumor efficacy of expanded NK cells against CXCL9, -10, or -11-secreting disseminated OS tumors.

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#88 Ephrin receptor A4 is a regulator of metastatic colonization in triple negative breast cancer.

Wenchao Liu, Hoi Wan Lee, Madeline H. Bungert, Geetha P. Yerradoddi, Marsha R. Rosner

University of Chicago, Chicago, IL

Triple negative breast cancer (TNBC) is the most aggressive breast cancer subtype, affecting more than 40,000 people in the US. Most TNBC patient deaths are due to distal metastasis, a stage for which effective treatment is not yet available. Metastasis is an inefficient, multi-step process. The bottleneck for establishing the life-threatening macro-metastasis is considered to be metastatic colonization, the step at which cancer cells exit the circulation, survive in the new microenvironment and re-initiate aggressive growth. Numerous studies have found that cancer cell adhesion and migration pathways are required for metastatic colonization. However, the mechanisms by which these pathways are modulated are incompletely understood. Ephrin and Ephrin receptors are a family of proteins with conserved functions related to modulation of cell repulsion and adhesion, particularly in the regulation of pattern formation during development. Here we show that Ephrin Receptor A4, a cell surface receptor tyrosine kinase, regulates cell-cell interactions, migration and metastatic formation in TNBC, similar to its role in development. Depletion of EPHA4 in either human xenograft MDA-MB-231 or mouse syngeneic 4T1 TNBC tumors does not significantly alter tumor growth, but results in differential expression of genes involved in cell-cell adhesion, cell-matrix adhesion, and cell migration. *In vitro* assays suggest that EphA4 loss promotes collective rather than single cell migration, which can lead to increased metastatic formation. Metastatic lung colonization assays in mice indicate that loss of EphA4 increases metastatic lesions and/or metastatic burden in the MDA-MB-231 and 4T1 tumor models. Consistent with these findings, Ephrin Receptor A4 expression in TNBC is downregulated at metastatic sites relevant to the primary tumor. These results suggest that EphA4 regulates cell adhesion in cancer cells to reduce the efficacy of metastatic colonization.

IMMUNOLOGY: NK Cells and Innate Immunity

#880 Accumulation of cytosolic single-stranded DNA triggers innate immune responses via a novel sting-independent mechanism.

Jing Zhang

Hangzhou Institute of Medicine, Chinese Academy of Sciences, Hang Zhou, China

Immune checkpoint blockade (ICB) has shown durable responses in a subset of patients with hypermutated cancers. Although some non-hypermutated cancer patients have also demonstrated clinical responses to ICB, the majority do not respond, prompting research into novel combination immunotherapies. Ongoing clinical trials have explored such combinations, but challenges like hematological toxicities and resistance have limited their effectiveness. Therefore, there is an urgent need for more effective therapies. Recent studies suggest that mislocalized cytoplasmic DNA may serve as a potent mediator of innate immune responses, potentially enhancing ICB efficacy. However, the mechanisms by which intracellular single-stranded DNA (ssDNA) activates the innate immune system remain poorly understood. In this study, we report that accumulation of cytosolic ssDNA in cancer cells by silencing TREX1 improves ICB response and promotes the infiltration of immune cells via DDX3X. Additionally, we further developed mRNA-based therapeutic agents HIM-mRNA-001 to enhance tumor sensitivity to ICB with minimal toxicities. These findings suggest that targeting cytosolic ssDNA accumulation could provide a new therapeutic strategy for non-hypermutated cancers, offering a promising alternative to current immunotherapies.

#881 Innate immune cell-mediated anti-tumor activity against lung cancer and pleural mesothelioma cells.

H. Tomono[1], K. Akagi[1], Y. Umeyama[2], M. Matsuo[1], H. Taniguchi[1], H. Gyotoku[1], S. Takemoto[1], Y. Tanaka[1], H. Mukae[1];
[1]Nagasaki University, Nagasaki, Japan, [2]Sasebo City General Hospital, Nagasaki, Japan

[Objectives] Immune checkpoint inhibitors have played a pivotal role in cancer treatment, and various combination therapies are being developed. However, their add-on effects remain limited, highlighting the urgent need for novel therapeutic modalities. Among various approaches, the adoptive transfer of immune effector cells has attracted particular attention, especially the use of allogeneic immune effector cells due to the frequently immunosuppressed status of cancer patients. We have previously focused on Vδ2 γδ T cells and NK cells, developing methods for their large-scale expansion. These innate immune effector cells are highly suitable for allogeneic adoptive transfer, as they exhibit tumor cytotoxicity independently of the major histocompatibility complex. In this study, we evaluated the cytotoxic properties of these innate immune effector cells, including innate cytotoxicity, antigen-specific cytotoxicity, antibody-dependent cellular cytotoxicity (ADCC), and cytokine production.
[Materials and Methods] After obtaining informed consent, peripheral blood mononuclear cells (PBMCs) were collected from healthy adults, lung cancer patients, and pleural mesothelioma patients to prepare PBMCs. The PBMCs were stimulated with tetrakis-pivaloyloxymethyl 2-(thiazole-2-ylamino) ethylidene-1,1-bisphosphonate (PTA), a bisphosphonate prodrug, along with IL-2 to enable the expansion of Vδ2 γδ T cells. The expanded Vδ2 γδ T cells were then co-cultured with human lung cancer cell lines to evaluate their effector functions in vitro. Additionally, CD3-negative PBMCs were cultured with IL-2 and IL-18 to expand NK cells, which were subsequently co-cultured with human pleural mesothelioma cells to assess the effector functions of NK cells in vitro. PTA was used as the antigen, and anti-EGFR antibody was used for ADCC assays.
[Results] Vδ2 γδ T cells exhibited PTA-dependent cytotoxicity against lung cancer cells. Moreover, Vδ2 γδ T cells with high CD16 expression demonstrated ADCC and IFN-γ production against lung cancer cells. NK cells displayed innate cytotoxicity against pleural mesothelioma cells, and this cytotoxic activity increased in an antibody-dependent manner.
[Conclusion] The use of PTA/IL-2 enabled the high-purity expansion of Vδ2 γδ T cells, which exhibited robust immune effector functions against lung cancer cells via T cell receptor and CD16-dependent mechanisms. Similarly, IL-2/IL-18 facilitated the high-purity expansion of NK cells, which demonstrated strong innate cytotoxicity and ADCC against pleural mesothelioma cells. Moving forward, in vivo studies are planned to advance the potential for infusion therapy with Vδ2 γδ T cells and NK cells.

#882 Soluble TNF blockade enhances trastuzumab-deruxtecan innate antitumor immune response and type-I IFN signalling in HER2-positive breast cancer.

Sofia Bruni[1], Camila Jencquel[2], Martin A. Rivas[1], Roxana Schillaci[2], Maria F. Mercogliano[2]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Instituto de Biologia y Medicina Experimental, Buenos Aires, Argentina

Since DESTINY-Breast03 results where trastuzumab-deruxtecan (T-DXd) showed remarkable overall survival improvement, this drug is used to treat patients with unresectable or metastatic HER2-positive (HER2+) breast cancer who have received prior anti-HER2-based regimen. One antitumor mechanism of T-DXd is attributed to DXd inhibition of topoisomerase I in the tumor cells that internalized the drug, and to the bystander effect of DXd on neighbor tumor cells**.** Reports describe that topoisomerase I inhibitors produce DNA fragmentation, stimulating cGAS/STING pathway and producing type-I IFN, a key mediator of the innate immune response against tumors. Previously, we reported that soluble TNF (sTNF) overproduction by HER2+ tumors generates resistance to trastuzumab-based therapies. Blocking sTNF with INB03 (DN), a dominant-negative molecule, sensitized tumors to therapy and improved the antitumoral immune response. Here, we explore if blocking sTNF can also improve T-DXd antitumor effect, and its impact on the innate immune response involving cGAS/type-I IFN, in a model with resistance to multiple HER2-targeted therapies.Female nude mice bearing JIMT-1 tumors were treated i.p. twice/week with 5 mg/kg of IgG or 10 mg/kg DN, or with 5, 2.5 or 1.25 mg/kg of T-DXd i.v. on days 0, 7 and 14, or the combination therapies. Tumor volume was measured twice/week for 21 days (n=6-8). Tumor-infiltrating macrophages and NK cells were studied by flow cytometry. ISG15, a downstream mediator of type-I IFN pathway, and cGAS were evaluated by western blot on tumor extracts.The dose-response curves showed a tumor growth inhibition of 83% (T-DXd 5 mg/kg), 61% (T-DXd 2.5 mg/kg) and 37% (T-DXd 1.25 mg/kg) vs. IgG ($p<0.0001$, 0.0001 and 0.05, respectively). Adding DN enhanced this inhibition to 98% (5 mg/kg), 81% (2.5 mg/kg) and 73% (1.25 mg/kg), $p<0.0001$ vs. IgG. T-DXd 1.25 mg/kg +DN achieved an antitumor effect that resembles T-DXd 5 mg/kg alone. Furthermore, addition of DN to T-DXd 1.25 and 5 mg/kg increased macrophage infiltration and polarization to the antitumoral M1-like phenotype. T-DXd 1.25 mg/kg +DN treatment mimics the increase of infiltrating NK cells observed in the higher doses of T-DXd alone. Finally, we observed an increase in cGAS and ISG15 expression in tumor extracts form T-DXd 1.25 mg/kg +DN, compared to T-DXd 1.25 mg/kg alone.Our results suggest that sTNF blockade with DN enhances T-DXd antitumor effect, inducing a reinforced innate immune response with increased infiltration of M1-like macrophages and NK cells, and activation of cGAS and type-I IFN pathway, measured by its surrogate ISG15. Adding DN allows to de-escalate T-DXd dose without impairing the antitumor effect. Neutralizing sTNF could improve the outcome of patients treated with T-DXd by enhancing the antitumor immune response.

#883 Scalable differentiation of cytotoxic natural killer (NK) cells from human pluripotent stem cells.

Marcus Bunn[1], Lindsay Bailey Steinitz[2], Vivek Chandra[2], Michael Akenhead[1], Logan Wilson[1], Erica Heipertz[1], Chris Yankaskas[1], **Colin Paul**[1], Matt Dallas[1], Mark Kennedy[1], David Kuninger[1]

[1]Thermo Fisher Scientific, Frederick, MD,[2]Thermo Fisher Scientific, Carlsbad, CA

Cell therapy is expanding as a treatment for various cancers. FDA-approved autologous therapies, such as chimeric antigen receptor (CAR) T cells and tumor infiltrating lymphocytes (TILs), are used for aggressive or late-stage cancers. However, these therapies face challenges due to lengthy manufacturing times and patient variability. Manufacturing is already a bottleneck, which is expected to worsen as these therapies are tested in earlier cancer stages and become available to more patients. An emerging solution for cancer treatment is the use of natural killer (NK) cells as an "off-the-shelf" therapy. These cells target malignant cells independent of antigens, without needing HLA matching, and have not caused cytokine release syndrome like some T cell therapies. Clinical trials typically administer 5x10^6 to 1x10^8 NK cells per kilogram of body weight per dose. Therefore, developing methods to produce large quantities of functional NK cells is crucial. Current methods, such as sourcing primary cells or differentiating from human pluripotent stem cells (PSCs) in two dimensions (2D), yield variable results, often require co-culture or embryoid body formation, and usually fail to produce enough functional NK cells for therapy. To address these limitations, we developed a scalable 3D PSC culture differentiation protocol to hematopoietic stem cells (iHSCs), a multipotent progenitor cell population, and then to induced natural killer (iNK) cells that primarily uses GMP grade reagents with regulatory documentation. Differentiation occurs in suspension using shake flasks. After 38 days, over 50% of cells are CD56+ CD3-, and can be cryopreserved, thawed, and further expanded. This method, tested in up to 100 mL cultures, produces 5-10x10^6 CD56$^+$CD3$^-$ iNK cells/mL, sufficient to treat one patient at the lower dosing range. Multiple 100 mL cultures can be cultivated in parallel to increase the yield, and future efforts will focus on optimizing the protocol in larger culture volumes. To evaluate iNK cell cytotoxicity, they were co-cultured with three-dimensional (3D) patient-derived cancer organoids, a physiologically relevant in vitro cancer culture that better mimics tumor tissue than traditional 2D cancer cell lines and are harder to kill. iNK cells induced apoptosis in breast, colorectal, and endometrial cancer organoids in a dose-dependent manner. Against the same target colorectal cancer organoids, iNKs were more cytotoxic than the NK-92 cell line at equal doses, and matched primary NK cells at roughly double the dose. In summary, we demonstrate a novel scalable protocol for generating functional iNK cells, showing potency in a cytotoxicity assay with patient-derived cancer organoids, which could be further developed for cell therapy research.

#884 Development of allogeneic persistence-enhanced PB-derived NK cells in treating solid tumors.

C. Wang[1], T. Liu[1], Q. Wang[1], Y. Gong[1], F. Gao[1], F. Zhou[2], **Z. Cao**[1];
[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China, [2]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Although chimeric Antigen Receptor (CAR)-T cell therapy has emerged as a promising immunotherapeutic approach to fight cancers, the utilization is limited due to safety concerns such as serious cytokine release syndrome, neurotoxicity, or graft-vs-host-disease. Natural killer (NK) cells can be derived from multiple sources and scaled manufactured as an off-the-shelf product likely with fewer toxicities. While NK cell therapies have been demonstrated to elicit clinical efficacy against hematopoietic malignancies, many challenges exist including issues related to cell persistence, overcoming the immunosuppressive microenvironment, and optimizing specific cytotoxic efficiency. To address those challenges, we used a single retroviral vector to engineer peripheral blood (PB) derived NK to express: soluble IL15 armor for proliferation and activation, a non-cleavable CD16 with high affinity to Fc receptor to enhance ADCC response, alloimmune defense receptor (ADR) targeting alloreactive T cells to overcome host immune cell-mediated rejection. Our preclinical results demonstrated the multiplexed engineered PBNK (eNK) showed improved persistence, resistance to allorejection, as well as anti-tumor efficacy. To evaluate ADRs functions, both anti-rejection CD5 and CD70 ADRs expressing eNK were generated and characterized. eNK with CD5 ADR displayed comparable phenotype and expansion to non-transduced NK, whereas eNK with CD70 ADR showed significantly aberrant growth due to CD70-mediated fratricide. eNKs with CD5 ADR demonstrated better persistence and enhanced tumor cells killing when cocultured with tumor cells and allogeneic T cells in a mixed lymphocyte reaction, compared to eNK cells without CD5 ADR or eNK with CD70 ADR. To determine whether non-cleavable CD16 and IL15 engineering could improve eNK proliferation and ADCC, serial re-stimulation *in vitro* cytotoxicity assays (luciferase-/RTCA-based) were performed in the presence and in the absence of Cetuximab, at a 1:2 E:T ratio. eNK plus Cetuximab showed more potent cytotoxicity against HCT116 colon cancer cells and NCI-H1975 lung cancer cells compared to non-transduced NK combo, eNK only and EGFR targeted CAR-NK cells. Using different xenograft mouse models, we demonstrated eNKs combined with therapeutic antibodies could performed superior tumor inhibition and extended NK persistence. Taken together, these results supported the development of allogeneic PB-derived NK cell therapies armoring with soluble IL15, non-cleavable CD16 and anti-allorejection ADR, and demonstrated the efficacy and safety of eNK mono and combination treatments, significantly enhancing their therapeutic potential in clinical settings.

#885 Generation and characterization of NK-92®(aNK™) cells with hypoimmunogenic modifications.

Ivan Ting Hin Fung, Laurent Boissel, Patrick Soon-Shiong, Hans Klingemann

ImmunityBio, Inc., Culver City, CA

The next generation of NK-92® (also known as aNK™) cells will include inducible kill switches and enhanced cytotoxicity to make them safer and more effective, without the need to irradiate them before infusion into patients. Because of their enhanced longevity *in vivo* and their allogeneic nature, NK-92 cells are susceptible to rejection by the patient's own immune system and need to be equipped with mechanisms to prevent such rejection. We have genetically engineered NK-92 cells by targeting a combination of molecules that allow them to be undetected by the patient's T-cells as well as resistant to lysis by peripheral blood NK cells (PBNKs). HLA-I-deficient NK-92 cells generated by electroporation of Cas9-sgRNA ribonucleoprotein complexes to knockout the common β_2 microglobulin subunit (NK-92_B2M^{KO}) completely inhibited CD8$^+$ T-cell proliferation after 7 days in a mixed lymphocyte reaction with peripheral blood mononuclear cells (PBMCs) isolated from multiple healthy donors. Because downregulation of HLA-I on the cell surface can increase lysis by PBNKs via the 'missing-self' mechanism, we further engineered NK-92_B2M^{KO} cells to re-express the non-classical MHC class I molecule HLA-E (NK-92_B2M^{KO}_HLAE) to deliver an inhibitory signal through engagement with the NKG2A/CD94 heterodimer. Using flow cytometry-based cytotoxicity assays, we confirmed that the lack of HLA-I molecules rendered NK-92_B2M^{KO} cells highly susceptible to lysis by both resting and IL-2-activated PBNKs from healthy donors, relative to wild type NK-92. We also demonstrate that re-expression of HLA-E on NK-92_B2M^{KO} cells provides significant protection against both resting and IL-2 activated PBNKs (42.5% ± 9.0% reduction in killing at 5:1 E:T ratio, p=0.0002). HLA-E can also convey a lysis-activating signal through the NKG2C/CD94 dimer. NKG2C$^+$ NK cells are naturally present at low numbers in blood and can be expanded in individuals who are seropositive for human cytomegalovirus. To determine whether NK-92_B2M^{KO}_HLAE cells are sensitive to killing by NKG2C$^+$ NK cells, we performed co-culture assays using PBNKs and our engineered NK-92 cells and examined CD107a degranulation in different NK subsets. We observed that HLA-E expression completely inhibits degranulation in NKG2A$^+$ NK cells, while it was not increased any further in NKG2C$^+$ cells, suggesting that the re-expression of HLA-E did not make NK-92_B2M^{KO}_HLAE cells more susceptible to NKG2C$^+$ PBNK lysis. We report here that abolishment of HLA class-I and re-expression of HLA-E on NK-92 cells effectively inhibited CD8$^+$ T-cell recognition as well as provided significant protection against resting and IL-2 activated PBNKs. Our results also suggest that these modifications are likely sufficient to allow the engineered NK-92 cells to evade immune alloreactivity in a majority of patients after infusion.

#886 Response to g-NK is associated with higher CD8+ T cells and lower MDSC in bone marrow of multiple myeloma patients.

Aimee M. Merino[1], Zachary Davis[1], Jacob Rugloski[1], Madison Shackelford[1], Matt Collinson-Pautz[2], Austin Bigley[2], Stefanie Mandl-Cashman[2], Jeffrey A. Miller[1]

[1]University of Minnesota, Minneapolis, MN,[2]Indapta Therapeutics, Seattle, WA

Patients with relapsed/refractory (R/R) multiple myeloma (MM) have poor outcomes and no curative therapies. In an ongoing, open-label Phase I/II trial of g-NK cells (IDP-023), we recently reported a mean maximum decrease in serum M-protein or light chain of 73% in eight R/R myeloma patients, with three patients achieving a reduction of 84% or greater (Patel, Merino et al, SITC 2024). G-NK are a subgroup of adaptive NK cells that are epigenetically reprogrammed to exhibit higher antibody-dependent cytotoxicity following engagement of CD16 than conventional NK cells. G-NK also lack the inhibitory checkpoint NKG2A enabling them to kill HLA-E+ target cells. Because the impact of the tumor microenvironment (TME) on outcomes after cellular therapy is poorly understood, we collected bone marrow samples for cytometry time-of-flight (CyTOF) with a commercial 37 marker panel designed to identify immune populations in patients treated at the University of Minnesota. Four patients had bone marrow collected for this analysis. One patient (#004) achieved a partial response (PR) by International Myeloma Working Group (IMWG) criteria in monoclonal protein and had improvement in the activity of lytic lesions on their PET scan thirty days after treatment. One patient (#003) had a minimal response (MR) and the other two patients had stable disease (SD) by IMWG. Interestingly, two of the three patients with relatively stable monoclonal protein in the blood (MR or SD) had significant improvement in PET scans after NK-cell therapy (#003, #001). One of the patients with SD (#001) and improvement in lytic lesions as measured by PET, maintained SD for five months before proceeding to their next therapy. Patients #001 and #004 had post-treatment bone marrow samples showing decreased expression of the exhaustion marker PD1 by CD8+ T cells. The patients who had improvement of their lesions on PET saw decreases in T cell expression of the inflammatory markers CXCR3 and CD38. The patient (#001) with SD and improvement in bone lesions that lasted five months saw a 5x increase in CD8+ T cells in his post-treatment biopsy with near complete clearance of MDSC (<1%). Additionally, our data suggest that the pre-treatment condition of the bone marrow may be predictive of anti-tumor activity. For example, of the four evaluable patients, the patient who achieved a PR had the highest percentage of CD8+ T cells and lowest percentage of myeloid derived suppressor cells (MDSC) at baseline. The patient with SD and no improvement by PET had the highest % of MDSC, the lowest CD8+ T cell percentage, and the highest expression of PD-1 on CD8+ T cells of all the patients. Collectively, these data suggest that g-NK cell therapy can alter the TME and may promote MM control by influx of non-exhausted T cells. Furthermore, the amount of MDSC in the bone marrow at time of treatment may be inversely correlated with anti-tumor activity.

#887 Human microRNA-1250-5p targets IGFBP2 expression to regulate NK cell proliferation in hypoxia.

Kyung-Mi Lee, Minwha shin, Seon Ah Lim

Korea University, Seongbuk-gu, Korea, Republic of

Insulin-like growth factor binding protein 2 (IGFBP2) is involved in many physiological events, such as progression and survival of many types of cells. However, little is known about its role in human natural killer (NK) cells. Here, we report that miR-1250-5p regulates IGFBP2 expression, the most expressed gene in hypoxia-activated NK cells, thereby promotes NK cell proliferation in hypoxia. We found that IGFBP2 was not only highly expressed in cellular level, but also secreted from NK cells exposed to hypoxia. Both endogenous and secreted IGFBP2 are involved in NK cell proliferation in hypoxia. We identified miR-1250-5p directly binds to the 3'untranslated region of IGFBP2, and negatively regulates the expression of IGFBP2 in hypoxia-activated NK cells. Overexpression of miR-1250-5p has decreased NK cell proliferation, whereas inhibition of miR-1250-5p shows dramatically opposite effect. Clinical data showed that IGFBP2 expression was increased in tumor infiltrating NK cells compared with non-tumor infiltrating NK cells in patients of hepatocellular carcinoma (HCC), which is one of the representative tumors of hypoxia. We further demonstrated that miR-1250-5p negatively regulates IGFBP2 expression in tumor infiltrating NK cells of HCC patients. Furthermore, proliferation and survival markers, Ki-67, PCNA, cIAP1, cIAP2 as well as NK cell activating receptor, NKp44, were upregulated, whereas apoptotic and senescence markers, Bax, p53 and p16 were downregulated in tumor infiltrating NK cells in patients of HCC. These results indicate that the proliferation of NK cells in hypoxia is regulated by miR-1250-5p and its target gene IGFBP2, thereby enhancing therapeutic potential of NK cells against hypoxic tumor microenvironment.

#888 NKC and KIR humanized mice: a powerful tool to develop NK-targeting drugs.

Qiurong Wang, Qi Zhang, Na Kang, Huizhen Zhao, Lili Liu, Jiawei Yao, Yanshuang Li

Biocytogen, Waltham, MA

Natural killer (NK) cells are leukocytes within the innate immune system, acting as a first line of defense against cancer and virally infected cells. NK cell responses—whether “killing” or “tolerant”—are regulated by interactions between activating and inhibitory receptors and their ligands. Currently, there remains a need for comprehensive in vivo models featuring humanized NK cell receptors, including key proteins encoded by the KIR and NKC gene clusters.

Killer cell immunoglobulin-like receptors (KIR) form a highly polymorphic gene cluster expressed by NK and certain T cell subtypes, while the Natural Killer Gene Complex (NKC) encodes several C-type lectin-like receptors, such as the NKG2 family, found across various immune cells. To introduce a novel NK gene cluster-related in vivo model, Biocytogen has used advanced gene-editing technology to humanize ~150,000 base pairs of KIR gene cluster DNA (B-hKIR mice) and 0.9 million base pairs of NKC gene cluster DNA (B-hNKC mice) on a C57BL/6 background. In this combined B-hNKC/hKIR mouse model, 29 functional genes have been modified.

The immunophenotype of B-hNKC/hKIR mice is consistent with that of wild-type C57BL/6 mice. Human proteins NKG2A, NKG2C, CD94, NKG2D, and CD161 are detectable on NK cells, while human CLEC9A is observed on CD8a+ and CD103+ dendritic cells in the spleen. Human CLEC12A is expressed on T cells, macrophages, monocytes, and dendritic cells, and human LOX1 is present on activated macrophages, monocytes, and neutrophils in the bone marrow. Additionally, human CD69 is expressed on activated T cells, B cells, NK cells, macrophages, monocytes, neutrophils, and dendritic cells in the spleen. In B-hKIR mice, human KIR2DL1, KIR2DL3, and KIR3DL2 are detectable on NK cells, and mRNA for human KLRF2, CLEC2A, TMEM52B, CLEC1A, and CLEC2D is also expressed in B-hNKC/hKIR mice.

This B-hNKC/hKIR mouse model provides an advanced platform for NK-targeted research and serves as a valuable in vivo system for preclinical studies.

#889 T cell help enhances anti-CD38-mediated NK cell ADCC of multiple myeloma despite expression of CD38 by NK cells.

Reza Amani[1], Jyoti Arora[1], George J. Weiner[2]

[1]Holden Comprehensive Cancer Center, University of Iowa, Iowa City, IA,[2]Department of Internal Medicine, University of Iowa, Iowa City, IA

Anti-CD38 monoclonal antibodies such as daratumumab and isatuximab are effective therapeutic agents for some patients with multiple myeloma (MM) even though CD38 is expressed by B cells, monocytes and a significant subset of NK cells as well as MM cells. Treatment with anti-CD38 antibodies has been shown to deplete NK cells from the peripheral blood. This raises questions concerning the mechanisms of action of anti-CD38 as a treatment for MM such as NK cell mediated antibody dependent cellular cytotoxicity (ADCC). Since many NK cells express CD38, such NK cells could be susceptible to anti-CD38-induced fratricide, where CD38-expressing NK cells are targeted and eliminated. In previous studies in vitro, in animal model and in clinical correlative studies, we demonstrated that T cells play a key role in supporting NK cell viability and cytotoxicity following NK cell activation by anti-CD20 coated target cells. This T cell help is provided largely through IL2 production in the local microenvironment by CD4+ T cells. Here, we evaluated the role of T cell help in anti-CD38 mediated NK cell ADCC. Peripheral Blood Mononuclear Cells (PBMCs) were obtained from normal donors. T cells were depleted and added back to the PBMCs in known numbers to create PBMCs with controlled numbers of T cells. These PBMCs were cultured with MM.1S myeloma cells for 1, 3, or 7 days with and without anti-CD38. The presence of T cells had limited impact on tumor cell numbers or NK cell phenotype in the absence of anti-CD38 confirming modest direct anti-MM effect of T cells in this culture system. CD38 expression by NK cells was decreased after culture with anti-CD38 under all conditions. NK mediated ADCC was observed despite loss of NK cell CD38. This ADCC was dependent on T cell help. MM cells were reduced by day 3 and were largely eliminated by day 7 in samples treated with anti-CD38. Greater anti-MM effects were seen with PBMCs that contained larger numbers of T cells while ADCC was less apparent in samples with fewer numbers of T cells. At day 7, IL2 restored the longer-term anti-MM effect of anti-CD38 in the absence of T cells. A T cell dependent increase in NK cell numbers was also seen at day 7. We conclude that anti-CD38 can induce NK cell mediated ADCC of MM cells despite loss of CD38 expression by NK cells suggesting down-modulation of CD38 on NK cells as opposed to fratricide of CD38-expressing NK cells. T cell help, likely mediated in large part by local production of IL2, enhances anti-CD38-induced NK cell activation, viability and ADCC. These data indicate NK cell ADCC, enhanced by local T cell help, may be an important mechanism of action for anti-CD38 in MM.

[1]Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Urology Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Gerstner Sloan Kettering, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Gerstner Sloan Kettering Graduate School, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Sloan Kettering Institute, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Genitourinary Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY,[8]Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[9]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: To identify the patients with urothelial cancer (UC) at greatest risk of metastasis, we performed an integrated analysis of clinicopathologic and somatic mutation data from a prospectively generated tumor genomic sequencing cohort.
Methods: We collected detailed clinicopathologic data from 1,617 patients with bladder and upper tract UC treated at Memorial Sloan Kettering. Tumors were sequenced with MSK-IMPACT, a targeted DNA sequencing assay that identifies genomic alterations in 341-505 genes. Metastatic site involvement was inferred using a natural language processing model, as reported in the MSK-CHORD dataset. Patients were considered never metastatic if there was no evidence of metastases after 2.5 years of follow-up from diagnosis. Comparisons were made between ever-metastatic (EM) and never-metastatic (NM) patients. In a time to metastasis analysis, metastatic patients at diagnosis and patients that had metastasis within 6 months of diagnosis were excluded. Continuous variables were analyzed using Wilcoxon rank sum test and two-sided Fisher's exact test for categorical variables. Univariable Cox proportional hazard models were used to assess time-to-metastasis. Benjamini-Hochberg was used to correct for multiple hypothesis testing and q-values <0.1 were considered significant.
Results: EM patients were more likely to be former smokers (64% vs 50%, q<0.001) and be diagnosed after age 80 (17% vs 10%, q=0.033). NM patients were more likely to be never smokers (48% vs 34%, q<0.001) and diagnosed before age 65 (36% vs 28%, q=0.016). EM tumors had a higher fraction genome altered (0.20 vs 0.10, q<0.001) and higher rates of *TP53* (55% vs 44%, q=0.003), *ELF3* (15% vs 9%, q=0.018), and *CDKN2A* (29% vs 21%, q=0.069) alterations. NM tumors were more likely to have *FGFR3* (18% vs 26%, q=0.002) and *ERCC2* (6% vs 13%, q<0.001) alterations. In a time to metastasis analysis: former smoking (HR: 1.44, q=0.041), *CDKN2A* (HR: 1.59, q=0.005), and *ELF3* (HR: 1.64, q=0.030) alterations were associated with a higher risk of bone metastasis. *CDKN2A* (HR: 1.98, q<0.001) and NRF2 pathway alterations (HR: 2.13 q=0.026) were associated with higher risk of lung metastasis. Former smoking (HR: 1.41, q=0.029), *CDKN2A* alterations (HR: 1.33, q=0.086), *ERBB2* amplifications (HR: 1.81, q=0.009), NRF2 (HR: 1.92 q=0.026) and HIPPO (HR: 1.62 q=0.031) pathway alterations were associated with higher risk of lymph node metastasis. *ERCC2* alterations were associated with lower risk of bone, (HR: 0.33, q=0.017), lung (HR: 0.48, q=0.098), and lymph node metastases (HR: 0.43, q=0.026).
Conclusion: Through integration of tumor genomic profiling data with NLP-derived clinical annotation, we identified clinical and genomic features associated with a higher risk of developing metastatic disease in patients with UC, as well as alterations associated with organ-specific metastatic tropism.

#890 NK-92® (aNK™) whole cell lysate exerts potent cytotoxic and anti-proliferative activity on tumor cells.

Himani Chinnapen, Laurent Boissel, Thomas Bickett, Courtney Fleenor, Vidya Godbole, Manju Saxena, Patrick Soon-Shiong, Hans Klingemann

ImmunityBio, Inc., Culver City, CA

Lysates from human cells represent biofluids that are used in the biotechnology field for a number of applications, such as biomarker identification and antibody detection. Lysate from human blood platelets is widely used in the clinical setting to control bleeding. We hypothesized that whole cell lysate prepared from the natural killer cell line NK-92® or 'activated' NK (aNK™) has the potential as an immunotherapy modality for local treatment of cancer lesions, as it would be expected to contain an abundance of cytotoxic granule-associated serine proteases (granzymes), the pore-forming cytolytic protein (perforin), as well as an array of chemokines and cytokines that could contribute to a more immune-active tumor microenvironment.
Here, we have generated whole cell lysate from NK-92 cells, and its high-affinity CD16 Fc receptor (158V) and erIL-2 -engineered variant haNK® cells, by repeated freeze/thaw cycles at a density of 10^8 cells/mL in a balanced salt solution (BSS) buffer containing no detergent, protease inhibitors, or EDTA. The resulting whole cell lysates were characterized for composition and cytotoxic activity. Western blot analysis confirmed the presence of perforin, granulysin, exosomal markers, and the full spectrum of granzymes known to be expressed in NK-92 cells. Biomarker profiling by Meso Scale Discovery-based assays revealed the presence of various chemokines and cytokines at significant concentrations in both NK-92 and haNK lysates, notably IL-2 (haNK only), IL-8, IL-10, IL-16, TNF-β, IFN-γ, and MIP-1α and β. A fluorometric assay confirmed enzyme activity of Granzyme B was maintained before and after cryopreservation of the lysate. Incucyte® SX3 live cell imaging assays showed that fresh lysate prepared from haNK cells displays cytotoxic and anti-proliferative activity against human and canine cancer cell lines after only a 15-minute exposure *in vitro*, suggesting cross-species specificity. Importantly, under the same conditions the lysate had no effect on primary human or canine cells. Intra-tumor injection of cryopreserved haNK lysate into intradermal tumors in immunocompetent C57BL/6 mice provided tumor control and clearance in two-thirds of the animals. Strikingly, when re-challenged with the same tumor cells 6-8 weeks later, no tumor growth occurred suggesting a vaccine-like effect of the haNK lysate. In conclusion, we have developed a simple, scalable method to prepare bioactive cell lysates from NK-92 and haNK that show anti-tumor activity and a potential for immune modulation both *in vitro* and *in vivo*.

#891 Therapeutic role of NK cells in treatment of myeloid malignancies using hypomethylating agents.

Junshik Hong[1], Suji Min[1], Jihyun Park[1], Carly Fielder[2], Qianni Hu[2], Seula Kim[1], Sung-Soo Yoon[1], Tae Kon Kim[2]

[1]Department of Internal Medicine, Seoul National University College of Medicine, Jongno-gu, Korea, Republic of,[2]Division of Hematology/Oncology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN

We previously analyzed serial bone marrow (BM) aspirates from a patient with high-risk myelodysplastic syndrome (HR-MDS) who responded to a hypomethylating agent (HMA), azacitidine using single-cell RNA sequencing. Our finding showed an increased proportion of NK cells in the BM, with elevated CXCR4 expression following azacitidine treatment (Hong J, et al. AACR 2023). Building on these observations, we tested our hypothesis that HMA can potentiate BM homing and cytotoxic effect of NK cells in myeloid leukemia. To test our hypothesis, we will carry out in vitro assays, animal experiments, and patients' serial BM samples. First, we assessed NK cells changes in BM aspirates from AML or HR-MDS patients before and after HMA treatment. Flow cytometric analysis revealed that patients who achieved complete remission after HMA treatment exhibited a significant increase in NK cells proportion in the BM compared to non-responders (add statistics). Additionally, CXCR4 expression on NK cells was higher in patients with a favorable response, suggesting a link between NK cell dynamics and treatment outcomes (add statistics). To carry out mechanistics studies, C1498 mouse AML cells were transplanted into C57/BL6 mice, which were treated with decitabine or vehicle for 5 days. Decitabine not only inhibited in vivo AML proliferation but also increased the proportion of NK cells cells in the BM. Of interest, CXCR4, a chemokine receptor that has been known for BM homing, was also upregulated on the surface of NK cells. In addition, CXCR4 expression was first increased in NK cells, and then NK cell homing was followed. To investigate whether HMA treatment increases CXCR4 expression and induces NK cell migration, an in vitro Transwell migration assay was performed using NK92 cells (a human NK cell line) with AML cell lines (MV4-11 and OCI-AML3) and mesenchymal stromal cells (MSC) from AML patients. CMFDA-labeled NK92 cells showed higher migration and increased CXCR4 expression in decitabine-treated wells compared to vehicle controls, with the effect being more pronounced in the presence of MSCs. Taken together, these findings suggest that HMA-induced NK cell recruitment to the BM via CXCR4 upregulation may play a key role in the anti-leukemic effects of HMAs in AML and HR-MDS. Increased NK cell migration and CXCR4 expression are associated with better treatment responses, highlighting the potential of enhancing NK cell immunity as a therapeutic strategy.

#892 Development of iPSC-derived feeder cells to enhance NK cell expansion and cytotoxicity for cancer therapy.

Z.-Q. Lin[1], M.-T. Hsu[2], Y. Lin[1], L.-F. Chen[1], B.-H. Chen[1], Y.-C. Sun[3], K.-F. Hung[2];
[1]Taipei Veterans General Hospital, Taipei, Taiwan, [2]National Yang Ming Chiao Tung University, Taipei, Taiwan, [3]Taipei Tzu-Chi Hospital, the Buddhist Tzu-Chi Medical Foundation, New taipei City, Taiwan

Natural killer (NK) cells have been considered a promising candidate for cell therapy in cancer treatment. However, since NK cells constitute a minor fraction of peripheral blood mononuclear cells (PBMCs), recent efforts have concentrated on enhancing the efficiency of *in vitro* expansion. Among various approaches, the genetically engineered K562 cell line has shown promising potential in NK cell expansion. Nonetheless, as K562 cells are a cell line derived from human leukemia cells, the use of K562 as feeder cells raises significant safety concerns. To address this issue, we developed a novel feeder cell system by engineering hematopoietic progenitor cells (HPCs), derived from induced pluripotent stem cells (iPSCs), to express co-stimulatory molecules and cytokines on their surface via viral transduction. We showed that iPSC-derived HPCs efficiently prolong the lifespan of primary NK cells beyond two weeks, surpassing the typical half-life of NK cells in regular culture conditions. To further enhance the stimulatory effect of membrane-bound interleukin on the surface of feeder cells, we engineered a bispecific antibody comprising a recombinant cytokine and a single-chain variable fragment (scFv) with binding specificity to feeder cells. Interestingly, we found that the combination of HPC feeder cells and recombinant cytokines significantly enhance NK cell expansion and cytotoxicity. We also found that iPSC-derived feeder cells efficiently sustain the cytotoxicity activity of iPSC-derived NK cells, showing that iPSC-derived cells can serve as a powerful platform for cancer therapy. In conclusion, our novel feeder cell system shows great potential to enhance NK cell proliferation and activation. While further optimization is required, this non-cancerous source of feeder cells offers an appealing alternative to K562 cells, facilitating the development of NK cell-based cancer therapy.

#893 A novel approach to treating HER2-low breast cancer: surface-engineered NK/tz cells targeted immunotherapy.

Maria Jose Godoy Calderon[1], Eric Gauchat[2], VK Gadi[1]

[1]Medicine, University of Illinois at Chicago, Chicago, IL,[2]Cancer Center, University of Illinois at Chicago, Chicago, IL

Background: The majority (60-70%) of metastatic breast cancers (MBC) are HER2-low expressing, and in distinction to HER2+ disease, is not addicted for growth to this oncogene. Trastuzumab-based treatments have failed to improve the outcomes of patients with HER2-low breast cancer. Despite promising results with trastuzumab-deruxtecan (T-DXd), significant systemic toxicity and disease progression were observed highlighting the need to develop safer and more effective, and accessible therapies. This study evaluates the therapeutic potential of surface-engineered NK cells (SE-NK) modified with trastuzumab (Tz) for targeting HER2-low breast cancer cells.
Methods: To establish a preclinical model, the triple-negative murine breast cancer cell line 4T1 was transduced with a lentiviral vector encoding human HER2, generating clones with HER2 expression comparable to HER2-low human breast cancer cells (MDA-MB-175). HER2 expression was validated using flow cytometry, confocal microscopy, and Western blot analysis. SE-NK/Tz cells were generated by embedding 25 ug Tz onto the NK cell surface using a hydrophobic linker. These cells were tested in vitro for HER2-specific cytotoxicity against the engineered 4T1-HER2-low cells.
Results: Transduced 4T1-HER2-low cells exhibited HER2 expression levels consistent with HER2-low human breast cancer cells. In vitro, SE-NK/Tz cells demonstrated significantly enhanced cytotoxicity against 4T1-HER2-low cells (24%, $p < 0.05$) compared to NK cells alone (0%) when an effector to target ratio of 1.25:1 was used.
Conclusions: This study establishes the feasibility of using SE-NK/Tz cells as a novel immunotherapeutic approach for HER2-low breast cancer. We created for the firsttime to our knowledge a murine cell line with human HER2-low status comparable to expression values reported in patients. The preclinical findings support the potential of this strategy to overcome the limitations of current therapies by offering an effective and accessible treatment option. Future studies will explore mechanisms of immune activation and therapeutic efficacy in diverse in vivo HER2-low models.

#894 Generation of cytokine-induced memory-like PD-L1 t-haNK (NK-92®) cells.

Dustin Elwood, Devapriya Segaran, Joseph Thibault, Vidya Godbole, Manju Saxena, Hans Klingemann, **Laurent Boissel**, Patrick Soon-Shiong

ImmunityBio, Inc., Culver City, CA

Cytokine-induced memory-like NK cells have garnered a lot of attention as cellular therapeutic agents due to their much-increased lifespan in patients and their enhanced memory response upon re-challenge by cytokines or target cells. A key part of this memory recall feature is the increased secretion of interferon gamma (IFNγ). This potent immune stimulator can trigger upregulation of MHC-I molecules expression on the surface of tumor cells, thereby pushing the tumor towards an immunologically “hot” status. However, IFNγ also triggers expression of the immune checkpoint molecule PD-L1. We show here that the Natural Killer cell line NK-92®, or ‘activated’ NK (aNK™), can acquire a memory-like phenotype upon overnight induction with IL-12, IL-18, and the IL-15 superagonist N-803, as evidenced by increased steady-state IFNγ secretion (>50-fold increase) and up-regulation of CD25. Although the initial increase in IFNγ secretion subsides after 48hrs, memory-like NK-92 cells display memory recall for several days post-activation, as evidenced by an enhanced IFNγ response upon challenge with K562, Raji, and THP-1 cells compared to non-memory-like cells (2.3, 6.9, and 3.8-fold increases after 1 week, respectively). Further, NK-92 cells engineered to express a high-affinity Fc receptor and an anti-PD-L1 Chimeric Antigen Receptor (PD-L1 t-haNK) maintained their susceptibility to memory-like cytokine induction. Exposure of the NK-resistant cells lines THP-1 and SK-ES-1 to culture supernatant from memory-like PD-L1 t-haNK triggered expression of PD-L1 on their surface, rendering them highly sensitive to PD-L1 CAR-mediated targeted killing by the PD-L1 t-haNK cells in a 4-hour *in vitro* cytotoxicity assay (respectively 91% and 88% killing at E:T ratio of 1.25:1, compared to 54% and 41% for target cells exposed to regular PD-L1 t-haNK supernatant), while not affecting their resistance to NK-92 cells. Infusion of a cellular therapy product that constitutively secretes high IFNγ may cause detrimental side effects. Memory-like PD-L1 t-haNK cells may circumvent this problem through their memory recall ability and deliver increased amount of IFNγ specifically at the tumor site when locally engaging with tumor cells. This increase would then drive upregulation of PD-L1 expression on neighboring tumor cells, creating an expanding wave of targets sensitized to killing by PD-L1 t-haNK cells. A next generation, memory-like PD-L1 t-haNK cell line equipped with inducible safety switch features to remove the need for irradiation and extend their half-life in patients is being developed and would constitute a promising “off-the-shelf” cellular therapy against immunologically cold cancers.

#895 A systemically administrated STING agonist in albumin formulation activated neutrophils for anti-cancer immunotherapy.

Jinsong Tao, Hongyi Zhao, Chengyi Li, Zhongwei Liu, Hanning Wen, Qiuxia Li, Miao He, Bo Wen, Fang Ke, Wei Gao, Duxin Sun

University of Michigan, Ann Arbor, MI

Background: Neutrophils, the most abundant leukocytes (50-70%) in human circulation, are key players in the innate immune response and increasingly recognized for their multifaceted roles in cancer biology. Beyond their established functions in infection control and inflammation, they have been shown to significantly influence tumor progression through complex interactions within the tumor microenvironment. Neutrophils exhibit remarkable phenotypic heterogeneity and plasticity, which allows them to adopt either tumor-suppressing or tumor-promoting functions. How to program neutrophils in vivo for anti-cancer therapy? We developed a systemically administrated STING agonist formulated within albumin formulation to activate neutrophils for anti-cancer immunotherapy.
Methods & Results: We synthesized a novel non-nucleotide STING agonist dimer ZSA-51D encapsulated in albumin nanoparticles (nano ZSA-51D), which exhibited a potent STING pathway activation in THP1-Blue^{TM} ISG cells (EC 50 0.44 nM) and mouse myeloid cells (EC 50 < 10 nM). Interestingly, we found the Nano ZSA-51D highly activated CD101-CD14+ and CD101+CD14+ neutrophils in vitro and in vivo, which was STING pathway dependent. The pharmacokinetic studies in mice shown Nano ZSA-51D highly accumulated in bone marrow (BM). Most of the Nano ZSA-51D were absorbed by neutrophils in BM, blood and Tumor, which resulted in high neutrophil activation in vivo. The Nano ZSA-51D plus α-PD1 achieved complete remission in the MC-38 colon cancer and robust anti-cancer effects in pancreatic cancer model. The tumor immune cell infiltration was examined by flow cytometry at 24 h after treatments. We found the neutrophils were highly activated in BM and blood, then the activated (CD101-CD14+ and CD101+CD14+) neutrophils largely infiltrated into tumor after Nano ZSA-51D treatment. The bulk mRNA sequence analysis showed the neutrophils were activated through Toll-like receptor, TNF-α and NF-κB signaling pathway. Surprisingly, the activated CD101-CD14+ and CD101+CD14+ neutrophils enhanced the antigen presentation of exogenous peptide antigen via MHC class I, further promote the proliferation and activation of T cells, which shown robust anti-cancer effects in vivo after rejected the activated neutrophils into tumor.
Conclusion: In this study, we developed a novel systemically administered STING agonist formulated within albumin formulation (Nano ZSA-51D) to activate neutrophils for anti-cancer immunotherapy. Nano ZSA-51 plus α-PD1, demonstrated superior anticancer efficacy through activating neutrophil to promote the proliferation and activation of T cells in vivo.

#896 Unleashing the power within: enhancing cancer treatment with invariant natural killer T cells.

Daniah Alkassab, Carolina de Amat Herbozo, Thierry Mallevaey

Immunology, University of Toronto, Toronto, ON, Canada

Invariant natural killer T (iNKT) cells are a promising target for adoptive cell therapy (ACT) due to their unique ability to recognize glycolipid antigens presented by the non-polymorphic MHC class I-like CD1d molecule, enabling heterologous application without the risk of alloreactivity. Activated, iNKT cells exhibit potent antitumor activity through cytokine secretion, chemokine release, and cytolysis, making them ideal candidates for off-the-shelf cancer therapies. However, limited knowledge of iNKT cell biology, particularly their functional heterogeneity, has hindered their therapeutic optimization. This study aimed to (a) investigate the functional heterogeneity of iNKT cells, (b) expand iNKT cells from human peripheral blood mononuclear cells (PBMCs), and (c) optimize the generation of cytotoxic iNKT cells by evaluating their phenotypic and functional profiles in response to various cytokine stimulations. PBMCs from 14 healthy donors (7 males and 7 females) were analyzed using spectral flow cytometry to assess the expression of key iNKT cytotoxic markers, along with markers associated with natural killer cells and CD8+ T cells. Phenograph clustering revealed distinct iNKT subpopulations, including one characterized by high expression of cytotoxic markers such as CD57, granzyme B, and granulysin, and another enriched for CD62L, a marker linked to central memory-like phenotypes with the potential to differentiate into cytotoxic subsets with enhanced antitumor activity. To optimize iNKT cell expansion, PBMCs were co-cultured with artificial antigen-presenting cells loaded with the iNKT ligand α-galactosylceramide in the presence of IL-2. iNKT cells were sorted two weeks post-initial stimulation and restimulated every 2-3 weeks using anti-CD3, resulting in the generation of millions of cells. To further enhance cytotoxic potential, iNKT cells were treated with cytokines such as IL-7, IL-15, IL-12, and IL-21. Preliminary findings demonstrated that cytokine stimulation influences the phenotypic profiles of iNKT cells. These findings provide a robust foundation for generating large quantities of cytotoxic iNKT subsets optimized for in vitro and in vivo assays. This work not only enhances the understanding of iNKT cell biology but also represents a significant step toward leveraging iNKT cells as versatile and powerful tools in ACTs.

#9 Genetic and oncogenic viruses as risk factors in Egyptian breast cancer patients.

Sarah Mohamed Mahmoud ElSayed[1], Rania Abdulmonem Eissa Al Najar[1], Nasra Fathy Abdel Fattah[2], Ayman Abdel-Samie Gaber[3], Tarek Hashem[4], Wafaa Khalaf[5], Ahmed Basyony[5], **Mohamed A. Eltokhy**[6], Sahar Mohamed Ramzy Radwan[7], . Amany abdullah EL-Sharif[7], Samah Loutfy[8]

[1]Clinical Pharmacy, Breast Cancer Comprehensive Center, National Cancer Institute, Cairo, Egypt,[2]Virology and Immunology, Cancer Biology Department, National Cancer Institute, Cairo, Egypt,[3]Medical Oncology Department, National Cancer Institute, Cairo, Egypt,[4]Surgical Oncology Department, National Cancer Institute, Cairo, Egypt,[5]Microbiology and Immunology Department, National Cancer Institute, Cairo, Egypt,[6]Texas Tech Health Science Center (TTUHSC), Abilene, TX,[7]Microbiology and Immunology Department, Faculty of Pharmacy (Girls), Al-Azhar University (Cairo), Cairo, Egypt,[8]National Cancer Institute, Cairo, Egypt

Introduction: Breast cancer (BC) is a leading cause of death worldwide. Genetic factors, such as ATM, BRCA1, BRCA2, CHEK2, and PALB2 are detected in 5%-7% of women with breast cancer elevating risk of disease development. The role of environmental factors such as oncogenic viruses remained under investigation. Therefore, we aimed to investigate correlation between variations in some exons of BRCA1, BRCA2, CHEK2, and PALB2 and presence of human papillomavirus (HPV), human mammary tumor virus (HMTV), and Epstein-Barr virus (EBV) DNAs in the blood of BC patients, hoping to understand role of oncogenic viruses in cancer development
Methods: Genomic DNA was extracted from 55 fresh tissues and blood samples of BC patients, as well as ten blood samples from healthy women, served as a control using Gene JET Extraction Kit (Thermo Scientific/US, Canada). PCR assay was employed to detect presence of HPV, HMTV and EBV DNAs. Additionally, variations in BRCA1, BRCA2, PALB2, and CHEK2 genes were screened using high resolution melting assays.
Results: HPV and HMTV DNAs were detected in the blood of 25.5% and 23.6% BC patients, respectively, with 9% of patients exhibiting co-presence of both viruses. No viral DNAs was detected in the healthy controls. In tumor tissues, *HPV* DNA, *HMTV* DNA, and *EBV* DNA were detected in 47.2%, 27.2%, and 25.5% of BC patients (P=0.012). Regarding genetic analysis, variations were detected in BRCA1 25.5%, BRCA2 43.6%, PALB2 42%, and CHEK2 52.7% genes of the blood of 55 BC patients. Our results demonstrated overlapping between PALB2, CHEK2, and BRCA2 variants in BC patients. Among PALB2 carriers, 30% harbored BRCA2 variants, among CHEK2 carriers, 32% harbored BRCA2 variants. Moreover, 25% of PALB2 carriers and 18% of CHEK2 carriers presented with BRCA1 variants. Additionally, our findings revealed co-occurrence of genetic variations among BC patients. Notably, 45.4% with BRCA2 exon11 variants, exhibited variations in both PALB2 exon 4 and CHEK2 exon 10. Additionally, 43% had variations in BRCA1 exon 6, and in CHEK2 exon 10, 57% had variations in BRCA1 exon 9 and PALB2 exon 4.
Results indicated an association between presence of viral DNAs and some genetic variations. Among 26 HPV-positives, 19.2% exhibited variations in exons 11 and 27 of BRCA2, and 50% had variations in PALB2 exon 4. In 15 HMTV-positives, 20% had variations in BRCA2 exon 27, and 66.7% exhibited variations in CHEK2 exon 10.
Conclusion: Results suggest a potential association between genetic variations in *BRCA1, BRCA2,* PALB2, and CHEK2, and presence of oncogenic viruses (HPV, HMTV) in the pathogenesis of BC. Further investigations are required to confirm these observations. Data indicated a correlation between CHEK2, BRCA2, and HMTV, and between PALB2, BRCA1, and HPV. Understanding these associations, especially if present in certain exons may aid in understanding the role of oncogenic viruses and developing new markers for early detection and prognosis of disease.

#90 OTUD7B activates the caspase 8-RIP1-NEMO complex-regulated NF-kB pathway to promote triple-negative breast cancer metastasis.

Hui-Yu Lin[1], Kun-Ju Chen[2], **Yuan-Feng Lin**[2]

[1]Fu-Jen Catholic University, New Taipei City, Taiwan,[2]Taipei Medical University, Taipei, Taiwan

Background: Triple negative breast cancer (TNBC) is a highly metastatic BC subtype and refers to a poorer prognosis of BCs. Distant metastasis of TNBCs to other organs, e.g. lungs and brain, risks the patient's life. However, the molecular mechanism underlying TNBC metastatic progression is still under investigation. The aim of this study was made to delineate the role of ovarian tumor deubiquitinating enzyme 7B (OTUD7B) in the molecular mechanism for TNBC metastasis. **Methods:** Site-directed mutagenesis was performed to confirm that the deubiquitinating activity of OTUD7B is required for promoting TNBC metastatic potentials. Human Ubiquitin Array kit was employed to identify the potential target of OTUD7B in the highly metastatic TNBC cell line MDA-MB231. Pathway enrichment analysis was utilized to predict the possible pathways involved in TNBC metastasis. Pulldown assay was utilized to validate the deubiquitinating activity of OTUD7B towards the identified protein targets. Cycloheximide-chased assay was used to measure the degradation of identified protein targets in response to OTUD7B knockdown in MDA-MB231 cells and its overexpression in poorly metastatic TNBC cell line HCC1937. **Results:** Site-directed mutagenesis indicated that the mutation of Asn193 to Leu or Met, which leads to the loss of OTUD7B deubiquitinating activity, as compared to wild-type gene fails to promote cellular migration ability and lung colony-forming capacity of the tested TNBC cells. The employment of Human Ubiquitin Array kit demonstrated that Caspase-8 and NEMO, also named IKKγ, are the potential targets for OTUD7B deubiquitinating activity in MDA-MB231 cells. Pathway enrichment analysis predicted the pathway in which NF-κB activation through FADD/RIP-1 axis mediated by Caspase 8 is probably activated in the primary tumor from TNBC patients with lymph node metastasis. Pulldown assay further confirmed the deubiquitinating activity of OTUD7B towards Caspase-8 and NEMO in TNBC cells. Cycloheximide-chased assay revealed that OTUD7B knockdown accelerates protein degradation of Caspase-8 and NEMO in MDA-MB231 cells. The pharmaceutical inhibition of NEMO complex with IKKα/β dramatically suppressed NF-κB activity and metastatic potentials in the OTUD7B-overexpressing HCC1937 cells. Importantly the signature of combining lower levels of cleaved/active Caspase-8 and higher levels of pS536-NF-κB was found to highly correlate with lymph node metastasis and a poorer overall survival rate in TNBC patients. **Conclusion:** Our results suggest that OTUD7B upregulation promotes TNBC metastasis by recruiting the Caspase-8-RIP1-NEMO axis-activated NF-κB pathway.

IMMUNOLOGY: Tumor-induced Immune Suppression: Intrinsic and Extrinsic Factors

#900 Melanoma immune escape controlled by cancer cell-intrinsic STING signaling is linked to MHC-I suppression.

L. S. Jensen[1], A. Weiss[2], A. Draghi[2], S. Khan[2], A. S. Hansen[3], A. Etzerodt[1], B. W. Deleuran[1], M. Donia[2], M. R. Jakobsen[1];
[1]Aarhus University, Aarhus, Denmark, [2]Copenhagen University Hospital, Herlev, Denmark, [3]University of Southern Denmark, Odense, Denmark

Background: A crucial aspect of anti-tumor immunity is the infiltration of cytotoxic CD8+ T cells, which eliminate tumor cells by recognizing tumor antigens presented on major histocompatibility complex (MHC) class I molecules. The innate immune pathway regulated by Stimulator of Interferon Genes (STING) plays a significant role in modulating tumor immunity, and pathway activation is evident to impact T cell priming. In cancer cells, genomic instability leads to the accumulation of cytosolic DNA, activating the STING pathway and triggering a cytokine-driven immune response, which supports tumor control. However, to evade immune detection cancer cells continuously evolve mechanisms to evade immune recognition, such as downregulating MHC-I surface expression, thereby reducing the efficacy of CD8+ T cell-mediated cancer cell elimination.
Methods: We utilized a syngeneic mouse model of the murine YUMM.G/YUMMER.G melanoma cells that present high or low somatic mutational burden (SMB), along with a cohort of human melanoma patient-derived cell lines. We investigated the modulating role of cancer cell-intrinsic STING signaling in tumor immunity, focusing on its impact on antigen presentation and immune cell infiltration under varying levels of SMB both *in vitro* and *in vivo*.
Results: We observed that cancer cell-intrinsic STING signaling strongly associates with MHC I expression in our murine melanoma models. Similar correlations were found in a large group (n=76) of human melanoma patient-derived cancer cell lines. Our *in vivo* tumor models demonstrated that loss of STING expression significantly affected tumor control in melanoma models with high SMB. Notably, high SMB melanoma tumors deficient in STING expression escaped immune control by reducing infiltration and activation of cytotoxic CD8+ T cells. Conversely, STING depletion in low SMB melanoma cells had limited impact.
Conclusion: Our findings advocate that STING expression status in melanoma plays a critical role in determining tumorigenicity, with its influence being dependent on the somatic mutational burden of the cancer cells. This highlights the potential of STING expressions within cancer cells as a critical factor for tumor immunogenicity and should be considered as an exploratory biomarker in immunotherapy settings combined with tumor mutational burden.

#901 KLF4-induced melanocyte-schwann plasticity promotes immune escape in melanoma via LAG3 checkpoint.

A. Zhao[1], X. Liu[2], **Z. Zuo**[2];

[1]Zhejiang Cancer Institute, Zhejiang Cancer Hospital, Hangzhou Institute of Medicine, Chinese Academy of Sciences, Hangzhou, China, [2]Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Precision therapy is crucial to the successful treatment of rare tumors with limited treatment options. Here, we report a rare case of primary anterior mediastinal melanoma with liver metastasis. The patient had previously failed anti-PD1 treatment, leading us to profile the molecular features of the tumor to identify alternative therapeutic targets. Through comprehensive multi-omics analyses, we discovered a high degree of tumor cell plasticity in this rare case, with a subset of tumor cells displaying a Schwann cell phenotype evolved from melanocyte tumor cells. Cell-cell communication analysis revealed that the Schwann-like tumor cells may evade immune surveillance through the LAG3-LGALS3 immune checkpoint. The patient was then recommended for enrollment in a trial using combination therapy with anti-PD1 and anti-LAG3, and the disease remained stable for up to 24 months. Further investigation into the underlying mechanism showed that transcription factor KLF4-mediated transcription reprogramming drives B16 melanoma cell trans-differentiation into a Schwann cell phenotype. This trans-differentiation sensitizes the tumor cells to anti-LAG3 therapy. By analyzing melanoma tissue microarrays and external single-cell sequencing data, we found that this melanocyte-Schwann plasticity (MSP) existed in around 20% of melanoma cases. Moreover, a public immunotherapy cohort and our data indicate that MSP is associated with poor response to anti-PD1 treatment, suggesting that MSP may serve as a predictive biomarker for immunotherapy efficacy. Overall, our study not only provides a paradigm for precision immunotherapy in the context of rare tumors, but also reveals a potentially effective immunotherapeutic strategy for advanced melanoma with melanocyte-Schwann plasticity.

#902 Examining the impact of chromosome 1q-located gamma secretase subunits in the resistance to BCMA-targeted therapies in multiple myeloma patients.

Sejal Chikhale, Mansour Poorebrahim, Holly Lee, Elham Hasheminasabgorji, Anja Barbour, David Jung, Paola Neri, Nizar J. Bahlis

Arnie Charbonneau Cancer Institute, University of Calgary, Calgary, AB, Canada

Multiple Myeloma (MM) is an incurable hematological malignancy originating from abnormal plasma cells in the bone marrow. A common genetic abnormality in MM is the gain or amplification of chromosome arm 1q (chr1q), present in 30-40% of MM patients and typically associated with poor prognosis. Chr1q includes three subunits of the gamma-secretase (GS) enzyme- Nicastrin (NCSTN), Presenilin-2 (PS2), and Anterior Pharynx Defective 1 Homolog A (APH1A)—which catalyze the conversion of membrane-bound BCMA (mBCMA) to soluble BCMA (sBCMA). BCMA is a crucial target receptor for anti-BCMA therapies. Elevated sBCMA levels are linked to poor prognosis and reduced efficacy of BCMA-targeted therapies, apparently due to the sink effect. We hypothesize that chr1q amplification in MM leads to increased GS expression, resulting in reduced mBCMA and elevated sBCMA levels, which may drive resistance to BCMA-targeted therapies and contribute to adverse patient outcomes. To investigate this, we employed cloning and lentiviral transduction techniques to overexpress NCSTN, PS2, and APH1A individually, as well as in various combinations, in OPM2 myeloma cell lines, generating seven novel cell lines. Each subunit was fused with distinct tags to confirm successful transduction and overexpression. Using flow cytometry with BCMA-PE antibodies and sBCMA ELISA, we assessed mBCMA and sBCMA levels across these GS subunit-overexpressing cell lines compared to an empty vector control. Our results demonstrated that all seven GS subunit-overexpressing OPM2 cell lines exhibited decreased mBCMA levels. The triple-overexpressing cell line (NCSTN, PS2, and APH1A) showed a remarkable ten-fold reduction in mBCMA compared to the control. Additionally, differences in sBCMA levels were observed across the GS subunit-overexpressing cell lines relative to the control. These findings underscore the pivotal role of GS subunits encoded by chr1q in driving the poor prognosis associated with chr1q gain or amplification in MM. Ongoing analyses aim to elucidate the resistance mechanisms of these GS subunit-overexpressing OPM2 cell lines to anti-BCMA CAR-T therapies and T-cell engagers (TCEs).

#903 Mechanisms mediating hypoxic memory of type I IFN signaling suppression and implications for immune evasion in luminal breast cancer cells.

R. Marker, A. Moriarty, R. Klotz, M. Yu;
University of Maryland, Baltimore, Baltimore, MD

Solid tumors often contain patches of hypoxic regions that yield aggressive, pro-metastatic phenotypes. Prevention and understanding of metastases is critical for the future of breast cancer research, as metastatic cancer is extremely difficult to manage and treat. Recent work in our lab has shown that long-term hypoxia suppresses type I interferon (IFN) signaling in breast cancer cells. Even upon reoxygenation, these gene expression changes are maintained, indicative of “hypoxic memory.” Breast cancer cells that have disseminated from the primary tumor as circulating tumor cells with this “post-hypoxic” memory phenotype show enhanced metastatic potential. IFNs typically boost and enhance immune cell activity through interferon-stimulated genes (ISGs); thus, hypoxic suppression of IFN signaling yields an immunosuppressive tumor microenvironment. More research is needed to understand how ISGs are downregulated in hypoxia and how those changes in gene expression contribute to immunosuppressive ability of hypoxic and post-hypoxic cells. Interferon-inducible 44-like (IFI44L) is an ISG that has been associated with tumor-suppressive properties, and correlated with presence of tumor-infiltrating lymphocytes in other cancers, but its role in breast cancer has not been studied. We found that IFI44L is significantly suppressed in breast cancer cells in hypoxia and maintained after reoxygenation as a hypoxic memory. To try to understand possible mechanisms of hypoxic suppression, we overexpressed interferon regulatory factors (IRFs), which are positive regulators of the type I IFN pathway. However, this did not rescue hypoxic suppression and memory of IFI44L, suggesting that IRFs are not the sole regulator of IFN and ISG expression in hypoxia. Additional experiments are currently ongoing in the lab to address other possible mechanisms of hypoxic suppression and memory of IFN signaling. Additionally, co-culture experiments of breast cancer cells with knockdown or overexpression of IFI44L with different immune cell populations will shed light on the role of IFI44L in immune interactions in the tumor and in circulation. To better understand implications of maintained IFI44L suppression, we will also examine immune cell activity and metastatic potential using in vivo mouse studies. We expect to see less immune cell effect and enhanced metastasis with IFI44L knockdown and reversed phenotypes with overexpression of IFI44L. Understanding mechanisms of immune evasion mediated via IFI44L can lead to strategies for targeting hypoxia-mediated tumorigenesis and metastasis.

#904 Mapping the T cell-cold phenotype to the colorectal cancer genome identifies POFUT1 as a driver of tumor T cell inhibition.

C. J. Wagner;
Wake Forest University School of Medicine, Winston-Salem, NC

Colorectal cancer (CRC) patients with T cell-cold tumors experience rapid cancer progression and poor survival. While T cell-enhancing immunotherapies have improved outcomes for a subset of CRC patients, most remain nonresponsive. Therefore, better understanding the mechanisms that drive T cell dysfunction in CRC is needed. We used matched gene expression and copy number profiles from TCGA to evaluate CRC tumors (N=373) based on measures of T cell infiltrate, and developed a method to identify genes with potential roles in T cell exclusion. Leveraging the intersect between copy number amplification and gene expression in the T cell-cold state, we pinpointed a region of chromosome 20q11.21 where DNA- and RNA-levels were more strongly correlated with T cell exclusion than anywhere else in the CRC genome. This locus also contained the most frequently amplified and overexpressed genes in the CRC genome. Within this region, Protein O-Fucosyltransferase 1 (POFUT1) was the most distinguished gene, and correlated with CTL inhibition across 12/24 solid tumor types annotated in TCGA (SKCM, THCA, COAD, READ, LUSC, CESC, KIRC, STAD, HNSC, KIRP, LIHC, UCEC; $p<0.0001$). Stable overexpression of POFUT1 (POFUT1-OE) in MC38 mouse colon cancer cells enhanced proliferation relative to MC38-Vector (RTCA $p<0.0001$, CellTiterGlo $p=0.0011$); and in co-culture with c57BL/6 spleen-derived PBMCs, CD8+ T cell populations from MC38-POFUT1-OE co-cultures were significantly reduced over the course of 7 days. This effect persisted when PBMCs were stimulated with IL-2 and anti-CD2/CD3/CD28 in 50% conditioned medium (CM) from MC38-POFUT1-OE, prompting us to profile the CM for differences in secretomes. Of 110 profiled cytokines, two were at significantly higher levels in MC38-POFUT1-OE CM: IL-6 and IL-23 ($p=0.0003$, $p=0.0055$). These results were validated via ELISA and transient knockdown (KD) of POFUT1, where POFUT1-KD resulted in reduced cancer cell proliferation, diminished secretion of IL-6, and increased CD8+ T cell abundance in our CM models. Furthermore, siRNA-mediated KD of POFUT1 in MDST8 and HCT15 human CRC cell lines resulted in significant reductions in secreted IL-6 ($p=0.0003$, $p<0.0001$). Treatment of murine PBMCs with IL-6 (5.0 pg/mL - 50 ng/mL) decreased the proportion of CD8+ T cells to an analogous level as culture with POFUT1-OE CM. The decrease in CD8+ T cell proportion was also associated with less proliferation (CFSE, $p=0.0049$), and reduced surface expression of activating co-receptors CD25 and CD69 ($p=0.1008$, $p=0.0015$). Dosing with anti-IL-6 IgG (10 ng/mL) reversed the decrease in CD8+ T cell proliferation induced by CM from MC38-POFUT1-OE, establishing IL-6 as the downstream mechanism of POFUT1-dependent inhibition of CD8+ T cell activity. Together, these findings link POFUT1 amplification in CRC with dysregulation of CD8+ T cells via upregulation of cancer-intrinsic IL-6 secretion.

#905 SMARCA4 mutation induces tumor cell-intrinsic defects in enhancer landscape and resistance to immunotherapy.

Y. Lissanu, Y. Wang, I. Meraz, M. Qudratullah, S. Kotagiri, Y. Han, J. Roth;
UT MD Anderson Cancer Center, Houston, TX

SMARCA4 is a frequently mutated subunit of the SWI/SNF chromatin remodeling complex. Importantly, clinical reports indicate that SMARCA4-mutant lung cancers respond poorly to immunotherapy and have dismal prognosis. However, the mechanistic basis of immunotherapy resistance is unknown. Here, we corroborated the clinical findings by using immune-humanized, syngeneic, and genetically engineered mouse models of lung cancer harboring SMARCA4 deficiency. Specifically, we show that SMARCA4 loss caused decreased response to anti-PD1 immunotherapy associated with significantly reduced infiltration of dendritic cells (DCs) and CD4+ T cells into the tumor microenvironment (TME). Mechanistically, we show that SMARCA4 loss in tumor cells led to profound downregulation of STING, IL1β and other components of the innate immune system as well as inflammatory cytokines that are required for efficient recruitment and activity of immune cells. We establish that this deregulation of gene expression is caused by cancer cell-intrinsic reprogramming of the enhancer landscape with marked loss of chromatin accessibility at enhancers of genes involved in innate immune response such as STING, IL1β, type I IFN and inflammatory cytokines. Interestingly, we observed that transcription factor NF-κB binding motif was highly enriched in enhancers that lose accessibility upon SMARCA4 deficiency. Finally, we confirmed that SMARCA4 and NF-κB co-occupy the same genomic loci on enhancers associated with STING and IL1β, indicating a functional interplay between SMARCA4 and NF-κB. Taken together, our findings provide the mechanistic basis for the poor response of SMARCA4-mutant tumors to anti-PD1 immunotherapy and establish a functional link between SMARCA4 and NF-κB on innate immune and inflammatory gene expression regulation.

#906 High K+ in tumors impairs T cell effector activity via lysosomal acidification-induced autophagy.

Robert L. Eil, Chelsea Jenkins, Jessica Briones, Matthew McWhorter, Alexandra Bartlett

Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Effective antitumor T cell response necessitates nutrient uptake and utilization. Here, we demonstrate that potassium (K^+) accumulation within the tumor microenvironment (TME) drives adaptive changes in T cell metabolism via K^+-dependent lysosomal acidification. We found that lysosomal acidification promotes a catabolic state in $CD8^+$ T cells that persists independently of extracellular glucose levels (i.e. functional caloric restriction) and limits T cell effector functions while enhancing persistence.We previously identified a specific elevation in extracellular K^+ ($\uparrow[K^+]_{ex}$) within tumors, which dampens mTOR activation and effector functions in both CD8+ and CD4+ T cells (Eil et al, *Nature* 2016). $\uparrow[K^+]_{ex}$ increased intracellular K^+ ($[K^+]_{in}$) and drove selective mitochondrial acetyl-CoA accumulation at the expense of nuclear histone acetylation, enhancing mitochondrial function and limited epigenetic programming of T cells (Eil & Vodnala et al, *Science* 2019). Here, we report that $\uparrow[K^+]_{ex}$ in the TME also produced reduced glycolytic flux, even in the presence of abundant glucose, highlighting a rerouting of nutrient processing under K^+-rich conditions. The prior theoretical model of K^+ as a solely a regulator $V_{m,}$ and thereby TCR induced Ca^{2+} influx, fails to account for the metabolic reprogramming observed under K^+-rich conditions in the TME.To support the development of a new model defining effective ionic T cell responses to the high K^+ TME, we pursued an *in vivo* CRISPR-Cas9 screen targeting ion transporters in a syngeneic melanoma model. Our results pointed to the critical role of lysosomal H^+ importers in $CD8^+$ T cell persistence. Genetic or pharmacologic enhancement of lysosomal H^+ importers augmented autophagy, lysosomal acidification and function, and T cell persistence. Moreover, while $\uparrow[K^+]_{ex}$ enhanced lysosomal acidification and persistence, genetic depletion of $[K^+]_{in}$ produced lysosomal de-acidification, unleashed Akt-mTOR activation, and compromised persistence. These findings reveal lysosomal pH as a key determinant of T cell persistence in the TME, highlighting a mechanism of dynamic metabolic adaptation of T cells required to perform in differential ionic environments.Our findings suggest a model whereby lysosomal ion transport governs T cell adaptation, underscoring nutrient processing, in addition to availability, as a significant mediator of metabolism. The interplay between $[K^+]_{in}$ and lysosomal pH highlights novel intervention points for genetic and pharmacologic interventions modulating T cell function in cancer immunotherapy.

#907 Identification of a stem cell-specific secretory immune regulatory ligand.

Benjamin T. Nicholson, Ama Ofori, Jennifer Good, Weijie Guo, Yuxuan Miao

Ben May Department for Cancer Research, University of Chicago, Chicago, IL

Immunotherapies have transformed cancer treatment, but subsets of patients experience differential responses. Patients with squamous cell carcinomas (SCCs) in various tissues exhibit a high rate of relapse after their initial response to immunotherapies. Recent research highlighted the critical roles of a group of stem cell-like tumor-initiating cells (TICs) in driving the relapse of both cutaneous (CSCCs) and head and neck (HNSCCs). These TICs exhibit superior resistance to anti-tumor immunity despite their intact antigen presentation. Although TICs are the root cause of SCC relapse, they compose less than 5% of the total tumor cell population. Therefore, their unique immune resistance mechanisms have been largely overlooked. Here, we aim to identify the special immune regulatory mechanisms that are specifically activated in TICs endowing them with stronger immune resistance. By analyzing single-cell RNA-seq data profiling the gene signatures of various tumor populations in CSCCs, we identified cytotoxic T lymphocyte antigen 2a (*Ctla2a*) was specifically activated in TICs. Ctla2a is characterized as a cysteine peptidase inhibitor and has high homology to the I29 inhibitory domain in the proregion of mouse and human cathepsins. Silencing *Ctla2a* in SCC cells reduced tumor growth, enhanced CD8+ T cell infiltration, and elevated their antigen-specific cytotoxicity. Importantly, we have found that the conditioned medium collected from SCC cells overexpressing *Ctla2a* is sufficient to blunt the cytokine production of CD8 T cells, suggesting that Ctla2a proteins are secreted from TICs to modulate T cell immunity. Ongoing aims focus on 1) how the peptidase inhibitor activity of Ctla2a reduces cytotoxic cytokine production in CD8+ T cells and 2) whether the I29 inhibitory domain of human cathepsins is capable of conferring the immune-suppressive activity observed in Ctla2a expressing SCCs. Taken together, these results suggest that TICs can secrete these cathepsin inhibitory peptides to perform moonlighting functions and modulate CD8+ T cell anti-tumor cytotoxicity. This interaction may serve as a target for next-generation immunotherapy that is able to blunt TIC-specific immune resistance.

#908 Decoding the role of intrinsic pancreatic cellular signaling in shaping the immunosuppressive tumor microenvironment.

Bushangqing Liu, Ethan Agritelley, Junping Wei, Gangjun Lei, Tao Wang, Jason McBane, Daniel Nussbaum, Zachary Hartman

Duke University School of Medicine, Durham, NC

Background: Pancreatic ductal adenocarcinoma (PDAC) has the highest mortality rate among major cancers, with over 50% of patients having liver metastases at diagnosis. Given that conventional T-cell based immunotherapies have been ineffective against PDAC liver metastases, it is vital to elucidate the mechanisms regulating tumor immunity within the hepatic microenvironment to enhance anti-tumor T cell. Notably, PDAC cells exhibit exceptional plasticity and intrinsic heterogeneity, contributing to the evolution of immunosuppressive primary and early liver PDAC metastases. Our study leverages an array of congenic PDAC clones with varying degrees of immunogenicity to delineate the signaling pathways driving primary and liver immunosuppression.
Methods: We investigate the growth kinetics of PDAC clones both in vitro and in vivo, alongside their transcriptomic variations. Using model antigens (chicken ovalbumin), we assess how different clones modulate the immune microenvironment to elicit antigen-specific adaptive anti-tumor responses. Transcriptomic profiling informs CRISPR-based knockout and overexpression strategies to uncover intrinsic gene contributions to primary anti-tumor immunity in vivo. Additionally, we have developed stable PDAC liver metastasis models through portal vein injection to evaluate each clone's metastatic efficiency and associated immune landscape within the hepatic microenvironment.
Results: In vivo engraftment of PDAC clones revealed differential infiltration of CD4+/CD8+ T cells and neutrophils. While all OVA+ PDAC clones triggered antigen-specific immune responses, only immune-sensitive tumors were eradicated, whereas immune-insensitive tumors persisted. Despite OVA expression, all clones successfully established liver metastases following intraportal injection. RNA-seq analysis identified upregulation of key pancreatic development regulators, including PDX1 and RBPJ, in immune-insensitive clones. CRISPR knockout of these transcription factors in vivo demonstrated altered immune cell composition and reduced tumor growth in immunocompetent mice expressing OVA.
Conclusion: Using diverse PDAC models, we created tumors with immune heterogeneity and altered transcriptional profiles. We identified validated immune-altering cytokines (CXCL1 and CSF3) and immunomodulatory roles of PDX1 and RBPJ. Immune-insensitive clones evaded antigen-specific immunity in both subcutaneous and liver metastasis models, while immune-sensitive clones were eradicated subcutaneously but gained protection in the liver. Ongoing studies confirm the phenotypes of CRISPR-KO clones and delineate the immunomodulatory roles of these transcription factors in liver metastasis.

#909 A new chemokine identified as a key player of tumor immune microenvironment remodeling in β-catenin mutated hepatocellular carcinoma.

Justine Vache[1], Camille Dantzer[2], Isabelle Mahouche[3], Ramazan Akyol[4], Adel Hammoutene[5], Paulette Bouliac-Sage[3], Valerie Paradis[5], Violaine Moreau[3], Clotilde Billottet[1]

[1]Universite de Bordeaux, Inserm U1312 BRIC, Bordeaux, France,[2]University of Stuttgart, Institute of Cell Biology and Immunology, Stuttgart, Germany,[3]Inserm U1312 BRIC, Bordeaux, France,[4]Centre d'Immunologie de Marseille-Luminy, Marseille, France,[5]Hopital Beaujon, Inserm 1149 Research Center on Inflammation, Paris, France

The emergence of immunotherapy has revolutionized the treatment landscape for advanced hepatocellular carcinoma (HCC), significantly enhancing patient survival. However, accumulating evidence indicates that two-thirds of HCC harboring oncogenic mutations in the β-catenin coding gene (*CTNNB1*) exhibit resistance to immunotherapy. These tumors are largely devoid of immune infiltrates, highlighting a critical mechanism of immune escape. To investigate this phenomenon, we developed two 3D liver cancer spheroid models using a β-catenin-wild-type cell line (Huh7) and a β-catenin-mutated cell line (HepG2) co-cultured with PBMC (Peripheral Blood Mononuclear Cells). Flow cytometry analyses revealed that β-catenin mutation significantly impairs immune cell infiltration, particularly by Natural Killer (NK) cells. Our global transcriptomic analysis conducted in HepG2 cell line identified a specific chemokine, referred to here as CXX*, which is downregulated by mutated-β-catenin. In 2D and 3D cultured models, depletion of the mutated β-catenin in HepG2 cells led to an increase in CXX expression and secretion while β-catenin pathway overactivation in Huh7 cells induced its decrease. As CXX is known to recruit NK cells, we investigated the impact of its depletion or overexpression on immune cell infiltration in Huh7 and HepG2 spheroids. Our results demonstrated that CXX indeed plays a key role in the recruitment of NK cells in both models. In silico transcriptomic analysis of HCC patient cohorts corroborated these findings, revealing reduced *CXX* expression and diminished NK cell markers in tumors harboring β-catenin mutations, with these two results being positively correlated. Additionally, we report both a decrease in CXX expression and a reduced infiltration of NK cells in tumor sections from HCC patients with β-catenin mutation. Preliminary data obtained from supernatants of HCC patient Precision-Cut Liver Slices (PCLS) also revealed a reduction of CXX secretion by PCLS obtained from patients bearing the β-catenin mutation. In conclusion, our results identify CXX as a novel negative target of oncogenic β-catenin and provide new insights into how β-catenin mutations reshape the tumor microenvironment of HCC, enabling immune evasion. *A patent is in progress.

#91 Mechanistic insights on the regulation of IL-1β expression by the androgen receptor in prostate cancer cells.

Yetunde Oyende, Jaden Drumm, Anthony DiNatale, Alessandro Fatatis

Pharmacology and Physiology, Drexel University College of Medicine, Philadelphia, PA

Prostate cancer (PCa) in its early stages is driven by the activation of androgen receptor (AR) signaling. Local treatment modalities such as surgery and radiation cure most patients with locally confined or low-grade disease. However, over time, ~20% of patients recur with metastatic tumors and are treated with androgen deprivation therapy (ADT) and AR inhibitors (ARIs) but eventually develop incurable metastatic castration-resistant prostate cancer (mCRPC). A significant fraction of metastatic tumors in PCa harbor cancer cells that lack AR expression (AR^{Neg}). We have previously reported that AR^{Neg} cancer cells express IL-1β, which promotes bone colonization of PCa and other cancers. We have shown that this results from constitutively transcriptional repression by the AR, which binds to a half-ARE on the IL-1β promoter. Thus, we reveal that exposure to ADT and/or ARIs also results in the de-repression of IL-1β transcription in PCa cells that express AR. Here, we extend these studies to other AR variants and show that similarly to AR full-length, AR-V7, a constitutively active AR-variant, also represses the transcription of the IL-1β gene. These findings have high clinical relevance since the current targeting of AR – and possibly of AR-V7, which is detected in ~70% of mCRPC patients, would unleash the pro-metastatic effects of IL-1β. We also present evidence that histone deacetylases directly interact with the AR and act as co-repressors of IL-1β transcription. Furthermore, we found that IL-1β production in PCa cells is independent of inflammasome and caspase 1-8 recruitment. Finally, we show that IL-1β downregulates AR expression and alters EMT markers in PCa cells. Taken together, these findings help delineate a likely scenario of functional interactions occurring in metastatic tumors harboring PCa cells with mixed AR status, either *ab initio* or promoted by AR targeting. We propose that combining ADT/ARIs with inhibitors IL-1β signaling will address both the presence of AR^{Neg} PCa cells and unintended consequences of therapy-induced AR inhibition in the metastatic niche.

Introduction and purpose:
Lung squamous cell carcinoma (LUSC) is an aggressive tumor type accounting for 30% of all lung cancers, with a roughly 30% 5-year survival. The genetic nature of these tumors precludes the use of targeted therapies and the standard immunotherapy, either alone or in combination with chemotherapy, results in response rates below 50% after biomarker selection. Better patient selection for immunotherapy regimens requires a better definition of the molecular and immune landscape of LUSC. The purpose of this study is to comprehensively characterize the molecular, clinical and immune context of LUSC to identify novel biomarkers that can guide treatment decisions and to find novel therapeutic targets.
Experimental procedures:
A multiparametric study including a targeted DNA and RNA sequencing of genes related to tumor-immune system crosstalk was conducted in a cohort of 98 early-stage LUSC patients. Histopathological features including immune infiltrate and metabolic traits were defined by in the LUSC tissues. Consensus clustering algorithm classified the sample transcriptomes, and all this data was cross-analyzed with clinical, molecular and immune annotations.
Results:
Computational analysis of immuno-oncology gene expression data from 98 LUSC tumors led to the classification in 4 patient subgroups with specific molecular and immune characteristics. Interestingly, we found a genomic amplification of the chromosome region 3q, present in almost 30% of the patients, strongly associated with the low immunogenic, as previously shown, and high tumorigenic subgroup. To know the mechanism behind this robust association and given the nature of relevant genes in this region, we analyzed iron accumulation in the tumor samples. We found that iron-positive tumors showed a reduced infiltration of $CD8^+$ T cells compared to iron-negative tumours. The same tendency was observed in CD4, CD20 and CD68 analyses, further supporting an association of this amplification and iron accumulation with a low immunogenic tumor profile. These results were validated in an independent cohort of early-stage LUSC.
Conclusions:
Taken together, our results support the possible connection between iron accumulation and 3q amplification as a mechanism for immune exclusion in LUSC. We believe that this molecular alteration can be clinically relevant as a biomarker for immunotherapy selection in LUSC, at least in a neoadjuvant setting. Whether this association applies to other squamous carcinomas or might represent novel therapeutic vulnerabilities ensures further research

#911 Cancer stem cells establish intrinsic immune resistance through suppressing IFN-mediated antitumor immunity.
Xuejie Huang, Weijie Guo, Yuxuan Phoenix Miao

University of Chicago, Chicago, IL

Although the cancer immunotherapy has generated promising outcomes in the clinics, a substantial proportion of cancer patients either show resistance to immunotherapy or experience relapse following an initial response. This issue is particularly urgent for patients with squamous cell carcinomas (SCCs), highlighting the critical need to understand the mechanisms behind immune evasion and immunotherapy resistance in these cancers. Recently, our lab identified a subset of tumor-initiating stem cells (tSCs) in skin and head/neck SCCs that respond to transforming growth factor β (TGF-β) and play a key role in driving tumor relapse post-immunotherapy. Notably, these tSCs are resistant to T-cell attacks despite retaining functional antigen presentation, resulting in only transient responses to immune checkpoint blockade therapy across SCC types. Here, my current study has uncovered a central role for Sox2 as a master regulator that drives immune resistance in TGF-β-responsive tSCs. Through RNA-seq and qPCR analyses, we observed that Sox2 amplification in tSCs significantly blunted their interferon-γ (IFN-γ) responsive potentials. Mechanistically, we found that Sox2 neither blocks IFN-γ signaling transduction nor directly binds to the enhancers or promoters of most IFN-γ-induced genes. Instead, we discovered that the reduced IFN-γ response in Sox2-overexpressing cells is likely due to the altered Stat1-mediated transcriptional repression. This study uncovered a stem cell specific transcription regulation that provides new insights in developing new strategies to abolish tSC-specific immune resistance.

#914 Differential expression of Cbl-b in tumor infiltrating immune cells in patients with solid tumors.

Elli Narvi[1], Reetta Virtakoivu[1], Endrit Elbasani[1], Nelson Kibinge[2], Laura Ravanti[2], **Anil K. Thotakura**[1]

[1]Immuno-Oncology, Orion Corporation, Turku, Finland,[2]Orion Corporation, Turku, Finland

Introduction: To mechanistically elucidate the differences in the cancer patient clinical response, several pre-clinical and clinical biomarker studies have suggested the existence of several novel intracellular immune checkpoints. Casitas B cell lymphoma (Cbl-b) is an intracellular immune checkpoint protein that impedes the T cell and NK cell function.

Methods: Immunohistochemistry (IHC) analysis was performed on the tissue micro array (TMA) from five different cancer indications (n=25) and healthy tissue controls (n=5). TMAs were stained utilizing commercially available IHC antibodies for Cbl-b, CD8, CD56 and FoxP3, nuclei were stained with DAPI. For in vitro studies, T cells were activated with anti-CD3/CD28 and NK cells with recombinant human IL-2 and IL-15. SiRNA mediated Cbl-b silencing in primary T and NK cells was also confirmed by western blot analysis and the effects of Cbl-b silencing were evaluated by measuring IFN-γ, IL-2, TNF-α and Granzyme-B accumulation by ELISA. For single-cell analysis, we leveraged publicly available Gene Expression Omnibus (GEO) data to perform an in-depth single-cell analysis of *CBLB* expression in different immune cell-types. This workflow included quality control, normalization, dimensionality reduction, clustering and cell type annotation

Results: Compared to healthy tissue controls, tumors have high number of Cbl-b positive immune cells. The proportion of Cbl-b positives CD8 T cells and CD56 NK cells varied between indications. Interestingly, $FoxP3^+$ regulatory T (Treg) cells have low levels of Cbl-b. The IHC observations was complemented by scRNA sequencing data. Consistent with the published data, Cbl-b silenced immune cells (T and NK cells) showed rapid activation and cytokine production as assed by a significant increase in IFN-γ, IL-2, TNF-α and Granzyme-B levels. Furthermore, Cbl-b silenced T cells are dependent on TCR alone and become independent of CD28 co-stimulation. Interestingly, the basal level of Cbl-b expression is high on NK cells compared to T cells, but upon TCR activation Cbl-b expression in T cells was rapidly increased while in NK cells IL-2 and IL-15 cytokine activation did not alter the CBL-B expression as assessed by western blot.

Conclusion: Previous studies have established the role of Cbl-b in suppressing T cell and NK cells function, however, differential expression of Cbl-b and Cbl-b expression kinetics in different immune cell type remained unknown. Using IHC method and scRNA sequencing, we found that the Cbl-b expression is high in CD8 and NK cells, and low in Treg cells. Furthermore, in vitro Cbl-b silencing and Cbl-b expression in TMA suggest that silencing or inhibiting Cbl-b in T cells and NK cell is a valid approach.

#916 Tumor extracellular vesicles trigger a dendritic cell stress response to promote immune evasion and immunotherapy resistance.

Mandy Wang, Michael Plebanek, Kaylee Villarreal, Nicholas C. DeVito, Bala Theivanthiran, **Brent A. Hanks**

Medicine, Pharmacology and Cancer Biology, Duke University Medical Center, Chapel Hill, NC

Previous studies have demonstrated dendritic cell (DC)-mediated T cell activation to be impaired within the tumor microenvironment (TME). This has included studies showing that activation of XBP1 within the unfolded protein response (UPR) pathway triggers lipid accumulation by DCs within the TME, however the signal mediating XBP1 activation has remained unclear. We have previously demonstrated that fatty acid oxidation (FAO) as well as the activation of the SREBP2-dependent mevalonate biosynthetic pathway leads to the development of mregDCs in the TME, exhibiting impaired antigen cross-presentation and an enhanced capacity to drive regulatory T cell (Treg) differentiation. Despite the critical role of the DC in orchestrating anti-tumor immunity, there are currently no therapeutic strategies to augment their function. Using an autochthonous model of $BRAF^{V600E}$ melanoma, we demonstrate that tumor-dependent generation of extra-cellular vesicles (ECVs) suppresses anti-tumor immunity and supports tumor progression. Using bulk and single-cell RNA sequencing analysis, we show that tumor ECVs upregulate various components of the UPR pathway in conventional DCs (cDCs), including IRE1alpha-XBP1 and SREBP2 activation based on qPCR and Western blot studies. We further show that XBP1 activation leads to PPARalpha nuclear translocation and enhanced FAO. We verify that lymph node DC populations engulfing labeled tumor ECVs harboring a CD81-GFP fusion protein also exhibit both enhanced XBP1/PPARalpha activation as well as the transcriptional signature of mregDCs. Together, these ECV-dependent effects suppress DC-mediated antigen cross-presentation and $CD8^+$ T cell activation while promoting DC-dependent Treg differentiation *in vitro* and *in vivo*. Additional studies were conducted showing similar effects generated by ECVs derived from models of colon and breast cancer. We subsequently found DC-specific knock-out of PPARalpha to partially reverse the effects of tumor ECVs on DC functionality in an engineered transgenic murine model. Indeed, a PPARalpha antagonist, TPST-1120, overcomes resistance to anti-PD-1 immunotherapy in a poorly immunogenic autochthonous melanoma model while suppressing DC lipid stores and DC FAO *in situ*. Together, this work suggests that pharmacologic targeting of pathways elicited by tumor-derived ECVs can reverse DC tolerization in the TME and overcome immunotherapy resistance in select tumors. Understanding which tumors rely on ECVs to suppress anti-tumor immunity will be a critical step in prospectively developing targeted therapeutics to block these immune evasive pathways and enhance the efficacy of checkpoint inhibitor immunotherapy.

#918 Tumor-induced interleukin 16 (IL-16) is associated with suppression of antitumor functions of NK cells in ovarian cancer.

Animesh Barua[1], James T. O'Donnell[2], Dale B. Hales[3], Janice M. Bahr[4]

[1]Oncology, Simmaron Research Inc, Milwaukee, WI,[2]Pharmaconsultant Inc, Barrington, IL,[3]Physiology, Southern Illinois University, Carbondale, IL,[4]Animal Science, University of Illinois at Urbana Champaign, Urbana-Champaign, IL

Background: Natural Killer (NK) cells kill tumor cells directly and provide first line of defense against the development and progression of ovarian cancer (OVCA). OVCA progresses mainly through local diffusion by suppression of NK cells. Factors and mechanism(s) involved in tumor-induced NK suppression are unknown. Such information is critical to develop NK-targeted therapies and OVCA prevention as current immunotherapies including T-cell targeted ones show poor efficacies against OVCA. Ovarian and fimbrial tissues are persistently exposed to inflammation/stress due to ovulation or infection and accompanied with high expression of interleukin 16 (IL-16), a proinflammatory cytokine. IL-16 is suggested to be associated with malignant transformation and secretion of IL-15 by ovarian tumors. IL-16 may play a role in suppression of NK cells by exhausting them through persistent stimulation by IL-15, a stimulator of NK cells. The goal of this study was to examine if tumor-induced IL-16 is associated with suppression of NK cell functions during OVCA development and progression and if so, to determine the mechanism of IL-16-induced suppression of NK cell functions.
Materials and Methods: Association of ovarian/fimbrial tumor-induced IL-16 expression with the suppression of anti-tumor functions of NK cells was examined in an exploratory study using laying hen model of spontaneous OVCA. Fimbrial and ovarian tissues from normal hens (n=10, 3-4 years old), hens with early (n = 8) and late stage OVCA (n = 10) were examined. Tissue expression of IL-16, GRP78 (glucose regulated protein 78, a marker of cellular stress), NK cells (CD56+), IL-10/IL-15 and CISH (a marker of NK cell exhaustion) were examined. Changes in the frequencies of immunopositive cells or intensities of their expression and association among them during OVCA development were determined. Data were analyzed by ANOVA and t-test and significance was taken when $P<0.05$.
Results: Frequency of IL-16-expressing cells and intensities of GRP78 expression were significantly ($P<0.001$) increased during OVCA development. Frequency of NK cells in tumor stroma was significantly higher in hens with early and late stage OVCA than normal hens ($P<0.001$). IL-16 expression was positively correlated with IL-15 expression. However, frequency of intratumoral NK cells was not increased significantly in late stage than early stage OVCA suggesting that OVCA progresses with reduction in intratumoral influx of NK cells. It is possible that consistent exposure of NK cells to persistent high levels of tumor-induced IL-15 might be a reason.
Conclusion: The results of this study suggest that enhanced IL-16 expression during malignant transformation may inhibit intra-tumoral influx of NK cells. Thus, tumor-induced IL-16 offers a potential target for immunotherapy to enhance anti-tumor functions of NK cells.
Support: Ovarian Cancer SPORE, Roswell Park.

#919 Regulation of PS externalization on tumor cells by TMEM16F and P2X7 receptors.

Rachael Pulica[1], Varsha Gadiyar[1], David C. Calianese[2], Mariana De Lorenzo[3], Raymond B. Birge[1]

[1]Microbiology, Biochemistry, and Molecular Genetics, Rutgers Graduate School of Biomedical Sciences, Newark, NJ,[2]Osaka University, Suita, Osaka, Japan,[3]Cell Biology and Molecular Medicine, Rutgers Graduate School of Biomedical Sciences, Newark, NJ

Immune evasion in the tumor microenvironment (TME) is critical for tumor progression, and many therapeutic strategies are under development to activate host anti-tumor immunity. Tumors avoid immune detection and clearance through several mechanisms, one of which is the chronic externalization of the phospholipid phosphatidylserine (PS) to the outer leaflet of the plasma membrane. Externalized PS on tumor cells alters the tumor microenvironment to an immunosuppressive phenotype. Immune cells expressing PS-binding TAM (Tyro3, Axl, MerTK) receptors interact with the tumor-exposed PS and release immunosuppressive cytokines, leading to the polarization of the TME to pro-tumorigenic. While it is understood how PS is externalized by calcium-induced scramblase TMEM16F in non-pathological conditions and caspase-cleaved scramblase Xkr8 in apoptotic conditions, the mechanism through which the constitutive externalization of PS on tumor cells occurs is still unknown. We hypothesize that the increased concentration of calcium in tumor cells activates TMEM16F to externalize PS, and the increased levels of extracellular ATP bind P2X7 receptors (P2X7R), further leading to PS externalization in the TME.

To better understand the mechanisms of PS exposure under oncogenic stress, we have developed both TMEM16F and P2X7R CRISPR knockout EO771 breast cancer cell lines. These cells are unable to externalize PS when subjected to their respective triggers (calcium or ATP). They have additionally been shown to be unable to upregulate immune-suppressive MerTK signaling upon exposure to their PS-externalizing triggers, whereas wild-type EO771 cells show large upregulation in MerTK binding upon treatment. Orthotopic injection into the mammary fat pad of C57/Bl6 mice yielded a reduction in tumor size in TMEM16F knockout tumors compared to the wild-type EO771 tumors (P2X7R knockout tumor experiments are ongoing). Based on these studies, we show that both calcium-induced TMEM16F and ATP-binding P2X7R contribute to the externalization of PS and immune suppression in the TME, resulting in tumor growth and progression. Our studies add new insights to how PS acts as an immunosuppressive signal in the tumor microenvironment.

TUMOR BIOLOGY: Molecular Regulation of Metastasis

#92 The role of AKT3 in prostate cancer.

Dineen Vogler[1], Seamus Degan[2], Henry Withers[1], Irwin Gelman[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]University of North Carolina at Chapel Hill, Chapel Hill, NC

The five-year survival rate for metastatic prostate cancer (mPC) patients remains significantly lower than that of patients with primary prostate cancer (PC). The loss of PTEN, a lipid phosphatase that negatively regulates PI3K/AKT pathway, is one of the most frequent mutations in prostate cancer. Although AKT inhibitors seem promising for mCRPC patients, they often perform poorly in the clinic as monotherapies. We hypothesize that this poor response to AKT inhibitors may be due to a failure to account for the distinct and opposing roles of AKT isoforms. Previously published data from our lab suggests that AKT2 and possibly AKT3, are the mediators of PC progression while AKT1 is responsible for PC development. To further investigate the mechanisms underlying AKT isoform plasticity in the context of PTEN loss, we conducted a phosphoproteomics analysis that identified *Akt* isoform-specific substrates using T402 (mouse prostate epithelial cells with $PTEN^{-/-}/Rb^{-/-}$) and T402[PTEN] (T402 cells with PTEN re-expression). We identified both canonical (RXRXXS/T*P) and novel non-canonical phosphorylation motifs. Interestingly, more substrates were associated with *Akt3* compared to *Akt1 and Akt2*, indicating that *Akt3* may be an underappreciated driver of PC progression. Furthermore, *Akt3* was found to preferentially phosphorylate substrates with non-canonical motifs. However, the direct mechanisms through which AKT3 and its substrates contribute to PC progression and metastasis remain unclear. From our phosphoproteomics analysis, we identified $PAK4^{S181}$ as a potential *Akt3* direct substrate. Knockdown of PAK4 in PTEN deficient PC cells resulted in a greater reduction in chemotaxis compared to PTEN intact PC cells. We hypothesize that AKT3 directly phosphorylates $PAK4^{S181}$ to promote PC metastatic progression. These studies will provide a functional characterization of the downstream activity of AKT3, through substrate usage, to aid in the development of an AKT3 specific inhibitor. This research highlights the importance of discovering biomarkers to unveil a more targeted approach toward treating advanced stage prostate cancer patients.

#920 Determining the role of Siglecs in macrophage mediated immune evasion in prostate cancer.

Nathan S. Lam, **Ru M. Wen**, James D. Brooks

Urology, Stanford University School of Medicine, Stanford, CA

Siglecs (sialic acid-binding immunoglobulin-like lectins) are a family of cell surface proteins that are mainly expressed in immune cells. Recent studies show that Siglecs play important roles in immune evasion for tumors. We previously reported that Siglec-7 and Siglec-9 contribute to immune evasion by interacting with their ligands in prostate cancer, and blocking these interactions inhibits prostate cancer tumor progression. Further, Siglec-7 and Siglec-9 are highly expressed in macrophages in metastatic human prostate tumors. However, how macrophages mediate immune evasion via Siglec-dependent pathways remains unknown. Here, we have found that Siglec-7 and Siglec-9 are expressed in monocyte-differentiated macrophages derived from peripheral blood mononuclear (PBMC) cells. We will further profile Siglec expression in macrophages derived from PBMC and tumor tissues from patients with prostate cancer. The Siglecs on macrophages will be modulated, and their function will be evaluated through in vitro and in vivo models. Our study will provide insight into understanding macrophage-mediated immune evasion through Siglec-dependent mechanisms.

#921 SOX11-mediated antigen presentation suppression: A mechanism of immune evasion in triple-negative breast cancer.

Salomat Abdulkhuseynova[1], Ashok Pullikuth[2], Lance Miller[2], Shay Soker[1]

[1]Department of Cancer Biology and Wake Forest Institute for Regenerative Medicine, Wake Forest University School of Medicine, Winston-Salem, NC,[2]Department of Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype with no targeted therapies and limited response to immunotherapy. TNBC evades immune surveillance by repressing antigen presentation machinery (APM) genes, reducing MHC Class I expression. Using bioinformatics, we identified SOX11 as a potential transcriptional regulator associated with APM suppression and immune evasion in TNBC.

Methods: Gene expression data from basal breast cancer (BRCA) tumors (n = 189) in TCGA and cancer cell lines (n = 1,189) in DepMap were analyzed. Spearman correlation coefficients were used to evaluate associations between a T-cell infiltration signature (e.g., CD3, CD8) and an APM signature (e.g., TAP1, TAP2, B2M, HLA-ABC). SOX11 was prioritized as it was strongly negatively correlated with both signatures. Differential expression analysis of SOX11-overexpression (OE) and knockdown (KD) datasets confirmed potential downstream targets, including MEX3A. To validate, SOX11 KD was performed in CAL-148 cells (high level of endogenous SOX11) using siRNA for 96 hours. Western blot assessed SOX11 and MEX3A protein levels, while flow cytometry measured surface MHC Class I (HLA-ABC) expression.

Results: SOX11 was strongly inversely correlated (rho < -0.4, adjusted $p < 0.01$) with APM and T-cell infiltration signatures in basal BRCA and DepMap datasets. In basal BRCA tumors, SOX11 expression was enriched in T-cell cold tumors compared to T-cell hot tumors ($p < 0.01$). Reanalysis of SOX11-modulated datasets (KD and OE) confirmed APM-suppressive downstream targets, with MEX3A showing a strong co-expression pattern (Spearman $p<0.05$). SOX11 KD in CAL-148 cells significantly reduced MEX3A protein levels and increased surface HLA-ABC expression. These findings suggest that SOX11 represses antigen presentation pathways, contributing to immune evasion in TNBC.

Conclusions: SOX11 suppresses HLA-A/B/C expression and may contribute to immune evasion in TNBC. Its high expression in T-cell cold tumors and its regulation of APM targets, including MEX3A, highlight its potential as a therapeutic target. Targeting SOX11 could restore antigen presentation, promote immune recognition, and enhance immunotherapy responses in TNBC.

#922 Mutant KRAS enhances immune evasion via epitranscriptomic regulation of NT5E in colon cancer.

Seungjae Shin, Yoojin Yang, Sung-yup Cho

Seoul National University, Jongno-gu, Korea, Republic of

Colorectal cancer (CRC) is the third most common cancer and the second leading cause of cancer-related deaths worldwide. Mutation in KRAS occurred in approximately 40% of patients, and leading to resistance to FDA approved anti-EGFR agents. Also, CRC patients harboring KRAS mutations do not respond well to immune checkpoint blockades. Therefore, additional therapeutic strategies to overcome KRAS mutations are strongly required. In recent years, N6-methyladenosine (m6A) modification on mRNA has been recognized for its significance in various cancer phenotype. This modification plays a crucial role not only in cancer cell behavior but also in shaping the tumor microenvironment (TME). Many studies about m6A in cancer focus on the direct roles and effects of m6A regulators. These regulators include writers, which attach m6A to RNA; erasers, which remove it; and readers, which bind to m6A to regulate the fate of mRNA. However, how oncogenic mutations affect the landscape of m6A deposition remains poorly understood. To explore the impact of KRAS mutations on m6A modifications, we performed MeRIP-seq and discovered significant changes, particularly in NT5E/CD73, a molecule known for its immune suppressive role in the TME. Our result suggest the potential for developing novel therapies by modulating the KRAS-m6A-NT5E axis in KRAS-mutated colorectal cancer.

#923 The role of NNMT in anti-tumor immunity in LKB1 deficient NSCLCs.

Thi Na Nguyen, Wenjing Na, Pawel Nowialis, Thi Kim Ngan Bui, Kunyang Li, Ryan Clay, Lina Song, Lingtao Jin

Molecular Medicine, UT Health Science Center at San Antonio, San Antonio, TX

Lung cancer is the leading cause of cancer-related deaths with non-small cell lung cancer (NSCLC)accounting for 85% of all lung cancers. Loss or inactivating mutations of serine/threonine kinase STK11 encoding the LKB1 protein occurs in approximately 20% of lung adenocarcinoma (LUAD). Although treatment of NSCLCs with immune checkpoint inhibitors (ICI) has responded in overall survival in a subset of patients, studies have revealed that co-occurring KRAS/LKB1 mutations promote primary resistance to ICIs in NSCLCs, the mechanism of which is still not completely understood. Nicotinamide N-methyltransferase (NNMT) is a metabolic enzyme that catalyzes the methylation of nicotinamide (Nam) using the co-factor S-adenosyl-L-methionine to form 1-methyl-nicotinamide (1-MNA). In this study, we discovered that levels of NNMT and its product 1-MNA are elevated inNSCLCs with loss of function of LKB1. Mechanistically, we found that LKB1-SIK1/2/3 axisdirectly suppresses NNMT expression transcriptionally. Therefore, loss of function of LKB1 leadsto upregulation of NNMT and its products 1-MNA. Interestingly, knockout of NNMT or 1-MNA treatment did not impact cell proliferation or survival in NSCLC cells with or without functionalLKB1. Global metabolomic and transcriptomic studies revealed that 1-MNA promotes FOXP3induction and regulatory T cell (Treg) expansion, consequently leading to reduced CD8 T cellfunction both in vitro and in vivo. Knockout of NNMT in KPL cells ($Kras^{G12D}$Tp53/LKB1 KO)enhanced anti-tumor immune response and promoted ICI efficacy by suppressing Tregaccumulation in vivo. Importantly, NNMT inhibitor improves the therapeutic efficacy of anti-PD-1antibody in KPL model in vivo. The present study revealed that NNMT/1-MNA signaling plays animportant role in regulating Treg function in LKB1 deficient NSCLC. Targeting NNMT with smallmolecular inhibitor may hold promise to improve the efficacy of ICIs for LKB1 deficient NSCLCs.

#924 Tumor-initiating stem cells fine-tune the plasticity of neutrophils to sculpt a protective niche.

Weijie Guo, Jingyun Luan, Yuxuan Miao

University of Chicago, Chicago, IL

The abundant accumulation of neutrophils in various solid cancers has been well recognized, but the functions of tumor-associated neutrophils (TANs) remain controversial. TANs have long been believed to be immune suppressive and have thus been referred to as “myeloid-derived suppressor cells”. However, effective tumor control induced by immunotherapy was recently found to be associated with strong neutrophil signatures. These seemingly contradictory findings highlight the unexpected degree of plasticity and heterogeneity unique to TANs. How the cellular plasticity and functional heterogeneity of TANs are regulated remains unknown. Here, we show that, while anti-PDL1/CD40 agonist immunotherapy can induce interferon responses to reprogram many TANs, allowing them to regain anti-tumor activities in squamous cell carcinomas, a subset of TANs residing at the tumor-stroma interface can preserve their immune suppressive state. Importantly, we identified a group of $Sox2^{Hi}$ tumor-initiating stem cells (tSCs) at the tumor-stroma interface that could upregulate Fatty Acid Desaturase 1 (Fads1) to produce arachidonic acid. This tSC-specific pathway enhances the autocrine prostaglandin E_2 (PGE_2) signaling in TANs, which can disrupt their interferon responsive potentials, preventing the interferon-mediated reprogramming. Thus, by fine-tuning the plasticity of neutrophils, tSCs shape neutrophil heterogeneity, and sculpt a protective micro-niche to survive from immunotherapy and drive cancer relapse.

#925 Golgi-derived extracellular vesicles lack conventional tetraspanins and mediate immune evasion in cancer.

Ikjot Singh Sohal, Sydney N. Shaw, Lauren N. Meeks, Andrea L. Kasinski

Biological Sciences, Purdue University, West Lafayette, IN

Immunotherapy has significantly improved the survival of patients with various malignancies. However, immunotherapies have largely remained ineffective in tumors that have reduced infiltration of T cells, also called immune-cold tumors. Despite an extensive understanding of factors that mediate poor T cell infiltration, current therapies that target these factors have shown modest clinical benefit, indicating that other factors contribute to this process. One such factor that has been shown to contribute to immunosuppression are extracellular vesicles (EVs). However, due to significant EV heterogeneity, discovery of specific EV subpopulations that are responsible for these immunosuppressive effects has remained a challenge. Overcoming this challenge, we first established relevant lung cancer models to study EV-mediated T cell suppression and then identified a previously uncharacterized population of lung cancer-derived EVs that strongly inhibit the proliferation and activation of T cells. We further identified that this novel T cell-suppressive EV subpopulation originates from the *trans*-Golgi network and expresses the classic *trans*-Golgi marker protein, TGN46. In addition, the TGN46+ EV subpopulation lacks conventional EV markers CD81 and CD63. In the immunosuppressive lung cancer model, while total EVs suppress T cells, specifically removing the TGN46+ EV subpopulation ameliorated this effect. Conversely, overexpressing TGN46 in a lung cancer model that had no EV-mediated effect on T cells was sufficient to increase TGN46+ EV release and the ability of the EVs to suppress T cells, underscoring the physiological significance of the TGN46+ EV subpopulation. Analysis of patient data from The Cancer Genome Atlas (TCGA) indicates that high TGN46 expression (both transcript and protein) correlates with worse progression-free survival in lung cancer and overall survival in other cancer types - glioblastoma, lower grade glioma, testicular cancer, and large B-cell lymphoma. Most importantly, tumor-immune association analysis of TCGA data suggests that high tumor TGN46 expression significantly correlates with an immunologically-cold tumor signature, i.e., low infiltration of CD8+ T cells and activated NK cells, and high infiltration of M2 macrophages, across several cancer types, stressing the clinical relevance of our findings. The data elucidates that TGN46+ EVs are a novel factor that potentially contributes to immune-cold tumor microenvironment. How TGN46+ EVs suppress T cells mechanistically and their role in overall tumor microenvironment modulation are currently under investigation, which may inform strategies to enhance immunotherapy effectiveness in immune-cold tumors.

#926 Myeloperoxidase limits tumor-associated neutrophils mediated immunosuppression in pancreatic cancer.

Angisha Basnet, Kaitlyn M. Landreth, Tracy W. Liu

Microbiology, Immunology and Cell Biology, West Virginia University. School of Medicine, Morgantown, WV

Pancreatic ductal adenocarcinoma (PDAC) is a deadly disease with a survival rate under 13%. Treatments like immunotherapy and chemotherapy are ineffective in PDAC due to the immunosuppressive tumor microenvironment, in which tumor-associated neutrophils (TANs) are a major component. The immunosuppressive function of TANs has been shown to depend upon increased production of reactive oxygen species, with myeloperoxidase being a major source of it. We investigated the contribution of myeloperoxidase in mediating tumor-associated neutrophils immunosuppression using orthotopic PDAC models in wild-type and syngeneic myeloperoxidase-deficient mice. We observed a significant delay in tumor growth and improved clinical scores when myeloperoxidase was deficient. Additionally, treatment with the myeloperoxidase-specific inhibitor verdiperstat delayed tumor growth. Flow cytometry analysis of the tumor microenvironment revealed a significant increase in CD8+ T cells and natural killer (NK) cells in MPO-deficient mice, accompanied by elevated granzyme B levels in both cell subsets. Additionally, MPO deficiency was associated with increased expression of activation and memory markers among both CD8+ and CD4+ T cells. *Ex vivo* studies with isolated TANs from tumor-bearing mice showed reduced CD8+ T cell and NK cell suppression, and reactive oxygen species level in the absence of myeloperoxidase. These data suggests that loss of myeloperoxidase in TANs results in decreased immunosuppressive functions and increased cytotoxic and activated T cells and NK cells within the tumor microenvironment. Depletion of NK cells in myeloperoxidase-deficient mice abolished the antitumor effects observed with myeloperoxidase loss, underscoring the critical role of NK cells as key mediators of the antitumor response in the absence of myeloperoxidase. Additionally, we observed an enhanced chemotherapy (Gemcitabine) and immunotherapy (anti-PD1 and ant-CTLA4) response with myeloperoxidase deficiency. Overall, our results demonstrate the contribution of myeloperoxidase in regulating PDAC tumor progression, TAN immunosuppression, treatment response and immune cell infiltration using an orthotopic PDAC model.

#928 Advancing CAR-Ts and anti-immunosuppressive therapy development: Immunosuppressive TME 3D co-culture platform grounded on a fully characterized PDX tumor bank.

Mara Gilardi, Veena Jagannathan, Brandon Walling, BanuPriya Sridharan, Stefano Cairo, Marianna Zipeto, Michael Ritchie

Champions Oncology, Inc., Hackensack, NJ

Solid tumors represent a significant challenge in oncology due to their complex and highly immunosuppressive tumor microenvironment (TME). This hostile environment, shaped by immunosuppressive cytokines, and immune evasion mechanisms, limits the efficacy of immune-based therapies, including checkpoint inhibitors, chimeric antigen receptor (CAR) T cells, and bispecific antibodies. Although therapeutic strategies have been developed to overcome immune suppression, accurate preclinical models with predictive value remain critically needed. To address this, Champions Oncology has developed a robust ex-vivo 3D co-culture platform based on its extensive patient-derived xenograft (PDX) tumor bank, comprising over 1,500 fully characterized models. These models are annotated with comprehensive multi-omic data, including RNA sequencing, proteomic, and phospho-proteomic profiles, enabling the selection of tumor models aligned with specific indications, clinical history, and target expression, mimicking patient cohorts. The platform uses rigorously characterized organoids derived from this tumor bank as its core ensuring fidelity to the original tumor. Developing the ex-vivo immunosuppressive co-culture system requires careful integration of relevant cellular players, including human cancer-associated fibroblasts (CAFs), infiltrating immune cells such as M2-polarized macrophages, and tumor cells from 3D PDX organoids. Co-culture of these cell types creates a biologically accurate representation of the human TME. Here we describe a novel complex co-culture platform, with fully optimized conditions enabling the differentiation of cellular components and functional co-cultures. This system was used to test the potency of diverse CAR-T therapies engineered to overcome immune suppression. A custom high-throughput flow cytometry panel was developed to interrogate the system, measuring both cancer cell killing and immune activation. The co-culture system proved ideal for evaluating CAR-T cancer-killing capacity and understanding mechanisms of immunosuppression-mediated therapeutic resistance. Additionally, the platform supports testing combination therapies, such as checkpoint inhibitors paired with TME reprogramming agents, to combat resistance mechanisms. In conclusion, this ex-vivo co-culture platform represents a transformative tool in preclinical immuno-oncology. Combining a deeply characterized tumor bank with a robust organoid-based system enables testing anti-immunosuppressive therapies in a clinically relevant setting. This innovation promises to accelerate the development of next-generation therapies, offering unparalleled insights into tumor biology and immune dynamics to improve outcomes for patients with immunosuppressive tumors.

#929 Altered lipid metabolism drives immunotherapy resistance via an EGFR/CERS4/PD-L1/PGE2 signaling axis in solid tumors.

Wyatt O. Wofford, Han Gyul Lee, Bryan Granger, Elif Percin, Mohamed Faisal Kassir, Lucy Mulligan, Odai Darawshi, Paramita Chakarborty, Salih Gencer, Natalia Oleinik, Stefano Berto, Shikhar Mehrotra, Besim Ogretmen

The Medical University of South Carolina, Charleston, SC

Immunotherapy has transformed cancer treatment, yet durable responses to immune checkpoint blockade (ICB) are limited to a subset of patients. Identifying tumor-intrinsic resistance mechanisms is critical to improving ICB efficacy and outcomes. We recently identified crosstalk between lipid metabolism via the downregulation of ceramide synthase 4 (CerS4) and internalized programmed death-ligand 1 (PD-L1) signaling, which promotes metastasis and impairs ICB response. Our data also demonstrated that αPD-L1 therapy enhanced internalized PD-L1 signaling, suggesting a role in adaptive ICB resistance. To investigate the underlying mechanism, we established an E0771-allograft-based triple-negative breast cancer (TNBC) model of ICB resistance, E0771-2RA, through serial αPD-L1 treatment and subculturing of resistant tumors. The 2RA model is resistant to both αPD-L1 and αPD-1 therapy *in-vivo*, with reduced CerS4/ceramide levels and increased PD-L1 internalization, consistent with our prior findings. Whole transcriptomic RNA sequencing of E0771 and 2RA tumors revealed enrichment in epidermal growth factor receptor (EGFR) and prostaglandin E2 (PGE2) signaling in 2RA tumors. Mechanistically, we found that (1) EGFR signaling negatively regulates CerS4 expression; (2) CerS4 suppression enhances PD-L1 internalization and subsequent association with Caprin-1; and (3) the intracellular PD-L1-Caprin-1 complex stabilizes prostaglandin-endoperoxide synthase 2 (Ptgs2, Cox2) mRNA to promote PGE2 production. Immune profiling of E0771 and 2RA tumors using flow cytometry and single-nuclei RNA sequencing revealed M2 macrophage polarization, PMN-MDSC recruitment, and T cell dysfunction in 2RA tumors. However, pharmacological targeting of PGE2 signaling and exogenous CerS4/ceramide restoration in ICB-resistant 2RA tumors primarily alleviated T cell dysfunction, suggesting the T cell compartment is the primary target of this signaling axis. Single-nuclei RNA sequencing and CellChat analyses revealed abundant TGF-β signaling in 2RA tumors, which we found to regulate PD-L1 internalization *in-vitro,* presenting a possible therapeutic vulnerability. Thus, to target this mechanism, we combined αPD-1 therapy with TGF-β inhibition *in-vivo*, which restored ICB sensitivity and prolonged survival. Using TCGA and human ICB resistance datasets, we validated the link between EGFR, CerS4, PD-L1, and PGE2 signaling in TNBC, head and neck squamous cell carcinoma (HNSCC), and melanoma. Based on our mechanistic and sequencing data, we additionally curated a gene signature to predict ICB response vs. resistance in solid tumors. Our findings uncover a novel mechanistic link between altered CerS4-dependent lipid metabolism, EGFR, PD-L1, and PGE2 signaling and introduce mechanism-based therapeutic strategies for overcoming ICB resistance in solid tumors.

#93 Alternative splicing reveals epigenetic subtypes in gastric cancer peritoneal metastasis.

Joseph J. Zhao[1], Xiaonan Fan[2], Jia Jia Chan[2], Daryl Kai Ann Chia[3], Robert Walsh[1], Haoran Ma[4], Wei Peng Yong[5], Jimmy So[6], Patrick Tan[4], Yvonne Tay[2], Raghav Sundar[7]

[1]Department of Haematology-Oncology, National University Cancer Institute, Singapore, Singapore,[2]Cancer Science Institute, Singapore, Singapore,[3]Department of Surgery, University Surgical Cluster, National University Health System, Singapore, Singapore,[4]Cancer and Stem Cell Biology Program, Duke-NUS Medical School, Singapore, Singapore, Singapore,[5]National University Cancer Institute, Singapore, Singapore,[6]Department of Surgery, University Surgical Cluster, National University Health System, Singapore, Singapore, Singapore,[7]Yale Cancer Center, New Haven, CT

Background: Gastric cancer (GC) with peritoneal metastases (PM) carries a grim prognosis. Despite progress in elucidating transcriptomic mechanisms of metastasis, epigenetic factors and vulnerabilities are still not fully understood.
Methods: Primary tumor (PT, n=157), primary normal (PN, n=33) and peritoneal metastases (PM, n=97) from patients with GC were retrieved and sequenced with whole transcriptome sequencing. PSI-Sigma was conducted to retrieve alternative pre-mRNA splicing (AS) changes. Differential splicing events (DSE) that were concordant between PT vs PN and PM vs PT were utilized to identify AS event hubs through non-negative matrix factorization. Transcriptomic derivatives such as epithelial-mesenchymal transition (EMT)-scores, mesenchymal subtypes were retrieved utilizing log2(FPKM) gene expression. Epigenetic subtypes of GCPM samples were retrieved through hierarchical clustering of AS event hubs and survival analyses were conducted with a Cox-proportional hazard model.
Results: Nine hundred and nine overlapping DSE were identified between PT vs PN and PM vs PT comparisons, with majority being mutually exclusive exons (44.6%). Of this 909 DSEs, 45 DSE were found to be concordant across comparisons. Unsupervised clustering with gene hubs retrieved from 45 DSEs reveals 2 GCPM epigenetic clusters, characterized by divergent EMT states ($p<0.001$). The clusters were subsequently coined GCPM-Mesenchymal (n=47, mean EMT-score=1.06) and GCPM-Epithelial (n=50, mean EMT-score=0.17). GCPM-Mesenchymal samples were predominantly found to be nested within an inflamed immune-infiltrated peritoneal niche ($p=0.002$) and participants with GCPM-Mesenchymal only samples had significantly poorer survival outcomes upon PM diagnosis (Log-rank, $p=0.037$).
Conclusions: This study sheds light on alternative splicing in transcoelomic metastasis and highlights potential for splicing-based patient stratification in GCPM.

#932 Somatic EGFR mutations and oncogenic viruses in NSCLC Egyptian patients.

Shaimaa Saeed[1], Amira Salah El-Din Youssef[1], Ahmed M. Fahmy[2], Nasra F. Abdel Fattah[1], Zeinab K. Hassan[1], Mohamed M. Hafez[1]

[1]Cancer Biology, National Cancer Institute, Cairo University, Cairo, Egypt,[2]Cancer Pathology, National Cancer Institute, Cairo University, Cairo, Egypt

Background: Lung cancer (LC) is the leading cause of cancer-related mortality worldwide, with non-small cell lung cancer (NSCLC) accounting for approximately 75-80% of cases. Genetic alterations, particularly somatic mutations in the *Epidermal Growth Factor Receptor* (*EGFR*) gene, play a critical role in NSCLC tumorigenesis and treatment responsiveness. Oncogenic viruses, such as Human Papillomavirus (HPV) and Epstein-Barr virus (EBV) as environmental factors, have also been implicated in various cancers including lung cancer. This study aimed to investigate *EGFR* somatic mutations profile and its association with theses oncogenic viruses in NSCLC Egyptian patients, hoping to provide new insights on role of *EGFR* mutations associated with oncogenic viruses in lung cancer development.

Methods: This study was conducted on ninety-three formalin-fixed, paraffin-embedded (FFPE) samples of NSCLC Egyptian patients, as well as ten FFPE from safety margins served as control group. The somatic *EGFR* mutations in exon 18(G719A\G719C and G719S), exon 19(19 deletion), exon 20 (insertions, T790M, S768I), and exon 21(, L858R and L861Q) were detected using AmoyDx® EGFR 29 Mutations Detection Kit. Moreover, the HPV DNA was detected by common primers (MY09 and MY11) targeting the L1 gene using conventional PCR assay. The EBV DNA was detected using the Artus EBV TM PCR Kit, targeting the EBNA 1 gene by real-time PCR.

Results: Our results revealed that the *EGFR* mutations were detected in 19 out of 93 NSCLC patients (20.4%); these mutations were distributed in exon 18 (9.5%), exon 19 (42.8%), exon 20 (28.5%), and exon 21(19%). On the other hand, no mutations were detected in the control group. The total number of *EGFR* mutations was 21 per 19 NSCLC patients; where all *EGFR*-mutated NSCLC patients had one mutation, except for two patients had two mutations. The most frequent detected *EGFR* mutations in NSCLC patients were; 19 del (42.8%), T790M (23.8%), L858R (19%), G719S (9.5%), and insertions (4.7%). Furthermore, the DNA of HPV and EBV were detected in 29 (31.1%) and 2 (2.1%) of NSCLC patients, respectively. On the other hand, these viruses were not detected in the control group. Regarding association of oncogenic viruses with somatic *EGFR* Mutations, 26.3% were positive for HPV DNA among *EGFR*-mutated NSCLC patients. No EBV DNA was detected in the *EGFR*-mutated NSCLC patients (0%).

Conclusion: Our findings show that *EGFR* mutations in conjunction with certain oncogenic viruses, may contribute to the pathogenesis among Egyptian NSCLC patients, however a larger sample size is needed to confirm these findings. The prognosis of EGFR-TKI treatment may vary according to different *EGFR* actionable mutations and the co-presence of oncogenic viruses. Thus, understanding this association may provide a relevant modification for developing personalized therapeutic options for treatment of NSCLC patients associated oncogenic viruses.

#933 Effect of mRNA vaccine-induced neutralizing antibodies on human T-cell leukemia virus type-1.

D. Frias[1], N. Banu[2], X. Cheng[2], A. Joseph[2], Z. Liu[2], S. Whelan[2], L. Ratner[2], L. Ratner[2];
[1]Universidad de Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico, [2]Washington University School of Medicine, St. Louis, MO

Introduction/Background: Human T-cell leukemia virus type 1 (HTLV-1) is a retrovirus linked to severe conditions such as adult T-cell leukemia/lymphoma (ATL) and HTLV-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP). The absence of a preventative therapy for HTLV-1 represents a significant gap in public health. Our lab has developed a codon-optimized HTLV-1 envelope (Env) mRNA vaccine encapsulated in lipid nanoparticles (LNP), which demonstrated partial protection in a rabbit model. However, further research is required to optimize its efficacy.
Methods: The study involved evaluating the neutralizing antibody response induced by the HTLV-1 mRNA vaccine against HTLV-1a and HTLV-1c in various assays. Western blot analysis assessed the expression of the gp46 envelope glycoprotein and HIV capsid protein p24 in HEK 293T cells transfected with HTLV-1a or HTLV-1c Env plasmids. Fusion assays measured cell-cell fusion using mCherry fluorescent protein in 293T cells, with the effects of IgG serum from infected rabbits assessed. Virus titration involved VSV-HTLV Env and VSV-eGFP to evaluate viral infection inhibition. Neutralizing antibody assays tested IgG from HTLV-infected and non-infected rabbits to determine the extent of viral inhibition.
Results: Expression of gp46 and HIV-1 p24 was confirmed in 293T cells co-transfected with HTLV-1a or HTLV-1c Env plasmids. Fusion assays indicated that IgG from infected rabbits effectively inhibited fusion in HTLV-1a and HTLV-1c Env-expressing cells. Virus titration presented significant inhibition of viral infection by IgG from HTLV-infected rabbits, with an IC50 of 0.05 µg.
Conclusion: The study demonstrates that the HTLV-1 envelope mRNA vaccine induces neutralizing antibodies that can inhibit HTLV-1 infection and fusion processes. These findings support the potential of the mRNA vaccine as a preventive measure against HTLV-1-associated diseases and provide a basis for further research to optimize vaccine efficacy.

#934 Defining the role of Epstein-Barr virus (EBV) in diffuse large B-cell lymphoma (DLBCL) pathogenesis.

Quincy Rosemarie[1], Mitch Hayes[1], Eric C. Johannsen[2]

[1]McArdle Laboratory for Cancer Research, University of Wisconsin - Madison, Madison, WI, [2]Department of Medicine & McArdle Laboratory for Cancer Research, University of Wisconsin - Madison, Madison, WI

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common aggressive lymphoma. DLBCL is not a single disease, but a group of histologically similar yet genetically distinct cancers with unique prognostic and therapeutic features. The recently defined genetic landscape of DLBCL includes at least seven subtypes, but does not consider Epstein-Barr virus (EBV) status, despite up to 14% of DLBCL being EBV-positive and EBV's known role in B cell lymphomagenesis. We performed a reanalysis of published DLBCL genetic data to molecularly define EBV-positive DLBCL, and characterized its cell line models.

Methods: Published whole exome (WES) and RNA sequencing data were analyzed *in silico* to identify EBV-positive (EBV+) DLBCL tumors. Differential analyses of the mutation and transcriptomic profiles of the viral and cellular genes of EBV+ and EBV-negative tumors were performed. WES, RNAseq, and immunoblotting were performed on EBV+ DLBCL cell lines Farage, BCKN1, IBL1, and Val to assess the extent to which they accurately reflect profiles from EBV+ DLBCL tumors.

Results: We identified 20 EBV+ DLBCLs in the NCI cohort (n=481). EBV+ DLBCL is significantly enriched within the BN2 subtype (p=0.0051, Barnard's test) and comprised ~1/3 of EBV+ DLBCLs. The remaining ~2/3 are distinct from currently defined subtypes. Several differentially mutated genes within the BN2 tumors were found to correlate with EBV status. These include subtype-defining genes, genes involved in B cell receptor signaling and cell cycle regulation, and those known to be downstream of EBV. This finding supports our hypothesis that EBV oncogenes can functionally compensate for specific cellular mutations in DLBCL. Preliminary transcriptomic analyses found EBV+ DLBCL to have increased inflammatory and immune signatures, and JAK/STAT and NF-kB signaling. By RNAseq and immunoblot we determined the cell lines Farage, BCKN1, and IBL1 to have EBV Latency III, while Val has Latency II. All lines are infected with EBV Type 1 strain, except IBL1 which harbors EBV Type 2. Genes mutated in BCKN1, IBL1, and Val are consistent with 'Unclassified' subtype, whereas Farage is ST2 subtype.

Conclusion: EBV+ DLBCL, like DLBCL itself, is not a single disease. A subset of EBV+ DLBCL is enriched within, and likely have a shared pathogenesis with, BN2 DLBCL. The remaining EBV+, 'Unclassified' DLBCL may constitute a novel subtype(s). EBV status correlates with distinct mutation and gene expression profiles, including subtype-defining features. Thus, integrating EBV status into the classification of DLBCL is likely to better inform tumor subtyping and molecular studies, and resolve the specific role(s) of EBV in DLBCL. Characterization of EBV+ DLBCL cell lines revealed limited correspondence with EBV+ tumors, underscoring the need for additional cell line models to support in vitro studies of EBV+ DLBCL.

#935 HPV16 E6 splicing induces partial epithelial-mesenchymal transition in oropharyngeal squamous cell carcinoma.

Yvonne Xinyi Lim[1], Min Liu[1], Allison Furgal[2], Jake McGue[3], Shiting Li[4], Bailey Garb[2], Timothy Frankel[3], Veera Baladandayuthapani[3], Laura Rozek[5], Maureen Sartor[2], Nisha D'Silva[1]

[1]University of Michigan School of Dentistry, Ann Arbor, MI,[2]University of Michigan School of Public Health, Ann Arbor, MI,[3]University of Michigan Medical School, Ann Arbor, MI,[4]University of Michigan, Ann Arbor, MI,[5]Georgetown University, Washington, WA

The incidence of HPV16-positive oropharyngeal squamous cell carcinoma (HPV+ OPSCC) is rising at an alarming rate and has overtaken cervical cancer to become the most prevalent HPV+ cancer in the United States. Although most patients with HPV+ OPSCC respond favorably to standard chemoradiation, a substantial proportion of patients have highly aggressive tumors that recur. Biomarkers are needed to reliably stratify patients into risk subgroups. Using multiple complementary models that recapitulate HPV+ OPSCC, our group demonstrated that enhanced splicing of HPV16 E6 oncogene increased migration and invasion. *In vivo*, HPV+OPSCC with higher spliced E6 (E6*) generated more isolated clusters of tumor cells that spread further away from the main tumor relative to the original full-length isoform (E6FL). This is consistent with an adverse phenotype seen in human HPV+ OPSCC. However, the mechanisms of how spliced E6 enhanced invasion remain unclear.Epithelial-mesenchymal transition (EMT) drives invasion in OPSCC, and is commonly characterized by a loss of epithelial genes and gain in mesenchymal genes. However, recent studies also identified a partial EMT (p-EMT) phenotype, where cancer cells co-express both epithelial and mesenchymal genes. In this study, we explored whether spliced E6 enhances invasion via EMT in OPSCC. Immunofluorescence staining of E-cadherin (epithelial phenotype) and vimentin (mesenchymal phenotype) was performed on formalin-fixed paraffin-embedded tissue of 46 human HPV+ OPSCC. Analysis of the tumor regions on whole-slide images showed that patients with increased E6* relative to E6FL had reduced membrane localization of E-cadherin. In contrast, total expression of E-cadherin and vimentin were unchanged. This finding corroborates with our *in vivo* chick chorioallantoic membrane model and *in vitro* studies in OPSCC cell lines, where E-cadherin was more localized at cell-cell junctions in cancer cells with increased E6 splicing. Therefore, we propose that splicing of HPV16 E6 oncogene promotes p-EMT by inhibiting translocation of epithelial E-cadherin from the cell membrane to cytoplasm to reduce cell-cell adhesion. Overall, our findings may shed valuable insights into the mechanisms driving aggressive HPV+ OPSCC and substantiate E6* as a prognostic biomarker to distinguish HPV+ OPSCC risk subgroups for personalized treatment.

#936 HPV-related cancer model development and its application in the efficacy evaluation of a saRNA cancer vaccine.

Zhongbao Song, GuangXu Ding, Anran Xia, Lihuan Bai, Wanqing Ma, Qiuhong Li, Xu Chen, Zhixiang Zhang, Qingyang Gu

WuXi AppTec, Nantong, China

Cancer remains one of the most serious diseases threatening human health, influenced by many factors, such as genetic, physical, chemical and biological factors. Among various cancers, a special subtype is associated with viral infections. Globally, about 10% of all cancers are caused by viral infections including those from HPV, HBV, EBV and KSHV. After infection, these viruses manipulate the proliferation, metabolism, immunity and other life processes of the host cells through various mechanisms, resulting in malignant cell lesions. Therefore, targeting these viruses offers a novel therapeutic approach for virus-related cancers. In this study, codon optimization and site-direct mutagenesis were performed on HPV18 E6 and E7 genes, which were then cloned into a lentivirus vector to establish an HPV18 E6/E7-overexpressing cell line (EMT6-HPV18). EMT6-HPV18 cells stably expressed HPV18 oncogenes E6 and E7 *in vitro* and *in vivo*, and induced tumor formation in mice. To further investigate the potential of this model for evaluating HPV18-related anti-tumor drugs, we designed a self-replicating RNA (saRNA) expressing HPV18 E6 and E7, linked to FLT3L and CCL11 with the 3' and 5' terminal, respectively. Immunogenicity of the saRNA was validated after three rounds of immunizations by ELISpot and ICS flow cytometry, showing a marked increase in E6/E7-specific IFN-γ^+ T cell response. Subsequently, the therapeutic effect was evaluated in the EMT6-HPV18 subcutaneous tumor model, where saRNA treatment remarkably inhibited tumor progression, improved early-stage survival rates, and induced long-term anti-tumor immunity. Immune profiling revealed significant infiltration of immune cells into the tumors post-saRNA treatment, namely $CD4^+$ T cells, $CD8^+$ T cells and DCs with significant increase in E6/E7 specific IFN+ T cell and memory T cell subsets. In conclusion, we have successfully established an HPV18 E6/E7-expressing tumor model, demonstrating that the saRNA therapeutic vaccine effectively inhibits tumor progression in HPV18-related malignancies. Keywords: Oncogenic virus, HPV18, E6, E7, saRNA

#937 mRNA-encoded HPV16/18 therapeutic vaccine with co-stimulator to activate antigen presenting cells and promote T cell-mediated anti-tumor activity.

Qiang Zhang, Beibei Cao, Lei Li, Shaoli Liu, Xiaoju Zhang, Andong Liu, Xiaoyun Ma, Hongya Han, **Wei Xu**

METiS Pharmaceuticals, Hangzhou and Beijing, China

Background: Persistent infection with human papillomavirus (HPV) 16 and 18, two most prevalent high-risk subtypes, is a predominant cause to human cancers such as head and neck, and cervical cancers. Although prophylactic vaccines can provide protection from infection, therapeutic and efficacious drugs for already developed HPV-related cancers are badly needed. The conventional therapeutic vaccines based on protein or peptides have not reached satisfactory efficacy for patients due to a lack of strong immunogenicity to fully unleash the power of T cell immunity. Here, we developed a lipid nanoparticle (LNP)-encapsulated mRNA-encoding for multiple antigenic signals: E6/E7 antigens from both HPV16 and 18, and an optimized co-stimulatory adjuvant to help both antigen presentation and T cell stimulation.

Methods: The mRNA backbone of the vaccine was designed with mutated HPV16/18 E6/E7 at the N-terminus to bypass p53 and pRb degradation, thus avoiding carcinogenic risk. A T2A element is used to space genes from co-stimulatory signals. A suitable LNP was identified both in vitro and in vivo for its expression efficiency and safety profiles. The efficacy and mechanistic studies of the lead mRNA-LNP were further evaluated in both TC-1(HPV16$^+$) and HPV18 transgenic MC38 syngeneic models.

Results: Our lead LNP MLX0487-23 could effectively target the splenic dendritic cells and macrophage, leading to dose- and time-dependent tumor eradication in tumor-bearing mice. The optimized mRNA antigen construct named as P016-2 translated the proteins at high level *in vitro* and as desired, with p53 and pRb remaining intact. Our lead mRNA-LNP showed superior anti-tumor activity both in the HPV16$^+$ TC-1 and the HPV18$^+$ MC38 models, as compared to the benchmark construct lacking co-stimulatory signals OX40L and/or GM-CSF. We observed an expansion of HPV-specific CD8$^+$ T cells and intra-tumoral infiltration of T cells into tumors. After rechallenging with the same TC-1 tumor cells in the contralateral dorsal skin in the complete regression mice induced by P016-2, no tumor was formed, indicating long-term immune memory.

Conclusion: We conclude that MLX0487-23 (LNP) encapsulated P016-2, a 4 antigen and GM-CSF expressing mRNA, effectively expanded HPV-specific CD8$^+$ T cells and mediated potent anti-tumor efficacy in the preclinical models, making it an excellent candidate therapeutic mRNA vaccine for clinical testing its safety and efficacy in HPV-driven malignancies.

#938 HHV-7-mediated downregulation of HLA-F: a mechanism for immune evasion in angiosarcoma.

Bavani Kannan[1], Janos Luka[2], Tun Kiat Ko[1], Jason Chan[1]

[1]National Cancer Centre Singapore, Singapore, Singapore,[2]Kintla Research Technology, Belgrade, MT

Background: Human herpesvirus-7 (HHV-7) is a ubiquitous, CD4+ T cell lymphotropic virus. It establishes lifelong latency and may reactivate, particularly in immunocompromised individuals. We had previously detected the presence of HHV-7 in two-thirds of angiosarcoma clinical samples. HHV-7-positive (HHV-7+) tumors were shown to be relatively enriched for B- and mast cells and had high tumor inflammation signature scores compared to HHV-7-negative tumors.
Objective: To investigate HHV-7 pathogenesis in host cells and its role in angiosarcoma.
Methods: A SupT1 infection model was established. Images and cell pellets were collected at Days 0 and 4 (early infection phase) and Days 8 and 14 (late infection phase) for bulk RNA-seq analysis. Gene expression data was validated with quantitative PCR (qPCR). RNA-seq and Nanostring gene expression profiling with the Pancancer IO360 panel were previously performed on HHV7+ fresh frozen and FFPE angiosarcoma samples respectively.
Results: Infected SupT1 cells exhibited cytopathic effects (CPEs) such as membrane blebbing, syncytia formation and growth arrest during early infection phase. Cell lysis, followed by recovery of cell growth, were observed during late infection phase. RNA-seq revealed significant pathway alterations across the infection course, supporting these observations. Early infection showed notable upregulation in arachidonic acid metabolism and antigen processing and presentation pathways, indicating an anti-viral response in host cells. The downregulation in actin cytoskeleton and cell cycle pathways were seen, corresponding to the observed CPEs. During late infection, there was a significant downregulation in antigen processing and presentation pathways (padj. <0.05), suggesting immune evasion the virus, along with a significant downregulation of tumor suppressor genes such as RNF43 and CBFA2T3. Through the course of infection, a general upward trend of oncogenic and inflammatory pathways was seen, with the latter being observed in HHV-7+ angiosarcomas as well. Narrowing down on specific genes, we observed the significant downregulation of HLA-F and upregulation of HK2 in both late-stage SupT1 infection and HHV-7+ angiosarcomas, implicating these genes in immune evasion and tumor progression.
Conclusions: Our study provides the first RNA-seq profiling of HHV-7 infection in host cells. The study reveals alterations in key cellular pathways that promote an immunosuppressive and pro-inflammatory environment. These changes likely facilitate tumor progression and immune evasion in angiosarcoma.

#939 Development of a dual fluorescent reactivation reporter Epstein-Barr virus (DFRR-EBV) to optimize lytic-induction therapy of EBV-associated cancers.

Emilie Greene, Eric Johannsen, Ahmed Ali

University of Wisconsin-Madison, Madison, WI

Epstein-Barr virus (EBV) is a highly successful γ-herpesvirus, infecting >95% of the human population. Approximately 0.01% of infected individuals will develop an EBV-associated cancer later in life, resulting in 200,000 annual cases globally. EBV-associated cancers, such as Diffuse Large B-Cell Lymphoma, are dependent on the expression of EBV latency genes for their continued growth and survival, making the disruption of latent infection a promising therapeutic target. “Lytic induction therapy” combines small molecules capable of reactivating EBV from latency with anti-viral drugs to increase toxicity to tumor cells and prevent EBV particle production. The full potential of this approach will require the development of second-generation lytic induction agents that induce a much greater proportion of tumor cells to enter the lytic cycle. Efforts to study the mechanisms of EBV reactivation are essential to this endeavor. EBV entry into the lytic phase is controlled by two viral transcription factors, Rta and Zta, and activators of the Rta and Zta promoters have previously been identified using reporter assays. These approaches, however, failed to capture major regulatory mechanisms that govern viral reactivation in EBV-positive tumors, such as long-range enhancer effects and epigenetic regulation of viral transcripts. To overcome these limitations, we constructed a dual fluorescent reactivation reporter virus (DFRR-EBV) that replaces Rta and Zta with GFP and RFP, respectively. This reporter is being used to screen a library of FDA-approved small-molecules to identify agents that reactivate EBV, in addition to a genome-wide unbiased CRISPR/Cas9 screen to identify negative regulators. Significantly, our reporter will distinguish between which small molecules are Rta versus Zta induction agents. Although Zta had been considered the principal regulator of the latent/lytic switch, we and others have demonstrated that expression of both Rta and Zta are essential for EBV reactivation[1,2]. Therefore, the combination of an Rta induction agent with a Zta inducer should act synergistically, offering a significant improvement over the current approach of single-agent lytic induction therapies for EBV-associated cancers.

#94 Tumor RNA isoforms are associated with recurrence in resected non-small cell lung cancer.

Kelly M. Cagin[1], Arsalan Khan[1], Savan Shah[1], Wara Naeem[1], Minha Ansari[1], Oluwamuyiwa W. Adebayo[1], Hita Moudgalya[2], Michael J. Liptay[1], Christopher W. Seder[1], Jeffrey A. Borgia[1]

[1]Rush University Medical Center, Chicago, IL,[2]Pathology, Ohio State University, Columbus, OH

Introduction: Surgical resection remains a mainstay of treatment for individuals with non-small cell lung cancer (NSCLC). However, disease recurrence rates remain a major concern, standing at 5-19% for stage I disease, 11-27% for stage II disease, and 24-40% for stage III disease. This study focused on identifying tumor transcript variants that allow patients to be risk-stratified for recurrence/disease progression.

Methods: Patients with stage I-IIIA NSCLC tumors ($T_{1-2}N_{0-2}M_0$) who did not receive neoadjuvant therapy and had follow-up clinical data available were included. The primary outcome was event free survival (EFS), defined as time until recurrence or death. Tumor RNAseq data was interrogated for RNA isoforms at the splice variant (n=645 subjects) and fusion transcript (n=555 subjects) levels, identifying 225,896 unique splice variants via FRASER and 1,382 unique fusion transcripts via STAR-Fusion, respectively. Differential analyses were performed via edgeR based on nodal and recurrence status (i.e. N_0 Non-recurrent, N_0 Recurrent, N_{1-2} Non-recurrent, and N_{1-2} Recurrent) at the individual isoform level using mean feature importances of a supervised learning model (3 random forest ensemble) to rank isoforms on prognostic value. Aggregate analyses were also performed, assessing the relationship between recurrence and tumor fusion burden in two ways (sum of normalized counts and sum of unique transcripts).

Results: From the intersection of top features and differential expression analysis comparing the N_0 Non-recurrent group (n=325) to those that recurred/progressed (N_0 Recurrent, N_{1-2} Non-recurrent, and N_{1-2} Recurrent; n=230) we identified differential utilization at multiple splice site loci, including at chr 7: 16,861,429 - 16,861,430 (RGA3 exon 6) that was associated with progression ($q = 2.145 \cdot 10^{-7}$; log fold change = 0.374). Total normalized fusion transcript fragments (as FFPM) per subject pass Kruskal-Wallis test for differences between the four individual groups (p = 0.3126). Tumors with greater than 10 unique fusion transcript variants detected were associated with a superior 5-year EFS (HR = 0.59 (95%CI: 0.4-0.86), p = 0.0069).

Conclusions: These data suggest multiple loci producing splice variants associated with recurrence exist, and a fusion burden >10 unique transcripts correlates with a superior EFS in patients with resected stage I-IIIA NSCLC, which may be reflective of increased neoantigen load and immune activation. Current efforts are focused on validation of these findings in the TracerX cohort and mass spectrometry.

#940 Harnessing oncolytic virus VSV and combination therapy to advance treatments for relapsed refractory multiple myeloma using Vk*MYC models.

Yi Ying Ma[1], Lianwen Zhang[1], Rebecca A. Nace[1], Marta Chesi[2], Stephen J. Russell[3], Kah Whye Peng[1]

[1]Molecular Medicine, Mayo Clinic, Rochester, MN,[2]Medicine, Mayo Clinic, Scottsdale, AZ,[3]Vyriad, Rochester, MN

VSV-IFNβ-NIS (VV1) is a Vesicular Stomatitis Virus (VSV) that encodes the interferon beta (IFNβ) and the iodide symporter (NIS) gene. The IFNβ gene confers tumor selectivity and enhances host antitumor immunity while the NIS gene acts as an imaging biomarker, allowing noninvasive imaging of viral infection sites using PET/SPECT. Multiple myeloma (MM) is a cancer of plasma cells and poses a challenge for treatment due to its biological heterogeneity. As MM usually relapses and is refractory, current therapies face the issue of drug resistance and patients may have to turn to novel therapies. Therefore, we set out to understand the activity of VSV which could be a new approach for patients with relapsed refractory MM (RRMM). Our study utilized two unique bortezomib resistant Vk*MYC transplantable models, Vk12598 and Vk12653, with distinct genomic features. Upon re-transplantation of splenocytes from these mice, flow cytometry revealed that Vk12598 and Vk12653 mice had high MM populations in the spleen and bone marrow. To assess VV1 efficacy in tumor bearing mice, we performed a VV1 dose escalation study, showing efficacy in delaying MM development and prolonging survival in both mice models, with Vk12598 being the more responsive model. Later studies also showed that VV1 induces tumor remission in the Vk12598 model when treatment was initiated at low tumor burden (gamma/albumin ratio ~0.2). IFNβ levels increased significantly post 24-72h of VV1 treatment, indicating targeted infection and replication of the virus in MM cells. However, high doses of VV1 led to toxicity, as observed from early mortality and weight loss. To determine the sites of MM metastasis and VV1 infection, timepoint harvests were carried out. Hematoxylin and eosin and immunostainings showed the onset of MM of Vk*MYC in the bone marrow and spleen first, then later in the liver. Immunofluorescent staining confirmed that the higher the tumor burden observed, the more VV1 was present in the tissues. To enhance VV1 efficacy, we performed in vivo combination therapies of VV1 with anti-PD-1, an inhibitor of PD-1 which is overexpressed on MM patient T cells; and bortezomib, which inhibits NF-κB which in turn prevents IFN pathway protein transcription, potentially enhancing the replication of VV1 virus. In Vk12598 mice, VV1 combined with both drugs induced tumor regression and doubled the median survival time compared to treatment with VV1 only or VV1 coupled with either of the drugs individually. Addition of VV1 to either anti-PD-1 or bortezomib alone also increased survival time significantly. Studies are still ongoing to understand the mechanisms of VSV and its combination treatments in Vk*MYC models. This translational study will allow us to gain the knowledge needed to refine VSV treatments and provide novel therapy combinations to improve MM patient survival.

#944 Evaluation of oncolytic herpes simplex virus overexpressing granulocyte-macrophage colony-stimulating factor as a potential therapeutic against pancreatic ductal adenocarcinoma.

Biplov Sapkota[1], Naveen Chintala Ramulu[1], Shilpa Thota[1], Rizwana Begum[1], Shreya Pokharel[1], Brent Stanfield[2], Dayanidhi Raman[3], Gus Kousoulas[2], Joseph Francis[1]

[1]Department of Comparative Biomedical Sciences, Louisiana State University, Baton Rouge, LA,[2]Department of Pathobiological Sciences, Louisiana State University, Baton Rouge, LA,[3]Department of Cell & Cancer Biology, University of Toledo - Health Science Campus, Toledo, OH

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal and drug-resistant cancers. The 5-year overall survival (OS) for PDAC remains low at 12.8%, largely due to its advanced presentation stage that prevents curative resection, and due to a high tendency for recurrence. The PDAC tumor microenvironment (TME) is desmoplastic and highly immunosuppressive. Oncolytic viruses (OV) are known to transform the TME from ‘cold’ to ‘hot’ by increasing immune cell infiltration within the TME. The primary objective of this study is to investigate the potential of Herpes simplex virus (HSV-1), strain VC2, overexpressing granulocyte-macrophage colony-stimulating factor (GM-CSF), HSV-1 (VC2) GM-CSF, as a potential therapeutic agent in *in vitro* and *in vivo* models of PDAC. We will assess the intricate molecular mechanisms involved in the interaction between OV and PDAC TME and perform immunoprofiling. We hypothesize that the administration of HSV-1 (VC2) GM-CSF as a monotherapy or combination therapy will improve treatment outcomes via cytopathic effects (CPE) of OV against cancer cells and immunomodulation of PDAC TME by GM-CSF. We evaluated the effect of HSV-1 (VC2) GM-CSF on human MIA PaCa-2 (KrasG12C, Trp53R248W) and murine KPC (KrasG12D, Trp53R172H, and Cre control) PDAC cell lines. Both cell types showed notable CPE, including cell aggregation, rounding and eventual detachment, following treatment with HSV-1 (VC2) GM-CSF, in contrast to the effects observed with wild-type HSV-1 (VC2) or in uninfected controls after 24 h of viral exposure. The observed CPE was corelated with cell death using trypan blue staining. We determined the viral titers to be 9.6×10^7 pfu/ml for wild-type HSV-1 (VC2) and 1.2×10^7 pfu/ml for HSV-1 (VC2) GM-CSF. The infection of both human and murine PDAC cells lines with HSV-1 (VC2) GM-CSF at 0.1, 1.0 and 10 MOIs significantly increased the expression of proinflammatory markers (IL-10, COX-2, iNOS) and upregulated Fas ligand (FasL) and PD-L1 expression suggesting immunomodulatory activity. An orthotopic PDAC model in C57BL/6 mice has been established, providing a solid foundation for further research. Ongoing studies employing advanced 2D and 3D cell culture systems, including cell-derived spheroid co-cultures and patient-derived organoid models, along with preclinical evaluation in established orthotopic mouse models, will elucidate the therapeutic potential of HSV-1 (VC2) GM-CSF, both as a standalone treatment and in combination with anti-PD-L1 immunotherapy and Gemcitabine.

#945 Live attenuated MMR vaccines modulate tumor immune cell infiltration and synergize with standard of care to prolong survival in preclinical HCC models.

M. Z. Tesfay[1], A. Cios[1], K. U. Ferdous[1], R. S. Shelton[1], B. Mustafa[1], C. C. Simoes[1], S. Post[1], T. Kelly[1], M. Moaven[2], L. R. Roberts[3], M. J. Borad[4], M. J. Cannon[1], A. Basnakian[1], N. Bolni[1];

[1]University of Arkansas for Medical Sciences, Little Rock, AR, [2]Louisiana State University (LSU) Health-New Orleans, New Orleans, LA, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Phoenix, AZ

The global burden of hepatocellular carcinoma (HCC) continues to rise, driven by increasing metabolic risk factors such as nonalcoholic fatty liver disease, obesity, and type II diabetes. Patients with advanced HCC have limited therapeutic options and a dismal prognosis. While recent advancements in combination therapies—including immune checkpoint blockade (ICB) with anti-PD-1/PD-L1 and anti-CTLA-4 agents and anti-angiogenics—have improved survival for some, up to 80% of patients fail to respond, underscoring an unmet need for new strategies. Emerging data indicate a strong association between increased tumor-infiltrating lymphocytes (TILs) and better responses in ICB-treated HCC, suggesting TIL enhancement as a promising approach. However, HCC's inherent low immunogenicity and immunosuppressive tumor microenvironment (TME) limit the efficacy of current TIL-promoting strategies. Here, we demonstrate that low-dose intratumoral immunotherapy using the trivalent MMR vaccine—composed of live attenuated measles, mumps, and rubella viruses—modulates TME immune infiltration, increases cytotoxic T cell frequency, and delays tumor growth in multiple murine HCC models. Importantly, intratumoral or systemic MMR administration in combination with dual ICB (anti-mPD-1/anti-mCTLA-4) significantly prolongs survival, promoting tumor-specific and memory immune responses in both subcutaneous and orthotopic HCC models. These findings reveal a unique mechanism of vaccine-induced anti-tumor activity, highlighting MMR as a viable, globally accessible option for enhancing immune responses in advanced HCC therapy.

#946 Novel oncolytic virus targeting GPC3 and CTNNB1 demonstrates complete response in hepatocellular carcinoma (HCC) xenograft with a single, systemic administration.

Chad M. Moles[1], Rupsa Basu[1], Brenda Ho[1], Manal Farhat[1], Jason Kent[1], Peter Weijmarshausen[1], Bruce F. Smith[2], Michael A. Whitt[3]

[1]Humane Genomics Inc., New York, NY,[2]Scott-Ritchey Research Center, Auburn University College of Veterinary Medicine, Auburn, AL,[3]Department of Microbiology, Immunology and Biochemistry, The University of Tennessee Health Science Center College of Medicine, Memphis, TN

Introduction: Oncolytic viral therapies (OVTs) have shown promise in cancer treatment, though efficacy and selectivity challenges remain. HGI627 is an engineered vesicular stomatitis virus (VSV) featuring a synthetic glycoprotein retargeted to glypican-3 (GPC3) and a beta-catenin (CTNNB1)-dependent aptazyme as a genetic ON switch. This dual targeting strategy enhances specificity to liver cancer cells.

Methods: HGI627 was constructed and rescued using a synthetic virology platform [Moles et al., Viruses 2024], and viral titers were measured by $TCID_{50}$ assay on Hep3B cells. Cytotoxicity and selectivity were evaluated using real-time imaging (IncuCyte system) on liver cancer (e.g. Hep3B), off-target (e.g. SW-480), and normal (e.g. THLE-2) cells. To further evaluate this virus *in vivo*, an efficacy study performed in Hep3B xenograft-bearing NSG mice. To evaluate potential acute toxicity and maximum tolerated dose (MTD), a study in NSG mice (n=5/group) was then conducted using single and multiple $1x10^9$ $TCID_{50}$ doses.

Results: HGI627 demonstrated robust lytic activity *in vitro* at low MOIs (0.01) in GPC3+/CTNNB1+ cells with minimal to no cytotoxicity in off-target and normal cells at MOI=10. *In vivo*, a single intraperitoneal (i.p.) injection of 1×10 $TCID_{50}$ HGI627 (n=9) achieved a 100% complete response and significantly extended survival to day 49 (end of study) compared to median survival of 15 days in vehicle group ($p<0.005$). In the safety study, even multiple (n=3) high-dose (1×10 $TCID_{50}$) administrations of HGI627 were well tolerated, and no signs of clinical toxicity were observed up to 14 days; Importantly, this highest dosing group received an equivalent of >100× the proposed first-in-human starting dose without adverse effects.

Conclusion: These results highlight HGI627's potency, selectivity, and safety, overcoming previous OVT challenges. HGI627 exemplifies a promising approach for liver cancer treatment using a dual-targeting mechanism for enhanced precision. Current studies include an orthotopic HepG2-luciferase model to further validate efficacy.

#947 Engineering a synthetic oncolytic virus to overcome apoptotic resistance and induce immunogenic cell death in pancreatic ductal adenocarcinoma.

Aleksandra Cios[1], Khandoker Usran Ferdous[1], Mulu Z. Tesfay[1], Alicja Urbaniak[2], Bahaa Mustafa[3], Steven R. Post[1], Thomas J. Kelly[1], Martin J. Cannon[4], Alexei Basnakian[5], Omeed Moaven[6], Bolni Marius Nagalo[1]

[1]Department of Pathology, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Department of Biochemistry and Molecular Biology, University of Arkansas for Medical Sciences, Little Rock, AR,[3]Department of Pharmaceutical Sciences, University of Arkansas for Medical Sciences, Little Rock, AR,[4]Department of Microbiology and Immunology, University of Arkansas for Medical Sciences, Little Rock, AR,[5]Department of Pharmacology and Toxicology, University of Arkansas for Medical Sciences, Little Rock, AR,[6]Division of Surgical Oncology, Department of Surgery, Louisiana State University (LSU) Health, New Orleans, LA

Introduction: Oncolytic viruses, particularly vesicular stomatitis virus (VSV), combat cancer through tumor lysis and immune response enhancement. However, pancreatic ductal adenocarcinoma (PDAC) often resists apoptosis due to p53 mutations and overexpression of anti-apoptotic proteins. We developed an innovative VSV variant, VMG, incorporating the glycoprotein of the Morreton virus (MORV-G) to enhance safety, tumor targeting, and immune engagement. VMG was further engineered to encode a proprietary synthetic caspase-activating protein (VMG-apo), activating both intrinsic and extrinsic apoptotic pathways via ER stress and caspase activation.
Methods: Experiments were conducted on three PDAC cell lines: HPAFII, HS766T, and Panc1. Viral cytotoxicity was analyzed using the xCELLigence system over 40 hours post-infection. Cells were infected at MOI of 1 and harvested at 15 HPI for proteomic analysis. Additional analyses included apoptosis/necrosis assays, calreticulin expression, and Western blotting.
Results: Proteomic analysis revealed distinct responses across cell lines. In Panc1 cells, VMG-apo altered 74 genes, notably downregulating CD9, COL1A1, and NQO1, while inhibiting extracellular matrix remodeling. HPAFII cells showed changes in cell cycle regulation. Both cell lines exhibited strong CASP3 overexpression (fold change >5.60). The resistant HS766T line showed minimal changes. VMG-apo downregulated DAMP and PAMP-associated genes while promoting calreticulin release. Panc1 showed highest sensitivity, with significant cell death at 15 hours post-infection. HPAFII cells underwent primarily apoptosis, while HS766T remained resistant. Calreticulin expression decreased in Panc1 and HPAFII cell lines, while in HS766T remained the same as control. Western blot analyses detected caspase-3 but no cleaved caspase-3.
Conclusions: The results provide insights into immunogenic cell death and apoptotic mechanisms in PDAC following VMG-apo treatment. The differential responses across cell lines underscore VMG-apo's therapeutic potential and complexity. The heterogeneous responses indicate the need for personalized strategies in oncolytic virotherapy. These findings advance the understanding of how oncolytic viruses can enhance both direct tumor cell death and anti-tumor immunity, offering a promising avenue for improving PDAC treatment outcomes.

#948 PAX3-FOXO1-driven oncolytic herpes virus designed for treatment of alveolar rhabdomyosarcoma.

C. W. Peters, T. Nowicki, M. Kawakami, C. Kidd, A. Lechein;
UCLA - University of California Los Angeles, Los Angeles, CA

Background: Alveolar rhabdomyosarcomas (aRMS) often express an oncogenic fusion protein PAX3-FOXO1. PAX3-FOXO1 (P3F) acts as an oncogenic transcription factor, driving aggressive and lethal tumors in children and young adults. P3F has proven elusive to small molecule inhibitors, and the low immunogenicity of aRMS tumors has impaired efforts to treat with immune checkpoint blockade. The absence of an effective targeted treatment for fusion-positive aRMS represents an important an unmet therapeutic need.
Methods: We designed a system to combine and compare sequences which bind PAX3-FOXO1 to drive a transgene reporter system. We then used this system in a variety of rhabdomyosarcoma cell lines which either expressed PAX3-FOXO1, or were fusion negative. We then inserted this P3F-driven promoter into the oncolytic herpes simplex virus (oHSV) G47Δ, driving the cytotoxic ICP34.5 gene, and tested its ability to kill P3F-positive and P3F-negative aRMS cell lines in vitro. To determine the effects of P3F expression on tumor cell response to oHSV infection, we performed RNA sequencing and differential gene expression using DESeq2 to assay alterations between P3F-positive and negative tumor cells during the lifetime of oHSV infection. Enrichment analysis on genes identified as significantly different were then analyzed via EnrichR to evaluate gene ontology and pathways significantly enriched during infection which differed based on PAX3-FOXO1 expression.
Results: We identified two synthetic promoters which exhibited expression of luciferase or GFP reporter genes only in the presence of P3F (T-Test $p<0.05$, $n=10$). We then inserted the cytotoxic HSV1-ICP34.5 gene into the ICP6 gene of the previously validated oHSV G47Δ under this synthetic promoter. These novel G47Δ-P3Fpro:ICP34.5 elicited quicker cell killing in several P3F-positive RMS lines faster than the parental virus, while exhibiting the same cell killing kinetics in matched fusion negative cells (2-way ANOVA $p<0.05$, $n=3$, Tukey multiple comparisons test). Differential gene expression over time demonstrated PAX3-FOXO1 is involved in modulating a substantial amount of immune response genes during oHSV infection including IFI16, SAMD9, and DUSP4. Expression was also significantly altered between fusion positive cells infected with the ICP34.5-armed virus compared to fusion negative cells infected with the same virus.
Conclusions: We demonstrate the synthesis of a novel PAX3-FOXO1-controlled gene expression system, and its implementation within an oHSV to combat PAX3-FOXO1 fusion oncogene-positive aRMS. Our study demonstrates the influence of PAX3-FOXO1 during viral infection with an oHSV and the potential to tailor P3F specific promoters to novel cancer targeting vectors.

#949 Boosting oncolytic virus-mediated antitumor immunity by dendritic cell vaccine therapy via p53-activated immune response.

Naohiro Okada[1], Hiroshi Tazawa[1], Motohiko Yamada[1], Satoru Kikuchi[1], Shinji Kuroda[1], Yasuo Urata[2], Shunsuke Kagawa[1], Toshiyoshi Fujiwara[1]

[1]Department of Gastroenterological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan,[2]Oncolys BioPharma, Inc., Tokyo, Japan

Background: Dendritic cell (DC) vaccine therapy represents a promising immunotherapeutic approach by inducing tumor antigen (TA)-specific immune responses. The tumor suppressor gene p53 is one of the most frequently mutated genes, and mutant or wild-type p53 epitopes function as TAs. Previous studies have demonstrated that DCs transduced with a non-replicative adenovirus expressing wild-type p53 (Ad-p53) (Ad-p53-DCs) induces p53-specific cytotoxic T lymphocytes (CTLs), leading to antitumor immunity. We have previously developed OBP-702, a tumor-specific replication-competent oncolytic adenovirus expressing p53, and demonstrated that OBP-702 exhibits direct cytotoxicity via p53-mediated induction of apoptosis and indirect immune activation via p53-mediated enhancement of immunogenic cell death (ICD). In this study, we investigated whether Ad-p53-DCs or OBP-702-transduced DCs (OBP-702-DCs) in combination with OBP-702 augment antitumor immune responses in murine colorectal cancer models.
Methods: Bone marrow-derived DCs were harvested from BALB/c mice and cultured with IL-4 and GM-CSF for five days, followed by infection with Ad-p53 or OBP-702 for two days. Maturation of DCs was evaluated by flow cytometric analysis of surface markers CD11c, CD86, CD103, and MHC-class II. RT-PCR confirmed the expression of p53 RNA in p53-expressing virus-transduced DCs. Ad-p53-DCs or OBP-702-DCs were administered subcutaneously weekly for four cycles before CT26 tumor cell inoculation. Tumor-bearing mice were treated with intratumoral injection of OBP-702 weekly for two cycles. Four experimental groups were established: (1) control, (2) p53-expressing virus-transduced DC alone, (3) OBP-702 alone, and (4) combination of p53-expressing virus-transduced DC and OBP-702. Tumor growth was monitored, and the immune microenvironment was analyzed using immunohistochemistry to evaluate the tumor infiltration of CD8+ T cell and CD11c+ DC.
Results: Ad-p53-DCs and OBP-702-DCs displayed significantly increased expression of DC maturation marker compared to control DCs. Combination of Ad-p53-DCs or OBP-702-DCs with OBP-702 markedly suppressed tumor growth compared to OBP-702 monotherapy, demonstrating a synergistic antitumor effect. Immunohistochemical analysis revealed that tumors treated with the combination therapy had significantly increased infiltration of CD8+ T cells and CD11c+ DCs, indicating robust activation of the antitumor immune responses.
Conclusions: Our data suggest that immunization with p53-expressing virus-transduced DCs enhances the antitumor efficacy of p53-armed oncolytic adenovirus OBP-702 in murine colorectal cancer models via induction of p53-specific antitumor immune responses.

TUMOR BIOLOGY: Molecular Regulation of Metastasis

#95 MTAP deficiency closely correlates with p16 status in non-small cell lung cancer but is unrelated to tumor aggressiveness or patient prognosis.

Natalia Gorbokon[1], Nina Schraps[1], Katharina Moller[1], Seyma Buyucek[1], Maximilian Lennartz[1], Florian Viehweger[1], Christoph Fraune[1], Christian Bernreuther[1], Elena Bady[1], Lisa Hornsteiner[1], Ronald Simon[1], Guido Sauter[1], Martin Reck[2], Till Olchers[2], Florian Lutz[1], Till S Clauditz[1], Martina Kluth[1], Stefan Steurer[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]German Center for Lung Research, Grosshansdorf, Germany

Loss of S-methyl-5′-thioadenosine phosphorylase (MTAP) expression is often caused by genomic deletions of chromosome 9p21 in non-small cell lung cancer (NSCLC). Complete MTAP loss results in a critical vulnerability of cancer cells towards drugs targeting adenine synthesis and the methionine cycle. To study the clinical impact and heterogeneity of MTAP expression in lung cancer, a tissue microarray containing 470 adenocarcinomas and 235 squamous cell carcinomas, and conventional whole sections from all (5-15, average 7.4) tumor-containing tissue blocks of 5 lung cancers were analyzed by for immunohistochemical (IHC) expression of MTAP. MTAP expression was lost (0+) in 13.2%, weak (1+) in 45.4% and strong (2+/3+) in 41.4% of 423 interpretable adenocarcinomas (ADC), and 0+ in 25.8%, 1+ in 46.4% and 2+/3+ in 27.8% of 209 interpretable squamous cell carcinomas (SQCC) of the lung. MTAP deficiency was unrelated to parameters of tumor aggressiveness, including pT status, pN status, histological grade, and patient survival, in ADC and in SQCC. In 40 analyzed mesotheliomas, a MTAP loss was seen in 45% ($p<0.0001$ for adenocarcinoma vs. mesothelioma). Among the 5 consecutive lung cancers from which a total of 37 whole sections were analyzed, MTAP was homogeneously deficient in 1 case, heterogeneously deficient in another case, and homogeneously retained in the remaining 3 cases. In conclusion, loss of MTAP expression occurs in 13% (ADC) to 25% (SQCC) of NSCLC irrespective of tumor extent or metastasis stage. These findings identify a potential application of MTAP IHC in NSCLC for diagnosis of malignancy and the identification of patients who might benefit from MTAP-based therapies. However, the possible therapeutic efficacy could be impaired in patients with heterogeneous MTAP loss.

#950 Engineered oncolytic vesiculovirus downsizes pancreatic tumor and boosts immune response.
K. Ferdous, M. Z. Tesfay, A. Cios, I. R. Miousse, B. M. Nagalo;
University of Arkansas for Medical Sciences, Little Rock, AR

Vesicular stomatitis virus (VSV) is one of the leading oncolytic virus prototypes used in both preclinical and clinical cancer research. A newly engineered chimeric vesiculovirus, VMG, has been tested against various cancer types, including pancreatic ductal adenocarcinoma (PDAC). However, the effectiveness of virotherapies for PDAC is often limited by the immunosuppressive factors present in the tumor microenvironment. Moreover, the presence of hyaluronic acid (HA) and collagen (CN) in the microenvironment contributes to increased tumor stiffness and interstitial fluid pressure, which impede the delivery of drugs, oncolytic viruses, and immune cells into the tumor. To address these challenges, we developed VMG expressing bacterial collagenase (CNase), mouse hyaluronidase (mPH20), or a special enzyme (Enz) having both CNase and PH20-like effects; and evaluated their efficacy in a preclinical Pan02 PDAC model. Genetic modifications to VMG did not compromise its oncolytic activity or replicability *in vitro*, as shown by MTS assays and kinetic studies. *In vivo* studies revealed that VMG-Enz significantly reduced tumor volume compared to other synthetic viruses. Immunohistochemistry (IHC) and quantitative polarized light imaging (QPLI) confirms that the hybrid VMG viruses effectively dismantled stromal components, facilitating enhanced viral infection and propagation into the tumor. Flow cytometry analysis indicated a substantial increase in $CD8^+$ T cells, granzyme B^+ T cells, dendritic cells, and natural killer cells, alongside a decrease in M-MDSCs, which are indicators of successful onco-immunotherapy. However, we also noticed an elevation of immune checkpoint markers, including PD-1, PDL-1, PDL-2, and anti-viral resistance genes for IFN-α, IFN-β and Mx-1 after viral treatment which may have limited complete tumor remission by the VMG vectors. We conclude that VMG-Enz successfully enhanced immune response and significantly reduced tumor volume by altering stromal HA and collagen levels. Further studies are needed to explore VMG-Enz's potential as combination therapy with immune checkpoint inhibitors or type I interferon antagonists to achieve complete tumor eradication and enhance survival benefits in experimental animals.

#951 A novel oncolytic adenovirus platform with multi-gene immunomodulation for ovarian cancer treatment.

Er Yue, Edward Wang

Department of Medical Oncology & Therapeutics Research, City of Hope Comprehensive Cancer Center and Beckman Research Institute, Duarte, CA

Ovarian cancer (OC) remains a challenging malignancy with limited treatment options and a poor prognosis, emphasizing the urgent need for innovative therapeutic strategies. We have established a conditionally replicating oncolytic adenovirus (CRAd) platform designed to selectively target CA125 transactivation for OC treatment. To enhance therapeutic efficacy, we engineered the CRAd to include two gene-expression cassettes in the E3 region and each cassette can express two genes linked by a P2A peptide, enabling the incorporation of four exogenous genes in one virus. We rationally chose the following cytotoxic and immunoregulatory genes to integrate into one virus to enhance oncolytic and immunoregulatory capacity and amplify the anti-cancer immune response, full-length tumor necrosis factor-related apoptosis-inducing ligand (fl-TRAIL), CD137L, granulocyte-macrophage colony-stimulating factor (GM-CSF), and interferon alpha-2b (IFN-α2b). We successfully generate the virus by transfecting the recombined Ad/Muc16 genome into HEK293 packaging cells. Ovarian cancer cells expressing CA125 were infected with Ad/Muc16, and expression of all four genes were confirmed via ELISA or flow cytometry. The anti-cancer efficacy of Ad/Muc16 was evaluated in immune-competent syngeneic mouse models of ovarian cancer (ID8/C57BL/6 and STOSE/FVB mice). Mouse ovarian cancer cells (ID8 and STOSE) infected with Ad/Muc16 were served as a whole-cell cancer vaccine in a subcutaneous inoculation model to establish an immune response. The vaccinated mice were re-challenged with parental ovarian cancer cells. Ad/Muc16 treatment elicited a robust anti-cancer immune response, significantly suppressing the growth of re-challenged parental cells and prolonging survival compared to control groups. This CRAd platform integrate with multiple genes demonstrates a novel strategy for specific targeting OC by combining oncolytic virotherapy with immune modulation.

#952 Intravesical instillation of a TME engineering viral vector increases survival in an orthotropic bladder cancer model.

Emma Eriksson, Ioannis Nikoloudis, Mariela Mejia Cordova, Tanja Lovgren, Angelica Loskog

Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden

Gene engineering of the tumor microenvironment (TME) with viral vectors encoding immunostimulatory genes can inflame the TME and create the basis for an immune response against the tumor cells. Adm703 is an adenoviral vector based on the AdEasy system. Adm703 encodes for two murine immunostimulatory genes, trimerized membrane-bound CD40L and 4-1BBL that are expressed by all infected cells (tumor and stroma). The transgenes can induce maturation of dendritic cells and expansion and memory formation of T cells as well as shift the general pro-tumorigenic environment towards anti-tumor state by influencing both tumor and stroma cells. Non-muscle invasive urinary bladder cancer is currently treated with bacillus Calmette-Guérin (BCG) instillations followed by nadofaragene firadenovec-vncg for BCG refractory patients. If the tumor becomes muscle invasive, the patients are subjected to radical cystectomy in which the urinary bladder is removed. This surgery is severely disabling and there is an urgent need to develop a treatment that will lead to a long lasting immune control with a possibility to delay or avoid surgery. We hypothesize that LOAd703, the human equivalent to Adm703, may be an interesting option for these patients. An orthotopic bladder cancer mouse model was treated intravesically with Adm703 to evaluate if Adm703 can control tumor growth. Bladders of female C57Bl/6 mice were incubated with poly-L-lysin to enhance tumor uptake before implantation of MB49 cells. The mice received four intravesical treatments with Adm703 or sodium chlorine (control) on day 1, 8, 15, 22 after tumor instillation. Mice were monitored for hematuria which is an early sign of tumor take. If more than 10 percent weight loss occurred the mice were sacrificed. The mice treated with Adm703 had less hematuria during treatment and had increased survival (mOS=40 days) compared to the control group (mOS=12 days). In conclusion, TME gene engineering with TMZ-CD40L and 4-1BBL increased survival of mice with orthotopic bladder cancer. Further studies investigating Adm703's effect on the immune system are planned.

#953 Oncolytic viruses as in situ personalized tumor vaccines for durable efficacy.

William WEI GUO Jia

Virogin Biotech Ltd, Richmond, BC, Canada

Tumor vaccines have shown clinical promise in treating certain cancers. However, their long-term effectiveness is often hindered by two major challenges:

1. The immune-suppressive tumor microenvironment (TME).
2. Selective targeting of antigen-positive tumor cells, which can lead to the expansion of antigen-negative cells and eventual tumor relapse.

To address these challenges, we explored a combination approach using mRNA tumor vaccines and oncolytic virotherapy in HPV and HER2 mouse tumor models. Our findings reveal that while mRNA vaccines effectively eradicate antigen-positive tumors and suppress tumor growth, resistance quickly emerges, enabling tumors to evade the vaccine's effects. When mRNA vaccination was followed by intratumoral administration of an oncolytic virus—either with or without HPV or HER2 antigen expression—a significantly more durable anti-tumor response was achieved in both models. The oncolytic virus initiated broad tumor antigen presentation by lysing tumor cells, releasing diverse tumor-associated antigens, and increasing the overall antigenic load within the tumor. Furthermore, the lytic activity of the virus reprogrammed the TME, transforming it from an immune-suppressive environment into one more favorable for anti-tumor immune responses. This combination therapy elicited a potent local immune response, leveraging enhanced antigen presentation by the virus. The modified TME allowed the systemic immune response generated by the mRNA vaccine to penetrate and act effectively within the tumor. Additionally, the treatment induced systemic antigen-specific T-cell responses, and treated animals developed resistance to subsequent tumor challenges, demonstrating the establishment of immune memory. Our study highlights the unique role of oncolytic virotherapy as an intratumoral "boost" mechanism. By lysing tumor cells, oncolytic viruses amplify the range of tumor antigens presented to the immune system and reshape the TME to support robust immune activity. This synergy between mRNA vaccination and oncolytic virotherapy—when employed in a prime-boost regimen—produces a powerful and durable anti-tumor immune response that is both localized and systemically protective against recurrence. In conclusion, this research underscores the potential of combining mRNA tumor vaccines with oncolytic virotherapy to overcome immune evasion mechanisms, enhance tumor antigen presentation, and reprogram the TME, providing a promising strategy for achieving long-lasting anti-tumor immunity.

#954 Preoperative p53-armed oncolytic virus therapy enhances the efficacy of postoperative adjuvant ICI therapy.

Daisuke Kadowaki[1], Shinji Kuroda[1], Makoto Matsumoto[1], Hitoshi Minagi[1], Tetsuya Katayama[1], Yu Mikane[1], Shunya Hanzawa[1], Masashi Hashimoto[1], Nobuhiko Kanaya[1], Yoshihiko Kakiuchi[1], Satoru Kikuchi[1], Kazuhiro Noma[1], Hiroshi Tazawa[1], Shunsuke Kagawa[1], Yasuo Urata[2], Toshiyoshi Fujiwara[1]

[1]Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan,[2]Oncolys BioPharma, Tokyo, Japan

Background : In recent years, the importance of perioperative treatment in cancer therapy has increased, and postoperative adjuvant therapies using immune checkpoint inhibitors (ICIs) have been applied clinically in multiple cancer types. However, the efficacy of ICIs as monotherapy is often limited. We have developed a telomerase-specific oncolytic virus (OV), OBP-301, and its p53 gene-armed derivative, OBP-702. OBP-301 is currently undergoing clinical trials. Previous studies have demonstrated enhanced antitumor immunity, including an increase in CD8+ T cells following OV administration. This study investigates the combination effect of preoperative OV therapy and postoperative adjuvant ICI therapy.

Methods : Experiments were conducted using C57BL/6 mice implanted with MC38 colon cancer cells (p53 mutant/MSI-H) and PAN02 pancreatic cancer cells (p53 wild/MSS). OBP-702 was used as the OV, and anti-PD-1 antibody was used as the ICI. A subcutaneous tumor model in mice was employed to evaluate the therapeutic effects and immune responses using flow cytometry under a protocol combining preoperative OV therapy and postoperative ICI therapy. Additionally, Bulk RNA sequencing was performed to further analyze the mechanisms of enhanced antitumor immunity.

Results : The OV-treated group exhibited significantly enhanced antitumor effects compared to the PBS-treated group. Analysis of tumor-infiltrating lymphocytes (TILs) in MC38 tumors revealed an increase in resident memory CD8+ T cells, PD-1+ CD8+ T cells, and p15E tetramer+ CD8+ T cells. Ex vivo CTL assays showed that TILs induced by OV exhibited stronger tumor specificity and antitumor activity. Additionally, in the OV group, p15E tetramer+ CD8+ T cells persisted significantly in the spleen for three weeks following primary tumor resection. In a rechallenge model where new tumors were established after tumor resection, preoperative OV therapy was shown to suppress postoperative recurrence and tumor growth while enhancing the effect of postoperative ICI therapy. Bulk RNA-seq of OV treated MC38 tumor with reactome pathway analysis revealed the upregulation of pathways associated with enhanced antitumor immunity.

Conclusion : OV therapy not only demonstrated direct antitumor effects but also induced tumor-specific systemic immunity and sustained long-term immune activation. These results suggest that preoperative OV therapy can enhance the effectiveness of postoperative ICI therapy.

#955 Single cell sequencing delineates immune features of oncolytic virus therapeutic response in murine high-grade gliomas.

Jack Hedberg, Alexia Martin, Doyeon Kim, Jaye Navarro, Adithe Rivaldi, Yeaseul Kim, Elizabeth Garfinkle, Katherine Miller, Ravi Dhital, Kevin Cassady, Elaine Mardis

Nationwide Children's Hospital, Columbus, OH

Oncolytic virotherapy (OV) comprises a developing family of cancer treatments that exploit cancer-specific vulnerabilities in viral defense through treatment with therapeutic viruses modified for safety and tumor-selective infection. Beyond direct infection and lysis of cancer cells, OVs are additionally capable of stimulating powerful immune responses that pose an opportunity to redefine the immune system's behavior in the tumor microenvironment. This may hold particular significance for highly immunosuppressive malignancies, including glioblastoma and other high-grade gliomas (HGG). Our labs developed OV C134, now under evaluation in a phase I clinical trial of recurrent glioblastoma (NCT03657576). While additional refinements to the activity and control of OVs within the tumor microenvironment may lead to superior performance, little is known about the exact features or timing of immune changes undergone in the setting of positive therapeutic response to oncolytic virus treatment. Here, using the widely-adopted C57BL/6 syngeneic high-grade glioma model CT2A modified to express luciferase, we applied bioluminescence imaging to measure tumor progression in vivo and identify therapeutic responders after intracranial treatment with C134, C002 (IL-12-expressing C134), or control (saline). We then performed single cell RNA sequencing of CD45-sorted high-grade glioma immune infiltrate (n=10 mice total; n=3 C002 responder and n=3 C002 nonresponder). Analysis of single cell sequencing data revealed that OV treatment produced diverse changes in gene expression consistent with activation of antigen presentation and antigen-specific immune responses throughout a variety of innate and adaptive immune populations. Further, cell type-specific immune signatures of C002 therapeutic responders as compared to nonresponders were identified, including responder-specific increases in major histocompatibility complex class II in macrophages/monocytes, interferon gamma in CD4+ and CD8+ T cells, tumor necrosis factor-alpha in CD4+ T cells, and a decrease in interferon gamma receptor 1 in T regulatory cells. Collectively, our findings contribute to the knowledge of how OV therapy alters tumor immune microenvironments and reveal prioritized candidates whose further study could advance the understanding of how to achieve positive responses to OV therapy in patients.

#956 HB-200: A novel viral vector vaccine platform that can improve immunotherapy treatment in HPV16+ HNSCC.

Sydney Fisher, Matthew Ji, Yuxuan Miao

The University of Chicago, Chicago, IL

Human papillomavirus-associated (HPV+) oropharyngeal squamous cell carcinoma (OSCC) is the most common head and neck cancer in the United States. While many HPV+ OSCC are curable using current standard treatment, the efficacy of these treatments diminishes when the cancers become metastatic. The viral associated malignancy provides unique opportunities for immunotherapy, however, immune checkpoint inhibitors only induce weak and unsustainable immunity against HPV+ cancer. Thus, there remains a need for new treatment modalities that improve outcomes while also reducing adverse effects. Previously, HB-200, a novel HPV-specific therapeutic vaccine containing two replicating live-attenuated vectors expressing the highly antigenic HPV16 E7E6 protein, has been shown to elicit a more robust anti-tumor immune response alongside chemotherapies compared to standard immunotherapies in clinical trial. However, the underlying mechanisms of why this vaccine can induce stronger immune response than immune checkpoint blockade remains unclear. Here, we utilize mouse models of HPV16 E6/E7+ OSCC to elucidate how HB-200 enhances anti-tumor immunity. To achieve this goal, we first established two complementary HPV16 E6/E7+ oral SCC tumor models: 1) grafting syngeneic MOC2 cells expressing the E6 and E7 oncoproteins of HPV16 on immune-competent C57BL/6 mice; 2) exposing the oral cavity of K14CreER; Rosa26-LSL-E6/E7 mice with 4-NQO to induce spontaneous oral SCCs. With these novel models, mice were then treated with either anti-PD-L1 or HB-200 plus chemotherapy to mimic clinical trials in humans. At 4 weeks post-tumor grafting, we profiled the immune landscape of these tumors by flow cytometry to quantify the frequency of specific CD8 T cell, CD4+ Tfh cell, and B cell populations which we hypothesized to be enriched following HB-200 treatment. This study addresses the central question of how viral immunotherapy can induce stronger immune responses than standard immune checkpoint immunotherapy and better enable T cells to achieve tumor control in HPV-associated cancer, providing an important mechanistic understanding of the HB-200 vaccine platform. Thus, findings from this study give critical insights for optimizing HPV-specific immunotherapy with the exciting potential to translate into novel clinical interventions for HPV+ OSCC patients.

#957 A novel therapeutic modality integrating antibody therapy and oncolytic virotherapy for enhanced tumor targeting and treatment.

Wenxin Xu[1], Can Chen[2], Huan Zheng[1], Jieying Xu[1], Mengshi Jiang[1], Li Zhang[1], Deyu Xu[1], Hongjie Cheng[1], Yang Zhang[1], Mengmeng Liu[1], Jinlu Cai[2], Fang Hu[2], Lieming Ding[1]

[1]Betta Pharmaceuticals Co., Ltd., Hangzhou Shi, China,[2]Hangzhou Converd co., Ltd, Hangzhou Shi, China

Background: In contemporary oncopharmacology, antigenic targets remain a pivotal focus, especially within the realm of immunotherapy, where tumor-specific antigens are of critical importance. Extensive research on these antigens has spurred the development of innovative therapeutic modalities, such as antibody therapies, CAR-T/NK cell therapies, XDC conjugate drug therapies, tumor neoantigen therapies, and gene therapies. However, these therapeutic strategies encounter significant challenges related to antigen target specificity. Although engineered antigen-targeting drugs typically provide high specificity and low toxicity, they can still disrupt normal signaling pathways and produce off-target effects, leading to adverse reactions that may compromise treatment duration and patient outcomes.To mitigate these challenges, we have devised a novel oncological strategy that synergizes antibody therapy with oncolytic virotherapy. This approach uses a genetically modified oncolytic virus to present a human-absent antigen on the surface of tumor cells, which is then targeted by a CD3 bispecific antibody to achieve the desired therapeutic effect. This combinatorial approach could expand treatment options for cancer patients, especially those with resistant tumors. It may also alter the tumor microenvironment, creating a bystander effect that boosts treatment effectiveness.

Methods: Through comprehensive mega data analytics, non-primate endogenous antigenic proteins were identified. Advanced genetic engineering techniques were employed to integrate the antigenic complex TT3 into the genome of a genetically modified oncolytic vaccinia virus, ensuring stable expression on the surface of virus-infected tumor cells. Then a TT3/CD3 bispecific antibody, designated BK-001, was developed. The binding affinity of BK-001 was rigorously evaluated using ELISA, FACS, and BLI methodologies. The functional potency was determined using RGA, and in vitro cytotoxicity assessed via RTCA. Anti-tumor efficacy of BK-001 was validated using preclinical models, and a comprehensive non-clinical safety assessment was conducted on cynomolgus monkeys.

Results and Conclusion: BK-001 is a bispecific T-cell engager antibody designed to boost the immune response against tumors infected by oncolytic viruses, promoting the destruction of cancer cells and improving the tumor microenvironment. The activation of BK-001 relies on the presence of TT3 antigen, which guarantees targeted immune response against tumors. In efficacy studies, BK-001 demonstrated robust tumor growth inhibition at minimal doses, with statistically significant differences compared to control groups. Furthermore, BK-001 exhibited prolonged activity and a favorable safety profile, underpinning its clinical development potential when used in conjunction with oncolytic virus therapy.

#958 Myeloid cell populations drive early Vaccinia-induced anti-tumor responses differentially based on tumor cell immunogenicity.

Duale Ahmed[1], Robyn Skillings[1], Omar Abdo[1], Aroosha Fareghdeli[2], Zoya Versey[1], Alicia Boxma[1], Leila Mostaco-Guidolin[2], Edana Cassol[1]

[1]Department of Health Sciences, Carleton University, Ottawa, ON, Canada,[2]Department of Systems and Computer Engineering, Carleton University, Ottawa, ON, Canada

Cancer poses an enormous burden on the healthcare system, with approximately 1 in 5 people worldwide expected to develop cancer in their lifetime according to the World Health Organization. Given this, there is a significant need for new therapeutics that are highly selective and evade tumor resistance to therapy. Oncolytic viruses (OVs) have been shown to selectively target and kill cancer cells while simultaneously activating local and systemic immune responses. Among these, Vaccinia (VACV) virus is a potential OV candidate with a high safety profile and a large genome, providing opportunities for genetic modification. However, in clinical trials it has shown to have limited success. To improve its efficacy, we need a more thorough understanding of VACV's immunomodulatory activity both within and across distinct tumor microenvironments (TME). In these studies, we treated weakly immunogenic (B16-F10) and highly immunogenic (MC38) tumors with a mouse-adapted wild-type VACV (3 intratumoral injections, 48 hours apart). Changes in immune cell infiltration and tumor associated macrophage (TAM) activation were assessed in tissues collected 24 hours after each injection and up to 21 days after completion of the treatment regimen. We found that VACV treatment significantly reduced tumor volume and was associated with an early influx of CD45+ cells across both models. This infiltration occurred earlier, was more pronounced, and lasted longer in MC38 vs. B16-F10 tumors. While both models were associated with a significant decrease in the relative frequency of immunosuppressive TAMs (24 hours after first injection), VACV treatment of MC38 tumors was associated with higher and more sustained levels of newly recruited inflammatory monocytes. Similarly, the MC38 TME maintained higher levels of activated TAMs (↑CD80/CD86 expression) and sustaining this phenotype for a longer period. Importantly, these changes were linked to increased infiltration of CD8 T cells, anti-tumor immune responses and a slower rebound of tumor growth (>2 weeks). Collectively, our results suggest that VACV treatment can help limit tumor growth in both MC38 and B16-F10 models but that the anti-tumor response is more pronounced and sustained in highly vs. weakly immunogenic tumors. This increased activity is not dependent on early loss of immunosuppressive TAMs but is dependent on the increased recruitment of inflammatory monocytes and the maintenance of activated TAMs in the TME. Further studies are required to assess the specific contribution of these cells in driving anti-tumor immune responses and whether sustained viral replication is required for these processes.

#959 Engineering tumor-avid bacteria as anticancer immunotherapy.

Noah Chen[1], Mathieu Rouanne[1], Zaofeng Yang[1], Tal Danino[2], Nicholas Arpaia[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Columbia University, New York, NY

The observation that bacteria colonize tumors, but not normal organs, after intravenous administration has spurred new interest in bacteria as tumor-targeted delivery systems. Since bacteria replicate within the tumor site, intravenous administration of bacteria leads to specific expression of peptide-based therapeutics at the tumor site. However, most prior bacterial cancer therapies have relied on this natural tumor tropism since the mechanisms behind this tumor-specificity are poorly understood. Additionally, clinical trials with bacterial therapeutics have shown lower tumor colonization rates in humans, which limits their translatability. This study used a pooled barcode library approach to screen the *E. coli* genome for pathways which may influence tumor colonization. We found specific pathways, include glucose catabolism, which promote *E. coli* tumor colonization, and non-glucose catabolic pathways which inhibit *E. coli* tumor colonization. KO of these inhibitory metabolic pathways increase *E. coli* glucose uptake and utilization. This was associated with increased tumor colonization as validated by competitive infection experiments, which was further enhanced when glucose was introduced into the tumor microenvironment. Together, these results support a major role for *E. coli* glucose catabolism in defining bacterial tumor tropism and suggest a promising method by which bacterial tumor tropism can be fine-tuned.

TUMOR BIOLOGY: Molecular Regulation of Metastasis

#96 Elucidating the role of CXCL17/GPR35 axis in breast cancer bone metastasis.

Gunjan Sharma, K. M. Abdullah, Seema Singh, Ajay P. Singh, Jawed A. Siddiqui

Cell and Molecular Biology, University of Mississippi Medical Center, Jackson, MS

Breast cancer (BC) has a high propensity to metastasize to the bone, but the molecular mechanisms driving bone metastasis (BoM) are not yet fully understood. BC cells establish bidirectional interactions with the bone microenvironment through altered expression of several chemokines and their receptors to facilitate metastasis and niche formation. Various G protein-coupled receptors are involved in oncogenic processes. Recently, it has been reported that G protein-coupled receptor 35 (GPR35), a cognate receptor for CXCL17, plays a significant role in tumor progression, metastasis, and drug resistance; however, its role in the modulation of bone microenvironment has not been elucidated. Here, we analyzed the expression of GPR35 in BC patients using the TCGA database. Furthermore, we also employed immunohistochemistry to examine the expression profile of GPR35 in BC tissue microarray. Our findings revealed high GPR35 expression in BC relative to the normal breast tissue. High GPR35 expression in BC also correlated positively with poor patient outcomes. Moreover, GPR35 expression was elevated in human as well as syngeneic BC bone metastatic cell lines (SCP2, SCP28, and E0771/Bone) compared to their relative parental cell lines (MDA-MB-231 and E0771P), advocating its significant potential in bone metastasis. Since most of the BC bone metastasis is osteolytic (bone destructive) in nature, and osteoblasts (OBs) regulate the osteoclasts (OCs) functions, therefore we examined the effect of conditioned media (CM) from the BC cells treated with either vehicle or rhCXCL17 on OBs and OCs. BC-CM induced bone cell differentiation, which was remarkably significant in OBs and OCs treated with BC-CM of rhCXCL17-treated cells. Together, these findings highlight the critical role of the CXCL17/GPR35 signaling axis in bone microenvironment remodeling supporting BC cell colonization.

#961 Scalable isolation of bacterial extracellular vesicles for macrophage-activating immunotherapy.

Irem Karaman, Asmita Pathak, Oriana Teran Pumar, Brandon Emanuel Leon, Jonathan Mitchell, Carlos David Oliva, Selma Maacha, Wael El-Rifai, Defne Bayik, Dionysios C. Watson

University of Miami Miller School of Medicine, Miami, FL

The efficacy of immune checkpoint inhibitors (ICIs) is hampered by tumor-associated immunosuppressive myeloid cells. Secreted nano-sized (~25-100 nm) bacterial extracellular vesicles (bEVs) modulate myeloid cells in the context of infection and colonization, and are being developed for cancer immunotherapy. However, lack of standardized bEV purification strategies limit reproducibility across laboratories and hamper translational development. Herein, we aimed to develop a scalable isolation workflow for bEV therapeutics. We grew the human commensal strain *E. coli Nissle* to early stationary phase to generate bEV-rich conditioned cell culture medium; removed bacteria by centrifugation and filtration; concentrated conditioned medium by tangential flow filtration (TFF; 100 kDa MWCO); and purified bEVs by semi-automated size-exclusion chromatography (SEC). During TFF concentration, we observed conditioned media becoming turbid, suggesting prescipitation of macromolecules, including potentially nucleic acids. Indeed, when we assessed DNA content at sequential purification steps via gel electrophoresis, and found that commercial bacterial culture media contains significant amounts of DNA which co-isolate with bEVs. We thus expanded our workflow to include clearance of baseline culture medium nucleic acid content by 30 kDa ultrafiltration of the culture medium prior to use. In addition, we treated TFF-concentrated conditioned media with the promiscuous DNAse/RNAse Benzonase (25 units/mL) which reduced nucleic acid content of bEVs by 66%, suggesting that Benzonase further increased bEV purity by depleting nuclease-sensitive non-vesicular nucleic acids. After SEC, we identified bEV-containing fractions by DNA/RNA/protein quantification, transmission electron microscopy and nanoparticle tracking analysis. Next, we assessed the immunologic activity of bEVs ex vivo by adding to cultured mouse splenocytes and bone marrow cells, and observed broad effects on myeloid cells and lymphocytes. Our optimized workflow provides a broadly applicable approach for isolating bEVs from species requiring complicated medium. This standardized method will enhance reproducibility and minimize non-specific effects of contaminants, facilitating translational development of bEV immunotherapy. Future experiments will test the role of bEVs from different microbial species in augmenting ICI efficacy in mouse models of cancer.

#962 Activation of natural killer cells by small molecule inhibits growth of BCG-resistant bladder cancer cells.

A. Gupta, S. Verma, S. Gupta;
Case Western Reserve University, Cleveland, OH

Bacillus Calmette-Guérin (BCG) is the standard treatment for non-muscle invasive bladder cancer (NMIBC) patients, but resistance declines its efficacy, emphasizing the need for alternative therapies. BCG therapy triggers a specific cytotoxic immune response by activating and expanding CD56/natural killer (NK) cells and T cells, which effectively target and eliminate bladder cancer cells. This priming of NK and T cells by BCG leads to the release of cytokines such as interferon-gamma (IFNγ) and tumor necrosis factor-alpha (TNFα), which stimulate adaptive immunity and enhance tumor cell destruction. Evidence suggests that impaired T-cell and cytotoxic responses are key factors in immunotherapy failure. We designed the study to identify compounds which have the ability to activate the NK cells and generate a robust immune response within the bladder microenvironment. Our preliminary studies exhibited a notable elevation in HLA-B expression and an increased NK cell presence in recurrent NMIBC patients. Yet, despite the increased NK cell population, our findings suggest that NK cell activation may be insufficient, possibly due to inhibitory signals that suppress NK cell cytotoxicity. Bioinformatics analyses revealed a strong association between HLA-B and the NK cell inhibitory receptor KIR3DL3, prompting us to explore potential inhibitors of this interaction. In-silico screening identified 4′,5,7-trihydroxyflavone, a natural flavone as a small-molecule blocker of the KIR3DL3-HLA-B interaction. We hypothesized that inhibiting this pathway, 4′,5,7-trihydroxyflavone could potentially reduce inhibitory signaling, thus enhancing NK cell-mediated cytotoxic activity against bladder cancer cells. Treatment of BCG-resistant human bladder cancer T24 cells with BCG or 4′,5,7-trihydroxyflavone alone for 8 hours no notable effect was noted on cell viability. Incubation of NK cells with 4′,5,7-trihydroxyflavone, without BCG, resulted in a significant increase in cancer cell death, indicating that the compound alone could induce a potent cytotoxic response. Furthermore, qRT-PCR analysis demonstrated elevated expression of CD244, a type-I transmembrane protein involved in immune system regulation, and CD160, a glycoprotein closely linked to NK cell activity, specifically following treatment with 4′,5,7-trihydroxyflavone but not with BCG. Taken together, our data provide evidence that 4′,5,7-trihydroxyflavone may act as a reactivator of NK and T cell-mediated responses in BCG-resistant bladder cancer cells. By effectively blocking the inhibitory KIR3DL3-HLA-B interaction, this compound enhances NK cell cytotoxicity, resulting in a higher percentage and more sustained immune-mediated cancer cell death. This suggests a promising therapeutic approach for patients who are unresponsive to BCG, potentially leading to improved outcomes in resistant NMIBC.

#963 Evolved therapies specifically activate and expand endogenous γ;δ; T cells to remove the barriers to broadly effective immunotherapies.

Jonathan W. Kotula, Ed Lemmens, Rafael Rivera-Lugo, Ying Feng, Daniel A. Portnoy

Laguna Biotherapeutics, Inc., San Francisco, CA

Live bacterial therapeutics have the potential to generate transformative outcomes for cancer patients. CAR-T cells are a synthetic attempt to combine B and T cell biology to maximize targeted killing and deliver abundant and active cells to overcome the limitations of endogenous immune cells. Although these therapies have provided some immunotherapy success, they are limited by practical challenges such as an inability to manufacture sufficient material, extreme cost, an inability to re-dose, and severe acute toxicities.

In contrast, $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cells have emerged as an exciting alternative to CAR-T. Because they have evolved to fill a unique niche at the interface of the innate and adaptive immune system they may be a solution to the limitations of CAR-T. Where CAR-T cells carry the risk of GvHD, $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cells are MHC-independent, and possess multiple checkpoints that prevent killing healthy cells. The tumor microenvironment prevents CAR-T penetration, but resident $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cells exist within every tissue, awaiting activation and expansion. $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cell dominance of immunotherapy has so far been prevented by our inability to durably or repeatedly expand endogenous cells.

Our solution to these limitations is to exploit the natural properties of Listeria monocytogenes to induce the proliferation and durable activation of endogenous $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cells. Our pre-clinical *in vitro* and *in vivo* data, combined with results from previous clinical studies show that Listeria expanded endogenous $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cell populations to >1x10^9 cells, orders of magnitude more than other approaches. Furthermore, Listeria-activated $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cells are uniquely cytotoxic, durable, and safe. They eliminate cancer cell lines in vitro at E:T ratios of ~1, whereas antibody and cell therapies require E:T ratios >10. They down-regulate exhaustion markers and remain active for multiple rounds of cell killing, and they express 5-fold less IL-6, the primary indicator of CRS toxicity. Listeria-activated $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cells are more abundant, cytotoxic, durable, and less toxic than CAR-T, and they can be re-dosed for persistent efficacy.

To improve on the safety profile of previous Listeria-based therapeutics, we have generated a quadruple attenuated strain (QUAIL) that cannot grow extracellularly. Our *in vitro* and *in vivo* data show that QUAIL cannot grow in human serum or on stents or indwelling ports, where previous therapeutic strains thrived, and cannot persist in RAG1 -/- mice that lack T and B cells, all while maintaining the $\boldsymbol{\gamma}$;$\boldsymbol{\delta}$; T cell activation and expansion that was observed in cancer patients. QUAIL will enter the clinic in multiple myeloma in 2025, and we believe that this novel therapy will generate meaningful and lasting cancer remission where current cell therapies have provided a glimpse of what's possible.

POPULATION SCIENCES: Bridging Gaps in Cancer Care: Disparities, Social Determinants, Innovations, and Strategies Poster Session

#967 Geographic and social determinants of late-stage breast cancer diagnoses in Guam: The role of social vulnerability and access to care.

Michael Basaliza Cajigal, Grazyna Badowski, Louis Jane B. Dulana

University of Guam, Mangilao, GU

Background: Breast cancer is the second leading cause of cancer deaths among women in Guam. Despite a lower incidence than the mainland U.S. (86.6 vs. 126.8), Guam has a higher mortality rate (27.3 vs. 20.3, 2013-2017), suggesting that late-stage diagnoses and social determinants of health (SDOH) contribute to poorer outcomes. Access to mammography screening clinics is uneven across Guam, with most facilities concentrated in the northern and central regions. The Social Vulnerability Index (SVI), a measure of SDOH, offers a framework to explore these disparities. This study investigates geographic variation in late-stage breast cancer rates across Guam's municipalities and the association with municipal-level SVI scores.
Methods: A cross-sectional analysis was conducted using data from the Guam Cancer Registry for all breast cancer cases diagnosed between 1998 and 2021. Late-stage rates were calculated for each municipality. Socioeconomic vulnerability was measured using Guam-specific Social Vulnerability Indices (SVIs), derived from 15 variables reflecting socioeconomic and demographic factors, with adjustments for additional Guam-specific characteristics. The beta regression model with mixed effects was applied to examine the relationships between advanced-stage diagnoses and SVI.
Results: Overall, 36% of breast cancer cases were diagnosed at a late stage, with regional disparities ranging from 14% in certain areas to as high as 40% in others. These variations underscore significant geographical differences in healthcare access and early detection. Beta regression analysis revealed that higher scores on the Social Vulnerability Index (SVI), which captures socioeconomic and environmental risk factors, were significantly associated with increased rates of late-stage diagnosis ($PR = 1.04$, $p = 0.02$). Women residing in the South region of Guam were particularly at risk, showing a 43% higher likelihood of late-stage diagnosis compared to those in the central region ($PR = 1.43$, $p = 0.01$).
Conclusion: Significant disparities in late-stage breast cancer diagnoses exist in Guam, especially among areas with higher social vulnerability. Living in the South region and limited access to mammography services increased the likelihood of late-stage diagnosis. These findings highlight the urgent need for targeted public health interventions to improve early detection, address social inequities, and enhance healthcare access across Guam.
Acknowledgement: This research was funded by the National Cancer Institute: The University of Guam/University of Hawaii Cancer Center Partnership to Advance Cancer Health Equity (PIPCHE), Grant U54CA143728 (University of Guam)/Grant U54CA143727 (University of Hawaii Cancer Center).

#968 Predictors of advance care planning documentation in female patients with breast cancer: A multilevel model analysis.
A. Garcia Sierra, M. Tan;
The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL

Background: Advance care planning (ACP) is a process that supports adults at any age or stage of health in understanding and sharing their personal values, life goals, and preferences regarding future medical care. Likewise, ACP is associated with multiple benefits, such as lower rates of hospitalizations and reduced futile, aggressive cancer treatment at the end of life. However, ACP rates remain low in the U.S., especially for patients with advanced cancer. Despite being more likely to be diagnosed at advanced stages and hospitalized due to advanced cancer with poor prognosis, Black and Hispanic/Latino populations continue to have very low rates of ACP. Research has shown that both individual-level and systems-level factors contribute to these racial disparities in ACP. Considering these disparities among vulnerable populations, interventions that increase ACP among minority patients with cancer are needed.
Objective: To analyze using multilevel model analysis the predictors of ACP documentation in female patients with breast cancer over 5 years in the UChicago Health System.
Methods: Using the Clinical Data Research Warehouse, this study included women diagnosed with breast cancer (N=7,814) from 2016 to 2021. Descriptive statistics were performed to characterize ACP, and potential differences in ACP rates among control variables were assessed using odds ratio (OR) estimations. Analyses were conducted using random effects (mixed effects) multilevel modeling. To account for individual differences in ACP documentation completeness over time, both intercept and slope were included as random effects. In the multilevel model, level 1 modeled individual ACP documentation and level 2 tested the group effects in ACP documentation. The effect of time was tested in level 1, and the variances in the intercept and slopes were represented in level 2.
Results: 8.74% of women with breast cancer had at least one type of ACP documented in their medical records; 4.25% had a power of attorney and 5.75% had an advanced directive. Age and the time elapsed between diagnosis and ACP completion are related to an increased likelihood of ACP completion over time. Being divorced increased the likelihood of ACP completion at baseline. Outpatient services decreased the likelihood of ACP completion over time. Conclusion: Understanding the factors that are related to ACP documentation will allow us to manage them and improve their completion. These results will help to inform the development of tools to increase the integration of ACP into care, especially those that are technology-based. Further work could include the design of a predictive model to prioritize patients who require ACP. Providing knowledge about ACP in nonclinical areas can lead to increased education about ACP and its benefits to families and communities.

#969 Deciphering sex differences in clear cell renal cell carcinoma at the single-cell resolution.

Xiangwei Fang, Yize Li, Xiyi Wei, Siqi Chen, Chia-Kuei Mo, Wagma Caravan, Preet Lal, Ruiyang Liu, Ilya Strunilin, Yizhe Song, Yuwei Zhang, Song Cao, Cody Weimholt, Feng Chen, Li Ding

Washington University in St. Louis, School of Medicine, St. Louis, MO

Clear cell renal cell carcinoma (ccRCC) is the most prevalent subtype of renal cell carcinoma, accounting for approximately 70% of cases. Strikingly, ccRCC exhibits a marked sex disparity in prevalence, being significantly more common in men than women. This disparity underscores the importance of systematically investigating sex differences to elucidate their implications for the diagnosis, prognosis, and therapeutic strategies of ccRCC. To address this, we generated a comprehensive single-nucleus sequencing atlas (snRNA-seq and snATAC-seq) comprising over 400,000 nuclei from 65 ccRCC cases. This dataset was complemented by paired bulk proteogenomic data, enabling a multi-layered analysis of the molecular landscape. The study cohort, including 21 females and 44 males, reflects the sex distribution observed in ccRCC incidence within the general population. Our analysis uncovered sex-associated molecular differences in key pathways driving ccRCC progression. These include genes regulating the hypoxia-inducible factor (HIF) pathway, a hallmark of ccRCC, as well as lipid metabolism and energy homeostasis pathways, which are critical to ccRCC progression. Furthermore, genomic characterization revealed significant sex differences in tumor mutational burden (TMB) and specific genetic alterations, including higher mutation frequencies in *KDM5C* and *MTOR* in male tumors. These genetic differences were linked to distinct downstream effects, suggesting sex-specific impacts on tumor biology. These findings illuminate new opportunities for developing sex-informed therapeutic strategies and biomarkers, enabling a more precise and tailored approach to ccRCC screening and treatment.

#97 Microtubule dynamics in regulating bone metastasis of breast cancers: a novel function of tubulin β-2 and tubulin β-3.

Shreya Patel[1], Marcus Winogradzki[1], Waddell Holmes[1], Alan Blank[2], Niyati Patel[1], Jitesh Pratap[1]

[1]Anatomy and Cell Biology, Rush Univ. - Rush Medical College, Chicago, IL,[2]Section of Orthopedic Oncology, Rush Univ. - Rush Medical College, Chicago, IL

Introduction: Bone metastases (BM) represent a significant hurdle in advanced cancer management, with median survival rates of 12 to 50 months. Current treatment options, including surgical resection and microtubule (MT)-targeting chemotherapies like paclitaxel, often provide palliative rather than curative outcomes. MTs, composed of α- and β-tubulin heterodimers, are essential for cell division, migration, and trafficking. Dysregulated expression of β-tubulin isotypes, TUBβ2 and TUBβ3, has been implicated in chemoresistance, yet their specific roles in breast cancer bone metastases (BMBC) remain poorly understood. This study explores the novel functions of TUBβ2 and TUBβ3 and investigates their potential as therapeutic targets by disrupting their unique C-terminal domains.
Methods: RNA-Seq datasets and patient survival data from publicly available databases were analyzed to evaluate the expression of TUBβ2 and TUBβ3. Immunohistochemistry (IHC) was performed on matched primary and BM tumor biopsies (n=16) from BC patients. CRISPR/Cas9-mediated knockdowns (KDs) in bone-derived MDA-MB-231 cells were employed to assess cell growth, survival, adhesion, migration, and metastatic properties. MT polymerization rates were evaluated using MT regrowth assays, subcellular trafficking was analyzed via immunofluorescence imaging. Focal adhesion turnover were assessed by western blotting, and IL6 secretion-analyzed by ELISA.
Results:
Elevated expression levels of TUBβ2 and TUBβ3 significantly correlated with poor survival in breast cancer patients and were markedly higher in BM tumors compared to primary and normal breast tissues. CRISPR KD revealed distinct morphological changes, with TUBβ2KD inducing giant cell formation and TUBβ3KD leading to elongated cytoplasmic extensions.

- Metastatic properties: TUBβ2KD reduced adhesion but enhanced migration, while TUBβ3KD diminished migration but increased adhesion. Reduced focal adhesion kinase (FAK) levels were observed in both KDs, impairing adhesion and migration.
- MT dynamics: KDs caused significant delays in MT repolymerization, indicating isotype-specific integration into MT polymers.
- Cytokine secretion: Loss of TUBβ2 led to a 2-fold increase in IL6 production, whereas TUBβ3 loss resulted in a 70% reduction in IL6 secretion.
- Subcellular trafficking: Loss of perinuclear endosomal puncta revealed novel roles for TUBβ2 and TUBβ3 in endosomal trafficking.

Conclusions and Impact: This study identifies TUBβ2 and TUBβ3 as critical regulators of MT dynamics and metastatic properties in BMBC. Their roles in cell adhesion, migration, and trafficking underscore their potential as therapeutic targets. Current clinical approaches to BM focus largely on palliative care, but targeting TUBβ2 and TUBβ3 offers a promising strategy for more precise interventions that could improve patient survival and quality of life.

[1]Rutgers School of Public Health, Piscataway, NJ,[2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[3]New Jersey State Cancer Registry, Trenton, NJ

Background: The Cancer Analytics and South Asian Health - Breast Cancer (CANSAH-BC) pilot study was launched in New Jersey (NJ) in 2022 to evaluate the drivers of aggressive breast cancer, familial aggregation, and quality of life among South Asian American (SAA) females, who are an understudied population.
Purpose: To compare the CANSAH-BC cohort with SAA patterns in the National Health Interview Survey (NHIS), the California Health Interview Survey (CHIS), & breast cancer survivors identified in the Surveillance, Epidemiology, and End Results (SEER) NJ program, and assess familial aggregation.
Methods: Eligible CANSAH-BC participants were SAA females aged 21+, diagnosed with primary invasive breast cancer in NJ (2017-2023), who provided consent. Sociodemographic, lifestyle factors, family, and medical history were collected via interviews, with tumor data from the NJ State Cancer Registry. We compared CANSAH-BC participants with SAA females from NHIS, CHIS, and SAA breast cancer survivors in SEER using descriptive statistics. Familial incidence rate was calculated by dividing breast cancers in relatives by total person-years. Using the Institute of Health Metrics and Evaluation (IHME) population rates for South Asia, we calculated the standardized incidence ratio (SIR) and its 95% confidence interval (CI). Assuming a lognormal distribution for breast cancer risk and leveraging the known relationship between SIR and coefficient of variation of the risk distribution, we estimated the proportion of breast cancers in SAA women at highest and lowest 25% risk.
Results: Among 101 CANSAH-BC participants, most were first-generation immigrants (94%), married (86%), insured (99%), and non-smokers (99%). Compared to NHIS and CHIS, more participants held a college degree (71%, 82%, 87%, respectively), were employed (62%, 68%, 73%, respectively), and had hypertension (17%, 11%, 33%, respectively) or diabetes (9%, 8%, 22%, respectively). Stage (60% localized) and triple-negative subtype (10%) distributions were similar to SEER NJ SAA survivors (62% localized, 9% triple-negative) but CANSAH-BC participants were younger (Mean (SD) = 52 (12) years vs. 56 (13) years in SEER NJ; p = 0.0017). The SIR was 3.86 (95% CI: 3.11 - 4.74), indicating significant familial aggregation. Under a lognormal distribution of risk, 68.7% of breast cancers will occur in SAA women at the top 25% risk group, while only 3.3% in the lowest 25%.
Conclusion: CANSAH-BC participants closely mirror NHIS and CHIS respondents, but are significantly younger than SEER NJ survivors. The significant familial aggregation and likely concentration of breast cancers in the top 25% risk group underscore the predictive influence of shared genetic and environmental factors among relatives of SAA women with breast cancer. Our future direction will investigate these shared factors using germline and genomic markers.

#971 Biological sex disparities in oral HPV infection and vaccination rates in people with HIV in Puerto Rico: a public health concern.

Jurelis Torres-Reyes, Juliana M. Serrano-Rodriguez, Gabriel Borgez-Velez, Jeannette L. Salgado-Montilla, Maria Sanchez-Vazquez, Magaly Martinez-Ferrer, Ana P. Ortiz-Martinez, Josue Perez-Santiago

UPR - Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Human papillomavirus (HPV) is the most common sexually transmitted infection, with estimates for the probability of infection with the virus exceeding 80% for women and 90% for males across their lifetime. People with HIV (PWH) are at a higher risk of acquiring oral HPV infection, despite antiretroviral therapy, making them more susceptible to Oropharyngeal cancer (OPC). Puerto Rico (PR) has a significant burden and disparity of HPV and HIV-related malignancies, and socio-economic disadvantages, which limit access to HPV vaccine. While HPV vaccination rates in the US is 46% in young adults, HPV vaccination rates in PR are limited, particularly in PWH. Here, we described the prevalence of oral HPV infection among PWH in PR and investigated socio-behavioral factors associated with HPV infection.
Methods: We evaluated 135 sexually active PWH with a median age of 48 years old. Oral rinse samples were collected and analyzed for HPV and genotyped using the DNA ELISA kit HPV SPF10 and RHA kit HPV SPF10-LiPA25. An administered questionnaire collected sociodemographic characteristics and lifestyle variables. Statistical analyses were performed in R-statistical software.
Results: There was a 32% prevalence of oral HPV infection, of which 61% were high-risk genotypes, with HPV-18 being the most abundant (39%). The prevalence of oral HPV was higher in males than females (34% vs. 17%), and high-risk genotypes were only present in males. High proportion of our cohort (67%) did not have the HPV vaccine while 60% have the knowledge of HPV infection. Knowledge of HPV infection was higher in males than females (56% vs 33%), but even then, vaccination rates were very low (20% males vs 11% females).
Conclusion: High prevalence of oral HPV infection was observed in PWH, higher than previously observed in PR. Limited HPV vaccination rates may possibly be due to age ineligibility, access, or lack of awareness of the vaccine. Males had a higher prevalence of oral HPV infection and were the group in which high-risk HPV genotypes were detected. Although female vaccination rates were low, the lack of high-risk genotypes may be due to early access to HPV vaccine based on regular established screening protocols for cervical cancer, but these protocols have not been established for high HPV-related cancer risk male populations. The incidence in OPC is increasing and it is expected to exceed that of cervical cancer, these findings highlight the need to establish better preventive public health strategies from an educational standpoint, and medical care access.

#972 Identifying patient navigation needs and gaps in cancer care in Puerto Rico: insights from the START-PR study.

Lorena Gonzalez-Sepulveda[1], Stephanie Cameron-Maldonado[1], Karina M. Rivera-Mejia[1], Natalia E. Dominguez-Betancourt[2], Maria M. Vazquez-Torres[1], Alejandra Diaz-Rohena[3], Liamarys Ortiz-Torres[1], Noedly Ayala-Sanchez[4], Yadielis S. Arce[4], Nancy Cardona-Cordero[1], Marievelisse Soto-Salgado[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]University of Puerto Rico, Rio Piedras Campus, San Juan, Puerto Rico,[3]University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico,[4]University of Puerto Rico, Cayey Campus, Cayey, Puerto Rico

Background: Patient navigation (PN) services in cancer care have significantly benefited cancer patients by reducing disparities in cancer outcomes, screening, and treatment. Identifying the characteristics of cancer patients who need PN services and the services they need may assist in the design of targeted future PN programs. Therefore, our study aims to identify the PN services that are most needed in this population and determine the association between the need for PN services among cancer patients in Puerto Rico and sociodemographic and health-related factors.
Methods: Our ongoing pilot cross-sectional study, START-PR, has recruited cancer patients aged 21+ years who received active treatment in the last year and resided in Puerto Rico, through an online survey. Data on PN services, sociodemographic, and clinical characteristics were assessed in this study. Multivariate logistic regression models, including covariates with p-values < 0.25 in univariate models, were performed to determine associations between the selected characteristics and the need for PN services. McNemar's test was used to determine differences in the proportions between the need and the receipt of PN services.
Results: To date, 547 individuals have accessed the survey and met the eligibility criteria, with 538 (98.4%) completing the survey. Most of our sample were women (69.2%), aged between 40-64 years (56.1%), had a higher educational attainment than high school (72.6%), and had cancer in localized stages (64.4%). About 29% of the patients self-reported needing PN services. Among these patients (n=156), the most commonly needed services were: (1) coordination of tests, procedures, and treatments (36.5%), (2) education (34.6%), and (3) assistance in scheduling appointments or finding a new doctor (29.5%). Participants aged 40 to 64 (34.8%), with education beyond high school (31.4%), with comorbidities (32.1%), without a partner (32.5%), with public health insurance (34.3%), and diagnosed with cancer for more than a year (32.8%) had higher PN service needs than their counterparts ($p<0.25$). After controlling for potential confounders, patients with comorbidities had 2.2 times the odds (95% CI: 1.28, 3.79) of needing PN services compared to those without comorbidities. About 10.8% did not need the PN services but ended up receiving them, while 18.4% needed the PN services but did not receive them ($p=0.001$). Conclusion: The results of this study provide valuable information to guide the design of targeted future PN programs in Puerto Rico. Further studies should include in-depth qualitative methods to better understand the reasons behind these needs and identify the specific barriers patients face to receive cancer care.
Fundings: Partially supported by the Office of Cancer Research Training and Education Coordination of the UPR Comprehensive Cancer Center and the Hispanic ALLIANCE (NIGMS-U54GM133807).

#973 Silent suffering: the urgent need for improved palliative care and opioid access for breast cancer patients in the Caribbean.

Alexandria E. Curry, Advith Suresh, Robin Williams, Samrawit Zinabu, Miriam Michael

Howard University, Washington, DC

This study aims to investigate the availability and accessibility of palliative care and opioid-based pain management for patients with advanced breast cancer in the Caribbean, highlighting regional disparities and barriers to effective end-of-life care. We analyzed the availability of palliative care services and opioid medications in Caribbean countries, focusing on gaps in healthcare infrastructure, regulatory challenges, and cultural or legal barriers to opioid use. We collected data from national reports, healthcare registries, and published literature. Our study found that access to palliative care in the Caribbean is severely limited, with some nations, like Haiti, having no palliative care physicians. The Bahamas, which has the highest breast cancer mortality in the region, only has one. Countries with established programs, like Barbados and the Cayman Islands, struggled to expand services beyond limited geographic and population reach due to funding constraints and a lack of trained professionals. Despite the inclusion of at least two forms of opioid medications in most national formularies, their actual use remains significantly lower than global standards—20 times less than the per capita usage in the United Kingdom and 60 times less than the usage in the United States. Barriers included restrictive laws, negative perceptions of opioids, and logistical inadequacies in medication access. In many countries, opioids could only be obtained from hospital pharmacies, further restricting access and stigma and fear of addiction contributed to underprescription and underuse, even when medications were available. These issues were compounded by a lack of provider education in safe opioid prescribing, resulting in unnecessary suffering for patients with advanced disease. These gaps in palliative care result in inadequate care, leaving many patients without the necessary support to manage their symptoms and maintain quality of life. Access to palliative care and effective pain management for advanced breast cancer patients in the Caribbean is critically inadequate. There is an urgent need for enhanced palliative care services, including professional training, and the development of formal guidelines to address regulatory barriers to opioid access. To address these challenges, we recommend the creation of a resource-specific guide for low- and middle-income countries that focuses on integrating pain medication into palliative care protocols as a central component of treatment. Additionally, we propose a basic level of supportive care for patients with organ-based metastatic disease, which provides site-specific recommendations for managing symptoms and complications in resource-limited settings. These measures are essential to improving the quality of life and ensuring equitable care for patients in the region.

#974 Social determinants in healthcare utilization among women diagnosed with cervical cancer: data from *The All of Us Research Program*.

Brenda C. Torres-Velasquez[1], Josue Perez-Santiago[2], Natalie Alamo-Rodriguez[3], Julie Dutil[2], Vivian Colon-Lopez[3]

[1]Division of Shared Resources and Scientific Operations, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Division of Clinical and Translational Cancer Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[3]Division of Cancer Control and Population Sciences, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Despite significant declines in cervical cancer incidence and mortality, disparities persist, particularly among underserved populations. This study aims to investigate how social determinants of health contribute to the barriers faced by women diagnosed with cervical cancer, affecting healthcare utilization. Utilizing the *All of Us Research Program* database, we analyzed a cohort of women diagnosed with malignant tumors of the cervix, including carcinoma in situ, using ICD-10-CM codes C53 and D06. Participants, all identifying as women, completed validated surveys assessing overall health, healthcare access and utilization, personal and family health history, and social determinants of health. Univariate and multivariate logistic regression models were conducted to assess social determinants of health in relation to healthcare access. Key dependent variables included delays in seeking healthcare due to limited time-off, caregiving responsibilities, inadequate transportation, and financial constraints such as difficulties affording medications or copayments. Data was analyzed using RStudio Cloud Environment within All of Us Workbench. Among the 1,310 cervical cancer patients analyzed, 299 (22.8%) identified themselves as Hispanics, 670 (51.1%) as non-Hispanic White, 265 (20.3%) as non-Hispanic Black, and 76 (5.8%) as other or unknown. Educational attainment was high, with 852 (65%) attending or having completed college. Most participants (95%) had some form of insurance; however, (43.7%) reported annual earnings below $50,000. Participants earning between $25,000 and $50,000 were 3.6 times more likely [OR=3.6; 95% CI: 1.2-15.8] to delay seeking healthcare due to time-off issues compared to those earning $200,000 or more. Participants earning $25,000 or less compared to those earning $200,000 or more identified transportation access as a significant barrier to healthcare (OR=6.3 [95% CI: 1.8-40.1]), still were 4.2 times more likely [95% CI: 1.1-17.3] to seek advice from a general doctor. This OR slightly decreased to 4.1 [95% CI: 1.1-17.0] when adjusting for insurance coverage awareness, to 3.8 [95% CI: 1.01-15.5] when considering the nervous emotional state, and returned to 4.2 [95%CI 1.1-17.4] when perceiving easily understandable health information. Income and transportation are critical factors influencing healthcare-seeking behavior among low-income women diagnosed with cervical cancer; however, they do not act in isolation. Barriers related to social determinants significantly affect their ability to maintain appropriate follow-up care. Interestingly, race and ethnicity did not emerge as significant disparities in this cohort. Further investigation into insurance specifics, family dynamics, cultural beliefs, and other social determinants is essential for achieving equity in healthcare access for women with cervical cancer.

#976 Evaluation of causes of late presentation among female cancer patients in a tertiary cancer center in Nepal: Mixed method study.

Shweta Baral[1], **Ashim Khadka**[2], Deep Lamichhane[3]

[1]Bhaktapur Cancer Hospital, Kathmandu, Nepal,[2]Nepal College of Information and Technology, Kathmandu, Nepal,[3]Surgical Oncology, Bhaktapur Cancer Hospital, Kathmandu, Nepal

Introduction: Gender disparity in cancer diagnosis and treatment is prevalent in LMICs. Late presentation among female cancer patients is of the challenging issue here leading to poorer treatment outcomes. This study is first of kind in Nepal to investigate factors contributing to delayed presentation for treatment.
Methodology: A convergent mixed-method design was conducted in a government cancer center to evaluate the factors contributing to the late presentation among female cancer patients with an average age of 54.19 years. The quantitative component surveyed 200 late presenting female cancer patients and 15 patients who were purposefully chosen to participate in a focus group discussion to examine socioeconomic and demographic factors. Descriptive statistics, Chi-square tests and logistic regression were used to identify the factors associated with late presentation.
Results: Among the 200 patients surveyed, 88 presented in a locally advanced stage without much symptoms, and 58% patients (116/200) delayed seeking treatment after being symptomatic. Quantitative analysis showed that the following factors were significantly linked to late presentation among delayed treatment seeking patients : rural residency (Odds Ratio [OR] = 2.15, 95% Confidence Interval [CI]: 1.42-3.25), education below 12th grade (OR = 3.76, 95% CI: 2.10-6.72), extended joint family living (OR = 1.85, 95% CI: 1.12-3.04), and unemployment (OR = 2.54, 95% CI: 1.63-3.97). Chi-square analysis also showed significant associations between late presentation and factors like rural residency ($p < 0.01$), education below 12th grade ($p < 0.01$), joint family living ($p < 0.05$), and unemployment ($p < 0.01$). A majority of late presenters (63.79%, 74/116) hid their symptoms for an average of 15 months, while 24.13% (28/116) postponed their visit due to financial difficulties, and 12.06% (14/116) were ignored by family members until their symptoms worsened. Four major themes emerged from the focus group discussions that contributed to the presentation's delay: 1) fear of destabilizing the family due to illness, 2) financial hardship in covering treatment costs, 3) underestimating the seriousness of symptoms, and 5) fear of abandonment after receiving a cancer diagnosis, especially by spouses and in-laws.
Conclusion: This study highlights the need for interventions addressing both the socioeconomic and cultural barriers that delay timely healthcare access for female cancer patients in Nepal. Enhancing community awareness, improving healthcare accessibility, and providing financial support could mitigate the identified challenges, potentially leading to better outcomes for women.

#977 Metabolomic and proteomic signatures of ultra-processed foods with liver cancer and liver disease.

Longgang Zhao[1], Yun Chen[1], Alyssa Clay-Gilmour[2], Jiajia Zhang[2], Xuehong Zhang[1], Susan Steck[2]

[1]Yale University, School of Nursing, West Haven, CT,[2]Arnold School of Public Health, University of South Carolina, Columbia, SC

Introduction: Higher intake of ultra-processed foods is associated with increased risk of obesity and type 2 diabetes, but evidence is limited on associations of metabolomics and proteomics with ultra-processed foods and liver diseases. We aimed to evaluate associations of metabolomic and proteomic signatures related to ultra-processed food intake with liver cancer and liver disease.
Methods: Data from a total of 173,840 participants aged 40-69 years from the UK Biobank were analyzed. Ultra-processed food intake was assessed by 24-hour dietary recalls. Metabolites were measured by nuclear magnetic resonance spectroscopy and plasma proteome was profiled using the Olink platform. Liver disease outcomes were ascertained using data from the in-hospital, cancer registry, and death registry including metabolic dysfunction-associated steatotic liver disease (MASLD), cirrhosis, liver cancer, and severe liver disease (hepatocellular carcinoma and other severe liver diseases). Elastic net regression with 10-fold cross validation was used to calculate the omics signatures related to ultra-processed food intake. We used Cox proportional hazards regression models to estimate hazard ratios (HR) and 95% confidence intervals (CIs) for ultra-processed food intake and its omics signatures and liver disease outcomes adjusting for multiple potential confounding factors.
Results: With a median of 8.9 years follow-up, ultra-processed food intake was positively associated with risk of MASLD ($HR_{\text{Tertile 3 vs. tertile 1}}$ 1.42; 95% CI 1.21-1.67), cirrhosis (HR 1.25; 95% CI 1.05-1.48), and severe liver disease (HR 1.52; 95% CI 1.21-1.91) but not with liver cancer (HR 1.30; 95% CI 0.89-1.91). The metabolic signature score of ultra-processed foods was positively associated with risk of MASLD (HR 3.25; 95% CI 2.06-5.14). The proteomic signature score of ultra-processed foods was positively associated with risk of MASLD (HR 1.99; 95% CI 1.04-3.80) and cirrhosis (HR 2.00; 95% CI 1.12-3.60). A total of 34 metabolites and 65 proteins were significantly associated with ultra-processed food intake based on the multivariable-adjusted model and elastic net regression. These metabolites and proteins are linked to biological pathways such as lipids metabolism, oxidative stress, and inflammatory response.
Conclusions: Ultra-processed food intake and its metabolic and proteomic signatures are positively associated with risk of adverse liver outcomes.

#979 Caregiver experiences and prostate cancer survivor quality-of-life in the Detroit Research on Cancer Survivors study.

Colleen B. McGrath[1], Jamaica R. M. Robinson[2], Konrad H. Stopsack[1], Julie J. Ruterbusch[2], Michelle O. Sodipo[1], Kathryn L. Penney[1], Briana J. K. Stephenson[3], Laura D. Kubzansky[4], Lorelei A. Mucci[1], Jennifer Beebe-Dimmer[2]

[1]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Department of Oncology, Wayne State University School of Medicine, Detroit, MI,[3]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA,[4]Department of Social and Behavioral Sciences, Harvard T.H. Chan School of Public Health, Boston, MA

Introduction: Cancer survivorship is influenced by informal (unpaid) caregiving received by survivors. However, informal caregivers often experience caregiving-related burden, or strain from providing care, which may, in turn, impact health-related quality-of-life (HRQoL) among cancer survivors. We investigated associations of caregiver burden and involvement intensity with HRQoL of prostate cancer survivors receiving care.

Methods: We included 323 prostate cancer survivor-caregiver dyads who participated in the Detroit Research on Cancer Survivors study, a population-based cohort of Black cancer survivors. Informal caregivers were invited to report on their experiences, including caregiving burden (via Zarit Burden Interview [ZBI]) and involvement intensity (via Level of Care Index); these were measured at caregiver enrollment. Survivors completed enrollment and follow-up (approximately annually) surveys, including measuring HRQoL using the Functional Assessment of Cancer Therapy tool; we measured HRQoL for up to 6 years. We examined overall QoL (range 0-108), subscales of functional, social, physical (each 0-28), and emotional (0-24) wellbeing, and prostate cancer-specific QoL (0-48); higher scores reflect better HRQoL. We used linear mixed effects models including exposure-time interactions to evaluate differences in survivor HRQoL scores at enrollment and over time by each exposure, adjusting for survivor and caregiver sociodemographics, survivor health, and cancer and dyad relationship characteristics.

Results: Survivor median age at diagnosis was 62 years. Most informal caregivers were the survivor's partner (68%) and were women (94%). Most caregivers reported low burden (ZBI < 21; 82%), and most were highly involved (60%). At enrollment, low vs. moderate or higher caregiver burden was associated with better overall QoL (mean difference 8.7, 95% Confidence Interval [CI] 4.1, 13.2), prostate cancer-specific QoL (3.1, 95% CI 0.8, 5.4), functional wellbeing (3.1, 95% CI 1.4, 4.8), and slightly, emotional and physical wellbeing. Having a low vs. high involved caregiver was associated with better overall QoL (7.3, 95% CI 2.8, 11.7), prostate cancer-specific QoL (4.0, 95% CI 1.7, 6.3), functional wellbeing (3.2, 95% CI 1.5, 4.9) and slightly, physical wellbeing at enrollment. On average, the additional change in physical and prostate cancer-specific QoL scores per year comparing survivors with caregivers who have low vs. moderate or higher burden was -0.5 (95% CI -0.8, -0.1) and -1.3 (95% CI -2.4, -0.3) lower, respectively.

Conclusion: While informal caregivers' experiences immediately influenced survivor HRQoL, we also observed that the relationship of caregiver burden with physical forms of wellbeing differed over time. Supporting informal caregivers can impact the care recipients, potentially having long-term influence for cancer survivors.

#98 STK11 loss in KRAS driven lung adenocarcinoma promotes cancer stemness.

Kyla R. Esposito, Shannon M. Prior, Cole M. Royer, David J. Seward, Paula B. Deming, Melissa N. Scheiber

University of Vermont, Burlington, VT

Lung adenocarcinoma (LUAD) is the most common subtype of non-small cell lung cancer. A significant proportion (25% to 30%) of LUAD cases are driven by mutations in the KRAS oncogene, with 10-15% of these patients harboring a loss of function (LoF) mutation in the tumor suppressor gene *STK11* (serine/threonine kinase 11). Loss of STK11 function in lung cancer has been associated with an immunosuppressive environment, altered metabolism, epithelial-mesenchymal transition (EMT), and destabilization of cell polarity. Retrospective patient studies have demonstrated that concurrent oncogenic *KRAS* and *STK11* LoF mutations are associated with metastatic disease, poorer patient survival, and inferior therapeutic response. We hypothesize that STK11 loss in KRAS-driven LUAD enriches the cancer stem cell (CSC) population, resulting in a pro-metastatic phenotype. CSCs represent a small subset of tumor cells capable of self-renewal, asymmetric division, and tumor initiation. Given their role in metastasis, chemoresistance, and disease progression, CSCs could be key contributors to the aggressiveness observed in KRAS-driven STK11 LoF LUAD. To test this hypothesis, we utilized the KRAS-driven LUAD cell line NCI-H2009 and an STK11 knockout variant (ΔSTK11) to assess differences in CSC properties. CD44 is a common biomarker for CSC and is involved in many aspects of cancer progression. Both parental and ΔSTK11 cells grown in 2-D monolayers were found to express similar levels of CD44 of mRNA and protein, as assessed by qRT-PCR and flow cytometry. However, in 3D culture, ΔSTK11 multicellular spheroids (MCTs) showed a significant increase in CD44 mRNA when compared to both monolayers and parental MCTs. We have also observed increased mRNA expression of two additional CSC markers, NANOG and OCT4, in ΔSTK11 MCTs compared to parental MCTs. CD44, plays a critical role in maintaining the stem-like properties of cancer cells, however, the precise mechanisms connecting CD44 expression and STK11 remain unclear. To address this, we are investigating transcription factor pathways, including NF-kB and HIPPO, to elucidate their roles in mediating enhanced CD44 expression upon STK11 loss. To characterize the function of the CSCs in KRAS-driven STK11 LoF LUAD, we have employed an embryonic zebrafish xenograft model. This in vivo system allows for real-time visualization of tumor cell survival and dissemination, providing critical insights into the metastatic behavior of cells. In conclusion, our research highlights the role of STK11 loss in driving CSC enrichment and enhancing metastatic potential in KRAS-driven LUAD. By elucidating the underlying mechanisms, we aim to identify new therapeutic targets to improve outcomes for patients with this aggressive cancer subtype.

POPULATION SCIENCES: Bridging Gaps in Cancer Care: Disparities, Social Determinants, Innovations, and Strategies Poster Session

#980 Deaths from cardiovascular disease in rural and African American men with prostate cancer.

Caroline Himbert[1], Heather M. Munro[2], Adam Bress[1], Philip W. Kantoff[3], Kenneth J. Mukamal[4], Martha J. Shrubsole[2], Konrad H. Stopsack[5]

[1]University of Utah, Salt Lake City, UT,[2]Vanderbilt University Medical Center, Nashville, TN,[3]Convergent Therapeutics Inc, Boston, MA,[4]Beth Israel Deaconess Medical Center, Boston, MA,[5]Leibniz Institute for Prevention Research and Epidemiology, Bremen, Germany

Background: Cardiovascular disease (CVD) is a major cause of morbidity and mortality among men diagnosed prostate cancer. Different CVD risk factor profiles and disparities in healthcare access may place a higher burden on Black men and those living in rural areas diagnosed with prostate cancer.
Methods: This cohort study aimed to evaluate differences in CVD deaths by rurality and race among men with prostate cancer. The Southern Community Cohort Study (SCCS) is a prospective cohort, which enrolled 34,313 racially diverse, predominantly low-income men aged 40-79 in twelve southeastern states of the United States. Between 2002 and 2021, 1,544 men with prostate cancer were free of prevalent CVD (i.e., coronary heart disease and stroke). Prostate cancer cases, vital status, and causes of death were identified through linkages to state cancer registries and the National Death Index as of December 31, 2022. Residence at enrollment was classified into rural and urban using community area codes. Lifetime risk for CVD death from Aalen-Johansen estimators and cause-specific hazard ratios (HRs) were computed.
Results: 356 participants (23%) were classified as rural and 1,174 (76%) self-identified as African American. Over 21 years of follow-up (median 8 years), 618 deaths occurred, of which 149 (24%) were from CVD. The lifetime risk of CVD death was similar comparing men with prostate cancer living in urban and rural areas at about 20%. After adjusting for sociodemographics, cancer, and CVD risk factors, the hazard ratio (HR) for rurality and CVD death was 0.95 (95% confidence interval (CI): 0.66, 1.40). African American men had a higher lifetime risk of CVD death (21%, 95% (CI): 16, 28) than White men with prostate cancer (16%, 95% CI: 11, 24). The cause-specific HR for CVD deaths was 1.36 (95% CI: 0.91, 2.04) in African American men compared to White men. African American men tended to be diagnosed with prostate cancer at a younger age (age adjusted HR: 1.68; 95% CI: 1,12, 2.52). The association was attenuated upon adjustment for social determinants of health reflected in community health center enrollment (HR: 1.02; 95% CI: 0.66, 1.59) and was essentially unchanged after further adjustments (HR: 0.99, 95% CI: 0.63, 1.57). African American men with CVD risk factors at prostate cancer diagnosis (hypertension, diabetes, hypercholesteremia), lower education level, or no insurance or Medicaid/Medicare coverage were at the highest risk for CVD death.
Conclusions: African American men with prostate cancer face a higher age-adjusted risk of death from CVD than White men with prostate cancer. This association could mainly be explained by racial differences in social determinants of health reflected in community health center enrollment. Integrating sociodemographic characteristics into treatment planning and prioritizing CVD prevention and management along prostate cancer care may reduce CVD mortality among men with prostate cancer.

#982 Disparities in allogeneic hematopoietic stem cell transplantation for acute myeloid leukemia are increasing.

Lixin Kang[1], Mark A. Fiala[2], Kimberly J. Johnson[1]

[1]Washington University in St. Louis, St. Louis, MO,[2]Washington University School of Medicine in St. Louis, St. Louis, MO

Introduction: Acute myeloid leukemia (AML) is the most prevalent form of leukemia. Allogeneic hematopoietic cell transplantation (allo-HCT) is the most effective and often the only curative treatment. Due to advancements in donor selection, a suitable donor is available for nearly all patients, and this may have remediated the previously reported disparities in allo-HCT based on race and ethnicity. To date, no studies have comprehensively examined allo-HCT rates and trend disparities after expanded donor availability. Therefore, this study aimed to identify and quantify trends in allo-HCT rates and disparities among different racial and ethnic groups. We hypothesized that transplant disparities have decreased over time between those identified as racial and ethnic minorities and non-Hispanic Whites (NHWs).

Methods: Data on AML patients diagnosed from 2004 to 2021 were obtained from the National Cancer Database Participant User Data File. Utilizing a multiple linear regression model with a difference-in-differences approach, we calculated the annual absolute change in allo-HCT rates and corresponding p-values across racial and ethnic groups to compare trends in allo-HCT rates adjusted for covariates.

Results: Over the study period, non-Hispanic Asian or Pacific Islanders (NHAPIs) exhibited the highest allo-HCT rate at 20.9%, starting at 12.1% in 2004 and influenced by an outlier increase to 34.0% in 2021. NHWs had the second highest rate of 19.7%, increasing from 9.1% in 2004 to 22.9% in 2021. The allo-HCT rate for Hispanics increased from 9.4% in 2004 to 24.3% in 2021; however, a period of low rates from 2006 to 2011 resulted in a lower overall allo-HCT rate of 15.9%. Non-Hispanic Blacks (NHBs) had the lowest allo-HCT rate at 9.8%, with an increase from 2.3% in 2004 to 11.5% in 2021.

From 2004 to 2021, the annual percentage increase in allo-HCT in NHBs was estimated at 0.41% lower than NHW (95% Confidence Interval [CI]: -0.61%, -0.21%; $p<0.01$). Hispanics also had a statistically significant 0.27% lower annual increase in allo-HCT rate compared to NHW (95% CI: -0.51%, -0.03%; $p=0.03$). Although NHAPI exhibited a higher overall allo-HCT rate compared to NHW, the annual rate increase was 0.23% lower than NHW (95% CI: 0.55%, 0.09%; $p=0.16$), which reduced the differences in allo-HCT rates between these groups over the study period.

Conclusion: NHB and Hispanics exhibited lower overall allo-HCT rates than NHW from 2004 to 2021, with evidence of widening disparities. NHAPI had overall higher allo-HCT rate than NHW, but the difference narrowed over time as NHW patients experienced a steeper increase in allo-HCT rates. These results suggest that despite the availability of suitable allo-HCT donors, not all patients have benefited equally. Further research is needed to investigate individual and systemic factors associated with allo-HCT disparities among racial and ethnic minorities.

#983 Characterizing somatic copy number alterations in African American renal cell carcinoma patients.

Musinu Zakari, Egbenoma A. Aigboeghian, Khadijah A. Mitchell

Cancer Prevention and Control Program, Fox Chase Cancer Center, Philadelphia, PA

Background: Renal cell carcinoma (RCC) has one of the highest mortality rates of all urologic cancers in the US. Somatic copy number alteration (SCNA) profiles have been linked with RCCC mortality. African American (AA) RCC patients have higher mortality and lower survival rates when compared to European Americans (EAs) with the disease. AA RCC patients are underrepresented in cancer genomic studies, and RCC mortality and survival disparities may be attributed to SCNA differences. We hypothesize there are distinct population-enriched SCNAs in RCC tumors from AAs compared with EAs.

Methods: DNAs were isolated from fresh frozen primary tumors for each RCC patient in the Geisinger-Cooperative Human Tissue Network discovery cohort (n=20), followed by OncoScan CNV (whole-genome copy number microarray) analyses. SCNAs at the genome-wide, chromosomal, chromosomal region, and gene levels were compared in AA (n=10) and EA (n=10) RCC patients using Chromosome Analysis Suite v7. Population differences were calculated using t-tests with Welch's corrections and multiple unpaired t-tests ($P < 0.05$). STRING was used to identify protein-protein interaction networks and functional enrichment analyses. GraphPad Prism 10 v7 and STRING v12 were used to generate all images.

Results: Genome-wide across 22 autosomes, a combined 397 chromosomal regions (n=292 amplifications; 105 deletions) were altered in AA RCC patients compared to 476 chromosomal regions (n=302 amplifications; 174 deletions) in EA RCC patients. We observed AAs had significantly higher amplifications across 13 chromosomes (3, 4, 6, 7, 9,10, 13-15, 18, 20-22) when compared to their EA counterparts ($P < 0.05$; AA: 164/292, EA: 156/302). A total of 12,114 genes in AAs and 11,320 genes in EAs were amplified. Uniquely amplified genes (n=1,095) in AA RCC patients corresponded with keratin-associated protein (KRTAP) networks (PPI enrichment P value: 3.38e-08). EA RCC patients had 301 uniquely amplified genes that corresponded with trace-amine and natural killer cell lectin-like receptor activities (PPI enrichment P value: 0.000334).

Conclusion: KRTAPs are known RCC oncogenes. KRTAP amplifications may drive expression and help to explain more aggressive tumor biology in AA RCC patients.

Future Direction: Integrate SCNA data with matched bulk mRNA-sequencing data for each RCC patient.

#984 Implementation of tissue next generation sequencing in a real world diverse safety-net setting.

Kavya Athipatla[1], Lindsay C. K. Reynolds[2], Susmita Potti[3], Mitchell S. von Itzstein[4], Janet Miles[5], Kalyani Narra[6]

[1]Carroll High School, Southlake, TX,[2]Office of Clinical Research, John Peter Smith Health Network, Fort Worth, TX,[3]JIPMER, Puducherry, India,[4]Internal Medicine (Division of Hematology-Oncology), University of Texas Southwestern, Dallas, TX,[5]Pathology, John Peter Smith Health Network, Fort Worth, TX,[6]Oncology and Infusion Center, John Peter Smith Health Network, Fort Worth, TX

Background: Next-generation sequencing (NGS) is generally considered the standard of care for molecular testing in advanced cancer cases across professional organization guidelines. Implementing expensive NGS testing in safety-net settings poses significant challenges due to limited resources. John Peter Smith Health Network (JPS) serves a large diverse population of uninsured and underinsured patients, and we addressed this challenge by partnering with ProPath and Bernhardt Laboratories (BHL) to facilitate tissue NGS testing.

Methods: Patients at JPS with tissue NGS tested between 1/1/24 to 9/30/24 using a ProPath authorization program and BHL testing were included. AuraSeq-Comprehensive was the NGS test utilized and includes a panel detecting clinically relevant alterations in 500 cancer-related genes, including base pair substitutions, small insertions and deletions, copy number variations, and gene fusions. Data analysis was performed using Excel.

Results: A total of 152 patients underwent tissue analysis, each patient undergoing a single NGS test during this period. The average age was 62 years and there were 76 (50%) females. 41 (27%) were Hispanic, 54 (36%) non-Hispanic White, 41 (27%) non-Hispanic Black, 16 Asians and others. Excluding tumor mutational burden (TMB), homologous recombinant deficiency (HRD) and Microsatellite instability (MSI), 146 patients had at least one genomic alteration, 118 had two, 87 had three, 55 had four, and 26 had five. TMB testing was conducted on 150 patients and 29 (19%) had high TMB using a cutoff of 10 mut/Mb. HRD testing was positive in 14 out of 150 (9%). MSI was high in 2 out of 15 tested. A total of 5 (10%) *ALK* fusions, 10 (21%) activating *EGFR* alterations, 1 (2%) *MET* exon 14 skipping mutation, and 9 (19%) *KRAS* G12C mutations were noted in 48 non-squamous NSCLC cases. Of the 9 Hispanic patients with non-squamous NSCLC, 2 had *ALK* fusions, 3 had *EGFR* mutations and 1 had *KRAS* G12C. Of the 21 patients with squamous NSCLC, one patient had *BRAF* mutation. Of the 43 patients with gastrointestinal cancers, there were 1 *KRAS* G12C, 2 *BRAF*, 1 *BRCA*2, 2 *ERBB*2 amplifications. Of the 13 breast cancers, there were 3 *PIK3Ca*, 1 *BRCA*2, 1 *ERBB*2 amplification and 1 *ERBB*2 alterations. JPS enrolled the nationwide 1st patient on PrE1702 Real-World Data Study in October 2024 and has opened clinical trials for patients with *KRAS* and *PIK3Ca* alterations.

Conclusions: This study demonstrates the successful implementation of NGS in a safety-net healthcare setting through public-private partnership. Our analysis revealed a high prevalence of actionable genomic alterations across various cancer types, with significant findings in non-squamous NSCLC, especially among Hispanic patients. Future efforts should focus on expanding access to genomic testing to further improve
patient care and outcomes with opportunities for more clinical trials in safety-net settings.

#985 CARIB-CARES: the first exploratory research center addressing the intersection of climate and the cancer control continuum.

Ana P. Ortiz[1], Noreen Michael[2], Nancy R. Cardona-Cordero[1], Marievelisse Soto-Salgado[1], **Polaris N. Torres**[1], LaVerne E. Ragster[2], Leticia Nogueira[3], Frank E. Muller-Karger[4], Zack Guido[5], Tracy E. Crane[6], Pablo Mendez-Lazaro[7]

[1]UPR - Comprehensive Cancer Center, San Juan, Puerto Rico,[2]University of the Virgin Islands, St Thomas, Virgin Islands, U.S.,[3]American Cancer Society, Atlanta, GA,[4]University of South FLorida, St Petersburg, FL,[5]University of Arizona, Tucson, AZ,[6]University of Miami, Miami, FL,[7]UPR- Medical Sciences Campus, San Juan, Puerto Rico

Background: Climate change is a threat to human health, impacting the cancer control continuum. Frequent extreme weather events in the US Caribbean (Puerto Rico [PR] and US Virgin Islands [USVI]) have harmed human health and socioecological ecosystems and have disrupted cancer prevention and control efforts. This has unveiled the vulnerabilities of critical infrastructure systems, which, when disrupted, cause catastrophic failures with fatal and long-lasting consequences. Addressing these challenges is crucial for promoting resilient and healthy island communities, mitigating cancer risk, and sustaining cancer control infrastructure.
Methods: The Caribbean Climate Change, Cancer, and Health Disparities Research Center (CARIB-CARES) is a regional initiative aimed at tackling these critical issues, with the participation of a multidisciplinary team of experts in environmental health, climate, oceanography, and cancer research. A partnership between the University of PR Comprehensive Cancer Center, the University of PR-Medical Sciences Campus, and the University of the Virgin Islands together with other institutions in the continental US, government agencies, health clinics, and non-governmental organizations, CARIB-CARES seeks to address the impact of multi-hazard climate-related stressors on the cancer control continuum and increase research and adaptation capacity in the field.
Results: Funded in September 2024, CARIB-CARES has initiated capacity-building initiatives, delivering webinars on climate change, health, and the cancer control continuum to over 100 community members, health professionals, and students across PR, USVI, and mainland US. Student engagement and mentorship has initiated, supporting more than 15 students from various academic backgrounds (public health, nursing, and biology) and different career levels (undergrad, grad, and post-doc) and from underrepresented populations as mentees, providing them with research opportunities on the intersection of climate change and cancer. Research projects are also underway, evaluating environmental disparities and cancer risk across the US Caribbean and climate change awareness among oncology health professionals. Community partnerships are being reinforced, developing a Community Coalition of Partners that includes academic institutions, nonprofits, and government agencies, leading to actionable collaborations in addressing cancer-related disparities within the context of climate change.
Conclusion: Through its comprehensive approach, CARIB-CARES has begun building a robust framework to advance research, strengthen governance, and build equitable adaptation to effectively address the challenges of climate change and cancer control across vulnerable and underserved small islands in the Caribbean.
Acknowledgments: Funding NIH Award: 1P20CA294096-01.

#986 *SMARCB1* missense mutants destabilize SWI/SNF complex stability and remodeling activity.

Garrett W. Cooper[1], Benjamin Lee[1], Won Kim[2], Eliseo Salas[3], Yongdong Su[1], Victor Chen[1], Xiaoping Yang[4], Robert Lintner[4], Frederica Piccioni[4], Andrew Giacomelli[2], Thomas Howard[2], Karen Conneely[5], David Root[4], William Hahn[2], David Gorkin[6], Bo Liang[3], Jaclyn Biegel[7], Susan Chi[8], Andrew Hong[1]

[1]Department of Pediatrics, Emory University, Atlanta, GA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Department of Biochemistry, Emory University, Atlanta, GA,[4]Broad Institute of MIT and Harvard, Boston, MA,[5]Department of Human Genetics, Emory University, Atlanta, GA,[6]Department of Biology, Emory University, Atlanta, GA,[7]Department of Pathology, University of Southern California, Los Angeles, CA,[8]Boston Children's Hospital, Boston, MA

SMARCB1-deficient cancers are aggressive and highly lethal pediatric malignancies. Loss of SMARCB1 protein expression, a subunit within the SWI/SNF chromatin remodeling complex, remains the key diagnostic feature of these cancers. This can occur through large deletions, balanced translocations, frameshift mutations, or truncating nonsense mutations. Here, we sought to understand the effect of missense mutations on the tumor suppressor function of SMARCB1 through deep mutational scanning (DMS). Specifically, we developed and introduced a library containing >99% of all possible SMARCB1 amino acid substitutions, including frameshift and nonsense mutants, into three pediatric SMARCB1-deficient cell lines (G401 - malignant rhabdoid tumor of the kidney, BT16 - atypical teratoid/rhabdoid tumor, and CCLF_PEDS9001_T1 - renal medullary carcinoma) and assessed cell fitness after 8-14 days. We observed broad mutational intolerance in three SMARCB1 domains: the winged-helix domain, intrinsically disordered region, and the RPT2 domain. Following our high-throughput study, we then focused on two highly enriched residues predicted to closely interact within the RPT2 domain of SMARCB1. We validated that specific missense mutations in these two residues mimic loss of function while retaining protein expression. Mechanistic studies revealed that these mutations destabilize the SWI/SNF complex, notably resulting in decreased affinity for SWI/SNF subunits known to be associated with cancer pathogenesis. This complex instability leads to diminished nucleosome remodeling and subsequent transcriptional deregulation. These findings challenge our current understanding of what a loss-of-function mutation means in the context of SMARCB1, suggesting that the absence of SMARCB1 protein expression may not be the sole indicator of SMARCB1 deficiency. Furthermore, this dataset provides a valuable resource for researchers to investigate key residues of SMARCB1 that may drive critical intermolecular interactions necessary for proper SWI/SNF complex assembly and function.

#987 Enhancing oncology navigation services: a mixed methods approach to developing an EHR power form to improve metrics and reporting.

Kelsie Campbell[1], Joi Torrence-Hill[2], Karey A. Whitten[2], Melissa Abbud[3], Jynette Querubin[2], Charis Stewart[2], Mariana Dobre[2], Trista A. Beard[1], Fatimata Sanogo[1], Chanita Hughes Halbert[1]

[1]Department of Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA,[2]Norris Comprehensive Cancer Center, Los Angeles, CA,[3]Keck Hospital of the University of Southern California, Los Angeles, CA

Importance: Pioneered in the 1990s by Dr. Harold P. Freeman, patient navigation interventions are a key strategy for addressing cancer disparities among underserved populations. Despite widespread adoption, the efficacy and cost-effectiveness of oncology navigation interventions require further evaluation. Organizations such as the Academy of Oncology Nurse and Patient Navigators (AONN+) have established evidence-based metrics to demonstrate the value of oncology navigation programs. However, inconsistencies in data collection and the limitations of Electronic Health Record (EHR) systems hinder effective reporting.
Objectives: To identify critical gaps in navigation tracking practices and develop a standardized power form for integration into the Cerner EHR system to improve tracking and reporting of navigation metrics in an established cancer navigation program.
Design, Setting, and Participants: A cohort of 517 patients seen between July 1, 2022, and June 30, 2024, at University of Southern California Norris Comprehensive Cancer Center (USC NCCC). The cohort consisted of 137 breast, 312 lung, and 68 sarcoma cancer patients. We introduced an Excel-based navigation tracking tool in January 2023, adapted from a tool provided for the *American Cancer Society's Navigational Capacity Building Initiative*; shadowed navigators and interviewed with leadership to gather qualitative data on patient flow, tracking protocols, and program priorities.
Main Outcomes/Measures: Primary outcomes included navigation caseload, diagnosis-to-treatment times, and treatment adherence for the cohort at USC NCCC. Qualitative data assessment included the consistency of the documentation of primary outcomes, clinical trial referrals, care transitions, and program goals.
Results: Most patients (82.0%) were over age 50, with 42.4% identifying as White, 15.4% as Asian, and 5.4% as Black/African American. Caseloads increased from 158 in July 2022 to 268 in June 2024, and average diagnosis-to-treatment times decreased from 33 to 22 days. Qualitative data identified critical gaps in tracking practices, such as inconsistent documentation of treatment initiation dates, clinical trial referrals, and care transitions (e.g., transfers to other facilities, transitions to survivorship, or ongoing treatment)
Conclusion: These findings informed the development of a power form to track diagnosis-to-treatment times, treatment adherence, no show rates, clinical trials referrals, and care transitions, to address data collection gaps and align with navigator and leadership priorities. Scheduled for implementation on January 1, 2025, the power form will streamline workflows, enhance data-driven decision making in cancer care, and support reimbursement for navigation services under the new Principal Illness Navigation designation by the Centers for Medicare & Medicaid Services.

#988 Impact of the COVID-19 pandemic on HPV vaccine hesitancy.

Eric Adjei Boakye[1], Jun Jin[1], Mrudula Nair[1], Dakshu Jindal[1], Joel Fokom Domgue[2], Olivia Aspiras[3], Samantha H. Tam[1], Nosayaba Osazuwa-Peters[4]

[1]Henry Ford Health System, Detroit, MI,[2]University of Texas at MD Anderson Cancer Center, Houston, TX,[3]Michigan State University, East Lansing, MI,[4]Duke University School of Medicine, Durham, NC

Background: A major reason for suboptimal HPV vaccination coverage in the US is parental vaccine hesitancy. The COVID-19 pandemic and the vaccine had an impact on public trust in public health authorities, science, and medicine. The novelty of the disease and concerns over safety and efficacy of COVID-19 vaccine led to several people refusing the vaccine and increasing hesitancy towards other vaccines, including the HPV vaccine. We examined if HPV vaccine hesitancy among parents with unvaccinated children have changed due to the COVID-19 pandemic in the US.

Methods: This study used data from the 2018, 2019, 2022, 2023 National Immunization Survey - Teen. Hesitancy was defined by responses to the question, “How likely is it that [your teen] will receive HPV shots in the next 12 months?” as “not too likely,” “not likely at all,” or “not sure/don't know.” The Fisher exact test with FDR control was applied to identify significant predictors among adolescent’s age, gender, race, healthcare engagement, poverty level, doctor recommendation, geographic region; and mother’s age, marital status, education, number of children under 18, COVID-19 phases (2018-2019 as pre-COVID, and 2022-2023 as post-COVID), and their interactions. Next, logistic regression with forward selection was employed to quantify the effects of these predictors.

Results: Analysis included 103,977 unvaccinated adolescents (i.e., had not received any HPV vaccine doses at the time of the survey) whose parents were classified as vaccine hesitant. All demographic predictors and the COVID-19 timeline significantly influenced HPV vaccine hesitancy based on the two-stage estimation. In adjusted difference-in-difference analyses, overall, parental hesitancy during post-COVID years decreased compared to the pre-COVID years (aOR=0.84; 95% CI 0.79, 0.88). The impact of children's age and race and mother’s age showed consistent and significant changes from pre-COVID to post-COVID years. HPV vaccine hesitancy increased from pre-COVID to post-COVID years among parents of adolescents who were 15 (aOR=1.38; 95% CI 1.28, 1.46), 16 (aOR=1.40; 95% CI 1.31, 1.51) and 17 (aOR=1.52; 95% CI 1.40, 1.63), and among mothers who were over 45 years or older (aOR=1.06; 95% CI 1.01, 1.13). Conversely, HPV vaccine hesitancy of parents of non-Hispanic black adolescents (aOR=0.90; 95% CI 0.83, 0.98) decreased from pre-COVID to post-COVID years. Incorporating COVID-related features significantly enhances the ability to predict hesitancy.

Conclusions: HPV vaccine hesitancy among parents of unvaccinated adolescents decreased overall from pre-COVID to post-COVID years. However, hesitancy increased within specific groups, notably among parents of adolescents aged 15 to 17 and mothers aged 45 years and older age. These trends highlight the need for future research to explore the underlying factors driving these differences, enabling more targeted and effective public health interventions.

TUMOR BIOLOGY: Molecular Regulation of Metastasis
Poster Session

#99 HMGB1deficiency occurs in a broad range of human cancers and is often associated with unfavorable tumor phenotype.

Viktoria Chirico[1], Hena Sharifi[1], Maria Christina Tsourlakis[1], Seyma Buyucek[1], Clara von Bargen[1], Katharina Moller[1], Florian Lutz[1], David Dum[1], **Claudia Hube-Magg**[1], Elena Bady[1], Lisa Hornsteiner[1], Georgia Makrypidi-Fraune[1], Piero Caneve[1], Maximilian Lennartz[1], Morton Freytag[1], Sebastian Dwertmann Rico[1], Simon Kind[1], Viktor Reiswich[1], Eike Burandt[1], Till S Clauditz[1], Patrick Lebok[1], Christoph Fraune[1], Till Krech[1], Sarah Minner[1], Andreas H Marx[2], Waldemar Wilczak[1], Ronald Simon[1], Guido Sauter[1], Stefan Steurer[1], Kristina Jansen[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Academic Hospital Fuerth, Fuerth, Germany

High-mobility group protein B1 (HMGB1) is a chromatin-associated protein with a role in maintenance of nucleosome structure, transcription control, and DNA repair. Both its overexpression and impaired function have been linked cancer development and progression. To better comprehend the role of HMGB1 expression in cancer, a tissue microarray containing 14,966 samples from 134 different tumor entities and 608 samples of 76 different normal tissue types was analyzed. A strong nuclear HMGB1 staining occurred in almost all normal cell types and in most cancers. Of 11,808 evaluable cancers, only 921 (7.8%) showed a complete HMGB1 expression loss (HMGB1 deficiency) while 1,172 (9.9%) showed a 1+, 2,956 (25%) showed a 2+, and 6,759 (57.2%) showed a 3+ HMGB1 positivity. HMGB1 deficiency most frequently occurred in pheochromocytoma (90%), seminoma (72.4%), gastrointestinal stromal tumor (28.6%), adrenal cortical carcinoma (25%), and Hodgkin's lymphoma (25%). Low HMGB1 expression was linked to poor histologic grade ($p<0.0001$), advanced pT stage ($p<0.0001$), high UICC stage ($p<0.0001$), and distant metastasis ($p=0.0413$) in clear cell RCC, invasive tumor growth in urothelial carcinoma (pTa vs. pT2-4, $p<0.0001$), mismatch repair deficiency ($p=0.0167$) in colorectal cancers, and advanced pT stage in breast cancer of no special type (NST) ($p=0.0038$). High HMGB1 expression was linked to nodal metastases in high-grade serous ovarian carcinomas ($p=0.0213$) and colorectal cancers ($p=0.0137$), as well as to high histological grade in squamous cell carcinomas ($p=0.001$). In conclusion, our data show that HMGB1 deficiency and reduced HMGB1 expression occurs in a broad range of different tumor entities and that low (and not high) HMGB1 expression is often linked to an aggressive tumor phenotype. Whether or not HMGB1 deficiency renders cells susceptible to specific drugs remains to be determined.

POPULATION SCIENCES: Bridging Gaps in Cancer Care: Disparities, Social Determinants, Innovations, and Strategies Poster Session

#990 Role pf viral infection in APOBEC3 dysreguation in cancer: a single-cell gene expression profiling approach.

Mohadeseh Soleimanpour-Moghadam, diako Ebrahimi

Texas Biomedical Research Institute, San Antonio, TX

The Cancer Genome Atlas (TCGA) provides comprehensive genomic and transcriptomic data from over 10,000 cancer patients, along with metadata including viral infection status and survival information. We investigated the role of viral infections in dysregulating the expression of A3 enzymes (A3A/B/C/D/F/G/H). These enzymes primarily function to restrict viral infections by introducing C-to-U mutations in viral genomes. However, certain members (notably A3A and A3B) can also mutate cellular DNA, contributing to tumor initiation and progression. Cancers such as breast, bladder, cervical, head & neck, and skin exhibit characteristic C-to-T mutations attributed to the aberrant expression/activity of A3 enzymes. Accurate quantification of A3 dysregulation in tumor cells using TCGA bulk RNAseq data is complicated by the ubiquitous expression of these enzymes in infiltrating immune cells. This highlights a broader challenge in analyzing heterogeneous tumor biopsies to uncover virus-specific dysregulated processes in cancer. To address this challenge, we employed Nonnegative Matrix Factorization (NMF) to deconvolute A3 expression profiles from TCGA bulk RNA-seq data, i.e. to separate tumor cell profiles from those of the tumor microenvironment. We validated our NMF-extracted profiles by analyzing publicly available single-cell RNA-seq datasets from approximately 3,000 cancer projects in the Gene Expression Omnibus (GEO). Additionally, to identify cell types represented by these profiles, we compared them with experimentally obtained A3 expressions from purified cell types. Our analyses identified up to four distinct A3 profiles: two associated with T cells and NK cells, one linked to dendritic cells and macrophages, and one corresponding to cancerous epithelial cells. Notably, the A3 profiles derived from our analysis of single-cell RNA-seq data closely matched those deconvoluted from TCGA bulk RNA-seq data, demonstrating that our bulk RNA-seq deconvolution effectively captures single-cell population-level profiles. We found that both tumor-specific and immune cell-specific A3 profiles correlate with viral infection; however, significant variations were observed across different viral types and tumor types. None of these profiles were correlated with the extent of A3 mutational signatures SBS2 and SBS13.In conclusion, our study demonstrates that deconvolution of bulk RNA-seq datasets can reveal single-cell population-level insights into the cellular composition of tumor biopsies. Moreover, this approach offers the resolution needed to pinpoint virus-specific dysregulated processes within the complex and heterogeneous tumor microenvironment.

#991 PARADIGM: an embeddings-based multimodal learning framework with foundation models and graph neural networks.

Asim Waqas[1], Aakash Tripathi[1], Mia Naeini[2], Paul A. Stewart[1], Matthew B. Schabath[1], **Ghulam Rasool**[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]Electrical Engineering, University of South Florida, Tampa, FL

Introduction: Cancer research faces significant challenges in integrating heterogeneous data across varying spatial and temporal scales, limiting the ability to gain a comprehensive understanding of the disease. PARADIGM(Pan-Cancer Embeddings Representation using Advanced Multimodal Learning with Graph-based Modeling) addresses this challenge by providing a framework leveraging foundation models (FMs) and Graph Neural Networks (GNN). PARADIGM framework generates embeddings from multi-resolution datasets using modality-specific FMs, aggregates sample embeddings, fuses them into a unified graph representation, and uses GNNs for survival prediction.

Methods: We applied PARADIGM for survival analysis of five squamous cell carcinomas; head and neck (527), lung (496), bladder (408), cervical (294), and esophageal (184) cancers, and five adenocarcinomas; colon (393), lung (549), prostate (490), rectum (157), and stomach (406) cancers. Additionally, we validated using lung squamous cell data from Moffitt Cancer Center (103 patients). Multimodal data for training and evaluation included EHR data (e.g., age, gender, and smoking status), whole slide images (WSIs), pathology reports, and molecular data (e.g., gene expression, miRNA, and protein expression). Model performance was assessed using concordance index (C-index) for survival prediction, with 7-fold cross-validation ensuring robustness.

Results & Conclusions: PARADIGM demonstrated significant improvements in survival prediction compared to unimodal and multimodal approaches such as multilayer perceptron, Transformers, and XGBoost (Table 1). Our findings indicate that integrating diverse data modalities into a cohesive representation yields more accurate and insightful predictions. This approach highlights the potential of embeddings-based multimodal learning to foster improved outcome predictions and provide actionable insights for personalized treatment strategies.

Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[8]General, Visceral and Transplantation Surgery, Heidelberg University Hospital, Heidelberg, Germany,[9]Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA,[10]Surgery, Washington University St. Louis, St. Louis, MO,[11]Department of Surgery, University of Tennessee Health Science Center, Memphis, TN,[12]Division of Cancer Control and Population Sciences, National Cancer Institute, Bethesda, MD,[13]Intermountain Health Care, Salt Lake City, UT,[14]Information and Communication, University of Applied Sciences and Arts, Hannover, Hannover, Germany

Introduction: Muscle mass and fat distribution are key components of body composition and have been linked to treatment response, treatment toxicity, and survival in cancer patients. Few studies have investigated body composition parameters in relation with rectal cancer, with no study evaluating body composition profiles in early-onset rectal cancer (EORC; diagnosed <50 years) and late-onset rectal cancer (LORC; diagnosed ≥65 years).

Methods: We utilized pre-treatment computed-tomography scans from 191 patients diagnosed with stage II/III rectal cancer recruited in Utah and Florida (two study sites of the ColoCare Study). Body composition parameters were assessed at L3 vertebral level including visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), skeletal muscle tissue (SKM), intramuscular adipose tissue (IMAT), body mass index (BMI; kg/m²; continuous), BMI categories, and sarcopenia (yes/no). Multinomial logistic regression models were used to estimate odds ratios (OR) and 95% confidence intervals (95% CI) for associations of body composition parameters with EORC and LORC, adjusted for sex, surgery, tumor stage, and study site, compared with average-onset rectal cancer (AORC; 50-64 years) as the reference group.

Results: Twenty-seven percent and 28% of patients were diagnosed with EORC and LORC, respectively. A one-unit increase in log-transformed IMAT area was associated with increased odds of LORC (OR 3.21 [1.46-7.08]) and decreased odds of EORC (OR 0.27 [0.13-0.59], p_{het}=<0.05) compared to AORC. A similar pattern emerged for sarcopenia (yes/no: OR_{LORC} 1.76 [0.86-3.62]; OR_{EORC} 0.43 [0.19-0.96], p_{het}=0.05) and VAT: OR_{LORC}1.03 [0.95-1.12]) and OR_{EORC} (0.91 [0.84-0.99], p_{het}=0.01) compared to AORC. The opposite pattern and magnitude of associations was observed for a one-unit increase in log-transformed SKM (OR_{LORC} 0.04 [0.004-0.31]; OR_{EORC} 9.49 [1.06-84.60], p_{het}<0.05). SAT area and BMI were not associated with onset of EORC or LORC.

Discussion: This study is the first analysis of a comprehensive panel of body composition parameters in EORC and LORC. LORC patients had higher IMAT or VAT areas and sarcopenia, consistent with associations in healthy older individuals. Similarly, EOCRC patients had greater SKM area, compared to AOCRC. It will be important to evaluate the associations of body composition parameters within each group with clinical outcomes and evaluate whether integrating body composition assessment into patient care may help optimize treatment response, reduce toxicities and improve outcomes.

#993 Exploring the tumor suppressive role of LRIG1 in breast cancer disparities.

A. H. Pajimola, B. Jenkins-Lord;
Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD

Background: Breast cancer (BC) is the second most common cause of cancer-related death among women in the United States (U.S.). Despite a lower incidence rate, African American (AA) women suffer a persistent 40% higher BC mortality rate compared to European American (EA) women. The aggressive breast tumor biology experienced by AA women is rooted in both genetic and environmental causes and we are interested in investigating the social and molecular drivers influencing this complex health disparities problem. In our recent study using breast tumor DNA extracted from a diverse cohort of women from the Baltimore, Maryland area, we performed a methylation array to compare differences in neighborhood conditions to DNA methylation levels, including differences by race. From this analysis, we identified the tumor suppressor LRIG1 as significantly hypomethylated among AA patients with deprived neighborhood conditions. This gene encodes a transmembrane protein predicted to downregulate growth receptor signaling, with lower expression associated with decreased survival. These findings were unique to the tumor, which points to epigenetic changes to LRIG1 impacting tumor mutational burden, gene expression, and protein expression.
Objective: The goal of this project is to assess the relationship between LRIG1 genetic variants and molecular, clinical, and sociodemographic data in a diverse historical cohort of BC cases and controls. We hypothesize that LRIG1 single nucleotide polymorphism (SNP) genotypes will be more strongly linked to increased BC susceptibility and adverse clinical outcomes in AA women compared to EA women.
Methods: We obtained breast tissue DNA from our previous cohort, including 216 breast tumors (AA=135, EA=81) and 203 normal breast tissues (AA=115, EA=88). We conducted DNA genotyping on a clinically relevant ancestrally informative SNP of LRIG1 (rs2306272) using PCR amplification and detection by fluorescent reporters. We analyzed the associations between LRIG1 rs2306272 SNP genotypes and race, BC risk factors, and clinical data.
Results: Our experimental minor allele frequencies were in line with what is expected for AA and EA populations for this LRIG1 SNP. Chi-square tests showed associations between the LRIG1 rs2306272 genotypes and self-reported race ($p<0.0001$), family history of BC ($p=0.0037$), and breast tumor grade ($p=0.0768$).
Conclusions: This is the first data showing clinical significance between rs2306272, self-reported race, and BC characteristics in patient samples. We will continue analyzing the rs2306272 SNP genotypes in our DNA cohort in addition to a second ancestrally relevant LRIG1 SNP, rs1403626. Furthermore, using matched methylation data, we will perform analyses to identify differentially methylated CpG sites for LRIG1 that may be influenced by genetic ancestry. Our investigations will further interrogate the impact of LRIG1 regulation in differential BC risk and outcomes.

#994 Advancing health equity and reducing disparities in prostate cancer in Black men: iCCaRE.

Kimlin Tam Ashing[1], Timethia Bonner[2], Ewan K. Cobran[3], Folakemi Odedina[4], Aj Merriweather[4], Ernie Kaninjing[4], Floyd Willis[4], Cassandra Moore[4], Joanne Oliver[4], Fornati Bedell[1], John McCall[5]

[1]City of Hope National Medical Center, Duarte, CA,[2]Mayo Clinic, Rochester, MN,[3]Mayo Clinic, Phoenix, AZ,[4]Mayo Clinic, Jacksonville, FL,[5]Temple Beth Baptist Church, Pasadena, CA

In the US and globally, Black men experience the highest prostate cancer burden among all racial and ethnic groups, underscoring the urgent need for research to guide the development and implementation of culturally tailored strategies aimed at reducing disparities and improving outcomes. In response, the Inclusive Cancer Care Research Equity (iCCaRE) Consortium was created to advance health equity and reduce disparities in prostate cancer. Importantly, a Survivorship Care Plan (SCP) is recommended to educate and empower patients, enabling them to be better informed about their cancer diagnosis, treatment, and survivorship care recommendations. To date, there is no SCP targeted to Black prostate cancer survivors (CaPS) who have the greatest disparities with the poorest survivorship outcomes (ACS F&F; AACR HD Report; Fullwood, 2024). Therefore, we aimed to develop a SCP tailored for Black men. Addressing the unique needs of Black men require a genuine bidirectional relationship between scientist and the community rooted in community engaged research (CER). The SCP was first informed by the literature (Bonner, 2024) and the ASCO template (canceradvocacy.org). With input from the iCCaRE leadership and the Partnership Engagement Services (PES) Core, the Whole Person SCP better responds to the informational, clinical and quality of life needs of Black Prostate Cancer survivors. Based on CER, we included 22 diverse, Black CaPs to further guide and tailor the iCCaRE. Our findings indicate that the iCCaRE Survivorship Care Plan (SCP) enhanced the ASCO template by incorporating and expanding several unique domains, including family history, care team contacts, follow-up and surveillance, symptoms, quality of life, survivor concerns, major comorbidities, health advisories, and culturally relevant resources, creating a comprehensive, whole-person SCP tailored specifically for Black men. It is crucial to continue to improve support for clinical research and advocate for Black men and their communities to reduce prostate cancer burden. Prostate cancer also needs to include incidence, mortality, and disparities for Black men to raise awareness of scarcely studied field of Black men and prostate cancer survivorship.

#996 Dietary patterns in plasma cell disorders: Opportunities for targeted interventions.

Kadiatou Traore[1], Francesca Castro[1], Alankrita Taneja[2], Elan Gorshein[3], Andriy Derkach[1], Jorge Arturo Hurtado Martinez[4], Edith Serrano[1], Alexander Lesokhin[1], Jennifer M. Ahlstrom[4], Torin Block[5], Jay R. Hydren[4], Ana M. Sahagun Sanchez Aldana[4], Patricia Alejandra Flores Perez[4], Cynthia A. Thomson[6], Saad Z. Usmani[1], Urvi A. Shah[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Hematology, Thomas Jefferson University Hospitals, Philadephia, PA,[3]Yale New Haven Health, Guilford, CT,[4]HealthTree Foundation, Lehi, UT,[5]NutritionQuest, Berkeley, CA,[6]University of Arizona, Tucson, AZ

Background: Multiple myeloma (MM), the second most common hematologic malignancy in the US, has seen improved survival with therapeutic advancements. This presents an opportunity to enhance outcomes through diet and lifestyle. Poor dietary habits and obesity are linked to adverse outcomes in MM and its precursors—monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM)—potentially mediated by intestinal dysbiosis which affects the immune microenvironment. High Healthy Eating Index (HEI) scores, which reflect better adherence to the Dietary Guidelines for Americans, are associated with reduced mortality. However, data on the dietary habits of individuals with plasma cell disorders (PCDs) remains limited.
Methods: We surveyed 443 individuals with MGUS, SMM, or MM on HealthTree Cure Hub using the Block Food Frequency Questionnaire (2022- 2023). We calculated HEI scores and analyzed by age, sex, race, BMI, PCD diagnosis, and education level. We also compared participants' scores to the general US population by age, sex, and race.
Results: Average HEI score was higher for participants (69) than for the US population (58) across all subgroups ($p<0.001$). Lower education was associated with lower HEI scores ($p<0.001$) and trended toward higher fruit and lower added sugar intake. Higher BMI trended toward lower HEI scores ($p=0.052$) and significantly increased fatty acid intake. Males consumed more calories with less vegetables, sodium, and fatty acid intake. Non-Hispanic Asians and Blacks consumed fewer calories but more fatty acids. MGUS and SMM participants consumed more vegetables and lower added sugar, but more sodium compared to MM patients.
Conclusion: Individuals with PCDs have more healthful diets than the general US population. However, females, non-Hispanic Asians, non-Hispanic Blacks, individuals with higher BMIs, and those with less education may benefit from targeted dietary interventions to improve health outcomes.

TABLE: Average Daily Food and Micronutrient Intake for Patients with Plasma Cell Disorders

#999 Spectrum of germline BRCA1/2 gene mutations in Nigerian breast cancer patients.

A. F. Onyia[1], P. Jibrin[2], T. Olatunji-Agunbiade[3], A. Oyekan[3], A. Lawal[4], A. Alabi[4], A. C. Sowunmi[4], E. A. Aje[4], O. B. Ogunniyi[1], E. S. Nkom[5], O. C. De Campos[1], O. A. Rotimi[1], J. O. Oyelade[1], **S. O. Rotimi**[1];
[1]Covenant University, Ota, Nigeria, [2]National Hospital, Abuja, Nigeria, [3]Lagos State University Teaching Hospital, Ikeja, Lagos, Nigeria, [4]Lagos University Teaching Hospital, Idi-Araba, Lagos, Nigeria, [5]Federal Medical Centre, Abeokuta, Nigeria

Breast cancer (BC) is the leading cause of cancer-related deaths in Nigerian women, with triple-negative breast cancer (TNBC) being the most prevalent. The TNBC subtype is characterized by mutations in BRCA1 and BRCA2 genes, and germline pathogenic carriers of these mutations have an increased risk for BC. Despite these challenges, the prevalence and spectrum of BRCA1/2 pathogenic variants in the Nigerian population differ, and there is a margin in the local capacity to characterize these variations. Therefore, this study aimed to identify and characterize germline variations in BRCA 1/2 genes in Nigerian BC patients and healthy aged-matched controls to understand the genetic risk profiles of BC in this population. Forty-five BC patients were recruited across four major hospitals in Nigeria and aged-matched with 51 healthy female controls. DNA was extracted from blood samples, followed by targeted sequencing of BRCA 1/2 intronic and exonic regions using the Ampliseq for BRCA panel and the Illumina Miseq Platform. Variant calling was performed, and the clinical significance of identified variants was evaluated on the ClinVar and BRCA exchange databases. Variants of unknown significance (VUS) were assessed using known *in silico* prediction software, and haplotype analysis was carried out using the Haploview 4.2 software. Pathogenic variants were identified in 6.7% of cases, all exclusive to BC patients. These variants included two BRCA1 variants (3: c.133_134delAA (p.Lys45fs) and c.5324T>A (21: p.Met1775Lys), and one BRCA 2 variant (22: c.8817_8820del (p.Lys2939fs) all found in patients with the TNBC subtype. Additionally, 97 benign or likely benign BRCA1/2 variants were found in both BC and control groups, with notable variants such as the rs799917 identified as a surrogate indicator of ancestry. Eighteen VUS were identified, with four predicted to be damaging by three *in silico* prediction software. The results of haplotype analysis identified distinct BC haplotypes in Nigerian BC patients. The identification of BRCA1/2 pathogenic variants in Nigerian BC patients, especially those with TNBC, suggests a potential for targeted therapies, such as PARP inhibitors, to improve treatment outcomes in this population. This further highlights the need for increased population-specific screening and the integration of genetic screening into BC management strategies, which could facilitate early detection, personalized treatment plans, and genetic counseling for Nigerian BC patients.

#1073 Integrated single cell atlas of human breast cancer enables highly-resolved analysis of tumor heterogeneity and metabolic comorbidities.

Andrew D. Chen[1], Christina Ennis[2], Lina Kroehling[1], Gerald Denis[2], Stefano Monti[3]

[1]Bioinformatics, Boston University, Boston, MA,[2]BMC Cancer Center, Boston University, Boston, MA,[3]Computational Biomedicine, Boston University, Boston, MA

Single cell transcriptomics (scRNAseq) remains the method of choice to quantify and annotate cellular heterogeneity in the tumor and its microenvironment (TME), yet most studies are under-powered to associate changes in tumor heterogeneity with phenotypes such as tumor subtype, grade, and patient age, among others. In this study, we created an integrated atlas of human breast cancer (BC), the largest resource of its kind, totaling more than 700,000 cells across 145 patients, and optimized computational methods to benchmark integration performance, and robustly perform hierarchical cell type annotation. By combining single profiles, a higher-resolution annotation of immune, stromal, and epithelial cell types was achieved. Further, using this integrated atlas, differential abundance analyses identified significant changes in immune and stromal cell type composition associated with tumor grade, subtype, and inferred metabolic comorbidities. For insulin resistance and obesity, we identified significant expansion in exhausted CD4 T Cell populations and interferon signalling in CD8 and macrophage populations. These changes in TME heterogeneity were not discernible or had effects in discordant directions when the analysis was limited to individual BC studies, highlighting the need for atlas-based mega-analysis approaches. This highly-resolved integrated scRNAseq BC atlas represents a valuable resource for hypothesis-driven analyses of tumor heterogeneity.

#1094 Harnessing neural networks for cancer prediction: clinical staging of head and neck cancer.

Amrit Menon[1], Nathan DeMichaelis[2], Dalton Schutte[3], Frank G. Ondrey[4]

[1]University of Chicago, Chicago, IL,[2]Dartmouth College, Hanover, NH,[3]Department of Surgery, University of Minnesota Medical School, Minneapolis, MN,[4]Department of Otolaryngology - Head & Neck Surgery, University of Minnesota Medical School, Minneapolis, MN

Introduction: Predictive oncology through the use of deep learning offers potential to both classify and assist in the treatment of head and neck cancer, a disease that has a relatively static rate of cure. More specifically, neural networks may allow for the classification of genomic expression data in a more complex manner. The present study applies neural networks to the larger NCI Cancer Genome Atlas (TCGA) and our previously published smaller U133A Affymetrix gene expression dataset.
Methods: The models were constructed using Pytorch, built from modular blocks of neural networks (Chunks) to facilitate extensive combinations of layers. Every Chunk consisted of a linear layer and optional predefined layers: rectifier (ReLU), normalization, and random neuron dropout (to prevent overfitting). The DeepChunk model (consisting of multiple Chunks) had additional tunable hyperparameters (optimization function, learning rate, etc.) The neural networks were trained to classify T and N staging data separately for both TCGA (split by HPV status) and Affymetrix chip datasets between early (T1/2) versus advanced (T3+) T stages, N0 versus N1+, respectively. Models were trained on larger datasets (HPV- T and HPV N, n >= 350) using randomly split data with 80% reserved for training and 20% reserved for testing, with proportional staging data across the split. The remaining datasets (n <= 50) had a split of 70% training and 30% testing. Hyperparameters (tuned for both the model and specific chunks) were assessed (by test accuracy and area under receiver operator characteristic curve, AUC-ROC) on the whole gene expression data. Settings selected during the hyperparameter screen were assessed with 20 trials using randomized initialization and data splits.
Results: The models (test accuracy [95% CI], AUC-ROC [95% CI]) trained on the TCGA HPV- N (0.619 [0.601, 0.637], 0.63 [0.602, 0.659]) and TCGA HPV+ T (0.72 [0.672, 0.768], 0.733 [0.671, 0.794]) datasets performed significantly better than the other models trained. The remaining models failed to significantly predict above random chance (with 95% CIs overlapping with 0.5). Unstable performance from these models could be attributed to overfitting or quickly converging during training with lack of improvement afterwards. Another potential cause involves high variance from the smaller size of training data.
Conclusions: The process used to tune and train the neural networks harbors potential in the analysis of large gene datasets. At the same time, it may benefit from feature reduction or functional annotations as the one dimensional feature lists are not inherently ordered or clustered, as is the case with two dimensional image neural networks.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 1

#1171 M9466 (HRS-1167): A highly potent and selective PARP1 inhibitor with DNA trapping activity, monotherapy antitumor activity and synergistic potential with DDR inhibitors and chemotherapies.

Heike Dahmen[1], Ada Sala Hojman[1], Steffie Revia[1], Xin Li[2], Ting Zhang[2], Nina Berges[1], **Astrid Zimmermann**[1], Thomas Grombacher[1], Brian Elenbaas[3]

[1]The healthcare business of Merck KGaA, Darmstadt, Germany,[2]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China,[3]EMD Serono, Billerica, MA

Poly(ADP-ribose) polymerase 1 (PARP1) plays a key role in the repair of single-stranded DNA breaks and DNA damage caused by endogenous replication and repair errors or by exogenous DNA damaging agents. Currently approved PARP inhibitors (PARPis) such as olaparib, niraparib and talazoparib show synthetic lethality in homologous recombination deficient (HRD) cancers including those with *BRCA1/2* mutations. Although approved PARPis provide a major therapeutic advance for patients with these cancers, they are associated with hematologic toxicities which limit their therapeutic window and their combinability. All currently approved PARPis non-selectively inhibit PARP1, PARP2 and often additional members of the PARP family. However, inhibition of PARP1 appears to be sufficient for antitumor activity, while PARP2 inhibition is associated with hematologic toxicities in preclinical models. M9466 is a highly potent and selective PARP1 inhibitor with DNA trapping activity. It shows a highly potent antiproliferative efficacy in the DLD-1 (BRCA2 KO) cell line, but not in the DLD-1 wild-type cell line. M9466 exhibited selective antiproliferative activity in a large panel of 96 cancer cell lines *in vitro* including several *BRCA1/2* mutant / PARP-sensitive models. M9466 also selectively inhibited PARP1 vs PARP2 (672-fold) in A549 cells as shown by PARylation inhibition assays after shRNA knockdown of individual PARP genes. M9466 strongly reduced tumor growth in a *BRCA1* mutant breast cancer tumor xenograft model *in vivo* with once daily, oral dosing. To identify top synergistic combination partners for M9466, a large *in vitro* drug combination screen was conducted with 101 compounds in 35 cancer cell lines. The screen highlighted synergistic activity of M9466 with certain DDR inhibitors (ATR and ATM kinase inhibitors) and with topoisomerase I (Topo I) inhibitors and temozolomide. The combination potential was further evaluated and confirmed in a series of *in vivo* tumor xenograft studies. Here, M9466 enhanced the antitumor efficacy of the ATR inhibitor tuvusertib and the chemotherapy carboplatin. Thus, M9466 has strong single agent synthetic lethal activity in HRD models and combinability with selected DDRis and chemotherapies. Based on these data, Phase I clinical trials are evaluating M9466-based combinations in patients with advanced solid tumors, and colorectal cancer (NCT06421935, NCT06509906).

#1217 Modelling GBM-vasculature interaction on chip.

Promise Emeh[1], Kevin Jimenez-Cowell[2], Martine Lamfers[2], Clemens Dirven[2], **Nick Saites**[1], Todd Burton[3], Karla Queiroz[3]

[1]MIMETAS, Oegstgeest, Netherlands,[2]Department of NeuroSurgery, Erasmus MC-University Medical Center Rotterdam, Rotterdam, Netherlands,[3]MIMETAS, oegstgeest, Netherlands

The tumor microenvironment (TME) in glioblastoma (GBM) is remarkably intricate, characterized by its dynamic nature and high heterogeneity that significantly influence tumor progression and treatment resistance. The heterogeneous TME comprises of blood vessels, immune cells, neurons, and the blood-brain barrier (BBB) presenting distinct tumor compartments that influence the tumor behavior. A recent classification based on the heterogeneous TME identified three distinct subtypes TME^{Low}, TME^{Med}, and TME^{High} distinguished by varying endothelial and immune cell populations. This study explores the complex interactions between glioblastoma (GBM) and its tumor microenvironment (TME), focusing specifically on the blood-brain barrier (BBB) and vascular compartment. To evaluate GBM's impact on the BBB, a compartmentalized model was developed that prevents direct cell-to-cell contact, allowing the observation of paracrine signaling. Using this model, distinct effects were identified across different GBM cell lines: one cell line caused significant BBB permeability with low transendothelial electrical resistance (TEER) values, while another had minimal impact on barrier integrity. To further investigate GBM-BBB interactions, a vascular network model incorporating brain endothelial cells, stromal cells and GBM cells within an extracellular matrix was developed. This model revealed consistent differences between the cell lines, aligning with the initial findings and reflected in endothelial cell morphology and vascular network density. Analysis of cytokines secreted by the GBM cell lines provided further insights into the observed changes in vascular organization. Ongoing investigation aims to use patient derived cells in this model to pick up interpatient variability and specifically look at the differences between the TME subtypes. This approach allows for the in vitro modelling and characterization of GBM TME subtypes and potentially the identification of novel druggable targets in the GBM TME.

#1218 A comprehensive and scalable human liver-on-a-chip model forfibrosis drug discovery and gene delivery applications.

Flavio Bonanini, Roelof Dinkelberg, Tessa Hagens, Nienke Kortekaas, **Nick Saites**, Manuel Torregrosa, Dorota Kurek, Paul Vulto, Kristin Bircsak

MIMETAS, Oegstgeest, Netherlands

Liver cancer, or hepatocellular carcinoma (HCC), is a formidable malignancy characterized by the uncontrolled growth of cells within the liver tissue. It represents a global health concern, with risk factors including chronic viral infections (such as hepatitis B and C), excessive alcohol consumption, fatty liver disease, and certain genetic conditions. The silent progression of HCC complicates early detection, emphasizing the need for a deeper understanding of the liver tumor microenvironment, which plays a crucial role in disease development. The liver model presented here incorporates a wide array of relevant liver cell types, including hepatocytes, endothelial cells, stellate cells, and resident immune cells. This is complemented by a complete vascularization system, allowing for fluid flow across a micro vascular network that faithfully models the dimensions of liver sinusoids. All these elements are seamlessly integrated into an automated and high throughput platform known as the OrganoPlate®. To model the liver tumor microenvironment, hepatocellular carcinoma cells were integrated into healthy liver tissue model. The resulting model allowed for the observation of integrated cancer colonies, providing a more realistic platform for therapy development compared to monocultures. Simultaneously, the liver's particle clearance mechanisms were investigated using fluorescent imaging. Endothelial cell phagocytosis of E. coli particles and resident macrophages' internalization of dextran molecules were studied to explore hepatic delivery of macromolecules and nanoparticles via the systemic circulation. The integration of hepatocellular carcinoma cells within healthy liver tissue revealed the formation of integrated cancer colonies, offering insights into the complex interactions within the liver tumor microenvironment. Fluorescent imaging showcased endothelial cell phagocytosis of E. coli particles and resident macrophages' internalization of fluorescent molecules. These findings elucidate the liver's particle clearance mechanisms, providing a foundation for understanding immunological processes and designing efficient drug delivery systems. Understanding the liver tumor microenvironment is critical for developing effective therapies for HCC. The integration of hepatocellular carcinoma cells within healthy liver tissue offers a more realistic platform for therapy development compared to traditional monocultures. We believe this system holds the potential for a groundbreaking progress in liver modelling which, besides including functional hepatic cells, also reflects the cellular organization and interactions found within the liver lobule. In conjunction with its high throughput capability, this has the potential to revolutionize drug discovery and develop therapies for complex liver diseases.

#1220 Cryopreserved 3D human tumor spheroid platform in 96-well format for robust & scalable discovery and screening.

Madhu Nag, Simon Strobel, Simon Hutter, Tala Issa, Laure-Anne Ligeon, Nils Goedecke, Olivier Frey

InSphero AG, Schlieren, Switzerland

Development of new therapies relies on rigorous testing in physiologically relevant, predictive in vitro models. This approach reduces the attrition of preclinical candidates going into animal studies and onto Phase 1 trials. While 2D tumor cell cultures have traditionally been the norm in early drug screening due to their automation compatibility and ease of use, they are no longer the optimal choice for drug development. This is due to their lack in translatability to human physiology, which is essential for assessing aspects of the cellular microenvironment, intercellular interactions, and the role of immune cells. The generation of 3D in vitro tumor spheroids for high-throughput screening campaigns can be labor-intensive, particularly at the lead discovery stage. The availability of a constant, reproducible supply of a panel of tumor spheroids for target ID and target validation studies represents a significant time and resource saving. To provide more flexibility in large-scale screening for therapeutic candidates in oncology, we developed a new platform offering a wide range of cryopreserved 3D tumor models in microplate format, enabling off-the-shelf high-content screening. The platform allows users to begin testing compounds within 3-5 days by just thawing an ARCTis™ plate (Always Ready Cryo Tissues) and following a few instructions. Another advantage of these cryopreserved 3D models is that they are manufactured in larger batches under highly standardized processes, ensuring a consistent starting point for compound testing. This results in enhanced data quality, an extended test window length, and data that is comparable across workgroups. Our current portfolio comprises 20 tumor cell lines from ATCC, representing the most common solid tumors. Staurosporine has been used as a positive control to detect a dose-dependent effect on cell viability. Following this treatment the dose-response indicated growth inhibition, shrinkage or tumor cell killing effects based on size and metabolic analysis (ATP). Furthermore, we demonstrated the robust performance of these assays for plates stored up to 6 months at -80 °C. This study demonstrates the efficacy of selected small molecules to show the functionality of the spheroids and to compare their functionality across different tumor models. Therefore, we will present applications for ARCTis™ plates that proof their relevance for pre-clinical testing. In conclusion, this innovative approach addresses the limitations of traditional 2D cell cultures by providing a high-throughput, in-plate frozen, 3D cell culture platform and access to a large tumor panel for parallel testing, offering a more physiologically relevant representation of tumor diversity. Our robust frozen flexible assay platform offers a promising new approach to advancing cancer drug discovery, streamlining the exploration of complex drug testing screens in vitro.

#1221 Modelling the heterogeneity of high grade serous ovarian tumors in 3D to study its metabolic response to atovaquone.

Paula M. Manan-Mejias[1], Nicha Boonpattrawong[2], Manish Patankar[1], Maria Virumbrales Munoz[1]

[1]University of Wisconsin - Madison, Madison, WI,[2]University of Wisconsin - Oshkosh, Oshkosh, WI

Ovarian cancers are the 8th most common cause of cancer related deaths in women, which outcomes have not meaningfully improved since the 1980s. High-grade serous ovarian carcinoma (HGSOC), is the most common subtype of ovarian cancer and the deadliest, responsible for 70-80% of ovarian cancer deaths. HGSOC is typically diagnosed at advanced stages, due to lack of reliable tests and vague external symptoms. When detected, treatment options are limited and result in a 60% recurrence rate. Consequently, there is an urgent need for new therapeutic agents for HGSOC. Atovaquone is an FDA-approved drug for malaria that has been effective against HGSOC in 2D models. Atovaquone (ATO) is an OXPHOS inhibitor that induces reactive oxygen species (ROS) by binding to complex III, leading to apoptosis. However, the mechanism of action of Atovaquone is not well understood, arguably limited to using traditional HGSOC models in mechanistic studies. For example, 2D *in-vitro* models fail to include oxygen and nutrient gradients, as well as relevant mitochondrial organization for 3D migration processes, whereas *in-vivo* models make real-time cell inspection challenging. To bridge this gap, we have designed a microphysiological system (MPS) to investigate the role of the 3D tumor microenvironment (TME) in the HGSOC response to therapeutics. Our MPS includes an HGSOC cell spheroid that models intra-tumor metabolic heterogeneity, by recapitulating a necrotic core, quiescent area, and proliferative edge. Adjacent to the tumor spheroid, we can include 3D tubular vessels to study the delivery and effects of atovaquone in lymphatic drainage. Migration and invasion of HGSOC spheroids decrease with ATO treatment. We also showed that atovaquone alters mitochondrial dynamics within 48-72 h of treatment. In addition, a non-destructive imaging technique capable of assessing real-time metabolic profiles in spheroids, revealed that ATO is capable of shifting cancer cell metabolism in spheroids, impeding ATP production. Using this HGSOC MPS, we aim to better understand the mechanism of action of atovaquone and accelerate its translation into the clinic as a sole or combination therapy agent.

#1222 Integrating i*n vitro* and *in vivo* data with algorithm-driven PK/PD modeling: a fast and efficient tool for evaluating cancer therapies in preclinical models.

Karina Adamowicz, David Cebrian, Fabio dell' Aquila, Leanne Doyle, Agnieszka Drzał, Simone Esposito, Bartosz Płociennik, Katarzyna Urbańska, **Martyna Sniegocka**

Selvita S.A., Krakow, Poland

Preclinical *in vivo* PK/PD studies of cancer therapies are invaluable for cancer drug discovery and the translation of therapies from bench to bedside. However, conventional *in vivo* experimentation are often time-intensive, resource-demanding, and may require redesign due to inefficient and/or toxic range of concentrations, or suboptimal study parameters. To address these challenges, we developed an integrated approach combining *in vitro* and *in vivo* data to generate *in silico* PK/PD models of anti-cancer compounds. Our algorithm was verified using standard chemotherapies, including Cisplatin and Dacarbazine, against tumoral cell lines for e.g. B16F10 and LLC. The algorithm was trained with the cells doubling time *in vitro* and with the tumor growth rate in mice. We then conducted an *in vitro* time-course experiment using a range of concentrations to assess cellular growth inhibition. This data was integrated into the algorithm thus it can calculate the IC_{50}, the drug plasma concentration, and the efficacy over-time of each drug against the engrafted cell lines in mice. Finally, we validated our model *in vivo* using selected doses from the calculated efficacy ranges, achieving tumor volume reductions comparable to the model's projections for the tested drugs. In conclusion, we generated a fast and resource-efficient method for PK/PD studies, broadly applicable to cancer drug candidates with minimal prior *in vivo* efficacy data.

#1223 A novel 3D high-throughput screen identified drugs that re-epithelialize colorectal cancer cells and enhance response to chemotherapy.

Sarah J. Harmych[1], Thomas P. Hasaka[1], Chelsie K. Sievers[2], Seung W. Kang[1], Vivian T. Jones[1], Zhiguo Zhao[2], Oleg Kovtun[1], Claudia C. Wahoski[1], Ken S. Lau[1], Robert J. Coffey[2], Joshua A. Bauer[1], **Bhuminder Singh**[2]

[1]Vanderbilt University, Nashville, TN,[2]Vanderbilt University Medical Center, Nashville, TN

Loss of polarity is a hallmark of cancer, and the related epithelial-to-mesenchymal transition (EMT) phenotype also impacts prognosis and therapy outcomes, particularly in colorectal cancer (CRC). However, the mechanisms and drugs that impact these morphologic changes are understudied, in part, due the complete failure of typical live/dead 2D high-throughput screens (HTS) to capture morphology or lack of robustness of 3D screens. Here, we designed an HTS using 3D type I collagen cultures of CRC cells to assess morphological changes in colonies and identified several FDA-approved drugs that re-epithelialize CRC colonies. One of these drugs, Azithromycin, increased colony circularity, enhanced E-cadherin membrane localization, and surprisingly, also elevated sensitivity to the chemotherapeutic, Irinotecan. A retrospective study of patient data demonstrated that the combination of Azithromycin with Irinotecan improved the 5-year survival of patients with CRC. These results highlight the importance of morphologic screens to identify novel drug candidates and synergistic mechanisms.

#1224 Unlocking the potential of 3D patient-derived tumor microtissues as reliable and scalable *in vitro* pre-clinical models.

Laure-Anne Ligeon, Charlotte Veser, Michal Rudnik, matthias Zbinden, Agnieszka Pawlowska, Simon Hutter, Tala Issa, Irina Agarkova, sue grepper, Nils Goedecke, Madhu Nag

InSphero AG, Schlieren, Switzerland

Over the last decade remarkable advances have been made in our understanding of tumor biology's microenvironment, allowing for the development of innovative drugs. However, the vast majority of oncology drug candidates entering clinical trials often fail due to the lack of clinical efficacy. This high rate of attrition is in large part due to the lack of physiologically relevant, clinically translatable, preclinical models. Indeed, current preclinical models often inadequately reflect tumor heterogeneity and intricate complexities of the tumor microenvironment (TME), which are important determinants of both the sensitivity and the acquired resistance of any tumor. In an effort to tackle both these issues, we developed a robust preclinical model based on 3D patient-derived tumor microtissues. While there are a few 3D *in vitro/ex vivo* models incorporating primary tumor tissue, such as patient-derived organoids, PDX-derived organoids, and organotypic slice cultures, our 3D InSight™ Primary Tumor platform provides the preserved original patient tumor microenvironment at a scale that no one else is able to offer, thereby making this platform amenable for both screening and validation. This platform also addresses the research field's challenge of mirroring patient heterogeneity in a plate. We successfully established uniform 3D patient-derived tumor microtissues from fresh surgically resected tissues from colorectal or breast cancer, with a success rate of 70%. The newly formed 3D patient-derived tumor microtissues were characterized physiologically. We were able to accurately identify the cell types comprising the tumor and the TME by flow cytometry after tissue dissociation. Furthermore, these 3D patient-derived tumor microtissues were treated with standard of care chemotherapeutic drugs, and mimicked the *in vivo* response which we would expect to see with the same original tumor. Therefore, our 3D InSight ™ Primary Tumor platform is a solution that allows for the testing of multiple therapeutics as single agents/combinations, in a model that very closely resembles its *in vivo* counterpart. The ability to do this at scale has never previously been offered on any platform. Furthermore, this platform will pave the way for the development of therapeutics in oncology that are truly tailored to specific patient profiles, thereby greatly improving the prognosis and quality of life for patients suffering from cancer.

#1225 Phenotypically-relevant patient-derived 3D cell models to interrogate personalized medicine approaches at scale.

Thomas Grundy[1], Peilin Tan[2], Joanna Wasielewska[1], Christine Yee[1], Tania Fowke[1], Sean Porazinski[1]

[1]Inventia Life Science, Sydney, Australia,[2]UNSW Sydney, Kensington, Australia

The complexity and heterogeneity of cancers both intra- and inter-patient have led to the precision medicine paradigm of cancer therapy where treatment is personalized to the individual patient. Recent clinical trials such as the I-PREDICT study [1] have underscored the benefits of approaches matching combination therapies to the patient's molecular alterations, leading to improved disease control and survival rates. Tumoroids are patient-derived cancer cells that grow as 3D self-organized, multicellular organoids that maintain key characteristics of the patient tumor of origin including molecular features such as genotype and gene expression, and biological behaviors. Whilst these models serve as valuable tools for studying tumor biology and responses of patient-derived cells to various anti-cancer therapies, the establishment and maintenance of tumoroids has historically been difficult and labor intensive, limiting more widespread use. Here, we utilize the Inventia RASTRUM^{TM} platform and OncoPro^{TM} colorectal cancer (CRC) Tumoroid Cell Lines (ThermoFisher Scientific [2]) to easily create plug and play patient-derived 3D cell models based on synthetic PEG-based hydrogel matrices, which were tuned to mimic the tissue stiffness and ECM composition of CRC tumors. We used this workflow to evaluate how these 3D models maintain the clinicopathological features of patient-derived tumoroid cells, as well as molecular features and cellular signaling native to the tumor and its microenvironment. We further demonstrate the utility of this approach for throughput drug screening and predicting personalized therapy responses. Overall, our approach provides a scalable framework for evaluating precision medicine approaches using clinically-relevant patient-derived tumoroids. Future work will focus on the development of processes to support direct dissociation and generation of patient-derived models from biopsies from a variety of cancer types and larger scale utility of the RASTRUM platform in workflows that could be leveraged to inform treatment decision making.

#1226 Advancing CAR-T cell therapies using Nilogen's ex vivo 3D tumoroid platform.

Vanessa Garrido, Jared Ehrhart, **Rikhia Chakraborty**

Nilogen Oncosystems, Tampa, FL

Background: Advancing CAR-T cell therapies for solid tumors remain a significant challenge due to the complexities of the tumor microenvironment, which impacts therapeutic efficacy, operational mechanisms, and biomarker discovery. Existing preclinical models, including patient-derived xenografts and traditional organoids, often fail to replicate the physiological and immunological intricacies of solid tumors and require extensive time for establishment. Nilogen's ex vivo 3D tumoroid platform overcomes these limitations by preserving the tumor-immune microenvironment and extracellular matrix (ECM) observed in patient tumors. This platform enables robust therapeutic evaluation in a physiologically relevant context. Renal cell carcinoma (RCC), which constitutes 3% of adult cancers, has seen an increasing focus on immunotherapies and combination regimens. CD70, a highly expressed antigen in RCC, represents a promising target for CAR-T cell therapy, currently in phase I clinical trials. However, patient-specific variability in CD70 expression highlights the need for models like tumoroids to capture this heterogeneity for robust assessment of CAR-T efficacy in a patient-specific manner.
Methods: This study assessed the performance and functionality of second-generation anti-CD70 CAR-T cell therapy in RCC tumoroids. We explored the impact of immune checkpoint inhibitor combination therapy on CAR-T cell function. Key evaluations included tumor cell apoptosis (measured through time-lapse imaging), T cell activation (monitored using CD69, CD25, 4-1BB, and OX40 expression), T cell exhaustion (monitored using PD-1, LAG-3, and Tim-3 expression), and inflammatory secretome focusing on Th1/Th2 cytokines. In addition, we explored the impact of immune checkpoint inhibitor combination therapy on CAR-T cell functional efficacy.
Results: In tumoroids derived from 13 RCC patients, CD70 CAR-T cell therapy showed variable tumor-killing efficacy, with approximately 50% of samples exhibiting a positive response. Activated CAR-T cells displayed expected activation markers upon CD70 recognition and co-expressed exhaustion markers in both responders and non-responders. Cytokine profiling and the evaluation of combination therapies provided further insights into additional opportunities for optimizing CAR-T cell therapeutic performance.
Conclusions: Nilogen's tumoroid platform provides a physiologically relevant system to evaluate CAR-T cell functionality in solid tumors, enabling the assessment of patient-specific variability in response to therapy. These findings underscore the potential of tumoroids to refine and accelerate the development of CAR-T therapies, which, in turn, enhances their clinical success, particularly for RCC and other solid tumors.

#1227 Cancer cell-specific killing by reduced dose of chemotherapeutic agents in combination with immune cell therapy may be optimized in 3D BioSPHEER™ cancer models.

Boye Schnack Nielsen, Natasha H. Madsen, Isabella Skandorff, Jesper Larsen, Kim Holmstrom, Monika Gad

Cellular Engineering & Disease Modeling, Bioneer A/S, Copenhagen N., Denmark

3D cancer models consisting of cancer and fibroblast cell lines (BioSPHEERs™) exhibit complex morphology depending on the cell lines used. We recently reported that such 3D cancer models can be used for drug testing by measuring cell killing and cell survival [Nielsen et al 2024, doi: 10.3389/fonc.2024.1386097]. Chemotherapeutic agents, like 5-FU, cisplatin and cyclophosphamide, at a certain dose, kill the majority of cancer cells, but also normal cells in the body, thus causing unappreciated discomfort and side effects. In contrast, therapeutic immune cells, like TILs and CAR-T cells perform cancer cell specific killing. Importantly, our 3D cancer models also enable studies on T cell infiltration and T cell directed cell killing. PBMC-derived T cells added to heterospheroids infiltrated the structures without excessive killing, unless the T cells had been activated by CD3/CD28 beads, or primed with the respective cancer cell line ahead of mixing. In this study we first combined low (sub-lethal) dose of the chemotherapeutic agent 5-FU with subsequent administration of PBMCs. 5-FU was added to spheroids, consisting of mCherry-engineered HT29 cells and 1BR3G fibroblast, at day 7 after seeding and after 24 hours the 5-FU was removed and PBMCs were added. 5-FU added at 500 µM (high dose) caused dramatic killing measured by a luciferase assay, whereas the drug at 100 µM (low dose) appeared quite harmless to the cells in the spheroids. We next treated spheroids with the low dose of 5-FU and after 24 hours added T cells. After additional 72 hours, histological examination showed that the T cells themselves partly infiltrated the vehicle-treated spheroids, but caused little killing. However, the same T cells added to the 5-FU-treated spheroids caused excess killing, suggesting a synergistic effect of the two agents. We are currently testing more PBMC donors in combination with other therapeutic agents, including antibody drug conjugates (ADC). Our observations suggest that well-known chemotherapeutic agents applied at sub-lethal dose may enhance the effect of immune cell therapies. The combination treatment may retain or improve drug efficacy and at the same time reduce severe side effects caused by the chemotherapeutic agent. We propose that the use of 3D BioSPHEER™ cancer models to study combination treatment, will allow better optimization of dosage and timing of combined chemo-immuno-therapy.

#1228 High throughput phenotyping and drug discovery using the TumorGraft3D co-culture platform and flow cytometry.

Sumanun Suwunnakorn, Fu-Ju Chou, Elena Bruni, Karolina Pilipow, Xiangyang Zhang, Chelsea Riveley, Mara Gilardi, Stefano Cairo, **Brandon Walling**

Champions Oncology, Inc., Hackensack, NJ

Many anticancer drugs fail in clinical trials due to issues resulting from inadequate efficacy and/or high toxicity emphasizing the need for improving clinically relevant, preclinical models for high throughput drug screening. Currently, 3D models have emerged as a highly promising tool for initial drug screening that closely mimics *in vivo* tumors through preserved morphology and molecular mechanisms. To further recapitulate the *in vivo* models, interactions between immune and tumor cells can be performed via co-culture models. As the complexity of the models has increased, the analytical methods have had to evolve as well. In this work, we have developed a high throughput flow cytometry (FlowHT) assay using Champions' TumorGraft3D (CTG3D) models. CTG3D are 3D organoids derived from our highly characterized and clinically annotated Patient Derived Xenograft (PDX) models. We have developed a method of TumorGraft3D dissociation which preserves cell viability and epitope stability. We further optimized a robust FlowHT workflow that allows for the detection of low-frequency targets and the characterization of unique subpopulations in modular multicolor panels to distinguish immune cells and CTG3D in mixed populations. Using this method, we have validated that the CTG3D models retain their original phenotype with minimal differences observed between source PDX tumors and expanded ex-vivo 3D models. At co-culture endpoints, our assay was highly sensitive to immune cell-mediated tumor killing as well as SOC drug responses. Interrogation in an allogenic PBMC coculture revealed the ability to detect cytotoxic T cells (Tc) and helper T cells (Th) activation and immune checkpoint markers such as CD69, TIM-3, and PD-1 among others. Collectively, we have developed a quantitative, sensitive, and robust assay that can be utilized as an analytical endpoint for both monoculture and coculture studies to enhance the interrogation of immune-oncology agents for tumor killing, ADCC effects, increasing T cell activation, reversal of T cell exhaustion and identifying specific markers across multiple cell types.

#1229 3D-bioprinted cancer models for prediction of drug response driven by H&E-based AI algorithm.

Ronit Satchi-Fainaro[1], Anne Krinsky[1], Anshika Katyal[1], Opal Avramoff[1], Yulia Liubomirski[1], Gal Dinstag[2], Omer Tirosh[2], Ranit Aharonov[2], Tuvik Beker[2], Iris Barshack[3], Shaked Lev-Ari[4], Shirly Grynberg[4], Ronnie Shapira-Frommer[4]

[1]Tel Aviv University, Tel Aviv, Israel,[2]Pangea Biomed, Tel Aviv, Israel,[3]Tel Aviv University, Sheba Medical Center, Ramat Gan, Israel,[4]Sheba Medical Center, Ramat Gan, Israel

Many drugs show promising results in laboratory research but eventually fail to show clinical benefit. One main reason for this translational gap is that the cancer models used are inadequate. Most models lack the complex tumor-stromal-immune cell interactions with their tumor microenvironment (TME) that are required for progression. Conventional 2D models, where cells grow on rigid plastic plates mainly as mono-cultures, fail to recapitulate these complex interactions. Hence, we developed two platforms of 3D cancer models that better mimic the TME: (i) a 3D tumoroid model consisting of all the cells from the patient's tumor tissue, following cell suspension, and isolated peripheral blood mononuclear cells (PBMC) from the same patient's blood, and (ii) a vascularized, hydrogel-based 3D-bioprinted tumor model consisting of patient-derived tumor, PBMCs and TME cells. Our 3D models are based on a library of hydrogels that we developed as scaffolds for different tumor types according to the mechanical properties of the tissue of origin which dictates the proteo-genomic signature and, hence, the response to different therapies. The patient-derived models consist of cells isolated from a freshly-resected tumor mass and include PBMCs that either surround the 3D tumoroids or flown through 3D-bioprinted functional blood vessels connected to a pump. Using these unique high throughput 3D models, we are currently validating their ability to mimic patient-specific tumors and TME, in order to serve as a tool to predict patient response to different treatments (e.g., chemotherapy, immunotherapy, and targeted therapies). To decide which therapies to test on our 3D platforms, we consider cancer specific standard-of-care (SoC), investigational therapies as well as therapies proposed by ENLIGHT-DP, an AI-based algorithm developed by Pangea Biomed that utilizes H&E slides to generate individual drug response scores for targeted and immune therapies. The ENLIGHT-DP first predicts gene expression from H&E slides using a deep-learning AI algorithm and then uses the predicted expression to generate response scores for a variety of therapies. To validate the ability of our models to predict patient responses, we are currently conducting an 80-patient clinical trial (IRB approved) testing different treatments on samples covering 7 different cancer types. An interesting case from this trial is a mucosal melanoma patient who failed SoC treatments correlated with failure to respond in our models. Interestingly, ENLIGHT-DP predicted that the patient would respond to regorafenib, a suggestion corroborated by our 3D model. Following this promising outcome, the patient received it as compassionate use, resulting in an immediate partial response lasting for 6 months so far. These unique 3D models have the potential to facilitate target discovery and drug development, as well as to serve as a reliable system for precision medicine.

#1230 High throughput quantitative molecular characterization of cytotoxic antibody-drug conjugates in spheroid models for improved functional characterization, screening and candidate selection.

Meghan Hogan[1], Andrea Hernandez Rojas[1], Araba Sagoe-Wagner[1], Jodi Wong[1], Sarah Church[1], Brigitte Lovell[2], Sergio Hernandez[2], Lakshmi Chandramohan[2], Anna Juncker-Jensen[2], **Kirsteen Maclean**[2]

[1]Zymeworks, Vancouver, BC, Canada,[2]Neogenomics, Fort Myers, FL

Background: Antibody-drug conjugates (ADCs) are a class of cancer therapeutics comprised of a linker-payload conjugated to a monoclonal antibody targeting a tumor-associated antigen (TAA), to enable the delivery of the cytotoxic payload to cancer cells. Presently, there is a need for improved in vitro models that better recapitulate in vivo tumor tissue complexity to aid in the screening and evaluation of novel ADCs during preclinical development. Specifically, we have developed in vitro 3D models from cancer cell lines yielding spheroids in a rapid, robust and uniform manner. Using these spheroid models, we have developed cell-based assays to functionally evaluate the cytotoxic activity of ADCs *in vitro*. For further comprehensive characterization of ADC activity in 3D cell line models, we utilized the nCounter® ADC Development Panel, a specialized gene expression tool for molecular characterization of biological function, with customizable gene content to address complex questions important for the success of ADCs throughout discovery, pre-clinical and clinical development.
Methods: Spheroids were generated by seeding ovarian cancer cell lines into microtiter plates treated with ultra-low attachment coating, using automated liquid-handling robots, followed by incubation with ADCs under standard culturing conditions, prior to functional transcriptomic evaluation. The nCounter ADC Development Panel was analytically validated and included performance specification of accuracy, precision, analytical specificity, and RNA input range of the panel to directly profile 770 genes addressing essential biological questions relevant to ADC activity, including tumor targeting and antigen expression; ADC internalization; payload release; drug mechanisms of action; target cell death; immunogenic cell death; and mechanisms of resistance.
Results: The combination of high-throughput spheroid assays and comprehensive transcriptomic analysis presented herein highlight an important and streamlined workflow to aid in the screening and selection of therapeutic cytotoxic ADC candidates for the treatment of solid tumors.

#1231 Exploring drivers of variability in patient tumor responses to HIF-2α inhibitor using the Xsphera patient-derived organotypic tumor spheroid (PDOTS) platform.

Alyssa Martin[1], Chunxiao Cui[1], Aaron Goldman[2], **Michael A. Perricone**[1]

[1]XSphera Biosciences, Inc., Boston, MA,[2]Department of Medicine, Harvard, Boston, MA

Background: The hypoxia-inducible factor 2 alpha (HIF-2α) complex is a critical driver of clear cell renal cell carcinoma (ccRCC), with FDA-approved inhibitor PT2977 (belzutifan) demonstrating promising clinical efficacy. Xsphera's patient-derived organotypic tumor spheroid (PDOTS) platform offers an innovative ex vivo approach to recapitulate the tumor microenvironment (TME) and assess patient-specific responses to cancer therapeutics. This study highlights how the PDOTS platform can bridge the gap between preclinical and clinical data, providing insights into patient-specific tumor responses and mechanisms of resistance.
Methods: Resected patient RCC tumors (n=7) were processed into PDOTS and cultured within a microfluidic device to preserve native TME. Baseline immune cell profiles were characterized using flow cytometry on dissociated single-cell sub-fractions. PDOTS from each patient tumor were treated with the HIF-2α inhibitors PT2977 (7.5-750 ng/mL) and PT2385 (50-5000 ng/mL), or vehicle control. Tumor responses were evaluated at day 3 post-treatment using Hoechst Propidium Iodide (HPI) automated image analysis. RNA was extracted post-treatment, and gene expression was profiled using the NanoString IO360 panel. Integrated analyses of immune cell composition, cytotoxicity, and gene expression were performed to explore potential correlations with response.
Results: Cytotoxicity: PT2385 induced dose-dependent cytotoxicity, in 4 of 7 samples (57%), while PT2977 demonstrated activity in 2 of 7 (28%) patient tumors without a clear dose-response relationship. Immune Profiles: No significant associations were observed between baseline immune cell composition and tumor response. Gene Expression: Preliminary NanoString analysis revealed distinct gene expression changes in responsive versus non-responsive tumors. Responsive tumors exhibited downregulation of pro-tumorigenic pathways, including cell proliferation and G2M checkpoint-related genes, relative to controls. Interestingly, markers associated with myeloid cells, such as CD163 and LILRB4, were elevated in responsive tumors following treatment, but remained unchanged in non-responsive tumors.
Conclusions: Xsphera's PDOTS platform effectively mirrors the clinical response rates to HIF-2α inhibitors, offering actionable insights into tumor variability and resistance mechanisms. By combining cytotoxicity, immune profiling, and transcriptomic analyses, the PDOTS platform provides a robust predictive and exploratory tool for oncology drug development. These findings underscore the utility of this platform in tailoring therapeutic strategies for ccRCC and other cancer types.

#1232 A 3D bioprinted prostate cancer ex vivo model with nanoengineered hydrogel for potential drug screening.

Anirud Chakravarthi Arava[1], Camar Ameril[2], Ananya Aggarwal[1], Gnanasekar Munirathinam[1], Mohammad Fazle Alam[1]

[1]University of Illinois College of Medicine (Rockford), Rockford, IL,[2]University of the Philippines, Los Banos, Philippines

Prostate cancer (PCa) is one of the most lethal cancers in men worldwide. As of 2024 there have been 2,001,140 new cases reported. The tumor microenvironment (TME) is a dynamic niche where tumor cells, stromal, and immune cell types interact within the tumor-specific extracellular matrix (ECM), playing a fundamental role in regulating tumorigenesis and dissemination. TME promotes signaling between tumor cells and non-malignant cells, which leads to tumorigenesis that results in metastasis. An *Ex vivo* model is required for understanding the tumor microenvironment and to study the changes that occur during metastasis but it remains challenging to achieve due to the complexity posed by the disease's heterogeneity. Currently, the latest advancement in 3D bioprinting and organoid technology offers to fabricate a physiologically relevant ex-vivo cancer model. However, challenges remain in terms of the choice of suitable bioink. In this study, we developed a nanoengineered hydrogel (NOEH) by mixing different ratios of Laponite with Gelatin Methacrylate (GelMA). After mixing, we characterized the rheological and swelling ratio, parameters. We observed that the viscoelastic property of Nanoengineered hydrogel (NOEH) gets enhanced as the ratio of laponite. To analyze the biocompatibility and proliferation of NOEH, we embedded the prostate cancer cells (WPMY-1 and PC3), mesenchymal cells (WPMY-1), and Human umbilical vein endothelial cells (HUVECs) and observed NOEH are compatible with all the cells. We optimized the printing parameter of NOEH to fabricate the 3D prostate cancer scaffold and mimic the TME by adding different proportions of cells. The outcome of the study revealed that the NOEH supports cellular properties like viability, migration, and proliferation in 3D bioprinted scaffolds. The combination of Laponite with GelMA enhances viscoelastic properties and swelling capacity, promoting cellular interactions for the co-culture of normal and cancer cells of PCa-TME. The combination of GelMA-Laponite also resulted in higher viability as the cell in co-culture maintained high viability for 10 days. This novel 3D-bio printed PCa-TME model is progressing towards a platform for drug testing personalized medicine but needs further analysis to understand complex interactions of the cellular and non-cellular components. The PCa-TME model is being utilized to explore how the stiffening of the Extracellular Matrix contributes to chemoresistance and the potential role of efflux pumps in this process.

#1233 Construction and application of an immune microphysiological model for lung cancer.

Jianli Dai, Qianqian Wang, Junhong Li, Yang Li, Wenbo Ma, Qing Zhang, Jingyu Yang, Panglian Xu, **Yanmei Zhang**

Institute of New Materials and Advanced Manufacturing, Beijing Academy of Science and Technology, Beijing, China

Tumor models are important tools for cancer research and drug development. The existing tumor models are unable to reconstruct the microphysiological processes of tumor immune responses in vivo, thus limiting their applications in the development of tumor immunological drugs and tumor immunotherapy. How to rapidly and accurately construct tumor models with a tumor immune microenvironment and an immune microphysiological system is a critical problem that urgently needs to be solved in the field of tumor immunology research and therapy. In this study, innovatively based on bio-3D printing and organ-on-a-chip technology, a lung cancer immune microphysiological system model(LCIMS) integrating the tumor area, blood vessels and lymphatic area was precisely constructed. Firstly, we screened a variety of biohydrogel materials where cells could coexist, and the hydrogel was mixed with the immune cells and fibroblastic reticular cells derived from the draining lymph nodes of lung cancer patients to generate a printable bioink. Then, lymphoid organoids with germinal centers were constructed through extrusion 3D printing. In addition, based on droplet microfluidic technology, we constructed lung cancer assembloids with intra-batch consistency and tumor microenvironment. Further, the lung cancer assembloids and lymphoid immune organoids were integrated together in an organ-on-a-chip with vascular channels, forming an immune microphysiological system with the tumor area, lymphatic area and vascular channels. In this LCIMS model, the cancer assembloids in the tumor area have similar molecular, cellular and histopathological characteristics to primary tumors, and the immune organoids in the lymphatic area have T cell and B cell regions. The results of single-cell sequencing and flow cytometry show that the organoids have similar cell subtypes and cell interaction characteristics to the patient's lymph nodes and can generate antibody responses under the stimulation of viral vaccine. In order to further explore the application value of the model in immunodrug screening, we evaluated the role of immune checkpoint inhibitor PD-1 on lung tumors. The activation of CD8+ T cells in the lymphatic area, their directed chemotaxis towards tumors, infiltration into tumors and tumor killing can be observed. In addition, the effects of CAR-T cells on cancer were tested in this model, compared to traditional tumor organoid models, the release of interleukin-6 and interferon γ in the lymphatic area can be clearly observed under the action of CAR-T cells in the model. This highlights the potential of our model to mimic the cytokine storm caused by cellular immunotherapy and its impact on tumor killing. In conclusion, the LCIMS model is a more ideal tumor immune model and has important application value in the development of tumor immunobiological drugs and the evaluation of tumor immunotherapy.

#1234 Mechanical control of cancer-associated adipocyte plasticity orchestrates pancreatic cancer progression.

Bo Han[1], Zhi Yang[1], Shuqing Zhao[1], Thomas Schmittgen[2], Jamel Ali[3], Jonathan Barajas[1], Carolyn Ruiz-Rivera[1], Ba Xuan Hoang[1]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]University of Florida, Gainesville, FL,[3]Florida A&M Univeresity, Tallahassee, FL

Cancer-associated adipocytes (CAAs) are key components of the pancreatic tumor microenvironment, yet how their phenotype and function are regulated by environmental conditions remains poorly understood. Here, we demonstrate that oxygen tension and matrix stiffness dramatically alter CAA behavior and their subsequent effects on pancreatic ductal adenocarcinoma (PDAC) progression. Under normoxic conditions and soft matrix, CAAs exhibit an activated phenotype characterized by extended podia formation and enhanced secretion of matrix-degrading enzymes, particularly MMP-2 and MMP-9, leading to dissolution of organoid extracellular matrix (ECM) and restriction of PDAC cell growth through direct cell-cell contact. In contrast, when cultured within stiff ECM environments (~30 kPa), CAAs maintain a rounded, stem cell-like morphology without matrix-degrading activity, but notably promote PDAC cell migration. Gene expression confirmed that ECM-primed CAAs revealed upregulation of stemness markers including OCT4, SOX2, and SOX9, along with enhanced expression of pro-inflammatory cytokines. Using ectopic pancreatic tumor models, we found that CAAs primed in stiff ECM significantly accelerate tumor progression and invasion compared to controls, with increased tumor volume and invasion into the muscle layer 4 weeks post-implantation. Mechanistically, stiff ECM-primed CAAs showed distinct stem cell-like phenotype and altered secretome profiles. When cocultured with PDAC cells, their crosstalk promoted increased secretion of pro-inflammatory cytokines IL-6 and TNF-α while downregulating anti-inflammatory cytokine IL-10, creating a more tumor-supportive microenvironment. IHC reveals macrophage F4/80 showed no significant difference between groups, however, CD163+ macrophages were more prevalent at the early stage in the inactivated CAA-PDAC group. These findings reveal previously unrecognized plasticity in CAA function regulated by mechanical and oxygen tension cues, suggesting that the spatial distribution of these environmental factors within pancreatic tumors may create distinct zones of tumor promotion versus restriction. Our results highlight the complex role of CAAs in PDAC progression and suggest that targeting ECM stiffness could be a strategy to modify CAA behavior for therapeutic benefit. Understanding this mechanical control of CAA function could lead to novel therapeutic strategies for PDAC treatment.

#1235 Complex in vitro tumor models screen NK therapy and reveal mode of action.

Bin Xue[1], Christopher Harrod[1], Long Le[1], Julia Schueler[2], **Kolin C. Hribar**[1]

[1]Cypre Inc., San Francisco, CA,[2]Charles River Laboratories, Freiburg, Germany

NK cell therapy is an emerging and increasingly promising modality for various cancers. Whereas T cell-based adoptive cell therapy (e.g. tumor infiltrating lymphocytes or TILs, and CAR-T) is mainly limited to patient's autologous cells due to concerns around allogeneic responses with MHC (major histocompatibility complex) mismatch, NK therapies do not suffer from this due to their low risk of introducing GvHD (Graft-versus-host disease), enabling the development of NK therapies using either patient-sourced NK cells or allogeneic, healthy donor-sourced cells. NK therapies have demonstrated early success in some hematologic cancer, however, the inadequate infiltration and persistence in the tumor microenvironment (TME) limits their application in solid tumors. Therefore, the ability to model solid tumors in vitro to screen efficacy and study mode of action would be highly beneficial to gaining early and actionable insights for clinical translation. Here, we developed several patient-derived xenograft (PDX) 3D in vitro non-small cell lung or colorectal cancer models using a proprietary hydrogel platform. The platform resembles the TME to enable consistent growth of tumor cells, fibroblast elongation, and immune cell interactions. An activated NK cell population ("NK therapy"), featuring $CD56^{bright}$ CD16+ (~50%) and $CD56^{bright}$ CD16- (~50%) phenotypes by flow cytometry, was highly potent in the 3D models. These NK therapy cells demonstrated a significant increase in tumor infiltration and tumor cytotoxicity compared to the non-activated NK ("NK control") counterparts from the same donor. Interestingly, key cytokines like IFNg were downregulated in the NK therapy as compared to the NK control. These data demonstrate a robust and comprehensive in vitro analysis for NK therapy, offering a new preclinical tool for validating their effectiveness and mode of action.

#1236 Immune competent 3D pancreatic adenocarcinoma (PDAC)-on-chip model for preclinical drug discovery.

Alina Deipenbrock[1], Ben Eric Wilmes[1], Kyra Moustakas[1], Irene Esposito[2], **Thomas Sommermann**[3], Martin Raasch[3], Nicole Teusch[1]

[1]Institute of Pharmaceutical Biology and Biotechnology, Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany,[2]Institute of Pathology, University Hospital Dusseldorf, Dusseldorf, Germany,[3]Dynamic42, Jena, Germany

Representing the most common malignancy of the pancreas, pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer type with a five-year survival rate of less than 13%. To date, targeted treatment regiments are not available, leaving only cytotoxic chemotherapy with gemcitabine or FOLFIRINOX as the first-line-treatment for patients who are ineligible for surgical resection. One factor which contributes to the lack of efficient treatment options is the presence of a highly fibrotic and immunosuppressive tumor microenvironment (TME), mainly consisting of cancer associated fibroblasts (CAF) and tumor associated macrophages (TAM). Furthermore, effective treatments require drug candidates to pass the endothelium into the tumor. This barrier is not addressed in most *in vitro* models traditionally used in drug screening. Thus, novel PDAC models reflecting, the cellular heterogeneity within the TME including a vascular linkage will be essential to find efficacious treatment strategies. Using the Dynamic42 biochip platform, which allows dynamic culturing of cells in three channels each separated by porous membranes, we generated a fit-for-purpose 3D model of human PDAC. The model combines a perfused vasculature with an underlying tumor tissue consisting of tumor spheroids with a CAF hull embedded into an extracellular matrix (ECM). We first used this PDAC-on-chip model as a proof-of-principle to deliver small molecule drug candidates via a vasculature to the 3D spheroids. As one example, we identified vorinostat, a histone deacetylase inhibitor already approved for cutaneous T cell lymphoma, significantly reducing PDAC spheroid viability in a dose dependent manner without impacting the vascular integrity. We further expanded the PDAC-on-chip model by introducing peripheral blood mononuclear cells (PBMC)-derived monocytes. We show that monocytes applied through the vasculature invade through the endothelial barrier and migrate into CAF rich areas, where they differentiate to M2-like macrophages upregulating CD163 and loosing CD86 and HLA-DR expression. We now use this system to study T cell invasion, as well as direct vascularization of PDAC tumors.

TUMOR BIOLOGY: Cancer Evolution In Response to Therapy
Poster Session

#1240 Genomic characterization of changes in the molecular profile of locally advanced rectal cancer treated with neoadjuvant therapy.

Sharafudeen D. Abubakar, Christina I. Lee, Farheen Shah, Chin-Tung Chen, Paolo Manca, Henry Walch, Walid K. Chatila, Rona Yaeger, Julio Garcia-Aguilar, Francisco Sanchez-Vega

Memorial Sloan-Kettering Cancer Center, New York, NY

Background: Locally advanced rectal cancer (LARC) patients exhibit a widely heterogeneous degree of response to neoadjuvant therapy (NAT) and many experience disease relapse. By examining tumors at multiple timepoints before and after NAT, we investigated 1) pre-treatment genomic predictors of metastasis to specific anatomic sites that could potentially inform future therapeutic strategies and 2) genomic mechanisms driving tumor evolution under NAT stress. Methods: We analyzed 687 specimens from LARC patients treated at Memorial Sloan Kettering Cancer Center (MSKCC). This included 473 endoscopic biopsies collected before NAT and 214 samples after NAT. Post-NAT specimens included 99 surgical resections (SR), 19 local recurrences (LR) and 96 distant recurrences (DR). The DR set included 33 liver, 33 lung, and 30 metastases located in other organs. All samples underwent targeted DNA sequencing with MSK-IMPACT, an assay that identifies genomic alterations in 341-505 genes. We assessed somatic DNA alterations at the gene and the pathway levels, tumor mutational burden (TMB), fraction genome altered by copy number changes (FGA), tumor purity and whole-genome doubling (WGD) status. Results: Pre-NAT biopsies from patients who never developed any metastasis had higher Wnt pathway alterations than those whole developed metastases (85.9% vs 73.2%, p=0.0055), driven by APC alterations (84.6 vs 71.1%, p=0.0046), and higher rates of FBXW7 (17.8 vs 9.3%, p=0.044) and BCL2L1 alterations (6.7 vs 1%, p=0.01). In contrast, patients who develop metastases tend to have more alterations in KRAS (51.6 vs 39.6%, p=0.038) and PTEN (6.2 vs 1.1%, p = 0.0065). Liver metastases tend to occur earlier than lung metastases (median 12.9 vs 16.1 months from end of NAT, p=0.034). Pre-NAT specimens had higher rates of APC alterations than post-NAT specimens (81.8% vs 74.3%, p=0.025), while TGFβ pathway alteration rate was higher post-NAT (15.4% vs 24.3%, p=0.0074), driven by SMAD4 inactivation (10.8 vs 17.8%, p=0.014). LR specimens exhibited higher FGA (median 0.8 vs 0.55, p<0.001), higher rates of WGD (68.8% vs 37.5%, p=0.017), and lower rates of APC (52.6% vs 80.2%, p=0.007) than non-LR specimens. Among DR samples, KRAS alterations were more frequent in lung than liver metastases (60.6% vs 39.4%, p=0.14), while the opposite trend was observed for SMAD4 alterations (9.1% vs 30.3%, p=0.06). Conclusion: We observed significant differences in alteration rates in several driver genes in LARC specimens sequenced before and after NAT, which might be explained by NAT stress driving tumor evolution. The distinct genomic profile of LRs may be indicative of differences in their biological mechanisms of emergence. Differences in the somatic landscape of liver and lung metastases may have translational implications for the treatment of patients with advanced disease.

#1241 Deciphering heterogeneity and tumor evolution in bladder cancer using multi-omics and liquid biopsies from rapid autopsies.

Pushpa Itagi[1], Samantha Schuster[1], Sonali Arora[1], Patricia Galipeau[1], Thomas Persse[1], Funda Vakar-Lopez[1], John K. Lee[2], Petros Grivas[3], Robert Montgomery[1], Jonathan Wright[1], Hung-Ming Lam[1], Andrew Hsieh[1], Gavin Ha[1]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]Human Biology Division, Fred Hutchinson Cancer Center, Seattle, WA,[3]Department of Medicine, University of Washington, Seattle, WA

Introduction: Metastatic bladder cancer (mBLCA) exhibits significant heterogeneity at the genomic, transcriptomic, molecular, and epigenetic levels, contributing to challenges in diagnosis, prognosis, and treatment. While 75% of mBLCA cases are urothelial carcinomas, 25% show divergent differentiation with variant histological features. This work characterizes intra-patient and inter-patient heterogeneity through comprehensive genomic and transcriptomic analyses of a rapid autopsy cohort of 20 patients with multiple tumors, matched normal tissue, and cell-free DNA (cfDNA). Our findings provide critical insights into tumor heterogeneity, clonal evolution, metastatic seeding, and the tumor microenvironment.

Approach: Using bioinformatics tools, we reconstructed clonal evolution trees from whole-genome sequencing (WGS) analysis of tumors and inferred migration patterns to determine metastatic seeding. COSMIC mutational signatures were examined to correlate histological subtypes with clinical history. Single-nucleus RNA sequencing (snRNA-seq) revealed cell types and transcriptional heterogeneity using the human protein atlas and known marker annotations. To investigate alterations and clonality in tumors and their matched cfDNA, we used custom methodologies to evaluate mutations, CNAs, SVs, and rearrangements.

Results: The clonal evolution trees and bulk RNA-seq highlight cisplatin resistance in the plasmacytoid urothelial carcinoma subtype, driven by upregulation of the DNA damage response pathway. Significant mutational heterogeneity (~20-30% subclonal) emerges in later stages of tumor evolution, potentially contributing to therapy resistance. Additionally, a substantial proportion (60-70%) of structural variants arise later in tumor progression, particularly in driver genes. snRNA-seq revealed distinct clusters of epithelial cells, macrophages, fibroblasts, and other cell types. cfDNA analysis captured over 80% of subclonal deleterious tumor mutations in BLCA driver genes. Nucleosome profiling of cfDNA helps distinguish mBLCA from healthy samples and identify key transcription factors to differentiate between variants.

Conclusion: This comprehensive study of mBLCA, leveraging a rapid autopsy dataset, uncovers critical insights into variant histologies across multiple omics layers. Integrating cfDNA analysis captures intra-patient and inter-patient tumor heterogeneity, providing a holistic view of clonal dynamics. By elucidating the patterns of clonal evolution, this work advances our understanding of tumor progression and establishes a foundation for precision therapies targeting adaptive and evolving clones.

#1243 The pro-metastatic phenotype of chemoresistant breast cancer is stable and transcriptionally defined.

Alberto Dalmasso, Andrea Cossa, Ilaria Servidio, Guido Campani, Elisa Bugani, Francesco Antonio Tucci, Lucrezia Stabellini, Salvatore Pece, Pier Giuseppe Pelicci

IEO - European Institute of Oncology, Milano, Italy

Chemotherapy remains the most used systemic treatment option for triple-negative breast cancer. Lineage tracing studies demonstrated that the treatment does not significantly alter the clonal composition of primary breast tumors. Nevertheless, the specific transcriptional phenotype(s) conferring chemoresistance at primary tumor (PT) level, as well as at metastatic level, are still largely undetermined, specifically at single-clone resolution.To tackle such unmet clinical issues, we leveraged our recently published *in vivo* single-cell lineage tracing approach under therapeutic pressure, using two chemotherapeutic agents: adriamycin and cyclophosphamide (A+C). Upon administration of A+C we obtained stable disease, as confirmed by histopathological and IHC analyses. Chemoresistance was formally demonstrated by *ex vivo* IC50.By using single-cell lineage tracing on treated and untreated matched PT-lung metastases, we found that chemotherapy shifted clonal hierarchy, with few high-fit clones outcompeting the others, at primary level. Despite this, we noticed the striking increase of pro-metastatic clone frequencies in the chemoresistant model, thus suggesting that chemotherapy selects for few highly-aggressive clones. At metastatic level we found general drop of clonality.Using scRNA-seq, we observed that chemotherapy shapes distinct chemoresistant patterns in the PT and metastases. We then explored the transcriptomics features of the most fit clones within treated tumors, so-called dominant: they were characterized by enrichment of distinctive cancer hallmarks with respect of the whole chemoresistant tumor, including tumor-promoting inflammation and sustained angiogenesis.Chemoresistant/pro-metastatic clones were characterized by the expression of genes that were prognostic for poor survival across patients. Importantly, we observed that the chemoresistant/pro-metastatic phenotype was exacerbated by re-challenge with the same treatment but also stable across multiple re-transplantations. Among the of chemoresistant/pro-metastatic genes, PAEP appeared as the top marker. This was corroborated by GRN analyses, where we observed that the network around PAEP was extremely perturbed by therapeutic pressure. We tested the pro-metastatic effect of PAEP expression in a chemoresistant scenario. We orthotopically injected MDA-MB-231 cells silenced for PAEP expression via shRNA into recipient NSG mice and we performed neoadjuvant and adjuvant chemotherapy. Upon PAEP silencing, we observed slight increase of chemosensitivity at primary tumor level. Strikingly, chemoresistant metastases formation was significantly impaired by PAEP downregulation, as compared to controls.Overall, our data demonstrate that the pro-metastatic phenotype of chemoresistant breast cancer is stable, transcriptionally defined and driven by the expression of PAEP.

#1244 Investigating prostate cancer cellular heterogeneity and treatment response at singe-cell level.

Romuald Parmentier[1], Julien Roux[2], Robin Dolgos[1], Raphaelle Servant[1], Kirsten Mertz[3], Subotic Svetozar[4], Lukas Bubendorf[5], Helge Seifert[6], Cyrill A. Rentsch[6], Clementine Le Magnen[1]

[1]Institute of Pathology, Department of Urology, Department of Biomedicine, University Hospital Basel, Basel, Switzerland,[2]Department of Biomedicine, University of Basel, Basel, Switzerland,[3]Institute of Pathology, Kanton Baselland Liestal Hospital, Liestal, Switzerland,[4]Clinic for Urology, Kanton Baselland Liestal Hospital, Liestal, Switzerland,[5]Institute of Medical Genetics and Pathology, University Hospital Basel, Basel, Switzerland,[6]Department of Urology, University Hospital Basel, Basel, Switzerland

Context and Objectives: Androgen deprivation therapy (ADT) is the mainstay for treatment of advanced castration-sensitive prostate cancer (CSPC); yet most patients eventually relapse and progress to lethal castration-resistant prostate cancer (CRPC). Here we aimed at generating single-cell transcriptomic profiles from advanced CSPC samples and ADT-treated patient-derived organoids (PDOs) to dissect cellular dynamics underlying response to androgen deprivation at single-cell resolution.
Material and Methods: Nine radical prostatectomy or metastasis resection specimens obtained from treatment-naïve high-grade CSPC patients were collected and processed into single-cell suspensions. Single-cell RNA sequencing (scRNA-seq) was carried out on six specimens meeting necessary quality criteria. In parallel, four PDO lines were established, characterized using whole exome sequencing, IHC and immunofluorescence, and cultured in androgen-deficient conditions to mimic ADT. Viability assay confirmed treatment efficacy before scRNA-seq was performed with a lipid-based multiplexing strategy (MULTI-seq).
Results: We generated an atlas encompassing the transcriptomic profiles of more than 20 000 cells originating from rare tissue material. While highlighting patient-specific tumor features and integrating cells from the microenvironment, our single-cell atlas also revealed various epithelial subtypes. This included a subset of intermediate cells, referred to as club/hillock cells, which were previously proposed to play a role in tumor progression. Interestingly, these cells were maintained in PDOs derived from non-metastatic tissues, whereas PDOs derived from metastatic ones were exclusively composed of tumor-like cells. Treated organoids exhibited diverse viability responses and pathway alterations, including changes in the Androgen Response Signature, reflecting their sensitivity to ADT and underscoring their value as clinically relevant *in vitro* models. Simultaneously, scRNA-seq revealed transcriptional shifts within specific subpopulations of treated PDOs, highlighting significant changes in additional pathways that provide insights into the mechanisms driving the onset of castration resistance. Ongoing analyses aim to determine whether these populations pre-exist in the tumor or if this state is gradually acquired during treatment.
Conclusion: PDOs effectively mirror original prostate tumor characteristics and represent functional castration-sensitive models. By leveraging the generated scRNA-seq atlases and transcriptomic shift analyses, we anticipate identifying castration-tolerant cell populations potentially contributing to tumor heterogeneity and relapse.

#1245 Delaying resistance to Gefitinib in EGFR+ NSCLC through optimized treatment scheduling: an integrated experimental-theoretical approach.

Maximilian Strobl[1], Jinling Wu[1], Dagim Tadele[2], Mina Dinh[1], Jacob Scott[1]

[1]Cleveland Clinic, Cleveland, OH,[2]Medical Genetics, Oslo University Hospital, Oslo, Norway

Tyrosine kinase inhibitors (TKI) have revolutionized treatment of oncogene-driven non-small cell lung cancer (NSCLC). However, almost all patients with advanced disease eventually acquire resistance and the disease remains largely incurable. Much research is dedicated to identifying and targeting the molecular mechanisms of resistance. But even when challenged by our most advanced treatments, cancers display a remarkable ability to adapt. We seek to complement the development of new agents by investigating treatment scheduling - the dose and frequency at which drugs are administered - as a means to slow the emergence of therapy resistance. Work by us and others on so-called adaptive therapy has demonstrated that well-timed treatment breaks in prostate can maintain sensitive cells which slow the growth of resistant cells through competition, and they can also induce phenotypic switching of some resistant cells to more sensitive states in melanoma. In this study, we use an integrated experimental-theoretical approach to investigate how treatment scheduling impacts the evolution of resistance to Gefitinib in EGFR+ NSCLC, and we lay the foundation for an adaptive therapy protocol to delay resistance. Using fluorescent, time-lapse microscopy we characterize the evolutionary dynamics of co-cultures of Gefitinib-sensitive and paired resistant cell lines (PC9; PC9+BRAF knock-in; PC9 with evolved resistance to Gefitinib) across four different treatment schedules: i) continuous therapy, ii) intermittent therapy (on/off), iii) intermittent therapy (off/on), iv) continuous therapy at half the full dose. Our results clearly demonstrate that both the dose and the frequency of treatment influence evolutionary dynamics. Intermittent therapy minimizes the final resistant cell and total cell count after six treatment changes (18 days total), across all four dose levels examined (2uM, 200nM, 100nM, 20nM Gefitinib). Moreover, the off/on intermittent schedule outperforms the on/off schedule, suggesting a role for spatial competition in suppressing the outgrowth of resistant cells. Leveraging our in vitro data, we develop a mathematical model of the treatment response dynamics, which reveals an additional subpopulation of drug-tolerant persister cells in the “sensitive” population. Using a step-wise model selection approach we characterize their contribution to the evolution of drug-resistance and investigate how to optimally schedule treatment to balance the three populations. Overall, we provide novel insights into how treatment scheduling impacts resistance evolution in EGFR+ NSCLC and we demonstrate the power of an integrated experimental-theoretical approach for developing more effective treatment schedules.

#1246 Driver and signaling cascade in therapy pressure driven cancer cell plasticity.

Poorvi Subramanian, Sreenidhi Mohanvelu, Sivasubramani Narayanan, Afsana Parveen Jahir Hussain, Sabir Salim, Madhi Oli Ramamurthy, Loganayaki Periyasamy, Natarajan Aravindan

Oklahoma State University, Stillwater, OK

Dynamic adaptations in cancer cell-state due to therapy is a growing concern. Despite multimodal clinical therapy, tumor cells surpass treatment resulting in frequent relapses in rapidly decreasing timeline. We have shown that, in accordance with therapy pressure associated tumor microenvironment, progressive disease (PD) cells exhibit reversible lineage transformation and unparalleled plasticity. However, our understanding of the genetic determinant(s) and/ or mechanism(s) that coordinate cancer cell plasticity is a far reach. Herein, we investigated the crucial cancer cell phenotypic switching in response to therapy pressure. Using a panel of 14 well characterized human neuroblastoma (NB) cells derived during diagnosis (Dx) and PD, we investigated the association of retinal degeneration protein 3 (RD3) status (ELISA) to their migratory and invasive capabilities (transwell assay), clonal expansion (BrDu), EMT (E-CAD, N-CAD, Vimentin, SLUG), metastatic state (Ron-β, MMP-9, MMP-2), stemness maintenance (CD133, CD117, CD114, Oct3/4, Sox2, NANOG, CD54, NOTCH1) and cellular dedifferentiation (β-3 tubulin, NF-L, GFAP, GAP43) (immunoblotting). Further, to investigate the function of RD3 in coordinating cancer cell plasticity, we utilized six select NB cells, three derived during Dx and three derived during PD, representing both primary and metastatic tumors. These patient derived cells were reverse engineered for stable expression of RD3 in $RD3^-$ PD cell lines; stable silencing of RD3 in $RD3^+$ Dx cell lines and were subjected to end-point readouts as above. RD3 loss in PD correlated with the increased cellular migration, invasion, metastatic potential, EMT and stemness maintenance. Directed simulation experiments with stable restoration and silencing systems clearly identified the function of RD3-loss in cancer cell plasticity by regulating stemness (ALDH, CD133), EMT (Vimentin, E-CAD, N-CAD), metastasis (Ron-β, MMP-9), pluripotency maintenance (Oct3/4, Sox2, NANOG), dedifferentiation (β-3 tubulin, NF-H, GFAP, GAP43) and clonal expansion (BrDu). Our findings for the first time identified the defined function and relevance of RD3 in regulating cancer cell EMT, stemness and pluripotency maintenance, metastatic state and prompting differentiation. Crucially, our findings recognized therapy pressure directed RD3 loss dictates cancer cell lineage transformation to cancer stem cells. These outcomes together pave way to develop novel and effective molecular-targeted maintenance therapeutic strategy for patients presented with therapy defying progressive disease.

Funding: This work was partially or in full, funded by Department of Defense CA-210339; OCAST-HR19-04; NIH-P20GM103639 to Dr. Aravindan; and by the NIH-NCI-Cancer center support Grant P30CA225520, NIGMS P30GM154635, Oklahoma Tobacco Settlement Endowment Trust [R23-03] to the OU Health Stephenson Cancer Center.

#1247 Characterizing the evolution of osimertinib resistance in EGFR mutated non-small cell lung cancer .

Mina N. Dinh, Jinling Wu, Masahiro Hitomi, Maximilian Strobl, Jacob G. Scott

Cleveland Clinic Lerner Research Institute, Cleveland, OH

Osimertinib is a 3rd generation EGFR inhibitor and the newest FDA approved adjuvant therapy for non-small cell lung cancer (NSCLC) with EGFR exon 19 deletions or exon 21 L858R mutation. Although the drug can yield impressive initial responses, the majority of patients eventually progress due to the evolution of resistance. While the molecular mechanisms underlying resistance have been well studied, little is known about the ecological and evolutionary laws that govern the creation and subsequent expansion of these mutant populations. How frequently are different evolutionary routes taken and to what degree is evolution repeatable? To study the repeatability of osimertinib resistance evolution, we conducted a large-scale evolution experiment aimed at characterizing the distribution of resistant states that emerge, along with the pathways and vulnerabilities associated with their development. In our experimental design, we evolve PC-9, an EGFR-mutated NSCLC cell line to osimertinib independently 10 times (evolutionary replicates) for 10 cycles (serial passages). We also evolved 6 control replicates that undergo no treatment. At the end of the experiment, we will employ a multi-faceted approach to studying the resistance phenotype: 1) IC50 against osimertinib; 2) bulk RNA-seq; 3) DNA/mutational profiling; 4) a collateral sensitivity screening against 20 FDA approved drugs; and 5) a radiation sensitivity assay against 6 doses. The initial pretreatment dose response curve (DRC) against osimertinib showed a double plateau, suggesting the pre-existence of tolerant or even resistant subpopulation. In our control arms, we see consistent persistence of our double plateau throughout all 10 cycles, indicating this population is maintained in the absence of treatment but cannot expand. Conversely, across all 8 treated replicates we see a large shift in IC50 within the 1st treatment cycle, consistent with rapid selection and outgrowth of this population. More detailed analysis using time-lapse microscopy shows while these cells have a higher IC50, they also have a reduced growth rate, even if treatment is completely removed again (a “resistance cost”). This suggests potential evolutionary vulnerabilities which could be leveraged through strategic treatment breaks or drug sequences.

#1248 Single-cell RNAseq revealed multiple resistance mechanisms in patient-derived xenograft model of rectal cancer during treatment.

Yuwei song[1], Regina K. Irwin[2], Karin M. Hardiman[2], Zechen Chong[1]

[1]Department of Biomedical Informatics and Data Science, University of Alabama at Birmingham, Birmingham, AL,[2]Department of Surgery, University of Alabama at Birmingham, Birmingham, AL

Background: Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the US, with rectal cancer (RC) accounting for one-third of cases. Only 20% of RC patients have a complete response to chemoradiation therapy (CRT) and may be able to avoid surgery, therefore, therapeutic resistance remains a major barrier to improving outcomes. The genetic and cellular heterogeneity of RC, particularly in treatment-resistant sub-clones, suggests that this diversity could be a harbinger of adverse outcomes. A detailed characterization of treatment responses at the subclonal level is critical to advancing targeted therapeutic strategies.
Methods: Patient-derived xenograft (PDX) models and single-cell RNA sequencing were employed to investigate the cellular and molecular landscape of RC tumors. Two PDX models were established from the primary tumors of pre-treatment RC patients. Mice bearing tumors were subjected to a standard CRT regimen, consisting of 2 Gy daily radiation and 100mg/kg capecitabine daily for two weeks, followed by a week-long rest period. Tumor tissues were collected at baseline and at various post-treatment intervals for sequencing.
Results: Our scRNA-seq analysis of one PDX model identified five distinct tumor clusters with varying responses to treatment. Two clusters demonstrated initial sensitivity to CRT, followed by a resurgence, indicating potential therapy resistance. Pathway analysis revealed cluster-specific activation of critical oncogenic pathways, including HIF-1, p53, and FoxO signaling pathways. These pathways are implicated in tumor progression and therapeutic resistance, and the associated marker genes present potential targets for intervention. Lineage tracing of tumor cells uncovered two differentiation trajectories, with one showing increased resistance. Cell-cell communication analysis highlighted extensive interactions among tumor sub-populations, particularly mediated by CLDN3-CLDN3 adhesion, which may contribute to therapeutic resistance. Additionally, our investigation into copy number variations identified alterations in the chr6p21.31-p21.1 region, which harbors several oncogenes with copy number changes directly implicated in tumor progression. In the second PDX model, scRNA-seq identified two therapy-resistant tumor clusters among five detected clusters. The resistant tumor clusters exhibited enrichment of HIF-1, Hippo, and p53 signaling pathways, similar to the first PDX model but also unique activation of pathways like TGF-β and Hippo signaling.
Conclusion: Our study highlights the dynamic, heterogeneity of RC tumors to CRT, identifying both shared and patient-specific resistance mechanisms in two PDX models. These findings underscore the complexity of RC tumor biology and offer a foundation for developing precision therapies targeting treatment-resistant subclones.

#1249 Chemotherapy enriches one of two pre-existing coordinated cellular programs characterized by inflammatory and stress pathways in high grade serous ovarian cancer.

Nomeda Girnius[1], Muyi Liu[1], Laura M. Selfors[1], Jaeyoung Kang[1], Linna Lahmadi[1], Mayura Thomas[1], Aylin Z. Henstridge[1], Morgan Gruner[2], Jordan Mattson[2], Dennis J. Slamon[3], Gottfried E. Koneckny[4], Andrew C. Nelson[2], Timothy K. Starr[2], Ronny Drapkin[5], Boris J. Winterhoff[2], Joan S. Brugge[1]

[1]Harvard Medical School, Boston, MA,[2]University of Minnesota, Minneapolis, MN,[3]University of California, Los Angeles, CA,[4]University of California, Los Angeles, Los Angeles, CA,[5]University of Pennsylvania, Philadelphia, PA

Women diagnosed with high grade serous ovarian cancer (HGSOC) often respond to initial rounds of neoadjuvant chemotherapy, but then undergo multiple rounds of relapse and regression before acquiring resistance. This pattern of response and relapse suggests that transient, non-genetic resistance mechanisms are engaged by a subpopulation of tumor cells allowing them to survive and re-form a tumor. To elucidate the mechanisms underlying this transient resistance, we performed scRNASeq and cyclic immunofluorescence (CyCIF) on matched pre- and post-treatment tissues from seven patients. Our transcriptomics data revealed that the interferon (IFN) pathways, IFNα and IFNγ, and the tumor necrosis factor alpha (TNFα) pathway were enriched following therapy in six out of the seven patients. The enrichment of the IFN and TNFα pathways following chemotherapy exposure suggested that tumor cells expressing these programs may survive treatment and thus contribute to relapse, prompting us to study this population further. Spatial analysis of three interferon-stimulated genes (ISGs) revealed that a large proportion of ISG+ tumor cells appear to occupy specific niches containing ISG+ immune cells, while other ISG+ tumor cells were not adjacent to ISG+ immune cells, suggesting both intrinsic and extrinsic mechanisms of IFN pathway activation. It has been reported that IFN is activated in the early lesions of HGSOC known as serous tubule intraepithelial carcinomas (STICs). To investigate whether the IFN pathway activity early in tumorigenesis may be associated with reactivation of retroviral DNA, we performed CyCIF on samples containing STICs and found correlated expression of ISGs and the LINE1 protein product, ORF1P. These STIC areas were typically not associated with immune cells. Similarly, we detected correlated expression of ORF1P with ISGs in invasive tumor cells. Together, our findings suggest that endogenous retroviral reactivation may activate the cGAS/STING pathway, turning on IFN and establishing an IFN+ tumor cell population. To further investigate the cellular heterogeneity of HGSOC and identify pathways that are co-expressed with the inflammatory pathways, we sub-clustered individual patients' tumors. This analysis revealed two distinct tumor cell states: one associated with high expression of the inflammatory pathways with additional stress-related programs and EMT, and the other with MYC pathway, cellular proliferation, and metabolic pathways. We were able to confirm this coordinated expression in an additional 40 pre-treatment samples. Using an independent cohort from the TRIO14 ovarian cancer trial, we found the same pattern in HGSOC tumors from 46 patients. Future studies of this population aim to understand the functional importance of the IFN/inflammatory/stress state and to identify targetable vulnerabilities.

#1250 Genetically-defined organoid models reveal early mechanisms of squamous neoplastic progression and therapeutic vulnerabilities in squamous cell carcinoma.

Hua Zhao[1], Young Min Park[2], Yueyuan Zheng[3], Qiong Mao[3], Luda Lin[4], Casey Collet[1], Stephanie Wong[1], Boyan Hu[1], Uttam K. Sinha[1], Alice Soragni[4], **Dechen Lin**[1]

[1]USC - University of Southern California, Los Angeles, CA,[2]Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Sun Yat-sen University, Shenzhen, China,[4]University of California Los Angeles, Los Angeles, CA

Upper aerodigestive squamous cell carcinoma (UASCC) represents an aggressive and often fatal group of malignancies. Mechanistically, the early steps of neoplastic transformation remain poorly defined. Translationally, despite extensive genomic characterization of UASCC, the application of these findings to clinical practice remains highly limited. We have identified a crucial gap in the field - the lack of viable and valid human models that can: *i)* faithfully recapitulate the stepwise progression from precursor lesions to tumors, and *ii)* rigorously model genotype-phenotype relationships. Here, we developed two complementary, cross-species, genetically-defined organoid systems: (1) a genome-sequenced, patient-derived organoid platform comprising 46 models spanning normal tissue, precursor lesions, and tumors along the oral-esophageal neoplastic continuum; and (2) a CRISPR/Cas9-engineered organoid platform of 16 models, targeting key UASCC genomic drivers to recreate the full spectrum of malignant transformation (hyperplasia → dysplasia → carcinoma). Using these models, we uncovered critical insights into early squamous neoplastic evolution. For example, single-cell RNA sequencing of TP53/CDKN2A double-knockout (DKO) organoids revealed an expanded population of quiescent basal and proliferative squamous cells, alongside a reduction in differentiated squamous cells. This differentiation imbalance was exacerbated by the introduction of additional drivers, such as $PIK3CA^{E545K}$ mutation (DKOP). Furthermore, a senescence-like program, identified as a hallmark of normal squamous epithelium, was markedly attenuated in DKO organoids and further diminished in DKOP organoids, with ANXA1 emerging as a master regulator. We identified a novel ANXA1-SMAD3-p27KIP1 pathway as a critical driver of this senescence-like program, suppressing neoplastic phenotypes in squamous organoid models. Leveraging these genetically-defined organoid systems, we further performed high-throughput drug screening at single-organoid resolution, utilizing bioprinting technology coupled with machine learning. As anticipated, PIK3CA mutations conferred a survival advantage against most therapies tested. However, intriguingly, genetically-engineered organoids with PIK3CA mutations demonstrated heightened sensitivity to mitomycin C and onalespib. These findings were further validated using independent patient-derived HNSCC organoids harboring PIK3CA mutations. In summary, this study provides critical insights into the mechanisms of early squamous neoplastic progression and underscores the utility of genetically-defined organoid platforms for forward genetic studies in cancer. These rigorously validated models offer a powerful platform for identifying genome-guided therapies and advancing precision oncology.

#1251 Decoding tumour evolution and relapse drivers in EGFR mutant NSCLC in never smokers.

Komal Gupta[1], Dawn Lau Pingxi[1], Ngak Leng Sim[2], Kenneth Chow[1], Lan Ying Wang[1], Mengyuan Pang[2], Stephanie Saw[2], Wanjin Hong[3], Anders Martin Jacobsen Skanderup[2], Regina Hoo[1], Daniel Shao Weng Tan[1]

[1]National Cancer Centre, Singapore, Singapore,[2]Genome Institute of Singapore (GIS), Singapore, Singapore,[3]Institute of Molecular and Cell Biology (IMCB), Singapore, Singapore

Non-small cell lung cancer (NSCLC) remains the leading cause of cancer-related deaths worldwide. Unlike smoking-related NSCLC, the incidence of lung cancer among never-smokers in East Asia is rising, often driven by oncogenes such as EGFR. While Tyrosine Kinase Inhibitors (TKIs) have improved outcomes in EGFR-mutated NSCLC, resistance remains a significant challenge. Identifying the genomic and transcriptomic features that underpin tumour progression and relapse in early-stage EGFR-mutated NSCLC in non-smokers is crucial for developing novel therapeutic approaches to improve patient outcomes. Due to the diverse evolutionary trajectories of EGFR mutated NSCLC, our capacity to forecast disease trajectory is still limited. To address this, we performed 578 multi-region whole-exome and transcriptome sequencing from 180 treatment naïve early-stage EGFR-mutated resected NSCLC tumours. Among these, 56 (31%) patients eventually relapsed, while 124 (69%) did not, with a mean follow-up of 5.4 years. Our findings revealed that driver mutations in *EGFR, TP53*, and *RBM10* were predominantly clonal, while a multitude of subclonal driver mutations contributed to increased tumour diversity. Interestingly, mutational signature SBS40a, of unknown origin, was prevalent as clonal alterations, suggesting early involvement in EGFR-mutated tumours. Notably, relapsed tumours exhibited distinct genomic features, including elevated subclonal APOBEC mutational signatures, higher rates of whole-genome doubling, and increased chromosomal aberrations, linking these features to greater mutational burden, intra-tumour heterogeneity and poorer outcomes. Overall, our results demonstrate the diversity of clonal and subclonal mutational processes that shape the clonal architecture of EGFR-mutated NSCLC in non-smokers and identify key features driving relapse. Ongoing efforts are focused on leveraging these features to identify potential prognostic markers for risk stratification and therapeutic targets for early-stage disease.

#1252 Evolution of transcriptomic and epigenomic intra-tumor heterogeneity in high-grade serous ovarian cancer with chemotherapy.

Yuna Landais[1], Juliette Bertorello[1], Marta Puerto[2], Baptiste Simon[3], Amelie Roehrig[3], Adeline Durand[2], Marceau Quatredeniers[3], Constance Lamy[2], Fabrice Lecuru[2], **Christophe Le Tourneau**[2], Celine Vallot[1]

[1]Institut Curie & One Biosciences, Paris, France,[2]Institut Curie, Paris, France,[3]One Biosciences, Paris, France

Background: Intra-tumor heterogeneity (ITH) refers to the presence of diverse cell populations within a single tumor, each with distinct genetic, epigenetic, and phenotypic characteristics. This complexity presents significant challenges in treatment, as different subpopulations may respond variably to therapies, yet the non-genetic component of ITH and its contribution to treatment response remains poorly understood. We mapped transcriptomic and epigenomic ITH to explore evolution of non-genetic ITH in response to therapy in high-grade serous ovarian cancer (HGSOC).
Methods: The SCANDARE study (NCT03017573) included patients with HGSOC that are treated with neo-adjuvant chemotherapy (NAC). Biopsies were performed at baseline, after NAC surgery and at recurrence for single-cell RNA sequencing (scRNA-seq, n=17 samples, 111,946 with 1,773 median gene coverage), single-nuclei RNA sequencing (snRNA-seq, n=35 samples, 151,719 nuclei with 2,843 median gene coverage), and single-cell epigenomics (snCUT&Tag, n=24 samples, 58,892 nuclei with 1,409 unique fragments median coverage). Our snCUT&Tag dataset is one of the first single-cell epigenomic map of cancer patients under treatment, focusing on the histone modification H3K4me1, which accumulates at primed and active enhancers and promoters. We integrated these clinically annotated single-cell/nuclei datasets with publicly available scRNA-seq data of HGSOC.
Results: We constructed a consensus map of functional tumor states in HGSOC, based on scRNA-seq analysis of over 200,000 tumor cells. This analysis revealed 15 recurrent tumor cell phenotypes, ranging from stressed to cycling or inflammatory states. We identified the transcription factors and cell-cell communications specific to each tumor cell state. These tumor states are encoded at the epigenomic level, we could identify in each tumor epigenetic clones - clusters of cells with the same epigenome - each displaying a H3K4me1 landscape characteristic of one tumor state. These results show that tumor states correspond to tumor populations with distinct non-genetic features. Longitudinal sampling by snRNA-seq further showed that tumor state composition consistently evolves upon chemotherapy exposure in patients: tumors lose their cycling, hypoxic and interferon cells while gaining cells with partial mesenchymal and inflammatory characteristics.
Conclusions: We propose a consensus map of transcriptomic and epigenomic tumor states in HGSOC. Our work is a proof of concept that we can monitor functional ITH with high resolution snRNA-seq from frozen biopsies of the standard of care. We show that these consensus tumor states consistently evolve upon treatment in all patients, pinpointing tumor cell states that are not successfully targeted by NAC, that would need to be targeted by adjuvant therapies.

#1253 Single-cell analysis reveals intricate subclonal heterogeneity and evolution in response to standard of care treatments in glioblastoma.

Yueshan Zhao[1], Xiaoyu Lu[2], Verah Nyarige[2], Junfei Zhao[2], Gonzalo Lopez[2], Ann Forslund[2], Maria Ortiz-Estevez[2], Jorge Benitez-Hernandez[2], Wei Zhang[2], Celia Fontanillo[2], Kai Wang[2], **Ha Dang**[2]

[1]University of Pittsburgh, Pittsburgh, PA,[2]Bristol Myers Squibb Company, San Diego, CA

Glioblastoma multiforme (GBM) is the most common and lethal brain cancer. Standard of care treatments (SOC) are limited to surgery, radiation and chemotherapies, providing an average overall survival of only ~16 months. Tumor heterogeneity and cellular plasticity are major contributions to treatment resistance in this disease. We constructed an integrated patient-level and cohort-level framework and analyzed single-nucleotide RNA sequencing data in matched primary and recurrence specimens to understand tumor heterogeneity, evolution, and drug resistance in SOC treated GBM patients (N=23). Patient-level tumor analysis revealed distinct tumor cell transcriptional subclones representing widespread intra-patient heterogeneity. Tumor evolution analysis from primary to recurrence revealed diverse treatment responses representing sensitive, intrinsic resistant, and acquired resistant subclones. Further characterization of tumor subclones and clustering analyses indicated that tumor heterogeneity under SOC treatments was linked to diverse biological mechanisms including neural development and oncogenic pathways, contributing to varying levels of subclonal resistance. Our analysis also highlighted intrinsic resistance was prominent as primary tumors often harbored substantial proportion of resistant tumor cells. This insight on resistant status at cell level then allowed us to compare resistant to sensitive cells and identify both established and potentially novel mechanisms of SOC resistance that were not always obvious in the comparison between primary and recurrence samples. These included activation of PI3K/AKT, MAPK, TGF-β, EMT, and WNT signaling pathways. Taken together, our novel analytical strategy revealed complex tumor heterogeneity and evolution landscape in SOC treated GBM, offering insights on potential mechanisms driving these phenomena and providing a resource for further exploration and development of therapeutic strategies.

#1254 Neural-like progenitor pancreatic cancer cells are enriched in residual disease following neoadjuvant chemoradiotherapy and acquire invasive and stem-like features through inflammatory reprogramming.

Dennis Gong[1], Jimmy A. Guo[2], Jennifer Su[3], Sueda Cetinkaya[3], Peter Wang[4], Ashley Lam[5], Carina Shiau[6], Laleh Abbassi[7], Seema Chugh[8], Andrew J. Aguirre[8], William L. Hwang[4]

[1]Massachusetts Institute of Technology (MIT), Cambridge, MA,[2]School of Medicine, University of California San Francisco, San Francisco, CA,[3]Graduate School of Arts and Sciences, Harvard University, Cambridge, MA,[4]Massachusetts General Hospital, Boston, MA,[5]University College London, London, United Kingdom,[6]Harvard Medical School, Boson, MA,[7]Dana Farber Cancer Institute, Cambridge, MA,[8]Dana Farber Cancer Institute, Boston, MA

Pancreatic ductal adenocarcinoma (PDAC) is notable for a high rate of recurrence and metastasis despite intensive multi-agent chemoradiation. We previously identified a neural-like progenitor (NRP) transcriptional program strongly enriched in PDAC specimens with neoadjuvant chemoradiation and correlated with improved response to therapy. However, the mechanisms for why malignant cells in the post-treatment setting had collectively increased expression of NRP transcriptional signatures remained unclear. In this study, we sought to understand the contexts in which NRP becomes expressed as well as phenotypic effects of NRP genes that may contribute to cancer recurrence. Here, we profile NRP signature expression in human and mouse PDAC model systems, finding that NRP signatures are strongly enriched in regenerative stages of the murine pancreas post-injury, both in oncogene transformed and wild type pancreata. We provide additional evidence that NRP is expressed by a stressed stem-like ductal progenitor population in normal human pancreata and a DCLK1 expressing cancer cell population with undifferentiated cellular morphology in patient tumors. Using 1000-plex whole slide spatial transcriptomic profiling, we identify microenvironmental features associated with NRP cells and propose an inflammatory niche that maintains NRP expression in vivo, that is lost upon in vitro monoculture. Spatial colocalization analysis nominated inflammatory CAFs and IL1B+ macrophage populations as producers of inflammatory factors that upregulate NRP genes. We find that cells utilizing the NRP program have increased reliance on transcription factors involved in pancreatic development and identify Glis3 as a transcription factor highly expressed in NRP cells. We establish isogenic KP ($Kras^{G12D/+}$;$Trp53^{FL/FL}$) murine organoid overexpression models using Gata6 and dNTrp63 for the established classical and basal-like PDAC cell states, as well as Glis3. Notably, we find that Glis3 isogenic organoids have markedly higher metastatic proclivity in the orthotopic transplant setting, greater colony formation capacity, and increased invasive and migratory index relative to Gata6 and dNTrp63 driven isogenic models. Glis3 is enriched in matched human PDAC metastases relative to the primary tumor and is also strongly enriched in human cell lines with high metastatic rate in MetMap. Our work deepens understanding of the neural-like progenitor cell state, and particularly the role of developmental transcription factor GLIS3, which is emergent following cytotoxic chemoradiation. Furthermore, we highlight how treatment induced inflammation and tissue injury in the tumor microenvironment contribute to cellular reprogramming that can lead to cancer recurrence and metastasis in the post-treatment setting.

#1255 Apoptotic DNase DFFB mediates cancer acquired drug resistance by suppressing persister cell intrinsic interferon signaling.

August (Gus) Finley Williams, David A. G. Gervasio, Claire E. Turkal, Anna E. Stuhlfire, Michael X. Wang, Brandon E. Mauch, Ariel H. Nguyen, Michelle H. Paw, Rhea Plawat, Mehrshad Hairani, Cooper P. Lathrop, Sophie H. Harris, Jennifer L. Page, Matthew J. Hangauer

UC San Diego, La Jolla, CA

Tumor adaptation driving cancer acquired drug resistance during oncogene targeted therapy treatment frustrates therapeutic responses and results in patient mortality. Unfortunately, the adaptive mechanisms residual surviving cancer cells utilize to overcome therapeutic stress are not well described. Understanding the processes that drive cancer acquired drug resistance may lead to novel therapeutic strategies to prevent tumor relapses. We used cell culture and mouse xenograft models of chronic, continuous, and toxic oncogene targeted therapy exposure (weeks to months) to study residual surviving “persister” cells and their regrowth into expanded colonies which models acquired drug resistance. Here, we describe how cancer persister cells experience sublethal apoptotic signaling and utilize the caspase-activated DNase DFFB to promote regrowth under drug pressure. We found that while DFFB WT persister cells were able to form colonies in drug, DFFB-deficient cells were severely restricted in their ability to regrow. Mechanistically, DFFB induces persistent DNA damage which both promotes mutagenesis and suppresses growth-arresting interferon signaling. During drug stress, the mitochondrial outer membrane permeabilizes and activates pattern recognition receptors to induce interferon signaling. From single cell RNA sequencing analysis of persister cells, we observed elevated interferon signaling gene sets in DFFB KO cells compared to WT cells. Furthermore, DFFB KO cells also had increased levels of STAT1 and STAT2. This elevated interferon signaling was growth suppressive because colony formation was rescued in DFFB KO cells with a JAK1/2 inhibitor. We then discovered that the stress response transcription factor ATF3 is selectively induced in DFFB WT cells whereas DFFB deficient cells lack ATF3 upregulation. ATF3 is a known modulator of interferon signaling, is induced following DNA damage stress, and has increased expression in patient minimal residual disease tumors on targeted therapy treatment. Consistent with ATF3-mediated interferon suppression, ATF3 depletion in persister cells increased STAT1 levels whereas ATF3 overexpression in DFFB KO persister cells reduced STAT1 levels. This data shows that DFFB-mediated activation of ATF3 promotes residual tumor regrowth by suppressing growth-restricting interferon signaling. This novel tumor adaptation mechanism represents an exciting new therapeutic strategy that could potentially extend the efficacy of targeted therapy treatments and increase patient survival. Importantly, DFFB is a nonessential gene since DFFB knockout mice develop normally. Additionally, increased expression of DFFB and ATF3 correlate with worse patient survival. Therefore, DFFB represents a promising therapeutic target against cancer acquired drug resistance.

#1256 BCL11B predetermines an immature drug-resistant cell state in breast cancer that is vulnerable to TNF-α treatment.

Zhen Qi[1], Gunsagar S. Gulati[2], Angera H. Kuo[1], Shaheen S. Sikandar[3], William Hai Dang Ho[1], Dalong Qian[1], Frederick M. Dirbas[4], Aaron M. Newman[1], Shang Cai[5], Michael F. Clarke[1]

[1]Institute for Stem Cell Biology and Regenerative Medicine, School of Medicine, Stanford University, Stanford, CA,[2]Dana-Farber Cancer Institute, Boston, CA,[3]Department of Molecular Cell and Developmental Biology, University of California, Santa Cruz, CA,[4]Department of General Surgery, Stanford University, Stanford, CA,[5]Westlake Laboratory of Life Sciences and Biomedicine, School of Life Sciences, Westlake University, Hangzhou, China

Background: The development of chemoresistance in many cancer patients poses a significant clinical challenge, while the underlying causes for heterogeneous drug responses remain largely elusive. Increasing evidence suggests that tumors exhibit extensive heterogeneity and harbor cancer subpopulations in less differentiated states that are linked to treatment resistance. Therefore, dissecting immature cancer cell states pre-existing in tumors is essential for identifying biomarkers associated with chemoresistance and establishing targeted therapeutic strategies, particularly in breast cancer, where specific biomarkers are largely lacking.
Methods: We utilized CytoTRACE, a robust computational framework for predicting the cellular differentiation status from single-cell RNA sequencing data, to unveil the immature cancer cell state and its associated markers in single-cell atlases of human breast cancer. The association between the identified immature cell state and patient survival was determined by inferring the proportions of epithelial cancer cells expressing the marker gene in bulk gene expression datasets. The MMTV-PyMT mouse breast cancer model was used to experimentally investigate the role of the immature cancer cell state in conferring chemoresistance. Single-cell profiling was conducted on tumor samples before and after treatment to examine the inherent characteristics of immature cancer cells and their response to drug pressure. The results obtained from mouse tumors were subsequently confirmed using human breast cancer models.
Results and Conclusion: We revealed that BCL11B, a zinc finger transcription factor, defines a distinct immature cancer cell state in human breast cancer that displays basal cell features and demonstrates a heterogeneous expression pattern across breast tumors. Breast cancer patients with higher levels of *BCL11B*$^{+}$ cancer cells face a significantly increased risk of relapse following chemotherapy. This pre-existing tumor subpopulation exhibits intrinsic fitness advantages and demonstrates a remarkable ability to evolve into a drug-resistant state through various BCL11B-dependent pre-existing and transcriptional adaptation mechanisms. Notably, TNF-α was pinpointed as a natural inhibitor of BCL11B, and treatment with TNF-α significantly increases chemotherapy efficacy by inducing the exit of the drug-resistant cell state. In conclusion, our findings identify BCL11B as a valuable biomarker for predicting chemotherapy resistance and suggest TNF-α combination treatment for breast cancer patients at high risk of developing chemoresistance.

#1257 Response to primary therapy predicts tumor evolution dynamics at relapse in ovarian cancer.

Jaana Oikkonen[1], Giulia Micoli[1], Susanna Holmstrom[1], Kari Lavikka[1], Mai T. N. Nguyen[1], Yilin Li[1], Giovanni Marchi[1], Anna Rajavuori[2], Heidi Koskela[2], Johanna Hynninen[2], Sampsa Hautaniemi[1]

[1]University of Helsinki, Helsinki, Finland,[2]Turku University Hospital and University of Turku, Turku, Finland

Chemotherapy resistance is a major contributor of cancer-related deaths. Resistance can either be acquired during treatments or pre-exist at the time of the diagnosis. Previous studies on high-grade serous carcinoma (HGSC) have shown contradictory findings on the role of genetic causes explaining emergence of chemotherapy resistance at relapses, for example selection of resistant clones during chemotherapy. HGSC is often diagnosed at an advanced stage, showing multiple genetically heterogeneous clones present before therapeutic intervention. While most patients respond well to primary therapy, cancer relapses within few years, leading to treatment resistance. To understand genetic impact on emergence of resistance, we used matched pretreatment and treated samples from 214 unselected HGSC patients collected at DECIDER trial (NCT04846933). We constructed phylogenetic trees based on whole-genome sequencing of 804 tumor samples and whole-exome sequencing of 63 circulating tumor DNA (ctDNA) samples from plasma. Cancer evolution analysis identified patients with and without selection during treatments: patients with remained heterogeneity with stalled evolution, and others dominated by subclones originating from single resistant clone. Patients with better primary therapy outcome were linked to re-expansion of a single major clone at relapse, while multiple ancestral clones founded relapse populations in poorer outcome patients. The single-clone expansion pattern also emerged in later relapses, after multiple lines of therapy. Majority of the relapsed cancers evolved further from the ancestral clones already present at pretreatment. The relapse emerging subclonal mutations affected pathways such as carbohydrate metabolism and cAMP signaling. In contrast, sensitive clones eliminated by treatment carried mutations affecting extracellular matrix and NTRK3 signaling. Interestingly, some cancers did not acquire new mutations at relapse, despite becoming chemoresistant, suggesting that non-genetic mechanisms, such as phenotypic plasticity or microenvironmental factors, might underlie their resistance. In summary, we discovered heterogeneous cancer evolution trajectories during treatment which were linked to mutations in key pathways and prior therapy responses. While chemotherapy often selects persistent cancer subclones that seed later relapses, some patients acquire resistance through non-genetic mechanisms, highlighting the complexity of cancer evolution and resistance dynamics. Understanding these dynamics is crucial to define better therapeutic interventions in these poor prognosis patients with advanced HGSC.

#1258 Deciphering evolutionary dynamics and transcriptomic adaptions under therapy in small cell lung cancer.

Laura Constanze Kaiser, Marcel Schmiel, Christian Muller, Maria Cartolano, Martin Peifer, Roman K. Thomas, Julie George

University of Cologne, Cologne, Germany

Introduction: Small cell lung cancer (SCLC) represents a major medical challenge due to its aggressive progression and a dismal 5-year overall survival rate of only 7%. While SCLC initially responds well to chemotherapy, the rapid relapse and emergence of therapy-resistant tumors remain critical barriers to effective treatment. We hypothesized that therapy response is associated with genome evolution, which, in turn, influences transcriptional plasticity. This study aims to decipher the clonal evolution and transcriptomic adaptations in response to chemotherapy in SCLC.

Methods: We established over 100 patient-derived xenotransplant models from clinical SCLC specimens, capturing diverse genetic features and clinical characteristics. A representative subset of 33 models was selected to replicate clinical scenarios in mice, modeling the effects of platinum-based chemotherapy and evaluating tumor responses under controlled conditions. Whole-exome sequencing and single-cell transcriptome profiling were performed to investigate genomic evolutionary trajectories and transcriptional plasticity in therapy-naïve and relapsed tumors.

Results: Xenotransplant models accurately reflect patient responses to chemotherapy. To our surprise, several models from relapsed patients retained sensitivity to treatment. Chemotherapy-resistant models maintain their tumor clones, whereas sensitive models show dynamic shifts from a common ancestral clone with emerging subclones shaped by mutations associated with platinum damage, APOBEC activity, and defective DNA damage repair. The genomic landscape, defined by subclonal mutations and copy number alterations, strongly impacts transcriptomic patterns. Specifically sensitive models post-chemotherapy reveal a strong shift of transcriptional programs reflecting adaptive plasticity as a consequence of genome evolution.

Conclusion: Here we provide an in-depth functional *in vivo* characterization of clonal adaptions in SCLC under therapy. Chemotherapy drives the selection of subclones with favorable genomic features, which in turn impact the broader transcriptomic landscape. Our data provides critical insights into the molecular mechanisms of therapy resistance.

#1259 Studying the role of chromatin accessibility in lineage plasticity of Rb1-deficient EGFR-mutant lung adenocarcinoma.
Bradley Balk, David W. Goodrich

Pharmacology and Therapeutics, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Lung cancer is the leading cause of cancer mortality worldwide. Mutations in the epidermal growth factor receptor (EGFR) account for approximately 27% of all lung adenocarcinoma (LUAD) cases. Osimertinib is a third generation EGFR tyrosine kinase inhibitor (TKI) that is, initially, remarkably effective at treating patients with EGFR mutant LUAD. Acquired resistance to Osimertinib develops in most patients leaving few therapeutic options. This highlights an unmet clinical need to prevent/combat Osimertinib resistance. Lineage plasticity, an epigenetic process characterized by transcriptional heterogeneity and molecular adaptation, has been identified as a mechanism of Osimertinib resistance in the clinic. As more potent targeted therapeutics are deployed for treating cancer patients, plasticity-based resistance will likely increase. The molecular basis of lineage plasticity is not well understood, and greater characterization of lineage plasticity is imperative for developing new therapies aimed at preventing/reversing plasticity-associated resistance. Loss of the major tumor suppressor gene Rb1 has previously been implicated in lineage plasticity of several different cancers including LUAD. How loss of Rb1 contributes towards lineage plasticity remains poorly understood. Rb1 is a known regulator of chromatin accessibility, playing a key role in recruiting epigenetic writers to silence gene expression through repressive methylation of histones and DNA. Whether altered chromatin regulation in the absence of Rb1 contributes to LUAD lineage plasticity has not been examined. To begin examining the chromatin accessibility/plasticity axis *in vitro*, we are developing a PROTAC-based, rapidly inducible Rb1 protein degradation system utilizing the dTAG degron system to characterize the dynamics of molecular changes subsequent to Rb1 loss of function. Changes in chromatin accessibility will be assessed by micrococcal nuclease digestion and a novel nuclear propidium iodide staining technique. Plasticity will be assessed indirectly by *in vitro* colony formation and time to resistance assays. The timing of changes in transcriptional plasticity and chromatin accessibility will be compared. The goal of this project is to gain a greater understanding of how Rb1 loss impacts chromatin structure and subsequently, whether increased chromatin accessibility promotes plasticity-associated Osimertinib resistance.

#1260 Establishment of intratumor heterogeneity models using lung cancer cells.

Tomoko Funazo[1], Hiroaki Ozasa[1], Takahiro Tsuji[2], Yusuke Shima[1], Keiichiro Suminaga[1], Kentaro Hashimoto[1], Hiroshi Yoshida[1], Kazutaka Hosoya[1], Hitomi Ajimizu[1], Takashi Nomizo[1], Hironori Yoshida[1], Toyohiro Hirai[1]

[1]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[2]Fred Hutchinson Cancer Center, Seattle, WA

Intratumor heterogeneity has been shown to be associated with treatment resistance in multiple cancers, including lung cancer. Elucidating intratumor heterogeneity is an issue that must be resolved to improve the prognosis of patients. Previous studies of intratumor heterogeneity have mainly involved collecting and analyzing cancer cells from patients, classifying subpopulation with different properties, and conducting comparative analysis. However, there are few studies focusing on the early phase of intratumor heterogeneity. We exposed alectinib to a commercially available ALK-positive lung cancer cell line (H2228) and established alectinib resistant cells (H2228-AR1S). H2228-AR1S was observed two cells with different appearances. In this intratumor heterogeneity model, flow cytometry (FACS) showed that the cell surface CD47 of the parent line was unimodal, whereas that of H2228-AR1S was bimodal, indicating that there were differences in the properties of migration and tumor formation between subpopulation having the CD47 high expression and subpopulation having CD47 low expression. Next, We exposed molecular targeted drugs to patient-derived lung cancer cell lines and evaluated the expression of cell surface markers using FACS. KTOR83-Dab, a cancer cell line derived from a BRAF-positive lung cancer patient that was exposed to dabrafenib for one month, showed bimodal EpCAM expression. The subpopulation of EpCAM low expression had high migration ability and showed reduced epithelial gene expression and increased mesenchymal gene expression, suggesting EMT (epithelial-mesenchymal transition). It was suggested that KTOR83-Dab is a patient-derived intratumor heterogeneity model. Furthermore, experiments are being conducted using these intratumor heterogeneity models to elucidate the mechanism of intratumor heterogeneity. H2228-AR1S is a intratumor heterogeneity model established from commercially available monoclonal cells, and single-cell analysis is performed to extract genes whose expression changes during the process of homogeneous cells becoming heterogeneous. KTOR83-Dab is a patient-derived lung cancer cell line and is therefore polyclonal. We will clone KTOR83-Dab and examine whether there are any cells that become heterogeneous when administered dabrafenib. In addition, based on the results of single-cell analysis of H2228-AR1s, we will also analyze genes involved in heterogeneity in KTOR83-Dab.

#1261 Assessing intratumoral genetic heterogeneity in locally advanced rectal cancer.

Vandeclecio Lira da Silva[1], Ezequias Santos Torres[2], Ramon Torreglosa Do Carmo[2], Franciele Hinterholz Knebel[2], Fabiana Bettoni[2], Guilherme Pagin Sao-Juliao[3], Bruna Vailati[3], Bruna Vailati[3], Leonardo Corbi[3], Natalia Mariana Felicio[3], Angelita Habr Gama[4], Anamaria Camargo[2], Cibele Masotti[2], Rodrigo Oliva Perez[1]

[1]Hospital Beneficencia Portuguesa de Sao Paulo, Sao Paulo, Brazil,[2]Hospital Sirio Libanes, Sao Paulo, Brazil,[3]Hospital Alemao Oswaldo Cruz (HAOC-SP), Sao Paulo, Brazil,[4]Instituto Angelita e Joaquim Gama, Sao Paulo, Brazil

Locally Advanced Rectal Cancer (LARC) is typically treated with neoadjuvant chemoradiotherapy (nCRT), aimed at reducing tumor size to facilitate surgical resection. Patients achieving a complete clinical response (cCR) may be eligible for organ preservation strategies, such as the Watch-and-Wait protocol. However, clinical and radiological evaluations lack precision in predicting treatment response, with tumor regrowth occurring in 30% of cases within two years. We previously demonstrated that rectal tumors present high ITGH and that this heterogeneity increases after nCRT in patients who do not achieve a complete clinical or pathological response. Therefore, ITGH has emerged as a potential biomarker for assessing nCRT response, and we herein evaluate the association between distinct ITGH estimates and nCRT response using local and public genomic datasets. We analyzed a local cohort of 71 LARC patients who underwent long-course nCRT with 5FU-based chemotherapy or Capecitabine (SP cohort). Pre-treatment tumor biopsies were subjected to whole exome sequencing (WES), and patients were classified into two groups: nCRT-R (N=16), nCRT-NR (N=55). Public WES, mRNAseq, and clinical data from 81 patients from Chatila et al. (2022, MSKCC cohort) were also used to ITGH estimates using MATH score (in WES) and DEPTH2 (in mRNAseq). The treatment response was evaluated based on cCR or pathological complete response (pCR) in patients treated with 5FU, Capecitabine or Cisplatin, receiving nCRT alone or combined with induction/consolidation. Low ITGH values correlated with nCRT response in the SP cohort (median MATH score of 28.89 versus 50.97 in nCRT-R and NR, respectively; $p \leq 0.05$, Wilcoxon test). We used ROC curve analysis to determine the best MATH score threshold (26.34, sensitivity=90%, specificity=50%, AUC=0.67). Multivariate analysis with the clinical-radiological features showed a marginal association between MATH-low with nCRT-R (OR:16.05; p=0.003). We observed opposite tendencies for the MSKCC cohort (higher ITGH in nCRT-R): median MATH score of 38.65 (nCRT-R, N=18) versus 33.51 (nCRT-NR, N=63), but the difference was not significant (p=0.2536, Wilcoxon test). Considering MATH score limitations (e.g., number of somatic mutations, WES coverage) we also inferred ITGH from expression data for a subset of these patients. Still, we observed similar, non-significant results: median ITGH of 0.667 versus 0.652 for nCRT-R (N=18) and NR (N=54), respectively (p=0.503, Wilcoxon test). The results from our cohort suggest that ITGH remains a potential biomarker of response. The conflicting data observed may simply reflect the limited statistical power of the analyses. We believe it is necessary to increase the sample size and stratify response groups based on treatment regimens. Therefore, we consider it important to disclose these findings to encourage collaboration and facilitate the expansion of our case series.

#1263 Reconstructing small cell lung cancer evolution using deep whole genome sequencing of circulating tumor DNA.

Benjamin B. Morris, Zhihui Zhang, Andrew R. Lynch, Simon Heeke, Kyle Concannon, C. Allison Stewart, Runsheng Wang, Alexa Halliday, Waree Rinsurongkawong, Vadeerat Rinsurongkawong, J. Jack Lee, Jianjun Zhang, Don L. Gibbons, Ara A. Vaporciyan, Carl M. Gay, Hai T. Tran, John V. Heymach, Lauren A. Byers, Peter Van Loo

UT MD Anderson Cancer Center, Houston, TX

Background: Small cell lung cancer (SCLC) is the most lethal form of lung cancer. This poor prognosis is due in large part to SCLC's recalcitrance to therapy. The standard of care for extensive-stage SCLC (ES-SCLC) is chemotherapy with immunotherapy. While most tumors initially respond, responses are transient and >80% of tumors progress within one year of treatment. Seminal studies have shown that sequencing aggressive tumors before and after therapy identifies drivers of resistance. Unfortunately, the aggressive clinical course of ES-SCLC has precluded collection of patient-matched naïve and recurrent tumor tissue traditionally required to study evolution. In lieu of this, other groups have used circulating tumor DNA (ctDNA) to study SCLC evolution. However, these studies used sequencing panels that analyze <0.004% of the SCLC genome. Using new methods to comprehensively trace how SCLCs evolve to therapy resistance is a significant unmet need.
Methods: Medical records were reviewed to identify treatment naïve ES-SCLC patients with longitudinal liquid biopsies collected pre- and post-therapy using IRB-approved protocols. ctDNA was isolated from plasma using NucleoSnap cfDNA kits. Germline DNA was extracted from buffy coats using NucleoSpin Blood kits. Whole genome sequencing (WGS) libraries were prepared using Twist cfDNA Library Preparation with UMI Adapter kits. Deep WGS of ctDNA (>100X) and germline DNA (>40X) was performed using an Illumina NovaSeqX sequencer. Reads were aligned to the hg38 reference genome with BWA-mem. Somatic mutations were called using a two-of-three consensus approach and Mutect2, Strelka2, and MuSE. Structural variants were called using a consensus approach with GRIDSS, SvABA, and Manta. Subclonal copy number alterations were identified with Battenberg. Pyclone was used to reconstruct clonal populations.
Results: As expected, we identified deleterious genomic alterations impacting TP53 and RB1 tumor suppressor genes, known drivers of SCLC development. COSMIC mutational signature analysis identified high activity of tobacco carcinogen, APOBEC, and replicative-based processes across tumors. We found highly varied patterns of genomic evolution following frontline chemoimmunotherapy across patients. Most ES-SCLC tumors exhibited genomic evolution at recurrence, with evidence of focal amplifications and deletions or whole genome duplication. Some tumors exhibited minimal copy number evolution at relapse, suggesting non-genomic mechanisms driving resistance. We also found that second line therapies forced additional genomic evolution following initial recurrence.
Conclusions: Our data demonstrates that deep WGS of ctDNA recapitulates known genetics of ES-SCLC and enables sensitive characterization of resistant clones. Our data highlights the under-appreciated role of genomic evolution in ES-SCLC frontline therapy resistance.

#1264 Enhanced genomic characterization and clonal profiling in acute myeloid leukemia.

Sanjeeth Rajaram[1], Ruwan Gunaratne[1], Crystal Zhou[1], Emily Yang[1], Charu Tiwari[1], Grace Zhang[1], Ravindra Majeti[1], Asiri Ediriwickrema[1], David Kurtz[2], Tian Yi Zhang[1]

[1]Division of Hematology, Department of Medicine, Stanford University, Stanford, CA,[2]Division of Oncology, Department of Medicine, Stanford University, Stanford, CA

Introduction:
Acute myeloid leukemia (AML) is an aggressive blood cancer characterized by serial acquisition of somatic mutations in hematopoietic stem and progenitor cells which lead to their clonal expansion and differentiation arrest. Current methods for genomically profiling AML are limited by (1) the need for serial invasive bone marrow biopsies and (2) paucity of recurrently shared mutations across AML patients using standard NGS sequencing approaches.
Methods:
We integrate an AML-specific CAPP-Seq (Cancer Personalized Profiling by Deep Sequencing) hybrid capture panel targeting 58 recurrently mutated, 'canonical' AML genes, with personalized panels derived from whole exome sequencing (WES) of flow-sorted AML blasts and T cells (germline) in 56 AML patients. We quantify WES-derived single nucleotide variants (SNVs), indels, and copy number alterations (CNAs) in both canonical and 'noncanonical' genes (non-recurrently mutated) across a median of 5 follow up timepoints from cellular (bone marrow mononuclear cell/BMMC, peripheral blood mononuclear cell/PBMC) and cell-free (PB-ctDNA, BM-ctDNA) compartments. Variant pathogenicity was assessed using CADD, an ensemble model; ESM-1b, a protein language model; PolyPhen2, SIFT and a novel graphical association method. Mutation signatures were extracted using the SigProfiler suite. Clonal hierarchy was modeled using SciClone and latent class analysis.
Results:
We observed a median of 32.5 (IQR 21-42) tumor SNVs per patient compared to only 2.5 (IQR 1-4, $p < 0.0001$) if using the canonical AML panel alone. Overall variant detection was highly concordant across compartments: median of 94% (BMMC vs PBMC), 85% (PB-ctDNA vs BMMC), 94% (PB-ctDNA vs PBMC) and 98% (PB-ctDNA vs BM-ctDNA) respectively. Noncanonical mutations were 99.9% unique across patients and less pathogenic across our ensemble of measures ($p < 0.0001$). C-to-T transitions were enriched in both canonical and noncanonical mutation sets, but other signatures suggest distinct etiology.
Moreover, personalized patient-specific AML-CAPP-Seq enabled better inference of clonal dynamics compared to our institutional standard-of-care bulk NGS assay. Our approach predicted clonal hierarchies supported by single-cell genotyping (Tapestri) and helped predict potential mechanisms of therapy resistance. Finally, we show AML-CAPP-Seq permits monitoring of donor chimerism after allogeneic hematopoietic stem cell transplantation.
Conclusions:
AML-CAPP-seq enables ultrasensitive, WES-scale, non-invasive detection of patient-specific mutations, revealing novel biology in AML pathogenesis and allowing improved clonal profiling for in-depth characterization of therapy resistance mechanisms.

TUMOR BIOLOGY: Human and PDX Models 2
Poster Session

#1268 A matter of TIME: Advancing a humanized mouse model to decode tumor immune microenvironment and uncover mechanisms of resistance in soft tissue sarcoma.

I. Karnik[1], W. Liu[2], M. Liu[2], W. Tan[2], S. Tan[2], S. Fong[2], V. Yang[3], Q. Chen[2];
[1]National University of Singapore, Singapore, Singapore, [2]Institute of Molecular and Cell Biology, Agency for Science, Technology and Research, Singapore, Singapore, [3]National Cancer Centre Singapore, Singapore, Singapore

Background: Humanized mouse models are invaluable tools in cancer research. These immunodeficient mice, engrafted with human hematopoietic stem cells (HSCs) allow the exploration of immune dynamics and therapeutic responses in cancer. However, traditional models underrepresent key immune cells, particularly natural killer (NK) cells, which are crucial for anti-tumor immunity. We developed an improved humanized mouse model with optimized NK cell reconstitution to better reflect human immune responses. Using this model, we studied soft tissue sarcoma (STS), a malignancy with an immunosuppressive tumor immune microenvironment (TIME) that contributes to therapy resistance. Our goal was to better understand immune dynamics and resistance mechanisms within the TIME and explore novel immunotherapy strategies.
Methods: Humanized mice were generated by engrafting immunodeficient mice with HSCs, partially HLA-A matched to the SK-UT1 cell line for better immune representation of STS. NK cell reconstitution was improved with human IL-15 (hIL-15). Mice were engrafted with SK-UT1 STS cells to simulate the TIME. Tumor-infiltrating lymphocytes (TILs) and peripheral immune cells were analyzed by flow cytometry and single-cell sequencing to assess infiltration, activation, and exhaustion. Key immune checkpoints (PD-1, TIM-3, LAG-3, CTLA-4) and cytokines were evaluated to identify differences between TILs and peripheral immune cells.
Results: Diverse immune cell populations were observed within the TIME, including T cells, NK cells, and macrophages. Tumor-infiltrating CD4+ and CD8+ T cells showed higher expression of exhaustion markers compared to circulating T cells, indicating immune suppression and impaired cytotoxic function. The model demonstrated increased infiltration of CD56+ NK cells, offering a more accurate representation of NK cell function in the TIME. The gradient of exhaustion markers across immune cells suggested a highly immunosuppressive environment, contributing to tumor progression and resistance.
Conclusions: Our improved humanized mouse model offers a robust platform for studying immune-tumor interactions, particularly TILs and their role in the TIME. This model holds significant potential for testing novel immunotherapy combinations, including immune checkpoint inhibitors and targeted therapies aimed at reversing immune exhaustion. Ongoing analyses are focused on identifying key pathways involved in immune evasion through single-cell and TCR sequencing, and uncovering distinct resistance mechanisms within the tumor, potentially revealing new strategies to overcome immunotherapy resistance. These insights will reshape our understanding of the TIME and pave the way for innovative treatments to improve outcomes in STS.

#1269 Development of humanized PDX mouse model for high grade serous ovarian cancer.

Tsz Yin (Jacky) Lam[1], Farhia Kabeer[2], Shary Chen[2], Makoto Kishida[3], Yuchen Ding[2], Lorena Zoltan[2], Yvette Drew[4], David Huntsman[2]

[1]Department of Medicine, University of British Columbia, Vancouver, BC, Canada,[2]Department of Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada,[3]Centre for Lymphoid Cancer department, BC Cancer, Vancouver, BC, Canada,[4]Department of Gynecology and Obstetrics, University of British Columbia, Vancouver, BC, Canada

Introduction: High-grade serous ovarian cancer (HGSOC) is one the most lethal gynecological cancer, accounting for 70% deaths and with a 5-year survival rate below 50%. Traditionally, HGSOC are considered 'immune-cold' tumors, characterized by low immune infiltration and poor response rates to single agent immune checkpoint blockers (ICB). To improve the therapeutic potential of immunotherapies in HGSOC, combination treatments are being applied such as the Phase 2 MEDIOLA trial, which aims to identify mechanisms of response and resistance. A major challenge in this field remains the lack of suitable preclinical models for ICB-based treatments. Although patient-derived tumor xenografts (PDX) are valuable for developing new therapies, they are limited by the absence of an immunocompetent host. Here we present humanized mouse models incorporating human immune cells.
Methods: Female NRG-W41-3GS mice (ENW) aged 7-8 weeks were used to generate the humanized PDX model. HGSOC tumors originally sourced from human patients and maintained in our laboratory's previous PDX models using NRG mice, were injected subcutaneously into ENW mice. After 3 weeks, $5x10^4$ human hematopoietic CD34+ cells collected from umbilical cord blood of healthy donors were intravenously injected via the tail vein. To monitor human cell engraftment, bone marrow (BM) aspiration was performed at week 6 post-CD34+ cell injection, and peripheral blood (PB) samples were collected from saphenous vein starting from week 7 until the experimental endpoint. BM and PB samples were analyzed by flow cytometry using antibodies against human CD45 and mouse CD45 to determine humanization level. Tumors were harvested at the endpoint, embedded in paraffin, and remaining tumor tissues were cryopreserved for future. To confirm human immune cell infiltration into the tumors, fresh frozen paraffin embedded tumor sections were immunohistochemically stained with rabbit anti-human CD45 antibodies.
Results: We successfully generated sixteen huENW PDX mice. Robust engraftment of human CD34+ cells was confirmed in each mouse, with human CD45+ cells ranging from 35% to 90% (mean ± SD: 76.2 ± 18.5%) in BM samples and from 7% to 35% in PB samples. The huENW PDX model have revealed strong evidence of human immune infiltration with CD45+ cells on immunohistochemistry of the PDX tumors and spleen.
Conclusion: Humanized mouse models offer a valuable resource for advancing HGSOC research. Our humanized PDX HGSOC mouse model demonstrated significant engraftment of human immune infiltration into HGSOC tumors. Future works will focus on characterizing tumor cell heterogeneity, analyzing spatial gene expression patterns and human immune cells distribution using Xenium *in situ* coupled with scRNA seq. We believe our model has the potential to enhance our understanding of HGSOC clonal diversity, microenvironment interactions, and contributing to the development of new therapies.

#1270 An isogeneic Trop-2 expression heterogeneity model for evaluating the bystander killing effect of anti-Trop-2 ADC.

Jingwei Huang[1], Xiangyi Wang[1], **Zhixiang Zhang**[1], Jingxuan Yan[1], Jinyan Ma[2], Man Zhang[1], Qingyang Gu[1]

[1]WuXi AppTec, Shanghai, China,[2]WuXi AppTec, Nantong, China

Antibody-drug conjugates (ADCs) have recently made significant advancements in cancer treatment, particularly for solid tumors. Among the multiple mechanisms of action of ADC drugs, the bystander effect—where the cytotoxic payloads released by the antibodies diffuse into and kill nearby tumor cells—plays a crucial role, especially in tumors with heterogeneous antigen expression. Therefore, constructing an antigen heterogeneity model for evaluating this bystander killing effect is essential for the preclinical assessment of ADC drugs. To establish a stable Trop-2 antigen expression heterogeneity model, we deleted Trop-2 in the Trop-2-positive NCI-H292 cell line and selected a clone with a similar *in vitro* proliferation rate to the parental cells. Additionally, to distinguish Trop-2-negative from Trop-2-positive cells in both *in vivo* and *in vitro* experiments, we introduced luciferase and mCherry into the Trop-2-negative cells. *In vitro*, Trop-2-negative and Trop-2-positive cells were mixed in multiple ratios and treated with graded concentrations of anti-Trop-2 ADC. After five days, flow cytometry quantified Trop-2-negative cells to evaluate the bystander killing effect. *in vivo*, Trop-2-positive and Trop-2-negative cells were mixed in various ratios and implanted subcutaneously in mice, followed by intravenous drug administration. Tumor volume and bioluminescence were measured to assess the efficacy of the anti-Trop-2 ADC and bystander killing activity. The results showed that the anti-Trop-2 ADC exhibited a significant bystander killing effect, significantly inhibiting Trop-2-negative cells both *in vitro* and *in vivo*. In summary, we have successfully established an isogeneic Trop-2 expression heterogeneity model and validated the bystander killing activity of anti-Trop-2 ADCs *in vitro* and *in vivo*. This model provides a robust platform for the pharmacological and efficacy assessment of anti-Trop-2 ADC therapies.

#1271 Generation and optimization of humanized mice models in metastatic uveal melanoma.

S. Deguchi[1], T. Alcaro[1], R. Tanaka[2], S. Koshkin[1], V. Alexeev[1], K. Mccorkell[1], U. Gergis[1], T. Sato[1], M. Terai[1];
[1]Sidney Kimmel Medical College of Thomas Jefferson University, Philadelphia, PA, [2]Osaka Metropolitan University, Osaka, Japan

Background: Uveal melanoma (UM) is the most common primary intraocular malignancy in adults, with poor prognosis in cases of liver metastasis. Tebentafusp, a bispecific T cell engager, has shown survival benefits in patients with metastatic uveal melanoma (MUM); however, the response rate is low (<10%), and there is an unmet need to improve the outcome of immunotherapy against MUM. A major challenge of translational research in MUM immunotherapy is the lack of suitable preclinical models. To address this, we developed a humanized mouse model using human bone marrow (BM)-derived $CD34^+$ hematopoietic stem cells (HSCs).

Method: HSCs were injected into NSG Flt3KO, hFLT3LG Tg mice (NSG-hFLT3) via the spleen or tail vein after 150 cGy whole body irradiation. Blood specimens from the mice were routinely collected to confirm the development of chimerism through human and mouse CD45 staining. Mice were sacrificed at 9 or 20 weeks, and blood specimens and various organs were collected. The distribution and differentiation of human $CD45^+$ cells in BM, spleen, and blood were analyzed by flow cytometry. Furthermore, human $CD45^+$ cells were isolated from the mouse spleen and BM for immune potency assays. For the liver metastasis model in humanized mice, the tdTomato-labeled human MUM cell line, UM001 (HLA-A2), was injected into the mouse liver, 3 or 9 weeks after injection of HLA-A2 matched HSCs into NSG-hFLT3 mice. MUM tumor specimens in the liver were collected 4 weeks after MUM cell line inoculation, and the interactions between human MUM tumors and human $CD45^+$ cells were analyzed.

Result: Three weeks post-injection, human $CD45^+$ cells were confirmed in the blood, indicating the differentiation of injected human $CD34^+$ HSCs. Flow cytometry detected human $CD3^+$, $CD19^+$, $CD14^+$, $CD11c^+$, and $CD56^+$ cells in hematological organs. Monocytes and B cells predominated in the spleen at 9 weeks, while T cells were more abundant in the peripheral blood at 20 weeks. There was no difference in HSC injection routes regarding $CD45^+$ cell differentiation and distribution. Human TNF-α production with LPS was detected from human $CD45^+$ cells obtained from the mouse BM. IFN-γ production with phytohemagglutinin (PHA) was also confirmed in 21.1% of human $CD3^+$ T cells obtained from the mouse BM. In the spleen, B cells and T cells were confirmed, but those cells were rarely seen in other organs. Interestingly, human $CD45^+$ cells infiltrated the MUM tumors in the liver of humanized mice.

Conclusion: NSG-hFLT3 mice successfully adopted human $CD34^+$ HSCs and developed the chimerism with functional human immune cells. This indicates that this mouse model can be utilized to study the interaction between MUM tumors and human immune cells and serve as a platform for investigating the efficacy and resistance mechanisms of cancer immunotherapies. This approach may also be used for an autologous humanized mouse model using $CD34^+$ cells and patient-derived xenograft (PDX) from the same patients.

#1272 The development of PDX models from ADC-resistant breast cancer patient tissue for next-generation therapy evaluation.

Q. Liu, J. Wang, X. Zhang, W. Qian, L. Zhang, L. Bourre, J. Wang;
Crown Bioscience, Inc., San Diego, CA

Introduction: Antibody-drug conjugates (ADCs) are monoclonal antibodies targeting tumor cells linked to cytotoxic drugs via chemical linkers. Trop-2 targeting ADCs like sacituzumab govitecan (SG), datopotamab deruxtecan (Dato-DXd), and SKB-264 have shown success in clinical settings. However, they face challenges such as complex pharmacokinetics, insufficient tumor targeting, suboptimal payload release, side effects and drug resistance. This study developed SG-resistant PDX models to replicate clinical resistance to support new therapy development and understanding of resistance mechanisms.

Methods: Subcutaneous PDX models were established and characterized by histology and sequencing, with Trop-2 expression assessed by immunohistochemistry (IHC) and RNA sequencing (RNA-seq). For *in vivo* efficacy studies, models were treated 3-4 weeks after tumor inoculation with SG (3 or 5 mg/kg, i.v.) and Dato-DXd (5 mg/kg, i.v.) based on clinical SG treatment schedule. Tumor growth inhibition (TGI) was calculated as [1 - (mean treated tumor volume / mean control tumor volume)] * 100%. Homologous recombination deficiency (HRD) scores were calculated (using scarHRD and PureCN from whole exome sequencing, with a cutoff value of 38).

Results A female TNBC patient underwent 8 rounds of chemotherapy and targeted treatment, including 2 cycles of SG in the sixth round. Tissues collected at different treatment stages following SG treatment were used to establish BR9690, BR9806 and BR9801 PDX models. High Trop-2 expression was detected at both gene and protein levels in all three models. To evaluate Trop-2 ADCs efficacy, SG and Dato-DXd were tested in the PDX models. Tumor progression was observed in BR9690 for both SG (3mg/kg TGI=9.40% and 5mg/kg TGI=16.77%) and Dato-DXd (TGI=32.15%). In BR9806, tumor progression was observed in SG with limited TGI (3mg/kg TGI=27.52% and 5mg/kg TGI=25.75%), while Dato-DXd showed a partial response (TGI=59.47%). For BR9801, both SG and Dato-DXd showed limited TGI (SG: 3mg/kg TGI=-2.60% and 5mg/kg TGI=0.21%, Dato-DXd: TGI=24.78%). These results indicate clinical consistency with SG resistance and resistance to other Trop2-ADCs as the disease progresses. Besides, HRD scores for all three PDX models were above the cutoff (BR9690: 42, BR9806: 39, BR9801: 50) indicating genomic instability. In this study, the limited response of the models despite HRD may suggest other factors affecting the drug's efficacy targeting DNA repair mechanism, such as acquired resistance mechanisms or drug efflux activity, overriding the vulnerability provided by HRD.

Conclusion The study successfully established longitudinal breast cancer PDX models from a patient with demonstrated resistance to Trop2-ADCs. These models will aid in evaluating new treatments or combination therapies and understanding drug resistance mechanisms.

#1273 Advancing precision oncology: Development and utilization of breast cancer PDX models for *in vivo* drug discovery.

Erin E. Trachet, Chelsea Holmquist, Stephanie Nagl, Paul M. Gonzales

Translational Drug Development (TD2), Scottsdale, AZ

Breast cancer is a highly heterogeneous disease that poses significant challenges for drug development and personalized treatment. Patient-derived xenograft (PDX) models have emerged as essential tools for preclinical research, faithfully preserving the genetic, transcriptomic, and histopathological features of primary tumors, including intratumoral heterogeneity and the tumor microenvironment. The *Nature* publication, *"A human breast cancer-derived xenograft and organoid platform for drug discovery and precision oncology"*, highlights the utility of breast PDX models in advancing precision medicine and accelerating therapeutic discovery. Through a collaboration with the University of Utah, TD2 has developed three well-characterized in vivo breast cancer PDX models: HCI-015, HCI-043, and HCI-044. HCI-015 and HCI-043 are triple-negative breast cancer (TNBC) models, with HCI-015 harboring BRCA1 and BRCA2 deletions. HCI-044 is an estrogen receptor-positive (ER+), progesterone receptor-positive (PR+), and HER2-negative. These models were selected based on their organoid performance and clinically relevant drug responses. For example, HCI-015 was sensitive to docetaxel and a Notch inhibitor but refractory to navitoclax, while HCI-043 showed high sensitivity to eribulin. The ER+ HCI-044 demonstrated minimal dependence on estrogen supplementation, with growth maintained despite ovariectomy. To preserve tumor heterogeneity and the microenvironment, TD2 developed a low-passage tumor propagation process using orthotopic implantation into the fourth mammary fat pad via a surgical technique. Tumors in HCI-015 and HCI-043 established and grew progressively within 35 days, while HCI-044 required 60 days but maintained reliable growth. Pilot studies confirmed the reproducibility of tumor propagation and response profiles, supporting their use in efficacy testing. For efficacy evaluations, PDX tumors were implanted into female NSG or CIEA NOG mice, and therapeutic regimens were assessed. HCI-015 was highly sensitive to docetaxel, achieving 100% complete regression (CR), while tamoxifen treatment confirmed its ER-negative status, resulting in progressive disease (PD). Similarly, HCI-043 demonstrated 100% CR with carboplatin and eribulin. For the ER+/PR+ HCI-044 model, tamoxifen treatment resulted in PD, but eribulin achieved 100% CR, highlighting subtype-specific therapeutic responses. Despite their transformative potential, breast PDX models face limitations, including cost and incomplete human immune system representation. However, by optimizing these models and integrating patient history, researchers are advancing their fidelity and expanding their applications. These models bridge the gap between preclinical research and clinical outcomes, offering new opportunities to accelerate targeted therapy development and improve patient care.

#1274 Comparative analysis of biological and multi-omics profiling in PDCs and PDOs models.

Ye Jin Moon[1], Woo Sun Kwon[2], Tae Soo Kim[2], Harim Koo[3], Sun Young Rha[4]

[1]Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Song-Dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Cancer Biomedical Science, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Seoul, Korea, Republic of,[4]Division of Medical Oncology, Department of Internal Medicine, Yonsei Cancer Center, Yonsei University Health System, Seoul, Korea, Republic of

Patient-derived cells (PDCs), cultured in 2D environment, have limitations in reflecting patient's characteristics, while patient-derived organoids (PDOs) better capture heterogeneity and complexity of tumor microenvironment. However, PDOs do not always reflect the patient's condition, and in certain contexts, PDCs may offer distinct advantages. Since most PDCs and PDOs are established from primary tumors, research models from metastatic tumors are necessitated for studying metastatic cancers, like peritoneal metastases. In this study, we aim to compare established PDCs and PDOs models derived from ascites of two advanced gastric cancer patients and to explore the limitations and potential of each model by integrating fundamental characteristics and multi omics analysis.
Morphological features in PDCs and PDOs models of each sample were observed using IHC staining and microscopy. Biological features, including proliferation, cell cycle and HER2 expression were evaluated, while multi-omics was conducted to explore comprehensive biological processes and molecular pathways. Drug sensitivity using Paclitaxel, 5-FU, SN-38 and Oxaliplatin was performed to evaluate the drug responsiveness, and underlying mechanisms were explained by multi-omics.
In PDCs, both samples (YCC-GO10PDCs and YCC-GO30PDCs) exhibited adherent cell morphology, whereas PDOs showed structural variations, presenting compact (YCC-GO10) and grape-like (YCC-GO30) formations. The HER2 expression in YCC-GO10PDCs was consistent with the patient's clinical data. At the stabilized stage of PDCs (24h) and PDOs (72h), the cell cycle showed a normal S-phase distribution (YCC-GO10PDCs 26.4%, YCC-GO30PDCs 14.5% and YCC-GO10 21.62%, YCC-GO30 14.87%). In tumor purity of YCC-GO10, PDCs had 99%, while PDOs had 55%. Similarly in tumor mutation burden, as determined by whole genome sequencing, PDCs (16.27) was higher than PDOs (9.93). In proteomics, genes significantly upregulated in PDOs were associated with microenvironment interactions, such as ECM remodeling and stemness-related pathways, while genes upregulated in PDCs were primarily linked to metabolic and proliferative activities, reflecting the biological differences between two models. Drug response of YCC-GO10 showed similar patterns while YCC-GO30 showed higher sensitivities in PDCs than PDOs. Proteomics revealed that COL4A1 gene, associated with oxaliplatin and enhances cancer cell invasiveness and drug resistance, was upregulated in PDOs.
In conclusion, established PDCs and PDOs models from patient's fluid were used for comparative analysis and provided insights into each model's characteristics. Each research model is expected to serve as representative models reflecting the patient's condition and are anticipated to contribute to the development of personalized treatment.

#1275 Advancing cancer research with PDX-derived organoids: Insights into cancer stem cells and metastasis.

Nicolas Ancellin, Olivier Duchamp, Didier Grillot, Kenny Herry, Nicolas Legrand, **Caroline Mignard**

Oncodesign Services, Dijon, France

Patient-derived xenograft (PDX) organoids (PDXOs) are emerging as powerful tools for studying cancer biology and advancing therapeutic discovery. In this study, we report the generation of PDX-derived organoids from pancreatic ductal adenocarcinoma (PDAC) and colorectal cancer (CRC) PDX models, establishing a translational framework for personalized cancer research.

A key focus was the detection and enrichment of cancer stem cells (CSCs) within colorectal cancer PDXOs (CR PDXOs). Through optimized culture conditions, we achieved a remarkable 30-fold enrichment of CSCs, a pivotal population driving tumor progression, therapeutic resistance, and metastasis. This enrichment highlights the utility of PDXOs in dissecting stem cell biology and targeting CSC-associated mechanisms.

Using the PDAC model, we implemented tricistronic transduction to generate stable PDXOs expressing NanoLuc, mCherry, and EGFP fluorescent proteins. This genetic engineering strategy enables real-time monitoring of organoid dynamics and facilitates downstream applications, including in vivo studies. The reimplantation of these labeled PDXOs into immunocompromised mice successfully reestablished PDX tumors, demonstrating growth curves features nearly identical to those of the original PDX tumors. This PDXO-to-PDX approach underscores the fidelity of PDXOs in recapitulating patient-derived tumor biology.

Further, we investigated metastatic potential using full single-cell dissociation and marker-based detection. Analysis of various tissues from mice bearing reimplanted PDAC PDXOs revealed the presence of metastatic cells in the liver, indicating the ability of PDXOs to model metastatic dissemination. This capability provides a unique platform to study metastatic mechanisms and evaluate anti-metastatic therapies.

In conclusion, our study highlights the versatility and translational relevance of PDXOs in cancer research. By generating PDXOs from diverse models, enriching CSC populations, and employing advanced genetic tools for functional studies, we demonstrate the utility of PDXOs in capturing tumor complexity. The reimplantation experiments and detection of metastasis further validate PDXOs as robust systems bridging in vitro and in vivo research. This integrated approach offers critical insights into tumor biology, therapeutic responses, and metastatic behavior, paving the way for improved drug discovery and personalized treatment strategies.

#1276 UNLOCK, a preclinical platform of PDX models resistant to innovative therapies.

Ludovic Bigot[1], Nobre Nobre[1], Alice Da silva[1], Melissandre Meteau[1], Mathis Delavigne[1], Miguel Soares[1], Francesco Facchinetti[1], Loic Poiraudeau[1], Floriane Braye[1], Inmaculada Inmaculada Alonso Garcia[1], Natalie Ngoi[2], Alexandre Halimi[2], Emlie Natali[2], Damien Vasseur[2], Kristi Beshiri[2], Claudio Claudio Nicotra[2], Maud Ngo-Camus[2], Lambros Tselikas[2], Beatriz Beatriz Alonso de Castro[2], Julieta Rodriguez[2], Maria Fernanda Mosele[2], Maud Kamal[2], Gerome Jules-Clement[2], Karim Fizazi[2], Christophe Massard[2], Benjamin BESSE[2], Luc Friboulet[1], Yohann Loriot[1]

[1]INSERM U981 (Gustave Roussy), Villejuif, France,[2]Gustave Roussy, Villejuif, France

Introduction: Over the past 20 years, advances in precision oncology and cancer genetics have identified numerous actionable oncogenic drivers, leading to new drug development and clinical application. However, tumor cells can adapt and develop resistance mechanisms (MoR), and the mechanisms of action (MoA) of these drugs are only partially understood, highlighting the need for research focused on both MoR and MoA. Following the success of the MATCH-R clinical trial (NCT02517892, 2015-2022), the UNLOCK program was launched in 2022 to better understand the MoA and MoR of innovative drugs (phase 1 to approval) through integrated clinical and translational research. As part of this initiative, we developed preclinical models, including PDX models from patients who developed resistance, to support the development of new therapeutic strategies.
Methods: Fresh tumor biopsy specimens were prospectively collected from patients through the MATCH-R clinical trial (NCT02517892) or the UNLOCK program. PDX models were established in NOD Scid Gamma (NSG) mice, which were then developed and characterized. These models underwent immunohistochemistry, comprehensive molecular profiling (including whole exome sequencing [WES] and bulk RNA sequencing [RNA-seq]), and pharmacological validation.
Results: As of November 2024, 197 PDX models have been successfully generated from 519 biopsies, with a global take rate of 38%. These models are developed across several cohorts, including castration-resistant prostate cancer (22 PDX: 18 AR pathway inhibitors, 1 post-PARPi, and 3 Lu-PSMA), lung cancer (40 PDX with EGFR inhibitors, including 28 post-osimertinib, and 22 PDX with ALK inhibitors, including 2 post-brigatinib, 9 post-lorlatinib, and 6 post-alectinib). Additionally, 34 PDX models have been developed for the FGFR cohorts with FGFR2/FGFR3 alterations across various cancers, including cholangiocarcinomas, bladder carcinomas, gynecological carcinomas, and pancreatic cancers. We also developed 32 PDX models with KRAS mutations (G12C, n=23; G12D, n=9) from various tumors, including lung, pancreatic, gynecological, and colon cancers. Recently, we launched a new UNLOCK cohort focused on antibody-drug conjugate therapy, developing 12 additional PDX models. These PDX models faithfully replicate the genetic, transcriptional, phenotypic, and pharmacologic features of the original biopsies, providing a unique preclinical platform for testing novel drugs and combination therapies. Adaptive treatments with new or combinatorial strategies are being explored to restore drug sensitivity.
Conclusion: The development of 197 PDX models under the UNLOCK program represents a significant resource, enabling the evaluation of novel drugs, adaptive treatment strategies, and combinatorial approaches. This unique collection of PDX models paves the way for advancing precision oncology and overcoming therapeutic resistance.

#1277 *Ex ovo* system for rapid and quantitative modelling of immunotherapy responses in pre-clinical and patient-derived xenografts: PDX*ovo*.

Olivia R. Grafinger, Kabir A. Khan, Esther I. Matus, Sara Mar, Yan Li, David Goertz, Jean Gariepy, Katarzyna J. Jerzak, Robert Kerbel, Hon S. Leong

Sunnybrook Research Institute, Toronto, ON, Canada

Precision oncology for triple-negative breast cancer (TNBC) is urgently needed because not all patients will benefit from PDL1-based immunotherapy. Unfortunately, the expression of PDL1 or abundance of tumor infiltrated lymphocytes (TILs) does not correlate with objective response rates and/or overall survival. We have developed a novel patient-derived xenograft (PDX) model system that offers phenotype-based metrics to predict immunotherapy response prior to receiving treatment. In our PDX model (PDX*ovo*), the patient's tumour is engrafted onto the chorioallantoic membrane (CAM) of chick embryos. Our PDX model offers significant advantages over mouse PDXs which are expensive, time-consuming, and cannot evaluate immunotherapies. To test the efficacy of this model, we implanted immunocompetent mice with a murine mammary cancer cell line (serving as a surrogate for patients), and implanted tumours into the PDX*ovo* system. We found our model to reliably recapitulate immunotherapy responses observed in mice, with anti-PDL1-treated tumours being significantly smaller in volume as compared to IgG-treated tumours. We also found our model to reliably predict patient response to adoptive cell therapy, wherein TILs were FACS-sorted from murine tumour digests, activated and expanded in vitro, and then engrafted together with cultured murine mammary carcinoma cells. We are now testing this model with patient-derived tumours of a variety of origins, in partnership with the Ontario Institute of Cancer Research. To date we have tested tumour responses to Pembrolizumab in five patient-derived samples from various sites, with an 80% success rate in xenograft formation. We have observed varied responses to immunotherapy, which did not correlate with PDL1 expression on TILs in these samples, highlighting the importance of such a qualitative model for precision oncology. This technology has the potential to make a positive impact in the clinic and improve objective response rates, increase progression-free survival intervals, and increase overall survival.

#1278 Tertiary lymphoid structure formation in patient-derived xenograft (PDX) of head and neck paraganglioma: A novel xenogeneic model.

Sara Pagotto[1], Simone De Fabritiis[2], Carola Di Camillo[1], Francesco Del Pizzo[2], Silvia Perconti[2], Diana Liberata Esposito[3], Mario Sanna[4], Pasquale Simeone[5], Paola Lanuti[5], Manuela Iezzi[6], Renato Mariani-Costantini[2], Fabio Verginelli[3], Rosa Visone[1]

[1]Department of Medical, Oral and Biotechnological Sciences, University of Chieti Pescara, Chieti, Italy,[2]University of Chieti Pescara, Chieti, Italy,[3]Department of Sciences, University of Chieti Pescara, Chieti, Italy,[4]"Gruppo Otologico" Piacenza, Piacenza, Italy,[5]Department of Medicine and Aging Science, University of Chieti Pescara, Chieti, Italy,[6]Department of Neurosciences, Imaging and Clinical Sciences, University of Chieti Pescara, Chieti, Italy

Head and neck paragangliomas (HNPGL) are a rare type of neuroendocrine tumor that, although typically slow-growing, can become invasive and deadly. Treatment is primarily surgical, which can be highly invasive and, in some cases, not feasible. Alternative therapies, such as chemotherapy and targeted radiotherapy, have demonstrated limited efficacy. This study aims to address the critical need for suitable in vivo HNPGL models to advance translational research by establishing murine models of immunodeficient NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Wjl}/SzJ (NSG) mice engrafted with patient-derived tumor xenografts (PDXs). Interestingly, although HNPGL is not typically classified as a lymphocyte-dominant tumor due to the reduced presence of immune cells in its microenvironment, two consecutive generations of NSG mice engrafted with PDXs derived from a single aggressive HNPGL case in an adolescent patient, exhibited varying degrees of xenogeneic graft-versus-host disease (GVHD). This suggests the co-existence of the patient's tumor-infiltrating lymphocytes (TILs) within the PDXs. In the first generation, 34 days after PDXs implantation, mice exhibited clinical signs of GVHD, including weight loss, severe kyphosis, lethargy, piloerection, and fur loss. *Ex vivo* analysis revealed extensive lymphoid infiltration in multiple organs, including the spleen, lung, liver, and kidney. Immunohistochemical staining confirmed the presence of predominantly human T cell (CD3+) infiltrates, with a minor human B cell (CD20+) component, in both xenografts and the primary tumor. Notably, surgical resection and reimplantation of primary PDX into secondary NSG mice significantly promoted human B-cell expansion and the formation of a well-defined peritumoral tertiary lymphoid structure (TLS). Mice bearing these xenografts exhibited reduced GVHD, and a TLS with a histological organization resembling secondary lymphoid organs at 89 days. This TLS was characterized by a central core of hCD20+ B cells surrounded by a peripheral mantle of hCD3+ T cells, suggesting the formation of a mature TLS with a germinal center that may harbor reactive B cells. Our findings suggest that TLS formation in PDX model may facilitate tumor-specific antibody production and antigen presentation.These insights provide a foundation for leveraging PDX models with TLS as innovative tool for studying HNPGL microenvironment and asses immune signatures that could be used for the development of novel immunotherapeutic strategies.

#1279 Preclinical syngeneic model and xenograft model for evaluating CD3/HER2 bispecific antibody therapy.

Fengqian Chen, Chong Li, Qinjun Wang, Qiang Liu, Baihong Liu, Jiansu Zhang, Xiaofei Zhou

Biocytogen, Waltham, MA

Abnormal expression of HER2 in normal cells and tissues makes them susceptible to carcinogenesis, leading to tumor formation. HER2 gene amplification or protein overexpression has been found in various human tumors, including breast cancer, gastric cancer, and ovarian cancer. The approval of multiple anti-HER2 drugs has greatly improved the prognosis for patients with HER2-positive solid tumors. However, in clinical practice, some HER2-positive patients have developed resistance, possibly due to an immunosuppressive tumor microenvironment (TME). The CD3/HER2 bispecific antibody (BsAb) is considered a strategy to overcome this immunosuppressive TME by redirecting T cells to HER2-expressing tumor cells, thereby killing HER2-positive tumor cells. Biocytogen developed a BsAb Ab1 that targets human CD3 and human HER2, and evaluated its efficacy and mechanism of action in preclinical studies. In vitro cytotoxicity assays showed that CD3/HER2 BsAb Ab1 significantly induced T cell activation and exhibited effective killing effects against B-hHER2 MC38 plus cell line expressing human HER2. In a syngeneic transplantation model using B-hCD3E/hHER2 mice inoculated with the B-hHER2 MC38 plus cell line, BsAb Ab1 effectively inhibited tumor growth. Additionally, CD3/HER2 BsAb also significantly inhibited the growth of human tumor cells NCI-N87 in a PBMC reconstitution model using B-NDG mice. These results indicate that both models are suitable for the preclinical evaluation of the CD3/HER2 BsAb.

#1280 Accessing PDX genomic and treatment response data using the Mouse Models of Human Cancer database (MMHCdb) cBioPortal resource.

Dale A. Begley[1], Debra M. Krupke[1], Emily L. Jocoy[2], Steven B. Neuhauser[1], Carol J. Bult[1]

[1]The Jackson Laboratory, Bar Harbor, ME,[2]The Jackson Laboratory, Sacramento, CA

Mouse models of human cancer are one of the most important sources of information on human disease, and research using mouse models has led to fundamental insights into the genetic and molecular basis of human cancers. Mouse models are also powerful platforms for pre-clinical research into novel therapeutic agents for cancer treatment. Patient Derived Xenografts (PDXs), in particular, have proven to be useful for testing single agent and combination therapies in both adult and pediatric cancers. The Mouse Models of Human Cancer database (MMHCdb) (http://tumor.informatics.jax.org) has implemented a PDX-specific version of cBioPortal that integrates rich genomic characterization data for PDX models with treatment response data obtained from diverse sources, including the Jackson Laboratory, NCI-funded PDXNet consortium, and the Preclinical Pediatric In Vivo Testing (PIVOT) program. The cBioPortal for Cancer Genomics is an open-access, open-source resource that enables web-based exploration, visualization, and analysis of molecular profiles and clinical attributes from large-scale genomics data sets. The MMHCdb PDX specific cBioPortal contains data for 8,231 samples from 1,492 patients representing over 170 different adult and pediatric tumor types. Available genomic data include non-synonymous mutations (682 samples), Copy Number Alteration (CNA) (683 samples), RNA-Seq (4,229 samples), and de-identified patient demographic and clinical data. There is also preclinical efficacy study data available for 415 treatment arms from 100 patients. MMHCdb is an expertly curated, comprehensive knowledgebase of diverse models of human cancer obtained from peer-reviewed scientific publications and direct data submissions from individual investigators and large-scale projects. Information in MMHCdb is standardized using controlled vocabularies and official mouse gene, allele, and strain nomenclature. Information in the knowledgebase is linked to many other cancer model data from other bioinformatics resources, including PathBase, the Mouse Phenome Database (MPD), CancerModels.org, the Gene Expression Omnibus, and ArrayExpress. MMHCdb contains information on over 66,000 mouse models, including Genetically Engineered mice, Diversity Outbred and Collaborative Cross mice, and PDXs. Available data from over 5,400 references includes over 120,000 tumor frequency records, over 9,000 pathology reports, and more than 6,986 histology images. MMHCdb also provides access to over 3,157 histology/immunohistochemistry PDX images. MMHCdb is supported by NCI grant CA089713

#1281 Transfer of a PDX biobank in a humanized setting to enable immune-oncology studies.

Eva Oswald, Lea Grohne, Dorothee Lenhard, Loreen Weichert, **Julia B. Schueler**

Charles River Laboratories, Inc., Freiburg, Germany

The field of cancer immunology is rapidly moving towards immunomodulatory therapeutic strategies, including multi-specific antibodies, immune checkpoint inhibition, as well as potential vaccination strategies. Consequently, large biobanks of patient-derived tumor xenografts (PDX) models can serve as powerful tools. While one well-known major drawback of the PDX platform is the lack of an immunological competent host, the implantation of PDX models in humanized mice compensates for this. The focus of this project was to evaluate subcutaneous implanted PDX models of different tumor types in human immune system (HIS) reconstituted mice for presence of human immune cells. We determined the immune cell infiltration of more than 30 PDX models across different tumor types. PDX were implanted subcutaneous in 1-3 HIS mice per PDX, including models of lung, colon, breast and kidney cancer. Flow cytometry (FC) and immunohistochemistry (IHC) was performed to determine and characterize tumor infiltrating lymphocytes (TIL) in tumor tissue and human immune cells in hematopoietic organs of the mice. In addition, the expression of different surface markers related to immune-oncology pathways such as PDL-1 was determined by IHC in the tumor tissue. Overall, we confirmed good engraftment in the hematopoietic organs of the tumor bearing animals ranging from 40% - 80% in peripheral blood, spleen and bone marrow. The engraftment rate was not influence by the respective PDX model nor the donor of the CD34+ cells used for humanization. In contrast, the TIL rate was variable across the analyzed tumor panel and mainly driven by the tumor model ranging from 0.13% - 45% CD45+ cells. Tumors with a TIL rate >5% were defined as hot vs the cold tumors with a TIL rate < 5%. Up to now, there is no clear pattern of tumor types or molecular subtypes being specifically hot or cold. However, in the group of renal cancer an increased number of hot tumors was determined. The comparison with donor patient samples displayed a high correlation between TIL rate of donor patient tissue and PDX, emphasizing the tumor model as the main driver for this feature. The expression of PDL-1 was influenced by the presence of human immune cells: PDL1 expression was more than threefold upregulated in hot tumors, whereas it was downregulated in cold tumors although this effect was less pronounced. In continuation of the current study, we will examine more PDX models and expand the characterization to the corresponding tumoroids to provide in vitro and in vivo platforms that can robustly translate preclinical results of immunomodulatory drug testing into the clinic.

#1282 Development of a humanized multiple myeloma mouse model using bone-derived MM.1S cells.

Mari I. Suominen[1], Katja M. Fagerlund[1], Mervi Ristola[1], Justyna Zdrojewska[1], Yumei Diao[2], Kristina Witt-Mulder[2], Stefan Svensson Gelius[2], Jukka P. Rissanen[1], Jenni H. E. Maki-Jouppila[1]

[1]Pharmatest Services Ltd., Turku, Finland,[2]Oncopeptides AB, Stockholm, Sweden

Multiple myeloma (MM) is a hematological malignancy characterized by the uncontrolled proliferation of plasma cells in the bone marrow. The symptoms of MM patients include e.g. bone lesions, renal dysfunction, and anaemia. While advancements in treatment have improved outcomes for many patients, MM remains largely incurable. The development of preclinical models is crucial as they provide information on drug efficacy and mechanisms of action. 5 x 10^6 MM.1S cells tagged with GFP and luciferase (BPS Bioscience) were inoculated intravenously to NSG-Tg(huIL-15) mice (The Jackson Laboratory) and harvested for further *in vitro* cell culture at day 77. 20 x 10^6 cells of parental or bone-derived MM.1S cells were later inoculated intravenously to NSG-Tg(huIL-15) mice for comparison of the growth rate. Tumor growth was followed by weekly bioluminescence imaging. *In vivo* micro-CT imaging of the left tibia was performed in each group for evaluation of the bone lesions when the first mouse was sacrificed, at day 35 in the study group with bone-derived cells and at day 60 in the study group with parental cells. The animals with bone-derived cells were euthanized within study days 35-40 based on humane end point criteria. The study groups with parental cells were sacrificed at study day 73, when most mice were at humane end point. The bioluminescence signal was detected in skeletal sites (spine, pelvis, hind limbs, calvaria, ribs) and in soft tissues (spleen, brain, lungs, ovaries). Extensive osteolytic lesions were observed in all mice that had received the bone-derived cells, compared to 40% in the parental cell group. The bone-derived cell line was further characterized for cell surface marker expression. Both parental and bone-derived cells are positive for BCMA, CD138, and SLAMF7, which can be used for tumour cell identification in bone marrow. We conclude that the bone-derived MM cells induce disease progression in this mouse model with shorter study length compared to the parental cell line and that both cell lines express BCMA, CD138, and SLAMF7. The interaction between myeloma cells and their surrounding microenvironment in bone marrow plays a critical role in MM. The bone-derived MM.1S model can be combined with human NK cells or peripheral blood mononucleic cells (PBMCs) to study therapeutics affecting the interaction of cancer and immune cells.

#1283 Targeted genetic profiling of a de novo neuroendocrine patient-derived xenograft (PDX) and organoid model of prostate cancer from patient with African Ancestry.

Diana Rodriguez, Surendra Gulla, Tej Sharma, John Bodkin, Roberto Pili, John E. Tomaszewski, Remi M. Adelaiye-Ogala

Jacobs School of Medicine and Biomedical Sciences at the University at Buffalo, Buffalo, NY

Patient-derived xenograft (PDX) and organoid (PDO) models provide platforms to study prostate cancer (PCa) progression and therapy, especially in underrepresented populations. Here we report the first *de novo* neuroendocrine prostate cancer (NEPC) from a consented patient of African Ancestry with localized disease and no prior treatment before radical prostatectomy. African American patient had a pTN2 tumor, Gleason7 (4+3) and PSA or 3.6. Acquired tissue was collected for PDX and PDO establishment as well as for downstream molecular characterization. To uncover genetic drivers of aggressive phenotypes, we performed whole exome sequencing on DNA from the primary tumor and the established PDX using the Illumina Exome Kit and Twist Biosciences Exome Panel 2.0, followed by bioinformatic analysis. Computational workflows using Nextflow, including nf-core/sarek, identified somatic single nucleotide polymorphisms (SNPs), mutations (Mutect2, Strelka), and copy number variations (CNVs) (CNVkit, Control-FREEC). Variant annotation with Variant Effect Predictor and SnpEff linked variants to cancer progression. Analysis of the tumor samples revealed CNAs and mutations in genes similar to those seen in previously published NEPC. Protein expression by western blot and IHC identified altered protein expression peculiar to the NEPC phenotype further validating our primary tissue and its derived PDX models to have the NEPC phenotype. Furthermore, novel markers identified provide insight into molecular drivers of this prostate cancer phenotype and may inform targeted therapies for high-risk localized PCa.

#1285 PBMC-humanized, MHC-deficient NCG mice support growth of human tumor xenografts, do not develop rapid onset GvHD, and provide enhanced performance in oncology studies.

Steven Bronson[1], Kyle Draheim[2], Christopher Currie[2], Sydney Scatigno[2], Jenny Rowe[1], **David P. Harris**[2]

[1]Charles River Laboratories, Inc., Wilmington, MA,[2]Charles River Laboratories, Inc., Durham-RTP, NC

The application of new in vivo animal models with greater translational relevance is important for successful drug development. Severely immunodeficient mouse strains engineered for enhanced engraftment and persistence of diverse human immune cell types are now widely used in drug discovery across different therapeutic areas. These models allow for testing of immune modulating agents that target specific components of the human immune system, including both lymphoid and myeloid lineages. They have been particularly useful in drug development for oncology and for evaluating cell therapies such as TCR and CAR modified T cells. One approach commonly used to generate humanized mice involves engrafting peripheral blood mononuclear cells (PBMC) into immunodeficient mice. Since PBMC humanization results in efficient engraftment of hCD3+ T cells, xenogeneic GvHD (graft versus host disease) responses can occur with some donors. GvHD responses, which are characterized by progressive weight loss and a decline in animal well-being, can significantly compromise the results of studies in human tumor-bearing mice. In the studies reported here we compared outcomes in three NCG mouse strains. The parental NCG was modified to lack either B2-micoglobulin (NCG-B2m-KO mice deficient in the expression of mouse MHC class I molecules) or a double knock out of both mouse MHC class I and MHC class II molecules (NCG-MHC-dKO mice). RKO colorectal tumor cells were implanted subcutaneously in the three NCG mouse strains (parental NCG, NCG-B2m-KO and NCG-MHC-dKO) and 7 days later mice were engrafted with 10 million PBMCs obtained from two different donors, a Reference Donor and a Rapid Engrafter known to induce GVHD. The growth of RKO tumors and engraftment kinetics of donor PBMCs was evaluated. We observed consistent RKO tumor growth in non PBMC-treated NCG mice. HuPBMC NCG mice engrafted with the Rapid Engrafter showed clear signs of GvHD and reduced tumor growth. Importantly, there was a delay in the onset and significantly reduced severity of GvHD (by body weight loss or general clinical observations) in both MHC-modified strains. The engraftment rate of PBMCs was slightly delayed in both HuPBMC NCG-b2m-KO and NCG-MHC-dKO mice. The lack of GvHD provides a compelling rationale for the use of MHC deficient NCG strains in oncology tumor model studies and cell therapy studies.

#1286 Humanized avian xenograft models: advancing preclinical evaluation of immunotherapies and immune cell therapies with enhanced predictive accuracy.

Marjorie Lacourrege[1], **Romain Teinturier**[1], Paola Bonaventura[2], Clelia Costechareyre[1], Loraine Jarrosson[1], Camille Futelot[1], Mayrone Mongellaz[1], Stephane Depil[2], Celine Delloye-Bourgeois[1], Valerie Castellani[1]

[1]Oncofactory, Lyon, France,[2]ErVimmune, Lyon, France

Despite the success of immunotherapies and immune-cell therapies, clinical attrition remains high due to the limited predictive power of current preclinical models. This underscores the urgent need for innovative tumor-based platforms to facilitate the rapid and reliable evaluation of therapeutic efficacy. To address this challenge, we have developed advanced humanized avian xenograft models, leveraging our proprietary AVI-PDX™ technology. These models involve implanting human cancer cells into avian embryos, enabling the evaluation of therapeutic responses in a matter of days. Our humanized models, IMMUNO-AVI-PDX™ and IMMUNO-AVI-CellDX™, utilize two distinct approaches: (i) co-implantation of human peripheral blood mononuclear cells (PBMCs) and cancer cells, or (ii) implantation of cancer cells followed by intravenous injection of human PBMCs. Using a combination of whole embryo light-sheet microscopy, molecular marker analysis via immunolabelling of cryosections, and flow cytometry on microdissected tumors, we demonstrated efficient PBMC intake, robust immune cell survival, and minimal allogenicity. This approach successfully establishes tumor-immune interactions, with enhanced infiltration and persistence of human T cells, B cells, monocytes, and NK cells within tumors. We validated the functionality of our models by testing the anti-PD1 immune checkpoint inhibitor, pembrolizumab. Intravenous administration of the anti-PD1 monoclonal antibody (mAb) efficiently targeted PD1 receptors on T cells, resulting in their activation and subsequent tumor response. Next, we evaluated anti-PD1 efficacy in a panel of humanized AVI-PDX™ and AVI-CellDX™ models, including colorectal cancer (CRC), breast cancer, and melanoma. Using whole embryo light-sheet imaging and tumor volume quantification, we observed that our models successfully replicated the known response to anti-PD1, showing efficacy in sensitive cell lines and resistance in resistant ones. Notably, our CRC models revealed patient-specific heterogeneity in tumor responses, correlating with molecular features currently used to predict clinical outcomes. Finally, in collaboration with ErVimmune, we extended the application of our models to immune cell therapy by demonstrating the efficacy of a co-implanted HERV-specific T cell clone in an ovarian cancer IMMUNO-AVI-CellDX™ model. Together, these findings highlight the potential of our humanized avian xenograft models to advance the study of immune-based therapies and to identify predictive biomarkers for therapeutic efficacy.

#1287 Clinical relevance and translatability of NSCLC patient-derived xenograft (PDX) models for evaluating cMET-targeted therapies.

Nathlie Leger, Kayla Tyskiewicz, Hanna Koster, Paul Heverly, Mara Gilardi, Stefano Cairo, Frank Smith

Champions Oncology, Inc., Hackensack, NJ

Adoption of tyrosine kinase inhibitors (TKIs) has improved outcomes for Non-Small Cell Lung Cancer (NSCLC) by disrupting tumor-promoting growth factors, but patients develop resistance to these therapies through acquired alterations in other receptors. MET amplification is a common mechanism of resistance to FDA-approved small molecule EGFR inhibitors. Antibody Drug Conjugates (ADCs), such as c-MET targeting telisotuzumab-vedotin, are emerging as a promising therapy for EGFR inhibitor-progressed NSCLC, but understanding ADC efficacy across diverse profiles of advanced tumors remains a challenge. There is a need to develop more translational preclinical models to understand next-generation experimental agent efficacy prior to clinical trial enrollment. Here, we investigate the therapeutic potential of an experimental anti-cMET ADC in a panel of NSCLC low-passage patient-derived xenograft (PDX) models derived from patients pre-treated with EGFR therapies.10 NSCLC PDX models from Champions Oncology's tumor bank were established In Vivo from patient tumors and maintained at a low passage. Genomic and pharmacologic profiling was conducted on established models to characterize EGFR resistance. Models were then treated with 1 or 3 mg/ kg experimental agent every 4 days for 8 doses, with tumor volume and survival data collected over a 4-week treatment period. The experimental anti-cMET ADC demonstrated a range of tumor growth inhibition across the selected models, which is reflective of the heterogeneity seen in NSCLC patients in the clinic. Several cMET-amplified models showed significant tumor regression, while other cMET-amplified models exhibited more variability ranging from partial response to full resistance to treatment. The use of low-passage NSCLC PDX models is essential in preserving the clonal heterogeneity and molecular landscape of patient tumors, making them highly relevant for the preclinical evaluation of novel therapies. Notably, Champions low-passage models preserved the molecular and histological features of the original patient tumors, including mutations and copy number variations, which were critical for understanding the response to therapy. Our study highlights the translational potential of Champions PDX models, serving as a platform for investigating the efficacy and mechanisms of resistance to targeted therapies.

#1289 A preclinical platform of PDX breast cancer models and their cellular counterparts to identify resistance mechanisms and novel therapeutic options.

Emilie Indersie[1], Lea Sinayen[1], Aurore Gorse[1], Marie Tavernier[1], Enora Le Ven[1], Ester Morgado[2], Laurent Pouyet[2], Francois Romagne[2], **Olivier Deas**[1]

[1]XenTech, Evry-Courcouronnes, France,[2]MImAbs, Marseille, France

Despite significant advancements in understanding the biology and genetics of breast cancer, the development of effective therapies requires predictive and physiologically relevant preclinical models for their evaluation. In this context, patient-derived xenografts (PDX) have become a standard tool as they reproduce the biology of the original tumors in terms of histology, genotype, and response to chemotherapy. They have proven their relevance in studying pathways leading to cancer development and progression, mechanisms related to tumor resistance, and identifying new effective therapies. We offer a preclinical platform of over 60 fully characterized breast cancer PDX models and their in vitro cell derivatives for preclinical evaluation of new treatment modalities. Our platform consists of a PDX collection of 43 TNBC models, 9 ER+, 5 HER2+, 3 Luminal B (ER+ HER2+) models, and 14 cellular models derived from a subset of these PDX (PDXDC), representing the diversity of breast cancer. PDX models were obtained by transplanting post-operative tumor samples, either by grafting tumor fragments into the interscapular region of nude mice or by injecting dissociated tumor cells into the mammary fat pad of NOD-Scid mice. PDXDC were obtained from dissociated PDX tumors cultured under various media and matrix conditions. All models (PDX and PDXDC) were characterized at molecular level, including transcriptomic, whole exome sequencing, IHC marker staining and/or cytometry analysis. PDX were characterized pharmacologically for response to standards of care as a single agent or in combination. Our PDX and PDXDC panels primarily reflects the molecular heterogeneity of breast cancer and accurately reproduces the molecular and drug response profile of patient tumors. It is widely used for standard drug evaluations, but also for in vivo "mouse clinical trials" (MCT) which provide more predictive preclinical data on the efficacy of a single agent or drug combination. Additionally, we generated standard-of-care resistant models from our PDX panel to study the resistance mechanisms underlying breast cancer progression and to mimic what is observed in the clinic. Associated to in vitro cell derivatives, our collection provides a powerful preclinical platform for translational and preclinical research to identify mechanisms underlying acquired resistance to current therapies and develop novel treatment strategies against breast Cancers.

#1290 Mice humanized for the immune system as validated tool for therapeutic antibody development.

Lise Pasquet[1], Alice Marchand[1], Marion Mars[1], **Sophie Chabot**[1], Frederique Dol-Gleizes[1], Sebastien Tabruyn[2], Dan Georgess[2], Melanie Pichery[1], Thomas Eden[3], Welbeck Danquah[3], Gerhard Niederfellner[4], Pascale Lejeune[1]

[1]Translational Biology department, Evotec (France) SAS, Toulouse, France,[2]TransCure bioServices, Archamps, France,[3]Evotec International GmbH, Hamburg, Germany,[4]Evotec International GmbH, Gottingen, Germany

Therapeutic antibodies modulating the immune response are frequently specific for human proteins but fail to cross-react with the corresponding rodent homologs. Hence, their preclinical development requires suitable “humanized” mouse models, i.e. mice bearing a human immune system, so that immunotherapies can be evaluated in a more relevant immune context *in vivo*. Such “humanized” mice are developed by reconstituting the immune system of immunodeficient animals with human immune cells from 2 possible origins: $CD34^+$ hematopoietic stem cells ($huCD34^+$ mice) isolated from cord blood, or mature peripheral blood mononuclear cells prepared from buffy coats (huPBMC mice). According to the compound to be tested and the goal of the research, one model may be preferred over the other. $HuCD34^+$ mice exhibit multilineage immune populations allowing the evaluation of immune checkpoint inhibitors. We developed the human A375 melanoma model in $huCD34^+$ NCG mice to evaluate the combination strategy of relatlimab (anti-LAG-3 antibody) and nivolumab (anti-PD-1 antibody) approved at the beginning of 2024 as a first-line treatment for specific melanoma indications. Anti-PD-1 single treatment tended to, albeit without statistical significance, decrease tumor growth compared to isotype control group while anti-LAG-3 alone had no impact on tumor growth. The combination strategy induced a significant decrease in tumor growth compared to single agents in line with the data observed in the RELATIVITY-047 clinical trial (Tawbi H., NEJM, 2022). We also developed huPBMC mice that exhibit exclusively T-cell lineage and are suitable option to evaluate T-cell engagers like the CD3xEpCAM bispecific antibody, solitomab. We observed a dose-dependency between the dose of PBMC injected and the obtained level of human immune cell reconstitution. We observed that the level of reconstitution did not impact engraftment or tumor progression of the A375 melanoma or the BT474-clone5 breast cancer model, and conversely, that the tumor growth did not impact T-cell reconstitution. Finally, in the BT474-Clone5 model, we confirmed a dose-dependent efficacy of solitomab in controlling tumor growth. Moreover, solitomab efficacy was further potentiated by combination treatment with an Evotec proprietary co-stimulatory bispecific antibody. Mice humanized for the immune system exhibiting either multiple lineages (CD34+ huNCG) or just T-cell lineage (huPBMC) proved themselves suitable tools to assess non-mouse cross-reactive anti-tumor immunotherapy assets. Expertise in handling such models and deep knowledge in their benefits and limitations are required to selecting the most valuable model to perform preclinical studies predictive of human therapeutic response.

#1292 Innovative 3D ecm platforms for tumoroid development, drug screening, and personalized treatment.

Navneet Kaur[1], Dazhi Yang[2], Jamel Ali[1]

[1]Florida State University, Tallahassee, FL,[2]Acrogenic Technologies Inc, Rockville, MD

New advances in cancer research require robust *in vitro* and *in vivo* models that mimic the complexity of human tumors. Traditional 2D cell cultures lack the complexity of the tumor microenvironment (TME), leading to unreliable prediction of drug efficacy. Animal models are costly, time-intensive, and fail to fully replicate human tumor biology due to interspecies differences. To overcome these limitations, we present an innovative approach that involves TME-mimetic extracellular matrix (ECM)-based 3D platforms and co-culture systems for the development of tumoroids, circulating tumor cell (CTC) expansion, and PDX models. These 3D systems provide a physiologically relevant TME by mimicking the native cellular and extracellular interactions that drive tumor growth and progression. Tumoroids established through co-culturing a pool of primary cells dissociated from human solid tumors using a solid micro extracellular matrix (smECM) exhibited pathohistological properties, biomarker expression, and tissue architecture closely resembling the original tumors. Incorporating human foreskin fibroblasts (HFFs) in co-culture further enhanced tumor growth and stromal support, making these 3D models highly effective for drug screening and functional studies. Additionally, the use of smECM provided an innovative solution for expanding rare CTCs *ex vivo*. Unlike traditional methods, the 3D smECM platform supported the sustained viability and proliferation of CTCs, preserving their heterogeneity and allowing for rapid generation of CTC-seeded PDX models. These models demonstrated a high degree of clinical relevance by maintaining genomic profiles and chemoresistance characteristics of the original patient tumors. By integrating these advanced 3D platforms, we offer a powerful tool to develop versatile models for cancer research.

#1293 PMed-TRIAL database: an efficient and intelligent data integration platform shaping the future of drug development.

Xinlei Chen[1], Youbing Guo[1], Loc Van[2], Josh Caggiula[2], **Danyi Wen**[1]

[1]Shanghai LIDE Biotech Co., Ltd., Shanghai, China,[2]LIDE Biotech Co., Ltd., Doylestown, PA

With the rapid advancements in artificial intelligence (AI) and big data technologies, the fields of precision medicine and drug development have entered a transformative data-driven era. Leveraging years of accumulation and expertise, LIDE launched the PMed-TRIAL Database in 2023. Through continuous iteration and expansion, PMed-TRIAL has evolved into a comprehensive data integration and query platform, encompassing PDX (Patient-Derived Xenograft), CDX (Cell Line-Derived Xenograft), Syngeneic models, and Conditional Reprogramming Cell Lines. The platform enables efficient data retrieval and intelligent integration, providing indispensable support for clinical and drug research in this new era.

The database currently hosts nearly 1,800 PDX models, making it one of the largest PDX repositories worldwide. These models integrate and standardize a wide range of key datasets, including clinical information, treatment history, growth curves, SOC (standard of care), and H&E (hematoxylin and eosin staining) results, among others, which greatly facilitates the filtering and selection of suitable models for drug research. Furthermore, the associated whole-exome sequencing (WES) and RNA sequencing datasets provide critical evidence for drug mechanisms research. In addition to standard PDX models, the database also includes induced drug-resistance models, providing an essential resource for studying drug resistance mechanisms and screening drugs to overcome resistance.

In addition to PDX models, the PMed-TRIAL Database incorporates information on Patient/PDX-derived conditional reprograming cell lines, PDXO (PDX Derived Organoids), Syngeneic models, and CDX models. This expanded scope addresses the multi-faceted demands of drug development, accelerating research timelines and enhancing the efficiency of the drug discovery process.

Most importantly, the PMed-TRIAL Database standardizes and efficiently integrates diverse model datasets. The accumulation of large-scale, high-quality data not only streamlines current research efforts but also lays the groundwork for advancing AI applications in drug development in the future. By bridging innovative technologies with comprehensive data resources, PMed-TRIAL empowers researchers to unlock new possibilities in precision medicine and therapeutic innovation.

#1294 Primed human immune cell and cancer cell co-inoculated model for immuno-oncology drugs evaluation.

Bin Xie[1], Xin Hou[1], Pengfei Yang[1], Yanbing Zhou[1], Loc Van[2], Diandong Jiang[1], Josh Caggiula[2], **Danyi Wen**[1]

[1]Shanghai LIDE Biotech Co., Ltd., Shanghai, China,[2]LIDE Biotech Co., Ltd., Doylestown, PA

Systemic peripheral blood mononuclear cell (PBMC) humanized model is a straightforward tool to evaluate therapeutic immuno-oncology (IO) drugs, including immune checkpoint blockers (ICB) and bispecific antibodies (BsAb). However, the model has a limited dosing regimen window due to graft-versus-host disease (GVHD), as seen in most immune deficient recipients. There is also a relative lower responsible rate from insufficient antigen specific immune cells infiltration into tumor microenvironment (TME). Thus, application of this PBMC humanized model is restricted in evaluation of multiple ICBs and myeloid cell- *or* lymphocyte-mediated BsAbs. To overcome this, LIDE has developed a unique co-inoculation model with primed human PBMC (or/and its derived immune cell subsets) and cancer cells. Cancer-priming human PBMCs are well mixed with fresh cancer cells in MatriGel, co-inoculated into immune deficient mice to form an immune cell relatively warm tumor tissue for late immunotherapy. This model can significantly delay the graft-versus-host-reaction for another month compared with traditional systemic PBMC humanized model, and achieves maximal therapeutic effect of the testing drugs by pre-activating T cells with specific tumor antigens. Considering minimum innate immune cells in TME, dendritic cells or macrophages are expanded ex vivo, then transferred into this co-inoculated system to work together with T cells with a proper survival rate in the dosing period, mimic clinical biopsy complexity, to help determine the overall effect induced by integrated signals. It seems CD40 agonist or CD47 antagonist could well synergize with anti-PD(L)1 to control melanoma and triple negative breast cancer development, respectively. This optimized immune cell humanized cancer-bearing mice models have been tested for various cancer targets, e.g., PD(L)1, Tim3, Lag3, Tigit, PVRIG, TGFβ1, CD73/CD39, CD47/Sirpa, DLL3/CD3, Claudin18.2/4-1BB/CD3, B7H3/CD3/ADC, GPC3/CD3, GPRC5D/CD3, CSF1R, GITR, (Pro)IL2/IL15, to better understand the interaction and modulation between cancer cells and immune cells.

#1295 A translational approach to ADC evaluation: preclinical single-mouse basket trial with Bayesian modelling analysis.

Diandong Jiang[1], Yuan Ji[2], Jiaxin Liu[2], Bin Xie[1], Hongkui Chen[1], Shizhu Zhao[1], Le Li[1], Yu Di[1], Xinlei Chen[1], Xiaorong Gu[1], Huanhuan Zhang[1], Zhenle Bi[1], Kaimeng Hu[1], Loc Van[3], Josh Caggiula[3], Yulan Tang[1], **Danyi Wen**[1]

[1]Shanghai LIDE Biotech Co., Ltd., Shanghai, China,[2]Bayesoft, Shanghai, China,[3]LIDE Biotech Co., Ltd., Dolyestown, PA

Introduction: Antibody-drug conjugates (ADCs) have revolutionized cancer therapy, exemplified by the clinical success of HER2-targeting ADCs like Trastuzumab-Deruxtecan (T-Dxd), which demonstrates efficacy across a spectrum of HER2 expression levels. However, ADC development remains challenging due to translational gaps between preclinical and clinical findings. This study introduces a robust translational approach for ADC evaluation, combining a single-mouse preclinical model using MiniPDX® technology with Bayesian statistical analysis—a widely recognized and commonly applied statistical approach in clinical research. Bayesian analysis offers the advantage of integrating prior knowledge with experimental data to generate probabilistic predictions, providing a dynamic and nuanced understanding of treatment efficacy. Our study mimics clinical trials of T-Dxd and Trastuzumab-Emtansine (T-DM1) using this robust, translational framework to bridge the gap between preclinical and clinical evaluation.

Methods: We selected 20 PDX models over six cancer types, representing HER2 expression levels (high, medium, low, and negative control). Tumor tissues were dissociated into single-cell suspensions and implanted subcutaneously in mice via MiniPDX capsules. Each mouse received a single 10 mg/kg dose of T-Dxd or T-DM1 over 10 days. Tumor cell viability was assessed using CellTiter-Glo, and tumor relative proliferation rate was calculated as Treatment/Control ratios (T/C%). A T/C ratio <50% indicated significant response. Bayesian modelling was applied to estimate the probability of tumor inhibition across HER2 cohorts.

Results: T-Dxd demonstrated a 100% overall response rate (ORR) in HER2-high models, with significant tumor inhibition. Additionally, T-Dxd exhibited substantial efficacy in HER2-medium (ORR 75%) and HER2-low (ORR 60%) groups. In contrast, T-DM1 displayed strong tumor inhibition in HER2-high models but limited efficacy in HER2-medium and HER2-low groups. In addition, Bayesian analysis yielded posterior probabilities of 83%, 66%, and 54% that T-Dxd slows down tumor growth by 50% when compared to control for the HER2-high, HER2-medium, and HER2-low groups, respectively.

Conclusion: Our study demonstrates the feasibility and promising results of preclinical single-mouse trials using MiniPDX®. The Bayesian statistical analysis provides a rich summary of the effects of T-Dxd and T-DM1. This approach bridges the translational gap, offering a platform to predict ADC efficacy and guide candidate selection in the preclinical setting.

#1296 Development of a novel NCG-hIL15-FcγR-KO model for precise drug efficacy evaluation.

Hongyan Sun[1], Jun Xing[1], Jianming Xu[1], Shiying Guo[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Humanized mice, particularly immunodeficiency mice reconstituted with human immune systems by the transplantation of human hematopoietic stem cells (HSCs) or human peripheral blood mononuclear cells (PBMCs), have been widely used in tumor immunology. The NCG-hIL15 model has been developed to reconstitute both human T and natural killer (NK) cells, which allows the study of immune checkpoint inhibitors (ICIs) and antibody-dependent cellular cytotoxicity (ADCC)-dependent drugs. However, the remaining murine cells from the myeloid compartment can interfere with the mAb-based drug clearance and efficacy. To precisely evaluate the function of mAb-based drugs, we have successfully developed the NCG-hIL15-FcγR-KO model by disrupting the murine FcγRI, FcγRII, FcγRIII, and FcγRIV genes in NCG-hIL15 mice, resulting in the absence of murine FcγRs. In this model, the interference from mouse FcγRs to induce ADCC was minimal.

Compared to the parental NCG-hIL15 mice, NCG-hIL15-FcγR-KO mice can reconstitute comparable levels of human NK and T cells post-HSC transplantation. Both NCG-hIL15-FcγR-KO and NCG-hIL15 mice showed stable body weight changes with a long survival period. In our study, we found that rituximab could inhibit tumor growth through murine innate cells in the absence of human NK cells in NCG-hIL15 mice bearing Raji tumors, obscuring the interpretation of the results, while it had no inhibitory effect on tumors in NCG-hIL15-FcγR-KO mice bearing Raji tumors. Therefore it was suggested that the NCG-hIL15-FcγR-KO model was able to avoid false positives of ADCC drugs and was able to accurately evaluate the true drug efficacy. Furthermore, compared with the PBMC-NCG-hIL15 mice, nivolumab was able to significantly inhibit the growth of tumors in PBMC-NCG-hIL15-FcγR-KO mice bearing NCI-H1975 tumors. This demonstrated that NCG-hIL15-FcγR-KO mice may provide a good platform to study anti-tumor T cell responses in the absence of murine FcγRs.

Taken together, the NCG-hIL15-FcγR-KO model is the ideal model to accurately reflect the true efficacy. We present this model as a valuable addition to the preclinical research toolkit, promising a deeper understanding of efficacy evaluation for clinical applications.

#1297 Novel mouse models to study bone and brain metastasis.

Hongyan Sun[1], Xue Wu[1], Fang Zhu[1], Jianming Xu[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Metastasis refers to the dissemination of cancer cells from the primary (original) tumor to distant areas of the body, where they give rise to secondary and more aggressive cancers. This process constitutes a crucial aspect of cancer progression and is frequently linked with poor prognosis. Many cancer patients progress to metastasis at a later stage of tumor development before proper treatment is available. Hence, inhibiting metastasis is an important focus of cancer research. Common tissues where cancer metastasizes include the lung, liver, bone, and brain. Anti-metastatic drugs consist of antibody drugs, small molecule inhibitors, peptides and nucleic acids. According to the different mechanisms of action, they can be categorized into angiogenic factor inhibitors, cell adhesion molecule antagonists, metalloproteinase inhibitors, cellular messenger regulators and so on. Despite significant progress in the therapeutic strategy for treating cancer metastasis, several limitations such as drug resistance and limited druggable pathways remain unsolved.

To better understand the underlying mechanism and support the discovery of novel biomarkers in cancer metastasis, we have developed robust mouse models for bone and brain metastasis. MDA-MB-231-Luc cell line was injected into the left ventricle of the mouse heart using an ultrasound-guided intracardiac injection technique. Through multiple rounds of *in vivo* and *in vitro* screening, we have successfully obtained MDA-MB-231-Luc subclone cell line, which can be colonized in the spine and lower limb bones, recapitulating bone metastasis in clinic. In another approach, we have successfully established a brain metastasis model by injecting the lung cancer cell line LLC1-Luc into the common carotid artery of mice via carotid artery injection. *In vivo* imaging analysis confirmed cancer cells colonization and proliferation in the correspondence tissue.

In conclusion, we have developed preclinical mouse models which recapitulated bone and brain metastasis observed for cancer patients in clinics. Those models can be valuable tools to study metastasis mechanisms as well as for the biomarker discovery.

TUMOR BIOLOGY: Model Systems for Metastasis
Poster Session

#1301 Multiple-channel hybrid neural network to achieve quantitative bioluminescence tomography for cancer research.

B. Deng[1], Z. Tong[1], Y.-c. Tsai[1], J. Kim[1], H. Dehghani[2], **K.-H. Wang**[1];
[1]UT Southwestern Medical Center, Dallas, TX, [2]University of Birmingham, Edgbaston, Birmingham, United Kingdom

Purpose: Bioluminescence tomography(BLT) enhances commonly used 2D bioluminescence imaging by reconstructing 3D distributions of bioluminescence activity, allowing in vivo tumor localization. However, traditional physics model-based BLT struggles with model uncertainties and ill-posedness, limiting its ability to provide quantitative information, such as tumor volume. To address this, we introduce the Multiple-channel Hybrid Neural Network(McHyNN), a machine learning(ML) framework integrating light propagation model, multimodal imaging, and cross-animal data. We demonstrate McHyNN's ability to accurately identify tumors and quantify their volumes, particularly in cases of small and multiple brain metastases(BM), making it highly valuable for cancer research.
Method: McHyNN is a feed-forward neural network(NN) grounded in a light propagation model based on the diffusion equation. It incorporates multi-data channels, including multi-animal and multimodal data. For a given animal set, the data includes BL images emitted from internal tumors and corresponding MRI scan, if tumor is MRI-detectable. The NN outputs n+1 BL tumor distributions, including the *n* existing animal sets and the new subject, whose tumor information is to be determined. McHyNN leverages mutual information from light propagation across multiple animals and multimodal images, and the NN is optimized accordingly using loss function $L = L_{diff} + L_{image}$. L_{diff} and L_{image} minimize the difference between calculated and actual BL tumor distributions based on surface BLI measurement, and MRI data, respectively. We will first present numerical results based on simulated brain metastases in mice with experimentally determined noise, followed by showing the capability of BLT to reconstruct in vivo BMs in SCLC spontaneous animal model.
Results: McHyNN accurately quantifies three small BMs (1.2 to 1.9 mm in length, volume: 0.9 to 1.9 mm^3) within simulated mouse brain at localization accuracy of < 0.5mm and volume errors within 0.8 mm^3, even when the tumors are separated by only 2-2.7 mm. In contrast, the compressive sensing algorithm commonly used in conventional BLT fails to distinguish these tumors. Moreover, we simulated single brain metastasis ranging from 1.0-3.6 mm in length, 0.4-17.2 mm^3 including 10 tumors 1.5<mm or="" 1.75="" mm3. McHyNN successfully localized all cases within 0.5 mm and faithfully reconstructed tumor volumes, showing a linear correlation with ground truth (R^2=0.99). The in vivo BMs study is ongoing. <mm or="" 1.75="" mm
<mm or="" 1.75="" mmConclusions: Our BLT platform incorporating the McHyNN approach has potential to transform qualitative bioluminescence imaging into a 3D quantitative modality, particularly for tumor volume quantification and detecting small malignancies. This innovation will significantly enhance investigators' capabilities in cancer studies.

#1302 A practical method of delivering induced electric field (iEF) therapy.

J. West, C. Barron, **V. Subramaniam**;
EMBioSys Inc., North Andover, MA

Among non-pharmacological treatments, induced electric field (iEF) therapy is the only bioelectric approach that is truly contact-free and non-invasive. In iEF treatment, the permeability of magnetic fields varying in time is exploited to induce electric fields inside cells and tissues without the need for electrodes or adhesive contact with the skin. Induced electric fields are a non-ionizing form of electromagnetic radiation demonstrated to have strong anti-metastasis and anti-tumor activity *in vitro* and *in vivo* against triple negative breast cancer (TNBC), including significant host immune response in a pre-clinical animal model. Moreover, combination treatment of MDA-MB-231 and MDA-MB-468 cells with standard of care chemotherapeutic agents (paclitaxel, capecitabine) plus iEF *in vitro*, significantly improve their anti-viability and anti-proliferation activity (half-maximal inhibitory concentrations or IC_{50} values decreased by ~50% for both paclitaxel+iEF and capecitabine+iEF treatments). EMBioSys has developed technology translating iEF therapy into clinical treatment and delivered in the form of wearable, washable garments such as camisoles. Special conducting threads integrated into the camisole enable a current to be driven through the insulated threads at voltages less than 10 Volts. The time-varying current generates a temporally varying magnetic induction within the space enclosed by the camisole and generates iEFs by Faraday's law. We measured the magnetic inductions, compared with their calculated values, and determined iEF distributions within the space enclosed by the garment. We find that iEF intensities found to have anti-metastasis and anti-tumor effects in animal models of TNBC can be easily attained at human anatomical scales and delivered in a practical manner for use by patients. Our work lays the foundation for first in human studies by extending a treatment developed in the laboratory into a wearable and washable treatment device for cancer patients.

#1303 Tunable ECM interfaces in microfluidic chips for interfacial metastatic studies of breast cancer spheroids.

Hsiang-Pei Chen[1], Hwanseok Jang[2], Seung-Cheol Shin[2], Seok Chung[2]

[1]National Cheng Kung University, Tainan City, Taiwan,[2]Korea University, Seoul, Korea, Republic of

Background: Metastasis remains one of the most challenging aspects of cancer progression to study. Recent research highlights that the physical characteristics of the extracellular matrix (ECM)—such as stiffness, porosity, and microarchitecture—are critical regulators of cancer invasion and metastasis. Tumor cells often encounter heterogeneous microenvironments, including matrix-matrix interfaces (MMIs), which provide unique interfacial cues influencing invasion and dissemination. Despite growing recognition of these interfacial dynamics, the mechanisms by which MMIs modulate metastatic behaviors remain poorly understood. To address this, we developed a microfluidic chip with tunable ECM interfaces, enabling precise modulation of stiffness and structural heterogeneity. This platform facilitates the study of interfacial metastatic behaviors of breast cancer spheroids (BCS) in a controlled and reproducible in vitro setting.
Methods: A tunable microfluidic chip was fabricated using polydimethylsiloxane (PDMS) via photolithography. The chip comprises three distinct channels: a central channel engineered to create defined MMIs with combinations of soft and stiff ECM regions, and two lateral channels designed for nutrient supply. Collagen type I hydrogels were employed as the ECM material, and their physical properties—stiffness and microarchitecture—were characterized using rheometry and scanning electron microscopy (SEM). MDA-MB-231 and MCF7 BCSs were placed near the MMIs formed by juxtaposing ECMs of varying stiffness to model interfacial metastatic behaviors. Spheroid dispersion, invasion, and single-cell migration were observed and recorded using bright-field microscopy after 24 and 48 hours of incubation.
Results: The stiffness of the soft and stiff ECMs measured 5.18 ± 0.19 MPa and 6.58 ± 1.20 MPa, respectively, with porosity differing significantly between the inner regions of soft (6.56 ± 0.22) and stiff (2.71 ± 0.10) ECMs. In homogeneous environments, MDA-MB-231 spheroids exhibited enhanced dispersion and invasive behavior in soft ECM compared to stiff ECM. At MMIs, the presence of a stiff interface further enhanced MDA-MB-231 spheroid invasiveness, compared to soft-soft or homogeneous ECM conditions. In contrast, MCF7 spheroids showed minimal migration across all MMI conditions.
Conclusion: This study underscores the importance of tunable ECM interfaces in understanding the role of physical and structural heterogeneity on the invasive behaviors of BCSs. The results demonstrate how MMIs modulate metastatic dynamics, particularly in response to stiffness variations, and highlight the utility of microfluidic platforms in investigating the interplay between mechanical and biochemical microenvironments.

#1304 A novel organoid-based model to study pediatric tumor metastasis to the lung.

Martha Magdalena Zylka[1], Christoph Hafemeister[1], Lukas Watzke[2], Ulrike Mann[3], Didier Surdez[4], E. Alejandro Sweet-Cordero[5], Bernadette Liegl-Atzwanger[6], Matthias Dettmer[7], Femke Ringnalda[8], Marc van de Wetering[8], Karin Sanders[8], Matthias Farlik[3], Florian Halbritter[1], Martin Metzelder[9], Heinrich Kovar[1], Branka Radic Sarikas[1]

[1]St. Anna Children's Cancer Research Institute, Vienna, Austria,[2]Department of Pathology, Medical University of Vienna, Vienna, Austria,[3]Department of Dermatology, Medical University of Vienna, Vienna, Austria,[4]Faculty of Medicine, Balgrist University Hospital, Zurich, Switzerland,[5]Division of Pediatric Oncology, Department of Pediatrics, University of California San Francisco, San Francisco, CA,[6]Diagnostic and Research Institute of Pathology, Medical University of Graz, Graz, Austria,[7]Institute of Pathology, Klinikum Stuttgart, Stuttgart, Germany,[8]The Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands,[9]Department of Pediatric Surgery, Medical University of Vienna, Vienna, Austria

Metastasis is the primary cause of mortality in pediatric cancer, with the lung being a common site for secondary tumor growth. A major challenge in treatment is the lack of models that accurately replicate the interactions between tumors and the lung metastatic niche observed in patients. This limitation hinders the investigation of the molecular mechanisms driving lung metastasis in pediatric solid tumors. Furthermore, it impedes the development and testing of potential inhibitors to prevent or treat lung metastases, ultimately delaying progress in improving patient outcomes. We have developed an advanced *in vitro* lung metastasis model using tumor-lung organoid co-cultures. To this end, we first established lung organoids from healthy pediatric lung tissue and characterized them based on the presence of airway, alveolar, and other rare lung epithelial subtypes. Next, we analyzed primary and PDX-derived cells from two types of tumors that frequently metastasize to the lungs: Ewing sarcoma (ES) and osteosarcoma (OS). Our co-culture system revealed two groups of tumor cells with distinct behaviors: The first group of tumor cells actively infiltrated the lung organoids, while the second remained closely associated without invasion. We hypothesized that this behavior *in vitro* corresponds to differences in metastatic potential *in vivo*. In line with this hypothesis, scRNA-seq analysis confirmed a high expression of EMP1, a key driver of metastatic behavior, in infiltrative cells. In contrast, non-infiltrative cells showed no change in EMP1 expression between co- and mono-culture conditions, highlighting EMP1’s specific association with tumor cell infiltration. Furthermore, we noticed phenotypic changes in lung organoids in response to specific tumor co-cultures, suggesting a reactive response to infiltrating tumor cells. Using scRNA-seq, we are currently exploring the underlying molecular mechanisms driving these changes, characterizing overall gene expression changes and signaling pathways. Experiments with conditioned media revealed that lung-organoid secreted factors attract ES and OS cells. Further analysis of the lung organoid secretome identified paracrine signals that direct tumor cell homing, making our model a powerful tool for studying and targeting lung-specific tumor attraction. To further assess the model’s relevance to lung metastases in patients, we performed spatial transcriptomics analysis (10x Visium platform) on paired primary tumors and lung metastases from ES and OS patients. This analysis will both inform the refinement of our organoid model and enhance our understanding of lung metastatic niche spatial organization.In conclusion, our study provides a framework for understanding pediatric tumor lung metastasis and establishes a versatile platform for testing pathway-specific anti-metastatic therapies targeting tumor-lung interactions.

#1305 Brief pulses of high-level fluid shear stress enhance metastatic potential and rapidly alters the metabolism of cancer cells..

Amanda N. Pope[1], Devon L. Moose[1], Sujata Birua[1], Guy O. Hudson[1], Hank Weresh[1], Patrick Breheny[2], **Michael D. Henry**[1]

[1]Molecular Physiology and Biophysics, Univ. of Iowa Holden Comprehensive Cancer Ctr., Iowa City, IA,[2]Biostatistics, Univ. of Iowa College of Public Health, Iowa City, IA

During their journey through the circulation, circulating tumor cells (CTCs) face challenges to their survival including mechanical stresses related to their dynamic fluid microenvironment and oxidative stress related to their detached cell state. Recently, we identified a mechano-adaptive response to transient fluid shear stress (FSS) exposure that enables cancer cells to survive mechanical destruction in the circulation and found that it involves an increase in the activation of RhoA-actomyosin signaling (Moose et al., Cancer Cell 2020). Because RhoA is likely to influence other phenotypes involved in metastasis, such as invasiveness, we hypothesized that activation of RhoA by FSS may promote metastatic behavior in CTCs. Here we find that cancer cells (PC-3, MDA-MB-231, Myc-CaP) exposed to brief pulses of high-level FSS (~1msec, τ =750-6400 dynes/cm^2) exhibit enhanced invasiveness (dependent on RhoA) and anchorage-independent proliferation *in vitro* and enhanced metastatic colonization/tumor formation *in vivo* as compared to static controls. To investigate how exposure to FSS confers these phenotypes, we conducted transcriptomic and metabolomic profiling. Transcriptomic analysis at 3, 6, and 24h post FSS exposure revealed enrichment of gene expression involved in oxidative phosphorylation. Consistent with this, we found elevated oxygen consumption of cells exposed to FSS at 24h. Metabolomic profiling of cells immediately after exposure to FSS demonstrated rapid energy utilization consistent with actin remodeling and contractility as well as depletion of amino acids acids associated with the folate pathway. Cells exposed to FSS exhibit a reduced reactive oxygen species burden as compared to static controls. Consistent with the hypothesis that FSS-dependent activation of the folate pathway reduces oxidative burden in cells exposed to FSS, we found that exposure of cancer cells with the folate inhibitor methotrexate, sensitized those cells destruction by FSS. Taken together our data indicate that cancer cells that survive exposure brief pulses of FSS are primed for metastatic colonization in part through rapid metabolic programming that enables them to withstand oxidative stress associated with cell detachment. Thus, some CTCs may derive an unexpected survival benefit through encountering FSS in the circulation.

#1307 Pericytes promote colorectal cancer metastasis by remodeling perivascular matrix.

Xiaobo Li[1], Jinghua Pan[2], Qun Miao[1], Xiaoyu Wu[1], Zhan Zhao[2], Yihai Cao[3], Minfeng Chen[1], Dongmei Zhang[1], Wencai Ye[1]

[1]State Key Laboratory of Bioactive Molecules and Druggability Assessment, Jinan University, Guangzhou, China,[2]The First Affiliated Hospital of Jinan University, Guangzhou, China,[3]Department of Microbiology, Karolinska Institute, Stockholm, Sweden

Backgrounds: Hematogenous dissemination is a prevalent route of colorectal cancer (CRC) metastasis, whereas the underlying mechanism is unclear. Tumor pericytes (TPCs) are important components of tumor vessels, which are attached to the endothelial cells and embedded within the walls of capillaries. However, as the gatekeeper of vessels, the role of TPCs in hematogenous metastasis remains largely unknown. Here, we aimed to investigate the heterogeneity of TPCs and their effects on CRC metastasis.
Methods: TPCs were first isolated from the primary CRC tissues using microdissection combined with pericyte medium-based approach. Then, TPCs derived from CRC liver-metastatic (CRCLM) and CRC non-metastatic (CRCNM) patients were analyzed by single-cell RNA sequencing (scRNA-seq). Clinical CRC specimens were collected to analyze the association between the molecular profiling of TPCs and CRC metastasis. The mechanisms by which TCF21 regulated perivascular matrix remodeling and integrin α5 modulated *TCF21* DNA hypermethylation were investigated using RNA-sequencing, chromatin immunoprecipitation-sequencing and bisulfite-sequencing. Pericyte-conditional *Tcf21*-knockout mice were constructed to investigate the effects of TCF21 in TPCs on CRC metastasis. Masson staining, atomic force microscopy, second-harmonic generation and two-photon fluorescence microscopy were employed to observe perivascular extracellular matrix (ECM) remodeling. Pericyte TCF21-targeting peptide was designed by AlphaFold and its mechanisms were examined by microscale thermophoresis.
Results: Thirteen TPC subpopulations were identified by scRNA-seq. A novel subpopulation of $TCF21^{high}$ TPCs was found to bed associated with liver metastasis in CRC patients. Genes highly-expressed in $TCF21^{high}$ TPCs were enriched in ECM and ECM remodeling, thus termed as matrix pericytes. TCF21 in TPCs increased perivascular ECM stiffness, collagen rearrangement and basement membrane degradation, establishing a perivascular metastatic microenvironment to instigate CRC liver metastasis. Mechanistic studies indicated that loss of integrin α5 inhibited the FAK/PI3K/AKT/DNMT1 axis to impair *TCF21* DNA hypermethylation in $TCF21^{high}$ TPCs. Conditional deletion of *Tcf21* in TPCs or pharmacological blocking the transcriptional activity of TCF21 in TPCs could mitigate perivascular ECM remodeling and CRC liver metastasis.
Conclusions: This study first uncovers the heterogeneity of TPCs during CRC liver metastasis and reveals a novel mechanism that TPCs drive CRC liver metastasis through remodeling perivascular matrix, which provides a potential diagnostic marker and therapeutic target for CRC metastasis.

#1308 Protein profiling of breast cancer cell-derived extracellular vesicles in breast to bone metastasis.

Guan Huang, Golnaz Morad, Marsha A. Moses

Surgery, Vascular Biology Program, Boston Children's Hospital and Harvard Medical School, Boston, MA

Breast cancer is the most common cancer among women worldwide, with bone being one of the most common sites for breast cancer metastasis. Despite improvements in systemic therapies for breast cancer, the mechanisms underlying breast cancer metastasis to bone remain incompletely understood thereby limiting the development of effective therapeutic options. Emerging evidence suggests that extracellular vesicles (EVs), nanosized particles secreted by cells including cancer cells, play a pivotal role in organ-specific metastasis. However, relatively little is known regarding the contribution of breast cancer cell-derived EVs to bone metastasis. To begin to investigate the potential role(s) of breast cancer cell-derived EVs in breast to bone metastasis, we first analyzed the protein profiles of EVs derived from parental MDA-MB-231 breast cancer cells (P-EVs) and from bone-seeking MDA-MB-231 breast cancer cells (B-EVs) using iTRAQ (isobaric Tags for Relative and Absolute Quantification) quantitative mass spectrometry. Among a total of 126 identified proteins, 13 were upregulated in B-EVs, 8 were upregulated in P-EVs and 105 were shared by both EVs. Gene Ontology (GO) enrichment analyses and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analyses identified three key biological processes of interest: osteoclastogenesis, EV-cell attachment and bone extracellular matrix-receptor interactions which may contribute to bone-tropism and pre-metastatic niche preparation. Importantly, confocal microscopy studies demonstrated that B-EVs are preferentially internalized by osteoclast precursor cells. This finding was further confirmed by quantitative flow cytometry which demonstrated significantly higher fluorescent signal intensities for B-EVs compared to P-EVs in these osteoclast precursor cells also suggesting enhanced uptake specificity. Moreover, we found that B-EVs can induce the differentiation of osteoclast precursors into multinucleated osteoclasts in long-term *in vitro* studies as confirmed by tartrate-resistant acid phosphatase staining, indicating that EVs derived from a bone-seeking subpopulation of breast cancer cells may promote osteoclastogenesis, a process critical for bone resorption. This, in turn, may contribute to the development of a pre-metastatic microenvironment for bone metastasis. Taken together, these studies begin to enhance our understanding of the role of breast cancer cell-derived EVs in breast to bone metastasis and may ultimately offer potential avenues for therapeutic intervention and early detection of bone metastasis.

(This work was supported by the Breast Cancer Research Foundation, NIH R21 CA253051-01 and the Nile Albright Research Foundation. The authors acknowledge the gift of the MDA-MB-231 parental cell line and its bone-seeking variant from the Massagué Lab.)

#1309 Decellularized extracellular matrix hydrogel for esophageal cancer model.

Yunqing Kevin Kang

Department of Biomedical Engineering, Florida Atlantic University, Boca Raton, FL

Esophageal cancer is currently the sixth most common cancer worldwide and one of the most lethal cancers. The lack of physiologically relevant human esophageal cancer models has hindered the progress of developing effective strategies against esophageal cancer. To address the issue, we developed a decellularized esophageal matrix derived hydrogel. We then characterized the physicochemical properties of the decellularized extracellular matrix (dECM) hydrogel. To bioengineer the cancer model using the dECM hydrogel, we seeded esophageal squamous cell carcinoma KYSE30 on the dECM hydrogel and in the dECM hydrogel. They grew well and spread out in/on the dECM hydrogel. We also casted KYSE30-laden dECM hydrogel on a side of a well to see if KYSE30 will migrate out of the hydrogel. After culturing 3 days, we found that KYSE30 cells grew and started to migrate out of the dECM hydrogel, and migrated more after day 5. We counted the number of migrated cells. We found that cell migrated more at day 5. We then quantified cell proliferation of KYSE30 in the dECM hydrogel. We found that KYSE30 cells proliferated in the dECM hydrogel with time. These findings bring new potential to using the decellularized matrix derived hydrogel for future experiments in studying cancer behavior and practical applications for esophageal cancer models.

#1310 Targeting pro-metastatic stress networks in triple-negative breast cancer using patient-derived models.

Margarite D. Matossian[1], Ali Yesilkanal[1], Michael East[2], Denis Okumu[2], Geetha P. Yerradoddi[1], Rita Nanda[3], Gary Johnson[2], Marsha R. Rosner[1]

[1]The University of Chicago, Chicago, IL,[2]Department of Pharmacology, The University of North Carolina, Chicago, IL,[3]Department of Medicine, The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL

Metastatic triple-negative breast cancer (mTNBC) remains one of the most challenging forms of breast cancer to treat due to profound heterogeneity; chemotherapy-based regimens continue to be the mainstay of treatment. Kinases are attractive therapeutic targets, but while kinase inhibitors have improved outcomes in many metastatic solid cancers including HER2/Neu-amplified and kinase-driven hormone receptor positive breast cancers kinase inhibitors have not shown durable efficacy in mTNBC and many have failed in clinical trials. Furthermore, the high doses of kinase inhibitors to achieve cytotoxicity have unacceptable side effects for patients limiting real-world use. Preclinical research and secondary analyses from clinical trial data from our group and others demonstrate important differences in how kinase signaling networks, and not individual pathways, drive TNBC metastatic transformation compared to other breast cancer subtypes. Chronic stress states such as those initiated by hypoxia, poor nutrient delivery and higher metabolic demands promote pro-metastatic transcriptional programs in TNBC. Our research focuses on identifying and targeting regulators of the chronic stress response to suppress TNBC metastasis. Our previous work showed that activation of the physiologic metastasis suppressor RKIP effectively reduced TNBC metastasis in cell line models through inhibition of stress MAPK networks (p38, JNK, ERK1/2, MLK) resulting in decreased transcription of the pro-metastatic transcription factor BACH1. We demonstrated that low dose inhibition of multiple kinase nodes of networks, rather than single kinase nodes, more effectively reduces oncogenic signaling output and prevents compensatory signaling activation. Here we take the next step to translate this concept into the clinic. We show that combinations of kinase inhibitors used in early phase clinical trials (Ralimetinib (p38), JNK-in-8 (JNK) or FDA approved (Trametinib (MEK & ERK1/2)) can inhibit stress kinase networks, pro-motility gene expression and TNBC cell migration. Using patient-derived organoids that recapitulate heterogeneous TNBC molecular characteristics we successfully generated stable BACH1-knockout TNBC organoids. We utilized mass spectrometry-based techniques with a kinase inhibitor system (MIB-MS) and proteomics to characterize the activation state of kinase signaling networks in organoids and are investigating the effect of metastatic inhibitors on these pathways. Inhibition of these stress kinase networks should enable effective reprogramming of metastatic or high-risk cancers to more benign states and make tumors more susceptible to approved anti-proliferative therapies such as chemotherapy or immunotherapy while limiting toxicities from kinase inhibitors using a low-dose, multi-drug combination approach.

#1311 CREB-driven tumor cell invasion and ECM remodeling promote metastasis.

Sudhakar Jinka[1], Siddharth Mehra[1], Varunkumar Krishnamoorthy[1], Andrew M. Adams[1], Anna Bianchi[1], Luis N. Alberto[1], Yuguang Ban[2], Jashodeep Datta[1], Nipun Merchant[1], Nagaraj Nagathihalli[1]

[1]Department of Surgery, University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL,[2]Department of Public Health Sciences, University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL

Background: Pancreatic ductal adenocarcinoma (PDAC) is projected to become a leading cause of cancer-related mortality, driven by its late-stage diagnosis, aggressive progression, and propensity for metastasis. Currently, no approved therapeutic effectively targets PDAC metastasis. Emerging evidence implicates extracellular matrix (ECM), and cytoskeletal dynamics are key to invasion, a pertinent contributor to PDAC metastasis. Our previous studies identified cAMP-response element binding protein 1 (CREB) as a key regulator of ECM alterations in PDAC. This study investigates the role of CREB-ROCK in regulating tumor cell invasion and metastasis at the molecular level.

Methods: Expression profiles of *CREB* and invasion-related genes were analyzed using The Cancer Genome Atlas (TCGA) PDAC patient's dataset. CREB expression and localization were examined in PDAC patient's tissue microarrays (TMAs) and patient-derived xenograft (PDX) models. A novel conditional *Creb* knockout ($Creb^{fl/fl}$) model, in an $LSL\text{-}Kras^{G12D/+;}\ Trp53^{R172H/+;}\ Pdx1^{Cre/+}$ (KPC) background ($KPCC^{-/-}$), was generated to delineate CREB's role in PDAC progression and metastasis. Functional studies included lentiviral *creb* overexpression, CRISPR/Cas9-based *Creb* knockout, RNA sequencing (RNA-seq), and chromatin immunoprecipitation sequencing (ChIP-seq). Metastatic lesions were assessed in genetically engineered mouse and orthotopic models (GEMMs). Matrigel invasion assays, immunohistochemistry, immunoblotting, and qPCR were used to validate the findings *in vitro* and *in vivo*.

Results: TCGA analysis revealed elevated *CREB* and invasive gene expression in PDAC compared to normal pancreatic tissues. Immunostaining of TMAs showed increased CREB expression localized to ductal tumor cells. *Creb* knockout in $KPCC^{-/-}$ mice reduced metastatic burden, while *Creb* overexpression induced liver metastasis in orthotopic models. Invasion assays confirmed decreased invasiveness of tumor cells with CREB inhibition or deletion. CREB inhibition showed reduced expression of ROCK1/2, a key mediator of cytoskeletal dynamics and ECM remodeling. RNA-seq, qPCR, and ChIP-Seq analysis identified CREB as a transcriptional regulator of genes essential for invasion and ECM remodeling. CREB deletion or inhibition attenuated the expression of these targets, decreasing tumor cell invasion and metastatic potential.

Conclusion: These findings establish CREB-ROCK as a central mediator of PDAC metastasis and targeting CREB-ROCK represents a promising therapeutic strategy for inhibiting invasive PDAC progression and metastasis.

#1312 FOXF2 expression triggered by endocrine therapy orchestrates therapeutic resistance through reorganization of chromatin architecture in breast cancer.

Rui Zhang, Wen-Jing Jiang, Shuai Zhao, Li-Juan Kang, Qing-Shan Wang, **Yu-Mei Feng**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Estrogen receptor-positive (ER+) breast cancer accounts for 80% breast cancer cases. The estrogen-ERα signaling pathway plays a pivotal role in driving the progression of ER+ breast cancer cells. Thus, endocrine therapy targeting the estrogen-ERα signaling pathway is a predominant treatment for ER+ breast cancer. Most patients with ER+ breast cancer require long-term treatment with endocrine agents. Although endocrine therapy effectively improves the survival of patients with ER+ breast cancer, bone metastasis frequently occurs in patients receiving long-term endocrine therapy due to acquired resistance. Elucidating the molecular mechanisms underlying endocrine-resistance and developing effective strategies to reverse resistance or treat resistant tumors are crucial unresolved issues. Enhancer reprogramming-mediated lineage-specific transcriptional rewiring systemically regulates the transdifferentiation and plasticity of cancer cells. Enhancers are DNA regulatory elements composed of clusters of transcription factor (TF) binding sites. Enhancer-bound TFs recruit chromatin-modifying enzymes to establish unique histone modifications in enhancer regions, subsequently recruiting cofactors to facilitate or repress the transcription of specific target genes by reorganizing chromatin architecture and altering DNA accessibility. Our previous studies found that forkhead box F2 (FOXF2), a mesenchymal TF, is barely expressed in ER+/luminal breast cancer (LumBC) cells but is commonly expressed in triple-negative breast cancer (TNBC)/basal-like breast cancer (BLBC) cells with mesenchymal characteristics. In the present study, we found that ERα represses *FOXF2* transcription in ER+ breast cancer through H3K27me3 modification, therefore endocrine therapy triggers *FOXF2* transcription by loss of H3K27me3. *FOXF2* transactivation orchestrates endocrine-resistance and bone metastasis. Mechanically, FOXF2 globally activates enhancers of genes involved in epithelial-mesenchymal transition (EMT)/epithelial-osteogenic transition (EOT), as well as super-enhancers of *NCOA3* (a coactivator of FOXF2) and *SP1* (an upstream trans-activator of FOXF2) by recruiting SWI/SNF complex that mediates the reorganization of chromatin architecture. Targeting BRD4, an essential transcriptional coactivator of FOXF2, significantly inhibits FOXF2-orchestrated endocrine-resistance and bone metastases. Our findings uncover a mechanism underlying endocrine-resistance and provide a promising strategy for managing endocrine-resistant breast cancer.

#1314 Enhanced metastasis modeling in mice: impact of primary tumor removal and optimized injection techniques on therapeutic assessment.

Jonas Hummel, Philipp Metzger, Roland Sonntag, Dennis Borrero-Wolff, Gojko Bijelic, Cynthia Obodozie, **Holger Weber**

Reaction Biology Europe GmbH, Freiburg, Germany

The clinical potential of therapies on tumor metastases can be specifically tested on metastases that have naturally developed through the migration of the tumor cells from the primary tumor. Removing the primary tumor allows for a clearer assessment of a substance's efficacy in targeting metastatic sites alone, free from the influence of the primary tumor. If the primary tumor is still present during treatment, it is difficult to determine whether the reduction in metastatic spread is due to the anti-metastatic effect of the treatment or merely to the reduced growth of the primary tumor, which could indirectly limit the progression of metastases. In addition, the rapid growth of the primary tumor reduces the therapeutic window. The intra-mammary implantation approach (also referred to by us as subQperior for non-breast tumor cells) allows for clean surgical removal of the primary tumor, as the tumor remains isolated without adhering to the skin or peritoneum. This uncomplicated removal minimizes local trauma and residual primary tumor and provides a consistent basis for studying metastatic development after tumor resection.

The study of metastasis in mouse models following primary tumor removal provides essential insights into the progression and treatment of metastatic disease. In this context, the luciferase-labelled 4T1 tumor cell line, known for its high metastatic potential, offers a robust model, particularly for investigating lung metastasis. After subQperior implantation of mice, we show that 4T1 cells even at small tumor sizes metastasize rapidly, predominantly to the lungs, making this model highly suitable for evaluating therapeutic strategies against metastatic spread.

Furthermore, experiments with LL-2 tumor cells have shown that subQperior injection and removal of the primary tumor provides significantly better metastasis compared to traditional subcutaneous application. The approach of subQperior application not only increases the homogeneity and growth of the tumor and simplifies the removal of the primary tumor, but also comes closer to an orthotopic implantation with regard to the natural tumor environment and the progression of tumor growth. The advantages of subQperior injection suggest it may be a preferable method for achieving more consistent and representative metastasis in preclinical studies.

Together, the methodological improvement of primary tumor removal and refined injection techniques enable a more precise evaluation of drugs targeting metastasis, avoiding confounding effects associated with the presence of the primary tumor. By isolating the impact of therapies on metastatic sites, researchers can more accurately assess the effectiveness of anti-metastatic agents, advancing our understanding and treatment of metastatic disease.

TUMOR BIOLOGY: Novel Therapeutic Targets for Metastasis
Poster Session

#1317 Lung-specific CRISPR/Cas9 delivery using sulfonium lipid nanoparticles effectively suppresses lung metastases by targeting ATAD3A.

F. Chen[1], D. O. Popoola[2], F. Yang[1], W. Zhen[1], Y. Li[2], **Y. Teng**[1];
[1]Emory University, Atlanta, GA, [2]Upstate Medical University, Syracuse, NY

Metastasis is the leading cause of cancer-related morbidity and mortality. The lung is the second most common site of metastasis. It is estimated that 20 to 54% of malignant tumors that develop elsewhere in the body will have pulmonary metastases. However, limiting metastatic tumor growth and progression in the lung remains a significant bottleneck. ATAD3A, a mitochondrial-localized protein, has been shown to play a critical role in maintaining the growth and survival of metastatic tumors in the lung. The current challenge lies in genetically depleting ATAD3A in lung metastatic tumors. Among various mRNA delivery systems, lipid nanoparticles (LNPs) are the most advanced for clinical use. While clinical trials mainly focus on mRNA/LNP therapies for liver diseases, the potential for gene editing therapies extends far beyond this and remains underexplored. In our previous work, we developed lung-specific sulfonium lipid nanoparticles (sLNPs) for selective mRNA delivery to the lung. Building on this, we have now created CRISPR-based ATAD3A-targeting nanodrugs, termed ltLNP3AKO, which encapsulate Cas9 mRNA and anti-ATAD3A sgRNA in the lung-specific sLNPs. In an experimental mouse model of lung metastasis, intravenous administration of ltLNP3AKO efficiently and specifically delivered Cas9 mRNA and anti-ATAD3A sgRNA to the lung, where it successfully depleted the ATAD3A gene. Most notably, ltLNP3AKO induced significant regression of lung metastatic tumors without causing lung or systemic inflammation or toxicity in major organs. These groundbreaking results not only highlight the safety and efficacy of the lung-targeted sLNP platform, but also provide a novel approach to selectively inhibit ATAD3A in lung metastases. Our study further demonstrates the great potential to advance gene editing therapies for patients with lung metastases.

#1318 Cytotoxic effect of plant-based alkaloid veratridine on patient-derived colorectal cancer spheroid cells.

Kate Schraufnagel, Morgan Eikanger, Khosrow Rezvani

Division of Basic Biomedical Sciences, Sanford School of Medicine, University of South Dakota, Vermillion, SD

Colorectal cancer (CRC) causes approximately 900,000 deaths annually worldwide. The survival rate for patients diagnosed with localized CRC is 90 percent; however, once the cancer metastasizes or spreads to other parts of the body, the five-year survival rate drops to a dismal 15%. There is a clear need for a new generation of targeted therapies that can safely and efficiently target the metastatic features of CRC cells. Our lab has shown that veratridine (VTD), a lipid-soluble plant alkaloid, can enhance the expression of a ubiquitin-like protein called UBXN2A as a colon-specific tumor suppressor protein. UBXN2A binds and negatively regulates the Rictor protein, a key member of the mTORC2 signaling pathway. This results in suppression of mTORC2-AKT's downstream signaling pathway in cancer cells. We hypothesize that the VTD-UBXN2A axis decreases migration in human CRC tumors. Human colon cancer cells and patient-derived xenograft cell lines in 2D and 3D spheroid forms were used to complete this project. Real-time cell migration and invasion analysis using xCELLigence technology and Cytation 1 cell imaging system revealed the VTD-UBXN2A axis can suppress metastatic characteristics of CRC cells, including cell proliferation and migration. Small molecule targeted compounds have been successfully developed in clinical medicine to prolong the survival time of patients with advanced tumors. This ongoing study will provide detailed insight into the therapeutic efficacy of a potential targeted therapy to safely and effectively target CRC cells while normal cells can remain intact.

#1319 Luminal reprogramming, druggable mitogenic pathway activation, and rare outgrowth of occult basal cancers define ER loss in HR+/HER2- MBC.

Nolan Priedigkeit*[1], Stefania Morganti*[1], Alinés Lebrón-Torres[2], Kalie Smith[1], Melissa E. Hughes[1], Busem Binoga Kurt[1], Yvonne Y. Li[1], Hersh Gupta[1], Heather A. Parsons[1], Daniel L. Abravanel[1], Rinath M. Jeselsohn[1], Elizabeth A. Mittendorf[3], Adrian V. Lee[4], Steffi Oesterreich[4], Sara M. Tolaney[1], Andrew D. Cherniack[5], Nancy U. Lin[1], Ana C. Garrido-Castro[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Broad Institute of MIT and Harvard, Boston, MA,[3]Brigham and Women's Hospital, Boston, MA,[4]University of Pittsburgh, Pittsburgh, PA,[5]Broad Institute of MIT and Harvard, and Dana-Farber Cancer Institute, Boston, MA

BACKGROUND: Estrogen Receptor (ER) expression is often lost in treatment-refractory, hormone-receptor (HR) positive metastatic breast cancers (MBC). The biological mechanisms allowing tumors to maintain viability—without the key driver of HR+ disease—are relatively unknown. To better define this subclass of MBCs, we analyzed transcriptome and targeted DNA-sequencing data of HR+/HER2- cases that lost ER at the time of recurrence.

METHODS: A cohort of patients with primary HR+/HER2- breast cancer and subsequent loss of ER in the metastatic setting was identified. Loss of ER was defined as ER<1% in at least one metastatic sample. Transcriptome-capture RNA-sequencing was performed along with differential pathway analysis, PAM50 assignments, and fusion discovery. A subset of cases was analyzed with DNA-sequencing.

RESULTS: We identified 46 patients with ER loss and archival tissue. Of them, 21 patient-matched primary and metastatic pairs were interrogated with RNA-seq. The metastases were collected at a median time of 6 years [range 1-14] from the HR+/HER2- primary diagnosis. In contrast to prior studies of patient-matched tumors, metastases harboring ER loss were more often transcriptionally distinct from their primary tumor—with 15/21 metastases (71.4%) having a discordant PAM50 subtype. The most common discordances were tumors switching from LumA to HER2-Enriched or LumA to LumB (both in 5 of 21 cases, 23.8%). Notably, none of the HER2-E cases harbored *ERBB2* amplification. Luminal to basal switching was observed in two patients, but case review suggested the metastases being from occult primaries. Differential pathway expression analysis showed upregulation in mTOR, G2M checkpoint, and E2F pathways, suggesting selection of bypass mitogenic signaling in the absence of ER. Druggable features driving this transcriptional remodeling were identified, including an acquired in-frame 3' *BRAF* fusion and biallelic loss of *NF1* in two LumA to LumB cases. Further integration with clinicopathological features and DNA-level alterations will be presented.

CONCLUSIONS: Altogether, these results demonstrate significant transcriptomic shifts in HR+/HER2- cancers that lose ER in the metastatic setting. We find ER loss is associated with ER-independent transcriptional reprogramming and multimodal mechanisms of druggable mitogenic pathway activation. In rare cases, an apparent luminal to basal switch occurs—but these events likely stem from occult disease. Importantly, most ER loss cases do not become basal-like, but rather retain their luminal identity in the absence of ER and co-opt other mitogenic pathways to achieve a more proliferative, ER-independent state. We propose that triple-negative disease in the setting of ER loss is biologically unique from canonical basal-like tumors and could benefit from a distinct therapeutic approach.

#1320 Nanotopographical cues enhance glioblastoma migration: Harnessing biomimetic matrices and machine learning to uncover cancer invasion.

Christopher P. Miller[1], **Satvik R. Kethireddy**[2], Seung-Hyuk T. Lee[3], Patrick A. Ting[4], Alex Wu[2], Paul Lazarchuck[3], Raymond J. Monnat[3], Deok-Ho Kim[5], Eun Hyun Ahn[6]

[1]Department of Bioengineering, University of Washington, Seattle, WA,[2]Department of Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD,[3]Department of Laboratory Medicine & Pathology, University of Washington, Seattle, WA,[4]Department of Electrical and Computer Engineering, Johns Hopkins University, Baltimore, MD,[5]Departments of Biomedical Engineering and Medicine, Johns Hopkins University, Baltimore, MD,[6]Department of Biomedical Engineering, Johns Hopkins University, Baltimore, MD

Glioblastoma (GBM), the most aggressive brain cancer, invariably recurs after surgery and rapidly develops resistance to radiation therapy and chemotherapy. The invasiveness and genetic variation (heterogeneity) of GBM cells are major challenges for developing effective therapies. Furthermore, the study of glioblastoma invasion is particularly challenging due to the lack of robust experimental models that recapitulate the tumor microenvironment. To simulate *in vivo* brain tissue extracellular matrix (ECM), we have established nanotopographically defined extracellular matrix (ECM)-mimetic platforms. Moreover, to preserve the GBM cancer stem cell (GSC) phenotype and mimic tumor microenvironment, GBM cells were cultured on these nanopatterned surfaces in neuro stem cell media under hypoxia. The migration, motility, and morphological changes of the cells were analyzed using live cell microscopy and machine learning (ML). The migratory abilities of GBM cells were enhanced on these nanopatterned surfaces (cells elongate and move along the ridges) in comparison to unpatterned surfaces. Approximately 9 times more number of GBM cells migrated distances exceeding 400 micrometer along the direction of the ridges in the nanopatterned surface than the unpatterned surfaces. The MARS-Net ML analysis demonstrates that stromal nanotopography induces directional migration of GBM cells, and a 64% increase in skewness from rounded to more elongated cell shapes over time when compared to unpatterned surfaces. The genetic landscape of the GBM cells was characterized using whole exome sequencing (WES). About 55% of the single base substitutions (SBS) in GBM cells are missense mutations causing amino acid changes. The most prevalent SBS types are C>T/G>A, followed by T>C/A>G and C>A/G>T. We have developed radiation resistant GBM cells (rGBM) by expanding surviving cells after a series of cytotoxic x-ray treatments. rGBM cells exhibit higher migratory properties and colony formation abilities than normal GBM cells, implying they can be more invasive and oncogenic. Our results underscore the important role of nanotopographical cues in guiding GBM migration and invasiveness. To our knowledge, this study is the first to apply MARS-Net ML analysis to investigate changes in cell motility and morphology within an ECM-mimetic and hypoxic environment. The study has implications in the preclinical screening of anti-migratory chemotherapeutic agents and the molecular classification of glioblastoma.

#1321 Glycosylation dependent metastatic seeding of circulating tumor cells in breast cancer.

Nurmaa Khund Dashzeveg

Pharmacology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Chemotherapy has been standard of care for triple negative breast cancer for decades; however, how chemotherapy evasion enables metastasis remains elusive and is one of the biggest challenges impacting patient survival in cancer clinics. Circulating tumor cells (CTC) are pivotal component of longitudinal liquid biopsies. Most of the CTCs are detected as a single cell, whereas small proportion of CTCs are found in multicellular clusters which possess 20-100 times higher metastatic potential than single CTCs and corelates with unfavorable survival in breast cancer patients. Here we observed that chemotherapy evasion is linked to the aggregation of CTCs in breast cancer. Chemo-evasive linked aggregated CTCs show specific loss of ST6GAL1-catalyzed alpha2,6-sialylation. Deficiency of ST6GAL1 promotes CTC cluster formation for metastatic seeding and enables cellular quiescence to evade paclitaxel treatment in metastatic breast cancer. Glycoproteomic analysis identified protein substrates of ST6GAL1, such as adhesion and stemness markers PODXL, ICAM1, ECE1, ALCAM1, CD97, and CD44, contributing to CTC clustering (aggregation) and metastatic seeding. As proof-of-concept, neutralizing antibody against one of the most significant contributors, PODXL, inhibits CTC cluster formation and lung metastasis exacerbated by paclitaxel treatment for breast cancer. This study sheds light in the evaluation of chemotherapy response and developed potential therapy approach against chemotherapy resistance.

#1322 The DNA methylation signature of the driver gene GPRASP1 serves as an early indicator of progression in prostate cancer.

Chengyu Huang[1], Shuo Fang[1], Yuhao Cui[2], Xin Huang[2], Yuhan Lin[3], Yichen Xiao[2], Xinyu Ye[1], **Yi Lu**[2]

[1]School of Medicine, Southern University of Science and Technology (SUSTech Shenzhen), Shenzhen, China,[2]Dept. of Human Cell Biology & Genetics, the Guangdong-Hong Kong Joint Lab, Southern University of Science and Technology (SUSTech Shenzhen), Shenzhen, China,[3]Southern University of Science and Technology (SUSTech Shenzhen), Shenzhen, China

Prostate cancer (PCa) is one of the most common tumors in men in Europe and the United States. Patients with primary localized PCa typically demonstrate long-term survival. However, the disease becomes incurable once it progresses to metastatic PCa. Our research focuses on uncovering the early events in tumorigenesis and progression of PCa using multi-omics strategies. In this study, we identified several methylation driver genes associated with PCa by analyzing RNA sequencing and methylation data from The Cancer Genome Atlas (TCGA) database. The R package *Methymix* was applied to calculate the methylation driver genes. GPRASP1 was selected for further investigation due to its significant role in predicting PCa prognosis. Our analysis of two GEO datasets revealed that GPRASP1 is downregulated in primary PCa, with even lower expression levels observed in metastatic PCa. This finding was supported by immunohistochemistry results from tissue microarray of PCa patients, demonstrating reduced protein levels. Additionally, we identified the downregulation of GPRASP1 due to DNA methylation in its promoter region, as confirmed by targeted DNA methylation sequencing conducted in PCa and normal cell lines. Simultaneously, the use of DNMT inhibitors was found to reverse this downregulation. To investigate the function of GPRASP1 in PCa, we conducted RNA sequencing following the knockdown of GPRASP1 expression to assess changes in the transcriptome. Additionally, we analyzed its interactome using liquid chromatography-mass spectrometry (LC-MS) following immunoprecipitation. The results suggested that GPRASP1 downregulation may promote tumor metastasis through upregulation of CXCR4 and SERPINE1. Moreover, GPRASP1 appears to play a significant role in tumor immunity. To further elucidate this, we performed tumor infiltration analysis by several algorithms. These analyses revealed that GPRASP1 contributes to suppressing anti-tumor immune responses and promotes the remodeling of the tumor microenvironment, thereby facilitating tumor growth. In conclusion, this research identified methylation driver genes by analyzing data from TCGA patients. We specifically focused on GPRASP1 as a pivotal factor for its roles as a driver and its downstream functions in PCa. This investigation provided insights into the early changes associated with PCa and their connections to tumor initiation and progression. These findings enhance our understanding of the genomic landscape in the early stages of PCa and offer a novel approach for this condition's early diagnosis and treatment. This work was supported by the NSFC Project (82173336, 81972766, 81972420), The Science and Technology Project of Shenzhen (JCYJ20210324104214040), the Medical Research Innovation Project (G030410001).

#1323 Monoamine oxidase B: a potential therapeutic target for colorectal cancer.

Unnati Hemant Shah[1], Shivani Soni[1], Lesly Torres-Gonzalez[1], Joshua Millstein[2], Pooja Mittal[1], Francesca Battaglin[1], Karam Ashouri[1], Sandra Algaze[1], Priya Jayachandran[1], Wu Zhang[1], Jean C. Shih[3], Heinz-Josef Lenz[1]

[1]USC Norris Comprehensive Cancer Center, Los Angeles, CA,[2]Department of Population and Public Health Sciences, USC Keck school of Medicine, Los Angeles, CA,[3]Department of Pharmacology and Pharmaceutical Sciences, USC Alfred E. Mann school of Pharmacy, Los Angeles, CA

Background: Colorectal cancer (CRC) is one of the most prevalent cancers globally. Tumor recurrence occurs in approximately 30% of late-stage patients largely due to distant metastases. Angiogenesis plays a pivotal role in CRC progression. Recent studies have reported elevated expression levels of monoamine oxidases (MAO A and MAO B) in several cancers. However, the specific roles of MAO B in CRC progression and prognosis remain largely unexplored. Our previous work demonstrated improved survival outcomes and therapeutic efficacy of MAO A inhibitors in CRC preclinical models. In-silico analyses reveal that MAO B expression is significantly elevated in CRC tissues compared to normal tissues, correlating with higher recurrence rates and mesenchymal-type gene expression patterns.

Objective: This study investigates the therapeutic efficacy of MAO B inhibitors- deprenyl, rasagiline, and safinamide in CRC cell lines, assessing their potential to reduce metastasis through epithelial-mesenchymal transition (EMT) reversal and to study their role in modulating angiogenesis.

Methods: We studied the effects of MAO B Inhibitors on cell viability of CRC cell lines HCT116 and HT29 following treatment by MTS assay. Changes in EMT-related genes were analyzed at transcription and translation level through RT-qPCR, western blot, and immunocytochemistry (ICC). Scratch assays were used to evaluate the metastatic potential of treated cells, and RT-qPCR quantified angiogenesis-related markers.

Results: Our findings confirm that MAO B expression is significantly elevated in CRC cell lines-HCT116 and HT29 compared to normal colon cell - FHC. Treatment with MAO B inhibitors effectively reduced MAO B expression in CRC cells while showing no cytotoxic effect to normal colon cells with the same dose treatment. EMT marker analysis revealed a reduction in mesenchymal characteristics and an increase in epithelial markers, indicating a shift toward less metastatic phenotypes. Scratch assays demonstrated a decrease in metastatic potential in treated cancer cells, further supported by RT-qPCR results showing reduced expression of metastatic markers (N-cadherin, TWIST and Snail) and increased expression of epithelial markers (E-cadherin). We also observed a significant decrease in angiogenesis-related markers (VEGFR2) at transcription level. Western blot and ICC validated these findings at the protein level. Notably, HT29 cells (BRAF-mutant) exhibited greater sensitivity to MAO B inhibitors, showing better reduction in metastatic and angiogenic markers compared to HCT116 cells.

Conclusion: MAO B is a promising biomarker and therapeutic target for CRC. MAO B inhibitors effectively reduce metastatic and angiogenic potential in CRC cells, providing a novel approach for CRC treatment. These findings warrant further investigation to establish their clinical applicability and therapeutic potential.

#1324 MECOM a novel player in AR-driven treatment resistant castration-resistant prostate cancer.

Surendra Gulla[1], Tej K. Sharma[1], Ephraim Gardner[1], Shreya Shyam Sundar[2], Brian Capaldo[3], Jonathan E. Bard[1], Tobi Ogunbowale[1], Abbas Jawadala[1], Min Ma[1], Roberto Pili[1], Jun Qu[1], David J. VanderWeele[4], Remi Adelaiye-Ogala[5]

[1]SUNY at Buffalo, Buffalo, NY,[2]University at Buffalo, Buffalo, NY,[3]National Institutes of Health, Bethesda, MD,[4]Northwestern University Feinberg School of Medicine, Chicago, IL,[5]Medicine, SUNY at Buffalo, Buffalo, NY

The androgen receptor (AR) remains a pivotal target in castration-resistant prostate cancer (CRPC), as its continued activity presents a therapeutic vulnerability. Reprogramming of the AR cistrome, shifting from a canonical (typical or standard) to a non-canonical (atypical or non-standard) form, is associated with disease progression. While canonical AR signatures are prevalent in benign and localized prostate cancer, advanced CRPC exhibits a predominance of non-canonical AR elements. This non-canonical AR cistrome is linked to enzalutamide resistance, a standard AR-targeted therapy in the clinic. In preclinical prostate cancer models, non-canonical AR signatures correlate with enzalutamide resistance, and bulk RNA sequencing and AR-ChIP-seq data suggest an association with the EVI1-target gene set. EVI1, a zinc-finger transcription factor and product of the MECOM locus, is associated with poor prognosis and acts as a co-activator in cancer cell survival. Yet, its role in AR therapy resistance remains unclear. Functional assays demonstrated that MECOM expression, confined to CRPC and enzalutamide-resistant models, interacts with AR and influences cell proliferation. MECOM knockdown in CRPC cells inhibited proliferation in 2D and 3D cell cultures and significantly affected noncanonical AR signature profiles. This suggests a potential re-sensitization to AR inhibitors, a finding that could significantly impact the treatment of CRPC. Poly-ADP ribose polymerase inhibitors (PARPi), particularly Talazoparib, effectively reduced tumor growth in vivo and MECOM protein expression in CRPC cells, organoids derived from PDXs, and tumors. Our findings indicate that MECOM is a key driver of non-canonical AR signaling in CRPC. We propose that patients with MECOM expression may benefit from PARPi therapy, regardless of DNA Damage Repair (DDR) or homologous DNA Repair (HDR) gene mutation status.

#1328 Imaging tumor oxygenation during interstitial photodynamic therapy.

Emily Oakley-Gawrys[1], Irene Canavesi[2], Navin Viswakarma[2], Boris Epel[3], Mrignayani Kotecha[2], **Gal Shafirstein**[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]O2M Technologies LLC, Chicago, IL,[3]University of Chicago, Chicago, IL

Background: Interstitial photodynamic therapy (I-PDT) is a promising treatment for patients with large locally advanced or deeply seated tumors. In I-PDT, light is administered to activate a photosensitive drug (photosensitizer), which, in the presence of oxygen, results in the production of reactive oxygen species. In previous preclinical studies, we demonstrated that the light dose rate (irradiance, mW/cm^2) is a main predictor of tumor response to I-PDT. The objective of this investigational study was to perform electron paramagnetic resonance oxygen imaging (EPROI) during I-PDT of locally advanced murine tumors to investigate how changes in the delivered light irradiance, mW/cm^2, correlate to changes in tumor oxygenation.

Methods: C3H mice with locally advanced squamous cell carcinoma (SCC7), between 260-740 mm^3, were treated with I-PDT using the photosensitizer porfimer sodium administered at a dose of 5.0 mg/kg via tail vein injection. Interstitial light was delivered through two 2-cm light diffuser optical fibers placed 6 ± 1 mm apart in the tumor 24 ± 2 hours post the photosensitizer injection. The light intensity delivered from each fiber was either 60 mW/cm, which is associated with low light irradiance and low cure rate (n = 4) or 100 mW/cm, which is associated with high light irradiance and high cure rate (n=3). Partial oxygen pressure (pO_2) maps were acquired prior to and during I-PDT using a 25 mT/720 MHz EPROI instrument and tris(8-carboxyl-2,2,6,6-tetra(2-(1-hydroxy-2,2-d2-ethyl))benzo[1,2-d:4,5-d']bis(1,3)dithiol-4-yl) methyl trityl as the oxygen-sensitive contrast agent. Trityl was delivered to mice via intra-peritoneal injection (300µL, 36.1mM) followed by three intra-tumor injections (50µL, 20mM each). pO_2 maps were derived with following acquisition and reconstruction parameters: pulse sequence - inversion recovery electron spin echo, π/2 and π pulse lengths- 60 ns, spin-echo delay - 400 ns, 16-step phase-cycling, 828 projections, 1.5 G/cm gradient, 9 delays - 204 ns to 40 µs, TR - 45 µs, acquisition time: ~9 min, filtered back projection reconstruction, image resolution 1.32 x 1.32 x 1.32 mm^3, R_1-pO_2 calibration - slope: 111.23 torr/μs^{-1} & intercept: 0.16 μs^{-1}. Results: The mean pre-treatment pO_2 was 9.74 ± 2.37 torr. The average decrease in pO_2 as measured with EPROI was 77.8 ± 17.4% (n = 3) for the 100 mW/cm cohort and 63.0 ± 9.4% (n = 4) for the 60 mW/cm cohort.

Conclusion and Discussion: In conventional PDT, in which the light is administered to the tumor surface, a high irradiance is associated with high oxygen consumption and poor tumor response. In contrast to conventional PDT, the results from this study suggest that a high irradiance, which induces a high oxygen consumption, is required to obtain high cure rates and local tumor response following I-PDT. Future experiments are ongoing to correlate changes in the tissue oxygenation during I-PDT with the delivered light irradiance and overall tumor response.

#1329 Intraoperative light transmission: A translational dosimteric marker for tumor response in interstitial photodynamic therapy.

Cristopher Lawson[1], Emily Oakley-Gawrys[1], Sarah Chamberlain[1], Alan Hutson[1], Nathaniel Ivanick[1], Keith Cengel[2], Theresa Busch[2], **Gal Shafirstein**[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]University of Pennsylvania, Philadelphia, PA

Background: Interstitial photodynamic therapy (I-PDT) has shown promising outcomes in controlling locally advanced tumors refractory to standard of care therapies. I-PDT utilizes interstitial laser light delivery to activate a light-sensitive drug (photosensitizer) to produce singlet oxygen within the target tumor. The response to I-PDT is controlled by the intratumoral light dosimetry, photosensitizer concentration and tumor oxygenation. We hypothesize that changes in laser light transmission due to changes in tumor vasculature are a dosimetric marker for response to I-PDT. We test this hypothesis in murine models with locally advanced cancer.
Methods: The relationship between light transmission and tumor response was studied in eight- to twelve-week-old C3H and C57BL/6 female mice with locally advanced (400-600 mm^3) subcutaneous tumors. C3H with squamous cell carcinoma VII (SCCVII) or C57BL/6 with LL/2 (Lewis lung carcinoma) tumors were treated with I-PDT alone or with palliative x-ray radiotherapy (p-XRT) followed by I-PDT at 24 ± 2h after the second fraction of 10 Gy x2 over two days. The I-PDT was conducted with 2 mg/kg verteporfin for injection administered via intravenous tail vein injection 3 h prior to the intratumoral illumination with 689±3 nm laser light planned to generate a minimum of 5 mW/cm^2 and 30 or 37.5 J/cm^2 in the target tumor. The laser light was delivered through a single 2-cm cylindrical diffuser fiber and measured with a light dosimetry fiber at the tumor margins. Photoacoustic imaging was conducted before and after p-XRT and prior to I-PDT. Tumor progression was monitored over 60 days.
Results: In C3H mice with locally advanced SCCVII, the I-PDT produced a 20% (2/10) tumor control rate, while p-XRT followed by the same I-PDT regimen resulted in better ($p<0.05$, log-rank test) tumor control 88% (8/9). In the C57BL/6 mice with LL2, we observed tumor control at day 60 (0/18) in mice treated with I-PDT and 27% (5/18) complete tumor response at day 60 in mice treated with p-XRT followed by I-PDT. There was a significant improvement in light transmission ($p<0.05$, t-test for comparing differences of non-linear regression models) in tumors treated with p-XRT prior to I-PDT in comparison to tumors treated with I-PDT only. The photoacoustic imaging shows a significant increase in tumor blood flow ($p<0.05$, t-test) after the p-XRT and prior to the I-PDT.
Conclusions: Increased light transmission due to increases in tumor blood flow results in better tumor response to I-PDT. Changes in light transmission during I-PDT are a potential dosimetric marker to assess tumor response. This measure can be used in clinical settings to adjust laser power to increase light transmission to improve tumor control in I-PDT of refractory cancerous tumors.

#1330 *In vitro* and *in vivo* YTN16 gastric cancer response to low dose focal SmART+ X-ray irradiation.

Nathaniel Fredette, Yogindra Vedvyas, Yanping Yang, Moonsoo Jin

Houston Methodist Research Institute, Houston, TX

Background: Prior to 2018, no mouse gastric cancer cell line was implantable in C57BL/6 mice. However, now that this YTN16 mouse cancer model has been established, it can be used for evaluating various therapies in an immunocompetent strain. X-ray radiation therapy is a widely used cancer treatment known to cause DNA damage and dimmish a cells ability to proliferate. The Houston Methodist Research Institute has recently acquired a small animal radiation therapy (SmART+) machine developed by Precision X-ray Irradiation (Madison, CT). This machine is capable of image guided radiation delivery through lower energy computed tomography and 225 kV X-ray irradiation. The machine is designed for use with small animals such as mice, rats and rabbits, but is also capable of irradiation of cells in a dish.

Methods: The response of YTN16 cancer cells to SmART+ radiation therapy was studied in a 96-well plate and in both NSG and C57BL/6 mice. For the *in vitro* study, focal plane (at isocenter) X-rays were applied to the plate in six distinct quadrants (four by four well grids). The six quadrants of the plate were exposed to X-ray doses of zero (control), two, five, ten, twenty, and forty Gray. Bioluminescence (Tecan Spark) along with bright field and green fluorescent protein microscopy (EVOS M5000) was used to quantify cell survival. For the *in vivo* study, ten male NSG and ten male C57BL/6 mice were subcutaneously xenografted with one million YTN16 gastric cancer cells per hundred microliters media in a 50% - 50% mixture with Matrigel. Tumors were monitored with a caliper and allowed to grow until they were measured to be one hundred cubic millimeters. Mice were then divided into treatment groups of three mice per cohort with four mice in the control groups. After which, X-ray radiation was applied locally to the tumor in three doses of zero, ten, or twenty Gray. After radiation therapy, one mouse from each cohort was sacrificed and tumors were harvested for tumor microenvironment imaging. The remaining seven mice were monitored for weight loss and tumor shrinkage through scale and caliper measurements.

Results: In the dish, irradiated YTN16 cells showed survival characteristics like other gastric cell cancer lines such as RKO and SW480. In NSG mice, radiation slowed the progression of tumor growth and even caused some shrinkage. In C57BL/6 mice, heightened levels of T-cells and macrophages at the tumor site shown through imaging on the Akoya PhenoCycler show natural immune response to radiation. The level of immune activity was proportional to the radiation dose for the three dose cases explored herein.

Conclusions: Our studies demonstrate that focal SmART+ X-ray radiation can be used to slow or halt YTN16 gastric tumor growth in the petri dish and in immunodeficient and immunocompetent mice. Coupling X-ray radiation with other therapies such a T-cells may have the ability to reduce tumor activity completely.

#1331 Deciphering PSMA7 modulation by RT and TMZ for enhanced GBM treatments.

Christian A. Showalter, Priyani V. Rajasekera, Ramasamy Santhanam, Ashok Kumar, Karnika Singh, Xiaomei Meng, Sagarika Jain, Heather R. Manring, Saikh J. Haque, Arnab Chakravarti

The Ohio State University, Columbus, OH

Objective: Glioblastoma (GBM, WHO grade 4) is one of the most lethal malignancies, with limited advancements since temozolomide (TMZ) and radiation therapy (RT) became the standard of care nearly two decades ago. A critical challenge and overarching goal of our lab is to understand and overcome the resistance mechanisms that undermine these therapies. Using multi-omics profiling, we identified proteasome subunit alpha type-7 (PSMA7), a non-catalytic subunit of the 20S proteasome, as overexpressed in GBM. Elevated PSMA7 correlates with poor survival, and work by our group demonstrated its potential as a therapeutic target. This study investigated how RT and TMZ modulate PSMA7 expression, shedding light on its role in resistance and its feasibility as a target for novel interventions.
Materials/Methods: Patient-derived primary human GBM cells (08-387 and 3359) and normal human astrocytes (NHAs) were used. Protein expression was quantified by Western blot analysis. Cell viability was assessed by ATP assays. TMZ (*in vitro*: Sigma T2577; *in vivo*: SelleckChem S1237). A Rad Source 2000 irradiator was used to treat cells with ionizing radiation *in vitro*. *In vivo*, mice anesthetized with isoflurane were irradiated using a Clinac linear accelerator, with a 1.7-cm x 1.7-cm copper collimator targeting radiation to the tumor. Dosimetry was performed using GafChromic films placed under the irradiated area.
Results: GBM and NHA cell viability decreased with increasing TMZ dose *in vitro*. Western blots showed that PSMA7 expression did not change when GBM or NHA cells were treated once daily for three days with 300 or 600 μM TMZ. However, cleaved PARP expression increased in GBM cells treated with TMZ, but not in NHAs. *In vivo*, PSMA7 expression increased in flank tumors of mice treated with 50 mg/kg TMZ for five days starting at day 7 post-implantation compared to vehicle-treated mice. NHAs treated once daily for three days with 0, 2, 3, or 4 Gy RT had no change in PSMA7 expression *in vitro*, while GBM cells had decreased PSMA7 expression with increasing RT dose. We also performed an *in vivo* study where GBM cells were implanted in the flank of mice and tumors were treated with up to 14.70 Gy RT. Tumors were collected at mouse removal and PSMA7 expression examined by Western blot.
Conclusion: Our findings underscore the selective regulation of PSMA7 by RT and TMZ, highlighting its potential as a therapeutic target. RT's ability to downregulate PSMA7 supports the rationale for integrating PSMA7-targeted small molecule inhibitors into the standard of care following validation in preclinical and clinical trials. Such inhibitors, particularly blood-brain barrier-permeable derivatives actively under development in our lab, offer a promising strategy to synergize with RT and enhance the therapeutic landscape for GBM. By targeting PSMA7, we may overcome the limitations of current treatments and revolutionize GBM therapy by improving outcomes for this aggressive malignancy.

#1332 Major histocompatibility complex class I chain-related gene A and B expression induced by heavy ion beam irradiation in cervical cancer cells.

Sumitaka Hasegawa, Nakako Nakajima

Charged particle therapy research, National Institutes for Quantum Science and Technology, Chiba, Japan

Major histocompatibility complex class I chain-related gene A and B (MIC) are transmembrane glycoproteins to function as a ligand for human NKG2D that is a main activating receptor of NK cells. MIC is minimally expressed on normal cells, but frequently upregulated via viral infection, cellular stress signals, and malignant transformation. NKG2D recognizes MIC, resulting in the activation of NK cells. Recent progress on radiation biophysics has shown that photon or particle radiation can modulate anti-tumor immunity in host irradiated via regulation of immune recognition protein expression on cancer cells. The aim of this study is to investigate the effects of heavy ions beam irradiation on membrane MIC expression in human cervical cancer cells. We used HEK293 cells stably overexpressing HPV-E6 or E7 oncoproteins and 5 human cervical cancer cell lines in this study. Carbon ions beam irradiation (CIR, 290 MeV/n; LET, ~70 keV/μm, mono peak), a beam of heavy ion beams, was performed at the in-house synchrotron accelerator that is able to produce carbon ion beams. Irradiated doses ranged from 0 to 10 Gy of carbon-ions. Cell membrane MIC expression was evaluated by flowcytometry using an anti-MIC antibody. MIC expression was upregulated in HPV-E6 or E7 overexpressing HEK293 cells and 5 human cervical cancer cells in a dose-dependent manner. HPV16-positive human cervical cancer Caski cells showed a remarkable upregulation of MIC expression after CIR. Other cervical cell lines (ME-180, HeLa, SiHa, and C33A) showed a modest MIC upregulation. E6- or E7-overexpressing HEK293 cells exhibited a considerable induction of MIC expression after CIR. We investigated the impact of DNA damage responses on HIR-mediated MIC upregulation using drug inhibitors of proteins that are involved in DNA damage responses. Both pharmacological Chk1 inhibition and ATM inhibition cancelled CIR-mediated MIC upregulation in HPV oncoprotein-positive HEK293 cells. The results indicated that ATM/ATR-Chk1 pathways were involved in MIC upregulation on HPV-positive cells including cervical cancer cells. These findings support the favorable combination of MIC-targeted therapy with heavy ion therapy against cervical cancers.

#1333 Uncovering the mechanisms of action of ^{177}Lu- and ^{212}Pb- based PSMA radioligand therapies.

Feifei Liu, Melissa E. Monterosso, Didier Boucher, **Stelle Shakti**, Kwong Ching Li, Aimee Horsfall, Saawan Kumar, Johannes Koehbach, Kevin Kuan, William Tieu, Stephen Rose, Anna Karmann, Simon Puttick, Gary Li, Thomas Kryza

AdvanCell Isotopes Pty Limited, Sydney, Australia

Introduction: ^{177}Lu-PSMA-617 is the first FDA-approved targeted radioligand therapy (RLT), and in clinical trials, significantly prolonged survival and improved quality of life in patients with metastatic castration resistant prostate cancer (mCRPC). However, approximately 30% of the patients do not respond to the treatment and most initial responders ultimately relapse. Compared to the beta-emitter ^{177}Lu, the alpha therapy isotope ^{212}Pb may prove to be advantageous due to its short half-life, high linear energy transfer, and efficient induction of immunogenic cell death. Here we used *in vitro* and *in vivo* models to elucidate the intrinsic cellular mechanisms of response to ^{177}Lu-PSMA and ^{212}Pb-PSMA treatment.

Methods:^{177}Lu-PSMA-I&T and ^{212}Pb-ADVC001 were used as PSMA-targeted ^{177}Lu- and ^{212}Pb-RLT, respectively. The cytotoxic activity in prostate cancer (PC) cell lines was measured by a cell viability assay. *In vivo* studies were performed in human PC-bearing mice to compare preclinical efficacy of ^{177}Lu- and ^{212}Pb-PSMA therapy. The kinetic mechanisms associated with ^{177}Lu-PSMA-I&T and ^{212}Pb-ADVC001 mediated cell-death were assessed *ex vivo* using proteomics, and their impact on the PC cell cycle by flow cytometry.

Results: ^{212}Pb-ADVC001 displayed potent cytotoxic activity with an average EC50 of 2.7, 7.2 and 3.3 kBq/mL in PC cell lines PC-3-PIP (PSMA^{high}), C4-2 (PSMA^{int}) and LNCaP (PSMA^{int}), respectively, compared to ^{177}Lu-PSMA-I&T (430.7, 434.9 and 814.4 kBq/mL, respectively). In PSMA^{high} xenograft models, ^{212}Pb-ADVC001 (0.43 MBq) significantly improved median survival to 84 days compared to 48 days for ^{177}Lu-PSMA I&T (20 MBq). Multidose efficacy studies demonstrated superior tumor response with two cycles of ^{212}Pb-ADVC001 (0.46 MBq) compared to two cycles of ^{177}Lu-PSMA I&T (15 MBq). ^{212}Pb-ADVC001 administration in ^{177}Lu-PSMA I&T-relapsed mice resulted in improved survival. In PSMA^{int} xenograft models, ^{212}Pb-ADVC001 (0.9 MBq) also suppressed tumor progression more effectively than ^{177}Lu-PSMA-I&T (30 MBq), resulting in prolonged survival. Proteomics analysis of RLT-treated tumors revealed a specific impact of ^{212}Pb-ADVC001 on cell cycle checkpoints and DNA replication. *In vitro* cell cycle experiment further confirmed that ^{212}Pb-ADVC001 caused significant DNA damage, and reduced DNA content in the S-phase of the cell cycle with a concomitant increase in the G1 and G2/M-phase arrest compared to ^{177}Lu-PSMA-I&T ($p<0.05$).

Conclusion: Comparison studies of ^{177}Lu- and ^{212}Pb-PSMA treatment on PC cells showed a higher efficacy of ^{212}Pb-PSMA *in vitro* and *in vivo* supporting the clinical application of ^{212}Pb-PSMA for mCRPC. Mechanistic studies furthered the understanding of PC radiobiology and cellular responses to beta- and alpha-RLT with the identification of a cell cycle arrest in PC specifically induced by ^{212}Pb-PSMA.

#1334 FLASH proton radiotherapy mitigates corneal damage and stimulates wound healing in mice.

Elias El Hoyek[1], Uri Amit[1], Brent A. Bell[2], Vivian Lee[2], Joshua L. Dunaief[2], Costantinos Koumenis[1]

[1]Department of Radiation Oncology, University of Pennsylvania, Philadelphia, PA,[2]Department of Ophthalmology, University of Pennsylvania, Philadelphia, PA

Eye cancers are rare but highly aggressive, with significant risk to vision and quality of life. Worldwide, thousands are affected by ocular cancers, which are challenging to treat due to their proximity to sensitive structures. Proton radiotherapy (PRT) is the current gold standard for intraocular tumors due to its precision in limiting RT exposure to surrounding healthy tissue. However, the delicate location restricts the PRT dose that can be safely administered without risking damage to essential orbital structures. FLASH (FR), a novel approach delivering PRT at ultrahigh dose rates (>40 Gy/s) compared to standard dose rate PRT (SR, <0.003 Gy/s), has shown reduced toxicity in normal tissues like the brain and skin without compromising tumor control. However, its protective effects on eye structures remain unexplored. This study aims to investigate the potential of FR in preserving ocular tissues in a mouse model. Female C57BL/6J mice received 24 Gy of either FR or SR or remained untreated (control) using a "shoot-through" approach, in which both eyes received the same dose. Retinal and corneal damage were monitored using optical coherence tomography and confocal scanning laser ophthalmoscopy, with retinal vascular permeability evaluated by fluorescein angiography and retinal function by electroretinography (ERG). Corneal wound healing was assessed using corneal micro puncture. Evaluations occurred at one week, one, three, and five months post-PRT. Mice treated with SR showed significant corneal thickening and ulceration, leading to visual impairment, while those treated with FR did not. SR mice also showed declining ERG responses, suggesting diminished response to light stimuli, while FR mice demonstrated significantly less ERG abnormalities. Additionally, mice treated with SR showed over 55% reduction in eye surface area compared to both FR and control mice. Both SR and FR reduced retinal thickness, with no significant difference between the PRT treatment groups. Fluoresceine angiography showed no leakage in the retinal microvasculature. To further characterize corneal repair following PRT, we performed a corneal wound healing assay. Notably, FR demonstrated an enhanced wound healing response, with faster recovery of corneal incisions compared to both SR and control mice. This study presents a novel model for evaluating PRT-induced ocular damage, highlighting FR's potential to protect healthy tissues. FR was particularly effective in preserving corneal integrity and promoting wound healing, which are crucial for maintaining both visual function and cosmetic outcomes. Ongoing studies aim to quantify the preservation of stem cells in the corneoscleral junction as a potential mechanism for the observed tissue-sparing effects.

#1335 Comparison of X-ray and gamma-ray irradiators for in vitro and in vivo biological effectiveness.

Caroline Mae Mork[1], Shrey Ramesh[1], Keith Kunugi[2], Kwangok P. Nickel[1], Larry Dewerd[3], Nina Zitzer[4], Randall Kimple[1]

[1]Department of Human Oncology, University of Wisconsin Carbone Cancer Center, Madison, WI,[2]UW Medical Radiation Research Center, University of Wisconsin-Madison, Madison, WI,[3]Department of Medical Physics, University of Wisconsin-Madison, Madison, WI,[4]Department of Pathobiological Sciences, University of Wisconsin-Madison - School of Veterinary Medicine, Madison, WI

Objective: The Cesium Irradiator Replacement Program (CIRP) was established in 2014 to replace radioisotope-based irradiators with non-radioactive alternatives, such as X-rays. As most dosimetry is based on ^{137}Cs irradiators, transitioning to X-ray systems has presented challenges in radiobiological research. A key obstacle stems from the inaccurate assumption of dose as a directly transferable constant across different irradiation types. To mitigate this issue, the University of Wisconsin-Madison, as a CIRP participant, has undertaken a study to establish consistency in dose measurement and biological response, both in vitro and in vivo, with a specific emphasis on the relative biological effectiveness of X-rays compared to cesium.

Methods: Radiation dose was calibrated using experimental phantoms and thermoluminescent dosimeters. To determine dose response in vitro, HeLa cells were treated with 0 to 8 Gy of radiation in 2 Gy increments delivered from a ^{137}Cs, ^{60}Co, or 195 kVp X-ray source. Colony formation and comet assays were used to evaluate clonogenic survival and DNA damage, respectively. For in vivo studies, C57BL/6 mice received a single 8 Gy whole-body radiation dose from a ^{137}Cs, ^{60}Co, 220 kVp, or 300 kVp X-ray source. Lethal Dose$_{50/30}$ ($LD_{50/30}$) was used as the primary end point. Histopathological analysis of the spleen and bone marrow was performed to identify primary radiation-induced organ damage. Quantitative assessment of tissue injury was conducted using Halo image analysis. Hematology and blood chemistry were measured to monitor radiation-induced toxicity and subsequent recovery.

Results: The 195 kVp x-ray source produced the highest number of DNA double-strand breaks, followed by ^{137}Cs and ^{60}Co. This was most evident as the total radiation dose increased and translated to a greater impairment of clonogenic survival, particularly evident at 4, 6, and 8 Gy for 195 kVp X-rays. While ^{137}Cs and ^{60}Co had similar effects at lower doses, ^{137}Cs induced a more pronounced reduction in colony formation at 6 and 8 Gy. In animal studies, ^{60}Co exhibited the highest $LD_{50/30}$ (8.5 Gy), followed by ^{137}Cs (8.1 Gy), 300 kVp (7.3 Gy), and 220 kVp (6.2 Gy), respectively.

Conclusion: The differences were found in the biological effects between radioisotope-based and X-ray irradiators when delivered the identical physical dose. In animal models, radiation from a ^{60}C source demonstrated a weaker biological effect than ^{137}Cs, while 220 kVp X-rays showed the strongest biological effect. Given the differences in the energy spectra of the radiation sources, we will further investigate how dose-energy distribution influences biological effects in radiation-sensitive organs, particularly superficial tissues and hematopoietic systems.

#1336 Combination of gemcitabine and local tumor ablation WST-11 vascular-targeted photodynamic therapy displays superior efficacy compared to either monotherapy in a urothelial cancer model.

Kwanghee Kim[1], Sadna Budhu[2], Fengshen Kuo[1], Lilach Agemy[3], Stephen La Rosa[1], Sylvia Jebiwott[1], Karan Nagar[1], Chris Hughes[1], Jasmine Thomas[1], Laura Alvim[1], Rebecca Dubrovsky[1], Caoimhe Ryan[1], Daniel Rodriguez[1], Abraham Meyerson[1], Philip A. Watson[1], Natalia Kudinova[1], Andreas Aulitzky[1], Lucas M. Nogueira[1], Andrew T. Tracey[1], Wesley Yip[1], Phillip Wong[1], Taha Merghoub[2], Avigdor Scherz[3], Jonathan A. Coleman[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Weil Cornell Medicine, New York, NY,[3]Weizmann Institute of Science, Rehovot, Israel

Vascular-targeted photodynamic therapy (VTP) with the photosensitizing agent padeliporfin (WST-11/TOOKAD Soluble) has demonstrated safety and efficacy for upper tract urothelial cancer (UTUC) in phase 1 (NCT03617003) and ongoing phase 3 clinical trials (NCT0420239). Here, we conducted a correlative study to assess immune modulatory activities of VTP using peripheral blood mononuclear cells (PBMCs) from 19 UTUC patients treated with VTP in the phase 1 trial. We complemented these findings with a preclinical assessment of a potential combination strategy with the chemotherapeutic agent gemcitabine. The frequency of CD8+ T cells among the CD3+ total T cells in patient PBMC was increased immediately after VTP in complete and partial responders (CR and PR), but the increase was more prominent and durable among CR than PR/non-responder (NR), suggesting an association of treatment response with CD8+ T cell driven immune modulation. An analysis of VTP induced effect in ovalbumin (OVA) expressing MB49 bladder tumor model showed an increase in OVA-specific CD8+ T cells in the blood and tumor samples, suggesting an association of treatment response with CD8+ T cell driven tumor antigen specific adaptive response that may be durable. We also observed an immediate increase in the population of myeloid derived suppressor cells (MDSCs) in patient PBMCs up to 24 hours post-VTP among all treated patients. The chemotherapy gemcitabine has been previously shown to reduce MDSCs in many cancer types, which makes it a rational strategy to combine with VTP. Combination of VTP with gemcitabine exhibited statistically significant local tumor control of MB49 and prevented lung metastasis, thereby improving overall survival compared to VTP or gemcitabine alone. Assessment of systemic anti-tumor responses using a bilateral tumor model, re-challenge in surviving mice and host immune effect in $Rag1^{-/-}$ (lacking T-cell and B-cell populations) mice bearing MB49 suggests that there is a long-term systemic immune modulation and antitumor activity enforced by the combination of VTP and gemcitabine. Additional analyses by flow cytometry and immunohistochemistry suggests that the combination of gemcitabine and VTP induces both innate and adaptive immune responses.

#1337 Androgen receptor mediates radioresistance through autophagy and DNA repair in AR-positive prostate cancer.

K.-i. Kudo[1], Q. Feng[2], M. Chosco[2], L. Wenning[2], Z. Huang[2], J. Anzules[2], J. Mohan[2], N. Lin[2], Z. V. Wang[1], J.-W. Rhee[2], Y. Li[2];
[1]City of Hope Beckman Research Institute, Duarte, CA, [2]City of Hope National Medical Center, Duarte, CA

Background: Androgen receptor (AR) is a critical therapeutic target in prostate cancer (PC) and androgen blockade is known to act synergistically with radiotherapy (RT), however, the mechanisms through which AR modulates RT response is complex and remains poorly elucidated.
Aims and Methods: We compared the radiation responses in LNCaP (AR-positive), PC3 (AR-negative), and HEK293T (non-malignant) cells by analyzing DSB induction, cell cycle arrest, and apoptosis. Mechanistic studies, including AR silencing and inhibition, were validated through RNA sequencing and IHC analysis of cell lines and irradiated patient-derived prostate tumors.
Results: At 24-hours post-RT, the apoptotic rate increased by 6-fold in HEK293T and PC3 cells versus LNCaP cells. Cell viability at 48-hours post-RT was decreased to less than 10% in HEK293T, remaining at ~60% in LNCaP cells. Moreover, over 70% of LNCaP cells were arrested in the G_1 phase post-RT, accompanied by rapid p53 activation and p21 induction within 3-hours. AR silencing significantly increased radiosensitivity and reduced cell proliferation in LNCaP but did not alter the expression of p53 downstream genes, eg. *BAX* and p21. Interestingly, AR silencing reduced the phosphorylation of DNA-PKcs, a critical mediator of non-homologous end joining (NHEJ) repair, suggesting that AR facilitates NHEJ. This was further supported by the comet assay results showing that LNCaP repaired RT-induced DSBs more efficiently than PC3 cells.
Moreover, AR regulates autophagy post-RT as AR silencing decreased autophagy-related gene (ATG) expression, and macroautophagy was augmented in LNCaP cells post-RT through LC3-II expression and autophagic vacuole formation. Bulk transcriptome analysis revealed significant upregulation of 11 ATGs, including *ULK1* and *ATG2*, at 24-hours post-RT. Moreover, IHC analysis of patient-derived PC *ex vivo* irradiated tumors consistently showed that RT-induced autophagy supports the survival of AR-positive PC cells.
Discussion and Conclusion: Our results demonstrate that AR plays an essential role in mediating radioresistance in AR-positive PC by enhancing both autophagy and DNA repair, with ongoing spatial transcriptome analysis to further explore these mechanisms in patient-derived tumors.

#1338 System biological approach identifies heterochromatin modification as an important mechanism of acquired cancer radioresistance.

Chaw Yee Beh[1], Sharon Pei Yi Chan[2], Celestia Pei Xuan Yeo[1], Boon Hao Hong[1], Evelyn Mui Cheng Tan[1], Dewi Susanti[1], Pei Ling Tai[1], Eugenia Li Ling Yeo[1], Khee Chee Soo[1], Edward Kai-Hua Chow[2], Melvin Lee Kiang Chua[1]

[1]National Cancer Centre Singapore, Singapore, Singapore,[2]Cancer Science Institute of Singapore, Singapore, Singapore

Radiotherapy (RT) is an integral modality for the treatment of cancer, with >70% patients requiring RT. However, tumor responses to RT are heterogeneous and influenced by several intrinsic and extrinsic factors. Clonal dynamics have identified that in some cancers, radioresistance is dominated by a process of clonal selection and adaptation, thereby suggesting that tumor cells harbor an adaptive pro-survival mechanism to RT. To understand the mechanisms underpinning this process, we generated four radioresistant (RR) cancer models - prostate (22Rv1, DU145) and head and neck (FaDu, HK1) cancer cell lines by exposing them to 90 Gy over 45 fractions delivered over 12 weeks, which mimicked the fractionated radiotherapy schema employed in the clinic. First, WES revealed an enrichment of mismatch repair mutational signatures (SBS6, 14, 15, 20) across our RR models and identified several non-synonymous single nucleotide variants in RAD51AP1, SMC1A, and APC2 genes that are associated with pro-survival pathways. At the transcriptome level, we observed several up- and down-regulated genes across the 4 models, but were able to identify five common overexpressed genes - ATP8A1, BAHD1, CTSD, JAK1, and MYLIP. Over-representation pathway analyses highlighted the association of the BAHD1 gene with an activated heterochromatin formation pathway (rich factor=0.01, adjusted P-value=0.02). This corroborated WB and IF analyses showing an increased expression of heterochromatin markers (H3K9me3 and H3K27me3) in the RR cells post-irradiation, but not in their respective wild-type (WT) parentals. Knockdown of BAHD1 by siBAHD1 treatment consequently reduced the expression of H3K9me3 and H3K27me3 and reversed the RR phenotypes (Clonogeic SF_{2Gy} siBAHD1:control=1.72 [FaDu-RR], SF_{4Gy} siBAHD1:control=1.63 [22Rv1-RR]). Collectively, these findings point to the model that BAHD1-dependent heterochromatin formation is an acquired phenomenon integral to radioresistance in our models. Simultaneously, parallel high-throughput drug screening of our RR and WT cancer cells identified susceptibility to Panobinostat (Pano) - a pan-HDAC inhibitor in vitro and validated in vivo. Combinatorial Pano and AZD7762 - a Chk1 inhibitor exhibited stronger anti-tumor activity against the RR than WT cells (IC_{50}: 0.45 nm [RR] vs 0.60 nm [WT]). Downstream analyses of Pano-treated RR compared with WT tumors further indicated higher apoptosis and reduced proliferation in the former. Finally, knockdown of class I and II HDACs pointed to reversal of HDAC6 expression as the primary target of Pano. Herein, our systems approach of investigations of our RR cancer models uncovered the importance of the heterochromatin in acquired cancer radioresistance, and presented a potential new molecular vulnerability of RR cancer cells to targeting by epigenetic drugs.

#1339 Claudin 18.2-targeted ^{68}Ga-labeled NODAGA-SNA014 for gastric cancer imaging by PET.

Y. Yang, H. Qi, **Z. Qiao**, F. Sun, F. Li, J. Xu, T. Xu;
SmartNuclide Biotech, Suzhou, China

Introduction: Claudin 18.2 is a tight-junction protein with primary expression in nonmalignant gastric epithelium and limited expression in normal tissues. Its upregulation has been identified as the result of the malignant transformation of gastric epithelial tissue. CLDN18.2 therefore becomes a highly selective theranostic target for the development of gastric cancer radiopharmaceuticals. We preclinically evaluated ^{68}Ga-NODAGA-SNA014 as a novel PET imaging agent for gastric cancer.

Methods: SNA014 is a single domain antibody (SdAb) derived from alpaca immunization and screened out by phage display. SNA014 was then conjugated with NODAGA to enable efficient ^{68}Ga labelling. The binding property of ^{68}Ga-NODAGA-SNA014 was characterized by saturation binding assay on claudin 18.2-expressing AGS cells. Screening of renal uptake inhibitors was conducted by *in vivo* biodistribution studies on NDG mice bearing claudin 18.2-expressing tumors. Biodistribution properties, pharmacokinetic profile and competitive blocking effects were determined by *ex vivo* biodistribution studies on AGS 18.2-bearing NDG mice. Organ-adsorbed doses were estimated using OLINDA software to extrapolate to the adult female phantom the *ex vivo* biodistribution data of ^{68}Ga-NODAGA-SNA014.

Results: Radiolabeling was quantitative (>99%) after 15 min of incubation at room temperature. The saturable specific binding of ^{68}Ga-NODAGA-SNA014 indicated a dissociation constant of 2.18 nM. Gleofusine showed effective reduce in the kidney uptake of ^{68}Ga-NODAGA-SNA014 without lowering tumor uptake when compared to other inhibitors. The *ex vivo* biodistribution studies showed the tumor, kidney and stomach uptake of ^{68}Ga-NODAGA-SNA014 were at 15.57 ± 6.06, 6.15 ± 0.90 and 75.27 ± 7.93 %ID/g at 1 h postinjection, respectively. Competitive blocking assay suggested NODAGA-SNA014 was able to block uptake of ^{68}Ga-NODAGA-SNA014 at stomach in a dose-dependent fashion, ranging from 10 to 60 μg, without dramatically altering the tumor and kidney uptake. Pharmacokinetic profile revealed ^{68}Ga-NODAGA-SNA014 had a plasma half-life of 45.23 ± 3.87 min. In addition, the effective dose was estimated at 0.0608 mSv/MBq.

Conclusions: We developed a novel claudin 18.2-targeted PET agent ^{68}Ga-NODAGA-SNA014 for gastric cancer imaging. The ^{68}Ga-NODAGA-SNA014 showed specific *in vitro* binding to claudin 18.2, favorable *ex vivo* biodistribution properties in terms of tumor, kidney and stomach uptake, and safety profile based on dosimetry studies, which prompt us to further develop NODAGA-SNA014-based radiopharmaceuticals for radiotherapy.

#1340 Interstitial photodynamic therapy enhances the efficacy of immune checkpoint inhibitor in estrogen receptor high-expressing breast cancer.

Kohei Chida[1], Emily Oakley-Gawrys[2], Christopher Lawson[2], Amber McKenery[3], Craig M. Brackett[2], John M. L. Ebos[3], Kenichi Hakamada[4], Gal Shafirstein[2], Kazuaki Takabe[1]

[1]Department of Surgical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Department of Cell Stress Biology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Cancer Genetics and Genomics, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Department of Gastroenterological Surgery, Hirosaki University Graduate School of Medicine, Hirosaki, Japan

Introduction: Systemic chemotherapies improve the response to immune checkpoint inhibitors (ICIs) by provoking an immune response in primary breast cancer (BC). However, chemotherapy has systemic side effects, and recent clinical trials in estrogen receptor (ER)-positive BC have shown that higher expression of ER correlates negatively with response to ICI, even when combined with systemic chemotherapy. Photodynamic therapy (PDT) that uses light to activate a photosensitive drug not only ablates primary tumors but also enhances systemic immune response with minimal systemic adverse effects. We hypothesized that ER high-expressing BC will respond to ICI when combined with interstitial PDT (I-PDT), which allows deep light penetration with minimum skin damage by illuminating the tumor with optical fibers inserted directly into the tumor.
Methods: Two syngeneic murine BC cells tagged with luciferase (TS/A-luc: BALB/c background with high ER expression, and E0771: C57BL/6 background with low ER expression) were surgically inoculated into #2 mammary fat pad of 6-8 weeks old female mice. I-PDT (Verteporfin, 2 mg/kg and 689-nm laser light) with/without anti-PD-1 i.p. (200 µg/mouse) was performed when tumors reached 8mm. “Cure” was defined as the absence of detectable tumors by caliper measurement and bioluminescence 60 days after I-PDT.
Results: Response to I-PDT alone was compared between TS/A-luc and E0771-luc models with differing levels of ER expression. I-PDT treatment delayed the growth in all TS/A-luc tumors (6/6), whereas only half of E0771-luc tumors (3/6) were delayed. Among the mice that initially responded to I-PDT, 5 out of 6 mice with TS/A-luc and all 3 mice with E0771-luc demonstrated local recurrence, and the cure rates were 16.7% (1/6) for TS/A-luc and 0% (0/6) for E0771-luc models treated with I-PDT alone. Next, ICI treatment alone did not show any change in ER high-expressing TS/A-luc tumor growth, which is similar to what we see in human patients. On the other hand, the combination of I-PDT and anti-PD-1 demonstrated the cure rate of 43.8% (7/16) in TS/A-luc tumors.
Conclusion: Our study showed that I-PDT delayed the tumor growth in both TS/A-luc and E0771-luc syngeneic murine models. Further, I-PDT enhanced the efficacy of ICIs in TS/A-luc model, which expresses high ER. These findings show the potential of I-PDT as a combinatorial approach with ICIs in ER-positive BC.

#1341 A novel ATR inhibitor combined with radiation sensitizes an immunologically cold tumor to immunotherapy.

Mandira Manandhar[1], **Scott J. Bright**[1], Poliana C. Marinello[1], Jayesh B. Majithiya[2], Desiree Piscitello[2], Marco Ranzani[2], Helen Robinson[2], Graeme Smith[2], Gabriel O. Sawakuchi[1]

[1]Radiation Physics, UT MD Anderson Cancer Center, Houston, TX,[2]Artios Pharma, Cambridge, United Kingdom

ATR is a major DNA damage response (DDR) protein and an attractive target to combine with radiotherapy to amplify radiosensitization and immune-sensitization. ATR has several roles in DDR, including DNA double-strand break (DSB) repair through homologous recombination (HR) and S/G2 cell-cycle checkpoint control. Cancer cells can survive radiation-induced complex DNA lesions by their capacity to repair DSB lesions. The disruption of the G2/M checkpoint by ATR inhibition in cells with elevated DNA damage caused by irradiation increases micronuclei numbers, which activate the cGAS-STING pathway, promoting immune signaling. We hypothesize that inhibition of ATR radiosensitizes cancer cells to photons and protons and amplifies immune activation. To test our hypothesis, we treated H1299, H460 and 4T1 cell lines with a novel ATR inhibitor in clinical development, ART0380, prior to irradiation with 6 MV x-rays (photons) or 3.9 keV/µm protons. We then analyzed clonogenic cell survival [sensitization enhancement ratio (SER) and relative biological effectiveness (RBE)], cell cycle populations at 6 and 24 after irradiation, DNA damage (γH2AX and 53BP1 foci) at 1 and 24 h after irradiation, inhibition of HR (Rad51 foci) at 2 and 6 h after irradiation, micronuclei and cGAS colocalized micronuclei at 24, 48 and 72 h after irradiation, and expression of proteins involved in the cGAS-STING pathway at 24 and 48 h after irradiation. For *in-vivo* studies, syngeneic leg allograft tumors in Balb/c mice with the 4T1 murine breast cancer cell line were irradiated with 6 MV x-rays or 3.9 keV/µm protons (3×8 Gy) in combination with 100 mg/kg ART0380 BID for 3 days on/4 days off for 2 weeks. Tumor volumes were monitored. Compared to radiation alone, radiation+ART0380 decreased the G2 population and increased the mitotic population. Cell lines were also radiosensitized by ART0380 treatment (SER>1) and RBE was modulated. ART0380 treatment increased persistence of the DNA damage caused by radiation. We observed significantly more micronuclei and cGAS colocalized micronuclei in the radiation+ART0380 groups compared to radiation alone, validating our hypothesis of increased immune activation. Interestingly, protons+ART0380 induced a higher effect compared to photons+ART0380. To assess if the increased immune activation induced by the combination of ART0380 with radiation is clinically actionable, we combined in vivo radiation+ART0380 to anti-CTLA4 antibody in a tumor model that is resistant to anti-CTLA4 alone. Remarkably, we detected sensitization to anti-CTLA4 when it was combined with both protons+ART0380 or photons+ART0380. Overall, radiation+ART0380 sensitized an immunologically cold tumor to anti-CTLA4, with protons inducing long-lasting tumor regression. Protons combined with ART0380 may be a novel strategy to sensitize radioresistant and immunologically cold tumors to immunotherapy.

#1342 Double knockdown of RAD51 and RAD54 overcame the radioresistance in bladder cancer.

H. Ide[1], T. Murakami[1], E. Kashiwagi[2], S. Kitaoka[1], T. Shishido[3], M. Yamaguchi[1], M. Katsui[3], S. Funakoshi[3], H. Miyamoto[4], M. Oya[1]; [1]Keio University, Tokyo, Japan, [2]The University of Occupational and Environmental Health, Fukuoka, Japan, [3]Tokyo Saiseikai Central Hospital, Tokyo, Japan, [4]University of Rochester School of Medicine and Dentistry, Rochester, NY

Introduction and Objective: Radical cystectomy remains a main treatment for muscle-invasive bladder cancer (MIBC) because outcomes of radiotherapy (RT) have still been insufficient compared to surgery. Recent evidence indicated the involvement of DNA repair pathways with radio-resistance in MIBC. Previous study showed that RAD51 and RAD54 which promoted DNA repair cooperatively, were significantly associated with radio-sensitivity. More recently, our study demonstrated the significant association between estrogen receptor β signaling which was involved in radio-sensitivity in bladder cancer (BC), and their expression in it. However, there has been no study evaluating the relationship between RAD51/54 and radio-sensitivity in it. Therefore, we evaluated this association in BC cells.
Methods: We compared the inhibitory effect of RT on BC cell viability between control and RAD51 and/or RAD54 knockdown BC cells (5637 and T24) cells. Moreover, we evaluated it on tumor growth in a mouse xenograft model between irradiated control and their knockdown cells. We also compared DNA double-strand breaks (DSB) via γ-H2AX foci formation, and DNA repair gene expressions in these cells after RT.
Results: We then established radio-resistant cells and confirmed considerable elevation of the expressions of RAD51 and RAD54. *In vitro* experiments showed that RT reduced the viability in RAD51 or RAD54 knockdown cells more significantly than control cells. Moreover, double knockdown cells significantly reduced the cell viability more than each knockdown cell after irradiation *in vitro* and *in vivo*. Double knockdown of RAD51 and RAD54 resulted in a delay in DSB repair after RT.
Conclusions: These results suggest that inhibition of both RAD51 and RAD54 has a potential of enhancing the cytotoxic effects of radiation in BC cells.

TUMOR BIOLOGY: Uncovering How Secreted Factors Sculpt the Tumor Microenvironment
Poster Session

#1346 MYC-YTHDF1-IRF2BP2 axis drive tumor metastasis and immune escape in CMS2 colorectal cancer.

Ting Li[1], Yao Shang[2], Dongwen Chen[2], Chong Chen[2], Xinxin Huang[2], Yiran Bie[2], Zhengyu Wei[2], Zhengran Zhou[2], Chuling Hu[2], Xuanhui Liu[2], Yufeng Chen[2], **Peishan Hu**[2]

[1]Department of Gastroenterology and Urology, The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University/Hunan Cancer Hospital, Changsha, China,[2]Department of Colorectal Surgery, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Colorectal cancer (CRC) has a particularly low 5-year survival rate in patients with metastases. Based on the molecular and pathological characteristics of CRC, the disease can be classified into four consensus molecular subtypes (CMS1-4), with CMS2 being the most prevalent. CMS2 colorectal cancer is characterized by sustained activation of MYC, which drives the elevated expression of the m6A-binding protein YTHDF1. YTHDF1 (YTH m6A RNA-binding protein 1) is an m6A reader that facilitates mRNA translation and plays critical roles in tumor progression. However, its specific mechanisms in CRC remain poorly understood. Investigating the functional role of YTHDF1 could provide valuable insights for developing precise therapeutic approaches and combination treatment strategies for CRC.Interferon regulatory factor 2-binding protein 2 (IRF2BP2) encodes a member of the IRF2BP family of transcriptional regulators. IRF2BP2 is ubiquitously expressed in normal and tumor tissues across various organisms and is involved in regulating numerous cellular processes. However, its specific roles and mechanisms in CRC have not been elucidated. This study aims to systematically investigate the MYC-driven activation of the YTHDF1-IRF2BP2 axis and its impact on distant metastasis and immune evasion in CRC. Our findings aim to provide a foundation for identifying novel prognostic biomarkers and potential therapeutic targets for CRC.We analyzed YTHDF1 expression in CMS2 colorectal cancer using publicly available databases and patient samples from our center. Our findings revealed that CMS2 CRC exhibits elevated YTHDF1 expression, which is positively correlated with MYC expression. To validate the regulatory relationship between MYC and YTHDF1, we knocked down MYC in CRC cell lines. Western blot analysis demonstrated that MYC knockdown significantly suppressed YTHDF1 expression. Given that MYC is a downstream effector of the WNT signaling pathway, we treated CRC cells with the WNT activator Wnt3a, which resulted in increased MYC protein expression alongside enhanced YTHDF1 protein levels. Dual-luciferase reporter assays confirmed that MYC functions as a key transcriptional regulator, directly promoting YTHDF1 transcription.To identify downstream targets of YTHDF1, we performed RIP-Seq and proteomic profiling. Among the identified targets, IRF2BP2 was selected for further validation. Correlation analysis, Western blot, and RIP-PCR assays demonstrated that YTHDF1 regulates IRF2BP2 expression in an m6A-dependent manner. Functional studies and in vivo experiments showed that knocking down YTHDF1 or IRF2BP2 significantly inhibited CRC cell migration. These findings suggest that YTHDF1 promotes distant metastasis and immune evasion in CRC by regulating IRF2BP2, thereby contributing to CRC progression and malignancy.

#1347 The acidic tumor microenvironment drives stemness and chemoresistance in colorectal cancer through DHCR7.

Yiran Bie[1], Zhengyu Wei[2], Dongwen Chen[1], Yao Shang[1], Zhengran Zhou[1], Chong Chen[2], Chuling Hu[1], Xinxin Huang[1], Yufeng Chen[2], **Peishan Hu**[1]

[1]Guangdong Institute of Gastroenterology, The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China,[2]Department of Colorectal Surgery, The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Relapse and chemoresistance are critical determinants of poor prognosis in colorectal cancer (CRC). Cancer stem cells (CSCs) significantly contribute to chemoresistance and relapse in CRC. The acidic tumor microenvironment (TME) not only drives the emergence of CSC phenotypes but also impacts cholesterol metabolism reprogramming. However, whether the acidic TME influences CSC phenotypes and chemoresistance by modulating cholesterol metabolism remains to be elucidated.In this study, we utilized the ARGO and TCGA databases to identify cholesterol metabolism-related genes significantly upregulated under acidic conditions. The gene responsible for the final step in cholesterol biosynthesis, DHCR7(7-dehydrocholesterol reductase), was identified as highly expressed in advanced staging CRC and closely associated with poor prognosis in CRC patients.We confirmed that the acidic TME regulates cholesterol metabolism via DHCR7, thereby modulating cancer stemness and chemoresistance in CRC. Using DHCR7-overexpressing and control cell lines, we conducted subcutaneous tumorigenesis experiments in nude mice. Intratumoral injection of the DHCR7-specific inhibitor AY9944 in combination with oxaliplatin demonstrated that AY9944 enhances the cytotoxic effect of oxaliplatin on CRC by inhibiting DHCR7.To investigate the downstream mechanisms of DHCR7 in regulating the malignant phenotype of CRC, we performed transcriptomic profiling of the overexpressing and knockout cell lines. Differential gene analysis revealed an inverse correlation between DHCR7 and CLCA1 expression. Using CHIP-qPCR and dual-luciferase reporter assays, we confirmed that nuclear DHCR7 binds to the promoter region of CLCA1, suppressing its transcription and activating the Wnt/β-catenin signaling pathway. Additionally, at the cellular and organoid levels, we verified that cytoplasmic DHCR7 enhances cholesterol synthesis, thereby upregulating cancer stemness marker LGR5 expression.The acidic tumor microenvironment promotes DHCR7 expression. DHCR7 functions as a transcription factor in the nucleus to inhibit CLCA1 transcription and activate the Wnt/β-catenin pathway. Concurrently, it enhances cholesterol synthesis in the cytoplasm, leading to increased LGR5 expression. Together, these mechanisms drive the stemness and chemoresistant phenotypes of CRC cells. Our findings suggest that targeting cholesterol metabolism, particularly the key enzyme DHCR7, could inhibit CRC stemness and drug resistance, thereby improving patient prognosis.

#1348 Investigation of sex disparity in hepatocarcinogenesis using a hydrodynamic tail vein injection mouse model.

Araceli Selena Bernal[1], Morgana McLaughlin[1], Ankur Tiwari[2], Brittany Barre[1], Francisco Cigarroa[2], LuZhe Sun[1]

[1]Cell Systems and Anatomy, UT Health Science Center at San Antonio, San Antonio, TX,[2]Department of Surgery, UT Health Science Center at San Antonio, San Antonio, TX

The incidence of hepatocellular carcinoma (HCC), the major form of liver cancer, is two to three times higher in men than in women. Understanding the gender disparity in HCC incidence is challenging due to HCC development being multifactorial, including variations in risk factors, behaviors, and hormones. The liver is a sexually dimorphic organ, and estrogen has been proven to have a protective effect against the development of HCC, although the mechanism is not fully understood. We used the hydrodynamic tail vein injection (HTVI) mouse model of HCC to investigate potential mechanisms underlying the sex disparity of HCC incidence. This model eliminates social and behavioral aspects of gender disparity and allows us to determine if there is biological sex disparity and what role estrogen and androgens play in tumor development. In our preliminary study, the expression vectors of oncogenes, ΔN90-β-catenin and c-MET, to be integrated into the hepatocyte genome via transposons, were co-injected with a Sleeping Beauty (SB) transposase to induce HCC in FVB/NJ mice. Based on plasma alpha-fetoprotein (AFP), an HCC blood biomarker, male FVB/NJ mice had a significantly higher mean AFP trend in comparison to females, indicating that the males developed liver tumors at a faster rate than females. ΔN90-β-catenin and c-MET gene copy number were confirmed to be equally transfected and integrated in both male and female FVB/NJ tumors by quantitative PCR (qPCR). The expression of ΔN90-β-catenin and c-MET transgenes was also shown to be similar between male and female mouse HCC tumors by RT-qPCR and RNA-seq. We plan to repeat the HTVI of ΔN90-β-cat, c-MET, and SB to validate that the males will develop liver tumors at a faster rate than female mice. We will also Western Blot to determine if there is sex disparity in the abundance of the transfected oncogene proteins. In addition, we will compare the abundance of various types of immune cells present in the tumor immune microenvironment (TIME) to interpret potential sex-dependent immune cell differences in the tumor liver. Our research has the potential to uncover mechanisms underlying the sex-dependent disparity in HCC development and progression and the contribution of immune cells to the sex disparity.

#1349 Single-cell transcriptomic architecture deciphering the complexity of tumor microenvironment in ampulla of Vater carcinoma.

Hyemin Kim[1], Young Hoon Choi[1], Hyoung-oh Jeong[2], So Jeong Yoon[1], Yo Han Jeon[1], Hongbeom Kim[1], Sang Hyun Shin[1], Jin Seok Heo[1], In Woong Han[1], Kee-Taek Jang[1], Se-Hoon Lee[1], Kwang Hyuck Lee[1], Kyu Taek Lee[1], Jong Kyun Lee[1], Semin Lee[2], Joo Kyung Park[1]

[1]Samsung Medical Center, Seoul, Korea, Republic of,[2]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

Background: Ampulla of Vater carcinoma (AVC) is a rare gastrointestinal tumor that is associated with a high mortality rate and it's often diagnosed at later stages due to lack of clinical symptoms. Elucidating complex ecosystems and molecular features of AVC is pivotal to proactive cancer prevention and optimal therapeutic intervention.
Methods: We performed single-cell RNA sequencing (scRNA-seq) of treatment-naïve AVC biopsies (N=8), and bulk RNA sequencing of surgically resected tissues (N=62) to investigate the transcriptomic signature in tumor microenvironment (TME) of AVC.
Results: We analyzed the single-cell transcriptome of 34,672 cells and epithelial cells were classified into 4 subtypes by consensus non-negative matrix factorization (cNMF) based on their gene expression profiles. Among them, the $KRAS^{high}$ subtype showed more increased copy number variation than other subtypes and was less differentiated with a high stemness score. Moreover, the $KRAS^{high}$ subtype was reversely related to overall survival (OS) and enriched with granzyme K^{+} CD8 T cells. Deconvolution of bulk RNA-seq data validated the poor OS and progression-free survival (PFS) in the AVC patients with the $KRAS^{high}$ subtype. Also, it was revealed that this subtype was associated with early tumor recurrence in AVC.
Conclusions: We understood the heterogenous TME of AVC and found the prognostic biomarker to predict postoperative recurrence and survival in AVC.

#1350 *ESR1* expression as a predictive biomarker for immune checkpoint inhibitor efficacy in estrogen receptor-positive, HER2-negative breast cancer.

Jun Arima[1], Kohei Chida[2], Rongrong Wu[3], Kohei Taniguchi[4], Mitsuhiko Iwamoto[1], Takashi Ishikawa[3], Kenichi Hakamada[5], Sang-Woong Lee[1], Kazuaki Takabe[2]

[1]Department of General and Gastroenterological Surgery, Osaka Medical and Pharmaceutical University, Takatsuki, Japan,[2]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Breast Surgery and Oncology, Tokyo Medical University, Tokyo, Japan,[4]Center for Medical Research & Development, Division of Translational Research, Osaka Medical and Pharmaceutical University, Takatsuki, Japan,[5]Department of Gastroenterological Surgery, Hirosaki University Graduate School of Medicine, Hirosaki, Japan

Introduction: Immune checkpoint inhibitors (ICIs) hold promise for preventing late recurrence, a major cause of mortality in estrogen receptor-positive/HER2-negative (ER+/HER2-) subtype, which constitutes the majority of breast cancer (BC) cases. The response to ICIs is worse in this subtype compared to triple-negative breast cancer (TNBC). Recent clinical trials, CheckMate 7FL and KEYNOTE-756, have uniformly demonstrated that ER+/HER2- BC with less Estrogen Receptor (ER)-α staining in cancer cells shows a better response to ICIs. Considering the relatively precise quantification achievable through transcriptomic analysis, we hypothesized that ER-α gene (ESR1) expression level is a negative predictive biomarker of ER+/HER2- BC response to ICIs.
Methods: Total of 4138 BC patients from ten cohorts (GSE271080, I-SPY2 [GSE173839], TCGA, METABRIC, SCAN-B [GSE96058], GSE246613, GSE255107/GSE248288, GSE161529, GSE167036) were analyzed. High expression of ESR1 was defined as the top two-thirds of expression levels for each gene.
Results: In the ER+/HER2- subtype, high ESR1 expression was associated with significantly less intratumoral-Tumor Infiltrating Lymphocytes in both TCGA and METABRIC cohorts ($p<0.001$). High ESR1 expression was also associated with less infiltrations of CD8+ T cells, dendritic cells (DCs), cancer-associated fibroblasts (CAFs), a lower CD8/Treg ratio, and a lower cytolytic activity consistently in TCGA, METABRIC, SCAN-B cohorts (all $p<0.01$). Further, the low ESR1 group significantly enriched multiple immune-related gene sets, including IL2 signaling, TNF-α signaling, and interferon-γ response. In the I-SPY2 trial, high ESR1 expression correlated with lower pathological complete response rates after neoadjuvant immunotherapy ($n=50$, $p<0.001$). The predictive accuracy of ESR1 expression (AUC=0.88) exceeded that of PDL1 (AUC=0.60) in HR+/HER2- BC. Single-cell analysis (GSE246613) revealed negative associations between ICI response and ESR1 expression in cancer/normal epithelial cells, endothelial cells, and plasmablasts, as well as activation of estrogen signaling in these cell types. Notably, CAFs showed a positive association between ESR1 expression, estrogen signaling activation, and ICI response.
Conclusion: ESR1 expression is a promising predictive biomarker for ICI response in ER+/HER2- BC. Additionally, CAF infiltration and estrogen signaling activation in CAFs may enhance ICI response, highlighting their potential as therapeutic targets.

#1352 Extracellular adenosine suppress CD8+ T cell attraction resulting in poor prognosis in pancreatic ductal adenocarcinoma.

Eriko Katsuta[1], Yasushi Ichikawa[2], Kazuaki Takabe[3], Subhamoy Dasgupta[3], Daisuke Ban[1]

[1]Institute of Science Tokyo, Tokyo, Japan,[2]Yokohama City University, Yokohama, Japan,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: CD73 is a cell surface enzyme. Extracellular ATP and ADP are converted to AMP catalyzed by CD39, then AMP is converted to adenosine by CD73 in the tumor microenvironment (TME). Accumulating extracellular adenosine is known to play an immune suppressive role in TME of various cancers, however, its role in pancreatic ductal adenocarcinoma (PDAC) remains elusive. This study aimed to explore the role of CD73 in PDAC.
Methods: To examine CD73 role in PDAC, we used both bioinformatical and experimental approaches. We employed a publicly available dataset, The Cancer Genome Atlas (TCGA) to analyze clinical relevance by bioinformatic approaches. In order to confirm the findings and explore the mechanisms from the bioinformatical analyses, we conducted in vitro, in vivo experiments. Murine PDAC cell line, Panc02 was used together with overexpression technique.
Results: We found that high expression of CD73 was significantly associated with poor disease-free survival ($P<0.001$) and overall survival ($P=0.002$) in PDAC patients of TCGA cohort. Multivariate analyses revealed that CD73 was an independent prognostic factor in both disease-free ($P=0.001$) and overall survival ($P=0.005$). A deconvolution algorism, xCell showed that the CD73 high expression tumor showed less CD8+ T cell infiltration compared to the counterpart in TCGA cohort ($P=0.009$). There was no significant survival difference between the control and CD73 overexpressing PDAC cell bearing mice of carcinomatosis model when the experiment was conducted in immune deficient mice. On the other hand, when we implanted the cells into immune competent mice, CD73 overexpressing tumor showed significantly shorter survival ($P<0.001$). Further, the CD73 overexpressing tumor had less CD8+ T cell infiltration compared to the control mice ($P=0.041$). Co-culture experiments revealed that CD8+ T cell proliferation was suppressed when they were cultured with CD73 overexpression PDAC cells ($P=0.011$).
Conclusion: We found that high expression of CD73 was associated with poor prognosis along with less CD8+ T cell infiltration in PDAC. These results suggest that accumulated adenosine in the TME suppressed CD8+ T cell infiltration in CD73 high expression tumor.

#1353 Characterizing biological functional changes in cancer tumor microenvironment by integrating histology-based gene imputation with scRNA-seq foundation models.

Paveethran Swaminathan[1], Pengtao Dang[1], Haiqi Zhu[2], Zheng An[1], Xin Lu[1], Zhi Li[1], Yue Fang[1], Min Yang[1], Yuhui Wei[1], Tingbo Guo[1], Xinyu Zhou[2], Xiao Wang[2], Jia Wang[2], Chi Zhang[1], Sha Cao[1]

[1]Center for Biomedical Data Science, Oregon Health & Science University, Portland, OR,[2]Indiana University-Bloomington, Bloomington, IN

Background and Aim: Spatially resolved transcriptomics (SRT) offers insights into tumor microenvironments (TME), mapping gene and cell activities across tissue regions. While systems biology methods utilize SRT data to characterize tissue and cell neighborhood variations, high costs and limited scalability hinder large-scale applications and clinical correlations. In contrast, histological imaging (HI) provides accessible, high-resolution morphological insights with clinical context. Existing HI-based gene expression imputation methods rely on small datasets and cover a limited gene fraction, leaving much of the transcriptome unexplored. This study develops a robust framework for imputing spatially resolved gene expression profiles from HI data by integrating HI-based imputation with scGPT - a foundation models trained on single-cell RNA-seq (scRNA-seq) data. We hypothesize HI data can impute genes linked to TME, tissue structure, and cell types, while scGPT infers additional genes using gene and cell type-specific relationships.
Methods: The proposed framework merges an advanced HI-based gene imputation algorithm with scGPT to predict spatially resolved full-transcriptome profiles. The HI-based model first imputes 500-1,000 tissue structure- and cell type-dependent genes. We enhanced existing methods by (1) incorporating cross-pixel multi-attentions for spatial adjustments, (2) enabling residual connections to preserve early features, and (3) introducing a composite loss function for spatial coherence, gene-gene interaction preservation, and distribution alignment. Tissue annotations provide contextual information that enhances model predictivity. scGPT refines and expands predictions into whole gene profiles, leveraging its robust architecture to capture complex molecular relationships.
Results: The framework demonstrates strong performance across unseen specimens, achieving low mean squared error (0.38) and high correlations (0.79) while mitigating batch effects. Spatial heatmaps capture tissue heterogeneity, with tumor, immune, and stromal boundaries aligning well with annotations. Gene Enrichment analysis shows the model's capability to capture immune, stromal, and tumor compartments, though challenges remain for underrepresented genes. Integrating scGPT generates accurate and meaningful whole-genome profiles. This enables implementation of systems biology models for transcriptomics - including pathway, metabolism, stemness and CNV analysis - into HI data analysis.
Conclusion: This framework bridges histology and transcriptomics by combining advanced imputation algorithms with powerful capabilities of scGPT, enabling scalable, spatially resolved gene expression mapping. Its robust extrapolation transforms understanding of tissue biology and the TME complexity.

#1354 Identification of *GREM-1* and *GAS6* as specific biomarkers for cancer-associated fibroblasts derived from patients with non-small cell lung cancer.

B.-G. Kim[1], K. Park[2], M. Hwang[3], H. Lee[3], K.-M. Park[4], J. Choe[3], S. Shin[3], B.-H. Jeong[3], K. Lee[3], J. Lee[3], Y. Jeon[3], J. Cho[3], H. Kim[3], W.-Y. Park[2], **S.-W. Um**[3];

[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [2]Samsung Genome Institute, Seoul, Korea, Republic of, [3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of, [4]Kyung-Mi, Samsung Medical Center, Sungkyunkwan University Sc, Korea, Republic of

Background/Aims: Cancer-associated fibroblasts (CAFs) play a crucial role in the tumor stroma. They are primarily associated with tumor maintenance and promotion via diverse mechanisms in cancer. Using RNA sequencing, we conducted an analysis aimed at distinguishing distinct markers indicative of CAFs compared to normal fibroblasts (NFs) within the context of non-small cell lung cancer (NSCLC) across diverse conditions.

Methods: We conducted RNA sequencing analysis on 22 CAFs and 11 NFs from patients with NSCLC. CAFs and NFs were isolated and cultured from tumor tissues (primary tumor or metastatic lymph nodes) and from the most distant non-tumor tissues of the resected lungs, respectively, in NSCLC patients. We performed bulk-RNA sequencing analysis using total RNA from cultured cell pellets of CAFs or NFs. Differential expression, gene set enrichment and CAF subpopulation prediction analyses were performed.

Results: Notably, *COL11A1*, *GREM1*, *CD36*, and *GAS6* showed higher expression in CAFs than in NFs, whereas *TNC* and *CXCL2* were more highly expressed in NFs. *CD36* levels were elevated in CAFs from lymph nodes (LN-CAFs) compared with those from lung specimens (Lung-CAFs) and NFs. *COL11A1* levels in Lung-CAFs surpassed those in LN-CAFs and NFs. Both *GREM1* and *GAS6* showed strong expression in Lung-CAFs and LN-CAFs relative to NFs. CAFs exhibited features of the myofibroblast CAF subpopulation, whereas NFs displayed traits of the antigen-presenting CAF subtype.

Conclusions: In NSCLC, *GREM1* and *GAS6* can be valuable diagnostic and therapeutic targets for CAFs from primary tumors and metastatic sites; they warrant further study.

#1355 Inflammation-related gene signature as a predictor of survival in adrenocortical carcinoma: machine learning and bioinformatics analysis.

Jaber H. Jaradat[1], Lujia Chen[2], Anwaar Saeed[3], Azhar Saeed[4]

[1]Mu'tah University, Al-Karak, Jordan,[2]Department of bioinformatics, University of Pittsburgh, Pittsburgh, PA,[3]Department of Medicine, Division of Hematology & Oncology, University of Pittsburgh Medical Center, Pittsburgh, PA,[4]Department of Pathology and Laboratory Medicine, University of Vermont, Burlington, VT

Background: Adrenocortical carcinoma (ACC) is a rare malignancy with poor outcomes. Inflammation is increasingly recognized to play a significant role in the tumorigenesis of ACC. This study examines the relationship between inflammation-related genes and survival outcomes in patients with ACC.

Methods: We analyzed the RNA-seq and clinical data of 79 patients with ACC obtained from TCGA. Principal component (PC) analysis was performed on the expression data of 222 inflammation-related genes (MSigDB) to categorize patients into high and low inflammation groups (IG) based on the median of the first PC. Differentially expressed genes (DEGs) related to inflammation between the two groups were identified. Stepwise AIC identified the best model based on all DEGs, then genes were fitted to LASSO to mitigate multicollinearity. Uni- and multivariate Cox proportional hazards were used to identify independent predictors of survival. PC analysis was then conducted on the independent predictors of survival genes to compute the inflammation score (IS), with a cutoff point determined based on survival data. The correlation between IS and overall survival (OS) and disease-free survival (DFS) was assessed using the log-rank test. Clinical variables were investigated for possible association with the IS using Welch's t-, chi-square, Fisher's exact, and Wilcoxon tests. Immune infiltration analysis was conducted using CIBERSORT.

Results: Five inflammation-related DEGs associated with survival were identified, namely *ITGB3*, *MARCO*, *MSR1*, *SLAMF1*, and *SELE* with the first 2 identified as independent predictors. *ITGB3* is associated with worse OS (HR= 1.29, P= 0.036) and *MARCO* is linked to worse DFS (HR= 1.17, P= 0.048). Patients were split into high (n=39) and low (n=40) IGs based on inflammation-related DEGs. We calculated IS based on independent predictors of survival genes and the patients were grouped into high and low IS with a cutoff point of - 0.47 determined based on OS data (low IS n= 20, high IS n= 59). Log-rank test revealed significantly lower OS and DFS in the high IS group in comparison to the low IS group. No significant associations were detected between the IS groups and sex, age, T, N, & M stages, or the disease stage. The absolute immune fraction score was significantly higher in the high IS group compared to the low IS group, with means of 26.59 and 11.96, respectively ($P < 0.00001$, Welch's t-test). Gene Ontology (GO) analysis of the DEGs showed overrepresentation in biological processes associated with cell adhesion in high IS group and overrepresentation of processes related to mitochondrial function and energy production in the low IS group.

Conclusions: Our findings underscore the potential link between inflammation and survival outcomes in ACC and support the use of an inflammation-related gene signature as a prognostication tool for survival in this aggressive cancer type.

#1356 The lactylation of SLC26A3 in acidic micro-environment contributes to colorectal carcinoma malignant progression.
Chong Chen, Peishan Hu, Yufeng Chen

The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

A recently discovered post-translational modification, lactylation, can regulate the structure and function of proteins, influencing cellular functions and disease progression. However, its role in tumor progression remains unclear.This study explored the contribution of lactylation modification of solute carrier family 26 member 3 (SLC26A3) in acidic microenvironments to the malignant progression of colorectal carcinoma (CRC). The findings revealed that the acidic tumor microenvironment reduced the stability and expression of SLC26A3 by promoting its lactylation. co-IP experiment results showed SLC26A3 interacted with RNA-binding proteins HuR and CUGBP1, and when the expression of SLC26A3 was decreased, its binding capacity to HuR/CUGBP1 was weakened. This led to an increased interaction of HuR and CUGBP1 with a subset of oncogenic mRNAs, regulating their stability and expression, ultimately promoting the progression of malignant tumors. The study also indicated that the expression of SLC26A3 was negatively correlated with the expression of tumor stem cell markers, and low expression of SLC26A3 promoted the stemness of CRC cells. Furthermore, the expression of SLC26A3 affected the resistance to oxaliplatin (OXA), invasiveness, and migratory ability of CRC cells. In animal models, normalizing the tumor acidic microenvironment and inducing the expression of SLC26A3 inhibited the development of CRC.These findings highlight the role of SLC26A3 as a potential suppressor of CRC recurrence, drug resistance, and metastasis, providing new insights for improving the clinical treatment and prognosis of CRC.

#1357 miR-16-5p and miR-124-3p block the immunosuppressive phenotype of GBM cells in vitro.

TC Taylor[1], Amanda Johnson[2], Harmon Khela[1], Jack Korleski[3], Sophie Sall[1], Bachchu Lal[1], Karen Smith-Connor[1], Hernando Lopez-Bertoni[1]

[1]Hugo W. Moser Research Institute at Kennedy Krieger., Baltimore, MD,[2]Department of Neurology, Johns Hopkins University School of Medicine., Baltimore, MD,[3]Department of Internal Medicine, Mayo Clinic School of Graduate Medical Education., Baltimore, MD

A hallmark of GBM is its highly-immunosuppressive tumor microenvironment (TME). GBM stem-like cells (GSCs) can evade immune surveillance to allow for continued tumor growth and propagation. GSCs regulate the immune TME through recruitment and production of immunosuppressive cells and factors via tumor cell-intrinsic mechanisms. Blocking these cell-intrinsic immunosuppressive mechanisms is widely viewed as a way to enhance the effects of current immune therapies. We recently showed that TGFβ type II receptor (TGFBR2) promotes a mesenchymal transition in GBM cells characterized by high expression levels of immunosuppressive genes NT5E (CD73), ENTPD1 (CD73), LGALS1 (galectin-1), CD274 (PD-L1), PDCD1LG2 (PD-L2), and TGFB1. miRNA network analysis identified miR-16-5p and miR-124-3p as high-confidence candidates to block the expression of these immunosuppressive signaling axis in GBM cells. Transgenic miR-16-5p and miR-124-3p simultaneously reduced expression of CD274, ENTPD1, NT5E, TGFB1, and LGALS1 and increased tumor cell killing of PBMC-derived CD4+ and CD8+ T cells. We also measured an increase in drivers of the CD8+ effector state and a decrease in expression of exhaustion marker PD1 in PBMC-derived CD8+ T cells. In addition to the effects on CD4+ and CD8+ T cell activation and function, miRNA-mediated knock-down of this immunosuppressive gene signature in tumor cells also resulted in a decrease in CD206 expression and reduced release of anti-inflammatory chemokines in THP1 cells. These findings demonstrate that miRNA-based gene inhibition can block cell-intrinsic immunosuppressive pathways to enhance anti-tumor immune cell function in vitro and predicts that delivering these miRNAs using advanced nanocarriers will cooperate with current immunotherapies in vivo.

#1358 Single nuclei sequencing reveals altered gene expression and immune signaling in tumors from obese endometrioid adenocarcinoma patients.

Jessica L. Long[1], Sophia Agrusa[1], Swornalata Pukhrambam[1], Areebah Qazi[1], Katherine Gurdziel[2], Julie Boerner[1], Michael Wilson[1]

[1]Wayne State University School of Medicine, Detroit, MI,[2]Genome Sciences Core, Wayne State University, Detroit, MI

Over the past several decades, the incidence of endometrial cancer has risen. This trend is largely attributed to the increased prevalence of obesity and is especially pronounced in endometrioid adenocarcinoma, the most common histologic subtype of uterine cancer. These cancers are regarded as hormonally driven tumors and are linked to obesity through the production of aromatase, an enzyme that converts androgens into estrogen, in peripheral adipose tissue. Though the association between obesity and endometrial cancer is well-established, whether excess adiposity has an effect outside of this mechanism—and exactly how that hormonal imbalance perturbs the tumor and its microenvironment—is not well understood. Thus, to examine the impact of obesity on the cellular diversity and transcriptome of endometrial cancer and its microenvironment, we integrated single-nuclei RNA-seq data from seven obese and six normal-weight patients' endometrioid tumor samples. Through evaluation of marker gene expression patterns, we annotated seven clusters distributed across normal-weight and obese tumor samples. To pinpoint major changes in biological networks in tumor cells from obese and normal-weight patients, we performed single-nucleus pathway gene ontology analysis on differentially expressed genes. We then independently conducted Weighted Gene Correlation Network Analysis on the cancer cells in our normal and obese groups and compared the resultant networks. Our analysis revealed a large number of differentially expressed genes in both our cancer cluster and macrophage subcluster. In the cancer cluster, most of the differentially regulated genes were associated with estrogen signaling and epithelial-mesenchymal transition. The results from our Weighted Gene Correlation Network Analysis revealed large differences in the networks containing estrogen receptors. To model obesity in vitro, we treated 12Z endometrioid cells and KLE endometrioid adenocarcinoma cells with adipose-conditioned media derived from human omental tissue, which revealed large differences in cellular morphology. In our macrophage subcluster, our gene ontology analysis yielded differences in macrophage organization and function. Few tumor-infiltrating lymphocytes were detected, which is consistent with the classification of most endometrial cancers as immunologically “cold.” Overall, our results show that obesity influences gene expression in the endometrioid adenocarcinoma tumor microenvironment and tumor itself. Furthermore, the outcomes of our experiments provide additional insights into the impact of obesity on endometrioid adenocarcinoma outside of its role in estrogen signaling.

#1359 iNOS inhibition reprograms the tumor microenvironment enhancing antitumor immunity in obesity associated triple negative breast cancer (TNBC).

Ivonne Uzair[1], Fotis Nikolo[1], Sean Hynes[2], Gianmarco Melone[1], Karina Ortega[1], Jenying Deng[1], Wei Qian[1], Jianying Zhou[1], Liliana Guzman[1], Christoforos Thomas[1], Keith Chan[1], Jenny Chang[1]

[1]Houston Methodist Research Institute, Houston, TX,[2]University of Galway, Galway, Ireland

Purpose of the study: Obesity fosters an adverse tumor microenvironment (TME) characterized by immune suppression, metabolic dysfunction, and pro-tumoral cytokines. Elevated nitric oxide (NO) levels produced by inducible nitic oxide synthase (iNOS) exacerbate vascular dysfunction and metastasis. This study investigates whether combining the NOS inhibitor N(G)-monomethyl-L-arginine (L-NMMA) with docetaxel enhances antitumor efficacy in an obese TNBC model. Experimental Procedures: An orthotopic TNBC model was developed by injecting E0771 cells into the mammary fat pad of C57BL/6 mice fed either a normal diet (ND) or high-fat diet (HFD). Upon tumors reaching 100 mm^3, mice were randomized into vehicle and L-NMMA treatment groups. Immune phenotyping and TME composition were assessed using digital spatial transcriptomics. Results: HFD mice showed significantly accelerated tumor growth and elevated pro-inflammatory cytokines (TNF-α, IL-6, IL-17) and G-CSF levels, alongside reduced T-cell recruiting chemokines (Eotaxin, RANTES), indicative of a pro-tumoral inflammatory state. L-NMMA combined with docetaxel reduced tumor growth and lung metastases compared to single treatments. Heatmap clustering revealed HFD tumors exhibit a distinct immune profile compared to ND or HFD+LNMMA tumors. L-NMMA treatment decreased immunosuppressive macrophages and exhaustion markers, shifting the TME toward an immune-supportive phenotype like ND tumors. L-NMMA-treated HFD tumors displayed decreased expression of proliferation (Ki67) and survival markers (p53, pAktSer473). Immune profiling revealed fewer cancer stem cells (CSCs; $CD44^+CD24^-$), M2 macrophages ($F4/80^+CD206^+$), and exhausted $CD8^+$ T cells ($PD1^+$) in LNMMA-treated tumors, alongside increased $CD4^+$ T cells, dendritic cells, and plasma cells. Moreover, epithelial-mesenchymal transition (EMT) markers shifted, with elevated epithelial cells ($CD71^+$) and reduced mesenchymal cells (Vim^+), further supporting an antitumor shift. Conclusion: L-NMMA effectively remodels the obesity-altered TME, reducing tumor growth and metastasis while promoting an immune-supportive environment. Targeting iNOS with L-NMMA in combination with chemotherapy emerges as a promising therapeutic strategy to enhance TNBC treatment, particularly for obese patients.

#1360 Neutrophil extracellular traps establish the pre-metastatic niche in the omentum by expanding innate-like B cells that express IL-10.

WonJae Lee[1], Song Yi Ko[1], Hironari Akasaka[1], Melanie Weigert[2], Ernst Lengyel[2], Honami Naora[1]

[1]Molecular and Cellular Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Obstetrics and Gynecology, The University of Chicago, Chicago, IL

Disseminated cancer cells in the peritoneal fluid frequently implant on the omentum, an immune cell-rich fatty tissue that drapes from the stomach, but the underlying mechanisms are poorly understood. In this study, we identified that innate-like B cells accumulate in the uninvolved omentum of mice and women with early-stage ovarian cancer concomitantly with the release of chromatin fibers by neutrophils called neutrophil extracellular traps (NETs). Studies using genetically modified NET-deficient mice, pharmacologic inhibition of NETs, and adoptive B cell transfer showed that NETs induce expression of the chemokine CXCL13 in mesothelial cells in the pre-metastatic omentum, stimulating recruitment of innate-like B cells from the peritoneal cavity. Furthermore, studies using IL-10-reporter mice showed that NETs stimulate innate-like B cells to produce IL-10 that in turn expands regulatory T cells in the pre-metastatic omentum and potentiates metastasis at this site. *Ex vivo* studies showed that NETs elicit IL-10 production in innate-like B cells by generating reactive oxygen species and by inactivating SHP-1, a phosphatase that inhibits B cell activation pathways, through dissociating SHP-1 from CD22. These findings reveal that NETs alter immune cell dynamics in the pre-metastatic omentum and render this niche permissive for cancer cell colonization.

#1361 Severe hyperglycemia and hyperlipidemia alters tumor growth and immune profiles in syngeneic tumor models.

Hao Sun, Ying Zheng, Ryan Strauch, Yi Zhang, Minqi Huang, Luke Tsai

HD Biosciences Co., Ltd., San Diego, CA

Background and Objective: The global prevalence of obesity is increasing rapidly, causing the rise of obesity-associated diseases, such as diabetes and cancers. It has been established that obesity increases the risks for various types of cancers. Over the past decades, studies have proposed that obesity promotes cancer progression through mechanisms like chronic low-grade inflammation, which alters immune responses and the tumor microenvironment, ultimately affecting tumor response to therapies. Previous studies in diet induced obese models showed T cells in the colorectal cancer are reduced in obesity. However, it is not clear how the tumor microenvironment is changed under both severe hyperglycemia and hyperlipidemia in different types of cancers. This poster will highlight the changes of immune cell population in syngeneic tumor bearing mice with various cancer types in genetic obese models characterized by severe hyperglycemia and hyperlipidemia. Our study provides a detailed comparisons of how severe hyperglycemia and hyperlipidemia change the immune cells populations and tumor microenvironment in cancer. Notably, these changes observed in different cancer models provide insights into why the risk of various cancer types increases differently under conditions of severe obesity. In addition, we also provide a platform for studies on cancer therapeutics in hyperglycemia and hyperlipidemia mouse models.

Method and Result: db/db mice and C57BL/6 mice were fed with normal chow diet or high fat diet were used to examine syngeneic tumor growth kinetics. Changes of immune cells populations in different tissues were evaluated by FACS analysis. Both B16F10 melanoma and MC38 colorectal cancer tumors in db/db mice, with severe hyperglycemia and hyperlipidemia, grew significantly faster comparing to lean mice. Changes immune cells populations were observed in both models but differently. Although increased macrophages population is observed in both models, the obesity resulted changes of activated cytotoxic T cells and activated helper T cells were significant in blood and tumors from MC38 bearing mice but not B16F10 bearing mice. The results indicate that MC38 colorectal cancer exhibits more pronounced immune cell changes under obese conditions. RNAseq analysis in the tumor also revealed altered metabolic pathways and oncology pathways in the db/db mice, consistent with the observed faster tumor growth in db/db mice.

Conclusion: Hyperglycemia and hyperlipidemia in obesity promote the tumor growth of many types of cancers. The immune cell population, tumor microenvironment and tumor energy metabolism shift in hyperglycemia and hyperlipidemia condition, leading to an altered tumor growth rate and response to cancer therapies. HD Biosciences, a WuXi AppTec company, provides obese tumor models and have in vivo capability for preclinical cancer drug efficacy study in obese condition.

#1363 Cancer cell-derived exosomal microRNAs enhance immunosurveillance in long-term survivors of high-grade serous ovarian cancer.

Chi Lam Au Yeung, Marina A. Talor, Yadira J. Pacheco, Basant T. Gamal, Sammy Ferri-Borgogno, Samuel C. Mok

UT MD Anderson Cancer Center, Houston, TX

Epithelial ovarian cancer (EOC) is the leading cause of gynecologic cancer-related death in the United States. The major clinical determinant to ovarian patient survival was thought to be the effectiveness of the initial debulking surgery. A more recent study in a large clinical trial, however, showed that the existence of biological differences in advanced stage EOC, including genomic signatures and tumor microenvironment (TME), determined tumor complexity and debulking status and will ultimately affect overall survival. Current studies showed that cells in TME could communicate through the exchange of microRNAs (miRs) via exosomes, which are shed or secreted by almost all cell types, to exert biological functions. As a result, our goal was to investigate the roles of miRs in modulating the activities of various cell types in the TME and identify miRs and their targets that are associated with prolonged survival rates in advanced stage EOC to allow the development of new therapeutic regimens to the disease. To identify exosomal miRs that were transferred from ovarian cancer cells to various cell types in the TME, which modulate the malignant phenotype of HGSC, exosomal miRs were isolated and quantified from nine human HGSC cell lines using miR sequencing analysis. In-situ quantification of miRs identified in exosomes in HGSC tissue sections followed by Kaplan-Meier analysis demonstrated that miR-181c-3p overexpression is associated with improved survival rate in HGSC patients. Further functional studies showed that miR-181c-3p suppresses HGSC cell growth and was correlated with intraepithelial $CD8^+$ cytotoxic T cell (CTL) density. We identified two key immune-regulatory molecules, leukemia inhibitory factor (LIF) and Smad4, as potential direct gene targets of miR-181c-3p using online target prediction algorithms. Altering LIF expression in tumor-associated macrophages (TAMs) was also found to modulate CTL activity in the TME. These findings suggest the role of miR-181c-3p-LIF/Smad4 axis in $CD8^+$ CTL infiltration/activation/function, and subsequently in improving HGSC patients' survival rates. In conclusion, high-grade serous ovarian cancer (HGSC) expresses high levels of miR-181c-3p will secrete and transfer higher levels of exosomal miR-181c-3p to various cell types in the TME. The transfer of miR-181c-3p attenuates the growth promoting effects in cancer cells and endothelial cells and modulates TAMs, which will lead to increased densities of activated $CD8^+$ CTLs in HGSC, thereby improving patients' survival rates.

#1364 Low density lipoprotein cholesterol modulates anti-tumor activity of NK cells within NSCLC tumor microenvironment.

Ying Yang[1], Kai Wang[2], Andreas Lundqvist[1]

[1]Department of Oncology-Pathology, Karolinska Institutet, Stockholm, Sweden,[2]Department of Respiratory and Critical Care Medicine, The Fourth Affiliated Hospital, Zhejiang Univeristy School of Medicine, Zhejiang, China

Background: Non-small cell lung cancer (NSCLC) is a leading cause of cancer-related mortality worldwide. While immunotherapy shows promise for improving survival, reliable treatment response biomarkers are still lacking. Despite evidence showing that body mass index (BMI) link to immunotherapy benefits in NSCLC, the underlying mechanism remains unclear. Natural killer (NK) cells are critical for tumor eradication and hold promise in immunotherapy. This prompts the need for better understanding into the biological link between lipid metabolism and NK cells in tumor microenvironment (TME). Therefore, we sought to elucidate how lipids, particularly low-density lipoprotein (LDL) in the NSCLC TME influence NK function.
Methods: Primary tumor samples from a cohort of 20 patients with NSCLC were analyzed to assess correlations between tissue-resident NK cells and serum lipid profiles. Public TCGA-LUAD and GEO databases were analyzed to assess the clinical significance of LDL receptor-related gene expression in relation to NK cell infiltration in NSCLC. The effect of LDL/oxidized LDL (oxLDL) on NK cell infiltration was investigated in a 3D tumor model, where A549 lung cancer spheroids were co-cultured with NK cells isolated from healthy donor peripheral blood and analyzed via real-time imaging. NK cell cytotoxicity and phenotype were further assessed using flow cytometry.
Results: Analysis of surgically resected NSCLC tumors revealed a positive correlation between increased intra-tumoral NK cell populations and elevated serum levels of total cholesterol, LDL, and apolipoprotein B. *In vitro* co-culture experiments showed that LDL supplementation significantly enhanced NK cell infiltration into lung cancer spheroids ($p<0.001$). Notably, infiltrating NK cells exhibited higher levels of lectin-like oxidized LDL (oxLDL) receptor-1 (LOX-1). Analysis of the TCGA-LUAD cohort showed a positive correlation between LOX1 (*OLR1*) gene expression and NK cell infiltration, which also associated with improved overall survival (HR = 0.734, 95% CI 0.559-0.963, $p<0.05$). Furthermore, *OLR1* expression correlated with enhanced overall survival and progression-free survival in NSCLC patients treated with immune checkpoint inhibitors (ICI). NK cells treated with oxLDL exhibited enhanced killing capacity against A549 cells, potentially driven by an increased presence of $LOX1^{High}$ $CD107a^{+}$ and Granzyme B^{+} NK cell populations ($p<0.05$), along with elevated lipid raft formation ($p<0.05$) on NK cells following oxLDL exposure.
Conclusion: Our findings highlight the interplay between lipid metabolism and NK cell-mediated anti-tumor immunity in NSCLC, suggesting that enhancing LDL/oxLDL uptake by NK cells within the TME could provide a promising therapeutic strategy for advancing NK cell-based immunotherapy in NSCLC.

#1365 Histamine from mast cells protects against breast cancer recurrence.

Claire P. Schane[1], Adam T. Nelczyk[2], Cheng Chen[3], Shruti V. Bendre[1], Erin Weisser[4], Hashni E. V. Gamage[5], Mohammed Kadiri[6], Michael T. McHenry[7], Jiyoung Seo[1], Yu Wang[1], Natalia Krawczynska[1], Dhanya Pradeep[1], Lara I. Kockaya[1], Yifan Fei[1], Shin-Hsuan Hsiao[8], Nicki J. Engeseth[9], Michael K. Wendt[10], Timothy M. Fan[8], William G. Helferich[9], Erik R. Nelson[1]

[1]Molecular and Integrative Physiology, University of Illinois Urbana-Champaign, Urbana, IL,[2]Helixon US Inc, Champaign, IL,[3]University of Pittsburgh Medical Center, Pittsburgh, PA,[4]University of Illinois Chicago, Chicago, IL,[5]Medicine, Dana-Farber Cancer Institute, Boston, MA,[6]Rosalind Franklin University, Chicago, IL,[7]University of Illinois College of Medicine at Chicago, Chicago, IL,[8]College of Veterinary Medicine, University of Illinois Urbana-Champaign, Urbana, IL,[9]Food Science and Human Nutrition, University of Illinois Urbana-Champaign, Urbana, IL,[10]University of Iowa, Iowa City, IA

One in eight women will develop breast cancer in their lifetime. 20-30% of these women develop recurrent metastatic disease, for which clinical treatments have limited efficacy. Metastasis is thought to be a stepwise process, terminating with extravasation into distal tissues. After this distal extravasation, cancer cells do not always immediately proliferate, but remain dormant. These dormant cells may awaken through yet-unknown mechanisms. There is therefore an urgent need to better understand dormancy and reawakening to mitigate the risk of metastatic recurrence. Previous work from our group has shown that elevated circulating cholesterol, and particularly an oxidized metabolite 27-hydroxycholesterol (27HC), has a pro-metastatic effect with breast cancer. Bacon is a high cholesterol food that is often prepared in a highly oxidative pan-frying process. Using mouse models, we demonstrate that consumption of cured, fried bacon promotes metastatic recurrence from dormancy. Assessment of metastatic tissues showed that consumption of cured fried bacon fat dramatically reduced mast cell (MC) numbers. MCs are granulocytic innate immune cells whose function in reemergence from dormancy is not well characterized. Interestingly, depletion of mast cells also stimulated reemergence, suggesting that mast cells might be protective against cancer progression. A major mediator of MC function is histamine. Therefore, we used small molecules to test the effects of histamine. Importantly, histamine 2 receptor antagonism stimulates recurrence. RNA-Sequencing data revealed that H2-receptor antagonism yields a unique transcriptional profile enriched with genes associated with platelet activation. Subsequent work indicates that H2 antagonism primes platelets towards activation which then increases neutrophil NETosis. Thus, we establish a novel metastatic axis: *Diet - Mast cell - H2-receptor - Dormancy.* The ultimate goal is to leverage this axis to develop novel therapeutic targets or lifestyle interventions to prevent recurrence. This work was supported by the American Institute for Cancer Research grant (713063), the National Cancer Institute (R01CA234025) and Department of Defense Breast Cancer Research Program Era of Hope Scholar Award (BC200206). Further support awarded to CPS from the National Institute of Biomedical Imaging and Bioengineering of the National Institutes of Health under Award Number T32EB019944 and ATN from a National Institutes of Environment Health Sciences and Research Training in Toxicology and Environmental Health (T32) Fellowship (ES007326).

#1366 Single-cell gene expression profiling of the tumor immune microenvironment (TIME) and its association with immunotherapy response in syngeneic mouse models.

Jia Wang, Minjuan Deng, Bin Jiang, Han Yan, Yu Jiang, Siyuan Wang, Xiao Ding, Pei Zhang, Wei Jin, Zhirong Shen

BeOne Medicines, Beijing, China

The TIME, comprised of the extracellular matrix and a milieu of both immune and non-immune cells, plays a critical role in tumor development, disease progression, and response and resistance to immunotherapy. Much of our understanding of the TIME's immunological features, cellular heterogeneity, and associations with immunotherapy response have come from the use of syngeneic mouse models representing various cancer cell types. To provide further characterization of the TIME in syngeneic mouse lines commonly used for immunogenic drug discovery, Cd45+ single-cell RNA sequencing was performed in 10 syngeneic mouse models representing 7 distinct cancer types (breast mammary carcinoma: 4T1, EMT6, MMTV-PyMT; colon carcinoma: CT26.WT, MC38; glioma: GL261; renal adenocarcinoma: Renca; lung carcinoma: LL2; melanoma: B16F10; and pancreatic adenocarcinoma: Pan02). Further, to unveil cellular subpopulations that correspond to immunotherapy response, anti-PD-1 therapy efficacy studies were performed in the syngeneic models and correlations with the abundances of distinct immune cell populations were explored.

Across all syngeneic tumor lines examined, seven major immune cell populations were identified and subpopulations within T cells, NK cells, innate lymphoid cells, and distinct myeloid cells were characterized. Efficacy of anti-PD-1 treatment was positively correlated with a unique population of ISGhigh macrophages. Moreover, an over-representation of neutrophils and proliferating/C1Q+ macrophage subsets was observed in models exhibiting resistance to anti-PD-1 treatment.

These findings provide further characterization of these syngeneic lines to aid in rational model selection to facilitate translational relevance. This study also provides further insight into how immune cell composition and abundance within tumors may contribute to immune checkpoint blockade resistance.

#1367 Antigen recognition induces chemokine secretion to promote universal CAR-T cell infiltration.

Ruxuan Li, Youngbin Cho, Matthew Laird, Walter Kaminski, Elisa Ruffo, Jason Lohmueller, Ioannis Zervantonakis

University of Pittsburgh, Pittsburgh, PA

The lack of CAR-T cell infiltration and immune-mediated cancer cell destruction is a dominant mechanism of immunotherapy failure. The characteristics and mechanisms of cognate recognition induced CAR-T cell infiltration have yet to be revealed. In this study, we developed an in-vitro 3D collagen droplet co-culture system to simulate CAR-T cell infiltration in the tumor microenvironment and track T cell motility and interactions with tumor cells in real-time under different micro physiological environments. We employed CAR-T cells overexpressing the SNAP tag (SNAP-CAR T cells), where the contacts between CAR-T cells and HER2+ breast tumor cells can be initiated by adding benzyl guanin-conjugated Herceptin (BG-Herceptin). Quantification of infiltrating cell numbers showed that 3D collagen matrices with HER2+ breast tumor cells significantly recruited a higher number of SNAP CAR-T cells compared to cell-free matrices. Upon initiating the contacts between target and effector cells by adding BG-Herceptin, CAR-T cell infiltration to HER2+ breast cancer matrices were significantly increased. To investigate whether chemokine secretion mediates this process, we employed chemokine arrays. Chemokine secretion such as CCL2 were significantly higher with antigen-specific interactions. Further, CAR-T cell infiltration was inhibited by CCL2 neutralization, which indicates CCL2 plays a major role in cognate induced CAR-T cell infiltration. By analyzing CAR-T cell motility patterns, we found that CAR-T cell infiltration and interaction with tumor cells are dependent on cognate recognition. With BG-Herceptin, CAR-T cell interaction with and swarming around HER2+ breast tumor cells were significantly higher. By inhibiting CCL2, CAR-T cell motility was significantly impaired. Our findings suggest that CAR-T cell infiltration towards the solid tumors is dependent on antigen-specific interactions. Moreover, we demonstrated cognate induced chemokine secretion as a crucial factor in CAR-T cell infiltration and motility.

#1369 Chronic stress drives ovarian cancer progression via MDSC infiltration and notch signaling pathway activation.

Yadiel Alejandro Rivera-Lopez[1], Luinet L. Melendez-Rodriguez[1], Jaydiel A. Casiano-Martinez[1], Alanis P. Torres-Rosado[1], Sofia M. Hernandez-Carrasquillo[1], Melanie Ortiz-Leon[1], Luis M. Rivera-Perez[1], Zuliann S. Galarza-Ruiz[2], Orlando I. Torres-Rodriguez[1], Guillermo N. Armaiz-Pena[1]

[1]Ponce Health Sciences University, Ponce, Puerto Rico,[2]Interamerican University of Puerto Rico, Ponce, Puerto Rico

Ovarian cancer (OC) is the fifth leading cause of cancer-related deaths among women in the U.S. Studies indicate that cancer patients have elevated stress hormones due to various stressors, which can disrupt cancer progression and immune response in the tumor microenvironment (TME). Myeloid-derived suppressor cells (MDSC) are immature, immunosuppressive cells that play a crucial role in the TME and are associated with poor prognoses in cancer patients by disrupting several pathways, including the Notch signaling pathway (NSP). In various cancers, NSP dysregulation contributes to cancer progression. Increasing evidence suggests that chronic stress enhances MDSC infiltration, which promotes immunosuppression in the TME. However, the role of the NSP in stress-mediated MDSC infiltration and OC progression remains poorly understood. This study investigates how chronic stress affects NSP and MDSC biology in the OC TME and its role in disease progression. We hypothesize that chronic stress increases MDSC infiltration in the OC TME, enhancing NSP activity in OC cells. To test this, we inoculated female C57BL/6 mice with $ID8^{Luc}$ or $IG10^{Luc}$ OC cells and subjected them to daily restraint stress. Mice were sacrificed weekly for tumor and bone marrow collection, followed by immunofluorescence and flow cytometry analyses to characterize MDSC based on surface markers. We also isolated bone marrow from naïve C57BL/6 mice to differentiate myeloid cell precursors into MDSC. These cells were then exposed to stress hormones (norepinephrine (NE), epinephrine (EPI), and corticosterone (CC)) for 72 hours to analyze MDSC populations. Our results indicated that chronic restraint stress increased MDSC infiltration and enriched polymorphonuclear-MDSC (PMN-MDSC) in the TME and bone marrow of both OC mouse models. Results from the *ex vivo* experiments showed increased PMN-MDSC enrichment alongside a depletion of monocytic-MDSC in the groups treated with stress hormones. To further investigate the impact of stress hormones on NSP dysregulation, we treated OC cells (ID8 and IG10) *in vitro* with NE, EPI, or CC. Our findings revealed that stress hormones significantly upregulated the expression of the Notch Intracellular Domain (NICD) in OC cells. We also observed increased levels of Notch1, Jagged2, and Hes1 mRNA and protein, which may be mediated by GSK-3 phosphorylation. Additionally, we analyzed the expression of NSP members in tumors from the *in vivo* experiments. The results indicated higher expression levels of Notch1, Jagged2, NICD, and HES1 in tumors from mice subjected to restraint stress. These data suggest that chronic stress may induce MDSC infiltration and activity, possibly mediated by the activation of the NSP, thereby contributing to the immunosuppressive TME and progression of OC.

#1370 Antibodies derived from patient tumors augment response to immune checkpoint blockade in cancer.

Fridman[11], James P. Allison[12], Padmanee Sharma[13], Emily Z. Keung[1], Tina Cascone[14], Christina L. Roland[1], Alexander J. Lazar[5], Kevin M. McBride[2], Jennifer A. Wargo[1]

[1]Department of Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Molecular Carcinogenesis, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Sarcoma Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[5]Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[6]Department of Colon and Rectal Surgery, UT MD Anderson Cancer Center, Houston, TX,[7]Department of Epidemiology, UT MD Anderson Cancer Center, Houston, TX,[8]Department of Surgery, Medical College of Wisconsin, Milwaukee, WI,[9]Department of Surgery, University of Virginia Health Medical Center, Charlottesville, VA,[10]Department of Immunology, University of Pittsburgh, Pittsburgh, PA,[11]Department of Immunology, University of Paris, Paris, France,[12]Department of Immunology, UT MD Anderson Cancer Center, Houston, TX,[13]Department of Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[14]Department of Thoracic Head and Neck Medical Oncology, UT MD Anderson Cancer Center, Houston, TX

Background:Immune checkpoint blockade (ICB) has revolutionized treatments for cancer; however, only a minority of patients achieve a durable response. Landmark studies have now shown that B-cells and Tertiary Lymphoid Structures (TLS) within the tumor typify exceptional response to ICB. However, the functional role of B-cells and TLS in cancer remains largely unexplored. Here, we produce and evaluate the therapeutic efficacy of tumor-derived antibodies alone or in combination with ICB-based regimen.
Methods and Results:Tumors from high-risk resectable melanoma patients treated with neoadjuvant ICB were analyzed. Major pathologic response (MPR), defined as $\leq$10% viable tumor at the time of surgery, was used to evaluate response (R - responder; NR - non-responder). Formalin-fixed paraffin-embedded (FFPE) surgical resections were analyzed on NanoString GeoMx. TLS+ regions of interest (ROI) were selected based on melanoma (S100B) and immune markers (CD45 and CD20). Principal component (PC) analysis of ~18,000 probes revealed distinct transcriptional profiles between R and NR TLS, with PC1 strongly correlating with response status ($r=0.88$, $p<0.0001$). Differential immune analysis showed that R TLS were enriched for CD8+ T-cells ($p<0.001$), NK cells ($p=0.004$), γδ T-cells ($p=0.017$), and memory B-cells ($p=0.026$). Pathway analysis indicated an upregulation of NK-cell mediated cytotoxicity pathways in R TLS. Targeted BCR sequencing performed on fresh surgical resections from 12 high-risk, resectable melanoma patients (R=9, NR=3) yielded 1277 unique BCR amplicons and 546 unique heavy and light chain-matched antibodies. In silico analysis revealed that BCR clones from R tumors showed higher levels of somatic hypermutation ($p=7.2e-9$) and isotype switching (50.1% in R vs 32.6% in NR). Flow cytometry and immunofluorescence microscopy identified 73 unique antibodies (R=59, NR=14) that bound to A375 human melanoma cells in vitro. Next, an in vitro ADCC assay (NK:tumor ratio of 10:1) was used to identify that 10 of the 73 melanoma-binding antibodies induced significant cell death of both A375 human and BP ($Braf^{V600E}Pten^{-/-}$) murine melanoma cells. In vivo experiments in BP melanoma bearing mice revealed that 4 ADCC+ antibodies (RAPC5-7-156, RAPC5-9-9, RAPC5-9-8, and RAPC5-9-98) homed to the TME within 24 hours of systemic administration. Remarkably, when combined with αPD-L1, RAPC5-7-156 significantly reduced BP melanoma tumor growth compared to mice treated with isotype control ($p=0.0003$) and α-PD-L1 alone ($p=0.005$). Importantly, melanoma derived RAPC5-7-156 did not demonstrate this synergistic effect in ICB-treated MC38 colon carcinoma or LLC1 Lewis lung carcinoma models.
Conclusion:These findings suggest that tumor-resident antibodies are capable of augmenting response to ICB thus presenting new opportunities for target discovery and for improving clinical outcomes with ICB.

#1371 ChemoNETosis is associated with chemotherapy resistance in pancreatic cancer.

Shohei Nogi, Shunsuke Kagawa, Atsuki Taniguchi, Nobuhiko Kanaya, Yoshihiko Kakiuchi, Kazuya Yasui, Satoru Kikuchi, Shinji Kuroda, Hiroshi Tazawa, Toshiyoshi Fujiwara

Gastroenterological surgery, Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

Background: Chemotherapy resistance is a major contributor of the poor prognosis of pancreatic cancer, yet its underlying mechanisms remain poorly understood. Neutrophil Extracellular Traps (NETs), a form of neutrophil-specific cell death, have been reported to be associated with poor prognosis in various cancers because they act to suppress tumor immunity and promote metastasis. Recently, chemotherapy-stimulated NETs, termed “ChemoNETosis”, were reported to contribute to chemotherapy resistance in breast cancer (Mousset A, Cancer cell. 2023). Therefore, we investigated the role of NETs in resistance to cytotoxic chemotherapy in pancreatic cancer.
Methods: The abundance of NETs in the tumor microenvironment was analyzed in relation to chemotherapy efficacy using immunohistochemical staining of resected specimens from pancreatic cancer patients treated with neoadjuvant chemotherapy. The ability of pancreatic cancer cells to induce NETs was assessed with and without gemcitabine stimulation by extracellular DNA staining in vitro and by immunohistochemical analysis in vivo. Finally, the efficacy of the combined anti-NETs treatment and gemcitabine was examined in a mouse subcutaneous tumor model.
Results: NETs were more abundant in unresponsive tumors compared to responsive tumors in clinical sample. Gemcitabine-treated pancreatic cancer cells induced significantly higher levels of NETs than untreated cells in vitro as well as in vivo tumor models. This “ChemoNETosis” was effectively inhibited by Navarixin, a CXCR2 inhibitor. Combination therapy with Navarixin and gemcitabine achieved greater tumor reduction compared to gemcitabine alone with, a complete response (CR) rate of 28.6% (2/7) vs 0% (0/7).
Conclusion: NETs may play a key role in chemotherapy resistance in pancreatic cancer. Targeting NETs could provide a novel approach to enhancing the efficacy of chemotherapy in preclinical models and warrants further investigation.

#1372 Development of a multi-omic spatial phenotyping assay for affirmative detection of CAR-T cells in the tumor immune microenvironment of solid pediatric tumors.

Jasmine T. Plummer[1], Felipe Segato-Dezem[1], Yutian Liu[1], Arjumand Wani[1], Hannah Chasteen[1], Arne Christians[2], Jannik Boog[2], Randy Chen[3], Harry Choi[3], Aneesh Acharya[3], Oliver Braubach[2], Giedre Krenciute[1], Jason Chiang[1], Christopher De Renzo[1], Kelsey Bertrand[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]Bruker Spatial Biology, Seattle, WA,[3]Molecular Instruments, Los Angeles, CA

Certain pediatric cancers, like blood leukemia, have shown high cure rates, but effective treatments of solid tumors remain elusive and survival rates for affected children remain low. While CAR-T therapy has demonstrated success in treating acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL), its effectiveness against solid tumors has been limited. Yet, pediatric patients with solid tumors may still receive CAR-T therapy with minimal prior evidence of treatment efficacy. It is imperative to understand why CAR-T treatments succeed or fail in solid pediatric tumors, as such knowledge can guide the development of future treatment options. This study focuses on a pediatric patient enrolled in a Phase 1/2 clinical trial exploring the use of CAR-T therapy for solid tumors. The patient underwent tumor resection before receiving CAR-T therapy (PRE). Following treatment, the tumor did not respond, leading to recurrence and a second resection (POST).Using advanced spatial transcriptomic profiling we compared the tumor immune microenvironment (TiME) between the PRE and POST treatment samples. Our findings revealed significant differences, including changes in immune cell populations and the spatial distribution of T cells in the TiME. However, while we observed alterations in T cell distribution, the precise localization of CAR-T cells relative to other cell types remained unclear. To address this, we developed a novel targeted spatial multi-omics assay that combines next-generation RNA fluorescence *in situ* hybridization (HCR™ Gold RNA-FISH) with multiplex immunofluorescence (mIF). HCR™ Gold RNA-FISH is broadly compatible with protein imaging methods, and therefore enables RNA and protein co-detection on the same tissue sample, which is needed to affirmatively detect and map the putative infiltration of CAR-T cells in the TiME. CAR-T cell detection was enabled by custom-designed HCR™ HiFi probes, targeted against B3-H7. Affirmative identification, phenotyping, and spatial profiling of these cells were enabled via VistaPlex™ mIF assay panels deployed serially on the same formalin-fixed paraffin-embedded (FFPE) tissue samples. All experiments were automated on the CellScape™ spatial biology platform and image data were processed and integrated with a custom image analysis pipeline. Our method enables conclusive follow-up investigations into the efficacy of CAR-T treatments in solid pediatric tumors. With this toolkit in hand, it is possible to (a) confirm the status of the CAR-T cell infiltration, (b) define the phenotype and activation states of these cells, and (c) map the spatial biology and cell-to-cell interactions of the CAR-T cells within the TiME.

#1373 Adenosine-driven immune profile in breast cancer.

Xi Chen, Yong Qin

The University of Texas at El Paso, El Paso, TX

Adenosine accumulation in tumor microenvironment (TME) suppresses T cell activation and effector functions, posing challenges for immune therapies in cancers, including breast cancer (BC). Upregulated adenosine A2A receptor (A2AR) has been observed in BC tumors compared to normal tissues. However, the immune patterns shaped by adenosine signaling across BC subtypes, particularly triple-negative breast cancer (TNBC), remain poorly understood. To examine adenosine-driven immune profile in BC, we analyzed 138 tumor cores from 69 BC patients using multiplex immunofluorescence staining for 12 markers: CD73, A2AR, CD8, CD4, CD56, FOXP3, CD68, CD11b, Ki67, PD-1, Glut-1, and IDO, alongside the nuclear marker DAPI. Our findings revealed elevated levels of A2AR, CD68, CD4, CD8, Ki67, PD-1, and Glut-1 in BC tumors, indicating a TME enriched with CD4+ T helper cells, C8+ cytotoxic T cells, and CD68+ macrophages. Tumors with high A2AR expression exhibited increased PD-1+ immune infiltrates and elevated Ki67 levels, suggesting that A2AR activation impairs T cell function and promotes tumor proliferation. A2AR was predominantly expressed on CD4+ and CD8+ T cells, suggesting the connection among adenosine receptor activation, immunosuppression, and tumor growth. We further explored the role of CD73, an enzyme converting AMP to adenosine, in the BC TME. CD73+ tumors showed significantly higher infiltration of CD4+ cells, CD56+ NK cells, CD68+ macrophages, and PD-1+ immune cells compared to CD73- tumors. CD73 expression, linked to adenosine production, was tied to an adenosine-rich TME increasing immune infiltration but reducing immune functionality, characterized by elevated PD-1 and IDO expression. Additionally, PD-1+ immune infiltrates correlated with higher levels of CD4+, CD8+, CD68+, and CD11b+ cells and increased IDO expression. High CD73 levels correlated with elevated CD68+ macrophage and PD-1 expression, despite greater CD4+ T cell infiltration. These findings suggest that CD73-driven adenosine signaling contributes to an immunosuppressive TME, even with immune cell presence. In TNBC tumors (n=16), Glut-1 expression, a hypoxic marker, was significantly higher than in non-TNBC tumors (n=49), indicating a more hypoxic and adenosine-rich TME. TNBC tumors also showed a higher proportion of CD73+ tumor cells. Ki67 analysis levels revealed higher cancer cell proliferation in TNBC compared to HER2+ tumors (n=17), indicating TNBC's aggressive nature. In conclusion, BC tumors display unique immune profiling linked to adenosine signaling within the TME. High A2AR and CD73+ expressions are associated with tumor proliferation and immunosuppressive infiltrates driven by adenosine and PD-1 signaling. The hypoxic, adenosine-rich TME in TNBC highlights adenosine regulation's critical role in progression. These findings underscore adenosine as a promising therapeutic target for developing anti-tumor strategies, particularly for TNBC patients.

#1374 Targeting lipid-laden macrophage efferocytosis enhances immune response to EGFR-tyrosine kinase inhibitor in EGFR-mutant lung cancer.

Sook-Hee Hong[1], Nahyeon Kang[1], Okran Kim[1], Juyeon Park[1], Soon Auck Hong[2]

[1]Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea, Republic of,[2]Department of Pathology, College of Medicine, Chung-Ang University, Seoul, Korea, Republic of

During macrophage phagocytosis, efferocytosis is the process of removing senescent or apoptotic cells and, unlike phagocytosis, induces anti-inflammation, angiogenesis, and wound repair. Inhibition of efferocytosis, one of the macrophage responses to apoptosis induced by EGFR-TKIs, may enhance their immunologic effects. We analyzed early immune microenvironment changes following osimertinib treatment in an human EGFR L858R genetically engineered mouse model, focusing on the effect of tumor-associated macrophage (TAM) efferocytosis signals on the immune microenvironment in response to osimertinib-induced tumor cell apoptosis. Methods: Doxycycline-induced transgenic mice (human EGFRL858R) were maintained with doxycyclin-impregnated food pellets to activate rtTA protein phosphorylation. Tumor progression and treatment response were monitored by MRI. Lung tumor development was confirmed, and mouse immune cells were isolated by CD45 MACS for single-cell RNA sequencing. Immediate immune profile changes after osimertinib or osimertinib and MERTK inhibitor (LDC1267) treatment were analyzed (days 1, 5, 15). All animal experiments were approved by the Institutional Animal Care and Use Committee of the Catholic University of Korea. Results: Six macrophage clusters were identified from scRNA-seq of the human EGFR-mutated lung cancer transgenic mouse model. These were categorized as antigen-presenting, alveolar, IFN-responsive, proliferative, and lipid-containing macrophages, with the latter further divided into cluster 2 (*Lepr, Dapk1, MerTK, Olr1, Adarb1*) and cluster 4 (*FSTL1, Fabp5, Gpnmb, S100a1*). Osimertinib treatment increased the proportion of cluster 2 from 8.9% to 13.4%. The top GO terms enriched in cluster 2 included response to oxidative stress, wound healing, immune response activation, tissue remodeling, and response to hypoxia, which demonstrated activated efferocytosis. In vitro macrophage co-culture models showed MerTK-mediated efferocytosis occurring 24 hours post-osimertinib treatment, MerTK inhibition of macrophage significantly decreasing CD206 expression and increasing pSTAT3 in U937 macrophages. Osimertinib and LDC1267 (MERTK inhibitor) combination treatment in the human EGFR mutant lung cancer mouse model increased pSTING expression in macrophages and inducing type 1 IFN response. The combination also enhanced CD8 T cell activation, evidenced by increased IFN-γ, TNF-α, granzyme, and CD25 expression compared to osimertinib alone (days 5 and 15). No change was observed in the CD44+/CD62L-/CD8 T cell population. Conclusions: EGFR-TKI-induced tumor cell death stimulated macrophage efferocytosis. Inhibiting macrophage efferocytosis can increase the type 1 IFN response, potentially inducing of starting immunogenic cell death.

#1375 Active inhibition of chemokine-mediated migration impairs tertiary lymphoid structure formation.

Victoire Boulat[1], Elena Alberts[1], Carin Andrea Brundin[2], Dinis P. Calado[1], Anita Grigoriadis[1]

[1]The Francis Crick Institute, London, United Kingdom,[2]King's College London, London, United Kingdom

The presence of tumor-infiltrating B cells (TIL-B) and tertiary lymphoid structures (TLS) in the primary tumor microenvironment carries prognostic value across cancer types. We have shown that triple-negative breast cancer (TNBC) patients with robust germinal center (GC) responses in their lymph nodes (LN) exhibit higher levels of TILs and more TLS. In this study, we investigated human and mouse immune-cold TNBCs to uncover mechanisms by which tumor-LN crosstalk may be impaired.

In orthotopic TNBC mouse models, we observed robust GC responses in tumor-draining LNs. However, minimal TIL-Bs and no TLS were detected in the primary tumors. The tumor-draining LNs were confirmed as the source of the few TIL-B by using FTY720, a drug that blocks LN exit. Transcriptomic analysis of 124 untreated TNBC patients confirmed a strong association between TIL-B/TLS presence and chemokine-enriched pathways. Notably, in orthotopic TNBC mouse models, multiplex proteomic analyses of the tumor secretome revealed that most TIL-B- and TLS-associated chemokines were absent. Next, we conducted *ex vivo* migration assays and found unexpectedly that supplementing mouse tumor-conditioned medium with chemokines induced significantly less migration compared to chemokine-supplemented culture medium. *In vivo*, co-injection of genetically engineered chemokine-expressing cancer-associated fibroblasts (CAFs) did not elicit TLS formation nor increased TIL-B infiltration in the primary tumors.

These findings suggest the presence of specific inhibitory factors within the tumor secretome that impair chemokine-mediated migration and immune cell infiltration. Using molecular weight-based fractionation and high-throughput analysis, we are narrowing down the identity of these components and conducting functional studies to validate their effects. Preliminary experiments show that removing these factors can restore chemokine activity, permitting B cell migration. In vivo, we are evaluating the combination of genetically engineered chemokine-expressing CAFs and systemic inhibition of these factors to promote TIL-B infiltration and TLS formation. Preliminary data indicate this dual treatment promotes the formation of large peritumoral B cell aggregates, providing critical insights into the factors enabling tumor immune infiltration and organization. Ongoing human transcriptomic analyses on internal and publicly available datasets support a strong association between chemokine expression, reduced inhibitory factor secretion, and TIL-B presence across human cancer types, including TNBC, colon and lung cancer.

This work defines that the absence of TIL-B and TLS in cancer is the consequence of a combination of mechanisms: insufficient chemokine production by the tumor microenvironment to drive immune infiltration from the LN, coupled with the active secretion of factors that impair chemokine functionality.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Apoptosis and BCL2 Family
Poster Session

#1379 Discovering the essential functions of MCL-1 in hematopoiesis using gene-swap mice.

A. Tee[1], A. J. Kueh[2], L. Gibson[1], S. Malelang[1], M. J. Herold[2], G. Kelly[1], A. Strasser[1], K. Brinkmann[1];
[1]WEHI - The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [2]Olivia Newton-John Cancer Research Institute, Heidelberg, Australia

Pro-survival BCL-2 proteins (e.g., MCL-1, BCL-XL, BCL-2, A1) are over-expressed in human cancers, making them critical targets for anti-cancer therapies [1]. While the BCL-2 inhibitor Venetoclax is highly successful in treating certain blood cancers, inhibitors of BCL-XL and MCL-1 cause toxicity to non-malignant tissues, including hematopoietic cells [2]. These findings from gene targeted mice showed that different pro-survival BCL-2 proteins are critical for the survival of distinct hematopoietic cell subsets. Notably, MCL-1 is essential for implantation, with *Mcl-1*$^{-/-}$ embryos dying at E3.5, the survival of hematopoietic stem and progenitor cells as well as many immature and mature lymphoid and myeloid cell populations[3]. In contrast, the essential roles for BCL-2 and BCL-XL are restricted to the survival of select hematopoietic cell populations. Of note MCL-1 (and to a minor extent BCL-XL) but not BCL-2 have been ascribed some apoptosis unrelated functions in cellular metabolism, such as mitochondrial import of long chain fatty acids. We aim to determine the unique anti-apoptotic and apoptosis unrelated roles of MCL-1 in comparison to the other pro-survival BCL-2 family members in embryogenesis and hematopoiesis.We used CRISPR to produce “gene-swap” mice in which the MCL-1 coding region was replaced with the coding region for BCL-2 (*Mcl-1*$^{Bcl\text{-}2}$), BCL-XL (*Mcl-1*$^{Bcl\text{-}xL}$) or A1. Remarkably, homozygous *Mcl-1*$^{Bcl\text{-}xL/Bcl\text{-}xL}$ and *Mcl-1*$^{Bcl\text{-}2/Bcl\text{-}2}$ embryos could develop until at least E11.5 on a C57BL/6 background. This demonstrates that only the anti-apoptotic function of MCL-1 - but not its apoptosis-unrelated roles - are essential for early embryogenesis.To examine the impact of replacement of MCL-1 by BCL-XL on hematopoiesis, lethally irradiated mice were reconstituted with *Mcl-1*$^{Bcl\text{-}xL/Bcl\text{-}xL}$ hematopoietic stem progenitor cells from E12.5 embryos. Interestingly, the expression of BCL-XL in place of MCL-1 in the hematopoietic system allowed the generation of all blood cell types with a marked increase in platelets and B lymphocytes. Notably, adult heterozygous *Mcl-1*$^{Mcl\text{-}1/Bcl\text{-}2}$ mice showed even more substantial accumulations of B cells and antibody secreting plasma cells in their spleen and bone marrow, and with progressing age they develop SLE-like autoimmune disease similar to what is seen in *vav-bcl-2* transgenic mice that overexpress BCL-2 [4]. These findings show that distinct pro-survival BCL-2 proteins with their differences in protein stability and interactions with the pro-apoptotic members of the BCL-2 family are best suited to safeguard normal hematopoietic cell survival, with too much pro-survival activity causing disease.

#1380 Role of cytokine-induced cell death on efficacy of teclistamab-mediated T cell killing of multiple myeloma cells.

Allison Carr[1], Adrian Ting[2]

[1]Mayo Clinic Graduate School of Biomedical Sciences, Rochester, MN,[2]Department of Immunology, Mayo Clinic, Rochester, MN

Multiple myeloma (MM) is the second most common hematologic malignancy among US adults, characterized by high rates of relapse and refractory disease. Anti-Myeloma T cell immunotherapies, such as chimeric antigen receptors (CAR-Ts) and bispecific T cell engagers (BiTEs), have been able to induce deep responses in the clinic and extending survival for many. However, even these responses are not durable and majority of patients still relapse. MM cell signaling in response to cytokines released by these T cells, such as Tumor Necrosis Factor (TNF) Alpha, and Interferon gamma (IFNγ), may offer additional insight into mechanisms of relapse and resistance as well as avenues of therapeutic manipulation. To evaluate the effects of TNF and IFNγ on MM cell death and proliferation, we obtained human MM cell lines (MMCLs) and stably transduced them with a GFP-NLS reporter. We then monitored these cell lines in the presence of TNF, IFNγ, or TNF+IFNγ and tracked their cell death and growth kinetics over time using DiYO-3 incorporation and GFP count, respectively, via IncuCyteS3 live cell imaging. We next utilized Teclistamab, a B cell maturation antigen (BCMA)-directed BiTE, to co-culture MMCLs with healthy donor derived T cells at various effector to target (E:T) ratios and monitored for T cell mediated death again via IncuCyteS3 live cell imaging. While all MMCLs were able to be killed at high E:T ratios (1:1), only cytokine-sensitive lines remained susceptible to T cell killing at lower E:T ratios (1:10). The addition of TNF and/or IFNγ blocking antibodies confirmed that the increased sensitivity of these lines to T cell killing was indeed mediated by the two cytokines. In summary, were able to show an in vitro model of differential MM cell response to Teclistamab mediated T cell killing, and that this difference in response was predicated on the MM cells' baseline sensitivity to cytokine mediated cell death via TNF and IFNγ. Thus, further dissecting mechanisms underlying resistance or sensitivity of MM cells to cytokine induced death could suggest therapeutic targets with the potential to enhance the efficacy of anti-MM T cell immunotherapies.

#1381 BCL-2 selective inhibitor venetoclax combined with topoisomerase I inhibitor irinotecan is effective in small cell lung cancer (SCLC).

Yanli Xing, Krista M. Dalton, Jane L. Roberts, Anthony C. Faber

VCU Philips Institute for Oral Health Research Oral and Craniofacial Molecular Biology, Virginia Commonwealth University - VCU, Richmond, VA

Background: Lung cancer is the third most common cancers globally, and small cell lung cancer (SCLC) accounts for 10-15% of all lung cancer cases. Extensive stage (ES)-SCLC has an overall five-year survival rate of ~5%. Although ES-SCLC initially responds well to platinum-based combination chemotherapy, it almost invariably develops resistance over time. Immunotherapy can induce some responses in ES-SCLC, and arlatamab-dlle, a DLL3 targeted bi-specific T-cell engager, was recently given advanced approval to treat relapsed ES-SCLC. However, ES-SCLC remains a dismal prognosis. Venetoclax is a Bcl-2 selective inhibitor that induces apoptosis by binding to the hydrophobic groove of BCL-2. We previously demonstrated that venetoclax is effective in SCLC with high BCL-2 expression (Lochmann et al., *Clinical Cancer Research* 2018). Irinotecan is an antineoplastic enzyme inhibitor that blocks the topoisomerase I-DNA complex, preventing DNA repair and causing double-strand breaks that lead to cell death. It is often given in the relapsed setting as second-line therapy for ES-SCLC.
Aims: We aimed to determine if venetoclax could enhance responses to irinotecan in SCLC preclinical models, and vice versa.
Methods: Venetoclax was combined with irinotecan and SCLC cell viability was evaluated including CellTiter-Glo (CTG), immunoblotting, and in mouse models, including patient-derived xenografts, in vivo.
Results: Our data showed that combining the BCL-2 selective inhibitor venetoclax with irinotecan demonstrated in many SCLC models, enhanced activity over single-agent alone. In vivo, the combination enhanced survival compared to either single-agent.
Conclusion: We demonstrate that combining the BCL-2 selective inhibitor venetoclax with irinotecan could enhance responses and survival in the refractory SCLC setting.

#1382 The discovery of a novel antibody, 14G6, as a tool for understanding BAK conformational dynamics and their relationship to venetoclax response in leukemia.

Michelle S. Miller, Hema P. Subas-Satish, Sweta Iyer, Melissa X. Shi, Agnes W. Wong, Karla C. Fischer, Ahmad Z. Wardak, Daisy Lio, Rachel T. Uren, Peter E. Czabotar, Ruth M. Kluck

The Walter & Eliza Hall Institute of Medical Research (WEHI), Parkville, Australia

Venetoclax, a BCL2-specific inhibitor, is FDA-approved for the treatment of acute myeloid leukemia and chronic lymphocytic leukemia with varying patient responses. Conformation specific antibodies can help unravel the regulation of BCL2 family proteins and its relation to venetoclax response. We used mouse B cell cloning to identify 14G6, the first antibody that is specific for the non-activated, monomeric BAK conformation. The crystal structure of the 14G6 Fab bound to BAK revealed a binding site encompassing both the α1 helix and α5-α6 hinge regions of BAK, the two sites involved in the transition to the active, dimerisation-ready, conformation of BAK. This makes it a useful tool for determining the levels of non-activated, monomeric BAK in cancer cells by blue native PAGE. We found that 14G6 bound the majority of BAK in several leukemia cell lines, and binding decreased following treatment with venetoclax, indicating only minor levels of activated or sequestered BAK in those cells. 14G6 is thus an important new tool to assess BAK status in response to anti-cancer treatments and understand mechanisms of resistance to venetoclax, potentially aiding in the development of more reliable biomarkers to predict patient response.

#1383 A gated hydrophobic funnel within BAX binds long-chain alkenals to potentiate pro-apoptotic function.

Jerry Edward Chipuk

Oncologial Sciences, Icahn School of Medicine at Mount Sinai, New York, NY

Mitochondria maintain a biochemical environment that cooperates with BH3-only proteins (e.g., BIM) to potentiate BAX activation, the key event to initiate physiological and pharmacological forms of apoptosis. The sphingosine-1-phosphate metabolite 2-trans-hexadecenal (2t-hexadecenal) is one such component described to support BAX activation, but molecular mechanisms remain largely unknown. Here, we utilize complementary biochemical and biophysical techniques to reveal that 2t-hexadecenal non-covalently interacts with BAX, and cooperates with BIM, to stimulate early activation-associated intramolecular rearrangements prior to membrane permeabilization. Integrated structural and computational approaches suggest 2t-hexadecenal binds an undefined region - a hydrophobic cavity formed by core-facing residues of α5, α6, and gated by α8 - we term the "BAX actuating funnel (BAF).” Alkenal length and α8 mobility are critical determinants for the interaction, intramolecular rearrangements, and functional outcome of 2t-hexadecenal binding to the BAF; we also present a first-in-class small molecule that functionally mimics 2t-hexadecenal contributions to apoptosis. Collectively, this work imparts detailed molecular insights into how pro-apoptotic BCL-2 proteins and lipids assemble to initiate the mitochondrial pathway of apoptosis, and reveals the therapeutic potential of targeting the BAF.

#1384 Mitochondrial complex I inhibition enhances chemotherapy efficacy in melanoma.

Semmer Ali[1], Mehrdad Zarei[2], Luke D. Rothermel[2], Jordan M. Winter[2]

[1]Biology, Case Western Reserve University, Cleveland, OH,[2]Department of Surgery, Division of Surgical Oncology, University Hospitals Cleveland Medical Center, Cleveland, OH

Background: Melanoma, characterized by the uncontrolled proliferation of melanocytes, is one of the most common types of cancer in the United States. Despite improvement in therapeutics, it remains a formidable adversary in oncology due to its aggressive resistance to treatment and propensity for metastasis. Metabolic reprogramming is a hallmark of cancers implicated in resistance to therapies. Previous efforts have focused on targeting glycolysis, while mitochondrial oxidative phosphorylation (OXPHOS) and TCA metabolism remain underexplored in melanoma research due to limited understanding of contexts in which OXPHOS is required for cancer cell growth and survival.

Methods: To determine the impact of chemotherapies (Temozolomide and Cisplatin) on cellular metabolism, metabolomics profiling was performed using liquid chromatography-mass spectrometry (LC-MS) and bioenergetics analyses. Therapeutic responses were studied with chemotherapy in combination with a complex I inhibitor (Phenformin and IACS-010759). In vivo studies investigating the combination of complex I inhibitors and Temozolomide were conducted in immunocompetent C57BL/6J mice. Murine YUMM1.7 melanoma cell allografts were established to evaluate tumor growth and therapeutic efficacy through tumor volume analysis.

Results: Our study examined OXPHOS diversity across different melanoma cell lines, identifying those with high and low mitochondrial OXPHOS activity. We found that melanoma cells exhibit significant mitochondrial dependency as evidenced by increased TCA cycle intermediates, ATP production, and oxidative capacity in response to chemotherapy. Additionally, melanoma cells increase mitochondrial electron transport chain (ETC) complex I as an adaptive response to chemotherapy. Pharmacological inhibition of ETC complex I synergizes with conventional anti-melanoma chemotherapy in preclinical models. Furthermore, the combination of complex I inhibitors and Temozolomide proved to be the most effective treatment in vivo, significantly suppressing tumor growth in a murine melanoma model compared to either treatment alone. The combination therapy was well-tolerated, with no observed reduction in body weight, indicating minimal systemic toxicity.

Conclusion: These findings underscore the clinical promise of employing mitochondrial complex I inhibition as part of a combined therapeutic approach to enhance chemosensitivity for individuals with advanced and refractory melanoma.

#1385 Mitochondrial-Nuclear Retrograde Regulator 1 (MNRR1): A novel regulator of apoptosis.

H. Elshenawy, J. Wu, N. Purandare, S. Aras;
Wayne State University School of Medicine, Detroit, MI

Mitochondrial Nuclear Retrograde Regulator 1 (MNRR1, aka CHCHD2) is a bi-organellar regulator protein localized in the mitochondria and the nucleus. In the mitochondria, MNRR1 regulates oxidative phosphorylation (OxPhos) to generate ATP and inhibits intrinsic apoptosis. Nuclear MNRR1 regulates the transcription of ~ 5000 genes, including many cancer-related genes. Reasonably, this explains the upregulated MNRR1 expression in different cancers. Triple-negative breast Cancer (TNBC) is associated with an aggressive phenotype. The lack of hormonal receptors and tumor heterogeneity cause resistance to conventional therapies and the inability to develop targeted treatments. Using TNBC as a model system, we aim to identify the mechanism of MNNR1 function as an anti-apoptotic protein. Intrinsic apoptosis involves disruption of equilibrium between pro- and anti-apoptotic proteins. Anti-apoptotic proteins are translocated upon apoptotic stimuli by pro-apoptotic proteins that accumulate on the outer mitochondrial membrane (OMM), causing its permeabilization. This allows the release of cytochrome *c* from mitochondria to cytosol to activate the caspase pathway. Our findings show that MNRR1 resides in two different forms in the mitochondria based on its Y99 phosphorylation (pY99R1). pY99R1 induces OxPhos, while the non-phosphorylated protein (npR1) interacts preferentially with the anti-apoptotic protein Bcl-xL. Induction of MNRR1 inhibition using knockout cells or chemical inhibitors sensitize cells to an apoptotic stimulus. MNRR1 knockout cells display a pro-apoptotic phenotype as observed by Bax oligomerization. Voltage-dependent anion channel (VDAC) is an OMM protein that interacts with Bcl-xL, preventing the release of cytochrome *c* to the cytosol. Our study shows that npR1 enhances the VDAC-Bcl-xL interaction complex. This anti-apoptotic function is facilitated by N-terminal 52 amino acids constituting the putative Mitochondrial localization Sequence (MLS) in MNRR1 protein. Collectively, the findings of our study highlight the potential use of MNRR1 as a therapeutic target for novel therapeutics or in combination with existing therapies in TNBC.

#1386 The HSP90 Co-chaperone UNC45A is essential for prostate cancer cell proliferation in vitro and tumor growth in vivo.

Taoufik LLBIYI, Asif Elahi, Digvijay Singh, Nada Eisa, Yasmeen Jilani, Ahmed Chadli

Georgia Cancer Center, Augusta, GA

UNC45A is a key co-chaperone supporting cancer cell proliferation and tumorigenesis. Interestingly, UNC45A is essential for cancer cells but not for normal cell proliferation. However, the mechanism underlying UNC45A regulatory function is not well studied. We have previously shown that UNC45A functions as a glucocorticoid receptor (GR) co-activator to drive the mitotic kinase NEK7 gene transcription. NEK7 is essential for centrosome separation, mitotic spindle formation, and cytokinesis. GR has been implicated in promoting aggressive prostate tumor growth and resistance to therapy. Indeed, GR upregulation is an established mechanism to bypass the androgen receptor blockade therapy in metastatic-resistant prostate tumors. Here, we tested the hypothesis that UNC45A promotes GR-mediated resistance to hormonal therapy. To this end, we used shRNA-mediated gene silencing to evaluate the impact of UNC45A loss on PC3 prostate tumor progression. Our results show that silencing UNC45A reduces cell proliferation *in vitro* and tumor growth *in vivo*. TUNEL analysis and Ki67 staining show that loss of UNC45A triggers DNA damage, reduced cell proliferation, and apoptosis in PC3 tumors grown in the NOD SCID mice model. Immunofluorescence analysis shows a remarkable disorganization of centrosomes in tumor cells expressing UNC45A shRNA. The importance of UNC45A in promoting enzalutamide resistance is being tested in tridimensional spheroid culture and *in vivo* and will be discussed in this meeting. Overall, our results support the hypothesis that UNC45A is a promising cancer therapeutic target and highlight the need for developing UNC45A small molecule inhibitors to treat aggressive diseases such as prostate and breast cancers.

#1387 Superoxide induces phosphorylation-mediated Mcl-1 stability to promote vresistance in hematologic malignancies.

Stephen J. F. Chong[1], Jolin X. H. Lai[1], Kartini Iskandar[1], Chuqi Wang[1], Yuhan Wang[1], Romaine Guieze[2], Deepika Raman[1], Rachel H. F. Lim[3], Catherine J. Wu[4], Wee Choo Chng[1], Alice M. S. Cheung[5], Charles T. H. Chuah[3], Matthew S. Davids[4], **Shazib Pervaiz**[1]

[1]National University of Singapore, Singapore, Singapore,[2]Universite Clermont Auvergne, Clermont Ferrand, France,[3]Singapore General Hospital, Singapore, Singapore,[4]Dana Farber Cancer Institute, Boston, MA,[5]Duke-NUS Graduate Medical School, Singapore, Singapore

Acquired resistance to Bcl-2 inhibitor, venetoclax, poses a therapeutic challenge in the management of chronic lymphocytic leukemia (CLL) and acute myeloid leukemia (AML). Venetoclax-resistant cells exhibit increased accumulation of Mcl-1, thereby switching dependence from Bcl-2 to Mcl-1. However, the mechanism behind increased Mcl-1 accumulation upon the acquisition of venetoclax resistance remains elusive. Given that a change in cellular redox state affects cell survival and drug sensitivity, we sought to investigate the interplay between cellular redox state and Mcl-1 accumulation in venetoclax-resistant cells. Our findings reveal that increased Mcl-1 levels in venetoclax-resistant hematologic malignant cells is associated with increased mitochondrial oxygen consumption and intracellular superoxide ($O_2^{\cdot-}$) levels. Corroborating the link between cellular redox state and Mcl-1 accumulation, increased $O_2^{\cdot-}$ levels in venetoclax sensitive cells was accompanied by enhanced threonine-163 phosphorylation of Mcl-1 (T163pMcl-1), thereby reducing Mcl-1 ubiquitination and degradation. Furthermore, $O_2^{\cdot-}$-induced T163pMcl-1 is mediated by AKT, as evidenced by increased serine-473 phosphorylation. Notably, reducing $O_2^{\cdot-}$ levels or inhibiting AKT decreases T163pMcl-1 and Mcl-1 levels, heightens mitochondrial apoptotic-priming, and restores sensitivity to venetoclax-induced apoptosis. Collectively, our findings unravel redox-dependent mechanism of Mcl-1 stability and accumulation upon the acquisition of venetoclax resistance, which could have implications for the design of novel therapeutic strategy targeting cellular pro-oxidant state or AKT in various venetoclax-resistant hematologic malignancies.

#1388 Exploring the apoptosis-inducing potential of *Cannabis sativa* and cannabidiol in pancreatic cancer *in vitro*.

D. J. Tshabalala, X. Sebutsoe, L. R. Motadi;
University of Johannesburg, Johannesburg, South Africa

Pancreatic cancer is deemed one of the most aggressive types of cancer, with a high mortality rate and poor prognosis. It is ranked the 12th most prevalent cancer globally, with 510,992 new cases and 467,409 deaths reported in 2022. In South Africa, it is ranked the 9th most common cancer, with a mortality rate of approximately 84%. Pancreatic cancer is often diagnosed in advanced stages when the disease is too aggressive to manage, rendering the available treatments ineffective. *Cannabis sativa* (*C. sativa*) is a medicinal plant that has been used for centuries based on its health benefits; more recently, it has been explored for its anti-cancer properties. However, knowledge of the impact of *C. sativa* on pancreatic cancer is still limited. This study aimed to explore the apoptosis-inducing potential of *C. sativa* and cannabidiol (CBD) in pancreatic cancer cells. Crude *C. sativa* extracts were obtained by dissolving dried *C. sativa* leaves in absolute ethanol; CBD was isolated from the crude extract using column chromatography. The cytotoxic effects of the crude extract and CBD on pancreatic cancer cells (Mia-PaCa2) and normal lung cells (MRC-5) were determined using the AlamarBlue reagent. Apoptosis was investigated by analysing morphological changes using light microscopy. This was followed by an evaluation of phosphatidylserine externalisation and nuclear condensation, hallmarks of apoptosis, using Annexin V staining and Hoechst staining, respectively. Furthermore, levels of ATP and activation of caspase-3 and -7, key executioners of apoptosis, were measured. DNA fragmentation was analysed using agarose gel electrophoresis. Lastly, gene expression of apoptosis-related genes was assessed using quantitative polymerase chain reaction (qPCR). The results show that the crude and CBD induced substantial cytotoxic effects on Mia-PaCa2 cells but not MRC-5. *C. sativa* and CBD caused significant morphological changes in Mia-PaCa2 cells, including cell detachment and rounding, phosphatidylserine externalisation, and nuclear condensation as seen through light microscopy, Annexin V staining, and Hoechst staining. Furthermore, the crude and CBD extracts reduced ATP levels and activated caspase-3 and -7, with more pronounced effects in the crude extract. DNA fragmentation was also more distinct in cells treated with the crude extract, validating that crude *C. sativa* and CBD induced apoptosis in Mia-PaCa2. This was further supported by the upregulation of BAX, BAK-1, and p53 and the downregulation of BCL-2, indicating the activation of the intrinsic apoptotic pathway. In conclusion, both crude and CBD have apoptosis-inducing potential in pancreatic cancer cells.

#1389 Obesity paradox on ccRCC: A role of fatty acids?.

Isadora Ramos de Andrade

Radiation Oncology, University of Miami Miller School of Medicine, Miami, FL

Introduction: Obesity is a risk factor for clear cell renal cell carcinoma (ccRCC), the most common type of kidney cancer; coincidentally obesity correlates with better outcomes in ccRCC patients, a phenomenon known as the obesity paradox. Obesity is frequently associated with the consumption of diets enriched in lipids. However, how dietary composition, especially the role of different fatty acids (FAs), can affect ccRCC development, as well as how dietary modification could be used in combination with other therapies for better responses is still unclear. We hypothesize that obese individuals with ccRCC respond better to the therapies due to increased amounts of specific FAs in the circulation, which somehow can sensibilize the tumor cells.
Methods: We used two ccRCC cell lines, UOK101 and 786-O, and a proximal tubular cell line derived from normal kidney, HK-2, as a control. Palmitic acid (PA), oleic acid (OA), and linoleic acid (LA), which are saturated, monounsaturated, and polyunsaturated FAs, respectively, were used as stimuli for the cells, mimicking the levels of FAs found in circulation of individuals with obesity [200 μM]. Lipid droplets (LDs) were evaluated by Oil Red O staining; Viability by MTT; Protein expression by Western Blotting; Oxygen Consumption rate (OCR) by Seahorse; Survival by clonogenic assay; mRNA by RT-qPCR, Cell death by Annexin-V/PI kit; ROS by DCFDA/H2DCFDA kit; Mitochondrial potential by MitoTracker®, Gene expression profile by RNAseq.
Results: All FAs increased the amount of LDs compared to the control, but PA was the least potent. PA impaired the growth rate for the tumor cells compared to the control from 24h, which remained in 72h, even at the lowest concentration [50 uM]. LA also decreased the growth rate, but only at 72h. PA, even at a lower concentration, impaired the formation of colonies for both cell lines compared to control and other FAs. LA impaired colony formation only at the higher concentration. PA also decreased cells migration at the time of 12h, induced cell death and increased cleaved caspase3 expression in 24h, a phenomenon observed only for the tumor cell lines. Regarding lipid metabolism, all FAs decreased fatty acid synthase and increased CPT1 expression, suggesting increase in fatty acid oxidation (FAO). In contrast all FAs decreased OCR, and blocking FAO did not rescue cell death induced by PA. PA decreased mitochondrial membrane potential and also DRP1 protein for UOK, although cytochrome C expression or either ROS production were not increased. Gene expression profiling indicated that PA induces endoplasmic reticulum stress.
Conclusion: In summary, we demonstrated that PA decreased malignant characteristics in ccRCC, such as viability, colony formation, migration, and induced cell death. Taken together, our data suggest that PA could be employed as an intervention in ccRCC treatment, although additional studies are required to evaluate how an enriched PA-high fat diet can impart a better outcome for patients.

#1390 Dysregulation of microtubule dynamics caused by *LOXL3* knockout triggers mitosis catastrophe and senescence in U87MG and U251 cells.

Talita de Souza Laurentino[1], Roseli da Silva Soares[1], Ricardo Cesar Cintra[2], Antonio Marcondes Lerario[3], Suely Kazue Nagahashi Marie[1], **Sueli Mieko Oba-Shinjo**[1]

[1]Neurology, University of Sao Paulo, School of Medicine, Sao Paulo, Brazil,[2]Radiology and Oncology, University of Sao Paulo, School of Medicine, Sao Paulo, Brazil,[3]Internal Medicine, Division of Metabolism, Endocrinology, and Diabetes, University of Michigan, Ann Arbor, MI

The amine oxidase LOXL3 has been implicated in tumor development and progression, with elevated expression in glioblastoma (GBM), the most malignant central nervous system tumor. This enzyme influences adhesion, migration, and proliferation of GBM cells. Furthermore, LOXL3 upregulation contributes to poorer GBM patient outcomes, and its expression is correlated with genes encoding tubulins. Microtubules, the major component of the cytoskeleton, are crucial for the cell cycle and mitotic progression. In this study, LOXL3 knockout was performed using CRISPR-Cas9 in two GBM cell lines, U87MG and U251, which resulted in decreased cell viability and migration in both cell lines. Transcriptome enrichment analysis revealed downregulation of genes associated with tubulin acetylation, which was subsequently confirmed by western blot and immunofluorescence analyses. Both U87MG and U251 cells exhibited downregulation of cell cycle- and proliferation-related genes. Functional assays confirmed that *LOXL3*-knockout cells exhibited delayed cell cycle progression and significant alterations in mitotic spindles during the metaphase-anaphase transition. Nuclear analysis revealed morphological changes indicative of mitotic catastrophe in U87MG cells (with wild-type *TP53*) and senescence in U251 cells (with mutated *TP53*). U87MG cells with LOXL3 knocked out presented increased apoptotic cells, which was enhanced after TMZ treatment. Our results suggest that LOXL3 is a potential therapeutic target for GBM treatment, especially in those with higher LOXL3 expression. LOXL3 inhibition can induce tumor cell senescence in GBM with *TP53* mutation and apoptosis in cases with wild-type TP53 boosting TMZ treatment, improving GBM patients´ outcome.

#1391 The role of lysosomal membrane permeabilization in ECM-detached cancer cells.

Hannah M. Tanczos, Lauren Young, Paulina Harnisch, Isabella Gomez, Jianping He, Jordan Cockfield-Iratishe, Zachary T. Schafer

Department of Biological Sciences, University of Notre Dame, Notre Dame, IN

The progression of metastatic cancer invariably leads to a lower 5-year survival rate compared to patients diagnosed with primary tumors alone, so the elimination of metastasizing cells is crucial to improve patient outcomes. A barrier to cancer metastasis is anoikis, an apoptotic form of cell death induced when a cell loses attachment to the extracellular matrix (ECM). However, cells that do successfully metastasize develop anoikis resistance and are able to survive in ECM-detachment. The survival of ECM-detached metastatic cancer cells can result from a variety of changes including elevated antioxidant activity and altered metabolism. Many of these adaptive changes rely on lysosomes, which are acidic, membrane-bound organelles that are responsible for degradation of materials. Therefore, we hypothesize that lysosomal dynamics contribute to anoikis resistance. We have found that lysosomes in non-cancerous mammary epithelial cells grown in ECM-detached conditions exhibit signs of lysosomal membrane permeabilization (LMP) and dysfunction, suggesting that LMP is caused by ECM-detachment and contributes to anoikis. In support of our hypothesis, we have found that some breast cancer cell lines and oncogenically transformed cells are able to maintain intact, functional lysosomes during ECM-detachment. Preliminary data also demonstrate that the downstream effects of LMP, specifically the release of lysosomal protease cathepsin B into the cytosol, may contribute to anoikis signaling. Ongoing work aims to elucidate the mechanism(s) by which ECM-detachment causes LMP in normal cells and understand the changes in this mechanism that confer LMP resistance in cancer cells. In a translational setting, this information could lead to a therapy that prevents metastasis by sensitizing resistant cancer cells to LMP-mediated cell death, thus improving patient outcomes.

#1392 Mechanism of chemoresistance in esophageal squamous cell carcinoma based on mitochondrial DNA copy number.

Koji Tanaka, Yuto Kubo, Kotaro Yamashita, Tomoki Makino, Tsuyoshi Takahashi, Yukinori Kurokawa, Kiyokazu Nakajima, Hidetoshi Eguchi, Yuichiro Doki

Osaka University, Osaka, Japan

Epithelial-to-mesenchymal transition (EMT) has been reported to be associated with metastasis and resistance to therapy in various carcinomas. However, the mechanism of EMT induction and its regulation remain unresolved. Esophageal cancer is one of the most difficult-to-treat cancers that metastasize and are refractory to therapy. In this study, we focused on mitochondrial DNA to elucidate the mechanism of EMT induction in esophageal cancer and to search for therapeutic targets. We established a resistant strain (TE11-R) by long-term exposure of an esophageal cancer cell line (TE11) to chemotherapy (CDDP), and found that TE11-R acquired mesenchymal characteristics. We also observed that the mtDNA copy number was decreased in TE11-R. Next, we established ESCC with reduced mtDNA copy number (TE11-shT) by knockdown of mitochondrial transcription factor A (sh-TFAM). First, mtDNA copy number was reduced to 60% in TE11-shT. Complex IV activity and membrane potential (MMP) were reduced in TE11-shT compared to control TE11. Next, exposure of TE11 to depolarizing agents (CCCP) decreased expression of epithelial markers (CDH1) and increased expression of mesenchymal markers (CDH2, Vimentin, ZEB1) by qPCR and WB. Exposure of TE11-shT and CCCP to DNMT inhibitors increased expression of E-cadherin, decreased expression of N-cadherin and Vimentin, and improved CDDP sensitivity. and CDDP sensitivity were observed. Decreased mtDNA copy number in esophageal squamous cell carcinoma induced EMT via increased DNMT expression, suggesting that DNMT inhibitors may be therapeutic targets for treatment-resistant esophageal cancer cells.

#1393 Functional analysis of mitochondria-targeting Wnt-inhibitors on metabolically distinct breast cancer cell types.

Yoonseok Kam, Lisa Winer, Natalia Romero

Agilent Technologies, Inc., Lexington, MA

Mitochondria are essential organelles responsible for energy production and survival. In cancer cells, mitochondrial function is often altered through metabolic reprogramming, which enhances their growth, survival, and resistance to therapy. Recent findings suggest that bi-directional crosstalk between Wnt signaling and mitochondrial function plays a crucial role in tumorigenesis, as well as in the differentiation and self-renewal of stem cells. This study investigates the potential of targeting the interplay between Wnt signaling and mitochondrial function in breast cancer cells. We screened 71 agents known to alter Wnt signaling and assessed their impact on mitochondrial function and cell viability in BT474 and Hs578T breast cancer cell lines. The Mito Tox Index (MTI) obtained using the Agilent Seahorse XF MitoTox Assay was used as the parameter to evaluate the impact of test compounds on mitochondrial function. The screening identified Pyrvinium, Niclosamide, and Hexachlorophene as the most potent mitochondrial modulators. Pyrvinium and Niclosamide inhibited the mitochondrial electron transport chain, whereas Hexachlorophene acted as an uncoupler when the cells were exposed to the drugs for 24 hours. The mechanisms of mitochondrial perturbation induced by these drugs were further investigated using BT474 cells permeabilized with the Seahorse XF Plasma Membrane Permeabilizer (PMP), which selectively permeabilizes the cellular plasma membrane without affecting mitochondria integrity. This approach enabled detailed characterization of key components in mitochondrial function, including transporters, enzymes, and electron transport chain complexes. Our results indicated that Niclosamide inhibited complex I/II, either directly or indirectly, while Pyrvinium appeared to suppress mitochondrial function indirectly. Despite the different bioenergetic phenotypes of BT474 (highly oxidative) and Hs578T (highly glycolytic) cells, there was no significant difference in mitochondrial susceptibility to the three drugs. However, significant differential effects on ATP production rates were detected using the Agilent Seahorse XF Real-Time ATP Rate, BT474 cells exhibited a significant metabolic energy crisis in the presence of all three compounds, whereas Hs578T cells maintained stable total ATP production despite mitochondrial inhibition. This differential impact on ATP production rates corresponded directly to differences in cell viability, with BT474 cells showing higher susceptibility to these compounds. These findings suggest that the anti-cancer efficacy of mitochondrial modulators can vary depending on the metabolic phenotype of the target cell and should be considered in therapeutic design. Targeting mitochondrial function through Wnt signaling inhibitors presents a promising strategy for developing effective cancer therapies.

#1394 Apoptosis of pancreatic cancer cells after co-treatment with eugenol and tumor necrosis factor-related apoptosis-inducing ligand.

Hyun Hee Kim, Dae-Hee Lee

Department of Marine Bio Food Science, Gangneung-Wonju National University, Gangneung, Korea, Republic of

Pancreatic cancer is a refractory cancer with limited treatment options, and resistance to tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) poses a significant therapeutic challenge. This study aimed to investigate whether eugenol, the main component of clove oil with known anticancer, anti-inflammatory, and antioxidant properties, could enhance TRAIL sensitivity by upregulating death receptor (DR) expression levels in pancreatic cancer cells. To explore this, we treated pancreatic cancer cells with eugenol and TRAIL, individually and in combination, and evaluated apoptosis and cell proliferation rates. Expression levels of key proteins, including DR5, FLICE-inhibitory protein (FLIP), and p53, were assessed. Additionally, reactive oxygen species (ROS) generation, endoplasmic reticulum (ER) stress, and C/EBP-homologous protein (CHOP) involvement were analyzed using siRNA knockdown approaches. Our findings revealed that combined treatment with eugenol and TRAIL significantly increased apoptosis and inhibited cell proliferation compared with eugenol alone. Eugenol upregulated DR5 expression, downregulated the anti-apoptotic protein FLIP, and increased levels of the tumor suppressor protein p53. Furthermore, eugenol induced ROS generation and caused ER stress, with CHOP playing a critical role. CHOP knockdown decreased DR5 expression and reduced the synergistic apoptotic effects of eugenol and TRAIL, confirming the ROS-mediated ER stress-CHOP pathway as a key mechanism. These results demonstrate that eugenol enhances TRAIL-induced apoptosis by upregulating DR5 through ROS-mediated ER stress and CHOP activation, which further enhances ER stress via p53 induction and FLIP downregulation. This suggests that eugenol has the potential to serve as a novel TRAIL sensitizer and offers a promising approach to overcoming TRAIL resistance in pancreatic cancer treatment.

#1395 Constitutive photomorphogenesis (COP)-1 leads to apoptosis in B16F10 metastatic melanoma model.

Joanne Kramer Tobacman[1], Insug O-Sullivan[1], Jiyuan Yang[2], Fuming Zhang[2], Sumit Bhattacharyya[1]

[1]Medicine, University of Illinois at Chicago and Jesse Brown VAMC, Chicago, IL,[2]Chemical and Biological Engineering, Rensselaer Polytechnic Institute, Troy, NY

The E3 ubiquitin ligase Constitutive Photomorphogenesis (COP)-1 inhibits UVB-induced light activation in plants by interaction with UV Receptor (UVR)8 and effects on hypocotyl elongation (HY)5-induced growth. UVB is recognized as a causative factor in human melanomas, and this is the first identification of the role of COP1 in inhibition of melanoma growth and the correlation between effects in UVB-stimulated growth in plants and human melanomas. Following tail-vein injection of 200,000 B16F10 cells in 14-week-old female C57BL/6J mice, intravenous treatment with rhARSB (2.0 mg/ml) or saline occurred on days 2 and 7 and mice were euthanized on day 14. Marked reduction in number and size of pulmonary melanomas was evident in the ARSB-treated mice. To determine the mechanisms underlying the inhibition of melanoma growth, assays were performed in the melanoma tissue, in the human A375 melanoma cell line, and in normal human melanocytes. Experiments included: activated caspase-3 by live cell imaging of A375 cells following ARSB and PBMC; ELISA assays of activated caspase-3/7, cytosolic cytochrome c, BCL2, nuclear ETS1, and phospho(Tyr)-ROR1; Western blots of phospho(Ser473)-AKT1; disaccharide analysis of A375 cells following ARSB silencing and exogenous ARSB; chromatin immunoprecipitation of nuclear FOXO3 and COP1 promoter; mRNA expression of COP1; siRNA inhibition of COP1, ARSB, Insulin Growth Factor 2 Receptor, carbohydrate sulfotransferase (CHST)15; treatment by ROR1 inhibitor cirmtuzumab; and treatment by other inhibitors of signaling pathways. Enhanced apoptosis was evident by increase in activated caspase-3. Live imaging of human A375 melanoma cells treated with rhARSB with and without PBMC showed increase in activated caspase 3/7. The apoptotic mechanism was determined to follow declines in nuclear ETS1 and in ETS1-mediated expression of BCL2, with increase in cytosolic cytochrome c and activated caspase-3. COP1 silencing blocked these effects. Expression of COP1 increased following rhARSB-initiated declines in phospho(Tyr)-ROR1 and phospho(Ser473)-AKT1, leading to increased nuclear FOXO3 and COP1 expression, demonstrated by chromatin immunoprecipitation assay of FOXO3 and COP1 promoter sequence. Effect of exogenous ARSB required insulin-like growth factor 2 receptor (IGF2R), a mannose-6-phosphate receptor. Exogenous ARSB reduced carbohydrate sulfotransferase (CHST)15 expression, shown by disaccharide analysis of chondroitin 4,6-sulfate disaccharides. Decline in CHST15, by rhARSB or CHST15 siRNA reduced phospho(Tyr)-ROR1 and phospho(Ser473)-AKT1, leading to increased nuclear FOXO3 and COP1. This series of signaling and transcriptional events in A375 cells and normal human melanocytes provides new insight into how a conserved, inhibitory response to light-stimulated growth can impact on inhibition of human melanoma growth.

#1396 Additional flexibility and choice with Annexin V StarBright^{TM} Dyes.

Michael Blundell[1], Ryan Mendoza[2], Sharon Sanderson[1]

[1]Bio-Rad Laboratories, Kidlington, United Kingdom,[2]Bio-Rad Laboratories, Hercules, CA

Annexin V staining combined with a viability dye is the gold standard to detect apoptotic cells and necrotic cells by flow cytometry due to its quick and reliable detection of externalized phosphatidylserine on cell membranes. Annexin V staining can be readily combined with immunophenotyping using fluorescently labeled antibodies to obtain cell specific apoptosis information. Unfortunately, when it comes to choice of fluorescent label on Annexin V there are limited options, with traditional fluorophores such as FITC, PE and APC being prevalent. This can cause issues with spillover and spreading when multiplexing, with bright fluorescent proteins such as GFP and with viability dyes that have excitation by multiple lasers, leading to suboptimal data and an inability to expand panel size. Here we present data using StarBright Dye Annexin V conjugates. Not only are the dyes bright so you get excellent separation of positive and negative populations, but they are available in a range of eight excitation and emission wavelengths. StarBright Dyes have been selected to have spectral properties that avoid excitation and emission of common viability dyes, such as 7-AAD and propidium iodide, fluorescent proteins like GFP, and are proven to be compatible in large immunophenotyping panels. When combining with immunophenotyping panels you still have the flexibility and choice to apply best practice, even with larger panels, improving the data obtained. Simplify compensation and avoid resolution issues caused by excessive spreading by using Annexin V conjugated to StarBright Dyes in your flow cytometry panels.

#1397 Inhibition of anti-apoptotic Bcl-2 family members leads to synergistic cell death with ER-stress inducers via disruption of autophagy in glioblastoma.

Tianyi Huang[1], Satoshi Takagi[1], Ryohei Katayama[2]

[1]Japanese Foundation for Cancer Research, Tokyo, Japan,[2]Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo, Japan

Glioblastoma (GBM) remains one of the most challenging brain tumors, necessitating the exploration of novel therapeutic strategies. The purpose of this study was to employ the inhibitor library and combination screening to identify potential therapies for GBM. We uncovered a model that shows inhibition of anti-apoptotic Bcl-2 family members disrupts the protective autophagy under ER-stress condition, thus aggravating the stress level, which synergizes with the inhibition of Mcl-1 and Bcl-xL to cause enhanced cell death in GBM. Eight GBM cell lines were treated with our in-house library compounds, revealing that a pan-Bcl-2 family inhibitor, obatoclax, effectively reduced cell viability across all GBM cell lines. siRNA-mediated knockdown of anti-apoptotic Bcl-2 family members confirmed that simultaneous targeting of Mcl-1 and Bcl-xL leads to enhanced apoptosis and growth inhibition, demonstrating their roles as potential survival factors in GBM. To further enhance its efficacy, we combined obatoclax with a large chemical library containing over 350 compounds to evaluate potential combination effects. Significant synergistic effects, including reduced IC_{50} values and enhanced apoptosis induction, were observed between obatoclax and several ER-stress inducers. It was revealed that when GBM cells were undergoing ER stress, inhibition of Mcl-1 and Bcl-xL further exacerbated the stress level and apoptosis, as evidenced by upregulation of ATF-4, CHOP, Bim, and increased caspase-3/7 activity. Such regulation was found to be achieved by the autophagy disruption induced by the presence of obatoclax or the inhibition of anti-apoptotic Bcl-2 family members. The protective autophagy process, serving as a cellular defense mechanism under ER stress, was observed to be terminated in obatoclax-treated GBM cell lines, with decreased autophagic flux, incomplete autophagic degradation, and accumulation of both autophagy markers p62 and LC3-II. Such disruption was proved to directly result in enhanced ER stress and overwhelmed cell homeostasis, leading to significant upregulation of ATF-4, which, on one hand, promotes the translation of pro-apoptotic genes such as CHOP, and, on the other hand, mediates the upregulation of BH3-only proteins like Bim. Bim also cooperates to inhibit anti-apoptotic Bcl-2 family members, especially Mcl-1 and Bcl-xL, contributing to the synergistic cell death in GBM. In conclusion, our study suggests a unique model in which targeting anti-apoptotic Bcl-2 family proteins, such as Mcl-1 and Bcl-xL, coupled with ER-stress induction, demonstrates promising synergism and enhanced cell death in GBM. This highlights the potential of pan-Bcl-2 family inhibitors to overcome current therapeutic limitations in GBM, providing a novel foundation for future therapeutic approaches via the pro-apoptotic targeting method.

#1398 Caspase-1 dependent lytic cell death influences intra-tumoral neutrophil-to-lymphocyte ratio that limits chemotherapy efficacy.

Stephen (Qi Rong) Wong[1], Ethan Subel[1], Kazukuni Hayashi[2], Hongbo Gao[1], Fotis Nikolo[1], Keith Chan[1]

[1]Houston Methodist Research Institute, Houston, TX,[2]Stanford University, San Fransisco, CA

Chemotherapy remains a cornerstone in the treatment of bladder cancer, with most studies emphasizing its direct cytotoxic effects to induce tumor cell death. However, the influence of various cell death modalities—such as apoptosis, pyroptosis, necroptosis, and ferroptosis—on the immune system remains underexplored. These modalities can either promote an immunogenic response or foster immunosuppression, notably through mechanisms such as altering the neutrophil-to-lymphocyte ratio (NLR), which can impact chemotherapy efficacy. In our study, we observed that gemcitabine treatment in a murine bladder cancer model enriched for a caspase-1-dependent lytic cell death that was non-immunogenic and contributed to an immunosuppressive tumor microenvironment by increasing intra-tumoral NLR. Notably, genetic deletion of caspase-1 shifted this non-immunogenic cell death to an immunogenic form. Additionally, pharmacological inhibition of caspase-1 using VX-765 provided therapeutic benefits by reducing NLR, significantly suppressing tumor growth. While lytic or pyroptotic cell death may be advantageous in the context of infections, our findings highlight a paradox: in the context of chemotherapy treatment, caspase-1-dependent lytic cell death/ pyroptosis can play a detrimental role by promoting an immunosuppressive environment that limits efficacy. These results underscore the importance of understanding and modulating cell death pathways to optimize therapeutic outcomes in cancer.

#1399 Selective induction of apoptosis in pancreatic ductal epithelioid carcinoma PANC-1 cells and normal pancreatic ductal epithelial HPDE6c7 cells by Chinese medicinal herbs *Scutellaria barbata* and *Oldenlandia diffusa*.

Abby Shim[1], Jessica Lee[1], Ryan Hayes[2], **Brian Yuen Yau Wong**[1]

[1]Biology, Andrews University, Berrien Springs, MI,[2]Biochemistry, Andrews University, Berrien Springs, MI

Pancreatic cancer is a highly lethal disease, marked by late-stage diagnosis and rapid metastasis. Despite treatment advances, chemoresistance persists, leading to poor survival outcomes. Conventional therapies often lack selectivity, causing damage to healthy cells. *Scutellaria barbata* (SB) and *Oldenlandia diffusa* (OD) are traditional Chinese medicinal herbs used in treatment formulas in Taiwanese hospitals. We previously showed that SB and OD significantly induce apoptosis in PANC-1 cancer cells. To investigate their potential selective ability, aqueous extracts of these herbs were used on pancreatic ductal epithelioid carcinoma PANC-1 cells derived from a 56-year-old male and on normal pancreatic ductal epithelial HPDE6c7 cells obtained from the pancreatic duct of a 63-year-old female. This study used a green/red/blue fluorescent Apoptosis/Necrosis Detection Kit and Human Apoptosis Antibody Array - Membrane (43 Targets) Test (Abcam). Our fluorescent apoptosis data showed that a 2-hour treatment with 1.0 mg/mL aqueous extract of SB induced a statistically significant percentage of apoptosis in PANC-1 cells as compared to the negative control (88.9 ± 5.6% > 2.7 ± 0.9%); $p<0.05$. In contrast, there was no notable induction of apoptosis in the normal HPDE6c7 cells under SB treatment (1.75 ± 0.25%). Similar apoptotic induction was observed under OD treatment in PANC-1 cells (92.0 ± 0.1% > 2.7 ± 0.9%); $p<0.05$, while HPDE6c7 cells remained non-induced (5.25 ± 4.25%). Furthermore, antibody array membrane data revealed significantly higher upregulation of various pro-apoptotic proteins – such as Caspase 8, IGFBP-3, sTNR-R2, and TRAILR-1 – in PANC-1 cells under OD treatment in comparison to normal HPDE6c7 cells. Modulation of pro-apoptotic proteins was also observed under SB treatment. Both OD and SB treatments led to higher expression of anti-apoptotic proteins in HPDE6c7 cells compared to PANC-1 cells. These results suggest that SB and OD contain phytochemicals capable of selectively inducing apoptosis in pancreatic ductal cancer cells PANC-1 while leaving normal HPDE6c7 cells non-induced. Further research could reveal their precise impact on regulating apoptotic pathways, which may uncover their potential as chemopreventive and therapeutic agents for pancreatic cancer.

#1400 Selective induction of apoptosis by aqueous extracts of Chinese medicinal herbs *Oldenlandia diffusa* (OD) and *Scutellaria barbata* (SB) in human pancreatic adenocarcinoma BxPC-3 cells and pancreatic ductal epithelial HPDE6c7 cells.

Jessica Lee[1], Abby Shim[1], Ryan Hayes[2], **Brian Yuen Yau Wong**[1]

[1]Biology, Andrews University, Berrien Springs, MI,[2]Biochemistry, Andrews University, Berrien Springs, MI

Oldenlandia diffusa (OD) and *Scutellaria barbata* (SB) have been used in traditional Chinese medicine to treat liver, lung, and rectal tumors. They are used in most herbal cancer treatment formulas in hospitals in Taiwan. Pancreatic cancer is one of the most lethal and aggressive human cancers with high mortality rates due to late prognosis. BxPC-3 is a human pancreatic cancer cell line derived from a 61-year-old female with adenocarcinoma while HPDE6c7 is a normal ductal epithelial cell line from the pancreatic duct of a 63-year-old female. Apoptosis is the body's programmed cell death process to combat the proliferation of cancer cells. We previously demonstrated that aqueous extracts of OD and SB selectively induced apoptosis in colon HCT-116 cancer cells but not in colon CCD 841 CoN normal epithelial cells by modulating the pro-apoptotic and anti-apoptotic protein expression. Induction of apoptosis and modulation of apoptotic proteins were also observed in BxPC-3 cells with OD and SB treatments. In this study, the effects of SB and OD on the selective induction and modulation of apoptosis in pancreatic adenocarcinoma BxPC-3 cells and HPDE6c7 normal pancreatic cells were assessed using the Apoptosis/Necrosis Detection Kit and Human Apoptosis Antibody Array-Membrane (43 Targets) test (Abcam). Our fluorescent apoptosis data demonstrates that 2 hours of 1.0 mg/mL OD treatment significantly induced apoptosis in BxPC-3 cells as compared to the negative control (79.95 ± 8.95% > 3.6 ± 1.4%); $p<0.05$, while there was no notable induction of apoptosis in normal HPDE6c7 cells (5.25 ± 4.25%). Most HPDE6c7 cells remained non-induced with OD treatment (94.0 ± 4.5%), comparable to the negative water control (98.75 ± 0.25%). A similar selective induction of apoptosis was obtained from the SB treatment in the BxPC-3 cell line as compared to the negative control (25 ± 8.5% > 3.6 ± 1.4%). There was no significant induction of apoptosis in the normal HPDE6c7 cell line treated with SB, similar to the negative control (1.75 ± 0.25% ≃ 1.25± 0.25%). From the antibody array-membrane experiments, modulation of apoptotic markers, such as the up-regulation of pro-apoptotic proteins CD40, CD40L, cytoC, and TRAILR-1 in BxPC-3 cells with OD treatment; and the upregulation of p53, Caspase 8, and HTRA in BxPC-3 cells with SB treatment was observed. Upregulation of various anti-apoptotic proteins was observed in HPDE6c7 cells. These results suggest that OD and SB contain phytochemicals that selectively induce apoptosis in BxPC-3 cancer cells by modulating certain apoptotic markers while not affecting normal HPDE6c7 cells. Further investigation into their specific effects on regulating apoptosis is warranted to uncover their potential as chemopreventive and therapeutic agents against pancreatic and other cancers.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Gene Regulation and Transcription Factors 2
Poster Session

#1404 Coactivator-associated arginine methyltransferase 1 regulates the transcriptional coactivator function of glioblastoma tumor suppressor Quaking.

Kaylene Lu[1], Tanner Wright[2], Seula Shin[1], Mark T. Bedford[2], Jian Hu[1]

[1]Department of Cancer Biology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Epigenetics and Molecular Carcinogenesis, The University of Texas MD Anderson Cancer Center, Houston, TX

As the most common and malignant primary brain tumor in adults, glioblastoma (GBM) remains highly refractory to current therapeutic efforts, and patient outcome has not markedly improved in the past decades. Significant intratumor heterogeneity drives aggressive invasion, immune evasion, and tumor recurrence. Novel therapeutic paradigms informed by deeper mechanistic insights of gliomagenesis are urgently needed. Quaking (Qki, encoded by *Qk*) is frequently altered in GBM patients, with the *Qk* gene mutated or deleted in 35% percent of GBM cases and the Qki protein absent in 50-60%. Our lab has established Qki as an important tumor suppressor in GBM, where *Qk* deletion in a genetic mouse model induces the formation of tumors with high penetrance that recapitulate human GBM. Mechanistically, Qki acts as a transcriptional coactivator for the expression of lipid metabolism genes, in which loss of Qki dysregulates lipid homeostasis and compromises the integrity and dynamics of various membrane structures. While several downstream processes governed by Qki have been delineated, upstream regulators of Qki are largely unknown. By examining cancer patient genomic data, we observe recurrent mutations to specific Qki arginine residues that implicate the dysregulation of arginine methylation. This post-translational modification is catalyzed by protein arginine methyltransferases, which play key roles in transcriptional regulation and co-activator function. Through *in vitro* methylation assays, we demonstrate that Qki is selectively methylated by the coactivator-associated arginine methyltransferase 1 (CARM1), also known as PRMT4. This methylation occurs specifically in the C-terminal Quaking regulatory domain (QRD), where cancer mutations have been reported. We observe that Qki directly interacts with known CARM1 substrates including RNA polymerase II and MED12 of the Mediator complex and is co-detected with these binding partners at the promoters of lipid metabolism genes. Through mutagenesis studies, we identified arginine 242 (R242) and arginine 256 (R256) as specific CARM1-mediated methylation sites on Qki. Mutations to these sites in glioma stem cells compromise Qki's activity as a transcriptional coactivator. Moreover, brain-specific deletion of CARM1 in a novel genetic mouse model results in neurological phenotypes reminiscent of those observed previously with Qki deletion. Altogether, we provide evidence that CARM1-mediated arginine methylation represents a novel regulatory mechanism for Qki, an essential tumor suppressor in GBM.

#1407 Alterations of *EIF1AX* and carboplatin treatment induce non-canonical translation initiation in ovarian cancer.

Jermaine Austin, Subin Myoong, Natalia Badnarek, Sridevi Challa

University of Chicago, Chicago, IL

Ovarian cancer (OvCa) is the deadliest gynecologic malignancy with high mortality due to chemoresistance. High grade serous ovarian cancer (HGSOC) is the most common subtype of ovarian cancer. The standard of care for women with HGSOC is cytoreductive surgery and chemotherapy using carboplatin, which causes DNA damage and oxidative stress. Despite aggressive treatment strategies, most patients with high grade HGSOC relapse. We recently demonstrated that post-translational modification of ribosomal proteins affects mRNA translation and protein homeostasis in ovarian cancer cells by regulating polysome formation and stress granule assembly. In this study we aim to understand the role of errors in translation initiation in chemoresistance in ovarian cancers. Eukaryotic Initiation Factor 1A X-linked (*EIF1AX*) is an essential eukaryotic initiation factor (eIF) that is responsible for both scanning and recognizing the canonical start codon on mRNA transcripts: Adenosine-Uracil-Guanine (AUG). Genetic alterations in *EIF1AX* are frequently observed in several cancers including low grade ovarian serous carcinoma (LGSOC) and high grade ovarian serous carcinoma (HGSOC). Using luciferase reporter assays, we have observed that *EIF1AX* ablation and carboplatin treatment in epithelial ovarian cancer cells increases translational initiation from the non-canonical start codon Uracil-Uracil-Guanine (UUG). We have also observed that *EIF1AX* knockdown specifically decreases the growth of carboplatin-resistant ovarian cancer cells, whereas depletion of *EIF1AX* enhances the growth of carboplatin-sensitive ovarian cancer cells. Moreover, EIF1AX knockdown sensitizes ovarian cancer cells to carboplatin treatment. Collectively, our results suggest that *EIF1AX* ablation and carboplatin treatment result in increased non-canonical translation and play a role in chemoresponses in ovarian cancers.

#1408 CSTF2-induced alternative polyadenylation of GPC3 RNA contributes to hepatocellular carcinoma.

Suk Woo Nam, Soyoung Jeon, Sang Yean Kim, Min Jeong Na, Jin Woong Ha

Catholic University of Korea, College of Medicine, Seoul, Korea, Republic of

Alternative polyadenylation (APA) involves the addition of a polyadenylate (poly-A) tail to the 3' end of an mRNA molecule, which is essential for mRNA stability and translation into proteins. This mechanism is critical for gene expression and function, particularly in cancer. Glypican-3 (GPC3) is significantly overexpressed in hepatocellular carcinoma (HCC) and is associated with poor prognosis. APA profiling analysis showed that the 3' UTR of GPC3 is shortened, which strongly correlates with increased GPC3 expression in HCC. Disruption of GPC3 led to inhibited cellular growth and increased apoptotic cell death in HCC cells, while ectopic overexpression of a GPC3 plasmid stimulated growth and proliferation in these cells. Furthermore, Cleavage Stimulation Factor Subunit 2 (CSTF2), a component of the cleavage stimulation factor complex, was found to promote the shortening of GPC3's 3' UTR through APA regulation in HCC cells. CSTF2 expression also correlated with GPC3 levels and the dPDUI (Percentage of Distal PolyA Site Usage Index) of GPC3 in HCC. Knockdown of CSTF2 resulted in decreased GPC3 expression, which inhibited cell growth and proliferation while increasing apoptotic cell death in HCC cells. Additionally, CSTF2 knockdown led to lengthening of the GPC3 3' UTR, whereas overexpression of CSTF2 shows the opposite effect. Using predictive analysis with online tools TargetScan, miRDB, and miRabel, 40 miRNAs were identified as potential binders to the GPC3 3' UTR. *In vitro* functional analysis demonstrated that miR-96-5p and miR-140-5p sustain the normal expression of GPC3 in hepatocytes, and that the shortening of the 3' UTR of GPC3 RNA contributes to hepatocarcinogenesis. Overall, these findings suggest that the aberrant overexpression of GPC3, driven by selective APA regulation mediated by CSTF2, contributes to the malignant transformation and growth of hepatocytes, providing a novel therapeutic target for liver malignancies.

#1409 Reprogramming the alternative polyadenylation of an oncogenic transcription factor as a therapeutic strategy for prostate cancer.

Giulia Pagani[1], Chiara Casirati[1], Stefania Fornezza[1], Roberta Cacioppo[2], **Paolo Gandellini**[1]

[1]University of Milan, Milan, Italy,[2]MRC Laboratory of Molecular Biology, Cambridge, United Kingdom

Alternative polyadenylation (APA) of mRNAs is emerging as a powerful new player in cancer biology, driving aggressive cancer behavior by reshaping how oncogenes are regulated. In particular, altered APA typically fuels cancer growth by shortening the 3'UTR of oncogenes, thus altering mRNA stability and reducing the ability of miRNAs to suppress cancer-promoting genes. This marks APA as a new hallmark of cancer malignancy and a promising novel therapeutic target. We focused on prostate cancer (PCa), the tumor with the highest incidence in male population worldwide, and on *NFYA* oncogene, a driver of aggressive PCa. *NFYA* encodes for the regulatory subunit of the transcription factor NF-Y, a key player in cell cycle regulation and a well-established actor in cancer. We determined that *NFYA* undergoes 3'UTR shortening in PCa cells, thus resulting in increased protein level by means of enhanced mRNA stability, reduced nuclear retention, and attenuation of miRNA-mediated repression. Thus, it was of interest to investigate the effect of APA on the remodeling of the quantity and activity of NF-YA oncoprotein in PCa cells, and how this influences PCa behavior and aggressiveness. To explore this process, we aimed to reprogram *NFYA* APA towards 3'UTR lengthening in PCa cells and evaluated the effects on PCa cell features. Through CRISPR/Cas9 editing and non-degrading antisense oligonucleotides (ASO), we abrogated the usage of the polyadenylation signal (PAS) of the most abundant *NFYA* 3'UTR isoform, which led to a shift towards increased utilization of the longest *NFYA* 3'UTR and decreased NF-YA protein. This, in turn, curbed PCa cell proliferation. Similarly, ASO-treated cells forced to use only the most distal PAS displayed reduced protein level and impaired cell growth. Therefore, these findings highlight APA as a crucial post-transcriptional mechanism regulating NF-YA activity in PCa. Moreover, they provide the proof-of-concept for a possible APA-directed and gene-specific therapy. This is further strengthened by the emerging application of ASOs in the clinics, which opens the possibility of their use to therapeutically manipulate the effects of APA in PCa. Overall, our results build the biological rationale for the development of novel and innovative therapeutic opportunities for aggressive PCa based on *NFYA* APA modulation, possibly combined with standard therapies, which could help treatment optimization and improve patients' survival in the medium-long term.

#1411 ADAR1 enhances ribosome biogenesis and triggers oncogenic translation.

Xuliren Wang, Zhibo Shao, Qi Zhang, Han Zhu, Bingqiu Xiu, Yayun Chi, Jiong Wu

Department of Breast Surgery, Key Laboratory of Breast Cancer in Shanghai,Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, China

Background: Ribosome biogenesis (RiBi) is a critical process underpinning cellular protein synthesis, meticulously regulated to maintain homeostasis. Dysregulated RiBi and translational control are integral to the uncontrolled proliferation of tumors, a hallmark of cancer, yet the molecular mechanisms remain poorly understood. Adenosine Deaminase Acting on RNA 1 (ADAR1), a key enzyme mediating RNA editing, has been linked to tumor transcriptomic heterogeneity and resistance to PD-1 immune checkpoint blockade. However, its precise role in tumor ribosome biogenesis and oncogenic translation remains unclear. Here, we uncover a novel connection between ADAR1 and RiBi, revealing its unrecognized role in driving tumorigenesis and therapeutic vulnerability. **Methods**: To identify ADAR1-regulated pathways, RNA sequencing (RNA-seq), ribosome profiling (Ribo-seq), and gene set enrichment analysis (GSEA) were performed in ADAR1-siRNA-treated tumor cells. The association between ADAR1 and RiBi was validated using single-sample GSEA (ssGSEA) in TCGA datasets and the RiBi Alu Editing Index (AEI) in the FUSCC TNBC cohort. Nucleolar morphology was evaluated using immunofluorescence and electron microscopy, while ribosome abundance and translational efficiency were assessed via sucrose density gradient centrifugation, rRNA quantification, and SUnSET assays. RNA pull-down and Sanger sequencing validated downstream targets. Functional and therapeutic potential of ADAR1 inhibition were assessed in mouse xenograft models and patient-derived organoids (PDOs) treated with CX-5461, an RNA polymerase I inhibitor. **Results**: ADAR1 was found to play a pivotal role in driving onco-RiBi, enhancing ribosome production and translation of oncogenic pathways such as MYC, mTOR, and DNA repair. Ribo-seq revealed that ADAR1 knockdown suppressed the translational efficiency of pro-tumorigenic genes, including *MCM2* and *CDC6*. Mechanistically, ADAR1-mediated A-to-I RNA editing of Nucleolar Protein 14 (NOP14) stabilized fibrillarin (FBL), a key nucleolar marker, preserving nucleolar integrity and promoting ribosome assembly. High ADAR1 expression and elevated RiBi AEI scores correlated with poor prognosis in TCGA and FUSCC cohorts. CX-5461 disrupted RiBi, induced nucleolar stress, and suppressed tumor growth in preclinical models. PDOs with high ADAR1 expression demonstrated increased sensitivity to CX-5461, highlighting its therapeutic potential for targeting ADAR1-driven ribosomal dysregulation. **Conclusions**: Our study establishes a critical link between post-transcriptional RNA editing, tumor ribosome biogenesis, and oncogenic translation, addressing a key gap in the field. ADAR1 emerges as a pivotal regulator of onco-RiBi, and targeting ADAR1 in tumors with high expression using CX-5461 represents a promising therapeutic strategy.

#1412 Translational regulation of *MYC* in acute lymphoblastic leukemia.

Sankalp Srivastava[1], Jagannath Misra[1], Rodney Claude[1], Michael Holmes[1], Gang Peng[1], Kirk Staschke[1], Sandeep Batra[1], Utpal Dave[1], Chi Zhang[1], Ronald Wek[1], Jing Fan[2], Ji Zhang[1]

[1]Indiana University, Indianapolis, IN,[2]University of Wisconsin-Madison, Madison, WI

Acute lymphoblastic leukemia (ALL) is the most frequently diagnosed childhood cancer, with a prevalence of almost 25%. ALL cells are auxotrophic for asparagine and have been targeted therapeutically by treatment with bacterial-derived asparaginase. Although asparaginase has been a cornerstone of treatment, ALL can relapse in 10-15% of cases. We previously published that asparagine synthetase (*ASNS*) induction in response to asparagine depletion is a primary resistance mechanism to asparaginase therapy. Using auxotrophic DND-41 cells, we also showed that asparagine starvation suppresses the expression of c-MYC (MYC) protein, a critical oncogenic driver in ALL cells. We did not observe a change in *MYC* transcript levels or protein stability, suggesting the acute decrease in protein level was due to a decrease in translation of *MYC* mRNA. We performed a polysome profiling in DND-41 cells to measure the translation of *MYC* mRNA. Compared to asparagine-replete control, asparagine starvation caused a significant decrease in the amount of heavier polysomes associated with *MYC* mRNA. We further performed a Ribo-seq experiment, where cell lysates were treated with RNAse I, leaving ribosome-protected fragments (RPFs) intact for high throughput sequencing. Our analysis showed that RPFs were distributed throughout the *MYC* coding sequence (CDS) for the control samples but enriched in the N-terminal of the *MYC* CDS when asparagine was limiting. Of note, these RPFs were around closely spaced asparagine codons (+4, +9, +11) near the translation initiating AUG codon, suggesting this is a critical cis-element regulating the translation of *MYC* mRNA. We designed a MYC-translation reporter with the MYC N-terminal region fused to an eYFP-DD construct. The fused protein rapidly degrades upon translation due to the destabilization domain (DD), leading to reduced fluorescence. Treating cells with a small molecule, trimethoprim (TMP), stabilizes the fusion protein, enhancing fluorescence. We defined the translation rate by calculating the ratio of fluorescence intensities with and without TMP. Our results showed that fusing the MYC N-terminal region to the reporter significantly reduced translation compared to the eYFP-DD construct upon asparagine starvation. We also found that deleting the asparagine codons partially rescued the reporter translation, when asparagine is limiting. We will use this system to identify trans-factors regulating *MYC* translation using a dedicated CRISPR library targeting mRNA regulators.

#1413 Dissecting the biology of mutant p53 with the Cellular Thermal Shift Assay (CETSA).

Tomas Friman, Merve Kacal, Laurence Arnold, **Daniel Martinez Molina**

Pelago Bioscience AB, Solna, Sweden

The tumor suppressor protein p53 is one of the most important safeguards against malignant transformation of mammalian cells, but it is also one of the most frequently mutated proteins in cancers. Therefore, p53 constitutes an attractive drug target in oncology. However, there has been little success in finding clinical candidate drugs that directly manipulate the function of p53. The p53 protein offers several challenges for investigators wanting to manipulate its function e.g., the absence of accessible binding pockets, lack of enzymatic activity, and its intracellular location. Moreover, another complication with p53 is the plethora of mutations that alter the protein's characteristics. Most mutational changes in p53 result in a loss of function, but there are also examples of gain of function mutations in p53. We have applied the Cellular Thermal Shift Assay (CETSA) for screening of new chemical hit matter for binding to p53. As CETSA exploits the compound induced changes in protein melting behavior it is important to know the melting characteristics of the protein under investigation. Since p53 displays a wide variety of mutational variants, we decided to investigate three different variants present in three separate breast cancer cell lines: SK-BR-3 ($p53^{R175H)}$, BT-474 ($p53^{E285K}$), and MCF-7 ($p53^{WT}$). The melting behavior of p53 protein was similar irrespective of genomic status of p53 in intact cells. However, in lysed cells there was striking difference in p53 protein melting between MCF-7 cells that carry WT p53 and the two other breast cancer cell lines that carry mutations in the gene coding p53. The melting temperature for WT p53 was nearly the same in both lysate and intact cells, whereas there was 3 to 4°C difference between intact cells and lysates derived from the two cell lines that expressed mutated p53. Both of the mutated forms of p53 found in SK-BR-3 cells and BT-474 cells displayed greater thermal stability in lysate compared to MCF-7. Intrigued by this difference we set out to investigate its cause. It is known that certain mutated forms of p53 are rescued from proteasomal degradation by associating with chaperone proteins like Hsp90. Therefore, the different breast cancer cell lines were treated with inhibitors of Hsp90 function and protein melting of the respective form of p53 was assessed. Hsp90 modulation by Geldanamycin had a much more potent effect on thermal stability of mutant p53 compared to the WT counterpart, which indicates that Hsp90 could be involved in conferring increased thermal stability of mutant p53.

#1415 FraAP, a peptide antagonist against the activator protein 1 transcription factor complex, demonstrates cancer cell cytotoxicity and reduced invasion in vitro and tumor regression in vivo in HNSCC models.

Karen Mendelson, Zachary F. Mattes, Siok Leong, Ricardo Ramirez, Mark Koester, Claudio Scuoppo, Julia Diehl, Erin Gallagher, Binh Lee, Franco Abbate, Lila Ghamsari, Gene Merutka, Barry J. Kappel, Abi Vainstein-Haras, Jim A. Rotolo

Sapience Therapeutics, Inc., Tarrytown, NY

The AP-1 transcription factor complex, comprised of Fra1 and Jun heterodimers, plays a pivotal role in the pathogenesis of head and neck squamous cell carcinoma (HNSCC). This complex significantly contributes to tumor progression and metastasis with its expression positively correlating with poor prognosis. As dimerization of components of the AP-1 complex is required for DNA binding and subsequent transcriptional activity, we designed a peptide (Fra1 antagonizing peptide, FraAP) targeting the basic leucine zipper motif of AP-1 to antagonize AP-1 complex formation and prevent associated activity. Bio-layer interferometry (BLI) and DNA ELISA assays demonstrate target binding and selectivity of FraAP towards AP-1 family members, co-immunoprecipitation experiments reveal that FraAP blocks protein-protein interactions between cJun and Fra1, and reporter assays confirm inhibition of AP-1 transcriptional activity in vitro. Transcriptomic analysis reveals that FraAP suppresses AP-1-driven pathways required for cell cycle progression, proliferation, and invasion and promotes apoptosis. RNAseq data was confirmed by qPCR analysis of relevant target genes. Corresponding functional in vitro assays reveal that FraAP exhibits an inhibitory effect on invasion in Boyden chamber assays and induces a phenotypic mesenchymal to epithelial transition characterized by decreased mesenchymal marker N-cadherin and increased epithelial marker E-cadherin. Annexin V characterization of FraAP treated cells by flow cytometry confirms that FraAP induces dose-dependent apoptosis. Further, in a HNSCC subcutaneous xenograft model, administration of FraAP results in significant tumor growth inhibition, demonstrating the anti-cancer potential of targeting the AP-1 complex. In summary, these data support FraAP as a potent peptide antagonist of the AP-1 transcription factor family that warrants further development as a potential therapeutic option for AP-1 driven tumors.

#1416 Defining the mechanisms of cancer specific transcription factor, tGLI1.

Haddie DeHart[1], Nolan Gregg[2], Julie Heldman[2], Richard Carpenter[1]

[1]Indiana University School of Medicine, Bloomington, IN,[2]Indiana University, Bloomington, IN

Glioblastoma (GBM) is the most common malignant central nervous system tumor in adults with a five-year survival rate of less than 7%. First identified in GBM, truncated GLI1 (tGLI1), an alternative splicing isoform of GLI1, has emerged as a cancer specific GLI1 variant as tGLI1 is highly expressed in both GBM cell lines and primary specimens but not in normal tissue. Despite an in-frame loss of 41 amino acids, the tGLI1 protein has retained all known GLI1 functional domains and appears to respond to sonic hedgehog in a similar manner as GLI1. However, tGLI1 operates as a gain of function transcription factor with the ability to bind to and activate genes unique from GLI1 to promote invasion, migration, angiogenesis, and stemness in both GBM and breast cancer. Despite the advancements in our understanding of tGLI1, a genome wide DNA binding pattern of tGLI1 has not been established and the mechanism by which tGLI1 gains access to these genes is unknown. To establish a more robust understanding of the differential DNA binding patterns of GLI1 and tGLI1, we carried out ChIP-sequencing (ChIP-seq) and found only 14% of GLI1 and tGLI1 binding sites are shared. These results suggest GLI1 and tGLI1 have even more unique binding pattens across the entire genome that previously thought. However, the underlying mechanism for why GLI1 and tGLI1 bind different regions of the genome remains elusive. To determine whether variations in protein interactions of GLI1 and tGLI1 contribute to the unique binding pattern of tGLI1, we carried out immunoprecipitation (IP) followed by mass spectrometry (mass spec). Results identified 45 GLI1 associated proteins and 52 tGLI1 associated proteins with only a 29% overlap between the two. Furthermore, gene ontology analysis revealed 43% of the tGLI1-specific associated proteins are involved in processes related to RNA binding, processing, and metabolism. From these RNA-related proteins, we validated an interaction between tGLI1 and the protein NONO. NONO, which can bind both RNA and DNA, is involved in a range of molecular processes including paraspeckle formation and transcriptional regulation. In GBM, high NONO expression correlates with poor patient outcomes and the mesenchymal subtype. Interestingly, we observed a greater interaction between NONO and tGLI1 as compared to GLI1 and that co-expression of NONO and tGLI1 increased the nuclear localization of both proteins. Overall, these findings enhance our understanding of tGLI1's distinct role in the cell and suggest a potential mechanism underlying its contribution to GBM. Future research will focus on further elucidating the NONO-tGLI1 interaction and investigating the role of NONO in tGLI1-driven phenotypes and GBM progression.

#1417 Defining the mechanism of androgen receptor activation by ABI1.

Kevin Mengen Lin, David M. Solano, Baylee A. Porter-Hansen, Xiang Li, Leszek Kotula

Urology; Biochemistry and Molecular Biology, SUNY Upstate Medical University, Syracuse, NY

Prostate cancer is the most common non-skin cancer among men worldwide and the second leading cause of cancer-related deaths. Prostate tumor development is driven by androgen receptor (AR) signaling, and while early-stage prostate cancer responds well to anti-androgen therapies, resistance frequently emerges. This resistance often involves aberrant reactivation of AR signaling, underscoring the critical need for a deeper understanding of AR regulation to inform new therapeutic strategies.AR activation is mediated by the intrinsically disordered N-terminal domain (NTD), which contains several proline-rich (PXXP) motifs that serve as consensus sequences for SH3 domain binding. Our previous work identified Abelson-interactor 1 (ABI1) as a novel AR-binding protein via ABI1's SH3 domain. ABI1, a key regulator of the actin cytoskeleton as part of the WAVE complex, exhibits dysregulated expression during prostate cancer progression. We hypothesize that ABI1 regulates AR, and its splice variant AR-V7, through multivalent interactions between ABI1's SH3 domain and PXXP motifs in the AR NTD. To investigate this, we used purified AR PXXP peptides and ABI1-SH3 probes in far-western blotting assays, demonstrating that ABI1-SH3 preferentially binds to two of the seven canonical PXXP motifs within AR-NTD. *In vivo* studies with AR NTD-truncation mutants further confirmed that ABI1 regulates AR activity through these interactions. These findings position ABI1 as a regulator of AR activity, potentially linking AR dysregulation with cytoskeletal reorganization and cancer cell metastasis. This work enhances our understanding of ABI1's role in AR-driven tumorigenesis and provides a foundation for future studies aimed at targeting ABI1-AR interactions to develop novel therapies for advanced prostate cancer.

#1418 Mapping the FOXA1 interactome in ER+ breast cancer cells using proximity labeling reveals a novel interaction with NR2C2.

Carla Sofia Rodriguez-Tirado[1], Rosemary Plagens[2], Shen Li[3], Christine Mills[4], Laure Herring[4], Hector Franco[1]

[1]Division of Translational and Clinical Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]Lineberger Comprehensive Cancer Center, Department of Genetics, School of Medicine, University of North Carolina at Chapel Hill, Chapell Hill, NC,[3]Lineberger Comprehensive Cancer Center, Department of Genetics, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]UNC Proteomics Core Facility, Department of Pharmacology, University of North Carolina at Chapel Hill, Chapell Hill, NC

Approximately 70% of breast cancers are driven by the estrogen receptor alpha (ER), and despite the advent of endocrine therapy to block ER signaling pathways, a significant proportion of women develop resistance to these drugs. The pioneer factor FOXA1 has been shown to facilitate nearly all DNA-binding events of ER in response to estrogen in ER-positive breast cancer (ER+BC). Notably, up-regulation of FOXA1 is a hallmark of endocrine-resistant tumors. Furthermore, FOXA1 has been shown to alter the transcriptome in endocrine therapy resistance. FOXA1 interacting partners, such as ER, androgen receptor (AR), MLL3, YAP1 and GATA-3 mediate transcription activation of genes important for cancer progression. There have been previous studies showing interactors of FOXA1, but none have addressed a comprehensive list of interactors of FOXA1, especially in breast cancer. To address this challenge, we generated MCF-7 cell lines stably expressing the biotin ligase miniTurbo fused to the N- or C-terminus of FOXA1 to classify interactors of FOXA1 in ER+BC. Using proximity labeling (PL) coupled with LC-MS/MS, we aimed to comprehensively catalog interactors of FOXA1. We were able to identify expected proteins such as ER, AR, MLL3, YAP1, and GATA-3. Moreover, we have discovered 157 previously unpublished interactors of FOXA1. Importantly, poorer prognosis for relapse-free survival among ER+BC patients is associated with several of these novel interactors, including NR2C2, an orphan nuclear receptor previously shown to regulate various nuclear receptor signaling but whose roles in breast cancer remain unclear. NR2C2 ChIP-seq in MCF-7 cells under FOXA1-depleted conditions revealed NR2C2 binding loci dependent on FOXA1 levels and binding. By integrating proteomic and genomic approaches, we highlight new mechanisms of FOXA1-mediated transcriptional regulation, with promising potential for endocrine therapy resistance.

#1419 RCZY-711, a novel, highly potent, and orally bioavailable menin-MLL inhibitor with superior efficacy in preclinical acute leukemia models.

Celia X.-J. Chen, Zhengyong Wan, Yu Bai, Xiaohong Liu, Jianming Bao

Rongchang Pharmaceuticals, Ltd., Shanghai, China

Menin, encoded by the MEN1 gene, is a scaffold protein widely expressed in human tissues, regulating diverse functions through interactions in key signaling pathways. The menin-MLL1 (KMT2A) complex plays a critical role in acute leukemias with KMT2A rearrangements or NPM1 mutations, driving aberrant expression of HOX genes and MEIS1, which promote leukemia development. MLL is a histone H3K4 methyltransferase essential for transcription in embryonic development and hematopoiesis and frequently forms oncogenic fusion proteins via chromosomal translocations. Disrupting the menin-MLL interaction is an effective therapeutic strategy for MLL-rearranged and NPM1-mutant leukemias. The FDA-approved menin inhibitor SNDX-5613 treats relapsed/refractory acute leukemia with MLL translocations, while ongoing trials explore its use in KRAS-mutant solid tumors and Wnt-driven cancers. Another menin inhibitor, KO-539, is being tested in advanced gastrointestinal stromal tumors. Developing novel menin inhibitors with enhanced safety and efficacy remains a significant clinical priority.

Herein, we report RCZY-711, a novel, highly potent, and orally bioavailable menin inhibitor with subnanomolar binding affinity, as demonstrated by SPR. Its potency in disrupting the menin-MLL interaction was further validated using a fluorescence polarization assay (subnanomolar IC_{50}). RCZY-711 displayed potent growth inhibition (single-digit nanomolar IC_{50}) in cancer cell lines with KMT2A rearrangements or NPM1 mutations, without cytotoxicity in wild-type MLL cell lines. The compound demonstrated desirable drug-like in vitro ADME characteristics, clean in vitro safety characteristics (hERG IC_{50} > 20 μM), and excellent pharmacokinetic characteristics across multiple preclinical species. Oral treatment with RCZY-711 also showed strong in vivo anti-tumor efficacy in acute myeloid leukemia xenograft mouse models, including the MV-4-11 xenograft model with the MLL-AF4 fusion. The observed superior in vivo efficacy may be attributed to its high cellular potency and improved half-life (mouse: $T_{1/2}$ = 2.0 h). In conclusion, RCZY-711 is a novel, highly potent and orally bioavailable menin-MLL inhibitor with best-in-class clinical potential for treating MLL-rearranged and NPM1-mutant acute leukemias.

#1420 Long-read sequencing of single-stranded DNA of colorectal cancer patients.

Bela Molnar[1], Kristof R. Rada[2], Nikolett Szakallas[2], Barbarad K. Bartak[2], Alexandra Kalmar[2], Istvan Takacs[2]

[1]3DHISTECH Ltd., Budapest, Hungary,[2]Semmelweis University, Dept. of Internal Medicine, Budapest, Hungary

Introduction: The presence of single-stranded (ss) DNA in biological samples has been known for many years, but whole-genome level ssDNA sequencing has only recently become feasible due to advancements in technology.
Aims & Methods: To investigate the potential role of ssDNA further, we measured the ss/dsDNA ratio and fragment length distribution of nearly 200 human biopsy, normal adjacent tissue (NAT) and peripheral buffy coat (BC) samples. This included samples from healthy patients (n=31), as well as individuals suffering from inflammatory bowel disease (n=13), colorectal adenoma (n=53) and carcinoma (n=97).A small subset of these were subjected to a dual enrichment method: negative selection *via* dsDNA digestion is followed by positive selection by AMPure XP beads to yield gDNA enriched in the ss form, which was polyA-tailed and reverse transcribed into an ssDNA-cDNA hybrid, that we subjected to library preparation and whole-genome sequencing on Oxford Nanopore's PromethION platform using various modalities: copy number variations, structural variants, and methylation profiling (5mC and 5hmC). We compared the ds- and ssDNA results of matched samples to highlight key differences between the two forms.
Results: ssDNA concentration was 214 (±14.8) ng/ul, with an integrity (DIN) of 4.45 (±0.13) and length of 14.53 (±1.53) kbs. In the case of dsDNA, this was 152 (±14.6) ng/ul, 7.84 (±0.9) and 59.11 (±3.7) kbps, respectively. Average ss/dsDNA concentration ratio was 2.5 (±0.18), with a few samples having equal amounts, while most of them have at least twice as much single-stranded form. After sequencing, the average coverage was 20x (± 2.14) for dsDNA and 7.33 (±1,17) for ssDNA, with a read length of 4.5 (±0.26) and 2.01 (±0.16) kilobases, consistent with the more fragmented condition of the ss form. CpG 5mC methylation of ssDNA is 43.4% (±2.6) of dsDNA (86.9% when considering one strand is synthetic), which is significant hypomethylation ($p<0.05$). 5hmC methylation ratio is doubling from 4.0% (±1%) on dsDNA to 9.5% (±1%) on ssDNA samples ($p=0.006$). However, we can only detect 1.5% of transversions and transitions, and 0.5% of indels when normalized for coverage differences - strongly uneven representation of the genome in the ssDNA fraction might explain this finding.
Conclusion: Third generation long-read sequencing is a promising and flexible method that can be adapted to examine the ssDNA fraction of the genetic material, providing potential new insights into the background of pathologies.

#1421 RNA-seq for somatic tumor detection reveals synergy between whole transcriptome and targeted RNA library preparation methods.

Chelsea Pinegar, Chen Song, Gautam Naishadham, Jian Sun, Bradley W. Langhorst, Keerthana Krishnan

New England Biolabs, Inc., Ipswich, MA

The interplay between variations in transcriptome profiles and disease progression is an important area of study emerging in cancer diagnostics. Whole-genome or targeted sequencing are conventional methods for somatic tumor assessment, but RNA sequencing has emerged as a powerful tool that can provide additional information on translation events in tumorigenesis. Transcriptome dynamics reflect cell state and can reveal key features in the evolution of disease. RNA sequencing (RNA-seq) has transformed cancer research by providing a more comprehensive view of the tumor especially in comparison to adjacent tissue allowing for advances in characterization and therapeutic options. Using streamlined RNA library preparation workflows in combination with a target enrichment approach can provide quick and cost-effective surveillance of samples, with the addition of sensitivity achieved with targeted sequencing. In this study, we compare bulk RNA-seq datasets with and without target enrichment and assess the power of each data type. They can be used in combination with other DNA based screening methods for biomarker detection in somatic tumors. RNA extracted from paired tumor and normal tissue samples were collected and prepared for Illumina sequencing using the NEBNext UltraExpress RNA Library Prep Kit. Target enrichment panels from Twist Bioscience were utilized to enrich specific transcripts and fusion-gene targets using the same Illumina libraries. Comparison of the whole transcriptome RNA-seq data with the target enrichment dataset for the same libraries reveals the strengths of each approach. The non-enriched RNA-seq library dataset provides a view of transcript levels, and can also be used to call SNVs and short structural variants, as well as splice variants and fusion genes. Target-enriched RNA-seq datasets provide more consistent depth and enhance sensitivity for low-level allele variants in targeted regions. The combination of both methods highlights the synergy between datasets in revealing well-known pathogenic mutations and gene fusions as well as rare or novel events. These sequencing methods, in combination with well validated bioinformatic pipelines, have the power to reveal genetic variations that may otherwise be omitted in more conventional detection methods.

#1422 STAG2-mediated gene expression programs promote invasion in muscle invasive bladder cancer.

S. R. Athans[1], N. Krishnan[2], S. Ramakrishnan[2], A. Stablewski[2], S. Lage-Vickers[3], G. Gueron[3], Z. Kazmierczak[4], A. Woloszynska[2]; [1]University at Buffalo, Roswell Park Comprehensive Cancer Center, Buffalo, NY, [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [3]University of Buenos Aires, Buenos Aires, Argentina, [4]University at Buffalo, Buffalo, NY

Stromal antigen 2 (STAG2) is associated with worse overall and progression free survival of muscle invasive bladder cancer (MIBC) patients. Furthermore, STAG2 expression is associated with motility and invasiveness of MIBC cell *in vitro*, suggesting that STAG2 acts as an oncogene in MIBC. In normal cells, STAG2 assists with sister chromatid cohesion, DNA damage repair, and maintenance of genome organization as part of the cohesin complex. However, mechanisms underlying the pro-oncogenic function of STAG2 in MIBC remain unknown. After knockdown of STAG2 in T24 MIBC cells, thousands of genes are differentially expressed. Given this data and the established role of STAG2 genome organization, we hypothesized that STAG2 exerts a pro-oncogenic function through regulating expression of invasion-related genes. To identify target genes, we utilized chromatin immunoprecipitation (ChIP) followed by sequencing and qPCR. From these, we identified the cholesterol efflux pump *ABCA1* as a direct STAG2 target gene, which is significantly downregulated after STAG2 knock out (KO). ABCA1 overexpression is associated with invasion of melanoma and colorectal cancer cells, and therefore we hypothesized that STAG2 mediated *ABCA1* expression may enforce an invasive phenotype in MIBC cells. To assess the mechanism of *ABCA1* regulation, we investigated possible co-regulators and found that in the absence of STAG2, the co-repressor TRIM28 becomes enriched at the *ABCA1* promoter. This suggests that STAG2 and TRIM28 may compete to regulate expression of *ABCA1*, where STAG2 promotes and TRIM28 represses *ABCA1* transcription. In support of this, analysis of patient transcriptome data demonstrates that patients with upper quartile *STAG2* expression or lowest quartile *TRIM28* expression have significantly higher *ABCA1* expression. To further query how loss of STAG2 downregulates *ABCA1,* we analyzed the histone landscape at the *ABCA1* promoter region by ChIP-qPCR. Results show that STAG2 KO is associated with decreased H3K4 and H3K27 acetylation, which are typically associated with active gene promoters. Altogether, these results suggest that STAG2 promotes invasion by enforcing expression of *ABCA1,* which is achieved through displacement of TRIM28 and a subsequent decrease in histone acetylation. This work lays the foundation for investigation of ABCA1 as a targetable molecule in STAG2-high MIBC - for which novel therapies are critically needed.

#1423 Locus-specific proteomics to define transcriptional regulation of GUCY2C hormone expression in colorectal cancer.

Adi Caspi[1], Ariana A. Entezari[1], Jasmine R. Alvarez[1], Jeffrey A. Rappaport[2], Adam E. Snook[1], Scott A. Waldman[1]

[1]Department of Pharmacology, Physiology, and Cancer Biology, Thomas Jefferson University, Philadelphia, PA,[2]Department of Medicine, Johns Hopkins University, Baltimore, MD

The GUCY2C intestinal receptor regulates fluid secretion and epithelial transformation through its hormone ligand guanylin (*GUCA2A*). GUCY2C supports intestinal homeostasis and has been characterized as a tumor suppressor in colorectal cancer. In early tumorigenesis, GUCY2C signaling is silenced through transcriptional repression of guanylin. Guanylin repression is mediated by Wnt/β-catenin/TCF4, a critical signaling pathway aberrantly activated in ~90% of colorectal cancers. Specifically, Wnt signaling regulates expression at a recently characterized 2,683-base pair locus control region (LCR) upstream of the *GUCA2A* gene. This regulation is conferred indirectly, and TCF4, the transcription factor effector of the Wnt cascade, does not interact with the LCR. However, many downstream TCF4 targets are transcription factors canonically implicated in tumorigenesis. Therefore, our goal is to identify factors specifically interacting with the LCR and regulating guanylin expression. Colorectal cancer cell lines expressing inducible Wnt-silencing constructs were used to toggle the expression of guanylin. Using these models, we sought to interrogate Wnt regulation at the LCR by employing C-BERST (d***C***as9-APEX2 ***b***iotinylation at genomic ***e***lements by ***r***estricted ***s***patial ***t***agging), an unbiased proteomics-based approach to profile locus-specific protein interactions. This system relies on peroxidase-mediated biotinylation of proteins by a dCas9-APEX2 fusion protein, driven to a locus of interest by a targeting gRNA. Following localized biotinylation, proteins are enriched by streptavidin pulldown and identified by mass spectrometry analysis. Assessing proteins in the presence and absence of Wnt signaling can reveal Wnt-regulated factors controlling target gene expression. By ChIP-qPCR, we have captured the *GUCA2A* gene locus using targeted gRNAs. Further, dCas9-APEX2 binding does not interfere with the expression of guanylin or its Wnt regulation. Finally, streptavidin-based pulldowns reveal protein interactions at the promoter that can be further characterized by mass spectrometry to elucidate the Wnt regulatory machinery at the *GUCA2A* locus. Identifying the mechanism of Wnt-mediated guanylin silencing, and the transcription factors controlling that regulation, will provide novel insights to inform therapeutic targeting to reconstitute the GUCY2C signaling axis to prevent colorectal cancer.

#1424 Delineating pancreatic ductal adenocarcinoma risk using stem cell derived exocrine pancreas organoids.

K. E. Connelly[1], M. Patel[1], G. Prasad[1], T. Truong Vo[2], H. Arda[2], L. Amundadottir[1];
[1]National Cancer Institute, Rockville, MD, [2]National Cancer Institute, Bethesda, MD

Pancreatic ductal adenocarcinoma (PDAC) is predicted to become the second leading cause of cancer-related deaths by the end of this decade. There is an urgent need to improve risk stratification for prevention and diagnosis and identify novel targets for therapeutic intervention. Both epidemiological factors and genetic variants influence PDAC risk. Epidemiological risk factors include obesity, type 2 diabetes, smoking, and pancreatitis, all of which are associated with inflammation. Genome-wide association studies (GWAS) for PDAC have identified common risk variants with small effect sizes at over 20 loci. Most variants lie in non-coding regions of the genome and thus, the mechanism underlying risk is not obvious. Often enriched in gene regulatory elements, it is thought that the variants influence risk through allele-specific effects on gene regulatory mechanisms, which require extensive follow-up studies. Gene regulatory elements mediate cell-type and stimulus-specific transcriptional programs. Thus, it is crucial to study germline risk variants in models that accurately represent the environment where they exhibit their effects. In an effort to improve our model system for post-GWAS functional studies beyond PDAC-derived cell lines, we have implemented an inducible pluripotent stem cell (iPSC) differentiation protocol to develop exocrine pancreas organoids comprised of acinar and duct-like cells. Preliminary studies demonstrate an enrichment of acinar (*CPA1*, *CTRC*, *AMY2b*) and duct (*SOX9*, *KRT19*, *CA2*) cell markers relative to iPSCs in both the pancreatic progenitor and exocrine organoid cell populations using quantitative PCR. This was further confirmed using immunofluorescence staining of the organoids for CPA1 (acinar), KRT19 (duct) and ongoing flow cytometry analysis. Using Paired-Seq, we are characterizing the chromatin accessibility and transcriptome of the organoids at single-cell resolution to map their gene regulatory elements and compare them to those of PDAC-derived cell lines and FACS-sorted primary exocrine cells. Additionally, we are optimizing different conditions using exogenous cytokine treatment of the organoids to create an *in vitro* system that better resembles an environment conducive to PDAC tumorigenesis. Implementing an iPSC-derived exocrine pancreas model for post-GWAS functional studies opens the door for improved, more in depth functional characterization of risk variants, including how they interact with the cellular environment. This work will help identify risk mechanisms and new therapeutic targets and assist in improving risk stratification of patients.

#1425 Transcriptional and epigenomic landscape of paclitaxel resistant MCF-7 cells.

Julie Hanson Ostrander[1], Thu Truong[2], Marygrace Trousdell[3], Kyla Hagen[2], Nuri Alpay Temiz[4], Michael Ciccone[3], Fatemah Iman Dewji[1], Camila dos Santos[3], Carol A. Lange[1]

[1]Masonic Cancer Center, University of Minnesota, Minneapolis, MN,[2]BMBB, University of Minnesota, Minneapolis, MN,[3]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[4]University of Minnesota, Minneapolis, MN

PELP1 and SRC-3 function as essential coregulatory proteins in normal development and cancer. Overexpression of SRC-3 and PELP1 independently influence cancer cell biology through the regulation of 1) proliferation; 2) apoptosis and autophagy; 3) migration, invasion, and metastasis; and 4) therapy resistance. PELP1 and SRC-3 have both nuclear and cytoplasmic functions, and prior reports indicate that cytoplasmic localization of SRC-3 is necessary for SRC-3 phosphorylation that impacts the transcriptional coregulatory function of SRC-3. Cytoplasmic localization of PELP1 promotes tamoxifen and paclitaxel resistance, and breast cancer stem-like cell (CSC) phenotypes. We previously showed that cytoplasmic and nuclear PELP1/SRC-3 complexes are enriched in ER+ therapy resistant breast cancer. Our published data suggests that altered PELP1/SRC-3 signaling leads to altered gene expression that contributes to the expansion of breast CSC population in therapy resistant ER+ breast cancer. To better understand the transcription and epigenomic landscape of this therapy resistant model, we used a combination of RNA-seq and CUT&RUN. Genes previously shown to be associated with paclitaxel resistance were found upregulated in MCF7 TaxR CSC-enriched tumorspheres (i.e. ABCB1, TUBB2B), with ABCB1 being the most differentially expressed gene compared to parental MCF7 cells. RNA-seq analysis suggests that an upregulation of genes involved in interferon and inflammatory response, as well and Ras signaling and EMT in TaxR cells. We also identified 114 overlapping genes from our TaxR model and our previously published cytoplasmic PELP1 model. Pathway analysis indicates that these genes are regulated by nuclear receptors (i.e. ER and PR), which is supported by an increase in PR expression in TaxR CSC-enriched 3D cultures. CUT&RUN data indicates an enrichment in PELP1/SRC-3 overlapping peaks in TaxR cells. Genes associated with overlapping peaks are associated with androgen response, cholesterol homeostasis, notch signaling, protein secretion and TGF-beta signaling MSigDB Hallmark pathways. Together these data support our hypothesis that PELP1/SRC-3 complexes are reprogrammed to promote therapy resistances and CSC phenotypes. We aim to use these studies to identify pathways that can be targeted within CSCs to eliminate this quiescent population and prevent breast cancer metastasis.

#1426 Mechanism study of METTL3/HIF-2α positive feedback loop promoting multidrug resistance in anaplastic thyroid carcinoma.

Junya Ning, Jinpu Yu

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Research Background: Anaplastic Thyroid Carcinoma (ATC) is an extremely lethal malignant tumor, with patients having an average survival period of typically less than five months. For ATC patients, conventional treatment methods such as surgery and radioactive iodine therapy are not effective. To date, there is no widely recognized standard treatment protocol, which has resulted in no significant improvement in patient survival rates over the past several decades. In clinical treatment, chemotherapeutic drugs doxorubicin and cisplatin are the primary treatment methods. Additionally, research shows that the multi-targeted tyrosine kinase inhibitor lenvatinib is effective for some ATC patients. However, the reality is that many patients exhibit resistance to these drugs from the early stages of treatment, greatly limiting their potential to benefit from the therapy.

Research Results: Our previous research data found that compared to differentiated thyroid cells and normal thyroid cancer cells, ATC cells have a higher degree of hypoxia, and ATC patients with high tissue hypoxia scores have a worse prognosis compared to those with low hypoxia scores; in vitro experiments demonstrated that hypoxic conditions can induce ATC cell resistance to cisplatin, doxorubicin, and lenvatinib. By comparing tissues with high and low hypoxia scores, we discovered significant enrichment of ABC transport proteins. In ATC tissues, hypoxia scores were significantly negatively correlated with METTL3 expression. Under hypoxic conditions, METTL3 in ATC cells downregulates HIF-2α, thereby reducing ABC transport protein expression. We further found that METTL3 catalyzes m6A methylation modification on HIF-2α RNA, and the "reading protein" YTHDF2 recognizes this modification and participates in RNA degradation, thus reducing HIF-2α RNA levels. Interestingly, we also discovered that HIF-2α can downregulate METTL3 expression through the histone demethylase KDM2B, which removes methylation marks from the 4th lysine of histone H3, thereby suppressing downstream gene transcription.

Research Conclusion: In ATC cells, the hypoxic microenvironment upregulates KDM2B through the HIF-2α pathway. KDM2B downregulates METTL3 through its demethylation action, and METTL3 performs m6A methylation modification on HIF-2α RNA, which is then recognized by YTHDF2, ultimately downregulating HIF-2α expression. This positive feedback loop significantly upregulates the expression of ABC transport proteins involved in multidrug resistance, leading to resistance to drugs such as cisplatin, doxorubicin, and lenvatinib.

#1427 Characterization of epigenetic regulation of MYC in acute myeloid leukemia.

William S. Streitfeld[1], William M. Yashar[1], Itallia V. Pacentine[1], Thai T. Nguyen[1], Samantha J. Worme[2], Gurkan G. Yardimci[2], Andrew C. Adey[3], Theodore P. Braun[1]

[1]Cell, Developmental and Cancer Biology, Oregon Health & Science University, Portland, OR,[2]Cancer Early Detection Advanced Research, Oregon Health & Science University, Portland, OR,[3]Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR

Abnormal epigenetic regulation of *MYC* gene expression is a key driver of aberrant proliferation in Acute Myeloid Leukemia (AML). Using functional and single-cell genomics, we identified enhancer hijacking as a mechanism of *MYC* overexpression in AML cells, describing a new mechanism of oncogenesis. The c-MYC transcription factor is an integral regulator of healthy hematopoiesis and is aberrantly upregulated in multiple malignancies, including AML. The c-MYC protein acts as a fulcrum that balances the differentiation and proliferation of blood cells. Therefore, it represents a target for therapeutic intervention because it acts upstream of a network of additional regulatory factors. However, c-MYC is classically considered undruggable because of its lack of enzymatic function and the high likelihood of treatment-related toxicity owing to its role in nearly all tissues. Recent data have shown that *MYC* transcription depends on interactions with distal enhancer DNA elements, including the *MYC* Blood Enhancer Cluster (BENC). Previous studies have demonstrated that the BENC interacts with the *MYC* promoter to control c-MYC-dependent hematopoiesis and the aberrant upregulation of *MYC* transcription in AML. Additionally, previous characterization of the BENC suggests that eight discrete subregions (BENC modules) independently control the differentiation programs necessary for specific myeloid cell types. Using single-cell ATAC-seq on AML patient samples, we demonstrate that module-specific BENC activation patterns differ between AMLs that display differentiated and primitive phenotypes. However, the functional implications of these patterns remain unknown. We created a map of BENC chromatin activity using CUT&Tag for H3K27ac in human hematopoietic stem and progenitor cell populations isolated by FACS. We also used CRISPR knockout followed by cell culture to demonstrate the functional requirements of each BENC module during healthy human hematopoietic differentiation. Additionally, we used CRISPRi to validate the role of each BENC module in AML cell survival and demonstrated that the proliferative rates of AML cells are sensitive to module-specific BENC inhibition. Our data indicate that BENC usage patterns differ between AML and healthy human hematopoietic cells and suggest that AML cells hijack BENC modules to aberrantly upregulate *MYC* during disease progression. Further characterization of the factors involved in *MYC* regulation by the BENC will provide a framework for identifying and testing new drugs to selectively reverse *MYC* overexpression in AML, with the ultimate goal of improving the treatment outcomes for this difficult-to-treat and highly morbid disease.

#1428 Dissecting a triple-negative breast cancer super enhancer: insights into oncogenic gene regulation.

Natalia Maldonado Vazquez, Nicole Zaragoza Rodriguez, Hector Franco

University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Triple Negative Breast Cancer (TNBC) is an aggressive and therapeutically challenging subtype of breast cancer, characterized by significant intra-tumoral heterogeneity and the absence of actionable molecular markers. This study addresses the urgent need for targeted therapies by investigating the role of non-coding regulatory elements, specifically super enhancers (SEs), in TNBC pathogenesis. SEs are large clusters of enhancers with high transcription factor occupancy and enhancer RNA (eRNA) production, regulating key genes involved in cell identity and cancer progression. Using Chromatin Immunoprecipitation sequencing (ChIP-seq) and Global Run-On sequencing (GRO-seq) across 13 cancer cell lines, we identified a novel TNBC-specific, transcriptionally active SE on chromosome 17, located upstream of the ITGA3 gene. To elucidate its functional role, we conducted CRISPR-interference (CRISPRi) assays coupled with RNA sequencing in TNBC cells, revealing genome-wide SE target genes. Integration with high-throughput chromosome conformation capture (Hi-C) data established direct chromatin interactions linking the SE to its target genes, which collectively form a gene signature predictive of poor clinical outcomes. Perturbation of this SE via CRISPR significantly impaired tumor cell proliferation, highlighting its role as a potential driver of oncogenic phenotypes. These findings provide new insights into enhancer-target gene interactions in TNBC and identify this SE and its associated gene network as promising therapeutic targets.

#1429 Ubiquitin specific peptidase 37 facilitate prostate cancer oncogenesis by regulation replication stress.

Gunjan Dagar[1], Asha Khuswaha[1], Lakshay Malhotra[2], Ashna Gupta[1], Ajaz Bhat[3], Ammira S Al-Shabeeb Akil[4], Atul Batra[1], Seema Khausal[5], Mayank Singh[1]

[1]Medical Oncology Department, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India,[2]Department of Biochemistry, Sri Venkateswara College, University of Delhi, New Delhi, India,[3]Sidra Medical and Research Cente, Sidra medicine, Qatar,[4]Department of Human Genetics-Precision Medicine in Diabetes, Sidra Medicine, Doha, Qatar, Doha, Qatar, Qatar,[5]Pathology, All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Prostate cancer (PC) is one of the second most common cancer diagnosed and the second most common cause of cancer death in men worldwide. Currently combinations of tumor surveillance, surgery, radiation, hormonal, and chemotherapies are used in the management and treatment of prostate cancer. The molecular basis of disease is complex and mutations in many different oncogenes and tumor suppressor genes have been found including *TP53*, *RB1*, *EZH2*, *BMI*, and *PTEN*. The oncogenesis of prostate cancer appears to be caused by dysregulation of many different cellular signalling pathways especially those involved in cell survival and apoptosis. Protein deubiquitination controls many intracellular processes, including cell cycle progression, transcriptional activation, and signal transduction. Ubiquitin specific peptidases (USPs) remove ubiquitin tags from target proteins to alter protein configuration and function. Recent studies have revealed that Ubiquitin specific peptidase 37 (UPS37) regulates replication stress by regulating important protein involved in several important cellular functions. Analysis of TCGA data indicated that overexpression of USP37 correlated with reduced progression free survival (PFS) in prostate cancer patients. Mass spectrometery analysis of Prostate cancer cells (DU145) indicated that distinct set of genes were altered on overexpression or knockdown of USP37. Our data indicate that USP37 overexpression confers survival advantage while its depletion enhances sensitivity for cell killing in PC cells. USP37 overexpressing cells were able to resolve DNA damage foci much more rapidly than the control cells or cells in which USP37 was depleted in response to genotoxic stress. USP37 depletion results in reduced resolution of γ H2AX and 53BP1 DNA damage foci which indicates the reduced ability of cells to carry out constitutive DNA replication. USP37 was found to interact with different replication factors as also seen in our mass spectrum analysis . We further correlated our data with archived tissue blocks of PC patients by analysing if USP37 overexpression correlated with disease progression. Present data suggests that USP37 is required for tolerance of replication stress in PC and is required to dock additional replication factors and stabilize DNA replication fork. The current data provides new mechanistic details for the regulation of replication stress by USP37 which merits the development of targeting strategies to explore its therapeutic potential in PC by inducing synthetic lethality.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Gene Regulation and Transcription Factors 3

#1432 HMGA1 disrupts 3D genome architecture and chromatin looping to repress MHC-II genes and drive immune evasion.

Linda M. S. Resar, Joseph Kim, Audrey Supreme, Li Z. Luo, Bailey West, Isha Maloo, Jung-Hyun Kim, Leslie Cope, Jerry Spivak

Johns Hopkins University School of Medicine, Baltimore, MD

While targeting immune escape has revolutionized cancer therapy, many tumors, such as acute myeloid leukemia (AML), develop strategies to evade a T-cell mediated immune attack. Myeloproliferative neoplasms (MPN) are clonal hematopoietic stem cell disorders at high risk for transformation to secondary AML (sAML). Leukemic transformation in MPN is almost universally fatal and targetable mechanisms have remained elusive. The *High Mobility Group A1* (*HMGA1*) gene encodes an architectural transcription factor that binds to DNA at AT-rich sequences where it recruits chromatin complexes to modulate gene expression. *HMGA1* is highly expressed during embryogenesis and in adult stem cells, but silenced in differentiated cells. *HMGA1* becomes re-expressed in aggressive cancers where high levels portend adverse outcomes. We previously discovered that *HMGA1* is overexpressed in MPN with highest levels after leukemic transformation. Further, our studies in murine models reveal that HMGA1 is required for MPN progression to sAML. To determine how HMGA1 functions in MPN transformation, we performed multiomic analyses to assess gene expression and chromatin state in MPN AML cells. Here, we uncover a novel role for HMGA1 chromatin regulators as drivers of immune escape by modulating three-dimensional (3D) genome architecture to repress antigen-presenting (AP) genes that trigger a T cell-mediated anti-tumor attack. Mechanistically, HMGA1 binds throughout the class II major histocompatibility complex (MHC-II) locus at key regulatory regions and recruits repressive histones to compact chromatin. HMGA1-mediated chromatin compaction at MHC-II enhancers disrupts binding by the genome organizer, CCCTC binding factor (CTCF), thereby preventing CTCF from orchestrating 3D chromatin loops to activate AP genes and stimulate a T-cell mediated anti-tumor immune attack. Using artificial intelligence, we predicted that the histone deacetylase inhibitor, entinostat, targets HMGA1 networks. Strikingly, *HMGA1* gene silencing or treatment with entinostat restores CTCF-mediated chromatin loops and induces AP genes, resulting in a robust T cell-mediated attack on MPN AML cells. Single cell transcriptomics in patient samples demonstrate that *HMGA1* correlates inversely with MHC-II repression, particularly in AML with bi-allelic *TP*53 mutations, demonstrating the relevance of this HMGA1 network in humans. Together, our data illuminate the HMGA1-MHC-II axis as a promising immunotherapeutic target to activate AP genes and trigger a T cell anti-tumor attack in MPN AML and potentially other cancers overexpressing *HMGA1*.

#1433 Roles of noncoding RNAs in tumor dormancy of breast cancer recurrence.

Noriko Saitoh, Maierdan Palihati, Hiroaki Tachiwana, Tomoko Fujita

The JFCR Cancer Institute, Tokyo, Japan

The vast majority of nuclear long non-coding RNAs (lncRNAs) are expressed in a cell type- or disease-specific manner. They often function as epigenetic factors, and are involved in higher-order chromatin structure [1-3]. Dysregulation of lncRNAs sometimes results in diseases, but the detailed mechanisms remain to be investigated.We have identified ELEANORS (ESR1 locus enhancing and activating non-coding RNAs), a cluster of lncRNAs in a model of endocrine therapy-resistant estrogen receptor (ER)-positive breast cancer, the LTED (long-term estrogen deprivation) cells [4]. ELEANORS are transcribed from a large chromatin domain including the gene encoding ER, *ESR1*. They associate with chromatin, and form a molecular condensate, the ELEANOR cloud, which is required for *ESR1* gene activation. C-technologies, including Hi-C, revealed that ELEANORS define a chromatin domain, TAD (topologically associating domain) of about 0.7 Mb [5]. They also equilibrate cell growth and apoptosis by mediating a long-range chromatin interaction between the *ESR1* and *FOXO3* genes. The active transcription of the *ESR1* locus with ELEANORS may represent frequent RNA polymerase II loading to the locus by a novel transcription initiation mechanism.Analysis of clinicopathological features of ELEANORS using patient tissues revealed that ELEANOR expression in primary tumors positively correlates with late recurrence [6]. Further, cancer stem cell populations that are involved in tumor dormancy for late recurrence were increased in LTED cells. They were decreased upon the ELEANOR knockdown, and the transcription level of the CD44 gene, a stem cell marker, also decreased. The *ELEANOR* and *CD44* genes were frequently co-localized in the LTED cells. Thus, ELEANORS may be involved in stem cell maintenance through chromatin interactions. Our results suggest that nuclear lncRNAs are involved in 3D genome structure and pathological mechanisms.

#1434 Advancing multiomic single-cell ATAC-seq assays by expanding scalability and flexibility using nuclear sample multiplexing and gentle sample preservation techniques.

Hongduan Huang[1], Quyen Bao[1], **Rosary Nguyen**[1], Hye-Won Song[2], Aruna Ayer[1]

[1]BD Biosciences, Milpitas, CA,[2]BD Biosciences, San Diego, CA

Recent advances in multiomic single-cell ATAC-seq assay development have enabled researchers to unravel complex biological questions by simultaneously profiling chromatin accessibility and gene expression in a single nucleus. One major challenge, however, remains in boosting scalability and flexibility while still capturing high-quality multiomic data. Sample preparation and batching could be the key to resolving these issues. Here we demonstrate the feasibility of sample multiplexing utilizing oligo-conjugated nucleoporin antibody for nuclei hashing, allowing higher throughput and more efficient workflows. Up to 6 nuclei samples can be tagged separately and then pooled as one multiplex sample in a single ATAC-seq experiment, which minimizes batch effects and lowers per-sample cost. Additionally, we show the compatibility of sample preservation prior to scATAC-seq workflows using BD® OMICS-Guard Sample Preservation Buffer, providing added flexibility of timing without compromising the health of the cell. Moreover, we have combined these approaches and tested sample multiplexing capabilities on stored samples, further enhancing assays' scalability and flexibility. Our data showed that PBMCs preserved with BD® OMICS-Guard Buffer consistently provided high sensitivity and high specificity ATAC-seq data. High ATAC peak correlation and whole transcriptome (WTA) gene expression correlation indicated that chromatin accessibility, RNA integrity and cell biology were well preserved by BD® OMICS-Guard Buffer. Successful sample multiplexing was observed in both cell line samples and PBMCs. Clear sample de-multiplexing was achieved with > 95% cell identification efficacy and > 95% tagging specificity. No significant impact on scATAC-seq or scRNA-seq data quality was observed, compared to unstained controls. Finally, to understand the usability of both techniques, we tested nuclei tagging of nuclei isolated from cells preserved with OMICS-Guard. The data showed that nuclei tagging and de-multiplexing efficiency remained unaffected by cell preservation. Together, our data support that the applications of BD® OMICS-Guard Sample Preservation Buffer and/or nuclei tagging increase scalability and flexibility to design and perform multiomic ATAC-seq and RNA-seq experiments without compromising data quality, which can profoundly impact experiment costs and overall success.

#1435 ATRX loss blocks the differentiation of mesenchymal stem cells and advances undifferentiated sarcoma development.

Y. Cai, J. Yao, D. Pan, Y. Jin, J. You, W. Yao, H. Ying;
UT MD Anderson Cancer Center, Houston, TX

Soft tissue sarcomas (STSs) are a collection of rare tumor types originated from the mesenchymal tissues. Among the over 70 histological subtypes of STS, undifferentiated sarcoma (US), which lacks any discernible morphological features of differentiated tissues, accounts for over 20% of all STSs and is correlated with high tumor grade and poor prognosis. Recent genomic profiling in US has identified p53 and ATRX among the most frequently mutated or deleted genes. ATRX is a SWI/SNF2 type of chromatin remodeling factor which functions in a histone variant H3.3-specific chaperone complex to orchestrates replication-independent nucleosome assembly at repetitive heterochromatic DNA regions including telomeres. Loss-of-function mutations occur frequently in many tumor types and is associated with the development of alternative lengthening of telomere (ALT). However, how loss of ATRX function may contribute to tumorigenesis is largely unknown. Here, we demonstrated that ATRX is required for the terminal differentiation of mouse mesenchymal stem cells (MSCs) into multiple lineages, such as adipocytes and osteocytes. Targeted deletion of Atrx in mouse MSCs, but not terminally differentiated mesenchymal lineage cells, accelerated sarcoma initiation induced by loss of p53 and significantly shortened the overall survival. Atrx-deficient tumors express high level of MSC markers such as CD44 and CD29 and exhibit pathological features highly reminiscent of human high-grade US. By analyzing the transcriptome alterations in Atrx null MSC and tumor cells, we identified a cluster of histones, highly involved in stemness maintenance, chromatin structure modifications and cell cycle, are upregulate under Atrx deletion. On the other hand, further assessment in chromatin remodeling reveals abnormal increased chromatin accessibility under Hist1/2 cluster, where most differential expressed histones are located. Transcriptomic analysis under single cell level also indicates that Atrx deficiency is associated with enhanced cell proliferation. Together, our data indicates that ATRX deficiency contributes to undifferentiated sarcoma development by inhibiting mesenchymal stem cell differentiation.

#1436 The nonenzymatic effects of LSD1.

Rachel D. Dreher, Ira Miller, Emily R. Theisen

Nationwide Children's Hospital, Columbus, OH

Ewing sarcoma is an aggressive malignancy and the second most frequent bone tumor afflicting the adolescent and young adult population. Despite knowing the oncologic driving event of Ewing sarcoma for decades, outcomes and treatment options for this disease have not improved. A chromosomal translocation between chromosome 11 and 22, fusing the *EWSR1* gene to the *FLI1* gene (EWSR1::FLI1), is the cause of eighty five percent of Ewing sarcoma cases. Due to the inability to therapeutically target EWSR1::FLI1, the field has instead attempted to target critical co-regulators to disrupt the oncogenic program of EWSR1::FLI1. Histone specific lysine demethylase 1 (LSD1) is overexpressed in Ewing sarcoma and higher levels of LSD1 correlate with poor patient prognosis. Furthermore, LSD1 directly interacts with, colocalizes with, and targets a similar gene set as EWSR1::FLI1, making it a promising target for targeted therapy. Multiple LSD1 inhibitors have been studied with varying effects on the Ewing transcriptome. In particular, OG-L002, a tranylcypromine derivative with potent and specific LSD1 inhibition has little effect on Ewing sarcoma cells, while noncompetitive small molecule inhibitors targeting enzymatic and nonenzymatic functions of LSD1 kill Ewing sarcoma cells at sub micromolar concentrations. As such, we hypothesize that LSD1 has important nonenzymatic functions in Ewing sarcoma. We have curated a suite of molecular tools to deplete LSD1 DNA, mRNA, and protein to define the nonenzymatic effects of LSD1 in Ewing sarcoma. We have knocked out LSD1 via CRISPR genome editing at the DNA level, degraded LSD1 mature RNA via short hairpin RNA interference, degraded LSD1 protein with the UM171 protein degrader, and enzymatically inhibited LSD1 with OG-L002. In every condition we measured the effect on cellular proliferation with Incucyte growth assays, tested the impact on anchorage independent growth with soft agar transformation assays, and found the differentially expressed transcripts with RNA-sequencing. There are only 4 differentially expressed genes when cells are treated with the enzymatic inhibitor OG-L002, compared to hundreds of differentially expressed genes when nonenzymatic functions are depleted as well. In addition, 39 genes that are commonly targeted by depletion at the DNA, RNA, and protein level, corresponding to genes regulated by the nonenzymatic functions of LSD1. We rescued the LSD1 knock out cells with an enzymatically dead mutant (LSD1 K661A) to further specify genes regulated by LSD1 nonenzymatic functions. These genes are related to transcription factor coregulation, axon development, and synaptic organization and signaling. We believe LSD1 serves a scaffolding or recruitment role in various larger chromatin regulatory complexes that are essential for regulation of these genes in Ewing sarcoma oncogenesis that is distinct from LSD1 demethylase activity.

#1437 Enhancer of zeste homologue 2 (EZH2) knockdown reveals molecular drivers of EMT and metastasis in triple negative breast cancer (TNBC).

Maciej Pietrzak[1], Xilal P. Rima[2], Gautam Sarathy[3], Shivani Dhekne[3], Lara Rizzotto[4], Dario Palmieri[4], Sanjay Gupta[5], Daniel Stover[6], Eduardo Reategui[7], Christian Rolfo[8], **Eswar Shankar**[3]

[1]Biomedical Informatics, The Ohio State University College of Medicine, Columbus, OH,[2]William G. Lowrie Department of Chemical and Biomolecular Engineering,, The Ohio State University, Columbus, OH,[3]The Ohio State University Wexner Medical Ctr., Columbus, OH,[4]Cancer Biology and Genetics, The Ohio State University College of Medicine, Columbus, OH,[5]Urology, Case Western Reserve University School of Medicine, Cleveland, OH,[6]Internal, The Ohio State University Wexner Medical Ctr., Columbus, OH,[7]William G. Lowrie Department of Chemical and Biomolecular Engineering, The Ohio State University, Columbus, OH,[8]Internal Medicine, The Ohio State University Wexner Medical Ctr., Columbus, OH

EZH2 drives TNBC metastasis by promoting epithelial-to-mesenchymal transition (EMT), enhancing cancer stem cell traits, and activating pro-metastatic pathways like Wnt/β-catenin and TGF-β signaling. It also represses tumor suppressor genes through H3K27 trimethylation. EZH2 is overexpressed in TNBC, promoting tumor progression via epigenetic silencing, stemness, EMT, and oncogenic pathways, causing drug resistance and reducing the efficacy of therapy. We hypothesized that silencing EZH2 could uncover its target key genes and pathways responsible for driving metastasis in TNBC. EZH2 knockdown was achieved by CRISPR-cas9 in MDA-MB-231 cells. EZH2 knockdown was confirmed by Western blotting. To test the proper formation of spheroid, we employed a 3D culture system of MDA-MB-231 parental and EZH2 KO cells encapsulated in calcium-alginate microgels seeded from a microfluidic droplet generator. The knockdown of EZH2 inhibited tumor spheroid formation and displayed cytoskeleton de-arrangement. The knockdown of EZH2 also attenuated TNBC growth, migration and proliferation in vitro. RNA from parental MDA-MB-231 cells harboring the cas9 control and the EZH2 knockdown (KO) MDA-MB-231 cells was isolated in quadruplets and used for gene expression profiling using RNA sequencing. Differential gene expression (DGE) analysis was performed using edgeR. KO of EZH2 in TNBC and resulted in the upregulation of 1,096 genes and the downregulation of 1,010 genes. Differential gene expression analysis revealed alterations of expression of key regulators of processes such as EMT, migration, and the tumor microenvironment remodeling such as: EGF, IL6, IL6R, JAG1/2, WNT5A, ITGA2/5/V, FN1, and GDF15. Knockdown of EZH2 had a substantial effect on TNBC growth, disrupting the regulation of essential genes and pathways critical for metastasis. Enrichment analysis of the differentially expressed genes identified key biological functions and pathways associated with EZH2 knockdown, including extracellular matrix organization (M610), collagen formation (M631), focal adhesion (MM15913), and degradation of the extracellular matrix (M587). These pathways are crucial for tumor invasion and metastasis, emphasizing the role of EZH2 in regulating the tumor microenvironment. Our findings demonstrate that EZH2 knockdown significantly impairs TNBC growth in vitro and disrupts the regulation of key genes and pathways central to metastasis. #1438 HMGA2 and protein leucine methylation drive pancreatic cancer lineage plasticity.

S. Kugel[1], S. Dobersch[1], N. Yamamoto[1], A. Schutter[1], S. M. Cavender[1], T. M. Robertson[1], G. Jang[2], A. N. Samraj[3], B. Doron[1], L. A. Poole[1], M. Roudier[1], C. L. Wladyka[1], I. English[1], G. Barreto[4], R. Sears[5], S. Raghavan[6], F. Notta[7], R. N. Eisenman[1], A. C. Hsieh[1]; [1]Fred Hutchinson Cancer Center, Seattle, WA, [2]PanCuRx Research Initiative, Toronto, ON, Canada, [3]University of Washington, Seattle, WA, [4]Max Planck Institute for Heart and Lung Research, Bad Nauheim, Germany, [5]Oregon Health and Sciences University, Portland, OR, [6]Dana-Farber Cancer Institute, Boston, MA, [7]University of Toronto, Toronto, ON, Canada

Pancreatic ductal adenocarcinoma (PDAC) is classified into two distinct subtypes, classical and basal. Basal PDACs (~25% of PDACs) have the worst overall survival and are the only class to act as an independent poor prognostic factor. Therefore, there is an urgent need to understand basal PDAC development, identify biomarkers and find its unique vulnerabilities. We found high expression of the chromatin architectural protein, HMGA2 in the basal subtype of pancreatic cancer. This was across patient-derived cell lines, organoids and in RNA-seq and scRNA-seq patient datasets representing hundreds of patients. We also validated by multiplex immunohistochemistry (mIHC) in >500 diverse patient tissue microarray. We introduce a novel genetically engineered mouse model (GEMM) of basal pancreatic cancer. We find that in this model and in human orthotopic xenografts, HMGA2 is required for cancer growth and sufficient to drive a basal subtype. While HMGA2 is a chromatin factor, we have unexpectedly discovered that it plays an essential role in mRNA translation. Our data demonstrate that HMGA2 controls protein synthesis dynamics through reduced methylation of the protein phosphatase PP2A and subsequent activation of S6 Kinase, a key node of translation regulation. HMGA2 accomplishes this through inhibiting the expression of leucine carboxyl methyltransferase 1 (LCMT1). Importantly, loss of LCMT1 in the classical subtype is sufficient to increase mRNA translation and cause the acquisition of basal features. Thus, we describe a new mechanism by which lineage plasticity is regulated in pancreatic cancer. Most importantly, we demonstrate that high levels of HMGA2 in the basal subtype, and high levels of mRNA translation, render basal pancreatic cancer uniquely susceptible to inhibitors of protein synthesis. As such, we describe a new biomarker and subtype-specific treatment for basal pancreatic cancer.

#1439 Gene expression profiling of canine diffuse large B-cell lymphoma: Insights from RNA sequencing.

Nelly Elshafie[1], Ekramy SayedAhmed[2], Michael O. Childress[3], Andrea Pires dos Santos[2]

[1]Purdue University, West Lafayette, IN,[2]Department of Comparative Pathobiology, Purdue University, West Lafayette, IN,[3]Department of Veterinary Clinical Sciences, Purdue University, West Lafayette, IN

Introduction: Diffuse large B-cell lymphoma (DLBCL) is a common and aggressive form of lymphoma in dogs, closely resembling human DLBCL in its clinical behavior and molecular features. While CHOP chemotherapy is the standard treatment, many dogs experience poor responses or early relapse, underscoring the need for a more comprehensive understanding of the disease's molecular underpinnings. This study aimed to investigate the gene expression profiles in canine DLBCL to identify potential biomarkers and therapeutic targets.
Materials and Methods: Fresh frozen lymph node samples were collected from six dogs diagnosed with DLBCL and four healthy controls. Total RNA was extracted, and RNA sequencing (RNA-seq) was performed to profile global gene expression. Differentially expressed genes were identified using DESeq2, and principal component analysis (PCA) was used to distinguish expression patterns between groups. Key findings were validated using quantitative PCR (qPCR) to confirm the dysregulation of selected genes.
Results: RNA-seq analysis revealed 3,156 differentially expressed genes, including 1,418 upregulated and 1,738 downregulated in DLBCL samples. PCA showed distinct clustering between DLBCL and healthy groups, confirming significant gene expression divergence. qPCR analysis validated these results, highlighting the upregulation of genes such as NIT2 (fold change: 3.145; FDR: 0.0074), MYC (fold change: 3.086; FDR: 0.0494), and CDK4 (fold change: 2.151; FDR: 0.0331), suggesting their involvement in tumorigenesis and disease progression. Conversely, genes such as AICDA (fold change: -4.338; FDR: 0.0284), BCL6 (fold change: -2.352; FDR: 0.0469) and CDH1 (fold change: -1.699; FDR: 0.0469) were significantly downregulated, indicating potential suppression of tumor-suppressive pathways.
Conclusion: This study provides valuable insights into the molecular mechanisms underlying canine DLBCL. The identification of differentially expressed genes and pathways highlights novel biomarkers and potential therapeutic targets. Moreover, the findings demonstrate the translational relevance of canine DLBCL as a comparative model for human lymphoma, advancing our understanding of both veterinary and human oncology. *This abstract was edited and formatted with the assistance of generative artificial intelligence (Chatgpt) to enhance clarity and presentation.*

#1440 GEM-X Universal Multiplex: a cost-effective, sample agnostic multiplexing solution for scRNA-seq in cancer research.

Jui-Szu Chen, Sunny Yang, Joe Shuga, Winnia Hui, Ace Santiago, Ivan Akhremichev, Brett Olsen, Daniel Reyes, Mohammad Rahimi, Peter Smibert, Jessica Terry

10x Genomics, Inc., Pleasanton, CA

Resolving heterogeneity within cancer subtypes is critical to better understand the underlying disease mechanisms and to select the most effective treatment options. Single cell RNA sequencing (scRNA-seq) has revolutionized cancer research by providing unprecedented insights into tumor heterogeneity, immune microenvironment, and treatment responses - areas that were previously difficult to explore using bulk RNA-seq. Recently, sample multiplexing has emerged as a significant advancement in scRNA-seq workflows, enhancing throughput, reducing library preparation workload, and lowering per-sample costs. However, traditional multiplexing methods usually require either samples to have distinct genotypes, or the application of cell-specific barcoding before sample pooling, leading to challenges such as high cell input requirements, laborious sample preparation steps, and compatibility limitations across species and sample types.

To address these issues, we present GEM-X Universal Multiplex, a cost-effective, streamlined approach that eliminates the need for upstream tagging, and offers greater flexibility across different sample types, species, and assays. GEM-X Universal Multiplex utilizes a microfluidic chip to co-partition cells from up to four samples, each with a unique gel bead set, simplifying the multiplexing process. After encapsulation, library generation, and sequencing, 10x Barcodes are employed to trace cDNA-derived reads back to their original sample and gel bead set.

We validated GEM-X Universal Multiplex using human kidney dissociated tumor cells derived from a renal cell carcinoma patient and fixed peripheral blood mononuclear cells from patients with acute lymphoblastic leukemia, primary myelofibrosis, multiple myeloma, and squamous cell carcinoma. Our platform demonstrated its ability to uncover the heterogeneity of different sample types and their unique clonotypes. We also compared GEM-X Universal Multiplex with our singleplex product, GEM-X Universal. Both approaches yielded comparable data in terms of library quality and complexity, the number of V(D)J clonotypes detected, and consistent cell type identification and proportions. In conclusion, GEM-X Universal Multiplex provides a powerful and scalable tool for cancer research, offers high accuracy and reduced technical challenges, and enables broader applications in the study of cancers.

#1441 Elevated HOXC gene expression in castration-resistant prostate cancer.

Isaacson B. Adelani, Akira Kurozumi, Tobiloba Owojuyigbe, Sanchit Sanyal, Su Mi Choi, Srinivasan Yegnasubramanian, Shawn E. Lupold

Johns Hopkins University, Baltimore, MD

Background: Androgen deprivation therapy or Androgen receptor-targeted therapies are used to treat metastatic Prostate Cancer (PCa). However, nearly all cases eventually progress to castration-resistant prostate cancer (CRPC). The molecular pathways associated with CRPC development and progression remain incompletely defined. This study aims to identify new drivers and delineate the underlying mechanisms in CRPC.

Methods: Three isogenic castration-sensitive and castration-resistant prostate cancer cell lines were analyzed by miRNA and RNA sequencing. Gene transcripts associated with castration resistance were further characterized by RT-PCR and bioinformatic analyses. Gene knockout and knockdown in CRPC cell lines were carried out using the CRISPR/Cas9 technology and RNA interference (RNAi) technique. In addition, the HOXC gene cluster was overexpressed in castration-sensitive prostate cancer cell lines using predesigned synthetic sgRNAs and the CRISPR activation (CRISPRa) system. Cell growth and survival were assessed using the IncuCyte®-SX5 live cell analysis system.

Results: Differential gene expression analysis identified significantly elevated miR-196a expression in CRPC cell lines. Visualization of RNA sequencing read density peaks in IGV revealed pri-miR-196a-2 as the source of elevated miR-196a expression in CRPC cells. MIR196A2 is located within the HOXC gene cluster. Transcriptional analyses demonstrate that miR-196a-2 is an intronic miRNA co-transcribed within HOXC gene transcripts. Multiple HOXC gene transcripts were more active in CRPC cell lines. Bioinformatic analyses demonstrated significantly higher HOXC gene expression in a subset of metastatic and CRPC tumors. *The elevated* expression was further validated in clinical samples by RT-qPCR. HOXC8 gene over-expression using plasmid gene expression vectors and CRISPRa enhanced prostate cancer cell proliferation, and HOXC8 gene knockout attenuated CRPC cell proliferation.

Conclusions: *HOXC* gene cluster is activated in in a subset of metastatic and castration-resistant prostate cancer with HOXC8 playing a crucial role in regulating cell proliferation.

#1444 Wnt/β-catenin/TCF signaling suppresses GUCY2C hormone transcription by silencing p38.

Ariana A. Entezari[1], Adi Caspi[1], Jasmine R. Alvarez[1], Jeffrey A. Rappaport[2], Adam E. Snook[1], Scott A. Waldman[1]

[1]Pharmacology, Physiology, and Cancer Biology, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA,[2]Department of Medicine, Johns Hopkins University, Baltimore, MD

Sporadic colorectal cancers (CRCs) are initiated by APC mutations inducing aberrant β-catenin/TCF signaling regulating gene transcription. Similarly, the guanylyl cyclase C (GUCY2C) tumor suppressive axis is universally silenced in CRC. While the GUCY2C receptor is retained, transcriptional silencing of its paracrine hormones guanylin and uroguanylin by β-catenin/TCF signaling is among the earliest events in colorectal transformation. Moreover, suppression of the β-catenin/TCF pathway reconstitutes hormone expression. P38 is a tumor suppressor, and its loss promotes tumorigenesis in chemical and genetic mouse models of CRC. We aim to identify mechanisms by which β-catenin/TCF signaling silences the transcription of GUCY2C hormones to enable targeted reconstitution of ligand expression to prevent CRC. Here, we employed four human CRC cell lines with conditional β-catenin/TCF signaling and healthy human and mouse intestinal organoid models to explore the role of p38 in oncogenic transcriptional signaling. Indeed, toggling oncogenic β-catenin/TCF activity regulates p38 phosphorylation and downstream signaling, suggesting that β-catenin/TCF gain-of-function represses the p38 pathway. Further, pharmacological and genetic repression of p38 activity recapitulates β-catenin/TCF gain-of-function and directly eliminates GUCY2C hormone expression. Finally, beyond GUCY2C hormones, regulation of ~80% of a core set of β-catenin/TCF-dependent genes common to human CRC cells is controlled by p38 signaling. Here, we reveal β-catenin/TCF regulation of p38 activity and its role in mediating transcriptional regulation of gene expression underlying nuclear oncogenic signaling in CRC.

#1445 The functional role of promoter germline variants in breast cancer susceptibility genes.

Nelly A. Arroyo[1], Lenin Godoy[1], Doralis De Leon Vazquez[2], Sol V. Perez Martir[2], Julie Dutil[2]

[1]Department of Basic Sciences, Ponce Research Institute, Ponce Health Sciences University, Ponce, Puerto Rico,[2]Clinical and Translational Cancer Research, Comprehensive Cancer Center, San Juan, Puerto Rico

Introduction: Germline variants are associated with breast cancer risk (BC). It is estimated that inherited deleterious or pathogenic variants in high- to moderate-penetrance BC susceptibility genes such as BRCA1, BRCA2, STK11, CDH1, ATM, PALB2, and CHEK2 may explain up to 27% of the BC cases. For the remaining cases, BC develops due to the complex interaction between environmental and lifestyle risk factors and inherited familial predisposition. While low penetrance genetic variants have a limited impact on BC risk when taken individually, their combined effect on polygenic risk scores may provide a risk elevated enough to justify clinical actions. Most of the previous work in hereditary breast cancer research has focused on variants located in the coding region of the genes. and information on regulatory variants remains limited. This study aims to assess germline variants in the promoter region of BC susceptibility genes on gene expression level. We selected the single promoter genes CDH1 and STK11 and the bidirectional promoter genes PALB2/DCTN5 and ATM/NPAT.
Methods: A bioinformatics approach was developed to identify and prioritize promoter variants that could have a functional impact on gene expression levels. Promoters of each gene of interest were cloned into a luciferase reporter expression system. Side-directed mutagenesis was used to introduce the variants of interest in promoter constructs. The reporter constructs were transfected in MCF7 and MCF10A cell lines and the luciferase activity induced by reference promoter was compared to that of the construct carrying the genetic variants All statistical analyses and graphical visualization were conducted in R implemented in R Studio.
Results: A total of 6,427 variants spanning the promoter regions of interest were identified. Of those, thirteen were selected based on conservation level and predicted binding of transcription regulatory proteins. We identified two variants in the promoter region of STK11 that significantly decrease the expression of Luciferase by a factor of 0.83 and -0.04-fold, almost inhibiting the expression of STK11, while the change in CDH1 has a more subtle effect with a variant significantly increase Luciferase expression by a factor of 2.41-fold. Work is on the way to finish characterizing CDH1 variants and the bidirectional promoters ATM/NPAT and PALB2/DCTN5.
Conclusion: This work demonstrates the functional significance of genetic variants located in regulatory regions of BC susceptibility genes. At the clinical level, expanding genetic testing to include regulatory variants could help better define BC risk in women with negative hereditary cancer test results.

#1446 Gene expression characteristics of the young tongue cancer patient.

Bryan Yichong Shi[1], Yi Ren[2], Wei Keat Teo[2], Jerome Wen Jun Bin[2], Joseph W Foley[2], Chor Hiang Siow[2], Kwok Seng Loh[1], Bingcheng Wu[3], Joshua K Tay[1], Donovan Eu[1]

[1]Department of Otolaryngology - Head & Neck Surgery, National University Hospital, Singapore, Singapore, Singapore,[2]Department of Otolaryngology - Head & Neck Surgery, National University of Singapore, Singapore, Singapore,[3]Department of Pathology, National University Hospital, Singapore, Singapore, Singapore

Introduction: Historical risk factors for tongue cancer include age, chronic exposure to tobacco and alcohol use. Smoking-related tongue cancer has declined due to active anti-tobacco campaigns in developed countries, yet the incidence of tongue cancer has increased, particularly in women and patients under in a younger age group. This study aims to investigate differences in the genomic processes driving oncogenesis in young and old patients with tongue cancer.

Methods: We perform laser-capture microdissection on 54 formalin-fixed paraffin-embedded (FFPE) tongue cancer samples collected from glossectomy surgeries performed from 2009 - 2020 at the National University Hospital, Singapore. To ensure purity, tumor epithelial and microenvironment compartments were separately microdissected for each specimen. Gene expression libraries for each compartment were prepared using a specialized RNA-Seq technique optimized for tiny amounts of FFPE material, followed by next generation sequencing. Differential gene expression and geneset enrichment analysis was performed, comparing patients aged ≤ 50 years (Young Group) and > 50 years (Old Group).

Results: We present a large cohort of 149 microdissected gene expression libraries, including 65 tumor epithelial, 61 microenvironment and 23 normal-adjacent regions. Principal component analysis showed distinct clusters of tumor epithelial and microenvironment gene expression profiles, confirming sample purity. Kaplan-Meier survival analysis revealed poorer outcomes in the Young Group compared to the Old Group. Analysis of the tumor epithelial compartment revealed that young and old tongue cancers exhibited similar gene expression profiles. Notably, there were few differentially expressed genes in the Young Group compared to the Old Group. However, in the microenvironment compartment, we observed that genes involved in immune response were downregulated in the Young Group, including cell killing (Normalised Effect Size =-1.80, p-adj=0.00704) and leukocyte-mediated cytotoxicity (NES=-1.77, p-adj=0.0367). Instead, genes involved in muscle cell development (NES=1.93, p-adj=0.000301) were enriched in the Young Group, indicating the presence of tongue muscle tissue instead of an inflamed tumor microenvironment.

Conclusion: The “young tongue cancer” patient has been suggested to be a unique and aggressive biological entity that exhibits distinct epidemiological and clinical characteristics. Our findings indicate that while tumor epithelial compartment in young and old tongue cancers have similar gene expression profiles, differences in the tumor microenvironment, particularly an immune-cold phenotype in young tumors, may explain their poorer survival outcomes and aggressive behavior. Establishing these biological differences will provide critical insights and support the development of treatment strategies to improve survival outcomes for these patients.

#1447 Histone demethylase JMJD1A regulates glutamine metabolism in prostate cancer.

S. Khadka, M. Pornour, H.-Y. Jeon, A. Hussain, J. Qi;
University of Maryland, Baltimore, Baltimore, MD

Epigenetic regulation plays a crucial role in the development and progression of prostate cancer. JMJD1A (also called KDM3A) promotes prostate cancer progression by upregulating gene expression through the removal of repressive H3K9 methylation marks. Here, we found a role for JMJD1A in the regulation of glutamine biosynthesis in prostate cancer cells. JMJD1A knockdown (KD) significantly reduced cellular glutamine levels and inhibited prostate cancer cell growth under glutamine-deprivation conditions. RNA-seq studies showed that JMJD1A KD reduced the levels of GLUL, a key enzyme in *de novo* glutamine synthesis. mRNA levels of JMJD1A and GLUL were positively correlated in human prostate cancer datasets. Re-expression of GLUL in JMJD1A-KD cells significantly restored cellular glutamine levels and partially rescued the growth defect of prostate cancer cells in glutamine-free growth media. Further, ChIP-seq studies showed that JMJD1A interacted with the methyltransferase EZH2 on the GLUL gene promoter, and JMJD1A/EZH2 cooperatively upregulated H3K27ac levels to promote GLUL expression. Our study revealed cooperation between JMJD1A and EZH2 in regulating gene expression and glutamine metabolism and supports the co-targeting of JMJD1A and EZH2 for potential prostate cancer therapy.

#1448 An evolutionarily conserved chromatin remodeling factor, FACT, in regulation of chromatin, gene expression and cancer.

Priyanka Barman, Sukesh Bhaumik

Biochemistry and Molecular Biology, Southern Illinois University, Carbondale, IL

Eukaryotic genome is packed in the form of chromatin that is an array of nucleosomes. Such nucleosomal organization acts as a barrier for gene regulatory factors to access DNA for transcription. Importantly, cells have evolved with mechanisms for nucleosomal disassembly and reassembly for transcription to occur through chromatin. A heterodimeric chromatin remodeling factor, FACT (Facilitates chromatin transcription), plays a key role in nucleosomal disassembly and reassembly to promote transcription. Intriguingly, FACT is upregulated in breast and other cancers, and FACT upregulation induces oncogenesis. Thus, the upstream regulatory pathways/factors of FACT can emerge as cancer biomarkers which can be targeted for an effective cancer therapy. Further, FACT is found to be downregulated and/or mutated in various cancers including breast cancer. Thus, it is crucial to understand regulatory mechanisms lying upstream of FACT with downstream functions in regulation of chromatin to orchestrate gene expression towards understanding cancer pathogenesis with targeted therapeutic potential. In this conference, we will present our recent work on FACT regulation and functions in controlling chromatin and gene expression with implication in cancer.

#1449 The MAPK pathway regulates cellular identity in lung and pancreatic adenocarcinoma.

Sydney N. Larsen, Walter Orellana, Katherine Gillis, Eric Snyder

University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Recently published data from our lab indicates that downstream signaling from oncogenic KRAS can alter the differentiation state of NKX2-1-negative lung adenocarcinoma (LUAD), a subtype of lung cancer with a foregut-like identity similar to classical pancreatic ductal adenocarcinoma (PDAC). In NKX2-1-negative LUAD, inhibition of the MAPK pathway induces a FoxA1/2-dependent lineage switch marked by the down regulation of gastric surface mucosal epithelium markers and induction of genes associated with zymogenic chief cells of the stomach. We used a pharmacological approach to investigate whether MEK/ERK signaling regulates the differentiation state of classical PDAC. Treatment of murine PDAC organoid lines with a MEK inhibitor led to the induction of zymogenic chief cell markers. Further analyses showed that the deletion of either *Foxa1/2* or *Hnf4α* blocked the induction of chief cell transcripts in response to MEK inhibition. Moreover, exogenous expression of FoxA1/2 revealed that the expression of FoxA1/2 alone was sufficient to rescue MEK inhibitor-induced chief cell programming in genetically FoxA1/2-null organoids. This prompted the hypothesis that the genomic localization and activity of FoxA1/2 and HNF4α are regulated by MAPK signaling in PDAC. To elucidate the mechanisms by which FoxA1/2 and HNF4α activate the zymogenic chief cell program in PDAC in response to MAPK pathway inhibition, we treated KRAS-driven, P53-null murine PDAC organoids with various MEK inhibitors. We then performed ChIP-seq for FoxA1/2 and HNF4α on these organoid lines with pharmacological MEK/ERK manipulation to determine whether MEK/ERK activity modulates binding FoxA1/2 and HNF4α to zymogenic chief targets, facilitating this lineage switch. The evaluation of FoxA1/2 binding patterns and differential binding analysis revealed no direct binding of FoxA1/2 and chief cell targets of interest in these PDAC organoids upon MEK/ERK inhibition. This suggests that the induction of the chief cell lineage switch may not be directly orchestrated by FoxA1/2 relocalization but by alternative methods. We are currently investigating potential indirect mechanisms by which FoxA1/2 and HNF4α induce this lineage switch using ChIP-seq and ATAC-seq.

#1450 Differences in expression levels of putative breast cancer risk genes in normal breast tissues between Black and White Americans.

Lili Liu[1], Guochong Jia[2], Jie Ping[2], Xingyi Guo[2], Ran Tao[2], Bingshan Li[2], Qiuyin Cai[2], Wei Zheng[2]

[1]Vanderbilt University, Nashville, TN,[2]Vanderbilt University Medical Center, Nashville, TN

Background: Despite having a similar incidence of breast cancer, Black American women persistently endure higher mortality rates than their white counterparts. Reasons for this disparity are unclear. We evaluated possible racial differences in expression levels of putative breast cancer susceptibility genes identified in recent studies.

Methods: Included in this analysis are 429 lincRNA or protein-coding risk genes identified in our recent transcriptome-wide association and fine-mapping studies using multi-ancestry data. In this study, The RNA sequencing data for these genes were derived from normal breast tissue samples obtained from 161 Black and 287 white participants recruited in the Susan G. Komen Biobank. To address potential batch effects, we used residuals after the probabilistic estimation of expression residuals correction, with standardized gene expression levels as input data after quantile and inverse rank normalization. Generalized linear regressions were used to investigate racial difference in gene expression levels. Models were adjusted for age, body mass index, and menopausal status. The significance threshold was set at 0.05 divided by the number of independent tests.

Results: Out of the 429 genes evaluated in the study, 50 genes showed significant racial differences in expression levels at $P < 4.54e^{-4}$ (0.05/110), the significant threshold after adjusting for multiple comparisons. Of them, 28 genes showed a higher expression level in Black than white participants. The top three genes with highest percent differences were *GSTM1*, *PRSS45*, and *DIRC3*. The *GSTM1* gene showed a 65.86% higher expression level in Black samples (P=2.58e^{-9}), followed by *PRSS45* (percent difference = 37.75%, P = 9.84e^{-9}) and *DIRC3* (15.52%, 2.95e^{-11}). On the other side, the top three genes with lowest percent difference were *LRRC37A*, *ARL17A* and *LRRC37A2*. Gene *LRRC37A* showed a 35.27% lower expression level in Black than white samples (P=2.22e^{-16}), followed by gene *ARL17A* (-25.14%, 1.35e^{-15}) and *LRRC37A2* (-15.38%, 6.51e^{-13}).

Conclusion: We identified 50 genes showing racial differences in expression levels in breast normal tissues. Further research is needed to understand the reasons for these differences.

#1451 *TPM4* isoform expression modulates a cancer stem cell phenotype in human colon cancer cells.

Nia Lowe[1], Giulio Ferrero[2], Barbara Pardini[3], Alessio Naccarati[3], **Michael Papetti**[1]

[1]Touro University, New York, NY,[2]University of Turin, Turin, Italy,[3]Italian Institute for Genomic Medicine, Turin, Italy

Tropomyosin 4 (TPM4) regulates contractility and migration in many cell types and is important in the migration of colon epithelial cells. Several different alternatively-spliced *TPM4* isoforms are predicted to exist in mammalian cells. However, *TPM4.1* and *TPM4.2*, differing only in the inclusion of 1 (*TPM4.2*) or 2 (*TPM4.2*) unique exon(s) at the 5' end, are the only two isoforms experimentally validated. We previously showed that *TPM4* expression may be an early, premalignant molecular event that contributes to adoption of a tumorigenic state and, specifically, that overexpressed *TPM4.2* blocks certain aspects of induced differentiation in colon epithelial cells and promotes a highly proliferative state. Many studies have shown that *in vivo*, tumors are heterogeneous and contain a very small subpopulation of cancer stem cells that not only drive growth of the tumor via robust proliferation but also are highly invasive and resistant to conventional anti-cancer treatments. Identifying molecular characteristics that promote cancer stem cell formation is therefore critical to developing effective strategies to treat and prevent colon cancer. Adherent LS123 cells (LS123 2D), representing minimally-invasive colon cancer cells at an early stage of tumor development, express both *TPM4.1* and *TPM4.2* transcripts, while nonadherent LS123 tumorspheres (LS123 3D), having a highly invasive, robustly proliferating phenotype similar to cancer stem cells, exclusively express *TPM4.2*. Therefore, we hypothesize that *TPM4.2* overexpression, either by itself or in combination with *TPM4.1* suppression, plays a role in transforming colon epithelial cells to a cancer stem cell phenotype. To test this hypothesis, we determined whether knockdown of *TPM4.1* and/or overexpression of *TPM4.2* will induce a gene expression pattern characteristic of cancer stem cells in the LS123 2D cell line. Specifically, we measured the expression of Sox2, Lgr5, epithelial cell adhesion molecule (*EpCAM*), activated leukocyte cell adhesion molecule (*ALCAM*)/*CD166*, aldehyde dehydrogenase I (*ALDH1*), and *CD44* in LS123 2D cells treated with siRNA targeting *TPM4.1* or *TPM4.2* or in these cells in which *TPM4.1* or *TPM4.2* is overexpressed. Our results indicate that favoring *TPM4.2* over *TPM4.1* expression in LS123 cells increases expression of certain stem cell markers, particularly *CD44* and to a lesser extent *EPCAM* and *ALCAM*, whereas favoring *TPM4.1* over *TPM4.2* expression shows the reciprocal effect on cancer stem cell marker expression. These results may identify distinct roles for expression of individual *TPM4* isoforms in colon epithelial cells and may specifically elucidate whether *TPM4.2* overexpression can contribute to a more aggressive tumorigenic phenotype. Ultimately, our studies may identify therapeutic strategies that target perturbations in cell contractility and migration at early stages of colon tumorigenesis.

#1452 DVL1 regulates global transcriptomic changes and associates with the transcription factor ETS1.

Dalia Martinez-Marin[1], Monica Sharma[2], Jenna C. van Wunnik[3], Flavia Sardela de Miranda[2], Geetha P. Boligala[2], Ella C. Jull[4], Grace C. Stroman[4], Rachel L. Babcock[2], Kevin Pruitt[4]

[1]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Cell Biology and Biochemistry, Texas Tech University Health Sciences Center, Lubbock, TX,[3]Immunology and Molecular Microbiology, Texas Tech University Health Sciences Center, Lubbock, TX,[4]Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Signaling pathways are integral to the regulation of essential biological processes within cells, and their coordinated control across tissues is critical for numerous vital functions. Dysregulation of these pathways can contribute to the development of various diseases, particularly cancer. In the context of Wnt signaling, aberrations in the pathway can induce chromatin modifications that regulate the epigenome, thereby promoting tumorigenesis and metastasis. A key component of this pathway is Dishevelled (DVL), which, although traditionally considered a cytoplasmic protein, has been shown to translocate to the nucleus. However, the nuclear role of DVL remains perplexing, and little is known about what genomic loci it binds, what regulates its binding, and what DNA binding proteins may be novel interacting partners.

Key Results: Our study utilizes data from our recent DVL ChIP/RNA-seq analyses, publicly available datasets, and extensive genomic and bioinformatics evaluations to investigate the poorly understood role of nuclear DVL1. Our findings uncover novel mechanisms by which DVL regulates downstream signaling. First, we demonstrate that DVL not only binds to promoters of genes linked to tumorigenesis but also targets numerous genes involved in immune system regulation. Second, we identify an interaction between DVL1 and transcription factors such as ETS1. Notably, our discovery that nuclear DVL1 and ETS1 form a complex and co-localize at specific genomic loci is, to our knowledge, the first report of such an interaction. Third, we show that ETS1 is essential for DVL1 binding to several genes not previously associated with Wnt/DVL signaling.

Impact: Our study offers some of the first insights into the novel functions of nuclear DVL, revealing its critical role in regulating ETS1 and a broad range of genes essential for developmental biology, antigen presentation, metabolism, chromatin remodeling, and tumorigenesis. By uncovering these previously uncharacterized functions, our research substantially advances the understanding of DVL's involvement in aberrant Wnt signaling, providing new perspectives on its potential contributions to disease mechanisms. This work not only enriches the current knowledge of DVL's multifaceted role but also opens avenues for targeted therapeutic strategies in diseases driven by dysregulated Wnt signaling.

#1453 Investigating the Role of FOXO4 in glioblastoma.

Megan Keniry[1], David Uribe[2]

[1]University of Texas Rio Grande Valley, Edinburg, TX,[2]SIBCS, University of Texas Rio Grande Valley, Edinburg, TX

Evolutionarily conserved partially redundant Forkhead box transcription factors FOXO -1, -3, and -4 drive stem cell maintenance in embryonic, cancer, mesenchymal, hematopoietic, and neural stem cells. Canonically, high PI3K output leads to cytoplasmic/inactive FOXO factors. Stem cells, however, are fundamentally rewired to have high PI3K Pathway activity and nuclear/active FOXO factors. Our previously published work and the work of others show that FOXO factors directly bind to and activate stem genes in both embryonic stem cells and the poor prognosis of cancer glioblastoma multiforme (GBM) to drive stem cell fate. However, the precise mechanisms utilized by FOXO transcription factors in driving stemness, hindering differentiation, and promoting cancer are incompletely understood. To gain insight into the role of nuclear FOXO4 in glioblastoma, we disrupted the gene encoding this factor using CRISPR Cas9 genome editing and performed RNA-seq in the U87MG background. We identified 2,519 differentially expressed genes in *FOXO4*-deleted U87MG cells compared to unmodified controls, including those that drive invasion. Current work is examining whether FOXO4 promotes invasion of glioblastoma cells.

#1454 Investigating the expression of PTPRN2 and MT1X genes in glioblastoma cell migration using hydrogel-based models.

Ananya Bharadwaj[1], Talia Sanazzaro[2], Stephanie K. Seidlits[3]

[1]College of Natural Sciences, The University of Texas At Austin, Austin, TX,[2]Graduate School; Biomedical Engineering, The University of Texas At Austin, Austin, TX,[3]Associate Professor; Biomedical Engineering, The University of Texas At Austin, Austin, TX

Glioblastoma (GBM) is an aggressive brain tumor originating from glial cells and presents difficulty in treatment. GBM are highly heterogeneous, presenting a challenge in treatment. In addition, cells migrate away often as single cells from primary tumor sites making GBM impossible to be fully resected. GBM cells adapt their behavior based on the mechanical properties of their surrounding microenvironment, making it significant to investigate gene markers associated with these mechanical changes. Our recent efforts to investigate particular gene markers included using an interface hydrogel platform that replicates the local microenvironment from the tumor edge to peritumoral tissue. Using this model we successfully separated migratory and non-migratory cells. Results from single-cell RNA (scRNA) sequencing identified gene targets that were overexpressed within the migratory group. We found the gene PTPRN2, which plays a role in vesicle trafficking and exocytosis, was overexpressed in migratory cells. This could be a promising target for future therapeutic methods to limit glioblastoma cell migration. In addition to PTPRN2, we are exploring the role of MT1X, a gene in the metallothionein family, to validate these findings. We are currently investigating the expression of the PTPRN2 and MT1X genes using GBM xenograft mouse models. We have observed PTPRN2 expression in the GBM mouse models, with the highest expression detected in migratory cells compared to non-migratory cells in soft gel conditions. In the future, we plan to perform western blot analysis to further confirm PTPRN2 and MT1X protein expression and validate their roles as potential target proteins for GBM treatment.

#1455 Impact of ZFHX3 loss on endometrial cancer progression.

Areebah Qazi, Sophia Agrusa, Swornalata Pukhrambam, Juveria Ali, Sanjeev Ganesh, Jessica Back, Mike R. Wilson

Oncology, Wayne State University, Detroit, MI

Endometrial cancer (EC) is the sixth most common cancer among women and ranks as the leading type of gynecological cancer. Although EC is often diagnosed early, current treatment plans significantly limit fertility-sparing options, posing challenges for younger patients. This research focuses on the role of the gene ZFHX3 (ATBF1) to understand its effects on the advancement of endometrial cancer. In order to investigate this, we first transfected 12Z-ESR1 epithelial endometrial cells with ZFHX3 siRNA to create transient gene knockdowns. Following cell collection, western blotting was performed to measure ZFHX3 protein expression levels. Furthermore, we used CRISPR Cas9 plasmid guides tagged with GFP to establish more stable knockdowns. After bacterial transformation, we utilized flow cytometry to sort GFP-expressing cells and confirm successful gene editing. Subsequent western blots were conducted to validate which guide were successful in creating an efficient knockdown of ZFHX3. In vivo studies complemented these cellular experiments. We dissected the uteri of mice with ZFHX3 homozygous and ZFHX3/Pten heterozygous knockdowns. Analysis through H&E staining allowed us to quantify the number of endometrial glands. Our findings revealed that ZFHX3 loss disrupts progesterone signaling, a critical regulator of endometrial function, and leads to increased cell proliferation, which may drive tumor growth. These results highlight ZFHX3 as a potential target for therapeutic strategies aimed at balancing fertility preservation and inhibiting the progression of cancer.

#1456 Tumor lineage plasticity blockade by therapeutic targeting of an epigeneticregulator.

X. Zhang, Sr.[1], Y. Yang[1], E. Corey[2], H. Chen[1];
[1]UC Davis Medical Center, Sacramento, CA, [2]University of Washington, Seattle, WA

Tumor lineage plasticity (LP) is an emerging hallmark of cancer progression in solidtumors, such as prostate cancer, pancreatic cancer and lung cancer. However, theexact molecular mechanisms that drive the aberrant LP programs remain poorlydefined. Here we identified bromodomain protein BRD4 as a crucial player. BRD4knockdown and its inhibitors potently suppressed the LP programs both in vitro and invivo. Integrated ChIP-seq and RNA-seq analysis of tumors revealed that BRD4 drivesLP by increasing local chromatin accessibility and directly activating LP gene programswhich includes neurogenesis, axonogenesis and stem cells and key drivers such asBRN2, ASCL1/2, SOX2, SOX9 and RUNX1/2. Significantly, we demonstrated thatBRD4 inhibitor AZD5153, currently at clinical development, possesses potent activity inalmost complete blockade of tumor growth of both de novo neuroendocrine prostatecancer (NEPC) and treatment-induced NEPC PDXs. Further study revealed thatsuppression of tumor expression of LP programs through reduction of local chromatinaccessibility is a primary mechanism of action (MOA) by AZD5153. Together, ourfindings demonstrated that BRD4 plays a fundamental role in directly activating tumorLP programs and that its inhibitor AZD5153 is highly promising in effective treatment ofthe lethal forms of the diseases.

#1457 YAP tyrosine phosphorylation regulates lineage commitment in liver tumorigenesis.

Muhammed D. Aksu[1], Jayla T. Millender[1], Ryan D. Watkins[1], Jennifer A. Yonkus[2], EeeLN H. Buckarma[1], Nathan W. Werneburg[1], Daniel R. O'Brien[1], Chantal E. McCabe[1], Rondell P. Graham[1], Gregory J. Gores[1], Rory L. Smoot[1], Caitlin B. Conboy[1]

[1]Mayo Clinic, Rochester, MN,[2]University of Texas Health Science Center at Houston, Houston, TX

Background: The transcriptional cofactor Yes-associated protein (YAP) is activated in CCA pathophysiology. While canonical regulation by the Hippo pathway resulting in phosphorylation at serine 127 (S127) is inhibitory, SRC-family kinases (SFKs) phosphorylate YAP at tyrosine 357 (Y357), causing activation. Previously, cholangiocytes, hepatic progenitor cells (HPCs), and even mature hepatocytes were suggested as potential cells of origin of CCA, which highlights the plasticity in the liver. However, the role of YAP activation in selecting the cell of origin and lineage commitment during hepatobiliary oncogenesis is unknown.

Aim: To determine if YAP Y357 phosphorylation is required for CCA tumorigenesis, we utilized an *in vivo* model. Unexpectedly, a shift in tumor phenotype to hepatocellular carcinoma (HCC) was identified. Subsequently, we further explored cell signaling and cell of origin contributions to this phenotypic switch.

Method: C57BL/6 mice underwent biliary transfection with Sleeping Beauty transposase and transposons encoding myr-AKT and either YAP S127A (YAP-S) or YAP S127A/Y357F (YAP-SY), followed by IL-33 treatment. Tumor nodule count, histologic classification, and liver-to-body ratio were assessed at necropsy after 10 weeks. RNA sequencing and ingenuity pathway analysis (IPA) were performed on HCC and CCA nodules. To determine the cell of origin, tumors were generated in lineage tracing mice (Rosa26 mT/mG mice treated with AAV8-TBG-Cre). Finally, two tumor-derived cell lines with YAP-SY and constitutive AKT expression were isolated.

Results: Both YAP-S and YAP-SY models developed similar tumor numbers and bulk. YAP-S mice generated frequent CCA (25.3%) in addition to combined HCC-CCA (cHCC-CCA) tumors (10.7%) and HCC (64%), whereas YAP-SY mice developed predominantly HCC (86.7%), with rare CCA (8.8%) and mixed tumors (4.5%). Transcriptome analysis identified 3,367 differentially expressed genes (DEGs) between HCC from YAP-SY mice and CCA from YAP-S mice. Notably, YAP-regulated genes had decreased expression in the HCC from YAP-SY mice. IPA revealed key upstream regulators, including cytokines and growth factors (e.g., *TGFB1*, *TNF*, *INFG*, *CSF2*, *IL6*, *IL1B*, *IL4*) and transcription factors (e.g., *TP53*, *JUN*, *SP1*, *NFKBIA*, *STAT3*). Lineage tracing demonstrated HCC originated from hepatocytes and CCA from cholangiocytes in both models. Finally, gene expression analysis of novel syngeneic cancer cell lines from YAP-SY mice showed mixed features of both HCC and CCA.

Conclusion: In this murine model, we found that sub-maximal YAP activation is associated with increased formation of HCC from hepatocytes, while a higher level of YAP activation due to YAP Y357 phosphorylation is associated with efficient formation of CCA. We identified cytokines and growth factors that may orchestrate this phenotypic switch. Finally, we developed novel syngeneic cancer cell lines with cHCC-CCA characteristics.

#1458 Tolerance of SOX2 and BRN2 in prostate cancer cell lines: effects on cell cycle and lineage transformation.

Connor Purcell[1], Praveen R. Srinivasan[2], Shengliang Zhang[1], Maximilian Pinho-Schwermann[3], William J. MacDonald[4], Lanlan Zhou[1], Andrea Schmidt[1], Claire Lin[5], Xiaobing Tian[1], Tyler J. Roady[1], Vida Tajiknia[1], Viva Voong[1], Wafik El-Deiry[1]

[1]Legorreta Cancer Center at Brown University, Providence, RI,[2]Weill Cornell Medicine, New York, NY,[3]Brown University Health, Providence, RI,[4]Columbia University Vagelos College of Physicians and Surgeons, New York, NY,[5]Warren Alpert Medical School at Brown University, Providence, RI

Introduction: Prostate cancer (PCa) is the most prevalent malignancy in American men excluding skin cancer. In metastatic disease, resistance to androgen pathway inhibitors (APIs) is a major obstacle to curative treatment. One such resistance mechanism is the histological transformation from adenocarcinoma to a neuroendocrine (NE) phenotype, driven by transcription factors like SOX2 and BRN2. Of note, SOX2 is typically overexpressed in PCa lacking functional Rb and p53 and can regulate cell cycle proteins including Cyclin D1. These findings warrant an investigation into a potential connection between SOX2, the cell cycle, and tumor suppressors to further establish molecular mechanisms of neuroendocrine differentiation (NED). We also plan to investigate the potential role of BRN2 in this process.

Methods: Lentiviral Tet-On® systems were cloned and transduced into the PCa cell lines LNCaP (WT RB1, WT TP53) and DU145 (RB1 -/-, TP53 mutant) for the inducible expression of SOX2 (iSOX2) and BRN2 (iBRN2). In vitro growth assays were performed by plating 5,000 cells/well in a 96 well plate and adding doxycycline the following day (DOX). Western blots were performed to determine protein expression. Cell cycle analysis was performed by PI staining and flow cytometry.

Results: Inducible models showed robust induction of SOX2 or BRN2 after 24h induction. At 4d, iBRN2 cell lines demonstrated NE marker upregulation, specifically synaptophysin. SOX2, but not BRN2, induction decreased Cyclin D1 expression irrespective of Rb and p53 status. Intriguingly, LNCaP iSOX2 cells were less viable following induction and had distinct morphological changes including the loss of their stellate shape. LNCaP iBRN2 cells had less profound, but apparent, changes in morphology. No significant morphological changes were identified in DU145. Cell cycle analysis found a greater percentage of LNCaP iSOX2 cells in the sub-G1 state and a lesser percentage in the G2/M phase versus the empty vector.

Conclusions: These results suggest that SOX2 overexpression (OE) may only be tolerated in an Rb and/or p53 deficient setting. Further research will seek to determine if this phenomenon is due to SOX2-induced repression of Cyclin D1. Subsequent experiments will use RB1 and/orTP53 KO cell lines to generate new SOX2 and BRN2 inducible systems. Novel experiments will seek to determine if RB1 and/or TP53 KO increases tolerance to SOX2 OE. Connecting this knowledge of the SOX2 protein to the cell cycle and hormonal signaling in PCa may offer insight into the interplay between emerging cell cycle-targeting therapeutics and the NED process.

#1460 Clinical relevance of a super-enhancer-associated actin polymerization promoting-factor in endometrial cancer.

Kuniko Horie[1], Erina Iwabuchi[2], Kazuhiro Ikeda[1], Takashi Suzuki[3], Satoshi Inoue[4]

[1]Division of Systems Medicine & Gene Therapy, Saitama Medical University, Saitama, Japan,[2]Institute of Science Tokyo, Tokyo, Japan,[3]Department of Anatomic Pathology, Tohoku University Graduate School of Medicine, Sendai, Japan,[4]Department of Systems Aging Science and Medicine, Tokyo Metropolitan Institute for Geriatrics and Gerontology, Tokyo, Japan

Super-enhancers (SEs) are defined as large clusters of enhancers regulating transcription of genes that exhibit cell-type specific functions. SEs in cancers are often different from those in healthy states and responsible for the development and progression of the disease. We here study the clinical role of a super-enhancer-associated actin polymerization promoting-factor, cordon-bleu WH2 repeat protein-like 1 (COBLL1), in endometrial cancer, since we previously demonstrated its tumor-promoting role in castration-resistant prostate cancer [Proc Natl Acad Sci USA 115:4975, 2018]. In the present study, using multiple patient-derived spheroid cultures established by our group [Endocrinology 160:1895, 2029], endometrial cancer-specific SEs were identified by chromatin immunoprecipitation (ChIP) sequencing for H3K27ac binding sites. Among top-ranked SE-associated genes, we focused on the relevance of COBLL1 in endometrial cancer. Then, we showed that COBLL1 silencing in endometrial cancer cells substantially repressed cell proliferation and reduced the populations of cells in S phase of the cell cycle. Of note, immunohistochemical study of clinical endometrial cancer tissues revealed that COBLL1 immunoreactivity was well correlated with poor prognosis of the patients. Our findings suggest that COBLL1 plays a relevant role in the pathophysiology of endometrial cancer and can be applied as a promising diagnostic and therapeutic target in endometrial cancer management.

#1461 Super-enhancer driven NR3C1 expression promotes 5-FU resistance in gastric cancer.

B. Liu, Junxian Yu, Haorang Feng, Jianfang Li;
Shanghai Jiao Tong Univ., School of Med., Shanghai, China

Background: This study aims to describe the Super-enhancer (SE) landscape in 5-FU resistant gastric cancer (GC), and to illustrate the biological mechanism of SE-driven NR3C1 mediating 5-FU resistance. The study might provide new possibilities of improving chemotherapy efficacy for GC.
Methods: The induced drug-resistant gastric cancer cells were constructed with long-term 5-FU medication. The cChIP-Seq and rank ordering of super-enhancers (ROSE) algorithms were applied to calculate SE in GC cells. The core regulating transcription factor (TF) NR3C1 was determined by siRNA libraries. The correlation between NR3C1 expression and the sensitivity to 5-FU was verified by drug sensitivity curves. In induced resistant cells, NR3C1 expression was detected and was knocked down as a rescue experiment. Confocal microscopy was used to observe the purified NR3C1 fluorescent protein droplets in vitro, and to observe dynamic droplets in the nucleus. Fluorescence recovery after photobleaching (FRAP) verified the droplet fluidity. The CUT&Tag of NR3C1 was applied to analyze the co-binding pattern between NR3C1 and SE on the genome. The SE changes of NR3C1 knockdown cells were detected and were analyzed for downstream target genes. PDX models and GC cells were used to evaluate the inhibitory effect of epigenetic inhibitors JQ1 on NR3C1 and its target genes, and to improve 5-FU responsivity in GC cells.
Results: The SE profiles of 5-FU-sensitive, spontaneously resistant and induced resistant cells were described. SiRNA libraries were used to identify the master TF NR3C1. The 5-FU drug sensitivity curve verified that GC cells with high NR3C1 expression were resistant to 5-FU. Moreover, NR3C1 expression was increased in 5-FU-resistant cells, and knocking down NR3C1 in resistant cells could restore the 5-FU sensitivity. NR3C1 inhibition also improved the sensitivity of GC organoids to 5-FU. NR3C1 protein formed phase separation in vitro, and also formed droplets in the nucleus, together with transcription cofactors. With NR3C1 knockdown, SE profile changed through enhancer reprogramming, and the SE-associated genes transcription was inhibited. Then, NR3C1 downstream target genes, which were associated with 5-FU resistance, were significantly reduced. The use of JQ1 effectively inhibited the expression of downstream target genes, and efficiently improve the tumor inhibition effect of 5-FU in PDX models.
Conclusion: The high expression of NR3C1 driven by SE is positively correlated with 5-FU resistance in GC patients. SE-driven NR3C1 formed phase separation at the SE region in the nucleus, activating the positive feedback loop of TF. NR3C1 inhibition led to remarkable enhancer reconstruction of GC cells. SE-driven NR3C1 strongly promotes the transcription of downstream target genes and mediates the resistance of GC to 5-FU. JQ1 can effectively improve the 5-FU sensitivity of GC

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Genome Maintenance: Mechanisms and Novel Therapeutics
Poster Session

#1465 RAD52 and ERCC6L/PICH have a compensatory relationship for genome stability.
B. Osia, A. Merkell, F. Lopezcolorado, X. Ping, J. M. Stark;
Beckman Research Institute of The City of Hope, Duarte, CA

Human RAD52 plays essential roles in several homology-driven DNA repair pathways, including single strand annealing, transcription-coupled homologous recombination, and mitotic DNA synthesis (MiDAS). Although RAD52 is not essential, RAD52 loss with disruption of either the breast cancer 1 (BRCA1) or breast cancer 2 (BRCA2) genes is synthetic lethal. Thus, RAD52 is an intriguing potential target for treatment of BRCA-deficient cancers. However, the full breadth of pathways and factors that create a state of RAD52-dependence when compromised are not understood. To query RAD52 synthetic lethal relationships, we performed genome-wide CRISPR knock-out screens and identified hundreds of candidate synthetic lethal interactions. We then performed secondary screening and identified genes for which depletion causes reduced viability and elevated genome instability (increased 53BP1 nuclear foci) in RAD52-deficient cells. One such factor was ERCC6L, which marks DNA bridges during anaphase, and hence is important for genome stability in mitosis. Additionally, pan-cancer studies of altered ERCC6L expression have identified increased ERCC6L expression as a marker of poor prognosis in multiple types of cancer, making it a relevant target for cancer therapy. Thus, we investigated the functional interrelationship between RAD52 and ERCC6L. We found that RAD52 deficiency increases ERCC6L-coated anaphase ultrafine bridges, and that ERCC6L depletion causes elevated RAD52 foci in prometaphase and interphase cells. These effects were enhanced with replication stress (i.e. hydroxyurea) and topoisomerase IIα inhibition (ICRF-193), where post-treatment effect timings were consistent with defects in addressing stress in mitosis. Altogether, we suggest that RAD52 and ERCC6L co-compensate to protect genome stability in mitosis.

#1466 Comprehensive analysis of breast and ovarian cancer-identified RAD51D variants.

Kristie Darrah[1], Katherine Oppenheimer[2], Nicole Banks[1], Phoebe Parker[1], Ella Roberts[2], Gayatri Ganesan[1], Kara Bernstein[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]University of Pittsburgh, Pittsburgh, PA

The RAD51 paralogs are essential genes in coordinating the early steps of homologous recombination (HR)-mediated repair of DNA double strand breaks (DSBs). Currently, there are over 300 epidemiology studies linking a single mutation or polymorphism in one of the five canonical RAD51 paralogs to cancer predisposition and tumorigenesis. As one of the most frequently mutated RAD51 paralogs, mutations in RAD51D have been identified in 5% of hereditary ovarian cancers and pathogenic variants are associated with a 25% lifetime risk for breast cancer. We have uncovered more than 160 patient-identified missense variants in *RAD51D*, the majority of which are clinically classified as variants of unknown significance (VUS) and have little to no prior functional analysis. Herein, we have performed a comprehensive screen of all known missense RAD51D VUS identified in breast and ovarian cancer patients, identifying 7 potentially pathogenic variants which disrupt native protein interactions, reduce HR proficiency, and exhibit varying degrees of sensitivity to the typical chemotherapeutics used to treat HR-deficient (HRD) cancers. In defining the functional consequences of RAD51D VUS, we hope to inform formal clinical classification of these VUS in hopes of better estimating cancer risk and leverage precision therapeutic approaches for mutation carriers.

#1468 Chemotherapy-resistant bladder cancer: Involvement of homologous recombination repair.

Nils C. H. van Creij[1], Francisco J. Roa[1], Florian Handle[2], Frederic R. Santer[1], Per Sonne Holm[3], Zoran Culig[1], Renate Pichler[1]

[1]Department of Urology, Medical University of Innsbruck, Innsbruck, Austria,[2]Institute of Pathology, Neuropathology and Molecular Pathology, Medical University of Innsbruck, Innsbruck, Austria,[3]Department of Oral and Maxillofacial Surgery, Medical University of Innsbruck, Innsbruck, Austria

Introduction: Radical cystectomy after neoadjuvant cisplatin-based chemotherapy (NAC) remains the standard of care for localized and locally advanced muscle invasive bladder cancer (MIBC). However, around 65% of patients exhibit resistance to this regimen. HUS1, an important protein in the homologous recombination repair (HRR) pathway, has been associated with NAC resistance in different studies. While the HRR pathway, including proteins such as CHK1 and RAD51, is known to play a role in chemotherapy resistance, the specific mechanisms in MIBC remain underexplored. This study aims to investigate the role of HRR in cisplatin-based chemotherapy resistant bladder cancer.

Materials & Methods: Cisplatin-resistant (CR) HT1197 and UMUC3 cell lines were developed via gradual cisplatin exposure for more than 3 months. To measure HRR in the cells, we developed a DRGFP assay. Using western blot and RNAseq, we compared differences in protein and RNA levels of DNA repair pathway members between the parental and CR cells. Using an Incucyte® imager, we analyzed cell proliferation after silencing or overexpressing HUS1 and RAD51 alone, or in combination with cisplatin treatment. Furthermore, we tested olaparib and radiation therapy in our models.

Results: RAD51 and CHK1 protein levels are respectively 2.69 and 2.07 times higher expressed in our CR cells, underscoring enhanced HRR activity as a potential mechanism of resistance. These elevated RAD51 and CHK1 levels represent promising new biomarkers for predicting cisplatin response. Additionally, our DRGFP assay revealed a 2.5 times increased HRR activity in the CR cell lines compared to their parental lines. We observed a decreased proliferation in the parental (1.3x fold decrease), but not in the CR cells, when combining cisplatin treatment with silencing HUS1. In contrast, decreased proliferation was observed in both parental and CR cells when combining cisplatin with silencing RAD51 (fold decrease of respectively 4.5 and 2.25). Therefore, targeting RAD51 might be a novel approach to overcome chemotherapy resistance. Moreover, western blot data revealed a regulatory interaction between HUS1 and RAD51. Our data also indicated that CR cells exhibit increased resistance to other DNA-damaging agents, such as radiation therapy and the PARP inhibitor olaparib. Finally, RNAseq identified additional signatures potentially involved in chemotherapy resistance, including energy-related pathways and epithelial-mesenchymal transition markers.

Conclusion: To the best of our knowledge, we are the first to show increased HRR in cisplatin-resistant bladder cancer cells and to give initial insights into the role of HRR in platinum-based chemotherapy resistance. Our findings propose promising therapeutic strategies to overcome chemotherapy resistance in bladder cancer.

#1469 Deciphering mechanisms of intrinsic radioresistance in breast cancer: Insights from transcriptomics and CRISPRi screens.

Breanna McBean[1], Priyanka S. Rana[2], Benjamin Hauk[2], Anna R. Michmerhuizen[1], Samuel Lichtman-Mikol[2], Reine Abou Zeidane[2], Vesna Markovic[2], Kari Wilder-Romans[1], Mingfang Tao[2], Alan P. Boyle[1], Corey W. Speers[2]

[1]University of Michigan Medical School, Ann Arbor, MI,[2]Case Western Reserve University, Cleveland, OH

Background: Breast cancer (BC), the most common cancer globally and a leading cause of death in women, often utilizes radiation therapy (RT) as part of treatment, with over 85% of patients receiving RT after breast-conserving surgery. Still, over 15% of women experience local recurrence despite RT, underscoring the need to better understand the molecular mechanisms driving RT response and resistance. We hypothesized that transcriptomic changes that occur after ionizing radiation in intrinsically radiosensitive and resistant BC models would offer mechanistic insight into mediators of this differential response. To test this, we conducted *in vitro* and *in vivo* RNA-seq experiments to characterize transcriptomic changes following RT across a panel of BC cell lines of varying levels of intrinsic radiation sensitivity. Furthermore, we conducted a genome-wide CRISPRi screen to identify genes which are critical to radiation survival and drive radioresistance.

Methods: Eight BC cell lines representing all intrinsic subtypes were treated with 4 Gy RT and RNA was collected 24 hours after treatment for RNA-seq. For 2 cell lines, we also conducted *in vivo* mouse xenograft experiments in which mice received fractionated daily RT (6 fractions of 2 Gy each). Differential gene expression analysis with DeSeq2 was performed, followed by pathway analysis with Advaita Bioinformatics' iPathwayGuide. For the CRISPRi experiments, we used the Dolcetto library in two TNBC cell lines: BT-549 and HCC-1937. Cells were transfected with the library and then treated with 3 fractions of 3 Gy RT. DNA was isolated for sequencing after 7 days and analyzed with MaGeCK to determine sgRNA abundance.

Results: An average of 935 differentially expressed genes were noted in the *in vitro* models (S.D. 906); 142 and 324 were found in the *in vivo* models. Among the most highly enriched pathways from the transcriptomic data in both resistant and sensitive cell lines after RT, we found processes including cell cycle, cellular senescence, and estrogen signaling. Pathways uniquely differentially expressed in the *in vivo* samples for both cell lines include IL-17 signaling and transcriptional misregulation in cancer. From the CRISPRi screen, we identified genes involved in similar pathways, as well as canonical regulators of DNA damage response.

Conclusions: Ionizing radiation induces transcriptomic expression changes that differ between intrinsically radiosensitive and resistant BC models. These data, coupled with results from the CRISPRi radiosensitivity screen, identify pathways that offer potential insight into the mechanisms underlying intrinsic radioresistance and suggest biologic vulnerabilities that may be targeted to more effectively treat women at a high risk of local BC recurrence. Ongoing studies are exploring the potential of therapeutic targeting of these pathways when combined with RT in breast cancer.

#1470 Inhibition of protein myristoylation sensitizes pancreatic cancer cells to DNA damage agents.

Jiaxuan Hu[1], Nho C. Luong[1], Xin Xu[2], John Kim[1], Jinmeng G. Jiang[1], Roshika Roshika[1], Priya Kapoor-Vazirani[1], Sandip K. Rath[1], Ramona Haji-Seyed-Javadi[1], Ronghu Wu[2], David S. Yu[1]

[1]Radiation Oncology, Emory Winship Cancer Institute, Atlanta, GA,[2]School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA

Pancreatic ductal adenocarcinoma (PDAC) has one of the highest cancer mortality rates with a 5-year survival rate of only 12% despite tumor removal and/or chemo-radiotherapy. The poor prognosis is partly due to therapy resistance driven by genes and pathways regulating cell signaling, proliferation, and metastasis. DNA damage response (DDR) pathways contribute to this resistance by enabling cancer cells to repair treatment-induced DNA damage, evade apoptosis, and adapt through alternative repair mechanisms, emphasizing the need for new therapeutic targets. We explored the role of protein myristoylation, which is the addition of a 14-carbon myristic acid to lysine and glycine catalyzed by N-myristoyl transferase (NMT) 1 and 2, in DDR regulation as potential therapeutic targets for PDAC. Analysis of The Cancer Genome Atlas (TCGA) database revealed correlation of lower levels of NMT1 and NMT2 with higher microsatellite instability score, a marker of genomic instability. Inhibition or knockdown of NMT1 and NMT2 in PDAC cells increased γH2AX levels, a marker for genomic instability, suggesting that NMTs may have a role in maintaining cellular genomic stability and regulating the DDR. TCGA and TARGET pan-cancer database analyses showed correlation between lower NMT1/2 expression with better cancer patient outcomes, including overall survival, progression-free survival, and disease-free progression. Gene expression analysis from the TNMplot database revealed elevated NMT1/2 levels in PDAC tumor tissues compared to nontumorigenic tissue. We then confirmed an increased level of NMT1 and NMT2 in PDAC cell lines, including MIA PaCa-2, PANC1, and HPAC, compared to nontumorigenic HPDE pancreatic ductal epithelial cells. Notably, NMT1/2 knockdown with siRNA significantly sensitized MIA PaCa-2 cells to DNA-damaging agents, including ionizing radiation (IR), topoisomerase inhibitor camptothecin (CPT), and poly (ADP-ribose) polymerase (PARP) inhibitor veliparib. Chemical inhibition of NMTs also sensitized MIA PaCa-2 cells to CPT and veliparib. These results suggest that NMTs could govern resistance of PDAC cells to DNA-damaging treatments by regulating DDR and genome stability. To further explore NMTs' role in DDR, we performed affinity purification coupled with quantitative proteomics in HEK293T cells expressing EGFP-tagged NMT1 or NMT2. This approach identified 641 and 678 proteins, respectively, including 32 NMT1-associated proteins and 33 NMT2-associated proteins related to DNA repair. Additionally, global profiling of protein myristoylation using mass spectrometry revealed 576 myristoylated proteins in HCT116 cells, including 14 DNA repair proteins. Thus, NMT-mediated myristoylation may modulate the dynamic and functions of DNA repair proteins, thereby enhancing PDAC cell survival under therapeutic stress.

#1471 Roles of the KU70 C-terminus SAP domain in resilience to ionizing radiation.

Yuan Wang, Michael S. Czap, Hailey Kim, Huimei Lu, Jingmei Liu, Zhiyuan Shen

Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Ionizing radiation (IR) is a critical modality in cancer therapy but also carries carcinogenic risks, necessitating precise optimization. The KU70 protein is integral to DNA repair, primarily known for its N-terminal domain's role in dimerizing with KU80 to repair DNA double-strand breaks (DSBs). Our study aims to elucidate the function of the less-explored C-terminal SAP domain of KU70. We engineered a variant, KU70-ΔSAP, lacking this domain, to assess its role in cellular responses to radiation. KU70-ΔSAP mice exhibited increased sensitivity to an 8 Gy dose of whole-body irradiation (TBI), significantly affecting hematopoietic stem cells, with marked reductions in long-term and short-term stem cells, as well as in common myeloid and granulocyte-monocyte progenitors post-irradiation. These findings suggest that the SAP domain is crucial for the survival of hematopoietic stem and progenitor populations following IR-induced damage, as well as for the subsequent hematopoiesis necessary to replenish bone marrow and blood. Further analysis using mouse embryonic fibroblast (MEF) clones from our mouse model indicated that deletion of the SAP domain impaired KU70's early recruitment to UV-laser-induced DSB sites, coinciding with decreased Ligase IV levels, an essential enzyme for DNA repair, and increased γH2AX signals, which indicate DNA damage and repair inefficiency. These results highlight the SAP domain's essential role in orchestrating effective DNA repair mechanisms post-IR and enhance our understanding of KU70’s function in improving radiation therapy outcomes and bolstering cellular resilience against radiation-induced damage.

#1473 POLQ facilitates annealing mediated long deletions at chromosomal break in homologous recombination deficient cancers.

Manisha Jalan[1], Erika S. Buechelmaier[1], Jonathan Rafailov[2], Yingjie Zhu[1], Xin Pei[1], Sebastian Brylka[2], Joan Gomez-Aguilar[1], Niamh McDermott[1], Nadeem Riaz[1], Marcin Imielinski[2], Simon N. Powell[1]

[1]Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Perlmutter Cancer Center, NYU Grossman School of Medicine, New York, NY

Tumors deficient in homologous recombination (HRD) predominantly rely on alternative DNA repair pathways for maintaining genome stability, especially once end resection has been initiated after a double strand break (DSB). These back up repair mechanisms, especially microhomology-mediated end-joining (MMEJ) and single-strand annealing (SSA), once considered minor contributors to genome stability, have garnered increased attention as recent evidence supports their significant roles in tumorigenesis and their potential as therapeutic targets. Consequently DNA polymerase theta (POLQ), a key regulator of MMEJ, emerges as an attractive target for the selective treatment of HRD cancers, and recent efforts in the development of POLQ inhibitors have demonstrated their potential to enhance the efficacy of existing therapies and overcome resistance mechanisms. In our study, we investigated the genetic drivers of the under-investigated SSA and its connection to the related MMEJ pathway in human cells. A previously unidentified role for POLQ in regulating the frequency of SSA was observed in addition to its role in MMEJ. Beyond its established role as a gap-filling polymerase, we show that the helicase activity of POLQ is critical for homology-mediated annealing in both MMEJ and SSA. POLQ is shown to be a key facilitator of SSA through its ability to process DNA ends and promote annealing of homologous sequences with at least 80% sequence identity (homeology), resulting in a range of deletion sizes. We also provide evidence for these homeology-dependent SSA-like repair scars in tumor genomes and show that they are associated with HRD and elevated POLQ expression, suggesting the utilization of these mechanisms as a critical repair pathway in these tumors. These findings suggest POLQ is the ideal target for therapies of HRD cancer.

#1474 Recurrent PRKCI gene fusions represent a drug target in gastric cancer and esophageal junction cancer.

Shivani Jagannathan Murali, Bharath Kumar Karre, Cristina Ivan, Chao Sima, Asfetaw Abera, David Spetzler, Milan Radovich, Heather O'neill, Ravi Chakra Turaga

Caris Life Sciences, Inc., Tempe, AZ

Background: Protein kinase C (PKC) is a phospholipid-dependent, calcium-independent Ser/Thr protein kinase family with eight members, each involved in processes including apoptosis, migration, and proliferation. PRKCI promotes tumor growth in many types of cancer, including pancreatic, lung, ovarian, and renal cell carcinoma. Structurally, PKCι has an N-terminal regulatory domain and a C-terminal catalytic domain. While PRKCI fusions have been reported, they remain uncharacterized. This study aims to investigate these fusions in gastric cancer and esophageal junction carcinoma, exploring potential mechanisms and co-occurring mutations to inform targeted therapies that could improve patient outcomes.
Methods: We performed a comprehensive analysis of PRKCI fusions identified from whole transcriptome sequencing (WTS) and associated co-occurring pathogenic mutations from whole exome sequencing (WES). We screened 6437 EJC and 3615 gastric adenocarcinoma cancer cases retrospectively and calculated the frequency of occurrence of PRKCI fusions. Additionally, we characterized and mapped the domains of PRKCI fusions and its partners. We further analyzed patient demographics, co-occurring mutations and copy number amplifications.
Results: PRKCI fusions were identified in 0.19% and 0.3% of EEJC and Gastric adenocarcinoma cancer cases. All the PRKCI fusions are formed with other genes on chromosome 3 from intra-chromosomal rearrangement (PHC3, TNIK, SKIL and YES1) proximal to the PRKCI gene. The most common fusions of PRKCI are formed with partner PHC3 and SKIL which account for 11 patient cases. This is followed by 4 cases of TNIK and unique cases of fusions with LRRC31, PCYT1A, ERBB2, VPS13D and YES. Further, the genomic landscape of PRKCI indicated co-occurring mutations in TP53 (46.7%), ARID1A (13.3%), 6.7% inactivating mutations of ATM, FBXW7, CDH1. Expression of PRKCI in PRKCI fusion positive cases was significantly higher as opposed to patient cases that did not harbor gene fusions. PRKCI fusion cases were commonly observed to have PRKCI amplification (46.7%). PRKCI fusions lack the regulatory domain, leading to constitutive kinase activation, which may drive tumor progression by disrupting normal regulation and altering protein localization.
Conclusion: Our studies are the first to identify PRKCI fusions in gastric cancer and EEJC patients, along with associated mutations and amplifications suggesting a novel mechanism. This highlights the importance of personalized molecular diagnostics to guide tailored treatments. PKCι kinase inhibitors may improve survival and outcomes for patients with PRKCI fusions in gastric cancer and EEJC.

#1475 HDAC8 as a critical regulator of cancer cell genome stability: therapeutic implications.

Zih-Yao Yu[1], Wei-Jan Huang[1], Stanton Gerson[2], **Sung-Bau Lee**[1]

[1]Taipei Medical University, Taipei, Taiwan,[2]Case Western Reserve University, Cleveland, OH

In cancer cells, chromatin replication is often misregulated in part due to mutations in oncogenes and tumor suppressor genes, leading to increased replication stress and genomic instability. While this instability drives cancer progression, it also makes cancer cells more dependent on genome maintenance pathways, presenting a therapeutic target. A promising strategy is to exacerbate replication stress, causing lethal genome instability. We have developed a sensitive reporter to monitor replication stress via single-stranded DNA at stressed forks. Our earlier study identified Tousled-like kinases (TLKs) crucial for chromatin assembly during genome replication and discovered TLK inhibitors to treat cancers through increasing replication stress. Additionally, we recently uncovered histone deacetylase 8 (HDAC8) inhibitors that disrupt chromatin replication and compromise genome integrity, particularly when combined with checkpoint kinase inhibitors. In this presentation, I will show you how HDAC8 behaves as caretakers of genetic and epigenetic integrity and how we targeted replication stress to create cancer-specific synergistic vulnerabilities.

#1476 Enhancing radiation sensitivity in CHD5 dysregulated NSCLC by targeting NHEJ repair pathway.

Seohyun Kim, Sandip K. Rath, Gina Cutlip, David S. Yu

Radiation Oncology, Emory University, Atlanta, GA

Lung cancer, particularly non-small cell lung cancer (NSCLC), is a leading cause of cancer deaths, with 5-year survival rates decreasing from 65% for localized cases to 9% for distant metastases. Radiation therapy's effectiveness is often limited due to the upregulation of DNA repair pathways like non-homologous end joining (NHEJ), which helps cancer cells survive DNA damage from radiation. Chromatin remodeling plays a crucial role in regulating DNA repair pathways, including NHEJ. We have identified CHD5, a tumor suppressor involved in chromatin remodeling, as a regulator of DNA double-strand break repair pathway choice. DNA reporter assays show that CHD5 promotes homologous recombination (HR), and its depletion enhances NHEJ activity. Analysis of The Cancer Genome Atlas (TCGA) reveals that CHD5 is downregulated in lung adenocarcinoma (LUAD) patients. This suggests that NSCLC cells may rely more on NHEJ due to reduced CHD5 function. Therefore, targeting CHD5-dysregulated NSCLC cells with NHEJ inhibitors could increase their sensitivity to radiation therapy. Our data indicate that overexpressing CHD5 in H460 NSCLC cells reduces levels of phosphorylated and total DNA-dependent protein kinase catalytic subunits (DNA-PKcs), essential components of the NHEJ pathway. This suggests that CHD5 negatively regulates NHEJ. Cell viability assays confirm that CHD5 depletion via siRNA in H460 NSCLC cells sensitizes them to ionizing radiation (IR) when combined with the DNA-PK inhibitor Nu7441, leading to increased cell death. In summary, CHD5 regulates NHEJ in NSCLC, and its depletion makes cancer cells more dependent on NHEJ for DNA repair. Targeting NHEJ in CHD5-deficient NSCLC cells offers a promising therapeutic strategy for enhancing the efficacy of radiation therapy in NSCLC.

#1477 Do MSH3 mutations really affect colorectal cells neoplastic transformation: an evolution of three African Americans novel mutations within the MSH3 ATPase domains.

Mudasir Rashid[1], Hassan Brim[1], Katherine Casazza[2], Jennifer A. Surtees[2], Shaolei Teng[1], Adebiyi Sobitan[1], Adeyinka O. Laiyemo[1], Zaki Sherif[1], Koi Minoru[3], John Carethers[3], **Hassan Ashktorab**[1]

[1]Howard University, Washington, DC,[2]University of Buffalo, Buffalo, NY,[3]UCSD, San Diego, CA

Background: DNA Mismatch Repair (MMR) genes' (including MSH3) alterations through silencing and/or mutations plays a role in colorectal cancer (CRC) carcinogenesis. MSH3 interacts with MSH2 to form MutSβ, which recognizes and directs repair of insertion/deletion loops during in DNA replication; deficiencies lead to elevated mutation rates. Msh3 alterations are associated with instability at tetranucleotide repeats (termed Elevated Microsatellite Alterations at Selected Tetranucleotide repeats, EMAST), a phenotype elevated frequency among African American (AA). CRCs and associated with poor patient prognosis. Aim: To assess functional impact of 3 out of 4 Exomes (E) E20, E-21, E22, E23 novel deleterious AA variants within the ATPase domain of MSH3. Methods: We used CRISPR-Cas9 knock-in and successfully introduced 3 of these mutations (confirmed by Sanger sequencing) in Msh3 ATPase domain (c.G2926A, c.C3028T, c.G3241A) in SW620 colon cancer cell line (carry Msh3 gene wild-type). In Silico and wet-lab MSH3 functional analysis was performed. We used MTT for cell proliferation, tetranucleotide repeats instability assays, immunofluorescence for MSH3 localization, Western blot for protein expression, co-immunoprecipitation for MSH3 interaction with MSH2 MMR protein, and thin layer chromatography ATPase assays with purified MutSβ complexes.
Results: In silico analysis showed deleterious effect of the 4 novel msh3 mutants. However, biological phenotypic assays revealed no observable changes in cell morphology or proliferation between wild-type and MSH3-variant knocked-in cells, with no EMAST after 7 to 10 passages. Subcellular localization of variant MSH3 was unaffected compared to wild type MSH3, and interaction between mutant MSH3 and MSH2 proteins was not impacted, However, the ATPase activity of two of the variant MutSβ complexes was affected. MSH3 c.G2759T (E20) exhibited overall reduced ATPase activity compared to wildtype and was not affected by the presence of DNA. MSH3 c.C3028T (E22) exhibited elevated ATPase activity compared to wildtype in the presence of specific (loop) or non-specific DNA (homoduplex).
Conclusion: Despite computational deleterious predictions, novel MSH3 variants identified from AA CRCs appeared to show no biological or genetic evidence of pathogenicity, but did reveal altered in vitro biochemical properties. Altered MutSβ ATPase activity, both decreased and increased, has been shown to disrupt proper MMR activity. We propose that disruptions in the ATP hydrolytic cycle contribute to MMR deficiency, resulting in elevated mutation rates with contribution to colorectal cancer pathogenesis. This effect may be enhanced in distinct genetic backgrounds, and directly affect cancer cells' proliferation and cell division.

#1478 A novel HK2 inhibitor HIC-29 exhibits synthetic lethality with PARP inhibitors in ovarian cancer.
Xiu Shi

Xiu Shi (Individual), Suzhou, China

Purpose: In this study, we developed a novel HK2 inhibitor, HIC-29, and investigated its potential to enhance the sensitivity and expand the clinical utility of PARP inhibitors in ovarian cancer.
Methods: The HK2 protein was modeled using a Molecular Operating Environment (MOE), and the most favorable model was selected based on a GBVI/WSA dG scoring function. The Chembridge Compound Library was screened, and the top 50 candidate compounds were tested for their interaction with HK2 and downstream substrates, CHK2-pS19 . HIC-29 emerged as the most promising drug candidate and was further evaluated using multiple assays.
Results: HIC-29 exhibited selective and potent inhibition of HK2. The IC50 of HIC-29 correlated inversely with endogenous HK2 expression in ovarian cancer cell lines. Treatment with HIC-29 significantly inhibited cancer cell growth and sensitized cells to PARP inhibitors in vitro, as well as in ovarian cancer organoids and xenograft models. Mechanistically, HK2 knockdown and HIC-29 treatment reduced CHK2 phosphorylation at Ser19, impaired DNA homologous recombination repair, ultimately inducing apoptosis. These findings highlight the crucial role of HK2 in the DNA HR repair pathway and demonstrate the significant PARP inhibitor sensitization achieved by HIC-29 in ovarian cancer.
Conclusions: HIC-29, a novel HK2 inhibitor, effectively inhibits tumor cell growth in ovarian cancer by interfering with CHK2-mediated DNA HR repair. Furthermore, HIC-29 enhances the efficacy of PARP inhibitors, providing a promising therapeutic strategy to improve outcomes for ovarian cancer patients.

#1479 Defining the interplay between DNAPKcs and shieldin during chromosomal break repair.

K. Makins, M. Cisneros-Aguirre, F. W. Lopezcolorado, J. M. Stark;
City of Hope National Medical Center, Duarte, CA

Chromosomal DNA double strand breaks (DSBs) are the effective lesion of cancer radiotherapy and other cancer therapeutics, such as topoisomerase 2 poisons. Understanding how cancer cells repair DSBs can provide insight into cancer cell resistance to these therapeutics, as well as inform development approaches to improve cancer sensitivity. DSB repair is also significant for cancer biology because aberrant repair of DSBs can cause mutations and chromosomal rearrangements that drive cancer. Repair of DSBs occurs through several pathways, including non-homologous end joining (NHEJ). DNA-PKcs (DNA-dependent protein kinase) promotes NHEJ, inhibits HDR, and is an emerging drug target with kinase inhibitors in oncology clinical trials. DNA-PKcs phosphorylates itself and other DNA damage response proteins and promotes long-range DSB end synapsis to facilitate NHEJ. Another protein complex implicated in long-range DSB end synapsis is Shieldin, which includes the proteins 53BP1, RIF1 (Rap1-interacting factor 1), and other factors. Shieldin is critical for NHEJ to promote class switch recombination, which is a programmed DSB repair event during antibody maturation. However, the role of Shieldin in NHEJ repair outside this context remains poorly understood. Indeed, a specific gap in knowledge is the functional interplay between how DNA-PKcs and Shieldin promote synapsis of DSB ends to favor NHEJ. To study end joining outcomes, I use Cas9 reporter assays to measure end joining frequencies via flow cytometry. These reporter assays are chromosomally integrated into human HEK293 cells. Additionally, I examine end joining junctions using deep sequencing to compare parental HEK293 cell junctions between wild-type and 53BP1-knockout or RIF1-knockout cell lines. This PCR-based approach allows me to categorize junction types into four categories: No Indels, Insertions, Deletions, and Complex Indels. My studies indicate that RIF1 and 53BP1 are genetic modifiers of DNA-PKcs function during DSB repair. I will present our current efforts to address this gap in knowledge.

#1480 Unlocking DNA repair mechanisms with dynamic single-molecule analysis.

Paul Pease, Jack O'Sullivan, Trey Simpson, Josephine Yeh, Andrea Candelli

LUMICKS, Waltham, MA

The maintenance of genomic information through processes such as DNA replication, recombination, and repair is critical to cellular function. Errors in these underlying mechanisms play a major role in diseases such as cancer. As a result, insights into the molecular details are needed to advance our understanding, improve biological models, and develop novel therapeutics. Dynamic single-molecule technologies offer an exciting opportunity to meet these challenges and to study protein function and activity in real time. Here, we present our efforts for enabling discoveries in the field of DNA repair using the combination of fluorescence microscopy with optical tweezers. This technology has been used to study CMG helicase dynamics, the role of BRCA2 in RAD51 nucleation, and the mechanism of the DNA repair complex FANCD2-FANCI. It is also suitable for many applications involving mismatch repair (MMR), base excision repair (BER), and nucleotide excision repair (NER), among other lesions. We present several examples in which our technologies and biochemistry enhanced the understanding of these systems. Importantly, we show that advances in dynamic single-molecule methods can be turned into an easy-to-use and stable instrument that is unlocking new avenues for studying DNA-binding proteins in the field of DNA repair.

#1481 Targeting DNA damage responsive pathways in cancer therapy.

J. Chen;
UT MD Anderson Cancer Center, Houston, TX

DNA double strand breaks (DSBs) result in activation of several key DNA damage response (DDR) kinases including ATM, ATR, and DNA-PK. These protein kinases not only promote DNA damage-induced checkpoint control, but also facilitate DSB repair in humans. Thus, these DDR kinases have become promising drug targets for cancer therapy. However, the benefits of targeting DDR kinases remain to be realized, in part due to the lack of predictive biomarkers. By undertaking CRISPR screens with inhibitors targeting key DDR kinases, we obtained a global and unbiased view of genetic interactions with DDR inhibition. Additionally, we compared the synergistic effects of combining different DDR inhibitors and found that ATM and PARP inhibitors showed remarkable synergy, which depends on the dominant negative function of ATM inhibition. Moreover, to provide comprehensive and unbiased perspective of DDR signaling pathways, we performed 30 fluorescence-activated cell sorting-based genome-wide CRISPR screens with antibodies recognizing distinct endogenous DNA damage-signaling proteins to identify new regulators involved in DNA damage response (DDR). We discovered that proteasome-mediated processing is an early and prerequisite event for cells to trigger camptothecin- and etoposide-induced DDR signaling. Furthermore, we identified PRMT1 and PRMT5 as new modulators that regulate ATM protein level. Additionally, we discovered that GNB1L is a master regulator of DDR signaling via its role as a co-chaperone for PIKK proteins. Collectively, these screens offer a rich resource for further investigation of DDR, which may provide insight into strategies of targeting these DDR pathways to improve therapeutic outcomes. More recently, we have adopted dTAG technology for the investigation of many essential DDR and replication proteins, which provide mechanistic insights into the roles of these essential proteins in genome maintenance. Additionally, we have expanded FACS-based screens for the studies of other cancer-associated pathways and explored key biological processes critical for cancer progression in vivo. These studies will facilitate the development of better therapies for cancer patients.

#1482 Discovery of HW221043, a potent and orally bioavailable KIF18A inhibitor for treating chromosomal instability in cancer.

Qun Li[1], yang zang[1], xin zhao[1], qian wu[1], tiejun bing[2], lifei liu[1], xuejun zhang[1]

[1]Humanwell Healthcare (Group) Co.,Ltd, Wuhan Hubei, China,[2]ICE Bioscience Inc., Beijing, China

Background: KIF18A, a molecular motor protein, is crucial for regulating microtubule length, essential for maintaining proper cell function and division. Chromosomal instability (CIN) significantly contributes to cancer progression and is targeted by emerging therapies such as PARP inhibitors, which exploit synthetic lethality in cancer cells. CIN resulting from whole genome duplication (WGD) is associated with poor outcomes and metastatic disease, with cancers demonstrating sensitivity to spindle assembly checkpoint disruption. This makes KIF18A a promising target in this drug class.
Methods and Results: We have discovered HW221043, a highly potent and orally bioavailable small molecule inhibitor of KIF18A. Biochemical assays revealed that HW221043 potently inhibits the ATPase activity of KIF18A (IC50, 6 nM) without affecting other kinesin family members, even at the highest tested concentration of 10 μM. In cell-based assays, HW221043 markedly inhibited the viability of CIN-positive tumor cell lines at nanomolar concentrations, with no effect on CIN-negative cells even at 10 μM. The compound demonstrated excellent pharmacokinetic (PK) profiles in mice, rats, dogs, and monkeys. In two cell-derived xenograft (CDX) models (OVCAR3 and BT549), oral administration of HW221043 dose-dependently inhibited tumor growth, with nearly complete inhibition observed at 15 mg/kg once daily. Higher doses led to tumor regression. All in vitro and in vivo PK and safety tests yielded favorable results, supporting the preclinical development of HW221043.
Conclusion: These findings provide pharmacological proof-of-concept for the synthetic lethal effect of HW221043 and support KIF18A inhibition as a novel therapeutic strategy in oncology. HW221043 is currently in the Investigational New Drug (IND) enabling stage of development.

#1483 Effect of USP1 inhibitor with or without radiotherapy and chemotherapy on cell viability and biomarkers, independent of BRCA or HRD status.

Mrinal Sivastava[1], Nirjharni Saha[1], Partha Pratim Sarma[2], Prashant Kashinath Bhavar[2], **Uday Kumar Surampudi**[2]

[1]Tata Institute of Fundamendal Research, Hyderabad, India,[2]VeGen Therapeutics, Hyderabad, India

The efficacy of USP1 inhibitors, which target deubiquitinating enzymes critical to DNA damage response pathways, was evaluated in combination with radiotherapy and chemotherapy across different cellular types including BRCA1/2, BRCA null and, homologous proficient BRCA mutations. Here, we investigate the impact of USP1 inhibition, as single agent or in combination with RT or CT, in a panel of three distinct cell lines, UWB1.289, HCT-116 and NCI H-1792 representing diverse gene alterations and tumor types. Our results demonstrate that USP1 inhibition significantly sensitizes BRCA mutant and HRD proficient cell lines to both RT and CT, amplifying DNA damage and enhancing apoptotic responses. Interestingly, the combination of USP1 inhibitors with UV radiation resulted in significant reduction of cell proliferation in HCT-116, known to demonstrate significantly higher HR activity scores compared with the BRCA1/2 deficient cells, suggesting a broader role of USP1 inhibitor beyond HR deficient cell lines. The synergy between USP1 inhibition and radiotherapy was most pronounced in the HRD+ models, underscoring the potential of USP1 inhibitors as a therapeutic strategy in DNA repair deficient cancers. The activity was established using both the cell viability as well by performing immunofluorescence assay using PCNA as a marker. These findings provide novel insights into the role of USP1 in modulating the response to DNA damaging therapies, with implications for personalized treatment strategies in cancers independent of HRD status. Future studies will explore the underlying molecular mechanisms driving the observed therapeutic synergy and validate these results in-vivo.

#1484 USP36-governed p21 homeostasis confers radioresistance in pancreatic cancer.

Haihua Feng, Sindhu Nair, Veronica Castro Aceituno, Linlin Yang, Haiqing Li, Tiantian Cui, Sergio Corrales Guerrero, Ling Gui, Nicholas Eustace, Terence M. Williams

Radiation Oncology, City of Hope National Medical Center, Duarte, CA

Purpose: Pancreatic cancers are highly aggressive tumors that carry a poor prognosis. More than 90% of pancreatic ductal adenocarcinoma (PDAC) harbors mutationally activated KRAS, and oncogenic KRAS signaling has been implicated in contributing to replication stress and PDAC radioresistance. Cell cycle inhibitor $p21^{waf1/cip1}$ (p21) can be transcriptionally induced by oncogenic KRAS and p53 in response to DNA damage. DNA damage can also induce p53-independent p21 nucleolus accumulation. Several studies revealed the antagonistic duality of p21 in oncogenesis depending mainly on its intracellular localization, with a tumor suppressor role in the nucleus and oncogenic role in the cytoplasm. The nucleolar deubiquitinase USP36 is pivotal in some cellular processes such as cell cycle maintenance, ribotoxic stress, and DNA replication stress. However, whether and how USP36 regulates p21 in the nucleolus in response to irradiation-induced DNA double-strand breaks remain unclear.
Experimental Design: We examined p21 protein level in HEK 293T and PDAC cell lines (MIA PaCa-2, PANC-1) by overexpressing wild-type USP36 and its catalytic-inactive mutant (C131A). We monitored the colocalization of GFP-p21 and mcherry-USP36 in both HEK 293T and MIA PaCa-2 cells. We assessed the association of p21 and USP36 by Co-IP. We determined the residues of USP36 that are phosphorylated in response to DNA damage by point mutation, and analyzed cell cycle distribution by flow cytometry. We examined the roles of USP36 and p21 in radiosensitivity with clonogenic assay. β-galactosidase staining was performed to assessed the cell senescence after radiotherapy.
Results: Overexpression of USP36, but not its catalytic-inactive mutant (C131A) induced protein levels of p21 in HEK 293T, MIA PaCa2 and PANC-1 cells. Mcherry-USP36 induced the accumulation of GFP-p21 in nucleolus of HEK 293T cells. In response to DNA damage, p21 translocated to the nucleolus and colocalized with USP36 in cells. Through domain mapping, we determined that the N-terminal of USP36 interacts with p21. Additionally, ATM and ATR phosphorylate USP36 at Ser356 and Ser519. USP36 depleted cells exhibited G1 release and G2/M arrest following DNA damage, and loss of USP36 induced cell senescence in cells following DNA damage. Finally, loss of USP36 sensitizes pancreatic cancer cells to radiation in vitro.
Conclusions: Here we report that loss of USP36 sensitizes pancreatic cancer cells to radiotherapy. Our findings support a model in which, in response to DNA damage, USP36 is hyperphosphorylated and activated by ATM/ATR, resulting in stabilization of p21 through USP36-mediated deubiquitination. Stabilization of p21 alters cell cycle progression, ultimately leading to pancreatic cancer radioresistance through enhanced cell recovery after DNA damage. Together, our data supports targeting USP36 and/or p21 for therapeutic intent.

#1485 BRCA2 haploinsufficiency leads to mitotic DNA synthesis at common fragile sites in human mammary epithelial cells.

Kavya Vipparthi[1], Ariana Bellare[2], **Mihriban Karaayvaz**[1]

[1]Cleveland Clinic Lerner Research Institute, Cleveland, OH,[2]Case Western Reserve University, Cleveland, OH

Germline mutations in BRCA2 confer up to a 70% lifetime risk of developing breast cancer due to BRCA2's critical roles in homologous recombination repair, replication fork stability, and cell cycle regulation. In BRCA2 mutation carriers, mammary epithelial cells are haploinsufficient, meaning a single functional allele is inadequate to maintain genomic stability and suppress tumorigenesis. Genomic instability, a hallmark of cancer, frequently involves fragile site instability, particularly at common fragile sites (CFSs), which are hotspots for chromosomal rearrangements under replication stress. While the association between fragile site instability and cancer has been documented, the specific link between BRCA2 haploinsufficiency and CFS instability remains unexplored. To address this gap, we modeled BRCA2 haploinsufficiency in human mammary epithelial cells using small-interfering RNA (siRNA)-mediated knockdown and induced replication stress with the DNA polymerase inhibitor aphidicolin (APH). Cytogenetic analysis using DAPI banding revealed increased CFS instability, particularly at FRA18B, in BRCA2-deficient cells compared to controls. Furthermore, we observed elevated levels of mitotic DNA synthesis (MiDAS) in BRCA2-deficient cells, a process typically activated at under-replicated regions of CFSs during mitosis to preserve genome integrity. These findings demonstrate that BRCA2 haploinsufficiency promotes CFS instability and aberrant MiDAS, uncovering novel mechanisms of genomic instability in preneoplastic mammary epithelial cells. By elucidating these early molecular events in BRCA2-associated breast cancer, our study provides critical insights into the etiology of tumorigenesis and lays the groundwork for innovative strategies to stabilize the genome in high-risk individuals, potentially improving breast cancer prevention and outcomes.

#1486 Early biomarker dynamics are associated with treatment efficacy in a preclinical model of radiotherapy combined with a DNA damage response agent.

Pablo Binder, Theoni (Tania) Katopodi, Lyndsey Hanson, Charlotte Bell, Eimear Flanagan, Paul Farrington, Nick Moore, Emily Wright, Tobias Bunday, Stewart Brown, Amy Cantrell, Jon Greenall, Shannon Sharman, John Woolley, **Lorraine Mooney**, Jane Kendrew

Sygnature Discovery, Alderley Edge, United Kingdom

Introduction: Radiotherapy is an essential treatment for many types of cancer, with almost half of all cancer patients undergoing it as part of their treatment regimen. It can initiate cytotoxic signaling pathways to induce cancer cell death, but it can also activate cytoprotective mechanisms that respond to cellular damage. These protective mechanisms can be targeted by anticancer agents like DNA damage response (DDR) agents, indicating that radiotherapy might boost the effectiveness of these drugs. Early response biomarkers can be utilized to support preclinical studies to assess the pharmacodynamic effects of a drug, providing insights into its mechanism of action. RNA sequencing technologies provide an opportunity to elucidate gene expression profiles across the breadth of the transcriptome, uncovering disease-specific gene signatures and biomarker candidates.
Methods and Experimental Procedures: The A549 lung cancer cell line was utilized to establish in vitro assays and the in vivo preclinical model for the study. An inhibitor targeting DNA PK (AZD7648) was used as it targets pathways crucial for the repair of radiation induced DNA double strand breaks. The effects on cell viability and DDR biomarkers were assessed after radiotherapy, compound or in combination both in vitro and in vivo. Targeted X rays were delivered to the tumor only using an Xstrahl CIX3 cabinet irradiator. Total RNA was isolated from excised tumors, and RNAseq analysis was performed (Illumina NovaSeq). Differential gene expression and pathway analysis was performed using Qiagen Ingenuity Pathway Analysis software. Protein biomarkers were assessed using the Jess Simple Western platform.
Data: In vitro assays showed increased sensitivity to the AZD7648 inhibitor when combined with radiotherapy, compared to standalone treatments. This combination also resulted in delayed tumor growth in vivo, with radiotherapy being well tolerated. The induction of biomarkers by radiotherapy, either as a monotherapy or in combination with the inhibitor, was assessed. Changes in biomarker expression were consistent with target engagement and treatment efficacy. Notably, γH2AX upregulation was evident in the irradiation monotherapy group but was delayed when combined with the DNA PK inhibitor, demonstrating target engagement as DNA PK inhibition alters the kinetics of γH2AX.
Conclusion: In summary, both in vitro assays and in vivo models have been developed to explore the synergistic effects of combining radiotherapy with DDR agents. The combination of radiotherapy with the AZD7648 inhibitor resulted in delayed tumor growth in vivo. Early changes in protein and gene biomarkers were consistent with target engagement and treatment efficacy. These assays can serve as preclinical tools to investigate compounds or mechanisms that can be effectively combined with radiotherapy.

#1487 MYC inhibition modulates DNA damage response and is capable of enhancing PARPi therapeutic impact.

Fabio Giuntini[1], Andrea Herencia-Ropero[1], Inigo Gonzalez-Larreategui[1], Silvia Casacuberta-Serra[2], Sandra Martinez-Martin[2], Mariano F. Zacarias-Fluck[1], Hugo Thabussot[2], Flaminia Pedretti[1], Laia Foradada[2], Erika Serrano[1], Judit Grueso[1], Sergio Lopez-Estevez[2], Olga Rodriguez[1], Marta Guzman[1], Adela Rodriguez-Hernandez[3], Fara Braso-Maristany[3], Marie-Eve Beaulieu[2], Lara Nonell[1], Violeta Serra[1], Aleix Prat[3], Jonathan Richard Whitfield[1], Daniel Masso-Valles[2], **Laura Soucek**[1]

[1]VHIO Vall D'Hebron Institute of Oncology, Barcelona, Spain,[2]Peptomyc S.L., Barcelona, Spain,[3]IDIBAPS, Barcelona, Spain

Background: The MYC oncogene, amplified or dysregulated in about 70% of human tumors, orchestrates multiple cancer hallmarks. Interestingly, its role in DNA damage response (DDR) has been debated for decades. On one hand, oncogenic MYC has been shown to promote genomic instability, while, on the other hand, it can also enhance DNA repair. We developed Omomyc, the first MYC dominant negative to have successfully completed a Phase I clinical trial, and used it as a research tool to study MYC's role in DDR. We focused on TNBC, where defective DDR is clinically associated with the use of PARP inhibitors (PARPi).
Methods: First, RNAseq, WB, immunofluorescence and flow cytometry were used to test Omomyc's effect on DDR genes in a panel of TNBC cells and its direct contribution to DNA damage. In addition, proliferation, apoptosis and synergy assays were performed to test the combination of Omomyc and PARPi *in vitro*. Then, cell derived xenografts (CDXs) and patient-derived xenografts (PDXs) were treated with the combination *in vivo*. Furthermore, bulk RNAseq from 35 patient derived xenografts (PDXs) was performed to elucidate the role of MYC transcriptional activity in PARPi resistance. Lastly, digital spatial profiling (DSP) of 18 patients' biopsies prior to PARPi treatment is being performed to evaluate if MYC transcriptional signature could be a predictor of patients' response to PARPi.
Results: We found that Omomyc shuts down genes and gene-sets related to homologous recombination repair (HRR) in both BRCA wild-type and PARPi-resistant BRCA-mutated cell lines, by depleting DDR proteins. Also, we observed that Omomyc causes early DNA damage, inducing phosphorylation of H2AX. Importantly, we found that the combination with PARPi, further increases H2AX phosphorylation, resulting in apoptosis in the long term, both *in vitro* and *in vivo*. RNAseq of 35 PARPi-treated PDXs showed that those resistant to PARPi therapy have a significantly increased MYC transcriptional activity, suggesting its role in drug resistance. At the time of submission of this abstract, DSP of 16 patients' biopsies is being performed to evaluate if the MYC transcriptional signature can be used as a predictor for PARPi response.
Conclusions: Overall, we show evidence that MYC inhibition by Omomyc phenocopies HR deficiency and induces DNA damage in TNBC. In addition, our research shows that combining Omomyc with PARPi would be an effective therapy in PARPi-resistant TNBC, where MYC transcriptional activity is over-represented and could potentially be a predictive biomarker of resistance to therapy.

#1488 DNA polymerase kappa slows replication fork speed by promoting fork reversal in glioblastoma.

R. S. Sewilam, M. R. Reed, R. L. Eoff;
University of Arkansas for Medical Sciences, LittleRock, AR

Replication fork stalling in response to replication stress triggers the activation of replication stressresponse (RSR) pathways to facilitate repair and restart replication processes, including fork reversal andtranslesion DNA synthesis (TLS). During fork reversal, the replication fork undergoes a structural rearrangementto form a four-stranded structure, known as a "chicken foot," which helps regulate fork speed by recruitment ofdifferent fork reversal factors, including HLTF, and SMARCAL1. Optimal replication conditions ensure a relativelyconstant and rapid fork progression rate, which is essential for timely genome duplication. TLS requiresspecialized DNA polymerases that assist fork progression by promoting direct bypass of replication blocks. Inglioblastoma, the most aggressive and resistant form of brain cancer, the TLS polymerase kappa (Pol κ) isoverexpressed. This overexpression causes resistance to standard therapeutics and is associated with poorprognosis. A major goal of our study is to understand how Pol κ protects glioma cells from endogenous oncogenicstressors and the DNA-damaging effects of chemotherapeutics. Results from Eoff lab indicate that Pol κ slowsreplication fork speed in glioma cells (T98G, U118-MG) without significantly affecting non-glioma cells (HAP-1,U2OS, RPE). We hypothesized that Pol κ slows replication fork speed by promoting fork reversal in glioma cells.To test this hypothesis, we used a proximity ligation assay (PLA) to verify the colocalization of fork reversalfactors SMARACL1, and HLTF to sites of DNA synthesis in glioma cells. PLA measures the proximity betweenproteins and newly synthesized DNA labeled with nucleotide analog 5-ethynyl-2 -deoxyuridine (EdU), indicatingtheir potential interaction or colocalization, as evidenced by the appearance of fluorescent foci**.** EdU-SMARCAL1,or EdU-HLTF PLA foci were increased in T98G WT without a significant increase in POLK KO T98G cellsfollowing treatment with 50 nM CPT with no considerable increase in POLK KO T98G cells. These resultssuggest that Pol κ has a role in promoting the colocalization of fork reversal proteins to sites of DNA synthesisin T98G (glioma) cells. To support this conclusion and to study how this affects fork speed, we used DNA fiberspreading (DFS) to determine fork speed with/without depletion of the fork reversal factor SMARCAL1 and HLTF.Depletion of SMARCAL1 and HLTF produced longer IdU tracts in T98G WT cells, indicating faster fork speed.The fork acceleration phenotype in POLK-KO T98G cells remained unaffected by the knock-down ofSMARCAL1, suggesting that these proteins work in the same pathway to regulate fork dynamics in glioblastomacells. These results are the first to establish a link between Pol κ and fork reversal, helping to explain how glioma-specific mechanisms tolerate high rates of DNA damage in the tumor microenvironment.

#1489 Targeting the DNA double-strand break repair pathways in MYCN-amplified neuroblastoma increases tumor sensitivity to chemotherapy.

Mahnaz Norouzi, Subin Kim, B. Mark Evers, Eric J. Rellinger, Piotr Rychahou

University of Kentucky, Lexington, KY

Background: DNA double-strand break (DSB) repair is regulated by non-homologous end joining (NHEJ) and homologous recombination (HR). In neuroblastoma (NB), extensive genomic instabilities such as MYCN amplification, 11q and 1p deletions, and 17q gain are linked to tumor progression and high-risk disease. These abnormalities are associated with defective DSB repair and are enriched in high-risk NB. Here we demonstrate the association between DSB repair pathways and MYCN amplification (MNA) in high-risk NB and explore the potential response of MNA NB to therapies targeting these pathways.
Methods: The R2 Genomics Analysis and Visualization Platform was used for gene set enrichment (GSEA) and differential expression analysis in NB cohorts. DNA-PKcs gene knockdown models, along with Peposertib and Olaparib treatment, were used to inhibit DNA repair activity. Western blotting (WB) was performed to verify DNA-PKcs inhibition and measure PARP cleavage in response to DNA-PKcs inhibition in BE(2)-C and SK-N-DZ cells. DNA damage was induced by Doxorubicin and detected using γ-H2AX immunofluorescence staining followed by confocal microscopy. Clonogenic assays were performed to assess the efficacy of DNA repair inhibition on the survival of NB cells.
Results: GSEA using the Kocak cohort study, which contains microarray gene expression data from 649 NB samples from the NB Research Consortium (NRC), revealed that NHEJ was upregulated in MNA high-risk NB (GSE score = 1.183), while the HR pathway showed moderate downregulation (GSE score = -0.428). Additionally, differential analysis revealed that key components of NHEJ, including and PRKDC, XRCC5, NHEJ1 and Rad50, showed significantly higher expression in MNA high-risk NB compared to non-MNA ($p < 0.05$). Confocal imaging demonstrated increased γ-H2AX foci formation in DNA-PKcs knockdown cells, indicating enhanced DSBs in response to DNA damage due to the loss of active NHEJ repair. Increased cleaved PARP was demonstrated in DNA-PKcs siRNA SK-N-DZ and BE(2)-C knockdown cells, indicating increased apoptosis in response to its inhibition in MNA NB cells. Clonogenic analysis showed a significant decrease in NB cell survival in response to Doxorubicin treatment, with a more pronounced decrease in response to the combination with both Peposertib and Olaparib.
Conclusion: High-risk NB is correlated with extensive genomic instability, and here we showed that upregulation of NHEJ is associated MNA high-risk NB. DNA-PKcs knockdown studies revealed that the survival of MNA NB cells depends on the activity of NHEJ pathway, paving the way for more targeted treatments. The significant response of NB cells to the combination of Peposertib and Olaparib highlights a promising strategy to enhance NB cell sensitivity to conventional therapies, particularly Doxorubicin.

#1490 RAD51C-deficient cancer cells require DNA polymerase zeta to bypass cisplatin-induced lesion.

Mohd Azrin Jamalruddin[1], Emmanuel Tawiah[1], Isabela Contreras[1], McKenzie Grundy[2], Kara Bernstein[1]

[1]Biochemistry and Biophysics, University of Pennsylvania, Philadelphia, PA,[2]University of Pittsburgh, Pittsburgh, PA

RAD51C is a RAD51 paralog protein that mediates RAD51 filament formation on single-stranded DNA (ssDNA) in a canonical homologous recombination (HR) pathway. This step is vital for homology search to repair double strand breaks. RAD51C deficiency is linked to increased risks of developing breast and ovarian cancers. Fortunately, RAD51C-deficient cancer patients are generally responding well to chemotherapeutics drug like cisplatin. HR is one of the important pathways to repair cisplatin-induced lesion. Hence, cancer cells that lack RAD51C are more susceptible to cisplatin treatment. Nonetheless, high grade serous ovarian cancer patients are often relapse even though initial cisplatin treatment were successful. There is still incomplete knowledge on how different DNA repair factors contribute to cisplatin-induced damage repair in HR-deficient cancer cells. Our study is aimed to identify and study these factors to better understand how RAD51 paralog-deficient cancer cells evade cell death upon cisplatin treatment. Apart from HR, there are several DNA damage tolerance mechanisms in which cancer cells can adopt to bypass cisplatin-induced lesions. Based on our synthetic lethality screen in yeast, we observed that translesion synthesis (TLS) factors (*rev1* and *rev3*) deletion, increase the cisplatin sensitivity in RAD51 paralog knockout (KO) cells. Cisplatin often causes the formation of bulky DNA lesions that provide structural barrier to DNA polymerase during DNA replication. TLS DNA polymerases are error-prone DNA polymerases that bypass these lesions to continue DNA replication and evade cell cycle arrest. We also observed the same scenario in human ovarian cancer cells. TLS depletion, that include REV3L of DNA pol zeta, (POL ξ), increase cisplatin sensitivity in RAD51C-deficient cancer cells. Using DNA fiber assay, we discovered that POL ξ limits the replication fork speed in RAD51C-KO cells upon cisplatin treatment. Based on S1 nuclease DNA fiber assay, we showed that POL ξ also prevents the accumulation of ssDNA in cisplatin-treated RAD51C-KO cells. These preliminary data suggest that POL ξ plays a role in DNA replication dynamics in RAD51C-deficient cells to ensure them to survive under cisplatin treatment. Uncharacterized RAD51C point mutations that found in cancer patients are often classified as variants of unknown significance (VUS). While cells that lack RAD51C are generally sensitive to cisplatin, some of these RAD51C VUS variant cells are resistant to it. In our clonogenic assay, we observed that REV3L depletion sensitizes several cisplatin-resistant RAD51C variants to cisplatin. Upon cisplatin treatment and REV3L depletion, we also observed an increase of ssDNA accumulation in RAD51C variant. Our data reveal the potential role of POL ξ in therapeutic avenue for cisplatin-resistant RAD51C variants.

#1491 ATM, CHEK2 and BLM mutant prostate cancers do not have high homologous recombination deficiency scores.

Ekaterina Sh. Kuligina, Aglaya G. Iyevleva, Anna P. Sokolenko, Svetlana N. Aleksakhina, Maria V. Syomina, Ekaterina A. Otradnova, Evgeny N. Imyanitov

N.N. Petrov National Medical Research Center of Oncology, St. Petersburg, Russian Federation

Background: Homologous recombination deficiency (HRD) resulting from inactivating mutations in the BRCA1 and BRCA2 genes promotes increased chromosomal instability and renders tumor cells susceptible to platinum derivatives and PARP inhibitors. Hereditary and/or somatic mutations in BRCA2, ATM, CHEK2 and other loci involved in homologous recombination DNA repair (HRR) have been reported in up to 25% of metastatic prostate cancer (PC) cases. The contribution of alterations in HRR-related genes beyond BRCA1/2 to homologous recombination deficiency remains largely unknown. The aim of the current study was to compare the HRD scores in prostate tumors with alterations in different HRR genes.
Methods: HRD scores were determined as the sum of genomic loss of heterozygosity (LOH), large-scale state transition (LST) and telomeric allelic imbalance (TAI) scores by targeted NGS using HiSNP Ultra Panel v1.0 (Nanodigmbio, China) in two PC groups. The first group consisted of 58 PC cases with germline or somatic mutations in any of 34 HRR genes, while the second group included 214 cases without HRR mutations. The cut-off for the presence of homologous recombination deficiency was set as an HRD score ≥ 42.
Results: HRD was observed more frequently in PCs with HRR mutations (9/58, 16%) than in cases without detectable HRR alterations (10/214, 5%, p = 0.008). In the HRR-mutated subgroup, high HRD scores were found in cases with BRCA2 (n = 4), ATM (n = 2), CDK12, NBN and FANCM mutations. The median HRD scores in PCs with mutations in BRCA2 (n = 9), ATM (n = 12), CHEK2 (n =8), NBN (n = 3), FANCM (n = 3), BRCA1 (n = 3), BLM (n = 3) were 41, 22.5, 7.5, 3, 10, 6, and 3, respectively. The comparison of HRD scores between BRCA2-mutant cases and ATM- (p = 0.046), CHEK2- (p = 0.005), or BLM-mutant PCs (p = 0.042) reached statistical significance. The presence of somatic TP53 mutations was associated with a higher degree of chromosomal instability and elevated HRD scores (p = 0.0001).
Conclusions: A high HRD score is observed in a noticeable proportion of prostate tumors lacking mutations in the HRR genes. Prostate cancer cases with alterations in ATM, CHEK2, BLM, and possibly also NBN, FANCM genes are unlikely to have severe HRD. This work has been supported by the Russian Science Foundation (grant number 23-15-00262).

#1492 Clinical validation on the PAOLA-1/ENGOT-ov25 cohort of HRD calculation performed with the OncoDEEP® kit comprehensive genomic panel.

Marcel Trautmann[1], Simon Lefevre[2], Sebastien Sauvage[2], Jessie Hong[2], Maxime Lienard[2], Karim Ashour Garrido[2], Jean-Francois Vanbellinghen[2], Rapahel Leonard[2]

[1]Gerhard-Domagk-Institute of Pathology, Munster University Hospital, Munster, Germany,[2]OncoDNA, Gosselies, Belgium

Introduction: Homologous Recombination Repair (HRR) pathway repairs DNA double-strand breaks. Loss of HRR capability is known to lead to genomic instability resulting in a phenotype called Homologous Recombination Deficiency (HRD). The utility of HRD biomarker in cancer treatment lies in its ability to predict response to specific types of therapy such as platinum-based chemotherapy and PARP inhibitors (PARPi). HRD tests evaluating scores of allelic imbalances, such as genomic scar (GS) or loss of heterozygosity (LOH), have been shown to identify a subgroup of BRCA wild-type (wt) tumors showing a HRD phenotype. Currently, HRD status is being used as a biomarker in cancer profiling, helping clinicians determine the best treatment option for their patients. In this perspective, OncoDNA® has developed a pan-cancer tumor profiling solution, the OncoDEEP® kit, facilitating the genomic analysis of both tumor DNA and RNA, and supported with Bio-IT analysis and clinical reporting. This end-to-end solution screens for a very wide range of cancer biomarkers and genomic signatures such as HRD. Hence, the OncoDEEP® kit can aid in reducing the costs of testing and deliver faster results for the selection of appropriate cancer treatment.

Methods: OncoDEEP® kit, based on Twist technology, was performed at OncoDNA laboratory facilities on 246 extracted DNA from FFPE ovarian carcinoma of the PAOLA-1/ENGOT-ov25 cohort. Those samples were previously characterized with Myriad Mychoice DX and obtained at Arcagy Gineco®. Sequencing was performed on Illumina Novaseq X. All 638 genes on OncoDEEP® panel, inclusive of BRCA1/2 and other HRR genes, were analyzed *via* OncoDNA proprietary bioIT pipeline and GS was calculated using Loss of Heterozygosity (LOH), Allelic Disparity on Telomere (ADT) and Large-scale Rearrangements (LR), with a positive threshold of 37. Afterwards, results were matched with PFS and treatment.

Results: HRD analysis of OncoDEEP® showed a high correlation with Myriad MyChoice DX, with an overall concordance of 85 %. In addition, OncoDEEP showed to be highly predictive (p-value≤0.001) of tumor response to olaparib+bevacizumab. Tumors harboring a positive HRD phenotype and treated with olaparib+bevacizumab exhibited a median PFS of 36.4 months, while median PFS of placebo-treated tumors was 18.75 months. Finally, OncoDEEP analysis presented a lower failure rate (0.8%) compared to Myriad MyChoice Dx (6.5%).

Conclusion: OncoDEEP® kit is an end-to-end solution allowing the detection of variants in 638 genes and the calculation of genomic signatures such as TMB, MSI and HRD. OncoDEEP® HRD analysis showed to be highly predictive of tumor response treated by olaparib+bevacizumab and is therefore applicable to the identification of ovarian cancer patients eligible to PARPi therapy in oncology routine.

#1496 Understanding a novel interaction between HSF1 and ERRα in breast cancer.

Sunandan Chakrabarti[1], Yuan Feng[2], David Adelfinsky[3], Jason Tennessen[4], Richard Carpenter[5]

[1]Medical Sciences, Melvin and Bren Simon Comprehensive Cancer Center, Indiana University School of Medicine - Bloomington, Bloomington, IN,[2]Medical Sciences, Indiana University School of Medicine - Bloomington, Bloomington, IN,[3]Medical Sciences, Indiana University Bloomington, Bloomington, IN,[4]Biology, Indiana University Bloomington, Bloomington, IN,[5]Biochemistry and Molecular Biology, Melvin and Bren Simon Comprehensive Cancer Center, Indiana University School of Medicine, Bloomington, IN

Breast Cancer is the most common type of cancer in women with 1 in 8 women being predicted to develop breast cancer during their lifetimes. Even after decades of ground-breaking research, new cases and deaths continue to rise. Oncogenesis can often be attributed to genetic alterations, which inadvertently lead to transcriptional dysregulation, often allowing them to successfully mitigate the effects of oxidative stress, metabolic stress, and others, ultimately giving them survival benefits. ERRα is an orphan nuclear receptor that regulates metabolic gene expression and has been linked to poor prognosis in many cancers, including that of the breast. Inhibiting ERRα has been identified as a potential therapeutic strategy but the underlying mechanism is not fully understood. HSF1, a master transcription regulator involved in heat shock response and protein homeostasis, has been implicated in oncogenesis and promotes cell proliferation and invasion. However, any interaction or cooperation between ERRα and HSF1 has not been investigated. Analyses of ChIP Seq data revealed a substantial number of overlapping binding peaks and shared target genes between HSF1 and ERRα. Gene ontology enrichment revealed these shared target genes are enriched for cellular pathways frequently dysregulated in cancer, such as cell proliferation. Using a novel ERRα transcriptional activity signature, it was observed that ERRα activity was strongly correlated with HSF1 activity in breast cancer patients. Furthermore, patients with high activities of both ERRα and HSF1 were found to have poorer prognosis. Since HSF1 and ERRα are transcription factors, we wanted to check for any cooperativity in their transcriptional activities. Luciferase-based reporter assays revealed ERRα enhanced HSF1 transcriptional activity. To further understand any interaction between ERRα and HSF1, we treated HEK293FT (non-cancer cell line) and HCC1937 (triple negative breast cancer cell line) with an ERRα inhibitor (XCT790) and an HSF1 inhibitor (DTHIB). We observed a reduction in HSF1 protein with ERRα inhibition and a reduction in ERRα with HSF1 inhibition. Moreover, co-immunoprecipitation assay results suggest a physical interaction between HSF1 and ERRα. Taken together, our data suggests a possible protein complex with HSF1 and ERRα that stabilizes both proteins and regulates genes supportive of breast tumor growth. Future studies will be looking at the role of this complex on oncogenesis and progression of breast cancer. These studies will lead to identification of probable therapeutic strategies exploiting this interaction.

#1497 PERK as a biomarker to optimize therapy of GRP78 inhibitor, BOLD-100, in gastric cancer.

Sea Young Choo[1], Ah-Rong Nam[1], Kyoung-Seok Oh[1], Jae-Min Kim[1], Ju-Hee Bang[1], Yoojin Jeong[1], Hyo Jung Kim[1], Jeesun Yoon[2], Tae-Yong Kim[2], Do-Youn Oh[2]

[1]Seoul National University Cancer Research Institute, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of

Background: Targeting endoplasmic reticulum (ER) stress is emerging as a potential therapeutic strategy for developing therapies against solid tumors. GRP78, also known as the master regulator of unfolded protein response (UPR), is an anti-apoptotic ER chaperone that adjusts protein folding capacity to restore ER homeostasis. Moreover, GRP78 is an inhibitory PERK-binding protein that regulates the activation of death-triggering UPR pathways to avoid cell apoptosis. In gastric cancer (GC), GRP78 expression is elevated compared to normal tissue making GRP78 an attractive therapeutic target in GC. However, there have been limited studies on targeting GRP78 in GC. This study investigates the antitumor effects of GRP78 inhibition with BOLD-100 and explore potential biomarkers for therapeutic response in GC.
Methods: A total of 9 gastric cancer cell lines (KATO-III, SNU-601, NCI-N87, MKN-45, SNU-216, SNU-719, SNU-668, AGS, SNU-638) were used. BOLD-100 (GRP78 inhibitor), TUDCA (Tauroursodeoxycholic acid; ER stress inhibitor), and AZD6738 (ATR inhibitor) were used. MTT assay, RT-qPCR, western blot, cell cycle analysis, DCF-DA staining, immunofluorescence, and Annexin V assay were performed to evaluate the antitumor effects of BOLD-100. To evaluate the effect of PERK expression level on the efficacy of BOLD-100, siRNA was used to downregulate PERK and consequent BOLD-100 effects were analyzed by MTT assay, western blot, and flow cytometry.
Results: The antitumor effect of BOLD-100 positively correlated with PERK expression. BOLD-100 suppressed the mRNA level of GRP78 leading to a subsequent increase in unfolded protein load and ROS level in a PERK expression-dependent manner. In PERK-high GC cells (KATO-III, SNU-601), BOLD-100 exerted pronounced activation of PERK-eIF2a-CHOP pathway, resulting in inhibited tumor cell growth and induced apoptosis. PERK knockdown reversed BOLD-100 induced ROS accumulation and UPR activation suggesting that PERK expression level regulates sensitivity to BOLD-100. Conversely, in PERK-low GC cells (AGS, SNU-638), BOLD-100 exerted minimal effects on UPR pathway. Rather, it induced R-loop accumulation and upregulated active forms of ATR and Chk1 - effects not observed in PERK-high cells - suggesting activation of DNA damage repair pathway. A combination of BOLD-100 and AZD6738 showed synergistic effects in PERK-low GC cells by suppressing BOLD-100 induced ATR phosphorylation.
Conclusion: The expression of PERK determines sensitivity to GRP78 inhibition by BOLD-100 in GC. PERK-high GC cells are sensitive to BOLD-100 and show efficacy as monotherapy. In PERK-low GC cells, the combination of BOLD-100 and ATR inhibitor is an optimal therapeutic option for GC treatment.

#1498 SELENOF maintains proteostasis through UPR-IRE1α axis in breast cancer.

An Zhang, Irida Kastrati

Cancer Biology, Loyola University of Chicago, Maywood, IL

Background: SELENOF is an understudied selenoprotein that incorporates selenium in the form of selenocysteine. Our lab's investigation into SELENOF's function in breast cancer indicates that it is likely a tumor suppressor. SELENOF resides in the endoplasmic reticulum (ER) and has been hypothesized to assist in protein folding, specifically disulfide-bond formation. Disruption of protein folding efficiency leads to the accumulation of misfolded proteins, a process referred as EnR stress. In turn, the unfolded protein response (UPR) is triggered to relieve EnR stress and to restore protein processing functions. In cancer, UPR is a double edge sword. To meet the challenges of rapid proliferation, cancer cells exploit this intrinsic adaptive mechanism of UPR. However, with prolonged and unresolved EnR stress, the cell switches UPR from an adaptive response to a terminal death-inducing response. We hypothesize that SELENOF may play a role in UPR stress resolution, and how this affects breast cancer initiation of progression remains to be determined.

Objective:Our study aims to determine the crosstalk between SELENOF and EnR using normal mammary gland tissue and breast cancer models.

Results: SELENOF levels were manipulated by overexpression or knockout in normal breast epithelial cells and in breast cancer cell lines. Loss of SELENOF does not change baseline UPR measured by Thioflavin T staining and EnR stress markers include IRE1a phosphorylation and XBP1 mRNA splicing. Instead, overexpression of SELENOF increased UPR. We also determined that the IRE1-XPB1 axis required, but not the other two, Upon induction of EnR stress using Tunicamycin, Thapsigargin, we find that SELENOF levels is increased via IRE1-XBP1, thus uncovering a crosstalk between UPR and SELENOF. Furthermore, loss of SELENOF reduces the overall UPR. These findings were validated in vivo using wild type and SELENOF knockout mice.

Conclusion: Our findings establish a feed-forward model between UPR and SELENOF; SELENOF level increase upon UPR induction to amplify the UPR response towards terminal UPR. Loss of SELENOF restricts UPR response within adaptive levels to bypass cell death. This may provide a mechanism for cancer cells to survive while coping with higher proteotoxic stress.

#1499 Combination HIF-2alpha inhibition with cholesterol biosynthesis inhibition decreases colorectal carcinoma growth.

Prarthana Dalal[1], Boyan Hu[1], Rashi Singhal[2], Yatrik Shah[1]

[1]University of Michigan, Ann Arbor, MI,[2]Odyssey Therapeutics, Ann Arbor, MI

Hypoxic stress in solid tumors promotes cancer cell growth and survival and confers therapeutic resistance. Hypoxia inducible factors (HIFs) are transcription factors that help cells adapt to hypoxic stress. HIFs are often overexpressed in tumors and are associated with worse clinical outcomes. HIF inhibition is a novel therapeutic strategy and belzutifan is a first-in-class HIF-2α inhibitor. Belzutifan has recently been approved for metastatic renal cell carcinoma treatment. However, despite studies showing that HIF-2α is a critical regulator of colorectal carcinoma, belzutifan is not effective in pre-clinical studies of colorectal carcinoma (CRC) growth. HIF-2α inhibition with a small molecule inhibitor, belzutifan, does not affect proliferation of CRC cells (HCT116, SW480) under normoxic or hypoxic conditions. The primary objective of this study was to identify metabolic vulnerabilities in CRC caused by HIF-2α inhibition that can be synergistically targeted to increase cancer cell death. We first performed an unbiased CRISPR screen and identified the cholesterol biosynthesis pathway as a potential target. Inhibiting the cholesterol biosynthesis pathway with HMG-CoA reductase inhibitors, statins, potentiates cell death and reduces in vitro proliferation of HCT116 and SW480 cells when combined with HIF-2α genetic knockdown or HIF-2α inhibition. This effect is dose-dependent in nature and is preserved across the statins class as tested with pitavastatin, simvastatin, and atorvastatin. Planned future studies include in vivo experimentation with autochthonous mouse models of CRC to assess how combination treatment with statin and HIF-2α inhibition affects tumor progression. Ultimately, statins are a widely used, safe, and affordable treatment for atherosclerosis and our data shows that combining statins with belzutifan may be a synergistic therapeutic strategy for CRC.

#1500 Inhibition of tumor hypoxia response with synthetic transcriptional repressors.

Long Chi Nguyen, Zeyu Qiao, Dongbo Yang, Christopher Dann, Deborah Thomas, Madeline Henn, Andrea Valdespino, Colin Swenson, Scott Oakes, Marsha Rich Rosner, Raymond Moellering

University of Chicago, Chicago, IL

Hypoxia, a hallmark of aggressive solid tumors, promotes metastasis and therapy resistance by activating factors such as hypoxia-inducible factors (HIFs) that support cellular adaptation and tumorigenesis. Under hypoxic stress, transcription factors like HIFs and X-box-binding protein 1 (XBP1) are activated and bind to unfolded protein response element (UPRE) and hypoxia response element (HRE) motifs, regulating oncogenic gene expression. We identified that the core HRE motif (5'-ACGTG-3') is embedded within the canonical UPRE motif (5'-TGACGTGG-3'), and prior research shows overlap in the binding patterns of HIF1α/ARNT and XBP1. We propose a novel strategy to target the tumor hypoxia response by using fully synthetic transcriptional repressor (STR) peptides that mimic the basic leucine zipper DNA-binding domain of XBP1. These peptides effectively bind to UPRE and HRE DNA elements. Our lead peptide, STR22, inhibits the DNA binding of both XBP1 and HIF1A, resulting in global suppression of the hypoxia response transcriptional program in vitro and in triple-negative breast cancer (TNBC) tumor models. STR22 has shown no observable toxicity with either intratumoral or intravenous administration and significantly inhibits tumor growth and metastasis in TNBC-bearing mice. Our findings validate STRs as a safe and promising approach for targeting DNA motifs, including tumor hypoxia response elements, through direct DNA binding competition with oncogenic transcription factors. This strategy offers potential to outperform single-factor therapies, presenting a novel option for clinical applications.

#1501 Ras-dependent activation of BMAL2 regulates hypoxic metabolism in pancreatic cancer.

A. Curiel Garcia[1], C. H. Maurer[2], C. Castillo[3], R. M. Schmid[2], P. Laise[1], L. Tomassoni[1], C. Palermo[1], S. Sastra[1], A. Andren[3], L. Zhang[3], T. Y. S. Le Large[4], I. Sagalovsky[1], D. R. Ross[1], V. Rosario[1], K. Lu[5], E. Ferraiuolo[5], N. Spinosa[5], W. Wong[1], K. Shaw[6], J. A. Chabot[6], J. Genkinger[1], H. Hibshoosh[1], G. A. Manji[1], A. C. Iuga[7], M. A. Badgley[1], K. C. Johnson[5], A. Califano[1], Y. M. Shah[3], C. A. Lyssiotis[3], K. P. Olive[1];

[1]Columbia University Irving Medical Center, New York, NY, [2]Technical University of Munich, Munich, Germany, [3]University of Michigan, Ann Arbor, MI, [4]Dijklander Ziekenhuis Location Hoorn, Hoorn, Netherlands, [5]University of New Hampshire, Manchester, NH, [6]Columbia University, New York, NY, [7]University of North Carolina at Chapel Hill, Chapel Hill, NC

To identify novel drivers of pancreatic ductal adenocarcinoma (PDAC) malignancy, we employed a systems biology approach called regulatory network analysis, which accurately infers the activity of transcription factors and other regulatory proteins based on the integrated expression of their positive and negative target genes. This highly validated approach enables the identification of the most hyper-activated and hyper-repressed regulatory proteins (“master regulators”) that drive phenotypic distinctions. We applied this technique to a set of 200 laser capture microdissected human PDAC samples as well as 45 low-grade precursors for which we had matched histopathological, clinical, and epidemiological annotation. We identified the master regulators associated with 4 malignancy phenotypes: tumor initiation, tumor progression, survival post resection, and association with KRAS activity. Integrating across these phenotypes, the top master regulator was BMAL2, a member of the PAS family. Although BMAL2 is classically associated to the circadian rhythm, gene set enrichment analysis highlighted a potential role in hypoxia response, a key phenotype in PDAC evolution. We previously demonstrated that PDAC in humans and in the genetically engineered “KPC” mouse model is hypovascularized and hypoperfused, and we have since shown that KPC tumors are profoundly hypoxic. Sequence conservation analysis of BMAL2 demonstrated close analogy to hypoxia-related genes, its activity is induced in response to it and inhibited following treatment with multiple RAF, MEK, and ERK inhibitors, validating its computationally inferred association with RAS activity. Strikingly, knockout of BMAL2 in human PDAC cells led to defects in viability and invasion in the setting of hypoxia. Metabolically, loss of BMAL2 impairs the ability to induce glycolysis - key metabolic pathway unregulated during hypoxia response - upon exposure to severe hypoxia. Surprisingly, knockout of BMAL2 in multiple PDAC cell lines led to a complete loss of HIF1A stabilization in response to hypoxia. By contrast, HIF2A was further upregulated under hypoxia in the setting BMAL2 loss. Additionally, metabolomic studies showed an overrepresentation of glycolysis metabolites and related metabolic pathways in hypoxic control conditions but to a lesser degree in BMAL2 knockout cells. Finally, preliminary *in vivo* experiments in cell line derived xenograft models displayed lower tumor growth rates in BMAL2 knock out cells. Together, our data indicates that BMAL2 loss blunts hypoxia response providing also a potential answer to the long-standing question of how these proteins are differentially regulated. Certainly, a connection between RAS signaling and glycolysis has long been apparent, but our findings provide a novel mechanistic understanding of the relationship between RAS and hypoxic metabolism.

#1502 Hypoxia-driven genomic instability and EcDNA formation in lung cancer: insights from TRACERx.

Natasha Sharma[1], Chris Bailey[2], Corentin Richard[1], Jeanette Kittle[1], Charles Swanton[2], Mariam Jamal-Hanjani[1], Nnennaya Kanu[1]

[1]University College London (UCL), London, United Kingdom,[2]The Francis Crick Institute, London, United Kingdom

Tumors exhibit dynamic oxygen gradients, leading to hypoxia, which is linked to poor prognosis and genomic instability. The molecular features of hypoxia and their role in lung cancer outcomes remain unclear. Hypoxia has been linked to the forma on of fragile sites, resulting in chromosomal instability. Recent research has highlighted the generation of extrachromosomal DNA (EcDNA) because breaks. Genes amplified as EcDNA exist acentric circular structures capable driving rapid and significant genomic copy number amplifications. Inherent instability oncogene amplification on EcDNA provides tumor cells with a selective advantage adapting to changing environments. Thus, hypothesize that formation hypoxic tumors provide survivein unfavorable conditions like hypoxia contributes their poor prognosis. This study aims investigate impact disease outcomes formation. Furthermore, can act pressure, we examined its effects mutational burden, positive selection mutations, mutational signatures associated with hypoxia lung TRACERx cohort. TRACERx is multicenter prospective study collects samples from various regions of primary for high-depth next-generation sequencing. Analyzed bulk RNA sequencing data establish levels examine and EcDNA detection. Our preliminary findings reveal variability within between primary tumors, indicating inter- intratumoral hypoxia heterogeneity. High status correlates poorer overall disease-free survival in LUAD, but not LUSC. Additionally, presence significantly associated necrosis. Hypoxia increased circulating tumor (ctDNA) shedding ($p < 0.05$) and elevated whole-genome index (wgii) scores. High-hypoxia exhibit alterations, tumor suppressor b2m, increased expression immunosuppressive chemokines (cxcl8, ccl8, cxcl10). Furthermore, extrachromosomal was detected both LUAD average" hypoxia scores were -0.006 EcDNA-positive compared -0.248 EcDNA-negative samples, highlighting prevalence tumors. In conclusion, shows existence heterogeneity of hypoxia within cohort association clinical outcomes. We highlight link hypoxia, detection, the increased expression contributing a tumor microenvironment.

#1503 Elucidating the role of transcription coregulator MED15 in cancer cell oxidative stress response and proliferation.

Chiaki Shuzenji[1], Xuanjin Cheng[2], Stefan Taubert[1]

[1]Medical Genetics, University of British Columbia Faculty of Medicine, Vancouver, BC, Canada,[2]Canada's Michael Smith Genome Sciences Centre (GSC), Vancouver, BC, Canada

Hyperproliferation is a hallmark of cancer that leads to increased ROS levels, leading to oxidative stress, which causes DNA damage and reinforces cell proliferation. To grow in these conditions, cancer cells activate cellular pathways to rewire the transcriptome to promote oxidative stress resistance. Mapping these response pathways can lead to potential new drugs. Mediator complex subunit MED15 is upregulated in many cancer types and confers oxidative stress resistance in lower animals. To test if MED15 promotes oxidative stress resistance in cancer, we generated three MED15 knockout A549 lung adenocarcinoma cells. Transcriptome, real-time quantitative PCR, and Western Blot analysis showed that MED15 loss downregulates oxidative stress response genes, both at baselines and after stress-inducing compounds. Furthermore, the MED15 knockouts were observed to proliferate slower, so I performed cell cycle analysis using flow cytometry which showed that MED15 knockouts arrest cell cycle more after serum starvation compared to their wild-type counterparts. In sum, our data indicate that MED15 is required for normal cancer cell stress resistance and growth. This has clinical potential, as MED15 can be targeted by small molecules, making it a promising drug target.

#1504 Harnessing the power of mangifera indica: Activation of Nrf2 by leaf-derived oxylipins.

Atif Ali Khan Khalil, Min Seok Woo, **Jung-Hwan Kim**

Gyeongsang National Univ., Jinju, Korea, Republic of

Mangifera indica L., a member of the Anacardiaceae family, is grown all over the world and is known for its therapeutic properties because of its abundance of bioactive chemicals. In the current study, we investigated the effect of mango leaf extract on oxidative stress in HeLa cells. At a concentration of 100 µg/mL, the n-hexane fraction (MLHx) significantly increased antioxidant response element (ARE)-luciferase activity, surpassing other fractions. Furthermore, via raising nuclear NRF2 levels, MLHx enhanced the HO-1 mRNA expression. Increased phosphorylation of ERK1/2 and stability of NRF2 are the fundamental mechanisms. Through bioactivity-guided isolation, six oxylipins were identified: 13(R)-hydroxy-octadeca-(9Z,11E,15Z)-trienoic acid (C-1), 9(R)-hydroxy-octadeca-(10E,12Z,15Z)-trienoic acid (C-2), 13(R)-hydroxy-(9Z,11E)-octadecadienoic acid (C-3), 9(R)-hydroxy-(10E,12Z)-octadecadienoic acid (C-4), 9-oxo-(10E,12E)-octadecadienoic acid (C-5), and 9-oxo-(10E,12Z)-octadecadienoic acid (C-6). Their structures were confirmed by advance spectroscopic methods, such as ^{1}H NMR and MS. Additionally, the structures of compounds C-7 (9-oxo-(10E,12Z,15Z)-octadecatrienoic acid) and C-8 (13-oxo-(9E,11E)-octadecadienoic acid) were characterized via LC-MS/MS mass fragmentation. This work is the first to disclose the isolation of components 1-6 from *M. indica*. In HeLa cells, compounds 3, 5, and 6 showed significant, dose-dependent stimulation of ARE-luciferase activity when tested for their impact on NRF2 activity

#1505 E-cigarette aerosols increase NRF2 expression and enhance cancer stemness in human oral epithelial cells.

Vengatesh Ganapathy[1], Jimmy Manyanga[1], Gautham Chengizkhan[1], Mayilvanan Chinnaiyan[1], Balaji Sadhasivam[2], Ilangovan Ramachandran[3], David A. Rubenstein[4], Lurdes Queimado[1]

[1]Departments of Otolaryngology-Head and Neck Surgery, The University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Occupational and Environmental Health, The University of Oklahoma Health Sciences Center, Oklahoma City, OK,[3]Department of Endocrinology, Dr. ALM Post Graduate Institute of Basic Medical Sciences, University of Madras, Chennai, India,[4]Biomedical Engineering, Stony Brook University, Stony Brook, NY

Background: The popularity of e-cigarettes has surged among cigarette and non-cigarette users, in part due to their promotion as a safer choice compared to traditional smoking. Yet, the true health implications of vaping are still uncertain and need to be explored. E-cigarette aerosols contain harmful substances that can cause oxidative stress. We and others have reported that exposure to e-cigarette aerosols increases reactive oxygen species (ROS) and reduces total antioxidant capacity, leading to a significant increase in DNA damage in oral epithelial cells. This raises important questions about the long-term health effects. Nuclear factor erythroid 2-related factor 2 (NRF2), the master regulator of antioxidant signaling, is crucial for managing oxidative stress and regulating cell stemness. In this study, we examined how exposure of oral epithelial cells to e-cigarette aerosols affect the expression of NRF2 and its downstream targets, which play a critical role in stem cell regulation.
Methods: Human oral epithelial cancer (UM-SCC-1) cells were treated with aerosol extracts of e-cigarettes (tobacco flavor) from two brands, every other day for two weeks at 30 ng/ml nicotine. Standard combustible tobacco extracts were used as a positive control. Changes in gene and protein expression were assessed by qRT-PCR and western blotting analysis, respectively. The stemness of cancer cells was evaluated by spheroid assay, and the $ALDH^{+ve}$ cancer stem cell population was measured by the ALDEFLUOR assay. Data analysis was performed using Student's t-test.
Results: Exposure to e-cigarette aerosol extracts significantly increased the mRNA and proteins levels of NRF2, SOD2, CAT, and HMOX1, along with a decrease in KEAP1 protein. We observed enhanced spheroid formation in oral epithelial cells exposed to e-cigarette extracts. Notably, a significant rise in the cancer stem cell population was observed in oral cancer cells exposed to e-cigarette aerosols. Furthermore, we observed a marked increase in the expression levels of specific mRNAs related to stemness factors (e.g., *BMI1*, *OCT4*), which are crucial for maintaining stem cells.
Conclusion: Our findings indicate that exposure to e-cigarette aerosols significantly activates the NRF2 signaling pathway and promotes stemness of oral epithelial cells. The increased expression of NRF2 and its downstream targets suggests an enhanced response to oxidative stress. Additionally, the upregulation of stemness markers highlights the potential of e-cigarette aerosols to enhance cancer stem cell characteristics and tumor progression. These results raise concerns about the role of e-cigarette aerosols in oral carcinogenesis and imply that the perceived safety of e-cigarettes may be misleading, thus warranting further investigation into their long-term effects on human health.
Funding: TSET HPRC (Ganapathy), NIH/NCI (R01CA242168, Queimado).

#1506 Protein acyl-protein thioesterases affect redox homeostasis and ROS signaling through peroxiredoxin.

Tian Qiu, Saara-Anne Azizi, Shubhashree Pani, Bryan C. Dickinson

Department of Chemistry, University of Chicago, Chicago, IL

Peroxiredoxins (PRDXs) are among the most abundant antioxidants and are widely distributed in cancers. They are associated with tumor cell resistance to cell death, such as apoptosis and ferroptosis. Post-translational modifications of PRDX play a critical role in modulating its activity and tuning the balance between reactive oxygen species (ROS) signaling and stress. We previously discovered that mitochondrial localized PRDX3 and PRDX5 are *S*-acylated, with dynamic PRDX5 active site cysteine acylation regulating mitochondrial redox homeostasis. In this investigation, we found that all the PRDX family proteins are subject to *S*-acylation at the nucleophilic cysteine residue in their active site, and that PRDX *S*-acylation responds dynamically to ROS levels in the cell. The PRDX *S*-acylation level decreases under acute ROS stress, and increases under physiological, signaling levels of H_2O_2. Using activity-based fluorescent imaging with DPP-Red, a red-shifted fluorescent indicator for acyl-protein thioesterase (APT) activity, we also discovered that ROS-stress via exogenous H_2O_2 activates both the cytosolic and mitochondrial APTs, whereas EGF-stimulated endogenous H_2O_2 deactivates the cytosolic APTs. These results indicate that APTs help tune H_2O_2 signal transduction and ROS protection through PRDX *S*-deacylation.

#1507 Oxidative stress increases the aggressiveness of colorectal cancer by activating the antioxidant transmembrane chloride intracellular channel 1 (tmCLIC1).

Francesca Cianci[1], Guido Rey[1], Carlotta Tacconi[2], Luca Palloni[1], Matteo Ranucci[3], Giulia Bertolini[4], Luca Roz[4], Alessandro Fantin[1], Michele Mazzanti[1]

[1]University of Milan, Milan, Italy,[2]Libera Universita Vita-Salute San Raffaele, Milan, Italy,[3]Universitaat of Zurich, Zurich, Switzerland,[4]Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy

Colorectal cancer is the third leading cause of death in developed country, especially in the presence of metastases. Metastatic cancer cells depend on antioxidants like glutathione (GSH) to tackle oxidative stress as they adapt to distinctive environments different from those of the primary tumor. The mechanisms that cause oxidative stress in cancer cells are poorly understood, but it was recently discovered that the Chloride Intracellular Channel 1 (CLIC1) protein supports tumor cell Reactive Species of Oxigen (ROS) overproduction. CLIC1 is a ubiquitous protein from the CLICs family, which is unique in its ability to be metamorphic. In normal cells, CLIC1 protein is expressed as a cytosolic form and binds antioxidant glutathione (GSH). Under the chronic stress typical of cancer cells, CLIC1 undergoes a conformational change, translocating to the plasma membrane (tmCLIC1). This transition releases GSH into the cytoplasm while tmCLIC1 facilitates reactive oxygen species (ROS) overproduction, fostering an aggressive cancer phenotype. Studies reveal a contradiction where cancer cells simultaneously exhibit high levels of both ROS and GSH, which are usually inversely related. In this work, we demonstrate that this paradox is linked to tmCLIC1 activity, where GSH release acts as a defense mechanism, while tmCLIC1 overexpression amplifies ROS production, driving cancer cell proliferation and metastasis. Blocking tmCLIC1 activity has shown a reduction of proliferation, migration, and invasion of metastatic colorectal cancer cells (CRC). The study also demonstrated that forcing non-metastatic CRC cells (SW480) to release GSH using the antioxidant N-Acetyl Cysteine (NAC) enriched cytoplasmic GSH and increased tmCLIC1 expression. This effect, however, was absent in cells where CLIC1 was silenced, proving that GSH release depends on tmCLIC1 activity. These cells were converted from non-aggressive cell lines to metastatic ones in vitro and in vivo. These findings challenge the traditional view of antioxidants in cancer treatment, suggesting that tmCLIC1 inhibition could serve as a novel therapeutic strategy against metastatic colorectal cancer, addressing a pressing societal health concern.

#1508 Therapy resistant cancer cells containing stress granules display signatures of oxidative stress.

Louis T. A. Rolle, Luke V. Loftus, Kenneth J. Pienta, Sarah R. Amend

Urology, Johns Hopkins University School of Medicine, Baltimore, MD

Understanding and overcoming therapy resistance in cancer is crucial, as it remains a major driver of lethality. We have shown that following chemotherapy, surviving cancer cells repeatedly skip mitosis, leading to increased genomic content concomitant with an increase in cell size. This survival mechanism has been observed in multiple tumor types and in response to multiple therapy classes, suggesting a convergent phenotype. We hypothesize that this surviving cell phenotype is the actuator of therapy resistance observed in patients with cancer recurrence.

It is widely known that chemotherapies elevate levels of reactive oxygen species (ROS) by indirectly disrupting the electron transport chain, leading to the generation of superoxides. When ROS levels exceed cellular antioxidant capacities, cells experience oxidative stress whereby ROS molecules directly damage important macromolecules, potentially leading to cell death. Using live cell imaging with DCFDA and CellROX dyes, we found that the cells surviving even long after therapy release contain elevated levels of ROS as compared to untreated controls across two cell lines of different tumor types (PC3 prostate cancer and MDA-MB-231 breast cancer) and following treatment with two classes of chemotherapy (cisplatin and docetaxel). In single-cell RNA sequencing datasets, we further find an enrichment for downstream targets of NRF2, a major transcription factor that regulates the response to oxidative stress in cells that survive therapy. This suggests that the cells that survive chemotherapy continue to experience oxidative stress even after therapy is removed and respond by initiating defensive mechanisms to promote survival.

Stress granule formation is a common cellular response to oxidative stress that form immediately following a translational arrest. Stress granules are cytoplasmic aggregates of RNA bound by proteins, such as G3BP1, which form a stable core and recruit binding partners to form a mature granule. Stress granules are transient and offer cells the capacity to resume translation rapidly following recovery from stress. Alternatively, autophagy of stress granules during recovery offers cells a rich pool of biomolecules upon relief from stress.

In both of our cell line models, we find that while stress granules are virtually absent in untreated cells, up to 18% of surviving cells induce stress granule formation, depending on cell type and chemotherapy. We further demonstrated that surviving cells that containing stress granule have enriched nuclear NRF2 levels, suggesting a positive relationship between stress granule formation and cellular response to ROS. Based on these data, we hypothesize that surviving cells experiencing oxidative stress induce stress granule formation. Future work aims to show the pro-survival role of stress granule formation through time-lapse imaging of cells expressing a G3BP1-GFP construct.

#1509 Discovery of choroid plexus targeted gene therapy to protect cancer chemotherapy-related cognitive impairment.

Ahram Jang[1], Boryana Petrova[2], Taek-Chin Cheong[2], Miriam E. Zawadzki[2], Jill K. Jones[2], Andrew J. Culhane[2], Frederick B. Shipley[2], Roberto Chiarle[2], Eric T. Wong[3], Naama Kanarek[2], Maria K. Lehtinen[2]

[1]Division of Endocrinology, Diabetes and Metabolism, Beth Israel Deaconess Medical Center, Boston, MA,[2]Department of Pathology, Boston Children's Hospital, Boston, MA,[3]Brain Tumor Center & Neuro-Oncology Unit, Beth Israel Deaconess Medical Center, Boston, MA

Chemotherapy-induced neurotoxicity in non-cancerous cells can cause lifelong complications including cognitive impairment, also known as chemobrain, which is a devastating side effect for cancer patients and survivors. One mechanism by which chemotherapy damages healthy cells is through oxidative stress. The choroid plexus (ChP)-cerebrospinal fluid (CSF) system delivers important health-promoting factors, such as the antioxidant superoxide dismutase 3 (SOD3), to increase survival in response to oxidative stress, while cell-intrinsic pathways protect neurons from oxidative damage. However, the consequences of chemotherapy on ChP and CSF composition are unknown. Here, we show that the chemotherapeutic drug methotrexate (MTX) induces a global metabolic change in the brain, which is reflected in the CSF. Leveraging metabolomics, we found that MTX caused oxidative stress in the CSF of MTX-treated mice, including a reduction in important antioxidant metabolites. The ChP is the main source of secreted SOD3 in the brain. Following MTX treatment in mice, ChP-SOD3 expression was diminished as well as CSF-SOD3 was decreased. Moreover, overall CSF-antioxidant activity was compromised, indicating that cancer chemotherapy damaged the ChP, resulting in an impoverished CSF with reduced antioxidant capability. MTX-induced oxidative stress may also be tracked to tissues in contact with CSF that are functionally vulnerable to the toxicity of cancer chemotherapy. For example, glutathione peroxidase (GPx) enzyme activity was decreased in the hippocampus, where lipid peroxidation was elevated following MTX treatment. Analyses of CSF samples from primary and secondary central nervous system (CNS) lymphoma patients supported our hypothesis that MTX treatment is associated with diminished antioxidant levels in patient CSF. We employed an intraventricular adeno-associated viral (AAV) gene delivery technique to augment SOD3 production by the ChP. ChP-SOD3 gene therapy inhibited oxidative stress indicators in CSF and mitigated MTX-induced toxicity in the adjacent hippocampus. Furthermore, this gene therapy prevented MTX-induced anxiety as well as short-term learning and memory deficits. Collectively, our findings on AAV-based gene therapy via the ChP-CSF system may represent an underutilized approach for widespread and long-term delivery of health-promoting factors to the brain.

#1510 Glutathione-oxidation of ovarian tumor deubiquitinase-1 promotes lung adenocarcinoma survival through stabilizing system x_c^-.

Reem Aboushousha[1], Jos van der Velden[1], Nicholas Hamilton[2], Cuixia Erickson[1], David J. Seward[1], Jianing Li[3], Yvonne M. W. Janssen-Heininger[1]

[1]Pathology and Laboratory Medicine, University of Vermont, Burlington, VT,[2]Chemistry, University of Vermont, Burlington, VT,[3]Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN

The small thiol antioxidant glutathione (GSH) is critical in maintaining redox homeostasis that is essential in combating oxidative stress. We and others have reported increases of GSH in KRAS-mutant lung adenocarcinoma (LUAD). However, little is known about GSH-dependent protein oxidation (S-glutathionylation- PSSG) in LUAD development and progression. We recently discovered that glutaredoxin (GLRX), the enzyme that reverses PSSG, is decreased in human LUAD, and that $Kras^{G12D}$-induced lung tumorigenesis is enhanced in mice lacking *Glrx*. To elucidate the link between PSSG and GSH levels we conducted a redox proteomics screen and identified ovarian tumor deubiquitinase-1 (OTUB1) as a glutathionylation target. We determined that OTUB1 glutathionylation at Cys23 and Cys204 is a regulator of GSH in LUAD cell lines and organoids. Mechanistically, glutathionylation of OTUB1, specifically at Cys23, promoted interaction with the E2-conjugating enzyme UBCH5A, leading to diminished ubiquitination and proteasomal degradation of the active subunit of system x_C^-, SLC7A11, thereby augmenting GSH. The cystine-glutamate antiporter, System x_C^-, has been linked to aggressive tumors with worse survival. The use of a specific inhibitor of OTUB1-SSG, led to decreased SLC7A11 and GSH levels in LUAD cell lines. These findings provide an intricate link between S-glutathionylation of OTUB1, GSH and system x_C^- and provide a mechanism by which LUAD cells combat oxidative stress. Avenues to interfere with OTUB1-SSG may provide a promising therapeutic approach to overcome LUAD progression and resistance. Funded by: R01 CA273238

#1511 Cancer adaptation to acidic tumor microenvironment.

Manami Hasegawa, Keisuke Maede, Miyuki Nishida, Xu Bo, Sho Aki, Rika Tsuchida, Tsuyoshi Osawa

RCAST, the University of Tokyo, Tokyo, Japan

Cancer cells exhibit a characteristic metabolic pattern known as the Warburg effect, which upregulates glycolysis even in aerobic environments. As a result, cancer cells are exposed to an acidic environment due to enhanced excretion of proton and lactate. We have previously reported that this acidic tumor microenvironment induces the activation of the cholesterol biosynthesis pathway and the accumulation of N1-acetylspermidine. Although the acidic tumor microenvironment is known to suppress cancer cell proliferation, the survival strategies employed by cancer cells under such harsh conditions remain unclear. This study aims to elucidate the cell death pathways triggered by acidic pH using an environment even more acidic than physiological conditions and to reveal how cancer cells evade such cell death under physiological conditions.

Live imaging was performed by exposing the cervical cancer cell line HeLa to an acidic environment (pH 5.6), which confirmed that cell death with membrane rapture was induced. Furthermore, in the pancreatic cancer cell line PANC1, phosphorylation of RIP1 and MLKL was observed, and cell death was suppressed by treatment with Nec-1, an inhibitor of RIP1. These findings identified Necroptosis induced under pH5.6.In addition, PANC1 cells that transitioned to a floating state under acidic conditions (pH 5.6-6.8) regained their adhesion and proliferation abilities when cultured under normal tissue pH conditions (pH 7.4). These findings indicate that some of the floating cells under acidic conditions avoid cell death and adopt certain survival strategies. Then, RNA-seq was performed on cells fractionated into those in suspension and those remaining adherent under pH6.8. Pathways related to the acquisition of stemness such as HDACs deacetylation pathway and PRC2 methylation pathway were observed to be active in the floating cells. Furthermore, the upregulation of EMT transcription factors was also confirmed.

Furthermore, we cultured PANC1 cells under pH6.8, using a genome-wide CRISPR-Cas9 knockout screening system over a 30-day time course and identified key genes essential for the acquisition of tolerance to acidic tumor microenvironment.

We elucidated a mechanism in pancreatic cancer cells whereby Necroptosis is avoided in physiologically acidic environments. This cell death-avoidance pathways under acidic conditions could potentially be applied to the development of novel therapeutic strategies that induce cell death in pancreatic cancer cells, which are highly influenced by the tumor microenvironment, particularly in acidic conditions.

#1512 EGR1 regulates phenotypic plasticity to promote breast cancer progression upon metabolic stress through elaborating HERPUD1-mediated unfolded protein response.

Yi-Zhen Wu[1], Ge-Jyun Liu[1], Shan-Ting Lei[1], Wei-Huan Zeng[1], Mei-Ju Juan[1], Yu-Shu Liu[1], Yong-Han Su[1], David K. Ann[2], Ching-Ying Kuo[1]

[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, National Taiwan University, Taipei, Taiwan,[2]Diabetes and Metabolism Research Institute, City of Hope, Duarte, CA

Uncontrolled proliferation is one of the most important hallmarks of cancer. Consequently, cancer cells exhibit a high demand for oxygen and nutrients from the tumor microenvironment. Nonetheless, cancer cells in the core region of a solid tumor often undergo nutrient and oxygen deficiency owing to the restricted vascularization, ultimately leading to the occurrence of metabolic stress. To survive under stress, series of stress response will be activated, providing opportunities for cancer cells to confront unfavorable circumstances and further developing phenotypic plasticity. Without altering genetic sequence, phenotypic plasticity enables cancer cells to adjust their behavior to survive from stress. This critical ability of cancer cells is orchestrated by multiple stress response under different stress stimuli, but its regulatory mechanism upon metabolic stress still requires further investigation. We identified a transcription factor EGR1 that is rapidly induced upon metabolic stress in breast cancer (BC). Known as an immediate early gene, EGR1 can be upregulated by multiple types of stimulation and further regulates tumor progression. Through cell viability and anoikis assay, we found that EGR1 could promote BC cell survival upon metabolic stress under both attach and detach condition. Furthermore, through xenograft tumor model, we noticed the inhibitory effect of EGR1 on tumor growth was more obvious in the late phase of tumor development, when metabolic stress mostly occurred. These results demonstrated the role of EGR1 in regulating phenotypic plasticity to promote BC cell growth upon metabolic stress. To identified genes regulated by EGR1 upon metabolic stress, EGR1-based ChIP-Seq was performed, and further compared with glucose deprivation RNA-Seq data to identify overlapping genes. Being the most upregulated overlapping gene upon glucose deprivation, *HERPUD1* was chosen for further validation. HERPUD1 has been found to be important for degrading unfolded or misfolded protein in unfolded protein response (UPR). However, the role of HERPUD1 upon metabolic stress remains elusive. We found HERPUD1 expression significantly increased upon metabolic stress and was higher in EGR1 knockdown (KD) cells, suggesting EGR1 was a transcriptional suppressor upon metabolic stress. As a critical stress response to promote phenotypic plasticity, UPR was diminished in EGR1 KD cells due to higher expression of HERPUD1, potentially explaining the increased vulnerability of these cells to metabolic stress. Collectively, EGR1 was identified as a transcription factor significantly upregulated upon metabolic stress. By suppressing HERPUD1 expression, EGR1 maintained UPR at an optimal level, which promoted the development of phenotypic plasticity of BC cells and assisted cells to survive and thrive from metabolic stress.

#1513 Morphological analysis of compressed nuclei reveals conserved irregularities of different cell types.

Julian Najera, Bianca Batista, Triston Acher, Meenal Datta

University of Notre Dame, Notre Dame, IN

Solid tumors such as mammary and brain exert compressive forces on the surrounding host tissue over the course of tumor expansion. However, how these forces impact neighboring peritumoral cells remains poorly understood. In this study, we used an *in vitro* transwell compression device to evaluate the effect of compression on mouse fibroblasts and human astrocytes, the most abundant stromal cell types in the breast and brain peritumor, respectively. Strikingly, we noticed that compression altered nuclear morphology in the two cell types. We then utilized an unsupervised machine-learning clustering algorithm to determine the relative abundance of various nuclear geometries present in both groups. We found that compressed nuclei predominantly exhibited diverse morphologies, including circular, elongated, and kidney bean-like shapes. In contrast, uncompressed nuclei were morphologically homogeneous, with most maintaining a canonical circular or elliptical shape. We validated these observations using ImageJ, showing that compressed nuclei possessed significantly lower circularity, roundness, and solidity, while displaying significantly higher eccentricity compared to uncompressed nuclei. Because fibroblasts and astrocytes share analogous roles, we sought to determine whether these observed differences were recapitulated in functionally distinct cell types such as immune cells. Surprisingly, murine macrophages exhibited the same predominant shape modes and similar quantitative differences in shape factors seen in the stromal cells. Furthermore, we performed nuclear morphometric analysis to numerically characterize the relative irregularity of compressed nuclei in astrocytes based on the calculation of a nuclear irregularity index (NII). Our analysis revealed that the NII of compressed nuclei is significantly higher than their uncompressed counterparts while the nuclear area in both groups was similar. Among 7 morphological categories, uncompressed nuclei were classified as “normal” while compressed nuclei were classified as “irregular.” These findings suggest that compressed nuclei may either be undergoing mitotic catastrophe or another nuclear damaging event rather than acquire aberrant morphologies due to mechanically induced senescence or apoptosis. In fact, we were able to demonstrate in preliminary live-dead cell imaging experiments that these morphologies are captured in compressed live cells. Altogether, these results indicate that compression appears to induce morphological changes that are conserved in distinct cell types.

#1514 CRISPRi screening reveals RNA editing as a major determinant of platinum sensitivity in high-grade serous ovarian cancer.

Yi Wen Kong, Erika D. Handly, Robin A. Lu, Molly A. Bird, Jack W. Schaeffer, Samkyu P. Yaffe, Michael B. Yaffe

Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Cambridge, MA

Platinum-based chemotherapeutic drugs induce intra- and interstrand purine crosslinks causing DNA damage and tumor cell death. Although these drugs are widely used as front-line treatment for multiple human cancers, particularly high-grade serous ovarian cancer (HGSOC), platinum resistance and tumor recurrence remains a common clinical problem. Here we report results from both a genome-wide CRISPRi screen and an RNA-binding protein-focused CRISPRi screen for modulators of sensitivity and resistance of HGSOC cells to two widely used platinum agents, cisplatin and oxaliplatin, and an microtubule-targeting taxane. Using an *in vitro* approach that mimics clinical treatment protocols, we found that cell lethality after cisplatin or oxaliplatin treatment in p53-defective ovarian cancer cells is markedly enhanced by suppressing genes in the Fanconi anemia (FA) and homologous recombination (HR) pathways, but considerably less enhanced by suppressing genes in the nucleotide excision repair (NER) pathway, despite the well-established importance of NER in reversing platinum-induced intrastrand crosslinks, particularly for cells in G1. Our findings suggest that cell death induced by platinum-DNA crosslinks results from replication stress, which can be further exacerbated by interference with error-free DNA repair mechanisms known to be particularly active during the S- and G2 phases of the cell cycle. These screens further implicated several known and novel RNA-binding proteins (RBPs) as potent sensitizers of HGSOC to both platinum agents and taxanes, including the RNA-modifying enzyme ADAR1, that catalyzes the deamination of adenosine-to-inosine in RNA, altering mRNA coding potential, modifying RNA structure, and regulating RNA localization. Additionally, ADAR1 has been implicated in controlling the integrated stress response (ISR), a signaling network that allows cells to adapt to changes in environment. These findings suggest that activation of an ADAR1-dependent ISR underlies the resistance of HGSOC cells to both platinum-based agents and anti-microtubule drugs that form the current clinical standard of care for HGSOC treatment.

#1515 GCN2 eIF2 kinase promotes polyamine metabolism and progression of prostate cancer.

Noah R. Sommers, Ricardo A. Cordova, Ronald C. Wek, Kirk A. Staschke

Biochemistry and Molecular Biology, Indiana University School of Medicine, Indianapolis, IN

The Integrated Stress Response (ISR) features multiple protein kinases that each sense distinct cellular stresses, phosphorylating eIF2 to direct gene expression that serves to mitigate cell damage and restore homeostasis. Previously, we reported that the eIF2 kinase GCN2 and the ISR are constitutively active in prostate cancer (PCa) and required to maintain amino acid (AA) homeostasis to sustain tumor growth (Cordova et al., 2022, *eLife*, 11:e81083). GCN2 is induced by nutrient limitation, and basal GCN2 activation in PCa enhances the expression of transporters that ensure sufficient AAs are available for PCa proliferation. However, while genetic or pharmacological inhibition of GCN2 sharply reduces AAs and growth of PCa cells in culture and mouse models, there is minimal cell death. We hypothesized that signaling pathways function to support cell survival in GCN2-deficient PCa cells and can be targeted to promote cell death in combination therapies. Indeed, we discovered that loss of GCN2 leads to compensatory activation of p53 signaling that blocks cell growth and lowers nutrient expenditure (Cordova & Sommers et al., 2024, *Science Signaling*, 10.1126/scisignal.adp1375). In this recent report, we also carried out a targeted CRISPR-interference screen in castration-resistant 22Rv1 PCa cells with functional wild type (WT) GCN2 or in cells deleted for GCN2 (GCN2 KO). We discovered that reduced expression of ornithine decarboxylase, the rate-limiting enzyme for polyamine (PA) biosynthesis, was synthetically lethal with loss of GCN2. PAs are polycationic metabolites derived from AAs that are ubiquitous among tissues, but especially abundant in prostate tissue. Given that PA biosynthesis requires AAs and GCN2 maintains AA homeostasis in PCa, we propose that GCN2 regulates PA levels in PCa. Indeed, intracellular levels of both AAs and PAs were decreased in GCN2-inhibited LNCaP cells compared to cells treated with vehicle alone. We sought to determine whether defects in PA metabolism also contribute to the growth defect of GCN2-deficient cells. One of the best characterized functions of PAs involves PA-derived hypusination of the translation factor eIF5A, a post-translational modification of eIF5A that is required for efficient translation of mRNAs encoding polyproline tracts. Interestingly, we found that GCN2 promoted eIF5A hypusination and enhanced the expression of several genes associated with PA metabolism in 22Rv1 cells. To investigate whether GCN2-deficient cells are sensitive to defects in eIF5A hypusination, we cultured WT or GCN2 KO 22Rv1 organoids and treated them with a small molecule inhibitor of eIF5A hypusination. While inhibition of eIF5A hypusination resulted in minimal death of WT cells, there was induced death in GCN2 KO cells. Our study suggests that GCN2 maintains PAs in PCa cells and combined therapies targeting GCN2 and PA processes are an effective strategy for the treatment of PCa.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolic Dependencies
Poster Session

#1519 Therapeutic targeting of phosphoglycerate mutase 1 disrupts cellular redox balance and promotes DNA damage in head and neck cancer.

Md Roman Mogal[1], Krishna Awasthi[1], Ishrat Nourin Khan[2], Andrean Simons-Burnett[1]

[1]Free Radical and Radiation Biology Program, Department of Radiation Oncology, University of Iowa, Iowa City, IA,[2]Interdisciplinary Graduate Program in Human Toxicology, University of Iowa, Iowa City, IA

Head and neck squamous cell carcinomas (HNSCCs) are extremely aggressive cancers that exhibit notable metabolic reprogramming and resistance to therapy. Phosphoglycerate mutase 1 (PGAM1), a glycolytic enzyme, has emerged as an important regulator of cancer cell metabolism and is highly expressed in HNSCCs compared to normal (untransformed) tissues. PGAM1 catalyzes the conversion of 3-phosphoglycerate (3PG) into 2-phosphoglycerate (2PG) which is a highly important step in glycolysis due to the importance of 2PG in serine biosynthesis. In contrast, PGAM1 inhibition results in decreased 2PG production and 3PG accumulation which suppresses both glycolysis and serine metabolism. More importantly, the accumulation of 3PG downregulates the pentose phosphate pathway (PPP) via deceased glucose-6-phosphate dehydrogenase (G6PD) which is necessary for optimal NADP+/NADPH production and cellular redox balance. Given the critical function of PGAM1, this enzyme may be promising as a potential target for treating HNSCC. Here we test if PGAM1 inhibition affects cell viability, NADP+/NADPH ratios, and DNA integrity in HNSCC cells in vitro. Gene expression levels of PGAM1 were compared between control and HNSCC patient groups, and survival analysis based on PGAM1 expression was conducted utilizing data from the TCGA database. PGAM1 was shown to be highly overexpressed in HNSCCs relative to healthy/control patients ($P<0.001$), with its expression linked to poorer survival (HR = 1.43). In addition, the PGAM1 expression level was evaluated based on human papillomavirus (HPV) subtype and found that PGAM1 is expressed significantly higher in HPV-negative patients compared to HPV-positive. The PGAM1 inhibitor - HKB99, was used to detect changes in cell viability via MTT assays in FaDu, Cal-27 and SQ20B HPV-negative HNSCC cell lines. HKB99 over a range of 0.5 - 64 μM for 48 hours decreased cell viability in a dose-dependent manner and IC50 concentrations were established which were 4 μM, 3.4 μM and 6.4 μM for FaDu, Cal-27 and SQ20B respectively. Treatment of the 3 cell lines with HKB99 at respective IC50 doses did not affect PGAM1 mRNA expression level using PCR analyses. However, protein expression of PGAM1 using western blot was decreased in treated cell lines compared to untreated cells. Moreover, HKB99 at respective IC50 doses increased levels of γ-H2AX, a marker for DNA double-strand breaks and significantly increased NADP+/NADPH ratios. Lastly, the antioxidant N-acetylcysteine (NAC) partially rescued the cytotoxic effect of HKB99 in all 3 cell lines using MTT and clonogenic assays. These findings suggest that inhibition of PGAM1 with HKB99 in HNSCC cells increases DNA damage, disrupts redox homeostasis, and triggers cell death. Taken together, our findings indicate that PGAM1 may represent a promising therapeutic target and may potentially sensitize HNSCCs to DNA-damaging therapies.

#1520 Obesity delays melanoma resistance to BRAF/MEKi inhibitors and alters melanoma metabolism.

Mahnoush S. Shafiei, Jacob Sellers, Craig Slingluff, Allan Tsung, Russell Witt

Department of Surgery, University of Virginia School of Medicine, Charlottesville, VA

Background: Obesity is linked to more aggressive melanoma and impaired anti-tumor immunity. However, obese patients show improved survival on BRAF/MEK inhibitors. Obesity induces endoplasmic reticulum stress (ERS), and BRAF/MEK inhibitors shift metabolism from glucose to fatty acid oxidation (FAO), utilizing CPT1A for cell viability. We hypothesize that obesity-induced metabolic reprogramming causes downregulation of CPT1A, impairing melanoma cell metabolism and potentially contributing to longer tumor progression-free survival (PFS) in obese individuals.

Methods: Mice were fed either a standard diet (lean) or a high-fat diet (HFD) to induce obesity. Twelve-week-old mice were subcutaneously injected with 1×10^6 YUMMER 1.7 melanoma cells. Tumors were allowed to grow for 2 weeks, after which the mice were treated with BRAF/MEK inhibitors until tumor resistance was observed.

Results: Obese mice treated with BRAF/MEK inhibitors showed delayed tumor recurrence compared to lean mice with a median of 80 days in obese mice versus 28 days in lean mice (log-rank $p<0.0001$). Tumors from obese mice had elevated DRP1 expression ($P<0.05$) and increased ER stress markers (XBP1, IRE1A, GRP78, PERK). Metabolic reprogramming, including alterations in melanoma state, fatty acid oxidation (FAO), and glycolysis via the BRAF/MEK pathway, resulted in higher levels of CD36, ACADS, and CPT1 in lean mice compared to obese mice ($P<0.05$). Conversely, NGFR, MITF, DUSP59, HK2, and GLUT-1 levels were elevated in tumors from obese mice ($P<0.05$).

Conclusions: Our findings suggest that obesity contributes to delayed tumor progression, potentially due to alterations in endoplasmic reticulum and mitochondrial function, which disrupt the expression of key metabolic enzymes. These results underscore the potential of targeting metabolic pathways as a complementary therapeutic approach in melanoma treatment.

#1521 High-fat diet-induced tumor promotion was abolished by blocking fatty acid oxidation in PDAC.

J. Kang, **W. Ham**, H. Lee, W. Choi, J. Chun, S. Woo, S. Sim, S.-Y. Kim;
National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of

Purpose: Obesity is well known to promote pancreatic ductal adenocarcinoma (PDAC) tumor development. However, the direct link between obesity and cancer has not been interpreted. We found that ATP production in cancer cells depends on fatty acid oxidation (FAO). Therefore, we propose blocking FAO in cancer may stop obesity from promoting PDAC growth.

Experimental Design: To block FAO, *SLC25A20* (carnitine-acylcarnitine carrier) was knocked down in human PDAC cells, which was implanted for xenograft in mice and treated with a high-fat diet (HFD, 60% fat) or no-fat diet (NFD, calorie-balanced 0% fat). To compare cancer development, survival rates, and histopathological differences were analyzed with KPC mice (*Kras*$^{G12D/+;}$ *Trp53*$^{R172H/+;}$ *Pdx1-Cre*) and KPC/*Slc25a20*$^{+/-}$ mice treated with regular diet (RD, 18% fat).

Results: The median survival of KPC mice with HFD was decreased by 2.0 weeks compared to KPC mice with RD (regular diet). Xenografts of PDAC cells with HFD promoted tumor growth 2-fold compared to the xenograft with regular diet (RD). Xenograft with *SLC25A20* knockdown PDAC cells in NFD reduced a 40-95% of tumor growth, and xenograft with *SLC25A20* knockdown PDAC cells in HFD also resulted in a 65-95% reduction in tumor growth compared to controls.

Conclusion: Blocking FAO reversed HFD-induced tumor growth promotion in pancreatic cancer. Cancer cells take advantage of HFD for ATP production by FAO. IGF or inflammation by HFD is no longer a direct mechanism to understand how HFD promotes tumor development.

Funding source: This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF), funded by the Ministry of Science and ICT to SK (NRF-2019M3A9G1104345) and by a grant from the National Cancer Center of Korea to SHS (NCC 24H1210-2).

#1522 High-throughput screening identifies HSP-90 inhibitor for pancreatic cancer therapy.

Chiamaka Joy Ezeh, Darren Binder, Rohan Binder, Zeribe C. Nwosu

Molecular Biology and Genetics, Cornell University, Ithaca, NY

Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive and lethal malignancies. Currently, it has an overall five-year survival rate of about 13%. This poor prognosis is attributed to the disease's late-stage diagnosis, rapid progression, and high resistance to available therapies. PDAC tumors often exhibit metabolic plasticity and oncogenic signaling dependencies, contributing to their ability to evade treatment, sustain growth under adverse conditions, and develop resistance to the current standard of care. These characteristics highlight the urgent need to identify novel therapeutic targets. In our study, a high-throughput drug screening was conducted to identify novel compounds capable of targeting key survival mechanisms and metabolic pathways in PDAC cells. Among the tested compounds, PU-H71, a heat shock protein 90 (HSP90) inhibitor, emerged as a promising candidate. Functional assays revealed that PU-H71 effectively inhibits the growth and proliferation in a panel of PDAC cell lines. Pathway analysis revealed that PU-H71 acts by disrupting multiple metabolic pathways. Our findings identify PU-H71 as a potent therapeutic candidate for PDAC treatment.

#1523 Discovery and Validation of a novel small molecule metabolic inhibitor targeting glioblastoma growth.

Maheedhara R. Guda, Andrew J. Tsung, Swapna Asuthkar, **Kiran Velpula**

University of Illinois College of Medicine (Peoria), Peoria, IL

Glioblastoma (GBM) is an aggressive brain tumor with poor prognosis and limited treatment options. Pyruvate dehydrogenase kinase 1 (PDK1) plays a critical role in the metabolic reprogramming of GBM cells, making it an attractive therapeutic target. In this study, we investigated the efficacy of a novel PDK1 inhibitor, in inhibiting GBM progression. Using U87 glioblastoma cells, we demonstrated that the UIC novel inhibitor significantly reduced cell viability, induced G2/M cell cycle arrest, inhibited glycolysis, and promoted oxidative phosphorylation. In vitro assays revealed that the UIC novel inhibitor effectively suppressed U87 cell migration and invasion compared to dichloroacetate (DCA), another PDK1 inhibitor. Wound healing and transwell invasion assays showed that the UIC novel inhibitor reduced wound closure and cell invasion by 83%, outperforming DCA. Furthermore, the UIC novel inhibitor treatment increased reactive oxygen species (ROS) production and decreased lactate release, indicating a shift from glycolysis to oxidative metabolism. In vivo, intracranial implantation of U87 cells into mice followed by the UIC novel inhibitor treatment resulted in prolonged survival, delayed tumor-associated weight loss, and reduced tumor burden compared to vehicle controls. Hematoxylin and eosin (H&E) staining confirmed smaller tumor sizes in treated mice, while immunohistochemistry (IHC) revealed decreased expression of PDK1 and phosphorylated EGFR (pEGFR), key oncogenic markers in GBM. These findings suggest that the UIC novel inhibitor is a potent inhibitor of PDK1 with significant anti-tumor activity in GBM models, offering a promising therapeutic strategy for targeting metabolic vulnerabilities in GBM. Further clinical evaluation of the UIC novel inhibitor is warranted to explore its potential as a novel treatment option for glioblastoma patients.

#1524 The cancer specific intramembrane serine protease RHBDL2 serves as a master regulator of glutamine metabolism and chemoresistance in TNBC.

Yosuke Matsushita[1], Kazumasa Okumura[2], Masato Komatsu[2], Tetsuro Yoshimaru[1], Masaya Ono[3], Mitsunori Sasa[4], Yasuo Miyoshi[5], Toyomasa Katagiri[1]

[1]National Institutes of Biomedical Innovation, Health and Nutrition, Ibaraki, Japan,[2]Division of Genome Medicine, Inst. Advanced Med. Sci., Tokushima University, Tokushima, Japan,[3]Dept. Clin. Proteomics, Natl. Cancer Ctr. Res. Inst., Chuo-ku, Japan,[4]Dept. Surg., Tokushima Breast Care Clinic., Tokushima, Japan,[5]Dept. Breast and Endocrine Surg., Hyogo College of Medicine, Nishinomiya, Japan

Glutamine metabolism is critical in cancer, driving cell proliferation and chemoresistance by supporting anabolic processes and energy production. This dependency offers a potential for therapeutic intervention; however, attempts to inhibit glutamine transporters and related enzymes have largely failed due to tumor plasticity, which enables cancer cells to adapt and bypass metabolic blockades. Our studies focus on RHBDL2, a cancer-specific intramembrane serine protease that regulates the glutamine metabolism in triple-negative breast cancer (TNBC).RHBDL2 plays two pivotal roles in glutamine metabolism. First, it binds and stabilizes ASCT2 at the plasma membrane, ensuring efficient glutamine uptake, which is crucial for ATP production and cell proliferation. Second, highlighting RHBDL2 localizes to the endoplasmic reticulum (ER), where it modulates N-glycosylation of ASCT2 by regulating glycosyltransferase activity. This glycosylation is essential for ASCT2 trafficking and stabilization. Collectively, these functions underscore RHBDL2' pivotal roles in maintaining tumor metabolism of TNBC cells. In addition to regulating ASCT2, RHBDL2 forms complexes with other proteins and transporters involved in glutamine metabolism, enhancing cancer cells' adaptability to metabolic stress. Our studies reveal that the RHBDL2-ASCT2 complex correlates with poor prognosis in cancer patients. Moreover, RHBDL2 upregulation has been associated with increased chemoresistance in TNBC, identifying it as a critical factor in therapeutic resistance. We successfully develop the RHBDL2 polyclonal antibody, which inhibits tumor growth by reducing glutamine uptake. Building on this, we are now developing monoclonal antibodies designed to disrupt RHBDL2 function, thereby reducing glutamine uptake and restoring chemotherapy sensitivity. This approach has the potential to impair cancer metabolism, suppress tumor growth, and improve outcomes in TNBC patients.

#1525 Regulation of cellular metabolic stress by aquaporin-7 in breast cancer.

Verodia Charlestin, Chen Dai, Daniel Fulkerson, Carlos E. Arias Matus, Madeline Sheely, Man Wang, Junmin Wu, Zixuan Song, Norman J. Dovichi, Jun Li, Laurie E. Littlepage

University of Notre Dame, South Bend, IN

The reprogramming of metabolism during cancer progression supports metastasis and response to therapies. The underlying relationships between cancer metabolism, gene expression, and oncogenic driver genes have the potential to identify novel biomarkers and targets with prognostic and therapeutic value. To understand these relationships, we used a novel unbiased correlation-based network analysis to integrate metabolomics and gene expression data from breast cancer mouse models to identify driver genes and metabolic pathways of mammary cancer. This approach identified 35 metabolite and 34 gene hubs with the most network correlations. Significantly, these hubs have prognostic value and likely are integral to tumor metabolism and breast cancer. The gene hub Aquaporin-7 (human AQP7/mouse Aqp7), a water and glycerol channel, emerged as a novel regulator of breast cancer. We identified AQP7 as a negative prognostic marker of overall survival and metastasis in breast cancer patients. In vitro and in vivo experiments showed that AQP7 is required for proliferation, primary tumor progression, and lung metastasis. Metabolomics of Aqp7 knockdown mammary cancer cells and tumors further revealed significantly altered lipid levels, redox, and urea/arginine metabolism. Given the prognostic value of AQP7 with breast cancer and its involvement in glycerol transport and lipid homeostasis, we investigated the metabolic reprogramming by AQP7 and evaluated the efficacy of AQP7 inhibition as a cancer therapeutic. We find that AQP7 is a critical regulator of metabolic and signaling responses to environmental cellular stresses and of endocrine therapy efficacy in breast cancer metastasis to lung. Interestingly, in patient data, AQP7 expression is expressed higher in breast tumors that do not respond to endocrine therapy compared to tumors that do respond, which suggests that Aqp7 may be a therapeutic vulnerability in endocrine therapy resistance. We evaluated AQP7 inhibition in combination with endocrine therapy in breast cancer. Interestingly, the aquaporin inhibitor Auphen cooperated with endocrine therapy tamoxifen to reduce the viability of breast cancer cells. This suggests that Auphen treatment makes the cells more susceptible to tamoxifen. Together, this study highlights AQP7 as a potential cancer-specific therapeutic vulnerability and that AQP7 inhibition can be exploited for therapeutic benefit in overcoming endocrine therapy resistance.

#1526 An impaired ability to engage in oxidative phosphorylation as a unifying feature of renal carcinogenesis.

Ziad Bakouny[1], Sonia Boscenco[1], Ruobing Cui[1], Keunwoo Ryu[1], Ritesh R. Kotecha[1], Maria I. Carlo[1], Martin H. Voss[1], A. Ari Hakimi[1], Robert J. Motzer[1], Payam A. Gammage[2], Ed Reznik[1], Craig B. Thompson[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Cancer Research UK Scotland Institute, Glasgow, United Kingdom

Introduction: *VHL* loss is a cardinal feature of renal cell carcinoma (RCC), specifically of the clear cell RCC (ccRCC) subtype, and leads to activation of aerobic glycolysis and suppression of oxidative phosphorylation (OxPhos). In contrast, Non-*VHL* driven forms of RCC are a heterogeneous group of tumors with few known nuclear oncogenic drivers, none of which are shared across these tumors. Recent studies have shown that mitochondrially-encoded electron transport chain (ETC) genes, responsible for OxPhos, can be mutated in a range of cancers.

Methods: Mitochondrial mutations were called using a previously published custom pipeline for variant calling (PMID: 33833465). On-target (whole genome sequencing) and off-target (whole exome and gene panel-based sequencing) reads were used. Only samples with sufficient coverage (>=5 reads across >90% of the mitochondrial genome) were included. This was performed (N with sufficient coverage) in TCGA (N= 3,265; N=324 RCC), the institutional MSK-IMPACT cohort (N= 22,252; N=568 RCC), and CCLE/Depmap (N= 377; N=11 RCC). Mutual exclusivity between each established RCC nuclear driver gene (N=16, PMID: 29617669) and the heteroplasmy of ETC truncating variants was evaluated using pairwise t-tests comparing heteroplasmy between the mutated and wild-type RCC samples for each nuclear driver gene. CERES scores from genome-wide CRISPR screens in Depmap were used to compare gene dependency between cell lines. Benjamini-Hochberg correction was used to control type I error.

Results: Across all cancer types in TCGA, RCC tumors were among the most enriched in ETC truncating mutations. These mutations most commonly affected components of mitochondrial complex I and were enriched to high levels of heteroplasmy. *VHL*-driven ccRCC was relatively depleted in these mutations compared to other subtypes (ccRCC: 8.6%, chRCC: 20.0%, pRCC: 34.0%). Further, the heteroplasmy of truncating mutations was significantly increased in chRCC and pRCC compared to ccRCC ($p<0.05$). Among all established RCC nuclear driver genes, *VHL* was found to be mutually exclusive with high heteroplasmy ETC truncating mutations ($q<0.05$). These results were independently replicated in the MSK-IMPACT cohort. Using data from CCLE/Depmap, we find that while cell lines with high heteroplasmy (>50%; N=13) truncating mitochondrially-encoded ETC mutations have differential dependencies compared to other cell lines, ETC mutations were not synthetically lethal with *VHL* mutations.

Conclusion: We established that mutations in *VHL* and in mitochondrially-encoded ETC genes are mutually exclusive in RCC and that this mutual exclusivity is not accounted for by synthetic lethality. These results suggest that mitochondrial mutations may be phenocopying the effect of *VHL* on OxPhos and form the basis for our planned experimental work evaluating OxPhos dysregulation as a unifying feature of renal carcinogenesis.

#1527 Reversal of the Warburg Effect with BPM31510 treatment in a quinone deficient C6 Glioma resulting in efficacy.

Michael A. Kiebish[1], Abbas Khojasteh[2], Sylwia Stopka[1], Juan J. Aristizabal-Henao[1], Seema Nagpal[2], Lisa Ghiglieri[2], Mustafa Kendirli[2], Maria-D Nastke[1], Stephane Gesta[1], Niven R. Narain[1], Vijay Modur[1], Lawrence Recht[2]

[1]BPGbio, Framingham, MA,[2]Stanford University, Palo Alto, CA

BPM31510-IV is a drug-lipid conjugate nanodispersion comprised of oxidized Coenzyme Q10 (CoQ10) in clinical development for glioblastoma multiforme (GBM). BPM31510 reengineers tumor metabolism, while supporting efficient metabolism of non-tumorigenic tissue. Recent evidence suggests that GBM tumors have a deficiency in quinones, most notable CoQ10, leading to altered mitochondrial function. Additionally, emerging data suggests that the rat C6 glioma also is deficient in quinone metabolites. Herein, we explored the therapeutic MOA of BPM31510 in the treatment of GBM based on twice a day dosing vs intermittent dosing. Survival assessment was performed with untreated, 100 mg/kg BID dosing (IP), 200 mg/kg IV dosing (every other day) and 400 mg/kg IV dosing (every other day) in rats implanted with a C6 glioma. Tumor implantation was confirmed using MRI at day 9 and treatment began at day 11. In a parallel treatment study, rats were treated in a corresponding manner and tissue samples were collected at day 14. Rat brains were immediately frozen and were assessed by spatial metabolomics/lipidomics and quinone assessment (quinomics) to spatially resolve metabolic changes at a single cell level post-treatment. C6 glioma exhibited a deficiency in CoQ9 (dominant CoQ in rats) and treatment with BPM31510 was able to increase CoQ9 in tumors reengineer metabolic activity, thus reversing the Warburg effect. Analysis of BPM31510 treated animals revealed a dose dependent and dosing sequent dependent response impacting survival and tumor resolution as well as an impact on spatial metabolic effect of BPM31510 treatment in brain compared to C6 glioma tissue. Additionally, changes in lactate and citrate were also evident in tumor compared to brain in a dose and cycling dependent manner, which demonstrates reengineering of mitochondrial metabolism in cancer compared to normal brain. These data definitely demonstrate that BPM31510 is capable of entering the brain and tumor, reengineering mitochondrial metabolism resulting in a resolution of the glioma which impacts survival. Both dosing and sequencing of doses impact outcome and metabolic response.

#1528 JAG1-driven macropinocytosis as a critical regulator of nutrient scavenging and tumor progression in pancreatic cancer.

Mofei Huang[1], Bingqing Zou[1], Yimin Ma[1], Wei Xin[2], Lan Zhou[1]

[1]Department of Pathology and Genomic Medicine, Houston Methodist Research Institute, Houston, TX,[2]Department of Pathology, University of South Alabama Hospital, Mobile, AL

Pancreatic cancer (PanCan), known for its aggressive nature, poor prognosis and often resistant to therapeutics, remains a major global health burden (Conroy, Desseigne et al. 2011, Von Hoff, Ervin et al. 2013, Howlader N 2021, Bray, Laversanne et al. 2024). Exploring new therapeutic targets is urgent. Studies have reported that PanCan cells undergo metabolic reprogramming in response to oncogenic signals for survival and tumor progression. Macropinocytosis, as an important nutrient scavenging metabolic pathway, fuels KRAS-driven PanCan cell growth, especially under nutrient-deficient condition (Ramirez, Hauser et al. 2019). The Notch signaling pathway is pivotal in PanCan initiation and development (Miyamoto, Maitra et al. 2003, Thomas, Zhang et al. 2014). Here, we demonstrated that Jagged-1 (JAG1) is the predominant Notch ligand expressed in human PanCan tissues and patient-derived xenografts, but only weakly presented in endothelial cells of normal pancreas. Elevated JAG1 gene expression is associated with worse survival in TCGA PanCan patient cohort, implicating that JAG1 is a prognostic marker for PanCan. However, whether JAG1-driven Notching signaling affects PanCan cellular metabolism remains poorly understood. Preliminary RNA-seq analysis on JAG1-depleting KPC tumor lines shows deactivated pathways activities, including “PI3k-AKT-mTOR”, “positive regulation of endocytosis” and “actin cytoskeleton organization”, all of which are important molecular events for macropinocytosis processes. We further investigated and noticed decreased dextran-TMR uptake capacities in those JAG1-depleting KPC cells, indicating attenuated macropinocytic activity upon JAG1 extinction. Along this line, the widely targeted metabolomics assay revealed peptides and amino acids as the most abundant metabolite family with significant reduction in JAG1-depleting KPC tumor cells. Finally, JAG1 ablation decreased KPC cell proliferation and spheroid forming efficiency in vitro. In addition, JAG1 deletion reduced tumor growth in syngeneic subcutaneous KPC mouse models (6419C5, 7160C2 and 6422C5) as well as in a KPC orthotopic model (6419C5). Collectively, our findings suggest JAG1 as a key driver of macropinocytosis in PanCan cells and imply the potential of JAG1 ablation to inhibit nutrient scavenging and tumor progression.

#1529 Colon cancer cells activate CCL20 and IL10 signaling to combat effects of 5 fluorouracil.

Janani Muralidharan, Shailesh Singh, **Hina Mir**

Microbiology, Biochemistry and Immunology, Morehouse School of Medicine, Atlanta, GA

Advances in screening and therapy have significantly decreased colon cancer mortality rates; however, predictions indicate that by 2030, approximately one million patients may still die from this disease each year. While chemotherapies are effective, cancer cells often develop resistance mechanisms that necessitate higher doses, which can lead to severe toxicities that hinder treatment effectiveness and pose additional health risks for patients. Depending on the stage of cancer, 5FU, an antimetabolite, is typically administered alone or in combination with oxaliplatin. Despite its cytotoxic properties, 5FU can induce inflammation in the colon, which may counteract its effectiveness against cancer. This inflammation, characterized by altered cytokine profile, contributes to the resilience of cancer cells. The focus of our study is on the proinflammatory chemokine CCL20, which is elevated during colon cancer, and plays a significant role in liver metastasis. CCL20 signaling is linked to epithelial to mesenchymal transition and can influence the efficacy of chemotherapy. Our research findings indicate that colon cancer cells treated with cytotoxic doses of 5FU show a notable increase in CCL20 secretion, as well as elevated levels of extracellular fatty acids compared to untreated cells. Furthermore, treatment with palmitic acid enhances CCL20 secretion. After 5FU treatment, there is also an increase in interleukin 10 (IL10). Interestingly, inhibiting CCL20 signaling, either by neutralizing CCL20 or blocking its receptor CCR6, further elevates IL10 levels. This suggests that colon cancer cells increase their tolerance to 5FU by raising CCL20 and IL10.Our study highlights the need for further investigation into these mechanisms to develop more effective treatment strategies that maintain or improve patients' quality of life.

#1530 Elucidating the role of exogenous lipids in ferroptosis in castration resistant prostate cancer.

Jose C. Valentin Lopez[1], Scott M. Dehm[2]

[1]University of Minnesota Medical School, Minneapolis, MN,[2]Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, MN

Prostate Cancer (PCa) is the leading cause of cancer cases in U.S. men and the second leading cause of male cancer death. An advanced form of the disease, termed castration-resistant PCa (CRPC), is not curable, and accounts for most PCa mortality. Several studies have observed that the use of statins, cholesterol-lowering drugs, leads to a reduced risk of PCa advancing to the metastatic CRPC stage. Additionally, in combination with abiraterone or enzalutamide, statins have been able to prolong time to progression and overall survival in patients with metastatic CRPC. The purpose of this study is to understand the mechanism of how a systemic reduction of cholesterol leads to these outcomes. Ferroptosis is a lipid peroxidation-dependent form of cell death. Several metabolites in the cholesterol synthesis pathway have been observed to protect cells against ferroptosis. We hypothesize that extracellular cholesterol, in conjunction with its precursors, protect CRPC cells from ferroptosis.We used the isogenic LNCaP and LN95 cell line models of CRPC progression as well as PC3 cells, another model of CRPC. We analyzed relative cell number using crystal violet assays and used flow cytometry to assess proliferation, cell death, apoptosis, and lipid peroxidation. Additionally, RNA sequencing and mass spectrometry-based metabolomics were used to analyze changes to the transcriptome and metabolome. We observed that all cell line models exhibit dependence on extracellular lipids for their growth and proliferation. Additionally, removal of extracellular lipids (EL) led to an increase in non-apoptotic forms of cell death. Further experiments showed that the growth reduction caused by removal of EL was rescued in the CRPC models by Ferrostatin-1, a ferroptosis inhibitor, but not the apoptosis inhibitor Q-VD-OpH. Removal of EL also led to an increase in lipid peroxides. Upon gene set enrichment analysis of RNA sequencing data, we identified the Hallmark Cholesterol Homeostasis gene set as the most upregulated across all models cultured in lipid free medium. Additionally, we observed a reduction in cholesteryl ester levels upon the removal of EL across all models. Interestingly, the growth reduction caused by removal of EL was rescued by cholesterol only in the CRPC models but not in the LNCaP model. Cholesterol supplementation after lipid depletion also led to a protection of cells from lipid peroxides and a reduced sensitivity to the ferroptosis inducing agent JKE-1674. Collectively, these data indicate the dependence of PCa models, particularly CRPC models, on extracellular cholesterol for their growth and proliferation. Additionally, CRPC models showed susceptibility to ferroptosis upon removal of EL, which was prevented by adding back cholesterol to the growth medium. These results show cholesterol as an antiferroptotic molecule in cell line models of CRPC.

#1531 The role of HDAC1 in pancreatic cancer metabolism.

Don-Gerard Cavakiah Blanchard Conde[1], Evan J. Zhou[2], Maximillian Farma[2], Chiamaka J. Ezeh[1], Laiba Shiekh[2], Matthew Cheung[2], Zeribe C. Nwosu[2], Nwosu Lab, Cornell University

[1]Cornell University, Ithaca, NY,[2]Molecular Biology and Genetics, Cornell University, Ithaca, NY

Pancreatic cancer is a malignant disease often driven by mutations in the KRAS gene. It is associated with significant metabolic reprogramming driving tumor growth, drug resistance, and adaptation in its dense, nutrient-limited tumor microenvironments. To date, the mediators of PDAC metabolism are not fully understood. Analyzing gene expression changes in PDAC tumors compared to normal tissues identified histone deacetylase 1 (HDAC1) as a consistently upregulated gene. We found that HDAC1-high tumors display strong metabolic alterations, including the upregulation of genes in glycolysis and other metabolic processes, and that treatment with Class I selective HDAC inhibitors (HDACi) selectively blunted growth. Initial experiments altering HDAC1 expression transiently in multiple pancreatic cancer cell lines demonstrate alternate metabolic responses. Consistent with existing literature, we observe that HDACi effectively suppressed pancreatic cancer cell growth, primarily class I selective inhibitors. Furthermore, we recently developed HDAC1 knockout cell lines that demonstrate shifts in metabolic profiles of pancreatic cancer and slowed growth rates in HDACi sensitive cell lines through immunoblotting, metabolomics and Seahorse assay. We expect that our findings will show the significance and prospects of targeting HDAC1 in pancreatic cancer therapy and its potential to overcome resistance with current therapeutic.

#1533 Regulatory mechanism of bile acid-induced hepatokine ORM2 expression and its implication in the liver cancer.

J. Suh[1], **I. Cheon**[1], H.-J. Jung[1], S. Lee[2], M. Heo[1], M. DeBerge[1], C. Wooton-Kee[3], Y.-H. Ahn[4], K. Kim[1];
[1]McGovern Medical School, University of Texas Health Science Center at Houston, Houston, TX, [2]Gwangju Health University, Gwangju, Korea, Republic of, [3]Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX, [4]Ewha Womans University, Seoul, Korea, Republic of

Bile acids (BAs) are increasingly recognized as key signaling molecules with various metabolic effects in diverse pathophysiologic contexts. Uncontrolled BA synthesis or impaired BA flow leads to cholestasis, a severe liver disease, characterized by extensive hepatic damage and progression to liver failure or liver cancer. The nuclear receptors (NRs) farnesoid X receptor (FXR) and small heterodimer partner (SHP) play critical roles in maintaining BA homeostasis; consequently, FXR/SHP double knockout mice (FS-DKO) exhibit juvenile onset cholestasis that ultimately develops liver cancer. We recently identified orosomucoid 2 (ORM2) a novel liver-secreted hormone (i.e., hepatokine), which is highly induced in response to hepatic BA stress. In this study, we identified the molecular mechanism underlying BA-induced *Orm2* transcription, potentially mediated by activation of the xenobiotic NRs, constitutive androstane receptor (CAR) and pregnane X receptor (PXR). BA supplementation directly upregulated *Orm2* expression whereas it was completely abolished in CAR/PXR double knockout livers. Given the diverse roles of BAs and ORM2 in metabolic and carcinogenic processes, our study highlights that BA stress activates CAR and PXR to induce ORM2 expression, which initially exerts a protective function in acute liver injury but eventually promotes liver cancer. These insights suggest a potential link between hepatic BA signaling, CAR/PXR activation, and systemic outcomes in the pathology from cholestasis to liver cancer.

#1534 Targeting oxygen consumption with metformin and phenformin have differential effects on immune cells in the tumor microenvironment.

Sadna Budhu[1], Anais Assouvie[1], Juan Zurita[2], Mamadou A. Bah[1], Svena Verma[1], Mehdi Benzaoui[1], Inna Serganova[3], Jason Koutcher[4], Vladimir Ponomarev[2], Jedd D. Wolchok[3], Taha Merghoub[1]

[1]Pharmacology, Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY,[2]Radiology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Medicine, Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY,[4]Medical Physics, Memorial Sloan Kettering Cancer Center, New York, NY

Immune checkpoint blockade (ICB) has yielded durable clinical responses which led to its FDA approval as a first-line therapy for melanoma and other malignancies. However, only ~20-40% of patients show benefit when used as monotherapies. This is mainly due to inherent or acquired resistance to these therapies within the tumor microenvironment (TME). There is increasing evidence in pre-clinical studies that tumor metabolism (e.g., glycolysis and oxygen consumption (OXPHOS)) presents a barrier to anti-tumor immunity. High levels of OXPHOS in tumor cells lead to tumor hypoxia. Hypoxia causes altered tumor physiology, increased immunosuppression, and resistance to several therapies such as ICB. We propose that blocking tumor oxygen consumption using drugs that target the mitochondrial complex I (metformin and phenformin) will enhance the efficacy of immunotherapies such as ICB in preclinical models. In this study, we examined how low oxygen levels (hypoxia) influence T cell effector function such as cytotoxic activity and cytokine production in vitro. We co-cultured mouse B16 melanoma cells in the presence of tumor specific T cells and incubated at 37ºC in either normoxia (~21% O2) or hypoxia (3% O2) and assessed killing and intracellular cytokine production 24 - 48 hours later. We show that the ability of tumor antigen-specific T cells to kill tumor cells or make effector cytokine such as IFNγ and TNFα is significantly reduced in hypoxia settings. We also examined the effects of metformin and phenformin on T cell priming and activation. When T cells were activated in the presence of each drug in vitro, there was enhanced expression of T cell activation markers (CD25, Granzyme B) as well as an increase in their differentiation into central memory T cells. We treated mice bearing melanoma and breast cancers with metformin and phenformin and tested whether these drugs could delay tumor growth and improve overall survival in vivo as a monotherapy or in combination with anti-PD1. While both drugs can significantly delay tumor growth as monotherapies, only metformin showed improved anti-tumor efficacy when combined with anti-PD-1 in vivo. We performed flow cytometry on mice bearing melanoma and breast cancers treated with metformin and phenformin in vivo. We found that these drugs have differential effects on the immune system in the tumors and periphery in the two cancer models. These studies show that while both drugs target tumor oxygen consumption (via inhibition of complex I), and can delay tumor growth in vivo, they have differential effects on the TME and will need further considerations when combining with ICBs and other immunotherapies. In addition, these studies will advance our understanding of how tumor metabolism impacts anti-tumor immune responses and could lead to better design of combination therapies for cancer patients treated with diabetes management drugs.

#1535 Glycogen metabolism is critical for cancer-associated fibroblast proliferation and immunosuppressive activity.

Xudong Zhu, Yuning Zhou, Zhijie Yin, Jinpeng Liu, Chi Wang, B.Mark Evers, Qingding Wang

Markey Cancer Center, The University of Kentucky, Lexington, KY

Background: Metabolic reprogramming is a characteristic feature of both cancer cells and their neighboring cells in the immunosuppressive tumor microenvironment (TME). Cancer-associated fibroblasts (CAFs) are the major sources of secreted cytokines contributing to the immunosuppressive activity in the TME. Dysregulation of glycogen metabolism is integral to cancer cell proliferation and metastasis. The purpose of this study was to identify whether glycogen metabolism is important for CAF proliferation and cytokine production.
Methods: CAFs were isolated from colorectal cancer (CRC) patient samples and cultured in conditioned medium (CM) derived from HCT116 human CRC cells. The expression of glycogen phosphorylase liver form (PYGL), glycogen phosphorylase brain form (PYGB), hexokinase 2 (HK2), lactate dehydrogenase A (LDHA), IL6, CLCF1, LIF, and CXCL6 was determined by either real time (RT)-PCR or western blot. Glycogen levels were determined using a Glycogen Analysis Kit. Cell proliferation was determined using WST-1.
Results: (i) Data set analysis identified an elevated glucose metabolism in CAFs compared to normal fibroblasts. (ii) Treatment of CAFs with CM derived from HCT116 cells resulted in activated glycogen metabolism as noted by elevated protein expression of glycogen synthase, PYGL, PYGB, and the reduced level of glycogen in CAFs. In addition, CM increased glucose metabolism in CAFs as noted by significantly increased expression of HK2 and LDHA. Moreover, CM increased the expression of IL6 family cytokines such as IL6, CLCF1, LIF and CXCL6 in CAFs. (iii) Inhibition of glycogen metabolism by treatment with the PYG inhibitor, CP-91149, significantly repressed CAF proliferation and reduced the expression of these cytokines. Consistently, knockdown of PYGB or PYGL significantly decreased the level of these cytokines in CAFs. (iv) Inhibition of glycogen synthase by treatment with the glycogen synthase inhibitor, MZ-101, or knockdown of glycogen synthase 1 decreased the expression of these cytokines in CAFs.
Conclusion: Our results demonstrate that glycogen metabolism is crucial for promoting CAF proliferation and cytokine production. Importantly, our findings suggest that targeting glycogen metabolism in CAFs reshapes the immunosuppressive TME and may enhance the efficacy of immunotherapy for CRC.

#1536 Unsaturated fatty acids promote cell cycle progression and proliferation of platinum resistant ovarian cancer cells.

Ana Maria Isac[1], Andres Valdivia[1], Guangyuan Zhao[1], Yinu Wang[1], Jian-Jun Wei[1], Sandra Orsulic[2], Daniela Matei[1]

[1]Northwestern University, Chicago, IL,[2]University of California, Los Angeles (UCLA), Los Angeles, CA

Introduction: Ovarian cancer (OC) depends on fat as fuel for metastasis and growth. We have previously demonstrated that cisplatin resistant (Pt-R) OC cells uptake higher amounts of fatty acids (FAs) compared to sensitive (Pt-S) cells. Here, we determined the mechanism through which FAs support cancer survival.

Materials and Methods: We used two isogenic OC cell lines pairs, sensitive and resistant to cisplatin: OVCAR5 Pt-S (IC50 = 2.881mM) vs Pt-R (IC50 = 6.831 mM) and PEO1 (IC50 = 4.901 mM) vs PEO4 (IC50 = 8.285 mM). Cells were cultured under low serum conditions, supplemented with 50 µM oleic (OA) or 50 µM palmitic acid (PA), and used for viability assays, RNA-Seq, cell cycle, and cell death analysis. Quantitative RT-PCR measured expression of key FAs transporters in Pt-S and Pt-R cells. Immunohistochemistry (IHC) assessed expression of FABP4 in primary and recurrent human tumors. The FABP inhibitor BMS-309403 was used to pharmacologically inhibit the FA transporters *in vitro* and *in vivo*.

Results: Pt-R cells rely more on unsaturated FAs than Pt-S cells, upregulating transporters for increased FA uptake. Cell viability assays showed Pt-R cells were less viable under serum depletion, with oleic acid (OA, unsaturated) promoting proliferation of both OC cell lines. OA rescued Pt-R cells significantly more than Pt-S cells: 268.4% vs 91.6% for OVCAR-5 and 38.1% vs 12.1% for PEO4 vs PEO1. OA also reduced apoptosis, as shown by Annexin V assays, and decreased Caspase-3 and -8 cleavage. RNA-Seq analysis linked OA-induced proliferation to upregulation of cell cycle-related pathways, including *G2/M checkpoints*, driven by E2F1. OA increased S- and G2/M phase populations (e.g., 6.95% to 11.6%; $p<0.05$), while E2F1 inhibition reduced OA-induced proliferation. Pt-R cells also expressed higher levels of transported proteins FABP4 and CD36. Inhibiting FABPs reduced Pt IC50 values (e.g., from 11.893 µM to 5.0415 µM in OVCAR5) and blocked ovarian cancer progression i*n vivo*. IHC showed FABP4 overexpression in metastatic and recurrent tumors (n=21 paired tumors, $p<0.05$).

Conclusion: Pt-R OC cells are more dependent on unsaturated FAs compared to Pt-S cells and upregulate key transporters to allow increased uptake of FAs. Inhibiting intracellular FA transport reduces OC progression *in vivo*. OA supports proliferation of Pt-R cells by rescuing them from apoptosis and by promoting cell cycle progression from G1 to S- and G2/M phases.

#1537 The extracellular matrix supports pancreatic cancer cell growth under nutrient deprivation.

Ifeoluwa Feyisayo Oyelade, Elena Rainero

Biosciences, University of Sheffield, Sheffield, United Kingdom

Pancreatic cancers have a poorly vascularized and nutrient-deficient microenvironment making them more susceptible to nutrient deprivation. Evidence has shown that Pancreatic Ductal Adenocarcinoma (PDAC) cells survive in a nutrient-deprived and hypovascular microenvironment. Here, we investigate the roles of the Extracellular Matrix (ECM) in supporting the growth of PDAC cells in different nutrient-deprivation conditions. Our cell proliferation, microscopy and targeted Mass Spectroscopy metabolomics data showed that Matrigel, but not collagen I, supports the proliferation of PDAC cells in Glucose and Glutamine deprivation conditions, as well as in Tissue Interstitial Fluid Media (TIFM), which has been reported to mimic the physiological nutrient availability in PDAC tumors. In addition, we found that the role of Matrigel in supporting the growth of pancreatic cancer cells is linked to increasing cell proliferation rather than reducing cell death. Importantly, our Targeted Mass spectrometry metabolomics data showed that the Arginine metabolism is upregulated when the cells are grown under starvation on Matrigel compared to plastic. We have identified some genes that are likely to play a role in the upregulation of this metabolic pathway and we are currently using qPCR and Western blotting techniques to identify whether the ECM and/or nutrient availability affect their expression. Finally, we will determine their role in promoting ECM-dependent PDAC cell proliferation under starvation. Overall, our study has established that the ECM can alter the metabolism of PDAC cells to support their cell growth under nutrient-limiting conditions.

#1538 Impact of MCT1 inhibition on NSCLC metabolism and sensitivity to therapy.

Robert Cameron[1], Massar Alsamraae[2], Maia G. Clare[2], Nia G. Hammond[2], Christine Bestvina[1], Marina Chiara Garassino[1], Brandon Faubert[1]

[1]Department of Medicine, Section of Hematology/Oncology, UChicago Medicine, Chicago, IL,[2]Division of Biomedical Sciences, University of Chicago, Chicago, IL

Introduction: Despite the advent of targeted therapies, prognosis of lung of non-small cell lung cancer (NSCLC) remains poor. Thus, identifying metabolic programs in aggressive disease may allow for the development of novel treatment strategies. Prior work in early-stage NSCLC has demonstrated that lactate import via monocarboxylate transporter 1 (MCT1) is associated with higher recurrence and mortality. However, the potential for targeting MCT1 in treatment efficacy and resistance remains unknown.
Methods: NSCLC cells were cultured in standard RPMI or, to better model in vivo metabolism, human plasma-like media (HPLM). MCT1 was inhibited genetically (CRISPR-KO) or pharmacologically (AZD3965). Isotope tracing experiments were performed using [U-^{13}C]glucose or [U-^{13}C]lactate. DNA damage was assessed via the protein expression of γH2AX. MCT1 inhibition was combined with pemetrexed, and cell viability/cell death was measured using annexin V/propidium iodide. Combinatorial/synergy effects were assessed using synergyfinderplus.org.
Results: H1299 cells incorporate lactate into tricarboxylic acid cycle (TCA) intermediates in both standard and physiologic culture media. Lactate incorporation into the TCA was decreased by treatment with AZD3965. Both genetic and pharmacologic inhibition of MCT1 increased the expression of the DNA damage marker γH2AX. Following 24 hours of pemetrexed treatment, pemetrexed alone significantly decreased cell viability in RPMI but not HPLM. The addition of AZD3965 decreased cell viability in both conditions, but decreases were less pronounced in HPLM cultured cells. In both media conditions, combinatorial dosing of AZD3965 and pemetrexed led to increases in cell death, and these were more pronounced at increasing doses of AZD3965. AZD3965 did not confer additional cytotoxic effect to cells treated with paclitaxel.
Conclusions: MCT1 inhibition decreases lactate import and oxidation in vitro and causes DNA damage to enhance the cytotoxic effects of pemetrexed. Metabolic reprogramming in NSCLC leads to the use of alternate carbon sources, such as lactate, and this can be modeled in both standard and physiologic culture conditions. Notably, this does not appear to be a general sensitization to cell death. Further studies are ongoing to identify the metabolic underpinnings of these effects and how they translate to in vivo systems.

#1539 Lactate induced c-Myc lactylation drives prostate cancer progression by influencing gene transcription.

M. Howlader, A. O. Akinyemi, M. Alam, J. Wang, L. Gu, Z. Li;
University of Kentucky, Lexington, KY

Prostate cancer (PCa) is a leading cause of cancer-related morbidity and mortality, characterized by complex metabolic reprogramming that supports tumor growth and progression. Recently, lactate has emerged as a critical factor in PCa metabolism, produced via aerobic glycolysis and influenced by oncogene/tumor suppressor gene mutations, androgen signaling, and hypoxia. Glycolytic cancer cells and cancer-associated fibroblasts can secrete lactate, fostering "symbiotic" interactions with oxidative cancer cells through lactate shuttling. Lactate accumulation subsequently promoting the lactylation of proteins which is a novel post-translational modification involving proteins that is induced by lactate. The Warburg effect emphasizes the importance of lactylation in cancer biology, influencing gene transcription and supporting rapid tumor growth. Excessive lactate production and rapid lactate transport in cancer cells are mainly driven by the upregulation of c-Myc which is a master regulator of multiple biological programs. Its persistent activation results in abnormal expression of glycolytic enzymes and lactate transporters, contributing to PCa progression. While c-Myc undergoes various post-translational modifications, the potential for c-Myc lactylation and its role in PCa development remain unexplored. Preliminary studies indicate that sodium lactate exposure increases lysine lactylation in PCa cells. We also show that c-Myc oncogene is lactylated. The lactylation of c-Myc not only promotes tumor growth but also contributes to the metabolic flexibility of PCa, enabling them to thrive in hypoxic and nutrient-deprived environments. Understanding the molecular mechanisms underlying c-Myc lactylation provides new insights into PCa biology and opens potential avenues for therapeutic intervention targeting metabolic pathways.

#1540 ADAR1 regulates lipid remodeling through MDM2 to dictate ferroptosis sensitivity.

Che-Pei (Pat) Kung[1], Nick Terzich[2], Michael J. Prinsen[1], Raleigh D. Kladney[3], Alex Mabry[3], Luisangely Soto Torres[3], Jade Weber[4], Ma Xenia G. Ilagen[5], Leonard Maggi[3], Leah P. Shriver[2], Gary J. Patti[2], Jason D. Weber[3]

[1]Washington University in St. Louis, Saint Louis, MO,[2]Chemistry, Washington University in St. Louis, Saint Louis, MO,[3]Medicine, Washington University in St. Louis, Saint Louis, MO,[4]Biomedical Engineering, Washington University in St. Louis, Saint Louis, MO,[5]Biochemistry and Molecular Biophysics, Washington University in St. Louis, Saint Louis, MO

Triple-negative breast cancer (TNBC), lacking expression of estrogen, progesterone, and HER2 receptors, is aggressive and lacks targeted treatment options. An RNA editing enzyme, adenosine deaminase acting on RNA 1 (ADAR1), has been shown to play important roles in TNBC tumorigenesis. We posit that ADAR1 functions as a homeostatic factor protecting TNBC from internal and external pressure, including metabolic stress. We tested the hypothesis that the iron-dependent cell death pathway, ferroptosis, is a ADAR1-protected metabolic vulnerability in TNBC by showing that ADAR1 knockdown sensitizes TNBC cells to GPX4 inhibitors. By performing single-reaction monitoring-based liquid chromatography coupled to mass spectrometry (LC-MS) to measure intracellular lipid contents, we showed that ADAR1 loss increased the abundance of polyunsaturated fatty acid phospholipids (PUFA-PL), of which peroxidation is the primary driver of ferroptosis. Transcriptomic analysis led to the discovery of the proto-oncogene MDM2 contributing to the lipid remodeling in TNBC upon ADAR1 loss. A phenotypic drug screen using a ferroptosis-focused library was performed to identify FDA-approved cobimetinib as a drug-repurposing candidate to synergize with ADAR1 loss to suppress TNBC tumorigenesis. By demonstrating that ADAR1 regulates the metabolic fitness of TNBC through desensitizing ferroptosis, we aim to leverage this metabolic vulnerability to inform basic, pre-clinical, and clinical studies to develop novel therapeutic strategies for TNBC.

#1541 Possible role of ectopic ATP synthase mediating metabolic hypoxic adaptation in retinoblastoma.

Samantha A. McLaughlin[1], Zelia M. Correa[1], Stefan Kurtenbach[1], J. William Harbour[2], Daniel Pelaez[1]

[1]Department of Ophthalmology, Bascom Palmer Eye Institute and Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL,[2]Department of Ophthalmology Department of Ophthalmology and Harold C. Simmons Comprehensive Cancer C, University of Texas Southwestern Medical Center, Dallas, TX

Altered metabolism is a hallmark of cancer. Yet how metabolic reprogramming benefits tumor growth remains unclear. In retinoblastoma (RB), we have shown that estrogen-related receptor gamma (ESRRG) undergoes continuous positive selection during tumor evolution as evidenced by an ongoing accumulation of genomic aberrations that increase ESRRG activity. Transcriptional analysis revealed that ESRRG is pivotal in mediating metabolic reprogramming, with cells displaying preferential aerobic fermentation and microenvironment acidification. Here, we show that the combination of hypoxic stress and ESRRG deregulation leads to increased ectopic expression of mitochondrial ATP synthase on the plasma membrane, where it is critical to cancer cell proliferation. Translocation of ATP synthase to the plasma membrane was augmented in a time-dependent manner when RB cells were exposed to hypoxia. Pre-treatment of cells with an ESRRG inhibitor eliminated this ATP synthase translocation. Both the F_0 proton channel and F_1 catalytic domains were identified on the outer plasma membrane by confocal microscopy and flow cytometry. Intracellular ATP concentration, measured by luciferase reaction, was significantly increased by media acidification. Inhibition of lactate/proton export through monocarboxylate transporters resulted in media alkalinization and a significant decrease in intracellular ATP, which could be rescued by subsequent exogenous acidification of the media, suggesting that ectopic ATP synthase uses the proton motive force generated by extracellular acidification to synthesize ATP. A novel F_0-targeting ATP synthase inhibitor resulted in near complete cell death of RB cells but showed minimal effect on non-malignant control cells. Interestingly, this drug did not impact the reductive capacity of cancer cell mitochondria compared to control cells, indicating that the drug preferentially affects plasma membrane ATP synthesis at these concentrations. These findings suggest that ATP synthase on the surface of RB cells plays an important role in metabolic adaptation and cell proliferation. These results demonstrate that the use of ATP synthase inhibitors targeting the F_0 domain may represent an innovative new strategy to target cancer cells.

#1542 Metabolic dysregulations of aged bone marrow mesenchymal cells in Acute Myeloid Leukemia reveal novel therapeutic targets..

Mary E. Fuentes[1], Julia K. Christian[1], Amy Kovacs[2], James R. Lerma[3], Liang Niu[4], Alice S. Mims[2], Christopher C. Oaks[2], John C. Byrd[3], Erin K. Hertlein[3], Amina Abdul-Aziz[1]

[1]Fels Cancer Institute for Personalized Medicine, Temple Univ. Lewis Katz School of Medicine, Philadelphia, PA,[2]Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[3]Internal Medicine, University of Cincinnati College of Medicine, Cincinnati, OH,[4]Environmental and Public Health Sciences, University of Cincinnati College of Medicine, Cincinnati, OH

Background: Despite recent efforts to elucidate the dependence of acute myeloid leukemia (AML) on the bone marrow microenvironment, the contribution of aged bone marrow mesenchymal stem cells (BMMSCs) to AML patient survival and treatment response remains understudied. Deregulated nutrient sensing is an established hallmark of aging and previous works have identified age-dependent metabolic dysregulations in cancer. The dependence of AML on oxidative phosphorylation (OXPHOS) has been well established, as AML adapts to fluctuations of nutrient and oxygen availability in the bone marrow microenvironment. We hypothesized that metabolic pathways, such as oxidative phosphorylation, are critical in aged AML-BMMSCs as they drive pro-tumorigenic properties and drug resistance.

Methods: Our group expanded primary Normal Donor (ND)-BMMSCs and AML-BMMSCs (n=9 CBF-AML, n=11 CK-AML, n=7 ND-BMMSCs) under conditions that mimic the bone marrow microenvironment (91% nitrogen, 4% oxygen, and 5% CO2). We isolated DNA and RNA from early passaged cells to perform methylation analyses using 850k Illumina DNA methylation arrays and gene expression analyses using mRNA-seq. We utilized the Horvath Skin and Blood clock to calculate epigenetic age based on DNA methylation. qPCR assessing mRNA expression of OXPHOS-related genes in ND- and AML-BMMSCs was performed to validate sequencing results. Western blot analyses of Total OXPHOS and its complexes were performed to assess expression levels of OXPHOS-related proteins in ND- and AML-BMMSCs. Seahorse assays were performed to obtain live and repeated metabolic measurements of Oxygen Consumption Rate (OCR) and Extracellular Acidification Rate (ECAR) in ND- and AML-BMMSCs. Lastly, 2D co-culture experiments were performed to assess cell viability of AML cell lines with BMMSCs treated ± OXPHOS inhibitors (IACS-010759 and Tamoxifen) utilizing AO/PI staining.

Results: Our integrative omics approach showed that with increased epigenetic age, as measured by the Horvath Skin and Blood clock, AML-BMMSCs reveal upregulations in hallmark gene sets for MYC and OXPHOS when compared to ND-BMMSCs. Western blot analyses confirmed upregulation of MYC and OXPHOS complexes in AML-BMMSCs when compared to controls. Results from seahorse assay revealed an increase in OCR and ATP production in AML-BMMSCs when compared to controls. Lastly, our 2D co-culture experiments *in vitro* revealed a decrease in cell viability on AML cells that were co-cultured with AML-BMMSCs treated with IACS-010759 and/or Tamoxifen.

Conclusions: Our results elucidate age-dependent metabolic dysregulations within the bone marrow microenvironment in AML and provide novel targetable approaches. Future portions of testing aim to identify the mechanism of action of AML-BMMSCs and OXPHOS.

#1543 Obesity promotes triple negative breast cancer progression through regulating the plasticity of adipose tissue.

Xi Xu[1], Yang Lin[2], Shalini Bahl[2], Mathieu Lupien[1]

[1]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[2]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada

The rising global prevalence of overweight and obesity is linked to cancer initiation and poorer overall survival in triple-negative breast cancer (TNBC), making it a modifiable risk factor for both cancer prevention and treatment. The tumor microenvironment (TME) plays a crucial role in tumor development, progression, and response to chemotherapy, and is influenced by both local and systemic factors, such as aging and metabolism. However, most previous studies in this area have relied on animal models or in vitro systems, which provide limited insights into the comprehensive nature of the TME. The mammary gland consists of lobules and ducts with a connective stroma composed of fibro-adipose pockets. Excessive fat deposition in obese patients alters the quantity, function, and plasticity of adipose tissue. It was reported that the adipose tissue undergoes metabolic reprogramming during mammary tumor infiltration into the stromal compartment, which leads to adipose tissue possessing fibroblast/myofibroblast and macrophage-like features, modifying the TME through ECM remodeling and immune response activation, potentially contributing to cancer progression. Adipocyte precursor cells (APCs) are key regulators of adipose tissue plasticity, with the ability to differentiate into either adipogenic or fibrotic cell types. Moreover, fibroblasts are the most abundant stromal cells in TME and strongly associated with breast cancer progression and chemoresistance. Based on the above, I hypothesize that obesity promotes the differentiation of APCs into fibrotic cells, thereby accelerating cancer progression. Single cell multiomics (ATAC + RNA sequencing) has emerged as a powerful tool for studying the TME, as it enables the simultaneous analysis of epigenetic and genetic profiles from the same tumor sample. In this study, we performed single cell multiomics sequencing on primary TNBC tissue samples from 7 lean and 7 obese patients, stratified by body mass index (BMI). Our results revealed that the fibroblasts population in obese patients was more abundant than in lean patients, with significantly increased interactions between fibroblasts and cancer cells. The dominant subtype of fibroblasts in the obese group were identified as myofibroblasts (mCAFs), which were highly enriched in the TGFβ signaling pathway. This enrichment was correlated with a higher epithelial-mesenchymal transition (EMT) signature in cancer cells, observed at both the epigenetic and genetic levels. Furthermore, we leveraged a published human white adipocyte tissue atlas and found that mCAFs shared a high degree of transcriptomic similarity with APCs. This suggests that obesity promotes the differentiation of APCs into mCAFs via the TGFβ signaling pathway, thereby contributing to cancer progression. Our findings provide a novel direction for targeted therapeutic development in the obese patient population.

#1544 Fatty acid oxidation inhibition with anti-cancer agents abrogated tumor growth in a melanoma cancer model.

Jeong Hwan Park, Wonyoung Choi, Woojin Ham, Woosol Hong, Chae-Young Kim, Ho Lee, Soo-Youl Kim

National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of

Purpose: We found that chemotherapy on melanoma induced fatty acid oxidation (FAO). Therefore, we propose that FAO inhibition may suppress tumor growth synergistically with anti-cancer therapeutics.
Experimental Design: To block FAO, CAC (carnitine-acylcarnitine carrier, gene: SLC25A20) in the mitochondria inner membrane and ACAA1 (acetyl-CoA acyltransferase1, gene: ACAA1) in the peroxisome were targeted for inhibition. KN510 and KN713 were identified through drug screening for their inhibitory effects on CAC, and ACAA1, respectively. Using allograft and xenograft models with mouse and human melanoma cancer cells, we investigated the anti-cancer effects of KN510713 in combination with standard chemotherapy.
Results: Anti-cancer drug treatment such as dabrafenib and dacarbazine induced fatty acid catabolism as well as mitochondrial oxidative phosphorylation for ATP production which is the core metabolic pathway for FAO. Increase of ATP production correlated with mTOR activation. Anti-cancer drug treatment combined with KN510713 induced cell death significantly concomitantly with mTOR inactivation in vitro. Melanoma cancer models of allograft and xenograft showed significant suppression of tumor growth by KN510713 treatment with anti-cancer agents such as dabrafenib or dacarbazine.
Conclusion: FAO inhibition abrogated tumor growth by ATP depletion in melanoma. The changes in molecular signaling upon FAO inhibition revealed that ATP levels are a key regulator of all signaling. Thus, combinations of systemic anti-cancer agents with FAO inhibitors have shown excellent anti-cancer activity in mice. Even if signal transduction is induced by various growth receptors, ATP down-regulation through FAO inhibition may provide a novel therapeutic effect.
Funding source: This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF), funded by the Ministry of Science and ICT to SK (NRF-2019M3A9G1104345) and by a grant from the National Cancer Center of Korea to WC (NCC 2410891-1).

#1545 IL-9-mediated glutathione synthetase (GSS) expression modulates anti-oxidant response in cutaneous T cell lymphoma (CTCL).

Diksha Attrish[1], Bhavuk Dhamija[1], Ditipriya Mukherjee[1], Vinanti Sawant[1], Neha Sharma[2], Tanuja Shet[3], Hasmukh Jain[2], Rahul Purwar[1]

[1]Biosciences and Bioengineering, Indian Institute of Technology, Bombay, Mumbai, India,[2]Tata Memorial Hospital, Mumbai, India,[3]Pathology, Tata Memorial Hospital, Mumbai, India

CTCL is a rare and clinically heterogeneous blood disorder with an increased incidence. Management of the disease poses a significant challenge, and there is an urgent need for novel therapies that can cure the disease. Since CTCL is a rare disease, the pathophysiology is not completely characterized. Inflammation is a crucial driver of CTCL progression, and IL-9, an inflammatory cytokine, is prevalent in the tumor microenvironment. Previously, our lab reported that the Th9 axis reduces oxidative stress, and in this follow-up study, we deduced the signaling mechanism underlying IL-9-mediated antioxidant response to have a comprehensive understanding of the metabolic rewiring in CTCL.

High-throughput label-free quantitative LC-MS/MS of IL-9-treated lymphoma cells revealed some of the differentially expressed antioxidant enzymes, including peroxiredoxin-4 (fold change = 2.015, $p = 0.018$), glutathione synthetase (fold change = 4.381, $p = 0.001$), and glutathione peroxidase 1 (fold change = 1.88, $p = 0.021$) among which glutathione synthetase was highly expressed. Further, IH NMR spectroscopy identified the metabolic pathways affected by IL-9 signaling. Pathway analysis using MetaboAnalyst 5.0 depicted enhanced glutathione metabolism and elevated glutathione levels. To substantiate the multi-omics predictions, we checked the expression of GSS in multiple CTCL lymphoma lines (MJ, HuT 78, and Jurkat) and activated T-cells using flow cytometry. We found a high intensity of GSS in MJ (4605.75 ± 641 vs. 3921 ± 1187, $p = 0.04$), HuT 78 (11305 ± 530 vs. 8912 ± 603.8, $p = 0.003$), Jurkat (2955 ± 678 vs. 2190 ± 696, $p = 0.001$) and activated T cells (4593 ± 172 vs. 3657 vs. 206, $p = 0.005$) under IL-9 exposure. In agreement, the biochemical assay demonstrated elevated glutathione levels in lymphoma cells treated with IL-9. Immunohistochemical analysis revealed that GSS was widely expressed by infiltrating T-cells in skin biopsy specimens from 5 patients with mycosis fungoides (MF). Subsequently, flow cytometry analysis of liquid biopsy specimens from 11 patients demonstrated its strong expression with a 52% ($p = 0.005$) increase in circulating CD3+ T-cells in patients with MF compared to healthy volunteers. This cumulative analysis asserted its clinical relevance and identified it as a crucial enzyme in IL-9-mediated antioxidant signaling. Further, treating cells with plumbagin depleted GSS levels and increased ROS generation to many folds in all the lymphoma cell lines and activated T cells. In line with this, depleted GSS levels through plumbagin treatment reduced cell growth and potentiated cell death, suggesting that targeting this metabolic pathway sensitizes cancer cells. In conclusion, this study underscores GSS as a critical metabolic vulnerability.

#1547 CXCL17 targets macrophage efferocytosis to modulate cutaneous squamous cell carcinoma (cSCC).

Alok R. Khandelwal[1], Dhananjay Kumar[2], Arif Yurdagul[2], Cherie-Ann O. Nathan[1]

[1]Otolaryngology, Head and Neck Surgery, LSU Health Shreveport, Shreveport, LA,[2]Molecular and Cellular Physiology, LSU Health Shreveport, Shreveport, LA

Cutaneous squamous cell carcinoma (cSCC) is a keratinocyte-derived invasive and metastatic tumor of the skin. It is the second-most commonly diagnosed form of skin cancer, striking 200,000 Americans annually. Excision of cSCC of the head and neck area results in significant facial disfigurement. An increased understanding of the mechanisms involved in the pathogenesis of cSCC could identify means to prevent, inhibit, and reverse this process. Chemokine (C-X-C motif) ligand 17 (CXCL17) is the latest chemokine family member, and an increased CXCL17 protein expression was observed in both mouse and human cSCC cell lines. Further, deletion of CXCL17 was associated with significant inhibition of tumor cell-intrinsic properties such as proliferation, migration, and motility. CXCL17 is identified as a potent chemoattractant for macrophages, dendritic cells and myeloid-derived suppressive cells. Accordingly, utilizing a syngeneic, tumor-cell xenograft cSCC mouse model, we evaluated the effect of CXCL17 deletion on cSCC tumor-immune evasion and elucidated the underlying mechanism. Deletion of CXCL17 was associated with a significant reduction in tumor volume compared to the wild-type counterparts. Further, CXCL17 deleted cSCC tumor cell xenografts exhibited a significant increase in CD8+, cytotoxic T cells in the tumor microenvironment, suggesting an important role of CXCL17 in mediating tumor-immune evasion. Interestingly, treatment with CXCL17 induced macrophage M2 polarization, increased oxidative phosphorylation and promoted macrophage efferocytosis *via* modulating efferocytotic machinery proteins such as MERTK, TIM4, GAS6 and AXL. Our studies have established substantial evidence for the role of CXCL17 in modulating tumor-cell extrinsic properties to affect the progression of cSCC.

#1548 Deletion of peroxisomal 3-ketoacyl-CoA thiolase promoted overall survival in the KPC mice.

Mingyu Kang, **Woosol Hong**, Woojin Ham, Chaeyoung Kim, Ho Lee, Sang Myung Woo, Wonyoung Choi, Sung Hoon Sim, Jung Won Chun, Soo-Youl Kim

National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of

Background: Fast-growing cancer cells obtained ATP from fatty acid oxidation (FAO). We found that medium-chain acyl-carnitines (MC-AC) were increased by carnitine acyl-carnitine carrier knockdown in pancreatic ductal adenocarcinoma. MC-AC can be produced only in the peroxisome. Therefore, we propose that ATP production in cancer cells may depend on the peroxisomal FAO in addition to mitochondrial FAO.

Methods: We have tested whether peroxisomal FAO is reduced by knockdown of peroxisomal 3-ketoacyl-CoA thiolase (acetyl-CoA acyltransferase 1, *ACAA1*). We have examined effects on ATP level and tumor growth by *ACAA1* knockdown in PDAC cells, and cancer survival by crossbreeding of KPC mice (*Kras*$^{G12D/+}$; *Trp53*$^{R172H/+}$; *P48-Cre*) and *Acaa1*$^{+/-}$ mice.

Findings: Peroxisomal FAO target levels in PDAC patients are higher than in normal individuals. In *in vitro* experiments, *ACAA1* knockdown in PDAC cells reduced 40% of ATP production. In *in vivo* experiments, xenograft mouse models using human PDAC cells with *ACAA1* knockdown showed significantly reduced tumor formation. Crossbreeding of the KPC mice with *Acaa*1$^{+/-}$ mice significantly increased the survival rate.

Interpretation: While normal cells rely on glucose oxidation, ATP production in PDAC cells is critically dependent on FAO in peroxisomes and mitochondria. This suggests that to achieve complete FAO inhibition in cancer, it is necessary to block FAO in both peroxisomes and mitochondria.

Funding source: This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF), funded by the Ministry of Science and ICT to SK (NRF-2019M3A9G1104345) and by a grant from the National Cancer Center of Korea to SHS (NCC 24H1210-2) and JWC (NCC 2410892-2).

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Antibody-Based Cancer Therapeutics 1
Poster Session

#1552 Novel anti-CD3 heavy chain-only antibodies for use in T-cell engaging therapeutics.

Paul Khalife, Hannah C. Watkins, Elizabeth A. McGurk, Elizabeth R. Parker, Cameron M. R. Henkel, Todd M. Boland, Hailey M. Heston, Whitney E. Renaud, Christin R. Strong, Jingfu Zhou, Carissa Metzger, Michael E. Brown, Jessica P. Dawson, Andrew D. Avery, C. Garrett Rappazzo, Beth H. Sharkey, Morgan B. Morrill, Cory L. Ahonen, Michael B. Battles, Noel T. Pauli

Adimab, Lebanon, NH

T-cell engagers (TCEs) display increasing potential as an immunotherapeutic treatment for both hematologic and solid cancers. These multi-specific antibody-based therapeutics consist of a CD3-targeting arm and one or more tumor associated antigen (TAA) targeting arms. The multimeric nature of these therapeutics can present antibody engineering and manufacturing challenges. Developing an anti-CD3 heavy chain-only antibody (HCAb) reduces the design complexity of the final TCE therapeutic. Functional anti-CD3 HCAbs were discovered by combining llama immunization and a novel yeast-based HCAb presentation and discovery technology. Following several rounds of yeast-based HCAb selection, T-cell stimulating anti-CD3 HCAbs were identified that predominantly competed with UCHT1. Stimulating CD3-specific HCAbs were reformatted into CD3 X CD20 bispecifics, which displayed potent T-cell activation and Raji cell killing in a redirected T-cell cytotoxicity (RTCC) assay. This panel was further validated as a bispecific VHH-TCR fusion using a TCR specific for the gp100 peptide HLA complex; donor T-cell activation and target killing was observed against both SK-MEL-5 and MeWo cancer cell lines. The panel was subsequently humanized while maintaining functional activity and favorable drug developability profiles. These humanized anti-CD3 HCAbs are promising candidates for replacing conventional anti-CD3 IgG Fab arms in next-generation multispecific TCE antibodies.

#1554 Harnessing the Beacon® optofluidic platform for streamlined discovery of internalizing antibodies.

Brittany Benlian, Leqian Liu, Alexander Mastroianni, Minha Park, Vincent Pai, **Alireza Salmanzadeh**

Bruker Cellular Analysis, Emeryville, CA

Antibody drug conjugates (ADCs) are an innovative class of biopharmaceuticals which combine the potency of cytotoxic molecules with the targeted specificity of monoclonal antibodies. The success of a traditional ADC not only hinges on tumor antigen-specific binding but internalization to maximize cytotoxicity from the payload and minimize off-target damage to healthy tissue. The development of an ADC therapy is a complex, multistep process that involves identifying a target antigen, discovering an ideal antibody, selecting the cytotoxic payload and linker, and optimizing the conjugation chemistry - all of which can take years from initial research to therapeutic application. One significant bottleneck within this process is the lack of early phase assays to guide the down-selection of functional antibodies from hundreds of antigen binding clones. Therefore, developing an efficient high-throughput assay for antibody internalization is crucial for accelerating ADC development. The Beacon® optofluidic platform from Bruker Cellular Analysis is an advanced solution for this problem that enables researchers to identify valuable monoclonal antibodies within a week, bypassing the time consuming and laborious process of hybridoma library generation and screening. With this platform, tens of thousands of single primary cells can be isolated using Opto-Electronic Positioning (OEP) technology and assayed for antibody secretion, antigen binding, and receptor-specific internalization in live reporter cells within a single day. This cutting-edge technology is the only platform capable of screening and measuring >10,000 antibodies simultaneously for rapid internalization (1-2 hours). We showcase the ability to streamline early-phase discovery of internalizing antibodies, going beyond mere antigen specificity to enable high-throughput, real-time evaluation of functional antibodies. The Beacon optofluidic platform significantly reduces hands-on time and resource expenditure, focusing efforts on the most promising ADC candidates for downstream characterization and optimization, ultimately expediting the progression of ideal antibodies into clinical applications.

#1556 B7-H7-CD3 bispecific T cell engaging antibodies demonstrate potent anti-tumor activity in B7-H7+ preclinical tumor models.

Karishma Vekaria, Susannah Hewitt, Melissa W. Hayes, Emilien Loeuillard, Jamie Strand, Riale Gilligan, Maja Razlog, Emma Aeschliman, Quangvinh Tran, McKenna Lamb, Bijan Etemad-Gilbertson, Silvia Ferrati, Tatiana Novobrantseva, **Matthew Rausch**

NextPoint Therapeutics, Cambridge, MA

Background: B7-H7 is a B7 family member that suppresses T and NK cell activation through an inhibitory receptor, KIR3DL3, and stimulates immune cell activation through a distinct receptor, TMIGD2. B7-H7 is upregulated on tumor cells of many histological subtypes and is, therefore, explored as a novel tumor targeting antigen. NextPoint has developed two B7-H7-targeted CD3 bispecific antibodies, NPX372 and NPX387, to redirect T cell-mediated immunity toward B7-H7+ tumors. Both antibodies bind B7-H7 with similar avidity and block interaction with KIR3DL3, but induce the formation of distinct immune synapses.
Methods: B7-H7 and CD3 binding were evaluated on-cells expressing human and non-human primate (NHP) versions of the proteins by flow cytometry. Bispecific antibody-mediated T cell activation was assessed using Jurkat reporter assays. Primary T cell activation was evaluated in vitro in co-culture assays with B7-H7+ tumor cell lines by flow cytometry and multiplex cytokine analysis. T cell redirected killing of B7-H7+ tumor cells was assessed using PBMC co-culture assays and flow cytometry. Finally, humanized mouse models were used to test the anti-tumor activity of both NPX372 and NPX387 in B7-H7+ tumor models in vivo.
Results: NPX372 and NPX387 bound to both human and NHP B7-H7 and CD3. While both bispecific antibodies demonstrated similar on-cell avidity to B7-H7, NPX372 demonstrated stronger affinity for human CD3 compared to NPX387. Co-culture assays with Jurkat reporter cells and primary T cells demonstrated that both NPX372 and NPX387 could crosslink B7-H7 on tumor cells to CD3 leading to T cell activation. However, despite having a stronger affinity for CD3, NPX372 induced less cytokine production in primary T cell cultures with B7-H7+ tumor cells compared to NPX387. Both bispecific antibodies also induced potent T cell-mediated killing of multiple B7-H7+ tumor cell lines in vitro with similar potency. Finally, both NPX372 and NPX387 demonstrated anti-tumor activity in a B7-H7+ tumor model in vivo at clinically relevant doses that are tolerated in NHP toxicity studies.
Conclusion: These data demonstrate that B7-H7 represents a novel tumor associated antigen for CD3 bispecific T cell engagement that can induce potent T cell-mediated anti-tumor immunity.

#1558 HDP-201 - a novel multimeric linker exatecan-based ADC targeting Guanylyl cyclase C (GCC) for treatment of gastrointestinal malignancies.

Sarah Jane Neuberth, Christian Orlik, Hendrik Gruss, Christoph Mueller, Kristin Decker, Nick Neubacher, Marisa Schmitt, Aniko Palfi, Irina Dranova, Michael Kulke, Andreas Pahl, Torsten Hechler

Heidelberg Pharma, Ladenburg, Germany

Background: HDP-201 is a novel multimeric linker ADC directed against GCC based on topoisomerase 1 inhibitor exatecan. GCC is highly expressed in gastrointestinal malignancies including gastric and colorectal cancers. The multimeric linker-payload featured with a solubility enhancer facilitates the delivery of more than one hydrophobic payload per conjugation site. HDP-201 employs a proprietary, site-specific conjugation technology based on cysteine-engineered and Fc-silenced antibodies which are devoid of Fc-mediated uptake.
Methods: The cysteine-reactive multimeric exatecan-linker construct was synthesized at Heidelberg Pharma and site-specifically conjugated to engineered cysteine residues of a proprietary anti-GCC antibody, yielding ADCs with a DOL of 2.0 and a DAR of 4.0. HDP-201 potency was tested in cytotoxicity assays using a GCC-overexpressing HEK293-GUCY2C cell line. The anti-tumor efficacy was evaluated in subcutaneous HEK293-GUCY2C tumor models in female NOD SCID mice, and patient-derived xenografts (PDX) treated intravenously with single and multiple doses of HDP-201. Safety and tolerability of HDP-201 was assessed in cynomolgus monkeys.
Results: HDP-201 showed favorable *in vitro* cytotoxicity, with nanomolar activity against the GCC-expressing cell line and no cytotoxicity against target-negative cells. A potent by-stander effect of HDP-201 was demonstrated in co-culture experiments with target-positive and -negative cells, indicating its potential to treat tumors with heterogenous target expression. In mouse xenograft models, intravenous HDP-201 single dose treatment resulted in complete tumor remission in HEK293-GUCY2C xenografts. In gastrointestinal PDX models, HDP-201 significantly inhibited tumor growth. Multiple dosing further enhanced this anti-tumor efficacy without impacting toxicity. In cynomolgus monkeys, a single intravenous dose of 60 mg/kg was well tolerated without severe clinical signs and only transient changes in hematology and serum chemistry parameters.
Conclusion: Targeted delivery of topoisomerase 1 inhibitor to GCC-positive cells was achieved using HDP-201 comprised of an anti-GCC antibody conjugated to a multimeric linker-exatecan. HDP-201 showed target-specific potency, strong anti-tumor efficacy, and high tolerability in preclinical models. The use of HDP-201 in the therapy of GCC-positive gastrointestinal malignancies represents a promising approach in cancer treatment.

#1559 Assessing efficacy of anti-glypican-1antibody-drug conjugate as potential therapeutic approach for gastric cancer.

Y. Suzuki[1], S. Serada[1], K. Kawabata[2], T. Takahashi[2], Y. Doki[2], T. Naka[1];
[1]Iwate Medical University, Yahaba, Japan, [2]Osaka University, Osaka, Japan

Background: Despite significant advancements in cancer treatment, gastric cancer (GC) still has a high incidence and mortality rate. Antibody-drug conjugates (ADCs) are emerging as viable treatment option for GC. We previously identified glypican-1 (GPC1) as a novel cancer antigen in esophageal squamous cell carcinoma using quantitative protein expression profiling analysis focused on plasma membrane proteins, and recognized it as a potential target for ADCs.Glypican-1 (GPC1), a cell surface proteoglycan, has gained interest for its role in tumor growth and as a potential biomarker. This study evaluated the efficacy of an ADC comprising a humanized anti-GPC1 monoclonal antibody with monomethyl auristatin E (GPC1-ADC) to target GPC1 in GC.
Methods: GPC1 expression was assessed in GC cell lines and tissues. The cytotoxic efficacy of GPC1-ADC and its mechanism of action were evaluated using comprehensive *in vitro* assays. Further, *in vivo* efficacy was assessed in xenograft mouse models, focusing on tumor growth inhibition and its performance against peritoneal dissemination.
Results: *In vitro,* GPC1-ADC exhibited significant cytotoxicity against GPC1-positive cell lines by inducing cell cycle arrest and apoptosis. Additionally, GPC1-ADC exhibited promising bystander-killing activity through cancer-associated fibroblasts, underscoring its potential to target the heterogeneous tumor cell microenvironment characteristics of GC. *In vivo*, GPC1-ADC significantly inhibited tumor growth, demonstrating a substantial therapeutic effect in a peritoneal dissemination model. Immunohistochemical analysis of tumor specimens from patients with GC revealed that 90.2% of differentiated types and 66.7% of poorly differentiated types exhibit high GPC1 expression. High GPC1 expression in tumor samples was significantly related to poorer clinical outcomes for progression-free and overall survival.
Conclusions: GPC1-ADC exerts a direct antitumor effect on GPC1-positive GC cells. Additionally, GPC1-ADC can impact GPC1-negative cells via GPC1-positive stromal cells. This mechanism is likely owing to the characteristics of MMAE, which has a bystander effect as the payload of GPC1-ADC. Our results suggest that GPC1-ADC may be a potential therapeutic candidate for GPC1-positive GC.

#1560 SCR-A0011, a novel bispecific ADC targeting cMET and B7H3, exhibits potent anti-tumor efficacy.

Yayuan Fu, Guangcun Cheng, Hui Zheng, Shuai Wang, Lei Jiang, Chunlei Xia, Huipeng Guo, Xiyuan Wang, Renhong Tang

Simcere Zaiming, State Key Laboratory of Neurology and Oncology Drug Development. Simcere Pharmaceutical Group, Shanghai, China

Background: The HGF/cMET signaling pathway plays an important role in the regulation of cell proliferation, differentiation, migration and other normal physiological functions. cMET is expressed in many different normal tissues but is usually expressed at low levels. Abnormal expression and dysfunction of cMET have been found in a variety of tumors. cMET is a well-established target in clinical, but its clinical application is limited, because clinical efficacy was mainly observed in cMET signaling driving tumor or cMET-high expression tumors. To extend the potential therapeutic population and anti-tumor activity, we searching for some new approaches, such as bispecific antibody drug conjugates. Bioinformatics analysis and translational research showed that cMET and B7H3 are co-expressed in multiple types of solid tumors without high expression in normal tissues. Therefore, targeting both B7H3 and cMET could be a new and powerful strategy in pan-tumor therapy.

Methods & Results: We developed a novel B7H3xcMET targeted bispecific antibody-drug conjugate (ADC) called SCR-A0011, which is comprised of B7H3/cMET bispecific antibody conjugated with novel topoisomerase 1 inhibitor (CPT116). SCR-A0011 specifically bind B7H3 and cMET with high affinity, and showed enhanced internalization and binding capacity compared to parental monoclonal antibody ADC separately in the B7H3/cMET co-expressing cell line. SCR-A0011 induced tumor cell lysis in various tumor cell types including NSCLC, CRC, OC, HNSCC, etc. SCR-A0011 showed remarkable anti-tumor efficacy in several CDX models in a dose dependent manner. SCR-A0011 exhibits significantly stronger anti-tumor activity than their parental monoclonal-ADC or clinical ADC in B7H3+cMET+ double positive tumor cells. SCR-A0011 also have very good stability and favorable developability.

Conclusion: These findings illustrated SCR-A011 could be a potential First-in-Class BsADC to conquer the resistance or non-response of current treatment in broad cancer types and may provide a new therapeutic approach for B7H3 and cMET positive cancer patients in the future.

#1561 Antitumor effect of farletuzumab ecteribulin in molecular subtypes of endometrial cancer patient-derived xenograft models.

Shigehiro Yagishita[1], Sho Sato[2], Daisuke Shintani[2], Tadaaki Nishikawa[3], Aiko Ogasawara[2], Masanori Yasuda[4], Hironori Ishii[5], Keiji Furuuchi[6], Toshimitsu Uenaka[6], Hiroshi Yoshida[7], Kosei Hasegawa[2], Akinobu Hamada[1]

[1]National Cancer Center Japan, Tokyo, Japan,[2]Department of Gynecologic Oncology, Saitama Medical University International Medical Center, Saitama, Japan,[3]Department of Medical Oncology, National Cancer Center Japan, Tokyo, Japan,[4]Department of Pathology, Saitama Medical University International Medical Center, Saitama, Japan,[5]Precision Medicine Business Unit, Konica Minolta, Tokyo, Japan,[6]Eisai Inc., Exton, PA,[7]Department of Diagnostic Pathology, National Cancer Center Japan, Tokyo, Japan

Background:Endometrial cancer (EC) represents a significant health burden globally, particularly in postmenopausal women. Current treatment options for advanced-stage EC remain limited, emphasizing the need for novel therapeutic strategies. This study aimed to investigate farletuzumab ecteribulin (FZEC), an antibody-drug conjugate (ADC) targeting folate receptor alpha (FRα), as a potential new therapeutic agent for EC using tumor models. Methods:We utilized a panel of 24 patient-derived xenograft (PDX) models, representing various histological and molecular subtypes of EC with different levels of FRα expression, to evaluate the antitumor effect of FZEC. FZEC was administered intravenously at doses of 5 mg/kg and 12.5 mg/kg. Intratumoral accumulation of eribulin, the payload of FZEC, was visualized using phosphor-integrated dot imaging. Results:FZEC demonstrated dose-dependent antitumor effects across the EC-PDX panel. At 5 mg/kg, the FZEC efficacy was associated with FRα expression, with 100% of FRα 3+ models exhibiting tumor shrinkage compared to 27.2% of FRα-negative models. FZEC also demonstrated broad activity across both histological and molecular subtypes of EC. Intratumoral eribulin accumulation was highly correlated with antitumor effects, even in models with low FRα expression. Follow-up studies confirmed FRα-dependent antitumor effects, while also indicating potential FRα-independent mechanisms of action. Conclusion:FZEC demonstrated robust antitumor effect against the FRα high EC-PDX models. Importantly, significant antitumor effects were observed, even in FRα-low or negative models. Intratumoral eribulin accumulation exhibited a stronger correlation with efficacy than with FRα expression alone. These results support further clinical development of FZEC for EC treatment and highlight the complexity of ADC mechanisms of action.

#1562 Pre-clinical research of ZHB015, an anti-CD26/CD3 bispecific T-cell-engaging antibody.

Chennan Ge, Peipei Cao, Jianhua Hang, Tao Zhang, Yu Zhuang, Na Ding, Bruce Y. Ma

Zonhon Biopharma Institute, Inc., Changzhou, China

PURPOSE: CD26 is a highly expressed transmembrane target in multiple solid tumors such as renal cell carcinoma, prostate cancer and malignant pleural mesothelioma. YS110 is the first reported monoclonal antibody targeting CD26 and has been proved safe in phase I/II clinical trials in Japan and France, but the efficacy is not satisfying. Although FDA approved axitinib in combination with avelumab as the first-line treatment for PD-L1 positive advanced renal cell carcinoma in 2019, the problems still exist such as individual differences and drug tolerance. Consequently, we developed ZHB015, a bispecific T-Cell-Engaging antibody that targets CD26 high-expressing solid tumors, and furtherly to validate its efficacy and safety.

METHODS: ZHB015, which is expressed and manufactured from recombinant CHO cells, has a tandem single chain variable fragment antibody (BiTE) structure. CD26 expression level in tumor cells was detected by FACS. CD26 expression in tumor tissues was detected by immunohistochemistry. The affinity between ZHB015 with human CD26 or CD3 were detected by Octet. The killing effect of ZHB015-mediated PBMC on tumor cells was detected by Calcein-AM release. ELISA was used to detect the cytokine secretion of ZHB015 in the process of mediating the killing effect. The antitumor activity in vivo was studied in mouse xenograft models. Daily intravenous administration dosage of ZHB015 was 1.5mg/kg. Both axitinib in combination with avelumab and YS110 were served as control in vivo.

RESULTS: ZHB015 pilot production process was performed and confirmed good scale-up feasibility. The positive rates of CD26 in 786-0, 0S-RC-2 and A498 renal cancer cells were all over 95%. 99.4% mesothelioma cell NCI-H226 and 93.8% prostate cancer cell PC-3 were CD26 positive. IHC experiments confirmed that CD26 is highly expressed in renal cancer tissues. ZHB015 has an affinity of 0.91nM with CD26 and 0.75nM with human CD3. ZHB015 can bind to both CD26 and CD3 simultaneously. 786-0, OS-RC-2, NCI-H226, and PC-3 CD26 expressing tumor cells were lysed with EC_{50} values in a range of 219.6 to 752.3pg/ml, and the killing activity was significantly higher than homemade YS110. In the process of mediating PBMC to kill target cells, ZHB015 induced a lower cytokines secretion than control molecule YS110-BiTE. In the xenograft models of OS-RC-2 and A498, TGI of ZHB015 was 100%, TGI of different doses of axitinib in combination with avelumab did not exceed 71%, and YS110 had no antitumor effect. The TGI of ZHB015 in PC-3 and NC1-H226 models was 96% and 66%, respectively.

CONCLUSION: ZHB015 simultaneously binds to tumor CD26 and T cell CD3, inducing T cell mediated antitumor effects. ZHB015 has an outstanding anti-tumor activity in vitro and in vivo, which is superior to YS110 and the current first line treatment. Thus, ZHB015 is being further developed as a potential therapy for CD26 positive solid tumor.

#1563 ADRX-0134 as a novel auristatin-based NaPi2b antibody-drug conjugate with widened therapeutic window.

Andrew M. Hau, Kris Zhang, Maria Shahmoradgoli, Mario M.-C. Kuo, Dong Jun Lee, Anna Y. Wang, Peter P. Challita, Oscar Betancourt, Wes Sisson, Erin Nye, Monica Leung, Albert Goldson, Felipe Acosta, Alexander Chu-Kung, Hui Li, Sabine Rottmann, Pia M. Challita-Eid

Adcentrx Therapeutics, Inc., San Diego, CA

Sodium-dependent phosphate transport protein 2B (NaPi2b; SLC34A2) is overexpressed in a variety of cancers, including lung carcinomas, ovarian, and endometrial cancers with restricted normal tissue expression. Based on this differential expression profile, a proof-of-concept for an antibody-drug conjugate (ADC) approach utilizing NaPi2b was achieved with lifastuzumab vedotin and upifitamab rilsodotin. Both ADCs used auristatin tubulin inhibitor payloads but have been discontinued due to adverse toxicities driven by the linker-payload technologies, resulting in reduced drug exposures impacting efficacy. To overcome these limitations in therapeutic window, Adcentrx has developed ADRX-0134, a NaPi2b-targeting next-generation ADC with a drug-antibody ratio (DAR) of 8. ADRX-0134 is conjugated to a novel tubulin inhibitor payload AP052 with a proprietary cleavable linker utilizing Adcentrx' proprietary i-Conjugation® technology, resulting in an ADC with refined biophysical features. The antibody of ADRX-0134 was selected based on its strong nanomolar and highly specific cell binding affinity and similar cross-reactivity to cynomolgus monkey and rodent orthologs. The ADC exhibits sub-nanomolar cytotoxic activity to NaPi2b-expressing tumor cells and has a very stable PK profile with minimal deconjugation. This translates to the observed strong efficacy and durable tumor regression in mouse models of ovarian, endometrial and non-small cell lung cancers with high as well as low/heterogenous NaPi2b expression. Most notably, ADRX-0134 achieved tumor regression in settings where deruxtecan- and vedotin-based NaPi2b ADCs were insufficient. Besides the improvement in efficacy, ADRX-0134 was highly tolerated in a repeat dose non-human primate study at up to 18 mg/kg, the highest tested dose. Here, the stable TK profile ensured minimal and recoverable hematology findings, an unchanged clinical chemistry profile and normal histology of lung, liver, GI and eye, which were key safety liabilities for other NaPi2b ADCs. In summary, ADRX-0134 exhibits excellent biophysical features with highly selective and increased efficacy in NaPi2b-expressing tumors, while being well-tolerated in cynomolgus monkeys at doses that are expected to provide a widened therapeutic window over first-generation NaPi2b ADCs.

#1564 Receptor quantification in the context of human epidermal growth factor receptor 2 (HER2) antibody-drug conjugates.

Mandy W. E. Drossaert-Smeets, Eef F. P. Smits, Milan M. Bolwerk, Janneke J. T. Melis, Dimitri Pappaioannou, **Guido J. R. Zaman**

Oncolines B.V., Oss, Netherlands

Antibody-drug conjugates (ADCs), comprised of cancer cell-specific antibodies linked to cytotoxic drugs, represent an innovative and promising class of anticancer agents. ADCs often rely on high receptor numbers for target binding, followed by internalization and release of the payload to exert a tumor-targeted, intracellular effect. Determination of the exact number of receptors per cell is therefore highly valuable in the context of ADCs. Here, we focused on the quantification of the human epidermal growth factor receptor 2 (HER2), since expression of this target is often amplified in various tumor types. Two HER2-targeting ADCs, *i.e.,* ado-trastuzumab emtansine (T-DM1) and fam-trastuzumab deruxtecan-nxki (T-DXd), have already been approved for clinical use, while roughly twenty HER2-targeting ADCs are currently under investigation. The development and improvement of ADCs could benefit from *in vitro* studies investigating the internalization, cytotoxic effect and possible bystander effect of ADCs related to receptor numbers. The number of HER2 per cell was quantified in a panel of thirteen cancer cell lines originating from different cancer types. The cell lines BxPC-3, CAL-27, COLO 205, HCC1954, HEC-251, K-562, MOLM-13, NCI-H23, RT-112, SK-BR-3, SK-OV-3, SW837 and U-87MG ATCC were cultured for one week in the supplier's recommended medium. Quantification of the number of surface-expressed receptors was performed with flow cytometry using Quantibrite PE beads and PE-conjugated ErbB2/HER2 antibody. The effect of T-DM1 and T-DXd on the viability of HER2 high-, intermediate- and low-expressing cells was determined in proliferation assays in 9-point dose ranges. Three independent flow cytometry experiments revealed that the breast and ovarian cancer cell lines HCC1954, SK-BR-3, and SK-OV-3 expressed the highest number of HER2 per cell, ranging between 20,000 and 53,000 receptors. Intermediate expression was observed on the COLO 205, HEC-251, RT-112 and SW837 cell lines, with a range of 1800 to 3800 receptors per cell. BxPC-3, CAL-27, K-562, MOLM-13, NCI-H23 and U-87MG ATCC belong to the group with the lowest or no expression of HER2, ranging up to 400 receptors per cell. T-DM1 and T-DXd induced efficient cell death in cells expressing high receptor numbers, while little or no effect was observed in cell lines with intermediate, low or no expression of HER2. Since high target expression is correlated with higher efficacy for several ADCs, as shown for T-DM1 and T-DXd is our study, this indicates that HCC1954, SK-BR-3 or SK-OV-3 cells could serve as an attractive model to study HER2 internalization. Moreover, co-cultures of HER2-positive and HER2-negative cells could aid in the investigation of ADC bystander effect. This research demonstrates the importance of receptor number quantification in the context of ADCs and may therefore contribute to future ADC development.

#1565 Design and development of biparatopic antibody-drug conjugates against protein tyrosine kinase 7.

Luying Yang, **Vincent Fung**, Alex Wu, Dunja Urosev, Saki Konomura, Tik Nga Tong, Katina Mak, Elizabeth M. Porter, Diego A. Alonzo, Catrina M. J. Kim, Janice P. H. Tsui, Linglan Fu, Lemlem Degefie, Kaylee Wu, Matthew Bonderud, Jamie R. Rich, Stuart D. Barnscher

Zymeworks Inc., Vancouver, BC, Canada

Background: Biparatopic antibodies and antibody-drug conjugates (ADCs) can provide many functional benefits over their traditional monoparatopic counterparts including increased binding, greater cell surface decoration, superior receptor blockade, and enhanced internalization and payload delivery; however, not all antigens are amenable to biparatopic targeting. We sought to leverage our prior knowledge of biparatopic antibody development and our Azymetric™ technology to develop a novel biparatopic ADC against protein tyrosine kinase 7 (PTK7) that could provide a functional enhancement over monoparatopic ADCs. PTK7 is an attractive ADC target due to preliminary clinical activity demonstrated with cofetuzumab peledotin in non-small cell lung cancer, ovarian cancer, and metastatic breast cancer and evidence that PTK7 is overexpressed in other solid tumor indications including esophageal cancer, colorectal cancer, head and neck cancer, and cervical cancer.

Materials and Methods: Twenty-nine PTK7-targeting paratopes were isolated from a mouse antibody discovery campaign and paratope pairs were combined into a panel of biparatopic antibodies using Azymetric™ Het_Fc mutations. A high-throughput screen was used to assess the functional properties of these antibodies and to identify the top paratope combinations. ADCs were produced by conjugating the top biparatopic and monoparatopic antibodies to ZD06519, a topoisomerase 1 inhibitor payload used in ZW191, an ADC targeting FRα under evaluation in a phase 1 clinical trial (NCT06555744). ADC activity was investigated in a series of in vitro and in vivo experiments using ovarian, lung, and breast cancer models.

Results: Across multiple cancer cell lines with varying PTK7 expression we compared a lead monoparatopic antibody and cofetuzumab with the top biparatopic antibody which demonstrated greater cell surface decoration and better internalization. At clinically relevant doses, the biparatopic ZD06519 ADC was more efficacious than cofetuzumab pelidotin in triple negative breast cancer and lung cancer cell line derived xenograft models. Additional studies of the PTK7 biparatopic ADC in patient-derived xenograft models and a non-human primate tolerability study are planned.

#1566 A novel drug discovery platform identifies epitopes on driver receptors that can be targeted to induce widespread kinase inhibition and cancer cell death.

Rachel S. Welt[1], Virginia Raymond[2], David Kostyal[3], Sydney Welt[1]

[1]Welt Bio-Molecular Pharmaceutical, Briarcliff Manor, NY,[2]Biogent Consultants, Armonk, NY,[3]ARDL, Akron, OH

Welt Bio-Molecular Pharmaceutical (WBMP) has developed a drug discovery platform that identifies critical peptide segments of membrane receptors, which, when targeted with an antibody, block transmembrane signal transmission, leading to widespread kinase inhibition. This platform was first used to generate our lead monoclonal antibody (mAb), WBMP-4, which binds to a region on membrane-bound IgM, a subunit of the B-cell Receptor (BCR), and induces cell growth inhibition (at low doses) and apoptosis (at high doses) in IgM-expressing B-cell malignancies. Here we present the results of kinome and protein expression studies that characterize the mechanism of action of WBMP-4 and validate the algorithm underlying our platform.

We evaluated kinase activity in lymphoma cells treated with WBMP-4 (at 5 and 20 ug/mL, and at 6 and 24 hours) via the PamGene phosphotyrosine kinase assay. This assay measures kinase activity in cell lysates using a microarray chip containing peptide sequences that serve as substrate for 189 phosphotyrosine sites on well-characterized signaling proteins. Additionally, we measured protein expression and phosphorylation of key targets downstream of the BCR with western blot analyses of WBMP-4 treated and untreated IgM-expressing B-cells.

Our detailed kinome analysis reveals widespread kinase modulation following WBMP-4 treatment, with >180 of 189 phosphosites showing a significant change in phosphorylation signal intensity (>153 significantly decreased) upon treatment. Western blot analyses similarly show changes in phosphorylation of kinases (ZAP70, mTOR, AKT, and MEK). However, we also find decreased protein expression of CD79b, ZAP70, BTK, MEK, Myc, and increased LCK following WBMP-4 treatment.

These results show that kinase activity across signaling pathways is altered upon WBMP-4 binding to the BCR's mIgM, with the vast majority exhibiting a downregulation of phosphorylation. We also find that protein expression is impacted in several kinases directly downstream of the BCR. We hypothesize that kinase inhibition induced by WBMP-4 modulates transcription factor activity, and resultantly, protein expression, which maintains growth inhibition signaling and prevents recovery signals, determining the fate of the cells. Further analysis will assess earlier time points and lower dosages to examine the more immediate effect of WBMP-4 inhibition.

WBMP-4's global kinase inhibition encompasses the effects of approved kinase inhibitor drugs (i.e. BTK, PI3K, and Bcl-2 inhibitors), and is designed to be more tumor-restrictive; WBMP-4 only affects IgM-expressing B-cells, sparing healthy B-cells that express other classes of Ig (i.e. IgG, IgA, IgD, or IgE). This tumor specificity and potent inhibitory effects make WBMP-4 a promising clinical candidate.

#1567 GLR1059, next-generation nectin-4-targeted ADC with a novel mechanism-of-action payload, demonstrated significantly potent anti-tumor efficacy and reduced toxicity in preclinical evaluation.

J. Jiao, Y. Sun, J. Wang, L. Che, M. Cui, W. Shao, H. Yuan, Y. Huang, N. Zhai, Y. Tang, X. Zheng, S. Li;
Gan & Lee Pharmaceuticals, Beijing, China

Background: Nectin-4 is a tumor-associated antigen, which was observed in multiple cancer types, including bladder, breast, lung, pancreatic and ovarian cancer. Enfortumab Vedotin (EV) is the first approved nectin-4 antibody-drug conjugate (ADC) with MMAE as its payload for the treatment of urothelial carcinoma (UC). However, beyond UC, EV hasn't been approved for other indications. In addition, severe skin adverse reactions were reported in EV-treated patients. There are several new nectin-4 ADCs in development but haven't entered confirmative clinical studies so far. To overcome the limitations of efficacy and safety, we developed a novel mechanism nectin-4 ADC GLR1059, with a payload that was more effective for potential indications with nectin-4 expression and had lower toxicity, including skin adverse reactions.
Methods: For in vitro studies, binding affinity and specificity, internalization, cancer cell killing, bystander effect and serum stability were performed. For in vivo studies, efficacy studies were conducted on cell line-derived xenografts (CDX) of multiple cancer types, e.g. breast cancer (including triple-negative breast cancer), and urothelial carcinoma. Pharmacokinetic (PK) properties were studied in BALB/c mice and tumor-bearing nude mice, and safety studies were conducted in humanized nectin-4 mice.
Results: GLR1059 is a nectin-4 ADC composed of a novel humanized IgG1 monoclonal antibody, a cleavable linker and a microtubule targeting agent (not auristatin derivatives). Moreover, to generate DAR4 ADCs with higher homogeneity, the payload was site-specifically conjugated to the antibody via a disulfide bond bridge. In surface plasmon resonance (SPR) assays, GLR1059 had strong and specific binding to human nectin-4, and it did not bind to nectin-1, nectin-2, or nectin-3. Furthermore, GLR1059 exhibited efficient internalization and potent activity in nectin-4 expressing cell lines and effective bystander activity. In a panel of CDX models, GLR1059 demonstrated compelling anti-tumor activity across bladder cancer and breast cancer (including TNBC), with tumor growth inhibition rates (TGI) significantly higher than EV (approximately 2-4 times). In the tumor-bearing mice PK study, the Cmax of free payload in tumor tissue was approximately 100-fold higher than that in the blood (131±14ng/g vs 1.04±0.27ng/mL). GLR1059 demonstrated longer survival and less weight loss in the single- and repeated-dose toxicity studies in humanized nectin-4 mice. Notably, GLR1059 significantly reduced the incidence and severity of skin toxicity compared with EV (1/6 vs 6/6).
Conclusion: Preclinical data show that GLR1059 has the potential to achieve better efficacy and safety, and the different drug mechanisms provide new options to overcome drug resistance of current nectin-4 ADCs.

#1568 Humanized PD1 mouse with MC38-hCLDN18.2 cell line provide powerful syngeneic model platform for evaluating Claudin18.2-targeted therapies.

Jane Hong[1], Shuang Li[2], Xiaolei Qiu[1], Hechun Ma[1], Yi Li[1], Ruilin Sun[1]

[1]GenoBioTX, Sugar Land, TX,[2]GenoBioTX, Sugar land, TX

Claudin18.2 is a highly specific tight junction protein that is minimally expressed in normal tissues but aberrantly activated and overexpressed in various malignancies, particularly digestive system tumors such as gastric cancer (approximately 70%) and pancreatic cancer (around 50%). In these tumors, the loss of cell polarity exposes Claudin18.2 on the cell surface, making it accessible to biologics and effector cells. Innovative therapeutic strategies, including monoclonal antibodies, bispecific antibodies, ADCs, and CAR-T cells, leverage this accessibility to enhance tumor-targeting precision and immune activation. Combining Claudin18.2-targeted therapies with immune checkpoint inhibitors, such as PD-1 blockade, holds promising therapeutic potential.To evaluate the efficacy of antibody drugs and ADCs, tumor cell lines overexpressing tumor-associated antigens are critical. We generated MC38-CLDN18.2 murine colon cancer cell lines by overexpressing human CLDN18.2 in MC38 cells. Human CLDN18.2 protein expression was confirmed by flow cytometry. The tumorigenic potential of MC38-CLDN18.2 cells was further validated in vivo.To investigate novel combination therapies or bispecific antibodies targeting CLDN18.2 and PD-1 in an immunocompetent model, we developed a humanized PD-1 (hPD1) mouse model on a C57BL/6 (C57) background. Using CRISPR/Cas9-based gene engineering, the murine *Pdcd1* gene was replaced with the human *PDCD1* gene, ensuring full-length human PD-1 protein expression in the knock-in model. Human PD-1 protein expression was validated by FACS analysis after in vivo anti-CD3 stimulation.The tumor growth inhibition of two CLDN18.2 monoclonal antibodies (IMAB362 and ASKB589) was evaluated in hPD1 mice engrafted with MC38-CLDN18.2 syngeneic tumors. The therapeutic effects of these antibodies were also investigated in combination with anti-PD-1 treatment. Both anti-CLDN18.2 monotherapies demonstrated moderate antitumor efficacy, while their combination with PD-1/PD-L1 immune checkpoint blockade produced significant synergistic effects, resulting in enhanced tumor suppression and increased antitumor immunity with robust T-cell infiltration.In summary, the humanized PD-1 mouse model and MC38-CLDN18.2 cell line provide robust in vivo platforms to evaluate novel therapeutic candidates targeting CLDN18.2.

#1569 Dual action tumor immune agonist (DATIA) ADCs activating STING pathway and subsequently inducing cytotoxicity of tumor cells exhibits potent and lasting in vivo tumor growth inhibition in multiple preclinical tumor antigen positive cancer models.

Yanliang Zhang, Chunlan Dong, Guangming Chen, Qianxiang Zhou, Tony Zhang

Tyligand Bioscience (Shanghai), Ltd., Shanghai, China

Introduction : TSN222, currently in Phase 1 clinical development for solid tumors, is a novel dual action tumor immune agonist (DATIA) via intratumoral administration. Its half-lives inside cells and in plasma were designed to be long enough for it to activate tumor STING pathways, and short enough to limit systemic inflammation. Its active metabolite is a DNA synthesis inhibitor, which subsequently induces apoptosis of the tumor cells and provides neoantigens for the emerging adaptive immune responses. The sequential dual actions of type I interferon production through STING pathway activation and latent cytotoxicity connects the innate and adaptive immune systems.
Method : Antibody drug conjugates (ADCs) employing TSN222 as a payload were characterized for their activities in STING pathway activation and tumor killing by modulating the tumor microenvironment and adaptive immunity against the tumors, through selective tumor targeting by antibody and more convenient administration of i.v. injection.
Results : TSN222 in cell-based assays has shown STING pathway stimulating activity that leads to type I interferon secretion and subsequent cytotoxicity to the cells. TSN222 is well tolerated in preclinical toxicology studies by s.c. administration and Phase 1 clinical trial by i.t. administration. One case of partial response (PR) has been observed during dose escalation at 800μg dosage level. Antibodies against Her2, Trop2 and Claudin18.2, respectively conjugated with TSN222 as a payload, have shown potent tumor growth inhibition (TGI) in antigen specific cancer cell lines and animal models. For example, a single i.v. dose of anti Her2 DATIA ADC at 0.6 mpk in SK-OV-3 her2+ CDX model afforded 109% TGI after 22 days, while the payload TSN222 at 1 mpk i.t. QWx3 gave a TGI of 21%. In EMT6-huHer2+ breast cancer model, a single i.v. dose of the ADC at 3 mpk induced complete remission (CR) at day 20. Upon rechallenging of the CR mice at day 33 with EMT6-huHer2+ and CT26 colorectal tumor cells, TGIs were 64% and -23 % relative to that in naïve mice, respectively, indicating tumor specific immunity was induced in the EMT6-huHer2+ mice.
Conclusion : We have developed a tumor targeting immune stimulating ADC platform with novel mechanism of action that differentiates from other immune stimulating ADC approaches. The dual action of STING pathway activation and subsequent induction of apoptotic signals in tumor cells by the moderately toxic metabolite renders timely presentation of antigens to bridge the innate and adaptive immune system. With the preclinical proof-of-concept studies and ongoing clinical trial data of the payload to inform on safety and tolerability, the DATIA ADC platform is positioned to serve as a distinctly different approach for better safety and efficacy.

#1570 PermaLink®, a stable and scalable bioconjugation platform as an alternative to maleimide-based conjugation.

Adam Lodge, Justyna Mysliwy, **Will A. Stanley**, James Stephenson, Sarah Robinson, Alexander Sanders, Robert Murawski, Bryony Moss, Patrick Higgs, Jutta Deckert, Jenny Thirlway, Robert J. Lutz

Iksuda Therapeutics Ltd., Newcastle Upon Tyne, United Kingdom

IKSUDA Therapeutics' proprietary PermaLink® platform comprises simple, stable, and adaptable conjugation chemistry that overcomes the instabilities associated with the retro-Michael exchange of traditional maleimide-based chemistry. This platform enables ADC generation with a range of drug-to-antibody ratios (DAR) and can be applied to multiple payloads and linker chemistries to improve conjugate properties and maximize the therapeutic index of ADC therapeutics.

ADCs are generated by reducing the hinge region disulfides and/or decapping engineered cysteines with TCEP, conjugation with PL-payload followed by purification. DAR was measured by HPLC. The stability of PL-based ADCs was compared to traditional maleimide-based ADCs in murine and human plasma. In vitro activity and bystander effect were assessed using mono or co-culture experiments by CellTiter-Glo assay. In vivo efficacy studies were conducted in SCID mice with human cancer xenografts. Toxicology and PK studies were conducted in cynomolgus monkeys.

PL-based conjugation followed a simple process of reducing the antibody disulfides with TCEP, conjugation with PL-payload and removal of excess linker toxin by size exclusion chromatography, desalting or filtration. Control of process parameters such as TCEP and linker-payload excesses yielded conjugates with DARs ranging from 4-8 for native wildtype antibodies. Additionally, DAR 10 was achieved for an antibody with two engineered cysteines. The resulting ADCs demonstrated favorable biophysical properties with minimal aggregation by SEC and DAR assessment was consistent by PLRP-HPLC and MS. Typical yields at the research scale ranged from 70-90%.

For preclinical proof-of-concept, MMAE conjugates of Isumab01, targeting FRA, were prepared with a protease-cleavable valine-citrulline (vc) and enzymatically cleavable β-glucuronide (glu) linker. Both PL-based conjugates showed excellent stability in murine and human plasma, whereas FDA-approved maleimide-based ADCs brentuximab vedotin and trastuzumab deruxtecan displayed a significant decrease in DAR. PL-MMAE conjugates were highly potent against JEG-3 cancer cells in vitro, with IC50 values in the pM range. Isumab01-PL-glu-MMAE resulted in complete tumor regression in a JEG-3 xenograft model following a single dose of 2.5 mg/kg and was very well tolerated in cynomolgus monkeys at 12 mg/kg single dose and 10 mg/kg Q3W x2 (highest doses tested), showing improved tolerability over MMAE-based ADCs with maleimide-cathepsin B cleavable linkers. The Isumab01-PL-glu-MMAE conjugate demonstrates a favorable PK profile in monkeys with high stability in circulation consistent with improved bioconjugation.

PermaLink offers a simple, stable alternative to maleimide-based ADC bioconjugation moieties and confers a favorable preclinical anti-tumor activity and safety profile

#1571 Discovery of c-MET degrading bispecific antibodies (EpiTACs) for NSCLC and other c-MET driven tumors.

Jonathan Sitrin, Hai Tran, Lisa Marshall, Kenneth Ng, May Dayao, Jacob Cohen, Kimberly Hoi, Josef Gramespacher, Zhong Huang, Andy Goodrich, Kevin Carlin, Noah Solomon, Shruti Yadav, Aleysha Chen, Katarina Pance, Rami Hannoush, Maia Vinogradova, Isaac J. Rondon, Shyra J. Gardai

EpiBiologics, San Mateo, CA

Extracellular targeted protein degradation (eTPD) has emerged as a promising new drug modality focused on the elimination of pathogenic extracellular and transmembrane proteins. In contrast to intracellular degraders, which require the ubiquitin-proteosome system, extracellular degraders can also harness endosomal-lysosomal protein degradation pathways. EpiTACs are a novel class of bispecific antibody-based eTPD therapeutic, in which one arm binds a target of interest, and the other arm binds a degrading receptor. EpiTACs leverage a novel atlas of disease- and tissue-enriched degrading receptors comprised of transmembrane ubiquitin ligases, cytokine/chemokine receptors, and internalizing receptors, resulting in selective protein degradation. EpiTACs are agnostic of oncogenic mutation status and can deeply antagonize oncogenic signaling through removal of the target and its associated scaffolding function. They also have advantageous pharmacological and drug-like manufacturing properties compared to other degradation technologies. We developed EpiTACs against oncogenic receptor tyrosine kinase family members including cellular mesenchymal-epithelial transition (c-MET) and epidermal growth factor receptor (EGFR). Genomic alterations of c-MET are oncogenic in a variety of cancers, including non-small cell lung cancer (NSCLC), where small molecule inhibitors have been clinically approved for exon 14 skipping mutations. Aberrations in c-MET have also been reported in gastric, colorectal, renal, pancreatic, skin and brain cancers. However, therapeutic benefit to patients has been limited by the broad array of primary and acquired c-MET mutations. Biologics against this target have demonstrated insufficient activity, likely related to antibody-mediated receptor dimerization, and associated pro-oncogenic signaling. A bioinformatics-informed set of cancer-focused degrading receptors was screened in tumor cell-based assays to identify degraders for c-MET. Top hits were enriched in NSCLC and other overexpressed/amplified tumors. c-MET degraders were overlapping and unique compared to previously reported screens conducted against EGFR. They drove internalization and degradation of c-MET in multiple tumor cell-based assays, including those carrying exon 14 skipping mutations and amplifications. Degradation of c-MET robustly inhibited tumor cells in vitro, and strongly suppressed patient-derived xenograft tumor models in vivo. These newly discovered degraders are being paired with novel c-MET binders that lack dimerization-induced signaling capacity, to create safer and more efficacious c-MET degrading therapeutics. In conclusion, eTPD represents a promising new drug modality, and EpiTACs have expanded the toolbox of extracellular targeted protein degraders to address challenging drug targets with a new approach.

#1572 Preclinical activity and safety of STRO-004, a novel ADC targeting tissue factor for solid tumors.

Andrew McGeehan, Helena Kiefel, Brian Vuillemenot, Guifen Xu, Sihong Zhou, Grace Lee, Mark Armanini, Xiaofan Li, Krishna Bajjuri, Miao Wen, Cuong Tran, Jeff Hanson, Daniel Calarese, Amandeep Gakhal, Hanspeter Gerber, Werner Rubas, Gang Yin, **Alice Yam**

Sutro Biopharma, Inc., South San Francisco, CA

Tissue Factor (TF) is a type I transmembrane protein that is aberrantly expressed in multiple solid tumor indications including cervical, head and neck, non-small cell lung, and pancreatic cancers. Its expression is associated with poor prognosis and has been linked to pro-tumorigenic activities such as metastasis, inflammation, and angiogenesis. Under normal physiological conditions, TF plays an important role in blood clotting and, as such, is broadly expressed in many normal tissues, typically in the subendothelium. Upon endothelial damage, TF can combine with clotting factors in circulation to initiate a coagulation cascade, thus constituting a "hemostatic envelope". TF-targeted vedotin ADCs are approved in metastatic cervical cancer and in clinical testing across a range of solid tumor indications. However, toxicities such as peripheral neuropathy, epistasis, and ocular toxicities have been dose-limiting. We have developed STRO-004, a novel TF-targeted ADC with a DAR8 β-glucoronidase-exatecan linker-payload, with enhanced potency and safety in preclinical models. STRO-004 is a TF-targeted ADC, engineered for a wider therapeutic index. The ADC is constructed on an antibody that has been designed to avoid interference in the blood coagulation pathways, thus reducing the potential risk for bleeding. The anti-TF antibody is conjugated to exatecan, a topoisomerase 1 inhibitor, via a β-glucoronidase-cleavable linker (SC3417) at a drug-to-antibody ratio (DAR) of 8. The drug-linker is site-specifically conjugated to the non-natural amino acid p-azidomethylphenylalanine (pAMF) incorporated at optimized sites within the antibody (Ab) sequence using Xpress CF+^{TM}. In preclinical xenograft models, STRO-004 demonstrates potent, dose-dependent activity from 0.25-7.5 mg/kg, including in models with low and heterogeneous levels of TF expression. STRO-004 was evaluated in patient-derived xenograft (PDx) models of cancers with prevalent TF expression and demonstrated 50% overall response rate and 70% disease control rate across all models after single dose treatment. Exploratory toxicology studies show that STRO-004 has a favorable safety profile in cynomolgous monkeys up to 50 mg/kg, the highest dose tested. In circulation, STRO-004 demonstrated extended half-life, low clearance, and stable drug-linkage. Consistent with this finding, only low levels of free exatecan could be detected. Based on these promising preclinical observations, STRO-004 is advancing to IND-enabling studies for the treatment of TF expressing malignancies.

#1573 MW-C1, a novel CLDN1-targeting ADC demonstrates compelling anti-tumor efficacy and favorable safety profile in preclinical studies.

Zhongfei Li[1], Jun Yang[1], Peng Fang[2], Rongrong Hu[1], Cuicui Guo[1], Xiaoding Tan[2], Hai Wu[1], **Xun Gui**[1]

[1]Mabwell (Shanghai) Bioscience Co., Ltd., Shanghai, China,[2]Jiangsu Mabwell Health Pharmaceutical R&D Co., Ltd., Taizhou, China

Background: Claudins are a family of tight junction proteins characterized by four transmembrane domains, with critical roles in epithelial cell junction formation. While claudins localize to tight junctions in healthy tissues, their overexpression in solid tumors leads to aberrant exposure outside of these junctions, making them attractive targets for ADC therapies. CLDN1, in particular, is overexpressed in several solid tumors, including head and neck squamous cell carcinoma (HNSCC), lung squamous cell carcinoma (LUSC), and hepatocellular carcinoma (HCC), where its expression correlates with tumor proliferation, invasion, metastasis, and poor prognosis. Here, we developed a novel CLDN1-targeting ADC, MW-C1, that has shown potent anti-tumor activity across various preclinical models, along with an encouraging safety profile in non-human primates (NHPs).

Methods: MW-C1 was engineered by conjugating monomethyl auristatin E (MMAE) to a CLDN1-targeting monoclonal antibody using site-specific interchain-disulfide conjugation technology and a cleavable linker, resulting in a drug-to-antibody ratio (DAR) of 4. *In vitro*, the internalization and cytotoxicity of MW-C1 were assessed in SCC4, Cal27, Huh7, and OVCAR3 cell lines, which express varying levels of CLDN1. *In vivo* efficacy was evaluated in multiple cell-line-derived xenograft (CDX) and patient-derived xenograft (PDX) models. Toxicology and pharmacokinetic studies were conducted in cynomolgus monkeys.

Results: CLDN1 was found to be overexpressed in 85.7% of HNSCC, 91.7% of HCC, 58% of LUSC, and 77% of cervical cancer samples. MW-C1 demonstrated robust binding, rapid internalization, and potent cytotoxicity in CLDN1-positive cancer cell lines. In *in vivo* studies, MW-C1 induced significant and durable tumor regression in both CDX and PDX models, with varying CLDN1 expression levels. Pharmacokinetic studies revealed favorable properties for MW-C1 in both mice and cynomolgus monkeys, which were attributed to its optimized biophysical characteristics and site-specific conjugation. In a non-GLP NHP toxicology study, MW-C1 was well tolerated, with no significant off-target toxicity or adverse events observed.

Conclusions: MW-C1 demonstrated potent anti-tumor efficacy and a favorable safety profile, highlighting its potential as a transformative therapeutic candidate for the treatment of CLDN1-overexpressing malignancies.

#1576 RenBiologics- a fully human antibody library generated by RenMice facilitates the development of antibody drugs.

Ting Yi, Jun Du, Yue Zhang, Yuting Hu, Shujin Zhang, Xin Ji, Mingyue Gu, Lei Zhang, Yi Yang, **Yong Xie**

Biocytogen, Waltham, MA

Therapeutic antibodies have become important drugs in the field of targeted therapy because of their high specificity to target antigens. Currently, over 100 antibody drugs have been approved for the treatment of various human diseases, yet the targets covered are indeed limited, with approximately half of these drugs targeting only 10 common targets. Approved drugs encompass not only monoclonal antibodies but also antibody-drug conjugates, bispecific antibodies, and antibody fragments. The scarcity of antibody drug targets and subsequent conjugation or engineering modifications pose challenges for the development of novel antibody drugs. In response to the growing demand for fully human antibody drugs, Biocytogen's antibody discovery team has generated a library of antibodies targeting hundreds of antigens using fully human antibody transgenic mice (RenMice). Our RenMice undergo additional gene-editing procedures to knock out designated target genes. Subsequently, antibodies obtained by conventional immunization have a wide range of epitope-binding properties to homologous protein targets, but also exhibit cross-species reactivity. We have completed over 900 fully human antibody target projects and established a library containing over four hundred thousand off-the-shelf fully human antibody sequences. The antibodies generated from RenMice can be used in a variety of applications, and many of the TAA (tumor-associated antigen)-targeting antibodies have been screened for internalization activity to ensure suitability for ADC development. In addition to fully human monoclonal antibody derived from RenMab platform (fully human immunoglobulin variable domains replacing the mouse loci), RenLite-derived common light chain antibodies are easy to assemble into bispecific antibodies (BsAb) with low mismatch rate and ideal physiochemical properties, which are suitable for BsADC, biparatopic antibody (BpAb) and other modalities. Small and flexible fully human nanobodies based on RenNano platform (fully human heavy chain only) also provide solutions for specific antigen epitopes or multi-targets, multi-epitope antigens. Thus, the fully human antibody library can accelerate the development of antibody drugs.

#1577 PF-08046876: A new camptothecin antibody-drug conjugate directed to integrin beta-6 with potent antitumor activity in multiple preclinical solid tumor models.

Rebecca C. Mazahreh, Narayana Yeddula, CB Lim, Gina LoMastro, Nicolas H. Garcia, Vineet Kumar, Christopher Frantz, Lauren Farr, Ryan Lyski, Lori Westendorf, Robert P. Lyon, Vivian H. Trang

Pfizer, Inc., Bothell, WA

Integrins are a large family of cell surface receptors with diverse roles in cellular adhesion, motility, and cytokinesis. Functional integrins exist as heterodimers consisting of single alpha and beta chains. Within this family, integrin beta-6 (IB6), which dimerizes exclusively with integrin alpha-v, is a target of interest in the clinic for its role in cancer. IB6 expression is low in normal adult epithelial tissues and high in solid tumors. In some cases, high IB6 expression has been demonstrated to be associated with poor prognosis such as in non-small cell lung, colorectal, gastric and cervical carcinomas. PF-08046876 is an investigational antibody-drug conjugate (ADC) composed of an anti-IB6 antibody conjugated to a camptothecin-class topoisomerase I (TOPO1) inhibitor, AMDCPT, using a traceless enzyme-cleavable glucuronide linker. The AMDCPT payload was optimized for potency, reduced susceptibility to MDR efflux pumps and enhanced bystander activity. PF-08046876 leverages the same antibody backbone from Sigvotatug Vedotin (SV) and is specific for IB6 but does not bind other alpha-v family members. In preclinical studies, PF-08046876 has demonstrated activity in vitro and in multiple in vivo models spanning a range of antigen expression levels in several solid tumor carcinomas including non-small cell lung, head and neck squamous cell, urothelial, and pancreatic carcinomas. PF-08046876 demonstrates a tolerability profile in non-human primates that is consistent with camptothecin ADCs. These results suggest that PF-08046876 is promising ADC for the treatment of multiple carcinomas and supports further clinical investigation. A Phase 1, first-in-human study is planned to evaluate the safety and anti-tumor activity of PF-08046876.

#1578 Preclinical evaluation of BLB-101, a topoisomerase-inhibitor-based anti-CLDN6/9 antibody-drug conjugate featuring a proprietary hydrophilic linker.

Suk Hyung Lee, Alice Juang, Aastha Jain, Jun Liu, Wen Zhang, Zuoan Yi, Darren Buchwald, **Alice Chen**

Baylink Biosciences, Inc., Palo Alto, CA

Claudin 6 (CLDN6) is a tight junction protein that is highly expressed in various human cancers, including ovarian and endometrial cancers, while it is not found in normal adult tissues. Claudin 9 (CLDN9), which shares significant homology with CLDN6, displays similar expression patterns, being nearly absent in normal tissues but upregulated in ovarian and endometrial cancers. We propose to target both CLDN6 and CLDN9 simultaneously to enhance anti-tumor efficacy and broaden treatment options for more patients. We successfully discovered an antibody that binds with high affinity to CLDN6 and CLDN9 while sparing other claudin family members. The humanized version of this candidate antibody demonstrates stronger binding and higher internalization compared to a benchmark antibody currently in clinical development. BLB-101 is an antibody-drug conjugate (ADC) candidate featuring a topoisomerase-inhibitor-based payload optimized in-house with a proprietary hydrophilic linker. Design features of the linker enable efficient delivery of hydrophobic drug payloads and low likelihood of off-target endocytosis. BLB-101 has drug-to-antibody ratio of 8 (DAR8), demonstrates enhanced potency, favorable in vivo PK, and excellent plasma stability. In vitro studies revealed that BLB-101 ADC quickly internalizes in CLDN6+ or CLDN9+ cancer cells. BLB-101 exhibited strong cytotoxic effects across several cancer cell lines, including PA-1 and JEG-3. In addition, we confirmed the bystander killing effect of BLB-101 under a coculture condition of CLDN6-positive cells and negative cells in vitro. Furthermore, BLB-101 maintains the mAb's capability to induce antibody-dependent cellular cytotoxicity. In xenograft models expressing CLDN6, BLB-101 treatment led to a substantial reduction in tumor size. Additionally, repeated administration of BLB-101 was well tolerated in both mice and in non-human primates. Together, these findings provide strong support for the continued development of BLB-101directed against CLDN6/CLDN9 positive tumors.

#1579 PA289, a prodrug linker-payload with a novel mechanism of action for the development of antibody drug conjugates.

Justyna H. Mysliwy, Jutta Deckert, Adam Lodge, Jenny Thirlway, James Stephenson, Patrick Higgs, Daniel Williamson, Robert J. Lutz

Iksuda Therapeutics Ltd., Newcastle upon Tyne, United Kingdom

Background: PA289, is a novel seco-CBI-based prodrug payload which appears to exert cell-killing activity through the alkylation of one or more cytosolic proteins (Tietze *et al*, 2010). PA289, is the lead linker-payload from our ProAlk payload technology platform and is designed with tumor-selective glucuronide triggers that attenuate the potency of the payload until uptake into target cancer cells and selective release in the lysosome. The glucuronide linker and PermaLink (PL) conjugation chemistry ensure ADC stability. The unique mechanism of action of PA289 compared to currently used chemotherapies and ADC payloads, led us to generate proof-of-concept data for this novel ADC payload.

Methods: The free payload and ADCs were tested for cell-killing activity *in vitro* by CellTiter-Glo assay. The prodrug linker-payload PA289, was conjugated using PermaLink technology to generate ADCs with a drug to antibody ratio (DAR) of approximately 4. Stability was determined in mouse and human plasma and *in vivo* efficacy was performed with subcutaneous human tumor xenografts in nude mice. Bystander effect was analyzed *in vitro* and compared to ADCs composed of MMAE and MMAF payloads. An exploratory toxicology study was conducted in cynomolgus monkeys.

Results: The free payload showed highly potent *in vitro* activity against 248 cancer cell lines representing 15 solid cancer indications with IC50 values in the fM to pM range. Isumab01-PL-PA289, a model ADC targeting FRA, displayed excellent plasma stability and was highly potent against the JEG-3 cell line *in vitro*, with IC50 values in the pM range. A single administration of Isumab01-PL-PA289 in the FRA-positive JEG-3 xenograft model induced complete tumor regression by day 30 when dosed at 2.2 mg/kg, while the Isotype-PL-PA289 non-binding control resulted in weak tumor growth inhibition. Evaluation of bystander killing *in vitro* with a model ADC targeting CA242, Isumab04-PL-PA289, demonstrated stronger bystander cell-killing than benchmark ADCs containing MMAE and MMAF. A pilot toxicity study in cynomolgus monkeys treated with Isumab04-PL-PA289 showed the ADC was well-tolerated with minimal to no test-article related findings at the highest dose tested (7 mg/kg single dose).

Conclusions: ADCs comprised of PA289, a novel protein alkylator prodrug linker-payload, demonstrate 1) strong *in vitro* potency and bystander effect, 2) durable tumor regressions in xenograft models, and 3) excellent tolerability in monkeys. The free payload is highly active against a broad array of cancer cell lines representing a variety of solid tumors suggesting that PA289 is a promising candidate for the development of ADCs with a novel MOA for the treatment of solid tumors.

#1580 HuB14-VA-PL2202, a novel antibody-drug conjugate targeting ASCT2, a novel ADC target over-expressed in both solid and hematological cancers.

Danilo Cucchi, Elizabeth Horsley, Alina Chrzastek, Ben Leatherdale, Simone Sims, Nicole Bledowski, Banusha Rajeenthira, Narinder Janghra, Lara Montolio, Abigail Kimpalu, Christopher Gallagher, Charlie Britten, Lolke de Haan, Paul W. Hogg, Chris Pickford, Patrick H. van Berkel

ADC Therapeutics, London, United Kingdom

SLC1A5 (Solute Carrier family 1 member 5), also known as ASCT2 (Alanine, Serine, Cysteine Transporter 2), is a Na^+ dependent antiporter with its preferred substrate being glutamine. ASCT2 expression is reported in normal tissues, however it has been shown to be dramatically increased in several solid tumors (lung, colorectal) and hematological malignancies (acute myeloid leukemia (AML), multiple myeloma). Moreover, high ASCT2 expression was associated with a worse prognosis in liver and lung cancers. Because of this profile of expression, ASCT2 is an appealing membrane protein for pharmacological targeting. We have developed a new antibody-drug conjugate (ADC) targeting ASCT2 (HuB14-VA-PL2202), composed of a humanized IgG1 directed against human ASCT2, to which PL2202, consisting of a proprietary cleavable linker and exatecan, a topoisomerase I inhibitor, has been site-specifically conjugated with a drug to antibody ratio ~6. FcγR-mediated effector function was abrogated via mutation in the Fc portion of the antibody. The aim of this study was to characterize the *in vitro* cytotoxicity of HuB14-VA-PL2202 in human cancer cell lines, and determine its *in vivo* efficacy. The safety and tolerability of HuB14-VA-PL2202 was also evaluated in cynomolgus monkeys. Membrane expression of ASCT2 was confirmed by IHC in sections from xenograft biopsies and human tissues.*In vitro*, HuB14-VA-PL2202 was readily internalized by ASCT2+ve cancer cells, showed specific binding to CHO cells expressing recombinant human or cynomolgus monkey ASCT2, and displayed potent cytotoxic activity in a range of target positive cancer cell lines, both from solid and hematological tumors. *In vivo*, HuB14-VA-PL2202 dosed once at 6 mg/kg was able to significantly delay tumor growth in the subcutaneous (sc) G-402 human renal leiomyoblastoma cancer xenograft model. Likewise, in the sc MOLM-13 AML xenograft model, HuB14-VA-PL2202 dosed once at 10 mg/kg achieved 5/10 tumor free survivors at the end of the study. In a PK study in human FcRn Tg32 SCID mice, HuB14-VA exhibited a 7.4 day half-life; whilst in a DRF study in cynomolgus monkeys, HuB14-VA-PL2202 was tolerated at 40 mg/kg, indicating there is a favorable therapeutic index. Membrane expression of ASCT2 was confirmed by IHC, in sections of xenograft models and tissue microarray (TMA) of human cancer indications. ASCT2 expression in NSCLC and HNSCC was found to be significantly higher than in the correspondent normal tissue. In conclusion, ASCT2 represents an interesting novel tumor target for an ADC approach. HuB14-VA-PL2202 demonstrated potent and specific *in vitro* cytotoxicity and *in vivo* anti-tumor activity in both hematological and solid tumor models, and was well tolerated in cynomolgus monkeys. Together, the data generated with HuB14-VA-PL2202 warrants its further development into the clinic in cancers over-expressing ASCT2.

#1581 Two novel antibodies targeting different tumor-associated carbohydrate (TACA) antigens for the treatment of solid tumors show promising preclinical activity using different modes of action.

Francesco Muraca, **Wiebke Winkler**, Gustavo M.S.G. Moreira, Fausto G. Gomes, Karla E. G. Soto, Samina Naz, Peter Sondermann, Matthias Ocker

TACALYX GmbH, Berlin, Germany

Tumor-associated carbohydrate antigens (TACAs) are short oligosaccharides that are often overexpressed on the surface of cancer cells. They are derived from changes in glycosylation pathways associated with malignancy, which lead to overproduced or aberrant structures, and represent a still unexplored target class for cancer therapy. We focus on the generation of antibodies against these specific and difficult antigens and were able to obtain two high-affinity monoclonal antibodies (mAbs), TCX-101 and TCX-201, against two distinct TACA structures that are highly expressed across a broad range of cancer indications. Both mAbs show superior affinity and specificity to their target compared to previously generated ones, as assessed by glycan array, flow cytometry, and immunohistochemistry or immunofluorescence. By investigating the characteristics of our glycan targets, we explored different modes of action to tailor the most effective treatment. Previously, our team has shown that TCX-101 can be effectively used as an antibody-drug conjugate (ADC), which showed encouraging results *in vivo* against breast and small cell lung cancer (SCLC). In addition, we here present TCX-101 in a bispecific T-cell engager (TcE) format, showing efficient *in vitro* T-cell activation and killing of cancer cells from different indications endogenously expressing low (SW837), medium (LoVo) to high levels (MCF7) of our TACA target already at an effector:target ratio of 4:1 with antibody concentrations in the pico- to low nanomolar concentration range, i.e. IC50 of 9 nM (SW837), 0.13 nM (LoVo) and 0.0078 nM (MCF7), respectively. *In vivo* evaluation of this TcE is currently investigated using cell-line derived xenograft models in humanized mice. TCX-201, targeting a different TACA, is currently being evaluated as an ADC with two different payloads, monomethyl Auristatin E (MMAE) and Exatecan (XTC). *In vitro* studies show effective killing of various pancreatic (e.g. high expressing HuP-T4 cells with an IC50 for MMAE payload of 0.3 nM) and colon cancer cell lines expressing different levels of the target (e.g. Colo-205 (high expressing) with an IC50 of 0.013 nM or LS180 (medium expressing) with an IC50 of 4.7 nM), and high efficacy for both payloads in a xenograft mouse model using HuP-T4 pancreatic cancer cells. In conclusion, our antibodies against TACAs represent new promising treatment options for different cancer indications and can be effectively employed with different modes of action, depending on the target characteristics.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Apoptosis: Therapeutic Manipulation / Role of Microenvironment in Therapeutic Response
Poster Session

#1586 KH815, a novel dual-payload TROP2-directed antibody-drug conjugate, shows potent antitumor efficacy in pre-clinical tumor model.

Yonghao Zhao, Pengfei Ren, Menglong Guan, Jiao Tang, Lu Qi, Xinzou Fan, Shijun Yin, Gang Lei, Xiao Ke

Kanghong Pharmaceutical Group, Chengdu, China

TROP2 (trophoblast cell surface antigen 2) is expressed at high levels in various human carcinomas and is associated with tumor differentiation and pathological aggression. Several antibody-drug conjugates (ADCs) targeting TROP2, such as sacituzumab govitecan and datopotamab deruxtecan, have shown promising anti-tumor activity in multiple solid tumors, particularly in breast cancer. However, their clinical application remains limited by inadequate efficacy, highlighting the unmet clinical need for improving the efficacy of single payload TROP2-targeting ADCs.This study presents the preclinical evaluation of a novel dual-payload TROP2-targeting ADC, KH815, composed of a humanized IgG1 antibody (hRS7) directed against TROP2 which is conjugated to a topoisomerase I inhibitor(TOP1i) and an RNA polymerase II inhibitor(RNA POL IIi). KH815 achieves an average drug-to-antibody ratio (DAR) of about 7.5 (4+3.5) using cysteine and glycoside antibody coupling technologies with an appropriate DAR, high SEC purity, homogeneous particle size distribution, and favorable thermal stability.The dual mechanism of KH815 enables the simultaneous inhibition of RNA synthesis and the induction of DNA double-strand breaks, resulting in a potent and synergistic anti-tumor effect both in vitro and in vivo xenograft mouse models in comparison to other TOP1i-TROP2-targeting ADCs. In both cell-derived xenograft (CDX) and patient-derived xenograft (PDX) models, KH815 exhibited dose-dependent tumor growth inhibition and demonstrated superior anti-tumor activity compared to the single-TOP1i ADC, at equivalent or even lower doses. Furthermore, KH815 has been shown to be more effective than TOP1i-ADC (sacituzumab govitecan and datopotamab deruxtecan) in tumor inhibition in a PDX model derived from Trodelvy pretreated patients and in a HCT-15 cell CDX model, which expresses P-gp protein, a pump that can extrude DXd. This provides additional evidence that KH815 has the potential to overcome resistance to TOP1i-ADCs. The non-GLP toxicity study in cynomolgus monkeys provided evidence of the favorable safety profile of KH815, the highest non-severely toxic dose (HNSTD) is 40 mg/kg/dose.In summary, KH815, an ADC with dual toxins and unique mechanisms of action, displayed superior anti-tumor effects, the ability to overcome drug resistance, and an acceptable safety profile in preclinical studies. These findings support the potential of KH815 as a promising advanced therapeutic candidate for tumors.

#1587 A novel dual-payload HER3-directed antibody-drug conjugate, shows potent antitumor efficacy in HER3-low *in vivo* tumor models.

Yonghao Zhao, Pengfei Ren, Menglong Guan, Jiao Tang, Lu Qi, Xinzou Fan, Shijun Yin, Gang Lei, Xiao Ke

Kanghong Pharmaceutical Group, Chengdu, China

HER3 (Receptor tyrosine-protein kinase erbB-3) is broadly expressed in several cancers, including breast, lung, pancreatic, colorectal, gastric, prostate, and bladder cancers. Elevated HER3 expression is associated with poor patient outcomes and therapeutic resistance. Several HER3-ADCs have been developed for cancer therapy. To date, patritumab deruxtecan (U3-1402) is the only HER3-targeting therapy that has demonstrated clinical efficacy in both non-small cell lung cancer. But patritumab deruxtecan is ineffective in more challenging tumor type including low HER3 expression tumors.This study presents preclinical evaluation of a novel dual-payload HER3-targeting ADC, KHN922, composed of a humanised IgG1 antibody (patritumab) directed against HER3 which is conjugated to a topoisomerase I inhibitor (TopoIi) and an RNA polymerase II inhibitor (RNA POL IIi). KHN922 achieves an average drug-to-antibody ratio (DAR) of about 7.5 (3.9+3.6) using cystein and glycosite antibody coupling technologies with an appropriate DAR, high SEC purity, homogeneous particle size distribution, and favorable thermal stability.The dual mechanism of KHN922 enables the simultaneous inhibition of RNA synthesis and the induction of DNA double-strand breaks, resulting in a potent and synergistic anti-tumor effect both in vitro and in vivo xenograft mouse models in comparison to other TopoIi-TROP2-targeting ADCs. In low and ultra-low HER3 expression CDX models, the KHN922 demonstrated superior tumor suppression effects compared to single-TopoIi ADCs, patritumab deruxtecan and patritumab exatecan.Furthermore, KHN922 still showed strong activity to DXd-ADC treatment resistance CDX models. The non-GLP toxicity study in cynomolgus monkeys provided evidence of the favorable safety profile of KHN922, the highest non-severely toxic dose (HNSTD) is 50 mg/kg/dose.In summary, KHN922, an ADC with dual toxins and unique mechanisms of action, displayed superior anti-tumor effects, the ability to overcome treatment-resistance and tumour recurrences, and an acceptable safety profile in preclinical studies. These findings support the potential of KHN922 as a promising advanced therapeutic candidate for HER3 tumors.

#1588 The novel trispecific tumor-conditional TRAIL-R agonist M0674 induces tumor cell apoptosis and deepens therapeutic efficacy of systemic and targeted chemotherapies.

Christina Esdar, Doreen Musch, Carolin Sellmann, Ana Hecht, Achim Doerner, Enrico Guarnera, Julian Kreis

the healthcare business of Merck KGaA, Darmstadt, Germany

Background: TRAIL death receptors are upregulated in a wide range of tumors, and their pharmacological activation induces apoptosis. Targeting TRAIL receptors (TRAIL-R) has emerged as a critical therapeutic strategy for cancer treatment. Despite some evidence for preclinical activity with past and present TRAIL-R agonists, only limited clinical efficacy has been reported so far, likely due to insufficient TRAIL-R clustering, decoy receptor binding, and hepatotoxicity. To address these limitations, M0674 has been designed as a trispecific antibody that simultaneously binds to tumor-associated (TA) MUC1, TRAIL-R1 and TRAIL-R2 but not to TRAIL decoy receptors.
Methods: We conducted a detailed pharmacological characterization of M0674 compared to other TRAIL-R agonists through in vitro and in vivo studies. Apoptosis and viability assays were performed on cancer cells and human hepatocytes. The antitumor activity of M0674, both as a monotherapy and in combination with chemotherapy and an anti-CEACAM5 ADC with an exatecan payload (M9140), was evaluated using cell line-derived (CDX) and patient-derived (PDX) xenograft models.
Results: Treatment with M0674 results in potent TA-MUC1-dependent induction of apoptosis and inhibition of viability in cancer cell lines, while human hepatocytes remain unaffected. M0674 demonstrates superior antitumor activity compared to other TRAIL-R agonists in both in vitro and in vivo studies. In vivo models show strong antitumor effects, including regressions, when M0674 is combined with systemic and targeted chemotherapies. MUC1-dependent single-agent activity and combination benefits with docetaxel are observed in three out of five nsqNSCLC PDX models that do not respond to docetaxel alone. Additionally, five out of six PDAC PDX models exhibit a strong combination benefit of M0674 with gemcitabine. Furthermore, the combination of M0674 with the anti-CEACAM5 ADC M9140 induces complete regression in a gastric CDX model.
Conclusion: M0674 induces tumor-specific hyperclustering of TRAIL-R1 and R2 by binding to TA-MUC1, effectively triggering apoptosis in tumor cells without affecting healthy cells. The robust preclinical antitumor activity across various cancer types highlights the potential of M0674 as a safe and effective combination partner for systemic chemotherapies and ADCs.

#1589 Morin activates mitophagy via the PINK1/Parkin pathway, promoting apoptosis and suppressing tumor growth in pancreatic cancer cells.

Vinit Sharma, Mayank Sharma, Ankita Semwal, Ankita Arora, Sakshi Bansal, Anjali Aggarwal

Anatomy, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background: Pancreatic cancer (PC) is an aggressive malignancy characterized by high rates of invasiveness, chemoresistance, and relapse. Mitochondrial dysfunction, often due to mutations or metabolic imbalances, results in excessive ROS production and DNA damage, enhancing tumor aggressiveness. Additionally, stromal fibrosis in PC hinders drug delivery, complicating treatment outcomes. Therefore, we aim to investigate the effect of Morin, a bioflavonoid with antioxidant and anti-inflammatory properties, in promoting mitophagy in PC cells to inhibit tumor progression.
Methods: Experiments were conducted under control and Morin-treated conditions on PANC-1 cells and normal pancreatic epithelial cells. Cytotoxicity was assessed via the MTT assay, while invasiveness, migration, morphology, and stemness were evaluated using colony-formation, transwell, spheroid-formation assays, and ALDH activity. Mitochondrial membrane potential, functional mitochondria, superoxide production, and ROS were analyzed using JC-1, Mitotracker Green/Red, MitoSOX™ Red, and DCFDA dyes. Apoptosis was quantified with Annexin V/PI staining, and ATP synthase activity was measured using ATP Synthase Profiling Kit. Expression of markers related to mitochondrial function, transport, and apoptosis was analyzed via PCR microarray, qRT-PCR, and immunofluorescence.
Results: Morin exhibited a dose- and time-dependent cytotoxic effect on PANC-1 cells, with an IC50 of 50.018 µM at 24 hours. Treatment reduced spheroid size, made them rounder, and formed pores, indicating apoptosis. Morin also decreased colony formation, migration, and ALDH activity, suggesting reduced cancer stem cell properties. JC-1 staining showed a lower mitochondrial membrane potential, while DCFDA indicated reduced ROS, and MitoSOX Red revealed increased superoxide levels. Mitotracker Red/Green staining indicated fewer dysfunctional mitochondria. Following Morin treatment, Annexin V/PI staining showed significant increases in apoptosis and reduced ATP synthase activity ($p = 0.0286$). Microarray results indicated significant downregulation of genes related to mitochondrial fusion (MFN2, $p = 0.000616$), and apoptosis regulator (SH3GLB1, $p = 0.037$). qRT-PCR and immunofluorescence showed Morin upregulated mitophagy genes (PINK1, Parkin), autophagy markers (LC3b), and apoptosis markers (Cytochrome c), while increasing epithelial markers (E-Cadherin) and decreasing mesenchymal (N-Cadherin, Snail, ZEB1), and stemness markers (Sox2, Nanog, OCT4). *In silico* docking showed stable binding of Morin to mitophagy marker PINK1 (docking score: -8.3 kcal/mol).
Conclusion: Morin targets mitochondrial dysfunction via the PINK1/Parkin pathway, promoting apoptosis and reducing cancer cell survival, highlighting its promise as a potential therapeutic agent.

#1591 Mechanisms of BPM31510-induced cell death in cancer: lipid peroxidation and apoptosis pathways.

Abbas Khojasteh[1], Michael A. Kiebish[2], Lisa Ghiglieri[1], Sylwia Stopka[2], Juan J. A. Aristizabal-Henao[2], Seema Nagpal[1], Maria-D Nastke[2], Stephane Gesta[2], Niven R. Narain[2], Vijay Modur[2], Lawrence Recht[1]

[1]Stanford University, Palo Alto, CA,[2]BPGbio, Framingham, MA

BPM31510, an oxidized Coenzyme Q10 (CoQ10) nanodispersion, has shown potential as an anticancer agent through its ability to induce the generation of reactive oxygen species (ROS) within the mitochondria of cancer cells. Recent studies have highlighted ferroptosis — a form of regulated cell death driven by iron-mediated lipid peroxidation, as a promising mechanism for cancer therapy, particularly for cancers that are highly vulnerable to oxidative stress. Ferroptosis differs from apoptosis in that it involves the accumulation of ROS, leading to lipid peroxidation and cell membrane damage, rather than DNA fragmentation and caspase activation characteristic of apoptosis. Given the strong correlation between BPM31510-induced cytotoxicity and elevated ROS levels, we investigated if BPM31510 induces cancer cell death through ferroptosis. To evaluate lipid peroxidation, we assessed both cancerous (HT1080, U87, GL261 and C6) and non-cancerous cells (NIH 3T3, TNC1, rat astrocytes, and human astrocytes). Lipid peroxidation was quantified using the fluorescent probe BODIPY 581/591. Cells were treated with BPM31510 and Erastin (a ferroptosis inducer) for 3 hours, and fluorescence intensity was measured to assess lipid peroxidation levels. To address whether BPM31510-induced cytotoxicity involves ferroptosis, we performed a cytotoxicity assay with additional conditions including Ferrostatin-1 (a ferroptosis inhibitor) combined with BPM31510 or Erastin. Inhibition of lipid peroxidation by Ferrostatin-1 would suggest ferroptosis involvement. Lastly, we assessed cell death pathways using annexin V and propidium iodide (PI) staining to distinguish apoptotic versus necrotic cell death in cells treated with BPM31510. BPM31510 treatment resulted in significantly elevated lipid peroxidation in cancer cell lines (HT1080, U87, Gl261, C6) compared to healthy cells (NIH 3T3, TNC1, astrocytes), suggesting differential vulnerability of cancer cells to BPM31510-induced oxidative stress. Although Ferrostatin-1 significantly reduced lipid peroxidation induced by Erastin, it did not reverse the lipid peroxidation caused by BPM31510. This resistance to Ferrostatin-1 indicates that BPM31510's cytotoxic effects are independent of ferroptosis, distinguishing its mechanism from that of traditional ferroptosis inducers. Apoptosis assays further confirmed that BPM31510 predominantly activates apoptotic pathways, with limited necrotic cell death observed**.** Our findings demonstrate that BPM31510 differentially induces lipid peroxidation in cancer cells through a mechanism independent of ferroptosis, instead activating apoptosis as the primary pathway of cell death. The ferroptosis-independent cytotoxicity of BPM31510, combined with its selective targeting of cancer cells, highlights its potential as a unique therapeutic agent in glioblastoma.

#1592 Targeting cFLIP to overcome resistance of BRAF V600E melanoma cells with the small molecule CB001.

Claire Lin[1], Matthew J. Hadfield[2], Connor Purcell[3], Shengliang Zhang[3], Vida Tajiknia[3], Wafik S. El-Deiry[3], Benedito A. Carneiro[2]

[1]The Warren Alpert Medical School of Brown University, Providence, RI,[2]Hematology-Oncology Division, Brown University Health, Providence, RI,[3]Department of Pathology and Laboratory Medicine, Brown University, Providence, RI

Background: Over 50% of metastatic melanoma harbor activating BRAF V600E mutations. Vemurafenib selectively inhibits mutant BRAF. However, resistance to vemurafenib frequently develops within a few months of initiating treatment. Vemurafenib-induced apoptosis is inhibited by overexpression of cellular FADD-like IL-1β-converting enzyme-inhibitory protein (cFLIP), an endogenous inhibitor of caspase 8 in the extrinsic apoptosis pathway. Studies have also shown that suppression of cFLIP expression restores the extrinsic pro-apoptotic pathway in melanoma cells. Thus, targeting cFLIP with CB001, a novel cFLIP inhibitor, may represent a novel therapeutic strategy to overcome resistance to BRAF inhibitor in melanoma.
Methods: We investigated the prevalence of cFLIP and BRAF molecular alterations in melanoma and its impact on patient survival using The Cancer Genome Atlas (TCGA) dataset. We investigated cytotoxic effects of CB001 (0-10μM) or the BRAF inhibitor vemurafenib (0-500nM) in BRAF V600E melanoma cell lines (RPMI-7951, SH4, SK-MEL28). Combination indexing for dual treatment with CB001 [0-10μM] and vemurafenib [0-500nM] was performed on SynergyFinder. cFLIP and cPARP expression was investigated after treatment with CB001 (10μM) +/- vemurafenib (400nM) at 24 hours by western blot (WB). Melanoma cells were co-cultured at a ratio of 1:5 with natural killer cells (NKc) in the presence of CB001 (10μM), and fluorescent co-culture images were quantified using the MetaXpress cytoplasmic/nuclear staining software.
Results: cFLIP alterations are frequently enriched in patients with BRAF-mutated tumors (p= 4.049e-3), and amplification of the gene encoding cFLIP is correlated with inferior overall survival compared to wild type tumors. Single-agent CB001 showed variable cytotoxicity across melanoma cell lines, with RPMI-7951 (13.4μM) requiring a higher IC50 than SH4 (3μM) and SK-MEL28 (1.29μM). While interaction between CB001 and vemurafenib was only additive, the combination treatment did overcome apoptosis resistance in vemurafenib-resistant RPMI-7951 (vemurafenib IC50 > 500nM). CB001 with vemurafenib decreased cFLIP expression and increased PARP and caspase 8 cleavage on WB, consistent with increased extrinsic apoptosis pathway activation, in RPMI-7951. CB001 also increased immune-mediated NKc killing of RPMI-7951 (p=6.23e-4), SH4 (p=5.5e-4), and SK-MEL28 (p=5.55e-4) cells in co-culture experiments at a 5:1 NKc:melanoma ratio.
Conclusion: CB001 demonstrates potent cytotoxicity in metastatic melanoma cell lines and may overcome resistance to vemurafenib via downregulation of cFLIP and activation of the extrinsic apoptosis pathway. CB001 also enhances immune-mediated NKc killing of melanoma cell lines, suggesting that targeting cFLIP has an immunomodulatory effect in addition to direct tumor cytotoxicity.

#1594 Lipid-laden macrophages are associated with KRAS therapy resistance in pancreatic cancer.

P. Hou, T.-y. Chu, Y. Huang, D. Deng, H. Begum;
Rutgers New Jersey Medical School, Newark, NJ

Our recent discovery in pancreatic ductal adenocarcinoma (PDAC) demonstrates that tumor-associated macrophages (TAMs) are pivotal in driving resistance to KRAS-targeted therapy. Using a genetically engineered mouse (GEM) model of PDAC with doxycycline-inducible $KRAS^{G12D}$, pancreas-specific p48-Cre, and conditional p53 knockout (known as "iKPC"), we found that myeloid cell remodeling from a neutrophil-rich to a macrophage-rich phenotype occurred after KRAS depletion. TAMs were sufficient and essential for PDAC cells to bypass KRAS dependency. Consistent with our findings, KRAS inhibition (KRASi) rewired the tumor microenvironment (TME) with increased TAM presence in several cancer models, including those of the pancreas, colon, and lung. However, the exact role of TAMs in promoting or impairing KRASi resistance remains controversial. Considering the heterogeneous, plastic, and multi-functional features of TAMs, we performed single-cell RNA sequencing (scRNA-seq) to compare KRAS on and off tumors from iKPC GEM. We identified two major subclusters of TAMs: *Siglecf*+ and *Apoe*+, with only *Apoe*+ TAMs expressing high levels of *Ccr2*, indicating their origin from circulating macrophages. Both subclusters express immune regulatory genes, but genes related to cholesterol homeostasis are upregulated in *Apoe*+ TAMs compared to other cell types. Notably, lipid metabolism regulatory gene signatures are significantly enriched in TAMs from KRAS off tumors versus KRAS on tumors. Specifically, we observed upregulation of genes encoding scavenger receptors, lysosome enzymes, lipid binding proteins, galectins, and complement factors in TAMs from KRAS off tumors versus KRAS on tumors, resembling the characteristics of lipid-laden macrophages. Lipidomic profiling comparing tumor-educated macrophages (TEMs) exposed to conditional media from KRASi pre-treated KPC (*p48*-Cre, $p53^{Lox/+}$, LSL-$KRAS^{G12D}$) PDAC cells (KRASi CM) and DMSO control (DMSO CM) revealed that the most significantly increased lipids were phospholipids, very long chain fatty acids, and ultra-long chain fatty acids. After examination of the expression of rate-limiting enzymes and key receptors involved in fatty acid synthesis, breakdown, and transportation, we found that *Elovl1* and *Abcd1* were significantly upregulated in TEMs exposed to KRASi CM compared to those exposed to DMSO control CM. Consistently, lipid content was higher in KRASi CM-treated TEMs compared to controls, as shown by BODIPY staining. Additionally, we observed an increased number of peroxisomes in KRASi CM-treated TEMs compared to control TEMs. These data collectively indicate that macrophages associated with KRASi-treated tumors exhibit aberrant accumulation of fatty acids.

#1595 Transforming tumor terrain: Effect of datopotamab deruxtecan (Dato-DXd) on the tumor microenvironment in three-dimensional explant lung tumor models.

K. F. Goliwas, S. C. Chabattula, A. Ismail, J. M. Donahue, B. Wei, T. S. Winokur, J. S. Deshane, Y. Boumber, A. Desai;
University of Alabama at Birmingham, Birmingham, AL

Introduction: Antibody-drug conjugates (ADCs) targeting Trop-2 (human trophoblast cell surface antigen 2) are a promising class of therapeutics with potential to enhance therapeutic outcomes for non-small cell lung cancer. Dato-DXd, a Trop-2 targeted ADC, has demonstrated encouraging activity, leading to further interest in testing combinatorial approaches. However, a greater understanding of its effects on the tumor microenvironment (TME) are needed to identify optimal combinations. Herein we examine tumor-stromal interactions in response to Dato-DXd in ex vivo three dimensional-lung tumor models (3D-LTMs).

Methods: 3D-LTMs were generated utilizing freshly isolated, remnant human lung tumor specimen from patients undergoing tumor resection (Institutional Review Board approved protocol) and continuously perfused with culture media to provide nutrient circulation. Starting on day 3 of culture, 4, 6, or 8 mg/kg Dato-DXd or vehicle control was added to circulating media. Dato-DXd used in this study was purchased from a 3rd party commercial vendor (MedChemExpress). On day 14 of culture (day 11 of ADC treatment) histologic and flow cytometry analyses were performed.

Results: An increased trend in the percentage of apoptotic cells (18.5±1.5 vs. 13±1.5; p=0.13) was noted with 6 mg/kg Dato-DXd when compared to vehicle control. Additionally, a significant reduction in the percentage of tumor cells (p=0.025) and a significant increase in non-viable tumor cells (p=0.047) was observed with this dose when compared to vehicle treated tissues. No differences in fibroblasts, $CD45^+$ immune cells, $CD8^+$ T cells, endothelial cells, or non-viable fibroblasts was observed between 6 mg/kg Dato-DXd and control. When an 8 mg/kg dose was utilized a significant increase in total $CD45^+$ immune cells (p=0.0007) and $CD8^+$ T cells (p=0.012) and an increasing trend in endothelial cells (p=0.099) was observed when compared to vehicle control. No significant changes in apoptosis, tumor cells, fibroblasts, or non-viable tumor cells or fibroblasts were observed when comparing this dose to control. When proportions were normalized to reduce variability across tissues, an increase in apoptotic cells was observed in 3 of 5 samples assessed at 4 mg/kg, and 4 of 5 samples at 6 and 8 mg/kg. An increase in immune cells ($CD45^+$) was observed in 3 of 5 samples at 6 and 8 mg/kg. An increase in $CD8^+$ T cells was observed in 3 of 5 samples at 8 mg/kg.

Conclusion: We observed a notable trend towards an increase in immune cell populations (e.g. $CD8^+$ T cells) following Dato-DXd treatment in 3D-LTMs. These preliminary findings indicate an enhanced anti-tumor immune response following treatment with Dato-DXd. Collectively, data suggest that Dato-DXd induces significant alterations in the TME which may facilitate the evaluation of rational drug combinations to amplify the anti-tumor response.

#1596 Tumor-derived RAC1^{A159V} gain-of-function mutation promotes an immunosuppressive tumor microenvironment and represses response to immune checkpoint inhibitors.

M. Cai, M. Adam, F. Guo, Y. Zheng;
Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Immune checkpoint inhibitors (ICIs) specifically target immune checkpoint molecules and activate cytotoxic T lymphocytes (CTLs) to kill cancer cells and have seen great success in various solid tumors. However, the overall response rate of ICI monotherapy in patients is only ~15% due to an immunosuppressive microenvironment of many tumors, and understanding the mechanism of ICI therapy resistance is urgently needed to improve the outcomes. RAC1, a member of Rho GTPase family, regulates multiple cellular processes in cancer, including vesicle trafficking, glycolysis, gene transcription, and exocytosis/endocytosis, all of which are tightly associated with the creation of a tumor immune microenvironment (TIME). RAC1^{A159V} is a gain-of-function mutation found in several cancer types including colon cancer, head and neck cancer, and lung cancer, and is related to poor prognosis. Mammalian target of rapamycin (mTOR) signaling, one of the downstream effectors of RAC1, promotes tumor progression via diverse mechanisms including glycolytic metabolism and tumor cell proliferation. To define the role of RAC1^{A159V} in cancer immune therapy, we have generated RAC1^{A159V} knock-in MC38 colon cancer cells by CRISPR/Cas9 gene editing. PAK-PBD pull-down assay and western-blotting confirmed that RAC1^{A159V} mutation resulted in upregulated RAC1 activity and mTOR signaling *in vitro*. In subcutaneous MC38 tumor xenograft models we found that while MC38 RAC1^{A159V} tumor grew similarly as RAC1^{WT} tumor cells in immunodeficient mouse recipients, it grew faster than RAC1^{WT} tumors and are highly resistant to anti-PD1 therapy in immune competent mice. Flow cytometry analysis revealed that the RAC1^{A159V} tumors have an immunosuppressive TIME with a significantly higher Treg/CTL ratio than RAC1^{WT} tumors. ScRNA-seq of the whole tumors showed that RAC1^{A159V} tumor is a “cold” tumor with suppressed tumor-immune cell interactions. Deep RNA-seq analysis of the tumor cells further indicated that RAC1^{A159V} activates mTORC1 signaling in tumor cells, which in turn increases tumor cell glycolysis and inhibits chemokine production. Rapamycin, a mTORC1 inhibitor, could sensitize RAC1^{A159V} tumors to anti-PD1 treatment by inhibiting tumor glycolysis and promoting chemokine production in tumor cells. RT-qPCR studies further indicated that inhibiting RAC1^{A159V} tumor cell glycolysis by 2-DG also enhanced chemokine production in vitro, similar to the effect observed with rapamycin. Overall, our studies demonstrate that tumor-derived RAC1^{A159V} mutation turns the TIME to “cold” and renders the tumor resistant to ICIs via mTOR mediated changes in glycolysis and chemotaxis. The results provide mechanistic insights of RAC1 mutation-mediated TIME and suggest a combination therapeutic approach for “cold” tumors by combining RAC1 signaling inhibition with ICIs.

#1597 Immune suppression of the lymph node microenvironment causes oligoprogression of metastatic cancer after neoadjuvant immuno-chemotherapy.

P. Ding[1], X. Huang[1], Q. Peng[1], K. Ren[1], L. Gong[2], B. Wang[2], **L. Yang**[1];

[1]Shenzhen People's Hospital（The Second Clinical Medical College，Jinan University；The First Affiliated Hospital, Southern University of Science and Technology）, Shen Zhen, China, [2]Genecast Biotechnology Co., Wuxi, China

Oligometastatic disease is recognized as an intermediate state between localised and systemically metastasised disease. The diagnosis, treatment and prognosis of oligometastatic disease is currently based mainly on imaging examination. Previous clinical studies indicated that standard systemic therapy followed by radical local therapy was beneficial for survival in tumor patients with oligometastatic disease. However, different clinical outcomes (such as oligopersistant and oligoprogression) were found in synchronous and/or metachronous oligometastatic disease after the same systemic therapy. This report explored potential factors of different outcomes in tumor patients with oligometastatic disease after neoadjuvant immuno-chemotherapy. A lymphoepithelioma-like carcinoma (LELC) case with stage IIIa was synchronous oligometastatic disease, which was treated with neoadjuvant immuno-chemotherapy (four courses of Albumin-Bound Paclitaxel (300 mg), Carboplatin (400 mg) and Durvalumab (500 mg)) and subsequent surgery. Lymph nodes 1R and 4R were considered as oligoprogression and oligopersistant, respectively. Whole exome sequencing results showed that single nucleotide variation (SNV), copy number variation (CNV), tumor mutational burden (TMB), microsatellite instability (MSI), human resource development (HRD) and mutant-allele tumor heterogeneity (MATH) were similar between 1R and 4R samples. Tumor-infiltrating immune cells using a multiplex immunoflourescence histochemistry (mIHC) test revealed that immune checkpoints PD1, PD-L1 and CD39 were high expression and there was a low level of CD8+ T cell in the 4R sample. But levels of CD39+CD8+ and PD-L1+CD8+ T cells were higher in the 1R sample than the 4R sample, suggesting a suppressive tumor immune microenvironment in the 1R oligoprogression lymph node. To demonstrate the result, oligometastatic samples from eight non-small-cell lung cancer (NSCLC) cases with neoadjuvant immuno-chemotherapy and surgery were examined using the mIHC. The results indicated that CD39+CD3+/PD-L1+CD3+/TIM3+CD3+ T cells and/or CD39+CD68+ macrophages in the oligometastatic samples with oligoprogression were high levels. Thus, suppression of tumor-infiltrating immune cells might result in one major factor of different outcomes in oligometastatic disease after neoadjuvant immuno-chemotherapy. Funding Sources: This work was supported by the Wu Jieping Medical Foundation (320.6750.2024-16-16).

#1598 Involvement of atypical PKCs in liver cancer.

Abigail Oluwafisayo Olatunji, Mahfuza Marzan, Nuzhat Nowshin Oishee, Mildred Acevedo-Duncan

University of South Florida, Tampa, FL

The liver is an essential organ in the human body, it carries out important biological functions including detoxification, nutrient metabolism, protein synthesis, production of bile and other biochemical reactions necessary for growth. Liver cancer is a disease in which cancer cells form in the tissues of the liver. The death rate for liver cancer was 6.6 per 100,000 men and women per year. HepaRG is an immortalized hepatic cell line that retains many characteristics of primary human hepatocytes while HEPG2 and PLC5/PRF/5 are liver cancer cell lines isolated from liver cancer donors. Atypical Protein Kinase C (aPKC) is a type of protein kinase that does not require Ca2+ or diacylglycerol for their activation, aPKC consists of two isoforms: PKCiota (PKC-ι) and PKCzeta (PKC-ζ). We have previously reported the dose dependent response of HEPG2 and PLC5/PRF/5 cell line to treatment with 5-amino-1-(1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide (ICA-1S). However, there is no clear understanding of which intracellular chemicals are involved in liver cancer progression and what the involvement of aPKCs is in liver cancer. In this study, we investigated the status and function of aPKC in proliferating and confluent liver cells, our objective was to determine if the expression of PKC-ι and PKC-ζ are altered in liver cancer cells compared to normal liver cells. HepaRG, HEPG2, and PLC5/PRF/5 cells were seeded in 100mm plates and maintained with fresh media. Samples from each cell line were collected in lyses buffer at 50% and approximately 100% confluence. The protein concentration of the prepared samples was quantified with Bradford, Laemmli buffer was added, samples were heated, and Western blot analyses were carried out with equal amounts of protein. Samples were probed for PKC-ι, PKC-ζ, and Caspase3. There was a 32% downregulation of PKC-ι in the HepaRG cell line and a 37% and 9% upregulation were observed in HEPG2 and PLC5/PRF/5 respectively for the expression of PKC-ι as the liver cancer cells gain confluency (N = 3). The results for the expression of PKC-ζ showed a 26% downregulation in HepaRG but a notable 61% upregulation in HEPG2 and a slight 12% upregulation in PLC5/PRF/5 at 100% confluence (N = 3). The unchanged caspase 3 expression confirms that the difference in the expression level of the aPKC is not due to apoptosis. Results demonstrated a relationship between cell confluence and aPKCs protein levels depicting that PKC-ι along with PKC-ζ, play a different role in proliferation of the normal liver cells compared to liver cancer cells. Our ongoing investigation on the effect of aPKCs through the knockdown of PKC-ι resulted in about 30% reduction of HEPG2 proliferation

#1599 CD40L-dependent regulation of BIM leads to lymphoma survival and therapy resistance in protective niches.

Candice Madiot[1], Celine Bellanger[1], Christelle Dousset[1], Salome Decombis[1], Antonin Papin[1], Agnes Moreau-Aubry[1], Benoit Tessoulin[2], Catherine Pellat-Deceunynck[1], David Chiron[1]

[1]INSERM U1232 (CRCINA), Nantes, France,[2]Centre Hospitalier Universitaire de Nantes, Nantes, France

Introduction: Mantle Cell Lymphoma (MCL), an aggressive B-cell lymphoma, is tightly dependent on the microenvironment (TME) for expansion and a dynamic cellular dialogue within lymph node (LN) niches results in ecosystem corruption and tumoral resistance. Within the TME, we identified modulations of the BCL2 family, including a deep inhibition of the pro-apoptotic protein BIM. The aims of this project were to identify the molecular pathways involved in the TME-dependent regulation of BIM and to evaluate the functional consequences in tumor survival and resistance.

Methods: To decipher TME-dependent molecular regulations, we performed RNA-seq and ATAC-seq of MCL and normal B cells (NBC) in culture models previously set up to mimic signals observed in the LN ecosystem (Chiron et al., Blood, 2016). Identified hits/pathways were validated by qPCR and Western Blot. To evaluate the functional consequences of BIM inhibition, we generated BIM-/- MCL cells using CRISPR/Cas9 and performed BH3-profiling, drug testing (chemo, targeted and immune-therapies), serum-free survival studies and *in vivo* tumor growth assays in CAM model.

Results: MCL cells stimulated by CD40L (T-cell signal) recapitulated BIM regulation, which was tumor-specific. Unsupervised analysis of annotated BIM transcription factors, using RNA-seq and TOBIAS (Transcription factor Occupancy prediction By Investigation of ATAC-seq Signal) analysis, highlighted FOXO1 as a candidate for MCL-specific and CD40L-dependent regulation of BIM. FOXO1 nuclear exclusion was further observed upon CD40L stimulation. Downstream of CD40, we demonstrated activation of the AKT, ERK and NFKB pathways. The involvement of AKT and/or ERK pathways in FOXO1/BIM regulation are under investigation. Functional studies showed an increased survival of BIM-/- cells in serum-free condition and an increase tumor growth *in vivo.* While primary MCL cells do not survive without TME support *ex vivo,* BIM-/- cells derived into TME-independent cell lines, reinforcing the association between BIM expression and tumor dependence to their TME. This is also consistent with BIM deletions being enriched in MCL lines. In addition, BIM -/- cells showed reduced mitochondrial priming and resistance to therapies (chemo, targeted). In contrast, T-cell engager efficiently killed both WT and BIM -/- lines, suggesting that modern immunotherapies could overcome BIM downregulation associated resistance.

Conclusions: By integrating high-throughput technologies and cutting-edge functional studies, we have identified BIM inhibition as a TME-dependent source for therapeutic resistance and tumor cell survival. Innovative therapies, such as bispecific T-cell engager, could counteract this TME-induced resistance and provide new strategies for patients with these high-risk hemopathies.

#1600 Tracking adaptation and response to targeted therapies in EGFR-mutant non-small cell lung cancer.

Regina Hoo[1], Aaron Tan[1], Dawn Lau[1], Komal Gupta[2], Kenneth Chow[1], Jia Chi Yeo[3], Lan Ying Wang[1], Poh Sheng Joe Yeong[2], Anders J. Skanderup[3], Daniel S. W. Tan[1]

[1]Division of Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore,[2]Agency for Science, Technology and Research, Institute of Molecular Cell Biology, Singapore, Singapore,[3]Agency for Science, Technology and Research, Genome Institute of Singapore, Singapore, Singapore

Non-small cell lung cancer (NSCLC) accounts for the majority of lung cancer cases, with EGFR-mutant NSCLC among never smokers being particularly prevalent in Asian populations. A major clinical challenge in treating advanced NSCLC is the development of resistance to targeted tyrosine kinase inhibitors (TKIs), highlighting the need to comprehensively profile the cellular mechanisms underlying drug resistance. We propose to tackle this by investigating the adaptive features of residual cancer cells and the role of the tumour microenvironment in sustaining tumour growth, resistance, and disease progression. In this study, we utilise single nucleus and spatial transcriptome profiling to decipher the response of EGFR-mutant tumours in more than 30 NSCLC patients before and during on-TKI treatment, including those that have developed resistance. We present an analytical framework that maps individual residual cancer cell populations that persist after treatment. We then examine the functional phenotypes of neighbouring immune cells including T lymphocytes and mononuclear phagocytes on these populations, and then comparing the immune dynamics to tumours that have fully acquired resistance. Our study reveals a potential mechanism by which metabolic plasticity and paracrine signaling from myeloid cells in the lung tumour microenvironment contribute to the maintenance of cancer stem cell properties, likely driving disease recurrence. We propose to incorporate a wider range of ongoing clinical trial and preclinical data to support our current findings, and with the aim of defining novel therapeutic strategy that can selectively eliminate drug tolerant persister population in EGFR-mutant NSCLC.

#1601 Advancing cancer immunotherapy: Unveiling the potential of PD-L1-targeted IFN-α2a dutaflip molecule through patient-derived tumor explants.

Steffen Dettling[1], Martina Antoniolli[2], Kerstin Patzold[2], Manuela Gies[2], Jakob Rosenhauer[2], Jens Liedke[2], Laura Krumpelmann[2], Marion Lichtenauer[2], David Lamparter[3], Tai-Hsien Ou Yang[4], Petra Schwalie[5], Gabriel Schnetzler[6], Andreas Roller[7], Moritz Rapp[2], Meher Majety[2], Pablo Umana[8], Marina Bacac[8]

Hoffman-La Roche AG, Basel, Switzerland,[6]Project Team Leaders, F. Hoffman-La Roche AG, Basel, Switzerland,[7]Biomarker Strategy and Integrative Sciences, F. Hoffman-La Roche AG, Basel, Switzerland,[8]pRED oDTA, F. Hoffman-La Roche AG, Zurich, Switzerland

This study aims to elucidate the mode of action (MoA) of the programmed cell death ligand 1 (PD-L1)-targeted Interferon alpha (IFN-α2a) Dutaflip molecule (RO7694744) in human patient-derived tumor explants (PTEs). PTEs are highly translationally relevant models due to their ability to closely mimic the native tumor microenvironment (TME) and maintain the heterogeneity of patient-specific tumor biology. The goal is to evaluate the specificity and efficacy of immune responses in preclinical development. RO7694744 is a trivalent bispecific antibody-cytokine fusion protein designed to specifically activate IFN-α on PD-L1 positive cells. This targeted activation enhances anti-tumor immune responses while minimizing systemic toxicity and non-specific activity.

Fresh human PTEs from various cancer types (non-small cell lung cancer (NSCLC) n=16 and bladder cancer (BLCA) n=5) were cultivated ex vivo in a dynamic flow 3D cultivation system (MIVO), and treated with RO7694744 for 20 hours. Untreated samples and those treated with recombinant human IFN-α2a (rhIFNAα2a) served as negative and positive controls, respectively. After cultivation, cytokine secretion was analyzed, and single nucleus RNA sequencing (snRNA-seq) was performed to evaluate immune responses and transcriptional changes at the single-cell level. Comprehensive baseline characterization, including clinically relevant histopathological analysis, bulk RNA sequencing, and flow cytometry analyses, was conducted to correlate drug response with tumor-intrinsic features.

RO7694744 treatment induced a consistent cytokine response (IP-10, ISG-15, IFNg) across NSCLC and BLCA samples, comparable to rhIFNAα2a but to a slightly lower extent. Pearson correlation revealed a positive relationship between PD-L1 positive cells and elevated cytokine response levels in samples treated with RO7694744, a specificity not observed with rhIFNAα2a. SnRNA-seq data analysis identified 44 cellular subpopulations, with a preferential activation of PD-L1 positive tumor cells and immune cells by the RO7694744. This activation was characterized by an up-regulation of an inflammatory gene signature in PD-L1 positive cells, not seen in untreated conditions.

In summary, RO7694744 demonstrates a specific immunomodulatory effect on PD-L1 positive tumor and immune cells, inducing a targeted inflammatory response. The use of fresh human PTEs in this study resulted in translationally-relevant findings, underscoring the PTE model as an advanced next-generation tumor model for the precise evaluation of cancer immunotherapies. These findings enhance the understanding of RO7694744's MOA, confirming its PD-L1-dependent tumor targeting and activity within the TME. This supports a patient selection strategy and identifies clinically-relevant pharmacodynamic biomarkers.

#1602 Advancing personalized medicine using precision-cut tumor slices - assessing individual responses to immunotherapy in the tumor microenvironment.

Julia Thiel[1], Jan Schlegel[1], Adrian Kneer[2], Sascha Dreher[3], Annelie Schafer[4], Oliver Seifert[4], Katrin S. Kurz[5], Marc-H Dahlke[6], Georg Sauer[2], Gerhard Preissler[3], Laureano Simon[7], Myriam Fabre[7], Isabel Egana[7], Roland Kontermann[4], Monilola Olayioye[4], German Ott[5], Walter E. Aulitzky[8], Thomas E. Murdter[1], Matthias Schwab[1], Meng Dong[1]

[1]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, Stuttgart, Germany,[2]Department of Gynecology and Obstetrics, Robert Bosch Hospital, Stuttgart, Germany,[3]Department of Thoracic Surgery, Robert Bosch Hospital, Stuttgart, Germany,[4]Institute of Cell Biology and Immunology, University of Stuttgart, Stuttgart, Germany,[5]Department of Clinical Pathology, Robert Bosch Hospital, Stuttgart, Germany,[6]Department of Surgery, Robert Bosch Hospital, Stuttgart, Germany,[7]Oncomatryx Biopharma S.L., Derio, Spain,[8]Department of Oncology, Robert Bosch Hospital, Stuttgart, Germany

Immunotherapies have emerged as a promising pillar for cancer therapy. However, due to their reliance on the individual, complex and dynamic tumor microenvironment, treatment success remains limited to a subset of patients. A deeper understanding of the response of individual tumors and their heterogeneous microenvironment is essential to improve patient stratification and develop novel treatment approaches. This requires suitable model systems which allow tracking of the tumor microenvironment‘s (TME) response to immunotherapy.

In this study, we combined patient-derived precision-cut tumor slices (PCTS) with multiplex immunofluorescence staining and cytokine analyses to trace the treatment response of different cell types in their native TME while preserving their location. PCTS derived from ovarian cancer, lung cancer and colorectal cancer tissue (n=13) were treated with OMTX305, an anti-FAP T-cell engaging bispecific antibody, for up to three days. A co-culture system integrating PCTS with autologous PBMCs was established to mimic the *in vivo* environment, and enable monitoring of immune cell activities. While treatment responses were patient-specific, determination of overall ATP levels of PCTS showed a significant decrease in viability after three days of treatment. Multiplex immunofluorescence stainings were performed to spatially analyze therapeutic effects, including T cell infiltration and distribution, T cell activation (Granzyme B) and cell death induction (Cleaved Caspase-3) in different cell types. T cells were significantly activated after treatment, and tumor slices showed significant cell death induction on the second day of treatment. Some patients showed T cell infiltration into FAP+ regions in response to treatment. Analysis of over 10 cytokines in the culture medium provides deeper insights into how the treatment induced immune cell activation.

By integrating spatial biology and cytokine analysis with our PCTS platform, we can map the relationship between the tumor, stromal, and immune cell components within the TME, visualize inter-patient differences, and predict individual therapy responses to immunotherapy. This makes our platform a valuable tool for personalized cancer medicine.

#1604 Homeobox transcription regulatory gene HOXA10 in pancreatic cancer treatment response.

Addanki Pratap Kumar[1], Amanda Munoz[1], Xiaoyu Yang[1], Meagan Marie Ybarra[1], Joel Michalek[2], Shaye Hagler[3], John Baer[3], Ramya Chengalvala[3], Sukeshi A. Patel[4], Danielle Fritze[5], Glenn Halff[5], Zhao Lai[1], Yuji Ikeno[6], Yidong Chen[2], Rita Ghosh[7]

[1]Molecular Medicine, UT Health Science Center at San Antonio, San Antonio, TX,[2]Epidemiology and Biostatistics, UT Health Science Center at San Antonio, San Antonio, TX,[3]Canopy Biosciences, St. Louis, MO,[4]Medicine, UT Health Science Center at San Antonio, San Antonio, TX,[5]Surgery, UT Health Science Center at San Antonio, San Antonio, TX,[6]Pathology, UT Health Science Center at San Antonio, San Antonio, TX,[7]Urology, UT Health Science Center at San Antonio, San Antonio, TX

Gemcitabine/nab-paclitaxel (GnP) or FOLFIRINOX (FFX) are recommended guidelines for use as first line regimens for pancreatic ductal adenocarcinoma (PDAC) patients. Use of FFX is usually limited to a small subset of younger, fit patients with minimal comorbidities. This underscores the need to focus on efforts to test and develop effective regimens that can be used in a wide range of patients due to potentially minimal toxicity profile and cost. We identified palmatine, a protoberberine alkaloid fulfilling the Lipinski's 5-rule as a potential candidate drug. We show that relative to gemcitabine, palmatine in combination with gemcitabine was more effective against a panel of human PDAC cultured cells, human ex vivo cultured cells, and human PDAC organoid models. Furthermore, repeated measures linear model changes in bioluminescence at the time of termination from baseline (Log_{10}), showed that gemcitabine alone and in combination with palmatine resulted in significant reduction of tumor burden relative to control KPC orthotopic syngeneic mouse model of PDAC. The combination was tolerated well by the animals. Bulk RNA-sequencing from tumors treated with combination showed that expression of *Hoxa10* was significantly reduced. Gene-set enrichment analysis further showed enrichment of B-cell receptor signaling in responding relative to non-responding mice. Spatial transcriptomic analyses of responding and non-responding tumors showed that expression of *Hoxa10* was found in the mesenchymal cell population and that *HoxA10* expression correlated with differentially expressed genes in B cell population. Exploration of tumor immune microenvironment (TIME) using CellScape revealed increased density of B-cells and decreased regulatory T-cells (Tregs) in tumors from responding but not non-responding mice. The *HOXA10*-associated gene signature is reported to be prognostic for survival. Recent evidence shows that *HOXA10* expression correlates differentially with immune cell populations. We found CD274 (PD-L1), IFNGR1, NFκB1 and STAT3 as potential HOXA10 targets based on ChIP-seq data with HOXA10 pull-down from ENCODE project. *In silico* analysis of the pancreatic cancer database shows that HOXA10 expression is elevated in human pancreatic tumors and that high expression is associated with increased survival. *HOXA10*, the homeobox transcription regulatory gene is involved in multiple roles in cancer including cell survival, epithelial mesenchymal transition (EMT), cancer progression, metastasis, and therapeutic resistance and in the context of PDAC it also promotes stromal cell proliferation. Taken together, these findings suggest the potential utility of palmatine in therapeutic sensitization of gemcitabine through deregulation of HOXA10 signaling.
Supported in part through VA Merit Award BX003876 (APK).

#1605 Pretreatment of bone anabolic agent delays or prevents multiple myeloma progression.

Syed Hassan Mehdi[1], Dongjoon Lee[1], Alex Lee[2], Paul Lee[2], **Donghoon Yoon**[1]

[1]Internal Medicine, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Marah Natural Co., Coquitlam, BC, Canada

Multiple myeloma (MM) is the second most common blood cancer. It remains an incurable disease due to relapsing and developing treatment resistance. Treatment resistance and disease progression are not solely due to intrinsic MM characteristics but are also fostered by alterations within the surrounding BM microenvironment. The bone serves as a home for growing myeloma but is also a target organ for myeloma cells. The MM-bone disease (MMBD) is one of the defining features of MM. A previous report showed that myeloma cells colonize the endosteal niche, enter a dormant state, and are activated by bone-lining cells. Many attempts, including ours, were made to test novel or existing bone anabolic drugs for anti-MMBD and found they did not significantly affect myeloma progression, although bone formation has improved. Interestingly, we found that the surviving mice from myeloma transplants become tolerable to subsequent tumor transplantation. *We hypothesized that improving the bone environment may lead to the prevention of myeloma growth.* We pretreated mice with a bone anabolic agent, Sigma Ant-Bonding Calcium Carbonate (SAC), and then tested myeloma growth. It may mimic a treatment in the pre-emerging or -relapsed period of MM. SAC is a chemically/physically modified calcium carbonate with a unique weak bonding and a commercially available dietary supplement. It induces bone formation by increasing the active ionized calcium in the body. We divided the 8-12-week-old NOD SCID gamma mice into three groups: PBS, the SAC-Treated group before Transplant (TbT), and the SAC-Treated group after Transplant (TaT). SAC was gavaged twice daily, five days/week, for four weeks before the transplantation (TbT) or two weeks after transplant (TaT), while PBS was gavaged to the control group when TbT started. The $1x10^6$ luciferase-expressing 5TGM1 cells were injected into the mice *via* the tail vein. Mice were imaged weekly by IVIS imager to assess the myeloma progression and terminated when endpoint criteria were met. All surviving mice were sacrificed one week after all PBS group mice died. We found that the median survival of PBS-treated mice was 39 days, while 45 days in the TaT group. To our surprise, 80% of TbT group mice survived until the end of the study. The bioluminescence image analysis showed that myeloma slowly progressed in both treated group mice. DEXA results demonstrated that bone minerals significantly increased in the spine of SAC-treated mice compared to the control mice. Trabecular thickness and bone volume density were significantly higher in the SAC-treated group at the lumbar spine compared to the PBS group. In conclusion, our results showed that improving the bone microenvironment with SAC pretreatment delays or prevents myeloma cell growth in mice. These results may suggest a novel therapeutic regimen for MM during pre-emerging or -remission of multiple myeloma patients.

#1606 Unraveling the microbiome-iNOS connection in obesity-driven triple-negative breast cancer.

Ivonne Uzair[1], Ann C. Anselme[1], Wei Qian[1], Jianying Zhou[1], Adriana E. Rosato[2], **Roberto R. Rosato**[2], Jenny C. Chang[1]

[1]Houston Methodist Neal Cancer Center, Houston, TX,[2]MaineHealth, Portland, ME

Introduction: A recent Phase 1/2 clinical trial evaluating the efficacy of the inducible nitric oxide synthase (iNOS, NOS2) inhibitor L-NMMA in combination with taxanes for patients with chemorefractory, locally advanced breast cancer or metastatic triple-negative breast cancer (TNBC) reported an overall response rate (ORR) of 45.8%. Notably, stratification by body mass index (BMI) revealed that obese patients had a significantly higher ORR (85.6%) compared to non-obese patients (46.7%), correlating with elevated iNOS expression in tumor biopsies from obese patients. While obesity typically worsens disease-free and overall survival in TNBC, these findings suggest a potential role for iNOS inhibition in overcoming obesity-driven tumor progression. To investigate further, we studied the impact of iNOS inhibition on tumor growth and treatment response in an obese mouse model and examined the role of the gut microbiome. Obesity was induced in C57BL/6 mice using a high-fat diet (HFD) for 10 weeks prior to orthotopic implantation of E0771 TNBC cells in the mammary fat pad of female mice. Control mice were fed a normal diet (ND).
Results: - HFD-fed mice developed larger, more aggressive tumors, with detectable burden occurring ~3 weeks earlier. Tumors in HFD mice reached humane endpoints ~17 days sooner than ND mice, whose tumors grew to 80% of HFD tumor size in the same period. Lung metastasis was significantly higher in HFD mice. - L-NMMA combined with docetaxel delayed tumor growth in both diet groups, though the untreated/treated tumor size ratio was higher in HFD mice (6.5) than ND mice (2.1). - Gut microbiome analysis revealed diet- and tumor-associated compositional changes. FMT (fecal microbiota transplantation) from ND mice to HFD mice reduced tumor size and improved therapeutic response, while FMT from HFD mice to ND mice increased tumor size and impaired response. Immunohistochemistry showed elevated iNOS levels in tumors of HFD mice, which normalized following ND-FMT. Conversely, ND mice receiving HFD-FMT displayed increased iNOS expression. Serum cytokine profiles reflected these tumor and treatment differences.
Conclusion: These findings suggest that HFD-induced gut microbiome alterations create a pro-inflammatory environment driving increased iNOS expression, promoting tumor aggressiveness and influencing therapeutic response. Targeting the gut microbiota, alongside iNOS inhibition, could provide novel strategies for managing obesity-associated TNBC.

#1607 Versican status in the tumor microenvironment heterogeneously impacts immune infiltration and inflammatory pathway expression.

Ruchi Shah[1], Sean G. Kraus[1], Somak Chaudhuri[1], Elizabeth L. Field[1], Cheri A. Pasch[1], Katherine A. Johnson[1], Dustin A. Deming[2]

[1]University of Wisconsin-Madison, Madison, WI,[2]Department of Medicine, University of Wisconsin-Madison, Madison, WI

Background: Versican (VCAN) and its proteolysis product, Versikine (Vkine), have been shown to regulate CD8+ T-cell infiltration in cancers. Here, we evaluate the impact of VCAN proteolysis and accumulation on immune infiltration and immune-related pathway expression across cancer types.

Methods: RNA expression (Z-score) signatures of $VCAN^{hi}/ADAMTS4^{hi}/TIMP3^{lo}$ and $VCAN^{hi}/ADAMTS4^{lo}/TIMP3^{hi}$ were used to identify VCAN proteolytic predominant (VPP) and weak (VPW) cohorts, respectively, from TCGA Pan-cancer Atlas datasets. Gene-set enrichment analysis was performed between VPP and VPW cohorts for each cancer type. 10 tissue microarrays (TMAs, UW Carbone Cancer Center Translational Science Biocore and TissueArray.com) were used to evaluate VCAN, Vkine, and CD8+ tumor infiltrating lymphocytes (TILs) by immunohistochemistry (IHC). VCAN and Vkine stromal intensity was scored from 0-3+. Cancers were categorized by IHC as VPP (VCAN low, Vkine high), VVL (VCAN low, Vkine low), and VPW (all others). CD8+ TILs were quantified per high-powered field (HPF).

Results: Patients (n = 4664) were evaluated across 9 cancer types [breast, esophageal (EsC), gastric, kidney (KC), lung, melanoma, endometrial (EnC), bladder (BlC), and colorectal (CRC)], of which 400 were VPP or VPW. In ≥ 6 cancer types with VPP status, E2F targets and TNFα signaling via NFκB were enriched in ($q < 0.001$). In ≥ 2 cancer types with VPW status, myogenesis, coagulation, IFNα response, and epithelial mesenchymal transition were enriched ($q < 0.05$). *IL6* (average log2 fold change 2.33), *CSF3* (2.26), *CXCL2* (1.76), *CXCL3* (1.71), *CXCL1* (1.47), *CXCL8* (1.42) were upregulated across all VPP groups. *SPP1* (0.96), *PPP1R3C* (0.95), and *COMP* (0.84) were upregulated across most VPW groups. IHC was performed on BlCs, KCs, EsCs, EnCs, triple-negative breast cancers (TNBCs), non-TNBCs, pancreatic ductal adenocarcinomas (PDACs), non-small cell lung cancers, and mismatch repair deficient (dMMR) and proficient (pMMR) CRCs. The most prevalent phenotype was VPP for EnCs (46.3%) and EsCs (52.0%), VPW for TNBCs (63.9%), pMMR CRCs (64.8%), PDACs (80.7%) and non-TNBCs (84.5%), and VVL for BlCs (78.6%) and KCs (85.9%). There were 0 VPP PDACs. CD8+ TILs were higher in VPP than VPW KCs (VPP average 16.3 CD8+ TILs/HPF = 16.3, VPW 13.7), EsC (39.9, 16.8), EnC (13.8, 9.8), dMMR CRC (31.5, 3.1), pMMR CRC (16.4, 2.2), and TNBC (37.0, 7.3). Cancers with < 5 average CD8+ TILs/HPF included VPW dMMR CRCs (3.1), pMMR CRCs (2.2), and PDACs (0.7) as well as VVL PDACs (2.9) and VPP non-TNBCs (4.5).

Conclusion: VCAN proteolysis is associated with CD8+ TIL abundance, especially in EsCs, EmCs, dMMR and pMMR CRCs, and TNBCs, and expression of inflammatory genes and pathways. Further insight into VCAN prevalence and interactions with inflammatory pathways and other TME components is necessary to establish its potential as a pan-cancer biomarker for immunotherapy response.

#1608 Quantifying changes to macrophage recruitment to the breast tumor microenvironment and metastasis in response to Notch4 blockade.

Debdutta Mandal[1], Katherine A. Alexander[1], Jason L. Eng[1], Yu Kato[2], Bhairavi Swaminathan[1], Christie Kang[1], L. A. Naiche[1], Yasuhiro Funahashi[2], Junji Matsui[2], Jan K. Kitajewski[1]

The Notch signaling pathway is a highly conserved pathway that regulates cell fate and cell differentiation in multicellular organisms. The Notch pathway plays a vital role in tumor angiogenesis. Notch1 is broadly expressed throughout the body, and preclinical studies demonstrate that targeting Notch1 limits tumor vessel perfusion. However, Notch1 blockade has been linked to gastric toxicity and tissue hypoxia, impeding the pharmaceutical development of Notch1 antagonists. In contrast, Notch4 is primarily expressed in the vascular endothelium and is known to be upregulated in human patients with triple-negative breast cancer (TNBC). High levels of Notch4 expression have been associated with poor overall survival in breast cancer. In mice, implantation of mammary tumors into Notch4 null animals reduces mammary tumor angiogenesis, perfusion, and volume. Notch4 inhibition could enable targeting of the Notch signaling pathway in tumor stroma without disrupting normal organ function, making it a valuable potential therapeutic target in the treatment of breast cancer. Multiple inflammatory diseases have been associated with increased Notch4 expression, suggesting that Notch4 might regulate the immune response. Although Notch4 is mainly expressed on the endothelium, some publications have observed Notch4 expression on immune cells, particularly macrophages. We found that treatment with a novel anti-Notch4 neutralizing antibody, E7011, caused a significant increase in the number of tumor-associated macrophages (TAMs). To test the functional importance of TAMs in the mechanism of E7011, we depleted TAMs with an intra-tumoral injection of liposomal chlodronate before administering E7011. Depletion of macrophages via clodronate abrogated the tumor volume reduction of E7011 treatment, suggesting that TAMs are an important player in E7011 efficacy. Therefore, we hypothesize that tumor-associated macrophage Notch4 is responsible for breast cancer metastasis and tumor progression. My project will center on visualizing the effect of Notch4 inhibition on macrophage recruitment to primary mammary carcinoma tumors and dissemination of lung metastasis by immunohistochemistry. I will section cryopreserved primary tumors and lungs from two syngeneic murine mammary carcinoma models, Py8119 and spontaneously metastatic E0771.LMB. Tumor cells from this line can be visualized by red fluorescent protein (RFP). Then, I will perform immunofluorescent staining of frozen primary tumors to quantify changes in total macrophage (CD68+) recruitment and macrophage Notch4 expression in response to E7011 or control IgG treatment. I will also perform immunofluorescent staining of frozen primary lung sections to quantify lung metastatic colonies (RFP+) from tumor-bearing mice treated with E7011 and or control IgG.

#1609 Targeting the oncogenic MAP4K4 regulatory axis in pancreatic cancer tumor microenvironment.

Sunil Singh, Sandeep Kumar, Saket Jha, Harsh Vyas, Piush Srivastava, Rakesh S. Nair, Basabi Rana, Ajay Rana

Surgery, University of Illinois at Chicago, Chicago, IL

Pancreatic Ductal Adenocarcinoma (PDAC) remains remarkably lethal, with a 5-year survival rate of less than 12%. Due to its widespread resistance to conventional therapy, PDAC is expected to be the second most common cause of cancer-related death in the United States by 2030. One of the major impediments to therapeutic failure in PDAC is the presence of an immunosuppressive tumor microenvironment (TME). We examined the function of Mitogen-activated protein kinases (MAPKs) upstream member, MAP4K4, in the PDAC-TME and tested the efficacies of MAP4K4 inhibitor and immunotherapy to overcome PDAC tumor burden. The role of MAP4K4 in regulating innate and adaptive components of PDAC-TME was determined *in vivo* using a preclinical immunocompetent murine model (i.e., in KPC) of PADC. The genes related to T cell dysfunctions were determined by the RT^2 PCR array. Flow cytometry analyses were performed to determine the immune checkpoint proteins and cytotoxic cytokines in T cells. The therapeutic efficacy of MAP4K4 inhibitor and agonists of 4-1BB and OX40 was determined in the murine model of PDAC. The IHC analyses showed that overexpression of MAP4K4 increases tumor infiltration of macrophages and neutrophils and decreases T cells in the murine model of PDAC. Furthermore, treating PDAC mice with MAP4K4 pharmacological inhibitor GNE-495 decreased tumor-infiltrating macrophages and neutrophils and increased T cell counts. However, the GNE-495 treatment increased tumor-infiltrating T cells and was not associated with increased cytotoxicity of T cells. The RT^2 PCR array analysis showed that treatment of GNE-495 decreased 4-1BB gene expression in peripheral and tumor-infiltrating T cells. The combined therapy of GNE-495 and 4-1BB agonistic mAb showed noticeable tumor regression and increased survival in the preclinical model of PDAC. Our study suggests that MAP4K4 regulates innate and adaptive immune cells in pancreatic-TME, and pharmacological inhibition of MAP4K4 decreases tumor macrophages and neutrophil counts. Moreover, the rationalized approach of combining a MAP4K4 inhibitor and a 4-1BB agonist mAb induced a T cell-mediated antitumor response, and this combination could serve as a viable treatment for PDAC.

#1610 Notch4 plays distinct roles in different cell types of the breast cancer microenvironment.

Katherine A. Alexander[1], Jason W. L. Eng[2], Yu Kato[3], Bhairavi Swaminathan[2], Debdutta Mandal[4], L. A. Naiche[2], Yasuhiro Funahashi[3], Junji Matsui[5], Jan Kitajewski[2]

[1]Department of Pharmaceutical Sciences, University of Illinois Chicago Retzky College of Pharmacy, Chicago, IL,[2]Department of Physiology and Biophysics, University of Illinois College of Medicine, Chicago, IL,[3]Eisai Co., Ltd., Ibaraki, Japan,[4]University of Illinois Chicago, Chicago, IL,[5]Eisai Inc., Woodcliff, NJ

The Notch developmental pathway regulates cell fate in tumor angiogenesis and influences immune cell phenotypes in the tumor microenvironment (TME). While Notch receptors Notch1-3 have been extensively studied, the role of Notch4 in the tumor microenvironment is poorly understood. Previous efforts to target Notch signaling and tumor angiogenesis have been limited by broad expression of Notch receptors and their cognate ligands, leading to significant gastrointestinal toxicity. However, Notch4 is thought to be expressed primarily in the endothelium, making it a highly specific and, therefore, more attractive candidate to attenuate Notch signaling in cancer. To this end, we collaborated to develop a first-in-class Notch4 neutralizing antibody, E7011. We demonstrated that E7011 treatment caused reduced tumor growth in multiple tumor types, including mammary tumors, that express Notch4 in tumor endothelium. To specifically examine the role of endothelial Notch4 on breast cancer growth, we used a Notch4 conditional endothelial-specific knockout (ECKO) mouse and implanted orthotopic murine breast cancer cells. We found that tumors implanted into Notch4 ECKO mice were consistently and significantly larger in two distinct models of murine mammary carcinoma, Py8119 and E0771.LMB, suggesting that endothelial Notch4 has an anti-tumor role. These results indicate that the anti-tumor effect of blocking Notch4 with E7011 is mediated by Notch4 in other cell type(s). Single-cell RNA sequencing of Py8119 tumors treated with E7011 revealed that although Notch4 transcripts were found primarily in endothelial cells, the most notable effect of E7011 was a dramatic increase in the number of tissue-resident macrophages (TRMs). Confirmatory immunohistochemistry showed that E7011 alters macrophage populations during multiple stages of tumor development. Analysis of the macrophage transcriptome showed decreased expression of markers associated with anti-inflammatory, “pro-tumor” macrophage populations. To examine whether macrophages are required for treatment efficacy, we performed clodronate-based intratumoral depletion of macrophages. While treatment with E7011 or clodronate reduced tumor volume as expected, co-administration of both E7011 and clodronate was not significantly different from control tumors. This finding suggests that macrophages potentiate the anti-tumor effect of E7011. These findings support distinct and opposing roles for Notch4 on endothelial and macrophage populations in the breast cancer microenvironment. Further studies of the contrasting roles of Notch4 in breast cancer can guide considerations for tailoring anti-Notch therapies.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Cell Death Pathways and Treatment
Poster Session

#1614 Ferroptosis mediated cell death in colorectal cancer cells through oxidative stress.

Mohamed A. Eltokhy, Shreyas R. Gaikwad, Morgan Moore, Sanjay K. Srivastava

Texas Tech University Health Sciences Center, Abilene, TX

Ferroptosis, a regulated form of non-apoptotic cell death, occurs due to lipid peroxide accumulation resulting from impaired cellular antioxidant defenses, particularly the inactivation of glutathione peroxidase 4 (GPX4). This process has gained attention as a novel therapeutic target, particularly for colorectal cancer (CRC), a malignancy often resistant to conventional apoptosis-based therapies. Our study investigated the anticancer potential of HLN, an antimicrobial agent. The cytotoxicity of HLN was evaluated in CT26, HCT116 & HT29 cell lines by SRB assay. To confirm HLN-induced ferroptosis, we employed ferro-orange staining to detect lipid peroxidation, GSH and malondialdehyde (MDA) assays to quantify oxidative damage. Mitochondrial membrane potential and ROS generation were determined by flow cytometry, Western blotting was used to determine GPX4, GPX1, NRF2, KEAP1 and SLC7A11/xCT expression in CRC cells. HLN exhibited significant cytotoxic effects across all CRC cell lines, with IC50 values ranging from 1-4 μM. Ferro-orange staining and MDA assays confirmed extensive lipid peroxidation by HLN treatment. HLN treatment also significantly depleted intracellular GSH levels and depolarized mitochondrial membrane, whereas increased ROS production, indicating oxidative stress. Western blot results showed reduced GPX4 and SLC7A11/xCT as well as modulation in ferroptotic markers, such as GPX1, NRF2, KEAP1, by HLN treatment. In conclusion our data suggests that HLN induces ferroptosis in CRC cells by promoting lipid peroxidation, mitochondrial dysfunction, and oxidative stress

#1615 Targeting PGK1 to enhance ferroptosis in breast cancer.

F. F. Oyelami[1], A. T. Shinkle[1], C. M. Ngule[1], X. Ren[1], F. A. Oyelami[2], O. Obaleye[1], J.-M. Yang[1];
[1]University of Kentucky, Lexington, KY, [2]University of Ilorin, Ilorin, Nigeria

A key feature common to triple-negative breast cancer is metabolic reprogramming that contributes to the malignant phenotype. Dysregulation of phosphoglycerate kinase 1 (PGK1), an essential player in glycolysis, is involved in several oncogenic pathways. In the current study, we aimed to determine whether PGK1-mediated glucose metabolism impacts the induction of ferroptosis in breast cancer. We found that expression of PGK1 varies in TNBC cell lines, with MDA-MB-231, MDA-MB-458 and MDAMB-453 lines showing significantly higher PGK1 expression than BT-549 and HCC70, and than the luminal breast tumor cell lines MCF7 and T47D. Depletion of PGK1 by siRNA or inhibition of the kinase by the small molecule inhibitor NG52 resulted in elevations of the core ferroptosis markers, ACSL4, CD71 and TFRC, but led to a decreased level of GPX4 - a key enzyme in the regulation of ferroptosis via detoxifying lipid peroxides to their corresponding alcohols using glutathione as a co-factor. Induction of ferroptosis was glucose-dependent, as the higher glucose-containing culture caused increased cell death. Notably, depletion of PGK1 sensitized TNBC cells to ferroptotic cell death induced by erastin, an activator of ferroptosis, and decreased colony formation and attenuated migratory ability of tumor cells. Similar observation was made in the murine TNBC cell line, mammary 4T1 adenocarcinoma. Furthermore, we demonstrated that the glycolytic inhibitor, sodium dichloroacetate (DCA), enhanced ferroptosis, while the glycolysis inducers such as hypoxia and oligomycin reduced ferroptotic cell death, in the tumor cells subjected to PGK1 depletion. Immunofluorescence assay demonstrated an interaction of PGK1 with GPX4, the anti-ferroptosis peroxidase, and the pulse-chase experiment showed that the proteasomal turnover of GPX4 protein was faster in the PGK1-depleted tumor cells than that in the tumor cells without depletion of PGK1. Moreover, the tumor cells with depletion of PGK1 showed an upregulation of pyruvate dehydrogenase as compared with the cells without PGK1 depletion, suggesting that PGK1 mediated-down-regulation of pyruvate dehydrogenase plays a role in ferroptosis resistance in TNBC cells. Animal studies are ongoing to recapitulate our in vitro findings on the role of PGK1 in ferroptosis resistance using 4T1 TNBC mouse model. This study demonstrates that PGK1 inhibition can attenuates GPX4, elevate pyruvate dehydrogenase expression, and cause a metabolic shift, thereby sensitizing tumor cells to ferroptosis induction. Thus, PGK1 may be exploited as a therapeutic target for overcoming ferroptosis resistance in breast cancer.

#1616 Artesunate-induced ferroptosis: A novel strategy to overcome chemoresistance in ovarian cancer.

Y. Chan, O. Wong, C. Cheung, E. Wong, X. Cong, A. Cheung;
The University of Hong Kong, Hong Kong, Hong Kong

The high propensity of ovarian cancer to develop chemoresistance contributes to its generally poor prognosis. Therefore, novel therapeutic approaches tackling this issue are highly sought after. Ferroptosis is a form of cell death characterized by iron dependency, increased lipid peroxidation, and disrupted cellular membranes. Many studies suggest that ferroptosis plays a crucial role in tumor suppression, thus providing new opportunities for cancer therapy. Artesunate is a well-known anti-malarial agent that can induce ferroptosis in multiple cancer types. Here in this study, we aim to investigate the potential of artesunate to induce ferroptosis and to attenuate cisplatin resistance in ovarian cancer cells. Cell viability assays indicated that artesunate effectively induced cell death. Cell death caused by artesunate was partially mitigated by the ferroptosis inhibitor ferrostatin-1 and the autophagy inhibitor chloroquine, suggesting the cytotoxic effects of artesunate are mediated through induction of both ferroptosis and autophagic cell death. Moreover, artesunate treatment significantly increased levels of reactive oxygen species (ROS) and lipid peroxidation (LPO), which are key hallmarks of ferroptosis. Western blot analysis also demonstrated that artesunate altered the expression of protein markers associated with increased ferroptosis, autophagy, and apoptosis in a time-dependent manner, suggesting a complex interplay between different cell death pathways. Co-treatment of artesunate with sub-cytotoxic concentrations of cisplatin significantly reduced cell viability after 48 hours, whereas ferrostatin-1 co-treatment partially rescued cell death. The combined treatment also led to an upregulation of ROS and LPO levels. Results suggested artesunate may enhance the cytotoxic effects of cisplatin by promoting ferroptotic cell death. These findings highlight the potential of artesunate as a novel agent to combat ovarian cancer chemoresistance through induction of ferroptosis, thereby enhancing therapeutic efficacy in clinical settings.

#1617 Targeting CDK11 in high-risk B cell acute lymphoblastic leukemia.

Yuki Murakami[1], Elizabeth Helmke[1], Kamhung Lam[1], John McPherson[2], Noriko Satake[1]

[1]Department of Pediatrics, University of California Davis School of Medicine, Sacramento, CA,[2]Department of Biochemistry and Molecular Medicine, University of California Davis School of Medicine, Sacramento, CA

The outcome for children with high-risk B-cell acute lymphoblastic leukemia (B-ALL) is poor. Disease relapse is speculated to be due to leukemia cells escaping treatment. Cyclin-dependent kinases (CDKs) have been demonstrated to be therapeutic targets in many cancers, and inhibitors of some CDKs have already been developed in the clinic. For example, CDK4/6 inhibitors have been used for treating patients with breast cancer, and a CDK2 inhibitor is being evaluated in a clinical trial for solid cancers. CDK11, known as a direct splicing regulator in CDKs, is overexpressed in several types of tumors, such as osteosarcoma and multiple myeloma and is shown to be a therapeutic target in many cancers. In B-ALL, dysregulated RNA splicing is linked to drug resistance and disease relapse. In this study, we investigated the therapeutic potential of CDK11 inhibition in B-ALL. CDK11 protein expression was significantly higher in B-ALL cell lines (Reh and JM1) and 26 primary B-ALL samples (13 each for standard-risk and high-risk), regardless of the risk group, than in normal B-cells and hematopoietic stem cells. A CDK11 inhibitor, OTS964, showed significant dose-dependent cytotoxicity in the cell lines with IC50 of 22nM and 14nM. OTS964 also showed significant cytotoxicity in three harvested high-risk patient-derived xenograft (PDX) samples with high CDK11 expression. OTS964 did not show cytotoxicity in normal B-cells at the same tested concentrations. OTS964 is known to regulate RNA splicing by the deactivation of SF3B1, a core component of the spliceosome. We confirmed OTS964 rapidly inhibited the phosphorylation of SF3B1, which is highly activated in B-ALL. G2/M cell cycle arrest and apoptosis induction were observed 24 hours after treatment in B-ALL cell lines. OTS964 induced p53 expression, which regulates cell cycle and apoptosis, as early as 1 hour after treatment. Furthermore, OTS964 induced short pro-apoptotic spliced isoforms, instead of anti-apoptotic forms, in *MCL-1,* a gene within the BCL-2 family, as early as 3 hours after treatment. The combination of splicing modulators and BCL-2 inhibitors shows synergism by each drug inhibiting different BCL-2 family genes. Therefore, we tested the combination with OTS964 and navitoclax, a BCL-2 inhibitor inhibiting BCL-2, BCL-x, and BCL-w in BCL-2 family genes. As expected, the combination showed strong synergisms in B-ALL cell lines and in the three harvested high-risk PDX samples. It was also effective in the sample with low CDK11 expression *in vitro*. Our *in vivo* study of the combination therapy is ongoing.In conclusion, these data demonstrated the therapeutic potential of CDK11 inhibition in high-risk B-ALL. OTS964 rapidly deactivated SF3B1 and induced the pro-apoptotic forms of MCL-1, leading to cell apoptosis. Additionally, the new combination with OTS964 and navitoclax showed synergism. In future studies, we will investigate how CDK11 inhibition regulates splicing factors other than SF3B1.

#1618 Blocking MDM2 induces downregulation of PARP and enhances apoptosis in SK-N-SH neuroblastoma cells.

Shyam Sundar Jaganathan, Umamaheswari Natarajan, Appu Rathinavelu

Rumbaugh-Goodwin Institute for Cancer Research, Barry & Judy Silverman College of Pharmacy, Nova Southeastern University, Davie, FL

Introduction: Neuroblastoma is a pediatric cancer originating from neural crest cells often characterized by poor prognosis and resistance to standard therapies. RG-7388 is a potent MDM2 inhibitor that disrupts the interaction between p53-MDM2. However, the impact of RG-7388 on cellular pathways, particularly its role in post-translational modifications of cancer cells, remains unexplored. PARP is a critical protein in DNA repair and apoptosis, is often targeted for degradation in cancer therapies. However, the mechanisms underlying PARP degradation in response to RG-7388 treatment in neuroblastoma cells largely remain unclear. We hypothesize that MDM2 re-activation by the rebound mechanism of RG-7388 induces PARP degradation in SK-N-SH neuroblastoma cells, possibly through a E3 ligase mediated ubiquitination mechanism that is eventually contributing to enhanced apoptosis.
Methods: To test this hypothesis, SK-N-SH cells were treated with RG-7388 (2 µM), MDM2 specific E3 ligase inhibitor (10 µM), and iRucaparib-AP6 (10 µM), alone or in combination with RG-7388. Cell viability was evaluated using the Trypan Blue Dye Exclusion (TBDE) assay method, while Caspase-3/7 activation was quantified through cleavage of DEVD-*Amc* substrate. qRT-PCR, Western blot, and Immunofluorescence analyses were conducted to assess expression levels of the cell cycle and apoptotic markers, such as MDM2, p53, p21, and PARP.
Results: Treatment with RG-7388 significantly reduced the viability of SK-N-SH cells compared to the control. The decrease in PARP levels seen after RG-7388 treatment is more significant than the levels observed in iRucaparib-AP6. In addition, the Caspase-3/7 activity, that was measured *via* the DEVD-*Amc* substrate cleavage assay, was markedly higher in RG-7388 treated cells compared to control. qRT-PCR analysis revealed upregulation of p53 and p21 in RG-7388 treated cells and a significant downregulation in PARP expression. Western blot analysis also confirmed a reduction of PARP levels in RG7388-treated cells, which was greater than the decrease seen with iRucaparib-AP6 treatment. Reversal of the RG-7388 and iRupacarib-AP6 induced downregulation of PARP by E3 Ligase inhibitor suggested that degradation may be major contributor to the downregulation in SK-N-SH cells.
Conclusion: Our study results indicate that RG-7388 induces significant downregulation of PARP in the SK-N-SH cells, which was leading to enhanced apoptosis. Furthermore, the results of RG-7388 treatment obtained from SK-N-SH cells confirmed its ability to induce cell death through both p53 activation and downregulation of PARP.

Chemotherapy resistance is a major challenge in epithelial ovarian cancer (EOC) treatment. Standard treatment involves cytoreductive surgery in combination with platinum (Pt)-based chemotherapy. While initial treatment is often successful, over 80% of patients develop recurrent Pt-resistant disease. Therefore, therapeutics which increase sensitivity to platinating agents such as CDDP are essential to kill EOC cells. One candidate drug that may increase the sensitivity of CDDP to resistant EOC cells is the HIV protease inhibitor nelfinavir (NFV), which has previously shown anti-cancer activity against EOC *in vitro*. The goal of this study was to determine if the combination of NFV and CDDP is effective against EOC cells. Four EOC cell lines, with varying degrees of CDDP resistance, were exposed to increasing concentrations of CDDP in the presence or absence of NFV. In all cell lines, the addition of NFV significantly enhanced the cytotoxicity and decreased the IC_{50} of CDDP. Furthermore, the combination of NFV and CDDP was determined to be synergistic using the Loewe model of drug interaction. Interestingly, EOC cells treated with NFV and CDDP displayed characteristics of lytic cell death, such as an increased proportion of annexin-V and 7-AAD co-staining, and the release of LDH into the culture supernatant. Additionally, morphological assessment with brightfield and fluorescent microscopy revealed significant cellular swelling and cytoplasmic vacuolization, signs of inflammatory cell death. Immunoblotting revealed cleavage of the pyroptotic effector proteins gasdermin D and gasdermin E, suggesting a shift from apoptosis to pyroptosis with NFV and CDDP combination. Further evidence for pyroptosis include cleavage of the inflammatory caspase-1, as well as release of the inflammatory cytokine IL-1β into the supernatant as determined through ELISA. Interestingly, the combination of CDDP and NFV resulted in decreased expression of mature lamin A, leading to severe nuclear deformation and increased DNA damage. Furthermore, the loss of lamin A was associated with the leakage of nuclear DNA into the cytosol, as analyzed through droplet digital PCR (ddPCR) after cellular fractionation. Cytosolic dsDNA is an activation signal for the AIM2 inflammasome; to confirm its involvement, EOC cells were incubated with CDDP and NFV in the presence or absence of the AIM2 inhibitor suramin. Addition of suramin to the CDDP and NFV treated EOC cells rescued cell viability, and simultaneously decreased IL-1β. Overall, these results demonstrate a transition from apoptotic to pyroptotic cell death when EOC are treated with CDDP and NFV. Resistance to apoptosis is a major mechanism by which EOC cells become Pt-resistant. Therefore, NFV and CDDP together, may be a feasible therapeutic option for these patients through the induction of pyroptosis.

#1620 Vulnerability to selective CTPS1 inhibition in cancers lacking CTPS2.

Philip A. Beer[1], John P. Thomson[2], Charlie Gourley[2], Alison Meynert[2], Andrew E. Parker[1], Brian Schwartz[1], Patricia Roxburgh[3]

[1]Step Pharma, Saint-Genis-Pouilly, France,[2]University of Edinburgh, Edinburgh, United Kingdom,[3]University of Glasgow, Glasgow, United Kingdom

Background
De novo pyrimidine synthesis is a universal requirement for cancer cell proliferation; however, targeting this pathway results in toxicity to all dividing cells. The rate limiting conversion of UTP to CTP is catalysed by two isoforms with the same enzymatic activity (CTP synthase 1 and 2; CTPS1 & CTPS2). CTPS1 plays an essential role in lymphoid cell proliferation; differential targeting of CTPS1, sparing the paralog CTPS2, is a therapeutic strategy in lymphoid cancers that can potentially avoid toxicity. In epithelial tissues (and cancers derived from them), CTPS2 is also active and may compensate for CTPS1 inhibition. Somatic loss of CTPS2 would expose a synthetic lethal vulnerability to CTPS1 inhibition. A highly selective, orally available CTPS1 inhibitor has entered clinical development.
Methods
Pan-Cancer Analysis of Whole Genomes data were accessed via cBioPortal. Ovarian cancer tumour microarrays (n=117 tumours) were analysed by immunohistochemistry (IHC) using a monoclonal CTPS2 antibody. CTPS2 was disrupted in cancer cell lines by clustered regularly interspaced short palindromic repeats (CRISPR); protein loss was confirmed in clonal progeny by western blotting. STP-B is a potent and highly selective inhibitor of CTPS1 (PMID: 37008165); IC50 values for isogenic cell line pairs (n=5) and primary ovarian cancers (n=10) were assessed using CellTiter-Glo. Immunodeficient mice were transplanted subcutaneously with a CTPS2 positive or negative primary ovarian cancer (n=1 each) and treated with STP-B at 10-50 mg/kg/day or vehicle control (n=10 mice per arm).
Results
Hemi/homozygous loss of CTPS2 (chrX gene) was most prevalent in ovarian, lung, bladder and gastroesophageal cancer (17 to 19%). IHC analysis of tumour microarrays confirmed lack of CTPS2 protein in 24% of ovarian cancers, as well as in other cancer types at prevalences broadly commensurate with the genomic data. CRISPR-induced CTPS2 loss in cancer cell lines resulted in an 11-fold mean increase in sensitivity to CTPS1 inhibition by a highly selective small molecule (STP-B). CTPS2 null primary ovarian cancers showed uniformly greater sensitivity to STP-B in vitro and underwent tumour regression with STP-B treatment in vivo. CTPS2 loss was largely mutually exclusive with BRCA1/2 mutation in two independent ovarian cancer cohorts.
Conclusions
In vitro and in vivo studies demonstrate that loss of CTPS2 exposes a synthetic lethal vulnerability to selective CTPS1 inhibition. The prevalence of CTPS2 loss is >10% in a number of common cancer types. A highly selective oral CTPS1 inhibitor is currently in clinical development for the treatment of lymphoma (NCT05463263). Dose escalation in solid tumours commenced September 2024, and will be followed by a safety expansion cohort for patients with CTPS2 null ovarian cancer (NCT06297525).

#1621 Investigate PARP1-dependent cell death in hepatocellular carcinoma.

Chun Yin YU, Hoi Tang MA

The University of Hong Kong, Hong Kong, China

Hepatocellular carcinoma (HCC) is one of the most prevalent types of liver cancer, representing the third-leading cause of cancer-related mortality worldwide. It is typically characterized by an environment of high oxidative stress and persistent DNA damage. The persistent DNA damage in HCC triggers and initiates the ADP-ribosylation signalling pathway, which locates the DNA lesion sites for the recruitment of proteins involved in DNA damage repair. While ADP-ribosylation is critical for DNA damage repair, the impact of disrupting the homeostasis of ADP-ribosylation on HCC remains poorly understood. To explore the impact of dysregulated ADP-ribosylation in HCC, a degron-mediated gene silencing system was employed in HCC cell lines with PARG and ARH3 knockout (KO). With the addition of doxycycline (Dox) and Auxin (IAA), the degron-tagged PARG was degraded, establishing the PARG and ARH3 KO environment. Acute loss of PARG and ARH3 resulted in PARP1 hyperactivation, leading to PAR accumulation in the cells, followed by massive cell death in a time-dependent manner. The PARP1-dependent cell death induced by PARG and ARH3 KO was confirmed using the PARP1 KO model and the supplementation of a PARP1 inhibitor to cells. While activation of apoptosis and parthanatos (canonical PARP1-dependent cell death pathways) was observed, targeting the key enzymes in these pathways failed to suppress PARG and ARH3 KO-mediated cell death, indicating that the underlying mechanism is yet to be identified. Nevertheless, an interconnection between the NAD cycle and PARP1-dependent cell death was also examined. Supplementation of the metabolite in the NAD cycle suppresses PARP1-dependent cell death. Interestingly, targeting the rate-limiting enzyme in the NAD salvage pathway using CRISPR-Cas9-mediated KO or NAMPT inhibitor could suppress cell death. Altogether, these results extend the understanding of PARP1-dependent cell death mediated by the loss of PARG and ARH3 and provide insights into the therapeutic development for targeting the homeostasis of ADP-ribosylation in HCC.

#1622 Inhibition of bone morphogenetic protein receptor 2 increases mitochondrial bioenergetics and synergistically enhances cell death induced by BCL 2 inhibitors in lung cancer and leukemia cells.

Ashley Toussaint, Manohar Singh, Arindam Mondal, Dongxuan Jia, John Langenfeld

RWJMS, New Brunswick, NJ

Background: Bone morphogenic proteins (BMP) proteins are highly overexpressed in non-small cell lung carcinomas (NSCLC) and leukemia cells. Studies have shown that BMP signaling is growth promoting and enhances survival of cancer cells. The mechanism by which BMP signaling promotes tumorigenesis has not been fully elucidated. Our prior studies revealed that BMP signaling suppresses AMP kinase activation in lung cancer cells, which is conserved in C elegans. We also found that the BMP2 ligand significantly suppressed tricarboxylic acid (TCA) cycle intermediates in lung cancer cells. These studies suggest that BMP signaling suppresses mitochondrial bioenergetics. To better understand the role of BMP signaling in cancer, our team developed specific small molecules inhibiting the BMP type 2 receptor (BMPR2). In this study, the BMPR2 inhibitor JL189 and genetically engineered BMPR2 knockout (KO) cells were used to examine the effects of BMP signaling on mitochondrial bioenergetics. We also examined if altering mitochondrial bioenergetics increased cytotoxicity of BCL-2 inhibitors, which promote mitochondrial induced apoptosis. Mitochondrial metabolic metabolites were measured by liquid chromatography mass spectrometry. Mitochondrial mass was determined by MitoTracker Green labeling quantified by flow cytometry. Metabolomic studies demonstrated that JL189 significantly increased TCA intermediates in lung cancer cells. Knockout of BMPR2 in A549 cells also significantly increased TCA cycle intermediates. Agilent Seahorse analyzer demonstrated that BMPR2 inhibition increased oxidative phosphorylation in NSLC cells. Inhibition of BMPR2 signaling with JL189 or KO cells increased mitochondrial mass in NSCLC and leukemia cell lines. JL189 synergistically enhanced cell death induced by the BCL-2 inhibitors ABT-263 (navitoclax) and ABT-199 (venetoclax) in both NSCLC (A549, H1299, Calu-1) and leukemia cell lines (Jurkat, Kasumi-1, THP-1). By Western blot analysis, the activation of caspase-3 was higher in cancer cells treated with JL189 combined with ABT-263 compared to each compound alone. Cell death induced by BMPR2 inhibition alone and in combination with BCL-2 inhibitors was more pronounced in leukemia cells lines compared to NSCLC cell lines.
Conclusion: Inhibition of BMPR2 signaling increased mitochondrial biogenesis in NSCLC and leukemia cell lines, suggesting that the cancer cells are more susceptible to mitochondrial induced cell death. BMPR2 inhibition also significantly increased cancer cell death when combined with a BCL-2 inhibitor. Priming the mitochondria with a BMPR2 inhibitor may represent a novel strategy to enhance cancer therapeutics that promote mitochondrial induced apoptosis. Our data suggests that BMPR2 inhibition may be more effective in leukemia compared to NSLC.

#1623 Mechanistic insights into low-frequency ultrasound-induced cancer cell apoptosis.

Aditi Singh, Felix Margadant, Michael Sheetz

University of Texas Medical Branch (UTMB), Galveston, TX

Cancer cells undergo rigidity independent growth due to low expression of mechanosensory cytoskeletal protein known as tropomyosin 2.1, acting as rigidity sensing module. This enables their survival on soft matrices by inciting distinct response to the mechanical cues, in contrast to non-transformed cells. We previously found that treatment of cancer cells with low-frequency ultrasound results in calcium influx through activation of piezo1 channels, microtubule depolymerization through calpain proteases, activation of RhoA-ROCK pathway and increased myosin IIA-mediated actomyosin contractility, ultimately causing cell death in calcium-induced calcium release manner. However, the underlying processes connecting the initiation of apoptosis upon mechanical stimuli remain inadequately understood. Our research focus involves ER-mitochondrial stress pathway comprising of mitochondria-associated ER membranes (MAMs), that might be involved in causing apoptosis in cancer cells exhibiting variations in their mechanoresponse via differential cell killing, while leaving the normal cells unaffected. Recently, we found lowering of mitochondrial membrane potential in cancer cells post-ultrasound treatment. Mitochondrial distribution of normal and cancer cells after ultrasound treatment varied dramatically, leading to increased punctate forms in cancer cells. Inhibition of mitochondrial fission showed significant decrease in apoptosis of cancer cells after ultrasound treatment. We conclude crucial role of mitochondrial fission, ROS and electron transport chain in low-frequency ultrasound-mediated apoptosis in cancer cells along with the cytoskeletal proteins. Tuning of desired parameters involving frequency, pressure and pulse duration could aid in the development of non-invasive cancer therapeutics.

#1624 Stat1 promotes lesion growth and tumor immunity of tuberin-deficient cells in lymphangioleiomyomatosis.

Tasnim Olatoke, Jane Yu

University of Cincinnati, Cincinnati, OH

Lymphangioleiomyomatosis (LAM) is a cystic lung disease that primarily affects women, with an estimated global prevalence of 19 per million women. LAM is caused by the invasion of metastatic smooth muscle-like cells into the lung parenchyma, leading to abnormal cell proliferation and progressive respiratory failure. LAM cells have TSC gene mutations, which occur sporadically or in people with Tuberous Sclerosis Complex. Although it is known that hyperactivation of the mechanistic target of rapamycin complex 1 (mTORC1) due to TSC2 mutations contributes to aberrant cell growth in LAM lung, tumor origin and invasive mechanism remain unclear. Integrative single-cell omics and validation analyses revealed the activation of a novel uterine-similar HOX/PBX transcriptional network in the LAM lung compared to other lung cells, suggesting that the uterus is one of the origins of LAM cells. Further omics studies indicated that STAT1 and STAT3 interact with PBX1 to increase LAM cell survival. The objective of this study is to delineate mechanisms by which STAT signaling may regulate LAM pathogenesis, with hopes to find potential therapeutic options for LAM and TSC-associated disorders. We hypothesize that STAT1 suppression attenuates LAM patient-derived (TSC2-null) cell viability and tumor growth in LAM. We first confirmed our network prediction analysis by showing that aberrant PBX1 activation upregulates STAT1 in LAM cells and tissues. Our cell viability assays show that STAT1 suppression induced TSC2-null cell apoptosis compared to controls. Similarly, our mouse models show that STAT1 suppression attenuates lung lesion and uterine tumor growth in TSC2-deficient LAM models. We also show that STAT1 activation induced PD-L1 upregulation, indicating that STAT1 helps tumor cells to evade immune surveillance in LAM. Our findings provide proof of concept that STAT1 mediates LAM tumor proliferation through two mechanisms. (1) by promoting lesion growth and (2) by promoting immune evasion via upregulation of PD-L1. STAT1 signaling is critical for LAM cell survival and could be targeted to treat LAM and TSC-associated disorders.

#1625 Redox homeostasis is a therapeutic vulnerability in lethal neuroendocrine prostate cancer.

Mu-En Wang[1], Wei-Ling Tu[1], Ji-Hoon Kim[1], Yi Lu[1], Alyssa Bawcom[1], Andrew J. Armstrong[1], Qianben Wang[1], Yuzhuo Wang[2], Jiaoti Huang[1], Ming Chen[1]

[1]Duke University School of Medicine, Durham, NC,[2]University of British Columbia, Vancouver, NC, Canada

Background: Neuroendocrine prostate cancer (NEPC) is an aggressive and lethal subtype of prostate cancer that often develops after second-generation anti-androgen therapies. The current treatment options for NEPC are limited and only produce disappointing results, highlighting the urgent need for novel therapies. Previously, we have found that NEPC cells are vulnerable to BCL2 and GPX4 inhibitors compared to their counterparts, prostate adenocarcinoma (PADC). Here, we aim to determine whether and how combining BCL2 and GPX4 inhibitors would enable optimal therapeutic effects in NEPC.

Methods: We conducted drug synergism analyses of BCL2 and GPX4 inhibitors using NEPC cell lines and determined their impacts on the major cell death pathways by performing rescuing experiments. To further determine the molecular mechanisms of BCL2 and GPX4 inhibitors-induced cell death in NEPC, we measured the intracellular reactive oxygen species (ROS) levels and tested the rescuing effects of various antioxidants and reducing agents on cell death. Finally, we determined the *in vivo* therapeutic efficacy of BCL2 and GPX4 inhibitors in an NCI-H660 cell line-derived xenograft (CDX) tumor model.

Results: Our results demonstrate that the BCL2 inhibitor ABT-199 and GPX4 inhibitor C18 synergistically induced apoptosis in NEPC cell lines in a ROS-independent manner. Although N-acetylcysteine (NAC) rescued ABT-199 and C18 cotreatment-induced apoptosis, the CellROX Green assay revealed no significant changes in ROS levels in ABT-199 and C18-cotreated cells. Surprisingly, reducing agents including tris(2-carboxyethyl)phosphine (TCEP) and Dithiothreitol (DTT) strongly rescued cell death induced by ABT-199 and C18 cotreatment. Our findings therefore suggested that the cell-killing effects of ABT-199 and C18 were due to ROS-independent disruption of redox homeostasis. Lastly, our preclinical tumor study showed that the ABT-199 and C18 combinatorial therapy significantly suppressed the tumor growth of NEPC.

Conclusions: Our study validated the combination of BCL2 and GPX4 inhibitors as a feasible approach for the treatment of NEPC and suggested that redox homeostasis is a therapeutic vulnerability in NEPC.

#1626 CDK9 inhibition enhances apoptosis of TP53 mutated AML when combined with standard chemotherapy.

E. C. Trull, D. B. Sykes, P. C. Amrein;
Massachusetts General Hospital, Boston, MA

Background: The prognosis of patients with acute myeloid leukemia (AML) remains poor for those with mutations or deletions of the TP53 gene. Inhibiting CDK9 is a strategy to trigger apoptosis downstream of p53 with the goal of overcoming the poor prognostic nature of mutant p53. Here we test dinaciclib, a multi-CDK and potent CDK9 inhibitor, alone and with azacitidine and venetoclax to demonstrate that CDK9 inhibition as monotherapy and in combination leads to apoptosis in TP53 mutated AML.
Methods: To determine the effect of inhibiting CDK9 on the cytotoxicity of AML and normal cells, we treated p53 mutated AML cell lines (THP1, NOMO1, and U937), wild type (WT) p53 AML cell lines (MV4-11 and HL-60) and peripheral blood mononuclear cells (PBMCs) from healthy donors with azacitidine, venetoclax, and dinaciclib. We performed viability assays to examine cell death and determine the IC_{50} and optimal exposure time of these drugs. Apoptosis was measured through flow cytometry with Annexin-V and 7-AAD staining, and through the quantification of apoptotic proteins with immunoblotting.
Results: Treatment of mutant and WT p53 AML cell lines with azacitidine, venetoclax, and dinaciclib as monotherapy demonstrated a dose-dependent decrease in cell viability. After testing various concentrations and exposure times of these drugs, we determined concentrations of 200nM azacitidine, 6000nM venetoclax, and 10nM dinaciclib at an exposure time of 8-hours were highly effective with dinaciclib monotherapy and in the triple-drug combination. When used in the mutant p53 cell line, THP1, and WT p53 cell line, MV4-11, the addition of dinaciclib to azacitidine and venetoclax showed increased synergy (scores of 29.6 and 12.9, respectively, using the HSA reference model) compared to azacitidine and venetoclax alone (synergy scores of -0.98 and 1.4, respectively). The addition of dinaciclib to THP1 cells resulted in increased apoptosis (55.2%) when compared to the two-drug combination of azacitidine and venetoclax (17.0%) as measured by the quantification of c-PARP expression normalized to beta-actin through immunoblotting. When this drug combination was tested in PBMCs of healthy donors, they were notably less sensitive and had lower synergy scores (1.2) than the AML cell lines.
Conclusions: We have shown that the addition of a CDK9 inhibitor to azacitidine and venetoclax results in enhanced cytotoxicity of mutant p53 and WT p53 AML cell lines at low nanomolar concentrations. These results suggest that inhibition of CDK9 sensitizes AML cells independently of TP53, with less pronounced cytotoxicity in normal PBMCs of healthy donors. We plan to further examine the effect of CDK9 inhibition using a highly selective CDK9 inhibitor and validate these results with primary AML and normal bone marrow samples. Ultimately, we hope these experiments will guide the development of human clinical trials to benefit those patients with p53 mutated AML.

#1627 Switching cell fate from senescence to apoptosis by the combination of a p53 corrector with the MDM2 antagonist ASTX295.

George Ward, Judit Espana-Agusti, Keisha Hearn, Mark Wade, Lynsey Fazal, Hugh Walton, Andrea Biondo, John Lyons, Martin Sims, Simone Jueliger, Jessica Brothwood, Andrew Woodhead, Louise Walsh, Tomoko Smyth, Nicola Wilsher, **Maria Ahn**

Astex Pharmaceuticals, Cambridge, United Kingdom

Background: ASTX295 is a potent MDM2 antagonist designed to have a shorter half-life ($t_{1/2}$ 4-6 hours in plasma), which leads to an improved safety profile (bone-marrow sparing), making it more amenable to combinations compared to other MDM2 antagonists. The recent success of targeting *TP53:Y220C* mutant cancers with a p53 corrector molecule holds great promise for treatment of all *Y220C TP53* mutant cancers. However, for effective therapy, a high level of p53 signalling will be required to overcome the elevated apoptotic thresholds seen in some cancer cells with co-mutations in pro-survival signalling pathways. We rationalised that this could be achieved by removing the MDM2-driven negative feedback loop that is triggered following *Y220C* correction.

Materials and Methods: Corrected p53 signalling was determined in two *TP53:Y220C* mutant pancreatic cancer cell lines with additional MAPK mutations: BxPC3 (*BRAF:L485-P490del*) and T3M-4 (*KRAS:Q61H*). Two small-molecule TP53:Y220C correctors were tested alone and in combination with ASTX295 using real-time microscopy, western blotting, and qPCR. Markers of p53 signalling (at the protein and mRNA level), senescence (β-galactosidase), apoptosis (Annexin V), and DNA damage (phospho-H2A.X) were measured after treatment with compounds. A mouse xenograft model was established in male CB17 SCID mice inoculated subcutaneously with BxPC3 cells, allowing PK/PD and efficacy evaluation.

Results: The combination of ASTX295 and the *Y220C* corrector led to increased cell death in both BxPC3 and T3M-4 cell lines *in vitro*, with elevated p53 signalling (p21), apoptosis (PUMA), and DNA damage (phospho-H2A.X) when MDM2 is antagonised. The *KRAS* mutant line, T3M-4, was less sensitive to the combination, but could be driven to apoptosis at higher concentrations of the corrector. PK/PD evaluation in BxPC3-xenograft-bearing mice demonstrated prolonged p53 signalling following combination treatment up to 16 h post dose, with a subsequent reduction at 24 h consistent with the ASTX295 exposure profile.

Conclusions: We have shown that MDM2 antagonism leads to sustained corrected p53 signalling over time, which drives cell death, even in tumor cells harbouring co-mutations conferring higher apoptotic resistance. Indeed, our study provides proof of concept that efficacy could be achieved in multiple tumor types in which the p53 pathway can be targeted therapeutically through combination with ASTX295, which would drive and maintain p53 signalling levels above the apoptotic threshold.

#1629 Targeting HSBP1 Cys137 residue by 4-Iodobutyl acetate selectively kills triple-negative breast cancer.

Ruei-Chen Hung[1], Chiou-Feng Lin[1], Yuan-Feng Lin[2]

[1]Graduate Institute of Medical Sciences, College of Medicine, Taipei Medical University, Taipei City, Taiwan,[2]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei City, Taiwan

Background: Triple-negative breast cancer (TNBC) accounts for 15-20% of breast cancers and has a higher mortality rate because of metastatic character as compared to the non-TNBC subtypes. Chemotherapy is a non-selective anti-cancer treatment and currently remains as a first-line regimen for TNBC patients. As a result, identifying a more effective and selective drug target is urgently needed for TNBC. The aim of this study was made to discover the iodoacetamide derivative-targetable cysteine (Cys) residues of protein which is involved in the specific protein-protein interactions (PPIs) that are critical for TNBC survival.
Methods: MTT assay was used to discover the iodoacetamide derivative that has a cytotoxic effectiveness on TNBC cell line HCC1806 better than normal mammary cell line MCF10A. Mass spectrometric analysis was utilized to identify the iodoacetamide derivative-targetable proteins and Cys residues. Site-directed mutagenesis was employed to validate the specific incorporation of iodoacetamide derivative candidate into the identified protein Cys residue. Cell-based assays and mouse models were established to determine the anti-TNBC effectiveness of iodoacetamide derivative candidate. Pulldown assay was performed to determine the specific PPIs of iodoacetamide derivative candidate-targeted protein in TNBC cells.
Results: MTT assays revealed that 4-Iodobutyl Acetate (IBA) is able to selectively kills HCC1806 cells with half maximal inhibitory concentration (IC_{50}) at 0.01 μM which is much lower than that of MCF10A cells (IC_{50} = 7.91 μM). Mass spectrometric analysis indicated that IBA incorporates into the Cys137 residue of HSPB1 protein and thereby induces cell apoptosis in HCC1806 cells. Either the removal of iodo-group from IBA or the mutation of Cys137 to Ser significantly abolished its cytotoxic effects on HCC1806 cells both *in vitro* and *in vivo*. Pulldown assay demonstrated that the incorporation of IBA into Cys 137 leads to the disruption of HSPB1 PPIs with Akt, Cytochrome c and Caspase-3, which ultimately results in the loss of metastatic ability and induction of cell apoptosis in HCC1806 cells.
Conclusion: Our results provide a novel, selective and even more safe therapeutic strategy for combating TNBC via targeting the pocket surrounding the Cys137 of HSPB1 protein.
Keywords: Triple-negative breast cancer; iodoacetamide derivative; protein-protein interactions; HSPB1; 4-Iodobutyl Acetate

#1630 Targeting the LIF/LIFR axis reduces the progression of inflammatory breast cancer by promoting ferroptosis.

Bianca A. Romo[1], Zenaida Fuentes[2], Lois Randolph[1], Megharani Mahajan[1], Emily J. Aller[1], Behnam Ebrahimi[1], Bindu Santhamma[3], Hareesh B. Nair[3], Christoforos Thomas[4], Ratna K. Vadlamudi[1], Suryavathi Viswanadhapalli[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Vanderbuilt University, Nashville, TN,[3]Evestra Inc., Shertz, TX,[4]Houston Methodist, Houston, TX

Background: Inflammatory breast cancer (IBC) is a rare subtype of breast cancer affecting 2-4% of the U.S. population. With the incidence being quite low, IBC is responsible for 7% of breast cancer related mortality often affecting younger women. The only currently approved options for treatment are surgical resection, chemotherapy, and radiation. Novel therapeutic targets are desperately needed for the generation of new therapeutics. IBC progression has been linked to growth factor and cytokine signaling abnormalities. In previous studies, the cytokine LIF/LIFR signaling axis has been identified as a crucial pathway in the progression of triple negative breast cancer. However, the role of LIF/LIFR in IBC progression remains unknown. The objective of this study is to test the utility of LIFR and test the effectiveness of LIFR inhibitor at treating IBC.

Methods: The utility of using LIFR inhibition as a treatment strategy in IBC was tested using cell survival, apoptosis, and colony formation assays using established IBC cell models (SUM149, SUM190PT, and KPL-4). We have reduced LIFR levels by 70% in IBC cells utilizing two different siRNAs that target LIFR. Western blotting, luciferase reporter assays, RT-qPCR, and lipid peroxidation assays were used to establish the mechanism of EC359 mediated growth suppression of IBC. *In vivo* treatment of cell-derived xenografts (KPL-4) was used to assess the utility of EC359.

Results: All three IBC models exhibited detectable expressions of LIF and LIFR. Reduction of LIFR using siRNA decreased cell survival, colony formation, and invasion capacity of IBC cells relative to cells transfected with control siRNAs. Pharmacological inhibition of LIFR with EC359 effectively reduced cell survival and clonogenic capacity of IBC cells in the low nanomolar range. RT-qPCR tests revealed EC359 markedly decreased the expression of LIFR target genes. Western analyses confirmed that EC359 treatment suppressed downstream LIF/LIFR signaling pathways, including STAT3, AKT, and pS6, and promoted apoptosis. Treatment of cells with the ferroptosis inhibitor Ferrostatin 1 negated the capacity of EC359 to induce cell death. The evaluation of lipid peroxidation in cells via flow cytometry, utilizing the oxidation of BODIPY™ reagent, further confirmed EC359 induction of ferroptosis. Mechanistic investigations demonstrated that EC359 predominantly triggered ferroptosis by inhibiting the glutathione antioxidant defense system through the downregulation of SLC7A11 and GPX4 levels. EC359 (5 mg/kg/day) was effective in reducing the growth of the IBC KPL4 xenograft tumors. Immunohistochemical examinations of tumors validated reduced cell proliferation as assessed by Ki67 staining.

Conclusion: Collectively, our research suggests that the inhibition of LIFR promotes ferroptosis-mediated cell death in IBC, and LIFR inhibitors represent a novel therapeutic option for IBC.

#1631 Targeting ER stress for treating hepatocellular carcinoma (HCC).

Adriana Baker[1], Xue Yang[2], Uday P. Pratap[1], William C. Arnold[1], Alyssa D. Friudenberg[3], Gaurav Sharma[1], Chia-Yuan Chen[4], Scott Elmore[4], Sukeshi Patel Arora[1], LuZhe Sun[1], Suryavathi Viswanadhapalli[1], Ganesh V. Raj[5], Jung-Mo Ahn[4], Ratna K. Vadlamudi[1]

[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX,[2]The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Texas State University at San Marcos, San Marcos, TX,[4]The University of Texas at Dallas, Dallas, TX,[5]EtiraRx, Dallas, TX

Background: Hepatocellular carcinoma (HCC) accounts for more than 90% of instances of liver cancer, which ranks as the fifth most frequent cancer in the United States. Furthermore, Texas leads the nation in the age-adjusted incidence of HCC. Most patients are diagnosed with advanced, unresectable HCC, and their 5-year survival rate is less than 5% when using current systemic treatments. Therefore, there is an immediate unmet need for new treatment approaches for HCC. Recently, the unfolded protein response (UPR) and endoplasmic reticulum (ER) stress have been recognized as targetable vulnerabilities. From a curated screen, we have previously identified that a synthetic oligo-benzamide, ERX-315, that targets protein encoded by lysosomal acid lipase A (*LIPA*), causes ER stress and cancer cell death without affecting normal cells. This study aims to evaluate the utility of ERX-315 for treating HCC by targeting ER stress

Methods: Tissue micro arrays (TMAs) and Immunohistochemistry (IHC) were used to confirm the expression of LIPA in HCC. LIPA expression in HCC tumors was also confirmed using TNM database. The impact of ERX-315 on 6 well-established HCC cell lines was evaluated using the MTT and colony formation assays. The specificity of ERX-315 targeting activity was confirmed by CRISPR-KO of *LIPA* in one of the HCC cell lines. For mechanistic investigations, Western blotting, RT-qPCR, and splicing assays were employed. Huh7 organoids generated from xenografts were utilized to evaluate the effects of ERX-315 *ex vivo*. Huh7 cell-based xenografts and patient-derived xenograft (PDX) models were used to validate the efficacy of ERX-315 in vivo.

Results: TNM plot analysis revealed that HCC tumors exhibited elevated levels of LIPA expression in comparison to normal tissue. Analysis of TMA samples showed that compared to normal tissue, HCC samples exhibit increased levels of LIPA expression. ERX-315 treatment significantly decreased both colony formation and cell viability (IC_{50} between 30-150nM) and promoted apoptosis in HCC cells. In contrast, ERX-315 did not cause apoptosis in normal liver epithelial cells. Compared to wild type cells, KO of LIPA dramatically attenuated the effect of ERX-315 on colony formation and cell viability in HCC cells. Mechanistic studies using splicing assay, RT-qPCR, and Western blotting demonstrated elevated levels of ER stress indicators upon treatment with ERX-315 in a dose dependent manner. Xenograft-derived Huh7 organoids' cell viability was considerably reduced by ERX-315. ERX-315 therapy dramatically decreased the tumor volume in Huh7 xenograft and PDX models in both male and female mice.

Conclusion: Collectively, our results suggest that ERX-315 promotes ER stress and cell death in HCC *in vitro*, *ex vivo*, and *in vivo*. ERX-315 represents a promising novel therapeutic option for HCC. Since ERX-315 is in clinical trials, these data strongly support evaluation of ERX-315 in patients with liver cancer.

#1632 EGFR-TKIs facilitate cuproptosis via regulating SLC31A1 in cancer cells.

Xiyi Wei[1], Weiyu Kong[1], Zijie Yu[1], Chao Qin[1], Bing Yao[2], Zhou Yang[1]

[1]Department of Urology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China,[2]School of Basic Medical Sciences, Nanjing Medical University, Nanjing, China

Cuproptosis, a novel cellular demise pathway linked to copper homeostasis and copper ionophores, offers promising therapeutic avenues across diverse human ailments. However, the effectiveness of copper ionophores in cancer treatment is not that satisfactory. Tyrosine kinase inhibitors (TKIs) have revolutionized the approach to combating various types of cancer by regulating different cell death manners. In this research, we identified EGFR-TKIs and MEK-TKIs significantly sensitized cuproptosis. Our investigation delineates that the EGFR/MEK signaling cascade phosphorylates JUND, augmenting its transcriptional prowess as a key repressor of SLC31A1. Interestingly, EGFR-TKIs enhance the interaction between EGFR and SLC31A1, impeding UBE3C-mediated degradation, thereby stabilizing SLC31A1 levels. Moreover, copper binding to the extracellular domain of EGFR promotes its dimerization and downstream phosphorylation, orchestrating a protective mechanism under copper-induced stress, whereas EGFR-TKIs interrupt EGFR-SLC31A1 cascade to sensitize cuproptosis. Overall, our findings shed light on the dual roles of EGFR-TKIs and MEK-TKIs in sensitizing cuproptosis within cancer contexts through intricate transcriptional and post-transcriptional regulation of SLC31A1. The prospective combination of EGFR/MEK-TKIs with copper emerges as a promising strategy for cuproptosis-targeted therapies across multiple malignancies with or without EGFR mutation, underscoring the innovative contributions of our study.

#1634 The role of the deubiquitinase USP7 and the E3/E4 ubiquitin ligase complex ITCH/UBE4B in the regulation of cell death in neuroblastoma.

Christophe Le Clorennec, Carla Sampaio, Peter E. Zage

UCSD Moores Cancer Center, La Jolla, CA

Dysregulation of the Ubiquitin Proteasome System has been linked to many human diseases, including cancer. Expression of UBE4B ubiquitin ligase is associated with neuroblastoma patient outcomes and its functional roles in neuroblastoma pathogenesis are not known. We have recently identified an ubiquitin ligase complex ITCH/UBE4B which mediates ubiquitination of Ku70 and c-FLIPL proteins for proteasomal degradation allowing HDAC inhibitor-mediated caspase-8 dependent apoptosis. We also confirmed that the deubiquitinase USP7, critical player in tumor suppression and DNA repair, can be a potential therapeutic target for neuroblastoma. Highly selective USP7 inhibitors have demonstrated significant antitumor activity in preclinical models of adult cancer, and we reported that these inhibitors alone can be more effective against neuroblastoma tumor growth. Our hypothesis is that USP7 inhibition will be more effective against neuroblastoma tumors through destabilization of ITCH/UBE4B complex protein targets allowing a stronger induction of cell death in response to treatment for the children. To evaluate efficacy of USP7 inhibitors in combination with HDAC inhibitors or chemotherapy against neuroblastoma tumor growth, neuroblastoma cell lines depleted for UBE4B or USP7 were treated with increasing concentrations of USP7 inhibitors alone or in combination with chemotherapy or with HDAC inhibitors. Cell proliferation was measured using continuous live cell imaging and apoptosis by caspase cleavage and PARP cleavage detection by western blot. We have evaluated also, whether ubiquitination/deubiquitination and degradation rates of p53, Ku70 and c-FLIPL proteins could modulate induction of apoptosis and necroptosis. USP7 inhibition resulted in decreases in cell viability in p53 wild-type neuroblastoma cell lines via the induction of apoptosis and necroptosis by increasing phosphorylation of MLKL, RIPK3 and RIPK1. In UBE4B or USP7 depleted cells, a huge induction of necroptosis and a small rate of apoptosis were observed. We also identified USP7 as a deubiquitinase of Ku70 and c-FLIPL, stabilizing the Ku70/c-FLIPL/Bax “FLIPosome” complex. USP7 inhibition destabilizes ku70 and c-FLIPL for protein degradation leading to induction of apoptosis as well as necroptosis. UBE4B depletion in neuroblastoma inhibits HDAC inhibitors mediated caspase-8 mediated apoptosis but enhances necroptosis, notably because the stabilization of the FLIPosome Ku70-c-FLIPL can allow the blockade of caspase-8 activation and can trigger the activation of the necroptosome. Our data suggests that USP7 and ITCH/UBE4B can control the switch between apoptosis and necroptosis in response to USP7 and HDAC inhibitors. USP7 inhibition and ITCH/UBE4B activation by HDAC inhibitors could be a promising therapeutic strategy for children with high-risk and relapsed neuroblastoma.

#1635 Targeting ferroptosis in CCDC88A-overexpressing metastatic triple-negative breast cancer.

Wei-Ling Tu, Mu-En Wang, Ji-Hoon Kim, Alyssa Bawcom, Yi Lu, Ming Chen

Pathology, Duke University, Durham, NC

Triple-negative breast cancer (TNBC) is a form of breast cancer that does not express estrogen receptor (ER), progesterone receptors (PR) or human epidermal growth factor receptor 2 (HER2). It accounts for 15-20% of all breast carcinomas and preferentially affects women who are African American, younger than age 40, or have a *BRCA1* mutation. The TNBC subtype is highly aggressive and heterogeneous and has a poor prognosis relative to other breast cancer subtypes due to a lack of highly recurrent and actionable biomarkers that can be used to direct therapy. Although standard chemotherapies show a high initial response rate in TNBC, tumor relapses and metastasis often occur rapidly. Moreover, for patients who have recurrent disease or progressive disease during chemotherapy, treatment options are limited. Therefore, there is an unmet need to identify effective therapies targeting TNBC. By analyzing public human datasets, we found that CCDC88A (also known as Girdin or GIV), a putative oncogene, is highly expressed in TNBC compared to other breast cancer subtypes. CCDC88A has been found to be involved in key cancer development events such as tumor angiogenesis, invasion, wound healing, and metastasis. Interestingly, we found that, although the high expression of CCDC88A conferred the ability of lung metastasis, it increased the susceptibility of TNBC to ferroptosis, a type of cell death induced by iron-dependent lipid peroxidation. Mechanistically, CCDC88A sensitized TNBC cells to ferroptosis by limiting intracellular glutathione (GSH) levels. shRNA-mediated CCDC88A knockdown in TNBC cells significantly increased GSH levels and in turn blunted cellular sensitivity to ferroptosis. On the other hand, inhibition of GSH synthesis with a glutamate-cysteine ligase (GCL) inhibitor, BSO, restored the ferroptosis sensitivity in CCDC88A knocked-down TNBC cells. Thus, our findings uncover CCDC88A as a novel ferroptosis regulator and also suggest that ferroptosis is a therapeutically tractable target for metastatic TNBC that overexpresses CCDC88A.

#1636 Novel CDK12/13 inhibitor CTX-439 downregulates MCL1 via transcriptional mRNA read-through and synergistically acts with BCL-XL inhibitors for cancer therapy.

Hiroko Yamakawa[1], Raghda Khatab[2], Yusuke Tarumoto[2], Mariko Takano[2], Seiichi Sugino[2], Shafiqul Islam[2], Shunsuke Ebara[1], Kosuke Kawaguchi[3], Masakazu Toi[3], Akio Mizutani[1], Midori Sugiyama[1], Misaki Yoshida[1], **Daisuke Morishita**[1], Kosuke Yusa[2]

[1]Chordia Therapeutics Inc., Fujisawa, Japan,[2]Stem Cell Genetics, Institute for Life and Frontier Sciences, Kyoto University, Kyoto, Japan,[3]Department of Breast Surgery, Graduate School of Medicine, Kyoto University, Kyoto, Japan

Combination therapeutic strategies for cancer use multiple agents targeting distinct pathways to enhance the treatment efficacy and minimize resistance. By simultaneously disrupting key cancer cell survival mechanisms, these strategies improve the outcomes better than monotherapies, effectively combating cancer complexity and adaptability. Cyclin-dependent kinase (CDK)-12/13 regulates RNA transcription by phosphorylating RNA polymerase II, promoting the elongation of transcripts involved in the DNA damage response, such as BRCA1/2. As an emerging drug target, the potential of CDK12 to enhance the poly (ADP ribose) polymerase (PARP) inhibitor effects has been re-evaluated. CDK12/13 and PARP inhibitors exert synergistic effects. CDK12/13 inhibitor is currently undergoing clinical trial. However, therapeutic potential of CDK12/13 inhibitor combinations with other factors beyond PARP remains unclear, necessitating further investigations to expand their clinical applications. We successfully developed CTX-439, a novel orally bioavailable ATP-competitive CDK12/13 small-molecule inhibitor (Yamakawa *et al*., AACR2022/2024). CTX-439 exhibited anti-tumor activity alone and in combination with PARP inhibitors. To identify other factors synergistic with CTX-439, we performed a CRISPR activation screening using the SUM149 breast cancer cell line and identified four genes, whose overexpression conferred CTX-439 resistance. Anti-apoptotic factors BCL-XL and BCL2 were among the top candidates, whose inhibition enhanced CTX-439 efficacy. Moreover, dual inhibition of CTX-439 and AZD4320, which targets BCL-XL, synergistically induced rapid apoptosis *in vitro* and significantly suppressed tumor growth *in vivo*. Mechanistically, CTX-439 downregulated the protein levels of anti-apoptotic factor MCL1, but not BCL-XL, thereby shifting the dependency to BCL-XL for cell survival, suggesting BCL-XL inhibition as a critical apoptosis mechanism in CTX-439 combination strategies. Notably, CTX-439 significantly increased the read-through transcription of the *MCL1* mRNA, leading to its nuclear retention. Furthermore, lack of mature mRNA supply resulted in the rapid turnover of cytosolic *MCL1* mRNA due to its short half-life, leading to the downregulation of MCL1 protein levels. In summary, previously reported combination strategies with CDK12/13 inhibitors focused on regulating long mRNAs, particularly those associated with the DNA damage response. Interestingly, our study revealed a novel CDK12/13 inhibition mechanism targeting short mRNAs, such as *MCL1*, that can be used to establish new therapeutic combination strategies with BCL-XL inhibitors. Additionally, our study provides a new avenue to improve cancer therapy outcomes.

#1637 GPX4-mediated Pathway Regulates Iron Efflux to Prevent Ferroptotic Cell Death and Promote Immunosuppressive Signals in Osteosarcoma Cells.

Md Abdullah, Donghee Lee, Rong Li, Eslenur Nipa, Jong Hyuk Kim

University of Florida, Gainesville, FL

Osteosarcoma is a malignant bone sarcoma prevalent in children, adolescents, and young adults, with limited treatment options. Targeting ferroptosis, an iron-dependent form of cell death driven by lipid peroxidation, presents a potential therapeutic strategy for cancers. However, the molecular mechanisms that regulate iron metabolism in ferroptosis remain unclear. In this study, we explored cell defense mechanisms against ferroptosis mediated by intracellular iron regulation and immune signaling pathway in osteosarcoma cells. First, we found that xCT and GPX4 protein were detected with variable expressions across five osteosarcoma cell lines. Erastin, an xCT inhibitor, and RSL3, a GPX4 inhibitor, induced ferroptotic cell death in these cells. Specifically, higher inhibitory dose of RSL3 induced a significant reduction in GPX4 levels in U2OS and MG-63 cells in a dose- and time-dependent manner. In contrast, xCT expression increased in these cells, suggesting an adaptive mechanism to counteract oxidative stress following GPX4 depletion. RSL3 treatment elevated lipid peroxidation levels in U2OS and MG-63 cells, which were restored by Ferostatin-1. Our RNA-seq analysis identified 18 differentially expressed genes in response to RSL3 treatment in U2OS cells, with the highest expression in AKR1C1 gene, which plays a significant role in oxidative stress. We confirmed that GPX4 inhibition upregulated AKR1C1 gene expression as well as other oxidative stress markers, including NRF2, HMOX1, and NQO1.Our data also showed that osteosarcoma cells modulated intracellular iron homeostasis in response to GPX4-mediated ferroptotic stress. GPX4 inhibition significantly enhanced FPN and FTH1 expression, which are essential for iron efflux and storage, in U2OS cells, while MG-63 cells only increased FTH1 with minimal change in FPN. Furthermore, macrophage stimulating protein receptor (MSPR) protein expression was significantly increased by GPX4 inhibitor using Proteome Profiler analysis. We observed that combination treatment with dual MSPR and MET inhibitor, BMS-777607, showed synergistic effects with GPX4 inhibition. Altogether, our findings demonstrate that ferroptotic cell death is inducible in osteosarcoma cells, and the potential resistance mechanism to ferroptosis is mediated by oxidative stress mechanism and intracellular iron regulation. We also identified novel target, MSPR, regulated by GPX4 inhibition, which potentially contribute to the activation of immunosuppressive signals from osteosarcoma. In conclusion, this study underscores that targeting the ferroptotic pathway holds a great promise for therapeutic potential in osteosarcoma by regulating both intracellular pathway and the immunosuppressive tumor microenvironment.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Degraders and Glues 2
Poster Session

#1642 Next trip: a promising CK1α-selective molecular glue degrader in MSS colorectal cancer.

Hyunsun Jo, Hoon Choi, Hyemin Kim, Sohyun Park, Yelim Shin, Hyewon Shin, Yeonju Yoo, Dohee Yoon, Cheongbi Kim, Jinuk Kong, Goun Choi, Hadong Kim

Pin Therapeutics, Seongnam-si, Korea, Republic of

Casein kinase 1α (CK1α) is a serine/threonine kinase that plays a critical role in cellular homeostasis. In previous studies, CK1α promotes p53 inactivation by regulating MDM2 and MDMX, and this mechanism may represent a promising anticancer target Indeed, many studies have been reported recently on the development of CK1α inhibitors and degraders as anticancer agents. We recently developed PIN5018, a selective CK1α inhibitor, and reported that it exhibits promising anticancer activity in acute myeloid leukemia (AML) and adenoid cystic carcinoma (ACC). Interestingly, PIN5018 showed anti-tumor activities in aggressive subtypes of AML patient xenograft (PDX) and ACC patient-derived xenograft (PDX) model. Strikingly, our CK1α MGD not only achieved complete remission in the ACC PDX model during drug administration but also maintained this effect for more than 20 days after discontinuation of the treatment. We conducted 2D or 3D *in vitro* activity assessments to screen for anticancer activity in additional candidate solid tumors. Based on these results, we focused our research on colorectal cancer (CRC). CRC is the third most prevalent cancer and a leading cause of cancer-related deaths worldwide. Over 80% of CRC patients are of the microsatellite stable (MSS) type, which, unlike the MSI group, represents a population with high unmet needs. For example, while chemotherapy and certain targeted therapies are available, they are applicable to only a subset of MSS patients, resulting in limited treatment options. From this perspective, we aimed to investigate the correlation between specific biomarkers and the *in vitro* and *in vivo* efficacy of PIN5018 in MSS CRC. As a result, we identified promising anticancer efficacy of PIN5018-mediated CK1α degradation under specific combinations of biomarker mutation conditions. Furthermore, we observed synergistic effects with PIN5018 when combined with standard of care (SoC) drugs. Taken together, these findings demonstrate the potential of our CK1α-selective MGD as a promising therapeutic candidate not only for AML and ACC but also for MSS CRC. Lastly, we are aiming for clinical entry by 2025 Q1.

#1643 Establishing rational combination strategies with selective CBP degraders in solid tumor indications.

Molly M. Wilson, Hafiz Ahmad, Benjamin Adams, Ketaki Adhikari, Wesley Austin, Breanna Bullock, Mike Collins, Danette Daniels, Julie Di Bernardo, Thomas Dixon, Claudia Dominici, Brian Ethell, Anais Gervais, Md Imran Hossain, Dave Lahr, Laura La Bonte, Michael Lehrke, Mei Yun Lin, David Mayhew, Karolina Mizeracka, Paige Monsen, Solymar Negretti, John Pulice, Abira Ramakrishnan, Darshan Sappal, Shawn Schiller, Samantha Schultz, Gromek Smolen, Nihan Ucisik, Grace Werosta, Elizabeth Wittenborn, Xiaohuan Wu, Qianhe Zhou, Mark Zimmerman

Foghorn Therapeutics, Cambridge, MA

The paralog lysine acetyltransferases CREB binding protein (CBP) and E1A binding protein P300 (EP300) function as transcriptional coactivators that regulate diverse cellular programs. Mutations in *CBP* and *EP300* have been implicated in the biology of various cancer types. The bidirectional synthetic lethal relationship between these paralogs in tumor cells highlights a therapeutic opportunity in targeting CBP selectively in *EP300*-mutant cancers. We have previously demonstrated that our selective CBP degraders have potent antiproliferative activity in *EP300*-mutant cancers through both in vitro assays and cell line-derived xenograft models when used as a single agent. We have now expanded our studies to explore strategies for combination treatment with approved chemotherapies to enhance tumor growth inhibition.

Here, we demonstrate that our selective and potent CBP degrader compounds provide combinatorial benefit when used with approved chemotherapeutic and targeted agents. Through a large-scale in vitro combination screen, we show that CBP degrader treatment synergizes with multiple standard-of-care chemotherapies, including paclitaxel, as well as targeted agents, including CDK4/6 inhibitors. Furthermore, by genome-wide CRISPR knockout screening across four cell line models of different solid tumor types, we establish genetic determinants of resistance and sensitivity to CBP degradation in an *EP300*-mutant background, providing further mechanistic insight into combination therapy approaches. Collectively, we have defined cellular processes that present therapeutic vulnerabilities that can be leveraged for rational combination strategies with selective CBP degraders in solid tumor indications.

#1644 Novel CDK9 degrader XY0597 potently inhibits gastroesophageal cancer growth and overcome resistance by increasing chromatin accessibility and down-regulating YAP/TEAD signaling.

Yan-ting Yann Zhang[1], Mikel Ghelfi[1], Yu Xue[2], Haiying Chen[2], Gennaro Calendo[1], Dipti Athavale[1], Curt Balch[1], Xiaodan Yao[1], Woonbok Chung[1], Luke Chen[1], Francis Spitz[3], Generosa Grana[4], Jia Zhou[2], Jean-Pierre Issa[1], Shumei Song[1]

[1]Coriell Institute for Medical Research, Camden, NJ,[2]Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX,[3]Departments of Surgery, Cooper University Hospital, Camden, NJ,[4]MD Anderson Cancer Center at Cooper, Cooper University Hospital, Camden, NJ

Gastroesophageal cancer (GEAC) consists of upper GI malignancies of the esophagus, gastroesophageal junction, or stomach. Despite recent advancements in treatment modalities, GEAC remains a major health burden and listed as the second leading cause of cancer-related deaths globally. GEAC poses a significant challenge with short survival and lack of effective therapeutics. Thus, uncovering novel targets is urgent need. Cyclin-dependent kinase 9 (CDK9), one of the transcription-associated CDKs, has been implicated in regulation of transcription via RNA Pol II pausing/release, and epigenetic modification of genes that contribute to tumorigenesis. However, the functional role of CDK9 and its potential targeting in GEAC remain largely unknown. In this study, we demonstrated that nuclear CDK9 expression was significantly elevated in primary GEAC tumor tissues including PDXs compared to normal tissues, in association with poor survival. Moreover, we developed a novel CDK9 degrader, YX0597 and showed that YX0597 strongly suppresses CDK9 expression, inhibits RNA Pol II Serine 2 phosphorylation and dramatically decrease its target MCL-1 that accompanied by potently inhibition of GEAC cell growth, decreased tumor cell invasion and tumor sphere formation especially in radiation resistant tumor cells. Mechanistically, YX0597 strongly enhanced chromatin accessibility and activated epigenetically silenced genes. Further, both CDK9 and YAP1 colocalized in tumor tissues and significantly correlated in GEAC; and RNAseq revealed YAP1, TEAD4 and its targets (CTGF, Cyr61) were dramatically reduced upon XY0597 treatment that correspond to CDK9 inhibition. Correspondingly, XY0597 strongly suppress expression of CDK9, MCL-1, YAP1, YAP1 transcription factor TEAD4 in radiation resistant cells compared to parental cells and showed more potently suppressed radiation resistant tumor cell growth *in vitro* and *in vivo*. Most importantly, the combination of CDK9 degrader XY0597 and a novel YAP1/TEAD inhibitor, VT00278, synergistically attenuated resistant tumor growth and progression *in vitro* and in the PDX model. Taken together, our studies open a new avenue for targeting CDK9 hyperactivated GEAC tumors especially in combination with YAP1/TEAD inhibition.

#1645 Developing first-in-class AR-V7/AR-fl molecular glue degrader to revolutionize prostate cancer therapeutics.

CheukMan Cherie Au[1], Michelle Naidoo[1], Catrina Estrella[1], Prerna Vatsa[1], Ying Wang[2], Zhao Wang[2], David M. Nanus[3], Urko del Castillo[1], Paraskevi Giannakakou[3]

[1]Department of Medicine, Weill Cornell Medicine, New York, NY,[2]Baylor College of Medicine, Houston, TX,[3]Meyer Cancer Center, Weill Cornell Medicine, New York, NY

Metastatic castration resistance prostate cancer (mCRPC) is a lethal disease due to the resistance of standard-of-care (SoC) treatments, including androgen receptor (AR) pathway inhibitors and taxanes. Treatment resistance occurs partly due to the expression of constitutively active AR splice variants, that hijack AR signaling even after castration. AR-V7 is the most prevalent variant and is expressed in ~75% of patients with mCRPC, which confers resistance to SoC treatment. Currently, there is no AR-V7 pharmacologic inhibitor, limiting patients' therapeutic options. Thus, AR-V7 inhibition remains an urgent clinically unmet need. To address this gap, we performed a robust high-throughput phenotypic screen of ~170K compounds to identify the first AR-V7 protein glue degraders. In addition to degrading AR-V7, our hit compound also degraded full-length AR (AR-fl), having a unique chemotype compared to all existing AR modulators. Hit-to-lead optimization through medicinal chemistry and SAR studies has yielded more potent lead AR-V7/AR-fl degraders (IC50 of <100 nM). Mechanistically, our lead compounds promoted Cullin-RING E3 ligase-mediated proteasomal degradation of AR-V7 and AR-fl within 4 hours, which was blocked by the proteasome inhibitor, bortezomib. Currently, while several AR-fl-PROTAC degraders are in preclinical and early clinical development, no AR-V7 degrader exists. Our lead compounds are the only degraders that target both AR-fl and AR-V7. They bind to the TAU1 and AF-1 functional subdomains within the AR N-terminus (NTD), which is shared by both AR isoforms. Preliminary molecular docking experiments using RoseTTAFold2 further supported this binding. Additionally, Cryo-EM analysis identified conformational changes of AR-fl in the presence of our compounds indicating direct binding, which was also confirmed by cellular thermal shift assays. Importantly, our lead compounds effectively reversed SoC treatment-resistance in preclinical models and demonstrated higher potency than enzalutamide or ARV-110 (AR-fl-PROTAC). Our lead compounds showed excellent on-target activity, favorable drug-likeness, and promising pharmacokinetics, with strong stability, oral bioavailability, and efficacy in enzalutamide-resistant mCRPC xenografts expressing both AR-V7 and AR-fl. We are also conducting an E3-ligase CRISPR screen to nominate the E3 ligase that mediates the degradation activity and using global proteomics to assess potential off-target effects. Collectively, these data support a first-in-class molecular glue degrader mechanism, enabling rapid degradation of both AR-fl and AR-V7 through targeting the AR NTD. In summary, our compounds offer a dual-targeting approach in a single treatment and have the potential to dramatically improve survival for patients with mCRPC and prevent the emergence of AR-V7 expression in patients with earlier-stage disease.

#1646 Elucidating the molecular mechanism of action of the first in human SMARCA2 selective degrader PRT3789.

Min Wang, Miles Cowart, Joy Cote, Justin Kurian, Stephanie Rodgers, Chaoyi Xu, Corey Basch, Philip Pitis, Klare Bersch, Raul Leal, Liang Lu, Michael Hulse, Andrew Moore, Alexander Grego, Joseph Rager, Tom Emm, Koichi Ito, Neha Bhagwat, Andrew Combs, Sandy Geeganage, Peggy Scherle

Prelude Therapeutics, Wilmington, DE

Mammalian SWI/SNF (BAF) complexes play an important role in controlling gene expression by remodeling chromatin. SMARCA2 (BRM) and SMARCA4 (BRG1) are the core catalytic subunits of the SWI/SNF complexes and regulate the composition of nucleosomes via their ATPase activity. Approximately 10-12% of non-small cell lung cancer (NSCLC) patients harbor SMARCA4 mutations, resulting in loss of SMARCA4 protein or loss of its function (LOF). These SMARCA4-deficient cancer cells are highly dependent on the paralog gene SMARCA2 for their growth and survival. We have identified PRT3789, a first-in-class SMARCA2 selective targeted protein degrader currently in clinical trials (NCT05639751). PRT3789 promoted the formation of ternary complexes between the bromodomain of SMARCA2 or SMARCA4 with the VHL E3 ligase. Although SMARCA2 and SMARCA4 share 87% identity in their bromodomain, the structural differences between PRT3789 induced SMARCA2-VHL and SMARCA4 -VHL ternary complexes lead to more productive ubiquitination on SMARCA2 compared to SMARCA4. Proteomics and mutagenesis studies identified specific lysine residues that were ubiquitinated on the bromodomain of SMARCA2 and SMARCA4, and a unique loop on SMARCA2 that contributed to ternary complex stabilization and ubiquitination. In summary, we describe the systematic characterization of PRT3789 mediated SMARCA2 degradation and illustrate the molecular mechanism of action for how PRT3789 achieves degradation selectivity against SMARCA4.

#1647 CC2000199, a potent and selective androgen receptor ligand-directed degrader (AR LDD) with a dual mechanism of action, exhibits anti-tumor activity in multiple enzalutamide-resistant preclinical models for metastatic castration-resistant prostate cancer.

S. Nayak[1], **M. Ammirante**[1], E. Rychak[1], D. Liao[1], J. D. Norris[2], S. E. Wardell[2], S. Kasibhatla[1], V. Plantevin-Krenitsky[1], E. Horn[1], J. R. Piccotti[1], S. Norris[1], R. Kandimalla[1], J. Meiring[1], S. Reiss[1], J. M. Baughman[1], M. Khater[1], D. S. Mortensen[1], B. Cathers[1], N. Bence[1], D. W. Pierce[1], J. D. Hansen[1], L. G. Hamann[1], D. P. McDonnell[2], R. K. Narla[1], M. Rolfe[1], S. Xu[1];

[1]Bristol Myers Squibb, San Diego, CA, [2]Duke University School of Medicine, Durham, NC

The androgen receptor (AR) is a key driver of the cellular processes that contribute to the pathology of prostate cancers at most stages, and drugs that inhibit the activity of this receptor or which interfere with androgen biosynthesis have become the cornerstone of treatments for prostate cancer. Nevertheless, *de novo* and acquired resistance remains an impediment to a durable clinical response in patients with metastatic castration-resistant prostate cancer (mCRPC), and overcoming resistance to AR pathway inhibitors (ARPIs) has emerged as a major challenge in the treatment of patients with mCRPC. CC2000199 (also called CC-199) is a heterobifunctional ligand-directed degrader (LDD) that enables $CRL4^{CRBN}$ E3 ligase-dependent ubiquitination and degradation of AR and a close analog of BMS-986365. It is a highly potent and selective AR degrader that induces rapid and deep degradation of both wildtype and mutant forms of the receptor. In addition to AR degradation, CC-199 displays AR-inhibitory activity as a direct receptor antagonist with a potency similar to enzalutamide (ENZ) for wildtype AR. The drug is ~100-fold more potent than ENZ at inhibiting androgen-stimulated transcription of AR target gene FKBP5, and ~10- to 40-fold more potent than ENZ at inhibiting AR-dependent proliferation of multiple prostate cancer cell lines *in vitro*. In animal models of advanced prostate cancer, CC-199 demonstrates on-target activity, inducing deep AR degradation, suppressing AR signaling, and inhibiting tumor growth. Indeed, significant tumor volume reductions were achieved by CC-199 in validated models of advanced CRPC and therapy resistant patient-derived xenografts, including those with acquired resistance to ENZ. Collectively, our preclinical data suggest that the AR degrader CC-199 is superior to standard-of-care AR antagonists, such as ENZ, in disease-relevant animal models and ENZ-resistant mCRPC that remain dependent on AR.

#1648 LT-010366, a first-in-class orally bioavailable KRAS G12D degrader in the treatment of multiple KRAS G12D-mutated cancer models *in vitro* and *in vivo*.

Shuang Yan, Zhengqing Ye, Haiji Chen, Chenli Ding, Juan Xu, Yan Feng

Leadingtac Pharmaceutical (Shaoxing) Co., Ltd, Shanghai, China

Recent successes in targeting $KRAS^{G12C}$ have provided both insight and inspiration for targeting alternative KRAS mutants. Among KRAS mutations, KRAS G12D is the most frequent driver mutated isoform and is found in approximately 34% of patients with pancreatic ductal adenocarcinoma (PDAC), 12% of patients with colorectal cancer (CRC), 4% of patients with lung adenocarcinoma, and in a subset of patients with other solid tumors. We have developed LT-010366 as a first-in-class orally bioavailable KRAS G12D degrader with high potency and selectivity. In *In vitro* degradation assays, LT-010366 demonstrated extraordinary degradation activities with DC_{50} of 0.96-2.55 nM and efficiency (D_{max}) over 95% against KRAS protein in multiple cancer cell lines harboring KRAS G12D mutation, as well as remarkable inhibition of p-ERK with IC_{50} of 0.52-26.06 nM in those cell lines. In cell proliferation assays, LT-010366 showed a strong antiproliferative potency with IC_{50s} of 0.12-15.77 nM and max inhibition of 74.42-98.4% in tested KRAS G12D mutant cancer cell lines. Moreover, LT-010366 selectively degrades KRAS, sparing HRAS and NRAS. In CDX tumor, daily oral administration of LT-010366 exhibited potent antitumor activities in both PDAC (PK-59) and CRC (GP2D) models with KRAS G12D mutation, resulting in profound tumor regression without body weight loss. In GP2D xenograft model, LT-010366 demonstrated dose-dependent tumor inhibition at the dose of 10 mg/kg, 30 mg/kg and 100 mg/kg PO, QD with TGI of 95.7%, 114.4% and 116.5% after 14-day treatment, respectively. In PK-59 model, LT-010366 demonstrated dose-dependent tumor inhibition at the dose of 3 mg/kg, 10 mg/kg and 30 mg/kg PO, QD with TGI of 69.3%, 116% and 126.8% after 15-day treatment, respectively. In GP2D model, LT-010366 also exhibited dose-dependent degradation of KRAS protein and demonstrated marked inhibition of downstream p-ERK and p-S6. In addition, LT-010366 also displays a high-quality drug-like profile. In summary, our results demonstrated that LT-010366 induced degradation of KRAS G12D protein, inhibition of KRAS downstream signaling mediators and exhibited antitumor activity in multiple KRAS G12D-mutated cancer cells *in vitro* and *in vivo*. LT-010366 is a promising therapeutic agent to be advanced to clinical development for patients with tumors harboring KRAS G12D mutation.

#1649 Discovery of first-in-class potent and selective oral degraders of KAT6A that demonstrate anti-cancer activity in pre-clinical models.

Monisha Sivakumar, Sarah Pawley, Anthony Reichelderfer, Corey Basch, Jimin Park, Jessica Burtell, Chaoyi Xu, Min Wang, Chun Chen, Justin Kurian, Joy Cote, Miles Cowart, Stephanie Rodgers, Amy Crossan, Joseph Rager, Koichi Ito, Sandy Geeganage, SangHyun Lee, Andrew Combs, Peggy Scherle, Andrew Buesking, **Jack Carter**

Prelude Therapeutics Incorporated, Wilmington, DE

MYST proteins (e.g. KAT6A, KAT6B, KAT7) are histone acetyltransferases that epigenetically regulate chromatin accessibility. KAT6 expression is associated with cancer growth and *KAT6A* is recurrently amplified in several cancer types, including breast and lung. KAT6A complexes with multiple proteins, such as bromodomain and PHD finger containing 1 (BRPF1), enhancing its regulation of cell cycle, estrogenic, and other oncogenic genes. Recent first-in-human clinical data with a dual KAT6A/B inhibitor demonstrated promising efficacy in heavily pre-treated patients with ER+/HER2- breast cancer and provided insight into on-target safety considerations like neutropenia. Reports describing the role of KAT proteins in hematopoietic cells, and non-catalytic functions for KAT6A, led us to hypothesize that a targeted protein degradation approach to selectively degrade KAT6A may improve the anti-cancer activity and safety profile for KAT6 therapies. We report the discovery of potent (<1 nM DC_{50}) oral KAT6A degraders with excellent selectivity over KAT6B and KAT7. Degradation occurred via the proteosome and was dependent on target and E3-ligase binding. KAT6A degraders suppressed breast cancer cell proliferation, enriched in ER+/HER2- models expressing KAT6A, and retained activity in endocrine therapy resistant cells. To assess the differential biology of KAT6A degradation, we compared an inhibitor with a degrader. Strikingly, KAT6A degradation had a deeper anti-proliferative effect in breast cancer cell lines compared to the inhibitor. The superior response was reversible by competition with the binder warhead and an E3-inactive degrader displayed limited activity, suggesting that KAT6A degradation drove this effect. Encouragingly, KAT6A degraders also demonstrated superior anti-proliferative activity in multiple lung cancer cell lines. Mechanistically, RNA-seq revealed degraders induced a more profound global effect on gene expression, enriched in estrogenic, cell cycle, DNA replication and repair, and MYC signaling pathways. Consistent with the gene expression changes, KAT6A degraders induced a deeper reduction in estrogen receptor (ERα) expression. Notably, only KAT6A degraders reduced BRPF1 expression, a subunit of the KAT6 complex, suggesting that degradation of KAT6A may destabilize the protein complex. *In vivo*, we show a KAT6A degrader robustly inhibits tumor growth, while degrading KAT6A and reducing ERα expression, in a breast cancer xenograft. Lastly, we utilized a predictive assay for neutropenia (CFU-GM), where we found KAT6A-selective degraders were inactive, in contrast to KAT6A/B inhibitors. Our first-in-class KAT6A degraders demonstrated proof-of-concept for a differentiated strategy with potential to improve the depth of response and safety profile for a clinically active anti-cancer target.

#1651 NRX-0305: a pan-mutant BRAF degrader with broad preclinical efficacy, brain penetrance, and synergistic potential with MEKi across class 1/2/3 BRAF-mutant cancers.

Alexandra Borodovsky, Ya-Wen Lu, Ge Peng, Karthik Arumugam, Paul Auger, Robert Cass, Stefan Gajewski, Scott Kimura, Daniel Medina-Cleghorn, Mariah Mesner, Davorka Messmer, Madeleine Nemchek, Prabu Raman, Ryan Rountree, Rusha Sardhara, Sangita Sridharan, Jennifer Stokes, Leslie Tong, Jennifer Tung, Ge Wei, Jeffrey Wu, Jordan Ye, Gwenn M. Hansen

Nurix Therapeutics, Inc., San Francisco, CA

Mutations in BRAF, a key component of the mitogen-activated protein kinase (MAPK) pathway, drive constitutive pathway activation and oncogenic transformation and are commonly found in a variety of cancers including melanoma, NSCLC and CRC. BRAF mutations are categorized into three classes: Class 1 (e.g., V600X), which are RAS-independent and targetable with currently approved BRAF inhibitors (BRAFi); Class 2, which require dimerization; and Class 3, which are kinase-impaired and rely on upstream RAS activation. While approved BRAFi provide significant survival benefit to Class 1 patients, drug durability and efficacy are limited by the emergence of primary and acquired resistance that often involves RAF dimerization and BRAF amplification. Furthermore, patients who have progressed on BRAFi, especially in melanoma, frequently present with brain metastases, for which there are limited treatment options due to poor CNS penetrance of available drugs. To address this, we developed NRX-0305, a pan-mutant BRAF degrader that selectively degrades mutant BRAF across all classes while sparing wildtype BRAF. In vitro, NRX-0305 potently degrades mutant BRAF protein and suppresses downstream pERK1/2 signaling. NRX-0305 exhibits strong anti-proliferative effects across a panel of Class 1/2/3 BRAF-mutant cell lines including those expressing BRAF fusion proteins. In vivo, daily oral dosing with NRX-0305 induces robust BRAF degradation and exhibits single agent efficacy in several cell line and patient-derived xenograft models of Class 1/2/3 BRAF mutant cancers. Notably, NRX-0305 demonstrates robust single agent activity in BRAFi resistant Class 1 PDX models and a melanoma brain metastasis model, highlighting its brain penetrant properties. Furthermore, NRX-0305 in combination with MEK inhibition achieves complete tumor regression in a Class 3 bladder cancer PDX model, demonstrating its synergistic potential. These findings establish mutant-specific BRAF degradation as a promising therapeutic strategy, displaying activity across a broad range of mutations and addressing the limitations of BRAFi in Class 1/2/3 BRAF-mutant cancers.

#1653 Preclinical characterization of PLX-61639, a potent and orally bioavailable SMARCA2-selective monovalent direct degrader.

Gregory Parker, Geoffray Leriche, Aleksandar Jamborcic, Taylor Kampert, Linette Yang, Julia Toth, Kenneth Steadman, Jay Chung, Duc Tran, Luis Lopez, Farhana Barmare, Kyohei Hayashi, Gang Liu, Jianguo Ma, Alex Campos, Meg McCarrick, Kevin Freeman-Cook, Peggy Thompson

Plexium, San Diego, CA

SMARCA2 and SMARCA4 are essential, yet redundant, catalytic subunits of human BAF complexes, which are involved in controlling gene expression through the remodeling of chromatin structure. In a subset of solid tumors, SMARCA4 is commonly mutated, rendering SMARCA4-deficient cancer cells highly dependent on SMARCA2 for viability. Therefore, selectively targeting SMARCA2 in patients with SMARCA4-deficient tumors may provide an effective and safe treatment option. Targeted protein degradation (TPD) using the endogenous Ubiquitin Proteasome System (UPS) is a drug discovery strategy that may be well suited for exploiting this SMARCA2/4 synthetic lethal relationship. Here we describe the discovery and characterization of PLX-61639, a potent, selective, and orally bioavailable SMARCA2 degrader. To enable degrader discovery, we utilized a monovalent direct degrader strategy where small molecules are designed to bind the target protein and induce its degradation through the recruitment of an E3 ligase complex. Rational design of compound libraries from known family VIII bromodomain binders resulted in the identification of monovalent direct degraders of SMARCA2/4. Subsequent chemical series optimization dramatically improved degradation selectivity and ultimately resulted in our development candidate, PLX-61639. PLX-61639 induces potent and selective degradation of SMARCA2 across a panel of tumor cell lines, eliciting anti-proliferative activities supportive of the synthetic lethal dependency in $SMARCA4^{MUT}$ tumors. A UPS focused CRISPR screen identified a specific E3 ligase complex involved in the degradation mechanism, which follow up mechanistic studies confirmed. Omics studies identified PLX-61639-induced changes to chromatin mapping and SMARCA2-dependent transcriptionally regulated gene sets. *In vivo*, oral administration of PLX-61639 in $SMARCA4^{MUT}$ xenograft models exhibited sustained target degradation and dose-dependent tumor growth inhibition at well tolerated doses. PLX-61639 had no impact on tumor growth using a $SMARCA4^{WT}$ xenograft model, supporting the dependency of SMARCA4 mutational status for SMARCA2-selective degrader efficacy. These results highlight the efficient discovery and development of potent and selective SMARCA2 monovalent direct degraders. Further, the preclinical characterization of our development candidate, PLX-61639, demonstrates its activity and potential utility in the treatment of $SMARCA4^{MUT}$ solid tumors.

#1654 Discovery of the first-in-class DOT1L PROTAC degrader.

H. Yim, Z. Xu, H. Kaniskan, J. Jin;
Icahn School of Medicine at Mount Sinai, New York, NY

The histone methyltransferase, DOT1L is often dysregulated in MLL-rearranged (MLL-r) leukemia, which leads to hyperactivation of MLL target genes and poor prognosis. This dysregulation is particularly common in infants, who are highly vulnerable to treatment-related toxicity. However, current treatment options remain limited, with intensive chemotherapy as the standard approach. Given these circumstances, targeting DOT1L with PROteolysis TArgeting Chimeras (PROTACs) could represent a promising alternative therapeutic strategy. Here, we report the discovery of the first-in-class DOT1L PROTAC degrader, MS2133, which induces DOT1L degradation in a dose- and time-dependent manner via the ubiquitin-proteasome system, without affecting DOT1L mRNA expression. MS2133 shows selectivity for DOT1L over other methyltransferases and effectively inhibits the growth of MLL-r leukemia cells while having no toxic effect on normal cells. Overall, MS2133 is a valuable chemical biology tool for studying DOT1L functions and offers promise as a therapeutic option for MLL-r leukemia treatment.

#1655 ARV-393, a PROTAC B-cell lymphoma 6 (BCL6) degrader, combined with biologics or small molecule inhibitors (SMIs) induces tumor regressions in diffuse large B-cell lymphoma (DLBCL) models.

Anna Van Acker, Lynn DeCarr, Sarah Eaton, Dan Sherman, Elizabeth Bortolon, Mark Bookbinder, Jennifer Pizzano, Morena Scopel, William Corwin, Ignacio Juncadella, Yongqing Huang, Ram Lingamaneni, Stephanie Renzullo, Jennifer Cantley, XiaoZhe (Janet) Wang, Ian Taylor, Sean Landrette, Sheryl M. Gough

Arvinas Operations, Inc., New Haven, CT

BCL6 is a preclinically validated oncogenic driver of DLBCL historically considered to be undruggable. ARV-393, a PROteolysis TArgeting Chimera (PROTAC) degrader, directly binds an E3 ubiquitin ligase and BCL6 to induce ubiquitination of BCL6 and its subsequent proteasomal degradation. ARV-393's iterative activity overcomes rapid resynthesis of BCL6 resulting in potent, single-agent activity and tumor regressions in many cell- and patient-derived xenograft (CDX and PDX) DLBCL models. ARV-393 monotherapy is being evaluated in a phase 1 trial (NCT06393738) in patients with non-Hodgkin lymphoma, including DLBCL.

Given the heterogeneity and multiple resistance mechanisms of DLBCL and that BCL6 regulates hundreds of genes linked to oncogenesis and resistance, BCL6 degradation has the potential for broad drug combinability. For example, CREBBP/EP300 and BCL6 have opposing transcriptional activities and BCL6 degradation may prevent CD20 downregulation by restoring CREBBP/EP300 chromatin access, supporting combination with anti-CD20 biologics; cooperation of EZH2 with the BCL6 repressor complex supports combining with tazemetostat (taz). Thus, we assessed the activity of ARV-393 in combination with biologics or SMIs based on potential complementary mechanistic roles.

ARV-393 was administered in combination with clinically relevant doses of the standard of care (SOC) biologics rituximab, tafasitamab (tafa) and polatuzumab to mice bearing SU-DHL-4 CDX, representing a high-grade B-cell lymphoma (HGBCL, with *MYC, BCL2* and *BCL6* rearrangements). ARV-393 was also combined with investigational SMIs of EZH2 (taz), BCL2 (venetoclax) and BTK (acalabrutinib), in HGBCL or aggressive CDX models SU-DHL-6 (*EZH2*^{mut}), OCI-Ly1 (*BCL2+*) and activated B-cell (ABC)-like OCI-Ly10 (*MYD88*^{mut}), respectively.

ARV-393 combined with SOC biologics resulted in superior tumor growth inhibition (TGI) compared with monotherapy, with complete tumor regressions in 9/9 mice when combined with rituximab, 4/10 with polatuzumab, and 10/10 with tafa (vs 55% TGI tafa + lenalidomide). ARV-393 also produced tumor regressions in 10/10 mice when combined with taz, 10/10 with venetoclax, and 10/10 with acalabrutinib. In a SU-DHL-6 model, MYC, EZH2 and BCL2 protein levels were increased 56%, 66% and 12%, respectively, with ARV-393 alone vs vehicle, but were decreased 75%, 80% and 96% vs vehicle, with greater BCL6 degradation (65% vs 87%) when combined with taz. Studies to examine the molecular mechanisms underlying the combination synergies are ongoing.

ARV-393 demonstrates synergistic antitumor activity, including complete regressions, in combination with SOC agents and select SMIs in high grade and aggressive DLBCL models. These findings support future clinical investigation of ARV-393 in combination with other therapies for DLBCL.

#1656 TGRX-3544 is a highly potent and mutant-selective degrader of oncogenic KIT with oral activity.

Yanxia Shi, Linxin Li, Xiangyu Hong, Yingying Zuo, Zhen Dong, Yixin Ai, **Yihan Wang**

Shenzhen TargetRx, Inc., Shenzhen, China

Oncogenic mutations of the receptor tyrosine kinase KIT drive cancers such as gastrointestinal stroma tumors (GIST) and systemic mastocytosis (SM). The mutations in the juxtamembrane domain (Exon 11, E11) and extracellular domain (E9) are most commonly found in GIST, and the A-Loop D816V mutation (E17) in over 90% SM cases. Currently approved KIT inhibitors either lacked efficacy against certain mutants, like imatinib, or lacked selectivity such as the multi-kinase targeting sunitinib and regorafenib. Primary or acquired resistance or intolerance is common and poses a great clinical challenge. Non-kinase scaffold functions of oncoproteins are being revealed, as exemplified by EGFR, BTK, and BCR-ABL1. Since all the currently approved TKIs only inhibit the catalytic activity, the scaffold functions may constitute residual oncogenic signaling and eventually lead to acquired resistance and disease progression. We reasoned that a degrader, rather than an inhibitor, may potentially provide more benefit for patients with oncogenic KIT. TGRX-3544 is a heterobifunctional degrader which promotes ubiquitination and proteasomal degradation of oncogenic KIT. In GIST T1 cells, TGRX-3544 potently induced degradation of Del560-578 (E11) mutant KIT (DC_{50} = 1.6 nM at 24h). The degradation activity was also robustly observed in Ba/F3 isogenic cells expressing KIT Del557-558 (E11), InsAY502-503 (E9), D816V (E17), and Del557-558/D816V (E11/E17) mutants, but not wildtype KIT. TGRX-3544 potently inhibited proliferation of GIST T1 (KIT E11) cells and Kasumi-1 (KIT N822K, E17) cells. It also inhibited proliferation of Ba/F3-KIT cells expressing KIT E11, E17, and E11/E17 mutants (IC_{50} 0.9 to 3.9 nM), as well as the E9 mutant. The cellular activity of TGRX-3544 against the E11, E17 and E11/E17 mutants was superior to that of all the currently approved KIT inhibitors imatinib, sunitinib, regorafenib, avapritinib and ripretinib. Unlike other KIT inhibitors, TGRX-3544 had little or no activity against the closely related PDGFRA or FLT3, nor did it show cytotoxicity in a panel of normal cell lines (IC_{50} > 10000 nM), suggesting its high selectivity. *In vivo*, TGRX-3544 led to dose-dependent tumor regression in xenograft models expressing E11 or E11/E17 mutant KIT. In the E11/E17 model, TGRX-3544 was much more efficacious than the corresponding warhead. TGRX-3544 rapidly reduced the protein levels of E11 or E11/E17 mutant KIT by over 50% 4h after oral dosing. It also diminished the downstream signaling pathways of tumor samples as indicated by reduced phosphorylation of KIT, STAT5, AKT and ERK1/2. In summary, we have developed a highly mutant-selective, event-driven, scaffold-eliminating KIT degrader with superior cellular potency and *in vivo* oral activity. The balanced preclinical profile of TGRX-3544 supports its further clinical investigation in KIT-driven malignancies such as GIST and SM.

#1657 HZ-S109, a potent and selective HPK1 degrader with enhanced T cell modulation efficacy and improved bioavailability.

Yizhe Wu, Jiangfeng Xie, Jinglai Huang, Mengchao Zheng, Xinglu Zhou

HealZen Therapeutics Co., Ltd., Hangzhou, China

Background: Hematopoietic Progenitor Kinase 1 (HPK1/MAP4K1) has been demonstrated to restrain T cell activation through phosphorylating SLP-76 at Serine 376 during the T-cell activation process. Given its irreplaceable negative regulation role in TCR pathway, HPK1 is considered as a promising target in immuno-oncology. Recently, HPK1 has been shown to function as scaffolding protein and bind to adaptor proteins to promote JNK signaling and actin cytoskeleton rearrangement involved in lymphocyte adhesion. Additionally, the turnover rate of HPK1 is low. These evidences suggest that HPK1 is a suitable target to develop protein-degrader.
Objective: Accordingly, we described our state-of-the-art work in discovery and identification of HPK1 degrader HZ-S109. We asked if this degrader could exhibit stronger engagement with the HPK1 target, leading to the restoration of suppressed T-cell function and inhibition of tumor growth.
Methods: HZ-S109 was identified based on our in-house unique DaTProD® platform. CCK-8, ELISA and WB detection were performed by PEG2, NECA and TGF-β induced depleted cell model in vitro.PK/PD detection and tumor measurement were performed by oral gavage of CT-26 subcutaneously transplanted tumor models in C57BL/c mice.
Results: HZ-S109 exhibits potent HPK1 degradation with DC_{50} values lower than 10 nM across various cell types, including Jurkat, Ramos, PBMC, and CAR-T cells. Importantly, HZ-S109 demonstrated no significant effect on other family members, such as GCK, GLK, HGK, or KHS. HZ-S109 can significantly enhance the activation of primary T cell at nanomolar level concentrations, with the maximum activation fold exceeding 15-fold. Furthermore, HZ-S109 restores T cell function in the presence of multiple immune-suppressed conditions including NECA/ PGE2/ TGF-β or their combination. Despite its higher molecular weight, HZ-S109 boasts superior oral bioavailability. In in-*vivo* anti-tumor efficacy evaluation, oral administration of HZ-S109, either as a single agent or in combination with PD-L1 antibody, robustly suppressed the tumor growth in CT26, A20 and MC38 syngenic mice model, achieving a tumor growth inhibition (TGI) of over 90%. These results suggest that HZ-S109 stands out as a potent and distinct HPK1 modulator, exhibiting enhanced potency and oral bioavailability. At present, HZ-S109 is in the IND-enabling study stage.

#1658 REM-422, a first-in-class mRNA degrader of the MYB oncogene, demonstrates anti-tumor activity in xenograft models of adenoid cystic carcinoma and acute myeloid leukemia.

Samantha Levin-Furtney, Michael P. Thomas, Alycen Harney, Alexander Ivliev, Jesper Maag, Sudeep Prajapati, Michael Seiler, Dominic Reynolds, Silvia Buonamici, **Charles Kung**

Remix Therapeutics, Inc., Watertown, MA

The c-MYB (MYB) oncogenic transcription factor is a key regulator of hematopoietic cell differentiation and proliferation. Recurrent genetic lesions and dysregulation of MYB have been identified in a variety of cancers, including adenoid cystic carcinoma (ACC), acute myeloid leukemia (AML), colorectal cancer (CRC), and others.

We describe the mechanism of action and biological activity of REM-422, a first-in-class, potent, selective, oral small molecule messenger RNA (mRNA) degrader of MYB being developed for the treatment of ACC (NCT06118086) as well as AML and high-risk myelodysplastic syndrome (HR-MDS) (NCT06297941).

Using biophysical and cellular assays, REM-422 is shown to act by selectively facilitating the binding of the U1 snRNP spliceosome complex, which governs exon usage by recognizing 5' splice sites, to a normally unused 'poison exon' (PE), which contains a premature termination codon, in the MYB pre-mRNA transcript. Cells treated with REM-422 demonstrated increased MYB poison exon inclusion, leading to degradation of MYB mRNA by nonsense-mediated decay and subsequent reduction in MYB protein levels. REM-422 phenocopied gene expression changes observed with shRNA hairpin-mediated knockdown of MYB and demonstrated preferential anti-proliferative activity in cell lines with high MYB expression and known MYB genetic dependency.

To understand the pharmacokinetic, pharmacodynamic, and anti-tumor effects of REM-422 in vivo, ACC patient-derived xenograft (PDX) models harboring MYB translocations were established in nude mice. QD PO administration of REM-422 demonstrated strong and dose-dependent reductions in MYB mRNA and protein levels. Furthermore, REM-422 treatment led to dose-dependent inhibition of tumor growth and tumor regressions at well tolerated doses. RNAseq and immunohistochemistry analysis confirmed modulation of MYB target genes in tumors from mice exposed to REM-422.

To evaluate the activity of REM-422 in a disseminated PDX model of AML, patient cells were engrafted by tail vein injection into NOG mice and mice were dosed PO QD with REM-422. After 24 days of dosing, REM-422 led to the eradication of human leukemia cells from both compartments and prevented AML cell engraftment-induced body weight loss. Immunohistochemistry staining confirmed the reduction of MYB protein in the bone marrow of treated animals. Flow cytometry analysis of bone marrow and whole blood demonstrated that REM-422 treatment led to an increase in blasts expressing CD14 and CD11b, known myeloid differentiation markers, as well as an increased frequency of Annexin V+ blasts, a marker of early apoptosis.

These data illustrate the potential for REM-422 as an investigational agent for the treatment of a variety of solid tumor and hematological malignancies.

#1659 ETX-636, a novel allosteric pan-mutant-selective PI3Kα dual inhibitor and degrader with best-in-class potential.

Robert F. Koncar, Mingzong Li, Jingyan Gao, Fei Pang, Ying Lin, Raj Nagaraja, Yong Tang, Hannah Szeto, Zipeng Fan, Karan Kapoor, Robbie Chen, Eric Simone, Minghong Hao, Shengfang Jin, Tao Liu, Meghana Kulkarni, Jeffery Kutok

Ensem Therapeutics, Inc., Waltham, MA

PIK3CA, which encodes p110α, the catalytic subunit of phosphatidylinositol 3-kinase alpha (PI3Kα), is one of the most frequently mutated oncogenes and dysregulated PI3Kα activity is important for tumor growth. Up to 40% of hormone receptor (HR)-positive breast cancer (BrCA) tumors and 13% of all solid tumors harbor *PIK3CA* mutations, with the majority of mutations occurring within p110α kinase and helical domains. Orthosteric ATP-competitive inhibitors, alpelisib and inavolisib, which inhibit both Wild-type (WT) and mutant PI3Kα, are approved in combination regimens for treating *PIK3CA*-mutant, HR+/HER2-, advanced or metastatic BrCA. However, because PI3Kα is critical for insulin signaling, inhibition of WT PI3Kα results in hyperglycemia, and limits the clinical utility of these inhibitors. To overcome this limitation, ETX-636 was designed as an allosteric, pan-mutant-selective PI3Kα inhibitor and degrader by leveraging our Kinetic Ensemble® platform for optimal binding to a unique metastable state of p110α. In addition to greater biochemical selectivity for mutant PI3Kα over WT PI3Kα, ETX-636 has stronger target binding affinity, better on-target potency in biochemical and cellular pharmacodynamic assays, and demonstrates superior anti-tumor activity *in vivo* when compared to other allosteric, pan-mutant-selective PI3Kα inhibitors (i.e. RLY-2608 and STX-478). In viability assays run on a panel of 65 cancer cell lines, the presence of *PIK3CA* mutations was a strong predictor of ETX-636 sensitivity and ETX-636 potency was superior to both RLY-2608 and STX-478. *In vitro* and *in vivo* mechanistic studies revealed ETX-636 induces significant proteasome-dependent degradation of mutant p110α, while sparing WT protein (a feature not seen with other pan-mutant allosteric inhibitors), resulting in more durable pathway inhibition. ETX-636 dosed orally, once daily, results in deep and durable pathway inhibition and induces tumor regression in kinase and helical domain *PIK3CA*-mutant xenografts. In an ER-positive, HER2-negative, PI3Kα-mutant BrCA xenograft, ETX-636 is efficacious as a single agent and shows synergistic activity with fulvestrant, inducing tumor regression while being well-tolerated. Blood glucose levels after dosing in multiple species indicate that ETX-636 does not disrupt glucose homeostasis at efficacious exposures, even under non-fasting conditions. In addition, based on pharmacokinetic, pharmacodynamic, efficacy, and toxicology studies, predicted human efficacious doses of ETX-636 are not projected to cause hyperglycemia. The preclinical profile of ETX-636 underscores its best-in-class potential as an allosteric pan-mutant-selective PI3Kα dual inhibitor and degrader, and supports its clinical development both in single agent and combination clinical trials in patients with *PIK3CA*-mutant tumors, including HR+/*PIK3CA*-mutant BrCA.

#1660 Seeking new glues - Toward an E3 ligase-agnostic molecular glue degrader identification platform.

Allan M. Jordan[1], Kuhulika Bhalla[1], Helen Burston[2], Francesca Cavallo[1], Prasamit Baruah[2], Martin Soste[3], Polina Scichkova[3], Roland Bruderer[3], Daniel Redfern[3], Matevz Stefancic[3], Yuehan Feng[3], Stuart Thomson[1], Roland Hjerpe[1]

[1]Sygnature Discovery, Nottingham, United Kingdom,[2]Sygnature Discovery, Saint-Laurent, QC, Canada,[3]Biognosys AG, Schlieren, Switzerland

Targeted Protein Degradation (TPD) is a rapidly growing modality in oncology and is broadly driven by development of bifunctional (PROTAC-type) or monovalent degraders. Whilst the latter group largely consists of molecular glue degraders (MGDs), it also encompasses compounds that act as degraders via allosteric or other mechanisms. Screening for compounds with MGD properties can be undertaken via biophysical methods, where proximity of an effector and target protein is measured, limiting the effect of the compound to a known, selected effector, such as a particular ubiquitin-ligase of interest. Whereas this approach benefits from full control over the target and ligase pairing, cell-based systems offer the advantage of screening for target degradation against the entire complement of expressed ubiquitin ligases, potentially increasing the probability of identifying a hit compound. Conversely, a key challenge with cell-based screening approaches is to understand the mechanism by which the target is degraded, relying on the identification of the ubiquitin ligase or adaptor protein that is mediating the effect of the compound.

Here, we demonstrate the utility of our cell-based screening platform by developing degrader assays for two separate targets, Cyclin K and GSPT1, both therapeutically relevant for oncology, and with respective MGDs in clinical trials (CT7439 for cyclin K by Carrick Therapeutics, and MRT-2359 and Eragidomide from Monte Rosa Therapeutics and Cellgene/BMS, respectively).

Further, to address the challenge of deconvoluting the mechanistic basis for monovalent degrader hits from cell-based assays, we have utilized limited proteolysis coupled with mass spectrometry (LiP-MS). LiP-MS has become a powerful, label-free technique for identifying small molecule and peptide targets directly in cell lysates. This methodology allows the identification of the proteins involved in mediating degradation of a target, such as a ubiquitin ligase recruited to a target via an MGD.

Our approach integrates flexible cell-based assays for degrader screening with a powerful method of mechanistic deconvolution, allowing identification of the specific ligase driving target degradation. This knowledge can then facilitate the development of ligase- and target-specific molecular glue assays to drive hit optimisation and, ultimately, the delivery of novel MGD chemotypes against new oncology targets of choice.

#1661 Discovery of an SHP2 degrader with potent anti-cancer activity as a monotherapy and exceptional combination effects in KRAS mutant cancers.

Soohyun Lee, Jiyoung Kim, Ji Youn Park, Beomseon Suh, Han Wool Kim, So Hyuk Kim, Hyun-Hwi Kim, Onnuri Bae, Jeonghwa Han, Ju Young Kang, Jihye Lee, Je Ho Ryu, **Song Hee Lee**

Ubix Therapeutics Co., Ltd., Seoul, Korea, Republic of

Background: SHP2 is a key regulator of the RTK/RAS/MAPK signaling pathway, which is often disrupted in various cancers. Numerous allosteric SHP2 inhibitors are being actively developed to treat cancers driven by this pathway. However, these inhibitors face certain challenges, including their inability to target the active form of SHP2 and a narrow therapeutic window that requires intermittent dosing to manage toxicity. To address these limitations, we have developed SHP2 protein degraders as next-generation therapeutic agents targeting SHP2. In this study, we present the compelling characteristics of our SHP2 degraders.
Methods: For inhibitor combination assay, we did clonogenic assay in NCI-H358 KRAS G12C mutant NSCLC and 3D proliferation in various cell lines. For in vivo assessment of pharmacological profile, we utilized an NCI-H358 xenograft. SHP2 protein levels in cell lysates and tumors were analyzed to assess SHP2 degradation efficiency and DUSP6 mRNA levels were analyzed to evaluate downstream effects. For selectivity analysis, we analyzed phosphatase panel profiling and proteomics.
Results: Our compounds showed superior degradation activity achieving sub-nanomolar DC_{50} levels and significant cell growth inhibition exhibiting single digit nanomolar IC_{50} levels in NCI-H358 NSCLC (non-small cell lung cancer). In clonogenic and 3D cell proliferation assay, compound 5 showed significant growth inhibition with various inhibitors such as EGFR, MEK, ALK, RAF and KRAS G12C inhibitors. Phosphatase panel profiling and proteomics demonstrated compound 5 degraded SHP2 selectively. In particular, the superior anti-cancer effects of combination treatments with other drugs were confirmed across various cancer cell lines. In vivo experiments using a KRAS mutant CDX model revealed compelling in vivo profiles. Once-weekly intravenous administration achieved strong tumor growth inhibition without inducing the hematological and liver toxicities that were issues in the clinical studies of SHP2 inhibitors.
Conclusion: We have successfully identified new SHP2 degraders with exceptional activity. Our findings demonstrate that, by leveraging the characteristics of these degraders as a strategy to overcome toxicity, they have the potential to address the limitations of allosteric SHP2 inhibitors, offering a promising therapeutic approach for patients with RTK/RAS/MAPK-dependent cancers.

#1662 Preclinical studies of RP04340: an orally available and potent PROTAC compound targeting KRAS G12C/D/V mutant tumors.

Xiang Ji, Chao Deng, Gang Wu, Qiguo Zhang, Xiaolin He, Yanpeng Wu, Bing Zong, Xiaojin Xu, Chao Liang, Beibei Wang, Yuwei Zhang, Qingyao Hu, Huanping Li, Bing Bai, Lin Wang, Jinchao Ai, Leduo Zhang, Honggui Zhou, Shihao Sun, Yijie Wang, Youhong Wang, Xianqi Kong, Dawei Chen, **Tianlun Zhou**, Jiasheng Lu

Risen Pharmaceuticals Private Ltd., Shanghai, China

Mutations in the RAS oncogene are highly prevalent in pancreatic ductal adenocarcinoma (PDAC), colorectal cancer (CRC), and lung adenocarcinoma (LUAD), with codon 12 of the *KRAS* gene being the most frequently altered site. Substitutions of glycine at codon 12 to cysteine (G12C), glutamate (G12D), or valine (G12V) occur in 66.3%, 23.7%, and 24.4% of PDAC, CRC, and LUAD patients, respectively. While recently approved drugs targeting KRAS G12C mutation have shown clinical benefit, there remains a significant unmet need for therapies addressing the highly prevalent G12D and G12V mutations. Proteolysis-targeting chimeras (PROTACs) represent a novel therapeutic strategy for the targeted degradation of oncogenic proteins, potentially offering superior efficacy and mitigating resistance. In this study, we present RP04340, a potent and orally bioavailable PROTAC compound that selectively degrades KRAS G12C/D/V proteins and demonstrates robust anti-tumor activity. RP04340 induced significant degradation of KRAS G12C, KRAS G12D, and KRAS G12V proteins in cell lines Miapaca-2, PK-59, and NCI-H727, respectively, with a 50% degradation concentration (DC50) in the low nanomolar range. Within 12 hours of treatment, RP04340 reduced KRAS G12C/D/V protein levels by over 80% and effectively suppressed downstream signaling pathways, including pERK and DUSP6. Additionally, RP04340 inhibited cell proliferation in multiple KRAS G12C/D/V mutant cell lines, surpassing the anti-tumor efficacy of its enzymatic inhibitor warhead. In vivo studies using mouse xenograft models (Miapaca-2, PK-59, and NCI-H727) demonstrated significant tumor growth inhibition following daily oral administration of RP04340 at doses of 25, 50, and 100 mg/kg, with a clear dose-response relationship. Pharmacokinetic analyses revealed that RP04340 accumulated preferentially in tumor tissues, achieving high intratumoral concentrations with repeated dosing. Furthermore, tissue distribution studies in mouse showed significant accumulation of RP04340 in the lungs and pancreas after 15 days of consecutive dosing, supporting its suitability for treating cancers in these organs. In conclusion, RP04340, a PROTAC compound with compelling preclinical efficacy and favorable pharmacokinetic properties, represents a promising therapeutic candidate for KRAS G12C/D/V-driven cancers.

#1663 Discovery of novel, potent and orally bioavailable SMARCA2 PROTACs with synergistic anti-tumor activity in combination with KRAS G12C inhibitors.

Y. Lissanu, S. Kotagiri, N. Blazanin, Y. Wang, Y. Han, X. Liang;
UT MD Anderson Cancer Center, Houston, TX

Cancer genomic studies have identified frequent mutations in subunits of the SWI/SNF chromatin remodeling complex including SMARCA4 in non-small cell lung cancer with a frequency of up to 33% in advanced stage disease, making it the most frequently mutated complex in lung cancer. We and others have identified SMARCA2 to be synthetic lethal to SMARCA4, indicating SMARCA2 is a high value therapeutic target. Here, we disclose the discovery and characterization of potent, selective and orally bioavailable Cereblon-based SMARCA2 PROTACs. Biochemically, YDR1 and YD54 are potent SMARCA2 degraders with an average DC50 of 7.7nM and 3.5nM respectively in SMARCA4 mutant lung cancer cells. Phenotypically, both YDR1 and YD54 selectively inhibited growth of SMARCA4 mutant cancer cells. Further, we showed anti-tumor growth inhibitory activity of YDR1 and YD54 in SMARCA4 mutant xenograft models of lung cancer. Finally, we show that YDR1 and YD54 synergize with the KRAS G12C inhibitor sotorasib to inhibit growth of SMARCA4 and KRAS G12C co-mutant lung cancer cells. These findings provide additional evidence for the utility of single agent or combination regimens containing SMARCA2 PROTACs as synthetic lethal therapeutics against SMARCA4 mutant cancers.

#1664 Survivin degrader 7I14 synergizes with docetaxel in castration-resistant prostate cancer by disrupting survivin dimerization and inducing its proteasome-dependent degradation.

Qingbin Cui[1], Caoqinglong Huang[1], Xunzhen Zheng[1], Zizheng Dong[1], Jing-Yuan Liu[2], Jian-Ting Zhang[1]

[1]Department of Cell and Cancer Biology, University of Toledo College of Medicine and Life Sciences, Toledo, OH,[2]Department of Medicine, University of Toledo College of Medicine and Life Sciences, Toledo, OH

Survivin, the smallest member of the Inhibitor of Apoptosis Protein (IAP) family, forms homodimers and coordinates with other IAPs to inhibit apoptosis by suppressing pro-apoptotic caspase 3/9 activation, contributing to drug resistance. Due to its overexpression in cancer cells and lack of expression in normal adult tissues, survivin is an attractive cancer target. However, developing survivin-selective inhibitors has been challenging due to the absence of suitable active sites for targeting. Strategies have been pursued to inhibit survivin expression by targeting its upstream transcriptional regulators, notably leading to discovery of YM155, which unexpectedly suffers from poor pharmacokinetics and multiple targets, including the ubiquitous transcription factor Sp1. We recently developed a novel approach to directly target survivin for discovery of survivin degraders by disrupting its dimerization, exposing the hydrophobic interface, and promoting proteasome-mediated degradation. The compound 7I, a quinoxaline-based survivin degrader, likely interacts with key residues for survivin dimerization via π-π interactions. We hypothesized that electron-withdrawing groups on 7I enhance its binding to survivin. To test this hypothesis, we synthesized a series of 7I analogs and identified two improved leads, 7I10 and 7I14, with up to 20-fold greater activity, selectively degrading survivin in castration-resistant prostate cancer (CRPC) cell lines C4-2 and PC-3. Both 7I10 and 7I14 dose-dependently induced spontaneous apoptosis and synergized with docetaxel, a first-line therapy for metastatic CRPC. In a PC-3 xenograft model, 7I14 at 15 mg/kg administered via IP twice/week effectively suppressed tumor growth and enhanced docetaxel’s effects by degrading survivin, with no added toxicity, as assessed by body weight, white blood cell counts, and hemoglobin levels. Thus, targeting survivin's dimerization domain is a promising strategy for its degradation, and 7I10 and 7I14 have potential as single agents or in combination with docetaxel for treating metastatic CRPC.

#1665 A comprehensive platform for the screening and assessment of IRAK4-targeting PROTACs.

Zhaoxia Yin, Xiaojian Wang, **Tj (Tiejun) Bing**

ICE Bioscience, Inc., Beijing, China

Interleukin-1 receptor-associated kinase 4 (IRAK4) serves as a pivotal mediator in the signaling cascades of both the interleukin 1 receptor (IL-1R) and toll-like receptor (TLR) pathways. It is crucial for myddosome signaling, as its kinase and scaffolding activities are indispensable for the proper formation and signaling of the myddosome complex. This complex, in turn, initiates the activation of key downstream pathways, including NFkB and interferon-responsive factors 5/7 (IRF 5/7), culminating in the release of inflammatory cytokines and chemokines such as TNF-α, IL-6, IL-1β, and IL-23. These molecules are associated with the development of various autoimmune diseases, such as pyogenic tonsillitis, psoriasis, and atopic dermatitis, positioning IRAK4 as a promising therapeutic target for dampening inflammation mediated by TLR/IL-1R.

In this context, we have developed a comprehensive screening and evaluation platform for IRAK4 that spans from in vitro to in vivo studies. The platform encompasses an array of assays at both the biochemical and cellular levels. It features tests for binary and ternary complexes, intracellular detection of ternary complex formation, and a suite of methods for detecting target protein degradation, including flow cytometry, enzyme-linked immunosorbent assay (ELISA), and HiBiT. The platform also offers cellular function assays, such as cytokine release assays utilizing peripheral blood mononuclear cells (PBMCs) and whole blood, as well as assays focused on proteins associated with signal transduction pathways. It also includes off-target and selectivity testing, and extends to in vivo efficacy assessments within the IMQ-induced psoriasis model. Collectively, these assays are designed to facilitate a swift and thorough discovery and evaluation process for IRAK4-targeting PROTACs.

#1666 Novel endoxifen-based proteolysis targeting chimera (PROTAC) small molecules synergize with olaparib and exhibit potent antitumor activity in triple negative breast cancer through induction of DNA damage.

Aamod S. Dekhne[1], Swaathi Jayaraman[1], Lucy Rai Thulung[1], Becky Bruinsma[1], Baustin M. Welch[1], Samuel Wyatt[1], Esther P. B. Rodman[1], Sayantani Bhattacharya[1], Thomas R. Caulfield[2], John R. Hawse[1], Matthew J. Schellenberg[1], Matthew P. Goetz[1]

[1]Mayo Clinic, Rochester, MN,[2]Mayo Clinic, Jacksonville, FL

Breast cancer (BC) is the most common cancer diagnosed in American women. The majority of breast cancers express estrogen receptor (ER), progesterone receptor (PR), or human epidermal growth factor receptor 2 (HER2). However, 15-20% lack expression of all three and are called triple-negative breast cancer (TNBC). TNBC accounts for a disproportionately large amount of morbidity and mortality due to its aggressive nature and the paucity of effective adjuvant maintenance therapy, driving an urgent need for novel therapeutics. Z-endoxifen (ENDX) is a potent tamoxifen metabolite that dually targets ERα and protein kinase C beta I (PKCβI). We recently described next-generation molecules, the first-in-class endoxifen-PROTAC (ENDX-PROTAC) compounds which incorporate ENDX as the warhead and cereblon (CRBN) as the E3 ubiquitin ligase recruitment moiety (Jayaraman 2024, SABCS). We used the PRISM screen of over 900 cancer cell lines to determine that ENDX-PROTACs have broad antitumor activity in both TNBC and ER+ breast cancer in addition to, leukemia, pancreatic, lymphoma, lung, melanoma, and ovarian cancer cells, among others. ENDX-PROTACs primarily target a key translation termination factor, G to S phase transition 1 (GSPT1). Here, we demonstrate for the first time that these compounds also cause marked DNA damage. The lead compounds of this series, EPrC-007 and EPrC-009 demonstrated potent anti-proliferative effects in MDA-MB-231, BT549, and MDA-MB-436 TNBC cell lines. EPrC-007 induced substantial DNA double strand breaks in MDA-MB-231 cells as assessed by γ-H2AX Western blotting. Interrogation of DNA repair pathways revealed activation of ATM/CHK2 and downregulation of ATR/CHK1, suggesting inhibition of DNA repair as a potential mechanism. Additionally, EPrC-007 also induced γ-H2AX foci in MDA-MB-231 and BT549 cells, but not in the MCF10A normal breast tissue cell line, suggesting selective anti-tumor activity. Since we suspect that EPrC-007 blocks DNA repair machinery, we next sought to determine if these molecules would synergize with DNA damaging agents or other DNA repair inhibitors. Promisingly, EPrC-007 demonstrated remarkable synergy with olaparib (poly-(ADP-ribose) polymerase (PARP) inhibitor), hydroxyurea (ribonucleotide reductase inhibitor), and cisplatin (direct DNA damaging agent), but not camptothecin (topoisomerase I inhibitor). Importantly, only olaparib co-treatment demonstrated synergy in the PARP- and PROTAC-resistant HCC1143 TNBC cell line. Furthermore, the combination of EPrC-007 with olaparib induced markedly more γ-H2AX foci than either agent alone, confirming synergy at the DNA damage level. Taken together, our studies demonstrate the remarkable potential of ENDX-PROTACs in the single-agent setting as well as in combination with PARP inhibitors.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Combination Strategies for Cancer Treatment
Poster Session

#1670 The SHMT inhibitor SHIN1 augments the antitumor efficacy of 5-Fuin preclinical models of gastric cancer.

Huan Deng, Yajie Wang, Lin Xiao, Yisheng Pan

Peking University First Hospital, Beijing, China

Advanced gastric cancer (GC) is a malignant tumor with poor prognosis, which requires in-depth exploration of its malignant progression mechanism and the development of efficient therapeutic protocols. Serine hydroxymethyltransferase (SHMT), an important hub in serine-glycine-nucleotide metabolic pathways, plays a crucial role in the occurrence and progression of GC. Bioinformatics analysis and cytological experiments preliminary identified the important role of SHMTs in GC. Drug synergistic screening assays were used to build the therapeutic model in the study. The transcriptomic analysis was performed to clarify the underlying mechanism of combination treatment. Here, we found that the SHMT1 and SHMT2 promoted malignant progression and 5-Fu resistance on GC, and their targeted inhibitor SHIN1 is a promising antitumor drug for GC. The synergistic screening analysis showed that SHIN1 was an efficient synergist for 5-Fu, and combination therapy, alleviated 5-Fu resistance to GC. Mechanistically, The combination treatment induces cell cycle arrest, DNA damage and cellular senescence through the activation of the P53 signaling pathway. These unique characteristics of cell growth inhibition, which are induced via interfering with nucleotide synthesis, were validated by substantial in vitro and in vivo assays. The regimen of SHIN1 combination with 5-Fu may be an efficient preclinical model for the treatment of GC.

#1671 Targeting histone H3K27 demethylase for anti-tumor activity: Monotherapy and combination with ceralasertib in non-small cell lung carcinoma.

Pony Yu-Ling Lee[1], Kun-Yuan Lin[1], Chao-Di Chang[1], Shan-Yun Cheng[1], Ya-Wen Hung[1], Chih-Chieh Yang[1], Yu-Hsien Chang[1], Chien-Chang Shen[1], Shu-Ping Wang[2]

[1]Pharmacology Discovery Services Taiwan, Ltd., New Taipei City, Taiwan,[2]Institute of Biomedical Sciences, Academia Sinica, Taipei City, Taiwan

Lung cancer is the leading cause of cancer-related deaths worldwide, with non-small cell lung carcinoma (NSCLC) accounting for 85% of cases and associated with poor prognosis. The lysine-specific demethylase KDM6A, responsible for removing H3K27 trimethylation at gene promoters and enhancers, is frequently mutated in various cancers. While KDM6A is predominantly considered as a tumor suppressor gene, recent studies suggusted it may support oncogenic transcriptional regulation. To investigate the role of KDM6A in tumorigenesis, we utilized CRISPR-Cas9/sgRNA to knock out (KO) KDM6A in NCI-H1975 NSCLC cells. Phenotypic assessments demonstrated cell cycle arrest with inhibitory effects in cell proliferation with KDM6A-depleted NCI-H1975 cells. RNA sequencing in conjunction with CUT&RUN revealed KDM6A target genes involved in cell cycle regulation, DNA replication, and DNA damage repair pathways, which were further validated using RT-qPCR and CUT&RUN-qPCR. Immunofluorescence confirmed the effects of KDM6A loss on DNA replication and DNA damage-induced repair mechanisms. These findings support our hypothesis that KDM6A is a highly pleiotropic factor in tumorigenesis, playing a critical role in regulating DNA replication-associated gene activation and facilitating the repair of replication stress-induced DNA damage. Notably, loss of KDM6A induced hyperactivation of checkpoint signaling pathways such as the ATR-CHK1 axis, suggesting KDM6A-depleted tumor cells attemption to alleviate replication stress to avoid apoptosis. To evaluate the therapeutic potential of KDM6A along with inhibition of the KDM6A-depletion-induced ATR-CHK1 pathway, ceralasertib (formerly AZD6738), an oral selective ATR inhibitor, was combined with KDM6A depletion for in vivo evaluation. Introducing KDM6A depletion significantly reduced NCI-H1975 tumor volume compared to the control group, demonstrating anti-tumor activity. Consistent with in vitro cell-based assays, the combination therapy of ceralasertib with KDM6A depletion showed enhanced tumor growth inhibition and regression in the NCI-H1975 xenograft model. Our findings reveal a pro-oncogenic role of KDM6A in sustaining tumor maintenance through engagement in DNA replication and repair pathways. Targeting KDM6A alone emerges as a promising therapeutic strategy for NSCLC. Furthermore, combining KDM6A depletion with ceralasertib significantly enhances anti-tumor activity by disrupting the ATR-CHK1 checkpoint signaling pathway, leading to an enhanced anti-tumor activity.

#1672 Synergistic efficacy of FGFR4 inhibitor (H3B-6527) and oxaliplatin combination therapy in gastric cancer models.

Nadeem Bhat, Mohammed Soutto, Ahmed Gomaa, Shoumin Zhu, Selma Maacha, Marwah Al-Mathkour, Mohammed Chwihne, Ahmed El-Rifai, Oliver McDonald, Wael El-Rifai

University of Miami, Miami, FL

Background: Resistance to chemotherapy remains a significant challenge in the treatment of gastric cancer. This study evaluates the therapeutic potential of a combination of the FGFR4 inhibitor H3B-6527 and Oxaliplatin in preclinical models, focusing on their synergistic effects on tumor suppression and cell death mechanisms.
Material and Methods: To evaluate the efficacy of H3B-6527 and oxaliplatin combination, we employed IC50 analyses, colony formation assays, patient-derived xenograft (PDX) models, immunofluorescence (IF), immunohistochemistry (IHC), western blotting, and caspase-3/7 luminescence assays. These techniques were used to assess the impact of the drug combination on tumor cell proliferation, DNA damage, and apoptosis in gastric cancer cell lines (MKN28 and HGC27) and tumor tissues.
Results: IC50 analyses demonstrated significantly enhanced sensitivity to the combination therapy in both MKN28 and HGC27 cell lines compared to either agent alone. Colony formation assays revealed that the combination therapy drastically reduced colony counts relative to monotherapies, highlighting its superior anti-proliferative effects. In PDX mouse models, the combination therapy led to pronounced tumor growth inhibition and significantly prolonged survival compared to controls. IF and IHC analyses showed marked increases in DNA damage, as evidenced by γH2AX expression, along with reduced proliferation (Ki67) and elevated apoptosis (cleaved caspase-3). Caspase-3/7 luminescence assays confirmed heightened apoptotic activity in treated cell lines. Western blot analysis revealed elevated levels of cleaved PARP and γH2AX in both gastric cancer cell lines and PDX tissues, corroborating the enhanced DNA damage and apoptotic response induced by the combination therapy.
Conclusions: This study demonstrates the synergistic efficacy of H3B-6527 and oxaliplatin in promoting apoptosis, enhancing DNA damage, and inhibiting tumor proliferation in gastric cancer models. These findings provide compelling evidence for the potential clinical application of this drug combination as a promising therapeutic strategy for gastric cancer patients, especially those with chemoresistance.

#1673 Advancing bladder cancer treatment with live attenuated salmonella ZH9: from monotherapy to combination strategies.

Nicholas Glanville[1], Claudia Prevosto[1], Sonia Domingos-Pereira[2], Lenka Polak[2], Victoria Morel[3], Marine Leblond[3], Gregory Verdeil[3], Denise Nardelli-Haefliger[2], Livija Deban[1]

[1]Prokarium Ltd., London, United Kingdom,[2]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland,[3]University of Lausanne, Lausanne, Switzerland

For over 30 years, microbial immunotherapy with Bacillus Calmette-Guérin (BCG) has been the standard-of-care for non-muscle invasive bladder cancer (NMIBC). Global demand for BCG however exceeds supply and BCG therapy is associated with disease recurrence and high treatment burden. Most novel bladder cancer treatments in development either target BCG unresponsive patients as second line or are administered in combination with BCG and thus share its shortcomings. There remains a significant need for innovative therapies to replace BCG in bladder cancer treatment, and live-attenuated Salmonella Typhi ZH9 presents a promising alternative, both as a monotherapy and as a combination partner. Efficacy of ZH9 was investigated in syngeneic mouse MB49 and *p53*$^{-}$/*Pten*$^{-}$ GEMM orthotopic tumor models in which animals were treated in the bladder via catheterization, with or without combination intraperitoneal anti-PD-L1 or anti-PD-1 treatment. Immune responses were characterized by flow cytometry and histology analyses of bladder tissue. Intravesical ZH9 monotherapy following orthotopic MB49 tumor inoculation demonstrated significant survival benefit compared to both vehicle control and BCG treatments. A single administration of ZH9 was sufficient for efficacy, inducing far greater magnitude and duration of immune responses than standard-of-care BCG, and resulting in systemic anti-tumor immunity that protected against both local bladder and distant MB49 tumors. Combination of local ZH9 treatment with regimens of checkpoint inhibitor antibodies anti-PD-L1 (MB49 model) and anti-PD-1 (GEMM model) that were otherwise ineffective, led to significant efficacy, suggesting local *Salmonella* ZH9 treatment can synergize with systemic immunotherapies. These data support Salmonella ZH9 as an effective first-line monotherapy and checkpoint inhibitor combination therapy for bladder cancer, with potential to reduce treatment burden on patients, lower associated healthcare costs and to ease microbial therapy supply constraints due to a scalable manufacturing process. Clinical evaluation of ZH9 in a Phase 1b study evaluating safety, pharmacology, and early efficacy in NMIBC is ongoing.

#1674 Combinatorial screen with standard of care and selected anticancer agents identifies multiple combinations with activity against a panel of patient-derived colorectal organoids.

Nathan P. Coussens[1], Thomas S. Dexheimer[1], Phillip R. Sanchez[1], Thomas Silvers[1], Eric M. Jones[1], Bryce M. N. Butler[1], John R. Britt[1], Carmen Allegra[2], James H. Doroshow[2], Beverly A. Teicher[2]

[1]Applied and Developmental Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD, [2]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD

Thirty-two patient-derived colorectal organoid models were selected from the NCI's Patient-Derived Models Repository (https://pdmr.cancer.gov) to serve in a high-throughput screening panel. The models were derived from primary or metastatic tumors of patients with varied ancestries, ranging in age from 32–90 yrs, that were either previously treated or treatment naïve. Variations were determined in microsatellite stability, consensus molecular subtype, and genetics, including clinically relevant oncogenic variants of RAS, BRAF and PIK3CA. A screen was conducted with twenty-two combinations of agents, including SOC and investigational oncology drugs. Organoids were exposed to single agents or combinations at four concentrations covering 2 logs up to the clinical Cmax, if known. Following compound addition, organoid growth was measured by live bright field imaging every 24 h and cell viability was determined by CellTiter-Glo 3D at 48 h and 168 h. Modest responses were observed in most models from the combination of leucovorin with 5-FU; however, >1 log of cytotoxicity was observed in only several models. The panel was more responsive to FOLFOX, which was consistent with the sensitivity of models to oxaliplatin. Responses to TAS-102 varied and >1 log of cytotoxicity was observed in several models. The MEK inhibitor cobimetinib was active in models with wild type KRAS and generally more active in models with oncogenic KRAS. Combination of the BCL-2/BCL-xL inhibitor pelcitoclax plus cobimetinib achieved >1 log of cytotoxicity in most organoid models. Combinations of cobimetinib with the EGFR inhibitors erlotinib, afatinib or cetuximab demonstrated synergy in many organoids according to the Bliss independence model and frequently achieved ≥1 log of cytotoxicity. As a single agent, the KRAS G12D inhibitor MRTX1133 was active against organoid models harboring KRAS G12D. The combination of cobimetinib and MRTX1133 had synergistic activity by Bliss independence in multiple organoid models and frequently achieved >1 log of cytotoxicity. Additionally, combinations of MRTX1133 with an EGFR inhibitor had additive and greater-than-additive cytotoxicity in a range of organoids. The pan-RAS(ON) inhibitor RMC-6236 had substantial single-agent activity against organoid models with wild type KRAS and most models with an oncogenic KRAS variant. In combination with cobimetinib, RMC-6236 demonstrated additive and synergistic cytotoxicity, frequently ≥1 log, in organoid models with BRAF V600E and harboring wild type KRAS or an oncogenic variant. When combined with the pan-PI3K inhibitor copanlisib, RMC-6236 demonstrated substantial synergy, achieving ≥2 logs of cytotoxicity in several organoid models with wild type KRAS. Complimentary PDX studies are in progress. Funded by NCI Contract No. 75N91019D00024 & 75N91020F00032.

#1675 Evaluation of combination strategies with RAS-targeted inhibitors in multi-cell type spheroids.

Thomas S. Dexheimer[1], Nathan P. Coussens[1], Thomas E. Silvers[1], Eric M. Jones[1], Naoko Takebe[2], James H. Doroshow[2], Beverly A. Teicher[2]

[1]Molecular Pharmacology Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD,[2]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD

RAS genes are among the most frequently mutated oncogenes in cancer. Though previously considered undruggable, agents have recently been developed that specifically target RAS. The agents can be categorized as (1) those that selectively target specific RAS oncoproteins and (2) pan-RAS inhibitors that target a wide range of RAS alterations, including oncogenic variants and amplifications. This study evaluated the activity of four novel RAS-targeted inhibitors in combination with other targeted agents in thirty solid tumor cell lines of diverse cancer types. These included twenty-six patient-derived cancer cell lines from the NCI Patient-Derived Models Repository (https://pdmr.cancer.gov/) and four established cell lines. The cells were grown as multi-cell type (mct) tumor spheroids from 60% malignant cells, 25% endothelial cells, and 15% mesenchymal stem cells. All agents were tested at concentrations up to the clinical C_{max} value, if known or 10 μM. As single agents, the KRAS-G12C inhibitors RMC-6291 and divarasib, along with the KRAS-G12D inhibitor MRTX-1133, demonstrated selective activity against the mct tumor spheroids harboring the targeted variants. In contrast, the pan-RAS(ON) inhibitor RMC-6236 demonstrated activity against the mct tumor spheroids harboring a range of KRAS variants or wild-type KRAS. When used in combination, each of the four RAS-targeted inhibitors exhibited strong synergistic effects with SHP2 inhibitors as determined by the Bliss independence model and reductions in cell viability and spheroid volume. In tumor models harboring different KRAS variants, the pan-RAS(ON) inhibitor showed increased cytotoxicity with the MEK inhibitor cobimetinib, as well as PI3K-AKT-mTOR pathway inhibitors, such as inavolisib (PI3Kα), ipatasertib (AKT), and sapanisertib (mTORC1/2). When the same agents were combined with variant-specific KRAS inhibitors similar effects were observed in mct tumor spheroids carrying the corresponding RAS variant. These preclinical findings might provide guidance for the selection of combination regimens with KRAS inhibitors to improve clinical efficacy. Funded by NCI Contract No. 75N91019D00024.

#1677 Navitoclax, a Bcl-2/xL inhibitor, and YM155, a survivin inhibitor, in combination with carboplatin effectively inhibit ovarian cancer tumor growth.

Tejas Samantaray[1], Hilary Kenny[1], Lucy Kelliher[1], Ernst R. Lengyel[1], Carman K.M. Ip[2], Kasjusz Kordylewicz[1], Rachael Hoffmann[1], Sarah Rauch[1], Beatrice Malacrida[3], Sophie Skingsley[3], Frances R. Balkwill[3], Chiara Battistini[4], Ugo Cavallaro[5], Wolf R. Wiedemeyer[6]

[1]Obstetrics and Gynecology, University of Chicago, Chicago, IL,[2]Cellular Screening Department, University of Chicago, Chicago, IL,[3]Queen Mary University of London, London, United Kingdom,[4]Unit of Gynecological Oncology Research, European Institute of Oncology IRCCS, Milan, Italy,[5]Department of Experimental Oncology, European Institute of Oncology IRCCS, Milan, Italy,[6]Abbvie Inc., Chicago, IL

Introduction: High-grade serous ovarian cancer (OvCa) is generally treated with upfront chemotherapy, including carboplatin. Recurrent disease is driven by the persistence of platinum-resistance cells.
Experimental Procedures: A high throughput screen (HTS), using a 3D organotypic culture assembled with extracellular matrix, primary human fibroblasts, and mesothelial cells, was established and validated. Using a library of FDA approved drugs, the 3D HTS was performed with the goal of identifying a combination of drugs that synergistically target two populations of OvCa, aldehyde dehydrogenase (ALDH) high and ALDH low enzyme activity cells, that are less sensitive to carboplatin treatment than the bulk OvCa cells. Summary of Results. Initial results showed that Omipalisib, Verteporfin, CA3, Mitoxantrone, Navitoclax, Venetoclax and YM155 had significant single drug activity in either the ALDH low or both the ALDH low/high cell populations. Synergistic drug activity was identified with three drug combinations, Navitoclax/Omipalisib, Navitoclax/YM155, and YM155/Omipalisib. *In vitro* the combination of Navitoclax/YM155 was most efficient at blocking primary human OvCa sphere formation and the proliferation of four different OvCa cell lines in the 3D organotypic culture. *In vivo* the combination of Navitoclax/YM155/carboplatin decreased the total number and weight of metastases, decreased the percentage of ALDH high OvCa cells in tumors, and increased survival when compared to carboplatin treatment alone in xenograft models.
Conclusion: Our results suggest that the combination of Navitoclax/YM155/carboplatin has promise as a therapy for the treatment of OvCa.

#1679 APG-2449, a novel focal adhesion kinase (FAK) inhibitor, enhances the antitumor activity of chemotherapy in preclinical models of small-cell lung cancer (SCLC) with activated FAK.

Zhou Yu[1], Zhiyan Liang[2], Xinyi Yao[1], Daojie Liu[1], Dajun Yang[1], Yifan Zhai[1]

[1]Ascentage Pharma (Suzhou) Co., Ltd., Suzhou, China,[2]Ascentage Pharma Group Inc., Rockville, MD

Background: SCLC is a genetically heterogeneous disease with no standardized targeted therapy options. Despite the recent advancement of immune checkpoint inhibitors, improvements in overall survival have been modest, and platinum-based chemotherapy combined with topoisomerase inhibitors remains the standard of care in SCLC. FAK, a non-receptor tyrosine kinase, has been reported to regulate cellular proliferation, migration, invasion, and DNA-damage repair. Previous studies have shown that FAK is amplified and overexpressed in SCLC tumors. Although non-small-cell lung cancer cells harboring $FAK^{6,7}$ (splicing isoforms of FAK that increase phosphorylation of FAK [pFAK]) are more sensitive to FAK inhibition than wild-type FAK (FAK^{WT}), the expression and implications of $FAK^{6,7}$ expression in SCLC remain unclear. Given the role of FAK in cancer progression, we hypothesized that inhibition of FAK would augment the antitumor effects of chemotherapy in SCLC. The aim of this study was to evaluate the antitumor activity of investigational agent APG-2449 alone and combined with chemotherapy in SCLC.

Methods: Cellular proliferation was measured by CellTiter-Glo® assays and apoptosis assessed via flow cytometry. Protein expression levels were examined via western blot. An H446 xenograft model was used to evaluate antitumor effects *in vivo*.

Results: SCLC cell lines harboring $FAK^{6,7}$ (H446, H69, and H526) showed increased sensitivity to APG-2449 in a dose-dependent manner compared to a FAK^{WT} cell line (DMS-114). When combined with chemotherapy (topotecan or etoposide plus carboplatin), APG-2449 synergistically decreased cell viability and increased apoptosis in H446 and H526 cell lines. Mechanistically, APG-2449 combined with topotecan and etoposide plus carboplatin enhanced DNA damage and apoptosis compared to either therapy alone in western blot assays. APG-2449 synergistically enhanced the antitumor effects of topotecan (synergy ratio: 22.08) and etoposide plus carboplatin (synergy ratio: 3.81) in the H446 xenograft model.

Conclusions: Novel FAK inhibitor APG-2449 demonstrated a synergistic enhancement when combined with first- and second-line chemotherapies in SCLC, significantly increasing antitumor activity. These encouraging findings support further clinical development of APG-2449 for the treatment of patients with SCLC.

#1680 Therapeutically targeting genes and pathways activated by high-fat diet in high-risk neuroblastoma.

Md Jahidul Hasan[1], Ritu Mittra[1], Marie Joseph[1], Mukesh Raipuria[1], Nisitha Jayatilleke[1], Daniel R Carter[1], Margaret J Morris[2], Belamy B Cheung[1], Glenn M Marshall[1]

[1]Children's Cancer Institute, Lowy Cancer Research Centre, UNSW, Sydney, New South Wales, Australia,[2]Faculty of Medicine and Health, UNSW, Sydney, New South Wales, Australia

MYCN-amplified neuroblastoma (NB) is one of the most aggressive and treatment refractory cancers in children. NB has a prenatal origin, and therefore environmental factors *in utero* may play a critical role in driving NB tumorigenesis. A recent epidemiological study showed that children born to mothers who gained weight more than 30 kg during pregnancy had a 2-fold higher risk of developing NB. Using the *Th-MYCN* NB transgenic mouse model, we found that high-fat diet (HFD)-induced maternal obesity resulted in accelerated NB tumorigenesis in the Th-MYCN homozygous offspring. Transcriptomic patterns in tumour tissues from Th-MYCN homozygous offspring of HFD-fed mothers showed upregulation of fatty acid (FA) metabolism and mitochondrial oxidative phosphorylation (OXPHOS) pathways. We then used human NB cell lines exposed to excess FA to study mechanisms and therapeutics. *In vitro* studies showed that excess FA increased growth, proliferation, and colony formation in human NB cell lines, which was reversed by Fatostatin, a FA metabolism inhibitor, with an effect which was partially MYCN-dependent. Fatostatin showed significant synergy in combination with doxorubicin and vincristine in reversing FA-accelerated growth, proliferation, and colony formation in human NB cell lines, with a wide therapeutic window. ATP5G1 and ATP5G2 (genes encoding human mitochondrial ATP synthase membrane c-subunit) were identified as candidate genes in the HFD-activated OXPHOS pathways. siRNA knockdown of both genes significantly reversed FA-accelerated growth and proliferation in human NB cell lines. Chromatin immunoprecipitation (ChIP)-PCR showed that ATP5G1 and ATP5G2 are transcriptional targets of MYCN, and their transcription is significantly increased in the presence of FA. Further, the overall ATP production was significantly increased in the presence of FA in human NB cell lines, but not in human normal fibroblasts. siRNA knockdown of ATP5G1 and ATP5G2 significantly decreased this effect. Together, our data strongly support a role for OXPHOS and FA metabolism pathways in HFD-accelerated NB tumorigenesis and highlight a key role of the mitochondrial ATP synthase membrane c-subunit genes, ATP5G1 and ATP5G2 in HFD-accelerated NB tumorigenesis.

#1681 Strong synergistic activity of an EZH1/2 dual inhibitor, HM97662, in combination with standard chemotherapy in preclinical models of advanced solid tumors.

Seon Yeong Han, Gunwoo Lee, Aran Park, **Seung Hyun Jung**, Jooyun Byun, Young Gil Ahn

Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

Many cancer patients eventually develop resistance to chemotherapy drugs after treatment. For instance, platinum-based drugs are commonly used as first-line treatments for ovarian cancer. While many patients initially respond well to this therapy, approximately 80% experience tumor recurrence within two years and ultimately acquire platinum-resistance. Recent studies have shown that EZH2 plays a role in regulating cisplatin resistance in ovarian cancer. As a similar example, small cell lung cancer (SCLC) is aggressive with poor prognosis, particularly in relapsed or refractory cases. While irinotecan is commonly used as 2nd-line therapy due to its manageable toxicity and efficacy, its effectiveness as a monotherapy is limited by chemotherapy resistance. Preclinical studies suggest that combining EZH2 inhibitors with chemotherapy may enhance anticancer efficacy by modulating the epigenetic environment and disrupting DNA repair mechanisms. This combination holds promise for overcoming resistance and improving outcomes in SCLC and other cancers. EZH2, an enzymatic subunit of the polycomb repressive complex 2 (PRC2), catalyzes the tri-methylation of histone H3 at lysine 27 (H3K27me3), repressing target genes involved in cell cycle regulation, differentiation, and tumor suppression. EZH2 and SWI/SNF have opposing roles in chromatin regulation, and EZH2 overexpression is linked to SWI/SNF mutations. This interaction affects cancer cell survival, highlighting EZH2 as a critical therapeutic target. Dual inhibition of EZH1 and EZH2 may offer greater anti-tumor efficacy, as EZH1 can compensate for the loss of EZH2 activity. Herein, we introduce a novel EZH1/2 dual inhibitor, HM97662, which concurrently suppressed the methyltransferase activity not only wild-type EZH1, but also wild-type and gain of function mutant EZH2 at nanomolar concentrations. HM97662 potently repressed tri-methylation of H3K27me3 in cancer cell lines. HM97662 also showed a wide and strong growth inhibitory effect in various solid cancer cell lines. Moreover, HM97662 exhibited potent antitumor activities in xenograft mouse models with various solid cancer cells including ovarian, bladder, small cell lung cancer, and gastric cancers. Additionally, HM97662 showed synergistic effects with chemotherapies such as topoisomerase inhibitors and platinum-based standard treatment in those xenograft models. These results suggest that concurrent treatment with HM97662 and chemotherapy enhances in vivo tumor regression at well-tolerated doses. In conclusion, this preclinical study demonstrated that HM97662, an EZH1/2 dual inhibitor, has promising therapeutic potential against advanced solid tumors, either alone or in combination with standard-of-care cytotoxic agents. It is urgent to assess the effectiveness of HM97662 in further clinical trials.

#1682 Novel CDK2/CDK9 inhibitor fadraciclib targets cell survival and DNA damage pathways and synergizes with encorafenib in human colorectal cancer cells with BRAF(V600E).

Md Mohiuddin[1], Vanda Povoa[2], Rita Fior[2], Frank A. Sinicrope[1]

[1]Department of Medicine, Gastrointestinal Research Unit, Mayo Clinic Alix School of Medicine, Rochester, MN,[2]Champalimaud Centre for the Unknown, Champalimaud Research, Champalimaud Foundation, Lisbon, Portugal

Background: Mutant *BRAF(V600E)* is present in 8-12% of human colorectal cancers (CRCs) and is associated with treatment resistance and poor survival. Targeted therapy with inhibitors of BRAF and EGFR is associated with only an incremental survival benefit.
Methods: We studied the novel CDK2/CDK9 inhibitor, fadraciclib, alone and in combination with the BRAF inhibitor encorafenib on isogenic CRC cells with two, one, or no $BRAF^{V600E}$ alleles ($RKO^{+/+}$, $A19^{+/-}$, $T29^{-/-}$). Analysis of apoptosis, colony formation, and the cell cycle was performed. The effect of drug treatment on growth of tumor xenografts was determined in a zebrafish model.
Results: Fadraciclib induced apoptosis and inhibited colony formation in a gene dose-dependent manner. Its growth inhibitory effect when combined with encorafenib was synergistic. Mechanistically, fadraciclib suppressed the expression of pro-survival MCL-1 and decreased the phosphorylation of RNA polymerase II indicating suppression of RNA transcription. Fadraciclib also impaired Rb phosphorylation and promoted a DNA damage response indicated by the cleavage of PARP, pH2AX (ser139), and activation of p53. Drug treatment was associated with a greater suppression of Rb phosphorylation, cell cycle inhibition, and apoptosis in $RKO^{+/+}$ versus $A19^{+/-}$ and $T29^{-/-}$ cells. In a zebrafish tumor xenograft model, fadraciclib plus encorafenib significantly reduced the tumor xenograft size concurrent with increased caspase-3 activation.
Conclusion: Fadraciclib plus encorafenib potently induced apoptosis and synergistically suppressed tumor cell growth in a gene dose-dependent manner in $BRAF^{V600E}$ CRC cells, and exerted anti-tumor effects in a tumor xenograft model. These data suggest a novel therapeutic strategy in this CRC subtype.

#1683 Combining annamycin, a non-cardiotoxic potent topo II poison, with azacitidine, cytarabine, gemcitabine, ifosfamide, trabectedin, or vincristine to synergize anticancer effects and identify potential clinical applications.

Rafal J. Zielinski, Krzysztof Grela, Stanislaw Skora, Izabela Fokt, Roberto Cardenaz-Zuniga, Natalia Baran, **Waldemar Priebe**

UT MD Anderson Cancer Center, Houston, TX

Background: Annamycin (ANN) is a potent topoisomerase II poison structurally related to doxorubicin (DOX) but displaying superior biological properties, such as high *in vivo* efficacy, reduced toxic side effects, and activity against cancers resistant to common therapeutic agents. ANN is currently clinically evaluated as a liposome formulated drug product, L-ANN. Importantly, L-ANN preclinical and clinical data clearly indicate a lack of cardiotoxic activity, which is a common dose-limiting factor in this class of therapeutics. In addition, ANN and L-ANN display unique organotropism that significantly differs from that of DOX. This finding further increased our interest to study the potential synergistic or additive effects of combining ANN with different anticancer agents. The efficacy of L-ANN has been established in multiple tumor models covering both liquid cancers and solid tumors, further strengthening the rationale of this study. Objective The objective of the study was to assess the efficacy of ANN in combination with different anticancer agents in order to identify the potential clinical application of ANN alone and with a therapeutic partner.

Methods: The activity of ANN in combination with selected FDA approved drugs was assessed *in vitro* after 72 hours of treatment using a cytotoxicity assay followed by determination of the combination indexes. In separate *in vitro* experiments, ANN activity was tested against drug resistant cell lines, including cells resistant to cytarabine and venetoclax. The most efficacious drug combinations from the *in vitro* studies were then tested using *in vivo* models of leukemia and solid tumors, including sarcoma and pancreatic cancer.

Results: The *in vitro* screening performed in set of cancer cell lines led to selection of the following agents combined with ANN for testing efficacy in clinically relevant animal models: 1) Cytarabine, 2) Azacitidine, 3) Venetoclax, 4) Vincristine in AML model; 5) Ifosfamide in fibrosarcoma; 6) Irinotecan and 7) Gemcitabine in PATC53 pancreatic cancer model. All combinations listed above showed improved survival when compared to single agent control groups. Importantly, our preclinical studies led to the clinical development of L-ANN plus cytarabine regimen, a combination that demonstrated clinical anticancer activity in Phase I/II studies in AML patients. Phase III clinical studies of L-ANN in a combination with cytarabine is expected to be initiated in early 2025.

Conclusion: ANN appears to be a versatile drug forming efficacious combinations with numerous mechanistically different anticancer agents. Our studies are working toward identifying new clinical applications for ANN with a long-term goal of developing novel therapeutic strategies for drug-resistant cancers.

#1684 Combination of L-NMMA and sacituzumab govitecan as a novel targeted therapy for inflammatory breast cancer.

Karina A. Ortega Martinez, Maria F. Chervo, Wei Qian, Jianying Zhou, Liliana Guzman-Rojas, Ivonne D. Uzair, Gianmarco Melone, Mailin Li, Christoforos Thomas, Jenny C. Chang

Breast Oncology Department Cancer Center of Excellence, Houston Methodist Research Institute, Houston, TX

Background: Inflammatory breast cancer (IBC) is a rare and aggressive form of breast cancer characterized by rapid progression, early metastatic potential, and distinct clinical and pathological features. The main treatment includes systemic cytotoxic therapy, surgery, and radiation. There is a need for novel targeted therapies to improve patients'outcomes. Inducible nitric oxide synthase (iNOS) is a mediator of various cancers including breast cancer. The pan-NOS inhibitor L-NMMA has been studied in preclinical and clinical settings, primarily focusing on cancers with high iNOS expression. Our preclinical studies provided the rationale for a recently completed phase I/II clinical trial of L-NMMA plus taxane for treating patients with triple-negative breast cancer (TNBC), with favorable toxicity and robust responses. Exploring the interaction between iNOS and IBC could identify novel therapeutic strategies, improving management approaches for this aggressive and highly lethal breast cancer subtype.
Hypothesis: we hypothesize that, in combination with sacituzumab govitecan, the inhibition of iNOS by L-NMMA will significantly reduce tumor progression and survival in preclinical models of IBC. Sacituzumab govitecan is an antibody-drug conjugate where SN-38, a topoisomerase I inhibitor, is coupled to an anti-trophoblast cell-surface antigen 2 (Trop-2) monoclonal antibody, currently used in the treatment of TNBC.
Experimental Procedures: The IBC xenograft SUM149 was orthotopically established in the mammary fat pad of female NSG mice by injection of $2x10^6$ cells/mouse. Once tumors reached 200 mm^3 in size, mice were randomly assigned into the following groups (n=7 mice per group): 1) Control (Saline, administered via i.p. injection); 2) Sacituzumab (administered at 5 mg/kg via i.v. injection weekly); 3) L-NMMA plus the calcium channel blocker amlodipine (LNMMA administered at 400 mg/kg on day 1 followed by 200 mg/kg per subsequent day by daily oral gavage; amlodipine administered at 10 mg/kg via i.p. injection daily); 4) Combination of Sacituzumab, L-NMMA, and amlodipine (Combo). Animals were treated as indicated for 21 days. Tumor size was monitored twice per week using caliper measurements.
Results: The Combo treatment was more effective at reducing tumor volume than each individual drug (adj p value = 0.0010 by one-way ANOVA).
Conclusions: Treatment with the Combo significantly reduced tumor growth compared to single drugs and control group. There was no statistically significant difference between the L-NMMA group and sacituzumab govitecan-treated mice. Overall, our findings demonstrate the synergism between L-NMMA and sacituzumab govitecan, highlighting the potential use of these drugs in future clinical trials.

#1685 Evaluation of antitumor and molecular responses to abiraterone acetate plus capivasertib in mouse PTEN-deficient prostate cancer.

Marco A. De Velasco[1], Yurie Kura[1], Kazuko Sakai[1], Simon T. Barry[2], Cath Eberlein[2], Claire Rooney[3], Kazuto Nishio[1], Kazutoshi Fujita[1], Hirotsugu Uemura[1]

[1]Kindai University, Faculty of Medicine, Osaka-Sayama, Japan,[2]Bioscience Early Oncology, AstraZeneca, Cambridge, United Kingdom,[3]Translational Medicine, AstraZeneca, Cambridge, United Kingdom

Inhibition of the androgen receptor (AR) is the primary treatment for metastatic hormone-sensitive prostate cancer (mHSPC). The addition of antiandrogen therapies to androgen deprivation therapy (ADT) has greatly improved patient outcomes. However, loss of the tumor suppressor PTEN is common in prostate cancer (PCa), and the resulting increase in AKT signaling contributes to PCa progression. Capivasertib (AZD5363) is currently being investigated as an oral pan-AKT inhibitor in combination with abiraterone (Abi) and ADT for treating mHSPC in patients with PTEN loss (CAPItello-281). We previously demonstrated the efficacy of targeted AKT inhibition using capivasertib in preclinical mouse models of PTEN-deficient PCa (PMID: 26910118). In this study, we evaluated the antitumor and molecular responses to the combination of Abi and capivasertib in vivo using conditional knockout mouse models with targeted deletions of *Pten* (KO) and both *Pten* and *Trp53* (DKO). In DKO mice, four weeks of ADT (via surgical castration) followed by four weeks of Abi resulted in a 9.4% tumor growth inhibition (TGI) compared to ADT alone. Additionally, 3/8 (37.5%) mice treated with Abi had tumor burden reductions >20% compared to ADT alone. In a hormone-sensitive model using DKO mice, four-week treatment with ADT/Abi resulted in a 7.4% TGI based on genitourinary tract weight compared with ADT alone. The combination of ADT and Abi+capivasertib further improved the TGI to 21.8%. DKO mice with advanced PCa also exhibited improved antitumor activity with the combination of ADT/Abi+capivasertib compared with ADT/Abi. In survival studies involving DKO mice with advanced PCa, the addition of capivasertib to ADT/Abi reduced metastasis, extended tumor doubling time, and improved OS compared with ADT/Abi alone. Immunohistochemical analysis revealed that mice treated with ADT/Abi+capivasertib exhibited significantly lower proliferation and increased apoptotic rates. Molecular profiling studies revealed that mice treated with Abi exhibited increased AKT signaling, as indicated by increased PRAS40 and S6 phosphorylation, but this enhancement was inhibited by capivasertib. Syngeneic allograft transplantation models using PTEN-expressing TRAMP-C1 and *Pten*-null-derived PCa cells demonstrated that, while both models responded to capivasertib, *the Pten*-null allografts exhibited greater sensitivity to the ADT/Abi+capivasertib combination. In conclusion, we provide preclinical evidence that abiraterone-resistant tumors with hyperactivation of AKT due to loss of PTEN are sensitive to AKT inhibition.

#1686 Enhancing chemotherapy efficacy in PTEN-deficient prostate tumors with targeted AKT inhibition.

Marco A. De Velasco[1], Yurie Kura[1], Kazuko Sakai[1], Simon T. Barry[2], Cath Eberlein[2], Claire Rooney[3], Kazuto Nishio[1], Kazutoshi Fujita[1], Hirotsugu Uemura[1]

[1]Kindai University, Faculty of Medicine, Osaka-Sayama, Japan,[2]Bioscience Early Oncology, AstraZeneca, Cambridge, United Kingdom,[3]Translational Medicine, AstraZeneca, Cambridge, United Kingdom

Taxane chemotherapy is the standard treatment for metastatic castration-resistant prostate cancer (mCRPC). The tumor suppressor PTEN is frequently deleted in advanced prostate cancer (PCa), contributing to cancer progression and poor clinical outcomes. Hyperactivation of AKT resulting from PTEN loss and reciprocal crosstalk between AR and PI3K/AKT signaling may impair the efficacy of taxane therapy. Capivasertib (AZD5363) is a potent oral pan-AKT inhibitor that has shown efficacy against PCa in preclinical and early phase clinical studies. Capivasertib is currently being evaluated in a Phase 3 trial (CAPItello-280) along with docetaxel (Dtx) for the treatment of patients with mCRPC. Here, we assessed the in vivo preclinical efficacy of Dtx plus capivasertib using transgenic mouse models of *Pten*-null PCa. In an early-stage model of PCa using double knockout mice with conditional inactivation of *Pten* and *Trp53*, four weeks of treatment with Dtx resulted in tumor growth inhibition (TGI) of approximately 25% and 7% compared with vehicle-treated control mice in hormone-sensitive PCa (HSPC) and CRPC settings, respectively. Adding capivasertib to Dtx further increased tumor TGI by ~14% in both settings. More robust improvements were observed with the combination therapy in CRPC compared with HSPC. Namely, 7/10 (70%) and 9/10 (90%) of HSPC mice treated with Dtx and Dtx+capivasertib, respectively, exhibited a >25% reduction relative to the control group. In contrast, 2/15 (13.3%) and 8/18 (44.4%) of CRPC mice treated with Dtx and Dtx+capivasertib, respectively, showed similar reductions. After one week of treatment, capivasertib suppressed the phosphorylation of PRAS40 and S6 downstream molecules of AKT, and this suppression was sustained for four weeks. In HSPC, Dtx+capivasertib resulted in a greater decrease in cancer cell proliferation compared with DTx alone and control mice. One week of administration of Dtx with or without capivasertib in CRPC mice increased cleaved caspase-3 levels to levels higher than those in control mice, whereas both Ki67 and cleaved caspase-3 levels plateaued in atrophic acini during week four suggesting M-phase cell cycle arrest. The therapeutic benefits of Dtx+ capivasertib were further evaluated in a late-stage CRPC model. Mice with tumors treated with Dtx+ capivasertib after progression to androgen deprivation therapy (surgical castration) and apalutamide had longer survival and longer tumor doubling times than those treated with Dtx alone. In conclusion, PTEN-deficient CRPC is less sensitive to Dtx than HSPC. However, our model showed that adding capivasertib to Dtx suppressed tumor growth and improved the therapeutic efficacy of CRPC.

#1687 Estrogen-related receptor gamma (ERRγ) as a therapeutic target and the synergetic anti-tumor effect of DN200434 (ERRγ inverse-agonist) and MK2206 (Akt inhibitor) in non-small cell lung carcinoma (NSCLC).

T. Singh;
All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Introduction: Non-small cell lung cancer (NSCLC) accounts for over 85% of all lung cancer cases and has the greatest mortality rates among both men and women, making it the primary cause of cancer-related fatalities globally. Estrogen Related Receptor Gamma (ERRγ), a member of the NR3B nuclear receptor subfamily, holds therapeutic promise in various cancer treatments. This study delves into the mechanistic understanding of ERRγ expression in NSCLC cells to gauge its therapeutic potential and examine the anti-tumor impact of combining DN200434 (ERRγ inverse agonist) with MK2206 (Akt inhibitor) in vitro.
Experimental procedures: Expression of ERRγ were investigated in different NSCLC cell lines (A-549, H-1299, H-460) by western blot. Different dose of DN200434 was treatment to study the proliferation effect in NSCLC cells. CCK-assay was used to measure the IC50 value post DN200434 or/and MK2206 in NSCLC cells after 24 hours. NSCLC cells were treated with single drug or in combination to assess their inhibitory effect, apoptosis, cell cycle arrest, colony formation efficiency, migration potential, and spheroid forming ability and the markers of the corresponding events was validated by western blot.
Summary of unpublished findings (Results): ERRγ was found to be overexpressed in the NSCLC cells. Treatment of DN200434 in NSCLC cells inhibit cell proliferation via apoptosis and cell cycle arrest in dose dependent manner. DN200434 in combination with MK-2206 demonstrate synergetic killing effect in NSCLC cells. Combination treatment inhibits cell proliferation via apoptosis and cell cycle-arrest, colony formation efficiency, migration potential, and sphere forming ability of NSCLC cells. This combination not only reduced the toxic concentration of both the drug but also target multiple key driving factors of NSCLC progression. Further, DN200434/MK-2206 reduced the stemness property of NSCLC cell-derived spheroids.
Conclusions: Our present findings thus demonstrate that ERRγ functions as a positive regulator of NSCLC progression and a potential therapeutic target. DN200434, inverse agonist of ERRγ, along with MK-2206 suppresses cancer growth and represses the expression of ERRγ mediated signalling. This combination is certainly providing a new strategy to proceed towards clinical trial.

#1688 CRISPR-Drug combinatorial screening identifies effective combination treatments for *MTAP* null cancer.

Nikola Knoll[1], Sarah Masser[1], Devishi Kesar[2], Eliana Destefanis[1], Guangyan Li[3], Blanka Bordas[1], Jayu Jen[3], Yao He[3], Srivatsan Raghavan[3], William Sellers[3], Kathleen M. Mulvaney[1]

[1]Virginia Polytechnic Institute & State University, Washington, DC,[2]Heidelberg University, Heidelberg, Germany,[3]Broad Institute, Cambridge, MA

Homozygous deletion of *CDKN2A/MTAP* occurs frequently in non-small cell lung cancer and other solid tumors including glioblastoma and pancreatic ductal adenocarcinoma. Lung cancer remains the leading cause of cancer-related mortalities and fewer than 15% of glioblastoma or pancreatic cancer patients survive 5 years underscoring the need for more effective therapies. PRMT5 is a synthetic-lethal dependency in *MTAP* null tumors and an attractive therapeutic target for *CDKN2A/MTAP* deleted cancers. A new revolutionary class of inhibitors, referred to as MTA-cooperative PRMT5 inhibitors, has shown promising results in ongoing early phase clinical trials. Nonetheless, effective cancer treatment typically requires therapeutic combinations to improve response rates and defeat emergent resistant clones. Thus, we sought to determine whether perturbation of other pathways could improve the efficacy of MTA-cooperative PRMT5 inhibitors. Using a paralog and single gene targeting CRISPR library we screened *MTAP* deleted cancers in the presence or absence of PRMT5 inhibitors. We identified several genes sensitizing to PRMT5 inhibition including members of the MAP kinase pathway. We demonstrate that genetic depletion or chemical inhibition of MAP kinase pathway members using KRAS, MEK, ERK, and RAF inhibitors synergize with PRMT5 inhibition to kill *CDKN2A/MTAP* null, RAS-active tumors. Further, MTA-cooperative PRMT5 inhibitors combined with either KRAS or RAF inhibitors led to durable *in vivo* complete responses, emphasizing the potential benefit for patients.

#1689 Targeting PARP to enhance sensitivity to MEK inhibitors in low-grade serous ovarian cancer.

Gamze Bildik[1], Rumeysa Ozyurt[1], Weiqun Mao[1], Marta Llaurado-Fernandez[2], Hannah Kim[2], Olivier De Wever[3], Kwong K. Wong[4], Mark S. Carey[2], **Robert C. Bast**[1], Zhen Lu[1]

[1]Department of Experimental Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Obstetrics and Gynecology, University of British Columbia, Vancouver, BC, Canada,[3]Department of Human Structure and Repair, Ghent University, Ghent, Belgium,[4]Department of Gynecologic Oncology and Reproductive Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Low-grade serous ovarian cancer (LGSOC) presents therapeutic challenges due to its unique characteristics including a distinct genetic profile and high chemoresistance. Up to 40% of cases involve RAS-MAPK pathway mutations, driving cell growth and metabolic dysregulation. MEK inhibitors, such as trametinib and selumetinib, hold therapeutic potential, but their efficacy is often limited by inherent or acquired resistance linked to dysregulated lipid metabolism and ferroptosis. PARP1 has also been implicated in detoxifying phospholipid peroxidation, independent of its DNA repair function. This study explores the combination of MEK inhibitors with olaparib, an FDA-approved PARP inhibitor, to enhance therapeutic efficacy by co-targeting lipid metabolism and ferroptosis, leveraging their complementary mechanisms. We tested a panel of LGSOC cell lines with diverse mutations in KRAS (PM-LGSOC-01, HCC5075, HOC-7, VOA-7681), NRAS (VOA-6406), or with WT RAS (VOA3448). We also used a murine LGSOC cell line (PKOSE10) isolated from a mouse with the $Pten^{fl/fl}$ -$Kras^{G12D/+}$Amhr2-Cre genotype which had developed an LGSOC with peritoneal metastases. Cells were treated with MEKi ± PARPi and drug sensitivity was measured via ATP-based bioluminescence. Synergy was quantified using SynergyFinder Plus (Loewe additivity synergy scoring model). Reverse Phase Protein Array (RPPA) was conducted to confirm ferroptosis and explore whether additional pathways might be involved. The combination of trametinib and olaparib displayed robust synergy, enhancing trametinib efficacy in 5 of 7 cell lines, increasing cytotoxicity, reducing colony formation, and potentiating cell death. Effects were observed regardless of RAS mutation status, though the synergistic magnitude varied. In contrast, selumetinib combined with olaparib showed only additive cytotoxicity in 3 of 7 LGSOC cell lines. Trametinib and olaparib combination treatment induced ferroptosis, as evidenced by the downregulation of GPX4, SLC7A11, and NRF2, alongside increased iron-dependent phospholipid peroxidation. Elevated ROS levels and mitochondrial iron accumulation further indicated a transition to a ferroptosis-sensitive state, driven by reduced expression of antioxidant enzymes. RPPA analysis reinforced these findings, revealing changes in key signaling proteins, including 4EBP-1, FTO, WTAP, Vimentin, Yap, LRP6, Connexin-43, and YTHFD3, highlighting the interactions between epithelial-mesenchymal transition (EMT) pathways and ferroptosis. In conclusion, treatment with the PARP inhibitor olaparib substantially enhances the efficacy of MEK inhibition in LGSOC by inducing ferroptosis, with synergy between olaparib and trametinib. This approach offers a promising strategy to extend clinical benefits, potentially address treatment resistance, and broaden the therapeutic landscape for LGSOC patients with limited options.

#1690 Sulforaphane enhances cytototoxic effects of novel non-thermal plasma and Tirapazamine combined therapy in pancreatic adenocarcinoma cells.

Ishfar Shaan[1], Brandon Gulledge[2], Maksym Poplavskyi[2], Michelle Eubank[1], Dilbar Alseid[2], Anya Weinrieb[3], Gamal Rayan[2], **Shoshanna N. Zucker**[2]

[1]University at Buffalo, Buffalo, NY,[2]D'Youville College School of Pharmacy, Buffalo, NY,[3]Ithaca College, Ithaca, NY

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal cancers, with a five-year survival rate of only 12% due to late detection and limited treatment options. A promising novel combination therapy of Non-Thermal Plasma (NTP) and Tirapazamine (TPZ) has shown success in treating cancers such as melanomas and glioblastoma. This study investigates the efficacy of the novel NTP+TPZ therapy on premetastatic BxPC-3 and metastatic AsPC-1 PDAC cells in vitro and the effects of adding sulforaphane (SF) as a sensitizing agent to enhance the effectiveness of the combined therapy. NTP produces reactive oxygen and nitrogen species (RONS), which induce oxidative stress and apoptosis, while TPZ, a hypoxia-activated prodrug, causes further DNA damage in tumor cells by acting as a topoisomerase II inhibitor. SF was chosen to act as a sensitizing agent since previous studies suggest SF can upregulate Connexin 43 (Cx43) gap junctions, which is an indicator of reversing EMT phenotype, so we hypothesized SF could enhance the therapeutic efficacy of NTP+TPZ. The cytotoxicity of TPZ was determined for both cell lines, yielding IC50 values of 33μM for BxPC-3 and 101μM for AsPC-1. Cell viability assays showed that NTP+TPZ reduced viability by 68.4% in BxPC-3 and 70.1% in AsPC-1 cells, indicating a synergistic effect. Additional trials with SF added at 10 μM in combination with NTP+TPZ resulted in viability decreasing by 86.7% in BxPC-3 and 97.6% in AsPC-1 cells which is an average additional reduction of 32% in BxPC-3 and 40% in AsPC-1 cells compared to treatments without SF. Western blot analyses of EMT markers vimentin and E-cadherin revealed that while SF alone reduced vimentin expression in AsPC-1 cells, it also decreased E-cadherin expression and did not upregulate Cx43 in any SF concentration. In addition, adding SF to the NTP+TPZ therapy unexpectedly stabilized vimentin and decreased E-cadherin expression across multiple conditions, neither of which suggest reversal of the EMT phenotype to explain the increased cytotoxicity of NTP+TPZ. Overall, the data shows that SF increases the cytotoxicity of NTP+TPZ. However, the Western blots show inconsistent loss of vimentin, consistent loss of E-cadherin, and no upregulation of Cx43. While these results suggest SF has potential as an adjunct agent, further investigation is needed to understand the causes of increased cytotoxicity between SF and NTP+TPZ in pancreatic adenocarcinomas.

#1691 Tumor treating fields (TTFields) sensitize BRCA wild type pancreatic cancer cells to treatment with FOLFIRINOX.

H. Ene, K. Ben Meir, H. Gabay, **R. Engelman**, E. Dor-On, A. Haber, M. Giladi, Y. Palti;
Novocure Ltd, Haifa, Israel

Background: FOLFIRINOX is a first-line chemotherapy treatment for patients with advanced pancreatic cancer and good performance status. This combination regimen of fluorouracil, oxaliplatin, irinotecan and leucovorin seems to be more effective in BRCA-mutated tumors due to the platinum-based component, acting by the induction of DNA damage. Tumor treating fields (TTFields) are electric fields that disrupt cellular processes crucial for cancer cell viability. TTFields have shown efficacy in preclinical pancreatic cancer models, and to reduce expression of proteins from the BRCA-dependent DNA repair pathway in various cancer types. The current study examined the potential use of TTFields to sensitize BRCA wild-type pancreatic cancer cells to treatment with FOLFIRINOX.
Methods: Human pancreatic BRCA wild-type cancer cells BxPC3 and AsPC1 were treated with TTFields, using the inovitro device (Frequency: 150 kHz; Intensity: 0.7 V/cm RMS for BxPC3 cells; 1 V/cm RMS for AsPC1 cells). FOLFIRINOX was administered to the cells at increasing concentrations, with or without co-treatment with TTFields. After 72h of treatment, cell count, colony formation, and apoptosis were measured. For mechanistical insight, RNA was isolated from TTFields-treated and control samples following 24- and 48-hours treatment and examined by RNA-sequencing and real-time PCR. Additionally, protein was isolated from 72-hours treated samples and examined by Western blot.
Results: TTFields application to the pancreatic cells together with FOLFIRINOX reduced cell count and colony formation and induced apoptosis relative to FOLFIRINOX or TTFields alone. TTFields downregulated DNA damage repair, DNA replication, and cell cycle related processes, with reduced expression of several central players in the BRCA DNA damage repair pathway.
Conclusions: Application of TTFields together with FOLFIRINOX exhibits potential improvement relative to FOLFIRINOX alone in treatment of pancreatic cancer cells lacking background BRCA mutations. This outcome may be rationalized based on downregulation of key DNA repair pathways.

#1692 PRMT5 inhibitor displays synergy with PARP inhibitor in bladder urothelial carcinoma models.

Maryam Ghandali[1], Connor Purcell[1], Leiqing Zhang[1], Lanlan Zhou[1], Dinara Ryspayeva[1], Maximilian Pinho-Schwermann[1], Brian K. Baker III[2], Paola Gyuliane[1], Benedito A. Carneiro[1], Wafik S. El-Deiry[1]

[1]Legorreta Cancer Center at Brown University, Providence, RI,[2]Morehouse School of Medicine, Atlanta, GA

Introduction: Approximately 30% of bladder cancers exhibit loss of methylthioadenosine phosphorylase (MTAP), a key enzyme in the methionine salvage pathway. This loss leads to an increase in its substrate, MTA, a metabolite that acts as an endogenous inhibitor of Protein arginine methyltransferase 5 (PRMT5) activity. PRMT5 uses S-adenosylmethionine (SAM) as a methyl donor to methylate various cellular substrates, including transcription factors, thereby regulating gene expression and DNA damage response (DDR) pathway. MTAP-deletion are suggested to be sensitive to PRMT5 inhibitors. We investigated the potential synergy between PRMT5 and PARP inhibitors in models of bladder cancer (BCa) harboring MTAP deletion.
Methods: We investigated the effect of PRMT5 inhibitor AZ14209703 on viability of bladder cancer cell lines (MTAP-deficient: Umuc-3, RT4; MTAP-proficient: 5637, j82) and a patient-derived MTAP-deleted bladder cancer organoid model. Viability assays were performed after 72 hours and 10 days of treatment using the CellTiter-Glo and colony formation assays. Additionally, the synergy between the AZ14209703 and the PARP inhibitor (PARPi) olaparib was assessed through viability testing.
Results: Cell viability assays conducted after 10 days of treatment revealed that MTAP-deficient cell lines (UMUC-3, RT4) are more sensitive to the PRMT5 inhibitor compared to MTAP-proficient cell lines (5637, J82). The 10-day IC50 values, measured by CellTiter-Glo, were as follows: MTAP-deficient cell lines RT4 (100 nM) and UMUC-3 (260 nM), and MTAP-proficient cell lines 5637 (2.24 μM). J82 exhibited even lower sensitivity, with treatment up to 10 μM failing to reduce viability by 50%. Similar results were obtained from colony formation assays, where the maximum dose of 4 μM for 10 days showed comparable outcomes. Additionally, the 10-day IC50 value for patient-derived MTAP-deficient organoids was 90 nM, as determined by CellTiter-Glo. The combination of PRMT5 inhibitor and olaparib demonstrated synergy in both MTAP-deficient and MTAP-proficient cell lines, as well as in patient-derived MTAP-deficient organoid models. This synergy was also observed in MTAP-proficient GBM cell lines (SNB19, LN229), an MTAP-proficient prostate cancer cell line (22RV1), an MTAP-deficient pancreatic cancer cell line (Capan-1), and an MTAP-proficient colorectal cancer cell line (HCT116).
Conclusion: Our results highlight a promising new therapeutic approach for bladder cancer with potential application in the treatment of other cancers. The PRMT5 inhibitor AZ14209703 combined with olaparib offers a novel therapeutic strategy for MTAP-deficient tumors. Our ongoing studies are exploring the mechanisms of synergy and effects of PRMT5 inhibitors and combinations on immune-mediated killing of cancer cells.

#1693 Elraglusib (9-ING-41), a glycogen synthase kinase-3β inhibitor in combination with imipridones for treatment of solid cancer.

Maryam Ghandali, leiqing Zhang, Benedito A. Carneiro, Wafik S. El-Deiry

Legorreta Cancer Center at Brown University, Providence, RI

Glycogen Synthase Kinase-3 (GSK-3) is a serine/threonine kinase with multiple biological roles, including cancer progression, therapeutic resistance and immune regulation. The GSK3β inhibitor elraglusib has shown promising preclinical and clinical activity in multiple tumor types. Previous studies demonstrated that GSK3 inhibitors can sensitize cancer cells to TRAIL-mediated apoptosis and downregulate the NF-κB pathway. Imipridones are a family of small molecule compounds that induce Death Receptor 5 and tumor necrosis factor (TNF)-related-apoptosis inducing ligand (TRAIL), causing cell death in multiple cancer models; the compounds can also inhibit the NF-κB pathway. We hypothesized that combining these two compounds would enhance anti-tumor activity. Ovarian, GBM, pancreatic, and colorectal cancer cell lines were treated with the novel drug combination of elraglusib and imipridone ONC206. CellTiter-Glo viability assays were performed after 72 hours to investigate the combinational treatment synergy. The combination treatment showed synergy in ovarian cancer (TOV21G, A2780, SKOV3), glioblastoma (SNB19, U251, LN229), pancreatic cancer (Capan-1), and colorectal cancer (HCT116) cell lines. In pancreatic and colorectal cancer cell lines, synergy was also investigated and observed between elraglusib and imipridone ONC212. Western blot analysis was performed to investigate the combinatorial effects. Single and combination treatments showed decreased expression of NF-κB p65 , anti-apoptotic proteins MCL-1 and survivin in cancer cells. Our ongoing studies are exploring other potential mechanisms of synergy and effects on immune-mediated killing of cancer cells. Our results show a potentially effective new combination of Elraglusib and Imipridones that can be further developed for cancer treatment.

#1694 Combination of inhibitors of RAD51 and FLT-3 and other tyrosine kinase inhibitors synergistically inhibits proliferation of cultured human leukemia cell lines.

Mark D. Vincent, Peter Ferguson, **Morgan Black**, Jenny Ho, James Koropatnick

London Health Sciences Centre, London, ON, Canada

Ten to 20% of acute myeloid leukemias (AML) are driven by a mutation in FMS-like tyrosine kinase 3 (FLT3), a membrane-based ligand-inducible signal transducer. These FLT-3-mutant AMLs have a poor prognosis and high rate of relapse in spite of the use of inhibitors that specifically target this protein (Cancer Sci. 2019;111: 312-322. doi: 10.1111/cas.14274). However, FLT-3 remains an attractive therapeutic target if new iterations of these drugs are able to circumvent acquired mechanisms of resistance as well as target the wild-type (wt) FLT-3 protein to inhibit tumor growth. Also, chronic myeloid leukemia (CML) in blast crisis continues to have a poor prognosis. IBR2, an inhibitor of the DNA repair protein RAD51, was previously demonstrated to enhance the antiproliferative activity of imatinib against the CML blastoid cell line K562 (EMBO Mol Med 5: 353-365, 2013. DOI 10.1002/emmm.201201760). In our studies, IBR2 enhanced the antiproliferative activity of regorafenib, an inhibitor of multiple tyrosine kinases, in a concentration-dependent manner by up to 80% against K562 cells (J Pharmacol Expt Ther, 364: 46-54, 2018. doi.org/10.1124/jpet.117.241661). JKYN-1-mesylate, a derivative of IBR2, works synergistically with numerous anticancer agents to inhibit proliferation of cell lines derived from a broad range of tumor types (Proc Amer Assoc Cancer Res, 63: Abst. 346, 2022). In an effort to develop a potential drug combination to treat acute leukemias with either mutated or wt FLT-3 we tested combinations of JKYN-1-mesylate and FLT-3 inhibitors against FLT-3-wt HL-60 and FLT-3-mutant MV-4-11 AML cell lines. MV-4-11 cells were 100- to 1000-fold more sensitive to quizartinib and gilteritinib than HL-60. Proliferation of both cell lines (4 days, alamarBlue™ assay) was inhibited by monotherapy JKYN-1-mesylate with IC_{50} values in the range of 3 to 5 μM. The combination of JKYN-1-mesylate and quizartinib synergistically inhibited proliferation of HL-60 cells with an apparent decrease in the IC_{50} value of quizartinib by up to 80%. However, inhibition by the combination of JKYN-1-mesylate and gilteritinib was only additive in this FLT-3-wt cell line. As well, JKYN-1-mesylate was at best additive with quizartinib or gilteritinib against FLT-3-mutant MV-4-11. These findings suggest that: (1) the combination of quizartinib and a RAD51-inhibitor could be a useful treatment against FLT-3-wt AML; (2) quizartinib and gilteritinib may not act in exactly the same way against the FLT-3 target or other related targets; (3) novel combinations of a RAD51 inhibitor with non-traditional treatments for CML may provide a potential improvement in outcome for CML blast crisis; (4) RAD51 inhibitors may be active as monotherapy in myeloid leukemias. The combination of JKYN-1-mesylate with FLT-3 inhibitors under current development is being tested.

#1695 Paricalcitol plus hydroxychloroquine enhances gemcitabine activity and induces mesenchymal to epithelial transition in pancreatic ductal adenocarcinoma.

G. P. Nagaraju[1], M. S. Saddala[2], S. Sarvesh[1], D. R. Bandi[1], A. M. Khaliq[3], A. Masood[3], M. Akce[1], B. F. El-Rayes[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]University of California at Irvine, Irvine, CA, [3]Indiana University, Bloomington, IN

Epithelial mesenchymal transition (EMT) describes a process by which the epithelial cells acquire mesenchymal properties associated with increased migration, invasion, and resistance to therapy. Targeting the intercellular communications and molecular changes that enable EMT is a rational therapeutic approach in PDAC. Our group has previously reported on KPC-Luc PDAC orthotopic mouse models treated with 1. Sham, 2. paricalcitol plus hydroxychloroquine (PH), 3. gemcitabine (G), and 4. GPH. Single cell RNA sequence (scRNASeq) was performed and analyzed using hdWGCNA (high dimensional Weighted Gene Co-expression Network Analysis) and GSEA (Gene Set Enrichment Analysis) to plot and determine intracellular interactions as well as gene expression changes in various treatment conditions. GPH treatment reduces EMT, which is associated with the downregulation of the essential gene fibronectin (*Fn1)*. *Collagen* and *Fn1* pathways co-expression decreases in GPH-treated KPC-Luc tumors. Cancer-associated fibroblasts (CAFs) appear dominant in Collagen signaling, whereas macrophages mediate Fn1 signaling. GPH treatment reduces the expression interaction strength between ligands and receptors (Collagen-Integrin and Fn1-Cd44 or Fn1-Sdc4) compared to sham, PH, and G. This comprehensive study of cell-cell communication and molecular changes during therapy offers a deep understanding of the molecular underpinnings of PDAC-EMT and metastasis and identifies possible targets for GPH.

#1696 Combination therapy of cell cycle inhibitor and HDAC inhibitor induces metabolic alterations in pancreatic cancer.

Shraddha P. Bhutkar, Anjali Yadav, Vikas V. Dukhande

St. John's University, Queens, NY

Pancreatic ductal adenocarcinoma (PDAC), characterized by several multigene mutations, is one of the lethal solid cancers accounting for several drug treatment challenges. NCI statistics show that the overall 5-year survival rate of PDAC remains at 12.8%. The tumor aggressiveness and invasive-metastatic potential of the cancer, along with drug resistance issues, demand the development of novel and effective multi-drug therapies. Our initial results show that combination therapy of a cell cycle inhibitor Abemaciclib (Abe), and histone deacetylase inhibitor Panobinostat (Pan) effectively decreases pancreatic cancer cell proliferation and growth and causes apoptotic cell death. Cell cycle and epigenetic changes drive tumor progression by rewiring metabolic signaling pathways of pancreatic cancer cells. Therefore, we hypothesized that co-treatment of pancreatic cancer with Abe and Pan modulates cancer cell metabolism, developing energy imbalance leading to cell death. Our Seahorse metabolic experiments depicted a reduced oxygen consumption rate upon combination treatment in pancreatic cancer cells with upregulation of extracellular acidification rate. We also performed metabolomic profiling upon combination treatment in pancreatic cancer cells, revealing alterations in the levels of metabolites involved in carbohydrate, lipid, and amino acid metabolism in the combination treatment group compared to control pancreatic cells. We also observed a moderate increase in mitochondrial membrane potential upon combination treatment, suggesting altered mitochondrial metabolic signatures compared to control and individual drugs along with combination treatments. These results suggest that mitochondrial dysfunction may underlie the Abe and Pan combination treatment, impairing metabolic homeostasis and energy balance. Our future studies include deciphering the in-depth mechanism of alterations in mitochondrial dynamics and metabolic signaling pathways upon combining cell cycle and HDAC inhibitor treatment in pancreatic cancer cells by performing transcriptomic profiling on PDAC cells and *in vivo* xenograft studies.

This study is funded by the College of Pharmacy and Health Sciences at St. John’s University, New York, and is also supported by the National Institute of General Medical Sciences (Award Number R16GM145557).

#1697 Chemotherapy combined with fatty acid oxidation inhibition completely regressed tumor growth in a pancreatic cancer model.

S. Woo, **C. Kim**, W. Ham, J. Kang, M. Kang, W. Hong, J. Park, W. Choi, S. Kim;
National Cancer Center - Korea, Goyang-si, Gyeonggi-do, Korea, Republic of

Purpose: We found that most ATP production in cancer cells depends on fatty acid oxidation (FAO). Most chemotherapeutic reagents including FOLFIRINOX regimen targeted anabolic metabolism of cancer cells such as DNA replication. All synthesis mechanisms require ATP for chemical reactions. Therefore, we proposed that blocking FAO together with chemotherapeutics may synergize anti-cancer effect by suppressing cancer growth metabolism.

Experimental Design: To block FAO, CAC (carnitine-acylcarnitine carrier, gene: *SLC25A20*) in the mitochondria inner membrane and ACAA1 (acetyl-CoA acyltransferase1, gene: *ACAA1*) in the peroxisome were targeted for inhibition. KN510 was selected for CAC inhibition, and KN713 was selected for ACAA1 inhibition. To achieve maximum anti-cancer effect of FAO inhibition, KN510 and KN713 were combined for the treatment as KN510713. Anti-cancer effect was examined by xenograft model using human pancreatic cancer cells. Synergy of KN510713 with chemotherapeutic drugs also tested using a xenograft model.

Results: Chemotherapy combined with KN510713 showed synergistic anti-cancer effect on 11 cancer types in in vitro analysis. Furthermore, xenograft pancreatic cancer showed completely suppressed effect of KN510713 treated with chemotherapeutics such as irinotecan only or FOLFIRINOX regimen.

Conclusion: FAO inhibition stopped tumor growth by ATP depletion in pancreatic cancer. The changes in molecular signaling upon FAO inhibition revealed that ATP levels are a key regulator of all signaling. This suggests that whatever the signaling induced by the growth receptor, ATP down-regulation through FAO inhibition may provide a novel therapeutic effect. Thus, combinations of chemotherapeutic agents with FAO inhibitors have shown excellent anti-cancer activity in mice.

#1698 Synergy with decitabine expands the utility of talazoparib: A novel therapeutic strategy for BRCA-proficient pancreatic cancer.

Zachery Keepers[1], Brandon Carter-Cooper[2], Hurley Ryan[1], Stephen B. Baylin[3], Rena Lapidus[2], Feyruz V. Rassool[1], Hem D. Shukla[1], Aaron T. Ciner[2]

[1]Radiation Oncology, Univ. of Maryland School of Medicine, Baltimore, MD,[2]Medicine, Univ. of Maryland School of Medicine, Baltimore, MD,[3]Oncology, The Johns Hopkins School of Medicine, The Sidney Kimmel Comprehensive Cancer Center, Baltimore, MD

Background: Patients with pancreatic ductal adenocarcinoma (PDAC) have a 5-year survival rate of 13%. In those with unresectable disease, standard chemotherapy offers limited benefit, with a median survival between 8 and 12 months. Approximately 17% of patients with PDAC carry a germline or somatic mutation in the BRCA or PALB2 genes. These patients may benefit from poly (ADP-ribose) polymerase inhibitors (PARPi), which induce synthetic lethality in tumors with homologous recombination deficiency. The POLO trial showed that maintenance olaparib - a PARPi - doubled progression-free survival in patients with germline BRCA mutations and metastatic PDAC. We've previously reported that DNA methyltransferase inhibitors (DNMTi) can induce a "BRCAness" phenotype in other types of cancer, thus sensitizing BRCA-proficient cancer cells to PARPi. Here we explore the synergistic potential of PARPi talazoparib (TAL) and DNMTi decitabine (DAC) in pancreatic cancer cell lines and patient-derived pancreatic tumor organoids (PTOs).
Methods: Synergy studies with TAL and DAC were performed in two murine (Panc02 and KPC) and three human (Capan1, SW1990, and MIA PaCa-2) pancreatic cancer cell lines with diverse genetic profiles. Of note, Capan1 harbored a BRCA2 mutation. Combination TAL+DAC treatment was performed in a dose-dependent and fixed ratio scheme, and the various degrees of synergy were determined using Chou-Talalay mathematical modeling (Compusyn). Clonogenic assays were performed with murine cell lines. Three patient-derived PTOs were treated with single agent (TAL or DAC) or combination (TAL+DAC) regimens and response was determined by MTS assay. Methylomic profiles including gene level methylation and hydroxymethylation fraction in treated and untreated PTOs were acquired using Biomodal's Duet Multiomics Assay. Statistical analyses for clonogenic and MTS assays were performed using GraphPad Prism.
Results: A synergistic inhibitory effect was observed in all pancreatic cancer cell lines when treated with TAL+DAC. The Capan1 cell line was more sensitive to TAL, as expected. Clonogenic survival assays showed a statistically significant decrease in colony numbers after treatment with the combination regimen compared to single-agent treatment. All PTOs exhibited growth inhibition when treated with DAC alone, whereas TAL alone had limited effects. The combination of TAL and DAC at low doses was more effective than either agent alone. Methylomic analysis revealed decreased methylation of key genes in DAC-treated PTOs, validating DAC's mechanistic effects.
Conclusions**:** The combination of TAL and DAC demonstrates synergistic cytotoxicity in pancreatic cancer cell lines and tumor organoids, suggesting potential for this treatment strategy in BRCA-mutated and BRCA-proficient PDAC.

#1699 A study on prediction model of drug sensitivity using patient-derived organoids.

Rie Hayashi, Norikatsu Miyoshi, Rie Mizumoto, Kengo Haruna, Shiki Fujino, Mitsunobu Takeda, Yuki Sekido, Tsuyoshi Hata, Atsushi Hamabe, Takayuki Ogino, Mamoru Uemura, Yuichiro Doki, Hidetoshi Eguchi

Department of Gastroenterological Surgery, Osaka University, Graduate School of Medicine, Suita, Japan

Background: Cancer treatment is increasingly based on precision medicine, which tailors therapies to the genetic and biological characteristics of a patient's tumor. PDOs offer a promising platform for predicting drug sensitivity, helping to identify effective therapies. However, existing models still face limitations in replicating clinical tumor heterogeneity and predicting drug responses accurately. In this study, we developed a novel two-dimensional (2D) culture system (2DO) for CRC PDOs that improves reproducibility and better mirrors the tumor microenvironment compared to traditional methods.
Purpose: The goal of this study is to evaluate the effectiveness of PDO-based drug sensitivity assays in predicting clinical outcomes for CRC patients. We aim to explore the potential of PDO assays in personalized treatment strategies, improving CRC treatment outcomes.
Methods: Tumor samples from CRC patients were obtained via surgery or endoscopic biopsy. These tumors were washed, dissociated, and filtered to isolate viable tumor cells, which were then cultured as PDOs under optimized conditions that preserve the tumor's genetic and phenotypic characteristics. Drug sensitivity assays were performed by treating PDOs with different chemotherapeutic agents and measuring cell proliferation using a method: the Incucyte system (SARTRIUS, Germany) for live-cell imaging.
Results: Drug sensitivity assays using PDOs showed promising results. The Incucyte system had a positive predictive value (PPV) of 75% and a negative predictive value (NPV) of 33% when compared to clinical outcomes. This result suggests that PDOs are useful for predicting tumor response to chemotherapy, though improving the NPV is necessary for more reliable predictions. The combination of imaging and biochemical assays offered a comprehensive evaluation of drug effects, and the PDOs closely mimicked patient-specific treatment responses.
Conclusion: This study demonstrates the potential of PDO-based drug sensitivity assays as a tool for personalized treatment in colorectal cancer. While promising, further refinement is needed, particularly in improving the negative predictive value, to optimize PDO models for clinical use. PDO-based assays may help bridge the gap between laboratory findings and real-world therapeutic outcomes, contributing to more individualized cancer treatments in the future.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Drug Resistance in Molecular Targeted Therapies 2
Poster Session

#1700 Valproic acid potentiates the efficacy of anti-EGFR monoclonal antibodies in sensitive and resistant RAS/BRAF wild type colorectal cancer models.

Roberta Affatato[1], Elena Di Gennaro[1], Alessandra Leone[1], Biagio Pucci[1], Susan Costantini[1], Rita Lombardi[2], Eleonora Perfetto[1], Maria Serena Roca[1], Francesca Bruzzese[2], Francesca Collina[3], Claudia Cardone[4], Tania Moccia[1], Elena Sinopoli[5], Antonio Avallone[4], Alfredo Budillon[6]

Background.Colorectal cancer (CRC) is a major global health issue, with fewer than 20% of metastatic CRC (mCRC) patients surviving beyond 5 years. Although, monoclonal antibodies (MoAbs) targeting EGFR, such as cetuximab or panitumumab (PAN), combined with chemotherapy, are standard treatments in RAS/BRAF wild type (wt) mCRC patients, their efficacy is limited by intrinsic and acquired resistance mechanisms. Here, we evaluated a novel therapeutic strategy, based on the repurposing of valproic acid (VPA), an anticonvulsant drug with histone deacetylase inhibitor and anticancer properties, in combination with anti-EGFR MoAbs, with or without irinotecan (IRI)-based chemotherapy, in CRC models.
Methods.The antitumor effect was assessed in a panel of RAS/BRAF wt CRC cell lines, sensitive, intrinsically or acquired resistant to anti-EGFR MoAbs, by evaluating clonogenic growth, apoptosis and tumor spheroids formation. Acquired resistant models were characterized using biological assays and multi-omics approaches (proteomics, phosphoproteomics and metabolomics).
Results.PAN-resistant models exhibited significantly higher proliferation rates in both 2D and 3D cultures, as well as increased migration compared to parental cells. An integrated multi-omics analysis revealed that secondary resistance to PAN was associated with metabolic alterations, extracellular matrix remodeling, impaired DNA damage repair pathways and alterations of growth factor receptors signaling. Interestingly, the combination of VPA and PAN with or without IRI-based chemotherapy induced synergistic antiproliferative and pro-apoptotic effects across all tested cell lines, including PAN-acquired resistant models. Mechanistically, VPA/PAN treatment led to a significant downregulation of pEGFR (Tyr1068) and its downstream signaling molecules, including pMAPK and pAKT, key drivers of anti-EGFR resistance, confirming multiomic data. *In vitro* and *in vivo* experiments are underway to confirm the ability of VPA to enhance anti-EGFR efficacy, overcome, delay or prevent resistance and provide further insights into the underlying molecular mechanisms. Based on these evidences, we launched the randomized phase 2 trial in mCRC patients in a third-line rechallenge setting (VICTORIA trial). In details, RAS/BRAF ctDNA wt patients are randomized to receive either standard rechallenge with IRI and PAN alone (ARM A) or in combination with VPA (ARM B). In patients in ARM A, at time of disease progression, a second study will explore if the addition of VPA to IRI and PAN might revert the resistance occurrence.
Conclusions.Overall, our findings propose a novel therapeutic strategy for the management of mCRC patients that could optimize the treatment of RAS/BRAF wt mCRC patients and expand the continuum of care in later treatments lines.

#1701 Investigating trastuzumab-deruxtecan (DS-8201) resistance mechanisms using clinically relevant PDX models and combination strategies with anti-PD-1 antibody.

Diandong Jiang[1], Bin Xie[1], Yulan Tang[1], Hongkui Chen[1], Xin Hou[1], Cui Xu[1], Dan Shao[1], Xinlei Chen[1], Xiaorong Gu[1], Loc Van[2], Josh Caggiula[2], **Danyi Wen**[1]

[1]Shanghai LIDE Biotech Co., Ltd., Shanghai, China,[2]LIDE Biotech Co., Ltd., Doylestown, PA

Background: Trastuzumab-Deruxtecan (T-Dxd, DS-8201), an antibody-drug conjugate (ADC) targeting HER2, is clinically approved for cancer patients with high and low HER2 expression levels; however, the response rate to DS-8201 are modest, especially in gastric cancer and the mechanisms of resistance remain elusive. In this study, we aimed to address this gap by developing clinically DS-8201 resistant patient derived xenograft (PDX) models in gastric and breast cancer. Our objectives were to elucidate possible mechanisms of resistance with this topoisomerase inhibitor-linked HER2 ADC and explore whether combining DS-8201 with an anti-PD-1 antibody could overcome resistance by using a humanized mouse model.

Method: Humanized mice were established by injecting human CD34 positive hematopoietic stem cells into NCG mice, followed by inoculation with PDX tissues from DS-8201-resisatnt gastric or breast cancer patients. Once tumors reached approx.150-200mm^3, the mice were administered a single dose of DS-8201, pembrolizumab (twice weekly for 4 weeks) and a combination. Tumor samples were harvested 24h after the final dose, fixed with 10% NFB overnight, and subjected to IHC staining with antibodies targeting CD8, CD4 and HER2 to assess changes in the tumor microenvironment. Furthermore, DNA and RNA were extracted from tumor samples using the K-Cell® kit for subsequent whole-exome sequencing (WES) and RNA sequencing (RNAseq) analysis, respectively.

Results: the data revealed limited tumor inhibition in DS-8201 treated group, consistent with clinical findings. Elevated expression of ATP-binding cassette (ABC) transporters, known as drug efflux pumps, was observed in this group, suggesting a potential strategy for overcoming resistance by targeting these transporters. Concurrent administration of pembrolizumab enhanced the efficacy of DS-8201, leading a significant inhibition in tumor growth compared to both the vehicle and monotherapy arms. An increase in CD3+ T cells in blood and CD8+/CD4+ T cell ratio was observed in the combination therapy group, suggesting modulation of the tumor microenvironment.

In conclusion, the establishment of novel gastric and breast PDX cancer models, derived from patients exhibiting resistance to DS-8201 in clinical settings, provided a valuable approach for investigating mechanisms of resistance in HER2 targeted ADCs. Our findings suggest that combining pembrolizumab with ADC may represent a promising strategy for overcoming resistance by modulation of tumor-infiltrating lymphocytes.

#1702 OBI-992, a novel TROP2 antibody-drug conjugate, exhibits distinct resistance profiles compared to other TROP2 targeting ADCs.

Lifen Shen, Tzer-Min Kuo, Yu-Hsuan Tsao, **Ya-Chi Chen**, Ming-Tain Lai

Biology Discovery, OBI Pharma, Inc, Taipei, Taiwan

BACKGROUND/AIM: Trophoblast cell surface antigen-2 (TROP2), a transmembrane glycoprotein often overexpressed in a variety of cancers, has been proposed as a potential cancer driver in colorectal cancer (CRC) cells. As a result, several antibody-drug conjugates (ADC) have been developed targeting TROP2, such as Sacituzumab Govitecan (SG) and Datopotamab Deruxtecan (Dato-Dxd). One of the major challenges in the development of ADC is the emergence of resistance via different mechanism of actions. This study aims to characterize the potential resistant mechanisms of TROP2 ADCs, including a novel TROP2 ADC OBI-992 in CRC cells.
METHODS: DLD1 CRC cells resistant to OBI-992, SG, and Dato-Dxd analogs were established with sequential increase of respective ADC concentrations. Cytotoxicity of three ADCs and their payloads, including exatecan, SN-38, and Dxd, was evaluated to assess the fold of resistance. Cell surface and total TROP2 protein were measured by flow cytometry and western blotting. DNA mutation and gene expression profiling were conducted by whole exome sequencing (WES) and RNA sequencing (RNA-seq).
RESULTS: TROP2 reduction and multidrug resistance proteins (MRPs) enhancement were not detected in OBI-992-induced resistant cells. Notable different DNA mutations in ATRX, BRCA2, and PALB2 of OBI-992 resistant cells were detected compared to those found with Dato-Dxd and SG-selected resistant cells. A TOP1 inhibitor-resistant mutation, TOP1 R364H, was identified as 100% variant allele frequency (VAF) in Dato-Dxd and SG resistant cells, whereas lower percentage of VAF was observed in OBI-992 resistant cell lines (29 % and 48.6 % in 0.5 uM and 2uM of OBI-992, respectively). OBI-992 resistant cells showed a clear divergence in differential expression gene (DEG) profiles, whereas Dato-Dxd and SG resistant cells were similar. c-MET and REG4 levels were greatly increased in cells with Dato-Dxd and SG resistance but not with OBI-992. Extracellular matrix (ECM) receptor interaction pathway was enriched in OBI-992 resistant cells.
CONCLUSION: OBI-992, a novel TROP2 targeting ADC, emerges as a potential promising therapeutic option for patients who are resistant to other TROP2 targeting ADCs such as SG and Dato-Dxd. OBI-992 exhibits distinct resistance profiles compared to other TROP2 targeting ADCs. Understanding of potential mechanisms of resistance can provide potential combination options for TROP2-targeting ADCs to combat the drug resistance.

#1703 Molecular drivers of enzalutamide resistance in prostate cancer: insights into CYP3A5 and associated pathways.

Imran Khan Mohammed, Ranjana Mitra

Roseman Univ. of Health Sciences, Las vegas, NV

Prostate cancer (PC) disproportionately affects Black/African American (AA) men, who experience higher incidence rates, more aggressive disease, and worse outcomes compared to non-Hispanic White Americans (NHWA). CYP3A5, a cytochrome P450 enzyme, is expressed at higher levels in individuals carrying the *1 variant, prevalent in AAs, compared to the *3 variant, more common in NHWA. Elevated CYP3A5 expression in AAs has been associated with aggressive prostate cancer phenotypes, potentially due to its role in activating androgen receptor (AR) signaling and promoting crosstalk with Wnt signaling pathways. Resistance to AR-targeted therapies, such as enzalutamide, remains a major challenge in metastatic castration-resistant prostate cancer (mCRPC), particularly in aggressive disease subtypes.

To investigate mechanisms underlying enzalutamide resistance, we generated resistant PC cell lines of NHWA origin (low CYP3A5-LNCaP) and AA origin (high CYP3A5-MDAPCa2b). In resistant MDAPCa2b cells, RT2 androgen receptor profiler arrays revealed upregulation of MME, SGK1, SNAI, and STEAP, genes implicated in Wnt pathway regulation (SGK1), epithelial-to-mesenchymal transition (SNAI), and enhanced proliferation and migration (STEAP). Additionally, tumor suppressors and regulatory genes, including ADAMTS1, KLK4, MT2A, NDRG1, and TIPARP, were significantly downregulated, suggesting reduced ECM remodeling, oxidative stress responses, and DNA repair capacity in resistant cells. Importantly, CYP3A5 expressions were significantly elevated in resistant MDAPCa2b cells but remained unchanged in resistant LNCaP cells, highlighting a potential link between high CYP3A5 expressions and resistance mechanisms.

The upregulation of SGK1, SNAI, and STEAP, alongside the downregulation of ADAMTS1, KLK4, MT2A, NDRG1, and TIPARP, suggests that resistance to enzalutamide involves AR and Wnt signaling, EMT, and loss of tumor suppressive functions. These findings support the hypothesis that the *1 CYP3A5 variant in AAs drives aggressive disease and therapeutic resistance, providing a molecular basis for observed clinical disparities and potential pathways for targeted intervention.

#1704 Overcoming resistance in HER2-positive gastric and breast cancers: Efficacy of disitamab vedotin in preclinical models resistant to trastuzumab emtansine and trastuzumab deruxtecan.

Negar Pourjamal[1], Vadim Le Joncour[1], Gyorgy Vereb[2], Cilla Honkamaki[1], Jorma Isola[3], Jeffrey V Leyton[4], Pirjo Laakkonen[1], Heikki Joensuu[5], Mark Barok[1]

[1]Faculty of Medicine, University of Helsinki, Helsinki, Finland,[2]Faculty of Medicine, University of Debrecen, Debrecen, Hungary,[3]Faculty of Medicine, University of Tampere, Tampere, Finland,[4]Faculty of Medicine, University of Ottawa, Ottawa, QC, Canada,[5]Oncology, Helsinki University Hospital, Helsinki, Finland

BACKGROUND: HER2-positive gastric and breast cancers often develop resistance to the approved antibody-drug conjugates (ADCs) trastuzumab emtansine (T-DM1) and trastuzumab deruxtecan (T-DXd). Disitamab vedotin (DV), a novel anti-HER2 ADC, binds to a distinct epitope on HER2 compared to trastuzumab. This study investigated the therapeutic potential of DV in preclinical models of gastric and breast cancer, including those resistant to T-DM1 and T-DXd and explored whether combining DV with these ADCs could enhance anti-tumor efficacy.

METHODS: We evaluated the efficacy of DV, T-DM1, and T-DXd individually and in combination using AlamarBlue cell proliferation assays in HER2-positive gastric and breast cancer cell lines, including models resistant to T-DM1 and T-DXd. We assessed the in vivo efficacy of DV in SCID mouse xenograft models of gastric and breast cancer that had progressed on T-DM1 and/or T-DXd. We examined dual combinations of the three ADCs in xenograft models to evaluate potential synergistic effects.

RESULTS: DV demonstrated significant anti-tumor activity in both in vitro and in vivo models, including cell lines and xenografts that were resistant to T-DM1 and T-DXd. In xenograft models, DV effectively inhibited tumor growth in cancers that had progressed following treatment with T-DM1 and/or T-DXd. Notably, combining DV with either T-DM1 or T-DXd resulted in superior anti-tumor effects compared to the use of single agents alone, both in cell culture and in xenograft studies.

CONCLUSIONS: This study highlights the effectiveness of DV in overcoming resistance to T-DM1 and T-DXd in preclinical models of HER2-positive gastric and breast cancer. The combination of DV with these ADCs demonstrated enhanced efficacy, underscoring the potential of dual ADC strategies to improve outcomes in HER2-positive cancers.

#1705 MUC1-C is a target for antibody-drug conjugate treatment of MRTX1133-resistant KRAS G12D mutant pancreatic ductal adenocarcinomas.

Hiroki Ozawa, Keisuke Shigeta, Shinkichi Takamori, Atrayee Bhattacharya, Donald Kufe

Dana-Farber Cancer Institute, Boston, MA

Background: The *MUCIN 1* (MUC1) gene evolved in mammals to protect barrier tissues from biotic and abiotic insults. *MUC1* encodes a transmembrane MUC1-C subunit that is activated in response to the loss of homeostasis and promotes proliferative, inflammatory, and remodeling responses necessary for wound repair. However, in contrast to its protective function, prolonged activation of MUC1-C by chronic inflammation drives cancer progression. In cancer cells, MUC1-C forms complexes with receptor tyrosine kinases (RTKs), such as EGFR, at the cell membrane, contributing to downstream RTK→RAS signaling pathways. Previous research identified MUC1-C addiction in KRAS G12D mutant pancreatic ductal adenocarcinoma (PDAC) cells, against which there are limited therapeutic options. Treatment of KRAS G12D mutant PDACs has been advanced by development of the MRTX1133 inhibitor; however, resistance to this agent invariably occurs by unclear mechanisms.

Results: We report that treatment of PDAC KRAS G12D cells with the MRTX1133 inhibitor is associated with marked induction of cell surface MUC1-C expression. Our results demonstrate that MRTX1133 activates an inflammatory MUC1-C/NF-κB p65 auto-inductive pathway. We further demonstrate that MRTX1133-induced MUC1-C/NF-κB signaling (i) regulates the gasdermin E (GASDME) pore-forming protein that paradoxically protects PDAC cells from pyroptosis, (ii) drives ZEB1 and the epithelial-mesenchymal transition (EMT), and (iii) is necessary for MRTX1133 resistance. These results indicate that MUC1-C is a target for the treatment of MRTX1133 resistant PDAC tumors. There are presently no effective antibody-drug conjugates (ADCs) for PDAC treatment. In extending our results, we show that an anti-MUC1-C ADC is highly effective against MRTX1133-resistant PDAC KRAS G12D cells and that targeting MUC1-C with the ADC is synergistic with MRTX1133 in vitro. We also demonstrate that the anti-MUC1-C ADC inhibits growth of PDAC MRTX1133 resistant tumor xenografts and PDX models.

Conclusions: These findings indicate that MUC1-C confers resistance of PDAC KRAS G12D mutant cells to MRTX1133 and identify MUC1-C as a target for ADC treatment of patients refractory to MRTX1133 treatment.

#1706 Establishment and characterization of a panel of ovarian XPDX models from patients with clinical resistance to anti-folate receptor therapies.

Alyssa Simonson[1], Johnnie Flores[1], Anna Stackpole[1], Jennifer Garcia[1], Crystal Moreno[1], Gabriella Graciano[1], Erika Mata[1], Danielle Trevino[1], Rodolfo Castellanos[1], Sarah Lopez[1], Leatrice Wilson[1], Maria Jose de Miguel[2], Sreenivasa Chandana[3], Andrew Cunningham[1], Michael J. Wick[1]

[1]XenoSTART, San Antonio, TX,[2]START Madrid, Madrid, Spain,[3]START Midwest, Grand Rapids, MI

Background: Folate receptor α is an actionable therapeutic target in cancer. Mirvetuximab (MIRV) is an antibody-drug conjugate (ADC) consisting of a humanized anti-folate receptor alpha (FRα) IgG1 antibody conjugated to soravtansine (DM4) recently approved for treatment of FRα-positive, platinum refractory ovarian cancer. MIRV has been shown effective; however, patients that progress on this therapy often have few remaining treatment options. To better understand mechanisms of resistance to FRα-targeting therapies, we established four XPDX models from three ovarian cancer patients who progressed clinically on MIRV or farletuzumab, a humanized anti-FRα antibody. These models were characterized by DNA and RNA sequencing, folate receptor expression, and in vivo sensitivity to various therapies including MIRV.

Methods: Four post-FRα ovarian XPDX models were established and characterized: ST409 was from a 59-year-old Hispanic female pretreated with chemotherapy and eleven months of farletuzumab; ST6205B and ST6205D were collected two months apart from a 74-year-old Hispanic female pretreated with chemotherapy, four months of niraparib, and seven months of MIRV; STM476 was from a 65-year-old Caucasian female pretreated with chemotherapy, eleven months of rucaparib, and two months of MIRV. Models were passaged, banked, and profiled using genomic analysis, including WES and RNA_{seq}, receptor expression, and in vivo drug sensitivity studies. For in vivo studies, each model was tested against cisplatin, a PARP inhibitor, and MIRV. In vivo study endpoints included tumor volume and time from treatment initiation with %T/C values and tumor regression reported at study completion; a %T/C of ≤ 20% versus control was considered sensitive.

Results: All models were positive for FRα staining with values of 2+ or 3+. Genomic characterization identified a $BRCA1^{L1254X}$ truncation in ST409 and an RB1 frameshift in ST6205B and ST6205D; TP53 mutations were identified in all models. In vivo, ST409 was found sensitive to single agent cisplatin (%T/C<0%) but resistant to MIRV (%T/C=73%), while STM476 was resistant to cisplatin (%T/C=41%) and MIRV (%T/C=78%). ST6205B and ST6205D were resistant to cisplatin and MIRV (%T/C>30%); no model was sensitive to PARPi at the evaluated treatment regimens.

Conclusion: We have established and characterized a panel of ovarian XPDX models from patients with clinical resistance to anti-folate receptor therapies. These models can be utilized as a valuable tool in better understanding mechanisms of resistance to FRα-targeting therapies and in developing novel therapies for patients who progress clinically on MIRV or similar agents.

#1707 Characterization of egfr ectodomain mutation in acquired resistance to cetuximab in colorectal cancer.

Neeraj Joshi, Hidenori Tanaka, Galina Bogatcheva, Ramona Graves Deal, Claudia Wahoski, Sarah Harmych, Claiborne Tydings, Marisol Ramirez, James Higginbotham, Maria J. Irudayam, Jeffrey L. Franklin, Qi Liu, Jens Meiler, Robert J. Coffey, Eben L. Rosenthal, Bhuminder Singh

Vanderbilt University Medical Center, Nashville, TN

Colorectal cancer (CRC) remains the second leading cause of cancer-related deaths in the United States (US), and individuals with surgically unresectable stage four CRC have a five-year overall survival of 13%. Targeting of the receptor tyrosine kinase (RTK), EGF receptor (EGFR) with therapeutic monoclonal antibodies (cetuximab, panitumumab) is approved for use in wild-type KRAS/NRAS/BRAF (RAS/RAF) advanced CRC. However, these antibodies as a single agent have response rates of 12-17% and expected progression-free survival of only 3-4 months. Accordingly, resistance may be present at the outset (de novo resistance) or develop during treatment (acquired resistance). To model and understand drug resistance, we cultured CRC lines in a defined 3D matrix (type 1 collagen) with anti-epidermal growth factor receptor (EGFR) antibody cetuximab. Here, we report the identification of an EGFR ectodomain missense mutation acquired *in vitro* in response to cetuximab treatment. Using 2D and 3D drug sensitivity assays, we demonstrate that this EGFR ectodomain mutation, in addition to being resistant to cetuximab and panitumumab, also could not be targeted by the oligoclonal anti-EGFR antibody cocktail MM-151. To determine whether this EGFR ectodomain mutation is necessary and sufficient to impart cetuximab resistance, (i) we engineered stable cell lines that inducibly overexpress mutant EGFR and (ii) demonstrated the sufficiency of mutant EGFR overexpression in conferring cetuximab resistance under both *in vitro* and in nude mouse xenografts. Further, our structural, functional, and biochemical studies implicate reduced binding of EGFR mutant to cetuximab and sustained downstream signaling activity as a cause of cetuximab resistance. Collectively, this mutation necessitates additional treatment strategies for a subset of subjects with advanced CRC who do not respond to treatment with current anti-EGFR biologics.

#1708 CKD-702, a novel bispecific antibody, enhances anti-tumor effect of combination with EGFR TKIs in NSCLC preclinical model.

Mi Jin Yoon, Soon-Ki Hong, Gun-Woo Park, Kyung-Woo Lee, Sunhong Kim, Young-Shin Kwak, Ju-Hee Lee

CKD Research Institute, Yongin-si, Korea, Republic of

The development of drug resistance is a major cause of poor prognosis and therapeutic failure in NSCLC. The mutual synergism between cMET and EGFR is known to promote acquired drug resistance, which complicates effective treatment strategies. In NSCLC, cMET gene amplification is reported in 2-4% of previously untreated patients and in 5-20% of patients with EGFR mutations and acquired resistance to EGFR TKIs. This crosstalk between the cMET and EGFR pathways underscores the need for dual inhibition as a promising treatment for NSCLC patients, especially those with acquired cMET activation. cMET, a proto-oncogene encoding the RTK HGFR, plays a crucial role in cell proliferation, motility, and survival. Aberrant activation of cMET through gene amplification, mutation, or overexpression has been implicated in the development of various cancers, including NSCLC. EGFR, another critical RTK, is frequently mutated in NSCLC, leading to uncontrolled cell growth and survival. The interplay between cMET and EGFR signaling pathways facilitates the emergence of resistance to EGFR TKIs, a common occurrence in NSCLC patients undergoing treatment. This resistance often results from secondary mutations in the EGFR gene, such as T790M and C797S, or from activation of alternative signaling pathways, including cMET amplification. CKD-702 is a bispecific antibody specifically designed to target both cMET and EGFR. It is a tetravalent IgG1-like bispecific antibody, in which a single-chain variable fragment specific to EGFR is genetically fused to the C-terminus of a conventional IgG1 of cMET. This innovative design allows CKD-702 to bind with high affinity to the extracellular domains of both cMET and EGFR, effectively inhibiting their signaling by blocking ligand binding. Additionally, CKD-702 induces the internalization and degradation of both receptors, thereby further inhibiting their activity and downstream signaling pathways. This study aims to evaluate the efficacy of combination therapy with EGFR TKIs and CKD-702 for overcoming resistance in NSCLC, particularly in EGFR exon 20 insertion mutant models and triple mutant models, including the C797S mutation. The combination therapy demonstrates superior efficacy compared to monotherapy in both cellular and animal models, effectively inhibiting signaling pathways and tumor growth. These findings are promising for addressing the significant challenge posed by the development of resistance to EGFR TKIs in the treatment of NSCLC. A Phase I study of CKD-702, which began in 2020, is currently ongoing. Current clinical trials of CKD-702 monotherapy show promising results, with combination therapy being considered to address resistance mechanisms in NSCLC.

#1709 Cyanobacteria-derived RNA aptamer supports prostate cancer hormone sensitivity.

Carlos David Cruz-Hernandez, Bethany Smith, Sandrine Billet, Manish Thiruvalluvan, Gabrielle Gonzalez, Neil Bhowmick

Medicine, Cedars-Sinai Medical Center, Los Angeles, CA

Prostate cancer (PCa) hormone therapy resistance is the second leading cause of cancer death among American men. Multiple mechanisms inherent to the disease can lead to castrate-resistance, including those that mediate lineage plasticity. We have reported that inhibiting AR signaling can increase glutamine (L-Gln) secretion by cancer-associated fibroblasts (CAF). L-Gln-free media significantly limits PCa cell growth. However, targeting L-Gln metabolism or transporters provides limited benefit. On the other hand, non-metabolizable L-Gln analogues like 6-Diazo-5-oxo-l-norleucine (DON) and DRP104 have shown promising antitumor effects. We reasoned that extracellular interruption of L-Gln uptake could be a therapeutic strategy that bypasses metabolic adaptation of a specific enzyme or transporter, especially if it could be tumor-selective. To target L-Gln, we explored cyanobacteria-structured non-coding RNA riboswitches, which are typically associated with metabolite-binding for gene regulation. Riboswitches in cyanobacteria that sense L-Gln through an aptamer motif, glnA, were chosen due to their stability and high specificity. Since L-Gln concentrations in bacteria can be higher than those in the tumor microenvironment, we optimized an RNA aptamer binding affinity through structural analysis, computer modeling, and in vitro and in vivo testing. The optimized aptamer depleted L-Gln from PCa cells by both L-Gln sequestration and the recruitment of extracellular glutaminase activity, serving as an allosteric activator. Glutamine depletion reduced FOXM1 transcriptional occupancy on the FGF8 promoter, known mediator of PCa castrate resistance. Further tumor targeting was achieved by functionalizing gold nanoparticles with the aptamer. The L-Gln-depleting aptamer, with demonstrated serum stability, limited the proliferation, and lineage plasticity of the castrate resistant prostate tumors alone and in combination therapy with AR antagonists, enzalutamide and apalutamide in subcutaneous and orthotopic mouse models. A point mutation in the binding pocket of the 56mer rendered the aptamer ineffective in L-Gln binding, FGF8 regulation, and had a limited impact on tumor growth. Superiority of the functionalized nanoparticle targeting was demonstrated in an orthotopic PCa model over the un-targeted aptamer in reducing tumor weight. The studies demonstrated elevated L-Gln can be necessary and sufficient for castrate resistance, as its depletion sensitizes prostatic tumors to AR inhibition.

#1710 Advancing HER2-targeted ADC drug discovery through resistant cell line generation and cancer cell panel analysis.

Lili Chai, Taotao Cao, Xue Yang, Wei Liu, Zhengtai Li, Xiaojian Wang, **Tj (Tiejun) Bing**

ICE Bioscience, Inc., Beijing, China

Antibody-drug conjugates (ADCs) represent a cutting-edge class of targeted cancer therapeutics, seamlessly integrating the high specificity of monoclonal antibodies with the cytotoxic power of chemotherapy agents. This strategic union facilitates the precise delivery of a potent cytotoxic payload to HER2-expressing cancer cells, where HER2 is a well-established therapeutic target. Despite the promising efficacy of HER2-directed ADCs in treating HER2-positive breast cancer, the emergence of resistance in tumor cells poses a significant obstacle to their therapeutic potential.

The present study is designed to meticulously assess the anti-tumor efficacy of HER2-targeted ADCs across a diverse panel of cancer cell lines exhibiting varying levels of HER2 expression. Furthermore, to delve into the complexities of resistance, we have developed in vitro models of resistance by subjecting cells to cyclical exposure to DS-8201, a leading HER2-targeted ADC, and its payload, Dxd. Our findings reveal a pronounced inhibitory effect of HER2-targeted ADCs on HER2-positive cancer cell lines, underscoring their selective cytotoxicity. A critical insight from our research is the observation of a significant reduction in HER2 protein levels in cell lines that have developed resistance. This decrease is hypothesized to be a key factor in the resistance mechanism, potentially by limiting the availability of the target for ADC binding. The elucidation of these resistance mechanisms is pivotal, as it informs the strategic development of next-generation HER2-targeted therapies. By addressing the issue of resistance, we aim to enhance the efficacy of HER2-targeted treatments and ultimately improve patient outcomes in the battle against breast cancer.

#1711 Genomic and transcriptomic mediators of resistance to antibody-drug conjugates (ADCs) in metastatic breast cancer (MBC): A comprehensive multi-center study.

Samer Alkassis[1], Marla Lipsyc-Sharf[1], Catherine Hegarty-Traverso[2], Jacob Mercer[2], Binyam Yilma[2], Stamatina Fragkogianni[2], Yuan Yuan[3], Funda Meric-Bernstam[4], Hope Rugo[5], Joyce O'Shaughnessy[6], Mothaffar Rimawi[7], Rachel Schiff[7], David Elashoff[1], John Glaspy[1], Martina McDermott[1], Amy Cummings[1], Calvin Chao[2], Aditya Bardia[1]

[1]UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA,[2]Tempus AI, Inc., Chicago, IL,[3]Cedars Sinai Medical Center, Los Angeles, CA,[4]MD Anderson Cancer Center, Houston, TX,[5]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA,[6]Baylor University Medical Center, Texas Oncology, Sarah Cannon Research Institute, Dallas, TX,[7]Baylor College of Medicine, Baylor College of Medicine, Lester and Sue Smith Breast Center and Dan L Duncan Comprehensive Cancer Center, Houston, TX

ADCs have revolutionized the therapeutic landscape in oncology. Three ADCs are US FDA-approved in MBC: sacituzumab govitecan (SG), trastuzumab deruxtecan (T-DXd) and trastuzumab emtansine (T-DM1), with many others in development. Despite these advances, ADC resistance mechanisms remain unknown. To discern biomarkers of therapeutic resistance, we evaluated genomic and transcriptomic differences in MBC before and after ADC treatment (tx).

We analyzed next-generation sequencing (NGS) data from patients (pts) in the Tempus Database that received SG, T-DXd or T-DM1 pre or post biopsy (bx) (n_{SG}=157, $n_{T\text{-}Dxd}$=120, $n_{T\text{-}DM1}$=84; 32.4% TNBC, 27.1% HR+/HER2-, 20.2% HER2+, 20.2% NOS). Pre-tx groups included pts with bx collected < 1 year before or < 15 days after the ADC start date. Post-tx groups included pts who had bx collected < 3 months (mo) after ADC end date. Acquired resistance (AcqRes) was analyzed by comparison of pre- and post-tx bx for pts treated with ADC for > 3 mo. Primary resistance (PrRes) was defined as pre- and post-tx bx for pts treated with ADC for < 3 mo. We evaluated resistance based on ADC mechanisms of action (MoA), including genes related to antigen expression, processing mechanism, payload effect and efflux pumps. Somatic differences were compared using Pearson's Chi-squared test or Fisher's exact test, as appropriate. In this exploratory analysis, all p-values are reported as uncorrected. The median log2(TPM) gene expression was compared between groups using the Wilcoxon rank sum exact test.

In the AcqRes cohort, there were no significant differences in mutation frequency or expression of the target antigen for pre/post-SG or T-DXd bx, though in the pre- vs post-T-DM1 bx there was a decrease in *ERBB2* alterations (69% vs 40%, p=0.047) and expression (10.9 vs. 8.4, p=0.024). A trend toward higher expression across efflux pump genes was seen in pts with AcqRes for SG (*ABCB1*: 2.7 vs 3.4, p=0.08; *ABCC2*: 2.4 vs 3.4, p=0.2) and T-DXd (*ABCC1*: 6.3 vs. 6.7, p=0.016; *ABCB1*: 2.77 vs. 3.44, p=0.4), with mixed changes in T-DM1 (*ABCB1*: 3.3 vs. 2.7, p=0.08; *ABCC1*: 6.3 vs. 6.8, p=0.05; *ABCC2*: 3.19 vs. 3.18, p=0.2). A trend of higher efflux pump gene expression was associated with PrRes to SG and T-DXd. Overall, there were no significant differences in expression of genes associated with ADC processing or DNA damage repair, though rare mutations in *TOP1* and *ATM* were associated with PrRes to T-DXd.

Genomic and transcriptomic analysis identified potential mechanisms of AcqRes and PrRes to SG and T-DXd, including higher drug efflux pump expression. This might be related to the ADC MoA, particularly the payload release and bystander effect. Additional research is needed to validate these novel findings and the molecular underpinnings mediating resistance to ADCs.

#1712 CD36 enrichment in HER2+ mesenchymal stem cells potentiates therapy refractoriness in HER2+ breast cancer.

Lorenzo Castagnoli[1], Valeria Cancila[2], Martina Bigliardi[1], Matteo Dugo[3], Paola A. Corsetto[4], Claudia Chiodoni[1], Viola Regondi[1], Michela Francesconi[1], Antonino Belfiore[5], Andrea Vingiani[6], Giancarlo Pruneri[7], Francesca Ligorio[8], Elda Tagliabue[1], Claudio Tripodo[9], Claudio Vernieri[10], Tiziana Triulzi[1], **Serenella M. Pupa**[1]

[1]Department of Experimental Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[2]Tumor Immunology Unit - Department PROMISE, Universita di Palermo, Palermo, Italy,[3]Department of Medical Oncology, IRCCS Ospedale San Raffaele, Milan, Italy,[4]Department of Pharmacological and Biomolecular Science "Rodolfo Paoletti", Universita degli Studi di Milano, Milan, Italy,[5]Department of Diagnostic Pathology and Laboratory Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[6]Department of Diagnostic Pathology and Laboratory Medicine/ Department of Oncology and Hemato-Oncolo, Fondazione IRCCS Istituto Nazionale dei Tumori/ Universita degli Studi di Milano, Milan, Italy,[7]Department of Diagnostic Pathology and Laboratory Medicine/ Department of Oncology and Hemato-Oncolo, Fondazione IRCCS Istituto Nazionale dei Tumori/ Universita degli Studi di Mialano, Milan, Italy,[8]Medical Oncology Department/the AIRC Istitute of Molecular Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori/IFOM ETS, Milan, Italy,[9]The AIRC Institute of Molecular Oncology, IFOM ETS, Milan, Italy,[10]Medical Oncology Department/The AIRC Istitute of Molecular Oncology, Fondazione IRCCS Istituto Nazionale dei Tumori/IFOM ETS, Milan, Italy

Approximately 15-20% of breast cancers (BCs) are characterized by amplification/overexpression of HER2. Although the introduction of anti-HER2 drugs has improved the prognosis of HER2-positive (HER2+) BC patients, a considerable number of tumors fail to respond to or acquire resistance to targeted therapies, highlighting the need for new strategies. Emerging evidence shows that the reprogramming of fatty acid (FA) metabolism plays a key role in the aggressiveness and therapeutic resistance of HER2+ BC. HER2+ BC has been defined as a "lipogenic disease" due to the functional reciprocal crosstalk occurring between HER2-mediated oncogenic signaling and fatty acid (FA) biosynthesis via fatty acid synthase activity. Once lipid biosynthesis is inhibited by anti-HER2 agents, cancer cells could enhance their ability to uptake extracellular FAs to guarantee their supply. In this context, the functional role of the reprogramming of CD36-mediated FA uptake in HER2+ BC progression remains unclear. Our study provides an in-depth molecular, biological and functional characterization of the transmembrane FA transporter CD36 in epithelial (MET-like)- and mesenchymal (EMT-like) HER2+ breast cancer stem cell (CSC) subsets, selected HER2+ BC cell lines and patients treated with neoadjuvant trastuzumab. We reveal consistent enrichment of CD36 in HER2+ EMT-like CSCs from all tested preclinical and clinical therapy-refractory BC models. Notably, we demonstrate the functional interplay occurring between Wnt signaling regulation/activation and CD36 enrichment in HER2+ BC cells. Dual blockade of CD36 and HER2 increases the anti-CSC efficacy of anti-HER2 drugs. Additionally, expression of CD36 in intratumor HER2+ mesenchymal CSCs is significantly associated with resistance to trastuzumab in HER2+ BC patients. These results support the critical role of CD36-mediated FA uptake in HER2+ therapy-refractory BC. Our study provides evidence that targeting CD36 might be an effective therapeutic strategy for this malignancy. (Supported by AIRC)

#1713 Disrupting ER-AR crosstalk using AR degraders: a novel approach to treating endocrine resistant breast cancer.

Matt Konda, Obdulia Covarrubias-Zambrano, Stefan H. Bossmann, Joan Lewis-Wambi

University of Kansas Medical Center, Kansas City, KS

Background: Estrogen receptor positive (ER+) breast cancer accounts for approximately 70% of all breast cancer cases and is the most diagnosed subtype amongst women. Current treatments include aromatase inhibitors (AIs), which block the biosynthesis of estrogens, tamoxifen (ER antagonist), and fulvestrant (ER degrader) (FUL). Despite therapeutic effectiveness, 30% of patients develop resistance, necessitating a deeper understanding of the underling mechanisms. Recent evidence points to the upregulation of androgen receptor (AR) signaling pathway as a potential mechanism of acquired resistance in breast cancer. To address the role of ER/AR crosstalk in acquired endocrine resistance, we generated an AI-resistant breast cancer cell line, MCF-7:5C (5C), mimicking the resistance seen in patients undergoing AI treatment.
Methods: The inhibitory effect of FUL and ARCC4 (AR PROTAC degrader) on AI-resistant 5C and parental MCF-7 cells was examined using CellTiter-Blue® Cell Viability assay and trypan blue cell counting. Western blot, immunofluorescence, and nuclear fractionation assays were performed to determine ER and AR protein expression and cellular localization in response to FUL and ARCC4 treatments. siRNAs were used to knockdown ER and AR expression in resistant 5C cells to assess functional significance. Additionally, flow cytometry analysis using the RhodB-PTP (10mg/mL) was used to probe for surface expression of plectin in resistant cells.
Results: AI-resistant 5C cells expressed markedly elevated levels of ER and AR and were more sensitive to the inhibitory effects of FUL and ARCC4 compared to parental MCF-7 cells. Immunofluorescence and nuclear fractionation assays revealed predominant nuclear localization of ER and AR in 5C cells compared to MCF-7 cells, and both proteins were markedly reduced (>95%) by FUL and ARCC4 treatments and siRNAs targeting both ER and AR. Notably, flow cytometry data revealed a strong correlation between ER, AR, and surface Plectin in 5C cells, thus identifying an additional target in these cells.
Conclusions: Plectin is a cytoskeleton linker protein found in non-transformed cells, however, evidence suggests that its cancer-specific mislocalization to the cell surface contributes to its oncogenic function. As such, therapeutic targeting of surface plectin, along with ER/AR using FUL and ARCC4, represents an attractive opportunity to impede tumorigenesis and possible reverse endocrine resistance in breast cancer.

#1714 Understanding ADC resistance using preclinical enhertu-induced resistant models.

Hongyan Sun[1], Yuan Fang[1], Fang Zhu[1], Jianming Xu[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Antibody-drug conjugates (ADCs) combine the specificity of monoclonal antibodies (mAbs) with potent cytotoxic payloads, offering a promising approach for targeted cancer therapy. Enhertu (trastuzumab deruxtecan, DS-8201), an ADC targeting HER2-positive cancers, has demonstrated remarkable efficacy in clinical settings, setting new benchmarks for anti-HER2 ADCs. However, drug resistance remains a significant challenge, underscoring the need to elucidate resistance mechanisms and develop strategies to overcome them. To address this important question, we established a robust preclinical platform to study Enhertu resistance by subjecting HER2-positive JIMT-1 xenograft tumors to a series of *in vivo* passaging and drug induction. Massive parallel sequencing analyses, including RNA sequencing (RNA-Seq) and whole-exome sequencing (WES), revealed multiple resistance-associated pathways, with a particular emphasis on payload-resistance mechanisms. Flow cytometry and IHC analyses confirmed no significant changes in HER2 expression levels between resistant and parental tumors, ruling out target downregulation as the main resistance mechanism. Notably, the resistant tumor provided a valuable platform for studying interactions within the tumor microenvironment (TME), including stromal and immune components that may contribute to resistance development.

The establishment of these preclinical Enhertu-resistant models offers a unique opportunity to investigate resistance mechanisms that may not yet be observed in clinics. Furthermore, these models provide a foundation for testing innovative therapeutic strategies, such as combination treatments targeting multiple pathways or the development of next-generation ADCs with improved payload efficacy. By enhancing our understanding of ADC resistance, these findings contribute to the advancement of personalized cancer therapies and may ultimately improve outcomes for patients with HER2-positive malignancies.

#1715 Novel patient-derived organoids (PDOs) models for studying HER2-positive endometrial cancer.

Natalia Bednarek[1], Anh Q. Nguyen[2], Julieta Barroeta[3], Benedikt Nagele[4], Subin Myong[1], Katherine Kurnit[2], Diane Yamada[2], Gini Fleming[2], Sridevi Challa[2]

[1]The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL,[2]Obstetrics and Gynecology, The University of Chicago Medicine, Chicago, IL,[3]Pathology, The University of Chicago Medicine, Chicago, IL,[4]The University of Chicago, Chicago, IL

Endometrial carcinoma (EC) is the most common cancer of the reproductive organs in women with 66,200 new cases and 13,030 deaths in United States in 2023. Recent clinical trials are evaluating the use of antibody-drug conjugates (ADCs), such as trastuzumab-deruxtecan (T-Dxd) for the treatment of solid tumors, including EC. T-Dxd consists of anti-HER2 antibody (trastuzumab) and topoisomerase I inhibitor (deruxtecan). The mechanism of action of T-Dxd involves the HER2-directed cytotoxic effect induced by deruxtecan, as well as the bystander killing effect when deruxtecan is released into neighboring cells. This dual mode of action makes T-Dxd a suitable candidate for the treatment of both HER2-high and HER2-low cancers.

Patient-derived organoids (PDOs) have emerged as models for studying tumor biology and screening for new drugs. As opposed to regular 2D cultures, organoids provide a more accurate representation of the key features and therapeutic response of patient tumors. The primary goal of our project is to generate endometrial cancer PDOs to test the efficacy of new combination treatments including T-DXd.

We have successfully generated several organoid lines from endometrioid and clear cell cancer tissues using patient samples obtained from surgeries. Established organoids were submitted for pathological review and genetic testing which demonstrated that tissue morphology and genetic alterations of PDOs strongly correlate with patient tumors. Immunohistochemical analysis has shown that T-DXd treatment of the organoids causes a decrease in HER2 levels and an increase in pERK1/2 levels. We also treated the HER2-positive organoids with the combination of T-DXd and MEK inhibitors and monitored changes in growth. We observed decreased growth of organoids after combination treatment compared to untreated control.

In conclusion, we successfully generated PDOs models of endometrial tumors and confirmed the response to single-agent and combination treatments. Obtained organoid lines can be further utilized to study tumor biology and test new combinations of drugs.

#1716 Acquired cell adhesion molecule 1 (CADM1) ADC resistance model for optimizing payload efficacy and toxicity in osteosarcoma preclinical testing.

Zhongting Zhang, Wendong Zhang, Xin Zhou, Caterina Longo, Yifei Wang, Dongxue Mao, Yanhua Yi, Zhaohui Xu, Zhao Li, Simon Olivares, Sylvester Jusu, Harjeet Singh, Michael Roth, Jonathan Gill, Bissan Al-Lazikani, Richard Gorlick

UT MD Anderson Cancer Center, Houston, TX

Instruction: Antibody-drug conjugates (ADCs) are a rapidly advancing therapeutic approach. A proof of principle CADM1 ADC has shown significant efficacy in osteosarcoma preclinical studies; however, its activity may be compromised by inherent or acquired resistance during prolonged treatment. In this study we generated osteosarcoma models resistant to a CADM1 ADC to define the underlying molecular mechanisms.

Methods: The antitumor efficacy of CADM1 ADC was validated in vivo in six osteosarcoma patient-derived xenografts (PDXs) at a 3 mg/kg dose. To model acquired resistance, osteosarcoma PDXs were subjected to three cycles of treatment with a low-dose (0.5 mg/kg) CADM1 ADC. Tumor samples were harvested from pre-treated controls and post-treatment resistant PDXs. These samples were analyzed using immunohistochemistry (IHC), flow cytometry, whole-genome sequencing (WGS), and bulk RNA sequencing (RNA-seq). Resistant PDXs were further tested with two alternative ADCs: one using the same payload but targeting a different antigen and another using the same target antigen but with a different payload. IC_{50} values were determined in pre-treated and resistant PDX-derived cells to evaluate cytotoxicity.

Results: After three cycles of low-dose CADM1 ADC treatment, PDX models exhibited a gradual decline in tumor regression, indicating the development of resistance. IHC and flow cytometry analyses demonstrated variable CADM1 expression between pre-treatment and resistant samples, with only some tumors exhibiting decreased target expression. Whole-genome sequencing (WGS) revealed increased gene copy number gains in resistant tumors compared to controls. RNA-seq analysis identified significant changes in gene expression, including reduced CADM1 expression in some samples and upregulation of resistance-associated pathways. Notably, the multidrug resistance-associated protein (MRP) transporter *ABCC3* was significantly overexpressed in resistant tumors compared to pre-treatment samples. Cytotoxicity assays further confirmed resistance, with resistant PDX-derived cells exhibiting higher IC_{50} values compared to pre-treated cells, indicating reduced sensitivity to CADM1 ADC.

Conclusions: CADM1 ADC demonstrates potent antitumor activity in osteosarcoma PDX models but resistance can develop. Future studies will delve deeper into protein localization and post-translational modifications as well as single cell genomics to better understand the mechanisms of resistance.

#1717 Establishment and characterization of enzalutamide resistant prostate CDX models.

Haiting Dai, Jie Yang, Xiu Fan, **Wen-Jen Yu**

ICE Bioscience INC, Beijing, China

Prostate cancer (PCa) is common and mostly androgen dependent cancer occurred in men and ranked fifth of the causes of death over the world, reduction the serum level of androgen become the priority therapy method for treating PCa patients. Although the first generation of anti-androgen receptor (AR) new drugs such as flutamide, nilutamide, and bicalutamide were launched few years ago and lighted new hopes for treatment of androgen dependent PCa, drug resistance was developed quickly and push the second generation of anti-AR drugs such as enzalutamide, apalutamide, and darolutamide to the market by their high specific binding to AR and better drug efficacy. Despite new anti-AR drugs exerted better efficacy, drug resistance still hampered the treatment of PCa patients, new challenge was burst for anti-PCa drugs through AR pathway. In this study, we developed an enzalutamide resistant C4-2B cell line in vitro by escalated the enzalutamide concentration gradually. The phenotype and genotype of C4-2B cell line were checked while enzalutamide concentration was increased. After 6 months of induction and identification, C4-2B enzalutamide resistant cell line was established and showed 140 times of drug-resistant index compare to that of parental cell. The in vivo drug-resistant efficacy was also confirmed in C4-2B enzalutamide resistant (C4-2B Enz-R) CDX models using 30 mpk enzalutamide through PO administration for 28 days (TGI=8.37%, T/C=93.22%) compared to the enzalutamide efficacies on LNCAP and 22RV1 CDX models. Western blot for androgen receptor expression level in tumor tissues and ELISA assay for prostate specific androgen (PSA) level in serum are highly correlated to the tumor volume of C4-2B Enz-R CDX models. The well characterized novel C4-2B Enz-R cell line and CDX model were appropriate for new drug discovery of anti-PCa drugs through AR pathway in vitro and in vivo.

#1718 Role of IKKε in resistance to second-generation hormone therapy in prostate cancer.

Fayrouz Annab, Mariana Llasera, Benjamin Peant, Anne-Marie Mes-Masson, Francis Rodier, Fred Saad

Centre de Recherche du Centre Hospitalier de L'universite de Montreal, Montreal, QC, Canada

Introduction: Prostate cancer is the most commonly diagnosed cancer and the third leading cause of cancer-related death among men in Canada. Patients with castration-resistant prostate cancer (CRPC) are treated with various agents, including Enzalutamide, a second-generation hormone therapy that improves overall survival. However, in the long term, all patients eventually develop resistance. This highlights the critical need to better understand the mechanisms of Enzalutamide resistance in mCRPC and to identify new therapeutic strategies to improve patient outcomes. IκB kinase-epsilon (IKKε), a member of the IKK protein family, is involved in the inflammatory response and the inflammation phenotype of rheumatoid arthritis. IKKε has been identified as an oncogene, and deregulation of its expression has been associated with prostate cancer progression. Preliminary experiments conducted in our laboratory have shown an increased expression level of IKKε in Enzalutamide-resistant cell lines. We previously demonstrated that IKKε inhibitors, such as Amlexanox, reduce the proliferation of CRPC cells.
Hypothesis: We hypothesize that inhibiting IKKε using Amlexanox restores sensitivity to Enzalutamide in Enzalutamide-resistant prostate cancer cells. Our overarching goal is to characterize the role of IKKε in the development of Enzalutamide resistance and to evaluate the therapeutic potential of the Amlexanox-Enzalutamide combination to treat CRPC patients.
Methodology and Results: We obtained Enzalutamide-resistant and -sensitive CR cell lines derived from LNCaP. Cells have been treated with an increased dose of Amlexanox and Enzalutamide for 7 days to calculate the IC_{50} of each drug for each cell line. Based on these IC50, we performed real-time imaging assays using different dose combinations to determine the additive or synergistic effect of Amlexanox and Enzalutamide cotreatment. In addition, we confirmed IKKe and AR inhibition using Amlexanox and Enzalutamide, by Western blot assays. We also looked for the expression of apoptosis and senescence markers to determine the behavior of each studied PC cell line in response to treatments. Finally, we started Bulk RNA barcoding and sequencing (BRB-seq) assays on all LNCaP-derived cell lines treated with Enzalutamide and Amlexanox, alone or in combination.
Conclusion: We aim to develop a combination therapy that can restore sensitivity to Enzalutamide, improve patients' quality of life, and more effectively control disease progression.

#1719 Constitutive aryl hydrocarbon activity promotes resistance to bortezomib which is exacerbated by leptin and potentially involves Src phosphorylation by JAK2 in prostate cancer cells.

Kofi K. Khamit-Kush[1], Daniel J. Walters[2], Nathan J. Bowen[1], Jeffrey A. Handy[3], Joann B. Powell[1]

[1]Biological Sciences, Clark Atlanta University, Atlanta, GA,[2]Biological Sciences, Morehouse School of Medicine, Atlanta, GA,[3]Biological Sciences, Morehouse College, Atlanta, GA

The aryl hydrocarbon receptor (AhR) plays a role in regulating diet-induced obesity and is a nuclear transcription factor involved in the transcriptional regulation of target genes, such as enzymes of xenobiotic metabolism (CYP1, UGTs) or genes involved in the transcriptional regulation. Induced enzymes facilitate the metabolism of various endogenous compounds and drugs, such as bortezomib. We report that the constitutive activity of AhR promotes drug resistance which is exacerbated in the presence of leptin and potentially involves AhR-mediated Src phosphorylation by JAK2 in a prostate cancer in vitro model. Leptin is known to contribute to cancer progression and has an emerging role in chemoresistance. Of note, both leptin receptor and aryl hydrocarbon receptor are overexpressed in prostate cancer cell lines. Additionally, our lab previously reported an integrative bioinformatics analysis using TCGA data (n=498) which revealed a positive correlation in AHR and LEPR mRNA expression in patients with prostate cancer. Our in vitro results also show AhR protects androgen-insensitive C4-2 cells but not LNCaP cells from apoptosis induced by anti-androgens, suggesting AhR activity leads to androgen independence and potentially multi-class chemoresistance. Further investigation into AhR as a drug target in obesity-associated conditions for the treatment of advanced prostate cancer upon entering the phase of drug resistance coupled with failure of first-line androgen deprivation therapy.

#1720 IGFBP3 signaling promotes resistance to next-generation antiandrogens therapeutics in advanced prostate cancer.

Amy Rose Leslie[1], Shu Ning[1], Masuda Sharifi[1], Zachary A. Schaaf[1], James P. Maine[1], Wei Lou[1], Chengfei Liu[1], Alan P. Lombard[2], Allen C. Gao[1]

[1]Urologic Surgery, UC Davis, Davis, CA,[2]Biochemistry and Molecular Medicine, UC Davis, Davis, CA

Background: Next-generation antiandrogen therapeutics (NGATs) have irrefutably improved the survival of prostate cancer patients. However, treatment resistance to NGATs remains a clinical challenge for men with castration-resistant prostate cancer (CRPC). The molecular mechanisms underlying resistance to NGAT remain confounding. Insulin growth factor binding protein 3 (IGFBP3) is associated with prostate cancer tumorigenesis and progression. It is known that IGFBP3 induces sphingosine kinase (SphK1) activation subsequently inducing sphingosine-1-phosphate (S1P) production. Previously, we found that IGFBP3 is necessary for PARP inhibitor resistance in acquired resistant models (OlapR cells). We hypothesize that IGFBP3 is required for acquired and intrinsic NGAT resistance.

Methods: Enzalutamide-resistant (MDVR), Abiraterone-resistant (AbiR), Apalutamide-resistant (ApalR), and Darolutamide-resistant (DaroR) C4-2B subline cells exhibit stout NGAT resistance compared to C4-2B parental cells. In addition, this study also utilized 22Rv1 cells that display intrinsic resistance to Enzalutamide. We performed transcriptomic analysis on enzalutamide-treated patients' cohorts and the enzalutamide-resistant prostate cancer cell lines. RNAseq, real time qPCR, immunoblot, and ELISA were used to determine IGFBP3 expression and secretion levels. Cell viability was determined in resistant cell lines after silencing IGFBP3 and SphK1 using siRNA or inhibiting SphK1 using SphK1 inhibitor, SKI-II.

Results: This study found that IGFBP3 was upregulated in NGAT resistant models (MDVR, AbiR, ApalR, DaroR, and 22Rv1 cells) using transcriptomics. We found that NGAT resistant models highly express IGFBP3 and SphK1 using RNA-seq, qPCR, and immunoblot. SphK1 is a lipid kinase that phosphorylates sphingosine to form S1P metabolite which promotes tumor survival, proliferation, and resistance. We discovered high levels of IGFBP3 and S1P secretion in the resistant models. We found that inhibition of IGFBP3/SphK1 decreased both SphK1 expression and S1P secretion. Mechanistically, IGFBP3 activated the Sphingolipids pathway to promote cell survival and subsequently enforce the growth factor signaling to enhance cell proliferation. Ablating the expression of IGFBP3 promotes the formation of ceramide which induces the apoptotic cascade.

Conclusion: We demonstrated that increased IGFBP3 expression by NGAT treatment leads to increased sphingolipid metabolism by simultaneously demoting ceramide-induced apoptosis and fostering S1P production through SphK1 activation. Thus, IGFBP3 induces the activation of SphK1 to hijack the sphingosine metabolism to fuel NGAT resistance. Our findings demonstrate that targeting the IGFBP3/SphK1 signaling axis enhances our ability to resensitizes resistant CRPC to NGAT therapeutics.

#1721 AXL signaling promotes adaptive resistance to HER2 tyrosine kinase inhibitors in HER2 aberrant tumor cells.

M. Ishida[1], T. Yamada[1], Y. Katayama[1], K. Yasumoto[2], K. Takayama[1];

[1]Department of Pulmonary Medicine, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Department of Medical Oncology, Kanazawa Medical University, Uchinada, Ishikawa, Japan, Kanazawa, Japan

Introduction:Human epidermal growth factor receptor 2 (HER2) is an oncogene target in various cancers, including lung, stomach, and breast cancers. Several HER2-tyrosine kinase inhibitors (TKIs) have been developed for clinical use in patients with tumors exhibiting HER2 aberrations. However, achieving complete tumor remission remains challenging. Therefore, identifying optimal combined therapeutic approaches with HER2-TKIs is crucial for improving clinical outcomes. This study focuses on elucidating the adaptive resistance mechanisms to HER2-TKIs and the therapeutic strategies needed to overcome this resistance.
Methods:We conducted in vitro and in vivo experiments using HER2-aberrant tumor cell lines to evaluate the adaptive responses to HER2-TKIs. The involvement of AXL signaling was examined using MTT assays, western blotting, qPCR, and flow cytometer.
Results:We showed that adaptive resistance to HER2-TKIs in HER2-aberrant tumors is mediated by AXL signaling, activation of which is induced by its ligand GAS6 production. Inhibition of AXL reduced the viability of HER2-aberrant tumor cells that overexpress AXL by enhancing apoptosis and cell cycle arrest induced by HER2 inhibition. This process contributed to adaptive resistance to HER2-TKIs in HER2-aberrant cancers through the Shc1BP-Shc1 axis, one of the adaptor proteins. HER2-TKIs induced the dissociation of ShcBP1 from Shc1, promoted the binding of Shc1 to AXL, and triggered the translocation of ShcBP1 to the nucleus, which is associated with the cell cycle. In xenograft models of AXL-overexpressing HER2-aberrant tumors treated with HER2-TKIs, initial combination therapy with an AXL inhibitor significantly reduced tumor size and delayed tumor regrowth compared to HER2-TKI monotherapy.
Conclusion:These findings highlight the critical role of the GAS6-AXL signaling axis in intrinsic resistance to HER2-TKIs and the potential benefits of its inhibition in overcoming this resistance.

#1722 Targeting synaptotagmin 4 to overcome enzalutamide and abiraterone resistance in castration resistant prostate cancer.

Masuda Sharifi, Shu Ning, Amy Rose Leslie, Zachary A. Schaaf, James Patrick Maine, Wei Lou, Allen C. Gao

Urologic Surgery, UC Davis, Sacramento, CA

Background: Castration-resistant prostate cancers (CRPCs) are predominantly driven by androgen receptor (AR) signaling. Although next-generation anti-androgen therapies (NGATs), such as enzalutamide (Enza) and abiraterone (Abi), have been shown to extend patient survival, resistance to these therapies often develops. The underlying mechanisms driving resistance to these treatments remains unclear. Synaptogamin 4 (SYT4), a membrane protein involved in vesicle trafficking, is highly expressed in our established Enza and Abi resistant CRPC cells. Here, we explore the contribution of SYT4 in disease progression and NGATs resistance in CRPC.
Methods: Differences in SYT4 expression were determined in Enza-resistant C4-2B MDVR (MDVR) and Abi-resistant C4-2B AbiR (AbiR) cells versus parental C4-2B cells by RNA-sequencing, real time PCR, western blot and immunofluorescence microscopy. SYT4 expression was analyzed in GEO and cBioPortal databases from patients with prostate cancer. Specific siRNAs were used to inhibit SYT4 expression. The effect of SYT4 knock down on global gene expression, cell growth and sensitivity to Enza and Abi was assessed in our resistant cell lines.
Results: SYT4 gene expression was found to be markedly elevated in MDVR and AbiR cells compared to their parental C4-2B counterparts. Analysis of clinical data further revealed that SYT4 expression is significantly upregulated in patients with advanced prostate cancer; with high SYT4 levels being associated with poorer overall survival outcomes. Transcriptomic profiling identified enrichment of genes involved in calcium-mediated cell adhesion in MDVR cells, which is suppressed upon transfection with SYT4-specific siRNA. Additionally, silencing SYT4 expression via siRNA not only inhibited prostate cancer cell growth but also restored sensitivity of MDVR and AbiR cells to their respective treatments, underscoring SYT4 as a promising therapeutic target for treatment-resistant prostate cancer.
Conclusions: Our findings indicate that elevated expression of SYT4 promotes resistance to Enza and Abi; correlating with poorer outcomes in prostate cancer patients. Targeting SYT4 reduces the expression of genes involved in calcium-dependent cell adhesion and reduces cellular viability, thereby restoring sensitivity to NGATs like Enza and Abi, offering potential new strategies for overcoming treatment-resistant prostate cancer.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Kinase and Phosphatase Inhibitors 1
Poster Session

#1726 Preclinical development of APL-045: A selective PERK inhibitor targeting ER stress pathways in cancer.

Krishna Kolluri[1], Clara Stead[1], Susanne Wright[1], Paul Glossop[2], Emmanuel Demont[1], Richard Butt[1], Nadine Clemo[1]

[1]Apollo Therapeutics Limited, Cambridge, United Kingdom,[2]Sandexis, Sandwich, United Kingdom

The unfolded protein response (UPR) is a critical component of the integrated stress response (ISR) pathway, activated in response to the accumulation of unfolded or misfolded proteins within the endoplasmic reticulum (ER). A key mediator in this pathway is protein kinase RNA-like ER kinase (PERK), which becomes active under conditions of ER stress. Upon activation, PERK phosphorylates eIF2α, temporarily halting general protein translation to reduce the burden on the ER. Cancer cells can exploit PERK signalling to enhance their survival and proliferation under stress, leveraging this pathway to adapt to UPR triggered by hypoxic, nutrient-deprived tumour microenvironments, or as a response to anticancer therapies. Inhibition of PERK is therefore a promising therapeutic target in oncology.
APL-045 is a novel, selective, ATP-competitive inhibitor of PERK. APL-045 demonstrated potent inhibition of PERK, with a Ki of 4.6 nM and IC50 for eIF2α phosphorylation inhibition of 20 nM. Selectivity screening showed high specificity, with very limited off-target effects among 468 kinases tested in a Kinome Scan®.
In vitro studies demonstrated that APL-045 effectively inhibited downstream effectors of the PERK-mediated UPR pathway, ATF4 and CHOP, in a dose-dependent manner with the IC50 values ranged from 50 to 250 nM across renal cell carcinoma (RCC) and colorectal cancer cell lines. In vivo, APL-045 significantly reduced tumour volume in 786-O RCC xenograft models, achieving over 95% tumour growth inhibition after three weeks of treatment. These findings underscore the potential of APL-045 as a promising therapeutic candidate for cancers driven by PERK-dependent pathways.
APL-045 has a highly favourable pharmacokinetic profile, with good solubility, high permeability, and robust metabolic stability in both microsomal and hepatic assays in rodent, dog and human in vitro systems. These properties have translated to high bioavailability. This favourable profile is projected to represent a best-in-class PERK inhibitor.
These data describe the efficacy and drug-like properties of APL-045, a candidate stage, best-in-class PERK inhibitor poised to progress into IND-enabling and clinical studies.

#1727 Sequencing MEK inhibitor therapy after tovorafenib in *BRAF* fusion-driven cancers: Preclinical evidence of sustained tumor regression.

S. Perino[1], Y. Wang[1], S. Rastogi[1], N. P. Damayanti[2], K. E. Pollok[2], S. G. Raju[1], M. W. Kieran[1], S. C. Blackman[1], E. Venetsanakos[1]; [1]Day One Biopharmaceuticals, Brisbane, CA, [2]Indiana University School of Medicine, Indianapolis, IN

BRAF fusions and BRAF V600 point mutations are oncogenic drivers found in many pediatric and adult cancers, and constitutively activate the downstream MAPK pathway (Jones et al 2009, Yaeger and Corcoran 2019). Tovorafenib is the first and only type II RAF inhibitor approved for the treatment of *BRAF*-altered relapsed/refractory pediatric low-grade glioma (pLGG) in patients ≥ 6 months of age. In the ongoing ph 2 study, FIREFLY-1, tovorafenib demonstrated robust clinical activity in patients with *BRAF*-altered pLGG who progressed on systemic therapy, which may have included MEK inhibitors (Kilburn et al 2024). This preclinical study evaluated if tovorafenib-sensitive *BRAF* fusion tumors that have regrown during a drug holiday would also respond to a MEK inhibitor. The potential emergence of resistance with long-term exposure to tovorafenib was also explored. Due to the lack of availability of pLGG *KIAA1549*::*BRAF* fusion (the most commonly occurring *BRAF* fusion in pLGG) PDX models, in vivo experiments were conducted using a *AGK*::*BRAF* fusion melanoma PDX model. Mice bearing *AGK*::*BRAF* fusion melanoma tumors were treated with a clinically relevant dose (25 mg/kg oral, once daily) of tovorafenib for 14 days or until complete regression of tumors was observed. An off-treatment period was then initiated, during which tumors regrew. Once individual tumors regrew to 100-200 mm^3 size (within approximately 2 weeks), mice were treated for 14 days with a MEK inhibitor (trametinib; 0.3 mg/kg oral, once daily), or tovorafenib was resumed. Complete tumor regression was observed in all tumors in response to either trametinib or tovorafenib retreatment. Further evaluation of other MEK inhibitors and different dosing sequences of MAPK inhibitors is ongoing. In addition, the efficacy of tovorafenib in a *CDC42SE2*::*BRAF* anaplastic pleomorphic xanthoastrocytoma (APXA) PDX model is also being investigated. To explore potential mechanisms of acquired resistance, we also evaluated whether resistant tumors would emerge with continuous dosing of tovorafenib. Tovorafenib was administered (25 mg/kg oral, once daily) to mice bearing *AGK*::*BRAF* fusion tumors for 90 days. Over the entire course of treatment, significant tumor regression was maintained with no emergent tumors. In conclusion, our study provides evidence for the efficacy of sequencing MEK inhibitor treatment after tovorafenib in a PDX model of *AGK*::*BRAF* fusion melanoma. Furthermore, long-term efficacy was maintained with continuous dosing of tovorafenib in vivo, with no signs of emerging resistance preclinically, supporting the hypothesis that acquired resistance may be less common in *BRAF* fusion driven tumors treated with tovorafenib.

#1729 Mutagenesis screens support potential best-in-class profile for neladalkib (NVL-655), a brain-penetrant and TRK-sparing ALK inhibitor.

Anupong Tangpeerachaikul, Henry E. Pelish

Nuvalent, Cambridge, MA

Introduction. ALK fusions drive ~5% of non-small cell lung cancer (NSCLC). Three generations of ALK tyrosine kinase inhibitors (1G, 2G, and 3G TKIs) have been approved for the treatment of ALK-positive NSCLC. However, response to these TKIs can be limited by acquired drug resistance. Single ALK mutations have been reported in >50% of patients progressing on a 2G ALK TKI, whereas compound (i.e., ≥2 cis-allelic) ALK mutations have been observed after sequential treatment with 2G-3G ALK TKIs. NVL-655 is an investigational ALK TKI designed to be brain-penetrant, spare TRK, and maintain broad activity against single and compound ALK mutations that confer resistance to previous-generation therapies. Here, in vitro N-ethyl-N-nitrosourea (ENU) mutagenesis screens further support NVL-655 as more effective than previous-generation therapies at suppressing single and compound ALK mutations.
Methods. Cells were treated with ENU for 1 day followed by alectinib (2G), lorlatinib (3G), or NVL-655 for 28 days. Wells with proliferating cells were counted on day 28, indicating TKI-resistant clones. Mutations in the ALK kinase domain were identified by Sanger sequencing. Some resistant clones harboring ALK kinase-domain mutations were isolated and used to profile the potency of ALK TKIs.
Results. ENU screens were performed on Ba/F3 EML4-ALK, to simulate a first-line treatment setting, and on Ba/F3 EML4-ALK G1202R, the most common point mutation observed at progression on 2G ALK TKIs, to simulate a later-line treatment setting. NVL-655 unbound concentrations in the two screens were 8.0 and 3.2 nM, respectively, both below its 14 nM average clinical exposure at the recommended phase 2 dose (RP2D). Resistant clones emerged in only 9 (<2%) and 3 (<1%) of 480 wells, respectively, suggesting that resistance to NVL-655 would be unlikely in both treatment settings. By contrast, all 480 out of 480 wells became resistant to alectinib (in Ba/F3 EML4-ALK) or lorlatinib (in Ba/F3 EML4-ALK G1202R) at clinically relevant exposures, indicating lower effectiveness than NVL-655 at suppressing resistance in these screens.
Conclusion. NVL-655 was highly effective at suppressing resistance in ENU mutagenesis screens simulating first-line (EML4-ALK) and later-line (EML4-ALK G1202R) treatment. At clinically relevant concentrations, <2% of all wells became resistant to NVL-655, compared to 100% for alectinib and lorlatinib. This preclinical study indicates the potential for NVL-655 to prevent acquisition of on-target resistance and thereby provide deeper and more durable target inhibition. The broad preclinical activity against ALK and diverse ALK mutations, together with its brain penetrance and TRK-sparing design, suggests NVL-655 as a potential best-in-class ALK therapy.

#1730 Onvansertib in combination with carboplatin demonstrates enhanced anti-tumorigenic effects in pre-clinical models of serous endometrial cancer.

Glenn P. Boyles[1], Haomeng Zhang[1], Chelsey Vranes[1], Michael Emanuele[2], Chunxiao Zhou[1], Victoria Bae-Jump[1]

[1]Obstetrics and Gynecology, Division of Gynecologic Oncology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Pharmacology and Cancer Cell Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Objectives: Polo-like kinase 1 (PLK1) has key roles in regulating cell division and DNA damage responses, among other critical cellular functions. It is overexpressed in many cancers including endometrial cancer (EC). Onvansertib is a highly selective PLK1 inhibitor that has shown synergistic effects combined with chemotherapy in preclinical models of multiple solid tumors, and combination therapy is currently being evaluated in phase I/II clinical trials of breast and colon cancer. Serous endometrial cancer is an aggressive subtype of EC with a poor prognosis. The backbone adjuvant treatment consists of a platinum-based doublet. We aimed to investigate the effects of onvansertib in combination with carboplatin on cell proliferation, cellular stress, apoptosis, and cellular adhesion and migration in serous EC cell lines.

Methods: The human serous EC cell lines, ARK1 and SPEC2, were treated with both onvansertib and carboplatin, alone and in combination. Cell proliferation was evaluated by MTT and colony formation assays. Cellular stress was evaluated by measuring levels of reactive oxygen species (ROS) via DCFH-DA assay and change in mitochondrial membrane potential via JC-1 assay. Apoptosis was evaluated using cleaved caspace-3 assay. Cell adhesion was evaluated using laminin-1 assay, and cell migration was assessed by wound healing assay. Western immunoblotting was used to measure downstream protein expression related to cell cycle progression, cellular invasion, and apoptosis.

Results: Onvansertib and carboplatin both inhibited the proliferation and colony formation of ARK1 and SPEC2 cells, and combined treatment produced a synergistic response (CI<1). Combination treatment with onvansertib and carboplatin of serous endometrial cancer cells resulted in significantly higher levels of ROS production ($p<0.05$) and decreased mitochondrial membrane potential ($p<0.01$) relative to single-agent treatment. Onvansertib combined with carboplatin also significantly increased the activity of cleaved caspase-3 compared with single-agent treatment ($p<0.05$). Importantly, compared to each single-drug treatment, combination treatment impeded cell migration (scratch closure) and significantly decreased cell adhesion (laminin assay) in the ARK1 and SPEC2 cell lines (all $p<0.05$). Western immunoblotting supported these results, showing combination treatment resulted in downregulation of cell cycle regulatory proteins CDK2, CDK4, and cyclin D1 and the EMT markers SLUG and beta-catenin, and upregulation of the pro-apoptotic protein Bax.

Conclusions: The combination of onvansertib and carboplatin demonstrated potent anti-tumorigenic effects in serous EC cells compared with onvansertib or carboplatin alone. Further studies are warranted to evaluate if this combination may translate into a novel clinical therapeutic option for serous EC.

#1731 Combination therapy with onvansertib and carboplatin demonstrate anti-tumorigenic effects in endometrioid endometrial cancer cell lines.

Chelsey Vranes, Glenn Boyles, Haomeng Zhang, Michael Emanuele, Chunxiao Zhou, Victoria Bae-Jump

University of North Carolina, Chapel Hill, NC

Objectives: Polo-like kinase 1 (PLK1) is a serine/threonine kinase that plays a key role in cell cycle regulation, tumor cell proliferation, and DNA damage repair. PLK1 has arose as a potential cancer therapeutic target, since it is overexpressed in many tumor types including endometrial cancer (EC). Onvansertib is a highly specific PLK1 inhibitor and has shown promising results when combined with chemotherapy in pre-clinical models of several solid tumor types. Onvansertib is being tested in phase 1/2 trials for breast and colon cancer. PLK1 is also a downstream product of the mTOR pathway, a pathway often altered in EC, supporting that ovansertib may be a logical drug for EC treatment. We aimed to investigate the effects of onvansertib combined with carboplatin on cell proliferation, adhesion, apoptosis, and cellular stress in endometrioid EC cells.
Methods: Human endometrioid EC cell lines, HEC1B and KLE, were treated with onvansertib and carboplatin, both alone and in combination. Cell proliferation was assessed by colony formation and MTT assays. Cellular stress was evaluated by quantifying levels of reactive oxygen species (ROS) via DCFH-DA assay and changes in mitochondrial membrane potential (MMP) via the JC-1 assay. Apoptosis was measured using cleaved caspace-3 assays. Cell adhesion was evaluated using laminin-1 assay, and cell migration by wound healing assay. Western immunoblotting was used to measure downstream protein expression related to cell cycle progression, cellular invasion, and apoptosis.
Results: Onvansertib and carboplatin both inhibited cell colony formation in endometrioid EC cells, and when combined, showed a synergistic effect (Combination Index or CI<1). Combination therapy in both cell lines exhibited increased levels of ROS formation ($p<0.05$) and decreased MMP ($p<0.05$) compared to single-drug treatment. Combination therapy was found to significantly increase caspase-3 activity relative to either drug alone ($p<0.05$). Combination therapy also decreased cellular adhesion and inhibited migration (scratch closure) of the endometrioid EC cells ($p<0.05$). These results were confirmed by western immunoblotting demonstrating that combined therapy upregulated the cellular stress protein Bax, and downregulated the cell cycle regulatory proteins CKD2, CDK4, and cyclin D1. Proteins important for cellular adhesion and migration, SLUG and beta-catenin, were also downregulated with combination therapy.
Conclusion: Combination therapy with onvansertib and carboplatin demonstrate compelling anti-tumorigenic effects in endometrioid EC cell lines. Ongoing investigation is merited for pursuit of possible translation into clinical treatment options of this novel drug combination in EC.

#1732 Mastering metastases by novel selective CDK9 Inhibitor ORI-15412.

G. Galabova, M. Almstetter, N. Brusis, C. Gilch, R. Koestler, J. Kondrotas, J. Kubitzki, H. Kuhn, F. Medda, P. Perez-Galan, J. Tassel, N. Traube, A. Treml, D. Wifling, N. Yehia, P. Zegar, **M. Thormann**;
Origenis GmbH, Planegg, Germany

Metastases, the leading cause of cancer-related morbidity and deaths, remain a major therapeutic challenge, highlighting the critical need for novel treatments. Our study evaluates the efficacy of ORI-15412, an oral and fully brain-penetrant CDK9 inhibitor developed by Origenis, designed to meet this need through selective inhibition of CDK9 and modulation of key pathways involved in cancer progression and metastasis. ORI-15412 was engineered using Origenis' proprietary technologies - MOREsystem®, MolMind®, BRAINstorm™, and Cippix® - for optimized blood-brain barrier penetration, selectivity, and potency. By targeting the pTEFb complex and downstream effectors, including phospho-RNA Pol II, MCL-1, and c-Myc, ORI-15412 induces apoptosis and suppresses osteoclast differentiation in cancer models. It also demonstrates dose-dependent reduction in NF-κB-dependent p52 expression, suggesting potential immune modulatory effects. In vivo studies using the aggressive intracardial MV4-11_luc metastatic mouse model showed that ORI-15412 achieved 95% tumor growth inhibition (TGI) and up to 99.99% reduction in metastasis across the brain, bones, bone-marrow, lymph nodes, and lungs. The drug was well-tolerated with no observed toxicity, and efficacy was dose-dependent, underscoring its potential for treating metastatic cancers. Having completed all IND-enabling safety and toxicity studies with NOAEL at efficacious doses, ORI-15412 is positioned as a clinical-ready candidate, offering a promising new approach for patients with metastatic cancers, particularly those with brain and bone involvement.

#1733 XL495 is a potent, selective, and orally bioavailable inhibitor of PKMYT1.

Dana Gwinn[1], Jimmy Lai[1], Alice Rico[1], Christopher Kochansky[1], Nina M. Munoz[1], Ragadeepthi Tunduguru[1], Aditya Kumar[1], Pragalath Sundararajan[1], Akhil Choppa[1], Donna Fong[1], Mi Chen[1], Amy Hildebrand[1], Jeremy Murray[1], Christopher Szeto[1], Matthew G. Rees[2], Melissa M. Ronan[2], Jennifer A. Roth[2], Wei Xu[1], Paul Gillespie[1], Paige Mahaney[1], Dana T. Aftab[1], Lisa D. Belmont[1], Jae H. Chang[1]

[1]Exelixis, Alameda, CA,[2]Broad Institute of MIT and Harvard, Cambridge, MA

Background: Protein kinase, membrane-associated tyrosine/threonine-1 (PKMYT1) phosphorylates cyclin-dependent kinase 1 (CDK1) at threonine-14 (Thr14), inhibiting the catalytic activity of the CDK1/cyclin B kinase complex, which blocks cells in G2 from entering M phase. Disruption of this PKMYT1-mediated G2/M checkpoint in cancer cells allows mitotic events to occur while DNA synthesis is still ongoing, resulting in catastrophic levels of DNA damage and cell death. We report preclinical data for XL495, a potent and selective orally bioavailable small molecule inhibitor of PKMYT1.

Methods: XL495 selectivity was assessed using a KinomeProfiler™ assay. Viability across hundreds of cancer lines was assessed using the PRISM screen. Viability of cell lines treated with a combination dose response matrix was measured using CellTiterGlo®. Antitumor activity of XL495 orally administered as a single agent was evaluated in a colorectal cancer and a breast cancer cell line-derived xenograft (CDX) model. Antitumor activity of XL495 in combination with irinotecan or gemcitabine was evaluated in a colorectal cancer CDX model. Phosphorylation of CDK1 at Thr14 and phosphorylation of KAP1 at Ser824 from tumors was measured by AlphaLISA™. Drug-like properties were assessed and pharmacokinetic (PK) parameters were determined following administration of XL495 in rat, dog, and monkey.

Results: XL495 is a potent, selective inhibitor of PKMYT1 in biochemical and cellular assays. Cancer cell lines with *CCNE1* amplification were more sensitive to XL495 than other models. XL495 demonstrated dose-dependent antitumor activity, inhibition of phosphorylation of CDK1 at Thr14, and induction of phosphorylation of KAP1 at Ser824 in CDX tumors. When XL495 was dosed in combination with gemcitabine or irinotecan in the CDX model, tumor regression was achieved. XL495 showed favorable drug-like properties including high solubility and moderate permeability in Caco-2 cells. XL495 exhibited low clearance (CL) in rat and monkey and moderate CL in dog. Bioavailability was high in rat and moderate in dog and monkey. Preliminary PK assessments predict low CL and a long half-life for XL495 in humans.

Conclusions: XL495 is potentially a best-in-class PKMYT1 inhibitor. PK assessments in conjunction with preclinical antitumor activity suggest that once-daily oral administration of XL495 may achieve clinical activity alone or in combination with DNA-damaging agents. XL495 is currently under investigation in a phase 1 first-in-human study in patients with advanced solid tumors (NCT06630247).

#1734 RP-1664: A potent and selective PLK4 inhibitor causing tumor regressions in TRIM37-high xenograft models of solid tumors.

Elliot Goodfellow[1], Frederic Vallee[1], Matias Casas-Selves[1], Monica Bubenik[1], Martin Duplessis[1], Boubacar Sow[1], Catalina Suarez[1], Li Li[1], Cathy Caron[1], Robert Papp[1], Marie-Eve Leclaire[1], Bingcan Liu[1], Simon Surprenant[1], Philippe Mochirian[1], Shou Yun Yin[1], Parham Nejad[2], Joseph D. Schonhoft[2], Rino Stocco[1], Claude Godbout[1], Prasamit Baruah[1], Alexanne Bonneau-Fortin[1], **Anne Roulston**[1], C. Gary Marshall[2], Michal Zimmermann[1], Michel Gallant[1], W. Cameron Black[1], Stephen J. Morris[1], Marc Hyer[2]

[1]Repare Therapeutics Inc., Saint-Laurent, QC, Canada,[2]Repare Therapeutics Inc., Cambridge, MA

Introduction: Polo-like kinase 4 (PLK4) is a Ser/Thr mitotic kinase crucial for centriole duplication prior to mitosis. During PLK4 inhibition centrioles are lost, however microtubules can still be nucleated from within the pericentriolar material (PCM), allowing cell division. Overexpression of the E3 ligase TRIM37, often driven by gene amplification in cancer cells, results in degradation of the PCM, rendering these cancer cells hypersensitive to PLK4 inhibition due to increased dependence on centriole duplication. TRIM37 amplification occurs at high frequency in neuroblastoma, and in several solid tumors including HER2+ and HR+/HER2- breast cancers, making PLK4 inhibition a compelling cancer drug target.

Methods: The identification of RP-1664 was assisted by biochemical & cell-based target engagement assays, standard ADME and PK assays and selectivity determined by kinome profiling. Functional activity of RP-1664 was measured in cell growth assays and by monitoring PLK4 and p21 levels in cells by IHC and western blot. In vivo efficacy was evaluated in several breast and solid tumor xenograft models.

Results: RP-1664 is a potent and selective PLK4 inhibitor with excellent oral bioavailability. In vitro, TRIM37 high cell lines across multiple lineages are more sensitive than non-TRIM37 amplified lines to RP-1664 mediated PLK4 inhibition, confirming the synthetic lethality phenotype. RP-1664 treated cells exhibit the expected loss of centrioles, and an accumulation of PLK4 and p21 protein, consistent with PLK4 inhibition results observed by others. In vivo, RP-1664 is highly efficacious, resulting in >80% tumor growth inhibition and sustained regressions in multiple cell and patient-derived xenograft models of breast cancer at well tolerated doses and on various schedules. PK/efficacy relationships demonstrate a steep dose response suggesting a threshold of PLK4 inhibition is required for anti-tumor activity and that efficacy correlates better with extent of drug exposure (AUC) rather than maximum blood concentration (C_{max}) or duration of target inhibition.

Conclusions: The highly selective, orally bioavailable PLK4 inhibitor RP-1664 demonstrates overall profound efficacy in pre-clinical in vitro and in vivo xenograft models and activation of the appropriate biomarkers indicating the expected on-target activity. These data suggest that further clinical investigation of RP-1664's anti-tumor activity in breast and other solid tumors is warranted (NCT06232408).

#1735 The discovery of PKMYT1 inhibitors to exploit synthetic lethality caused by replication stress.

Richard M. Marais, Joanna Grabarek, Myria Ioannou, Leo Leung, Ali Raoof, Mike Brown, Deborah Smithen, Chris Fitzpatrick, Chris Chester, Jacob Leigh, Mohammed Aljarah, Monika Lisauskaite, Oleksandr Grytsai, Ryan Burgin, Dan Niculescu-Duvaz, Graeme Thomson, Caroline Springer

ONCODRUG LTD, Manchester, United Kingdom

Background: Replication stress is a feature of the hyper-proliferation experienced by many cancers, leading to genome instability and accumulation of potentially lethal DNA damage. During their evolution, many cancer cells inactivate specific DNA-damage response pathways, placing high dependence on the pathways that remain, one of which is regulated by PKMYT1. This protein kinase prevents unscheduled G2 to M transition to allow cells the time needed for DNA repair before division. In cells that rely on PKMYT1, its inhibition forces cells to divide when they are not ready, leading to synthetic lethal killing. PKMYT1 is important when replication stress is driven by Cyclin E amplification and other processes. Thus, PKMYT1 inhibitors offer therapeutic opportunities that can be exploited in combination with DNA damaging agents across a range of cancers.
Materials and Methods: We synthesized over 1500 novel PKMYT1 inhibitors and validated their activity in biochemical, biophysical, cell biology and tumor growth analyses. Target engagement and cellular responses were monitored with validated target engagement and cell response biomarkers.
Results: We have discovered low nM PKMYT1 inhibitors that are exquisitely selective when assayed against a range of other protein kinases, which includes >1000-fold selective over the closely related protein kinase WEE1. Our inhibitors show extremely slow dissociation kinetics from the target in cells and selectively inhibit proliferation in cells with the genetic features of replication stress. Extensive biomarker analyses confirm target engagement in cells and demonstrate that our inhibitors cooperate with DNA damaging agents to increase accumulation of DNA damage in sensitive cells, but not in insensitive cells. The inhibitors are orally bioavailable, and we confirm target engagement in human tumor xenografts grown in immunocompromised mice. Critically, our inhibitors cooperate with DNA damaging agents to achieve regressions of human tumor xenografts.
Conclusions: We have discovered novel orally bioavailable well tolerated PKMYT1 inhibitors. Our inhibitors are exquisitely selective for PKMYT1 over a range of protein kinases, including the closely related protein kinase WEE1. We confirm PKMYT1 engagement in cells and show that our inhibitors display extremely long dissociation kinetics from the target. We show that our PKMYT1 inhibitors cooperate with DNA damaging agents to increase accumulation of DNA damage in cancer cells with high levels of replication stress but not in healthy cells. In human cancer xenografts, our well tolerated inhibitors enhance the anti-tumor efficacy of DNA damaging agents achieving significant tumor growth delay benefits compared to chemotherapy alone.

#1736 Novel fourth-generation ALK inhibitors targeting compound mutations in *ALK*-positive cancers.

Yuhao Gao[1], Jinghan Wang[2], Kai Zhang[1], Chang Lu[1], Yun Bai[1], Tianxia Liu[1], Miao Zhang[1], Sanxu Chen[2], He Wang[3], Xijie Liu[2], Hong Luo[3], **Yinghui Sun**[1]

[1]Department of Discovery Biology, Shouyao Holdings (Beijing) Co., Ltd, Beijing, China,[2]Department of Medicinal Chemistry, Shouyao Holdings (Beijing) Co., Ltd, Beijing, China,[3]Department of Drug Metabolism and Pharmacokinetics, Shouyao Holdings (Beijing) Co., Ltd, Beijing, China

The emergence of compound mutations in the ALK tyrosine kinase domain presents a significant challenge in treating *ALK*-positive cancers, especially in patients who have received sequential therapy with second- and third-generation ALK tyrosine kinase inhibitors (TKIs). Key compound mutations, such as G1202R/L1196M, I1171N/D1203N, single mutations (G1202R and I1171N) induce conformational changes that hinder drug binding and severely limit the efficacy of existing therapies, highlighting the urgent need for advanced fourth-generation (4G) ALK TKIs with enhanced potency, selectivity, and increased central nervous system (CNS) penetration. In this study, we developed a series of novel 4G ALK TKIs targeting ALK compound mutations, demonstrating potent activity *in vitro* and *in vivo*. Enzymatic assays revealed robust inhibition of ALK compound mutations, with IC_{50} values below 1 nM and high selectivity against off-target kinase NTRK. Strong cellular antiproliferative effects were observed in series of Ba/F3 EML4-ALK compound-mutant cell lines with low-nanomolar IC_{50} values. These compounds significantly inhibited ALK autophosphorylation and downstream signaling pathway in a dose-dependent manner, resulting in G0/G1 cell cycle arrest and cell apoptosis. *In vivo* efficacy studies using subcutaneous xenograft models with EML4-ALK wild-type and compound-mutant cell lines (Ba/F3 and NCI-H3122) demonstrated dose-dependent tumor growth inhibition, with some cases achieving complete tumor regression. Notably, these 4G ALK TKIs exhibited effective transport across the blood-brain barrier (BBB) with a notable Kp,uu in rats. In intracranial xenograft models harbouring EML4-ALK (wild-type or compound-mutant), these 4G ALK compounds substantially inhibited intracranial tumor growth, underscoring the potent CNS antitumor activity. And the treatments were well tolerated across all animal models, with no significant body weight loss, supporting a favorable safety profile. Meanwhile, pharmacokinetic studies in animals also revealed favorable properties of these compounds. In conclusion, these selectivity 4G ALK compounds demonstrate significant *in vitro* and *in vivo* efficacy, effective CNS penetration, and a favorable safety profile. They represent a promising advancement in the treatment of *ALK*-driven cancers, providing potential benefits for refractory cases following second- and third-generation ALK TKI sequential therapy and as viable front-line options. Comprehensive preclinical evaluations are warranted to support further clinical investigation.

#1738 Pan-inhibition of super-enhancer-driven oncogenic transcription by novel synthetic ecteinascidins yields potent anti-cancer activity.

J. Obid, M. Cigrang, M. Nogaret, F. Coin;
IGBMC - Univ. of Strasbourg, Illkirch CEDEX, France

Transcriptional addiction is a cancer hallmark, defined as the strong dependence of cancer cells on the high transcriptional activity of specific oncogenes promoting their proliferation and survival. This phenomenon often involves the acquisition of large clusters of enhancers known as super-enhancers (SE), which are bound by extremely abundant levels of ubiquitous transcription factors that sustain the robust oncogenic expression. Despite recent efforts to develop compounds disrupting SE-driven oncogenic expression, such as CDK7 and BRD4 inhibitors, their clinical success has been limited due to poor pharmacokinetics and short half-lives. Skin cutaneous melanoma (SKCM) serves as a valuable model for studying transcriptional addiction, as melanoma cells can dynamically shift between various cellular states through transcriptional and epigenetic reprogramming, posing a challenge for current therapeutic strategies. To address this, we developed two novel synthetic ecteinascidin derivatives of lurbinectedin, a drug approved for the treatment of advanced small cell lung cancer. Our results demonstrate that these newly developed ecteinascidins, along with the parent compound lurbinectedin, exhibit potent anti-tumor effects against melanoma, both *in vitro* and in mouse xenografts models resistant to current therapies, leading to reduced tumor growth and prolonged animal survival. Mechanistically, our extensive RNA-seq and chem-map assays reveal that synthetic ecteinascidins significantly suppress SE-mediated oncogene expression in melanoma cells by directly binding to and inhibiting the promoters of genes encoding ubiquitous transcription factors and coactivators that are highly enriched at oncogenic SE sites. Overall, our study provides the first evidence that the clinically approved drug, lurbinectedin, as well as its derivatives, can target and disrupt SE-dependent oncogenes, highlighting their potential as therapeutic options for cancers with transcriptionally heterogeneous landscapes where conventional therapies face significant challenges.

#1739 Identification of a potent and selective KAT6A/6B inhibitor: HW321005 exhibits strong antitumor activity in KAT6A-high ER+/HER2– breast cancer.

Xin Zhao[1], qun li[1], qian wu[1], zexin tong[1], yang zang[1], tiejun bing[2], lifei liu[1], xuejun zhang[1]

[1]Humanwell Healthcare (Group) Co.,Ltd, Hubei Wuhan, China,[2]ICE Bioscience, Beijing, China

KAT6A and its paralog KAT6B are histone lysine acetyltransferases (HATs) that regulate gene transcription via the acetylation of histones. Dysregulation of KAT6 leads to lineage-specific gene expression changes in cancer. Overexpression of KAT6 is associated with poorer clinical outcomes in ER+/HER2– breast cancers. Dysregulation of KAT6 activity, including gene amplification, overexpression, fusion, and mutation, is observed in various cancers, including breast cancer. We have developed potent and selective small molecule inhibitors targeting KAT6A/6B. Our proprietary compound, HW321005, inhibits KAT6A/6B with single-digit nanomolar IC50 values, demonstrating high selectivity over other KAT family members. The efficacy of HW321005 was evaluated in multiple cancer cell lines, including ZR-751 (IC50 = 1.7 nM). Treatment with HW321005 led to a marked downregulation of KAT6A-mediated histone acetylation and estrogen receptor signaling in KAT6A-high ER+ breast cancer models. Consistent with in vitro findings, HW321005 showed significant anti-tumor efficacy and a robust pharmacodynamic response (H3K23Ac, acetylation marker; ERα, estrogen receptor signaling marker) in ZR-751 xenograft model in a dose-dependent manner. HW321005 demonstrates substantial biological potency and high selectivity, with favorable drug-like properties, including desirable in vitro ADME characteristics, excellent in vivo exposure, clearance, and good oral bioavailability across multiple preclinical species. These findings highlight the potential of HW321005 as a novel and highly effective KAT6A/6B inhibitor for the treatment of KAT6A-high ER+ breast cancer. IND-enabling studies for HW321005 are planned for early 2025.

#1740 Generation of a best-in-class AR-NTD inhibitor targeting a unique binding pocket identified by computational modeling.

Jeffrey N. Lindquist[1], Sumana Ghosh[2], Naveen Naganaboina[3], Nishan Shettigar[4], Sanjita Banerjee[1], Michael Green[1], Ravi K. Muttineni[5], Hirdesh Uppal[1]

[1]Capulus Therapeutics LLC, San Francisco, CA,[2]Capulus Therapeutics LLC, New Delhi, India,[3]Capulus Therapeutics LLC, Hyderabad, India,[4]Capulus Therapeutics LLC, Ashburn, VA,[5]Immunocure Discovery Solutions Pvt Ltd, Hyderabad, India

Background: Current prostate cancer (PC) therapies for both mCRPC and nmCRPC patients are limited to targeting the ligand-binding domain (LBD). But due to the emergence of LBD lacking variants, and mutations in the LBD of androgen receptor (AR), these therapies become ineffective over time. Thus, there is an unmet need to develop treatments targeting N-terminal Domain (NTD) of the AR to potentially inactivate AR. Although the AR-NTD is a promising target but the structural aspects such as conformational flexibility and lack of a stable secondary structure without defined binding pocket make it technically challenging for designing NTD specific inhibitors. Thus, our efforts are being focused on generating consensus structure and developing small molecules antagonists that bind to AR-NTD.
Methods: For NTD targeting we generated a consensus AR-NTD structure by proprietary and integrated drug discovery AI (Artificial Intelligence)-based platform. Multiple MDS (T= 100 ns) together with deep learning neural networks identified two druggable sub-pockets in the consensus NTD structure model (M5). Fragment and structure based virtual screening against one of the deep sub pockets of AR-NTD combined with novel protein motion evaluation methods generated novel chemical matters by cell based assay that resulted nano-molar inhibitors over several SAR rounds.
Results: To validate the binding of NTD binding small molecules to the AR-NTD protein in real time, surface plasmon resonance (SPR) analysis was performed. This allowed for the measurement of binding kinetics and affinity, providing robust evidence of the direct interaction between the lead CAP-molecules and AR-NTD with K_d 5-10 micromolar/sec. Research Lead molecules, selected based on their favorable in vitro potency, ADME, pharmacokinetic, and tolerability profiles, were advanced to 28-day AR/ARV7 driven VCaP xenograft model to test for in vivo efficacy. One molecule showed outstanding efficacy and was well tolerated and moved to an ARV7 driven model, 22RV1, a model known for its expression of AR variants & resistance to standard AR-targeted therapies, making it ideal for evaluating the potential of NTD inhibitors. The study results showed significant tumor growth inhibition and impressive synergistic effect when combined with enzalutamide while maintaining stable animal weight. This promising effect of an NTD targeted inhibitor towards 22RV1 xenograft model validates the computer modelling, AI driven structure prediction and virtual screening for generating IP protected allosteric small molecule NTD inhibitor with novel druggable pockets in AR. The novel AR-NTD inhibitor has been further incorporated into two chemistry strategies: AR-NTD targeting PROTACs, AR-NTD & cellular essential protein targeting heterobifunctional molecules; pharmacological activity evaluation is being pursued for these two approaches.

#1741 STAT3 Orchestrates common and divergent mechanisms in different cell types to promote pancreatic cancer development and progression.

Monday O. Ogese[1], Lihong Huo[2], Yue Chen[1], Benjamin Jackel[3], Francisco Lopez-Tapia[1], Richard T. Waldron[3], Aurelia Lugea[3], Stephen J. Pandol[3], **James Turkson**[1]

[1]Department of Medicine, Division of Medical Oncology; Cancer Biology Program, Cedars-Sinai Cancer, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Department of Medicine, Division of Gastroenterology, Cedars-Sinai Medical Center, Los Angeles, CA,[3]Cancer Biology Program, Cedars-Sinai Cancer; Department of Medicine, Division of Gastroenterology, Cedars-Sinai Medical Center, Los Angeles, CA

Pancreatic adenocarcinoma (PDAC) is a major healthcare challenge. Currently, there are no good treatments for PDAC, and patient survival is dismal. *In vitro* and *in vivo* models to study PDAC pathogenesis have shed some light on the molecular and cellular landscape of the disease, including the prevalence of altered signal transducer and activator of transcription 3 (STAT3) functions. While constitutively-active STAT3 is implicated in PDAC progression, its functional role in driving PDAC development is not fully understood. Using human PDAC (hPDAC) cell lines, hPDAC-derived cancer-associated fibroblasts (hCAFs), and high-fat diet (HFD)-fed mutant *KrasG^{12D}* (KC) mice, we interrogated aberrantly-active STAT3 and its cell-type specificity to delineate STAT3's role in PDAC development and therapeutic response. Human PDAC cell lines (AsPC-1, Mia-PaCa-2, and PANC-1) and hCAFs harbor constitutively-active STAT3, and their stimulation with IL-6, EGF or PDGF further enhanced the phospho-tyrosine-STAT3 (pYSTAT3) levels. In KC mice, feeding a HFD led to constitutive pYSTAT3 induction in the pancreas in parallel with the development of precancerous pancreatic intraepithelial neoplasia (PanIN) lesions. Induction of pYSTAT3 occurred across diverse cell types, including acinar-ductal-metaplasia (ADM) elements, neoplastic ducts, stromal and immune cells, but not in acinar cells. Treatment with the STAT3 inhibitor, H182, blocked the pYSTAT3 levels in the hCAFs and hPDAC cells *in vitro.* Significant profile changes for IL-6-stimulated cytokine and chemokine secretion were also observed, including decreased IL-8, SERPINE1, CXCL1, CXCL12, CCL2 and MIF secretion. Mia-PaCa-2 cells exposed to H182 for 48 h showed a repression of genes involved in immune evasion (HLA-E, AGRN), angiogenesis (LOXL2), cell proliferation and migration (IL-8, UBC, JAG1), oxidative stress (NQO1, SRXN1, TXNRD1) and tumor progression (BCL10, HMOX1, HMGA1, SERPINE1), in parallel with the upregulation of TP53 and NBPF1 tumor suppressor genes. H182 treatment of the hPDAC lines further repressed mitochondrial oxygen consumption rate and viable cell numbers and induced apoptosis. Administration of H182 to HFD-fed KC mice prevented acinar cell differentiation into ADM/PanINs and suppressed pro-fibroinflammatory genes in the pancreas, including CXCL12, CCL2 and CCL5, while inhibiting the growth of subcutaneous hPDAC xenografts in mice. The decreased proinflammatory cytokine and chemokine profiles across diverse cell types, associated with the enrichment of acinar cells in the pancreas of KC mice in response to STAT3 inhibition underscores declining STAT3-dependent pro-tumorigenic mechanisms that are orchestrated through a HFD-induced chronic inflammation. The translational significance is that the blockade of aberrant STAT3 functions suppresses growth of PanINs and cancer cells in PDAC.

#1742 Discovery and preclinical profiling of a novel PKMYT1 inhibitor, EVT-0003023, with high efficacy in late-stage, post-treatment non-small cell lung cancer models.

Daniel Miller, Alfie Brennan, Jan Lanz, Oliver Vipond, Noah Harrison, James Aaronson, Anna Hercot

Evariste Ltd, London, United Kingdom

Protein kinase membrane-associated tyrosine/threonine 1 (PKMYT1) is a negative regulator of CDK1 activity and has been identified as a putative synthetic lethal target in cancers which up-regulate cyclin E (CCNE1) or harbor mutations in genes such as FBXW7. We used our internal Frobenius platform to identify highly potent and differentiated inhibitors of PKMYT1 with exceptional selectivity over key off targets, including the Raf family and WEE1. Machine learning-driven optimization delivered a preclinical candidate compound, EVT-0003023, with best-in-class selectivity and a significantly improved pharmacokinetic profile in relevant animal models, and in vivo efficacy in CCNE1-high and FBXW7-mutated xenograft models.

Compounds from this series were used to validate a differentiated biomarker for sensitivity to PKMYT1 inhibition in cellular and PDX-derived models, expanding the patient population treatable with PKMYT1 inhibitors into non-small cell lung cancer. Using clinical data, we demonstrated that this biomarker is significantly up-regulated in patients who have progressed on existing standard-of-care treatment, and demonstrated exceptional monotherapy activity for EVT-0003023 in PDX models reflecting this patient population, as well as tumor regression when combined with low doses of chemotherapy.

#1743 QLS1209, A highly potent and selective PKMYT1 inhibitor demonstrates activity in tumors with CCNE1^{Amp} and/ or FBXW7^{LoF} mutations.

Yuxing Zhang[1], Jiasheng Fu[1], Rongyan Wang[1], Jianping Chen[1], Changliang He[1], Junguo Hao[1], Xinrui Shao[1], Ling Li[1], Hua Qin[1], Guangyue Lei[1], Ping Chen[1], Dong Yang[1], Xinghua Cheng[1], Qingmei Zheng[2], Zheng Wang[1], Guqin Shi[1], Wenyuan Qian[1], Daqing Sun[1], Weimei Sun[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center Ltd., Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Cell cycle checkpoints serve as cellular critical safeguard mechanisms that ensure orderly progression through the cell cycle. PKMYT1, a membrane-associated kinase, functions as a negative regulator of CDK1 activity by phosphorylating CDK1 at the Thr14 residue. This enzyme is frequently overexpressed in a variety of cancers. Recent studies suggest that cancer cells harboring CCNE1 amplification (CCNE1^{Amp}) and/or FBXW7 loss-of-function (FBXW7^{LoF}) mutations are particularly relying on PKMYT1 for orderly entry to mitosis. As a result, inhibition of PKMYT1 can lead to premature mitotic entry, inducing DNA damage, and triggering mitotic catastrophe. CCNE1^{Amp} is a common genetic alteration found across a spectrum of cancer types, with particular prevalence in gynecological malignancies. Elevated levels of cyclin E are linked to genomic instability, whole-genome doubling, and resistance to existing therapeutic interventions. FBXW7, a tumor suppressor gene, is frequently mutated in various cancers, including colorectal and ovarian serous carcinoma. Loss of FBXW7 function is recognized as an independent prognostic factor, significantly correlating with tumor cell resistance to chemotherapy and unfavorable disease outcomes. Moreover, FBXW7 acts as an E3 ubiquitin ligase for cyclin E, potentially leading to increased levels of cyclin E through post-translational mechanisms. QLS1209, an orally bioavailable, potent, and selective inhibitor of PKMYT1 was discovered and evaluated preclinically. QLS1209 exhibited single-digit nanomolar potency in inhibiting PKMYT1's enzymatic activity and demonstrated approximately 30-fold selectivity over its paralogue Wee1. QLS1209 potently suppressed phosphorylation of CDK1 at Thr14, with a minimal impact on Tyr15. QLS1209 was well tolerated and demonstrated anti-tumor activity in CCNE1^{Amp} HCC1569 and OVCAR3 xenograft models in vivo, it also showed enhanced efficacy when combined with Gemcitabine. In a gastric patient-derived xenograft (PDX) model harboring an FBXW7^{LoF} mutation, QLS1209 dose-dependently inhibited tumor growth, with higher dose leading to tumor regression. QLS1209 exhibits excellent pharmacokinetic profile, and promising in vitro ADME properties, along with a favorable safety profile. IND enabling studies are currently underway and are expected to be completed by the end of 2024. Collectively, these findings highlight the promising potential of QLS1209 as a therapeutic strategy, either as monotherapy or in combination with other anti-cancer therapies, for a variety of cancer types characterized by CCNE1^{Amp} and/ or FBXW7^{LoF} mutations.

#1744 Preclinical efficacy of a selective, orally bioavailable HER2 small molecule inhibitor targeting HER2 alterations and Enhertu-resistant cancers.

Jiyoung Jeon, Sun Young Jang, Ho Yeon Nam, HyungSeok Yoo, Jooyun Byun, Gunwoo Lee, Soye Jeon, Young Gil Ahn

Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

HER2 alterations, including overexpression, amplification, and other mutations are found in various solid tumors and have a significant impact on cancer cell growth and metastasis. To address this issue, HER2-targeted therapeutics are being developed and evaluated across multiple tumor types, including breast cancer, gastric cancer, HER2-positive cholangiocarcinoma, colorectal cancer, non-small cell lung cancer, and bladder cancer. Existing HER2 inhibitors inhibit not only HER2 alteration but also EGFRWT, causing issues with EGFR-related toxicity (skin rash, diarrhea, etc.). This highlights the need to develop selective HER2 inhibitors that specifically target HER2 and its mutations without affecting EGFRWT. The Hanmi compound selectively targets the HER2 receptor tyrosine domain via covalent binding, sparing EGFRWT and minimizing EGFR-related toxicity. The Hanmi compound inhibited both HER2 mutant and HER2WT cells and enzymes, had a DMPK profile compatible with oral administration. It also demonstrated potent antitumor activity as a single agent in various HER2 mutant xenograft models. Despite the good efficacy of Enhertu (trastuzumab deruxtecan), which is approved for the treatment of all HER2 cancers, resistance that develops within 12 months of drug administration remains a major clinical challenge. To address this unmet need, we evaluated a novel HER2 inhibitor in a preclinical model that acquired resistance to Enhertu. The Hanmi compound effectively inhibited tumor growth in Enhertu resistant NCI-N87 mouse models. In conclusion, Hanmi compound, an orally bioavailable small molecule inhibitor, showed high efficacy against both HER2 mutant and HER2WT tumors, while preserving EGFRWT and minimizing EGFR-related toxicities. Furthermore, it demonstrated the potential to overcome resistance to Enhertu by effectively inhibiting tumor growth in Enhertu-induced resistant xenograft mouse model, and these preclinical results support Hanmi compound as a promising treatment for HER2 altered cancers.

#1745 Combining HRI/PERK/GCN2 inhibitor CRD-799 with proteasome inhibitors provides a novel approach to overcoming resistance in multiple myeloma treatment.

Yasumichi Inoue[1], Koki Hikami[2], Shunsuke Ebara[2], Midori Sugiyama[2], Robert Oda[2], Akio Mizutani[2], Misaki Yoshida[2], Hiroko Yamakawa[2], Shigehiro Yagishita[3], Akinobu Hamada[3], Hidetoshi Hayashi[1], Takaomi Sanda[4], Masaki Ri[4], Shinsuke Iida[4], **Daisuke Morishita**[2]

[1]Department of Cell Signaling, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan,[2]Chordia Therapeutics Inc., Fujisawa, Japan,[3]Division of Molecular Pharmacology, National Cancer Center Research Institute, Tokyo, Japan,[4]Department of Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

The introduction of novel treatments for multiple myeloma (MM), particularly proteasome inhibitors (PIs) such as bortezomib (BTZ), has significantly improved patient outcomes. However, many patients eventually relapse, underscoring the urgent need for new therapeutic strategies to overcome PI resistance. The integrated stress response (ISR) is a conserved intracellular signaling network activated by various intrinsic and extrinsic stressors. This response is mediated by four specialized kinases, HRI, PERK, PKR, and GCN2, which converge on the phosphorylation of eIF2α. Phosphorylated eIF2α promotes the translation of ATF4, a critical regulator of cellular survival and homeostasis. Our prior studies demonstrated that PI treatment induces mitochondrial stress, endoplasmic reticulum stress, and amino acid starvation, triggering the activation of HRI, PERK, and GCN2, respectively. Targeting this triple kinase axis has shown potential in overcoming PI resistance. Building on these findings, we developed CRD-799, an orally bioavailable small-molecule inhibitor designed to target HRI, PERK, and GCN2. CRD-799 effectively inhibited ISR kinase activity, leading to complete suppression of eIF2α phosphorylation and ATF4 activation under PI treatment conditions. When combined with BTZ, CRD-799 exhibited potent anti-proliferative effects both *in vitro* and *in vivo* (AACR 2024 #1233, Inoue *et al.*). Further investigation revealed a novel mechanism of cell death induced by the combination of CRD-799 and PIs. Apoptosis inducers, including NOXA and CHOP, were significantly upregulated during combination treatment, yet this process appeared independent of the canonical ATF4-mediated transcriptional pathway. Comprehensive RNA-seq analysis revealed suppression of the canonical ATF4-driven stress response, while ATF3 induction and NOXA-dependent apoptosis were preserved. Notably, the combination treatment activated the IRE1-TRAF2-JNK1/2-c-Jun/ATF3 signaling axis, suggesting its role in driving NOXA-mediated apoptosis independently of the classical ISR-ATF4 pathway. This mechanism may underlie the variability in treatment sensitivity observed across MM models. In summary, the combination of the HRI/PERK/GCN2 inhibitor CRD-799 with PIs offers a promising strategy to overcome PI resistance in MM. These findings provide critical mechanistic insights into the heterogeneity of treatment responses, potentially guiding the personalized application of this combination therapy in clinical settings.

#1746 FGFR3 inhibition is a highly effective therapy in MTAP-deficient, FGFR3 altered urothelial carcinoma .

Yu-Yi Chu[1], Jianfeng Chen[1], Cindy Y. Jiang[2], Ying Mei[1], Yuxue Zhang[1], Arlene Siefker-Radtke[1], Jianjun Gao[1]

[1]Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Hematology/Oncology Fellowship program, UT MD Anderson Cancer Center, Houston, TX

FGFR3 alterations are observed in more than 15% of metastatic urothelial cancers. In 2019, erdafitinib was the first FGFR inhibitor approved by the FDA for treatment of FGFR3-altered metastatic urothelial cancer with an objective response rate of 40%. However, a high percentage of patients with FGFR3 alterations still do not respond to erdafitinib. Thus, it is critical to identify additional biomarkers to stratify patients and increase the therapeutic efficacy of FGFR inhibitors. Our previous study identified that FGFR3 was more frequently altered in methylthioadenosine phosphorylase (MTAP)-deficient tumors (MTAP-deficient: 31% vs MTAP-proficient: 8%), which raises our interest to investigate whether MTAP deficiency leads to enhanced dependency on FGFR3 activity and increases tumor treatment response to FGFR inhibitors. Here, we report that IC_{50} of FGFR inhibitors is significantly lower in MTAP-deficient tumors compared to MTAP-proficient tumors. Notably, an MTAP enzyme, which was developed to deplete its substrate, MTA [a known inhibitor of protein arginine methyltransferase 5 (PRMT5)], significantly increases the PRMT5 activity and results in resistance to FGFR inhibitors in MTAP-deficient tumors. Moreover, our data demonstrate that PRMT5 inhibition sensitizes MTAP-proficient tumors to FGFR inhibitors, suggesting that inhibition of PRMT5 activity by MTA contributes to tumor response to FGFR inhibitors in MTAP-deficient tumors. Taken together, our current findings suggest that: 1) MTAP deficiency could serve as a rational biomarker to predict response of FGFR inhibitors and; 2) FGFR inhibitors may be highly effective therapies for patients with MTAP-deficient, FGFR3 altered urothelial cancer.

#1747 Targeting NRF2-responsive kinases for the treatment of esophageal squamous cell carcinoma.

Boopathi Subramaniyan[1], Zhaohui Xiong[2], Yahui Li[1], Chorlada Paiboonrungruang[2], Francis Spitz[1], M. Ben Major[3], Xiaoxin Chen[1]

[1]Cooper University Health Care, Camden, NJ,[2]Coriell Institute for Medical Research, Camden, NJ,[3]Washington University in St. Louis, St. Louis, MO

Esophageal squamous cell carcinoma (ESCC) ranks as the 8th most commonly diagnosed cancer and the 6th leading cause of cancer-related deaths worldwide. NRF2 has been identified as a *bona fide* cancer driver in human ESCC, with mutation rates ranging from 10% to 22%. Hyperactivation of NRF2 promotes tumor growth, metastasis, and resistance to conventional therapies in ESCC. Evidence suggests that NRF2 also regulates kinases influencing ESCC phenotypes, though the specific kinases involved are yet to be identified. NRF2 ChIP-seq analysis revealed enrichment of 42 kinases, including *Akt2* and *Pkm*, and 31 phosphatases, such as *Pten* and *Dusp16*, in the *Keap1*$^{-/-}$ mouse esophagus compared to wild-type tissue. We confirmed NRF2 binding at the promoter regions of *Akt2* and *Pte*n. mRNA expression profiling revealed enrichment of the PI3K/AKT, RAS, ERK, and GSK3β signaling pathways in the *Keap1*$^{-/-}$ esophagus relative to *Nrf2*$^{-/-}$*;Keap1*$^{-/-}$ esophagus. Immunohistochemical staining showed overexpression of pAKT, p-mTOR, pS6, and PKM2 in the esophagus of both *Keap1*$^{-/-}$ and *Sox2CreER;LSL-Nrf2*$^{E79Q/+}$ mice. Using PhosphoExplorer and PamChip arrays, we identified several kinases, including PI3K, as NRF2-responsive kinases in *NRF2*^{W24C}-KYSE70 cells compared to isogenic *NRF2*^{null}-KYSE70 cells, as well as in *Sox2CreER;LSL-Nrf2*$^{E79Q/+}$ mouse esophageal epithelium versus wild-type tissue. In *NRF2*^{null}-KYSE70 cells, expression of pAKT, pS6, p-PTEN, PIK3CA, AREG, and pEGFR was significantly downregulated compared to *NRF2*^{W24C}-KYSE70 cells. Similar results were seen in *NRF2*^{D77V}-KYSE180 cells treated with NRF2 siRNA. Furthermore, *NRF2*^{null}-KYSE70 cells showed increased sensitivity to EGFR inhibitor (Gefitinib), PIK3CA inhibitor (Alpelisib), and AKT inhibitor (Capivasertib), compared to *NRF2*^{W24C}-KYSE70 cells. Notably, Alpelisib and an NRF2 inhibitor (Pyrimethamine) synergistically suppressed *NRF2*^{W24C}-KYSE70 cell growth. Consistent with these findings, pNRF2 expression correlated with PI3K signaling proteins, including pAKT and p-mTOR, in human ESCC tissues. These studies highlight the potential of combining an NRF2 inibitor with a PI3K pathway inhibitor as a promising therapeutic strategy for ESCC.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 1
Poster Session

#1749 Discovery of MOMA-313, a potent and selective inhibitor of the Polθ DNA helicase domain for the treatment of HR-deficient tumors.

Jordan A. Krall, Michael Reutershan, Vinny Motwani, Kelly McGlynn, Yonghong Bai, Christopher Quinn, Manaswni Dhingra, Cen Gao, David Waller, Salah Nabhan, Marc Ballas, Timothy Guzi, Peter Hammerman, Erica Evans

MOMA Therapeutics, Cambridge, MA

Loss of homologous recombination (HR), a core DNA damage repair pathway, is common in many types of cancer that are caused by inactivating mutations in BRCA1, BRCA2 and functionally related proteins. HR-deficient tumors are widely treated with PARP inhibitors, but the duration of response and survival benefit is often limited by tolerability issues and by the emergence of clinical resistance mediated by secondary mutations that restore HR activity. MOMA-313 is a novel, potent and selective small molecule inhibitor of DNA polymerase theta (Polθ) in development with a PARP inhibitor to drive deeper and more durable responses in HR-deficient tumors. Polθ is a DNA repair enzyme composed of both a helicase and a polymerase domain that work in tandem to repair DSBs through a process called theta-mediated end-joining (TMEJ). Polθ functions as a back-up DNA repair pathway in most contexts, and genetic ablation of Polθ is well-tolerated in mouse models and in HR-proficient cell lines. However, when HR is disabled, cells rely heavily on Polθ activity for DSB repair. Loss of Polθ activity may also prevent the emergence of clinical PARP inhibitor resistance caused by BRCA reversion mutations which have been linked to Polθ DNA repair activity. MOMA-313 is an inhibitor of the Polθ helicase domain that inhibits cellular TMEJ activity in vitro and in vivo with single-digit nM potency. MOMA-313 synergizes with PARP inhibitors against HR-deficient cell lines in vitro, with no combination impact on HR-proficient cells. Low doses of MOMA-313 drive the regression of HR-deficient tumor xenografts when combined with the PARP inhibitor olaparib, including in models with limited response to olaparib alone. A PK/PD/efficacy relationship directly links exposures required for tumor regressions to target inhibition, as determined by measuring TMEJ inhibition within tumor xenografts. Mechanistically, cryo-EM studies demonstrate MOMA-313 binds to the DNA channel, preventing DNA translocation and synapse formation between opposing ends of the broken DNA. By inhibiting the first of the two sequential Polθ DNA repair activities, MOMA-313 likely prevents the engagement of either Polθ functional domain. MOMA-313 has been optimized to achieve high target coverage at a low human dose, a strong safety profile, and broad combinability especially with PARP inhibitors, where mechanistic synergy may drive deeper responses and prevent clinical resistance in HR-deficient tumors. Clinical evaluation of MOMA-313 is ongoing (NCT06545942), with monotherapy and PARP inhibitor combination arms.

#1751 Beta catenin c-mods are orally bioavailable small-molecules targeting Wnt-driven tumors.

Isaac Klein, Kip West, Doug Baumann, Adam Talbot, Thomas Durand-Reville, Karl Hsu, Ann Boija

Dewpoint Therapeutics, Inc., Boston, MA

Constitutive activation of the Wnt/beta catenin pathway drives malignancy in a wide range of cancers. The oncogenic transcription factor beta catenin has been notoriously difficult to target due to its disordered nature and lack of defined drug-binding pockets. Using Dewpoint's proprietary AI/ML-powered discovery platform, we have identified and optimized small molecule condensate modulators (c-mods) that act via a novel mechanism of action, sequestering beta catenin into inactive condensate depots. Sequestering beta catenin into nuclear condensates selectively inhibits beta catenin-driven transcription and induces robust cancer cell death. The development candidate DPTX3186 is an orally bioavailable small molecule that demonstrates strong anti-tumor activity across multiple tumor types driven by various defects along the Wnt/beta catenin pathway and modulates Wnt pathway activity in vivo. Profound pharmacological efficacy, including regressions and complete responses, has been observed in murine models of gastric cancer. Collectively, these findings highlight the potential of condensate biology to target previously undruggable, high-value oncology targets, paving the way for novel treatments for patients with significant unmet medical needs.

#1752 SY-13380, a novel menin-MLL inhibitor, exhibits efficacy against resistant mutations and anti-tumor activity for MLL-rearranged and NPM1-mutant acute myeloid leukemia in pre-clinical models.

Xiaopeng Li[1], Tiantian Hao[2], Hongjuan Li[1], Chang Lu[1], Shikang Cheng[1], Xinhe Xu[2], Huiyan Luo[3], Xijie Liu[2], Hong Luo[3], **Yinghui Sun**[1]

The menin-KMT2A interaction is a critical epigenetic regulator for leukemogenesis in many acute leukemias, including KMT2A-rearranged (KMT2Ar) acute leukemia and NPM1-mutant (NPM1m) acute myeloid leukemia (AML). Patients with these alterations always have dismal response rates and poor prognosis. Some selective inhibitors of the menin-KMT2A complex have demonstrated encouraging activity in patients with R/R AML. However, early trials with revumenib have reported the rapid acquisition of resistance somatic mutations of MEN1 gene in about 40% patients which can impair treatment success. Herein, we introduce SY-13380, a novel menin-MLL inhibitor, exhibits potent binding affinity against wild type and resistant mutations and displayed excellent anti-tumor activity in pre-clinical models. Biochemical assay revealed that SY-13380 potently blocked menin-MLL binding with an IC_{50} under 10.0 nM, and it also displayed very strong potency on series of resistant mutants (M327I, M327V, G331R and T349M) similar to that on WT proteins. In cellular assays, SY-13380 also strongly inhibited cell proliferation in multiple cancer cell lines carrying KMT2Ar or NPM1m, especially in M327I mutant MOLM13 cells which was insensitive to approved Menin inhibitor SNDX-5613. In cell functional studies, SY-13380 dose-dependently down-regulated menin-MLL target gene HOXA9 and MEIS1, and induced the expression of differentiation marker CD11b. *In vivo* studies showed that treatment of SY-13380 achieved excellent tumor growth inhibition in various xenograft tumor models including MV-4-11, RS4;11, OCI AML3 and MOLM13 harboring M327I mutant menin. Notably, tumor regression was found in MV-4-11 xenograft tumor models after treatment with SY-13380 at dosage of 10mpk. In addition, SY-13380 displayed good PK parameters and tolerability *in vitro* and *in vivo* models. These data indicate that SY-13380 is a novel and potent menin-MLL inhibitor with robust anti-tumor activities, favorable PK and safety profiles making it promising for further clinical development and efficacy against resistant mutations warranting it long-term response for treatment of MLL-r and NPM1m acute leukemias.

#1753 A novel FOXM1 inhibitor inhibits FOXM1 cell proliferation, migration, and invasion tumor growth in triple negative breast cancer.

Sayra Dilmac[1], Nermin Kahraman[1], Ogun Ali Gul[1], Ferah Comert Onder[2], Bulent Ozpolat[1]

[1]Department of Nanomedicine, Houston Methodist Research Institute, Houston, TX,[2]Department of Medical Biology, Canakkale Onsekiz Mart University, Canakkale, Turkey

Triple-negative breast cancer (TNBC) accounts for ~15-20% of breast cancer cases (52,000 women in the US only), is characterized by lack of estrogen, progesterone, and HER2 receptor expression; aggressive phenotype, high rates of early relapse and metastasis and the worst mortality rates among all breast cancer subtypes. TNBC is insensitive to the available targeted therapies, including anti-estrogens (i.e, tamoxifen, aromatase inhibitors), anti-HER2 and EGFR antibodies due to lack of actionable targets. Unfortunately, about 50-70% of the patients cannot achieve complete pathological remission in response to chemotherapy and die within the first 5 years after diagnosis. Therefore, there is a critical need for the development of highly effective and novel therapies to improve patient survival. We previously validated for the first time FOXM1 protooncogenic transcription factor as a potential molecular target in TNBC through genetic knockdown studies and demonstrated that genetic inhibition of FOXM1 completely blocks TNBC tumor growth in multiple tumor models in mice with no detected toxicity. We also found that FOXM1 expression is associated with dramatically shorter patient survival and identified it as a poor prognostic marker. We demonstrated that FOXM1 drives tumorigenesis, progression by inducing cell proliferation, invasion/metastasis, drug resistance by transactivating expression of multiple oncogenes. We found that FOXM1 is broadly overexpressed in TNBC tumors due to widespread *p53* mutations which are detected in about 84% of TNBC patients, suggesting that *TP*53 mutations are the major driver of FOXM1 overexpression. Overall data suggest that FOXM1 is an excellent potential molecular target for TNBC. However, currently, there is no FDA approved inhibitor of FOXM1**.** To identify potential inhibitors, utilizing silico docking and molecular dynamics studies we screened the chemical libraries and found identified a novel which interacted with FOXM1 protein based on in silico molecular dynamics studies and demonstrated that this inhibitor suppresses FOXM1 expression and cell proliferation, migration, invasion, and induces apoptosis in TNBC cells and more potent that well known FOXM1 inhibitor (FDI-6). *In vivo* treatment mice bearing MDA-MB-231 tumors with novel FOXM1 inhibitor (20mg/kg, twice a week) incorporated in single-lipid nanoparticles suppressed growth of TNBC tumor xenografts in mice with no toxicity. In conclusion, the findings indicate that the novel FOXM1 inhibitor represents a potent and safe therapeutic agent with significant potential for the treatment of TNBC and other FOXM1-driven cancers. This discovery offers new hope for improving outcomes in a disease that currently has limited treatment options.

#1754 Evaluating the synergism between circadian clock compounds with chemoradiation against GBM.
