The circadian clock has been associated with numerous diseases and, in recent years, been linked to every known cancer hallmark. In the case of glioblastoma (GBM), high expression of positive regulators of the clock, such as Brain and Muscle ARNT-Like 1 (BMAL1), has been linked to shorter survival time while high expression of the negative regulators of the clock confers longer survival time. Furthermore, BMAL1 and Circadian Locomotor Output Cycles Kaput (CLOCK) were found to be essential for GBM stem cell (GSC) proliferation, stemness, and metabolism. GSCs are typically resistant to chemoradiation and secrete factors that drive neoangiogenesis and immune suppression in the tumor microenvironment (TME). However, we found that GSCs are specifically sensitive to genetic and pharmacological perturbation of these core clock components. Consequently, in this study, we sought to explore the anti-GBM effects of chemoradiation in combination with the novel Cryptochrome (CRY) stabilizer SHP1705, which inhibits BMAL1 and CLOCK transcriptional activity, and the novel REV-ERB agonist SR29065, which inhibits *BMAL1* transcription. SHP1705 has proven to be safe and well-tolerated in Phase I clinical trials and SR29065 is well-tolerated in mice without evidence of cytotoxicity. Our findings highlight the potential of small molecule circadian clock modulating compounds as a novel treatment paradigm that sensitizes resistant GBM cell populations to chemoradiation.

#1755 Discovery of a novel, selective WRN inhibitor, DAT-5000A, in the treatment of microsatellite-unstable tumors.

Jingxi Zhang, Huixian Chen, Dan Yan, Xi Chen, Jincong Zhuo, **Kevin Zhou**

Danatlas Pharmaceuticals Co., Ltd., Beijing, China

Werner syndrome ATP-dependent helicase (WRN) is a member of RecQ helicase involved in DNA replication and repair and is identified as a synthetic lethal target in microsatellite instability-high (MSI-H) tumors. MSI-H feature has been found in a variety of tumor types including colorectal, gastric and endometrial cancers. The clinical benefits of immune checkpoint inhibitor (ICI) such as anti-PD-1 or anti-PD-L1 antibodies on MSI-H cancers have been well documented; however, nearly 20-50% of these cancer patients are intrinsically resistant to PD-(L)1 therapies or develop acquired resistance with prolonged treatment. Thus, agents targeting MSI-H tumors are of great interest. Here we described the discovery of a novel non-covalent WRN inhibitor, DAT-5000A, with excellent potency and PK profile. DAT-5000A potently inhibited WRN *in vitro* activity both on ATPase and unwinding assays and showed good selectivity over BLM, another member of RecQ helicase. DAT-5000A also showed selective killing of MSI-H SW48 but not MSS (microsatellite stability) SW620 tumor cell line. In addition, DAT-5000A demonstrated good drug-like properties including high cell permeability and microsomal metabolic stability, as well as favorable PK profile with low *in vivo* clearance and optimal oral bioavailability, across multiple species. DAT-5000A exhibited single-agent activity with tumor regression on MSI-H cell-line derived xenograft (CDX) tumor models, meanwhile DAT-5000A did not cause any abnormality on these mice. Our data demonstrated that DAT5000A is a potent, selective WRN inhibitor with sufficient *in vivo* exposure and acceptable preliminary safety profile, which supports DAT-5000A to be further evaluated in human clinical trials.

#1756 A fully characterized KIF18A inhibitor with superior potency and good druggability ready for IND application.

Congcong Cai[1], Shiya Zhu[1], Chunlin Chen[2], Jian Liu[2], Hongkun Li[1], Shu Cai[1], Linjun Wang[1], Min Wen[1], Mingxin Qian[1], Shifeng Liu[1], **Bin Shi**[1], Hancheng Zhang[1]

[1]Hangzhou Innogate Pharma Co., Ltd, Hangzhou, China,[2]Shanghai Medicilon Inc, Shanghai, China

About ~90% of the solid tumors and ~75% of the hematologic malignancies are aneuploidy. The process that gives rise to aneuploidy is chromosomal instability (CIN), characterized by chromosome mis-segregation and other mitotic aberrations. KIF18A (kinesin family member 18A), part of the kinesin family of motor proteins, is expressed in the G2/M phase of the cell cycle and regulates chromosome positioning during cell division. Genetic depletion of KIF18A impacts the chromosome alignment, elongation of mitotic spindles, and traps chromosomally unstable tumor cells in mitosis, while having negligible impact on normal cells. KIF18A and CIN or whole genome doubling (WGD+, or aneuploidy) have been tested and are synthetic lethal in tumor cells. Thus, KIF18A inhibition has become an attractive approach for the treatment of the vulnerable CIN/WGD+ related tumors. Here we report the discovery and development of small-molecule KIF18A inhibitors, leading to the nomination of a preclinical candidate compound (PCC). The PCC molecule had superior *in vitro* potency, *in vivo* efficacy in cancer models, and good druggability. Thereafter we completed IND-enabling studies and submitted the pre-IND application in November 2024, with a scheduled IND filing in early 2025.

The PCC molecule exhibited potent target engagement both in enzymes and cell-based assays with IC_{50} in double digit nM in multiple cancer cell lines including breast cancer, ovarian cancer, NSCLC, and colorectal cancer. The enzyme activity is highly selective within the kinesin superfamily members (CENP-E, Eg5, Chromokinesin, KIF3C, KIFC3, MCAK and MKLP) with IC_{50} all >30 μM. In the 435-kinase panel screening, 1 μM of the PCC molecule did not significantly inhibit any of the 435 kinases (<25% inhibition in all tested kinases), demonstrating great selectivity in the kinase panel. The PCC molecule also exhibited a good in vitro safety profile in hERG assay and in the 44-enzyme/receptor/ion-channel safety panel profiling. The PCC molecule proved desirable in vitro ADME characteristics and excellent in vivo pharmacokinetic profile with low clearance, long half-life, as well as good oral bioavailability in mice, rats, beagle dogs and non-human primates. Furthermore, The PCC molecule exhibited excellent in vivo efficacy in CIN+ ovarian cancer OVCAR3 CDX model, and two CIN+ triple negative breast cancer (MDA-MB-231 and HCC1806) models, without body weight loss and other safety issues observed. These anti-tumor efficacies were dose-dependent and well correlated with a robust pharmacodynamic (PD) western blot detection using phosphor-H3, a mitotic marker. In non-GLP and GLP-tox studies in rats and beagle dogs, the PCC molecule was well tolerated, providing a potential good therapeutic window. Overall, a novel and highly potent KIF18A inhibitor is ready to enter phase 1 clinical trials in 2025 for the treatment of CIN/WGD+ cancers.

#1758 ATX-559, a first in class DHX9 inhibitor, and targeted therapeutic for molecularly defined tumors with genomic instability and replicative stress.

Jennifer Castro, Matthew H. Daniels, Sunaina Nayak, David Brennan, Cindy Collins, Sophie A. Shen, Monique Laidlaw, Jie Wu, Anugraha Raman, Deepali Gotur, Kevin Knockenhauer, Shihua Yao, Simina Grigoriu, Gordon J. Lockbaum, Kate Newberry, Stephen J. Blakemore, P. Ann Boriack-Sjodin, Kenneth W. Duncan, Stuart Ince, Jason A. Sager, Robert A. Copeland, Serena J. Silver

Accent Therapeutics, Lexington, MA

DHX9, a multi-functional RNA helicase, contributes to genome stability by unwinding nucleic acid secondary structures, including DNA/RNA hybrids (R-loops), circular RNA and G-quadruplexes. Multiple cancer types exhibit increased expression of DHX9, and selective dependance to DHX9 has been observed in molecular defined tumors that exhibit genomic instability. These tumors often have elevated replicative stress due to rapid unregulated proliferation and defective DNA damage repair (DDRD) pathways; DHX9 inhibition in these tumors further increases replicative stress and DNA damage to catastrophic levels. We previously demonstrated that DHX9 genetic loss or inhibition by the DHX9 tool compound ATX968 was efficacious in tumor types that exhibit DDRD and/or genomic instability; these include tumors with defective mismatch repair and/or high microsatellite instability (dMMR/MSI-H) or alterations in the DDR genes BRCA1 and/or BRCA2 (BRCA).

Here we describe ATX-559, a potent, selective, orally bioavailable, small-molecule inhibitor of DHX9 helicase activity that is currently in clinical development. In preclinical studies, ATX-559 treatment leads to increased accumulation of R-loops and G-quadruplexes resulting in increased replicative stress and stalling, subsequent DNA damage, and cell death selectively in cancer models with high genomic instability. In a panel of 36 colorectal (CRC) and endometrial cancer (EC) cell lines, approximately 55% were sensitive ($IC_{50} \leq 1$ μM) to ATX-559 treatment, with enriched antiproliferation activity (80%) in dMMR/MSI-H cells. ATX-559 sensitivity was also enriched in breast cancer cell lines, including 76% of BRCA altered triple negative breast cancer (TNBC) models.

ATX-559 is well tolerated *in vivo* across multiple cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models, when dosed orally BID for periods out to 28 days or more. Robust dose-dependent tumor growth inhibition (TGI) and regression are selectively observed in CRC and EC dMMR/MSI-H and BRCA altered TNBC CDX models. TGI is correlative with plasma and tumor drug exposure, as well as with induction of the target engagement PD biomarker, circBRIP1, in both tumors and mouse PBMCs. ATX-559 was also profiled in a PDX mouse clinical trial design *in vivo* study of 46 models including TNBC, CRC, EC, and gastric cancers. Oral treatment of 45 mg/kg BID demonstrated enriched sensitivity in BRCA altered TNBC (75%) and dMMR/MSI-H (68%) PDX models.

Together, these findings represent preclinical pharmacological validation of DHX9 as a selective therapeutic target in cancers that exhibit genomic instability and replication stress. ATX-559 is currently in a first-in-human, Phase 1, open-label, dose-escalation and expansion study in patients with locally advanced or metastatic solid tumors and molecularly defined cancers (NCT06625515).

#1761 SYNB011128: A novel bispecific peptide-drug-conjugate targeting EGFR and CAIX.

Caihong Zhou[1], Michael Poss[2], Cheng Lu[1], Ruochi Zhang[3], Yu Wang[3], Yuanpeng Xiong[3], Xin Gao[3], Xiao Zhang[3], **Yan Degenhardt**[2]

[1]Syneron Tech, Shanghai, China,[2]Syneron Tech, Lawrenceville, NJ,[3]Syneron Tech, Beijing, China

Peptide-drug-conjugates (PDCs) are emerging as promising alternatives to antibody-drug-conjugates (ADCs) in oncology. PDCs, with their smaller size (<10 kDa), can offer improved tumor penetration. Additionally, PDCs can potentially exhibit a better safety profile due to their shorter blood PK, absence of an Fc domain, and reduced immunogenicity. Furthermore, PDCs can be entirely chemically synthesized, providing a homogeneous chemical entity. Epidermal Growth Factor Receptor (EGFR) is a key target that is overexpressed in many tumor types. Current EGFR inhibitors primarily focus on mutant forms, creating a treatment gap for tumors with only wild-type overexpression. Carbonic Anhydrase IX (CAIX) represents another cancer-specific marker that supports tumor survival in hypoxic or acidic conditions and is frequently co-overexpressed with EGFR in cancers such as non-small cell lung cancer (NSCLC), head and neck cancers, and pancreatic cancers. SYNB011128, a bispecific PDC, exhibits high affinity and specificity for binding both EGFR and CAIX. Upon internalization, SYNB011128 releases MMAE, a potent tubulin inhibitor, through linker cleavage by tumor-specific proteases. In total, SYNB011128 employs three primary anti-cancer mechanisms: 1) Competing with EGF to inhibit the EGFR pathway. 2) Inhibiting CAIX enzyme function, crucial for cancer cell survival in hypoxic environments and resistance clone development. 3) Delivering the cytotoxic MMAE payload. Preclinical studies showed that SYNB011128 achieved complete tumor regression in multiple pancreatic and colon cancer models, outperforming EGFR-antibody-drug conjugates (EGFR-ADCs). Additionally, SYNB011128 showed efficacy in models of Osimertinib-resistant non-small cell lung cancer (NSCLC). With a molecular weight of 4 kDa, SYNB011128 exhibited rapid and deep tumor penetration. PDC induced biomarker was detected in both the periphery and core of the tumor within 6 hours post-dosing. Despite its relatively short blood half-life, SYNB011128 ensured sustained accumulation of the payload within tumors. This pharmacokinetic profile may reduce on-target toxicity and enhance safety. In mouse studies, SYNB011128 demonstrated no adverse effects, such as weight loss or liver/kidney damage, after 28 days of treatment at doses that induced tumor regression. Chemically, SYNB011128 is synthesized as a single enantiomer, without diastereomeric isomers. In summary, PDC SYNB011128 effectively targets both EGFR and CAIX, utilizing multiple anti-cancer mechanisms and achieving deep tumor penetration, which may lead to robust clinical efficacy. By binding to two cancer antigens to enhance tumor selectivity over normal tissues, and a pharmacokinetic profile of sustained tumor accumulation vs a short blood half-life, SYNB011128 may also have an improved safety margin.

#1762 Preclinical and clinical studies of PEP07, a novel brain penetrating oral Chk1 inhibitor, on AML and MCL treatments.

Hui-Ling Chen, Chieh-Fang Cheng, Feng-Yu Lee, Cheng-Hao Liu, Hong-Ren Wang

PharmaEngine Inc., Taipei, Taiwan

PEP07 is an orally available and brain penetrating selective Chk1 inhibitor. Chk1 is involved in the DNA damage response and cell cycle regulation and helps maintain the integrity of the genome during cell division, especially in response to DNA damage or replication stress. Acute myeloid leukemia (AML) is characterized by an impaired DNA damage response (DDR) pathway and elevated Chk1 expression, which correlates with poor patient outcomes. Likewise, mantle cell lymphoma (MCL), a rare and aggressive form of Non-Hodgkin lymphoma, features a chromosomal translocation that leads to cyclin D1 overexpression. Since Chk1 regulates cdk1/cyclin activity, Chk1 inhibitors have been proposed as a novel therapeutic approach in this cancer.

In addition to *in vitro* inhibitory effect on multiple hematology cancer cell lines, PEP07 has been demonstrated as monotherapy to show tumor growth inhibition and tumor regression in the AML and MCL xenograft models, respectively. It also showed enhanced tumor growth inhibition in the cytarabine-resistant AML xenograft model when combined with cytarabine.

PEP07 is currently being evaluated in clinical studies for both hematologic and solid cancers. PEP07-101 (NCT05659732), a Phase 1b, open-label, multi-center PK/PD and dose-escalating study, employs an accelerated titration design combined with a traditional 3+3 approach. This study is ongoing in multiple countries and evaluates oral PEP07 as monotherapy for AML and MCL. With its ability to penetrate the blood-brain barrier (BBB), PEP07 is also being considered for investigating treatment options for brain cancer in clinical settings.

#1763 Arsenoplatin-7, a family member of arsenoplatins, as a novel therapeutic strategy to overcome platinum-resistance in ovarian cancer.

Wenan Qiang[1], Denana Miodragovic[2], Yi Yang[1], Bong Jin Hong[3], Chi-Hao Luan[1], David Fang[4], Daniela E. Matei[5], Thomas V. O'Halloran[3]

[1]Chemistry Life of Processes Institute, Northwestern University - Evanston, Evanston, IL,[2]Chemistry, Northeastern Illinois University, Chicago, IL,[3]Microbiology, Genetics & Immunology; Chemistry, Michigan State University, East Lansing, MI,[4]Chemistry, Northwestern University - Evanston, Evanston, IL,[5]Obstetrics & Gynecology, Northwestern University -Chicago, Chicago, IL

Ovarian cancer (OC) is the fifth leading cause of cancer death in women. OC inevitably acquires resistance to platinum-based chemotherapy, leading to treatment failure and disease progression. There is an unmet need to overcome platinum OC resistance. Arsenic trioxide (ATO) is an approved drug for treating acute promyelocytic leukemia, but not in solid tumors. Arsenoplatins (APs), a family of novel anticancer dual-pharmacophore agents containing ATO in the form of arsenous acid attached to a platinum center, can deliver ATO into the tumor cells. APs have previously shown in vitro potency in leukemia, breast, and ovarian cell lines in NCI-60 screens. It was hypothesized that APs (AP-1 and AP-7) could have therapeutic effects in cisplatin (CDDP) resistant OC due to the unique nature of the drug delivery. Three paired CDDP-sensitive and resistant OC cell lines (A2780, SKOV3, and OVCAR5) were used to test the potency of AP-1 and AP-7 compared to CDDP, ATO, or a combination of both. In addition, a single dose of maximum tolerated dose (MTD) was determined in mice, and the efficacy of AP-1 and AP-7 was evaluated in clinically translational platinum-resistant OC PDX tumor models. RNA-seq analysis of tumor tissue and in silico molecular docking was further studied to explore the mechanism of action to identify potential biomarkers for AP-7 therapy. AP-1 and AP-7 demonstrated great potency and showed similar cell growth inhibition in all tested CDDP-resistant cell lines. AUC, a parameter of combined measurement of both Emax and IC_{50}, was used to rank the effectiveness of APs in these cell lines, with ATO being the most potent, followed by a combination of ATO and CDDP, then AP-1, AP-7, and CDDP was the least potent. Compared to the MTD for CDDP and ATO in mice, APs have much lower toxicity(higher MTD). AP-7, but not AP-1, demonstrated efficacy in the platinum-resistant OC PDX tumor study. AP-7 showed significant tumor volume reduction starting from week 3 ($P<0.01$); at the end of 5 weeks, there was a significant reduction of 60.78% ($P<0.001$) in tumor volume and 42.80% ($P<0.01$) in tumor weight over control. No body weight change was observed throughout the study. Molecular docking of AP-7 with GLI1 revealed that AP-7 binds to a pocket in proximity to the Zn-binding site of GLI1, potentially disrupting Zn coordination by interacting with key cysteine and histidine residues. The RNA-seq sequencing from AP-7 treated PDX tumor tissues was completed, and data analysis is ongoing for differential gene expressions and alternative splicing. Our preliminary results indicate that AP-7 is a potential therapeutic agent for overcoming platinum resistance in OC by delivering arsenous acid to tumor cells with greater efficacy and less toxicity. However, the prediction of potential target GLI1 warrants further validation.

#1764 A highly potent novel STAT5 and STAT3 direct dual inhibitor in acute myeloid leukemia.

Eunhye Hong, Minjung Kong, Hyeryung Kang, Minhee Kim, So Jung Son, Sungjae Choi, Kyeong Eun Kim, Woon-Ki Cho, Chae Won Kang, gijeong Seong, A Young Ji, Seon Ho Koh, Sehee Cha, Sangyeop Hyun, Ji Min Shin, Eori Nam, Yeon Ju Hong, Chan-Hee Park

C&C Research Laboratories, Gwacheon-si, Korea, Republic of

Background: Acute myeloid leukemia (AML) is a heterogeneous hematologic malignancy caused by abnormal differentiation and uncontrolled proliferation of myeloid cells, along with various mutations. FLT3-ITD mutation, found in approximately 25-30% of AML cases, is known to be associated with poor prognosis, including a high risk of relapse and shorter overall survival. Furthermore, acquired point mutations in tyrosine kinase domain (TKD), such as the 'gatekeeper' mutation (F691L), is considered as a main culprit of acquired resistance to FLT3 inhibitors in clinic. Different mechanisms of resistance have been reported in FLT3 inhibitor treated patients in clinic and novel strategies have been tried to overcome the resistance issue. Here we report novel direct STAT5 and STAT3 dual inhibitor, CNC-01 would be promising option for FLT3mt AML patients having acquired resistance to FLT3 inhibitors.
Methods: We developed CNC-01, a selective dual inhibitor targeting STAT5 and STAT3, which is an orally available small molecule capable of overcoming drug-resistant FLT3-TKD mutations. We established FLT3 inhibitor-resistant models using OCI-AML5 cell lines, incorporating the gatekeeper point mutation (F691) and continuously interleukin 3 (IL3)-expressing cells to mimic the bone marrow microenvironment. The direct binding to STAT5 and STAT3 was confirmed using SPR assay and cryo-EM analysis. We evaluated anti-tumor effects and target gene expression inhibition compared to Gilteritinib, and also assessed its efficacy in Venetoclax non-responsive models.
Results: CNC-01 directly binds to STAT5 and STAT3 proteins, which are implicated in resistance to FLT3 inhibitors. By inhibiting pY694-STAT5 and pY705-STAT3, CNC-01 abrogates pro-tumorigenic transcriptional activities mediated by these proteins. Furthermore, CNC-01 demonstrated potent anti-tumor effects and inhibited target gene expression more effectively than Gilteritinib. Synergistic effects were observed when CNC-01 was combined with Venetoclax, a major treatment option for AML. Additionally, CNC-01 showed high anti-tumor effects in Venetoclax non-responsive models.
Conclusion: CNC-01, a novel selective direct STAT5 and STAT3 inhibitor, shows promising results in overcoming FLT3 inhibitor resistance and demonstrates efficacy in Venetoclax-resistant models, too. CNC-01 is under preclinical stage and is expected to be highly promising treatment option for AML patients. This program is to submit Phase 1 IND next year.

#1765 RPT1G, a first-in-class hyperbolic NAMPT inhibitor that avoids on-target toxicity.

Gregory Thomas Crimmins[1], Min Wu[1], Timothy Jarvela[1], Yushma Bhurruth-Alcor[1], James Digel[1], Francis Roushar[1], Claudia Ramos Aguilar[1], Dexter Davis[1], Caroline M. Robb[1], Michael Schelle[1], Banumathi Cole[1], Frank McCormick[2], Dennise A. De Jesus-Diaz[1]

[1]Remedy Plan Therapeutics, Gaithersburg, MD,[2]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Therapeutic inhibition of NAD^+ synthesis has been challenging to achieve in the clinic due to severe on-target toxicity stemming from the critical role of NAD^+ in living systems. The elevated energy requirements of cancer cells necessitate increased NAD^+ recycling through the nicotinamide phosphoribosyltransferase (NAMPT) salvage pathway. Drug candidates have attempted to reduce NAD^+ in cancer cells by complete inhibition of NAMPT, resulting in systemic, dose-limiting toxicity. RPT1G is a first-in-class hyperbolic inhibitor that significantly reduces, but does not eliminate, NAMPT activity. This unique mechanism-of-action reduces NAD^+ below survival thresholds in cancer cells while allowing survival of healthy tissues, manifest by limited on-target toxicity in GLP studies and robust therapeutic efficacy in multiple oncological models. RPT1G has been approved to start clinical testing in healthy volunteers. This first-in-human study will determine the safety and pharmacokinetics of hyperbolic NAMPT inhibition while measuring metabolic changes resulting from reduced NAMPT activity. RPT1G represents the first hyperbolic NAMPT inhibitor to be tested in humans, opening opportunities to therapeutically modulate NAD^+ synthesis and providing a roadmap for the development of hyperbolic inhibitors of other essential enzyme targets.

#1766 PE-0260, an oral brain-penetrant MTA-cooperative PRMT5 inhibitor, drives tumor regressions in MTAP-deleted solid tumors.

Cheng-Hao Liu, Hui-Ling Chen, Chieh-Fang Cheng, Feng-Yu Lee, Long-Zhi Lin, Hong-Ren Wang

PharmaEngine Inc., Taipei, Taiwan

PE-0260 is a potent and selective oral methylthioadenosine (MTA)-cooperative protein arginine methyltransferase 5 (PRMT5) inhibitor leveraging the synthetic lethal relationship of PRMT5 with methylthioadenosine phosphorylase (MTAP) gene deletion. The well-studied synthetic lethality is an attractive approach for multiple cancer treatments due to the 10-15% incidence rate of *MTAP* deletion in all cancers. PE-0260 shows good potency of MTAP del cell viability (<5 nM IC_{50}) and >200X selectivity compared with isogenic MTAP WT cells. In a diverse cell line panel, PE-0260 selectively inhibits MTAP del cell lines over MTAP WT cell lines with median IC_{50} < 30 nM and >50X selectivity across NSCLC, GBM, pancreatic and breast cancers. This outstanding potency was successfully translated to dose-dependent anti-tumor activities observed in xenograft models with tumor regressions, and significant inhibition of symmetric dimethylarginine (SDMA) modified protein formation in tumors. Through the PK-PD analysis, on-target driven efficacy has been demonstrated, suggesting a low likelihood of off-target toxicity. PE-0260 also shows balanced *in vitro* ADME properties with low risk for drug-drug interactions and the capability to penetrate the blood-brain barrier. In conclusion, PE-0260 is a potential best-in-class MTA-cooperative PRMT5 inhibitor and a strong candidate for further clinical development.

#1767 Discovery of novel STING allosteric activators for targeted cancer immunotherapy.

J. Lee[1], E. Kim[2], S. Y. Baek[1], W. Park[2], J. Lee[1], Y. S. Kim[1], **E. Kim**[2], S. Lee[1];
[1]Korea Institute of Science and Technology, Seoul, Korea, Republic of, [2]Ajou University, Suwon, Korea, Republic of

The Stimulator of Interferon Genes (STING) serves as a pivotal regulator of innate immunity, but the therapeutic modulation of this pathway poses a risk of triggering hyperimmune responses. To address this challenge, our study explores a natural STING agonist (cGAMP)-dependent STING allosteric activator as a potential solution. This novel allosteric activator demonstrates synergistic efficacy specifically under the low cGAMP conditions across various rodent and human cell lines. The compound induces structural modification in STING, enhancing its sensitivity to minimal cGAMP levels and thereby elevating type-1 interferon production.
In vivo studies reveal that the compound enhances type I interferon induction, promotes a shift from innate to adaptive immune responses, and increases lymphocyte infiltration into tumors, leading to significant tumor regression with tumor-specific immune memory in a mouse model. In addition, co-administration with an immune check point inhibitor markedly enhances immuno-oncological efficacy. These findings underscore the potential of allosteric STING activators to expand the therapeutic index of cancer immunotherapy, offering new insights into the development of safer and more effective agents in cancer immunotherapy.

#1768 Pharmacological inhibition of METTL1 as a novel therapeutic strategy against aggressive malignancies.

Eliza Yankova[1], Alexandra Sapetschnig[2], Beth Thomas[2], Sian Evans[1], Maria Eleftheriou[1], James Russell[1], Vidur Tandon[1], Natalie Webster[2], Harry Fischl[2], Sarah Bucknell[2], George S. Vassiliou[1], Walid T. Khaled[1], Maria P. Alcolea[1], Oliver Rausch[2], Konstantinos Tzelepis[1]

[1]University of Cambridge, Cambridge, United Kingdom,[2]Storm Therapeutics, Cambridge, United Kingdom

METTL1 catalyzes N7-methylation of guanine (m^7G) in a subset of transfer RNAs (tRNAs). We have shown that METTL1 is a promising therapeutic target for various malignancies, including acute myeloid leukemia (AML), melanoma, and pancreatic ductal adenocarcinoma (PDAC). Here, we present characterization of STM9005, a novel small-molecule inhibitor of METTL1, as an effective therapeutic strategy against cancer.**Aims:** To evaluate the therapeutic potential of STM9005, a novel and bioavailable METTL1 tRNA methyltransferase inhibitor, in aggressive malignancies.

Methods: High-throughput screening and subsequent chemical optimization identified STM9005 as a potent small-molecule inhibitor of the catalytic activity of METTL1. STM9005 was tested *in vitro* to assess its impact on cancer models, including effects on growth, differentiation, and cell cycle regulation. RNA sequencing, m^7G profiling of tRNAs, and proteome analysis identified molecular pathways affected by the inhibition of METTL1. *In vivo* experiments assessed therapeutic efficacy in solid and hematological cancer models.

Results: The impact of STM9005 was measured by cellular mechanistic assays and modification-induced misincorporation tRNA sequencing, revealing decreased m^7G methylation and lower levels of target tRNAs. The efficacy of STM9005 was determined in a panel of cancer models, including AML, melanoma, and PDAC. METTL1 inhibition impaired cell proliferation and viability in multiple cancer models, with no effects in non-cancerous cells, suggesting a cancer-specific mechanism of action. *In vitro* treatment with STM9005 led to significant differentiation of AML, suggesting an important connection between m^7G and status of oncogenesis. STM9005 treatment also reduced cell cycle progression and downregulated cell cycle oncogenes. Mechanistic interrogation using m^7G profiling of tRNAs, RNA sequencing, and proteome analysis identified drug-specific changes at both RNA and protein levels. *In vivo* characterization of STM9005 demonstrated excellent bioavailability in mice with no detectable toxicity. We evaluated its anti-cancer effects across a range of aggressive cancer models, including melanoma, PDAC, and AML patient-derived xenografts (PDX). Daily administration of STM9005 significantly inhibited disease progression, indicating potent anti-cancer activity. Target engagement was confirmed by reduced m^7G levels on METTL1-dependent tRNA substrates.

Summary We describe STM9005 as a first-in-class inhibitor targeting the tRNA methyltransferase METTL1. Small-molecule inhibition of METTL1 demonstrates potent anti-cancer effects *in vitro* and *in vivo* using physiologically and clinically relevant models of advanced malignancies. These findings provide proof-of-concept that pharmacological inhibition of METTL1 offers a novel therapeutic strategy for aggressive cancers with unmet clinical needs.

#1769 A selective BRM (SMARCA2) inhibitor for the treatment of BRG1 (SMARCA4) mutant cancers.

D. Zhou, Z. Wang, Y. Liu, T. Fu, Z. Cheng;
Zion Pharma Limited, Shanghai, China

Background: ATP-dependent BRG1/BRM associated factor complexes play a key role in regulating gene expression by remodeling chromatin. BRG1 is mutated in ~5% of all tumors, and in ~7-10% of NSCLC tumors. BRM is essential for the growth of tumors that harbor loss of function BRG1 mutations. BRM and BRG1 ATPase share high protein-sequence homology (76% similarity), particularly in the ATPase domain (92% similarity). The Phase 1 clinical trial results of a BRG1/BRM dual inhibitor, in patients with BRG1 mutated cancers, showed potential safety risks. Improved safety margins may be achieved through the selective suppression of BRM activity. We identified a selective and potent BRM inhibitor (ZN-7035) with an excellent safety margin.
Methods: The inhibition potency of ZN-7035 against isolated recombinant full-length BRM or BRG-1 ATPase activity was assessed by ADP-Glo assay. BRM-dependent KRT80 gene-expression in a BIG1-mutant NCI-H838 cell line was measured by Real-Time PCR. In vivo pharmacology was conducted to evaluate the efficacy of ZN-7035 oral administration monotherapy and in combination with a MCL1 inhibitor or chemotherapy in NCI-H838 NSCLC xenograft models. The pharmacokinetics of ZN-7035 was evaluated in mice, rats and dogs. The toxicity of ZN-7035 was assessed in 28-day orally administered repeat-dose studies in Sprague Dawley rats. Safety margins were determined based on the ratio of unbound AUC obtained from 28-day toxicology studies and predicted human PK at efficacious dose.
Results: ZN-7035 exhibited strong inhibition (IC_{50}=3.3 nM) against BRM ATPase as well as potent inhibition (IC_{50}=8.3 nM) of KRT80 mRNA expression, a PD biomarker of BRM. ZN-7035 monotherapy demonstrated anti-tumor activity and synergistic tumor growth inhibition in combination with AMG176, a MCL1 inhibitor, in an NCI-H838 xenograft model carrying BRG1 loss-of-function mutation. KRT80 PD biomarker modulation in NCI-H838 established an exposure-response relationship. Further, ZN-7035 (20mg/kg) free concentration in plasma covers KRT80 IC_{90} for ~17-19h and achieved 80% tumor inhibition. In addition, ZN-7035 demonstrated dose dependent anti-tumor activity and synergistic tumor growth inhibition in combination with chemotherapy in NSCLC xenograft models. In these studies, ZN-7035 demonstrated excellent pharmacokinetic and safety properties. Due to good BRG1 selectivity, ZN-7035 was well tolerated in rats at 120 mg/kg/day following repeat dosing for 28 days. Based on DMPK and rat DRF data, the predicted human efficacious dose is 115 mg BID, and the predicted human safety margin is >30-fold.
Conclusion: ZN-7035 is a highly potent, selective, orally available, small-molecule, enzymatic inhibitor of BRM. Preclinical findings highlight that ZN-7035-based combination therapies have the potential to be effective and safe treatments for patients with tumors harboring BRG1 mutations.

#1770 HM100760, a potent and selective MAT2A inhibitor, demonstrates a synergistic anticancer effect when combined with a PRMT5 inhibitor in MTAP-deleted cancer.

Minjeong Kim, Eun Joo Kwak, Miyoung Lee, Soonki Park, Hobin Lim, Soyeon Kim, Hye Sun Han, Seung Hyun Jung, Jooyun Byun, Sang Hyun Lee, Young Gil Ahn

Hanmi Pharmaceutical Co., Ltd., Hwaseong-si, Korea, Republic of

Methionine adenosyltransferase 2A (MAT2A) is the primary enzyme responsible for the synthesis of S-adenosylmethionine (SAM) from methionine and ATP. SAM serves as a universal methyl donor in various transmethylation and biosynthetic pathways. Recently, MAT2A has emerged as a synthetic lethal target in cancers harboring deletions of the methylthioadenosine phosphorylase (MTAP) gene, which occurs in approximately 15% of all cancers.

MTAP deletion results in the accumulation of methylthioadenosine (MTA), which partially inhibits protein arginine methyltransferase 5 (PRMT5). Inhibition of MAT2A in MTAP-deficient cancers leads to reduced intracellular SAM levels, which sensitizes PRMT5 to further inhibition. Likewise, this interplay offers a strong rationale for the combinational use of MAT2A inhibitors, which block SAM synthesis, with MTA-cooperative PRMT5 inhibitors.

Here, the biochemical activity of HM100760, a potent and selective MAT2A inhibitor, was evaluated in terms of its effect on MAT2A enzymatic function, cellular SAM levels, and symmetric dimethylarginine (SDMA) regulation. HM100760 exhibited strong inhibition of MAT2A catalytic activity, leading to significant reductions in SAM and SDMA levels in HCT116 MTAP-null cells. In addition, HM100760 displayed robust anti-proliferative effects across a range of MTAP-deficient cancer cell lines, including those derived from pancreatic, bladder, and non-small cell lung cancer (NSCLC).

In preclinical in vivo studies, HM100760 demonstrated dose-dependent tumor growth inhibition in multiple MTAP-null xenograft models, including HCT116, KP-4, and LU99. Moreover, combining HM100760 with a PRMT5 inhibitor in the endogenous MTAP-null LU99 xenograft model resulted in a synergistic antitumor effect, outperforming monotherapy treatments. Notably, HM100760 achieved this therapeutic efficacy without causing significant body weight loss or observable clinical symptoms, underscoring its favorable safety profile.

In conclusion, HM100760 is considered a promising therapeutic candidate for MTAP-deleted cancers. It exhibits potent antitumor activity as a monotherapy and demonstrates enhanced efficacy when combined with a PRMT5 inhibitor. Ongoing preclinical studies aim to further characterize HM100760’s therapeutic potential and broaden its application in MTAP-deficient cancer treatment.

#1771 Ecubectedin's role in targeting transcriptional regulators in neuroendocrine prostate cancer.

Laura Almale[1], Maria Jose Guillen[2], Paula Diaz[3], Ismael Fernandez-Miranda[2], Paula Iglesias[1], Marcelo Lima Ribeiro[2], Maria Ovejero-Sanchez[3], Elena Castro[1], Pedro P. Lopez-Casas[1], Carmen Cuevas[2], Pablo M. Aviles[2], David Olmos[1]

[1]Prostate Cancer Genomics and Therapuetics Research Group, Instituto de Investigacion Hospital 12 de Octubre, Madrid, Spain,[2]Pharma Mar, S.A., Madrid, Spain,[3]Translational Research in Cancer Genetics Group, Instituto de Investigacion Hospital 12 de Octubre, Madrid, Spain

Introduction: Neuroendocrine prostate cancer (NEPC) is a highly aggressive variant of prostate cancer with poor clinical outcomes and limited treatment options, highlighting the urgent need for therapies targeting its unique molecular profile of ecubectedin, a novel inhibitor of transcription from the ecteinascidin's family, in both *in vitro* and *in vivo* models of NEPC. **Methodology:** Human NEPC cells, NCI-H660, along with eight NE-SCLC cell lines (as the well-known NE model) were treated with ecubectedin for 72 hours. Cell viability was assessed using a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) short-term assay. Treatment-induced changes in gene expression profiles were analyzed by bulk RNA sequencing. *In vivo* antitumoral activity of ecubectedin was evaluated in in two human-derived NEPC models: H660 (cell-derived xenograft or CDX) and CP-IBI-034 (a transformed NEPC patient-derived xenograft or PDX obtained from a liver metastasis, confirmed histologically). Both H660 and CPI-IBI-034 were implanted subcutaneously (s.c.) in athymic *nu/nu* mice. Ecubectedin/placebo was intravenously (i.v.) administered (at 0.75 mg/kg) on days 0, 7 and 14 in n=6-8 mice per arm and model. **Results:** Ecubectedin markedly reduced NCI-H660 cell viability in similar proportions to NE-SCLC, with an average IC_{50} of 2.3 nM. At a transcriptional level, ecubectedin induced significant downregulation of key NE regulators, including ASCL1, NEUROD1, POU3F2, MYCN, EZH2 and SOX2, in both NEPC and NE-SCLC. In CP-IBI-034 tumor bearing mice, ecubectedin significantly reduced (*vs* placebo) the tumor volume during the experimental phase (up to Day 35) with a 22% of ecubectedin-treated mice resulting in complete tumor remissions. In H660 xenografts, a significantly antitumor activity (*vs* placebo) was also observed with complete tumor remissions in 100% of mice that lasted until the end of the experiment (Day 91). **Conclusions:** Ecubectedin may impact transcriptional networks driving the cell plasticity and NE transformation in NEPC tumors. More importantly, a significant *in vitro* and *in vivo* antitumor activity of ecubectedin was observed in NEPC models, suggesting a significant potential as a promising novel therapeutic for this indication associated to very poor outcomes.

#1772 A novel small molecule inhibitor, HO-4200, modulates macrophage polarization and suppresses MDSCs to enhance antitumor immune responses in ovarian cancer.

Ganesh Yadaigiri, Kalpana Deepa Priya Dorayappan, Lakshmi Narasimhan Chakrapani, Shyam Sundaram, Jessica Velasquez, Casey Cosgrove, David M. O'Malley, David E. Cohn, Selvendiran Karuppaiyah

Obstetrics and Gynecology, The Ohio State University Wexner Medical Center, Columbus, OH

Introduction: Ovarian cancer (OC) remains the deadliest gynecologic malignancy, with minimal improvement in the 5-year survival rate over the past three decades despite advancements in treatment. High-grade serous ovarian cancer (HGSOC) is characterized by aggressive progression, driven by elevated secretion of extracellular vesicles (EVs), tumor-associated macrophage (TAM) activation, and increased myeloid-derived suppressor cell (MDSC) populations. These factors contribute to immune suppression, metastasis, and poor patient outcomes. Here, we report on a novel small-molecule inhibitor, HO-4200, which modulates macrophage polarization and suppresses MDSCs within the ovarian tumor microenvironment.
Methods: EV quantification and size characterization were performed using nanoparticle tracking analysis (NTA) and transmission electron microscopy (TEM). In vivo studies using immunocompetent mice evaluated HO-4200's anticancer efficacy. Macrophage polarization and MDSC populations were analyzed via flow cytometry. The effects of HO-4200 on ovarian cancer and primary ascites-derived cell lines were examined in vitro. Additionally, expression levels of EV secretion pathway proteins TMEM205 and Rab27a were measured by ELISA and RT-PCR.
Results: HO-4200 demonstrated significant antiproliferative effects, reducing ovarian cancer cell viability by 60-75% at concentrations of 2-5 μM after 48 hours. HO-4200 also inhibited the expression of EV secretion pathway proteins TMEM205 and Rab27a in ovarian cancer cells. Mechanistic studies revealed that HO-4200 promoted M1 macrophage polarization and reduced MDSC populations in vitro and in vivo immunocompetent mouse models. These findings suggest that HO-4200 suppresses EV secretion, thereby enhancing antitumor immune responses and reducing tumor progression and metastasis in ovarian cancer.
Conclusion: This study provides the first evidence that HO-4200 inhibits ovarian cancer cell proliferation, promotes M1 macrophage polarization, and reduces MDSC populations by targeting EV secretion pathway proteins. These results highlight the therapeutic potential of HO-4200 in modulating the immune microenvironment and combating ovarian cancer progression and metastasis.

#1773 PM54, a novel transcription inhibitor with promising broad-spectrum antitumor activity.

Marta M. Diez[1], Gema Santamaria Nunez[1], Tommy Darriere[2], Federico M. Ruiz[2], Carlos Fernandez-Tornero[2], Ismael Fernandez-Miranda[1], Maria Jose Guillen[1], Pablo M. Aviles[1], **Marcelo Lima Ribeiro**[1], Carmen Cuevas[1]

[1]Pharma Mar, S.A., Madrid, Spain,[2]Centro de Investigaciones Biologicas Margarita Salas, CSIC, Madrid, Spain

PM54, a novel synthetic member of the ecteinascidin family, is derived from lurbinectedin, a marine-derived compound recognized for its potential in cancer therapy. This study aimed to characterize the *in vitro* antitumor activity of PM54, elucidate its mechanism of action through transcriptomic profiling and validate its antitumor efficacy *in vivo*. The antineoplastic activity of PM54 was assessed using a panel of 37 cancer cell lines representative of breast, gastric, melanoma, ovary, small cell lung cancer (SCLC), and prostate cancers through MTT assays. Cell cycle analysis, as well as apoptosis assessment, were both performed after a 24-h incubation period with PM54 at 50 nM by FACS. DNA binding capacity was assessed using electrophoretic mobility shift, DNase I footprinting and FRET-based assays, with further interaction mode evaluation by X-ray analysis. ^{3}H-uridine incorporation assays were conducted to measure mRNA synthesis. RNA-seq was used to analyze gene signatures associated with 6-h of incubation with 50 nM of PM54. The *in vivo* antitumor efficacy of PM54 was characterized in relevant xenograft models of breast, gastric, melanoma, ovary, SCLC, and prostate cancers. PM54 exhibits potent *in vitro* antitumor activity, with mean GI_{50} values in the low nanomolar range. It exhibits a strong covalent binding affinity for specific DNA triplets, particularly those with guanine in the second position and either guanine or cytosine in the third position. Mechanistically, PM54 inhibits mRNA synthesis by causing the stalling and proteasomal degradation of RNA Polymerase II. This disruption results in double-strand DNA breaks, S-phase cell cycle arrest, and ultimately culminates in apoptotic cell death. RNA-seq analysis revealed that PM54 robustly downregulates genes associated with cell cycle regulation, key signaling pathways (WNT, MAPK, NOTCH, ERBB) and DNA damage response, including homologous recombination repair. Weekly intravenous (i.v.) administration of PM54 at its maximum tolerated dose (MTD) demonstrated significant antitumor activity and survival benefits across multiple preclinical tumor models, including breast, melanoma, gastric, ovarian, SCLC, and prostate. Tumor reduction and survival improvements were statistically significant in all models, with p-values ranging from 0.0002 to <0.0001. Median overall survival (OS) times in PM54-treated groups were markedly longer than in controls, highlighting PM54's potential as an effective therapeutic agent. In conclusion, PM54 demonstrates robust antitumor effects across various cancers by impairing mRNA synthesis and inducing DNA damage, underscoring its therapeutic promise.

#1774 A novel role of SNORA71D in the regulation of proteasome inhibitor induced apoptosis.

Alexei F. Kisselev, Olasubomi A. Akintola, Addison M. Wilson

Auburn University, Auburn, AL

Small nucleolar RNAs (snoRNA) are 60-300 nucleotide long RNAs that guide modification of rRNAs during ribosome biogenesis. Many of them have non-canonical functions, such as regulation of splicing of specific mRNAs. We have made a serendipitous discovery that treatment of cells with proteasome inhibitors (PIs) induces expression of a poorly characterized snoRNA, SNORA71D. Two other agents that induce production of misfolded proteins, tunicamycin and thapsigargin, also induced SNORA71D, but DNA-damaging agent doxorubicin did not. Knocking SNORA71D down reduced PI-induced apoptosis. The mechanisms of SNORA71D involvement in this process is under investigation. These findings indicate a novel and unexpected role of SNORA71D in cellular response to proteotoxic stress.

#1775 Oncogenic reduction after exposure to capsaicin in oral squamous cell carcinoma.

Samira B. F. Abdullah-Vargas[1], Riseilly Ramos-Nieves[2], Angel J. Amaral-Maisonet[1], Amanda Prats-Marrero[1], Jeannette L. Salgado-Montilla[1], Gabriel Borges-Velez[1], Josue Perez-Santiago[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, PR,[2]University of Puerto Rico Medical Sciences Campus, San Juan, PR

Background: Oral Squamous Cell Carcinoma (OSCC) is the sixth most common type of cancer worldwide with an increasing death rate of 0.6% each year from 2009 through 2021. Although there have been advances in the treatment, survival rates for oral cancer patients remain low, highlighting the need for alternatives. Capsaicin, an alkaloid compound that acts as a metabolite, could be a potential alternative for cancer treatment due to its anti-proliferative and apoptotic effect on cancer cells. Additionally, previous data from our lab has demonstrated an increased cell viability in OECM-1 cells when treated with Lipopolysaccharides (LPS) from *P. gingivalis*. Therefore, in this study, we evaluated the effects of capsaicin on the viability, proliferation, and migration of the OSCC cell line OECM-1 with and without *P. gingivalis* LPS treatment.

Methodology: Cell viability was measured by AlamarBlue after 24 and 48 hours (h) of treatment with capsaicin using serial dilutions starting at 1000µM and calculated capsaicin's half-maximal inhibitory concentration (IC50). Cell proliferation was measured by seeding 150,000 cells per well and counting with TrypanBlue the change in cell number after treatment with capsaicin (100µM and 200µM) for 24h and 48h. Cell migration was assessed by wound healing assays, in which the length of the wound was measured before and after exposure to treatment by calculating the percentage of wound closure after 24h and 48h. We also measured the impact of capsaicin in the proliferation and migration of OSCC cells using a combination of capsaicin (100µM and 200µM) and LPS derived from *P. gingivalis* (4ng/mL and 8ng/mL).

Results: Higher concentrations of capsaicin reduced cell viability at both timepoints with IC50s of 470uM and 398uM at 24h and 48h, respectively. While cell proliferation increased at 24h of exposure to capsaicin at only 200µM ($p=0.010$), cell proliferation significantly decreased at both 100µM and 200µM of capsaicin after 48h ($p=0.004$ and $p=0.005$, respectively). Higher concentrations of capsaicin decreased the percentage of closure of the wound at both timepoints. On the other hand, cell proliferation decreased when treated with *P. gingivalis* LPS (4ng/mL) and 100µM ($p=0.016$) and 200µM ($p=0.029$) of capsaicin at 48h. In the wound healing assay, both concentrations of capsaicin with *P. gingivalis* LPS (8ng/mL) presented a decreased percentage of closure of the wound.

Conclusion: Capsaicin was able to reduce oncogenic phenotypes in OSCC and counteract the proliferative effects of *P. gingivalis* LPS. Understanding the molecular impact of capsaicin in OSCC may lead to a novel treatment strategy.

#1776 Investigation into the enhancement of 20S proteasome-mediated proteolysis as a therapeutic for HPV-associated cervical cancer.

Shannon M. Cartwright, Linh Le, Kate Hartnett, Jetze J. Tepe

Chemistry, University of Virginia, Charlottesville, VA

Human papillomaviruses (HPVs) are one of the most common sexually transmitted infections (STIs) in the world. HPVs can be divided into two main categories, low-risk and high-risk. Low-risk HPVs do not cause cancer and can often be cleared by the infected person's immune system. However, high-risk HPVs are responsible for approximately 5% of cancers worldwide - most commonly cervical cancer, and there is currently no cure once infection occurs. While prophylactic vaccines exist that can successfully prevent the infection of many high-risk HPVs, vaccination rates worldwide are low. After infection, the virus incorporates its genome into the host cell genome, and the cell begins to produce HPV proteins. In high-risk HPVs, two of these proteins, HPV E6 and E7, are oncoproteins with partially disordered structures. E6 and E7 proteins have many functions impacting cancer development, including inducing the degradation of tumor suppressor proteins p52 and pRB, respectively, through the ubiquitin-26S proteasome system (UPS). The removal of these cell cycle progression checkpoints allows for uncontrolled cell growth, which can promote cancer. The Tepe lab works on the development of small molecules which can increase the protein degradation capacity of the 20S proteasome, a protease that specifically degrades disordered proteins in a ubiquitin-independent manner. This project works to establish if the 20S proteasome can degrade HPV E6 and E7 proteins, and if the use of 20S proteasome enhancing small molecules can deplete levels in HPV+ cervical cancer cells. We have discovered that treatment with two of these compounds decreases E6 and E7 levels in a HPV18+ cervical cancer cell line and work is ongoing to determine if this impact is through 20S proteasome activation. Additionally, we are investigating if this decrease is enough to inhibit the out-of-control cell growth caused by E6 and E7. The goal of this project is to understand if 20S proteasome activators can be used as a therapy for HPV-mediated cervical cancer.

#1777 OST11098, an orally available and selective Cyp11A1 inhibitor for the treatment of castration-resistant prostate cancer (CRPC) with next-generation hormone agents (NHAs) resistance.

F. Wu, L. Deng, z. Ma, Z. Lu, G. Deng;
Open Source Therapeutics, Suzhou, China

Next-generation hormone agents (NHAs) such as abiraterone and enzalutamide have become standard treatments for castration-resistant prostate cancer (CRPC), significantly prolonging patient survival. However, resistance to NHAs inevitably develops, presenting a critical and unmet clinical challenge. Inhibition of CYP11A1 disrupts the entire biosynthesis pathway of androgens and other steroids by blocking the formation of pregnenolone. This mechanism halts the activation of the androgen receptor (AR) axis, thereby preventing further cancer progression and potentially overcoming NHAs resistance in heavily pretreated CRPC patients.In this study, we introduce OST11098, a newly identified, orally bioavailable, selective, and potent CYP11A1 inhibitor with demonstrated anti-tumor efficacy against NHA resistance. OST11098 displays favorable pharmacokinetic and safety profiles. In vitro, it effectively inhibited pregnenolone biosynthesis at low nanomolar concentrations in the H295R adrenocortical carcinoma cell line, leading to a rapid and complete blockade of all measured downstream steroid hormones. When administered orally, OST11098 showed consistent, dose-dependent pharmacokinetic/pharmacodynamic (PK/PD) correlations in adult non-castrated male mice, successfully inhibiting the biosynthesis of androgen receptor (AR) activators. In a VCaP CRPC xenograft mouse model, OST11098 demonstrated significant anti-tumor efficacy. Moreover, an engineered LNCaP CRPC xenograft mouse model with NHA resistance was successfully established and evaluated for its response to OST11098 treatment, providing compelling preclinical evidence supporting the use of CYP11A1 inhibitors as a promising strategy for managing NHA-resistance.Overall, our studies demonstrated OST11098 as a highly potent and selective CYP11A1 inhibitor with great PK properties, clean safety profiles, and significant anti-tumor activity for the treatment of CRPC. These promising preclinical results strongly support the potential of OST11098 to address unmet needs in CRPC treatment, justifying its further clinical development.

#1778 MALAT1 and TUG1 long non-coding RNAs signalling mechanisms in response to SRPK1 inhibitor in prostate cancer.

Linomtha Gabada[1], Zodwa Dlamini[1], **Rahaba Makgotso Marima**[2]

[1]University of Pretoria, Pretoria, South Africa,[2]University of Pretoria, Johannesburg, South Africa

Introduction: Prostate cancer (PCa) is a leading cause of cancer death, and there are significant racial disparities in patient outcomes. Non-coding RNAs (lncRNAs) MALAT1 and TUG1 are recognised for their roles in oncogenic pathways. Their precise interacting mechanisms with splicing factors and splicing factor kinases is understudied.
Aim: This study aims to map the biological pathways influenced by TUG1, MALAT1 in response to SRPK1 inhibitor prostate cancer cells
Materials and Methods: Bioinformatics tools LncSEA 2.0, STRING, DAVID and Reactome were used to analyse the interactions between MALAT1, TUG1 and relevant miRNAs and their target genes. Resozuring cell viability assay was used to measure PCa cell viability (PC-3 cells vs HEK) in response to Sphinx31 at 24hrs and 48hrs. Next, RT-qPCR was used to measure gene expression levels of the lncRNAs.
Results and Discussion: MALAT1 and TUG1 act as competing endogenous RNAs (ceRNAs) to sponge miRNAs that regulate critical tumour proliferation and migration genes, including PTEN and BCL2. SRPK1 regulates splicing factors to enhance tumour aggressiveness. The MALAT1-miR-125b-BCL2 and TUG1-miR-29b-PTEN axes are critical pathways for PCa progression, especially in advanced stages. Sphinx31 is cytotoxic in a time dependent manner to the PCa cells, while the 2 lncRNAs expression is elevated in PCa cells prior to Sphinx31 treatment.
Conclusion: Targeting lncRNA-miRNA networks and splicing factor interactions, especially MALAT1 and SRPK1, is a potential therapeutic target for PCa.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Drug Delivery Technologies
Poster Session

#1782 Preclinical development of iSAP-0909: A novel self-assembled fluorescent contrast agent targeting XIAP for image-guided surgery in bladder cancer.

Min Han[1], Gantian Lyu[1], Yuzhen Qian[1], Hongwei An[2], Yingbin Zhang[1], Lin Fu[1], Hao Wang[1]

[1]Isap (Beijing) Biotechnology Co., Ltd., Beijing, China,[2]National Center for Nanoscience and Technology, Beijing, China

Background: Fluorescence-guided surgery as an intraoperative optical imaging technique offers surgeons real-time guidance on for tumor delineation. However, there is still a pressing clinical need for next-generation tumor-targeted fluorescent imaging agents that exhibit enhanced specificity, sensitivity, and photostability. iSAP-0909 is developed as an experimental peptide-based tumor-targeting fluorescent agent employing an *in vivo* self-assembly approach for adjunctive diagnosis and intraoperative localization in non-muscle-invasive bladder and other solid tumors.

Method: This research involved extensive preclinical studies, comprising *in vitro* assays on human bladder cancer cells, *Ex vivo* near-infrared (NIR) imaging on clinical bladder cancer specimens, *in vivo* imaging evaluation on mouse orthotopic bladder cancer model, and comprehensive toxicity studies on rats and dogs.

Results: iSAP-0909 is a novel peptide-conjugated NIR fluorescent cyanine dye targeting X-linked inhibitor of apoptosis protein (XIAP). The peptide binding activates downstream caspase enzyme, promoting cleavage of iSAP-0909 to initiate self-assembly process. Hereby, formation of β-sheet structure-enriched nanofibers within tumor cells is triggered, resulting in enhanced accumulation and retention of the cyanine dye. *In vitro* uptake and retention assays indicated that iSAP-0909 has notably higher tumor cell selectivity greater than HAL (by 5.4 fold), and showcases prolonged intracellular retention. *Ex vivo* imaging studies on human bladder revealed that iSAP-0909 distinctly delineates tumor boundaries and minor lesions through fluorescence imaging, with specificity of 97.96% and sensitivity of 99.58% derived from 338 clinical specimens. In an orthotopic tumor model derived from KU19-19 (human bladder cancer cell), iSAP-0909 achieved detection rate of 83.3% within 4 hours post-administration at a pharmacologically active dose, and the resulting signal-to-noise ratio was 7.53. Repeat-dose toxicology and safety pharmacology studies in rats and dogs indicated no adverse effects for iSAP-0909, suggesting favorable tolerability and no-observed genotoxic risk. Toxicokinetic analysis also reflected minimal plasma drug exposure (≤0.5%/BQL).

Conclusion: iSAP-0909 represents a novel self-assembled fluorescent contrast agent, demonstrating high specificity and sensitivity for bladder tumor tracing. This probe offers potential clinical advantages in localizing malignant lesions in patients with bladder cancer. The FDA has granted clinical approval of iSAP-0909 (IND 172343). Concurrently, an investigator initiated trial (IIT) study is underway to assess the safety and feasibility of imaging following intravenous administration of iSAP-0909 in cancer patients.

#1783 Harnessing macrophage-drug conjugates for allogeneic cell-based therapy of solid tumors.

Bartłomiej Taciak[1], Maciej Białasek[1], Malgorzata Kubiak[2], Ilona Marszalek[1], Paulina Kucharzewska Siembieda[2], Tomasz Rygiel[3], **Magdalena Krol**[1]

[1]Cellis AG | Warsaw University of Life Sciences, Zurich, Switzerland,[2]Warsaw University of Life Sciences, Warsaw, Poland,[3]Cellis AG, Zurich, Switzerland

The treatment of solid tumors remains a significant challenge, necessitating the ongoing development of innovative therapeutic strategies. Tumor-infiltrating macrophages play a crucial role in the tumor microenvironment, making them an attractive target for drug delivery systems. Here, we introduce the Macrophage-Drug Conjugate (MDC) platform, a pioneering approach that leverages macrophages as delivery vehicles for ferritin-drug complexes. We demonstrate that macrophages actively internalize human heavy chain ferritin (HFt) via macrophage scavenger receptor 1 (MSR1) in vitro. These drug-loaded macrophages transfer ferritin to neighboring cancer cells through a novel mechanism termed **TRAnsfer of Iron-binding proteiN (TRAIN)**. This process requires direct cell-to-cell contact facilitated by an immune synapse-like structure, enabling precise drug delivery. MDCs were formulated with various anti-cancer drugs and evaluated for safety and efficacy in multiple preclinical models, including syngeneic mouse and orthotopic human tumor models. MDC-250 exhibited potent anti-tumor activity in an orthotopic human pancreatic cancer model (BxPC3). MDC-735 demonstrated remarkable efficacy across diverse cancer models, including pancreatic cancer (BxPC3), ovarian cancer (SK-OV-3), breast cancer lung metastases (EMT6), bladder cancer (MB49), and head and neck cancer (SCC7). These effects were observed both as a monotherapy and in combination with immune checkpoint inhibitors. Significantly, MDCs were prepared as off-the-shelf products, maintaining their activity upon thawing, highlighting their potential for clinical translation. This MDC platform represents a breakthrough in solid tumor therapy, offering a targeted, scalable, and effective treatment approach with broad applicability across multiple cancer types.

#1784 Dynamic control of cerebrospinal fluid to achieve personalized drug delivery in the central nervous system.

Priya Kumthekar[1], Marcie Glicksman[2], Margaret Schwartz[1], Seema Nagpal[3], Isabella Glitza,[4], Peter Forsyth[5], Ernesto Ruiz[2], Adam Sonabend[1]

[1]Northwestern University, Chicago, IL,[2]EnClear Therapies, Newburyport, MA,[3]Stanford University, San Francisco, CA,[4]University of Texas MD Anderson, Houston, TX,[5]Moffitt Cancer Center, Tampa, FL

Background: Systemically delivered therapeutics have limited access to the brain due to the tightly regulated blood brain barrier. There is a fine balance between production (20 mL/h), volume (150 mL), and removal/turnover (every 5h) of cerebrospinal fluid (CSF). The high turnover of CSF and the active efflux makes CNS therapeutics particularly challenging. Direct delivery of therapeutics to the CSF intrathecally is increasingly utilized in clinical practice but penetration deep into the brain parenchyma is poor. This poses a significant challenge for the efficacy of intrathecally delivered small molecules, antibodies and gene therapies. Ideally, a CSF delivery system would have the capability to deliver therapeutics broadly within the CSF compartment, while simultaneously also improving parenchymal delivery. We show with our device how we can move dye between the two ventricles in a controlled fashion resulting in improved distribution of methotrexate.

Methods: Sheep (n=8) were used as a model, which have a brain size and geometry closer to humans when compared to rodents. EnClear's drug delivery system utilizes two CSF access points; Group 1 accessed the right and left lateral ventricle (V2V) and Group 2 accessed the right or left lateral ventricle and lumbar thecal sac (V2L). An extracorporeal pump was used to control the speed and direction of CSF flow at 50 µL/mL. Sensors continuously monitored pressure, respiration, and heart rate. Imaging studies with Omnipaque dye determined the best parameters for controlling CSF flow. Administration of methotrexate was followed by a protocol to move CSF between the two access points. Methotrexate levels were measured with LC/MS in CSF, blood, brain regions, spinal cord, kidney, and liver.

Results: Omnipaque dye in V2V demonstrated the dye was observed to move between the two ventricles, whereas, in V2L, the dye disappeared within minutes from the ventricles. In Group 1 (V2V), safe pressures (< 25 mmHg or 34 cm water) were sustained in all subjects. In both groups, effective levels of >1 ug/mL methotrexate were measured in all brain tissues, including deeper brain tissues. There was a three-fold higher level of methotrexate in striatum with the V2V compared to V2L subjects. Consistently, CSF levels were two-fold higher at 2h. Importantly, methotrexate levels were significantly lower in lumbar spinal cord, kidney, and liver-potential sources of toxicity.

Conclusions: In this large animal study, EnClear's system delivered high(er) levels of methotrexate in the parenchyma of deep brain structures than traditional IT injection. To the authors knowledge, this first intraCSF drug delivery device to show improved distribution throughout the CNS including deep brain structures, while keeping lumbar spinal cord, liver, and kidney levels very low. Clinical trials with the device are currently being planned.

#1785 Development of dual-payload anti-GPC3 antibody-drug conjugate by dual-payload antibody conjugation (AD2C) platform for hepatocellular carcinoma treatment.

Hao-Kang Li, Cheng-Wei Lai, Chien-Yu Lin, Yi-Jang Chen, Pei-Ju Leng, Chao-Min Cheng, **Sai-Wen Tang**, Shih-Chia Hsiao

Acepodia Biotech Inc., Alameda, CA

Glypican-3 (GPC3) has been reported as a promising target for the treatment of hepatocellular carcinoma (HCC). Although current therapies are available, tumor heterogeneity and the development of drug resistance continue to pose significant challenges to effective treatment. Therefore, combination therapy has emerged as a promising strategy to address these challenges. Acepodia successfully established a Dual-Payload Antibody Conjugation (AD2C) platform utilizing our proprietary bioorthogonal chemistry, which allows conjugating two (or multiple) different payloads to the antibody without requiring antibody engineering. In this study, we developed an anti-GPC3 antibody with dual payloads (anti-GPC3 AD2C) through our AD2C platform to enhance treatment efficacy of HCC. The anti-GPC3 AD2C exhibits comparable GPC3 binding affinity and internalization to the parental anti-GPC3 antibody. No significant degradation or aggregation was observed after long-term storage, demonstrating the stability of anti-GPC3 AD2C. In the pharmacokinetics study, anti-GPC3 AD2C showed a similar terminal half-life ($T_{1/2}$) to the parental antibody, and its volume of distribution (Vss) was equivalent to the blood volume, indicating primary distribution in the blood. These findings suggest that the dual-payload conjugation has a limited impact on the *in vivo* stability and safety of the anti-GPC3 AD2C. The in vitro efficacy studies show that anti-GPC3 AD2C exhibits enhanced cytotoxicity compared to the mono-payload ADCs and parental antibody in GPC3-expressing cancer cell lines but not in the GPC3 negative cell lines and primary normal cells. The HCC xenograft study further demonstrated that the anti-GPC3 AD2C completely suppressed tumor growth at doses of up to 10 mg/kg, with no significant body weight change observed. In conclusion, the dual-payload ADC produced by AD2C platform offers a potential strategy to overcome tumor heterogeneity and drug resistance while maintaining an ideal safety profile, supporting its potential clinical application in HCC treatment.

#1786 AST-203, a novel Trop2-targeting aptamer-drug conjugate, exhibits potent antitumor efficacy for the treatment of solid tumors.

Ju-hyung Kang, Daekyun Lee, Seo-young Kwak, Jieon Lee

Aptamer Sciences Inc., Seongnam-si, Korea, Republic of

Background: Trophoblast cell surface antigen 2 (Trop2), a transmembrane glycoprotein overexpressed in various epithelial cancers, including pancreatic ductal adenocarcinoma (PDAC), breast, lung, and bile duct cancers, represents an attractive target for cancer therapy. Trodelvy, a Trop2-targeting antibody-drug conjugate (ADC) linked to the topoisomerase I inhibitor SN-38, has been approved for the treatment of triple-negative breast cancer. This study focuses on the development of a novel Trop2 aptamer-MMAE conjugate (AST-203) and its characterization in comparison to the ADC.
Methods: AST-203 was designed by attaching a Trop2-targeting aptamer to three MMAE molecules (a microtubule inhibitor) using a proprietary branched linker (Blinker). Binding affinity (kd) to rhTrop2 was measured by BLI, with specific Trop2 targeting confirmed by FACS and ICC. The internalization rate of the aptamer was determined by FACS. In vitro cytotoxicity was evaluated in 2D and 3D cultures using CellTiter-Glo assays. The penetration capability was assessed through ICC in BxPC3 spheroid models. For in vivo studies, AST-203 was administered intravenously at doses of 2, 3, and 4 mpk, and Trodelvy (6 mpk) was used as a comparator in a PDAC xenograft model.
Results: The Trop2 aptamer binds to human Trop2 with an affinity of 8.6 nM and specifically targets Trop2-positive cells (BxPC3, Capan1) but not Trop2-negative PANC1 cells. It internalizes with a half-time of 15.23 minutes (95% CI: 11.30-23.34 minutes), localizing to lysosomes as confirmed by ICC. The IC50 of AST-203 was 20 nM in BxPC3 cells and 99 nM in Capan-1, while >1 μM in PANC1 cells. Additionally, studies on the anticancer effects in various cancer cells revealed a correlation with Trop2 expression levels. Notably, the Trop2 aptamer showed 6-10 times better penetration in spheroid cultures than a Trop2 antibody. AST-203 treatment significantly reduced Ki-67 expression in spheroid interiors compared to Trodelvy, consistent with its superior penetration. In addition, conditioned media from AST-203-treated cells also elicited a bystander effect on Trop2-negative PANC1 cells. Cell cycle arrest and the activation of apoptotic signal cascade was demonstrated as the mechanism of cell death. AST-203 showed minimal cytotoxicity in PBMCs and megakaryocyte (platelets precursor cell) compared to Trodelvy. In vivo, AST-203 effectively inhibited tumor growth in a BxPC xenograft model, showing superior efficacy at doses of 3 and 4 mpk compared to Trodelvy (6mpk).
Conclusion: AST-203 shows the potential of a promising next-generation therapeutic for Trop2-positive solid tumors. Its superior efficacy and safety compared to traditional antibody-drug conjugates highlight its potential to improve therapeutic outcomes for Trop2-expressing cancers. These findings underscore AST-203 as a significant advancement in aptamer-based therapeutics.

#1787 Novel strategy for producing ovarian cancer-targeting antibodies using cancer-derived small extracellular vesicles.

Maryam Firouzi, Changsun Kang, Xiaoyu Ren, Seonghyun Ryu, Dongin Kim

Pharmaceutical Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Introduction: Despite advancements in tumor-targeting agents, meta-analyses reveal that only 0.7% (mean value) of the injected therapeutic dose reaches the tumor site, leading to significant off-target adverse effects. This highlights the need for innovative targeting agents to enhance tumor-targeting efficacy. We developed a novel tumor-targeting antibody production method using cancer-derived small extracellular vesicles (sEVs). Since sEVs inherit their structure and function from their parent cells, the antibodies produced against sEVs could target both cancer cells and sEVs. Using this approach, antibody-decorated drug delivery systems may achieve enhanced tumor-targeting efficiency, overcoming the suboptimal drug concentration in the tumor. **Methods:** sEVs were isolated from ovarian cancer cells (OVCAR-8) and injected into mice. After confirming the specificity of the collected plasma to OVCAR-8 cells, hybridoma cells were generated by fusing the mice's B cells (antibody-producing cells) with myeloma cells. Hybridomas were screened to produce monoclonal antibodies (mAbs) with the highest cytotoxicity against OVCAR-8 cells (AB1, based on CCK8 assay) and the best OVCAR-8-targeting efficacy (AB2, determined through immunocytochemistry). The antibodies (AB1 and AB2) were purified and conjugated to paclitaxel-loaded CD8+ T cell sEVs (AB-TSEV/P). The formulations (AB1-TSEV/P and AB2-TSEV/P) were injected into OVCAR-8-bearing mice, and tumor volume and body weight were monitored over 80 days. An in vivo biodistribution study was performed using an IVIS Spectrum Imaging System based on fluorescence intensity measurement of IR-780 loaded AB-TSEV (AB-TSEV/IR) to assess tumor-specific accumulation. **Results:** Characterization showed that both OVCAR-8 and CD8+ T cell-derived sEVs were ~150 nm in size. Plasma from mice injected with OVCAR-8-derived sEVs demonstrated significantly higher cytotoxicity and targeting specificity against OVCAR-8 cells than non-cancerous HOSE cells. Based on the results from antibody screening, AB1 exhibited the highest cytotoxicity to OVCAR-8 cells, while AB2 showed the best OVCAR-8 cell-targeting efficacy compared to HOSE cells. Tumor volume measurements indicated that AB1-TSEV/P and AB2-TSEV/P significantly reduced tumor growth ($p<0.0001$) without affecting body weight, suggesting good tolerability. Biodistribution studies showed that antibody-decorated sEVs accumulated significantly ($p<0.0001$) at the tumor site. **Conclusions:** We developed an innovative strategy for producing tumor-targeting antibodies using cancer-derived sEVs, significantly enhancing tumor-specific drug delivery. Although focused on ovarian cancer, this approach could be applied to other cancers and diseases, offering a promising method for targeted therapies and addressing the limitations of current treatments.

#1788 Exosomal formulation of cannabidiol (CBD) inhibits lung cancer proliferation and enhances uptake and tumor targeting.

Disha Nagesh Moholkar[1], Raghuram Kandimalla[1], Jeyaprakash Jeyabalan[2], Ramesh C. Gupta[1], Farrukh Aqil[1]

[1]Department of Pharmacology and Toxicology, University of Louisville, Louisville, KY,[2]3P Biotechnologies, Inc, Louisville, KY

Lung cancer remains a leading cause of cancer-related deaths, with treatment specificity posing a major challenge. Thus, we aim to repurpose cannabidiol (CBD) as an antitumor agent, delivered via tumor-targeted exosomes (Exo). We demonstrated that oral CBD administration inhibited orthotopic lung tumor growth by ~60% ($p < 0.01$), with enhanced efficacy (~80%; $p < 0.001$) achieved using folic acid-functionalized exosomes loaded with CBD. We hypothesized that the enhanced antitumor efficacy is due to 1) increased accumulation at the tumor site due to FA-targeting; 2) improved cellular uptake of CBD via exosomal delivery; and 3) modulation of mechanistic pathways by CBD. To evaluate tumor targeting, FA-Exo labeled with Alexa Fluor-750 (AF750) were administered orally to tumor-bearing mice. Single doses of free AF750, Exo-AF750, and FA-Exo-AF750 were compared (n=3 per group). After 12 hr, mice were euthanized and imaged *ex vivo* using Odyssey LiCor Imager. For bioavailability studies, female C57BL/6 mice were given a single oral dose of 40 mg/kg CBD or ExoCBD, and tissue CBD levels were quantified 4 hr post-administration. Additionally, ER stress modulation by CBD was assessed in A549 lung cancer cells through analysis of key markers. FA-Exo-AF750 exhibited 3-fold higher signal in tumor tissues compared to non-functionalized exosomes ($p<0.01$). In bioavailability studies, ExoCBD demonstrated significantly higher CBD levels in the liver (5-fold) and mammary pads (10-fold) compared to free CBD ($p<0.001$). Notably, free CBD was undetectable in plasma, whereas ExoCBD achieved plasma CBD levels of 500 ng/mL, suggesting enhanced bioavailability and prolonged circulation time. In A549 lung cancer cells, CBD downregulated key ER stress markers, including PERK, IRE1α, BiP, CHOP, Calnexin, and PDI, anti-inflammatory marker NFκB and oncogenic CB2. Furthermore, combination of CBD with paclitaxel (PAC) substantially reduced the IC50 value of PAC against both drug-sensitive (12.5 to 5 nM) and drug-resistant (325 to 80 nM) A549 cells compared to PAC alone. In fact, the activity of PAC and CBD was synergistic against A549 cells, as shown by the combination index (CI = 0.62) calculated using Calcusyn software. Importantly, CBD reversed PAC resistance by downregulating MDR-1 in drug-resistant A549 cells. Overall, tumor-targeted exosomal formulations significantly enhance CBD's bioavailability, tumor accumulation, and therapeutic efficacy. Combined with its ability to overcome chemotherapy resistance, these findings highlight the promise of CBD-loaded exosomes as a novel therapeutic against lung cancer.

#1789 Preclinical characterization of BGB-B3227, a MUC1 x CD16A bispecific engager, for the treatment of MUC1-expressing solid tumors.

Hengrui Zhu[1], Hui Li[2], Zhuo Li[1], Qi Liu[2], Liu Xue[2], Liang Qu[2], Ming Jiang[2], Jie Li[1], Xin Chen[2], Wenjie Wang[2], Yun Chen[1], Jie Pan[1], Yuanyuan Xie[2], Ting Shao[2], Peiqi Li[1], Renke Li[1], Caizhi Liu[2], Xiaoliang Chen[2], Lei Jiang[2], jingyuan Sun[2], Lingmin Zheng[2], Xiangli Ma[2], Juan Yang[1], Haoxuan Song[1], Fuyun Sun[1], Jiyuan Zhang[1], Xi Wu[2], Xianyan Tang[2], Qiansheng Ren[2], Chichi Huang[2], Mingchao Kang[2], Xiaomin Song[2], Zhirong Shen[2], Lai Wang[2]

[1]BeiGene Ltd., Shanghai, China,[2]BeiGene Ltd., Beijing, China

Background: MUC1 is frequently overexpressed in various human epithelial cancers, including NSCLC, gastrointestinal, breast, pancreatic, ovarian, and colon carcinomas. Despite the development of MUC1 targeted therapies, none have shown significant clinical efficacy. BGB-B3227, a novel bispecific antibody targeting MUC1 and CD16A, is designed to induce NK cell activation and subsequent cytotoxicity against MUC1-expressing tumor cells.
Methods: The target binding activity of BGB-B3227 was characterized using biochemical and cell-based assays. The ability of BGB-B3227 to avoid the interference from soluble MUC1 was assessed by a competitive FACS assay. The ADCC and ADCP activities of BGB-B3227 were evaluated in co-culture systems consisting of effector cells and tumor cells expressing varying levels of MUC1, both in the presence and absence of human IgG proteins. Furthermore, the in vivo anti-tumor efficacy of BGB-B3227, both as a monotherapy and in combination with anti-PD-1 antibody, was evaluated in the MC-38/hMUC1X model in human CD16A knock-in mice.
Results: BGB-B3227 demonstrated high binding affinity to recombinant human CD16A protein and CD16A expressing cells, with comparable binding affinities to both CD16A-158V and 158F variants. BGB-B3227 displayed no detectable binding to either human CD16B NA1 (A) and NA2 variants, underscoring its high selectivity for CD16A. Additionally, BGB-3227 demonstrated high binding affinity to the recombinant SEA domain of human MUC1 protein and MUC1 expressing tumor cells. Compared to HMFG1, which targets MUC1-N, the BGB-B3227's binding to MUC1 expressing cells was less interfered by soluble MUC1. In cellular assays, BGB-B3227 induced potent ADCC and ADCP activity against MUC1-expressing cells in a dose-dependent manner, which was greater than that of Fc-enhanced mAb and was less affected by human IgG. No activity was observed in MUC1-negative tumor cells, indicating the effect of BGB-B3227 is MUC1 dependent. In mouse models, BGB-B3227 monotherapy demonstrated a dose-dependent anti-tumor efficacy, which was further enhanced when combining with an anti-PD-1 antibody. Importantly, no significant changes in animal body weight were observed across all treatments, suggesting good tolerability of BGB-B3227 in mouse models.
Conclusion: BGB-B3227 is a bispecific MUC1xCD16A NK engager demonstrating potent ADCC and ADCP activity, along with notable in-vivo anti-tumor efficacy when used as a monotherapy or in combination with anti-PD-1 therapy. BGB-B3227 represents a promise therapeutic option for MUC1-expressing cancers, with the potential to overcome the limitations of MUC1-N antibodies by mitigating the sink effect from soluble MUC1. Currently, BGB-B3227 alone and in combination with Tislelizumab is under clinical investigation in participants with advanced or metastatic solid tumors (NCT06540066).

#1790 Enhancing ADC efficacy through Fc-binding peptide engineered with ECM binding moiety: A versatile platform targeting various tumors and other malignancies.

Dae Young Kim, Yujin Park, Dahye Sim, Hana Kang, Sung Min Kim, Yejin Bang, Hee Young Kang, Hoil Choi

Peptron Inc., Daejeon, Korea, Republic of

Antibody-drug conjugates (ADCs) are an emerging class of immunotherapeutics permitting the delivery of therapeutics with sufficient potency and specificity by doing so systemic toxicity typical of conventional chemotherapy is minimized. However, the challenges in controlling their internalization have posed a hurdle in maximizing the therapeutic potential of ADCs. Here we present a novel FcBP-based modality called FcBC17, an FcBP coupled with an extracellular matrix (ECM)-binding moiety, which plays an ADC enhancer by improving the cell binding and internalization of ADCs through a biologically active mechanism. FcBC17 comprises an FcBP, a linker, and an ECM-binding peptide and tightly associates with IgG antibodies. The efficacy of FcBC17 was demonstrated using PAb001, a humanized IgG1 antibody targeting MUC1-C developed by Peptron. Due to its reversible binding to the Fc-region of PAb001, the structural and functional integrity of PAb001 remains and also additional effort to modify PAb001 is unnecessary, representing a simple, broadly applicable strategy to enable antibody delivery into cells. We show that FcBC17 improved cell binding of PAb001 in diverse cancer cells with different levels of MUC1. In addition, PAb001-FcBC17 conjugate showed a better internalization in cancer cells and intriguingly, a biologically active mechanism such as endocytosis seemed to mediate the internalization, suggesting that FcBC17 might enhance the cytotoxicity of PAb001-ADC (PAb001-MMAE or PAb001-DXd) through enhancing its cell binding and internalization actively. Indeed, the cytotoxicity of PAb001-ADC was greatly improved with the conjugation of FcBC17 against cancer cells that otherwise showed a poor IC50 with the treatment of PAb001-ADC, and no cytotoxicity was observed with the treatment of FcBC17 alone, indicating that the ADC enhancement was likely due to the improved internalization of PAb001-ADC through the conjugation of FcBC17. Moreover, due to the nature of FcBP whose binding is separated on acidic pH conditions, PAb001-FcBC17 conjugate remains stable under normal physiological conditions, ensuring that the efficacy of PAb001-ADC is not compromised upon clinical treatment. In conclusion, the binding and internalization of PAb001-ADC on cancer cells could be greatly enhanced with the conjugation of FcBC17 which in turn has resulted in the dramatic improvement of the cytotoxicity mediated with PAb001-ADC, implying that the critical limitation of conventional ADCs in controlling cellular internalization may be ameliorated through our FcBP-based approach. The versatility of our approach as an ADC enhancer will be further demonstrated across various applications, not only in targeting MUC1-expressing tumors but also in treating other types of cancers and malignancies through diverse therapeutic antibody formats.

#1791 An injectable depot technology for sustained locoregional delivery improves the efficacy and safety of immunotherapies and adoptive cell therapies.

John H. Klich, **Anthony C. Yu**, Eric A. Appel

Materials Science & Engineering, Stanford University, Stanford, CA

Advances in immunotherapy have revolutionized care for cancer patients. Unfortunately, many approaches fail to mount a robust anti-cancer effect, in part due to the highly immunosuppressive tumor microenvironment in solid tumors. Similarly, while adoptive cell therapies (ACT) like CAR-T therapies have demonstrated immense potential in treating various B cell malignancies, they have been less successful in treating solid tumors on account of the immunosuppressive environment. To address these challenges, the field has turned to either combination immunotherapies or locoregional delivery of therapies as systemic administration of potent therapies can result in severe immune related adverse effects. Enabling potent combination immunotherapies requires administering these immune agonists in a way that more closely resembles the endogenous cancer immunity cycle, a tightly regulated sequence of cues in both space and time. Here, we will discuss the development of an injectable hydrogel depot technology for rational localization and prolonged exposure of potent immunotherapeutic cytokines (IL-12, IL-2), antibodies (OX40a, PD1), and ACTs to improve these therapies. Specifically, we have developed a self-assembled polymer-nanoparticle (PNP) hydrogel system that is both highly shear-thinning and rapidly self-healing, enabling minimally invasive implantation though direct injection or catheter delivery to tissues. First we will discuss how these hydrogels enable targeted delivery of immunomodulatory cargo either intratumorally (IT) or peritumorally (PT). We hypothesized that selectively altering biodistribution would more effectively augment the immune response more than sustained locoregional delivery alone. Using *in vivo* imaging, we demonstrated that site of administration is critical to redistributing cargo to either the tumor or tumor draining lymph node (tdLN). In this way we demonstrated that targeted localization of cytokine and antibody therapies synergistically improved treatment efficacy in the B16F10 and MC38 tumor models and altered cellular phenotypes in these microenvironments. Second we will discuss how these hydrogels enable the controlled co-delivery of stimulatory cytokines and adoptive cells to improve treatment of solid tumors. The unique architecture of these materials simultaneously enables prolonged retention of entrapped cytokines while maintaining active motility of entrapped cells. Upon administration this hydrogel depot forms a transient inflammatory niche that induces more tumor-reactive phenotypes and sustains exposure of activated adoptive cells, thereby improving treatment efficacy. Overall, this presentation will discuss how PNP hydrogels represent a crucial new tool for improving therapeutic efficacy of immunotherapies and adoptive cell therapies for cancer.

#1792 A novel lipid nanoparticle formulation transfects acute myeloid leukemia cells and primary AML samples with high efficiency and low toxicity.

L. Zhang[1], Y. Yan[1], J. Chen[2], R. Hurren[1], J. Bu[1], J. Chen[1], D. Ling[1], N. Duong[1], A. Arruda[1], H. He[1], M. D. Minden[1], R. Bremner[3], G. Zheng[1], B. Li[2], A. D. Schimmer[1];

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada, [2]Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada, [3]Lunenfeld-Tanenbaum Research Institute, Toronto, ON, Canada

RNA interference is a powerful research tool for studying gene function in cancer cells. However, functional genomic studies in Acute Myeloid Leukemia (AML) remain challenging. Classic lipid-based transfection reagents are ineffective in delivering siRNA to AML cells and lentiviral delivery of shRNA is complex and time-consuming. Lipid Nanoparticles (LNPs) are a novel approach to deliver genetic material to cells that are difficult to transfect. However, a formulation of LNP capable of transfecting AML cells and primary AML samples with high efficiency and low toxicity is lacking. Here, we developed an LNP formulation that delivers siRNA to AML cell lines and primary samples without impacting their growth and viability.

To identify LNPs able to transfect AML cell lines, we generated a library of LNPs that differed in lipid compositions, aqueous phase pH, and RNA-to-ionizable lipid weight ratio through the Design of Experiment (DOE). We synthesized 54 unique LNPs formulations encapsulating siRNA targeting luciferase. We then screened this library of LNPs against OCI-AML2 leukemia cells over-expressing luciferase. From this screen and subsequent validation studies, we identified a novel formulation, LNP 1-28, as the top hit based on transfection efficiency and safety. LNP1-28 also suppressed luciferase expression in 3 AML cell lines (OCI-AML2, OCI-AML3, MOLM13) with > 80% target knockdown with 100nM of siRNA 3 days post-transfection.

Next, we asked if LNP 1-28 could deliver siRNA to knockdown an endogenous protein, CD45. AML cell lines (OCI-AML2, OCI-AML3, MOLM13) were treated with LNP 1-28 carrying siRNA targeting CD45 or control sequences. Knockdown of CD45 protein was observed by flow cytometry in all tested AML cells with knockdown being time and concentration dependent. CD45 knockdown was observed as early as 1-day post-transfection and persisted for 7 days before gradually returning towards baseline. Greater than 82.5% knockdown was observed 4 days after 100nM siRNA-LNP treatment in all tested cell lines. LNP 1-28 had no effect on cell growth and viability. Using the low passage primary AML culture model 8227 cells, we demonstrated that LNP 1-28 could deliver siRNA to both bulk and CD34+/CD38- stem populations of AML. Finally, LNP 1-28 efficiently transfected primary AML patient samples and delivered siRNA to knock down CD45.

In summary, we developed a novel LNP formulation capable of transfecting AML cells and primary AML samples with siRNA at high efficiency and without toxicity. Thus, we have developed a nanocarrier system for *in vitro* transfection that will aid in functional genomics studies of AML.

#1793 Pre-targeting with in vivo click chemistry enables preferential drug exposure in tumors versus normal tissues.

Travis L. Biechele, Masa Aleckovic, Stefanie Wagner, George Coricor, Sangeetha Srinivasan, Tri-Hung Nguyen, Jesse M. McFarland, Nathan A. Yee, Michael Zakharian, Jose M. M. Oneto

Shasqi, San Francisco, CA

Off-target toxicity has long been a dose-limiting factor for antibody-drug conjugates (ADCs) and targeted radiopharmaceutical therapies (TRT). This fundamental limitation primarily arises due to the catabolic elimination process of both therapeutic modalities which exposes healthy tissues to cytotoxic agents. Pre-targeting offers a transformative solution to overcome these challenges as it separates the tumor-targeting and payload-delivery steps, thereby minimizing systemic exposure and maximizing on-target effects. Leveraging this concept, we present Click Activated Protodrugs Against Cancer (CAPAC®) technology as the ideal pre-targeting reunion platform.

CAPAC uses in vivo click chemistry to selectively capture drug payloads at tumors with minimal systemic exposure, thus extending the therapeutic window of targeted therapies. CAPAC employs a two-component system: 1) a clickable binder infusion targeting a tumor antigen, and 2) a subsequent infusion of a clickable payload ("protodrug"). These two components "click" at tumors, enabling delivery of high therapeutic payload to the target while sparing normal tissues.

We have generated proof-of-concept data on CAPAC using clickable binders against HER2, TROP2, and CEACAM5, which we paired with different clickable payloads, including a *trans*-cyclooctene (TCO)-modified biotin probe and a protodrug of monomethyl auristatin E (MMAE). We evaluated the anti-tumor efficacy, pharmacokinetics (PK), and biodistribution across CDX models or in tumor-free mice. Payload capture was antigen-dependent and markedly higher in tumors vs plasma and normal tissues, with tumor levels exceeding systemic levels by more than 10-fold at 8.5 hours post-infusion. Tumor payload exposure was proportional with receptor density, as the HER2-binder captured more biotin than the TROP2-binder. Slower antigen internalization (HER2, CEACAM5) extended the duration of payload exposure in tumor vs plasma compared to faster internalization (TROP2). These PK and biodistribution results validate the highly selective tumor targeting of CAPAC. Importantly, enhanced tumor payload exposure translated into significant anti-tumor efficacy with the MMAE protodrug, which achieved dose-dependent tumor growth inhibition across various CDX models. These findings underscore CAPAC's potential to overcome the limitations of off-target toxicities and extend the applicability of cytotoxic agents to poorly internalizing targets.

Our preclinical data confirm in vivo click chemistry as a powerful pre-targeting reunion technology, offering modularity to accommodate various antigen targets and payloads. By delivering targeted therapies with unprecedented precision, CAPAC fulfills Paul Erlich's vision of a truly targeted delivery system. CAPAC opens new avenues for safer and more effective cancer treatments, addressing needs are yet unmet by ADCs and TRTs.

#1794 Preclinical development of TGW101, a first in class click-cleavable ADC with MMAE against non-internalizing pan-carcinoma marker TAG72.

Raffaella Rossin[1], Martijn H. den Brok[1], Lieke W. M. Wouters[1], Joep Houkes[1], Ron M. Versteegen[2], Marleen H. M. van Stevendaal[1], Luc H. M. Zijlmans[1], Maria Cincotta[1], Jay M. Feingold[1], laurens H. J. Kleijn[1], **Marc S. Robillard**[1]

[1]Tagworks Pharmaceuticals B.V., Nijmegen, Netherlands,[2]SyMO-Chem, Eindhoven, Netherlands

Current ADCs typically rely on intracellular drug release. However, the number of suitable internalizing receptors in solid cancers is limited while there are suitable non-internalizing tumor markers, provided effective extracellular cleavage can be achieved. To expand the ADC target scope, Tagworks is pioneering a radically new approach to ADCs based on its Click-to-Release platform, which centers on selective payload release from a *trans*-cyclooctene (TCO) linker upon click reaction with a tetrazine molecule (the trigger). In this approach, following tumor accumulation and blood clearance of the click-cleavable ADC, a tetrazine trigger molecule is administered i.v. that rapidly releases the payload from the extracellular ADC, allowing it to distribute into surrounding cells, maximizing the bystander effect. The first in class click-cleavable ADC therapy TGW101 combines a tetrazine trigger (TRG001) with a click-cleavable ADC, TGW101-ADC, targeting non-internalizing tumor marker TAG72, expressed by many adenocarcinomas. The ADC comprises a 60 kD diabody, site specifically conjugated with TCO-linked MMAE at a drug to antibody ratio of 3.8. TGW101 uses a new TCO / tetrazine combination with 100-fold higher reactivity than in previous versions, allowing markedly lower trigger doses, as low as 3 mg/kg, for complete ADC conversion in mice. The purpose of this study was to characterize the anticancer activity of TGW101, and its tolerability and pharmacokinetics (PK) in the rat and non-human primate (NHP). In vitro, TGW101-ADC showed fast and quantitative release of MMAE upon reaction with TRG001. Cell killing was dependent on binding to TAG72 on the cell and extracellular reaction with TRG001. In vivo, TGW101 gave high and stable free intratumor MMAE concentrations (300 nM at 2 mg/kg ADC) and showed strong dose dependent activity in several TAG72-positive xenografts in single and repeated cycles, using a 2-day interval between TGW101-ADC and TRG001, without TGW101-related toxicity. TGW101-ADC alone was stable and very well tolerated in NHPs at repeated doses at 50 mg/kg (NOAEL) with a clearance half-life of 25h. Similarly, TRG001 was very well tolerated, with HNSTD/NOAEL of 700 mg/kg and 300 mg/kg in rat and NHP, respectively, with a half-life of 0.6h in NHP. When used in combination in NHPs, biweekly cycles of ADC followed 4 days later by a high dose of trigger (75 mg/kg) afforded an HNSTD of 5 mg/kg for TGW101-ADC (which equates to 12.5 mg/kg for mAb size), with reversible and non-adverse effects consistent with free MMAE released from residual circulating ADC by Trigger. In conclusion, TGW101 demonstrated potent and specific in vitro and in vivo anti-tumor activity, while it was well tolerated in rats and NHPs at doses at or higher than current MMAE ADCs. This warrants clinical development of this promising click-cleavable ADC with the aim to expand the ADC target scope.

#1795 Targeting the blood-brain tumor barrier with engineered tumor necrosis factor synergizes with temozolomide antitumor activity against glioblastoma.

Giulia Taie[1], Anna Maria Gasparri[1], Federica Pozzi[1], Barbara Colombo[1], Federico Rossari[2], Nadia Coltella[2], Elisa Sangiovanni[3], Giulia Anderluzzi[1], Matteo Monieri[1], Tamara Canu[4], Elisa Bruno[5], Antonello Spinelli[4], Anna Palmisano[5], Antonio Esposito[5], Andres J. M. Ferreri[6], Imane Nafia[7], Corti Angelo[5], **Flavio Curnis**[1]

[1]Division of Experimental Oncology, IRCCS Ospedale San Raffaele, Milan, Italy,[2]San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS Ospedale San Raffaele, Milan, Italy,[3]Division of Immunology, Transplantation and Infectious Diseases, IRCCS Ospedale San Raffaele, Milan, Italy,[4]Preclinical Imaging Facility, IRCCS Ospedale San Raffaele, Milan, Italy,[5]Vita-Salute San Raffaele University, Milan, Italy,[6]Department of Onco-Hematology, IRCCS Ospedale San Raffaele, Milan, Italy,[7]Explicyte Immuno-Oncology, Bordeaux, France

Background: The blood-brain tumor barrier (BBTB) is an obstacle in delivering anticancer drugs to brain tumors. Therefore, novel strategies aimed at targeting and breaching this structure are of high experimental and clinical interest. We developed a derivative of tumor necrosis factor-α (TNF) that can target and alter the BBTB. This drug, called NGR-TNF, consists of a TNF molecule fused to the Cys-Asn-Gly-Arg-Cys-Gly peptide (called NGR), a ligand of aminopeptidase N (CD13)-positive tumor blood vessels. Administration of low-dose NGR-TNF to patients with primary central nervous system lymphomas promotes BBTB alteration, increases the efficacy of R-CHOP (a chemo-immunotherapy regimen), and improves patient survival. Unfortunately, the inherent instability and heterogeneity of NGR-TNF have limited the further development of this drug. We have shown that fusing a serine to its N-terminus generates a new drug (called S-NGR-TNF) with increased stability, reduced heterogeneity and improved antitumor activity in preclinical lymphoma and sarcoma models, alone or in combination with chemotherapy.

Methods: We evaluated the antitumor activity of murine S-NGR-TNF (5 ng/kg) alone or with temozolomide (TMZ, 20 mg/kg, administered 48 h and 96 h post S-NGR-TNF) in 2 glioblastoma (GBM) mouse models. These models involved intracranial implantation of GL261 cells engineered to express Luc2 firefly luciferase (GL261-Luc2) or Luc2 firefly luciferase along with the truncated human nerve growth factor-receptor (GL261/SR-Luc2 cells). Tumor growth was monitored using bioluminescent imaging, with pharmacological treatments starting 7 d after tumor implantation and repeated every 11-13 d for 2-4 cycles. Major immune cell populations infiltrating the tumors were assessed by FACS 48 h after S-NGR-TNF administration.

Results: In the GL261-Luc2 model, S-NGR-TNF-treated mice showed a significant antitumor response compared to controls, with complete tumor regression in 4 out of 10 treated mice, while none in the control group showed a similar response. No treatment-related toxicity was observed. Cumulative results from 3 independent experiments using the GL261/SR-Luc2 model also showed significant antitumor effects. The S-NGR-TNF/TMZ combination group showed stronger antitumor effects than the groups treated with TMZ, S-NGR-TNF, or vehicle (19/30, 12/28, 12/29, and 6/28 cured mice, respectively). Analysis of GL261-Luc2 tumors after S-NGR-TNF treatment showed reduced tumor-infiltrating B lymphocytes, CD8+ T cells, Tregs and M2 macrophages.

Conclusion: S-NGR-TNF synergizes with TMZ in GBM models, potentially by decreasing tumor-infiltrating immunosuppressive cells. Further preclinical studies combining S-NGR-TNF with TMZ and radiotherapy, the current standard of care for GBM, are warranted to evaluate its clinical application potential.

#1796 Development of a CSF-1Ri liposomal formulation using a continuous manufacturing approach and design of experiments (DOE).

Asma M. AlTerawi[1], Raneem R. Aldaqqa[1], Fatemah S. Sunbul[2], David Edwards[3], Sandro R. P. da Rocha[1]

[1]Department of Pharmaceutics and Center for Pharmaceutical Engineering - School of Pharmacy, Virginia Commonwealth University, Richmond, VA,[2]Department of Respiratory Therapy, A-Mana College for Medical Sciences, Saudi Arabia, Dammam, Saudi Arabia,[3]Department of Mathematical Sciences, The Military College of South Carolina, Charleston, SC

Osteosarcoma (OS) predominantly metastasizes to the lungs, with approximately 20% of patients presenting detectable osteosarcoma lung metastases (OSLM) at first diagnosis, while most of the other patients are expected to have undetectable lung micrometastases. OSLM is associated with a 5-year survival rate of only 20%, which not improved over the past four decades. Current OSLM pharmacotherapies are not curative, and experimental immune checkpoint inhibitor therapies have shown minimal efficacy. PLX-3397 (PLX), an FDA-approved colony-stimulating factor-1 receptor inhibitor (CSF-1Ri), targets tumor-associated macrophages (TAMs) in solid tumors, offering a promising strategy to support standard of care in OSLM. However, systemic administration of PLX is limited due to poor tissue distribution and serious off-target toxicities. This study aimed to develop a clinically translatable liposomal PLX (L-PLX) suspension for localized lung delivery via nebulization. A scale-independent continuous manufacturing process and a Design of Experiments (DOE) approach were employed to optimize L-PLX formulations to meet the Quality Target Product Profile (QTPP). Critical quality attributes (CQAs), including hydrodynamic diameter (HD), polydispersity index (PDI), zeta potential (ζ), drug encapsulation efficiency (EE%), and drug loading (DL%), were evaluated. Optimization was performed using A-Optimal DOE with 24 runs, assessing material attributes (MAs) such as Lipid-to-PLX (L:D) ratio and aqueous medium composition, alongside process parameters (PPs) including total flow rate, temperature, and flow rate ratio (FRR).The optimized formulation showed excellent model adequacy with R-squared and adjusted R-squared values of 0.995493 and 0.990575, respectively, confirming its predictive accuracy for particle characteristics. Key factors identified were FRR, L:D ratio, and heating. The optimal formulation, with a L:D ratio of 5, PBS as the aqueous phase, FRR of 5, and room temperature, was validated experimentally, aligning predicted and observed outcomes for particle size, PDI, EE%, and DL%. After additional purification via Tangential Flow Filtration (TFF) to reduce ethanol content to 0.5%, and sterilization, the final product remained stable for over three months at 2-8 ºC, showing consistent HD, PDI, and zeta potential. Aerosol characteristics, tested with a hand-held nebulizer, maintained HD/PDI, suggesting compatibility with pulmonary delivery. Particle size distribution was similar to Arikayce®, the only FDA approved inhaled nanoformulation for lung administration. *In vitro* experiments with RAW 264.7 macrophages polarized to an M2-like phenotype showed that L-PLX reduced M2-like phenotype, confirming its potential to modulate TAM phenotypes while retaining therapeutic activity. These results highlight L-PLX as a promising candidate for OSLM therapy.

#1797 Dendrimer cisplatin and salinomycin complexes as a new combination therapy for ovarian cancer.

Sridharan Jayamohan[1], Sushesh Srivatsa Palakurthi[2], Jessica D. Johnson[1], Salvador C. Alejo[1], Prabhakar P. Venkata[1], Diksha Jamwal[1], Suryavathi Viswanadhapalli[1], Rajeshwar R. Tekmal[1], Edward Kost[1], Ratna K. Vadlamudi[1], Srinath Palakurthi[2], **Gangadhara R. Sareddy**[1]

[1]Obstetrics & Gynecology, UT Health Science Center at San Antonio, San Antonio, TX,[2]Department of Pharmaceutical Sciences, Texas A&M University, Kingsville, TX

Background: Ovarian cancer (OC) is the most lethal gynecologic cancer that initially responds to platinum-based therapy but often becomes resistant, leading to high mortality rates. Given the heterogeneity of OC, it is critical to develop a safe and effective drug combination that targets different tumor cell populations, including chemosensitive, resistant, and cancer stem cells (CSCs). In this study, we evaluated the efficacy of nanocarriers designed to specifically target CD44-expressing OC cells utilizing hyaluronic acid (HA)-conjugated poly(amidoamine) (PAMAM) dendrimer complexes of cisplatin and salinomycin to treat OC. Methods: The efficacy of HA-dendrimer-cisplatin (HA-CIS) and HA-dendrimer-salinomycin (HA-SAL) nanoformulations on cell viability, survival, and apoptosis of established and patient-derived OC cells were examined by Cell Titer Glo, colony formation, and Annexin V assays, respectively. Stemness and self-renewal of CSCs were examined using sphere formation and extreme limiting dilution assays. Mechanistic studies employed RNA-sequencing, RT-qPCR, Western blotting, and immunohistochemistry. The effect of combination therapy on DNA double-strand break (DSB) repair was determined using gH2AX, RAD51 foci, and comet assays. Orthotopic, PDX, and PDEX models were used for the preclinical evaluation.
Results: The combination of HA-CIS and HA-SAL synergistically reduced the cell viability, survival, and self-renewal and promoted apoptosis of OC cells. RNA-seq studies showed that HA-CIS upregulates the DNA-DSB repair pathway, specifically homologous recombination (HR). However, combination treatment resulted in the attenuation of HR. Accordingly, combination therapy significantly decreased the DNA repair ability of OC cells, which was evident from increased gH2AX foci formation and reduced RAD51 foci formation. Further, comet assays demonstrated enhanced DNA damage with combination treatment compared to monotherapy. Importantly, the combination treatment of HA-dendrimer-CIS and HA-dendrimer-SAL significantly reduced tumor progression in orthotopic intrabursal models and in patient-derived xenograft (PDX) and explant (PDEX) models.
Conclusions: Our results establish that HA-dendrimer-CIS and HA-dendrimer-SAL combination therapy may represent a novel therapeutic combination for treating OC.

#1798 K-679: A novel, ultra-high-DAR antibody drug-loaded unimicelle conjugate (ADUC) enabling more effective treatment in EGFR-expressing solid tumors compared to general ADCs.

H. Yoshida, K. Suzuki, K. Hosono, N. Fujimaki, M. Tamiya, M. Shiraishi, H. Higashi, M. Mori;
Kowa Company, Ltd., Tokyo, Japan

Background: Conventional antibody-drug conjugates (ADCs) face significant challenges in treating solid tumors due to heterogeneous antigen expression or low antigen levels, resulting in suboptimal targeting and reduced therapeutic efficacy. While increasing the drug-to-antibody ratio (DAR) could enhance efficacy, traditional high-DAR approaches often compromise pharmacokinetics due to increased hydrophobicity and molecular size. To address these limitations, we engineered a novel platform technology: a compact, 20-nm antibody drug-loaded unimicelle (unimer-micelle) conjugate (ADUC) utilizing single-chain polymer nanoparticles. This platform achieves an unprecedented DAR of approximately 40 while maintaining favorable physicochemical properties. Using this platform, we developed K-679, which combines cetuximab with DM1-loaded unimicelles.
Methods: Antigen-binding specificity and cellular internalization of K-679 were evaluated using surface plasmon resonance, flow cytometry, and fluorescence microscopy. In vitro cytotoxicity, in vivo anti-tumor activities, pharmacokinetics, and biodistribution were investigated in multiple human cancer cell lines and xenograft models. The bystander killing effect was quantified using an in vivo imaging system in mice co-inoculated with EGFR-positive and luciferase-expressing EGFR-negative cells. The benchmark ADCs were prepared by conventional conjugation of cetuximab with DM1.
Results: K-679 exhibited EGFR-binding affinity equivalent to that of unconjugated cetuximab, efficient cellular internalization, and triggered cell-cycle arrest, apoptosis, and cell-growth inhibition in EGFR-positive cells, even in chemotherapeutic drug-resistant lines. In vivo studies demonstrated superior tumor-targeted delivery compared to conventional antibodies, and efficient payload release in tumors with minimal DM1 levels in circulation. This resulted in potent anti-tumor effects across multiple EGFR-positive tumor xenograft models, while showing no activity in EGFR-negative models. These observations reveal that K-679 mediates its anti-tumor effects in an EGFR-dependent manner through DM1-mediated cytotoxicity. Notably, K-679 showed significant bystander killing of EGFR-negative cells within heterogeneous tumors and exhibited efficacy in EGFR-low tumor models in which benchmark ADCs proved ineffective. Comparative studies further highlighted that K-679 outperformed lower-DAR variants at equivalent payload doses.
Conclusion: Our findings establish K-679 as a promising therapeutic candidate for heterogeneous EGFR-expressing solid tumors, characterized by a more potent anti-tumor effect through an exceptionally high DAR, enhanced drug accumulation into tumors and significant bystander effect.

#1799 Harnessing the GlycOBI® enabling technologies: next-generation site-specific glycan ADCs with versatile DAR to enhance therapeutic index.

Teng-Yi Huang, Ka-Shu Fung, Yu-Chao Huang, Chi-Sheng Shia, Chi-Huan Lu, Nan-Hsuan Wang, Ya-Chi Chen, Ming-Tain Lai

OBI Pharma, Inc, Taipei, Taiwan

The GlycOBI® enabling technologies represent a novel approach for the development of antibody-drug conjugate (ADC) to achieve site-specific glycan conjugation through the proprietary dual-action enzyme EndoSymeOBI®. This innovative technology is capable of attaining homogeneous ADC at specific drug-to-antibody ratio (DAR) while maintaining antibody integrity and function. A key feature of the technology is its exclusive linker, which has a unique design to enhance payload stability and enable selective release in the tumor microenvironment, thereby potentially broadening the therapeutic index. The ADCs that use the GlycOBI® enabling technologies are shown to be highly homogeneous while achieving uniform DAR configurations. These next generation ADCs, combined with optimized and novel linker designs, exhibit superior pharmacokinetics, stability, and antitumor activity compared to conventional ADCs in various animal models. The technology supports mono-specific and multi-specific antibodies, expanding its versatility for various therapeutic modalities. The flexibility of DAR configurations and proprietary linker design further demonstrate the technologies' adaptability across diverse payload classes, including cytotoxic agents, immunomodulators, and degraders. In preclinical models, OBI-902 (TROP2 GlycOBI® DAR4 ADC) and OBI-904 (Nectin-4 GlycOBI® DAR8 ADC), both using Exatecan, a potent topoisomerase 1 inhibitor as the payload, have demonstrated promising antitumor activities. Notably, OBI-904, with its DAR8 format, exhibits superior activities in animal models, including in low antigen expressing tumor models, compared to approved and other benchmark Nectin-4 ADCs. Further, both ADCs maintained their stability and avoided antibody aggregation. Both candidates are targeted for IND submissions in 2025, representing an important milestone in advancing the GlycOBI® ADCs to the clinics. The integration of glycan engineering, EndoSymeOBI®, and a novel linker design establishes the GlycOBI® suite of technologies as a robust and adaptable solution to address the current ADC limitations. These advancements underscore its transformative potential in driving the next generation of therapeutics.

#1800 BL0175: An intramuscular nano-conjugate of fulvestrant, exhibits superior tumor distribution and antitumor efficacy compared to fulvestrant injection in MCF-7 xenograft mouse model.

Haoyuan Jiang, Xianjie Chen, Yuxiang Shao, Fuyao Zhang

Shanghai Best-Link Bioscience, LLC, Shanghai, China

Background: Breast cancer (BC) was the most commonly diagnosed cancer and the second leading cause of cancer death among women worldwide. Fulvestrant injection was the first approved SERD (selective estrogen receptor degrader) for metastatic/advanced HR positive (HR+) breast cancer. Although the clinical efficacy of fulvestrant has been defined, its higher efficacy has not been achieved due to several inherent disadvantages, such as low solubility, poor pharmacokinetics (PK), injection site pain with oil-based concentrate formulation. To overcome these drawbacks, we developed a novel nano-conjugate candidate BL0175 for targeted delivery of fulvestrant. BL0175 is highly water-soluble and has a low viscosity intramuscular formulation with high drug loading, which can result in improved efficacy along patient compliance compared to original formulation of fulvestrant. In this preclinical study, we evaluated the efficacy as well as PK/PD properties of BL0175 in MCF-7 xenograft model.
Methods: PK/PD study was performed in MCF-7 xenograft model in a 336 h-period. The drug of fulvestrant concentration was determined in plasma and tumor tissue at different time points. MCF-7 (human BC) tumor fragments were implanted subcutaneously in NOD/SCID mice. Three doses of BL0175 (containing 25, 50 and 100 mg/kg of fulvestrant) or fulvestrant injection(100 mg/kg) were administered subcutaneously (s.c.) weekly for 3 weeks.
Results: In the PK/PD experiments, BL0175 showed excellent pharmacokinetic properties. The 336-h tumor AUC of released fulvestrant from BL0175 was 140 times higher than fulvestrant injection in tumor tissue. The tumor-accumulation efficiency (AUC_{Tumor}/AUC_{Plasma}) of fulvestrant released from BL0175 was 210, which was 21 times higher than that of fulvestrant injection. In the MCF-7 xenograft model, BL0175 had much better efficacy than fulvestrant injection as monotherapy. All three treatment groups of BL0175 showed strong efficacy (TGI 75.1% at 25 mg/kg, 81.0% at 50 mg/kg, 87.3% at 100 mg/kg, $p < 0.001$) compared to fulvestrant injection (TGI 36.7% at 100 mg/kg, $p < 0.001$) on day 28. Furthermore, BL0175 was safe and well tolerated without sign of clinical toxicity and body weight loss.
Conclusions: BL0175 is a unique preclinical nano-drug candidate that exhibited remarkedly enhanced tumor retention and excellent pharmacokinetic properties compared to fulvestrant injection. Furthermore, BL0175 demonstrated superior anti-tumor efficacy against fulvestrant injection in breast cancer. The pre-clinical efficacy and safety studies supported its further development in the clinical stage for HR+ breast cancer therapy.

#1801 Development and evaluation of KMD111: A HER2-targeted novel drug delivery system for gastric and breast cancer therapy.

Jong Kook Rho, Gyeong Hee Lee, Seung Min Byun, Hyo Kyoung Park, JinBeam Kim, YoungKuk Yun, Myung Hoon Kim

KMD Bio Co., Ltd., Daejeon, Korea, Republic of

Background: HER2-low expressing cancers, including gastric and breast cancers, have historically been categorized as HER2-negative, limiting targeted therapy options. To address this, we developed KMD111, a novel HER2-targeted drug delivery platform using mesoporous silica nanoparticles (MSNs) loaded with a potent anticancer drug and coated with HER2-targeting affibody proteins via a glutathione-sensitive GST-GSH bio-linker. KMD111 demonstrated high tumor-targeting efficiency, superior anti-tumor efficacy, and a favorable safety profile in preclinical models, providing stability in the bloodstream and selective drug release regulated by GSH concentrations in the tumor microenvironment.
Methods: KMD111 was synthesized by conjugating HER2-targeting affibody proteins to drug-loaded MSNs. Binding affinity and internalization were assessed in HER2-expressing cancer cell models. Anti-tumor efficacy was evaluated in gastric and breast cancer xenografts, while mechanistic studies examined cell cycle arrest, apoptosis activation, and HER2 signaling inhibition. Safety was evaluated through macrophage uptake, histopathological analysis, and toxicity testing.
Results: KMD111 demonstrated efficient drug loading and GSH-responsive drug release in vitro, with high tumor-targeting efficiency and strong internalization in HER2-expressing cancer cells. It exhibited superior anti-tumor efficacy compared to Enhertu®, Kadcyla®, and Cyramza® and effectively triggered cell cycle arrest and apoptosis activation through a potent anticancer drug. KMD111 also showed a favorable safety profile, including minimal macrophage uptake, negligible myelosuppression, and no significant off-target toxicity, with a therapeutic index exceeding five times the effective dose.
Conclusion: KMD111 demonstrates robust targeting, high therapeutic efficacy, and a favorable safety profile in HER2-expressing gastric and breast cancer models. This innovative approach, leveraging a glutathione-regulated bio-linker for enhanced delivery and tumor specificity, represents a promising foundation for next-generation drug delivery systems targeting HER2-expressing malignancies.

#1802 Exosomes-mediated oral gene delivery to treat lung cancer.

Raghuram Kandimalla[1], Margaret Wallen[2], Disha N. Moholkar[1], Jeyaprakash Jeyabalan[2], Wendy Spencer[2], Farrukh Aqil[3], Ramesh C. Gupta[4]

[1]Brown Cancer Center, Department of Pharmacology & Toxicology, University of Louisville, Louisville, KY,[2]3P Biotechnologies Inc., Louisville, KY,[3]Brown Cancer Center, Department of Medicine, University of Louisville, Louisville, KY,[4]Brown Cancer Center, Department of Pharmacology & Toxicology, University of Louisville, 3P Biotechnologies Inc., Louisville, KY

Gene therapy is an emerging field in cancer therapeutics that targets specific proteins to control cancer cell proliferation. In recent years, several attempts to treat lung cancer using gene therapy have shown promise, but clinical translatability remains a significant challenge. Factors such as immunogenicity, toxicity, inflammatory responses, and cost-effectiveness hinder the widespread use of gene delivery vectors. Oral delivery of genes could potentially address these challenges; however, achieving therapeutic dosages at the targeted site is difficult due to the degradation of nucleic acids in the gastrointestinal tract before reaching systemic circulation. In the current study, we report a novel exosome-polyethyleneimine (PEI) matrix (EPM) for the oral delivery of nucleic acid therapeutics (siRNA) to treat lung cancer. Exosomes were isolated from bovine colostrum powder by rehydration and differential centrifugation. The tumor-targeting ligand folic acid (FA) was covalently attached to the exosome surface via click chemistry, while PEI was conjugated through ionic interaction to form FA-EPM. The siRNA entrapment efficiency by EPM was found to be more than 90% of the supplied siRNA (up to 20 µg). The transfection efficiency of EPM-siRNA was assessed *in vitro* via western blot analysis, determining KRAS and NRF2 knockdown in human lung cancer cells (A549). Results demonstrated that EPM-si*KRAS* and EPM-si*NRF2* suppressed KRAS and NRF2 expression by 70-80% in A549 cells in a dose-dependent manner. The therapeutic efficacy of orally administered EPM-si*NRF2* and FA-EPM-si*KRAS* was tested in subcutaneous and orthotopic lung tumor xenografts generated in nude and nod scid mice, respectively. The EPM-si*NRF2* formulation inhibited subcutaneous lung tumor growth by 59% compared to control animals ($p < 0.01$), matching the tumor inhibition by the same formulation administered intravenously. Additionally, orally administered FA-EPM-si*KRAS* inhibited orthotopic lung tumor growth by 74% ($p < 0.01$) accompanied with >80% downregulation of the tumor KRAS expression level. This study demonstrated that colostrum exosome-based EPM technology effectively delivers siRNA to tumor sites when administered orally, achieving significant gene knockdown and lung tumor suppression. These findings suggest a simple and effective exosome-based oral gene delivery strategy for cancer therapeutics.

#1803 Exosome-encapsulated PD-L1 siRNA reduces tumor growth by modulating the tumor-associated macrophages.

Raghuram Kandimalla[1], Omar S. Sarkar[2], Disha N. Moholkar[3], Margaret Wallen[4], Chuanlin Ding[5], Kavitha Yaddanapudi[6], Ramesh C. Gupta[7], Farrukh Aqil[8]

[1]Brown Cancer Center, Department of Pharmacology & Toxicology, University of Louisville, Louisville, KY,[2]Department of Microbiology and Immunology, University of Louisville, Louisville, KY,[3]Brown Cancer Center, Department of Pharmacology & Toxicology, University of Louisville, Louisville, KY,[4]3P Biotechnologies Inc., Louisville, KY,[5]Brown Cancer Center, Department of Surgery, University of Louisville, Louisville, KY,[6]Brown Cancer Center, Department of Microbiology and Immunology, Department of Surgery, University of Louisville, Louisville, KY,[7]Brown Cancer Center, Department of Pharmacology & Toxicology, 3P Biotechnologies Inc.; University of Louisville, Louisville, KY,[8]Brown Cancer Center, Department of Medicine, University of Louisville, Louisville, KY

Immunotherapy, a rapidly advancing cancer treatment, influences the patient's immune system to combat tumors. However, cancer cells evade T-cell immunosurveillance by overexpressing PD-L1 on their surfaces. Additionally, tumor-associated macrophages (TAMs) further complicate the therapeutic efficacy of immune checkpoint inhibitors (ICIs) within the tumor microenvironment. The success of immunotherapy in solid tumors is limited to 20-45%, primarily due to tumor heterogeneity, an immunosuppressive tumor microenvironment, and inefficient tumor-specific trafficking of therapeutics. In this study, we developed an exosome-polyethyleneimine matrix (EPM) nanoplatform functionalized with a tumor-targeting ligand, folic acid (FA-EPM), for the targeted delivery of PD-L1 siRNA to the lung tumor. This approach efficiently silences PD-L1 expression on both tumor cells and TAMs. Exosomes were isolated from bovine colostrum through rehydration and differential centrifugation processes, resulting in exosomes with an average particle size of 66±2.5 nm, a zeta potential of -9.6 mV, and a polydispersity index (PDI) of 0.28. The entrapment efficiency of siPD-L1 within the EPM matrix exceeded 90%. siPD-L1 sequences with specificity for mouse and human PD-L1 were screened *in vitro* against LLC and A549 cells, respectively. Protein lysate analysis revealed that EPM-siPD-L1 significantly downregulated PD-L1 expression in LLC-1 cells (up to 80%) and in A549 cells (>80%). The most effective siPD-L1 candidate from the *in vitro* studies was tested *in vivo* in C57BL/6 mice bearing orthotopic lung tumor xenografts established with LL/2-Luc2 cells (50 × 10^3 cells/mouse). Tumor-bearing mice were divided into three groups (n = 7-9) and treated intravenously with vehicle, FA-EPM-scrambled siRNA, or FA-EPM-siPD-L1 (15 µg/dose). Tumor growth was monitored twice weekly using bioluminescence imaging. FA-EPM-siPD-L1 treatment significantly reduced tumor growth (>70%; $p < 0.01$) compared to vehicle or scrambled siRNA-treated mice. Additionally, a significant reduction in tumorous lung weight (~60%; $p < 0.01$) was observed in the FA-EPM-siPD-L1 group. At euthanasia, tumorous lungs were processed into single-cell suspensions and analyzed for myeloid and T-cell markers using flow cytometry. The tumor reduction was found to be associated with the marked reduction in PD-L1 expression, a significant depletion of immunosuppressive TAMs and increased levels of anti-tumoral gamma delta T cells. In summary, these results demonstrate that EPM-mediated delivery of siPD-L1 enhances immune surveillance, effectively inhibits lung tumor progression, and establishes EPM as a promising nanoplatform for delivering siRNA-based therapeutics.
Funding: Supported by Immunotherapy CCII CoBRE pilot project (P20GM135004) and the Agnes Brown Duggan Endowment.

#1804 An innovative dual-payload ADC combining topoisomerase 1 inhibitor and a tubulin inhibitor efficiently overcomes drug resistance.

Ailin Shan, Chun Deng, Peng Zou, Shuai Song, **Jiaqiang Cai**, Tongtong Xue

MediLink Therapeutics (Suzhou) Co., Ltd., Suzhou, China

Antibody Drug Conjugates (ADC) have achieved great success as anti-cancer therapies, with 15 ADC drugs approved in global market. Despite the initial response to ADC treatment, drug resistance and tumor relapse inevitably happen due to the high heterogeneity in advanced tumors. The mechanism of resistance can be due to downregulation of drug targets, upregulation of multi-drug resistance mechanisms, such as ABCB1/ABCG2 and others. Overcoming these resistance mechanisms are a big challenge to next-generation ADC development for cancer therapy. To address these challenges, MediLink has developed an innovative dual-payload ADC with two payloads of different MOAs: a topoisomerase 1 inhibitor and a tubulin inhibitor. Two conjugation methods were developed: (1) Tubulin inhibitor payload-linkers were conjugated at specific lysine sites of antibody while Topo1i payload-linker were conjugated with free cysteine thiols via TMALIN® Technology, resulting in a dual-payload ADC with DAR of 2 and 8 for each payload-linker, respectively. (2) Reduced antibody conjugates with pre-mixed or step wisely added Topo1i payload linker and Tubulin payload linker in different proportions to obtain any desired ratio of the two different payloads. ADC characterization showed good stability, homogeneity and precise DAR values for the conjugation of both payload-linkers to Trastuzumab. In vitro, the dual-payload Her2 ADC demonstrated strong cytotoxicity against tumor cells with different levels of Her2 expression, especially in cells overexpressing ABCB1 and ABCG2, and Enhertu-resistant tumor cells. In vivo, the dual-payload ADC exhibited superior efficacy in Enhertu-resistance CDX model and Her2 low CDX models. In summary, we developed dual-payload ADCs with intention for resolving topo1 inhibitor induced tumor resistance issues. The dual-payload Her2 ADC demonstrated potent in vitro and in vivo anti-tumor activities, showing the potential to overcome the multidrug resistant mechanism and Enhertu resistance.

#1805 Dual-payload TME-activated ADC platform.

Cheng Liu, Yuan Liu, Rui Zhang

Affinity Biopharmaceutical Co., Ltd., Shanghai, China

The combination of Antibody-Drug Conjugates (ADCs) and Immuno-Oncology (IO) agents is regarded as one of the most exciting and promising trends in the rapidly evolving field of cancer treatment. Affinity Biopharma has developed the Tumor MicroEnviroment Activated (TMEA) platform, with proprietary TMEA linkers applicable in both Small Molecule Drug Conjugates (SMDCs), ADCs and dual-payload ADCs. The TMEA linkers could achieve extracellular activation of payloads in the Tumor MicroEnviroment (TME) by a tumor-specific protease Legumain (AEP), which is an acid endopeptidase with tumor site over-expression and a strict specificity for one particular amino acid (Asn), making it a first-in-class, highly specific and pan-solid tumor target in novel drug design. Compared to GGFG linkers cleaved by lysosomal enzymes such as cathepsins B and L, the TMEA linkers exhibited superior stability in human plasma at 37℃, and demonstrated higher cleavage efficiency under identical condition in tumor homogenates (pH=6.5), generating a remarkably clean cleavage profile with minimal to no inactive intermediates. Such advantageous characteristics of TMEA linkers could be supported by a TMEA-SMDC drug Legubicin in clinical trial that releases payload Doxorubicin. For dual-payload TMEA-ADCs, each hydrophilic TMEA linker is paired with two insoluble payloads such as TLR7/8 agonists and topoisomerase I inhibitors, which show similar maximum tolerated doses (MTD) in mice as linker-single-payload. Dual-payload TMEA-ADCs have effectively addressed the CMC challenges and enabled homogenous formation of 8-DAR dual-payload design. In various PBMCs-CDX models, dual-payload TMEA-ADCs such as IMD526 (HER2-ADC), IMD2126 (PD-L1-ADC) and IMD2113 (EGFR&TROP2-ADC) have displayed significant dose-dependent antitumor activities and induced complete tumor regressions with no observable toxicities. Compared to mono- or combo treatments with single-payload ADCs, IMD526 validated its superiority in the *in-vivo* CT26-HER+ syngeneic mouse model, and long-term elimination of detectable tumors was achieved with IMD526 both alone and combined with IMD101 (a TMEA-Cytokine releasing IL-2). In tumor re-challenge studies, mice that were cured exhibited immune memory and were resistant to tumor re-implantation. In non-human primate (NHP) studies, dual-payload TMEA-ADCs showed excellent stability in circulation and a strong safety profile, indicating a greatly expanded therapeutic window. And different from the tumor cell endocytosis activation by GGFG-DXd ADCs, the bio-distribution of TMEA-ADCs resulted in faster and higher levels of payload accumulation in the tumor local tissues. In summary, by integrating antibody targeting, TME activation, cytotoxic therapy, and I/O therapy into one single molecule, the dual-payload TMEA-ADCs has demonstrated the synergistic effects of ADCs conjugated with 16 insoluble payloads from 2 distinct mechanisms of action in tumor models.

#1806 Cymirafen: A protein-drug conjugate that target LGR4/LGR5/LGR6-positive cancer stem cells.

M. Mulero Roig, S. A. Jadhav, W. Pi, O. Tai, S. B. Howell;
UCSD Moores Cancer Center, La Jolla, CA

INTRODUCTION: Cancer stem cells (CSC) are often drug-resistant and the source of recurrence; their destruction is a major therapeutic goal. LGR4/LGR5/LGR6 mark active stem cells and highly expressed in many solid cancers. Cymirafen consists of a human IgG1 Fc domain fused to the receptor-binding domains of RSPO1. The sortase reaction is used to site-specifically conjugate cleavable Gly_3-val/cit-PAB-MMAE linkers to the C-terminal ends of the two chains through the formation of a highly stable peptide bond. We report here pre-IND studies that support the further development of cymirafen.

METHODS: The protein component of cymirafen is constitutively produced by a stable CHO-K1 clone. Kd values were determined by ELISA using recombinant human and cynomolgus LGR5-His. In vitro growth rate inhibition assays used the CCK8 reagent. CDX models used SC implantation. Plasma cymirafen was measured by ELISA using antibodies to different RSPO1 epitopes for capture and detection. Free MMAE in plasma was determined by LC-MS/MS.

RESULTS: Cymirafen binds to human and cynomolgus LGR5 with Kd of 0.27 and 0.38 nM, respectively**.** Its DAR is in the range 1.8-2.0. Across a panel of human cancer cell lines of multiple types, 76% had an IC_{50} of <10 nM, and in 36% IC_{50} was <5 nM. Against pairs of isogenic LGR5-low and LGR5-high OVCAR8 and HEK293 cells, cymirafen exhibited a 1.5 log differential IC_{50} in vitro. When grown as CDX, cymirafen was >2-fold more effective against OVCAR8/LGR5 than OVCAR8/EV. On a dose schedule of 85 mg/kg q7dx4, cymirafen was well tolerated in mice and active in CDX models of multiple types of cancer (colon, gastric, ovarian, neuroblastoma). Only 0.001, 0.002 and 0.013% of the MMAE was released from cymirafen in human, rat and cynomolgus plasma during 96 h at 37°C. MTD in mice is ~128 mg/kg. A dose-ranging study in rats identified a single dose STD_{10} of 75 mg/kg. Serum chemistries disclosed no organ dysfunction. Adverse events were limited to dose-related neutropenia > thrombocytopenia with recovery by two weeks at all doses. Initial and terminal plasma half-lives were 0.8 and 21.5 h; PK was close to linear over the range of 30 - 75 mg/kg. In SKNAS CDX tumors, cymirafen peaked at 4 h and remained above the IC_{50} value for this tumor for ~24 h.

CONCLUSIONS: Cymirafen targets tumors with increased levels of LGR4, LGR5 and potentially LGR6, and co-receptors RNF43 and ZNRF3; an ADC can target only one receptor at a time. This favors greater control of drug resistance and recurrence. Unlike MMAE ADCs with long half-lives and cumulative toxicity, cymirafen delivers MMAE to tumors at high concentrations over a shorter period of time. It has a much higher normalized MMAE content than MMAE-containing ADCs. This permits administration of much higher doses on a well-tolerated weekly schedule. These features distinguish cymirafen from all MMAE ADCs and support its further development as a stem cell-targeted therapeutic.

#1807 Distribution, fate, inhalation exposure of nanoparticles: advancing noninvasive strategies for lung cancer treatment.

Rahul Tiwari, Meghana Kolli, Neeraj Chauhan, Eswara N Ghali, Iris Enriquez, Vivek Kumar Kashyap, Subhash Chauhan, Murali Yallapu

The University of Texas Rio Grande Valley, McAllen, TX

Background: Lung cancer remains the leading cause of cancer-related morbidity and mortality worldwide, including in the United States. Noninvasive nebulized inhalation represents a promising therapeutic strategy for lung cancer, offering enhanced nanoparticle targeting efficiency and prolonged retention within lung tissue. Gambogic acid is an experimental chemotherapeutic agent for lung cancer. Suboptimal biodistribution, and multi-targeting properties can lead to significant systemic toxicity challenges. To mitigate these undesirable side effects and improve clinical translation, nanotechnology-based strategies offer a promising solution. This study aims to develop inhalable nanoparticles (INPs) for effective delivery of therapeutic agents in lung cancer cell lines and *in-vivo* models.
Methods: INPs were synthesized via solvent evaporation and self-assembly and characterized for particle size, drug loading efficiency, and drug release using various analytical methods. Their cellular uptake, intracellular distribution, and colocalization efficacy of INPs were assessed in 2D and 3D lung cancer cell line (A549 and NCI-H1299) models using flow cytometry and confocal microscopy. The fate and biodistribution of INPs were monitored using live animal imager at 24 and 48 hrs post-treatment. The accumulation of INPs in lung tissue was evaluated using in vivo, ex vivo, and microscopy methods. The therapeutic efficacy evaluation of gambogic acid encapsulated INPs was evaluated through in vitro assays, using cell proliferation, clonogenicity, migration, and apoptosis assays.
Results: The developed INPs exhibited an average size of approximately 110 nm based on dynamic light scattering measurements. These formulations exhibited notable mucoadhesion and mucopenetration potential in-vitro models. Drug release experiments displayed a sustained and higher drug release at lysosomal pH (pH 5.0) compared to pH environment (pH 7.4), attributed to the pH-sensitive bonding. The gambogic loaded INPs were confirmed to have superior inhibitory effects on cellular proliferation, colony formation, and migratory characteristics of lung cancer cells. Biodistribution analysis of INPs in mice demonstrated that the particles were predominantly concentrated in lung tissues, with minimal distribution to other organs. Immunohistochemistry and blood chemistry analyses indicate that the INPs possess biologically safe properties.
Conclusions: This study confirms the potential of INPs a novel therapeutic modality for lung cancer treatment. The INPs formulation demonstrated superior therapeutic benefits, including improved drug delivery, enhanced cellular uptake, and increased anti-cancer efficacy across various lung cancer models. These findings suggest that INPs could serve as an innovative therapeutic modality for the treatment of lung cancer.

#1808 Engineering lipid-polymer nanoparticles for siRNA delivery to breast cancer cells.

Abdulelah Alhazza[1], Arthur Manda[1], Hamidreza Montazeri Aliabadi[1], Hasan Uludag[2]

[1]Chapman University, Irvine, CA,[2]University of Alberta, Edmonton, AB, Canada

RNA interference (RNAi) is a powerful tool that can specifically target the expression of virtually any protein without the expensive and time-consuming drug development studies. Despite the initial excitement and extensive efforts, the potential impact of RNAi approaches is yet to be materialized fully in clinical settings. This is mainly due to the challenges in delivering RNA molecules. Lipid nanoparticles (LNPs) have been the leading delivery system for nucleic acids, an achievement established by introducing the first FDA-approved small interfering RNA (siRNA) drug and COVID-19 vaccine to clinics. However, targeted delivery to a solid tumor still eludes the developed LNPs. On the other hand, polymers are among the oldest delivery systems for nucleic acids, and polyethyleneimine (PEI) was once considered the gold standard in nucleic acid delivery. In this study, we introduce a novel lipid-polymer nanoparticle (LPNP) platform, meticulously engineered for targeted delivery of siRNA to cells implicated in breast cancer. We hypothesized that specially designed low molecular weight PEIs can partially or completely replace the ionizable lipids for a more accommodating structure for additional moieties, which could lead to a safer and more efficient nucleic acid delivery. We first optimized the LNP formulations as a point of reference for cellular uptake, cytotoxicity, and protein silencing efficiency, employing sophisticated designs facilitated by the Design-Expert software. Leveraging the optimal LNP formulation, we integrated specifically designed cationic polymers as partial or complete replacements for the ionizable lipid. This methodological approach, incorporating optimal combined designs and response surface methodologies, refined the LPNPs to an optimal efficiency. Our results indicate that these refined LPNPs enhance the delivery of siRNA, leading to efficient gene silencing in targeted cancer cells. The improved delivery efficiency not only underscores the potential for specific therapeutic applications, but also suggests a broader utility for this platform in various cancer treatments.

#1809 The role of HyDIFFUZE^{TM} in co-formulation with subcutaneous infliximab.

Younseo Oh, Hyungip Kim, Heeyoun Kim, Donghwan Kim, Boyoung Park, Juyoung Byun, Chaeyoung Lim

Huonslab Co., Ltd, 17, Changeop-ro, Sujeong-gu, Seongnam-si, Gyeonggi, Korea, Republic of

Background : Recombinant human Hyaluronidase PH20 (rHuPH20) is an enzyme that degrades subcutaneous (SC) hyaluronan and has been used as a drug dispersion agent to optimize the SC delivery of co-formulated therapeutic antibodies. HyDIFFUZE^{TM}, a stand-alone rHuPH20 is under development as a dispersion agent and tissue permeation modifier for co-formulated drugs in the stage of the registration study(N=243) in S. Korea. Recently, SC formulation of Infliximab, a tumor necrosis factor inhibitor, has been approved for the treatment of autoimmune diseases. Although the therapeutic response to infliximab is strongly associated with drug exposure, the effect of HyDIFFUZE^{TM} on absorption and therapeutic response of co-formulated infliximab remains unclear. The purpose of the study was to demonstrate the applicability of HyDIFFUZE^{TM} as an effective drug dispersion agent by evaluating the effects of HyDIFFUZE^{TM} on the pharmacokinetics (PK) of co-formulated infliximab, compared to SC infliximab alone.

Methods : To investigate whether HyDIFFUZE^{TM} enhances dispersion of infliximab, PK of infliximab was analyzed after SC injection along with HyDIFFUZE^{TM} and compared with that of infliximab without HyDIFFUZE^{TM}. A single dose was administered to SD rats (n=5/group), and blood samples were collected at 12 time points over 28 days post injection. Plasma concentrations of infliximab were determined using ELISA and PK parameters were obtained by Phoenix WinNolin.

Results : In vivo PK studies showed that formulation of 84 mg/kg Infliximab combined with 1400 unit/kg HyDIFFUZE^{TM} resulted in AUC_t 127.2% and C_{max} 119.9%, compared to 84 mg/kg infliximab without HyDIFFUZE^{TM}. Furthermore, PK profiles of 63 mg/kg infliximab with HyDIFFUZE^{TM} similar to that of 84 mg/kg infliximab alone with AUC_t 105.5% and C_{max} 95.1%. These results suggest that HyDIFFUZE^{TM} might reduce the dose of infliximab required to generate equivalent therapeutic effects. Increasing the dose of Infliximab/HyDIFFUZE^{TM} resulted in a greater-than-dose-proportional increase in AUC_t, C_{max}, and $T_{1/2}$, indicating enhanced systemic drug exposure. Additionally, SC formulated of 168 mg/kg infliximab with HyDIFFUZE^{TM} showed an AUC_t approximately 90% of that achieved with IV injection of 60 mg/kg infliximab.

Conclusions : This study demonstrated that the HyDIFFUZE^{TM} significantly enhanced intravascular uptake of infliximab, with sustained therapeutic plasma concentrations of Infliximab observed over an extended duration as the dose increased. These findings suggest that combining infliximab with HyDIFFUZE^{TM} may allow enhanced systemic drug exposure even at lower dose sand potentially extend dosing intervals. Furthermore, the results presented the possibility that SC infliximab/HyDIFFUZE^{TM} may potentially replace intravenously (IV) infliximab in the induction regimen resulting in an entire treatment of induction and maintenance with SC infliximab/HyDIFFUZE^{TM} only.

#1810 Development miR-205-loaded tannic acid-stabilized liposomes for enhanced therapeutic delivery.

Victoria Herrera, Rahul Tiwari, Bridgette Lozano, Neeraj Chauhan, E N Kumar Ghali, Subhash Chauhan, Murali Yallapu

University of Texas Rio Grande Valley, Edinburg, TX

Background: The therapeutic potential of microRNAs (miRNAs) in cancer treatment has garnered significant research interest. miR-205 emerging as a promising therapeutic candidate for cancer treatment due to its tumor-suppressive properties. Despite its potential, the clinical translation of miR-205 is hindered by the lack of efficient and scalable delivery systems. Liposomal formulations offer a versatile platform for miRNA delivery, with broad applications in vaccines and anticancer therapies (e.g., mRNA, small molecule drugs). However, challenges such as large-scale production, precise size control, and unform size distribution of lipid-based drug delivery systems remain significant barriers to the widespread use in the pharmaceutical industry. This study aims to develop stable miR-205 liposome formulations for cancer therapeutics.

Methods: A microfluidics chip-based platform, leveraging commercially available microfluidic device technology, was employed to synthesize miR-205-loaded liposomes. Liposomes were produced at a total flow rate (TFR) of 10 ml/min and a flow rate ratio (FRR) of 1:3. The effect of key formulation parameters, including TFR, FRR, and total lipid concentration, on particle size and size distribution, was systematically investigated. Liposomes were also produced using a conventional method for comparative analysis. The formulations were characterized for their physiochemical properties using dynamic light scattering (DLS) and Fourier-transform infrared spectroscopy (FTIR), and their stability. The cell viability of endometrial cell lines treated with different concentrations of liposome were assessed by 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay and cell counting. Cell migration was evaluated using wound-healing assay.

Results: All liposomal formulations displayed an average particle size below 200 nm with acceptable physicochemical stability and a low polydispersity index (PDI). The microfluidic approach demonstrated superior control over liposome size and PDI compared to traditional bulk methods, highlighting its potential for scalable and reproducible production. Furthermore, miR-205-loaded liposomes produced via microfluidics exhibited robust encapsulation efficiency and effective intracellular delivery of miR-205 in cancer cell models. The in vitro functional assays confirm superior anti-cancer potential in cancer cells.

Conclusions: This study highlights the potential of microfluidic platforms as a scalable and efficient technology for manufacturing of liposomal formulation. The miR-205-loaded liposomes developed in this study showed significant promise in delivering therapeutic miRNAs to cancer cells, demonstrating the feasibility of this platform for clinical translation.

#1811 Use of lipid nanoparticles to generate CAR T cells targeting colon cancer.

Pedro Pires Goulart Guimaraes, Walison Nunes da Silva, Marco Tullio Rodrigues Alves, Pedro Henrique Dias Moura Prazeres, Gabriel Henrique Costa da Silva, Gabriel Vieira Azevedo, Maria Luiza Gomes Viana

Physiology and Biophysics, Universidade Federal de Minas Gerais (UFMG), Belo Horizonte, Brazil

Introduction: Chimeric Antigen Receptor (CAR) T cells represent a breakthrough in cancer immunotherapy. However, current methods for engineering T cells to express CARs are expensive and typically rely on viral vectors, which are integrative and have been linked to severe adverse effects resulting from the continuous expression of CARs. In contrast, non-viral vectors, particularly lipid nanoparticles (LNPs), have emerged as a promising alternative for generating CAR T cells with transient CAR expression. In this study, we developed a nanoparticle-based mRNA platform to generate CAR T cells targeting Claudin 6, a marker for various solid tumors.
Methods: mRNA encoding the CAR targeting Claudin 6 was synthesized via in vitro transcription and subsequently loaded into LNPs. The LNPs were synthesized using microfluidic mixing, incorporating an ionizable lipid and excipient lipids at different molar ratios. To assess transfection efficiency, Jurkat cells and primary human T cells were transfected with CAR mRNA encapsulated in LNPs (LNP-CAR) and analyzed by flow cytometry. T cell activation was evaluated by co-culturing CAR-expressing cells with colorectal cancer cells (Colo 205) for 24 hours, followed by measurement of CD69 expression in CAR+ cells. Primary human T cells were transfected with an optimized LNP formulation and co-cultured with colorectal cancer cells at varying effector-to-target (E:T) ratios to assess specific killing by flow cytometry.
Results: We developed an LNP formulation to deliver mRNA encoding the CAR to T cells. The LNPs had a size of 98 nm, a polydispersity index of 0.19, a slightly negative zeta potential of -3.4 mV, and an encapsulation efficiency of 82%. Enhanced CAR expression was observed in both Jurkat and primary human T cells treated with LNP-CAR, compared to control cells, with peak CAR expression occurring 24 hours after treatment. When co-cultured with colorectal cancer cells at a 1:1 ratio, Jurkat and primary human T cells transfected with LNP-CAR exhibited increased CD69 expression, indicating T cell activation. Importantly, primary T lymphocytes transfected with the optimized LNP-CAR formulation effectively killed colorectal cancer cells in vitro.
Conclusion: In this study, we identified a lead LNP formulation that induced CAR expression in primary T lymphocytes, which were subsequently activated and capable of specific killing of colorectal cancer cells. This non-viral delivery method using LNPs offers a promising alternative for producing CAR T cells. Furthermore, this approach can be adapted to other CAR constructs, potentially broadening its applicability to the treatment of solid tumors, an area where immunotherapies currently face significant challenges.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Radiation Treatment Combinations for Tumors, Normal Tissue Poster Session

#1815 Targeting the serine metabolism-NRF2 axis to overcome radiation resistance in pancreatic cancer.

Prince Kumar, Huseyin Ayhan, Lobna Abdulrahman, Justine Bailleul, Jonathan Ng, Erina Vlashi

Radiation Oncology, UCLA - University of California Los Angeles, Los Angeles, CA

Pancreatic ductal adenocarcinomas (PDAC) have very poor prognosis largely due to extreme resistance to existing therapies, including radiation therapy (RT). Metabolic reprogramming has been shown to promote therapy resistance in PDAC, but little in known in the context of RT. Here, we present findings of a critical intersection between serine metabolism and antioxidant defenses following RT of PDAC that place serine metabolism in a radio*protective* role. We find that this is enabled, in part, by the upregulation of the NRF2 (nuclear factor (erythroid-derived 2)-like 2) pathway following RT, beyond basal, mKRAS-induced levels. Our discovery is in line with the role that the serine metabolism coupled with one-carbon metabolism (1CM) plays in generating antioxidants for offsetting oxidative damage, as well as generating nucleotide precursors for DNA repair. Our TCGA analysis on patient PDAC shows a significant correlation between tumor NRF2 expression and SLC1A5 serine transporter, PSPH (the last enzyme in serine synthesis) and NADPH-producing enzymes of 1CM. Moreover, co-overexpression of PHGDH and NRF2 correlates with poorer overall survival, underscoring the intersection of serine metabolism and NRF2-regulated antioxidant responses in human PDACs. In pre-clinical models we show that RT enhances PDAC cellular glucose consumption in excess of anabolic basal levels, and this is accompanied by increased gene expression levels of enzymes that drive the *de novo* serine biosynthesis pathway (SBP), a branch of glycolysis. PDAC radiosensitization can be achieved by interfering with serine metabolism, be it through inhibiting the first SBP enzyme, phosphoglycerate dehydrogenase, or by removing exogenous serine. The radiation-induced antioxidant pathway involving NRF2 is also implicated in metabolic PDAC reprogramming in part by promoting upregulation of glucose consumption following RT and driving flux of glucose carbons into the SBP. In keeping with this, PDAC radiosensitization can also be achieved by inhibiting the NRF2 pathway (*in vitro* and *in vivo).*
Our findings suggest that NRF2-serine-metabolism axis generates a synchronized metabolic response that protects PDAC from lethality in the aftermath of RT and constitutes a promising and novel radiotherapeutic target.

#1816 BRD4 inhibitor I-BET151 sensitizes glioblastoma to radiotherapy by suppressing super-enhancer-driven COL1A1.

Xichen Fan, Xuenan Li, Ziheng Wang, Weichen Duan, Yafei Wang, **Jiajia Chen**

Department of Oncology, Shengjing Hospital of China Medical University, Shenyang, China

Glioblastoma (GBM) is a highly aggressive and fatal brain tumor typically treated with high-dose radiation (RT) and chemotherapy. However, the limited RT efficacy has spurred interest in radiosensitizing strategies. BRD4, a BET protein, promotes tumor progression by regulating oncogenes through super-enhancers (SEs). Consequently, BRD4 inhibitors, such as I-BET151, are being investigated as potential therapeutic agents. This study investigates the synergistic efficacy of I-BET151 in combination with RT for GBM therapy. Analysis of public databases revealed elevated BRD4 expression in recurrent GBM compared to newly diagnosed cases, correlating with poor prognosis. Immunofluorescence analysis showed increased BRD4 expression in human (T98G and U87) and murine (GL261) GBM cells 48- and 96- hours post-RT (5 Gy). Pretreatment with I-BET151 (1μM or higher) sensitized GBM cells to RT (2.5 Gy or higher), enhancing RT-induced suppression of clonogenic survival, reducing proliferation and invasion, and significantly increasing apoptosis [e.g., GL261: 63.3% ± 0.5% vs. 10.9% ± 0.6% with RT alone ($p < 0.001$), 11.6% ± 0.6% with I-BET151 ($p < 0.001$)]. Co-treatment also amplified RT-induced DNA damage (γH2AX foci) 24 hours post-RT. In a subcutaneous GBM GL261 model in C57BL/6 mice, I-BET151 (10 mg/kg/day, intraperitoneally) administered concurrently with fractionated RT (2 Gy daily for 5 days) significantly reduced tumor growth compared to either treatment alone [e.g., tumor volume at 4 weeks: 259 ± 92.9 mm^3 vs. 574.8 ± 126.5 mm^3 with RT alone ($p < 0.001$), 705.8 ± 168.3 mm^3 with I-BET151 ($p < 0.001$)]. Tumor tissues from the combination group consistently showed the highest levels of apoptosis (TUNEL staining), and lowest Ki67 index, confirming improved therapeutic efficacy. Mechanistically, BRD4 drives activation of SEs marked by H3K27ac. ChIP-seq analysis for H3K27ac in GL261 cells revealed that RT significantly increased SEs, which were reduced with I-BET151 co-treatment. RNA-seq identified 75 RT-upregulated genes that were downregulated with I-BET151 co-treatment. Pathway analysis linked these BRD4-regulated, RT-responsive genes primarily to extracellular matrix pathways. Integrated ChIP-seq and RNA-seq analysis identified COL1A1 as a key BRD4-dependent SE target post RT. I-BET151 suppressed COL1A1 expression both in vitro and in vivo. Moreover, RNAi-mediated COL1A1 silencing reduced proliferation, increased apoptosis, and enhanced RT-induced DNA damage, underscoring its pivotal role in BRD4-mediated radioresistance. In conclusion, I-BET151 enhances radiosensitivity in GBM cells by blocking RT-induced SE-activation and COL1A1 expression, thereby amplifying DNA damage and apoptosis. Further validation in orthotopic GBM models is essential to advance the clinical translation of this promising combination therapy.

#1817 Overcoming tumor hypoxia in MPNSTs using an implantable micro-catheter.

Samual Hatfield, Ryan Courtney, Emily Witt, Jianling Bi, James Byrne

Carver College of Medicine, University of Iowa, Iowa City, IA

Malignant peripheral nerve sheath tumors (MPNSTs) are a devastating and rare type of tumor, accounting for 5-10% of all soft-tissue sarcomas, with a 5-year overall survival rate of only 50%. A key contributing factor to the poor outcomes is treatment resistance due to tumor hypoxia. Despite efforts to mitigate tumor hypoxia as a therapeutic strategy, significant challenges remain, including the kinetics of oxygenation, peak partial pressures achieved, and the safety of existing methods. Here, we report on an implantable system for direct intratumoral oxygen injection that synergizes with radiotherapy. We demonstrate that tumor oxygenation using this system slows tumor growth and extends survival in a mouse model of MPNST. Six-to-eight-week-old female C57BL/6J mice bearing subcutaneous right-flank MPNST allograft tumors were separated into four treatment cohorts: oxygen infusion + radiation, radiation, oxygen infusion, and no treatment. For mice receiving oxygen infusion, the center of the tumor was catheterized once tumors reached a volume of 200 mm^3. Intratumoral oxygen infusion was achieved using a syringe pump to deliver oxygen at a partial pressure of 50 mmHg. The microcatheters were then removed, and a single 15 Gy radiation dose was administered using a small animal radiation research platform. Following treatment, tumor growth was monitored and measured three times weekly using calipers. Tumor volume was approximated using the formula $V = 0.5 \times \text{length (L)} \times \text{width (W)}^2$, where length and width correspond to the x and y measurements of the tumor in mm. Animals were euthanized, and tumors were harvested once their volume reached 2000 mm^3. In a separate cohort of mice, tumors were resected one hour after irradiation, formalin-fixed, paraffin-embedded, and stained for γ-H2AX foci. Intratumoral oxygen infusion combined with radiation inhibited tumor growth and extended the median survival of mice with MPNSTs from 13 days (no treatment) to 25 days (oxygen infusion + radiation). Additionally, there was a significant increase in γ-H2AX foci per nucleus in tumors treated with oxygen infusion + radiation compared to radiation alone. We demonstrate that direct intratumoral oxygenation can radiosensitize MPNSTs in a mouse model. The significant reduction in tumor growth observed in mice receiving oxygen infusion + radiation, compared to radiation alone, suggests that tumor oxygenation may improve outcomes when combined with current standard-of-care therapies.

#1818 Enhancing double-strand break induction in hypoxic glioblastoma cells through dNTP modulation and its potential therapeutic implications.

Edidiong R. Usoro, Dominique Monroe, Kristen Carver, Emily Steinbeck, Arilyn Williams, Waaqo Daddacha

Augusta University, Augusta, GA

Glioblastoma (GBM), the most lethal primary brain tumor, remains resistant to current treatment modalities that include surgical resection, chemotherapy, and radiotherapy (RT). A critical challenge in GBM therapy is the presence of severe hypoxic tumor regions caused by the rapid growth of solid tumors and poor vascularization. Hypoxia drives therapeutic resistance by impairing DNA damage induction and repair mechanisms, particularly double-strand breaks (DSBs), which are the most cytotoxic lesions induced by RT and chemotherapeutic agents.Cellular deoxyribonucleoside triphosphate (dNTP) pools, tightly regulated by ribonucleotide reductase (RNR) and SAM- and HD-domain-containing protein (SAMHD1), play a pivotal role in DNA replication and repair. Hypoxia disrupts this balance by reducing dNTP synthesis due to the oxygen dependency of RNR, a rate-limiting enzyme, leading to diminished replication and cell cycle arrest. These metabolic adaptations hinder the efficacy of DSB-inducing agents in hypoxic GBM cells. Notably, rapidly replicating cells are more sensitive to cancer therapeutic agents, partly due to replication-induced conversion of single-strand breaks and other manageable damages into highly lethal DSBs.To address this resistance mechanism, we investigated the role of dNTP modulation in enhancing DNA damage and therapeutic outcomes in hypoxic GBM cells. Our study reveals that pharmacologically increasing dNTP levels in hypoxic GBM cells restored cell cycle progression and DNA replication, thereby sensitizing cells to DSB-inducing therapies. Specifically, we found that:

1. Elevated dNTP pools reversed hypoxia-induced cell cycle arrest: Flow cytometry analysis demonstrated a marked increase in S-phase entry upon dNTP modulation under hypoxic conditions.
2. Increased DSB formation following therapy: Single-cell microscopic analysis revealed enhanced DSB induction in hypoxic GBM cells treated with ionizing radiation (IR) or bleomycin after dNTP elevation.
3. Enhanced apoptotic response: Pharmacological dNTP modulation amplified apoptosis activation following DSB induction, indicating improved therapeutic efficacy.

This study establishes the critical link between dNTP availability, DNA replication, and hypoxia-induced therapeutic resistance in GBM. By leveraging dNTP modulation, we provide a novel preclinical strategy to overcome hypoxia-mediated resistance to DSB-inducing therapies. Our findings support further exploration of this approach as an adjunctive treatment to improve outcomes in patients with hypoxic GBM.

#1819 Inhibition of the cell-scaffolding protein DLG5 sensitizes glioblastoma stem cells to radiotherapy.

Somanath Kundu[1], Soham Mitra[1], Abigail Venskus[2], Harish Babu[2], Jason Horton[3], Mariano Viapiano[4]

[1]Neuroscience & Physiology, SUNY Upstate Medical University, Syracuse, NY,[2]Neurosurgery, SUNY Upstate Medical University, Syracuse, NY,[3]Neuroscience & Physiology and Orthopedics, SUNY Upstate Medical University, Syracuse, NY,[4]Neuroscience & Physiology and Neurosurgery, SUNY Upstate Medical University, Syracuse, NY

Glioblastoma (GBM) is a fatal CNS tumor that responds poorly to conventional chemo- and radiotherapy. Although radiation achieves a significant adjuvant effect after surgical debulking, radioresistant tumor cells repopulate the tumor bed, resulting in unavoidable recurrence. GBM radioresistance has been largely associated with a population of GBM stem cells (GSCs) driven by Sonic Hedgehog (SHH) and Hippo pathways that promote metabolic reprogramming, DNA repair, and cell proliferation. We have previously described that GBM stemness pathways such as SHH are regulated by a cell-scaffolding member of the Scribble/DLG family, DLG5, which is a "high hierarchy" target that maintains a persistent GSC population. Given the related identity of stemness and post-treatment resistance in GSCs, we have investigated here if DLG5 can be targeted to increase the sensitivity of GSCs to conventional radiotherapy. Our results in cultured GSCs confirmed that DLG5 not only regulates the SHH pathway -as we have previously shown- but also the Hippo pathway. Specifically, DLG5 knockdown increased the expression of the Hippo-repressor kinases, MST-1/MST-2, and phosphorylation of the Hippo effector YAP; these alterations were accompanied by downregulation of Hippo-downstream genes (CTGF, BIRC5) as well as genes involved in DNA-damage repair (BRCA1, RAD51) and stemness (OCT4, NANOG). In agreement with these results, DLG5-deficient GSCs subjected to different irradiation regimes (2 - 8 Gy) showed decreased cell viability, reduced survival fraction in clonogenic assays, and reduced self-renewal ability compared to control GSCs. Irradiated DLG5-deficient cells had elevated cleaved Caspase-3 and PARP1 compared to control cells, increased long-term DNA damage, and accumulation in G2/M phase suggesting mitotic catastrophe. The sensitizing effects of DLG5 deficiency were also tested in intracranial GSC-derived tumors subjected to fractionated radiotherapy (5 x 2Gy q24h). Radiotherapy significantly increased the survival of animals implanted with DLG5-deficient tumor cells compared to controls. Overall, our work suggests that targeting DLG5 increases the efficacy of radiotherapy in GBM by disabling the ability of this cell-scaffolding protein to regulate signaling pathways that drive tumor stemness. Work in progress is currently focused on identifying critical functional domains of DLG5 and developing inhibitors to block DLG5-driven mechanisms in GBM tumors.

#1820 Investigating whether FLASH radiotherapy spares late-responding organs using a rat spinal cord model.

Banghao Zhou[1], Lixiang Guo[1], Yi-Chun Tsai[1], Albert van der Kogel[2], John Wong[3], Iulian Iordachita[3], Rongxiao Zhang[4], Varghese Anto Chirayath[5], Robert Timmerman[1], Weiguo Lu[1], Kai Jiang[1], Chul Ahn[1], Paul Medin[1], **Ken Kang-Hsin Wang**[1]

[1]UT Southwestern Medical Center, Dallas, TX,[2]University of Wisconsin-Madison, Madison, WI,[3]Johns Hopkins University, Baltimore, MD,[4]University of Missouri, Columbia, MO,[5]University of Texas at Arlington, Fort Worth, TX

Purpose: FLASH radiotherapy (FLASH-RT) delivers curative dose to tumors at ultra-high dose rates (UHDR, >40 Gy/s) while offering normal tissue protection via the FLASH effect. Most supporting evidence relies on acute toxicity, but data on late-responding tissues are limited. Inadequate understanding of dose-response relationships has led to severe late toxicity, such as bone necrosis, halting a FLASH trial in cats. To establish FLASH-RT as a clinical modality, determining the dose-response for late-responding organs is essential. The spinal cord, with its steep dose-response curve and risk of myelopathy, serves as an ideal model. This study investigates whether FLASH-RT mitigates late toxicity using the rat spinal cord, a critical step for clinical translation.

Methods: The cervical-thoracic spine (C1-T2) of rats was irradiated with an 18 MeV LINAC-based FLASH beam with a posterior-anterior $2\times1cm^2$ field in a single fraction. A pulse control and monitoring system was developed to ensure precise delivery at single-pulse resolution required to establish the dose response curve. A scintillation detector was placed within the C1-T2 region of a rat carcass for validating Monte Carlo (MC) dose calculations. A custom immobilization device, combined with portable X-ray imaging, was used for precise C1-T2 localization for irradiation. An ion chamber was placed beneath the electron cone to monitor Bremsstrahlung as the surrogate for real-time UHDR output measurement. Dose groups were based on the reported median effective dose (ED_{50}) for conventional dose rate (CONV) treatments (20.4-21.5 Gy) and dose-modifying factors (DMF) for FLASH (1-1.4). Sprague Dawley rats were irradiated with FLASH doses ranging from 15.3 to 28.4 Gy. The dose-related paresis incidence was assessed over a 7-month follow-up period to determine the dose-response curve and whether FLASH enhances spinal cord tolerance compared to CONV-RT.

Results: MC calculations demonstrated that the 18 MeV FLASH achieved profile non-uniformity of <5% along the 12 mm length of the C1-T2, effectively mitigating the dose-volume effect, and was reproducible across animals. The dose rate achieved 390 Gy/s, exceeding the threshold of 40 Gy/s. Radiation-induced skin damage healed spontaneously by 10 weeks post-irradiation. The animals showed steady weight gain after irradiation, suggesting that no significant radiation-induced esophagitis was observed. Preliminary results indicated that 3 out of 8 rats in both 21.8 and 28.4 Gy FLASH groups exhibited paralysis. The data collection is still ongoing, and the full dose-response curves for both UHDR and CONV irradiation will be established.

Conclusions: Our project addresses a critical knowledge gap in FLASH-RT by elucidating the FLASH dose-response relationships for a key late-responding organ, the spinal cord. The findings will have significant implications for the use of FLASH-RT in clinical setting.

#1821 *In vivo* synergy is observed with AMG-232 and radiotherapy in endometrial cancer.

Aaron P. Petty, Yvonne Parker, Daniel Lindner, Roberto Vargas

Cleveland Clinic, Cleveland, OH

Background: Approximately 15% of high-grade *TP53*-mutated endometrial cancers (EC) are heterozygous and retain wild-type (WT) signaling. Our previous *in vitro* findings nominated MDM2 inhibitors as potential radio-sensitizing strategies that leverage *TP53* WT signaling. Here, we further explore this radio-sensitizing role for one particular inhibitor, AMG-232, in an *in vivo* xenograft model with a *TP53* WT EC cell line.

Methods: To evaluate the radio-sensitizing potential of AMG-232 *in vivo*, we utilized a xenograft tumor model with the JHUEM-2 (*TP53* WT) cell line. Cells ($2x10^6$) were injected subcutaneously in the bilateral flanks of 6-8 week old female NSG mice. Mice were separated into 4 treatment groups and 6 mice (n= 12 tumors) were included in each group: Vehicle, Radiation (RT), AMG-232, and Combination. Once the largest tumors were 200-300mm^3 in size, mice were given either Vehicle or AMG-232 (30 mg/kg) by gavage for 9 days. In the RT and Combination groups, a single dose of 1 Gy of radiation was given 24 hours following first drug dose. Assessment of treatment synergy was carried out using both the Highest Single Agent (HSA) and Bliss Independence models with bootstrap analysis at either single timepoints, or over the entire growth curve based on area under the curve (AUC). Synergy scores were calculated as a measure of deviation from additivity, with positive values indicating synergy. Synergy analyses were carried out using the invivoSyn package in R software.

Results: AMG-232 and RT together significantly suppressed tumor growth at treatment days 7 and 9 compared to either RT alone (P= 0.004 and P= 0.0014, respectively) or AMG-232 alone (P= 0.003 and P= 0.0061, respectively). Synergy analysis of growth inhibition at treatment day 9 using both the HSA and Bliss models showed significant synergy in the combination group, with mean synergy scores of 27 (P= 0) and 25 (P= 0.003), respectively. Entire growth curve AUC analysis also showed synergy only in the less stringent HSA model, with synergy score of 37.5 (P= 0.033).

Conclusions: Overall, these findings further support the use of MDM2 inhibitors to improve radiotherapy response in EC. The improved tumor response that we observed at clinically relevant doses further highlights the potential of these agents to either enhance responses to current therapeutic strategies, or to lower the radiotherapy dose necessary for complete response.

#1822 O-GlcNAcylation of NDRG1 mediates radiation resistance in prostate cancer.

Manish Thiruvalluvan, Sandrine Billet, Neil A. Bhowmick

Cedars-Sinai Cancer, Cedars-Sinai Medical Center, Los Angeles, CA

Prostate cancer (PCa) remains one of the most prevalent malignancies worldwide, with localized cases commonly treated through surgical resection and radiation therapy (RT). Both RT and androgen-targeted therapies can stimulate glutamine (L-Gln) secretion by the PCa-adjacent stroma, promoting tumor adaptation and resistance. Beyond its metabolic role, our findings revealed that L-Gln critically influences protein O-GlcNAcylation, a key process for DNA repair and therapy resistance. We hypothesized that targeting L-Gln signaling could enhance PCa sensitivity to RT. Our studies demonstrated that L-Gln starvation significantly increased RT sensitivity in both parental and radio-resistant PCa cell lines, a phenotype recapitulated by silencing OGT, the key enzyme mediating O-GlcNAcylation. Conditioned media from stromal fibroblasts elevated global O-GlcNAcylation and enhanced cell viability in PCa cells, highlighting the role of the tumor microenvironment. Sodium phenylbutyrate (SPB), a clinically available compound that sequesters L-Gln, effectively mimicked the effects of L-Gln depletion, contrasting with metabolic inhibitors of L-Gln that have failed to show clinical benefit. In subcutaneous xenograft models of PCa epithelia co-implanted with cancer-associated fibroblasts, the combination of SPB and RT markedly reduced tumor size compared to either treatment alone. Further, SPB significantly decreased plasma and intratumoral L-Gln concentrations. Mass spectrometry analysis of tumor tissues identified NDRG1 as a protein highly O-GlcNAcylated in response to RT, a modification suppressed by SPB. CRISPR/Cas9-mediated substitution of key O-GlcNAcylated serine residues in NDRG1 significantly enhanced RT sensitivity by destabilizing the protein and impairing its nuclear translocation. Mechanistically, NDRG1 dysfunction was associated with elevated endoplasmic reticulum (ER) stress, evidenced by increased CHOP and NRF2 expression and reduced Akt phosphorylation. RNA sequencing further revealed that SPB disrupted PCa cell metabolism by inhibiting fatty acid oxidation and reducing amino acid transporter activity, leading to diminished nucleotide pools and energy availability. This dual disruption of metabolic and O-GlcNAcylation processes compromised DNA repair and the detoxification of radiation-induced reactive oxygen species, thereby enhancing radiosensitivity. These findings suggest that targeting L-Gln bioavailability is a clinically viable strategy to overcome therapy resistance and improve therapeutic outcomes in PCa patients.

#1823 Spatial transcriptome profiling shows a decrease in heterogeneity of GBM xenografts that regrow after irradiation and suggests novel therapeutic targets.

C. M. Degorre;
National Cancer Institute, Bethesda, MD

Radiation remains a primary treatment for glioblastoma, yet tumors frequently recur within two years. As a model for investigating the biology of recurrent GBMs, we used orthotopic xenografts initiated of GBM-stem like cells (GSCs) implanted into the right striatum of nude mice. Thirty-five days post-implant, mice bearing brain tumor xenografts were locally irradiated (10Gy) and brains collected 14 and 21 days later. In untreated mice, tumors were highly diffuse with tumor cells invading from the injection site in the right hemisphere (RH) to the anterior part of the brain, invading the corpus callosum, cortex, and olfactory bulb (OB). A different growth pattern was detected in tumors that regrew after irradiation. At 14 days post-10Gy, tumors were located primarily in the OB with an increased cell density and a clearly demarcated border. 21 days post-10Gy tumor cell density increased with the demarcated border extending further into the hemisphere, i.e., farther away from the OB. This growth pattern suggests that tumor regrowth after irradiation is initiated in the OB, consistent with previous results showing that GBM cells in the OB are radioresistant compared to those in the RH. To compare transcriptomes of untreated and recurrent tumors we used digital spatial profiling (DSP). Tumor cells were identified by Sox2 staining, and regions of interest (ROIs) were selected in various locations within the OB and the RH of untreated tumors, and throughout recurrent tumors (D21 post-10Gy). Cluster analysis showed that ROIs across the OB and RH of untreated tumors were more similar to each other as compared to ROIs from the tumors that regrew after irradiation. Variance in the expression of individual genes across the ROIs was reduced in the recurrent tumors compared to the untreated tumors. These results suggest a reduction in phenotypic heterogeneity among the cells of the regrown tumor. Comparative gene expression analysis identified 463 differentially expressed genes with 319 downregulated and 144 upregulated in the recurrent versus untreated tumors. GSEA revealed a significant enrichment of pathways related to cell cycle regulation in the regrown tumors as compared to non-irradiated tumors. Further examination of the cell cycle control related pathways indicated an enrichment in proteasome genes. Specifically, 22 genes encoding proteasome proteins were significantly upregulated in the recurrent tumors compared to the untreated group, suggesting that the proteasome may provide a therapeutic target unique to the recurrent GBM. Altogether, these results suggest that this xenograft model of GBM regrowth after irradiation, characterized by an altered growth pattern and a distinct molecular profile may be useful for investigations into the biology and treatment of recurrent GBM.

#1824 Harnessing a radiation-resistant organoid platform to propose novel strategies for precision treatment of advanced oral cancer.

Sumin Kang[1], Mi Rim Lee[2], Jonghyun Lee[2], Dongkwan Shin[2], Sun-Young Kong[2], Jong-Ho Lee[2], Ikjae Kwon[3], Dohyun Kwon[3], Soung-Min Kim[3], Joo Yong Park[2], Wonyoung Choi[2], Jiyoung Lee[2], Yu-Sun Lee[2], Hye Won Shon[2], Gyeongmin Kang[1], Sung Weon Choi[2], Yun-Hee Kim[2]

[1]Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of,[2]Research Institute and Hospital, National Cancer Center, Goyang, Korea, Republic of,[3]Oral and Maxillofacial Surgery, Oral Cancer Center, School of Dentistry, Seoul National University, Seoul, Korea, Republic of

Oral squamous cell carcinoma (OSCC) has high recurrence rates and limited treatment options, with 40-60% of patients diagnosed at advanced stages (III/IV). Despite surgery following radiotherapy, over 40% of patients with advanced OSCC experience recurrence, with 70% being locoregional. Postoperative radiotherapy reduces recurrence but causes significant side effects, such as xerostomia and osteoradionecrosis. The challenge of accurately reflecting the clinical characteristics and tumor heterogeneity of oral cancer hinders clinical application. Therefore, research models that preserve patient traits are essential for developing tailored treatments, reducing side effects, and improving outcomes. In this study, we used a radiotherapy-relapse mimicking patient-derived organoid model to identify intrinsic radiation resistance and overcome it in advanced oral cancer. Radiation-resistant (RR) organoids were successfully developed by gradually increasing radiation intensity over 10 passages, with a total dose of 60 Gy. Of the 23 cases, 14 successfully generated RR organoids. These RR organoids exhibited enhanced radiation resistance and proliferation. Evaluation with multiple radiation fractions proved more reliable than single-fraction assessments, as it minimized interference from proliferation-related factors. By linking patient recurrence status with the establishment of RR organoids, it was observed that organoids derived from recurrent patients had a higher success rate. This suggests that radiation resistance is driven by pre-existing subclones. The characteristics of subclones that survived radiation exposure were examined through differential gene expression (DEG) analysis, revealing upregulation of genes related to the cell cycle, DNA damage repair, and inflammatory response pathways, while genes associated with apoptosis and differentiation were downregulated. Inhibitors targeting the altered pathways were selected, and combination treatments with radiation were performed. The ATR inhibitor, BAY1895344, demonstrated synergistic effects. Finally, genes with sequentially altered mRNA levels based on radiation responsiveness were selected to develop the radiation resistant index (RRI). This study aims to address the limitations of existing preclinical models by utilizing patient-derived organoids that preserve tumor heterogeneity, thereby providing a platform and treatment prediction for clinically relevant research. These findings are anticipated to contribute significantly to the development of precision medicine-based therapeutic strategies for advanced oral cancer.

#1825 Pharmacological evaluation of bioconjugated trastuzumab using the AbYlink™ regio-selective conjugation technology in gastric cancer expressing HER2+.

Celine Mothes[1], Peggy Provent[1], Marie Ruch[2], Mathieu Moreau[2], Michael Claron[2], Alex Helbling[3], Viktoriia Postupalenko[4], Leo Marx[4], Patrick Garrouste[4], **Eftychia Koumarianou**[1]

[1]Oncodesign Services, Dijon, France,[2]Institut de Chimie Moleculaire de l'Universite de Bourgogne, Dijon, France,[3]Centre Georges Francois Leclerc, Dijon, France,[4]Debiopharm Research & Manufacturing SA, Martigny, Switzerland

Purpose/introduction

Bioconjugation is a critical step in the development of Antibody Drug Conjugates with two main strategies dominating the field. One approach employs covalent chemistry to randomly bind a drug to the accessible Lysines or Cysteines on an antibody. The other strategy is site-specific, using covalent chemistry to bind a drug ligand at defined amino acid positions within the antibody. AbYlink™ is a novel regio-selective labeling method for antibodies, enabling a single-step covalent conjugation of payloads such as radionuclide chelators to the Fc domain of an antibody. Given the selectivity of this reaction for the Fc region of the immunoglobulin, the affinity of the antibody to the antigen isn't compromised, unlike randomly labelled antibodies. The chelators that are covalently attached to the antibody enable radiolabeling with radioisotopes such as Gallium-68, Lutetium-177 and Indium-111 for molecular radiotherapy or molecular imaging purposes.

Experimental design

The commercially available trastuzumab was labeled via regio-selective conjugation with a DOTA-GA chelating agent using the AbYlink™ technology, then radiolabeled with Indium-111. The in vivo biodistribution of the HER2 radiolabeled bioconjugate was evaluated in mice bearing NCI-N87 gastric cancer tumors.

Results

Trastuzumab conjugation resulted in a homogeneous labeling of antibodies with a Degree of Conjugation (DoC) close to 2, conducted in a regio-selective manner. The biodistribution and imaging experiments demonstrated successful accumulation of the antibody within the NCI-N87 tumour implanted in mice. The radiolabeled conjugate remained stable in vitro and in vivo, demonstrating the AbYlink™ as a valuable tool for biologics conjugation.

Conclusion

We have successfully validated in vivo the use of AbYlink™ technology in the context of Antibody Radio Conjugates. This regio-selective bioconjugation strategy holds potential for wider application across molecular radiotherapies or pharmacodynamic assessment of antibodies.

#1827 Investigating the efficacy of 177-Lu therapeutics in a series of castrate resistant prostate cancer PDX models.

Stefano Cairo[1], Benedetta Arno[2], Mara Gilardi[1], Hsiu-Wen Tsai[1], Juliana Maynard[2], Marianna Zipeto[1], Michael Ritchie[1]

[1]Champions Oncology, Inc., Hackensack, NJ,[2]Medicines Discovery Catapult, Cheshire, United Kingdom

Recent advancements in alpha and beta particle-emitting radiopharmaceuticals underscore the therapeutic potential of targeted radionuclide therapy, presenting a promising alternative for patients with advanced or metastatic disease where conventional treatments fall short. This field is pushing the boundaries of personalized medicine, allowing clinicians to tailor treatments to individual patients' genetic and molecular profiles, thereby improving outcomes. As translational research in radiopharmaceutical development progresses, it holds significant promise for redefining therapeutic options and setting new standards in patient care. Targeting and maintaining high specificity to chosen targets, such as PSMA, is crucial for the clinical success of novel radiopharmaceuticals. The development and translation of these therapies require a series of steps through the drug discovery pipeline, including selecting the right radionuclide, chemistry, model, and biomarkers for patient selection. Historically, radiopharmaceutical development has relied on cell lines. While cell-derived xenografts are cost-effective and essential for initial characterization, screening, biodistribution, and efficacy, clinically relevant pre-clinical models predictive of patient outcomes are indispensable for de-risking radiopharmaceutical development. Unfortunately, these models have been underutilized due to the limited availability of combined PDX and radiopharmaceutical capabilities. Here, we present an end-to-end approach for testing 177-Lu therapeutics, from dosimetry and biodistribution in cell lines to efficacy in metastatic castration-resistant PDX models. When treated with 177-Lu based prostate therapeutics, PDX models exhibited a diverse range of responses. RNA-seq and proteomics analyses confirmed that Champions Oncology metastatic castration-resistant prostate cancer PDX models expressed varying levels of PSMA, reflecting the patient population in clinical settings. Our results highlight the importance of integrating robust radiochemistry and biodistribution workflows with clinically relevant patient-derived models to derive translational insights and accelerate the development of radiopharmaceuticals. This comprehensive approach not only enhances the predictive power of pre-clinical models but also ensures that the therapeutic strategies developed are closely aligned with the clinical realities faced by patients.

#1828 Efficacy and mechanism of radiotherapy combined with fruquintinib and tirelizumab in mCRC.

Mingsheng Zhang, **Qingqing Yu**, Huiying Hou, Xiaoting Su, Qin Huang, Hong Qiu, Le Huang, Liang Zhuang, Qiang Fu, Yanmei Zou, Li Sun, Liu Huang, Shunfang Liu, Fei Liu, Xianglin Yuan

Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: Immune checkpoint inhibitors (ICIs) targeting programmed cell death protein 1 (PD-1) or programmed death ligand 1(PD-L1) respond well to deficient-microsatellite(dMMR) colorectal cancer and poorly to proficient-microsatellite (pMMR) CRC. Anti-vascular therapy is the standard backline treatment regimen for advanced metastatic colorectal cancer and also potentiates the immunotherapeutic efficacy of CRC by promoting immune cell infiltration and remodeling the tumor immune microenvironment (TIME). However, it is not clear whether combining radiotherapy, anti-vascular and anti-PD-1 can affect the efficacy of pMMR CRC. In this experiment, we investigated the antitumor efficacy of radiotherapy combined with fruquintinib and tirelizumab in pMMR CRC mice.
Methods: CT26 cellular hormonal tumor corresponding to pMMR CRC. A mouse model with subcutaneous transplanted tumors is established, divided into control, radiotherapy (IR), fruquintinib + tirelizumab (F+T), and radiotherapy + fruquintinib + tirelizumab (IR+F+T) groups. Immunofluorescence (IF) experiments were conducted to investigate the number and function of tumor vessels. Immunohistochemistry (IHC) and flow cytometry (FC) were utilized to examine immune cell infiltration and alterations within the TIME.
Results: Compared to the control group, tumor growth was significantly inhibited after treatment. When compared to IR and F+T, IR+F+T demonstrated a remarkable suppression of tumor growth. The quantitative analysis results showed a significant decrease in Ki-67 positive cells in the target tumors with IR+F+T compared to IR and F+T. The TUNEL results indicated that treatment promoted tumor cell apoptosis, and the effect was further enhanced with triple combinational therapy. Both F+T and IR+F+T repressed CD31 expression and improved the ratio of α-SMA$^+$/CD31$^+$ in tumor tissue, yet there was no significant difference between the two groups. The immunohistochemistry and flow cytometry results demonstrated that triple combinational therapy increased tumor-infiltrating CD8$^+$ T cells and significantly elevated the proportions of CD8, CD69, and CD86. Both F+T and IR+F+T boosted PD-L1 expression, with no significant difference between them.
Conclusions: Combined irradiation on top of fruquintinib and tirelizumab treatment enhanced the efficiency in CT26 murine CRC syngeneic tumor model. There was no significant effect of radiotherapy on the anti-angiogenesis of fruquintinib and the promotion of normal vascular function. Irradiation promoted CD8$^+$ T cell and dendritic cell infiltration and activation.

#1829 Potentiating antitumoral type 1 interferon immune signaling in triple-negative breast cancer (TNBC) via combination treatment of Aurora kinase B (AURKB) inhibition and radiation therapy.

Kassidy M. Jungles[1], Caroline R. Bishop[1], Cydnee Wilson[1], Meilan Liu[1], Corey W. Speers[2], Lori Pierce[1], James Rae[1]

[1]University of Michigan, Ann Arbor, MI,[2]Case Comprehensive Cancer Center, Cleveland, OH

Purpose: Triple-negative breast cancer (TNBC) is an aggressive BC subset that is less responsive to standard therapies resulting in the need for novel treatment options. Radiotherapy (RT) is common for treating TNBC patients; however, locoregional recurrence remains a clinical issue. Modulation of the antitumoral immune response may improve tumor control in TNBC. Type 1 interferon (T1IFN) is a crucial regulator of antitumoral immunity that can activate cytotoxic immune cells. AURKB is upregulated in TNBC patients, yet it is unknown whether AURKB modulates T1IFN signaling. While our preliminary data suggests that AURKB inhibition makes TNBC cells more sensitive to RT, the effects on T1IFN are unknown. Here, we examined the effects of combined RT and AURKB inhibition on T1IFN signaling in TNBC.

Methods: The half-maximal inhibitory concentrations (IC_{50}) were calculated using cell viability assays with the treatment of AURKB inhibitors Barasertib-HQPA and SP-96 in human and murine TNBC cells. Micronuclei formation was assessed using DAPI stain and immunofluorescent microscopy following treatment with AURKB inhibitors and RT. T1IFN signaling was assessed via a T1IFNβ-GFP reporter transfected into human TNBC cells, rt-qPCR for T1IFN response genes, and flow surface staining for T1IFN markers. For these studies, TNBC cells were pretreated with AURKB inhibitor 24 hours prior to RT and harvested five days later.

Results: Aurora kinase B inhibitors (Barasertib-HQPA and SP-96) reduced cell viability in human and murine TNBC cells (IC_{50} values: 500 nm - 5 μM). AURKB inhibition delivered before RT induced micronuclei—a known ligand of T1IFN signaling—in TNBC cells. Further, sub-IC_{50} concentrations of AURKB inhibitors (25 nM Barasertib-HQPA, 100 nM SP-96) and RT (6 Gy in 1 fraction) induced T1IFN signaling in the human Cal-51 T1IFN reporter system ($p<0.0001$). This was also observed in combination with fractionated RT (2 Gy in 3 fractions), suggesting that combined AURKB inhibition and RT potentiate T1IFN ($p<0.0001$). Combined treatment (6 Gy RT + 10 nM Barasertib-HQPA) also induced expression of the T1IFN response genes *Cxcl10* and *PD-L1* in human TNBC BT549 cells compared to vehicle control ($p<0.001$). Further, AURKB inhibition and RT also potentiated the T1IFN markers PD-L1 and MHC1 in human and murine TNBC cells.

Conclusion: AURKB inhibition and RT induces T1IFN signaling in human and murine TNBC cells. Combination treatment also induces micronuclei formation, suggesting an upstream mechanism for the observed T1IFN signaling. These data suggest that AURKB inhibition and RT may be a promising strategy for the treatment of TNBC and can modulate the tumor immune microenvironment. Further studies are warranted to examine the extended effects of this treatment in vivo and further implications on the antitumoral immune response.

#1830 A chemoradiation platform for evaluating multimodal therapy effects on tumor viability and invasion ex vivo.

Luda Lin, Krishna K. Bommakanti, Bowen Wang, Yazeed Alhiyari, Christian Wooten, Andreanne Sannajust, Lauran K. Evans, Peyton Tebon, Maie A. St. John, Alice Soragni

UCLA - University of California Los Angeles, Los Angeles, CA

Treatment of advanced head and neck squamous cell carcinoma (HNSCC) involves radiotherapy combined with chemotherapy, targeted therapy or immunotherapy. We have developed a high-throughput organoid-based drug screening platform to assess the combined effects of radiotherapy and chemotherapy or targeted therapies on HNSCC viability and invasion. To validate the platform, we used HNSCC cell lines establishing bioprinted 3D models in mini-ring format (Phan et al, 2019; Tebon et al, 2023; Al Shihabi et al 2024; Nguyen et al, 2024). Cells are exposed to X-ray radiation in combination with various small molecules and biologics. We quantified viability via ATP-release assays and extracellular matrix (ECM) invasion using a machine-learning-based brightfield image analysis pipeline (Al Shihabi et al, 2022). Proof-of-concept experiments with HPV-negative HNSCC lines (HN30 and HN31, established from primary and metastatic disease from the same patient) and HPV-positive HNSCC cells (SCC154) revealed that treatment with cetuximab and ibrutinib enhances radiosensitivity in HN31 cells. The PI3K inhibitor copanlisib radio-sensitized both HN30 and HN31, while alpelisib sensitized SCC154 cells. Additionally, copanlisib, afatinib, and ibrutinib were shown to limit ECM invasion of HN31, while the AKT inhibitor ipatasertib and the mTOR-targeting rapamycin promote invasion of HN30 cells, as observed in previous studies (Brolih et al., 2018). Our pilot experiments using bioprinted patient-derived HNSCC organoids confirmed the feasibility of performing sensitivity screening by integrating bioprinting, conventional viability assays, and advanced image analysis techniques. Our goal is to establish a personalized therapeutic pipeline for patients with advanced HNSCC, maximizing responses to radiotherapy and targeted agents to improve outcomes, and avoiding modulators that may promote tumor invasion.

#1831 Development and characterization of a radiation resistant GBM cell line from PDX for the screening of novel treatment modalities.

Sigrid Cold[1], Jeremy Ariey-Bonnet[2], Monica Brandt[1], Rikke Norgaard Boge[1], Emma Papin[1], Ida Thoroe Michler[1], Lotte Kellemann Kristensen[1], Jacob Hald[1], Michael Wick[3], Andreas Kjar[1], Krister Wennerberg[2], Carsten Hagen Nielsen[1], **Sebastian Gnosa**[1]

[1]Minerva Imaging ApS, Olstykke, Denmark,[2]Biotech Research and Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark,[3]Xenostart, San Antonio, TX

Glioblastoma (GBM) remains one of the most lethal brain tumors, with standard-of-care therapies such as radiation and temozolomide offering limited survival benefit. Patient-derived xenograft (PDX) models have become critical tools for studying treatment resistance and identifying novel therapeutic strategies. Here, we report the establishment and characterization of a novel GBM cell line, ST146c, derived from a radiation-resistant PDX model (ST146). This cell line retains the therapy-resistant phenotype observed in the patient, making it a valuable resource for preclinical studies. To uncover vulnerabilities, ST146c was subjected to a mid-throughput drug screen, identifying SIK as a promising target. Subsequent in vitro studies confirmed that SIK inhibition significantly impairs ST146c cell proliferation and survival. To validate these findings, we conducted in vivo experiments using the parental PDX model. SIK inhibition demonstrated robust anti-tumor activity, corroborating the in vitro results and underscoring its potential as a therapeutic target in radiation-resistant GBM. Building upon these findings, we performed a focused synergy screen, testing 40 handpicked drugs in combination with radiation. Among these, SIK3 inhibition emerged as a top candidate, showing evidence of synergistic effects with radiation in vitro. We are now extending these investigations to in vivo models to further evaluate the potential for SIK3 inhibitors to enhance the efficacy of radiation therapy. This study highlights the translational potential of the ST146c model for identifying and validating novel therapies targeting radiation-resistant GBM. The discovery of SIK3 as both a monotherapy target and a radiation-sensitizing agent opens new avenues for overcoming resistance in this challenging disease.

#1832 Identifying GSK3b inhibitor as a radiation induced type I interferon stimulator in lung cancer.

Chen Braun, Nan Li, Steven H. Lin

Department of Radiation Oncology, University of Texas MD Anderson Cancer Center, Houston, TX

Radiation therapy (RT) is commonly used to treat multiple tumor types to reduce the risk of tumor recurrence. Despite impressive clinical responses only a subset of patients responds to RT, due to the lack of an adequate immune response within lung tumors. There is a strong motivation to develop novel approaches to overcome immunosuppression in tumors after radiation therapy. Here, we aim to identify pathways that could specifically augment type I interferon (IFN) response with RT to bypass the immune suppressive effects. We combined radiation and >700 pharmacological inhibitors in a high throughput screen to identify agents that induced type I IFN response. We revealed a GSK3β inhibitor (GSK3βi), Kenpaullone, as a drug hit that induced synergistic response with RT to enhance type I IFN expression. The selected GSK3βi was validated for its IFNβ1 induction in the mRNA and protein levels in multiple lung cancer cell lines, and by examining the associated AKT/GSK3β/IRF3 pathway. The effectiveness of this unique GSK3βi-RT combination to enhance IFNβ1 immunologic stimulation was tested in syngeneic tumor bearing animals and significantly reduced tumors size compared to radiation or drug alone. COMET analysis from mice tumors showed that combination therapy increased T cells and M1 macrophages at the tumor microenvironment (TME), while M2 macrophages and PDL-1 decreased. This pharmacological-RT combination approach has the potential to enhance the immunologic response to RT in lung cancer patients to reduce tumor burden in those that already exhausted standard of care therapies.

#1833 Assessment of shifts in tumor-specific frequencies on the proliferation of hepatocellular carcinoma cells.

Callum T. McGrath[1], Preeya F. Achari[1], Carl Blackman[1], Janaka P. Liyanage[2], **Hugo Jimenez**[2], Boris C. Pasche[2]

[1]Wake Forest University School of Medicine, Winston Salem, NC,[2]Department of Oncology, Wayne State University School of Medicine, Detroit, MI

Background: Radiofrequency Electromagnetic Fields Amplitude-Modulated at tumor-specific frequencies (AM RF EMF) are FDA approved for the treatment of advanced hepatocellular carcinoma (HCC) and have been shown to inhibit cancer growth *in vitro*, *in vivo*, and in clinical trials. The mechanism behind AM RF EMF induced proliferative inhibition is intracellular Ca^{2+} influx via the $Ca_v3.2$ T-type calcium ion channel exclusively within malignant cells. However, it is unknown how AM RF EMF opens the $Ca_v3.2$ channel. We hypothesize that the tumor specific frequencies are the natural frequencies of the malignant $Ca_v3.2$ channels and thus AM RF EMF is a resonance phenomenon. To test this, we first assessed the impact on proliferative inhibition from the RF carrier wave and ambient magnetic fields. We then shifted base HCC treatment frequencies from +0.1 Hz to +0.0001 Hz logarithmically and compared proliferative inhibition to base treatment frequencies.

Methods: Huh7, Hep3B and SNU-423 HCC cell lines were treated with HCC-specific AM RF EMF under two conditions: normal incubator conditions, and within a magnetically shielded metal box. Growth inhibition relative to control was measured between the two groups via thymidine incorporation assay. Next, Huh7 and Hep3B cells were exposed to the unmodulated 27.12 MHz RF carrier wave and growth inhibition compared to control via thymidine incorporation assay. Lastly, Huh7 and Hep3B cells were treated with HCC AM RF EMF frequencies shifted by either +0.1 Hz, +0.01 Hz, +0.001 Hz, or +0.0001 Hz. Growth inhibition relative to standard treatment was measured via thymidine incorporation assay.

Results: There was no change in growth for Huh7 and Hep3B cells exposed to the unmodulated carrier wave compared to their respective controls. There was no change in proliferative inhibition between normal and magnetically shielded conditions for Huh7, Hep3B, and SNU-423 cells. All frequency shifts resulted in significantly decreased treatment efficacy relative to base frequencies (+0.0001 Hz: $p = 0.0021$, +0.001 Hz: $p = 0.0172$, +0.01 Hz: $p = 0.0145$, and +0.1 Hz: $p = 0.0279$)

Conclusion: Neither the unmodulated carrier wave nor ambient magnetic fields contribute to AM RF EMF induced proliferative inhibition. AM RF EMF is not a resonance phenomenon but is highly sensitive to small fluctuations in treatment frequencies, highlighting the specificity required for optimal treatment.

#1834 Tumor treating fields (TTFields) plus chemotherapy abrogates pancreatic ductal adenocarcinoma (PDAC) proliferation and alters the tumor microenvironment.

Hani M. Babiker, Santanu Bhattacharya, Douaa Albelal, Shamit Kumar Dutta, Enfeng wang, Debabrata Mukhopadhyay

Mayo Clinic Florida, Jacksonville, FL

Background: TTFields are non-invasive and novel treatment modality that utilizes low intensity, alternating, and intermediate frequency electrical fields to inhibit cancer cell proliferation through a multitude of mechanisms. These include inhibition of mitosis, disruption of cancer cell membranes, metabolomic dysregulation of cancer cells, and immunogenic activation of the tumor microenvironment (TME). TTFields are approved in glioblastoma multiforme, non-small cell lung cancer and malignant mesothelioma. The PANOVA2 trial demonstrated promising efficacy for TTFields when applied together with chemotherapy in patients with PDAC. Mechanisms of TTFields in PDAC need further delineation. We sought to investigate the efficacy of TTFields *in vitro* and *in vivo* in PDAC cell lines and mouse models. Preclinical studies were conducted in concert with an going clinical trial (NCT04605913).

Experimental Procedures: Utilizing the *inovitro* apparatus we studied the effect of TTFields (150kHz, intensity 2.9+0.2 V cm RMS, 37ċ, over 72 hrs) in an array of PDAC (Panc1, KPC, Panc2, and AsPC1) and human pancreatic stellate cells (hPSC) cell lines, alone or together with cisplatin (Cis, 0.1µM) or gemcitabine (Gem, 0.01µM), compared to control. Cell viability analysis was conducted in each of the groups. In addition, cell lysates from Panc1 cells from concomitant treatment of TTFields plus Gem were probed for STAT3 and α-SMA to analyze stromal proteins and RAS pathway components (KRAS, P38, P42, and others) were performed via Westen Blot. We also performed RNA sequencing for the different groups to analyze gene expression levels. We further assessed the effect of TTFields (150kHz, intensity 1.8-2 V/cm RMS, over 2 weeks) using the *inovivo system* with and without chemotherapy (Cis, 0.25 mg/Kg per dose (i.p.) 3 times a week) compared to control in C57BL6 orthotopic murine models (6-7 weeks old C57BL6 mice).

Summary of Results: Our analysis revealed statistically significant abrogation of PDAC cancer cell lines for the different groups and hPSC cell viability when compared to control for TTFields monotherapy ($p < 0.001$) and TTFields concomitantly with Gem or Cis ($p < 0.0001$). Western blot analysis demonstrated that TTFields alone and when combined with chemotherapy alters both the stroma and RAS pathways with confirmed downregulation of pSTAT3 and α-SMA and KRAS, P-P38, and P-P42. *In vivo* analysis revealed significant decrease in tumor volume and weight for the concomitant effect of TTFields + Cis.

Conclusion: Our preclinical studies demonstrated the efficacy of TTFields as monotherapy and concomitantly with chemotherapy in PDAC and hPSC cell lines and mouse models. Mechanistic insights from the pre-clinical studies will inform the design of future TTFields studies in PDAC.

#1835 The impact of artemin depletion on acute radiation-associated oral pain.

Faihaa A. Ahmed, Thitsana Ingkasri, Sophi Schofield, Elizabeth Wright, B. Duncan X. Lascelles, Santosh K. Mishra, Michael W. Nolan

North Carolina State University, Raleigh, NC

A common complication of therapeutic radiotherapy for head and neck cancer is the development of severe pain. The biological mechanisms underlying acute orofacial radiation-associated pain (RAP) are unknown but may involve cold-sensing and cold-signaling pathways. A key cold receptor is TRPM8 (Transient Receptor Potential Melastatin family member 8), whose activation might be mediated by the neurotrophic factor artemin (ARTN) acting on its primary receptor, GFRα3. To test the hypothesis that radiation triggers release of ARTN, which results in activation of TRPM8 to cause RAP, we performed tongue-irradiation in mice that had been treated with either monoclonal anti-ARTN-neutralizing antibody or control (IgG). Lingual ARTN expression (IHC) increased after lingual irradiation, and this was mitigated by anti-ARTN treatment. Assessments of glossitis severity, body weight, and behavioral pain measures indicated that irradiation caused severe pain, which ARTN depletion failed to mitigate. However, after topical ophthalmic application of cold saline solution, tongue-irradiated anti-ARTN treated mice wiped their eyes less than their IgG-treated counterparts, and as assessed via ex vivo calcium imaging of trigeminal ganglia neurons, their afferent sensory nerves were less responsive to cold buffer. We therefore conclude that at the molecular level, ARTN depletion reduced radiation-induced cold sensitivity, but was insufficient to reduce behavioral indicators of RAP. Ongoing work in tissues from these mice is exploring whether changes in cold sensitivity correlated with TRPM8 expression, and future experiments are planned to assess: (1) whether genetic deletion of ARTN reduces RAP, and (2) if modulation of ARTN leads to upregulation of alternative TRPM8 activators.

#1836 Radiation effects in normal oral tissues caused by boron neutron capture therapy.

Lin Ma[1], Yupeng Luo[2], Jianyue Liu[2], Yonghui Luo[2], Zhiyi Wang[2], Zexi He[2], Haotian Tang[2], **Qi Liu**[3]

[1]Shenzhen University General Hospital, Shenzhen University, Shen Zhen, China,[2]Shenzhen University, Shen Zhen, China,[3]International Cancer Center, Shenzhen University, Shen Zhen, China

As a promising modality of binary radiation therapy, boron neutron capture therapy (BNCT) combines the advantages of boron-10 delivery agents for tumor-targeting and heavy charged particles for robust cell killing. BNCT has been approved for clinical treatment of head and neck cancer in Japan. However, the heavy ion rays generated from ^{10}B (n,α) ^{7}Li reactions as well as the concurrent gamma ray and thermal neutron radiation during BNCT can not only destroy cancer cells but also inevitably damage normal oral tissues, which constitutes the primary concern for head and neck cancer patients who are suitable for BNCT. Unfortunately, our knowledge about the radiobiology of BNCT-caused oral tissue damage is very limited to date. Therefore, we set out this study to explore the potential mechanisms in oral tissue reactions following BNCT. We collected various oral tissues from a mouse tumor model treated with BNCT and extracted total RNA from tongue tissues of 11 mice (4 controls without BNCT and 7 BNCT-treated samples with 2.5 mM/kg boron-10 delivery agents) for transcriptome sequencing. By comparing the gene expression profiles between the BNCT-treated group and the control group, we identified a total of 308 differentially expressed genes. Notably, these genes were enriched in cell junctions and cell membrane pathways. We further analyzed the interactome network of the 308 genes by common topological algorithms, i.e., Maximal Clique Centrality (MCC), Maximum Neighborhood Component (MNC), and Degree, where we identified a subset of 11 genes based on the shortest paths with the algorithm Stress. Among the 11 genes, both β-Catenin (CTNNB1) and Annexin A2 (ANXA2) were significantly downregulated in BNCT-treated group ($P<0.05$). Further RT-qPCR analyses confirmed the results, while immunohistochemistry analyses demonstrated consistent BNCT effects in protein levels of these two genes. The encoded protein from CTNNB1 constitutes adherens junctions and anchors the actin cytoskeleton for maintenance of epithelial cell layers. In addition, ANXA2 plays an important role in tissue inflammation and vascular integrity. Thus, we speculate that BNCT induces cell-cell junction disorder through CTNNB1 and ANXA2, leading to damaged cell junctions in blood vessels and normal tissue inflammation. Indeed, disrupted epithelial structure as well as increased interferon-γ expression was detected in oral tissue microenvironment following BNCT. These findings set a basis for developing strategies of normal tissue protection and improving quality of life of head and neck cancer patients that were treated with BNCT.

#1840 Potent antitumor efficacy of Dato-DXd compared with sacituzumab govitecan in brain metastases mouse model of triple negative breast cancer.

Chikako Funasaka[1], Hiroki Takashima[2], Daisuke Okajima[3], Tsuyoshi Karibe[3], Takanori Maejima[3], Satoru Yasuda[3], Toru Mukohara[4], Toshihiko Doi[1], Masahiro Yasunaga[2]

[1]Experimental therapeutics, National Cancer Center Hospital East, Kashiwa City, Japan,[2]Developmental Therapeutics, Exploratory Oncology Research & Clinical Trial Center, Kashiwa City, Japan,[3]Daiichi Sankyo Company, Limited, Tokyo, Japan,[4]Medical Oncology, National Cancer Center Hospital East, Kashiwa City, Japan

Background: Metastatic brain tumors are common, especially in patients with triple-negative breast cancer (TNBC) and lead to poor prognosis. Current drug therapies are unsatisfactory, and the development of new drugs is needed. TROP2 is overexpressed in various cancers and an attractive target molecule in breast cancer. Datopotamab deruxtecan (Dato-DXd) is an antibody-drug conjugate (ADC) targeting TROP2 and designed to selectively release the payload in the tumor cell via a cleavable tetrapeptide-based linker. Dato-DXd has demonstrated preliminary intracranial activity in patients, but its pharmacodynamics in brain metastases is not yet clarified. Here, we evaluated the efficacy and payload distribution of Dato-DXd and sacituzumab govitecan (SG), another TROP2-directed ADC that was designed to be cleaved by hydrolysis which may result in gradual payload release in blood circulation and the tumor, in a mouse brain metastasis model of TNBC.
Methods: We prepared a brain metastasis model by transplanting luciferase-expressing TROP2-positive TNBC cells into the brains of nude mice. To characterize ADC in treatment against intracranially transplanted tumors, the antitumor activity by measuring chemiluminescence and the concentration of the payload in tumors after intravenous administration of Dato-DXd were compared with those of SG.
Results: Chemiluminescence showed that Dato-DXd administered at 10 mg/kg on Day 1 significantly reduced tumor size in the brain metastasis model compared with SG administered at 10 mg/kg on Days 1 (average -99.5% vs. -1.8%, p=0.02). Median survival was 18 days (95% confidence interval [CI]; 14-not assessed [NA] days) in control group, 48 days (15-NA days) in SG group, and 83 days (49-NA days) in Dato-DXd group. The DXd payload from Dato-DXd was rarely detected in the serum (Lower limit of quantification [LLOQ] of DXd: 0.01 ng/mL), while the SN-38 payload from SG was gradually increased (LLOQ of SN38: 0.015ng/mL). After administration of Dato-DXd, the payload in the tumor was accumulated and maintained, whereas the payload concentration gradually decreased in SG group (the area under the concentration-time curve [AUC] of the payload: 320.9 vs. 161.8 ng*hr/g). In contrast, the AUC of the payload in normal brain after administration of Dato-DXd was significantly lower than that after administration of SG (13.7 vs. 48.5 ng*hr/g).
Conclusion: In this mouse model of brain metastases, Dato-DXd showed more potent antitumor activity against intracranially transplanted tumors of TNBC with higher accumulation of the payload in tumors compared with SG. The dosing utilized in this model does not directly correlate with human dosages, necessitating caution in interpreting the study results. This study warrants further clinical evaluation of Dato-DXd in TNBC patients with brain metastases.

#1841 NanoGhost - A drug targeting system for treatment of solid tumors.

Haim Tsubery[1], Ziv Azoulay[1], Shir Weber[1], Michal Lulu[1], Limor Matzrafi[1], Yonatan Malca[1], Marcell Machluf[2], **Osnat Bohana-Kashtan**[1]

[1]NanoGhost, Natanya, Israel,[2]Technion - Israel Institute of Technology, Haifa, Israel

Introduction: NanoGhosts (NGs) are nanovesicles derived from the cell membrane of human bone marrow mesenchymal stem cells (hBM-MSCs). NGs preserve MSCs cell membrane architecture and characteristics, thus harnessing MSCs' innate targeting capability towards tumors. SN38 (a topoisomerase 1 inhibitor) is a highly potent anti-cancer drug with poor water solubility, low plasmatic stability, high systemic toxicity, and low bioavailability. SN38 is approved for colorectal cancer (CRC), and pancreatic cancer as the prodrug Irinotecan or as liposomal Irinotecan, respectively. It is also approved as the antibody drug conjugate sacituzumab govitecan-hziy for triple negative and HR+HER2- breast cancer and metastatic urothelial cancer. We aim to target SN38 to various solid tumors by utilizing the inherent tumor targeting capability of MSCs derived NGs while minimizing SN38 systemic exposure.
Methods: MSCs derived NGs were loaded with SN38 using an NHS ester-activated linker. NGs bearing SN38 were tested for anti-cancer activity in vitro and in-vivo.
Results: SN38-NHS linker reacted in excess of 20 equivalents to protein content in NGs suspension resulted in average loading of ~0.08 µg SN38 per 1 µg NGs lipid. SN38 loaded NGs demonstrated relatively low leakage (of up to 34%) after up to 6 hr at 37°C in mouse serum. In vitro, SN38 loaded NGs inhibited proliferation of H460 lung cancer cells (IC50 of 1.6 µg/mL after 6 hr exposure). In vivo, IV administration of SN38 loaded NGs at a dose level of 5 mg/kg NGs lipid (~0.4 mg/kg SN38), resulted in tumor growth inhibition of HCT116 CRC in mice, similar to the positive control given at a dose level that was ~25 fold higher. Biodistribution analysis showed concentration of Cy7 labeled SN38-NGs at the tumor site while minimal-no retention in infiltrating organs. Maximal tolerated dose of SN38 loaded NGs was not yet achieved following administrating of up to 10 mg/kg, supporting use of higher levels in follow on studies.
Summary: Our data support the use of NGs for targeting highly potent and toxic drugs with draggability barriers (such as SN38) to tumors.

#1843 Therapeutic implication of pH/hypoxic responsive nanoencapsulated tunicamycin on pancreatic cancer by targeting K-Ras^{G12D}.

Axel H. Breier[1], Debasmita Dutta[2], Anjali Kambhampati[1], Inamul Haque[3], Archana De[1], Sunil P. Upadhyay[1], Sushanta K. Banerjee[4], Mohiuddin Quadir[5], Snigdha Banerjee[6]

[1]Cancer Research Unit, Kansas City VA Medical Center, Kansas City, MO,[2]Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA,[3]Kansas City VA Medical Center, Kansas City, MO,[4]University of Kansas Medical Center, Kansas City, MO,[5]Coatings and Polymeric Materials, North Dakota State University, Kansas City, MO,[6]Cancer Research Unit, University of Kansas Medical Center and VA Medical Center, Kansas City, MO

Pancreatic ductal adenocarcinoma (PDAC) remains one of the leading sources of cancer mortality worldwide, including US Veterans. An initial response to chemotherapy, such as Gemcitabine (GEM) alone or in combination with other chemotherapies, is often followed by emergent resistance, reflecting an urgent need for targeted therapies. PDAC cells are highly addicted to oncogenic K-RAS mutations for their growth, progression, immunosuppression, and drug resistance, but mutant K-RAS in PDAC is still tricky to target. A glycosylation inhibitor, Tunicamycin (TM), is a potent killer of PDAC cells. However, free-form TM is found to be very toxic in *in vivo* implication as a therapy. To repeal the limitation of TM, we have synthesized a pH/Hypoxic-responsive iRGD-tagged biodegradable nano-encapsulated TM (^{NP}TM) that was found to inhibit PDAC cell growth parallel with blocking K-RAS^{G12D} expression and its downstream signaling pathways associated with desmoplasia, and program cell death ligand 1 (PD-L1) expression. Moreover, ^{NP}TM markedly reduced the xenograft tumor growth, increased intratumoral CD8+ T cells, and increased in overall survival of treated mice. Furthermore, ^{NP}TM treatment synergizes with GEM to further regress PDAC growth in a PDAC xenograft model. These studies provide insights into ^{NP}TM treatment with a potential clinical application.

#1844 From barrier to bullet: Genetically engineered CAF-derived exosomes for PDAC therapy.

Leyla Escalante Gonzalez[1], Subin Yu[1], Aya Jaros[1], Alaa Bakr[1], Cuiyan Xin[2], Luke Lee[1], Ahmed Elzoghby[1]

[1]Engineering in Medicine Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[2]Renal Medicine Division, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Pancreatic ductal adenocarcinoma (PDAC) remains one of the most lethal cancers, with a five-year survival rate of less than 10%. This poor prognosis is due in part to the tumor's dense desmoplastic stroma, which impedes nanoparticle penetration and immune cell infiltration, rendering conventional therapies ineffective. The current therapeutic paradigm, which directly targets PDAC cells with nanoparticles or relies on immune modulation, often fails due to the "immune cold" PDAC tumor microenvironment (TME) characterized by low infiltration of cytotoxic T lymphocytes (CTLs) and abundance of cancer-associated fibroblasts (CAFs) that create a formidable stromal barrier. Therefore, there is a critical need for a paradigm shift in PDAC treatment—moving beyond traditional strategies that directly target cancer cells or modulate the immune system, and instead, focusing on harnessing the unique properties of the TME itself to combat the tumor. Therefore, we transformed the inherent limitations of the PDAC TME into therapeutic opportunities by reprogramming CAFs to act as endogenous factories of cytotoxic exosomes capable of selectively targeting and killing cancer cells. By leveraging the natural abundance and strategic location of CAFs within the TME, we employed exosome fusion protein technology to engineer CAFs to produce exosomes loaded with cytotoxic proteins, such as granzyme B (GrB), or pro-melittin, fused to one of the exosomal components e.g., CD63 on gene level, and specific targeting motifs e.g., B7-H3 single-chain variable fragment (scFv) to ensure selective uptake by PDAC cells inducing their apoptosis. These cytotoxic exosomes bypass the need for CTL infiltration, thereby overcoming the challenges posed by the "immune cold" TME. We engineered CAF-targeted lipid nanoparticles (LNPs) for delivering plasmid DNA (pDNA) encoding the fusion proteins into PDAC patient-derived CAFs. The cells could be successfully transfected in vitro and subsequently produced the desired cytotoxic exosomes. The expression of fusion proteins in the exosomes was confirmed in vitro via western blot and proteomic analysis. The GFP-expressing exosomes showed efficient internalization into PDAC cells as evidenced by immunofluorescence imaging and flow cytometry. The genetically engineered CAF-derived exosomes induced efficient apoptosis of patient-derived PDAC cells in vitro revealing their cytotoxic power. Moreover, intravenous administration of the pDNA-loaded lipid nanoparticles into pancreatic tumor mouse model significantly suppressed tumor growth. Histopathological studies and biochemical analysis showed the safety of our engineered nanoparticles. This approach leverages the unique properties of the TME to provide a new paradigm in cancer therapy that avoids the need for direct targeting of cancer cells or enhancement of immune cell infiltration.

#1845 Increased antitumor activity and reduced organ toxicity of doxorubicin administered using RRx-001 modified RBCs.

Ana Sanchez, Garett Soapes, Chris Larson, **Tony Reid**, Bryan Oronsky

EpicentRx, Inc., La Jolla, CA

RRx-001 is currently in a phase III clinical trial for small cell lung cancer and showed activity in a phase II trial in colorectal cancer. It has negligible side effects so could be used in combination regimens with low risk of additive toxicity. It has multiple mechanisms of action including binding to hemoglobin to alter red blood cell (RBC) properties, increasing RBC adhesion to the endothelium and increasing membrane phosphatidyl serine exposure. Importantly, RRx-001-treated RBCs are known to preferentially localize to solid tumors. Existing therapeutics that partition into RBCs could therefore be localized to cancers and have a greater therapeutic index by combining with RRx-001. Doxorubicin has been a cornerstone of treatment for many cancer types for decades and has well-known limiting side effects including cardiotoxicity and cytopenias. It partitions into RBCs at equilibrium with approximately 60% of doxorubicin becoming intracellular. Therefore, treatment with RBCs loaded with doxorubicin and modified with RRx-001 to promote localization to tumors may improve its activity and reduce its potential side effects. Previous research in mice carrying H22 tumors found that biodistribution to the tumor was higher after treatment with RBCs loaded with doxorubicin and treated with RRx-001 than with free doxorubicin or RBCs loaded with doxorubicin without RRx-001, while biodistribution to the heart and skin was decreased. H22 tumor growth was lower after treatment with RBCs loaded with doxorubicin and treated with RRx-001 than with doxorubicin alone or RBCs loaded with doxorubicin without RRx-001. Further experiments identified an approach for loading RBCs with doxorubicin and treating with RRx-001 that could be implemented clinically while achieving high doxorubicin loading efficiency given its rate of equilibration into RBCs, avoiding hemolysis, and minimizing doxorubicin precipitation. The final chosen procedure would be to draw blood with citrate anticoagulation while mixing with RRx-001 to reach 5 μM, add 2 mg/mL doxorubicin in normal saline to reach a final concentration of 0.3 mg/mL, mix for 1 hour at 37°C, and re-infuse the treated blood. For a clinical trial with a starting dose of 20 mg/m^2 doxorubicin weekly, a patient with a BSA of 2 m^2 would require 101 mL of blood to be drawn for mixing and re-infused 1 hour later, which would be practical even for patients with advanced cancer who are candidates for doxorubicin. For reference, a typical blood donation is approximately 450 mL. In conclusion, this describes the pre-clinical rationale and establishes a clinical procedure for administering RBCs loaded with doxorubicin and treated with RRx-001 as a way to improve its activity and reduce side effects.

#1846 Enhancing chemoimmunotherapy of metastatic TNBC through potent and immunomodulatory drug combination nanoparticles.

Caroline B. Linde, Xiaolin Xu, Rodney J. Y. Ho, Mary L. Disis, **Qingxin Mu**

University of Washington, Seattle, WA

Breast cancer is the most common cancer in women worldwide, and triple-negative breast cancer (TNBC) represents the most challenging subtype to treat due to the lack of hormone or HER2 receptors. Current guidelines for metastatic TNBC recommend a combination of pembrolizumab with chemotherapy for patients with PD-L1 expression (CPS ≥ 10). To enhance the efficacy of existing regimens, we previously reported that water soluble gemcitabine (G) and insoluble paclitaxel (T) can be stabilized with lipid excipients and a novel process into drug combination nanoparticle suspension (GT-in-DcNPs, ~60 nm) capable of co-delivering both drugs to the tumor. We demonstrated that a single IV dosing of GT-in-DcNP, but not soluble form, inhibited lung metastasis of 4T1 in mouse by nearly 100%. In this study, we hypothesized that GT-in-DCNPs not only improve tumor inhibition compared to free GT, but also increase PD-L1 expression in the primary tumor and reduce myeloid-derived suppressor cells (MDSCs), thereby sensitizing tumors to anti-PD-1/PD-L1 immune checkpoint inhibitor therapy. Consequently, combining antibody therapy with GT-in-DcNPs could further improve therapeutic outcomes. Our *in vitro* studies showed that free G or T increased PD-L1 mRNA and protein expression in 4T1 TNBC cells in a dose- and time-dependent manner. When the drugs were combined in G-to-T molar ratios of 30:1 to 1:1, PD-L1 mRNA levels were upregulated by 4- to 5-fold after 24 hours. Under static cellular incubations, GT-in-DcNPs and free GT counterpart produced a similar impact on PD-L1 upregulation. We further investigated orthotopic 4T1 tumoral PD-L1 upregulation in BALB/c mice. Six days after a single IV dose of 35/3.5 mg/kg GT-in-DcNP (~30:1 molar ratio) but not free GT elevated PD-L1 mRNA expression in tumor by ~70%. In a preliminary efficacy study with the orthotopic 4T1 model (~100 mm^3), a single GT-in-DcNP (35/3.5 mg GT, IV, day 0) and anti-PD-L1 antibody (100 µg, IP, day 6) combination exhibited significant tumor growth reduction (168%) than the GT-in-DcNP or free drug treatment (248% and 265%, respectively; $n = 8$, $p < 0.05$), by day 12. Flow cytometry analysis of tumor and spleen cell suspensions revealed that MDSC populations (Gr-1+ CD11b+) in both tissues were reduced by GT-in-DcNPs on day 6 post-treatment, whereas no changes were observed in the free drug groups. Furthermore, the spleen CD8+ T cell population on day 12 was increased by 65% in DcNP-antibody combination group compared to free GT-antibody combination group ($p < 0.05$). Overall, these data suggest that GT-in-DcNP treatment elevates PD-L1 expression in 4T1 TNBC cells *in vitro* and *in vivo* and reduces MDSC populations *in vivo*, and its combination with PD-L1 antibody enhances tumor inhibition beyond that achievable by GT in conventional dosage form. Thus inclusion of GT-in-DcNP with immune checkpoint inhibitor against PD-L1 may provide additional benefits.

#1847 Closed-loop drug delivery system to personalize chemotherapy dosing.

L. DeRidder[1], K. Hare[1], T. Smierciak[1], M. Chao[1], A. Lopes[1], J. Jenkins[1], N. Fitzgerald[1], E. MacPherson[1], N. Fabian[1], J. Morimoto[1], J. Chu[1], A. Kirtane[1], W. Madani[1], K. Ishida[1], J. Kuosmanen[1], N. Zecharias[1], C. Colangelo[2], H.-W. Huang[1], M. Chilekwa[1], N. Lal[1], S. Srinivasan[1], A. Hayward[1], B. Wolpin[3], D. Trumper[1], T. Quast[4], D. Rubinson[3], R. Langer[1], G. Traverso[1];
[1]Massachusetts Institute of Technology (MIT), Cambridge, MA, [2]Agilent Technologies, Santa Clara, CA, [3]Dana-Farber Cancer Institute, Boston, MA, [4]University of South Florida, Tampa, FL

While most oncologists know that many chemotherapies are dosed on a body surface area (BSA) basis, fewer know that the equations used to estimate BSA are based on a study done over 100 years ago using data from just 9 people. Moreover, two patients with the same BSA can have many factors, such as body composition and genetics, which can impact a drug's pharmacokinetics and pharmacodynamics, resulting in worse therapeutic outcomes. To solve this problem, we developed a medical device that can personalize the dose of chemotherapy to the patient during an infusion center visit. Our medical device, which we call CLAUDIA (the Closed-Loop AUtomated Drug Infusion regulator) is a closed-loop drug delivery system that measures the concentration of drug and changes the infusion rate in real time to keep the concentration of drug within the therapeutic window. CLAUDIA uses high performance liquid chromatography-mass spectrometry (HPLC-MS) as the sensor, which allows it to be relatively easily translated to control many different drugs, either individually or in a combination chemotherapy regimen. We demonstrate CLAUDIA can control the concentration of 5-fluorouracil (5-FU) in rabbits, which were manipulated to capture the pharmacokinetic variability observed clinically. We then adapted CLAUDIA to also control the concentration of irinotecan, demonstrating its ability to be rapidly translated to additional chemotherapies. Finally, we perform a cost-effectiveness analysis that demonstrates that CLAUDIA is cost-effective compared to the current standard of care for drug dosing of 5-FU (i.e., BSA). Overall, CLAUDIA presents promising medical device that can personalize the dosing of chemotherapy, which may be able to improve the therapeutic outcomes for multiple chemotherapies.

#1848 Layered zirconium phosphate nanoparticles as anticancer drug carrier.

Aleannette Lopez-Cubero[1], Getsemary Cabrera[1], Armando Santiago[2], Yairisis Rivera[2], Maria M. Rivera[3], Alianys Rosario[4], Magaly Martinez-Ferrer[5], Jorge L. Colon[1]

[1]Chemistry, University of Puerto Rico, San Juan, Puerto Rico,[2]Biology, University of Puerto Rico, San Juan, Puerto Rico,[3]Division of Cancer Clinical & Translational Research, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[4]Program SEED, American Chemical Society, San Juan, Puerto Rico,[5]2Division of Cancer Clinical & Translational Research, School of Pharmacy, University of Puerto Rico Comprehensive Cancer Center, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

Layered zirconium phosphate nanoparticles (ZrP), inorganic structures with a layered composition of zirconium atoms linked by phosphate groups, exhibit no cytotoxic effects on healthy or cancer cells, indicating a strong safety profile. We are investigating ZrP as a carrier for mitoxantrone (MTX), an anticancer drug that inhibits topoisomerase II and disrupts DNA synthesis but lacks selectivity between healthy and cancer cells. MTX shows prolonged retention in the body, with potential systemic toxicity affecting thyroid, hepatic, and cardiac tissues. This study aims to reduce systemic toxicity and protect healthy tissues from MTX by intercalating MTX into ZrP (MTX-ZrP) via ion exchange, determining the conditions that affect MTX's release, and evaluating the cytotoxicity of MTX-ZrP on prostate cancer cells.

MTX was intercalated with ZrP nanoparticles, forming MTX-ZrP, which was then characterized by Fourier Transformed infrared spectroscopy, scanning electron microscopy/energy dispersive X-ray spectroscopy, and X-ray powder diffraction at different molar ratios. A drug release study to determine conditions affecting MTX liberation from ZrP at different pHs using simulated body fluid and lysosomal fluid showed that ZrP nanoparticles maintain stable and intercalated MTX at biological pH 7.4. However, at pH 4.5, which simulates the extracellular environment of the tumor, MTX is released, implying that this process is pH-regulated. Cell viability studies with androgen receptor-negative prostate cancer cell line PC3 showed that MTX-ZrP produced a cytotoxic effect. These findings represent the initial phase of a possible drug delivery method that may greatly minimize adverse effects and harm to healthy tissues, offering promise for a more bearable cancer treatment. In the future, we expect to further improve the drug carrier system's efficacy by modifying the surface of MTX-ZrP, which could significantly enhance its selectivity and specificity.

#1849 Developing a formulation of MDM2 inhibitor: Idasanutlin for enhanced stability, solubility, and anticancer activity in p53 sensitive lung cancer.

Bhoomi Dholariya, Akanksha Patel, Henis Patel, Ketan Patel

St. John's University, Queens, NY

Lung cancer is generally categorized into two major class, non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC). Both types chiefly disrupt the lung's primary function of supplying oxygen to the body due to uncontrolled cell growth. Lung cancer metastasis is a major obstacle in controlling the prevalence of the tumor. One contributing factor is the over expression of MDM2 protein which inhibits the tumor suppressive effect of p53 protein, thereby fostering the proliferation and metastasis of NSCLC. To address this, we employed a second generation MDM2 inhibitor - Idasanutlin (IDA) to develop and characterize self-emulsifying nanocomplex of idasanutlin-ionizable lipid (IDLIN). IDA has demonstrated promising anticancer activity *in vitro* in p53 sensitive lung cancer cell lines. However, as a brick-dust molecule with poor solubility in both water and oil, it poses a significant challenge in development of lipid based nano formulation. We hypothesized that forming a hydrophobic complex between the carboxylic group of anionic IDA and the tertiary amine of DLin-DMA would improve the stability of IDA in water. The anticancer efficacy of this formulation was tested using various 2D and 3D cell culture assays in wild type p53 cells (A549 and H460). To formulate IDLIN, we used IDA along with Dimethyl Acetamide (DMA) as a cosolvent, DLin-DMA as the ionizable lipid, and 1:1 preconcentrate of oil and non-ionic surfactant. Medium Chain Triglycerides (MCT) served as oil, while Solutol HS 15 was used as surfactant. The inclusion of DMA and DLin-DMA significantly enhanced drug loading, achieving 3%w/w compared to 0.5%w/v in the conventional self-nanoemulsifying system. The observed particle size and zeta potential for IDLI (formulated with IDA, DMA, and MCT:HS15 without ionizable lipid) were 63.98nm and -30.7mV, respectively, whereas for IDLIN, the particle size and zeta potential were 71.69nm and -23.1mV, respectively. The *in vitro* anticancer efficacy of IDLIN was assessed against IDA dissolved in dimethyl sulfoxide at a concentration of 1 µM using a multicellular 3D spheroid assay. Both treatments resulted in a significant reduction in spheroid diameter and area compared to control group. By the end of the treatment, both groups also exhibited higher levels of red fluorescence compared to the control group, indicating a substantial increase in dead cells across both cell lines. In A549 cells, the treatment groups showed a decrease in spheroid area by 45.70% for IDA and 46.18% for IDLIN. In H460 cells, the decrease was 57.64% for IDA and 59.23% for IDLIN. The observed IC_{50} of IDA and IDLIN in A549 cells were 3.615µM and 4.766µM respectively and in H460 cells, 0.641µM and 0.707µM was respectively. This is the very first research in use of ionizable lipid in stabilizing anionic hydrophobic molecules and testing nano-formulation of MDMD2 inhibitor in lung cancer.

#1850 MUC13-targeted PPNPs efficiently inhibited pancreatic tumor growth and influenced tumor immune surveillance.

Vivek Kumar Kashyap, Neeraj Chauhan, Mohammed Sikander, Eswara N. HK Ghali, Fnu Shabnam, Rahul Tiwari, Sheema Khan, Bilal B. Hafeez, Murali M. Yallapu, Meena Jaggi, Subhash C. Chauhan

University of Texas Rio Grande Valley, McAllen, TX

Pancreatic ductal adenocarcinoma (PDAC) is one of the most lethal types of cancer, characterized by a dismal 5-year overall survival rate, primarily due to lack of early detection and limited effective treatment. Gemcitabine (GEM) is most effective therapy for pancreatic cancer (PanCa), but it only offers a marginal survival benefit of 6 months. A combination of Paclitaxel (PTX) albumin nano-formulation (Abraxane) and GEM has shown marginal improvement in PanCa treatment. This poor treatment response has been associated with desmoplastic stroma, microbiome effects, altered tumor microenvironment (TME), suppressive immune cells and PDAC-specific signaling pathways. Our research has demonstrated that MUC13 is highly overexpressed in PanCa and is associated with cancer progression and metastases. Considering these facts, we have generated an MUC13 antibody targeted nanoparticle formulation for tumor specific targeted delivery of paclitaxel using a multi-layered Pluronic F127 and polyvinyl alcohol stabilized and poly-L-lysine coated poly(lactic-co-glycolic acid) nanoparticles (PPNPs) to improve therapeutic outcome of PanCa therapy. Our MUC13-targeted PPNPs (MUC13-PPNPs) showed enhanced cellular uptake of MUC13-PPNPs formulation in HPAF-II (MUC13+) compared with Panc-1 (MUC13) PanCa cells as determined by immunofluorescence. Further, our novel formulation effectively inhibits growth and metastatic phenotypes in MUC13+ cells as compared with MUC13- cells of PanCa *in vitro.* In our PanCa xenograft mouse model (HPAF-II + stromal cells), we found that PPNPs alone significantly inhibited growth of tumor ($P < 0.05$ when compared with control (PLGA) and treatment group PTX. Furthermore, the tumor volume of MUC13-PPNPs group was not only highly significantly lower than control PLGA and PTX ($P < 0.05$), but also lower than PPNPs alone group ($P < 0.05$) or control ($P < 0.05$). Our findings also demonstrated that PPNPs/MUC13-PPNPs synergize GEM therapy response *in vitro* and *in vivo* mouse models. Further, tumor tissue treated with PPNPs/MUC13-PPNPs demonstrate the downregulated expression of sonic hedgehog and other oncogenic signaling axis determined by qPCR, Western blots, and immunofluorescence analyses. Additionally, our nano formulation effectively reduced tumor volume in syngeneic orthotopic xenograft mouse model involving injection of KPC-Luc in C57Black/6 mice and target tumor-associated macrophages (TAM) by repolarizing M2 into M1 phenotype *via* inhibiting expression of M2 markers and an increase in M1 markers. In conclusion, we observed that our novel formulation has high therapeutic ability for achieving pancreatic tumor specific delivery PTX, synergize GEM therapy response and altered the tumor immune surveillance mechanisms. Thus, this unique approach can effectively enhance therapeutic efficacy main line chemotherapies and immune checkpoint immunotherapies.

#1851 Development of a smart nanocarrier system for prostate cancer immunotherapy.

Imani Roundtree[1], Angelo Altenor[1], Rodney Valdivia[1], Tovah St. Ignac[1], Alexandra Esposito[1], Karelys DiazDavila[2], Richard Lamptey[2], **John Fetse**[3]

[1]Larkin University College of Pharmacy, Miami, FL,[2]Palm Beach Atlantic University, West Palm Beach, FL,[3]School of Pharmacy and Pharmaceutical Sciences, Binghamton University, Binghamton, NY

Prostate cancer (PCa) is characterized by the overexpression of monoamine oxidase-A (MAO-A), a driver of tumor growth, metastasis, and treatment resistance. Monoamine oxidase inhibitors (MAOIs), such as phenelzine, have shown promise as repurposed agents for PCa therapy. However, systemic administration of phenelzine at effective doses carries significant risks of neuropsychiatric side effects, including aggression, seizures, and suicidal ideation, highlighting the need for a targeted delivery approach. This study aims to develop a smart nanocarrier system for the co-delivery of phenelzine (PHE) and the anti-programmed death ligand 1 (PD-L1) peptide (C7), enhancing therapeutic efficacy while reducing off-target effects. The nanocarrier employs a pH-sensitive hydrazone bond and a matrix metalloproteinase-2 (MMP-2) cleavable linker to achieve site-specific drug release. The system integrates polyethylene glycol-hydrazone-phenelzine (PEG-HZ-PHE) and an MMP-2cleavable linker tethered to the anti-PD-L1 peptide (C7-MMP2), into a lipid nanocarrier platform. Characterization using dynamic light scattering (DLS) revealed a particle size of 190.0 ± 3.9 nm, a polydispersity index (PDI) of 0.17 ± 0.02, and a zeta potential of -33.6 ± 1.3 mV. pH-dependent release studies showed that phenelzine release was highest at pH 5.4 (74.7 ± 0.6%) and lowest at pH 7.4 (11.3 ± 0.1%) after 18 hours, with a 42.3 ± 0.6% release at pH 6.4. Enzyme cleavage studies demonstrated that 73.8 ± 14.5 % of C7 was released within 4 hours of incubation with MMP-2 enzyme, with only 20.3 ± 2.1% of C7-MMP2 remaining after the same period. Cytocompatibility assessment using a red blood cell (RBC) hemolysis assay showed no significant hemolytic activity compared to the negative control (PBS buffer), while the positive control (0.5% Triton X-100) caused significant hemolysis. In conclusion, the developed dual-responsive nanocarrier is stable at physiological pH (7.4) but efficiently releases therapeutic agents in acidic and MMP-2 enzyme-rich environments, offering potential for improved PCa therapy by minimizing off-target effects.

#1852 Uncovering regulatory mechanisms and therapeutic targets in EV-mediated nanoparticle transfer: A proteomics and high-throughput screening approach.

Xian Wu, Hong-Bo Pang

University of Minnesota, College of Pharmacy, Minneapolis, MN

Extracellular vesicles (EVs) are naturally occurring vesicles that facilitate the transfer of biomolecules between cells, playing a vital role in cellular communication and regulation. Recently, EVs have been discovered participating active transport of nanomaterials between cells, suggesting a novel method to enhance the delivery of nanoparticles. A 3D intercellular exchange assay has been developed by our group to monitor and quantify EV-mediated transfer of silver nanoparticles (AgNPs) across different cell types. Furthermore, distinct EV subpopulations, those containing AgNPs (AgNP-containing) and those without (AgNP-free), were isolated from AgNP-exposed cells using density gradient ultracentrifugation. In this study, we leverage proteomics and high-throughput screening (HTS) to reveal the regulatory mechanisms of EV-mediated intercellular communication and identify compounds that regulate this process. Using mass spectrometry and advanced bioinformatics, unique protein signatures associated with each EV type were identified, uncovering biomarkers that indicate origin and functional relevance in EV-mediated transport process. To investigate potential regulators of EV-mediated intercellular exchange, we combined HTS with our 3D intercellular exchange assay to identify compounds that modulate EV-mediated transfer of nanomaterials. Integrating HTS with quantitative proteomics enabled us to identify key compounds that specifically impact the formation and secretion of AgNP-free and AgNP-containing EV subpopulations. These findings not only provide new insights into the regulatory mechanisms controlling nanomaterial-sorting and EV genesis but also highlight potential therapeutic targets for modulating EV-mediated intercellular exchange, which may further improve nanomedicine delivery. This work underscores the utility of combining proteomics and HTS for the discovery of small molecules capable of regulating EV-mediated transfer, with implications for therapeutic development and biomarker discovery.

#1853 BIK-E715E, an integrin-targeting ligand-drug conjugate equipped with a novel drug delivery system, demonstrates enhanced antitumor efficacy in glioblastoma.

K. Shin, H. Sung, J. Jung, S. Kim;
BIK Therapeutics Inc., Seongnam, Korea, Republic of

We developed a novel drug delivery system ELiTE-DDS, designed to enhance target-selective intracellular delivery of therapeutic agents, where ELiTE stands for enhancing ligand targeting and endocytosis. Integrins $\alpha_v\beta_3$ and $\alpha_v\beta_5$, highly expressed in glioblastoma tumor cells, are molecular targets for glioblastoma treatment. In this study, we applied the ELiTE-DDS platform to a conjugate consisting of a high-affinity integrin $\alpha_v\beta_3/\alpha_v\beta_5$-binding ligand, D-[c(RGDfK)]$_2$, and a topoisomerase I inhibitor exatecan, yielding BIK-E715E as a drug candidate for glioblastoma. BIK-E715E exhibited high selectivity and binding affinities for integrins $\alpha_v\beta_3$ and $\alpha_v\beta_5$ and was internalized through an Arf6-dependent, dynamin-independent endocytic pathway. Cellular treatment with BIK-E715E produced PARP cleavage and phosphorylation of Chk1 and histone H2AX, indicating drug-induced apoptosis and DNA damage, respectively. There was significant translocation of BIK-E715E in a hCMEC/D3 in vitro blood-brain barrier (BBB) model, suggesting its receptor-mediated transcytosis across the BBB. In U87MG subcutaneous and orthotopic xenograft mouse models, BIK-E715E accumulated in tumors with high efficiency and resulted in marked inhibition of tumor growth, which was greater than exatecan-induced growth inhibition. These data demonstrate that BIK-E715E is an attractive drug candidate for glioblastoma, equipped with a novel drug delivery system. Further, they also suggest that our ELiTE-DDS platform has great potential for enhancing target-selective intracellular delivery of therapeutic agents across the BBB.

#1854 Neurotransmitter-derived lipid nanoparticles (LNPs) for brain-targeted drug delivery.

Shuyu Wang

Cancer Molecular Diagnostics Core, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

The treatment of central nervous system (CNS) diseases, such as neurodegenerative disorders, brain tumors, brain infections, and stroke, is severely constrained by the blood-brain barrier (BBB) because it prevents the transfer of most of small-molecule drugs and macromolecules (e.g., peptides, gene drugs, and protein drugs) into the brain. We have developed a previously unknown class of neurotransmitter-derived lipidoids (NT-lipidoids) as simple and effective carriers for enhanced brain delivery of several BBB-impermeable cargos. Particularly, doping the NT-lipidoids into BBB-impermeable lipid nanoparticles (LNPs) gave the LNPs the ability to cross the BBB. Using this novel brain delivery platform, we successfully delivered small molecular drug, genes and proteins into the mouse brain via systemic intravenous administration. For example, the BBB-impermeable paclitaxel was delivered to the brain to treat glioma, and genome-editing fusion protein (–27)GFP-Cre recombinase was delivered for effective genome editing in neuronal cells of the Ai14 mouse brain through intravenous injection. Our recent results demonstrate that by doping the NT-lipidoids into BBB-impermeable clinical used liposome nanomedicines can give the nanomedicines the ability to cross the BBB to treat brain tumors and brain infections. We believe this NT-derived LNPs is a new, simple, universal, and effective brain delivery system, which may find wide applications in treating CNS diseases including brain tumors and providing a tool to study the brain function.

#1855 Insights from drug development experts: Surveying challenges and outcomes for large-volume subcutaneous oncology drugs.

Mehul Desai[1], Omar Rahman[1], Beate Bittner[2], Wei Chen[3], Maxwell Koobatian[4], Deepa Rajagopalan[5]

[1]Medical Affairs, Enable Injections, LLC, Cincinnati, OH,[2]Global Product Strategy, Roche, Basel, Switzerland,[3]Wuxi Biologics (US), Worcester, MA,[4]Corporate Development, Crinetics Pharmaceuticals, San Diego, CA,[5]45 Management LLC, New York, NY

With several well-known large-volume subcutaneous (SC) oncology drugs, such as daratumumab, trastuzumab, rituximab, nivolumab, and pembrolizumab, either approved or in trials, understanding how administration volume impacts drug development is critical. Patients generally prefer SC over intravenous administration. However, SC adoption is often limited by the perception that delivery volumes must stay below 3 milliliters without a permeation enhancer. This misconception hampers SC oncology drug prioritization and stifles innovation. To better understand these challenges, a survey was conducted to investigate decision-making processes surrounding large-volume SC oncology drug candidates. The online survey, conducted November 20-26, 2024, targeted 80 drug development professionals with SC drug development experience equally representing new product planning, drug formulation, combination products, and clinical development. Of the participants, 43 primarily worked in oncology. The 23-item survey explored perceptions of SC volume thresholds, factors influencing the deprioritization of oncology drug candidates, the potential of large-volume delivery solutions in oncology, and how organizations track and revisit deprioritized candidates. The oncology respondents stated that 32% of drugs are abandoned due to challenges with drug volume. The most common reason for abandonment of the asset was lack of experience with large-volume formulations or devices. Similarly, the respondents stated that 29.5% of drugs are deprioritized due to difficulties in reducing subcutaneous drug volumes. When it came to deprioritizing assets, the primary reason was that large-volume drugs are only pursued if they address a unique unmet need regardless of the competitive landscape. Participants rated the commercial potential of these abandoned or deprioritized drugs at a 3 on a scale of 1-4 (1 = low potential, 4 = high potential) indicating that these drugs had worthwhile commercial potential. Fortunately, participants ranked the organizations willingness to revisit these drug candidates at a 3 on a scale of 1-4 (1 = not open at all, 4 = extremely open). The results suggest that oncology molecules with worthwhile commercial potential remain unexplored within companies due to misconceptions around large-volume SC delivery, with a high willingness to revisit these candidates.

#1856 Synergistic combination of PROTACs degrading oncogenic proteins: In vitro studies and formulating a long-acting injectable for in vivo testing in lung tumor-bearing mice.

Akanksha Patel, Mukti Vats, Ketan Patel

St. John's University, Queens, NY

Introduction: Lung cancer remains a leading cause of cancer-related mortality worldwide, with accountability of more than 85% of cases of non-small cell lung cancer (NSCLC). Current therapies, such as EGFR inhibitors (e.g., erlotinib, gefitinib), face significant challenges, including severe side effects, drug resistance, and financial burdens, leading to patient noncompliance. In recent years, Protein-Targeting Chimeras (PROTACs), a class of protein degraders, is a groundbreaking strategy that degrades, rather than merely inhibits, targets proteins. This work investigates a combination of PROTACs degrading key oncogenic proteins of lung cancer. BRD4 degrading PROTAC (BPRO) and an EGFR degrading PROTAC (EPRO) were combined to simultaneously degrade BRD4 and EGFR to suppress c-MYC, EGFR and K-RAS, offering therapeutic potential for NSCLC with diverse genetic profiles.

Objectives: Our study objectives include (a) evaluating BE-PRO synergism in various NSCLC cell line i.e. wild-type EGFR (H460 cells), EGFR TKI-sensitive (PC9 cells), and EGFR TKI-resistant (H4006/GR) cells; (b) assessing anticancer efficacy of BE-PRO in 2D and 3D NSCLC models; and (c) optimizing a self-injectable biodegradable subcutaneous depot formulation (BERD) for sustained delivery; (d) to analyze the *in vivo* anticancer efficacy of BERD in NSCLC cells tumor xenograft model.

Methods: *In vitro* assays - IC_{50} and combination index (CI), invasion assay, clonogenic assay, and 3D spheroids growth were carried out to identify the synergistic ratio of BPRO and EPRO in different NSCLC cell lines. 3D-cell viability and apoptosis were studied using Cell Titer-Glo® 3D and Live/Dead Cell imaging assays. Further, depot formulation was developed using a biodegradable polymer and tested using a subcutaneous tissue-mimicking phantom using IVIS imaging. To determine the *in vivo* efficacy of BERD, a subcutaneously engrafted HCC827 cells xenograft model has been developed, and currently, we are measuring tumor growth using ultrasound and vernier caliper methods.

Results: The combination index and cytotoxicity interaction graph demonstrated of BPRO and EPRO (CI = 0.25±0.026 in H460; 0.151±0.047 in PC9, 0.693±0.013 in H4006/GR) and significant inhibition of invasion and clonogenic activity. The combination showed minimal toxicity in healthy cells, HEK 293, and lung fibroblast. In 3D spheroids, BE-PRO achieved ~74.5% and ~53.3% growth inhibition under chronic and acute dose regimens, respectively. BERD ensured sustained drug release over 72 hrs, with minimal precipitation and reduced initial burst effects compared to the individual drug solution.

Conclusion: A sustained-release combination of BRD4 and EGFR degrading PROTACs could be a promising approach, tackling key oncogenic drives while minimizing dosing frequency and off-target toxicities.

#1858 Nanoformulation strategy for oral delivery of KRAS inhibitor (sotorasib): pH-independent dissolution to mitigate PPI drug interaction.

Henis Patel, Akanksha Patel, **Ketan Patel**

St. John's University, Queens, NY

Biovariability poses a significant challenge in the oral administration of sotorasib (AMG 510), an FDA-approved KRAS G12C inhibitor for non-small cell lung cancer (NSCLC). Sotorasib, a weakly basic drug with limited aqueous and pH-dependent solubility, necessitates a high daily dose (960 mg; 8 tablets). In general, high doses, pill burdens, and poor solubility often result in poor patient compliance and therapeutic outcomes. Co-administration with proton pump inhibitors (PPIs) in cancer patients significantly reduces the bioavailability of weakly basic drugs including sotorasib. To address these limitations, we developed a pH-independent nanocrystalline formulation through wet media milling, aiming to achieve a stable formulation with enhanced bioavailability, improved redispersibility, and minimized fasted/fed variability. The nanosuspension, formulated using anionic surfactant and non-ionic polymer as stabilizers, achieved a high drug load (45% w/w) with uniformly distributed nanocrystals (173 ± 21.54 nm) and a negative zeta potential (-36.0 ± 0.57 mV). Cryoprotectants hydroxypropyl-β-cyclodextrin (HPβ-CD) and trehalose were effective in preventing aggregation, ensuring excellent redispersibility across pH conditions in both simulated gastric (pH 4.0) and intestinal (pH 6.8) environments. *In vitro* dissolution studies demonstrated > 95% drug release within 5 minutes at both pH levels, indicating rapid dissolution and robust stability. Solid State Characterization studies, including X-ray diffraction (XRPD), differential scanning calorimetry (DSC), scanning electron microscopy (SEM), and cryo-TEM, confirmed the preserved crystallinity, reduced particle size, and improved homogeneity. Additionally, BET surface area analysis indicated an increased surface area for the lyophilized nanosuspension, supporting enhanced dissolution. The *in-silico* model predicted increased absorption in the intestinal region, particularly the duodenum and jejunum due to improved saturation solubility and minimized drug precipitation. *In vivo* pharmacokinetic studies in SD rats revealed superior systemic exposure, with a significant increase in C_{max} (3529 ± 564.57 ng/mL) and AUC_{last} (8294.5 ± 1346.66 h*ng/mL) compared to the physical mixture. It may address the challenges of high dosing requirements and drug interactions with acid-reducing agents, offering a promising solution to enhance therapeutic outcomes for lung cancer patients.

#1860 Development of novel AXL inhibitor-loaded PLGA nanoparticles for targeted therapy in triple negative breast cancer.
Fatma Kazdal, Nermin Kahraman, Bulent Ozpolat

Nanomedicine, Houston Methodist Research Institute, Houston, TX

Triple Negative Breast Cancer (TNBC) is the most aggressive and heterogeneous subtype of breast cancer with the highest mortality rates. TNBC is characterized by a lack of Estrogen (ER), PR, and HER2 receptors and currently, there is no effective targeted therapy for TNBC patients. AXL, a receptor tyrosine kinase (AXL-RTK), is overexpressed in TNBC cells and patient tumors and has been linked to poor prognosis. Despite its potential as a therapeutic target, there are currently no FDA-approved inhibitors for AXL in TNBC. In this study, we aimed to develop AXL- inhibitor-based targeted therapy and evaluate its therapeutic potential for TNBC using a PLGA (poly-lactic-co-glycolic acid)) nanoparticle delivery system. We formulated it into PLGA nanoparticles to improve bioavailability and enable targeted delivery to TNBC tumors. Various dosages of AXL inhibitor-loaded PLGA nanoparticles were tested on MDA-MB-231 and MDA-MB-436 human TNBC cell lines, and significant inhibition of cell growth and colony formation was observed, with a half-maximal inhibitory concentration (IC50) of 5 μM. The size and morphology of the nanoparticles were characterized using Atomic Force Microscopy (AFM) and Scanning Electron Microscopy (SEM), which revealed nanoparticle sizes ranging from 63-99.9 nm. Western blot analysis showed that the AXL inhibitor-loaded PLGA nanoparticles effectively inhibited AXL protein expression and its downstream signaling pathways, leading to superior anti-proliferative effects compared to free AXL inhibitors. These results suggest that AXL inhibitor-loaded PLGA nanoparticles offer a promising strategy for enhancing the therapeutic efficacy of AXL inhibitors in TNBC. In vivo, efficacy studies are currently underway to evaluate their potential for targeted therapy in both primary and metastatic TNBC models.

#1861 A study of the effects of sodium alginate concentration on the physical properties of injectable alginate scaffolds for the treatment of glioblastoma.

Serenade N. Trevino[1], Dorina A. Madrid[1], Samantha Davila[2], Marco A. Arriaga[3], Sue Anne Chew[1]

[1]Health & Biomedical Sciences, University of Texas - Rio Grande Valley, Brownsville, TX,[2]UTRGV Mathematics and Science Academy, Brownsville, TX,[3]School of Medicine Division of Human Genetics, University of Texas - Rio Grande Valley, Brownsville, TX

Glioblastoma Multiforme (GBM) is a Grade IV malignant brain cancer with a high recurrence and low survival rate. Despite advances in various therapeutic methods, prognosis has not improved much, thus, alternative treatment methods are needed. Minocycline (MINO), an antibiotic, has been shown to have anti-angiogenic properties useful for GBM treatment. Alginate is a biodegradable polysaccharide that can be used for the fabrication of injectable hydrogels for drug delivery. The objective of this study was to investigate the effects of sodium alginate (SA) concentrations (i.e., 1.00, 1.50, and 2.00 wt./vol.%) on scaffold pH, gelation time, dimensions, weight, and cell viability. Scaffolds were fabricated by dissolving SA and calcium carbonate (CaCO3) in water, homogenizing with glucono-delta lactone (GDL), then injecting the solution into a 24-well plate to form uniform scaffolds. Scaffold properties were evaluated by determining pH values with a pH meter, gelation time using a tilt test with a digital timer, dimensions with a digital caliper and wet and dry weight (after lyophilization) using an analytical scale. To determine cell viability, U87 GBM cells were treated with 24 hr scaffold release solution, and an MTT assay was performed after 48 hrs. Scaffolds made with the different SA concentrations reached similar pH values after 60 min. (~6.0). They had workable gelation time (~15-36 min.) and were able to conform to the topography of the mold. The increase in SA concentration resulted in a decrease in gelation time and a significant increase in diameter, height, dry weight, and overall stability of the scaffold. The increase in SA polymer chains (with higher concentration of SA), allowed for more cross-linking which could have led to the sturdier scaffolds with a significant increase in scaffold height. As expected, as the concentration of SA increases, more components make up the scaffold structure, resulting in a significant increase in scaffold dry weight. The wet weights were not significantly different, probably due to the high-water content of the hydrogels masking the difference in the weight of the scaffold components. Increasing the concentration of SA had no significant effect on the cell viability of the blank scaffolds. The blank and minocycline-loaded scaffolds resulted in 65-70% and 40-45% cell viability, respectively. The drug-loaded scaffolds were able to enhance cell death compared to the control and blank scaffolds. In conclusion, the concentration of SA can be optimized to tune the physical properties of the scaffolds (which may lead to different scaffold degradation rates and drug release kinetics). The alginate scaffolds fabricated in this study may be a promising adjuvant therapy for GBM treatment and future studies will focus on evaluating the effects of the SA concentration on scaffold degradation rate and drug release kinetics.

#1862 Biomimetic poly lactic acid based nanoparticles for tumor targeted delivery of chemotherapeutic drugs.

Harshdeep Kaur, Harpal Singh

Center for biomedical engineering, Indian Institute of Technology Delhi (IIT Delhi), New Delhi, India

Global cancer burden is increasing day by day and to mitigate this situation, chemotherapy is widely used as systemic treatment modality. Along with many pros, chemotherapy does have various cons such as: systemic toxicity, faster degradation in physiological conditions hence low bioavailability and poor tumor accumulation. To overcome these shortcomings, nano-drug delivery systems are used. The nanoparticles can be tailor made according to physiological conditions of the tumor microenvironment. Herein, the redox responsive polymer has been synthesized by introducing the disulphide linkage in the polymer. The chemo-drug Pirarubicin has been encapsulated by double emulsion method in the nanoparticles prepared with redox-responsive polymer. The drug release profile indicated the release of the drug is more efficient in presence of 10mM Dithiothreitol (reducing agent for disulphide linkage) when compared to 0mM dithiothreitol, hence suggesting the successful synthesis of stimulus responsive drug delivery system. In this context, this study investigates the therapeutic efficacy of Pirarubicin encapsulated in polylactic acid based redox responsive nanoparticle(NP) whose surface have been modified with tumor and macrophage cell membranes. The coated cell membrane provides advantages such as immune escape, long blood circulation time, specific molecular recognition and tumor cell targeting. The prepared nanoparticles have a hydrodynamic size in nano-range with high negative zeta potential. The cellular internalization studies of free drug vs the cell membrane coated NPs (CMNPs) were done and it was confirmed with fluorescence microscopy as well as flow cytometry that CMNPs were internalized more efficiently in one hour drug incubation study. The same was confirmed when cancer cell proliferation inhibition assay was done, and half maximal inhibitory concentration was highest in case of uncoated NP, then that of free a drug, and lowest in case of CMNPs. This study provides the synthesis and characterization of redox responsive polymer, preparation of cell membrane coated nanoparticles and in-vitro studies for the same. This study has a future scope in the field of personalized medicine at much cheaper price when compared to active targeting methods by antibodies, CART, proteins etc.

#1863 A cytotoxic peptide designed for tumor-targeted delivery of co-injected molecules.

Norio Miyamura[1], Chisato M. Yamazaki[2], Kyoji Tsuchikama[2], Kazuki N. Sugahara[1]

[1]Department of Surgery, Columbia University, New York, NY,[2]McGovern Medical School, The University of Texas Health Center at Houston, Houston, TX

Clinical trials have highlighted its promise as a tumor-targeted delivery system and enhancer of anti-cancer therapies. In this study, we developed and analyzed an iRGD, tumor specific homing peptide, conjugate linked to monomethyl auristatin F (MMAF), a highly potent antimitotic agent. This conjugate demonstrated dual functionality as a tumor-targeted cytotoxic agent and a delivery platform for co-administered drugs. The iRGD-MMAF conjugate selectively internalized and killed tumor cells in vitro through αv integrin-dependent pathways. In vivo, systemic injection of iRGD-MMAF resulted in tumor-specific localization and widespread distribution within the extravascular tumor tissue, consistent with iRGD's tumor-penetrating properties. Additionally, iRGD-MMAF significantly improved tumor-specific uptake of a co-injected drug, confirming its efficacy as a delivery scaffold. These findings suggest that chemically modified iRGD peptides with added therapeutic properties maintain their ability to enhance co-administered drug delivery to tumors.

#1864 Folate-mediated delivery of tumor-suppressive miRNA-34a to treat osteosarcoma.

Iman T. Mevaa[1], Ahmed M. Abdelaal[1], Ikjot S. Sohal[1], Shreyas G. Iyer[1], Kasireddy Sudarshan[2], Harish Kothandaraman[3], Nadia A. Landman[4], Philip S. Low[2], Andrea L. Kasinski[1]

[1]Biological Sciences, Purdue University, West Lafayette, IN,[2]Chemistry, Purdue University, West Lafayette, IN,[3]Purdue University Institute of Cancer Research, West Lafayette, IN,[4]Comparative Pathobiology, Purdue University, West Lafayette, IN

Osteosarcoma is a common type of bone cancer primarily observed in children, teenagers, and young adults. Current treatments (including surgery, chemotherapy, and radiotherapy) are invasive and induce aggressive side effects. Alternative approaches such as using microRNAs (miRNA) are emerging as promising anticancer agents. miRNA modulates tumorigenesis via tumor-suppressive and oncogenic miRNAs. Tumor-suppressive and oncogenic miRNAs respectively downregulate oncogenic and tumor-suppressive mRNA transcripts. Hence, leveraging the anticancer activity of tumor-suppressive miRNAs appears as a viable anticancer treatment approach. The overarching challenges with miRNA therapy are 1) achieving specific non-toxic delivery of tumor-suppressive miRNA to cancer cells, and 2) enhancing the stability of the miRNA, which can be degraded by nucleases. To circumvent these obstacles, we developed a folate-conjugated fully modified miRNA-34a that specifically targets osteosarcoma cells, which often overexpress folate receptor-α on their surface. The fully modified miRNA-34a bears phosphorothioate linkages at the 3’ and 5’ ends of the sense and antisense strands which significantly reduces nucleases attack. The substitution of the 2’ hydroxyl with 2’ methoxy and 2’ fluoro groups in an alternative fashion further enhances stability. Overall, the fully modified miRNA-34a shows continuous downregulation of target genes 120 hours post-delivery in breast cancer in-vivo models. Here, we present preliminary results for folate-mediated delivery of fully modified miRNA-34a in osteosarcoma samples. This study highlights the potential of miRNA-34a as a safe and effective anticancer agent for osteosarcoma treatment.

#1865 Optimization of miRNA-6883 lipid nanoparticles for targeted CDK4/6 and HIF1a inhibition in colorectal and breast cancer cells.

Connor Purcell[1], Kadhambari Rajendran[2], Wafik S. El-Deiry[1], Theresa M. Raimondo[2]

[1]Legorreta Cancer Center at Brown University, Providence, RI,[2]School of Engineering, Brown University, Providence, RI

The design of delivery vehicles to protect microRNAs (miRNAs) from degradation, enable tissue-specific targeting, and avoid potential off-target effects is a central challenge for their therapeutic application. miRNA encapsulation by lipid nanoparticles (LNPs) has been used to extend in vivo half-life, and LNPs may also be conjugated to an antigen targeting moiety to guide delivery to tumors. In vitro studies have identified miR-6883 as a promising therapeutic agent which targets CDK4/6, induces apoptosis, and reduces HIF1α levels in colorectal and breast cancer. In the present study, we employ a partial factorial design of experiments (DOE) to determine the optimal molar ratios of LNP components for on-target tumor potency, and use the miRNA-LNPs to further explore the potential therapeutic application of miR-6883. Methods: LNPs were formulated with MC3 or Lipid 331, DOTAP, DSPC, cholesterol, and DMG-PEG2k. Aqueous and lipid phases were combined a 3:1 ratio, followed by rapid pipetting and overnight dialysis. Encapsulation and RNA concentration were determined by Ribogreen assay. Polydispersity index (PDI) and diameter were determined by dynamic light scattering. Cancer cell lines were reverse transfected with 50nM of LNP-encapsulated RNA (miR-6883 or control). Viability was determined via CellTiter-Glo assay and protein levels by western blot. Fluorescent imaging and flow cytometry were performed to evaluate uptake of fluorescently-labeled LNPs. Partial factorial DOE was used to survey a design space consisting of a 4-part mixture (ionizable lipid, phospholipid, cholesterol, and PEG molar ratios) and a binary categorical variable to include 5% cationic lipid (JMP software). Results: Initial dosing with fluorescently labeled LNPs showed a dose-dependent increase in fluorescence, at lipid doses as low as 1μg/mL. Following formation of 12 LNP formulations based on the DOE screening design, LNPs had a maximum RNA encapsulation of 94.32%, PDIs from 0.07-.279 and diameters from 98.85-240.3nm. Multiple formulations showed potent anticancer activity, with a maximal 93.52% reduction in viability observed in HCT116 after 72h of 50nM miR-6883 compared to an untreated control. Protein level modulation of CDK4 and CDK6 was observed in all LNPs tested, as well as a reduction of HIF1α after 4 days. Notably, multiple samples exhibited an *increase* in CDK6, warranting further investigation. Conclusions: Our DOE identified candidate miR-6883-LNP formulations for further optimization. Future work will assess the optimized miR-LNP therapeutic in murine models of colorectal and breast cancer. Currently, we are generating antibody-conjugated LNPs, with the aim of increasing potency and mitigating off target toxicity, and are continuing LNP optimization for in vivo studies.

#1866 EphA2 siRNA-loaded lipid nanoparticles decrease tumor burden in breast cancer liver metastases models by modulating the tumor microenvironment.

Anjana Tiwari[1], Eric Chau[1], Jenna Carr[2], LaMargaret Temukisa Johnson[3], Dylan Goodin[4], Hermann Frieboes[3], Biana Godin[1]

[1]Houston Methodist Research Institute, Houston, TX,[2]Texas A&M, College Station, TX,[3]Department of Bioengineering, University of Louisville, Louisville, KY,[4]Department of Bioengineering,, University of Louisville, Louisville, KY

Breast cancer is the leading cause of cancer-related mortality in women, with distant metastasis being the primary reason. The liver is the third most frequent site of breast cancer distant metastasis. Unlike primary tumors and metastatic lesions in other organs, breast cancer liver metastasis (BCLM) growth relies heavily on the organ vasculature, leading to lesions that are hypovascularized. This prevents systemically administered agents from efficiently reaching the cancer cells in these lesions, causing transport-related resistance to therapy. Macrophages are the most abundant immune cell type in the cancer tumor microenvironment (TME), playing important roles in tissue remodeling, homeostasis, angiogenesis, progression, and response to therapy. These phagocytic cells remain in close proximity to BCLM and have been clinically utilized for imaging with nanomaterials. Transport barriers can be overcome using macrophages as carriers for nanotherapeutics, leading to efficient therapy for BCLM. siRNA therapeutics are nucleic acid-based macromolecules that hold promise for tumor therapy. Challenges related to siRNA delivery and clinical translation include poor stability and limited transport across biological barriers, which necessitate using nanoparticles as carriers. Ephrin type-A receptor 2 (EphA2) tyrosine kinase regulates important tumor-driving processes and is overexpressed in breast cancer. In the present study, we designed, characterized and evaluated the effect of siRNA EphA2 loaded lipid nanoparticles (siEphA2-LNP) in combination with albumin bound paclitaxel (nAb-PTX) on macrophage phenotype, transport and anti-cancer efficacy in *in vitro* and *in vivo* BCLM models. The siEphA2-LNP and nAb-PTX treated macrophages shifted the TME towards the pro-inflammatory, anti-tumorigenic milieu by polarizing the macrophages from the M2 to M1 phenotype. This resulted in increased apoptosis and decreased proliferation in MCF7 and MDA-MB-231 human breast cancer cells in treated groups as compared to controls. Studies in the 3D *in vitro* model that mimics clinically observed hypovascularized BCLM surrounded by macrophages, suggested that a balance between M1 and M2 macrophage phenotypes in the TME is required to optimize nanotherapeutic efficiency. *In vivo* studies in a syngeneic model of primary triple negative breast cancer and experimental BCLM showed decreased tumor volume when treated with siEphA2-LNP. Additionally, there was an increase in CD163 (M2 marker), F4/80 (pan-macrophage) and Ki67 (apoptosis) in the lesions. These findings were further utilized to computationally simulate BCLM therapeutic response to siEphA2-LNP and evaluate clinically relevant dosing strategies. Altogether, this study shows that EphA2 siRNA-loaded lipid nanoparticles can decrease BCLM tumor burden by modulating the tumor microenvironment.

#1867 Development and validation of fluorescent lipid nanoparticles for RNA delivery applicable to personalized in vitro oncology models.

Xavier Warnet, Celia Bosso-Lefevre, Erica Cirri, Eric Mennesson, Marie Morin, Melanie Sapateiro, Maxime Rochet, Laetitia Edmond, Alexandra Foucher, Armelle Vindrios, Alzbeta Komarkova, Flavien Carpenier, Romain Cordonnier-Goulay

TebuBio, Le Perray-en-Yvelines, France

Tebubio offers contract services in RNA-based therapeutic discovery, in vitro modeling, biomarker mapping, and data analysis. Leveraging these platforms, we have developed innovative lipid nanoparticles (LNPs) designed to encapsulate and deliver RNA. This advancement features a fluorescent lipid, created by Echelon Inc., which enables imaging-based tracking of the LNPs. Using this fluorescent lipid, we formulated LNPs encapsulating a mRNA Coding for a fluorescent protein. We validated the distribution of these LNPs within 2D mammalian cell line model and confirmed RNA expression in these cells through imaging techniques. This technology is applicable to in vitro oncology models, including patient-derived spheroids and tumoroids, which allow for a personalized approach to therapeutic testing. Ultimately, Tebubio's platform provides end-to-end support, from RNA optimization and custom LNP formulation to efficacy validation in vitro, enabling personalized medicine models for RNA-based therapeutics.

#1872 MSH6 modulates PARP inhibitor sensitivity in BRCA-proficient high-grade serous ovarian cancer.
O. Deng, T. Nepomuceno, B. Fang, E. A. Welsh, R. H. Martin, E. M. George, A. N. Monteiro, U. Rix;
Moffitt Cancer Center, Tampa, FL

Ovarian cancer is the leading cause of gynecologic cancer-related deaths, with high-grade serous ovarian cancer (HGSOC) being the most common subtype. While BRCA1/2 deficiencies are established biomarkers to predict PARP inhibitor (PARPi) sensitivity, some HGSOC patients with BRCA-proficient tumors also respond to PARPi therapy. However, the mechanisms driving PARPi sensitivity in BRCA-proficient HGSOC remain poorly understood. We hypothesized that PARP1 protein complex composition and PARylation-mediated signaling regulate PARPi sensitivity or resistance in BRCA-proficient HGSOC. Through viability screening of BRCA-proficient ovarian cancer cell lines treated with PARPis we identified three sensitive and three resistant lines. Chemical proteomics with rucaparib showed enrichment of PARP1, PARP2, and associated binding proteins, with notably higher MSH6 levels in sensitive cell lines compared to resistant ones. Co-immunoprecipitation further revealed differences in PARP1-MSH6-PARP2 complex compositions between sensitive and resistant cells lines. Genetic knockout or knockdown of MSH6 via CRISPR and siRNA, respectively, conferred resistance to rucaparib, with a more pronounced effect in sensitive cells. To investigate downstream signaling, we performed ADP-ribosylation proteomics using clickable NAD+ analogs, uncovering distinct PARylation profiles between sensitive and resistant lines. CHAF1A, a known MSH6 binder and PARP1 substrate, was identified in PARPi-sensitive cells. More importantly, MSH6 knockdown elevated CHAF1A levels, while rucaparib treatment reduced CHAF1A expression, particularly in sensitive cells. These findings suggest that CHAF1A upregulation through MSH6 inhibition may rescue PARPi-induced cell death. This study integrates chemical proteomics and ADP-ribosylation analysis to delineate the interplay between PARP1 complex composition and signaling dynamics in PARPi response. Our findings highlight MSH6 and CHAF1A as critical modulators of PARPi sensitivity, providing new insights into resistance mechanisms and identifying potential biomarkers to improve PARPi efficacy in BRCA-proficient HGSOC.

#1873 Deep plasma proteome profiling to discover drug treatment related novel biomarkers in non-small cell lung cancer.

Cui Liu[1], Dongsheng Yue[2], Bin Zhang[2], Ruiqi Huang[3], Wenting Du[3], Xiaopeng Ma[1], Cunjing Yu[1], **Wenhao Li**[1], Xikun Wu[3], Yongchun Tong[1], Lanjun Xu[1], Si Mou[1], Changli Wang[2], Zhirong Shen[1]

[1]BeiGene (Beijing) Co., Ltd., Beijing, China,[2]Department of Lung Cancer, Tianjin Lung Cancer Center, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China,[3]BeiGene (Shanghai) Biotechnology Co., Ltd., Shanghai, China

Background: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of various cancers. A better understanding of ICI induced dynamics and response / resistance mechanisms may contribute to the optimization of treatment strategies. In early-stage non-small cell lung cancer (NSCLC) cohort with neoadjuvant chemoimmunotherapy, we utilized the plasma proteomics platform to deepen the understanding of disease biology and explore potential response and resistance biomarkers. **Methods:** Plasma samples collected at various time points during neoadjuvant chemoimmunotherapy were analyzed using an unbiased mass spectrometry-based plasma proteomics platform. Taking advantage of the protein corona formed on the surface of nanoparticles, low-abundant proteins related to immunomodulation and signal transduction were enriched and identified. A comprehensive statistical analysis framework was adapted to reveal mechanism and explore predictive and prognostic biomarkers. Immunotherapy-induced changes of blood proteins were estimated by linear mixed model. Molecular insights were studied through mediation analysis. In the association analysis with clinical outcomes, classic logistic regression was applied for binary clinical outcomes, while cox proportional hazard model for survival outcomes. **Results:** 180 plasma samples from 92 individuals were profiled, resulting in the quantification of 2303 proteins in peripheral blood. The consistency between quantitative proteomics and established techniques were demonstrated by known biomarker CA125, CRP and gender related proteins. A total of 541 upregulated proteins and 504 downregulated proteins after neoadjuvant chemoimmunotherapy were identified. Pathway enrichment analysis revealed that neoadjuvant chemoimmunotherapy promoted immune activation. **Conclusion:** Deep plasma proteome profiling enables a deeper understanding of the dynamics and mechanisms induced by ICI treatment.

#1874 Glycoproteome and surfaceome mapping of epithelial-to-mesenchymal transition reveals key ion channel regulation and novel biomarkers in cancer metastasis.

Xing Xu, Kejun Yin, Ronghu Wu

Department of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA

The epithelial-to-mesenchymal transition (EMT) is a crucial process driving cancer metastasis. In this transition, cell morphologies and properties are dramatically changed, but the underlying molecular mechanisms remain to be explored. In this work, we performed a comprehensive analysis of the proteome, the glycoproteome, and the surfaceome during the EMT process induced in A549 lung carcinoma cells using mass spectrometry-based proteomics. We identified five distinct EMT states characterized by alterations in protein expression and N-glycosylation patterns. We characterized 8,891 proteins, including 1,366 N-glycoproteins and 635 surface glycoproteins, and further bioinformatic analyses provide valuable insights into the mechanisms of EMT. Notably, we observed significant regulation of sodium, chloride, and calcium ion channels during EMT, underscoring their importance in cancer metastasis. Surface glycoproteins such as MET and SLC2A1 emerged as potential biomarkers for partial EMT, paving the way for advancements in early cancer diagnosis and targeted therapies. Furthermore, our findings reveal that EMT-associated N-glycosylation occurs in specific protein domains and aggregation-prone regions (APRs), affecting protein stability and trafficking. This work advances our understanding of the molecular mechanisms of EMT and underscores the therapeutic potential of targeting glycoproteins and ion channels in metastatic cancer.

#1875 PBK expression promotes the aggressive phenotypes of mesothelioma.

Kazumi Hori[1], Ichidai Tanaka[1], Tatsuhiro Sato[2], Mika Sato[1], Yuta Kodama[1], Hideyuki Itoigawa[1], Yuichi Abe[3], Taketo Kato[4], Ayumu Taguchi[5], Mitsuo Sato[6], Yoshitaka Sekido[7], Toyofumi Fengshi Chen Yoshikawa[4], Makoto Ishii[1]

[1]Respiratory Medicine, Nagoya University, Nagoya, Japan,[2]Division of Cancer Biology, Aichi Cancer Center Research Institute, Nagoya, Japan,[3]Division of Molecular Diagnostics, Aichi Cancer Center Research Institute, Nagoya, Japan,[4]Thoracic Surgery, Nagoya University, Nagoya, Japan,[5]Molecular Diagnostics, Aichi Cancer Center Research Institute, Nagoya, Japan,[6]Integrated Health Sciences, Nagoya University, Nagoya, Japan,[7]Cancer Biology, Aichi Cancer Center Research Institute, Nagoya, Japan

Mesothelioma is one of the most aggressive neoplasms worldwide that has a particularly poor prognosis. Novel therapeutic strategies to effectively treat patients with mesothelioma are urgently needed. We have previously discovered that oxytocin receptors (OXTR) are highly expressed in mesothelioma and that *OXTR* knockdown significantly decreases the proliferation of mesothelioma cells with high *OXTR* expression by disturbing the tumor cell cycle but targeted therapies utilizing the OXTR signaling system have not emerged. In this study, we performed quantitative proteomic profiling of two mesothelioma cell lines with high *OXTR* expression using mass spectrometry to investigate the downstream signals of OXTR in mesothelioma cells. We found that *OXTR* knockdown significantly downregulated PDZ-binding kinase (PBK)—a serine/threonine protein kinase belonging to the bispecific MAPKK family which is a crucial factor in cell mitosis, cell proliferation, migration, and anti-apoptosis and support of testicular functions. *PBK* knockdown significantly suppressed proliferation, migration, and colony formation in mesothelioma cells with high *PBK* expression, and decreased Akt and MAPK phosphorylation levels. We also found that a PBK inhibitor, OTS-514, suppressed the proliferation of these cell lines at low concentration. Furthermore, immunohistochemical analysis of PBK in surgical specimens obtained from patients with mesothelioma showed that high PBK expression was strongly associated with poor overall survival (log-rank test *P*=0.0031; hazard ratio 3.339 and 95% confidence interval 1.12-10.00) and recurrence-free survival (log-rank test *P*=0.0024; hazard ratio 3.355 and 95% confidence interval 1.25-9.04). In addition, the clinical significance of PBK expression was validated in mesotheliomausing datasets from TCGA. Multivariable Cox regression analysis, incorporating stage and *OXTR* mRNA expression, demonstrated that *PBK* mRNA expression was the strongest independent predictor of overall survival and the hazard ratio for *PBK* was higher than that for *OXT*R. Our findings indicate that PBK plays a crucial role in the aggressiveness of mesothelioma, making it a promising therapeutic target and potential prognostic biomarker for mesothelioma.

#1876 Distinct kinase signatures define therapeutically relevant subtypes in colorectal cancer.

Gitanjali Dharmadhikari, Simar Pal Singh, Monique Mommersteeg, Liesbeth Houkes, Martijn Dankers

PamGene, 's-Hertogenbosch, Netherlands

Introduction: Colorectal cancer (CRC) is heterogenous disease and second leading cause of cancer-related mortality worldwide. Despite advances in understanding its pathophysiology, molecular mechanisms underlying this heterogeneity remain poorly understood. Identifying actionable molecular markers is crucial to improve patient stratification and therapeutic decision-making. Recent studies have highlighted the kinome—a dynamic network of kinase signaling pathways—as a promising avenue to uncover molecular signatures associated with cancer progression and treatment response. We hypothesized that profiling global kinase activity in CRC patient-derived xenografts (PDXs) could provide valuable insights into subtype-specific signaling alterations.
Methods: Kinase activity profiling was conducted using PamGene's KinomePro platform on 12 CRC-PDX models. Frozen tissue sample were lysed with M-PER Mammalian Extraction Buffer supplemented with Halt Phosphatase and Protease Inhibitor Cocktail and protein quantification was determined using Pierce Coomassie Plus (Bradford) Assay Kit. Tyrosine and Serine/threonine kinase activity profiles were generated using PamChip® comprising 340 different phosphosites that are the known downstream substrates. Peptide phosphorylation and Upstream Kinase Analysis was performed with PamGene's Tercen analysis pipeline.
Results: Kinase activity profiling revealed two distinct molecular subtypes of CRC based on EPH and SRC kinase activity. The EPH-high subgroup showed elevated JAK kinase activity, whereas EPH-low tumors exhibited heightened SRC kinase activity. Functional validation was conducted using dose-response assays with specific inhibitors: Ruxolitinib (JAK inhibitor) and Dasatinib (SRC inhibitor). These experiments demonstrated strong correlation between kinase activity status and inhibitor sensitivity, with the EPH/JAK-high group exhibiting a higher IC50 for Ruxolitinib compared to the low subgroup. To further elucidate signaling perturbations in these subtypes, we integrated transcriptomic data with kinase activity profiles. This in silico analysis confirmed their distinct RNA expression signatures, underscoring the heterogeneity in molecular signaling across the cohort.
Conclusions: This study highlights the utility of kinase activity profiling as a robust approach for molecular stratification of colorectal cancer, identifying EPH and SRC kinase activity as potential biomarkers. The validation of differential inhibitor sensitivity supports the potential clinical utility of these markers in guiding personalized therapies. By integrating kinome analysis with transcriptomics, we provide a comprehensive framework for understanding the molecular underpinnings of CRC heterogeneity. PamGene's KinomePro technology emerges as a promising tool for biomarker discovery and patient stratification in CRC.

#1877 Decoding cancer prevention: Exercise, dark proteome signatures, and spatial proteomics.

Parthiban Periasamy[1], Patrick Sitjar[2], Xinru Lim[1], Jiangfeng Ye[1], Meng Jia[1], Jorming Goh[2], Yap Yoon Sim[3], Darren Wan-Teck Lim Wan- Teck Lim[3], Roger Ho[4], Joe Yeong[1]

[1]Cancer Signalling & Therapy Division, A*STAR - Inst of Molecular and Cell Biology (IMCB), Singapore, Singapore,[2]Department of Physiology, Yong Loo Lin School of Medicine, National University of Singapore (NUS), Singapore, Singapore,[3]Medical Oncology, National Cancer Centre Singapore, Singapore, Singapore,[4]Department of Psychological Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

With rising cancer rates and widespread physical inactivity—a known risk factor for non-communicable diseases like cancer—exercise is increasingly recognized for its potential in cancer prevention and management. Despite strong evidence supporting its benefits, exercise remains underutilized in clinical oncology. Physical activity may reduce cancer risk and progression through mechanisms such as hormone regulation, reduced inflammation, improved insulin sensitivity, antioxidant enhancement, immune support, and direct tumor effects. Studies suggest that regular exercise could lower breast, colon, and lung cancer incidence by up to 40%. Exercise is generally safe for cancer patients, enhancing physical function, mental health, and potentially slowing tumor progression. Given that one-third of adults globally are inactive, incorporating exercise into cancer care offers a holistic approach to improve patient outcomes alongside conventional treatments. In our study, we used mass spectrometry-based serum proteomics to investigate exercise's molecular effects on both the known and "Dark Matter" proteome—regions of proteins lacking structural characterization and potentially holding novel cancer biomarkers. We compared protein profiles between healthy individuals and pre-cancer patients, identifying early cancer signatures. Notably, Factor Xa (FA10), a vitamin K-dependent glycoprotein with pro-inflammatory effects, and fibulin-1 (FBLN1), a potential tumor suppressor involved in cell adhesion, were upregulated in pre-cancer patients. In an exercise intervention cohort, we observed that FA10 levels, initially elevated in pre-cancer patients, could be restored to baseline through exercise. This finding suggests that exercise may mitigate early cancer risk by reversing specific molecular changes associated with cancer progression. Ongoing work includes determining if unique proteins within the dark proteome can serve as distinctive cancer markers. We are currently performing spatial proteomics to determine the spatial distributions of selected dark proteome-derived proteins and to functionally characterize their roles in cancer prevention and progression.

#1878 Profiling protein-protein interactions to predict sensitivity to drugs targeting BCL2 family members in lymphoma models.

Alberto J. Arribas[1], Byungsan Choi[2], Elisa Civanelli[1], Eleonora Cannas[1], Camila Scalise[1], Saem Hong[2], Hongwon Lee[2], Francesco Bertoni[1]

[1]IOR - Institute of Oncology Research, Bellinzona, Switzerland,[2]PROTEINA Co., Ltd., Seoul, Korea, Republic of

Introduction: Pharmacological inhibition of anti-apoptotic proteins, especially with BCL2 inhibitors (i), has proven its clinical efficacy for treating patients with hematological cancers. However, there are not yet widely available tools to predict the sensitivity of individual patients to the different drugs targeting BCL2, MCL1, or BCLXL. A new technology, Single-molecule Protein Interaction Detection (SPID), based on immunoprecipitation of anti-apoptotic proteins followed by the addition of fluorescently labeled probes and detection at single-molecule accuracy, has shown promising results in predicting the sensitivity of acute myeloid leukemia cells to the BCL2i venetoclax (Chun et al., 2024). Here, we explored SPID to perform extended profiling of protein-protein interactions of BCL2, BIM, BAX, BAK, BCLXL and MCL1 in models derived from mantle cell lymphoma (MCL), marginal zone lymphoma (MZL) including models of secondary resistance to BTK, PI3K and BCL2i.
Methods: Cell viability was assessed by MTT assay after 3 days of exposure to increasing concentrations of drugs or DMSO. Sensitivity parameters included IC25, IC50, IC90, area under the curve, cell viability at 1μM of drug, or at the median of the concentration range used in the experiment. BCL2 family members' levels as single proteins or in complexes were measured by SPID. Drug sensitivity parameters were integrated with protein data using Spearman Correlation and Multiple Linear Regression (MLR, Lasso).
Results: We exposed MCL (n=10, JVM2, REC1, JEKO1, UPN1, SP49, SP53, MAVER1, GRANTA519, Z138, MINO), MZL (n=6, VL51, SSK41, Karpas1718, HC1, HAIRM, ESKOL) cell lines and MZL models of secondary resistance (MZL-RES) to idelalisib (n=2), copanlisib (n=2), ibrutinib (n=2), venetoclax (n=1) and copanlisib/venetoclax (n=2), to BCL2i (venetoclax, sonrotoclax), BCL2/BCXLi (navitoclax), and MCL1i (S63845). MCL models showed increased sensitivity to BCL2i, while MZL cells were more sensitive to MCL1i and BCLxLi. Elevated BCL2, BCL2-BAX, and, to a lesser extent, BCL2-BIM were associated with sensitivity to BCL2i, while high levels of MCL1-BIM, BCLxL and BCLxL-BIM were associated with BCL2i resistance. Expression of BCLxL, BCLxL-BAK and BCLxL-BIM predicted sensitivity to navitoclax, while resistance was observed with elevated MCL1-BIM. The response to the MCL1i did not correlate with MCL1 or MCL1-BIM levels, but an MLR model combining BCL2-BIM, BCLxL-BIM and MCL1 levels significantly enhanced the prediction of response.
Conclusions: Anti-apoptotic inhibitors show variable heterogeneous activity in MCL and MZL models, including those resistant to PI3Ki and BTKi, which could be predicted quantifying the BCL2-family members levels and interactions using the SPID. Such an approach might have a clinical potential to predict the sensitivity of patients with mature B cell lymphomas to this class of agents.

#1879 Serum biomarker candidates for predicting radiotherapy response in glioblastoma.

Paulo Roberto Del Valle, Janette Herr, Miah Elizabeth Nicolls, Kaylie Cullison, Alessandro Valderrama, Gregory A. Azzam, Jessica J. Meshman, Scott Welford, Macarena I. De La Fuente, Eric A. Mellon

Univ. of Miami Sylvester Comprehensive Cancer Ctr., Miami, FL

Introduction: Glioblastoma remains an incurable disease with limited treatment options. Imaging remains the primary diagnostic tool, but it has limitations in distinguish tumor progression from benign events like pseudoprogression. Currently, no biomarkers exist to differentiate these conditions. This study aimed to identify predictive biomarkers of glioblastoma progression by profiling serum proteins, seeking candidates for future validation.
Methods: Blood samples were collected from patients pre-therapy, and during the first and fourth weeks of chemoradiotherapy. We selected 11 samples for non-progression (NP), 12 for progression (P), and 6 for pseudoprogression (PS) based on availability and clinical classification. Proteomic analysis was performed using a proximity extension assay platform targeting more than 5400 serum proteins. Differential protein expression was assessed among groups and correlated with clinical outcomes.
Results: Pre-therapy analysis (NP vs P vs PS) identified 185 different proteins (Kruskal-Wallis, $p<0.05$). Enrichment analysis linked these to glutamatergic synapse, cell proliferation, and neuronal activity. Comparing responders (P) vs. non-responders (NP+PS) revealed 86 proteins (Wilcoxon, $p<0.05$), associated with interferon regulation and calcium homeostasis and clustered samples accordingly. In PS vs. NP+P, 87 proteins (Wilcoxon, $p<0.05$) were enriched for homologous recombination and neuronal apoptosis and clustered samples accordingly. At the first therapy week, NP vs. P vs. PS comparisons revealed 301 proteins (Kruskal-Wallis, $p<0.05$), linked to innate immunity and apoptosis. P vs. NP+PS revealed 95 proteins (Wilcoxon, $p<0.05$) associated with T cell activation. PS vs. NP+P identified 172 proteins that clustered samples accordingly (Wilcoxon, $p<0.05$), linked to receptor activity and carbohydrate binding. By week four, protein differences decreased. NP vs. P vs. PS comparisons identified 197 proteins (Kruskal-Wallis, $p<0.05$) related to nervous system development and wound healing. P vs. NP+PS identified 94 proteins (Wilcoxon, $p<0.05$) linked to cell adhesion. PS vs. NP+P revealed 75 proteins (Wilcoxon, $p<0.05$) that discriminated and clustered all PS samples on the same group and enriched for defense response and TRAIL production.
Conclusion: This study demonstrates that a sensitive proteomic approach can point to candidate biomarkers predictive of glioblastoma progression. These findings offer insights into radiotherapy response and warrant further mechanistic studies and validation in larger cohorts.

#1880 Advancing spatial discovery multiomics: Integration of a novel 1,000+ plex discovery proteome atlas with an 18,000+ plex whole transcriptome atlas for same-slide investigation of multiple cancer pathologies.

Ashley Heck, Hiromi Sato, Christine Kang, Brian Filanoski, Lori Hamanashi, Giang Ong, Terence Theisen, Erin Piazza, Kyla Teplitz, Margaret Hoang, Michael D. Rhodes, Joseph Beechem

Bruker Spatial Biology, Seattle, WA

Spatial multiomics at high plex represents a transformative approach to understanding complex biological systems. Whereas high plex spatial transcriptomics have transformed tissue analyses, spatial proteomics have been limited by low plex and lacking coverage of major biological pathways. Proteins, which represent the functional units of cellular response and activity, are essential for studying the heterogeneity of cancer and immune pathology. Furthermore, cellular responses to intrinsic and extrinsic stimuli are often driven by post-translational modifications of proteins. Enabling simultaneous analyses of proteins and RNA in FFPE tissue sections in spatial context with a sequencing readout and theoretically unlimited plex, the GeoMx® Digital Spatial Profiler (DSP) platform is uniquely positioned to support high plex proteomics and multiomics. In prior work, we demonstrated a same slide spatial multiomics workflow using the GeoMx DSP platform with the GeoMx Whole Transcriptome Atlas (18,000+ genes) and the GeoMx Human Immuno Oncology Proteome Atlas (570+ proteins). In the present study, we expand this platform by adding 500 additional protein targets, increasing the spatial proteomic atlas to over 1,000 targets. This expanded content allows for the discovery of novel biomarkers and potential therapeutic targets across multiple domains, including immune-oncology, immunology, oncology, neuroscience, signaling pathway regulation, cell death, metabolism, and epigenetics. We introduce the Discovery Proteome Atlas, a 1,000+ plex antibody-based proteomic assay and validate its performance in terms of specificity, sensitivity and reproducibility of each antibody in multiplex. When applied on the same-slide with the WTA assay to a tumor tissue microarray containing 50+ cases from various organs (e.g., skin, lung, testis, prostate, pancreas), we observe distinct multiomic profiles of cells with specific tumor regions and assess the abundance of multiple phosphorylated targets. Phosphorylation, like other post translational modifications, can only be studied through proteomics. By combining proteomic and transcriptomic atlases with spatial context in the same cell populations, this approach provides comprehensive insights into heterogenous tissues with complex disease mechanisms, offering a discovery portal for novel therapeutic or biomarker identification.
-Bruker Confidential-

#1881 Bimodality in pan-cancer proteomics reveals new biomarker discovery opportunities.

Wen Jiang[1], Damian Bikiel[2], Jan Zaucha[3], Jixin Wang[1], Sanddhya Jayabalan[4], Yongjin Li[4], Matthew Sung[4], James Harper[3], Jimmy Zhao[2], Krishna Bulusu[3], Wenyan Zhong[2]

[1]AstraZeneca US, Gaithersburg, MD,[2]AstraZeneca US, New York, NY,[3]AstraZeneca UK, Cambridge, United Kingdom,[4]AstraZeneca US, Waltham, MA

Bimodal protein expression, characterized by a protein distribution with two modes, is linked to phenotypic variation across various biological systems. While previous studies focused on RNA expression data, we developed a bimodality model tailored for proteomics to enhance the identification of cancer-associated biomarkers and targets, facilitating precision oncology. We analyzed proteomics data from various cancer types and identified 2,401 tumor-associated bimodal proteins. These tumor-associated bimodal proteins were evaluated for pathway enrichment, revealing significant associations with critical cancer pathways, such as metabolism of non-essential amino acids, interaction between the extracellular matrix and its receptors on the surface of cells and central carbon metabolism in cancer. Utilizing an AI-enhanced knowledge graph, we further delineated common patterns among pan-cancer tumor-associated bimodal proteins. A case study on the bimodal expression of TROP2 in colon adenocarcinoma highlighted up-regulation of MYC and WNT-beta-catenin signaling pathways and down-regulation of inflammatory and interferon-related pathways in the TROP2-high group. The biological difference between TROP2-high and TROP2-low groups underscored its significance in determining cancer severity and informing potential treatment approaches. Our findings show the utility of proteomics in uncovering novel biomarkers and advancing precision medicine, setting a precedent for further multi-omics integration and clinical validation.

#1882 Development of hit compounds targeting STAT3 for autoimmune diseases and cancers using a chemoproteomics-driven approach.

Heejung Yang[1], Hojin Yoo[1], Sang-Jun Han[2], Sijin Kim[2], Donggyun Hong[1], Jeongyeon Kang[1], Birang Jeong[3], Go-Yeon Jung[2], Namgil Lee[1], Hoguen Kwak[1], Byung-Seok Kim[2]

[1]Bionsight Inc., Chuncheon, Korea, Republic of,[2]Incheon National University, Incheon, Korea, Republic of,[3]Kangwon National University, Chuncheon, Korea, Republic of

Signal transducer and activator of transcription 3 (STAT3) is a critical regulator of immune responses, cellular proliferation, and survival, positioning it as a promising therapeutic target in autoimmune diseases and cancer. In this study, we present a chemoproteomics-based approach for the discovery and optimization of small-molecule inhibitors targeting STAT3. A series of novel small molecules capable of selectively modulating STAT3 activity were identified. By integrating structure-based design with our chemoproteomics platform, we not only validated the interactions of these compounds with STAT3 but also elucidated their downstream signaling effects in disease-relevant autoimmune models. Our chemoproteomics platform facilitates the unbiased identification of drug targets and off-target effects at a proteome-wide scale, significantly accelerating the lead optimization process. These findings highlight the potential of our STAT3 inhibitors as a novel class of therapeutics for autoimmune diseases. Ongoing studies are focused on optimizing these compounds for clinical trials by using the chemoproteomics platform to identify their molecular mechanisms of action and to predict potential off-target effects.

#1883 Large-scale proteomic analysis of glioblastoma tissues reveals novel molecular insights and potential therapeutic targets.

Juanjuan Wang[1], Simone Maarup[2], Vincent Fougner[2], Annelaura B. Nielsen[3], Ulrik Lassen[2], Luca Robinson[3], Frederik O. Bagger[4], **Dorte S. Noeroexe**[2]

[1]Center for protein research, Copenhagen University, Copenhagen, Denmark,[2]Department of oncology, Copenhagen University Hospital, Copenhagen, Denmark,[3]Center for genomic medicine, Copenhagen University Hospital, Copenhagen, Denmark,[4]Center for genomic medicine, Copenhagen University hospital, Copenhagen, Denmark

Introduction: Glioblastoma (GBM), classified as WHO grade 4, is a highly aggressive and incurable brain tumor with limited treatment options. Standard treatment consists of maximum safe surgery followed by concurrent chemo/radiation and adjuvant chemotherapy, the Stupp protocol. Despite extensive molecular characterization through DNA sequencing and RNA expression studies, the complex heterogeneity of GBM has yet to translate into improved standard treatments. A key challenge lies in predicting the impact of genetic and transcriptomic alterations at the protein level.
Aim: To identify promising protein biomarkers in GBM and trace these back to DNA and RNA data to determine whether they can be detected at earlier stages. We seek to uncover mechanisms of relapse and identify proteomic alterations that may be therapeutically targeted, integrating our findings with clinical data to discover potential prognostic and predictive biomarkers.
Experimental Procedures: We collected tumor tissue from 360 newly diagnosed GBM patients between 2016 and 2023, who provided informed consent for whole-exome/genome and RNA sequencing. In total, 514 protein samples were analyzed, including a subset of 58 samples from primary tumors and their matched first relapse. High-throughput proteomic analysis was performed using an Evosep system coupled with a high-sensitivity Orbitrap Astral mass spectrometer. Concurrently, we are analyzing the corresponding RNA and DNA data and plan to analyze 150 plasma samples from 50 of the included patients.
Results: Proteomics analysis of 514 GBM tissue samples identified 12,446 proteins, establishing this study as one of the most extensive proteomic investigations of GBM to date. Notably, O6-methylguanine-DNA methyltransferase (MGMT) exhibited significant regulation in MGMT-methylated patients. Furthermore, in patients with Neurofibromatosis type 1 (NF1) mutations, NF1 was significantly downregulated. Functional analysis revealed that proteins involved in glycosaminoglycan metabolism were upregulated in patients who responded to the STUPP protocol, suggesting key alterations in extracellular matrix composition and signaling pathways. Hedgehog signaling was markedly downregulated in relapse samples, a finding associated with increased cancer aggressiveness, poor prognosis, and elevated mortality. Additionally, the KRAS oncogenic signaling pathway was downregulated, pointing to potential changes in the tumor microenvironment and growth dynamics in relapsed GBM.
Conclusion: Our findings provide new insights into GBM proteomics and highlight potential therapeutic targets that could lead to more effective treatment strategies. By linking proteomic data to genetic and transcriptomic profiles, this study offers a valuable resource for improving patient stratification and developing targeted therapies for GBM.

#1884 Pancreatic cyst fluid proteins distinguish dysplasia grade of intraductal papillary mucinous neoplasm.

Chunliang Liu[1], Amber Mosley[1], Ehsan Irajizad[2], Michele Yip-Schneider[1], Huangbing Wu[1], Whitney R. Smith-Kinnaman[1], Thoa Tran[1], James P. Long[2], Kim-Anh Do[2], Johannes Fahrmann[2], John M. DeWitt[1], Samir Hanash[2], C. Max Schmidt[1], **Jianjun Zhang**[1]

[1]Indiana University, Indianapolis, IN,[2]The University of Texas MD Anderson Cancer Center, Houston, TX

Pancreatic cancer is the third leading cause of cancer-related death and is projected to be the second by 2030 in the US. The 5-year relative survival rate of pancreatic cancer is only 12.8% as over 80% of patients have a late diagnosis. To improve survival, it is vital to detect early-stage pancreatic cancer and its precursors. One such precursor is intraductal papillary mucinous neoplasm (IPMN), the most common type of pancreatic cyst often incidentally detected in asymptomatic patients. The current consensus guidelines, largely based on imaging features, have high sensitivity but low specificity in differentiating benign from malignant IPMNs, leading to widespread overtreatment of presumed “high-risk” cysts that have a low risk of malignancy on surgical pathology. Therefore, it is highly warranted to discover and validate biomarkers for improving the preoperative risk stratification of IPMN. Pancreatic cyst fluid is proximal to the tumor microenvironment and may thus harbor enhanced tumor-derived predictive biomarkers. Pancreatic cyst fluid samples were obtained from patients with pathologically confirmed low-grade (n=73) or high-grade/invasive (n=18) IPMN resected at Indiana University from 1992 to 2019. Global proteome quantitation was performed using liquid chromatography-tandem mass spectrometry. Differentially expressed proteins (DEPs) between the two groups were analyzed using Wilcoxon rank-sum test. We discovered 152 upregulated and 74 downregulated DEPs by comparing low-grade IPMN with high-grade/invasive IPMN (all $p < 0.05$). The enriched upstream regulators of these DEPs included let-7, miR-122, IL15, and FLT1 ($p = 2.45 \times 10^{-5}$ - 5.97×10^{-3}). Five discriminatory biomarkers with the largest LASSO coefficients and each with the area under the receiver operating characteristic curve (AUCs) of >0.75 (FAHD2A, TCEAL3, TWF1, MMUT, and NTPCR) were identified. The combined five-protein model achieved an AUC of 0.96 (95% CI: 0.92, 1.00). The AUCs of cyst fluid and serum CA19-9 measured in the same patients (Spearman's rank correlation coefficient: 0.65) were 0.67 and 0.70, respectively, both of which were smaller than the AUCs of each of the top five proteins identified. Combining the five best-performing proteins with cyst fluid or serum CA19-9 yielded a near complete separation of malignant from benign IPMN (AUC: 0.981 for the cyst fluid panel and 0.997 for the serum panel). A combined analysis of TCGA and GTEx databases revealed TWF1 overexpression in pancreatic cancer ($p < 0.0001$) that was associated with poor prognosis ($p = 0.0029$). In conclusion, the present study identified a panel of cyst fluid proteins (particularly TWF1) that are predictive of malignant pancreatic cysts. If validated in other patient populations, these biomarkers could increase the accuracy of the preoperative detection of high-risk IPMN and thereby improve patient outcomes.

#1885 Identification of the novel immune synapse-localized proteome for immuno-oncology using Microscoop®-induced targeted photo-biotinylation.

Chantal Hoi Yin Cheung[1], **Weng Man Chong**[1], Chun-Kai Huang[1], Hsiao-Jen Chang[1], Chia-Wen Chung[1], Jung-Chi Liao[1], Joseph Breier[2]

[1]Syncell Inc., Taipei City, Taiwan,[2]Syncell Inc., Watertown, MA

Although numerous immune synapse (IS) protein species have been identified, many IS-localized protein species remain unknown. Understanding the proteome of the IS between a target cell and a lymphocyte is crucial for advancing immuno-oncology. However, the low abundance of ISs and the absence of a definitive enrichment marker have hindered efficient proteomic profiling. In this study, we utilized Microscoop®, an innovative system that integrates microscopy, machine learning, and photochemical labeling to enable precise and spatially specific enrichment of IS proteins, thereby facilitating proteomic discovery for the IS. We employed Raji B cells as antigen-presenting cells (APCs) and induced IS formation with Jurkat T cells. The system first employed immunofluorescence imaging of CD3, a common IS marker in Jurkat T cells, and utilized a convolutional neural network-based deep learning algorithm to recognize IS formation from CMTPX-stained Raji B cells. Our automated system successfully achieved spatially targeted biotin-tagging of proteins at ISs through multiple rounds of imaging, deep learning-driven pattern generation, and photochemical labeling. Subsequent streptavidin pull-down and mass spectrometry analysis enabled the identification of IS-specific proteins. Remarkably, our spatial proteomic approach led to the isolation and identification of hundreds of different species at the IS interface, including proteins associated with key components of T-cell receptor (TCR) signaling pathways such as the TCR/CD3 complex, Src and Tec family tyrosine kinases, and pivotal NF-kB signaling proteins. Additionally, we identified a significant enrichment of proteins not previously associated with the IS. Our study not only illuminates previously unknown aspects of immune regulation at the IS interface but also has significant implications for cancer research, particularly in understanding and manipulating immune responses for therapeutic purposes.

#1886 Proteogenomic insights into chemotherapy resistance and therapeutic strategies in triple-negative breast cancer.

Dong Ki Lee[1], Min Hwan Kim[2], Yumi Hwang[3], Seul-Gi Kim[2], Gun Min Kim[2], Kyung-Hee Kim[4], Jong Bae Park[4], Min Jung Kim[5], Jee Ye Kim[6], Hyung Seok Park[6], Seho Park[6], Seung Il Kim[6], Heon Yung Gee[1], Joohyuk Sohn[2]

[1]Department of Pharmacology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[2]Division of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Avison Biomedical Research Center, Yonsei University College of Medicine, Seoul, Korea, Republic of,[4]Department of Cancer Biomedical Science, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of,[5]Department of Radiology, Yonsei University College of Medicine, Seoul, Korea, Republic of,[6]Division of Breast Surgery, Department of Surgery, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Triple-negative breast cancer (TNBC) is an aggressive subtype associated with high mortality and frequent chemotherapy resistance, necessitating the identification of biomarkers to predict treatment outcomes and elucidate resistance mechanisms. To address this challenge, we conducted a comprehensive proteogenomic analysis to uncover molecular determinants of chemotherapy response in TNBC.
Methods: Pretreatment tumor samples from stage II or III TNBC patients (n=50) treated with adriamycin, cyclophosphamide, and taxane-based neoadjuvant chemotherapy, along with post-treatment samples from patients (n=31) who did not achieve a pathologic complete response (pCR), were analyzed. Multiomics integration of exome sequencing, RNA-seq, and TMT-based proteomics and phosphoproteomics identified key pathways and molecular subtypes.
Results: Non-negative matrix factorization (NMF) clustering identified five molecular subtypes: “immune-enriched” (n=9), “xenobiotic metabolism” (n=2), “epithelial-mesenchymal transition (EMT)” (n=7), “Myc target” (n=12), and “myogenesis” (n=11). The “immune-enriched” subtype exhibited the highest pCR rate (5/9, 55.6%), whereas no pCRs were observed in the “xenobiotic metabolism” or “EMT” subtypes. Gene set enrichment analysis (GSEA) revealed immune-related pathways enriched in the pCR group across RNA and protein data, while EMT pathways were predominant in the non-pCR group. Notably, the estrogen response pathway was enriched in the non-pCR group exclusively in the protein GSEA data, emphasizing the greater clinical relevance of proteomics over transcriptomics in this context. Differentially expressed genes in the immunomodulatory subtype, based on the Lehmann classification, demonstrated upregulation of doxorubicin metabolism (*ARK1C2*) and efflux (*ABCA13*) genes in non-pCR patients, contributing to chemotherapy resistance. Cytoband GSEA identified ITGB8, a membrane protein on chromosome 7p21, whose loss correlated with a significantly higher pCR rate (48.3% vs. 14.3%, p = 0.031). Phosphoproteomics-based PTM-SEA highlighted the GRK2 pathway as enriched in non-pCR tumors and tumors without ITGB8 loss, suggesting its role as a resistance mechanism. In vitro experiments confirmed that GRK2 silencing enhanced the efficacy of taxane-based chemotherapy. Comparison of pre-treatment and post-treatment tumor phosphoproteomes unveiled enrichment of the AURKB pathway in post-treatment samples, with functional validation demonstrating a synergistic effect of AURKB inhibition with paclitaxel, suggesting a promising combination therapy.
Conclusion: This integrative proteogenomic analysis identifies proteomic estrogen signature, ITGB8, GRK2, and AURKB as promising biomarkers and therapeutic targets, providing new insights into chemotherapy resistance and response in TNBC.

#1887 Proteomics unveil characteristic proteins of patients with benign and malignant pulmonary nodules.

Ximin Gao, Zhangyan Lyu, Guojin Si, **Fengju Song**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: LDCT screening can significantly lower the mortality rate of lung cancer among high-risk individuals. Nevertheless, the limitations of CT might lead to frequent follow-up examinations and false positive outcomes, thereby causing unnecessary interventions and overtreatment. Therefore, the development of reliable and convenient biomarkers to accurately differentiate between benign and malignant nodules and to assess the likelihood of cancerous transformation is essential. We attempted to provide meaningful biomarkers based on plasma proteomic studies.

Methods: The participants in this study were chosen from individuals aged 40 to 74 years in the Chinese Colorectal, Breast, Lung, Liver, And Stomach Cancer Screening Trial (C-BLAST). We selected 10 patients with malignant lung nodules and 10 with benign lung nodules, matched for age and sex. Malignant lung nodules were defined as those with a LUNG-RADS diagnostic category of 4A, 4B, or 4X, accompanied by a biopsy confirming malignancy; benign nodules were those with a diagnostic category not exceeding 3. Plasma samples from two groups were collected and subjected to proteomic analysis using the Somascan Assay 11k detection platform. Paired t-tests were employed to identify the differential proteins between malignant and benign pulmonary nodules. The functional pathways enriched by these proteins were determined based on Gene Ontology (GO) analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis. Finally, the STRING was utilized to construct a protein-protein interaction network (PPI) and determine the key proteins related to malignant nodules.

Results: The average age of both groups was 61.4 years. A comparison of the proteomics between the malignant pulmonary nodule group and the benign pulmonary nodule group identified 188 differentially expressed proteins ($P < 0.05$), among which 102 were up-regulated proteins and 86 were down-regulated proteins. GO analysis of the differential proteins indicated functional enrichment in pathways such as chemical carcinogenesis, fluid shear stress and atherosclerosis, and biosynthesis of cofactors. According to KEGG analysis, they were mainly enriched in pathways like chemical carcinogenesis-reactive oxygen species, fluid shear stress and atherosclerosis, and metabolism of xenobiotics by cytochrome P450. Through PPI analysis, ten key proteins were determined, including CRP, FCGR3B, CCL2, CYP3A5, GSTA3, GSTM1, GSTM3, GSTM5, CD163, and GSTM4. These molecules possess anti-atherosclerotic and anti-inflammatory activities, as well as chemotactic activity for monocytes and basophils, and play roles in hydrolyzing nucleotides and host defense.

Conclusions: Our research results provide ten potential plasma protein biomarkers for the discrimination of benign and malignant pulmonary nodules, which might broaden our understanding of their characteristics.

#1889 Proteomic profiling using high-dimensional multiplex platforms to identify prospective risk factors for lymphoid malignancies across multiple cohorts.

Pieter Martijn Kolijn[1], Karl Smith-Byrne[2], Vivian Viallon[3], Matthew Lee[4], Keren Papier[2], Anton W. Langerak[5], Florentin Spath[6], Arjan Diepstra[7], Raul Zamora-Ros[8], Alessandra Macciotta[9], Amaia Aizpurua[10], Rosario Tumino[11], Ruth C. Travis[2], Elio Riboli[12], Marc J. Gunter[12], James McKay[13], **Roel C. H. Vermeulen**[1]

[1]Population Health Sciences, Utrecht University, Utrecht, Netherlands,[2]University of Oxford, Oxford, United Kingdom,[3]Population Health Sciences, International Agency for Research on Cancer, Lyon, France,[4]University of Bristol, Bristol, United Kingdom,[5]Erasmus MC, Rotterdam, Netherlands,[6]Umea University, Umea, Sweden,[7]University of Groningen, Groningen, Netherlands,[8]Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain,[9]University of Turin, Turin, Italy,[10]Biodonostia Health Research Institute, San Sebastian, Spain,[11]Iblea Association - Epidemiological Research (AIRE-ONLUS), Ragusa, Italy,[12]Imperial College London, London, United Kingdom,[13]International Agency for Research on Cancer (IARC), Lyon, France

Introduction: Circulating proteins play a central role in the development of lymphoid malignancies and the immune system's response to these cancers.
Methods: In this study, we measured 6,412 unique proteins in prediagnostic plasma samples using the SomaScan 7K panel from a total of 4,565 participants of a case-cohort study nested within the European Prospective Investigation into Cancer and Nutrition (EPIC)—484 who later developed a lymphoid malignancy (median follow-up 9 years) and 4,081 who did not. We conducted subtype-specific analyses for non-Hodgkin lymphoma (NHL, n=348), chronic lymphocytic leukemia (CLL, n=80), multiple myeloma (MM, n=116), diffuse large B-cell lymphoma (DLBCL, n=80), follicular lymphoma (FL, n=51) and Hodgkin lymphoma (HL, n=20) using Prentice-weighted Cox regression with Benjamini-Hochberg correction for multiple testing.
Results: We observed significantly altered plasma levels prior to NHL diagnosis for 147 unique proteins (161 aptamers), of which 131 were upregulated and 16 were downregulated. Increased plasma levels of members of several major immunomodulatory protein families, including the FC-receptor family and the semaphorin family, were associated with increased risk of NHL. Alongside established biomarkers such as sCD23 for CLL, CXCL13 for DLBCL, and sBCMA for MM, we identified potent novel markers, including FCMR and FDCSP for NHL. Time-stratified analyses revealed that a subset of these protein-lymphoma associations are evident over a decade before diagnosis, underscoring the protracted preclinical phase of lymphoid malignancies. Pathway analyses revealed dysregulation in immune modulation, epigenetic regulation, cytokine and chemokine signaling, B-cell receptor signaling, the NF-κB signaling pathway, alternative splicing and N-glycan biosynthesis. In total, 2136 out of 6412 proteins measured in our current study overlapped with those measured in a recent UK biobank study. The significant protein-cancer associations observed in our current analyses within EPIC showed high concordance in the UK biobank in terms of both FDR-adjusted significance (58%-82%) and the direction of the association (89%-92%), meaning positively or negatively associated with cancer risk.
Conclusion: In conclusion, we identified hundreds of proteins associated with lymphoid malignancy risk, revealing a robust set of markers detectable many years prior to diagnosis, and advancing our understanding of lymphoid malignancy pathogenesis.

#1890 Proteomic analysis of colorectal cancer risk across two prospective cohorts.

Gunter[13]

[1]International Agency for Research on Cancer, Lyon, France,[2]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, United Kingdom,[3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[4]Cancer and Nutrition Unit, Cancer Epidemiology Research Program, Catalan Institute of Oncology-IDIBELL, Bareclona, Spain,[5]Institute for Cancer Research, Prevention and Clinical Network, Fiorentina, Italy,[6]University of Naples Federico II, Naples, Italy,[7]University of Turin and CPO Piemonte, Turin, Italy,[8]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom,[9]Provincial Health Authority (ASP), Ragusa, Italy,[10]Erasmus MC, Rotterdam, Netherlands,[11]UMC Utrecht, Utrecht, Netherlands,[12]University of Cambridge, Cambridge, United Kingdom,[13]Department of Epidemiology and Biostatistics, School of Public Health, Imperial College London, London, UK, London, United Kingdom

High-throughput proteomic profiling in prospective cohorts has the potential to uncover biomarkers of cancer risk and biology of cancer development. We investigated prospective associations of up-to 7,335 aptamers with overall and site-specific colorectal cancer in a case-cohort study within the European Prospective Investigation into Cancer and Nutrition (EPIC) and then evaluated associations in the Atherosclerosis Risk in Communities (ARIC) study.

Hazard ratios and 95% confidence intervals were estimated using Prentice weighted Cox-proportional hazard models (stratified by recruitment center, sex, and 5 year age group and adjusted for fasting status, day of blood draw, body mass index, smoking status, daily alcohol consumption, physical activity level, and highest level of education) in 977 incident colorectal (colon, 658; rectum, 319) cancer cases and 5,057 non-cases under a case-cohort design. The identified associations were then evaluated in ARIC in a cohort design including 271 colorectal (colon, 235; rectum, 36) cancers in 9,495 individuals using multivariate Cox-proportional hazard models.

Overall, 37 aptamers were associated (false discovery rate[FDR] p-value < 0.05) with colorectal cancer in EPIC; data on 27 of these were available in ARIC, 7 of which had consistent directions of association in both studies and met a nominal p-value (0.05) threshold in ARIC (positive associations: ACAA1, ASL, GDF15, IQCF1, TFF3; inverse associations: CLEC3B, COMP). Associations did not change after 5-year follow-up exclusion. In site-specific analyses in EPIC, 66 and 6 aptamers were specifically associated with colon and rectal cancer, respectively at FDR<0.05. Four of these aptamers were nominally (P<0.05) associated with colon cancer in ARIC (inverse association: CLEC3B; positive association: ACAA1, GDF15, TFF3) while a further 29 showed associations directionally consistent with those in EPIC.

These large-scale proteomic analyses identified a set of proteins associated with colorectal cancer risk across two independent cohorts. These proteins reflect pathways involved in cell migration and adhesion, colorectal mucosal integrity and growth and differentiation, among others, and may represent novel biomarkers of colorectal cancer risk.

#1891 Identification of highly accurate early-stage specific NSCLC biomarkers from extracellular vesicles identifies immune response and metabolic biomarkers associated with cancer.

Zack Opheim[1], Cheryl Bandoski[1], Poorva Mudgal[1], Valesca Anschau[2], Issa Isaac[2], Martin Mehnert[2], Alan Ezrin[1], **Todd A. Hembrough**[1]

[1]Nexosome Oncology, Durham, NC,[2]Biognosys, Schleiren, Switzerland

Lung cancer is one of the leading causes of cancer-related deaths worldwide, with non-small cell lung cancer (NSCLC) accounting for approximately 85% of cases. Early-stage lung cancer is often asymptomatic, leading to delayed diagnosis. Challenges in early detection underscore the need for more reliable, non-invasive diagnostic biomarkers. Plasma extracellular vesicles (EVs) represent a promising target for tumor detection and monitoring as they provide an abundant, stable, an easily accessible source of biomarkers. The purpose of this study is to utilize EVs to identify novel cancer related biomarkers and translate these findings into a clinical/immunoassay. To identify novel biomarkers, we enriched EVs using size exclusion chromatography and a proprietary buffer system. TrueDiscovery™ Data-independent acquisition (DIA) mass spectrometry (MS) analysis was conducted on EVs from 74 NSCLC patients (IA/B (32), IIA/B (8); III (17); IV (17)) and 50 normal plasma samples. An in-house machine learning (ML) pipeline was developed to identify differentially expressed proteins and model candidate multiplexes to identify those with extremely high diagnostic accuracy (> 0.98). Additionally, candidate multiplex targets were tested by ELISA to assess mass spectrometry translation to a clinical platform.

Comparing tumor vs normal samples (avg=2735 protein IDs) using our ML pipeline we identified 595 Pan Lung cancer differentially expressed proteins (absolute Log2FC>0.5; FDR adjusted p-value <0.01; AUC >0.5). When individual stages were compared to control plasma, a large number of differentially expressed proteins were also seen: Stage I – 549, Stage II – 120, Stage III – 355, and Stage IV – 373 proteins (absolute Log2FC>0.5; FDR adjusted p-value <0.01; AUC >0.5). Significant proteomic differences were also seen between early-stage and late-stage NSCLC, suggesting Stage specific biomarkers may be necessary for maximal diagnostic accuracy. Using the best individual biomarkers, we used Support Vector Machine to test all possible 3-Plexes and identify 3-Plexes with nearly perfect accuracy (>0.99) for each NSCLC Stage: Stage I (140 plexes), Stage II (92), Stage III (67), and Stage IV (50). Early-stage 3-Plexes consist largely of immune, inflammatory, and metabolic pathway proteins. Differential expression of key biomarkers was confirmed using ELISAs, and the performance of multiple highly accurate 3-Plexes is currently being assessed by ELISA on independent intended use case/control cohorts, for potential clinical development.

The potential of these highly accurate 3-Plexes to detect even the smallest Stage Ia1 tumors suggests that multiplexed proteomics of EV-associated biomarkers may be an extremely sensitive and specific platform for detection of very small early-stage and recurrent tumors.

#1892 Proteomic profiling identifies and validates a prognostic survival biomarker and pathways associated with novel subtypes of esophogeal adenocarcinoma.

Adel T. Aref[1], Daniel Bucio-Noble[1], Ahilya Singh[1], Jerresa Jabson[1], Myra Cheung[1], George Craft[1], Daniella Jaber[1], Rebecca Poulos[1], Erin K. Sykes[1], Jennifer M. Koh[1], Erin M. Humphries[1], Dylan Xavier[1], Peter G. Hains[1], Phillip J. Robinson[1], Thejaani Udumanne[2], Sarah J. Lord[2], Yi Jin Liew[3], Jason Ross[3], Dan Falkenback[4], Jan Johansson[4], Duncan McLeod[5], David Whiteman[6], Reginald V. Lord[2], **Roger R. Reddel**[1]

[1]ProCan, Children's Medical Research Institute (CMRI), Sydney, Australia,[2]St. Vincent's Centre for Applied Medical Research, Sydney, Australia,[3]CSIRO Health and Biosecurity, Sydney, Australia,[4]Lund University, Lund, Sweden,[5]Institute of Clinical Pathology and Medical Research, Sydney, Australia,[6]QIMR Berghofer Medical Research Institute, QLD, Australia

Introduction: Esophageal adenocarcinoma (EAC) is an aggressive malignancy with poor survival rates. Current management relies on tumor stage and grade, with neoadjuvant therapy (NT) showing improved outcomes over surgery alone. However, robust biomarkers are still required to improve staging and patient selection for therapy, including NT.

Methods: A training cohort of fresh frozen samples from 64 patients with EAC, not treated with NT, was analyzed by data-independent acquisition mass spectrometry. Formalin-fixed paraffin-embedded samples from an independent cohort of 188 patients with EAC treated with NT were used as validation. Unsupervised consensus clustering (CC) was performed followed by differential abundance (DA) analyses (DAA) and pathway enrichment analyses (PEA) to identify the DA proteins and enriched pathways in each cluster. Survival analyses using Cox regression were performed to assess the prognostic power of the proteomic clusters for overall survival (OS). Finally, a prognostic signature for OS was built on the training cohort using multivariable Cox regression analyses with LASSO regularization followed by StepAIC to select the most prognostic proteomic combination. The predictive power of the proteomic signature was tested using the Area Under the Receiver Operating Characteristic (AUROC) analysis and via inclusion in a nomogram with other prognostic variables.

Results: Proteomic analyses identified 8,730 and 5,214 proteins in the training and validation cohorts, respectively. The CC analyses revealed five clusters in the training cohort. Clusters 2 and 3 showed shorter OS compared to the other clusters ($p=0.0025$). Independent DAA and PEA revealed upregulation in extracellular matrix-related pathways in the poor prognostic clusters within both cohorts. A five-protein signature was developed in the training cohort and was associated with OS ($p<0.001$). This signature was independent of other prognostic variables, including N stage, T stage, grade, and age. The five-protein signature was also associated with higher odds of having positive nodes at the time of resection (Odd Ratio 6.3, $p=0.009$). The proteomic signature demonstrated an AUROC of 0.81 and was the most prognostic variable in a nomogram for survival risk. Finally, the proteomic signature maintained its prognostic power in the validation cohort ($p=0.016$) and was independent of other clinical variables, showing the highest prognostic value in the nomogram.

Conclusion: Using two independent cohorts of EAC surgical samples, we were able to identify a prognostic proteomic-based classification and develop a proteomic-based signature that was prognostic for OS and independent of other clinical variables. This signature may be investigated further as a criterion to tailor treatment and select patients who can benefit from treatment de-escalation.

#1893 Proteomic profiling of advanced hepatocellular carcinoma identifies predictive signatures of response to treatments.

Adele Delamarre[1], Marie Decraecker[1], Sylvaine Di-Tommaso[2], Cyril Dourthe[1], Jean-William Dupuy[3], Melanie Moreau[1], Nathalie Allain[1], Isabelle Mahouche[1], Julie Giraud[1], Giovanni Benard[4], Claude Lalou[5], Paulette Bioulac-Sage[1], Jerome Boursier[6], Jean-Frederic Blanc[7], Brigitte LeBail[1], Anne-Aurelie Raymond[1], **Frederic Saltel**[1]

[1]U1312 (BoRdeaux Insitute of onCology), Inserm, Bordeaux, France,[2]TBMcore, Inserm, Bordeaux, France,[3]TBMcore, Bordeaux University, Bordeaux, France,[4]Rare Diseases Laboratory: Genetics and Metabolism, Inserm U1211, Inserm, Bordeaux, France,[5]U1211 MRGM, Inserm, Bordeaux, France,[6]Department of Hepatology and Oncology,, Angers University Hospital, Bordeaux, France,[7]CHU Bordeaux, Bordeaux, France

Background and Aims: Hepatocellular carcinoma (HCC) is the most common form of liver cancer but, due to late diagnosis, the prognosis is extremely poor and the majority of cases are advanced HCC, which are only eligible for palliative systemic therapies. After a decade of exclusive sorafenib monotherapy, with a response rate of < 10%, the advent of new combinations including immunotherapies represents a revolution in the management of HCC. The combination of atezolizumab/bevacizumab is recommended as the first-line systemic treatment for HCC, with a response rate of no more than 30%. Additionally, less than 25% of non-responding patients are eligible for second-line treatment. However, there are currently no predictive factors for response to these different treatment options.
Method: We profiled, by high-resolution mass spectrometry-based proteomics combined with machine learning analysis, a selected cohort of formalin-fixed, paraffin-embedded biopsies of advanced HCC adenomas with clinical follow-up collected from several French hospitals. We grouped subject according to their objective response to treatments, corresponded to a tumor regression > 30% (G1) and tumor progression > 20% (G2) at 6 months after the beginning for atezolizumab/bevacizumab and sorafenib treatments.
Results: We generated a proteome database of 50 selected HCC samples. We compared the relative protein abundance between tumoral and non-tumoral liver tissues from advanced HCC patients treated with atezolizumab/bevacizumab or sorafenib. The clear distinction of these two groups for each treatment using principal component analysis with a deregulation for 141 protein or 87 for atezolizumab /bevacizumab and sorafenib treatment, respectively. These signatures were sufficient to predict the response. Moreover, these signatures reveal the biological pathways involved in the resistance to treatments. Particularly, we revealed and validated a shift in tumor cell energy metabolism inducing an immunosuppressive environment involved in the resistance to atezolizumab/bevacizumab.
Conclusion: We performed an in-depth analysis of quantitative proteomic data from HCC biopsies using statistical packages and found that their proteome includes information to predict the treatment response to advanced HCC giving the ability to optimize patient management.

#1894 Correlative multiscale 3D spatial proteomics.

Jingtian Zheng, Seung Young Lee, Yi-Chien Wu

Pharmaceutical Sciences, University of Illinois at Chicago, Chicago, IL

Tissues and organisms are complex systems, characterized by 3D structures, interconnected distinct functional subregions, and cellular heterogeneity, particularly in diseased states. To comprehensively understand the cellular and molecular mechanisms underlying disease, like tumor or neurodegenerative disease, it is crucial to construct a complete 3D map of tissues that integrates microanatomical structures, spatial cell composition, and molecular expression landscape, providing a holistic view of tissue pathophysiology. Existing tissue imaging methods can provide 2D spatial cellular and molecular information in tissue slices; however, only a fraction of the full 3D tissue architecture, leaving critical spatial and contextual information about the tissue microenvironment unresolved. To address this gap, we developed a novel methodology that integrates spatial proteomics with multiscale 3D optical tissue microscopy. The workflow begins with an overall 3D imaging of the tissue by light-sheet microscopy (LSFM), utilizing immunofluorescence (IF) or autofluorescence (AF) to visualize whole tissue morphology, cells, and molecules, providing a preview to identify Regions of Interest (ROIs). Using a tracking-based approach, macrosections containing these ROIs are physically isolated for subsequent 3D multiplex IF staining by cyclic staining and confocal microscopy (CLSM), allowing detailed, high-resolution cellular-level image and analysis. These sections are then subjected to thin-slicing and Super-Resolution Microscopy or Laser Capture Microdissection (LCM), which precisely extracts tissue regions for spatial proteomics analysis. Finally, the spatial proteomics data are aligned with multiscale 3D imaging data to provide a comprehensive, integrated analysis of the tissue. This integrated pipeline not only bridges 3D tissue imaging with molecular profiling but also enables selective analysis of ROIs, significantly saving time and resources while maintaining spatial and molecular fidelity, offering new insights into complex biological systems and disease mechanisms.

#1895 Improving capability for biomarker discovery of glioblastoma-enriched poly-ligand profiling library using aptamer capture microarrays.

Xixi Wei, Justin Saul, Daniel Martin, Alexis Rodin, Anna Walton, Danielle Richard, Tassilo Hornung

Caris Life Sciences, Inc., phoenix, AZ

Adaptive dynamic artificial poly-ligand targeting (ADAPT) biotargeting system is an innovative aptamer-based poly-ligand profiling and therapeutic target discovery platform employed to uncover the complexity of cancer in various sample types including Formalin-fixed paraffin-embedded tissue (FFPE). The enrichment process, selective evolution of ligands by exponential enrichment (SELEX), selects single-stranded oligodeoxynucleotides (ssODNs) from a diverse starting pool of ssODNs, which are supposed to preferentially bind to markers expressed in cancer tissues. In practice, the biological and technical complexity of sequence selection leads to an enriched library of ssODNs that contains many persistent sequences with poor differential binding between cancer and normal control tissues. Traditionally SELEX is performed to enrich a library from which the top performing candidates are synthesized and characterized, leading to indistinctive sequences being screened out through this time-consuming and expensive process. ADAPT, on the other hand, is predicated on many thousands of unknown interactions between the sequences in the enriched library and their cognate markers in the FFPE tissues. Consequently, the performance of an enriched library for ADAPT is susceptible to the abundance of indiscriminate ssODN sequences. In this work, after identifying potential binder sequences from an enriched library against glioblastoma (GBM) FFPE tissue, we proposed using Aptamer Capture Microarrays (ACM) to isolate sub-pools of sequences of interest and remove indiscriminate ssODNs from the library. Clinical GBM patient and normal control FFPE tissues were stained with a GBM-enriched ADAPT library. The bound libraries were recovered and sequenced with next generation sequencing (NGS). Different analytical strategies were used to identify sub-pools of sequences that potentially bind preferentially to GBM tissues. By designing microarray probes to capture selected sequences, and then eluting these targeted sequences from the microarray, the percentage of sample reads of the selected sequences were increased from a less than 5% in original enriched library to more than 80% in final cleaned up library. Our results show enhanced discrimination of GBM and normal tissues through FFPE tissue staining. This novel application of microarray capture is a highly cost-effective alternative to oligo pool synthesis, affording multiple partitions of a library to test varied ssODN selection methodologies. Libraries optimized by this method is expected to improve our ability to identify biomarkers.

#1896 Spatial proteomics and tumor-immune phenotyping identifies a diverse immune landscape in syngeneic murine tumor models.

A. Bose[1], E. Q. Alonzo[2], S. Struble[1], J. Fisher[2], R. A. Heil-Chapdelaine[1], N. F. Diaz Granados[1], V. Agrawal[1];
[1]Leica Microsystems, Inc., Waltham, MA, [2]Cell Signaling Technology, Danvers, MA

Syngeneic mouse models have a functionally intact immune system, and therefore, serve as a crucial tool for evaluation of the immune response to tumors and pre-clinical evaluation of immunotherapeutic strategies. However, the immune response varies between different syngeneic models. Identification and selection of appropriate models for pre-clinical evaluation is challenging. To understand the dynamic interplay between the tumor and immune system, we implemented multiplexed spatial proteomics across various syngeneic tumor models. Spatial mapping of multiple tumor and immune markers in untreated tumor provides an overview of the tumor immune architecture. This information can be applied to identify optimal models for preclinical immunotherapy approaches, to understand the response to therapies at the preclinical stage, and to identify potential biomarkers for clinical evaluation. The Cell DIVE Multiplexed Imaging Solution, in combination with IHC-validated antibody conjugates from Cell Signaling Technology (CST), enables profiling of immune cell populations in the context of human and mouse tumor tissue. Here, we demonstrate multiplexed Cell DIVE imaging of syngeneic mouse tumor models using a novel CST® panel of mouse-reactive antibodies. We apply segmentation and clustering analysis to identify spatially co-localized populations of cells and discuss the complexities of immune cells and their interactions. Cell type specific markers combined with multiplexed tissue imaging and spatial mapping is an approach that enables a better understanding of the anti-tumor immune response, which can be applied to address challenges associated with developing immune-based therapies. The study highlights the importance of simultaneously observing multiple immune cell types and tumor characteristics in spatial context.

CLINICAL RESEARCH: Diagnostic Biomarkers 3: Early Detection Biomarkers
Poster Session

#1901 Applications of silicon quantum dots as biomarkers for cancer detection and treatment, emphasizing biocompatibility studies.

Dorra Gargouri, Artjima Ounkaew, Xuyang Liu, David Antoniuk, Jonathan Veinot

Applied Quantum Materials Inc., Edmonton, AB, Canada

Silicon quantum dots (SiQDs) are emerging as advanced nanomaterials for cancer treatment and detection. SiQDs are an attractive alternative to organic dyes for biological labeling, offering tunable photoluminescence response and high resistance to photobleaching. In our hands, SiQDs possess tailorable surface chemistry, as well as stable size and surface chemistry dependent luminescent response spanning visible and near-infrared spectral regions with high photoluminescence quantum efficiencies (approaching 85%). SiQDs are an enticing heavy-metal-free, non-toxic and biocompatible alternative to status quo QDs. Applied Quantum Materials Inc. (AQM) possesses world leading expertise to produce high-purity narrow size distribution SiQDs with custom surface modifications, including biomolecules (8 kDa to 150 kDa) for biology applications. We have performed a biocompatibility study that shows AQM SiQDs have achieved over 90% cell viability, even at concentrations up to 500 µg/mL after 24 h of incubation. In addition, we modified SiQDs to improve cancer cell uptake to enhance photodynamic therapy (PDT) efficacy under low-level laser therapy (LLLT). Using NIR laser irradiation, AQM SiQDs significantly reduced cancer cell viability, enhancing reactive oxygen species (ROS) generation and establishing SiQDs as effective photosensitizers for cancer therapy. SiQDs exhibited excellent photostability and minimal toxicity, outperforming organic dyes. Bioconjugation of SiQDs with biomolecules are proving to be powerful tools for cancer cell detection. This opens new possibilities for oncologists to select the most suitable therapy based on a comprehensive understanding of the cancer type and its progression. We are currently developing a liquid biopsy system for precision cancer management. Powered by SiQDs, this advanced diagnostic tool will enable automated blood analysis to identify and quantify rare circulating tumor cells (CTCs) with high sensitivity in blood patients. Working with our academic collaborators, we are addressing the complexities of brain tumor resection in glioblastoma. We synthesized a novel nanoscale material combining SiQDs with anti-cancer DNA aptamers for fluorescence-guided surgery. These SiQDs labeled aptamers will be validated on resected brain tumor samples and compared with pathological margin assessments. Additionally, the imaging potential of AptaSiQDs for primary and metastatic brain tumors will be evaluated in preclinical in vivo models. As we progress to in vivo studies, we will assess their cytotoxicity and biocompatibility in mice, aiming to expand their use in targeted drug delivery, imaging, and theranostics for personalized medicine. SiQDs are at the forefront of life sciences, offering diverse benefits, making them ideal for cancer diagnosis.

#1902 Novel monoclonal antibodies specific for cancer-associated proliferating cellular nuclear antigen for tumor monitoring and diagnosis.

Malaney C. Young[1], Caroline M. Li[1], Robert G. Lingeman[1], Chun Li[1], Aimin Li[2], Linda H. Malkas[1], Robert J. Hickey[1]

[1]Beckman Research Institute of The City of Hope, City of Hope, CA,[2]City of Hope, City of Hope, CA

Proliferating cellular nuclear antigen (PCNA) is a biomarker associated with cancer progression and is expressed in all cancer types. Its expression is increased before DNA synthesis with the transition of cells from G1 to S phase, making it a useful diagnostic marker for tumor cell proliferation. Our lab has identified an acidic and basic isoform of PCNA that can be resolved using 2-dimensional gel electrophoresis (2DE). Cancer cells express the acidic, cancer-associated isoform of PCNA (caPCNA), whereas healthy cells only express the basic, non-malignant isoform of PCNA (nmPCNA). Thus, caPCNA is an important biomarker that can be used for identifying early-stage cancer and monitoring tumor growth, metastasis, and response to treatment. Immunohistochemical staining (IHC) of tissue biopsies is an essential method for tumor detection and monitoring of cancer progression. Antibodies are used either individually or in panels and typically require markers that are specific to each tumor's origin. Because caPCNA is not specific to a single cancer type, it is a universal biomarker which can be used to monitor cancer of any origin. Commercially available antibodies for PCNA do not distinguish between the cancer isoform and the non-cancer associated normal isoform. We have developed a series of monoclonal antibodies that are capable of distinguishing caPCNA from nmPCNA and have characterized these antibodies using 2DE and IHC. These novel monoclonal antibodies targeting the caPCNA isoform could enable pathologists to distinguish the presence of cancer cells in difficult to diagnose biopsy specimens, more efficiently monitor surgical margins, and potentially identify the presence of circulating tumor cells in blood samples.

#1903 Actionable mutational landscape in solid tumors: a case study of ovarian and colon cancer.

Amit Kumar[1], Samir Agarwal[2], Pankaj Khanna[1], Shobit Gupta[1], Rama Chandran[1], **Ananth S. Bommakanti**[1]

[1]Genes2Me, Gurugram, India,[2]Army Hospital Research And Referral, New Delhi, India

Background: Solid tumors are abnormal tissue masses that can be benign or malignant. They are named after the type of cells that form them, and can be categorized by where they originate such as breast, colon, bladder, ovary, and lung.
Methods: Genomic profiling was done with sequencing of FFPE tumor samples 40 using Genes2Me PanCancer assay with 681 genes and the target size of 1.7 Mb on Illumina platform. Bioinformatics analysis was performed using standard GATK.v4.1.2 somatic variant calling pipeline. Mutational plots were generated using MAFtools and inhouse python script for post data analysis.
Results: The number of mutant allele frequency (MAF) of the most frequently mutated genes varied significantly across tumor types, with the highest MAF observed in this cancer type. Significantly mutated cancer-related genes in solid tumors found the most frequently altered genes to be TP53(45%), KRAS(18%), TERT(14%), CDKN2A(12%), PIK3CA(11%), APC(36%), EGFR(10%), ESR1(20%), KIT(9%), AR(64%), MYC(44%), FGFR1(21%), BRCA1(22%), BRCA2(63%), CCND1(46%) in colon and ovarian carcinoma. Tumormutational burden (TMB) varied significantly across tumor types, and patients with high MAF had a significantly higher TMB score with one of the investigated platforms.
Conclusion: These findings describe the similarities and differences between mutational signature of different solid tumors from cancer patients, providing valuable information for personalized medicine and also an important implication for the selection of patients for clinical trials with molecularly targeted therapies.

#1904 Cell-based reference standards for the development and validation of assays for the assessment of minimal residual disease in acute myeloid leukemia.

Colt W. Nash, Matthew G. Butler, Jayanthi Ramprakash, Ojaswee Dahal, Andrew T. Anfora, David E. Merriam, Russell K. Garlick, **Yves Konigshofer**

LGC Clinical Diagnostics, Inc., Gaithersburg, MD

Here, we describe the generation of novel cell-based reference standards for the development and validation of molecular diagnostic assays that assess measurable residual disease (MRD) in acute myeloid leukemia (AML). Unlike other hematological malignancies that are characterized by a defined genetic abnormality - such as the BCR::ABL1 translocation in chronic myelogenous leukemia - AML is associated with numerous different mutations that vary between patients. While about third of AML patients harbor a mutation in NPM1 and/or an internal tandem duplication (ITD) in FLT3, this is not the case for the majority of patients. This complicates the monitoring of the presence or absence of MRD during and after treatment because assays need to be very sensitive but inexpensive enough to allow for repeated measurements over time. For example, in the absence of an NPM1 or FLT3-ITD mutation, it may be beneficial to design patient-specific assays that focus on only the mutations found in that patient's AML.

As an initial proof of concept, we engineered an AML cell line to add NPM1 and/or FLT3-ITD mutations. The number of mutations per cell was quantified by digital PCR. This allowed for the generation of clones that represented AML cells with only a defined NPM1 or FLT3-ITD mutation, as well as AML clones with both. These were combined with peripheral blood mononuclear cells to dilutions as low as 1:100,000 and analyzed by flow cytometry (a traditional way of monitoring for MRD in AML), electrophoresis (FLT3-ITD), digital PCR, and NGS. Compatibility was observed with all methods, but digital PCR and NGS appeared to be more sensitive.

We then expanded the NPM1 variants beyond type A (c.860_863dup) to include types B, D, and J, and added additional FLT3-ITDs to include duplicated lengths as long as 228 bp. In order to increase the information obtained from a single sample in NGS, which is capable of independently measuring multiple variants, we combined these into a pool that was quantified by digital PCR and analyzed by NGS but also retained compatibility with flow cytometry to enable sorting and single-cell analyses.

In conclusion, we have generated reference standards that incorporate multiple variants in NPM1 and FLT3, which are designed for the development and validation of molecular biology-based assays. In order to expand beyond the mutations found in only a third of AML patients, we are applying the same method to add mutations in additional genes such as IDH1, IDH2, and TP53.

#1905 Deep learning-based histomorphological classification to identify novel causal genes in gastric cancer.

Moonyoung Lee[1], Kwangil Yim[1], Sangjeong Ahn[2], Hyun-Jong Jang[3], Sung Hak Lee[1]

[1]Department of Hospital Pathology, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of,[2]Department of Pathology, Korea University Anam Hospital, College of Medicine, Korea University, Seoul, Korea, Republic of,[3]Catholic Big Data Integration Center, Department of Physiology, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of

Introduction: Gastric cancer (GC) has high mortality and limited treatment options, with histomorphological features predicting outcomes and treatment response. Stricter criteria for undifferentiated GC in Japanese guidelines underscore its poor prognosis. This study developed a deep learning (DL) model to classify GC as differentiated or undifferentiated, reducing diagnostic variability. The model revealed genetic differences aligned with or distinct from pathologist classifications, providing precise spatial insights into GC phenotypes to enhance molecular understanding, diagnosis, and therapy.

Methods: A fully automated method was utilized to classify gastric cancer tissue whole-slide images (WSIs) from The Cancer Genome Atlas stomach adenocarcinoma dataset (TCGA-STAD) into differentiated and undifferentiated tumor types. To focus on the analysis of differentiated and undifferentiated types, GC samples of Epstein-Barr virus-positive, microsatellite-unstable/instability types were excluded from the study. For SNV variants, the downstream analysis focused on splice sites, nonsense mutations, and frameshift insertions/deletions within protein-coding regions that are directly related to the phenotype and likely to cause the disease. In addition to SNV analysis, CNV analysis was also performed to identify novel causal genes. All experiments were analyzed based on three classification outcomes: classifications made by expert pathologists, classifications made by the DL model, and the overlapping classifications agreed upon by both expert pathologists and the DL model.

Results: SNV analysis identified *TP53, CDH1, CNGA4,* and *SPTA1* as causal genes for undifferentiated GC, with recurrent variants across all three classification methods. The identification of *TP53, CDH1,* and *CNGA4,* known causal genes in gastric cancer, validates our findings. Additionally, *SPTA1* was identified as novel causal gene of undifferentiated GC. In addition, in the results of mutation signature analysis, we confirmed that SBS1, SBS10b, and SBS6, which are commonly related to carcinogens, stood out in the results classified by three criteria. We also confirmed that the TMB and CNV results were similar among subgroups.

Conclusion: This study demonstrated the potential of a DL-based approach in the task of subclassification of GC using WSIs, highlighting its utility in identifying genes associated with GC subtypes. In this study, in addition to previously well-known genes, a novel gene, *SPTA1,* was identified as causative genes. This information may enhance our understanding of the prognostic significance of tissue slides and provide additional insights to guide therapeutic decision-making.

#1906 Comprehensive genomic profiling for solid tumors.

Shobit Gupta[1], Amit Kumar[1], Pankaj Khanna[1], Rama Chandran[1], Samir Agarwal[2]

[1]Genes2Me, Gurugram, India,[2]Army Hospital Research And Referral, New Delhi, India

Background: Next-generation sequencing technologies provides deep knowledge into the foundation of tumors and can advance the field of precision oncology. It can be used to effectively select the treatment based on druggable genomic alterations. In the present study, we prospectively investigated the clinical utility of a CGP assay in patients with metastatic tumors of the lung, breast, gynecologic, and colon etc.

Methods: Genomic profiling was done on FFPE tumor samples using Genes2Me PanCancer assay. This assay, specifically adapted for the present molecular screening, is validated for clinical use and accredited by CEIVD and based on the guidelines published by the Association for Molecular Pathology, College of American Pathologists. It is a NGS-based product especially designed to identify genomic alterations, based on Food and Drug Administration, National Comprehensive Cancer Network guideline references, European Medicine Agency approvals, European Society for Medical Oncology (ESMO), updated every 3-6 months. It Targets around 681 genes with the size of 1.7 Mb containing different biomarkers such as DNA/RNA fusions, TMB, MSI and HPV related genes. It also incudes homologous recombinational repair (HRR) related genes. This panel was also designed to identify large scale rearrangements and special biomarkers such as MET exon 14skipping. Sequencing was done on Illumina platform. Bioinformatics analysis was performed using standard GATK.v4.1.2 somatic variant calling pipeline.

Results: Most of the samples were sequenced with average depth of >1000X. On target ration ranged between 82-94% with coverage % at 10X and 30X was more than 99%. In all the samples mutations were identifies with VAF ranges from 8-28%. mutations More than 50% samples have identified mutations with actionable FDA approved drugs.

Conclusion: Although further studies are needed to support, this CGP assay is a noninvasive assay to guide therapeutic choice in oncology. It provides tumor heterogeneity profile that could be incorporated in routinely clinical practice. These findings may support the modification of the primary treatment in patients with metastatic solid tumors thus be the first step for future advances in precision oncology

#1907 A novel DNA library prep method enables high sensitivity variant detection from matched fresh frozen and FFPE patient tissues.

Chen Song, Margaret R. Heider, Jian Sun, Adrian Reich, Brittany S. Sexton, Bradley W. Langhorst, Laura Blum, Keerthana Krishnan

New England Biolabs, Inc., Ipswich, MA

In cancer genomics, a common source of DNA is formalin-fixed, paraffin-embedded (FFPE) tissue from patient surgical samples, where in most cases high quality fresh or frozen tissue samples are not available. FFPE DNA poses many notable challenges for preparing NGS libraries, including low input amounts and highly variable damage from fixation, storage, and extraction methods. It is difficult to obtain libraries with sufficient coverage and the sequencing artifacts arising from damaged DNA bases confound somatic variant detection. Additionally, many laboratories process FFPE tumor samples alongside matched, high quality, normal DNA and many library prep workflows are not readily compatible with both sample types.

We developed a novel NGS library prep method compatible with both high quality and very low quality FFPE DNA samples, employing a novel enzymatic DNA repair mix, enzymatic fragmentation mix, and PCR master mix. To validate this workflow on real patient sample sets, we obtained DNA extracted from matched tumor and normal tissue of various tissue types preserved by both fresh frozen and FFPE methods. The FFPE DNA samples ranged in quality from DNA integrity number (DIN) 1.5 to 6.8 and fresh frozen DNA was DIN 8 to 9. We prepared libraries using this method compared against other library prep workflows and sequenced them by WGS and target capture. We assessed the performance of these workflows by library yield, library quality metrics, depth and evenness of coverage, and somatic variant calling with fresh frozen-extracted DNA providing the gold standard for library quality and mutation content.

This new enzymatic fragmentation-based library prep workflow not only reduced the false positive rate in somatic variant detection by repairing damage-derived mutations in FFPE DNA samples but also improved the library yield, library quality metrics, library complexity, coverage depth and uniformity, and hybrid capture library quality metrics. Comparing the variant calls from matched FFPE and frozen tissues revealed an improved sensitivity and accuracy of variant calling using this library prep method compared to mechanical shearing and other enzymatic fragmentation library prep approaches. Furthermore, library quality and variant detection sensitivity were equivalent when using this FFPE workflow compared to gold standard mechanically sheared libraries.

This new suite of enzyme mixes allows even highly damaged FFPE samples to achieve high quality libraries with a greater sensitivity for somatic variant identification. The workflow is robust and flexible, compatible with both FFPE DNA and matched high quality DNA samples as well as automation-friendly for convenience in sample processing.

#1909 Extracellular vesicle-derived biomarkers surpass cfDNA performance in a next-generation early detection strategy for colorectal cancer.

Sudipto Kumar Chakrabortty, J. Christian J. Ray, Dulaney Miller, Kyle Manning, Yang Yang, Shuran Xing, T. Jeffrey Cole, Christopher J. Benway, Sinead Nguyen, Allan George, Julia Doo, Yiyuan Yao, Pawan Upadhyay, Joe Johnson, Sonia Kumar, Sivakumar Gowrisankar, Brian Haynes, Johan Skog

Exosome Diagnostics, a Bio-Techne brand., Waltham, MA

Introduction: Colorectal cancer (CRC) increasingly impacts younger individuals, emphasizing the urgent need for earlier, more accurate, and minimally invasive screening methods. Current plasma-based liquid biopsy tests, typically relying on cell-free DNA (cfDNA) and/or free proteins, effectively detect CRC but fall short in identifying early pre-cancerous lesions such as advanced adenomas (AAs). We hypothesized that a multi-omic approach combining cfDNA and extracellular vesicle (EV)-derived biomarkers could enhance early detection of CRC, including AAs, which for current cfDNA-based assays have poor performance of detection.
Methods: A predefined statistical analysis plan guided the enrollment of approximately 230 individuals undergoing colonoscopy across three independent clinical sites. Plasma cfDNA methylation levels were analyzed using a combination of enzymatic conversion and enrichment of a panel covering over 4 million CpG sites. Comprehensive profiling of EV-derived long RNAs to measure gene expression and splice variants was performed using a hybrid capture panel covering 20,000 protein coding RNAs and 20,000 lncRNAs. Unbiased EV small RNA profiling was performed to measure all small non-coding RNAs between 18-200nts in length. Levels for up to 552 cancer associated proteins in EVs were measured using the Olink platform. Stringent quality control ensured reproducibility and no significant batch effects were seen across sites. Feature selection and model development employed a stratified, 5-fold cross-validation approach with a support vector machine (SVM) model. Sensitivities were evaluated using a Clopper-Pearson estimator at a target specificity of 91%, and prevalence-adjusted.
Results: Among the omics channels, EV-derived RNA demonstrated the highest sensitivity for detecting both CRC and pre-cancerous AAs at 87% (±6%) and 34% (±7%) respectively, significantly outperforming cfDNA methylation (76% ±7% and 10% ±4% respectively), EV-derived protein (85% ±7% and 24% ±7% respectively), and EV-derived miRNA (49% ± 9% and 21% ±7% respectively). Cross-validation identified key features relevant to CRC biology, with pathway enrichment analysis of EV-derived gene expression revealing significant activation of immune and inflammatory pathways.
Conclusion: While most EV derived analyte surpassed the performance achieved by cfDNA methylation, EV long RNAs emerged as the most sensitive analyte for early detection of CRC and pre-cancerous AAs. This study highlights the potential of EV-derived multi-omic biomarkers to address critical gaps in CRC screening, offering a transformative approach to improving early detection and patient outcomes. Combining EV RNA with cfDNA may give synergistic improvements in performance when applied in a larger cohort.

#1910 Allelic imbalance for early detection of breast cancer in high depth whole genome sequencing.

Laura Andersen[1], Konner Nelson[2], Julia Ah-Reum An[2], Pedram Razavi[2], Mark Robson[2], Dan Landau[3], Nicolai Birkbak[1], Adam Widman[2]

[1]Aarhus University Hospital, Aarhus, Denmark,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Weill Cornell Medicine, New York, NY

Liquid biopsy for circulating tumor DNA (ctDNA) offers potential for noninvasive early cancer detection. However, existing mutation- and methylation-based multi-cancer early detection tests have poor sensitivity in low-shedding, high-aneuploidy tumor types like breast cancer.

We previously developed an ultrasensitive tumor-informed liquid biopsy approach that used B-allele frequency (BAF) to detect cancer aneuploidy. Our BAF classifier, which measures allelic imbalance from the millions of single nucleotide polymorphisms (SNPs) across the genome, demonstrated high sensitivity for minimal residual disease in triple-negative breast cancer (TNBC) using only standard whole genome sequencing (WGS). To expand our BAF approach to the tumor-naïve early detection context, we sought to enhance aneuploidy signal through (i) high-depth plasma WGS (150-200x) using Ultima Genomics to better interrogate allelic imbalance at individual SNP sites and (ii) long-read sequencing of normal tissue to phase A and B haplotypes, allowing for the aggregation of signal from large regions of neighboring SNPs. We characterized two metrics of allelic imbalance: BAF and a fragment length score (FRAG) characterized by cancer-specific differences in fragment lengths between phased alleles.

To assess the performance of integrated BAF and FRAG signals for ctDNA detection, we collected a pilot cohort of BRCA-mutant, early-stage breast cancer patients with 7 pre-treatment and 28 post-surgery plasma samples from patients with no documented recurrence. ctDNA was overtly detected in pre-treatment samples from a stage III HR+/HER2- breast cancer and a stage II TNBC. We further sought to evaluate performance in stage I breast cancer, a particularly challenging setting for ctDNA detection through existing early detection approaches. We detected a stage I pT1c HR+/HER2- breast cancer and a stage I pT1b (<1 cm) TNBC at 100% specificity against post-surgery samples, demonstrating the potential of our classifier for non-invasive early cancer detection. Overall area under the curve (AUC) between pre-treatment (n=7) and post-surgery (n=28) samples was 0.86 in this challenging cohort that included 3 HR+/HER2- stage I (2 pT1a, 1pT1b) breast cancer samples. Longitudinal analysis of serial plasma samples throughout neoadjuvant treatment and following surgery demonstrated the ability of our tumor-naïve classifier to track therapeutic response.

Our method demonstrates promising potential for early cancer detection and tumor-naïve monitoring of treatment response in breast cancer patients, including those with very small tumors. We expect this method to extend beyond breast cancer to the many highly aneuploid cancer types where ctDNA detection through conventional methods has been limited. Additional samples will further validate our approach.

#1911 Platform agnostic lung cancer plasma signature identified using multidimensional proteomics and explainable machine learning.

P. J. Liu[1], H. R. Ferguson[1], L. Hankey[1], H. Huang[1], J. Syed[1], I. Kaneva[1], E. Mi[1], D. A. Szulc[1], L. J. Zhan[2], D. Patel[2], M.-S. Tsao[3], R. Fischer[4], B. M. Kessler[4], G. Liu[3], N. I. Gushterov[1], A. J. Halner[1];

[1]Oxford Cancer Analytics, Oxford, United Kingdom, [2]Princess Margaret Cancer Centre, Toronto, ON, Canada, [3]University of Toronto, Toronto, ON, Canada, [4]University of Oxford, Oxford, United Kingdom

Introduction: Lung cancer is the leading cause of cancer mortality worldwide with 70% diagnosed at the late stage. Low-dose CT (LDCT) is available for screening but its uptake remains low. A blood test providing a molecular signature that identifies those at highest risk of lung cancer can integrate with existing screening pathways to increase uptake and enable earlier detection. The blood proteome harbors promising information for minimally invasive biomarker discovery especially for early stage and low tumor-burden lung cancer with limited circulating tumor DNAs.

Methods: We combined data-independent acquisition mass spectrometry (MS) as an unbiased approach with a targeted proximity extension assay (PEA, Olink) for biomarker discovery in 614 patients: 490 lung cancer (180 stage I/II, 310 stage III/IV, all major histologies) and 124 matched control (from a LDCT screening program) plasma samples collected under standardized protocol (PMCC, Toronto, 2008-2019). To identify a lung cancer molecular signature, we used a 80/20% discovery/holdout testing approach and incorporated explainability in a tailored machine learning (ML) platform (iScience, 2023) to provide ranking and rationale for feature selection decision making. Finally, aptamer based proteomic profiling (SomaScan) validated a focused molecular signature panel.

Results: In total 5,403 distinct protein groups were identified, 3,655 by MS, 2,884 by PEA, with 1,136 overlapping. Both approaches identified proteins significantly enriched for inflammation, chemotaxis/migration, humoral immune response, and complement activation in lung cancer. MS identified additional proteins distinctly enriched for epithelial cell migration and ROS metabolism. ML directed feature selection identified focused panels of 17 and 20 proteins from MS and PEA datasets, each achieving 92% and 98% area under the ROC curve (AUC) respectively in hold-out validation, demonstrating sensitivity/specificity for overall lung cancer detection at 88/90% and 94/90% using ≤20 biomarkers. Importantly, each panel accurately detects early stage, late stage, small cell, adenocarcinoma, and squamous cell carcinoma of the lung, with AUCs of 88%-98% (MS) and 95%-99% (PEA) for each subtype. Further evaluation of the signatures using an aptamer platform confirmed a biomarker panel with strong concordance across the three distinct proteomic approaches, creating a platform agnostic lung cancer plasma signature for disease detection.

Conclusion: We identified a platform agnostic plasma molecular signature for lung cancer using three distinct proteomic approaches and explainable ML. This molecular signature can be highly scalable across different protein detection platforms, with prospective studies underway to assess its impact enhancing existing screening programs, enabling earlier detection, and improving survivorship.

#1912 Immune and molecular markers in benign breast disease predict risk of node-positive breast cancer.

Matilde Rossi[1], Nicole Cruz-Reyes[1], Trista Navarro[1], Melody L. Stallings-Mann[1], Bryan M. McCauley[2], Robert A. Vierkant[2], Stacey J. Winham[2], Mark E. Sherman[3], Amy C. Degnim[4], Derek C. Radisky[1]

[1]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[2]Department of Qualitative Health Sciences, Mayo Clinic, Rochester, MN,[3]Department of Epidemiology, Mayo Clinic, Jacksonville, FL,[4]Department of Surgery, Mayo Clinic, Rochester, MN

Background: Breast cancer (BC) remains a leading health concern worldwide and is often undetected until it metastasizes, limiting treatment options and worsening prognosis. Early detection of molecular and immune markers in benign breast disease (BBD) could identify women at elevated risk of developing invasive, node-positive BC, enabling targeted surveillance and prevention efforts. Building on this premise, we investigated the immune and molecular landscape of BBD biopsies preceding BC development to enhance risk stratification and inform preventive strategies.

Methods: Utilizing the Mayo Clinic BBD cohort, we conducted a case-control study comparing women who developed node-positive BC following their BBD biopsy (cases; n=8) to those who remained cancer-free (controls; n=11), matched on patient age and biopsy date. Differential gene expression was assessed using the NanoString nCounter system to identify differentially expressed genes between cases and controls. We developed a multiplex immunofluorescence (MxIF) approach using the Opal system by Akoya Biosciences for comprehensive marker detection in formalin-fixed, paraffin-embedded (FFPE) tissue samples. Digitized images were segmented for cell phenotyping, and spatial relationships of immune cells were analyzed and compared between cases and controls.

Results: Our findings revealed significantly increased expression levels of immunosuppressive genes in the case group, including CD48, CD84, IL-32, and LAIR1. Immunohistochemical analyses showed that controls exhibited higher frequencies of $CD68^+$ (macrophages), $CD11c^+$ (M1 macrophages), and $CD206^+$ (M2 macrophages) cells compared to cases. Notably, controls had a significant increase in $CD68^+CD11c^+$ cells, indicative of a pro-inflammatory, antitumorigenic M1 macrophage polarization. Furthermore, our MxIF analyses provided novel insights into spatial biomarker localization, enhancing prognostic accuracy.

Conclusions: The decreased numbers of immune cells and increased expression of immunosuppressive genes in BBD biopsies may be associated with an elevated risk of developing axillary node-positive BC. These findings emphasize the importance of dissecting molecular and immune interactions in BBD for risk assessment. Our results have the potential to improve individualized risk stratification, leading to more targeted surveillance and informed screening. This research not only contributes to our understanding of BC pathogenesis but also opens avenues for developing novel preventive strategies, potentially reducing BC incidence and mortality through early intervention.

#1913 Cystic fluid acetylated polyamines predict risk of malignancy of intraductal papillary mucinous neoplasms of the pancreas.

R. A. Leon Letelier[1], **R. Ballaro**[1], Y. Chen[1], R. Dou[1], E. Irajizad[1], M. Yip-Schneider[2], R. Wu[1], R. Ejaz[1], J. Vykoukal[1], M. Hurd[1], A. Maitra[1], J. Dennison[1], K.-A. Do[1], J. Zhang[3], S. Hanash[1], C. Smith[2], J. F. Fahrmann[1];

[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Richard M. Fairbanks School of Public Health, Indianapolis, IN

Background: Intraductal papillary mucinous neoplasms are recognized precursor lesions to pancreatic ductal adenocarcinoma (PDAC). There remains an unmet need to establish biomarkers for identifying IPMN at high-risk of malignant progression for early interception. Previously, we reported that acetylated polyamines inform upon presence of PDAC. Here, we assessed to what extent cystic fluid polyamines predict risk of malignancy for patients with IPMN.

Methods: Using mass spectrometry, we screened for polyamines in cystic fluid from 19 patients with either high-grade dysplasia (HG; N=12) or HG with a concurrent PDAC (IPMN/PDAC; N=7) and 70 patients with low-grade (LG) dysplasia). A total of 8 polyamines were detected and quantified, consisting of six that are host derived (spermidine, spermine, N-acetylputrescine (NAcPut), acetylspermidine (AcSpmd), diacetylspermidine (DiAcSpmd), and diacetylspermine (DAS) and two of microbial origin (acetycadaverine (AcCad) and diacetylcadaverine (DiAcCad). Predictive performance of individual polyamines for identifying HG or PDAC/IPMN was determined and complementarity with cystic fluid CA19-9 assessed. Findings were compared to metabolic profiles generated on 9 IPMN tumors (N= 3 LG; 3 HG, and 3 IPMN/PDAC) as well as cell lysates and conditioned medium from doxycycline-activated mutant *Kras;Gnas* IPMN cell lines. Publicly available spatial and single cell transcriptomic datasets of IPMN tumors were used to evaluate for spatial and cell-type specific differences in transcript levels of cognate enzymes involved in polyamine metabolism.

Results: Of the 8 quantified polyamines, spermine, AcSpmd, DAS, and DiAcCad were statistically significantly elevated in cystic fluid of patients with HG or PDAC/IPMN compared to those with LG IPMN. DAS had the highest predictive performance for HG or PDAC/IPMN with an overall AUC of 0.73 (95% CI: 0.58-0.88). An OR-rule based on CA19-9, DAS, and AcSpmd achieved sensitivity of 52.6% and specificity of 91% for detecting HG and PDAC/IPMN. Polyamines were elevated in PDAC/IPMN tissues compared to LG IPMN tissues and polyamine levels accumulated in condition medium of mutant *Kras;Gnas* IPMN cells. Spatial and single cell transcriptomic data revealed transcript levels of polyamine-metabolizing enzymes to be preferentially elevated in neoplastic epithelium and in tumor-associated macrophages.

Conclusion: Cystic fluid polyamines offer potential utility for determining risk of malignancy of IPMN, capable of complementing CA19-9. The polyamine signature may aid clinical management of patients with IPMN.

#1914 Highly accurate detection of early-stage colorectal cancer using tumor and immune extracellular vesicles biomarkers.

Poorva Mudgal[1], Zack Opheim[1], Cheryl Bandoski[1], Valesca Anschau[2], Martin Mehnert[2], Issa Isaac[2], Alan Ezrin[1], **Todd A. Hembrough**[1]

[1]Nexosome Oncology, Durham, NC,[2]Biognosys, Schleiren, Switzerland

Colorectal cancer (CRC) is one of the most common cancers worldwide, and early detection is critical for treatment and improved survival rates. Precancerous and early-stage CRC present significant diagnostic challenges due to the small size of lesions and the very low expression of tumor-specific biomarkers in plasma. Current genomics-based diagnostic methods struggle to detect these lesions, making it imperative to develop more sensitive and specific approaches. Circulating extracellular vesicles (EVs) are emerging as a promising solution for early-stage CRC detection, since EVs are produced by tumor, microenviroment and host cells. Plasma EVs may offer a novel means to detect and monitor small early-stage tumors through detection of tumor-associated biomarkers, tumor specific host response, and microenvironment biomarkers To identify novel early-stage CRC specific biomarkers, we performed proteomic analysis on EVs purified from patient plasma using size exclusion chromatography and a proprietary buffer system that enhances EV and corona protein recovery. TrueDiscovery™ Data-independent acquisition (DIA) mass spectrometry (MS) analysis was conducted on 24 pre-cancer/stage 0 and 25 stage 1 CRC and 75 normal patient plasma samples. An in-house machine learning (ML) pipeline was developed to identify differentially expressed proteins and model multiplexes to identify those with extremely high diagnostic accuracy (> 0.99).An average of ~2,500 QCed proteins were identified per sample and included in bioinformatics analysis. Comparative analysis of control patient EVs and either pre-cancerous/Stage 0, or Stage 1 colon cancer EVs using our ML pipeline identified 336 and 493 differentially expressed proteins for each group respectively (absolute Log2FC>0.5; FDR adjusted p-value <0.001; AUC>0.5). The 17 best pre/stage 0 proteins and 53 stage 1 proteins were trained and tested using Support Vector Machine to assess all potential 3-plexes to identify those with mean diagnostic accuracy > 99%. Our analysis yielded five 3-plexes in precancer/stage 0 and thirty-four 3-plexes in stage 1 with near perfect diagnostic accuracy in the discovery cohort. 3-Plexes were translated to ELISAs and initial testing retained very high accuracy (0.953), sensitivity (0.948) and specificity (0.958) classifying cancer vs control samples. The performance of highly accurate ELISA multiplexes is currently being assessed on an independent intended use case/control cohorts. Key biomarkers from CRC patient EVs indicate the potential to detect and diagnose early-stage and low tumor burden cancers using our methods. Interestingly, the most accurate 3-plexes consist of proteins from immune, inflammatory and metabolic processes, suggesting that for the detection of early-stage cancer it may be critical to include both tumor and host specific biomarkers.

#1915 A plasma biomarker panel of microRNAs miR-133-3p and miR-153-3p for diagnosis of prostate cancer.

S. Verma, C. L. Thompson, P. Fu, G. T. MacLennan, **S. Gupta**;
Case Western Reserve University School of Medicine, Cleveland, OH

Prostate cancer is highly prevalent and the second-leading cause of cancer-related death among men in the United States. Its incidence rate has been rising by 3% per year overall and by about 5% per year for advanced-stage disease. Current diagnostic methods, particularly the PSA test, remain controversial due to variable sensitivity and limited specificity, highlighting the need for more precise and minimally invasive diagnostic tools. MicroRNAs (miRNAs)—19-24-nucleotide, non-coding RNAs—have emerged as critical regulators of gene expression and are frequently deregulated in cancer. These miRNAs exhibit cancer-specific dysregulation, high sensitivity, and stability, positioning them as strong candidates for blood-based biomarkers in early cancer detection and prognosis. Using computational miRNA target prediction analysis, we identified several miRNAs—namely, miR-133a/b, miR-144, miR-153, and miR-590—that could serve as highly sensitive and specific biomarkers for early prostate cancer detection. Our bioinformatics analysis further revealed that these miRNAs regulate glutathione S-transferase P1 (GSTP1), a gene often epigenetically silenced in early prostate cancer stages, suggesting their potential diagnostic value. To evaluate this, we analyzed miRNA levels in 84 human plasma samples from 56 prostate cancer patients and 28 non-cancer individuals served as controls using quantitative real-time PCR. Sensitivity and specificity were assessed through Receiver Operating Characteristic (ROC) curve analysis. The expression of miR-133-3p and miR-153-3p were significantly elevated in the plasma of prostate cancer patients compared to the control group, with p-values of 0.021 and 0.0006, respectively. Binary logistic regression and ROC analyses comparing these miRNAs to PSA showed significantly higher sensitivity and specificity, with p-values of 0.0001 and 0.0003. This two-miRNA panel exhibited near-perfect diagnostic accuracy, with an area under the curve (AUC) ranging from 0.98 to 1.0. Compared with previously identified miRNA biomarkers, this 2-miRNA panel demonstrated greater diagnostic stability and superior performance across public dataset cohorts. Our findings suggest that miR-133-3p and miR-153-3p could serve as reliable blood-based biomarkers for diagnosis of prostate cancer. Their association with GSTP1—a gene implicated in early prostate cancer through epigenetic silencing—underscores their biological relevance to the disease. The high sensitivity and specificity of this panel represent a significant improvement over PSA-based screening and indicate its promise for clinical application in prostate cancer diagnostics. Overall, this study supports the development of miRNA-based diagnostic tests to enable earlier detection, reduce unnecessary treatments, and ultimately improve outcomes for prostate cancer patients.

#1916 Oncogenic fusion detection for leukemia patients using droplet digital PCR.

Hannah C. Davis, Ellie R. Wilson, Xiaojuan Cao, Maggie J. Cox, Francesca Ferraro, David H. Spencer, Stephen T. Oh, Grant A. Challen, Andrew L. Young

Washington University in St. Louis, St. Louis, MO

Accurate quantification of residual disease burden in acute myeloid leukemia (AML) patients is of paramount importance for treatment decision-making and long-term survival. Currently, measurable residual disease (MRD) detection is assessed using multiparameter flow cytometry, RT-qPCR or sequencing. Unfortunately, these techniques are limited by high costs, utility in only a subset of patients, and slow turnaround.

In half of leukemia patients, gene fusions drive their disease. Despite oncogenic fusions representing the ideal biomarker for MRD monitoring in these patients, molecular assays to detect these fusions are available in only a limited subset of cases (e.g. *BCR-ABL*, *RUNX1-RUNX1T1*). This is largely due to qPCR-based assays not being scalable to cover all the potential fusions, reliance on standard curves, and relative quantification. To address this unmet need, we have developed a sensitive, specific, rapid and scalable droplet-digital PCR (ddPCR)-based assay for personalized gene fusion detection. This assay uses fusion break-point information obtained from clinical sequencing to inform a personalized ddPCR assay targeting each individual's disease-defining fusion. As proof of principle, we applied our assay to *KMT2A* fusion detection. We selected *KMT2A* fusions because they are challenging to target for MRD detection given the diverse spectrum of fusion partners and the clinical need to assess response to therapy with novel Menin inhibitors that target these fusions.

In this proof-of-principle study at Washington University, we banked serial specimens from 19 patients with *KMT2A* fusion driven acute leukemia. From sequencing obtained at diagnosis, we determined each patient's fusion breakpoint and designed their personalized fusion detection assay. In diagnostic specimens, these assays reliably detected each patient's oncogenic fusion. We subsequently banked 1-17 serial peripheral blood or bone marrow specimens per patients for longitudinal monitoring. For four patients with treatment failure, we were able to detect persistent/increasing fusion abundance in the peripheral blood up to 100 days before detection by standard of care bone marrow assessment. For the remainder of patients who achieved a remission, we observed clearance of their fusions to a limit of detection of 1:100,000.

This study highlights the utility of our approach for sensitive, personalized fusion MRD detection. This assay has the potential to change the paradigm for MRD monitoring in acute leukemia from discrete testing of bone marrow samples at the end of induction or consolidation to serial peripheral blood monitoring throughout treatment. This is possible because our assay is inexpensive, rapid to turnaround, and highly sensitive in peripheral blood. Long-term this could improve real-time disease burden assessment to improve treatment decision-making and outcomes for patients with any fusion driven leukemia.

#1917 Validation of Oncuria for the early detection of bladder cancer.

Lynne Wilkens[1], Loic Le Marchand[1], Gong Yang[2], Jian-Min Yuan[3], Martha Shrubsole[2], Michael Luu[4], Ian Pagano[1], Sunao Tanaka[4], **Hideki Furuya**[4], Charles J. Rosser[4]

[1]University of Hawaii Cancer Center, Honolulu, HI,[2]Vanderbilt University, Nashville, TN,[3]UPMC Hillman Cancer Center, Pittsburgh, PA,[4]Cedars-Sinai Medical Center, Los Angeles, CA

Objectives: Longitudinal multi-marker combinations have the potential to improve sensitivity while maintaining the high specificity required for early detection of bladder cancer, i.e. before the development of symptoms. Our objective was to identify a multi-marker panel suitable for bladder cancer, where each individual marker has its own baseline, permitting longitudinal algorithm development.
Materials and Methods: In this multicenter case-control study, we measured the 10 protein biomarkers associated with Oncuria (ANG, APE, A1AT, CA9, IL8, MMP9, MMP10, PAI1, SDC1 and VEGF) in mid-stream spot voided urine samples from 247 subjects who would go on to develop bladder cancer in the ensuring 3-60 months and 247 matched controls. Statistical analyses included: reporting mean/median of the biomarkers, bootstrapping analysis, regression analysis with the biomarkers as explanatory variables, logistic regression analysis to generate the nonparametric receiver operating characteristic (ROC) curve for each biomarker and using a generalized estimating equation (GEE) model to depict difference between biomarkers from cancer and control subjects at the varying time points.
Results: Urinary concentrations of all 10 biomarkers were elevated in patients who went on to develop bladder cancer compared with non-bladder cancer with significance approached in all biomarkers except MMP10. Furthermore, the following biomarkers were significant elevated in bladder cancer subjects vs controls at 12 months prior to bladder cancer presentation; angiogenin at 12 months ($p=0.008$), APOE at 12 months ($p<0.001$), CA9 at 12 months ($p=0.010$), MMP10 at 12 months ($p=0.002$), MMP9 at 12 months ($p=0.011$), PAI1 at 12 months ($p=0.005$), SDC1 at 12 months ($p=0.003$), and VEGF at 12 months ($p=<0.001$). IL8 approached significance at 12 months ($p=0.067$) while A1AT approached significance at 24 months ($p=0.070$).
Conclusions: In this case-control multicenter study assessing 10 protein biomarkers in voided urine, we found clinically relevant differences in 9 of the 10 biomarkers 12-60 months prior to bladder cancer subjects developing cancer compared to matched controls. Therefore, this multiplex urine-based immunoassay test holds promise for facilitating the early detection of bladder cancer in at risk patients, i.e., heavy smokers (>20 pack-year history) over the age of 50 years and help to identify early stage cancers when they are more amenable to our current treatment strategies.

#1918 Investigation of early dissemination in ductal carcinoma in situ patients using circulating tumor cells.

N. Nagpal[1], B. Rupp[1], Y. Hong[2], F. Behbod[2], M. Wicha[1], S. Nagrath[1];
[1]University of Michigan, Ann Arbor, MI, [2]University of Kansas Medical Center, Kansas City, KS

In this study, circulating tumor cells are enriched from blood samples of ductal carcinoma in situ (DCIS) patients and investigated as a potential prognostic biomarker. Raised awareness of the importance of early diagnostics in breast cancer is leading to an increased incidence of DCIS detection through mammographic screening. DCIS is widely defined as a 'Stage 0' carcinoma with neoplastic cells still confined to the basement membrane. However, the 20-year breast cancer mortality rate following a DCIS diagnosis, with or without treatment, remains at 3.3%. Ultimately, the goal of the project is to better inform DCIS patient risk stratification via the isolation and analysis of circulating biomarkers.

We establish a workflow that targets the gaps in traditional tissue-based diagnostics with liquid biopsies. Our study builds on emerging literature on the early dissemination of breast cancer cells by investigating the value of circulating tumor cells (CTCs) as a biomarker in DCIS. To achieve a more holistic understanding of a patient's carcinoma, we supplement our study with the Mouse INtraDuctal (MIND) models - an animal model that recapitulates the tumor microenvironment of DCIS in the mammary ducts of mice.

Methods: We employed a high throughput, label-free microfluidic platform to enrich CTCs from DCIS patient samples. Enriched CTCs underwent single cell RNA sequencing (scRNA-seq) along with matched tissue samples to understand the clonal origin of these cells. Further, to correlate findings in patient samples to an animal model wherein the timeline of progression to invasive disease can be shortened to 9 to 12 months (vs. 10+ years in patients), we analyzed blood samples from 3 MIND models longitudinally.

Results: Applying our workflow to 34 patient samples and 10 healthy controls, we identified CTCs in 76% of the patient samples. The median concentration of CTCs per mL of blood in DCIS patients (6.1 CTCs/mL) was significantly greater than that in healthy controls (0.92 CTCs/mL; $p < 0.0001$, Mann-Whitney U Test). Via scRNA-seq, inferred CNVs were identified in CTCs. Distinct, dominant subclones were also identified in the tissue epithelial cells as potential contributors to the CTC population. In addition, during the MIND model time course study, CTCs were found in circulation as early as 4 months after formation of the models and while the models were still pre-invasive.

Overall, our study enables the assessment of CTCs as a prognostic biomarker for DCIS patients. Not only have we successfully enumerated CTCs in patient samples, but we have also identified distinct subclones in the tissue epithelial cells from which the CTCs could originate, supporting our overarching goal of demystifying early dissemination. Ultimately, we hope to investigate the value of CTCs as a clinical biomarker to inform personalized risk stratification for DCIS patients.

#1919 Development of a diagnostic method for early-stage pancreatic cancer through exosome-derived microRNA profiling.

Takahiko Sakaue, Hironori Koga, Hideki Iwamoto, Toru Nakamura, Atsutaka Masuda, Toshimitsu Tanaka, Hiroyuki Suzuki, Yohei Hara, Kyoyoshi Saito, Yutaka Shimamatsu, Sohei Yoshimura, Shingo Hirai, Hiroya Terabe, Hidetoshi Takedatsu, Takumi Kawaguchi

Kurume University, Kurume, Japan

[Background] Pancreatic cancer has an extremely poor prognosis, making early detection and treatment crucial. We have previously identified pancreatic cancer-specific exosomal microRNAs (Ex-miRs) from pancreatic juice in close contact with pancreatic cancer (Patent pending: PCT/JP2021/026597). [Purpose] To compare the diagnostic capability of pancreatic cancer-specific Ex-miRs in pancreatic juice and serum with existing tumor markers, and to evaluate their potential as non-invasive early diagnostic tools by investigating their detectability in stool samples.
[Methods] We initially performed miRNA array analysis using pancreatic juice-derived Ex-miRs and identified pancreatic cancer-specific Ex-miRs through our proprietary methodology. qPCR was conducted using pancreatic juice from 15 pancreatic cancer patients (Stage 0/I/II/III/IV: 0/0/6/3/6) and 11 chronic pancreatitis patients. Subsequently, we analyzed serum samples from 4 pancreatic cancer patients and 5 chronic pancreatitis patients who provided both pancreatic juice and serum. We compared Ex-miR expression levels before and after curative resection in two Stage II cases and performed in situ hybridization (ISH) on one resected specimen. Further qPCR analysis was conducted on serum samples from 75 cases, including 40 pancreatic cancer patients (Stage 0/I/II/III/IV: 0/6/8/4/22) and patients with other gastrointestinal cancers. Finally, we analyzed Ex-miR expression in stool samples.
[Results] We identified novel pancreatic cancer-specific Ex-miR-4516 and Ex-miR-4674 in pancreatic juice. In pancreatic juice diagnosis, Ex-miR-4516 and Ex-miR-4674 showed sensitivity, specificity, and accuracy of 80% and 73.3%, 81.8% and 90.9%, and 80.8% and 80.8%, respectively. Combining these Ex-miRs with cytology improved diagnostic accuracy (sensitivity/specificity/accuracy: 93.3/81.8/88.5%). In serum diagnosis, Ex-miR-4516 demonstrated high sensitivity (97.5%) for pancreatic cancer detection, with positive results in all six Stage 0/I cases. Ex-miR-4516 expression significantly decreased after curative resection in two Stage II cases ($p<0.001$). ISH analysis revealed high expression of miR-4516 and miR-4674 exclusively in pancreatic cancer cells. Stool analysis confirmed the feasibility of Ex-miR-4516 extraction and quantitative measurement, showing varying expression levels across samples.
[Conclusions] These two pancreatic cancer-specific Ex-miRs were quantifiable in serum from early-stage pancreatic cancer patients. Serum Ex-miR-4516 showed promise for treatment response assessment and disease monitoring. Furthermore, Ex-miR-4516's detectability in stool suggests potential clinical application as a non-invasive early diagnostic tool for pancreatic cancer.

#1920 XAGE1 cancer-testis antigen is a diagnostic and therapeutic target in lung adenocarcinomas.

Mikio Oka[1], Koji Kurose[2], Yuji Nojima[3], Shinsuke Saisho[3], Katsuhiko Shimizu[3], Toru Oga[2], Masao Nakata[3]

[1]Immuno-Oncology, Kawasaki Medical School, Kurashiki, Japan,[2]Respiratory Medicine, Kawasaki Medical School, Kurashiki, Japan,[3]General Thoracic Surgery, Kawasaki Medical School, Kurashiki, Japan

Introduction: Lung cancer is the leading cause of cancer deaths worldwide, and lung adenocarcinomas (LUAD) occupy approximately 50% among lung cancers. For LUAD, novel target therapies, immunotherapies, and ADCs have been extensively developed. TTF-1 has been widely used in pathological diagnosis of LUAD, although it is generally positive in normal alveolar and bronchial epithelial cells. There have never been LUAD-specific molecules and cancer antigens. On the other hand, we have reported that XAGE1 cancer-testis antigen expression is comparatively specific in LUAD and XAGE1 elicits spontaneous humoral and cellular immune responses in LUAD patients. Additionally, serum XAGE1 antibody (Ab) predicted clinical response to immune checkpoint therapy for non-small cell lung cancer (NSCLC), regardless of tumor PD-L1 status. Here, XAGE1 expression and serum XAGE1 Ab were examined in LUAD including adenosquamous carcinomas.

Patients and Methods: We analyzed 415 (57% [415/727]) LUAD patients among 636 NSCLC and 91 small-cell lung cancer (SCLC) between 2015 and 2024 at Kawasaki Medical School Hospital. XAGE1 was stained in LUAD surgical specimens, using USO9-13 anti-XAGE1 Ab. The patients' sera were obtained at diagnosis, and serum XAGE1 Ab was quantitatively measured by ELISA. The cutoff value of the positive Abs was defined as ≥ 100 titer.

Results: XAGE1 Ab was detected in 20% (84/415) of overall LUAD patients, and 6% (8/134) of stage I, 15% (6/39) of II, 23% (16/69) of III, and 31% (53/169) of IV. XAGE1 protein was positive in 97 (42%) of 231 NSCLC surgical specimens, 93 (52%) of 179 LUAD, and 4 (8%) of 52 non-LUAD. Ninety-three (97%) of 97 XAGE1-positive NSCLC was LUAD, resulted in LUAD diagnostic accuracy of 52% sensitivity and 97% specificity. According to pathological stages of LUAD, XAGE1 protein was positive in 50% (61/123) of stage I, 50% (16/32) of II, and 64% (14/22) of III, regardless of driver gene status. Additionally, there were no differences in positive rates of XAGE1 cells across stages. Serum XAGE1 Ab was positive in 8% (5/61) of XAGE-positive stage I LUAD, 25% (4/16) of II, and 29% (4/14) of III. In analyses of tumor immune microenvironment, LUAD with XAGE1 protein and Ab showed abundant CD8 T-cell and few Treg infiltrations, conversely, LUAD without XAGE1 Ab did few CD8 T-cell and abundant Treg infiltrations.

Conclusions: Our study demonstrated that XAGE1 protein was specifically expressed in approximately 50% or more of LUAD across disease stages but XAGE1 Ab was detected only in 10 to 30% of LUAD patients. Thus, XAGE1 is promising diagnostic marker in LUAD and novel therapeutic target especially in immunotherapy of LUAD.

#1922 Selective microfluidic capture and molecular analysis of plasma extracellular vesicles from meningiomas.

Abha Kumari[1], Harika Lingamarla[2], Mateo Gomez[3], Scott Smith[1], Kathleen McCortney[3], James Chandler[3], Craig Horbinski[3], David Raleigh[4], Adam Sonabend[3], Stephen Magill[3], Mark Youngblood[3], Sunitha Nagrath[5]

[1]Chemical Engineering and Biointerfaces Institute, University of Michigan, Ann Arbor, MI,[2]Biomedical Engineering and Biointerfaces Institute, University of Michigan, Ann Arbor, MI,[3]Feinberg school of medicine, Northwestern University, Chicago, IL,[4]Radiation Oncology, University of California-San Francisco, San Francisco, CA,[5]Chemical and Biomedical Engineering, Biointerfaces Institute, Rogel Cancer Institute, University of Michigan, Ann Arbor, MI

Abstract: Meningioma (MGM) comprises 39% of all primary intracranial tumors and is classified by the WHO into three grades depending on potential for recurrence. Risk stratification plays a crucial role in determining post-operative therapy and treatment response. Current classifications depend on tumor histology and a small number of genomic markers, though molecular profiling (DNA methylation, copy number, gene expression) may carry higher prognostic value. Minimally invasive liquid biopsy approaches could improve clinical management of MGM by identifying high-risk patients prior to surgery, as well as tumors that have transformed post-operatively. Extracellular vesicles (EVs) are nanometer sized membrane-bound capsules that carry cellular cargo and are abundant in plasma. In this work, we demonstrate the use of a microfluidic based technology (MGMExoChip) to isolate EVs specifically from MGM tissues using a specific protein (MGM-p). Using various characterization methods, we confirmed high capture efficiency and abundant proteins and RNA from 100 µL of plasma. These EVs were isolated from patients with high- and low-grade meningiomas, and then studied using proteomics and mRNA sequencing to identify features that associate with tumor aggression.

Methods: MGMExoChip has a polydimethylsiloxane top and a glass bottom. Experiments were performed using MGM cell-line CH157, as well as primary cell cultures and plasma samples collected from MGM patients. Isolated EVs were characterized using nanoparticle tracking analysis, scanning electron microscopy, western blot, and proteomics. RNA extraction was performed using Norgen Biotek kit, sequenced in Illumina platform at 40M raw reads. Data analyses were done using R.

Results: MGMExoChip was optimized for flow and capture conditions using EVs harvested from CH157 and two patient-derived primary cell cultures. Using MGM-p-based capture, the capture efficiency of EVs was significantly higher in CH157 relative to lung cancer (A549) (80.5±0.9% vs 6.2±4.2%). Among three antibodies tested for capture (anti-CD63, anti-MGM-p, and annexin-V), western blot confirmed that MGM-p had the highest specificity to isolate MGM EVs. We determined that only 100 µL of plasma was needed to extract an average of 7 µg of proteins and 5 ng of RNA without saturating the device. We further utilized proteomics, and mRNA-seq to explore molecular features that distinguish EVs in low and high grade meningiomas from normal controls among a cohort of 19 plasma samples.

Conclusions: The use of microfluidics for liquid biopsy is a novel approach to study meningioma. ^{MGM}ExoChip isolates MGM-specific EVs from patient plasma that allows extraction of molecular cargo for downstream characterization. Investigation of MGM EVs in a larger cohort could identify promising biomarkers for risk stratification of meningioma and determination of post-operative therapy.

#1923 A tract of homozygosity analysis reveals methylation-driven *CSMD1* expression in non-small cell lung cancers.

Jing Jin[1], Yasir Rahmatallah[2], Horacio Gomez-Acevedo[2], Yong-Moon Mark Park[3], David W. Ussery[2], Mohammed S. Orloff[3]

[1]Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR,[2]Biomedical Informatics, University of Arkansas for Medical Sciences, Little Rock, AR,[3]Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR

INTRODUCTION: The genetic and epigenetic alterations associated with smoking remain incompletely defined in Non-Small Cell Lung Cancer (NSCLC) carcinogenesis. This study investigates methylation-driven gene expression differences by smoking behaviors in lung adenocarcinoma (LUAD) and squamous cell carcinoma (LUSC) using the Tracts of Homozygosity (TOH) approach.
METHODS: Genetic, epigenetic, and environmental factors were examined to identify potential methylation-driven genes in NSCLC by subtype and smoking status. The analysis incorporated data from a genome-wide association study (GWAS), the Cancer Genome Atlas Program (TCGA), including methylation arrays/RNA-Seq, and clinical information among European Americans. A TOH block is defined as a string of SNP genotypes that harbor both common and rare variants. Multivariable logistic regression models were used to identify significant genes that also overlapped significant TOH clusters and contained differentially methylated regions (DMRs). A refined analysis was performed to assess methylation status at the probe level for all differentially expressed genes in the overlapping TOH regions and DMRs. Further, the multivariable Cox proportional hazards regression model was used to evaluate the association between gene expression levels and mortality risk.
RESULTS: Analysis of differentially expressed genes in TOH regions and DMRs showed hypermethylation at a CpG promoter site (cg08383399) upstream of *CSMD1* in smokers with LUAD and negatively correlated with *CSMD1* expression ($r=-0.18$; $p=0.004$). LUAD smokers with high *CSMD1* expression showed better survival probability than those with low *CSMD1* expression, especially among those with > 30 pack-years of smoking history (Hazard Ratio: 0.57; 95% Confidence Interval: 0.32, 0.99). In addition, we identified several genes related to smoking-induced inflammation from the list of differentially expressed genes overlapping DMRs and differentially methylated probes in TOH regions.
CONCLUSION: The TOH approach identified smoking-associated methylation patterns linked to differentially expressed genes in NSCLC by subtypes. These findings contribute to the identification of smoking-induced biomarkers for NSCLC facilitating personalized screening and suggesting intervention strategies to reduce smoking-related risks.

#1924 Urine extracellular vesicles derived CA9 and CIZ1 as non-invasive biomarkers for early diagnosis of clear cell renal cell carcinoma.

Xiyi Wei[1], Xi Zhang[1], Xinghan Yan[1], Zijie Yu[1], Weiyu Kong[1], Yize Li[2], Chao Qin[1], Hongwei Liang[3]

[1]Department of Urology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China,[2]Division of Oncology, Department of Medicine, School of Medicine, Washington University in St. Louis, St. Louis, MO,[3]School of Life Science and Technology, China Pharmaceutical University, Nanjing, China

Renal cell carcinoma (RCC) is a common malignant tumor of the urinary system, with clear cell renal cell carcinoma (ccRCC) being the most prevalent pathological subtype. Metastasis is observed in 20-30% of patients at initial diagnosis, and 20% of cases develop metastasis even after surgery, resulting in poor prognosis due to insensitivity to radiotherapy and chemotherapy. Early and accurate diagnosis is critical to improving outcomes and survival rates. However, specific humoral markers for non-invasive early screening and diagnosis of RCC are currently lacking. Urinary extracellular vesicles (EVs) have emerged as promising biomarkers for urinary system diseases due to their stability and ease of collection. In this study, we conducted a comprehensive analysis of urine EVs to identify specific biomarkers for ccRCC. Urine samples were collected from 100 healthy donors, 100 renal cyst patients, and 300 RCC patients (200 ccRCC, 50 papillary RCC [pRCC], and 50 chromophobe RCC [chRCC]). Agglutinin-coupled magnetic beads were employed to enrich exosomes, followed by proteomic analysis to identify differential protein expression. Results revealed significant upregulation of CA9 and CIZ1 proteins in urine EVs from ccRCC patients compared to controls. Importantly, these proteins were elevated in early-stage and small-sized ccRCC cases. Stability testing demonstrated that CA9 and CIZ1 proteins in EVs maintained stability over time and increased with urine volume. Diagnostic efficacy was evaluated in a larger cohort (1,500 cases) using receiver operating characteristic (ROC) curve analysis. CA9 and CIZ1 achieved area under the curve (AUC) values of 0.8917 and 0.8843, respectively, in distinguishing ccRCC from normal and other RCC cases. A combined model of the two markers achieved the highest discriminative power, with an AUC of 0.9633, sensitivity of 96.52%, and specificity of 86.69%. This study highlights the potential of CA9 and CIZ1 in urine-derived EVs as non-invasive biomarkers for ccRCC diagnosis. These findings provide a foundation for novel early screening methods and lay the groundwork for future research to validate these biomarkers in larger cohorts and investigate their stage-specific expression, ultimately facilitating personalized diagnosis and treatment of ccRCC.

#1925 Development of a multi-omics diagnostic approach for the early detection of ovarian cancer in asymptomatic women.

Rachel Culp-Hill[1], Charles Nichols[1], Collin Hill[1], Brendan Giles[1], Robert A. Law[1], Enkhtuya Radnaa[1], Kian Behbakht[2], Benjamin G. Bitler[2], Maria Wong[1], Connor Hansen[1], Mattie Goldberg[1], Vuna Fa[1], Violeta Guthrie[1], James R. White[3], Anna Jeter[1], Abigail McElhinny[1]

[1]AOA Dx, Inc., Denver, CO,[2]University of Colorado Anschutz Medical Campus, Aurora, CO,[3]Resphera Biosciences, Baltimore, MD

Objectives: Ovarian cancer (OC) is the fifth leading cause of cancer-related deaths among women. Unfortunately, for most patients, detection of OC occurs at late stages (III/IV) when the five-year survival rate is <30%. To change this paradigm, screening methods must be developed that are minimally invasive, highly sensitive, and disease specific. We have determined that utilizing multi-omics, which include novel classes of lipid and protein biomarkers with machine-learning, enables the robust detection of ovarian cancer across stages and subtypes, while requiring <500µL of serum.

Methods: We utilized a multi-omics approach to characterize a clinically annotated cohort comprising serum samples from individuals with ovarian cancer (N=235) and normal donors (N=82). The cohort was obtained from the University of Colorado Gynecologic Tissue and Fluid Bank (IRB #07-935 and 21-4787) and commercial vendors. UHPLC-MS data were generated from 20µL of extracted serum to profile lipids and fatty acids, while manual immunoassays were performed for a panel of protein biomarkers using unextracted serum. Machine learning (ML) model training was performed using the biomarker classes separately and in combination to identify top-performing models, using 20-fold cross validation.

Results: We profiled a total of 611 features of the lipidome by UHPLC-MS and protein biomarkers by immunoassay. The main molecular drivers contributing to best performing initial OC-specific signatures included a combination of lipids, fatty acids, and proteins together: multi-omic model consistently exhibited highest AUC when compared to individual biomarker classes. The AUC for High Grade Serous OC (HGSOC) was 0.98. At 98.2% specificity, sensitivity was 93.1% for all stages and subtypes of OC (93.8% sensitivity for all subtypes of early-stage (I/II) OC). The sensitivity for early stage HGSOC was 92.6%.

Conclusions: Early detection of OC is critical to improve patient outcomes, but current screening tools for OC lack early-stage sensitivity and specificity. The application of a multi-omics, machine learning approach for the screening of post-menopausal asymptomatic women offers significantly improved performance over CA125 for the detection of early-stage HGSOC. Future research will validate the performance of this approach in a large prospective cohort.

#1927 High-sensitivity screening of a large number of samples for KRAS and PIK#CA mutations using digital PCR.

J. Qin;
QIAGEN, Inc., Germantown, MD

Colorectal cancer (CRC) is one of the top commonly occurring cancers with 1.9 million new cases and 935,000 deaths worldwide in 2020 according to CDC. KRAS plays an important role in colorectal metastasis and progression, affects the tumor microenvironment and has been implicated in angiogenesis. KRAS mutations are the most common, presenting in approximately 25% of all tumors and is one of the most common gene mutations linked to cancers. It drives 40% of colorectal cancers, 32% of lung cancers, and 85% of pancreatic cancer cases. Phosphatidylinositol 3-kinases (PI3Ks) participate in signaling pathways essential for cell proliferation, adhesion, survival and motility; and are the initiators of carcinogenic process. PI3K mutations produce an altered p110a subunit, which allows PI3K to signal without regulation and initiates broad spectrum carcinogenic process. (Cell Cycle. 2009 May 1; 8(9): 1352-1358). Studies have shown a strong association of simultaneous mutations in PIK3CA exon 9 and KRAS exon 2 were the most common (67.2% of CRC cases) (Oncol.Rep.25(6) (2011) 1691-1697). When that happens, tumors with the bi-mutations were found to be significantly associated with aggressive pathological features compared with WT tumors, for example, increased proportions of proximal colon cancer that were prone to metastasize to distal organs at initial surgery. (Q. Luo et. al. Elsevier Translational Oncology 13 (2020) 100874). There is an increasing need for simple and robust tools to frequently screen and monitor such activating mutations with a sensitivity of 0.05-0.5%, which is suitable for testing of FFPE DNA samples. (I. Oscorbin et. al. Cellpress Heliyon 8 (2022) e11804). Here we introduce a novel digital PCR instrumentation and nanoplate technology that allows the screening of a large number of samples within 2 hours. We selected KRAS/G12S and PIK3CA/H1047R LNA mutational assays from the QIAGEN Geneglobe assay database and tested them against mutants from 2 germline cell models (Horizon Discovery) under various amount of WT gDNA backgrounds. Data shows good detection sensitivity at the 0.05-0.1% level.

#1929 Metabolomic insights into androgen deprivation therapy, and saliva as a non-invasive surrogate for serum to enable community-based biomarker studies.

Alireza Abdshah[1], Mohammad Alyamani[1], Marijo Bilusic[2], Dipen J. Parekh[1], Benjamin Spieler[3], Rakesh Singal[2], Brandon A. Mahal[3], Erin Kobetz[2], Sanoj Punnen[1], Matthew C. Abramowitz[3], Jaime R. Merchan[2], Nima Sharifi[1]

[1]Desai Sethi Urology Institute, University of Miami, Miller School of Medicine, Miami, FL,[2]Sylvester Comprehensive Cancer Center, University of Miami, Miller School of Medicine, Miami, FL,[3]Department of Radiation Oncology, University of Miami, Miller School of Medicine, Miami, FL

Introduction: Androgen deprivation therapy (ADT) significantly alters metabolism in prostate cancer patients. Serum metabolomics are the gold standard for studying these effects; however, saliva offers a non-invasive alternative for biomarker assessment. This study evaluates the impact of ADT on serum and saliva metabolites and the correlation between the two matrices. By evaluating saliva as a potential surrogate for serum, this work explores its application in biomarker analysis of chronic risk factors within community health programs.

Methods: Blood and saliva were collected from 20 eugonadal men and 20 men receiving hormonal therapy for prostate cancer, and were processed per standard protocols and stored at -80°C. Untargeted metabolomics using UPLC-MS analysis of polar and non-polar metabolites were performed; and glucocorticoids were quantified using targeted LC-MS/MS. Data were analyzed using MassHunter, METLIN database, and MetaboAnalyst, with log-transformation and by Mann-Whitney tests (False Discovery Rate (FDR)-adjusted P-values < 0.05).

Results: In untargeted metabolomics, 1,198 metabolites were identified across serum and saliva. Comparing ADT to eugonadal serum, 35 metabolites had fold-changes (FC)>2 and 35 had FC<0.5, with 248 metabolites reaching statistical significance (adjusted-P<0.05). Similarly, in saliva, 54 metabolites had FC>2 and 69 had FC<0.5, with 82 metabolites showing significant differences (P<0.05). Comparing serum to saliva across all participants, 248 metabolites had FC>2 and 268 had FC<0.5, with 697 reaching statistical significance (P<0.05). When integrating fold changes (FC>2 or FC<0.5) and significance thresholds (adjusted-p<0.1), we identified 14 upregulated and 20 downregulated metabolites in serum, and 14 upregulated and 28 downregulated metabolites in saliva of ADT patients compared to eugonadal patients; and 247 upregulated and 268 downregulated metabolites in saliva compared to serum among participants. Targeted metabolomics also confirmed strong correlations between serum and salivary cortisol ($r=0.612$, $p<0.001$) and cortisone ($r=0.618$, $p<0.001$). These findings underscore the potential of glucocorticoids as biomarkers for stress-related metabolic alterations, suggesting that saliva potentially reflects the systemic metabolomic profile. This highlights saliva's promise for non-invasive biomarker studies in stress and broader community health applications.

Conclusion: ADT is associated with significant changes in serum and salivary metabolome, highlighting its systemic and local impact on metabolism. Moreover, targeted metabolomic analysis revealed strong correlations between glucocorticoids in serum and saliva, suggesting saliva may serve as a non-invasive surrogate for serum in biomarker studies to facilitate research in community health programs.

#1930 Advancing cervical cancer early detection: A novel lateral flow immunoassay targeting p16INK4a.

Samrin F. Habbani[1], Sayeh J. Dowlatshahi[2], Scott C. Bolton[2], Lucy T. Tecle[2], Lisa Flowers[3], Jacqueline C. Linnes[2], Sulma I. Mohammed[1]

[1]Comparative Pathobiology, Purdue University, West Lafayette, IN,[2]Weldon School of Biomedical Engineering, Purdue University, West Lafayette, IN,[3]Emory University School of Medicine, Atlanta, GA

Cervical cancer ranks as the fourth most prevalent cancer among women globally, with a stark disparity in disease burden and mortality between high-income and low- to middle-income countries (LMICs). Sub-Saharan Africa faces the highest incidence and mortality rates, primarily due to limited access to preventive measures such as vaccines, screening, early detection, and treatment. With approximately 90% of cervical cancer cases occurring in LMICs, there is an urgent need for effective, affordable screening solutions. This study addresses this critical gap by developing a cost-effective, easy-to-use point-of-care (POC) screening test. Specifically, we aim to create a lateral flow immunoassay (LFIA) to detect the overexpression of cyclin-dependent kinase inhibitor 2A (CDKN2A or p16INK4a), a key tumor suppressor protein overexpressed in cervical cancer. The LFIA is designed to be capable of detecting p16INK4a in precancerous and cancerous cells from cervical swab samples, thereby providing an accessible and efficient tool for cervical cancer screening in resource-limited settings. The developed POC LFIA utilizes antigen-antibody interactions. It has four key components: a sample pad, a conjugate pad, a reaction membrane, and an absorbent pad. Cervical swab samples applied to the sample pad rehydrate the dried conjugates, allowing them to interact with the analyte and migrate to the reaction zone, where a gold nanoparticle (AuNP)-conjugated antibody facilitates detection. Initial validation of p16INK4a levels in clinical swab samples was performed using an enzyme-linked immunosorbent assay, which revealed significant overexpression of p16INK4a in high-grade squamous intraepithelial lesions (HSIL), confirming its role as a biomarker for cervical precancerous conditions. Biolayer interferometry was used to select antibodies with optimal nanomolar to picomolar binding affinities. The chosen antibody was conjugated with AuNPs through passive adsorption, achieving a stable 100:1 molar antibody-to-AuNP ratio over seven days. The test and control lines were optimized using in-house dipsticks, with 1.5 mg/mL anti-mouse immunoglobulin G proving ideal for the control line. The current test can reliably detect p16INK4a concentrations as low as 0.5 µg/mL, with further refinements underway to lower the detection limit for clinical use. This simple and cost-effective LFIA offers robust performance, addressing the critical need for affordable and accessible cervical cancer screening, particularly in LMICs. With continued optimization, this tool holds significant promise for improving early detection and treatment outcomes in resource-limited settings. Keywords: point-of-care test, cervical cancer, p16INK4a, early detection, prevention, LMICs

#1933 Improving detection of colorectal cancer recurrence using serial ctDNA measurements: A systematic literature review.

Ning Yan Gu[1], Christine Waters-Banker[2], Gebra Cuyun Carter[1], Danielle Badgley[2], Aleksandra (Sasha) Vidisheva[2], Melanie Palomares[1], Heather Johnson[1], Nathaniel J. Smith[2]

[1]Exact Sciences, Madison, WI,[2]Maple Health Group, LLC, New York City, NY

Introduction: Detecting molecular residual disease (MRD) in solid tumors via circulating tumor DNA (ctDNA) is an emerging practice to effectively assess curative treatment success and inform risk for future recurrence.
Methods: A systematic literature review (SLR) search was executed in PubMed and Embase from 01/01/2018 to 11/01/2023 to identify studies detecting MRD via ctDNA in adult patients with solid tumors after surgical resection. Studies providing diagnostic sensitivity and specificity for recurrence, and clinical lead times for colorectal cancer (CRC) are reported.
Results: A total of 4,308 non-duplicate records were screened by title and abstract; 224 were screened as full texts; 19 of the included studies reported the outcomes of interest in CRC. There was notable heterogeneity related to sample timing and frequency, length of follow-up time, and ctDNA assay methodology. Most patients were stage II/III; median follow-up time ranged from 12.5-49 months. Overall sensitivity for detecting recurrence ranged from 27.0%-100%; specificity from 80.1%-100%. Sensitivity for recurrence for single post-surgical or post-adjuvant samples ranged from 27.0%-67.0% (n=5). Sensitivity was higher for studies employing serial sampling (e.g., every 3-6 months), ranging from 66.7%-100%; with most studies (n=4) reporting values ranging from 82.6%-100%. Importantly, ctDNA detected recurrence several months earlier than radiological imaging for all studies reporting lead time (i.e., difference between ctDNA and radiological detection) (Table).
Conclusion: Variability of ctDNA sensitivity in detecting recurrence may be due to factors related to the heterogeneity of sample timing, follow-up duration, population, and assays. Regardless of the variation in sensitivity, ctDNA appears to be a valuable tool for assessing MRD and detecting recurrence earlier than radiological imaging, especially with repeated sampling.

Table: Diagnostic performance and lead time for included CRC studies

	Sensitivity for Recurrence (Range %)	**Specificity for Recurrence (Range %)**	**Median Lead Time**	**Mean Lead Time**
Overall (All Studies)	27.0%-100% (13 studies, n=1,917)	80.1%-100% (10 studies, n=1,688)	1-11.5 months (6 studies, n=88)	2.6-8.7 months (3 studies, n=36)
Single Sample	27.0%-67.0% (5 studies, n=746)	86.5%-100% (5 studies, n=746)	3 months (1 study, n=9)	2.6 months (1 study, n=3)
Serial Sampling (Predetermined Intervals)	66.7%-100% (5 studies, n=452)	84.0%-100% (4 studies, n=394)	5.3-11.5 months (2 studies, n=23)	5.01-8.7 months (2 studies, n=33)

#1934 Gene expression profiling of circulating tumor cells provides prognostic insights in oral squamous cell carcinoma.

Anshika Chauhan[1], Geeta S. Boora[1], Sushmita Ghoshal[2], Arindam Maitra[3], Arnab Pal[1]

[1]Biochemistry, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[2]Radiotherapy, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[3]BRICS-National Institute of Biomedical Genomics, Kalyani, West Bengal, India

Background: Oral Squamous Cell Carcinoma (OSCC) often presents with bad prognosis due to high frequency of loco-regional metastasis and relapse. Circulating Tumour Cells (CTCs) are precursors for metastasis, can be identified through liquid biopsy, but their molecular analysis has been challenging due to limitations in current isolation and downstream analysis techniques. To address this, we developed an innovative FACS-based method for CTC isolation and explored the prognostic potential of CTC gene expression in OSCC.

Methods: We developed an innovative technique that isolates CTCs by depleting CD45+ hematogenous cells and positively selecting CTCs using four markers— EpCAM, EGFR, CK, and Vimentin (Chauhan et al., 2024) using FACS. Next, we performed whole transcriptome analysis of isolated CTCs and paired primary tumours from 24 OSCC patients. Gene expression signatures in CTCs were validated in separate cohort of 60 patients.

Results: Data analysis revealed distinct gene expression profiles between CTCs and primary tumours, with 521 differentially expressed genes. Interestingly, PADI4 gene, an enzyme that is involved in the citrullination of various proteins was significantly upregulated in CTCs ($p<0.0001$). Validation of this finding in the separate patient cohort showed that patients with detectable PADI4 levels in CTCs had significantly poorer disease-free survival ($p=0.038$, HR=2.571). Interestingly, PADI4 expression was more in CTCs which having EMT signatures. Upon unsupervised hierarchical clustering of CTC transcriptome data, two subclusters of CTCs (namely C1A and C1B) with a total of 372 differentially- expressed between genes between them were found. Patients in CTC cluster C1B had significantly poorer overall survival ($p=0.0028$) and disease-free survival ($p=0.0185$), with a higher incidence of loco-regional metastasis ($p=0.0082$). We also validated topmost upregulated genes in separate cohort of patients and identified that TNFAIP2, NFKBIZ, CTSS and PTGS2 are significantly associated with increased probability of cancer relapse. Multiple logistic regression modelling using these genes identified that cumulative expression of baseline TNFAIP2, NFKBIZ, CTSS and PTGS2 expression can successfully predict recurrence in our cases. The developed model was validated using calibration plot analysis.

Conclusion: Our study demonstrates that the gene expression profiles of CTCs can serve as prognostic indicators in OSCC and we successfully developed a four-gene panel model for predicting relapse in OSCC patients.

#1935 New emerging patients-derived circulating tumor cells (CTCs) as promising tools for cancer research.

Paul Lovell, Karlie Wysong, Fang Tian

American Type Culture Collection (ATCC), Manassas, VA

Circulating tumor cells (CTCs) play a significant role in understanding the mechanisms of cancer biology and, more specifically, metastatic tumors. CTCs are cells from a primary tumor that break away to circulate through the bloodstream and metastasize in other areas of the body. CTCs have been proposed as valuable tools for the early diagnosis, monitoring, and identification of tumor progression as they provide possible new therapeutic targets. However, CTCs have relatively low numbers in the bloodstream as compared to other cell types, which makes isolating and establishing a CTC line difficult. Further, while researchers are able to identify and isolate these cells with new techniques, there is a lack of established CTC lines that are widely available to the research community for basic mechanism studies and translational research. Collaborating with leading research institutions, ATCC® is putting effort into developing methods and protocols for the expansion and characterization of human CTC lines isolated from clinical patient samples. In this study, we demonstrated the propagation and characterization of a melanoma CTC line MEL 167 (ATCC® CRL-3651™), which originated from a metastatic melanoma patient sample. Here, we evaluated the MEL 167 cell line at the genetic and protein levels and assessed its bio-functional aspects. Genetic profiling of MEL 167 by sequencing analysis revealed various oncogenes that may enable the progression of metastasis. Immunofluorescence staining was performed to assess the presence of a distinct melanoma molecular marker panel. Additionally, the drug response to BRAF-inhibitors of MEL 167 was evaluated. We also compared the drug profile of this new CTC model to the established melanoma cell line model A375 and two other drug-resistant melanoma cell lines that were created through CRISPR gene editing. We found that melanoma metastases are highly malignant with a low response rate to immunotherapies and high potential for relapse from drug-resistance stemming from tumor heterogeneity. As a newly emerging CTC model, MEL 167 (ATCC® CRL-3651™) offers a promising tool for pre-clinical studies and for evaluating CTCs in the early diagnosis and monitoring of metastatic melanoma.

#1936 Circulating epithelial tumor cells as a biomarker to predict treatment failure of radiotherapy in breast and prostate cancer.

Dorothea Schott[1], Matthias Maurer[2], Monika Pizon[1], Katharina Pachmann[1]

[1]Laboratory Dr. Pachmann, Bayreuth, Germany,[2]Department of Radiotherapy and Radiation Oncology, University Hospital Jena, Jena, Germany

Background: In primary breast and prostate cancer, radiotherapy is an integral part of the treatment toolbox. However, despite the significant reduction in local relapses in both breast and prostate cancer, distant relapses still occur in a considerable number of patients. Therefore, biomarkers are urgently needed to identify patients at increased risk of developing metastatic disease. Distant metastases arise from cells released from the primary tumor that are capable of forming metastatic tumors in distant organs, ultimately leading to fatal outcomes.
Methods: We have therefore used the maintrac® approach to monitor and characterize circulating epithelial tumor cells (CETC/CTC) numbers during radiotherapy and to correlate them with treatment outcomes.
Results: In breast cancer, an increase in CETC/CTC numbers during the course of radiotherapy was highly predictive of relapse, particularly in the neoadjuvant setting, with a hazard ratio of 4.886 ($p<0.01$). This finding suggests that an increase in CETC/CTC during radiotherapy in breast cancer patients previously treated with neoadjuvant chemotherapy indicates the need for additional treatment following radiotherapy.In prostate cancer, where radiotherapy is increasingly used without surgery due to the advanced age and frailty of patients and the considerable side effects of prostatectomy, adjuvant radiotherapy was administered to 12 patients. Among these, two patients showed an increase in CETC/CTC numbers from mid-treatment to the end of radiotherapy, and both experienced relapse.In patients receiving definitive radiotherapy without surgery, cell counts were available for 27 individuals. Of these, 8 showed an increase in CETC/CTC numbers. Three of the 8 patients experienced relapse, while 5 have remained in complete remission for up to 8 years despite increasing cell numbers. Additionally, 1 out of 19 patients with decreasing cell numbers experienced a local relapse.Although patients with increasing CETC/CTC counts from mid-treatment to the end of radiotherapy had a significantly higher risk of relapse, not all of them experienced relapse. Other cell characteristics, such as PD-L1 expression, might also play a crucial role. In fact, the fraction of PD-L1-positive cells increased from before to after radiotherapy in patients who experienced relapse during adjuvant radiotherapy but decreased in patients who remained in complete remission. This pattern was similarly observed in patients undergoing definitive radiotherapy.
Conclusion: These results highlight the potential of monitoring both CETC/CTC numbers and their characteristics as a prognostic tool. This approach could help identify patients who require more intensive adjuvant treatment, which may contribute to improved treatment outcomes in the future.

#1937 How circulating tumor cells disguise.

Dorothea Schott, Monika Pizon, Andreas Riess, Katharina Pachmann

Laboratory Dr. Pachmann, Bayreuth, Germany

Background: The most threatening aspect of malignant tumors is their ability to develop metastases in distant organs eventually leading to fatal outcome. These metastases must be derived from cells seeded into the circulation from the primary tumor. It is, however, well known that the majority of metastases do not develop during growth of the primary tumor but only months or even years after the removal of the primary tumor. Circulating tumor cells have been claimed to rapidly disappear from the blood after surgical removal of the primary tumor leading to the assumption that they are eradicated with a half- life of few hours. Therefore, already the presence of circulating tumor cells has been (over) interpreted as a sign of metastatic disease. Indeed, initially, we, like most other approaches for circulating tumor cell detection, did not find any tumor cells right after surgery. However, using a standardized approach (1) we were able to detect increased numbers of tumor cells in blood days after surgery not only in lung (2) but also in breast cancer (3). Rapid disappearance of cells shed from the tumor is not necessarily due to eradication of these cells by the immune system but dormant cells obviously can survive due to recirculation into foreign tissues or encryption. The question is: How can cancer cells conceal in the circulation?
Methods: Using the maintrac® approach including resting the samples for 24 hours at room temperature on the shelf lead to detection of cells previously concealed from detection with anti-EpCAM antibody. In addition the presence of platelets was monitored using red fluorescing anti CD36 or anti-CD41/CD61 antibody.
Results: The maintrac® approach allowed detection of live tumor cells seeded at any time into the circulation. When, accidentally, we stained cells and platelets right after blood draw we found aggregations of red fluorescing platelets which upon inspection in transmitted light were shown to be clustered on cells. In time lapse photography on individual cells for 24 hrs it was observed that platelets were increasingly released from the cells and anti-EpCAM staining became more and more apparent. This indicates that platelets initially clustered around epithelial tumor cells prevent anti-EpCAM from binding to the cells and only if platelets are released the cells can be identified as positive cells. Most possibly hypoxic conditions induce release of the platelets.
Conclusion: Rapid disappearance of cells shed from the tumor may be due to occultation of the cells by platelets. Since platelets express PD-L1 this may contribute to suppress anti-cancer immune cell activity.

#1938 Immune regulatory molecule expression on circulating tumor cells and circulating cancer stem cells in breast cancer patients.

Monika Pizon, Dorothea Schott, Erika Schill, Ulrich Pachmann, Katharina pachmann

Laboratory Dr. Pachmann, Bayreuth, Germany

Background: Circulating Epithelial Tumor Cells (CETCs/CTCs) are known to evade host immune surveillance by modulating the expression of immune regulatory molecules such as PD-L1 and CTLA-4 in cancer patients. Circulating Cancer Stem Cells (cCSCs) play a critical role in cancer recurrence and metastasis. Although the exact mechanisms underlying immune evasion by cCSCs remain unclear, recent studies suggest that the increased expression of specific immune checkpoint molecules on these cells may facilitate immune evasion and enhance their self-renewal capacity. In this study, we analyzed CETCs/CTCs and cCSCs for the expression of immune checkpoint molecules, particularly PD-L1 and CTLA-4, as non-invasive biomarkers of immune evasion and potential predictors of immunotherapy efficacy.
Methods: The study included 80 patients with breast cancer at various stages of the disease. CETCs/CTCs and cCSCs determination was performed using maintrac and the sphere formation assay, respectively. Additional staining with anti-PD-L1 and anti-CTLA-4 antibodies was used to assess the expression of PD-L1 and CTLA-4 on both CETC/CTCs and breast tumorspheres.
Results: CETCs/CTCs were detected in all patients, with counts ranging from 100 to 1150/ml of peripheral blood. The proportion of PD-L1-positive CETCs/CTCs ranged from 25% to 89%, with significantly higher PD-L1 expression observed in patients with triple-negative breast cancer (TNBC) compared to those with other biological subtypes. The proportion of CTLA-4-positive CETCs/CTCs ranged from 10% to 66%, which was significantly lower than PD-L1 expression levels. The expression of immune checkpoint molecules on CETCs/CTCs exhibited heterogeneity both within and between patients. The number of tumorspheres increased significantly with tumor progression and the aggressiveness of the primary tumor. All tumorspheres in all patients expressed both immunoregulatory molecules, PD-L1 and CTLA-4, with substantial heterogeneity in their expression levels.
Conclusion: The findings indicate that evaluating PD-L1 and CTLA-4 expression on CETCs/CTCs and cCSCs from breast cancer patients is both feasible and informative. The quantity of tumorspheres cultured from peripheral blood serves as a direct marker of the primary tumor's aggressiveness and proliferative capacity. Tumorspheres with elevated PD-L1 and CTLA-4 expression may play a key role in immune regulation. Gaining deeper insights into the interplay between cCSCs and tumor immunology could pave the way for strategies to target this small, therapy-resistant subpopulation more effectively.

#1939 The potentiality of capillary electrophoresis as a novel detection method for circulating tumor cells.

T. Yamamoto, H. Fukita, R. Nishizawa, K. Mitamura, A. Taga;
Kindai University, Osaka Prefecture, Japan

Background: Circulating tumor cells (CTCs) are involved in metastasis, and detection of CTC has clinical utility as a biomarker for diagnosis of metastatic cancer patients. Therefore, detection of CTCs from blood is one of the most important approaches to identify metastatic cancer. However, the number of CTCs present in blood is considered less than a few hundred per mL of blood. Therefore, development of sensitive analytical method is required for CTC detection. We previously described a direct cell analysis method based on differences in cell surface charge using capillary electrophoresis (CE). In the present study, we investigate whether this analytical method can detect cancer cells in blood.
Methods: We used the two human colorectal cancer cell lines (DLD-1 and SW480) and one pancreatic cancer cell line (BxPC-3), and blood sample from healthy donor as model samples. To prepare CTC model blood, cancer cells solution was added to blood sample. The stability of CTCs in blood was determined to analyze the model CTC samples after repetition of freeze-thawing. Capillary electrophoresis was performed at room temperature (ca. 25°C) using a linear polyacrylamide-coated fused silica capillary tube (50 cm × 75 μm i.d., effective length 9.5 cm), and 50 mM phosphate buffer (pH 6.8) was used as running buffer. The sample solution was introduced to the anodic end of the capillary with the hydrostatic introducing method (10 cm × 10 s).
Results: Analysis of each sample revealed that peaks corresponding to cancer cells and blood cells were detected at different migration times. To clarify whether cancer cells in blood can be detected, we prepared CTC model blood by mixing cancer cell line and blood. We could successfully detect peaks corresponding to cancer cells in the blood separately from peaks corresponding to blood cells. These findings suggested that cancer cells can be distinguished from blood cells as cancer cell surfaces are more charged than blood cells. On the other hand, peak pattern of CTC model sample which repeated freeze-thawing was not different that of CTC model sample with non-freezing. This finding suggested that stored frozen blood samples might be useful for blood test to detect CTCs using this analytical method by CE.
Conclusion: Therefore, direct cell analysis method using CE might be a potentially novel detection method for CTCs in blood.

#1940 EpCAM and L1CAM expression signatures in circulating tumor cells of advanced colorectal cancer.

G. Felix, J. Gong, F. Aguirre, L. Zhou, R. Ramirez, M. P. Hitchins;
Cedars-Sinai Medical Center, Los Angeles, CA

Background: Colorectal cancer (CRC) is the third most common deadliest cancer among both men and women in the United States. Hence, to improve CRC clinical management, there is an unmet need for affordable and personalized approaches, such as non-invasive blood tests that analyze circulating tumor cells (CTCs). However, there is limited data about the expression of markers associated with epithelial-mesenchymal transition (EMT) of CTCs in advanced CRC. In this study, we sought to evaluate EMT markers signatures in CTCs of advanced cases of CRC.
Method: Peripheral blood samples (10-20 mL) were collected from five patients with metastatic CRC. CTCs were isolated using the Single-cell CellSelect Slides™ enrichment or in-house protocol, followed by FACS (Fluorescence-Activated Cell Sorting). The following markers were analyzed: Ghost Dye™, CD45, CD133, LGR5, L1CAM, CD326 (EpCAM), CD325 (CDH2), CD274 (PD-L1), CD87 (VIM), and Cytokeratin-7/-8. FACS data analysis was done in FlowJo and plugins needed.
Results: The average age of diagnosis was 51.6 years. At the time of blood collection, all CRC patients had stage IV disease and were progressing. Self-organizing map clustering and dimensionality reduction algorithm analysis of 10,197 sorted CD45 negative living cells showed that LGR5 was the least expressed marker. The highest expression of CD133 was associated with highest expression of either EpCAM or L1CAM, which were both inversely correlated with LGR5. Co-expression of EpCAM and L1CAM were negatively associated with CD133, but positively associated with LGR5. EpCAM and L1CAM expression had significant association with CDH2, VIM, Cytokeratin-7/-8 and PD-L1.
Conclusion: In advanced CRC, the mutually exclusive expression of EpCAM and L1CAM in the presence of CD133, and absence of LGR5 could be linked to increased plasticity leading to EMT, and increased risk of metastasis and recurrence. In addition, it is important to consider other markers alongside EpCAM for the identification of CTCs in advanced CRC.

#1941 Development of a multiomic approach for the detection of actionable biomarkers in metastatic breast cancer.

Martin Blankfard[1], David Bourdon[1], Raj Srikrishnan[1], Alessandra Cunsolo[1], Kenneth Valkenburg[2], Cynthia Maddox[2], Renee Sears[3], Taylor Jensen[2]

[1]Epic Sciences, San Diego, CA,[2]Labcorp, Baltimore, MD,[3]Velsera, Boston, MA

Background: Thirty percent of all primary breast cancer patients develop metastatic disease with a 5-year survival rate of 22%. At the forefront of treatment are molecular diagnostic tests that guide treatment options for patients. The multiomic approaches of utilizing protein biomarker detection and next generation genomic analysis has improved blood-based diagnostics. We have coupled the characterization of circulating tumor cells (CTC) by immunofluorescence (IF) assays and single cell measurements of chromosomal instability with next-generation sequencing (NGS) of ctDNA in this multiomic approach. The combined assays identify actionable genomic variants, CTC chromosomal instability and protein biomarkers to characterize MBC.

Methods: Contrived samples were created with cell line cells (CLCs) spiked into noncancerous blood from healthy donors for analytical validation. 46 patients with complete pathology and tissue biopsies were included in the clinical validation. Whole blood was collected in Streck® tubes and centrifuged for the isolation of plasma. cfDNA was extracted from plasma, and actionable variants were identified with PGDx elio plasma complete™ (EPC) NGS assay. EPC is a 521-gene NGS test, validated in a CAP/CLIA laboratory, that detects SNVs, Indels, fusions, CNVs, MSI, and bTMB. Red blood cells were lysed, and all nucleated cells were deposited on glass slides at a density of 3M cells per slide. CTC protein biomarkers were analyzed on the glass slides with IF assays. CTCs were identified as cytokeratin-positive and CD45/CD31-negative cells. CTCs were probed with HER2 and ER IF assays to determine biomarker status. CTCs were isolated and DNA was extracted for single cell sequencing and analysis for chromosomal instability and ERBB2 amplification.

Results: EPC exhibited greater than 93% analytical sensitivity, and specificity. Overall precision was greater than 85%. An LOD of 1 CTC in 6 million cells and range of 1 - 300 cells/slide was reported. Sensitivity, specificity, accuracy and precision of the CTC assays was greater than 90%. 100% of the healthy donors exhibited no presence of CTCs and exhibited no actionable variants by the NGS ctDNA assays. Conversely, 19 (59%) cancer cases were found to have actionable alterations. CTCs were identified in 28 (88%) of the cases. Chromosomally unstable CTCs were found in the 24 (75%) of the patients. HER2-overexpressing CTC were found in 14 (43%) of cases, and concordant with 59% of matched tissue cases by HER2 (IHC). ER-overexpressing CTCs were found in 23 (71%) of the cases and concordant with 68% of matched tissue cases by IHC.

Conclusion: This multiomic approach allowed for the identification of biomarker status in patients with MBC and for identification of actionable variants by NGS ctDNA. These data show the value of using a multiomic approach in liquid biopsy to provide an informed decision for further treatment in the metastatic setting.

#1942 Copy number aberrations in the ctDNA uncover clinical and biological heterogeneity in aggressive B-cell lymphomas.

Maare Arffman[1], Leo Meriranta[1], Judit Jorgensen[2], Marja-Liisa Karjalainen-Lindsberg[3], Klaus Beiske[4], Mette Pedersen[5], Kristina Drott[6], Oystein Fluge[7], Sirkku Jyrkkio[8], Peter Brown[9], Harald Holte[10], Sirpa Leppa[1]

[1]Research Programs Unit and Department of Oncology, University of Helsinki and Helsinki University Hospital Comprehensive Cancer Centre, Helsinki, Finland,[2]Department of Hematology, Aarhus University Hospital, Aarhus, Denmark,[3]Department of Pathology, Helsinki University Hospital, Helsinki, Finland,[4]Department of Pathology, Oslo University Hospital, Oslo, Norway,[5]Department of Pathology and Department of Clinical Medicine, Zealand University Hospital and Faculty of Health and Medical Sciences, University of Copenhagen, Roskilde, Denmark,[6]Department of Oncology, Skane University Hospital, Lund, Sweden,[7]Department of Oncology, Haukeland University Hospital, Bergen, Norway,[8]Department of Oncology, Turku University Hospital, Turku, Finland,[9]Department of Hematology, Rigshospitalet, Copenhagen, Denmark,[10]Department of Oncology, Oslo University Hospital and KG Jebsen Centre for B-cell malignancies, Oslo, Norway

Introduction: Circulating tumor DNA (ctDNA) has emerged as a valuable tool in revealing molecular heterogeneity and risk factors of large B-cell lymphoma (LBCL). Several ctDNA estimates, such as variant profiling and minimal residual disease kinetics, have been thoroughly dissected, while multiple other molecular aspects accessible in the liquid biopsy (LB), such as DNA copy number aberrations (CNAs) and changes in serum proteome, remain to be disclosed. We studied CNAs from the ctDNA of LBCL patients treated in a Nordic phase II trial to expand the clinically applicable LB repertoire.

Materials and methods: The patients (n=123) included in the study were young (18-64 years), had clinically high-risk LBCL and were treated in a Nordic LBC-06 trial with dose-dense immunochemotherapy. A duplex adapter informed 750 kb gene panel was applied to pretherapeutic plasma ctDNA samples, and variants and CNAs were called using Illumina's DRAGEN pipeline. Clinical data, ctDNA variants (n=123), and serum protein levels, including inflammatory (PD-L1, IL10, IL18, and CXCL9) and subtype-specific (TARC and TACI) markers measured with Luminex assay (n=122) were explored in the context of CNAs.

Results: Profiling of ctDNA revealed CNAs (range 1-38) in 80 (65%) patients. The detection of CNAs was affected by ctDNA variant allele frequency. The most recurrently altered regions included gains in the *REL* (2:p16) and *BCL6* (3:q27) genes and losses in the *CDKN2A/B* (9p:21) and histone (6p:22) loci. Comparison of *TP53* status (loss in 11 (9%) patients) with clinical data uncovered that *TP53* assessment from the LB was more predictive than routinely performed FISH-informed *TP53* analysis for overall survival (OS; HR 7.23, $p = 0.001$ vs HR 2.84, $p = 0.09$). Moreover, loss of *TP53* correlated with P53 immunohistochemistry positivity ($p < 0.001$) and remained prognostic for OS in multivariable analysis together with age-adjusted International Prognostic Index (HR 8.49, $p < 0.001$). Correlation with serum protein profiles showed associations between high levels of inflammatory proteins and CNAs in key oncogenic pathways. These included gains in the NFκB pathway genes *MALT1* ($p < 0.001$) and *REL ($p < 0.01$)*, immune evasion genes, such as *CD274 ($p < 0.05$)*, and losses in the tumor suppressor genes *PRDM1* ($p < 0.05$) and *CDKN2A ($p < 0.05$)*. Furthermore, extended LB analysis of serum TARC levels, ctDNA variants, and CNAs revealed a subgroup of patients initially diagnosed as diffuse LBCL with a primary mediastinal B-cell lymphoma-like molecular fingerprint.

Conclusions: Together, we show that minimally invasive CNA profiling improves risk stratification and molecular characterization of LBCL subtypes. By integrating several LB approaches, we present CNA landscapes that reflect immune evasion and a more aggressive clinical course of the disease and provide potential actionable vulnerabilities for clinical decision-making.

#1943 Promoter methylation as a cancer biomarker: insights from ctDNA-based targeted methylation data.

Margaret Antonio, Eran Mick, Roham Razaghi, Chun Zhang

GRAIL Inc., Menlo Park, CA

Introduction: Promoter methylation is a hallmark of cancer and holds promise as a biomarker for early cancer detection, prognostication, treatment guidance, and response monitoring. This study explores the utility of GRAIL's ctDNA-based targeted methylation assay in detecting gene-specific promoter methylation signals and assessing their potential as cancer biomarkers.
Methods: A comprehensive literature review was conducted to identify genes with promoter methylation proposed as a cancer biomarker, focusing on those covered by GRAIL's ctDNA targeted methylation assay. We then prioritized genes implicated in multiple cancer types across several studies. As a proof-of-concept, four genes (*EYA4*, *SFRP1*, *BNIP3*, *ASCL1*) were evaluated using the ctDNA targeted methylation data from the Circulating Cell-free Genome Atlas (CCGA; NCT02889978) study. Contrived samples with known methylation fractions were utilized to establish the limit of detection (LoD) and linearity. Our analysis included 6127 CCGA cancer samples, spanning 21 cancer types, and 2323 non-cancer samples. We estimated the fraction of methylated fragments in each promoter region for all samples and the prevalence of promoter methylation for each cancer type. A Cox proportional hazard model was employed to evaluate the association of promoter methylation for a given gene with 5-year overall survival, adjusting for cancer stage.
Results: *EYA4* promoter methylation was prevalent in colorectal (39%,108/279, 95% CI: 32%-44%) and liver/bile duct cancer (68%,47/69, 95% CI: 56%-79%). Significant association of *EYA4* promoter methylation with survival was observed in colorectal cancer (HR=2.79, p<0.001) and in the pan-cancer setting (HR=1.71, p<0.001). *SFRP1* promoter methylation was significantly associated with poorer survival in lung (HR=1.62, p=0.006), colorectal (HR=1.96,p=0.036) and stomach cancers (HR=2.79, p=0.048). *BNIP3* promoter methylation, reportedly associated with chemoresistance, was prevalent in colorectal (37%, 104/279, 95% CI: 32%-43%) and pancreatic (34%, 70/205, 95% CI: 23%-41%) cancer, with significant association with worse survival (pancreatic: HR=2.72, p<0.001; colorectal: HR=1.98, p=0.009). *ASCL1* promoter methylation correlated with clinical HPV status of HPV-associated cancers, with higher fraction of methylated fragments in HPV-positive head and neck and cervical cancers (p=0.015).
Conclusion: This proof-of-concept study underscores the potential of GRAIL's ctDNA-based targeted methylation assay in detecting clinically informative promoter methylation signals. It also demonstrates the value of the CCGA cohort in facilitating biomarker discovery in plasma samples across multiple cancer types. Further validation and investigation in therapeutic settings are necessary to fully leverage promoter methylation as a biomarker in precision oncology.

#1944 Longitudinal circulating tumor DNA (ctDNA) analysis and acquired mechanisms of resistance to osimertinib (osi) in the China cohort of the FLAURA study.

Ying Cheng[1], **Dan Wang**[2], Jacqulyne Robichaux[3], Yong He[4], Wei Li[5], He-long Zhang[6], Qing Zhou[7], Buhai Wang[8], Chunling Liu[9], Yao Wang[10], Xiangning Huang[11], Zhanjian Dong[10], Rui Mao[12], Tianyuan Zhou[2], Ryan Hartmaier[3]

[1]Department of Medical Oncology, Jilin Provincial Cancer Hospital, Changchun, Jilin, China,[2]Translational Medicine, Oncology R&D, AstraZeneca, Shanghai, China,[3]Translational Medicine, Oncology R&D, AstraZeneca, Boston, MA,[4]Respiratory Disease, Daping Hospital, Chongqing, China,[5]The First Hospital of Jilin University, Changchun, Jilin, China,[6]Tang du Hospital of Fourth Military Medical University, Xi'an, Shaanxi, China,[7]Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital and Guangdong Academy of Medical Sciences, Guangzhou, China,[8]Department of Oncology of Northern Jiangsu People's Hospital Affiliated to Yangzhou University, Yangzhou, China,[9]Tumor Hospital, Xinjiang Medical University, Urumqi, Xinjiang, China,[10]Biometrics, Oncology R&D, AstraZeneca, Shanghai, China,[11]Global Medicines Development, GMED Oncology, AstraZeneca, Cambridge, United Kingdom,[12]Clinical Science, Oncology R&D, AstraZeneca, Shanghai, China

Background: In the China cohort of the FLAURA study (NCT02296125), first-line (1L) osi demonstrated clinically meaningful progression-free survival (PFS) and overall survival benefits vs comparator EGFR-TKI in Chinese patients (pts) with EGFR-mutated (EGFRm) advanced NSCLC. This exploratory longitudinal ctDNA analysis from the FLAURA China cohort assessed if EGFRm alone vs 168-gene panel (including EGFRm) ctDNA testing identified PD before RECIST PD, the correlation of baseline (BL) plasma EGFRm detection and its clearance with PFS and investigated acquired resistance mechanisms to osi.

Methods: Pts ≥18 yrs with untreated, EGFRm (Ex19del or L858R) locally advanced or metastatic NSCLC were randomized 1:1 to osi 80 mg once daily (QD; n=71) or comparator EGFR-TKI (gefitinib or erlotinib; all sites selected gefitinib 250 mg QD, n=65). ctDNA samples were collected at BL, throughout the osi treatment period, and after investigator-assessed RECIST PD and were sequenced by a capture-based 168-gene panel (Burning Rock OncoCompass^{TM}). ctDNA profiling was assessed for acquired resistance and vs PFS for molecular response and ctDNA PD.

Results: Overall, 2426 ctDNA samples from 127 pts in China were analyzed. At BL, pts with undetected plasma EGFRm (n=17, 13%) had longer median PFS (mPFS) vs pts with detected EGFRm (n=110); 20.6 mo vs 13.8 mo, respectively (HR 0.68; 95% CI 0.33, 1.25). At Week 3, 64% (38/59) and 72% (36/50) of pts in the osi and comparator arms, respectively, had EGFRm clearance. In both arms, pts with EGFRm clearance had longer mPFS than pts with non-clearance (osi: HR 0.38; 95% CI 0.19, 0.77; comparator: HR 0.23; 95% CI 0.12, 0.48); a positive association with mPFS was also seen at Week 6. When analyzing all mutations (mut) in the 168-gene panel at Week 3, the results were consistent; those pts with EGFRm clearance also had clearance of other BL detected mut. For pts with samples at Week 3 and RECIST PD, 52/81 (64%) had EGFRm ctDNA PD (by predefined criteria) that was equivalent (within 1 week) or earlier than RECIST PD, with median lead times of 2.4 and 2.1 mo for the osi and comparator arms, respectively. Similarly, using the entire 168-gene panel, 56/81 pts (69%) had total ctDNA PD equivalent/earlier than RECIST PD, with median lead times of 2.7 and 2.8 mo for the osi and comparator arms, respectively. In 35 pts in the osi arm with detected EGFRm at BL and PFS events, the most common acquired mut in the last 3 samples up to RECIST PD were MET amplification (6%), EGFR L718Q (6%), PIK3CA mut (6%) and CDKN1B/CDKN2A (6%).

Conclusions: BL undetected or early clearance of EGFRm ctDNA were associated with longer mPFS. Longitudinal ctDNA analysis could detect molecular PD before RECIST PD. Analysis of EGFRm was as informative as a 168-gene panel in its association with PFS and detection of molecular PD lead time. Acquired resistance mut profiles to 1L osi were consistent with prior reports.

#1945 High-sensitive gastrointestinal cancers early detection by cell-free DNA targeted methylation sequencing with an innovative modeling approach.

Ping Lan[1], Zhihua Liu[2], Hong Xu[3], Xiaosheng He[1], Zhigang Li[4], Lei Lian[1], Yin Li[2], Songbing He[5], Xiaofeng Guo[6], Qun Zhao[7], Jianhong Lian[8], Zhijian Xu[2], Nan Lin[9], Jiandong Tai[3], Quan Wang[3], Feng Li[8], Jian Li[10], Lulu Zheng[10], Zhihui Xu[10], Yanzhan Yang[10], Yonghui Li[10], Baoliang Zhu[10], Xiaohui Wu[10]

[1]The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[2]Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China,[3]The First Hospital of Jilin University, Changchun, China,[4]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China,[5]The First Affiliated Hospital of Soochow University, Suzhou, China,[6]Anyang Cancer Hospital, Anyang, China,[7]The Fourth Hospital of Hebei Medical University, Shijiazhuang, China,[8]Shanxi Cancer Hospital, Taiyuan, China,[9]The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[10]Shanghai Weihe Medical Laboratory Co., Ltd, Shanghai, China

Background: Gastrointestinal (GI) cancers, including esophageal squamous cell carcinoma (ESCC), colorectal cancer (CRC) and stomach adenocarcinoma (STAD), contribute to nearly one-third of cancer-related deaths in China. The late-stage diagnosis of these cancers is largely due to limited access to endoscopic procedures and low screening adherence. A blood-based multi-cancer early detection (MCED) test offers a more convenient alternative; however, the efficacy in detecting early-stage cancers remains unsatisfactory. This study presents an MCED assay utilizing targeted DNA methylation sequencing to detect GI cancers by implementing an innovative modeling approach integrating synthesized early-stage cancer samples.

Methods: A targeted sequencing panel was developed to identify tumor-specific hyper- and hypo-methylation markers. A cohort consisting of 1,618 plasma samples (238 ESCC, 262 CRC, 309 STAD, 809 non-cancers controls; stage: I 15%, II 29%, III 40%, IV 16%) was collected from a prospective, multicenter study (the PROFUTURE study, NCT05874648) and randomly split into training and validation sets (4:1) with 20 iterations of splitting. A novel Methylation-Guided Synthetic Sample (MGSS) model was trained through a combination of real and synthetic samples using a machine learning XGBoost algorithm, validated by real samples. In each iteration, synthetic samples were generated by blending late-stage cancer plasma samples with a pool of 20 independent healthy plasma samples, optimized to closely mimic authentic early-stage methylation patterns. And the number of synthetic samples was set to half the number of cancer samples in the training set.

Results: The MGSS model demonstrated high performance, achieving an area under the curve (AUC) of 0.934 (95% CI: 0.912-0.956), with a sensitivity of 69.7% (95% CI: 64.0%-75.5%) at a specificity of 98.8% (95% CI: 96.4%-100%). CRC exhibited the highest sensitivity at 83.8% (I 47.9%; II 81.4%, III 88.7%, IV 100.0%), followed by ESCC with a sensitivity of 77.6% (I 36.9%; II 67.6%; III 95.0%; IV 100.0%), and STAD at 53.7% (I 21.1%; II 46.9%, III 69.2%, IV 90.3%). Additionally, the sensitivity for stage I-III GI cancers was 68.1% (CRC: 82.8%; ESCC: 76.6%; STAD: 50.5%).

Conclusions: The MGSS model, which leverages synthetic sample methodologies, represents a cost-effective advancement and performance improvement in GI cancers. This innovative approach holds promise for enhancing the performance of MCED for other cancers potentially improving early diagnosis and outcomes.

#1946 Postoperative lymphatic exudate in HPV-negative head and neck cancer detects recurrence prior to adjuvant treatment decisions.

Seka Lazare[1], Zhuosheng Gu[1], Noah Earland[2], Adam Harmon[1], Maciej Pacula[1], Megan Long[1], Ashley Tellis[1], Damion Whitfield[1], Adam Benson[1], Lucien Khalil[3], Robert L. Ferris[3], Marra Francis[1], Aadel A. Chaudhuri[4], Jose P. Zevallos[3], **Wendy Winckler**[1]

[1]Droplet Biosciences, Inc., Cambridge, MA,[2]Washington University School of Medicine, St. Louis, MO,[3]University of Pittsburgh Medical Center, Pittsburgh, PA,[4]Mayo Clinic, Rochester, MN

Recurrence after surgery remains a major cause of failure in head and neck squamous cell carcinoma (HNSCC), particularly for HPV-negative patients whose 2-year failure rate is > 50%. There is unmet need for an accurate diagnostic test that predicts risk of recurrence prior to adjuvant therapy selection. We evaluated ctDNA in lymphatic exudate ("lymph") collected via surgical drains at 24 hours to detect molecular residual disease (MRD) and compared its performance to plasma and adverse pathology features.
Lymph, plasma and blood were collected from 76 HPV- HNSCC patients 24 hours after surgery. Tumor tissue was collected at surgery. 73 patients passed QC. Samples were sequenced using a 699-gene custom panel to a median of 6322x (lymph and plasma cfDNA) or 533x (tumor and blood genomic DNA). Tumor variants were directly genotyped in lymph and plasma using a tumor-informed pipeline. MRD status was determined using a calibrated cutoff based on mean variant allele fraction. Wilcoxon signed-rank test was used for comparisons. Kaplan-Meier estimator with log-rank test and Cox proportional hazards model were used for survival analysis.
We previously demonstrated that 24 hour postoperative lymph ctDNA detects recurrence in HPV(-) HNSCC across two independent multi-site cohorts and by orthogonal sequencing approaches (sensitivity (SN) = 72%, specificity (SP) = 65%, p = 0.003, hazard ratio (HR) = 3.1, n = 73). When compared to other data available at this early time point (pathology and 24 hour postoperative plasma), lymph ctDNA outperformed each for recurrence detection (extranodal extension (ENE, p = 0.30), lymphovascular invasion (p = 0.02), perineural invasion (p = 0.38), positive lymph nodes (p = 0.03), plasma (p = 0.8)).
We next evaluated lymph ctDNA in a critical subpopulation: patients considered intermediate risk by pathology (negative for ENE or margins but with one or more other adverse pathologic feature). Current NCCN guidelines recommend radiotherapy and to "consider systemic therapy" for these patients. Lymph ctDNA accurately stratified recurrence in this group with high sensitivity (SN = 88%, SP = 69%; P = 0.013, HR = 9.1, n = 24). Within this cohort, 77% of patients who received RT alone and later recurred were positive for lymph ctDNA at 24 hours, suggesting an opportunity to use molecular data in concert with pathology to identify patients who may benefit from adjuvant treatment intensification.
Postoperative lymph represents a novel proximal analyte for MRD detection in HPV- HNSCC designed specifically for use in the immediate post-surgical window when adjuvant therapy decisions must be made. Lymph ctDNA is significantly associated with recurrence and outperforms both time-matched plasma and pathology. Accurate MRD identification at this early timepoint has the potential to augment traditional pathology and personalize adjuvant treatment paradigms in HPV-negative HNSCC.

#1947 Assessment of cancer subtypes across multiple cancer types using a circulating tumor DNA (ctDNA)-based targeted methylation assay.

Joerg Bredno[1], Rita Shaknovich[1], Alexis Thornton[2], Susanne Tilk[2], **Oliver Venn**[2], Chun Zhang[2]

[1]GRAIL, Inc. (Affiliation at time of study), Menlo Park, CA,[2]GRAIL, Inc., Menlo Park, CA

Background: Accurate identification of cancer subtypes is essential for effective diagnosis, prognosis, and treatment selection. Traditionally, histologic type, cell of origin, and underlying pathogenesis are determined using tissue histology, requiring invasive biopsies. This study evaluates the use of a ctDNA-based targeted methylation sequencing assay to identify cancer subtypes across multiple cancer types through a tissue-free blood test.
Methods: Within the Circulating Cell-free Genome Atlas (CCGA, NCT02889978) study, clinical data were recorded and plasma samples processed using the targeted DNA methylation assay. We defined a set of 14 cancer subtypes spanning histologic types (adenocarcinoma, squamous cell carcinoma, neuroendocrine cancer, urothelial carcinoma), lineages of the cell of origin (lymphoid, myeloid, plasma cell, hepatocellular, mesenchymal, melanocytic, mesothelial, Mullerian), or an oncogenic process (human papillomavirus-mediated). Pathology reports were used to assign a subtype to each sample. An “other” category was used for less frequent subtypes not captured by these subtypes. A machine learning classifier was trained using ctDNA methylation data from 3,340 non-cancer and 3,239 cancer participants with informative pathology to predict subtype. GRAIL’s Cancer Research Solution is a tissue-free, Research Use Only (RUO) multi-cancer detection test. To ensure a reliable assessment of the subtypes, cancer patients found positive by the RUO test in the held-out test set were shedding sufficient cell-free DNA and were reported for performance evaluation.
Results: 1,404 out of the 2,669 cancer participants in the held-out test set were detected as cancer by the RUO test. This included 165 stage I, 293 stage II, 416 stage III, 493 stage IV and 37 non-informative stage across 54 different AJCC-defined cancer types. Classifier prediction accuracy was 92.7% (95% CI 91.3-94%, 1,302/1,404) across all 14 subtypes. In the subtypes with more than 50 samples in the data, high accuracy was observed in histologic types (e.g. adenocarcinoma: 730/749 = 97.5%), lineage of the cell of origin (e.g. Mullerian: 91/103 = 88.3%) and oncogenic process (e.g. HPV associated carcinoma: 92/96 = 95.8%).
Conclusions: A ctDNA-based targeted methylation platform based on a previously validated assay demonstrated the ability to accurately predict cancer subtypes in a wide range of cancers using only a single blood draw. It offers potential in clinical decision-making, especially when tissue biopsies are unavailable, by supporting early cancer detection, identifying cancer types with unknown primaries, informing treatment selection, and monitoring resistance mechanisms (e.g. lineage switching). Further validation is needed to enhance personalized cancer diagnosis and therapy in precision medicine.

#1948 Real-world insights into the accuracy and precision of the decentralized MSK-ACCESS powered with SOPHiA DDM solution.

Florian Klemm[1], Alex Tuck[1], Fuad Mohammad[1], Xiaobin Xing[1], Anne Pradines[2], Laura Keller[2], Daniel Kazdal[3], Markus Ball[3], Morten Lapin[4], Oddmund Nordgard[4], Persephone Du-Parcq[5], Alasdair Heasman[5], Sasha Hansel[5], Julia Stevenson[6], Gareth Gerrard[7], Justin Wheelan[8], Eric Antoniou[8], Rehan Faridi[9], Faisal Khan[9], Leah Thompson[10], Thomas Stricker[10], Cristovam Scapulatempo-Neto[11], Marie Piecyk[12], Lea Payen[12], Paul Hofmann[13], Zhenyu Xu[1]

[1]SOPHiA GENETICS, Rolle, Switzerland,[2]Laboratoire de Biologie Medicale Oncologique, Institut Universitaire du Cancer de Toulouse Oncopole, Toulouse, France,[3]Center for Molecular Pathology/Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany,[4]Department of Haematology and Oncology, Stavanger University Hospital, Stavanger, Norway,[5]Cancer Genetics Laboratory at Guy's Hospital, Synnovis, London, United Kingdom,[6]King's Health Partners Cancer Biobank, Guy's Cancer Centre, Guy's Hospital, London, United Kingdom,[7]South East Genomic Laboratory Hub, Guy's & St. Thomas' NHS Trust, London, United Kingdom,[8]Oncology Genomics, BioReference Laboratories, Elmwood Park, NJ,[9]Molecular Diagnostics, OncoHelix, Calgary, AB, Canada,[10]Center for Molecular and Genomic Studies, Tennessee Oncology, Nashville, TN,[11]Diagnosticos da America S.A. (DASA), Sao Paulo, Brazil,[12]LBMMS du CHU de Lyon, Service de Biochimie et Biologie Moleculaire, Hospices Civils de Lyon, Lyon, France,[13]IHU RespirERA, Cote d'Azur University, Nice, France

Objectives: Liquid biopsy (LBx) is a powerful, non-invasive approach to identify treatment selection or resistance markers, assess treatment efficacy, monitor disease, and predict relapse. To facilitate genomic profiling of cell-free DNA (cfDNA) in cancer SOPHiA GENETICS has developed a decentralized version of MSK-ACCESS (Memorial Sloan Kettering Cancer Center - Analysis of Circulating cfDNA to Evaluate Somatic Status). The MSK-ACCESS powered with SOPHiA DDM solution interrogates 146 cancer-associated genes for somatic variants and exhibits a high concordance to the original single-site test. It incorporates white blood cell (WBC) sequencing to reduce the risk of including germline and clonal hematopoiesis (CH) alterations in the tumor variant set. To evaluate the real-world performance of MSK-ACCESS powered with SOPHiA DDM an observational, multi-center study was initiated to evaluate accuracy (concordance to orthogonal tests and tumor tissue analyses) and precision (repeatability & reproducibility).
Methods: In participating laboratories sequencing libraries were generated from peripheral blood plasma cfDNA and WBC DNA samples and a common set of reference materials using MSK-ACCESS powered with SOPHiA DDM and sequenced on Illumina NovaSeq 6000 or NextSeq 2000. Variant detection and annotation of germline and CH variants were performed with the SOPHiA DDM platform. Accuracy was determined in the clinical samples through the concordance to orthogonally reported variants, tumor tissue genomic profiling results and to the reference cfDNA variants. Repeatability and reproducibility were measured through reference material variant allele frequency (VAF) variability.
Results: In clinical samples 94.1% of reported SNVs/Indels with an expected VAF ≥ 0.5% were detected (159/169, positive percent agreement per site: 71.4% - 100%). Across all externally reported variants (n = 246), 58 were not enriched in cfDNA compared to WBC DNA and annotated as germline or CH. The average percent agreement in the 0.5% VAF reference samples was 99.1%. The coefficient of variation of the 0.5% VAF samples had the same magnitude within intra-lab repeatability (0.29, mean VAF 0.48, SD 0.14) as for inter-lab reproducibility comparisons (0.29, mean VAF 0.48, SD 0.14).
Conclusion: Interim real-world results of the MSK-ACCESS powered with SOPHiA DDM solution illustrate its accuracy in clinical samples. By distinguishing cfDNA from CH/germline origin variants, potential biological false positives were removed. Further analyses of patient-matched tissue will be used to establish concordance between cfDNA and tumor tissue genomic profiles and investigate causes of discordance, including biological, technical and protocol factors. The assay’s observed precision demonstrates that site-to-site discordance, a major barrier to the adoption of LBx testing, has been addressed by this solution.

#1949 *ESR1* mutations in circulating tumor DNA (ctDNA) are significant predictors of chemotherapy resistance to paclitaxel and carboplatin in metastatic breast cancer (MBC).

Q. Zhang[1], J. W. Zhang[2], A. Davis[3], J. Jiao[4], P. D'Amico[5], L. Gerratana[6], W. Qin[4], X. Wang[1], A. Chawla[1], L. Flaum[1], L. C. Platanias[1], W. Gradishar[1];

[1]Robert H. Lurie Cancer Center, Feinberg School of Medicine, Northwestern University - Evanston, Chicago, IL, [2]Northwestern University and Whitney Young High School, Chicago, IL, [3]Washington University in St. Louis, St. Louis, MO, [4]Xijing Hospital, Innovation Center for Tumor Immunocytology Therapy Technology, Xijing Innovation Research Institute, Fourth Military Medical University, Chicago, China, [5]Merck, Rahway, NJ, [6]University of Udine, Udine, Italy

Background: *ESR1* (estrogen receptor 1) mutations play a significant role on resistance to endocrine therapy in estrogen receptor-positive (ER^+) MBC. Our previous work demonstrated that monitoring ctDNA ESR1 mutations serves as a predictive tool for poor prognosis in MBC (ASCO 2022 #1057, SABCS 2024 #1421). Here, we report new findings indicating that increasing ctDNA *ESR1* mutations are associated with chemotherapy resistance, an area that has been scarcely explored.

Methods: The study included 158 ER^+ MBC patients enrolled under IRB-approved trial (NU16B06) who received treatments in 2016-2022 at Robert H. Lurie Cancer Center, Northwestern University. The median follow-up period was 126.3 months. Baseline ctDNA was analyzed by Guardant 360 NGS panel. Only patients with *ESR1* mutations were included for statistical analysis (Causal Inference) of correlation between the ESR1 mutations with the chemotherapy resistance.

Results: *ESR1* mutations were identified in 10 hotspots among 40 out of 158 patients. The ctDNA *ESR1* mutations including 8 E380Q (mean 6.3%), 12 Y537S (mean 5.6%), 13 D538G (mean 11.9%), 1 V392I (0.1%), 1 Y537N (1.7%), 1 L536P (3.4%), 1 L536R (11.0%), 1 L536H (23.9%), 1 K520K (0.6%) and 1 K362 (15.8%). The criterion for chemotherapy resistance is defined as a change in the drug following treatment or disease progression observed by the last visit after this treatment. The numbers of cases sensitive vs resistant to chemotherapy along with the corresponding drugs are as follows: Doxorubicin (22 vs 18), Epirubicin (33 vs 7), Pegylated Liposomal doxorubicin (37 vs 3), Carboplatin (25 vs 15), Paclitaxel (21 vs 19), Docetaxel (23 vs 17), Vinorelbine (29 vs 11) , Ixabepilone (34 vs 6), Eribulin (32 vs 8), Capecitabine (17 vs 23), Cyclophosphamide (16 vs 24), Gemcitabine (36 vs 4), and Nab paclitaxel (35 vs 5). Significant differences were observed in rising ctDNA ESR1 mutation levels with a cut-off above 2.9% between the Paclitaxel-resistant group (19 patients) and the Paclitaxel-sensitive group (21 patients), with a chi-square statistic of 6.352 ($P=0.011$). Similarly, significant differences were found in ESR1 mutation levels with a cut-off above 2.1% between the Carboplatin-resistant group (15 patients) and the Carboplatin-sensitive group (25 patients), with a chi-square statistic of 4.177 ($P=0.041$). No significant associations were identified between *ESR1* mutations and resistance to other drugs.

Conclusions: These findings demonstrate for the first time that ctDNA *ESR1* mutations are associated with chemotherapy resistance to both Carboplatin and Paclitaxel. Such mutations contribute to tumor heterogeneity, enabling mutated receptors to support tumor survival despite cytotoxic treatment. Detecting ESR1 mutations in MBC may serve as a consideration for guiding chemotherapy decisions and exploring alternative therapeutics.

#1950 Enhanced detection of pancreatic cancer through methylation-based liquid biopsy: insights into tumor heterogeneity, early alterations, and stromal contributions.

Rui Wang[1], Diego Almanza[1], Mari Olsen[2], Xiaoman Kang[1], Daniel King[3], Maximilian Diehn[1], Ash Alizadeh[1]

[1]School of Medicine, Stanford University, Palo Alto, CA,[2]Stanford University, Palo Alto, CA,[3]Zucker School of Medicine, Hofstra University, Hempstead, NY

Pancreatic cancer is one of the deadliest malignancies, with a high mortality rate attributed to late-stage diagnosis and limited treatment options. Recent advancements in liquid biopsy, particularly through cell-free DNA (cfDNA) analyses, offer hope for early detection and prognosis. Specifically, cfDNA methylation profiling shows promise, outperforming traditional mutation-based methods such as single nucleotide variants (SNVs) and copy number variations (CNVs) in terms of sensitivity and specificity. In this study, we conducted paired CAPP-seq and EM-seq analyses on 29 pancreatic cfDNA samples. Our results indicated that methylation-based detection achieved a detection rate of 62.10% with 95% specificity, significantly higher than the 44.82% detection rate observed with CAPP-seq. Following the application of JEEPERS (Jagged-End Error Polishing of Enzymatically misRepaired Sequences) to mitigate methylation errors from jagged ends, the detection rate further improved to 72.41%. This aligns with existing literature highlighting the superior sensitivity of methylation profiling. We propose three hypotheses to explain this enhanced sensitivity: (1) Some pancreatic tumors exhibit CNVs prior to SNVs or contain subclonal KRAS mutations that are not detectable via SNV-based methods; (2) Methylation alterations may occur early during the PanIN stage, allowing the release of both normal and tumor-derived epithelial cells into circulation, identifiable by tissue-specific methylation markers; (3) PDAC tumors characterized by increased fibroblast content and epithelial-to-mesenchymal transition engage unique methylation signatures. To validate these hypotheses, we analyzed both pancreatic tumor tissues and cfDNA samples using CAPP-seq, LPWGS, emWGS, and single-cell nuclear sequencing data. Our findings confirm that CNVs frequently precede SNVs and highlight that pancreatic cfDNA comprises a notable proportion of epithelial cells. Importantly, methylation-based methodologies are capable of detecting signals from both normal and tumor-derived epithelial cells, leveraging cell-type-specific patterns. In contrast, SNV-based approaches are restricted to tumor-only signals. Furthermore, fibroblast methylation markers elucidate stromal contributions to the overall methylation landscape. These findings underscore the potential of methylation-based cfDNA analysis as a robust method for pancreatic cancer detection. We advocate for further validation through the development of a targeted panel that integrates SNVs, CNVs, and cell-type-specific markers to enhance diagnostic accuracy in clinical settings.

#1951 Inferring immune and tissue cell type contributions to cell-free DNA (cfDNA) with a DNA methylation assay.

M. Gloudemans[1], E. Zotenko[1], T. Banh[1], K. Zhu[1], G. Martovetsky[1], S. Wienke[1], M. Sun[1], A. Selewa[1], S. Liang[2], J. Connolly[2], S. Mortimer[1], N. Vardi[1], E. Tsang[1], D. Kennedy[1], M. Singer[1];
[1]Guardant Health, Palo Alto, CA, [2]Parker Institute for Cancer Immunotherapy, San Francisco, CA

Background:
In tissue-localized disease, dying cells release DNA into the bloodstream, enabling disease detection and characterization via blood draws. Circulating tumor DNA (ctDNA) is a key biomarker for cancer screening and monitoring. Quantification of immune cell- and tissue-derived DNA in plasma can expand the range of conditions identifiable through liquid biopsies. Here, we demonstrate the ability to infer cell type contributions to plasma cell-free DNA (cfDNA) from a clinically validated differential methylation-based cfDNA assay.
Methods:
We first implemented and validated a non-negative least squares cell type deconvolution method that uses single-site methylation (SSM) data. Accuracy was assessed by comparisons to gold-standard CyTOF and RNA-seq-based deconvolution on blood samples, as well as *in silico* simulations in blood and plasma.
Next, we developed a model to estimate immune and tissue cell types contributing to plasma based on data derived from a clinically validated differential methylation-based cfDNA assay. Using molecule counts from >2700 regions, we trained a model to optimize alignment with our validated SSM deconvolution method run on the same samples. Training and evaluation was done using leave-one-out cross validation.
Results:
Within the cellular blood compartment, SSM deconvolution accurately estimated T cell, B cell, and neutrophil proportions compared to CyTOF ($r \geq 0.82$; N=13) and RNA-seq-based deconvolution ($r \geq 0.78$; N=70).
Within the plasma compartment, we used SSM deconvolution to infer, in 106 healthy plasma samples, the frequencies of cell types commonly contributing to cfDNA: T cells, B cells, neutrophils, monocytes, megakaryocytes, erythroid cells, hepatocytes, and endothelial cells. *In silico* simulations showed the limit of detection (LOD90) for these cell types in plasma to be <=1.1% (median=0.28%). Inferred abundances aligned with distributions in published literature (Loyfer et al., Nature 2023).
We compared the hypermethylation assay-derived cell type estimates to our validated SSM deconvolution approach on 106 healthy plasma samples run on both assays. We observed Pearson correlations of 0.66-0.98 for all evaluated cell types except for monocytes ($r = 0.3$; $P<0.003$), indicating accurate estimation of the main cell types contributing to cfDNA in plasma.
Conclusions:
We developed an algorithm using a clinically validated cfDNA assay to accurately infer immune and tissue cell type contributions to plasma cfDNA. This technology has the potential to improve disease detection and management by identifying biological processes involving immune and/or tissue shedding into plasma. Further development of this technology will include application and evaluation on additional sample cohorts, including various disease states.

#1952 Circulating tumor DNA for assessing neoadjuvant treatment response and recurrence risk in rectal cancer patients.

Malene Krabbe Ostergaard[1], Christina Demuth[1], Tenna Vesterman Henriksen[1], Nadia Ogaard[1], Per Vadgaard Andersen[2], Kare Andersson Gotschalck[3], Lene Hjerrild Iversen[4], Claudia Jaensch[5], Mads Falk Klein[6], Jeppe Kildsig[6], Nis Hallundbak Schlesinger[7], Ole Thorlacius-Ussing[8], Claus Lindbjerg Andersen[1]

[1]Department of Molecular Medicine, Aarhus University Hospital, Aarhus N, Denmark,[2]Department of Surgery, Odense University Hospital, Odense, Denmark,[3]Department of Surgery, Regional Hospital Horsens, Horsens, Denmark,[4]Department of Surgery, Aarhus University Hospital, Aarhus N, Denmark,[5]Department of Surgery, Regional Hospital Godstrup, Herning, Denmark,[6]Department of Surgery, Copenhagen University Hospital - Herlev & Gentofte, Herlev, Denmark,[7]Department of Surgery, Copenhagen University Hospital - Bispebjerg and Frederiksberg Hospital, Bispebjerg, Denmark,[8]Department of Surgery, Aalborg University Hospital, Aalborg, Denmark

Introduction: Disease recurrence after surgery is the main factor affecting survival in rectal cancer patients. Hence, identifying high-risk patients is important to optimize postsurgical treatment. In recent years, effective use of neoadjuvant therapy (NAT) has led to increased focus on non-operative “watch-and-wait” strategies. However, clinical modalities for assessing complete response following NAT are not sufficiently accurate for selecting patients suitable for non-operative management. Novel biomarkers such as circulating tumor DNA (ctDNA) offer great potential for predicting neoadjuvant treatment response and identifying patients at risk of recurrence.
Materials and
Methods: The Danish IMPROVE trial (NCT04084249) recruited 2750 stage I-III colorectal cancer patients between 2018 and 2023 with the purpose of evaluating the clinical utility of ctDNA analyses. Of these, the present study includes 114 patients with locally advanced rectal cancer, who were treated with NAT prior to curative-intent surgery in accordance with national guidelines. Plasma samples were collected before NAT, after NAT, and after surgery (n=319). Analysis of ctDNA was performed using a tumor-agnostic droplet digital PCR test targeting three methylation markers. Recurrence-free survival (RFS) was calculated as the time between surgery and radiological recurrence (local or distant), with censoring at the end of radiological follow-up. Overall survival (OS) was calculated as the time between surgery and death from any cause, with censoring at end of follow-up. The median follow-up was 21.9 months (Interquartile Range (IQR) 11.8-36.0) for recurrence and 34.7 months (IQR 22.6-47.0) for survival.
Results: The ctDNA detection rates were 86.8% (n=79/91) pre-treatment, 28.9% (n=33/114) after NAT, and 22.8% (n=26/114) after surgery. Post-NAT ctDNA status was significantly associated with pathologic complete response (pCR; p=0.03, Fisher’s exact). None of the 11 patients with pCR had ctDNA detected following NAT and the sensitivity for detecting residual disease was 32%. Detectable ctDNA was associated with worse RFS and OS, both after NAT (RFS HR 3.2, 95%CI 1.5-6.8, p=0.004; OS HR 3.0, 95%CI 1.1-8.4, p=0.03) and after surgery (RFS HR 8.3, 95%CI 3.7-18.9, p<0.001; OS HR 10.6, 95%CI 3.4-33.4, p<0.001).
Conclusions: In conclusion, we showed that ctDNA status after NAT was significantly associated with tumor response to preoperative therapy and could potentially aid in patient selection for nonoperative management. Moreover, our study demonstrated a strong prognostic value of ctDNA analysis in predicting recurrence and survival outcomes, highlighting its potential to improve postoperative management through risk stratification.

#1953 Detection of clinically actionable somatic variants in post-operative samples from patients with molecular residual disease.

Thereasa A. Rich, Jun Zhao, Christopher Pretz, Yupeng He, Derek Dustin, Katie Quinn, Tingting Jiang, Errin Lagow, Krysten Shipley, Kristin Price, Leslie Bucheit, Kimberly Banks

Guardant Health, Palo Alto, CA

Introduction: Molecular residual disease (MRD) detection via ctDNA analysis refines recurrence risk estimation. Patients with MRD have substantial risk for metastatic disease and may have genomic biomarkers that could inform treatment. We describe detection rates of clinically actionable genomic biomarkers in plasma based on ctDNA fraction (TF) in the post-operative MRD setting.
Methods: Positive Guardant Reveal samples were tested using Guardant360. Reveal is a tissue-free epigenomic assay for post-operative MRD detection and quantitation in stage II-III colorectal (CRC), breast, and lung cancers; Guardant360 is intended for comprehensive epigenomic and genomic profiling (739 genes). Actionable variants were defined based on associations with targeted or immunotherapy benefit referenced in guidelines and those suggestive of another primary cancer (e.g., ESR1 resistance mutations in lung or CRC). We evaluated the association between TF and likelihood of actionable variant detection.
Results: 4,203 Reveal positive samples (median TF 0.17%, IQR 0.05-1%) from 4,165 patients were sequenced on Guardant360. Actionable variants were detected in 28% (1% were suggestive for another primary cancer). Increasing TF was associated with higher likelihood of clinically actionable variant detection. Across all three cancer types, TFs >0.05% had high yield of actionable genomic findings (~36%) and 97% of all actionable variants found were above this threshold (Table 1). Samples <0.05% TF rarely had detectable actionable variants.
Conclusion: These data suggest profiling with Guardant360 is reasonable in MRD-positive samples with TF >0.05%. Reflex testing may have utility for rapid return of genomic data to facilitate treatment planning in these high-risk patients. This paradigm may be particularly beneficial for patients with limited tumor specimens or who acquired resistance mutations to targeted therapy in the (neo)adjuvant setting.

Table 1. Rate of actionable variant detection by MRD TF and cancer type

	CRC	**Breast**	**Lung**	**Overall**
No. samples	2,769	781	653	4,203
% with actionable variant	29%	29%	24%	8%
% >0.05% TF	77%	79%	63%	75%
% with actionable finding by TF				
<0.05%	2%	6%	5%	3%
>0.05%	37%	35%	36%	36%
Proportion of all detected actionable variants by TF				
<0.05%	2%	4%	8%	3%
>0.05%	98%	96%	92%	97%
Top five actionable genes/variants detected in samples with >0.05% TF				
	KRAS (26%), *BRAF* V600E (5%), MSI-H (4%), *NRAS* (2%), *ESR1* (1%)	*PIK3CA* (18%), *ESR1* (12%), TMB-H (7%), *PTEN* (3%), *AKT1* (2%)	*KRAS* (16%), *EGFR* (10%), *ERBB2* (3%), *ESR1* (3%), *MET* (2%)	

#1955 Blood-based mapping of the personalized tumor epigenomic landscape.

Elena Zotenko, Rachel Gittelman, Alan Selewa, Noam Vardi, Tam Banh, Gleb Martovetsky, Oscar Westesson, Emily Tsang, Sara Wienke, Drew Kennedy, **Meromit Singer**, Stefanie Mortimer, Darya Chudova

Guardant Health, Palo Alto, CA

Background: Mapping the epigenetic landscape of tumors provides insights into regulatory and functional aspects beyond somatic mutations, offering valuable information that can influence clinical decisions and benefit the patient journey. Given the challenges of obtaining tissue biopsies, especially in the longitudinal monitoring or progression setting as tumors evolve due to selective pressure from treatment, the advantages of non-invasive liquid biopsies to characterize tumors through blood are highly beneficial. Here, we demonstrate that the epigenetic landscape of a patient's tumor can be evaluated in plasma using an epigenetics circulating tumor DNA assay, providing a promising approach for non-invasive tumor profiling.

Methods: We collected paired tumor and plasma samples from lung, breast and colorectal cancer patients, and applied an analytically validated next-generation sequencing epigenomics hybrid capture assay to measure DNA methylation across over 1.3 million CpG loci. A total of 44 patients (10 colorectal, 13 breast, 21 lung) with circulating tumor DNA (ctDNA) detected at a level of 0.5% or greater were included in the analysis. For each patient, we identified personalized tissue differentially methylated regions (DMRs) as the set of regions that were highly methylated in tissue but showed low methylation in an independent set of 197 cancer-free plasma samples. For each region from a personalized tissue DMR list, we computed the expected count in plasma as a function of tumor fraction and assay efficiency.

Results: Across the 44 analyzed tissue samples, the median number of personalized tissue DMRs identified was 1,133, with a range of 136 to 4,220 and a standard deviation of 850. For paired tissue and plasma samples from the same patient the Spearman correlation between the expected and observed counts in plasma was high across all samples (Mean=0.687, SD=0.120). The correlation between expected and observed signals at personalized tissue DMRs was calculated for all possible plasma and tissue sample pairs, regardless of whether the samples were from the same patient. Notably, for 43 out of 44 plasma samples, the highest correlation between expected and observed plasma counts occurred with the plasma's matched tissue sample (Mean difference=0.196, SD=0.096).

Conclusions: These data demonstrate a strong concordance between a tumor tissue's unique epigenetic landscape and the epigenetic signal in plasma. Furthermore, the finding that each plasma sample correlated most with its paired tissue sample over other pairings indicates that the assay can reliably measure personalized tumor epigenetic features in plasma. This supports the use of an epigenetics-only ctDNA assay for monitoring patients and guiding treatment decisions.

#1956 Comparison of somatic variations between circulating tumor DNA and paired tissue in 1,111 pan-cancer patients.

Meng Zhang[1], Yi Feng[1], Xue Du[1], Changda Qu[1], Meizhu Meng[1], Meiying Ye[1], Min Liang[1], Ziran Yang[1], Wenjuan Gong[1], Xingyu Ma[1], Jialiang Guo[1], Wenmei Li[1], Chenxuan Wang[2], Qiuxiang Ou[2], Sha Wang[2], **Haimeng Tang**[2], Shuqin Jia[1]

[1]Peking University Cancer Hospital & Institute, Beijing, China,[2]Geneseeq Technology Inc, Nanjing, China

Circulating tumor DNA (ctDNA) offers a noninvasive method to assess tumor-specific mutations. This retrospective study investigated the concordance of genomic variations between ctDNA and tissue and its influence factors. Paired blood and tissue samples were collected from 1,111 patients with ten tumor types and underwent sequencing of 425 genes. We evaluated the relationship between the concentration of cell-free DNA (cfDNA), sensitivity of ctDNA, mutation landscape, variant allele frequency, and various clinical parameters. The median concentration of cfDNA and overall sensitivity of ctDNA was 16.8 ng/ml and 61.5%, which correlated positively with clinical stage and tumor diameter and negatively with treatment response. The overall concordance rate of genomic alterations between ctDNA and tissue was 24.6%. The top five altered genes and pathway-based disruption signatures identified by ctDNA profiling were similar to tissue. For mutations with a normalized allele frequency less than 0.2, the proportion of ctDNA-specific mutations was higher than concordant mutations (61.5% and 9.7%). Advanced clinical stage, large tumor diameter, poor treatment response, the presence of liver metastasis, and impaired liver function lead to a high concordance rate. Patients with ctDNA-positive status, subclonal mutations, and more ctDNA-specific mutations had shorter overall survival than those with ctDNA-negative status, no subclonal mutations, and fewer ctDNA-specific mutations, respectively. In conclusion, a higher concordance rate of somatic variations between ctDNA and tissue indicated an advanced clinical stage, larger tumor size, worse treatment response, and presence of liver metastasis. Subclonal or more ctDNA-specific mutations detected were associated with poor prognosis.

#1957 MORIOKA study: Tumor-informed frequent ctDNA monitoring for quantitative tumor burden assessment using digital PCR across 23 cancer types during treatment.

S. S. Nishizuka[1], H. Hiraki[1], A. Yashima-Abo[1], T. Iwaya[2];

[1]Iwate Medical University Institute for Biomedical Sciences, Yahaba, Japan, [2]Iwate Medical University School of Medicine, Yahaba, Japan

Background: The ultimate goal of post-treatment surveillance in advanced cancer is the quantification of tumor burden, represented by somatic mutations identified in the treatment-targeted tumor. However, as most circulating tumor DNA (ctDNA) variant allele frequencies (VAFs) during treatment are below 1%, it has been challenging to measure ctDNA without mutation-specific probes for target sequences. To address this, we developed a digital PCR (dPCR) primer/probe library, OTS-Probes, comprising over 1,000 probes targeting human cancer-related mutations. This study investigates the clinical validity of frequent ctDNA monitoring across 23 types of advanced cancers.

Patients and Methods: From May 2019 to May 2023, 314 patients were enrolled in the MORIOKA study, representing 23 tumor types, including lung (n=57), colorectal (53), esophagus (26), uterus (25), liver (22), stomach (17), ovary (13), brain (12), bone and soft tissue (10), prostate (10), bile duct (10), urothelium (9), renal (8), breast (7), head and neck (7), pancreas (6), bladder (5), malignant melanoma (5), cervix (3), pediatric (3), gallbladder (2), multiple myeloma (2), and unknown primary (2). Tumor-specific somatic mutations were identified and then selected for ctDNA monitoring. Blood samples were collected approximately every three months until patients were censored or observed for up to 730 days. ctDNA VAFs were quantified using dPCR with the OTS-Probes, and ctDNA dynamics were analyzed in conjunction with clinical and imaging data.

Results: As of November 20, 2024, analyzable patients had received at least one treatment regimen across 585 treatment opportunities. A total of 1,568 imaging studies were conducted, averaging 5.6 per patient. Panel sequencing identified somatic mutations for ctDNA monitoring in 89.7% of tumors. During treatment, approximately 90% of ctDNA VAFs from 2,474 time points were below 1%. Among ctDNA-analyzable cases, the median pre-treatment ctDNA VAF was 0.12%, with ctDNA undetectable in 27% of cases. Using OTS-Probes, nearly 80% of somatic mutations were promptly monitored via dPCR without the need for additional validation. Changes in ctDNA VAFs before and after treatment correlated with imaging results: VAFs increased in progressive disease (PD), decreased in partial response (PR), and decreased in many cases of stable disease (SD). Further analyses of ctDNA monitoring by tumor type, treatment regimen, and metastasis pattern are ongoing.

Conclusion: Tumor-informed frequent ctDNA monitoring enabled timely quantitative tumor burden estimation across a broad range of cancer types. ctDNA dynamics were particularly useful in clarifying ambiguous imaging findings, such as decreased ctDNA levels in SD. The timely assessment of ctDNA demonstrated robust clinical validity, supporting imaging diagnoses and treatment decisions.

#1958 Chromatin accessibility landscapes of colorectal cancer development and genome-wide cell-free DNA fragmentation.

Nicholas A. Vulpescu[1], Zachariah H. Foda[1], Pieter H. A. Wisse[2], Christopher Cherry[1], Jamie E. Medina[1], Stephen B. Baylin[1], Kasper D. Hansen[1], Vilmos Adleff[1], Remond J. A. Fijneman[2], Michael A. Beer[1], Robert B. Scharpf[1], Gerrit A. Meijer[2], Beatriz Carvalho[2], Victor E. Velculescu[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Netherlands Cancer Institute, Amsterdam, Netherlands

Introduction: The stepwise progression of colorectal cancer (CRC) from healthy epithelium, to premalignant adenoma, to cancer is accompanied by genome-wide epigenetic reprogramming which may be reflected in circulating cell-free DNA (cfDNA). However, current analyses of these processes have been hampered by the complex mixture of cells associated with colonic epithelial tissue, as well as the absence of suitable adenoma model systems. Cultured colorectal organoids, comprised of pure epithelial cells, could enable insights into the epigenetic changes leading to progression from healthy tissue to cancer. Such features could be instrumental in early cancer detection using genome-wide analyses of cfDNA fragmentation.
Methods: Using 43 patient-derived colorectal organoids derived from healthy, adenoma, and cancer tissues, as well as 10 freshly collected peripheral blood mononuclear cell (PBMC) control samples, we examined the chromatin landscape of tumor development using transposase accessible chromatin analyses with next-generation sequencing. We analyzed enrichment for gapped-kmer abundance to reveal gene regulatory networks underlying differences between tissue types. We defined a consensus set of nucleosome depleted regions (NDRs) for each disease state and identified loci with differential accessibility between PBMCs, colon healthy, adenoma, and cancer tissues. We analyzed these differential loci for fragmentation characteristics in the circulating cfDNA of 250 healthy individuals and 51 patients with metastatic CRC.
Results: Across all organoid samples, we identified a consensus set of 62,890 NDRs. Associating these regions with nearby genes, we identified unique CRC-related signatures comprising genes of known and novel pathways, including those involved in WNT, hippo, and RAS signaling. Additionally, we discovered a gene regulatory network which drives chromatin accessibility differences between the healthy, adenoma, and carcinoma tissue in colon. While most chromatin accessibility differences were shared between adenomas and cancers, we identified 895 chromatin changes which were unique to adenoma. In healthy individuals, we found that cfDNA coverage was negatively correlated with accessibility at white blood cell NDRs (Spearman ρ= -0.56), while in individuals with cancer, changes in NDRs were associated with independent circulating tumor DNA abundance by droplet digital PCR (R^2=0.69, $p<0.001$). Consequently, genome-wide cfDNA fragmentation features could be used to distinguish healthy individuals from those with CRC (AUC=0.94).
Conclusions: These analyses reveal chromatin accessibility landscapes that were unique to different pathologic stages of CRC development, highlighting important genes and networks regulated by chromatin remodeling and providing an avenue for evaluating these through genome-wide analyses of cfDNA fragmentation.

#1959 Variant Origin Prediction (VOP) determines the tumor-somatic, germline, or clonal hematopoiesis (CH) origin of short variants (SVs) detected in liquid biopsy (LBx).

Derek W. Brown, Alexander D. Fine, Daokun Sun, Hanna Tukachinsky, Michael McDevitt, Kerriann Pontbriand, Eliana Polisecki, Angela Kou, Mingyue Li, Shumeng Zhang, Zheng Kuang, Aparna Aiyer, Bahar Yilmazel, Brennan Decker, Jason Hughes, Chang Xu

Foundation Medicine, Inc., Boston, MA

Introduction: Distinguishing the origin of variants detected by LBx is essential as tumor-somatic and germline, but not CH variants, can provide prognostic insights and inform treatment decisions. We describe a machine learning model that generates variant origin predictions for SVs (including base substitutions and short indels) detected by LBx.
Method: For all SVs detected in the FoundationOne®Liquid CDx (F1LCDx) assay, VOP generates a 3-way probability that the variant originated as germline, CH, or tumor-somatic. Tumor-somatic and germline probabilities can be summed to predict that the SV is in the tumor. This model was trained using 1977 F1LCDx results for which matched buffy coat (BC) DNA was also sequenced to equal depth. A variety of features, including fragmentomics and variant allele frequency, but no patient demographics, were used to train the classification model. Probability cutoffs were applied to pathogenic SVs and validated for accuracy from paired BC (658) and reproducibility using LBx replicates.
Results: VOP made accurate best call predictions (>50% probability cutoff) for pathogenic SVs across all origin types, with high sensitivity and high positive predictive value of tumor and CH (PPA > 93%, PPV > 91%). Critically, VOP performs well for SVs with VAFs ≤ 1% (PPV > 90%), as well as in genes known to harbor both CH and tumor-somatic SVs, such as *TP53* (PPV > 88%). For a use case requiring higher confidence in tumor origin, an 80% tumor cutoff maintained high PPA (90%) while increasing PPV overall (99%), including low VAF and *TP53* SVs (PPV > 96%). These cutoffs were assessed in 31 unique samples across 546 replicates and showed high reproducibility (Table).
Conclusion: VOP is a highly accurate and reproducible method to predict the origin of SVs from LBx alone. VOP performs well even when VAF ≤ 1% and in heavily confounded genes such as *TP53*. Increased confidence in variant origin is valuable for improving clinical care.

Table. VOP validation accuracy and reproducibility performance in pathogenic SVs

	Positive Percent Agreement (PPA)	Positive Predictive Value (PPV)	Positive Reproducibility	Negative Reproducibility	PPA (VAF ≤1%)	PPV (VAF≤1%)	PPA (*TP53*)	PPV (*TP53*)
High confidence tumor (germline + tumor-somatic)	90.11% (1458/1618)	98.51% (1458/1480)	98.02% (4909/5008)	90.11% (565/627)	78.80% (461/585)	96.85% (461/476)	84.19% (245/291)	98.79% (245/248)
Best call tumor (germline + tumor-somatic)	94.81% (1534/1618)	96.12% (1534/1596)	98.67% (5250/5321)	94.27% (296/314)	89.23% (522/585)	91.74% (522/569)	93.13% (271/291)	96.44% (271/281)
Best call CH	93.81% (940/1002)	91.80% (940/1024)	94.27% (296/314)	98.67% (5250/5321)	92.54% (583/630)	90.25% (583/646)	94.01% (157/167)	88.70% (157/177)
Best call tumor-somatic	93.61% (1420/1517)	95.82% (1420/1482)	97.13% (4780/4921)	92.02% (657/714)	88.89% (520/585)	91.71% (520/567)	92.71% (267/288)	96.39% (267/277)
Best call germline	99.01% (100/101)	89.29% (100/112)	86.82% (349/402)	98.97% (5179/5233)	NA (n < 5)	NA (n < 5)	NA (n < 5)	NA (n < 5)

#1960 Evaluation of mono- and di-nucleosomal cell-free DNA in fragmentome analyses.

Sarah Short[1], Shashikant Koul[1], Akshaya V. Annapragada[1], Dimitrios Mathios[2], Jamie E. Medina[1], Zachariah H. Foda[1], Carolyn Hruban[1], Elaine J. Chiao[1], Vilmos Adleff[1], Robert B. Scharpf[1], Victor E. Velculescu[1], Jillian Phallen[1]

[1]Johns Hopkins University, Baltimore, MD,[2]Washington University School of Medicine, St. Louis, MO

INTRODUCTION: Liquid biopsies are promising, noninvasive tools for cancer detection. Genome-wide fragmentomes reflect the nucleosomal origin of cell-free DNA (cfDNA) in the blood. Variations in cfDNA concentrations and characteristics of mono-nucleosomal (mono) compared to di-nucleosomal (di) cfDNA have not been well described.

METHODS: We evaluated liquid biopsies from 356 individuals in the LUCAS cohort (Mathios et al, 2021) including 146 without cancer, 85 with benign lung lesions, and 125 with lung cancer. Plasma (2.2-4 mL) was isolated from whole blood, cfDNA was extracted, and genomic libraries for whole-genome sequencing (WGS) were prepared. WGS was performed on the Illumina NovaSeq6000 S4 at 10X coverage. Mono and di cfDNA concentrations were quantified post-extraction and post-library preparation using the Agilent Bioanalyzer at each peak, and post-sequencing using fragment sizes of 0-250bp (mono) or 251-500 bp (di). Chromosomal representation and fragmentation patterns in cfDNA were analyzed using z-scores and short-to-long fragment ratios, respectively. The DNA Evaluation of Fragments for early Interception (DELFI) approach for lung cancer detection in high-risk individuals was used to evaluate total extracted cfDNA concentration (ng/mL) as an additional feature.

RESULTS: The fraction of mono to total cfDNA per mL of plasma increased significantly from cfDNA extraction (a), to library preparation (b), to sequencing (c) in individuals without cancer (median=0.77(a), 0.87(b), 0.92(c); IQR=0.71-0.83(a), 0.85-0.90(b), 0.91-0.94(c); $p<0.0001$ (a vs b and a vs c)), in those with benign lung nodules (median=0.78(a), 0.88(b), 0.93(c); IQR=0.72-0.85(a), 0.84-0.90(b), 0.92-0.94(c); $p<0.0001$ (a vs b and a vs c)), or in patients with lung cancer (median=0.76(a), 0.87(b), 0.92(c); IQR=0.71-0.82(a), 0.85-0.91(b), 0.91-0.94(c); $p<0.0001$ (a vs b and a vs c)). Changes appeared to be driven by decreases in di cfDNA across experimental steps in all individuals. Mono fragment sequences more accurately reflected copy number changes in individuals with or without cancer compared to di fragments. Inclusion of cfDNA concentration (ng/mL), reflective of both mono and di cfDNA, as an additional DELFI feature did not improve lung cancer detection (AUC=0.93, 95% CI: 0.88-0.97) compared to fragmentation and copy number features alone (AUC=0.93, 95% CI: 0.89-0.97).

CONCLUSION: We observed that mono cfDNA was retained, while di cfDNA was largely lost throughout experimental steps. Copy number changes were more apparent from sequenced mono cfDNA compared to di cfDNA. Including total cfDNA concentration as an additional feature to DELFI did not enhance performance.

#1961 Analysis of lung cancer clinical characteristics using cell-free DNA fragmentomes.

Milou Schuurbiers[1], Zachary L. Skidmore[2], Paul van der Leest[3], Jamie E. Medina[2], Garrett Graham[2], Tony Wu[2], Jacob Carey[2], Alessandro Leal[4], Bryan Chesnick[2], Kim Monkhorst[3], Nicholas Dracopoli[2], Robert B. Scharpf[5], Victor E. Velculescu[5], Daan van den Broek[3], Michel van den Heuvel[1], **Lorenzo Rinaldi**[2]

[1]Department of Pulmonary Diseases, Radboud University Medical Center, Amsterdam, Netherlands,[2]Delfi Diagnostics, Baltimore, MD,[3]Netherlands Cancer Institute, Amsterdam, Netherlands,[4]Comprehensive Cancer Center, NYU Langone Health Perlmutter, New York, NY,[5]The Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University School of Medicine, Baltimore, MD

Liquid biopsy approaches provide an opportunity for both cancer detection and clinical assessment in a non-invasive manner. Here we apply a blood-based lung cancer screening test to 578 individuals diagnosed with lung cancer through a real-world diagnostic prospective trial (LEMA, NCT02894853). Pre-treatment plasma samples were processed through the DELFI assay, a validated cell-free DNA (cfDNA) test based on a locked machine learning analysis of genome-wide fragmentation patterns. Clinical data, including tumor stage (I=165, II=60, III=147, IV=206), histologic subtypes, lymph node invasion, comorbidities, medications, smoking history, treatment type and overall-survival data were collected from all patients. Tissue molecular profiling was performed to identify actionable alterations in driver oncogenes.

Genome-wide cell-free DNA fragmentome analyses revealed that LEMA patients had similar chromosomal gains (1q, 3q, 5p, 8q) and losses (3p, 4q, 5q, 10q, 13q) to lung cancer patients collected in TCGA (LUAD and LUSC) and L101 trial (NCT04825834), suggesting the landscape of cfDNA alterations are consistent with other lung cancer studies in Europe and the United States.

DELFI fragmentation scores were significantly different amongst both tumor stage ($p<0.0001$, kruskal-wallis) and lymph node invasion ($p<0.0001$, kruskal-wallis), exhibiting progressively higher scores with increasing disease burden. Lung adenocarcinoma displayed lower DELFI scores compared to squamous cell carcinomas, while small-cell lung cancer cases presented the highest scores among all lung cancer subtypes.

Stage III patients not eligible for surgery with curative intent (n=96) had significantly higher DELFI scores compared to surgery-eligible stage III patients ($p=0.02$, Wilcox rank-sum).Localized cancer cases (I-III) experiencing cancer relapse after complete surgical resection also showed significantly higher DELFI scores compared to patients who did not experience relapse ($p<0.01$, log-rank). Metastatic cancer patients, treated with chemotherapy, immunotherapy or targeted therapy had a median overall survival of 8.7 months. For all these treatment types, patients with low DELFI score at baseline (below the median) had longer overall-survival (OS) compared to patients with high DELFI score (above the median $p<0.01$, log-rank).

Neither systemic comorbidities nor medications were found to significantly alter DELFI scores amongst groups ($q>0.05$, Wilcox rank-sum) and cancer cases driven by oncogenic alterations showed equivalent DELFI scores to cases without any driver mutation detected by tissue profiling.

Overall, this study reveals that DELFI fragmentomes can be used as prognostic biomarkers, similarly in lung cancer patients from US and European populations. DELFI scores increase with stage and tumor burden, predict survival, and are not altered by mutational status, comorbidities, or medications.

#1962 Detection of plasma circulating tumor DNA is not affected by kidney and liver function in patients with muscle-invasive bladder cancer..

Deema Radif[1], Sia V. Lindskrog[1], Iver Nordentoft[1], Karin Birkenkamp-Demtroder[1], Mads Agerbak[2], Jorgen B. Jensen[3], Lars Dyrskjot[1]

[1]Department of Molecular Medicine, Aarhus University Hospital, Aarhus, Denmark,[2]Department of Oncology, Aarhus University Hospital, Aarhus, Denmark,[3]Department of Urology, Aarhus University Hospital, Aarhus, Denmark

Introduction: Circulating tumor DNA (ctDNA) has demonstrated significant potential for early relapse detection and therapeutic monitoring in patients with muscle-invasive bladder cancer (MIBC). Advancing its clinical utility requires examining factors that may affect plasma ctDNA levels, including those influencing clearance. Here, we evaluated the association between plasma ctDNA detection and kidney and liver function markers in MIBC patients. Secondly, we explored the association between plasma ctDNA detection and immune markers, as well as the prognostic potential of the evaluated biochemical markers.
Methods: Tumor-informed plasma ctDNA analysis was available for 276 MIBC patients undergoing radical cystectomy (RC), of which 174 patients received neoadjuvant chemotherapy (NAC). Biochemical measurements collected within 10 days of an available ctDNA test (median: 0 days [IQR: 0-2 days]) and clinical data were retrieved from the patients' electronic health records. Immune marker measurements were confined to the pretreatment period. The median levels of all biochemical markers were within normal reference ranges, except for the neutrophil-to-lymphocyte ratio (NLR) which was above normal range in ctDNA positive patients. Wilcoxon rank-sum test, Spearman's correlation and Bonferroni correction for multiple testing were applied.
Results: The primary analysis indicated no correlation between kidney (plasma creatinine, eGFR) and liver (albumin, lactate dehydrogenase, alanine aminotransferase (ALAT), bilirubine, alkaline phosphatase) function markers in MIBC patients and plasma ctDNA detection or ctDNA variant allele frequencies (VAFs). Subgroup analyses of NAC-treated and NAC-naïve patients showed similar results, with no association observed, except for a weak positive correlation between ALAT and plasma ctDNA detection in NAC-naïve patients (P=0.036, n=72; not significant after multiple test correction). Levels of leukocytes (P=0.00098, n=146), neutrophils (P=0.0004, n=134), NLR (P=0.00016, n=77) and C-reactive protein (P=0.04, n=241), demonstrated positive correlations with plasma ctDNA detection. Multivariable logistic regression including tumor stage at diagnosis confirmed significant correlations between ctDNA detection and leukocytes (P=0.00322, n=146), neutrophils (P=0.00152, n=134) and NLR (P=0.00185, n=77). None of the biochemical parameters were associated with pathological downstaging after NAC. Reduced pretreatment plasma lymphocyte levels correlated with recurrence in the NAC-treated patients (P=0.012; not significant after multiple test correction).
Conclusion: Clinical application of ctDNA can be implemented with minimal risk of detection being influenced by fluctuations in the patients' kidney and liver function. Finally, biochemical parameters alone showed no strong prognostic value.

CLINICAL RESEARCH: Liquid Biopsy: Circulating Tumor Cells 1
Poster Session

#1966 Evaluation of circulating tumor cells as a real-time biomarker in metastatic urothelial carcinoma.

Wadih Issa[1], Navneet Kaur[1], Qinhan Zhou[1], Andrew DeVilbiss[1], Ze Yu[2], Damla Gunenc[1], Michael Poellmann[3], Changchuan Jiang[1], Qian Qin[1], Jue Wang[1], Suzanne Cole[1], Seungpyo Hong[3], Chao Xing[4], Andrew Z. Wang[5], Tian Zhang[1]

[1]Division of Hematology and Oncology, Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX,[2]Eugene McDermott Center for Human Growth and Development, University of Texas Southwestern Medical Center, Dallas, TX,[3]Pharmaceutical Sciences Division, School of Pharmacy, University of Wisconsin-Madison, Madison, WI,[4]Eugene McDermott Center for Human Growth and Development; Lyda Hill Department of Bioinformatics, University of Texas Southwestern Medical Center, Dallas, TX,[5]Radiation Oncology, University of Texas Southwestern Medical Center, Dallas, TX

Background: Patients with metastatic urothelial carcinoma (mUC) have poor prognosis and need biomarkers to guide treatment and monitor treatment responses. Circulating tumor cells (CTCs) offer a minimally invasive approach to capture tumor dynamics in real-time. This study aim to correlate mUC CTCs with treatment response and evaluate therapy-induced molecular alterations.
Methods: Patients with mUC were prospectively enrolled at the University of Texas Southwestern Medical Center. Peripheral blood samples were collected at baseline, 4 weeks, and 12 weeks of treatment. CTCs were isolated using a dendrimer-based assay functionalized with antibodies against EpCAM, Trop-2, Nectin-4, and FGFR3, identifying nucleated CTCs (DAPI+/CK+, CD45-). Single cell proteomic profiling of CTCs was performed via the Nanostring GeoMx Immuno-Oncology (IO) Proteome Atlas panel. The primary objective was to assess CTC variation as a biomarker for treatment response. CTC changes were considered concordant if they decreased in patients with complete or partial response (CR or PR), remained stable in those with stable disease (SD), or increased in patients with progressive disease (PD), as defined by RECIST 1.1.
Results: Eighteen patients with mUC were enrolled with median age of 76 years-old, 89% male and 61% Caucasian. Among the cohort, 78% (n=14) received enfortumab vedotin (EV) and pembrolizumab (P), 17% (n=3) received chemotherapy, and 5% (n=1) received sacituzumab govitecan. The median CTC counts (cells/ml) were assessed at baseline (39.3, IQR 26.5-64.4), week 4 (31.05, IQR 7.6-43.6), and week 12 (32.5, IQR 23.25-44.98). 13 patients had sufficient radiographic and clinical follow up. CTC changes were concordant with treatment responses in 77% (10/13) of patients, including 6/7 patients with PR, 1/2 with SD, and 3/4 with PD. Preliminary proteomic profiling of three patients who responded to 1L EV-P showed 58 upregulated and 70 downregulated proteins from baseline to week 4. We found that post-therapy, proteins related to antigen presentation (HLA-A, HLA-C, HLA-E), metabolism (beta glucuronidase), GLB1/Beta-galactosidase (Hexokinase 1), cell death (pro-apoptotic protein Bax, Smac/Diablo), and epithelial-mesenchymal transition (c-MET, N-cadherin, and vimentin) were upregulated, while proliferation signals (Ki67, Her2/ERBB2), metastasis (E-Cadherin, Phospho S431 Cytokeratin 8, c-Jun), and DNA damage repair (BRCA1, γH2A, ChK1, cleaved PARP1) were downregulated.
Conclusion and Future Directions: Novel capture of CTCs in patients with mUC can be potential biomarkers for monitoring treatment response and detecting therapy-induced molecular alterations. Some on treatment molecular expression changes may be further targeted with targeted treatments. We continue to characterize CTCs to identify key molecular pathways that contribute to treatment sensitivity and resistance.

#1967 Plexin-B2 mediates tumor cell clustering with monocyte interactions in breast cancer metastasis.

Emma Schuster[1], Nurmaa Dashzeveg[1], **Fangjia Tong**[1], Yuzhi Jia[1], Lamiaa El-Shennawy[1], Tong Zhang[2], Andrew Hoffmann[1], Kibria Golam[1], Youbin Zhang[3], Joshua Squires[1], Erika Ramos[1], Rokana Taftaf[1], David Scholten[1], Hannah Almubarak[1], Valery Adorno-Cruz[1], David Sullivan[4], Carolina Reduzzi[5], Allegra Minor[6], William Purev-Ochir[6], Rong Xu[7], Kalliopi Siziopikou[6], Leonidas Plantanias[6], Ami Shah[6], William Muller[6], William Gradishar[6], Chia-Feng Tsai[2], Tujin Shi[2], Huiping Liu[1]

[1]Pharmacology, Northwestern University, Chicago, IL,[2]Biological Sciences Division, Pacific Northwest National Laboratories, Richland, WA,[3]Department of Medicine, Northwestern University, Chicago, IL,[4]Pathology, Northwestern University, Chicago, IL,[5]Weill Cornell School of Medicine, New York, NY,[6]Northwestern University, Chicago, IL,[7]Case Western Reserve University, Cleveland, OH

The dogma of single tumor cell-mediated metastasis has been challenged by the discovery of multicellular circulating tumor cells (CTCs) clusters which are 20-50 times more likely to produce viable metastasis than single CTCs. However, the molecular mechanisms underlying CTC clusters and CTC interactions with immune cells are largely unknown. Combining integrated proteomic ranking, targeted analyses, and functional determination, we identified the transmembrane protein Plexin-B2 (PLXNB2) as one of the top hits whose expression in human primary tumors is associated with unfavorable distant metastasis-free survival. PLXNB2 expression is also enriched in CTC clusters compared to single CTCs from patients with advanced breast cancer. Loss of PLXNB2 reduces the formation of homotypic tumor cell clusters and heterotypic tumor-myeloid cell clusters in triple-negative breast cancer. Interactions between PLXNB2 and its ligand Sema4C on tumor cells mediate homotypic cluster formation, and PLXNB2 binding with Sema4A on myeloid cells (monocytes) promotes heterotypic CTC cluster formation, thereby driving lung metastasis in breast cancer. Depletion of *Plxnb2* in mouse breast tumor cells also blocked CTC-myeloid cell clustering and spontaneous metastasis in immune-competent mice. Additionally, using global proteomic analysis, we identified novel downstream effectors of the PLXNB2 pathway associated with tumor cell clustering in breast cancer. Thus, PLXNB2 is a novel therapeutic target for preventing new metastasis in triple-negative breast cancer.

#1968 Comparable detection of large tumor-derived vesicles (oncosomes) by known CTC platforms: Potential new analyte for biomarker monitoring?.

Eszter Papp[1], Pieter Mestdagh[2], Luc Y. Dirix[3], Peter Vermeulen[4], Mark Kockx[2]

[1]CellCarta, Montreal, QC, Canada,[2]CellCarta, Antwerp, Belgium,[3]Medical Oncology, ZAS St-Augustinus Hospital, Antwerp, Belgium,[4]Translational Oncology Research Unity, ZAS St-Augustinus Hospital, Antwerp, Belgium

Background: Monitoring tumors and detecting biomarkers through blood analysis remains challenging. Large oncosomes (LOs) are tumor-derived extracellular vesicles that offer a promising avenue for understanding tumor biology and biomarker status, potentially surpassing circulating tumor cells (CTCs) in accuracy. Validated LO detection methods are required to unlock LOs analytical potential. We evaluated two LO detection methods using known CTC platforms, the FDA-approved CellSearch, and RareCyte to compare their performance. In addition, we assessed the potential of LOs for HER2 detection in metastatic breast cancer (MBC) patients.
Methods: LO counts were analyzed in parallel blood samples from 96 MBC patients using either the CellSearch/ACCESS tdEV analysis package, or the RareCyte method with in-house LO analysis. Overall survival (OS) was defined as the time from baseline blood draw to death or last follow-up. HER2 scores from primary tumor biopsies were retrieved from patient charts. HER2 overexpression in LOs and CTCs was determined using the RarePlex HER2/ER CTC panel kit (n=9). Correlations between LO and CTC counts were assessed using Spearman's Rho test, and comparability of LO counts between platforms was evaluated with the Wilcoxon Signed Ranks test. Cutoffs for favorable vs. unfavorable LO counts were determined using an online tool. Survival curves for these groups were compared using the log-rank test. Correlation of HER2+ analytes with tissue biopsy HER2 scores was also analyzed using Spearman's Rho test.
Results: A strong positive correlation was observed between LO counts from the two platforms ($r = 0.49$, $p < 0.001$). LO counts also correlated with their respective CTC counts (CellSearch: $r = 0.88$, $p < 0.001$; RareCyte: $r = 0.93$, $p = 0.001$). Higher LO counts were associated with worse survival outcomes (CellSearch: $r = 0.35$, $p < 0.001$; RareCyte: $r = 0.39$, $p = 0.006$). Patients with unfavorable LO counts had significantly shorter survival compared to patients with favourable LO counts (CellSearch: HR = 3.5, $p < 0.001$; RareCyte: HR = 3.6, $p = 0.02$). RareCyte detected significantly more LOs than CellSearch (median LO count: 132 vs. 41, $p = 0.01$).
HER2 signal was detected in 5/9 patients with CTCs and in 8/9 patients with LOs. Notably, the proportion of HER2+ LOs positively correlated with tissue biopsy HER2 score ($r=0.799$, $p=0.01$). In contrast, the proportion of HER2+ CTCs did not correlate with tissue biopsy.
Conclusions: While RareCyte captured more LOs than CellSearch, LO counts were highly concordant across platforms, validating both methods. The association of LO counts with overall survival suggests that LOs reflect tumor progression, and may complement CTC-based monitoring. Furthermore, the correlation between LO HER2 status and tumor biopsy HER2 scores underscores the potential of LO analysis for biomarker monitoring in metastatic breast cancer.

#1969 Advancing metastatic prostate cancer diagnostics: STEAP1-based imaging flow cytometry for circulating tumor cell detection and characterization.

Minzhi Sheng[1], Shuyang Feng[1], Omar Alawamry[1], Urban Emmenegger[2], Kristin Cimolini[1], Danny Vesprini[3], Andrew Loblaw[3], Laurence Klotz[4], Christopher S. Lim[5], Stanley K. Liu[6], Hon S. Leong[1]

[1]Sunnybrook Research Institute, Toronto, ON, Canada,[2]Department of Hematology and Oncology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[3]Department of Radiation Oncology, University of Toronto, Toronto, ON, Canada,[4]Department of Urology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada,[5]Department of Radiology, University of Toronto, Toronto, ON, Canada,[6]Biological Sciences Platform, Sunnybrook Research Institute, Toronto, ON, Canada

Prostate cancer (PCa) is the most common cancer among Canadian men, with metastatic PCa (mPCa) patients experiencing a low 5-year survival rate of just 30%. Liquid biopsies using circulating tumor cells (CTCs) offer a non-invasive approach to diagnosing and monitoring treatment efficacy. Six transmembrane epithelial antigens of the prostate 1 (STEAP1) have been identified as a promising biomarker due to its significant overexpression in most PCa cases compared to normal tissues. We have developed monoclonal antibodies specifically targeting STEAP1 and propose their application in imaging flow cytometry (imFC) for identifying CTCs in mPCa patients. Our CTC staining and imFC protocols were validated and optimized using benign prostate hyperplasia and PCa cell lines. We also compared two CTC isolation techniques: density-based separation using Ficoll-Paque and microfluidic isolation with the BioRad Genesis Cell Isolation System for the best CTC purity. Isolated peripheral blood mononuclear cells (PBMCs) were labelled with our STEAP1 antibodies, DAPI for nuclear staining, CD45 antibodies for hematopoietic cells, and EpCAM antibodies, a widely used marker for CTCs. Additionally, we developed analytical pipelines leveraging imaging software with built-in machine-learning capabilities to classify probe binding patterns and identify subtypes of CTCs and cancer-derived extracellular vesicles (EVs) in immune cells. These optimized protocols were then tested on blood samples from patients with localized and metastatic PCa. CTCs were successfully detected in mPCa patients based on their expression of PCa biomarkers and lack of immune cell markers. Furthermore, STEAP1-positive vesicle-like signals were observed in association with hematopoietic cells, suggesting the uptake of PCa EVs by immune cells. Our findings demonstrate that STEAP1 antibodies in imFC can effectively detect and characterize CTCs. This approach represents a next-generation liquid biopsy for mPCa, offering improved diagnostic accuracy and the potential to enhance long-term outcomes for mPCa patients.

#1970 Quantitative analysis of HER2, HER3, and ɣ-H2AX expression on circulating tumor cells for clinical trials.

Erin G. Bayer, Brock Bartels, Rachel Ponting, Casey Helmicki, Arturo B. Ramirez

RareCyte, Inc., Seattle, WA

Background: Circulating Tumor Cells (CTCs) are an attractive target for pharmacodynamic measurements in clinical trials, providing quantitative biomarker expression of the tumor, independent of tissue biopsy. The increasing challenge to obtain tissue samples continues to focus attention on non-invasive liquid biopsy approaches. The RareCyte platform offers a highly sensitive method for CTC enumeration and protein expression on CTCs. In this study, we describe the development of assays to quantify HER2, HER3, and ɣ-H2AX protein expression on CTCs. Each of the single biomarker assays allow for the inclusion of an additional biomarker of interest to be measured on each CTC.

Methods: Cell lines with known positive or negative expression for each biomarker were spiked into healthy donor blood to generate model CTCs. Nucleated cells were collected from these samples using the AccuCyte® sample preparation kit and spread onto microscope slides. Slides were fixed and stained with antibodies targeting cytokeratin, EpCAM, and CD45 to detect CTCs and exclude white blood cells (WBCs), as well as primary antibodies to HER2, HER3 or ɣ-H2AX to evaluate protein expression on identified CTCs. Slides were imaged with the CyteFinder® automated immunofluorescence scanning microscope, to quantitatively measure Mean Fluorescence Intensity (MFI) of biomarkers to assess protein expression on individual CTCs.

Results: Assays for the detection of HER2, HER3, and ɣ-H2AX on CTCs were designed and optimized to maximize the signal-to-background ratio. The final assays were run on replicate slides of positive and negative cell lines over 3 independent days to evaluate the analytic performance of each assay. Thresholds for biomarker positivity were established based on MFI measurements from positive and negative control slides. The accuracy of all three biomarker assays was >90%. Both repeatability (intra-run precision) and inter-run precision, assessed by the Coefficient of Variations (CV), were <20% for all three assays. The HER2 biomarker assay was tested on 16 cell lines with varying levels of HER2 expression, demonstrating its ability to confirm HER2 protein levels and distinguish between cell lines with known HER2 expression (0, 1+, 2+, 3+).

Conclusions: We developed biomarker assays for quantifying protein expression on individual CTCs, that demonstrate high accuracy and reproducibility for assessing biomarker expression of tumors through liquid biopsy and are currently being utilized in clinical studies. Recent findings suggest that patients may respond to targeted therapies even when their tumors have low or ultra-low HER2 expression, if HER2 expression is detected on CTCs. Quantifying target protein expression on CTCs offers a promising approach for patient selection and longitudinal, non-invasive monitoring of cancer patients, generating valuable data for clinical trial sponsors.

#1971 Leveraging CK and CD45 dual positive cells as cancer diagnostic markers in liquid biopsy.

Sumin Lee[1], Amos Chungwon Lee[1], Wooseok Lee[2], Han-Byoel Lee[3], Sunghoon Kwon[2]

[1]Meteor Biotech, Seoul, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of,[3]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of

Liquid biopsy has emerged as a revolutionary, non-invasive diagnostic tool, enabling real-time monitoring of tumor dynamics. Circulating tumor cells (CTCs), shed from primary or metastatic tumors into the bloodstream, represent a critical component of liquid biopsy with immense potential for early cancer detection, prognosis, and therapeutic monitoring [1]. While identification of CTCs as cytokeratin (CK) positive and CD45 negative is standard of immunofluorescence assay among cells in blood sample, curious cases have been reported that the presence of CK and CD45 dual positive (DP) cells [2]. However, neither the identity of DP cells nor the roles of them had been understood. Rather, their presences were neglected so far. This presentation highlights recent findings of the DP cells about their identity and their potential roles as biomarkers, especially cancer diagnostic markers. Our state-of-the-art technologies [3] enabled detection and isolation of the DP cells, streamlined to single cell RNA-seq and the downstream analysis with high quality of data in spite of heterogeneity. Our studies focus on the molecular profiling of CTCs and DP cells to identify transcriptional signatures that correlate with tumor metastasis mechanisms. Additionally, emerging evidence underscores the potential edges of the prognostic value of DP cell enumeration over CTCs. By bridging the gap between liquid biopsy innovations and clinical application, DP-cell-based diagnostics hold promise for transforming precision oncology. Future directions include integrating DP analysis with other biomarkers, such as CTC, circulating tumor DNA and extracellular vesicles, to construct a comprehensive liquid biopsy platform. This work emphasizes the role of DP cells as a novel target of liquid biopsy, paving the way for earlier interventions and more personalized therapeutic strategies in cancer care.

#1972 Utilization of flow cytometry for the characterization of mesenchymal and embryonic properties of circulating tumor cells.

Tamas Ricard Linkner[1], Zsofia Brigitta Nagy[1], Nikolett Szakallas[2], Eszter Farkas[1], Fruzsina Banyai[1], Istvan Takacs[1], Bela Molnar[1]

[1]Semmelweis University, Budapest, Hungary,[2]Eotvos Lorand Tudomanyegyetem, Budapest, Hungary

Background: Circulating tumor cells break off from the primary cancer tissue and enter into the bloodstream, where they reach the distant parts of the body where they can form metastases. The tumor cell could lose its adhesive properties and takes on a mobile, mesenchymal phenotype and they undergo epithelial-mesenchymal transition (EMT). The detection of these circulating tumor cells carries great diagnostic potential. Their identification is based on specific cellular markers such as cytokeratin or vimentin expression, which are key molecules in EMT, or SOX9 which plays a prominent role in the development of stem cell-like properties of tumor cells and carries therapy resistance potential.
Aims: The aim of our study was to develop and optimize a technique suitable for the detection of circulating tumor cells and cells undergoing epithelial-mesenchymal or embryonic transition from blood.
Materials and Methods: Magnetic cell separation technique (autoMACS Pro, Miltenyi) was performed in order to deplete CD45 immune cells from blood. Additionally, flow cytometry technique was used to detect fluorescent antibody labeled circulating tumor cells. CD45-AF700, CD15-PeVio770, CK-FITC, Vimentin-APC, SOX9-PE labeled antibodies were utilized. Peripheral whole blood of colorectal carcinoma patients (CRC) were analyzed, four of the patients were classified with grade II and grade III. Data was compared to healthy controls.
Results: After the depletion of CD45 positive immune cells from the blood 5CTC/100000 counted cell were characterized as cytokeratin positive cell. Moreover, 50CTC/100000 counted cell was observed as vimentin positive cells. Additionally, SOX9 positive cells (6CTC/100000) were also detected from patients. These results indicates the presence of cancer cells with mesenchymal and stem cell characteristics in the circulation of cancer patients.
Conclusion: Overall, magnetic separation is suitable technique for the enrichment of circulating tumor cells from whole blood. Moreover, flow cytometry is a key method for the detection of circulating tumor cells and cancer stem cells that have undergone embryonic transformation. With the sorting of these cells we hope that we can create the base of future diagnostic analysis of cancer patients.

#1973 The expression of PD-L1 in circulating tumor cells is correlated with positive estrogen receptor status and higher CTC counts in HER2-negative metastatic breast cancer.

Background: Hormone therapies alter the tumor microenvironment with the potential to sensitize estrogen receptor (ER)-positive metastatic breast cancer (MBC) to immunotherapy. Current trials are ongoing investigating the combination of hormone therapies, including aromatase inhibitors or selective ER modulators, with immune checkpoint inhibitors that target PD-1/PD-L1. We previously reported a significant correlation between tumor markers (e.g., *ESR1*) and circulating tumor cells (CTCs) regarding therapy resistance in MBC (2023 ASCO, 2024 SABCS). Herein, we sought to evaluate the if PD-L1 expression is associated with ER status, and CTC enumeration in patients with HER2-negative MBC.

Methods: This study included 23 HER2-negative MBC patients enrolled between 2017 and 2022 at Robert H. Lurie Comprehensive Cancer Center of Northwestern University. Whole blood sample (7.5 mL/each) was collected from each patient. CTC enumeration and PD-L1 detection was conducted using the FDA-approved CellSearch® System (Menarini). CTCs were identified as $CK^+/DAPI^+/CD45^-$. We assessed the association between PD-L1 expression, ER status, and CTC enumeration using Kruskal-Wallis test for statistics.

Results: Among 23 patients, 12 patients were ER-positive and 11 were ER-negative, as determined through pathological identification. CTC counts of ≥5 were detected in 16 patients, while 7 patients had CTC counts <5. In the ER-positive group, the mean total CTC count was 68.9, with a mean of 25.1 $PD\text{-}L1^+$ CTCs and 10 CTC clusters. In contrast, the ER-negative group had a significantly lower mean total CTC count of 48.5, with an average of 2.4 $PD\text{-}L1^+$ CTCs and no CTC clusters ($p < 0.0001$). These findings indicate that PD-L1 expression in CTCs is strongly associated with ER-positive status in MBC patients. Additionally, PD-L1+ CTCs were found in 16 patients, who exhibited a mean total CTC count of 61.4 and 6.5 CTC clusters, significantly higher than the 7 PD-L1-negative patients who had a mean total CTC count of 49.1 and no CTC clusters ($p<0.05$). Among patients with CTC counts ≥5, four had a PD-L1+ CTCs/total CTCs ratio above 50%, with an average of 87 total CTCs per patient, which was significantly higher than the average of 80.5 total CTCs seen in the other 12 patients with a ratio below 50% ($p < 0.05$).

Conclusions: Our findings indicate that ER-positive, HER2-negative MBC is associated with significantly higher PD-L1 expression in CTCs compared to ER-negative, HER2-negative MBC. This increased PD-L1 expression in CTCs may contribute to immune evasion by affecting immune cell infiltration and response, potentially reducing the effectiveness of immunotherapy in ER-positive cases and predicting a more aggressive metastatic potential. Adding ER status and CTC enumeration when assessing PD-L1 expression in CTCs could be considered for treatment stratification in MBC.

#1974 Prostate cancer lineage states detected by circulating tumor cell RNA sequencing are prognostic biomarkers for overall survival and resistance to androgen receptor pathway inhibitors and177Lutetium-PSMA-617.

Joshua M. Lang[1], Marina Sharifi[1], Jamie Sperger[1], Amy K. Taylor[1], David Kosoff[1], Hamid Emamekhoo[1], Christos Kyriakopolous[1], Andrew Armstrong[2], Xiao Wei[3], Rana McKay[4]

[1]University of Wisconsin-Madison, Madison, WI,[2]Duke University, Durham, NC,[3]Dana Farber Cancer Institute, Boston, MA,[4]University of California-San Diego, San Diego, CA

Background: The development of treatment resistance remains universal for metastatic prostate cancer patients, driven by AR alterations and lineage state transitions. Identifying the evolution of molecular alterations during treatment has been limited by the challenges of serial tumor biopsies, which can be overcome by blood-based liquid biopsies. However, standard cell-free DNA approaches cannot directly assess changes in gene expression, crucial to understanding resistance.

Patients and Methods: We developed a novel circulating tumor cell (CTC) isolation approach with purity comparable to tissue biopsies and performed CTC RNA sequencing of 273 blood samples from a prospective multi-institutional cohort of 117 metastatic prostate cancer patients. We examined prostate cancer lineage states associated with prognosis and response to 177Lu-PSMA-617 in men with metastatic prostate cancer.

Results: Single sample pathway analysis of high CTC purity samples identified four transcriptional phenotypes: luminal A-like (LumA), luminal B-like (LumB), low proliferation (LP), and neuroendocrine (NE). Compared to patients with low CTC burden/purity (median OS not reached), patients with LumA and LP phenotypes showed similar survival, while patients with LumB and NE CTC phenotypes had shorter survival (LumB: median OS 6m, HR 9.1[3.8-21.8], p<0.0001, NE: median OS 3.7m, HR 11.8[2.4-57.2], p=0.0019). We isolated CTCs longitudinally from 37 patients receiving 177Lu-PSMA-617. LumA/LP/Low burden samples had significantly greater benefit from ARPIs compared to LumB and NEPC, as hypothesized. Pretreatment LumA/LP/Low burden CTC phenotypes had a significantly higher clinical benefit rate with 177Lu-PSMA-617 than the LumB phenotype (64% vs 14%, Fisher's Exact p=0.033), which was associated with early progression on 177Lu-PSMA-617 (Fisher's Exact p=0.038).

Conclusion: We report the largest CTC RNA-seq cohort of patients with metastatic prostate cancer and demonstrate that high-purity CTC RNA-seq identifies prostate cancer lineage states mirroring those in tissue, including an NE phenotype concordant with small cell/neuroendocrine histology. We also identified a more common LumB phenotype defined by persistent AR signaling and high proliferation and associated with poor prognosis and poor response to 177Lu-PSMA-617.

#1975 The use of circulating tumor DNA (ctDNA) in HER2+ metastatic breast cancer (MBC) for prognostication and management.

Surbhi Warrior[1], Diana Jaber[1], Natalie Heater[1], Sarah Marini[1], Yangruijue Ma[1], Zequn Sun[1], Lisa Flaum[1], Patricia Robinson[1], Regina Stein[1], Regina Stein[1], Massimo Cristofanilli[2], William Gradishar[1], Janice Lu[1]

[1]Northwestern Memorial Hospital, Chicago, IL,[2]Weill Cornell, New York, NY

Background: HER2+ breast cancers account for 20% of all breast cancers, and survival rates in the metastatic setting remain low. There have been advances in treatment with HER2 targeted therapies, but progression free survival (PFS) decreases after each subsequent line of therapy. Understanding patients' mutational profile with the use of ctDNA may identify resistance to HER2 targeted therapies, aid in prognostication, and guide the addition of further targeted therapies to improve outcomes.
Methods: Patients with HER2+ MBC were enrolled from 2016-2024 under an IRB approved clinical trial (NU16B06) at Northwestern University were retrospectively analyzed. Plasma ctDNA was analyzed by Guardant 360 and tissue NGS was performed using commercially available tests such as FoundationOne or TempusX. Mutations that developed as well as additional clinical, pathologic, treatment, and response data were collected for analysis.
Results: There were 67 patients with HER2+ MBC included in the analysis. The mean initial PFS following HER2 targeted therapy was 29.8 months, the mean second PFS was 12 months, and the overall mortality was 63%. The overall second PFS was significantly shorter than the initial PFS (HR 4.00, $p < 0.001$). ESR1+ patients had a significantly shorter initial PFS compared to ESR1 wildtype (wt) patients (14 vs 22 months, $p=0.038$). There was no significant difference between second PFS for ESR1+ patients compared to ESR1wt patients (5.5 vs 6.8 months, $p=0.28$). There was a significant difference in initial PFS for patients FGFR+ patients and FGFRwt patients (12 vs 22 months, $p=0.002$) but not for second PFS (6 vs 8 months, $p=0.07$). The initial PFS for PIK3CA+ patients was shorter compared to PIK3CAwt (12 vs 22 months, $p=0.087$) but was similar for the second PFS (6 vs 6 months, $p=0.52$).
Conclusion: The use of ctDNA in HER2+ MBC can aid in understanding a patient's genomic landscape and prognosis. There is overall shorter PFS in patients with identified mutations and that significantly worsens with progression of disease. The initial PFS in patients with ESR1, FGFR, and PIK3CA mutations is significantly less than in respective wildtype patients. While targeted therapies for these mutations currently exist in the hormone positive breast cancer setting, our findings demonstrate that HER2+ patients may also benefit from additional targeted therapy in adjunct to HER2 directed therapy in the early metastatic setting. This therapeutic benefit should be prospectively studied in a larger cohort to understand if there exists a clinically significant improvement in outcomes.

#1976 Circulating tumor cell (CTC) RNA sequencing and single cell protein phenotyping reveal heterogeneity of cell surface target expression in metastatic prostate cancer CTCs.

Alex H. Chang[1], Jamie M. Sperger[1], Viridiana Carreno[1], Katherine R. Kaufmann[2], Matthew L. Bootsma[3], Shannon R. Reese[2], Luke A. Nunamaker[2], Charlotte Linebarger[2], Amy K. Taylor[1], Katharine E. Tippins[1], Kyle T. Helzer[3], David Kosoff[4], Shuang G. Zhao[3], Joshua M. Lang[1], Marina N. Sharifi[1]

[1]Department of Medicine, Carbone Cancer Center, Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]Carbone Cancer Center, Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[3]Department of Human Oncology, Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[4]William S Middleton Memorial Veterans Hospital, Madison, WI

Background: Metastatic prostate cancer is an androgen receptor (AR) driven disease. While AR targeted therapies (ARPIs) have led to improvements in patient outcomes, development of treatment resistance remains universal. ARPI resistance can occur through lineage state transitions that bypass AR signaling and culminate in neuroendocrine prostate cancer (NEPC). Cell surface targeted therapies are a new therapeutic class that has shown promise for the treatment of ARPI-resistant metastatic prostate cancer. However, heterogeneity in cell surface target expression during lineage state transitions could impact the efficacy of these approaches. CTCs are uniquely suited to longitudinal profiling to understand the evolution of cell surface target expression during the lineage state transition from AR-driven adenocarcinoma to NEPC.

Methods: CTCs were isolated from peripheral blood from patients with ARPI-resistant metastatic prostate adenocarcinoma utilizing our automated microfluidic platform integrating immunomagnetic negative and positive selection, followed by protein staining on chip for single CTC fluorescent quantification of prostate adenocarcinoma (PSMA) and NEPC (DLL3) cell surface target expression (n=29) or RNA isolation on chip and bulk RNA sequencing (n=146).

Results: In the CTC RNA-seq cohort, 112/146 (76.7%) samples had expression of FOLH1 (PSMA) only, 5/146 (3.4%) samples had expression of DLL3 only and 9/146 (6.2%) samples had expression of both DLL3 and FOLH1. Median expression of DLL3 in the double positive group was similar to that in the DLL3 only group (4.34 v 6.67 log2(tpm+1), p = 0.076), while median expression of FOLH1 in the double positive group was similar to that of the FOLH1 only group (6.80 v 7.26 log2(tpm+1), p = 0.316). In the single CTC protein phenotyping cohort, 27/29 (93%) of samples had detectable CTCs, with a mean of 18 CTCs per patient (range 1-172). 19/29 (65.5%) samples had PSMA positive CTCs, 1/29 (3.4%) samples had DLL3 positive CTCs, and 2/29 (6.9%) samples had both PSMA positive and DLL3 positive CTCs, but no single CTCs with co-expression of both proteins were identified.

Conclusion: CTC RNA sequencing identifies a subset of ARPI-resistant metastatic prostate cancers with cell surface target expression associated with small cell/neuroendocrine differentiation (DLL3), including samples with co-occurring gene expression of adenocarcinoma (PSMA) and small cell (DLL3) markers. Single CTC protein phenotyping also identified patients with simultaneous detection of both PSMA positive and DLL3 positive CTCs, however no PSMA/DLL3 double positive CTCs. The presence of mixed lineage state populations with potentially mutually exclusive cell surface target expression suggests consideration of co-targeting approaches to improve therapeutic efficacy in the ARPI-resistant setting.

#1977 Implementation of a comprehensive clinical cfDNA analysis platform for aqueous humor liquid biopsy in retinoblastoma.

Laura A. T. Kagami[1], Eirini Christodoulou[2], Venkata Yellapantula[2], Dong Xu[2], Cindy Fong[2], Dejerianne Ostrow[2], Liya Xu[3], Jesse Berry[3], Jaclyn A. Biegel[2]

[1]Cancer and Blood Disease Institute, Children's Hospital Los Angeles, Los Angeles, CA,[2]Department of Pathology and Laboratory Medicine, Children's Hospital Los Angeles, Los Angeles, CA,[3]The Vision Center, Children's Hospital Los Angeles, Los Angeles, CA

Introduction: The development of liquid biopsy testing based on sequencing analysis of cell-free DNA (cfDNA) has the potential to transform cancer care in pediatric tumors, which are characterized by a wide array of genomic alterations including copy number alterations (CNAs), sequence variants, epigenetic alterations, and structural rearrangements in tumor-associated genes. In patients with retinoblastoma where direct tumor biopsy is not possible due to the risk of tumor spread, aqueous humor (AH) is a rich source of cfDNA. Comprehensive cfDNA testing, combining a low pass whole genome sequencing (LP-WGS) assay to detect CNAs and a custom targeted sequencing panel (TSP) to detect mutations, can provide a highly effective platform to inform diagnosis, risk stratification, response to therapy, and surveillance in patients with retinoblastoma.

LP-WGS Results: We validated a liquid biopsy LP-WGS assay, LBSeq4Kids, to detect CNAs in cfDNA from plasma, cerebrospinal fluid, or AH. Clinical testing has been performed for the past two years for diagnostic evaluation and monitoring response to therapy using AH from retinoblastoma patients.

Thirty-six children with unilateral or bilateral retinoblastoma (44 eyes) underwent LBSeq4Kids LP-WGS analysis. CNAs were detected in 30/32 (94%) samples at diagnosis or recurrence. Serial sampling of 22/44 (50%) eyes was performed using a range of 1-10 samples per patient. Seventeen of those 22 (77%) eyes demonstrated clearance of CNAs with treatment. Five eyes showed persistence of abnormal profiles, necessitating enucleation of 2 eyes. Treatment and evaluation are ongoing for the remaining three eyes.

Targeted Sequencing Panel Results: We are validating a custom cfDNA TSP to detect single nucleotide variants and small indels in the coding sequence of 136 genes and fusions involving *EWSR1, FOXO1*, and *BRAF* for patients with ocular disease, solid tumors and brain tumors.

To date, 17 children (21 eyes) diagnosed with retinoblastoma have had TSP testing using AH. All eleven (100%) patients with germline variants demonstrated the same *RB1* alterations in the AH using the panel. Six of these patients (55%) had a second somatic alteration in *RB1* detected with the panel. Two of 11 (18%) with known germline *RB1* mutations also demonstrated mutations in *BCOR, ARID1A,* or *MSH6*. Somatic variants in *RB1, ARID1A* and *BCOR* were detected in the remaining six patients with sporadic retinoblastoma. Targeted sequencing of the AH surveillance samples from these patients is in progress.

Conclusion: Here we demonstrate clinical utility for aqueous humor liquid biopsy molecular testing as a complementary means of diagnosis and monitoring treatment response in patients with retinoblastoma. Continued surveillance of these patients is ongoing to monitor disease status and rule out recurrence, as well as identify novel prognostic biomarkers.

#1978 Circulating rare events as a biomarker of anti-tumoral effect of ketamine therapy in non-small cell lung cancer.

Anya Shah[1], Stephanie Shishido[1], Jeremy Mason[1], George W. Fischer[2], David Amar[2], Dawn Desiderio[2], Joseph R. Scarpa[3], David R. Jones[2], Amitabh Gulati[2], Alessia Pedoto[2], Alessandro De Camilli[2], Cosmin Guaran[2], Jacob C. Jackson[2], Alexandra Lewis[2], Michelle Zanone[2], Lucy Nystrom[2], Howard Scher[2], Ethan Barnett[2], Joshua Mincer[2], Peter Kuhn[1]

[1]USC Convergent Science Institute in Cancer, Los Angeles, CA,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Weill Cornell Medicine, New York, NY

Non-small cell lung cancer (NSCLC) remains one of the leading causes of cancer-related mortality worldwide, with surgical resection (with or without adjuvant chemotherapy) often being the recommended treatment for resectable localized disease. However, even with curative-intent resections, 30% to 55% of localized NSCLC patients experience recurrence and will die from the disease. Tumor-associated cells detected in peripheral blood, referred to here as circulating rare events, are believed to play a key role in metastatic dissemination, underscoring their potential as indicators of treatment response and recurrence risk. Recent retrospective analyses have revealed that the use of intraoperative Ketamine (Ket) during primary tumor resection surgery is associated with a lower recurrence rate, suggesting a potential utility in cancer treatment beyond its approved indication as an adjunct anesthetic. The study presented here investigates the effects of different anesthetic protocols on circulating rare events in NSCLC patients, specifically comparing Ket and dexmedetomidine (Dex) (also commonly employed as an adjunct anesthetic), to assess whether Ket exhibits anti-tumor effects and modulates the systemic tumor environment. Peripheral blood samples (n=60) were collected from 22 early-stage NSCLC patients undergoing primary tumor resection, with samples taken preoperatively (before surgical incision and after surgical closure) and at a three-week follow-up. Circulating rare events were identified through advanced imaging and phenotypic analysis and validated by comparison to blood samples from normal donors, which served as controls. Results indicated no significant differences between the anesthetic agents in pre- and post-surgery samples; however, at the three-week follow-up, Ket was associated with a higher incidence of circulating rare events and an increase in a specific cellular phenotype consistent with endothelial cells. These findings suggest that Ket may influence tumor vasculature and enhance tumor shedding, which could lead to a better prognosis after tumor resection in lung cancer patients. This highlights the potential of Ket as a perioperative agent that modulates tumor biology, as demonstrated by increased rare cell detection, and supports further investigation into a possibly expanded role in surgical oncology for potential to improve long-term outcomes in NSCLC patients.

#1979 Low CD47 expression in specific populations of tumor macrophage fusion cells in blood correlates with progressive disease in metastatic cancers.

Sonia Muthuraj[1], Massimo Cristofanilli[2], Saranya Chumsri[3], Susan Tsai[4], Raymond C. Bergan[5], Cha-Mei Tang[6], Daniel L. Adams[7]

[1]Rutgers University, New Brunswick, NJ,[2]Weill Cornell Medicine, New York, NY,[3]Mayo Clinic Cancer Center, Jacksonville, FL,[4]Ohio State University, Columbus, OH,[5]Fred & Pamela Buffett Cancer Center, University of Nebraska Medical Center, Omaha, NE,[6]Creatv MicroTech, Inc., Rockville, MD,[7]Creatv MicroTech, Inc., Monmouth Junction, NJ

Tumor associated macrophages are known to fuse with cancer cells resulting in the formation of a cellular phenomenon called tumor-macrophage fusion cells (TMFCs). TMFCs are a highly aggressive cell subtype that may move into circulation, evade immune surveillance, and possibly aid in seeding of metastatic sites. The formation of TMFCs involves CD47, a ubiquitous surface receptor that acts as a “don’t eat me” signal, interacting with the macrophage protein SIRPa, a down regulator of phagocytosis, and syncytin-1, a mediator of hyperploidy cancer fusion. In this analysis, we isolated circulating TMFCs from the blood of n=39 metastatic cancer patients (pts) to evaluate the expressions of CD47, SIRPa and syncytin-1 as it relates to stable or progressive disease via 30 day imaging by PET scan. We conducted a prospective pilot study of n=39 pts with pathologically confirmed metastatic breast (n=17), prostate (n=7), pancreas (n=7), or colon (n=8) cancer receiving standard of care systemic therapy. We isolated TMFCs from 7.5ml peripheral blood using a CellSieve microfilter, and stained with CD47, SIRPa, & syncytin-1. TMFCs were identified based on large cell size (>30 µm) & multinucleated structure, and were categorized into 4 distinct subtypes: A) >2 distinct non-contacting nuclei within a TMFC, B) 2 distinct non-contacting nuclei, C) 2 contacting nuclei, D) a single multinucleated nuclei. CD47, SIRPa, and syncytin-1 expressions were categorized as negative, low, or high. TMFCs subtypes and marker expressions were compared to pts’ clinical status (i.e. progressive, stable or responding) at first available PET/CT scans after blood draw (~45 days). TMFCs were identified in 72% of pts (n=28/39), average 8 cells/sample, and ranged 1-77 cells. Of the TMFCs, 12% were subtype A, 11% as B, 11% as C, and 66% as D. CD47 expression was seen in 100% of TMFs, with low expression in 39% of subtype A cells, 58% subtype B, 39% subtype C, & 62% subtype D. Notably, CD47 was significantly lower ($p=0.010$) in subtype B than other groups. Further, the expression of syncytin-1 in subtype B cells was significantly lower ($p=0.02$) than in other subtypes, and subtype D cells had 75% higher syncytin-1 localized to the nuclear regions. No correlations were found in the SIRPa expression and subtypes. Interestingly, progressing pts had 200% more TMFCs, more subtype B (83%), and significantly lower ($p<0.001$) CD47 expressing TMFCs than non-progressing pts. In this pilot study on the expression profiles of circulating TMFCs, it appears that specific subtypes of TMFC with low CD47 expression may be associated with progressive disease. Interestingly, this contrasts existing studies on primary tumors which often correlate higher CD47 with more aggressive cancers. This finding suggests that low CD47 cancer cells circulate blood in some pts with progressing disease and may be pertinent to efforts targeting CD47 in cancer.

#1980 The significance of circulating tumor cells and circulating tumor DNA as prognostic markers in human papillomavirus-positive head and neck squamous cell carcinoma.

Hiroe Tada, Hideyuki Takahashi, Kazuaki Chikamatsu

Gunma University School of Medicine, Maebashi, Japan

Patients with human papillomavirus (HPV)-positive head and neck squamous cell carcinoma (HNSCC) respond favorably to treatment; however, some are resistant to treatment. Liquid biopsy is a potential prognostic biomarker for various types of cancer. In this study, we comprehensively investigated circulating tumor cells (CTCs), cell-free DNA (cfDNA), and circulating tumor DNA (ctDNA) and compared them to determine their potential as predictive biomarkers for HPV-positive HNSCC. First, we isolated CTCs and cfDNA from the peripheral blood of 42 HPV-positive HNSCC patients before treatment. CTCs were obtained using a size-based separation method with a microfilter or the CD45 depletion method. The expression of three epithelial-related genes (*EPCAM*, *MET*, and *EGFR*) in the isolated CTCs was determined by RT-qPCR. When at least one of the three epithelial-related genes was detected, the sample was defined as positive for CTCs. cfDNA was isolated from serum samples using the QIAamp Circulating Nucleic Acid Kit (QIAGEN) and quantified using an Agilent 4200 TapeStation. We then determined the level of cfDNA per 1ml of serum. Next, we examined ctDNA to detect E7 genes specific to HPV in cfDNA as ctDNA using droplet digital PCR. Finally, we analyzed the clinical significance of CTCs, cfDNA and ctDNA. CTCs were isolated in 21patients (50.0%) and the HPV E7sequence was detected in 17 patients (40.1%) of 42 HPV-positive HNSCC patients. Among the clinical factors, only N stage and ctDNA positivity were significantly associated(p=0.03). There were no associations between the presence of CTCs and clinical factors. We further investigated whether CTCs and ctDNA correlated with prognosis using multivariate analysis. CTC positivity was most strongly associated with progression-free survival (PFS) (Hazard Ratio=5.549, p=0.037); however, the presence of ctDNA was not correlated with PFS. The presence of CTCs was found to be the most prognostic factor in HPV-positive HNSCC patients compared to the presence of ctDNA. Moreover, the CTC-positive/ctDNA-negative group showed the most unfavorable PFS(p=0.02). The cfDNA levels were significantly lower in the CTC-positive/ctDNA-negative group (p=0.01). Previous studies have reported that cfDNA is primarily released by tumor apoptosis. The low levels of cfDNA in CTC-positive/ctDNA-negative patients suggest that CTCs may be shed into the peripheral bloodstream in a state of survival.Thus, our study provides new insights into predictive biomarkers of treatment resistance in patients with HPV-positive HNSCC.

#1981 Analytical validation of ANGLE's combined IF and FISH assay for assessment of HER2 in circulating tumor cells.

Mariacristina Ciccioli[1], Alex Young[1], Laila Vlietinck[1], Bethan Edwards[1], Chassidy Johnson[2], Anne-Sophie Pailhes-Jimenez[1]

[1]ANGLE Europe Limited, Guildford, United Kingdom,[2]BioView Inc., Billerica, MA

Background: Evaluation of HER2 status in tissue biopsies, through immunohistochemistry (IHC) and, in equivocal cases, fluorescence in-situ hybridization (FISH), is routinely performed to guide diagnosis and treatment decisions for breast cancer (BC) patients. Tissue biopsy is an invasive procedure for which re-examination is difficult and not commonly performed. Conversely, liquid biopsy is minimally invasive, with unbounded opportunity for recurrent sample collection, allowing monitoring of circulating tumor cells (CTCs). This study aimed to validate a Research Use Only assay by which HER2 immunofluorescence (IF) and FISH are performed on the same CTCs in each sample.
Method: Analytical performance of the test was established using contrived samples consisting of HER2+ (SKBR3) and HER2- (MCF-7 and Hs 578T) cultured cancer cells spiked into healthy volunteer blood samples, drawn in Streck Cell-Free DNA tubes. Blood was separated within 144 hours post-draw on ANGLE's Parsortix® instrument, a marker-independent microfluidic device which isolates CTCs based on size and deformability. Harvests were spun onto CellKeep™ slides and stained with ANGLE's HER2 IF panel, comprising a nuclear dye, epithelial, mesenchymal and leukocyte markers and an anti-HER2 antibody. Slides were imaged on a BioView Allegro Plus, a platform equipped with artificial intelligence for automated fluorescence imaging, quantitative cellular measurements, CTC candidate identification and reporting. IF stained slides were destained and probed for ERBB2 and CEP17 genes by FISH. Using the Allegro Plus single cell relocation capabilities, CTCs identified by IF were relocated and imaged at 40× to capture HER2 and CEP17 foci. Results. The workflow was performed on a total of 186 contrived samples to determine analytical performance of the assay. Linearity, specificity, sensitivity, repeatability, reproducibility (inter-donor, operators, days and reagents) and endogenous interference (Albumin, Haematocrit and Triglycerides) were assessed. The IF assay was observed to be linear over the range of 0 - 1000 cells, with R2 of 0.96 and degree of non-linearity of 0.004. Analytical specificity and sensitivity of all IF markers were >96%. Analytical specificity and sensitivity of the FISH assay were 100%. The assay was shown to be repeatable and reproducible across spiked donors, operators, days and reagents. Endogenous substances investigated did not affect qualitative results of the assay.
Conclusion: This study demonstrated that ANGLE's combined IF and FISH assay is a robust method for determination of HER2 protein expression and concomitant interrogation of HER2 gene amplification on the cancer cells. This workflow will be utilized to analyze CTCs isolated from a cohort of ~100 metastatic BC patients to evaluate its clinical feasibility and validity and these results will be reported at the AACR annual meeting.

#1982 Transcriptomic subtype identification of circulating tumor cells by label-free capture and single-cell RNA sequencing.

Yoon-Tae Kang, Patricia Schnepp, Rashika Shrestha, Rain Yu Hong, Errile Pusod, Will Chow, Floyd Watkins, Kyle Thurston, Dominique Winston, Marta Gonzalez-Plasky, Angelica Olcott, David Coe, Michelle Racey, Elizabeth Dreskin

Bio-Rad Laboratories, Hercules, CA

Introduction: Single-cell RNA sequencing (scRNA-Seq) of rare cells, such as circulating tumor cells (CTCs), is critical for identifying various cell subtypes and understanding intercellular heterogeneity at the genetic level. Despite recent advances in scRNA-Seq, transcriptomic profiling of single CTCs has been technically demanding due to its limited cell utilization and background noise from unwanted cells during sequencing. In addition, conventional CTC isolation methods often miss important rare cell subtypes due to their low abundance and reliance on specific surface markers for detection. This limitation hinders comprehensive transcriptomic analysis, especially for CTCs undergoing the critical epithelial-mesenchymal transition (EMT), which may not express typical epithelial markers. To address these challenges, we present an optimized workflow that integrates high-purity label-free CTC capture with in-droplet barcoding-based scRNA-seq to achieve higher cell utilization and lower background sequencing noise.
Methods: To model heterogeneous CTC subpopulations at different EMT status, samples were prepared by spiking in two types of cancer cells, MCF7 (epithelial CTCs) and HeLa (mesenchymal CTCs), into a total of 7.5 ml of whole blood from a healthy donor at a concentration of 100 cells/ml. CTCs were captured using the Genesis Cell Isolation System and the enriched CTCs were further purified to reduce leukocyte contamination or red blood cell (RBC) contamination using CD45 pre-conjugated magnetic beads or RBC lysis reagent, respectively. The processed CTC sample was then used to create scRNA-Seq libraries following the Bio-Rad ddSEQ Single-Cell 3' RNA-Seq Kit protocol, which includes single-cell in-droplet barcoding, reverse transcription, and cDNA synthesis.
Results: This Genesis System allowed for capturing both epithelial and mesenchymal CTCs to be sequenced. After sequencing and Omnition Software Analysis, individual cells were visualized using a Uniform Manifold Approximation and Projection (UMAP) plot and clustering analysis showed a distinct separation between epithelial and mesenchymal CTCs while each different cell population revealed expression of representative genes for each cell type.
Discussion and Conclusions: By combining rare single cell capture with scRNA-seq library prep and analysis, our workflow provides an easy, highly sensitive and cost-effective solution for CTC single-cell transcriptomic studies, compatible with commercially available instruments and kits. This scRNA-seq workflow can be integrated into a broad spectrum of applications in liquid biopsy across many different cancer types and empowering researchers to gain deeper insights into tumor heterogeneity and gene expression patterns with greater efficiency and within the same budget.

#1983 Phase II study of rucaparib and nivolumab in patients with leiomyosarcoma.

Carmelina Charalambous, Ronak H. Shah, Michael F. Berger, Sujana Movva

Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Rucaparib, a small molecule inhibitor of PARP, is approved for treating patients with refractory deleterious BRCA mutations, while nivolumab, a human monoclonal antibody targeting PD-1, is approved for various cancers. This phase II study aimed to explore whether rucaparib could enhance the immune response of nivolumab in patients with leiomyosarcoma (LMS). Here, we present an exploratory analysis of circulating tumor DNA (ctDNA) dynamics and imaging-based responses.
Methods: Twenty patients with LMS were enrolled in the trial and received rucaparib (600 mg twice daily for 28 days) in combination with nivolumab (480 mg day 1 of every 4-week cycle). Plasma samples were collected for ctDNA analysis at baseline and at weeks 5, 9, 17, 25, and the end of treatment, utilizing the MSK-ACCESS cfDNA assay to detect alterations across 129 genes. Matched tumor tissue was sequenced using MSK-IMPACT. Treatment continued until disease progression, unacceptable toxicity, or patient withdrawal. The primary endpoint was efficacy, measured by best response by week 24, according to RECIST 1.1 criteria.
Results: In this exploratory analysis in LMS patients, ctDNA was detected at baseline in 100% of samples. Concordance analysis between MSK-ACCESS and MSK-IMPACT revealed a baseline concordance of 63.6% in terms of the specific mutations detected, which increased to 72.7% when considering all plasma samples. The ctDNA dynamics were compared to RECIST imaging. Among the patients, eight exhibited RECIST-confirmed progression at the first imaging assessment, seven of whom had increasing ctDNA levels. Additionally, five patients discontinued the study due to clinical progression despite RECIST indicating stable disease, with 80% (4 of 5) showing rising ctDNA levels. This study highlights the limitations of using RECIST criteria and suggests that ctDNA dynamics may be a more sensitive indicator of disease progression. Baseline and post-chemotherapy cycle-2 ctDNA levels have been previously associated with survival outcomes in LMS. Consistently, our analysis revealed that ctDNA levels at week 5 predicted radiologic response, with 90% of patients experiencing disease progression showing increases in ctDNA. Notably, one patient who achieved a partial response demonstrated undetectable ctDNA at week 5, which remained so until treatment discontinuation due to toxicity.
Conclusion: The combination of ctDNA dynamics with RECIST imaging shows potential for improving the monitoring of patient response and predicting disease progression in LMS. Overall, while the study underscores the limitations of the rucaparib and nivolumab combination, ctDNA appeared to predict early progression and response to therapy and was a useful adjunctive test in cases where the treatment benefit was unclear. Further study is needed to validate these findings.

#1984 Correlating circulating tumor cell dynamics with clinical outcomes in patients with advanced stage melanoma.

Vincent T. Ma[1], Yeonhee Park[2], Matthew C. Mannino[1], **Jennifer L. Schehr**[1], Alexander Birbrair[3], Joshua M. Lang[1], George S. Zhao[4]

[1]Medicine; Division of Hematology, Medical Oncology, and Palliative Care, University of Wisconsin Carbone Cancer Center, Madison, WI,[2]Biostatistics and Medical Informatics, University of Wisconsin Carbone Cancer Center, Madison, WI,[3]Dermatology, University of Wisconsin Carbone Cancer Center, Madison, WI,[4]Human Oncology, University of Wisconsin Carbone Cancer Center, Madison, WI

Background: Liquid biopsies in advanced solid tumors can provide a unique noninvasive approach to monitor disease burden over time. Detection and capturing circulating tumor cells (CTCs) in melanoma patients have faced many challenges and limitations. In our study, we use our novel, high-sensitivity, CTC capturing technology to assess numerical heterogeneity of serially collected CTCs in advanced stage melanoma patients undergoing systemic treatment and correlate CTC dynamics with tumor response and risk of disease progression.

Methods: We utilize a unique microfluidic exclusion-based sample preparation (ESP) technology at the University of Wisconsin (Madison) to isolate CTCs from patients with stage III/IV melanoma. Capture specificity of antibodies against melanoma associated proteins, NG2 (MCSP) and CD146 (MCAM) were used. We prospectively collected plasma samples from patients and evaluated the quantitative and qualitative change in numerical CTCs at baseline to 1-3 months after the start of systemic therapy. Based on CTC dynamics, a logistic regression model was used to evaluate the odds of an objective response (partial response and complete response per RECIST v1.1) and a cox proportional hazard model was used to investigate its effect on progression free survival (PFS).

Results: 35 patients were evaluated and longitudinally followed. Patients were treated with immune checkpoint inhibitors (29), BRAF/MEK targeted therapy (4), or tebentafusp-tbn (2). Median follow up was 13.1 months. A range of 0 and 531 CTCs were detected at baseline (i.e. before start of treatment). Patients with an objective response had a mean slope of -22.2 CTCs/month and patients with stable disease or progressive disease had a mean slope of +10.4 CTCs/month (Wilcox p=0.0008). A qualitative decrease in CTC count was associated with an objective response (OR 6.50, 95% CI 1.80-41.57, p=0.0004) and a longer PFS (HR 0.38, 95% CI 0.15-0.91, p=0.031) compared to an increase in CTC count from baseline to 1-3 months after starting systemic therapy.

Discussion: Our study demonstrates the prognostic value of CTC enumeration in advanced stage melanoma patients. Using our novel ESP technology, we are able to successfully capture CTCs and correlate CTC dynamics with clinical outcomes, including objective response and PFS. A larger sample cohort is planned to validate its utility in predicting treatment outcomes in clinical practice.

#1985 5hmC-sequencing of matched cfDNA and tissue from men with mCRPC is concordant and identifies loss of AR signaling in NEPC and DNPC.

Rensheng Wan[1], Raunak Shrestha[1], Gulfem Guler[2], Yuhong Ning[2], Aishwarya Subramanian[1], Adam Foye[3], Meng Zhang[1], Xiaolin Zhu[3], Thaidy Moreno-Rodriguez[4], Haolong Li[1], Shuang G. Wyatt[7], David Quigley[4], Samuel Levy[2], Eric Small[3], Felix Feng[1], Martin Sjostrom[1]

[1]Radiation Oncology, UCSF - University of California San Francisco, San Francisco, CA,[2]Clearnote Health, San Diego, CA,[3]Medicine, UCSF - University of California San Francisco, San Francisco, CA,[4]Urology, UCSF - University of California San Francisco, San Francisco, CA,[5]Human Oncology, University of Wisconsin-Madison, Madison, WI,[6]Hematology and Oncology, University of Michigan Rogel Cancer Center, Ann Arbor, MI,[7]Urologic Sciences, University of British Columbia, Vancouver, BC, Canada

Purpose: In this study, we aimed to study whether 5-hydroxymethylcytosine sequencing (5hmC-seq) of circulating cell-free DNA (cfDNA) predicts gene expression in tumor tissue and can distinguish tumor subtypes defined in tissue in metastatic castration-resistant prostate cancer (mCRPC).

Methods: We performed 5hmC-seq on cfDNA samples from 86 mCRPC patients with matched tumor tissue profiled with 5hmC-seq (N=49) and RNA-sequencing (N=86) and we compared cfDNA 5hmC levels with matched tissue 5hmC levels and tissue gene expression. We developed a 5hmC-seq-based circulating tumor-DNA fraction (ctDNA-fraction) classifier and assessed if gene-level and pathway-level differences between mCRPC subtypes could be detected in cfDNA using a differential 5hmC-analysis adjusting for ctDNA-fraction.

Results: Patients with androgen receptor (AR)-positive prostate cancer (ARPC) exhibited lower ctDNA-fraction, whereas patients with neuroendocrine (NE) prostate cancer (NEPC) and double-negative prostate cancer (DNPC) tumors displayed higher ctDNA-fraction (median ctDNA-fraction across subtypes 0.09 [95% confidence interval (CI), 0.04-0.14] (ARPC), 0.41 [95% CI, 0.18-0.64] (NEPC) and 0.37 [95% CI, 0.30-0.44] (DNPC), pairwise t-test $P = 5.5 \times 10^{-2}$ (ARPC vs. NEPC) and $P = 8.8 \times 10^{-4}$ (ARPC vs. DNPC) respectively). Nearly 30% of all protein-coding genes showed significant concordance between cfDNA 5hmC and tissue RNA-seq, after adjusting for ctDNA-fraction (adjusted $p<0.05$ in linear model), which were enriched in the androgen response, EGFR, and ERBB signaling pathways. Compared to ARPC, NEPC displayed upregulated 5hmC enrichment in NE-related genes, and downregulated androgen response and MYC target pathways in cfDNA. As expected, an NE pathway score calculated from cfDNA 5hmC was significantly different between tissue-confirmed ARPC and NEPC ($p=0.03$). Double-negative prostate cancer (DNPC) showed downregulated androgen response and MYC targets and upregulated epithelial cell pathways compared to ARPC in cfDNA. Furthermore, DNPC indicated an aggressive phenotype with cell proliferation pathways even more upregulated when compared to NEPC.

Conclusions: We created a cohort of 86 matched tissue and cfDNA samples and demonstrated concordance for a significant number of transcribed protein-coding genes. Expected biological differences previously seen in tissue between NEPC and ARPC were readily detected via 5hmC profiles in cfDNA. Furthermore, DNPC showed a clear downregulation of androgen response signaling in cfDNA, indicating the possibility to identify a group of patients in addition to classical NEPC that may have reduced response to standard androgen-targeting agents. Future work will aim to develop single-sample multi-class subtype classifiers and evaluate differences in prognosis and treatment response based on cfDNA-based subtyping.

#1986 A novel single-cell CTC platform enables first liquid biopsy for ADC target expression profiling.

Antoine Herzog[1], Xiaokang Li[1], Mattia Lazzaroni[1], Salome Thuler[1], Sylvie Andre[2], Marina Alexandre Gaveta[2], Stefano Varricchio[1], Olivier Dubey[1], Bastien Vergnet[1], Krisztian Homicsko[2]

[1]Parithera SA, Epalinges, Switzerland,[2]Department of Oncology, CHUV, Lausanne, Switzerland

Introduction: Despite the expanding landscape of antibody-drug conjugates (ADCs), patient selection remains challenging due to limited liquid biopsy methods for target assessment. Current tissue approaches lack longitudinal assessments and provide insufficient resolution of target expression heterogeneity that could inform ADC selection. We present the first liquid biopsy platform specifically designed for ADC therapy, designed to inform treatment selection through single-cell RNA sequencing of circulating tumor cells (CTCs). This platform provides comprehensive profiling of target antigen expression across multiple ADC targets, establishing the foundation for target expression-based ADC selection. Beyond initial target profiling, this approach could provide a foundation for studying target dynamics and potential resistance mechanisms.

Methods: 10 patients with various solid tumors were consented for research from the observational clinical study CTC-M. Blood samples (3x10mL) were collected and processed using either our proprietary platform or a combination of existing commercial instruments. Individual CTCs were barcoded and analyzed via single-cell RNA sequencing to profile expression of multiple ADC targets (including HER2, TROP2, Nectin-4, and c-MET) along with global transcriptome patterns. Patient demographic and disease characteristics were collected in a de-identified database.

Results: Single-cell RNA sequencing of isolated CTCs revealed detection of ADC target expression across various cancers. Our fully automated platform delivers barcoded CTCs ready for single-cell sequencing in under 1 hour compared to 6+ hours for existing workflows, integrating both isolation and molecular barcoding steps. The novel isolation technology achieves a 10-100X improvement in CTC purity versus current methods, overcoming a key technological hurdle compared to other systems. The platform maintains plasma integrity throughout processing, enabling simultaneous CTC and ctDNA analysis from a single blood draw.

Conclusions: We have developed the first integrated platform enabling rapid, automated preparation of CTCs for single-cell ADC target profiling. Our workflow demonstrates significant advantages in speed, purity, and cost-effectiveness, while enabling concurrent CTC and ctDNA analysis from a single blood draw. This technology establishes the foundation for comprehensive liquid biopsy-based ADC target assessment, addressing a critical unmet need in precision oncology.

#1987 Circulating tumor cell-based molecular responses stratify EGFR-TKI efficacy in EGFR-mutant lung cancer patients.

Seoyoung Lee[1], Chaeyeon Kim[2], Chang Gon Kim[3], Min Hee Hong[3], Mina Han[2], Wonrak Son[2], Gamin Kim[2], Minseok Kim[4], Hye Ryun Kim[3]

[1]Gangnam Severance Hospital, Seoul, Korea, Republic of,[2]Yonsei university college of medicine, Seoul, Korea, Republic of,[3]Yonsei cancer center, Seoul, Korea, Republic of,[4]CTCELLS Inc., Seoul, Korea, Republic of

Background: Liquid biopsy offers a minimally invasive alternative to tissue biopsy, enabling therapeutic monitoring, precision medicine-based treatment decisions, and detection of tumor heterogeneity. Circulating tumor cell (CTC) analysis is a promising minimally invasive biomarker for monitoring treatment response and stratifying prognosis in *EGFR*-mutant non-small cell lung cancer (NSCLC). Meanwhile, detection of CTCs in peripheral blood is challenging due to their rarity and the limitations of both marker-dependent and marker-independent isolation techniques, which may compromise sensitivity and specificity. Continuous Centrifugal Microfluidics - Circulating Tumor Cell Disc (CCM-CTCD) enriches heterogeneous CTCs through automated microfluidic extraction and leukocyte depletion without interrupting centrifugation.

Method: In this study, 77 *EGFR*-mutant NSCLC patients treated with EGFR-TKIs were enrolled. CTCs were isolated using CCM-CTCD before and after EGFR-TKI treatment and compared with plasma cfDNA and tissue biopsy for *EGFR* mutation analysis. CK-positive, CD45-negative CTCs were isolated and visualized using immunofluorescence staining. Patients were categorized as CTC molecular responders or non-responders based on a ≥30% reduction in CTC count from baseline. Progression-free survival (PFS) and tumor burden changes were evaluated.

Results: The CCM-CTCD method showed concordance with Cobas® liquid biopsy but demonstrated superior sensitivity in detecting *EGFR* mutations. Mutational discordance between tissue, plasma cfDNA, and CTCs highlighted tumor heterogeneity. CTC molecular responders had significantly longer median PFS (46.3 vs. 12.2 months) and greater tumor burden reduction (-39.2% vs. -32.2%, $p = 0.025$) compared to non-responders. Multivariable analysis revealed that CTC molecular response was an independent predictor of improved PFS (HR 0.45, $p = 0.023$). Additionally, a non-significant trend was observed toward shorter PFS in patients receiving later-line treatments compared to first-line (HR 1.30, $p = 0.523$), first- or second-generation EGFR-TKIs compared to third-generation EGFR-TKIs (HR 1.59, $p = 0.196$), and in those with a history of smoking (HR 1.45, $p = 0.300$). CTC profiling was found to complement traditional methods for identifying genomic alterations and predicting early progression.

Conclusion: CTC analysis using CCM-CTCD demonstrates potential as a reliable tool for predicting treatment response and stratifying prognosis in *EGFR*-mutant NSCLC. Stratifying patients based on CTC molecular response may guide treatment intensification strategies, offering a pathway for risk-adapted precision oncology. Prospective studies are warranted to validate these findings and optimize therapeutic decision-making.

#1988 Detection of minimal residual disease using cell free plasma DNA to guide maintenance therapy in high grade serous ovarian cancer.

Pamela Soberanis Pina[1], Stephenie D. Prokopec (co-primary author)[1], Eduardo Gonzalez Ochoa[1], Derek Wong[1], Tracy Stockley[1], Amit Oza[1], Neesha C. Dhani[1], Robert C. Grant[1], Nitthusha Singaravelan[1], Alexander Fortuna[2], Bernard Lam[2], Ilinca Lungu[2], Madhuran Thiagarajah[2], Faridah Mbabaali[2], Sharanjit Singh[2], Danny Xie[3], Steven Siman[3], Judy Quintos[3], Valerie Bowering[3], Lisa Wang[3], Stephanie Lheureux (co-corresponding author)[3], Trevor Pugh (co-corresponding author)[3]

[1]Medical Oncology, UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]Medical Oncology, Princess Margaret Hospital, Toronto, ON, Canada

Purpose: Optimal maintenance strategy following re-challenge with platinum-based chemotherapy in patients with relapsed high grade serous ovarian cancer (HGSOC) after PARP inhibitor (PARPi) therapy remains to be established. Use of cell-free DNA (cfDNA) sequencing to detect minimal residual disease (MRD) has emerged as a promising strategy to identify patients at higher risk of relapse who might benefit from more timely, additional treatment.
Methods: Nineteen patients with histologically confirmed TP53 mutant HGSOC with platinum sensitive relapse were enrolled into an interventional cfDNA study selecting for patients with confirmed MRD (NCT04510584). Each patient provided a blood sample at the end of standard-of-care platinum treatment (pre or post cycle 6) from which cfDNA was analyzed using targeted sequencing (10,000X coverage) using a 10 gene panel. As a comparator, 30X cell-free whole genome sequencing (cfWGS) was performed for tumour-informed genome-wide mutational sampling benchmarked against 13 platinum-sensitive HGSOC patients and 25 healthy controls.
Results: The targeted panel approach detected a somatic TP53 mutation in 1/19 patients above the limit of detection of 1%. In contrast, 30X cfWGS identified evidence of MRD in 8/19 patients (47%) with detection of 319-2,327 known somatic mutations sampled genome-wide (including single-read evidence for 4 somatic TP53 mutations). Genome-wide fragmentomics approaches further identified MRD in 17/19 platinum-resistant patients (89%).
Conclusions: cfWGS can be used to examine numerous features capable of identifying patients likely to experience rapid relapse of high grade serous ovarian cancer.

#1989 Heterogeneity of epithelial, mesenchymal, progenitor, and stem cell phenotypes on CTCs correlates to clinical outcomes in metastatic cancer patients.

Alexis B. Duffy[1], Massimo Cristofanilli[2], Carolina Reduzzi[2], Cha-Mei Tang[3], Saranya Chumsri[4], Susan Tsai[5], Mohammed Aldakkak[6], Daniel L. Adams[1]

[1]Creatv MicroTech, Inc., Monmouth Junction, NJ,[2]Weill Cornell Medicine, New York, NY,[3]Creatv MicroTech, Inc., Potomac, MD,[4]Mayo Clinic Cancer Center, Jacksonville, FL,[5]Ohio State University, Columbus, OH,[6]Medical College of Wisconsin, Milwaukee, WI

Circulating tumor cells (CTCs) are cancer cells that detach from tumors, enter the blood and seed distant sites. CTCs spread as single cells, or cluster aggregates, and can be heterogenous with differing biological phenotypes, i.e. epithelial, mesenchymal, progenitor, & stem cell. Three clinically relevant CTC subtypes are often described in patients (pts) 1) CTCs with normal epithelial traits (strong filamentous cytokeratin (CK+ & CD45-/CD14-), 2) Epithelial-mesenchymal CTCs (EMTs), cancer cells with downregulated epithelial & upregulated mesenchymal traits (low diffused CK+, CD45-/CD14-) and 3) tumor-macrophage fusion cells (TMFCs), cancer cells that fuse with macrophages (polynucleated DAPI+, diffuse CK+ and CD14+/CD45+). To better elucidate the biological and clinical importance of the 3 CTC subtypes, we isolated CTCs by a marker agnostic method from the blood of n=49 metastatic cancer pts. We then enumerated and phenotypically subtyped CTCs comparing clinical utility of clustering and CTC heterogeneity over 2 years. Peripheral blood samples were collected from 49 metastatic cancer pts, breast (n=38), pancreatic (n=9), colon (n=3), lung (n=1), and prostate (n=1). Whole blood (7.5mL) was filtered by size exclusion using CellSieve microfilters and fluorescently stained for CD45, CD14, CK, and DAPI to identify CTCs, EMTs and TMFCs. Cells were imaged, enumerated and fluors quenched by the QUAS-R technique; followed by re-stained for CD44, CD24, CD133, CD144, N-Cadherin, EpCAM, and Vimentin. Markers were categorized as negative, low, medium, or high. A heterogeneity biomarker score was developed as high, 2-3 log deviations between marker expression, or low 0-1. Pt progressive free survival (PFS) and overall survival (OS) were analyzed over 2 years. CTCs were found in 40% of pts, EMTs in 51%, & TMFCs in ~93%. For subtyping, CD44 was in CTCs 88%, EMTs 59%, & TMFCs 91%; CD24 in CTCs 40%, EMTs 41%, & TMFCs 6%; CD133 in CTCs 100%, EMTs 8%, & TMFCs 100%; CD144 in CTCs 100%, EMTs 77%, & TMFCs 82%; N-cadherin in CTCs 100%, EMTs 0%, & TMFCs 45%; Vimentin in CTCs 51%, EMTs 100%, & TMFCs 83%; EpCAM in CTCs 74%, EMTs 12%, & TMFCs 20%. CTCs and EMTs were found to have high heterogeneity in 30% of samples in both individual cells and clusters, with a high biomarker heterogeneity significantly correlated with poorer outcomes (PFS: HR=15.4, p=0.0014, CI=3.4-68.9; OS: HR=12.4, p=0.0056, CI=2.6-59.1). TMFCs were found to have high heterogeneity, 40% of samples, but this was not correlated with outcomes. In this pilot study, it appeared that isolated CTC, EMTs and TMFCs subtypes have differing heterogenous expressions of epithelial, mesenchymal, progenitor, and stem cell markers. Further, high rates biomarker heterogeneity in CTCs and EMTs, but not TMFCs, correlated with faster rates of progression & death. Larger validation experiments with biomarker stratification is ongoing.

#1990 New diagnostic technology to detect myeloma cells in the blood of multiple myeloma patients.

Jihyun Lee, Hoin Kang, Soee Kim, Ju Bi Lee, Min-Ji Song, Jung Won Kim

Cytogen, Inc., Seoul, Korea, Republic of

Introduction: Androgen-receptor splice variant 7 (AR-V7) is constitutively activated isoform of AR and has been associated with the resistance towards AR targeting therapies and development into metastatic castration-resistant prostate cancer (mCRPC). Analysis of AR-V7 expression is an important step in prostate cancer diagnosis and determining the therapeutic drug, but the detection of AR-V7 with tissues has limitations such as clinical challenge to poorly accessible tumor tissues before and after treatment. Here, we developed the method of AR-V7 detection in circulating tumor cells (CTC) after isolation with CytoGen's. Smart Biopsy CTC isolator by droplet digital polymerase chain reaction (ddPCR) with high sensitivity and specificity, overcoming the limitations of tissue biopsy.
Method: Sensitivity and specificity were tested using AR-V7 positive cells (VCaP or 22Rv1) and negative cells (PBMC). Limit of detection (LOD) test of AR-V7 expression was performed that AR-V7 positive cells (10 and 5 cells) were spiked into human blood sample (5mL, healthy donor) to mimic CTC after isolation by CytoGen's Smart Biopsy CTC isolator, subsequently AR-V7 expression was tested with ddPCR. All ddPCR processes included droplet making and reading for each assay were performed on the QX200 ddPCR System (Bio-Rad). For the clinical evaluation, blood samples (each 20mL) of metastatic prostate cancer patients (n=5) were tested with IF assay (5mL) to count CTC number and ddPCR (15ml) to analyze the expression of AR-V7.
Results: In in vitro spiking test, AR-V7 expression was clearly detected in the LOD test of AR-V7 positive cells spiked into human blood and was not detected at all in the negative controls. In clinical evaluation study, isolation of CTC from the blood of prostate cancer patients using CytoGen's Smart Biopsy CTC isolator was confirmed from the result of IF assay, and the expression of AR-V7 in CTC was successfully detected by ddPCR. IF analysis identified 3 or more CTCs in 5 ml of blood from all patients, and expression of AR-V7 was verified by ddPCR in 4 out of 5 mCRPC patients.. These results demonstrate that it is possible to clearly detect the presence of RNA variants is related with drug resistance in mCRPC patients using liquid biopsy, utilizing CTCs, which exist in only very small quantities in the blood.
Conclusions: AR-V7 expresses only a part of cancer tissue, so it is difficult to accurately diagnose with traditional histological assays. Detection of AR-V7 (RNA signature) in intact live CTC might overcome limitations of tissue biopsy. In this study, we developed the method to detect AR-V7 in CTC, and presented the results of verifying AR-V7 expression using in vitro models and blood of mCRPC patients. Expanded clinical validation study with more patients' samples and clinical correlation between AR-V7 expression in CTC and clinical outcome will be performed and analyzed.

#1991 Circulating tumor cells migrate beyond the central nervous system in glioblastoma multiforme.

J. Srovnal[1], P. Stejskal[1], A. Rehulkova[1], A. Srovnalova[1], O. Kalita[2], M. Slachta[2], M. Hajduch[1];
[1]Palacky University. Faculty of Medicine, Olomouc, Czech Republic, [2]Olomouc University Hospital, Olomouc, Czech Republic

Introduction: The concept of liquid biopsy (LB) has garnered significant attention over the past decade, offering the potential to transform cancer care. However, its clinical utility requires further validation through rigorous trials. This study focuses on glioblastoma multiforme (GBM), an aggressive and fatal subtype of central nervous system malignancies. Circulating tumor cells (CTCs), which originate from primary tumors and migrate via peripheral blood to distant sites, are closely linked to tumor spread and recurrence. In GBM, systemic dissemination is rare due to challenges like the blood-brain barrier (BBB), lack of lymphatic drainage, and the disease's short survival timeframe. Despite these challenges, noninvasive detection of CTCs holds promise for diagnostic, predictive, and prognostic applications.
Materials and Methods: Peripheral blood samples from 110 curatively resected GBM patients were collected preoperatively using Cell-Free DNA BCT® tubes (Streck, Inc.) to preserve cell stability. CTC identification was conducted with the CytoTrack CT11TM (2/C) system, a semi-automated immunofluorescence microscopy platform employing glial fibrillary acidic protein (GFAP), vimentin, CD45 immunostaining, and DAPI counterstaining. The tumor origin of CTCs was confirmed through aCGH analysis using DNA extracted from single CTCs and matched FFPE tumor tissues in 10 GBM patients. A preliminary Kaplan-Meier survival analysis was performed on 55 patients with a follow-up period exceeding two years, stratified by CTC presence.
Results: We evaluated peripheral blood samples from 110 GBM patients, identifying CTCs or cancer cell clusters in 35% of cases. The aCGH genomic profiling verified the tumor origin of CTCs in 90% of cases (9/10). Kaplan-Meier survival analysis revealed no significant correlation between CTC presence and overall survival of GGM patients. This outcome may be attributed to the generally short survival associated with GBM, which could improve with advancements in oncology and palliative care. Another possibility is the suppression of tumor cell growth outside the CNS.
Conclusions: This study confirms the presence of CTCs in the peripheral blood of 35% of GBM patients, although currently without prognostic significance. Patient enrollment and the collection of clinical data are ongoing. Acknowledgments: This work was supported by the European Union - Next Generation EU (LX22NPO5102), Palacký University Olomouc (LF UP 2024_007), and the SALVAGE project (CZ.02.01.01/00/22_008/0004644).

#1992 Detection rate for *ESR1* mutations is higher in CTC-derived genomic DNA than in paired plasma cfDNA samples as revealed by ddPCR.

S. Smilkou[1], A. Ntzifa[1], V. Tserpeli[1], I. Balgkouranidou[2], A. Papatheodoridi[3], E. Razis[4], H. Linardou[5], C. Papadimitriou[6], A. Psyrri[7], F. Zagouri[3], S. Kakolyris[2], **E. Lianidou**[1];

[1]Analysis of Circulating Tumor Cells, Laboratory of Analytical Chemistry, Department of Chemistry, University of Athens, Athens, Greece, [2]University General Hospital of Alexandroupolis, Department of Medical Oncology, Alexandroupolis, Greece, [3]Alexandra Hospital, Department of Clinical Therapeutics, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [4]Third Department of Medical Oncology, Hygeia Hospital, Athens, Greece, [5]Metropolitan Hospital, Oncology Unit, Athens, Greece, [6]Oncology Unit, Aretaieion University Hospital, National and Kapodistrian University of Athens, Athens, Greece, [7]Department of Medical Oncology, Second Department of Internal Medicine, "Attikon" University General Hospital, Athens Medical School, National and Kapodistrian University of Athens, Athens, Greece

Plasma cell-free DNA (cfDNA) analysis to track estrogen receptor 1 (*ESR1*) mutations is highly beneficial for the identification of tumor molecular dynamics and the improvement of personalized treatments for patients with metastatic breast cancer (MBC). Plasma cfDNA is, up to now, the most frequent liquid biopsy analyte used to evaluate *ESR1* mutational status. Circulating tumor cell (CTC) enumeration and molecular characterization analysis provides important clinical information in patients with MBC. In this study, we investigated whether analysis of CTCs and circulating tumor DNA (ctDNA) provide similar or complementary information for the analysis of *ESR1* mutations. We analyzed both plasma cfDNA (*n*=90) and paired CTC-derived genomic DNA (gDNA; *n*=42) from 90 MBC patients for seven *ESR1* mutations. Eight out of 90 (8.9%) plasma cfDNA samples tested using the ddPLEX Mutation Detection Assay (Bio-Rad), were found positive for one *ESR1* mutation, whereas 11/42 (26.2%) CTC-derived gDNA samples were found positive for at least one *ESR1* mutation. Direct comparison of paired samples (*n*=42) revealed that the *ESR1* mutation rate was higher in CTC-derived gDNA (11/42, 26.2%) than in plasma cfDNA (6/42, 14.3%) samples. Our results, using this highly sensitive ddPLEX assay, reveal a higher percentage of mutations in CTC-derived gDNAs than in paired ctDNA in patients with MBC. CTC-derived gDNA analysis should be further evaluated as an important and complementary tool to ctDNA for identifying patients with *ESR1* mutations and for guiding individualized therapy.

#1993 A translational circulating tumor cell drug sensitivity screening platform for integrated drug development and precision medicine: Results from Antrodia cinnamomea profiling.

Chia-Liang Yen, Pei Yu Chen, **Shih Pei Wu**

CancerFree Biotech, Jersey City, NJ

Reliable preclinical drug sensitivity screening platforms are crucial for advancing precision medicine and drug development. We have established a circulating tumor cell (CTC) drug sensitivity screening platform that enables comprehensive applications, including treatment response prediction and molecular profiling. To demonstrate the platform's utility, we evaluated multiple compounds including Antrodia cinnamomea (AC) and standard chemotherapy across various cancer types.

For the AC study, CTCs were isolated from patients (n=9) with brain tumors (n=3), osteosarcoma (n=2), renal cell carcinoma (n=1), small cell lung cancer (n=1), breast cancer (n=1), and colon adenocarcinoma (n=1). CTCs were expanded using the E.V.A. Select platform with biomimetic 3D surface structure. Cells were treated with AC (0-125 μg/mL) and responses were compared with platinum-based chemotherapy (cisplatin/carboplatin). Cell viability was assessed using CellTiter-Glo® luminescent assay after 72 hours. Our platform has also demonstrated capability for next-generation sequencing in separate drug discovery cohorts. Data analysis was assisted by artificial intelligence tools (Claude, Anthropic).

AC demonstrated consistent dose-dependent cytotoxicity, with survival rates at 125 μg/mL ranging from 5.7-13.8% across cancer types. Compared to platinum drugs (survival rates 22-67%), AC showed stronger or comparable efficacy. Brain tumor samples showed particular sensitivity to AC (125 μg/mL: 5.7-13.8% survival vs. cisplatin: 66.5% survival). Osteosarcoma samples demonstrated consistent AC response (125 μg/mL: 6.1-10.0% survival vs. carboplatin: 31.4-43.5% survival). The platform has successfully supported both drug sensitivity screening and molecular profiling across multiple drug development programs.

This study showcases our platform's versatility in drug sensitivity screening and comprehensive drug development applications. The E.V.A. Select platform supports both drug response profiling and molecular characterization, making it a valuable tool for drug discovery and precision medicine applications. These capabilities enable systematic evaluation of novel compounds while supporting mechanistic understanding through molecular analyses.

#1994 Performance evaluation of the Smart biopsy™ CTC isolator for circulating tumor cells' isolation in liquid biopsy.

Soee Kim, Jihyun Lee, Hoin Kang, Ju Bi Lee, Minseon Hwang, Keoung Sun Son, Jung Won Kim

Cytogen, Inc., Seoul, Korea, Republic of

Introduction: Current cancer diagnostic methods primarily involve tissue biopsies, which are invasive and may not fully reflect tumor heterogeneity. Liquid biopsy, a minimally invasive alternative, has emerged as a promising solution to overcome the limitations of tissue biopsies, offering advantages such as real-time monitoring and reduced patient discomfort for cancer diagnosis. Therefore, the development of reliable, non-invasive diagnostic platforms is crucial for effective cancer management. CytoGen has developed the Smart biopsy™ CTC isolator, a liquid biopsy system designed to isolate circulating tumor cells (CTCs) in blood.. However, since CTCs are present in very low quantities in the blood, it is essential to consider key metrics such as the limit of detection (LoD) and cell recovery rates when developing liquid biopsy-based cancer diagnostic platforms. This study aims to evaluate the performance of the Smart biopsy™ CTC isolator in the isolation of CTCs by assessing LOD and cell recovery rates.

Method: To evaluate the performance of CytoGen's Smart Biopsy™ CTC Isolator, recovery rate and limit of detection (LOD) tests were performed using GFP-tagged cancer cell lines. MCF-7, H358, H1975, and RPMI8226 cells (each 200 cells) were spiked into a 5 mL blood sample from a healthy donor to simulate CTCs in patient blood. CTCs were isolated from these spiked samples using CytoGen's Smart Biopsy™ CTC Isolator. For the LOD test, H358 GFP-tagged cells (spiked at quantities of 20, 10, 5, 3, and 1 cell) were introduced into 5 mL of blood, and the recovery rate was assessed using CytoGen's Smart Biopsy™ CTC Isolator. Recovery rate and detection precision were analyzed across multiple trials to ensure reproducibility.

Results: The recovery rate of Cytogen's Smart Biopsy TM CTC isolator device demonstrated an average cell recovery rate of over 90% across the four cell lines tested. As a result of LoD test, H358-GFP cells were clearly isolated even in the small number of cells (3 cells in 5mL blood) were spiked into blood. These results suggest that the Cytogen's Smart Biopsy TM CTC isolator can isolate very small number of CTCs in a blood with high recovery rate, supporting its reliable application in liquid biopsy.

Conclusions: Cytogen's Smart Biopsy TM CTC isolator demonstrated high recovery rates and detection precision, establishing it as a promising tool for CTC isolation in liquid biopsy applications. Its consistent performance in CTC isolation highlights its potential as a non-invasive diagnostic platform, effectively addressing the limitations of traditional tissue biopsies. This study emphasizes the capability of Smart Biopsy TM CTC isolator to facilitate early cancer diagnosis and monitoring through liquid biopsy, contributing to significant advancements in non-invasive cancer diagnostics.

#1995 Clinical evaluation of new diagnostic system for the detection of androgen-receptor splice variant 7 in circulating tumor cells of mCRPC.

H. Kang, J. Lee, M. Hwang, K. Son, S. Pak, J. Kim;
Cytogen, Inc., Seoul, Korea, Republic of

Introduction: Androgen-receptor splice variant 7 (AR-V7) is constitutively activated isoform of AR and has been associated with the resistance towards AR targeting therapies and development into metastatic castration-resistant prostate cancer (mCRPC). Analysis of AR-V7 expression is an important step in prostate cancer diagnosis and determining the therapeutic drug, but the detection of AR-V7 with tissues has limitations such as clinical challenge to poorly accessible tumor tissues before and after treatment. Here, we developed the method of AR-V7 detection in circulating tumor cells (CTC) after isolation with CytoGen's. Smart Biopsy CTC isolator by droplet digital polymerase chain reaction (ddPCR) with high sensitivity and specificity, overcoming the limitations of tissue biopsy.

Method: Sensitivity and specificity were tested using AR-V7 positive cells (VCaP or 22Rv1) and negative cells (PBMC). Limit of detection (LOD) test of AR-V7 expression was performed that AR-V7 positive cells (10 and 5 cells) were spiked into human blood sample (5mL, healthy donor) to mimic CTC after isolation by CytoGen's Smart Biopsy CTC isolator, subsequently AR-V7 expression was tested with ddPCR. All ddPCR processes included droplet making and reading for each assay were performed on the QX200 ddPCR System (Bio-Rad). For the clinical evaluation, blood samples (each 20mL) of metastatic prostate cancer patients (n=5) were tested with IF assay (5mL) to count CTC number and ddPCR (15ml) to analyze the expression of AR-V7.

Results: In in vitro spiking test, AR-V7 expression was clearly detected in the LOD test of AR-V7 positive cells spiked into human blood and was not detected at all in the negative controls. In clinical evaluation study, isolation of CTC from the blood of prostate cancer patients using CytoGen's Smart Biopsy CTC isolator was confirmed from the result of IF assay, and the expression of AR-V7 in CTC was successfully detected by ddPCR. IF analysis identified 3 or more CTCs in 5 ml of blood from all patients, and expression of AR-V7 was verified by ddPCR in 4 out of 5 mCRPC patients.. These results demonstrate that it is possible to clearly detect the presence of RNA variants is related with drug resistance in mCRPC patients using liquid biopsy, utilizing CTCs, which exist in only very small quantities in the blood.

Conclusions: AR-V7 expresses only a part of cancer tissue, so it is difficult to accurately diagnose with traditional histological assays. Detection of AR-V7 (RNA signature) in intact live CTC might overcome limitations of tissue biopsy. In this study, we developed the method to detect AR-V7 in CTC, and presented the results of verifying AR-V7 expression using in vitro models and blood of mCRPC patients. Expanded clinical validation study with more patients' samples and clinical correlation between AR-V7 expression in CTC and clinical outcome will be performed and analyzed.

Merkel cell carcinoma (MCC) is an aggressive skin cancer characterized by high metastatic potential and poor survival rates. Identifying biomarkers for early detection of metastatic MCC is crucial for improving clinical outcomes. In this study, we analyzed bulk RNA-sequencing data from the GEO dataset GSE235092, identifying 481 differentially expressed genes (DEGs) between primary tumors (n=43) and metastases (n=28) (fold change >2, *adjusted p* <0.01). Among these, 66 genes were upregulated and 415 were downregulated in metastases. Downregulated DEGs were enriched in processes and pathways associated with metastasis, such as cell-cell adhesion, focal adhesion, and epithelial-mesenchymal transition. To further investigate, we performed pseudobulk differential expression analysis on tumor cells from primary (n=13) and metastasis tumors (n=10) using single-cell RNA-sequencing (scRNA-seq) data (GSE235090). This analysis revealed 43 DEGs (fold change >1.5, *adjusted p* <0.05), with 3 overlapping with the bulk RNA-seq findings. Subsequent subdivision of scRNA-seq metastasis samples into regional and distant metastases identified 6 DEGs specific to regional metastases compared to primary tumors, 5 to distant metastases, and 1 common to both. Validation of these DEG candidates in our MCC cohort of 102 primary tumors, based on RNA sequencing, identified *SLC4A7, CPVL, ENG, MYLIP,* and *MXRA8* as strong candidates linked to tumor metastasis, survival outcome, Merkel cell polyomavirus (MCPyV) status and other clinical characteristics. Additionally, scRNA-seq analysis highlighted distinct tumor microenvironment compositions among primary tumors, regional metastases, and distant metastases. Considering the role of MCPyV in MCC progression, we examined DEGs between primary and metastasis under MCPyV-positive and MCPyV-negative statuses using bulk RNA data. Gene set enrichment analysis uncovered 55 MYC-targeted genes and 52 E2F-targeted genes that were suppressed in MCPyV-positive patients but activated in MCPyV-negative patients. These findings provide new insights into MCC metastasis and highlight potential biomarkers for tumor progression and targeted therapies.

#2001 Proteomic analysis of plasma exosomes identifies biomarkers for liver and lung metastasis of colorectal cancer patients.

Boyeon Kim[1], Jwa Hoon Kim[2], Jiwon Lee[2], Soohyeon Lee[2]

[1]Korea University, Seoul, Korea, Republic of,[2]Korea University Anam Hospital, Seoul, Korea, Republic of

Metastasis is the leading cause of mortality in colorectal cancer (CRC), with liver and lung Metastasis being the most common sites of progression. Although early detection of metastasis is crucial for improving patient outcomes, non-invasive predictive strategies remain limited. Exosomes, a class of extracellular vesicles encapsulating cell-derived proteins, DNA, mRNA, and miRNA within a lipid bilayer, closely reflect the molecular characteristics of their originating cells and exhibit exceptional stability in biological samples. These unique features position exosomes as promising candidates for biomarker discovery. In this study, we utilized label-free liquid chromatography-tandem mass spectrometry (LC-MS/MS) to analyze plasma samples from 19 individuals: 5 healthy controls, 7 CRC patients with liver metastasis, and 7 CRC patients with lung metastasis. Blood samples were collected between March 2017 and April 2021, with only plasma from patients who developed metastasis repeatedly and exclusively in the liver or lung during the observation period included in the analysis. From 500 µL of plasma, we extracted an average of 149.9 µg of protein (173.8 µg from healthy controls, 145.9 µg from liver metastasis samples, and 136.8 µg from lung metastasis samples) and identified 851 proteins for further investigation. Our findings revealed that exosomes from CRC patients with metastasis contained elevated levels of proteins associated with angiogenesis, cell differentiation, and cell adhesion—such as ANGPTL6, COL1A1, LAMA2, and RENL—compared to healthy controls. Specifically, VCAN and ANGPTL6 were significantly upregulated in liver metastasis, while CFD and CRTAC1 were highly expressed in lung metastasis. These proteins are known to play critical roles in tumor progression and metastasis across various cancer types. Kaplan-Meier survival analysis based on the mRNA expression levels of these proteins indicated that CRC patients with higher expression exhibited worse overall survival (OS) and relapse-free survival (RFS) compared to those with lower expression levels. Future research will focus on the functional characterization of these identified proteins, the isolation of liver- and lung-specific exosomes, and the identification of small RNA biomarkers. This study represents a significant step toward the development of liquid biopsy-based approaches, particularly leveraging exosomes, for the early prediction of liver and lung metastasis in CRC patients.

#2002 A blood-based microbial metabolites signature for associated with metastatic duodenopancreatic neuroendocrine tumors in patients with multiple endocrine neoplasia type 1.

R. Ballaro[1], A. R. Wasylishen[2], C. R. C. Pieterman[3], C. Olsen[1], E. Irajizad[1], R. Wu[1], H. Katayama[1], H. Liu[1], Y. Cai[1], J. Dennison[1], S. Waguespack[1], K.-A. Do[1], S. Agarwal[4], M. Walter[5], J. Welch[4], L. Weinstein[4], J. E. Blau[4], S. Jha[4], N. Nilubol[4], M. R. Vriens[3], R. S. van Leeuwaarde[3], M. J. C. van Treijen[3], G. D. Valk[3], N. D. Perrier[1], S. M. Hanash[1], J. F. Fahrmann[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]University of Cincinnati College of Medicine, Cincinnati, OH, [3]University Medical Center Utrecht, Utrecht, Netherlands, [4]National Institutes of Health, Bethesda, MD, [5]National Institutes of Health, Bethesda, TX

Metastatic duodenopancreatic neuroendocrine tumors (dpNETs) are the primary cause of mortality among patients with Multiple Endocrine Neoplasia Type 1 (MEN1). Emerging evidence implicates the microbiome and microbial-derived secreted factors in promoting cancer development and progression. In the current study, we report that circulating microbial-associated uremic toxins trimethylamine N-oxide (TMAO), indoxyl sulfate (IS), cresol sulfate (CS), cresol glucuronide (CG), and phenol sulfate (PS) are elevated in MEN1 patients with metastatic dpNETs. Proteomic and metabolomic-based analysis of resected dpNET tissues from MEN1 patients revealed detectable levels of uremic toxins that positively correlated with peptide-based signatures corresponding to *Faecalibacterium prausnitzii, Faecalibacterium nucleatum,* and *Klebsiella pneumoniae* and negatively correlated with *Streptococcus pneumoniae* and *Streptococcus thermophilus*. A microbial-associated uremic toxin panel (MUTP) was developed and the panel yielded an area under the receiver operating characteristic curve (AUC) of 0.94 (95% CI: 0.85-1.00) with 67% sensitivity at 95% specificity for identifying MEN1 patients with metastatic dpNETS in an independent validation cohort. Increases in circulating microbial-associated uremic toxins during early stages of neoplasia were also found to be associated with poor overall survival in a $Men1^{fl/fl}Pdx1\text{-}Cre^{Tg}$ mouse model of MEN1 pancreatic neuroendocrine tumors. Our findings suggest that microbial dysbiosis is associated with disease aggressiveness and that increases in circulating microbial-associated uremic toxins may identify individuals who are at risk of having metastatic dpNETs to better guide clinical management and intervention.

#2003 Targeting the human adrenomenulin 2 hormone inhibits cancer cell intravasation.

S. Karimian, J. Lewis, K. Stoletov;
University of Alberta, Edmonton, AB, Canada

Cancer cell intravasation is the crucial step of cancer metastasis, and no therapeutic agents thattarget this process exist. Our laboratory uses high-resolution multidimensional intravital confocalimaging to visualize intratumoral cancer cell invasion and metastasis. Using this techniquecombined with fluorescent reporters, we discovered that in the live tumours, cancer cells withelevated ATF2 transcription factor (ATF+) are lining up the intratumoral vasculature, activelyinvading the perivascular space and responsible for 100% of cancer cell intravasation events. Incontrast, cancer cells low in ATF2 activity (ATF2-) fail to interact with the intratumoralvasculature and do not intravasate. Most cancer cell intravasation events occur in the large(~50µm) veins deep within the tumour mass (intravasation ports). Isolation of ATF2+ and ATF2-cells followed by their comparative RNAseq analysis revealed that ADM2 (Adrenomennulin 2)peptide hormone is significantly (~3x) overexpressed in ATF2+ compared to ATF2- tumour cells.shRNA-mediated knockdown of ADM2 expression in cancer cells decreased ATF2 activity,revealing a possible positive feedback loop. We found that shRNA knockdown of ADM2expression drastically inhibited the intratumoral cancer cell invasion and formation of the sizeableintratumoral vasculature. Notably, cancer cells deficient in ADM2 expression fail to invadeintratumoral perivascular space and intravasate. Our findings reveal Adrennomenulin 2 as a noveland potent anti-cancer metastasis target that can specifically inhibit cancer cell intravasation.

#2004 Integrative bioinformatics approach reveals potential liquid biopsy-based biomarkers for breast cancer metastasis monitoring.

Jina Kim[1], Cynthia Jinno[1], Hyoyoung Kim[1], Sunao Tanaka[1], Takeo Fujii[2], Sungyong You[1], **Hideki Furuya**[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]National Cancer Institute, Bethesda, MD

Background: Despite recent advances in screening and therapeutic strategies, breast cancer remains the first leading cause of cancer death among females. The 5-year survival rate is high as 95% at localized stages but drops significantly to 31% once the cancer metastasizes. Therefore, developing predictive tools of metastatic recurrence is an unmet clinical need to design preventive clinical trials.
Methods: This study used a public dataset (GEO ID: GSE102484), which is a microarray dataset that contains primary tumor samples (n = 683) sourced from subjects with (n = 95) and without (n = 582) distant recurrence (metastasis) of breast cancer (met and non-met, respectively). Our approach began with two sets of differentially expressed genes (DEGs). The first set of DEGs are from all the samples in the dataset regardless of breast cancer subtypes, while the second set of DEGs are from triple negative breast cancer (TNBC) samples only. To identify subjects with TNBC, basal-like breast cancer samples were selected using PAM50 algorithm with genefu R package. To select potential blood biomarker candidates, we developed an integrative bioinformatics pipeline. Briefly, 1) Differential expression analysis between met and non-met were performed using limma R package. We then selected DEGs with log2 fold change ≥ 0.58 and false discovery rate (FDR) < 0.1, 2) Genes with housekeeping/hematopoietic markers were removed, and 3) The genes that can be detectable in human bloods were selected using the human secretome database from the Human Protein Atlas (HPA).
Results: The differential expression analysis of all breast cancer samples identified 134 significantly upregulated genes in met and the selection process with the pipeline resulted in 13 marker candidates including COL10A1, CD93, HPRT1, MMP1, EPHB4, HSPD1, MAP4, CCDC80, MMP11, SAFB2, CALD1, CRISP3, and GAPDH. Subsequent GO enrichment analysis identified functions associated with these markers including angiogenesis, calcium ion binding, and extracellular matrix and structure organizations. Nucleotide metabolism was observed significance in pathway. We then focused on the TNBC samples from the dataset and identified 162 significantly upregulated genes in met from TNBC. Out of the 13 marker candidates from the 134 upregulated genes, 8 marker candidates including CALD1, CD93, EPHB4, SAFB2, HSPD1, MAP4, CCDC80, and HPRT1 were also found in TNBC.
Conclusion: Through an integrative computational analysis, we identified 13 markers associated with breast cancer metastasis, of which 8 were specifically linked to metastasis in TNBC. Future studies will focus on validating these biomarkers using liquid biopsy samples from breast cancer patients, potentially offering a less invasive diagnostic approach.

#2005 ROR1-specific extracellular vesicle tetraspanin-8 levels predict distant metastasis in triple-negative breast cancer.

Yinchao Zhang, Linze Xu, Jin Zhang, Dandan Wu, Yang Liu

Tianjin Medical University Cancer Institute & Hospital, National Clinical Research Center for Cancer, Key Laboratory of Cancer Prevention and Therapy, Tianjin's Clinical Research Center for Cancer, Tianjin, China

Background: Triple-negative breast cancer (TNBC), comprising 15-20% of all breast cancer cases, is the most aggressive subtype, with limited efficacy from targeted therapies and immunotherapies. Metastasis drives TNBC-related mortality, emphasizing the urgent need for predictive methods to identify high-risk cases early, guide clinical management, and facilitate timely interventions. Extracellular vesicles (EVs) play a pivotal role in cancer progression and metastasis, offering a promising avenue for metastasis research. However, isolating tumor-derived EVs from the total EV population remains a significant clinical challenge, underscoring the necessity for precise detection strategies.

Methods: EVs were isolated from MCF-10A cells, MCF-7 cells, and MDA-MB-231 cells using ultracentrifugation, followed by morphological characterization and surface marker protein validation. Mass spectrometry and UniProt gene ontology analyses were conducted to identify TNBC-specific EV proteins, classified by molecular functions or biological processes. TSPAN8 expression in breast cancer cells was analyzed using the CCLE and TCGA databases. Cholesterol-PEG-Biotin and Streptavidin-APC (Cholesterol-PEG-APC) were employed to anchor EV membranes, enabling concurrent detection of quantum dot-labeled EV proteins and membrane signals.

Results: ROR1, a transmembrane protein expressed in TNBC cells and EVs, was identified as a specific capture protein for TNBC-derived EVs. Database analysis revealed elevated TSPAN8 expression in highly metastatic TNBC MDA-MB-231 cells and in the tissue of TNBC-LAR subtype, where TSPAN8 plays a decisive role in metastasis. Using ROR1 to capture MDA-MB-231 EVs demonstrated that the fluorescence intensity from quantum dot-labeled QD605 anti-TSPAN8 and APC increased with EV concentration. Furthermore, higher average EV-TSPAN8/APC levels were associated with greater metastatic risk in patients. Correlation analysis using the TCGA database showed a positive relationship between ROR1 and TSPAN8 expression. VCAM1 was identified within the interaction network of ROR1 and TSPAN8, with positive correlations to both, providing a theoretical basis for leveraging ROR1-specific EV-TSPAN8 detection in metastasis research.

Conclusions: ROR1 effectively captures tumor-derived EVs and holds significant potential for enhancing EV-TSPAN8 detection, providing a promising strategy for predicting metastasis in TNBC. Evaluating ROR1-specific EV-TSPAN8 levels in TNBC blood samples and its link to disease progression warrants further investigation. Additionally, exploring its clinical utility across diverse TNBC subtypes and treatment regimens could refine its application, ultimately improving the precision of early metastasis prediction in TNBC.

#2006 Exploring a novel crosstalk between PTK7 and EPHA2 tyrosine kinase receptors in metastatic colorectal cancer.

Charlotte Dessaux[1], Constantin Semenchenko[1], Luc Camoin[2], Stephane Audebert[2], Emilie Baudelet[2], Avais Daulat[1], Flavio Maina[1], Jean-Paul Borg[1]

[1]Centre de Recherche en Cancerologie de Marseille (CRCM), Marseille, France,[2]Centre de Recherche en Cancerologie de Marseille (CRCM), Marseille Proteomics platform, Marseille, France

Colorectal cancer (CRC) remains a significant public health challenge, with an urgent need of novel prognostic biomarkers and therapeutic targets. PTK7, a membrane tyrosine pseudokinase and Wnt receptor, is overexpressed in CRC and linked to poor prognosis. In CRC, PTK7 expression correlates with metastatic progression and decreased survival in non-metastatic patients, positioning PTK7 as both a potential biomarker and a promising drug target. Notably, a targeted antibody-drug conjugate (ADC) against PTK7 has recently shown efficacy in inducing tumor regression in patient-derived xenograft (PDX) models of solid tumors and has progressed to a Phase I clinical trial with promising results. Other PTK7-targeting ADCs and anti-PTK7 CAR-T cells recently entered into preclinical development.

At the plasma membrane, PTK7 can interact with a range of membrane receptors, including VEGFR, EGFR, ROR2, and Plexins, enhancing their signaling capabilities. Using biotin proximity labeling in HCT116 CRC cells, we identified a novel network of PTK7-associated membrane proteins. Among these, we focused on EPHA2, an active tyrosine kinase receptor also implicated in cancer. Our findings indicate that PTK7 and EPHA2 interact via their extracellular domains (ECDs), and that PTK7 depletion significantly upregulates EPHA2 expression and signaling in response to its ligand EFNA-1 in HCT116 cells. Additionally, PTK7 regulates EPHA2's endosomal sorting through a Rab11-dependent mechanism, as well as its K63-linked ubiquitination and subsequent lysosomal degradation. Mechanistically, PTK7 does not appear to participate directly in EFNA-1 binding but instead promotes multimerization of active EPHA2, a crucial step in amplifying EPHA2 signaling.

This study aims to elucidate the functional role of the interaction between PTK7 and EPHA2 in colorectal cancer progression. By mapping the PTK7:EPHA2 interface using AlphaFold3 predictions and introducing targeted deletions and mutations within the ECDs of both receptors, we seek to understand how disrupting this interaction influences tumorigenic and metastatic processes. Our findings indicate that PTK7 depletion triggers cell rounding and detachment, with a marked increase in total and activated EPHA2 levels, which may drive pro-metastatic activity *in vivo*. Outcomes may significantly impact the use of anti-PTK7-ADCs or CAR-T cells and orient new therapeutic strategies to design agents interfering with PTK7 and EPHA2 interaction and function.

#2008 Intra-tumoral NK cell number is associated with immune response, and combination of it and clinical features is a strong prognostic biomarker in gastric cancer.

Masanori Oshi[1], Yuko Tamua[2], Rongrong Wu[3], Li Yan[1], Colin J. Rog[1], Kizuki Yuza[2], Takashi Ishikawa[3], Itaru Endo[2], Kazuaki Takabe[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Yokohama City University Graduate School of Medicine, Yokohama, Japan,[3]Tokyo Medical University, Tokyo, Japan

Background: The number of Natural Killer (NK) cell infiltration has been implicated for prognosis of gastric cancer patients. However, tumor immune microenvironment of gastric cancer patients with high NK cell infiltration has not yet been fully investigated.
Methods: NK cell infiltration fraction of gastric cancer in total 831 patients was quantified by using xCell algorithm, and its clinical relevance was investigated in gastric cancer patients at our institution (Yokohama City University Hospital (YCU), and publicly available cohorts with transcriptome (TCGA, GSE84437 and GSE167036), and single cell sequence cohort (GSE150290).
Results: In the single cell sequencing cohort, the distribution of NK cells was similar to that of NK cell-related gene expression, including *PRF1, NKG7, NCR1, GZMB, KLR-B1/C1/D1,* and *IFNG*. High NK cell infiltration in gastric cancer correlated with enriched immune gene sets, such as interferon (IFN)-α and IFN-γ responses (all normalized enrichment score (NES) > 1.50, and all false discovery rate (FDR) < 0.20), and also linked to increased cytolytic activity and low stromal cell infiltration, including fibroblasts, lymphatic/microvascular endothelial cells, pericytes, and adipocytes (all $p < 0.05$), consistently in both TCGA and GSE84437 cohort. Gastric cancer with high NK cell infiltration was also significantly associated with higher mutation rates ($p < 0.01$). However, they did not enrich with several pro-cancerous hallmark cancer gene sets, such as angiogenesis, epithelial mesenchymal transition, hypoxia, nor apoptosis. Clinically, high NK cell infiltration was associated with better overall survival ($p = 0.023$ in GSE84437, and $p = 0.015$ in TCGA). Interestingly, as the treatment response of chemotherapy improved, the infiltrating fraction of NK cell increased ($p = 0.012$ in YCU cohort). Furthermore, the NK cell score was independent factor for patient survival. Additionally, combining NK cell score with clinicopathological factors, including age at a diagnosis, AJCC T- and N-category, provided a powerful prognostic score for gastric cancer patients, consistently in multiple cohorts ($p < 0.001$, hazard ratio (HR) = 1.96 in TCGA, and $p = 0.017$, HR = 2.73 in the YCU cohort).
Conclusions: Gastric cancer with high NK cell infiltration is associated with increased immune activity and lower stromal cell infiltration. Combining clinicopathological factors with NK cell score may provide a powerful tool as prognostic predictor for gastric cancer patients.

#2009 Co-expression of interleukin-4 receptor alpha and KRAS correlates with disease severity and prognosis in pancreatic cancer patients.

Ashley Lea[1], Toshio Fujisawa[2], Hiroyuki Isayama[2], Supreet Khanal[1], Santosh Panthi[1], Mona Mansouri[1], Samir Lababidi[3], Steven R. Bauer[4], Kyung Sung[1], Nirjal Bhattarai[1], **Bharat H. Joshi**[1]

[1]FDA-CBER (Center for Biologics Evaluation and Research), Silver Spring, MD,[2]Juntendo University, Tokyo, Japan,[3]Mathematical Statics, FDA-Office of Commissioner, Silver Spring, MD,[4]Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC

Introduction: There will be 66,400 new cases of pancreatic cancer identified and 51,750 will die by end of 2024 in the United States. KRAS is the most common oncogenic driver occurring in ≥85% of pancreatic cancer patients. Previously, we identified an overexpression of high affinity binding protein Interleukin-4 Receptor alpha (α) of Interleukin 4 (IL-4) in numerous solid human cancers including pancreatic cancer. Herein, we investigated if IL-4Rα and KRAS co-expression can act as a biomarker of disease severity in pancreatic cancer patients.

Experimental: One hundred and seven archival tumor specimens were examined by six investigators for IL-4Rα and KRAS expression by IHC and ISH techniques in a blinded manner. The data were stratified into pathological grades and stages of the patients. The results were analyzed statistically if individual/combined expression of IL-4Rα or KRAS can serve as biomarker/s of disease severity. Kaplan-Meier survival analysis was performed to investigate if these gene-expression had any influence on overall survival of the patients.

Results: Our IHC results demonstrate that ≥68% samples overexpressed IL-4Rα alone in moderately to poorly differentiated grade tumors and in samples from clinical stage II + III patients with ≥2+ immunostaining intensity. Interestingly, ≥80 % of the specimens with moderately to poorly differentiated grades showed a co-expression for KRAS and IL-4Rα (≥2+). In contrast, patients with well differentiated grade and clinical stage I revealed ≤ 73% co-expression of these genes. We observed a similar pattern of mRNA expression in these patients by ISH. Further, Kaplan-Meier analysis revealed a significantly shorter survival ($P \leq 0.001$) in patients with ≥2+ positive expression of IL-4Rα plus KRAS in moderately to poorly differentiated grades and advanced clinical stages. In contrast, the patients overexpressing either of these genes alone, regardless of grades and stages, survived relatively longer compared to those expressing both IL-4Rα and KRAS .

Summary and Conclusion: Our data show that IL-4Rα and KRAS co-expression, correlate with disease severity in pancreatic cancer patients. Thus our study uncovers a novel role of combined expression of IL-4Rα and KRAS as a biomarker of prognosis and driver of oncogenesis in pancreatic cancer patients and may serve a unique druggable target/s for developing targeted cellular or gene therapy-based cancer immunotherapies.

#2010 A spatial profiling approach to evaluating the prognostic impact of heterogeneity in the triple-negative breast cancer immune microenvironment.

Prerana Sensharma[1], Huidan Zuo[2], Melanie Dawe[3], Megan Hopkins[4], Zeynep Baskurt[5], Osvaldo Espin-Garcia[5], Philippe L. Bedard[6], Melanie Spears[4], Susan J. Done[3]

[1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[3]Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada,[4]Department of Medical Biophysics, Ontario Institute of Cancer Research, Toronto, ON, Canada,[5]Department of Biostatistics, Princess Margaret Cancer Center, University Health Network, Toronto, ON, Canada,[6]Department of Medicine, University Health Network, Division of Medical Oncology & Hematology, Toronto, ON, Canada

Triple negative breast cancer (TNBC) is the most aggressive breast cancer subtype with the poorest patient outcomes. The composition and active immune pathways of the immune microenvironment play a critical role in tumor progression. TNBC is frequently characterized by a high and heterogeneous immune infiltration in the tumor stroma. The degree of immune infiltration impacts current management: neoadjuvant chemotherapy and anti-PD1 agent pembrolizumab.[1,2,3] Previously, our lab studied a treatment-naive cohort of 192 patients diagnosed with TNBC and found that patients with higher B cell infiltration in the stromal regions had better outcomes (Kanwar and Balde et. al, Cancer Res 2021)[4]. While previous studies employed low-plex methods of analysis to study archival formalin-fixed paraffin-embedded tissue samples, the emergence of high-plex in situ protein detection methods like the GeoMx Digital Spatial profiler (DSP) has drastically enhanced the resolution of the tumor microenvironment that can be assessed.[5] Using the GeoMx DSP, we are quantifying a panel of 40 immune proteins, to expand our understanding of the immune microenvironment of the pre-treatment cohort previously studied. The protein panel enables the detection of multiple immune cell types and subtypes, certain immune pathways like T cell activation and exhaustion, and the expression of immunotherapeutic targets. Preliminary results show that patients with high CD163 expression, associated with immunosuppressive macrophages had poorer outcomes ($p= 0.035$). The immune microenvironment for larger tumors expressed higher T cell activation markers ($p=0.016$). While the overall heterogeneity in immune cells did not have an impact on patient outcomes, a high heterogeneity in T cell activation markers was significantly associated with patient outcomes ($p=0.029$) as well as tumor size ($p=0.024$). We have characterized the stromal immune cell infiltrates and their spatial heterogeneity, finding immune markers that may significantly impact patient outcomes. Our findings aid in the identification of therapeutic targets prevalent in the TNBC stroma as well as potentially informing therapy decisions based on the tumor immune microenvironment composition.

#2011 Attenuated levels of surface TREM1 on circulating neutrophils impair NETosis and increase infection risk in DLBCL patients.

Hao-Yuan Wang[1], Po-Chun Liu[2], Fu-Chen Yang[2], Ching-Fen Yang[3], Chun-Kuang Tsai[1], Po-Shen Ko[1], Yao-Chung Liu[1], Nien-Jung Chen[2]

[1]Division of Hematology and Oncology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan,[2]Institute of Microbiology and Immunology, National Yang Ming Chiao Tung University, Taipei, Taiwan,[3]Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

Neutrophils can undergo NETosis, but their roles in lymphoma remain unexplored. The triggering receptor expressed on myeloid cells-1 (TREM1) amplifies inflammation and may regulate NETosis. This study investigates surface TREM1's role in NETosis regulation and predicting progression-free survival (PFS), overall survival (OS), and infection risk in untreated DLBCL patients. This prospective study enrolled 118 untreated DLBCL patients. Circulating neutrophils were isolated, identified as CD45+ CD15+ using flow cytometry, and stimulated with PMA to assess NETosis by SYTOX Green or confocal microscopy. Neutrophils from healthy donors (HDs) were paired with patients to calculate normalized TREM1 or NETosis levels: (Patient - HD) / (HD) x 100%. Among 118 DLBCL patients (median age 66, 61.9% male), 39.8% were stage IV, 33.1% high-risk IPI, 23.7% had bone marrow (BM) involvement, 72.9% were non-GCB subtype, 40.7% were double expressor lymphoma (DEL), and 9.3% were Epstein-Barr virus (EBV) positive. Clinically significant infections occurred in 26 patients, with typhlitis as the most common infection focus (n = 7) and *Escherichia coli* as the most commonly identified pathogen (n = 10). Most patients had lower neutrophil surface-TREM1 levels than HDs (median -40.1%). High-risk IPI and non-GCB patients had significantly lower normalized TREM1 levels than their counterparts (P = 0.036 and P = 0.031, respectively). Trends were also observed for lower TREM1 levels in patients with BM involvement, DEL, and age ≥75. Patients were classified into high (≥ -43.8%; n = 66) and low (< -43.8%; n = 52) TREM1 level groups using ROC and AUC analysis. After 25.3 months of follow-up, low TREM1 patients had worse PFS (2-year PFS rate: 57.8% vs. 79.3%, log-rank P = 0.001), OS (2-year OS rate: 62.9% vs. 90.6%, log-rank P < 0.001), and a higher infection risk (cumulative incidence rate of clinically significant infection within 180 days post-DLBCL diagnosis: 36.5% vs. 10.6%, log-rank P = 0.001). Multivariate analysis showed TREM1 as an independent predictor for PFS, OS, and infection risk. Neutrophils from all 118 patients were treated *ex vivo* with PMA (100 nM), and the supernatant was collected to measure MPO. Patients with low TREM1 had significantly impaired NETosis (-54.6% vs. -16.8%, P < 0.001) and reduced MPO levels (61.5 vs. 82.0 ng/mL, P = 0.006). Further treatment with PMA or *E. coli*, followed by immunofluorescent staining and confocal microscopy, showed that neutrophils from high TREM1 patients had mildly impaired NETosis, further inhibited by the TREM1 inhibitor LP17. Neutrophils from low TREM1 patients had significantly impaired NETosis, which was restored by the TREM1 agonist PY159.
In conclusion, low surface TREM1 levels on circulating neutrophils predict poorer PFS and OS, higher infection risk, and impaired NETosis in untreated DLBCL patients. These findings warrant further clinical investigation.

#2012 Prognostic role of CD3+and CD8+cells density in resected stage IIIAN2 non-small cell lung cancer (NSCLC): A study from the randomized Lung ART IFCT 0503 trial.

Victor Albarran-Artahona[1], Maria-Rosa Ghigna[2], Wael Zrafi[3], Nicolas Signolle[4], Guillaume Granier[5], Nathalie Cozic[6], Julien Adam[7], Ludovic Lacroix[8], Benjamin Besse[1], Cecile Le Pechoux[9], Antonin Levy[9]

BACKGROUND: Immune cells (IC) density has a prognostic role in NSCLC[1]. Most results come from small cohorts with limited representation of stage III samples and show heterogeneity[2-4].
METHODS: The LungART trial (NCT00410683)[5] randomized 501 patients (pts) with resected stage IIIAN2 NSCLC (AJCC 7th ed.) to adjuvant radiotherapy (ART) or observation. Up to 96% had (Neo)adjuvant chemotherapy (ChT). No disease-free survival (DFS) benefit was found for ART. For pts who consented, a primary tumor blocs was collected; $CD3^+/CD8^+$ cells were assessed by immunohistochemistry (DAKO/Roche). Automatic quantitative analysis of selected regions of interest was performed using the QuPath v.0.5.1 Bioimage software for assessment of IC density and correlated with outcomes.
RESULTS: 272/501 pts had available samples; 47% received ART. Baseline characteristics were well balanced (table 1). A higher $CD3^+$ cells density was found in non-squamous histology (p=0.003) and in pts receiving neoadjuvant ChT (p=0.03). Higher density of $CD3^+$ and $CD8^+$ cells correlated with the incidence of new events after 6 (p=0.0004 and 0.04, respectively) and 24 months (m) (p=0.003 and 0.04 respectively). High $CD3^+$ cells density correlated with longer median DFS: 52 m (95% CI: 26.1 m-NR) *vs* 22 m (95% CI: 22.5-31.2 m,) as well as high $CD8^+$ cells density (52.1 m; 95% CI: 34-NR *vs* 20.9 m; 95% CI: 16.9-28.8 m). A multivariate Cox model confirmed both high $CD3^+$ and $CD8^+$ cell density as independent prognostic factors for DFS (HR=0.68 [95%CI: 0.53-0.83], p=0.01 and HR=0.57 [95%CI: 0.38-0.86], p=0.07, respectively) and overall survival (HR=0.66; 95%CI: 0.49-0.88; p=0.005 and HR=0.5; 95%CI: 0,30-0.85; p=0.10, respectively).
CONCLUSIONS: Our study is the largest cohort showing a prognostic role of IC density in resected stage IIIAN2 NSCLC, composed solely by surgical samples, which may identify a subset of poor prognosis pts who could benefit of an intensive therapeutic approach.

Baseline characteristics of study's population

Characteristic	**RT, N=143**	**Observation, N=129**
Age	61 (55- 66)	61 (56- 67)
Female	45 (31%)	40 (31%)

Background: Predicting early response and immune-related adverse events (irAEs) is crucial for therapies with immune checkpoint inhibitors (ICI) in early-stage breast cancer (BC). This study evaluated serum immune markers at pre-treatment and early on-treatment, and changes between timepoints in women with BC treated with neoadjuvant chemotherapy plus ICI (anti-PD-1) or ICI plus SD-101 (an immunomodulatory toll-like receptor 9 agonist) in the I-SPY2 trial.

Methods: Serum samples from women with HER2-negative BC (N=114) in the I-SPY2 trial were collected at baseline (T0) and three weeks post-treatment initiation (T1). Patients received paclitaxel with anti-PD-1 (N=49) or anti-PD-1 plus SD-101 (N=65), followed by anthracycline/cyclophosphamide. Serum was analyzed for 18 immune markers, including checkpoint molecules (sPD-L1, LAG-3), cytokines (IL-6, IL-8, IL-10, sCD25, G-CSF, IFNγ, TNFα), chemokines (CXCL9, CXCL10, CXCL11, CCL2, CXCL13), angiogenesis markers (VEGF-C), proteins and macrophages with inflammatory roles (CRP, CD163), and molecules that induce cell apoptosis (Granzyme B). Associations between serum markers and pathologic complete response (pCR) or irAEs were assessed using the Mann-Whitney test, and significance was defined at $P<0.05$. Associations were also assessed within hormone receptor (HR+/HER2- N=68, HR-/HER2- N=46) and I-SPY2 immune positive (ImPrint+, N=54) subtypes in both treatment arms. ImPrint is a 53-gene signature that was independently validated to predict the likelihood of a pCR with PD-1/PD-L1 ICIs with high sensitivity and specificity.

Results: Among all HER2-negative patients, baseline CRP, CXCL10, and sCD25 levels were positively associated with pCR. In HR+/HER2- and HR-/HER2- patients, baseline CRP levels were also positively associated with pCR. In ImPrint+ patients, baseline G-CSF levels were positively associated with pCR, even after adjusting for HR status and treatment arm. T1 IFNγ levels were positively associated with pCR in HER2-negative patients, and within HR-/HER2- and ImPrint+ groups. Immune-related AEs were reported in 9 of 49 patients in the anti-PD-1 arm. VEGF-C increase between T0 and T1 was associated with irAEs in HR+/HER2- patients, while granzyme B increase was associated with irAEs in HR-/HER2- patients.

Conclusions: Serum immune markers may influence tumor immune cell infiltration, potentially affecting the likelihood of achieving pCR and systemic immune activity linked to irAEs. Serum levels of CRP, CXCL10, sCD25, G-CSF, and IFNγ could be used to monitor and predict clinical benefit from anti-PD-1 and immunomodulatory agents. This study also suggests that VEGF-C and granzyme B can be possible candidate prognostic biomarkers for irAEs in patients receiving anti-PD-1 therapy. Validation in a larger sample size is crucial to confirm the observed trends.

#2014 Immune exclusion signatures identify patients at high risk of relapse despite adjuvant chemotherapy in stage 2 colon cancer in the TOSCA phase 3 trial: PROSIT study.

Background: The decision to administer adjuvant chemotherapy (ACT) in stage II colorectal cancer (CRC) remains challenging. Clinical and histopathological criteria, even when integrated with ctDNA-based assessment of residual disease, are still suboptimal ACT benefit predictors. Immune cell infiltration has been repeatedly associated with better outcome, but the prognostic value of transcriptional immune signatures has not been assessed in prospective trial cohorts in a systematic way. We aimed to identify a prognostic immune transcriptional signature for high-risk stage II CRC patients undergoing ACT in the TOSCA trial. TOSCA tested the noninferiority of 3 vs 6 months of FOLFOX/CAPOX, and, with a median follow-up of more than 6 years, is an ideal patient set to test outcome-associated variables.

Methods: We built a case-control cohort nested in the TOSCA trial database, matching 62 patients with high-risk stage II CRC who relapsed (R) with 62 who did not (NR). Matching criteria included recruitment center, pT stage, ACT type and duration. Whole transcriptome sequencing (WTS) was conducted on formalin-fixed, paraffin-embedded (FFPE) blocks using stranded ribodepletion library prep. MMR status was derived from WTS by majority report of three well-established methods. Immune gene signatures were assessed by the Miracle and ssGSEA packages. Differentially expressed signatures between R and NR were evaluated with the Log Rank test. Covariates included in the multivariable Cox regression models included MMR status, ACT duration (3 vs 6 months) and type (FOLFOX vs CAPOX).

Results: Out of 124 stage II CRC samples, 72 were of sufficient quality for RNAseq and were included in the analysis (“final cohort”). No key matching variable was differentially represented in the final cohort. Median follow-up was 70.9 months. The median age was 62.5, 40% of cases were right-sided, 60% received FOLFOX, 54% received 3 months of ACT, and 19% were MSI-high. We tested 67 different signatures. Immune constant of rejection and immune-exclusion signatures (IES) were the only ones with significant adjusted p-values. IES-high patients (~27%) had significantly shorter disease-free survival (41 months vs median not reached, HR 2.5, p-value=0.02). IES signature remained significant after adjusting for known covariates. Longer (6 months) ACT duration did not show any advantage over 3 month ACT in neither IES-high nor -low patients.

Conclusion: IES signature identifies patients at high risk of relapse despite receiving standard ACT, irrespective of ACT duration. IES can be exploited to design novel adjuvant trials for treatment intensification in specific patient subgroups. #2015 Single-cell atlas of tumor and immune cells in disease progression from MGUS to MM.

Romanos Sklavenitis-Pistofidis[1], Ting Wu[2], Elizabeth Lightbody[1], Yoshinobu Konishi[1], Mahshid Rahmat[1], Michael Agius[1], Junko Tsuji[2], Jean-Baptiste Alberge[1], Ankit Dutta[1], Michelle Aranha[1], Nayda Bidikian[1], Hadley Barr[1], Nicholas Haradhvala[2], Gad Getz[2], Irene Ghobrial[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Broad Institute of MIT and Harvard, Cambridge, MA

Introduction: Multiple Myeloma (MM) is a bone marrow (BM) plasma cell malignancy that is preceded by asymptomatic stages; Monoclonal Gammopathy of Undetermined Significance (MGUS) and Smoldering Multiple Myeloma (SMM). Despite their early stage, patients with MGUS/SMM exhibit immune dysregulation. Understanding how immune dysregulation evolves and how tumor and immune cells interact to promote progression to MM may help predict and intercept it.
Methods: We performed single-cell RNA/BCR/TCR-seq (10X Genomics) on ~6 million tumor and immune cells from 877 samples, 533 BM/blood specimens, and 365 patients with MGUS/SMM/MM and healthy donors. For 241 individuals, both tumor and immune cells were sequenced to enable integrative analyses of tumor and immune biology.
Results: We observed a significant increase in the proportion of GZMB+ CD8+ effector memory T cells (TEMs) in MM compared to MGUS. This was due to increased clonal expansion and a differentiation bias in CD8+ TEMs, which also showed higher proliferative capacity and IFN-gamma expression. Despite these seemingly advantageous changes, GZMB+ CD8+ TEMs showed decreased activity of an expression signature marked by *SLC7A5* and *PIK3R1*, genes critical for T cell functionality. Patients with lower activity of this signature showed higher risk of progression. To characterize its impact on tumor cells, we split patients into high and low T cell functionality groups and compared their tumor cell expression profiles. The top upregulated gene in tumor cells from patients with high T cell functionality was *SERPINB9*, which neutralizes granzymes and protects tumor cells from cytotoxic T cells. From this analysis, we derived the transcriptional footprint of T cell functionality on tumor cells, which we termed the “immune control” signature. We found that it, too, decreases with progression, and validated it in two external cohorts. To test whether this observed decrease could be the result of tumor-intrinsic genomic evolution or, alternatively, reflects the receding immune pressure by progressively more dysfunctional T cells, we constructed tumor phylogenetic trees and compared the activity of the immune control signature across ordered subclones within tumors. We observed stable expression of the immune control signature across subclones in our trees, suggesting that this signature may reflect external immune pressure, rather than tumor genomic evolution. Independent of the patient’s disease stage, tumors with higher immune control showed lower cycling capacity, demonstrating that high T cell functionality is associated with disease control.
Conclusion: This study may have implications for: (i) the risk stratification of patients with MGUS/SMM/MM, (ii) patient selection for immunotherapy administration and interception of progression, (iii) preemptive T cell banking for future CAR-T cell therapy, and (iv) the development of novel immunotherapeutics.

#2016 Prediction of prognosis in tumor-associated macrophage using immunohistochemistry with artificial intelligence.

Rie Mizumoto, Ayumi Nagae, Norikatsu Miyoshi, Kengo Haruna, Rie Hayashi, Mitsunobu Takeda, Yuki Sekido, Tsuyoshi Hata, Atsushi Hamabe, Takayuki Ogino, Mamoru Uemura, Yuichiro Doki, Hidetoshi Eguchi

Gastroenterological Surgery, Osaka University, Suita, Japan

Tumor microenvironment (TME) is a cellular environment around the tumor. The quantification of lymphocyte populations called immunoscore has been developed and proven to have prognostic value. The impact of the degree of macrophage infiltration on the prognosis differs according to the type of cancer, and good prognosis with higher infiltration of macrophage is reported in colorectal cancer. Additionally, Image recognition technology based on deep learning is developing. There has been significant focus on classification by AI on immunohistochemistry (IHC) images. In this study, we evaluate correlation between tumor associated macrophage (TAM) distribution and prognosis of colorectal cancer, and we analyzed the data using artificial intelligence and deep learning techniques for predicting prognosis. Data from 159 patients who underwent R0 resection of primary colorectal cancer between April 2011 and December 2012 were reviewed. The 159 patients were divided into the following two cohorts: a training set of previous 100 patients and a validation set of 59 patients. Using the Anti-Iba-1 monoclonal antibody (NCNP27), we quantified TAM populations at the tumor invasive front in resected specimens and categorized by percentage of stained cytoplasm. A 0-75% density was assessed as low IM (invasive margin) score and a density between 75% and 100% was assessed as high IM score. In the training set, low IM score was also associated with poorer overall survival. The risk analysis of each factor for overall survival revealed significant difference in IM score. For the validation set, we employed MATLAB (Mathworks, R2021a) to analyze TAM distribution using a convolutional neural network (CNN). The sensitivity and specificity of the CNN mode for diagnosis were found to be 0.459 and 0.909, respectively. Consistent with the training results, a low IM score in the validation cohort was linked to the worst prognosis (P = 0.037). The findings emphasize the correlation between TAM distribution and patient prognosis in colorectal cancer, suggesting that IHC quantification of macrophages, when analyzed through AI techniques, offers valuable prognostic insights. This study highlights the potential of integrating AI with histopathological analysis to enhance prognostic prediction in oncology.

#2018 The co-expression of HER family members, EGFRvIII, putative stem cell marker CD44, and their prognostic significance in patients with glioblastoma.

Ermira Mulliqi[1], Said Khelwatty[1], Izhar Bagwan[2], Ahmad Kamaludin[3], Anna Morgan[1], Natalie Long[3], Keyoumars Ashkan[3], Helmout Modjtahedi[1]

[1]Kingston Univ. London School of Life Sci., Kingston upon Thames, United Kingdom,[2]Berkshire Surrey Pathology Services, Royal Surrey County Hospital, Kingston upon Thames, United Kingdom,[3]King's College Hospital and King's College London, London, United Kingdom

The aberrant expression and activation of HER family members is a known major oncogenic pathway for the proliferation, progression, and metastasis of a wide range of human malignancies including brain cancer. Despite numerous efforts to target EGFR, commonly dysregulated in glioblastoma, approaches directed against EGFR have not achieved the same degree of success as seen in other tumour types. The tumour heterogeneity and other redundant cell signalling pathways could be some of contributing factors to the treatment with the EGFR inhibitors. In this study, our aim was to examine the relative expression and prognostic significance of all members of the HER family, and the type III EGFR mutant (EGFRvIII) as well as the putative stem cell marker CD44, in patients with glioblastoma. The expression levels of wild-type EGFR (wtEGFR), HER2, HER3, HER4, EGFRvIII and CD44 were determined in tumour specimens from 80 patients by immunohistochemistry. The staining was scored at cut off value of >5%, 10%, 20% and 50% with positive staining, the intensity and the cellular location of immunostaining. The association between the expression level of the biomarkers and patient overall survival was evaluated using Chi-squared, Kaplan-Meier survival curves and log rank test. At cut-off value of >5% with positive staining, there was moderate to high expression of wtEGFR, HER2, HER3, HER4, EGFRvIII, and CD44 in 46%, 75%, 19%, 71%, 85%, and 95% of the cases examined, respectively. The cellular location of wtEGFR was found to be membranous and cytoplasmic, HER2 and HER3 predominantly cytoplasmic, whereas HER4 was membranous, cytoplasmic and nuclear. The expression of EGFRvIII was mainly cytoplasmic and nuclear and CD44 membranous. Interestingly, at a cut off value of >5% of tumour cells with staining, the expression of wtEGFR was accompanied with co-expression with HER2 (35%), HER3 (0%), HER4 (30%), EGFRvIII (36%), CD44 (44%), HER2/EGFRvIII (28%), HER2/CD44 (31%), EGFRvIII/CD44 (36%) of the cases examined. In 83% and 55% of the cases examined, there was co-expression of EGFRvIII with CD44 and HER2/HER4/CD44 respectively. With the exception of HER2 expression, at cut off values of >5% of tumour cells with staining, which was associated with better overall survival [HR=0.57 (p=0.038) in univariate , HR=0.56 (p=0.034) multivariate], there was no significant association between the expression of other members of the HER family, EGFRvIII and CD44 and overall survival in both univariate and multivariate analysis. Taken together, our results suggest that the co-expression of different members of the HER family, with EGFRvIII and CD44 occurs in patients with glioblastoma and warrants further investigation on the predictive value of these biomarkers and their potential as targets for therapeutic interventions with drugs targeting these receptors.

#2019 The relationship between pSMAD3 expression, clinicopathological features, tumor microenvironment and survival in operable colorectal cancer patients.

Chia Yew Kong[1], Natthamon Sonthi[1], Leonor Schubert Santana[1], Lily V. S. Hillson[1], Kathryn Pennel[1], Peter Alexander[1], Noori Maka[2], Joanne Edwards[1], Colin W. Steele[1], Campbell S. Roxburgh[1]

[1]University of Glasgow - School of Cancer Sciences, Glasgow, United Kingdom,[2]Department of Pathology, Queen Elizabeth University Hospital, Glasgow, United Kingdom

Background: Consensus molecular subtype 4 (CMS4) colorectal cancer (CRC) is associated with prominent Transforming Growth Factor-β (TGF-β) dysregulation & poorer prognosis. The TGF-β pathway has context-dependent tumor suppressor & promoting activity regulated by SMAD transcriptional factors. Increasingly, SMAD4 loss is shown to lead to tumor suppression loss in CRC (1). Evidence around other SMADs is lacking. We examined the relationship between phosphorylated SMAD3 (pSMAD3) expression, clinicopathological features, gene expression & survival in a large cohort of CRC patients.
Methods: Patients who underwent curative resection of primary CRC from 1997 to 2012 at 3 hospitals in Glasgow, UK, were included. pSMAD3 protein immunohistochemistry (abcam Ab52903) was performed on a tissue microarray. Tumor/stromal & subcellular pSMAD3 expression histoscores were quantified on Qupath. High/low expression thresholds were determined by maximally selected ranked statistics. Expression was correlated with clinicopathological factors & survival. Gene set enrichment analyses (MSigDB Hallmarks) were performed on bulk transcriptomic (TempO-Seq, Bioclavis) data in 318 patients (2).
Results: 1236 patients were eligible for analysis. High tumor cytoplasmic, nuclear & stromal cytoplasmic & nuclear pSMAD3 groups comprised 77.8%, 50.6%, 34.9% & 54.6% of the cohort respectively. High pSMAD3 expression across all compartments was associated with favourable tumor features: high tumor cytoplasmic, & stromal cytoplasmic & nuclear scores related to lower T-stage (all $p<0.05$). High tumor cytoplasmic & nuclear, & stromal cytoplasmic scores related to absence of venous invasion (all $p<0.01$). High tumor nuclear & stromal cytoplasmic scores also related to a strong Klintrup-Makinen immune microenvironment score (both $p<0.01$). High pSMAD3 was associated with TGF-β pathway gene set enrichment in CMS4 tumors alone. Within CMS4, high pSMAD3 was also associated enriched MYC & epithelial mesenchymal transition (EMT) pathways. Conversely, in non-CMS4 tumors, high pSMAD3 relates to suppressed EMT. High pSMAD3 across all compartments relates to better cancer specific survival (CSS) on univariate analyses (all $p<0.05$). On multivariate analysis, high stromal nuclear pSMAD3 retained independent prognostic significance (HR0.69, 95%CI 0.5-0.95, $p=0.023$). This survival relationship persisted in T2-3 & stromal poor tumors but not in T4 or stromal rich tumors.
Conclusion: High pSMAD3 expression relates to favourable tumor features & stage-independent improved CSS, indicative of preserved TGF- β tumor suppression. In contrast, within CMS4 tumors, high pSMAD3 relates to enriched tumor promoter pathways, suggesting contextual TGF-β pleiotropy.

#2020 Fibroblast derived type III collagen pro-peptides (PRO-C3) in plasma is associated with outcome for patients with NSCLC treated with anti-PD1 plus chemotherapy.

Nicholas Willumsen[1], Lola Lecru[2], Thibaut Brugat[2], John Stagg[3], Bertrand Routy[4], Morten A. Karsdal[1]

[1]Nordic Bioscience, Herlev, Denmark,[2]Domain Therapeutics, Illkirch, France,[3]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada,[4]Axe Cancer, Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada

Background: Tumor fibrosis is essential for defining outcome of patients with various solid tumors including lung cancer. The associated cancer associated fibroblasts (CAFs) activation and increased deposition of type III collagen leads to immune exclusion and high interstitial pressure in the tumor microenvironment. Recently, the USA FDA issued a Letter of Support to encourage use of the non-invasive fibrosis biomarker PRO-C3 (type III collagen pro-peptides) in patients with solid tumors (https://www.fda.gov/media/169332/download). Here we investigate PRO-C3 as a prognostic biomarker in patients with non-small cell lung cancer (NSCLC).

Methods: First, we investigated the PRO-C3 production (measured by ELISA) and total collagen deposition (Sirius red staining) in primary lung CAFs activated with TGF-beta, by use of the validated scar-in-a-jar in vitro model. Second, we measured PRO-C3 in pre-treatment plasma samples from 40 patients with stage IIIa to IVb NSCLC. Patients were treated with Pembrolizumab (anti-PD1) plus platinum-doublet chemotherapy (carboplatin, cisplatin, pemetrexed, or paclitaxel). PRO-C3 was correlated to overall survival outcome (OS) by Kaplan Meier analysis and Cox regression analysis after allocating patients into PRO-C3 subgroups (below/above the median of 51.5 ng/mL).

Results: PRO-C3 was produced by lung CAFs after activation with TGF-beta in vitro and PRO-C3 correlated to increased net-collagen deposition. Among the 40 patients with NSCLC, the median follow-up was 13.2 months. Patients with high PRO-C3 had a median OS of 9.0 months compared to 31.5 months in patients with low PRO-C3 (log-rank p-value=0.0023). In support, patients with high PRO-C3 had a Hazard Ratio (HR) for OS of 3.8 (95%CI: 1.5-9.7, p=0.004).

Conclusions: Type III collagen pro-peptides (PRO-C3) was produced by activated lung CAFs and is a surrogate of fibrogenesis. High PRO-C3 levels in pre-treatment plasma was associated with poor outcome for patients with NSCLC treated with anti-PD1 plus chemotherapy. These data suggest that quantifying tumor fibrosis is important for prognostication of patients with lung cancer.

#2021 Impact of corticosteroids on predictive and prognostic value of neutrophil-to-lymphocyte ratio in patients with non-small cell lung cancer treated with immune checkpoint inhibitor therapy.

A. Lim[1], A. Meyer[1], L. Polyakov[1], R. Cooper[2], A. Mades[2], S. Ye[3], J. Ni[1], H. Chen[4], L. Contreras[1], J. Sarkar[4], R. Sharma[5], B. H. Segal[4], R. Hsu[2], J. Nieva[2], G. K. Dy[4], F. Ito[1];

[1]University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, CA, [2]Keck School of Medicine, University of Southern California, Los Angeles, CA, [3]USC/Los Angeles General Medical Center, University of Southern California, Los Angeles, CA, [4]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [5]University at Buffalo Jacobs School of Medicine and Biomedical Sciences, the State University of New York, Buffalo, NY

Introduction: An elevated baseline neutrophil-to-lymphocyte ratio (NLR) can signal an imbalance between pro-tumor and anti-tumor inflammatory responses and has been associated with worse overall survival (OS) and lower response rates in patients with non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICIs). Corticosteroids, known to cause neutrophilia and lymphopenia, are widely used in NSCLC, but their impact on biomarker performance remains elusive. This study investigates how baseline steroid use affects biomarker performance in NSCLC patients on ICIs.

Methods: We retrospectively evaluated 252 patients with NSCLC treated with ICIs at the Roswell Park Comprehensive Cancer Center (RPCCC) (n=81) (discovery cohort) and the University of Southern California (USC) (n=171) (validation cohort). We analyzed the association between baseline NLR at ICI initiation with overall response rate (ORR), progression free survival (PFS), and OS. NLR was defined as absolute neutrophil count divided by absolute lymphocyte count. Patients were stratified by NLR: NLR ≥ 5 (high) and NLR < 5 (low). ORR was estimated using Fisher's exact test, and Kaplan-Meier survival distributions for PFS and OS were generated.

Results: In our cohort, 159 (63.1%) of 252 patients had an NLR < 5 and 93 (33.9%) had NLR ≥ 5. NLR < 5 at baseline was correlated with longer PFS (RPCCC: $p<0.0005$; USC: $p<0.005$) and OS (RPCCC: $p<0.0005$; USC: $p<0.05$) although there was no significant relationship between NLR and treatment response rates in RPCCC or USC cohorts. We identified 19 patients who were on systemic steroids at the time of initiation of ICI therapy. Indications for corticosteroids were brain metastases or comorbid lung conditions such as COPD, and all 19 patients remained on steroids for at least 12 weeks from the initiation of ICI therapy. When examining the predictive value of NLR by steroid and non-steroid subgroups in both cohorts, we found no significant association between NLR and treatment response rates for patients taking steroids and patients not taking steroids. Patients not taking steroids with low NLR showed markedly longer PFS (RPCCC: $p<0.005$; USC: $p<0.05$) and OS (RPCCC: $p<0.001$; USC: $p<0.05$). However, patients taking steroids showed no significant correlation of NLR with PFS or OS.

Conclusions: Baseline NLR was associated with prognosis of NSCLC patients undergoing ICI therapy who do not receive steroids at the initiation of ICI therapy but was not correlated with response to ICI therapy. The results of NLR can be obtained via routine bloodwork and readily available for prompt feedback to oncologists and patients; however, clinicians must take care in the prognostic value of NLR in patients who were on steroids at the initiation of ICI therapy.

#2023 AccuScan: an ultra-sensitive and robust MRD detection using WGS with single-read error correction.

Xinxing Li[1], Lui Ng[2], George Yeung[3], Yingyu Wang[3], **Paul Tang**[3], Tobias Wittkop[3], Malek Faham[3], Li Weng[3], William Cho[4], Dominic, Chi-chung Foo[2], Zhiqian Hu[1]

[1]Tongji Hospital, Shanghai, China,[2]University of Hong Kong, Hong Kong, Hong Kong,[3]AccuraGen, Inc., San Jose, CA,[4]Queen Elizabeth Hospital, Hong Kong, Hong Kong

Whole-genome sequencing (WGS) of cell-free DNA (cfDNA) holds tremendous potential for detecting molecular residual disease (MRD), but its accuracy has been constrained by errors introduced during library preparation and sequencing. To overcome these limitations, we introduced AccuScan, a novel and robust cfDNA WGS technology that enables genome-wide error correction at the single-read level, achieving an error rate of 4.2×10^{-7}, which is orders of magnitude improvement over conventional read-centric de-noising approaches. AccuScan has demonstrated analytical sensitivity down to parts per million (ppm) circulating variant allele frequency (cVAF), while maintaining 99% specificity at the sample level. By combining the convenience of WGS with the sensitivity and specificity of tumor-informed approaches, AccuScan enables precise detection of MRD in a timely manner, addressing critical unmet needs in colorectal cancer (CRC) adjuvant therapy decision-making. In the current clinical study involving 56 CRC patients who went through curative intended surgery (stages I: 7, 12.5%; stage II: 17, 30%; stage III: 26, 46.4%; stage IV: 6, 10.7%), AccuScan achieved ~88% sensitivity for MRD detection from a single sample collected within six weeks post-surgery. The test showed a strong correlation with recurrence risks over a three-year follow-up period while delivering 100% specificity. Notably, AccuScan captured MRD at <100 ppm cVAF, demonstrating its ultra-sensitive detection capabilities at the landmark timepoint when adjuvant therapy decisions need to be made. With a simple and distributable workflow, AccuScan demonstrated high performance and a high success rate in processing cfDNA samples across a broad range of input DNA quantities. Its current performance is powered by a straightforward statistical model that leverages single nucleotide variant (SNV) information. Future advancements in performance are anticipated with expanded cfDNA WGS datasets and the incorporation of cutting-edge machine learning strategies.

#2024 Circulating tumor DNA detectability and targetability in patients undergoing neoadjuvant therapy for localized breast cancer.

Arielle J. Medford[1], Elyssa Denault[2], Veerle Bossuyt[3], Michelle Hutchinson[4], Emily Westheimer[4], Jianhua Zhao[4], Bob Daber[4], Steven J. Isakoff[1], Beverly Moy[1], Dejan Juric[1], Laura M. Spring[1], Ryan Corcoran[1], Aditya Bardia[5]

[1]Mass General Cancer Center / Harvard Medical School, Boston, MA,[2]Mass General Cancer Center, Boston, MA,[3]Pathology, Mass General Cancer Center / Harvard Medical School, Boston, MA,[4]Labcorp Genetics, Burlington, NC,[5]UCLA Health Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: Circulating tumor DNA (ctDNA) detection can identify patients (pts) at higher risk for cancer recurrence. Hormone receptor positive (HR+)/HER2- breast cancer (BC) is typically less responsive to chemotherapy, and standard indicators of tumor response to neoadjuvant therapy (NAT) are less informative of prognosis. In this study, we analyzed banked plasma samples for ctDNA in pts receiving neoadjuvant BC treatment to determine the associations between ctDNA detectability and post-NAT surgical pathology and overall outcomes.

Methods: Plasma samples from pts with high-risk localized HR+/HER2- BC treated with NAT were retrospectively analyzed for ctDNA using the Invitae Personalized Cancer Monitoring™ assay. Primary tumors underwent whole exome sequencing (WES), and personalized primer sets were designed for up to 50 tumor-specific variants. High throughput next generation sequencing was then used to evaluate plasma samples for ctDNA at up to 3 timepoints: prior to, during, and after NAT. Levels of residual disease were determined by residual cancer burden index (RCB). WES data was interrogated for variants with approved matched targeted therapies.

Results: Retrospective plasma samples from twelve patients with high-risk early BC (9 stage II, 3 stage III) underwent ctDNA analysis. Five pts had +ctDNA pre-NAT; 3 experienced ctDNA clearance on NAT (all chemotherapy), and 2 of these pts showed sustained post-NAT ctDNA clearance. One of these pts had RCB-0 and the other RCB-2 disease. To date, these 2 pts have not had recurrence of their disease (f/u 45.7 & 47.1 months). Among the 2 pts with +ctDNA on NAT, 1 was receiving chemotherapy and 1 endocrine therapy. The other 3 pts with pre-NAT +ctDNA who did not have documented post-NAT ctDNA clearance experienced recurrences: 14.4, 68.4, & 72 months after surgery. The 7 pts with -ctDNA pre-NAT have not experienced recurrence to date (median f/u 62.7 months). Overall, 7/12 pts (58%) had targetable variants detected on tissue WES: 4 *PIK3CA* (N345K x2, Q546K, H1047R) and 3 *AKT1*^{E17K}. Three of these pts had +ctDNA, and all had activating *PIK3CA* mutations. One pt with *PIK3CA*^{N345K} experienced sustained ctDNA clearance.

Conclusions: Persistence of ctDNA despite NAT appears to be associated with disease recurrence, though the number of patients in this retrospective analysis was small. These hypothesis generating findings require validation in larger datasets. If validated, results could guide development of interception clinical trials with PI3K inhibitors for pts with ctDNA+ *PIK3CA*-mutant breast cancer.

#2025 Regulatory role of CDC20 phosphorylation in the onset and progression of endometrial carcinoma.

Wanbao Ding[1], Jiuqin Lu[1], Yanfang Zhao[1], Hui Dai[1], Feilong Zhao[2], Ding Zhang[2], Huan Guo[1]

[1]Kunming Yan'an Hospital., Kunming, China,[2]3D Medicine, Shanghai, China

Background: Phosphorylation is a critical post-translational modification regulating key biological processes. CDC20 is a key regulator in cell cycle control, but its phosphorylation's role in Uterine Corpus Endometrial Carcinoma (UCEC) is not well understood.
Methods: We used two datasets from the Clinical Proteomic Tumor Analysis Consortium (CPTAC). PDC000126 was the training set, and PDC000441 was used for validation. Both datasets contained proteomic and phosphoproteomic data. Differentially expressed phosphorylation (DEP) sites were identified. Kinase prediction was performed using a kinase-recognition motif library, and functional enrichment analysis was carried out using GSEA.
Results: We identified 7223 phosphorylation sites after filtering samples for data quality. Principal component analysis (PCA) distinguished normal from tumor samples but did not separate early- and late-stage tumors. CDC20(T106) and TRA2A(S100) phosphorylation (pCDC20 and pTRA2A for shot) were significantly upregulated in both early and late-stage tumors compared to normal tissues. No significant differences were found between early- and late-stage tumor phosphorylation levels, suggesting these sites are involved in tumor initiation and remain elevated during progression. pCDC20 was associated with worse survival outcomes, particularly when dichotomized using the 70th percentile as a threshold (HR 7.32, P = 0.022). pTRA2A was not significantly related to survival. Multivariate Cox regression, adjusted for tumor grade, confirmed pCDC20 as an independent prognostic factor. CDC20 protein expression alone was not significantly associated with prognosis, but pCDC20 remained significant after adjusting for protein levels (HR = 37.18, P = 0.025). Kinase prediction identified CDK1 and CDK2 as potential regulators of pCDC20. CDK1/2 expression was positively correlated with pCDC20, and protein interaction analysis confirmed strong interactions between CDC20 and CDK proteins. GSEA showed activation of epithelial-mesenchymal transition (EMT), vasculature development, and cell morphogenesis pathways in the pCDC20 high-phosphorylation group. pCDC20 was validated in the PDC000126 dataset, showing similar trends in early- and late-stage tumors. Correlation between pCDC20 and CDC20 protein was confirmed, as was the association between CDK1/2 expression and phosphorylation. Survival analysis in the validation set indicated poorer prognosis in patients with high pCDC20, which became significant after adjusting for tumor grade (HR 3.28, P = 0.04).
Conclusions: CDC20 phosphorylation is a prognostic marker in UCEC, possibly functioning by promotion of vasculature development and cell morphogenesis. Targeting pCDC20 may offer therapeutic potential in UCEC treatment.

#2026 Comprehensive molecular and immunological characterization of CLDN18.2 in pancreatic cancer.

M. Malla[1], S. Deshmukh[2], T. Samec[2], S. Wu[2], J. Xiu[2], M. Akce[1], G. Gupta[1], Q. Hussaini[1], D. Outlaw[1], R. Arrend[1], A. Desai[1], A. Basu[1], P. N. Ganji[1], M. Evans[2], H.-J. Lenz[3], E. Lou[4], D. Castillo[2], R. Schroff[5], D. Spetzler[2], B. El-Rayes[1];
[1]University of Alabama at Birmingham, Birmingham, AL, [2]Caris Life Sciences, Phoenix, AZ, [3]University of South California, Los Angeles, CA, [4]University of Minnesotta, Minnesotta, MN, [5]University of Arizona, Tucson, AZ

Introduction: Claudin 18 (*CLDN18*) is an emerging biomarker and transmembrane protein that maintains a tight junction between cells in pancreatic cancer (PC). Due to the high expression of *CLDN18.2,* an isoform of *CLDN18*, genomic profiling has demonstrated *CLDN18.2* as a potential target with prognostic impact; we aimed to characterize the molecular and immunological features associated with *CLDN18.2* expression in PC.
Methods: 9,837 PC samples were tested by NGS (592, NextSeq; WES, NovaSeq) and WTS (NovaSeq; Caris Life Sciences, Phoenix, AZ). PD-L1 expression was assessed using immunohistochemistry (SP142 clone). Immune cell fractions were calculated by deconvolution of WTS: Quantiseq. Tumors with *CLDN18.2*-high(H) and *CLDN18.2*-low(L) RNA expression were classified by top and bottom quartile, respectively. Real world overall survival (OS) was obtained from insurance claims and calculated from tissue collection to last contact using Kaplan-Meier estimates. Statistical significance was determined by chi-square and Mann-Whitney U test with *p*-values adjusted for multiple comparisons (q<0.05).
Results: Median *CLDN18.2* expression was higher in primary compared to metastatic PC (3-fold, *q*< 0.05). *CLDN18.2*-H primary and metastatic PC had higher frequency of *KRAS* (95.2% vs 83.8%, 91.7% vs. 82.8%) and *SMAD4* (28.4% vs 15.3%, 23.1% vs 14.9%), but lower frequency of *ARID1A* (6.6% vs 11.1%, 8.9% vs 13.2%) mutation (all q<0.05). *CLDN18.2*-H primary and metastatic PC had lower PD-L1 positivity (4.1% vs 27.9%, 5.3% vs 29.9%, q<0.05). *CLDN18.2*-H primary and metastatic tumors had higher infiltration of B cells (5.1% vs 3.8%, 4.4% vs 3.3%), M2 Mφ (3.6% vs 3.3%, 3.7% vs 3.1%), and NK cells (2.8% vs 2.5%, 2.5% vs 2.3%), all q<0.05. *CLDN18.2*-H primary and metastatic PC had differential expression of immune checkpoint genes (upregulation: *CTLA4*, *HAVCR2, FOXP3, CD47, BTLA, TIGIT, CD160*; fold change (FC): 1.1 - 1.46; downregulation: *CD274*, *LAG3, IDO1, CD276*, FC: 1.1 - 1.3, all q<0.05). *CLDN18.2*-H primary and metastatic PC had higher T-cell inflamed score (25 vs -28, 21 vs 18.5, q<0.05). *CLDN18.2*-H was associated with better OS compared to *CLDN18.2*-L in primary (mOS: 20 vs 13.2 months; HR: 0.73, 95% CI 0.64 - 0.83, p < .00001) and metastatic (mOS: 9.0 vs 5.9 months; HR: 0.76, 95% CI 0.7 - 0.83, p <.00001) PC. A multivariate Cox analysis revealed that above median values of NK cells were strongly associated with better survival in *CLDN18.2*-H primary (HR: 0.75, 95% CI 0.66 - 0.85, p <.00001) and metastatic (HR: 0.73, 95% CI 0.67 - 0.8, p <.00001) PC.
Conclusions: *CLDN18.2* expression is associated with distinct genomic alterations, a differentially modulated immune microenvironment and PC patients' survival. Prospective clinical trials using novel approaches to target *CLDN18.2* in PC are underway. Further studies are required to study the impact of *CLDN18.2* expression and targeted strategies on survival outcomes of patients with PC.

#2027 Developing an image analysis algorithm to evaluate immunofluorescence intensity for Rb and phospho-Rb expression in circulating tumor cells in HR+/HER2- breast cancer.

Shivaani Suresh Kanna[1], Mantasha Tabassum[2], Meghana V. Trivedi[1]

[1]Department of Pharmacy Practice and Translational Research, University of Houston, College of Pharmacy, Houston, TX,[2]Department of Pharmacological and Pharmaceutical Science, University of Houston, College of Pharmacy, Houston, TX

Introduction: Our lab is developing a multiplex immunofluorescence (IF) assay that can be used on circulating tumor cells (CTCs) to assess Rb and pRb expression to predict efficacy of CDK4/6 inhibitors. In this study, we aimed to develop an image processing algorithm for analyzing Rb and pRb expression.

Methods: Positive control (MCF7 and T47D) and negative control (MDA-MB-468 and T47D palbociclib-resistant) cell lines were stained with anti-Rb-AF594, anti-pRb-AF488, and DAPI. The IF-stained cells were imaged using a Leica SP8 STED confocal microscope and processed with the ImageJ Fiji software. An image analysis pipeline was developed by comparing various parameters for each condition for optimized z project (Max intensity vs. Sum slices), background subtraction (Rolling ball radius vs. Mean), and threshold settings (Default vs. Otsu). Mean fluorescence intensities (MFI) between various parameters were compared using the Mann-Whitney U test. A p-value of <0.05 was considered statistically significant. Signal-to-noise ratio (SNR) was calculated as (mean signal from positive control cells - mean background from negative control cells) / background standard deviation. This pipeline was further validated on mixed cell populations of MCF7 P + leukocytes, which were stained with anti-CK-AF647, anti-CD45-AF555, anti-Rb-AF594, anti-pRb-AF488, and DAPI. At least 3 independent experiments were included. MFI was determined for DAPI+/CK+/CD45- cells.

Results: A systematic approach was employed, beginning with standardizing image acquisition parameters, including laser intensity and gain settings, to ensure consistency between samples within an experiment using 2 positive and 2 negative control cell lines. For initial optimization with z-projection settings, significantly higher MFI was obtained with Sum slices compared to Max intensity for both positive and negative control cells. For background subtraction, Rolling ball radius versus Mean background subtraction showed no significant differences between the two settings. For threshold comparisons Otsu method introduced significant background noise in negative controls, compromising intensity accuracy, leading to the selection of Default method. Therefore, proposed pipeline included Sum slices, Rolling ball radius, and Default method optimized using internal controls with an SNR of 16 for Rb and 170 for pRb. Validation with MCF7 P + leukocyte samples produced MFIs (median (range)) of 103,802 (5,484 - 627,148) for Rb and 149,274 (8,379 - 791,202) for pRb for the DAPI+/CK+/CD45- cells.

Conclusion: We have established the IF image processing pipeline for Rb and pRb expression assessment, which will be further refined to assess the sensitivity and specificity of the IF assay, laying a foundation for its future application to patients' isolated CTC samples.

#2028 Development of a miRNA-based prognostic signature for clear cell renal cell carcinoma.

Minghui Zhang, Brock C. Christensen, Lucas A. Salas

Dartmouth Geisel School of Medicine, Hanover, NH

Background: Clear cell renal cell carcinoma (ccRCC) represents about 80% of renal cell carcinoma cases. MicroRNAs (miRNAs) play a critical role in RNA silencing and post-transcriptional regulation of gene expression, impacting tumorigenesis and cancer progression. This study aimed to develop a miRNA-based prognostic model to predict overall survival in ccRCC patients by leveraging genome-wide miRNA expression profiling.
Methods: Sequencing data from tumor kidney samples were obtained from the Dartmouth Renal Tumor Biobank. Data was processed using the Nextflow smrnaseq pipeline and analyzed in R. Log-transformed Transcripts Per Million (logTPM) values were used for downstream analysis. After quality control, survival-associated miRNAs were identified using Cox proportional hazards (CoxPH) models, controlling for batch effects and tumor stage. miRNAs with a p-value < 0.01 were further refined through the LASSO method, yielding an optimal set of miRNAs for prognostic modeling. The prognostic risk score was calculated as: Risk score = $\sum$(logTPM×coefficient). Patients were stratified into high and low risk groups based on the median risk score. Kaplan-Meier survival analyses and CoxPH models were used to assessed survival differences between risk groups. Covariates, including batch, cell proportion, grade, stage, age, and sex, were included in adjusted analyses. Predictive accuracy was assessed by calculating the area under the curve (AUC) for 1, 3, and 5 years using the survivalROC package with the nearest neighbor estimation.
Results: 147 tumor samples with complete covariates passed quality control. For the initial analysis, 37 miRNAs were associated with survival, and 19 miRNAs were retained using the LASSO method. Of these, 15 miRNAs were previously reported to have tumor-related functions. Notably, miR-466, -4437, and -524-3p were associated with prognosis in other cancers. The risk score, derived from the expression levels and coefficients of the 19 miRNAs, followed a normal distribution (Shapiro-Wilk normality test p-value = 0.15) with a median value of -4.29. Patients in the high-risk group had a significantly higher hazard for death compared to those in the low-risk group, with a hazard ratio (HR) of 6.21 (95% CI: 3.94-9.78, p-value = 3.28 E-15). After adjusting for relevant covariates, the high-risk group remained an independent predictor of poor survival (HR: 9.06, 95% CI: 4.99-16.46 , p-value = 4.66 E-13). The predictive performance was robust, with AUCs of 0.85, 0.86, and 0.81 for 1, 3, and 5 years, respectively.
Conclusion: The miRNA-based risk score effectively predicts survival in ccRCC patients, offering a potential prognostic biomarker for ccRCC. It may provide valuable insights for predicting survival outcomes and guiding clinical decision-making. Future studies should validate these findings in external cohorts and explore the underlying biological mechanisms of the identified miRNAs.

CLINICAL RESEARCH: Predictive Biomarkers 3
Poster Session

#2032 Interleukin-8 expression inversely predicts the therapeutic effectiveness of doxorubicin and paclitaxel on triple-negative breast cancer.

Hui-Yu Lin[1], Yuan-Feng Lin[2], Hui-Wen Chiu[2], Ling-Ming Tseng[3]

[1]School of Medicine, Division of Breast Surgery and General Surgery, Department of Surgery, Cardinal Tien Hospital, Fu-Jen Catholic University, New Taipei City, Taiwan,[2]Graduate Institute of Clinical Medicine, Taipei Medical Universtiy, Taipei City, Taiwan,[3]Comprehensive Breast Health Center, Surgery, Taipei Veterans General Hospital, Taipei, Taiwan

Background: Triple negative breast cancer is a subtype of breast cancer and exhibits highly metastatic potentials. Neoadjuvant or adjuvant chemotherapy, e.g. Anthracycline and Taxane, remains as a main regimen to treat TNBC currently. However, TNBC patients usually suffered from chemotherapy, e.g. doxorubicin and paclitaxel, owing to the lack of useful biomarkers to predict their therapeutic effectiveness. The aim of this study was made to estimate the usefulness of pro-inflammatory cytokine interleukin-8 (IL-8) for predicting the therapeutic efficacy of doxorubicin and paclitaxel in TNBC.

Methods: The *in silico* analysis was performed to the potential biomarkers for predicting the therapeutic effectiveness on TNBC patients. Cell-based cytotoxicity assay was established to measure the half maximal inhibitory concentration (IC_{50}) of doxorubicin and paclitaxel in the tested TNBC cells with IL-8 supplement or knockdown. Animal model was established to evaluate the therapeutic effectiveness of doxorubicin and paclitaxel on the xenograft tumors derived from TNBC cells without or with IL-8 overexpression or knockdown. Gene Set Enrichment Analysis (GSEA) was employed to predict the potential pathways associated with IL-8 upregulation in TNBC.

Results: The *in silico* analysis demonstrated that IL-8 is a potential biomarker to predict the therapeutic outcome of TNBC patients who received doxorubicin or paclitaxel. The IL-8 supplement desensitized TNBC cell line HCC1937 that harbors a lower endogenous IL-8 expression to doxorubicin treatment but enhances its sensitivity to paclitaxel; Accordingly, the administration of doxorubicin failed to but paclitaxel effectively suppressed tumor growth of the xenograft tumors derived IL-8-overexpressing HCC1937 cells compared to the control group. In contrast, the treatment with doxorubicin dramatically inhibited but paclitaxel did not affect tumor growth of the xenograft tumors derived IL-8-silenced MDA-MB231 cells compared to the non-silencing control. GSEA results indicated that IL-8 upregulation in primary tumor of TNBC patients highly associates with the activation of E2F and NF-κB pathway. The inclusion of IL-8 protein in HCC1937 cells dramatically promoted but its knockdown in MDA-MB231 cells blocked RB phosphorylation, E2F activity and NF-κB activation. Pharmaceutical inhibition of IL-8 receptor by Reparixin or NF-κB by SN50 and BAY 11-7082 significantly reversed the IL-8-triggered doxorubicin resistant/paclitaxel sensitive responsiveness in HCC1937 cells.

Conclusion: These findings demonstrated that IL-8 expression could be a useful indicator to predict the responsiveness of TNBC patients who are deciding to receive doxorubicin or paclitaxel therapy.

#2033 Identification of biomarkers for drug candidate LP-184 in precision oncology applications.

Aditya Kulkarni, Jianli Zhou, Giulia Agnello, Reggie Ewesuedo, Marc Chamberlain, Kishor Bhatia

Lantern Pharma Inc., Dallas, TX

LP-184, Lantern Pharma's acylfulvene small-molecule alkylator currently being evaluated in a Phase 1a trial, exhibits potent preclinical activity against multiple solid tumors. LP-184 is a prodrug bioactivated intracellularly by the enzyme prostaglandin reductase 1 (PTGR1), often elevated in cancer. In cell line experiments, PTGR1 expression by RNAseq was found to be highly concordant with that by RT-PCR ($r = -0.975$, $p < 0.0001$). The assay identified a ΔCt value of 7.5 as the PTGR1 (normalized to housekeeping genes ACTB and GAPDH) expression threshold associated with LP-184 sensitivity (IC50 < 300 nM) and with average peak plasma exposure from preliminary clinical pharmacokinetics. We then established an RT-PCR assay for PTGR1 quantification in FFPE tissue samples. In the ongoing Phase 1a trial, 80% of analyzed tumor samples showed PTGR1 expression greater than this threshold. In silico analysis of 20 solid tumor TCGA histologies showed that 78% of samples expressed PTGR1 levels greater than the corresponding RNAseq expression threshold (4.5 log2TPM+1) associated with LP-184 sensitivity. In cancer cell lines, LP-184 induced DNA double strand breaks (DSBs) and triggered DNA repair as measured by the SensiTive Recognition of Individual DNA Ends (STRIDE) assay. 24-hour LP-184 treatment in parental and engineered DLD1 colon cancer cell lines led to 2-fold elevated levels of DSBs and γH2AX (phosphorylated H2AX, DNA damage marker) in BRCA2 knockout cells compared to wild type. LP-184 demonstrated 3-fold higher in vitro sensitivity in DNA Damage Repair (DDR) deficient tumor models compared to non-DDR altered cell lines, along with complete, durable tumor regressions in multiple xenograft DDR deficient tumor models. Preclinical data on LP-184 anti-tumor activity and biomarker status indicate that the inactivation of BRCA1/2, ATM/ATR, and ERCC3/4, and the activation of EGFR are key biomarker candidates predicting response to LP-184. In addition, a genome-wide CRISPR chemogenetic screen of LP-184 in the TNBC cell line MDAMB231, suggested that ATRX, EZH2, HSP90AA1, CDKN2B, MAD2L2, PSMA6, NDUFA1, and BRAF are other potential predictive biomarkers of LP-184 activity. Drug-gene associations derived from preclinical studies have identified a panel of biomarkers associated with LP-184 bioactivation (PTGR1:RT-PCR/tissue), pharmacodynamics (DNA DSB, γH2AX: Multiplexed STRIDE or IF assay/tissue), and response prediction (BRCA1/2 etc.: liquid biopsy or tissue/ TSO500 NGS panel). A retrospective biomarker validation will be performed using established NGS assays to analyze liquid biopsy and/or tissue samples from the ongoing Phase 1a LP-184 trial. Future directions include determining associations between biomarker expression or mutation and clinical outcomes, refining PTGR1 expression threshold, and utilizing emerging biomarkers to guide patient selection in subsequent expansion studies.

#2034 Investigation of TROP2 expression and immune microenvironment in ovarian clear cell carcinoma.

Toru Imai[1], Yuki Kojima[1], Hiroshi Yoshida[2], Rui Kitadai[1], Mai Hoshino[1], Ayumi Saito[1], Munehiro Ito[1], Shosuke Kita[1], Aiko Maejima[1], Kazuki Sudo[1], Masaya Uno[3], Tatsunori Shimoi[1], Mitsuya Ishikawa[3], Kan Yonemori[1]

[1]Department of Medical Oncology, National Cancer Center Hospital, Japan, Tokyo, Japan,[2]Department of Diagnostic Pathology, National Cancer Center Hospital, Japan, Tokyo, Japan,[3]Department of Gynecology, National Cancer Center Hospital, Japan, Tokyo, Japan

Background: Ovarian clear cell carcinoma (OCCC) is a rare subtype of ovarian cancer, with a higher incidence in East Asia compared to Western countries and a tendency to affect younger individuals. OCCC has poor prognosis due to its low sensitivity to chemotherapy, presenting a significant unmet medical need. However, therapeutic development has been limited due to its rarity. Recently, advancements in antibody-drug conjugates (ADCs) targeting Trophoblastic cell-surface marker (TROP2) have shown promise, but the expression of these therapeutic targets in OCCC remains unclear. This study aimed to explore new therapeutic targets for OCCC by analyzing TROP2 expression and the immune microenvironment.
Methods: Clinical data were collected from OCCC patients who underwent surgery at the National Cancer Center Hospital between 2007 and 2024. TROP2 (MAB650), ARID1A (polyclonal), and PD-L1(E1L3N) were evaluated. PD-L1 expression was evaluated using both Tumor Proportion Score (TPS) and Combined Positive Score (CPS). TROP2 expression was assessed using the H-score, with a score of ≥10 defined as positive. Pathological features, including stromal characteristics, cytoplasmic features, and tissue architecture, were also analyzed.
Results: A total of 125 OCCC patients were included. TROP2 expression was positive in 90 patients (72.0%) and negative in 35 patients (28.0%). ARID1A was retained in 52 patients (41.6%) and lost in 73 patients (58.4%). TPS values were <1 in 44 patients (35.2%), 1-49 in 73 patients (58.4%), and ≥50 in 8 patients (6.4%). CPS values were <1 in 33 patients (26.4%), 1-9 in 30 patients (24.0%), and ≥10 in 62 patients (49.6%). No significant differences were observed in TROP2 expression across these variables. Overall survival did not significantly differ between TROP2-positive and TROP2-negative patients (HR=1.22, 95%CI: 0.48-3.09, p=0.67). ARID1A status was also not associated with survival (HR=1.48, 95%CI: 0.62-3.49, p=0.37). However, CPS ≥10 was associated with a trend toward worse prognosis (HR=2.92, 95%CI: 0.95-8.41, p=0.06). Poor prognosis was also observed in cases with high stromal inflammation (HR=2.47, 95%CI: 1.09-5.60, p=0.03) and solid tissue architecture (HR=2.89, 95%CI: 0.99-8.46, p=0.05). Patients with both CPS ≥10 and TROP2 positivity accounted for 47 individuals (37.6%) and showed a trend toward worse prognosis compared to CPS-negative and TROP2-negative patients (HR=3.17, 95%CI: 0.71-14.06, p=0.13).
Conclusions: In OCCC, 72% of patients exhibited TROP2 positivity, and 49.6% had CPS ≥10. Patients with CPS positivity tended to have worse prognosis, and those with both TROP2 and CPS positivity represented 37.6% of the cohort. These findings suggest that TROP2-ADC and combination immunotherapy may represent promising therapeutic strategies for this patient subgroup.

#2035 Clinical-immunological correlates in platinum resistant or refractory ovarian cancer patients treated with chimeric oncolytic adenovirus encoding TNFa and IL-2 (TILT-123) in combination with pembrolizumab.

James H. A. Clubb[1], Matthew Block[2], Johanna Maenpaa[3], Victor Arias[4], Mirte van der Heijden[4], Santeri Pakola[4], Dafne C. A. Quixabeira[1], Tatiana Kudling[4], Elise Jirovec[4], Lyna Haybout[1], Tuomo Alanko[3], Daniel Adamo[2], Susan Ramadan[3], Jorma Sormunen[3], Juha Kononen[3], Michael J. Chisamore[5], Julia W. Cohen[5], Nadena Singh[5], John Goldfinch[6], Suvi Sorsa[1], Riikka Havunen[1], Claudia Kistler[1], Joao M. Santos[1], Victor Cervera-Carrascon[1], Akseli Hemminki[1]

[1]TILT Biotherapeutics Oy, Helsinki, Finland,[2]Mayo clinic, Rochester, MN,[3]Docrates Cancer Center, Helsinki, Finland,[4]Translational Immunology Research Program, University of Helsinki, Helsinki, Finland,[5]Merck & Co., Inc, Rahway, NJ,[6]TILT Biotherapeutics Oy, Orchard Park, NY

Background: Ad5/3-E2F-D24-hTNFa-IRES-hIL-2 (TILT-123) is an oncolytic adenovirus armed with TNFa and IL-2. The cytokine pairing demonstrated superior tumor immunomodulation in preclinical studies. Subsequent studies supported evaluation of TILT-123 in PROTA, a phase 1 study of TILT-123 in combination with pembrolizumab in platinum resistant or refractory ovarian cancer patients. Biomarker analysis is ongoing.

Experimental procedures: In this phase 1a dose escalation trial (NCT05271318), 15 patients received an initial single intravenous dose of TILT-123 ranging from $3x10^{11}$ to $4x10^{12}$ VPs , followed by intratumoural and/or intraperitoneal injections ranging from $1x10^{11}$ to $5x10^{11}$ VPs. Patients also received i.v. pembrolizumab (200mg) every three weeks starting on day 36. The primary endpoint was safety by day 92, while efficacy by RECIST1.1 and overall survival (OS) were secondary endpoints. Collection of tumour biopsies and blood, including PBMCs and serum, enabled evaluation of MoA and identification of preliminary biomarkers.

Summary of data: ORR was 7.1% in evaluable patients (1/14). Disease control rate was 64% in evaluable patients (n = 14) and median OS was 190 days (n =15). Patients with disease control and no disease control by 92 achieved a median OS of 571 days and 138 days respectively. Correlations of complete blood count with differential to OS (n =15) and imaging response (n = 14) revealed a greater drop in lymphocyte count after treatment, as well as baseline lymphocyte count positively correlated with OS and disease control (PR/SD vs PD). Correlation of prothrombin INR to OS revealed patients with a slower blood-clotting rate at baseline and post-treatment positively correlated with OS. Analysis of anti-adenovirus neutralizing antibody (nAb) titer revealed 77% of all patients were positive for nAbs prior to treatment. All patients developed nAbs in blood and ascites (ascites n = 3). Patients presenting with nAbs at baseline achieved longer OS than those not positive. Additionally, a higher titer post-treatment positively correlated with OS and disease control. Percentage and fold change increase in IgM expression on plasma cells on day 36 positively correlated with OS. In addition, a higher expression of IgM on the surface of plasma cells at baseline was observed in patients achieving disease control.

Conclusion: These preliminary results identify a key role of circulating lymphocyte re-distribution and humoral immune response as markers of treatment benefit. Initial phenotyping implicates IgM producing plasma cells as a potentially relevant immune cell population. Additionally we observed a correlation between the coagulation cascade and OS.

#2036 Transcriptomic immune signatures and reconstructed immune cell types associated with pathological complete response to neoadjuvant chemotherapy in triple-negative breast cancer.

T. Oshino[1], T. Noguchi[1], N. Tomioka[2], K. Hatanaka[1], A. Evdokimova[3], P. Turova[3], V. Kushnarev[3], N. Kotlov[3], K. Chernyshov[3], Z. Polyakova[4], K. Kryukov[3], A. Makarova[3], M. Hosoda[1], S. Ariga[1], R. Moku[1], Y. Shiotsu[4], Y. Hatanaka[1], I. Kinoshita[1], M. Takahashi[1]; [1]Hokkaido University Hospital, Sapporo, Japan, [2]Hokkaido Cancer Center, Sapporo, Japan, [3]BostonGene, Waltham, MA, [4]BostonGene Japan, Tokyo, Japan

Background: Pathological complete response (pCR) following neoadjuvant chemotherapy (NAC) is positively correlated with long-term event-free survival and overall survival in patients with triple-negative breast cancer (TNBC). However, the molecular subtypes of TNBC associated with pCR remain to be elucidated.

Methods: We conducted a transcriptomic and clinical outcome analysis of 28 TNBC patients who underwent surgery following NAC at Hokkaido University Hospital and Hokkaido Cancer Center in Japan between 2017 and 2022. The research protocol was approved by the Internal Review Board at the medical institutes and BostonGene (023-0109). We used an internally developed algorithm (Breast Cancer Classifier, BCC) to classify tumors into 5 intrinsic subtypes: Basal, Luminal A (LumA), Luminal B (LumB), HER2 high, and HER2-low. Using methods described by Bagaev et. al. (*Cancer Cell, 2021*), we selected 21 functional gene expression signatures to identify tumor microenvironment (TME) subtypes. Next, we used deconvolution by Kassandra algorithm for precise reconstruction of TME. The Mann-Whitney U test and chi-square test with Benjamini-Hochberg correction were used for statistical analysis.

Results: Twelve patients achieved pCR, with a median age of 53 years, while 16 were non-pCR with a median age of 63 years. The clinical stages at diagnosis in the pCR group were stage I (n=3), stage II (n=7), and stage III (n=2), while the non-pCR group included stage II (n=7), and stage III (n=9). Anthracycline followed by taxane regimens were administered to 8 pCR and 13 non-pCR patients, and the remainder received investigational regimens as clinical trials. HER2 scores of 0, 1+ and 2+ were observed in 14, 5, and 9 patients, respectively. BCC revealed 54% (15/28) of patients had basal-like and 25% (7/28) had HER2-low TNBC. It also classified 12% (3/28) as having LumA and another 12% (3/28) as having LumB TNBC. The pCR rates across these subtypes were 53%, 43%, 33%, and 66%, respectively. Kassandra identified 4 TME subtypes: Immune-Enriched, Fibrotic (IE/F); Immune-Enriched, Non-Fibrotic (IE); Fibrotic (F); and Immune-Desert (D). Notably, 11 of 12 pCR patients exhibited the IE subtype, while the non-pCR group displayed a heterogeneous distribution of TME subtypes. Gene signatures of tertiary lymphoid structures were upregulated in pCR patients. Kassandra revealed increased infiltration of T cells, B cells, and NK cells in the TME of pCR patients, corroborated by the presence of lymphocyte clusters in hematoxylin and eosin staining.

Conclusion: Our study demonstrates that BostonGene's TME subtyping and Kassandra can accurately identify TNBC patients likely to achieve pCR after NAC. These findings warrant further prospective evaluation to establish the utility of these approaches in predicting treatment response in TNBC.

#2037 Early identification of long-term survivors on tremelimumab plus durvalumab and chemotherapy in POSEIDON from pre-treatment CT images.

Kedar Patwardhan[1], Harish RaviPrakash[1], Qin Li[2], Ross Stewart[3]

[1]Oncology Data Science, Oncology Research & Development, AstraZeneca, Waltham, MA,[2]Cancer Biomarker Development, Oncology Research & Development, AstraZeneca, Waltham, MA,[3]Translational Medicine, Oncology Research & Development, AstraZeneca, Cambridge, United Kingdom

Background: The combination of CTLA-4 and PD-(L)1 inhibitors either with or without chemotherapy is an approved treatment for metastatic non-small-cell lung cancer (mNSCLC). Identifying which patients are most likely to derive additional benefit from these regimens, as compared anti-PD-1 alone or in combination with chemotherapy (CTx) would help optimize clinical management of these patients.

Methods: Pre-treatment baseline Computed Tomography (CT) images of the thorax from patients treated with durvalumab plus tremelimulab (D+T; n=647) as part of the MYSTIC and NEPTUNE studies were split into a training (n=557) and a validation cohort (n=90). A 3D Deep Learning model with a *DenseNet* architecture was trained to predict patients with overall survival (OS) longer or shorter than the median (~1 year), and then optimized using the validation set. The final model (named RaDx) was then applied *de-novo* to the non-squamous mNSCLC cohort from POSEIDON.

Results: All reported hazard ratios (HR) are comparing RaDx+ and RaDx- groups unless specified otherwise. In the validation cohort, the median OS (mOS) in the RaDx+ (n=38) and the RaDx- (n=52) groups was 21 and 6.3 months respectively with HR=0.44 (0.27-0.73). In the anti-CTLA-4 containing arm of POSEIDON (D+T+CTx; n=187), the mOS for RaDx+ (n=77) and RaDx- (n=110) groups was 26.6 and 10.8 months respectively with HR = 0.44 (0.3-0.64). In the durvalumab and chemotherapy arm (D+CTx; n=182), the mOS for the RaDx+ (n=71) and RaDx- (n=111) groups was 17.2 and 11.2 months respectively with HR = 0.68 (0.48-0.97). In the CTx only arm (n=178), the mOS for the RaDx+ (n=73) and RaDx- (n=105) groups was 15.1 and 11.6 months respectively with HR = 0.82 (0.59-1.13). Within the RaDx+ sub-group a comparison of D+T+CTx to D+CTx patients favoured D+T+CTx with HR = 0.63 (0.42-0.96).

Conclusions: We demonstrated feasibility that a Deep Learning model using baseline CT images may be used to identify a sub-group of patients for whom the addition of tremelimumab to chemo-immunotherapy may bring additional benefit. Such a biomarker could have the potential to guide optimal treatment selection in this 1L mNSCLC population.

#2038 Antibody Drug Conjugates Treatment Response Score (ADC TRS) for predicting ADC treatment response.

S. P. Thomas[1], L. A. Habel[2], J. M. Suga[1], N. Achacoso[2], J. R. Nugent[2], C. Jiang[2], E. Chung[2], S. Bush[3], M. D. Nitchie[3], K. M. Robinson[3], J. Inman[3], R. White[3], K. Plouffe[3], D. R. Rhodes[3], S. A. Tomlins[3], B. Johnson[3];
[1]Kaiser Permanente, Vallejo, CA, [2]Kaiser Permanente Division of Research, Pleasanton, CA, [3]Strata Oncology, Ann Arbor, MI

Background: Predictive biomarkers for multiple ADCs/tumor types (beyond 3+ HER2 IHC) are lacking. We previously reported the discovery of ADC TRS—an algorithm combining individual ADC target expression, proliferation, and adhesion by RNAseq to predict ADC clinical benefit across tumor types/targets—and association with OS after ADC treatment (Abstract 3140, ASCO 2024). Here we evaluated the final ADC TRS biomarker (ADC-specific; tuned on >100 tumor type/ADC RRs) by a qRT-PCR based clinical trial assay (CTA) for predicting ADC clinical benefit.
Methods: Adults in the Kaiser Permanente Northern California (KPNC) system with advanced bladder or breast cancer in an observational trial (NCT03061305) who were treated with an approved ADC (enfortumab vedotin [EV], sacituzumab govitecan [SG] or trastuzumab deruxtecan [T-DXd]; first dose by Apr. 21, 2023) with valid CTA TRS results from FFPE tissue (collected prior to 1st ADC treatment) were eligible; patients with prior trastuzumab or hormonal (between tissue collection/ ADC start) treatment were excluded. KPNC oncologists (blinded to ADC TRS status) determined best response to therapy from chart review. ADC TRS status (+ vs. -) / response data were merged by the KPNC statistician and analyzed per a prespecified plan.
Results: A total of 117 KPNC patients with advanced bladder (n=58 [50%]) or breast (n=59 [50%]) cancer treated with an approved ADC (n= 56 [48%], 47 [40%], and 14 [12%] EV, SG, and T-DXd, respectively) were evaluable for TRS and RR. As shown in the Table, TRS+ status was associated with significantly higher RR and longer PFS and OS for approved ADC treatment; results were generally similar across ADCs and tumor type.
Conclusions: By a qRT-PCR based CTA, TRS+ status was associated with improved RR, PFS and OS for approved ADCs in an observational cohort of patients with advanced bladder or breast cancer. Prospective validation for approved and/or investigational ADCs is warranted.

Analysis	**TRS +**		**TRS-**		**Odds/Hazard Ratio**	**p-value[#]**
	n	**Outcome**	**n**	**Outcome**		
RR (95% CI)*	37	51% (34-68%)	68	32% (22-45%)	2.21 (0.95-5.14)	0.032
PFS (mo; 95% CI)^	37	6.5 (5.0-8.0)	68	3.5 (2.7-4.8)	0.64 (0.42-0.98)	0.02
OS (mo; 95% CI)^	40	15.5 (9.9-18.4)	77	8.3 (5.5-12.0)	0.51 (0.32-0.79)	0.0013
The primary objective evaluated whether ADC TRS status (Pos [+] vs. Neg. [-]) is associated with best response rate (RR) to ADC treatment ([partial response + complete response] / all patients) in those with at least one post ADC follow-up imaging. Exploratory analyses evaluated subgroups, progression free survival (PFS) and overall survival (OS).						
*Odds ratio and p value from logistic model with age, Charlson Comorbidity Index (CCI), and indication.						
^Cox proportional hazard ratios adjusted for age, CCI, and indication.						
[#]1-sided directional hypothesis test.						

#2039 High mesothelin expressing triple negative breast cancer is associated with enhanced cell proliferation but without impact on survival outcomes.

Takumi Sato[1], Brendan Hagerty[2], Rongrong Wu[3], Takashi Ishikawa[3], Kazuaki Takabe[4]

[1]The University of Tokyo Hospital, Tokyo, Japan,[2]Department of Surgical Oncology, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[3]Department of Breast Surgery and Oncology, Tokyo Medical University, Tokyo, Japan,[4]Department of Surgery, University at Buffalo Jacobs School of Medicine and Biomedical Sciences, State University of New York, Buffalo, NY

Introduction: Mesothelin (MSLN) is a cell surface glycoprotein commonly expressed on several types of cancer including breast cancer (BC). Despite lacking an intracellular signaling domain or known physiologic function, MSLN is implicated in aggressive tumor behavior. Although known for high MSLN prevalence, its biological role in triple-negative breast cancer (TNBC) remains largely unexplored. We utilized multiple independent large patient cohorts with comprehensive gene expression profile and clinical variables to unravel the functional and clinical implications of MSLN expression in TNBC.

Methods: Clinical variables and transcriptome of a total of 628 TNBC patients were gathered from three independent cohorts: The Cancer Genome Atlas (TCGA, n=160), the Molecular Taxonomy of Breast Cancer International Consortium (METABRIC, n=313), and The Sweden Cancerome Analysis Network - Breast (SCAN-B, GSE96058, n=155). Four neoadjuvant chemotherapy (NAC) cohorts; GSE32603, GSE25066, GSE163882, and GSE123845 were also analyzed.

Results: Using single-cell sequence cohorts, SCP1039 and SCP1106, we found that MSLN is exclusively expressed in cancer epithelial cells, and its expression is associated with less stromal cells (adipocytes and fibroblasts) in the TNBC tumor microenvironment. High expression of MSLN was associated with the TNBC subtype and advanced lymph node metastasis in BC of TCGA, METABRIC, and SCAN-B cohorts (all $p < 0.001$). Unexpectedly, MSLN expression was not associated with Disease-Free, Disease-Specific, nor Overall Survival in any of the TNBC cohorts analyzed (all $p > 0.05$). MSLN expression was significantly higher in TNBC that achieved pathological complete response after neoadjuvant chemotherapy in the GSE25066 cohort ($p < 0.001$), although there was no survival difference by MSLN expression in this cohort, either. Consistent with its immunological role, MSLN-high tumors exhibited a pro-inflammatory microenvironment, including higher Cancer-Testis Antigen (CTA) scores and increased activity of immune cells, notably immature dendritic cells (iDCs) and M1 macrophages (all $p < 0.05$). Biologically, MSLN expression was linked to elevated cellular proliferation, as evidenced by correlation with Ki67 gene expressions and histological grade consistently in TCGA, METABRIC and SCAN-B. Hallmark cell proliferation-related gene sets, G2M checkpoint, E2F targets, and Mitotic Spindle were significantly enriched in MSLN-high TNBC in METABRIC and SCAN-B (all FDR < 0.25).

Conclusion: MSLN-high TNBC is characterized by enhanced cell proliferation and a pro-inflammatory microenvironment, showing better response to neoadjuvant chemotherapy without significant
impact on long-term survival outcomes. These data may be useful for future studies in MSLN-targeted therapies.

#2040 βAlt score provides independent and significant clinical value in multiple tumor types.

Mary Helen Barcellos-Hoff[1], Hang Chang[2]

[1]UCSF - University of California San Francisco, Berkeley, CA,[2]Lawrence Berkeley National Lab, Berkeley, CA

We reported that a functional relationship between loss of TGFβ signaling and gain of error-prone alternative end-joining DNA repair in cancer cells is evident in RNA sequencing data as a negative correlation between the transcriptomic signatures of TGFβ targets and genes necessary for alternative end-joining DNA repair. A score, βAlt, was designed to represent this relationship, and was shown to predict response to genotoxic chemotherapy and radiotherapy in multiple cancers. High βAlt, indicative of loss of TGFβ signaling competency and gain of error-prone repair, is associated with better response to genotoxic therapy (DOI;10.1126/scitranslmed.abc4465). As previously reported (DOI: 10.1158/1078-0432.ccr-21-2846), we used quartiles to analyze human papilloma virus (HPV)-positive versus HPV-negative head and neck squamous cell carcinoma (HNSCC) using specimens from TCGA and the HPV-negative HNSCC GSE41613 data. The βAlt score predicted response in HNSCC TCGA specimens (p=0.0015) and HPV-negative HNSCC GSE41613 patients (p=0.0033). To demonstrate the independent and significant clinical value of βAlt score and to justify the potential clinical utility of βAlt, we optimized the cut-off of βAlt score. We defined the maximized overall survival difference between patient stratification (survminer package in R, version 0.4.9), and thereafter partitioned patients in each cohort of study into βAlt Low and βAlt High groups. We determined that the value of βAlt score was independent from other clinical factors revealed by multivariate Cox-proportional hazard regression analysis (survival package in R, version 3.3.1) in all cohorts: HPV-positive HNSCC TCGA, p=0.006, HR 5.586 (1.655, 18.851); HPV-negative HNSCC TCGA, p=0.029, HR 1.654 (1.052, 2.601); HPV-negative HNSCC GSE41613 patients, p=0.019, HR 2.068 (1.125, 3.803). The C-Index predictive power calculated using a bootstrapping strategy at an 80% sampling rate with 1,000 iterations of βAlt combined with these clinical factors was significantly improved (p<2.22e-16). We also analyzed βAlt using the TCGA glioblastoma (GBM) cohort. High βAlt in GBM also predicts longer survival (p<0.0001), remains significant after adjusting for important clinical factors, i.e., stage, age, and gender (p<0.001), and significantly improves C-Index predictive power of overall survival (p<2.22e-16). These data underscore that loss of TGFβ signaling, which underlies the marked sensitivity of HPV-positive HNSCC to standard of care chemoradiation, is predictive in non-HPV associated cancers. These results provide robust support that βAlt is a high-quality biomarker for the precision management of cancer patients.

#2041 Microsatellite instability as a biomarker for predicting chemoradiotherapy response in rectal cancer: insights from pathological and radiomic analyses.

Euna Jeong[1], **Hyowon Hong**[2], Jaemin Jo[3], Shin Kim[4], SangJun Byun[5], Incheol Seo[6], Woon Kyung Jeong[7], Seong Kyu Baek[7], Hye Won Lee[3]

[1]Department of anatomy, Keimyung University School of Medicine, Daegu, Korea, Republic of,[2]Research Affairs, Keimyung University Dongsan Medical Center, Daegu, Korea, Republic of,[3]Department of Pathology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[4]Department of Immunology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[5]Department of Radiation Oncology, Keimyung University School of Medicine, Daegu, Korea, Republic of,[6]Department of Immunology, Kyungpook National University School of Medicine, Daegu, Korea, Republic of,[7]Department of Surgery, Keimyung University Dongsan Hospital, Daegu, Korea, Republic of

Background: Colorectal cancer (CRC) is one of the common causes of cancer-related deaths around the world. Rectal cancer accounts for approximately 30% of all colon cancers, half of which are diagnosed as locally advanced rectal cancer. Microsatellite instability (MSI) is a key biomarker in colorectal cancer (CRC), impacting immunotherapy outcomes and potentially influencing chemoradiotherapy (CRT) responses. In this study, we investigate the correlation between treatment response to CCRT according to MSI status.
Methods: Tissue specimens were obtained by preoperative biopsy from 87 patients with rectal adenocarcinoma who underwent CRT. Patients received fluorouracil-based long-course neoadjuvant therapy. MSI analysis was performed on DNA extracted from tumors and matched normal tissue. The extracted DNA was tested by PCR targeting five microsatellite loci: BAT25, BAT26, D5S346, D2S123, and D17S250. Clinical and pathological parameters, including lymphovascular invasion and T/N stage, were compared between CRT responders and non-responders. In vitro, 3 MSI-H and 6 MSS colorectal cancer cell lines underwent gradient radiation exposure. Radiosensitivity was evaluated through XTT cell viability assays and apoptotic rates quantified via flow cytometry (FACS).
Results: Preoperative MSI status was observed divided into MSI (MSI-H+MSI-L) and MSS. In the responder group (n=27), there were 5 people (18.52%) with MSI and 22 people (81.48%) with MSS, and in the non-responder group (n=60), 0 (0.0%) MSI and 60 (100%) MSS were observed (P = <0.005). Additionally, there were significant differences in ypT stage (P<0.001), ypN stage (P=0.003), lymphovascular (P=0.043) and perineural invasion (P=0.035). MSI-H cell lines demonstrated greater radiosensitivity, with significantly reduced viability in XTT assays and higher apoptosis rates in FACS analysis compared to MSS cell lines.
Conclusion: Our findings suggest that MSI status is a significant predictor of response to CCRT, with patients exhibiting MSI tumors showing a higher likelihood of treatment response compared to those with MSS tumors. Enhanced radiosensitivity in MSI-H cell lines further supports the predictive value of MSI testing. Future studies should confirm these findings in larger cohorts.

#2042 ROS1 single nucleotide variants predict favorable survival outcomes on immunotherapy regimens in non-small cell lung cancer.

Yue Wu[1], Jaclyn LoPiccolo[2], Sebastian Carrasco Pro[3], Krishna C. Bulusu[1], Etai Jacob[1], Alexander Gusev[2], Gerald J. Sun[1]

[1]AstraZeneca, Waltham, MA,[2]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Tempus AI, Inc, Chicago, IL

Background: Only a fraction of non-small cell lung cancer patients who receive immune checkpoint inhibitor (ICI) treatment will respond, largely because current FDA-approved biomarkers still leave room for improvement to identify more responders. We hypothesized that modeling the time-dependent interaction between treatment and tumor genetics may reveal novel associations. We further hypothesized that real-world data (RWD), as opposed to clinical trial data, may contain these associations, as RWD possesses a potentially more diverse patient population and time-to-event treatment history across the diverse regimens used in routine clinical practice.

Methods: We examined the relation between tumor genetics, treatment, and real-world progression-free survival (PFS) in two RWD cohorts (Tempus discovery cohort, n = 1458; Dana Farber Cancer Institute Profile independent validation cohort, n = 466) by utilizing a Cox proportional hazards model with a time-dependent covariate for whether a patient was receiving an ICI-containing treatment regimen. Specifically, we included an indicator variable that denoted whether an individual was receiving an ICI regimen (=1) or not (=0), and enumerated the time intervals associated with each treatment status. We performed a univariate analysis for each mutated gene from tumor sequencing, and included a gene-treatment interaction term to permit identification of genes that were predictive (i.e. specific to a treatment) rather than prognostic. Our model included additional covariates to control for known predictive (tumor mutation burden [TMB]) and prognostic factors (age, sex).

Results: In the discovery cohort, we identified a significant association between ROS1 single nucleotide variants (SNV; prevalence = 5%) and favorable PFS on ICI therapy (interaction HR = 0.34, 95% CI = 0.18-0.64, p = 7.8e-4, q = 0.08) versus non-ICI treatment. This association was not explained by ROS1 rearrangement or ROS1 TKI therapy. ROS1 SNV associated with worse PFS when not on ICI treatment (marginal HR = 2.3, 95% CI = 1.4-3.6, p = 4e-4, q = 0.044). This ROS1 SNV association was replicated in the validation cohort, which exhibited a favorable interaction with ICI treatment (interaction HR = 0.11, 95% CI = 0.04-0.33, p = 7.46e-5), and poor PFS on non-ICI treatment (marginal HR = 5.39, 95% CI = 2.5-11.6, p = 1.96e-5). ROS1 SNV treatment interaction effect was also not explained by TMB or PD-L1 status. Finally, we observed the ROS1 SNV ICI-specific protective effect was specific to patients ICI-treated in the first line setting.

Conclusions: We identified an association between ROS1 SNVs and favorable PFS specific to ICI treatment, independent of common pre-existing predictive biomarkers for ICIs. Because this association was specific to the first line ICI setting, our finding may clarify ICI usage where clinical practice for ICI treatment is still evolving.

#2043 Circulating tumor DNA (ctDNA) mutation analysis at baseline (BSL) and end of treatment (EOT) with sacituzumab govitecan (SG) and clinical impact on efficacy in patients (pts) with HR+/HER2- metastatic breast cancer (mBC): Biomarker results from TROPiCS-02.

Hope S. Rugo[1], Yi Zhang[2], Shan Tang[2], Frederik Marme[3], Peter Schmid[4], Javier Cortes[5], Sara M. Tolaney[6], Oh Kyu Yoon[2], Wendy Verret[2], Meghna Das Thakur[2], Aditya Bardia[7]

[1]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[2]Gilead Sciences, Inc, Foster City, CA,[3]Medical Faculty Mannheim, Heidelberg University, Mannheim, Germany,[4]Centre for Experimental Cancer Medicine, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom,[5]International Breast Cancer Center (IBCC), Pangaea Oncology, Quironsalud Group, Barcelona, Spain,[6]Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA,[7]David Geffen School of Medicine, University of California, Los Angeles, Jonsson Comprehensive Cancer Center, Los Angeles, CA

Background: SG is approved in pretreated HR+/HER2- mBC based on the TROPiCS-02 study (NCT03901339). Mutations in specific genes may affect efficacy of SG, including *PIK3CA*/*TP53* (common in BC, may impact outcomes) and *TACSTD2*/*TOP1* (may confer resistance to Trop-2-directed ADCs like SG). We assessed specific mutations at BSL and EOT in TROPiCS-02 to identify genes that may be involved in acquired SG resistance.

Methods: Randomized pts received SG or chemotherapy treatment of physician's choice (TPC). Plasma samples were collected at BSL and EOT, and ctDNA was analyzed using Guardant Health's Infinity RUO ctDNA panel. Specific genes were analyzed to determine association with clinical outcomes (progression-free survival [PFS] and overall survival [OS]). Unbiased analysis at EOT was used to identify genes associated with SG resistance.

Results: Pt characteristics, PFS, and OS were similar between the intent-to-treat (ITT; N=543) and ctDNA (46% of ITT) populations. PFS and OS benefit was observed with SG vs TPC regardless of *PIK3CA* or *TP53* mutation status (Table). At BSL and EOT, no *TACSTD2* mutations were observed in the SG arm. At BSL, 3 *TOP1* mutations (I435V, D122H, M319I) were detected in 2 pts, and at EOT, 1 new *TOP1* mutation (G717V) was detected in the SG arm (184 days treatment). At BSL 64% of pts had ≥1 deleterious variant in the 69-gene DDR panel. No clear expansion or clearance of individual DDR genes or variants was observed at EOT.

Conclusions: Survival benefit was observed with SG vs TPC in pts with and without *PIK3CA* and *TP53* mutations, similar to the ITT population. Our matched BSL to EOT analyses did not identify any genes that were clear drivers of SG resistance in pretreated HR+/HER2- mBC. Future analyses would benefit from paired biopsies at BSL and at disease progression to identify potential drivers of SG resistance.

#2044 High TLR3 transcript levels correlate with high TIM3 and VISTA checkpoints, but not with outcome after immune checkpoint blockade.

Marvin Hsieh[1], Daisuke Nishizaki[2], Taylor J. Jensen[3], Sarabjot Pabla[3], Jeffrey M. Conroy[3], Paul DePietro[3], Shumei Kato[2], Razelle Kurzrock[1]

[1]Medical College of Wisconsin, Milwaukee, WI,[2]University of California, San Diego, La Jolla, CA,[3]Labcorp, Burlington, NC

Introduction: The Nobel Prize-winning discovery of Toll-like Receptors (TLR) in 2011 sparked the exploration of TLR3 as a key target in cancer pathogenesis and immunotherapy treatment. Upon activation by double-stranded RNAs, TLR3 stimulates the production of cytokines and chemokines that augment inflammation and cell death, which are risk-factors in several cancers including colorectal cancer (CRC). Despite the growing interest in TLR3, its specific role in influencing patient outcomes and interactions with other immune checkpoints remains inadequately understood. In this study, we evaluated the association between TLR3 RNA expression levels and clinical outcomes to determine its potential role as a biomarker in cancer prognosis and immune checkpoint inhibitor (ICI) treatment response.

Methods: RNA expression levels of TLR3 and other immune checkpoints were evaluated in 514 tumors (489 patients with full clinical outcome annotation) in a clinical-grade laboratory and categorized as “High” (75-100 percentile) or “Not-High” (0-74 percentile). Univariate logistic regression assessed the association between high TLR3 expression, patient characteristics, immune markers, and cancer subtypes, followed by multivariable logistic regression for variables with $p \leq 0.05$. Survival analyses was conducted through the Kaplan-Meier method on patients with available survival data. Overall survival (OS) and progression-free survival (PFS) were stratified by TLR3 expression (“High” vs “Not-High”) and compared using the log-rank test.

Results: High expression of TLR3 RNA was seen in 90/514 (17%) among all patients and 11/140 (8%) in CRC patients. The highest proportion of high TLR3 expressors were seen in liver and bile duct cancers (7/19, 36.8%), pancreatic cancer (16/55, 29.1%), and ovarian cancer (12/43, 27.9%). High TLR3 RNA expression was significantly correlated with high VISTA (OR = 2.12, p = 0.004) and TIM3 (OR = 2.10, p = 0.026) RNA levels, and was lower in CRC (OR = 0.39, p = 0.008). CRC was the only cancer subtype in logistic regression analyses with a statistically significant correlation with high TLR3 RNA expression. In survival analyses of all cancer patients and CRC patients, high TLR3 RNA expression did not significantly correlate with OS and PFS, regardless of ICI treatment status.

Conclusion: High TLR3 RNA expression was associated with higher levels of VISTA and TIM3 RNA; CRC had lower TLR3 levels than other cancers. However, TLR3 expression was not a statistically significant predictive biomarker for better outcomes (OS and PFS) in cancer patients, regardless of ICI treatment.

#2045 High-dose intervention with atorvastatin affects serum micro-RNAs in men with localized prostate cancer - an exploratory sub-analysis of ESTO1 placebo-controlled clinical trial.

Reetta Natkin[1], Tiina Jokela[2], Aino Siltari[1], Tia-Marje K. Korhonen[2], Eija Laakkonen[2], **Teemu J. Murtola**[1]

[1]University of Tampere, Tampere, Finland,[2]University of Jyvaskyla, Jyvaskyla, Finland

Introduction: Prostate cancer (PCa) is associated with increased cholesterol production, and statins, which inhibit the mevalonate pathway, can reduce PCa cell proliferation. This pathway regulates key cellular processes, including inflammation and growth. Previous trials have shown that statins lower PCa growth in men with localized PCa. Thus, further understanding the effect of statin intervention on PCa is crucial. MicroRNAs (miRNAs) are involved in the post-translational regulation of gene expression and have been linked to PCa risk and outcomes. This study aims to assess the impact of atorvastatin on the serum miRNA profile in men with localized PCa.
Materials & Methods: The ESTO1 trial enrolled 158 men with localized PCa who were scheduled for radical prostatectomy. Participants were randomly assigned to receive either 80 mg of atorvastatin or a placebo daily for 21 days before surgery. Serum samples were collected at baseline and the day before surgery. This exploratory sub-analysis included samples from 48 men, representing both high-grade (ISUP grade 3 or higher) and low-grade (ISUP 1-2) cases, with both atorvastatin and placebo groups. RNA was extracted from serum samples, pooled by trial arm and ISUP grade, and analyzed using small RNA sequencing on Illumina equipment. Differential expression was analyzed using DESeq2 in R Studio. MiRNAs showing the most significant changes were confirmed via dPCR analysis in individual samples.
Results: In pooled samples, the expression of several miRNAs shifted during atorvastatin treatment in comparison to the placebo group. Most of these miRNAs have been previously linked to PCa, including miRNA-205-5p, miRNA-21-3p, and miRNA-210-3p. Individual sample analysis confirmed atorvastatin-induced upregulation of miRNA-205-5p in high-grade cases ($p = 0.03$). Atorvastatin also altered the expression of certain miRNAs that have not been previously studied in the context of PCa, such as miRNA-10b-3p, miRNA-2355-3p, and miRNA-502-3p.
Conclusions: Atorvastatin treatment induced expression changes in several miRNAs, particularly increasing miRNA-205-5p in high-grade cases, which was confirmed through individual sample analysis. This suggests that atorvastatin's tumor growth-inhibiting effects in PCa may be partially mediated by its influence on miRNA expression and epigenetic regulation.

#2046 Coefficient variation of glycosylphosphatidylinositol-anchored 80 kDa protein (GPI-80) on neutrophil status in metastatic renal cell carcinoma (MRCC) patients treated with combination therapy of nivolumab plus ipilimumab.

Sei Naito[1], Yuji Takeda[2], Sabrina Saima[2], Hiromi Ito[1], Tomoyuki Kato[1], Takafumi Narisawa[1], Yuki Takai[1], Shinta Suenaga[1], Mayu Yagi[1], Hisanobu Asao[1], Norihiko Tsuchiya[1]

[1]Urology, Yamagata University, Yamagata, Japan,[2]Immunology, Yamagata University, Yamagata, Japan

Introduction: Immature neutrophils suppress T cell immunity as myeloid-derived suppressor cells. However, recent studies have demonstrated that neutrophils are essential for eradicating antigenically heterogenous tumors via T cell immunotherapies, and CTLA-4 antibodies can recruit neutrophils into tumors. Our previous research identified GPI-80 as a marker of neutrophil maturation, where the coefficient variation of GPI-80 (GPI-80 CV) inversely correlated with the T cell proliferation. We also demonstrated that MRCC patients with high GPI-80 CV had a poor prognosis before the advent of immune-checkpoint inhibitors (ICI). The aim of this study is to investigate the association between GPI-80 CV and the inflammatory marker C-reactive protein (CRP) status and prognosis in mRCC patients treated with the combination therapy of anti-PD-1 nivolumab plus anti-CTLA-4 ipilimumab (NI). Methods: Prior to ICI treatment, peripheral blood samples were collected from 25 patients treated with NI and 10 patients treated with nivolumab monotherapy. GPI-80 was measured using flow cytometry. NI response was categorized as follows: EPD (early progressive disease; disease progressed within 60 days), LPD (late progressive disease; disease progressed between 60 days and 2 years), DR (durable response; disease did not progress beyond 2 years). Results: In NI, GPI-80 CV was significantly higher in durable responder DR patients (P = 0.03, Steel-Dwass test) and marginally higher in EPD patients (P = 0.08) compared to LPD patients. Serum CRP was significantly higher in EPD compared to DR (P = 0.03). When patients were divided into groups 1-3 according to GPI-80 CV and CRP levels: group 1, >10 mg/dl CRP; group 2, <10 mg/dl CRP and <36 GPI-80 CV; group 3, <10 mg/dl CRP and >36 GPI-80 CV. Group 3 had significantly better time-to-treatment-failure (TTF) and overall survival (OS) compared to Group 1 (HR = 0.36 and 95% CI = 0.17-0.73 in TTF, HR = 0.29 and 95% CI = 0.12-0.67 in OS) and Group 2 (HR = 0.15 and 95% CI = 0.03-0.62 in TTF, HR = 0.18 and 95% CI = 0.03-0.93 in OS). In nivolumab monotherapy, TTF OS did not differ between these groups (HR = 1.85 and 95% CI = 0.41-8.16 in group 3 vs. group 2). Conclusions: In patients receiving NI therapy, high GPI-80 CV—a marker of immature neutrophils—was associated with improved TTF and OS. This association was not observed with nivolumab monotherapy, suggesting a unique role for neutrophil immaturity in the efficacy of combination immunotherapy including CTLA-4 blockade. The combination of GPI-80 and CRP is a candidate for predictive biomarker for NI efficacy in MRCC.

#2047 Homologous recombination deficiency in lung cancer in the INSPIRE study.

Katherine G. Roth[1], Kevin J. McDonnell[1], Ernest Nadal[2], Joseph D. Bonner[1], Arman Seuylemezian[1], Suravi Nahar[1], Lawrence Shaktah[3], Jonathan Salazar[1], Sidney Lindsey[1], Xiaoyu Xia[1], Sara A. Byron[4], Jonathan J. Keats[4], Allen Mao[1], Adrien Larsen[1], Bryce Turner[4], Ravi Salgia[1], Stacy W. Gray[1], Stephen B. Gruber[1]

[1]City of Hope National Medical Center, Duarte, CA,[2]Catalan Institute of Oncology, Barcelona, Spain,[3]Technical University of Dresden, Dresden, Germany,[4]Translational Genomics Research Institute, Phoenix, AZ

Introduction: Evaluating genomic signatures may improve prognostic information and outcomes for patients with lung cancer.
Objective: To determine if homologous recombination deficiency (HRD) is associated with clinical features or overall survival in patients with lung cancer.
Methods: This is a retrospective cohort study derived from City of Hope's Implementing Next-Generation Sequencing for Precision Intervention and Risk Evaluation (INSPIRE) study. Study participants with histologically confirmed lung cancer and adequate tissue for comprehensive paired tumor-normal whole exome sequencing were eligible for analysis. 197 patients were sequenced, excluding 14 with rare histologies. Clinical and treatment variables were obtained from cancer registries and the electronic medical record and were recorded by experienced data curation and abstraction specialists. HRD scores were calculated using the scarHRD R package. Mutational signatures were analyzed using SigProfiler and SigEstimation. Associations between clinical variables and HRD status were measured using univariate and multivariate methods. Unsupervised analysis was performed to identify genes in HRD-high (sum score greater than or equal to 42) and HRD-low samples (sum score less than 42). Overall survival was quantified using non-parametric Kaplan-Meier statistics and multivariate Cox-proportional hazards models.
Results: Of the 183 lung cancer samples analyzed, 63 (34.4%) samples were HRD-high. Of these, 43 had a *TP53* alteration and 20 did not; 120 (65.6%) samples were HRD-low, 50 with a *TP53* alteration and 70 without (OR 3.01 (95%CI 1.58, 5.72), p=0.0008).
Conclusion: *TP53* alterations were strongly associated with high HRD scores. Overall survival was improved in patients with HRD-high tumors treated with platinum therapy, although this difference did not reach statistical significance.

#2048 Extracellular vesicle-derived MASP2 as a prognostic indicator in pancreatic cancer.

Shatovisha Dey[1], Deep Pandya[1], Tammy Lo[2], Ryan Narbutas[3], Bhavna Khandpur[4], Pramila Krumholtz[2], Mohammadreza Shervinrad[4], Kiyoe Sullivan[4], Deborah August[4], Sarah Evans[2], Saraswathi Nair[4], Nader Okby[5], Gregory Niland[4], Richard C. Frank[2]

[1]Rudy Ruggles Biomedical Research Institute, Nuvance Health, Danbury, CT,[2]Department of Medicine, Nuvance Health, Norwalk, CT,[3]Department of Radiology, Nuvance Health, Norwalk, CT,[4]Department of Pathology, Nuvance Health, Norwalk, CT,[5]Department of Pathology, Nuvance Health, Danbury, CT

Advanced pancreatic cancer (APC) has an overall survival (OS) of 10 months with chemotherapy, yet some patients live only a few weeks whereas others up to two years. Novel early biomarkers are needed to guide prognostication and first-line chemotherapy efficacy, prior to tumor progression or treatment toxicity, which often preclude further therapy. In this study, serially collected serum extracellular vesicles (EVs) from chemotherapy-treated advanced pancreatic cancer (APC) patients were analyzed using mass spectrometry at three critical timepoints: pre-treatment, best response, and treatment resistance. Differentially expressed candidate proteins were identified, validated by ELISA, and correlated with treatment response and prognosis. Functional association studies were conducted using in-vitro assays with primary and metastatic pancreatic cancer (PC) cell lines, while immunohistochemistry (IHC) on tumor biopsies was performed for protein localization. Mass spectrometry analysis identified nine candidate proteins, with MASP2 emerging as the most promising candidate for further investigation. A >20% decline in EV-MASP2 levels after 2 months (M2) of chemotherapy predicted treatment response in 80% of responders (n=25), whereas a >20% increase predicted treatment resistance in 73% of non-responders (n=15). Analysis of a larger cohort (n=75) showed that a decrease vs increase at M2 was prognostic for EV-MASP2 (OS 11 vs. 8 months; p=0.0037) but not for CA19-9 (OS 11 vs. 12 months respectively, p=0.70). In situations where CA19-9 is not evaluable, EV-MASP2 retained prognostic significance. In-vitro studies indicate that systemic changes in EV-MASP2 levels are not directly driven by primary or metastatic PC cells, consistent with IHC staining patterns showing minimal or no MASP2 expression in tumor cells and moderate expression in stromal regions of both primary tumors and liver metastatic sites. In conclusion, our work indicates that serial analysis of serum EV proteins is a promising approach to identifying novel biomarkers for treatment response and prognosis in APC. Findings from this study suggest that changes in circulating EV-MASP2 levels soon after chemotherapy initiation may help guide treatment decisions and improve patient outcomes.

#2049 The 27-gene IO Score on the Ion Torrent Platform for classification of the tumor immune microenvironment.

Tyler J. Nielsen, Jim Fee, Geoff Bien, Brock Schweitzer

Oncocyte Inc., Nashville, TN

Background: The tumor immune microenvironment (TIME) plays a critical role in modulating cancer progression and therapeutic response, especially for immune checkpoint inhibitors (ICIs). DetermaIO, a 27-gene signature assay, has demonstrated clinical utility in predicting immune checkpoint inhibitor responsiveness through classification of the TIME. This study focuses on adapting DetermaIO to the Ion Torrent platform as a research-use-only (RUO) kit, OncoTIME. This assay enables precise and reproducible gene expression profiling of the immune system, tumor biology, and surrounding stromal biology in solid tumors, using this to derive the OncoTIME Score.
Method: OncoTIME was designed as a multiplexed targeted RNA sequencing assay using Ion AmpliSeq technology to quantify the expression of 27 immune-related genes and 5 housekeeping (HK) genes. Target regions for the 27-gene panel guided by prior design of the DetermaIO assay. HK genes were identified through a composite approach, combining three methodologies:

1. Expression Stability: Evaluated consistency across tissue types and tumor states using datasets from The Cancer Genome Atlas (TCGA) and internal NGS datasets.
2. Variance Filtering: Selected genes with minimal inter-sample variance within experimental datasets.
3. Biological Context: Ensured HK genes were biologically non-variable and minimally involved in immune-related pathways.

These methods ensured robustness of normalization across diverse sample types and RNA input qualities. The assay design used Thermo Fisher's Ion Torrent GeneStudio platform, leveraging its efficient library preparation and sequencing workflow.
Results: The OncoTIME panel demonstrated:

- High specificity and coverage of target regions for all 27 immune-related genes.
- Reproducibility assessed across intra- and inter-run precision studies.
- Consistent normalization using the 5 HK genes, enabling accurate quantification of immune signatures across a dynamic range of tumor microenvironment profiles. Preliminary studies confirmed that OncoTIME recapitulates the DetermaIO Score.

Conclusion: OncoTIME democratizes access to TIME classification for research use and provides a scalable, reproducible, and cost-effective assay for the Ion Torrent platform. This RUO kit recapitulates DetermaIO while enabling broader utility in characterizing the TIME and its potential biological associations.

#2050 The impact of cell cycle inhibitors on bladder cancer with low NECTIN-4 expression.

Jee Soo Park, Ji Eun Lee, Myung Eun Lee, Jongchan Kim, Won Sik Ham

Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Antibody-drug conjugates (ADC) combine a cytotoxic agent with a monoclonal antibody for targeted delivery. Enfortumab-vedotin (EV) links a monoclonal antibody targeting NECTIN-4 with the cytotoxic agent monomethyl auristatin E (MMAE). Given the near-ubiquitous expression of NECTIN-4 in urothelial cancer (UC) tissues, EV has shown efficacy in UC and is approved for metastatic urothelial carcinoma (mUC). However, significant heterogeneity in NECTIN-4 expression within UC limits therapeutic efficacy in cases with low NECTIN-4 expression. This study evaluated cell cycle inhibitors' efficacy in UC cells with low NECTIN-4 expression.
Methods: We measured NECTIN-4 and cell cycle-related molecules (Cyclin D1 and PLK1) in bladder cancer cell lines (253J, 253J-BV, 5637, RT4, T24, J82, HT1197, HT1376) and correlated these levels with sensitivity to the PLK1 inhibitor. Drug sensitivity was assessed by a CCK-8 assay over 72 hours following treatment with the PLK1 inhibitor (onvansertib). An ex vivo model using bladder tumor samples from patients validated the in vitro findings. NECTIN-4 levels in bladder cancer cell lines (HT1376 and RT4) were modulated by siNECTIN-4 transfection for 48 hours. Cell cycle analysis and the expression levels of cyclin D1 and PLK1 were examined in NECTIN-4 knockdown cell lines.
Results: The therapeutic efficacy of the PLK1 inhibitor was significantly enhanced in bladder cancer cell lines with reduced NECTIN-4 expression (253J, 253J-BV, 5637, T24, and J82), as indicated by an IC50 <0.1 μM. In contrast, cell lines with high NECTIN-4 expression (RT4, HT1197, and HT1376) were resistant to onvansertib (IC50 >1 μM). NECTIN-4 expression correlated with cell cycle-related molecule levels. Consistently, bladder tumor samples showed a negative correlation between NECTIN-4 expression and PLK1 inhibitor sensitivity. PLK1 inhibitor-resistant tumors (IC50 >40 μM) had lower NECTIN-4 levels than sensitive samples (20 μM < IC50 < 40 μM). NECTIN-4 knockdown via siRNA increased G0/G1 phase cells and reduced cyclin D1 and PLK1 levels. Furthermore, siNECTIN-4-transfected cells were more sensitive to the PLK1 inhibitor than control siRNA-transfected cells.
Conclusion: This study underscores the therapeutic potential of cell cycle inhibitors, notably PLK1 inhibitors, in bladder cancer cells with low NECTIN-4 expression, showing an inverse relationship between NECTIN-4 expression and sensitivity to PLK1 inhibitors. NECTIN-4 levels could predict PLK1 inhibitor treatment response. NECTIN-4 knockdown experiments confirmed that reduced NECTIN-4 expression disrupted cell cycle regulation and increased PLK1 inhibition efficacy. These findings advocate for further investigation of combination therapies involving ADCs and cell cycle inhibitors to counter resistance and improve outcomes in bladder cancer patients.

#2051 Baseline and adaptive activated kinome profiling identifies PTK6 as a mediator of resistance to vemurafenib and dabrafenib but not encorafenib in *BRAFV600*-mutant metastatic melanoma.

Steve P. Angus[1], Naim U. Rashid[2], Andrew J. Walther[2], David L. Corcoran[3], Steven D. Rhodes[4], Frances A. Collichio[5], C. Paige Jones[6], Mikaela J. Bauer[7], Joel S. Parker[3], Noah Sciaky[1], Alisha R. Coffey[3], Samantha M. Bevill[1], Brian T. Golitz[1], Timothy J. Stulhmiller[1], Nancy E. Thomas[8], David W. Ollila[6], Norman E. Sharpless[5], Carrie B. Lee[5], Gary L. Johnson[1], **Stergios J. Moschos**[5]

[1]Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC,[2]Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Pediatrics Medicine and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[5]Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC,[6]Surgery, University of North Carolina at Chapel Hill, Chapel Hill, NC,[7]University of North Carolina at Chapel Hill, Chapel Hill, NC,[8]Dermatology, University of North Carolina at Chapel Hill, Chapel Hill, NC

To investigate the landscape of the activated kinome in MM, we applied a proteomic approach that interrogates the activation status of more than half of the entire kinome (~300), termed multiplexed kinase inhibitor bead affinity chromatography coupled with mass spectrometry (MIB/MS) on 45 MM patient (pt) tumors (*BRAFV600*, n=25; *NRASQ61*, n=5, *NF1* loss-of-function, n=4; Triple wild-type n=11) in conjunction with whole exome sequencing and RNA sequencing (RNAseq). We performed exploratory analyses (Wilcoxon rank sum test for each kinase) on the untreated tumors to identify differentially activated kinases in *BRAFV600*-mutant MM vs. all others. While no activated kinases were differentially expressed in *BRAFV600*-mutant MM after adjustment for multiple testing, AKT1, PDGFRA, and MAP3K1 kinases exhibited higher MIB binding (i.e., more activated) in *BRAFV600E*-mutant pts (unadjusted p-value < 0.05). Spearman's rank correlation tests between the activated kinase and its gene expression by RNAseq and adjusted for multiple testing did not identify a significant correlation for any kinase, suggesting a complex mechanism of kinase activation other than sole gene expression. K-means clustering analysis to classify melanomas into 4 subtypes using a 6-gene discriminant expression signature showed that *BRAFV600*-mutant tumors were more frequently classified as melanocytic (9/24, *MLANA*/*MITF*/*SOX10*^{high}, *AXL*^{low}). In contrast, triple wild-type tumors were more frequently classified as transitory (5/10, *MITF*/*SOX10*/*ETV4*^{high}, *AXL*^{low}). We then performed similar exploratory analyses on the baseline (untreated) tumors from the subset of the 20 *BRAFV600E*-mutant pts who received D+T as part of a prospective clinical trial (NCT01726738; median follow-up 30.5 months, range 2.0-116.1 months) to identify differentially activated kinases that would predict shorter (<12 months) vs. longer progression-free survival. Again, while no kinases survived multiple comparison testing, the bromodomain protein TRIM28, known to regulate melanoma plasticity, exhibited a more consistent loss of MIB binding in *BRAFV600E*-mutant pts who progressed shorter than in pts who progressed longer than 12 months on D+T (unadjusted p-value < 0.05). 7 baseline-progression tumor pairs were evaluated for MIB/MS, and 6 were for RNAseq. Although diverse resistance mechanisms were identified, as previously described, we also identified melanoma subtype switch in 4/6 pt tumors and a consistent loss of MIB binding of the non-receptor tyrosine kinase PTK6 in response to D+T, an off-target of D and vemurafenib but not encorafenib. Our in vitro findings revealed that off-target PTK6 inhibition by D could activate beta-catenin signaling and contribute to the development of resistance.

#2052 Genomic and transcriptomic correlates of response to neoadjuvant chemotherapy and survival outcomes in breast cancer.

M. Dong[1], J. Chen[1], N. Lu[1], S. Wang[2], W. Wei[1], Z. Wang[1], J. Wang[1], J. Zhang[1], X. Han[1], F. Wang[2], Q. Ou[2], **H. Tang**[2], X. Ma[1], B. Shan[1], Y. Pan[1];

[1]The First Affiliated Hospital of University of Science and Technology of China (USTC), Division of Life Sciences and Medicine, University of Science and Technology of China, Hefei, China, [2]Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Neoadjuvant chemotherapy (NAC) is standard for breast cancer treatment, aimed at downgrading tumors and enhancing the feasibility of radical surgery. Pathological complete response (pCR), confirmed through histopathologic examination, is a potential surrogate marker of long-term survival. However, the absence of reliable biomarkers to predict NAC response and prognosis poses a significant challenge, hindering timely treatment adjustments and optimal adjuvant therapy selection.

Methods: This study included 73 stage II/III breast cancer patients who underwent NAC followed by curative-intent surgery. We analyzed whole-exome and transcriptome sequencing data from baseline and surgical tumors to identify biomarkers associated with pCR and survival outcomes. Plasma samples were collected at three time points: before NAC (P1), during NAC (P2), and after NAC (P3), to evaluate the predictive value of undetectable circulating tumor DNA (ctDNA) for pCR.

Results: *TP53*, *PIK3CA*, and *TTN* mutations were common in breast cancer but were exclusive to surgical samples from non-pCR patients. pCR was associated with baseline mutations in *ADGRL3*, *IFT172*, *DNHD1*, *MUC16*, *TPTE*, *ABCA13*, *SULF1*, *TRANK1*, *PLEC*, and genetic alterations in the HIPPO pathway. At the transcriptional level, pCR tumors exhibited heightened immune activation, characterized by higher fractions of memory B cells and resting NK cells, alongside fewer activated mast cells and cancer-associated fibroblasts. Responding tumors also showed significantly downregulation of pathways related to extracellular matrix organization, PI3K-Akt, and AGE-RAGE signalling compared to non-pCR tumors. Surgical samples from non-pCR tumors exhibited deminished leukocyte-mediated immunity and immune receptor activity, suggesting a potential resistance mechanism to NAC. Undetectable ctDNA at P2 and P3 time points was strongly correlated with pCR (P=0.03 and P=0.001, respectively), with P3 demonstrating slightly better sensitivity (0.90; 95% confidence interval [CI]: 0.55-1.00 vs. 0.80; 95% CI: 0.44-0.97) and specificity (0.63; 95% CI: 0.44-0.80 vs. 0.62; 95% CI: 0.44-0.79). Additionally, baseline *USH2A* mutations (hazard ratio [HR]: 11.9; 95% CI: 2.8-50.8; P<0.001) and chromosome 8q amplifications in surgical samples (HR: 4.3; 95% CI: 1.1-16.0; P=0.02) were predictive of shorter disease-free survival. Furthermore, elevated *NHSL1* expression, while indicative of initial response, was associated with tumor relapse and poor overall survival (P=0.026 and P=0.023, respectively).

Conclusions: This study identified key predictive and prognostic biomarkers associated with NAC response and long-term survival in breast cancer, providing valuable insights for developing individualized therapeutic strategies tailored to patient-specific molecular profiles.

#2053 Hemizygous focal deletions in *MACROD2* alter tumor biology and genomic instability in colorectal cancer.

Carmen Rubio Alarcon*[1], Soufyan Lakbir*[2], Elisabeth J. van Bree[1], Bram van den Broek[1], Amber Hondema[1], Petur Snaebjornsson[1], Steven L. C. Ketelaars[1], Marianne Tijssen[1], Anne Bolijn[1], Pien Delis-van Diemen[1], Margriet Lemmens[1], Maartje Alkemade[1], Mette Kalager[3], Magnus Loberg Loberg[3], Miriam Koopman[4], Jeanine M. L. Roodhart[4], Geraldine R. Vink[5], PLCRC-MEDOCC group, Ellen Stelloo[6], Jaap Heringa[7], Gerrit A. Meijer[1], Harma Feitsma[6], Beatriz Carvalho[1], Sanne Abeln[8], **Remond J. A. Fijneman**[1]

[1]Netherlands Cancer Institute, Amsterdam, Netherlands,[2]Netherlands Cancer Institute / Vrije Universiteit Amsterdam / Utrecht University /, Amsterdam/Utrecht, Netherlands,[3]University of Oslo / Oslo University Hospital, Oslo, Norway,[4]University Medical Center Utrecht / Utrecht University, Utrecht, Netherlands,[5]University Medical Center Utrecht / Utrecht University / Netherlands Comprehensive Cancer Organisation, Utrecht, Netherlands,[6]Cergentis B.V., a Solvias company, Utrecht, Netherlands,[7]Vrije Universiteit Amsterdam, Amsterdam, Netherlands,[8]Vrije Universiteit Amsterdam / Utrecht University, Amsterdam/Utrecht, Netherlands

Introduction: *MACROD2* is a large gene located within a common fragile site (CFS), a genomic region that is vulnerable to acquiring focal deletions under replicative stress. Structural variants (SVs) in *MACROD2* are highly prevalent in patients with colorectal cancer (CRC), but their putative role in tumor initiation and progression remains to be established.

Aim of this study*: In silico* and *in vitro* characterization of the effects of somatic SVs in *MACROD2* in CRC initiation and evolution.

Methods: Five datasets were used for *in silico* characterization of SVs in *MACROD2*: HMF (metastatic CRC, n=610), PCAWG (stage I-IV CRC, n=60), PLCRC-PROVENC3 (stage III CRC, n=234), PLCRC-MEDOCC (stage II-III CRC, n=214) and IntEnd (adenomas, n=634). The system-wide impact of intragenic SVs in *MACROD2* on gene expression profiles was evaluated using the tool CIBRA. SVs in *MACROD2* were associated with features of genomic instability, including tumor mutational burden (TMB), fraction of genome altered (FGA), tumor break load (TBL) and length of somatic SVs. The most frequently occurring SVs in *MACROD2* were mimicked in vitro by CRISPR-Cas9 genetic engineering of a colorectal cancer cell line and an adenoma organoid. Their effect on tumor biology was determined by evaluating mRNA sequencing data, cell viability, mono-ADP-ribose levels, DNA damage repair and drug testing.

Results: Focal deletions in *MACROD2* were absent in adenomas, and present in 56% primary non-metastatic tumors and 71% of the metastatic CRC lesions evaluated. Focal deletions affecting the MACRO domain, in particular *MACROD2* exons 5 or 6, were associated with system-wide expression changes (CIBRA score 0.37; FDR < 0.01), increased TBL ($p < 10^{-4}$) and an increased number of SVs genome wide, specifically deletions of approximately 100kb ($p < 10^{-15}$). *In vitro*, the models containing hemizygous or homozygous focal deletions showed lower levels of mono-ADP-ribose in the nucleus, and higher levels of DNA damage accumulation in the cancer cell line. Drug testing revealed that hemizygous deletions of *MACROD2* made the cells more susceptible to treatment with 5-fluorouracil compared to WT (GR50: 17.6 µM vs 62.1 µM, P= 0.004). A similar trend was observed for the homozygous deletion (GR50: 30.3 µM vs 62.1 µM, ns)

Conclusions: This study evaluated the effect of the most prevalent SV in CRC. Hemizygous intragenic focal deletions in *MACROD2* that affect exon 5 and/or 6 are sufficient to alter system-wide expression profiles, nuclear mADPr levels, DNA damage repair and response to 5-fluorouracil.

#2055 Molecular profiling of the PI3Kδ inhibitor roginolisib in metastatic uveal melanoma and its correlation with clinical outcomes.

Alessio Bevilacqua[1], Tan Ziyang[2], Lakshmikanth Tadepally[2], Petter Brodin[2], Anna Maria Di Giacomo[3], Michele Maio[3], Jeff Evans[4], Armando Santoro[5], Tracey Hammett[1], Paramijt Kaur[1], Lars van der Veen[6], Michael Lahn[1], **Giusy Di Conza**[1]

[1]iOnctura SA, Geneva, Switzerland,[2]Karolinska institutet, Stockholm, Sweden,[3]University hospital of Siena, Siena, Italy,[4]Beatson Cancer center, Glasgow, United Kingdom,[5]Humanitas Cancer Center, Rozzano-Milan, Italy,[6]iOnctura BV, Amsterdam, Netherlands

Introduction: Uveal melanoma (UM) is a rare orphan disease with significant unmet clinical need. Unlike cutaneous melanoma, UM has a low tumor mutational burden and a highly immunosuppressive microenvironment, rendering it largely unresponsive to checkpoint inhibitor therapies. PI3Kδ is involved in the pathophysiology of the disease, by enhancing regulatory T cell activity and supporting tumor cell survival. Roginolisib, a PI3Kδ inhibitor, was evaluated in 23 UM patients at an 80 mg biological effective dose (BED). Here, we report data from a comprehensive translational analyses of genomic, transcriptomic, proteomic and cellular data from UM patients, supporting PI3Kδ as a suitable therapeutic target for UM patients.

Methods: IOA-244-101 (NCT04328844) was conducted in patients with advanced cancer, which included metastatic uveal melanoma patients. Baseline and on-treatment blood and plasma samples were analyzed to evaluate circulating immune cells using mass cytometry, circulating tumor DNA (ctDNA) via whole exome sequencing, and circulating proteins through targeted proteomics. Additionally, biopsies at baseline and Day28 of treatment were analyzed for tumor transcriptomic and genomic profiles using whole transcriptome and whole exome sequencing.

Results: Roginolisib treatment induced progressive decrease of circulating regulatory T cells and increased CD39+CD8T cells, accompanied by reduction of soluble PD1, CCL22 and increase of IL15 and IFNGR2. We identified a subpopulation of mUM patients that particularly benefited from roginolisib treatment. Patients with RECIST 1.1-defined stable disease (SD) at 16 weeks experienced significantly longer median overall survival (28.5 months) compared to those with progressive disease (PD) (10.9 months). SD patients had enhanced $CD8^+$ T cell/Treg ratios and downregulation of PI3K/mTOR-associated proteins in plasma. Conversely, PD patients showed upregulation of these proteins after8 weeks of treatment , suggesting a potential resistance mechanism. Transcriptomic analysis of tumor biopsies revealed that SD patients had higher baseline expression of 325 genes, including 61 GPCR (G-protein coupled receptors), which were downregulated post-treatment. Longitudinal ctDNA profiling further demonstrated dynamic tumor evolution, with specific variants emerging or disappearing over time.

Conclusion: These findings highlight the importance of immune modulation, PI3K/mTOR signaling, and GPCR gene expression in potentially driving treatment outcomes, and encourage further evaluation of Roginolisib in a Phase 2 randomized study.

#2056 Development of a response prediction Model for venetoclax-based therapy utilizing molecular interactions among BCL2 family members.

Byungsan Choi[1], Yunseo Lee[1], Lilly Gu[2], Keonho Lee[1], Eunyoung Kim[2], Martha L. Arellano[2], William G. Blum[2], **Hongwon Lee**[1], Janghee Woo[2]

[1]PROTEINA Co., Ltd., Seoul, Korea, Republic of,[2]Winship Cancer Institute of Emory University, Atlanta, GA

Venetoclax (VEN), in combination with hypomethylating agents (HMAs) such as azacitidine or decitabine, is a widely used treatment for AML patients, yet the molecular biomarkers contributing to sensitivity to the VEN+HMA regimen remain incompletely elucidated, particularly with regard to the role of BCL2-family proteins.

In this study, we retrospectively collected BMMCs or PBMCs from AML patients prior to initiation of VEN+HMA therapy at Winship Cancer Institute of Emory University. A total of 47 specimens were analyzed, including 33 from newly diagnosed AML patients and 14 from relapsed or refractory AML cases at the time of sample collection. Clinical outcomes were categorized based on the best response to VEN+HMA therapy, with refractory cases labeled as "NR" (non-responders; 17 patients) and all other cases labeled as "R" (responders; 26 patients). To investigate protein interactions between the BCL2 family, we employed the Single-molecule Protein Interaction Detection (SPID) platform (Chun et al., Nat. Biomed. Eng., 8, 2024). 12 distinct protein biomarkers were assessed based on three anti-apoptotic proteins: BCL2, BCLxl, and MCL1. ROC analysis was performed to evaluate the association between individual biomarkers and clinical outcomes of VEN+HMA therapy. To develop a predictive model incorporating BCL2-family biomarkers, we utilized a linear model rectified with a ReLU activation function. The trained model was interpreted using SHAP value analysis.

To enhance the variability of biomarkers, we calculated normalized protein complex levels relative to protein levels. For example, the BCL2-BAX complex level was divided by the BCL2 protein level to assess the fraction of occupied BCL2 across samples. Among the 21 biomarkers analyzed, the normalized BCLxl-BAK complex level demonstrated the strongest predictive performance, with an AUC of 0.734 (95% CI: 0.536-0.859) for distinguishing responders to VEN+HMA therapy. We developed a response prediction model for VEN+HMA therapy with 12 biomarkers, and achieved performance with 96.2% sensitivity and 100% specificity. Interpretation of the model using SHAP analysis revealed key contributors to sensitivity and resistance to the VEN+HMA regimen. Specifically, Higher levels of the BCL2-BAX and BCLXL-BAK complexes were associated with sensitivity to VEN+HMA therapy. Conversely, lower levels of the BCL2-BIM and MCL1-BIM complexes were linked to resistance to the treatment. Notably, the expression level of MCL1 (measured after heat denaturation) significantly influenced sensitivity to VEN+HMA therapy.

This study highlights the potential of BCL2-family interaction profiles in developing a response prediction model for VEN+HMA sensitivity. Further model refinement and validation in independent cohorts are essential to improve its predictive performance and reliability.

#2057 CG>TG mutation frequency as negative predictor of homologous recombination deficiency in ovarian and breast cancer.

Jan Budczies, Eva Romanovsky, Michael Menzel, Klaus Kluck, Susanne Beck, Markus Ball, Peter Schirmacher, Daniel Kazdal, Albrecht Stenzinger

Heidelberg University Hospital (UKHD), Heidelberg, Germany

Homologous recombination deficiency (HRD) is a predictive biomarker for PARP inhibition and platinum-based chemotherapy. Copy number alteration-based scores such as HRDsum =LST+TAI+LOH are included in therapy approvals of PARP inhibition, but have limited sensitivity for HRD detection in samples of low tumor purity. Biomarkers based on single base substitutions (SBS) beyond Mutational Signatures are underinvestigated as predictors of HRD. WES data of the TCGA pan-cancer cohort and an in-house ovarian cancer cohort were annotated by genetic and epigenetic alterations of BRCA1/2 and additional genes causative of HRD. Using this reference, the new biomarker f_{deam} defined as frequency of C>T transitions at CpG sites in relation to all SBS and HRDsum were compared for the detection of HRD. In the TCGA ovarian cancer, the in-house ovarian cancer, and the TCGA breast cancer cohorts, f_{deam} performed non-inferior to HRDsum (AUC=0.84, AUC=0.85, and AUC=0.88). The cutpoint f_{deam}=13.1% maximized the balanced accuracy in the TCGA ovarian cancer cohort and resulted in sensitivity=89% and specificity=77% in the in-house cohort. In a simulation study, f_{deam} retained high sensitivity for HRD detection and outperformed HRDsum for tumor purity 40%, 20%, and 10%. Thus, the new biomarker overcomes the limited robustness of copy number alteration-based biomarkers against low tumor purity and offers the opportunity of a more sensitive HRD detection in clinical tumor samples. Further studies are warranted to confirm its clinical validity and utility and explore its potential for liquid biopsies.

#2058 Clinical and biological implications of plasma proteomic patterns in NSCLC patients treated with immune checkpoint inhibitors.

M. Harel[1], N. Dahan[1], C. Lahav[1], E. Jacob[1], Y. Elon[1], I. Puzanov[2], R. J. Kelly[3], Y. Shaked[4], R. Leibowitz[5], D. P. Carbone[6], D. R. Gandara[7], A. P. Dicker[8];

[1]OncoHost, Binyamina, Israel, [2]Roswell Park Comprehensive Cancer Center, Buffalo, NY, [3]Baylor University Medical Center, Dallas, TX, [4]Technion - Israel Institute of Technology, Haifa, Israel, [5]Shamir Medical Center, Zerifin, Israel, [6]The Ohio State University, Columbus, OH, [7]University of California Davis Comprehensive Cancer Center, Sacramento, CA, [8]Thomas Jefferson University, Philadelphia, PA

Introduction: Immune checkpoint inhibitors (ICIs) offer significant benefits for patients with advanced non-small cell lung cancer (NSCLC). However, resistance to ICIs poses a major clinical hurdle. Recently, we described PROphet, a treatment guidance tool that predicts clinical benefit from ICI-based treatment using baseline plasma proteins termed ‘resistance-associated proteins’ (RAPs). Here, we conducted an in-depth bioinformatic analysis of RAPs to uncover the biological mechanisms underlying ICI resistance and their clinical relevance.

Methods: 388 RAPs were analyzed using multiple bioinformatic and statistical tools. Putative tissue origins of the RAPs were explored using publicly available datasets. Enrichment analyses were performed to investigate RAP-related biological processes. Plasma proteomic data from healthy subjects (n=50) and NSCLC patients displaying clinical benefit (CB; n=76) or no CB (NCB; n=196) were compared to identify differential expression patterns between the three subpopulations.

Results: RAPs were found to originate from both host and tumor tissues, with significant enrichment of lung cancer- and liver-associated proteins. A comparison of RAP expression levels in healthy, CB and NCB populations revealed five distinct expression patterns that provide mechanistic insights into treatment resistance. One such pattern characterized by higher RAP expression levels in healthy subjects compared to NSCLC patients included proteins associated with antitumor activities. Another pattern characterized by elevated RAP expression levels in the NCB population included multiple proteins associated with treatment resistance mechanisms such as angiogenesis, cell proliferation, immune modulation, and chemoresistance. Patient-specific scores based on these four resistance mechanisms revealed inter-patient diversity, highlighting the potential of RAP profiles for guiding personalized combination therapies. A protein-drug database screen showed that 17.5% of the RAPs could be targeted therapeutically, demonstrating that the RAP set is a rich source of additional potential therapeutic targets.

Conclusions: The study provides insights into the biological processes associated with ICI resistance in patients with NSCLC and highlights the potential clinical value of RAP profiles for developing personalized therapies addressing resistance.

#2059 High intratumoral heterogeneity and altered immune microenvironment associated with 11q13 amplification in Chinese NSCLC implications for hyperprogressive disease.

Zuoqing Song[1], Yifan Yifan Zhang[2], Hao Zhang[2]

[1]Department of Lung Cancer Surgery, Tianjin Medical University General Hospital ; Tianjin Medical University General Hospital Airport Hospital, Tianjin, China,[2]Department of Lung Cancer Surgery, Tianjin Medical University General Hospital, Tianjin, China

Background: Immune checkpoint inhibitors have revolutionized the treatment landscape for non-small cell lung cancer (NSCLC), but a subset of patients experiences hyperprogressive disease (HPD) following immunotherapy. Previous studies indicate a potential link between specific genetic alterations and HPD. This study aims to investigate the role of the 11q13 chromosomal amplification, encompassing genes CCND1, FGF3, FGF4, and FGF19, in contributing to immunotherapy resistance and the occurrence of HPD in NSCLC patients.

Methods: We performed comprehensive genomic analyses on tumor specimens from 12,682 NSCLC patients using a next-generation sequencing (NGS) panel of 733 genes, alongside multiplex immunofluorescence assessments to characterize the immune microenvironment. Gene mutation profiles, tumor mutation burden (TMB), intratumoral heterogeneity (ITH), and immune cell infiltration profiles of 11q13 amplified and non-amplified patients were analyzed.

Results: Among these patients, we identified 208 cases with 11q13 amplification. Analysis revealed that patients without 11q13 amplification exhibited higher mutation frequencies in key DNA damage repair (DDR) pathway genes, including ATR (10.1%), ATM (8.65%), MSH3 (7.21%), and others, compared to patients with 11q13 amplification. Notably, TMB was significantly elevated in 11q13-amplified patients ($P<0.001$), contradicting the expected positive correlation between high TMB and better immunotherapy outcomes. Furthermore, ITH was significantly higher in the 11q13-amplified cohort ($P<0.001$), indicating greater tumor heterogeneity, which has been associated with poorer immunotherapeutic responses. Immune microenvironment analysis demonstrated a significantly decreased presence of CD68+ HLA-DR+ M1 tumor-associated macrophages (TAM) in the tumors of 11q13-amplified patients. In contrast, there was an elevated frequency of CD3+CD4+FOXP3+ regulatory T cells (Treg) in the tumor stroma of these patients, aligning with prior findings suggesting Treg involvement in HPD.

Conclusion: Our findings underscore that the 11q13 chromosomal amplification is associated with a unique genomic and immunological profile in NSCLC patients, characterized by high ITH and altered immune microenvironments, which may contribute to the development of HPD following immunotherapy. These insights highlight the potential need for tailored therapeutic strategies that address the specific challenges posed by 11q13 amplification in NSCLC.

#2060 Independent validation of endogenous retrotransposable elements as predictive biomarkers of immune checkpoint blockade response.

Mercedes Herrera[1], Sajid A. Marhon[1], Farnoosh Abbas-Aghababazadeh[1], David Chen[2], Amy Liu[1], Helen LooYau[1], Emily Van de Laar[1], Jeffrey Bruce[1], Helen Chow[1], Philippe L. Bedard[1], Albiruni Razak[1], Anna Spreafico[1], Aaron R. Hansen[1], Marcus O. Butler[1], Stephanie Lheureux[1], Trevor J. Pugh[1], Benjamin Haibe-Kains[1], Daniel D. De Carvalho[1], Lillian L. Siu[1], Pavlina Spiliopoulou[3]

[1]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[2]University of Toronto, Toronto, ON, Canada,[3]School of Cancer Sciences, University of Glasgow, Glasgow, United Kingdom

Background: Endogenous retrotransposable elements (EREs) can modulate antitumor immune responses via viral mimicry response. We previously described an association between ERE upregulation and radiological response to immune checkpoint blockade (ICB) in advanced solid tumors in the phase II INSPIRE trial (NCT02644369) (ASCO 2024). Here, we validate the association of EREs and ICB response in two independent cohorts of patients (pts) with melanoma and non-small cell lung cancer (NSCLC) treated with ICB.
Methods: Publicly available datasets were screened to identify cohorts of pts with solid tumors receiving ICB with accessible clinical outcomes (responders, RP; or non-responders, NR) and total RNA-sequencing data. Two independent datasets (*Riaz et al*., PMID 29033130; *Jung et al.,* PMID 31537801) were examined. ERE expression was analyzed in total RNA-seq from anonymized raw data in baseline (B) and on-treatment (T) samples of pts with melanoma and B samples of NSCLC. Differentially expressed EREs between RP and NR were quantified by the TPM*score* (mean of normalized transcript per million values for upregulated EREs in a sample comparison) and its standardized Z*score*. Immune cell infiltration was inferred from RNA-seq-based deconvolution. The cytolytic activity (CYT) immune score, derived from the mRNA expression of *GZMA* and *PRF1*, was reported in the melanoma cohort, while tumor mutational burden (TMB) data was available for both cohorts.
Results: A total of 43 pts (14 RP and 29 NR) in the melanoma cohort and 27 pts (8 RP and 19 NR) in the NSCLC cohort were identified for analysis. Baseline upregulated ERE classes included LINE (27%), SINE (30%), LTR (23%), simple repeats (10%), and others (10%) in melanoma, and LINE (34%), SINE (21%), LTR (29%), simple repeats (8%), and others (8%) in NSCLC. Differential ERE expression was observed in RP compared to NR across B samples in both cohorts (melanoma: RP vs NR Z*score* 0.50 vs -0.23, $p< 0.001$; NSCLC: RP vs NR Z*score* 0.89 vs -0.27, $p= 0.001$). In the melanoma cohort, on-treatment samples confirmed higher ERE expression in RP vs NR (Z*score* 0.77 vs -0.32, $p< 0.001$). A moderate positive correlation between TPM*score* of RP and $CD8^+$ T cell expression vs NR was seen in the melanoma pts in B samples (Pearson correlation $R = 0.54$, $p = 0.001$) and on-treatment ($R= 0.62$, $p< 0.001$), but no correlation was seen in B samples of the NSCLC cohort ($R= 0.2$, $p= 0.31$). Z*score* did not correlate with TMB in melanoma or NSCLC pts. In melanoma pts, the Z*score* showed a moderate positive correlation with CYT immune score ($R= 0.41$, $p= 0.017$).
Conclusion: This validation study on melanoma and NSCLC pts adds to the previously observed association of ERE upregulation and clinical outcomes during ICB treatment in a pan-cancer cohort. The association with $CD8^+$ T cell infiltration and CYT immune score, but not with TMB, suggests an immune activation independent of other biomarkers such as TMB.

#2061 Monitoring PD-L1 expression in cancer associated macrophage-like cells in blood predicts clinical outcomes in metastatic cancer patients treated with PD-L1 immunotherapies.

Dimpal M. Kasabwala[1], Steven H. Lin[2], Massimo Cristofanilli[3], Carolina Reduzzi[3], Cha-Mei Tang[4], Thai H. Ho5 H. Ho[5], Daniel L. Adams[6]

[1]Rutgers University, New Brunswick, NJ,[2]MD Anderson Cancer Center, Houston, TX,[3]Weill Cornell Medicine, New York, NY,[4]Creatv MicroTech, Inc., Potomac, MD,[5]Medical University of South Carolina, Charleston, SC,[6]Creatv MicroTech, Inc., Monmouth Junction, NJ

Studies have described the efficacy of immunotherapies (IMT) utilizing programmed death 1 receptor and its ligand (PD-L1) for treating solid tumors. However, many patients (pts) fail to respond to IMT, underscoring the need for better predictive biomarkers for improved pt identification and stratification. Poor IMT responses are often attributed to the dynamic nature of PD-L1 which may change after chemotherapy or radiation and is quantified by static immunostaining. Recently, studies have described PD-L1 upregulation in giant phagocytic stromal cells, i.e. Cancer associated macrophage-like cells (CAML), circulating macrophages that have engulfed tumors before entering circulation and may predict IMT responses. We conducted a pilot study to monitor the peripheral blood of n=46 metastatic cancer pts undergoing systemic treatment with IMT in combination with other therapies, to evaluate CAML PD-L1 prior to and post IMT induction with clinical correlation at 2 years. In a prospective pilot study of n=46 metastatic cancer pts, breast (n=14), non-small cell lung (n=24), and renal cell (n=8), all starting new lines of systemic chemotherapy in combination with IMT (pembrolizumab [n=30], nivolumab [n=13], Durva [n=1], or atezolizumab [n=3]) for newly diagnosed recurrent metastasis (n=24) or with previously treated progressive metastatic disease (n=22). We isolated CAMLs from 7.5 ml baseline (T0) blood using the LifeTracDx® PD-L1 test and scored PD-L1 as high or low. If possible, a follow-up sample (T1) was taken (~48 days) after IMT induction. Pts' progressive free survival (PFS) and overall survival (OS) hazard ratios (HRs) were analyzed by censored univariate analysis based on RECIST v1.1 over 2 years. T0 PD-L1 CAML data was available for 89% (n=41/46) of pts, with 39% (n=16/41) having high CAML PD-L1 which was not correlated with improved PFS (HR=0.9, p=0.985, CI=0.5-1.9) or OS (HR=1.0, p=0.899, CI=0.4-2.2). T1 PD-L1 CAML data was available for 74% (n=34/46) of pts, with 53% (n=18/34) having high CAML PD-L1, which significantly correlated with improved PFS (HR=2.9, p=0.012, CI=1.3-6.4) and OS (HR=5.5, p=0.0005, CI=2.2-13.6). In comparing CAML PD-L1 change post IMT, it was found that consistently low PD-L1 at T0 & T1 had the poorest responses, median PFS (mPFS)=2.3 months and median OS (mOS)=5.5 months. In contrast, consistently high PD-L1 at T0 & T1 had better responses, mPFS=6.1 months and mOS=16.7 months. Further, pts who increased in CAML PD-L1 after IMT had the best response rates, mPFS=10.3 months and mOS=14.8 months. Here, we describe a cancer agnostic blood-based biopsy to monitor dynamic PD-L1 changes in circulating tumor immune cells and predict clinical benefit to PD-L1 IMTs in several cancer types. While this initial pilot study appears to stratify pts with better IMT responses, larger validation studies are needed.

CLINICAL RESEARCH: Spatial Proteomics and Transcriptomics 2
Poster Session

#2065 A deep-learning approach for tissue mapping and cell phenotyping in imaging mass cytometry data analysis.

Smriti Kala[1], Katherine Hales[2], David Mason[2], Hiroyuki Suzuki[3], James Robert Mansfield[1], Regan Baird[4]

[1]Standard BioTools, Markham, ON, Canada,[2]Visiopharm A/S, Horsholm, Denmark,[3]Fukushima Medical University, Fukushima, Japan,[4]Visiopharm A/S, Horsholm, Denmark

Imaging Mass Cytometry™ (IMC™) technology is a multiplexed imaging technique that generates high-dimensional spatial data at subcellular resolution without the complications of autofluorescence and cyclic imaging. IMC technology has two distinct whole slide imaging (WSI) modes: Preview Mode (PM) and Tissue Mode (TM). PM rapidly scans stained tissue to provide a comprehensive overview within minutes, while TM provides fast acquisition of the entire tissue at 5-micron resolution, mapping out the distribution of over 40 markers and revealing tissue heterogeneity. Both WSI modes enable researchers to make informed decisions about selecting tissue areas that warrant closer examination at single-cell resolution. Following PM, regions of interest (ROIs) are selected on the same slide for high-resolution imaging using Cell Mode (CM). This facilitates single-cell analysis of the ROIs identified during PM. These imaging modes together with an automated slide loader function support non-stop acquisition of tissue samples all week.
Tissue sections of lung cancer were stained with a 40-marker IMC panel by combining the Human Immuno-Oncology IMC Panel with the Human Immune Cell Expansion IMC Panel to study spatial organization and cellular interactions in the tissue. Images were acquired on the Hyperion™ XTi Imaging System (Standard BioTools), first in PM and then in CM with automatic selection of ROIs using Phenoplex™ software (Visiopharm®). ROIs were automatically selected based on three criteria: 1) tertiary lymphoid structures (TLS) expressing CD20 and CD3; 2) Granzyme B-rich areas and 3) areas with high number of CD68 and Vimentin double-positive cell clusters. An adjacent serial section was acquired in TM for a whole slide morphologic segmentation comparison.
Tissue segmentation for all modes was performed using Phenoplex by training a deep-learning algorithm to recognize morphological features of the images, including the TLS. Single-cell analysis of the images generated in CM was performed using Phenoplex; cell segmentation was based on iridium DNA channels, and phenotyping was performed using the guided workflow. This data was used to compare the immune contexture through a series of t-SNE plots partitioned by spatial region and clinical variables.
Many mature TLS with proliferating germinal centers were present in the tissue. A high number of granzyme B-expressing neutrophils were found. Vimentin-positive macrophage-like cells were associated with the TLS. This work demonstrates that the Hyperion XTi Imaging System with its three acquisition modes (PM, TM and CM) can greatly advance the ability of IMC users to obtain answers from complex samples. The interactive capabilities of Phenoplex allow the user to quickly identify pertinent cell types, find them within a tissue map, define their spatial relationship and analyze their neighbors, leading to valuable biological insights.

#2066 Magnifying glass on sinonasal NUT carcinoma heterogeneity using spatial transcriptomics.

Diana Bell[1], Garret Choby[2], Michelle Afkhami[3], Ellie Maghami[4], Ehab Hanna[5], Raja Seethala[1]

[1]Pathology, University of Pittsburgh, Pittsburgh, PA,[2]Head and Neck Surgery, University of Pittsburgh, Pittsburgh, PA,[3]Molecular Pathology & Therapy Biomarkers, City of Hope Cancer Center, Duarte, CA,[4]Head and Neck Surgery, City of Hope Cancer Center, Duarte, CA,[5]Head and Neck Surgery, University of Texas MD Anderson Cancer Center, Pittsburgh, PA

Introduction: Nuclear protein in testis (NUT) carcinomas (NCs) are clinically aggressive, with signature translocation *NUTM1::BRD4* genes (70%), *BRD3::NUTM1* (15%), *NSD3::NUTM1* (6%). Histologically, NCs depict undifferentiated basaloid cells with squamous differentiation; broad lineage immunomarkers lack in NCs. Demonstration of translocation is imperative for NC diagnosis; NUT immunostaining is a surrogate. NC treatment faces obstacles (drug resistance, metastasis). Spatial transcriptomics (ST) technology emerged as ideal approach to elucidate cancer cell heterogeneity and spatial distributions within tissues.
Methods: 3 cases of sinonasal NC carcinoma with FFPE formed the study material. Next generation sequencing confirmed NC diagnosis: *BRD3::NUTM1* in NC #1, *BRD4::NUTM1* in NC # 2, NC # 3. A representative region of each of NCs was subjected to 10X Genomics Visium Spatial Gene Expression analysis. Ingenuity Pathway Analysis (IPA) employed for pathways and network analyses. Resulting data were visualized/ analyzed in 10X Genomics Loupe Browser.
Results: All cases demonstrated statistically distinct (graph-neural network based) transcriptomic clusters. These clusters were correlated with histologic characteristics by parsing all spots by region types based on tissue distribution including tumor, limited stroma and normal epithelium. Cluster constitution and transcriptomic pattern were consistent with the morphologic features of each tissue region. NC #3 had relatively low number of tumor clusters in comparison to NC #1, NC#2. Table 1- summary of results.
Conclusions: Spatial transcriptomic profiling corresponds to histopathologic features in NC and yet highlights cell type diversity across tumors and in the case of NC#2, within a given tumor. Behavior correlates are speculative, but NC#3 for which the patient had a rapidly lethal outcome showed a preponderance of neural gene expression which may be of interest in tumor cell progression/ evolution.

#2067 Single-cell spatial whole transcriptome reveals tumor heterogeneity and stromal dynamics in invasive ductal carcinoma of the breast.

Liang Zhang, Shanshan He, Michael Patrick, Stefan Rogers, Haiyan Zhai, John Lyssand, Michael Rhodes, Joseph Beechem

Bruker Spatial Biology, Seattle, WA

Invasive ductal carcinoma (IDC) is the most common and aggressive form of breast cancer, characterized by tissue invasion and metastasis, contributing to significant morbidity and mortality. The tumor microenvironment (TME), composed of stromal and immune cells, plays a critical role in IDC progression and therapy resistance. However, the spatial organization and molecular heterogeneity within the IDC TME remain underexplored. Spatial transcriptomics enables the preservation of tissue architecture while revealing molecular signatures at single-cell resolution, offering new insights into cancer biology. We utilized the CosMx® Spatial Molecular Imager (SMI) platform with the CosMx Whole Transcriptome panel (approximately 19,000 genes) to analyze a formalin-fixed, paraffin-embedded (FFPE) IDC tumor sample. The platform provides high-resolution, multiplexed RNA detection within its native tissue context. Hematoxylin and eosin (H&E) staining of the same slide provided a histological reference for spatial transcriptomics. Transcriptomic data were analyzed using Uniform Manifold Approximation and Projection (UMAP) for dimensionality reduction and Leiden clustering to identify cell clusters and spatial patterns. Marker genes for each cluster were used to annotate cell types and assess their roles within the TME. Analysis identified two distinct tumor regions, each subdivided into subregions with unique and shared gene expression profiles. These tumor regions aligned with histological features observed in H&E staining, validating the spatial transcriptomic findings. We observed region-specific stromal compositions, with fibroblast populations exhibiting distinct gene expression patterns. For example, one region was enriched for PIGR, CLU, and LTF, markers linked to immune response, tumor progression, and tumor-suppressive properties. These results highlight the molecular and spatial heterogeneity of IDC and the complex interactions within the TME. This study demonstrates the potential of spatial transcriptomics to uncover the molecular and spatial complexity of IDC. Integrating transcriptomic data with histological validation revealed novel insights into the TME, highlighting key gene signatures and stromal dynamics. The CosMx platform is a powerful tool for advancing precision oncology and guiding future therapeutic strategies in IDC.

#2068 Mapping the spatial whole transcriptome from normal to tumor tissue in renal clear cell carcinoma: tumorigenesis and microenvironmental shifts at single-cell resolution.

Shanshan He, Liang Zhang, Michael Patrick, Sierra McKenzie, Haiyan Zhai, Christine Kang, Michael Deryck Rhodes, Joseph Beechem

Bruker Spatial Biology, Seattle, WA

Renal clear cell carcinoma (ccRCC) develops through significant molecular and spatial reprogramming, transforming normal kidney tissue into a malignant state and reshaping the tumor microenvironment. To investigate the transition from normal to cancerous tissue, we utilized the CosMx® Whole Transcriptome (WTX) panel to perform high-resolution spatial transcriptomic imaging of FFPE sections containing ccRCC and adjacent normal kidney. H&E staining on the same tissue sections enabled direct correlation of molecular profiles with histopathological features, uncovering novel insights into tumorigenesis. FFPE tissue sections comprising equal parts ccRCC and adjacent normal kidney tissue underwent CosMx WTX imaging to analyze approximately 19,000 genes at single-cell resolution. The same sections were stained with H&E, providing histopathological context for tumor boundaries, tumor-normal interfaces, and regions of vascularization or necrosis. Custom software aligned transcriptomic and histopathological images, enabling the integration of molecular and morphological data for downstream analyses and AI model development. CosMx WTX detected thousands of transcripts per cell with exceptional sensitivity and accuracy. Spatial transcriptomics revealed distinct transcriptional programs and cell-type-specific changes across normal and tumor regions. Ligand-receptor analysis identified critical interactions driving tumorigenesis, while comparative analysis between transcriptome profile and H&E stain highlighted molecular shifts in tumor-adjacent normal areas, preserving renal tubule morphology but exhibiting subtle transcriptomic alterations. The tumor-normal interface displayed unique gene expression signatures, identifying spatially restricted therapeutic targets. This study presents a high-resolution spatial atlas of ccRCC, detailing molecular and cellular transitions from normal to tumor tissue. Integrating CosMx WTX with H&E-guided annotation not only identifies the tumor-normal interface as critical for understanding progression but also highlights the potential for AI-powered diagnostic tools. By linking transcriptomic signatures to routine histopathological images, this work sets the stage for future advancements in automated cell typing and transcriptome prediction, transforming research in clinical workflows and precision oncology.

#2069 Simultaneous, high-throughput detection of RNA and protein biomarkers using HCR™ Gold and the Orion™ imaging system for comprehensive analysis of tumor samples in clinical trials.

Jon J. Ladd[1], Adam Maddox[2], Aneesh Acharya[2], Arturo Ramirez[1]

[1]RareCyte, Inc., Seattle, WA,[2]Molecular Instruments, Inc., Los Angeles, CA

Background: Understanding the tumor microenvironment (TME) during cancer progression and treatment has been aided by multiomic analysis of tissues collected at initial patient screening and after treatment. Cyclic staining methods have recently demonstrated multiomic capabilities on a single tissue, but with drawbacks that can include tissue degradation and processing times up to several days. The Orion™ imaging system overcomes these limitations through single round staining and scanning of whole tissue samples of up to 18 biomarkers simultaneously. When paired with Molecular Instruments' HCR™ Gold RNA-FISH, a novel product featuring a truly protease-free workflow with next-generation amplification technology, transcriptomic and proteomic multiplex immunofluorescence (mIF) analysis can be carried out in parallel on a single tissue section in a straightforward, high-throughput approach to provide comprehensive insight into tumor biology and immune response.

Methods: A 16-plex multiomic assay featuring 5 RNA markers and 11 protein markers was developed to interrogate formalin-fixed paraffin-embedded (FFPE) tissue samples. Following dewaxing and antigen retrieval, HCR™ HiFi Probes against RNA targets of interest were incubated on the tissue sample followed by fluorescently-labeled HCR™ Gold amplifiers for signal generation. Subsequently, ArgoFluor™-conjugated antibodies directed to proteins of interest were incubated in a single cocktail on the same tissue, streamlining the staining procedure and decreasing downsides inherent to some amplification-based IF methods. Following coverslipping, whole tissues were scanned on Orion™ in one pass. Images were processed and interrogated with a custom analysis pipeline.

Results: HCR™ Gold RNA-FISH and mIF protein data for 16 biomarkers were obtained from human colon, lung, gastric, and pancreatic cancer tissues after a single round of staining and scanning. Immune cells were characterized within the TME based on biomarker expression. HCR™ Gold RNA-FISH was used to probe secreted factors, such as the cytokines IL-6, TNFα, and IFNγ , which were found to be colocalized with tumor-associated cells identified by protein mIF. Colocalization of RNA and protein markers differed across tissues.

Conclusions: The speed and versatility of Orion™ combined with the 1-step protease- and enzyme-free HCR™ Gold amplification enables development of custom assays to detect both protein and RNA markers on the same tissue in one cycle of staining and scanning. This powerful combination overcomes the limitations of low-plex cyclic staining and long protocol RNA-ISH methods to provide researchers and clinicians with a high-throughput method of translating basic research discoveries into assays for use in clinical trials and diagnostics.

#2070 Subcellular mapping of immune repertoire profiles with *in situ* sequencing on G4X.

Michael J. Lawson, Tung T. Le, Zane Hiatt, Ryan Shultzaberger, Kenneth Gouin III, Daan Witters, Eli N. Glezer

Singular Genomics, San Diego, CA

Detailed spatial analysis of immunology and pathology, such as immune repertoire profiling in tissue, requires *in situ* sequencing of variable gene regions. We introduce Direct-Seq, a novel technology using the G4X platform for *in situ* RNA sequencing at sub-cellular resolution, demonstrated by sequencing IgH and TCRB receptors in PBMCs and FFPE tissue.

We developed a probe panel that targets the conserved V and J-regions that flank CDR3 on IgH transcripts and a second panel that targets the V and C-regions that flank CDR3 and J regions on TCRB transcripts. PBMCs were seeded onto a glass substrate, followed by fixation. The diverse gap sequence was reverse transcribed into the probes, which were then clonally amplified. Clonal amplification products were sequenced *in situ* using Singular Genomics' SBS chemistry. We also applied the technique to tissue samples by transferring 5-µm thick FFPE tonsil sections to G4X slides, followed by deparaffinization and antigen retrieval. Amplicon preparation and sequencing were conducted in the same way as for PBMCs.

Direct-Seq successfully profiled ~ 60% of all B-cells (relative to CD19-positive fraction) and ~ 20% of all T-cells (relative to CD3-positive fraction) in PBMC populations. We observed the expected high diversity of clonotypes, with 92-98% of B and T-cells having distinct CDR3 sequences. Comparing multiple 50 bp reads within the same cell, we calculate the sequencing accuracy to be ~ 98%. For cells that had at least 1 read, we detected on average ~ 6 reads/cell for B-cells and ~ 2 reads/cell for T-cells. For FFPE tonsil samples we observed similar levels of diversity (94-99%) and accuracy (97-99%) as we did in PBMCs, but the detection efficiency was significantly lower, likely due to reduced RNA accessibility and degradation resulting from fixation.

In conclusion, Direct-Seq has demonstrated its unique capability for *in situ* sequencing of variable regions of IgH and TCRB transcripts in both PBMCs and FFPE tissues. This technology enables detailed mapping of immune cell clonality and diversity, providing a powerful tool for advancing our understanding of immunity and disease.

#2071 Spatial tracking of the pre-metastatic niche in colorectal cancer.

Chun Hua Hung[1], Chung-Ta Lee[2], Yu-Min Yeh[3], Chun-Hui Lee[3], Wen-Tai Liu[4], Meng-Ru Shen[5], Peng-Chan Lin[6]

[1]Department of Bioengineering, National Cheng Kung University, Tainan, Taiwan,[2]Department of Pathology, National Cheng Kung University, Tainan, Taiwan,[3]Department of Oncology, National Cheng Kung University Hospital, Tainan, Taiwan,[4]Department of Bioengineering, College of Engineering, National Cheng Kung University, Tainan, Taiwan,[5]Department of Pharmacology, National Cheng Kung University, Tainan, Taiwan,[6]Department of Genomic Medicine, National Cheng Kung University Hospital, Tainan, Taiwan

Lymph node metastatic positively correlates with poor prognosis of colorectal cancer. Thus, it is urgent to uncover the molecular mechanisms and develop better prediction criteria of the metastasis. Tumor budding refers to the presence of a cluster of tumor cells at the leading edge of tumor invasion and metastasis. This cluster is composed of either a single tumor cell or multiple tumor cells. Tumor budding is commonly observed in various types of cancer, including colorectal cancer (CRC), on histopathological slides. It is recognized as an independent predictive factor for lymph node metastasis and prognosis. In this study, the NanoString GeoMx equipment was applied to establish the expression profile of cancer transcriptomic atlas (CTA) in CRC specimens. According to the morphology of CRC tissues determined by markers including pancytokaretin, CD45, and alpha-smooth muscle actin, the regions of interest (ROIs) were categorized into four groups, including normal, deep tumor, superficial tumor, and budding-enriched area. With digital spatial analysis, we compared the CTA expression among the four groups of regions of interests (ROIs). We characterized a marker panel for tumor budding and poorly-differentiated clusters in CRC, which tracks the progression of CRC from normal part to tumor invasive front. Our data show that the tumor budding-enriched gene panel is primarily composed of genes regulating cytoskeleton, extracellular matrix (ECM), and some secreted factors. Furthermore, our data also indicate that a morphology-based gene panel better delineates the invasion progression. Those results allow us tracking the evolution of signaling transduction for metastasis from the primary tumor to tumor budding and subsequent distant metastasis, facilitating the development of targeted drugs aimed at preventing metastasis in colorectal cancer.

#2072 Spatial genomic ISH predicts prognostic significance of retinal degeneration protein 3 (RD3) transcriptional loss in colon cancer.

Natarajan Aravindan[1], Poorvi Subramanaian[1], Sreenidhi Mohanvelu[1], Sheeja Aravindan[2]

[1]Physiological Sciences, Oklahoma State University, Stillwater, OK,[2]OU Health Stephenson Cancer Center, Oklahoma City, OK

Our studies documented remarkable expression of Retinal degeneration protein 3 (RD3) in adult and fetal colon tissues and a significant loss in colon cancers. Further, in other solid cancers we recognized the function of RD3 in the disease pathogenesis. Here, we investigated the prognostic relevance of RD3 transcriptional loss in colorectal cancer, the second most common cause of cancer deaths. Additionally, we explored the real-time translational benefit of the spatial genomic ISH (RNAScope) as a tool for predicting the prognostic relevance and significance of RD3-loss in clinical outcomes. For this, tumor specimens (n=491) representing stage, primary/metastasis, diagnosis (Dx) or progressive disease (PD) from a test cohort of colon cancer patients (n=267) were assessed for RD3 status. Tissues in triplicate were custom archived in tissue microarrays (TMAs), and the spatiotemporal profiling of RD3 mRNA was performed using the chromogenic in situ hybridization (CISH) utilizing RNAScope with a custom designed target probe to human RD3 with PPIB and DapB (positive & negative) controls. Slides were scanned (40X, Zeiss Axio Scan) and group-analyzed for RD3 mRNA-specific positivity. Spatiotemporal distribution and quantitation of RD3 mRNA were performed using Halo image analysis configured to report copies per region of interest and probe copies per cell. RNAScope revealed significant fluctuations in RD3 transcription to cell and tissue-type, disease status (normal adjacent tissue to the tumor tissue), disease progression etc. Assessing the predictive relevance of RD3 transcription, our findings indicated a clear ‘low-is-worse’ association and RD3 profiling could serve as the independent variable (MANOVA) to predict disease aggression. The outcomes critically recognized that RD3 loss in cancers is significantly associated with the development of metastatic disease and could be designated as a prognostic marker for metastatic disease. Crucially, profiling RD3 transcription prior to and after therapy significantly recognized the anew loss of RD3 after the current first-line intensive multimodal clinical therapy. More importantly, a sizable low-is-worse correlation to the tumor recurrence, death, etc., Evidently, high levels of RD3 transcription exclusively displayed a significant association with better overall survival and showed that RD3 loss is an independent predictor of OS. Together, these results recognize transcriptional loss RD3 as an independent predictive biomarker for colon cancer progression and clinical outcomes. Further the results clearly imply that spatiotemporal RD3 RNAScope could serve as a clinical tool to predict disease evolution, that could lead to defined treatment stratification and better clinical outcomes in deadly colon cancer.

#2073 Technological benchmarking of integrated multiome analysis using multiplex immunofluorescence and spatial transcriptomics across cancer types.

Jonathan Chui[1], Asier Antoranz[1], Jon Pey[2], Nikolina Dubroja[1], Madhavi Dipak Andhari[3], Chiara Caprioli[4], Katy Vandereyken[1], Carmen Bravo Gonzalez-Blas[4], Julie Morscio[4], Alexandre Arnould[5], Pouya Nazari[4], Gautam Shankar[1], Bart de Moor[5], Thierry Voet[1], Francesca M. Bosisio[1], Frederik De Smet[1]

[1]KU Leuven, Leuven Institute for Single-Cell Omics (LISCO), Leuven, Belgium,[2]Intelligent Biodata, San Sebastian, Spain,[3]Department of Imaging and Pathology, KU Leuven, Translational Cell and Tissue Research Unit, Leuven, Belgium,[4]Department of Imaging and Pathology, KU Leuven, Laboratory for Precision Cancer Medicine (LPCM), Leuven, Belgium,[5]Dept. of electrical engineering, KU Leuven, Dynamical Systems, Signal Processing and Data Analytics (STADIUS),, Leuven, Belgium

Spatially resolved technologies are transforming cancer research by enabling the simultaneous visualization of molecular and cellular processes within tissue contexts. We performed a comprehensive benchmarking of various multiplex immunofluorescence (IF) platforms, including COMET™ and MILAN, and spatial transcriptomics technologies, including RNAscope™ and Xenium, and their combinations to evaluate their performance, compatibility, and potential for deep phenotypic profiling. Tissues from multiple cancer types were subjected to multiplex IF using the COMET and MILAN platforms. Complementary spatial transcriptomics analyses were performed using RNAscope and Xenium on the same sections. Performance metrics and cross-platform reproducibility were systematically assessed and the added value of evaluating protein and RNA markers simultaneously was also evaluated. To facilitate data processing and integration, we developed a novel bioinformatics software, DISSCOVERY, specifically designed for the integrated analysis of high-dimensional multiplex IF and spatial transcriptomics data. Each multiplex IF and spatial transcriptomics platform demonstrated unique strengths and limitations, both individually and in combination. Initial evaluations focused on the performance of each platform independently, followed by assessments of their combined application on the same tissue section. Notably, the combination of the Xenium and MILAN platforms provided unparalleled flexibility and scalability, enabling high-throughput analysis of both large marker panels and extensive sample sets. The COMET platform, which integrates RNAscope with multiplex IF, also proved highly valuable for its speed and automation, particularly in validating newly discovered mechanisms. Integration of these data through the DISSCOVERY software enabled seamless cross-platform analysis, uncovering spatial co-localization patterns and gene-protein associations. This approach allowed us to identify novel cellular niches and functional interactions across various cancer types, highlighting the powerful synergy of multiplex IF, IHC and spatial transcriptomics for advancing our understanding of cancer biology. Overall, our benchmarking underscores the complementary capabilities of multiplex IF and spatial transcriptomics technologies in dissecting the tumor microenvironment. The DISSCOVERY pipeline streamlines data integration, facilitating multi-omic insights into cancer biology. These findings provide a roadmap for selecting and combining spatial technologies to advance cancer research.

#2074 MALDI-ICC: a new tool for high-plex, multiomic profiling of single cells for cancer research and cancer therapy.

Mark J. Lim, Gargey Yagnik, Leonardo G. Dettori, Ziying Liu, Jonathan Bell, Kenneth J. Rothschild

AmberGen, Billerica, MA

Introduction: High-plex, multiomic profiling of single cells in cancer research and therapy is essential for understanding basic cancer mechanisms, discovery of new biomarkers and monitoring disease progression. Current profiling methods rely mainly on immunocytochemistry (ICC), multiparameter flow cytometry (MFC) and single cell RNA seq. However, these methods are limited by the number and/or classes of biomarkers that can be detected and/or inability to profile small molecular species such as lipids and metabolites. In contrast, a new method for high-plex, multiomic spatial imaging of single cells known as MALDI Immunocytochemistry (MALDI-ICC), based on novel photocleavable mass-tagged (PCMT) affinity probes in conjunction with single cell MALDI mass spectrometric imaging (MSI), facilitates the rapid profiling of individual cells at the proteomic, metabolomic, post-translational, and transcriptomic level in one integrated workflow on the same instrument.
Methods: A variety of cell types such as peripheral blood mononuclear cell (PBMC) suspensions spiked with HeLa and MCF7 cancer cells, and chimeric antigen receptor (CAR) expressing cells were profiled using MALDI-ICC. Cells were processed by randomly depositing and desiccating them on glass or conductive IntelliSlides followed by a modified immunostaining protocol that combined PCMT-antibody and PCMT-oligo probes. Label-free, untargeted MSI of lipids/metabolites was first performed using a Bruker timsTOF fleX followed by a second MSI scan after binding a high-plex panel of PCMT-probes. A dual-labeled fluorophore/PCMT histone-targeted antibody was also included for high resolution microscopy.
Results: High-plex PCMT-oligo and PCMT-antibody probe panels were utilized to target a variety of plasma membrane, cytoplasmic, and nuclear biomarkers at the mRNA and protein level, for several individual cell types, using the MALDI-ICC workflow. For example, MCF7 cells exhibited the epithelial marker E-cadherin, whereas HeLa did not but were detected with the mesenchymal marker vimentin, in full agreement with the Human Protein Atlas cell line database. Conversely, the lineage markers CD20 characteristic of B-cells and CD3 characteristic of T-cells were detected at the expected ratios for the cellular composition of the spiked PBMC. This method was further enhanced to detect >100 lipids/metabolites by performing an initial label-free, untargeted MSI scan before next implementing the MALDI-ICC protocol. AI clustering algorithms of all ‘omic’ layers revealed several distinct cell types.
Conclusions: These results demonstrate that MALDI-ICC can provide a new method for rapid, high-plex and multiomic profiling of the same cell population on the same instrument. Potential uses include profiling of cancer cells in the field of hematology/oncology and of CAR T-cells both during manufacture and after infusion into patients.

#2075 Combining Vizgen's MERSCOPE spatial transcriptomics profiling and InSituPlex (ISP) multiplex immunofluorescence (mIF) to unravel the complexity of the tumor-immune microenvironment (TiME).

Angela Vasaturo, Cassandra Kysilovsky, Lauren Duro, Sudhir Tattikota, Renchao Chen, Justin He, Manisha Ray, Jiang He He, George Emmanuel

Vizgen, Cambridge, MA

Despite remarkable results for many patients, cancer therapies have still a poor response rate. Biomarkers used to select patients for treatment are few and only single-biomarker assays are clinically approved. Such single-biomarker assays are unable to capture the complexity and dynamic nature of the TiME and fail to improve patients' clinical response rate. Here we aim to enable a comprehensive understanding of the molecular, morphological and functional landscape of tumors using a multi-omics approach combining spatial transcriptomics and proteomics assays. Vizgen's MERSCOPE® platform allows for high-resolution, spatially resolved analysis of up to 1000 genes, enabling the study of molecular and cellular signatures associated with the TiME while Vizgen's spatial proteomics ISP assays allow for ultrasensitive and high-throughput detection of tumor and immune cell interactions, functions and spatial distribution. We used these approaches to generate datasets from multiple tumors and evaluated the complementary nature of analytical spatial detection methods to elucidate how local microenvironment influence gene expression and protein activity. Formalin-fixed paraffin-embedded (FFPE) specimens from multiple tumors were cut into 5µm sections for both technologies. For mIF experiments, slides were stained with a cocktail of primary antibodies using Leica Biosystems BOND RX autostainer, amplified simultaneously, and imaged on the Zeiss AxioScan.Z1 using multiple rounds of detection. Images were co-registered and exported for analysis using Ultivue's STARVUETM image data science platform. Serial sections were profiled with Vizgen's MERSCOPE Platform and the 500 Gene Immune-Oncology (IO) Panel with MERFISH 2.0 chemistry. The resulting spatial transcriptomic data was segmented using Cellpose2 and analyzed using both UMAP and spatial projections for visualization. Concordance of RNA and protein results were established by evaluating the expression of markers present in both the 500-gene IO panel and the ISP probes. We then evaluated immune responses measured by gene signatures for multiple functions and the corresponding protein markers. We similarly examined changes between the tumor boundary and within the tumor mass. We demonstrate the ability to orthogonally validate findings and expand on the biomarker-driven protein data with pathway-level data from the transcriptomic data. The integration of gene expression profiling enabling screening of a broad range of targets, and mIF assays for target validation, allows for a holistic understanding of spatial and molecular insights of the TiME. These complementary technologies can be used in parallel for biomarker discovery and IO pathways interrogation providing synergistic insights into the complex and dynamic TiME.

#2076 Spatiotemporal mapping of colitis-associated colorectal cancer evolution.

Yoonho Lee[1], Yongjae Kim[1], Minseok Lee[2], Do Kyung Yoon[1], Jiwon Baek[1], Sung Wook Hwang[3], Jong Lyul Lee[4], Sang Hyoung Park[3], Dong-Hoon Yang[3], Jihun Kim[5], Suk-Kyun Yang[3], Buhm Han[2], Kyuyoung Song[1], Yong Sik Yoon[4], Byong Duk Ye[3], Ho-Su Lee[1]

[1]Department of Biochemistry and Molecular Biology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[2]Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]Department of Gastroenterology, Inflammatory Bowel Disease Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[4]Division of Colon and Rectal Surgery, Department of Surgery, Inflammatory Bowel Disease Center, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of,[5]Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Colitis-associated colorectal cancer (CAC) is a severe complication of inflammatory bowel disease, particularly ulcerative colitis. Despite its clinical significance, the spatiotemporal dynamics of neoplastic progression in CAC remain poorly understood. This study aimed to elucidate the evolutionary trajectory of CAC using spatial transcriptomics. We employed spatial transcriptomics to analyze four tissue samples from three patients with ulcerative colitis at various stages of neoplastic progression. Whole-slide spatial transcriptomics RNA sequencing was performed, enabling simultaneous analysis of gene expression and tissue architecture. Integrated spatial transcriptomic data revealed recurring epithelial programs along the progression of copy number variation (CNV). Our analysis using CNV score and hematoxylin and eosin staining image revealed progressive changes in gene expression patterns as tissue transitioned from non-tumor to pre-tumor and finally to tumor states. This progression was quantified using beta coefficient values, allowing us to track gradual alterations in gene expression across the disease continuum. We identified a core set of 412 genes that exhibited consistent changes in at least three of the analyzed samples. Among these, 349 genes showed a progressive decrease in expression, while 63 genes, including *CLDN1, E2F1,* and *RECQL4*, demonstrated a gradual increase in expression as the tissue advanced towards a tumorous state. These upregulated genes pointed to potential oncogenic drivers or compensatory mechanisms activated during tumor development. Pathway analysis revealed that downregulated genes were enriched in processes such as KRAS signaling, hypoxia, and inflammatory response, while upregulated genes were enriched in the MYC targets pathway. This study provides high-resolution mapping of evolutionary trajectory of CRC, revealing key molecular events and spatial features associated with neoplastic progression. Our findings enhance the understanding of CAC pathogenesis and highlight potential targets for early intervention and personalized treatment strategies, contributing significantly to the field and potentially informing future therapeutic approaches.

#2077 Elevated PI16 expression in fibroadenoma fibroblasts is associated with subsequent breast cancer development.

Pria Westerman[1], Nicole Cruz-Reyes[1], Camila Pacheco Erak[1], Robert Vierkant[2], Bryan McCauley[2], Stacey Winham[2], Mark Sherman[3], Amy Degnim[4], Derek Radisky[1]

[1]Department of Cancer Biology, Mayo Clinic College of Medicine and Science, Jacksonville, FL,[2]Department of Qualitative Health Sciences, Mayo Clinic College of Medicine and Science, Rochester, MN,[3]Department of Epidemiology, Mayo Clinic College of Medicine and Science, Jacksonville, FL,[4]Department of Surgery, Mayo Clinic College of Medicine and Science, Rochester, MN

Introduction: Fibroadenoma is the most common type of benign breast lesion and is not traditionally considered an indicator of increased breast cancer risk. This study aimed to identify biomarkers within fibroadenoma associated with subsequent breast cancer development using patient samples from the Mayo Clinic Benign Breast Disease (BBD) cohort.
Methods: We analyzed formalin-fixed paraffin-embedded (FFPE) breast biopsy samples from patients diagnosed with non-proliferative fibroadenoma who either developed breast cancer later (n=10) or remained cancer-free (n=5). NanoString RNA profiling identified differentially expressed genes in fibroblasts associated with subsequent cancer development. Immunohistochemistry was first done to compare overall expression of PI16 in this cohort. Opal multiplex immunofluorescence staining (mIF) was then performed to evaluate the expression of PI16 in fibroblasts (Vim^+PanCK^-) and assess immune cell infiltration ($CD45^+$) in different tissue compartments. Fibroblasts were identified by vimentin positivity (Vim^+), and epithelial cells were marked by pan-cytokeratin positivity ($PanCK^+$).
Results: Compared to patients who remained cancer-free, those who developed breast cancer showed significantly increased expression of PI16 in fibroblasts ($PI16^+Vim^+PanCK^-$, 3.25-fold increase, p=0.0011). Additionally, the number of immune cells ($CD45^+$) was significantly decreased (0.52-fold, p=0.03) in the fibroadenoma lesions of patients who later developed cancer.
Conclusions: Our findings suggest that elevated expression of PI16 in fibroblasts within fibroadenoma may serve as potential biomarkers for predicting breast cancer risk for women with fibroadenoma. PI16 encodes Peptidase Inhibitor 16, which is implicated in modulating fibroblast activity and extracellular matrix remodeling—processes that can contribute to a tumor-supportive microenvironment. Elevated levels of this protein in fibroblasts suggest an altered microenvironment that may foster tumor initiation and progression. The decreased immune cell infiltration further implies an immunosuppressive microenvironment that may facilitate cancer progression. As these markers can be detected in FFPE samples, our results could lead to the development of a readily applicable clinical test to identify fibroadenoma patients at increased risk for breast cancer, enabling earlier intervention and surveillance.

#2078 Single-cell spatial transcriptomics in colon adenocarcinoma reveals tumor heterogeneity and immune microenvironmental shifts.

Margaret Hoang, Yi Cui, Shanshen He, Michael Patrick, Megan Vandenberg, Stefan Rogers, Evelyn Metzger, Haiyan Zhai, Martin Shelton, Michael Rhodes, Joseph Beechem

Bruker Spatial Biology, Seattle, WA

Colon adenocarcinoma (CRC) features complex molecular changes and a dynamic remodeling of the tumor microenvironment (TME). Understanding spatial organization of gene expression in tumor and adjacent normal tissues is crucial for insights into tumorigenesis, immune modulation, and therapeutic resistance. Traditional methods like single-cell RNA sequencing (scRNA-seq) provide cellular insights but lack spatial context. Spatial transcriptomics addresses this gap, offering high-resolution, whole transcriptome analysis within tissue architecture. This study applies spatial transcriptomics to CRC, correlating molecular data with histopathological features to explore tumor heterogeneity, immune dynamics, and therapeutic targets. FFPE tissue sections (5 µm) from colon adenocarcinoma and adjacent normal tissues were analyzed using the CosMx® Spatial Molecular Imager (SMI) to create a spatially resolved whole transcriptome, single-cell map. The sections were stained with H&E for histopathological context, and spatial gene expression data was aligned with H&E-stained sections using custom software. Additionally, scRNA-seq was performed on a thicker curl (25 µm) from the same tissue block for comparative analysis. Spatial transcriptomic analysis revealed distinct gene expression patterns between tumor and normal regions, highlighting tumor heterogeneity with subpopulations of cancer cells showing varying differentiation states. Immune cell infiltration varied spatially, indicating diverse immune responses across the tumor. While both platforms identified similar transcriptional profiles, the CosMx Whole Transcriptome (WTX) panel preserved tissue architecture, allowing exploration of gene expression in its native context. CosMx WTX showed a more accurate cell composition ratio than scRNA-seq, which may introduce bias due to tissue dissociation. CosMx WTX also captured rare cell populations, such as tumor-infiltrating lymphocytes, often underrepresented in scRNA-seq due to sample size limitations. The spatial context enabled pathway activity analysis and ligand-receptor interaction mapping, providing deeper insights into tumor biology. This study highlights the power of spatial transcriptomics in colon adenocarcinoma, offering insights into tumor heterogeneity, immune infiltration, and the TME. Integrating spatial gene expression with histopathological features enhances understanding of tumor progression and immune modulation. The comparison with scRNA-seq underscores the unique benefits of spatially resolved profiling, presenting a more complete picture of cellular functions within their native tissue architecture. These findings emphasize the potential of spatial transcriptomics to advance cancer research, guide therapeutic strategies, and reveal novel insights into tumor biology.

#2079 Spatially guided single-cell analysis integrating spatial transcriptomics and spatial cell sorting for in-depth profiling.

Sumin Lee, Amos Lee

Meteor Biotech, Seoul, Korea, Republic of

Spatial transcriptomics technologies, such as Xenium, provide detailed spatial mapping of gene expression at the single-cell level, revealing intricate tissue organization and distinct cell populations. However, translating these spatial insights into actionable molecular information often requires further downstream analysis of specific cells of interest. To address this, we introduce an integrated workflow combining SLACS (Spatially-resolved Laser-Activated Cell Sorting) with Xenium-derived spatial data, enabling targeted isolation and in-depth transcriptomic analysis of defined cell populations. SLACS technology is a novel cell sorting method that utilizes laser-based activation for precise, spatially guided isolation of individual cells. In this study, we applied SLACS to samples previously analyzed using Xenium spatial transcriptomics, focusing on cell populations identified as functionally relevant or rare based on their spatial gene expression profiles. The targeted cells were isolated using SLACS, followed by high-resolution RNA-seq analysis to further characterize their unique transcriptomic signatures. Utilizing two distinct breast cancer samples analyzed via Xenium, we demonstrate the effective identification of regions of interest (ROIs) for SLACS-based isolation and subsequent high-resolution transcriptomic analysis. The integration of SLACS with Xenium spatial data significantly enhanced the resolution of single-cell transcriptomic analysis. In the luminal A sample, SLACS successfully isolated rare cell populations, including luminal B stem cells and CAFs, which exhibited distinct gene expression profiles. RNA-seq analysis revealed differential expression of key markers, such as ESR1 and PGR, which are crucial for understanding hormone receptor signaling pathways in luminal A breast cancer. In contrast, the TNBC sample displayed higher heterogeneity, with a prominent presence of EMT-transitioning cells and cancer cycling cells. These findings suggest active paracrine signaling between cancer cells and the surrounding stromal cells, contributing to the aggressive phenotype observed in TNBC. Our study demonstrates the powerful synergy of combining SLACS with Xenium spatial transcriptomics for targeted single-cell analysis. By leveraging spatial information to guide cell sorting, we achieved high-resolution characterization of rare and functionally distinct cell populations. This integrated approach provides new insights into the cellular and molecular mechanisms underlying breast cancer, highlighting key differences between luminal A and triple-negative subtypes.

#2080 Whole transcriptome single cell spatial imaging of tumor vs normal tissue microarray.

Wei Yang, Isabel Lee, Michael Patrick, Yi Cui, Shanshan He, Martin Shelton, Haiyan Zhai, Michael Rhodes, **Joseph Beechem**

Bruker Spatial Biology, Seattle, WA

Tissue microarrays (TMAs) are widely used for high-throughput research but present challenges due to variations in tissue fixation, morphology, and cellular composition, which can impact staining, RNA/protein preservation, and segmentation accuracy. Analyzing diverse tissue types, especially when comparing normal and tumor samples, requires advanced imaging and computational tools. The CosMx® Spatial Molecular Imager (SMI) addresses these challenges by enabling accurate definition of single cells with multi-tissue AI segmentation models and high-resolution data extraction from complex TMA samples. We employed the CosMx SMI with the CosMx Human Whole Transcriptome (WTX) panel, which targets approximately 19,000 RNA targets, to analyze human FFPE tissue microarrays. Two FFPE TMAs—one with normal and the other with cancerous tissue—were constructed with cores from multiple organs including breast, skin, lung, colon, liver, prostate, and brain. RNA was detected in its native tissue context, and hematoxylin and eosin (H&E) staining provided histological reference for spatial transcriptomics. Uniform Manifold Approximation and Projection (UMAP) and Leiden clustering were used for dimensionality reduction and cell type identification based on marker gene expression. Differential expression (DE) and pathway analyses identified molecular signatures and biological processes across tissue types. CosMx SMI achieved high cell counts per sample and precise segmentation, enabling reliable analysis of diverse tissue types. H&E staining on the same slide enhanced AI algorithm training, improving tissue structure identification and segmentation accuracy. We identified distinct cell types and tissue-specific biomarkers. DE and pathway analysis revealed potential therapeutic targets and biomarkers, such as PSA, PSMA, AR, PTEN, and ERG fusion in prostate cancer, along with key pathways like AR signaling and DNA damage repair. Transcript profiles localized to specific cell types, demonstrating the platform's robustness in spatial transcriptomics. CosMx SMI significantly enhances single-cell transcriptome studies, providing detailed molecular insights across diverse tissue types. This platform is a powerful tool for tissue analysis, biomarker discovery, and spatial genomics, supporting a wide range of molecular and cellular research applications.

#2081 Tissue-niche-based and cell-type-selective proteomics.

Yi-Chien Wu[1], Elie Abi Khalil[1], Aditi Upadhye[2], Jalees Rehman[2], Nermin Kady[3], Ryan Wilcox[3], Steve Lee[1]

[1]Pharmaceutical Sciences, University of Illinois at Chicago, Chicago, IL,[2]Biochemistry and Molecular Genetics, University of Illinois at Chicago, Chicago, IL,[3]Internal Medicine, University of Michigan, Chicago, MI

Background: The spatial organization of cell populations within tissues is crucial for maintaining physiological function and understanding the mechanisms underlying various diseases. Proteins are the functional components that drive essential processes such as tissue homeostasis, disease progression, and therapeutic response. Spatial proteomics integrates molecular profiling with cellular location data, offering a powerful approach to decode these mechanisms. Here, we present an innovative spatial proteomics (SP) tool that combines widely adopted methodologies in biological research, enabling cell type-specific and comprehensive proteomic insights within tissue niches.

Method: Our approach utilizes thick tissue macrosections (≥300 µm) to precisely select regions of interest (ROIs) based on 3D multiplexed microscopy images. We perform microscopic photobleaching on the immunofluorescence-stained cells in ROIs to create a distinguishable fluorescent label for capturing their spatial context. These labeled cells are subsequently dissociated and collected via flow sorting. Lastly, we conducted LC-MS/MS analysis for a comprehensive spatial proteomic analysis of the collected cells.

Result: We confirmed that our SP technology does not significantly alter the protein expression in the samples. No significant changes in protein expression were observed in the heatmap and the volcano plot compared to the control samples. Using this technology, we investigated dendritic cell (DC) subsets in mouse spleen during inflammation. The result reveals significant proteome differences among three splenic DC subsets, categorized by their locations (“inside” or “outside” spleen T-cell zones) and control DCs. Our results align with published proteome data on inflammatory splenic DCs, demonstrating the feasibility and reproducibility of our technology. Importantly, we identified 50 proteins, including cytoskeletal proteins FSCN1 and SH3BP1, with differential expression between the “outside” and “inside” DC subsets in the inflamed spleen. These findings suggest varying migration capabilities between these subsets, providing potential therapeutic targets for inflammatory diseases. Additionally, we adapted this technology to study T cell-macrophage interaction in mouse peripheral T cell lymphoma and explore tumor cell heterogeneity in human tumors.

Conclusion: Our SP technology provides extensive protein profiling tailored to cell-type-specific spatial proteomics. It also demonstrates a broad applicability across diverse tissue specimens in various diseases. These findings hold promise for identifying novel cell types and potential drug targets to enhance treatment strategies for inflammatory diseases and cancers.

#2082 Spatial deconvolution of non-small-cell lung cancer tissues prior to immune checkpoint inhibitor therapy.

James Monkman[1], Chin Wee Tan[2], Rafael Tubelleza[1], Ken OByrne[3], **Arutha Kulasinghe**[1]

[1]University of Queensland, Woolloongabba, Australia,[2]WEHI, Melbourne, Australia,[3]Princess Alexandra Hospital, Woolloongabba, Australia

Introduction. Immune checkpoint immunotherapy (ICI) has shaped disease management for patients with non-small cell lung cancer (NSCLC). The blockade of the interaction between PD-1 and PD-L1 elicits pro-immunogenic tumour clearance in a subset of patients, however current methods to stratify patients likely to benefit from ICIs is lacking. This study leverages full tissue sections from first-line nivolumab treatment in stage IV or recurrent NSCLC to understand the properties of tissues from patients that benefit from ICI compared to those with refractory disease.

Methods. Pre-treatment tissues from patients that received first-line nivolumab in advanced stage setting were processed by high-plex immunofluorescence on the Akoya PhenoCycler platform. Patient response to ICI was grouped by RECIST 1.1 category (CR=1, PR=4, PD=4, SD=1) Supervised clustering was performed to phenotype broad cell lineages, and gaussian mixture models were fit to assign positive expression of functional markers. Spatial K-means clustering on tumour or non-tumour cells allowed tumour, non-tumour, and tumour-interface regions to be defined. Additionally, contours of tumour density were mapped as discrete regions. Cell frequencies and cell-cell interactions were considered in each of these spatial compartments to delineate the features that aligned with clinical outcomes.

Results. The staining panel allowed for deep phenotyping of $3.3x10^6$ tumour cells and $3.4x10^6$ non-tumour cells. Of immune cell lineages, we identify the most abundant macrophage populations express discrete mixtures of LAMP-1, HLA-DR, PD-L1, MMP9 and VISTA. CD8 T cells most commonly express granzyme-B and PD-1, with discrete populations of LAMP-1^+/HLA-DR^+, while CD4 T cells and Tregs express discrete mixtures of PD-1 and ICOS. Interestingly, both CD8 and CD4 T cells display activated $CD38^+$/$IFNg^+$ populations. Spatially, we observe that higher vasculature as well as macrophages positive for LAMP-1 and HLA-DR in both tumour and tumour-interface regions are associated with refractory disease. Additionally, activated $CD38^+$ CD4 cells are enriched in the stroma of ICI responsive patients. Higher levels of tumour cells positive for both PD-L1 and FOXP3 were also associated with poorer ICI response.

Conclusion. Our study showcases deep cellular phenotyping of large tissue specimens and utilises unbiased and automated methods to identify tissue regions for which to measure cellular features. We identify a number of properties that define the characteristics of NSCLC tissue in relation to therapy outcomes.

#2083 Activated fibroblasts in benign breast tissue are associated with subsequent breast cancer development.

Nicole Cruz-Reyes[1], Pria Westerman[1], Matilde Rossi[1], Camila Pacheco Erak[1], Melody Stallings Mann[1], Bryan McCauley[2], Robert Vierkant[2], Stacey Winham[2], Mark Sherman[3], Amy Degnim[4], Derek Radisky[1]

[1]Department of Cancer Biology, Mayo Clinic, Jacksonville, FL,[2]Department of Qualitative Health Sciences, Mayo Clinic, Rochester, MN,[3]Department of Epidemiology, Mayo Clinic, Jacksonville, FL,[4]Department of Surgery, Mayo Clinic, Rochester, MN

Introduction: Pseudoangiomatous stromal hyperplasia (PASH) is a benign breast lesion characterized by stromal myofibroblast accumulation. While most women with PASH do not develop breast cancer, a subset eventually does, often in the same breast where PASH was originally diagnosed, even after surgical removal of the lesion. This pattern suggests the presence of a field effect, where alterations in the PASH microenvironment extend beyond the lesion itself, potentially influencing neighboring breast tissue. This study aims to identify specific fibroblasts within PASH-containing tissues that may create a microenvironment conducive to cancer initiation.
Methods: We conducted a retrospective analysis of formalin-fixed, paraffin-embedded breast tissue samples from women diagnosed with PASH, comparing those who later developed breast cancer (cases) to those who remained cancer-free (controls). Using transcriptional profiling with NanoString IO360/BC360 panels, multiplex immunofluorescence (MxIF), and spatial transcriptomics via NanoString CosMX SMI, we investigated molecular and histopathological differences. We focused on the expression of fibroblast activation markers (ITGB1, PDGFRβ) and their spatial relationships with proliferating epithelial cells, as well as changes in extracellular matrix (ECM) composition and stiffness.
Results: Transcriptional profiling revealed significant upregulation of proliferation-associated genes in epithelial cells from cases. MxIF showed higher Ki-67 levels in epithelial cells from cases, with proliferating cells forming clustered regions. Activated fibroblasts expressing ITGB1 and PDGFRβ were markedly increased in cases and were located closer to proliferating epithelial cells. Spatial transcriptomics uncovered gene expression changes in fibroblasts indicative of an activated phenotype, and in epithelial cells, consistent with responses to increased tissue stiffness and mechanotransduction signaling. Polarized light imaging with picrosirius red staining revealed enhanced collagen cross-linking and thick fibril formation in cases, indicating greater ECM stiffness.
Conclusions: Our findings suggest that a subset of activated fibroblasts in benign breast tissue creates a pro-tumorigenic microenvironment through ECM remodeling and increased tissue stiffness, promoting epithelial proliferation and potentially driving cancer development. The spatial proximity of these fibroblasts to proliferating epithelial cells underscores their possible role in early carcinogenesis. This study introduces the novel concept of cancer-predisposing fibroblasts in benign breast tissue, providing new insights into microenvironmental changes that precede cancer and offering potential targets for early detection and intervention.

#2084 Development of a novel tri-omic spatial biology assay that provides in-depth immune profiling of the tumor immune microenvironment.

Arne Christians[1], Jannik Boog[1], Daniel Jimenez Sanchez[1], Sara Bodbin[2], Agata Wicher[2], Subham Basu[2], Aneesh Acharya[3], Randy Chen[3], Hong Liang[4], Shruti Shridar[4], Tan Char Loo[4], Ng Siok Bian[4], Michelle Poon[4], Anand Jeyasekharan[4], Oliver Braubach[1]

[1]Bruker Spatial Biology, St. Louis, MO,[2]Navinci Diagnostics, Uppsala, Sweden,[3]Molecular Instruments, Los Angeles, CA,[4]National University Cancer Institute Singapore (NCIS), Singapore, Singapore

Spatial biology has advanced our understanding of cancer biology and shed light on the immense transcriptomic and proteomic heterogeneity that exists within the tumor-immune microenvironment (TiME). To date, most analytical and diagnostic approaches only provide one type of biological readout per tissue section, and the generation of true multi-omic data has remained challenging. We developed a workflow that allows the integration of multiple omic modalities on a single section. The workflow is centered around a new signal removal strategy, EpicIF™ technology, which effectively and rapidly removes fluorophores while leaving tissue and probe chemistries unaffected. Using this workflow on the CellScape™ platform, we iteratively performed spatial proteomic, transcriptomic, and interactomic assays all on the same tissue sections. Formalin-fixed, paraffin-embedded tissue sections were subjected to standard histological processing and then incubated with primary antibodies against PD1 and PD-L1, which were then treated with oligonucleotide-modified secondary probes designed for an in situ Proximity Ligation Assay (isPLA) to detect PD1 and PD-L1 interactions. Next, the detection of RNA targets was accomplished by adding 12 HCR™ HiFi RNA-ISH probes, which were visualized by addition of target-specific fluorescently labeled HCR™ Gold amplifiers (RNA-FISH). Lastly, spatial proteomic labeling was conducted with VistaPlex™ multiplex immunofluorescence (mIF) panels targeting 30+ biomarkers. We deployed this tri-omic assay on samples of primary CNS lymphoma (PCNSL), a rare and aggressive form of B-cell lymphoma that remains an area of unmet clinical need, with over half of diagnosed patients succumbing to the disease. Unlike diffuse large b-cell lymphoma (DLBCL), its morphologically identical systemic counterpart, PCNSL shows sensitivity to PD1 checkpoint inhibition. We investigated if our assay could describe unique interactions between the PD1-PDL1 axis and the lymphoma TiME in PCNSL (n=24), in comparison to DLBCL (n=152) cases. High-resolution imaging with the CellScape platform allowed for precise detection and quantification of isPLA, RNA-FISH and mIF signals on the same slide. The combined assay showed differential biomarker expression and interaction profiles associated with immune-regulatory processes in the interrogated tumor samples, revealing remarkable inter- and intra-tumoral heterogeneity. This spatial multi-omics approach allows for a more comprehensive insight into the complex interplay of immune and non-immune cell populations in the TiME.

#2085 Visium HD combined with deep-learning-based cell segmentation on H&E images yield accurate cell annotation at single-cell resolution.

Tianyou Luo, Mario G. Rosasco, Christine M. Hoeman, Sonal Khare, Daniel J. Gorski, Tim A. Rand, Richard A. Klinghoffer, Justin Guinney, Chi-Sing Ho

Tempus AI, Inc., Chicago, IL

Background: Bulk and single-cell next-generation sequencing (NGS) have been instrumental tools for characterizing gene expression profiles of tumor samples. However, the lack of spatial and cellular context limits their utility in investigating tissue architecture and cellular interactions in the tumor microenvironment (TME). NGS-based Spatial Transcriptomics (ST) technologies have gained increasing attention for their ability to provide spatial context of gene expression, but they have been constrained by low resolutions until the recent launch of 10X Genomics Visium HD platform. This platform achieves whole-transcriptome profiling at 2 µm resolution. However, there are complications in downstream biological interpretations with the default binning of Visium HD at 8 µm resolution.
Methods: Primary tumor samples were collected from 2 patients with non-small cell lung cancer (NSCLC). The 10X Genomics Visium HD platform was used to generate high-resolution ST data. To study spatial expression at the single-cell level, we trained a cell-segmentation neural network and applied it to H&E images, generating cell segmentation masks. These masks were used to summarize raw Visium HD data at 2 µm resolution into single-cell-level gene counts. Clustering was performed on the generated single-cell level data and a large language model-based (LLM-based) cell type annotator was used to infer the cell types of each cluster.
Results: The LLM-annotated cell clusters from Visium HD were highly consistent with pathologist's annotations based on H&E images. Specifically, in the immune-active sample, 93.1% of cells in annotated lymphocyte regions were classified as lymphocytes based on cell-level ST counts, and 88.8% of cells identified in annotated tumor regions were classified as cancer cells. Cell-level ST clustering also identified a benign epithelium cell cluster that is confirmed by pathologist's annotations. Similarly, in the immune-inactive sample, 72.8% of cells in annotated tumor regions and 95.8% of cells in annotated stroma regions were classified as cancer cells and stromal cells respectively.
Conclusions: Our findings showcase the feasibility and advantages of analyzing Visium HD data at single-cell resolution using deep-learning-based segmentation models applied to H&E images, empowering clinical biomarker discovery and new mechanistic insights.

#2086 Multiplex spatial bioimaging and AI-based image analysis for precision cancer therapeutics.

A. Bose[1], E. Q. Alonzo[2], S. Struble[1], J. Fisher[2], R. A. Heil-Chapdelaine[1], N. F. Diaz Granados[1], V. Agrawal[1];
[1]Leica Microsystems, Inc., Waltham, MA, [2]Cell Signaling Technology, Danvers, MA

Breast cancer (BC) is a heterogeneous disease both at the molecular and clinical level. Worldwide, BC is the leading cause of cancer-related deaths in women. Besides conventional chemo/radio therapy, immunotherapy is one of the most promising choices for a small subset of responding individuals. However, these treatments often fail to prevent recurrence and metastasis. Disease heterogeneity in BC poses challenges for survival prediction, as patients with similar diagnoses often respond differently to treatment. In this study, we apply multiplexed spatial proteomics analysis on breast cancer tissue paired with normal tissue and observe multiple immune cell types and biomarkers that could provide insight into features of the tumor microenvironment (TME) that influence response to immunotherapy. Our findings show that systematic mapping of the TME by multiplexed spatial proteomics, could empower precision immuno-oncology. The Cell DIVE Multiplex Imaging Solution allows probing and imaging of dozens of biomarkers on a whole single tissue section with an iterative staining and dye inactivation workflow. At its core, Cell DIVE is a precise and adaptable open multiplexing solution that enables flexibility in antibody selection of biomarker panels used in a multiplexed imaging study. Cell Signaling Technology (CST) has a broad portfolio of IHC-validated antibodies to detect key proteins in the TME, enabling immune cell detection and phenotyping in tissue. CST offers off the shelf (OTS), ready-to-ship antibody conjugates that have been verified to work on Cell DIVE. CST employs a rigorous approach to IHC validation, followed by verification on the Cell DIVE platform to ensure successful detection of proteins. Here, we demonstrate multiplexed Cell DIVE imaging using a novel panel of dozens of CST biomarkers across human breast cancer tissue samples. In summary, multiplexed whole slide imaging using validated antibodies and Aivia, AI-based image processing software enables spatially resolved tissue analysis of the tumor microenvironment.

#2089 Spatial profiling of exhausted T cells using high-plex imaging mass cytometry.

Thomas D. Pfister, Jyh Yun Chwee, Qanber Raza, Nikesh Parsotam, David Howell, Liang Lim, Christina Loh

Standard BioTools, Markham, ON, Canada

The spatial organization and cellular composition of the tumor microenvironment (TME) has the potential to inform clinical and translational researchers about mechanisms of disease progression and therapeutic success. Of particular interest are immune cells, especially T cells, which can become exhausted due to chronic stimulation. This poses a significant challenge in cancer therapy as exhausted T cells have reduced effector functions and sustained expression of inhibitory receptors such as PD-1 and CTLA-4, resulting in failure to effectively eliminate tumor cells.

Imaging Mass Cytometry™ (IMC™) technology is a high-plex imaging technique that enables deep characterization of the heterogeneity and complexity of the TME. The Hyperion™ XTi Imaging System utilizes IMC technology to provide signal intensities over a wide dynamic range and entails one-step detection of 40-plus markers without issues of tissue autofluorescence, making it ideally suited for spatial biology applications. Whole slide imaging modes and an automated slide loader function enable a streamlined, versatile scalable workflow for high-throughput analysis.

We used IMC technology to characterize immune cell populations and the spatial distribution of T cell exhaustion markers across various cancer types. We applied a 40-plus-marker IMC panel by integrating the Human Immuno-Oncology IMC Panel with the Human T Cell Exhaustion IMC Panel to study the TME of multiple human tissues.

IMC analysis revealed striking heterogeneity with distinct tumor and immune-rich niches in the TME. In colon adenocarcinoma, we detected functional effector T cells and multiple tertiary lymphoid structures (TLSs). In contrast, we observed fewer TLSs and more T cells expressing PD-1 and TIM-3 at the tumor periphery in the urothelial carcinoma tissue, suggesting that they are in advanced exhaustion stages. We also observed expression of PD-L1, IDO and VISTA in the tumor cells. t-SNE and PhenoGraph clustering analysis of Cell Mode data segregated and spatially resolved the T cells into effector and exhausted T cell subpopulations, which were mapped back to the segmented cell masks. Unsupervised pixel clustering and analyses of Tissue Mode data further delineated distinct tumor areas based on the presence of infiltrating immune cells, tumor replicative activity and spatial proximity to stromal components.

This work characterizing T cell exhaustion markers in multiple cancers showcases the capabilities of IMC technology and establishes it as a reliable high-plex, high-throughput spatial biology imaging platform. IMC technology is ideally suited for developing future translational and clinical applications and has the potential to help guide personalized therapeutic strategies for cancer treatment.

For Research Use Only. Not for use in diagnostic procedures.

#2090 Integrative spatial and single-cell analysis elucidates tumor microenvironment heterogeneity in NSCLC.

Qiming Zhou[1], Jiadong Zhou[2], Beixi Wang[2], Jingwen Shi[2], Han Yan[2], **Xin Chen**[3], Yun Zhang[2], Pei Zhang[2], Zhirong Shen[1]

[1]BeiGene (Shanghai) Co., Ltd., Shanghai, China,[2]BeiGene (Beijing) Co., Ltd., Beijing, China,[3]BeiGene USA, Inc, Ridgefield Park, NJ

Background: Tumor microenvironment (TME) heterogeneity plays a crucial role in cancer progression and therapeutic response. Advanced multi-omics spatial and single-cell technologies offer unprecedented resolution for dissecting TME complexity. However, the application of these technologies to formalin-fixed paraffin-embedded (FFPE) samples remains underexplored. This study aims to demonstrate the capabilities of these technologies in analyzing FFPE samples, as well as to benchmark and cross-validate different platforms and assays, and deepen our understanding of TME heterogeneity at the single-cell level and its spatial context.
Methods: We performed following assays including 1) High-plex multiple IHC platform: PhenoCycler Fusion (PCF) protein-level spatial analysis (n=10), 2) FFPE Single-Cell RNA Sequencing (FFPE scRNA-seq) (n=4) and 3) Bulk RNAseq RNA-level analysis with FFPE NSCLC samples.
Results: Firstly, to evaluate the PCF marker expression pattern, cell density of PanCK+PD-L1+ cell ratio (%) was compared to PD-L1 IHC TC score, which showed a high correlation. Further, By image co-registration between H&E with ML-based tumor/stromal classification and PCF PanCK-PD-L1 staining, PD-L1+ cell density in tumor cells specifically can be precisely calculated. To further evaluate the marker gene expression consistency, high gene expression concordance was observed across PhenoCycler Fusion (PCF), formalin-fixed paraffin-embedded (FFPE) single-cell RNA sequencing (scRNA-seq), and bulk RNA sequencing (bulk RNA-seq) data. This high concordance (average pearson r=0.84) validates the consistency and reliability of our multi-omics approach, ensuring that the data obtained from different sample types are comparable and robust. A diverse TME was identified, highlighting the complexity and heterogeneity of TME components. This diversity was evident in the range of immune cell subsets and cancer-associated stromal cells detected, underscoring the importance of comprehensive TME analysis even in small cohorts. In addition, FFPE scRNAseq enabled a deeper profiling at transcriptome level with a median gene recovery rate at 1130 genes per cell, which contribute to a more detailed cell lineage identification including small populations like Mast cells and neutrophils.
Conclusions: Overall, the study demonstrates the effectiveness and reliability of PCF in evaluating PD-L1 expression and the TME. The high concordance across multi-omics approaches and the detailed transcriptome profiling provided by FFPE scRNAseq highlight the robustness of these latest methodology on FFPE samples. Despite the limited sample size, the diverse TME identified emphasizes the need for comprehensive and personalized TME analysis. These findings provide a foundation for further investigations into the TME.

#2091 Integrating single-cell spatial whole transcriptome and histopathology to uncover drivers of tumor heterogeneity in lung adenocarcinoma and squamous cell carcinoma.

Michael Patrick, Liang Zhang, Patrick Danaher, Shanshan He, Sierra Mckinzie, Haiyan Zhai, Michael Rhodes, Joseph Beechem

Bruker Spatial Biology, Seattle, WA

Lung cancer, the leading cause of cancer-related deaths worldwide, primarily consists of non-small cell lung cancer (NSCLC), including subtypes like lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC). These subtypes exhibit distinct histopathological features but share overlapping molecular characteristics. Understanding the spatial and molecular heterogeneity of these tumors is critical for identifying novel biomarkers and therapeutic targets. This study utilizes the CosMx® Spatial Molecular Imager (SMI) platform to profile LUAD and LUSC, aiming to uncover shared and unique gene signatures, tumor heterogeneity, and rare tumor cell subtypes, while integrating histopathological insights from H&E staining. Two formalin-fixed, paraffin-embedded (FFPE) lung tumor samples—one LUAD and one LUSC—were profiled using the CosMx Whole Transcriptome (WTX) panel, which profiles approximately 19,000 genes with single-cell subcellular resolution. Spatial transcriptomic data were analyzed using Uniform Manifold Approximation and Projection (UMAP) for dimensionality reduction and Leiden clustering to identify cell clusters. Marker genes were used to annotate cell types and generate a high-resolution cellular atlas of the tumor microenvironment (TME). Hematoxylin and eosin (H&E) staining was performed on the same slides, providing histopathological context and validating CosMx-derived cell types, including immune and tumor hotspots. The alignment of H&E and CosMx SMI data highlights their potential for AI model training that integrates spatial transcriptomics and histopathology. Our analysis revealed shared and unique gene signatures between LUAD and LUSC. Shared signatures included common tumorigenic processes such as cell proliferation, immune modulation, and angiogenesis. Unique signatures distinguished each subtype, with LUAD enriched in epithelial-to-mesenchymal transition pathways, while LUSC showed upregulation of squamous differentiation markers. UMAP and Leiden clustering identified distinct tumor and immune cell subpopulations, demonstrating spatial and molecular heterogeneity with clear immune and tumor hotspots. CosMx SMI data and H&E staining corresponded well, suggesting their potential for AI model integration. Integrating spatial transcriptomics and histopathology using CosMx SMI provided valuable insights into the molecular and spatial complexity of LUAD and LUSC. This study identified rare tumor cell subtypes and mechanisms of tumor progression, underscoring the
-Bruker Confidential-potential for AI-driven biomarker discovery and therapeutic strategies in NSCLC and beyond.

#2092 Multiomic fluorescent co-detection of biomarkers in the tumor microenvironment using a new RNAscope™ assay on Roche DISCOVERY™ ULTRA.

Renzo Adilardi[1], Rose Delvillar[1], Wendy French[2], Qi Shen[1], Emerald Doolittle[1], Anushka Dikshit[1], Henry Lamparski[1], Maithreyan Srinivasan[1]

[1]Advanced Cell Diagnostics, Inc., Newark, CA,[2]Roche Tissue Diagnostics, Tucson, AZ

Understanding the interactions between different cell types in the tumor microenvironment (TME) is crucial for advancing cancer and immuno-oncology research. New spatial transcriptomic and proteomic technologies enable a context-based study of the TME. Automated RNAscope™ assays allow high throughput RNA *in situ* hybridization (ISH) and can be coupled with immunolocalization of proteins within the same tissue section. However, visualization of multiple biomarkers with standard chromogenic detection becomes challenging as the number of targets increases, due to the lack of color contrast for resolving different signals. Using fluorescent dyes enables imaging of each target in an independent channel and overlaying of each channel for the combined interpretation. Fluorescent analysis allows for greater confidence of signal identity when analyzing and quantifying complex cellular interactions. This is especially relevant in cancer research, where ISH can be used to visualize expression of multiple tumor biomarkers and combined with immunofluorescence (IF) to provide comprehensive information about the interaction between a tumor, infiltrating cells, and the surrounding environment. We developed a new assay enabling fluorescent detection of multiple RNAs that expands the current RNAscope™ assay capabilities on the Roche DISCOVERY™ ULTRA System. Here, we introduce a new, fully automated protease-free workflow to enable the fluorescent co-detection of multiple RNAs and proteins. This workflow includes harmonized cell conditioning for effective combined RNA and antigen retrieval, and a new pretreatment reagent, the protease-free VS PretreatPro, allowing for RNA detection without disruption of protease-sensitive epitopes. Following tissue pretreatment, new RNAscope™ Duplex Fluorescent reagents were used to detect two target RNA species with fluorophore-conjugated tyramide dyes, followed by sequential detection of multiple proteins by IF in the same sample. To demonstrate the capabilities of this new assay, we analyzed the interaction of tumors with their microenvironment by co-detecting tumor expression of hypoxia markers as *HIF1A* and *VEGFA*, and chemokines as *CXCL9*, *CXCL10* by ISH, followed by immunofluorescent detection of cell-surface markers to identify cells within the TME, including CD163+ macrophages, CD3+ T cells, as well as protease-sensitive targets, including CD45 (pan-hematopoietic) and CD20 for identification of B cells. Further, we analyzed the anti-tumor response and immune checkpoints identifying the expression of *IFNG*, *GZMB*, *LAG3*, and *CTLA4* by ISH, together with PD-1 and PD-L1 by IF. The combination of multiple dyes produced high-intensity signals and negligible background. This new automated multiomic assay demonstrated high sensitivity and specificity for the detection of diverse targets in tumor tissue.

#2093 Evaluation of IDH1, EGFR, IGF1R and Ki67 biomarkers in glioblastoma using Lunaphore COMET platform.

Jennifer C. Jones[1], Ashley Oliver[2], Jodi Hagen[2], Kristine Trueman[2], Grace Leland[2], Alexander Kalyuzhny[2]

[1]Bio-Techne Denver, Centennial, CO,[2]Bio-Techne Corporation, Minneapolis, MN

Glioblastoma (GBM) is the most aggressive primary neuroepithelial tumor diagnosed in the United States with approximately 14,000 diagnoses each year. Patients with GBM have a poor prognosis and only 5% of these patients survive for more than 5 years. Diagnosis of GBM requires tumor biopsies with consideration of histopathological and molecular characteristics. Typically, IHC is done using a single-biomarker HRP-DAB detection technique which is not suitable for the simultaneous spatial analysis of multiple biomarkers. Specific markers involved with the histopathology of glioblastomas include Isocitrate Dehydrogenase 1 (IDH1), Epidermal Growth Factor Receptor (EGFR), Insulin Like Growth Factor 1 Receptor (IGF-1R), and a cell proliferating marker, Ki67.

A deeper understanding of the pathology of GBM has the potential to improve early diagnosis and treatment options for patients. The complex nature of the tumor microenvironment (TME) makes spatial multiplex immunohistochemistry (IHC) and immunofluorescence (IF) ideal for visualizing biomarker expression and cellular localization. Emerging automated staining and imaging platforms rely on validated antibodies for accurate marker detection. Lunaphore COMET™ is a fully-automated, high-throughput, hyperplex platform for spatial analysis of Formalin Fixed Paraffin Embedded (FFPE) and frozen tissues. It performs sequential immunofluorescence (seqIF™) assays through cycles of staining, imaging, and elution.

Antibody specificity, sensitivity, and availability for multiplex IF is a critical success factor for TME characterization. We use a systematic process to qualify antibodies for use on COMET™ which includes specificity on a positive tissue sample, sensitivity using different antibody dilutions and elution efficiency using secondary antibody only incubation. In this study, we evaluated IDH1, EGFR, IGF-1R and Ki67 expression in GBM on COMET™. This will streamline multiplex panel development for spatial analysis of GBM to understand biomarker expression at the single-cell level.

#2094 Development of a multiomic workflow using Oncore Pro X to stain tissues for high performance Dual Channel™ Validation of RNA expression with downstream quantitation using AI-based image analysis with Oncotopix Discovery™..

Randy Chen[1], Aneesh Acharya[1], Daniel Winkowski[2], Jason Ramos[3], Harry Choi[1], **Regan Baird**[2]

[1]Molecular Instruments, Los Angeles, CA,[2]Visiopharm, Arvada, CO,[3]Biocare, Pacheco, CA

Accurate quantification of RNA expression remains a critical challenge in advancing RNA-ISH multiomic technologies for translational and clinical applications. Current barriers include lack of guidelines for assay validation and difficulties in correlating RNA abundance with spatial localization. In this study, we introduce a robust pipeline leveraging Dual Channel™ Validation (DCV) of HCR™ HiFi Probes and AI-enabled analysis to enable relative quantification of RNA abundance.

The DCV approach uses two spectrally distinct fluorescent channels to confirm the specificity and sensitivity of RNA detection. This dual-channel strategy minimizes false positives while providing a reliable proxy for RNA transcript abundance through fluorescent intensity correlations. To enhance RNA quantitation, our pipeline integrates automated tissue staining for consistent and high-quality labeling plus advanced AI-based algorithms trained on combined cellular nuclear plus membrane segmentation markers to precisely delineate cell boundaries. This dual-marker framework addresses limitations of rule based nuclear expansion-based segmentation methods and improves the accuracy of RNA spot assignment.

Our results demonstrate that DCV, combined with autostaining and AI-enabled cellular segmentation, achieves superior quantification fidelity. This approach not only validates RNA-ISH assay performance but also provides a scalable, reproducible method for relative RNA quantitation across diverse tissue types. By coupling high-performance probes with optimized automated tissue staining (on Oncore Pro X) and advanced computational analysis, our pipeline bridges critical gaps in RNA quantification, facilitating reliable, clinically meaningful insights into RNA expression within complex tissue environments.

CLINICAL RESEARCH: Spatial Proteomics and Transcriptomics 3: Other Topics/Biomarkers
Poster Session

#2098 Development and testing of specimen-protecting microscopy consumables that enable the automation of cyclic immunofluorescence methodology.

Michael Craft[1], **Noemi Kedei**[2], Nels Wedin[1], Geoffrey K. Feld[3], Nikolay Samusik[1]

[1]Parhelia BioSciences, Austin, TX,[2]National Cancer Institute, Bethesda, MD,[3]Geocyte LLC, Columbus, OH

Introduction: Spatial biology provides unparalleled proteomic and transcriptomic information on the organization of the tumor microenvironment. However, the manual handling and processing of microscope slides hinder the clinical impact of cutting-edge techniques.
Experiment and Data: We introduce and test “image-ready” coverpads to automate sample preparation workflows for multiplex immunofluorescence and immunohistochemistry methods on the Parhelia Spatial Station™ system to acquire single cell level spatial information on whole sides. These “permanent” coverpads with 0.07 mm spacers and thickness No. 1.5 simultaneously provide a reaction chamber for capillary-gap application of staining and washing reagents while protecting specimens from damage generally occurring during manual handling, and allow for imaging without the need for coverslip exchange. Image-ready coverpads were applied to different cyclic immunofluorescence (CycIF) assays using automation on the robot, whereby reagents (multiple antibodies or reporters) are cyclically applied, imaged, stripped, and re-applied to build a larger multiplex target panel. The final step in each cycle of these methods is to immerse the specimen in mounting medium and apply coverslip for imaging. Image-ready coverpads combined with Parhelia’s mounting medium that is fluid enough to be applied by the Spatial Station, allowed multi-cycle imaging on multiple microscopes/scanners (Zeiss Axioscanner, Phenocycler Fusion using adapted settings) without fading and tissue damage, and also saving significant amount of time by not having to remove coverslips. These experiments demonstrate the coverpad utility in efficient and consistent antibody staining in cyclic methods. Ongoing studies with assay manufacturers and academic collaborators will further extend and optimize automated protocols to other assays, expanding the utility of these coverpads to a menu of technologies.
Conclusion: Overall, Image Ready coverpads provide a facile mechanism enabling the standardization of cyclic immunofluorescence and immunohistochemistry techniques, an essential milestone in translating spatial biology from research to clinical settings.

#2099 Leveraging spatial transcriptomics and proteomics to assess the Immune response and DNA damage in high grade serous ovarian cancer (HGSOC) treated with neoadjuvant chemotherapy.

Dhruva Dave[1], Natalie R. Gassman[2], Emily O'brein[1], Fibiana Oladipo[1], Rebecca Arend[1]

[1]Obstetrics and Gynecology, University of Alabama at Birmingham, Birmingham, AL,[2]Pathology, University of Alabama at Birmingham, Birmingham, AL

Ovarian cancer is the sixth leading cause of cancer-related deaths among women in the United States. Many women (>80%) with OC are diagnosed at an advanced stage and a 5-year survival rate of less than 30%. Newer therapies, such as antibody-drug conjugates (ADCs), have revolutionized the treatment landscape for solid tumors, including ovarian cancer. While platinum-based chemotherapy stays the stalwart in systemic therapy for OC treatment, most of these patients experience recurrence (>50%) despite receiving standard of care therapy. Hence, significant efforts are made to target candidates for a personalized approach to therapy. 9 eligible patients with biopsy confirmed, newly diagnosed, advanced-stage serous EOC deemed appropriate for NACT seen at the University of Alabama at Birmingham Gynecologic Oncology clinic were recruited. EMR was reviewed and demographic, survival, surgery, and tumor response data were collected. Target receptor expression pre and post ADC treatment was also evaluated using IHC staining of the target protein. Actively, we are using spatial transcriptomics and proteomics to assess DNA damage and tumor immune microenvironment (TIME) pre and post NACT. Repair assisted damage detection (RADD) assay, The Lunaphore COMET and Nanostring GeoMx platform will all be utilized to perform this analysis. The RADD assay gives a DNA damage score that will be compared pre- and post-treatment. The Lunaphore COMET antibody staining panel will include antibodies against the surface and intracellular proteins pan-cytokeratin, CD3, CD4, CD5, CD8, CD20, CD25, CD31, CD68, DAPI, Granz B, FOXP3, CXCR3, CXCR5, CCR6, CTLA4, PD-1, PDL1, TIM3, and pan-cytokeratin, allowing us to evaluate changes in subpopulations within the tumor immune microenvironment in response to ADCs in combination with platinum therapy. NanoString GeoMX platform will use targeted transcriptomic sequencing to further evaluate PanCK+ tumor cells, CD20+ B cells, and CD8+ T cells, or subpopulations identified from COMET results. Results Median age of this cohort was 68.5 (52-81), most patients were white (n=7), all patients had stage III or IV disease (n=9). Based on RECIST 1.1 criteria, median change in tumor burden from baseline was -19.31% (+9.81% to -85.64%), showing the impact of NACT. The secondary outcomes of this study are to identify predictive biomarkers as potential therapeutic targets through analysis proteomics and transcriptomics. ADCs have demonstrated potential to monitor change in tumor burden, thereby validating the efficacy of targeted therapy based on protein or receptor expression in OC. Utilizing technologies such as COMET and Nano-string, our results will help us understand the intricacies of NACT therapy in the context of ADCs and contribute to pave the way for a more tailored therapeutic approach.

#2100 Integrative spatial analysis reveals tumor heterogeneity and immune colony niche related to clinical-outcomes in small cell lung cancer.

Chaoqiang Deng[1], Changbin Zhu[2], Tao Hu[2], Jing Wang[2], Haiquan Chen[1]

[1]Fudan University Shanghai Cancer Center, Shanghai, China,[2]Amoy Diagnostics Co., Ltd., Shanghai, China

Recent advances have shed light on the molecular heterogeneity of small cell lung cancer (SCLC), yet the spatial organizations and cellular interactions in tumor immune microenvironment remain to be elucidated. Here, we employed co-detection by indexing (CODEX) and multi-omics profiling to delineate the spatial landscape for 165 SCLC patients, generating 267 high-dimensional images encompassing over 9.3 million cells. Integrating CODEX and genomic data revealed a multi-positive tumor cell neighborhood within $ASCL1^+$ (SCLC-A) subtype, characterized by high SLFN11 expression and associated with poor prognosis. We further developed a cell colony detection algorithm (ColonyMap) and revealed a spatially assembled immune niche consisting of antitumoral macrophages, $CD8^+$ T cells and natural killer T cells (MT^2) which highly correlated with superior survival, and predicted improving immunotherapy response in an independent cohort. This study serves as a valuable resource to study SCLC spatial heterogeneity and offers insights into potential patient stratification and personalized treatments.

#2101 Absolute lymphocyte count after CAR-T therapy has different kinetics and predicts better outcomes in B-cell malignancies.

Juan Esteban Velez-Hernandez[1], Theresia Akhlagi[2], Caitlin Unkenholz[3], Juan Harvey Martinez[1], Juan Jose Fernandez-Rengifo[2], Christian A. Gordillo[4], Hei Ton Chan[4], Markus Mapara[4], Giorgio Inghirami[2], Ran Reshef[4], Samuel Yamshon[2], Mateo Mejia Saldarriaga[2], **Mark Bustoros**[2]

[1]Hospital Alma Mater, Medellin, Colombia,[2]Weill Cornell Medicine, New York, NY,[3]Weill Cornell Medical College, New York, NY,[4]Columbia University Irving Medical Center, New York, NY

Introduction: Chimeric antigen receptor (CAR) T-cell therapy targeting CD19 and BCMA antigens are now a valuable option for patients with relapsed or refractory (R/R) B-Cell malignancies Commercially available products consist of an antigen binding domain against CD19 or BCMA and one of two main co-stimulatory molecules, CD28 (Axi-Cel , Brexu-Cel) and 41-BB (Tisa-Cel, Liso-Cel, Cilta-cel, and Ide-cel). In this analysis, we studied the prognostic impact of absolute lymphocyte count (ALC) in patients with B-Cell malignancies treated with CAR-T therapy and investigated the differences in ALC kinetics between the products and co-stimulatory molecules.
Methods: We analyzed data from patients with R/R B-Cell malignancies treated with CAR-T therapy from 2017 to 2024 at our institutions. All relevant baseline characteristics were collected. ALC_{max} was defined as the highest ALC from day 0 through 15, not attributable to leukemic disease. The ALC values and kinetics were compared among products and co-stimulatory molecules. Survival and Cox proportional hazards analyses were performed with PFS as an outcome.
Results: We identified 245 patients with B cell malignancies (DLBCL, MCL, FL, CLL, and MM). The most common malignancy was DLBCL (62%) followed by MM (26%). Most used product was Axi-cel 119 (49%) in the lymphoma cohort in comparison to cilta-cel in the MM cohort. ALC_{max} was significantly higher in Liso-Cel and Tisa-Cel compared with Axi-cel and Brexu-Cel treated patients ($p < 0.001$). ALC_{max} was also higher in CD19 and BCMA 4-1BB CAR- T products compared to CD19-CD28 products (0.76 vs 1.28 vs 0.59 x 10^3/uL, respectively) ($p < 0.001$). In Univariate analysis of DLBCL patients treated with any of the CD19 CAR-T products, higher ALC_{max} was associated with improved PFS (HR: 0.71, CI: 0.5- 0.9), while an $ALC_{max} < 0.5$ x 10^3/uL was associated with worse PFS (Hazard ratio (HR) 2.2, CI 1.13 - 3.18). This ALC_{max} cutoff was still associated with worse PFS in CD19 CAR-T products with either CD28 or 41-BB co-stimulatory molecules. Similarly, ALC_{max} was associated with better PFS after accounting for lines of therapy and high-risk cytogenetics in MM patients treated with the BCMA CAR-T products (HR: 0.42, CI: 0.26 - 0.78, $p = 0.001$). In the DLBCL cohort, $ALC_{max} < 0.5$ x 10^3/uL and high LDH were independent risk factors of worse PFS after accounting for age, stage, ferritin levels. Flow cytometry data showed the ALC_{max} was positively correlated with CAR-T cells expansion in both MM and DLBCL.
Conclusions: ALC_{max} was associated with better PFS in DLBCL patients treated with both types of CD19 products and in MM patients treated with BCMA-41-BB CAR-T products. This data suggests that ALC_{max} is a good marker for response to CAR-T therapy and encourages better understanding of the factors influencing ALC levels between the CAR-T products and disease subtypes.

#2102 A comparative study of tissue and blood samples reveals the frequency and characteristics of BRCA and PALB2 mutations in Chinese pancreatic cancer.

Yue Zhu, Yanli Wang, Wenfen Lu, Zhihui Lu, Guihe Huang

Guizhou Aviation Group No.302 Hospital, Guizhou, China

Background and Purpose: Pancreatic cancer is a highly lethal malignancy often associated with genetic mutations, particularly in the BRCA1, BRCA2, and PALB2 genes. Identifying mutations in these genes is crucial for understanding the genetic basis of the disease, guiding treatment decisions, and providing genetic counseling. This study aims to evaluate the mutation frequency and types of BRCA1, BRCA2, and PALB2 in pancreatic cancer patients using both tissue and blood samples through next-generation sequencing (NGS) with a 733-gene panel.
Methods: A total of 1425 pancreatic cancer patients were included in this study, with 1228 patients undergoing tissue-based NGS and 197 patients undergoing blood-based NGS. The mutation frequencies, along with the proportions of germline and somatic mutations for BRCA1, BRCA2, and PALB2, were calculated and analyzed.
Results: The overall mutation frequency for BRCA1 was (772/1425) 54.18%, with (762/772) 98.7% being germline mutations and (10/772) 1.3% being somatic mutations. In tissue samples, the BRCA1 mutation detection rate was (769/1228) 62.62% (germline: 98.83%; somatic: 1.17%). However, the blood sample analysis yielded a significantly lower detection rate of (3/197) 1.52%, comprising 66.67% germline and 33.33% somatic mutations. For BRCA2, the mutation frequency was (136/1425) 9.54%, with 79.41% being germline alterations; the rates were (132/1228) 10.75% in tissue (germline accounted for 78.79%) and (4/197)2.03% in blood samples, the latter consisting entirely of germline mutations. PALB2 mutations had a frequency of (61/1425) 4.28%, with germline alterations accounting for 93.44%. Tissue analysis showed a PLAB2 mutation detection rate of (59/1228) 4.8% (germline accounted for 93.22%), whereas blood samples showed a rate of (2/197) 1.02%, all being germline mutations. Notably, nonsynonymous mutations were the most prevalent mutation type across all genes in both tissue and blood analyses.
Conclusion: The study reveals significant differences in the mutation frequencies and types of BRCA1, BRCA2, and PALB2 detected in pancreatic cancer patients, highlighting higher rates in tissue samples compared to blood samples. The predominance of germline mutations, particularly in BRCA1 and PALB2, emphasizes the importance of genetic testing for personalized treatment strategies and risk assessment in this patient population. These findings contribute valuable insights into the genetic landscape of pancreatic cancer and underscore the need for further investigation into the clinical implications of these mutations.

#2103 Pharmacogenomic biomarkers of oncology drugs approved by the US FDA classified on the basis of BEST (Biomarkers, EndpointS, and other Tools) resource: systematic review.

Tariq H. M. Alqurayshah, SFDA Oncology and Hematology Group

Oncology and Hematology, Saudi Food and Drug Authority, Riyadh, Saudi Arabia

Objective: To characterize pharmacogenomic biomarkers of oncology indications approved by the US FDA classified on the basis of BEST (Biomarkers, EndpointS, and other Tools).
Resource Design: Systematic review. Data sources: FDA oncology/hematologic malignancies approvals and databases, BEST (Biomarkers, EndpointS, and other Tools) Resource, and CDER / CBER's DDT Qualification Project Search database: Stage 1: Letter of Intent (LOI), Stage 2: Qualification Plan (QP), and Stage 3: Full Qualification Package (FQP).
Study Inclusion: All Biomarkers include germline or somatic gene variants (polymorphisms, mutations), functional deficiencies with a genetic etiology, gene expression differences, chromosomal abnormalities; and selected protein biomarkers in all approved labeling sections published by the FDA.
Results: BEST Resource defines seven biomarker categories: susceptibility/risk, diagnostic, monitoring, prognostic, predictive, pharmacodynamic/response, and safety. The biomarkers are more linked to three cancers: breast, lung and colorectal cancers.

#2104 Epigenetic, transcriptomic and genetic analyses of HR+/HER2- primary and metastatic breast cancer results in cohort stratification by aggressiveness and reveals heterogeneous mechanisms of endocrine therapy resistance.

Jomar Sangalang[1], Tony Sourisseau[2], Veronique Scott[1], Diep Tran[1], Nusaibah Ibrahimi[3], Alicia Tran-Dien[4], Hakim Benkirane[3], Nicolas Servant[5], Fabrice Andre[1], Sergey Nikolaev[1]

[1]U981, Institut Gustave Roussy, Villejuif, France,[2]Equipe 9 - Sarcotarget, Institut Bergonie, Bordeaux, France,[3]Oncostat, Institut Gustave Roussy, Villejuif, France,[4]Plate-forme de Bioinformatique, Institut Gustave Roussy, Villejuif, France,[5]CurieCoreTech Bioinformatics (CUBIC), Institut Curie, Paris, France

Endocrine therapy (ET) is typically the first-line treatment in hormone receptor-positive, human epidermal growth receptor 2-negative (HR+/HER2) breast cancer (BC) patients; however, almost half of the patients exhibit ET resistance after initial response. Mechanisms of ET resistance are not fully understood, and require an integrated epigenetic, transcriptomic and genetic approach. We conducted ATAC, RNA, and whole-exome sequencing on primary and metastatic BC (pBC and mBC) from 459 HR+/HER2- patients. pBC samples were derived from tumor resections of patients, which were then treated with adjuvant ET and experienced either a relapse or sustained remission over a five-year period. Samples of mBC were obtained from metastatic lesions of ET-resistant patients. We performed analysis of chromatin accessibility, gene expression, and mutational data aiming to understand relapse mechanisms in pBC and resistance mechanisms in mBC. PAM50 probability scoring of our cohort of HR+/HER2- BC revealed subgroups within pBC and mBC, which resembled PAM50 subtypes of BC. In pBC, the “Basal” and “Her2” subgroups displayed the highest percentage of relapse, compared to the “LumA” and “LumB” subgroups. TP53 alterations were enriched in “Her2” subgroups, while MAP3K1 alterations were more frequent in “LumA” subgroup. In mBC, ESR1 mutations characterized “LumB” tumors, "Her2” subgroup exhibited ERBB2 alterations, and “LumA” subgroup was enriched with FOXA1 mutations. In both pBC and mBC, the subgroups were enriched with gene sets pertaining to their associated PAM50 subtypes. “LumB” subgroup was associated with higher estrogen response. “Basal” and “Her2” subgroups showed enrichment of gene sets related to true Basal and Her2 subtypes, and transcription factor motifs of AP-1 and TFAP2. “Basal” and “Her2” subgroups was characterized by poor survival. PAM50 probability scoring was useful to dissect heterogeneity and to unveil insights into molecular mechanisms associated with the risk of relapse and ET resistance within HR+/HER2- BC. These findings may improve prognostic accuracy and patient stratification in HR+/HER2- BC cohorts.

#2105 Characterization of oral carcinoma risk in patients with oral epithelial lesions employing an AI-assisted cytopathology-on-a-chip platform.

Kritika Srinivasan Rajsri[1], Michael McRae[1], Nancy Ruel[1], A. Ross Kerr[2], Nadarajah Vigneswaran[3], Adam Jacobson[4], Jonathan Shum[5], Rachelle Wolk[2], Nicolaos Christodoulides[1], John T. McDevitt[1]

[1]Molecular Pathobiology, NYU College of Dentistry, New York, NY,[2]Oral and Maxillofacial Pathology, Radiology and Medicine, NYU College of Dentistry, New York, NY,[3]UT Health School of Dentistry, Houston, TX,[4]Otolaryngology-Head and Neck Surgery, NYU Grossman School of Medicine, New York, NY,[5]Oral and Maxillofacial Surgery, UT Health, Houston, TX

Oral squamous cell carcinoma (OSCC) accounts for >350,000 new cases and >177,000 deaths worldwide. Oral potentially malignant disorders (OPMD), harboring oral epithelial dysplasia (OED) are 15 times more common than OSCC - a significant proportion transforming to malignancy. Furthermore, field cancerization may contribute to multifocal disease-risk comprising other oral sites. Oral epithelia lesions (OEL) are often challenging to diagnose for front-line clinicians and process of monitoring patients for new/evolving local disease lacks consensus - challenging opportunities for triage, surveillance and early detection. To address these gaps there is a compelling need to complete accurate surveillance testing of OEL for disease evolution in at-risk patients chairside/point-of-care, aiding clinical decision making. This study leverages an NIH-funded, multisite time-course investigation of patients with a history of OSCC or OED, utilizing AI-linked cytopathology capabilities derived from a microfluidics engine analyzed with a three-color fluorescence analyzer. Minimally invasive oral brush cytology specimens were collected from suspicious lesions and contralateral sites, with clinical and histopathological diagnoses blinded until patient exit. The study employs a chairside-ready, AI-assisted *cytopathology-on-a-chip* (COC) platform. This platform integrates microfluidics-facilitated immunoassays, cytomic measurements, automated analysis of cellular and molecular signatures, and result generation. The output includes a numerical index that profiles disease severity and progression, linked to the patient's clinical and histopathological data, all delivered in approximately 40 minutes. Initial results from this study highlight the strong potential of a disease severity numerical index for assessing risk and distinguishing between oral cavity cancer patients who experience recurrence and those who do not. Similarly, OED patients at risk of malignant transformation exhibit higher numerical indexes. Moreover, contralateral lesions provide an advanced perspective on patients with a stronger predisposition to field cancerization. This noninvasive approach aligns well with findings obtained through more invasive biopsy and histological analysis. The AI-assisted chairside-ready COC minimally-invasive platform has strong potential to aid oral lesion characterization, for early-identification of disease risk and evolution. These capabilities include use of static numerical indexes and associated time-course changes. Measurement of contralateral-site specimen also offers new insights for referral or routine-surveillance, towards achieving better outcomes, disease prevention and management.

#2106 Comparing the methylation profiles between lung adenocarcinoma and squamous cell carcinoma.

Hyeyeun Lim[1], Christopher I. Amos[2], Jinyoung Byun[2], Aaron P. Aaron[1]

[1]Baylor College of Medicine, Houston, TX,[2]University of New Mexico, Albuquerque, NM

Background: Lung cancer is a leading cause of death. Despite advancements in early diagnosis and treatment, most patients are diagnosed at later stages, and the average 5-year survival rate is < 30%. Lung adenocarcinoma (LUAD) is the most common non-small cell lung cancer (NSCLC), representing about 40% of cases, followed by lung squamous cell carcinoma (LUSC) at 25%. The biological patterns and molecular characteristics of LUAD and LUSC exhibit differences. Changes in DNA methylation levels of various genes have been observed in lung cancer subtypes, yet research on differences in DNA methylation patterns between LUAD and LUSC is limited.

Methods: The methylation microarray dataset (GSE39279, Illumina HumanMethylation450 BeadChip) from Gene Expression Omnibus at the National Center for Biotechnology Information was used. The dataset comprised 444 NSCLC samples derived from tumor tissues, of which 322 were LUAD and 122 were LUSC. We used the Champ (Chip Analysis Methylation Pipeline) package to identify differentially methylated probes (DMPs, Benjamini-Hochberg adjusted p-value < 0.05) and genes representing specific biological pathways between LUAD and LUSC. Singular Value Decomposition regression analysis was used to estimate the impact of age, sex, and smoking status and then adjusted for the covariates with p-values < 0.05. We used the eFORGE TF database to calculate the Find Individual Motif Occurrences (FIMO) p-values for the overlap with transcription factor binding sites. The Gene Expression Profiling Interactive Analysis database was used to measure the gene expression levels of LUAD and LUSC samples in the Genotype-Tissue Expression and the Cancer Genome Atlas Program portals.

Results: In total, 223,007 DMPs were identified by comparing LUAD and LUAC, with 130,610 hypomethylated and 92,467 hypermethylated. Using the absolute difference of β values between groups ≥ 0.3, we identified 15 DMPs, 11 hypomethylated and four hypermethylated. The DMPs on promoter regions were all hypomethylated in LUSC compared to LUAD (cg00415665 and cg22997040 in *ZHX2*, cg27649037 in *ST18*, cg20691436 in *CALML3*, and cg24580076 in *C7orf20*). We also identified DMPs based on the importance scores (> 0.1) from a 5-fold cross-validation random forest analysis. The two DMPs in the *ZHX2* gene had the highest importance scores (> 8.0). Among those, cg00415665 was covered by the Zfp161_secondary motif (FIMO p-value: < 10^{-5}). The average expression level of *ZHX2* in LUSC (transcripts per million, TPM=9.7) was higher than in LUAD (TPM=8.2).

Conclusions: We characterized the methylation landscape of NSCLCs by histological subtypes and identified that the methylation pattern of cg00415665 in *ZHX2,* a tumor suppressor gene, was significantly associated with the histological subtype of NSCLC. Further investigation of these findings will provide additional insight into the biology and genetics of LUAD and LUSC.

#2107 Insights into inherited genetic variations and genetic ancestry of patients with high-risk melanoma.

Ahmad A. Tarhini[1], Zhihua Chen[1], Sandra J. Lee[2], F. Stephen Hodi[3], Islam Eljilany[1], Tingyi Li[1], Howard Streicher[4], Vernon K. Sondak[1], Xuefeng Wang[1], Peter A. Kanetsky[1], John M. Kirkwood[5]

[1]H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL,[2]Dana Farber Cancer Institute, Harvard Medical School, Boston, MA,[3]Dana-Farber Cancer Institute, Boston, MA,[4]National Cancer Institute, Investigational Drug Branch, Cancer Therapy Evaluation Program, Bethesda, MD,[5]UPMC Hillman Cancer Center, Pittsburgh, PA

Introduction. For melanoma patients (pts) with resectable regional or distant metastases, there is paucity of data related to inherited genetic variations and genetic ancestry in the North American patient population.
Methods. We conducted genome-wide genotyping on samples from 744 consenting pts enrolled in E1609 adjuvant trial that tested ipilimumab vs interferon-α in high-risk melanoma including sites across the U. S. and Canada. We used Illumina Infinium Global Screening Array v.3.0. After imputation, pruning, and incorporating genotypes from 1KGP3 as reference, genetic ancestry was estimated using admixture v1.3.0 in the unsupervised mode. Population structure was visualized through a UMAP dimensionality reduction (R package umap_0.2.9.0). Genetic ancestry proportions were visualized using python package PONG v1.5.
Results. In UMAP reduction, most (728) cases clustered with the 1KGP3 European (EUR) reference, with small subsets (12 and 14, respectively) clustering with the admixed American (AMR) and East Asian (EAS) references. Considering potential ancestral origins for the study pts, we assumed between 4 to 8 ancestral populations in order to capture a wider range of ancestral contributions. Unsupervised admixture inference on the combined genetic data from our cohort and the 1000 Genomes reference identified ancestral axes clearly along continental geographical lines. K=5 was deemed most optimal in broadly capturing the potential complexity of genetic contributions in U.S. context. The ancestry populations identified were Africa (AFR), AMR, EAS, EUR, South Asia (SAS). For most (734) samples, the estimated EUR proportion was >50%, while 4 had >50% EAS ancestry, 4 >50% AMR ancestry, and 2 >40% EUR and AMR ancestry. Most (725) participants self-reported their race as White, 4 as Asian, and 1 as multi-race; 14 missing information on race. For the 725 White participants, 13 identified as Hispanic and 24 missing information on ethnicity; and for these participants, there was a high degree of EUR ancestry (>95% in 22), with only 2 having between 4-6% combined AMR and AFR contributions. The 4 Asian participants had a high degree of EAS ancestry, and the multi-race participant had a high degree of EUR ancestry with minor degrees of AMR and EAS ancestry. Participants with missing information on self-reported race had either a high degree of EUR ancestry or various combinations of significant AMR, EUR, and AFR contributions. The 17 participants reporting Hispanic ethnicity had a significant AMR ancestral contribution. The vast majority of participants not reporting (699) or missing (28) information on Hispanic ethnicity did not have AMR ancestry.
Conclusions. Our analysis in the context of a U.S. Intergroup phase 3 trial revealed important insights into genetic ancestry of patients with high-risk melanoma. Ongoing analyses are investigating associations with survival outcomes and the risk of irAEs.

#2108 Comparative analysis of fusion gene detection rates in tissue versus blood samples from Chinese diverse solid tumors.

Jun-Ling Wang, Hong-Wei Li, Hong-Xia Liu, Xiu-Ping Li, Jian-Peng Hu, Qian Xiong, Jin-Si Yang, Zong-Sheng Wu, Ting Ji

Clinical Laboratory, Qujing First People's Hospital of Yunnan Province, Qu Jing Shi, China

Background: The landscape of genetic alterations, particularly fusion genes, plays a critical role in the diagnosis and treatment of various solid tumors. As liquid biopsy methods evolve, understanding the differences in mutation frequencies between tissue and blood samples becomes essential for precision oncology. This study aimed to evaluate the detection rates of specific fusion genes in both tumor tissue and blood samples from patients with diverse solid tumors using a 733-gene panel through Next-Generation Sequencing (NGS).

Methods: We conducted a comprehensive analysis of 23 types of solid tumors (including bladder cancer (BLCA), breast cancer (BRCA), biliary tract cancer (BTC), cervical cancer (CESC), colorectal cancer (COAD), esophageal cancer (ESCA), gastrointestinal stromal tumors (GIST), head and neck squamous cell carcinoma (HNSC), intestine cancer, kidney renal clear cell carcinoma (KIRC), liver hepatocellular carcinoma (LIHC), melanoma, neuroendocrine tumors, non-small cell lung cancer (NSCLC), ovarian cancer (OV), pancreatic adenocarcinoma (PAAD), prostate cancer (PRAD), sarcoma (SARC), small cell lung cancer (SCLC), stomach cancer (STAD), thyroid carcinoma (THCA), thymoma (THYM), and uterine corpus endometrial carcinoma (UCEC)). The frequencies of fusion genes (including ALK, BRAF, ESR1, FGFR1, FGFR2, FGFR3, MET, NRG1, NTRK1, NTRK2, NTRK3, PDGFB, PDGFRA, RET, ROS1) were calculated from NGS results of tissue and blood samples.

Results: Significant differences in fusion gene detection rates were observed between tissue and blood samples for several cancers. ALK fusions were significantly more prevalent in tissue samples from NSCLC (2.4% vs 0.9%, $P<0.05$), COAD (0.1% vs 0.5%, $P<0.05$), and THCA (1.6% vs 9.8%, $P=0.04$). BRCA fusions showed similar trends in NSCLC (0.1% vs 0.3%, $P<0.05$), HNSC (0.1% vs 1.5%, $P=0.03$), STAD (0.1% vs 0.4%, $P=0.01$), and COAD (0.1% vs 0.7%, $P<0.05$). Furthermore, FGFR2 fusions were detected significantly more in blood than tissue in STAD (0.5% vs 1.1%, $P=0.03$). Other fusion genes did not exhibit significant differences in detection rates between the two sample types. Notably, in blood tests, ALK (9.8% in THCA and 5.0% in THYM), BRAF (2.3% in melanoma), NTRK1 (2.4% in THCA), and NTRK3 (2.1% in intestine) had detection rates exceeding 2%. In tissue specimens, ALK (2.4% in NSCLC), FGFR2 (2.0% in BTC), and RET (3.1% in THCA) were the only fusion genes with detection rates over 2%.

Conclusion: This study highlights significant discrepancies in the detection rates of fusion genes between tissue and blood samples across various solid tumors, emphasizing the potential of blood-based biomarkers in clinical practice. These findings suggest the need for integrated approaches in managing and monitoring the genetic landscape of solid tumors, enhancing personalized treatment strategies.

#2109 Comparison of four non-enzymatic, mechanical dissociation methods for formalin-fixed tissue in flow cytometric analysis and single-cell workflows.

Hannah L. B. Veloz, Samantha M. Hill, Gloria Asantewaa, Lisa L. Gallegos, Nelson R. Alexander

Roche Tissue Diagnostics, Oro Valley, AZ

Introduction: Formalin-fixed tissue dissociation is a common method to isolate single cells from tissues that can be used for various downstream applications such as flow cytometry or other single-cell workflows. Common dissociation methods often use enzymes to break down tissue; however, this approach can inconsistently damage cell membranes, limiting the expression of biomarkers detectable by flow cytometric analysis. Non-enzymatic tissue dissociation preserves cell epitopes for optimal antibody recognition. In this study, we provide a comparison of four different mechanical dissociation methods and determine how each method affects cell integrity.
Methods: Surgically resected, formalin-fixed breast and colon tumors were processed using the representative sampling method and the non-tumor tissue was further homogenized into single cells using four different mechanical dissociation methods. The mechanical methods used in this comparison were the IKA tube mill, Miltenyi C tube, hand-held cordless homogenizer, and a pestle. Prior to mechanical dissociation, the tissue was incubated in a cell conditioning buffer. Single cell suspensions were quantified using the Countess II, and equal cell inputs were stained in suspension for Cytokeratin 8/18, CD45, CD68, CD163. DNA content was assessed via DAPI staining. Samples were analyzed on BD FACSMelody and data analysis was performed using FCS Express 7 software.
Results: The four non-enzymatic, mechanical tissue dissociation methods were successful at generating single cell suspensions with no significant difference in the total cell counts. Flow cytometric analysis showed no significant difference in singlet generation visualized by DAPI. There was no significant difference in the percentage of CD68 and CD163 positive populations seen via flow. A statistically non-significant difference was observed in the percentage of CD45 positive and Cytokeratin 8/18 positive populations, indicating that certain methods might be better at liberating immune vs tumor cells.
Conclusion: We demonstrate that four non-enzymatic, mechanical tissue dissociation methods are capable of liberating single cells from formalin-fixed tissues. Preservation of cell surface biomarkers is a significant improvement from isolation of nuclei that enables single-cell suspensions to be analyzed using fluorescently labeled antibodies and the enrichment of cell populations of interest via fluorescence activated cell sorting (FACS). Single cell generation and analysis of intact single cells from formalin fixed tissue is novel, and increases downstream applications that can be useful in the research and translational space, and may have clinical applications in the future.

#2111 In vivo expansion of autologous GD2-CAR-T cells in patients with aggressive primary tumors may be impaired by previous alkylator therapy.

Michael P. Brown[1], Sidra Khan[2], Jesikah Logan[1], Nga T. H. Truong[2], David S. Ziegler[3], Tessa Gargett[2], Abbey LeBlanc[1]

[1]RAH Cancer Clinical Trials Unit, Royal Adelaide Hospital, Adelaide, Australia,[2]Translational Oncology Laboratory, Centre for Cancer Biology, Adelaide, Australia,[3]Kids Cancer Centre, Sydney Children's Hospital, Sydney, Australia

GD2 is a validated cancer immunotherapy target and has a highly restricted normal tissue expression. Clinically activity of GD2-CAR-T cell therapy has been observed in the high GD2-expressing tumor types of diffuse midline glioma and neuroblastoma. Recently, we initiated two phase 1 clinical trials of escalating doses of intravenously administered autologous GD2-CAR-T cells either in pediatric patients with diffuse midline glioma at Sydney Children's Hospital (LEVI'S-CATCH; www.anzctr.org.au - ACTRN12622000675729) or adult patients with recurrent glioblastoma at Royal Adelaide Hospital (KARPOS; ACTRN12622001514796). Our ex vivo CAR-T cell manufacturing protocol was changed from the original method to a modified method, which permitted CAR-T cells of memory phenotype to dominate in vitro. Our published 12-patient GD2-CAR-T cell trial in solid tumor patients showed that in vivo expansion of GD2-CAR-T cells was significantly greater among patients whose cells were prepared using the modified over the original method. Hence, we adopted the modified method for our current brain tumors trials. In the KARPOS study, six patients have been enrolled without experiencing DLTs. In the first dose cohort of three patients, none received lymphodepletion chemotherapy whereas in the second dose cohort of three patients, all received lymphodepletion chemotherapy. Clinical histories, which recorded the extent of previous alkylator therapy used for the treatment of primary and recurrent glioblastoma in adult patients, led us to hypothesize that cumulative exposure to alkylator drugs limited CAR-T cell expansion in vivo.The presence of CAR-T cells in serial peripheral blood samples was measured using quantitative DNA-PCR. The extent of CAR-T cell expansion in peripheral blood samples was described using two measures: (i) area under the curve (AUC), and (ii) peak expansion or Cmax. From the concentration of the CAR transgene in total genomic DNA (ng/µg gDNA) in blood plasma as a function of time, AUC values were calculated using GraphPad Prism according to the trapezoid rule. We found correlation coefficients of -0.90 and -0.83 for the relationship between cumulative dose of prior alkylator therapy and AUC and Cmax, respectively. These data are consistent with previous clinical data that indicate temozolomide has deleterious effects on human lymphocyte number and function. Our data suggest that patient selection may be an important parameter to consider when enrolling glioblastoma patients to clinical trials of CAR-T cell therapy. For example, randomized controlled trial evidence indicates that patients who are considering such trials and whose tumors lack MGMT promoter methylation may reasonably be spared exposure to six months of consolidation temozolomide chemotherapy as part of the conventional treatment protocol.

#2112 Association between visceral fat obesity and perioperative complications of undernutrition in laparoscopic surgery for colorectal cancer.

Kengo Haruna, Norikatsu Miyoshi, Shiki Fujino, Rie Mizumoto, Rie Hayashi, Mitsunobu Takeda, Yuki Sekido, Tsuyoshi Hata, Atsushi Hamabe, Takayuki Ogino, Mamoru Uemura, Hirofumi Yamamoto, Yuichiro Doki, Hidetoshi Eguchi

Department of Gastroenterological Surgery, Graduate School of Medicine, Osaka University, Osaka, Japan

Background: Visceral obesity and malnutrition are each associated with poor prognosis in gastrointestinal cancers. This study investigates the impact of undernutrition combined with visceral obesity on perioperative complications in laparoscopic colorectal cancer surgery.
Methods: We retrospectively analyzed 223 colorectal cancer patients who underwent curative laparoscopic resection at our institution between January 2010 and December 2011. Undernutrition was defined as the Geriatric Nutritional Risk Index (GNRI), calculated using the ideal body weight ratio and serum albumin level, with GNRI < 107 indicating undernutrition. Visceral obesity was defined as a visceral fat area (VFA) >100 cm^2 at the umbilical level. Patients were divided into two groups: those with both undernutrition and visceral obesity (n=40) and others (n=183). Associations with perioperative complications were analyzed, along with background factors including age, gender, BMI, albumin (Alb), CRP, tumor markers, and other nutritional indices. Additionally, a new nutritional status score for predicting postoperative complications was developed using ROC curve analysis based on easily measurable indicators from blood tests, CT scans, and physical exams.
Results: The malnutrition and visceral obesity group showed a significantly higher incidence of Grade 2 or higher perioperative complications compared to the other group (25.0% vs. 10.9%; $p = 0.037$). Analysis of nutritional and oncological indicators identified age, BMI, VFA, CRP, lymphocyte count, and CA19-9 as associated with postoperative complications. A novel nutritional status score incorporating these factors predicted Grade 2 or higher complications with a sensitivity of 43.0% and a specificity of 83.3%.
Conclusions: Undernutrition combined with visceral obesity significantly increased the risk of perioperative complications. Preoperative nutritional interventions to improve patient status may reduce these risks and should be further investigated.

CLINICAL RESEARCH: Therapeutic Antibodies, Including Engineered Antibodies 1
Poster Session

#2115 SIM0680, a potent antibody-drug conjugate for the treatment of solid tumors expressing ENPP3.

Abdullah Emran[1], Yutian Zhang[2], Yi Yang[1], Liting Xue[2], Lu Gong[1], Amin Al-Shami[1], Yayuan Fu[2], Renhong Tang[2]

[1]Simcere Zaiming, Cambridge, MA,[2]Simcere Zaiming, Shanghai, China

Introduction: The ATP- and cGAMP-hydrolysing ecto-nucleotide pyrophosphatase/phosphodiesterase 3 (ENPP3 or CD203c) is an extracellular enzyme which has been implicated in checkpoint regulation of innate immune responses. Analysis of data in The Cancer Genome Atlas (TCGA) and Cancer Cell Line Encyclopedia (CCLE) indicates elevated expression of ENPP3 in multiple solid tumors compared to normal tissues. Moreover, immunohistochemistry studies suggest that the expression of ENPP3 on healthy epithelial lining is polarized toward the lumen of internal organs but becomes disorganized and non-apical after malignant transformation. This spatial distribution of expression could make ENPP3 an ideal target for antibody therapies, which may have access to CD203c exclusively on tumor cells and not on healthy tissues.
Results: We have developed an antibody-drug conjugate, SIM0680, which is a fully humanized antibody that binds a membrane-proximal epitope on ENPP3 with high affinity and is coupled to a payload through a proprietary linker. Immunohistochemistry confirmed strong expression of ENPP3 in liver, renal, and colorectal carcinomas. SIM0680 had potent and specific cytotoxic activity against cell lines originating from these tissues and displaying various levels of ENPP3 expression. Consistent with the observed in vitro efficacy, SIM0680 demonstrated strong single-dose and dose-dependent anti-tumor activity in vivo against multiple cell line- and patient-derived renal cell and hepatocellular carcinoma xenografts in mice, without causing significant weight loss. Similar potent anti-tumor efficacy was observed in human myeloid and megakaryoblastic leukemia models.
Conclusion: Our findings underscore the potential of targeting the apically restricted tumor antigen ENPP3 with antibody therapy and support clinical development of SIM0680 as a novel therapeutic modality for treatment of ENPP3-positive solid tumors.

#2116 2MW7061, a novel LILRB4xCD3 bispecific T-cell engager targeting monocytic acute myeloid leukemia.

Yu Pang, **Cuicui Guo**, Zhen Han, Fenglin Yun, Ao Li, Hai Wu, Xun Gui

Mabwell (Shanghai) Bioscience Co., Ltd., Shanghai, China

Background: Acute myeloid leukemia (AML) is a highly aggressive hematologic malignancy with a high recurrence rate, highlighting the urgent need for therapies that induce durable responses and improve survival outcomes. LILRB4 is highly expressed in FAB M4 and M5 subtypes of AML, while absent in normal hematopoietic stem and progenitor cells, making it an appealing target for selective immunotherapy. We developed 2MW7061, a bispecific LILRB4xCD3 T-cell engager, designed to target and eliminate LILRB4-expressing tumor cells by selectively activating T cells.

Methods: 2MW7061 was generated through the screening and optimization of bispecific antibodies with varying geometries, formats, and CD3-binding affinities. The final construct utilizes a 1+2 format, with two Fab arms targeting LILRB4 and one single-chain variable fragment (scFv) arm targeting CD3. The affinity of 2MW7061 was measured using Octet, and its binding to T cells and AML cell lines was assessed. Functional activity was evaluated using Jurkat NF-AT reporter assays, T-cell activation assays, and tumor-directed cytotoxicity assays (TDCC). *In vivo* anti-tumor efficacy was tested in B-NDG/hu-PBMC and B-NCG/hu-PBMC mouse models implanted with THP-1-luc and MOLM-13 tumors, respectively. Safety and tolerability were evaluated in cynomolgus monkeys.

Results: 2MW7061 demonstrated reduced binding to T cells in the absence of tumor cells, effectively minimizing off-target T-cell activation and mitigating the risk of cytokine release syndrome (CRS). *In vitro*, 2MW7061 exhibited tumor-associated antigen (TAA)-dependent binding and induced potent cytotoxicity. *In vivo*, 2MW7061 significantly inhibited tumor growth in both THP-1 (high LILRB4 expression) and MOLM-13 (low LILRB4 expression) xenograft models, indicating that its anti-tumor activity is LILRB4-dependent. In non-human primates, 2MW7061 administration resulted in minimal and transient increases in serum cytokines and C-reactive protein, with no significant signs of toxicity observed.

Conclusion: 2MW7061 is a bispecific T-cell engager with potent LILRB4-dependent anti-tumor activity in preclinical models of monocytic AML. Its low nonspecific T-cell binding and favorable safety profile in non-human primates support its continued development as a promising therapeutic candidate for clinical evaluation in AML.

#2117 GenSciP107, a MICA/B-directed and Fc-enhanced antibody, potently inhibits tumor growth via ADCC and stimulation of immune response.

Ming Lei, Jiuhe Sun, Hanxi Yu, Li Tong, Yihui Lin, Chunsheng Zhang, Lei Song, Yanshuang Liu, Yanhou Liu, Jiyuan Zhao, Yingxin Bi, Weiqing Li, Yunna Gao, Yuanyuan Yuan, Bo Guo, Fu Li, John L. Xu

Changchun GeneScience Pharmaceutical Co., Ltd., Changchun, China

Background: The expression of major histocompatibility complex class I polypeptide-related sequence A and B (MICA/B) is induced in normal cells under stress and in tumor cells including hepatocellular carcinoma (HCC), non-small cell lung cancer (NSCLC), renal cell carcinoma (RCC), and urothelial cancer (UC), etc. Membrane-bound MICA/B (mMICA/B) interacts and activates NKG2D, a stimulatory receptor on NK cells, γδ T cells and a subset of $CD8^+$ T cell. Shed MICA/B (sMICA/B), however, inhibits the function of NK and other $NKG2D^+$ immune cells. Thus, an anti-MICA/B antibody can be an intriguing immuno-oncology therapy for cancer, by inhibiting MICA/B shedding from tumor cells and by stimulating NK and $CD8^+$ T cell functions, resulting in potent killing of tumor cells.
Methods: GenSciP107 is an anti-MICA/B monoclonal antibody isolated from immunized mice and then humanized and affinity matured. The Fc region of GenSciP107 was mutated for enhanced effector functions and for extended half-life. A set of *in vitro* assays were conducted to examine the impact of GenSciP107 on the MICA/B-NKG2d axis in immune cells. *In vivo* anti-tumor activity of GenSciP107 was evaluated in CDX models of NSCLC and HCC in mice. Pharmacokinetic properties of GenSciP107 were assessed following an intravenous administration in cynomolgus monkeys.
Results: GenSciP107 bound to recombinant human MICA/B proteins with single digit nanomolar affinity, as analyzed using SPR technology. It stimulated NK cells and macrophages to lyse $MICA/B^+$ tumor cells with an EC_{50} in the double digit picomolar range in the LDH release-based ADCC assay and in the single digit nanomolar range in the ADCP assay, respectively. GenSciP107 also increased the apparent expression levels of MICA/B on tumor cells by preventing their shedding, resulting in excellent stimulation of NK cells and subsequent cytotoxicity of tumor cells. Furthermore, GenSciP107 reversed the inhibitory effect of sMICA/B on NK cells and on PBMCs in an *in vitro* ADCC assay. GenSciP107 significantly inhibited tumor growth in the CDX models of human HCC and NSCLC. Half-life of GenSciP107 was determined to be about 377 hours following an intravenous injection at the dose of 10 mg/kg in non-human primates.
Conclusion: These data highlight the potential of GenSciP107 as a novel cancer therapy with multiple mechanisms of action and support its further evaluation in IND-enabling studies.

#2118 ABN501: A CLDN3-targeted monoclonal antibody with proven safety, pharmacokinetics, and synergistic anti-tumor efficacy.

Saehyung Lee[1], **Jae Choi**[1], Sunghyun Hong[1], Ha Yeon Park[1], Ho Jin Lee[1], Jaemun Kim[1], Sangin Lee[1], Seung Hwa Jung[1], Myeung Ryun Seo[2], Hobin Yang[3], Sungyoul Hong[4], Jun Young Choi[1], Na Young Kim[1], Young Kee Shin[2]

[1]ABION Inc., Seoul, Korea, Republic of,[2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of,[3]College of Pharmacy, Kyungsung University, Busan, Korea, Republic of,[4]College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of

ABN501 is an afucosylated monoclonal antibody specifically designed to target claudin-3 (CLDN3), a protein frequently overexpressed in various solid tumors, including small-cell lung cancer (SCLC). Given the critical role of CLDN3 in cancer cell proliferation and tumorigenesis, it is recognized as a promising therapeutic target. In this study, we evaluated the preclinical safety and efficacy of ABN501, focusing on its potential for clinical development as a targeted cancer therapy. To identify suitable animal models for toxicity assessment, we investigated the cross-species reactivity of ABN501 with CLDN3. Our results confirmed that ABN501 binds to CLDN3 across human, mouse, rat, and cynomolgus monkey species. Based on these findings, rats and cynomolgus monkeys were selected for comprehensive toxicity evaluations, including single-dose and repeated-dose studies. Notably, even at the highest administered doses, ABN501 exhibited no significant changes in key toxicity markers, demonstrating its exceptional safety profile. We further assessed the therapeutic potential of ABN501 as both monotherapy and in combination with chemotherapy. Chemotherapy was shown to upregulate CLDN3 expression in lung cancer cell lines, thereby enhancing the antitumor activity of ABN501 and confirming a synergistic effect. In conclusion, our preclinical studies demonstrate that ABN501 is a safe and effective CLDN3-targeting monoclonal antibody for treating CLDN3-overexpressing cancers. Its excellent safety profile and synergistic effects in combination with chemotherapy present a promising strategy for improving treatment outcomes, particularly in cancers with limited targeted treatment options. These findings pave the way for further clinical investigation, particularly in lung cancer and other CLDN3-expressing malignancies.

#2119 Targeting KIT in chromophobe renal cell carcinoma.

M. Alchoueiry[1], H. Mansour[1], D. Khabibullin[1], T. Han[1], S. Chaturantabut[2], J. F. Williams[1], M. S. Hirsch[1], C. Priolo[1], W. R. Sellers[2], E. P. Henske[1];

[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Broad Institute of MIT and Harvard, Cambridge, MA

Background: Chromophobe renal cell carcinoma (ChRCC) arises from the specialized intercalated cells of the distal nephron. There are no proven therapies for patients with metastatic ChRCC. In the metastatic setting median survival is estimated to be 27 months. KIT (CD117) is a membrane-associated tyrosine kinase receptor. Binding of the ligand stem cell factor (SCF) to KIT results in kinase activation and internalization. Antibody-drug conjugates (ADC) targeting KIT were previously found to be effective in preclinical models and safe in primates, but have not been tested in ChRCC.

Results: In The Cancer Genome Atlas (TCGA), KIT (CD117) mRNA expression is higher in ChRCC than any other tumor type with the mean expression 12 times higher than matched normal kidney. In contrast, in clear cell RCC (ccRCC), KIT (CD117) is 5 times lower than matched normal kidney. Immunohistochemistry demonstrates KIT protein expression on the membrane of ChRCC tumor cells. Of the 14 metastatic ChRCC specimens stained for KIT at our institution, 85% (12) were positive. In the TCGA, mRNA levels of SCF (KITLG), the KIT ligand, in ChRCC are the second highest compared to other tumors, and in published single-cell RNA sequencing data, KIT and SCF are co-expressed in ChRCC tumor cells. We found that KIT (CD117) mRNA expression is significantly higher in ChRCC-derived cells compared to ccRCC-derived cells and HK cells (derived from normal human kidney). Western blot analysis confirmed KIT expression in five ChRCC cell lines. Despite the high KIT expression, knockdown of KIT or treatment with Imatinib, a tyrosine kinase inhibitor that targets KIT, did not decrease the proliferation of ChRCC-derived cells. This indicates that KIT is not driving the proliferation of ChRCC cells. LOP628 is a KIT ADC consisting of the anti-KIT antibody LMJ729 conjugated to the microtubule destabilizing maytansinoid DM1. The two ChRCC cell lines with the highest expression of KIT (RCJ T1 and RCJT2) and ccRCC-derived 786-0 cells (with low KIT expression, as a control) were treated with 20nM of LOP628 for 24 hours. LOP628 decreased the viability of the ChRCC-derived cells by ~60% with no effect on the ccRCC cells.

Conclusions: KIT and its ligand SCF are highly expressed by ChRCC cells and LOP628, a KIT ADC, decreases ChRCC cell proliferation.

#2120 A novel engineered IL-21-based immunocytokine as a therapeutic approach for tumor targeting in renal cancer.

Anna Rastorgueva, Nicholas A. Maskalenko, Ilia Fedorov, Ekaterina Davydova, Ashot Nazaretian, Kerry S. Campbell, **Peter Makhov**

Cancer Signaling and Microenvironment Program, Fox Chase Cancer Center, Philadelphia, PA

RCC is a lethal disease whose incidence is on the rise. Clear cell renal cell cancer (ccRCC), the most aggressive and the deadliest variant of this cancer, accounts for ~ 85% of all RCC cases. In the past decade, the landscape of immunotherapeutic approaches with the focus on use of cytokines for advanced ccRCC has expanded rapidly. The therapeutic potential of IL-21 as a novel treatment option for patients with advanced ccRCC has been evaluated in phase 1 and 2 clinical trials. Despite promising anti-tumor effects, severe dose-limiting toxicities of systemic administration of IL-21 were frequently reported in clinical trials. CD70, a TNF-ligand family member, is transiently expressed and restricted to a subset of highly activated T, B, and dendritic cells, but is highly overexpressed in all ccRCC tumors. In RCC, tumor-expressed CD70 results in exhaustion of immune cells, thereby promoting immune escape. Therefore, targeting CD70 has been thought to be promising therapeutic strategy for RCC. Thus, a variety of CD70-targeting approaches, focused on antibody dependent cellular cytotoxicity (ADCC) or antibody-drug conjugates, have been evaluated in multiple trials. Despite some studies demonstrated limited response rate, frequently related to dose-limiting off-target cytotoxicity, the successes indicated generation of an effective immune response toward RCC. To achieve our goals aiming to take an advantage to combine the benefits of anti-CD70 therapy with tumor restricted targeting of IL21, we have designed and generated for the first time a novel humanized anti-CD70-IL-21 fusion antibody. This fusion antibody simultaneously binds CD70, a ligand that is highly over-expressed in ccRCC, and induces IL-21 receptor (IL-21R) mediated downstream signaling. We also disrupted heparin binding activity by site-directed mutagenesis of IL-21 portion of the immunocytokine. This resulted in significant improvement of target specificity, PK/PD properties, and ADCC-inducing activity of the immunocytokine. Importantly, our novel immunocytokine has an advantage over existing anti-CD70 targeting approaches, as it markedly alleviates ADCC-mediated exhaustion of NK cells. Finally, our animal experiments indicate that our novel immunocytokine has a significant anti-tumor potential against ccRCC in humanized mouse model reconstituted with NK-92.CD16 cells. Taken together, our data demonstrate the superior efficacy of the novel immunocytokine against ccRCC. Furthermore, this successful immunotherapeutic approach can be expanded for the management of other CD70-positive tumors.

#2121 MAIT engagers: Providing a large therapeutic window for the treatment of solid tumors.

S. E. Plyte[1], M. Fraudeau[1], D. Winterberg[2], C. Germain[1], C. Rouseau[1], G. Sodaro[1], M. Audin[1], A. Ivagnes[1], H.-H. Oberg[2], P.-E. Gerard[1], M. Peipp[2], D. Wesch[2], J. Prigent[1];

[1]Biomunex Pharmaceuticals, paris, France, [2]Universitats Klinikum Schleswig-Holstein, Kiel, Germany

Background: MAIT cells are an abundant subset of non-conventional T-cells with potent cytotoxic capacity that are resident in most tissues and solid tumors. MAIT cell engagers are bispecific antibodies that are able to simultaneously bind the MAIT cell TCR and a tumor associated antigen, creating an immunological synapse, resulting in efficient elimination of cancer cells. These MAIT engagers only bind and activate MAIT cells and, at difference to classical CD3 engagers, do not cause cytokine release or activate regulatory T cells offering the promise of better safety and efficacy than CD3 engagers.

Methods: Using the Biomunex proprietary BiXAb platform, bispecific, tetravalent antibodies were generated that target the MAIT iTCR (invariant T cell receptor) and the HER2 tumor associated antigen. MAIT-cell activation, proliferation and degranulation were followed by gating on MAIT cells within a purified CD8 cell population. Tumor cell lines (varying [HER2]) were co-cultured with MAIT cells and the BiXAbs in several cytotoxic assays (evaluated by Chromium release). Cytokine release was assessed by Legend Plex assays or ELISA. Regulatory T cells were enriched from PBMCs. Cytotoxicity of tumor-resident MAITs, from fresh patient samples, was determined by impedance measurements and in patient derived 3D organoids by imaging (The Hub organoids). Cytokine levels in serum of Cynomolgus monkeys was measured by Legend plex.

Results: MAIT engagers induce the rapid activation, proliferation and degranulation of MAIT cells leading to efficient killing of engaged HER2+ cancer cells with a potency similar to that of a classical HER2-directed CD3-T cell engager (in clinical development). The MAIT engager did not activate the regulatory T cells or other CD4/CD8 subsets. In addition, using PBMCs, total cytokine release was 1000 fold less with the MAIT engager compared to a classical TCE, opening up a large therapeutic window, which should permit effective treatment of solid tumors. Strong signs of cytokine release syndrome and high blood cytokine levels were observed in cynomolgus monkeys treated with a CD3 engager whilst no effect was observed with the MAIT engager. *Ex vivo* cytotoxicity of tumor-resident MAIT cells using dissociated Ovarian cancer samples at “real E:T ratios” and MAIT engager-mediated cytotoxicity of patient derived organoids (CRC) demonstrate the antitumor capability of MAIT engagers in solid tumors.

Conclusions: MAIT cell engagers are a promising approach for the treatment of solid tumors that have the potency and efficacy of a classical TCE but with a significantly improved cytokine safety profile leading to a larger therapeutic window.

#2122 FS-8002, a bifunctional antibody fusion protein of anti-VEGF and anti-TGF-β, exhibits significant anti-tumor activity in preclinical studies.

Libo Zhou, Qiran Guo, Ruxia Zhou, Hua Jiang, Chaoyi Xu, **Xinzhong Jon Wang**

Fusion Bioscience, Inc., Shanghai, China

Background: FS-8002 is a bifunctional antibody fusion protein targeting vascular endothelial growth factor (VEGF) and transforming growth factor β (TGF-β), which is generated by fusing a humanized IgG1 antibody against VEGF and the extracellular domain of TGF-β receptor II (TGF-βRII). FS-8002 can simultaneously bind to and neutralize VEGF and TGF-β, thus achieving anti-tumor effects through the following proposed mechanisms: 1) inhibiting tumor neovascularization and normalizing tumor blood vessels; 2) relieving the suppression of anti-tumor immune cells in the tumor microenvironment (TME); 3) inhibiting the formation of the immune barrier or extracellular matrix (ECM) and promoting cytotoxic T cell infiltration into tumors, and 4) blocking the invasion and metastasis of tumor cells.

Methods: The mechanism of action (MOA) and anti-tumor effects of FS-8002 were evaluated in a series of studies including *in vitro* target binding, biological activity assays, and *in vivo* efficacy study in xenograft tumor models.

Results: *in vitro*, FS-8002 binds to VEGF and TGF-β simultaneously. FS-8002 bound to VEGF165 and VEGF121 and thus inhibited VEGF-induced human umbilical vein endothelial cell (HUVEC) proliferation. FS-8002 also specifically bound to TGF-β1 and TGF-β3, but only had weak affinity to TGF-β2. By neutralizing TGF-β, FS-8002 could block TGF-β/Smad signaling pathway, inhibit TGF-β1-induced tumor cell metastasis, and relieve immunosuppression in the TME by activating NK cells and inhibiting Treg proliferation. FS-8002 exhibited significant anti-tumor effect in two "cold tumor" xenograft models (human PBMC reconstituted MDA-MB-231 model and HT-29 cells model) as single agent or in combination with anti-PD-1 antibody (Keytruda®). IHC analysis of the tumors from the two mouse xenograft models revealed that FS-8002 treatment could inhibit the tumor neovascularization, inhibit the formation of the immune barrier by reducing fibrosis formation in tumor tissues, and promote T cells infiltration into tumor tissue to kill tumor cells, therefore exhibit anti-tumor effect. The results of GLP repeat-dose toxicity study in cynomolgus monkeys combined with safety pharmacology assessment indicated that FS-8002 was well tolerated under the doses ranged from 15 to 135 mg/kg/dose (HNSTD) after four weeks of weekly intravenous infusion administration, and the adverse effects were within expectations and can be managed in clinical trials. FS-8002 is currently under clinical evaluation for safety and activity in both US (IND approved) and China.

Conclusion: All the preclinical data supported FS-8002 to be studied in clinical trials.

#2123 KJ-103: First-in-class naked anti-TROP2 HCAb with immune modulatory mechanisms and tumor regression potential in clinical trials.

Amit Subedi, Hiba A. Zahreddine, Sophie E. Cousineau, Richard Wargachuk, Xiaowei Wang, Lucy Lai, Dominic Hou, Elijus Undzys, Gordon Ngan, Luis da Cruz, David Young

KisoJi Biotechnology, Montreal, QC, Canada

Trophoblast cell surface antigen-2 (TROP2) is a membrane protein highly expressed in a wide range of advanced epithelial cancers and is an attractive target for cancer therapies. TROP2-positive cancers have been targeted by antibody-drug conjugates (ADCs). Here we employed our proprietary heavy chain-only antibody (HCAb) transgenic mouse platform to discover and develop KJ-103, a novel naked anti-TROP2 HCAb.KJ-103 induced regression and eradication of large breast and colon cancer xenografts. The anti-tumor efficacy of KJ-103 was completely abolished when using an IgG1-LALAPG variant which lacks Fc gamma receptor (FcγR) interaction. Furthermore, the in vivo efficacy of KJ-103 was also abolished in a mouse model that lacks all FcγRs. These results underscored the importance of FcγR engagement in the therapeutic action of KJ-103. Although the precise immune cell responsible for this efficacy has yet to be determined, these results showed that, in immunodeficient mice, the anti-tumor efficacy of KJ-103 is mediated by effector function cells present in the tumor microenvironment. Further analysis of the tumor microenvironment via bulk RNA sequencing revealed that KJ-103 treatment reduced the content of immunosuppressive macrophages and activated genes associated with phagocytosis and cytotoxicity which may contribute to its potent antitumor effects. Additionally, KJ-103 treatment activated antigen-presenting genes, suggesting its potential to stimulate T-cell responses, which may amplify the immune-mediated anti-tumor response of KJ-103. These findings highlight the multifaceted immune response induced by KJ-103, making it a promising candidate for enhancing immune system-mediated tumor control. Surface plasmon resonance (SPR) analysis confirmed that KJ-103 strongly binds to human and cynomolgus TROP2 but has no interaction with murine and rat orthologs. KJ-103 was well tolerated in a five-week, weekly-dosing dose range finding (DRF) study in non-human primates, at levels up to 100mg/kg, with no clinical or lab-changes, and had a favorable PK profile. KJ-103 binds to the human and cynomolgus normal tissues where TROP2 is present, both by FFPE and frozen IHC highlighting its applicability for biomarker testing. Epitope mapping and co-crystal analysis revealed that KJ-103 targets a unique epitope on TROP2, which could not be competed by other known anti-TROP2 antibodies. This work highlights the feasibility of developing functional, payload-free anti-TROP2 antibodies for clinical use, addressing current challenges associated with ADCs and expanding therapeutic options for patients with TROP2-positive cancers. KJ-103, as the first naked anti-TROP2 HCAb is under development for clinical trials and represents a groundbreaking advancement in cancer immunotherapy.

#2124 A potent therapeutic antibody BGM-2121 targeting parathyroid hormone-related peptide (PTHrP) for pancreatic cancer.
C. Ho, C.-F. Tseng, C.-J. Huang;
BioGate Precision Medicine Corp., Taipei, Taiwan

Although approximately 35% of approved drugs target G-protein-coupled receptors (GPCRs), cancer-specific GPCR-targeted therapies remain limited. Notably, several GPCRs and their ligands, including parathyroid hormone-related protein (PTHrP), are overexpressed in various solid tumors, including pancreatic cancer. In about 30% of pancreatic cancer cases, the *PTHLH* gene is co-amplified with the *KRAS* oncogene on chromosome 12, a phenomenon also observed in lung and colorectal cancers. Furthermore, the *PTHLH* gene can drive cancer progression through self-amplification. To address this, BioGate has developed BGM-2121, a potent humanized IgG1 monoclonal antibody targeting the N-terminal region (a.a. 1-34) of PTHrP, aiming to treat pancreatic cancer by targeting the PTHrP/PTH1R pathway. Preclinical studies have confirmed the specificity and antitumor activity of BGM-2121. In vitro assays demonstrated the antibody's high affinity and specificity for PTHrP, while in vivo animal studies using human pancreatic cancer cell models in mice showed significant antitumor activity. Notably, BGM-2121 effectively reduced tumor growth, halted disease progression in mouse models, and significantly extended survival. Additionally, in lung squamous cell carcinoma models, BGM-2121 successfully prevented and even reversed hypercalcemia and weight loss—key contributors to humoral hypercalcemia of malignancy (HHM) and cancer cachexia in human patients. Comprehensive safety and pharmacokinetic (PK) studies, including toxicokinetics (TK) and GLP-compliant repeated-dose toxicity studies, have thoroughly evaluated the safety profile of BGM-2121. In conclusion, this potent PTHrP-targeting antibody shows considerable promise as a therapeutic agent for cancers with PTHrP overexpression (e.g., pancreatic and lung cancers), humoral hypercalcemia of malignancy, and PTHrP-mediated cancer cachexia. We are currently preparing to submit an Investigational New Drug (IND) application to the TFDA and plan to initiate clinical trials to evaluate its potential as a novel biologic treatment for hard-to-treat metastatic cancers in Taiwan.

#2125 The trispecific T cell engager platform enhances T cell function and therapeutic efficacy via integrated 4-1BB VHH antibody co-stimulation.

Kaiqing Zhang, Baihong Liu, Liu Yang, Saina Ma, Jiawei Wu, Jinhua Zhao, Yang Chen, Xueyuan Jiang, Peiyan Pan, Jing Zhang, Yi Yang

Biocytogen, Waltham, MA

CD3 T cell engagers (TCEs) have gained significant clinical interest, with 9 approvals in the past decade. Advances in solid tumor-targeting TCEs, such as DLL3xCD3, GP100xCD3, and STEAP1xCD3, indicate the potential to overcome the challenges posed by solid tumor barriers. However, issues like cytokine release syndrome (CRS), low T cell infiltration, treatment resistance, and limited patient response continue to pose hurdles. To optimize efficacy and minimize adverse effects, CD3 TCEs need further development.
The inclusion of the co-stimulatory molecule 4-1BB, which promotes T cell proliferation and upregulates T cell survival genes expression and activation, in the design of trispecific TCE presents an attractive approach. CAR-T cell therapies suggest that combining 4-1BB signaling achieves more robust and durable anti-tumor responses. Therefore, we developed a tumor antigen - dependent CD3×4-1BB trispecific antibody (TriAb) platform by integrating 4-1BB nanobody generated from RenNano^{TM} mice to maximize T cell activation and sustain the T cell response.
Compared with the canonical CD3 TCE, Our TriAb platform features a weaker binding activity to the CD3 receptor through steric hindrance, reducing safety risk relative to canonical CD3 TCEs. We validated the TriAb platform with three targets: Claudin18.2, DLL3 and CDH17. In vitro, TriAbs demonstrated robust antigen-dependent cytotoxic activity against tumor cell lines, surpassing bispecifc antibodies and benchmark counterparts in T cell activation and cytokine production. Importantly, TriAb did not induce cytotoxicity in tumor antigen-negative cells or non-specific cytokine release.
In xenograft model with established tumors, TriAbs showed significant tumor growth inhibition. Additionally, TriAbs exhibited an antibody-like PK profile in CD3ε×4-1BB humanized mice, supporting intermittent dosing in human. Taken together, these data indicate our TriAb platform holds promise as a next-generation therapeutic option for clinical development.

#2126 LY6G6D targeting with a T cell engager is a promising therapeutic for MSS colorectal cancer.

B. Yigit, P. Paluru, E. Jurgaityte, K. Nuno, J. Chen, N. Fisher, A. Martinko, M. Mumbach, A. Easton, R. Guerrero, M. O'Huallachain, P. Ram, J. Verboon, M. Lu, J. Granja, D. Rock, D. Kugler;
Cartography Biosciences, Inc., South San Francisco, CA

T cell engagers (TCEs) are proving to be a potent therapeutic strategy for the treatment of solid tumors. Clinical data have shown that TCEs can drive T cell activity in "cold" tumors, including colorectal cancer. However, identifying highly specific tumor antigen targets is crucial for delivering doses that achieve optimal tumor exposure and maximize therapeutic efficacy.
Analysis of primary patient samples indicated enrichment of LY6G6D in microsatellite stable (MSS) and instability-low (MSI-L) colorectal cancer (CRC). A highly potent, stable, and manufacturable CB21 TCE was designed to optimally engage LY6G6D and CD3. Strong binding affinity to the LY6G6D target antigen, and an optimized CD3 affinity, maximized T cell activation and cytokine production yielding significant cytotoxic effects across multiple cell lines with differing physiologically relevant levels of LY6G6D. Additionally, in endogenous LY6G6D expressing xenograft models the CB21 TCE displayed robust tumor growth inhibition in a dose-dependent manner. A pharmacokinetics (PK) and tolerability study with the cynomolgus cross-reactive CB21 TCE was administered to nonhuman primates. Exposure levels multiple times higher than the predicted clinical exposures were achieved with no significant cytokine release or meaningful alterations in clinical blood chemistry observed. Human PK were predicted to have antibody-like characteristics. Combined with the PK and PD data, human dose predicts efficacy with a favorable therapeutic window. An accelerated phase I clinical plan is presented.
Utilizing our ATLAS platform, we identified LY6G6D as the most promising target in MSS CRC due to its specific expression in malignant cells, high antigen surface stability, and persistence in both primary and metastatic CRC. The data presented support that the CB21 TCE has been meticulously engineered to be a potentially first and best-in-class TCE targeting LY6G6D.

#2127 Efficacy of monoclonal antibodies against pathogenic S100A8/9 in myelodysplasia and leukemia models.

Rahul Sanawar[1], Ariel Fromowitz[2], Srinivas Aluri[1], Sarah Aminov[1], Srabani Sahu[1], Leah Kravets[1], Shanisha Gordon Mitchell[1], Mani Mohindru[3], Aditi Shastri[1], Alan List[3], Eric Padron[4], Rongbao Zhao[1], Amit Verma[1]

[1]Department of Oncology, Montefiore Einstein Cancer Center, Albert Einstein College of Medicine, Albert Einstein College of Medicine, Bronx, NY,[2]Department of Stem Cell Transplantation and Cellular Therapy, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Roshon Therapeutics, Bronx, NY,[4]Malignant Hematology, Moffitt Cancer Center, Tampa, FL

Introduction: Myelodysplastic syndromes (MDS); chronic myelomonocytic leukemias (CMML) and acute myeloid leukemia (AML) are characterized by a block in normal differentiation of stem and progenitor cells that leads to cytopenias. The diseased marrow microenvironment is characterized by expansion of immunosuppressive myeloid derived suppressor cells (MDSCs) that produce S100A8 and S100A9 proteins. These proteins form heterodimers that bind multiple receptors including TLR4/MD2, CD33 and RAGE, and lead to leukocyte recruitment, inflammatory cytokine secretion and formation of MDSCs. Even though S100A8/9 heterodimers (also known as DAMPs, alarmins, calprotectin) are known drivers of disease pathogenesis, no specific targeting therapeutic approaches have been tested in MDS/CMML.

Results: Analysis of a large dataset of MDS patient derived CD34+ hematopoietic stem and progenitors (N=183) showed increased expression of S100A8/9 receptors TLR4/MD2, CD33 and RAGE when compared to healthy controls. Furthermore, within the MDS patient cohort, those with higher S100A8/9 expression had more severe anemia and required more RBC transfusions. Additionally, in a CMML dataset (N=39), scRNA-seq profiles showed significantly higher expression of both S100A8 and S100A9 in the disease initiating, inflammatory (cluster 2) cells. Distinct neutralizing monoclonal antibodies (mAbs) targeting human S100A8/9 homo/heterodimers were generated by single B cell cloning from immunized rabbits. Selected rabbit derived, chimeric and subsequently humanized antibodies demonstrated nanomolar neutralizing activity, effectively inhibiting interaction of S100A8/A9 with RAGE, Siglec-3, Siglec-9, CD147, CD146, CD300ld and CD69. In functional assays, these neutralizing mAbs also suppressed the formation of MDSCs and T-regulatory cells from human PBMC cultures. Primary MDS, CMML and AML mononuclear cells (N=11, with numerous mutations) were treated with monoclonal S100A8/9 neutralizing antibodies and grown in clonogenic assays. Neutralization of S100A8/9 led to increased erythroid colony formation and increased erythroid differentiation as evident from Glycophorin A and CD71 expression by FACS analysis.

Conclusion: We demonstrate overexpression of S100A8/9 and its receptors in MDS and leukemia samples and have developed potent neutralizing monoclonal antibodies against the S100A8/9 heterodimer that can deplete MDSCs and reduce T-reg cell formation. Additionally, antibody neutralization of S100A8/9 stimulates erythropoiesis in a broad range of primary MDS and myeloid leukemia patient specimens. These results provide compelling pre-clinical rationale for clinical development of S100A8/9 antibodies for the treatment of myeloid malignancies.

#2128 Uncovering the multiple therapeutic mechanisms of trastuzumab deruxtecan (T-DXd): effective extracellular payload release and immunomodulatory stimulation.

Li-Chung Tsao[1], John S. Wang[2], Xingru Ma[3], Sirajbir Sodhi[4], Joey V. Ragusa[3], Bushangqing Liu[1], Jason McBane[1], Tao Wang[1], Junping Wei[1], Cong-Xiao Liu[1], Xiao-Yi Yang[1], Gang-jun Lei[1], Ivan Spasojevic[5], Ping Fan[5], Timothy N. Trotter[1], Michael A. Morse[4], Herbert K. Lyerly[1], **Zachary C. Hartman**[1]

[1]Surgery, Duke University Medical Center, Durham, NC,[2]MSTP Program, Duke University Medical Center, Durham, NC,[3]Pathology, Duke University Medical Center, Durham, NC,[4]Medicine, Duke University Medical Center, Durham, NC,[5]PK/PD Core Laboratory, Duke University Medical Center, Durham, NC

Trastuzumab deruxtecan (T-DXd), also known as fam-trastuzumab-deruxtecan-nxki, is a novel HER2-targeting antibody-drug conjugate (ADC) that has shown remarkable clinical efficacy in breast cancer (BC) and other cancers with varying levels of HER2 expression. However, the mechanisms underlying its activity in HER2-low and HER2-ultralow BC, and the role of immune activation, remain poorly understood. Here, we demonstrate that T-DXd's efficacy in HER2-low/ultralow BC is predominantly driven by the extracellular tumor-specific protease Cathepsin L (CTSL), but not Ccathepsin B (CTSB). Our in vitro and in vivo studies reveal that extracellular CTSL cleaves T-DXd's linker, releasing the DXd payload (validated by mass spectrometry) and inducing cytotoxicity within HER2-low/ultralow tumor microenvironments. This mechanism mediates potent anti-tumor effects across multiple HER2-negative cancers. Importantly, analysis of BC biopsies and tissue microarrays from T-DXd-treated patients revealed high CTSL expression in tumor and stromal compartments, independent of HER2 levels, suggesting broad therapeutic potential. In addition to extracellular cleavage, we also found that T-DXd elicits immune activation as an anti-tumor mechanism in HER2-positive BC. The DXd payload induces immunogenic cell death, activating nearby myeloid immune cells via TLR4 and STING pathways, while its antibody backbone engages Fcγ-receptors to stimulate Antibody-Dependent Cellular Phagocytosis (ADCP). This process enhances tumor antigen uptake and drives the expansion of antigen-specific CD8+ T cells. Furthermore, DXd upregulates CD47 on tumor cells, making them more susceptible to immune clearance. Combining CD47 blockade with T-DXd significantly enhanced anti-tumor efficacy in an immune suppressive HER2-transgenic BC mouse model, promoting CD8+ T cell memory and preventing tumor recurrence post-treatment. These studies suggest that strategies targeting the CD47-SIRPa axis may enhance the ability of ADCs to elicit tumor-specific immunity, thus extending the efficacy of these agents and generating long term memory responses against non-immunogenic cancers.

#2129 An innovative multi-specific Fc fusion protein simultaneously targeting PD-L1, VEGF-A, and PLGF for pancreatic cancer treatment via reshaping the tumor microenvironment.

Hyungul (David) Yang, Jin A Shin, Hyeseong Lim, Eunbyul Cho, Daeseok Oh

Panolos Bioscience, Inc., Hwaseong, Korea, Republic of

Introduction: Pancreatic cancer is a notoriously cold tumor characterized by a dense extracellular matrix and an immunosuppressive microenvironment, resulting in the limited efficacy of many immune-oncology therapies. Here, we investigated the therapeutic potential of PB203, a novel multi-specific Fc fusion protein that simultaneously blocks PD-L1, VEGF-A, and PLGF, for the treatment of pancreatic cancer.
Methods: PB203 was engineered and assessed for its binding affinities to the target molecules and its inhibitory capacity against ligand-mediated signaling in vitro at the cellular level. Its therapeutic efficacy was further evaluated in an orthotopic human pancreatic cancer model using humanized mice. Endpoints included anti-tumor effects, fibrosis modulation, and immune profile remodeling within the tumor microenvironment (TME).
Results: PB203 demonstrated picomolar binding affinities to VEGF-A and PLGF and sub-nanomolar binding affinity to PD-L1. Remarkably, it maintained its binding affinities under conditions mimicking simultaneous target engagement, showing comparable efficacy to single-target interactions, regardless of binding sequence or target occupancy. The Fc fusion protein effectively inhibited ligand-mediated signaling without compromising the potency of its parental molecules. In an orthotopic pancreatic cancer model using humanized mice treated with gemcitabine, PB203 achieved significant anti-tumor efficacy, including cases of complete regression. Notably, gemcitabine treatment alone increased fibrosis within the TME; however, co-treatment with PB203 significantly reversed this effect. PB203-mediated fibrosis reduction correlated with a decreased abundance of several cancer-associated fibroblast (CAF) subsets, highlighting its potential to remodel the TME and enhance therapeutic synergy in pancreatic cancer.
Conclusions: PB203 demonstrated substantial anti-tumor activity in an orthotopic pancreatic cancer model featuring an immunosuppressive TME, closely mirroring patient conditions. Its ability to inhibit CAFs and reduce fibrosis within the TME, likely driven by PLGF blockade, represents a unique mechanism of action. These findings suggest that beyond emerging PD-(L)1/VEGF-A bi-specific strategies, triple blockade of PD-(L)1, VEGF-A, and PLGF with PB203 could offer a novel therapeutic option for highly desmoplastic and hard-to-treat cancers like pancreatic cancer. Further clinical investigations are warranted to validate these findings.

#2130 Optimization of tarlatamab step-up dosing regimen to mitigate cytokine release syndrome using quantitative systems pharmacology modeling.

Oleg Demin Jr, Galina Kolesova, Dmitry Shchelokov

InSysBio CY, Paphos, Cyprus

Tarlatamab is a DLL3/CD3 bispecific T-cell engager (TCE) recently approved by the FDA for the treatment of extensive-stage small cell lung cancer (ES-SCLC). The dosing follows a step-up regimen for the first cycle, with 1 mg given on day 1, and 10 mg given on days 8 and 15. A similar step-up dosing regimen, but with 100 mg instead of 10 mg, was also tested in a pivotal phase 2 trial (Ahn et al. *N Engl J Med*. 2023 Nov 30;389(22):2063-2075). The alternative step-up dose or step-up regimen were not investigated in the study. The aim of our work was to explore the alternative step-up regimens of tarlatamab, predicting trimer (complex of TCE with target receptors) kinetics in the tumor using quantitative systems pharmacology (QSP) modeling.

The QSP model integrated pharmacokinetics of tarlatamab, its distribution into the tumor of patients with ES-SCLC, binding with CD3 expressed by T-cells and DLL3 expressed by cancer cells, formation of trimer in the immunological synapse between T-cell and cancer cell, turnover of free and bound receptors, trimer internalization. Predicted peak trimer levels in the tumor are associated with cytokine release syndrome (CRS) incidence following tarlatamab administration. Higher peak levels of trimer are predicted for the doses and regimens causing more frequent CRS events.

The model showed that 1 mg is the optimal step-up dose for the regimens tested in clinical trials since lower doses led to a higher peak trimer level after second dose (10 mg given on day 8). However, split dosing of the 1st or 2nd doses and a longer step-up schedule decreased the peak trimer levels following tarlatamab administration. Splitting the first dose in the approved regimen resulted in a reduction of peak trimer by 30-40%, thus mitigating CRS incidence. Administration of the 0.5 mg on day 1 and 0.5 mg on day 4 also caused a minor decrease of peak trimer level after administration of 10 mg on day 8. A substantial reduction of the maximal level of the trimer after the second dose was predicted for the step-up regimen with 100 mg if the second dose given on day 8 is 3 mg instead of 100 mg. This dose optimization might lower the probability of CRS grade 3 events observed in patients treated with 100 mg.

Split-dose regimens and regimens with more than one step-up dose allow for minimizing CRS incidence without compromising the efficacy of TCEs. QSP modeling is a useful tool to investigate various doses and regimens of bispecific and multispecific antibodies.

#2131 Glycosylated protein targets open access to multiple tumor indications for different therapeutic modalities .

Aaron C. Groen[1], Nisha Shrestha[1], Boris Klebanov[1], Constantine Theodoropulos Constantine Theodoropulos[1], **Hans H. Wandall**[2]

[1]GO-therapeutics, Cambridge, MA,[2]University of Copenhagen, Copenhagen, Denmark

Using advanced O-glycoproteomics we pinpointed relevant glycopeptide epitopes and developed a highly cancer-specific, humanized monoclonal antibody (R800). This antibody binds to truncated O-glycans in the context of a peptide backbone with low nanomolar affinity. The crystal structure of R800 provides insights into its binding specificity showing direct interaction with both peptide and the truncated glycan. Development of a companion diagnostic assay based on immunohistochemistry with the humanized therapeutic antibody confirmed the specificity of R800 across multiple epithelial cancers. This included selective binding to 20-30% of both primary and metastatic triple negative breast, lung, pancreatic, colorectal, and ovarian cancers. There was no binding to healthy tissues. The versatility of R800 allows the application of the mAb in multiple therapeutic modalities, including chimeric antigen receptor T-cell therapies (CAR-T cells) and antibody-drug conjugates (ADCs). In CAR-T cell applications using R800's antigen-binding domain demonstrated potent, selective cytotoxicity against R800-target expressing cancer cells in vitro in vivo in CDX models. In ADC applications, R800 formulated with either the anti-mitotic agent, monomethyl auristatin E payload (R800-MMAE) or with the topoisomerase 1 inhibitor payload, exatecan (R800- exatecan) show potent activity in vitro (EC50 ~1nM) across multiple cell lines. Both R800 ADCs effectively eliminated tumors in preclinical PDX models, including lung, ovarian, and TN breast PDx models with a MED of 2mg/kg. By targeting the cancer-specific truncated O-glycans recognised by R800, we exploit a novel target space offering unparalleled cancer selectivity. This strategy holds significant potential for enhancing the efficacy and safety of treatments for solid tumors.

#2132 KA-3123-LD38: a novel bispecific antibody-drug conjugate (ADC) targeting EGFR and B7H3 with a DNA topoisomerase I inhibitor payload.

Guojin Wu[1], Chuanying Xu[2], Weihong Nian[2], Zhengcheng Guo[1], Jiabei Liang[1], Feng He[2], Qing Zhou[2]

[1]Kyinno Biotechnology Co., Ltd, Beijing, China,[2]Shanghai Escugen Biotechnology Co., Ltd, Shanghai, China

KA-3123-LD38 is a novel bispecific antibody-drug conjugate (ADC) designed to target both EGFR and B7H3, two markers that are highly expressed in various tumor cells but have limited expression in normal tissues. The co-expression of EGFR and B7H3 in tumor cells is particularly high, making them promising therapeutic targets. By targeting both of these markers simultaneously, KA-3123-LD38 aims to reduce the risk of "on-target/off-tumor" cytotoxicity, a common side effect in cancer therapies. This ADC is a IgG1 with a common light chain, conjugated with LD-38, an Escugen proprietary ADC platform composed of Topli payload and highly hydrophilic stable cleavable linker. KA-3123-LD38 binds to B7H3 with high affinity, with a Kd of less than 0.01 nM, while its affinity for EGFR is weaker, with a Kd greater than 10 nM. When compared to monoclonal antibodies targeting B7H3, KA-3123-LD38 exhibits a significantly faster internalization rate in tumor cells that co-express EGFR and B7H3. In vitro assays show that KA-3123-LD38 effectively induces cytotoxicity in tumor cells expressing either EGFR and B7H3 together or B7H3 alone. However, the cytotoxic effect is notably stronger in cells co-expressing both targets. Furthermore, KA-3123-LD38 demonstrates strong bystander killing activity, further enhancing its therapeutic potential. In xenograft mouse models, KA-3123-LD38 strongly inhibits the growth of a variety of tumor types, including NSCLC, esophageal squamous cell carcinoma, colorectal cancer, and gastric cancer. Ongoing toxicity studies suggest that KA-3123-LD38 has a favorable safety profile, with low toxicity observed. These promising results highlight KA-3123-LD38 as a potentially powerful treatment for a broad range of solid tumors.

#2133 KA-2887-LD38: a novel bispecific antibody-drug conjugate (ADC) targeting both EGFR and PD-L1.

Guojin Wu[1], Chuanying Xu[2], Weihong Nian[2], Zhengcheng Guo[1], Jiabei Liang[1], Feng He[2], Qing Zhou[2], Jinying Ning[1]

[1]Kyinno Biotechnology Co., Ltd, Beijing, China,[2]Shanghai Escugen Biotechnology Co., Ltd, Shanghai, China

PD-L1 is widely expressed across various cancer types and suppresses immune responses against tumor cells. EGFR is also highly expressed in many solid tumors and plays a key role in driving tumor growth. Targeting the PD-1/PD-L1 signaling pathway and the EGF/EGFR signaling pathway using antagonistic antibodies or ADCs has shown promising results in cancer therapy. However, both approaches can lead to undesirable "on-target/off-tumor" effects. Co-expression of PD-L1 and EGFR is rare in normal tissues but is commonly observed in most PD-L1-expressing tumor cells. In this study, we developed a bispecific antibody, KA-2887, using our common light chain antibody discovery platform to target both EGFR and PD-L1. This bispecific antibody was then used to construct the ADC KA-2887-LD38. KA-2887-LD38 has a conventional IgG1 structure, conjugated with LD-38, an Escugen proprietary ADC platform composed of Topli payload and highly hydrophilic stable cleavable linker. It binds to EGFR with an affinity of 3.7 nM and to PD-L1 with an affinity of 0.6 nM. KA-2887-LD38 effectively blocks both the interaction between EGF and EGFR, and the interaction between PD-1 and PD-L1.The expression of EGFR on tumor cells enhances the inhibitory effect of KA-2887-LD38 on the PD-1/PD-L1 interaction, and vice versa. Compared to monoclonal antibodies targeting PD-L1, KA-2887-LD38 shows a much faster internalization rate when binding to tumor cells co-expressing EGFR and PD-L1. In vitro, KA-2887-LD38 demonstrates cytotoxicity against tumor cells expressing either EGFR and PD-L1 together or EGFR alone, but has a weaker effect on tumor cells expressing only PD-L1. Tumor cells co-expressing EGFR and PD-L1 are more sensitive to KA-2887-LD38. Additionally, KA-2887-LD38 exhibits strong bystander killing activity. Xenograft mouse tumor models show that KA-2887-LD38 strongly inhibits the growth of various tumor types, including NSCLC, head and neck squamous cell carcinoma, and esophageal squamous cell carcinoma. Toxicity studies on KA-2887-LD38 are ongoing. The results suggest that KA-2887-LD38 holds significant potential for the treatment of a variety of solid tumors.

#2134 KA-2886-LD38: a bispecific antibody-drug conjugate (ADC) targeting both EGFR and MET, incorporating a novel linker-payload that inhibits DNA topoisomerase I.

Guojin Wu[1], Chuanying Xu[2], Weihong Nian[2], Zhengcheng Guo[1], Jiabei Liang[1], Feng He[2], Qing Zhou[2], Jinying Ning[1]

[1]Kyinno Biotechnology Co., Ltd, Beijing, China,[2]Shanghai Escugen Biotechnology Co., Ltd, Shanghai, China

Epidermal growth factor receptor (EGFR) and mesenchymal-epithelial transition factor (MET) are frequently co-expressed in multiple solid cancers, and over-activation of MET signaling is one of the major mechanisms of resistance to EGFR tyrosine kinase inhibitors (TKIs). Antagonistic bispecific antibodies targeting both EGFR and MET have been shown to overcome this resistance. KA-2886-LD38 is a bispecific ADC targeting both EGFR and MET. It is a bispecific common light chain IgG1 , conjugated with LD-38, an Escugen proprietary ADC platform composed of Topli payload and highly hydrophilic stable cleavable linker. It binds to MET with an affinity of 0.02 nM and to EGFR with an affinity of 1 nM. KA-2886-LD38 blocks the binding of HGF to MET with an IC50 of about 0.3 nM and the interaction of EGF with EGFR with an IC50 of about 2 nM. Compared to the benchmark ADC AZD9592, KA-2886-LD38 exhibits a similar internalization rate when binding to tumor cells but demonstrates significantly stronger cytotoxicity and bystander killing activity across different tumor cell lines in vitro. Additionally, in xenograft mouse tumor models with various tumor types, including NSCLC, head and neck squamous cell carcinoma, colorectal cancer, esophageal squamous cell carcinoma, and triple-negative breast cancer, KA-2886-LD38 showed much stronger in vivo efficacy compared to AZD9592. Moreover, KA-2886-LD38, when combined with osimertinib, also demonstrated a combination inhibitory effect on H1975 tumor growth. KA-2886-LD38 is well-tolerated at doses up to 30 mg/kg in EGFR and MET humanized genetically modified mice, and toxicity studies in monkeys are ongoing. These results suggest that KA-2886-LD38 has remarkable potential in the landscape of anti-EGFR/cMet therapies.

#2135 QLS4131, a proprietary T cell engager targeting both BCMA and GPRC5D for the treatment of multiple myeloma.

Liuqing Yang[1], Hongliang Qian[1], Juan Luo[1], Ke Liu[2], **Ling Zhang**[1], Shuyong Zhao[2], Hua Ying[1], Weikang Tao[1]

[1]Shanghai Qilu Pharmaceutical Research and Development Center LTD., Shanghai, China,[2]Qilu Pharmaceutical Co., Ltd., Jinan, China

Multiple myeloma (MM) is a genetically complex and heterogeneous malignancy with poor prognosis. Despite recent advances in the development of new therapeutics, clinical management of MM remains a big challenge largely due to quick emergence of drug resistance. Thus, novel therapies which can cause deeper response or overcome drug resistance are highly desired. It has been found that both BCMA and GPRC5D are overexpressed in MM in a manner of either co-expression or mono-expression. In fact, T cell engagers (TCE) targeting either BCMA or GPRC5D alone have been approved by FDA for MM treatment. Hence, TCE target both BCMA and GPRC5D have a great potential to demonstrate superior efficacy and overcome resistance to TCE only targeting a single antigen. QLS4131 demonstrated a higher affinity for MM tumor cell lines when compared to JNJ-79635322, which is a clinical stage TCE targeting both BCMA and GPRC5D developed by Janssen Research & Development. QLS4131 was capable of effectively depleting both dual (BCMA and GPRC5D) and single (BCMA or GPRC5D) target-expressing cells, and its cytotoxicity was substantially more potent than JNJ-79635322. Meanwhile, the level of IL-6 cytokine release was comparable to that of JNJ-79635322. Additionally, QLS4131 maintained robust TDCC activity even in the presence of 2.5 μg/mL soluble BCMA. The single-dose PK evaluation revealed linear pharmacokinetic characteristics with a half-life (T1/2) of approximately 120 hours, it also demonstrated high bioavailability (79.83%) when SC dosing. In in vivo pharmacology studies, QLS4131 could inhibit tumor growth in a dose-dependent manner and even induce tumor regression and exhibited superior antitumor efficacy related to JNJ-79635322. QLS4131 was well tolerated in a cyno monkey QW x 4 GLP toxicity study. Skin and nail toxicity (related to the GPRC5D target) was not observed. The HNSTD was 2 mpk for both intravenous and subcutaneous injections. In conclusion, the excellent efficacy, favorable PK, and safety profile support the potential of QLS4131 as a novel therapeutic agent to address the significant unmet needs in multiple myeloma. A Phase 1 dose-escalating study of QLS4131 in multiple myeloma is currently underway (NCT06500507).

#2136 ADORA2A specific antibodies show enhancement of anti-tumour immunity.

Paule Hermet[1], Siret Tahk[1], Gaily Kivi[1], Joan Teyra[1], Madis Jakobson[1], Ana Shahpazir[1], Liis Siigur[1], Robin Loving[2], Reet Kurg[3], Mart Ustav[1], Andres Mannik[1], Mart Ustav[1]

[1]Icosagen Cell Factory OU, Tartu, Estonia,[2]Salipro Biotech, Stockholm, Sweden,[3]University of Tartu, Tartu, Estonia

Background: ADORA2A (A2AR), is an adenosine receptor that suppresses immune cell toxicity through sensing extracellular adenosine. A2AR belongs to a group of seven-transmembrane receptor proteins called G protein-coupled receptors (GPCRs) which act as detectors to various signals from outside the cell. We aim to reduce the immunosuppressive properties of adenosine in the tumor microenvironment (TME) by targeting A2AR with monoclonal antibodies (mAbs). mAbs are an attractive modality to therapeutically target complex multi-pass membrane proteins, but mAb development is hindered by many challenges. Here we report the discovery and functional characterization of 23 A2AR-specific monoclonal antibodies developed using Icosagen's proprietary antigen displaying Virus-Like-Particle (VLP) based chicken immunization and mAb screening platforms.

Methods: Monoclonal antibodies against A2AR were generated using a DNA or mRNA and VLP-based immunization strategy. VLPs were generated using a proprietary technology ensuring high density of display of A2AR on VLPs. Chickens were selected as immunization hosts due to being evolutionally more divergent from mammals increasing the chance of immunogenicity and obtaining antibody candidates against conserved membrane proteins. Antibody discovery was performed with Icosagen's proprietary HybriFree B-cell cloning technology, complemented with chicken derived phage display library screening platform. Antibody specificity was confirmed using VLP-based immunoassays and overexpression cell lines. Antagonistic function of A2AR-specific antibodies was confirmed on immune cells and reporter cell line-based assays.

Results: Immunization of chicken and dynamic antibody discovery methods resulted in discovery of 23 unique A2AR-specific antibody clones. These antibodies exhibit high affinity binding to A2AR, as indicated by low nanomolar EC50 values determined through cell-based assays, complemented with SPR analysis using A2AR-expressing nanoparticles. Antibody clones with A2AR-antagonistic function show enhancement of T cell activation upon A2AR agonist treatment, highlighting their potential to boost anti-tumor immune response. These antibodies can further translate into boosting CAR-T efficacy in overcoming suppressive TME, thereby expanding it for treatment for solid tumors.

Conclusions: This study presents highly specific monoclonal antibodies targeting the adenosine receptor ADORA2A. The lead antibody clones exhibiting antagonistic function *in vitro* will undergo further optimization using Icosagen's phage display-based affinity maturation platform. This process aims to enhance their properties for development into clinical candidates, advancing therapeutic interventions targeting ADORA2A and supporting their potential in immunotherapy applications.

#2137 EVOLVE205, a dual (2:1) CD20 targeted CD3 trispecific T cell engager with CD2 costimulation for the treatment of B cell malignancies and B cell autoimmune disorders.

Xingyue An, Mohosin Sarkar, Guixian Jin, Tiffany Liang, Afsana Sabrin, Tracy Lichter, Danielle Klaskin, Evelyn Teran, Abliz Abduqadir, Hayden Karp, Julio Rodriguez, Hemachander Capiralla, Zengzu Lai, Louis Matis, Stella Martomo, Agnes Meade, Martin Preyer, Jay S. Fine, Jeremy S. Myers

EvolveImmune Therapeutics, Inc, Branford, CT

T cell engager (TCE) CD3-bispecifics have improved the treatment of patients with B cell lymphomas leading to recent approvals of the CD20-targeted CD3 bispecifics including Glofitamab, Mosunetuzumab, and Epcoritamab for patients with relapsed, refractory diseases. Recently, combinations of CD3-bispecifics and tumor-targeted costimulatory agonists have demonstrated enhanced efficacy in preclinical models. These combination approaches are currently being investigated in the clinic but may have challenges in establishing optimal dose scheduling and dose levels to ensure simultaneous CD3 and costimulatory pathway activation. T cell costimulation using CD2 is an alternative strategy that may provide significant benefits compared to 4-1BB and CD28 due to sustained CD2 surface expression on T cells found in the tumor microenvironment.

EVOLVE205 molecules are dual (2:1) CD20-targeting TCE with integrated CD2 agonism to redirect optimized T cell effector function through CD2 co-stimulation, increasing avidity-driven binding to CD20, to achieve potential superior performance to clinical benchmarks.

EVOLVE205 molecules show superior cytotoxicity in diffuse large B-cell lymphoma cell line models and primary tissue B cells. In a PBMC-HT ($CD20^{low}$) co-culture assay, EVOLVE205 displays improved T cell expansion and superior tumor cell killing without a substantial increase in cytokine release compared to 1:1 and 2:1 CD20-targeted clinical benchmark bispecifics. Importantly, in a B-cell depleted PBMC-HT tumor co-culture assay, the tumor-killing potency of EVOLVE205 was improved by up to 70-fold compared to Glofitamab, and by over 1,000-fold compared to anti-CD20 mAbs such as Rituximab. EVOLVE205 also demonstrated superiority in depleting primary tissue B cells over approved CD20 or CD19 targeting clinical benchmarks. These data suggest the potential for EVOLVE205 to establish an improved therapeutic index relative to these clinical benchmarks. In a PBMC-engrafted xenograft NSG mouse model with $CD20^{high}$ WSU-DLCL2 cell line, EVOLVE205 showed significantly enhanced tumor growth inhibition efficacy at the tumor growth permissible dosing level of Glofitamab.

CD20-targeted EVOLVE205 shows high tumor-killing potency without inducing exaggerated cytokine production in vitro. It also demonstrates significant in vivo efficacy and a favorable developability profile. Our data indicated that EVOLVE205 with integrated CD2 co-stimulation offers greater efficacy and safety advantages compared to clinically available CD20-targeted TCE therapies and anti-CD20 mAbs for the treatment of B cell lymphomas and for B cell-mediated autoimmune diseases.

#2138 ALG01, a next-generation anti-PD-L1×TROP-2 bispecific antibody-drug conjugate (BiADC) with STAR technology, demonstrated excellent anti-tumor efficacy & safety in preclinical studies.

J. Xiang, W. Gao;
Allygen Biologics, Shanghai, China

The combination of anti-TROP2 ADCs with PD-(L)1 inhibitors represents a promising therapeutic strategy, merging targeted therapy with immunotherapy to improve treatment outcomes. Clinical trials are underway to explore its safety and efficacy in various cancer types. However, challenges remain, including accumulative toxicity, dosing difficulties, and tumor resistance. Bispecific ADCs (BiADCs), which target two antigens simultaneously, offer a promising advancement by enhancing tumor specificity, improving therapeutic efficacy, and reducing damage to healthy tissues. BiADCs are emerging as a pivotal innovation in oncology, particularly for difficult-to-treat cancers.Here, we present preclinical findings for ALG01, a novel anti-PD-L1×TROP2 BiADC with STAR (Smart TME (Tumor Microenvironment) Activated Release) technology and incorporated with targeted therapy and immunotherapy in one molecule, has shown remarkable anti-tumor activity and a favorable safety profile. ALG01 comprises a humanized PD-L1-targeting IgG1 fused with TROP2-targeting biparatopic VHHs at the C-terminal of the heavy chain, linked to exatecan via transglutaminase-mediated site-specific conjugation. In vitro studies demonstrated that ALG01 exhibits potent cytotoxicity against various TROP2 and/or PD-L1-positive cancer cell lines. Ex vivo, ALG01 was selectively and efficiently cleaved by proteases as designed within tumor tissues, compared to plasma and normal tissues (e.g., liver, spleen, lung), resulting in the release of anti-PD-L1 IgG1 and small-size anti-TROP2 VHH-drug conjugates. In vivo, ALG01 significantly regressed tumors in a TROP2-positive cell line-derived xenograft (CDX) model. Furthermore, in a MC38-PDL1-TROP2 syngeneic model, ALG01 treatment led to complete tumor eradication in 7 of 8 mice, showing significantly superior efficacy compared to reference anti-TROP2 ADC and its combination with reference anti-PD-L1 antibody.A rechallenge study further supported long-lasting ALG01's anti-tumor efficacy. After complete (8 of 8 mice) tumor eradication following a single dose of ALG01, mice were re-inoculated with tumor cells without additional treatment. Remarkably, the newly implanted tumors in 7 of 8 mice were once again fully eliminated, revealing a lasting immune activated memory effect. In toxicology studies, ALG01 was well tolerated in cynomolgus monkeys, with the highest non-severely toxic dose (HNSTD) observed at ≥45 mg/kg for DAR6 or ≥65 mg/kg for DAR4.These preclinical findings indicate that ALG01 offers a wide therapeutic window and may benefit patients with challenging-to-treat cancers. An IND application is planned for submission in 2025.

#2139 Determination of first in human dose of the T cell-redirecting bispecific antibody CT-95 targeting mesothelin.

Stanley A. Roberts, Kelly Byrnes-Blake, **Eric Butz**

Context Therapeutics, Philadelphia, PA

CT-95 is a mesothelin (MSLN) x CD3 bispecific T cell-redirecting antibody that is entering phase 1 clinical development. It is affinity tuned to avoid the soluble MSLN sink that has interfered with earlier MSLN-targeting programs. The first-in-human dose of CT-95 was determined using the minimal anticipated biological effect level (MABEL) approach, as required for immune agonist drugs. This is the dose level expected to lead to a minimal biological effect level in humans. The most sensitive and pharmacologically relevant measure of CT-95 activity was determined to be induction of CD25 expression on human T cells using a panel of six human MSLN expressing tumor cell lines. The median EC50 for this panel was 9.94 pM and resulted in an estimated target serum concentration of 1.98 ng/mL. Based on nonclinical PK data, the predicted volume of distribution is 123.5 mL/kg, which suggests a starting dose of 0.24 µg/kg. An additional safety factor was applied to obtain a proposed starting dose of 0.1 µg/kg. From the results of the GLP monkey study, the highest non-severely toxic dose (HNSTD) was considered to be 0.01 mg/kg, and the no-observed-adverse-effect level (NOAEL) was 0.003 mg/kg. Relative to doses in the one-month repeat dose GLP-compliant toxicology study, the proposed starting dose for CT-95 (0.1 µg/kg) is 30-fold lower than the NOAEL (3 µg/kg) and 100-fold lower than the HNSTD (10 µg/kg). The weight of evidence of these data supports the safety of the proposed clinical starting dose of 0.1 µg/kg for CT-95.

#2140 Beyond antibodies and CAR-T: CC312, a first-in-class, anti-CD19, anti-CD3, anti-CD28 trispecific antibody in treatment with relapsed and/or refractory B-cell malignancies.

Yingfeng Huang, Xiaofang Zhang, Ruixia Zhang, Zhen Jing, Caizhi Zhao, Fangfang Pan, Beibei Zheng, Ruixue Dai, Yingying Yang, **Li Zeng**

CytoCares (Shanghai) Inc., Shanghai, China

Background: Depletion of B cells has resulted in major therapeutic benefits in hematological malignancies. Several FDA-approved B cell-depleting therapies are available, including CAR-T and T cell engagers (TCE). Blinatumomab, the only CD19-targeting bispecific T cell engager approved for B cell malignancies, has disadvantages in clinical setting including sub-optimal pharmacokinetics, neurotoxicity, CRS, and lack of long-term efficacy. In this study we present CC312, a trispecific antibody engineered for better efficacy by leveraging “Two Signal” co-stimulation, as well as improved safety via target-dependent activation and high potency / low dosage leading to low off-target effects.

Methods: Effects of CC312 on T cell activation, proliferation, central memory T cell differentiation/proliferation and T cell killing activity were compared with blinatumomab in *ex vivo* assays. *In vivo* efficacy for CC312 was investigated in a Raji-luc s.c. engraftment CD34+ HSC-NCG mouse model. Moreover, a Phase Ia, open-label study is currently ongoing, and is designed to characterize the safety and tolerability of CC312 in patients with R/R B-NHL and R/R lymphocytic leukemia, to determine recommended dose(s), schedule(s), and route(s) of administration for future studies, and to estimate the preliminary anti-tumor activity of CC312.

Results: *In vitro*, CC312 exhibited more robust T cell activation, higher proliferation and ~10-fold greater potency versus blinatumomab. Additionally, CC312 induced a higher proportion of central memory T cells, and resulted in longer target cell killing relative to blinatumomab. *In vivo*, CC312 demonstrated similar tumor growth inhibition versus blinatumomab when dosed twice-weekly and more potent tumor growth inhibition when dosed once-weekly. In the ongoing Ph1a trial, CC312 has completed five levels of priming dose escalation as well as upper levels of treatment dose escalation, and has exhibited a favorable clinical safety profile to date with no DLTs or grade 3+ CRS/ICANS. CC312 achieved multi-fold depletion of peripheral blood B cells across dosages as well as ignited CD4 and CD8 T cell expansion and activation in B cell lymphoma patients.

Conclusion: In this study, CC312 exhibited key advantages over leading CD3xCD19 TCE blinatumomab in multiple clinically relevant *in vitro* functional assays, demonstrated robust tumor growth inhibition in B cell lymphoma mouse models and achieved thorough depletion of CD19+ B cells and potent activation of T cells in B cell lymphoma patients across dosages while maintaining a favorable safety/tolerability profile. Therefore, via its “Two Signal” co-stimulation approach, CC312 represents a promising candidate for treatment of B cell lymphoma. CC312’s clinical benefit will continue to be explored at higher doses as part of ongoing Ph1a dose escalation study.

#2141 Exploration of FGL-1 and LAG-3 expression and nivolumab resistance mechanisms in esophageal cancer.

Hiroki Matsuda, Tomoki Makino, Takafumi Hagi, Kota Momose, Kotaro Yamashita, Takuro Saito, Koji Tanaka, Tsuyoshi Takahashi, Yukinori Kurokawa, Hidetoshi Eguchi, Yuichiro Doki

Osaka University, Osaka, Japan

[Background] Anti-PD-1 antibody therapy for esophageal squamous cell carcinoma (ESCC) faces challenges such as low response rates, emphasizing the urgent need to develop novel regimens or predictive biomarkers. Lymphocyte Activation Gene 3 (LAG-3) is an inhibitory immune checkpoint molecule primarily expressed on T cells. It has been demonstrated that combination therapies (anti-LAG-3 and anti-PD-1 antibodies) are more effective than monotherapy (anti-PD-1 antibody) in melanoma. Recently, Fibrinogen-like protein 1 (FGL-1) has been identified as a major ligand for LAG-3. While FGL-1 is secreted from normal hepatocytes, it is known to be secreted in greater quantities by tumor cells in several cancers. FGL-1 that is detectable in peripheral blood holds potential as a biomarker for predicting ICI efficacy and prognosis. However, there are few reports on LAG-3 and FGL-1 in ESCC.
[Objectives] To clarify relationship between LAG-3/FGL-1 expression and patient survival or expression of other immune cells in ESCC. To investigate the significance of FGL-1 levels of peripheral blood as a biomarker for ICIs.
[Methods] In 316 preoperatively untreated ESCC patients who underwent curative resection, immunohistochemical staining was performed to confirm FGL-1 expression and localization. The relationship between FGL-1 expression, prognosis, and expression of CD3 and CD8 was evaluated.Serum FGL-1 levels were measured using the ELISA method in blood samples before start of treatment of 53 ESCC patients that underwent radical resection. The expression levels were compared with those of healthy controls. In patients with unresectable advanced or recurrent ESCC, plasma FGL-1 levels were measured using the ELISA method before administering anti-PD-1 antibody and evaluated its relationship with treatment efficacy and prognosis.
[Results] FGL-1 was localized in tumor cells in ESCC. 121 patients were defined as high FGL-1 expression, which was identified as a poor prognostic factor. However, no correlation was found between FGL-1 expression in tumor cells and the number of T cells. Serum FGL-1 levels were higher in ESCC patients compared to healthy individuals. No association was found between FGL-1 expression in serum and tumor tissue. Plasma FGL-1 levels were significantly higher in the non-responders compared with responders before anti-PD-1 antibody administration.
[Conclusions] Using pre-treatment biopsy specimens, FACS analysis will confirm LAG-3+CD8+ T cell expression among tumor-infiltrating lymphocytes, and the relationship with T cell subsets and FGL-1 expression will be evaluated.

#2143 Sequential anti-folate (pemetrexed) and anti-PD-L1 (avelumab) combination therapy in patients with previously treated MTAP-deficient advanced urothelial cancer: Clinical outcomes and immune correlative analyses.

Amishi Y. Shah[1], **Xinmiao Yan**[2], Rebecca S. Tidwell[3], Jianfeng Chen[1], Arlene O. Siefker-Radtke[1], Sangeeta Goswami[1], Omar Alhalabi[1], Yuxue Zhang[1], Ying Mei[1], Charles Guo[4], Miao Zhang[4], Ana C. Adriazola[1], Abu Hena Mostafa Kamal[5], Nagireddy Putluri[6], Mark A. Titus[1], Bogdan Czerniak[4], Matthew T. Campbell[1], Linghua Wang[2], Jianjun Gao[1]

[1]Department of Genitourinary Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]UT MD Anderson Cancer Center, Houston, TX,[3]Department of Biostatistics, UT MD Anderson Cancer Center, Houston, TX,[4]Department of Anatomical Pathology, UT MD Anderson Cancer Center, Houston, TX,[5]Metabolomics Core, Advanced Technology Cores, Baylor College of Medicine, Houston, TX,[6]Baylor College of Medicine, Houston, TX

MTAP-deficiency in urothelial cancer is associated with poor clinical outcomes but correlates with sensitivity to antifolate chemotherapy. This single-arm phase 2 trial (N=15) assessed the clinical and biological effects of a sequential combination therapy using the immune modulating antifolate agent pemetrexed and anti-PD-L1 agent avelumab in patients with advanced urothelial cancer resistant to prior chemotherapy and/or immunotherapy. The combination regimen treatment resulted in an overall response rate (ORR) of 20% (95% CI: 5%, 42%), a disease control rate (DCR) of 47% (95% CI: 23%, 71%), a median progression-free survival (PFS) of 2.3 months (95% CI: 1.9, 5.5), and a median overall survival (OS) of 13.5 months (95% CI: 3.2. 22.4). To investigate the relationship between clinical outcomes and tumor microenvironment (TME), single-cell RNA sequencing was performed on tumor samples collected from 15 patients at three time points: baseline, after pemetrexed monotherapy (cycle 2, day 1), and following combined treatment (cycle 4, day 1). This analysis profiled 49,161 cells spanning nine major cell types, including T cells, B cells, plasma cells, myeloid cells, epithelial cells, fibroblasts, and endothelial cells. Correlating TME composition with clinical outcomes revealed that higher proportions of T and NK cells at baseline were positively associated with PFS and clinical benefit. Conversely, elevated levels of proliferating myeloid cells and macrophages correlated with poorer responses to therapy. Pemetrexed monotherapy notably reshape the immune landscape, promoting increased infiltration of type-2 conventional dendritic cells (cDC2). Furthermore, patients with augmented B and plasma cell infiltration following pemetrexed treatment exhibited better clinical outcomes. Resistance to treatment was associated with increased adenosine signaling, suggesting a potentially targetable pathway to enhance treatment efficacy. Preclinical data suggest that targeting adenosine signaling pathway may further enhance the therapeutic effects of pemetrexed and anti-PD-L1 for MTAP-deficient bladder cancer. Additionally, urine methylthioadenosine (MTA), which accumulates due to MTAP deficiency, emerged as a promising biomarker for treatment monitoring. These discoveries unveil the link between TME of MTAP-deficient tumors and response for this clinical trial, suggest potential targetable mechanism to improve efficacy, which better the understanding of MTAP-deficient tumors and design promising strategies to improv clinical translation. These findings underscore the intricate link between the TME and treatment response in MTAP-deficient tumors, offering insights into resistance mechanisms to optimize clinical outcomes in MTAP-deficient urothelial cancer.

IMMUNOLOGY: Interplay between Immune System and Radio-, Chemo- and Targeted Therapies 1
Poster Session

#2147 Radiosensitization via ATM inhibition in small cell lung cancer leads to increased immunogenicity and tumor infiltration.

Bell Wu[1], Xiaozhuo Ran[2], Mary Shi[2], Lifang Song[2], Vivek Philip[2], Ming-Sound Tsao[2], Benjamin Lok[2]

[1]University of Toronto, Toronto, ON, Canada,[2]University Health Network, Toronto, ON, Canada

Purpose: Small cell lung cancer (SCLC) is an aggressive form of lung cancer with a dismal survival. PD-1/PD-L1 inhibitors have improved survival outcomes, but many patients fail to respond possibly due to a lack of T cell infiltration. Ionizing radiation (IR) activates innate regulatory genes through micronuclei formation and cGAS-STING upregulation. A previous *in vitro* dropout CRISPR screen has identified ATM as a top-ranked determinant of radiosensitization in SCLC cell-lines. Evaluation of ATM inhibition (ATMi) in combination with IR increases tumour T cell immunogenicity through a cGAS-STING-mediated mechanism.
Methods and Materials: We investigated the combination of ATMi (AZD1390) and IR in SCLC cell-lines SBC5 and SHP77, to determine the synergism of cGAS-STING activation via immunofluorescence. Chemokine and cytokine expression following combination treatment was probed by qPCR and surface expression of PDL1 and HLA class I was quantified through flow cytometry. In the SCLC syngeneic mice, we evaluated the efficacy and immune-sensitizing effects of a triple combination of ATMi, RT and anti-PDL1 (ATMi+IR+ICB).
Results: ATMi plus IR (ATMi+IR) lead to a significant ($p < 0.001$) increase of micronuclei frequency and cGAS micronuclei translocation relative to RT alone. ATMi+IR also resulted in a significant increase in CCL5 and CXCL10 expression compared to IR alone in SBC5 (FC = 6 and 1.5, respectively) and SHP77 (FC = 1.5 and 2, respectively). This phenotype was partially abrogated in cGAS knockout in SBC5 and H1048 cell-lines. Surface PDL1 increased by a FC of 3 in H82 in ATMi+IR relative to IR, while no change in surface HLA was observed. Within the KP1 syngeneic SCLC murine model, ATMi+IR+ICB led to a significant increase (p-value < 0.001) in T cell ($CD45^{+}CD3^{+}$) infiltration at day 12 relative to ATMi+IR. Interestingly, ATMi+IR had no change in T cell infiltration relative to both IR alone and IR plus anti-PDL1. Although an increase in T cell infiltration was observed, there was no additional benefit in tumour control of ATMi+IR+ICB compared to ATMi+IR.
Conclusions: In this study, we demonstrated pharmacological inhibition of ATM enhanced SCLC chemokine expression in a cGAS-STING-dependent manner. We further validated this phenotype in a syngeneic SCLC murine model. Despite this marked improvement in SCLC T cell infiltration no further benefits was observed. Further studies are required to understand this lack of benefit.

#2148 HDAC6 inhibitors modulate macrophage functional activity in the post-radiotherapy tumor microenvironment.

Xintang Li[1], Satish Noonepalle[1], Karen Tan[1], Sonia Sebaoui[1], Manasa Suresh[1], Nithya Gajendran[1], Marie Durr[1], David Quiceno-Torres[1], Bryan Weselman[1], Vidhi Sharma[1], Abishek Sehgal[1], Scott Grindrod[2], Anatoly Dritschilo[2], Alejandro Villagra[1]

[1]Oncology, Georgetown University, Washington, DC,[2]Shuttle Pharmaceuticals, Gaithersburg, MD

Introduction: In recent decades, radiation therapy (RT) has been a significant therapeutic tool for treating multiple cancer types. Primarily, radiation-induced immunogenic tumor cell death re-modulates the tumor microenvironment (TME) with the potential to enhance the efficacy of immunotherapies. Tumor-associated macrophages (TAMs) play a critical role in the anti-tumor innate immune response. However, post-RT, the phenotype of TAMs can easily convert from the pro-inflammatory M1-like to the immunosuppressive and tumor-promoting M2-like due to their plasticity. M2-like macrophages cause relapse and metastasis of the tumor. Therefore, reprogramming TAMs is critical. Our lab has reported that targeting Histone Deacetylase 6 (HDAC6) in macrophages can disrupt their phenotype shifting from M1-like to M2-like in TME.

Methods: We demonstrated the suppressive effect of HDAC6 inhibitors (HDAC6i) on M2-like macrophage phenotype markers by flow cytometry and qRT-PCR. Furthermore, in-vitro assays were performed, including trans-well migration assays, phagocytosis assays, and in-vivo syngeneic tumor models against different tumor cell types, including SM1 murine melanoma, 4T1 breast cancer, and TRAMP-C2 prostate cancer.

Results: The trans-well-based migration assay indicated an increment in M2-like macrophage migration to irradiated cancer cells compared to M1-like macrophages. This increment was suppressed when culturing M2 macrophages with HDAC6i. Furthermore, the co-culture assay between macrophages and cancer cells indicated that M1 macrophages showed a higher phagocytosis rate when co-culture with irradiated cells and HDAC6i treatment increased tumor cell phagocytosis. Meanwhile, an in-vivo study based on the 4T1 and SM1 tumor models model suggested that RT combined with HDAC6i treatment has better efficacy than the monotherapy treatment arms due to increased M1/M2 macrophage ratio. These results demonstrate that targeting macrophages with HDAC6is could enhance the overall therapeutic outcome of radiation therapy.

#2149 Copper-67 based targeted radioligand therapy to the somatostatin receptor 2 (SSTR2) provides added efficacy and may prime small cell lung cancer for immunotherapy.

Jaclyn L. Lange[1], Lachlan E. McInnes[1], Kurt R. Gehlsen[1], Jessica Van Zuylekom[2], Benjamin Blyth[2], Stacey E. Rudd[3], Paul S. Donnelly[3], **Matthew Harris**[1]

[1]Clarity Pharmaceuticals, Sydney, Australia,[2]Peter MacCallum Cancer Centre, Melbourne, Australia,[3]School of Chemistry and Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Melbourne, Australia

Background and Purpose: Immune checkpoint therapy (ICT) has revolutionized cancer treatment; however, efficacy remains poor for some cancers, including small cell lung cancer (SCLC). Strategies to enhance immune responses include combining ICT with other existing cancer therapies. Targeted radioligand therapy uses a radiolabeled cancer-targeting vector, allowing for specific delivery of radiation to all tumor sites while minimizing radiation exposure to healthy tissues. Targeted Copper Theranostics (TCTs) is a targeted radioligand platform utilizing copper-64/67. We evaluated [^{67}Cu]Cu-SARTATE in combination with ICT in a murine animal model using RP116 tumor cells.

Methods: We administrated ~5 MBq [^{64}Cu]Cu-SARTATE to RP116 (a murine SCLC cell line expressing SSTR2) tumor-bearing immunocompetent C57BL/6 mice and assessed biodistribution and tumor uptake via PET imaging at 1, 4 and 24 h post IV injection. After completion of a dose escalation study, an efficacy study using [^{67}Cu]Cu-SARTATE, mouse ICT analogues and the combination of [^{67}Cu]Cu-SARTATE and ICT treatment groups in the same animal model was performed to evaluate therapeutic efficacy of copper-67-based TCT.

Results: Tumor uptake of [^{64}Cu]Cu-SARTATE was visualized by PET imaging over the first 24 h post-injection with high tumor uptake, consistent with multiple studies previously published showing uptake in human xenograft models with the same product. Tumor uptake of [^{67}Cu]Cu-SARTATE was confirmed by *ex vivo* biodistribution and Cherenkov imaging, with no significant radiotoxicity observed via body condition and body weight measurements in mice receiving injected activities up to the maximum tested dose of 30 MBq. The combination of 30 MBq [^{67}Cu]Cu-SARTATE, with both anti-PD-L1 and anti-CTLA4, improved median survival by 3, 7, or 13 days, compared to ICT-only (anti-PD-L1 plus anti-CTLA4), [^{67}Cu]Cu-SARTATE-only or saline-only treated groups respectively.

Conclusion: Biodistribution studies demonstrated high tumor-specific uptake for [64Cu]- and [67Cu]-Cu-SARTATE in this mouse syngeneic SCLC model. A dose escalation study demonstrated copper-67-based TCT could be used to effectively inhibit tumor growth with minimal radiotoxicity. The combination of TCT with ICTs improved overall survival compared to single-treatment control groups. Collectively, our results demonstrate that [67Cu]Cu-SARTATE in combination with ICTs improves overall survival. [67Cu]Cu-SARTATE may prime immunologically “cold” SCLC tumors to improve responsiveness to ICTs through a synergistic response. Tumor biomarkers are being investigated to understand how immune infiltration differs depending on treatment regime.

#2151 Combining PD1 inhibition with radiotherapy enhances anti tumor responses in the CT26 colorectal mouse model.

Charlotte Bell, Theoni (Tania) Katopodi, Pablo Binder, **Tobias Bunday**, Emily Wright, Amy Cantrell, Nick Moore, Stewart Brown, Paul Farrington, Shannon Sharman, Lyndsey Hanson, Lorraine Mooney, Jane Kendrew,

Translational Oncology, Sygnature Discovery, Alderley Edge, United Kingdom

Introduction In recent years, therapies that enhance anti cancer immune responses, like immune checkpoint inhibitors (ICIs), have transformed cancer treatment. Although these therapies can induce lasting responses across various cancer types, not all patients benefit from them. To maximize the potential of immuno oncology (IO) agents, researchers are exploring combinations with other treatments, such as radiotherapy, in both preclinical models and clinical trials. Understanding how IO therapies interact with radiotherapy to influence the tumor immune microenvironment (TIME), and other biomarkers is crucial for advancing drug discovery research. Methods and experimental procedures CT26 cells were exposed to various irradiation doses *in vitro*, and DNA damage response biomarkers were assessed using the Jess automated western blot system. Additionally, to establish a tolerated radiotherapy dosing regimen *in vivo*, different irradiation doses were tested in Balbc CT26 tumor bearing mice. The most effective and tolerated dose regimen was then combined with PD1 dosing. The response of the CT26 cancer model to PD1, with or without radiotherapy, was evaluated. Mice receiving radiotherapy were administered targeted X rays localized only to the tumor area. Changes to the tumor immune microenvironment (TIME) following these therapies were assessed using flow cytometry, while changes in splenic immune populations were analyzed by flow cytometry and ELISPOT. Serum cytokines at study termination were assessed using the Luminex x map technology. Data Treatment with radiotherapy or PD1 as monotherapies led to a mixed response, with tumor regressions obtained in a fraction of the animals treated. The combination of PD1 with radiotherapy significantly increased therapeutic efficacy. Characterizing the TIME following treatment with PD1 in combination with radiotherapy revealed modulation of the intra-tumoral immune infiltrate that reflected the increased therapeutic efficacy. Notably, a significant decrease in the frequency of tumor associated macrophages and an increase in T, NK, and B cells, was observed in tumors treated with the combination of anti PD1 and radiotherapy. Conclusion We have identified and established effective dosing regimens for radiotherapy in vivo in combination with PD1 therapy. Additionally, we have assessed changes to the tumor and spleen immune populations in a syngeneic mouse cancer model. These findings highlight the utility of these models in immuno-oncology (IO) drug discovery research.

#2152 NT-I7 increases lymphocytes and enhances chemotherapy and immunotherapy efficacy in HNSCC.

Zhibin Cui[1], Jacqueline L. Yee[2], Hua Li[1], Yan Zeng[1], Liam Woerner[1], Alexandra A. Wolfarth[3], Sara Ferrando-Martinez[3], Hyunseok Kang[4], Jennifer R. Grandis[1], Matthew H. Spitzer[5], Daniel E. Johnson[1]

[1]Department of Otolaryngology - Head and Neck Surgery, University of California, San Francisco, San Francisco, CA,[2]Department of Microbiology and Immunology, University of California, San Francisco, San Francisco, CA,[3]NeoImmuneTech, Inc., Rockville, MD,[4]Division of Hematology and Oncology, Department of Medicine, University of California, San Francisco, San Francisco, CA,[5]Department of Microbiology and Immunology; Department of Otolaryngology - Head and Neck Surgery, University of California, San Francisco, San Francisco, CA

Background: Lymphopenia is associated with poor outcomes and is exacerbated by conventional chemoradiation therapies in head and neck squamous cell carcinoma (HNSCC). NT-I7 (rhIL-7-hyFc, efineptakin alfa; NeoImmuneTech, Inc.), a long-acting human IL-7, has the potential to restore lymphocyte populations, modulate immune responses, and enhance anti-tumor activity. This study investigated NT-I7's effects on lymphocyte populations and its synergy with cisplatin and immune checkpoint inhibitors (ICIs) in syngeneic, immunocompetent HNSCC mouse models.

Methods: The impact of NT-I7 was studied in two syngeneic tumor models, MOC1 and MOC22. Flow cytometry and Cytometry by Time of Flight (CyTOF) analyses were used to evaluate NT-I7 effects on peripheral and intratumoral immune cells. Anti-tumor efficacy was assessed following NT-I7 treatment alone, in combination with cisplatin, or with anti-PD-1 therapy.

Results: Mice bearing syngeneic MOC1 and MOC22 tumors exhibited significant lymphopenia, characterized by reductions in $CD4^+$ and $CD8^+$ T-cells, Tregs, NK cells, and NKT cells, resembling clinical observations in HNSCC patients. NT-I7 treatment significantly increased lymphocyte levels in both spleen and tumor, with notable induction of $CD8^+$ T-cells and NKT cells, peaking at day 7 and day 4 post-treatment, respectively, and minimal impact on intratumoral Treg levels. NT-I7 modestly inhibited MOC1 tumor growth and potently suppressed MOC22 tumor growth. Combining NT-I7 with cisplatin significantly enhanced anti-tumor activity in MOC1 tumors, accompanied by increased numbers of peripheral and intratumoral CD4+, CD8+, and NKT cells. Furthermore, NT-I7 augmented the efficacy of anti-PD-1 therapy in MOC1 tumors, resulting in greater tumor growth inhibition compared to either treatment alone. CyTOF analysis revealed preferential expansion of CD8+ Tpex cells, a key subset of tumor-specific cells that expand in response to ICIs, highlighting NT-I7's role in overcoming lymphopenia and potentiating anti-tumor immunity.

Conclusions: NT-I7 effectively increases lymphocyte populations in HNSCC preclinical models that demonstrate tumor-associated lymphopenia, and enhances the efficacy of cisplatin and anti-PD-1 in HNSCC preclinical tumor models.

#2153 Preliminary analysis of immune cell profiling to neoadjuvant chemotherapy response in pancreatic cancer patients.

Byeong-Gon Kim, Sung Jun Kim, Gyuryang Park, Tae Young Kim, Sung-Sik Han, Sang-Jae Park, Woo Jun Lee, Sun-Young Kong, Yun-Hee Kim, Jung Won Chun, Sang Myung Woo

National Cancer Center, Goyang, Korea, Republic of

Background: Neoadjuvant chemotherapy (NAT) is used in the clinical setting to improve the chance of surgery for pancreatic cancer (PC) patients. Immune profiling shows great promise for improved prediction of response to chemotherapy, But the role of the immune system of PC remain unclear. This study aimed to identify immune biomarkers for improved prediction of response to chemotherapy.
Materials and
Methods: Blood samples were collected from 23 pancreatic cancer patients undergoing neoadjuvant chemotherapy (NAT) before (pre, n=23) and during the 2-month follow-up after treatment (post 2M, n=15). Peripheral blood mononuclear cells (PBMC) were isolated from whole blood samples using Ficoll buffer and flow cytometry analyzed using 18 colors-LSRFortessa for immune cell profile. The following fluorescent-labeled antibodies were used: Fixable viability stain 700, Fluorescein isothiocyanate anti-CD3, Brilliant violet (BV) 605 anti CD14, BV510 anti-HLA-DR, BV655 anti-CD123, BV421 anti-CD11c, Brilliant ultraviolet (BUV) anti-CD4, and BV711 anti-CD8. The immune cell profiling in peripheral blood mononuclear cells were analyzed by flow cytometry. Patients were classified as responders (compete response, partial response) or non-responders (stable disease, progressive disease) base on their response to NAT, and their immune cell profiles were compared.
Results: The baseline characteristics of the two groups were similar. The median number of NAT cycles was 8 (range, 4-9) in responders and 8 (4-12) cycles in non-responders, respectively. Among various immune cell types, the myeloid dendritic cells (mDC) levels were significantly increased in responder of the NAT group (P = 0.025); however, the levels of CD4, CD8, monocyte, overall DC, and plasmacytoid DC were not significantly different. After NAT 2-month, a decrease in mDC levels was frequently observed in the non-responder group (75% vs. 43%), but the difference was not significant.
Conclusion: Our study suggests that mDC in blood may be a useful biomarker for predicting NAT response and improving treatment responses in pancreatic cancer patients. Further research is required to fully assess the role of mDC in predicting NAT response.Funding: This work was supported in part by the National Cancer Center, Korea (No. 2410680).

#2154 Inhibition of CD39 by AB598 enhances the effects of chemotherapy and anti-PD-1 therapy to promote myeloid cell and T cell anti-tumor immunity.

K. Jin, J. Clor, L. Stetson, R. Fuchs, S. Cho, J. Singh, A. Kaplan, M. Peterson, M. Walters, E. Fernandez-Salas, C. Bowman; Arcus Biosciences Inc., Hayward, CA

Extracellular ATP (eATP) is a potent immunostimulatory signal in the tumor microenvironment (TME). Halting the degradation of eATP by inhibiting CD39 (gene: *ENTPD1*), the dominant extracellular ATPase in the TME, may lead to an immunostimulatory environment resulting in anti-tumor immunity. AB598 is a novel, humanized, Fc-silent anti-CD39 therapeutic antibody that inhibits CD39 enzymatic activity with sub-nanomolar potency and is currently being evaluated in ARC-25, a Phase 1/1b clinical trial in subjects with gastric cancer, in combination with FOLFOX and zimberelimab, an anti-PD-1 antibody. Analysis of publicly available gastric cancer single-cell RNA sequencing datasets demonstrates that *ENTPD1* is expressed predominately on endothelial cells, fibroblasts, and immune cell subsets in gastric tumors. Examination of CD39 expression at the protein level confirmed high levels of intratumoral CD39 present in the vasculature, stroma, and immune cells, but not cancer cells, in gastric tumors. Intratumoral ATP levels are modulated by CD39 regardless of the cellular origin, but the immunostimulatory effect of ATP results from signaling through purinergic receptors on the surface of immune cells. To fully understand the ability of AB598 to preserve eATP and prompt immune responses, we performed *in vitro* and *in vivo* studies to assess the effect of enhanced ATP levels on immune cell activation. Co-culture of macrophages and NK cells with the addition of ATP and AB598 resulted in NK cell activation, reflected in increased production of pro-inflammatory and cytotoxic cytokines. A triple co-culture system including HGC-27 gastric cancer cells, monocyte-derived dendritic cells (moDCs), and T cells was utilized to exemplify the therapeutic hypothesis. In this model, no exogenous ATP is added, instead, ATP is generated upon oxaliplatin-induced cell death of the HGC-27 cancer cells. The ATP produced by the HGC-27 cancer cells is preserved by AB598 to promote moDC activation and ultimately T cell cytokine production, providing evidence for the ability of AB598 to promote adaptive anti-tumor immunity. In a human CD39 knock-in mouse model, which retains the natural distribution of CD39 and a fully competent immune system, treatment of mice bearing MC38 tumors with the combination of murinized AB598 and PD-1 antibodies led to a reduction in tumor growth. Immunophenotyping of both tumor and tumor-draining lymph nodes demonstrated that myeloid cells and T cells were activated as a result of AB598 treatment. In conclusion, the co-culture *in vitro* and murine *in vivo* data support the combination of AB598 with the standard of care agents oxaliplatin and anti-PD-1 to enhance myeloid cell and T cell activation to drive anti-tumor immunity.

#2155 Phage display discovery of Trop-2 peptide for targeted liposomal chemo-immunotherapy in lung cancer.

B. S. Mustafa, B. Nagalo, M. Tesfay, U. Ferdous, A. Cios;
University of Arkansas for Medical Sciences, Little Rock, AR

Background: Lung cancer remains a leading cause of cancer-related mortality worldwide. Targeted therapies offer a promising approach to improve treatment efficacy and reduce systemic toxicity. Trophoblast cell surface antigen 2 (Trop-2) is a transmembrane glycoprotein that is overexpressed in multiple cancers including lung cancer. Trop-2 is an ideal candidate for targeted therapy of NSCLC as it is highly expressed in NSCLC in comparison to normal cells and it is a transmembrane protein with an extracellular domain that can be targeted by therapies. Recently various Trop-2-targeted therapies have been investigated in clinical trials, including anti-Trop-2 antibodies and Trop-2-targeted antibody-drug conjugates (ADC). This study aims to discover a Trop-2 specific peptide using phage display biopanning and develop a liposomal formulation surface-modified with the identified peptide for targeted chemo-immunotherapy.
Methods: A peptide phage display library was screened to identify peptides with high affinity for Trop-2 protein. The selected Trop-2 peptide was conjugated to the surface of liposomes encapsulating cisplatin and anti-PDL1 single-chain variable fragment (scFv). The targeting efficiency, cytotoxicity, and immunomodulatory effects of the Trop-2 peptide-modified liposomes were evaluated in vitro using A549 lung cancer cell lines and in vivo in Calu-3 NSCLC xenograft model.
Results: The phage display biopanning successfully identified a high-affinity Trop-2 peptide. Liposomes modified with this peptide demonstrated enhanced binding and uptake by A549 lung cancer cells compared to non-targeted liposomes. In vivo, the targeted liposomal formulation exhibited superior tumor growth inhibition and prolonged survival in the Calu-3 NSCLC xenograft model.
Conclusion: The discovery of a Trop-2 specific peptide via phage display and its application in targeted liposomal delivery of cisplatin and anti-PDL1 scFv represents a novel and effective strategy for lung cancer chemo-immunotherapy. This approach holds potential for improving therapeutic outcomes and minimizing adverse effects in lung cancer patients.

#2156 Combination therapy of platinum chemotherapy and HIF1α/c-MET peptide vaccine suppresses tumor growth and intraperitoneal metastasis by modulating tumor microenvironment in high grade serous ovarian carcinoma.

Soon Young Lim, Jinhwa Hong, DongGeRaMi Moon, Hye Yeon Roh, Ju Won Kim, Jiwon Lee, Kyong Hwa Park

Korea University, Seuol, Korea, Republic of

Ovarian cancer is the most lethal form of gynecological cancer. Approximately 75% of patients are diagnosed at stage 3 or 4, where the cancer has a high metastasis and mortality rate. Platinum chemotherapy is the standard first line treatment for ovarian cancer. However, 60% of patients with advanced stage disease experience drug resistance and side effects, with recurrence occurring within a few years. Resultantly, the five year survival rate for patients with advanced stage ovarian cancer is only 20-30%. Among the mechanisms proposed to explain platinum resistance, tumor hypoxia is known to contribute to the acquisition of several aggressive tumor characteristics, including increased cellular proliferation, inhibition of apoptosis, enhanced invasion and metastasis, chemoresistance, and immune evasion. Thus, immune checkpoint inhibitors are not the current central treatment in ovarian cancer. In this study, we aimed to investigate the role of tumor hypoxia in the development of platinum resistance and to explore the effect of a strong Type I immunity in overcoming platinum resistance in ovarian cancer. In ovarian cancer cell line, we evaluated the effect of tumor hypoxia on resistance to carboplatin and related proteins. We observed in hypoxia, the expression of relevant proteins was increased compared to normoxia, and the IC50 of carboplatin was also elevated in ovarian cancer cell line. On the contrary, treatment with IFN-γ in vitro induced a reduction in the expression of these proteins in hypoxia, and showed a synergy with carboplatin in cell death. Based on these findings, we identified HIF-1α and c-MET as potential therapeutic targets and developed a HIF1α/MET derived peptide vaccine to enhance local IFN-γ production via helper T-cell immunity. We evaluated the efficacy of a HIF1α/MET peptide vaccine in a high grade serous ovarian carcinoma mouse model (C57BL/6 mice). The mice were divided into four groups: control, carboplatin, vaccine, and combination of carboplatin and vaccine. After three vaccinations, tumor cells were injected, followed by carboplatin treatment, and the tumor suppression effect was evaluated. Tumor growth was significantly suppressed in both monotherapy compared to the control, with the combination demonstrating the most pronounced tumor inhibition. Immunohistochemical analysis revealed reduced expression of HIF-1α & c-MET and an increased infiltration of CD8+ T cells in both monotherapy, with the combination showing the greatest effect. In conclusion, immunotherapy using a HIF-1α/c-MET-derived peptide vaccine, a key player of tumor hypoxia, synergy with carboplatin by modulating the tumor microenvironment and enhancing antitumor immunity. This approach represents a promising strategy for overcoming hypoxia driven resistance in ovarian cancer.

#2157 Rational combination of chemotherapeutic agents with immune checkpoint inhibitors in orthotopic metastatic breast cancer models.

Balaji Ramachandran, Satheeshkumar Rajendiran, Rajendran Venkidusamy, Kowshik Karmakar, Raghu Patil, Krishnappa Haladasappa

Pharmacology, Adgyl Lifesciences Private Limited, Bangalore, India

Breast cancer is broadly diagnosed clinically and deadly among women. Due to heterogeneous nature of cancer and resistance, standalone treatments often fail. Consequently, combination therapy is essential as it targets multiple pathways and enhances efficacy and reduce resistance. Clinically relevant orthotopic mammary fat pads (MFP) implanted models are used for evaluating combination therapies. In the present study, we have evaluated efficacy of anti-PD1, anti-CTLA-4 antibody and Doxorubicin (DOX) as standalone and combination regimen in orthotopic breast cancer models [4T1, EMT6]. 0.5x10^6 cells were implanted orthotopically into fourth mammary fat pad. Mice were randomized based on tumor volume (~100mm^3) and treatment was initiated with anti-PD1 and anti-CTLA-4 at 10mg/kg, i.p; Q4D x 4 doses and DOX 4mg/kg, i.v; Q4Dx 4 doses as standalone or in combination. Tumor volume, changes in body weight, clinical signs, mortality, distant organ metastasis were monitored upto 4 weeks. At the end, lungs were harvested weighed, perfused with Indian ink, and fixed in 10% neutral buffered formalin for histopathology evaluation. In 4T1 tumor model, treatment with standalone anti-PD1, anti-CTLA-4, and DOX resulted in non-significant tumor growth inhibition (TGI). Whereas combination of anti-PD1 and anti-CTLA-4 with Doxorubicin demonstrated moderate TGI and marginally reduced distant organ metastasis compared to the standalone regimen. In EMT6 tumor model, standalone IO agents anti-PD1, anti-CTLA-4, and Doxorubicin treatment exhibited moderate TGI. However, combination of anti-PD1 and anti-CTLA-4 with DOX achieved synergistic significant tumor growth inhibition which was evident from absence of distant organ metastasis and resulted in prolonged survival. Overall, outcome of this study suggests combination therapy with conventional chemoagents, and immune checkpoint blockade can prevent progression to metastatic disease and may limit to overcome resistance. Such combination regimen represents a multimodal translational approach to enhance chemotherapeutic efficacy for the treatment of metastatic breast cancer.

#2158 Developing therapeutic strategy to address chemoresistance in cervical cancer using 3D *ex vivo* sensitivity testing drug.

L. R. Motadi;
University of Johannesburg, Johannesburg, South Africa

Cervical cancer (CC) is ranked the fourth most common cause of cancer related deaths amongst women. The situation is particularly dire in low to lower middle-income countries. It continues to affect these countries due to poor vaccine coverage and screening. Cervical cancer is mostly detected in the advanced stages leading to poor outcomes. Many different chemotherapy drugs are used to treat recurrent CC, including cisplatin, ifostamide, carboplatin and gemcitabine. These drugs may be used alone or in combination. However, in a country like South Africa limited in resources this has become a challenge. In this study we aimed to develop a new therapuetic strategy that include repurposing current HPV vaccine through immune targeting strategy. The 3D ex vivo cancer cells were used and cells were targeted with neutralizing antibodies from HPV targed with cannabidiol. Following treatement, Cell viability, qPCR, Annexin V, immunocytochemistry and DNA fragmantation was performed. The IC50 was observed to be at 26ug/ml. The DNA fragmentation showed positive apoptosis induction while genes like p53, bax and bak1 were all increased. immunocheckpoint were all down in all treatments. The staining for protein showed increase in proteins associated with apoptosis. The results suggest apoptosis induced mechanism.

#2159 B7-H3 as a strategic target for CAR-CIK immunotherapy to eliminate chemoresistant cancer stem cells across diverse tumor histotypes.

Letizia Vitali[1], **Alessia Proment**[1], Annamaria Massa[2], Chiara Donini[1], Alessandra Merlini[1], Federica Galvagno[2], Andrea Maria Lombardi[1], Elisa Vigna[1], Lucilla Minori[1], Elisa Landoni[3], Gianpietro Dotti[3], Claudia Chiodoni[4], Patrizia Gasparini[4], Silvia Novello[1], Valeria Leuci[2], Sandro Pasquali[4], Dario Sangiolo[1]

[1]Universita degli Studi di Torino, Orbassano, Italy,[2]Istituto di Candiolo FPO-IRCCS, Candiolo, Italy,[3]Lineberger Comprehensive Cancer Center University of North Carolina, Chapel Hill, NC,[4]Fondazione IRCCS Istituto Nazionale Tumori, Milan, Italy

Purpose. The objective of our study is the translational exploration of a cellular immunotherapy strategy with CAR-engineered lymphocytes to target solid tumors resistant to conventional treatments. Specifically, we focus on attacking the tumor stem-like component, considered responsible for relapses and resistance to therapies. We have chosen B7-H3 as the target molecule due to its broad expression across multiple tumor types and its association with stemness and tumor aggressiveness. As effectors we exploited Cytokine-induced Killer lymphocytes(CIK) that, given their T-NK function and intrinsic HLA-independent antitumor activity, could be advantageous against tumors with heterogeneous CAR target expression.

Experimental Design. Our preclinical platform is based on tumor cell lines from multiple histotypes (lung and ovarian cancer, osteosarcoma, soft tissue sarcomas) and patient-derived CIK engineered with a second-generation anti-B7-H3 CAR, including CD28 as costimulatory molecule. To visualize putative cancer stem cells (CSCs) within tumor cultures, we employed a strategy previously developed and published by our group. This involves transducing tumor cultures with a lentiviral vector (CSC-detector) encoding GFP under the control of the OCT4 stemness gene promoter, enabling the identification and tracking of CSCs as “GFP-positive”.

Results. Across all the various tumors studied, we confirmed homogeneous and intense expression of B7-H3 (80-100%), as well as key NKG2D ligands recognized by CIK (MIC A/B and ULBPs, > 70%). The rate of CSCs (GFP+) varied among tumor types (mean 24%±4). As expected, CSCs were more quiescent, with reduced proliferative potential *in vitro* compared to their differentiated counterparts, showing an extended G2 phase (2.5fold) in the cell cycle suggestive of a potential enhanced apoptotic resistance. Furthermore, GFP+CSC subsets across diverse histotypes were relatively resistant *in vitro* to reference chemotherapeutics (doxorubicin, cisplatin, PARPi). Functionally, anti-B7-H3 CAR-CIK exhibited potent killing activity against all tumor types, even at low effector-to-target (E:T) ratios (70-85% at E:T 1/1: >60% E:T 1/2). Unlike observed with chemotherapeutic drugs, anti-B7-H3 CAR-CIK effectively eliminated the CSC tumor component, with enhanced activity (2.5 fold) against this subset compared to surrounding tumor cells.

Conclusions. B7-H3 is a valuable and relevant target across diverse solid tumors, allowing to eliminate cell subset with stemness features, resistant to conventional treatments and potentially capable to promote disease relapse. CIK are a suitable platform for CAR-based approaches and our data provide rationale to promote clinical trials with anti-B7-H3 CAR-CIK for relapsed or refractory tumors.

#2160 Trastuzumab deruxtecan induces immunogenic cell death, immune cell activation and -migration in viable human breast cancer slices.

Nina Schulte[1], **Misa Ikuta**[2], Anne Mertes[1], Ivan Kanchev[1], Tsuneo Deguchi[2], Gernot Polier[1]

[1]Daiichi Sankyo Europe GmbH, Martinsried, Germany,[2]Daiichi Sankyo Co., Ltd., Tokyo, Japan

Trastuzumab deruxtecan (T-DXd) is an antibody-drug conjugate composed of a humanized immunoglobulin G1 monoclonal antibody specifically targeting HER2, a tetrapeptide-based cleavable linker, and a potent topoisomerase I inhibitor payload (DXd). It is approved for several indications including adult patients with HER2-positive and HER2-low breast cancers. While immune activation by T-DXd was reported in mouse models, it has not yet been shown in patient samples. We hypothesize that generation of an anti-tumor immune response could exist in patients' tumors treated with T-DXd.

In this preclinical research study we used primary human breast cancer tissue to evaluate the cell types which can internalize T-DXd in culture, induction of immunogenic cell death within tumor cells, intra-tumoral immune cell activation and autologous immune cell migration.

Viable human tumor slices (VHTS) were prepared from surgically removed, primary tumors from breast cancer patients using a vibratome. For each readout, we analyzed three to seven samples from an overall pool of five HER2-positive and 16 HER2-low patient samples (three neoadjuvantly treated). To analyze internalization, VHTS were cultured overnight in presence of fluorescently labeled T-DXd or control IgG (10-15 µg/ml). For functional assays, VHTS were cultured up to five days in the presence of unlabeled T-DXd (15 or 150 µg/ml), DXd (30 or 100 nM) or left untreated. After that the culture supernatants were collected for cytokine analyses and the slices were dissociated and submitted to flow cytometry analyses.

As a result, it was observed that T-DXd was internalized into tumor cells in a target-dependent manner. Compared to untreated slices, T-DXd-treated VHTS showed significantly enhanced levels of the apoptosis marker active/cleaved caspase-3 within tumor cells, significantly reduced HER2-harbouring tumor cell counts, and in some patient samples increased release of HMGB1 in culture supernatants indicating the induction of immunogenic cell death. In addition, we observed increased immune cell activation upon T-DXd incubation manifested by upregulation of CD86 levels, potentiated antigen presentation demonstrated by elevation of MHC class II on macrophages and MHC class I on tumor cells as well as increases of granzyme B+ cytotoxic T cell frequencies. In line with this, cytokine analysis of supernatants revealed higher levels of pro-inflammatory cytokines including GM-CSF, TNFα and IFN-γ. Finally, we also observed enhanced immune cell infiltration of autologous PBMCs into T-DXd-treated VHTS. These results suggest that T-DXd has immune activating effects in human HER2-positive and HER2-low breast cancer tissues. Further studies are needed to assess the use of T-DXd as a complementary treatment to immuno-oncology drugs in patients.

#2161 Improving the tumor microenvironment with liposomal gemcitabine, FF-10832, enhances the effects of immune checkpoint blockade.

Tadaaki Ioroi[1], Michie Morimoto[1], Hitomi Nishinakamura[2], Keisuke Watanabe[2], Shohei Koyama[2], Hiroyoshi Nishikawa[2], Mikinaga Mori[1], **Susumu Shimoyama**[3]

[1]FUJIFILM Corporation, Kanagawa, Japan,[2]National Cancer Center Japan, Tokyo, Japan,[3]FUJIFILM Pharmaceuticals, USA, Cambridge, MA

Cancer immunotherapy, including immune checkpoint blockade (ICB), is a type of cancer treatment that achieves tumor regression in various types of cancer. However, more than half of patients are resistant to ICB therapy. As the tumor microenvironment (TME) is different in each cancer patient, it is important to understand the state of immune cells in the tumor and develop strategies, including combination therapies. In the TME, immunosuppressive cells such as regulatory T cells (Treg), tumor associated macrophages (TAMs) and myeloid derived suppressor cells (MDSCs) work in correlation with ICB resistance. These immunosuppressive cells are promising targets for ameliorating resistance to ICB treatment and a lot of drugs targeting these cells have been developed. In particular, the therapy targeting TAMs have proved effective. We previously developed liposomal nanoparticle, FF-10832, encapsulating the cytotoxic anti-tumor drug, gemcitabine. Non-clinical studies demonstrated that FF-10832 was more stable than unencapsulated gemcitabine and preferentially distributed to solid tumor sites, resulting in an improved therapeutic index. A phase I clinical trial indicated that FF-10832 was well-tolerated in heavily pre-treated patients with advanced solid tumors at the recommended phase 2 dose (NCT03440450). Therefore, this study investigated the application of FF-10832 as an immunomodulator in combination therapy with ICB. Treatment of mouse models of solid tumor and in vitro analysis showed that FF-10832 is engulfed into the cytoplasm of TAMs in the tumor by phagocytosis. Combination therapy with FF-10832 and anti-PD-1 antibody resulted in significant tumor regression compared to gemcitabine monotherapy, altering the balance immunosuppressive cells in the TME. These results suggest that FF-10832 is a promising immunomodulator for TAM-targeted cancer immunotherapy. Combination therapy of FF-10832 and pembrolizumab is under investigation for non-small cell lung cancer and urothelial cancer in a phase 2a clinical trial (NCT05318573).

#2162 A potent and highly selective HPK1 inhibitor as a combination strategy to improve the clinical response of the immune checkpoint inhibitor.

J. Byun, J. Lee, S. Jo, D. Kim, H. Shin, J. Choi, S. Ji, H.-J. Kim, D. Kim, B. Kim;
HK inno.N Corporation, Seoul, Korea, Republic of

Combining the HPK1 inhibitor with the anti-PD-1 antibody has demonstrated clinical benefit by restoring suppressed immune response. Here, we present our novel HPK1 inhibitor IN-122517 exhibiting good HPK1 inhibition potency and selectivity against 468 kinases including immune-related off-target kinases. Consistently, it potently reduced SLP76 phosphorylation and induced IL-2 production in human peripheral blood mononuclear cells (PBMCs).
Preclinical studies have shown beneficial tumor response to IN-122517 as a monotherapy and also improved efficacy when combined with anti-PD-1 monoclonal therapy. In the combination group, complete responses (CRs) were observed in a subset of animals, and re-challenge experiments confirmed the absence of tumor regrowth, indicating the establishment of an immune memory response. Tumor-infiltrating lymphocytes showed increased infiltration of T cells, natural killer (NK) cells, and dendritic cells (DCs), demonstrating the compound's potency in activating and recruiting immune effectors within the tumor microenvironment (TME).
These data supported the nomination of IN-122517 into IND-enabling studies as a combination partner with Immune checkpoint inhibitors (ICIs).

#2163 Inhibition of HIF2A increases efficacy of immune checkpoint blockade in renal cell carcinoma.

K. Frazier[1], E. Muise[1], J. Stolz[1], L. Fischer[1], M. Buchanan[1], C. Schneider[2], B. Chan[2], R. Carr[3], A. Palmieri[1], R. Perini[1], B. Long[1], **D. Linn**[1];

[1]Merck & Co., Inc., Boston, MA, [2]Merck & Co., Inc., Cambridge, MA, [3]Merck & Co., Inc., West Point, PA

Hypoxia Inducible Factors (HIFs) are transcription factors implicated in cellular processes that are key to survival, proliferation, and function, particularly for cancer cells. In the context of clear cell renal cell carcinoma (ccRCC), HIF2A is an oncogenic driver of tumor growth via up-regulation of angiogenesis (VEGFA), cell cycling (CCND1), vascularization (EPO), and metabolism (GLUT1). HIF2A can be targeted by belzutifan (MK-6482), a first-in-class HIF2A inhibitor that is FDA-approved for VHL-associated and advanced ccRCC, significantly reducing tumor burden in patients. Both HIF1A and HIF2A are expressed by all cells in the hypoxic tumor microenvironment, including infiltrating immune cells, and HIFs have previously been implicated in T cell anti-tumor effector function. Several ongoing clinical trials are evaluating MK-6482 in combination with immune checkpoint blockade therapy for advanced ccRCC, however the potential impact that MK-6482 may directly have on the adaptive immune response remains poorly understood. Considering the functional link between HIF signaling and T cell function, we explored whether HIF-2A inhibition by MK-6482 could impact activation and/or anti-tumor action of T cells supported by anti-PD-1 and anti-CTLA-4 immune checkpoint blockade. Interrogation of primary T cell activation by mixed lymphocyte reaction revealed that MK-6482 did not induce significant changes in cytokine secretion (IFNg, IL-2) or cell proliferation with or without immune checkpoint blockade, despite evidence of HIF2A protein reduction in T cells. MK-6482 combined with immune checkpoint blockade resulted in almost complete tumor regression compared to either monotherapy in a ccRCC humanized mouse model. Histological analysis of tumors revealed a significant reduction in HIF2A protein following combined treatment, potentially driving the drastic tumor regression. By multiplexed IMC analysis, we found that tumors exhibited increased infiltration of CD4+ and CD8+ T cells with elevated markers of activation, proliferation, antigen-interaction, and cytotoxicity. mRNA sequencing of tumors also revealed increased expression of T cell activation pathways, further suggesting that the combination treatment induced greater anti-tumor activity of infiltrating T cells. Together, our data support ongoing clinical evaluation of belzutifan and checkpoint blockade combination treatment for ccRCC, and we continue to explore the potential mechanistic effects by both in vivo and in vitro follow-up studies.

#2164 BAL0891 as a dual kinase inhibitor inducing anti-tumor immunity: A promising partner for immune checkpoint inhibitors.

MinKyung Kang[1], Sanghee Yoo[2], Seunghyun Ma[3]

[1]Sillajen Inc, Seoul, Korea, Republic of,[2]Qureator, Inc., San Diego, CA,[3]Medical Affair, Sillajen Bio, San Francisco, CA

BAL0891 is a first-in-class dual inhibitor targeting threonine tyrosine kinase (TTK) and polo-like kinase 1 (PLK1). These kinases collaborate to activate the mitotic spindle assembly checkpoint (SAC) at the kinetochore, ensuring proper chromosome alignment and segregation prior to mitotic exit. Dual inhibition of TTK and PLK1 by BAL0891 rapidly disrupts the SAC, leaving tumor cells insufficient time for proper chromosome segregation, thereby exerting potent anti-cancer effects. Recent studies have underscored the potential of cell cycle inhibitors, including TTK and PLK1 inhibitors, as therapeutic partners for immune checkpoint inhibitors in various cancers. Given these findings, we investigated whether BAL0891 induces anti-cancer immune responses and evaluated its potential for combination therapy with immune checkpoint inhibitors.Our results demonstrate that BAL0891 induces aberrant cell cycle progression in cancer cells, leading to elevated levels of cytosolic DNA, a well-known activator of the cGAS/STING signaling pathway. Activation of this pathway by BAL0891 promotes cellular senescence and enhances anti-tumor immunity through the secretion of pro-inflammatory cytokines and chemokines. Notably, BAL0891 treatment increases pro-inflammatory factors such as IFNβ1, CXCL10, and CXCL11. Among these, IFNβ1 plays a pivotal role in upregulating PD-L1 expression on cancer cells, potentially enhancing the efficacy of immune checkpoint inhibitors like anti-PD-1/PD-L1 agents. Furthermore, CXCL10 and CXCL11 contribute to recruiting immune cells to the tumor microenvironment, further amplifying immune responses. In an in vivo syngeneic mouse model, BAL0891 treatment increased the presence of CD4+ T cells, CD11c+ dendritic cells (DCs), and NK1.1+ NK/NKT cells, while reducing immunosuppressive populations such as regulatory T cells (CD25+ FoxP3+ CD4+) and myeloid-derived suppressor cells (Gr-1+ CD11b+) in tumors and tumor-draining lymph nodes. These results demonstrate BAL0891's potential to reshape the tumor microenvironment in favor of anti-tumor immunity.This study highlights the potential of BAL0891 as a combination partner for immune checkpoint inhibitors in cancer therapy. By dual inhibition of TTK and PLK1, BAL0891 not only exerts potent anti-cancer activity but also enhances anti-tumor immunity through activation of the cGAS/STING pathway and modulation of the tumor microenvironment. These results support further investigation of BAL0891 in preclinical and clinical studies, particularly in combination immunotherapy strategies.

#2166 PTPN1/2 dual inhibition sensitizes solid tumors to checkpoint blockade immunotherapy by enhancing T cell cytotoxicity and by decreasing cancer cell immune evasion.

Alexandre Poirier[1], Luis-Alberto Perez-Quintero[2], Erika Walback[3], Rui Su[4], Chenyue Wu[3], Michel L. Tremblay[5]

[1]Goodman Cancer Institute, McGill University, Montreal, QC, Canada,[2]Charles River Laboratories, Montreal, QC, Canada,[3]Microbiology and Immunology, McGill University, Montreal, QC, Canada,[4]Cornell University, Ithaca, NY,[5]Biochemistry, Goodman Cancer Institute, McGill University, Montreal, QC, Canada

Immunotherapy has revolutionized the way we treat patients suffering from cancer. However, many patients are still refractory to immunotherapy, which highlights the importance of identifying new genetic targets that can achieve therapeutic outcomes. Recent work has revealed that protein tyrosine phosphatase non-receptor 2 (PTPN2) can act as such a target by enhancing T-cell and interferon responses against cancer. Development of PTPN2 inhibitors paves the way for a new therapeutic modality to fight solid malignancies. However, current inhibitors also inhibit PTPN1, a closely related phosphatase with largely different biological roles. There remains limited evidence, however, whether dual inhibitors are truly optimal in terms of efficacy, safety and biological activity, or whether PTPN2 specific inhibitors should be pursued. Our aim was thus to systematically investigate the role of these two phosphatases in T-cell responses and tumor immune escape, to further refine the use of PTPN1/2 inhibitors as a therapeutic modality against cancer. We found that in CD8+ T cells, PTPN2 is the major player in limiting cytotoxic activity against cancer cells. However, PTPN2 deletion alone shows only a modest increase in cytotoxicity and is accompanied by a compensatory enhancement of PTPN1 protein levels. Additional deletion of PTPN1 in PTPN2 deficient T cells (dKO) is required for maximal cytotoxic activity and for the establishment of a distinct T cell memory subcluster capable of resisting canonical exhaustion. On the tumor side, the deletion of both phosphatases results in the synergistic augmentation of CXCL9, a potent CD8+ T cell chemoattractant. Using various cancer models, we demonstrate that cancers insensitive to checkpoint blockade are made vulnerable to immunotherapy by PTPN1/2 inhibition. Dual PTPN1/2 inhibitors achieve this effect through distinct cancer cell and T cell-specific effects that act in a complementary manner to checkpoint blockade. We are now pursuing the development of our lead PTPN1/2 inhibitor in clinical trials for the treatment of solid malignancies.

#2167 AKT inhibition enhances antitumor efficacy of radiation and immune checkpoint blockade in triple-negative breast cancer by modulating tumor-infiltrating myeloid cells.

Nawon Park[1], Seung Hyuck Jeon[2], Yoomin Kim[1], Seongmin Kim[1], In Ah Kim[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Bundang Hospital, Seoul, Korea, Republic of

Although radiotherapy (RT) and immune checkpoint blockade (ICB) are effective for treatment of triple-negative breast cancer (TNBC), significant portion of patients do not experience a clinical benefit, partly due to activation of immunosuppressive cells. Capivasertib, an AKT inhibitor, is approved for use in advanced luminal breast cancer, but its immunomodulatory role in breast cancer remains still unclear. Given the ability of PI3K/AKT/mTOR inhibition to regulate immunosuppressive myeloid cells, we hypothesized that capivasertib could enhance the efficacy of RT and ICB in TNBC. In this study, we investigated the antitumor effects and phenotypes of immune cells in 4T1 syngeneic mouse TNBC model treated with RT, dual ICB (PD-L1 and CTLA-4 blockade), and capivasertib. A dual-tumor model was used to examine abscopal effects, with one tumor receiving RT and the other remaining unirradiated. We found that the quadruple therapy (i.e. RT + anti-PD-L1 + anti-CTLA-4 + capivasertib) resulted in greatest growth delay of both irradiated (primary) and unirradiated (secondary) tumors, along with the lowest number of metastatic lung nodules. Notably, compared to the RT + anti-PD-L1 + anti-CTLA-4 treatment, the quadruple therapy significantly reduced tumor-infiltrating macrophages, with an increase in inflammatory M1 macrophages and a decrease in immunosuppressive M2 macrophages. Moreover, $CD86^+$ mature dendritic cells within tumor microenvironment were increased by addition of capivasertib to RT + anti-PD-L1 + anti-CTLA-4 treatment. These changes were not observed within the spleen and tumor-draining lymph node. Proportion and phenotypes of myeloid-derived suppressor cells (MDSCs) and T cells in tumor were not significantly changed by the quadruple therapy. These findings suggest that capivasertib, when combined with RT and ICB, led to less immunosuppressive tumor microenvironment by modulating tumor-infiltrating myeloid cells. Taken together, this combination strategy could be a viable approach to overcome therapeutic resistance of ICB in TNBC patients.
(Work supported by grants from KHIDI & AstraZeneca, and the National Research Foundation of Korea #2023R1A2C3003782)

#2168 Targeting HDAC6 to modulate the tumor microenvironment and enhance anti-PD-L1 immunotherapy in MSS colorectal cancer.

Ahran Yu[1], Jeong Eun Kang[2], Ju Yeon Park[2], Seijong Kim[2], Hye Kyung Hong[2], Yong Beom Cho[3]

[1]Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of,[2]Institute for Future Medicine, Samsung Medical Center, Seoul, Korea, Republic of,[3]Department of Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Department of Health Sciences and Technology, SAIHST, Sungkyunkwan University, Department of Biopharmaceutical Convergence, Sungkyunkwan University, Seoul, Korea, Republic of

Colon cancer is one of the most prevalent malignancies of the digestive system, characterized by high morbidity and mortality rates. Its development is driven by a complex interplay of factors within cancer cells and the tumor microenvironment (TME). Microsatellite-stable (MSS) colorectal cancer, often referred to as a “cold tumor,” is characterized by chromosomal stability and a lack of neoantigen production. As a result, MSS tumors are generally unresponsive to immunotherapy. Post-translational modifications of proteins are critical in tumor remodeling and progression. Histone deacetylase 6 (HDAC6), a member of the HDAC family, plays a key role in regulating the deacetylation of both histone and non-histone substrates. Overexpression of HDAC6 has been reported in multiple tumor types and is associated with tumor growth and metastasis. While immune checkpoint blockade (ICB) therapies, such as those targeting programmed cell death protein 1 (PD-1) and its ligand programmed cell death ligand 1 (PD-L1), have achieved clinical success in several malignancies, the majority of colorectal cancer patients particularly those with MSS tumors fail to respond to these treatments. Recent evidence indicates that the intratumoral immune context strongly influences the efficacy of ICB therapies. Patients with high levels of intratumoral CD8+ T cell infiltration, elevated tumor mutational burden (TMB), and increased PD-L1 expression within the TME are more likely to respond favorably to immunotherapy. In this study, we focused on enhancing the immunogenicity of the TME and upregulating PD-L1 expression through selective HDAC6 inhibition to improve the efficacy of anti-PD-L1 immunotherapy. Analysis of The Cancer Genome Atlas (TCGA) data revealed that HDAC6 expression is inversely correlated with several immune-related genes, including PD-L1. This inverse relationship suggests a potential role for HDAC6 in regulating immune responses in MSS colorectal cancer. These findings imply that HDAC6 may influence the TME and immune evasion mechanisms, particularly by modulating immune checkpoint molecules such as PD-L1. In the CT26 syngeneic mouse model, inhibition of HDAC6 led to an enhanced immune response characterized by increased PD-L1 expression, improved antigen presentation, and upregulation of MHC-II. This was accompanied by a polarization toward M1 macrophages and elevated levels of pro-inflammatory cytokines, including TNF-α and IFN-γ, which are crucial for T cell activation. Furthermore, HDAC6 inhibition resulted in a reduction of TGF-β, a key immunosuppressive cytokine, thereby moderating immune suppression within the tumor microenvironment. These results highlight the potential of HDAC6 inhibitors to reprogram the tumor immune landscape and sensitize MSS colorectal cancer to immune checkpoint therapies.

#2169 TTK/PLK1 dual antagonist BAL0891 synergizes with pembrolizumab in a vascularized 3D tumor microenvironment model.

Junfeng Wang[1], MinKyung Kang[2], Byungjun Lee[1], Delaney Donnelly[1], Jihye Baek[1], Bushra Rajput[1], Tsung-Li Liu[1], Hyeon-geun Park[1], Yunha Shin[1], Aneesh Sathe[1], Yangji Kim[1], Kyusuk Baek[1], Sanghee Yoo[1], Salman Ahmed[3], Jae Jung Lee[2], Seunghyun Ma[3]

[1]Qureator, Inc., San Diego, CA,[2]SillaJen, Inc., Seoul, Korea, Republic of,[3]Medical Affair, SillaJen Bio, San Francisco, CA

Introduction: BAL0891, a first-in-class dual TTK/PLK1 inhibitor, activates the cGAS/STING pathway and induces a senescence-associated secretory phenotype (SASP), resulting in increased PD-L1 expression and pro-inflammatory cytokine production in cancer cells. These changes enhance tumor susceptibility to immunotherapies. However, evaluating the synergy between BAL0891 and immune checkpoint inhibitors like pembrolizumab (PD-1 inhibitor) is challenging in traditional preclinical models, which lack human immune cells and key features of the tumor microenvironment. To address these limitations, Qureator's advanced 3D tumor microenvironment (TME) model, incorporating perfusable vessels, human primary cells, and patient-derived organoids (PDOs) was utilized. This physiologically relevant system enabled a detailed investigation of BAL0891's mechanism of action (MOA) and its combination with pembrolizumab across multiple cancer types, aiming to guide clinical trial design and patient stratification.
Methods: Vascularized TME models were developed by co-culturing endothelial cells, fibroblasts, and PDOs derived from renal cell carcinoma, triple-negative breast cancer, gastric cancer, and colorectal cancer within Qureator's Microphysiological System (MPS). Following vasculature formation, models were primed with BAL0891 for two days and then treated with PBMCs and pembrolizumab or isotype control antibodies. Tumor growth, immune infiltration, and tumor cell killing were assessed via live cell imaging and immunofluorescence staining. Post-treatment immuno-profiling included flow cytometry to analyze macrophage polarization and T cell activation/exhaustion. Multiplex secretome analysis was performed to characterize chemokine and cytokine profiles associated with BAL0891 and the combination therapy.
Results: BAL0891 priming sensitized a subset of PDOs to pembrolizumab, demonstrating synergistic anti-tumor activity in the vascularized TME model. Responsive PDOs exhibited significant organoid shrinkage, increased immune cell infiltration, enhanced T cell activation, and macrophage polarization towards an anti-tumoral phenotype. Cytokine and chemokine analysis revealed a shift to a pro-inflammatory microenvironment. Conversely, non-responders showed limited immune infiltration and minimal activation.
Conclusion: Qureator's vascularized TME model provided a robust platform to evaluate the synergy between BAL0891 and pembrolizumab. The study demonstrated BAL0891's ability to reshape the tumor immune landscape and enhance the efficacy of the immune checkpoint inhibitor. These findings offer valuable insights into the MOA of BAL0891 within this highly representative tumor model, supporting its further clinical development in combination with checkpoint inhibitors.

#2170 S100a6-Lars2 oncogenic signaling shaping immunosuppressive environment contributes to platinum-based resistance.

Yuqing Wang, Chuxia Deng

University of Macau, Macau, China

Chemotherapy-induced drug resistance is a very complex process. About 20% of cancer patients have received effective therapy with platinum (Pt) medicines, and drug resistance has since emerged through several mechanisms. To investigate the complicated heterotypic interactions between cancer cells and immune cells during the resistant tumor outgrowth processes under Pt treatment, we dissected the crosstalk signals with single-cell RNA sequencing and performed functional studies on Pt-induced drug resistance using overexpression, knockout, and DOX-inducible technologies. In this study, we have identified that: 1) S100a6-Lars2 oncogenic signaling could promote TGF-β production from tumor and immune cells and induce expressions of PD1, Tim3, and Selplg on T cells, which could contribute to resistant tumor outgrowth under Pt treatment; 2) Pt drugs could promote the survival of cancer stem cells (CSCs) with elevated hyaluronan-mediated motility receptor (Hmmr) and mTOR oncogenic pathway; 3) we validated Lars2 oncogenic action in resistant tumor outgrowth in FVB immunocompetent mice and the dynamic changes of the immune cell population; 4) combinatory treatment involving the inhibition of TGF-β signaling, the mTOR pathway, and Hmmr action, along with PD1 antibody, shows a significant effect in inhibiting tumor growth. This study advances the understanding of the mechanism of Pt drug-induced resistant tumor outgrowth, which may allow us to better manage the tumor immune microenvironment (TIME) and postpone the onset of resistance.

#2171 Amezalpat, a peroxisome proliferator-activated receptor alpha (PPARα) antagonist, inhibits suppressive macrophage development, activation and function.

Mandy I. Cheng[1], Ademola Esomojumi[2], Dara Burdette[1], Valerie Chen[1], Jorg H. Fritz[2], Sam Whiting[1], Nathan Standifer[1]

[1]Tempest Therapeutics, Brisbane, CA,[2]Microbiology and Immunology, McGill University Research Center on Complex Traits (MRCCT), Dahdaleh Institute of Genomic Medicine (DIgM), Montreal, QC, Canada

Amezalpat (TPST-1120) is a first-in-class, small molecule competitive antagonist of peroxisome proliferator-activated receptor alpha (PPARα), the master transcriptional regulator of fatty acid oxidation (FAO). Analysis of biomarker data from a previous Phase I study demonstrated amezalpat dose-dependent changes in immune genes associated with myeloid populations. Suppressive M2 macrophages are a prominent myeloid population associated with poor prognosis in many cancers. As M2 macrophages are reliant on FAO, we sought to assess the effects of amezalpat on development, activation and function of these cells. Flow cytometry analysis of M2 macrophages polarized in the presence of amezalpat displayed concentration-dependent reductions in canonical M2 macrophage markers CD163, CD206, and Arg-1 ($p<0.05$ by Wilcoxon's test). ELISA measurement of cytokine production by amezalpat-treated M2 macrophages demonstrated a statistically significant reduction in the suppressive cytokines IL-10 ($n=8$; $p<0.05$ by Wilcoxon's test) and TGF-β ($n=3$ by One-way ANOVA), suggesting amezalpat-induced functional impairment of this population. Additionally, amezalpat treatment of M2 macrophages caused significant reductions in mitochondrial mass, measured with a mitochondria-specific dye by flow cytometry ($p<0.01$ by two-sample T test). Finally, in co-cultures of M2 macrophages with autologous activated CD8+ T cells and HCC tumor cells (SNU-449), amezalpat induced tumor cell cytotoxicity and M2 cell death commensurate with cell-type specific expression levels of its target PPARα. Together, these data suggest amezalpat modulates suppressive macrophage development and function and supports the contribution of an immune-mediated mechanism to anti-tumor activity reported in clinical studies.

#2172 NLRP3 inflammasome targeting to overcome platinum and PARPi resistance by modulating cancer related inflammation in ovarian cancer.

Shaheen Mahira[1], Mackenzy Radolec[2], Philip Jones[2], Santiago Panesso[2], Siddharth Krishnan[1], Fernando Munguia[3], Sibel Yilmaz[2], Robert P. Edwards[1], Alexander B. Olawaiye[1], Haider Mahdi[1]

[1]University of Pittsburgh, Pittsburgh, PA,[2]University of Pittsburgh Medical Center, Pittsburgh, PA,[3]Augustana College, Rock Island, IL

Background: Under chronic conditions, NLRP3 inflammasome acts as instigator of pathological inflammation causing inflammation-induced carcinogenesis. Despite killing the cancer cells and being primary treatment modalities, platinum and PARPi regimen activate NLRP3 inflammasome that drives the cancer-promoting inflammatory and immunosuppressive environment and promotes inflammation-associated tumor progression ultimately contributing to resistance and therapy failure. We hypothesize that combining NLRP3 inhibitor (NLRP3i)/IL-1β inhibitor (IL-1βi) to platinum agent and PARPi can improve their anti-tumor activity by modulating inflammation associated ovarian cancer (OvCa) and overcoming resistance in pre-clinical OvCa models.
Methods: The cytotoxicity of the drugs, platinum agent (cisplatin), PARPi (olaparib), NLRP3i (MCC950) and IL-1βi (AS101) as single agent and in combination against human OvCa cells (UWB1.289.BRCA1, OVCAR-3, PEO-1 and PEO-4) was analyzed by MTT assay and drug synergism was evaluated by combination index. qPCR, flow cytometry, multiplex immunoassay and immunoblot analysis were performed in human OvCa cells co-cultured with primary human blood monocytes and the human monocytic cell line (THP-1). Statistical significance was determined by two-tailed Student's t test. $p<0.05$ were considered statistically significant.
Results: The drug combination showed synergistic enhanced anticancer activity by apoptosis induction and cancer cell proliferation inhibition. Platinum agent and PARPi was associated with upregulation of inflammasome downstream genes, IL-1β, IL-6 and CCL2 in OvCa cells indicating NLRP3 activation. There was a significant decrease in NLRP3, IL-1β, IL-6 and CCL2 levels in combination groups indicating that NLRP3 blockade can delay OvCa cell growth by alleviating immunosuppressive and inflammatory microenvironment. Combination treatment polarized M2 macrophages by downregulating M2-related markers, CCR2, ARG1, CD163 and CD206 towards the M1 phenotype by upregulating M1-related markers, iNOS, CD86 and CXCL10 suggesting that NLRP3 regulates OvCa cell function by modulating recruitment and polarization of tumor associated macrophages. Enhanced anti-tumor immunity was evidenced by increased IFN-β level in combination groups.
Conclusion: Our study evaluated the effects of inflammasome modulation on anti-tumor efficacy of platinum agent and PARPi highlighting the interconnection between inflammatory mechanisms and carcinogenesis. Targeting NLRP3 inflammasome synergized and enhanced the anti-tumor activity of platinum agent and PARPi potentially by reshaping the tumor microenvironment (TME) and increasing the anti-tumor immunity and apoptosis. Overall, NLRP3 blockade can be a novel strategy for overcoming therapy resistance and for modulating TME in OvCa.

#2173 Targeting USP7 with MEK1/2 inhibition synergizes to induce pyroptosis and enhance immunotherapy in *NRAS* mutant melanoma.

L. Su[1], D. Wang[2], T. J. Purwin[3], S. Ran[1], Q. Yang[4], Q. Zhang[2], **W. Cai**[1];

[1]Simmons Cancer Institute at Southern Illinois University, Springfield, IL, [2]University of Calgary, Calgary, AB, Canada, [3]Thomas Jefferson University, Philadelphia, PA, [4]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

Introduction: There is an urgent need for targeted therapies in metastatic melanoma patients with NRAS mutations, who comprise more than 25% of this population. This study investigates the therapeutic potential of targeting Ubiquitin-Specific Peptidase 7 (USP7) with a highly selective inhibitor, FT671, in NRAS mutant melanoma. In addition, the synergistic effects of the combination of FT671 with MEK1/2 inhibitor (MEKi) on pyroptosis induction, tumor suppression and immune activation were evaluated. Moreover, the potency of triple combination of FT671, MEKi and anti-PD-1 antibody was assessed.

Experimental Procedures: We employed a combination of genetic knockout models and pharmacological inhibition to validate the selectivity of FT671 in vitro. Cell proliferation assays were used to determine IC50s and the synergistic effects. Flow cytometry assays were performed to monitor cell cycle arrest and cell death and analyze intratumoral immune cells. Western blot assays were used to examine if the combinations markedly induced the cleavage of GSDME. A CRISPR based screen was performed to explore the mechanism of action of FT671. We also utilize isograft melanoma models in immunocompetent mice to assess tumor growth, immune cell infiltration, and therapeutic outcomes.

Results: As a validated USP7 selective inhibitor (USP7i), FT671 treatment effectively induced cell cycle arrest, reduced cell proliferation in vitro, and delayed tumor growth in NRAS mutant melanoma models in vivo. Knockout of TP53BP1, TP53 or CDKN1A conferred resistance to FT671, indicating activation of a functional p53 pathway is a major mechanism of action for the efficacy of USP7i in melanoma. The combination of FT671 with MEKi resulted in synergistic effects, and induced pyroptosis in vitro. In vivo, the combined treatment significantly suppressed tumor growth, prolonged survival, and enhanced anti-tumor immunity, evidenced by increased infiltration of $CD8^+$ T cells and mature dendritic cells in tumors. Notably, the triple therapy with FT671, MEKi, and anti-PD-1 antibody led to tumor regression and durable responses in an isograft melanoma model.

Conclusions: These findings highlight the potential of USP7 inhibition, combined with MEKi, as a promising strategy for treating NRAS mutant melanoma, an 'undruggable' target. Moreover, this combinatorial approach is able to enhance the efficacy of anti-PD-1 antibody, providing a compelling rationale for its clinical application as an adjuvant for immune checkpoint inhibitors.

#2174 Diacylglycerol kinase inhibitors in MHC-I-induced ICB-resistant triple negative breast cancer.

Jacey L. Marshall[1], Justin M. Balko[2]

[1]Vanderbilt University, Nashville, TN,[2]Department of Medicine, Vanderbilt University Medical Center, Nashville, TN

This study is designed to assess how diacylglycerol kinase alpha/zeta inhibitors (DGKis) can be used to improve response to immune checkpoint blockade (ICB) in patients with downregulated MHC-I expression. Antigen presentation by MHC-I is required for CD8 T cell-mediated tumor death and response to ICB, e.g. a-PD-1/a-PD-L1 therapy. Triple negative breast cancers (TNBC) downregulate MHC-I to suppress anti-tumor immunity and patients with decreased antigen presentation have worse outcomes to ICB. Thus, loss of MHC-I expression may be a candidate biomarker for lack of ICB response, and therapeutic strategies to overcome MHC-I downregulation are an area of high translational relevance and interest. DGKis increase T cell activation by increasing concentrations of diacylglycerol (DAG) in T cells via inhibition of the conversion of DAG into phosphatidic acid and enhancing downstream DAG signaling. This putatively amplifies T cell responses to decreased levels of antigen presentation and low-affinity stimulation in vitro and enhances response to ICB in semi-responsive models. We hypothesized that DGKis will improve response to ICB in TNBC with low MHC-I expression by improving CD8 T cell response to decreased antigen presentation. Modeling low MHC-I expression, as opposed to CRISPR-mediated total KO, presents a technical challenge. Thus, we created a novel model of MHC-I post-transcriptional downregulation, leveraging miRNA binding element mutations to titrate MHC-I expression - miSFITs. We used isogenic miSFIT cell lines in the orthotopic EMT6 model of TNBC. We observed trends of increasingly aggressive tumor growth with decreased MHC-I expression. Coordinately, when treated with a-PD-L1, there was decreasing benefit of ICB treatment with decreasing MHC-I expression (IgG v aPDL1, day 14 tumor volume, n = 10 mice/group; 100% expression p = 0.002, 60% p = 0.02, 30% p = 0.02, 10% p = 0.19, 0% p = 0.2). In the moderately a-PD-L1 responsive parental EMT6 cell line, DGKi/a-PD-L1 dual therapy further improved response through decreased tumor growth (IgG v. DGKi/a-PD-L1, p=0.0023, n=20) and doubled survival rates. However, in non-ICB responsive models of TNBC (4T1 and E0771) the same benefit of combination therapy was not observed. Treatment of the MHC-I downregulated miSFIT cell lines with DGKi + a-PD-L1 revealed a trending benefit of single agent DGKi therapy which was only slightly enhanced by the addition of a-PD-L1 therapy and did not reach significance. This is in contrast with recent in vitro findings in which decreased T cell activation in response to low levels of antigen presentation was overcome with DGKi treatment, implying further nuance in vivo that remains to be understood. Thus far, our data shows that DGKis are beneficial in deepening responses to ICB in already response-prone patients but may not extend benefit to patients who are not responsive to ICB due to highly decreased tumor-specific MHC-I levels.

#2175 Combined anti-CSF-1R and anti-TIM-3 overcome immune-mediated mechanisms of PARP inhibitor (PARPi) resistance in BRCA1-associated triple negative breast cancer.

Adam Nelson[1], Anita K. Mehta[1], Madeline G. Townsend[1], Daniel E. Michaud[1], Madisson Oliwa[1], Kelly F. Zheng[1], Carlos Wanderley[1], Patrice A. Lee[2], Nicholas A. Saccomano[2], Filipa Lynce[3], Nabihah Tayob[4], Geoffrey I. Shapiro[3], Jennifer L. Guerriero[1]

[1]Department of Surgery, Brigham and Women's Hospital, Boston, MA,[2]Pfizer, Boulder, CO,[3]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Department of Data Science, Dana-Farber Cancer Institute, Boston, MA

Background: Poly (ADP-Ribose) polymerase inhibitors (PARPi) have improved outcomes for *BRCA*-associated triple negative breast cancer (TNBC); however, resistance develops, resulting in lack of durable responses. Our previous work demonstrated that PARPi activates the cGAS/STING pathway inducing recruitment of anti-tumor CD8+ T-cells, which are required for tumor clearance. These studies led to clinical trials testing PARPi plus immune checkpoint blockade (ICB). However, clinical trials demonstrated that PARPi + ICB is not superior to PARPi monotherapy, indicating T-cells in the tumor microenvironment (TME) are inhibited. We previously showed that PARPi induce CSF-1R+ suppressive tumor associated macrophages (TAMs) that restrict anti-tumor immune responses, contributing to PARPi resistance. Removing TAMs with anti-CSF-1R therapy significantly enhanced overall survival (OS) when combined with PARPi in naïve tumors. Here, we test if targeting CSF-1R can overcome PARPi resistance and if ICB can further enhance PARPi + anti-CSF-1R therapy in both naïve and PARPi-resistant tumors.

Methods: Mice bearing naïve or PARPi resistant BRCA1-deficient TNBC (*K14-Cre;Brca1$^{f/f}$;Trp53$^{f/f}$*) tumors were treated with PARPi ± anti-CSF-1R ± ICB and followed for tumor size and OS. Flow cytometry was employed to determine alterations in TME composition.
Results: In PARPi-resistant tumors, TAMs expressed higher levels of CSF-1R and PD-L1 and lower levels of antigen presentation machinery compared to PARPi-naïve tumors, indicating increased immunosuppression. Additionally, in PARPi-resistant tumors, CD4+ and CD8+ T-cells expressed higher levels of PD-1 compared to naïve tumors, indicating increased exhaustion. PARPi + anti-CSF-1R therapy significantly restored PARPi efficacy and increased overall survival in PARPi-resistant tumors. The combination of PARPi + anti-CSF-1R + anti-TIM-3 significantly increased OS in PARPi-resistant tumors, whereas combination of PARPi + anti-CSF-1R + anti-CTLA-4 did not improve therapy efficacy. While the combination of PARPi + anti-CSF-1R with anti-PD-1 improved therapy in PARPi-naïve tumors, it did not improve responses in PARPi-resistant tumors. PARPi + CSF-1R + anti-TIM-3 significantly increased CD8+ T-cell infiltration and granzyme B production indicating an increased anti-tumor immune response. Additionally, anti-TIM-3 increased TRAIL production by TAMs indicating a more pro-inflammatory phenotype.
Conclusion: We demonstrate that PARPi-resistant tumors have increased T-cell exhaustion and infiltration of immunosuppressive TAMs. Importantly, our data show that targeting TAMs can overcome acquired PARPi resistance, which select ICB can further enhance defining a novel strategy addressing a critical unmet medical need for PARPi-treated patients with BRCA-associated breast cancer.

#2176 Tumor treating fields (TTFields) together with gemcitabine and nab-paclitaxel (Gem/NabP) are effective against pancreatic ductal adenocarcinoma (PDAC), in vitro and in vivo.

Tal Kan, Tharwat Haj Khalil, Yiftah Barsheshet, **Tali Voloshin**, Avital Vorontsov, Boris Brant, Simona Zisman-Rozen, Lilach Koren, Roni Blatt, Shay Cahal, Catherine Tempel Brami, Sara Jacobovitch, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti

Novocure Ltd, Haifa, Israel

Background: Tumor treating fields (TTFields) are a cancer therapy, approved for the treatment of glioblastoma, pleural mesothelioma, and non-small cell lung cancer (NSCLC). The efficacy and safety of TTFields concomitant with standard-of-care gemcitabine and nab-paclitaxel (Gem/NabP) are currently being tested in a phase 3 trial as front-line treatment for locally advanced pancreatic ductal adenocarcinoma (PDAC). TTFields are electric fields that disrupt critical cellular processes and induce immunogenic cell death (ICD) in cancer cells. They have also been shown to elicit a systemic anti-cancer immune response in animal models and to provide clinical benefit in patients with NSCLC when applied together with immune checkpoint inhibitors (ICI). The current study aimed to investigate the involvement of a TTFields-induced immune response in PDAC and the therapeutic potential of applying TTFields together with standard-of-care chemotherapies in preclinical models.
Methods: Human BxPC-3 and AsPC-1, and mouse Panc02 (with stable luciferase expression) pancreatic cancer cells were treated with TTFields (150 kHz, 1.62 V/cm RMS) and examined for induction of apoptosis and ICD. The markers used to test ICD included ATP secretion, calreticulin surface exposure, and CD47expression. Panc02 cells were inoculated orthotopically into immunocompetent C57Bl/6 mice. The mice were randomized into four groups: control, TTFields, Gem/NabP, and Gem/NabP + TTFields. TTFields were applied continuously for 10 days, and the drugs were injected i.p. once a week for a total of two administrations at a concentration of 50 mg/kg for each drug. At the end of the treatment, tumor volume was measured using a caliper, after which the tumor was processed as a single-cell suspension for flow cytometry-based immunophenotyping. Blood was collected for immunophenotyping and examination of circulating levels of the ICD marker high mobility group box 1 protein (HMGB1).
Results: TTFields application induced apoptosis and elicited ICD in all tested pancreatic cell lines. The latter was identified by ATP depletion, increased calreticulin surface exposure, and decreased CD47 expression. In vivo, TTFields concomitant with Gem/NabP significantly reduced tumor volume compared to all other treatment groups. TTFields treatment elevated the levels of HMGB1 and of effector CD8+ T cells in the peripheral blood.
Conclusions: TTFields induce ICD and an antitumor immune response in PDAC and enhance the efficacy of standard-of-care chemotherapy for the treatment of PDAC in preclinical models. A phase 2 study evaluating the potential efficacy of TTFields together with Gem/NabP and ICI in metastatic PDAC is underway.

IMMUNOLOGY: Local and Systemic Immunity against Cancer: New Analytic and Prognostic Tools
Poster Session

#2177 Spatial transcriptomic and functional analysis of HLA/PD-1/CTLA4 multi-gene edited CD19 CAR-iNK cells targeting pericytes in the glioblastoma tumor microenvironment to inhibit tumor migration and growth.

Kyung-Sun Kang

Seoul National University, Seoul, Korea, Republic of

Targeting glioblastoma (GBM) stem cell-derived pericytes in the perivascular niche offers a promising strategy to overcome intratumoral heterogeneity and inhibit tumor migration. By targeting CD19-positive pericytes, CD19 chimeric antigen receptor (CAR)-expressing natural killer (NK) cells can mitigate off-tumor toxicity; however, their interactions within the GBM tumor microenvironment (TME) require further investigation. In this study, we developed a GBM TME xenograft model by transplanting GBM-blood vessel assembloids (GBVA) into immunodeficient mice to study the effects of CD19 CAR-expressing iPSC-derived NK (CAR-iNK) cells on pericytes and their interactions within the TME. Additionally, we enhanced the efficacy of CD19 CAR-iNK cells by knocking out PD1 and CTLA4, enabling these cells to better target GBM within an immunosuppressive TME. As a result, GBVA xenografts recapitulated the GBM TME including human pericytes and macrophages, providing a robust in vivo platform for validating CD19 CAR-iNK cell efficacy against GBM. Optimization of CAR-iNK cell dosing and efficacy resulted in significant antitumor effects. Spatial transcriptome analysis using SLACS (Spatially Linked Antibody and cDNA Sequencing) revealed that CD19 CAR-iNK cell infiltration altered gene expression in the TME, elucidating mechanisms of GBM lysis, migration inhibition, and evasion of immunosuppressive influences. These findings underscore the therapeutic potential of CD19 CAR-iNK cells for GBM treatment through precise targeting of pericytes and modulation of the TME.

#2178 Multimodal analysis of the PDAC tumor microenvironment in response to radiation and immunotherapy reveals insights into treatment resistance.

Sarah Kang[1], Aparna R. Parikh[2], Milan Parikh[1], Julie L. Koenig[2], Leon Pappas[2], Moshe Sade-Feldman[1], Lynn Bi[1], Nicole Carzo[2], Tarin M. Grillo[2], Islam Baiev[2], Olanike Asupoto[3], Irena Gushterova[2], Tom LaSalle[2], Anna Gonye[2], David P. Ryan[2], David T. Ting[2], Dana Pe'er[4], Theodore S. Hong[2], Nir Hacohen[1], Ryan J. Park[5], Arnav Mehta[1]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]Massachusetts General Hospital, Boston, MA,[3]Dana Farber Cancer Institute, Boston, MA,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]MD Anderson Cancer Center, Houston, TX

Pancreatic ductal adenocarcinoma (PDAC) is a deadly disease with few treatment options and poor prognosis. Immunotherapy is effective in other cancers but shows worse outcomes in PDAC due to a desmoplastic stroma, an abundance of immunosuppressive cells, and a lack of antigen-presenting dendritic cells, which result in low immune infiltration. We previously reported a study combining dual immune checkpoint blockade (ICB) and radiation therapy in metastatic PDAC patients who progressed on at least one line of chemotherapy and showed an 18% overall response rate (ORR) and 29% disease control rate (DCR). Here, we performed a follow-up phase 2 study on previously treated PDAC patients and observed 3.6% ORR, 10.7% DCR, 2.3 months median progression-free survival, and one complete response. To uncover mechanisms of treatment resistance, we profiled 33 samples from 23 patients with 13 paired pre and on treatment biopsies across distinct tissue sites including liver metastases and primary pancreas. Using single nucleus sequencing (>240k cells), single-cell RNA sequencing (>160k cells) with TCR (scTCR) sequencing (>25k cells), and Visium spatial transcriptomics of a subset of samples (n=15), we comprehensively characterized the cell states and gene programs in the TME of metastatic PDAC prior to and after radiation and ICB. Post radiation, tumor cells were enriched for classical states, exhausted CD8 and proliferating T cells were expanded, and interferon-related programs were upregulated in epithelial subtypes, C1QC+ and MHCII+ macrophages, and CD14+/CD16+ monocytes, suggesting cell type-specific responses to treatment. Expanded T cell clonotypes showed phenotypic shifts toward CD8 exhausted and cytotoxic activated states. Using a published gene signature, we identified tumor-reactive T cells, which correlated with known proxies for tumor reactivity including CXCL13 expression. Only 2.2% of T cells were tumor-reactive, and 71% of these came from the single patient who displayed complete response to treatment. Moreover, bulk TCR sequencing of serial peripheral blood samples showed long-term persistence of tumor-reactive clonotypes in this patient over a year post-treatment. Spatial transcriptomics demonstrated co-localization of CXCL13+ T cell, dendritic cell, and inflammatory chemokine gene programs, and separate co-localization of macrophage, CCL8+ CAF, Th17/Tc17, Class II MHC antigen presentation, and interferon stimulated gene programs. Together, our multimodal dataset offers valuable insight into radiation and immunotherapy-induced shifts in the TME.

#2179 Multiomic co-detection of proteins, mRNA and protein-protein interactions reveal PD1-PDL1 interactions in the tumor microenvironment of bladder cancer patients treated with anti-PD-L1.

Ge-Ah Kim[1], Sonali A. Deshpande[1], Li-Chong Wang[1], Julia Yu[1], Hamidreza Sepasizangabadi[1], Ji Zhang[1], Jason Au[1], Kathryn Allaire[2], Junyan He[2], Maithreyan Srinivasan[1], David Y. Oh[2], Lawrence Fong[3]

[1]Advanced Cell Diagnostics, a Bio-Techne brand, Newark, CA,[2]Division of Hematology/Oncology, Department of Medicine, University of California, San Francisco, San Francisco, CA,[3]Immunotherapy Integrated Research Center, Fred Hutchinson Cancer Center, Seattle, WA

Protein-protein interaction (PPI) is one of the mechanisms where individual cells communicate with nearby cells or the extracellular matrix through autocrine, juxtacrine and paracrine mechanisms. The network of interactions and the underlying stoichiometry both within a tissue and with the immune repertoire is adversely impacted in many diseases, including cancer. While screening technologies to predict and map the protein interactome are advancing our understanding of intercellular/intracellular protein-protein interactions (PPIs), no orthogonal technologies exist that can validate inferred PPIs in the context of known mRNA/protein markers. To address this need, we have developed a technology that uses modifications to RNAscope^{TM} - a validation technology known for its high sensitivity and specificity - to visualize PPIs, proteins, and mRNA *in situ* on a single tissue section. Oligonucleotides that bind RNAscope signal generation complexes were conjugated to antibodies and protein targets were visualized *in situ* along with PPIs/mRNAs using a fully automated, protease-free RNAscope Multiomic LS workflow on a BOND RX instrument followed by whole slide scanning and analysis. The assay, which interrogate one PPI and any combination of up to 5 mRNA and protein targets, was deployed on samples from patients with localized, muscle-invasive bladder cancer who received neoadjuvant anti-PD-L1 checkpoint inhibitor therapy prior to planned surgical cystectomy on a clinical trial (NCT02451423). To characterize tumor immune microenvironment of these patients, both responders and non-responders to the treatment, PD-1/PD-L1 interactions were assessed using a panel of targets to include cell phenotyping protein markers for both immune and tumor cells (CD3, CD4, CD8, FoxP3, and PanCK) and mRNA markers for effector molecules (*IFNG*, *GZMB*, *GZMK*). We visualized PD-1/PD-L1 interactions, and changes in cellular interactions between cytotoxic CD8+ T cells or regulatory CD4+ T cells and CK+ tumor cells before and after immunotherapy treatment. We will present data to illustrate the novelty of the assay as well as secondary analysis to characterize the importance of PPIs for more granular dissection of immune modulation in the tumor microenvironment.

#2180 Utilization of multiparameter flow cytometry for immune monitoring of tumor infiltrating lymphocytes isolated from fresh tumor tissue.

Rachel Owen, Angelina Bisconte, Deborah Phippard

Precision for Medicine, Frederick, MD

A multiparameter flow cytometry panel was designed to assess immune populations infiltrating solid tumors. Obtaining viable immune cells from fresh tissue for analysis can be challenging, however, using optimized shipping conditions and isolation procedures developed by Precision for Medicine (PfM) for fresh solid tumor biopsy pieces or fine needle aspirates, a variety of solid tumor indications, including melanoma, colorectal adenocarcinoma, sarcoma, triple negative breast cancer, renal cancer, head & neck cancer, lung cancer and stomach cancer, were analyzed by flow cytometry. Following overnight shipment from collection sites to PfM's laboratory, a real time sample processing procedure using a mechanical dissociation protocol followed by multiparametric flow cytometric analysis was performed. Post dissociation of tumor samples, cell viabilities ranged between 50-90%, and the sample quality was sufficient for flow cytometric analysis of tumor infiltrating lymphocytes (TILs). This analysis revealed that the frequency and phenotype of infiltrating immune cells could be assessed successfully. It was observed that variations in the frequency and phenotype of infiltrating cells were present in the tumor tissues. This study shows that real time multiparametric flow cytometric analysis of fresh tumor tissues, within 48 hours of collection, can be implemented in clinical trials with careful planning and consideration of clinical operations. This is of value for early phase clinical studies evaluating the impact of immune therapies on immune cell infiltration within solid tumors, and provides an additional immune monitoring tool.

#2181 Establishing a multi-modal, cell therapy characterization workflow to identify cell subsets with heightened cytotoxicity.

Richard Yau[1], Shreya Deshmukh[1], JangKeun Kim[2], Jiwoon Park[2], **Yanping Yang**[3], Makenzie Sacca[1], Shan Sabri[1], Teresa Ai[1], Pier Federico Gherardini[1], Gary Schroth[1], Christopher E. Mason[2], Moonsoo M. Jin[3]

[1]Cellanome, Inc., Foster City, CA,[2]Weill Cornell Medicine, New York, NY,[3]Houston Methodist Research Institute, Houston, TX

Cell therapies have been groundbreaking for B-cell lymphomas but optimizing efficacy for solid tumors remains challenging. Lack of consensus on potency measures, unknowns about novel engineering strategies, and product heterogeneity drive extensive characterization to discover product-specific mechanisms of action (MoAs). This process is costly and limited by variable results from simple molecular assays and need to infer relationships between data from disparate technologies. Thus, we created a multi-modal technology with which to establish a multi-functional, longitudinal cellular characterization workflow. With a single sample input, this workflow evaluates multiple live phenotypes from the same individual cells across tens of thousands of cells at once. We leveraged TALL-104 cells before validating compatibility with clinical-stage cell therapies with AIC100 - a Phase 1 CAR-T product targeting thyroid cancer (NCT04420754). Cellanome's technology enables multi-modal evaluation of live, cellular behavior at the resolution of single cells or single-cell interactions. Within an 8-lane flow cell, tens of thousands of single TALL-104 cells were enclosed with K562 target cells in bio-compatible hydrogel compartments called CellCage™ enclosures (CCEs). These CCEs enable longitudinal monitoring of single TALL-104 cells interacting with K562 cells for hours to days with time-lapse imaging. During this period, imaging-based evaluation of surface markers, cytokine secretion, and cytotoxicity are integrated from the same single T-cells. Our analysis pipeline links target cell death to single T cells in CCEs, enabling cell killing to be studied with unprecedented resolution. Similar to flow cytometry via CD107 as a surrogate for killing, with Cellanome's technology, we could identify cytotoxic T cells (~85%). Uniquely, we can directly evaluate killing by single TALL-104 cells and further segment them into groups. Group 1 consists of strong killers (killing 100% of targets), Group 2 of medium killers (50-99%), and Group 3 of weaker killers (0-49%). We next characterized single AIC100 cells enclosed with HeLa as targets and observed that, unlike TALL-104 cells where Group 2 was the largest, for AIC100, Group 3 was the largest, suggesting distinct killing mechanisms. Thus, we asked whether AIC100's heterogeneous composition of CD4 / 8 cells impacts product efficacy. We configured this workflow to test killing by ~100 combinations of CD4:CD8 AIC100 cells in a single experiment. Preliminarily, more killing occurred in CCEs containing a mixture of CD4 and CD8 T cells relative to CCEs containing only CD4 or CD8 cells. We are continuing to identify the optimal CD4:CD8 compositions for greater potency. We envision multi-modal characterization of clinical products with our platform, pre and post-patient infusion, will inform efforts to advance cell therapies for solid tumors.

#2182 Optimizing immunolabeling strategies in preparation for magnetic activated cell sorting for chimeric antigen receptor-natural killer and multiple myeloma cells.

Kaitlyn Bali[1], Yukiko Higa[2], Long Huynh[2], Lei Tian[3], Jianhua Yu[3], Nicholas Graham[2]

[1]Rosalind Franklin University of Medicine and Science, North Chicago, IL,[2]Mork Family Department of Chemical Engineering and Materials Science, University of Southern California, Los Angeles, CA,[3]Division of Hematology/Oncology, Department of Medicine, School of Medicine, University of California, Irvine, Irvine, CA

Chimeric antigen receptor (CAR) natural killer (NK) cells are of increased interest compared to CAR-T cell therapy because CAR-NK cells can circumvent the challenges of graft-versus-host disease, serve as an off-the-shelf therapy, and avoid the neurotoxic side effects and cytokine release syndrome that accompany CAR-T cell immunotherapy. However, CARs are currently optimized for use in T cells and are not optimized for NK cell mechanisms. There are currently no comprehensive studies that characterize CAR-NK cellular pathways for CAR-NK optimization. In preparation for a comprehensive CAR-NK phospho-proteomic pathway analysis, we evaluated strategies for magnetic-activated cell sorting (MACS) to isolate CAR-NK cells prior to phospho-proteomics including alternating formalin fixation and immunolabeling.

To identify the most optimal immunolabeling strategy, NK cells transduced with a viral construct that included a truncated CD34 component (tCD34) were tested for an ability to optimally bind Human CD34 Biotinylated Antibody followed by Streptavidin-Allophycocyanin (SAv-APC) with varying formalin fixation sequences. Cells were either formalin fixed before antibody and SAv-APC labeling, after antibody and SAv-APC labeling, or after antibody and before SAv-APC labeling. Human CD34 APC-conjugated Antibodies, NK cells without tCD34, and OPM-2 multiple myeloma cells were used as controls for understanding SAv-APC background binding. Lastly, CAR-NK and control NK cell labeling effectiveness was also tested against the cells' incubation periods.

There were no consistent notable differences in CAR-NK labeling efficiency with alternating fixation and immunolabeling patterns. However, increased labeling was consistently found in unfixed samples. Formalin fixation also leads to unintentional background binding as demonstrated by labeled control NK and OPM-2 cell numbers. Furthermore, incubation time for CAR-NK cell samples proves advantageous in labeling CAR-NK cells irrespective of fixation and staining patterns. By analyzing control NK and CAR-NK samples over four weeks, we found that control NK cells were dying at a faster rate while CAR-NK cells remained at a consistently high viability. This increased death rate of the control NKs in the CAR-NK samples allowed for a greater proportion of CAR-NK detection with reduced noise from background control NK binding.

Formalin fixation poses a challenge for optimal CAR-NK labeling due to background binding and a decrease in labeling levels when compared to non-fixed samples. However, incubation time of CAR-NK cells can potentially circumvent these difficulties and serve as a tool for cell sample preparation due to biological differences in CAR-NK and control NK proliferation. This can be a novel strategy for optimizing MACS for phosphoproteomic analysis of CAR-NK cells.

#2183 *DNAH* mutations as a potential biomarker for immune checkpoint inhibitor response and survival.

S. Wang, **H. Tang**, X. Wu, Q. Ou;
Nanjing Geneseeq Technology Inc., Nanjing, China

Introduction: The integration of immune checkpoint inhibitors (ICIs) with precision medicine offers a promising avenue for personalized therapies through the identification of biomarkers that predict clinical response and prognosis. However, existing biomarkers have shown limited predictive power, underscoring the need for continued research.

Methods: We analyzed whole-exome sequencing data from 342 melanoma patients treated with ICIs to identify genetic determinants of ICI response and survival. Two external cohorts were used to validate findings and explore underlying mechanisms: a non-small cell lung cancer cohort (N=91) and The Cancer Genomic Atlas pan-cancer cohort (N=942).

Results: Responders, defined as patients who achieved a complete or partial response to ICIs, were more likely to have received anti-PD-1 therapy compared to anti-CTLA-4 and had higher tumor mutation burden (both $P<0.001$). All 13 dynein axonemal heavy chain (*DNAH*) family genes were detected, with *DNAH2* ($P=0.03$), *DNAH6* ($P<0.001$), and *DNAH9* ($P<0.01$) more prevalent in responders. Five *DNAH* mutations were markedly associated with overall survival (OS), including *DNAH2* (hazard ratio [HR]: 0.66; 95% confidence interval [CI]: 0.44-0.98; $P=0.039$), *DNAH6* (HR: 0.48; 95% CI: 0.32-0.73; $P<0.001$), *DNAH9* (HR: 0.64; 95% CI: 0.46-0.90; $P=0.009$), *DNAH5* (HR: 0.67; 95% CI: 0.51-0.90; $P=0.006$), and *DNAH12* (HR: 0.57; 95% CI: 0.36-0.92; $P=0.019$). Only *DNAH6* mutations were associated with longer progression-free survival (PFS) (HR: 0.54; 95% CI: 0.36-0.80; $P=0.002$). Notably, *DNAH2*, *DNAH6*, and *DNAH9* mutations (collectively referred to as *DNAH*-altered) were more frequent in responders and significantly associated with longer PFS (HR: 0.69; 95% CI: 0.51-0.92; $P=0.013$) and OS (HR: 0.58; 95% CI: 0.43-0.78; $P<0.001$). These prognostic associations were consistently observed in the validation cohort (HR: 0.28; 95% CI: 0.12-0.61; $P<0.001$). Multivariate analysis identified *DNAH* mutations as the most significant predictor of improved OS (HR: 0.56; 95% CI: 0.42-0.76; $P<0.001$), independent of sex, distant metastases, treatment regimen, and *BRAF* V600E mutations. Functional analysis showed upregulation of chemokine signaling, cytokine-cytokine receptor interaction, cell cycle regulation, and p53 signaling in *DNAH*-altered melanomas, which were independently validated in the TCGA cohort. Immune-related signatures, including those implicated in interferon signaling, cytolytic activity, T-cell function, and immune checkpoint regulation, were also enriched in *DNAH*-altered tumors.

Conclusions: This study is the first to identify *DNAH* mutations as a potential biomarker for predicting ICI response and patient survival. These findings, initially observed in melanoma, may have broader implications for guiding personalized immunotherapy in other cancers.

#2184 Dynamics between germline immune checkpoint variants and susceptibility for cancer and autoimmunity.

Zade Akras[1], Benjamin M. Neale[1], Nina Mars[2]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]University of Helsinki, Helsinki, Finland

Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of cancer and are approved for a wide range of malignancies. ICIs block the interactions of checkpoint proteins that limit T cell-mediated immune responses, thereby boosting cytotoxic activity against cancers. The most widely used ICIs act through CTLA-4, PD-1, or PD-L1 pathway blockade, and numerous agents are at various stages of development. Due to increased T cell activity, ICIs are associated with immune-related adverse events, and little is known about their long-term impacts. Individual-level genetic variation mimics the effects that are seen with larger magnitude when the same pathways are perturbed through checkpoint modulation. Leveraging large-scale biobanks with genomics data, proteomics data, and rich health registries can enable us to understand the broad impacts of checkpoint modulation on adverse events and its potential for treatment of common diseases. We utilize FinnGen, a biobank study of 520,210 Finnish individuals, to investigate germline variants affecting immune checkpoint proteins and their associations with cancer and autoimmunity. The Finnish population, being a genetic isolate, has an unusual enrichment of disease-associated variants compared to many other ancestry groups, enabling variant-disease associations not detectable in many other populations. Using phenome-wide association analysis, we identify several coding variants in checkpoint protein-encoding genes with opposite associations to autoimmune diseases and cancer or other tumors. Such associations are supported by Olink proteomic quantitative trait loci for respective proteins (*cis*-pQTLs). For example, rs149722682 (*LAG3* missense variant; 440x enriched in Finns) is protective of colon adenomas (OR 0.26, $p=8.4x10^{-5}$) but increases the risk of asthma (OR 1.5, $p=1.1x10^{-4}$) and hypothyroidism (OR 1.9, $p=1.7x10^{-9}$). We also identify multiple variants with associations to a range of conditions beyond classical autoimmune diseases, pointing to potentially new or rare adverse events of ICIs. For instance, rs781221749 (*LAG3* missense; 2x enrichment) increases the risk of manic episode (OR 23.3, $p=1.6x10^{-4}$) and COVID-19 infection (OR 4.9, $p=1.2x10^{-4}$). Finally, we develop checkpoint protein-specific genome-wide polygenic risk scores to quantify the cumulative impacts of *cis* and *trans* checkpoint protein-associated variants on different cancer- and autoimmune-related endpoints. Our findings offer insight into the short- and long-term toxicities associated with checkpoint inhibition and provide a framework for detecting common and rare adverse events in current and emerging therapies.

#2185 Advancing macrophage-directed therapies: bioluminescent assays for macrophage effector function.

Jonathan Mitchell, Denise Garvin, Rich Moravec, Julia Gilden, **Adityarup Chakravorty**, Jim Hartnett, Pete Stecha, Mei Cong, Jamison Grailer

Promega, Madison, WI

Macrophages play a pivotal role in anti-cancer immunity through phagocytosis and presentation of tumor antigens to T cells. Antibody-dependent cellular phagocytosis (ADCP), mediated by macrophages and other myeloid cells, is a key mechanism-of-action (MoA) for antibody-based cancer immunotherapies. Strategies that enhance ADCP and other macrophage effector functions not only promote direct tumor destruction but also facilitate broader anti-tumor immunity. ADCP is initiated by the binding of antibody Fc domains to Fc gamma receptors (FcγRs), which triggers receptor crosslinking and signal transduction, leading to inflammatory cytokine production and phagocytosis. These effector functions are further regulated by immune checkpoints, and therapeutic interventions that block inhibitory checkpoints (e.g., SIRPα, ILT4, ILT2) or activate stimulatory pathways (e.g., TLR signaling) can enhance macrophage activity. However, current methods to measure macrophage functions are often low-throughput, labor-intensive, and highly variable. To address these challenges, we developed a suite of robust, cell-based bioluminescent bioassays to assess macrophage effector functions. These include: **1) ADCP**: Using monocytic cells with endogenous FcγR expression and a FcγR-activation-dependent luminescent reporter. **2) Direct Phagocytosis Detection**: Utilizing the HiBiT split luciferase system for sensitive and quantitative measurements. **3) Immune Checkpoint Modulation**: Bioassays to measure SIRPα/CD47, ILT2/HLA-G, and ILT4/HLA-G interactions. **4) TLR Activation**: Reporter bioassays for TLR activation. These assays are robust, easy-to-use, and pre-qualified according to ICH guidelines. Together, this comprehensive toolbox enables screening and the accelerated development of immunotherapies that target macrophage effector functions, paving the way for innovative cancer treatment strategies.

#2186 Deciphering the regulation and function of lipid associated macrophages in immunotherapy resistance of hepatocellular carcinoma.

Xiaohang Long[1], Stephen Lam Chan[2], Siyuan Huang[1], Joaquim Si Long Vong[1], Xiaoyu Zhan[1], Yalin Tu[1], Joseph, JY Sung[1], Alfred Sze Lok Cheng[1]

[1]School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Department of Clinical Oncology, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: Hepatocellular carcinoma (HCC) is a significant global health concern, ranking as the sixth leading cause of cancer-related deaths worldwide. While immune-checkpoint blockade (ICB) has revolutionized cancer treatment, its effectiveness is limited by the immunosuppressive tumor microenvironment (TME) and the diverse etiologies of HCC, resulting in response rates below 30%. We have previously identified key transcriptional and epigenetic regulators that promote immune exclusion and myeloid-mediated immunosuppression underlying ICB resistance in preclinical models (*Gut* 2018, 2020, 2023, *Sci Transl Med* 2021). Identifying the central nodes of TME landscapes from ICB-resistant patients is instrumental for developing precise immunotherapy strategies and improving clinical outcomes.
Methods: We performed single-cell RNA sequencing (scRNA-seq), single-cell Assay for Transposase-Accessible Chromatin using sequencing (scATAC-seq), and spatial transcriptomics to investigate the TME of HCC patients resistant to ICBs (NCT05873244) and treatment naïve-patients as controls.
Results:Our multi-omics analysis revealed a subcluster of tumor-associated macrophages (TAMs) that express high levels of lipid-associated genes. In our syngeneic and orthotopic ICB-resistant mouse models, which recapitulate human immune-excluded HCCs, we also found a subset of lipid-associated macrophages (LAMs) is enriched in concordance with the clinical data. Bioinformatics analysis of the open chromatin regions uncovered a transcription factor (TF) that is significantly up-regulated in the TAMs in ICB-resistant HCCs compared to the treatment-naïve tumors. Moreover, chromatin immunoprecipitation-sequencing showed that this TF occupancy in THP-1 cells was enriched in phagocytosis.
Conclusions: Our study provides insights into how this TF drives macrophage lipid phagocytosis to promote ICB resistance of HCC. This investigation elucidates the underlying epigenetic and transcriptional changes and identifies potential therapeutic targets for ICB resistance. Our findings may offer valuable insights into the molecular dysregulation of TAM within the immunosuppressive myeloid landscape, forming the basis for developing new strategies against the immunometabolic axis to avert ICB resistance.
Acknowledgment: This study is supported by the General Research Fund (14120621 and 14119023) and the Li Ka Shing Foundation.

#2187 Functional classification of tumor-associated macrophages and changes in TAM subpopulations in response to various immunotherapies.

Bryan T. Weselman, Satish K. R. Noonepalle, Manasa Suresh, Marie Durr, Nithya Gajendran, Alejandro Villagra, Xintang Li

Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Despite single-cell omics ushering in many attempts at reclassifying tumor-associated macrophages (TAMs), there remains a lack of a consensus for a widely applicable model that accurately describes their biological functions. Based on single-cell RNA seq data from both mouse and human melanoma tumors, we propose a new model for categorizing TAMs by their function in the tumor microenvironment (TME). We identified eight clusters with various functions including a distinct population of proliferating macrophages with tissue-resident characteristics. Samples from mice with SM1 melanoma tumors that have been treated with α-PD-1 immune checkpoint blockade, the novel HDAC6 inhibitor SS208, combination SS208 + α-PD-1, and adoptive cell therapy (ACT) using HDAC6 inhibition show changes in the proportions of putative subpopulations, most notably a significant decrease in “Pro-Angiogenic/Arginine Metabolism” macrophages within tumors after all treatments, an increase in “Antigen Presenting/Phagocytosis” macrophages in mice treated with α-PD-1 therapy, and an increase in proliferating macrophages in mice treated with ACT. We also identified heterogeneity in the expression of certain markers historically categorized as “M1” or “M2,” indicating that using specific markers interchangeably may be inaccurate in measuring different subpopulations within the tumor. In an attempt to move away from artificial polarization of macrophages *in vitro* via cytokines, TAMs were cultured in tumor-conditioned media and M-CSF to more accurately retain TME phenotype. The proposed functions of these subpopulations have been further confirmed by *in vitro* and *ex vivo* functional assays from isolated TAMs. Additionally, we outline an efficient method for applying the proposed subpopulation gene signature to bulk RNA seq data of macrophages, which allows for more accurate analysis of changes in TAM subpopulation in response to therapy.

#2188 Enabling sensitivity, repeatability and reproducibility required for immuno-oncology research on the CyTOF XT Pro mass cytometer.

Stephen Li, Rita Straus, Michael Sullivan, Andrea McEwan, **Ling Wang**, Christina Loh, Alexander Loboda

Standard BioTools, Markham, ON, Canada

Understanding the functional phenotype of immune cells from patients with cancer is critical for identifying mechanism of action, determining disease prognoses and monitoring the clinical efficacy of immunotherapies. The ability to reproducibly identify functional markers with low expression and use functional markers to identify rare cell populations can be challenging with fluorescence flow cytometry due to spectral spillover and autofluorescence. Mass cytometry overcomes many challenges of fluorescence-based cytometry, as low signal spillover and the absence of autofluorescence negate the need for spectral compensation and unmixing. To minimize technical variation, metal-tagged antibody cocktails and stained samples can be frozen for later use and acquisition. Antibody panels that detect both surface and intracellular markers can be rapidly designed, conveniently stained and acquired in a single tube to provide streamlined workflows with high consistency. In this study, human whole blood and PBMC samples were stained with antibody panels containing up to 50 surface and cytoplasmic targets. Stained samples were frozen and acquired on a later date using CyTOF™ XT PRO and CyTOF XT systems to assess repeatability and reproducibility, and to ensure data quality was not compromised when samples were acquired at 4x speed with the CyTOF XT PRO system. Population frequencies and resolution indices for markers were assessed by manual gating. There was no significant difference between population frequencies analyzed between the two CyTOF systems. Both the CyTOF XT and CyTOF XT PRO system had high sensitivity and dynamic range for both abundant and low-abundance markers. The cell population frequency and staining intensity results generated from the CyTOF XT and CyTOF XT PRO system were highly repeatable and reproducible across multiple instruments. Overall, these studies find that the CyTOF XT PRO system generates comparable signal resolution to the CyTOF XT system with up to 4x increased event-rate acquisition. Automated acquisition by the CyTOF XT PRO system enables researchers to accurately and reproducibly streamline human immunophenotyping and functional profiling, leading to accelerated discoveries.

#2189 A spectral flow cytometry panel and workflow for the reproducible assessment of colorectral tumor immunophenotype in the context of immunotherapies.

Joseph P. Kolb, Kathryn R. Meshaw, Timothy Hutchinson, Karsten Fynboe, Jacob Hauser, William D. Culp, Beth A. Hollister

Powered Research, LLC, Durham, NC

Multiparameter flow cytometry analysis of immune cells within solid tumors has provided insight into the mechanism of action of novel immunotherapies, but challenges exist regarding the interpretation of data stemming from variation in sample processing, selection of optimal combinations of fluorochrome-conjugated antibodies, and population gating strategy. Here we present a 20-color spectral flow cytometry backbone panel and gating scheme that can be applied to syngeneic colorectal tumor samples from different mouse strains with minimal manual adjustment. Using the CT26 and MC38 subcutaneous implant models in BALB/c and C57BL/6 mice, respectively, we tested the ability of our panel and workflow to identify changes in tumor immune cell populations after treatment with the immune checkpoint inhibitors (ICIs) anti-PD-1 and/or anti-CTLA-4 in two independent experiments. Our panel identified differences between the models, largely confined to protein surface expression within the monocyte, macrophage, and dendritic cell compartments. In addition, the panel provided readouts of T cell and NK cell function that correlated with ICI efficacy and with increases in tumor cytokines, including IFNγ, CXCL10, and CCL5, without the need for lengthy *ex vivo* stimulation and intracellular cytokine staining. The use of autofluorescence extraction and the designation of autofluorescence tags, which is possible on spectral flow cytometers, was essential to properly identify populations. We demonstrate the ability of modern spectral flow cytometers to produce remarkably consistent data over time, without the need for manual detector gain adjustments, which could improve data interpretation between investigators and facilitate the development of novel therapies.

#2190 Genomic scarring score is associated with T cell exhaustion in early stage non small cell lung cancer.

Introduction: We have recently reported that almost a third of the patients in an early stage NSCLC cohort harbor a high genomic scarring score (GSS) indicating HRD. Immunotherapy is an attractive partner of PARP inhibitors (PARPi), especially in case of PARPi resistance. Immunotherapy-based regimens are shown to be highly efficient and provide significant clinical benefit in the pre- and peri-operative setting in early-stage NSCLC suggesting that the TME is permissive for the immunotherapy effect in this tumor type.
Purpose: We wished to characterize the different subpopulations of tumor infiltrating lymphocytes (TILs) in early-stage NSCLC and correlate them with the clinical outcome.
Methods: Next generation sequencing was used to evaluate the GSS of primary tumors from 136 early-stage NSCLC based on a commercially available sequencing kit which also provides information on the genetic status of relevant HRR and other genes (Amoy Dx) and patients were stratified as low (<50, l-GSS) or high (>50, h-GSS) GSS. Analysis of the tumor microenvironment (TME) immune infiltrate was performed by single and double staining ICH using monoclonal antibodies against T cells and B cells as well as PD1 and TCF1.
Results: 39 (28.7%) and 97 (71.3%) tumors were h-GSS and l-GSS respectively. There was a marginal enrichment of somatic HRR gene mutations in the h-GSS compared to the l-GSS group but this was not statistically significant. There were no significant differences regarding the occurrence of co-mutations in the two groups except for *TP53* which was significantly higher in h-GSS (94.4%) compared to l-GSS samples (51.5%; p<0.001). TIL immunophenotyping did not show significant differences regarding the CD8+, CD4+ and FOXP3+ T cells and CD79+ B cells. Expression of $PD1^{+}TCF1^{+}$ and $PD1^{+}TCF1^{-}$, namely progenitor and terminally exhausted T cells respectively, was significantly higher in the h-GSS (5.1 ± 5.1; 15.0 ± 12.3) compared to l-GSS (2.5 ± 2.2; 8.8 ± 7.2; p=0.037 and p=0.040) group. In the subgroup of patients who received adjuvant platinum-based chemotherapy the increased infiltration of tumor center with both $PD1^{+}TCF1^{-}$ and $PD1^{-}TCF1^{+}$ cells was independently associated with DFS [HR=3.1 (p=0.040) and in these patients both DFS and OS was significantly improved in patients co-harboring a h-GSS with pathogenic/likely pathogenic TP53 mutations compared to patients with l-GSS/TP53wt (p=0.012 and p=0.032, respectively).
Conclusions: Our data demonstrate for the first time that a significant percentage of early-stage NSCLC patients exhibit genomic instability (h-GSS) which is associated with a unique *TP53* status and the immune profile of the exhaustion state. The latter highlights the heterogeneity of the different subpopulations of exhausted TILs in the TME of NSCLC, which seems to have substantial prognostic and predictive clinical relevance especially in patients with h-GSS.

#2191 A 50-marker mass cytometry intracellular cytokine staining panel: unprecedented resolution enables unrivaled detection of functional diversity present among human immune cell subsets.

Laura Polanco[1], Michael J. Cohen[2], Erika L. Smith-Mahoney[1], Lauren Tracey[2], Christina Loh[2], Amedeo J. Cappione[2], Anna C. Belkina[1], David King[2], Jennifer E. Snyder-Cappione[1]

[1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA,[2]Standard BioTools, Markham, ON, Canada

Understanding mechanisms of immune evasion to therapeutics or during responses to cancer, autoimmunity and infectious diseases requires high-dimensional functional profiling at the single-cell level. Measurement of functional immune cell signatures that include both inflammation and immunosuppression provides key insights into several facets of cancer research and therapy. If single-cell detection of cytokines spanning many cell lineages was possible, 1) determining mechanisms underlying success/failure of checkpoint blockade, 2) defining immunosuppressive activity of the tumor-resident cell subsets and 3) identifying immunological biomarkers that predict clinical outcomes would be within reach. We used CyTOF™ technology to achieve this goal of high-parameter cross-functional profiling to avoid the limitations of fluorescence-based cytometry, such as signal spillover, autofluorescence, compensation errors and spectral unmixing complications.

A 50-marker CyTOF panel that achieves comprehensive profiling of immune subpopulations with detection of 20-plus intracellular cytokines spanning Th1, Th2, Th17 and Treg lineages was developed. PBMC were cultured with an array of stimulation conditions, stained and acquired on the CyTOF XT system. Datasets were analyzed using PhenoGraph clustering and visualized with opt-SNE to determine cellular functional diversity. Our findings show clear detection of IL-5-, IL-10- and IL-13 producing cells, found in surprising co-expression patterns with pro-inflammatory cytokines such as IFNγ. More significantly, we were able to detect expression of a number of secretory analytes that are historically difficult to identify by flow cytometry at a single-cell level, including the immunosuppressive cytokine TGF-β.

Mass cytometry, in concert with this new expanded cytokine panel, provides a far wider lens of visualization of the functional diversity of human immune cells than has been achieved previously. We predict that through the use of this panel, novel immune regulatory mechanisms that abate/prevent cellular responses in tumors will be revealed. In sum, our findings indicate that the CyTOF XT platform is well positioned as a catalyst for seminal discoveries in immune profiling to drive therapeutic design and advanced disease monitoring in cancer.

#2192 Enhancing veterinary cancer drug development with innovative bioanalytical assays.

Jun Wang, **Ildiko Kasza**, Denise Garvin, Trish Trish, Rod Flemming, Jeff Nelson, Ngan Lam, Marjeta Urh, Mei Cong, Jamison Grailer

Promega Corporation, Fitchburg, WI

The development of biologic drugs for veterinary health requires precise and reliable bioanalytical tools. To that end, we have developed several new assays, extending our industry-leading portfolio of human bioassays to emerging veterinary therapeutic targets. Featured here are cell-based reporter bioassays: Canine ADCC Reporter Bioassay and Canine PD-1/PD-L1 Blockade Bioassay. Additionally, we present two new Lumit Immunoassays for characterizing binding to the FcRn receptor: Canine FcRn Binding Immunoassay and Feline FcRn Binding Immunoassay.

Utilizing luminescence detection, these assays offer sensitive and specific measurement of target interactions. Our assay development process involves rigorous testing for accuracy, precision, linearity, and specificity, adhering to ICH guidelines. The assays demonstrated high sensitivity and specificity, as well as robust performance in detecting and quantifying the potency of target molecules. Our cell-based bioassays are available in convenient thaw-and-use kit formats, allowing for easy adoption and highly reproducible results. These assays can be utilized from early development through lot release, supporting every stage of the drug development process.

Promega's advanced bioassays and immunoassays provide a comprehensive platform for the development and characterization of veterinary biologic drugs. These tools support the entire drug development pipeline, enhancing the efficacy and safety of veterinary therapeutics through high sensitivity, specificity, and reproducibility. Additionally, our Lumit Immunoassays significantly reduce assay time compared to traditional ELISAs, providing faster and more efficient workflows for the characterization of binding interactions to the FcRn receptor.

#2193 Patient-derived colorectal microtumors predict response to anti-PD1 therapy.

Duy T. Nguyen[1], Matthew A. Schaller[2], Krista P. Terracina[2], Xia Xu[3], Diego I. Pedro[1], Alfonso Pepe[1], Juan M. Uruena[2], Zadia Dupee[2], Nickolas Diodati[2], Ryan Smolchek[4], Jack E. Famiglietti[4], Tran Yen Nhi Nguyen[1], Gerik Tushoski[2], Kuoyuan Cheng[3], Lan Chen[3], Doug Linn[3], Vania Vidimar[3], Aquila Fatima[3], Soon Woo Kwon[3], Dongyu Sun[3], Hongmin Chen[3], Haiyan Xu[3], Brian Long[3], Lily Y. Moy[3], Bonnie J. Howell[3], George H. Addona[3], W. Gregory Sawyer[1]

[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]University of Florida, Gainesville, FL,[3]Merck & Co., Inc., Rahway, NJ,[4]Aurita Bioscience, Gainesville, FL

Immune checkpoint inhibitors have made remarkable impacts in treating various cancers, including colorectal cancer (CRC). However, CRC still remains a leading cause of cancer-related deaths. While microsatellite instability (MSI) colorectal cancer (CRC) has shown positive responses to anti-PD1-therapy, this subgroup represents a minority of all CRC patients. Extensive research has focused on identifying predictive biomarkers to understand treatment response in CRC. Interestingly, a growing number of clinical cases have reported favorable outcomes from a subtype of supposedly non-responder microsatellite stable (MSS) CRC, characterized by DNA polymerase ε (POLE) proofreading domain mutations with high tumor mutational burden (TMB). This subtype has shown a notable response, either partial or complete, to pembrolizumab as salvage treatment, often following significant disease progression. To improve efficiency, cost-effectiveness, and clinical outcomes, there is an essential need for a testing platform capable of promptly identifying evidence of anti-PD-1 response to inform treatment strategies. Here, we established a novel *ex vivo* immunotherapy model using patient-derived tumor microexplants (or microtumors <1 mm) co-cultured with autologous peripheral blood mononuclear cells (PBMCs) from treatment-naïve CRC patients. We demonstrate here that long-term *ex vivo* treatment with pembrolizumab induced a heterogeneous but appreciable interferon-gamma (IFN-gamma) secretion, accompanied by infiltrating PBMCs. Intriguingly, a case study involving an MSS CRC phenotype harboring POLE mutation and associated ultrahigh TMB demonstrated a response to PD-1 blockade, potentially from the intratumoral immune cell population. Ultimately, this novel model could serve as a valuable tool in complementing clinical diagnostics and guiding personalized treatment plans for CRC patients, particularly those with specific phenotypes and mutational profiles.

#2194 Patient-derived triple negative breast cancer organoids show heterogeneous radiation-induced immune signaling.

Diego Sialer[1], Xiaoxue Deng[1], Maud Charpentier[1], Neil Rupchand[1], Marvin Campos[1], Jenna Moyer[2], Wen Shen[1], Olivier Elemento[2], Doron Betel[3], Silvia Formenti[1], Sandra Demaria[1]

[1]Radiation Oncology, Weill Cornell Medicine, New York, NY,[2]Englander Institute for Precision Medicine, Weill Cornell Medicine, New York, NY,[3]Institute for Computational Biomedicine, Weill Cornell Medicine, New York, NY

Only a minority of triple-negative breast cancer (TNBC) patients respond to immune checkpoint inhibitors (ICI). Radiation therapy (RT) increases ICI responses in preclinical TNBC models and in some patients[1,2], but there are no biomarkers to predict RT benefit. TNBC comprises multiple subtypes and we hypothesized that patient-derived tumor organoids (PDOs) representative of such heterogeneity could be used to study RT-induced cancer cell-intrinsic responses.Two PDOs molecularly classified as Luminal Androgen Receptor (LAR) and Basal-Like 1 (BL1) TNBC subtypes[3] were mock-treated or irradiated with 3 daily doses of 8Gy and harvested 24 hours post-RT. Differential gene expression analysis (DESeq2), Gene Set Enrichment Analysis (GSEA), and Qiagen's Ingenuity Pathway Analysis® were performed. Protein expression was assessed by western blot and flow cytometry. Healthy donors CD14+ monocytes were matured in M-CSF for one day prior to culture with PDO. RT upregulated multiple pro-inflammatory pathways (padj < 0.05), including TNFα via NF-κβ, antigen presentation via MHC-I and type I interferon (IFN-I), in the LAR PDO. In contrast, in the BL1 PDO only TNFα via NF-κβ was upregulated by RT, while IFN-I and antigen presentation pathways were not. RT also upregulated genes with immunosuppressive functions (*CD73* and *TGFB1*) in the LAR PDO, and Pathway Analysis identified *TGFB1* as a key upstream regulator ($p = 7.33 \times 10^{-17}$). Epithelial to mesenchymal transition (EMT) pathway was induced by RT in both PDOs. Flow cytometry confirmed RT-induced increase in MHC-I and CD73 expression in the LAR PDO, while only CD73 was upregulated in the BL1 PDO. Given the central role of IFN-I induction via cGAS/STING in RT-induced anti-tumor immune responses[4], we investigated cGAS and STING expression by the two PDOs. Western blot revealed suppressed expression of STING in the BL1 PDO. STING repression induces resistance to ICI in mouse models of TNBC and was shown to be mediated by MYC amplification in human TNBC[5]. Consistently, the BL1 PDO was derived from a tumor with MYC amplification. Finally, macrophages co-cultured with the LAR PDO showed reduced MHC-II and CD86 expression, an effect that was reversed when the PDO was treated with RT before co-culture. Our data support the use of PDOs that reflect the heterogeneity of human TNBC as models to study the immunomodulatory effects of RT. Findings show differential induction of key pro-immunogenic mediators by RT in different PDOs and suggest that CD73 is an actionable target to improve RT-induced ICI responses[6]. Understanding the multifaceted effects of RT using a PDO-based platform may enable a precision use of RT that is tailored to the specific characteristics of a given patient TNBC. *Supported by BCRF 23-053 & DOD W81XWH-21-2-0034. #2195 Development of a faster potency assay for evaluation of immune cell-mediated cytotoxicity in vitro.

Danielle Califano, Ben Streeter, Sierra Barnes, **Skylar Dewees**, Denise Sullivan, Daniel Millard, Stacie Chvatal

Axion BioSystems, Atlanta, GA

Assessment of the efficacy of CAR T cell therapy relies on robust *in vitro* potency assays that evaluate the interaction between CAR T cells and cancer cells. Traditional methods require extended incubation periods of target cells of over 24 hours, limiting throughput and efficiency in assay development. In this study, we aimed to significantly reduce assay time by utilizing an impedance-based system to monitor the cytotoxic activity of CAR T cells against SKOV3 cancer cells. By comparing the standard protocol with an expedited approach that allows for a shorter resting period of target cells, we aim to establish a more efficient framework for potency testing that maintains accuracy, while facilitating faster advancements in CAR T cell therapies. In addition to shortening the overall assay time, adding CAR T cells at an earlier timepoint also ensures that the true Effector to Target (E:T) ratios are maintained by reducing the time for target cell doubling. Here, we describe an *in vitro* potency assay that shortens the assay time course from 72+ hours to 24 hours for immune cell-mediated cytotoxicity. SKOV3 target cells were seeded at 10k cells per well into a 96-well microplate with embedded electrodes in the substrate that detect the attachment and proliferation of target cells. HER-2 CAR T cells were added at either 4 or 24 hours post SKOV3 cell seeding at multiple E:T ratios (1:10, 1:5, 1:2, 1:1, and 5:1). The killing kinetics among each group were directly compared by calculating the Kill Time 50 (KT50), or the time required for 50% of the target cells to be killed. The KT50 for target cells treated at 4 hours was 91.6 ± 3.7 (1:10), 47.8 ± 22.7 (1:5), 19.8 ± 1.8 (1:2), 16.6 ± 0.9 (1:1), and 9.1 ± 0.7 (5:1) hours, while the KT50 for target cells treated at 24 hours was 150.0 ± 3.6 (1:10), 115.6 ± 7.1 (1:5), 83.8 ± 4.5 (1:2), 48.7 ± 2.5 (1:1), and 29.2 ± 0.8 (5:1) hours. As expected, the well groups treated with CAR T cells at 4 hours demonstrated faster KT50 times due to less SKOV3 cell proliferation and, therefore, more accurate E:T ratios. At 24 hours post CAR T addition, a dose response curve was generated and the EC50 was determined to be an E:T ratio of 1:2.4 for target cells treated 4 hours post seeding and E:T ratio of 1:1 for target cells treated 24 hours post seeding. Overall, the data described illustrates a label-free, *in vitro* workflow to assess potency of CAR T cells in a quicker, more efficient manner using the Maestro Z impedance assay.

#2196 Characterizing the impact of SOCS1 and Regnase-1 inactivation on tumor reactive T cells present in CRISPR/Cas9-engineered TIL (eTIL®) therapies derived from melanoma and NSCLC tumors through functional and single cell analyses.

David Monteiro[1], Meghan Travers[1], Tyler G. Searles[2], Gustavo J. Martinez[1], Sharon Lin[1], Ashish Yeri[1], Alex Smashnov[1], Mitali Ghose[1], Seamus McKenney[1], Paul Dunbar[1], Charles H. Yoon[3], Dipen Sangurdekar[1], Karrie Wong[1], Joseph D. Phillips[4], Mary Jo Turk[2], Micah J. Benson[1]

[1]KSQ Therapeutics, Inc., Lexington, MA,[2]Dartmouth Cancer Center and the Department of Microbiology and Immunology, The Geisel School of Medicine at Dartmouth, Lebanon, NH,[3]Brigham and Women's Hospital, Harvard Medical School, Boston, MA,[4]Department of Surgery, The Geisel School of Medicine at Dartmouth, Lebanon, NH

Tumor Infiltrating Lymphocyte (TIL) therapy involves the isolation and *ex vivo* expansion of TIL for the treatment of solid tumors. The T cell receptor (TCR) repertoires present within TIL drug products (DPs) are highly patient unique and include TCRs specific against tumor antigens at variable frequencies. The clinical activity of TIL is thought to be mediated in part by the anti-tumor functionality profile of TIL and the frequency of tumor reactive T cells (TRTs) within the TIL DP. Seeking to improve the clinical activity of TIL therapy, we developed KSQ-001EX and KSQ-004EX, two CRISPR/Cas9-engineered TIL (eTIL®) therapies wherein the genes encoding SOCS1 or SOCS1 in combination with Regnase-1 are inactivated, respectively. SOCS1 is a negative regulator of cytokine signaling while Regnase-1 is an RNase that degrades transcripts encoding proteins involved in regulating T cell anti-tumor function. We have shown in preclinical models that inactivation of SOCS1 and SOCS1/Regnase-1 enhance the anti-tumor functionality of TIL; however, the incidence of TRTs in eTIL DP and how inactivation of SOCS1 and Regnase-1 impact their functionality remains unclear.To identify and characterize TRT clones in eTIL, we generated KSQ-001EX and KSQ-004EX using TIL derived from patients with melanoma or non-small cell lung cancer (NSCLC) and analyzed them with distinct but complimentary methods. We functionally characterized melanoma-derived DPs via coculture with paired autologous melanoma tumor cell lines, with samples exhibiting cognate reactivity against tumor through induction of CD69 and CD137. Consistent with its biology, we observed strong SOCS1-driven enhancement of IFNγ and CD25 in this setting. We extended these insights to NSCLC using single cell RNA/TCR sequencing performed on DPs and tumor starting material. In tumor starting material, we identified $CD8^+$ T cell clusters aligning to *IL7R*$^+$ circulating/stem, *GZMB*$^+$ effector, and *CXCL13*$^+$ resident memory (T_{rm}) states. Predicted TRT (predTRT) clones were identified using a custom gene set constructed from published TRT signatures and cells from these clones were overrepresented in T_{rm}. The majority of predTRT clones were also detected in DPs, where they preferentially aligned to effector memory and proliferating states. Further demonstrating the impact of SOCS1 and Regnase-1 edits on predTRT clones, we observed enrichment of an activated interferon-stimulated gene signature in eTIL DPs, with predTRT clones in dual-edited KSQ-004EX uniquely enriched for heightened expression of a Regnase-1 transcriptional signature.To conclude, we observe that eTIL possess reactivity against tumor through retention of TRT clones, with SOCS1 and Regnase-1 inactivation enhancing the anti-tumor functionality of TRT clones within eTIL DP.

#2197 Uncovering immune evasion in EGFR-mutant and treatment resistant NSCLC: insights from a novel mouse model.

Anchit Bhagat, Cong-Xiao Liu, Xiao Yang, Melissa Gajda, Jason McBane, Herbert K. Lyerly, Zachary C. Hartman

Duke University, Durham, NC

Lung cancer remains one of the most prevalent and deadly malignancies globally, with non-small cell lung cancer (NSCLC) comprising approximately 84% of all cases. Despite advances in treatment, the overall 5-year survival rate for NSCLC remains at 15%. Among NSCLC cases, 15-20% are driven by activating mutations (such as L858R) in the epidermal growth factor receptor (EGFR), which are treated with EGFR tyrosine kinase inhibitors (TKIs). Although three generations of TKIs have been developed, a number of genetic mutations (T790M and C797S) have been shown to evolve that confer resistance in most patients. This has spurred interest in combination therapies, particularly with PD-1 and PD-L1 immune checkpoint inhibitors (ICIs), however, these have limited efficacy in patients with EGFR-mutant NSCLC. Therefore, understanding the immune landscape of these tumors is critical. We developed a mouse model of EGFR-mutant lung cancer using a transgenic mouse model expressing an EGFR carrying L858R activating, as well as T790M and C797S resistance mutations. We demonstrate the expression of this gene after intranasal delivery of an adenovirus carrying GFP-Cre (Ad-GFP-Cre) from a CAG promoter, along with expression of Td-tomato and Luciferase to allow for tumor tracking and visualization. In a time-course experiment, we monitored tumor progression and immune infiltration. By 4-6 weeks post-Ad-GFP-Cre injection, we observed consistent and palpable tumor growth, establishing a critical window for therapeutic intervention. At 2 weeks post-injection, lung tissues showed robust infiltration of CD8+ T cells, highlighting a strong initial immune response. However, levels of regulatory T cells (Tregs) increased significantly over time. This accumulation of Tregs coincided with tumor growth and suppression of cytotoxic T cell activity, suggesting a shift toward an immunosuppressive microenvironment. CD4+ T cells remained relatively constant, underscoring the specific role of Tregs in facilitating immune evasion. Systemic adaptive immunity against EGFR was detected in all tumor bearing mice, demonstrating the potency of local immune suppression in EGFR+ tumor evolution. To evaluate the therapeutic relevance of these findings, we treated mice with a PD-1 inhibitor starting at 4 weeks post-injection. Tumor response was minimal, mirroring clinical observations of limited efficacy for ICIs in EGFR-mutant NSCLC. The early wave of cytotoxic immune activity followed by Treg-mediated suppression offers insights into potential therapeutic targets. This will be a useful model to study the impact of different EGFR TKIs, as well as the combination of these agents with different immunotherapeutic modalities to identify strategies to optimize combination therapies. This work has the potential to inform innovative approaches for treating EGFR-mutant NSCLC and improving patient outcomes.

#2198 Platform for purifying antigen-presenting myeloid cells based on frequency of interactions with T cells.

Eric Ferguson[1], Zhixuan Huang[2], John M. Beierle[1], **Behrad Azimi**[1], Kenneth H. Hu[2]

[1]Narwhal Bio Inc., San Diego, CA,[2]Department of Immunology, The University of Texas MD Anderson Cancer Center, Houston, TX

Cell-cell interactions' underlying biology drives many promising therapeutic opportunities in treating cancer. However, studying cell-cell interactions is challenging because the cells are alive and remain motile, and the complexity of downstream analysis increases with every observed interaction event. Today, researchers study cell-cell interactions using a variety of commercially available spatial approaches on fixed tissue samples. While these approaches can help study regions of interest or groups of cells based on their location within the tissue sample, they don’t offer single-cell resolution and fail to provide information on the more complex behavior of said cells, including the frequency and temporal nature of their interactions. Narwhal Bio Inc.’s A1 instrument, software, and consumable platform allow for real-time cell identification, tagging, and downstream characterization of live cells in cell mixtures. The live-cell-in, live-cell-out process enables the purification of live cells based on cell behaviors for use in downstream multiomics analyses. Here, we apply this platform to study the clinically relevant T-cell activating interactions between myeloid and T cells. We screen myeloid cells presenting various concentrations and types of antigens and monitor interactions with T cells over days. Myeloid cells are tagged by the platform when in contact with T cells at multiple time intervals resulting in the ability to stratify highly involved antigen-presenting cells (APCs) from less involved APCs. The cells are then isolated live, stratified based on their level of T-cell interactions, and then subjected to further downstream characterization and assay. At the core of the presented application is the tenet that a better understanding of cell-cell interactions will expose important underlying biological pathways, thereby increasing the chance of discovering targets for therapeutic intervention.

#2199 Ready-to-use oxygen gradient microplates for customized in vitro assays for the phenotypic and functional characterization of primary macrophages in immuno-oncology drug development.

Christoph Schifflers[1], Martijn Vlaming[1], Emmanuelle Sidot[1], Jezabel Lefevre[1], Elise Pepermans[2], Ellen Boelen[1], Enrico Grassilli[3], Sofie Pattyn[1]

[1]IQVIA, Gosselies, Belgium,[2]Immunespec, Niel, Belgium,[3]insimili, Bologna, Italy

Ready-to-use oxygen gradient microplates for customized *in vitro* assays for the phenotypic and functionalcharacterization of primary macrophages in immuno-oncology drug developmentChristoph Schifflers[1], Martijn Vlaming[1], Emmanuelle Sidot[1], Jezabel Lefèvre[1], Elise Pepermans[2], EllenBoelen[1], Enrico Grassili[2] and Sofie Pattyn[1]1IQVIA Laboratories, In Vitro Immunology (formerly known as ImmunXperts), Rue Clément Ader 10, 6041Gosselies Belgium[2]ImmuneSpec, Galileilaan 18 bus 6, 2845 Niel, Belgium[3]InSimili srl, Viale Giuseppe Fanin 48, Bologna, 40050, ItalyOxygen level fluctuations in tumor micro-environment (TME) can alter the phenotype and function ofcancer cells as well as tumor-infiltrating immune cells, such as macrophages. For the functional evaluationof new immuno-oncology drug candidates, it can be key to take into consideration the effects of varyingO2 concentrations. In fact, it is well established that varying oxygen concentrations and tumor hypoxia candrive treatment resistance and cancer recurrence. Modeling this layer of functional complexity of thetumor microenvironment, typically requires the use of animal models or tumoroid systems which can becomplex to establish, time-consuming and expensive. InSimili developed a new technology that providesready-to-use microplates that model spatially controlled O2 levels at fixed O2 concentrations or O2 gradients(adaptable for individual wells). Combining this technology with highly optimized *in vitro* assays using highquality primary immune cells can provide a useful tool with improved predictive value for the cost-effectivefunctional characterization and lead selection of new immuno-oncology drug candidates.In this study, the impact of varying O2 concentrations (ranging from 20% to 1% O2) was assessed usingcustomized microplates on the phenotype of macrophages derived from healthy donor PBMCs.Furthermore, the impact of different O2 concentration on the capacity of M2-like macrophages to suppressT cell activation was explored. Finally, the impact of several oxygen concentrations on the reprogrammingof M2-like macrophages was evaluated.Taken together, this study showed that InSimili's plates provide a ready-to-use tool that can be used incustomized *in vitro* assays to model varying O2 concentrations. Integrating this technology with highlycustomized *in vitro* bioassays can serve as a valuable tool for immuno-oncology drug development whiletaking into account an additional degree of the complexity of the TME in 2D and 3D systems.

#2200 Development and optimization of cost-effective non-human primate in vitro assays for immunogenicity screening and functional evaluation of immuno-oncology drug candidates.

C. Schifflers[1], V. Martijn[1], E. Sidot[1], J. Lefevre[1], E. Pepermans[2], E. Boelen[1], S. Pattyn[1];
[1]IQVIA, Gosselies, Belgium, [2]ImmuneSpec, Niel, Belgium

A surge in demand and a decrease in supply of non-human primate (NHP) test subjects have caused acritical shortage and a major price hike for biomedical research. Therefore, researchers are actively lookinginto refinement and/or alternatives to studies using NHP. The development of cost-effective NHP *in vitro*assays with predictive value for the assessment of unwanted immunogenicity as well as the functionalityof drug candidates can provide useful tools in this context. For instance, PBMCs isolated from blood,sourced from Cynomolgus Macaques, can be cryopreserved and thawed thereafter on multiple separateoccasions to be used for isolation of immune cell subsets of interest.The development of customized *in vitro* assays based on cynomolgus monkey PBMCs can be used for thepre-selection of drug candidates and therefore reduce the number of NHP that are required for *in vivo*studies. For instance, cynomolgus PBMCs can be used to evaluate the unwanted immunogenicity of testcompounds *in vitro*. Here, it was shown that ATR-107, an anti-IL21R antibody and Bococizumab triggeredsignificant proliferation of cynomolgus PBMCs. Furthermore, using immunopeptidomics (in collaborationwith ImmuneSpec) Infliximab-derived peptide fragments that are known to be immunogenic in humanwere found to be presented at the surface of cynomolgus dendritic cells after their incubation withInfliximab during their maturation.We previously reported the development of cynomolgus monkey PBMC-derived *in vitro* assays that canbe used for the functional evaluation of new drug candidates (*e.g., macrophage reprogramming,* cytokinerelease, M2-suppression assay, ADCP etc.), target binding studies as well as Cynomolgus Macaque PBMCx human dendritic cell (DC) mixed lymphocyte reactions (MLR). Continuous efforts to optimize these assayscan additionally minimize the requirements of cynomolgus monkey material. For instance, it was shownthat by adapting the cell culture conditions for the generation of cynomolgus macrophages, cell yields canbe substantially improved, reducing the number of required PBMC samples, and allowing to perform largerassays for a given amount of NHP material.With our expanding portfolio and continuous optimization of Cynomolgus Macaque assays we aim to aidbiomedical drug development and to refine/reduce NHP usage.

IMMUNOLOGY: Microbiome, Inflammation, and Cancer
Poster Session

#2204 Probiotic *Lactobacilli* and their secreted metabolites exert anti-inflammatory and anti-genotoxic effects in Barrett's esophagus associated tumorigenesis *in vitro* and *in vivo*.

Maanya Pradeep, Divya Joshi, Joshua N. Bernard, Thomas Andl, **Claudia D. Andl**

Burnett School of Biomedical Sciences, University of Central Florida, Orlando, FL

Gastroesophageal reflux disease (GERD) leads to the accumulation of bile-induced reactive oxygen species and oxidative stress in esophageal tissues, causing inflammation and DNA damage. As GERD progresses to Barrett's esophagus (BE), the only known precursor lesion for esophageal adenocarcinoma, probiotic bacteria with anti-inflammatory and anti-genotoxic function are of significant interest in the prevention and treatment of Barrett's esophagus (BE) and esophageal adenocarcinoma. To assess the outcome of probiotic *Lactobacillus* administration *in vivo,* we used the model of L2-driven expression of IL1b for inflammation-associated Barrett's tumorigenesis. We administered 10^9 CFU/ml (colony-forming unit) *L. acidophilus* and *L. plantarum* by oral gavage starting at 6 weeks of age until the IL-1β mice were 6 months old (prevention model) or initiated treatments when the mice were 4 months old until 6 months of age (treatment group). At the end of the study, mice were sacrificed, and esophageal and forestomach tissues were harvested for DNA and RNA extraction and FFPE. Histopathological analysis following *Lactobacillus* spp. administration in the murine study showed a significant reduction in inflammation ($p<0.07$) and tumor incidence ($p<0.05$) compared to untreated sham mice in the prevention and treatment groups. Assessing mucin production at the GEJ visualized by Alcian Blue/PAS, we observed 80% of the sham mice had extended glands compared to significantly less when *Lactobacillus* spp. was administered ($p<0.03$).Multiplex immunofluorescence staining was used to evaluate immune cell recruitment and BE marker expression. *In vitro* assays utilized immortalized normal esophageal cells (STR), and the BE cell lines, CP-B and BAR-T and cell-free Lactobacillus supernatant. Upon DNA damage induction using deoxycholic acid or ox bile, cell lines were incubated with live Lactobacilli or cell-free supernatant secreted by *L. fermentum*, *L. acidophilus* and *L. plantarum.* To identify if inflammation and DNA damage can also be reduced using potential Lactobacillus-secreted bioactive metabolites, we detected 8-oxo-dG, pH2AX and RAD51 *in vitro* using immunofluorescence. We show a reduction in DNA damage and NF-KB-mediated inflammation in the presence of Lactobacillus cell-free supernatants similar to the effect of live bacteria.Our data demonstrate the feasibility of utilizing probiotic *Lactobacillus* supplementation in mouse models of BE, as well as support the hypothesis that *Lactobacillus* spp. aid in the prevention of disease progression and its treatment in experimental models of gastroesophageal reflux disease.

#2205 Exploring the presence and role of causative viruses in glioblastoma using a multi-omics approach.

Bavani Gunasegaran[1], Shamini Ayyadhury[2], Shivani Krishnamurthy[1], Seong Beom Ahn[1], Benjamin Heng[1]

[1]Macquarie University, Sydney, Australia,[2]The Donnelly Centre, University of Toronto, Toronto, ON, Canada

Glioblastoma (GB) is the most aggressive brain cancer with a poor survival rate. While molecular markers have been established to improve treatment response with modest outcomes, the cause of this cancer remains unknown. Viruses were proposed as potential contributing factors to glioblastoma, particularly given that approximately 20% of all human cancers are virus-induced. While previous studies have detected viral presence in glioblastoma tissues, these investigations were limited by small sample sizes and often focused exclusively on either viral DNA or proteins, restricting the scope of their findings. To address these shortcomings, we explored the role of viruses in glioblastoma by utilising advanced analytical chemistry and high-throughput technologies to study viral proteins and genes and their interaction with tumour signalling pathway(s). We analysed 233 publicly accessible mass spectrometry metaproteome datasets encompassing 196 glioblastoma, 21 adjacent, and 16 normal brain tissues (PMID: 31331834, 31154438, 36720864), using the Trans-Proteomic Pipeline (PMID: 36648445) which converts raw data files, identifies, validates and quantifies peptides, and protein inference. To expand our analysis, we incorporated metaproteomic data from 100 samples (52 glioblastoma, 48 normal) and metagenomic data from seven glioblastoma tumours sourced from Hunter Cancer Biobank. Our comprehensive analysis, integrating meta-proteomics and meta-genomics, revealed a higher prevalence of multiple herpesvirus species, including human Herpes Simplex Virus-1, Herpes Simplex Virus-2, and Herpesvirus 8 within tumour tissues compared to control and adjacent tissues. To further elucidate the role of viral infections in tumour progression, we are currently investigating meta-transcriptomic data from 15 tumours.We are also investigating human proteins within a cohort of 100 samples to identify potential associations with our detected viruses. We aim to explore whether viral infections may influence human proteins involved in critical biological processes in glioblastoma. In a preliminary analysis, we quantified 3,991 human proteins, of which 1,155 were found to be deregulated. Gene enrichment analysis revealed up-regulated gene ontology biological processes associated with interspecies interactions and defence responses to other organisms. This suggests that these genes may potentially play a role in the host's reaction to viral infections. Additionally, Ingenuity Pathway Analysis identified 182 deregulated pathways, including several that may be implicated in viral responses, warranting further investigation.Collectively, our findings indicate a potential role of viruses in tumour development, possibly having the capacity to redefine the stratification of tumour types in GB patients.

#2207 Intratumoral bacteria predict survival in clear cell renal cell carcinoma (ccRCC).

Alice C. Martin[1], Anne-Laure Cattin[1], Irene Lobon[1], Zayd Tippu[1], Fiona Byrne[1], Charlotte Spencer[1], Clara Becker[2], Martha Zepeda Rivera[3], Krupa Thakkar[4], Hongui Cha[4], Angel Fernandez-Sanroman[1], Annika Fendler[1], Taja Barber[1], Leo Bickley[1], Daqi Deng[1], Scott Shepherd[1], Parise Lockwood[1], Maximiliano Gutierrez[1], Susan Bullman[3], Kevin Litchfield[4], Samra Turajlic[1]

[1]Francis Crick Institute, London, United Kingdom,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]MD Anderson Cancer Center, Houston, TX,[4]UCL Cancer Institute, London, United Kingdom

Background: ccRCC is marked by niches of immune evasion in late-stage disease, that are associated with resistance to immune checkpoint inhibitors (CPI). Intratumoral microbes are emerging as key modulators of the tumor immune microenvironment and may therefore play a yet unrecognised role in ccRCC disease progression and therapy resistance, marking them as potential biomarkers, and novel therapeutic targets.

Methods: We extracted bacterial reads from three cohorts of treatment-naïve primary tumors and one cohort of pre- and post-CPI treated tumors: Genomics England Renal (GEL) (636 patients, WGS), TRACERx Renal (154 patients, 629 samples, WGS); TCGA Renal (494 patients, RNA) & ADAPTeR (15 patients, 56 samples, RNA). Bespoke denoising, and decontamination were applied. Live presence of intratumoral bacteria was confirmed through culture and RNAscope. Genera associated with survival were identified using ElasticNet feature selection.

Results: We observed significant heterogeneity in bacterial abundance within and across tumors, driven by differences in *Cutibacterium* abundance. *Cutibacterium* makes up ~90% of bacteria in each tumor sample and is enriched in tumors compared to adjacent normal tissue (p=7.1e-10). 9 of 11 colonies grown from two positive tumors were genotyped as *Cutibacterium acnes,* confirming its live presence and relative abundance in ccRCC tumors. *Cutibacterium* is higher in late-stage tumors (III&IV) than early-stage tumors (I&II) (p=7.8e-3). Its abundance also separates patients by progression free survival (PFS) and overall survival (OS) (p=9.9e-3, p=0.016) and is higher in CPI non-responders than responders (p=0.028). Association with survival is confirmed in the TCGA cohort independently of stage (PFS = 0.031, OS = 7.3e-4). While other genera associate with survival in either TRACERx or TCGA, only *Cutibacterium* is prognostic in both.

Enrichment analyses of bulk RNA (TRACERx & TCGA), show upregulation of leukocyte taxis and innate immune response with *Cutibacterium* abundance. To further probe this interaction with the immune microenvironment we are performing single cell spatial transcriptomics, and *in vitro* co-cultures. Results of these ongoing experiments will be presented at the conference.

Conclusions: *Cutibacterium* either creates or exploits a disease- and CPI-resistance-promoting environment in ccRCC tumors and can therefore act as a prognostic and predictive biomarker. The genus is known for causing chronic inflammation in sebaceous skin follicles, induces Nf-kB signalling, and M2-macrophage differentiation *in vitro*, and associates with myeloid response in ccRCC tumors. Together this supports a compelling hypothesis that *Cutibacterium* reduces survival in ccRCC by creating immunosuppressive niches, thereby fostering disease progression and CPI-resistance.

#2208 *Phocaeicola vulgatus* mediates immunotherapy resistance in hepatocellular carcinoma via reducing indoleacetic acid production.

Caining Zhao[1], Shanshan Li[1], Thomas Yau[2], Wenqi Chen[1], Ren Ji[3], Xinyuan Guan[4], Fengming Spring Kong[4]

[1]Clinical Oncology, University of Hong Kong-Shenzhen Hospital, Shenzhen, China,[2]Medicine, University of Hong Kong, Hong Kong, Hong Kong,[3]Surgery, University of Hong Kong-Shenzhen Hospital, Shenzhen, China,[4]Clinical Oncology, University of Hong Kong, Hong Kong, Hong Kong

Background: Gut microbiota has been widely reported to influence anti-PD-1 efficacy in melanoma and lung cancer, in both clinical specimens and animal models. However, the role of gut microbiota in hepatocellular carcinoma (HCC) remains less explored, with limited understanding of the underlying mechanisms. Method: Advanced HCC patients treated with anti-PD-1 with/without anti-CTLA-4 were prospectively enrolled, and categorized into responders and non-responders groups based on their radiological response after 6 months of immunotherapy according to modified Response Evaluation Criteria for Solid Tumors (mRECIST) guideline. The fecal metagenomics and plasma metabolome data were integrated to reveal the profiles of gut microbiota. Meanwhile, fecal microbiota transplantation (FMT), single strain and metabolite intervention animal models, as well as in vitro CD8+T cell culture were employed to study its mechanism of modulating immunotherapy efficacy in HCC. Results: In the metagenomic analysis of 65 patients, the responders and non-responders exhibited distinct gut microbiota profiles, which were replicated in mice via FMT. Lefse analysis revealed a higher abundance of *Phocaeicola vulgatus* (*P. vulgatus*) in non-responders compared to responders. Moreover, patients with higher *P. vulgatus* had a mean progression free survival (PFS) of 11.1 months and overall survival (OS) of 22.9 months, which were significantly shorter than those with lower *P. vulgatus* (PFS: 30.8 months, $p = 0.047$; OS: 63.2 months, $p = 0.037$). Notably, *P. vulgatus* enriched in non-responders restrained anti-PD-1 efficacy in syngeneic and orthotopic tumor models and inhibited the CD8+T cell cytotoxicity, evidenced by decreased IFN-γ+ and GzmB+ populations. Mechanistically, *P. vulgatus* reduced gut microbiota-derived indoleacetic acid (IAA), weakening CD8+ T cell effector functions and impairing immune response. Supplementation with IAA restored CD8+ T cell cytotoxicity and counteracted the immune-suppressive effects of *P. vulgatus*. Conclusion: *P. vulgatus* impaired anti-PD-1 efficacy in HCC via reducing IAA production, which in turn diminishes the effector functions of CD8+ T cells. This study establishes a causal link between *P. vulgatus* and anti-PD-1 resistance in HCC, highlighting gut microbiota-derived IAA as a potential therapeutic target.

#2209 MaaT034, a new co-cultured microbiome ecosystem therapy candidate, is capable to safely colonize the gastro-intestinal tract of germ-free mice to restore a healthy gut physiology and to stimulate immunity.

Bastien Laperrousaz, Julie Reygner, Charlotte Petitjean, Aurore Duquenoy, Cyrielle Gasc, Diane Plouchart, Sophie Declomesnil, Carole Schwintner, Nathalie Corvaia

MaaT Pharma, Lyon, France

Background: Increasing evidence suggests that gut microbiome composition modulates tumor response to therapies, including immune checkpoint inhibitors (ICI). Clinical proofs of concept were obtained in pilot studies using healthy or ICI-responder donor-derived fecal matter transplants to modulate the gut microbiome of non-responding cancer patients and improve their response to ICI. We have developed Microbiome Ecosystem Therapies^{TM} (MET) replicating at large industrial scale the effects of ICI-responders gut microbiome. MaaT034, the first-in-class co-cultured microbiome product, has been selected through artificial intelligence and *in vitro* screening assays to optimize intestinal homeostasis and to activate immune functions alone and in combination with an ICI treatment.
Method: We used germ-free mice to evaluate MaaT034 engraftment and safety, as well as its impact on metabolite production, immunity as well as gut morphology.
Results: Metagenomic analysis demonstrates that MaaT034 is capable of engrafting in the gut of germ-free mice, as evidenced by the presence of the four major phyla of the human product in mice. KEGG (Kyoto Encyclopedia of Genes and Genomes) analysis revealed the presence of genes involved in the synthesis of key metabolites such as short chain fatty acids, indoles, as well as secondary biliary acids. In line, metabolite quantification in the feces of mice further confirmed the capability of MaaT034 microbes to produce these metabolites. MaaT034 was able to improve the gastrointestinal physiology and to stimulate immunity in germ-free mice (reduction of the size of cecum, increase in the depth of intestinal crypts, increase in the percentage of Goblet cells, increase of spleen weight). All mice remained healthy throughout the experiment and no adverse event was observed.
Conclusion: Altogether, these findings underscore MaaT034's potential to safely colonize the gastro-intestinal tract of mice and to produce key metabolites allowing to restore a healthy gut physiology and to stimulate both local and systemic immunity. As such, MaaT034 could offer a promising therapeutic benefit for the treatment of solid tumors in combination with ICI therapy.

#2210 Microbiome profiling reveals that fecal microbiota transplantation (FMT) modulates response and toxicity when combined with immunotherapy in patients with lung cancer and melanoma (FMT-LUMINate NCT04951583).

Sreya Duttagupta[1], Meriem Messaoudene[1], Rahima Jamal[1], Catalin Mihalcioiu[2], Nicolas Marcoux[3], Sebastian Hunter[1], Gianmarco Piccinno[4], Michal Puncochar[4], Karl Belanger[1], Mustapha Tehfe[1], Normand Blais[1], Scott Owen[1], Jacques Raphael[5], Jade Maillou[1], Yongjia Hu[1], Myriam Benlaifaoui[1], Somayeh Nilli[1], John Lenehan[5], Wiam Belkaid[1], Seema Nair Parvathy[5], Diogjena Katerina Prifti[1], Marine Fidelle[6], Seunghee Kim-schulze[7], Thomas Marron[7], Sylvere Durand[6], Guido Kroemer[6], Nicola Segata[8], Lisa Derosa[6], Laurence Zitvogel[6], Antoine Desilets[1], Michael Silverman[5], Saman MalekiVareki[5], Bertrand Routy[1], Arielle Elkrief[1]

[1]Research Center of the Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada,[2]Mcgill University Health Centre, Montreal, QC, Canada,[3]Centre Hospitalier de l'Universite de Quebec, Quebec City, QC, Canada,[4]University of Trento, Trento, Italy,[5]Western University, London, ON, Canada,[6]Institut Gustave Roussy, Paris, France,[7]Mount Sinai, New York, NY,[8]IEO, European Institute of Oncology, IRCCS, Milan, Italy

Background: Trials have shown that FMT plus immune checkpoint inhibitors (ICI) could improve αPD-1 response in melanoma. The microbiome and immune shift, along with the clinical impact of FMT with αPD-1 in non-small cell lung cancer (NSCLC) and in combination with αPD-1+αCTLA-4 (dual ICI) in melanoma is unknown.
Methods: 20 patients (pts) with advanced NSCLC treated with first-line (1L) αPD-1 and 20 with advanced melanoma treated with 1L dual ICI were recruited. FMT from 1 healthy donor (HD) was administered orally to each pt post bowel prep. 1 week later ICI was initiated. A total of 11 different HD were used. The primary endpoint was objective response rate (ORR). The gut microbiome was profiled using shotgun metagenomics. Metabolomic profiling was performed using HPLC. Olink proteomics (96 markers) on plasma and flow cytometry (40 markers) on PBMCs were assessed. FMT was performed in germ-free (GF) mice to recapitulate engraftment.
Results: In NSCLC, ORR was 80% (16 PR) with no grade ≥3 immune-related adverse events (irAE). In melanoma, ORR was 75% (5 CR), with 65% (13 pts) developing grade ≥3 irAE, including 3 (15%) myocarditis. The irAE occurred earlier than previously reported (median onset of 42 days). Pre-FMT patient microbiome composition was distinct from HD. Post-FMT, the responders (R) and non-responders (NR) clustered separately (p=0.03). Post-FMT, we observed increased polyamines and bile salts in R. Elevation of exhausted T central and T effector memory cells were noted in R. Conversely, proteomics analyses revealed elevated markers of immune exhaustion including CD28 and IL10 in NR. Addressing the link between microbiome and irAE, in melanoma, 6 out of the 13 pts (46%) that developed grade ≥3 irAE, including 2/3 of the myocarditis received FMT from the same donor (D5). D5 was not associated with irAE in NSCLC treated with αPD-1 alone. Microbiome analysis revealed that D5 clustered separately ($p<0.01$) from other HD with a high relative abundance of *Prevotella copri*. We observed a signal for the development of irAE in pts that engrafted *P. copri*. Pts with grade≥3 irAE exhibited higher levels of leaky gut markers such as sST2 post-FMT (p=0.002). In GF mice, oral gavage of baseline stool of R, only when followed by the stool of the respective donor, led to a significant increase in α diversity and number of species engrafted over time ($p<0.01$), while those that received baseline stool from NR with or without donor had no change in α diversity or species engrafted.
Conclusions: This study validates the role of FMT to improve ICI activity in NSCLC and melanoma, while differentially modulating irAE according to ICI backbone. We demonstrated that the microbiome shift is distinct among R while engraftment of *P. copri* was associated with dual ICI irAE. Our results directly inform future microbiome-centered trials.

#2211 A novel combined immunotherapy of gut microbial metabolite butyrate and oncolytic adenovirus in colorectal cancer.

Tetsuya Katayama[1], Shinji Kuroda[1], Masaki Sakamoto Sakamoto[1], Eri Takeda[1], Yu Mikane[1], Shunya Hanzawa[1], Daisuke Kadowaki[1], Yusuke Yoshida Yoshida[1], Masashi Hashimoto[1], Nobuhiko Kanaya[1], Yoshihiko Kakiuchi[1], Satoru Kikuchi[1], Shunsuke Kagawa[1], Hiroshi Tazawa[1], Yasuo Urata[2], Toshiyoshi Fujiwara[1]

[1]Okayama University Medical School, Okayama city, Japan,[2]Oncolys BioPharma, Inc., Tokyo city, Japan

Butyrate, a short-chain fatty acid (SCFA) produced by gut bacteria in the colon, serves as a critical energy source for colonocytes. Gut microbiota and its primary metabolite, butyrate, have been reported to potentially modulate tumor sensitivity to chemotherapy or immunotherapy, although the underlying mechanisms remain unclear. Oncolytic virotherapy is a promising antitumor treatment that selectively induces oncolytic cell death in tumor cells. Previously, we developed OBP-702, a telomerase-specific oncolytic adenovirus armed with the p53 tumor suppressor gene, which demonstrated potent antitumor effects across various cancer types. Oncolytic virotherapy is also known to stimulate antitumor immunity. In this study, we investigated the combined effects of OBP-702 and butyrate on colorectal cancer and elucidated the underlying mechanisms. In vitro, the combination of OBP-702 and butyrate exhibited synergistic cytotoxicity against various human and murine colorectal cancer cell lines. In vivo, the combination therapy significantly suppressed tumor growth in HCT116 and CT26 subcutaneous tumor models compared to monotherapy with either OBP-702 or butyrate alone. These synergistic effects were mediated by butyrate enhancing OBP-702's efficacy through the upregulation of coxsackievirus and adenovirus receptor (CAR) and integrin expression on tumor cells, improving viral infection efficiency. Butyrate also increased MHC-I expression on tumor cells through activation of the cGAS-STING pathway, leading to enhanced CXCL10 expression. This, in turn, activated antitumor immunity by recruiting CD8-positive T cells to the tumor microenvironment. The synergistic effects of butyrate and OBP-702 were further confirmed in an orthotopic colorectal tumor model with liver metastases using luciferase-expressing CT26 cells. In this model, the combination therapy not only reduced tumor growth but also improved survival by enhancing antitumor immunity mediated by CD8-positive T cells. To translate these findings into a more clinically relevant approach, butyrate-producing bacteria, Clostridium butyricum Miyairi 588 (CBM588), were used in place of butyrate. The combination therapy of CBM588 and OBP-702 demonstrated similar synergistic antitumor effects in mouse subcutaneous and rectal tumor models. In conclusion, the combination of OBP-702 and butyrate shows promise as a synergistic antitumor strategy and may represent a novel therapeutic approach for colorectal cancer.

#2212 Microbial metabolic pathways guide response to immune checkpoint blockade therapy.

Iris L. Mimpen[1], Thomas W. Battaglia[1], Miguel Parra Martinez[1], Laurien J. Zeverijn[1], Birgit S. Geurts[1], Louisa R. Hoes[1], Vincent van der Noort[2], Hans Gelderblom[3], Krijn K. Dijkstra[1], Lodewyk F. A. Wessels[4], Emile E. Voest[1]

[1]Molecular Oncology and Immunology, The Netherlands Cancer Institute, Amsterdam, Netherlands,[2]Department of Biometrics, The Netherlands Cancer Institute, Amsterdam, Netherlands,[3]Leiden University Medical Center, Leiden, Netherlands,[4]Molecular Carcinogenesis, The Netherlands Cancer Institute, Amsterdam, Netherlands

Recent studies have identified a link between specific microbiome-derived bacteria and immune checkpoint blockade (ICB) efficacy. However, these species lack consistency across studies and their immunomodulatory mechanisms remain elusive. We hypothesized that community-level metabolic pathways across microbes are more suitable to predict ICB response. Using a curated resource of pan-cancer metagenomics data of ICB-treated patients, we identified several microbial metabolic processes significantly associated with response. Methylerythritol phosphate (MEP) pathway activity was associated with response and intratumoral Vδ2 T cell infiltration and induced Vδ2 T cell-mediated anti-tumor responses in patient-derived tumor organoids. In contrast, the riboflavin pathway was associated with ICB resistance, and its intermediates led to mucosal-associated invariant T (MAIT) cell-mediated immune suppression. Collectively, our results highlight the relevance and complexity of metabolite-mediated microbiome-immune crosstalk.

#2213 Obesity alters cancer-related microbial pathways in women with benign and malignant breast disease.

Jack W. Sample[1], Matteo Redaelli[1], Stephen Johnson[2], Tanya L. Hoskin[3], Marina R. Walther-Antonio[4], Jun Chen[2], Tina J. Hieken[1]

[1]Surgery, Mayo Clinic, Rochester, MN,[2]Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[3]Health Sciences Research, Mayo Clinic, Rochester, MN,[4]Obstetrics and Gynecology, Mayo Clinic, Rochester, MN

Breast cancer is the leading cause of cancer death among women worldwide. Most cases occur in those without identifiable modifiable risk factors, highlighting critical gaps in our understanding of breast cancer biology including the influence of the gut microbiome. Here we studied the gut microbiome with shallow shotgun metagenomic sequencing from preoperative stool samples in a well-characterized clinical cohort of 131 women, median age 59 years, undergoing breast-conserving surgery for benign (n=23), high-risk (n=47), or malignant (n=61) breast disease. Taxonomic profiling was performed with Sourmasth 4.2.4 with GTDBv202 as reference database; functional profiling of metagenomic data employed HUMAnN 3.6 with identified gene families mapped to MetaCyc pathways. Differences in alpha diversity in terms of species richness were observed across diagnosis groups (benign, high-risk, malignant) and was lowest for high-risk lesions (p=0.031). Decreased alpha diversity was also associated with higher body mass index (BMI) (Shannon p=0.12, Inverse Simpson p=0.025). Significant beta diversity differences across diagnosis groups also were seen (Bray-Curtis p=0.044, Jaccard p=0.013) as were differences in association with BMI (Bray-Curtis, Jaccard, both p=0.002). No significant diversity differences associated with age, mammographic breast density or menopausal status were observed. Functional pathway profiling stratified by BMI showed a correlation between increasing BMI and greater relative abundance of genes in nicotinamide adenine dinucleotide (NAD) biosynthesis, folate metabolism, and aromatic amino acid metabolism pathways (p=0.0279, 0.0667 and 0.0860, respectively) - pathways implicated in breast cancer detection, survival and prognosis. Cross-referencing our significantly (FDR <5%) differentially abundant taxonomic findings with these functional pathway data identified enrichment of several *Blautia* species, linked to NAD biosynthesis via tryptophan metabolism, in patients with higher BMI. We also noted enrichment of *Dorea formicigenerans,* a species associated with increased breast cancer risk in obese women due to its pro-inflammatory effects, in individuals with a higher BMI. Here we report significant differences in gut microbiome diversity, taxonomy and functional pathway signals in association with BMI in women with breast disease. Differentially abundant species seen with rising BMI may contribute to functional pathways that drive increased breast cancer risk and may provide an actionable target for risk reduction independent of conventional risk reduction strategies.

#2214 Inhibiting the mevalonate pathway with atorvastatin alters gut microbiota and has potential as an anti-cancer treatment for ovarian cancer.

Juliane M. Liberto[1], Emily Ke[2], Daniel Labbe[2], Sabrene Mechergui[2], Kala Visvanathan[3], Ie-Ming Shih[1], Tian-Li Wang[1]

[1]Pathology, Johns Hopkins School of Medicine, Baltimore, MD,[2]Johns Hopkins University, Baltimore, MD,[3]Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Statins, a mevalonate (MVA) pathway antagonist, are widely used to treat and prevent hypercholesterolemia by blocking cellular production of cholesterol. However, new research has uncovered that statins exhibit pleotropic anti-tumor and immune modulating effects, as downstream metabolites from the MVA pathway have been linked to several cellular systems commonly dysregulated in cancer patients. Furthermore, statins have been shown to induce significant changes in intestinal enterotypes in both humans and mice. This is uniquely important as studies on the intestinal microbiota have shown a strong correlation between gut health and cancer outcomes. Therefore, we hypothesized that statins could be utilized to therapeutically target pre-clinical models of ovarian cancer by modulating the systemic and tumor immune landscape as well as the intestinal microbiome. Female C57BL/6 mice injected with $5x10^5$ ID8-$BRCA1^{null}$ cells received low-dose atorvastatin (5mg/kg/day, n=14) or DMSO (<2%(v/v)/day, n=14) control for 5 weeks. Histopathology was performed on necropsy tissues, and immune profiling via flow cytometry was performed on splenocytes and cells isolated from ascites to examine the impact of statins on immune cell populations. In a separate study, we administered to female C57BL/6 mice atorvastatin (5mg/kg/day, n=5) or DMSO (<2%(v/v)/day, n=5) control for 4 weeks and sequenced 16S ribosomal RNA in their stool to determine how statin affected intestinal flora. Lastly, to determine if host genetics affect statin-mediate microbial changes, we simultaneously administered atorvastatin (5mg/kg/day) or DMSO (<2%(v/v)/day) control to three commonly used inbred mice strains (C3H/He, n=3; BALB/c, n=3; C57BL/6, n=5) and compared 16S sequencing results across all three strains.
Conclusion: We found that statins, in the absence of standard of care regimens, are able to elicit immune modulatory effects in an aggressive ascitic model of ovarian high-grade serous carcinoma thereby offering moderate improvements to tumor outcomes. Furthermore, we found that statins favorably alter the intestinal microbiome, increasing microbial diversity within the gut and increasing the abundance of beneficial microbiota. Importantly, our data emphasize the role of host genetics in shaping microbiome responses to statin therapy, which could have implications for patient-specific treatment strategies. Overall, these results support further research to evaluate statins' use as a therapeutic or preventive agent for ovarian cancer.

#2215 Age and indoleamine 2,3-dioxygenase 1 (IDO1) interact to affect gut microbiome homeostasis in subjects with glioblastoma.

Lijie Zhai[1], Akriti Shrestha[2], Kristen L. Lauing[1], Manon Penco-Campillo[1], Oluwatomilayo Odum[1], Prashant Bommi[1], Taylor Koch[1], Robert H. McCusker[3], Douglas E. Anderson[4], Anand Germanwala[4], Vikram C. Prabhu[4], Jigisha P. Thakkar[4], Jacob M. Allen[2], Rimas V. Lukas[5], Derek A. Wainwright[6]

[1]Cancer Biology, Cardinal Bernardin Cancer Center, Loyola University Medical Center, Maywood, IL,[2]Health and Kinesiology, Animal Sciences, University of Illinois at Urbana-Champaign, Urbana, IL,[3]Animal Sciences, University of Illinois at Urbana-Champaign, Urbana, IL,[4]Neurological Surgery, Loyola University Medical Center, Maywood, IL,[5]Neurology, Northwestern University Feinberg School of Medicine, Chicago, IL,[6]Cancer Biology, Neurological Surgery, Cardinal Bernardin Cancer Center, Loyola University Medical Center, Maywood, IL

Objective: This study aimed to determine how age and IDO1 interact to affect the gut microbiome, microbial metabolite levels, and survival outcomes in subjects undergoing IDO1-targeted immunotherapy against glioblastoma (GBM).
Methods: Serum and colon contents from younger 16-20- or older 92-118-week-old wild-type (WT), IDO1 knockout (IDO1-KO), and IDO1 enzyme null (IDO1-H350A) mice were analyzed for 16S rRNA gut microbiome composition and microbial-derived aromatic amino acid metabolites via LC/MS/MS. Fecal samples from younger 7-8 or older 81-85 week-old WT mice with intracranial syngeneic GL261 GBM cells treated with or without brain radiation (RT) and PD-1 mAb were also analyzed. Fecal and plasma samples from 12 newly diagnosed IDHwt/MGMT promoter unmethylated GBM patients who received RT plus PD-1 mAb and IDO enzyme inhibitor were also analyzed.
Results: Young and old IDO1-KO and IDO1-H350A mice demonstrated a unique gut microbiome signature with an elevated abundance of *Bifidobacterium* and *Helicobacter* ($p<0.05$) and a reduced abundance of *Ventriosum* and *Sireaum* compared to WT mice ($p<0.001$). *Prevotellaceae*, *Muribaculum*, *Alistipes*, *Enterohabdus*, *Clostridia*, and *Akkermansia* were different in IDO1-KO and IDO1-H350A mice compared to WT - but only in older mice. Serum microbiome-derived aryl-lactates phenyllactate (PLA), indolelactate (ILA), and 4-hydroxyphenyllactate (4HPLA) were increased in IDO1-KO mice compared to WT and IDO1-H350A mice ($p<0.001$) - but only in older mice. Older WT mice with GL261 GBM showed lower fecal aryl-lactates (PLA, 4HPLA, and ILA) compared to younger counterparts. Treatment with RT + PD-1 mAb also showed decreased serum indole propionic acid (IPA) levels in young but not old mice with GL261 GBM ($p<0.05$). Analyses from GBM patient baseline fecal samples revealed that higher abundance of *Massilioclostridium coli*, G*GB3819-SGB5184*, *Dysosmobacter welbionis*, and *Phocaeicola plebeius* was associated with longer survival ($p<0.004$), while higher levels of fecal ILA and lower levels of plasma IPA also correlated with elongated survival ($p<0.04$ and $p<0.01$ respectively). Combined treatment of RT + PD-1 mAb + IDO1 inhibitor decreased plasma IPA when compared to baseline ($p<0.01$).
Conclusions: IDO1 possesses both enzyme- and non-enzyme-dependent effects that change gut microbiota composition and bioactive microbial aromatic amino acid metabolite levels, which is also influenced by aging. Certain gut microbiota species and metabolites may serve as prognostic markers for predicting outcomes to immunotherapy for GBM. These findings warrant further investigation into how IDO1 interacts with age to affect immunotherapeutic efficacy in subjects with GBM.

#2216 Modulating gut microbiota to enhance the efficacy of immunotherapy in triple negative breast cancer.

Samarpan Majumder[1], Manisha Poudel[1], Fokhrul Hossain[1], Luis Del Ville[1], Lucio Miele[1], Justin Brown[2]

[1]LSU Health New Orleans, New Orleans, LA,[2]Pennington Biomedical Research Center, Baton Rogue, LA

Background: Triple-negative breast cancer (TNBC) is the most aggressive form of breast cancer and is diagnosed more frequently in younger, premenopausal women. Obesity is a known risk factor for increased TNBC incidence. The association of gut dysbiosis with obesity is now established. Immune checkpoint blockade with anti-PD-1 is currently the standard of care for early TNBC. Evidence suggests modulating the gut microbiome enhances cancer immunotherapy efficacy in a few cancer types. However, there are no studies on early TNBC.
Overarching Challenge: The number of patients with early TNBC who benefit from anti-PD-1 therapy remains suboptimal.
Objective: Our study aims to enhance the efficacy of anti-PD-1 therapy by modulating the gut microbiota in a mouse model of obesity and TNBC. We hypothesize that a probiotic supplement will enhance the efficacy of anti-PD-1 therapy.
Methods: We determined the efficacy and safety of two weeks of probiotic supplementation before anti-PD-1 therapy on objective response rates in an obese mouse model of triple-negative breast cancer. This was evaluated by measuring the objective response rate (tumor burden) after two weeks of anti-PD-1 treatment. FVB female obese mouse model and authenticated TNBC C0321 claudin low mouse tumor cells (In Vitro Technologies) were used for engrafting tumor. We used a probiotic formulation from Creative Enzyme which is a blend of 13 human probiotic strains (Cat # PRBT-035, NY).
Results: One way ANOVA comparing three groups of mice (anti-PD1, anti-PD-1+ serotype and probiotics + anti-PD1) produced a statistically significant outcome confirming our prediction that probiotics positively affect anti-PD1 therapy. A Kaplan-Meier survival plot based on our record of mouse survival over the course of the treatment demonstrates that only probiotics plus anti-PD1 therapy could provoke statistically significant survival benefit over isotype control ($p=0.046$) in our study. Analysis of cytokine profile revealed elevated level of interferon-γ and downregulation of proinflammatory cytokines in plasma from mice treated with probiotics only. Furthermore, we observed increased CD8+T and CD4 +T cells in the tumor tissue of probiotics treated mice when compared to untreated mice in our Immunohistochemistry analysis. For feasibility study in human subjects, our pilot study is recruiting volunteers (NCT06318507) to confirm whether the fecal microbiome differs between patients with and without obesity and early TNBC and who achieve pCR from preoperative anti-PD-1 therapy.
Impact: The study provides critical experimental data to demonstrate causality and feasibility to justify larger-scale interrogations to modulate the gut microbiome in women with early TNBC who plan to begin anti-PD-1 therapy.
Innovation: This study is the first to determine how a probiotic supplement can enhance anti-PD-1 efficacy in early TNBC.

#2217 Commensal bacteria are internal triggers of chronic inflammation and B-cell lymphoma development in myeloid cell-specific TRAF3-deficient mice.

Jaeyong Jung, Sining Zhu, Almin I. Lalani, Judith Shakarchi, Brygida Matracz, Guojun G. Wu, Wei-Xing Zong, Liping Zhao, **Ping Xie**

Rutgers University - New Brunswick, Piscataway, NJ

Myeloid cells are central players in innate immunity and inflammation. Their function is regulated by the adaptor protein TRAF3. We previously reported that aging myeloid cell-specific TRAF3-deficient (M-*Traf3*$^{-/-}$) mice spontaneously develop chronic inflammation and B-cell lymphoma (BCL). In the present study, we aimed to identify the internal trigger of this disease phenotype in these mice. We first detected gut dysbiosis and transmigration of commensal bacteria to the liver in aging M-*Traf3*$^{-/-}$ mice. Interestingly, depletion of commensal bacteria using antibiotics effectively prevented chronic inflammation and BCL development in these mice. Systemic IgG responses against commensal bacteria were induced and the IgH CDR3 sequences of malignant B-cell clones of M-*Traf3*$^{-/-}$ mice showed high homology to prevalent bacteria-reactive Ig clonotypes. Furthermore, M-*Traf3*$^{-/-}$ mice with BCL exhibited high titers of antibodies against commensal bacteria in their serum. Together, our findings suggest that commensal bacteria dysbiosis and transmigration can promote chronic inflammation and BCL development in individuals with compromised innate immunity. Accordingly, targeting relevant commensal bacteria may serve as a therapeutic strategy for preventing and treating chronic inflammation and BCL in these patients.

Background: Breast cancer (BC) is a highly heterogeneous disease, and refining additional clinical parameters is crucial for its effective management. The tumor immune microenvironment, influenced by factors such as infiltrating intratumoral microbiota, has been shown to play a key role in cancer prognosis and treatment response.
Methods: RNA was isolated from formalin-fixed paraffin-embedded (FFPE) tissue from 82 women with BC. Expression of 54 immune genes was analysed using Nanostring and differentially expressed genes (DEGs) were determined using ROSALIND®. Immune cell populations were profiled using Nanostring's cell type profiling module, while tumour infiltrating lymphocytes (TILs) were assessed via haematoxylin and eosin (H&E) staining. For microbiome profiling, DNA was isolated from 29 biopsy samples using MoBio PowerMag Soil DNA Isolation kit and sequenced with an Illumina MiSeq. In addition, the PIK3CA gene was genotyped for three hotspot mutations using qPCR. Log-rank test was performed to evaluate the prognostic significance of immune phenotypes.
Results: Hierarchical clustering of the gene expression profiles revealed four discrete immune phenotypes (IP1-4) characterized by differential expression of immune-activating and immune-regulatory genes. An immunologically inert phenotype (IP2) was identified, marked by consistent downregulation of both immune suppressive and immune activating genes, alongside the lowest levels of immune cell infiltration. In contrast, IP4 exhibited an immunologically active TME, characterized by upregulation of key cytotoxic genes and the highest abundance of immune cells. IP1 and IP3 had intermediate characteristics. A significant association was found between IPs and BC subtypes: luminal A tumors predominated in IP2, while basal BC tumors were most common in IP3. No significant differences in PIK3CA mutations were observed across the IPs. Importantly,
IPs with an active TME were associated with improved overall survival compared to those with an inert immune environment.Microbiota diversity and abundance did not show significant differences across the IPs. However, microbiota composition differed significantly between TIL groups. Notably, the *Firmicutes* and *Verrucomicrobia* phyla, as well as the *Lactobacillaceae, Akkermansiaceae* and *Caulobacteraceae* families, were more abundant in intermediate TIL groups. At the genus level, *Delftia* was significantly enriched in the high TIL group ($P < 0.0001$), while *Akkermansia* and *Cutibacterium* were more abundant in the intermediate TIL groups.
Conclusion: Immune phenotyping of the TME identified distinct immune subgroups that are associated with prognosis and could guide treatment selection. Additionally, potential immune-microbiome interactions were observed, suggesting a role in modulating anti-tumor immunity.

#2219 Clinical response to immune checkpoint inhibitors in melanoma is associated with distinct gut bacterial species that promote anti-tumor immunity by different mechanisms.

Matthew James Robinson[1], Laure Castan[1], Fernanda Schreiber[1], Clelia Villemin[1], Chiara Berlato[1], David J. Adams[2], Pippa Corrie[3], Tim Sharpington[1], Trevor D. Lawley[4], Ghaith Bakdash[1]

[1]Microbiotica, Cambridge, United Kingdom,[2]Experimental Cancer Genetics, Wellcome Sanger Institute, Cambridge, United Kingdom,[3]Oncology Department, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom,[4]Host-Microbiota Interactions, Wellcome Sanger Institute, Cambridge, United Kingdom

The gut microbiome of cancer patients impacts the response to immune checkpoint inhibitor (CPI) therapy. Using high precision microbiome profiling, we have recently identified 9 diverse species of gut commensal bacteria that are all consistently and strongly associated with CPI response across 4 independent cohorts of melanoma patients. These 9 species represent all 3 of the major phyla in the human intestinal microbiome, and include 4 novel species. A consortium of 9 strains, each representing 1 of these species, is being developed as a live biotherapeutic product (LBP), MB097. In the MCA-205 syngeneic tumor model, MB097 demonstrated synergistic tumor growth inhibition in combination with anti-PD1. The mechanisms by which each of the 9 species exert their anti-tumor effects were investigated, using in vitro assays with primary human immune cells. The bacteria strongly activate dendritic cells (DCs) inducing interleukin (IL)-12. These DCs stimulated by the bacterial strains very potently triggered $CD8^+$ Cytotoxic T Lymphocytes (CTLs) to upregulate Granzyme B and interferon (IFN)γ and kill tumor cells in vitro. Similarly, bacteria-stimulated DCs prompted natural killer (NK) cell activation, as demonstrated by increased expression of IFNγ and elevated capacity for killing tumor cells. DC stimulation by 3 of the 9 strains markedly skewed the cytokine profile to higher IL-12 and lower IL-10, and also led to particularly potent CTL and NK cell activation. These strains represent 3 different families of Firmicutes. Blocking IL-12 reversed the activation and tumor killing effect of DCs stimulated with these strains of Firmicutes. Moreover, the bacterial metabolites derived from 4 different strains triggered CTLs to upregulate the expression of granzyme B and IFNγ and kill tumor cells in vitro. In summary, we have identified 9 gut commensal bacteria as being consistently associated with response to CPI in metastatic melanoma. These bacteria can interact directly with DCs to potently activate CTLs and NK Cells, and some strains of Firmicutes do this via induction of IL-12. Other strains also release metabolites that directly enhance CTL activation. These data begin to identify the different mechanisms by which gut commensal bacteria drive immunotherapy response in human systems. MELODY-1 (NCT06540391) is an ongoing interventional phase 1b study to evaluate MB097 in combination with pembrolizumab in advanced melanoma patients.

#2220 Gut microbiome impacts the tumor microenvironment and enhances the effectiveness of anti-PD1 therapy in head and neck cancer.

Po-Han Lin[1], Ya-Hui Chen[1], Chi-Maw Lin[1], Jessica Tien Yu Ho[2], Chih-Hao Yu[1], Chen-Yi Wang[1], Yuan-Chia Chu[1], Chun-Yu Liu[3], Ying-Cheng Chiang[1], Ruey-Long Hong[1]

[1]National Taiwan University Hospital, Taipei City, Taiwan,[2]National Taiwan University, Taipei City, Taiwan,[3]Taipei Veterans General Hospital, Taipei City, Taiwan

Although the Food and Drug Administration has approved anti-PD1 as an effective therapy for recurrent head-and-neck squamous cell carcinoma (HNSCC), its response rate remains limited to approximately 10-30%, and the prognosis for patients is still poor. In this study, we seek to enhance the therapeutic efficacy of anti-PD1 for recurrent HNSCC. First, we compared the pathology of responders and non-responders to pembrolizumab treatment for HNSCC. Immunohistochemical staining revealed a significantly higher abundance of CD8 T cells in responders, and RNA sequencing, through Gene Set Enrichment Analysis (GSEA), demonstrated a significant activation of CD8 T cell pathways in responders compared to non-responders. Second, 16S full-length sequencing of stool DNA identified an enrichment of Eggerthella lenta (E. lenta) in responders. Furthermore, the presence of E. lenta was positively correlated with CD8 T cell activation and cytotoxic activity. Third, to assess the impact of E. lenta on the anti-tumor response to anti-PD1 therapy in vivo, we implanted HNSCC tumors subcutaneously in antibiotic-induced microbiome depletion mice. The mice were treated with anti-PD1 monoclonal antibody and oral E. lenta administration, resulting in significant tumor regression compared to that of the controls (no treatment), anti-PD1 alone, or E. lenta alone. The excised xenograft HNSCC tumors were analyzed by flow cytometry, revealing that the combination of anti-PD1 therapy and oral E. lenta synergistically increased tumor-infiltrating CD8 T cells and enhanced their activation, as evidenced by elevated interferon-gamma and TNF-alpha expression. Metabolomic analysis identified changes in fatty acid pathways linked to CD8 T cell activation, E. lenta administration, and responders. Our results suggest that E. lenta enhances the response to anti-PD1 therapy, offering new insights into the connection between the microbiome and cancer immunotherapy.

#2221 Obesity influences the tissue resident breast microbiota impacting complement signaling and tumorigenesis.

Mohamed Gaber[1], Adam S. Wilson[1], Adam J. Katz[2], Karen Haas[3], Katherine L. Cook[1]

[1]Department of Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC,[2]Department of Plastic and Reconstructive Surgery, Wake Forest University School of Medicine, Winston-Salem, NC,[3]Department of Microbiology and Immunology, Wake Forest University School of Medicine, Winston-Salem, NC

Obesity is a risk factor for breast cancer, influencing both the incidence and prognosis of the disease. Obesity alters the breast microbiome in ways that may promote breast carcinogenesis, and microbiome perturbations are evident in breast cancer patients. Yet, it is unclear if these microbial perturbations are drivers of breast cancer. Our group previously showed that diet and anti-cancer therapies modify the breast tissue microbiome. We further showed that certain commensal bacterial species in the mammary gland reduce tumorigenesis in high-fat diet-fed MMTV-PyMT mice, implicating tissue-resident microbiota in modifying breast cancer risk. Thus, we investigated the impact of obesity-induced microbiome alterations on genomic instability in mammary epithelial cells, as a hallmark of breast cancer risk. Our preliminary studies showed that obesity caused elevated systemic and breast tissue levels of lipopolysaccharide (LPS) and flagellin. *In vitro* and *in vivo* experiments demonstrated their ability to induce DNA damage in the mammary epithelium. 16S rRNA sequencing on DNA isolated from non-cancerous breast tissue revealed an enrichment of Proteobacteria in obese premenopausal subjects. Bacteria from this phylum harbors highly immunogenic LPS and the majority of them are flagellated. Importantly, Proteobacteria proportional abundance was associated with breast tissue levels of DNA damage. Intriguingly, these associations were absent in postmenopausal women. One key difference between breast tissues of the two menopausal groups was in their complement activity and immune responses to LPS and flagellin. Redox proteomics analysis showed that obesity caused an enrichment in the oxidation of several complement C3 peptides in both menopausal groups. Normally, oxidation of complement C3 causes its activation through the generation of a C3 convertase that cleaves C3 into the active fragments; C3a and C3b. However, this was only observed in premenopausal women where the C3 oxidized peptides showed significant correlations with C3a levels. Complement system dysfunction in postmenopausal women was also manifested by having lower C3a levels, higher B-cell trafficking and lower anti-LPS IgA levels in their breast tissues than premenopausal women. Ongoing experiments are being performed to determine if there are breast tissue differences in complement regulatory proteins such as factor H and CD59. To demonstrate causality, we performed a carcinogen-induced mammary tumorigenesis model in wild-type (WT) and C3 knockout (KO) mice fed a low-fat or high-fat diet. C3 KO mice showed increased tumor-incidence compared to WT in the context of a high-fat diet, but not a low-fat diet, suggesting a role of complement signaling in anti-tumor immunity in the context of obesity. Overall, this work identifies a novel immunity-microbiome signaling axis potentiating obesity-mediated breast cancer risk.

#2222 Trimethylamine-N-oxide (TMAO) mediates immunotherapy resistance in advanced HCC.

Mari Nakazawa, Vivian L. Raj, NV Rajeshkumar, Noushin Rastkari, Michael Davis, Elizabeth De Oliveria, Madelena Brancati, Ervin Griffin, Kabeer Munjal, James Leatherman, Sarah Mitchell, Marina Baretti, Won Jin Ho, Mark Yarchoan, Chi V. Dang

Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

Recent approvals of immune checkpoint inhibitor (ICI) based regimens have transformed the clinical landscape of advanced hepatocellular carcinoma (HCC), however, clinical responses are only observed in a minority of patients. Trimethylamine-N-oxide (TMAO) is an amine oxide biosynthesized from trimethylamine (TMA), generated when gut bacteria metabolize dietary choline via the enzyme CutC. While prior studies have shown that TMAO concentrations positively correlate with the risk of several gastrointestinal malignancies, newer studies have demonstrated that TMAO may enhance antitumor immunity in some tumor types. TMAO may therefore play an important role in modulating the tumor immune response, but its significance in HCC is unknown.

We prospectively collected whole blood from patients with HCC prior to initiating standard-of-care ICI-based therapy at Johns Hopkins (IRB #00267960). Clinical records were reviewed for demographic characteristics and clinical outcomes. Additionally, we studied the impact of acute and chronic choline supplementation on anti-PDL1 efficacy in a syngeneic murine model of HCC (Hep53.4 in C57BL/6 mice). Baseline choline, TMA, and TMAO plasma concentrations in clinical and preclinical specimens were quantified via liquid chromatography-mass spectrometry (LC-MS) utilizing the SCIEX Triple Quad 6500+ system.

The clinical cohort included 42 patients with advanced HCC. Patients were predominantly male (81.0%) with Barcelona Clinic Liver Cancer (BCLC) stage C disease (73.8%) who underwent treatment with atezolizumab + bevacizumab (52.4%) or durvalumab + tremelimumab (31.0%). In a multivariable Cox model, higher plasma TMAO concentration at baseline was associated with inferior progression-free survival (PFS; HR 1.36 per interquartile range [IQR] increase, $p=0.032$) and overall survival (OS; HR 1.63 per IQR increase, $p<0.001$) after controlling for BCLC stage, albumin-bilirubin index, alpha fetoprotein (AFP) concentration, and baseline choline and TMA concentrations. In our preclinical model, mice given chronic choline supplementation (1% choline diet for 14 days prior to treatment with anti-PDL1 therapy) had increased plasma TMAO concentrations ($p<0.001$) and exhibited no response to anti-PDL1 therapy, compared to mice given standard and acute choline (1% choline diet starting concurrently with anti-PDL1 treatment) diets.

Our clinical and preclinical results suggest that high plasma TMAO concentration is associated with inferior outcomes on ICI therapies in HCC. These findings contrast with existing preclinical studies that suggest TMAO may potentiate responses to ICI therapy. We hypothesize that chronic TMAO exposure may lead to immune cell exhaustion via promotion of an inflammatory microenvironment and oxidative stress. Studies examining the effect of CutC inhibition are ongoing in our laboratory and may provide further rationale for targeting TMAO in HCC.

#2223 Phase I clinical trial combining camu camu prebiotic enriched with castalagin modulates bile acids and metabolites in combination with cancer immunotherapy in patients with treatment-naïve lung cancer and PD-1 refractory melanoma (NCT05303493).

Jade Maillou[1], Reilly Pidgeon[2], Diogjena Katerina Prifti[1], Meriem Messaoudene[1], Sreya Duttagupta[1], Myriam Benlaifaoui[1], Yongjia Hu[1], Alyse Filin[1], Mayra Ponce[1], Wiam Belkaid[1], Julie Malo[1], Guido Kroemer[3], Sylvere Durand[3], Olivier Barbier[4], Nathalie Daaboul[5], Normand Blais[1], Mustapha Thefe[1], Marie Florescu[1], Rahima Jamal[1], Wilson Miller[6], Antoine Desilets[1], Bastien Castagner[2], Arielle Elkrief[1], Bertrand Routy[1]

[1]CHUM Research Centre, Montreal, QC, Canada,[2]McGill University, Montreal, QC, Canada,[3]Institut Gustave Roussy, Paris, France,[4]CHUQ Research Centre, Laval University, Quebec, QC, Canada,[5]Charles Lemoyne Hospital, Sherbrooke University, Montreal, QC, Canada,[6]Jewish General Hospital, Montreal, QC, Canada

Introduction: Several strategies to improve immune checkpoint inhibitors (ICI) activity are under evaluation. Pre-clinical murine studies have shown the potential of castalagin, a prebiotic polyphenol extracted from Camu Camu (CC) berry to beneficially shift the microbiome and metabolites leading to enhanced ICI response. We tested CC, an approved natural product, in a trial combined with ICI in melanoma (MM) and non-small cell lung cancer (NSCLC).

Methods: We completed a phase I trial combining 1.5g daily of CC in oral capsules, started 7 days prior ICI initiation and continued for 3 months. The study included 2 arms: (1) advanced treatment-naïve NSCLC patients (pts) with PD-L1 <50% receiving anti-PD-1 and platinum doublet chemotherapy (chemo), and (2) ICI-refractory MM pts rechallenged with ICI. The primary endpoint was safety, the secondary endpoint included disease control rate (DCR; rate of partial response (PR), complete response, and stable disease (SD)). Exploratory analyses focused on CC's impact on the microbiome composition and HPLC analysis for metabolites with particular focus on bile acid (BA) production. In parallel, murine experiments with supplementation of castalagin were conducted and *in vitro* assays were performed to explore its link to the BA pathway.

Results: Of the 29 pts enrolled, none experienced AE related to CC alone. Among 14 NSCLC pts receiving CC+ICI+chemo, incidence of grade 3 adverse events (AE) was 29%, the DCR reached 43% (all PR), with 0 patient experiencing primary progressive disease. In the refractory MM cohort, incidence of grade 3 AE related to CC+ICI was 16%. Among the 12 evaluable pts, the DCR was 35% with 1 achieving a PR, while 2 had durable SD over an 18-month period. We measured BA concentrations in the feces of NSCLC pts and observed a rise in both primary and conjugated BA post-CC. In addition, metabolomic analysis revealed higher phenylbutyric acid level in the plasma of NSCLC. In MM, conjugated BA were enriched in the plasma post-CC. Similarly, administration of castalagin in a murine model resulted in elevated levels of DCA and UDCA in feces and serum. In mice, the modulation of FXR (main BA receptor) inhibited castalagin antitumor activity, highlighting its reliance on BA pathway. Moreover, stimulation of liver cells with urolithins metabolites of castalagin, induced the upregulation of key BA transporters *Ostα/β*, *Tgr5* receptor and *Cyp8b1* enzyme.

Conclusion: Administration of CC showed no increase in toxicities with encouraging preliminary efficacy to ICI in pts mainly in the setting of refractory MM. Ongoing analyses aim to identify how microbial signature can shift BA pool and their functional role in clinical responses. These results position castalagin as a novel experimental therapeutic target in immuno-oncology.

#2224 Impact of NT/NTR1 signaling on metabolic pathways and tumor-associated microbiomes in colorectal cancer.

Haoming Wu, Yang Wang, Moumita Banerjee, Jinpeng Liu, Chi Wang, Dahe He, Therese Bocklage, Jing Li, B.Mark Evers

Markey Cancer Center, Lexington, KY

Background: Colorectal cancer (CRC) is a leading cause of cancer-related deaths worldwide with substantial heterogeneity in patient outcomes. Neurotensin (NT) and its high-affinity receptor (NTR1) have been implicated in CRC progression, particularly in modulating tumor metabolism and immune responses. NT/NTR1 expression has been linked to CRC progression and outcomes, while gut microbiota is increasingly recognized for its role in cancer development and therapy. The purpose of current study was to explore the relationship between NT/NTR1 expression, microbial communities, and transcriptomic changes in tumor versus adjacent normal tissues, focusing on their role in shaping tumor-associated microbiomes and influencing cancer progression.
Methods: We performed: (i) RNA sequencing of tumor samples from 96 Appalachian Kentucky CRC patients to assess NT/NTR1 expression and its association with transcriptomic pathways; (ii) paired RNA sequencing and 16S rRNA-based microbiome profiling from tumor and adjacent normal tissues of 15 patients to evaluate transcriptomic and microbial differences. Functional gene prediction was performed using Picrust2 based on 16S rRNA profiles, and differential expression analysis was conducted using DESeq2. NT/NTR1 expression and bacterial abundance were validated by qPCR.
Results: (i) RNA sequencing of the 96-patient cohort showed that high NT/NTR1 expression was associated with dysregulation of multiple metabolic pathways (e.g., lipid, carbohydrate, and amino acid metabolism) and immune-related pathways (e.g., "immune disease" and "infection disease: bacteria"). (ii) In paired tumor and adjacent normal tissues, NT/NTR1 expression was significantly elevated in tumor tissues. Microbial profiling revealed higher microbial abundance and diversity in tumor tissues, with notable enrichment of *Campylobacter* and *Chlamydia* species. Functional gene prediction using Picrust2 identified significant upregulation of flagellar assembly-related genes, such as K13626, in tumor microbiomes compared to normal tissues ($P = 3.66 \times 10^{-3}$). These findings suggest enhanced microbial motility and interaction in the tumor microenvironment facilitated by NT/NTR1-driven metabolic changes.
Conclusions: NT/NTR1 signaling remodels metabolic pathways in CRCs, enhances nutrient absorption and creates a more favorable environment for microbial colonization. The observed enrichment of motility-related bacterial species and functional genes highlights the role of the NT/NTR1 signaling pathway in promoting tumor-microbe interactions. Importantly, these findings provide potential avenues for CRC diagnosis and therapeutic strategies targeting the NT/NTR1 axis.

#2225 Diet with high soluble fiber induces favorable gut microbiota and metabolomic profiles, increases anti-tumor immunity, and suppresses lung cancer progression.

Manvi Sharma[1], Yuejiang Liu[1], Altai Enkhbayar[2], Sujuan Yang[1], Inti C. T. Reischle[1], Mohamed A. Jamal[1], Tieling Zhou[1], Zahraa Rahal[1], Lorena I. Gomez B.[1], Hannah Moreno[3], Matthew C. Ross[3], Lin Tan[1], Chidera O. Chukwuocha[1], Eleeka Nia[4], Anusha S. Thomas[1], Jennifer A. Wargo[1], Nadim J. Ajami[1], Philip L. Lorenzi[1], Robert R. Jenq[2], Seyed Javad Moghaddam[1], Kristi L. Hoffman[3], Humam Kadara[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]City of Hope, Duarte, CA,[3]Baylor College of Medicine, Houston, TX,[4]University of Houston, Houston, TX

Accumulating evidence suggests that taxonomic composition and phenotypic traits of the gut microbiome, which acts as a central regulator of cancer progression and response to immunotherapy, are influenced by diet. Prior studies have demonstrated that dietary constituents, notably soluble fibers, stimulate probiotic proliferation in the gut, maintain integrity of the intestinal barrier, and modulate immune responses. Yet, mechanisms by which a high soluble fiber diet (HSFD) impacts the gut-immune axis and pathogenesis of cancers external to the gut are poorly defined. Here, we employed a human-relevant mouse model in which knockout of G-protein coupled receptor 5A (*Gprc5a*$^{-/-}$) and exposure to tobacco lead to development of preneoplasia and lung adenocarcinoma. Mice were randomized in dietary treatments: no fiber, high insoluble fiber, or HSFD, administered either post-weaning (early life) or after transplant of lung cancer cells (prophylactic intervention). Tumor growth was most significantly reduced in HSFD-fed mice, with notable anti-tumor effects observed in both early life and prophylactic intervention settings. These effects were recapitulated in an independent syngeneic model and tobacco carcinogen-exposed *Gprc5a*$^{-/-}$ mice. 16S rRNA-Seq analysis revealed HSFD-induced enrichment of beneficial taxa including *Bacteroides*, *Faecalibaculum*, *Akkermansia,* and *Bifidobacterium,* alongside evident decrease in tumor-promoting genera such as *Odoribacter* and *Alistipes*, with some of these microbial changes correlated with dietary fiber intake in cancer-free individuals. These microbial shifts corresponded with elevated levels of key gut metabolites, notably butyrate. Flow cytometry of colonic lamina propria revealed changes in immune profiles, characterized by reduced pro-IL-1β^{+} macrophages and dendritic cells, with parallel systemic effects evidenced by decreased inflammatory cytokines in sera. HSFD also skewed the tumor microenvironment toward an antitumorigenic milieu, marked by expanded B lineage cells, cDC1s and M1-like macrophages and, conversely, decreased levels of activated cDC2s and M2 macrophages. Fecal microbiota transplant models showed that effects of HSFD were largely mediated by the gut microbiome as mice that received fecal microbiota from syngeneic HSFD-fed donors showed significant tumor inhibition compared to littermates receiving microbiota from no-fiber-fed donors. Moreover, butyrate supplementation in a fiber-free diet mimicked the anti-tumor effects of HSFD, as reflected in gut immune populations, tumor metabolomics and systemic cytokines. Our findings inform on novel mechanisms by which HSFD robustly impacts gut consortia and immune milieu in the inhibition of lung cancer, suggesting that incorporation of HSFD in cancer treatments could improve outcomes for patients with lung cancer.

IMMUNOLOGY: Modulation of Tumor Microenvironment: Enhancing Immunogenicity and Counteracting Suppression Poster Session

#2230 Persistent elimination of tumors via balanced regulation of immune signals.

Xiaodong Xiao[1], Lei Han[2], Yuan Yuan[3], Hua Jiang[1], Yueqing Xie[1], Jianwei Zhu[1]

[1]Jecho Laboratories, Frederick, MD,[2]Jecho Institute, Shanghai, China,[3]School of Pharmacy, Shanghai Jiao Tong University, Shanghai, China

Despite its success, there are still numerous unmet clinical needs in cancer immunotherapy. Many patients failed to respond due to the lack of effective and properly regulated T cell stimulation. Molecules capable of inhibiting multiple immune checkpoints, enhancing the co-stimulatory signals on T cells to “revive” the tumor antigen-specific T cell response, as well as sustaining the responses to prevent the recurrence of the tumor are highly desirable. Here we report a Fc-based, tripartite, multifunctional fusion protein JLM019 that has been rationally designed to integrate the multiple mechanisms of PD-1/PD-Ligands checkpoint inhibition and T cell co-stimulations through CD80-mediated signaling. Fused at the C-terminus of the Fc fragment, structure-guided mutations A132L and Loop15 were introduced into the human PD-1 ectodomain to improve affinity with its ligands. Fused at the N-terminus, the wild-type CD80 provided a canonical co-stimulatory signal compared to hyperreactive anti-CD28 agonistic antibodies. Combined effect of PD-1 signaling blockade and balanced T cell activation through CD80 binding with CTLA4/CD28 by JLM019 led to persistent elimination of wide spectrum of tumors, including tumors with no PD-L1 expression, or those resistant to conventional PD-1 checkpoint inhibitors in CDX models. JLM019 acts not only on the tumor but also through activating tumor-specific T cells that depend on other APCs and/or through PD-L2 signaling. Significantly, JLM019 treatment induced effective immune memory, which was confirmed by experiments using transferred splenocytes from cured mice that not only prevented tumor initiation but also eliminated tumors in the established tumor-bearing mice. The sophisticated mechanism of the action by JLM019 is explored and discussed. In summary, we developed an immune signal regulator JLM019 that can modulate immune signaling against advanced tumors in a potent yet well-balanced manner. Pre-clinical toxicity and PK/PD studies in cynomolgus monkey have shown a promising safety and toxicity profile, with a dose up to 100mg/kg being tolerated. These encouraging results prompted us to advance JLM019 for clinical studies in humans.

#2231 CY-101 inhibits the tumor growth and improves anti-PD-1 immunotherapy in beta-catenin-driven tumors.

M. Poussard[1], M. Noman[1], K. Van Moer[1], J. Hossain[2], R. Gao[1], E. Solel[2], F. Grego[3], L. Prestegarden[3], R. Bjerkvig[2], **B. Janji**[1];
[1]Luxembourg Institute of Health, Luxembourg City, Luxembourg, [2]University of Bergen, Bergen, Norway, [3]Cytovation AS, Bergen, Norway

CY-101 is a bi-functional peptide with a dual mechanism of action. It selectively targets cancer cell membranes, forming pores that release neoantigens to the tumor microenvironment, thereby triggering a robust anti-tumor immune response. In addition, CY-101 inhibits the oncogenic Wnt/beta-catenin signaling pathway, which is frequently dysregulated in several cancers such as colorectal carcinoma (CRC), adrenocortical carcinoma (ACC), and melanoma. Given the high prevalence of beta-catenin mutations in these tumors, targeting this pathway offers significant therapeutic potential.
We show that CY-101 induces a dose-dependent cell death across mouse and human beta-catenin-driven CRC, ACC, and melanoma cell lines *in vitro* following suppression of the Wnt/beta-catenin pathway. In preclinical animal models, CY-101 elicited a potent anti-tumor activity by completely eradicating ACC tumors and significantly enhancing the efficacy of anti-PD-1 therapy in CRC and melanoma models. Notably, CY-101 treatment reshaped the tumor immune landscape by modulating cytokine expression, leading to increased infiltration of cytotoxic CD8+ T cells. Mechanistically, CY-101-treated tumors exhibited downregulation of Wnt/beta-catenin downstream target genes, emphasizing its role as a potent Wnt/beta-catenin inhibitor.
These preclinical findings support the observations seen in the first in human CICILIA Phase 1/2a trial, which reported clinical activity in ACC and melanoma patients. Collectively, our study demonstrates the therapeutic potential of CY-101 in beta-catenin-driven tumors, both as monotherapy and in combination with anti-PD1 checkpoint inhibitors.

#2232 BGB-R046, an IL-15 pro-drug demonstrates robust pharmacodynamic effects and immune activation within tumor microenvironment in a mouse syngeneic model.

Yu Jiang[1], Amin Zhang[2], Minjuan Deng[1], Feihong Li[1], Qinyi Kong[2], Silu Liu[1], Xiaoyu Li[1], Li Luo[2], Yue Wu[1], Mengjia Wang[1], Xudong Luan[1], Huixia Hu[1], **Xin Chen**[3], Wei Jin[1], Zhirong Shen[1]

[1]BeiGene (Beijing) Co., Ltd., Beijing, China,[2]BeiGene (Shanghai) Biotechnology Co., Ltd., Shanghai, China,[3]BeiGene USA, Inc., Ridgefield Park, NJ

Background: Interleukin-15 (IL-15) is crucial for the proliferation and survival of NK and memory T cells, and has great potential in cancer immunotherapy. Rapid plasma clearance of conventional IL-15 and therefore insufficient tumor exposure and immune activation pose a significant limitation in its development as an immuno-oncology therapeutics. BGB-R046 is developed as an IL-15 pro-drug, which masks free drug release in circulation and is activated in tumors by utilizing tumor enriched proteases to release active IL-15Rα-sushi-IL-15, an IL-15 super-agonist(SITC#950). BGB-R046 induced pharmacodynamic effects and immune activation was evaluated in this study, in immune competent mice bearing syngeneic tumor model, to study its pharmacodynamic effects in both circulation and tumor.

Method: Anti-tumor efficacy was evaluated in the MC38 syngeneic model in IL-15 and IL-15 receptors humanized mice. Active IL-15 released from pro-drug induced downstream signaling events were evaluated in human primary CD8+T and NK cells. The pharmacokinetics (PK) and pharmacodynamic(PD) biomarkers were evaluated in humanized IL-15/IL-15 receptor mice bearing MC38 syngeneic tumor after BGB-R046 administration.

Results: BGB-R046 exhibits protease dependent activation and shows significant anti-tumor efficacy in MC38 syngeneic model. Active pro-IL-15 robustly engages the IL-15 pathway, demonstrated by STAT5 phosphorylation and CD122 downregulation in vitro, which are two target engagement PD markers induced by IL-15. Following BGB-R046 administration in vivo, minimum active drug release was detected in the circulation while active drug release was more sustained in tumor. Consistently, STAT5 phosphorylation was significantly increased in tumor, while undetectable in circulation on day 7 after BGB-R046 treatment. In addition, surface CD122 level on NK cells was downregulated in tumor while maintained in the circulation, suggesting robust IL-15R target engagement within tumor microenvironment by pro-drug design. Accordingly, BGB-R046 treatment induced significant immune activation in tumor, demonstrated by CD8+ T and NK cell proliferation and activation, consistent with its robust anti-tumor activity in this model.

Conclusions: BGB-R046 is an IL-15 prodrug with minimum free drug release in the peripheral and induced robust pharmacodynamic effects and immune activation within tumor microenvironment in the MC38 mouse syngeneic model. A clinical study evaluating BGB-R046 as monotherapy and in combination with tislelizumab (anti-PD-1 antibody) in patients with advanced or metastatic tumors is ongoing(NCT06487858).

#2234 SOF10, a novel selective anti-latent TGF-β1 antibody, augments the efficacy of anti-PD-L1 antibody via modulation of the tumor microenvironment.

Kenji Nakagawa[1], Izumi Sato[1], Masakazu Kanamori[1], Silvia Sun[2], Kentaro Asanuma[1], Hiroki Kawauchi[1], Chisako Kanamaru[1], Yoko Kayukawa[1], Saori Matsuo[1], Meiri Shida-Kawazoe[3], Takehisa Kitazawa[1], Tomoyuki Igawa[1], Hideaki Shimada[2]

[1]Chugai Pharmaceutical Co., Ltd., Yokohama, Kanagawa, Japan,[2]Chugai Pharmabody Research Pte. Ltd., Synapse, Singapore,[3]Chugai Pharmaceutical Co., Ltd., Chuo-ku, Tokyo, Japan

Background: TGF-β is a highly pleiotropic cytokine, consisting of three isoforms: TGF-β1, TGF-β2, and TGF-β3. The TGF-β signaling is known to be associated with a poor response to immune checkpoint inhibitors. Multiple agents targeting TGF-β have been developed with focus on the physiological effects of TGF-β in the tumor microenvironment; however, inhibition of multiple TGF-β isoforms have exhibited serious cardiac toxicity and bleeding in nonclinical studies. TGF-β1 is expressed as inactive latent complex and reported to be most highly expressed among all the isoforms in tumors. Selective inhibition of latent TGF-β1 activation may address the potential safety risk and provide an effective approach for targeting the TGF-β pathway in tumors.
Methods: We generated SOF10, a novel anti-latent TGF-β1 antibody, which selectively inhibits latent TGF-β1 activation. To assess the inhibitory mechanism of SOF10 for latent TGF-β1 activation, we evaluated multiple proteases-mediated TGF-β1 activation, integrin-mediated TGF-β1 activation, and determined the structure of the SOF10 Fab and latent TGF-β1 complex. We then tested combinational efficacy of SOF10 with anti-PD-L1 antibody in EMT6 murine breast cancer model, and CT26 murine colon cancer model. To analyze the effects on tumor microenvironment, we evaluated CD8 T cells and cancer-associated fibroblasts (CAFs). Finally, we conducted 3-month repeat-dose toxicity studies (GLP) in mice and cynomolgus monkey.
Results: SOF10 inhibited multiple proteases- and αvβ8-mediated latent TGF-β1 activation. Structural analysis of SOF10 showed the unique binding mode in which SOF10 inserted into the dimer surface of the LAP domain of TGF-β1. In vivo studies demonstrated combinatorial effect of SOF10 and anti-PD-L1 antibody in tumor growth inhibition for the treatment of EMT-6 and CT26 murine cancer models. Evaluation of CD8 T cells showed increased influx and enhanced activation of CD8 T cells in the combination group. RNA analysis of CAFs also revealed downregulation of ECM synthesis by SOF10 treatment. Lastly, no toxicologically relevant changes were observed in 3-month repeat-dose toxicity studies (GLP).
Conclusions: Our data suggest that SOF10, a selective anti-latent TGF-β1 antibody, can exert antitumor efficacy in combination with anti-PD-L1 antibody by modulating CAF dynamics and overcomes immune exclusion with preferable safety profile. Clinical studies of SOF10 are currently on-going for patients with solid cancer (NCT05867121)

#2236 A novel SIRPαxPD-L1 bispecific antibody remodels the innate and adaptive tumor microenvironment, and enhances tumor control.

Mariela Navarrete[1], Cristobal Costoya[1], Erik van Buijtenen[2], Simone Wouters[2], Joost Kreijtz[2], Paul Vink[2], Hans van Eenennaam[2], Sergio A. Quezada[1]

[1]Cancer Immunology Unit, Research department of Haematology, University College London (UCL) Cancer Institute, London, United Kingdom,[2]Sairopa, Rotterdam, Netherlands

Checkpoint blockade immunotherapy has transformed cancer treatment. However, many patients fail to respond to these therapies, underscoring the urgent need for new therapeutic strategies. Targeting alternative pathways and immune cell subsets within the tumor microenvironment (TME) holds promise for improving outcomes in these patients. One key mechanism of anti-tumour immunity is the phagocytosis of tumor cells by myeloid cells, which can be suppressed by the interaction between the SIRPα receptor on myeloid cells and its ligand CD47, a "do not eat me" signal, on tumor cells. Inhibition of the SIRPα/CD47 axis restores myeloid cell activity, promotes antigen presentation and enables tumor cell elimination. In this study, we evaluated a novel bispecific antibody that simultaneously blocks SIRPα and PD-L1 (SIRPαxPDL1), critical immune checkpoint molecules frequently overexpressed in the TME. SIRPαxPDL1 demonstrated enhanced macrophage-mediated phagocytosis of tumour cells *in vitro*. Moreover, in the MC38 murine tumor model, SIRPαxPDL1 significantly improved tumor control and survival, compared to monotherapies targeting either PD-L1 or SIRPα alone or in combination. High-dimensional flow cytometry revealed the unique ability of SIRPαxPDL1 to promote monocyte-to-macrophage differentiation whilst enhancing $CD8^+$ T cell infiltration and activation within the TME compared to the combination of SIRPα and PDL1 antibodies. Remarkably, SIRPαxPDL1 synergized with a tumour-targeting antibody, further augmenting tumor control and survival. These findings highlight, for the first time, the potential of SIRPαxPDL1 to remodel the myeloid compartment and activate antitumor immunity, offering a promising novel avenue in cancer immunotherapy and combination approaches.

#2237 IOMX-0675, a LILRB1/LILRB2 cross-specific antibody that repolarizes the tumor microenvironment to drive potent anti-tumor activity.

Kristina Heinig, Christina A. Hartl, Marisa Stebegg-Wagner, Eugenia Korotkova, Michail Maraslis, Carmen Ginzel, Thomas Jaquin, Bettina Langer, Jonas Schilz, Alina Huth, Maximilian Aigner, Alexander N. Marziale, **Stefan Bissinger**

iOmx Therapeutics AG, Martinsried / Planegg, Germany

IOMX-0675 is a monoclonal immunoglobulin G1 (IgG1) antibody targeting LILRB1 (ILT2) and LILRB2 (ILT4), key immunosuppressive receptors of the leukocyte immunoglobulin-like receptor (LILR) family, that play a pivotal role in tumor immune evasion. LILRB1 and LILRB2 recognize both classical and non-classical MHC-I molecules and are highly expressed on tumor-infiltrating myeloid cells, with LILRB1 also found on lymphoid cells. Their frequently observed upregulation in patients non-responsive to T cell checkpoint blockade, implicate a role in driving tumor resistance. Expression profiling revealed co-expression of immune-activating LILR members, LILRA1 and LILRA3, with LILRB1 and LILRB2 in specific cancer indications, underscoring the importance of selective receptor targeting to achieve effective therapeutic outcomes. IOMX-0675, identified through iOmx's proprietary phage display library, exhibits a highly differentiated binding profile with selective, high-affinity binding to the inhibitory receptors LILRB1 and LILRB2, while showing only weak affinity to the closely related immune-activating LILR family members LILRA1 and LILRA3. In autologous immune cell co-cultures, IOMX-0675 effectively reprograms immunosuppressive macrophages in a dose-dependent manner, restoring lymphoid immune cell function. Importantly, IOMX-0675 retains its high selectivity for LILRB1 and LILRB2 and its pharmacodynamic activity, even in environments dominated by LILRA1 and LILRA3. IOMX-0675 enhances phagocytic activity, stimulates pro-inflammatory functions across various macrophage subtypes and drives robust pro-inflammatory cytokine secretion in stimulated PBMCs, both *in vitro* and in *ex vivo* whole blood assays. In a $CD34^+$ stem cell-engrafted humanized mouse melanoma model, IOMX-0675 exhibited potent anti-tumor activity and repolarized tumor-associated macrophages, closely aligning with *in vitro* findings and underscoring its therapeutic promise. In summary, we developed IOMX-0675, a highly selective cross-specific antibody that effectively antagonizes both LILRB1 and LILRB2 while exhibiting negligible binding to immune-activating LILR family members. IOMX-0675 demonstrates robust reprogramming of the immunosuppressive myeloid compartment and restores cytotoxic T cell activity within the tumor microenvironment, both *in vitro* and *in vivo*. Its differentiated binding profile positions IOMX-0675 as a best-in-class therapeutic candidate with the potential to maximize anti-tumor efficacy and address significant unmet medical needs for patients.

#2238 NOX2 plays a key role in M2 polarization of macrophages associated with cancer-associated fibroblast in tumor microenvironment.

H. Jang, J. Um, E. Lee, S. Moon, S. Lee;
Aptabio Therapeutics Inc., Yongin, Korea, Republic of

The tumor microenvironment (TME) is a dynamic ecosystem surrounding a tumor. The TME consists of various components such as cancer cells, stromal tissue, immune cells and the extracellular matrix (ECM). In particular, the interaction between cancer-associated fibroblasts (CAFs) and tumor-associated macrophages (TAMs) is a key regulator of immunosuppression in the TME, subsequently contributing to tumor progression, resistance and metastasis. CAFs stimulate TAMs to differentiate into a M2-like macrophage phenotype, supporting immune evasion and tumor growth. It has been found that reactive oxygen species (ROS) produced by NADPH oxidase (NOX) enzymes are involved in process. ROS have been reported to stimulate CAF activity and TAM differentiation, but the role of NOX in the interaction between CAF and TAM has not yet been elucidated. Herein, we aimed to investigate the role of NOX2 in M2 polarization of macrophages, especially CAF-mediated TAM differentiation, and evaluate the therapeutic potential of targeting NOX2 in the TME. In this study, we utilized THP-1 monocytic cell lines and human pancreatic CAFs (pCAFs) to examine the functional significance of NOX2. NOX2 was predominantly expressed in THP-1 cells compared to other NOX isozymes when polarized into M2-like macrophages and knockdown of NOX2 effectively inhibited M2-like polarization of THP-1-derived macrophages. In addition, knockdown of NOX2 significantly reduced the secretion of M-CSF by pCAFs. These findings suggest that NOX2 plays a crucial role in CAF-mediated M2 differentiation of macrophages. Based on these findings, we confirmed the effects of NOX2 inhibition using com-19, a selective NOX inhibiting molecule. Com-19 modulated M2 polarization of macrophages and downregulated NOX2 mRNA levels in the cells. Moreover, com-19 also significantly reduced ROS production and the secretion of cytokines/chemokines in macrophages under M-CSF-induced conditions. Importantly, the results also demonstrated that com-19 inhibited pCAF-induced M2-like polarization of THP-1. Taken together, we confirmed that CAFs and TAMs interact closely and NOX2 inhibition could be a potential therapeutic target for CAF- and TAM-mediated immunosuppression, especially for M2-polarization of macrophages in the TME. Furthermore, com-19 can provide a novel approach to overcome immunosuppressive barriers by interrupting their interaction in the TME, offering the potential for more effective combination therapies in cancer treatment.

#2239 FB849, a highly selective HPK1 inhibitor, reshapes the tumor immune microenvironment by modulating various immune cells.

Seungmook Lim[1], A Yeong Park[1], Hyekyoung Kim[1], Seung Hyuck Jeon[2], Yong Joon Lee[2], Jinhwa Lee[1], Eui-Cheol Shin[2], Jamie Jae Eun Kim[1]

[1]1ST Biotherapeutics, Yongin-si, Korea, Republic of,[2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

A highly unmet medical need exists for immuno-oncology agents to modulate the tumor microenvironment through broad-spectrum immune cell modulation by promoting crosstalk among T cells, B cells, and APCs, to exert a strong and durable anti-cancer immunity. Beyond T cells, other immune cells can play a crucial role in driving clinical activity, particularly in combination with current checkpoint inhibitors or patients with T cell dysfunction. We have discovered and developed FB849, a potent, highly selective, and orally bioavailable HPK1 inhibitor. FB849 has demonstrated robust anti-tumor activity across multiple preclinical models and is currently being evaluated in a Phase I/II clinical trial for advanced solid tumors (NCT05761223). To elucidate its immune-modulatory mechanisms and impact on both T cells and non-T cells, we extended our research to human primary immune cells and tumor-infiltrating lymphocytes (TILs). FB849 effectively activated T cells increasing IL-2 and IFNγ production, and stimulated B cell secreting IgG, IL-6 and IL-8. In monocyte-derived DCs, FB849 also significantly enhanced the secretion of IL-12 and IL-1β, and CD80 and CD86 expression. In vivo mouse TIL analyses revealed that FB849 increased T cell activation while re-shaped the myeloid compartment within the tumors by increasing dendritic cell infiltration with elevated cDC1, promoting tumor-associated macrophage (TAM) depletion with M1 polarization, and increasing NK cell infiltration. These create a tumor microenvironment favorable to anti-cancer immunity. Notably, FB849 retained anti-tumor activity even after CD8 T cell depletion, highlighting the pivotal role of non-T cells. To further delineate FB849's effects on TILs, we conducted single-cell RNA sequencing and TCR sequencing with the single cell suspension samples from RCC, HCC, HNC and BRC patients. FB849 prominently expanded multiple types of T cell clones, especially the CXCL13+ CD8 TIL cluster enriched with neoantigen signature genes. Furthermore, TCR sequencing revealed a considerable overlap in between CXCL13+ CD8 and MKI67+ CD8 T cells when stimulated with autologous EpCAM+ tumor cells or NY-ESO-1 overlapping peptides, validating that CXCL13+ CD8 TILs are tumor-reactive. We hypothesize that the intra-tumoral expansion of CXCL13+ CD8+ T cells enhance interactions between T cells and various non-T cells including B cells and dendritic cells, potentially driving tertiary lymphoid structure (TLS) formation via the CXCL13 chemokine secretion, which warrants further validation in preclinical and clinical research. Altogether, our work represents a promising approach to modulate a broad spectrum of immune cells simultaneously and enhance their crosstalk, paving the way for durable clinical activity and supporting further development in the clinic.

#2240 High dose acetaminophen re-polarizes CD11B+ cells in the tumor microenvironment towards an activated macrophage phenotype.

A. Bryan[1], P. Pingali[1], B. Patel[1], W. Lee[1], J. Landry[2], **A. J. Neuwelt**[1];
[1]Richmond VA Medical Center, Richmond, VA, [2]VCU/Medical College of Virginia, Richmond, VA

Background: High dose acetaminophen (AAP) has demonstrated promising results in early phase clinical trials. When administered concurrently with the CYP2E1 inhibitor fomepizole, AAP can be dose-escalated 100-fold relative to standard dosing without liver toxicity and without compromising anti-tumor activity. The present study aims to characterize the effects of high dose AAP on the tumor immune microenvironment.

Methods: The current study used a 23-plex flow cytometry panel to study AAP induced changes in the tumor immune microenvironment of syngeneic mouse breast tumors. AAP-induced changes in macrophage phenotype were studied in vitro using phagocytosis and antigen presentation assays, both alone and in combination with PD-1 antibody therapy.

Results: Flow cytometric analysis of the tumor immune micro-environment revealed that the vast majority of CD45+ cells in triple negative breast cancer model are CD11B+ cells of the innate immune system. The CD11B+ cells in the tumor micro-environment of vehicle-treated mice were mostly comprised of GR1+ myeloid derived suppressor cells. On the other hand, the CD11B+ cells in the high dose AAP-treated mice were mostly of the activated macrophage phenotype (F4/80+CD80+MHCII+). Other observed changes within the tumor of AAP-treated mice include a large influx of B-cells, NK-cells and T-cells. Given the increased number of activated macrophages observed in the AAP-treated tumors, in vitro studies were performed to better understand AAP effects on macrophage function. It was demonstrated that AAP enhances phagocytosis as well as antigen presentation by macrophages to antigen-reactive T-cells. These effects are amplified when PD-1 antibodies are combined with AAP in the in vitro antigen presentation assay. Furthermore, AAP has synergistic anti-tumor activity in vivo when combined with PD-1 antibody therapy, an effect that is macrophage dependent.

Conclusion: High dose AAP can be administered safely when combined with fomepizole-based rescue in mouse models. The present study demonstrates profound AAP-induced changes in the tumor immune microenvironment, particularly within the phenotype of CD11B+ cells of the innate immune system leading to increased “M1” type macrophages in the tumor immune microenvironment.

#2241 Immune-modulatory therapeutic cancer vaccines against IDO1 and PD-L1 control tumor growth through target specific changes in the tumor microenvironment.

Marion Chapellier[1], Anne Madsen[1], Rasmus Agerholm-Nielsen[1], Lea Svendsen[1], Ines Lecoq[1], Evelina Martinenaite[1], Shih-Chun Shen[2], Erika Sutanto-Ward[2], James DuHadaway[2], Souvik Dey[2], Dema Ghaban[2], Mads Hald Andersen[3], Alexander J. Muller[2], Ayako Wakatsuki Pedersen[1]

[1]IO Biotech, Copenhagen, Denmark,[2]Lankenau Institute for Medical Research, Wynnewood, PA,[3]Center for Cancer Immune Therapy, Copenhagen, Denmark

Despite the established clinical efficacy of checkpoint inhibitors such as blocking antibodies against Programmed Death protein (PD)-1 and Programmed Death Ligand (PD-L)1, drug resistance remains a significant obstacle in various cancer types. Indoleamine 2,3-dioxygenase 1 (IDO1) and PD-L1 are critical immunosuppressive drivers in the tumor microenvironment (TME) that favor cancer progression. The development of immune-modulatory vaccines against IDO1$^+$ and PD-L1$^+$ immune suppressive and/or tumor cells in the TME (IO102-IO103) has revealed promising clinical results[1] and is now being investigated in a Phase 3 clinical trial in advanced melanoma. Using preclinical models, the present study aims to further characterize the mode of action of these vaccines and compare it with conventional checkpoint inhibitors.

Anti-tumor efficacy of the vaccines was evaluated by monitoring tumor growth in syngeneic murine models after treatment with IDO1 or PD-L1 peptides in Montanide adjuvant. Tumor tissues, spleens and lymph nodes were collected and processed for flow cytometry or functional readouts. T cell activity was assessed using IFNγ Elispot assay. Gene expression analysis was performed using the Nanostring nCounter PanCancer IO360 Panel on bulk tumors from animals treated with IDO1 or PD-L1 vaccines; or anti-PD1/PD-L1.

Vaccination against IDO1 and PD-L1 induced specific T-cell expansion in splenocytes, associated with reduced tumor growth. In particular, PD-L1 specific T cells were also detected in lymph nodes and tumor infiltrating lymphocytes from MC38 tumor-bearing animals. Target specific activation of T cells was confirmed *ex vivo* upon restimulation of cells by the detection of IFNγ and TNFα within CD8$^+$ cells. Gene expression analysis of tumors revealed distinct immune signatures for each treatment group, either supporting cytotoxic T-cell activity (PD-L1 vaccine) or reducing the immune suppression within the TME (IDO1 vaccine). Comparison with samples from animals treated with anti-PD-1 or anti-PD-L1 showed non-overlapping gene expression changes induced by PD-L1 vaccine.

Our results from murine models show that IDO1 and PD-L1 peptide vaccines each contribute to tumor growth control through the activation of target specific T cells and their recruitment at tumor site. Gene expression analysis suggests that this is achieved through changes in the expression of immune-suppressive markers and enhanced T cell activation and cytotoxic activity. The gene expression changes observed were different from the signatures of anti-PD-L1 and anti-PD1, suggesting a complementary mode of action to those therapeutics. Altogether, our data support the clinical potential of IDO1 and PD-L1 immune-modulatory vaccines to improve existing therapeutics in cancer.

#2242 Inhibition of the tumor cell TCA cycle suppresses ER stress-associated THBS2 to selectively potentiate antitumor response of CD36^{+} effector T cells.

J. Yang, F. Chen, Z. Fu, **Y. Teng**;
Emory University, Atlanta, GA

The tricarboxylic acid (TCA) cycle, occurring within the mitochondrial matrix, plays a pivotal role in mitochondrial metabolism, which is essential for generating energy to support tumor cell proliferation and survival. CPI-613 (devimistat) is a novel systemic therapeutic that targets the TCA cycle by inhibiting pyruvate dehydrogenase (PDH) through hyperactivation of its regulatory kinases and by inducing reactive oxygen species (ROS)-mediated inhibition of ketoglutarate dehydrogenase (KGDH). Here we report a novel mechanism by which CPI-613 potentiates the antitumor response of CD8^{+} T cells to head and neck squamous cell carcinoma (HNSCC). Using proximity biotinylation and LC/MS analysis, we found that CPI-613 inhibits the secretion of thrombospondin-2 (THBS2), a glycoprotein linked to poor prognosis and immune evasion in HNSCC patients. Mechanistically, CPI-613 blocks the TCA cycle in HNSCC cell mitochondria, leading to endoplasmic reticulum (ER) stress and upregulation of XBP1s, which transcriptionally suppresses THBS2 expression. As a result, CPI-613-treated HNSCC cells secrete reduced levels of THBS2, which leads to the inactivation of its receptor, CD36, on CD8+ T cells. This inactivation subsequently triggers the activation of the downstream AKT/mTOR signaling pathway, enhancing the proliferation and cytotoxic potential of CD8+ T cells. These results highlight the immunomodulatory effects of CPI-613 and provide a strong rationale for developing it as a promising treatment strategy for HNSCC.

#2243 Preclinical studies of BB-1709, a CD73-targeting ADC potentially suppresses tumor growth through dual mechanisms.

Bing Xia, Lixia Cao, Jianfeng Yang, Cui Feng, Fangdun Jiang, Chen Li, Lixia Gu, Yifan Yang, Jing Tian, Jiasheng Geng, Ziping Wei, Yuhong Zhou

Bliss Biopharmaceutical (Hangzhou) Co., Ltd., Hangzhou, China

CD73, also known as ecto-5'-nucleotidase, is a cell surface enzyme that catalyzes the conversion of AMP to adenosine. It is highly expressed in various types of cancers, including gastric, glioblastoma, non-small cell lung, and colorectal cancers. Elevated CD73 expression is highly correlated with poor prognosis, increased metastasis, and resistance to chemotherapy. In the tumor microenvironment, CD73-derived adenosine exerts multiple immunosuppressive effects, promoting tumor growth and metastasis. Currently, there are no approved antibody-drug conjugates (ADCs) targeting CD73. In this study, we introduce BB-1709, a CD73-targeting ADC that incorporates MMAE as its cytotoxic payload, demonstrating its antitumor activity through direct cytotoxicity against CD73-expressing tumor cells and its ability to inhibit CD73 enzyme activity.
A comprehensive set of studies was conducted to assess its in vitro cytotoxicity, in vivo antitumor activity as well as its ability to inhibit CD73 enzyme activity.
In vitro studies demonstrated that BB-1709 exhibited potent and selective cytotoxicity against various CD73-positive cancer cells and significantly inhibited CD73 enzyme activity, effectively blocking the conversion of AMP into adenosine. In vivo studies using xenograft models showed that a single dose of BB-1709 resulted in substantial antitumor activity. Pharmacokinetic and toxicology assessments in non-human primates revealed a favorable safety profile for BB-1709 at clinically relevant dosages and administration schedules.
In summary, these results suggest that BB-1709 not only exhibits good preclinical efficacy and safety, but also has the potential to promote anti-tumor immune responses by inhibiting CD73 enzymatic activity. A phase I clinical trial of BB-1709 is currently underway to further explore its therapeutic potential in cancer treatment.

#2244 ASO-mediated STAT3 knockdown relieves immunosuppression sensitizing tumors to immunotherapies.

Veronica Finisguerra[1], **Marie-Aline C. Neveu**[1], Joppe Lochten[1], Dido Van de Velde[1], Natalie De Geest[1], Marie Wallays[1], Marijke Pellens[1], Michel Janicot[2], Andrew Denker[1], Tiziana Girardi[1]

[1]Flamingo Therapeutics, Leuven, Belgium,[2]JMi ONConsulting, Brussels, Belgium

To improve the clinical outcome of cancer immunotherapies, strategies that modulate the immunosuppressive tumor microenvironment (TME) are currently under evaluation. Our study aims to dissect the immune-modulatory effects of danvatirsen, an antisense oligonucleotide (ASO) targeting the transcription factor Signal Transducer and Activator of Transcription 3 (STAT3) currently being studied in combination with pembrolizumab in the PEMDA-HN trial, a randomized Phase 2 trial in recurrent/metastatic head and neck squamous cell carcinoma (NCT05814666). In response to cytokines and growth factors, STAT3 regulates genes involved in cell differentiation, survival, inflammation, and angiogenesis. In tumors STAT3 is often hyperactivated, both in tumor and TME cells, and correlates with poor prognosis. Danvatirsen is a 16-mer generation 2.5 ASO designed by Ionis Pharmaceuticals to specifically target human STAT3 mRNA for degradation. Previous preclinical and clinical data have demonstrated tumor uptake of danvatirsen and STAT3 protein reduction in post-treatment biopsies. To better elucidate the mechanism, we performed *in vitro* and *in vivo* studies to assess STAT3 knockdown (KD) and effects on immune cell phenotype. Danvatirsen strongly reduces STAT3 mRNA and protein *in vitro*, both in human cancer cells and Peripheral Blood Mononuclear Cells (PBMCs), as well as *in vivo*, with a protein KD of 75% in human tumor xenografts implanted in immunodeficient mice. Interestingly, we found that danvatirsen increases the killing activity of PBMCs co-cultured with lung or liver human cancer cell lines, in line with the immunostimulatory effects of STAT3 KD. Moreover, we confirmed that danvatirsen affects the polarization of *in vitro*-differentiated pro-tumoral M2 macrophages towards an anti-tumoral M1 phenotype. A mouse surrogate STAT3 ASO administered *in vivo* reduced tumor STAT3 mRNA and protein levels by 60% and 75%, respectively, in the mouse breast cancers 4T1 and EMT6, and in the mouse lung cancer LL2. STAT3 KD was also observed in immune cells in circulation or infiltrating 4T1 tumors, with 33% and 55% KD in tumor-infiltrating T cells and macrophages, respectively. STAT3 ASO treatment *in vivo* remodels the TME composition, leading to pro-tumoral M2 macrophage repolarization towards an anti-tumoral M1 phenotype, among other effects. Those changes were associated with tumor growth inhibition (TGI) of 30% in 4T1-tumor bearing mice. When combined with anti-PD-1, STAT3 ASO reduced tumor growth by 55% compared to the control, and showed an additive effect to anti-PD-1 treatment alone, where TGI was 25%, supporting the combination of danvatirsen and pembrolizumab. Similar results were obtained in the EMT6 model. In conclusion, these data showed that ASO-mediated STAT3 KD relieves immunosuppression thereby sensitizing tumors to immunotherapies.

#2245 TFF-2-mediated CXCR4 partial agonism outperforms CXCR4 antagonism in reducing murine gastric cancer by suppressing PMN-MDSC generation.

Jin Qian[1], Chenkai Ma[2], Quin T. Waterbury[1], Xiaofei Zhi[1], Christine S. Moon[1], Ruhong Tu[1], Hiroki Kobayashi[1], Feijing Wu[1], Biyun Zheng[1], Yi Zeng[1], Hualong Zheng[1], Yosuke Ochiai[1], Ruth A. White[1], David W. Harle[1], Jonathan S. LaBella[1], Leah B. Zamechek[1], Lucas ZhongMing Hu[1], Ryan H. Moy[1], Arnold S. Han[1], Bruce L. Daugherty[3], Seth Lederman[3], Timothy C. Wang[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]CSIRO, Westmead, Australia,[3]Tonix Pharmaceuticals, Inc., Chatham, NJ

Introduction: Polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs) are pathologically activated neutrophils that impair immunotherapy responses. The chemokine receptor CXCR4, a central regulator of hematopoiesis, represents an attractive PMN-MDSC target.

Methods: We generated a novel peptide, TFF2-MSA, as a CXCR4 partial agonist by fusing Trefoil Factor 2 (TFF2) with murine serum albumin (MSA), and compared its treatment efficacy in combination with anti-PD-1 antibody to that of the clinically available CXCR4 antagonist plerixafor (AMD3100). Murine syngeneic gastric cancer cells were subcutaneously implanted into the Hdc-GFP transgenic mice, which enabled tracking of PMN-MDSCs via histidine decarboxylase (Hdc) expression across multiple tissues. Treatments were then initiated every three days. To elucidate mechanisms, myeloid progenitors were cultured with or without TFF2-MSA *in vitro*. Bone marrow $Lin^{-}c\text{-}Kit^{+}$ hematopoietic progenitors from tumor-bearing Hdc-GFP (CD45.2) mice following vehicle or TFF2-MSA treatments were transferred into CD45.1 mice to validate TFF2-MSA's effects on PMN-MDSC generation. In tumor-free mice, we compared the short-term bone marrow cell mobilization effects of TFF2-MSA and AMD3100. Additionally, we analyzed human blood and single-cell RNA sequencing (scRNA-seq) data from gastric cancer tissues for immune profiles.

Results: The combination of TFF2-MSA plus anti-PD-1 antibody showed significant efficacy in reducing/eradicating primary and metastatic tumors and extending mouse survival, in contrast to the CXCR4 antagonist AMD3100, which did not enhance anti-PD-1 response. Mechanistically, TFF2-MSA inhibited the expansion of CXCR4-high granulocyte-monocyte progenitors (GMPs) and the generation of Hdc-GFP^{+} PMN-MDSCs in culture, which underlies its systemic reduction of Hdc-GFP^{+} PMN-MDSCs in tumor, blood, and spleen and GMPs in bone marrow *in vivo*. In contrast, AMD3100 induced peripheral accumulation of Hdc-GFP^{+} PMN-MDSCs and compensatory elevation of GMP levels in bone marrow. Congenic adoptive transfer experiments confirmed that TFF2-MSA suppressed Hdc-GFP^{+} PMN-MDSC generation *in vivo*. Consistently, in tumor-free mice, TFF2-MSA did not significantly mobilize granulocytes from bone marrow, unlike AMD3100, thus better preserving bone marrow homeostasis. In gastric cancer patients, a $CXCR4^{+}LOX\text{-}1^{+}$ PMN-MDSC population expanded in both blood and tumor, exhibiting immunosuppressive potential, and associated with reduced TFF2 plasma level compared with healthy donors.

Conclusions: The novel CXCR4 partial agonist exhibited superiority in tumor control and effective PMN-MDSC reduction, and preservation of bone marrow homeostasis compared to the CXCR4 antagonist AMD3100. CXCR4 partial agonism may represent a promising strategy for targeting PMN-MDSCs in gastric cancer patients.

#2246 VISTA-induced tumor suppression and immunosuppression by shared cell-intrinsic mechanisms.

Yan Zhao, Tina Andoh, Ishrat Durdana, Joshua Gruber

University of Texas Southwestern Medical Center, Dallas, TX

VISTA is a key immune checkpoint receptor under investigation for cancer immunotherapy; however, its signaling mechanisms remain unclear. Here we identify a four amino acid (NPGF) intracellular motif in VISTA that suppresses cell proliferation by constraining cell-intrinsic growth receptor signaling. The NPGF motif binds to the adapter protein NUMB and recruits Rab11 endosomal recycling machinery. In tumor cells with high VISTA levels, the NPGF motif sequesters NUMB at endosomes, which interferes with epidermal growth factor receptor (EGFR) trafficking and signaling to suppress tumor growth, even without a functioning immune system. To understand if similar principles underlie VISTA-mediated immunosuppression we engineered mice with targeted mutations in the VISTA NPGF motif. These animals had increased T cell signaling and proliferation leading to improved control of tumor growth. These results define a generalizable mechanism by which VISTA represses NUMB to control cell signaling across disparate cell types that could be exploited for immunotherapies.

#2247 Adenosine production suppression and PD-1 immune check point inhibitor for treatment of malignant pleural mesothelioma. (MPM).

luciano Mutti[1], Antonio Giordano[2], Pierpaolo Correale[3], Caterina Costa[4]

[1]University of L'Aquila, L' Aquila, Italy,[2]Temple University, Philadelphia, PA,[3]GOM, Reggio Calabria, Italy,[4]Pascale, Napoli, Italy

Background: Although immune-checkpoint inhibitors (ICIs) have positively impacted the treatment of some tumors, several evidences clearly suggest that the actual relevance of these treatments has not been fully unraveled yet Hypoxic tumors activate the purinergic pathway, which acts as a major immunosuppressive mechanism. CD39 and CD73 are enzymes involved into ATP degradation to AMP and AMP degradation to the immune-suppressive adenosine, respectively thus the inhibitors of these pathways are progressively attracting the attention as actionable targets for immunotherapy in many solid tumors MPM is a highly aggressive malignancy whose treatment challenging for different reasons, including among others acidic and hypoxic tumor microenvironment (TME). Hypoxic TME and the expression of purinergic receptors and enzymes on tumor cells are considered criteria to select patients for immunotherapy with adenosine pathway inhibitor. We have already shown the expression of adenosine receptor 2 B (ADORA2b) and CD73 enzyme on MMP cells is inversely related to patients' survival and that MMP cells degrade AMP to adenosine via CD73. Aim of our study was assessing if ADORA2B and or CD73 with or without PD-1 ICi were able to curb tumor cells growth in a syngeneic mouse MPM model.
Methods: For orthotopic mouse models of MPM, CD73 ADORA2B positive 105 AB1B-LUC cells were injected intraperitoneally (i.p.) in immunocompetent BALB/C mice. After three weeks we started monitoring tumor growth and the animals were randomized into five groups of three mice each for treatment with PBS 100 µl (control), Pembro (anti murine PD-1; MCE) 4.4 mg/Kg, TT-4 (ADORA2 Inhibitor Portage), 3 mg/Kg, Pembro+TT-4, AB-680 (CD73 inhibitor, MCE, HY-125286) 20 mg kg) and Pembro+AB-680 were injected every two days for three weeks. Disease was measured with IVIS® Lumina XR in vivo imaging system, thus facilitating non-invasive longitudinal monitoring of disease progression or regression.
Results: after 21 days AB680 and TT4 resulted to be the most effective single treatments (fluorescence reduction vs control $p<0.01$) whereas Pembro+TT4 Pembro+AB680 did not differ significantly from the single treatments. IHC of murine samples from mice treated as above revealed infiltration of CD8 T cells mostly with AB680 single agent or in combo compared to the cold pattern of the control samples. No relevant toxicity was recorded.
Conclusions: Inhibition of the purinergic pathway exerts a significant immune-mediated MPM growth inhibition

#2248 Inhibiting NNMT in cancer-associated fibroblasts reduces immunosuppression.

Janna Heide[1], Agnes J. Bilecz[1], Maria F. Allega[1], Samarjit Patnaik[2], Gordon M. Stott[3], Matthew D. Hall[2], Andras Piffko[4], Ernst Lengyel[1]

[1]University of Chicago, Chicago, IL,[2]National Center for Advancing Translational Sciences (NCATS), National Institutes of Health (NIH), Rockville, MD,[3]Leidos Biomedical Research, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Department of Radiation and Cellular Oncology, University of Chicago, Chicago, IL

Cancer-associated fibroblasts (CAFs) are critical in supporting cancer progression, yet effective CAF-targeted therapies are lacking. Through spatial transcriptomics and single-cell RNA sequencing, we identified nicotinamide N-methyltransferase (NNMT) upregulation and the resulting histone hypomethylation as a global regulator across various CAF subtypes. NNMT-expressing CAFs activate the complement system and recruit myeloid-derived suppressor cells (MDSCs), driving an immunosuppressive tumor microenvironment. Using high-throughput screening, we developed a potent NNMT inhibitor (NNMTi) that significantly reduces tumor burden in murine cancer models by decreasing MDSC infiltration and enhancing $CD8^+$ T cell activation, thereby restoring the efficacy of immune checkpoint inhibitors. These findings establish NNMT as a key regulator of the CAF landscape and present a novel therapeutic strategy for reprogramming the tumor microenvironment.

#2249 Selective degradation of Helios induces Treg cell reprogramming and enhanced antitumor immunity.

Michael J. Barnes

Research, Cancer Immunology and Cell Therapy, Bristol Meyers Squib, Seattle, WA

Regulatory T (Treg) cell suppression of antitumor immunity can limit responses to immunotherapy in multiple solid tumor indications. The transcription factors Helios (IKZF2) and Eos (IKZF4) are abundantly expressed by Treg cells in the tumor microenvironment and act as critical nodes in a transcriptional network that enforces a stable immunosuppressive Treg cell phenotype. In preclinical models, inducible genetic loss of Helios in Foxp3-expressing Treg cells alone or with anti-PD-1 immune checkpoint blockade yields improved or complete responses to subcutaneous MC38 tumors, respectively, highlighting Helios as a druggable target for immunotherapy. BMS-986449 is a CELMoD molecular glue that redirects the E3 ubiquitin ligase Cereblon to interact with and induce the degradation of Helios and Eos. It was optimized to induce rapid and deep degradation of Helios and Eos in primary Treg cells with selectivity over other CELMoD neosubstrates, as assessed by global proteomic analysis of primary T cells. When primary human Treg cells were cultured under activating conditions with BMS-986449, a reprogrammed transcriptional phenotype emerged by 8 days in culture, including increased protein expression of effector molecules, such as Granzyme B, and abundant expression of inflammatory gene transcripts. In tumor bearing hCRBN-KI mice, BMS-986449 daily dosing induced monotherapy activity in the CT26, MB49, and MC38 tumor models with TGI values of up to 75%, 62%, and 42%, respectively; in combination with anti-PD-1 immune checkpoint blockade more robust efficacy was achieved with TGI values of 95%, 97%, and 92%, respectively. Additionally, in cynomolgus monkeys, daily dosing of BMS-986449 (0.1 mg/kg) maintained greater than 80% degradation of Helios in circulating Treg cells, supporting the advancement of BMS-986449 into Phase 1/2 clinical trials for patients with advanced solid tumors.

#2250 UCHL1 hijacks tolerogenic DC maturation and promotes mregDC-Treg crosstalk to nullify anti-PD-L1 therapy.

Yufei Zhao[1], Peiyi Xie[1], Qinghai Ye[1], Mien-Chie Hung[2], Hui Li[1]

[1]Zhongshan Hospital, Fudan University, Shanghai, China,[2]China Medical University, Taiwan, China

Background: Immune-checkpoint blockade (ICB) therapies have revolutionized cancer treatment, but such immunotherapy regimens fail in a subset of patients. Dendritic cells (DCs) are a heterogeneous group of professional antigen-presenting innate immune cells that activate adaptive immunity and determine the efficacy of immunotherapies. While they can also be hijacked by tumor-mediated factors to contribute to immune tolerance and tumor progression. However, little is known about the molecular mechanisms that drive the tolerance maturation of DCs in the tumor microenvironment (TME).

Methods: We enrolled 85 patients with advanced hepatocellular carcinoma (HCC) exhibiting varying response to immunotherapy, and profiled their tumor ecosystems using a single-cell transcriptomes sequencing (scRNA-seq) and mass cytometry by time of flight (CyTOF) for 10 patients, and plasma protein level quantification, conducted both pre-treatment and post-treatment across all patients. We integrated our in-house data and 6 additional published scRNA-seq cohorts of 83 donors to generate a comprehensive landscape of cellular dynamics underlying different responses to immunotherapy. We verified the prognostic value in our in-house tumor microarray of 342 patients.

Results: UCHL1 overexpression nullifies anti-PD-L1 therapy by driving conventional DC transformation into mature DCs enriched in immunoregulatory molecule (mregDC) via tolerogenic maturation and promoting mregDC and regulatory T (Treg) cell crosstalk, thereby restrains $CD8^+$ T anti-tumor immunity. Mechanistically, UCHL1 enhances glycolysis by stabilizing HIF1α and lactate accumulation in TME, which further promotes SREBP2 activation and nuclear translocation in DCs. We verified the positive correlations of UCHL1 with HIF1α/VEGFα/LAMP3/FOXP3 in 342 patients with HCC. Genetic ablation or pharmacological inhibition of UCHL1 all reduce the mregDC and Treg accumulation, restore the immuno-surveillance of tumor-infiltrating lymphocytes, and safeguard anti-tumor immunity and efficacy of anti-PD-L1 therapy in mouse models.

Conclusions: UCHL1 hijacks tolerogenic DC maturation and promotes mregDC-Treg crosstalk to nullify anti-PD-L1 therapy. Genetic ablation or pharmacological inhibition of UCHL1 unleash the immuno-surveillance of tumor-infiltrating lymphocytes, and safeguard the anti-tumor immunity. Plasma level of UCHL1 predicts the efficacy of anti-PD-L1 therapy.

#2251 Non-depleting anti-OX40 antibodies boosts tumor-infiltrating T cells and impairs Tregs without effector T cell depletion.

Cristobal Costoya, Mariela Navarrete, Aniruddh Tyagi, Dafne Franz Demane, Maria Vila de Mucha, Sergio A. Quezada

Cancer Immunology Unit, Research Department of Haematology, University College London (UCL) Cancer Institute, London, United Kingdom

While antagonistic antibodies targeting CTLA-4 and PD-1 have demonstrated significant success in cancer immunotherapy, agonistic antibodies such as anti-OX40 have shown limited efficacy. This disparity is potentially due to a lack of understanding of how antibody Fc regions interact with FcγRs on innate immune cells. Anti-OX40 antibodies currently in clinical trials are predominantly human IgG1, a strong FcγR engager. This design assumes differential surface OX40 expression will result in regulatory T cell (Treg) depletion and CD4+ effector T cell (Teff) activation, yet the therapeutic outcomes remain suboptimal. Using transplantable murine cancer models, we compared the efficacy of anti-OX40 isotypes with distinct FcγR-binding affinities. Weak FcγR-binding mouse IgG1 triggered robust pan-T cell activation and expansion within the tumor microenvironment while reducing Treg suppressive capacity and destabilizing their transcriptional program. Conversely, strong FcγR-binding mouse IgG2a resulted in the depletion of both Tregs and Teffs from tumors, compromising therapeutic efficacy. Notably, combining anti-OX40 mouse IgG1 with anti-PD-1 resulted in synergistic responses, achieving nearly 100% complete tumor rejection, while anti-OX40 mouse IgG2a failed to show such synergy. These findings indicate that anti-OX40 antibodies with strong FcγR-binding may hinder optimal anti-tumor activity. A more effective approach could involve using weak FcγR-binding isotypes, which preserve effector T cells while activating agonistic signaling and impairs Treg function, thereby enhancing therapeutic efficacy without off-target effects. Future studies will validate these results in patient-derived tumor models to inform the development of anti-OX40-based therapies.

#2252 ASO targeting of intratumoral human FOXP3+ Tregs in humanized SGM3-IL15 mice.

Wayne W. Hancock[1], Tatiana Akimova[1], Liqing Wang[2], Zhanna Bartosh[2], Lanette M. Christensen[1], Pali Kaur[3], Veenu Aishwarya[4]

[1]Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA,[2]Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA,[3]The Jackson Laboratory, Bar Harbor, ME,[4]AUM Biotech, LLC, Philadelphia, PA

Introduction: Humanized mice are an indispensable tool for pre-clinical cancer immunotherapy research, but there are limited data regarding human antitumor T cell immunity in such models, especially regarding the development of intratumoral T cell exhaustion.
Methods: We wanted to develop a Treg-dependent tumor model in humanized mice to study the effect of AUMsilence FOXP3 antisense oligonucleotides (ASO) targeting of intratumoral human CD4+ FOXP3+ regulatory T cells (Tregs) in vivo. The ideal model would support development and function of human Tregs, CD4+ and CD8+ T cells, allow tumor growth without apparent allogeneic reactivity, demonstrate the development of a suppressive tumor microenvironment, including with exhaustion of tumor-infiltrating T cells, and prove to be a Treg dependent tumor model. To do so, we evaluated two novel JAX strains of humanized CD34+ engrafted mice, NSG-SGM3 and NSG-SGM3-IL15.
Results: Both strains of mice had high (>80%) reconstitution by human CD45+ cells, no signs of GVHD, and increased proportions of FOXP3+ Tregs in their spleens, blood and livers (23-35% of CD4+ cells). Suppressive function of isolated liver and splenic Tregs were comparable with healthy donor blood Tregs. Both strains of mice supported similar growth of A549 lung tumor cells without rejection, and tumors were infiltrated by human CD45+ cells (8-20%), including 15-35% of FOXP3+ Tregs. Expression of T cell exhaustion markers was observed in tumors, but not in spleens, livers or blood. FOXP3 ASO treatment resulted in a decrease in tumor growth, while scramble treated mice developed multiple lung metastases and larger tumors. FOXP3 expression was also decreased in tumors (2.7 times, $p = 0.02$) but not in the spleens and livers of ASO treated mice. Of note, targeting of intratumoral Tregs led to decreased expression of most T cell exhaustion markers in tumors, confirming our previous report that intratumoral Treg may promote T cell exhaustion.
Conclusions: NSG-SGM3 and NSG-SGM3-IL15 mice provide a platform for preclinical drug testing involving an immunosuppressive tumor microenvironment and accumulation of exhausted T cells and fully functional Tregs. AUM*silence* FOXP3 ASO therapy has powerful anti-tumoral effects in vivo, decreases metastases and reverses features of T cell exhaustion.

#2253 HDAC6 inhibitors reprogram macrophages in antitumor-adoptive cell therapy.

Satish Kumar Reddy Noonepalle[1], Maria Gracia Hernandez[2], Nima Aghdam[3], Nithya Gajendran[1], Manasa Suresh[1], Xintang Li[1], Abishek Sehgal[1], David Quiceno[1], Michael Berrigen[4], Tessa Knox[1], Karen Tan[1], Eduardo Sotomayor[5], Katherine Chiappinelli[6], Duncan Wardrop[7], Anelia Horvath[8], Anatoly Dritschilo[9], Rohan Fernandes[10], Karthik Musunuri[11], Alejandro Villagra[1]

[1]Oncology, Georgetown University, Washington, DC,[2]George Washington University, Washington, DC,[3]Radiation Oncology, Beth Israel Deaconess Medical Center, Boston, MA,[4]School of Medicine, George Washington University, Washington, DC,[5]Cancer Institute, Tampa General Hospital, Tampa, FL,[6]Department of Microbiology, Immunology, and Tropical Medicine, George Washington University, Washington, DC,[7]Chemistry, University of Illinois, Chicago, IL,[8]Biochemistry and Molecular Medicine, George Washington University, Washington, DC,[9]Radiation Medicine, Georgetown University, Washington, DC,[10]Cancer Center, George Washington University, Washington, DC,[11]Avsetra Therapeutics, Malvern, PA

Tumor-associated macrophages (TAMs) exhibit hybrid phenotypes ranging between M1-like (anti-tumor) and M2-like (pro-tumor) macrophages. In most tumor types, a higher M1/M2 ratio favors antitumor immunity. Therefore, strategies to enhance the M1/M2 ratio can potentially alter the tumor microenvironment (TME) towards antitumor immunity. These strategies include reprogramming resident TAMs, altering the fate of tumor-infiltrating monocytes towards M1-like macrophages, and finally, adoptive cell therapy (ACT) with M1-like macrophages. A significant challenge with the above strategies is to retain the antitumor properties of M1-like macrophages in an overwhelmingly immunosuppressive TME. In this study, we demonstrate a macrophage-based ACT where treatment with HDAC6 inhibitors (HDA6is) retains the M1-like characteristics while significantly suppressing the tumor growth in syngeneic SM1 murine melanoma and with radiation therapy (RT). We reprogrammed GFP-expressing antitumor M1 macrophages ex-vivo with HDAC6 inhibitors to lock into the M1 phenotype and administered intratumorally as ACT in the syngeneic SM1 murine melanoma model and humanized NSG-SGM3 melanoma model. We performed histological analysis of tumors for macrophage markers, immune phenotyping of infiltrated immune cells, single-cell secretome analysis of tumor macrophages, and single-cell RNA-seq analysis of CD45+ immune cell populations. Initially, tail vein injected (i.v) administration of luciferase-expressing monocytes in combination with HDAC6i reached the tumors and diminished SM1 tumor growth compared to the control group. On the contrary, luciferase-expressing M1 macrophages failed to reach the tumor as visualized by IVIS imaging, suggesting that i.v is not an effective route for macrophage therapy. Whereas, intratumor HDAC6i treated M1 macrophage ACT resulted in diminished tumor growth. Single-cell (Sc) RNA-seq analysis of CD45+ sorted immune cells revealed a significant increase in the M1/M2 macrophage ratio in concurrence with flow cytometry data. NicheNet cell-cell interaction analysis indicated that M1-like TAMs activated infiltrating T-cells and monocytes through ligand-receptor interactions. Cell fate analysis of infiltrated monocytes indicated differentiation toward M1-like macrophages in ACT tumors. Flow cytometry analysis indicated an increase in CD8 effector T-cells. Sc-secretome analysis of F4/80 sorted tumor macrophages by the Isoplexis platform revealed polyfunctionality of HDAC6-treated M1 macrophages. Histological examination of tumor sections for macrophage phenotypic markers suggested that transplanted macrophages retained the M1 phenotype post-ACT in both SM1 murine and NSG-SGM3 melanoma tumor models. Our study comprehensively demonstrated the potential of reprogramming macrophages with HDAC6 inhibitors as a viable macrophage cell therapy for treating solid tumors.

#2254 Therapeutic depletion of FR-β-positive M2 macrophages in solid tumor indications: A novel IO strategy.

Michael Adam[1], R. Paul Wilson[1], Helen Sanderson[2], Chris Hopson[1], Julie Krueger[1], Veronica Herrera[3], Heidi Emerich[3], Andrew Sanderson[2], Carol Harris[2], James Smothers[4]

[1]GSK, Upper Providence, PA,[2]GSK, Stevenage, United Kingdom,[3]Johnson & Johnson, Springhouse, PA,[4]SpringWorks Therapeutics, Durham, NC

Traditional IO therapy has primarily focused on T cell checkpoints, however macrophages typically represent the largest immune population present within tumors and can constitute up to 50% of total tumor mass. Macrophages are implicated in both immune mediated control of tumors as well as tumor progression depending on the phenotype of macrophages in the tumor microenvironment (TME). Immune suppressive M2-like tumor associated macrophages (TAMs) release immuno-suppressive cytokines such as IL-10 and TGF-β which promote regulatory T cells, angiogenesis, metastasis, and tumor progression correlating with a poor prognosis in several solid tumor indications including breast, bladder, ovarian, gastric, prostate, RCC, melanoma, and lung cancers. Folate Receptor beta (FRβ) expression is associated specifically with M2-like immune suppressive macrophages and is not observed on proinflammatory M1-like macrophages. FRβ expression correlates with poor prognosis across lung cancer indications. Depletion of FRβ macrophages by natural killer (NK) cells using an Fc enhanced monoclonal antibody (mAb) to drive antibody-dependent cellular cytotoxicity (ADCC), is proposed as a therapeutic modality, by removing M2-like immunosuppressive macrophages from the TME, while preserving anti-tumorigenic M1-like macrophages. Modified Fc enhanced human FRβ targeting tool mAb M909 results in M2 specific ADCC activity in human monocyte derived macrophage populations *in vitro*. A single dose of modified Fc enhanced murine FRβ targeting tool mAb CL10 results in depletion of murine FRβ+ myeloid cells from MC38 tumors *in vivo* for up to 6 days. To guide patient stratification in lieu of highly invasive biopsy sampling, a soluble biomarker that can be assessed in peripheral blood and correlates to tumor FRβ expression is highly desirable. In patient matched peripheral blood and non-small cell lung cancer (NSCLC) tumor biopsy samples, peripheral blood FRβ+ nonclassical monocytes correlated with FRβ+ TAMs and CX3CR1+ cells which are known to drive macrophage recruitment to the TME. Interestingly, prevalence of NK cell marker NKG2D in peripheral blood also correlated to FRβ+ TAMs. Taken together, the data suggest further exploration of a depleting anti-FRβ+ Fc enhanced mAb as a therapeutic strategy for certain solid tumor indications is merited.
All studies conducted according to GSK's Policy on the Care, Welfare and Treatment of Lab Animals and reviewed by the Institutional Animal Care and Use Committee at GSK or by the ethical review process at the institution where the work was performed.

#2255 Pro-inflammatory macrophage phenotype skewing induced by tumor treating fields (TTFields).

Tal Kan, Yiftah Barsheshet, Boris Brant, Tharwat Haj Khalil, **Tali Voloshin**, Lilach Koren, Simona Zisman-Rozen, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti

Novocure Ltd, Haifa, Israel

Introduction: Tumor treating fields (TTFields) therapy is an approved cancer treatment based on the delivery of electric fields that disrupt cellular processes critical for cancer cell viability. TTFields have been shown to induce immunogenic cell death in cancer cells, elicit a systemic anti-cancer immune response in preclinical models, and are approved for concomitant treatment with PD-1/PD-L1 inhibitors or docetaxel in patients with metastatic non-small cell lung carcinoma after platinum-based therapy. The current study examined the possible effects of TTFields on macrophage phenotype modulation.
Methods: Bone marrow-derived macrophages (BMDMs), flushed from femurs and tibias of 8-10-week-old Balb\C or C57bl/6 mice, were cultured in the presence of granulocyte-colony stimulating factor (GM-CSF) for 7 days. BMDMs were then exposed to either IFN-γ alone or IFN-γ with LPS for M1 polarization or IL-4 for M2 polarization. The polarized BMDMs were next treated with TTFields (150 kHz) for 24 h, followed by flow cytometry examination of surface expression of the F4/80 macrophage marker and activation markers including CD80, major histocompatibility complex class II (MHC-II), inducible nitric oxide synthase (iNOS), CD206, and ARG-1. Lysates of TTFields-treated macrophages were examined for RhoA activation using an appropriate kit and by western blot for phosphorylation of GEF-H1, c-Jun, and the NF-κB subunit p65. iNOS expression was also examined in cells treated with IFN-γ in the presence of TJ-M2010-5, an inhibitor of the TLR component myeloid differentiation primary response 88 (MyD88).
Results: BMDMs exposed to TTFields demonstrated elevated expression of the pro-inflammatory M1 markers CD80 and MHC-II and decreased expression of the anti-inflammatory M2 markers CD206 and ARG-1. BMDMs treatment with TTFields also induced RhoA activation and GEF-H1, c-Jun, and p65 phosphorylation. TTFields treatment of BMDMs that were exposed to IFN-γ markedly elevated iNOS expression to a level similar to that of BMDMs that were exposed to IFN-γ together with LPS, while blockage of TLR signaling substantially reduced iNOS expression.
Conclusions: TTFields demonstrate immunomodulatory effects, promoting pro-inflammatory macrophage polarization and activation in vitro. TTFields exhibit LPS-like activity by acting as a second signal to polarize M1 macrophages, possibly via involvement of the TLR4 signaling pathway and the transcriptional response driven by the GEF-H1/RhoA/ROCK/NF-κB pathway.

#2257 A TGFβ-directed immune-modulatory vaccine induces T cell activation and drives antitumor activity by modulating the tumor microenvironment.

Justin Vareecal Joseph, Matteo Bocci, Ulla Kring Hansen, Marcos Iglesias, Ayako Wakatsuki Pedersen

IO Biotech, Copenhagen, Denmark

Activation of the Transforming Growth Factor (TGF)β signaling cascade plays an essential role in a wide range of tumors and other diseases. Indeed, cancer cells and components of the tumor microenvironment (*e.g.* fibroblasts, myeloid cells, and blood vessels) exploit this pathway to support disease progression during tumor evolution. Nonetheless, global inhibition strategies targeting TGFβ pathway in clinical studies thus far fell short of the anticipated success. These clinical observations suggest that TGFβ modulation - rather than its inhibition - could be the key in sustaining meaningful antitumoral activity in the clinical setting. We report here an alternative approach, where TGFβ-expressing cells are targeted *via* a peptide vaccine directed against TGFβ-specific T cell epitopes. This is based on earlier studies reporting the existence of intrinsic T cell immunity against TGFβ in human[1,2], thus supporting the rationale for targeting these T cells through a vaccine encoding TGFβ epitopes.

To test this approach, we employed a range of murine platforms including the syngeneic Pan02 model of pancreatic adenocarcinoma (PDAC), and a CRISPR/Cas9-driven model of prostate cancer[3]. Collectively, treatment with the TGFβ vaccine significantly reduced the total tumor burden, without affecting the body weight and overall welfare of the animals. *Ex vivo* T-cell responses evaluated through interferon (IFN)-γ ELISpot confirmed expansion and activation of TGF-β-specific T cells upon immunization. Compared to overt malignant masses in the control cohort, TGFβ-directed immunization slowed down the progression of prostate tumors in the CRISPR/Cas9 model, as evinced by the numerous premalignant-like hyperplastic glands and resembling more physiological structures. Furthermore, smooth muscle actin (α-SMA) staining in the Pan02 model uncovered that the treatment ameliorated the fibrotic response - a hallmark of PDAC in the clinical setting - in this experimental setup, with an increased infiltration of CD8+ lymphocytes and F4/80+ macrophages into the TME. Currently, to clarify the mechanism of action, we are implementing the 4T1 model of mammary carcinogenesis to model metastatic disease and exploring spatial relationships to identify which cell types and tissue architectures are pivotal for meaningful responses.In conclusion, our data indicate the efficacy of TGFβ peptide vaccine in eliciting an immune response and tumor growth inhibition in mouse models of cancer. These observations warrant further preclinical investigation to better understand the efficacy and the safety profile of this novel TGFβ-targeting strategy. References: 1. #2260 Social vulnerability and epigenetic signatures in adult survivors of childhood cancer with African ancestry: An epigenome-wide association study.

Yoonji Kim, Xiaoxi Meng, Jaesung Choi, Tiffany Eulalio, Noel-Marie Plonski, Heather Mulder, John Easton, Emily Walker, Geoff Neale, Kirsten Ness, Melissa M. Hudson, Gregory T. Armstrong, I-Chan Huang, Zhaoming Wang

Epidemiology and Cancer Control, St. Jude Children's Research Hospital, Memphis, TN

Background: Social determinants of health (SDOH) are increasingly recognized as critical factors in shaping long-term adverse health outcomes among childhood cancer survivors (survivors) because long-lasting toxicities from cancer treatment may be exacerbated by social adversity. Our previous epigenetic study of SDOH primarily focused on survivors of European ancestry, using measures such as educational attainment, personal income, and the Area Deprivation Index. This study aims to enhance understanding of the biological embedding of social adversity in survivors of African ancestry using the Social Vulnerability Index (SVI). The SVI provides a more comprehensive representation of SDOH, capturing neighborhood-level social vulnerabilities and aligning with the objectives of Healthy People 2030.
Methods: Survivors of African ancestry from the St. Jude Lifetime Cohort were included. DNA methylation (DNAm) profiles were generated with EPIC BeadChip v1 using blood-derived DNA. SDOH factors included social vulnerability (four domains from the SVI: socioeconomic, household composition/disability, minority status/language, and housing/transportation), educational attainment, and personal income. An epigenome-wide association study (EWAS) was used to evaluate the association between DNAm at each CpG and SDOH factors, adjusting for attained age, sex, cancer treatment exposures, and leukocyte composition.
Results: The study included 367 survivors (50.0% males; median age at blood draw for DNAm = 32.75 and interquartile range = 27.9-38.5 years). EWAS identified an epigenome-wide significant association between cg25793377 and overall SVI (beta=0.18, SD=0.033, $p=8.73\times10^{-8}$). Specifically, this association was significant for the socioeconomic domain of the SVI (beta=0.14, SD=0.035, $p=8.11\times10^{-5}$), but not significant for three other domains of SVI). Moreover, this CpG was not associated with personal-level SDOH factors, including educational attainment and personal income. This CpG maps to FFAR*4*, which encodes a G protein-coupled receptor (GPR) belonging to the rhodopsin family of GPRs and is a receptor for free fatty acids, including omega-3s, indicated in suppression of anti-inflammatory responses and insulin sensitizing; cg25793377 is also associated with protein levels in whole blood, including GZMK and TNFRSF17, both implicated in immune function and pro-inflammation.
Conclusion: This study highlights the potential impact of neighborhood-level socioeconomic status in epigenome alteration among childhood cancer survivors with African ancestry, suggesting that socioeconomic vulnerability has molecular effects. These findings support the hypothesis that distal social factors become biologically embedded through epigenetic modulation, potentially influencing health trajectories in childhood cancer survivors.

#2261 Distinct genomic and high-risk cytogenetic features in black multiple myeloma patients: Insights from the PE-CGS Network.

Yizhe Song[1], Reyka G. Jayasinghe[1], Mark Fiala[1], Michael J. Slade[1], Song Cao[1], Fernanda Martins Rodrigues[1], R. Fulton[3], Shelly O'Laughlin[3], Tracie L. Deluca[3], Eric J. Duncavage[4], David H. Spencer[1], Ravi Vij[1], Kiran Vij[4], Bettina F. Drake[2], Ryan C. Fields[2], Graham A. Colditz[2], Li Ding[1]

[1]Department of Medicine, Washington University School of Medicine, St. Louis, MO,[2]Department of Surgery, Washington University School of Medicine, St. Louis, MO,[3]Department of Genetics, Washington University School of Medicine, St. Louis, MO,[4]Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO

Introduction: Landmark cancer genome sequencing programs have significantly advanced cancer research, leading to novel therapies and preventive strategies. However, the underrepresentation of racial minority groups in these studies limits the applicability of findings and leaves critical gaps in understanding cancer disparities. The Participant Engagement and Cancer Genome Sequencing (PE-CGS) Network, established under the National Cancer Institute's Cancer Moonshot, seeks to address these gaps by engaging with understudied populations. Multiple myeloma (MM), which disproportionately affects Black patients with higher incidence, exemplifies the need for inclusive research. High-risk cytogenetic events are strongly associated with poor outcomes in MM but are not well characterized in Black patients due to limited data. To address these disparities, we analyzed the genomic landscape of Black MM patients recruited through the PE-CGS Network.

Methods: A total of 191 self-reported Black MM patients (59% female, aged 41-98 years, median: 66) were recruited. Whole-exome sequencing was performed on 124 tumor-normal paired samples, including 83 newly diagnosed MM (NDMM), 20 plasmacytoma, and 21 relapsed/refractory MM (RRMM) cases. We conducted a 1:2 matched case-control study comparing Black NDMM patients from the PE-CGS study with White NDMM patients from MMRF CoMMpass study, matched by age and sex, to identify genomic differences between two groups. Three high-risk cytogenetic events, del(17p), del(1p) and gain(1q), were assessed in both groups. Copy number variants (CNVs) were categorized based on the tumor-to-normal copy number ratio as high amplification (≥4 copies), gain (>2.5 & <4 copies), deletion (<1.5 copies), or neutral (1.5-2.5 copies).

Results: Among 124 tumor samples from Black MM patients, 36.4% harbored at least one high-risk cytogenetic event. In the 83 tumor samples from Black NDMM patients, del(17p) occurred in 22.3%. High amplification of 1q was present in 25.30% of Black patients, higher than 8.04% in White patients. Del(1p) was observed in 18.18% of tumors from Black patients. Somatic mutation analysis revealed that KRAS (22.1%) and NRAS (15.6%) were the most frequently mutated genes among Black patients. TP53 mutations were observed in 5.7% of Black patients, exceeding previously reported frequencies. TP53 CNVs varied by self-identified race, with high amplification more frequent in White (30.36%) than Black patients (1.61%).

Conclusions: In this study, we highlight the distinct genomic landscape in Black MM patients, including higher rate of high-risk cytogenetic events and unique mutational patterns compared to Whites. These findings underscore the importance of engaging underrepresented populations in cancer research, as exemplified by the PE-CGS Network, to improve risk stratification and advance equitable healthcare outcomes.

#2262 A case-control analysis of germline pathogenic variants among patients with sarcoma.

Adela Rodriguez Hernandez[1], Miki Horiguchi[2], Carolyn Horton[3], Linda M Polfus[3], Brittany L. Bychkovsky[1], Colin Young[3], Suzanne George George[4], Priscilla Merriam[4], Judy E Garber[1], Huma Q Rana[1]

[1]Division of Cancer Genetics and Prevention, Dana-Farber Cancer Institute, Boston, MA, USA, Dana-Farber Cancer Institute, Boston, MA,[2]Department of Data Science, Dana-Farber Cancer Institute,Department of Biostatistics, Harvard T.H. C, Dana-Farber Cancer Institute, Boston, MA,[3]Ambry Genetics, Aliso Viejo, CA,[4]Dana-Farber Cancer Institute, Boston, MA

Introduction: Sarcomas are heterogeneous malignancies with diverse subtypes and treatments. The utility of multi-gene germline testing in patients (pts) with sarcoma is unclear. This study examines the prevalence and distribution of germline pathogenic variants (PVs) in pts with sarcoma compared to controls to refine genetic testing recommendations.

Methods: This retrospective case-control study included pts with sarcoma who underwent germline testing of 37 cancer-related genes from January 2016 to January 2024 at Ambry Genetics (Aliso Viejo, CA). A control group of 1464 cancer-free individuals matched 1:3 by age, sex, and ethnicity, served as the comparator. The prevalence of PVs was compared between cases and matched controls using Fisher's exact test for each selected gene. The degree of association was summarized with odds ratios (ORs) and corresponding 95% exact confidence intervals (CIs). In the case-only cohort, clinical characteristics were evaluated using logistic regression to assess associations with the presence of PVs in any gene.

Results: Among 488 pts with sarcoma, 67.8% (n=331) were female and 32.2% (n=157) male, with a median age at sarcoma diagnosis of 47 years (IQR: 0.5-87.5). PVs were found in 26.2% (n=128) of the pts. The prevalence of PV in pts with sarcoma and no other cancer diagnosis compared to pts with sarcoma and multiple cancer diagnoses was 24.0% (n=61) and 28.6% (n=67) (p=0.141) respectively. PV burden was increased among cases compared to the control group (26.2% vs 12.0%) (OR 2.62, CI: 2.01-3.41; p <0.001). A higher frequency of PV was observed in the cases compared to the control group in the following genes: *BRCA2* (4.1% vs 2.1%; p= 0.028), *CHEK2* (2.8% vs 1.0%; p=0.012), *NF1* (2.7% vs 0.1%; p<0.001), *POT1* (0.9% vs 0.1%; p=0.047), *SDHA* (1.4% vs 0.4%; p= 0.043) and *TP53* (5.5% vs 0.1%; p < 0.001). Among *CHEK2* PV, 4/13 were not founder mutations, and the low-risk variants (*p.I157T*, *p.S428F*, *p.T476M)* were excluded from the PV count. There was no significant difference in age at sarcoma diagnosis (45.5 vs. 47.0 years; p=0.172) between PV carriers and non-carriers. Multivariable analysis identified male sex (OR 1.63; p=0.039) and younger age at testing (OR 0.99; p=0.037) as significant factors associated with PV presence.

Conclusions: This study reveals a prevalence of germline PVs exceeding 25% among pts with sarcoma, reinforcing associations with *BRCA2*, *POT1,* and *TP53* and uncovering potential new signals in *CHEK2*. Our findings underscore the importance of comprehensive genetic testing in adult pts with sarcoma, as age at diagnosis alone is insufficient to predict PV status. The lack of family history data in this study introduces potential bias related to referral patterns for germline testing. These results contribute to refining germline testing criteria and advancing personalized prevention strategies. Validation in future, unbiased cohorts is essential to confirm these findings.

#2263 DNA methylation-estimated C-reactive protein levels and lung cancer risk and mortality in individuals with a heavy smoking history.

L. Grieshober[1], S. Graw[2], M. J. Barnett[3], G. E. Goodman[3], C. Chen[3], D. C. Koestler[4], C. J. Marsit[5], J. A. Doherty[1];
[1]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, [2]Everest Clinical Research Corporation, Markham, ON, Canada, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]University of Kansas Medical Center, Kansas City, KS, [5]Rollins School of Public Health, Emory University, Atlanta, GA

Inflammation, a hallmark of cancer and chronic disease, is an established risk factor for lung cancer and is also associated with worse survival in lung cancer cases. C-reactive protein (CRP) is one circulating biomarker of inflammation that has been shown to be associated with DNA methylation (DNAm) in epigenome-wide association studies (EWAS). Several epigenetic CRP scores have been proposed using results from these studies, offering the unique opportunity to approximate CRP in studies without directly measured CRP. A validated DNAm CRP score was recently published by Hillary et al., which explains 18% of CRP variation beyond age, sex, and CRP-based genotype. This score, mCRP, includes 1,468 CpGs obtained from elastic net regression on EWAS results for measured CRP in a training set of nearly 18k individuals. Using an additive linear combination of the published CpGs and EWAS regression weights, we estimated pre-diagnosis mCRP in individuals with a heavy smoking history from the β-Carotene and Retinol Efficacy Trial (CARET) and assessed associations with both lung cancer risk and mortality for all cases and by histotype. Analytic samples included: 316 lung cancer case-control pairs through 2005, matched on age (±5 years), sex, race and ethnicity, enrollment year (±2 years), smoking status (ever/never), asbestos exposure, and follow-up time, (mean 57 pack years, range 11-185) for risk; and 372 lung cancer cases diagnosed through 2013 (mean 59 pack years, range 20-162) for mortality. DNAm data was assayed on the Illumina EPIC array in blood collected on average 4.3 years before diagnosis in cases for risk and 4.9 years for mortality. Conditional logistic regression models adjusted for age and pack years revealed no strong evidence of increased lung cancer risk with increasing mCRP. Cox proportional hazards models adjusted for age, sex, smoking status (current/former), pack years, and time from blood draw to diagnosis with stage as a stratification variable (early I/II, advanced III/IV, unknown) showed a greater hazard of death per standard deviation increase in mCRP among all lung cancer cases (Hazard Ratio (HR) 1.13, CI: 1.02-1.25), adenocarcinoma (HR 1.21, CI: 1.02-1.43), and small cell carcinoma (SCLC; HR 1.33, CI: 1.06-1.68). No associations were observed for squamous cell carcinoma, and results were similar for lung cancer-specific mortality among each case group. While these results do not provide support that pre-diagnosis mCRP is associated with lung cancer risk in individuals with a heavy smoking history, we observed that greater pre-diagnosis mCRP may be an indicator of mortality in members of this population. This work highlights the possible importance of pre-diagnosis inflammation via mCRP and mortality in heavy smokers who later develop lung cancer, particularly adenocarcinoma and SCLC.

#2264 Disparities in perceptions and uptake of genetic testing among the United States population: trends from 2011-2022.

Ariana Naaseh, Mengyao Shi, Steven Tohmasi, Erin L. Linnenbringer, Julie A. Margenthaler, Graham A. Colditz, Yin Cao

Department of Surgery, Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Over the last decade, genetic testing has become more readily available, but it is not known whether this has translated to greater public awareness and usage over time. We aimed to evaluate patterns and temporal trends in genetic testing awareness and usage, along with their sociodemographic and cancer history correlates, in the United States (US) population.
Methods: We performed a serial, cross-sectional analysis of nationally representative data from the National Cancer Institute's Health Information National Trends Survey (HINTS). We analyzed survey responses from adults aged 18 or older from HINTS 4 Cycle 1 (2011), 4 Cycle 2 (2012), 4 Cycle 3 (2013), 4 Cycle 4 (2014), 5 Cycle 1 (2017), 5 Cycle 4 (2020), 6 (2022). Crude linear trend was evaluated using a linear regression model and multivariable logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CIs).
Results: Data on 22,256 individuals (mean [SD] age, 46.7 [17.0] years; 13,208 (50.7%) female; non-Hispanic White 13,559 (65.2%)) were analyzed from 2011-2022 HINTS data. Awareness of genetic testing increased from 36.6% in 2011 to 81.7% in 2022 ($p<0.001$). Older adults, men, non-Hispanic Black individuals, non-Hispanic Asian individuals, Hispanic individuals, those with an education level less than some college, and individuals with annual household incomes less than $75,000 were significantly less likely to be aware of genetic testing. Uptake of genetic testing, however, lagged behind awareness with rates of 21.4% in 2020 and 35.6% in 2022. Uptake of genetic testing was significantly lower among non-Hispanic Asian individuals, those with household incomes under $35,000, and those without a personal history of cancer.
Conclusion: Despite high levels of awareness, genetic testing uptake remains disproportionately low, with notable disparities across sociodemographic groups. Targeted educational interventions focused on genetic testing are necessary for marginalized populations and the providers caring for them. Further study is needed to understand genetic testing uptake patterns in the US.

#2265 Identifying disparities in prostate cancer treatment and genomic data availability utilizing the All of Us Research Program.

Dhruv G. Pillai[1], Benjamin C. Brim[1], Nicholas G. Micheletti[2], Hyoyoung Choo-Wosoba[2], Laura M. Yee[2], Cindy H. Chau[1], William D. Figg[1]

[1]Genitourinary Malignancies Branch, National Cancer Institute, Bethesda, MD,[2]Office of Collaborative Biostatistics, National Cancer Institute, Bethesda, MD

The All of Us Research Program (AoURP) is a clinical and genomic database established by the National Institutes of Health that aims to encapsulate the diversity of the United States population. AoURP intends to enroll 1 million participants of diverse backgrounds through its robust outreach efforts, which selectively engage communities under-represented in biomedical research. AoURP may help elucidate disparities in prostate cancer (PCa) treatment and clinical research participation. This study aimed to explore whether PCa patients of various demographic backgrounds receive novel cancer treatments and participate in genomic research at different rates. To obtain a diverse cohort of participants, we identified every PCa patient in AoURP (n = 6271). We determined whether these patients opted for genetic testing by AoURP and extracted electronic health record data on commonly prescribed PCa treatments, including androgen deprivation therapy, second-generation anti-androgens, chemotherapy, prostatectomy, radiation, and bone-targeting agents. We stratified patients who obtained genetic testing and standard PCa treatments by demographic factors of household income, educational attainment, race, ethnicity, and distance from a National Cancer Institute (NCI)-designated comprehensive cancer center (NCIDCCC). To establish distance from an NCIDCCC as a categorical variable, we determined whether PCa patients resided within forty- and eighty-mile radii of one of these facilities. The study revealed that Black/African American patients received bone-targeting agents less frequently than their White/Caucasian counterparts. We also observed that more patients inside forty- and eighty-mile radii of an NCIDCCC obtained second-generation anti-androgens and bone-targeting agents than those outside these thresholds. Upon stratifying patients with history of prostatectomy or radiation based on additional thresholds (40, 50, 60, 70, 80, 90, and 100 miles), we found that more patients received prostatectomy than radiation at greater distances from NCIDCCCs. This result indicates that geographic factors may influence treatment of localized disease, with prostatectomy being more common for patients farther from major clinical centers. Additionally, we detected no variability in the rates at which different demographic groups underwent genetic testing. Overall, our study suggests that distance from an NCIDCCC and race may represent risk factors for treatment underuse in PCa patients, highlighting that additional outreach efforts by NCIDCCCs are necessary to encourage equitable usage of cancer treatments.

#2266 Evaluations of more than 1500 blood metabolite biomarkers with risk of eight common cancers and their subtypes using genetic instruments.

Zheng Guo, Guochong Jia, Fangcheng Yuan, Lili Liu, Shuai Xu, Jirong Long, Wei Zheng

Division of Epidemiology, Vanderbilt University Medical Center, Nashville, TN

Background: Many epidemiologic studies have measured blood metabolites and evaluated their associations with risk of cancers. However, conventional epidemiologic studies may suffer from various biases, limiting their ability for causal inferences. We performed a large Mendelian randomization (MR) study to systematically evaluate blood metabolite biomarkers in relation to cancer risk, including large numbers of associations not previously investigated in either convention epidemiologic or MR studies.
Methods: We systematically searched the literature and obtained data from 29 genome-wide association studies (GWAS) to identify blood metabolite-associated genetic loci (mQTLs) among 324,771 individuals of European ancestry. After systematically evaluating all metabolites and mQTLs evaluated in these studies, we selected 1630 metabolite biomarkers for MR analyses using summary statistic data generated from GWAS conducted among 2,068,121 individuals of European ancestry for eight common cancers (breast, colorectal, endometrial, kidney, lung, ovarian, pancreatic, and prostate) and 19 subtypes of breast, kidney, lung, and ovarian cancers. The inverse variance weighted (IVW) method was used as the primary approach for MR analyses. Other methods, including MR-Egger, and MR-PRESSO, were used to evaluate possible pleiotropic effects and robustness of study findings. Statistical significance was judged using Bonferroni and FDR corrected P-value to reduce type 1 errors.
Results: We identified 106 biomarker-cancer associations under the significant threshold after Bonferroni correction. Among these, 68 were associated with an increased risk of cancer, while 38 were associated with a decreased risk of cancer. Under an FDR-corrected $P < 0.05$ but not reaching the Bonferroni-adjusted significant threshold, we identified 119 additional associations, including 65 metabolite biomarkers as potential risk factors and 54 as potential protective factors.
Conclusion: Our MR analysis uncovered large numbers of novel associations and provided strong evidence for causal inferences of blood metabolite biomarkers with cancer risk.

#2267 Mapping genetic risk for Barrett's esophagus and esophageal adenocarcinoma to key tissues and transcriptional regulators.

Elnaz Naderi[1], Xu Zhang[1], Kathryn Graz[1], Carlos Maj[2], Johannes Schumacher[2], Li Yan[3], Matthew F. Buas[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]University of Marburg, Marburg, Germany,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Esophageal adenocarcinoma (EAC), the most common subtype of esophageal cancer in Western countries, typically arises from Barrett's esophagus (BE), a pre-neoplastic condition marked by replacement of the normal esophageal epithelium with intestinal metaplasia. Genome-wide association studies (GWAS) have revealed a substantial heritable component of BE/EAC susceptibility, but mechanistic understanding remains limited. Identifying tissues, cell types, and transcriptional regulators mediating genetic risk is essential for elucidating etiologic pathways and defining novel molecular targets for translation.
Methods: We employed a permutation-based approach to evaluate the enrichment of BE/EAC-associated variants in open chromatin regions (OCRs) across >50 diverse tissues and cell types. For a subset of implicated tissues, we further assessed enrichment in the binding regions of multiple transcription factors (TFs) using ChIP-seq profiles, with complementary analyses based on DNAse-I footprinting data and motif scanning. Multiple testing correction was implemented using the false discovery rate (FDR<0.05).
Results: BE/EAC variants were significantly enriched in OCRs of gastrointestinal tissues, particularly fetal stomach (OR = 1.6, P = 6e-04) and fetal large intestine (OR = 1.5, P = 1.5e-03). Enrichments were also observed in muscle (OR = 1.5, P = 9e-04) and fibroblast (OR = 1.4, P = 8.8e-03) cells, suggesting a broader multi-lineage regulatory landscape. Key TFs implicated in subsequent testing included GATA6 (OR = 3.0, P <1e-04) and GATA4 (OR = 2.2, P = 2e-04) in GI tissues; EZH2 in muscle cells (OR = 5.7, P = 2e-04); and EZH2 (OR = 3.5, P <1e-04) and AR (OR = 1.4, P = 1.2e-03) in fibroblast cells.
Conclusions: This study indicates that BE/EAC risk variants act through regulatory elements across diverse tissues, with prominent roles suggested in gastrointestinal, muscle, and stromal cells. The significant enrichment signals for transcription factors such as GATA6, GATA4, and EZH2 underscore their regulatory importance in GI-tract development and BE/EAC pathogenesis. These insights enhance our understanding of the cellular/molecular origins and genetic underpinnings of BE/EAC, providing a promising foundation for experimental and translational studies targeting specific transcriptional regulatory networks.

#2268 Prospective and genetic analyses implicate lower immunosurveillance in the aetiology of prostate cancer.

Mahboubeh Parsaeian[1], Wing Ching Chan[1], Joshua Atkins[1], Keren Papier[1], Trishna Desai[1], Zhe Huang[1], David Conti[2], David Bogumil[3], Jiayi Shen[3], Malcolm Sim[4], Konstantinos Tsilidis[5], James Yarmolinsky[5], Sabina Rinaldi[6], Rudolf Kaaks[7], Verena Katzke[7], Matthias Schulze[8], Catarina Schiborn[9], Saverio Caini[10], Lorenzo Milani[11], Raul Zamora-Ros[12], Marcela Guevara[13], Maria-Jose Sanchez[14], Maria-Dolores Chirlaque[15], Pilar Amiano[16], The PRACTICAL Consortium, Timothy Elliott[4], Ian Mills[17], Elio Riboli[5], Loic Le Marchand[18], Christopher Haiman[2], Tim Key[1], Karl Smith-Byrne[1], Ruth Travis[1]

Tumor promoting inflammation and the ability to evade immune destruction are two of the hallmarks of cancer, but there is limited prospective evidence for the role of specific inflammation and immune-related pathways and protein markers in the development of prostate cancer. This study used data on the circulating levels of 368 inflammation and immune-related proteins (Olink Explore Inflammation I panel) from a nested case-control design within the European Prospective Investigation into Cancer and Nutrition (EPIC), including 1,434 men who developed prostate cancer and 1,434 matched controls - 488 of the cases also had clinically aggressive disease. Conditional logistic regression was used to estimate protein associations with cancer risk in EPIC, per standard deviation and the effective number of tests (ENT) was used to control for multiple testing. We additionally performed a fixed-effect meta-analysis combining associations for these proteins estimated in EPIC with those in 21,481 men from UK Biobank (UKBB), of whom 1,147 developed prostate cancer. Logistic regression was used to estimate exome protein score association with cancer risk in UKBB and replication analyses were performed in the Multiethnic Cohort (MEC). Mendelian randomisation and colocalisation analyses using data on 79,148 overall prostate cancer cases from the PRACTICAL consortium were also conducted to aid triangulation. In EPIC, no inflammatory proteins were associated with prostate cancer risk overall or with more clinically aggressive subtypes after correction for multiple testing. In the EPIC+UKBB meta-analyses, FLT3LG and CNTNAP2 were significantly associated with overall prostate cancer risk (RR_{Meta}: 0.88, 95% CI: 0.84-0.92 and RR_{Meta}: 1.10, 95% CI: 1.05-1.16, respectively), and in the analyses stratified by time to diagnosis, IL15 was associated with risk of prostate cancer diagnosed more than seven years after blood draw (RR_{Meta}: 0.86, 95% CI: 0.81-0.93), along with five other proteins (FLT3LG, BCL2L11, PGF, CKAP4, and TNFRSF11A). Exome protein scores in UKBB identified PARP1 as associated with an increased risk of prostate cancer (OR: 1.05, 95% CI: 1.02-1.07), which replicated in MEC (OR: 1.04, 95% CI: 1.01-1.08). MR and colocalisation analyses also identified SPINT2 (OR: 2.11, 95% CI: 1.70-2.63) and NME3 (OR: 1.25, 95% CI: 1.11-1.41) as being associated with an increased risk of prostate cancer overall. Our findings suggest higher levels of proteins involved in immunosurveillance pathways, including the recruitment and activation of natural killer and T cells, may be linked to a lower risk of developing prostate cancer, while PARP1 inhibition may be relevant for prostate cancer prevention.

#2269 Factors associated with declining to participate in cancer genetic and genomic studies among Hispanic/Latine patients with colorectal cancer: findings from a Cancer Moonshot[SM] project.

Diego I. Alvarez-Lopez[1], Joel Sanchez Mendez[1], Jessica Sanchez[2], Fibi Berhane[1], Carmen Chavez[3], Lucia Enriquez[3], Vernon S. Pankratz[2], Andrew L. Sussman[2], Ursa A. Brown-Glaberman[2], Stephanie Solomon Cargill[4], Heinz-Josef Lenz[3], John D. Carpten[5], Shiraz I. Mishra[2], Mariana C. Stern[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]University of New Mexico Health Sciences Center, University of New Mexico Comprehensive Cancer Center, Albuquerque, NM,[3]Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA,[4]Alden March Bioethics Institute, Albany Medical College, Los Angeles, NY,[5]City of Hope Comprehensive Cancer Center, Duarte, CA

Introduction: Colorectal cancer (CRC) is the third leading cause of cancer-related mortality among Hispanic/Latine (H/L) men and women in the United States (US), yet H/L patients are underrepresented in cancer genetic/genomic studies. As part of the Cancer Moonshot[SM] initiative, the Center for Optimizing Engagement of Hispanic Colorectal Cancer Patients in Cancer Genomic Characterization Studies (COPECC) launched the ENLACE study. This study engages H/L patients with CRC to characterize germline genetics and tumor somatic mutations and gathers information on participation determinants. We examined factors influencing the decision to decline participation in cancer genetic/genomic research.

Methods: We compared characteristics of patients with CRC diagnosed between February 2014 and November 2024 who accepted to participate in the ENLACE study to those who declined and wanted no further contact. We descriptively summarized sociodemographic characteristics and made between-group comparisons using Student's t-tests for continuous variables and Fisher's exact tests for categorical variables. An open-ended question was included to capture reasons for declining participation, which were analyzed using inductive thematic analysis. To further explore these barriers, we initiated a scoping review on reasons for declining participation in cancer genetics/genomic studies in the US. We deployed a piloted search strategy across MEDLINE (PubMed), Embase (Ovid), and Scopus and have identified 12,726 peer-reviewed references in English (MEDLINE: 5,970; Embase: 1,657; Scopus: 5,099). Independent reviewers will assess full texts for inclusion, and findings will be summarized numerically and narratively.

Results: We included data from 249 patients in the analysis; 40 (16.1%) had declined to participate. Decliners were, on average, 5 years older than participants ($p<0.05$), less likely to be Catholic (52.5% vs. 71.8%; $p<0.05$), and more likely to be Christian (40.0% vs. 19.1%; $p<0.05$). The proportion of patients diagnosed with stage 3 or 4 CRC was similar (decliners = 45.0% vs. participants = 47.1%; $p=0.86$). The three most common reasons for declining were: 1) lack of energy due to treatment; 2) prior genetic testing; and 3) concerns about adding further stress to their health situation.

Conclusions: Despite the high burden of CRC among the H/L population, participation in cancer genetic/genomic studies remains low. Our findings highlight factors influencing engagement and offer insights for culturally tailored strategies to enhance participation in cancer research. Clarifying to patients that the testing offered by ENLACE is more comprehensive than prior genetic testing (e.g., standard commercial testing) could address this specific reason for declining participation and improve engagement in the study.

#2271 Real-World data of germline variants in 5,893 Korean hereditary cancer patients.

Ha-Eun Lee[1], Sang-Yoon Park[2], Seeyoun Lee[3], So-Youn Jung[3], Myong Cheol Lim[2], Han-Sung Kang[3], Jun-Ha Jang[1], Sun-Young Kong[1]

[1]Targeted Therapy Branch, National Cancer Center - Korea, Goyang, Korea, Republic of,[2]Center for Gynecologic Cancer, National Cancer Center - Korea, Goyang, Korea, Republic of,[3]Center for Breast Cancer, National Cancer Center - Korea, Goyang, Korea, Republic of

Background: The advent of next-generation sequencing (NGS) has significantly enhanced hereditary cancer comprehensive germline genetic testing. While initial efforts targeted BRCA1 and BRCA2, NGS now reveals a broader range of cancer susceptibility genes, highlighting diverse genetic variations. The variability of pathogenic variants (PVs) across ethnic groups underscores the critical importance of population-specific studies. This study evaluates PVs frequency and their clinical relevance in Korean hereditary cancer patients, providing detailed insights into the genetic characteristics in this population.
Methods: We analyzed real-world data from 5,893 patients who underwent genetic testing at the National Cancer Center in Korea between 2006 and 2023. Genetic testing included either *BRCA1/2* test (n=2,342) or NGS panel testing (n=3,551), with the type of test determined by the physician's clinical decision and insurance reimbursement criteria. We collected demographic characteristics, personal and family history and analyzed the impact of these factors on PV carrier status.
Results: The median age of the patients was 51.3 years (range: 4-92), with 96.3% female. The distribution of diagnosed cancers was as follows: breast cancer (55.8%), ovarian cancer (37.2%), thyroid cancer (2.4%), pancreatic cancer (2.4%), endometrial cancer (2.4%), colorectal cancer (1.9%), prostate cancer (1.7%), lung cancer (0.8%), gastric cancer (0.8%), other cancers (2.8%) and multi-organ cancers (n=677). Among 43.6% patients with a family history of cancer, 87.1% reported a first-degree relative (FDR), 40.5% a second-degree relative (SDR), and 5.2% a third-degree relative (TDR).PVs were observed in 184/1,612 (11.4%) breast cancer, 202/732 (27.5%) ovarian cancer in *BRCA1/2* test and 221/1,681(13.1%) breast cancer, 333/1,463 (22.8%) ovarian cancer in NGS panel testing. In patients who underwent NGS panel testing, 606 individuals represented 626 PVs. The genes most commonly affected included *BRCA1* (35.8%), *BRCA2* (27.3%), *RAD51D* (4.2%), *ATM* (3.8%), *PALB2* (3.5%), *MUTYH* (3.0%), *CHEK2* (2.4%), *MSH2* (2.4%), *BRIP1* (2.2%), *MLH1* (2.1%), *MSH6* (1.9%) and *PMS2* (1.8%).In breast and ovarian cancer, multiple organ involvement emerged as a significant risk factor for suspected germline PVs ($p < 0.01$). PV of breast cancer patients was significantly associated with family history of 50.9% with FDR, 13.8% with SDR, and 1.7% with TDR.
Conclusion: Our study identified overall 16.6% prevalence of germline PVs in Korean patients and there is a notable finding involving genes other than BRCA1/2, which highlights the broader spectrum of genetic alterations, suggesting the need for greater awareness and preparedness in hereditary cancer.This study was supported by grant from the National Cancer Center. (grant number NCC-2410821).

#2273 The spectrum of germline cancer gene mutations in Central American pediatric cancer.

Jesica M. Godinez Paredes[1], Claudia Garrido[2], Patricia Calderon[3], Isabel Rodriguez[1], Yi Xie[1], Jia Liu[4], Wen Luo[4], Herbert Higson[4], Kristine Jones[4], Hong Lou[4], Lisa Garland[1], Dulilio Leyton[3], Lesly Chapman[1], Edmundo Torres-Gonzalez[1], Julie Sawitzke[4], Matthew Gianferante[1], Sandra Luna-Fineman[2], Veronica Giron[2], Mauricio Castellanos[2], Federico Antillon-Klussman[5], Lisa Mirabello[1], Gerardo Mejia[6], Michael Dean[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[2]Unidad Nacional de Oncologia Pediatrica, Guatemala City, Guatemala,[3]Department of Hematology/Oncology, Children's Hospital Manuel de Jesus Rivera, Managua, Nicaragua,[4]Frederick National Laboratory for Cancer Research, National Cancer Institute, Frederick, MD,[5]Unidad Nacional de Oncologia Pediatrica and Universidad Francisco Marroquin, Guatemala City, Guatemala,[6]Department of Genetics, MINSA, Managua, Nicaragua

Pediatric cancers are a diverse set of both hematologic and solid malignancies. Approximately 5% of pediatric cancer cases are caused by known genetic conditions, but little is known about genetic susceptibility in Central American children. Most pediatric leukemia and lymphoma cases have high response and cure rates, and many solid malignancies have better outcomes than similar adult cancers. We evaluated the germline genetic variation of pediatric solid tumor cases in Guatemala and Nicaragua in reference hospitals, capturing most of the cancer cases nationwide. We performed exome sequencing on 1360 subjects (957 with solid tumors and 405 with leukemias) and classified variants using an automated pipeline using ClinVar and InterVar and by manual review. The most prevalent cancer types were acute lymphocytic leukemia (357), Hodgkin's lymphoma (229), osteosarcoma (119), and retinoblastoma (93). Pathogenic mutations were identified in 25 pediatric cancer susceptibility genes. Excluding retinoblastoma, 6.5% of cases had a Pathogenic or Likely Pathogenic germline mutation in a cancer-predisposing gene. As expected, *RB1* mutations were frequent in retinoblastoma patients, with 81% of confirmed bilateral cases having a Pathogenic or Likely Pathogenic mutation. Mutations in the *NF1* gene were observed in neurofibromatosis cases and non-rhabdomyosarcoma. *TP53* mutations were observed in osteosarcoma and rhabdomyosarcoma cases, and *WT1* mutations were observed in Wilms tumor and renal cancer cases. A single case of pheochromocytoma was found to have a novel *VHL* gene mutation. Higher rates of pediatric Hodgkin's lymphoma (HL) are found in Central American countries, and the cause of this is unknown. We did not find a significantly mutated gene in the HL cases, suggesting that a common germline mutation is not a significant factor. In conclusion, 6.5% of Central American solid tumor cases have a germline mutation in genes known or suspected to influence cancer risk.

#2274 Implications of multiple myeloma polygenic risk scores (PRS) for MGUS.

Angelica Macauda[1], Alyssa Clay-Gilmour[2], Cristine Allmer[1], Danelle Moonen[1], Aaron D. Normann[1], Nicholas J. Boddicker[1], Joselle M. Cook[1], Linda Baughn[1], Elizabeth E. Brown[3], Vincent S. Rajkumar[1], Esteban Braggio[4], David L. Murray[1], Susan L. Slager[1], Shaji Kumar[1], Celine M. Vachon[1]

[1]Mayo Clinic, Rochester, MN,[2]University of South Carolina, Greenville, SC,[3]University of Alabama, Birmingham, AL,[4]Mayo Clinic, Phoenix, AZ

Genome-wide association studies (GWAS) of multiple myeloma (MM) in individuals of genetic European ancestry (EA) have identified 35 susceptibility loci. Co-heritability analyses have revealed a strong genetic correlation between MM and its precursor condition, monoclonal gammopathy of undetermined significance (MGUS). Previous research validated the association between a polygenic risk score (PRS) based on 23 MM risk loci and the risk of MGUS. Went and colleagues recently reported 12 new MM risk loci. We constructed a MM-PRS using all 35 MM risk variants and assessed its association with MGUS. Additionally, among individuals with MGUS, we assessed associations of MM-PRS with established prognostic factors [M-protein (<0.2 g/dL; 0.2-1.5 g/dL; ≥1.5 g/dL); isotype (IgG, IgA, IgM); free light chain (FLC) ratio (Normal (0.26-1.65), Abnormal (<0.26 or >1.65))]. Our study population included 1,723 individuals with MGUS seen at Mayo Clinic, Rochester, MN and 14,175 controls from the Mayo Clinic Biobank who lived in the 27-county region around Rochester, MN, and screened negative for MGUS using MALDI-TOF MS. The majority of MGUS patients and controls were of EA. We used logistic or multinomial regression to calculate odds ratios (ORs) and 95% confidence intervals (CIs). All models were adjusted for age, sex, and the first three principal components. The MM-PRS was significantly associated with MGUS when assessed continuously (OR, 1.28 per standard deviation (SD); 95% CI, 1.22-1.35). When comparing to the middle quintile of the MM-PRS distribution, individuals in the highest quintile had 1.41-fold increased risk of MGUS (95% CI, 1.21-1.64), and individuals in the lowest quintile had 0.68 decreased risk of MGUS (95% CI, 0.57-0.81). Of the 35 SNPs evaluated, 27 demonstrated consistent directions of effect for risk of MGUS with published risk estimates for MM. The effect of MM-PRS differed by isotype ($P = 2.2 \times 10^{5}$), with higher MM-PRS associated with IgA MGUS (OR, 1.40 per SD; 95% CI, 1.08-1.81) and a lower MM-PRS associated with IgM (OR, 0.66 per SD; 95% CI, 0.52-0.84) compared to IgG MGUS. The MM-PRS was higher in MGUS patients with M-protein ≥ 1.5 g/dL compared to M-protein of size 0.2-1.5 g/dL, although not statistically significant (OR, 1.41 per SD; 95% CI, 0.95-2.08); there were no differences in the MM-PRS between MGUS patients with M-protein size <0.2 g/dL compared to 0.2-1.5 g/dL (OR, 1.01 per SD;95% CI, 0.81-1.26). There were also no differences in MM-PRS by FLC ratio, (OR, 0.95 per SD; 95% CI, 0.852-1.10 for abnormal vs. normal). Our findings of an association of the MM-PRS with risk of MGUS provides further evidence for shared heritability between MGUS and MM. Future studies are needed to examine whether the expanded MM-PRS adds to existing models for MGUS progression.

#2275 Exploring the genetic underpinnings of cancer-related fatigue in colorectal cancer patients.

Elham Kazemian[1], Qianxing Mo[2], Xiaoyin Li[2], Aasha I. Hoogland[2], Sylvia L. Crowder[2], Brian D. Gonzalez[2], Laura B. Oswald[2], Alix G. Sleight[1], Nathalie Nguyen[1], Nicole C. [1]Cedars-Sinai Medical Center, West Hollywood, CA,[2]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[3]Heidelberg University Hospital, Heidelberg, Germany,[4]University of Utah, Salt Lake City, UT,[5]Fred Hutchinson Cancer Research Center, Seattle, WA,[6], University of Tennessee Health Science Center, Memphis, TN,[7]Washington University St. Louis, St. Louis, MO,[8]University of California, Los Angeles, Los Angeles, CA

Background: Cancer-related fatigue (CRF) is a prevalent and debilitating symptom among colorectal cancer (CRC) patients. This study aimed to identify genetic variants associated with CRF trajectories and assess their relationships with clinical and demographic factors.
Methods: Participants (N=1,219) were recruited from the ColoCare Study across six U.S. sites and the University of Heidelberg in Germany. Eligible participants were adults (≥18 years) with a new diagnosis of primary colon or rectal cancer. CRF was assessed at five timepoints (baseline, 3, 6, 12, and 24 months) using the European Organization for Research and Treatment of Cancer (EORTC QLQ-C30) fatigue subscale. Longitudinal analysis of CRF patterns was performed using piecewise growth mixture models (GMMs), which identified three distinct trajectories: high, moderate, and low fatigue. Fatigue outcomes were assessed in three ways: as a binary variable (high vs. moderate/low trajectories), as a continuous measure (mean fatigue scores), and through an extreme phenotype approach (highest fatigue observed across all timepoints). Genome-wide association analyses (GWAS) were conducted using PLINK. Analyses were adjusted for potential confounders, including age, sex, cancer stage, smoking status, and population stratification (top two principal components). We performed fine-mapping analyses to identify independent secondary signals in known loci, focusing on SNPs previously associated with CRF and regions with p-values $<5 \times 10^{-6}$ in at least two of our GWAS models.
Results: Among 1,219 CRC patients, 378 (31.0%) reported high fatigue, while 651 (53.4%) were categorized as having low/moderate fatigue. Significant differences in cancer-related fatigue were observed by race/ethnicity, smoking status, cancer stage, recurrence status, and receipt of neoadjuvant treatment. When examining **fatigue as a binary outcome**, a locus on chromosome 4 near *LINC02505* was associated with higher risk of fatigue (rs6531463, OR = 3.25, 95% CI: 2.83-3.67, $p=3.88 \times 10^{-8}$). Several variants near *NEK10* and *SLC4A7* on chromosome 3 also showed suggestive associations (p-value range: $5\times10^{-8}<p<5\times10^{-6}$). Similar results were observed when examining **average fatigue as the outcome**. The most significant locus was on chromosome 3p24.1 near *NEK10* and *SLC4A7* (rs7617094, OR = 0.57, 95% CI: 0.47-0.69, $p=2.21 \times 10^{-8}$). For **extreme fatigue**, loci on chromosomes 3p24.1 and 5q13.1 also were associated with elevated risk (p-value range: $5\times10^{-8}<p<5\times10^{-6}$). Fine-mapping analyses identified 3 credible sets across 3 loci including 5q13.1, 3p24.1 and 5q13.1.

Conclusion: **This study investigates the genetic basis of CRF in CRC patients, identifying novel loci and refining known susceptibility regions.** Key loci associated with CRF include *LINC02505*, *NEK10*, and *SLC4A7*. These findings if validated offer potential targets for interventions focused on CRF prevention and management.</p<5×10</p<5×10

#2276 Whole exome sequencing of immune-mediated colitis in cancer patients treated with immune checkpoint inhibitors.

Pooja Middha[1], Zoe Quandt[2], Karmugi Balaratnam[3], Eduardo Cardenas[1], Christina J. Falcon[4], Princess Margaret Lung Group, Matthew A. Gubens[1], Scott Huntsman[1], Khaleeq Khan[3], Min Li[1], Christine M. Lovly[5], Devalben Patel[3], Luna Jia Zhan[3], Melinda C. Aldrich[6], Geoffrey Liu[7], Adam J. Schoenfeld[8], Elad Ziv[1]

[1]UCSF Helen Diller Family Comprehensive Cancer Ctr., San Francisco, CA,[2]Division of Endocrinology and Metabolism, Department of Medicine, University of California San Francisco, San Francisco, CA,[3]Princess Margaret Cancer Centre, Toronto, ON, Canada,[4]Fiona and Stanley Druckenmiller Center for Lung Cancer Research, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Department of Medicine, Division of Hematology and Oncology, Vanderbilt University Medical Center and Vanderbilt Ingram Cancer Center, Nashville, TN,[6]Vanderbilt University Medical Center, Nashville, TN,[7]Princess Margaret Cancer Centre, Temerty School of Medicine, Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada,[8]Memorial Sloan Kettering Cancer Center, New York, NY

Background: Immune checkpoint inhibitors (ICIs) have transformed cancer treatment, providing survival benefits across multiple cancer types. Despite this remarkable advancement, ~15-30% of patients develop immune-related adverse events (irAEs). One of the common irAEs is immune-mediated colitis, and the incidence ranges from 1% to 25% by type of therapy. Previously, we have shown that polygenic risk scores of ulcerative colitis predict colitis irAE. However, the role of rare coding variants on the development of colitis irAE remains largely unknown.

Methods: We conducted whole exome sequencing for colitis irAE in 1,215 cancer patients treated with ICIs. Association analyses were carried out for each gene separately for protein-truncating missense variants, predicted splice (Sp) variants, and non-synonymous predicted deleterious (deN; CADD≥20 or VEST≥0.8) or any non-synonymous (N) variants. The main association analyses were burden tests in which genotypes were collapsed to a 0/1 variable based on whether samples carried a variant of the given class. All models were adjusted for age at diagnosis, sex, type of ICI therapy, recruitment site, and five ancestry-informative principal components. The exome-wide threshold for significance was set at 2.5×10^{-6}, with genes beyond this considered significant.

Results: Among 1,215 patients treated with immune checkpoint inhibitors (ICIs), 60 (4.9%) developed colitis. We identified rare coding variants in two genes associated with an increased risk of colitis at the exome-wide significance level: PT+Sp+N variants in *LRRC47* (OR = 5.5, P = 2.4×10^{-6}) and PT+S+deN variants in *PFKP* (OR = 65.9, P = 1.2×10^{-6}). Additionally, PT+S+deN variants in *PTPRH* showed a suggestive association with colitis irAEs (OR = 8.8, P = 7.1×10^{-5}).

Conclusions: To our knowledge, this is the first study to assess the role of rare coding variants in colitis immune-related adverse events (irAEs) among cancer patients treated with ICIs. Our findings highlight two exome-wide significant associations, implicating variants in *LRRC47* and *PFKP* in the development of colitis irAEs. *LRRC47* has previously been linked to inflammatory bowel disease through differential methylation patterns. Furthermore, genes involved in glycolysis, including *PFKFB3*, *PKM*, and *PFKP*, have been shown to be upregulated in patients with ulcerative colitis. Abnormal activity of *PTPRH* has also been reported to disrupt the regulatory mechanisms of the intestinal mucosa, potentially contributing to inflammation. These findings provide novel insights into the genetic underpinnings of colitis irAEs in cancer immunotherapy.

#2277 Validation and context-dependent effects of a prostate cancer polygenic risk score in the All of Us Research Platform.

Shuyan Cheng[1], Austin Hammermeister Suger[1], Louisa B. Goss[2], Boya Guo[2], Sara Lindstrom[1], Burcu F. Darst[2]

[1]University of Washington, Seattle, WA,[2]Fred Hutchinson Cancer Center, Seattle, WA

Background: Polygenic risk scores (PRS) are valuable tools for assessing genetic susceptibility to prostate and other cancers. The All of Us (AoU) Research Program, with its diverse and inclusive cohort, provides a unique opportunity to validate and further investigate context-dependent associations of cancer PRS, offering insights into their applicability in diverse populations.
Methods: A previously established multi-ancestry PRS of 451 genetic variants associated with prostate cancer risk was calculated in AoU. Logistic regression models were employed to evaluate associations between the standardized continuous PRS and prostate cancer risk, adjusting for age and the top 10 principal components to account for population stratification. Comparisons were also made between individuals in the top PRS decile (90-100%) and those in the average range (40-60%). Analyses were stratified by genetic ancestry groups, age, BMI, and smoking status explored potential demographic and lifestyle factors affecting PRS predictive power.
Results: PRS validation included 4,668 prostate cancer cases and 71,644 controls across six genetic ancestry groups defined by AoU. Odds ratios (ORs) per unit increase in PRS were 2.23 (95% CI = 2.14-2.33) in European, 1.83 (95% CI = 1.67-2.00) in African, 2.16 (95% CI = 1.86-2.51) in American, 2.67 (95% CI = 1.53-4.67) in East Asian, 2.46 (95% CI = 1.14-5.33) in Middle Eastern, and 1.67 (95% CI = 1.00-2.77) in South Asian populations. Individuals in the top PRS decile (90-100% of the PRS) had ORs of 3.97 (95% CI = 3.42-4.61) in European, 3.16 (95% CI = 2.41-4.14) in African, and 3.51 (95% CI = 2.31-5.36) in American populations compared to the average 40-60% PRS category. Age-stratified analyses showed diminishing PRS effect sizes with advancing age, with ORs declining from 2.44 (≤55 years, 95% CI = 2.10-2.83) to 2.05 (>70 years, 95% CI = 1.91-2.20) in European, and from 1.92 (≤55 years, 95% CI = 1.57-2.36) to 1.48 (>70 years, 95% CI = 1.19-1.85) in African populations.
Moreover, BMI-stratified analyses showed slightly increased predictive performance in higher BMI categories, with ORs of 1.87 (95% CI = 1.22-2.88) in underweight, 2.06 (95% CI = 1.91-2.23) in normal weight, 2.12 (95% CI = 2.00-2.24) in overweight, and 2.26 (95% CI = 2.12-2.41) in obese individuals. Smoking stratified analyses demonstrated slightly higher PRS performance in never smokers, with ORs of 1.90 (95% CI = 1.68-2.16) in current smokers and 2.16 (95% CI = 2.03-2.29) in never smokers.
Conclusion: This study validates the multi-ancestry PRS as an effective tool for stratifying prostate cancer risk across diverse populations. The findings emphasize the importance of ancestry-, age-, and lifestyle-specific interpretations in PRS applications. Analyses are underway for breast, colorectal, and lung cancers to evaluate the broader utility of PRS for cancer risk stratification and screening strategies within AoU.

#2278 Correlation between DNA-methylation predicted and measured immune-cell type proportions by age in ARIC.

Z. Lin[1], D. S. Michaud[2], N. Zhao[2], V. A. Burk[1], E. Boerwinkle[3], J. Bressler[3], D. C. Koestler[4], K. T. Kelsey[5], E. A. Platz[1];
[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [2]Tufts University School of Medicine, Boston, MA, [3]The University of Texas Health Science Center at Houston, Houston, TX, [4]University of Kansas Medical Center, Kansas City, KS, [5]Brown University, Providence, RI

Background: DNA methylation (DNAm)-predicted deconvolution uses cell-specific methylation markers of leukocytes in peripheral blood to estimate immune cell type proportions. Validity is high for predicted proportions of immune cell types. Given known age-related immune system changes and changes in predicted immune cell proportions by age, we assessed whether the correlations between predicted and measured proportions differ across age. Such information is needed for cancer studies on immunoaging in cohorts without CBC differential or stored whole blood.
Methods: Lymphocyte, neutrophil, monocyte, eosinophil, and basophil proportions were previously estimated using DNAm deconvolution (Salas et al., PMID: 35140201) and measured by CBC among Black participants (N=151; 62% female) without cancer in the Atherosclerosis Risk in Communities study. Pearson correlation coefficients were calculated in age tertiles (T1: 47-53, T2: 54-60, T3: 61-67 years). To minimize confounding by health factors, we stratified by more (no diabetes, BMI <30 kg/m^2, and non-smoker) and fewer (≤ 2 of the factors) positive health factors. Correlations in age T1 and T3 were compared after Fisher's z-transformation.
Results: Correlations between predicted and measured proportion were similar across age tertiles, albeit slightly weaker in the oldest tertile (Table, except for basophils). This same pattern was present stratifying by health factors, although the correlations appeared slightly stronger for more vs. fewer positive health factors (e.g., age T1, T3 - neutrophils: more 0.81, 0.77; fewer 0.78, 0.66). However, all p-values were > 0.1 comparing correlations in the youngest and oldest age tertiles.
Conclusion: For each common immune cell type, correlations between DNAm-predicted and measured proportion were generally similar across mid- to older adulthood, supporting use of the algorithm in immunoaging studies. Studies with participant diversity, including ages ≥ 70 yrs are needed.

Correlation between DNAm predicted and measured immune cell proportions by age tertile, ARIC Visit 2

Immune Cell Type	Overall	Age at Blood Draw, Tertiles			p-value
		T1	T2	T3	
N	151	47	53	51	
Lymphocyte	0.78(0.71, 0.83)	0.83(0.71, 0.90)	0.76(0.61, 0.85)	0.72(0.56, 0.83)	0.2

#2279 Real-world data on germline pathogenic variants using GenMineTOP, a tumor/normal paired comprehensive genomic profiling test, in Japan.

Eri Habano[1], Miho Ogawa[2], Kousuke Watanabe[2], Nana Akiyama[3], Hyangri Chang[3], Aya Shinozaki-Ushiku[1], Masakazu Akahori[4], Toshimitsu Ichijo[4], Shuichi Tsutsumi[5], Kenji Tatsuno[5], Hiroyuki Aburatani[5], Hidenori Kage[6], Katsutoshi Oda[1]

[1]Division of Integrative Genomics Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[2]Next-Generation Precision Medicine Development Laboratory, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,[3]Department of Clinical Genomics, Hospital, The University of Tokyo, Tokyo, Japan,[4]KONICA MINOLTA, INC., Tokyo, Japan,[5]Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo, Japan,[6]Department of Respiratory Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

[Background] Comprehensive genomic profiling (CGP) expands treatment options for solid tumor patients and identifies hereditary cancers. However, confirmatory tests have been done in only 31.4% of patients who were found to have presumed germline pathogenic variants (GPVs) with a tumor-only test in Japan. Consequently, many GPVs are likely undiagnosed. Analysis of paired tumor and normal specimens enables distinction of somatic and GPVs. GenMineTOP, reimbursed by Japan's universal national health insurance in August 2023, analyzes tumor/normal paired samples and reports GPVs in 40 genes (updated to 59 genes, based on the ACMG SF v3.2). This study clarifies the landscape of GPVs by using real-world data from GenMineTOP.
[Methods] We analyzed 1,356 patients with solid tumors who underwent GenMineTOP testing in the Center for Cancer Genomics and Advanced Therapeutics (C-CAT) database between August 2023 and July 2024. C-CAT aggregates nationwide CGP data and allows combined analysis with clinical information. The study focused on GPV detection rates, distribution of targeted genes, and features of genes included in secondary findings. Additionally, GPVs were categorized as "On-Tumor" (associated with the tumor type) or "Off-Tumor" (not associated with the tumor type) according to NCCN Guidelines® and other various guidelines, and the proportion of GPVs detected as Off-Tumor was calculated.
[Results] The median age of patients was 61 years (range: 0-90), with equal gender distribution. The most common cancer types were colorectal (15%), soft tissue sarcoma (12%), and brain tumors (11%). Seventy-nine GPVs were detected in 76 patients (5.6%). Patients with detected GPVs had a median age of 56 years (range: 1-87) with an equal gender distribution. However, the age distribution showed that the most common age group was the 70s for males (24.3%, 9/37) and the 40s for females (30.8%, 12/39). The most frequently detected gene was *BRCA2* (n = 19), followed by *BRCA1* (n = 9), *RAD51D* (n = 8), and *NF1* (n = 8). Cancer types with GPV detection rates exceeding 10% included peripheral nervous system tumors (20%), prostate cancer (12.5%), and ovarian cancer (11.9%).Of the GPVs detected, 44.3% (36/79) were Off-Tumor, including 47.4% (9/19) of *BRCA2* patients. In addition, patients with homologous recombination deficiency (HRD)-related genes (*ATM, BRCA1, BRCA2, BRIP1, PALB2, RAD51C, RAD51D*) detected included 19 males (median age: 69 years) and 24 females (median age: 54 years). Among males, 57.9% (11/19) were aged 65 years or older.
[Discussion] GPVs were identified in 5.6% of patients using GenMineTOP. The high prevalence of Off-Tumor GPVs and elderly male patients highlights the under-recognition of hereditary cancer in this demographic. These findings support the use of paired CGP to improve the diagnosis of hereditary cancers that might otherwise remain undetected.

#2280 Whole-exome sequencing analysis of early-onset soft tissue sarcoma in a multiethnic family-based population study.

Naying Zhou, Joseph L. Wiemels

USC - University of Southern California, Los Angeles, CA

Background: Sarcomas are a rare group of cancers originating in bones and soft tissues, and represent approximately 1% of adult cancers and 15-20% of pediatric cancers. The development of sarcomas is often driven by inherited or de novo mutations in genes involved in critical processes such as cell growth, development, and signaling pathways, which play central roles in their pathogenesis. Notably, the risk of early-onset cancer (diagnosed before the age of 29) is significantly elevated—68 times higher—in siblings of individuals with soft tissue sarcomas, suggesting a strong contribution of inherited germline variants to the observed familial cancer risk.

Methods: Cancer patients included in this study were identified using a linked dataset integrating information from the California Cancer Registry and the California Birth Statistical Master File. To explore rare genetic predispositions associated with soft tissue sarcomas, a cohort of 54 patients from 43 families was analyzed. This cohort included 11 sibling pairs, each with at least one individual diagnosed with soft tissue sarcoma, ICDO-3 histology code 8900-8991. Additionally, 32 unrelated individuals diagnosed with multiple cancers, including soft tissue sarcoma, were included in the analysis. Whole-exome sequencing (WES) was performed on neonatal dried blood samples from these 54 participants. Germline short variant discovery, including single nucleotide variants and insertions/deletions (indels), was conducted using the Genome Analysis Toolkit pipeline. Variants were annotated according to guidelines from the American College of Medical Genetics and Genomics.

Results: A total of 603 cancer-associated variants were identified in this study, with 74 variants detected in multiple individuals. Among these, 12 variants were classified as "Pathogenic/Likely Pathogenic, " two of which were found in two children each. Notably, a mutation in the NF1 gene, previously linked to Neurofibromatosis Type 1 syndrome, was confirmed in a Latino-White family, where one child presented with mixed-type rhabdomyosarcoma and another with neurofibroma. Additionally, a novel association was observed between the USP6 gene mutation and rhabdomyosarcoma diagnosis in two unrelated Southeast Asian individuals, one of Filipino descent and the other Guamanian. Furthermore, a homozygous mutation in the AR gene on the X chromosome was identified in a single patient.

Conclusion: Our study employs WES analysis to investigate predisposition genes in individuals diagnosed with soft tissue sarcoma, alongside their cancer-affected siblings. Through this analysis, we have identified novel genetic mutations linked to soft tissue sarcoma diagnosis. Additionally, certain variants appear to exhibit ancestry-specific patterns in this multiethnic population.

#2281 The interrelationship between maternal periconception folate nutritional intake and child's genetic liability in the etiology of childhood acute lymphoblastic leukemia.

Yijin Xiang[1], Catherine Metayer[2], Scott Kogan[3], Xiaomei Ma[4], Joseph Wiemels[1]

[1]Department of Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA,[2]University of California, Berkeley, Berkeley, CA,[3]University of California, San Francisco, San Francisco, CA,[4]Yale University, New Haven, CT

Introduction Maternal prenatal folate intake is associated with a decreased risk of acute lymphoblastic leukemia (ALL) in children. Genome-wide association studies (GWAS) show that variations in genes regulating folate metabolism impact serum folate level irrespective of nutritional intake. Polygenic risk scores (PRS) summarize the cumulative genetic liability associated with specific phenotypes. This study aimed to examine if the child PRS related to folate level interacts with maternal periconception folate intake from food and supplements, contributing to ALL risk.

Methods Data on periconceptional folate intake spanning the year prior to pregnancy were obtained from the California Childhood Leukemia Study (CCLS). Folate intake from diet and supplement was measured in dietary folate equivalents (DFE). A PRS related to folate level was constructed using summary statistics from a GWAS of serum folate levels among Europeans. After assigning genetically predicted folate levels, odds ratios (ORs) and 95% confidence intervals (CIs) per 0.05 unit decrease of the folate PRS and per risk-associated T allele (at rs1801133 in the *MTHFR* gene) were estimated using logistic regression comparing ALL cases with controls, adjusted for child's age, sex, potential confounders, and ancestry principal components. Analyses were stratified by Latino and non-Latino Whites.

Results We identified significant interactions between folate PRS/ rs1801133 and total folate from food in the Latino population, with interaction p-values of 0.008 and 0.005. The positive association between lower genetically predicted folate and ALL diminished with the increase in total folate intake from food. For folate PRS, ORs of ALL decreased from 1.32 (95% CI: 1.02-1.70) at 0 DFE, to 1.05 (95% CI: 0.93-1.20) at median intake (517.4 DFE), and to 0.54 (95% CI: 0.31-0.93) at maximum intake (2018.4 DFE). For the number of T allele at rs1801133, ORs decreased from 2.09 (95% CI: 1.19-3.68), to 1.05 (95% CI: 0.80-1.36), and to 0.14 (95% CI: 0.04-0.56). No interaction was found with folate from supplements. Additionally, lower folate PRS and T allele were shown to be positively associated with an increased risk of ALL among non-Latino Whites, regardless of folate intake from food or supplements, with ORs of 1.23 (95% CI: 1.08, 1.43) and 1.41 (95% CI: 1.04, 1.91), respectively.

Conclusion Our findings underscore the critical role of dietary folate intake against ALL development within the Latino population, where increased folate intake appeared to mitigate the impact of genetic liability. In contrast, in CCLS non-Latino population, the risk of ALL associated with child genetic liability was independent of maternal folate intake. These results suggest that folate interventions tailored to genetic profiles may be effective for motivating improvements to nutrition status.

#2282 Genetic architecture of breast cancer across diverse populations: Assessing heritability, genetic correlation, and polygenicity.

Introduction: Breast cancer genome-wide association studies (GWAS) have identified over 200 susceptibility loci, many replicated in diverse populations. However, cross-ancestry evaluation of breast cancer genetic architecture remains limited. We examined breast cancer genetic architecture using GWAS summary results from European (EUR; cases (ca) = 188,474, controls (co) = 96,201), East Asian (EAS; ca = 20,393, co = 86,329), African American (AA; ca = 9,235, co = 10,184), and US Hispanic/Latina and Latin American (H/L; ca = 2,396, co =7,468) studies.

Methods: GWAS results were derived from the Breast Cancer Association Consortium, the African Ancestry Breast Cancer Genetics Consortium (AABCG), Biobank Japan, and a meta-analysis of five studies of H/L women with breast cancer. Linkage disequilibrium (LD) scores were generated for EUR, EAS, and AMR using the 1000 Genomes Project, while AA LD scores were derived from a subset of AABCG controls. Heritability was estimated for each ancestry group using LD score regression. Genetic correlations between populations were assessed via Popcorn. Polygenicity was analyzed using GENESIS; however, due to the limited sample size in the H/L studies, these estimates were restricted to AA, EAS, and EUR. Enrichment of heritability across regulatory elements was evaluated using stratified LD score regression across all populations.

Results: The logit-scale heritability and corresponding standard error (SE) were 0.466 (0.066) for EAS, 0.501 (0.050) for EUR, 0.588 (0.360) for H/L, and 0.614 (0.095) for AA. The estimated number of independent susceptibility loci was 4,446 for EAS, 5,235 for EUR, and 8,308 for AA. Using a clumping and thresholding approach, an optimal set of common variants were projected to explain 38.6% (EUR), 39.4% (EAS), and 26.2% (AA) of genetic variance for samples of 100,000 cases and 100,000 controls with AUCs from corresponding estimated polygenic risk scores (PRSs) of 0.621 (EUR), 0.634 (EAS), and 0.611 (AA). Genetic correlations were strongest between EUR and EAS ($\rho = 0.79$, SE = 0.08) and EUR and H/L ($\rho = 0.68$, SE = 0.21), and weakest between AA and EAS ($\rho = 0.42$, SE = 0.14) and AA and H/L ($\rho = 0.26$, SE = 0.24). Among 73 genomic features, we found significant ($P < 0.05/73$) enrichment in heritability in EUR for ‘ancient promoter’ regions, transcription factor binding sites, H3K4me3, ‘super-enhancers’, H3K4me1, H3K27ac; in EAS for ‘super-enhancers’; and in AA for H3K27ac. No genomic features were significantly enriched in H/L, likely due to limited power.

Conclusion: These findings suggest a shared breast cancer genetic architecture across diverse populations, as well as the potential for a similar level of breast cancer risk stratification by PRS in these populations. Expanding GWAS in underrepresented populations is essential to improve genetic risk predictions and foster equitable cancer prevention.

#2283 Ancestral and genetic determinants of pathologic tumor infiltrating lymphocytes in a large multi-ethnic population of women with breast cancer.

Peter N. Fiorica[1], Lucas Mendicino[1], Li Yan[1], Angela R. Omilian[1], Elisa V. Bandera[2], Scott I. Abrams[1], Lawrence H. Kushi[3], Thaer Khoury[1], Christine B. Ambrosone[1], Song Yao[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Cancer Epidemiology and Health Outcomes, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ,[3]Division of Research, Kaiser Permanente Northern California, Pleasanton, CA

Background: There are well-documented racial and ethnic disparities in breast cancer, with Black women having the highest mortality and Asian women having the lowest mortality. While reasons for this disparity are multi-factorial, differences in tumor biology and tumor microenvironment may contribute. Over the past two decades, pathologic tumor-infiltrating lymphocytes (TILs) have emerged as a histologic biomarker of prognosis, where higher TIL levels are associated with better outcomes and overall survival, and a predictive biomarker for cancer treatment. In recent years, there is increasing evidence of genetic determinants of immune response in the tumor microenvironment, which is known to vary by ancestral background and may explain differences in patient survival. We hypothesize that genetic selection and adaptation to distinct pathogenic environments during the evolution of diverse human populations led to ancestral differences in host immunity.

Methods: To investigate this hypothesis, we performed a local ancestry-informed GWAS of pathologic TILs using Tractor, a statistical framework and software package. With data from 4,728 women of European (n=2,740), African (n=1235), Amerindian (n=318), and East Asian (n=435) ancestry from the Women's Circle of Health Study (WCHS) and the Pathways Study, we estimated four-way local ancestry with the tool FLARE using reference genomes from 1000 Genomes Project and Human Genome Diversity Project. Given the non-normal distribution of TIL scores, we applied linear regression to the inverse normal transformation of TIL scores to assess genotype-local ancestry interaction effects.

Results: Global genetic similarity to African reference populations was significantly associated with increased TILs ($P=3.8x10^{-22}$). We identified rs17132663 on African haplotype ($P=1.7x10^{-8}$) and rs6812740 on Amerindian haplotype ($P=3.8x10^{-8}$) as genome-wide significant SNPs in our analyses. rs17132663 is an intronic variant of *AMZ1* and *GNA12*. rs6812740 is located 2 KB upstream of *HPGD* and is significantly associated ($P=1.6x10^{-12}$) with expression of the gene in GTEx version 10. To our knowledge, neither of these SNPs previously have been significantly associated with the tumor immune response. In addition, 20 other loci were significant at $P<1x10^{-6}$.

Conclusion: These findings underscore ancestral differences in breast tumor immune response and highlight the critical need to expand datasets with matched genotype and histology data to further explore these associations.

#2284 Linkage disequilibrium score regression identifies genetic correlations between hepatocellular carcinoma and clinically relevant traits.

Younghun Han[1], Vikram Shaw[2], Jinyoung Byun[1], Rikita Hatia[3], Katherine McGlynn[4], Lewis Roberts[5], Manal Hassan[3], Christopher I. Amos[1]

[1]The University of New Mexico Comprehensive Cancer Center, Albuquerque, NM,[2]Baylor College of Medicine, Houston, TX,[3]The University of Texas MD Anderson Cancer Center, Houston, TX,[4]National Cancer Institute, Rockville, MD,[5]Mayo Clinic, Rochester, MN

Hepatocellular carcinoma (HCC) mortality is increasing globally, partly due to the growing prevalence of non-viral liver diseases. Genome-wide association studies (GWAS) have identified genetic variants associated with HCC development. Leveraging GWAS summary statistics and linkage disequilibrium score regression (LDSR), we investigated disease co-development with non-viral HCC to provide unique insights into HCC etiology and prioritize relationships for further causal inquiry. We utilized the LDSR statistical framework to estimate the genetic correlation and heritability between non-viral HCC with 923 epidemiologic, behavioral, and clinical traits from the United Kingdom Biobank (UKBB) cohort. We observed a SNP-array heritability (h_2 obs) of 0.20 for non-viral HCC. Next, we estimated the pairwise genetic correlation between non-viral HCC and heritable (h_2 obs > 0.02) UKBB traits, identifying significant positive genetic correlations between non-viral HCC and blood-based biomarkers of liver injury (ALT, GGT) and allostatic load (including glycated hemoglobin, blood pressure, and total albumin). We also identified a positive genetic correlation between non-viral HCC and diseases associated with metabolic dysfunction-associated steatotic liver disease (MASLD), including diabetes, hypertension, chronic ischemic heart disease, and others. Non-viral HCC was negatively associated with filtered coffee intake but positively associated with instant coffee intake. In addition, smoking behavior and the amount of alcohol consumption in the UKBB cohort showed a positive association with non-viral HCC. Our study provides an atlas of cross-trait genetic correlations in non-viral HCC. Taken together, our results demonstrate possible polygenic pleiotropy between non-viral HCC and different phenotypic traits. The results support further exploration of the predictive power of blood-based biomarkers and selected behaviors for inferring HCC development among non-viral individuals.

#2285 Utility of ctDNA to detect minimal residual disease in colorectal cancer: A systematic review and network meta-analysis.

Tung Hoang[1], Moon Ki Choi[2], Jae Hwan Oh[2], Jeongseon Kim[3]

[1]University of Health Sciences, Vietnam National University Ho Chi Minh City, Binh Duong, Viet Nam,[2]Center for Colorectal Cancer, National Cancer Center, Goyang, Korea, Republic of,[3]Department of Cancer AI & Digital Health, National Cancer Center Graduate School of Cancer Science and Policy, Goyang, Korea, Republic of

Importance: Circulating tumor DNA (ctDNA) has shown promise as a biomarker for predicting minimal residual disease (MRD) in non-metastatic resected colorectal cancer (CRC) patients and guiding treatment decisions. A comprehensive review of clinical settings and optimal timing for ctDNA use in resected CRC patients is needed.
Objective: To examine the study designs and settings of ongoing clinical trials that use ctDNA to guide treatment decisions and determine the best timing for detecting MRD in non-metastiatic CRC.
Data sources: A search of studies published before October 2024 was conducted using PubMed, Embase, Web of Science, Cochrane Library, and clinicaltrials.gov for records in English, including clinical trials and prospective studies.
Study selection: We included studies of non-metastatic resected CRC patients with ctDNA testing done post-surgery (for clinical trials) or at any time (for prospective studies), reporting recurrence, relapse, or survival outcomes.
Data extraction and synthesis: Data on CRC stage, intervention, comparison, and endpoints for clinical trials, as well as the timing of ctDNA testing and effect size of the association with CRC prognosis for prospective studies, were extracted.
Main outcomes and measures: The ctDNA settings from clinical trials were categorized by randomization to ctDNA testing, treatment options based on ctDNA results, and the timing of ctDNA testing relative to adjuvant therapy. A network meta-analysis using a frequentist approach was conducted to examine pairwise associations of different ctDNA timing strategies with MRD, defined as recurrence, relapse, and progression.
Results: The main approaches in ctDNA-based interventional trial designs were categorized as ctDNA-guided treatment, ctDNA-by-treatment, ctDNA-guided surveillance, and ctDNA-enriched adjuvant therapy for guiding treatment decisions, including both escalation and de-escalation strategies, and surveillance. Overall, both preoperative and postoperative ctDNA detection were linked to higher risks of progression, with pooled HRs (95% CIs) of 5.23 (2.10-13.00) and 7.95 (5.30-11.91), respectively. Among timing strategies, ctDNA testing after adjuvant therapy was the most effective for identifying high-risk patients, strongly suggesting the presence of residual disease.
Conclusions and relevance: This study comprehensively reviewed clinical settings of ctDNA in ongoing trials and provided evidence supporting the selection of post adjuvant therapy as optimal timing for ctDNA testing.

#2286 Integrating multi-ancestry genomic and proteomic data to identify blood risk biomarkers and target proteins for breast cancer genetic risk loci.

Guochong Jia[1], Jie Ping[1], Ran Tao[2], Jirong Long[1], Lili Liu[1], Shuai Xu[1], Stefan Ambs[3], Mollie E. Genome-wide association studies (GWAS) have identified more than 200 risk loci for breast cancer. However, target genes and their encoded proteins in these loci remain largely unknown. In this study, we utilized genetic prediction models for 1,350 circulating proteins derived from individuals of African (n= 1,871) and European (n= 7,213) ancestry to investigate genetically predicted protein levels in association with breast cancer risk among females of African (n=40,138), Asian (n= 137,677), and European (n=247,173) ancestry. We identified 70 blood protein biomarkers associated with breast cancer risk, overall or by subtypes, at a false discovery rate (FDR) <0.05, including 37 proteins encoded by genes located at least 500kb away from any of the known risk loci identified in GWAS. Of the 33 proteins located at GWAS-identified risk loci, associations for 14 proteins were significantly attenuated after adjustment for the index risk variant of each respective locus, suggesting that these proteins may be target proteins for the risk loci. Encoding gene expression levels in normal breast tissue could be genetically predicted for 35 of the 70 identified proteins, and 17 encoding genes were associated with breast cancer risk in the same direction (P <0.05). Our study identified potential protein targets of GWAS risk loci and biomarkers for breast cancer risk and provided additional insights into breast cancer genetics and etiology.

#2288 APOBEC dominant mutational signature defines distinct oral cavity cancer subgroup.

Benjamin M. Wahle[1], Angela L. Mazul[2], D. Neil Hayes[3], Jose P. Zevallos[2], Sidharth V. Puram[4]

[1]Otolaryngology/Head and Neck Surgery, Indiana University School of Medicine, Indianapolis, IN,[2]Otolaryngology/Head and Neck Surgery, University of Pittsburgh, Pittsburgh, PA,[3]Department of Medicine, Division of Med Hematology, University of Tennessee Health Science Center, Memphis, TN,[4]Otolaryngology/Head and Neck Surgery, Washington University School of Medicine, St. Louis, MO

Background: Up to 25% of oral cavity squamous cell carcinoma (OCSCC) cases have no significant exposure to tobacco and alcohol. Compared to the rest of the OCSCC population, these cases tend to be older, more female, and display distinct patterns of oral cavity subsite dominance. The underlying molecular pathophysiology in atypical OCSCC cases remains poorly defined. We hypothesized that analysis of OCSCC genomes using single base substitution (SBS) mutational signatures, which computationally discern patterns associated with discrete mutational processes, would reveal discrete subgroups within the OCSCC population.
Methods: We performed an exploratory genomics study using data from The Cancer Genome Atlas (TCGA). Cases included primary oral cavity tumors with whole exome sequencing data. Cases were excluded if oral cavity subsite was not specified or if the tumor had fewer than fifty single bases substitutions. SBS signatures were generated using python packages SigProfilerMatrixGenerator and SigProfilerAssignment with COSMIC SBS Signatures V3.4 as the reference. APOBEC-dominant cases were defined as those where SBS2 and SBS13 accounted for the greatest proportion of mutations relative to the tumor's total mutational burden.
Results: A total of 217 OCSCC cases were included. Of these, 135 (62.2%) showed some degree of ABPOEC-related mutational burden, and in 62 (28.6%) cases APOBEC was the dominant mutational process. APOBEC-dominant cases showed greater SBS mutational burden (median difference 2.65 mutations/MB, Wilcoxon P = 2.22e-09). Compared to the rest of the OCSCC population, APOBEC-dominant cases were older in age (mean difference 4.08 years, 95% CI 0.35 - 7.81, T-test P 0.032), more female (46.8% vs 27.8%, OR 2.28, 95% CI 1.18 - 4.40), and had a significantly lower rate of tobacco use at diagnosis (OR 0.47, 95% CI 0.22 - 0.94). APOBEC mutational burden varied by oral cavity subsite (Kruskal-Wallis P = 1.66e-05), with the majority of hard palate and buccal mucosal tumors being APOBEC-dominant (85.7% and 66.7%, respectively) and floor of mouth tumors showing the lowest rate of APOBEC-dominance (16.1%). APOBEC-dominant cases showed a greater degree of mutations in RAC1, EP300, CASP8, and FAT1 (FDR corrected P <0.05). APOBEC dominant cases showed a trend toward a lower rate of TP53 mutations (OR 0.48, 95% CI 0.23 - 1.01).
Conclusions: In TCGA, ABPOEC-dominant OCSCC cases resemble these atypical populations by being enriched for female sex, older age, lower rates of tobacco use, and certain oral cavity subsites. However, APOBEC-dominance was not exclusive to any clinical characteristic, highlighting the potential importance of molecular class labels in understanding population heterogeneity in OCSCC. Further investigation focused on induction of APOBEC in OCSCC is warranted and may elucidate the pathophysiology of oral cavity cancer beyond tobacco and alcohol exposure.

#2289 *DDX41* - more than meets the eye?.

Jaclyn Zamzow, Jenna Gedminas, **Moon Ley Tung**

University of Iowa, Iowa City, IA

Introduction: Germline variants in the *DDX41* gene (OMIM: 608170) have been mainly associated with late onset myelodysplastic syndrome (MDA) and acute myeloid leukemia (AML). Based on a study of healthy adults within the UK Biobank sample, approximately 1 in 430 adults carry a germline pathogenic variant in *DDX41*. The odds ratio of these individuals developing MDS/ AML is between 7.5 t0 15.1 compared to individuals without any germline pathogenic variants in *DDX41*. Although some of the reported individuals diagnosed with DDX41-related hematological malignancies had received chemotherapy or radiation therapy for solid tumors prior to their diagnosis of MDS/AML, there has been no systematic analysis of *DDX41* as a tumor suppressor gene in childhood cancers. We describe a novel finding of a germline, likely pathogenic variant in the *DDX41* gene in a 2-year-old male who was diagnosed with a Stage 1, group 1, very low risk embryonal rhabdomyosarcoma of the oral commissure.

Case study: A 2-year-old, previously healthy male was found to have a growth in the right oral commissure at around 20 months of age. Excisional biopsy of this exophytic mass returned as an embryonal rhabdomyosarcoma on pathology. As part of the Children's Oncology Group evaluation, he underwent a paired tumor-germline genomic testing which detected a heterozygous, likely pathogenic *DDX41* variant (NM_016222.4: c.771del, p. Tyr259MetfsTer45). Tumor allele fraction was at 46% and the germline allele frequency was at 47%. He was subsequently referred to the Division of Medical Genetics and Genomics for further evaluation and post-test genetic counseling. Physical examination was unremarkable with no dysmorphic features except for two hyperpigmented nevus on his left shin and lower back. Birth and developmental history were normal. Interestingly, family history revealed that the proband's father had a personal history of a left parotid acinar cell carcinoma which was diagnosed at the age of 11. He underwent surgical resection but relapsed at the age of 27 and received surgery and consolidative radiotherapy. There was a history of a paternal great uncle diagnosed with leukemia in his sixties.

Results: Targeted parental testing for this *DDX41* variant was completed and revealed that this was a de novo variant in the proband. In view of the absence of evidence of presence of *DDX41* germline variants in childhood cancers, we searched the St Jude Cloud PeCan database and found 33 reports of embryonal rhabdomyosarcoma but no evidence of either somatic or germline *DDX41* variants described.

Conclusion: This is the first description of a pediatric patient with a de novo germline, heterozygous, likely pathogenic variant in *DDX41* and presents with a non-hematological malignancy. Increased access to paired tumor-germline genetic testing will likely uncover more patients with an underlying germline *DDX41* variant and will help decode the underlying pathology and risks of development of both solid and hematological malignancies.

POPULATION SCIENCES: Cancer Disparities in Behavioral, Psychological, Psychosocial, and Molecular Factors Poster Session

#2293 *KLRC2* gene deletion is associated with active cytomegalovirus infection and risk of head and neck cancer.

Heather H. Nelson[1], DeVon Hunter-Schlichting[1], Rondi Butler[2], Anna Prizment[1], Bharat Thyagarajan[1], Karl Kelsey[2]

[1]Masonic Cancer Center, Minneapolis, MN,[2]Brown Unversity, Providence, RI

Human cytomegalovirus (CMV) is a common infection that can have a profound impact on the immune system which, in turn, has the potential to impact cancer risk. Natural Killer (NK) cells are the front-line defense against viral infection and CMV seropositive individuals develop a specialized subset of NK cells, the adaptive NK (aNK), in response to CMV reactivation. A defining feature of aNK is surface expression of the NKG2C receptor, encoded by the *KLRC2* gene. There is a polymorphic 15.5 kb deletion of the *KLRC2* gene and approximately 5% of the Caucasian population completely lacks the NKG2C receptor due to this polymorphism. *KLRC2* gene copy number has been shown to influence steady-state levels of aNK cells in CMV seropositive individuals, and deletion of the gene is associated with both early life CMV infection and CMV viremia after transplantation. Here, we have evaluated whether the polymorphic *KLRC2* gene deletion is associated with active CMV infection and risk of head and neck squamous cell carcinoma (HNSCC) using the resources of the CoHANDS epidemiology study. *KLRC2* deletion was measured using PCR with gel visualization in 1,096 cases and 1,179 controls. Among a subset of the controls (n=207) we measured CMV DNAemia, the presence of cell free CMV DNA in serum, which is an established biomarker of active CMV infection. *KLRC2* deletion was associated with the presence of CMV DNAemia: among those with one copy of *KLRC2* the risk of active infection was 2.74 (95% CI 1.30 - 5.78), and among those with homozygous deletion of *KLRC2* the risk was 5.17 (95% CI 1.56 - 17.16). These results from a healthy population are consistent with prior reports that the *KLRC2* gene is important in the control of CMV reactivation. We then evaluated *KLRC2* as a risk factor for HNSCC. Homozygous deletion of the *KLRC2* gene was strongly associated with increased risk of HNSCC after adjusting for age and sex (OR 3.99; 95% CI 2.62 - 6.10). Collectively, these data support the hypothesis that active CMV infection may be a risk factor for HNSCC.

#2294 Association of analgesic use with risk of renal cell cancer in the Nurses' Health Studies.

Jinhui Li[1], Minji Jung[1], Benjamin Chung[1], Mark Preston[2], Marvin Langston[1], Rebecca Graff[3]

[1]Stanford University, Palo Alto, CA,[2]Brigham and Women's Hospital, Boston, CA,[3]University of California, San Francisco, San Francisco, CA

Objectives: This study aims to investigate the association between commonly utilized analgesics—aspirin, non-aspirin nonsteroidal anti-inflammatory medications (NSAIDs), and acetaminophen and the risk of renal cell cancer (RCC) in women.
Methods: In 1980, the Nurses' Health Study (NHS) collected data on aspirin usage from 92,125 women. Additional non-aspirin NSAIDs and acetaminophen were included in 1990. In 1989, 112,292 women were collected data in the NHS II and followed up since 1989. The association was also further investigated by stratification of histological subtypes, pathologic stage, and differentiation subtypes for RCC. Cox proportional hazards models were employed to generate cohort-specific, multivariable hazard ratios (HRs) and 95% confidence intervals (CIs) for each analgesic. Results from both cohorts were aggregated by random-effects meta-analyses.
Results: For the over 20-year follow-up period, there are 11,978, 22,838, and 28,350 women currently use acetaminophen, aspirin, and NSAIDs from the NHS study, and 25,416, 12,958, and 22,407 women currently use these analgesic medications individually. 575 RCC and 142 fatal RCC cases were identified across the two cohorts. For RCC, in NHS II. We observed a significantly increased risk of RCC among the current acetaminophen users (Relative risk (RR): 1.56, 95%CI:1.13,2.15). Pooled results showed positive associations: acetaminophen (RR:1.02, 95%CI: 0.75,1.95); aspirin (RR:1.11, 95%CI: 0.91,1.31); non-aspirin NSAIDs (RR:1.29, 95%CI:0.90, 1.83). Similar trends were observed for fatal RCC. When stratified the RCC subgroups, aspirin use shows a significantly positive association with the increased risk of different pathologic states (pooled RR: 1.29, 95%CI: 1.02, 1.63), and non-aspirin NSAID use was also associated with increased risk of different histological, pathological and differentiated RCC risk significantly.
Conclusions: These data illustrated that the use of analgesics in NHS and NHS II cohorts is potentially associated with an increased risk of RCC among women.

#2295 Molecular epidemiology of high-risk HPV circulating in women living with HIV in Nigeria: Protocol for a multi-center cross-sectional study.

I. M. Ifeorah[1], B. O. Olakunde[2], U. E. George[3], S. C. Eneh[1], U. U. Akpan[4], N. N. A. Awolola[5], A. A. F. Banjo[5], C. O. Chigbu[1], E. E. Ezeanolue[1], L. Hou[6], O. M. Adewumi[7];

[1]IVAN Research Institute, University of Nigeria Nsukka, Enugu, Nigeria, [2]College of Public Health University of North Texas Health Science Center, Forth Worth, Texas Houston, TX, [3]African Centre of Excellence for Genomics of Infectious Diseases, Redeemer's University, Ede Osun State, Nigeria, [4]Excellence Community Education Welfare Scheme (ECEWS), Abuja, Nigeria, [5]Lagos University Teaching Hospital, Lagos, Nigeria, [6]Feinberg School of Medicine, Northwestern University, Chicago, IL, [7]College of Medicine, University of Ibadan, Ibadan Oyo State, Nigeria

Introduction: Cervical cancer (CCa) is the second leading cause of CCa-related deaths among women in Nigeria. Specifically, women living with HIV (WLHIV) face a significantly higher risk of developing CCa. Despite this, comprehensive data on circulating high-risk HPV (hrHPV) strains among WLHIV in Nigeria remains scarce. This study aims to determine the distribution of hrHPV among WLHIV in Nigeria to inform and optimize interventions geared at CCa prevention.

Methods: This cross-sectional study will examine fifteen hrHPV in 1,320 consenting WLHIV in six health facilities from the Nigeria Implementation Science Alliance Model Innovation and Research Centers across Nigeria's six geopolitical zones. WLHIV will be eligible for participation if they are between 25-60 years; have not been diagnosed with CCa, have not undergone hysterectomy, and not pregnant. Clinical and demographic data will be collected using a pretested questionnaire. Cervical swab samples will be obtained with a cytobrush and Ayre spatula. The cytobrush will be placed immediately into a sterile specimen tube containing virus transport medium. The cervical specimen collected with ayre spatula will be used to make duplicate cytological smears, fixed in ethanol, and subsequently stained by papanicolaou method. Human Papilloma Virus genotyping assay will be used to detect hrHPV in the study population. For hrHPV-positive samples, papanicolaou staining will classify cytology results using the Bethesda system. Statistical analyses will include descriptive statistics of hrHPV prevalence and distribution. Associations between hrHPV and clinical as well as demographic factors will first be evaluated using Fisher's exact or Pearson's chi-squared tests. Multivariable logistic regression will further be used to identify factors associated with hrHPV. Cytological outcomes will be descriptively categorized by hrHPV genotype and participant characteristics.

Expected Results: This study will provide reliable and representative data on the prevalent circulating hrHPV and the geographical variation among WLHIV in Nigeria. It will also provide insights into the possible risk factors associated with hrHPV among WLHIV in Nigeria.

Conclusion: Findings from this study will be critical to effective CCa prevention and control among WLHIV in Nigeria by bridging the knowledge gap and providing evidence to inform optimization of HPV-DNA screening to target prevalent hrHPV circulating among WLHIV. In addition, it will elicit robust scientific engagement on the potential impact of the HPV vaccination program in this high-risk population.

#2296 Ascertainment of uterine cancer surgery in the Surveillance, Epidemiology, End Results (SEER)-Medicare linked database: Comparison of SEER and claims data.

Ashley S. Felix[1], Caitlin E. Meade[1], Qinhan Hu[1], Anusha M. Vable[2], Tasleem J. Padamsee[1], Marcarius Donneyong[3], Kemi M. Doll[4], Jennifer A. Sinnott[5]

[1]The Ohio State University College of Public Health, Columbus, OH,[2]University of California, San Francisco, San Francisco, CA,[3]The Ohio State University College of Pharmacy, Columbus, OH,[4]University of Washington School of Medicine, Seattle, WA,[5]The Ohio State University College of Arts and Sciences, Columbus, OH

Purpose: Hysterectomy with bilateral salpingo-oophorectomy (BSO) is the cornerstone of uterine cancer treatment. The Surveillance, Epidemiology, and End Results (SEER)-Medicare linked database provides two sources of surgery information: medical record abstraction (SEER) and billing claims (Medicare). Concordance between these two sources has not been evaluated among uterine cancer patients. Given the increasing use of SEER-Medicare for assessment of treatment-related uterine cancer survival effects, an understanding of the concordance of these two sources is needed.
Methods: Patients diagnosed with uterine cancer between 2000 and 2019 were identified using the SEER-Medicare linked database. We calculated sensitivity, specificity, positive predictive value, negative predictive value, and Kappa statistics for receipt of hysterectomy with or without BSO and receipt of hysterectomy with BSO using Medicare claims as the presumed gold standard. Analyses were repeated stratified by race, histology, and stage.
Results: A total of 34,904 uterine cancer patients [9% Black, mean (standard deviation) age at diagnosis: 74.6 (6.7) years] were included in the comparison of surgery derived in SEER vs. Medicare claims, after excluding 39.7% with unknown surgery status from SEER. A total of 30,943 patients were identified as having hysterectomy with or without BSO in both the claims and SEER, resulting in a moderately strong sensitivity [78.4%, 95% confidence interval (CI)= 77.1%,79.8%]. A total of 29,733 patients were identified as having hysterectomy with BSO in both the claims and SEER, resulting in a sensitivity of 69.5% (95% CI= 68.1%, 70.8%). For both procedures, lower sensitivity was noted for non-Hispanic Whites, those diagnosed with grade 1 endometrioid, or those diagnosed with stage 1 disease. Specificity was high for both treatment types and across race, histology, and stage categories (>96.9%). In cases where there was discordance between claims and SEER, claims were more likely to report a corresponding insurance claim when there was no corresponding surgery indication in SEER.
Conclusions: In the subset of uterine cancer patients with known SEER surgery, SEER data reliably identified receipt of hysterectomy with or without BSO and hysterectomy with BSO; however, variations according to patient characteristics were observed. Of concern is the large proportion of unknown surgery data in SEER, which has implications for research aimed at estimating the population prevalence of surgery and investigations comparing outcomes between surgically and non-surgically treated patients. Investigations of the origins of unknown SEER surgery data are warranted.

#2297 Racial and ethnic disparities in incidence of Langerhans cell histiocytosis differ across age groups.

J. Velazquez, K. L. McClain, P. J. Lupo, C. E. Allen, M. E. Scheurer, E. C. Peckham-Gregory;
Baylor College of Medicine, Houston, TX

Background: Langerhans cell histiocytosis (LCH) is an inflammatory myeloid neoplasia with a median diagnosis age of 30 months, though it can occur at any age. The estimated annual incidence is 5 cases per million children under the age of 15 and 1-2 cases per million adults. We previously reported an increased risk of LCH among children of Hispanic parents using data from the Texas Cancer Registry. However, less is known about differences in underlying biology between children and adults, and it is unclear whether incidence profiles differ across age groups. Therefore, this study aimed to compare the incidence of LCH by race/ethnicity in the United States (US) across the age spectrum using data from the US Cancer Statistics (USCS) database.

Methods: LCH incidence data were obtained from the USCS database for the period 2001-2021, representing 99.6% of the US population, and stratified by age at diagnosis and race/ethnicity. Age was defined as childhood (0-14 years), AYA (15-39 years), and adult (40+ years). Race/ethnicity was categorized as non-Hispanic White (NHW), non-Hispanic Black (NHB), non-Hispanic American Indian or Alaska Native (NHAIAN), non-Hispanic Asian or Pacific Islander (NHAPI), and Hispanic. Age-adjusted incidence rate-ratios (IRRs) and 95% confidence intervals (CIs) were calculated using SEER*Stat (v8.4.4) to assess differences in LCH incidence across these groups.

Results: We identified 3,825 childhood, 1,306 AYA, and 1,718 adult LCH cases in the USCS database. Hispanic children showed significantly higher LCH IRRs ($IRR_{Hispanic_0\text{-}14}$=1.17, 95% CI: 1.09-1.26) compared to NHW children. However, this trend was not observed in Hispanic AYAs or adults, who exhibited significantly lower IRRs than NHWs. In a sub-analysis of childhood cases, Hispanic children aged 0-4 and 5-9 showed significantly higher LCH IRRs compared to NHW children ($IRR_{Hispanic_children_0\text{-}4}$=1.26, 95% CI: 1.14-1.39; $IRR_{Hispanic_children_5\text{-}9}$=1.16, 95% CI: 1.01-1.34), while this trend attenuated among Hispanics aged 10-14 ($IRR_{Hispanic_children_10\text{-}14}$=0.94, 95% CI: 0.79-1.12). NHBs showed significantly lower LCH IRRs across all age groups compared to NHWs as well as in sub-analyses of NHB children aged 0-4, 5-9, and 10-14 ($IRR_{NHB_0\text{-}4}$=0.37, 95% CI: 0.31-0.45; $IRR_{NHB_5\text{-}9}$=0.37, 95% CI: 0.27-0.48; $IRR_{NHB_10\text{-}14}$=0.24, 95% CI: 0.16-0.35).

Conclusions: This study reveals significant differences in LCH incidence by racial/ethnic group across ages. Hispanic pediatric cases show higher incidence compared to NHWs, particularly in children aged 9 and below, a trend not seen in Hispanic AYAs and adults. In contrast, NHBs exhibit a decreased incidence across all age groups compared to NHWs. These disparities in LCH incidence by race/ethnicity may suggest differences in underlying LCH etiology across the age spectrum. Future studies are warranted to characterize the molecular components of LCH in adults compared to children.

#2298 Endometrial cancer incidence by age across Asian/Pacific Islander ethnic subgroups.

Minh Tung Phung[1], Elizabeth Gehrig[2], **Alice W. Lee**[2]

[1]University of Wisconsin-Madison, Madison, WI,[2]California State University, Fullerton, Fullerton, CA

Introduction: Endometrial cancer is the most common gynecologic cancer in the U.S. Although late-onset endometrial cancer (LOEC, diagnosed age 50+) is more common, the incidence of early-onset endometrial cancer (EOEC, age <50) is rising, with recent data showing EOEC incidence increasing twice as fast as LOEC incidence during 1995-2017. Interestingly, when these findings were looked at by race/ethnicity, only Asian/Pacific Islander (APIs) showed incidence of LOEC increasing faster than that observed for EOEC. However, because APIs constitute unique ethnic subgroups that differ in culture, socioeconomic status, and access to care, we have examined EOEC and LOEC incidence for the seven largest API subgroups.

Methods: The Surveillance, Epidemiology, and End Results Program (SEER-9) specialized database with Asian population denominators was used to examine EOEC and LOEC incidence from 1995 to 2014 for the following API subgroups: Asian Indian/Pakistani, Chinese, Filipino, Hawaiian/Pacific Islander, Japanese, Korean, and Vietnamese. Incidence rate ratios (IRRs) were calculated for each API subgroup, with NHW as the reference. Joinpoint Regression Program version 5.2.0.0 was used to calculate the average percent change (APC) of incidence rates in 4-year groups. All statistical tests were 2-sided, and statistical significance was defined as $P<0.05$.

Results: The analysis included 14,803 EOEC (2,365 API; 12,438 NHW) and 119,637 LOEC cases (8,213 API; 111,424 NHW). The proportion of EOEC was higher in all API subgroups than in NHW (10%), with the highest among Hawaiian/Pacific Islander (35%) and the lowest among Chinese (15%). EOEC incidence was 6-20 times lower than LOEC incidence. EOEC incidence rates among API subgroups range from 2.11 (Asian Indian/Pakistani) to 16.72 per 100,000 (Hawaiian/Pacific Islander). LOEC incidence rate ranged from 0.24 (Korean) to 93.94 per 100,000 (Hawaiian/Pacific Islander). Hawaiian/Pacific Islander is the only subgroup with both EOEC and LOEC incidence rates higher than NHWs (IRRs=3.64 and 1.18, respectively). There was an increasing trend in EOEC and LOEC incidence during 1995-2014 for most API subgroups. The APCs for EOEC were lower than LOEC in most API subgroups, except for Hawaiian/Pacific Islander. In contrast, the APC for EOEC was greater than LOEC among NHW. Among the API subgroups, the APCs for EOEC ranged from -0.80 (Japanese) to 3.73 (Hawaiian/Pacific Islander). The APCs for LOEC ranged from 1.46 (Japanese) to 3.72 (Asian Indian/Pakistani).

Conclusions: There was heterogeneity in incidence rates and trends of EOEC and LOEC by API subgroups. Both EOEC and LOEC incidence rates increased across nearly all API subgroups, and the increases were greater for LOEC, which is different from NHW. These differential increases underscore the need to monitor risk factor trends and develop tailored interventions to reduce endometrial cancer burden by age and API subgroups.

#2299 Risk assessment and development of a machine learning-based prediction model for survival in patients with medulloblastoma.

Yu Su[1], Kaiwen Deng[2], Tao Jiang[2], Xiaoguang Qiu[2], Jiao Zhang[3], Hailong Liu[2], Yu Tian[1]

[1]Capital Medical University, Beijing, China,[2]Beijing Tiantan Hospital, Capital Medical University, Beijing, China,[3]Texas Children's Hospital, Houston, TX

Background: While clinical risk factors have long guided medulloblastoma (MB) treatment, the significance of genetic events in therapeutic strategies has not been fully elucidated. We aimed to explore whether revised molecular risk categories could inform management by analyzing long-term follow-up profiles, and concurrently to establish and validate an explainable prediction model for MB based on machine learning (ML) approaches, and to assess its prognostic implications in patients.
Methods: A multicenter cohort of 729 patients from 2001 to 2023 was enrolled as a discovery cohort. Multivariate survival analyses assessed the associations between radiotherapy dose and survival by different revised molecular risk stratifications which integrated clinical and genetic events, followed by utilizing this cohort for training and internal validation of the model. The area under the receiver-operating-characteristic curve (AUROC) and decision curve analysis (DCA) were used to compare the predictive performance. The SHapley Additive exPlanation method was used to explain the final model.
Results: Fifteen-year OS and DFS rates were 64.1% (95% CI, 57.9 to 71.0) and 59.1% (95% CI, 53.2 to 65.5) for clinical average-risk group (n = 554), and 55.9% (95% CI, 44.4 to 70.2) and 60.6% (95% CI, 51.9 to 70.7) for clinical high-risk group (n = 175), respectively. Within this revised high-risk stratification of SHH-MB, higher PF dose (≥ 55.8 Gy) combined with reduced CSI dose (23.4 ~ < 30.6 Gy) was associated with better prognoses. In Gr.3-MB, MYC amplification (activation), as a high-risk marker of dissemination, indicated that CSI dose should be escalated to high intensity (36.0 Gy, p = 0.03) for survival benefits. In the revised model of Gr.4-MB, CDK6 activation well stratified the patients, with 10-year OS of 71.0% (95% CI, 54.0 to 93.5) for average-risk and 52.1% (95% CI, 39.5 to 68.8) for high-risk group. Furthermore, Clinical and molecular information from discovery and validation cohort was involved into model training. The Random survival forest method demonstrated the most optimal predictive efficacy among the six ML models, as evidenced by the training set AUROC of 0.73 (95% CI 0.68-0.78) for 5-year survival rates, 0.76 (0.70-0.82) for 10-year survival rates, and 0.86 (0.81-0.92) for 15-year survival rates in all patients. The final model could accurately predict survival rates in both internal and external validations, and has been deployed through a free, publicly available online software interface.
Conclusion: The revised molecular risk stratification was suggested to potentially guide risk-adapted radiotherapy. Except that 36.0 Gy CSI dose is warranted for Gr.3-MB with MYC amplification, CSI reduction is recommended. Furthermore, this study, based on clinical and molecular information, constructs an available survival prediction tools for MB patients.

#2300 Blood microbiome, circulating tumor cells, and survival in Black and White women with metastatic breast cancer.

Tengteng Wang[1], Prachi Trevedi[1], Mouadh Barbirou[2], Maysa Abu-Khalaf[2], Zheng Sun[3], Yang-Yu Liu[3], Mridula George[1], Elisa V. Bandera[1], Hushan Yang[2]

[1]Rutgers Cancer Institute, New Brunswick, NJ,[2]Sidney Kimmel Comprehensive Cancer Center, Thomas Jefferson University, Philadelphia, PA,[3]Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

Background: Metastatic breast cancer (MBC) is a devastating disease, and recent evidence suggests that the human microbiome may play a critical role in cancer metastasis. However, the role of the blood microbiome in MBC prognosis has not been explored.
Methods: This study analyzed sixteen blood samples collected from women diagnosed with MBC who participated in the hospital-based cohort at Thomas Jefferson University. Plasma DNA samples were extracted from these samples collected before initiating new lines of therapy. We utilized 2bRAD sequencing for Microbiome (2bRAD-M), a reduced sequencing technology capable of decoding the blood microbiome (bacteria, fungi, archaea, and viruses) with high precision and resolution. Circulating tumor cells (CTCs) were enriched from blood samples using CellSearch®. To investigate blood microbiome differences by CTC levels and race, both conventional statistical analysis and machine learning are performed to examine the variations in blood microbial diversity, taxonomic structures, and functional pathways. Cox proportional hazard regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for associations between microbial diversity index and MBC overall survival.
Results: We identified 265 microbial species in the plasma samples. Lower blood microbial alpha diversity was significantly correlated with higher CTC counts (R = -0.66, p = 0.01), a marker associated with poorer breast cancer outcomes. Random forest analysis identified fifteen key species (e.g., *Sphingopyxis_sp001468225, Malassezia restricta*) that can differentiate between CTC groups, with an area under the curve of 0.67 to 0.75. Pathway analysis revealed the bacterial Type VI Secretion System (T6SS) as the top pathway associated with differential microbes across CTC levels; women with a CTC count >5 showed over 1000-fold higher abundance of the T6SS pathway. For survival prediction, patients with low microbial alpha diversity (≤ median of 2.04) exhibited a nearly threefold increased risk of death (HR = 2.62, 95% CI=0.74 -17.26), with even higher risk after adjusting for tumor ER status (HR = 4.43), age at diagnosis (HR = 4.86), and CTC count (HR = 6.83). These findings indicate a strong negative association between blood microbial diversity and key prognostic factors in MBC. Lastly, we also observed that Black MBC patients had a lower microbial richness than White participants (median 27 vs. 42), and had a significantly lower abundance of *Klebsiella pneumoniae* than White women (p*<0.001*).
Conclusion: Our compelling pilot findings suggest that 1) blood samples may serve as a novel sample type for microbiome assessment in a diverse cohort of women with MBC, and 2) blood microbiome features differ by CTC levels and race and may significantly influence MBC survival. Further studies with larger cohorts are warranted as the next step.

#2301 CA125 levels as a proxy for residual disease in a diverse cohort of epithelial ovarian cancer patients: results from the Kaiser Permanente Research on Ovarian Cancer Survival (KPROCS) study.

Lindsay Jane Collin[1], Farzin Khosrow-Khavar[2], Valerie S. Lee[3], Juraj Kavecansky[3], Christine Garcia[3], Scarlett L. Gomez[4], Jennifer A. Doherty[5], Lawrence H. Kushi[3], Elisa V. Bandera[2]

[1]Emory University, Rollins School of Public Health, Atlanta, GA,[2]Rutgers Cancer Institute, New Brunswick, NJ,[3]Kaiser Permanente Northern California, Oakland, CA,[4]University of California at San Francisco, San Francisco, CA,[5]Huntsman Cancer Institute, Salt Lake City, UT

Background: Ovarian cancer has a poor 50% five-year survival rate. The presence of residual disease at the time of surgery is a key prognostic indicator; however, it is often not available or challenging to obtain. Cancer antigen (CA)125 is a well-established biomarker for monitoring ovarian cancer progression, but its utility as a biomarker to identify women with residual disease after surgery have not been evaluated.

Methods: We included 1218 epithelial ovarian cancer patients from the Kaiser Permanente Research on Ovarian Cancer Survival (KPROCS) cohort who had both information on residual disease from surgical notes (*i.e.,* gold standard) and CA125 measurements within 6 months of surgery. Residual disease from surgical notes was determined using natural language processing to classify as optimal (<1cm) or suboptimal debulking (≥1cm). For each patient, we obtained the lowest CA125 value during the period starting 2 weeks after surgery and up to 6 months post-surgery (if they did not have chemotherapy) or up to the date of the first chemotherapy cycle. CA125 values were then dichotomized (>100 vs ≤100 ug/mL) to evaluate utility in identifying presence or absence of residual disease by estimating sensitivity and specificity, as well as positive and negative predictive values (PPV and NPV, respectively), with corresponding 95% confidence intervals (CIs). We evaluated differences by race and ethnicity and time since surgery (≥30 days vs <30 days).

Results: In this validation study of 1218 epithelial ovarian cancer patients, 229 (19%) were Asian American/Pacific Islander, 66 (5.4%) were non-Hispanic Black, 171 (14%) were Hispanic, 738 (61%) were non-Hispanic white, and 14 (1.0%) were of other racial and ethnic groups. The average time since surgery to the lowest CA125 value was 33 days (interquartile range 25, 46 days). According to the surgical notes, 5% were classified as having suboptimal debulking status, whereas 80% were classified as having CA125 >100 ug/mL, which corresponded to sensitivity of 70%, specificity of 82%, PPV of 17%, and NPV of 98%. The sensitivity and specificity were 78% and 87% among Asian American/Pacific Islander individuals, 43% and 95% among non-Hispanic Black individuals, 63% and 83% among Hispanic individuals, and 77% and 79% among non-Hispanic White individuals. Finally, the sensitivity and specificity were 72% and 50% for those who had their lowest CA125 value <30 days after surgery and 56% and 72% for ≥30 days after surgery.

Conclusions: In our initial results, we demonstrate that elevated CA125 serves as a modest proxy to identify residual disease, with some variation by race and ethnicity and time since surgery. Future work will seek to explore CA125 cut points and variation by patient characteristics to optimize performance.

#2302 Overall survival and treatment patterns in elderly patients with stage IV colorectal cancer in the United States: SEER-medicare analysis, 2007-2020.

Alicia C. McDonald, Xinyue Liu, Ruixuan Jiang, Jae Min, Pierre Leconte, Anne C. Deitz, Changxia Shao

Merck & Co., Inc., Rahway, NJ

Introduction: Traditional therapeutic options in metastatic colorectal cancer (mCRC) are limited and associated with severe toxicity. This limitation may be greater in populations where cancer treatment disparities have been reported. To better understand survival outcomes and patterns of treatment in these populations, we conducted an observational study to examine overall survival (OS) and lines of therapy (LOT) by sex, age, and race/ethnicity in elderly patients with stage IV CRC in the United States using the Surveillance, Epidemiology, and End Results (SEER) Medicare database.

Methods: Patients aged ≥65 years with stage IV CRC were identified in the SEER-Medicare database between January 1, 2007, and December 31, 2020. The frequency of the first, second, and third LOT (1L-3L) and the regimens within each line were calculated. Kaplan-Meier curves were generated to examine OS. All analyses were conducted for the total population and by sex, age group, and race/ethnicity.

Results: There were 9,042 CRC cases identified with a median age of 76 years. Most patients were female (55.0%), non-Hispanic White (72.5%), and had a proximal site of initial diagnosis (44.8%). Overall, the median OS was 7.8 months (95% CI, 7.5-8.2). Older age (≥85 years), female, and non-Hispanic Black and non-Hispanic American Indian/Alaska Native (AI/AN) patients had worse OS compared with younger age groups, male, and other racial/ethnic patients, respectively. Of the 9,042 patients, 4923 (54.4%), 2761 (30.5%), and 1556 (17.2%) patients received 1L, 2L, and 3L, respectively. The most common regimens were FOLFOX ± anti-VEGF (47.7%) for 1L, FOLFIRI ± anti-VEGF (27.0%) for 2L, and FOLFIRI ± anti-VEGF (18.7%) and other (17.5%) for 3L. The most common regimens by LOT were similar by sex and race/ethnicity. However, different treatment patterns were observed by age group. Compared with younger age groups, older age groups received fewer 2L and 3L and more capecitabine-based regimens or anti-VEGF monotherapy. As for OS, compared to patients aged 65-74 years, worse OS was observed for patients aged 75-84 years within each LOT and patients aged ≥85 years within 1L (P values < 0.01). Compared to non-Hispanic White patients, worse OS was observed for non-Hispanic Black patients within each LOT and non-Hispanic AI/AN patients within 3L (*P* values < 0.01). OS was similar between male and female patients within each LOT.

Conclusion: Compared with younger patients, older patients received fewer 2L and 3L, received less intensive therapy regimens, and had worse OS. Although therapy regimens across LOT were comparable by sex and race/ethnicity, worse OS was observed in female, non-Hispanic Black, and non-Hispanic AI/AN. This study may provide insight on identifying needed treatment among patients with mCRC.

#2303 The impact of adherence to cancer prevention guidelines on cancer risk, cancer incidence and mortality in a large cohort of Canadian adults.

S. S. Fiati-Kenston, R. A. Murphy, J. M. Spiegel, T. J. B. Dummer;
University of British Columbia, School of Population and Public Health, Faculty of Medicine, Vancouver, BC, Canada

Background: The World Cancer Research Fund (WCRF) and the American Institute of Cancer Research (AICR) publish behavioral guidelines for cancer prevention. The guidelines provide standards on body weight, physical activity, diet, alcohol consumption, and smoking. This study examined the impact of adherence to these guidelines on cancer incidence and mortality in a large cohort of Canadian adults.
Methods: Data were obtained from the British Columbia Generations Project (BCGP), a longitudinal cohort of 30,000 adults aged 35-69 years recruited between 2009 and 2015, with a median follow-up of 10 years. Participants with a baseline cancer diagnosis were excluded, leaving 23,482 eligible individuals. A 3-level adherence score was constructed for each guideline. Cox proportional hazard models were employed to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for cancer incidence and mortality, adjusting for sociodemographic and health covariates. Propensity score matching was conducted to assess the robustness of the results.
Results: 3,068 new cancer cases and 769 cancer deaths were recorded during follow-up. Full adherence to the WCRF/AICR guidelines was achieved by only 19% of men and 31% of women. High adherence was associated with a significant reduction in all cancer incidence, with HRs of 0.81 (95% CI: 0.68-0.92) for women and 0.82 (95% CI: 0.73-0.95) for men. Cancer mortality was also lower among adherent individuals, with HRs of 0.83 (95% CI: 0.66-1.09) for women and 0.86 (95% CI: 0.70-0.96) for men. Additionally, total mortality decreased by 14% in women (HR = 0.86; 95% CI: 0.69-0.95) and 11% in men (HR = 0.89; 95% CI: 0.72-0.93). These associations remained robust after adjusting for sociodemographic and health covariates and were confirmed through propensity score matching.
Conclusions: Adherence to cancer prevention guidelines was associated with lower cancer incidence and mortality in both men and women. These findings highlight the importance of lifestyle modifications to reduce cancer risk among Canadian adults.
Keywords: cancer incidence, cancer prevention, physical activity, diet, body weight, smoking, alcohol

#2304 Plant-based dietary pattern and risk of pancreatic cancer: Findings from the Singapore Chinese Health Study.

Yen Thi-Hai Pham[1], Renwei Wang[1], Randall E. Brand[2], Tin C. Nguyen[3], Jian-Min Yuan[1], **Hung N. Luu**[1]

[1]UPMC Hillman Cancer Center, University of Pittsburgh, Pittsburgh, PA,[2]Division of Gastroenterology, Hepatology, and Nutrition, Department of Medicin, University of Pittsburgh, Pittsburgh, PA,[3]UPMC Hillman Cancer Center, Auburn University, Department of Computer Science and Software Engine, AL

Background: Pancreatic cancer is one of the leading causes of cancer-related death worldwide, with approximately 460,000 new cases and more than 430,000 deaths yearly. While most common cancers showed a declined trend in incidence, the incidence rate of pancreatic cancer has increased steadily by 1.5% per year during the past three decades. Established risk factors for pancreatic cancer are tobacco smoking, obesity, type 2 diabetes, and chronic pancreatitis. It is imperative to note that these established risk factors collectively account for less than 50% of pancreatic cancer burden. Recently, plant-based diets have received a significant attention due to their potential benefits to health outcomes, including cancer. The plant-based dietary indices (PDI) include total and healthful PDI (hPDI) and unhealthy PDI (uPDI), which were based on overall intake and sub-categories of food items that deem to be “healthfulness” and/or “unhealthfulness” to better account for the quality of plant foods, Limited number of prospective epidemiological studies have examined the association between PDI and pancreatic cancer risk. We, therefore, prospectively evaluated the associations for PDI, hPDI and uPDI scores with the risk of developing pancreatic cancer.

Methods: The current analysis used data from the Singapore Chinese Health Study, a prospective cohort study of 63,275 participants aged 45-74 living in Singapore who were recruited during 1993-1998 period. The three plant-based dietary scores (i.e., PDI, hPDI and uPDI) were derived from the semi-quantitative food frequency questionnaire at baseline. The incident cases of pancreatic cancer were identified through record linkage analysis with the nationwide Singapore Cancer Registry. Cox proportional hazard regression method was used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) for pancreatic cancer in relation with PDI, hPDI and uPDI scores, adjusted for potential confounding factors.

Results: After 17.6 years of follow-up, we identified 316 incident cases of pancreatic cancer. While there was a null association for total PDI or hPDI with risk of pancreatic cancer, uPDI was found to be associated with increased risk of pancreatic cancer. The respective HRs (95% CIs) for quartiles 2, 3, and 4 (the highest quartile) relative to quartile 1 of uPDI were 1.07 (0.75-1.52), 0.86 (0.63-1.24), and 1.61 (1.13-2.28), respectively (P_{trend}=0.02).

Conclusions: Our findings showed that higher level of unhealthy plant-based dietary index was associated with increased risk of pancreatic cancer. Our results have public health implications for primary prevention against the development of pancreatic cancer, a malignancy among a few with unimproved survival rate during the past four decades.

#2305 Plant-based diets and subsequent risk of gastrointestinal cancers in Black and low-income Americans: Findings from a large prospective cohort study.

Fangcheng Yuan, Lei Wang, Danxia Yu, Wei Zheng

Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, Vanderbilt University Medical Center, Nashville, TN

Background: Plant-based diets have been promoted for their health benefits. However, no study has specifically evaluated plant-based diets in relation to risk of gastrointestinal cancers in Black and low-income populations who disproportionately experience poor health outcomes. We aimed to investigate associations of plant-based dietary patterns with incident colorectal, liver, and pancreatic cancers in 70,255 participants of the Southern Community Cohort Study, a population-based prospective cohort conducted among predominantly Black and low-income Americans.
Methods: At baseline (2002-2009), dietary intakes were collected by a validated food frequency questionnaire from which adherences to overall, healthy, and unhealthy plant-based diets were assessed using established indices (i.e., PDI, hPDI, and uPDI). Incident cancer cases were ascertained via linkage to state cancer registries and the National Death Index. Hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated from Cox proportional hazards models after adjusting for potential confounders. In a subset of participants, we also examined associations of the three indices with shotgun metagenomic sequencing-profiled gut microbiome from stool samples (n=417) collected between 2018-2021 and mass spectrometry-measured metabolites from baseline plasma samples (n=1,581). Cancer cases diagnosed before stool or blood collection were excluded.
Results: During a median follow-up time of 12.6 years, 544, 370, and 276 incident primary colorectal, liver, and pancreatic cancer cases were identified after excluding participants with less than 2 years of follow-up. Compared with the lowest quartile, the highest quartile of PDI was associated with lower colorectal cancer (CRC) risk (HR=0.72, 95% CI=0.55-0.94, P_{trend}=0.01), whereas that of uPDI was associated with elevated CRC risk (HR=1.41, 95% CI=1.07-1.86, P_{trend}=0.02). A high hPDI was linked to reduced liver cancer risk (HR=0.60, 95% CI=0.42-0.87 for the highest versus lowest quartile, P_{trend}=0.006). No index was associated with pancreatic cancer risk. After adjusting for multiple testing (FDR-adjusted P<0.10), PDI was inversely associated with species *MGYG-HGUT.02013* within genus *Collinsella*. PDI, hPDI, and uPDI were associated with 201, 107, and 47 circulating metabolites, respectively. Over-representation analysis suggested that caffeine and branched-chain amino acids metabolism pathways were significantly enriched for PDI-associated metabolites.
Conclusion: Adherence to a diet characterized by healthy plant foods and low animal foods may lower colorectal and liver cancer risk.

#2306 Estrogen metabolism-related lifestyle scores and breast cancer risk among 62,000 Chinese and American postmenopausal women: Findings from two large prospective cohort studies.

Fangcheng Yuan[1], Wanqing Wen[1], Steven C. Moore[2], Wei Zheng[1]

[1]Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, Vanderbilt University Medical Center, Nashville, TN,[2]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD

Background: An increased 2-hydroxylation (2-OH) of estrogen has been linked to reduced risk of breast cancer (BC). We hypothesized that lifestyle patterns related to an elevated estrogen 2-OH metabolism were associated with lower BC risk and tested this hypothesis among post-menopausal women in two prospective cohorts.

Methods: Estrogens and estrogen metabolites (EMs) were profiled by liquid chromatography-mass spectrometry in a subset of post-menopausal women in the Shanghai Women's Health Study (SWHS, *n*=804) and Prostate, Lung, Colorectal and Ovarian Screening Trial (PLCO, *n*=842), respectively. Blood (PLCO) or urine (SWHS) samples used in these assays were collected at baseline prior to any cancer diagnosis. We applied elastic net regularized regression to derive two lifestyle scores that characterize relative abundance of 2-OH pathway EMs, estimated separately by the ratio of 2-OH EMs to parent estrogens and the ratio of 2-OH EMs to parent estrogens and all EMs combined. Intakes of foods and nutrients assessed by baseline food frequency questionnaires, and measures of body fat, alcohol intake, cigarette smoking, and leisure-time physical activity were included as predictors. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for associations of derived lifestyle scores with post-menopausal BC risk in the larger SWHS (*N*=35,453) and PLCO (*N*=26,758) cohorts, after adjusting for potential confounders.

Results: The lifestyle scores explained 10-12% of the total variance in the 2-OH EM ratios. A high lifestyle score for the ratio of 2-OH EMs to parent estrogens was associated with decreased BC risk in the SWHS (HR=0.73, 95% CI=0.59-0.90 for the highest versus lowest quartile, P_{trend}=0.001). This inverse association was seen only among estrogen receptor (ER)-positive BC cases ($P_{heterogeneity}$=0.03). A similar association was observed for the lifestyle score for the ratio of 2-OH EMs to the combined parent estrogens and EMs. In the PLCO, the score for the ratio of 2-OH EMs to parent estrogens was inversely related to BC risk (HR=0.83, 95% CI=0.70-0.99, P_{trend}=0.06), whereas no significant association was found for the other lifestyle score.

Conclusion: A lifestyle pattern reflecting elevated estrogen 2-OH metabolism may lower post-menopausal BC risk. Women with a low 2-OH of estrogen may benefit from diet and lifestyle modifications.

#2308 Sustained adherence to the American Cancer Society guideline for diet and physical activity for cancer prevention and 8-year all cancer risk: an emulated target trial in the Cancer Prevention Study-II Nutrition Cohort.

Valeria Elahy[1], Marjorie L. McCullough[1], Yu-Han Chiu[2], Alpa V. Patel[1], Erika Rees-Punia[1], Clara Bodelon[1], Anita R. Peoples[1], Ying Wang[1]

[1]American Cancer Society, Atlanta, GA,[2]Penn State College of Medicine, Hershey, PA

Background: The 2020 American Cancer Society (ACS) Guideline for Cancer Prevention recommends maintaining a healthy body weight, engaging in regular physical activity, following a healthy diet, and abstaining from alcohol. While evidence of the cancer preventive effects of individual guideline components is well-established, few studies have assessed the long-term impact of adhering to multiple recommendations jointly using an emulated target trial design. An emulated target trial design mimics a hypothetical pragmatic randomized trial to answer causal questions using observational data.
Objectives: To examine 8-year cancer risk under sustained adherence (intervention) to the physical activity, diet, and alcohol components of the ACS Guideline, both jointly and individually, compared to the behavior reported in the cohort (no intervention), stratified by body mass index (BMI) categories.
Methods: Data from cancer-free, nonsmoking participants aged 47-80 years at baseline (1999) in the Cancer Prevention Study-II Nutrition Cohort were analyzed, including 30,111 individuals with normal weight (BMI 18.5 - <25 kg/m^2), 27,986 with overweight (BMI 25 - <30 kg/m$^{2)}$ and 11,631 with obesity (BMI ≥30 kg/m^2). Using an emulated target trial design, we assessed the effect of sustained adherence to the ACS Guideline components on cancer risk. Sustained adherence over 8 years was defined as meeting recommendations for physical activity (≥15 MET-hrs/wk), diet (≥6 serv/d and ≥21 unique fruits and vegetables per month, ≥2 serv/d of whole grains, ≤0.5 serv/d of red/processed meat, 0 serv/wk of sugar-sweetened beverages, ≤25% of total energy from processed foods and refined grains), and alcohol abstinence (0 serv/wk). The g-formula estimated absolute 8-year all cancer risk, adjusting for factors related to adherence and loss to follow-up.
Results: The estimated 8-year risk of all cancers under no intervention was 13.5% for those with normal weight, 15.7% for those with overweight, and 14.4% for those with obesity. Compared to no intervention, sustained adherence to the joint ACS Guideline showed a 1.3% (95% CI: -2.3, -0.1), 1.0% (95% CI: -2.5, 0.4), and 0.7% (95% CI: (-2.7, 1.6) lower cancer risk for those with normal weight, overweight, and obesity, respectively. Among individual components, alcohol abstinence had the most pronounced mean risk reduction, ranging from 0.7% (95% CI: -1.7, 0.2) for those with overweight to 1.1% (95% CI: -1.9, -0.3) and 1.1 (95% CI: -2.2, 0.1) for those with normal weight and obesity, respectively.
Conclusions: Sustained adherence to the ACS Guideline modestly reduced cancer risk, particularly for individuals with normal weight. Alcohol abstinence was a key contributor to the observed risk reductions.

#2309 An ecological study on environmental exposure to PFAS and thyroid cancer incidence rates by races/ethnicities in Florida.

Ming S. Lee, Laura Wild, Niko DiStefano, Garrett Forman, Elizabeth Franzmann, Natasha Solle, Alberto Caban-Martinez, Erin Kobetz

University of Miami Miller School of Medicine, Miami, FL

Background: The incidence rate of thyroid cancer in the US has increased significantly over the last few decades. However, besides radiation exposure and obesity, no modifiable risk factors have been identified for thyroid cancer. Although theories suggest exposure to per- and polyfluoroalkyl substances (PFAS) could contribute to the development of papillary thyroid cancer, existing studies on the effects of PFAS on thyroid cancer risk do not yield consensus results. Using data for the state of Florida, this ecological study aims to determine whether incidence rates of thyroid cancer vary with respect to residential proximity to industrial facilities handling PFAS materials as well as living in areas where drinking water containing detectable levels of PFAS.
Methods: Florida cancer registry data from 2011 to 2020 was used to calculate the incidence rates of papillary thyroid cancer by race/ethnicity (Hispanic, non-Hispanic White (NHW), and non-Hispanic Black (NHB)) for all census tracts in Florida. Environmental Protection Agency data was used to identify the locations of industrial facilities handling PFAS as well as ZIP codes with public drinking water testing positive for PFAS above reportable levels. A geographic information system was used to calculate the number of PFAS facilities within 10KM of a census tract. Correlation, linear regression, and t-tests for sample mean comparison were used to assess the associations between PFAS exposure and thyroid cancer rates at the census tract level.
Results: A total of 14,994 cases (9,213 in NHWs, 3,995 in Hispanics, and 989 in NHB) of thyroid cancers were diagnosed in Florida from 2011 to 2020. Correlation analyses show a positive correlation between residential proximity to PFAS facilities and greater Hispanic and NHB population compositions by higher percentages of ($r=0.36$, $p<0.001$) with lower income ($r=-0.192$, $p<0.001$)) and higher obesity rate ($r=0.197$, $p<0.001$)). Regression analyses show that proximity to PFAS facilities is a significant factor for thyroid cancer rates in Hispanic ($p=0.006$) and NHW ($p<0.001$). Hispanic and NHW living are in IPZIP code areas with reportable PFAS in drinking water also have higher average thyroid cancer rates than those in areas with no reportable PFAS (t-test $p=0.036$ for Hispanic and $p=0.039$ for NHW). With a lower average incidence rate than Hispanic and NHW, thyroid cancer rates in NHB show no statistically significant associations to PFAS exposure.
Conclusions: ecological Our findings suggest potential effects of environmental PFAS exposure on thyroid cancer disparities. set up trials to validate these effects by sampling volunteers for blood-level PFAS measurement from neighborhoods with different levels of PFAS exposure (facility proximity and drinking water).

#2310 Food environment index is inversely associated with cancer survival in North Carolina.

S. Wu[1], S. Ulrich[1], T. Feng[1], Y. Liu[2], L. Tseng[1];

[1]Appalachian State University, Boone, NC, [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Exploring the potential role of the food environment on cancer survival could facilitate prevention and control approaches to improve cancer survivorship. This study examined the associations between food environment index (FEI) and survival for overall cancer in North Carolina.

Methods: This retrospective cohort study included 1,292,991 patients diagnosed with overall cancer from January 1, 2000 to December 31, 2022 from the North Carolina Cancer Central Registry. The individual-level demographic, tumor, and treatment information were provided by the North Carolina Cancer Central Registry. FEI and other county-level exposures were obtained from the County Health Rankings & Roadmaps databases. The county-level food environment index is an indicator of access to healthy foods (0 is worst, 10 is best). Cox regression was used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) for the associations between FEI and cancer survival after adjusting for individual-level and county-level covariates.

Results: Higher levels of FEI were associated with a statistically significant better survival for overall cancer (fully adjusted HR for every score increase=0.983, 95% CI 0.979, 0.988; P <0.0001; adjusted HR for the 3rd quartile vs. 1st quartile = 0.98, 95% CI 0.94, 0.99; and adjusted HR for the 4th quartile vs. 1st quartile = 0.95, 95% CI 0.94, 0.96).

Conclusion: These results suggest that a healthy food environment, as measured by FEI, may be a protective factor for cancer survival in North Carolina. To improve cancer survival, further strategies to improve food environment at the county level are warranted.

#2311 Temporal trends and HPV attributability in oropharyngeal cancer: A cross-sectional study in multi-racial Singapore.

Yew Mun Lee[1], Nhi Thi Mai Nguyen[2], Zhi Yong Lim[1], Zi Ting Corrina Tan[3], Jia Qi Gabie Chua[3], Yirong Dai[2], Xin Xiu Sam[4], Jia Hui Isabelle Jang[1], Eriko Yamada[5], Kok Hing Lim[4], **Chwee Ming Lim**[6]

[1]Department of Otolaryngology-Head and Neck Surgery, Singapore General Hospital, Singapore, Singapore,[2]Duke-NUS Medical School, Singapore, Singapore,[3]Department of Clinical Translational Research, Singapore General Hospital, Singapore, Singapore,[4]Department of Pathology, Singapore General Hospital, Singapore, Singapore,[5]MSD Pharma (Singapore), Singapore, Singapore,[6]Department of Otolaryngology-Head and Neck Surgery and Department of Clinical Translational Research, Singapore General Hospital, Singapore, Singapore

Introduction: The purpose of this study is to estimate the proportion of oropharyngeal squamous cell carcinoma (OPSCC) attributable to Human Papillomavirus (HPV) in Singapore across two different time periods (2008-2011 and 2018-2021).
Experimental procedures: This non-interventional, cross-sectional study involves the retrospective analysis of pre-treatment OPSCC tissue samples under Singapore General Hospital (SGH) after obtaining institutional ethics approval. Retrospective biobank records of primary OPSCC patients with archival pre-treatment tissue samples from 2008-2011 (cohort 1, n=60) and 2018-2021 (cohort 2, n=60) were retrieved. Both $p16^{INK4a}$ immunohistochemistry staining (IHC) and HPV-DNA testing to determine HPV genotypes for up to 32 HPV genotypes using INNO-LiPA® HPV Genotyping (Fujirebio, Japan) were performed. Data on patient demographics, tumor characteristics, and risk factors were collected from medical records and entered a case report form (CRF). Descriptive statistical analyses were performed to determine the HPV-attributable fractions (HPV-AFs) and their corresponding patient characteristics. The current abstract described the results from the cohort 1.
Results: The primary outcome of this study is to determine the proportion of OPSCC cases attributable to HPV, defined by the presence of both HPV-DNA and $p16^{INK4a}$ positivity. The secondary outcome is to identify the distribution of HPV genotypes within the HPV-AFs of the two cohorts. In cohort 1, approximately 70% of diagnosed OPSCC cases were men, with HPV-attributable cases making up 20% of the total. Among the HPV-AFs, more than half of the HPV-positive cases were male. HPV16 (83.3%) was the predominant genotype in the HPV-AFs, followed by HPV26 (8.3%) and HPV58 (8.3%). The mean age of cohort 1 was 63.1 years (±11.0). Reflecting Singapore's multi-racial demographic, 68% of cohort 1 were Chinese, and 17% were Indian.
Conclusion: Our study fills a critical evidence gap regarding the burden of HPV-related OPSCCs in a multi-ethnic Singaporean community. By comparing the burden of HPVs in OPSCC across the two distinct time periods, this study offers insights into the temporal changes in trends of HPV-attributable OPSCCs.

#2312 Analysis of mortality and survival in colon cancer at ISSSTECALI from 2017 to 2022.

Fernando Ramirez-Perales[1], Angelica Pon-Mendez[2], Diana Evelyn Villa-Guillen[3], Diego Fernando Ovalle-Marroquin[4]

[1]Urgent Care, Hospital General del Estado de Sonora, Hermosillo, Mexico,[2]ISSSTECALI, Mexicali, Mexico,[3]Research and Teaching, Hospital General del Estado de Sonora, Hermosillo, Mexico,[4]Universidad Autonoma de Baja California, Mexicali, Mexico

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-related deaths worldwide, including 2.68% of malignancies in Mexico. In 2018, it caused 880,000 deaths, primarily in low- and middle-income countries. In Mexico, the lack of organized screening programs leads to late-stage diagnoses and poor outcomes. ISSSTECALI, serving government workers in Baja California, faces challenges in CRC detection and management due to healthcare disparities.
Objective: This study aims to evaluate survival rates and identify factors associated with colon cancer mortality among patients treated at ISSSTECALI in Baja California, Mexico, from 2017 to 2022.
Methods: A retrospective cohort study was conducted, including patients diagnosed with colon cancer between January 2017 and September 2022. Survival functions were estimated using the Kaplan-Meier method, and differences between survival curves were assessed with the log-rank test. Mortality risk factors were analyzed using a multivariable Cox proportional hazards regression model. The dependent variable was survival, while age, sex, municipality, histology, metastasis, cancer stage, and treatment type were included as independent variables.
Results: A total of 118 colon cancer cases were analyzed, of which 42.3% (50) resulted in mortality. Survival rates were 80.9%, 70.8%, 54.6%, and 46.8% at 1, 2, 3, and 4 years, respectively. The overall survival rate at the median follow-up (1.58 years) was 76.5%. Significant differences in survival curves were observed based on age group, general syndrome, metastasis, and cancer stage ($p < 0.05$). In the Cox regression model, metastasis was the strongest predictor of a poor prognosis (HR = 4.32, 95% CI: 1.92-9.68). Although the stage at diagnosis showed significant differences in the log-rank test, it was not a significant predictor after adjustment in the Cox model (HR = 2.30, 95% CI: 0.46-11.35).
Conclusions: This study emphasizes the importance of early diagnosis in improving survival rates and reducing mortality from colon cancer. It highlights the need for organized and accessible screening programs, particularly in healthcare systems like ISSSTECALI, to ensure timely detection and treatment. Implementing non-invasive screening methods—such as Fecal Occult Blood Testing at age 25 and colonoscopies at age 45 for average-risk individuals—could enhance early detection. The identification of metastasis as a key predictor of poor prognosis highlights the need for targeted interventions for advanced disease. Addressing disparities in cancer detection and management is essential to improve survival rates and reduce the burden of colon cancer in Mexico.

#2313 Trends in use of neoadjuvant systemic therapy for head and neck squamous cell carcinoma.

Wesley L. Cai[1], **Vanessa Helou**[1], Angela L. Mazul[1], Dan P. Zandberg[2], Matthew E. Spector[1], Jose P. Zevallos[1], Robert L. Ferris[3], Kevin J. Contrera[1]

[1]Department of Otolaryngology-Head and Neck Surgery, University of Pittsburgh Medical Center, Pittsburgh, PA,[2]UPMC Hillman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA,[3]UNC Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC

Importance: Neoadjuvant systemic therapy, including chemotherapy and immune checkpoint inhibitors, have potential benefits in head and neck squamous cell carcinoma (HNSCC). These potentially include reducing distant metastases, organ preservation, and treatment personalization. KEYNOTE 689 has the potential to change the treatment paradigm; however, trends in the use of neoadjuvant therapy leading up to the publication of this study remain unclear.
Objective: To evaluate trends in the use of neoadjuvant systemic therapy in patients with HNSCC from 2015 to 2022.
Design, Setting, and Participants: This retrospective, population-based cohort study utilized data from the National Cancer Database (2015-2021) to analyze neoadjuvant systemic and immunotherapy trends in HNSCC. Neoadjuvant treatment was defined as therapy administered at least 8 weeks prior to definitive surgery. Clinical staging and p16 status were assessed using AJCC 8th edition staging for patients diagnosed after 2018. Associations were analyzed using chi-square tests.
Main Outcomes and Measures: The primary outcomes were trends in neoadjuvant therapy use and associations with tumor stage, anatomic site, and p16 status.
Results: Among 292,181 patients (216,048 [74%] male; 76,133 [26%] female), 922 received neoadjuvant systemic therapy, and 603 received neoadjuvant immunotherapy. Neoadjuvant therapy use began to rise in 2015 with an immunotherapy use rate of 0.078%, peaking at 0.325% in 2019 (a 4-fold increase) and stabilizing at 0.165% in 2022 (a 2-fold increase from 2015). Similarly, overall neoadjuvant chemotherapy use was 0.22% in 2015, 0.44% in 2019, and 0.26% in 2022. Sites with the largest increases in neoadjuvant immunotherapy use were the floor of mouth (3-fold), gums (2.4-fold), and tongue (2-fold). Patients receiving neoadjuvant therapy were significantly more likely to present with stage 4 disease compared to stages 1-3 (58% vs. 27%; $P = .0005$). p16 positivity rates were comparable between groups (84% vs. 80%; $P = .68$).
Conclusions and Relevance: The use of neoadjuvant immunotherapy increased by 112% from 2015 to 2022, while overall neoadjuvant systemic therapy use rose by 18%. Patients undergoing neoadjuvant therapy were more likely to present with advanced-stage disease. With the upcoming release of KEYNOTE 689, understanding the current trends and treatment approaches for neoadjuvant therapy are crucial.

#2314 The epidemiology and impact of aspiration pneumonia in patients admitted with esophageal cancer: a nationwide data analysis.

Abdu Mohammed[1], Adamsegd I. Gebremedhen[2], Yifang Song[1], Mamdouh Souleymane[2], Ibrahim Shanti[2], Malik Samardali[3], Toni O. Pacioles[4]

[1]Internal Medicine, Trinity Health System, Steubenville, OH,[2]Internal Medicine, Marshall University Joan C. Edwards School of Medicine, Huntington, WV,[3]Internal Medicine, St Elizabeth Youngstown Hospital, Youngstown, OH,[4]Hematology and Oncology, Marshall University Joan C. Edwards School of Medicine, Huntington, WV

Background: Esophageal cancer (EC) is frequently associated with dysphagia, arising from tumor invasion or treatment-related adverse effects, such as surgical resection or chemoradiation. Dysphagia substantially increases the risk of aspiration pneumonia (AP), a frequent complication in this population. Despite the established link between AP and head and neck cancers, its epidemiology and clinical impact in patients with EC remain underexplored. This study aims to delineate the burden of AP in EC hospitalizations and its effect on inpatient outcomes, addressing a critical gap in oncological and infectious disease literature.
Methods: Hospitalizations with a primary diagnosis of EC were extracted from the National Inpatient Sample (NIS) from 2019 to 2021, using ICD-10 codes. The cohort was split by the presence or absence of AP. Sociodemographic variables, comorbidities and the presence of concurrent COVID-19 infection were assessed. The primary outcome was all-cause in-hospital mortality, with secondary outcomes including rates of complications, resource utilization, length of stay (LOS), and hospitalization costs. Multivariate regression analyses were conducted with statistical significance set at $p < 0.05$.
Results: Among 42,059 EC hospitalizations, 3,550 (8.4%) were complicated by AP. The AP cohort was older (mean age 67.9 vs. 66.6 years; $p < 0.05$), predominantly from the southern United States (36.6%; $p < 0.05$), and exhibited a higher prevalence of severe comorbidities (Charlson Comorbidity Index ≥ 3: 79.1% vs. 75.4%; $p < 0.05$). AP was independently associated with a significantly elevated risk of in-hospital mortality (adjusted odds ratio [aOR] 3.28; 95% CI, 2.60-4.13). Furthermore, patients with AP demonstrated increased odds of respiratory failure (aOR 7.50; 95% CI, 6.35-8.86), mechanical ventilation (aOR 4.64; 95% CI, 3.68-5.86), severe sepsis (aOR 10.65; 95% CI, 8.15-13.92), and vasopressor use (aOR 3.11; 95% CI, 2.08-4.64). Additionally higher odds of shock (aOR 5.18; 95% CI, 4.10-6.52), acute kidney injury (aOR 2.11; 95% CI, 1.74-2.55), and deep venous thrombosis (aOR 2.13; 95% CI, 1.56-2.92) were seen. Hospitalizations involving AP were associated with significantly prolonged LOS (16.03 vs. 8.05 days; adjusted incidence rate ratio [aIRR] 1.89; 95% CI, 1.76-2.05) and higher total costs ($232,449 vs. $122,488; aIRR 1.84; 95% CI, 1.63-2.07).
Conclusions: Hospitalizations of EC patients complicated by AP are associated with markedly increased odds of in-hospital mortality, severe complications, prolonged LOS, and higher healthcare costs. These findings underscore the necessity for targeted interventions to mitigate AP-associated morbidity and mortality in this high-risk patient population. Further research should focus on optimizing preventative and therapeutic strategies to improve clinical outcomes in this subset of oncology patients.

#2315 Projecting lung cancer incidence in Guam: the impact of smoking prevalence, ethnic disparities, and aging population.

Cabrini Cruz Aguon[1], Grazyna Badowski[1], Aurienne Cruz[1], Grace G. Bordallo[2]

[1]University of Guam, Hagatna, Guam,[2]Guam Department of Public Health and Social Services, Hagatna, Guam

Lung cancer incidence in Guam is slightly lower than in the U.S. overall (50.9 vs. 52.6 per 100,000), but CHamoru and Micronesian populations have significantly higher rates (69.4 and 78.6 respectively). Given the established link between smoking and lung cancer, this study aims to project lung cancer incidence in Guam considering smoking rates across sex, age, and ethnic groups, accounting for the island's aging population (median age increased from 30.4 in 2010 to 33.7 in 2020). Data on 1,157 invasive lung cancer cases reported to the Guam Cancer Registry from 2001 to 2020 for individuals aged 34 and older were analyzed. Variables included age, sex, and ethnicity including CHamoru (52.3%), Filipino (20.9%), Micronesian (9.4%), Asian (6.4%), and White (7%). Smoking prevalence data from the 2011-2020 Behavioral Risk Factor Surveillance System (BRFSS) were used to estimate smoking rates for age × sex × ethnicity strata. A Poisson regression model was used to examine relationships between lung cancer incidence rates and demographic factors, including strata-level smoking prevalence. Temporal trends were evaluated across two periods: 2001-2010 and 2011-2020. Predicted rates were applied to 2020 Guam Census population counts to estimate lung cancer cases for 2021-2030 and the annual percent change (APC). From 2011 to 2020, smoking prevalence in Guam declined from 30.2% to 19% (APC = -3.7), with variation among ethnic groups. CHamoru and Asian males had the highest smoking rates. Micronesians showed the largest decrease (APC = -7.3%, from 35% to 10%), while CHamoru males had the smallest reduction (APC = -2.8%, from 46% to 35%). Lung cancer incidence was significantly higher for individuals aged 75+ compared to those aged 35-44 (IRR = 38, 95% CI: 26.9, 55). Males had over twice the rate of females (IRR = 2.3, 95% CI: 2.0, 2.7). Micronesians and CHamorus had significantly higher rates than Filipinos (IRR = 3.5 and 2.4, respectively). Each unit increase in smoking prevalence was associated with a 2% rise in lung cancer incidence for Micronesians and CHamorus. Projected lung cancer cases over 10 years are highest among CHamoru males (246) and females (130). The model predicts annual increases of 1.2% for males and 0.5% for females, with the largest increases among Asian males (2.6%) and Micronesian females (3.3%). Significant differences in lung cancer and smoking rates exist, with the highest burden among CHamorus and Micronesians. Despite a decrease, Guam's 2020 smoking prevalence remained significantly higher than the U.S. average of 12.5%, indicating persistent disparities. This study highlights the need for targeted tobacco control interventions and screening programs to address the evolving cancer burden. This research was funded by the National Cancer Institute Grant: U54CA143728 (University of Guam)/Grant U54CA143727 (University of Hawaii Cancer Center).

#2317 Historical trends in age of menarche and implications for breast cancer risk in the US population.

Lin Yang[1], Adetunji Torioa[2]

[1]CancerControl Alberta-Alberta Health Services, Calgary, AB, Canada,[2]Surgery, Washington University School of Medicine, St. Louis, MO

Background: Breast cancer incidence is increasing, especially among premenopausal women. Age of menarche is a critical marker of female pubertal development and a known risk factor for breast cancer. We, therefore, examined trends in the age of menarche among females born between 1910 and 2000 as well as the differences by race/ethnicity and country of birth.
Methods: This serial, cross-sectional study analyzed the age of menarche from the nationally representative National Health and Nutrition Examination Survey (NHANES). Participants included noninstitutionalized US women from ten NHANES study cycles (1999-2000 to 2017-March 2020 pre-pandemic). Age of menarche was assessed as the age of first menstrual period by participants responding to the question “How old when you had your first menstrual period?” (range 0-22 years old). Participants who responded with an age of first menstrual period > 16 years were excluded from the current analysis. The year of birth was categorized into eight birth cohorts from 1910-1930, then every 10-year interval to 1990-2000. We calculated the weighted mean age and standard error of age of menarche overall and by birth cohort, race/ethnicity, and country of birth. We calculated weighted prevalences of the age of menarche by ages ≤ 10, 11, and 12 years, overall, and by birth cohort, race/ethnicity, and country of birth.
Results: Data on 24,391 US women were analyzed. For women born between 1910-1930 to those born between 1990-2000, the mean age of menarche declined from 12.9 (95% CI: 12.8 to 10.3) to 12.4 (95% CI: 12.3 to 12.6) years (difference=0.5, 95% CI: 0.3 to 0.7, p for trend<0.001). The significant decline in age of menarche was observed in women of all racial/ethnic groups (non-Hispanic White: 12.9 [95% CI: 12.8 to 13.0] to 12.6 [95% CI: 12.4 to 12.8], difference=0.3 [95% CI:0.01 to 0.5], non-Hispanic Black: 13.1 [95% CI: 12.8 to 13.3] to 12.2 [95% CI: 11.9 to 12.4], difference=0.9 [95% CI: 0.5 to 1.2]; Hispanic: 13.2 [95% CI: 12.7 to 13.8] to 12.1 [95% CI: 11.9 to 12.3], difference=1.1 [95% CI: 0.5 to 1.7]; Others: 13.0 [95% CI: 12.4 to 13.6] to 12.3 [95% CI: 11.9 to 12.6], difference=0.8 [95% CI: 0.03 to 1.5]). The decline in age of menarche was observed in both US (12.9 [95% CI: 12.8 to 13.0] to 12.4 [95% CI: 12.3 to 12.6]) and non-US born (13.3 [95% CI: 13.0 to 13.7] to 12.4 [95% CI: 12.1 to 12.8]) women. Among women in the 1990-2000 birth cohort, 11.1%, 27.9%, and 53.9% of women attained their age of menarche at ages younger than 10, 11, and 12 years, respectively.
Conclusions: Women born in the 1990-2000 birth cohort experienced half a year younger age of menarche compared to those born between 1910-1930, with shaper declines in women of racial/ethnical minorities and those who were non-US born. These shifts suggest a growing proportion of women experiencing menarche earlier, likely contributing to the rising incidence of breast cancer.

#2318 Waist circumference and the risk of cancer: Two-sample mendelian randomization.

Su Hyun Lee[1], Sun Ha Jee[2], Yoon-Jung Choi[1]

[1]National Cancer Center - Korea, Goyong, Korea, Republic of,[2]Yonsei University, Seoul, Korea, Republic of

Background: The normal range of waist circumference for Asians is less than 90 cm for men and less than 85 cm for women, according to the Korean Society for the Study of Obesity (KSSO) guidelines. While observational studies have suggested an association between obesity and cancer, the causality of obesity in cancer development is not fully established. A two-sample Mendelian randomization (MR) analysis was used to assess whether a genetic predisposition index for waist circumference (WC) was associated with overall cancer and 10 site-specific cancer risk.While observational studies have suggested an association between obesity and cancer, the causality of obesity in cancer development is not fully established. A two-sample Mendelian randomization (MR) analysis was used to assess whether a genetic predisposition index for waist circumference (WC) was associated with overall cancer and 10 site-specific cancer risk.

Methods: The MR method can assess potential causal relationships in various diseases. Summary-level data for WC were extracted from The Korean Cancer Prevention Study-II (KCPS-II) Biobank, and summary-level data for cancer were extracted from The Korean Genome Epidemiology Study (KoGES).

Results: There was no causal relationship between WC and total cancer, but a positive correlation was found in colorectal cancer and thyroid cancer (total cancer OR=1.009, 95% CI=0.995-1.023; colorectal cancer OR=1.051, 95% CI=1.011-1.091; thyroid cancer OR=1.037, 95% CI=1.006-1.068). In cervical cancer and prostate cancer, protective results were shown for WC (cervical cancer OR=0.943, 95% CI=0.891-0.998; prostate cancer OR=0.874, 95% CI=0.766-0.998).

Conclusion: The evidence supporting a causal relationship between WC and cancer was limited. Genetically predicted WC was positively correlated with colorectal cancer and thyroid cancer. The current study found causal detrimental effects of WC on several cancers. We propose to strengthen cancer screening in patients with large WC to enable early detection of cancer.

#2319 Anti-diabetes medication use and risk of colorectal polyps: a colonoscopy-based study using natural language processing.

Jessica van Onselen[1], Ryzen Benson[2], Stephanie Richardson[3], Maci Winn[4], Candace Winterton[3], Bejamin Krick[5], Svenja Pauleck[4], Ainhoa Gomez-Lumbreras[4], Polly Newcomb[6], Neli Ulrich[1], John Inadomi[7], Sheetal Hardikar[1]

[1]Population Health Sciences, Huntsman Cancer Institute, University of Utah, Salt Lake City, UT,[2]Department of Biomedical Informatics, University of Utah, Salt Lake City, UT,[3]Huntsman Cancer Institute, Salt Lake City, UT,[4]Population Health Sciences, University of Utah, Salt Lake City, UT,[5]Department of Political Science, Duke University, Durham, NC,[6]Public Health Sciences, Fred Hutch Cancer Center, Salt Lake City, UT,[7]Internal Medicine, University of Utah, Salt Lake City, UT

Purpose: Type-2 diabetes (T2D) has been previously associated with an increased risk of colorectal polyps, but the effect of anti-diabetes medication use on polyp risk remains unclear.
Methods: Using pathology reports from the University of Utah (UU) Enterprise Data Warehouse (EDW), we developed a rule-based natural language processing (NLP) pipeline to extract colorectal polyp diagnoses and features (site, shape, number, size) on 15,679 patients who underwent a colonoscopy at the UU Gastroenterology clinic from 2011-2020. The NLP pipeline, validated by manual abstraction of 350 pathology reports, demonstrated excellent performance (accuracy 91%). We identified 6,556 T2D patients using ICD codes and extracted patient characteristics from the EDW, including age, sex, race, smoking, BMI, and active anti-diabetes medication prescriptions (insulin, metformin, other). Adjusted odds ratios (OR) and 95% confidence limits (95%CI) were calculated for medication use using multivariable polytomous logistic regression models.
Results: A total of 73% of patients with T2D used anti-diabetes medications and were, on average, 62 years old, 76% White, and 50% female, with a mean BMI of 33 kg/m2. Patients taking insulin had a statistically significant increased risk of colorectal polyps compared to patients not taking anti-diabetes medications or those who were taking medications other than insulin [OR(95% CI)= 1.44(1.22,1.70) and 1.36(1.17,1.60)], respectively. Metformin use was not associated with an increased risk of polyps when compared to patients not on anti-diabetes medications [OR(95% CI)= 1.16(1.00,1.34)]. When compared to patients taking medications other than metformin, those on metformin had a decreased risk for polyps [OR(95% CI)= 0.63(0.54,0.74)]. When evaluated by polyp subtype, insulin use was associated with an increased risk for adenoma and serrated polyps [OR(95%CI)= 1.28(1.08,1.53) and 1.76(1.44, 2.16), respectively], compared to no anti-diabetes medication use. Patients taking metformin had an increased risk for serrated polyps [OR95%CI= 1.36(1.11,1.67)], compared to non-users of metformin. When evaluating polyp severity, risks were higher for patients with advanced pathology (advanced adenoma and sessile serrated polyps) compared to those with non-advanced pathology.
Conclusion: Insulin use was associated with an increased risk, while metformin use was associated with a decreased risk for colorectal polyps, compared to patients taking other medications. These results are consistent with some published literature for colorectal cancer, suggesting that these pathways may be acting at the pre-neoplasia stage rather than during neoplastic conversion from polyps to colorectal cancer. Further research is needed to understand how T2D and its treatment contribute to colorectal neoplasia.

#2320 Cardiovascular disease mortality among breast cancer survivors in Puerto Rico: 2004-2019.

Carola T. Sanchez-Diaz[1], **Genesis Rodriguez-Ortiz**[1], Liliana Castro-JImenez[1], Barbara Segarra-Vazquez[2], Francisco Cordova[3], Vivian Colon-Lopez[1], Cynthia Perez-Cardona[4]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Clinical Laboratory Science Program, School of Health Professions, San Juan, Puerto Rico,[3]Section of Cargiology, Veterans Affairs Medical Center, San Juan, Puerto Rico,[4]Epidemiology and Biostatistics, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

Purpose: Cancer and Cardiovascular disease (CVD) are the two leading causes of death in both the United States and Puerto Rico (PR). Breast cancer (BC) survivors, considered since the time at diagnosis, face an elevated risk of CVD mortality, largely due to the cardiotoxic effects of cancer treatments and the presence of shared cardiometabolic risk factors with BC. However, there is a need for studies examining the risk of CVD mortality specifically among BC survivors in PR, one of the most rapidly aging populations in the world. This study aims to assess and compare the risk of CVD mortality among BC survivors and the general population in PR from 2004 to 2019.

Methods: Data on BC survivors were obtained from the PR Central Cancer Registry for the period 2004 to 2019. Follow-up started approximately 12 months after diagnosis to account for treatment completion and extended through 2021. Standardized Mortality Ratios (SMRs) were calculated to compare CVD mortality risk between BC survivors and of the general population of women in PR aged 18 and older. The expected number of deaths was determined using age-, sex- and calendar year-specific mortality rates from the general population, obtained from the National Vital Statistics System.

Results: The overall SMR for CVD mortality among BC survivors was 2.18 (95% CI: 1.99-2.38), with 470 observed, compared to 215.89 expected CVD deaths during the study period. The total person-years at risk amounted to 66,388. A significant positive trend in increased risk of CVD mortality was observed by calendar year ($p < 0.001$), starting with a SMR of 1.51 (95% CI: 1.13-2.03) in 2004 and peaking in 2019 (SMR: 8.39; 95% CI: 4.64-15.15). Women under 60 years of age faced a particularly elevated risk (SMR: 8.48; 95% CI: 5.82-12.37), with SMRs declining to 1.73 (95% CI: 1.53-1.95) in women over 80 years of age.

Conclusion: Our findings reveal a significantly elevated CVD mortality risk among BC survivors in PR, particularly in younger survivors, compared to the general population. Increasing SMRs over time highlight the importance of understanding cardiometabolic risk factors and stress-related social drivers throughout survivorship to guide targeted interventions for improving cardiovascular health.

#2321 Longitudinal evidence of healthy lifestyles slowing biological aging and reducing cancer risk.

J. Jia[1], C. P. Wen[2], H. Tu[1], J. Pan[1], W. Lu[1], M. Yang[1], A. Xu[1], S. Wang[1], W. Li[1], X. Wu[1];
[1]Zhejiang University, Hangzhou, China, [2]National Institute for Data Science in Health and Medicine, Hangzhou, China

Background: Aging is an important risk factor of cancer, and a healthy lifestyle is one possible measure to delay aging. Limited research has investigated the relationship between a healthy lifestyle, biological aging, and cancer incidence.
Methods: This prospective study enrolled 122,023 individuals from the Taiwan MJ cohort. The multivariable logistic regression model was utilized to examine the associations between the healthy lifestyle scores (HLS, integrating never or quitted smoking, non-harmful drinking, active physical activity, healthy body fat percentage, and healthy diet) and biological aging acceleration alteration, which was measured by changes in multi-dimensional aging measure acceleration (ΔMDAgeAccel). The Cox regression model was used to evaluated the joint association of HLS and ΔMDAgeAccel with cancer risk.
Results: Compared to individuals with HLS of 0, increasing HLS was associated with decreased odds of MDAgeAccel increase, with the adjusted odds ratio (aOR) of 0.684 (95% CI 0.557 to 0.841), 0.589 (0.483 to 0.718), 0.500 (0.411 to 0.610), 0.426 (0.349 to 0.519), and 0.379 (0.310 to 0.464) for HLS of 1, 2, 3, 4, and 5, respectively. These results remained consistent across stratifications by baseline aging acceleration status, age group, and sex. Individuals with accelerated aging at baseline and higher HLS exhibited lower odds ratio of persistent aging acceleration. The hazard ratio (HR) for cancer incidence was 0.774 (0.665 to 0.900) for individuals with a higher HLS and decreased MDAgeAccel, 0.932 (0.779 to 1.116) for individuals with a higher HLS and increased MDAgeAccel, compared with those with a lower HLS and increased MDAgeAccel.
Conclusions: Adherence to healthy lifestyle may lower aging acceleration, and reducing cancer risk.

#2325 Anatomical genomic and transcriptomic analyses of Helicobacter pylori-driven gastric transformation.

Yosuke Tanaka, Fumishi Kishigami, Toshihide Ueno, Shinya Kojima, Taiki Hashimoto, Yukinori Yamagata, Takaki Yoshikawa, Shigeki Sekine, Hiroyuki Mano

National Cancer Center Japan, Tokyo, Japan

Helicobacter pylori (HP) drives a chronic inflammation in the gastric mucosa, leading to atrophic gastritis, intestinal metaplasia (IM), and further culminating in gastric cancer. Oncogenesis by HP infection has been mainly attributed to epigenetic dysregulation, and recent advances in the understanding of clonal expansion have shed light on the mutational architecture of IM. However, these analyses have been performed separately, leaving our understanding fragmented. Furthermore, analyses on small-sized tissue cannot determine the spatial events in the entire stomach. These limitations of previous studies highlight the necessity for integrative genomic and transcriptomic analyses using the entire stomach samples. Here, we conducted exome sequencing on 295 crypts isolated from the gastric mucosa and 13 tumors of 13 individuals. In addition, we performed an extensive investigation of the spatial distribution of cell clones by characterizing crypts at 5 mm intervals from 360 areas in the pyloric region to the body regions throughout the stomach in 2 patients, which underwent RNA and exome sequencing. Mutational analyses revealed that the expansion of cell clones with gene mutations was accelerated by HP infection and smoking habits. Mutations in cancer-related genes, including *MUC6*, were positively selected in the crypts, specifically in the pylorus region. However, such gene sets mutated in the crypts were different from those in gastric cancer. Macroscopic spatial genomic analyses revealed the distribution profiles of these clones, and spatial transcriptomic examination further clarified an IM-specific expression profile with oncogenic potential. These results suggest a coordinated role for mutation acquisition and transcriptomic activation of the AP-1 signaling pathway or stem-like expression in HP-infected mucosa to drive oncogenesis. Our study elucidated the previously unknown coordinated relationship between clone formation and transcriptomic remodeling of HP-infected gastric mucosa. Given the oncogenic transcriptional circuit of IM, early Helicobacter pylori eradication, smoking cessation, and close monitoring of IM may be beneficial to reduce the opportunity of additional hazardous mutation acquisition.

#2326 Nicotinamide adenine dinucleotide precursors delay pancreatic cancer initiation and progression by promoting DNA repair and improving mitochondrial function.

Faith Nakazzi[1], Mehrdad Zarei[2], Omid Hajihassani[1], Hallie J. Graor[2], Priyashree Sunita[2], Goutam Dey[2], Akram S. Shalaby[3], Jordan M. Winter[3]

[1]Department of Biochemistry, Case Western Reserve University, Cleveland, OH,[2]Department of Surgery, Case Western Reserve University, Cleveland, OH,[3]Division of Surgical Oncology,, University Hospitals Cleveland Medical Center, Cleveland, OH

Background: Pancreatic cancer (PC) is the third leading cause of cancer-related death in the United States, with a dismal 5-year survival rate of just 13%. Because PC has no screening biomarkers and is aggressive and resistant to most chemotherapy, focus should be put on discovering PC preventative alternatives. Cancer progression is driven primarily by increased cellular reactive oxygen species and mitochondrial dysfunction in cells, which promote somatic DNA mutations and, eventually, cancer initiation. Nicotinamide adenine dinucleotide (NAD+) precursors have shown promise in maintaining redox balance, cellular signaling, DNA repair, and mitochondrial function in aging-related non-malignant conditions. We investigated the impact of NAD+ supplementation on stressed pancreatic ductal epithelial cells and PC progression in an autochthonous pancreatic cancer mouse model.
Methods: We evaluated three NAD+ salvage pathway precursors Nicotinamide mononucleotide (NMN), Nicotinamide (NAM), and Nicotinamide riboside (NR) on non-transformed pancreatic ductal epithelial cell lines (HPDE, HPNE) under various stressors: phenformin (to simulate mitochondrial dysfunction), oxaliplatin (to induce DNA damage), and hydrogen peroxide (to induce oxidative stress). We assessed cell viability, mitochondrial function, reactive oxygen species (ROS) levels, DNA repair, and mutation rates. Additionally, we treated $p48^{Cre/+}$-$LSL\text{-}KRAS^{G12D/+}$ mice with either vehicle or NAM (400mg/kg for 6 months starting at 8 weeks), sacrificed the mice, and obtained pancreases to asses pancreatic intraepithelial neoplasm (PanIN) progression, DNA damage, and immunological markers.
Results: NAM-treated mice showed predominantly focal low-grade PanINs, while vehicle-treated mice developed primarily diffuse high-grade PanINs, indicating delayed cancer progression. There were increased H2AX foci, increased inflammation markers (Cox-2 and pSTAT3), and increased lipid peroxidation in vehicle-treated mice's pancreases compared to those treated with NAM. In vitro, NMN enhanced cell survival under stress due to improved oxygen consumption rate, increased ATP production, and reduced cellular reactive oxygen species levels; NMN treatment also promoted Nrf-2 nuclear translocation and increased expression of superoxide dismutase and glutathione. NMN supplementation also enhanced DNA repair through increased PARylation. These effects resulted in reduced mutation rates in NMN-treated cells.
Conclusions: NMN protects pancreatic epithelial cells from stress by enhancing DNA repair, improving mitochondrial function, and maintaining redox homeostasis. These mechanisms likely contribute to the delayed cancer progression observed in NAM-treated mice, suggesting that NAD+ precursors are promising candidates for pancreatic cancer prevention.

#2327 Boosting cancer vaccine efficacy with Vitamin E for immunoprevention of ER- breast cancer.

Yi Xiao, Yuan Zhang, Yunhai Li, dihua Yu

UT MD Anderson Cancer Center, Houston, TX

Estrogen receptor negative (ER-) breast cancers have worse prognoses with no effective prevention strategies. Developing safe and effective tactics for immunoprevention of poorly immunogenic breast cancers is highly challenging. Recently, we found that vitamin E (VitE) stimulates dendritic cell (DC) functions and potentiates anti-tumor immunity of immunotherapies. Here, we explored whether VitE can enhance anti-tumor immunity of cancer vaccines for immunoprevention of ER- breast cancer. Indeed, VitE, delivered as a vaccine adjuvant, significantly increases dendritic cell antigen presentation and boosts potent antigen-specific T cell responses. We noted that local injection of VitE with vaccines yielded substantially higher efficacy than oral VitE administration Moreover, compared to the vehicle-treated and vaccine only groups, VitE, given as vaccine adjuvants, significantly delayed tumor outgrowth and extended tumor-free survival in multiple mammary tumor transplantation models and in spontaneous mammary tumor model of MMTV-neu transgenic mice, whereas anti-PD1 administration showed a marginal effect in these tumor models. Mechanistically, in addition to targeting DC checkpoint SHP1, VitE fosters antigen uptake, increases co-stimulatory molecules CD80/CD86/CD40 expression and downregulates PD-L1 in DCs, that ultimately boosts antigen-specific effector/memory T cells. Furthermore, VitE administration altered landscapes of CD8+ effector T cells and fostered their transition to memory T cells. Together, our study demonstrates that VitE potentiates cancer vaccine efficacy via DCs and memory T cells, thus can be given as a safe and effective adjuvant of cancer vaccine for immunoprevention of ER- breast cancer.

#2328 Predictive effect of IGFBP-3 on low-dose tamoxifen efficacy in non-invasive breast cancer in the phase III Tam-01 trial.

Harriet Johansson[1], Debora Macis[1], Martino Oliva[2], Matteo Puntoni[3], Eva Blondeaux[4], Aliana Guerrieri-Gonzaga[1], Valentina Aristarco[1], Irene Maria Briata[2], Tania Buttiron-Webber[2], Alessio Carbone[2], Luca Boni[4], Matteo Lazzeroni[1], Davide Serrano[1], Livia Giordano[5], Maria Digennaro[6], Laura Cortesi[7], Francesco Millo[8], Katia Cagossi[9], Giuseppe Aprile[10], Fabio Falcini[11], Elisa Gallerani[12], Bernardo Bonanni[1], **Andrea De Censi**[2]

Tamoxifen 5 mg/d (Babytam) decreases the incidence of new breast cancer events by 42% in women with breast intraepithelial neoplasia with limited toxicity, providing a new treatment option in these disorders. However, predictive biomarkers of Babytam efficacy are lacking. We studied whether baseline IGF-I, insulin-like growth factor binding protein-3 (IGFBP-3), estradiol, sex hormone-binding globulin (SHBG), and their ratios predict Babytam efficacy on breast cancer events in a pre-planned secondary analysis.Within a 1:1 placebo-controlled, randomized trial of Babytam or placebo given for 3 years after surgery in women with ADH or LCIS or DCIS, 406/500 participants consented to blood sampling at baseline, at 1 and 3 years. Serum IGF-I, IGFBP-3, estradiol, SHBG levels and their ratios were measured by chemiluminescent immune assays. Biomarker changes were estimated using mixed-effects models, and Incidence Rate Ratios (IRR) were calculated after 10 years of follow-up with Poisson regression. Subgroup analyses were performed using an interaction test and subpopulation treatment effect pattern plot.Baseline levels of IGFBP-3 in the three top quartiles (≥3.44 ug/mL), but not in the lower quartile, predicted greater Babytam efficacy compared to placebo (p-interaction=0.006, Table). Baseline IGF-I, estradiol, or SHBG were not predictive of Babytam efficacy, whereas the IGF-I/IGFBP-3 ratio was borderline significant (p-interaction=0.067).High baseline levels of IGFBP-3 (≥3.44 ug/mL) predicted Babytam efficacy and may help differentiate which women benefit most from this treatment.

Table. Mean event rate (x1000 person-years) by treatment arm and baseline IGF-I, IGFBP-3, E2, SHBG, and IGF-I/IGFBP-3 and E2/SHBG ratio at 10 year follow-up.

#2329 Understanding epigenetic-driven transposable re-expression and its impact on immune activation in the serrated pathway of colorectal tumorigenesis.

Zhengyi Chen[1], Sojung Lee[2], Alan J. Simmons[1], Robert J. Coffey[3], Martha J. Shrubsole[3], Jason W. H. Wong[2], Ken S. Lau[1]

[1]Vanderbilt University School of Medicine, Nashville, TN,[2]University of Hong Kong, Hong Kong, China,[3]Vanderbilt University Medical Center, Nashville, TN

An active immune system plays a central role in preventing the progression from precancerous lesions to invasive cancers. Identifying the molecular markers that dictate effective immune surveillance is essential for advancing cancer prevention strategies. A higher level of immune cell infiltration is observed in serrated lesions, a subtype of colorectal premalignant lesions, in comparison to the other common subtype, conventional adenoma. However, the mechanism underlying the elevated immune response in serrated lesions remains poorly understood because hypermutation, which is considered as the source of immunogenicity conventionally, is absent in serrated lesions. One alternative source of immunogenicity can be transposable elements (TEs), which are mobile DNA sequences typically epigenetically silenced in mature tissues but expressed in fetal developmental stage and cancers. We hypothesize that aberrant expression of TEs drives immune activation in serrated lesions. Notably, only serrated lesions exhibit a fetal gene expression program, suggesting a potential link to epigenetically deregulated TE expression mediated by the PIWI-piRNA pathway. We quantify and compare TE expression and methylation levels across subtypes of colorectal precancers and normal tissues, integrating these data with spatial transcriptomics to elucidate the relationship between TE expression and immune cell distribution. Our results reveal a significantly higher number of differentially expressed TEs in serrated lesions compared to conventional adenomas and suggest a positive association between TE expression and the immunogenic landscape in serrated lesions. These findings inform strategies to reprogram colorectal precancers toward an anti-tumor immune environment, offering potential benefits for cancer prevention and early immuno-intervention strategies in colorectal cancer.

#2330 The Jekyll and Hyde of DARC: Balancing prognosis and metastasis in breast cancer.

J. Talukdar, T. Srivastava, R. Dhar, S. Karmakar;
All India Institute of Medical Sciences (AIIMS) New Delhi, Delhi, India

Background: DARC, a decoy receptor for chemokines, is implicated in breast cancer progression. Understanding its interplay with key molecular markers and its impact on tumor behaviour is crucial for developing targeted therapies.
Methodology: This study employed a multi-faceted approach, including immunohistochemistry, quantitative PCR, and bioinformatical analysis of publicly available datasets (TCGA and METABRIC). The DARC, CCL8, c-MYC, ALDH1, and CHEK2 expression patterns were analyzed in breast cancer tissues. Correlation analyses and survival analyses were performed to assess the prognostic significance of these markers.
Results: Our findings revealed a positive correlation between DARC and CCL8 expression, suggesting a potential role of DARC in promoting tumor cell migration and invasion through CCL8 signalling. Additionally, elevated DARC expression was associated with increased c-MYC, ALDH1, and CHEK2 levels, indicating its potential involvement in tumor cell proliferation, stemness, and chemoresistance. Bioinformatical analysis further corroborated these findings and identified DARC as a potential prognostic biomarker.
Conclusion: These results highlight the complex interplay between DARC and key molecular markers in breast cancer. Targeting DARC may offer a novel therapeutic strategy to inhibit tumor progression and improve patient outcomes. Further validation studies are warranted to elucidate the precise mechanisms underlying DARC-mediated tumorigenesis.

#2331 WNT/β-catenin modulation by activation of the farnesoid X receptor for interception of familial adenomatous polyposis-associated colorectal cancer.

Abel Martel-Martel, Nan Deng, Fahriye Duzagac, Jacklyn V. Thompson, Mahira Zaheer, Araceli Garcia-Gonzalez, Krishna M. Sinha, Eduardo Vilar

Clinical Cancer Prevention, The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Familial adenomatous polyposis (FAP) is a hereditary syndrome caused by germline alterations in *APC* and characterized by the presence of multiple colorectal adenomas that are associated to high risk of colorectal cancer (CRC) development. *APC* mutations dysregulate WNT signaling leading to aberrant β-catenin activity. The Farnesoid X Receptor (FXR) is a key regulator of bile acid homeostasis and has been identified as a suppressor of intestinal tumorigenesis. FXR downregulation has been shown to exacerbate β-catenin activity, further promoting malignant transformation of intestinal stem cells. Therefore, pharmacologic FXR activation represents a promising preventive strategy for the FAP population. In this study, we investigate the ability of the FXR agonist obeticholic acid (OCA) to restore FXR function and stabilize WNT/β-Catenin signaling for CRC interception in FAP.

Methods: The effect of OCA was evaluated on colonic organoids generated from a FAP mouse model (*Cdx2-Cre;Apc*$^{LoxP/+}$), 4 different human CRC cell lines, and patient-derived intestinal (duodenal and colonic) organoids from FAP patients. Organoids and cell lines were treated with OCA at different doses and time points followed by analyses of cell viability, apoptosis, and gene expression. Co-culture assays with patient-derived organoids and matched peripheral blood mononuclear cells (PBMCs) were performed to assess immune-related FXR regulation after OCA treatment.

Results: OCA treatment led to a time- and dose-dependent decrease in cell viability in both mouse- and patient-derived organoids as well as in human CRC cell lines. In mouse-derived organoids, OCA significantly restored the gene expression levels of *FXR* (*Nrh14*) and downstream targets (*Nr0b2* and *Fabp6*), and increased *Epcam* levels while reducing intestinal stem cells (*Lgr5* and *Wnt3a*), cancer stem cells (*Ascl2*, *Myc*, *Axin2*, and *Acox2*), proliferation (*Ki67*), and invasion (*Vimentin*) markers. Further, FXR restoration by OCA also promoted apoptosis in all CRC cell lines tested in a dose-dependent manner. To further assess the effects of OCA on anti-tumor immune responses, a co-culture experiment using colonic and duodenal organoids from FAP patients and their matched PBMCs, showed that the combination of 10μM OCA with PBMCs significantly reduced cell viability after 48 hours of co-culture. Low and high doses of OCA are currently being analyzed *in vivo*, alongside single-cell RNA sequencing from co-culture assay to identify epithelial cell clusters affected by OCA exposure.

Conclusions: Taken together, our findings reveal that OCA has promising potential to intercept CRC progression in FAP patients, thus providing further support for ongoing clinical trials (NCT05223036) with the FXR agonist OCA in FAP patients.

#2332 Ductal carcinoma in situ: Potential to metastasize? A nationwide cancer registry-based study.

Merle van Leeuwen, Sandra van den Belt- Dusebout, Petra Kristel, Lennart Mulder, Joyce Sanders, Carmen Vlahu, **Esther H. Lips**, Jelle Wesseling

Netherlands Cancer Institute, Amsterdam, Netherlands

Background: The current clinical paradigm around Ductal Carcinoma in Situ (DCIS) is that it consists of malignant cells confined to the breast ducts, and therefore cannot metastasize. Nonetheless, several studies have reported DCIS with metastasis in the sentinel lymph node (SN+). For accurate risk communication and management, we aimed to assess to what extent registered “metastatic spread” in DCIS could be explained by limitations in registration or missed invasive breast cancer at time of diagnosis.
Methods: Data from the nationwide cancer registry and national pathology database on women diagnosed with DCIS SN+ in the Netherlands, spanning from 2005 to 2020, was curated and reviewed, taking into account their histories of prior DCIS, invasive breast cancer, or other malignancies. Cases were excluded from further analysis if pathology data indicated registration errors, DCIS mixed with other lesion types, or diagnostic uncertainties. Next, hematoxylin and eosin-stained tissue slides of eligible DCIS SN+ cases were independently reviewed by two pathologists to assess the presence of invasive breast cancer and SN status. Additional immunohistochemical staining (CK 5/6 or CK 8/18) was performed when findings were unclear. Inter-observer agreement was evaluated using the linearly weighted Kappa statistic.
Results: A total of 30,863 patients were identified with a DCIS diagnosis between 2005 and 2020, of which 16,070 (52%) underwent SN biopsy according to cancer registry data. SN+ was registered in 454 (3 %) patients: 47 (10%) had macrometastases (>2 mm), 78 (17%) had micrometastases (>0.2 to <= 2 mm), and 329 (73%) were positive for isolated tumor cells (<= 0.2 mm). Out of the 454 registered DCIS SN+ cases, 273 (60%) were excluded from further investigation based on pathology data, including registration errors (n=44), DCIS mixed with other lesions (n=147), and diagnostic uncertainties (n=82). Tissue material of 46 (37%) out of 125 registered cases with macro- and micrometastases was reviewed. Observer variability in assessing the presence of invasive breast cancer was high (k= 0.14; 95% CI 0.08 - 0.34; $p = 0.12$) and additional CK 5/6 staining was requested for 38 cases. Two cases were classified as primary invasive breast cancer, 25 as pure DCIS, while 19 remained inconclusive, due to variation in tissue sections or suboptimal tissue quality. In six cases the SN was scored as negative by pathology revision, likely due to tissue section variability.
Conclusions: Our study indicates that DCIS in itself has minimal to no metastatic potential. Ongoing clonality analysis of 9 cases with macrometastases aims to determine whether the SN metastases are clonally related to the DCIS lesions.

#2333 TRAIL-inducing imipridones ONC201, ONC206, and ONC212 demonstrate anti-neoplastic effects in colonic adenoma-derived organoids.

Alexis J. Lannigan[1], Jasper Chan[1], Lanlan Zhou[1], Varun V. Prabhu[2], Michael Dame[3], Dean Brenner[3], Jason Spence[3], Wafik S. El-Deiry[1], Alexander G. Raufi[1]

[1]Legorreta Cancer Center at Brown University, Providence, RI,[2]Chimerix Inc., Durham, NC,[3]University of Michigan Medical School, Ann Arbor, MI

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related death in the United States. Currently, screening is the most effective method to reduce mortality from CRC. Chemoprevention, which aims to delay or even prevent the onset of CRC through eradication or prevention of precursor colonic adenomas, is an alternative strategy to address this problem. The imipridone Dordaviprone/ONC201 is a potential chemopreventive agent that has been shown to induce apoptosis in cancer cells through both upregulation of tumor necrosis factor-related apoptosis-inducing ligand (*TRAIL*) and the integrated stress response. More recently, we have shown that ONC201 induces *TRAIL* and apoptosis in a dose-dependent manner in adenoma-derived organoids and reduces adenoma formation in the $Apc^{min/+}$ CRC mouse model. We hypothesized that ONC201's analogues, ONC206 and ONC212, would similarly enhance human colonic adenoma cell death through both *TRAIL*-dependent and *TRAIL*-independent mechanisms. We therefore evaluated the effects of ONC206 and ONC212 in two adenoma-derived organoid lines: one developed from an adenoma from an individual with familial adenomatous polyposis (FAP) and the second from a sessile serrated adenoma (SSA).

Methods: Sensitivity of the FAP and SSA organoid lines to ONC206 and ONC212 was assessed using CellTiter-Glo® luminescent cell viability assay. Organoids were plated in triplicates and treated with ONC206 and ONC212 (concentration ranging from 0 uM to 10 uM). Results were analyzed after 72 hours of incubation. Western blotting was performed on lysates generated from both FAP and SSA organoids treated with either DMSO, ONC206, or ONC212 for 24, 48, or 72 hours. Co-culture experiments were performed with the adenoma-derived organoids (dyed using blue CMAC dye) and human NK-92MI cells (dyed with green CMFDA dye) treated with either DMSO, ONC201, ONC206, or ONC212. Fluorescent images following administration of red live/dead dye were performed using DAPI, FITC, and cherry red channels on ImageXpress® at 0, 24, 48, and 72 hours.

Results: ONC206 and ONC212 demonstrated antineoplastic effects on adenoma-derived FAP and SSA organoids, with half maximal inhibitory concentrations (IC50) less than that of ONC201 in FAP and SSA organoids. As was noted in ONC201 studies, the mechanism of action of ONC206 and ONC212 appears to be mediated through modulation of multiple pathways including the *TRAIL* pathway (*TRAIL* and *DR5* upregulation) and the integrated stress responses (*ATF4* upregulation). Co-culture with NK cells revealed a significant increase in NK-mediated organoid cell death. The ability of ONC206 and ONC212 to enhance NK-mediated killing is being evaluated. Further analysis of the effects of ONC206 and ONC212 on stemness markers are currently underway and may reveal other potential biomarkers and chemopreventive strategies for ONC206 and ONC212.

#2334 Immunologic and proteomic biomarkers of progression risk in Barrett's esophagus.

H. Park[1], C. Lewis[1], A. Omstead[1], E. Grayhack[1], C. Sherry[1], K. Xiao[1], G. Kochhar[1], M. Landau[1], D. Stairs[2], A. H. Zaidi[1], P. L. Wagner[1];

[1]Allegheny Health Network, Pittsburgh, PA, [2]The Pennsylvania State University, Hershey, PA

Barrett's esophagus (BE) is an established risk factor for the development of high-grade dysplasia (HGD) or esophageal adenocarcinoma (EC), but clinical predictors of progression remain poorly defined. Biomarkers of progression risk are therefore in high demand, and in this study we examined the utility of immune cell density and proteomic profiling to identify progression risk indicators in biopsy samples from patients in surveillance for BE. Formalin-fixed paraffin embedded tissue samples (n=58) from patients with non-dysplastic BE undergoing surveillance biopsy were examined. During follow-up, 25 patients were diagnosed with HGD or EC ("progressors"), while 33 patients did not during at least 5 years of subsequent surveillance ("non-progressors"). To analyze immune markers for cell densities, samples were stained for CD3 and CD8 positive lymphocytes, CD68/CD86 co-positive ("M1- like") macrophages, and CD68/CD206 co-positive ("M2-like") macrophages. Regions of interest (ROI) were selected from the lamina propria of the gastroesophageal junction. Subgroup comparisons of cell density were carried out using the Wilcoxon rank sum test and logistic regression for the progression outcome. Proteomic profiling was assessed using label-free, liquid chromatography-tandem mass spectroscopy (LC-MS/MS), using data-independent acquisition. The raw LC-MS/MS data were searched using Spectronaut against a spectral library generated from 6 progressor and 6 non-progressor samples. Differential protein expression analysis was conducted using Perseus to compare the progressor and non-progressor groups. A total of 728 ROIs were examined for lymphocytes. lymphocyte cell densities were lower in progressors vs. non-progressors (CD3+: $p=0.03$; CD8+: $p=0.003$), as was the CD8:CD3 cell density ratio ($\bar{x}$: 0.66 vs 0.84, $p<0.0001$). On logistic regression, CD8+ cell density ($p=0.003$) and CD8:CD3 ratio ($p=0.007$) were significantly associated with progression. A total of 587 and 489 ROIs were examined for M1 and M2 cell densities, respectively. M1 like macrophages were significantly increased in progressors vs non-progressors ($\bar{x}$: 93.4 vs 35.4, $p=0.0004$). A total of 7,209 proteins were identified across the samples, among which 163 were differentially-expressed based on progression risk (false positive rate<0.05). 4 major GO processes and KEGG pathways were associated with progressors: rRNA processing, Wnt signaling, bacterial invasion of epithelial cells, and G protein-coupled receptor signaling. In this study, we present immunologic and proteomic biomarkers of progression risk in BE. More comprehensive assays for immune microenvironment and mechanistic studies are planned in a prospective BE surveillance cohort obtained from an ongoing registry-repository study. The enhanced understanding of malignant progression in BE could provide opportunities to improve surveillance or prevent progression in the future.

#2335 Predicting cirrhosis risk in patients with metabolic dysfunction-associated steatotic liver disease.

P. Sherpa[1], S. Armasu[2], J. Frank[2], I. Yan[1], K. Wangensteen[3], T. Patel[1], S. Antwi[1];
[1]Mayo Clinic Florida, Jacksonville, FL, [2]Mayo Clinic Rochester, Rochester, MN, [3]Mayo Clinic, Rochester, MN

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects about 32% of adults worldwide and is projected to increase in many parts of the world. Liver cancer is a recognized complication of end-stage MASLD. An estimated 20% of patients with MASLD will progress to cirrhosis, a premalignant state in liver cancer evolution. Because MASLD is usually asymptomatic, its progression to cirrhosis can be difficult to detect early for timely intervention. There are currently no known biological markers for predicting cirrhosis risk in patients with MASLD, making it challenging to identify patients at risk of disease progression. The aim of this study was to identify plasma protein biomarkers that can predict future cirrhosis development in patients with MASLD.
Methods: We performed a nested case-control study among patients with MASLD at baseline who later progressed to cirrhosis and control patients with MASLD at baseline who never progressed to cirrhosis, matched on age at MASLD diagnosis (± 1-year), sex, race, year of blood sample collection, and length of follow-up (± 1-year). An aptamer-based array (SOMAscan™) platform was used to measure over 7000 proteins in baseline plasma samples obtained from the participants. The study sample was split 70/30 for training and validation analyses. We identified plasma protein biomarkers significantly differentially expressed in the training sample, adjusting for multiple testing with Bonferroni-corrected p-values. The significant set of proteins from the training set was used for prediction modeling in the validation sample, computing prediction metrics (area under the curve [AUC], sensitivity, specificity, and accuracy).
Results: A total of 64 MASLD to cirrhosis cases matched to 64 MASLD controls were included in the analysis. Six protein biomarkers (*PTPRU, ATL2, MFAP4, C7, CSTN2*, and *COLEC11*) were overexpressed in cases, compared to controls, in the training data. Prediction modeling of the six-protein biomarker panel in the validation sample yielded an AUC = 0.85, sensitivity = 0.72, specificity = 0.78, and accuracy = 0.75.
Conclusions: We have identified a panel of six plasma protein biomarkers that predict risk of cirrhosis development in patients with MASLD. These proteins could serve as candidates for future mechanistic studies on MASLD progression to advanced liver disease. If validated in larger studies and with assays suitable for clinical laboratory testing (e.g., ELISA), these protein biomarkers could be useful clinically for cirrhosis risk prediction in MASLD patients, and hence those at risk of liver cancer, enabling timely surveillance or interventions to prevent disease progression.

#2336 Discovering plasma proteins associated with common solid cancer incidence in ARIC.

Ziqiao Wang[1], Vernon A. Burk[2], Nilanjan Chatterjee[1], Elizabeth Platz[2]

[1]Department of Biostatistics, Johns Hopkins University, Baltimore, MD,[2]Department of Epidemiology, Johns Hopkins University, Baltimore, MD

Background: Plasma proteins, reflecting both exogenous and endogenous factors, could serve as the basis for risk stratification to guide decision-making for primary and secondary prevention of cancer in adults. Published studies have investigated the prospective risk of cancers and other chronic diseases associated with Olink-based proteomic data available in the UK Biobank Study. There is a need for further investigations based on alternative measurement platforms, longer follow-up data, and diverse populations.
Aim: Identify proteins measured by SomaScan assay® 5K that are associated with risk of solid cancers in the Atherosclerosis Risk in Communities (ARIC) study, a prospective cohort of middle-aged and older Black and White men and women.
Methods: The study was conducted based on a cohort of 9,495 individuals for which a total of 590, 416, 22, 97, 271, 88, 136 incident cancers of prostate, lung, liver, kidney, colorectal, pancreatic, and bladder were observed over a maximum follow-up period of 25.9 years. Log_2-transformed relative fluorescence unit of 4,955 SOMAmers measured in plasma collected at Visit 2 were adjusted in a linear regression model including proteomic PEER factors, study sites, and ten genetic principal components (PCs). Corrected protein quantifications based on rank-inverse normalization of the residuals were used in the analysis. Incident cancers were ascertained primarily by cancer registry linkage. The Cox regression model and time-dependent coefficient Cox model for age at Visit 2 were applied to estimate associations between individual proteins and each solid cancer risk, adjusting for potential environmental risk factors, race, genetic PCs, and PEER factors. Sensitivity analyses examined associations with extended lag-time (diagnosis more than 5 years after Visit 2) and minimally adjusted Cox model for cancer risk.
Results: We identified 32 proteins (19 positively, 13 inversely) for liver cancer risk, 5 proteins (4 positively, 1 inversely) for lung cancer risk in both main and sensitivity analyses at false discovery rate (FDR) <0.05. 2 known proteins (MMP7 and HAVCR1) were identified to be positively associated with kidney cancer, and 2 (ACP3 and KLK3) were identified for prostate cancer. We further identified GSTM1 associated with bladder cancer risk [HR (95% CI): 0.68 (0.56, 0.82)] and found evidence of enrichment of signals for proteomics association with colorectal cancer at nominal threshold $P < 0.05$ (371 proteins for colorectal cancer, 401 proteins for colon cancer only, and 425 proteins for rectal cancer).
Conclusion: We discovered multiple circulating proteins associated with lung and liver cancer risks, and confirmed previously established circulating proteins for kidney and prostate cancer risks. Additional evaluations in independent and large cohort studies and laboratory testing will be necessary to validate our results. Support: NHGRI, NHLBI, NCI, NPCR.

#2337 Prediagnostic circulating proteins and risk of bladder cancer in the European Prospective Investigation into Cancer and Nutrition (EPIC).

Alison Dillman[1], Zhe Huang[1], Joshua Atkins[1], Marc Gunter[2], Pietro Ferrari[3], Antonio Agudo[4], Carlotta Sacerdote[5], David C. Muller[2], Domenico Pali[6], Giovanna Masala[6], Monique Verschuren[7], Nicholas Wareham[8], Raul Zamora-Ros[9], Roel C. H. Zamora-Ros[10], Rosario Tumino[11], Salvatore Panico[12], Vivian Vallon[3], Elio Riboli[2], Karl Smith-Byrne[1], Ruth Travis[1]

[1]University of Oxford, Oxford, UK, United Kingdom,[2]Imperial College London, London, United Kingdom,[3]International Agency for Research on Cancer, Lyon, France,[4]Institut Catala d'Oncologia, Barcelona, Spain,[5]University of Turin, Turin, Italy,[6]Institute for Cancer Research, Prevention and Clinical Network, Florence, Italy,[7]UMC Utrecht, Utrecht, Netherlands,[8]University of Cambridge, Cambridge, United Kingdom,[9]Unit of Nutrition and Cancer, Cancer Epidemiology Research Program, Catalan Institute of Oncology (ICO), Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain,[10]Division of Environmental Epidemiology and Veterinary Public Health, Institute for Risk Assessment S, UMC Utrecht, Utrecht, Netherlands,[11]Iblea Association, Epidemiological Research (AIRE-ONLUS), Ragusa, Italy,[12]University of Naples Federico II, Naples, Italy

Background*:* Bladder cancer is the tenth most common cancer globally. Circulating proteins are key regulators of cellular functions, and proteomic analyses allow for a comprehensive investigation of proteins that may have causal roles in cancer development.

Methods: We investigated the association between plasma proteins and bladder cancer risk in a case-cohort study within EPIC using a SomaLogic assay, comprising 4,047 sub-cohort members (15.3 years mean follow-up) and 254 bladder cancer cases (9.8 years mean follow-up), including 160 urothelial cell carcinoma (UCC) cases and 118 aggressive tumors. Prentice-weighted Cox regression models, with adjustment for smoking and other covariates, were conducted to estimate hazard ratios (HRs) and 95% confidence intervals (CIs), with false discovery rate correction. Covariates included smoking status (never; former; current: ≤15 cigarettes/day, occasional or cigar smoker; current: >15 cigarettes/day), alcohol consumption (mL/day), BMI (kg/m2), diabetes (yes, no), physical activity (inactive; moderately inactive; moderately active; active), education (primary/none, secondary, university degree).

Results*:* Of 7,363 aptamers, we identified 31 significant associations with bladder cancer risk after false discovery rate correction. All HRs changed less than 15% when comparing the multivariable-adjusted to the minimally-adjusted model, and 11 proteins were also conventionally significant among never-smokers. Subgroup analyses identified nine proteins associated with UCC and 31 proteins associated with aggressive tumors. Twenty-five proteins were significant ≥10 years from blood collection. Notably, positive associations for I3L1E1 were observed for bladder cancer overall (HR: 1.23, 95% CI: 1.11-1.36), in never-smokers, and for cases diagnosed ≥10 years from blood collection, for WFIKKN1 in relation to UCC (HR: 1.33, 95% CI: 1.18-1.51), and for IRF4 in relation to aggressive tumors (HR: 1.29, 95% CI: 1.16-1.45).

Conclusions: Evidence for several protein-cancer associations may suggest these could be used as novel biomarkers and provides insight into bladder cancer etiology.

#2338 Plasma proteomics associated with ovarian cancer risk in the Nurses' Health Studies.

Nan Lin[1], Allison F. Vitonis[1], Simon T. Dillion[2], Ngo Long[2], Shelley S. Tworoger[3], Towia A. Libermann[2], Kathryn L. Terry[1], Naoko Sasamoto[1]

[1]Department of Obstetrics and Gynecology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[2]Department of Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA,[3]Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Background: While inflammation and gonadotropin levels are hypothesized to contribute to ovarian cancer initiation, specific proteomic pathways and other potential mechanisms are unclear. Thus, we aimed to identify novel blood-based non-invasive proteomic risk biomarkers for invasive epithelial ovarian cancer.

Method: We measured 7,310 pre-diagnostic plasma proteins using SomaScan v4.1 in 169 incident ovarian cancer cases [140 high-grade serous (HGS) cases] and 169 matched controls nested within the Nurses' Health Studies. We excluded proteins with coefficient of variation ≥ 25% and influenced by delayed processing, resulting in 3,131 proteins included in this analysis. We transformed protein levels to probit scores to achieve normality and used conditional logistic regression modeling to calculate the odds ratios (ORs) and 95% confidence intervals (CIs) per one standard deviation increase in protein levels. We used Gene Set Enrichment Analysis to identify biological pathways and STRING to conduct protein-protein interaction network and functional enrichment analysis. We also conducted analyses restricted to HGS histotype.

Results: All ovarian cancer cases included in the current analysis had blood samples collected years prior to diagnosis (median=14 years). Average age at blood collection was 56.3 years in both ovarian cancer cases and controls. When examining individual proteins associated with ovarian cancer risk, 94 proteins were significantly associated with ovarian cancer risk with nominal p-value<0.05. Biological pathway analysis revealed complement cascade (NES=2.0; FDR p=0.049) and innate immune system (NES=1.5; FDR p=0.049) pathways being upregulated in ovarian cancer cases compared to controls. STRING analysis showed protein-protein interactions were enriched in pathways such as tissue remodeling (e.g., COL6A1, COL18A1, IGFBP2), lipid metabolism (e.g., NCOA2, ME1), and B cell function (e.g., IGLL5, MZB1) in ovarian cancer cases compared to controls. Similar results were observed for HGS ovarian cancer.

Discussion: We conducted a comprehensive examination of the plasma proteins associated with ovarian cancer risk in a prospective cohort study and observed upregulation of pathways related to innate immune system and complement cascade being associated with ovarian cancer risk.

#2339 Development of a blood cell analysis-based AI model for detecting early ovarian cancer signals.

Eunyong Ahn[1], Sungmin Park[1], Sarah Kim[1], Se Ik Kim[2], Hyejin lee[1], Heeyeon Kim[3], Seong Eun Kang[4], Ji Won Park[4], TaeJin Ahn[1], Yong-Sang Song[5]

[1]ForetellMyHealth, Inc., Pohang-si, Gyeongsangbuk-do, Korea, Republic of,[2]Department of Obstetrics and Gynecology, Seoul National University Hospital, Seoul, Korea, Republic of,[3]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]Division of Colorectal Surgery Department of Surgery, Seoul National University Hospital, Seoul, Korea, Republic of,[5]Department of Obstetrics and Gynecology, Myongji Hospital, Gyeonggi-do, Korea, Republic of

Ovarian cancer (OC) remains one of the most lethal gynecologic malignancies, primarily due to delayed detection. Blood cell analysis presents a promising non-invasive diagnostic approach, capable of detecting systemic signals associated with early OC. This study focuses on developing and validating an artificial intelligence (AI)-based diagnostic model to detect OC risk signals using comprehensive blood cell data. To minimize confounding factors, samples from male participants, symptomatic controls, drug-treated individuals, and pre-anesthesia collections were excluded. Additionally, samples with missing data were removed. A total of 185 samples, including 85 for training and 100 for testing, were analyzed, comprising OC, benign tumor, and control groups. The model utilized 24 features: 18 directly measured blood cell parameters (via Sysmex) and 6 derived composite indices, including the systemic immune-inflammation index (SII: [NEUT×PLT]/LYM). A Random Forest algorithm, optimized through 5-fold GridSearch cross-validation and soft voting, was trained and validated with balanced accuracy (BA) as the performance metric. The optimal cutoff values were determined based on the training set's best BA. In the training set, the model achieved a sensitivity of 100.0%, specificity of 92.6%, a positive predictive value (PPV) of 77.3%, and a negative predictive value (NPV) of 100.0%, with an area under the curve (AUC) of 0.987. For the test dataset, the model demonstrated a sensitivity of 75.0%, specificity of 92.9%, PPV of 66.7%, and NPV of 95.1%, with an AUC of 0.923. The platelet-to-lymphocyte ratio (PLT/LYM) and SII emerged as the most influential features, contributing significantly to model performance. The specificity for control samples, excluding benign tumors, was 1 in the training set, and validation confirmed a specificity of 0.984, demonstrating clear separation between the OC and control groups. Composite indices further improved the model's reliability in detecting OC risk signals. This AI-driven blood cell analysis model exhibited strong performance in identifying early ovarian cancer signals, achieving high sensitivity and specificity. By leveraging non-invasive biomarkers, it holds significant promise for clinical implementation in OC screening. Future efforts will focus on expanding the diversity of analyzed samples to better distinguish cancer-specific signals from those associated with other diseases and incorporating molecular markers to enhance the accuracy and precision of the diagnostic algorithm.

#2340 Proteomic profiling of breast tissue: identifying protein associations with breast density in premenopausal women.

Ghazaleh Pourali[1], Chao Li[2], Minsoo Son[3], Young Ah Goo[3], Graham A. Colditz[1], Xingyi Guo[2], Adetunji T. Toriola[1]

[1]Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, Saint Louis, MO,[2]Division of Epidemiology, Department of Medicine, Vanderbilt Epidemiology Center, Vanderbilt University Medical Center, Nashville, TN,[3]Mass Spectrometry Technology Access Center at the McDonnell Genome Institute, Washington University School of Medicine, Saint Louis, MO

Introduction: Mammographic breast density (MBD) is a well-established risk factor for breast cancer. However, the underlying molecular pathways that lead to breast cancer development in women with dense breasts remain less understood. Proteomics is a robust method of understanding these mechanisms by directly analyzing the functional state of cells. However, data on tissue proteomics of premenopausal breast cancer is limited. To address this, we performed proteomic profiling of breast tissues from premenopausal women with breast cancer and examined the associations between protein expression and MBD.
Methods: We performed proteomic profiling of adjacent normal breast tissues in 50 premenopausal women with breast cancer archived at St. Louis Breast Tumor Registry. Samples were analyzed with Orbitrap Eclipse Tribrid coupled with Vanquish Neo LC system (Thermo Fisher Scientific). Data were processed using MaxQuant (v2.5.0.0) with default settings. The Andromeda search engine scored MS2 spectra against tryptic peptides from the UniProt human reference proteome (20,419 entries, release 2023/11). Label-free quantitation was used for relative protein quantification, with precursor mass tolerance set at 4.5 ppm and fragment ion mass tolerance at 20 ppm. A target-decoy approach was used to ensure a false discovery rate of <1%. We performed imputation and quantile normalization in the Perseus framework. We investigated associations of protein expression with MBD (dense vs. non-dense) using logistic regression models, adjusted for confounders. We corrected for multiple testing by the Benjamini-Hochberg procedure. Statistical analyses were conducted in R (v4.3.2).
Results: Out of 3376 proteins, we identified 63 proteins positively associated with MBD, and 84 proteins inversely associated with MBD (adjusted-p <0.05). Top three proteins positively associated with MBD were MBD3 (β=3.49, SE=1.17; p=2.96×10^{-3}), involved in chromatin remodeling, KAT7 (β=2.95, SE=1.07; p=5.75×10^{-3}), a histone acetyltransferase that regulates gene expression, and ERBIN (β=3.54, SE=1.32; p=7.20×10^{-3}), which interacts with ERBB2/HER2. Conversely, top three proteins inversely associated with MBD were GPX4 (β=-1.67, SE=0.58; p=4.12×10^{-3}), an antioxidant enzyme, NDRG1 (β=-1.20, SE=0.42; p=4.31×10^{-3}), involved in stress responses, and CDKN2A (β=-3.02, SE=1.10; p=6.12×10^{-3}), a tumor suppressor that regulates the cell cycle by inhibiting cyclin-dependent kinases.
Conclusions: Our findings reveal several proteins associated with MBD in premenopausal women, some of which are targets of approved drugs, highlighting the potential for targeting them in premenopausal breast cancer prevention. Larger studies are needed to validate these findings. Additionally, these proteins and their downstream pathways can be investigated in preclinical studies to confirm their translational potential.

#2341 Impact of delayed processing on cell-free (cf) DNA quantity and quality using different cfDNA-stabilizing blood tubes: a Connect for Cancer Prevention Pilot Study Cohort.

Jazmyn Bess[1], Domonique Hopkins[1], Norma Diaz Mayoral[2], Heather Cooley[3], Angela de Palatis[2], David Wong[4], David Elashoff[4], Fang Wei[4], Feng Li[4], Mohammad Aziz[4], Chris Karlovich[2], Eric Greenbank[2], Stephanie Weinstein[1], Christian Abnet[1], Marie-Josephe Horner[1], Amanda Black[1], Michelle Brotzman[1], Kathleen Wyatt[1], Lynn Sorbara[1], Matthew R. Young[1], Mia Gaudet[1], Nicolas Wentzensen[1]

[1]National Cancer Institute, Rockville, MD,[2]Frederick National Laboratory for Cancer Research, Frederick, MD,[3]Frederick National Laboratory for Cancer Research, Rockville, MD,[4]University of California, Los Angeles, CA

Background: Prospective evaluations of cfDNA/liquid biopsy assays are critical to assess their potential for improved early detection of cancer. Important knowledge gaps related to blood collection, preservation, and processing practices must be addressed for adequate assay execution.[2] The NCI Connect for Cancer Prevention Cohort Study (Connect) aims to study new approaches in early detection. Connect conducted pilot studies evaluating the STRECK Cell-Free DNA BCT (DNA), Streck Nucleic Acid (NA), and PAXgene tubes to determine the impact of processing time on cfDNA quantity and quality utilizing quality control assays.
Methods: Plasma samples were collected from 40 healthy doners using Streck DNA, Streck NA, and PAXgene tubes through the NCI Frederick Research Donor Program. Half of the samples from each tube set were processed at room temperature immediately and the other half after five days. Three assays were performed to compare cfDNA quantity and quality: (1) Qubit/Spectramax assay measuring total DNA concentration (ng/uL); (2)TapeStation measuring %cfDNA and average fragment size (bp); and (1) an EFIRM Alu assay measuring Alu element concentration (copies/mL). Descriptive analyses were performed to compare metric concentrations between processing time points, with and without samples identified as outliers.
Results: After five-day processing, hemolysis for the PAXgene tubes (50.0%) and the Streck DNA tubes (40.0%), but not the Streck NA tubes (0.0%). No hemolysis was observed before immediate processing. Qubit/Spectramax and TapeStation assays showed that all three tube types had samples with normal fragment size between 50-700bp, over 90% of with normal total DNA concentration of less than 1.00ng/uL, and a majority with more than 60% of cfDNA. Streck DNA had the most outliers with less than 60% cfDNA (n=10) compared to PAXgene (n=9) and Streck NA (n=1). Streck DNA also had more outliers with 1.00 or greater total DNA concentration (n=4) compared to PAXgene (n=2) and Streck NA (n=0). EFIRM Alu results will be available during conference presentation.
Conclusions: Streck DNA, Streck NA, and PAXgene showed variable cfDNA quality and quantity performance. The Streck NA tube had the lowest number of samples with hemolysis and the lowest number of outliers for %cfDNA and total DNA concentration. With respect to preanalytical variables of prolonged processing time and tube type, the Streck Nucleic acid seems most suited at maintaining cfDNA quantity and quality.

#2342 Profiling microRNAs in fecal immunochemical test leftover buffer to improve colorectal cancer screening.

Barbara Pardini[1], Giulio Ferrero[2], Sara Bulfamante[3], Sonia Tarallo[1], Giulia Francescato[1], Davide Ricupero[1], Gianluigi Ferrante[3], Carlo Senore[3], Alessio Naccarati[1]

[1]Italian Institute for Genomic Medicine (IIGM), Candiolo, Italy,[2]Department of Clinical and Biological Sciences, University of Torino, Turin, Italy,[3]Epidemiology and Screening Unit-CPO, University Hospital Citta della Salute e della Scienza, Turin, Italy

Colorectal cancer (CRC) is one of the leading causes of cancer death worldwide, but large screening programs can effectively reduce both incidence and mortality. Fecal immunochemical test (FIT) is widely used in CRC screening programs and cost-effective. However, FIT test shows a low sensitivity for advanced adenomas (AA) and is also prone to false positive results, resulting in unnecessary total colonoscopies (TC). Leftover from FIT samples after hemoglobin measurement may offer unique opportunity to study alternative biomarkers, which may allow adopting a tailored screening approach. Altered miRNA profiles can be detected non-invasively in fecal samples. Our group studying the whole miRNome in stool recently contributed to the identification of a miRNA signature that accurately discriminates sporadic CRC at diagnosis (Pardini et al, Gastroenterology 2023) and demonstrated the feasibility of miRNA profiling in FIT leftovers (Birkeland et al. Mol Cancer 2023). However, a potential implementation of miRNA markers in FIT-based screening has not been fully explored. The aim of the study was to investigate the association of miRNA expression profiles with CRC or adenomas as well as the predictivity of miRNA signatures for outcomes at the subsequent screening round among screens examined within the population-based screening program in Turin, Italy. Small RNA sequencing was performed on leftover FIT samples of 438 subjects: 183 FIT positive (FIT+) detected with colorectal neoplasm (45 early adenomas, 110 AA, and 28 CRC), 93 with FIT+ and negative TC and 162 FIT negative (FIT-) controls. We compared the miRNA expression profiles of FIT+ screens with a negative TC and of those detected with neoplasia. For a subset of 213 subjects with a negative FIT at the previous round, we compared the miRNA profile at the first sample among screens with persistent negative results with those with a positive FIT and neoplasms. An average of 691 miRNAs were detected and 198 among them identified in more than 90% of the samples. Differential expression analyses between FIT+ and FIT- samples showed 379 miRNAs with significantly different levels (adj. $p<0.05$), mainly in AA or CRC. Notably, the previously identified 5-miRNA signature in stool was confirmed able to distinguish in FIT+ subjects with AA or CRC with respect to FIT-. miR-1246 was able to distinguish also subjects with neoplasm from those with negative TC. An increase of miR-1246 levels was observed in leftover samples of subjects at first round of screening who were detected AA or CRC following a positive FIT result at second round with respect to those with FIT- test. The previously identified miRNA signature shows a good performance in discriminating subject with neoplasm within FIT+ subjects. Further analyses to investigate the performance of various miRNA sets according to different FIT levels or screening rounds are ongoing.

#2343 CancerSpot: a multi-cancer early detection test using targeted methylation sequencing.

Urvashi Bahadur[1], Divya Vishwanath[1], Prakash Hiremath[1], Nihesh Rathod[1], Swaraj Basu[1], Sampuran Chakraborty[1], Aastha Tripathi[1], Preetha R T[1], Aditi Chatterjee[1], Arunima Ghosh[1], Sameer Phalke[1], Subuhi Yete[1], Ankita Khan[1], Sweta Sanguri[1], Mohammed Rahman[1], Sewanti Limaye[2], Charles Cantor[3], Vamsi Veeramachaneni[1], **Ramesh Hariharan**[1]

[1]Strand Life Sciences, Bengaluru, India,[2]Sir H N Reliance Foundation Hospital and Research Centre, Mumbai, India,[3]Strand Life Sciences Scientific Advisory Board, New York, NY

Background: Liquid biopsy-based cancer detection is a noninvasive method to identify cell-free DNA (cfDNA) fragment based signatures in the bloodstream characterized by distinct methylation patterns. Tumor-derived fragments (ctDNA) form a tiny fraction of all cfDNA fragments in the bloodstream. ctDNA originating from some specific genomic regions can have altered methylation patterns. Reliable and cost-effective detection of altered methylation pattern in these regions requires a broad targeted sequencing approach.
Methods: We developed CancerSpot, a multi-cancer early detection (MCED) test based on cfDNA methylation signatures in a cohort of 688 cancer patients and 326 healthy controls representing 10 cancer types. A custom genomics workflow prioritizes high-quality reads by rejecting poorly aligned or imperfectly converted data while rescuing reliable reads to calculate methylation scores across genomic regions at the read level accounting for detection of a weak signal from tumor derived DNA. Machine learning (ML) models were developed using methylation signatures from ~7000 genomic markers. A gradient-boosted trees approach with repeated cross-validation incorporated data perturbations to account for variability in lab protocols and sequencing platforms ensuring robust prediction accuracy and error tolerance.
Results: CancerSpot achieved 79% sensitivity and 97% specificity for detecting Stage I-III tumors across 10 cancer types. It also demonstrated a 77% accuracy in identifying the tumor tissue of origin within the top two predictions. The robust workflow enhances detection of tumor-derived cfDNA signals even in samples with low conversion efficiency while mitigating background noise from normal cfDNA. The regions used by the test show strong differential methylation in tumor-normal data from a diverse population in TCGA indicating its wide applicability.
Conclusions: CancerSpot provides a cost-effective and accurate MCED solution tailored to diverse cohorts.

Performance of CancerSpot on a leave-out set.

#2344 Novel multiplex paired-antibody amplified detection (MPAD) assay panel in combination with CA19-9 for early detection of pancreatic cancer using plasma samples.

Malcolm MacKenzie, Matthew Preimesberger, Shu Feng Zhou, Ilya Alexandrov

ActivSignal, Natick, MA

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is an aggressive malignancy with one of the lowest five-year survival rates among major cancers, due to asymptomatic progression and the lack of reliable biomarkers for early detection. CA19-9, the only FDA-approved biomarker related to PDAC, is significantly elevated in many individuals with PDAC, but falls short as a single marker early-detection screen due to its high levels of false negatives and positives. Therefore, identifying a novel biomarker panel to orthogonally buttress CA19-9's sensitivity and specificity is critical for enhancing early PDAC detection.
Objectives: This study is aimed to identify and test protein biomarkers and develop a non-invasive, high performing, affordable diagnostic screen for early-stage PDAC.
Methods: The study cohort included matched healthy controls, patients with benign pancreatic conditions, and early- and late-stage PDAC patients. A Multiplex Paired-Antibody Amplified Detection (MPAD) platform uses paired antibodies conjugated with unique DNA barcodes and optimized epitope selection. Specific read-out is done using NGS. This approach enables the simultaneous detection of multiple biomarkers in a single well. Signal amplification techniques enhance the sensitivity and accuracy of detecting low-abundance biomarkers frequently associated with PDAC.
Results: Using rigorous selection criteria, we designed a novel MPAD panel containing multiple protein targets as biomarkers for PDAC detection. These biomarkers demonstrated significant effect size for differentiating PDAC from non-cancer samples, and demonstrating low correlation with CA19-9, underscoring their complementary nature for this diagnostic application. The combination panel increased sensitivity from 58% (CA19-9 alone) to 89% for All PDAC vs. non-cancer samples, at a specificity of 96% and an AUC of 95.8%. While, for early-stage PDAC vs. non-cancer samples, the sensitivity was increased from 50% (CA19-9 alone) to 90% in the MPAD panel + CA19-9, suggesting that the MPAD panel can effectively buttress CA19-9 and that the combination shows potential as the basis for an early-detection diagnostic. In PDAC samples with low levels of CA19-9, the MPAD panel without CA19-9 showed strong discrimination between PDAC vs. both benign pancreatic and healthy control samples, with sensitivity of 80% and AUC of 86%, suggesting that the MPAD panel has potential to effectively salvage false negative samples missed by CA19-9 alone.
Conclusions: The MPAD panel complements CA19-9 with minimal correlation, providing an independent diagnostic advantage. It significantly enhances the sensitivity of early-stage PDAC detection, particularly in patients with low CA19-9, making it a promising basis for early diagnosis and surveillance.

#2345 Trans-renal DNA: Urine liquid biopsies methodology to increase compliance, convenience, and yield of systemic ctDNA.

Floyd E. Taub, Lindsey Ray, Charles Preston Neff, Elijah Barstis, Charles Henry, Kirsten Arnold

aiGENE, Inc., Golden, CO

Liquid biopsies promise monitoring residual disease, monitoring for minimal recurrence, evaluating the immediate effects of therapy, and even screening healthy subjects for cancer. Access and patient considerations should be built into the system from ground up. The success of all existing screening programs relies more on participation rates than incremental gains in sensitivity and specificity. Resistance to blood draws, especially for underserved patients is high and COVID, immunosuppression, and personal beliefs decrease participation when needle puncture is required. Venipuncture increases costs, biohazard waste and is sufficiently burdensome to lower participation and medical benefit. Urine is truly noninvasive. While long known to contain trans-renal cfDNA (tr-cfDNA), less effort has gone into specifically isolating this subset of urine DNA and using it as a substitute for blood cfDNA in cancer studies. Striking success has been seen but kits modified from blood kits typically isolate predominantly urinary DNA. Methods designed to handle shorter tr-cfDNA fragments are needed. The glomerular filtration limit of ~10 nm permits cfDNA of ≤100 bp to transit into the urine. Nucleosomes exceed 100 nm. Thus, we have designed a system to capture short non-nucleosomal tr-cfDNA. Urine is available in many hundreds of mls, compared to blood typically providing ≤10 mls of plasma. The latter is often insufficient to have the sequence of interest. Even with urine, data suggests that the more tested, the more likely rare sequences, like those from cancer, are detected. Further detailed understanding of diurnal, biological, daily, and weekly longitudinal ctDNA dynamics, in an outpatient setting, is facilitated by urine sampling. Herein we present a patient focused device that allows self-collection of urine voids (up to 500 mls) with immediate stabilization and separation, within minutes, of trans-renal and urothelial DNA onto separate filters contained within a filter cartridge. The tightly captured DNA excludes DNase binding, the DNA is thus stable at ambient temperature. A single filter cartridge can capture multiple voids and can then be sent by standard shipping. Even from small voids ≥2 ug rather than 10-20 ng amounts of cfDNA are collected. This allows higher sensitivity, methods requiring more DNA, as well as reuse should an initial assay fail, and banking for subsequent studies. The system specifically purifies tr-cfDNA based on interaction of the anionic free DNA with cationic filter bound polymer that does not bind urothelial nucleosomal DNA with positively charged histones. In the lab DNA is washed and eluted with simple syringe-based methods resulting in a purified preparation in 10 minutes. This generates a single peak of the expected trans renal size (80-100 bp) on capillary electrophoresis. Included data demonstrate single copy PCR and high quality (95% Q30s) in NGS.

#2346 Association of serum creatinine- and cystatin c-based diagnostic indices for sarcopenia with major chronic diseases.

Fangfang Song, Huijun Zhou, Fubin Liu, Yu Peng, Peng Wang, Jianxiao Gong, Jiale Gu, Ailing Qin

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Sarcopenia is a risk factor for chronic non-communicable diseases. The serum creatinine (Cr)/cystatin C (CysC) ratio (CCR) and the sarcopenia index (SI) have attracted attention as a surrogate marker for sarcopenia but have not been adequately studied in the general population. We aimed to explore the relationships of CCR and SI with major chronic diseases [cancer, cardiovascular disease (CVD), respiratory disease], investigate the validity of CCR and SI as predictors of sarcopenia and propose statistical cut-off values.
Methods: We utilized two large-scale cohorts: the UK Biobank (UKB) and the National Health and Nutrition Examination Survey (NHANES). Serum creatinine and cystatin C levels were measured at baseline to calculate the CCR and SI. Cox regression models were applied to evaluate the impact of CCR and SI on major chronic diseases' incidence and mortality risks. Diagnostic value was analyzed through receiver operating characteristic (ROC) curves. The Youden index was calculated to determine the optimal cut-off points. Sarcopenia was then defined separately utilizing CCR, SI, and the European Working Group of Sarcopenia in Older People 2 criteria.
Results: CCR and SI had negative associations with incidence and mortality risks of major chronic diseases as well as all-cause mortality. For the UK general population, the optimal cut-off values of CCR and SI for sarcopenia were 95.246 and 82.018 in men and 79.326 and 68.516 in women, respectively, with areas under the ROC curves (AUCs) of 0.717 and 0.709 in men, and 0.693 and 0.682 in women, respectively. For the USA general population, the optimal cut-off values of CCR and SI for sarcopenia were 94.521 and 85.296 in men and 90.993 and 76.904 in women, respectively, with AUCs of 0.755 and 0.752 in men and 0.595 and 0.588 in women, respectively. Furthermore, in the UKB database, CCR- and SI-defined sarcopenia were associated with a higher risk of pan-cancer and CVD incidence, as well as an increased risk of mortality from major diseases. In addition, CCR- and SI- defined sarcopenia in the NHANES database were positively associated with pan-cancer prevalence in women, and CCR-defined sarcopenia was dominantly correlated with an increased risk of mortality from major diseases in men. It is notable that CCR- and SI-defined sarcopenia were more strongly associated with the risks of major chronic diseases compared to EWGSOP2-defined sarcopenia.
Conclusions: CCR and SI are both negatively associated with the incidence and mortality risks of major chronic diseases in the general population and may serve as surrogate markers for sarcopenia. Considering serum Cr and CysC commonly assessed in clinical practice, the application of Cr and CysC-derived CCR and SI may facilitate the early detection of sarcopenia and the prevention of chronic diseases in the general population.

#2347 A genetic test for skin cancer shows potential for accelerating early personalized chemoprevention in ultra-high risk transplant patients.

Mathias Seviiri, Nirmala Pandeya, Catherine M. Olsen, Matthew H. Law, David C. Whiteman, Stuart MacGregor

Population Health, QIMR Berghofer Medical Research Institute, Brisbane, Australia

Background: Transplant patients are at extreme risk of multiple invasive skin cancers. Chemopreventive medication can reduce this risk by ~50%, but clinicians are unable to identify high-risk patients before cancer onset.
Objective: To assess the efficacy of a genetic test for skin cancer to identify ultra-high risk transplant patients who might benefit from chemoprevention or develop skin cancers with poor prognostic features.
Methods: We developed a polygenic risk test for skin cancer using data from 1.2 million people using a Bayesian approach that models genetic information from the whole genome. We applied the genetic test to a cohort of transplant patients (STAR n=357) from a high UV environment in Australia to assess whether it could predict ultra-high risk individuals suitable for chemoprevention.
Results: In the STAR cohort, higher genetic risk patients were more likely to: develop skin cancer (OR=2.04, 95%CI=1.54-2.71, P=8.72e-07), be treated with cancer-preventive medication (e.g. acitretin: OR=2.55, 95%CI=1.31 - 4.95, P=5.62e-03), have skin cancers with poor prognostic features, have poorly differentiated tumors (OR=2.29, 95%CI=1.39-3.77, P=1.18e-03), have tumors with unclear margins (OR=2.09, 95%CI =1.03-4.25, P=0.041), have large tumors >2cm (OR=4.09,95%CI=1.88-8.90, P=3.92e-04), and have highly invasive disease (OR=1.95, 95%CI=1.18-3.23, P=9.06e-03). We are now conducting a comparative analysis in a large cohort (QSkin) of non-transplantees.
Conclusion: Our genetic test for skin cancer has the potential to identify ultra-high risk transplant patients who should be prioritized by clinicians for personalized early chemoprevention.

#2348 Unveiling dichotomies between liver cancer and adjacent normal tissues in Wilson's disease model.

R. Adhikari[1], C. Dash[2], R. Roy[2];
[1]The Quarry Lane School, Dublin, CA, [2]Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC

Objective: The Long-Evans Cinnamon (LEC) rat is a model for Wilson's disease (WD) and is associated with chronic inflammation and hepatocellular carcinoma. This study performed a gene expression microarray using total RNA extracted from LEC liver tissue at 84 weeks late chronic hepatitis, tumor-adjacent normal (84 weeks N), and 84 weeks tumor (84 weeks T). Understanding the difference between a tumor and adjacent normal within the same animal can be very intriguing as both are in the same environment, and one becomes and sustains a tumor status, but the other still maintains its normalcy.
Experiment: Total RNA was extracted from liver tissue of three LEC rats at 84 weeks N and 84 weeks T and hybridized to the Affymetrix GeneChip Rat Genome 230 2.0 Array (Affymetrix Inc, Santa Clara). GeneGO Pathways software was used to analyze the differentially expressed genes using a cutoff of P-value ≤0.05 and FDR <0.25% and a fold change +/- 2. A volcano plot was generated to visualize significant gene change expression between 84 weeks N vs 84 weeks T. Agglomerative Hierarchical and K-means clustering were used to group similarly expressed genes into clusters and build a hierarchy of clusters. Each cluster obtained from K-means clustering analysis within the up or down-regulated groups were checked for pathway analysis to understand the interplay between biological pathways by QIAGEN Ingenuity® Pathway Analysis (QIAGEN IPA). In addition – log(p) > 1.3, a z-score cut-off ≥ 2 for activation and a z-score cutoff ≤ -2 for inhibition was used to call a pathway activation, and inhibition is significant.
Result: The seven most significant pathways that were activated are the S100 Family Signaling Pathway, Extracellular Matrix Organization, Response to Elevated platelet cytosolic Ca2+, HMGB1 Signaling, Sertoli Cell-Sertoli Cell Junction Signaling, Cachexia Sunaina Pathway, and Nicotine Degradation II. Except for Nicotine Degradation II pathway, all other pathways are shown activated in non-alcoholic fatty liver disease (NAFLD) and hepatocellular carcinoma (HCC) patients previously but shown in the WD model for the first itme. The Nicotine Degradation II pathway is shown to be activated in the NAFLD patient before.
Conclusion: To our knowledge, this is the first report where gene expression analysis was done between tumor-adjacent normal and tumor within the same animal in the WD model. Our results identified multiple pathways in the model that could lead us to new diagnostics and therapeutic targets when validated.

#2349 Implementation of a novel immune monitoring strategy for multicenter clinical trials to enable equity in cancer prognosis for individuals from remote settings of Australia.

Natalie Smith[1], Michael Cohen[2], Julie Alipaz[2], Christina Loh[2], David King[2], Steven Kao[3], Sandra Taylor[4], Rajat Rai[4], Barbara Fazekas de St Groth[1], **Helen McGuire**[1]

[1]The University of Sydney, Sydney, Australia,[2]Standard BioTools, San Francisco, CA,[3]Chris O'Brien Lifehouse, Sydney, Australia,[4]Dubbo Base Hospital, Dubbo, Australia

Improved cancer prognosis begins with the collection of high-quality data from clinical trials. However, the execution of longitudinal immune phenotyping studies by flow cytometry is complex, primarily due to logistical challenges that could affect data quality. The challenges of immune monitoring are exacerbated when considering remote and rural communities in Australia, which are burdened by both an increased prevalence and worse prognosis of cancer. Paradoxically, these communities are often underrepresented in clinical trials. Our group has developed a novel blood-based “immune signature” that robustly predicts failure to make a clinical response to checkpoint therapies targeting the PD-1/PD-L1 pathway in melanoma and lung cancer. These groundbreaking findings were achieved through applying a comprehensive 38-parameter immunophenotyping CyTOF™ panel to biobanked peripheral immune cells from cancer patients. We now aim to increase our clinical implementation in remote settings, with an expanded CyTOF panel of 50-plus-parameter analysis. Recent developments in CyTOF technology facilitate a highly simplified workflow of asynchronous sample collection and staining, compatible with current hospital laboratories that typically run on unpredictable schedules, to remote settings. This is uniquely enabled by using a dried-down cocktail of CyTOF antibodies that are stable, simple to use and yield reproducible staining while minimizing sample required. Furthermore, this workflow, unique to mass cytometry, provides flexibility and minimizes technical variation via sample barcoding and freezing of stained samples for shipment to a central site for batch acquisition. As such, this study is designed to ultimately demonstrate both clinical impact of the large panel and utility of CyTOF technology for a highly simplified and robust workflow for multi-site clinical trials. Here we present findings from the implementation of this novel workflow through a 100-sample pilot study. Remote asynchronous sample collection and surface staining was performed at five sites across Australia. Stained samples were then shipped to a central lab for multiplex barcoding and intracellular staining of several key functional markers. A combination of manual gating and automated high-dimensional clustering was performed in CellEngine, with principal component analysis of all samples demonstrating harmony across the sites. Overall, this workflow enables access to underserved communities, facilitating for the first time equity and scalability of immune phenotyping studies to harness truly geographically dispersed clinical centers.

#2350 Protein biomarkers of HCC development in patients with metabolic liver disease.

A. Siaw[1], S. M. Armasu[2], J. A. Frank[2], I. K. Yan[1], K. J. Wangensteen[2], T. Patel[3], **S. O. Antwi**[1];
[1]Mayo Clinic, Jacksonville, FL, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic Florida, Jacksonville, FL

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a fast-rising global public health problem. About 10% of patients with MASLD will develop hepatocellular carcinoma (HCC), but molecular markers for predicting future risk of HCC development in patients with MASLD are lacking. We investigated whether protein biomarkers in pre-malignant plasma samples can predict susceptibility to HCC in the setting of MASLD.

Methods: A nested case-control study was performed among patients with MASLD who later developed HCC (cases) and MASLD patients who never progressed to HCC (controls), matched on age at MASLD diagnosis (± 1-year), sex, the year of blood sample collection, and length of follow-up (± 1-year). MASLD at baseline was determined by the presence of hepatic steatosis (assessed by imaging or biopsy) plus at least one cardiometabolic condition (obesity, diabetes mellitus, hypertension, or dyslipidemia). Archival baseline plasma samples stored at -80°C were used to perform the SomaScan 7k v4.0 assay. We also performed genotyping of the well-established HCC susceptibility variant, *PNPLA3*-rs738409 (I148M), among the cases and controls. The study sample was split into discovery (70%) and validation (30%) sets, and we selected promising protein biomarkers in the discovery set using differential expression analysis with volcano plots and Bonferroni-corrected p-values. A final set of significant proteins was used for prediction modeling in the validation sample, calculating area under the receiver operating characteristic curve (AUC-ROC), sensitivity, specificity, and accuracy.

Results: The study sample included 54 MASLD to HCC cases and 54 MASLD controls, split into discovery and validation sets. We identified five significantly differentially expressed proteins in the discovery set, four overexpressed (*TSP2, GPR56, MIC-1, TIMP-1*) and one under-expressed (*IGFALS*) in the cases *versus* controls. Fitting the five proteins in the validation sample yielded an AUC=0.88, sensitivity=0.87, specificity=0.75, and accuracy=0.81. Adding *PNPLA3*-rs738409 to the model improved the model's specificity and accuracy (AUC=0.88, sensitivity=0.87; specificity=0.81, accuracy=0.84).

Conclusions: Our findings show that a five-protein biomarker panel can robustly predict future HCC development in patients with MASLD. Adding a well-established HCC genetic risk variant, *PNPLA3*-rs738409, slightly improved the model's performance. These initial findings provide evidence of HCC prediction with baseline plasma biomarkers and genetic risk variants, toward improving risk stratification and enhancing early detection of HCC in the setting of metabolic perturbations.

#2351 Association of germline genetic variants with CAR T-cell therapy outcomes.

Salem Werdyani[1], Xiaotong Sun[2], Yuanyuan Zha[1], Peter Riedell[1], Justin Kline[1], Xin He[2], Aly A. Khan[1]

[1]Biological Sciences Division (BSD), University of Chicago, Chicago, IL,[2]Department of Human Genetics, University of Chicago, Chicago, IL

Purpose: CAR T-cell therapy has shown promise in treating B-cell malignancies, but patient responses vary significantly. We hypothesize that germline genetics influence this variability by impacting T-cell programming and consequently CAR T-cell efficacy. This study aims to investigate the association between germline genetics and CAR T-cell therapy outcomes.
Materials and Methods: We assembled a retrospective cohort of 108 B-cell lymphoid malignancies patients who were treated with CAR T-cell therapy at the University of Chicago Cell Therapy Biobank from May 2018 to Nov 2023 (IRB approval: IRB23-1114). A comprehensive clinical dataset including demographics, disease characteristics, and post-treatment outcomes was obtained from patients' electronic health records and clinical notes. DNA samples were extracted from 105 patients' peripheral blood and underwent low-pass whole-genome sequencing (WGS). Genotype imputation and quality control filtering identified ~ 11 million genetic variants across the study participants. Polygenic risk scores (PGSs) from the PGS Catalog were calculated to test association of PGSs of major immune diseases with the CAR T-cell treatment response. We used 6-month progression-free survival (PFS) based on clinical evaluation as our primary measure of treatment outcome.
Results: Of 98 patients with comprehensive clinical and sequencing data, 55 responded (mean age 61.48 ±12.21 years; 30.91% female) to treatment, while 43 did not respond (mean age 61.60 ±11.28 years; 30.23% female) to treatment. Among clinical covariates, we reproduced a significant association between lactate dehydrogenase (LDH) concentrations and 6-month PFS (adjusted $P < .02$). We conducted multivariate logistic regression including LDH levels to explore correlations between computed PGSs and CAR T-cell treatment outcomes. PGSs related to type 1 diabetes (T1D) were associated with the CAR T-cell treatment response combining multiple PGSs with Aggregate Cauchy Association Test (ACAT $p = 0.016$), in contrast to type 2 diabetes (T2D) PGSs that did not show an association. These results suggest the immune component of T1D are specifically associated with CAR T-cell treatment response. Further analysis in larger T1D GWAS is required to substantiate these findings.
Conclusion: The association between T1D genetics and the CAR T-cell therapy outcomes suggests germline genetics, particularly autoimmune-related variants, modulate therapy efficacy. These genetic variants may elevate T-cell activation, contributing to autoimmunity but leading to increased CAR T-cell exhaustion and reduced effectiveness. Further research will explore these mechanisms. Integrating genetic insights into patient evaluation and CAR T-cell engineering could improve therapy personalization and clinical outcomes.

#2352 Evaluation of alcohol, tobacco, and HPV's synergistic regulation of HNSCC's potential treatment response to PD-L1 checkpoint inhibitor treatment.

Ruomin Xin, Omar Mokhashi, Miski Abdi, Riya Chhabra, Ling Duan, Alanna Sun, Daniel John, Wei Tse Li, Jessica Wang-Rodriguez, Weg M. Ongkeko

UC San Diego, La Jolla, CA

Background: Enhanced PD-L1 (Programmed Death-Ligand 1) expression in tumor cells aids the evasion of immune surveillance. Nivolumab and pembrolizumab, PD-L1 blockade agents, have been applied in clinical settings to treat Head and Neck Squamous Cell Carcinoma (HNSCC), yet low response rates, unimproved prognosis, and treatment resistance necessitate further research into the underlying molecular mechanism. While alcohol, tobacco, and HPV exposure are the most prominent risk factors responsible for HNSCC pathogenesis, their synergistic influence on PD-L1 blockade treatment responses is largely unknown. In this study, we characterized how different combinations of the three etiologic factors alters the molecular landscape of HNSCC, influencing either favorable or adverse PD-L1 blockade treatment outcomes.

Methods: HPV abundance was characterized in 498 primary HNSCC tumor samples. Together with alcohol and tobacco exposure history, samples were classified into 8 subgroups reflecting all possible combinations of the three exposure factors. Differential expression analysis was performed to examine both mRNA and miRNA regulation in relation to key PD-L1 signaling pathways (NF-κB, PI3K/Akt, and Ras/MEK/ERK). Tumor mutation burden (TMB) calculation and subgroup immune landscape profiling were performed to assess the potential response to PD-L1 blockade treatment. Gene Ontology (GO) and KEGG pathway enrichment analysis were then conducted to investigate genetic pathway and cellular processes associated with differential PD-L1 blockade treatment outcomes.

Results: PD-L1 was significantly downregulated in the triple-exposure group (1.51 fold reduction, $p < 0.05$). Dysregulation of PD-L1-related genes, including JAK2 (triple-exposure group: 1.44 fold reduction, $p < 0.05$) and BRAF and ATR, was observed in multi-exposure subgroups (cigarette + HPV group: BRAF 0.781 fold reduction, $p < 0.05$; ATR 0.722 fold reduction, $p < 0.05$). miR-106, implicated in HPV pathogenesis, was most dysregulated in triple-exposure cases. miRNAs including miR-374b-5, miR-16, miR-29b, and miR-143, associated with poor prognosis, and key PD-L1 regulating pathways (PI3K/Akt and P53), were significantly altered in triple-exposure group. Pathway disruptions, including those related to histone regulation and chromosomal structure, increased with additional exposure factors. Tobacco-HPV dual exposure group showed the highest TMB with a 1.94-fold increase ($p < 0.01$) compared to the unexposed subgroup. The triple-exposure group exhibited the highest M2 macrophage enrichment (1.59 fold increase, $p < 0.05$) and CD8+ T-cell reduction (2.03 fold reduction, $p < 0.05$). Further studies are required to identify specified immunotherapeutic administration techniques to address the differential molecular landscapes in different exposure subgroups.

#2353 CRHBP, a novel multiple cancer biomarker connected with better prognosis and anti-tumorigenicity.

Wonbeak Yoo, Yeeun Lee, Kyung Chan Park, Hyunji Choi

Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

Corticotropin-releasing hormone-binding protein (CRHBP) is a key modulator of the hypothalamic-pituitary-adrenal (HPA) axis and plays a crucial role in stress responses, immune regulation, and neuroendocrine functions. Despite its importance in physiological processes, the role of CRHBP in tumor biology and its clinical relevance remain largely unknown. This study aims to comprehensively investigate CRHBP expression across diverse cancer types, its prognostic significance, and its potential molecular mechanisms in tumor progression. We show that CRHBP expression was consistently downregulated in the majority of solid tumors, with the most significant reductions observed in LUAD, LIHC, and KIRC. Low CRHBP expression was strongly correlated with poor prognosis, including shorter OS and DFS, in multiple tumor types. Methylation analysis revealed that hypermethylation of the CRHBP promoter region was associated with its downregulation in several cancers. Further, we identified a set of miRNAs (miR-21, miR-155, miR-29a, and miR-181a) that were upregulated in these tumors and may contribute to the suppression of CRHBP expression. Gene enrichment analysis revealed that CRHBP is involved in key cellular processes, including intracellular signal transduction, metabolic regulation, and hormone-related pathways. CRHBP expression also showed significant correlations with the immune microenvironment, particularly with the infiltration of regulatory T cells (Tregs), macrophages, and dendritic cells. PPI network analysis indicated that CRHBP interacts with several proteins involved in the stress response, immune regulation, and cellular metabolism. Functionally, overexpression of CRHBP inhibited tumor cell proliferation in LUAD, LIHC, and KIRC cell lines, as measured by MTT and colony formation assays. Furthermore, CRHBP overexpression significantly reduced cell migration and invasion in KIRC and hepatocellular carcinoma (HCC) cell lines. Together, these data demonstrated that CRHBP expression is associated with tumor progression, immune cell infiltration, and key molecular pathways. Overexpression of CRHBP inhibits cell proliferation and mobility in multiple cancers, suggesting its potential as a biomarker and therapeutic target in cancer.

#2354 Developing a gene signature from circulating biomarkers to forecast Lu-PSMA response in advanced prostate cancer.

Srinivas V. Koduru[1], Mark Kidd[1], Alin Chirindel[2], Nicolas Guillaume[2], Abdel Halim[1]

[1]Wren Laboratories, LLC, Branford, CT,[2]Clinic for Radiology and Nuclear Medicine, University Hospital Basel, Basel, Switzerland

Introduction: ^{177}Lu-PSMA-targeted radioligand therapy (RLT) for metastatic castration-resistant prostate cancer (mCRPC) leverages the high PSMA expression on cancer cells. The radiolabeled molecule binds to PSMA, delivering beta radiation to selectively destroy cancer cells while sparing surrounding healthy tissue. Despite its sophistication, not all mCRPC patients with adequate PSMA expression respond to this therapy. Currently, there is no mean to predict response or optimize patient selection. We performed transcriptomic profiling on patients undergoing Lu-PSMA therapy, aiming to identify a gene signature that can predict treatment response and help select the most suitable patient population.
Methods: Whole blood samples were collected from mCRPC patients receiving Lu-PSMA-based RLT and categorized into three groups based on PCWG3 criteria: Responders (R, n=30), Partial Responders (RR, n=10), and Non-Responders (NR, n=26). Total RNA was isolated and subjected to RNA sequencing using the NovaSeq 6000 platform. Differentially expressed genes were identified through data analysis with Partek Flow, and pathway analysis was performed to investigate associated biological processes.
Results: RNA sequencing of the three groups (R, NR, and PR) revealed 825 statistically significant genes ($FC > 1$; $P < 0.05$) in the R vs. NR comparison, 1,807 genes in R vs. PR, and 1,548 genes in PR vs. NR. Furthermore, over 90% of responders exhibited prolonged survival, while more than 95% of non-responders and over 80% of partial responders were recorded as deceased.
Conclusion: Our findings suggest that the identified gene signature could serve as a predictive biomarker for clinical response prior to initiating ^{177}Lu-PSMA treatment. Additionally, the pronounced expression of certain genes in non-responders presents an opportunity for the development of novel therapeutic strategies.

PREVENTION / EARLY DETECTION / INTERCEPTION: Biomarkers and Molecular Targets for Prevention
Poster Session

#2358 XPO1 inhibition serves as an effective chemoprevention strategy in colorectal cancer mouse models.

Andrew E. Evans[1], Alexa N. Magstadt[1], Dan A. Dixon[2]

[1]University of Kansas, Lawrence, KS,[2]University of Arkansas for Medical Sciences, Little Rock, AR

Background: Familial Adenomatous Polyposis (FAP) is a hereditary condition resulting in a 100% chance of developing colorectal cancer (CRC) if left untreated. Individuals with FAP often undergo colectomies in their 20s. Thus, there is a critical need for novel chemopreventive approaches to reduce CRC risk in FAP patients. XPO1 is a nuclear export protein overexpressed in multiple cancer types, including CRC. The overexpression of XPO1 has been shown to promote tumorigenesis by excessively removing numerous tumor suppressors from the nucleus. To combat XPO1 overexpression, Selective inhibitors of Nuclear Export (SINE) compounds have been developed. One of those compounds, Eltanexor (KPT-8602), is a second-generation SINE compound currently in Phase I/II clinical trials. Eltanexor has been shown to exhibit fewer side effects compared to its predecessors.

Methods and Results: Our research shows that XPO1 is overexpressed in multiple different stages of CRC and in *Apc*$^{min/+}$ mice, a FAP mouse model, adenomas. In xenograft studies with HCT116 cells, Eltanexor significantly inhibits CRC tumorigenesis. Further analysis revealed that Eltanexor reduced cyclooxygenase-2 (COX-2) expression, a key target in chemoprevention, by downregulating Wnt/β-catenin signaling. Deletion mapping and TOPFlash luciferase assays confirmed Eltanexor's modulation of Wnt/β-catenin activity. Notably, Eltanexor enhanced nuclear retention of Forkhead Box O3a (FOXO3a), a known XPO1 cargo and Wnt/β-catenin regulator. Moreover, organoid drug sensitivity assays we performed indicated that *Apc*$^{min/+}$ adenoma organoids are more sensitive to XPO1 inhibition compared to wild-type intestinal organoids. To explore Eltanexor as a chemopreventive compound, we treated *Apc*$^{min/+}$ mice with Eltanexor for 6 weeks, leading to a significant 62% decrease in tumor burden and a reduction in tumor size. Moreover, to further evaluate Eltanexor's potential role in chemoprevention, Eltanexor was administered to *Apc*$^{min/+}$ mice with celecoxib, a COX-2 inhibitor shown previously to effectively limit *Apc*$^{min/+}$ mice tumorigenesis. Our results revealed mice administered the combined treatment experienced a significant >80% reduction in tumor burden and diminished tumor size. Importantly, both Eltanexor as a monotherapy and the combination treatment were well-tolerated, with no observed toxicity in the treated mice.
Conclusions: Our findings show XPO1 inhibition using the small molecule Eltanexor results in inhibition of the Wnt/ β-catenin signaling pathway, a crucial pathway in CRC tumorigenesis. Furthermore, we show that Eltanexor treatment is an effective chemoprevention strategy in *Apc*$^{min/+}$ mice, a FAP mouse model. These findings highlight a promising chemopreventive strategy for high-risk CRC individuals.

#2359 Age-dependent transcriptional changes in colonic fibroblasts revealed through single-cell RNA sequencing.

Jonathan M. Downie[1], Ryan J. Musich[2], Saleh Khawaled[3], Alexander Caraballo[1], Kylor Lachut[1], Shijie He[1], Marina Magicheva-Gupta[1], Ingrid Crumpton[1], Liza Hote[1], Karen Kirunda[1], Perry Labelle[1], Omer H. Yilmaz[3], Thaddeus Stappenbeck[2], Andrew T. Chan[1], David A. Drew[1]

[1]Gastroenterology, Harvard Medical School/Massachusetts General Hospital, Boston, MA,[2]Inflammation and Immunity, Cleveland Clinic, Cleveland, OH,[3]MIT Koch Institute for Integrative Cancer Research, Cambridge, MA

Introduction: Fibroblasts are key enhancers of colorectal cancer (CRC) development. Cancer-associated fibroblasts (CAF)s promote oncogenesis via extracellular matrix remodeling and the secretion of inflammatory cytokines. CAFs likely arise from normal tissue-resident fibroblast populations that are altered with aging/senescence and environmental exposures. Thus, fibroblasts may mediate CRC development by amplifying etiologic exposures or age-related mucosal changes. This study examines age-related transcriptional changes in fibroblasts from intestinal biopsies to assess the effects of aging.

Methods: Using 10X Genomics Chromium single-cell RNA sequencing, we profiled cells derived from rectosigmoid biopsies of 48 individuals with a history of colorectal adenoma (Young: 24, aged <55; Older: 24, aged >65). *Cellranger*, *Cellbender, and Seurat* were used to derive gene counts, cell types, and clusters. Analyses focused on the stromal cell compartment. *Milo* and *Nebula* identified age-related differences in cell abundance and differentially expressed genes (DEGs).

Results: Among 61,605 stromal cells, 39,074 fibroblasts (*ADAMDEC1*^{high}) were subtyped as crypt top fibroblasts (CTFs; *PDGFRA*^{high}), colon crypt fibroblasts type-1 (cCF1, *PDGFRA*^{low}/*GREM1*$^{-}$), colon crypt fibroblasts type-2 (cCF2, *GREM1*$^{+}$/*RSPO3*$^{+}$), and fibroblastic reticular-like cells (FRLCs, *CCL19*$^{+}$). We did not observe changes in the abundance of fibroblasts between the age groups. However, we found 181 ccF1, 68 ccF2, and 44 CTF specific age-associated DEGs. FRLCs had one significant DEG: *PLAU* (LogFC = 1.96; FDR = 0.021), a factor that converts fibroblasts into CAFs. In cCF1, *GDF15* (LogFC = 1.16; FDR = 5.73 x 10^{-5}), a marker of senescence and CRC risk, was the most upregulated age-associated gene. Gene set enrichment analysis revealed several inflammaging pathways were upregulated in aged fibroblasts, including interleukin-2, interleukin-6, tumor necrosis factor-α, and interferon-γ pathways. Additionally, *KRAS* signaling (all fibroblasts), p53 (cCF1), and epithelial-mesenchymal transition (cCF2) were upregulated with aging, while Myc targets (all fibroblasts) were downregulated.

Conclusions: Fibroblasts in individuals at CRC risk acquire a senescent phenotype with aging, promoting a chronic inflammatory microenvironment. These changes may alter colon crypt regeneration and increase susceptibility to CRC risk factors. Further studies may clarify fibroblast roles in early- and typical-onset CRC.

#2360 Targeting of microRNA let-7b-5p-mediated aberrant AR signaling inhibits the growth and proliferation of preneoplastic and preinvasive stages of triple-negative breast cancer.

Leslie Faye T. Cando[1], Zhenlin Ju[2], Leslie Michelle M. Dalmacio[3], Preethi H. Gunaratne[4], Jing Wang[2], Anjana Bhardwaj[1], Isabelle Bedrosian[1]

[1]Department of Breast Surgical Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, UT MD Anderson Cancer Center, Houston, TX,[3]Department of Biochemistry and Molecular Biology, College of Medicine, University of the Philippines Manila, Manila, Philippines,[4]Department of Biology and Biochemistry, University of Houston, Houston, TX

Background: In search for targets for triple-negative breast cancer (TNBC) prevention, we analyzed molecular changes that occur early in the tumorigenic process. We hypothesize that the early loss of microRNA let-7b-5p, and subsequent upregulation of its target gene androgen receptor (AR), promotes the growth and proliferation of preneoplastic and preinvasive lesions. And while targeting AR has been studied in the therapeutic setting for breast cancer, it may also have potential use in preventing disease progression.
Methods: TNBC patient samples included tumors and histologically normal tissue adjacent (<2 cm) and distant (>2 cm) from tumor. Sublines of MCF10A TNBC progression model corresponding to preneoplastic lesions MCF10.NeoT (hyperplasia) and MCF10.AT1 (atypical hyperplasia), and preinvasive tumor MCF10.DCIS (ductal carcinoma *in situ*) were used to study the effect of let-7b rescue and AR inhibition on proliferation, survival, or migration as measured by MTT, colony formation, and scratch assays. Let-7b gene targets were identified by cross-referencing the RNA sequencing data of MCF10A panel for upregulated genes that are predicted targets of let-7b. QPCR and RNA sequencing were used to measure AR and let-7b expression.
Results: In TNBC patients, let-7b expression is reduced by 68-74% in tumors compared to adjacent ($p=0.015$) and distant normal tissues ($p=0.048$)—confirming previous results in the MCF10A model, where let-7b expression is reduced from normal-like to AT1 by 35% and to DCIS by 65% ($p<0.05$). Let-7b rescue results in 15-32% lower proliferation ($p<0.0001$), 6-9% reduction in migration ($p<0.003$), and a 25% ($p=0.076$), 66% ($p<0.0001$), and 55% ($p=0.030$) decrease in colony formation compared to scramble control in NeoT, AT1, and DCIS cells, respectively. After screening potential let-7b targets, we selected AR for validation. As expected of the inverse regulation by let-7b, AR increases in the MCF10A model, with a notable 23-fold increase in DCIS as compared to normal-like ($p<0.0001$), and similarly in TNBC patient tumors compared to normal tissue controls ($p=0.018$). Furthermore, we validated AR as a direct target with let-7b overexpression causing AR downregulation by 67% in NeoT ($p=0.001$), 86% in AT1 ($p<0.0001$), and 15% in DCIS ($p=0.011$). Finally, treatment with AR inhibitor enzalutamide reduced DHT-dependent AR mediated proliferation by 29-41% ($p<0.0001$) and colony formation by 82-95% ($p<0.0001$) as compared to DHT only control at a minimal concentration of 25μM in AT1 and DCIS.
Conclusions: Let-7b-5p, which acts as a tumor suppressor microRNA, is lost early in tumorigenesis of TNBC, with resulting upregulation of AR. Inhibiting the AR signaling pathway impacts cellular growth and proliferation of preneoplastic and preinvasive cancer cells, suggesting a potential opportunity for TNBC prevention.

#2361 An *ex vivo* organoid study to identify biomarkers of sensitivity to ST316, a clinical-stage β-catenin antagonist peptide.

F. Abbate, L. Ghamsari, C. Scuoppo, Z. Mattes, R. Ramirez, M. Koester, S. Leong, B. Kappel, A. Vainstein-Haras, J. Rotolo; Sapience Therapeutics, Inc., Tarrytown, NY

Background. The WNT/β-catenin pathway, a key oncogenic driver in various cancers, was long deemed undruggable. Historically, attempts at targeting its components resulted in toxicity due to β-catenin's role in homeostatic functions such as intestinal stem cell renewal and bone osteogenesis. ST316 is a β-catenin antagonist peptide that disrupts its interaction with co-activator BCL9, targeting oncogenic signaling and immune exclusion while preserving homeostatic functions. ST316 reduces β-catenin transcriptional activity and tumor growth *in vitro* and *in vivo,* yet GLP-toxicology studies and Phase 1 clinical trial data confirm no WNT-inhibition-associated toxicity. ST316 has now progressed to a Phase 2 trial in patients with colorectal cancer (CRC), an indication with a high prevalence of WNT-related mutations. Here, we evaluated the anti-tumor activity of ST316 in 60 tumor-derived organoids with diverse genetic backgrounds to identify pathways associated with treatment responses. RNA sequencing and qRT-PCR identified transcriptional signatures of cell lines treated with ST316 or vehicle.

Results. The biomarker study of 60 organoids identified genetic backgrounds linked to ST316 responses, with TP53 WT models showing the highest sensitivity. Further analysis revealed higher ST316 sensitivity in models with BRAF, NRAS, and NF1 mutations, suggesting co-dependency between MAPK and WNT/β-catenin pathways. Given the importance of MAPK signaling in cancer, we evaluated dual inhibition of β-catenin and BRAF by combining ST316 with the BRAF inhibitor encorafenib in BRAF-mutant organoids. This combination showed additive/synergistic anti-tumor effects, highlighting new therapeutic opportunities for BRAFV600E-mutant CRC, a subgroup with limited treatment options.

Conclusions. ST316, a novel β-catenin antagonist, preserves WNT/β-catenin homeostasis while targeting oncogenic and immune-suppressive β-catenin/BCL9 signaling. Analysis on 60 patient-derived tumor organoids revealed that tumors with TP53 WT and mutations in the MAPK pathway significantly correlate with sensitivity to ST316. Additionally, combining ST316 with encorafenib showed additive/synergistic effects in BRAFV600E-mutant CRC organoids. β-catenin has been linked to resistance to BRAF inhibitors, and combination therapies targeting both β-catenin and BRAF are proposed to overcome resistance. Given the poor prognosis and limited treatment options for BRAFV600E-mutant CRC, ST316 offers a promising new therapeutic approach for this difficult-to-treat cancer. Our findings support rational combinations of ST316 with clinically relevant MAPK inhibitors.

#2362 Bitter taste receptors detect oral dysbiosis and trigger oral cancer cell death via β-arrestin-biased NLRP3 activation.

Sungmin Joo, Seong Yu, Jeong-Mu Shin, Yeshin Kwon, Na-Young Song

Yonsei University College of Dentistry, Seoul, Korea, Republic of

Bitter taste receptors (taste 2 receptors, T2Rs) are a family of G protein-coupled receptors (GPCRs) that transduce bitter taste signals in the taste buds via the gustatory G protein α-gustducin. Recently, T2Rs have emerged as novel regulators in various extraoral physiological processes, including microbial interactions and carcinogenesis. Notably, T2R4 and T2R14 can recognize bacterial quorum sensing (QS) molecules, such as N-(3-oxododecanoyl)-L-homoserine lactone (oxo-C12). Reanalysis of oral microbiome datasets from oral squamous cell carcinoma (OSCC) patients, a major subtype of head and neck squamous cell carcinoma (HNSC), revealed an upregulation of bacterial QS pathways associated with oxo-C12 synthesis. Lower expression levels of T2R4 or T2R14 correlated with poor outcomes and impaired bacterial defense responses in OSCC/HNSC patients. We hypothesized that T2R4 and T2R14 mediate the interplay between oral microbial dysbiosis and OSCC in response to the bacterial QS molecule oxo-C12. Our results showed that oxo-C12 induces pyroptosis and apoptosis in human OSCC cells, unlike other T2R agonists such as quinine and apigenin. Unexpectedly, T2R4 and T2R14 mediated oxo-C12-induced cell death independently of α-gustducin, instead activating the NLRP3 inflammasome via β-arrestin-1/2 (β-ARR1/2). This indicates that oxo-C12 acts as a β-ARR1/2-biased ligand, triggering OSCC cell death through the T2R-β-ARR1/2-NLRP3 axis. A positive correlation between β-ARR2 and T2R4, T2R14, or NLRP3 in HNSC patient datasets supports this signaling pathway. Taken together, T2R4 and T2R14 function as crucial interkingdom sensors that detect oral microbiome dysbiosis and trigger defensive cell death mechanisms in OSCC via β-ARR1/2-biased NLRP3 activation. These findings suggest the potential of T2Rs as chemotherapeutic targets, particularly through ligand-specific biased pathways involving either G protein- or β-ARR1/2-dependent signaling.

#2363 PRMT5 as a target in CRC interception: Synthetic lethal dependency identified in APC-LOF preclinical models of FAP disease.

Dana S. Gaffney[1], Jan Willem Thuring[2], Fabian Hulpia[2], Eileen Vesely[1], Edward Retzbach[1], Zienab Etwebi[1], Zhengyu Jiang[1], Albi Francis[1], Bethany Mattson[1], Victoria Wong[1], Mariana Silva[3], Gerben ten Hag[3], Rene Overmeer[3], Carla Verissimo[3], Sylvia F. Boj[3], Johan Nicolai[2], Mark Hixon[4], Gerry Chu[1], Andrea DiSandro[1], Kathleen Clancy[1], Alexandra Liddane[1], Kurtis Bachman[1], David Pocalyko[1]

[1]Johnson & Johnson Innovative Medicine, US, Springhouse, PA,[2]Janssen Pharmaceutica NV, Beerse, Belgium,[3]HUB Organoids BV, Utrecht, Netherlands,[4]Johnson & Johnson Innovative Medicine, US, La Jolla, CA

Colorectal cancer (CRC) is one of the most common causes of cancer-related deaths in the world and loss of the Adenomatous Polyposis Coli (*APC*) gene represents the disease-initiating event in the majority of CRC cases. Strategies for targeting *APC*-loss of function (*APC*-LOF) may provide an opportunity to intercept tumorigenesis in high-risk CRC patients, such as those with Familial Adenomatous Polyposis (FAP). To discover targets for therapeutic intervention in *APC*-LOF-driven disease, we conducted a high-throughput screen in isogenic *APC* knockout (APC^{KO}) colorectal organoids of >6000 compounds with known clinical relevance. From this screen, we uncovered a novel synthetic lethal dependency of *APC*-LOF on protein arginine methyltransferase 5 (PRMT5). JNJ-64619178 (JNJ-9178), a potent clinical PRMT5 inhibitor, demonstrated an >800-fold window in growth inhibition of engineered APC^{KO} organoids compared to wild-type (WT). Pharmacodynamic assessments showed a dose-dependent decrease in SmD3, an established biomarker for PRMT5 target engagement, with JNJ-9178 treatment, while no decrease was observed with a weakly active compound, providing evidence that the antiproliferative activity observed in the APC^{KO} organoids is a direct consequence of on-target PRMT5 inhibition. We further validated this PRMT5/APC dependency by testing other S-adenosylmethionine (SAM)-competitive PRMT5 inhibitors which show a similar trend in selectively inhibiting growth of the APC^{KO} organoids vs WT. Furthermore, we assessed the impact of JNJ-9178 on colon polyp burden in the $Apc^{min/+}$-DSS mouse model, an in vivo model of FAP, where we started treatment either before (early interception) or after (late interception) significant polyp burden had been established. A 72% and 66% reduction in polyp burden was observed, respectively, compared to vehicle-treated mice after 3 weeks of dosing (BID). Taken together, these findings showcase the impact of PRMT5 inhibition in both human and mouse models of FAP disease. Orally bioavailable PRMT5 inhibitors, including JNJ-9178, present challenges as therapeutics for CRC interception due to on-target cytopenias observed with systemic exposure. To address these dose-limiting toxicities, we have developed a GI-restricted approach and discovered new compounds that only inhibit PRMT5 activity locally in the intestinal tract. This strategy is detailed in a second abstract.

#2364 The role of β1 and β5 integrins as biomarkers in anti-motility therapy treatment response.

W. Chen, N. Woods, H. Law, F. Qiao, R. C. Bergan;
UNMC Eppley Institute, Fred & Pamela Buffett Cancer Center, Omaha, NE

Introduction. Metastasis is the major cause of mortality in patients with solid tumors. Our group has identified precision therapeutic inhibitors of cell motility and shown their ability to prevent metastasis. In striving to move novel first-in-class therapy into humans, it is important to identify biomarkers of therapeutic efficacy. As β1 and β5 integrins mediate prostate cancer cell migration, they are strong biomarker candidates. While our novel anti-motility agent, KBU2046, inhibits cell motility, its effects on β1 and β5 integrin expression and dynamics are not fully understood. We, therefore, investigated the impact of KBU2046 on β1 and β5 integrin patterns in cells and their potential as predictive biomarkers of therapeutic response.

Experimental procedures. Initial screening studies consisted of orthogonal protein expression measures, including mass spectrometry and Western blot-based analytics, in the context of time- and concentration-based treatment anti-motility therapeutics. This was then followed by immunofluorescence (IF) analysis by confocal microscopy of a panel of human prostate primary and metastatic cells, examining patterns of expression under conditions of static as well as synchronized cell attachment.

Results. Evaluation of the proteome through bioinformatic analytics identified changes in cell adhesion proteins as high-potential biomarkers. From this, we specifically investigated the dynamics of β1 and β5 integrins in response to antimotility treatment with KBU2046. In this manner, treatment induced significant alterations in cell morphology. This was associated with a dynamic, time-dependent redistribution of β1 and β5 integrins. The pattern of this change demonstrates disruption in normal integrin trafficking and supports a basis for disruption of normal integrin function. These findings provide orthogonal support for the established role of KBU2046 in inhibiting cell motility and identify β1 and β5 integrin expression patterns as high-potential biomarkers of therapeutic efficacy for anti-motility agents.

Conclusions. Our investigation reveals that treatment with KBU2046 induces significant changes in the dynamics of β1 and β5 integrins in prostate cancer cells, disrupting their normal function and trafficking. Using IF and protein expression analyses, we identified β1 and β5 integrins as potential biomarkers indicative of therapeutic efficacy in response to anti-motility treatment. These findings underscore the significance of β1 and β5 integrin expression patterns as key indicators for assessing the effectiveness of future anti-motility strategies. Further investigation of these biomarkers in clinical settings could offer valuable insights to inform therapeutic decisions in the treatment of prostate cancer.

#2365 Determining the role of pregnancy-induced IgG antibodies in parity-associated mammary oncoprotection.

Dhivyaa Anandan[1], Marygrace Trousdell[2], Amritha Varshini Hanasoge Somasundara[2], Johannes T.-H. Yeh[2], Camila O. dos Santos[2]

[1]Stony Brook University, Renaissance School of Medicine, New York, NY,[2]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

An early age of first pregnancy reduces the lifelong risk of developing breast cancer (BC) by ~30%. The dos Santos Lab has shown that pregnancy-induced alterations to the mammary immune microenvironment, including adaptive immune cells, are crucial for the oncoprotective effect of pregnancy. While plasma cells and memory B cells in the pregnant/lactating mammary gland (MG) are largely appreciated for their role in secreting antibodies into breastmilk, B cells may also encounter and secrete antibodies against self-antigens that arise during pregnancy-associated MG development and milk synthesis. Several antigens expressed in the pregnant/lactating MG are also expressed in BC. As a result, we hypothesize that pregnancy induces IgG production against antigens associated with pregnancy and mammary tumorigenesis, contributing to parity-associated mammary oncoprotection.

To obtain an unbiased profile of pregnancy-induced alterations to the mammary immune microenvironment, we performed single cell RNA-sequencing on virgin and parous non-tumor-bearing mammary tissue from a mouse model of pregnancy-induced mammary oncoprotection (Brca1 loss of function). Our analysis reveals an enrichment of plasma cells and memory B cells in the parous MG, raising the question of whether these cells and their antibody production may play a role in the inhibition of mammary tumorigenesis in parous mice in this model. To understand whether pregnancy induces alterations to the antigens recognized by B cells, we performed BCR-sequencing of MGs from virgin and parous wildtype mice. Using clonotype abundance analysis, we identified five IgG clonotypes that were most abundant and unique to the parous MGs. We used the BCR sequences of these clonotypes to synthesize five recombinant pregnancy-induced IgG antibodies. Through immunofluorescent staining analysis of mammary tissue from various stages of development and tumorigenesis, we have identified three clones that bind to pregnancy-induced mammary epithelial antigens that are also present in virgin pre-neoplastic mammary tissue. These results suggest that pregnancy may influence the BCR repertoire and enable IgG production against antigens expressed by pre-neoplastic cells in the MG. We are testing whether these recombinant pregnancy-induced IgG antibodies can be administered *in vivo* and inhibit mammary tumorigenesis in mouse models of BC.

#2366 Dynamic crosstalk between endothelial and epithelial cells drives tumor progression in lung adenocarcinoma.

Hong Chen[1], Bo Zhu[1], Junya Fujimoto[1], Yanhua Tian[1], Jian-Rong Li[2], Chenyang Li[1], Pingjun Chen[1], Alexandre Reuben[1], Monique Nilsson[1], Xiuning Le[1], Alissa Poteete[1], Shawna M. Hubert[1], Don L. Gibbons[1], Ignacio I. Wistuba[1], Jia Wu[1], Chao Cheng[2], John V. Heymach[1], Jianjun Zhang[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Baylor College of Medicine, Houston, TX

Background: Lung adenocarcinoma (LUAD) is a leading cause of cancer-related deaths, but the mechanisms driving its initiation and progression are not fully understood. This study investigates the interactions between epithelial and endothelial cells in LUAD and their roles in tumor progression.
Methods: Single-cell RNA sequencing and spatial transcriptomics (Visium) were employed to explore LUAD carcinogenesis in two mouse models: a genetically engineered KrasG12D mouse model (GEMM) and a urethane-induced carcinogen model (CITM), both in the 129S4 background. LUAD and its precursors (normal lung, hyperplasia, adenoma, and adenocarcinoma) were classified by pathologists. Lung tissues collected at multiple time points were analyzed to characterize epithelial-endothelial crosstalk during LUAD initiation and progression.
Results: As LUAD progressed, the proportion of epithelial cells gradually increased. In GEMM, tumor cells exhibited higher scores in KRAS signaling, hypoxia, apoptosis, and the P53 pathway compared to normal epithelial cells, indicating activation of these pathways during tumorigenesis. In endothelial cells (ECs), tip ECs were significantly upregulated during tumor progression, highly expressing Angpt2, Cxcr4, Pgf, Col4a1, Col4a2 and Insr, which are associated with EC migration, matrix remodeling, and vascular endothelial growth factor (VEGF) signaling. These cells were predominantly localized within tumor regions, as demonstrated by spatial transcriptomics, indicating their role in tumor angiogenesis. In contrast, aerocytes (aCap) decreased significantly over time, suggesting a shift from a quiescent to a more tumor-supportive phenotype. The upregulation of tip ECs and the downregulation of aCap cells suggest that tumor progression is accompanied by a dynamic reshaping of the endothelial compartment, which promotes the formation of a more permissive tumor microenvironment. We also observed enhanced crosstalk between tip ECs and epithelial tumor cells, particularly via the Col4a1-Cd44 and Mif-(Cd74+Cxcr4) ligand-receptor pairs, facilitating tumor cell adhesion, migration, and invasion. Notably, Cd44 and Mif expression in epithelial cells progressively increased, supporting further epithelial-endothelial interactions, and contributing to tumor cell survival and immune evasion. Furthermore, we observed a significant increase in BATF+ Tregs within the tumor microenvironment as LUAD progressed, indicating an evolving tumor-supportive immune environment.
Conclusions: This study highlights the critical role of tip ECs and endothelial-epithelial interactions in LUAD progression. The expansion of BATF+ Tregs underscores the complex immune interplay involved in this process. Targeting endothelial-epithelial crosstalk could provide a promising strategy to treat LUAD precancers and prevent the development of invasive disease.

#2367 Changes in breast hormone signaling and inflammation underlie radiologic features of cancer risk.

Nadine Goldhammer[1], Marin Bont[2], Michael Choi[1], Shruti Warhadpande[1], Heather Greenwood[1], Soumi Gottipati[1], Tam Binh Bui[1], Michael Bruck[1], Shoko Emily Abe[1], Michael Alvarado[1], Cheryl Ewing[1], Karen Goodwin[1], Rita Mukhtar[1], Jasmine Wong[1], Laura van't Veer[1], Nola Hylton[1], Laura J. Esserman[1], Jennifer M. Rosenbluth[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]University Medical Center Utrecht, Utrecht, Netherlands

Background: Image-based features of the normal breast such as mammographic density and background parenchymal enhancement (BPE) on contrast-enhanced breast magnetic resonance imaging (MRI) are independent breast cancer risk factors. Both are associated with estrogen signaling and respond to endocrine therapy. Yet, molecular and cellular mechanisms underlying these risk factors remain unclear. We aimed to investigate such mechanisms with the goal of identifying novel approaches for cancer risk stratification and personalized prevention.

Methods: Single-nucleus RNA sequencing on a 10x Chromium platform was performed on normal human breast tissues from 28 women undergoing prophylactic mastectomies (n = 11), lumpectomies (n = 10), or mastectomies for breast cancer (n = 7) who consented to our biobanking protocol. Differences in cell composition and signaling pathways between individuals with different breast densities and BPE levels were determined. Additionally we assessed estrogen responsiveness in patient-derived organoid (PDOs) from women with different levels of BPE using qRT-PCR. Evaluation of immune infiltration as potential mediator of BPE is underway using immunofluorescence and spatial transcriptomics.

Results: 12,377 nuclei from 28 women were analyzed, including 16 with low (minimal or mild) and 12 with high (moderate or marked) BPE levels on MRI, and 5 cases with not dense and 23 with dense breasts on mammography. All main breast epithelial and stromal cell types were represented in our data. We observed great heterogeneity in cell composition between patients. Samples from BPE-high patients contained luminal secretory cells with reduced expression of differentiation markers and luminal hormone sensing cells with higher expression of estrogen response genes like *PGR* and *GREB1*. In agreement with this, we observed increased response to estrogen signaling in PDOs from high (n = 5) versus low BPE cases (n = 5). Moreover, luminal cells from BPE-high samples expressed significantly higher levels of *CD74* which has been correlated with immune infiltration in cancer. Supporting this, interactions between luminal cells with macrophages via *CD74* and *APP*/*COPA* were predicted in BPE-high but not in low samples. Comparing samples with distinct mammographic densities, we observed a higher proportion of luminal secretory cells, basal cells, and fibroblasts in patients with high mammographic densities suggesting that distinct mechanisms mediate BPE levels and breast density.

Conclusions: Our findings indicate that BPE is influenced by two distinct mechanisms: estrogen-mediated changes in cellular composition and chronic inflammation, both potentially increasing breast cancer susceptibility. Understanding the basis of modifiable breast cancer risk factors will enable risk stratification and personalized treatment, ultimately reducing breast cancer incidence in high-risk populations.

#2368 The vesicle component released from renal cell carcinoma cells transforms tumor blood vessels into PSMA-positive and enhances angiogenic potential.

R. Watanabe[1], K. Kagimoto[1], M. Chosei[1], H. Arai[1], T. Sakaue[1], M. Kurata[2], N. Miura[1], R. Kitazawa[3], T. Kikugawa[1], S. Higashiyama[4], T. Saika[1];

Background: Prostate-specific membrane antigen (PSMA) expression rises as prostate cancer progresses and metastasizes. Recently, 68Ga-labeled PSMA PET imaging has been utilized in prostate cancer diagnosis. Previous studies have shown that PSMA-positive vesicles secreted by prostate cancer cells increase angiogenic activity in vascular endothelial cells, suggesting a role for PSMA in tumor-related angiogenesis. This study aims to explore the relationship between PSMA expression in peritumoral vessels and patient outcomes, particularly focusing on tumor recurrence in surgically resected renal cell carcinoma samples.

Methods: Immunohistochemistry was performed on renal cell carcinoma tissue from 45 patients who underwent nephrectomy or partial nephrectomy at our institution between January 2018 and December 2022. The intensity of PSMA expression in tumor vessels was compared with recurrence rates. Furthermore, PSMA levels in human umbilical vein endothelial cells (HUVECs) treated with conditioned media (CM) from the renal cancer cell lines Caki1 and ACHN were assessed via Western blotting (WB) and immunofluorescence (IF). Angiogenic activity was measured using a tube formation assay, while RNA sequencing (RNA-seq) was employed to examine gene expression changes in endothelial cells induced by vesicles from renal cancer cells. Spatial gene expression analysis was performed to compare differences in gene expression between tumor vessels near and vessels away from the tumor.

Results: Immunohistochemical staining for PSMA and CD31 demonstrated that only the vessels surrounding the tumors were positive for PSMA. The intensity of PSMA expression was classified as weak (18 cases), moderate (11 cases), or strong (16 cases), and was found to correlate with the recurrence rates. When the 10,000 g pellet fraction of CM from the renal cancer cell lines was applied to HUVECs, the cells became PSMA-positive, and tube formation was enhanced. RNA-seq analysis revealed that HUVECs treated with CM from renal cancer cell lines showed upregulation of pathways linked to angiogenesis.

Conclusions: Vesicles secreted by renal cancer cells stimulate PSMA expression in vascular endothelial cells and promote angiogenic activity. Future studies will investigate the mechanisms leading to PSMA expression in normal vascular endothelial cells, with the goal of developing novel anti-angiogenic treatments.

#2369 Targeting peroxiredoxin 2 prevents hepatocellular carcinoma development in metabolic liver disease.

Emilie Crouchet[1], Eugenie Schaeffer[1], Frank Juhling[1], Hussein El Saghire[1], Anouk Charlot[2], Naoto Fujiwara[3], Shija Zhu[3], Fahmida Akter Rasha[3], Julien Moehlin[1], Marine A. Durand[1], Marie Parnot[1], Nourdine Hamdane[1], Danijela Heide[4], Jenny Hetzer[4], Mathias Heikenwalder[4], Emanuele Felli[5], Patrick Pessaux[6], Joffrey Zoll[2], Nathalie Pochet[7], Laurent Mailly[1], Yujin Hoshida[3], Thomas F. Baumert[1], Catherine Schuster[1]

[1]University of Strasbourg, Inserm, Institute for Translational Medicine and Liver Disease UMR_S1110, Strasbourg, France,[2]University of Strasbourg, Biomedicine Research Center of Strasbourg (CRBS), UR 3072 "Mitochondrie, Stress oxydant et Plasticite musculaire", Strasbourg, France,[3]Division of Digestive and Liver Diseases, Department of Internal Medicine, Liver Tumor Translational Research Program, Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, TX,[4]Division of Chronic Inflammation and Cancer, German Cancer Research Center, Heidelberg, Germany,[5]Hospital Group Saint Vincent, Strasbourg, France,[6]Pole des Pathologies Hepatiques et Digestives, Strasbourg University Hospitals, Strasbourg, France,[7]Broad Institute of Harvard and Massachusetts Institute of Technology, Cambridge, MA

Background: HCC is the third most common cause of cancer-related death and the leading cause of death among cirrhotic patients. While several treatments for HCC have been approved, chemopreventive strategies for HCC are lacking. Aiming to discover novel therapeutic targets, we combined genome wide transcriptomic analysis of liver tissues from patients with advanced liver disease and HCC and a cell-based system predicting liver disease progression and HCC risk. Computational analysis identified peroxiredoxin 2 (PRDX2) as a candidate driver of hepatocarcinogenesis.

Methods: The role of PRDX2 in liver disease progression and HCC development was investigated by *Prdx2* KO in a state-of-art CRIPSR/Cas9 mouse model for MASH-induced hepatocarcinogenesis. The mechanism of action was explored using RNA-Seq analyses of mouse liver tissues and validated by perturbation studies in human liver cell-based models. The translatability of our results was confirmed by targeting *Prdx2* using GalNac siRNA in a mouse model of MASH, CDX mouse model, as well as perturbation studies in patient-derived HCC tumorspheroids.

Results: In vivo perturbation studies in mouse models for MASH driven hepatocarcinogenesis showed that *Prdx2* KO improves steatosis and robuslty prevents HCC development. RNA-Seq analyses of mouse liver tissues with validation in human cells showed that loss of *Prdx2* function suppresses oncogenic signaling (i. e. p38/MAPK, PI3K/AKT signaling) and improves metabolic liver functions (i.e cholesterol, fatty acid and bile acid metabolism) through activation of the AMPK pathways. Finally, PRDX2 loss-of-function studies in hepatoma cell-based models, a CDX mouse model and patient tumorspheroids unraveled that targeting PRDX2 sensitizes cancer cell to oxidative stress and triggers apoptosis.

Conclusion: Our findings demonstrate an important functional role of PRDX2 in hepatocarcinogenesis. Targeting PRDX2 is a previously undiscovered therapeutic opportunity for prevention of MASH-induced HCC.

#2370 Microbiome alterations of colorectal cancer according to age of onset, stage, anatomic location, and mismatch repair deficiency.

Colorectal cancer (CRC) is the third most common and lethal cancer type worldwide. Although CRC incidence in the older population has decreased in many countries, early-onset CRC cases (< 50 years age, EOCRC) have been rapidly increasing globally. The fecal microbiome has been reproducibly associated with CRC. However, microbiome differences according to age of onset, stage, anatomic location, and genomic instability remain only minimally explored. Here, we integrated data generated from the ONCOBIOME consortium, Cancer Grand Challenges PROSPECT project and the ARETHUSA study, providing seven new cohorts of gut microbiome samples from healthy, adenoma- and CRC individuals (n total = 1,668) combined with 12 public studies, for a total of 3,784 metagenomic samples, including 190 EOCRC and 270 age-matched control samples. Information on tumor stage, anatomic location, microsatellite stability/instability-high (MSS/MSI-H) has been curated and harmonized across datasets. Metagenomes were analyzed using the bioBakery suite for community-, species-, strain-level, and gene-level profiling, and downstream integrative analysis was performed via meta-analysis and leave-one-dataset-out learning tasks. We obtained increased microbiome-based CRC prediction capabilities (average leave-one-dataset-out AUC = 0.84) and accurate species- and strain-level characterization of CRC stages (e.g., Slackia exigua and Ruminococcus bicirculans, respectively, between stage 0-II and III/IV), while the microbiome in adenoma samples did not differ substantially from controls (average leave-one-dataset-out AUC < 0.6). The fecal microbiome of right-sided CRC cases presented lower species and higher oral commensals richness than left-sided cases. The gut microbiome composition of MSI-H CRC was significantly different than MSS, as reflected by machine learning discrimination performances (average cross-validation AUC = 0.71), and characterized by reduced alpha-diversity and fewer biomarkers than in MSS cases, such as Ligilactobacillus salivarius and Limosilactobacillus fermentum. We confirmed that EOCRC microbiome was significantly different from age-matched controls (average leave-one-dataset-out AUC = 0.84), harboring typical CRC-associated bacteria, such as F. nucleatum and D. pneumosintes. Overall, we defined cross-cohort reproducible microbiome associations across tumor stages, primary location, genetic instability, and EOCRC, providing improved resolution within the CRC microbiome and more refined targets for diagnosis and therapeutic stratification.

#2372 Circulating pre-diagnosis immune markers and breast cancer risk: findings from the Cancer Prevention Study-3.

Shamim Shahi[1], James Hodge[1], Mia Gaudet[2], Alpa V. Patel[1], Laure Dossus[3], Sabina Rinaldi[3], Lauren Teras[1]

[1]Department of Population Science, American Cancer Society, Atlanta, GA,[2]Department of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD,[3]Hormones and Metabolism team, Nutrition and Metabolism Branch, International Agency for Research on Cancer, Lyon, France

Background: Breast cancer is recognized as potentially immunogenic with early evidence suggesting patients may benefit from immunotherapy. Cytokines including tumor necrosis factor alpha (TNF-α), interferon gamma (IFN-γ), and those from the interleukin (IL) family (IL-6, IL-8, and IL-10) play a critical role in immune system regulation. However, the association of pre-diagnostic cytokines levels with breast cancer risk remains unclear with few studies reporting inconsistent findings.
Objective: The goal of this study was to examine associations between circulating cytokines (IL-6, IL-8, and IL-10, TNF-α and IFN-γ) and subsequent breast cancer risk.
Methods: For this study, we utilized data from the Cancer Prevention Study 3 (CPS-3), a prospective cohort study initiated by the American Cancer Society (ACS), which fully enrolled 198,632 women aged 30-65 years from 2006-2013, across 35 states, Washington D.C., and Puerto Rico. A nested case-control design was used for this study. The analytic sample included 606 primary invasive breast cancer cases, matched to 606 controls based on age at study enrollment, race, blood draw date, and menopausal status. Blood collected at CPS-3 enrollment was used to quantify five immune markers of inflammation and immune regulation: IL-6, IL-8, IL-10, IFN-γ, and TNF-α using the V-PLEX multiplex immunoassay at the International Agency for Research on Cancer (IARC). Each immune marker was analyzed both as a continuous and a categorical (quartiles) variable. Conditional logistic regression was used to estimate odds ratios for the association between each immune marker and overall breast cancer risk.
Results: The median age at diagnosis was 54 years (interquartile range (IQR): 48,59). Cases and controls were fairly comparable across key demographic, clinical and behavioral variables. For every one-unit increase in log-transformed IFN-γ, the odds of breast cancer decreased by 16% (OR=0.84, 95% CI: 0.72-0.99). All other immune markers were not significantly associated with overall breast cancer risk.
Conclusion: With the exception of IFN-γ, the findings do not provide evidence that these selected immune markers are associated with breast cancer risk. Given the heterogenous nature of breast cancer, future studies should consider breast cancer molecular and histologic subtypes and potential modifications by other clinical and tumor characteristics.

#2373 Colonic polyp preventive effect of rLON protease in FAP-rat intestinal polyposis model.

Venkateshwar Madka[1], Karthikkumar Venkatachalam[1], Gopal Pathuri[1], Nicole Stratton[1], Anil Singh[1], Shizuko Sei[2], Mark S. Miller[2], Vignesh Gunasekharan[2], Chinthalapally V. Rao[1]

[1]Center for Cancer Prevention and Drug Development, Department of Medicine, OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]Division of Cancer Prevention, National Cancer Institute, Rockville, MD

Hereditary Familial Adenomatous Polyposis (FAP) patients develop large number of colonic polyps that can progress to aggressive carcinomas. In the FAP patients, Apc or β-catenin mutations lead to c-Myc overexpression, which in turn drives the metabolic and immune alterations leading to colorectal cancer, making it a potential target for CRC prevention. Unfortunately, finding c-Myc inhibitors has been difficult and only recently studies show that uropathogenic *E. Coli* rLON protease (rLONP) can degrade the c-Myc in tumor tissues. In this study, PIRC rats (10- or 12- weeks age) were treated with rLONP (0.375mg/rat/day dose) in PBS by oral gavage twice daily for either 2- or 4- weeks and assessed for toxicity and intestinal tumor burden. Organ morphology and weight were not significantly different from control PIRC rats. Also, hematological profile was very similar in control and rLONP treated male rats, however in female PIRC rats, rLONP treatment for 4 weeks showed significant differences in WBC, neutrophils, and lymphocytes count compared to control. Serum analysis indicated a non-significant ($p>0.05$) increase in AST (297.6±74.3 u/L) and ALT (365.3±86.8 u/L) levels with 4-weeks rLONP treatment when compared to control group (133.9±27.5 u/L & 184.5±30.3 u/L respectively). ALKP levels were slightly lower (187.6±14.4 u/L) in rLONP treated rats compared to control (221.3±16.7 u/L). BUN (17.6±0.7 mg/dL) and CREA (0.15±0.03 mg/dL) of the rLONP treated rats were non-significantly different from control group (16.6±1.1 mg/dL & 0.15±0.02 mg/dL respectively). Histopathology of all major organs of rLONP treatment appeared normal, with no significant differences as compared to untreated groups. Colonic and small intestinal polyps were compared between control and rLONP treated rats. Average colonic polyps were less in rLONP treated male rats at both 2- and 4- week endpoints (40% reduction) compared to their respective control rats while this effect was not distinguishable in the females due to low polyp number and slow rate of polyp and tumor development. Small intestinal polyps also appeared to be less in number in rLONP treated male and female rats as compared to control. Total intestinal polyps showed ≥50% reduction of multiplicity, male ($p<0.012$; $p<0.009$) and female ($p=0.06$; $p<0.022$) with 2- and 4- week rLONP treatment, respectively, as compared to control group. Protein expression analysis of control and treated colonic polyp tissues suggested reduction of c-MYC expression with rLONP treatment. Also, IHC analysis showed reduction in Ki-67, Cyclin D1, and c-Myc expression in the rLONP treated rat colonic polyps when compared with control polyps. Based on these observations, it is concluded that rLONP treatment did not cause any overt-toxicities and reduced intestinal polyps in PIRC rats in a short-term study. (*Project funded in whole with Federal funds from the NCI, NIH, DHHS, under Contract 75N91019D00020_75N91022F00001*).

#2374 Identifying ZNF469 as a biomarker in cancer of the colon and stomach.

Aaron Shaykevich[1], Isaac Silverman[2], Radhashree Maitra[2]

[1]Public Health and Preventative Medicine, SUNY Upstate Medical University, Syracuse, NY,[2]Biology, Yeshiva University, New York, NY

Introduction: Zinc Finger Protein 469 (ZNF469) is a protein involved in the formation of the extracellular matrix. While the non-coding RNA linc-ZNF469-3 has previously been identified to be overexpressed in certain cancers and promote metastasis, there have yet to be any studies attempting to establish a link between the protein ZNF469 and cancer formation or growth. In this study, we attempt to determine whether ZNF469 may act as a biomarker in colon and stomach cancers.
Methods: A systems biology approach was used to explore the impact of varying ZNF469 expression and mutations. Patient data was retrieved from the TCGA database. TIMER2.0 software was utilized for statistical analysis along with visualization.
Results: The expression of ZNF469 was found to increase in cancer compared to non-tumor control in the colon ($p = 2.4e-11$) and stomach ($p = 2.2e-17$). Furthermore, Kaplan-Meier plots indicate that higher expression of ZNF469 resulted in worse probability of survival in colon (HR = 1.70, CI = 1.35-2.15) and stomach (HR =1.68, CI = 1.34-2.10). We also found an association between immune infiltration and ZNF469. In colon cancer, ZNF469 expression moderately correlated with the immune infiltration of macrophages (partial correlation = 0.50, $p = 6.2e-27$), neutrophils (partial correlation = 0.57, $p = 3.9e-35$), and dendritic cells (partial correlation = 0.56, $p = 3.9e-34$). In stomach cancer, these correlations were present but weaker in macrophages (partial correlation = 0.23, $p = 6.5e-6$), neutrophils (partial correlation = 0.25, $p = 8.5e-7$), and dendritic cells (partial correlation = 0.29, $p = 1.6e-8$). In the colon, arm level gain mutations of ZNF469 were found to correlate with altered immune infiltration in CD8+ T cells ($p < 0.001$), neutrophils ($p < 0.001$), and dendritic cells ($p < 0.01$) with a few additional mutations found to be significant as well. Conversely, in the stomach, arm level deletions were found to correlate with altered immune infiltration in B cells ($p < 0.01$), CD8+ T cells ($p < 0.001$), neutrophils ($p < 0.05$), and dendritic cells ($p < 0.001$) with additional mutations found to be significant.
Conclusion: The increased expression of ZNF469 in stomach and colon cancer suggests that it may facilitate in oncogenesis and may be induced by rapid tumor growth. The expression correlating with worse outcomes further supports ZNF469 as a pro-oncogenic protein in these cancers. High ZNF469 levels were also correlated with higher immune infiltration, especially in colon cancer, and arm level gain or arm level deletion mutations were associated with altered immune infiltration. Overall, the findings suggest that ZNF469 can serve as a biomarker in colon and stomach cancers. ZNF469 is upregulated in these cancers, and the increase of ZNF469 correlates with both worse outcomes as well as increased immune infiltration. This data suggests that further research into ZNF469 may be beneficial in stomach and colon cancers.

#2375 Investigating airway epithelial TP53 somatic mutation prevalence as a common risk factor for COPD and lung cancer.

Andrew Boring[1], Erin L. Crawford[1], Dan J. Craig[1], Heidi Chen[2], Rami Ahmad[1], Mohamed Omballi[1], Eric Grogan[2], Stephen Deppen[2], James C. Willey[1]

[1]University of Toledo College of Medicine and Life Sciences, Toledo, OH,[2]Vanderbilt University Medical Center, Nashville, TN

Background: Lung cancer (LC) and Chronic Obstructive Pulmonary Disease (COPD) are leading causes of morbidity and mortality both in the United States and worldwide. There is a high degree of association between COPD and LC, which is not well understood. Smoking is a risk factor for COPD, while both cigarette smoke and COPD are risk factors for LC. Approximately 10% of current smokers are at risk for developing COPD and every year an estimated 1% of COPD patients develop LC. We recently reported that in the airway epithelium of smokers, there is an increased prevalence of somatic TP53 mutations. Further, among heavy smokers TP53 mutation prevalence was associated with LC. Due to the known association between COPD and LC risk we investigated whether TP53 mutation prevalence in airway epithelium may be a common factor.

Methods: Patients undergoing bronchoscopy were recruited into an IRB-approved research study wherein soft brushings of the large airways were collected. Bronchial brush specimens from 59 subjects were sequenced by PCR-amplicon library NGS. The TP53 biomarker was measured from 59 subjects, 30 LC and 29 non-LC. The non-LC group comprised 7 COPD and 22 non-COPD subjects. Using specialized internal standards to compensate for sequencing error, VAF was observable down to 0.01%.

Results: The TP53 biomarker was associated ($p<0.05$) with COPD among all 59 subjects with 76% specificity, 62% sensitivity, positive predictive value (PPV) 59% and negative predictive value (NPV) 78%. When plotted on a receiver operator characteristic (ROC) curve the area under the curve (AUC) was 0.82. Notably, the TP53 biomarker was significantly associated with COPD among non-LC subjects, with 95% specificity, 57% sensitivity, PPV 80% and NPV 87.5%. When fit to an ROC curve, the AUC for the COPD cohort was 0.84

Conclusions: TP53 prevalence was associated with COPD diagnosis among both LC and non-LC patients in this small discovery set. We plan to validate the association in larger case-control studies. If validated, this biomarker may enable early detection of those at risk for COPD before the obstructive defect develops as well as those who should be prioritized for LC screening. We will also further investigate interindividual variation between which patients develop lung cancer and or without the background of COPD through the lens of the TP53 biomarker.

#2376 Transitional phenotype of epithelial progenitor cells in human lung adenocarcinoma premalignancy.

Khosbayar Lkhagvadorj[1], Bridget K Greuel[1], Alexis S Assante[1], Amy B Frey[2], Simran Randhawa[2], Adrie VanBokheven[3], York E Miller[1], Moumita Ghosh[1]

[1]Pulmonary Sciences and Critical Care Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO,[2]Rocky Mountain Regional Veteran Affairs Medical Center, Aurora, CO,[3]Cancer Center Biorepository, Department of Pathology, University of Colorado Anschutz Medical Campus, Aurora, CO

Introduction: Lung adenocarcinoma (ADC) is the most common subtype of non-small cell lung cancer with poor 5-year survival. Interventions during the premalignant stage of carcinogenesis can improve outcomes. Epithelial progenitors are critical cells that maintain and repair the epithelium due to their proliferation and multipotent differentiation. Previously, we discovered diminished function of progenitor cells in the premalignant lung containing ADC. In the current study, we tested whether progenitor dysfunction in premalignancy involves changes in progenitor proliferation and/or differentiation.
Methods: Lung tissues resected for early-stage ADC (N=14) were used, and progenitor function was determined using a 3D organoid culture. Lung organoids were grown from the uninvolved (UN, 5-15 cm) and tumor-adjacent lungs (TA, 0.2-2 cm) from the tumor. We hypothesized that processes active in these spatially distinct areas from the tumor-bearing lungs represent oncogenic changes in premalignancy. Organoids were cultured under either proliferation or differentiation conditions, and molecular profiles of organoids were examined by single-cell RNA-sequencing (ScRNA-seq).
Results: Analysis of proliferation and differentiation showed an opposing outcome for the UN and TA tissues. Under proliferation conditions, greater numbers of organoids were made by the cells from TA, while under differentiation, UN areas gave rise to higher numbers of organoids (p<0.05 both). Furthermore, proliferative organoids from UN tissues expressed higher numbers of $KRT5^+/P63^+$ basal stem cells compared to organoids from TA, while higher numbers of $Ki67^+$ proliferative cells were present in TA organoids (p<0.05 both). In contrast, there was no difference in epithelial cell types present in organoids grown from UN and TA tissues under differentiation conditions. ScRNA-seq comparing transcriptomic profiles of organoids from TA and UN tissues showed that under proliferation, TA organoids contained a specific cluster of basal cells that was enriched for genes belonging to EGFR signaling with higher expression of amphiregulin (AREG), a canonical ligand for EGFR. Immunostaining of organoids from TA and UN tissues confirmed significantly higher numbers of $AREG^+$ cells in TA organoids. The addition of exogenous AREG in proliferative media with or without EGFR inhibitor showed that AREG can drive progenitor cell proliferation independent of EGFR.
Conclusions: Our results suggest that progenitor dysfunction in ADC premalignancy involves increased proliferation and decreased differentiation. AREG has been described as a marker of transitional cells involved in cancer development. Thus, our findings indicate that progenitors within the TA tissue express transitional cell phenotype. Future analysis will focus on the AREG-mediated signaling in progenitor cell proliferation during premalignancy.

#2377 Gut microbiome modulation by a black raspberry nectar for improving anti-PD1 therapy effectiveness in pre-clinical cancer models.

Shiva Jahanbakhshi[1], Amna Bibi[2], Rebecca Hoyd[2], Caroline Dravillas[2], Nyelia Williams[2], Shiqi Zhang[3], Aaditya Pallerla[2], Shankar Suman[2], Joseph Amann[2], Mounika Goruganthu[2], Tamio Okimoto[2], Yangyang Liu[4], Marisa A. [1]Department of Food Science and Technology, College of Food, Agriculture, and Environmental Sciences, The Ohio State University, Columbus, OH,[2]Division of Medical Oncology, Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[3]Department of Human Sciences and Comprehensive Cancer Center, The Ohio State University College of Medicine, Columbus, OH,[4]Pelotonia Institute for Immuno-Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[5]The Ohio State University College of Medicine, Columbus, OH,[6]Department of Health Sciences, The Ohio State University College of Medicine, Columbus, OH,[7]Department of Microbiology, The Ohio State University, Columbus, OH,[8]Department of Biomedical Informatics, The Ohio State University College of Medicine, Columbus, OH

Immune checkpoint inhibitors (ICIs) have improved cancer survival rates, but only a small percentage of patients experience significant and sustained tumor responses. Recent evidence points to the gut microbiome as a modifiable factor that may improve the efficacy of ICIs. This study utilized a human clinical trial and an experimental model to assess whether a dietary intervention could enhance ICI therapeutic outcomes. Specifically, we investigated the effects of black raspberry nectar (BRB) consumption on the microbiome and subsequently in murine models of anti-PD1 cancer therapy. The BEWELL clinical trial was a randomized, placebo-controlled, cross-over dietary intervention trial where 40 individuals received 80 mL of BRB for 4 weeks or placebo for 4 weeks. The BRB altered the participants' microbiomes, significantly enriching microbes in the family *Lachnospiraceae*. Mice were gavaged with microbiomes from human participants who exhibited significant *Lachnospiraceae* enrichment post-BRB dietary intervention showed substantial reductions in tumor volume following anti-PD1 therapy. These results suggest that *Lachnospiraceae* may be key in enhancing ICI response. To further isolate the impact of specific microbes, we focused on *Blautia*, a representative *Lachnospiraceae* genus, to determine whether its presence could individually improve ICI therapeutic outcomes. Mice gavaged with *Blautia*-enriched microbiomes and provided anti-PD1 therapy demonstrated significantly lower tumor growth rates (p-value = 0.012) and a higher frequency of tumor-free status than controls (78% vs60%). A metabolomic analysis revealed distinct metabolic changes, with L-carnitine levels elevated in mice showing smaller tumors (p-value = 0.013). No significant changes were observed in butyrate, indole-derivatives, or inosine, which were previously shown to alter ICI response, suggesting a novel mechanism. Our findings underscore the potential of *Lachnospiraceae*, particularly *Blautia*, in improving cancer treatment outcomes. By extending human dietary modifications into preclinical models, this study reveals a promising strategy for using microbiome composition as a tool to enhance ICIefficacy.

#2378 Developing new potent therapeutic strategies for neuroendocrine carcinomas.

Tanya Ivanova Stoyanova

UCLA - University of California Los Angeles, Los Angeles, CA

Neuroendocrine carcinomas, such as neuroendocrine prostate cancer (NEPC), small cell lung cancer (SCLC), and neuroblastoma, share common histological features, including expression of neuroendocrine markers, rapid relapse after treatment, and poor prognosis. Due to the poor clinical outcome of patients with neuroendocrine carcinomas, there is a critical need to identify new drivers, therapeutic targets, and effective therapeutic strategies for these malignancies. Ubiquitin carboxy-terminal hydrolase L1 (UCHL1) is a protease that has a dual function in regulating protein stability. We demonstrated that UCHL1 is significantly elevated in tissues from patients with NEPC, SCLC, and neuroblastoma. Loss of UCHL1 decreases tumor growth and inhibits metastasis of these malignancies. UCHL1 maintains neuroendocrine differentiation and promotes cancer progression by regulating nucleoporin, POM121, and p53. UCHL1 stabilizes POM121 to regulate POM121-associated nuclear transport of key transcriptional factors, E2F1 and c-MYC. Here, we developed novel and more potent UCHL1 small molecule inhibitors as a new therapeutic strategy to target neuroendocrine carcinomas. Our new compounds demonstrate high potency with safety profile in vivo for neuroendocrine carcinomas. Importantly, treatment with UCHL1 inhibitors significantly reduces tumor growth of neuroendocrine carcinomas in pre-clinical settings. Our study reveals new mechanisms of UCHL1 function in neuroendocrine carcinomas tumorigenesis, identifies UCHL1 as a therapeutic target and potential molecular indicator for diagnosis and monitoring treatment responses in neuroendocrine carcinomas and develops new inhibitors to target UCHL1.

#2379 AptBCis2 plus pemetrexed for lung cancer leptomeningeal carcinomatosis and cancer-associated cachexia.

Emily Pei-Ying Lin, Bo-Tsang Huang

Medicine, Taipei Medical University, Taipei, Taiwan

Introduction: Cancer-associated cachexia (CAC) is a multifactorial syndrome characterized by anorexia and body weight loss. CAC is associated with poor survival outcomes and is common in patients with advanced lung cancer, such as leptomeningeal carcinomatosis (LM). Treatment for lung cancer CAC and LM is challenging, and remains an unmet clinical need worthy of investigation. Aptamers are small synthetic oligonucleotides considered as antibody surrogates for targeted delivery. Here we report a novel aptamer-cisplatin conjugate, AptBCis2, which suppressed tumor progression and restored body weights in the mouse LM models. The effects were even more pronounced when combination regimens with AptBCis2 plus pemetrexed were used.

Methods: The aptamer was identified via *in vivo* SELEX using a lung cancer LM orthotopic mouse model. The aptamer was conjugated with cisplatin to form AptBCis2. The tumor suppressive effects were investigated using mouse models. The AptBCis2 was administered through the tail vein; pemetrexed was injected intraperitoneally, and tumor burden was monitored *via* In Vivo Imaging System. The plasma and the CSF cisplatin concentrations were measured via Inductively Coupled Plasma Mass Spectrometry.

Results: AptBCis2 1 mg/kg (equivalent to cisplatin 0.35 mg/kg) alone or in combination with pemetrexed 100 mg/kg both showed superior tumor suppressive effects than cisplatin 2 mg/kg or pemetrexed 100 mg/kg monotherapy, as well as cisplatin 2 mg/kg plus pemetrexed 100 mg/kg combination therapy in lung cancer LM orthotopic mouse models. The treatments were given on day 2, 3, 5, 7, and 9 post tumor inoculation. On day 14 post tumor inoculation, percent of body weight change was about negative 20% in the cisplatin or cisplatin plus pemetrexed groups, positive 3% in the AptBCis2 group, and positive 20% in the AptBCis2 plus pemetrexed group (n = 8 in each group). The mice were sacrificed at day 14 for biochemical and image studies. Early mortality was observed on day 7 in the pemetrexed group with a negative body weight change of 20%.

Conclusion: AptBCis2 in combination with pemetrexed showed not only tumor suppressive effects in lung cancer LM orthotopic mouse models but also restored mouse body weights during the treatment course. The data suggested potential roles of AptBCis2 plus pemetrexed in lung cancer LM and CAC.

#2384 Improved non-invasive gene expression inference using advanced machine learning.

Jurik A. Mutter[1], **Amirsaman Ashtari**[2], Nick Phillips[1], Benoit Tessoulin[3], Jan Boegeholz[4], Cedric Rossi[5], Steven Le Gouill[6], Maximilian Diehn[7], Mohammad Shahrokh Esfahani[2], Ash A. Alizadeh[8]

[1]Division of Oncology, Stanford University, Stanford, CA,[2]Division Oncology, Department of Radiation Oncology, Stanford University, Stanford, CA,[3]Department of Hematology, University Hosptial Nantes, Nantes, France,[4]Department of Medical Oncology and Hematology, University Hospital Zurich, Zurich, Switzerland,[5]Department of Hematology, Central Hospital University (CHU) Dijon Bourgogne, Dijon, France,[6]Hematology Department, Institut Curie, Paris, France,[7]Department of Radiation Oncology, Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, Stanford, CA,[8]Division Oncology, Stanford Cancer Institute, Division of Hematology, Stanford University, Stanford, CA

Background: Gene expression profiling is crucial for understanding cancer dynamics and development, aiding in the identification of molecular subtypes, predicting patient outcomes, and discovering therapeutic biomarkers. Traditional profiling methods rely on invasive tissue specimens analyzed through RNA-seq or microarrays. These approaches can delay diagnosis due to scheduling challenges, pose risks of complications during and after surgery, and may be inaccessible to high-risk or frail patients. Recently, non-invasive gene expression inference from blood plasma has emerged as a promising alternative that analyzes fragmentation patterns of cell-free DNA molecules to infer gene expression (EPIC-Seq, Esfahani, Nat Biotechnol 2022). Further, we demonstrated that EPIC-Seq data can be effectively applied to lymphoma signatures derived from RNA-seq, yielding robust results (Mutter, ASH 2023). However, despite these advances, EPIC-Seq results cannot be directly compared to RNA-seq profiles on a single gene level. To address this challenge, we built a machine learning model that maps EPIC-Seq data into an RNA-seq-compatible format.
Methods: We developed an advanced, generative AI framework to learn mappings between non-invasive EPIC-Seq from blood plasma and tumor RNA-seq from invasive tissue biopsies. The model leverages advanced AI techniques to identify patterns in the EPIC-Seq domain and translate them into equivalent representations in the tumor RNA-seq domain and is designed handle complex, high-dimensional data while preserving key biological and functional features. For this, we sequenced a total of 304 formalin-fixed paraffin embedded (FFPE) and blood plasma samples from 227 diffuse large B-cell lymphoma (DLBCL) (n=110) and mantle-cell lymphoma (MCL) (n=117) patients using both paired (DLBCL: n=33; MCL: n=44) and unpaired data (DLBCL: n=52 FFPE, 25 plasma; MCL: n=56 FFPE, 17 plasma).
Results: Using a combination of paired and unpaired data we were able to robustly predict gene expression in RNA-seq space from non-invasive EPIC-Seq data. By splitting the cohorts in 80% training and 20% validation (n=88 patients, n=115 samples), we observed a high concordance of predicted gene expression and RNA-seq data in DLBCL samples (R=0.91). Similar accuracy was achieved in MCL (n=93 patients, n=129 samples) further confirming the model performance (R=0.94). In addition, applying the model trained on DLBCL data yielded high concordances in MCL data (R=0.68), emphasizing the robustness and applicability of the model to different lymphoma subtypes. Consistently, the model trained on MCL data achieved high concordance on DLBCL data (R=0.65).
Conclusion: These findings suggest that EPIC-Seq can serve as a reliable surrogate for RNA-seq data, offering comparable gene expression values for enhanced diagnosis and personalized treatment strategies in lymphoma patients.

#2385 Discovery of non-coding somatic driver mutations in single-cell chromatin accessibility data.

Song Cao[1], Liting Zhang[1], Alla Karpova[1], Fernanda M. Rodrigues[1], Yingduo Song[1], Nadezhda V. Terekhanova[1], Benjamin J. Raphael[2], Ryan C. Fields[1], Feng Chen[1], Li Ding[1]

[1]Washington University in St. Louis, St. Louis, MO,[2]Princeton University, Princeton, NJ

scATAC-seq data presents unprecedented opportunities to identify somatic mutations in regulatory regions. However, existing tools struggle to reliably detect somatic mutations from scATAC-seq data due to the unbalanced coverage between tumor and normal cells. To address this, we developed scVar, a pipeline designed to detect somatic mutations from scATAC-seq data. Applying scVar to snATAC-Seq data from about 200 tumor samples spanning 10 cancer types, we identified over 70,000 somatic mutations, with 95% located in non-coding regions. Comparison with bulk WGS and WXS data demonstrated that scVar achieves high accuracy in detecting somatic mutations. Notably, scVar effectively recaptured the UV mutational signature in skin cancer. Variant allele frequency (VAF) analysis revealed an increase in VAF in snATAC-seq data compared to WXS data. For tumor suppressor genes such as TP53, VHL, BAP1, CDH1, CBFB, TGIF1, and ZNF750, homozygous mutations with VAFs approaching 1 were consistently detected in snATAC-seq data, emphasizing the critical role of biallelic variants in tumor initiation. We also observed recurrent TERT promoter mutations across 20 samples, with VAFs close to 1, which were associated with increased chromatin accessibility and expression in glioblastoma, but not in skin cancer. Additionally, novel promoter mutations, such as in CDK12, were linked to increased gene expression. These findings highlight the utility of scVar in uncovering somatic mutations and their functional effects in non-coding regions from scATAC-seq data.

#2386 Preclinical model atlas to enable clinical translatability for precision oncology.

Anlu Chen[1], Thanh Bui[1], Weilong Zhao[1], Shaobo Qin[1], Vivian Prindle[2], Kimberly R. Sher[2], Adam Richardson[2], Joshua P. Plotnik[2], Aloma L. D'Souza[1], Marybeth A. Pysz[1], Josue A. Samayoa[1], Sarah Kongpachith[1], Xi Zhao[1]

[1]AbbVie Inc., South San Francisco, CA,[2]AbbVie Inc., North Chicago, IL

Preclinical models, such as 2D cultures, 3D organoids, and patient-derived xenograft (PDX) models, play a crucial role in drug development pipelines. However, their respective suitability for various research questions remains unclear. For example, RSL3-induced ferroptosis in 2D models is abolished in 3D models and *in vivo*. Similarly, some compounds targeting KRAS pathways are potent in 2D but not effective *in vivo*. Comprehensive understanding of the strengths and limitations of these models is paramount for drawing meaningful scientific conclusions. Identifying the models best suited to represent patient populations and forecast treatment response with precision is essential in enabling reverse translational research for hypothesis testing and target validation. Building upon our previous work which focused on 133 3D culture models from DEPMAP, we have expanded our efforts to encompass a larger, more comprehensive array of preclinical models. This includes DEPMAP models (207 3D and 2099 2D), 48 paired 2D-3D organoids from AbbVie, as well as around 800 internally generated and 4582 externally acquired PDX models, giving a grand total of roughly 7800 preclinical models with genomics and transcriptomics data. We employed CellTindeRX, a model-free and likelihood-based tool, to enable precision oncology by forecasting effective treatments for individuals. Briefly, we identify the tumor model most representative of a given human sample by their transcriptomics similarity, then we use the matching tumor model to further link the human sample to corresponding drug sensitivity measurements. Our approach preserves the transcriptomic signals from immune and stroma components of patient tumors, so that model comparisons consider both intrinsic and extrinsic aspects of the diseases. In general, we observe agreement for most human cancer types in TCGA between pre-clinical models and their corresponding patient diseases; however, some indications, such as stomach adenocarcinoma (STAD), show poor agreement, underscoring the biological gaps between preclinical models and patient samples. We further align preclinical models to patient samples from real world data and clinical trials to demonstrate a synthetic drug screen framework where we forecast patients' treatment response using PRISM drug sensitivity profiles from matched cell lines. Using this screening platform, TOP1i is identified as the top efficacious drug class for small cell lung cancer (SCLC). This observation is aligned with clinical treatment guidelines for this disease.These findings offer valuable guidance for selecting preclinical models that faithfully represent the patient population for reverse translational efforts, such as compound efficacy testing or MOA/target validation, thereby enhancing the accuracy and relevance of our drug development efforts.

#2387 Characterizing HERV expression patterns across breast cancer subtypes: Implications for tumor biology and therapeutic targets.

Nathalia Da Roz D'Alessandre[1], Gabriela Der Agopian Guardia[2], Helena Beatriz da Conceicao[2], Rafael Loch Batista[3], Pedro Alexandre Favoretto Galante[2]

[1]Hospital Sírio-Libanês, Sao Paulo, Brazil,[2]Hospital Sirio-Libanes, Sao Paulo, Brazil,[3]University of Sao Paulo, Sao Paulo, Brazil

Endogenous Retroviruses (ERVs) are remnants of ancient retroviral infections that have permanently integrated into host genomes, including humans. Human Endogenous Retroviruses (HERVs) are ‘fossil’ viral sequences, having lost their ability to generate infectious viruses due to mutations and deletions accumulated over millions of years. Although most HERVs are deemed non-functional, they constitute up to 8% of the human genome. Some HERVs have roles in gene expression regulation, and others are transcribed under specific conditions, such as in cancer. HERV-K is the most recently integrated class within our genome, with some members retaining relatively intact open reading frames (ORFs), suggesting their potential to encode proteins. In cancer, reactivation of HERV expression may impact gene expression, genomic stability, and cell signaling pathways.In this study, we investigated the expression of HERVs in breast cancer (BC) and non-tumor breast tissue using RNA sequencing (RNA-Seq) data from The Cancer Genome Atlas (TCGA). Specifically, we analyzed the expression profiles of HERVs across BC subgroups and their association with protein-coding gene expression profiles. We identified differentially expressed HERVs in BC subgroups (HR-/HER2-, HR+/HER2+, HR-/HER2+, HR+/HER2-) in comparison to non-tumor samples. Our analysis revealed 98 differentially expressed HERVs in HR-/HER2-, 51 in HR+/HER2+, 81 in HR-/HER2+, and 48 in HR+/HER2-. Distinct expression profiles across all subtypes were evident. Furthermore, we identified 45 differentially expressed protein-coding genes with transcription start sites within 5 kb of differentially expressed HERVs. This proximity suggests a potential regulatory influence of HERVs on these genes, indicating the need for further research to clarify the underlying mechanisms. In conclusion, the unique HERV expression profiles across BC subtypes suggest specific molecular characteristics and gene regulation patterns. These findings may aid in identifying new therapeutic targets and treatment strategies for breast cancer, emphasizing HERVs' importance in tumor biology.

#2388 Enhancing clonal hematopoiesis variant detection in tumor-normal matched sequencing using machine learning.

Anne Sonnenschein, Timothy Baker, Singer Ma, Christine Lo, Robert Tell, Brett Mahon, Nirali M. Patel, Jerod Parsons

Tempus AI, Chicago, IL

Introduction: The xT tumor-normal matched assay, which sequences solid tumor biopsy paired with matched buffy coat, has enabled the accumulation of large amounts of clonal hematopoiesis (CH) data. Although buffy-coat matched sequencing is the gold standard for distinguishing tumor from non-tumor variants, accurately identifying CH variants and distinguishing them from germline or artifactual variants presents unique algorithmic challenges. The buffy coat is sequenced at lower depth than the tumor, potentially impacting the accuracy of variant calling at low variant allele fractions (VAFs). For CH variants with high VAFs, which are the most clinically relevant, distinguishing germline variants is computationally challenging. Due to immune infiltration, CH may be found in both the normal and tumor samples, and copy number variants and loss of heterozygosity in tumor samples can substantially bias VAFs. Here, we demonstrate methods for identifying CH with high accuracy accounting for these challenges.
Methods: We developed an algorithm that calculates the expected VAF for a heterozygous germline variant in a tumor sample by integrating copy number variations, the balance between major and minor alleles, and tumor purity. This algorithm was incorporated into a machine learning model trained on common germline variants and canonical CH mutations sourced from xT data. We validated the accuracy of the xT CH pipeline against higher depth sequencing in xF+ liquid biopsy using 3,000 unique samples.
Results: Our algorithm substantially improves the separation between CH and germline variants. In a representative distribution of variants with VAFs over 20% held out for testing, sensitivity for CH variants improved from 77% to 91%, precision from 80% to 97%, and specificity from 99.5% to 99.9% (ROC-AUC of 0.995) compared to a heuristic logic that does not incorporate copy number. For canonical CHIP variants detected in xF+ with a VAF above 5%, 92% are detected as CH in xT. Variants identified as CH in xT with VAF above 2% are validated as true CH variants by xF+ with 90% precision. CH variants detected in both plasma and buffy coat have highly correlated VAFs (R^2=0.79, m=0.94), and 3.6% of the samples assessed contain a high VAF (>=20%) CH variant.
Conclusions: We demonstrate that the xT platform can distinguish between CH, germline, and artifactual variants with high sensitivity and a low false positive rate. Although CH at high VAF is present in only a minority of samples (3.6%), it is regularly observed in high throughput clinical sequencing. These variants are likely to be clinically significant and may represent secondary hematologic malignancies, which are more common in cancer patients than in healthy populations. Therefore, accuracy-driven approaches for identifying CH in buffy coat matched data are important for improving clinical outcomes and understanding the underlying biology of these variants.

#2389 The role of pyroptosis in the tumor microenvironment of head and neck squamous cell carcinoma (HNSCC).

Hani Samarah[1], Julian Jackson[1], Hannah L. Kenny[1], Zachary Kaplan[2], Parvesh Kumar[2], Zhao Lin[3], Adam Luginbuhl[1], Eric Mastrolonardo[1], Alban Linnenbach[4], Kelly Bridgham[1], Teresa Alnemri[5], Joseph Curry[1]

[1]Department of Otolaryngology, Thomas Jefferson University, Philadelphia, PA,[2]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA,[3]Medical Oncology, Thomas Jefferson University, Philadelphia, PA,[4]Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA,[5]Biochemistry & Molecular Biology, Thomas Jefferson University, Philadelphia, PA

Background: HNSCC exhibits diverse tumor microenvironments (TME), influencing progression and therapeutic responses. Pyroptosis, a form of inflammatory programmed cell death may be associated with TME's and anti-tumor immunity. This study investigates pyroptosis-related gene expression in HNSCC TMEs, classified into immune-enriched (IE), immune-enriched fibrotic (IE/F), immune-depleted (ID), and fibrotic (F).

Methods: RNA-seq data from TCGA HNSCC cohort were stratified into two TME subtypes. Tumors were grouped into IE (IE & IE/F) and ID (ID & F) for comparative analysis. Pyroptosis-related genes were curated from 838 gene sets using the MSigDB and validated through STRING protein-protein interaction analysis. Pathway enrichment was evaluated via supervised and unsupervised analyses using Gene Set Enrichment Analysis (GSEA) and Gene Set Variation Analysis (GSVA). Key contributors were identified through leading-edge analysis, with survival associations assessed using Cox proportional hazards modeling. Preliminary analysis using EcoTyper and CIBERSORTx has identified cell states and cancer ecotypes associated with TME.

Results: Unsupervised GSEA identified 31 enriched pathways in HPV-negative samples (FDR q-value <0.05), including Regulation of Cell Killing, Interferon Responsive Genes, and Pyroptosis. Leading-edge analysis revealed overlapping immune-regulatory pathways, such as Positive Regulation of Lymphocyte Apoptotic Process and Role of Phospholipids in Phagocytosis, with shared signals from genes including CD2, PDCD1, and TIGIT. Reactome Pyroptosis (FDR=2.04e-25) highlighted molecular interactions involving GSDME and CASP3. Core genes in IE phenotypes included CD3E, IL12RB1, and FASLG. Supervised analysis of pyroptosis pathways (NES=1.71, FDR q-value=0.069) identified 35 enriched genes such as CASP1, NLRC4, and GSDMD. STRING analysis highlighted pathways including cytotoxic T-cell pyroptosis (FDR=1.03e-03) and immune-associated pyroptosis (FDR=1.2e-14). GSVA revealed 424 significant pathway differences between immune-enriched and immune-depleted phenotypes, including Pyroptosis (p=0.0004) and Cell Killing (p=0.0021). IE phenotypes upregulated pathways including Interferon Gamma Signaling (p=0.0008) and Positive Regulation of Leukocyte Activation (p=0.0013). Cox analysis linked 82 pathways including Reactome Mitophagy (HR 3.56, p=3.13e-05) and Reactome Autophagy (HR 5.69, p=0.0003) to improved OS and PFS.

Conclusions: Pyroptosis and immune-regulatory pathways are more strongly associated with IE TME phenotypes and correlate with improved OS and PFS. These findings support pyroptosis as a modulator of prognosis in HNSCC, which might inform therapeutic mechanisms in overcoming treatment-resistant disease. Future study will apply this analysis to clinical trial RNA-seq data, among patients who underwent anti-PD-1 therapy.

#2390 Noninvasive early detection of colorectal cancer by a deep read-level model for accurate identification of methylation-specific circulating tumor DNA.

Ping Lan[1], Xiaosheng He[1], Hong Xu[2], Zhijian Xu[3], Nan Lin[4], Jingjing Hou[5], Xiaowen He[1], Yanzhen Cao[6], Jiandong Tai[2], Liyuan Zhao[7], Yiran Cai[7], Yonghui Li[7], Yanzhan Yang[7], Min Li[7], Yang Wang[7], Fang Liu[7], Hui Yu[7], Baoliang Zhu[7], Xiaohui Wu[7]

[1]The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[2]The First Hospital of Jilin University, Changchun, China,[3]Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China,[4]The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[5]Zhongshan Hospital of Xiamen University, Xiamen, China,[6]The Third Clinical Medical College/Affiliated Cancer Hospital of Xinjiang Medical University, Urumqi, China,[7]Shanghai Weihe Medical Laboratory Co., Ltd, Shanghai, China

Background: Liquid biopsy enables noninvasive cancer screening through the detection of plasma circulating tumor DNA (ctDNA), yet faces challenges due to the low ctDNA abundance in plasma, especially in early-stage cancer. Precise discrimination of ctDNA fragment can significantly enrich tumor signals and enhance detection accuracy, while having difficulties owing to the ambiguous labelling and insufficient characterization of tumor-derived reads. Here, we propose DREAM (a Deep Read-level model for accurate Identification of Methylation-specific ctDNA) for early colorectal cancer (CRC) detection, which can robustly identify ctDNA through simultaneous capture of DNA sequence and methylation information of tumor-derived reads.
Methods: The read-level model DREAM was trained on a well-labelled dataset derived from whole-genome bisulfite sequencing (WGBS) reads of 55 CRC tissues and 200 healthy plasma samples, which located in CRC-specific hyper- and hypo-methylated regions. The CRC tissue reads were firstly denoised based on the methylation continuity of healthy samples in these regions to filter non-tumor signal noise. The sequence and methylation information of the processed CRC reads and healthy plasma reads were then encoded as training set for a convolutional neural network (CNN)-based model to predict the tumor likelihood of each read. To validate the classification capability and subsequent CRC detection performance of DREAM, a plasma cohort including 208 CRC and 686 healthy plasmas with targeted bisulfite sequencing (TBS) was collected for model training. With DREAM, the regional ctDNA fraction of each sample was estimated and then utilized in an XGBoost classifier to predict sample-level cancer probabilities. The classifier was subsequently validated in the test set including 54 CRC, 170 healthy and 11 colon benign individuals.
Results: DREAM reached a remarkable read-level performance enhancement by the refined denoising procedure, with an accuracy increase from 0.80 to 0.96. For the test plasma cohort, DREAM achieves 85.2% sensitivity (95% CI: 84.1%-88.5%) at 95.6% specificity (95% CI: 95.1%-96.9%) for CRC detection. Specifically, the sensitivities for stage I to IV were 60.0% (3 / 5), 81.3% (13 / 16), 88.9% (24 / 27), and 100% (6 / 6). Notably, among the 11 benign samples in the non-cancer group, DREAM successfully differentiated them from malignant CRC with an AUC of 0.966, showing the effectiveness and accuracy of capturing tumor-derived signals.
Conclusions: In conclusion, DREAM showcases a significant advancement in early CRC detection through its precision in enriching tumor signals, which may contribute to more effective cancer screening and be further broadened in a wider range of cancer types.

#2391 Comprehensive quantification and annotation of viral gene integration and expression across thousands of human cancer models.

Sowmya Iyer, Moore van Tienen, Phillipp Trollman, Yao He, William R. Sellers, Catarina D. Campbell

Broad Institute of MIT and Harvard, Cambridge, MA

Viral infections have been demonstrated to influence host gene expression and drive tumorigenesis. This study aims to systematically annotate genome integration and expression of ~3000 exogenous and human-endogenous viral species across all public DepMap cancer cell lines, representing a diverse set of cancer types and lineages. Our preliminary results from this analysis pipeline successfully recapitulated known Human Papillomavirus (HpV strains 16, 18, 30 and 53) signatures in 12 cervical, 2 head and neck, and 4 engineered prostate cancer cell lines, demonstrating sensitivity at both the strain and gene levels. Associating these with genome-wide CRISPR screening data, we identified dependencies that were more correlated with viral presence rather than their respective lineages. Additionally, we observed expression of Epstein-Barr Virus(EBV) in multiple cancer types, a majority of which were of lymphoid lineage. We also found expression of the env gene of Human Endogenous Retrovirus-K (HERV-K113) in multiple lineages, with the highest average expression in skin cancers. By analyzing whole-genome sequencing we seek to identify viral integration sites in the cell lines' genomes, to complement viral gene expression. From this large-scale multimodal analysis of features derived from genomic and transcriptomic data combined with gene dependencies, we aim to uncover potential viral contributions to oncogenesis and biomarker or target discovery. This will provide a foundational resource for understanding the role of viruses in cancer, offering new insights into viral-driven mechanisms of disease.

#2392 The use of transcriptomic analysis to identify novel drug targets for DSA drug combination studies in acute myeloid leukemia.

William A. Chen[1], Valery Filippov[2], Jie Fang[3], Pedro Ochoa[4], Carlos A. Casiano[4], Kristopher E. Boyle[1], Sinisa Dovat[5], Hongjian Jin[6], Jun Yang[3], Olivia L. Francis-Boyle[7]

[1]Department of Pharmaceutical Science, Loma Linda University, Loma Linda, CA,[2]Department of Basic Sciences, Loma Linda University, Loma Linda, CA,[3]Department of Surgery, St. Jude Children's Research Hospital, Memphis, TN,[4]Center for Health Disparities and Molecular Medicine, Loma Linda University, Loma Linda, CA,[5]Departments of Pediatrics and Biochemistry & Molecular Biology, Pennsylvania State University, Hershey, PA,[6]Center for Applied Bioinformatics, St. Jude Children's Research Hospital, Memphis, TN,[7]Departments of Pharmaceutical Science; Basic Sciences; Pathology & Human Anatomy, Loma Linda University, Loma Linda, CA

Acute myeloid leukemia (AML) is a heterogeneous hematological malignancy that is commonly characterized by uncontrolled proliferation of myeloid blasts that overwhelm the bone marrow, leading to hematopoietic failure. AML is the most common form of acute leukemia in adults and its incidence increases with age. Despite recent advances, the overall prognosis of AML patients remains poor and relapse rates are high. Thus, there remains a need to identify potential therapeutic candidates that can improve patient survival outcomes and reduce the risk of relapse in AML patients. The objective of this study was to utilize transcriptomics to identify potential genes that can be targeted by drug candidates for future use in Duocarmycin SA (DSA)-targeted therapy combination studies in AML. DSA is a DNA alkylating agent that binds to the minor groove of DNA forming DNA adducts that lead to DNA damage. Previously, our lab showed that DSA reduced proliferation, induced cell cycle arrest at the G2/M phase, and triggered apoptosis in AML cells in a dose- and time-dependent manner. Therefore, we hypothesized that RNA sequencing analysis of genes obtained from DSA-treated AML cells will identify novel genes that can targeted by potential drug candidates. To test our hypothesis, human AML cell lines (Molm-14 and HL-60) were treated with high (Molm-14: 100 pM; HL-60: 500 pM) and low (Molm-14: 11.12 pM; HL-60: 112.7 pM) concentrations of DSA for 36 hours, cells were harvested, RNA was isolated and RNA sequencing and gene expression profiling analysis were performed by the Hartwell Center for Biotechnology and the Center for Applied Bioinformatics at St. Jude Children's Research Hospital, respectively. Pathway analysis was performed using the NIH's Database for Annotation, Visualization and Integrated Discovery (DAVID) tool to identify the top DSA-induced pathways and their associated genes. Differentially expressed genes (DEGs) for all four DSA treatment groups were identified using the cutoffs: P-value <0.05, Log2Fold Change >0.5 and <-0.5, and then the overlapping DEGs were visualized using Venny 2.1.0. Our results showed that the top pathways that were activated in all four DSA treatment groups included oxidative phosphorylation, chemical carcinogenesis - reactive oxygen species, and metabolic pathways. Genes that were upregulated within these pathways primarily included mitochondrial associated genes that play a role primarily in apoptosis (MT-*ATP6*, MT-CO2, and MT-*ND5*). Additionally, some of the pathway genes play a role in proliferation (*MT-ND2* and *TPM2*) and chemoresistance (*MT-ND2, MT-ND4* and *TPM2*). Our findings suggest that the genes associated with proliferation and chemoresistance can serve as potential therapeutic targets that can be used to develop novel targeted therapies to be evaluated in combination with DSA for the treatment of AML.

#2393 Gene regulatory networks of enzalutamide resistance in prostate cancer.

Sini Hakkola, Anni Peramaki, Karishma Sajnani, Antti Kiviaho, Alfonso Urbanucci, Matti Nykter, Mikael Marttinen

Prostate Cancer Research Center, Faculty of Medicine and Health Technology, Tampere University and Tays Cancer Centre, Tampere University Hospital, Tampere, Finland

Introduction: Castration-resistant prostate cancer (CPRC) is typically managed with antiandrogens, such as enzalutamide (ENZA), which can delay disease progression but are not curative, as resistance to these treatments eventually develops. This resistance is likely a consequence of significant remodeling of gene regulatory landscape of cells adapting to an androgen-deprived, stressful environment. Understanding the aberrancies in gene regulation underlying ENZA resistance is essential for improving the therapeutic strategies for CRPC.
Methods: Using single-cell chromatin accessibility (ATAC) and transcriptome sequencing data sourced from the parental and ENZA-resistant LNCaP prostate cancer cells, we have applied knowledge graph-based neural networks to model transcription factor (TF) regulons and their associated molecular processes underlying the cell states from initial ENZA response towards ENZA resistance.
Results: We have identified TF regulons associated with stress responses, cell cycle progression and androgen signaling, altered in ENZA-resistant cells. Specifically, the ENZA-resistant cells are characterized by the gain of SOX4 regulon, likely to contribute to the metabolic and proliferative reprogramming of the resistant cells. Cell cycle analysis revealed that while the cell proportion is largest in G1 phase in each treatment, the proportion of cells in S phase is increased in resistant samples, suggesting enhanced S-phase transition in resistant cells in contrast to G1 arrest caused by ENZA in treatment-responsive cells. We validate our findings in independent transcriptomic studies of ENZA-resistant VCaP and DuCaP cell lines indicating the robustness of the results. Moreover, utilizing spatial transcriptomic data from a longitudinal patient cohort, we pinpoint that the SOX4 regulon target genes are enriched in the epithelium of CRPC patients, compared to treatment-naïve and neoadjuvant-treated disease states.
Conclusion: In summary, we determine gene regulatory alterations associated with ENZA resistance in preclinical models, providing valuable insights into uncovering the mechanisms of resistance to antiandrogens in CRPC.

#2394 Survival and response modeling using diverse mouse mammary tumor models.

Matthew D. Sutcliffe[1], Kevin R. Mott[1], Denis O. Okumu[1], Michael P. East[2], Gary L. Johnson[2], Shawn M. Gomez[2], Timothy C. Elston[2], Charles M. Perou[1]

[1]Department of Genetics, University of North Carolina, Chapel Hill, NC,[2]Department of Pharmacology, University of North Carolina, Chapel Hill, NC

Triple-negative breast cancer (TNBC) is a clinically heterogeneous subtype of breast cancer with poor outcomes and limited molecular predictors of survival. To better understand TNBC tumor growth dynamics and to identify biomarkers of treatment response, we developed a diverse panel of 26 mouse mammary tumor models (syngeneic transplants (n = 23) and autochthonous (n = 3)) that are immune-competent and reflect the molecular subtypes seen in human TNBC. These 26 tumor models exhibit distinct baseline tumor growth rates, drug sensitivities, and molecular profiles, which we have extensively characterized through bulk RNA-seq, scRNA-seq, DNA exome sequencing, and mass spectrometry-based kinase proteomics. This comprehensive, multi-platform data set provides a unique resource to perform machine learning analyses for response and survival predictions.

Using this murine dataset, we first identified survival-associated gene expression features through Cox proportional hazards modeling. Murine tumors with high expression of basal-like subtype gene signatures were associated with shorter survival while luminal subtype and immune cell features correlated with longer survival; these findings closely align with patterns observed in human breast cancer. Second, we trained an Elastic Net-based survival predictor using untreated tumor RNA-seq data from each of the 26 mouse models and validated its prognostic utility using human breast cancer datasets such as SCAN-B (human set c-index = 0.63).

Additionally, our mouse tumor models dataset includes efficacy testing for immune checkpoint inhibitors (ICI; anti-PD1/anti-CTLA4) and MEK inhibitor therapy (trametinib). Pre-treatment tumor RNA-seq analyses identified features associated with greater survival benefit in ICI-treated models, including high PDL1 mRNA and multiple T-cell and B-cell associated gene expression signatures. Similar analyses for MEK inhibition revealed key resistance-associated genes, such as Akt1, whose high baseline expression correlated with MEKi resistance. DNA copy number analyses of the murine tumor data identified distinct chromosomal regions linked to MEKi sensitivity (i.e. chr 12q) and resistance (i.e. chr 2q). These genomic alterations overlapped the gene expression associations, suggesting potential biomarkers for MEKi response. Ongoing work involves developing predictive Elastic Net models for both ICI and MEKi sensitivity, which will be validated using available human clinical trial datasets. Overall, this work demonstrates the translational potential of this diverse mouse models dataset as a platform for biomarker discovery and therapy optimization.

#2395 The role of exonized mobile elements in chimeric transcript emergence in glioblastoma.

Rafael L. V. Mercuri[1], Thiago L. A. Miller[1], Filipe F. dos Santos[1], Matheus de Lima[2], Aline Rangel-Pozzo[2], Pedro A. F. Galante[1]

[1]Institudo de Ensino e Pesquisa do Hospital Sirio-Libanes, Sao Paulo, Brazil,[2]University of Manitoba, Winnipeg, MB, Canada

Background: Glioblastoma (GBM) is the most aggressive type of primary brain tumor in adults, with a median survival of approximately 15 months. Unfortunately, the prognosis for GBM has remained unfavorable for decades. The genetic and transcriptomic heterogeneity of GBM complicates treatment, underscoring the need for a more comprehensive understanding of its molecular basis. Recently, retrotransposons have been shown to influence gene expression and the formation of chimeric transcripts. Although they are associated with various cancers, their precise role in GBM remains unclear. In this study, using paired-end RNA-Seq data from The Cancer Genome Atlas (TCGA) and the GBM (U251) cell line, we examined the exonization of mobile elements and the generation of GBM-specific chimeric transcripts. For retroelement references, we utilized RepeatMasker annotations. To detect, characterize, and quantify the expression of chimeric transcripts, we developed FREDY, a tool designed to identify the exonization of retrotransposable elements in RNA-seq data. Initially, we identified 1,012 chimeric transcripts linked to the exonization of intragenic (intronic) mobile elements. Specifically, Alu element exonization was the most common (~45%) and occurred primarily in the 5' regions of transcripts. As expected, the majority (83%) of these exonizations involved Alu elements located in the opposite transcriptional direction of their host genes. In contrast, LINE1 elements and retrocopies of protein-coding genes were predominantly exonized (46% and 56.7%, respectively) in the 3' regions of host genes and in the same transcriptional direction as their host genes. Notably, we identified two candidate chimeric transcripts impacting the tumor suppressor gene ROS1. Furthermore, when comparing potential protein domains, we found that the coding sequences of these chimeric transcripts lacked two ROS1 domains, suggesting a premature cessation of transcription and potentially translation. Additionally, we quantified that these chimeric transcripts represent 84% of the total expression of the ROS1 gene in the identified GBM samples.
Conclusions: We have established a framework for detecting chimeric transcript formation in cancer through the exonization of mobile elements. We applied this approach to GBM samples and cell lines, identifying chimeric transcripts of the tumor suppressor gene ROS1 that may play a significant role in GBM carcinogenesis.

#2396 Gene fusion and variant-aware isoform detection with functional prediction from long-read RNA sequencing.

Colette Felton[1], Andrea Galvez[1], Leanne Sayles[2], Christopher Vollmers[1], Alejandro Sweet-Cordero[2], Angela Brooks[1]

[1]Biomolecular Engineering and Bioinformatics, University of California, Santa Cruz, Santa Cruz, CA,[2]Department of Pediatrics, University of California, San Francisco, San Francisco, CA

Although most cancer variant profiling is done with short-read-based methods, many cancers are driven by structural variants that are difficult to detect with these methods. Our current approach to understanding driver mutations is also limited to single variants and rarely considers the context in which they are expressed. Alterations in the expression and splicing of genes containing variants can both impact their tumorigenicity and allow them to develop resistance to therapies. We present FLAIR3, which generates a custom transcriptome from long-read RNA sequencing and identifies SNVs, insertions, deletions, and gene fusions from alignment to this transcriptome. We show that this improves accuracy above alignment to the genome or annotated transcripts. FLAIR3 then integrates these variants with the transcripts to predict functional changes to the amino acid sequence. We apply this approach to patient-derived osteosarcoma cell lines, a cancer whose pathology is driven by complex structural variation. In these samples, we identify more complex changes to previously identified amplified drivers such as alternative splicing of MYC and alternative splicing of a gene fusion in CCNE1. We also identify a novel set of actionable cancer gene alterations not previously detected by short-read methods. This includes a large deletion in KEAP1 and a number of novel gene fusions, including TP53 and other genes fused with intergenic regions and a complex 4-locus fusion in NOTCH1 not detected by any preexisting tools. We then validated the protein sequence of novel fusions with Quantum-Si protein sequencing. This analysis shows that long-read RNA sequencing can detect novel variants in actionable cancer genes and that integrating splicing and variant alterations provides the most complete picture of gene alterations in cancer.

#2397 Order parameter methods for interpretable comparisons across tumors and cell lines.

Lauren Golden[1], Naima Abdirahman[2], Xiaomeng Zhang[1], Maria Yampolskaya[3], Barbara DeKegel[1], Pankaj Mehta[3], Francisca Vazquez[1], Catarina D. Campbell[1]

[1]The Broad Institute of MIT and Harvard, Cambridge, MA,[2]Wellesley University, Wellesley, MA,[3]Boston University, Boston, MA

As precision cancer medicine develops, new bioinformatic tools that are both more granular and interpretable become imperative. In particular, when working with cancer cell lines to identify and validate potential treatment targets in cohorts of interest it is necessary to understand whether and precisely how cancer cell lines recapitulate tumor biology. As part of the Cancer Dependency Map project we are working to develop approaches for relating cell lines to patient tumors.

Here we demonstrate a simple supervised classifier inspired by order-parameter methods from spin-glass physics that uses a pre-determined set of tissue type labels to produce scores per-gene and per-type that can be evaluated on both tumors and cell lines. The model described here complements this previous work, producing scores that qualitatively agree with the unsupervised model, while also enabling a quantitative, gene-level understanding of the origin of the classification result. Further, this method allows multiple cohorts of tumors and cell lines to be compared directly, relative to a common basis.

We describe both the method itself, a variation of which has been deployed in single-cell developmental biology, as well as the metadata processing necessary for its effective use in comparing models to tumors. We developed an algorithm that defines our scope of tissue types maximizing granularity while minimizing collinearity and accounting for gaps and overlaps in annotation between tumor and cell line datasets, with over 35 total disease types assessed. We show using several examples from cell lines that this simple method can identify not only which type of tumor each cell lines most closely resembles, but also extract the most important genes involved in that determination. Our model, using 75 samples per tissue type, achieves >95% top-3 accuracy on a test dataset of over 10k tumor samples. The matchup between annotated type and predicted type is weaker in cell lines and also highly type-specific, ranging from 95% in some cohorts of 20% in others, and we explore the reasons for this. In one example of lung cell line models our method identifies cell line cohorts that match up to adenoid as well as squamous tumors, and another cohort that doesn't match with either set of tumors. Based on the genes identified by the model as important for classifying these lines we describe their phenotype as mesenchymal. Additionally, we show how this method can be augmented with normal tissue data from GTEx to foreground signals that are specific to cancer relative to related normal tissues.

#2398 Pregnancy-specific glycoproteins in tumors are strong predictors of outcome in female lung adenocarcinoma patients.

Jung Hun Oh[1], Gabrielle Rizzuto[1], **Rena Elkin**[1], Corey Weistuch[1], Larry Norton[1], Gabriela Dveksler[2], Joseph O. Deasy[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Uniformed Services University of Health Sciences, Bethesda, MD

Pregnancy-specific glycoproteins (PSGs) are normally critical regulators of maternal immune tolerance during pregnancy, preventing fetal rejection by modulating innate and adaptive immune responses. Recent studies have identified that mRNA expression of PSG genes in tumors is associated with poor prognosis in lung, mesothelioma, breast, and ovarian cancers. Given their pregnancy-related function, we hypothesized that PSGs could exert sex-specific effects in some cancers. An analysis of sex-differential effects of PSGs as prognostic markers was conducted using two datasets from The Cancer Genome Atlas (TCGA) including 235 male and 271 female patients and Clinical Proteomic Tumor Analysis Consortium (CPTAC) including 70 male and 36 female patients. To assess the predictive power of PSGs, we evaluated whether incorporating PSG expression levels improved machine learning models for survival prediction. Lung adenocarcinoma (LUAD) was identified as showing a significant sex-specific prognostic difference. Female LUAD patients expressing PSG genes had notably worse survival outcomes compared to those without PSG expression. Male patients did not show similar effects. Combinatorial analysis showed that a combination of PSG3, PSG7, and PSG8 expression resulted in particularly poor prognosis in the female group (30% of the female patients) with $p = 8.67E-06$. This finding was independently validated in the smaller CPTAC dataset with $p = 0.0382$. Further analysis of correlated pathway changes revealed that female LUAD patients with PSG expression exhibited enrichment of the "KRAS Signaling Down" pathway, suggesting a potential mechanism underlying the observed sex-specific effects. Including the KRAS pathway activity into the PSG model demonstrated robust performance in predicting survival outcomes for female patients (validated C-index = 0.78 using the CPTAC dataset) but did not improve prediction for male patients. These findings highlight a unique role for PSGs in influencing LUAD progression and survival in a sex-dependent manner. Targeting PSG-related pathways may offer a tailored treatment strategy for female LUAD patients, potentially improving outcomes. Further research is needed to unravel the relationship between PSG expression and KRAS pathway activation. We also plan to examine the sex-specific prognostic difference, looking into pregnancy history and the influence of hormone-related genes. Since PSGs are not typically expressed in the absence of pregnancy, they could be a promising drug target.

#2399 Genomic and transcriptomic profiling of advanced early-onset colorectal cancer.

Erika Zuljan[1], Shuba Varshini Alampalli[1], Eric Blanc[2], Bruno Kohler[3], Rene-Filip Jackstadt[4], Ulrich Keller[1], Sebastian Stintzing[1], Ulrich Keilholz[1], Hanno Glimm[5], Stefan Frohling[6], Dieter Beule[2], Ivan Jelas[1], Damian Rieke[1], Manuela Benary[1]

[1]Charite - University Medicine Berlin, Berlin, Germany,[2]Berlin Institute of Health (BIH), Berlin, Germany,[3]Heidelberg University Hospital, Heidelberg, Germany,[4]Deutsches Krebsforschungszentrum Heidelberg (DKFZ), Heidelberg, Germany,[5]Nationales Centrum fur Tumorerkrankungen Dresden (NCT), Dresden, Germany,[6]Nationales Centrum fur Tumorerkrankungen Heidelberg (NCT), Heidelberg, Germany

Background: Incidence rates of early-onset colorectal cancer (EO-CRC) are increasing in high-income countries, yet the underlying causes and optimal clinical management strategies remain unclear.
Methods: Comprehensive molecular profiling was conducted on colorectal cancer patients enrolled in the DKTK MASTER program, which includes patients with fresh tumor material, age <50 years, and/or rare cancer types. Profiling utilized RNA sequencing (RNA-seq) and whole-exome (WES) or whole-genome sequencing (WGS). WES data was analyzed for genomic variants, tumor mutational burden (TMB), and mutational signatures. WGS underwent metagenomic analysis, mapping unmapped reads to a metagenome assembled genomes (MAGs) of German CRC patients to identify CRC-associated microbiome. Transcriptomic data were analyzed for consensus molecular subtypes (CMS) and inflammation signatures. A small cohort of late-onset CRC patients (>50 years, n=10) and TCGA-COAD data were used as reference cohorts.
Results: The cohort included 168 patients, 154 aged <50 years (median age: 43; range: 19-50) and 10 aged >50 years (4 age data unavailable). Primary tumors were located in the right colon (n=32) or left colon (n=127) (9 NA).
Common molecular alterations included TP53 (77%), APC (70%), and KRAS (48%) mutations. The median TMB was 3.5 mutations/megabase and was comparable to TCGA-COAD (3.8 mutations/megabase). TMB>10 Mut/Mb was only identified in 2 samples. Age was not associated with inflammation levels. CMS subtypes I-IV were identified in 15%, 26%, 9%, and 34% of cases, resembling TCGA-COAD but with slightly higher CMS IV and lower CMS III. Findings suggest a molecular profile similar to late-onset CRC (LO-CRC).
Mutational signatures in WES analysis revealed a prevalence of clock-like and defective DNA damage repair signatures (SBS1, SBS3, SBS5, SBS6). Clock-like signatures (SBS1, SBS5) showed no significant age-related differences.
Metagenomic analysis revealed distinct prevalence patterns and notable dissimilarity in gut-associated microbes between early- and late-onset cohorts. Significant differences in abundance were observed in Firmicutes such as Blautia wexlerae, Coprococcus comes, Veillonella parvula, and Bacteroidetes such as Prevotella copri.
Conclusion: Comprehensive molecular profiling revealed no significant differences between sporadic EO-CRC and LO-CRC, thus not suggesting different clinical management in this setting. The identification of distinct microbiome compositions warrants further investigation.

#2400 Utilizing machine learning to predict clinical staging with head and neck cancer gene expression datasets.

Nathan DeMichaelis[1], Amrit Menon[2], Dalton Schutte[3], Frank G. Ondrey[4]

[1]Dartmouth College, Hanover, NH,[2]University of Chicago, Chicago, IL,[3]Department of Surgery, University of Minnesota Medical School, Minneapolis, MN,[4]Department of Otolaryngology - Head & Neck Surgery, University of Minnesota Medical School, Minneapolis, MN

Introduction: Head and neck cancer is a deadly disease with relatively stagnant cure rates. Predictive oncology might allow treatment stratification for surgery, radiation, and chemotherapy combinations based on both stage and other risks. As more high dimensional data from genomic expression datasets become publicly available, machine learning algorithms could be used for staging/treatment refinement. In the present study, we applied machine learning algorithms to our previously published smaller U133A Affymetrix gene expression dataset and the NCI Cancer Genome Atlas (TCGA).

Methods: Models were trained to classify T and N staging data for TCGA and Affymetrix chip datasets, by early (T1/2) versus advanced T stage (T3+), and for N0 versus N1+, respectively, for TCGA and Affymetrix data separately. TCGA data was split according to HPV status into two datasets. Models to predict early vs. advanced stage were trained and tested on randomly (proportional with respect to staging) split data: large dataset (HPV- T and HPV- N, n>=350) models were trained on 80% and tested on the unseen 20% samples, while for the remainder (n<=50), data were split 70%-30% for sufficient testing. Scikit-learn models utilized were: Bagged (aggregated) Support Vector Classifiers (BSVCs), Random Forest (RF), Gradient Boosting (GB), and Linear Regression (LR). LR was added unaltered as a baseline prediction, while the other three models were subjected to hyperparameter tuning (assessed for all combinations of selected settings) and feature selection: models were trained and tested on whole expression data, iteratively reduced to the top half important genes down to <=100 genes. Models were assessed by test accuracy and area under receiver operator characteristic curve (AUC-ROC), then hyperparameter-tuned models and respective gene lists were assessed over 50 trials (random initializations and data splits).

Results: Hyperparameter-tuned RF and BSVCs models with selected gene lists significantly outperformed LR in 6/6 tasks, while GB outperformed LR in 2/6 tasks. Example highest performing models (test accuracy [95% CI], AUC-ROC [95% CI]) were: For Affymetrix N, BSVCs (0.893 [0.872-0.915], 0.95 [0.931-0.969] outperformed LR (0.49 [0.453-0.527], 0.476 [0.435-0.517]). For TCGA HPV- N, BSVCs (0.832 [0.818-0.847], 0.892 [0.877-0.907]) outperformed LR (0.581 [0.568-0.595], 0.615 [0.6-0.631]). For TCGA HPV+ T, RF (0.835 [0.815-0.854], 0.954 [0.942-0.965]) outperformed LR (0.669 [0.645-0.694], 0.76 [0.732-0.789]).

Conclusions: Utilizing this hyperparameter tuning and feature selection approach, we have identified machine learning techniques that can be used to analyze high dimensional data of small and large genomic expression datasets to predict clinical features and identify predictive genes for further analysis, applicable to head and neck cancer, a relatively rare malignancy (about 3% of total cancers).

#2402 Comparative genomics at prostate cancer risk loci to identify human-specific risk variants predisposing the human male to prostate cancer.

Chidi N. Molokwu

Bradford Teaching Hospitals NHS Trust, Bradford, United Kingdom

Introduction: Prostate cancer (PCa) is the most common cancer in the human male but is absent in other primates, including our closest extant relative the chimpanzee. Predisposition to PCa is multifactorial and includes both genetic and environmental factors. Genome wide association studies (GWAS) have identified hundreds of PCa associated single nucleotide polymorphisms (SNPs), but it is not clear which SNPs are the most relevant to carcinogenesis and disease progression. PhyloP scores are a measure of conservation between species at each position in the aligned genome, with positive scores indicating higher conservation. Human Accelerated Regions (HARs) are regions in the genome that show conservation between mammalian species but unexpected divergence in humans. A comparative genomics approach was used to identify SNPs and candidate genes that confer PCa risk on the human male.

Methods: PCa associated SNPs were obtained from studies submitted to the GWAS Catalog (https://www.ebi.ac.uk/gwas/home), and the GWAS Diversity Monitor Database (https://gwasdiversitymonitor.com). Risk Allele Frequencies (RAFs) were obtained from Ensembl (https://www.ensembl.org/), using regional classifications and RAF data from the 1000 Genomes. Human and chimpanzee genomes were aligned using the Cactus genome alignment tool (https://cglgenomics.ucsc.edu/data/cactus/). PhyloP scores were determined for each SNP position and the closest HAR was identified using the Bedtools package. The allele for each specie at the PCa SNP position was compared to determine positions where the PCa risk allele was divergent from the ancestral primate allele.

Results: 520 PCa associated SNPs were identified. Eleven SNPs occurred at positions with PhyloP score>1.0, and where the PCa risk allele was different from the chimpanzee allele. Two of the 11 SNPs had the risk allele occurring in more than half of humans (rs6062509 at 71%, and rs8064454 at 58%). Two SNPs with the highest PhyloP scores had RAFs of 11% for rs76832527 (PhyloP score 8.616) and 17% for rs2277283 (PhyloP score 3.842). A non-coding region of chromosome 8 containing rs870167 had RAF of 17% in humans. ZGPAT, HNF1B, ANO7, INCENPS, GATA2-AS1 and CLND23 were identified as candidate genes for prostate cancer carcinogenesis and/or progression. There was no overlap of PCa associated SNPs with HAR regions.

Conclusions: Six candidate genes harbored PCa risk SNPs that are in loci that show high conservation between mammalian species, but a divergent PCa risk allele in human males. ZGPAT, HNF1B, ANO7 and GATA2-AS1 are relevant to PCa progression and are candidate genes for human-specific predisposition to PCa. Further studies on these genes and non-coding loci are needed to determine their role in PCa predisposition in the human male.

#2403 Efficient detection of whole genome duplication: a targeted sequencing approach.

Hua Bao, **Haimeng Tang**, Rui Liu, Ningyou Li, Min Wu, Xunbiao Liu, Zhili Chang, Xue Wu

Nanjing Geneseeq Technology Inc., Nanjing, China

Objective: Whole Genome Duplication (WGD) involves the replication of an organism's entire genome and is linked to increased evolutionary complexity and cancer progression. In tumors, WGD contributes to heterogeneity and therapy resistance, making its identification crucial for targeting genomic instabilities and informing treatment strategies. Current methods for detecting WGD are often expensive and time-consuming, highlighting the need for a cost-effective and efficient detection panel to improve therapeutic strategies, patient outcomes, and resource allocation in clinical settings.
Methods: We retrospectively analyzed 4,941 tissue samples from patients spanning 14 different cancer types, including ovarian, uterine, breast, pancreatic, prostate, cervical, liver, lung, colorectal, and gastric cancers. Using a targeted sequencing panel (GENESEEQ GENAVISTA) focused on 437 cancer-related genes, we performed comprehensive mutational profiling (~1,000X). WGD was determined by analyzing read depth, allele frequency, and employing variant calling algorithms to detect gene duplications and genomic rearrangements. Additionally, a prospective cohort of 33 cancer patients was evaluated to compare the performance of our panel with whole exome sequencing (WES, ~200X) and whole genome sequencing (WGS, ~30X).
Results: Our analysis revealed varying prevalence of WGD across cancer types, with significant rates observed in ovarian (50.93%) and breast cancers (52.32%). Pelvic cancer (60.61%) and melanoma (60.00%) also showed high WGD-positive rates. Conversely, endometrial cancer exhibited a notably lower rate of 19.41%. Pancreatic and prostate cancers showed moderate WGD frequencies of 27.46% and 21.51%, respectively, while liver and bile duct cancers had an incidence of 41.30%. In the prospective cohort, our panel demonstrated higher sensitivity compared to WES (100% vs. 84.62%) but slightly lower specificity (90% vs. 95%). The overall concordance with the gold standard WGS was 93.9%, surpassing that of WES (90.9%).
Conclusion: Our study highlights the significant variability of WGD across cancer types, with a notably high prevalence in ovarian and breast cancers. This underscores the potential of WGD as a biomarker for therapeutic targeting. Our targeted sequencing panel offers an efficient and cost-effective detection method, demonstrating substantial clinical potential for informing personalized treatment strategies and improving patient outcomes.

#2404 Change in expression of microRNAs following limb amputation in canine osteosarcoma patients predicts survival time after chemotherapy.

Heather Treleaven[1], Michael Edson[2], Latasha Ludwig[3], Alicia Viloria-Petit[4], R. Darren Wood[1], R. Ayesha Ali[5], Geoffrey A. Wood[1]

[1]Pathobiology, University of Guelph, Guelph, ON, Canada,[2]MaRS Centre, University Health Network, Toronto, ON, Canada,[3]Population Medicine and Diagnostic Sciences, Cornell Univeristy, Ithaca, NY,[4]Biomedical Sciences, University of Guelph, Guelph, ON, Canada,[5]Mathematics and Statistics, University of Guelph, Guelph, ON, Canada

Osteosarcoma (OS) is the most common primary bone tumour in dogs and humans. There are an estimated 8,000 new cases of canine OS per year in the United States compared to only 1,000 in humans. The most common primary location for both species is the appendicular skeleton, with metastases forming mostly in the lungs and bones. Appendicular OS is not only more common in dogs, but also more aggressive, making dogs a valuable spontaneously metastasizing animal model of aggressive human OS. Median survival after amputation and adjuvant chemotherapy in dogs is 1 year, less than 30% survive 2 years, and an estimated 90% of dogs develop metastases after therapy. In contrast, humans have a 76% 5-year survival rate and 15-25% will develop metastases. Predicting clinical outcomes after treatment is difficult in both species, particularly for those without clinically detectable metastatic disease at diagnosis. MicroRNAs (miRNAs) are small, non-coding RNA that control gene expression and are often dysregulated in cancer. MiRNAs share entirely or nearly identical sequences between dogs and humans and are present in blood, making them good potential biomarkers. Recently, we identified multi-miRNA models which could reliably predict survival using pre-amputation canine OS plasma samples. Tumour cells can release miRNAs into the blood via active and passive mechanisms; therefore, with the primary tumour removed after amputation, miRNA expression levels in the blood should be altered. We hypothesize these changes in miRNA expression can be used to prognosticate canine OS patients better. MiRNA expression was measured using real-time quantitative PCR in matched pre- and post-amputation plasma samples from canine OS patients (n=25) at the Ontario Veterinary College. Change in expression was calculated for each miRNA as [(post-amputation) - (pre-amputation)] for each matched pair of samples. For each dog, survival was measured as overall survival and disease-free interval (DFI). Overall survival is the time from diagnosis to death and DFI is the time from diagnosis to clinically detectable metastasis. Dogs were censored if they died from non-OS events, were lost during follow-up, or were still alive. Prognostic ability was evaluated for individual miRNAs by identifying an optimal expression cutoff point using the survminer package in R and visualized using Kaplan-Meier curves. Decision trees were grown using the rpart package in R to evaluate whether multi-miRNA models offered improved prognostic ability compared to single miRNAs. We found that a model combining miRNA-144 and miRNA-23a, for both overall survival and DFI metrics, was able to identify 3 distinct groups which reflected survival time worse, on par, and better than the median survival time reported in literature. These models offer a simple prognostic test that may have clinical applications for veterinary and human OS patients.

#2405 NGS-based molecular profiling reveals remarkable anticancer synergy of EZH1/2 dual inhibitor HM97662 with standard-of-care therapy on small cell lung cancer.

Gunwoo Lee, Seungheon Baek, Jungwha Park, Aran Park, Seung Hyun Jung, **Jooyun Byun**, Young Gil Ahn

Hanmi Pharmaceutical Co., Ltd., Gyeonggi-do, Korea, Republic of

The development of EZH1/2 inhibitors is crucial in targeting tumors due to their central role in epigenetic regulation. These EZH1/2 enzymes contribute to tumorigenesis by promoting transcriptional repression of tumor suppressor genes. Studies have shown that inhibiting EZH1/2 can suppress tumor growth and improve clinical outcomes, particularly in hematological malignancies. However, the selective potency of EZH1/2 inhibitors in a limited range of solid tumors highlights the need for precise selection of indications based on molecular characteristics. Recent research has discovered that cancers with a small cell neuroendocrine (SCN) phenotype, characterized by high aggressiveness and limited treatment options, share molecular characteristics and drug susceptibility profiles with hematological malignancies. Moreover, the role of EZH2 in the cancer with SCN feature, such as small cell lung cancer (SCLC) and neuroendocrine prostate cancer (NEPC), has been increasingly recognized. Notably, EZH2 contributes to chemo-resistance in SCLC by repressing the transcription of Schlafen 11 (SLFN11), a biomarker of sensitivity to DNA-damaging chemotherapies. Inhibition of EZH2 upregulates SLFN11 expression and restores chemosensitivity in chemo-resistant SCLC models, suggesting EZH2 blockade as a promising therapeutic strategy. Previously, we evaluated antiproliferative properties of HM97662 on diverse solid cancers and demonstrated its great potential in various SCLCs. Therefore, we explored to determine the molecular factors that influence the sensitivity to HM97662 and synergism with standard-of-care (SoC) in SCLC. Using next generation sequencing (NGS), we analyzed the transcriptomic profiles of HM97662-sensitive and non-sensitive SCLC cell lines, verifying the molecular determinants of the sensitivity. We also identified the transcriptomic changes when EZH1/2 were inhibited through HM97662 in the SCLC cell lines at the gene as well as pathway level. We found that HM97662 treatment selectively increased the expression of genes involved in cell cycle regulation including CDKN1A (p21) in sensitive SCLC cell lines. Similarly, SLFN11 level was also dose-dependently increased. Remarkably, HM97662 exhibited super-synergistic effect with SoC in SCLC xenograft models, outperforming to both an EZH2 inhibitor and another EZH1/2 dual inhibitor. This study highlights the transformative potential of combining epigenetic modulation with conventional treatment regimens to overcome therapeutic limitations. Leveraging NGS, we identified molecular signatures predictive of enhanced response to the EZH1/2 dual inhibitor HM97662. These findings pave the way for personalized therapeutic strategies, offering renewed hope for patients with small cell lung cancer and other cancers with SCN feature as well.

#2406 LossFinder: a novel algorithm for detecting PTEN homozygous deletions in cancer.

Ting Kuang, Chenglin Liu, Zhihong Zhang, Zhou Zhang, Fujun Qiu, Yuzi Zhang

Burning Rock Biotech, Guangzhou, China

Introduction: The PTEN gene, located at 10q23.31, is a tumor suppressor that regulates the PI3K/AKT signaling pathway. PTEN deletions and/or loss of protein are common in cancers, with The Cancer Genome Atlas (TCGA) reporting a prevalence of 10-85%, about half of which are due to copy number loss. PTEN homozygous deletions, more significant than hemizygous deletions, are key markers in cancer treatment, especially with the approval of the AKT inhibitor capivasertib. Homozygous PTEN deletions occurs in 4.28% of cancers, 5.08% in breast cancer, and 17.42% in prostate cancer. Detecting exon-level deletions in the PTEN gene is particularly challenging, given the short coding regions, the influence of tumor heterogeneity, and the effects of sample quality on Next-Generation Sequencing (NGS) data. To overcome these challenges, we developed LossFinder, a novel algorithm for detecting homozygous PTEN deletions.

Methods: LossFinder is designed to detect homozygous gene copy number deletions in tumor NGS sequencing. The algorithm: 1) employs multi-depth correction and noise reduction to enhance the signal-to-noise ratio, mitigating the effects of tumor heterogeneity and experimental noise; 2) uses the circular binary segmentation (CBS) algorithm for precise breakpoint localization, improving detection of small exon-level copy number alterations; 3) assesses tumor purity and ploidy through mutation frequency and copy number alterations, restoring absolute copy numbers to distinguish homozygous from hemizygous deletions. We evaluated limits of detection (LoD) and precision using mixed tumor cell lines from ATCC. Additionally, clinical tumor samples were analyzed for PTEN deletion prevalence, with IHC used as the gold standard for comparison.

Results: In cell line simulations, the algorithm demonstrated 100% specificity and 96.21% sensitivity when tumor purity was ≥30%. The LoD was achieved with 30% tumor purity, and precision with 35% tumor purity was 100%. In a cohort of 5,944 clinical FFPE tissue samples from over 20 cancer types, the prevalence of PTEN homozygous deletions was 4.32% overall, 6.56% (12/183) in breast cancer, 6.52% (3/46) in prostate cancer, and 3.77% (116/3078) in lung cancer, matching TCGA data for breast cancer but with a lower prevalence in prostate cancer, likely due to sample size limitations. Whole PTEN gene homozygous deletions accounted for 40% of PTEN homozygous deletion-positive samples. IHC validation in 97 clinical samples showed 85.71% consistency with NGS.

Conclusions**:** The LossFinder algorithm offers high sensitivity and specificity in detecting PTEN homozygous deletions. It accurately identifies both whole and partial homozygous deletions, showing a high level of consistency with IHC.

#2408 Bioinformatics analysis of genes that confers apoptosis resistance to EGFR-PI3K co-targeting.

Adeoluwa Adeluola[1], Humaira Noor[2], **A.R.M. Ruhul Amin**[1]

[1]Pharmaceutical Sciences, Marshall University, Huntington, OH,[2]Stanford University, Palo Alto, CA

Background: Large scale genomic studies have identified the overexpression of epidermal growth factor receptor (EGFR) and constitutive activation of the phosphoinositide-3-kinase/protein kinase B (PI3K/AKT) pathway as common genetic aberrations in head and neck cancer. Previously, we reported that the combination of EGFR inhibitor erlotinib with PI3K inhibitor BKM120 had synergistic effects and induced efficient apoptosis in a panel of head and neck cancer cell lines, but some cells were still resistant. The purpose of the current study is to identify molecular pathways that confer resistance to EGFR and PI3-K co-targeting through RNA-Seq and bioinformatics analysis.

Methods: JHU022, a cell line resistant to EGFR and PI3K co-targeting was treated with the combination of erlotinib and BKM120 ± dasatinib (Src inhibitor) or crizotinib (Met inhibitor) for 24h. Total RNA was isolated and used for RNASeq analysis. In order to identify major pathways that were associated with resistance to EGFR and PI3K co-targeting, bioinformatics pathway analysis was conducted using 2-folds differentially expressed genes. The mRNA expression levels of selected differentially expressed genes were confirmed by qPCR.

Results: FDR of ≥0.1% and fold-change of ≥2.0 were used as cut-off for selecting differentially expressed genes. A total of 961 genes were modulated by the combination of erlotinib and BKM120, 2205 by the combination of erlotinib, BKM120 and dasatinib, and 2251 by the combination of erlotinib, BKM120 and crizotinib when compared with untreated control. The addition of crizotinib to the combination of erlotinib and BKM120 resulted in the modulation of 624 genes, while the addition of dasatinib to erlotinib and BKM120 modulated 555 genes. KEGG pathway analysis identified DNA replication, cell cycle, mismatch repair, base excision repair, homologous recombination etc. as the major pathways affected by double and/or triple drug treatment. E2F targets, G2-M checkpoint, Myc targets were the common pathways identified by MSigDB analysis using differentially expressed genes. These pathways were also identified as major affected pathways in GO_Biological_Processes_2021 analysis.

Conclusions: SRC-Met signaling confers resistance to EGFR and PI3K co-targeting by modulating genes associated with cell cycle, DNA replication, and cellular response to DNA damage.

Grant Support: R15DE032063 and P20GM103434

#2409 Examining APOBEC3B in TCGA and ICGC breast cancer datasets reveals altered drug metabolism pathways.

Joel Pardo, Nuri Temiz, Douglas Yee

University of Minnesota, Minneapolis, MN

Despite advancements in screening and treatment, breast cancer mortality remains significant, with nearly one-third of patients worldwide succumbing to the disease. APOBECs, a large family of cytosine deaminase enzymes, function endogenously to restrict viral replication. However, their upregulation in many cancers has been linked to a distinct mutational signature characterized by cytosine-to-uracil conversions, leading to C-to-T transitions. Among these enzymes, APOBEC3B (A3B) is notably overexpressed in breast cancer. It remains uncertain, however, whether tumors with an enriched A3B mutational signature consistently exhibit elevated A3B expression across different breast cancer subtypes. Studies estimate the A3B mutational signature is present in 30-50% of breast cancer cases, with higher prevalence in triple-negative breast cancer (TNBC) and HER2-enriched subtypes. Understanding the pathways influencing A3B expression is an area of growing research interest. Using DNA and RNA sequencing data from breast cancer patients in The Cancer Genome Atlas (TCGA) and the International Cancer Genome Consortium (ICGC), we observed that over 64% of tumors with enriched A3B genomic mutational signatures exhibited above-median A3B mRNA expression compared to non-enriched tumors ($p < 0.001$). Pathway analyses, including KEGG, Gene Ontology (GO), and Reactome, of high versus low A3B-expressing tumors revealed associations with pathways involved in tumor drug metabolism. Notably, the tamoxifen regulatory pathway was altered in high A3B-expressing tumors, which showed reduced expression of *CYP2D6* and *CYP3A10*. This downregulation was consistent in luminal-A-like and luminal-B-like samples. Previous studies in mouse model systems have demonstrated diminished responses to tamoxifen in cells with high A3B expression; our findings suggest a potential relationship between high A3B expression and altered tamoxifen metabolism through *CYP2D6*. Additionally, pathways related to uracil synthesis, involving drugs such as 5-fluorouracil and 6-mercaptopurine, were downregulated in tumors with high A3B expression. Downregulated genes included *IMPDH1*, *NME1*, *TK1*, and *DPYS*, many of which are directly associated with pyrimidine synthesis. This pattern of downregulation was consistent across luminal-A-like, luminal-B-like, and basal-like breast cancer subtypes. These findings suggest that tumors with elevated A3B expression may have a heightened ability to develop resistance to therapies such as tamoxifen. Conversely, such tumors might exhibit increased susceptibility to treatments like 5-fluorouracil. Evaluating the functional consequences of A3B expression in breast cancers could pave the way for strategies to modulate A3B activity, enhancing the efficacy of existing therapies and mitigating drug resistance.

#2410 Copy number-based instability in breast cancer.

H. Wong[1], A. Korsakova[2], A. Wu[1], A. Perera[1], C. K. Patro[3], S. Chen[4], S. Sundararaman[1], V. Warrier[1], D. G. Tenen[1], J. J. Pitt[1]; [1]Cancer Science Institute of Singapore, Singapore, Singapore, [2]Calico Life Sciences LLC, San Francisco, CA, [3]National University of Singapore, Singapore, Singapore, [4]Yong Loo Lin School of Medicine, Singapore, Singapore

Copy number alterations (CNAs), involving the acquisition and loss of DNA segments, are common genetic changes associated with cancer initiation and genomic instability (GI). Similar to single base substitutions, CNAs in cancer genomes often accumulate non-randomly, linked to aberrant DNA damage and repair mechanisms. Investigating higher-order CNA patterns, especially in CNA-prone malignancies like breast cancer, offers insights into GI's nature, causes, and clinical implications. While GI is historically described using predefined scores or de novo CNA signature extraction, these approaches haven't been comprehensively combined and profiled in genomically diverse diseases such as breast cancer. Fourteen pre-existing CNA scores depicting diverse GI phenomena were reintegrated within a unified computational framework. Applied to a large cohort of breast cancer patients (n = 2,763) from TCGA and METABRIC, this framework, along with de novo CNA signature extraction, identified eight robust signatures. CNA scores and signature activities were associated with genomic features and clinical information, including subtype and patient outcomes. Breast cancer oncogenes such as ESR1, CCND1, and IKBKE were preferentially amplified by tandem duplication in a subtype-dependent manner. Additionally, two CNA signatures were characterized as harboring relatively few CNAs ("CNA quiet") within diploid and tetraploid genomes, respectively, with the latter representing an unreported subset of whole genome doubled tumors. Samples with a combination of CNA quiet genomes and low macrophage infiltration exhibited significantly better survival outcomes, independent of standard clinical risk factors. Intriguingly, several signatures coincided with the inactivation of BRCA1/2, genes critical for proficient homologous recombination (HR). These signatures showed differential activity in samples lacking BRCA1 and BRCA2, indicating a potential gene-specific CN pattern of HR deficiency. Segments assigned to another signature exhibited substantial overlap with chromothripsis-like patterns and extrachromosomal DNA (ecDNA), suggesting a common process underlying the generation of these complex GI phenomena. These findings emphasize how exploring scores and signatures can elucidate diverse mechanisms underlying CNA-driven GI in breast cancer. The relative activities of these signatures may hold notable prognostic potential, especially when integrated with other clinically relevant data modalities such as immune cell infiltration. Overall, comprehensive profiling of higher-order CNA patterns in breast cancer can not only uncover the diversity and sources of GI but also provides translational impact.

#2411 Identification of loss of heterozygosity-associated genes linked to loss of function in Korean population through in-silico analysis.

Sun-Woo Lee, Jae-Yoon Kim, Hyojin Heo, Seung-Woo Baek, Jee-Woo Seo, Jong-Lyul Park, Seon-Young Kim

Korea Research Institute of Bioscience & Biotechnology (KRIBB), Daejeon, Korea, Republic of

Loss of heterozygosity (LOH) is a common event in cancer development, disrupting gene and protein translation and resulting in loss of function (LOF). In terms of additional vulnerability, recent studies have suggested that investigating LOF due to LOH can be beneficial for cancer treatment. Additionally, genetic regions, including single nucleotide polymorphisms (SNP) linked to LOF caused by LOH, vary across cancer types. From this perspective, we conducted an in-silico analysis of Korean genomic data, cancer cell line data, and public genomic databases to identify genes associated with SNPs leading to LOF due to LOH. We analyzed a total of 10 million SNPs from a large cohort of 1,496 Koreans using whole genome sequencing (WGS) data, as well as up to 9 million SNPs from 1,007 cancer cell lines (including 129 lung, 21 stomach, and 28 colon samples) based on whole exome sequencing (WES). After filtering out rare variants, we identified 453 functional SNPs affecting protein translation in both Korean and cancer cell line data. Of these, 194 SNPs with heterozygous genotype frequencies between 0.1 and 0.9 were selected. Using copy number loss regions from the COSMIC database, we identified 39 genes associated with potential LOH-related SNPs. Finally, through the analysis of gene expression data from The Human Protein Atlas and previous studies, six LOH-associated genes linked to LOF in Koreans were identified: *ADAMTS1, ANXA2, IL17RB, LPL, TUBA8,* and *ZNF117*. Based on these six genes, we propose a list of drugs that, when used in combination, enhance the efficacy of conventional anticancer treatments. We plan to validate the effectiveness of these drugs in addressing additional vulnerabilities through in vitro experiments. While experimental validation is ongoing, we anticipate that our study will serve as a valuable resource for researchers aiming to identify population-specific LOH-associated genes using in-silico approaches.

#2412 Adenine AI: Advancing germline and somatic evidence discovery for variant assessment and gene validation.

Ronak Y. Patel

Nucleati LLC, Houston, TX

Technological advancements have significantly reduced the cost of panel assays, exome, and genome sequencing, yet the classification and interpretation of germline and somatic variants for pathogenicity and oncogenicity remain challenging. Irrespective of the guidelines used, genetic and functional evidence plays a crucial role in supporting variant classification and interpretation. For instance, at least eight evidence codes (PP1, PM6, PS2, PS3, PP4, BS3, BS4, and BP3) from ACMG guidelines and another eight evidence codes (OS1, OS2, OS3, OM4, OM3, OP3, OP4, and SBS2) from joint ClinGen/CGC/VICC guidelines rely on genetic or functional evidence. Published case reports, multi-patient studies, and functional assessments are essential in strengthening or refuting variant classification and gene-disease associations in both somatic and constitutional cancer contexts.However, the ever-expanding body of scientific literature—now exceeding 40 million articles—makes finding, collecting, and curating relevant evidence a daunting task. Manual efforts by expert professionals, while accurate, are labor-intensive, costly, and inherently unscalable. These limitations impede timely variant interpretation and indirectly affect patient care and diagnosis in both germline and somatic contexts.To address these challenges, we have developed an automated pipeline leveraging artificial intelligence (AI) and workflow automation to streamline literature collection and curation. Our system continuously scans newly published evidence, evaluates relevance, categorizes it into germline or somatic contexts (e.g., single case, multi-case, or functional assessments), and extracts critical details such as gene, disease, patient demographics, cohort size, study type, interventions, variant identity, and assay type. The extracted data is normalized, mapped to ontologies, and made available through our user-facing platform, Adenine AI (accessible at https://adenine.ai).Adenine AI simplifies evidence discovery through an intuitive interface while offering powerful, documented web APIs for seamless integration with electronic health records (EHR) and variant classification/interpretation systems. Beyond ease of access, our platform enables secondary analyses, confirming and extending findings on somatic hotspot mutations while revealing significant gaps in widely used resources such as ClinVar, where evidence for many genes remains absent.This study introduces our automated pipeline and Adenine AI, available for free trial, and demonstrates its potential to improve evidence accessibility and streamline variant classification workflows, ultimately advancing both research and clinical practice.

#2416 CELLama: cell embedding leveraging language model abilities for analyzing cell types and spatial relationship in tumor.

Jiwon Kim, Jeongbin Park, Sumin Kim, Dongjoo Lee, Sungwoo Bae, Haenara Shin, Daeseung Lee, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background: Single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics (ST) have opened up new avenues that will expand our knowledge on cellular heterogeneity and spatial tissue architecture in the tumor microenvironment. However, the mere volume of data as well as different error profiles pose significant challenges in comprehensive data integration and subsequent analysis, particularly for robust cell type identification and spatial context analysis. Here, we developed CELLama (Cell Embeddings Leverage Language Model Abilities), a foundation model that relies on natural language processing (NLP) methods to embed the information from the cell and space.
Methods: CELLama converts scRNA-seq data into natural language-like sentences of input, with major focus on gene expression and including metadata on tissue of origin and disease status. These will be projected to high-dimensional vectors for each cell by a pre-trained sentence transformer. This embedding was also fine-tuned with sentence pairs of the generated sets labeled for cosine similarity that utilized gene expression profiles. In testing the performances of CELLama and the other existing models on multitissue and disease datasets, zero-shot cell typing and spatial context analysis were performed. To analyze the spatial architecture of the tumor microenvironment, neighborhood cell type patterns were generated, and cell subtypes within the tumor microenvironment were clustered based on these patterns.
Results: CELLama demonstrated better integration and annotation of cells across multiple datasets. It showed better performance than other foundation cell embedding models including scGPT in terms of accuracy, precision, and recall, especially after the addition of metadata like tissue of origin. As an example of leveraging CELLama for
spatial analysis of tumor microenvironment architecture, it has been applied to identify five distinct fibroblast subpopulations in lung cancer, differentiated by their spatial context.
Conclusions: CELLama represents a unique cellular data analysis leveraging NLP, which changes more complicated transcriptomic data into highly interpretable language-like formats, integrates various metadata and spatial context, and will further extend to atlas-level integrations and disease-specific tissue analyses. It simplifies complex analyses by providing a thorough understanding of intricate cell types within the tumor microenvironment and accelerating the study of their spatial architectural patterns.

#2417 N-Orbit: An interpretable, distance-based framework for comparison of tumor microenvironments and beyond.

Barbara Xiong[1], Yuxuan Hu[2], Kai Tan[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]Xidian University, Xi'an, China

The tumor microenvironment (TME) plays a major role in cancer progression and treatment resistance. Advances in single-cell resolution spatial omics technologies have facilitated the exploration of the TME and its role in these processes. Recent developments in quantitative methods for tissue cellular neighborhood (TCN) detection have provided further insights into the organization of spatial heterogeneity within individual tissue samples. Yet a theoretical framework for modeling and comparing tissue architecture across time points and clinical subtypes remains lacking. We introduce, N-Orbit, a mathematical model that captures both cell type composition and spatial relationships within tissue cellular neighborhoods, encoding this information in a vector format for computationally efficient distance metric calculations. We benchmark our N-Orbit-based neighborhood distance metric on spatial omics datasets with manually annotated ground truth anatomical regions and on patient datasets with corresponding clinical variables. We also demonstrate that N-Orbit neighborhood distances recapitulate transitions across treatment phases and can be used to identify resistance-enriched neighborhood clusters in triple-negative breast cancer. Additionally, N-Orbit enhances model interpretability by allowing these neighborhood clusters to be traced back to enriched cell-cell interactions. N-Orbit holds significant potential for deepening our understanding of how TMEs, as well as tissue microenvironments more broadly, evolve across treatment timelines and clinical subtypes.

#2418 CellClique: Dissecting tumor microenvironments at the single cell level using generative AI and spatial transcriptomics.

Sachini Weerasekara[1], Natasha Darras[2], Nicolas Fernandez[3], Melinda Chen[2], Alina Ainbinder[2], **Colles Price**[2]

[1]Northeastern University, Boston, MA,[2]Takeda Pharmaceutical Company Ltd. (U.S.), Cambridge, MA,[3]Broad Institute, Cambridge, MA

Novel cellular therapy has the potential to change cancer treatment. However, to design new therapies requires a better understanding of the tumor microenvironment (TME) and the cellular dynamics that occur within the tumor. This requires a high resolution and subcellular view of cancer cells, immune cells while identifying the neighborhood architecture that exists between them. Spatial transcriptomics and spatial proteomics show subcellular information and can be used to identify cellular cell types and find spatial deviation between cells. However, there are a lack of tools to investigate cellular behaviors on an individual cell basis while integrating pathological information, limiting the future of spatial biology. We introduce CellClique, a tool that assists in dissecting TMEs using spatial transcriptomics with the Xenium platform and Hematoxylin and Eosin (H&E) stains. CellClique integrates both generative and analytical capabilities to provide a comprehensive view of TMEs. On the generative end, CellClique uses generative AI to model both gene expressions and cell-neighborhood interactions for cell annotation, gene expression prediction, and gene imputation. On the analytical end, CellClique offers a comprehensive four-way spatial analysis scheme aimed at 1) understanding the effects of neighboring cells on a target cell, 2) dissecting cancer-normal cell boundaries, 3) observing immune invasion mechanisms, and 4) exploring cellular subtypes with the TME. We applied CellClique to study the cellular landscape in lung and colon cancers using multiple different neighborhood analyses. We generated proximal (10 microns), local (60 microns), and distal neighborhoods (120 microns) for each cell within each tissue and found distinct expression profiles of tumor-infiltrated lymphocytes, which are functionally different from lymphocytes excluded from the tumor. Additionally, we discovered expression variation patterns in cancer-normal boundary cell communities with various cell compositions. These compositions changed significantly as distance from the boundary changed. We also compared lymphocytes at different stages of life by analyzing expression differences among lymphocytes classified with over 80% confidence, those with a 50% probability of being lymphocytes, and those with below 20% probability. We further compared how these neighborhoods changed between lung cancer and colon cancer and showed cancer specific spatial deviations and expression. Together, these methods paint a complex picture of the TME but also identifies numerous avenues for future discovery and molecular investigation. These new approaches will guide future cellular therapy and the development of new treatments. The future integration of AI and machine learning will continue to make a tremendous impact on spatial transcriptomics and our approach to treating disease.

#2419 Impact of immune contexture on immunotherapy response in NSCLC: insights from multiplex IHC and machine learning-based phenotyping.

Jean-Philippe Guegan[1], Imane Nafia[1], Florent Petraud[2], Lucile Vanhersecke[3], Christophe Rey[1], Alban Bessede[1], Antoine Italiano[2]

[1]Explicyte Immuno-Oncology, Bordeaux, France,[2]Department of Medicine, Institut Bergonie, Bordeaux, France,[3]Department of Pathology, Institut Bergonie, Bordeaux, France

Background: The relationship between immune phenotypes (infiltrated, excluded, and desert) and response to immunotherapy in non-small cell lung cancer (NSCLC) is an area of active investigation. Understanding the tumor immune contexture can indeed provide valuable insights into the tumor microenvironment (TME) and immune dynamics, potentially guiding personalized therapeutic strategies.
Methods: We analyzed a discovery cohort of 148 NSCLC patients using the CD8/PanCK multiplex immunohistochemistry (mIHC) panel to define the immune phenotype. Tumors with <2% of CD8+ cells were classified as "desert." Tumors with >2% CD8+ cells within the tumor area were categorized as "infiltrated," while those with >2% CD8+ cells restricted to the periphery were labeled "excluded." Correlations between immune phenotypes and immunotherapy responses (PFS, OS and response rates) were assessed. Validation was performed on an independent cohort of 117 patients.
Results: In the discovery cohort, tumors with an "infiltrated" phenotype demonstrated significantly better responses to immunotherapy compared to "excluded" and "desert" tumors (p = 0.009 “infiltrated” vs “desert”, p=0.045 “infiltrated” vs “excluded”). Immune exclusion was associated with lack of response. These findings were confirmed in the validation cohort, reinforcing the prognostic value of immune phenotyping in NSCLC. Additionally, tertiary lymphoid structures (TLS) and macrophage infiltration, known predictors of response to immunotherapy in NSCLC, were analyzed using an ISO-compliant multiplex immunohistofluorescence (mIHF) panel. Machine learning algorithms were employed to automate immune phenotyping and produce rapid summaries of TME characteristics. The multiplex IHF panel reliably assessed immune phenotypes, TLS presence, and macrophage infiltration with high reproducibility. Automated phenotyping using machine learning enabled rapid and accurate characterization of TME features, facilitating the integration of immune phenotyping into clinical workflows.
Conclusions: Tumor immune contexture significantly influences the outcomes of immunotherapy in NSCLC. "Infiltrated" tumors are associated with favorable responses, while immune exclusion predicts resistance. Our ISO-certified multiplex IHF panel, combined with machine learning automation, offers a robust and scalable approach to immune phenotyping, supporting its implementation in precision oncology.
Keywords: NSCLC, immune phenotyping, multiplex IHC, immune exclusion, infiltrated tumors, tertiary lymphoid structures, macrophage infiltration, machine learning, immunotherapy response.

#2420 Deep learning enables automated detection of circulating tumor cell-immune cell interactions with prognostic insights in cancer.

Yuanfei Sun[1], Joshua R. Squires[1], Andrew Hoffmann[1], Youbin Zhang[2], Allegra Minor[3], Anmol Singh[3], David Scholten[3], Chengsheng Mao[3], Yuan Luo[4], Deyu Fang[5], William J. Gradishar[2], Massimo Cristofanilli[2], Carsen Stringer[6], Huiping Liu[7]

[1]Department of Pharmacology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Department of Hematology and Oncology, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[3]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[4]Northwestern Univ. Institute for Artificial Intelligence in Medicine, Chicago, IL,[5]Department of Pathology, Northwestern Univ., Chicago, IL,[6]HHMI at Janelia Research Campus, Ashburn, VA,[7]Northwestern Univ. Feinberg School of Medicine; Chan Zuckerberg Biohub Chicago, Chicago, IL

Background: Circulating tumor cells (CTCs) are critical biomarkers for predicting therapy response and survival in breast cancer patients. Multicellular CTC clusters exhibit enhanced metastatic potential, yet their detection and characterization are constrained by low frequency in blood samples and reliance on labor-intensive manual analysis. Advancing these methods could significantly improve prognostic evaluation and therapeutic strategies.

Methods: Leveraging FDA-approved CellSearch technology and single-cell sequencing, we analyzed 2,853 blood specimens, longitudinally collected from 1358 patients with advanced cancer (breast, prostate, etc) and other diseases. Integrating machine learning and deep learning tools, we developed a novel *CTCpose* platform to automate detection and analysis of CTCs, immune cells, and their interactions. Using artificial intelligence (AI)-driven image analysis, we extracted over 270 cellular and nuclear features including intensity, morphometry, fourier shape, gradient/edge, and haralick of cytokeratin, CD45, and DAPI expression patterns, enabling precise characterization of CTCs, white blood cells (WBCs), CTC clusters, and their interactions with immune cells (WBCs).

Results: The *CTCpose* platform enabled automated identification of CTCs, WBCs, homotypic CTC clusters, heterogenous CTC-WBC clusters, and immune cell clusters, providing comprehensive insights into cell morphology, biomarker expression, and spatial organization. These features correlated with patient survival, disease progression, and treatment response. Our findings highlight the clinical significance of CTC-immune cell interactions and dynamic alterations of CTCs (singles and clusters) and underscore their potential in stratifying patients into distinct risk categories.

Conclusions: This study demonstrates the transformative potential of deep learning in overcoming limitations of traditional CTC detection methods and integrating imaging data with large cohorts of patient data. By automating and enhancing the analysis of CTC-immune cell interactions, we present a robust framework for developing predictive models with direct clinical relevance. This work opens avenues for personalized treatment strategies, underscoring the impact of AI in advancing precision oncology.

#2421 Development and validation of an AI-based model for lymphocyte identification in NSCLC H&E image using spatial transcriptomics.

Seo Hye Park[1], Haenara Shin[1], Hosub Park[2], Jaemoon Koh[3], Kwon Joong Na[1], Hongyoon Choi[1]

[1]Portrai, Inc., Seoul, Korea, Republic of,[2]Department of Pathology, Hanyang University Seoul Hospital, Seoul, Korea, Republic of,[3]Department of Pathology, Seoul National University Hospital, Seoul, Korea, Republic of

Background: Spatial transcriptomics (ST) enables the integration of gene expression data with spatial context in tissue samples, providing high-resolution insights without requiring single-cell dissociation. With subcellular resolution, ST offers a precise method for annotating cell types, surpassing traditional approaches based on manual pathologic annotation. Conventional AI models for pathology images typically rely on annotations from pathologists to label cellular compositions in hematoxylin and eosin (H&E)-stained slides. In contrast, our AI model leverages training data generated from subcellular resolution ST, providing a distinct advantage by achieving higher accuracy and objectivity in identifying specific cell types. In this study, we focus on lymphocyte identification in non-small cell lung cancer (NSCLC) pathology images to demonstrate the capabilities of this approach.
Methods: This model analyzes H&E slide images obtained from surgical specimens of NSCLC patients. The training dataset consisted of ST data (Xenium, 10X genomics) and H&E images from 90 NSCLC samples collected from a single institution. After aligning ST data with H&E images, cell-type masks were generated for lymphocyte labeling. For performance evaluation, 456 patches (256 × 256 pixels, 0.45 μm/pixel) were randomly selected from 30 NSCLC H&E slide images. Two pathologists independently annotated lymphocytes in these patches. Of the 456 patches, 355 with consistent annotations between the two pathologists were selected for model evaluation. The consensus annotations served as the reference standard to assess the model's performance in lymphocyte identification.
Results: This model achieved an AUROC of 0.8411, indicating high diagnostic accuracy. The optional threshold was determined to be 0.3870, with specificity and sensitivity of 72.76% and 78.92%. Compared to two pathologists' consensus annotations, the model showed a sensitivity of 81.66%, specificity of 69.70%, and accuracy of 77.29% for lymphocyte identification.
Conclusion: This AI model trained from subcellular ST provides a robust performance for analyzing the distribution of lymphocytes in NSCLC H&E images. This model offers an innovative approach to analyzing the composition of cells from H&E images, demonstrating its potential contribution to TME research and the development of precision medicine.

#2422 Fine-grained inflammatory cell segmentation in histopathology with deep learning.

Pierre-Antoine Bannier, Benjamin Adjadj, Sebastien Mandela, Guillaume Horent, Thomas Mathieu, Ulysse Marteau, Valentin Gaury, Laura Dumont, Aurore Lyon, Reda Belbahri, Benoit Schmauch, Kathryn Schutte, Lucie Gillet, Katharina Von Loga, Caroline Hoffmann

Owkin, Paris, France

Introduction: Deep learning can advance clinical research by improving patient subtyping and uncovering biological insights. However, many models have limited interpretability, reducing clinical utility. To address this, we developed a model that detects, segments, and classifies cells on hematoxylin and eosin (H&E) slides, including understudied types like neutrophils, eosinophils, and plasmocytes, enabling novel biomarkers related to the tumor microenvironment (TME).

Methods: We collected a novel training set composed of 1,479 patches of size 112µm x 112µm from H&E-stained TCGA slides across five indications: bladder cancer (n=400), colon adenocarcinoma (n=242), lung adenocarcinoma (n=231), lung squamous cell carcinoma (n=220), and mesothelioma (n=386). We collected two external validation sets including patches from muscle invasive bladder cancer (MIBC) (n=79) and mesothelioma (n=48) cohorts. For both training and validation, three expert pathologists annotated cells into seven classes: cancer cells, lymphocytes, fibroblasts, neutrophils, eosinophils, plasmocytes, and others. We used a consensus rule to resolve discrepancies at the cell level between pathologists. In total, 151,404 nuclei were annotated in the training set and 9,565 in the validation set.

We trained a model in 3-fold cross-validation on the training set. We independently evaluated its performance on our validation sets and on the Lizard dataset (colorectal cancer). For each cell type we report the panoptic quality (PQ), which combines detection accuracy and segmentation quality.

Results:

Class-wise panoptic quality metrics across training and validation cohorts

Class-wise PQ metrics	Cancer Cells	Lymphocytes	Fibroblasts	Neutrophils	Eosinophils	Plasmocytes
Cross-validation performance from literature for comparison:Lizard dataset. Source: https://arxiv.org/pdf/2108.11195	N/A	0.58 (0.05)	**0.50 (0.01)**	0.16 (0.04)	0.22 (0.04)	0.37 (0.04)
Cross-validation performance: our model (training set)	**0.61(0.02)**	**0.66(0.02)**	**0.50(0.01)**	**0.51(0.01)**	**0.53(0.04)**	**0.66(0.01)**
External transfer: Lizard dataset	N/A	0.42[0.41 - 0.42]	0.39[0.39 - 0.40]	0.40[0.38 - 0.41]	0.31[0.30 - 32]	0.42[0.41 - 0.43]
External transfer: MIBC	0.53[0.49 - 0.57]	0.49[0.40 - 0.60]	0.40[0.35 - 0.44]	0.27[0.19 - 0.49]	0.42[0.21 - 0.59]	0.52[0.26 - 0.65]
External transfer: Mesothelioma	0.56[0.53 - 0.59]	0.55[0.46 - 0.61]	0.43[0.39 - 0.48]	0.23[0.05 - 0.41]	0.46[0.33 - 0.76]	0.48[0.22 - 0.89]

Conclusion: Our model demonstrates consistent performance across multiple validation cohorts, including understudied cell types for which it even outperforms models trained in-domain on Lizard. This reliability highlights its potential for broader clinical applications. By enabling the identification of immune cells, the model paves the way for designing novel interpretable TME-related biomarkers.

Introduction: Pediatric sarcomas are challenging to accurately classify due to their rarity and the wide diversity of subtypes. The process requires highly specialized pathologists as well as molecular and genetic testing that is expensive, takes time, and is not universally available. Deep neural network models (DNNs) trained on histopathology slides can reduce the time and cost to diagnosis and attenuate disparities in care based on geographical location and socioeconomic status. Here, we demonstrate the efficacy of automated image analysis for assigning sarcoma diagnoses across centers by identifying Ewing Sarcoma (ES), distinguishing rhabdomyosarcoma (RMS) vs non-rhabdomyosarcoma soft tissue sarcomas (NRSTS), as well as classifying alveolar, embryonal, and spindle cell RMS subtypes.

Methods: Images were collected from Massachusetts General Hospital, Yale School of Medicine, St Jude Children's, and the Children's Oncology Group. A total of 691 images were collected across all centers, including 9 different sarcoma subtypes. Images were harmonized using our published STQ pipeline including focus checking, resolution standardization, and stain normalization. Image tiling and feature extraction was performed comparing multiple deep learning backbones (CTransPath, UNI, CONCH). Tile-level features were transposed to whole slide-level representations using our published SAMPLER method in which each feature is represented as the vector of decile values of its distribution across all tiles. Resulting feature sets were fed into logistic regression models for sarcoma classification tasks. We benchmark this approach against transformer based multi-head self-attention models trained on a V100 GPU.

Results: We are able to distinguish ES from all other sarcoma types with an AUROC of 0.966. In the task of NRSTS v. alveolar RMS v. embryonal RMS we achieve an AUROC of 0.939. Restricting to RMS subtypes, we distinguish alveolar from embryonal with an AUROC of 0.95. Also, despite uneven sample representation, we obtain an AUROC of 0.88 for alveolar v. embryonal v. spindle type RMS. Finally, we have developed spatially-resolved attention maps, which provide interpretability for the regions of a slide that contain malignant cells.

Conclusion: To our knowledge, we have amassed the largest multicenter pediatric sarcoma imaging dataset with broad representation across subtypes, anatomical locations, race, and sex. Our pipeline allows for further integration of images from any center, which may be co-analyzed to attenuate center-specific batch effects. Our classification accuracies are state of the art for multiple tasks fundamental to clinical sarcoma pathology, including novel multiclass distinction among three different RMS subtypes. Importantly, our pipeline and SAMPLER model can be run with minimal computational requirements, allowing for broad accessibility.

#2424 Integrating digital spatial profiling and H&E images to develop predictive biomarkers for immunotherapy outcomes in triple-negative breast cancer from imputed spatial gene expression.

Thazin Nwe Aung[1], Tianci Song[2], Lajos Pusztai[3], Mark Gerstein[4], David L. Rimm[1], Jonathan H. Warrell[5]

[1]Pathology, Yale School of Medicine, New Haven, CT,[2]Machine Learning Department, NEC Laboratories America, Princeton, NJ,[3]Medical Oncology, Yale School of Medicine, New Haven, CT,[4]Molecular Biophysics and Biochemistry, Yale School of Medicine, New Haven, CT,[5]Department of Molecular Biophysics and Biochemistry, Yale University, New Haven, CT

Introduction: Triple-negative breast cancer (TNBC) is an aggressive subtype with poor prognoses and limited biomarkers for predicting treatment outcomes [1]. Tumor-infiltrating lymphocytes and PD-L1 expression, while associated with immune checkpoint inhibitor (ICI) efficacy, fail to predict responses reliably [2, 3]. Spatial transcriptomics is a cutting-edge technology that enables the precise mapping of gene expression within tissue samples. However, the high cost of sequencing limits its clinical utility. This study aims to develop cost-effective predictive biomarkers by integrating spatial transcriptomic data and machine learning to impute gene expression from widely available Hematoxylin and Eosin (H&E) images.

Methods: This study involves two cohorts of TNBC patients treated with pembrolizumab (N=75) and durvalumab (N=57) in the neoadjuvant setting. Digital Spatial Profiling (DSP) was used to generate Spatial transcriptomics data. Gene signatures predicting ICI outcomes were developed and validated using Least Absolute Shrinkage and Selection Operator (LASSO) regression models. Imputed gene expression was derived from H&E images, employing adaptive spatial graph neural networks (asGNN [4]), and evaluated against DSP data on a subset of patients. Signatures were trained using imputed transcriptomics directly and in combination with a hold-out set of H&E images. Prediction accuracies were evaluated against spatial transcriptomics and clinical outcomes using mean squared error and AUC.

Results: Imputed gene expression from H&E images closely mirrors spatial transcriptomic profiles. Imputed spatial gene expression using asGNN achieved better prediction of DSP expression than competing methods (HE2RNA [5] and Sequoia [6]) and non-adaptive GNN methods (p=0.031). Signatures trained directly using H&E imputed spatial expression achieved accurate prediction of treatment outcomes (AUC=0.75±0.24). Integrating the DSP transcriptomics further increased the accuracy of the predictions; the signatures trained using imputed transcriptomics combined with DSP data achieved higher prediction accuracy (AUC=0.85±0.08), which significantly outperformed the non-DSP trained models (p=0.021).

Conclusion: This study demonstrates the feasibility of leveraging H&E images for gene expression imputation in TNBC. Future work will optimize models across diverse cancer types and expand validation with independent datasets. This innovation advances personalized medicine by bridging the gap between cutting-edge spatial transcriptomics and routine clinical diagnostics.

#2425 AI-powered approaches accurately predict t(11;14) positive multiple myeloma from H&E-stained histologic sections by identifying regions demonstrating lymphoplasmacytic cytology.

Neel Patel[1], Raymond Biju[1], Syed Ashar Javed[1], Sandrine Degryse[1], **Lara Murray**[1], Xiao Zhou[2], Jeremy A. Ross[2], William Wijaya[2], Pedro Munoz[2], Aditee Shrotre[2], Joann Palma[2], Patrick Calpazi[2], Yan Li[2], Pok Fai Wong[2], Francine Chen[2], Kenneth Emancipator[2], Kevin Kolahi[2]

[1]PathAI, Boston, MA,[2]AbbVie, Inc., North Chicago, IL

Venetoclax, a highly selective oral BCL-2 inhibitor, has demonstrated efficacy in patients with t(11;14) multiple myeloma (MM). Fluorescence *in situ* hybridization (FISH) is the mainstay methodology to determine t(11;14) status, but requires significant quantities of bone marrow tissue or aspirate and is low-throughput. Herein, we: (i) describe an artificial intelligence (AI)-based model that accurately predicts t(11;14) status from routine H&E-stained MM whole slide images (WSIs) and (ii) demonstrate that the biological signal underlying the model predictions is driven by regions containing the lymphoplasmacytic phenotype of t(11;14) positive MM cells.

H&E-stained MM WSIs (n=231) with known t(11;14) status were split into training/validation/test sets (60/20/20), and CNN-based tissue and cell segmentation models were trained from expert pathologist annotations to identify high density regions of MM cells. Additive multiple instance learning (aMIL) models with 5-fold cross validation were then trained using embeddings from pathology universal transformer (PLUTO) foundation model backbone [1], to predict t(11;14) status. To interpret the biological signal underlying aMIL model predictions, nuclear features [2] for MM cells and sparse autoencoder (SAE) dimensions [3] (based on PLUTO embeddings) were extracted from the model-predicted t(11;14) positive and negative regions. Mann-Whitney U test was used to compare distribution of nuclear features between t(11;14) positive and negative regions. Activation frequency (AF) delta (AF in positive images - AF in negative images) was used to find the SAE dimensions most active in t(11;14) positive regions.

Validation and held-out test sets were leveraged to evaluate the aMIL model's performance for predicting t(11;14) status, resulting in AUROC of 0.813 and 0.849, respectively. Upon investigating the regions predicted as t(11;14) positive, analyses revealed that these contained MM cell nuclei with higher circularity, solidity and less variability in shape and size (p-values<0.001 for all comparisons) compared to those predicted as t(11;14) negative. Additionally, SAE dimensions capturing circular cells (SAE-2202) and lymphocytes (SAE-1567, SAE-1355) were significantly more active in model-predicted t(11;14) positive images compared to the predicted negative images (AF delta- SAE-2202: 0.73, SAE-1567: 0.61, SAE-1355: 0.57).

t(11;14) status can be predicted with high accuracy using routine H&E WSI. Model predictions rely on biologically meaningful signals based on regions containing MM cells with lymphoplasmacytic morphology. This technology has the potential to facilitate screening for t(11;14)-directed MM clinical trials.

#2426 TMEseg: Connecting histopathology with spatial transcriptomics through tumor microenvironment segmentation for lung cancer.

Xiaoxi Pan[1], Maria E. Salvatierra[2], Caner Ercan[2], Lakshmi Kakarala[2], Wei Lu[2], Ou Shi[2], Idania C. Lubo Julio[2], Ignacio I. Wistuba[2], Luisa M. Solis Soto[2], Yinyin Yuan[1]

[1]Department of Translational Molecular Pathology, and The Institute for Data Science in Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX

The tumor microenvironment (TME) plays a key role in lung cancer progression. Spatial transcriptomics offers insights into tumor heterogeneity but relies on integration with histological features to decode tumor transcriptomic programs, which is challenging due to TME complexity. To overcome this, we developed AI models that accurately identify 10 tissue types from histology images, streamlining TME analysis.

We used public annotations to train AI models, DeepLabV3+ and Segformer, for TME segmentation. The training set included hematoxylin&eosin-stained slides from breast and lung cancers in TCGA, combined with newly curated annotations from TCGA and four internal slides of surgically resected tumors, totaling 3403 patches (breast: 3110; lung: 293) at 0.44 μm/pixel. The testing set included 2000 patches from lung cancer slides at 1 μm/pixel. The models were trained to classify 10 tissue types: tumor, stroma, inflammatory, necrosis/hemorrhage, adipose, bronchi epithelium, vessel, macrophage area, alveoli, and muscle. For comparison, predictions of adipose, vessel, and muscle were grouped into stroma, while inflammatory and macrophage areas were grouped as immune. Model performance was evaluated using the Dice score. We further validated the models using spot-level manual annotations from Visium data for four lung cancer samples. Pathologists labeled spots as tumor, stroma, immune aggregates, macrophage, bronchi epithelium, vessel, and alveoli using Loupe Browser. The type with the highest number of predicted pixels by AI within a spot-based patch was assigned as the predicted label. Concordance was assessed using Fleiss's kappa.

At pixel level, Segformer outperformed DeepLabV3+, achieving an average Dice score of 0.856 and 0.809. At spot level, kappa index between pathologist and Segformer was 0.28-0.66, showing fair (n=2) to good (n=1) agreement, consistent with the concordance between pathologist and DeepLabV3+ (0.34-0.722). Kappa index between Segformer and DeepLabV3+ showed good (n=3) to perfect (n=1) agreements (0.677-0.842). Interestingly, the first annotated sample showed good agreement between the pathologist and AI models (0.66-0.722), whereas the last annotated sample demonstrated only fair agreement (0.28-0.343). Notably, this discrepancy was not observed when comparing Segformer and DeepLabV3+ directly, implying a high reproducibility for AI models. In terms of efficiency, the pathologist required about five hours in theory to annotate a slide containing around 12000 spots, while AI models, running on an A100 GPU, completed the segmentation in about 20 minutes.

Our study shows the effectiveness and efficiency of AI models in recognizing the TME from histology images in lung cancer. These models streamline the integration of tissue histopathological features with Visium assay and facilitate the discovery of image-derived biomarkers.

#2427 Optimization of preprocessing strategies for developing AI-based disease diagnosis model using whole transcriptomic data.

Ki Wook Lee, Hye Jung Min, Hyun Woo Park, Balachandran Manavalan, Young-Jun Jeon

Sungkyunkwan University, Suwon, Korea, Republic of

Current research in medicine and biology predominantly focuses on applying artificial intelligence (AI) to analyze patient-specific imaging data, such as CT and MRI scans. However, the application of AI to next-generation sequencing (NGS) data, particularly transcriptomics, remains underutilized. RNA sequencing data is prone to biological and technical variability during generation, and the choice of error-correction and preprocessing methods can significantly influence downstream analyses. These challenges underscore the need for clear and systematic guidelines to optimize transcriptome data for AI-based analyses. In this study, we aim to identify optimal preprocessing strategies for developing AI models leveraging transcriptomic data. We utilized RNA sequencing datasets from 25 independent cohorts, comprising over 5,800 patients with conditions such as lung adenocarcinoma, colorectal cancer, diabetes, and other diseases. A total of 18 combinatorial preprocessing pipelines were systematically assessed, encompassing 6 normalization methods (Raw, CPMTMM, RLE, UQ, RPKM, TPM) and 3 scaling methods (None, MinMax, Z-score). Over 20,000 transcripts were processed using each combination of normalization and scaling techniques. We then developed disease diagnosis models using 13 machine learning and deep learning algorithms. The performance of these models was evaluated to identify the most effective preprocessing strategies for transcriptomic data. We identified algorithm-specific optimal preprocessing strategies to develop robust AI models utilizing transcriptomic data. Performance variations driven by normalization and scaling methods were observed for each algorithm, with these differences being particularly pronounced in datasets characterized by inherently lower model performance (difficult tasks). Our findings underscore the critical role of preprocessing in shaping model outcomes and provide a foundation for the development of tailored AI frameworks for disease diagnosis. This study offers a systematic approach to optimize transcriptomics-based predictive modeling, advancing the integration of AI into transcriptomic data analysis for clinical applications.

#2428 Artificial intelligence for predicting spatial proteomics using high-plex digital spatial profiling in carcinomas.

Yasin Shokrollahi[1], Tanishq Gautam[1], Alejandra Serrano[2], Simon P. Castillo[1], Pingjun Chen[1], Karina Pinao[1], Maria Esther Salvatierra[2], B. Leticia Rodriguez[1], Patient Mosaic Team[3], Luisa M. Solis Soto[2], Yinyin Yuan[1], Xiaoxi Pan[1]

[1]Department of Translational Molecular Pathology, and The Institute for Data Science in Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Translational Molecular Pathology, Division of Pathology and Laboratory Medicine, UT MD Anderson Cancer Center, Houston, TX,[3]UT MD Anderson Cancer Center, Houston, TX

Background: High-plex digital spatial profiling (DSP) enables mapping protein expression onto tissue context to study heterogeneity of tumor microenvironment (TME). However, current techniques rely on manual annotations to select representative regions for profiling, introducing subjectivity and uncertainty. We present a deep-learning approach to predict spatial proteomics associated with immune response and proliferation in carcinomas from tissue space to high-throughput protein expression analysis across the full sections while preserving spatial context.

Methodology: Our study utilized a diverse dataset of 62 carcinomas and adenocarcinomas cases, with major types including Papillary Urothelial Carcinoma (25) and Colorectal Adenocarcinoma (5) among others, totaling 721 regions of interest (ROIs). Using morphology markers (panCK, CD45) for mIF images and 12 proteins for profiling, we conducted a two-phase study. First, YOLOv8 identified epithelial (panCK+) and immune cells (CD45+) from mIF images and correlated their abundance with protein expression. Second, we developed a multi-instance learning framework using Swin Transformer to predict protein expression from mIF images, processing 256×256 pixel adjacent patches (average 1,947 per slide, total 120,729) with attention mechanisms. The dataset was split into training (47), validation (9), and test (6) sets.

Results: We observed strong correlations between cell abundance from mIF images and protein expression, (panCK: rho=0.624, p<0.001; CD45: rho=0.676, p<0.001), validating the effectiveness of the YOLOv8 model in cell recognition. The multi-instance model demonstrated promising prediction performance, marginally improving the correlations for panCK (rho=0.701, p<0.001) and CD45 (rho=0.699, p<0.001) when compared with YOLOv8. For markers included in the protein profiling DSP panel but not for the morphology, our model captured the signals for immune checkpoint and proliferation markers: PD-L1 (rho=0.741, p<0.001), Ki-67 (rho=0.730, p<0.001). Moderate correlations were observed for stromal and immune cell markers (FAP-alpha: rho=0.569, p<0.001; CD163: rho=0.465, p=1.45e-03; CD3: rho=0.409, p=2.02e-02; CD4: rho=0.381, p=7.46e-03; FOXP3: rho=0.344, p=3.24e-02) while a weak correlation for CD8 (rho=0.210, p=4.83e-02). These findings suggest that cellular morphology and spatially encoded information in the TME can be learned by our model to predict immune checkpoint expression and proliferation.

Conclusion: Our integration of mIF images with spatial proteomics enables high-throughput protein expression prediction from limited markers, potentially extending to H&E images. This could reduce sequential biopsies, enabling real-time treatment monitoring. The model's PD-L1 prediction capabilities provide insights into tumor-immune interactions to guide immunotherapy decisions.

#2429 A multi-modal learning framework to integrate digital pathology image and multi-omics data in breast cancer.

Naresh Prodduturi[1], **Xiaojia Tang**[1], Hamid R. Tizhoosh[2], Kevin J. Thompson[1], Richard Weinshilboum[3], Karthik V. Giridhar[4], Judy C. Boughey[5], Eric W. Klee[1], Liewei Wang[3], Matthew P. Goetz[4], Vera Suman[1], Krishna R. Kalari[1]

[1]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN,[2]Department of Artificial Intelligence and Informatics, Mayo Clinic, Rochester, MN,[3]Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester, MN,[4]Department of Oncology, Mayo Clinic, Rochester, MN,[5]Department of Surgery, Mayo Clinic, Rochester, MN

Deep learning has advanced digital pathology and multi-omics data analysis. However, there is still a critical need to integrate these modalities to better understand complex diseases. Deep learning models, such as Prov-Gigapath, a state-of-the-art pathology foundation model, have been developed for analyzing whole-slide images (WSI). Our previously published deep-learning framework, OmicsFootPrint (OFP), transforms high-dimensional multi-omics data into intuitive genomically-arranged circular images and utilizes transfer learning to overcome the challenges of high-dimensional, low-sample-size data. In this study, we aimed to combine WSI and multi-omics data to develop a framework capable of distinguishing between invasive ductal carcinoma (IDC) and invasive lobular carcinoma (ILC), which is clinically significant as it may help explain differential responses to therapies, such as tamoxifen versus letrozole. We enhanced the performance of our OFP model by dividing each multi-omics circular image (1024x1024x3 pixels) into 16 equal-sized patches (256x256x3 pixels). Each patch was trained using a separate EfficientNetV2 architecture with pre-trained ImageNet weights. The probability outcomes from these 16 models were subsequently combined through a meta-learner model using the AutoGluon framework. Concurrently, WSI images corresponding to the same patients were independently trained, maintaining consistent train/validation/test splits. The Prov-Gigapath model, which was trained using a dataset from the Providence Health System, was employed to extract patch-level embeddings from the WSI data. These embeddings were fine-tuned using a LongNet-based masked autoencoder to predict outcomes. Finally, predictions from the OFP model and the WSI-based Prov-Gigapath model were integrated through a meta-learner, preserving the original train/validation/test split. Model performances (AUC) were evaluated using the held-out test set. The gold standard used for the analysis was histological identification of IDC versus ILC, against which the performance of omics data alone, WSI data alone, and the multi-modal integration approach were compared. We evaluated our integrated model as a proof-of-concept using The Cancer Genome Atlas (TCGA) breast cancer cohort, comprising 92 ILC and 391 IDC samples. Multi-omics data, including gene expression, microRNA, copy number variation, and RPPA, were analyzed using the OFP framework, while WSI data were processed using the Prov-Gigapath method. The results demonstrated that the multi-modal integration approach significantly outperformed individual modalities, achieving an AUC of 0.98 compared to 0.87 for OFP (original), 0.95 for OFP (16-patches), and 0.92 for WSI. Integrating WSI and multi-omics data improves predictive accuracy, significantly improving the classification of breast cancer subtypes over histology alone.

#2430 Artificial intelligence enables prediction of MET amplification & associated morphologic features from H&E-stained NSCLC specimens.

Nhat Le[1], **Ylaine Gerardin**[1], Syed Ashar Javed[1], Jennifer Hipp[1], Jacqueline Brosnan-Cashman[1], Miles Markey[1], Lara Murray[1], Bahar Rahsepar[1], Aditee Shrotre[2], Adam Luo[3], William Wijaya[2], Dawn Spelke[2], Pok Fai Wong[2], Joshua Hernandez[2], Sheila Bheddah[2], Ramya Seshadri[4], Steven Chirieleison[2], Patrick Caplazi[2], Yan Sun[2], Athan Vasilopoulos[4], Amita Mistry[4], Yan Li[2], Francine Chen[2], Peter Ansell[4], Kenneth Emancipator[4], Kevin Kolahi[2]

[1]PathAI, Inc., Boston, MA,[2]Precision Medicine, AbbVie, South San Francisco, CA,[3]Exploratory Statistics, AbbVie, North Chicago, IL,[4]Precision Medicine, AbbVie, North Chicago, IL

Background: MET receptor tyrosine kinase, when upregulated by mutation, fusion, or gene amplification, acts as an oncogenic driver in many cancers, including non-small cell lung cancer (NSCLC). Tumors with MET gene amplification (MET-amp) exhibit distinct clinical behavior. Thus, distinguishing MET-amp from non-MET-amp cases, typically determined by fluorescent in situ hybridization (FISH), is crucial. Here, we introduce an artificial intelligence (AI) model to predict MET-amp status directly from whole slide images (WSIs) of routine hematoxylin and eosin (H&E)-stained histologic sections and reveal elevated densities of highly pleomorphic (HP) tumor cells in MET-amp NSCLC.
Methods: Additive multiple instance learning (aMIL) models were trained with 5-fold cross-validation to predict MET-amp, as determined by FISH, from H&E-stained WSIs from multiple cancers (Ntotal=1,384, Namp=545) using embeddings from the pathology universal transformer (PLUTO) foundation model backbone1,2. Model performance was assessed on a held-out test set of NSCLC H&E-stained WSIs (N=170) using the area under the receiver operating characteristic curve (AUROC) for FISH status comparison. PLUTO embeddings were also used to train a logistic regression classifier to identify HP tumor cells in WSIs. These embeddings were extracted from pathologist-annotated HP tumor cells (n=1,725) and non-HP tumor cells (n=4,872) in NSCLC WSIs. The trained model was deployed on embeddings extracted from all tumor cells in each WSI, and probability scores were converted to HP/non-HP cell predictions using a cutoff of 0.5. The proportion of predicted HP cells to total tumor cells was computed for each NSCLC WSI (Ntotal=262, Namp=131).
Results: The aMIL MET-amp prediction model achieved an AUROC of 0.74 when deployed on the NSCLC test set. The HP cell classifier consistently and accurately identified HP tumor cells on a test set for this task (n=340 HP tumor cells and n=778 non-HP tumor cells), achieving sensitivity=98% and specificity=84%. When deployed on NSCLC H&E-stained WSIs, the model-predicted proportion of HP cells was significantly elevated in MET-amp cases (p=0.0004, Mann-Whitney U test). The proportion of HP cells was also predictive of MET-amp in cases with adenocarcinoma (AUROC=0.65).
Conclusions: We demonstrate that an aMIL model using embeddings from a pathology foundation model accurately predicts MET-amp directly from H&E. MET-amp was further shown to be associated with an increased number of HP cells and is consistent with the report that MET-amp tumors are more likely to be poorly differentiated3. This work may enable a screening method to identify patients likely to have MET-amp from routinely collected H&E slides.

#2431 Enhanced cancer detection using TransUnet for low-resolution histopathology images across multiple cancer types.

Muhammad Shaiq Paracha, Faisal F. Khan, Arsalan Riaz, Madina Shirdel

Precision Medicine Lab, Peshawar, Pakistan

Digital histopathology has become an indispensable tool for cancer diagnosis and prognosis, enabling pathologists to analyze tumor morphology using Whole Slide Images (WSI). However, the high cost and limited availability of high-resolution imaging equipment in underdeveloped regions pose significant challenges. This study investigates the use of Low-Cost Low-Resolution (LCLR) histopathology images for detecting four cancer sites: Oral, Gastrointestinal, Colorectal and Breast cancers.
We compared the performance of four models: AlexNet, EfficientNet, Vision Transformer and TransUnet. These models were trained on two datasets: the Tabassum et al. (2020) OSCC dataset (1,223 images, 10X and 40X magnification) used for selecting the right model and HistoVault v1 (17,500 images, 10X and 40X magnification) for training the selected model for all cancer sites. TransUnet, which integrates U-Net's encoder-decoder architecture with Transformers, was fine-tuned with hyperparameters including a learning rate of 1e-5, batch size of 32 and a dropout rate of 20%. The evaluation metrics included accuracy, sparse categorical cross-entropy loss and confusion matrices to quantify the models' robustness.
TransUnet achieved the highest accuracy of 96.8% with a loss of 3% over other models on Tabassum et al. (2020) OSCC dataset. Individual accuracies for Oral, Gastrointestinal, Colorectal and Breast cancers were 98.7%, 95.9%, 96.1% and 97.2% on Histovault v1 dataset. Its coarse-to-fine attention refinement enabled precise segmentation in noisy, low-resolution images, outperforming other models. Notably, the model exhibited robust generalization for multi-class classification, achieving a test accuracy of 90.5% in differentiating eight classes (Non Cancerous and Cancerous with each cancer site).
TransUnet possesses significant promises for LCLR image-based cancer detection, especially in environments with limited resources. Its hybrid design improves accuracy and segmentation precision in challenging datasets by combining the advantages of transformers and convolutional neural networks. With the objective to improve precision diagnosis, future research will investigate cancer grading and use explainable AI algorithms.

#2432 Automated detection of genome-doubled tumors in H&E whole-slide images: towards a novel visual biomarker for predicting overall survival.

Bojan Karlas[1], Marc Glettig[2], Giuseppe Tarantino[3], Jiajia Chen[3], Guihong Wan[1], Tyler J. Aprati[3], Haitham A. Elmarakeby[3], Christine G. Lian[4], Yevgeniy R. Semenov[1], David Liu[3]

[1]MGH/Harvard Medical School, Boston, MA,[2]ETH Zurich, Zurich, Switzerland,[3]Dana-Farber Cancer Institute, Boston, MA,[4]Brigham and Women's Hospital, Boston, MA

Background: Several studies have outlined whole genome-doubled (WGD) tumor tissue characterized by elevated genome ploidy as an important biomarker positively associated with immunotherapy response and overall survival of cutaneous melanoma patients (Liu NatMed2019, Tarantino BioRXiv2022), as well as conferring therapeutic vulnerabilities (Quinton Nat2021). A robust and cost-effective method for detecting this biomarker would significantly improve patient risk assessment and treatment optimization. Unfortunately, current approaches depend on whole-exome sequencing of both tumor and normal tissue - a costly process rarely performed in standard clinical practice.

Methods: We focus on H&E-stained whole-slide images (WSIs) routinely collected to diagnose cancer patients. We use publicly available melanoma WSIs (TCGA SKCM) and ploidy calls (Conway NatGen2020) to train a machine learning pipeline for classifying WSIs as diploid or WGD. After splitting the WSI into tiles we apply a wide array of recently released deep-learning foundation models that have been pre-trained on vast amounts of WSIs and were shown to be effective at extracting biologically meaningful features. To demonstrate the utility of these features for predicting WGD, we use tile-level features to train several types of slide-level classifiers. To evaluate the prognostication potential of H&E-inferred WGD, we use it to fit a univariate Cox survival model using publicly available survival data (PanCanAtlas). We perform a cluster analysis on tile-level features and model-assigned importance scores leveraging the help of a board-certified pathologist to identify visually interpretable morphological features significantly correlated with WGD.

Results: We performed both an internal cross-validation using our training cohort and an external validation cohort collected at Dana Farber Cancer Institute. We evaluate 100s of deep learning pipelines, each characterized by a unique combination of foundation model, slide classifier, and various other hyperparameters. Best-performing pipelines predict WGD with AUC >0.7 on both internal and external validation cohorts, demonstrating a robust association between tissue morphology and ploidy. Furthermore, in univariate Cox survival analyses, best-performing pipelines achieve a hazard ratio <0.7 with a p-value <0.05, underlining the ability of WGD to serve as a visually identifiable biomarker for predicting melanoma outcomes.

Conclusion: Our study demonstrates the potential of H&E-based deep learning pipelines to robustly predict WGD in melanoma tissue with reliable performance across internal and external cohorts. Furthermore, WGD inferred from tissue morphology shows significant prognostic value for overall survival, offering a cost-effective and clinically feasible biomarker for personalized treatment strategies.

#2433 Uncovering molecular insights in breast cancer prognostics utilizing foundation model and digital pathology.

Shlomit Strulov Shachar[1], Tal Etan[2], Didi Feldman[2], Ariella Deutsch-Lukatsky[1], Lee Ben-Itzhak[2], Inbar Gilboa[3], Inbal Gazy[3], Ron Sinai[3], **Addie Dvir**[4], Reva Basho[5], Amir Sonnenblick[1], Dov Hershkovitz[6]

[1]Oncology Division, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel,[2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel,[3]Imagene AI, Tel Aviv, Israel,[4]Imagene AI, Miami, FL,[5]Ellison Medical Institute, Los Angeles, CA,[6]Institute of Pathology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

Despite widespread use of clinicopathologic features and multigene assays, such as the Oncotype DX test, to guide clinical decisions, Breast Cancer (BC) remains a leading cause of mortality. There is a need to identify novel biomarkers to better prognosticate patients and ultimately influence treatment strategies to improve patient outcomes. In this study we developed an AI model for the prediction of BC distant disease recurrence (DDR) risk and applied it on the TCGA cohort to extract insights from gene expression data. Whole slide images (WSIs) of early HR+ HER2- BC cases were collected from Sourasky Medical Center. The median age was 61 years (range 25-75), median follow-up time 122.8 months (range 22.5-197.4) and median time to DDR 36.2 months (range 2.5-55.2). Utilizing a version of our foundation model, CanvOI, embeddings were extracted from WSIs, and a 5-fold cross-validation scheme was applied to develop the recurrence risk model. The model was then applied on the TCGA BC cohort WSIs, which included 98.8% females (n=1027), 55.3% HR+ HER2- (n=575) cases, and a median age of 59 years (range 26-90). Analysis of the WSIs of the TCGA BC cohort using the established model assigned a recurrence prediction score for each sample. The cohort was then divided into high-risk samples with the highest prediction scores and low-risk samples with the lowest scores followed by analysis of differentially expressed genes between the groups. The model development cohort included 291 H&E WSIs of female patients with early DDR (n=19, 6.5%) or no recurrence. 1039 TCGA WSIs were then analyzed with the established BC DDR risk model. Analysis of differentially expressed genes between the high AI risk group (n=100) and low AI risk group (n=124) was conducted. Notably, genes linked to estrogen receptor (ER) signaling pathways showed lower expression levels in the high-risk group, consistent with the established association of ER with more favorable outcomes, thus supporting the concept of this method. Further comparative analysis identified PTPRT as the second most differentially expressed gene between the groups, with lower expression in the high-risk group. Previous studies have associated PTPRT with tumor growth suppression, suggesting it may be an interesting candidate for further investigation. This proof-of-concept study highlights the potential of this approach of developing an AI model using a clinical cohort and applying it to an external cohort to extract insights from expression data. This enables the use of small clinical datasets with known outcomes to train models that can then be applied to larger datasets, such as the TCGA, which contain rich expression data, not accessible in the clinical data, to extract meaningful insights. This method effectively bridges the gap between limited clinical cohorts and expansive multimodal datasets, creating opportunities for broader and more precise discoveries.

#2434 Preliminary feasibility of co-registering tissue autofluorescence with 3D spatial transcriptomics for multimodal analysis of destructively profiled colorectal tumor sections.

Zarif Azher[1], Gokul Srinivasan[1], Minh-Khang Le[1], Alos Diallo[2], Harsimran Kaur[3], Fred Kolling[2], Laurent Perreard[2], Scott Palisoul[4], Keluo Yao[1], Ken S. Lau[3], Louis J. Vaickus[4], Xiaoying Liu[4], Joshua Levy[1]

[1]Cedars-Sinai Medical Center, West Hollywood, CA,[2]Dartmouth College Geisel School of Medicine, Hanover, NH,[3]Vanderbilt University, Nashville, TN,[4]Dartmouth Health, Lebanon, NH

Spatial multiomics, combining spatial transcriptomics (ST), which maps gene expression across tissue sections, with assays like LA-ICPTOF-MS (1-micron resolution elemental profiling), can uncover nuanced biomolecular interactions within the tumor microenvironment (TME) linked to tumor progression. However, many spatial assays are destructive, often requiring co-registering serial or non-adjacent tissue sections, introducing discrepancies that hinder spatial multimodal association studies. To assess the impact of profiling distant tissue layers on data analysis from destructively profiled sections, we co-registered H&E staining, autofluorescence (AF) imaging, and ST data across 16 serial sections from two T4 N0/1 colon cancer patients (A & B). AF data were acquired using DAPI and GFP channels on the EVOS™ M7000 Imaging System. VALIS software aligned AF imaging with 40X H&E whole-slide images (Leica Aperio GT450) to create a 3D model of serial sections, applying transformations to same-section Visium CytAssist ST data. Co-registration accuracy across sections was assessed using target registration error (TRE) from QuPath annotations of matching points across 3D serial section inflammation and vascular TME components. ST data were analyzed using 3D and 2D spatial domain analyses with Leiden clustering to identify biologically relevant gene expression patterns. Enrichr gene set enrichment identified pathways (Reactome) associated with 3D domains present in all slices within patients. Correlations of the top 35 spatially variable genes' (Moran's I) expression across sections were assessed, with hierarchical regression modeling used to examine how gene expression correlations changed with increasing section separation (random intercept by gene). AF co-registered with ST across sections with high accuracy, with minor losses due to architectural changes (TRE- A: 9.5±1.0μm, B: 10.4±1.1μm). The number of 2D spatial domains varied across sections (A: 6.4±1.3, B: 5.1±1.5), while 3D ST identified more domains (A: 8, B: 8). Persistent 3D domains were linked to pathways associated with colorectal cancer progression (e.g., A: Extracellular Matrix Degradation, $p=0.001$, B: CD163 Mediating Anti-Inflammatory Response, $p=0.003$). Gene expression correlations across sections for spatially variable genes decreased with greater section separation (A: $\beta=-0.03$, $p<0.001$; B: $\beta=-0.02$, $p<0.001$). Our work demonstrates successful 3D AF-ST co-registration providing non-destructive capture of persistent histological features across sections, crucial for destructively profiled samples. The diminishing correlation across sections highlights the need to explore information loss and biases from serial sectioning, including imputing ST data to improve spatial multiomics associations tied to tumor progression.

#2435 Automatic detection of prostate cancer in 3D pathology datasets based on synthetic immunolabeling of cytokeratins.

Robert B. Serafin[1], Jennifer Salguero-Lopez[2], Rui Wang[1], Sarah Chow[1], Elena Baraznenok[3], Lydia Lan[3], Kevin W. Bishop[3], Michelle Downes[4], Xavier Farre[5], Lawrence D. True[6], Anant Madabhushi[2], Jonathan T. C. Liu[1]

[1]Mechanical Engineering, University of Washington, Seattle, WA,[2]Biomedical Engineering, Emory University, Atlanta, GA,[3]Bioengineering, University of Washington, Seattle, WA,[4]Laboratory Medicine & Pathobiology, University of Toronto, Toronto, ON, Canada,[5]Public Health Agency of Catalona, Lleida, Spain,[6]Laboratory Medicine & Pathology, University of Washington, Seattle, WA

For AI-analysis of 3D pathology datasets, delineating benign and cancerous tissue regions is often a critical first step. For prostate cancer (PCa) this can be challenging due to the complex intermixing of benign and cancerous glands in 3D. Automated detection of cancerous glands could improve the efficiency and accuracy of downstream computational tasks, such as risk stratification using 3D histomorphometric features. For example, we previously developed machine classifiers based on 3D glandular and nuclear morphologies in PCa biopsies but relied on pathologists to manually identify cancer-enriched volumes for analysis, which was tedious and could introduce bias. Here, we present an approach to automatically identify cancer-enriched regions in 3D pathology datasets of prostate tissue. The tissues are labeled with inexpensive small-molecule fluorescence analogs of H&E staining and are imaged with open-top light-sheet (OTLS) microscopy. Generative adversarial networks were used to train separate models to convert our H&E-analog datasets into synthetic 3D immunofluorescence datasets of two distinct biomarkers: a low-molecular weight cytokeratin (CK8) expressed by luminal epithelial cells found in all prostate glands, and a high-molecular weight cytokeratin (CK5) expressed by basal epithelial cells that are only found in benign prostate glands. Each 3D image-translation model was trained on OTLS microscopy images of prostate tissues that were tri-labeled with fluorescent analogs of H&E plus the antibody of interest (i.e. CK5 or CK8). The models achieved high accuracy for synthetic immunolabeling in held-out validation datasets (Dice scores of 0.72 and 0.83 respectively). By training these models to predict the expression of each CK target directly from H&E-analog datasets, we can avoid the time and cost of immunolabeling large intact tissues. The 3D image-translation models were applied to 3D pathology datasets of 3-mm diameter punch biopsies extracted from archived prostatectomies from 100 PCa patients with known biochemical recurrence outcomes. Using the predicted expression of CK5 and CK8, we developed a simple algorithm to generate a spatial heatmap of cancer-enriched regions throughout each biopsy. For validation, we compared these 3D heatmaps against annotations from 3 GU pathologists of 40 regions of interest, yielding an average Dice score of 0.82. We plan to show improved prognostication with classifiers trained on 3D histomorphometric features derived from cancer-enriched regions (identified by our method) vs. all regions of a prostate specimen.

#2436 Prostate cancer risk stratification based on 3D histomorphometric features related to perineural invasion (PNI).

Sarah S. L. Chow[1], Rui Wang[1], Yujie Zhao[1], Robert Serafin[1], Elena Baraznenok[1], Lydia Lan[1], Xavier Farre[2], Kevin Bishop[1], Gan Gao[1], Lawrence D. True[1], Anant Madabhushi[3], Jonathan T. C. Liu[4]

[1]University of Washington, Seattle, WA,[2]Public Health Agency of Catalonia, Lleida, Spain,[3]Georgia Institute of Technology and Emory University, Atlanta, GA,[4]Mechanical Engineering, Bioengineering, Laboratory Medicine and Pathology, University of Washington, Seattle, WA

Prostate cancer (PCa) treatment decisions rely heavily on the examination of 2D histology sections (i.e. Gleason grading). However, the limited sampling of specimens afforded by 2D histopathology, and the ambiguities of viewing cross-sections of complex structures such as prostate glands, can cause high interpathologist variability and nonoptimal treatment decisions, especially for low- to intermediate-grade PCa. Our lab has previously shown that computational analysis of 3D histomorphometric features, such as those derived from gland and nuclear segmentation, can improve PCa risk assessment compared to analogous 2D features. Here, we expand on these findings by exploring the prognostic value of 3D features from nerves. These structures are critical as prostate cancer cells follow them to migrate and metastasize, i.e. perineural invasion (PNI), which is correlated with worse patient outcomes. We therefore aim to show the analysis of 3D features related to PNI can provide additional prognostic value.

To analyze 3D nerve structures, we utilized a 3D deep learning-based segmentation model, nnU-Net, trained on 3D data from punch biopsies extracted from archived formalin-fixed paraffin-embedded (FFPE) prostatectomy specimens and imaged with a 4th-generation open-top light-sheet (OTLS) microscope. To train a segmentation model without requiring tedious manual annotations, prostate specimens were triple labeled with a fluorescent analog of H&E (nuclear and cytoplasmic stains) plus an antibody targeting PGP9.5, which labels nerves. The H&E-analog channels serve as inputs for the nnU-Net model. To train the model, ground-truth 3D segmentation masks were generated from the PGP9.5 immunofluorescence channel. The trained model allows us to generate 3D segmentation masks of nerves directly from specimens labeled with small-molecule (quickly diffusing) fluorescent analog of H&E, which is fast and inexpensive compared with thick-tissue immunolabeling.

The trained 3D nerve segmentation model achieved an average Dice score of 0.86 on held-out validation datasets of tri-labeled specimens (n=10). The segmentation performance was also evaluated on 2D regions (n=53) extracted from 3D pathology datasets of 8 prostatectomy specimens, yielding an average Dice score of 0.64 compared against annotations of nerves generated by a board-certified pathologist.

The trained model has been applied to 3D pathology datasets of 120 archived prostatectomy specimens from patients with known biochemical recurrence (BCR) outcomes. We are extracting 3D histomorphometric features (i.e. spatial features) from the resulting nerve segmentations and are integrating them with 3D features from previously developed segmentations of glands, nuclei, and/or cancer-enriched tissue regions. We aim to show that 3D features related to PNI are superior to analogous 2D features for PCs prognostication.

#2437 Deep-learning triage of 3D pathology datasets for accurate and efficient pathologist assessments.

G. Gao[1], A. H. Song[2], L. E. Barner[3], F. Wang[1], R. Yan[1], H.-C. Hsieh[1], D. Brenes[1], R. Wang[1], S. S. L. Chow[1], K. W. Bishop[3], L. D. True[1], D. M. Reddi[1], W. M. Grady[4], F. Mahmood[2], J. T. C. Liu[1];
[1]University of Washington, Seattle, WA, [2]Mass General Brigham, Boston, MA, [3]Broad Institute of MIT and Harvard, Boston, MA, [4]Fred Hutchinson Cancer Research Center, Seattle, WA

Introduction: Human tissue exhibits heterogeneous morphologies and microenvironments that are readily appreciated in 3D. In the current standard of clinical care, pathologists assess only a few thin 2D sections, typically sampled arbitrarily from one side of a tissue volume/biopsy, in which diagnostically important tissue structures may be missed or misinterpreted. Recent advances in non-destructive 3D pathology enabled by open-top light-sheet (OTLS) microscopy allow for comprehensive imaging of large clinical specimens (e.g. whole biopsies), thus offering the potential to improve the accuracy of diagnostic determinations. While fully automated computational analysis methods are being developed by us and others, a potential early route towards clinical adoption of 3D pathology is to rely upon pathologists for final diagnostic determinations based on viewing familiar 2D H&E-analog cross-sections from the 3D datasets. Because it is not practical for pathologists to manually review massive 3D pathology datasets (equivalent to hundreds of sections per specimen), we present a deep-learning-based triage method to automatically identify the highest-risk 2D cross-sections within 3D pathology datasets for time-efficient pathologist review.
Methods: For each 2D cross-section in a 3D pathology dataset, 2D tissue patches are converted into representative low-dimensional feature vectors using the pre-trained CONCH model. We perform attention-based aggregation of the patches within each 2D cross-section and then integrate neighboring 2D sections across depths to predict a context-aware 2.5D risk score. The ground truth labels for model training are based on consensus pathologist diagnoses.
Results: We implemented the AI-triaged 3D pathology workflow for two clinical scenarios. For prostate cancer risk stratification based on Gleason grading, our 2.5D method achieved an area under the curve (AUC) of 0.93 for triaging low vs. higher-grade prostate cancer cross-sections on around 110 specimens, outperforming AI analysis on individual 2D cross-sections without depth context (AUC 0.87). In another clinical scenario, where endoscopic biopsies from Barrett's esophagus patients were screened for neoplasia (dysplasia or adenocarcinoma), the 2.5D method similarly surpassed its 2D counterpart (AUC 0.92 vs. 0.89) for identifying benign vs. neoplastic cross-sections on around 95 specimens.
Conclusion: These preliminary results indicate that the integration of additional spatial context along the depth dimension enhances the model's discriminative capabilities to triage high-risk cross-sections from 3D pathology datasets. Finally, preliminary clinical validation studies comparing diagnoses based on AI-triaged 3D pathology vs. conventional 2D histopathology are underway to validate that our methods can improve diagnostic accuracy while minimizing pathologist workloads.

#2438 Bridging whole slide images and large language model for slide-level question answering.

Z. Gao[1], K. He[2], W. Su[3], W. McGough[1], I. Machado[1], M. Jimenez-Linan[4], B. Rous[4], R. Wray[1], C. Li[1], X. Pang[3], T. Gong[3], M. Feng[2], C. Li[3], M. Crispin-Ortuzar[1];

[1]University of Cambridge, Cambridge, United Kingdom, [2]National University of Singapore, Singapore, Singapore, [3]Xi'an Jiaotong University, Xi'an, China, [4]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background: Vision Language Models (VLMs), integrating large language models (LLMs) with vision encoders to enable better understanding and interaction with visual data, have broken entirely new ground in computational pathology. Recent studies have demonstrated that employing a simple linear layer as an 'adaptor' to transform image embeddings, extracted by pathology-specific vision encoders, into LLM-recognizable tokens is effective for developing patch-level VLMs in pathology. However, the gigapixel-scale size of whole-slide images (WSIs) and their pyramidal structure pose significant challenges in designing effective adaptors for slide-level analysis. In particular, different diagnostic questions and tasks at the slide level require focusing on various sub-regions at different magnifications or combining multiple regions and magnifications. Here, we aim to assess adaptors that meet these challenging demands and develop a slide-level VLM to enable slide-level question answering.
Methods: We develop Llama-Path, the first general-purpose slide-level VLM, using WSIs paired with descriptions and question-answer (Q&A) pairs. First, we collect 35,943 WSIs from public databases such as TCGA and GTEx, along with corresponding pathological reports or notes, covering a wide range of tumor and tissue types. Based on these reports and notes, we curate a WSI description dataset and a WSI Q&A dataset (337,000 Q&A pairs) using GPT-4. Then, we extract hierarchical patch embeddings from each WSI by the pathology foundation model, Conch. Next, we propose and evaluate six distinct slide-level adaptors: four vision-only, and two vision-text interactive. These adaptors are finetuned with Llama-3.1-8B across two stages to develop various versions of Llama-Path: The first stage uses the WSI description dataset to provide Llama-Path with a slide-level vision understanding ability. The second stage enhances the slide-level instruction-following capability of Llama-Path with the WSI Q&A dataset. Finally, we evaluate different versions of Llama-Path on a hold-out dataset consisting of 367 tumor and non-tumor cases with 4,440 Q&A pairs.
Results: All versions of Llama-Path demonstrated exceptional performance, each achieving over 90% accuracy in close-ended Q&A pairs. GPT-4 assessed open-ended performances with high accuracy, showing 36% of responses correct, 27% partially correct, and 3% incorrect. The remaining 34% could not be evaluated without access to the corresponding WSIs. The LongNet-based vision-text interactive adaptor outperformed others, likely due to its targeted capture of visual information and simultaneous optimisation of WSI embeddings.
Conclusions: Our findings highlight the potential of VLMs to enhance slide-level computer-aided diagnosis systems. Results from ongoing analyses, based on pathologists' evaluations, will be presented shortly.

#2439 Spatial transcriptomics-informed latent diffusion models generate histopathological images reflective of tumor microenvironment.

Gokul Srinivasan[1], **Minh-Khang Le**[1], Zarif Azher[1], Harsimran Kaur[2], Fred Kolling[3], Keluo Yao[1], Ken S. Lau[2], Xiaoying Liu[4], Louis J. Vaickus[4], Joshua J. Levy[1]

[1]Cedars-Sinai Medical Center, West Hollywood, CA,[2]Vanderbilt University, Nashville, TN,[3]Dartmouth College Geisel School of Medicine, Lebanon, NH,[4]Dartmouth Health, Lebanon, NH

While digitized whole slide images (WSIs) can improve cancer prognosis algorithms, limited data curation given high image complexity/size can hinder performance in underrepresented populations. Synthetic WSI generation offers a solution by simulating tissue heterogeneity and anonymizing data. However, current methods for histopathology cannot reproduce tumor microenvironment (TME) and other biomolecular features with high fidelity at gigapixel scale, limiting further application. Spatial transcriptomics (ST) paired with H&E-stained WSIs can provide this missing context. We present a novel method for using ST to guide image generation by conditioning latent diffusion models (LDM) on 55-micron resolution gene expression data from Visium ST. Preliminary evaluation demonstrates that LDMs can reproduce realistic TME histological features of primary colon tumors. We profiled 41 colon tumors with paired 40X H&E WSIs and Visium ST. A total of 255,744 WSI patches (512-pixel) were matched with 55-micron ST spots for subsequent LDM training. Inspired by single-sample gene set enrichment analysis methods, spot-level ST data were encoded into pathway representations via a CLIP text encoder using the top 50 genes, ranked through gene-wise comparison to non-zero median expression. A modified UNET was fine-tuned for 100,000 iterations (learning rate: 1e-5) to denoise CLIP-encoded ST data into histology images. Two pathologists evaluated 90 held-out randomly selected tissue patches, comparing original and ST-generated images at the same tissue locations. Pathologists- blinded to image origin (real/generated)- assessed the abundance of tumor, stromal, immune, and fat features on a four-point scale and determined whether the original and generated images contained similar histology. Hierarchical bivariate ordinal regression assessed correlations between original/generated features and calculated intraclass correlation coefficients (ICC) as a measure of interrater agreement. Hierarchical logistic regression determined proportion of images with similar histology, with image/pathologist random intercepts. Pathologic examination showed strong correlations for tumor (ρ=0.71; $p<0.001$) and immune (ρ=0.67; $p<0.001$) TME features. Excluding artifacts, stromal (ρ=0.68; $p<0.001$) and fat (ρ=0.57; $p<0.001$) features also correlated. Inter-rater agreement was high/comparable for most features (Real/Generated ICC- Tumor: 0.95/0.96, Stroma: 0.92/0.88, Immune: 0.63/0.69, Fat: 0.57/0.38; $p>0.05$). Pathologists found 86% of images reflected similar histologies (95% CI: [69%-95%]). This study is the first to generate realistic histology from spatially co-registered transcriptomic data. Further refinement is needed to scale the approach to whole tissue slides for prognostic modeling in cohorts with limited data.

#2440 Correlation analysis between AI-based H-score and clinical data in MET IHC stained WSIs.

Hyeon Seok Yang[1], Yunseob Hwang[1], DoKyung Kim[1], Yoon-La Choi[2], Kyungsoo Jung[2], Minjung Sung[2], Young Kee Shin[3], Ji-Hye Nam[4], **Tae-Yeong Kwak**[1], Sun Woo Kim[1], Hyeyoon Chang[1]

[1]Deep Bio Inc., Seoul, Korea, Republic of,[2]Samsung Medical Center, Seoul, Korea, Republic of,[3]Seoul National University, Seoul, Korea, Republic of,[4]LOGONE Bio-Convergence Research Foundation, Seoul, Korea, Republic of

Background: MET protein expression is considered a potential biomarker in lung cancer, but there is no guideline for analysis, and its clinical significance has not been sufficiently analyzed. In order to explore its potential as a biomarker, it is necessary to analyze the relationship between the expression level of the biomarker and clinical data. In this study, we analyze the relationship between H-score, which is automatically measured based on cell detection detected by a deep learning model, and clinical data.
Design: The dataset included 270 whole slide images (WSIs) of non-small cell lung cancer (NSCLC) immunohistochemically stained with a MET antibody (SP44), obtained through resection, biopsy, or endobronchial ultrasound (EBUS). For each of these WSIs, pathologists estimated the proportions for 0, 1+, 2+, and 3+ according to duty, and calculated the H-score based on these values. In addition, the analysis areas were manually specified to exclude the internal controls. We developed analysis models based on deep learning. The cancer area localization model identified the cancer areas for each patch, and the cell analysis model identified the cell membrane, cytoplasm, and nucleus of each cell. Additionally, the MET expression intensity of each cell was classified as 0, 1+, 2+, and 3+ based on the mean diaminobenzidine (DAB) optical density (OD) measured in the cell membrane. The H-score was calculated accordingly.
Result: For each WSI, the correlation between the H-score estimated by AI and the pathologist's H-score was calculated as Pearson's correlation coefficient = 0.6909 ($p<0.0001$). In addition, when analyzing the H-score estimated by AI by tumor subtype of clinical data, the mean H-score of adenocarcinoma samples was estimated to be 177, which was significantly higher than the mean H-score of 116 estimated for squamous cell carcinoma samples (Mann-Whitney test, $p < 0.0001$).
Conclusion: For MET IHC stained WSIs, H-scores were estimated through cell analysis using deep learning and image analysis, and the correlation with pathologist's H-scores was confirmed, and H-score differences between tumor subtypes were confirmed. Semi-automated AI analysis can be used to analyze the correlation between clinical data and MET staining expression.

#2441 Artificial intelligence-based quantification of PD-L1 staining intensity in non-small cell lung cancer: Beyond binary assessment.

Yunseob Hwang[1], Gui Young Kwon[2], Jeongwon Kim[3], Jiyoon Jung[3], DoKyung Kim[1], **Tae-Yeong Kwak**[1], Sun Woo Kim[1], Hyeyoon Chang[1]

[1]Deep Bio Inc., Seoul, Korea, Republic of,[2]Seoul Clinical Laboratories, Yongin-si, Korea, Republic of,[3]Kangnam Sacred Heart Hospital, Hallym University, Seoul, Korea, Republic of

Background: Determining the non-small cell lung cancer (NSCLC) patients likely to benefit from treatment based on the proportion of PD-L1-positive cells in immunohistochemistry (IHC)-stained slides, such as the Tumor Proportion Score (TPS), is effective but suboptimal. Manual PD-L1 quantification is labor-intensive, subjective, and restricted to binary assessment (positive/negative). To address these challenges, we developed an artificial intelligence (AI)-powered IHC image analysis pipeline that identifies cancer cells and their components while quantifying the staining intensity of the cancer cell membrane where PD-L1 is bound, on a scale from 0 to 100. We validated the AI-generated PD-L1 expression metrics by comparing them with clinically assessed PD-L1 TPS in NSCLC.
Methods: The AI pipeline consists of two deep learning components: cancer area localization and cancer cell staining analysis. The first component extracts patch images from whole-slide images (WSIs) and identifies cancer areas using a segmentation model for cancer localization. The second component classifies pixels of the tile image into the cell nucleus, cytoplasm, or membrane using a cellular compartment segmentation model. This component measures the optical density of Diaminobenzidine (DAB) staining at the target component corresponding to the target antibody for each cancer cell (e.g., PD-L1 on the cell membrane). We collected 366 PD-L1-stained NSCLC WSIs, which were clinically assessed for TPS by expert pathologists and used as the independent set for evaluation. Pearson's correlation coefficient (r) was used to compare clinically assessed TPS (C-TPS) values with PD-L1 staining metrics generated from the AI pipeline, such as TPS (AI-TPS), H-score, and the mean PD-L1 intensity of all tumor cells (Mean PD-L1 Intensity). The Mann-Whitney test was employed to compare the distribution of staining intensity values across NSCLC subtypes.
Results: The C-TPS values showed a strong correlation with AI-generated PD-L1 staining intensity metrics: Mean PD-L1 Intensity ($r = 0.9042$, $p < 1e-6$), H-score ($r = 0.8995$, $p < 1e-6$), and AI-TPS ($r = 0.8896$, $p < 1e-6$). Additionally, the C-TPS values exhibited a strong correlation with PD-L1 intensity heterogeneity metrics: the standard deviation of PD-L1 intensity ($r = 0.7261$, $p < 1e-6$), interquartile range of PD-L1 intensity ($r = 0.6125$, $p < 1e-6$). The Mean PD-L1 Intensity in lung adenocarcinoma was significantly higher than that in squamous cell carcinoma (Mann-Whitney test, $p < 0.0001$).
Conclusion: We demonstrated that the AI-driven PD-L1 staining intensity metrics show a high correlation with clinically assessed TPS values. This AI pipeline extends beyond binary PD-L1 assessment and can be applied to novel targets for PD-L1 evaluation.

#2442 STHD: Probabilistic cell typing of single spots in whole transcriptome spatial data with high definition.

Chuhanwen Sun[1], **Yi Zhang**[2]

[1]Department of Neurosurgery, Duke University, Durham, NC,[2]Department of Neurosurgery, Department of Biostatistics and Bioinformatics, Duke University, Durham, NC

Understanding of the cellular heterogeneity of tumor has been essential for uncovering cancer progression mechanisms and developing effective cancer immunotherapies. Emerging spatial transcriptomics (ST) technologies that enable single- and sub-cellular resolution profiling of gene expression across the whole transcriptome have recently become compatible with cancer samples. However, the transition to high-definition ST significantly increased data sparsity and dimensionality, posing significant computational challenges. For example, identifying cell types, deciphering neighborhood structure, and detecting differential expression are all crucial steps to interpret cancer ST samples. Here we present STHD, a novel machine learning method for probabilistic cell typing of single spots in whole-transcriptome, high-resolution ST data. Unlike the current binning-aggregation-deconvolution strategy, STHD directly models gene expression at single-spot level to infer cell type identities without cell segmentation or spot aggregation. STHD addresses sparsity by modeling count statistics, incorporating neighbor similarities, and leveraging reference single-cell RNA-seq data. We show in VisiumHD data that STHD accurately predicts cell type identities at single-spot level, which achieves precise segmentation of both global tissue architecture and local multicellular neighborhoods. The high-resolution labels facilitate various downstream analyses, including cell type-stratified bin aggregation, spatial compositional comparisons, and cell type-specific differential expression analyses. We applied STHD to analyze the newest colon cancer VisiumHD data, which identified patterns like spatial regions of cancer cell-specific stemness, spatially heterogenous cytokine communication activities, confined hypoxia macrophages, and distinct T cell-myeloid cell interactions and cytotoxicity activities located in different immune hubs. Moreover, STHD labels further reveal frontlines of inter-cell type interactions at immune hubs. STHD is scalable and generalizable across diverse samples, tissues, diseases, and cancer types, facilitating genome-wide analyses in various spatial organization contexts. Overall, STHD maps cell type of cancer ST samples with ultra-resolution and facilitates discovery of novel spatial biomarkers and molecular mechanism of cancer progression and treatment responses. The STHD software is publicly available at https://github.com/yi-zhang-compbio-lab/STHD.

#2443 High-resolution AI-based spatial biology tool for lung cancer trained by image-based spatial transcriptomics data to analyze tumor microenvironmnet.

Haenara Shin, Dongjoo Lee, Yooeun Kim, Daeseung Lee, Kwon Joong Na, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background: Spatial biology enables the analysis of tumor microenvironments by revealing cellular relationships within the heterogeneous tumor landscape, which are closely associated with tumor characteristics and immunology. In this study, we utilized high-resolution H&E images and image-based spatial transcriptomics (ST) data from lung cancer to develop a highly accurate deep learning model for mapping and AI-based workflow analyzing spatial relationships in the tumor microenvironment using only H&E images.
Methods: A total of 164 NSCLC samples with high-resolution ST data (Xenium) were used for model training. Tissue microarrays (TMAs) were prepared, and image and ST data were registered using manual keypoints followed by affine transformation. Refined and major cell types were mapped using label transfer based on ST data aligned with scRNA-seq references. Segmented cell-type maps served as ground truth for training the deep learning model to predict detailed cell-type distributions from H&E images. Model performance was evaluated using the area under the ROC curve (AUROC) for each cell type. External validation was conducted using independent H&E-ST datasets (6 TMA cores and 4 whole-slide images). The trained models were integrated with a customized StarDist-based nucleus segmentation tool for H&E images.
Results: In the external validation datasets, the model achieved mean AUROC values of 0.96, 0.92, 0.95, 0.94, 0.95, and 0.94 for epithelial cells, myeloid cells, fibroblasts, T-cells, endothelial cells, and B-cells, respectively. For refined immune cell types, including CD4+ T-cells, CD8+ T-cells, dendritic cells, and NK cells, the AUROC values were 0.94, 0.97, 0.94, and 0.97, respectively. The segmented cell-type maps were integrated with nucleus segmentation to generate spatial data formats comprising cell types, enrichment scores, and spatial coordinates. This integrated deep learning model provided an H&E-based AI tool for spatial biology, enabling the analysis of spatial relationships in the tumor microenvironment, such as cell type density in tumor epithelial niches.
Conclusion: Large-scale image-based ST data with precisely registered H&E images can achieve highly accurate cell-type definitions, even for refined immune cell types like CD4+ and CD8+ T-cells and dendritic cells. This integrated workflow offers a powerful tool for analyzing spatial features using only H&E images in tumor biology.

#2444 A deep learning framework for the reconstruction of gene expression profiles derived from formalin-fixed paraffin-embedded samples.

Lingli He[1], Kai Song[1], Ying Li[1], Celia Yujuan Dong[1], Cherry Y. N. Wong[1], Lin Qi[1], Xianrui Zhang[1], **Feng Gao**[2], Yufeng Chen[3], Louis Vermeulen[4], Shentao Zhou[5], Simon Siu Man Ng[1], Xin Wang[1]

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Department of General Surgery (Department of Colorectal Surgery), The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[3]The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[4]Amsterdam University Medical Centers, Amsterdam, Netherlands,[5]West China Second Hospital, Sichuan University, Chengdu, China

Formalin-fixed paraffin-embedded (FFPE) tissue samples often suffer from RNA degradation due to fixation, embedding, and storage processes, affecting the integrity of transcripts for RNA sequencing (RNA-seq). Herein, we developed a novel deep learning model to reconstruct gene expression profiles from FFPE-derived RNA-seq data. We first compared the transcript integrity numbers (TINs) of two in-house datasets derived from paired fresh frozen (FF) and FFPE tissues, with different fixation durations and library preparation strategies. We found that tissue samples fixed for 24 hours and subjected to the rRNA depletion-based library preparation strategy exhibited higher TINs. Using RNA-seq data for 832 FFPE samples across seven cancer types, we identified genes with consistently low TINs on the genome-wide scale. Interestingly, the signature genes of immune cells are more prone to degradation, compared to other cell types such as tumor epithelial cells. To reconstruct gene expression profiles, we developed a deep learning framework, based on 9568 FF tumor samples across 28 cancer types in the TCGA database. The framework demonstrated remarkable performance on both simulated data (672 transcriptomes) and in-house cancer cohorts with RNA-seq data, including one FFPE and three FF-FFPE-matched cohorts. On the simulated data with noise levels ranging from 10% to 60%, the reconstructed data achieved consistently high correlation coefficients (> 0.85) with the ‘clean’ data without noise. For the FF-FFPE-matched datasets, compared to the original FFPE-derived data, the reconstructed gene expression profiles significantly improved the correlation with matched FF profiles, even for immune cell signature genes (all $P < 0.05$). In our application to cancer subtyping, the gene expression profiles reconstructed improved the classification accuracy from 67% to 92%. Furthermore, the reconstructed profiles recapitulated the subtype-specific biological properties lost in the FFPE-derived data and showed more significant association with patient survival. As the first deep learning model to rectify FFPE-derived RNA-seq data, our framework enables more efficient use of archived FFPE tissue samples that are widely available in the clinic.

#2445 Extending ENPP3 expression inference from tissue microarrays to whole tissue sections: building a case for automated patient enrichment and IHC scoring.

Erik A. Burlingame, Fatemeh Koochaki, Tsun-wen Sheena Yao, Shajo Kunnath-Velayudhan, Chaitanya Parmar, Laurie Lenox, Tommaso Mansi, Joel Greshock, Kristopher Standish, Albert Juan Ramon

Johnson & Johnson, New Brunswick, NJ

Enrollment of patients with target-positive tumors is thought to be a factor of success in CD3-redirection targeted therapy trials. This process can incur significant testing costs for assays like immunohistochemistry (IHC) target expression assessment and requires laborious pathologist scoring. An ongoing Phase I study (NCT06178614) is evaluating the safety and preliminary anti-tumor activity of ENPP3xCD3 (JNJ-87890387) in ENPP3-unselected, advanced-stage solid tumors with a high prevalence of ENPP3 expression. This includes lung adenocarcinoma (LUAD) and colon adenocarcinoma (COAD) where ENPP3 cell surface expression is seen in >50% of patients. To help mitigate potential future IHC testing costs, we propose (1) an AI-based patient enrichment model that uses hematoxylin and eosin (H&E)-stained whole tissue sections (WTS) to infer ENPP3 expression and rule out LUAD and COAD patients likely to be ENPP3 negative. We also propose (2) a complementary model to infer H-scores from ENPP3 IHC-stained tissues as an alternative to pathologist scoring to help reduce workload. Training such models typically requires a large collection of WTS, which can be challenging to score, and may not be available in early clinical studies. Alternatively, tissue microarrays (TMAs) can incorporate hundreds of cases on a single slide and are readily available through commercial vendors, reducing the number of slides needed for model development. As TMA cores are typically orders of magnitude smaller than WTS, we (3) test the hypothesis that models trained on TMA cores can be deployed on WTS. To enable model training we developed a TMA preprocessing workflow that aligns paired serial H&E and IHC core images with their ground truth pathologist-derived H-scores. For our model backbone we use a vision transformer foundation model pre-trained on 55,000 H&E WTS spanning tissue types, which conditions the model for tasks in histopathology. We then train separate fully supervised models to achieve two goals: (1) infer whether an H&E core's paired ENPP3 H-score is greater than zero, i.e., H-score > 0 classification for patient enrichment, and (2) infer an IHC core's H-score directly, i.e., H-score regression for automated H-scoring. The H&E-based COAD H-score > 0 classification model achieved AUC=0.79 on a held-out test set of 29 WTS. The IHC-based H-score regression models for COAD and LUAD achieved intraclass correlation coefficients of 0.76 and 0.88 on their respective held-out test sets (n=29 WTS for COAD and n=46 cores for LUAD). This approach could (1) help reduce the number of patients requiring IHC assessment and (2) minimize pathologists' scoring workload, thus reducing trial costs and expediting patient enrollment. Our results suggest that (3) TMA cores may contain sufficient signal to train models for deployment on WTS for some tasks, which could help minimize modeling costs.

BIOINFORMATICS / COMPUTATIONAL BIOLOGY / SYSTEMS BIOLOGY / CONVERGENT SCIENCE: Digital Pathology Poster Session

#2449 Using digital pathology to differentiate survival phenotypes in high-grade serous ovarian cancer.

Kelsey C. Goon, Leonhard Donle, Ernst Lengyel

University of Chicago Pritzker School of Medicine, Chicago, IL

Background: High-grade serous ovarian cancer (HGSOC) has a median survival < 5 years. Yet approximately 10% of patients become long-term survivors (LTS), living > 10 years. Predicting extremes of survival may reveal insights into HGSOC biology. Machine learning (ML) can predict survival outcome in other malignancies from hematoxylin and eosin (H&E) whole slide images (WSIs) though no published models address overall survival (OS) in HGSOC. This project uses ML to predict OS in HGSOC H&E WSIs, comparing tumor and stromal regions.
Methods: Short-term survivors (STS) were defined as OS < 2 years and LTS as OS > 7 years. The model was trained on 138 H&E WSIs (56 LTS, 82 STS) at 20x magnification with 5-fold cross-validation repeated 3x and validated on The Cancer Genome Atlas-Ovary (TCGA) dataset (34 WSIs; 6 LTS, 28 STS). After converting WSIs to tiles, features were extracted using the UNI foundation model. A linear discriminant analysis predicted tile association with survival, a pretrained tumor segmentation model separated tumor and stroma, and a logistic regression classifier predicted survival based on the ratio of STS to LTS. Performance was compared across regions: whole slide, tumor alone, stroma alone, a 500-µm band at the tumor-stroma interface, and a combination of tumor-based and stroma-based predictions.
Conclusions: Models using both stroma and tumor outperformed compartmentalized models. This trend was consistent in the TCGA dataset though performance dropped significantly, proving the feasibility of using ML on H&E WSIs to predict survival in HGSOC. Our results identify a need to optimize generalizability for this relatively data-scarce malignancy and suggest that successful prediction of OS should acknowledge tumor-stromal interactions.

	Internal Test Set		**TCGA Validation**	
	AUC	**Balanced Accuracy**	**AUC**	**Balanced Accuracy**

#2450 Slide-level foundation models exhibit effective diagnostic and prognostic performance in H&E-stained histopathology.

P. Chen, A. G. Serrano, T. Gautam, **S. Ranjbar**, B. Rodriguez, P. Team, L. M. Solis Soto, Y. Yuan;
The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Computational pathology has progressed from tile-level to slide-level foundation models, eliminating the need to train separate tile aggregation networks. Slide-level foundation models are trained on extensive datasets of whole-slide images. For instance, Prism is trained on 587,196 slides from 17 tissue origins, while GigaPath is trained on 171,189 slides covering 31 tissue types, both sourced from private data cohorts. By leveraging vast amounts of data to capture intricate tissue patterns, slide-level models promise to extract clinically relevant features. However, currently there is limited independent research evaluating the performance of these models in more complex tasks, such as multiclass sub-typing diagnosis and survival predictions.
Methods: We curated FFPE H&E slides from both the public TCGA and our in-house cohort. From TCGA, we collected slides from 5 cancer types: 344 BLCA, 505 KIRC, 348 LIHC, 350 STAD, and 500 THCA cases. The in-house cohort consisted of rare cancer cases, categorized into 54carcinoma, 67 sarcoma, and 18 melanoma cases. We applied slide-level foundation models, Prism and GigaPath, to embed the slides into feature representations. For the diagnosis task, we used a support vector machine (SVM) model to classify TCGA slides into 5 categories and the in-house slides into 3 categories. For the prognosis task, we trained a multi-layer perceptron (MLP) model to predict the hazard risk. We conducted 5-fold cross-validation for both diagnosis and prognosis tasks.
Results: On TCGA slides, we achieved a classification accuracy of 0.973±0.008 using Prism and 0.944±0.022 using GigaPath. For the in-house slides, the classification accuracy was 0.885±0.042 with Prism and 0.848±0.056 with GigaPath. These results demonstrate the strong discriminative capabilities of the feature representations extracted by both slide-level foundation models. Notably, Prism outperformed GigaPath on both the TCGA and in-house datasets. For survival prediction, we applied the Prism model to five TCGA cancer types and the in-house cases. The C-index values were 0.595±0.029 for BLCA, 0.719±0.039 for KIRC, 0.655±0.058 for LIHC, 0.591±0.046 for STAD, 0.720±0.114 for THCA, and 0.592±0.025 for all in-house cases combined. These varying levels of survival prediction performance reflect the challenges posed by different tasks, while the lowest value being above 0.59 suggests prognostic information was adequately extracted.
Conclusion: By evaluating the diagnostic and prognostic capabilities of slide-level foundational models, we demonstrated their effectiveness on both public and in-house datasets. Our findings corroborate that these models can distill clinically relevant feature representations even without fine-tuning, underscoring their potential for broad computational pathology applications.

#2451 H&E whole-slide image (WSI) based artificial intelligence (AI) model to detect EGFR and ALK mutation in non-small cell lung cancer (NSCLC).

Chan Mi Jung[1], Brandon Park[2], Hannah Son[1], Liam IL-YOUNG Chung[1], Young Kwang Chae[1]

[1]Northwestern University, Chicago, IL,[2]University of Missouri-Kansas City School of Medicine, Kansas City, MO

Detection of mutated epidermal growth factor receptor (EGFR) and anaplastic lymphoma kinase (ALK) are essential to guide therapeutic decisions for patients with NSCLC. Although traditional molecular testing methods-immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH)-and comprehensive genomic profiling (CGP) can provide extensive molecular insights, they are limited by prolonged turnaround time, higher tissue requirements, and elevated costs. To address this challenge, we tested a deep learning model that leverages digital pathology to analyze scanned H&E-stained WSIs for identifying EGFR and ALK mutations in NSCLC patients.

The study utilized a commercial assay to predict EGFR and ALK genomic alterations directly from H&E-stained WSIs through a cloud-based platform. The assay was developed by Imagene Inc. using multiple instance learning (MIL) methods, trained with embeddings that were extracted by the commercial CanvOITM Foundation Model (FM). The FM ensured robust generalizability and computational power by leveraging 632,608 digitized H&E-stained tissue samples. Thresholds were optimized on a held-out dataset to achieve positive predictive values (PPVs) of 50% and 40% for EGFR and ALK, respectively, while maintaining a 99% negative predictive value (NPV) for both genes.

We tested the predictions in a blind retrospective evaluation including 164 digitized H&E images with EGFR molecular information and 158 images with ALK fusion data. In this study, 29 patients had EGFR-positive and 3 had ALK-positive mutations detected by commercial CGP providers. For EGFR mutation prediction, our model achieved a sensitivity of 48.3%, a specificity of 88.3%, a PPV of 66.7%, and an NPV of 100%. For ALK mutation prediction, the model achieved a sensitivity and NPV of 100%, specificity of 99.1%, and a PPV of 75%. Additionally, 54.88% (90/164) of EGFR and 28.48% (45/158) of ALK cases were classified as "intermediate," indicating uncertain results.

Our study highlighted the potential of our prediction model for identifying EGFR and ALK mutations to guide targeted therapies in NSCLC patients. The model's NPV of 100% demonstrates its strong ability to accurately rule out both EGFR and ALK mutations, ensuring that patients without these mutations are not subjected to unnecessary treatments. Furthermore, the ALK mutation prediction was promising with a sensitivity of 100% and specificity of 99.1%, demonstrating the model's ability to detect all true positive cases while effectively minimizing false positive results. The presence of intermediate results suggests the need for additional diagnostic steps to confirm or exclude mutations and ensure accurate clinical decisions. Excluding EGFR and ALK alterations directly from the diagnostic H&E image addresses the demand for rapid genomic analysis driven by the rising use of neoadjuvant immunotherapy.

#2454 Spatial profiling of arsenic-responsive gene expression in bladder cancer models via multiplex in situ hybridization.

Sonalika Singhal[1], Kevin Gardner[2], Michael L. Miller[2], Anushka Dixit[3], Samarth Singhal[1], Donald Sens[1], Sandeep Singhal[1]

[1]University of North Dakota, Grand Forks, ND,[2]Columbia University Medical Center, New York, NY,[3]Bio-Techne, Newark, CA

Multiplex Fluorescent In Situ Hybridization (mFISH) enables precise identification of distinct cell phenotypes and facilitates the assessment of spatial interactions within the tumor microenvironment. Analyzing images generated from mFISH studies allows for detailed characterization and comparison of the spatial distribution of tumor cells and tumor-associated immune cells. In our prior study, we developed a gene expression-based model for predicting bladder cancer risk under arsenic exposure, identifying three key genes - NKIRAS2, AKTIP, and HLA-DQA1 that demonstrated high predictive accuracy (AUC: 94 for training and 75 for testing) (PMCID: PMC8760535). The current study employs an image-based digital Pathology approach to further validate this model, exploring the role of these potential biomarkers at single-cell resolution.Bladder cancer biopsy samples contain RNA of sufficient integrity and quality for molecular analysis (RNA Integrity Number > 7), and confirmed through positive and negative control assessments, were selected for accurate and reliable gene expression analysis in downstream. Five mFISH images were generated by ACD Bio-Techne, and hematoxylin and eosin (H&E) images were annotated by the Department of Pathology and Cell Biology at Columbia University Medical Center. Using Warpy, the mF and H&E images were overlaid to delineate tumor and non-tumor regions on whole slide images (WSI). Quantification of the WSI was conducted with QuPath, where a custom data column containing the weighted 3-gene module score for each cell was appended to the sample data. Spatial distribution of cells was analyzed in python using Sklearn, padas, numpy and matplotlib libraries.The analysis demonstrated that the previously established three-gene risk prediction model exhibited a significantly higher signal density within tumor regions across all mFISH bladder cancer samples. Tumor regions displayed a markedly closer spatial proximity between cells compared to non-tumor regions. When comparing the genomic risk prediction equation for individual cells in tumor versus non-tumor regions, the model achieved a training AUC score of 0.92 and a test accuracy of 0.85. Notably, this trend was independent of tumor grade, whereas expression intensity declined with increasing patient age.In conclusion, this study reinforces the predictive significance of the previously identified gene set comprising NKIRAS2, AKTIP, and HLA-DQA1 in assessing bladder cancer risk. The methodologies utilized highlight the potential of low-complexity, single-cell gene expression profiling through multiplex mFISH, coupled with the integration of AI-driven digital pathology tools. However, the study is limited by its small sample size and the narrow range of clinical parameters evaluated, underscoring the need for further research to validate and expand these findings.

#2455 AI-based robust testicular cancer triaging, a promise for an efficient and cost-effective diagnostic/predictive modality.

Siddhesh Thakur[1], Ujjwal Baid[2], Andres Martin Acosta[1], Muhammad T. Idrees[1], Michael Feldman[1], Spyridon Bakas[1]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]Emory University, Atlanta, GA

Testicular cancer is one of the most common malignancies in males aged 20-44, with its two major subtypes being Seminoma and Non-Seminomatous Germ Cell Tumors (NSGCT). Accurate classification is essential for patient management and treatment, after initial histologic diagnosis on radical orchiectomy specimens or biopsies of metastases. Histopathological diagnosis, though effective, is time-consuming, costly, and subject to inter-observer variability. Digital pathology combined with artificial intelligence (AI) promises to improve diagnostic consistency and efficiency while benefitting settings without expertise in these tumors. We seek rapid and robust triaging of these subtypes through a foundation model interrogating H&E-stained tissue sections and an attention-based Multiple Instance Learning (abMIL) approach providing interpretable predictions highlighting decision-driving regions. Retrospective multi-institutional data from 144 patients (254 slides) were used to develop our AI model. 118 patients (202 slides) were used for model training, 14 (30 slides) for validation, and 14 (22 slides) as an independent hold-out set. The UNI foundation model was pre-trained on diverse datasets and fine-tuned using abMIL, identifying discriminative features from the training data without requiring pixel-level annotations. Independent hold-out set evaluation revealed Area Under the Curve=96%, Accuracy=94.54%, Specificity=92%, and importantly, Sensitivity=100%. Specifically, all predicted NSGCT are correctly identified as NSGCT, and all Seminomas are always detected. In other words, no Seminoma case is overlooked, while 8% of the actual NSGCT may be misclassified as Seminoma. A sensitivity of 100% supports our model as a triaging tool, enabling faster decision-making for high-risk patients. Our proposed abMIL approach leveraging the foundation model UNI, provides a perfectly sensitive and scalable solution for clinical triaging between Seminoma and NSGCT testicular tumors in digitized tissue sections, ensuring subtype detection and supporting pathologists in improving diagnostic accuracy and efficiency. Furthermore, the model's focus on highlighting AI decision-driving regions of the tissue section, renders it well-suited for large-scale clinical data, where it can make further data-driven contributions in extending our current disease knowledge.

#2456 Artificial intelligence-powered spatial analysis of tumor-infiltrating lymphocytes predicts prognosis in gallbladder cancer after resection.

Hyemin Kim, Young Hoon Choi, So Jeong Yoon Yoon, Cheolyong Joe, Se-Hoon Lee, Sang Hyun Shin, In Woong Han, Jin Seok Heo, Yo Han Jeon, Kee-Taek Jang, Kwang Hyuck Lee, Jong Kyun Lee, Kyu Taek Lee, Hongbeom Kim, Jookyung Sophie Park

Samsung Medical Center, Seoul, Korea, Republic of

Background: Tumor-infiltrating lymphocytes (TIL) play an essential role in various cancer types. However, their prognostic significance in resected gallbladder cancer remains largely unknown.
Methods: This study included 225 patients who underwent curative resection for gallbladder cancer. H&E-stained whole slide images were analyzed using the Lunit SCOPE IO, an artificial intelligence (AI)-powered spatial TIL analyzer. Based on the density of intratumoral TILs in the cancer epithelium and stromal TILs in the cancer stroma, three immune phenotypes (IP) were defined: immune-inflamed phenotype (IIP), immune-excluded phenotype (IEP), and immune-desert phenotype (IDP). Survival outcomes were analyzed, with subgroup analysis conducted for early-stage (stage 0-II) and advanced-stage (stage III-IV) disease.
Results: Of the 225 patients, 58 (25.8%) had IIP, 151 (67.1%) had IEP, and 16 (7.1%) had IDP. During a median follow-up of 71 months, 82 deaths (36.4%) were recorded. IIP and IEP were significantly associated with more prolonged disease-free survival (DFS) and overall survival (OS) compared to IDP.
Conclusions: Immune phenotypes identified through AI-powered spatial TIL analysis were associated with DFS and OS in resected gallbladder cancer, particularly in late-stage disease. These findings highlight the prognostic potential of immune phenotyping, especially in advanced disease.

#2457 Prognostic value of CD8+ T-cells at the invasive margin is comparable to immune score in non-metastatic colorectal cancer: A prospective multicentric cohort study.

Durgesh Wankhede[1], Niels Halama[1], Matthias Kloor[2], Dominic Edelmann[1], Hermann Brenner[1], Michael Hoffmeister[1]

[1]German Cancer Research Center, Heidelberg, Germany,[2]Institute of Pathology University of Heidelberg, Heidelberg, Germany

Background: Immunoscore predicts colorectal cancer prognosis but faces adoption barriers due to complex software and reimbursement issues. This study used open-source methods to explore a simplified prognostic model in non-metastatic CRC by focusing on single T-cell markers.

Methods: A multicentric prospective cohort study in non-metastatic CRC patients assessed CD3+ and CD8+ tumor infiltrating lymphocytes (TILs) in the invasive margin (IM) and tumor core (TC) using QuPath. An immune cell score, based on TIL densities (CD3-IM, CD8-IM, CD3-TC, CD8-TC), was calculated similarly to the Immunoscore®. A split sample approach (70:30) estimated adjusted hazard ratios for cancer-specific survival (CSS) in training and validation sets. CART analysis identified the most prognostic TIL, and its model was compared to an immune cell score model for performance (Brier score) and discrimination (Concordance Probability Estimate, CPE).

Results: Over a median follow-up of 9.0 years, 203 CRC-specific deaths occurred among 1,260 patients. CART-selected CD8-IM was the most prognostic TIL at a cut-off of 231 cells/mm2. Patients with CD8-IMHi had better CSS than CD8-IMLow in both training (HR 0.58, 95% CI 0.40-0.84) and validation sets (HR 0.35, 95% CI 0.21-0.60). Brier scores of CD-8IM and immune cell score survival models were comparable in both training and validation cohort, whereas the survival discrimination of CD8-IM slightly outperformed the immune cell score in the validation set (CPE: CD8-IM 0.748, IS 0.730).

Conclusion: CD8-IM alone provided prognostic information comparable to the immune cell score. Simplified, cost-effective TIL assessments could improve clinical translation and guide adjuvant therapy in early-stage CRC.

#2458 Prediction of atezolizumab benefit in NSCLC by computational pathology: Retrospective validation in a phase III trial.

Patrick Leo[1], Niha Beig[1], Barzin Y. Nabet[1], Chang Ho Ahn[2], Soohyun Hwang[2], Sanghoon Song[2], Chan-Young Ock[2], Daniel Ruderman[1]

[1]Genentech, Inc., South San Francisco, CA,[2]Lunit, Seoul, Korea, Republic of

Background: Anti-PD-(L)1 therapies are widely used to treat non-small cell lung cancer (NSCLC). However, suboptimal disease response motivates development of biomarkers to identify patients likely to benefit from these therapies. Here, we demonstrate an artificial intelligence (AI) powered model that analyzes the tumor microenvironment (TME) of hematoxylin and eosin (H&E) images to predict patient benefit from atezolizumab (anti-PD-L1) in NSCLC.
Methods: 1,243 digitized H&E slides were collected from two trials of atezolizumab versus docetaxel in second-line advanced NSCLC. POPLAR, a phase II trial, was used for training (n=162) and OAK, its phase III follow-on, was used as validation (n=1,081). Lunit Scope IO, a previously developed deep learning model specialized for TME analysis, was deployed on each image to label tissue and cells. Then, the densities of tumor cells, lymphocytes, fibroblasts, macrophages, endothelial cells, and mitotic figures were calculated in the tumor epithelium and intra-tumoral stroma. An elastic-net penalized Cox regression model using these density values was fit on the atezolizumab-treated patients of the training set to predict overall survival (OS) and applied to the entire dataset. To divide patients into model-low/high groups, the risk score threshold maximizing between-arm median OS difference in model-high patients was identified on the training set. Model performance was evaluated by concordance index (c-index) in each treatment arm, by hazard ratio (HR) between arms in the model-low/high groups, and by a Cox regression model with treatment arm, model-low/high category, and their interaction in the validation set.
Results: In the tumor epithelium, lymphocytes and tumor cell densities were positively correlated with OS in atezolizumab-treated patients, while mitotic cell and macrophage densities were negatively correlated. In the intra-tumoral stroma, densities of fibroblasts, macrophages, lymphocytes, and endothelial cells were positively correlated with OS. Model risk score was more strongly associated with OS in the atezolizumab arm (c-index=0.58 95% confidence interval: [0.55, 0.61]) than in the docetaxel arm (c-index=0.54 [0.51, 0.57]). Among the n=464 model-high validation set patients, atezolizumab-treated patients had significantly longer OS (HR=0.65 [0.53, 0.80]) with no significant difference between arms in model-low patients (n=617, HR=0.92 [0.78,1.10]). Model low/high category had a significant interaction (p=0.02) with treatment in survival prediction.
Conclusions: We applied AI-driven analysis of histology to large randomized trials to quantify how TME cellular composition correlates with benefit from immunotherapy. Our results suggest that digital pathology-based approaches in combination with AI analysis could yield biomarkers for patient stratification and treatment selection strategies.

#2459 Membrane stain-enhanced quantification of HCR™ Pro RNA-ISH using HALO image analysis software.

Randy Chen[1], Anne Hellebust[2], Aneesh Acharya[1], Harry Choi[1]

[1]Molecular Instruments, Inc., Los Angeles, CA,[2]Indica Labs, Albuquerque, NM

Accurate quantification of RNA in situ hybridization (RNA-ISH) signals is critical for understanding spatial gene expression, particularly at the single-cell level. Traditional methods using Hematoxylin or DAPI staining often fall short due to their inability to clearly define cell boundaries, leading to inaccurate dot counting. In the context of digital pathology, this challenge can hinder precise interpretation of spatial gene expression data. Here, we demonstrate how the incorporation of membrane stains enhances RNA-ISH signal quantification by delineating cell borders, enabling precise dot counting with HALO image analysis software.

Membrane stains were applied across both chromogenic and fluorescent HCR™ Pro RNA-ISH assays, facilitating robust signal detection in brightfield and fluorescent imaging modalities. This approach also enabled the integration of cell-type specific markers (e.g., CD3 and CD4) to provide insights into gene expression dynamics within distinct cell subpopulations relevant to pathology workflows.

Comparative analysis revealed superior accuracy in dot quantification when using membrane-enhanced staining compared to traditional Hematoxylin/DAPI-expanded methods. These findings underscore the importance of combining membrane stains with advanced imaging analysis tools like HALO in digital pathology for precise and reproducible quantification of RNA-ISH signals. This advancement paves the way for more detailed studies of differential gene expression and cellular heterogeneity within clinical and research pathology settings.

#2460 Judith: An agentic AI system for biomedical image analysis and scientific discovery in precision oncology.

Ming Y. Lu[1], Faisal Mahmood[2], **Richard J. Chen**[1]

[1]Modella AI, Boston, MA,[2]Pathology, Brighman and Women's Hospital, Boston, MA

The rapidly increasing volume of multimodal biomedical data presents unprecedented opportunities in precision oncology but poses significant challenges for researchers analyzing complex modalities such as gigapixel pathology slides. To address these challenges, we developed Judith, an AI-driven research assistant that leverages foundation models, multimodal generative AI, and other advanced computational tools for streamlining complex workflows in biomedical image analysis, predictive modeling, and biomarker discovery. Judith enables researchers to execute computational tasks through natural language commands, automating tasks such as response prediction, multimodal cancer prognosis, and histopathology image retrieval. We demonstrate Judith's capabilities in several precision oncology use cases. (1) Predictive modeling and biomarker discovery: Using a retrospective dataset of pretreatment biopsies from invasive breast carcinoma patients treated with Trastuzumab (n=85 patients), Judith trained an AI model that predicts pathologic complete response with an AUROC of 0.855. Judith could also interpret the model, identifying key cellular features linked to tumor proliferation and finding histologic biomarkers that explain cohort-level differences between responders and non-responders. (2) Multimodal data integration: Judith orchestrated the development of a survival prediction model integrating histology, radiology, and multi-omics data for progression-free survival prediction in low-grade glioma patients (n=127), achieving a C-Index of 0.684. Using an integrative analysis, Judith further stratified patients into high- and low-risk groups and identified unfavorable prognostic features for cancer progression such as high tumor cellularity and PSPH overexpression. (3) Histology slide retrieval: Judith automated the development of a histology slide search system (n=138), enabling pathologists to retrieve slides with similar cancer diagnoses and morphologies. Judith was then able to validate the performance of histology slide retrieval, with successful retrieval of rare cancer types such as leiomyosarcoma. Overall, Judith represents a major advancement in biomedical research by automating AI workflows and enhancing data-driven discovery. Its ability to analyze diverse data modalities, identify meaningful biomarkers, and generate interpretable insights empowers researchers to maximize the scientific insights in their data. Future developments will focus on expanding multimodal capabilities, refining interpretability tools, and integrating real-time collaboration features.

#2461 Federated learning enables multi-institution collaboration without sharing Hand E slides.

Kodi Taraszka[1], Oded Rosolio[2], Intae Moon[1], Yevgeniy Semenov[3], Alexander Gusev[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Duality Technologies, Tel Aviv, Israel,[3]Massachusetts General Hospital, Boston, MA

Hematoxylin and eosin slides provide vital visual information on a collected tissue sample and are a key component of cancer diagnostics. Previous work in computational pathology has utilized deep learning architectures to accurately and efficiently tackle complex tasks such as tumor classification. However, the generalizability of these algorithms is currently limited due to the inherent difficulty of cross institution collaboration. Here, we propose leveraging federated learning (FL) which aggregates model level information between institutions to enable collaboration without exposing sensitive data. This allows the deep learning model to incorporate diverse patient populations and heterogeneous data sources which are needed for generalizability while preserving patient privacy.

As a proof-of-concept, we used attention based multiple instance learning within the FL framework to perform cancer subtype classification between lung adenocarcinoma and lung squamous cell carcinoma with three distinct cohorts: Dana-Farber Cancer Institute (DFCI), Massachusetts General Hospital (MGH), and The Cancer Genome Atlas (TCGA). We present comparisons using three approaches: FL, institution specific analyses, and a centralized model where data is combined at one site (gold standard). We find all three approaches have comparable overall AUC. Additionally, we see that there is significant heterogeneity in AUC between cohorts which may indicate FL is more robust to overfitting and more generalizable. Comparing features generated using the foundation pathology model (UNI) to those generated from a ResNet50 model pre-trained on ImageNet (ResNet), we observed more institutional level heterogeneity in the UNI results than in ResNet which may indicate UNI is learning institution specific features that limit its generalizability. Overall our work shows FL enables generalizable deep learning across institutions without risking patient privacy.

Cohort	Total Sample Size	Sample Size Per Site	Number of Sites	ResNet: ResNet50 pretrained on ImageNet				UNI: Foundation Pathology Model

#2462 Novel digital pathology algorithms to explore the role of tumor microenvironment in next generation immuno-oncology clinical trials utilizing 17 plex fluorescent immunohistochemistry.

Richard Van Krieken, Jaspreet Kaur, James Santos, Naveen Dakappagari, Jennifer Bordeaux

Navigate BioPharma Services, Carlsbad, CA

Purpose: A deeper understanding of the intricacies between tumor microenvironments (TMEs) and immune cell infiltrates is critical for creation of next generation immune modulating therapies. We previously validated a clinical grade, 17 plex tumor immune landscape assay which characterizes T cells, B cells, myeloid cells, plasma cells, and tumor cells across five major cancer types. This assay was developed on the Orion platform, which images up to 18 markers concurrently and allows for same slide hematoxylin and eosin (H and E). Using the Orion platform, we characterized the TME through two approaches: cellular neighborhoods and clustering based on H and E and segmented fluorescent immunohistochemistry data. Our findings elucidate innovative strategies for leveraging high dimensional data from Orion to uncover clinically useful insights, opening new avenues for understanding mechanism of response or resistance in next generation immune oncology (IO) clinical trials
Study Design: We designed a mFIHC assay (Granzyme B, Ki67, CD3e, CD20, CD4, CD163, CD8a, CD56, PDL1, PD1, LAG3, FOXP3, CD11b, CD138, SOX10, Cytokeratin and Hoechst) to evaluate expression of immune markers on non small cell lung cancer, breast carcinoma, colorectal cancer, prostate cancer and melanoma. After the initial evaluation, we validated the mFIHC assay for clinical trial use with automated staining (IntelliPath FLX) and imaging (Orion). Image analysis was conducted using HALO technologies.
Results: HALO analysis revealed distinct tumor immune microenvironments in the examined tissues. Microenvironment data were assessed by analyzing immune cell infiltration alongside immune activation markers. Our analysis revealed unique cell clusters in these microenvironments.
Conclusion: Our clinically validated 17 plex mFIHC assay, combined with advanced spatial algorithms, offers improved characterization of the TME. We expect these novel algorithms to contribute to gaining novel insights into tumor biology and development of next generation IO therapies.

#2463 AI-based EGFR-mutation prediction from haematoxylin and eosin (H&E) images in non-small cell lung cancer (NSCLC): A global multi-cohort validation study.

Jongchan Park[1], Biagio Brattoli[1], Jack Shi[1], Michael Senior[2], Talha Qaiser[2], Jack Rawson[2], Woochan Hwang[1], Sangwon Shin[1], Taebum Lee[1], Chan-Young Ock[1], Sergio Pereira[1], Huw Bannister[2], Elia Riboni-Verri[2], Siraj Ali[1], **Luiza Moore**[2]

[1]Lunit, Seoul, Korea, Republic of,[2]Astrazeneca, Cambridge, United Kingdom

Background: Despite guideline recommendations for EGFR testing in NSCLC patients, many are under-tested due to resource constraints and long turnaround times. Existing AI-based genotype prediction models using H&E whole slide images (WSIs) have mostly been validated in limited settings, resulting in barriers to real-world applicability. To address these challenges, we developed and validated a deep learning model that demonstrates robust and consistent performance across various clinical settings and independent patient cohorts.

Method: Our study utilized WSIs from 4,684 EGFR-mutated and 7,576 wild-type NSCLC cases from multiple sites, including USA, China, and Republic of Korea, to train convolutional neural networks (CNN) and ViT-based models to predict EGFR mutations from H&E WSIs. To improve generalization performance, data-centric approaches, including augmentations, oversampling, and weighted losses, were adopted, and the ensemble of prediction scores was used as the final prediction. We report validation performance in three cohorts: an independent internal validation cohort; a multi-scanner cohort of paired images scanned by six different scanners and with two different magnifications; and independent external validation cohorts from AstraZeneca.

Results:The internal validation cohort (n=625) and the multi-scanner cohort (n=2,261; 323 in each subgroup) included 206 (33.0%) and 168 (52.0%) EGFR-mutated samples, respectively. Our methods showed significant improvement in performance, achieving an area under the ROC curve (AUC) of 0.880 compared to 0.723 from a model we previously presented. The model demonstrated generalized performance across mutation subtypes (AUC 0.843 to 0.894), specimen types (0.823 to 0.897), scanners (0.822 to 0.855), and magnifications (0.824 to 0.832). The model was further validated on independent external cohorts which include additional EGFR-mutated samples.

Conclusion:An AI model demonstrated robust validation performance across diverse settings for EGFR mutation prediction from H&E WSIs in NSCLC, representing a vital step toward real-world clinical impact.

#2464 Inferring genomic properties from H&E whole-slide images of >60,000 solid tumors.

Kevin M. Boehm[1], Arfath Pasha[1], Armaan Kohli[1], Raymond Lim[1], Tom Pollard[1], Darin Moore[1], JianJiong Gao[1], Nikolaos M. Dimitriou[1], Madison Darmofal[1], Meera Hameed[2], Ahmet Dogan[2], Natasha Rekhtman[2], Klaus J. Busam[2], Lora H. Ellenson[2], Jie-Fu Chen[2], Fresia Pareja[2], Daniel Gomez[3], Hikmat Al-Ahmadie[2], Nancy Lee[3], Eric Sherman[4], Jason Chang[2], Himanshu Nagar[3], Britta Weigelt[2], James Fagin[4], Susan Fu[5], Jonathan Alarcon[5], Neelraj Patil[1], Areej Alsaafin[1], Georgios Asimomitis[1], Anika Begum[1], Andrew Aukerman[1], Justin Jee[1], Christopher Fong[1], Michele Waters[1], Lior Z. Braunstein[3], Michael F. Berger[6], Luke R. G. Pike[3], Pedram Razavi[4], Paul Romesser[3], Walid K. Chatila[1], Aasiya Islam[1], Elana Sverdlik[7], Ino de Brujin[1], Karl Pichotta[1], Nikolaus Schultz[1], Sohrab P. Shah[1], Francisco Sanchez-Vega[1]

[1]Halvorsen Center for Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Pathology & Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[5]Digital Informatics & Technology Solutions, Memorial Sloan Kettering Cancer Center, New York, NY,[6]Marie-Josee & Henry R. Kravis Center for Molecular Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[7]Gerstner Sloan Kettering Graduate School of Biomedical Sciences, Memorial Sloan Kettering Cancer Center, New York, NY

Background: Clinical tumor-normal panel sequencing has enabled personalized approaches to targeted therapies. However, the impact of somatic mutations on tissue morphology remains incompletely understood, and financial hurdles limit universal adoption of personalized approaches.

Methods: We developed machine learning tools to infer genomic properties from hematoxylin and eosin (H&E) whole-slide images (WSIs). We assembled a pan-cancer cohort of 62,266 sequenced tumor samples matched to 315,383 H&E WSIs from 54,446 patients, the largest to date. Using these data, we developed transformer models to aggregate embeddings of tissue by part to infer genomic features. We then tested performance on 172 OncoKB-annotated predictive or prognostic biomarkers across 127 histologies and analyzed how the models could be used to identify indicated targeted therapies from H&E WSIs alone.

Results: We highlight four putative use cases of our models, two each for predictive and prognostic biomarkers. First, *BRAF* mutational status, inferred with AUROC 0.85 (precision 0.95, recall 0.63) in papillary thyroid cancer has level two evidence for dabrafenib and trametinib in metastatic differentiated thyroid cancer. Second, *FGFR3* mutational status, identified with AUROC 0.92 (precision 0.95, recall 0.42) in bladder cancer indicates erdafitinib, surpassing the prior state of the art of AUROC 0.73. Prognostically, the models accurately identify unfavorable *STK11* mutations in lung adenocarcinoma (AUROC 0.92) and favorable *POLE* exonuclease domain mutations in uterine endometrioid carcinoma (UEC) (AUROC 0.90), which could guide shared decision making around adjuvant therapy.

Furthermore, disaggregating disease subtypes reveals that phenome-genome relations cited by previous works vary significantly by subtype. For example In UEC, *WNT* pathway aberrations are detected with AUROC 0.87 (95% C.I. 0.82-0.91) in microsatellite-stable UEC, whereas in MSI UEC, there is no detectable phenome-genome relation (AUROC 0.61, 95% C.I. 0.44-0.76). MSI status itself can be inferred accurately from both colorectal adenocarcinoma (AUROC 0.99, 95% C.I. 0.98-0.99) and UEC (AUROC 0.91, 95% C.I. 0.87-0.95).

Conclusions: Taken together, our work uncovers phenome-genome relations for granular subtypes lumped together in prior studies. Such approaches advance our knowledge of how somatic mutations affect tissue morphology and have the potential to improve access to precision oncology.

#2465 Aperio manual scan software: beta testing for challenging slide imaging in research.

Erica Pawlak, Shubham Dayal, Elizabeth Sullivan, **Jacob Persky**, Diane Robirds, Timothy Murphy-Stevens, Duff Pickering

Leica Biosystems, Deer Park, IL

Purpose: The Aperio Manual Scan feature was developed to improve whole slide imaging for challenging samples, including faintly stained, sparse, or artifact-laden slides. This study evaluated the feature's usability and its ability to address imaging challenges.
Experimental Procedures: Fifteen challenging slides, including cytospins, wet tissue touch preps, immunohistochemistry (IHC), and in situ hybridization (ISH) samples, were scanned during a beta test at a pharmaceutical research facility. Laboratory scientists and technicians used the manual scan feature to adjust scan areas, focus points, and calibration points. Participants provided feedback through a structured questionnaire.
Results: Of 15 slides, 6 were successfully scanned using the automated workflow, while 9 required manual adjustments. The manual scan feature allowed successful imaging of sparse or faintly stained specimens, precise exclusion of artifacts, and focus optimization for multi-plane samples such as cell pellet arrays. Users highlighted the feature's intuitive interface and its ability to generate high-quality images for previously unscannable slides.
Conclusions: The Aperio Manual Scan software enhances flexibility and precision in whole slide imaging, complementing the automated workflow. It allows researchers to overcome imaging challenges efficiently and is anticipated to benefit research facilities significantly.

#2466 Pathomics prediction of thymic epithelial tumors histological subtypes: the AI-TET study.

Lodovica Zullo[1], Mathilde Bateson[2], Jose Carlos Benitez[3], Audrey Lupo[4], Damien Sizaret[5], Alvaro Lopez-Gutierrez[1], Daniela Miliziano[1], Kathryn Schutte[2], Juan David Florez-Arango[6], Pascale Missy[7], Vincent Thomas De Montpreville[8], Mercier Olaf[8], Jordi Remon[1], David Planchard[1], Nicolas Girard[9], Thierry Molina[10], Benjamin Besse[1]

[1]Gustave Roussy, Villejuif, France,[2]Owkin, Paris, France,[3]Biomedical Research Institute of Malaga (IBIMA Plataforma Bionand), Malaga, Spain,[4]Cochin Hospital, APHP Centre, Paris, France,[5]CHRU Tours - Hopital Trousseau, Chambray-les-Tours, France,[6]Instituto de Cancerologia - AUNA, Medellin, Colombia,[7]Intergroupe Francophone de Cancerologie Thoracique, Paris, France,[8]Hopital Marie-Lannelongue, Le Plessis-Robinson, France,[9]Institut Curie, Paris, France,[10]Hopital Necker-Enfants Malades, Paris, France

Background: Diagnosis of thymic epithelial tumors (TETs) is challenging due to multiple primary classes (A, AB, B1, B2, B3, C), based on tumoral and non-tumoral components, and their rarity. We aim to train and test a multiple-instance learning (MIL) model to classify the histological subtypes using hematoxylin-eosin+/-safran (HE/HES)-stained slides collected in the French RYTHMIC network.
Patients and Methods: HE/HES slides from TET (A, AB, B1, B2, B3, C) cases addressed to RYTHMIC between 2012 and 2016 were retrieved and digitized. All pathological diagnoses were revised by central pathologists within the network. A MIL model was trained on digitized images, with no adjoint clinical features; internally validated using 3-repeated 2-fold cross-validation; further tested on a set of prospectively digitized cases addressed to RYTHMIC (and centrally revised) between 2022 and 2024, to classify the main TET types. Class predictions were evaluated by AUC scores and ROC curves. Interpretability was performed via Shapley value and heatmaps.
Results: The training set comprised 456 slides from unique histological samples, with 243 (53%) obtained through thymectomy. Internal 3-repeated 2-fold cross-validation showed a mean AUC of 0.94 [std 0.005] for the overall prediction of subtypes. High-attention regions across slides contain both epithelial and lymphocytes, in different percentages according to subtype, showing the biological consistency of the prediction. In the test set (*n*=43), class prediction had a mean AUC of 0.96 [0.92-0.98]. Sensitivity/specificity for each class in the two sets are shown in the table.
Conclusion: Our model holds promise as a diagnostic tool for TET, highlighting the potential of digital pathology in diagnosing rare and challenging entities. These results will be validated on a larger scale, and mixed components will be integrated.

Internal cross-validation subtype*(n)*	Sensitivity	Specificity	Test set subtype*(n)*	Sensitivity	Specificity
A (33)	0.76	0.95	A (4)	0.25	1.00
AB (129)	0.74	0.95	AB (20)	0.85	0.87
B1 (26)	0.81	0.91	B1 (3)	0.33	1.00
B2 (110)	0.65	0.97	B2 (11)	1.00	0.81
B3 (60)	0.73	0.97	B3 (2)	1.00	1.00
C (98)	0.88	0.96	C (3)	0.67	1.00

#2467 Advancing multimodal machine learning techniques to predict platinum resistance in high-grade serous ovarian cancer.

Leonhard Donle, Kelsey C. Goon, Ernst Lengyel

University of Chicago Pritzker School of Medicine, Chicago, IL

Background: Median survival in high-grade serous ovarian cancer (HGSOC) drops to <2 years when it advances rapidly and is declared platinum-resistant (PR). Prior efforts using machine learning to predict PR from hematoxylin and eosin (H&E) whole slide images (WSIs) have shown modest success with an area under the curve (AUC) ~0.6. Current Computational Pathology (CPath) methods frequently overfit due to relative data scarcity and dimensionality mismatches between gigapixel-resolution WSIs and a binary outcome. This project aims to improve CPath performance in predicting PR in newly diagnosed HGSOC by optimizing multimodal fusion of clinical data elements.

Methods: We defined PR as progression or recurrence within 12 months of completing platinum-based therapy, and platinum sensitivity (PS) as recurrence > 12 months after completing treatment. The model was trained on 243 H&E WSIs from 127 patients (62 PR, 65 PS) with repeated 5-fold cross-validation and validated on The Cancer Genome Atlas-Ovary (TCGA) dataset comprising 1156 WSIs from 578 patients (188 PR, 390 PS). H&E WSIs at 20x magnification were tiled, with features extracted via the UNI foundation model and analyzed using attention-based multiple-instance learning to predict PR. FIGO stage and largest residual at primary cytoreduction were used as clinical parameters and fused into the model using different strategies - early, intermediate via concatenation, intermediate via Kronecker product (KP), and late - and performance compared across techniques.

Results: On the internal test set, intermediate-fusion via KP achieved the highest AUC and balanced accuracy (bAcc) (AUC 0.806, bAcc 0.744), followed by early (AUC 0.726, bAcc 0.661), intermediate via concatenation (AUC 0.680, bAcc 0.617), late (AUC 0.672, bAcc 0.628) and the model without clinical data (AUC 0.629, bAcc 0.593). On the TCGA dataset, the best-performing model had an AUC of 0.622 and bACC of 0.566, compared to published baseline AUC of 0.602 (Ahn et al, May 2024) which was trained on 754 WSIs of 394 patients (132 PR, 262 PS).

Conclusions: Despite a smaller training set, we surpass recently published models for predicting PR in HGSOC from H&E WSIs by adding simple clinical data points, favoring an interwoven intermediate fusion technique. Multimodal fusion via KP thus represents a means to expand the use of CPath to predict clinical outcomes in diseases with relative data scarcity. These results suggest progress towards better matching cases of PR HGSOC to non-platinum treatment.

#2468 Automated co-registration of histology and mass spectrometry imaging for enhanced prostate cancer pathomics.

Jader Giraldo-Guzman[1], Cameron A. Czerpak[1], Cody Weimholdt[2], Lewis J. Thomas[3], Sheng-Kwei Song[1], Peggi M. Angel[4], Richard R. Drake[4], Joseph E. Ippolito[1], **Jose Marcio Luna**[1]

[1]Department of Radiology, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Department of Pathology and Immunology, Washington University School of Medicine in St. Louis, St. Louis, MO,[3]Department of Surgery, Washington University School of Medicine in St. Louis, St. Louis, MO,[4]Department of Pharmacology and Immunology, Medical University of South Carolina, Charleston, SC

Background: Prostate cancer (PCa) progression has been shown to be influenced by the relationship of extracellular matrix (ECM) proteins within the stroma, and immune and tumor cells. However, the current standard of care for PCa patients does not take these factors into account. Previously, our team identified sets of ECM glycans using matrix-assisted laser desorption/ionization (MALDI) imaging that were associated with PCa. We also found preliminary evidence that MALDI imaging can guide pathomic textural analysis in H&E images. However, our approach required manual registration between the MALDI and hematoxylin and eosin stain (H&E) images to derive pathomic textural features. In this study, we aim to fully automate the image co-registration and segmentation to guide the identification of pathomic textural features, and to demonstrate that glycan expression in MALDI images can identify regions of PCa in H&E images as tumor.

Methods: We identified a cohort of PCa patients (n=10) who had undergone radical prostatectomy treatment (grade groups GG3-GG5), and with available H&E images, as well as five MALDI images per patient representing the distribution of N-glycan species at 1419, 2539, 2686, 1663, and 1809 m/z. The H&E and MALDI images were co-registered using feature-based deformable registration methods based on mutual information, and segmentations were automatically calculated using a computational imaging framework based on rolling ball, erosion, dilation, Otsu's thresholding, and large connected component analysis. This created 6 regions of interest on the H&E image (5 N-glycans, 1 Pathologist) for analysis of pathomic textural features. Dice scores were used to measure the overlap between the glycan mask and the pathologist segmentation in H&E. We measured 70 pathomic textural features using PyRadiomics on the H&E images for the 5 glycan regions and compared every combination of textural features using Wilcoxon signed rank tests.

Results: The median Dice scores between the N-glycan mask and pathology tumor segmentation were: 1419 (0.48 [0.39–0.65]), 2539 (0.64 [0.44–0.76]), 1663 (0.27 [0.15–0.37]), 1809 (0.38 [0.14–0.42]), and 2686 m/z (0.29 [0.09–0.35]). This indicates the glycans with the largest overlap with tumors were 1419 and 2539 m/z, while glycans 1663, 2686 and 1809 m/z overlap most with non-tumor regions. Out of the 70 pathomic textural features, 55 were significantly different ($p<0.05$) between the masks for 1419 and 1663 m/z, 48 between 1419 and 1809 m/z, 47 between 2539 and 1663 m/z, and 50 between 2539 and 1809 m/z. In addition, there were only 10 significantly different features between 1419 and 2539 m/z, and 4 features between 1663 and 1809 m/z.

Conclusions: We provided further evidence that tissue properties and pathomic textural analysis in H&E images can be guided by MALDI imaging, and preliminary evidence that the process can be fully automated.

#2469 Enhancing pathology workflows with chemical imaging and AI-driven generative models.

Kianoush Falahkheirkhah[1], Sudipta Mukherjee[1], John Cheville[2], Rohit Bhargava[1]

[1]University of Illinois at Urbana-Champaign, Champaign, IL,[2]Mayo Clinic, Rochester, MN

Histopathology has been a cornerstone of biomedical tissue assessment for decades, involving a labor-intensive and multi-step process that includes biopsy, gross examination, sampling, and subsequent tissue processing into snap-frozen or formalin-fixed paraffin-embedded (FFPE) blocks. These blocks are then sectioned, stained, and examined microscopically to diagnose and grade tissues. Despite its effectiveness, the traditional workflow is time-consuming, resource-intensive, and reliant on chemical dyes and expert interpretation. Recently, innovative chemical imaging techniques, such as Stimulated Raman Scattering (SRS) microscopy, have begun to redefine this field by enabling direct measurement of the molecular composition of tissues, thereby bypassing conventional tissue processing and staining protocols. This study demonstrates the integration of SRS microscopy into pathology workflows to rapidly acquire high-resolution chemical data from minimally processed fresh-frozen tissues. Unlike traditional methods that rely on thin-sectioned slides, this approach collects data from intact thick tissues using "optical sectioning," enabling the generation of three-dimensional datasets across multiple planes. These chemical images are processed through a generative adversarial network (GAN) pipeline to produce virtual hematoxylin and eosin (H&E) images that are visually and diagnostically comparable to traditionally stained specimens. Furthermore, the generative model is extended to simulate the morphology and staining patterns of FFPE-processed tissues, offering a versatile tool for creating archival-quality images. This method significantly enhances diagnostic capabilities by preserving lipids and small molecules that are often lost during conventional processing. Within minutes, it generates high-quality stained images that demonstrated high inter-pathologist agreement in tissue grading, proving diagnostically reliable for clinical use. We evaluate our approach through a comprehensive survey of pathologists, assessing its diagnostic utility and reliability. Our results demonstrate that the generated images are comparable in quality to real histological images, showing no discernible inferiority in diagnostic utility. In prostate pathology, the integration of SRS microscopy and AI significantly streamlines traditional workflows, reducing complexity and processing time while preserving diagnostic precision.

#2470 Transforming cancer diagnosis with digital chemical pathology.

Kianoush Falahkheirkhah[1], Kevin Yeh[1], Ji-Hun Oh[1], Yen-Ting Liu[1], Ruo-Jing Ho[1], Ishaan Sharma[1], Matthew Confer[1], Andres Orr[1], Mykolas Tamonis[1], John Cheville[2], Rohit Bhargava[1]

[1]University of Illinois at Urbana-Champaign, Champaign, IL,[2]Mayo Clinic, Rochester, MN

Pathology remains a labor-intensive discipline, relying on workflows rooted in practices established over a century ago. Despite incremental technological advancements, the diagnostic process—from tissue preparation to interpretation—still heavily depends on thinly sliced tissue sections stained and examined under brightfield microscopy by skilled pathologists. Difficult cases often necessitate iterative staining or complex immunohistochemistry (IHC) analyses. However, the recent emergence of machine learning (ML) presents an opportunity to revolutionize traditional diagnostic workflows. One promising advancement is Digital Chemical Pathology (DCP), a paradigm that combines modern ML algorithms with infrared (IR) imaging to streamline pathology and enhance diagnostic accuracy. Infrared wavelengths inherently align with molecular vibrational frequencies, providing intrinsic contrast based on the chemical composition of samples. Mid-IR spectroscopic microscopes leverage this principle to spatially resolve molecular distributions at the pixel level, creating "chemical fingerprints" that ML algorithms can correlate with cellular identities and disease states. Recent advancements, particularly the development of broadly tunable quantum cascade lasers (QCLs), have enabled faster IR imaging, paving the way for clinical applications of IR spectroscopic microscopes. In this research, we demonstrate the potential of DCP using frozen tissue samples. Our approach focuses on two core tasks: (1) virtual staining, translating IR images into realistic, stained images interpretable by pathologists, and (2) tissue segmentation, enabling the automated detection of cancer and the distinction between normal and cancerous tissues. Furthermore, we incorporate statistical safety algorithms to generate uncertainty maps, ensuring the reliability of predictions. Our findings highlight that the integration of IR imaging and ML can facilitate automated diagnostics, providing pathologists with powerful tools for enhanced healthcare delivery. By leveraging DCP, we aim to modernize pathology workflows, reduce diagnostic turnaround times, and improve patient outcomes through precise and efficient analysis.

#2471 Interpretable HPV detection in head and neck cancer using foundation models and synthetic digital pathology.

Hanna M. Hieromnimon[1], Anna Trzcinska[2], Frank Wen[3], Frederick M. Howard[3], James M. Dolezal[4], Emma Dyer[3], Sara Kochanny[3], Jefree Schulte[5], Cindy Wang[6], Heather Chen[7], Jeffrey Chin[3], Elizabeth Blair[3], Nishant Agrawal[3], Ari Rosenberg[3], Everett Vokes[3], Rohan Katipally[3], Aditya Juloori[3], Evgeny Izumchenko[3], Mark W. Introduction: Detecting human papillomavirus (HPV) status is crucial for treating Head and Neck Squamous Cell Carcinomas (HNSCCs). While p16 immunohistochemistry is the current standard for HPV detection, its moderate sensitivity and complex implementation limit its global utility. The ability to diagnose HPV status in HNSCC has become increasingly critical worldwide, as rising HPV-positive HNSCC rates observed in high-income countries may signal a global trend, and HPV status remains essential for treatment selection. Although hematoxylin and eosin (H&E) stained slides are clinically ubiquitous, artificial intelligence (AI) methods applied to these images have not matched molecular assays' performance nor provided needed clinical interpretability. Recent advances in vision transformer-based foundation models for computational pathology offer a promising approach to address this unmet need.

Methods: We analyzed H&E images from 981 HNSCC patients across four datasets: TCGA (n=HPV+ 33/total 401), CPTAC (n=1/109), UCH (n=159/364), and PENN (n=106/106). Fifty percent of the patients were used for validation. Using UNI, a foundation self-supervised learning (SSL) model, we extracted feature vectors from 10x effective magnification tile images across each whole slide. We identified an HPV feature axis using recursive support vector machine and principal component analysis to isolate SSL features that differentiated HPV tumors, then interpreted the relevant histologic features using HistoXGAN to generate synthetic histology images. This approach enabled the isolation of histologic features specific to HPV+ tumors, whereas real histology images contain multiple sources of variation. An expert pathologist validated the biological relevance of the identified HPV-axis features. We developed a predictive model for HPV status by varying the percentages of tiles within each slide required to exceed a binary threshold on the HPV-axis. This model was robust across threshold choices.

Results: Our method identified an HPV-axis that robust HPV detection performance (sensitivity 0.83, specificity 0.88) across all datasets (balanced accuracy - TCGA 0.77, CPTAC 0.98, UCH 0.78, PENN 1.00). Using synthetic histology images and pathologist validation, we identified key, morphological features aligning with established HPV-associated histology, including nuclei size, color, and cell borders. Together with our Grundium slide scanning pipeline the time-to-prediction for a slide is less than 3 minutes.

Conclusions: Foundation models and synthetic digital pathology enabled HPV detection from histology with accuracy comparable to current diagnostic standards, while providing pathologist-interpretable predictions. This accessible, rapid, and explainable method holds promise for expanding testing of HPV and potentially other molecular features in resource-limited settings.

#2472 HER2 protein localization in super-resolution and anti-HER2 therapy response in breast cancer.

Vicente Peg[1], **Yuko Saruta**[2], Yun Li[2], Santiago Ramon y Cajal[1]

[1]Vall d'Hebron University Hospital, Barcelona, Spain,[2]Sysmex R&D Center Europe, Hamburg, Germany

Introduction: Human epidermal growth factor receptor 2 (HER2) in breast cancer (BC) is an important biomarker for a better decision making of anti-HER2 therapy. Trastuzumab has been the standard of care treatment for HER2 positive patients, but recently new antibody-drug conjugates (ADCs) have given an alternative option in clinical practice. Since ADCs efficacy is due to HER2 antibody localization and internalization in the cell, we hypothesize that cellular sensitivity to the drug may be linked to cellular vesicle trafficking systems and membrane protrusions which indicate the resistance of HER2 internalization. Super resolution fluorescence microscope named HM-1000 achieves a resolution less than 20 nm. With this new tool, we aim to study the intracellular distribution pattern of HER2 including vesicle-like structures and membrane protrusions to better identify responders of anti-HER2 therapies, especially ADCs.
Method: A retrospective unicentric study is designed to recruit BC patients who have received ADCs treatment that have formalin fixed paraffin-embedded tissue samples stored for routine diagnosis. 5 baseline tumor samples were stained by commercialized HER2 in situ immunofluorescence, and O2 scavenging buffer was applied and sealed to capture the fluorescent blinking every 30 milliseconds by HM-1000. The 50,000 image frames per microscopic field were processed using ImageJ software and created super-resolution images.
Results: We observed that HER2 signals from ADCs responding patients exhibit predominant membrane localization, especially in those with 3+ immunohistochemistry staining status, compared to ADCs non-responding HER2 3+ cases which show low membrane localization of HER2 and more intracellular distribution. Additionally, this finding is highlighted by intense membrane protrusions in HER2 3+ tumor which present very good response of ADCs.
Conclusion: We found different HER2 localization in ADC responding and non-responding patients. The presence of membrane protrusions may facilitate HER2 targeted antibody binding and induce both cellular cytotoxicity from immune effector cells and endocytosis of cytotoxic drug, which explains ADCs response. Further studies are needed to support this finding and better predict the effectiveness of ADCs therapies in HER2 positive tumors.

#2473 Generative AI improves breast cancer genomic subtype prediction from histology.

Brennan G. Simon[1], Clemens L. Weiss[2], Christina Curtis[3]

[1]Cancer Biology, Stanford University, Stanford, CA,[2]Stanford Cancer Institute, Stanford University, Stanford, CA,[3]Genetics, Stanford University, Stanford, CA

Despite advancements in prognostic biomarker identification in cancer, the clinical infeasibility of testing for many biomarkers limits their adoption into clinical practice. Computational pathology has demonstrated remarkable success in efficiently predicting a variety of biomarkers from routine histology images that would otherwise require expensive sequencing or spatial profiling. However, current approaches are limited for data-poor and challenging tasks such as the prediction of genomic subtype in breast cancer. Here, we show that generative AI improves state-of-the-art computational pathology methods by leveraging the power of synthetic data in the task of predicting breast cancer genomic subtype from histology images. Incorporating generative AI to enrich the training dataset improves model AUC, overall accuracy, and accuracy on the underrepresented high risk subtype. Finally, we show that model interpretation using explainable AI techniques on the tile and pixel levels corroborates expected phenotypes as well as identifies previously unknown histologic features associated with genomic subtype. Our results present an improved framework for computational pathology for the enhanced clinical detection and translation of biomarkers.

#2474 Deep learning-based tissue segmentation enables quantitative assessment and identifies dynamic markers of response from routine staining in glioblastoma.

Georges Ayoub[1], Dina Elharouni[1], Connor Bossi[1], Seth Malinowski[1], Prem Prabhakar[1], Constantin Moller[1], Muhammad Shaban[2], Anurag Jayant Vaidya[3], Julia Japo[1], Andrew Zhang[3], Andres Santos[2], Drew F.K. Williamson[4], David Meredith[2], Faisal Mahmood[2], Keith L. Ligon[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA,[3]Harvard-MIT Health Sciences & Technology, Cambridge, MA,[4]Emory University School of Medicine, Atlanta, GA

Glioblastoma (GBM), the most common and aggressive primary brain tumor in adults, has a highly heterogeneous histopathologic profile on routine H&E staining with challenging traditional morphology assessment. The reliability of morphological features in reflecting response to therapy is debated, as current assessment approaches remain inherently qualitative with a lack of dynamic quantifications after treatment. To address this, we aimed to (1) train an interpretable deep convolutional neural network classifier for semantic segmentation of tissue regions in GBM whole-slide images (WSIs) from routine H&E staining, (2) establish a quantitative baseline of morphological variations after standard-of-care treatment (radiotherapy/temozolomide) in a paired clinical cohort, and (3) assess this approach's utility in identifying markers of response. Therefore, we annotated 3,545 region-level ground truth labels in a supervised approach and trained a DenseNet classifier on the HALO AI platform to segment seven tissue classes in GBM: TC1 (Geographic necrosis), TC2 (Palisading necrosis), TC3 (Mesenchymal tissue), TC4 (Hemorrhage), and TC5 (Parenchyma), subdivided into TC5.1 (Heavy infiltration) and TC5.2 (Mild infiltration). The classifier achieved high performance on an independent set of 828 annotations (precision = 0.88, recall = 0.84, F1-score = 0.86), and digital quantifications strongly correlated with manual estimations extracted from clinical pathology reports ($p < 0.001$). We then identified a retrospective longitudinal cohort of 142 IDH-wildtype GBM patients and scanned the corresponding 912 whole-slide images of tissue from diagnostic resection paired with tissue from recurrence after standard-of-care treatment. Between the two time points, quantifications by the applied classifier showed significant increases in the classes of mild infiltration (+87%) and geographic necrosis (+75%), coupled with parallel decreases in heavy infiltration (-31%) and palisading necrosis (-45%) ($p < 0.01$). On recurrence, the ratio of heavy to mild infiltration (TC5.1:TC5.2) allowed significant stratification of overall survival, and rapid progressors had significantly larger areas of geographic necrosis. On multivariable analysis, dynamic increase in mild infiltration and decrease in mesenchymal tissue were independently associated with reduced risk of poor outcome. Taken together, our AI-based tissue segmentation classifier enables an automated quantitative assessment and allows interpretable clinical response stratification from routine staining, providing a potential enhancement of GBM diagnostic reporting.

#2477 Accurate, high-throughput spatial profiling of whole slide samples with the NeoLYTX pipeline.

K. Gallagher, J. Kuo, J. Lock, J. Fei, M. Rohafza, C. Todorov, E. Parnell, M. Lazare, Q. Au, H. Nunns;
Neogenomics Laboratories, Inc., Aliso Viejo, CA

Multiplexed immunofluorescence (mIF) enables spatially resolved single-cell phenotyping within the tumor microenvironment (TME), which is being increasingly recognized as an important predictor of patient response to immunotherapies. MultiOmyx^{TM} is a mIF platform provided by NeoGenomics Laboratories, Inc capable of detecting up to 60 proteins on a single formalin-fixed paraffin-embedded tissue section, with an image-able area of 10 square centimeters. The platform enables profiling of millions of individual cells in a single slide, providing unbiased spatial phenotyping at scale.

Here we present an improved NeoLYTX^{TM} image analysis pipeline that has been optimized for whole-slide analysis. We demonstrate the pipeline's capabilities using a 16-marker TME panel to spatially characterize a set of 20 non-small cell lung cancer (NSCLC) samples. Accuracy is benchmarked against clinically validated immunohistochemistry (IHC) for a subset of representative immune phenotypes. Cell density and intensity data generated by the NeoLYTX pipeline demonstrated strong concordance with IHC assays for all markers evaluated.

To achieve high throughput whole slide processing while maintaining high accuracy, we use an automated pipelined backed by 100% human quality control (QC). Automation begins with image acquisition, where QC algorithms monitor image collection in real-time to detect imaging failures and trigger corrective action. In post-processing, tissue and stain QC algorithms then identify regions of tissue artifacts such as tissue loss, tissue folding, and necrotic regions to be excluded from downstream analysis.

We next transform our mIF images into a single-cell map of the TME by segmenting the tissue into spatial regions and phenotyping on a single cell level. Region segmentation delineates the tissue from surrounding glass, and then further segments the tissue into different regions such as intratumoral, stromal, vasculature, and leading-edge. Single cells and subcellular compartments are segmented and intensity is quantified over the relevant expression patterns of each marker. Cells are phenotyped using an in-house library of AI algorithms trained on millions of annotated cells - the models integrate morphological and intensity features to accurately distinguish target populations from artifacts and identify phenotypes across diverse tissue types and qualities.

Finally, we demonstrate our comprehensive spatial profiling on the cohort of 20 NSCLC samples. Cell distributions are quantified through a combination of unsupervised neighborhood clustering, nearest neighbor distances, and tissue region profiling. By mapping critical cell populations—such as tumor-infiltrating lymphocytes, cancer-associated fibroblasts, and other cellular signatures—across distinct tissue regions, we extract salient spatial information that provides biological insight into the TME.

#2480 DeMixT 2.0: A deconvolution framework for sparse sequencing data using embedded negative binomial distribution.

H. Yan[1], M. Montierth[2], L. Xie[3], P. Yang[1], S. Guo[1], R. Li[1], X. Pan[1], C. Ercan[1], Y. Yuan[1], K. Nemeth[1], G. A. Calin[1], W. Wang[1];
[1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Baylor College of Medicine, Houston, TX, [3]The University of Texas at Austin, Austin, TX

Background: Deconvolution methods have traditionally focused on estimating cell-type proportions in bulk tissues with mRNA profiles. They often overlook the cell transcriptional proportion (i.e., transcriptional activity), which reflects the cell functional states and could be important for understanding disease progression (e.g., tumor). Current methods face additional challenges when analyzing other RNA species, such as miRNAs, due to their low abundance and inherent sparsity. Similar limitations also affect spatial transcriptomics (ST) technologies, which enable *in situ* gene expression profiling but suffer from high data sparsity and limited resolution, with each spot mimicking a mini-bulk sample. Besides, methods for estimating transcriptional activity in ST data remain underdeveloped.
Methods: To fill this gap, we extended our semi-reference-based DeMixT framework by incorporating a negative binomial (NB) distribution to account for sparse profiling data, namely DeMixNB. DeMixNB models the observed mixed expression Y_{ig} for gene g in sample i as the sum of tumor (T_{ig}) and non-tumor (N_{ig}) components, with each component following an NB distribution parameterized by gene-specific means, dispersion parameters, and sample-specific tumor transcriptomic proportions. The NB framework naturally accommodates the sparsity and overdispersion. DeMixNB runs in two tiers: it first leverages non-tumor reference to estimate the non-tumor component parameters, then uses an Iterated Conditional Modes (ICM) to jointly estimate tumor-specific parameters and tumor proportions in mixed samples.
Results: We comprehensively validated DeMixNB from three aspects. First, we simulated data under various settings, including sample sizes, degrees of similarity between tumor and non-tumor components, and the number of distributions mixed in tumors. Across all scenarios, DeMixNB consistently achieved higher accuracy compared to existing methods. Then, to create a controlled experimental benchmark for miRNA analysis, we generated artificial mixtures using HS-5 fibroblasts combined with either wild-type or *Dicer1* knockout HCT116 colorectal cancer cells at varying proportions. This design represents real tumor samples with known ground truth. DeMixNB maintained robust performance on sparse miRNA expression. To assess its broader utility, we applied DeMixNB to ST data from multiple cancer types. The estimated transcript proportions showed strong concordance with pathological annotations and revealed cell differentiation patterns not captured by conventional cell-type deconvolution methods.
Conclusions: The DeMixT 2.0 framework, featuring DeMixNB, provides a robust solution for deconvolving sparse transcriptomic data. By accurately estimating tumor-specific transcriptional proportions, it enables deeper insight tumor heterogeneity at molecular and spatial levels.

#2481 Employing joint modeling to support clinical interpretation of ctDNA dynamics during the treatment of advanced colorectal cancer.

Christopher R. Pretz, Jiemin Liao, Aaron Hardin, Amar Das

Real World Evidence, Guardant Health, Palo Alto, CA

Background: Recent evidence suggests dynamic changes in cell-free circulating tumor DNA (ctDNA), defined as the maximum variant allele fraction (maxVAF), is predictive of overall survival (OS) in colorectal cancer (CRC) patents. As such, we leverage an advanced statistical approach, joint modeling of longitudinal and time-to-event data (JM), to associate ctDNA dynamics and OS. Contrasting with traditional methods, a unique advantage of JM is results assume the form of patient-specific adaptive dynamic predictions, where utilizing these predictions can enhance clinical decision-making in longitudinal monitoring.
Methods: We applied JM to a retrospective cohort of patients with advanced CRC who received chemotherapy (chemo). The cohort was extracted from GuardantINFORM, a real-world clinico-genomics database. Patients analyzed had baseline Guardant360 (G360) ctDNA tests within 14 days before chemo initiation and ≥2 G360 tests on treatment. JMs are comprised of two sub-models: a hierarchical cubic spline random effects sub-model evaluated the serial ctDNA measures and a Cox-regression sub-model examined OS. Covariates incorporated into each sub-model included: age, gender, smoking status, and the Charlson Comorbidity Index. JMs, based on different association structures (AS) designed to connect information between sub-models, were investigated. ASs included the biomarker's estimated value, instantaneous rate of change, and cumulative effect.
Results : In total, 137 patients with 759 ctDNA time points were analyzed using three different JMs, one for each AS. After controlling for confounders, each AS demonstrated a significant relationship between ctDNA progression and OS (respective p-values < 0.005). As results are best interpreted graphically, various dynamic predictions are provided, each accentuating how the AS modifies the relationship between ctDNA and OS.
Conclusions : To our knowledge, using JM to link dynamic ctDNA changes and OS in CRC patients is novel. In this study we demonstrate that a biomarker's updated estimated value, instantaneous rate of change, or cumulative effect can forecast OS. As such, JM may afford healthcare providers different options to monitor patient progression and update prognosis as new ctDNA information becomes available on clinical reports. In sum, these results establish a foundation for integrating serial ctDNA measures for prognostic clinical interpretation.

#2482 Inferring cancer type-specific patterns of metastatic spread using Metient.

Divya Koyyalagunta[1], Karuna Ganesh[2], Quaid Morris[2]

[1]Weill Cornell Medicine, Memorial Sloan Kettering Cancer Center, New York City, NY,[2]Memorial Sloan Kettering Cancer Center, New York City, NY

Reconstructing the metastatic spread of a cancer from molecular sequencing of primary and metastatic tumors is a challenging problem with broad applications in clinical cancer research. In particular, this problem often yields multiple solutions, which current methods resolve with ad hoc criteria that assume the most likely patterns of metastatic spread - thus sidestepping a core question of metastasis research. Here we introduce Metient, a statistical method which proposes multiple possible hypotheses of metastatic spread in a cohort of patients and rescores these hypotheses using independent data on genetic distance of metastasizing clones and organotropism. Metient is more accurate and is up to 50x faster than the current state-of-the-art, making it the first method capable of scaling to lineage tracing datasets with thousands of cells while providing a multi-hypothesis approach to metastatic spread. In a reanalysis of metastasis in 169 patients based on 490 tumors, Metient automatically identifies cancer type-specific trends of metastatic dissemination in melanoma, high-risk neuroblastoma, and non-small cell lung cancer. Its reconstructions often align with semi-manual expert analyses but frequently reveal more plausible migration histories, including those with metastasis-to-metastasis seeding. Furthermore, Metient's heightened sensitivity suggests that polyclonal seeding is far more common than previously reported. Together, these findings challenge existing assumptions about metastatic spread, enhance our understanding of cancer type-specific metastasis, and offer insights that could inform future clinical treatment strategies of metastasis.

#2483 DirectHRD enables sensitive scar-based classification of homologous recombination deficiency (HRD).

Ruolin Liu[1], Eugenia Roberts[2], Heather Parsons[3], Elizabeth Stover[3], Atish Choudhury[3], Justin Rhoades[1], Timothy Blewett[1], David Yang[3], Joyce Liu[3], Erica Mayer[3], Viktor Adalsteinsson[1]

[1]Broad Institute of MIT and Harvard, Cambridge, MA,[2]Yale University, New Haven, CT,[3]Dana-Farber Cancer Institute, Boston, MA

Introduction: Homologous recombination deficiency (HRD) is a predictive biomarker for response to PARP inhibition and platinum chemotherapy but remains challenging to detect. The discovery of patients without pathogenic mutations in known HR genes but exhibiting genomic scars indicative of HRD led to the FDA approval of the first scar-based HRD test. Despite advancements in whole genome sequencing (WGS) combined with machine learning models, current methods lack the sensitivity required for detecting HRD scars in low tumor purity samples such as liquid biopsies.

Method: We developed DirectHRD, a WGS-based HRD scar classifier. Compared to other HRD scar classifiers, DirectHRD exclusively utilizes a highly specific HRD scar—deletion with microhomology—and its associated signatures (COSMIC ID6 signature) in a probabilistic framework to detect HRD scars with higher sensitivity.

Results: We first applied DirectHRD to 474 tumor biopsy samples from the PCAWG (Pan-Cancer Analysis of Whole Genomes) project, focusing on the four cancer types with the highest HRD prevalences (breast, ovary, pancreas, and prostate). We achieved 100% detection of patients with bi-allelic BRCA1/2 losses with high specificity (>90%) across all four cancer types. Next, we applied DirectHRD to WGS of tumor biopsies and in-silico dilutions from 27 patients with stage II-III triple-negative breast cancer from the TBCRC030 trial. DirectHRD achieved an AUC of 0.99 at 5% tumor fraction, compared to an AUC of 0.62 and 0.48 for CHORD and HRDetect, respectively. Finally, we applied DirectHRD to 90 ctDNA (circulating tumor DNA) samples across three cancer types (breast, ovarian, and prostate). The ground truth HRD statuses were determined from tumor biopsies using scar-based methods for breast (Myriad MyChoice, scarHRD and SigMA) and ovarian cancers (scarHRD and SigMA) and by identifying germline and somatic pathogenic mutations in HR genes for prostate cancers. DirectHRD achieved an AUC of 0.86 in stage II-III breast cancers and 0.9 in metastatic breast cancers. For ovarian cancers and metastatic prostate cancers, DirectHRD achieved AUCs of 0.9 and 0.87, respectively.

Conclusion: Our findings suggest that DirectHRD can reliably detect HRD scars in low tumor purity samples, such as liquid biopsies, using moderate depths (e.g., 50x) of WGS. This could broaden access to HRD testing including when tissue biopsies are insufficient or infeasible.

#2484 A novel algorithm to expand mechanistic computational models of biochemical reaction networks to heterogeneous tumor cell communities.

Amy Gill, Feilim Mac Gabhann

Biomedical Engineering, Johns Hopkins University, Baltimore, MD

Background: Tumors are complex ecosystems of interacting cell types, and the effects of heterogeneous environments on cell signaling are challenging to study by experiment alone. Mechanistic computational modeling of biochemical reaction networks using ordinary differential equations (ODEs) is a powerful approach for analyzing cell signaling, yet most existing ODE-based models of cell signaling describe a population of homogeneous cells. We introduce Mechanistic Modeling of Cell Communities (M2C2), a novel algorithm to expand a biochemical reaction network model described in one cell type to a community of interacting cell types.
Summary: M2C2 represents a cell community as multiple intracellular compartments, each representing a pool of cells with similar properties (“cell types”), interacting through a common extracellular compartment. M2C2 algorithmically expands a one-cell-type model to describe an interacting community of any number of distinct cell types. The expansion assumes all compartments share the same set of possible reactions and rate equations, though the rate constants can be adjusted on a per-cell basis, e.g. for cell-specific mutations or inhibitors. Compartments have independent reactant concentrations, reflecting cell-specific protein expression and interventions. In the context of mass-action kinetics, this leads to different network dynamics in each cell type.
Algorithm: The M2C2 function takes two inputs: (1) an integer n representing the desired number of interacting cell types and (2) a single-cell-type model encoded in a vector-matrix form inspired by chemical master equation approaches for stochastic modeling.1 The matrices are arranged into blocks using location to group the molecular species (extracellular, cellular) and reactions (extracellular, interface, cellular). M2C2 expands the original matrix by replicating n copies of cellular and interface blocks while leaving the extracellular block intact. Because this expansion is algorithmic, it works for any integer n;;; without manual correction. M2C2 outputs the expanded model in vector-matrix form, which can be numerically solved using standard methods. Simulated molecular dynamics in each cell type can be analyzed with statistical and visualization methods.
Conclusions: Mechanistic Modeling of Cell Communities (M2C2) is a novel approach for mesoscale modeling of cell signaling within multicellular systems such as tumor microenvironments. Cell type proportions and cell-type-specific expression patterns of M2C2-expanded models could be parameterized with multi-omic single-cell data for in silico simulation of personalized tumors and treatments.
References: 1. Gillespie DT. Stochastic simulation of chemical kinetics. Annu Rev Phys Chem. 2007;58:35-55. doi: 10.1146/annurev.physchem.58.032806.104637. PMID: 17037977.

#2485 A Bayesian framework for unraveling disease biology from spatially resolved single-cell omics datasets by combining unbiased approaches with biological priors for cell-based microdomain discovery.

Brian Falkenstein[1], Raymond Yan[1], Shannon Quinn[1], Akif Burak Tosun[1], **S. Chakra Chennubhotla**[1], Arutha Kulasinghe[2], Filippo Pullara[1]

[1]PredxBio, Inc., Pittsburgh, PA,[2]Frazier Institute, Faculty of Medicine, The University of Queensland, Brisbane, Australia

Background: The emergence of single-cell spatial omics platforms generating high-plex proteomic and transcriptomic measurements sets the foundation for accurate downstream biologically interpretable analyses. This includes biased and unbiased approaches for cell typing, cell-cell interactions and the discovery of microdomains, complex multicellular microenvironments, underlying disease progression.

Problem: There is a lack of a computational framework for optimizing unbiased approaches with biological priors for unraveling a deeper understanding of disease mechanisms. This requires innovative integrational methods that assign confidence and robustness to data-driven biological hypotheses, e.g., presence of transition cells and other rare cell types, emergent microdomains and spatially modulated network biology.

Solution: We present a Bayesian computational approach, SpaceIQ™, that not only elucidates potential novel hypotheses driving disease mechanisms, but also cross-references existing working hypotheses from alternative methods. SpaceIQ is agnostic to imaging platforms with the ability to ingest any combinatorial forms of spatial data (e.g., transmitted light, proteomics and transcriptomics).

Results: To illustrate our approach, we compare the results from SpaceIQ to the interpretative analyses presented in He et al. Nat Biotech 2022, a publicly available 960-plex RNA data from CosMx platform on NSCLC samples. We aim to provide additional mechanistic insights underlying Stage II/III progression that can augment the biological annotations reported. We have identified 16 unbiased cell types with probabilistic representation of a priori phenotypes annotated as myeloid, lymphocytes, endothelial, epithelial/tumor, and fibroblast. IFI27, SOX4, MALAT1, TYK2, CD74, HLADRB1, and COL3A1 were among the highly-expressed discriminatory genes among cell types. 28 significant spatial interactions ($p<0.1$) were found resulting in 7 microdomains. Comparison of microdomains to niche neighborhoods defined in He et al. shows that macrophages in the stroma and TLS play a role in tumor progression. Ligand-Receptor analysis on microdomains identified IL-2 signaling, GPCR ligand binding, TNF activity, and TGF regulation to be significant cell-cell communication channels in NSCLC progression ($p<1e^{-04}$).

Conclusions: We proposed a Bayesian integration framework to further the biological interpretations of the spatially-resolved high-plex single-cell CosMx dataset on NSCLC patients presented in He et al. We've found unbiased cell types linked to known cell phenotypes in addition to potentially novel gene signatures. These unbiased cell types formulate microdomains with identified key signaling events that are associated with cancer progression.

#2486 Decoding tumor evolution through fitness landscapes of aneuploid cells.

Richard J. Beck, Noemi Andor

H. Lee Moffitt Cancer Center, Tampa, FL

Aneuploidy, prevalent in most solid tumors, significantly alters cellular phenotype and fitness. Despite its critical role in tumor evolution, a detailed quantitative understanding of its evolutionary dynamics remains elusive. To address this gap, we developed ALFA-K, a novel method to infer the fitness landscape of chromosome-level karyotypes. Utilizing longitudinal single-cell karyotype data from evolving cell populations, our method estimates the fitness of thousands of karyotypes proximal to the input data in karyotype space, enabling predictions of unseen karyotypes. We validated our approach using both synthetic data from an agent-based model (ABM) and empirical data from in vitro and in vivo passaged cell lines. The empirical data comprised over 40,000 sequenced cells across five cell lines, each sequenced longitudinally at 5-10 timepoints per lineage. Analysis of the fitted landscapes yielded several key insights: 1) WGD alters the distribution of fitness effects of copy number alterations (CNAs) (K.S. test: $P < 10^{-8}$). Specifically, karyotypes with WGD exhibit more mutations with positive selection coefficients compared to diploid karyotypes; 2) Mutations in cisplatin-treated lineages showed changes in fitness effects on average 2.3 times larger than those in untreated lineages (t-test: $P < 2.2 \times 10^{-16}$); 3) The fitness impact of a CNA varies depending on the parental karyotype; 4) The rate of chromosome missegregation can dictate the predominant karyotypes in an evolving population.

To further investigate how the tumor microenvironment shapes karyotype evolution, we are integrating these inferred fitness landscapes into an existing spatial ABM. This modeling simulates the spatially heterogeneous tumor microenvironment and its influence on karyotypic selection and adaptation. By leveraging this ABM, we aim to capture the effects of spatial constraints—such as resource availability, competition, and cellular interactions—on the fitness and distribution of karyotypes. Complementing these simulations, we are developing a bioinformatics pipeline for spatial transcriptomics data from glioblastoma clinical samples. This dataset includes samples from various regions (normal, tumor, and tumor-infiltrating) across 31 samples from 19 patients, using 10X Visium with an average of 3,100 spots per sample. The pipeline is designed to provide detailed information about the spatial organization of karyotypic diversity, elucidating how aneuploid karyotypes are distributed and interact within the tumor microenvironment. By integrating this spatially resolved data with the ABM, we aim to generate a comprehensive framework to explore how microenvironmental pressures in glioblastoma tumors shape the evolution of karyotypic diversity and drive the emergence of therapeutic resistance in patient-specific contexts.

#2487 LINMAP: A framework for comprehensive cell division lineage reconstruction via molecular barcoding and machine learning.

Lin Wang[1], Zheng Yin[1], Wenjuan Dong[1], Jianting Sheng[1], Li Yang[1], Kun Han[1], Dingcheng Gao[2], Stephen T. C. Wong[1]

[1]Houston Methodist Neal Cancer Center, Houston, TX,[2]Weill Cornell Medicine, New York, NY

Purpose: Reconstructing cell division lineages across generations is central to understanding developmental biology, cancer progression, cell differentiation, drug resistance, and tissue aging. By integrating CRISPR-Cas9 induced gene editing with single cell RNA-Seq, high-resolution lineage tracing through molecular barcoding becomes feasible. However, tracking mutation evolution across successive guide RNA edits, especially with homing guide RNA (hgRNA) technology, poses challenges due to ongoing dynamic retargeting and genetic modifications that complicate lineage reconstruction.
Methods: To overcome these challenges, we developed LINMAP, a computational framework that applies machine learning to trace and map evolving mutations across cell divisions, reconstructing intermediate histories. LINMAP calculates mutation transition probabilities at each division to identify potential paths for mutation accumulation and defines cell-cell distances based on these transition probabilities, enabling precise division count measurements between cell pairs.
Results: We created an MMTV-PyMT (mouse mammary tumor virus-polyoma middle tumor-antigen)-Cas9 tracing cell line with dual hgRNAs to investigate mutation evolution networks. LINMAP accurately inferred mutation evolution and predicted allele frequencies, aligning well with both in vitro data from MMTV-PyMT cell lines and computational simulations. Moreover, in a separate in silico experiment simulating lineage history from a progenitor, LINMAP reconstructed the cell division lineage with high precision. Applying LINMAP to a CRISPR-Cas9 lineage-traced lung cancer mouse model, we successfully traced tumors of varying clonality within a single mouse. Based on lineage characteristics, LINMAP differentiated tumors, reconstructed their complete lineage, and identified each tumor’s monoclonal or polyclonal origins. It recreated a timeline of tumor emergence and tracked cell state transitions, capturing cell state shifts during cancer progression. These findings aligned with gene expression-based cell state trajectories from the original study, further validating LINMAP's accuracy.
Conclusions: LINMAP integrates mutation ratios and transition probabilities at each cell division, surpassing precision than existing methods. It enables comprehensive single cell lineage tracing, providing insights into tumor evolution and complexity, tracking tumor development, distinguishing metastatic sites from primary tumors, and studying drug resistance through subclonal selection over time.

#2488 Employing RNA base editors to engineer personalized tumor-specific neoantigens.

Rona Merdler-Rabinowicz[1], Netanel Landesman[1], Eytan Ruppin[2], Erez Levanon[1]

[1]Bar-Ilan University, Ramat-Gan, Israel,[2]NCI, NIH, Bethesda, MD

Enhancing the quantity and effectiveness of neoantigens in tumors is essential for advancing immunotherapy and developing targeted cancer vaccines. Crafting neoantigens presents a challenge due to the need to specifically modify peptide translation in tumor cells while avoiding effects on normal cells. To tackle this challenge, we introduce a novel method that enables the editing of selected nucleotides in the mRNA of cancer cells in order to produce potent neoantigens. The method is built on the use of Endogenous-ADAR base-editors, an established technology that allows for precise RNA-level edits, which is safer than DNA-level modifications and eliminates the need for external peptides by leveraging the native ADAR enzyme. The algorithm designs a guide RNA tailored to each tumor unique genetic profile and the patient's HLA type, ensuring a precise and personalized approach to induce edits that are predicted to generate potent neoantigens in the cell. By targeting tumor-specific somatic mutations, our method ensures that edits are confined to tumor cells, sparing normal cells, thus offering a safer, more effective strategy for generating personalized neoantigens. We tested our computational algorithm on thousands of tumor samples available in The Cancer Genome Atlas (TCGA) database, demonstrating its capability to produce neoantigens across a broad spectrum of cases and cancer-types. As Endogenous-ADAR technology advances and delivery methods improve, the algorithm we present shows great promise as a valuable complement to immunotherapy and cancer vaccines.

#2489 The new approach for measuring nonuniformity of read coverages reveals the quality of RNA-seq data.

Wonyoung Choi, Miyeon Yeon, Jay Lee, Hyo Young Choi, David Neil Hayes

University of Tennessee Health Science Center, Memphis, TN

High-quality RNA is crucial for obtaining reliable RNA sequencing (RNA-seq) data, with metrics like RNA Integrity Number (RIN). However, these metrics, while effective for evaluating RNA integrity, do not always correlate with RNA-seq data quality, especially at the transcript level. This gap is particularly evident in total RNA-seq, where existing measures such as the coefficient of variation (CV) for read coverage fail to fully capture data quality and are influenced by confounding factors like read coverage depth. To address this, we developed a novel method to assess RNA-seq data quality by quantifying nonuniformity in read coverage while minimizing the influence of read coverage depth. In this study we invented new matric called windowCV (wCV) and applied to a diverse range of RNA-seq datasets, including fresh frozen (FF) and FFPE total RNA-seq data, as well as poly(A)-enriched mRNA-seq data. In mRNA-seq, our method captured 3' read coverage bias, a hallmark of RNA degradation, particularly in longer transcripts. For total RNA-seq data, we identified noisy coverage patterns associated with poor data quality, even in samples with high RIN values. By fitting regression lines between wCV and mean coverage depth (MCD) and calculating the area under the curve (wCVAUC), we refined the assessment to account for RNA quality variability. Using the TCGA pilot study and our own datasets, we demonstrated that wCVAUC reliably identified low quality RNA-seq data and highlighted its impact on downstream analyses, including gene expression quantification and clustering. Importantly, we observed that low RIN values do not always predict poor RNA-seq data quality, as some samples with RIN values below 7 exhibited high-quality RNA-seq data based on wCVAUC. It means that our analyses showed that wCVAUC effectively distinguished high-quality from low-quality samples, including cases where traditional metrics like RIN and CV were insufficient. Additionally, our investigation into the relationships between nonuniformity of read coverage, exon GC content, and RNA localization revealed that the transcript-level RNA-seq data quality of lncRNA genes in FFPE samples is influenced by low exon GC content and nuclear localization. In conclusion, our method provides robust, transcript-level metrics for assessing RNA-seq data quality across platforms, enabling more accurate identification of low-quality data and minimizing biases in downstream analyses. This approach offers a new standard for integrating RNA-seq data quality with sample variability, particularly for challenging datasets such as FFPE and total RNA-seq.

#2490 Empirical Bayesian batch effect correction for single-cell RNA-seq data.

Maximilien Colange, Guillaume Appe, Lea Meunier, Solene Weill, Akpeli Nordor, Abdelkader Behdenna

Epigene Labs, Paris, France

We introduce pycombat_sc, a Bayesian method to assess and correct batch effects in single-cell RNA-Seq data (scRNA-Seq).scRNA-Seq data is similar to bulk RNA-Seq data, except for a higher dropout rate, due to the much lower quantity of genetic material, which may drop below the detection threshold. Bayesian approaches for RNA-Seq data analysis (ComBat-Seq, DESeq2, edgeR) model RNA-Seq expression data with a negative binomial distribution. As suggested earlier (ZINB-WaVe) we propose to model scRNA-Seq data with a zero-inflated negative binomial distribution, where the inflation of zeroes accounts for the higher dropout rate.
Our approach is the continuation of ComBat and ComBat-Seq, which model microarray and RNA-Seq data with normal and negative binomial distributions, respectively. Our approach extends the ComBat-Seq model with a zero-inflation parameter. We propose two variants of the algorithm:• one where the zero-inflation component is batch-dependent - i.e. the drop-out rate differs from one batch to another;• one where the zero-inflation component is batch-independent - i.e. the drop-out rate is the same for all batches.
Parametric Bayesian approaches, such as ComBat or ComBat-Seq, are recognized for their versatility (through their ability to account for user-provided covariates in the model) and for their robustness to small-size cohorts. pycombat_sc retains the versatility of its predecessors with the ability to account for arbitrary covariates. This is in contrast to recent approaches based on deep learning, which typically require training data which incurs a dual limitations:• these methods are sensitive to any bias present in the training data. Combined with the lack of interpretability of the deep-learning models used, this shortcoming requires a thorough validation, to properly detect any bias in the training data.• training of deep-learning typically requires large amounts of data. While scRNA-Seq cohorts typically feature hundreds or thousands of cells, the stake here is to properly capture inter-cohort variability, or risk over-fitting to intra-cohort variability.
To properly assess the potential of our approach, we compare it to state-of-the-art tools, either based on clustering (Seurat, harmony) or on deep-learning models (scvi, scanvi, scanorama). For the sake of completeness, we also include ComBat and ComBat-Seq in our benchmark. To our knowledge, our study is the first to evaluate ComBat-Seq for batch effect correction in scRNA-Seq data, although its model is a priori more adapted to scRNA-Seq than the one of ComBat.

#2491 Conditional generation of mutational profiles in cancer.

Andy Wu, Hannan Wong, Aakansha Narain, Vedant Sandhu, Jason Pitt

Cancer Science Institute of Singapore, Singapore, Singapore

The accumulation of DNA damage on the cancer genome, often summarized as mutational profiles, is influenced by a complex interplay of environmental and cellular mutagenic conditions. Despite cancer genomics having some of the largest biological datasets in existence collected by pan-cancer consortiums, a significant portion of the diverse spectrum of cancer etiologies is still underrepresented and understudied. We leveraged the power of generative artificial intelligence (Gen AI) to develop MutaGen, a conditional variational autoencoder and generative adversarial network hybrid model (CVAE-GAN), to generate realistic mutational profiles conditioned on various clinical and genetic features. Trained on the PCAWG cohort, MutaGen can generate pan-cancer mutational profiles across four mutation types: single base substitutions (SBS96), small insertions and deletions (ID83), structural variations (SV32), and copy number alterations (CN48). MutaGen's cancer-conditioned generations show high similarities to the real PCAWG samples, with median cosine similarities of 0.98, 0.97, 0.92, and 0.96 for SBS96, ID83, SV32, and CN48 respectively. When conditioned on homologous recombination deficiency (HRD) status, MutaGen can generate zero-shot (i.e. cases not seen in training set) HRD lung cancers with high similarity to a real BRCA2-null lung cancer patient in both SBS96 and ID83 (0.93 and 0.78 cosine similarities respectively). The generation is significantly more similar than non-HRD lung cancer or non-lung HRD cancer in the PCAWG training set. Inspection of the generated profiles revealed the generations harbouring both lung cancer-associated and HRD-associated mutational patterns, showing that MutaGen can generate novel and biologically plausible profiles. By providing a versatile tool for generating synthetic mutational data, MutaGen can facilitate the exploration of understudied cancer subtypes and enable the training and benchmarking of predictive models.

#2492 Diagnostic algorithm for salivary gland oncocytic lesions.

Bacem Khalele, Alena Skalova

Charles University In Prague, Pilsen, Czech Republic

Aim: Diagnosing salivary gland lesions with oncocytic differentiation is challenging as it encompassing 21 reactive and neoplastic lesions. With the extensive differentiation, morphological overlapping is possible especially that some tumors can be purely oncocytic. We propose a diagnostic algorithm based on analyzing oncocytic detection in the salivary gland lesion in AS' registry (501 out of 6383 SGL) to propose a differential diagnosis based on morphology, immunohistochemistry, and molecular findings.
Methods: We developed a weighted probabilistic scoring algorithm incorporating dimensional reduction and hierarchical clustering analysis of morphological features, immunohistochemical profiles, and molecular labelling that represents the greatest weighted values. If molecular information is missing, the algorithm computes the values corresponding to morphology and immunohistochemical vectors respectively. The algorithm uses supervised machine learning with backpropagation for continuous refinement of classification boundaries.
Results: Salivary gland lesions with oncocytic differentiation comprise malignant neoplasms (e.g., acinic cell carcinoma, salivary duct carcinoma, myoepithelial carcinoma), benign neoplasms (e.g., pleomorphic adenoma, Warthin tumor, oncocytoma), cystic lesions and reactive process (e.g. multifocal oncocytic metaplasia), with different extent of oncocytic differentiation, either extensive, focal, or wall-lining, in which oncocytes are positive for MIA. Principal component analysis revealed three distinct oncocytic architectural patterns with eigenvalues >1.0: extensive (λ_1=2.84), focal (λ_2=1.92), and wall-lining (λ_3=1.37). Hierarchical clustering demonstrated discrete entity groupings with a cophenetic correlation coefficient of 0.89. The algorithm achieved a primary diagnostic accuracy of 92% (95% CI: 88.3-95.7%), while maintaining differential diagnostic sensitivity of 85% at a lower boundary condition of 0.3. Nevertheless, the algorithm is designed to propose a diagnosis for well-investigated cases only. Otherwise, the differentials are provided. A user-friendly interface will be made available at https://www.biopticka.cz/en/publications/tools/Oncocytic/
Conclusions: The algorithm demonstrates acceptable performance metrics in differential diagnosis generation. Although oncocytic differentiation can theoretically occur in any lesion, the inclusion of the salivary oncocytic lesions was confined to real data with adequate molecular investigation. Coverage could be expanded if reliable inputs show oncocytic differentiation, for example, in secretory carcinoma, polymorphous adenocarcinoma (and its cribriform subtype), microsecretory carcinoma, or palisading adenocarcinoma.

#2493 SCANs: SNP-based contamination assessment with nuanced signal in targeted methylation sequencing data.

Shaohua Ma[1], Chaoyang Liang[2], Shuliang Guo[3], Luyan Shen[1], XiaoSheng He[4], Zhihui Xu[5], Jing Zhao[5], Yonghui Li[5], Shiqing Chen[5], Baoliang Zhu[5], Xiaohui Wu[5]

[1]Peking University Cancer Hospital and Institute, Beijing, China,[2]China-Japan Friendship Hospital, Beijing, China,[3]The First Affiliated Hospital of Chongqing Medical University, Chongqing, China,[4]The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[5]Shanghai Weihe Medical Laboratory Co., Ltd, Shanghai, China

Background: Multi-Cancer Early Detection (MCED) represents a promising approach with the potential for high sensitivity in detecting rare tumor-derived signals in the blood. However, contamination from adjacent samples or from environmental sources poses significant challenges that can compromise the accuracy of these results. Current contamination detection methods primarily designed for tissue samples, leaving a notable gap in methodologies for assessing low-level contamination in cfDNA targeted methylation sequencing data in blood. The challenges include the absent of matched control samples, low sequencing depth, and probe capture bias. To address these limitations, we have developed a machine learning-based method aimed at improving contamination detection accuracy in MCED datasets.

Methods: We first identified single nucleotide polymorphisms (SNPs) with high prevalence in the East-Asian population. We calculated the allele frequencies of SNPs using in-silico synthetic contaminated samples and fitted the distributions of allele frequencies at varying contamination levels to identify informative SNPs. To enhance signal-to-noise value, we constructed features based on reads containing alternative bases of these informative SNPs at each tier, which was categorized according to its coverage and assumed contamination levels. This comprehensive feature matrix was used to train an XGBoost algorithm on 185 normal samples and their corresponding in-silico synthetic contaminated samples. The performance of our approach was validated using two distinct datasets: the first set comprised in-silico simulated contamination samples with contamination levels ranging from 0.05% to 10%, while the second was built by titrating three healthy cfDNA samples into three other healthy cfDNA backgrounds, with titration levels ranging from 0.05% to 2%.

Results: This method effectively identifies contamination, particularly in scenarios where coverage at SNPs is relatively low, ranging from 50X to 300X. It demonstrated the ability to detect contamination levels as low as 0.2% in the titrated samples, with an in-silico limit of detection (LoD) established at 0.1%.

Conclusions: We have developed SCANs, a tool designed to address the challenges posed by low sequencing depth and capture bias-induced abnormal allele signals in methylation data. SCANs enables the detection of low-level contamination, thereby facilitating the precise analysis of cfDNA methylation data in MCED.

#2494 Elucidating developmental methylation programs and cell type compositions in glioblastoma using combinatorial optimization.

X. C. Li[1], A. Hari[1], Y. Liu[1], O. Singh[1], Z. Wu[1], S. M. Mount[2], K. D. Aldape[1], E. Ruppin[1], S. Sahinalp[1], A. A. Schaffer[1];
[1]National Cancer Institute, Bethesda, MD, [2]University of Maryland, College Park, College Park, MD

Glioblastoma (GBM) is one of the most aggressive forms of brain cancer. Previous research has shown that GBM tumors may comprise one or more developed brain cell types, including astrocytes, oligodendrocytes, oligodendrocyte precursor cells, and neural stem cells. However, it is not yet known whether GBM tumors originate from mature or progenitor states of these brain cell types. To explore the interplay between the developmental program of the brain cells and GBM tumor progression, we leverage methylation, an epigenetic marker that has been established as a reliable signal for clinical subtyping of brain cancers and understanding tumor evolution and brain development. While methylation profiles for developed brain cell types are available, little is known about the methylation profiles of their progenitors. To simultaneously determine cell type composition in bulk GBM samples and infer the methylation profiles of progenitor brain cells, we developed a novel computational framework, Qombucha (Quadratic prOgraMming Based tUmor deConvolution with cell HierArchy).

Qombucha uses a tree hierarchy depicting the developmental progression of mature brain cells, with leaves representing established mature brain cell types and internal nodes representing unobserved progenitors. Based on the premise that the value of a specific progenitor methylation feature equals those of its mature descendants, provided the descendants are concordant, Qombucha infers the values of the remaining unknown progenitor methylation features by using bulk methylation profiles of tumor samples from GBM patients. Qombucha implements a combinatorial optimization formulation that simultaneously infers the cell type composition of each tumor sample. The objective of Qombucha is to minimize the differences between the inferred and observed methylation profiles across the entire cohort of tumor samples. The inferred cell type compositions for tumors can then be used to investigate differences between GBM subtypes.

We applied Qombucha to real GBM patient data we compiled, representing three most common methylation-based subtypes: receptor tyrosine kinase (RTK) I, RTK II, and mesenchymal typical (MES TYP). Qombucha successfully recapitulated the known finding that GBM MES TYP patients exhibit higher immune infiltration, as indicated by the increased Qombucha-imputed microglia fractions. We also identified GBM subtype-specific brain development processes. Interestingly, the Qombucha-imputed cell compositions demonstrate comparable or better performance in clustering GBM subtypes than state-of-the-art brain tumor classifying methylation sites used for clinical decision-making. Overall, Qombucha provides a novel framework for understanding the crosstalk between brain development and tumor progression and offers valuable insights into the heterogeneity among GBM subtypes.

#2495 Does single-cell gene expression reflect RNA abundance?.

Christie Jay Lau[1], Liliane Cabral-Fernandes[2], Yadong Wang[3], Sumaiyah K. Rehman[3], Geoffrey Liu[3], Catherine A. O'Brien[3], Gregory W. Schwartz[3]

[1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[3]Princess Margaret Cancer Centre, Toronto, ON, Canada

Transcriptional dysregulation is a hallmark of cancer that is often studied using single-cell RNA sequencing (scRNA-seq) to capture the transcriptomic profile of individual cells. However, these measurements are not directly representative of gene expression levels due to biased transcript detection which can lead to dramatic misinterpretations of the underlying biology. To demonstrate this phenomenon, we profiled baseline and drug-tolerant persister cells from a patient-derived colorectal cancer xenograft model. Although persister cells are known to be globally hypotranscriptive and exhibit lower total RNA and housekeeping expression by cell number-normalized (CNN) quantitative PCR (qPCR), significantly more transcripts and genes were detected by single-nuclei RNA-seq as compared to baseline. Additionally, we identified this trend in two independent lung adenocarcinoma persister scRNA-seq experiments and noticed an association with higher sequencing read depth per transcript. In all three cases, transcript over-detection could not be ameliorated through filtering, read subsampling, batch correction, or normalizations specifically developed to address read depth bias. As such, we developed a novel computational approach to correct the effects of sequencing read depth bias on scRNA-seq data and recover the relative expression of cells across samples. To benchmark the validity of our approach, we identified five genes predicted to be significantly upregulated from raw and conventionally-normalized counts but downregulated from our depth-normalized counts. Using CNN qPCR, we found decreased abundance of all five targets in colorectal cancer persister cells, in agreement with the depth-normalized analysis approach and results. Beyond the context of persister models, we also examined single-cell ATAC+RNA-seq and spatial transcriptomic data from lymphoma and prostate cancer specimens and demonstrate how depth normalization can be helpful for addressing technical anomalies, such as transcript under-detection due to tissue edge effects. Altogether, sequencing read depth normalization allows us to move beyond the current approach of scaling all cells to the same expression level and achieve more biologically accurate inference from scRNA-seq data.

#2496 GOALS: a novel approach for gene ontology analysis using layered shell to enhance functional insight mining in cancer genomics.

Zongliang Yue[1], Christopher D. Willey[2], Robert S. Welner[3], Rajesh Amin[4], Jake Y. Chen[5]

[1]Department of Health Outcomes Research and Policy, Auburn University, Auburn, AL,[2]Department of Radiation Oncology, the University of Alabama at Birmingham, Birmingham, AL,[3]Department of Hematology and Oncology, the University of Alabama at Birmingham, Birmingham, AL,[4]Department of Drug Discovery and Development, Auburn University, Auburn, AL,[5]Department of Biomedical Informatics and Data Science, the University of Alabama at Birmingham, Birmingham, AL

Gene Ontologies (GOs) are standardized descriptions of gene functions in terms of biological processes, molecular functions, and cellular components, capturing their Parent-Child relationships in a structured framework and advancing cancer biological modeling to provide consistent and meaningful insights into functional genomics analysis. The conventional GO hierarchical structure is defined by human curation experts, with levels determined by the shortest path to the root term. However, grouping GOs poses challenges due to the uneven distribution of gene members within GO terms and inconsistencies in the level of detail across terms at the same GO level. In this work, we introduce Gene Ontology Analysis using Layered Shells (GOALS), a novel tool that discretizes GOAs into optimal layers. GOALS creates a scalable number of GO layers (typically within 10) while maintaining a balanced number of genes across GOs in each layer. Unlike existing tools, GOALS organizes GO terms using a bottom-up approach based on their co-membership network, discreting GOs to achieve an exponential fit with GO's gene member size. Meanwhile, GOALS reveals clusters or supersets reflecting biological relevance by unsupervised clustering of GO's latent projections. In the glioblastoma (GBM) and chronic myeloid leukemia (CML) case studies, GOALS identified distinct GO functional clusters with multi-GO layers to reveal multiple levels of detail—from specific to abstract contexts—to maximize signal discovery and uncover those signal's association with drug resistance. More importantly, GOALS outperformed existing enrichment analysis tools by effectively classifying functional differences with varying treatment outcomes. GOALS offers a robust and innovative framework for exploring disordered GO clusters, mining GO activities, and analyzing potential GO-GO interplays. By addressing critical challenges in functional genomics, GOALS provides a powerful tool for advancing our understanding of cancer heterogeneity and uncovering actionable insights for therapeutic development.

#2497 Modeling the hidden danger of invisible tumor growth in the clinic.

Bryan Hawickhorst[1], Amy H. Tang[2]

[1]Old Dominion University, Norfolk, VA,[2]Department of Biomedical and Translational Sciences, Macon & Joan Brock Virginia Health Sciences at Old Dominion University, Norfolk, VA

Tumor dormancy, relapse, and resistance are not fully understood. Residual and resistant tumor cells often persist and remain invisible for months or years, despite clean MRI/CT scans following neoadjuvant and/or adjuvant systemic therapies. In current literature reviews we see that residual tumor sizes and tumor detection thresholds can vary widely, further complicating patient prognosis and risk stratification. To address this unmet need, we developed an algorithm to model the timing, frequency, and imaging detection limits of tumor measurements to augment tumor relapse prediction with improved accuracy for clinical application, especially when tumors are below the current detection limits in the clinic. To visualize how long it takes an invisible residual tumor to recur, we generated multiple tumor growth curves to model the remission and relapse time course of 1, 10^1, 10^2, 10^3, and 10^4 tumor cells, and calculated the time for these therapy-refractory invisible tumors to develop into large $3cm^3$ MRI/CT-visible tumors. Firstly, we used simple exponential growth curves to model an unimpeded cancer cell doubling time ranging from 2 days to 30 days. Secondly, we used the Spratt model, a modified logistic model, to model the complex tumor growth curves *in vivo*. Tumor doubling times were varied from 5 to 30 days, indicative of tumor aggressiveness, dynamic tumor/tumor microenvironment interaction, and other tempo-spatial-context-dependency. Treatment frequency and duration were varied as biweekly, monthly, and 6-month office visits to simulate the time course of tumor resistance development following multiple rounds of therapeutic interventions. Additionally, tumor remission and relapse were modeled utilizing smaller residual tumors with longer remission periods. Using these parameters, we generated multiple growth curves to model how invisible and resistant residual tumor sizes, ranging from 10^{-2} mm^3 to 10^{-6} mm^3, will determine the time of diagnosis to time of relapse. Our dynamic tumor progression models demonstrate a rapid tumor relapse time course to reach the detection threshold, highlighting the need for invisible residual tumor modeling for diagnosis and relapse prediction in the clinic. This work highlights the importance of minimizing residual tumor size and reducing drug resistance. We will develop an invisible tumor model as a companion prognostic machine learning tool to identify and quantify therapeutic efficacy, risk stratify patients, and improve outcome and survival in the future.

#2498 PharmaRonNet: integrating multi-omics data to reveal key biological pathways.

Kaiqiang Hu, Wanyu Tao, Yunyang Zhang, Pengwei Pan, Fang He

IVB, Pharmaron Beijing Co., Ltd., Beijing, China

In this study, we present PharmaRonNet, a new bioinformatics tool based on the ResponseNet algorithm. PharmaRonNet constructs weighted networks from either single-omics or multi-omics data, revealing key pathways and mediators involved in specific biological or pathological processes. To validate PharmaRonNet's functionality, a case study was conducted using a public transcriptomics dataset of the liver cancer cell line HepG2 treated with insulin. PharmaRonNet successfully identified several insulin-response-related genes as key factors, outperforming standard methods such as differentially expressed genes (DEGs) analysis and other gene network-building tools. Subsequently, PharmaRonNet was used to investigate the mechanisms leading to resistance to the selective CDK4/6 inhibitor, Palbociclib, in hormone receptor (HR)-positive breast cancer. With WES, transcriptome, and proteome data from the Palbociclib-resistant MCF7 breast cancer cell line, PharmaRonNet revealed the involvement of tyrosine phosphorylation and cyclic nucleotide-mediated signaling along with cell growth regulation. Within these pathways, certain "core" genes were identified with the most linkages within the PharmaRonNet. Synergy effect tests were then performed to validate the roles of these key factors in mediating Palbociclib resistance. Overall, PharmaRonNet helps link different layers of omics data, enabling the discovery of hidden mechanisms often overlooked by canonical bioinformatics analysis, and enhancing our understanding of complex biological phenomena. These insights pave the way for developing novel strategies to combat drug resistance in cancers.

#2499 Precision oncology empowered: A web platform for population pharmacokinetic modeling.

Ahmed Fadiel

University of Chicago, Chicago, IL

Background: More than 85% of oncology clinical trial failures are due to problems in pharmacokinetics, pharmacodynamics, and inter-patient variability. In cancer research, therapeutic windows are narrow, and inability to predict drug responses across genetically and clinically diverse populations further complicates the problem. Population pharmacokinetics thus provides a solution by characterizing variability and optimizing dosing; however, it is not yet widely adopted in translational oncology because of technical complexity. Herein, we describe an advanced web-based platform that streamlines PPK model creation, validation, and simulation to optimize trial design and therapy selection in oncology.

Methods: Advanced computational approaches tailored for cancer drug development are integrated into the platform. Hierarchical parameterizations for fixed effects, random effects, and residual error structures enable precise modeling of drug behavior in oncology settings. Hybrid estimation techniques combine stochastic approximation and nonlinear mixed-effects optimization for robust parameter convergence in high-dimensional cancer datasets. Real-time diagnostic plots and multi-dimensional parameter exploration refine models iteratively. Virtual trial simulations incorporate demographic and genetic heterogeneity to predict drug responses and optimize dosing strategies.

Results: The platform validated, with high accuracy, a one-compartment PK model for an anti-cancer agent. Virtual trial simulations demonstrated variability in dose-response across subgroups of cancer patients and identified strategies to optimize therapeutic windows. The platform reduced computational complexity, improved precision, and enabled rapid iteration of complex models. Simulations of alternative trial scenarios identified opportunities to refine inclusion criteria and dosing strategies, offering potential to reduce oncology trial failure rates.

Conclusion: This platform now offers sophisticated tools to tackle the most relevant challenges in drug development against cancer, thus allowing more successful clinical trials and personalized treatments. It is a quantum leap in precision oncology through the in-silico simulation of drug responses and optimization of trial parameters. Currently available internally, the tool will be broadly distributed following further validation.

#2500 An automated and scalable pipeline for high-dimensional immune cell phenotyping in mass cytometry datasets.

B. Waked[1], G. Bellan[1], X. Durand[1], A. Maillard[1], F. Verdonk[2], B. Gaudilliere[3], H. McGuire[4], N. Smith[4], C. Loh[5], D. King[5], D. Blanchard[1], J. Hedou[1];

[1]SurgeCare, SAS, Paris, France, [2]Saint-Antoine and Tenon Hospitals, Assistance Publique-Hopitaux de Paris, Paris, France, [3]School of Medicine, Stanford University, Stanford, CA, [4]University of Sydney, Sydney, Australia, [5]Standard BioTools Canada Inc, Markham, ON, Canada

Context: With the increasing use of spectral flow and mass cytometry technologies, efficient single-cell phenotyping has become essential for the identification of complex cell populations. Traditionally, these populations are identified through manual gating, a time-consuming process that is also subject to variability and a lack of reproducibility. Here, we adapted a deep learning model [1] to devise an automated gating pipeline with the goal of enhancing the accuracy, speed, and reproducibility of immune cell gating.
Methods: Our pipeline was evaluated on two mass-cytometry datasets [1], [2] (>5M cells, 35 markers), that had been previously gated by experts for comparison purposes. Phenotypic markers were used for identification, while the median expression of intracellular markers was used to determine the functional properties of populations. Accuracy and F1-score were used to compare classified populations against manually gated populations. A third dataset (15M events from 57 patients diagnosed with lung cancer) was used to compare the prediction of lung cancer progression after immunotherapy using properties based on manually vs. automatically gated populations.
Results: The automated gating pipeline achieved high overall accuracy comparable to expert manual gating (n=30 cell populations) (0.917 and 0.921 for dataset 1 and 2, respectively). Processing time was significantly reduced: <12min for both datasets (8CPUs, 8GB of RAM). High-level populations (n=10) were identified with excellent accuracy (e.g. Tcells, Bcells with f1-score of 0.993, 0.937 on the first dataset and 0.996, 0.934 on the second dataset). However, rare populations (n=20) showed higher discrepancies (e.g. intermediate monocytes, DC with f1-scores of 0.864, 0.816 and 0.678, 0.552 on dataset 1 and 2, respectively). Differences in identification scores had low effect on the functional properties of populations , as 91.4% of the functional properties defined from our pipeline were highly correlated (r>0.75) with those derived from manual gating. Further, the prediction of lung cancer progression after immunotherapy showed similar or improved results using functional properties based on automated identified populations (AUC=0.82) compared to manually gated populations (AUC=0.70).
Conclusion: This automated approach eliminates operator biases and handles multiple markers simultaneously, offering reliable and efficient analyses for research and clinical applications. To explore discrepancies, future work will incorporate datasets annotated by multiple experts to assess inter-expert variability.

#2501 pyVIPER: Enabling scalable and rapid insights from single-cell RNASeq data in cancer research.

Alexander L. E. Wang[1], Zizhao Lin[1], Luca Zanella[1], Lukas Vlahos[1], Miquel Anglada Girotto[2], Aziz Ur Rehman Zafar[1], Heeju Noh[1], Andrea Califano[1], **Alessandro Vasciaveo**[3]

[1]Department of Systems Biology, Columbia University, New York City, NY,[2]Centre for Genomic Regulation (CRG), The Barcelona Institute of Science and Technology, Barcelona, Spain,[3]NCI-Designated Cancer Center, Sanford Burnham Prebys Med. Discovery Inst., San Diego, CA

Single-cell sequencing has transformed cancer research by enabling the study of tumor heterogeneity and the complex interactions within the tumor microenvironment at an unprecedented resolution. However, the low signal-to-noise ratio in single-cell RNA sequencing (scRNASeq) poses challenges for quantitatively deciphering key cancer processes. We have demonstrated that gene regulatory network (GRN) analysis can address this by identifying Master Regulator (MR) proteins, using the VIPER algorithm, to pinpoint critical drivers of cancer and its microenvironment. As scRNASeq datasets from patient-derived tumors grow in size and complexity, there is a pressing need for scalable tools capable of analyzing datasets with hundreds of thousands of cells. To meet this need, we introduce pyVIPER, a highly efficient and scalable Python toolkit designed to assess protein activity in large-scale scRNASeq datasets. pyVIPER facilitates tumor and microenvironment analysis by supporting multiple enrichment algorithms, advanced data transformations, and a novel data structure for GRN manipulation. With seamless integration into publicly available state-of-art scRNASeq tools, as well as machine learning libraries, pyVIPER provides the ideal platform for analyzing tumor-derived samples. Benchmarking shows that pyVIPER reduces runtime from hours to minutes for large datasets, compared to previous tools, enabling a fast and comprehensive analysis of cancer and tumor microenvironment dynamics at single-cell resolution. This advancement makes VIPER-based analysis accessible for virtually any large-scale single-cell dataset from patient tumors, offering new insights into cancer biology and therapeutic targets.

#2502 Biologically informed cell typing in the tumor microenvironment with lightweight LLMs.

Yooeun Kim, Jiwon Kim, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background: The tumor microenvironment (TME) is a complex ecosystem of diverse cell types that interact dynamically, influencing tumor development and therapy response. Accurate cell type annotation in the TME is challenging due to partial overlap among marker genes, scarcity of representative reference datasets, and emergence of novel cell phenotypes. Our approach uses open-source Large Language Models (LLMs) including Llama 3.2 to provide a reference-free, efficient, and controllable method for cell type classification based on marker genes. Unlike tools that depend on curated reference datasets, this method demonstrates consistent performance across a wide range of cell types. By generating rationale for predicted cell types, our method offers a practical and interpretable framework for annotating diverse cellular populations while offering adaptability to the complexities of the TME.
Methods: LangChain is a “Swiss-knife” platform for LLM applications. We developed a framework identifying cell types in the TME leveraging marker gene contexts. This approach combines structured outputs with predefined constraints to ensure biological plausibility and marker-based reasoning for interpretable cell type identification. Prompt engineering and schema-enforced validation ensure robust, biologically informed outputs, offering flexibility in ambiguous contexts while minimizing hallucinations.
Results: Our method successfully identifies cell types in several cancer datasets, demonstrating high interpretability and reduced misclassification compared to competing methods, such as ScType and GPTCelltype. By employing a de novo cell typing approach, the model effectively resolves ambiguities in overlapping marker genes and adapts well to complex cell populations. The method also achieves superior performance in terms of agreement scores, TTFT (time-to-first-token), and TPOT (time-per-output-token), highlighting its efficiency in time-critical tasks. Explanations provided by the LLM support biological relevance and enhance user confidence in cell typing tasks.
Conclusion: This study highlights the potential of light-weighted LLM for heterogeneous cell typing in complex environments like the TME. By circumventing the limitations of other cell typing methods, including those of reference-dependent and independent, this approach offers a flexible, robust, and interpretable solution for identifying diverse cell types in challenging biological contexts.

#2503 Analytic platform for optimal target pair selection in bispecific antibody-drug conjugates using scRNA-seq and spatial transcriptomics data.

Minki Choi, Sungwoo Bae, Dongjoo Lee, Hongyoon Choi

Portrai, Inc., Seoul, Korea, Republic of

Background: Bispecific antibody-drug conjugates (BiADCs) are innovative anticancer therapeutics that simultaneously bind to two targets. The limitations of single-target antibody-drug conjugates(ADCs) have become evident due to tumor heterogeneity. BiADCs are expected to overcome the limitations of single-target ADCs by broadening the targetable regions within the tumor. Here, we have developed a platform based on single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics (ST) data to identify the optimal pair of targets that maximizes the therapeutic efficacy and minimizes the systemic toxicity of BiADCs.
Methods: We created an integrated cell atlas by combining the human single-cell transcriptomics atlas from 'Tabula Sapiens' and the cancer scRNA-seq datasets from the 'Curated Cancer Cell Atlas'. to calculate the 'Organ-Level Specificity' (expression fold-change between cancer and matched normal tissue) and the 'Critical Organ Toxicity' (average target expression in critical organs). And the ST data are used to calculate the 'Intratumoral target expression', 'Microenvironment-Level Target Specificity', defined by the expression of the target in malignant cells relative to normal cells. We utilized Visium data from 96 breast cancer based on the tissue microarray. These checkpoints were calculated for BiADCs by simultaneously analyzing two selected targets and computed for all possible target pairs. We focused on 13 targets that are actively being investigated in clinical trials for ADCs in solid tumors.
Results: After calculating the checkpoints for each target pair, we identified target pairs that are expected to perform better than single targets based on the following criteria. First, we selected pairs that showed higher checkpoint values compared to their corresponding single targets. Then, from these selected pairs, we chose those that outperformed their corresponding single targets in at least three checkpoints. Applying the criteria, we identified target pairs for BiADCs that are likely to achieve superior therapeutic outcomes compared to single targets. The pairs involving CEACAM5 or VTCN1 generally achieve a high therapeutic index. And the target pairs with VTCN1 exhibit lower critical organ toxicity compared to other targets for breast cancer.
Conclusion: The platform presented in this study utilizes scRNAseq and ST data to systematize the complex target selection process for BiADCs. We developed checkpoints to evaluate target efficacy at the systemic level using scRNAseq and at the tumor microenvironment level using ST data. Using breast cancer as an example case and the list of 13 ADC targets, we identified CEACAM5 or VTCN1-based target pairs as optimal partners for BiADCs. Consequently, our pipeline demonstrated its ability to identify target pairs that are expected to perform better than specific single-target ADCs.

#2504 SNAP: Streamlined Nextflow Analysis Pipeline for profiling circulating histone modifications identifies tumor epigenomic signatures in cancer plasma.

Ze Zhang, Paulo Cordeiro, Brad Fortunato, Karl Semaan, Razane El Hajj Chehade, Gunsagar Gulati, Garyoung Lee, Shahabeddin Sotudian, Ji-Heui Seo, Matthew Freedman, Sylvan Baca

DFCI/Harvard Medical School, Boston, MA

Background: Cell-free chromatin immunoprecipitation sequencing (cfChIP-seq) and methylated DNA immunoprecipitation sequencing (cfMeDIP-seq) are increasingly being used to profile cancer epigenomes from blood. The data these assays generate require specialized analytical approaches that are not met by conventional pipelines for ChIP-seq. ChIP-seq analysis focuses on calling “peaks” to identify where a protein of interest binds DNA, while cfChIP-seq often requires quantification of low-abundance signals from cancer chromatin. Additionally, input cell-free chromatin amounts are generally small and variable, and conventional indicators of data quality like peak number are not optimized for cfChIP-seq and cfMeDIP-seq. To address these challenges, we developed SNAP—a streamlined, containerized, Nextflow pipeline optimized for cell-free histone modification and DNA methylation profiling.
Methods: We implemented key steps in cfChIP-seq and cfMeDIP-seq data processing using Nextflow and Docker containerization to create a reproducible and portable workflow. Through reanalysis of > 800 datasets spanning H3K4me3, H3K27ac, and DNA methylation, we established quality metrics that identify datasets with acceptable quality for downstream analyses. Optimum thresholds were established for the total number of DNA fragments and enrichment of fragments mapping to “on-target” versus “off-target” regions. We tested strategies for signal normalization to optimize comparability between samples. SNAP performs quality control assessment and normalization, as well as genotype fingerprinting to rule out sample swaps and confirm that epigenomic profiles derived from the same individual where expected.
Results: Fragment count cut-offs were set at 2,100,000 for H3K4me3 and H3K27ac ChIP-seq, and 7,700,000 for MeDIP-seq. Enrichment score thresholds were established at 10.9, 10.3, and 3.2 for H3K4me3, H3K27ac, and MeDIP-seq, respectively. Filtering our cohort based on these thresholds maximized the ability to distinguish cancer vs. healthy plasma based on the signal at tumor-type-specific regulatory elements. Sample clustering based on SNP fingerprints reliably grouped samples derived from the same individual. SNAP has been successfully deployed on HPC clusters and is compatible with cloud computing platforms, ensuring accessibility for diverse research environments.
Conclusion: We developed SNAP, a Nextflow-based pipeline specifically optimized for plasma cell-free chromatin epigenomic profiling, including H3K4me3 ChIP-seq, H3K27ac ChIP-seq, and MeDIP-seq. Customized quality control metrics enhanced the detection of tumor-associated epigenomic signatures in cancer plasma samples compared to healthy controls. SNAP provides a robust, reproducible, and portable solution for high-sensitivity plasma epigenomic profiling.

#2505 Semi-automated image registration and cell typing integrates multiplexed imaging data to investigate the tumor microenvironment in clinical biopsies.

Cadence Chang[1], Egmidio Medina[1], Sarah Samordnitsky[2], Alan Zelin[1], Qin Zhou[3], Siwen Hu-Lieskovan[3], Michael C. Wu[2], Antoni Ribas[1], Katie M. Campbell[1]

[1]UCLA - University of California Los Angeles, Los Angeles, CA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]University of Utah, Salt Lake City, UT

Introduction: Spatial profiling technologies are individually limited by the number of proteins evaluated, making it beneficial to integrate imaging analysis across multiple slides from a single biopsy. Here, we describe a semi-automated workflow for the scaled image registration and downstream analysis of clinical melanoma biopsies treated with immunotherapy and evaluated across multiplexed protein platforms.

Methods: Clinical biopsies (n=119) from patients with melanoma (N=39) were assayed on the Vectra Polaris platform. Two sequential slides from each biopsy were individually processed under pre-specified custom named panels, being: PD1 panel (DAPI, CD8, PDL1, Ki67, PD1, SOX10, and CD68) or the L panel (DAPI, CTLA4, CD8, FOXP3, CD4, CD20, and PD1). The VALIS program was used to perform semi-automated image registration on these sequential slides. A bootstrapping approach determined cell marker positivity to identify cell types including melanoma cells (SOX10), CD8 T cells (CD8), CD4 T cells (CD4, FOXP3-), regulatory T cells (Tregs; CD4, FOXP3), B cells (CD20), and macrophages (CD68). Following image registration, cell type relationships were evaluated for regional annotation of tumor content, T-cell infiltration, and T-cell activation.

Results: There were 9,376,260 cell segments detected across biopsies (average n=42,235 segments per biopsy, range 1,611-214,050). Melanoma cells were detected based upon nuclear SOX10 staining. Biopsies had varied levels of tumor cellularity (average 8.9%, range 2.1-24.0%). Image registration was performed for samples that had corresponding PD1 and L panels (n=112). Automated registration was achieved for 86 of 112 paired samples (76.8%); 8 of the 86 (9.3%) required manual changes in parameters for accurate registration, and 18 samples were unable to be registered with VALIS due to imaging noise or poor-quality biopsies. This successful registration in the majority of cases led to the automated annotation across images, transferring of the PD1-panel image on to the registered L-panel image.

Conclusions: Semi-automated image registration can help to overcome protein expression measurement limitations in spatial profiling technologies, enabling the expanded knowledge transfer across these data modalities. This workflow allows the effective integration of data measurements from multiple stainings for more comprehensive analysis using these technologies to study the tumor microenvironment.

#2506 Microhunt: an integrated pipeline for precise microbial quantification in low-biomass clinical samples.

Gengwen Deng[1], Lingxuan Zhu[1], Weiming Mou[1], Liling Xu[1], Shujia Lin[1], Keren Wu[1], Hao Li[1], Zhixing Deng[1], Hongsen Huang[1], Zeji Guo[1], Qiheng Liang[1], Aimin Jiang[2], TIng Wei[1], Jiang Zhang[1], Quan Cheng[3], **Anqi Lin**[4], Peng Luo[1]

[1]Department of Oncology, Zhujiang Hospital, Southern Medical University, Guangzhou, China,[2]Department of Urology, Changhai Hospital, Naval Medical University (Second Military Medical University), Shanghai, China,[3]Department of Neurosurgery, Xiangya Hospital, Central South University, Changsha, China,[4]University of Macau, Guangzhou, China

Accurately quantifying microbial abundance from high-throughput sequencing data is challenging, especially in low-biomass samples where host DNA/RNA dominates microbial content. Host or environmental contaminants may obscure true microbial signals, leading to false positives. Here, we introduce MicroHunt, an advanced pipeline integrating quality control, host sequence depletion, microbial classification, and contaminant exclusion.MicroHunt incorporates comprehensive human reference genomes (hg38, T2T-CHM13, Gencode) to efficiently remove host-derived reads and eliminates contaminant sequences source, such as vectors, phages, and plasmids. It supports multiple microbial classification tools and utilizes a curated reference database encompassing archaea, fungi, bacteria, viruses, and protozoa. By incorporating host genome references into the classification process, MicroHunt clearly distinguishes host from microbial sequences, significantly improving classification accuracy and reducing false positives. MicroHunt also provides integrated contaminant control strategies effective even without negative controls, enabling reliable microbial quantification from low-biomass samples. Using ribosomal RNA-depleted whole-transcriptome sequencing data from 807 colorectal cancer (CRC) tumor samples in the AVANT Phase III trial, MicroHunt effectively characterized the dominant microbial phyla present within the tumor microbiome of CRC patients, with Pseudomonadota and Bacillota being the most prevalent. Further analysis revealed that CRC patients with high abundance of Lactobacillus iners (L. iners) in tumor tissues were significantly associated with poor prognosis following chemotherapy combined with bevacizumab treatment (Hazard Ratio = 2.21, 95% CI = 1.14-4.32, p = 0.017). Sequence alignment analysis confirmed that the reads identified as L. iners were not derived from potential contamination sources. Moreover, integrating microbiome data generated by MicroHunt with patient transcriptomic data uncovered complex interactions between the gut microbiome and host gene expression in CRC patients. Pathway enrichment analysis revealed a significant association between L. iners and the fatty acid oxidation pathway (Spearman's correlation coefficient r = 0.094, p = 0.0079), suggesting that microbial metabolism may influence patient prognosis in CRC. Finally, we validated the utility of MicroHunt using sequencing data from other tumor types, including non-small cell lung cancer and bladder cancer, successfully identifying intratumoral microbes and elucidating their potential biological significance.

#2507 Comparative assessment of data analysis methods to enable robust 10-second diagnosis of tissue pathologies with picosecond infrared laser mass spectrometry.

Darah Vlaminck[1], Alexa Fiorante[1], Lan Anna Ye[2], David Munoz[3], Sunit Das[3], Gelareh Zadeh[2], Howard Ginsberg[3], Arash Zarrine-Afsar[2]

[1]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]University Health Network, Toronto, ON, Canada,[3]Unity Health Toronto, Toronto, ON, Canada

A survey of clinical outcome data suggests surgical approaches of the central nervous system cancers must vary based on type of cancer, its aggressiveness, chance of recurrence and associated risks. This is usually informed by feedback from a neuropathologist on call wherein the accuracy of diagnosis depends highly on the experience and training level of the pathologist. As such, to deliver robust personalized resections, the subjectivity of intraoperative diagnosis must be reduced.Picosecond infrared laser mass spectrometry (PIRL-MS) generates a fingerprint of cancer-specific tissue lipids that can form the basis for non-subjective diagnosis in only 10 seconds. Here, a differential diagnosis model must be incorporated with finer data analytics methods to help tease out cancer-specific spectral features in complex datasets.A hierarchical differential diagnosis (decision tree) model optimizing evidence-based adjustment of the extent of resection for n=62 lymphoma (no resection), n=96 metastatic carcinomas (aggressive resection) and n=216 gliomas (maximum safe margin resection), the latter comprised of n=93 isocitrate dehydrogenase-1 (IDH1) positive and n=132 negative mutational status was created. This tree flows in a logical order based on what a neuropathologist would use for diagnosis, albeit utilized for automated non-subjective diagnosis based on 10-second PIRL-MS lipid analysis. The goal was to optimize the best machine learning method at each discrimination point from a list of principal component analysis-linear discriminant analysis (PCA-LDA), partial-least squares discriminant analysis, lasso regression, random forest, XGBoost, and support vector machine.The hierarchical approach enabled simplification of class comparisons to only those in differential diagnosis, as such, eliminating the misclassification between classes at finer branches of tree. This allowed performance metrics to be generated at each discrimination point not distinguished in simultaneous prediction of all classes using a single multiclass model.Within all nodes, PCA-LDA (a linear method) showed best performance, especially compared to ensemble approaches. Using this approach, the hierarchical method delivered diagnosis of lymphoma, glioma and metastatic tumours in node 1 with sensitivity and specificity of 87% and 93%, respectively and was able to differentiate between IDH1 mutant and WT gliomas with the sensitivity and specificity of >93%, the latter not being possible in current intraoperative diagnosis workflows due to long analysis times.The utility of this optimized hierarchical approach with PIRL-MS data is manifested in the users' ability to adjust the diagnosis depth commensurate with desired performance criteria, enabling incorporation of the clinical 'cost' of total resection of one tumour class compared to another.

#2508 A multiscale framework combining mechanistic models and LSTM-GCN networks for predicting drug sensitivity.

Chenhui Ma, Evren Gurkan-Cavusoglu

Case Western Reserve University, Cleveland, OH

Understanding tumor evolution and treatment resistance requires an integrative approach that combines cellular dynamics with molecular interactions. While mechanistic models excel in capturing physiological processes and predicting behaviors beyond the original data, their specificity limits their generalizability. Conversely, deep learning enables universal predictions but often lacks interpretability, posing challenges for application in cancer research. To address these limitations, we propose a novel computational framework that integrates mechanistic simulations, graph-based modeling, Long Short-Term Memory (LSTM) networks, and Bayesian inference to predict the sensitivity of six cancer types to targeted therapies, chemotherapy agents, immunotherapies, and their combinations. In this framework, mechanistic models provide an individualized baseline simulation for different cancer types, while deep learning integrates these outputs with drug-related information to generate robust and interpretable predictions tailored to specific types. Our hybrid framework leverages a mechanistic pan-cancer model that simulates molecular signaling pathways, cell cycle dynamics, and apoptosis across four biological compartments. The model is parameterized using published gene expression profiles and mutation data from xenograft models, including key mutations such as *KRAS*, *EGFR*, and *TP53*. Simulations are performed for six cancer types, including breast carcinoma, colorectal cancer, and pancreatic carcinoma, to approximate patient-specific tumor biology. Tumor cell populations generated from these simulations are represented as graphs, with each node corresponding to an individual cell characterized by proliferation status and dynamic molecular states (e.g., protein concentrations and phosphorylation levels). Edges are weighted and defined based on molecular similarity between cells. The graph is processed using a Graph Convolutional Network (GCN), which generates embeddings that capture tumor population heterogeneity. These embeddings are then fed into an LSTM to extract the temporal dynamics of the tumor population. The final hidden states computed by the LSTM are further combined with embeddings of drug chemical structure and drug-target interactions to make drug sensitivity predictions. To enhance the robustness of predictions, Bayesian inference is incorporated to quantify uncertainty in estimated drug responses. This framework bridges the gap between mechanistic modeling and machine learning, offering a scalable and interpretable approach to studying tumor evolution under the selective power of drug treatment. By integrating the physiological insights of mechanistic models with the predictive power of deep learning, it enables the identification of molecular drivers of resistance and informs the development of personalized therapies.

REGULATORY SCIENCE AND POLICY: Regulatory Science and Policy

#2512 History and summary of current practices for assessment of drug-induced QT-prolongation in oncology drug development.

Louis-Guillaume Marquier[1], Frederique Lemaux-Duvillier[1], Stephanie Le Goaller[2], Philippe L'Hostis[3], Eric Delpy[4], Mathieu Grace[1], Jean-Louis Pinquier[1]

[1]Biotrial, Rennes, France,[2]Biometrics, Biotrial, Rennes, France,[3]Neuroscience, Biotrial, Rennes, France,[4]Pharmacology, Biotrial, Rennes, France

The ICH E14 guideline issued in 2005 made the assessment of drug-induced QT-prolongation a mandatory step in the development of all new therapeutics. The guidance provided a clear requirement, however the means to achieve this requirement within the specific space of oncology clinical development remained challenging. Several updates to the guidelines, mainly in the form of Q&As published in 2012, 2015 and 2022 helped to clarify regulator expectations and thus determine the strategies available in a field where a straightforward investigation performed in Healthy Subjects (i.e. the dedicated TQT trial) is not feasible for reasons of drug tolerability ; a dedicated trial in the patient population also poses significant ethical questions in addition to logistical hurdles. Today, following the different updates to ICH E14 we feel that a clear strategy may be implemented by sponsors developing new treatments in the field of oncology. These strategies, which include in vitro and in vivo testing and a specific approach for ECG recordings in phase I, are followed by several companies, but are not yet universally included in development plans from their start. We thus believe that a simplified roadmap should hold value for professionals looking to develop novel oncology therapeutics. The focused and precise assessment of drug-induced QT prolongation also meets the needs of clinicians looking to assess this risk in complex clinical setting with multiple risk factors[1,2].
The purpose of our abstract will be to provide a clear history of the evolution of the ICH E14 guideline and illustrate what could be the current practice implemented for new therapeutics in the field of oncology. Our main interest will be for NCEs who cannot be safely administered to Healthy Participants however approaches for NBEs will also be described, with illustrations of results. This will include a description of the in vivo preclinical and clinical strategies which can be followed.

#2513 Factors influencing participant attrition in Phase 0 hybrid clinical trials for patients with high-grade glioma.

Jocelyn L. Harmon[1], Amy Hong[1], Artak Tovmasyan[1], An-Chi Tien[1], Kristin Hendrickson[1], Jennifer Eschbacher[1], Wonsuk Yoo[1], Igor Barani[2], William Kennedy[2], Zaman Mirzadeh[2], Yoshie Umemura[1], Shwetal Mehta[1], Nader Sanai[1]

[1]Ivy Brain Tumor Center at Barrow Neurological Institute, Phoenix, AZ,[2]Ivy Brain Tumor Center, Barrow Neurological Institute, Phoenix, AZ

Background: Phase 0 hybrid trial designs administer a subtherapeutic experimental agent pre-surgically and then use predetermined pharmacokinetic (PK) and/or pharmacodynamic (PD) thresholds to qualify patients for follow-on therapeutic dosing. While such protocols are rare, they are increasingly prevalent within neuro-oncology, necessitating a better understanding of factors influencing participation. Here, we investigate participant enrollment in Phase 0 hybrid trials for high-grade glioma patients at a single center.
Methods: This retrospective study examined characteristics of high-grade glioma patients enrolled in Phase 0 hybrid clinical trials at the Ivy Brain Tumor Center. Clinical, pathological and demographic data, as well as PK/PD profiles, were analyzed and related to participant enrollment and attrition.
Results: A total of 284 newly-diagnosed and recurrent high-grade glioma patients were analyzed and 276 (97.2%) participants completed the Phase 0 component of their study. Of these, 176 (63.8%) Phase 0 participant tumors did not meet criteria for therapeutic dosing, including 63 (35.8%) due to histological diagnosis, 62 (35.2%) due to PK/PD results, 39 (22.2%) due to clinical status decline, 7 (4.0%) due to patients' decision to not proceed, and 5 (2.8%) for unknown reasons. Six (2.1%) participants did not complete Phase 0 and 2 (0.7%) participants were screen failures.
Conclusions: In the upfront and recurrent settings, tumor histopathology and drug PK/PD performance are the principal determinants of participant suitability for the therapeutic dosing component of a Phase 0 hybrid study. In this single-center analysis, the graduation rate from Phase 0 to therapeutic dosing was 36.2%. This retrospective study, the largest to date in high-grade glioma patients, highlights participant- and protocol design-related features that will help refine future Phase 0 hybrid protocols in neuro-oncology.

#2514 Refining oncology dose selection: A framework for tailored dose optimization in the era of targeted and immunotherapies.

N. Dharia[1], J. Zhu[1], A. Schroeder[1], S. Frank[2], C. Boetsch[2], C. Jamois[2], N. Kassir[1], **K. Korfi**[2], E. Punnoose[1], A. Vaze[1], P. Trask[1], P. Gosai[3], J. Fridlyand[1], C. Li[1];

[1]Genentech, Inc., South San Francisco, CA, [2]F. Hoffmann - La Roche Ltd, Basel, Switzerland, [3]Hoffmann-La Roche Limited, Mississauga, ON, Canada

Historically, oncology dose selection was driven by the identification of the maximum tolerated dose, often resulting in significant toxicity. The advent of molecular targeted therapies and immunotherapies has created opportunities to achieve similar efficacy at a lower, more tolerable dose. Recent FDA draft guidance highlights the importance of dose optimization in drug development. Building on this, we present a novel framework categorizing drugs into four molecular classes based on their mechanisms of action: (1) small molecule targeted therapies and antibody-drug conjugates, (2) large molecule antagonists, (3) cancer immunotherapy agonists, and (4) molecules with limited or no single-agent activity.

Unique considerations and strategies for dose optimization are detailed for each class, supported by case examples. We propose integrating proof of activity as a gating criterion for dose expansion to inform robust dose decisions and maximize the use of patient resources. This perspective underscores the integration of preclinical and clinical data—including pharmacokinetics, pharmacodynamics, and patient-reported outcomes—combined with quantitative pharmacology and statistical modeling, to optimize doses effectively while balancing efficacy and safety.

While no one-size-fits-all approach exists, this tailored guidance for specific mechanistic classes provides balanced approaches to dose optimization that ultimately enhance the probability of success in drug development.

#2515 Enhancing oncology data collection and submission: The value of the national cancer institute (NCI) oncology codetable mapping file.

Karine Provost[1], **Stephanie Le Goaller**[1], Mathieu Grace[1], Pierre Montagne[2]

[1]Biotrial Biometrics, Rennes, France,[2]Biotrial Pharmacology, Rennes, France

Data collection for efficacy endpoints in oncology clinical trials present various challenges and thus require adapted strategies and tools. Use of the Guidances to follow for surrogate endpoint analysis and reporting, such as RECIST, Lugano, RANO or others are straightforward, as this depends on the target malignancies and the type of compound being studied. It is however challenging to ensure that, once the endpoints for a trial are selected, the method for their collection and identification be clearly defined. This paper will focus on the use of the tools developed by the NCI and CDISC communities to ensure that data be efficiently collected and organized, in line with regulatory requirements. We will be explaining the role of the following tools which are used throughout a trial, starting with the protocol design and all the way until the final reporting:- CDASH Implementation Guide (CDASHIG) : this refers to the guidances for data collection- SDTM Implementation Guide (SDTMIG) : this refers to the guidances for data submission- Therapeutic Area User Guides (TAUGs) : these include disease-specific metadata, examples and guidances on implementing CDISC standards for a variety of uses, including global regulatory submissions (ie : Breast Cancer, Prostate Cancer, Colorectal Cancer, Lung Cancer)
- RECIST 1.1 Disease Response Supplement to SDTMIG
- Controlled Terminology (i e: Tumor or Lesion Identification Test Code/Name Codelists Tumor or Lesion Properties Test Code/Name Codelists , Category of Oncology Response Assessment, Oncology Response Assessment Test Code/Name Codelists, Oncology Response Assessment Result)
- Newly Oncology Codetable Mapping File which shows relationships between terms (i.e : Modalities for Target/Non-Target Response for RECIST1.1, iRECIST or LUGANO)
It is of particular interest to evaluate the value added of the NCI Oncology Codetable Mapping File in oncology clinical trials, as demonstrated through its use in EDC and database design. We will describe the approach taken to integrate this new tool into EDC and Database design and this enables further alignment with guidelines (e.g. RECIST, Lugano), controlled terminologies and Regulator expectations. We will also investigate the value added for investigator sites, who can benefit from this further standardization of data collection practices across clinical trials, regardless of sponsor or CRO, to simplify their working practices.As a conclusion, we will summarize the value added by the NCI Oncology Codetable Mapping File to the existing landscape (CDISC tools, Surrogate Endpoint Guidances) of oncology clinical trials. We will emphasize its potential to simplify complex data requirements for topics specific to the field of oncology.

#2516 A qualitative research study on hematology and oncology consultants' experiences and opinions on using minimal residual disease (MRD) as a fast-track approval endpoint in early-phase clinical trials in multiple myeloma in Saudi Arabia.

Albandari A. Alnasser, Tariq H. M. Alqurayshah

Oncology and Hematology, Saudi Food and Drug Authority, Riyadh, Saudi Arabia

Introduction: The US FDA has recently considered minimal residual disease (MRD) as an acceptable accelerated approval endpoint in multiple myeloma (MM). Meta-analysis studies have shown the clinical benefit of MRD negativity in MM.
Objective: This qualitative research study aims to assess the opinions and experiences of hematology and oncology consultants in Saudi Arabia on MRD as an intermediate endpoint for fast-track drug approvals by the Saudi Food and Drug Authority in MM.
Study Design: Interviewing 30 registered physicians with more than one year of experience. The interviews will be conducted through a single focus group and several face-to-face interviews or performed online. The predetermined set of semi-structured questions will cover topics such as the definition of MRD, its clinical and research significance, MRD detection thresholds, duration of MRD negativity, and its correlation with other clinical endpoints, such as progression free survival (PFS) and overall survival (OS). The interviews will be conducted by scientific oncology and hematology evaluation experts at the Saudi Food and Drug Authority. Before starting any interview, participants will complete consent forms, including the study's goals and who will conduct the study.
Results: First focus group included seven consultants and highlighted MRD's value as a surrogate endpoint, emphasizing its strong correlation with PFS and OS. MRD negativity is associated with improved PFS and OS across all disease stages, including newly diagnosed and relapse/refractory multiple myeloma. It is particularly valuable in early phase trials for evaluating novel therapies and in maintenance therapy for monitoring sustained remission. However, the use of MRD as a surrogate endpoint for drug approval remains debated. While it is considered as a good endpoint for expedited approvals of MM new medicinal products and indications but not a perfect surrogate for overall survival. The focus group emphasized that while MRD is a valuable indicator, it does not replace the need for collecting and analyzing OS and PFS data to confirm long term benefit for patients. In Saudi Arabia, methods for detecting MRD include flow cytometry and next-generation sequencing (NGS). Flow cytometry is the most accessible and cost-effective method, widely available in many hospitals. The threshold for MRD negativity depends significantly on the detection method used, as each method offering varying level of sensitivity. Flow cytometry typically achieves a sensitive threshold 10-5 . Also, next-generation sequencing (NGS) can achieve a higher sensitivity of up 10-6.
Conclusion: MRD could be a promising surrogate endpoint in multiple myeloma due to its strong association with PFS and OS with the need for the long-term clinical data.

#2517 Meaningful change in the ability to perform physical activities for patients with cachexia and cancer.

Carrie Northcott[1], Abigail Newell[2], Soohyun Hwang[3], Josh Coulter[4], Lewis Kopenhafer[3], Mar Santamaria[5], Isik Karahanoglu[5], Martine C. Maculaitis[3], Joseph C. Cappelleri[1], Kathleen Beusterien[3], Maria Gonzalo[2], Erica Fortune[2], Claire Saxton[2], Elif Andac-Jones[6], Brett Hauber[4]

[1]Pfizer Inc, Groton, CT,[2]Cancer Support Community, Washington, DC,[3]Oracle Life Sciences, Austin, TX,[4]Pfizer Inc, New York, NY,[5]Pfizer Inc, Cambridge, MA,[6]Tigerlily Foundation, Stone Ridge, VA

Digital health technologies (DHTs) can quantify changes in physical activity in cachexia clinical studies. But what is a meaningful change? We estimated the meaningfulness to patients with cachexia and cancer of incremental changes in ability to perform physical activities of different intensity and time spent each day doing non-sedentary activity that can be measured with DHTs. An online survey was conducted with US adults with cachexia and cancer. Meaningfulness of 14 changes in ability to perform physical activities and 3 increases in daily time spent in non-sedentary activity were assessed on a 5-point rating scale (not at all meaningful to extremely meaningful). Subgroups (tumor type, cancer stage, ECOG performance status) were compared using chi-square (or Fisher's exact) tests. Overall, 181 patients participated. All changes in physical activity intensity, and both a 14-min and a 30-min increase in time spent in non-sedentary activity/day, were at least moderately meaningful to most patients, regardless of tumor type, cancer stage, or ECOG performance status (Table). Some meaningfulness ratings differed significantly by tumor type (both walking pace and distance were less meaningful in NSCLC and sitting to standing was less meaningful in pancreatic) and performance status (walking pace was less meaningful in patients with ECOG 3-4). Majorities of patients, except for those with colorectal, rated a 4-min increase/day in non-sedentary activity as at least moderately meaningful. Patients with cancer and cachexia perceived even small changes in physical activities and time spent in non-sedentary activity as being at least moderately meaningful, suggesting that DHTs that measure changes in movement duration can be used to capture important patient-centric endpoints in clinical studies.

Table

Change in Ability to do Physicial Activities	Proportion of Patients Rating Each Change as at Least Moderately Meaningful									
	All Patients	Tumor Type					Cancer Stage		Performance Status	
		NSCLC	Breast	Colorectal	Pancreatic	Other	Stage I-III	Stage IV	Higher	Lower
	N=181	N=20	N=69	N=30	N=15	N=47	N=123	N=52	N=147	N=34
Cannot go walking outside to Able to walk a short distance	93.9%	95.0%	94.2%	93.3%	93.3%	93.6%	92.7%	98.1%	93.9%	94.1%

#2518 Implementing an AI triage platform for identification and management of patients suspected of cancer risk to improve elective recovery post pandemic.

Miles Payling[1], Seema Dadhania[2], Michael Moss[1], Judith Gordon[1], Bea Bakshi[1]

[1]C the Signs Limited, London, United Kingdom,[2]Imperial College London, London, United Kingdom

Background: The COVID-19 pandemic caused a significant backlog in the UK National Health Service (NHS), with 7.6 million patients awaiting consultant appointments as of August 2024. A major consequence of this was a surge in urgent suspected cancer (USC) referrals, which rose by 27% compared to pre-pandemic levels without a proportional increase in cancer detection rates. General Practitioners (GPs) often default to USC referrals, bypassing initial investigations, which strains secondary care services.
C the Signs, an AI-led cancer prediction platform, supports GPs to improve cancer triage by identifying high-risk patients for appropriate pathways (such as direct access diagnostics or non-urgent referrals) without increasing referral volumes. This system optimizes USC referrals, reserving them for patients truly requiring intensive diagnostic resources, reducing pressure on secondary care.
Methods: From January 2020 to September 2024, data from 1,084 GP practices using C the Signs were analyzed, covering 235,662 risk assessments. The platform stratified patients into categories: urgent admission, USC referral, non-urgent referral, and direct access diagnostics (e.g. blood tests, FIT, X-ray). Patients not at risk were safely excluded from cancer pathways.
Results: C the Signs redirected 21.7% of patients away from the USC pathway, safely excluding 21,449 (9.1%), triaging 18,063 (7.7%) to tests and diagnostics, and 11,587 (4.9%) to non-urgent referrals—reducing USC pathway pressure by 61,099 patients. Meanwhile, 184,487 patients (78.3%) were appropriately referred for USC, ensuring focus on high-risk cases. Only 1.5% of assessments resulted in multiple USC referrals, and just 76 patients (0.0%) required urgent admission.
A total of 13,585 cancers were diagnosed, yielding a 7.3% conversion rate—20.9% higher than the NHS England average of 6.0%.
Conclusion: C the Signs effectively stratifies suspected cancer patients, excluding low-risk individuals from USC pathways and directing others to appropriate care. This enhances NHS resource efficiency and supports elective recovery while maintaining diagnostic safety. If implemented nationally, C the Signs could reduce USC referrals by 505,196 (17.5%) without compromising safety or outcomes. Longitudinal studies could further assess the platform's impact on healthcare outcomes and efficiency.

CLINICAL RESEARCH: Liquid Biopsy: Circulating Nucleic Acids 5 / Circulating Tumor Cells 2
Poster Session

#6357 A liquid biopsy-based targeted proteomic assay to identify druggable proteins from circulating tumor cells (CTCs).

Alec Horrmann[1], Ali T. Arafa[2], Kaylee Kamalanathan[1], Alexa Hesch[1], Grant Schaap[1], Mahdi Ahmadi[1], Nathaniel Bristow[1], Badrinath Konety[1], Howard Scher[3], Emmanuel S. Antonarakis[4], Jiarong Hong[1], **Justin M. Drake**[4]

[1]Astrin Biosciences, St Paul, MN,[2]Department of Medicine, University of Minnesota, Minneapolis, MN,[3]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[4]University of Minnesota, Minneapolis, MN

Background: While cancers often arise from a specific tissue the drugs designed to fight them are largely tissue agnostic. Drugs most commonly target mutant or amplified proteins such as transcription factors, kinases, or other cell surface proteins. An ever-growing body of research shows that these well characterized protein targets are commonly found across many cancer types and can serve as potential targets for pan-cancer therapies. Despite this growing consensus, enrollment criteria for clinical trials often do not include any test to detect or quantify the presence of the drug's target protein. However, patient-specific protein profiles should be utilized as a tool to not only minimize patient harm but also to categorize patients so drug trials can be designed to identify only the patients most likely to benefit in mind. To that end, we developed A liquid biopsy-based proteomic assay to identify druggable targets from CTCs from cancer patients' blood.
Methods: CTCs were isolated using Astrin Bioscience's proprietary enrichment system yielding matched CTC and white blood cell (WBC) fractions. Following enrichment, samples were processed in parallel using a custom developed protein aggregation capture protocol followed by protein digestion to yield peptide samples ready for bottom-up targeted peptide analysis on a FAIMS equipped Exploris 480 instrument with internal normalization to heavy labeled peptide standards.
Results: We prospectively enrolled 20 heavily-pretreated metastatic castration resistant prostate cancer (mCRPC) patients from whom matched CTC and WBC profiles were analyzed. The mean CTC count was 10.4 cells/mL with a median of 4.9 CTCs/mL. The median age of these patients was 74 years, 80% had Gleason GG4-5, 30% had visceral metastases, median number of prior systemic therapies was 5, and median PSA level was 135 ng/mL. Following CTC enrichment, we observed vastly diverse inter- and intra-patient proteomic profiles. Some of the highly relevant proteins to mCRPC identified and quantified from CTCs in 100% of patients for androgen receptor (AR) and B7 homolog 3 (B7-H3), 57% of patients for trophoblast cell surface antigen-2 (TROP2), 43% of patients for prostate specific membrane antigen (PSMA), 28% of patients for programmed cell death antigen 1 (PD-L1), and 14% of patients for neuroendocrine markers chromogranin A (CHGA) and delta like ligand 3 (DLL3) with significantly less or no detection of these proteins in the WBC fraction.
Conclusions: With the clear differences seen between the CTC and WBC fractions, combined with expected proteins observed in the CTC fraction, this demonstrates the successful isolation of CTCs. Together, this shows a first of its kind assay able to probe multiple highly relevant proteins from a patient's own CTCs that could be crucial to help minimizing patient harm and designing better precision therapeutics.

CHEMISTRY: Drug Delivery

#6893 Synthesis and characterization of IL-4R ligand mimic (AP1)-functionalized elastin-like polypeptide-based nanopolymers as selective delivery vehicles for paclitaxel in ovarian cancer.

Ridhima Goel, Deepak Gulwani, Thoudam Debraj Singh

All India Institute of Medical Sciences (AIIMS) New Delhi, New Delhi, India

Introduction- Elastin-like polypeptides (ELPs) have emerged as promising nanocarriers for drug administration, owing to their advantageous properties, including biocompatibility and distinctive biophysical behavior. These polymers can be tailored to incorporate functional motifs that allow for accurate drug loading and targeted delivery. In cancer therapy, ELP-based nanocarriers have shown potential by increasing drug solubility, stability, and allowing for tumor-specific targeting. This study aims to develop and evaluate AP1-functionalized ELP-based nanopolymers as vehicles for the “selective” delivery of paclitaxel (PTX) in ovarian cancer (OC).
Materials and methods- Maleimide-reactive cysteine residues were introduced into the ELP/AP1-ELP sequence. Paclitaxel, activated by N-ε-maleimidocaproic acid (EMCA), was coupled to ELP/AP1-ELP by a Michael addition reaction. Chemical conjugation was assessed using MALDI-TOF mass spectrometry, transmission electron microscopy (TEM), and dynamic light scattering (DLS). SKOV-3 and OVCAR-3 cell lines were analyzed for IL-4R expression followed by assessment of differential binding of Alexa-488 labelled ELP/AP1-ELP using flow cytometry (FACS). IC50 values of ELP/AP1-ELP-PTX were measured using the CCK-8 assay. Additionally, cell cycle progression and apoptosis were examined by FACS. Furthermore, an agarose-based 3D spheroid model of OC cells was used to establish the selective targeting efficacy of PTX-loaded AP1-ELP.
Results- Sanger sequencing confirmed the successful incorporation of maleimide-reactive cysteine residues into ELP polymers. MALDI-TOF, TEM, and DLS analyses demonstrated stable conjugation of the drug to the polymer. IL-4R expression in SKOV-3 and OVCAR-3 via FACS showed positivity for the receptor. Binding assays with Alexa-488-labelled ELP/AP1-ELP showed enhanced binding to IL-4R-expressing cells for the AP1-functionalized polymers compared to the non-functionalized ELP. Cytotoxicity assays revealed that AP1-ELP-PTX exhibited relatively lower IC50 values, indicating stronger anti-cancer activity compared to ELP-PTX. FACS-based analysis of the cell cycle and apoptosis further confirmed the higher cytotoxicity of AP1-ELP-PTX. Moreover, 3D spheroid cultures of OC cell lines established the significance of AP1-based targeting, displaying superior cytotoxicity in comparison to ELP-PTX.
Conclusion- In this study, we demonstrate the potential of AP1-functionalized ELP in the selective delivery of PTX in ovarian cancer. AP1-ELP exhibits superior cellular association, facilitating improved cytotoxic ability for the appended drug, PTX. Further evaluation of the AP1-ELP-PTX selective delivery ability *in vivo* is required for full realization of the AP1-ELP polymer as a delivery vehicle.

#7337 Development of novel anti BCMA as a low cost adoptive cellular therapy candidate in multiple myeloma.

Ashna Gupta, Gunjan Dagar, Ravi Chauhan, Kalpana Luthra, Mayank Singh

Medical Oncology, All India Institute of Medical Sciences, New Delhi, India

Background: Multiple myeloma (MM) involves the proliferation of malignant plasma cells (PCs) in the bone marrow (BM), leading to excessive monoclonal immunoglobulins in patients' blood and urine. The use of monoclonal antibodies (MoAbs) as immunotherapies in MM treatment has significantly improved outcomes. However, MM remains incurable for most patients due to the emergence and evolution of drug-resistant clones. BCMA (B Cell Maturation Antigen), overexpressed in MM, is being explored as a target for antibody-based and cellular therapies.
Method: BCMA expression in MM patients was quantified via RQ-PCR, and soluble BCMA levels were measured using ELISA to analyze BCMA dynamics in this cohort. The extracellular domain (ECD) of BCMA was cloned, sequenced, and expressed in the Expi293 system, with characterization confirmed through SDS-PAGE. To generate anti-BCMA ECD antibodies, mice were immunized with the purified ECD protein , leading to the development of hybridoma cells. These were purified and validated through western blotting and other assays to identify top-binding clones. The highest-affinity clone was purified using a protein A IgG purification kit. Molecular docking and dynamic simulations were then conducted to determine the BCMA ECD epitope/paratope targeted by our antibody.
Results: We analyzed BCMA expression in multiple myeloma (MM) patients and observed elevated mRNA levels and increased serum BCMA, both linked to poor treatment outcomes. BCMA was validated as a promising therapeutic target, and the BCMA ECD protein was successfully expressed in a eukaryotic system, facilitating hybridoma generation. From this, 20 unique clones were developed and screened via ELISA for optimal binding to the BCMA ECD protein, with the clone 9C4 emerging as the lead candidate. Molecular docking revealed four novel epitopes (S, Q, N, E) distinct from previously identified ones. Our antibody demonstrated superior binding, interacting with 23 BCMA residues compared to 12-16 residues targeted by existing antibodies. The ScFv sequence of the 9C4 clone was incorporated into a second-generation CAR construct. This novel Anti-BCMA CAR was successfully expressed on T cells, enabling the development of CAR-T cells for advanced therapeutic applications.
Conclusion: Our findings confirm BCMA as a key target in multiple myeloma, demonstrated by the successful development of the high-affinity 9C4 antibody. Incorporating the 9C4 ScFv into a second-generation CAR construct establishes a foundation for developing a novel academic Anti-BCMA CAR-T cell therapy for multiple myeloma.

To better understand the molecular mechanisms of drug resistance to CDK4/6 inhibitors (CDK4/6i) and inform precision medicine strategies, we retrospectively analyzed a multi-omics dataset of 400 HR+/HER2- mBC patients who received CDK4/6i plus endocrine therapies in routine clinical practice, including 200 pre-treatment (Pre), 227 post-progression (Post) samples. Integrative clustering analysis identified three subgroups of tumors harboring different drug resistance mechanisms: ER driven, ER co-driven and ER independent. The ER independent subgroup increased the most in prevalence from 4% pre-treatment to 23% post-progression and is characterized by down-regulation of estrogen signaling and enrichment of drug resistance markers including *TP53* and *RB1* mutations, Basal-like and Her2-like subtypes and *CCNE1* over-expression. We deconvoluted bulk tumor expression profiles to derive cancer-specific expression (CSE) profiles for investigating tumor intrinsic mechanisms that give rise to ER independent drug resistance. We then performed trajectory inference analyses often used in single-cell transcriptomics on CSEs and identified a latent pseudotime variable strongly correlated with ER independence and disease progression. Elastic principal graph (EPG) analysis further revealed bifurcated evolutionary trajectories for drug resistance that correspond to ER-dependent vs. ER-independent mechanisms. Using elastic net models trained on in vitro CRISPR knockout screen data, we predicted a shift in therapeutic dependency on *ESR1* and *CDK4* among ER-dependent tumors to *CDK2* among ER-independent tumors. These predictions were experimentally validated using genetically modified isogenic models.

Gold nanoclusters (AuNCs), commonly stabilized by thiol groups, hold significant promise for cancer theranostics, where their small size enables efficient renal clearance, and their atomically precise structures offer potential for drug-like properties [1-2]. N-heterocyclic carbene (NHC) ligands further enhance the versatility of AuNCs, introducing unique cluster compositions and improved stability [3]. Recently, NHC-protected AuNCs have emerged as tunable, emissive platforms with exceptional stability and photoluminescence, making them ideal candidates for applications in fluorescence imaging and photodynamic therapy [4]. In our work, we synthesized ultra-small bis-NHC-protected Au13 nanoclusters with π-extended aromatic systems, observing a correlation between increased structural rigidity and both high fluorescence quantum yield (57%) and reactive oxygen species (ROS) production efficiency (7%). Extensive stability and photophysical characterizations confirmed long emission lifetimes and high optical purity, with these nanoclusters maintaining robust stability and showing low toxicity under physiological conditions. Confocal microscopy and ICP-MS analyses verified effective cellular uptake across various cancer cell lines, and upon light activation, the nanoclusters functioned as potent photodynamic therapy agents, selectively inducing cancer cell destruction. PEGylation significantly improved water solubility and biocompatibility while maintaining photonic properties. Additionally, azide functionalization on cluster wings enabled targeted ligand attachment *via* click chemistry, demonstrated with folate receptor-mediated targeting for cancer imaging. With high stability, superior photoluminescence quantum yield, efficient cellular uptake, and clickable framework, these NHC-AuNCs provide a versatile and powerful nanoplatform for advanced cancer imaging and targeted therapy.References1. #2523 Porphyrin-lipid Nanoparticle-Based Multifunctional Cancer Imaging and Therapy: From Cell to Patient.

Robert A. Weersink[1], Theo Husby[1], Ivan Kosik[1], Michael Daly[1], Jason Townson[1], Ben Motx[1], Alessandra Ruaro[1], Juan Chen[1], Christine Demore[2], Stephanie Lheureux[1], Amit Oza[1], Jonathon Irish[1], Gang Zheng[1], Brian C. Wilson[1]

[1]University Health Network, Toronto, ON, Canada,[2]University of Toronto, Toronto, ON, Canada

Background: Porphysomes (PS) are first-in-class organic porphyrin-lipid nanoparticles with unprecedented intrinsic multifunctionality that enables a range of complementary imaging, image-guided interventions and therapies. Examples are presented in a range of preclinical tumor models, including head & neck, lung and gynecological cancers, demonstrating progress towards first-in-human trials.
Methods & Results: High-density packing of the porphyrin-lipid monomers in the nanoparticle bilayer enables efficient light absorption and conversion to heat for enhanced photoacoustic imaging (PAI) and photothermal therapy (PTT). Using wide-band acoustic detection at low frequencies multispectral PAI can quantify PS concentration in tumors that span sub-mucosal disease to several cm depth. A novel method has also been developed for direct temperature mapping to monitor PS-mediated PTT delivery.
Upon structural dissociation following cell uptake, the fluorescence (FL) and photodynamic therapy (PDT) activity of the porphyrin monomers are restored. Corresponding diffuse optical spectroscopy (DOS) has measured longitudinal PS pharmacokinetics *in vivo*. This will allow identification of residual tumor during surgical resection and also serve as a component of PDT dosimetry. FL imaging of tumor-targeted PS has been demonstrated in veterinary clinical trials of oral cancer, showing efficacy in tumor localization and surgical guidance. AI-assisted spatial-frequency-domain FL imaging in particular shows promise in measuring tumor depth prior to resection and tumor extent during resection.
Attaching gadolinium to the PS lipid chains enables combined intra-operative surgical planning and guidance, using Gd-contrast MRI for pre-resection planning and higher-resolution FGS during resection. We are evaluating MR-FGS in pre-clinical models, comparing PS localization using MRI and DOS to pathology and surgical resection outcomes.
Finally, PS chelated with ^{64}Cu for PET imaging of tumors has been demonstrated in several large animal models and serves as the key modality to assess PS pharmacokinetics in first-in-human studies in advanced ovarian cancer, leading to first therapeutic trials. ^{64}CuPS imaging will also be used for planning and dosimetry of ^{67}CuPS radioisotope therapy of disseminated disease.
Conclusions: Porphysomes provide unique multifunctional imaging and theranostic capabilities for cancer detection, localization and personalized therapy, both stand-alone and combined with standard modalities.

This work is supported by the Terry Fox Research Institute (Grant 1137-04).

#2524 Lipid-based nanoparticles for the theranostic treatment of brain tumors using focused ultrasound.

Paul Cressey[1], Chris Payne[2], Amelia Claxton[1], Benedetta Arno[3], Christopher Ireson[4], Maral Amrahli[5], David Thurston[1], Antonios Pouliopoulos[2], Maya Thanou[1]

[1]Institute of Pharmaceutical Science, King's College London, London, United Kingdom,[2]School of Biomedical Engineering & Imaging Sciences, King's College London, London, United Kingdom,[3]Medicines Discovery Catapult, Macclesfield, United Kingdom,[4]Pharmidex, London, United Kingdom,[5]Apeikon, London, United Kingdom

Glioblastoma is an extremely aggressive brain tumor and currently has limited effective treatment options, with a median survival of 14 months. This low survival is partially attributed to the blood-brain barrier (BBB), especially in early-stage glioblastoma. An emerging clinically approved technology to non-invasively and transiently open the BBB is focused ultrasound (FUS) in combination with microbubble cavitation. In this study, we formulated a dual-imageable drug-loaded lipid-based nanoparticle (ActNano) and tested their efficacy against U87-MG in vitro and in vivo (subcutaneous). In addition, we performed focused ultrasound (FUS) induced BBB opening to deliver ActNano into both healthy mice brains and mice bearing orthotopic brain tumors (U87-MG). ActNano uptake was determined and quantified in vivo and ex vivo using MRI and near-infrared fluorescence (NIRF) imaging, respectively. In addition, drug uptake enhancement following FUS BBB opening in orthotopic tumours was also determined using HPLC (SN-38) and ICP MS (carboplatin). ActNano was loaded with SN-38 (1.11 ± 0.08 mg/ml) and carboplatin (0.84 ± 0.14 mg/ml). The ability of ActNano to supress tumor growth was investigated with single treatments against a U87-MG subcutaneous flank xenograft model (10 mg/kg SN-38 & carboplatin). FUS-induced BBB opening was performed in mice (peak-negative pressure = 320 kPa, number of cycles = 500, pulse repetition frequency = 5 Hz, number of pulses = 600). SonoVue microbubbles (2 ml/kg) and ActNano (8 ml/kg, 10 mg/kg SN-38) were administered intravenously during FUS treatment. T_1-weighted MRI was performed in a 9.4-T MRI 4 hours after BBB opening, to allow time for ActNano to accumulate in the brain/tumors for optimal T_1 contrast. NIRF imaging, H&E staining and drug quantification was performed on perfused and excised brains after the final time point, to confirm successful liposome delivery into the sonicated volume. ActNano was successfully formulated with both MRI and NIRF contrast. ActNano (10 mg/kg SN-38) treatment caused an increase in survival of mice with xenograft tumours when administered alone and a significant increase in survival and tumor uptake when combined with FUS. MRI and NIRF imaging confirmed localized increased uptake of ActNano where FUS-induced BBB opening was performed compared to the contralateral control side. Quantification of Gd, carboplatin and SN-38 confirmed a significant increase in drug concentration in the tumor following BBB opening. These results suggest that MRI/NIRF-tagged drug loaded lipid-nanoparticles are suitable drug carriers for the treatment of glioblastoma in combination with FUS-induced BBB opening. Future work includes evaluation of the survival benefit of ActNano in tumor-bearing mice.

#2525 Translating clinically validated antibodies into a multiplexed immunofluorescent panel for the spatial profiling of lymphoid malignancies.

Tania Pannellini[1], Fabio Iannelli[1], Valentina Tabanelli[1], Carmen De Simone[1], Roberto Chiarle[1], Samuel Aubert[2], Pedro Machado Almeida[2], Maria Giuseppina Procopio[2], Saska Brajkovic[2]

[1]Haematopathology Division, IEO - European Institute of Oncology, Milan, Italy,[2]Lunaphore, Tolochenaz, Switzerland

Lymphoid malignancies present significant diagnostic challenges due to overlapping immunophenotypic features between tumor cells and reactive background cells, complicating the distinction between indolent lymphomas and benign lymph node hyperplasia [Nicolae A, Hemato, 2024, DOI:10.3390/hemato5030026]. Moreover, some Hodgkin lymphoma (HL) subtypes, such as lymphocyte-rich (LRHL) and nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL) and certain variants of diffuse large B-cell lymphoma (DLBCL), exhibit similar phenotypic profiles despite having different therapeutic implications [PMID: 35741318]. This study aims to leverage sequential immunofluorescence (seqIF™, PMID: 37813886) for the spatial profiling of lymphoma to improve differential diagnosis and to uncover spatial patterns unique to each lymphoma subtype, providing insights into potential predictors of immunotherapy response. Here, we optimized a seqIF™ panel of 21 markers, using antibodies approved for clinical immunohistochemistry (IHC), to phenotype mature B-cell lymphomas on the COMET™ platform. This panel was applied to tissue microarrays prepared from representative cases of DLBCL, HL, indolent lymphomas, and benign lymph node hyperplasia. Each marker of the optimized panel was visually validated by certified pathologists, comparing seqIF™ results against corresponding IHC images. Computation of spatial matrix successfully identified tumor cells and reactive cells using thresholding of fluorescence intensity and cell diameter, particularly in HL and DLBCL cases that exhibited similar immunophenotypes at first glance. This enabled us to map classified cells events back to the tissue sections, allowing direct spatial correlation with stained images for a comprehensive analysis of cell distribution. Ongoing work aims at refining our lymphoma spatial profiles through the integration of spatial transcriptomics readout on the same sample cohort. Together these results highlight the potential of multiplex immunofluorescence (mIF) for the diagnostic phenotyping of lymphoma, transferring clinically validated antibodies into a mIF panel. The ability to assess both phenotypic and spatial characteristics of tumor and reactive cells will enhance our understanding of lymphoma biology and provide new insights into predictive markers for immunotherapy responses.

#2526 Development of ultrahigh sensitivity magnetic particle imaging for stem cell tracking.

Yimeng Li[1], Yu An[1], Yang Du[2], Lin Shen[3], Jie Tian[1]

[1]Beihang University, Beijing, China,[2]Chinese Academy of Sciences, Beijing, China,[3]Peking University Cancer Hospital, Beijing, China

In vivo tracking of stem cells is critical to stem cell transplantation and regenerative medicine research. Achieving long-term, non-invasive imaging of transplanted cells demands highly sensitive imaging technology. Magnetic particle imaging (MPI) is an emerging modality capable of visualizing the distribution of superparamagnetic iron oxide nanoparticles (SPIOs). Previous studies have reported that MPI can detect clusters of approximately 2500 SPIO-labeled stem cells. However, more than this sensitivity level is needed to monitor the survival, migration, differentiation, and regeneration of stem cells. To address this limitation, we developed an ultrahigh-sensitivity magnetic particle imaging (US-MPI) device capable of detecting stem cells at scales of hundreds of cells.

Through full-chain design and optimization, US-MPI maximizes the capture of SPIO signals from stem cells. Using a commercial SPIO (VivoTrax), mouse mesenchymal stem cells were labeled, and samples with varying cell numbers (ranging from 50 to 1×10^7) were tested using US-MPI and 9.4 T MRI (uMR 9.4T, United Imaging Life Science Instrument, Wuhan, China) for comparison. US-MPI demonstrated the ability to detect as few as 50 labeled stem cells in vitro and 150 cells in vivo, whereas 9.4 T MRI required at least 1×10^5 cells for detection in vitro. Thus, US-MPI exhibited a sensitivity 2,000 times higher than that of 9.4 T MRI.

The efficacy of US-MPI for stem cell tracking was further validated in a lipopolysaccharide (LPS)-induced mouse hind limb inflammation model. Eight hours after SPIO-labeled stem cells were injected intravenously, US-MPI detected strong signals on the inflamed limb, which remained significantly higher than those of the healthy limb during a 48-hour monitoring period. Post-mortem Prussian blue staining of inflamed tissues confirmed the presence of blue-stained SPIO particles, verifying that the US-MPI signals originated from labeled stem cells. These results highlight the ultrahigh sensitivity of US-MPI for stem cell tracking, providing a valuable tool for advancing stem cell research.

#2528 Bioinspired multispectral imaging for intraoperative detection of metastatic lymph nodes: enhancing precision through UV and NIR fluorescence.

Zhongmin Zhu, Yifei Jin, Brianna Hajek, Shuming Nie, Viktor Gruev

Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, Urbana, IL

Intraoperative identification of metastatic lymph nodes (LNs) remains a clinical challenge, with current techniques often leading to unnecessary removal of healthy tissue or retention of cancer-positive nodes. To address this issue, we developed a bioinspired multispectral imaging system that integrates ultraviolet (UV) autofluorescence and near-infrared (NIR) fluorescence detection. This platform mimics the mantis shrimp's unique visual system, leveraging vertically stacked photodiodes and pixelated spectral filters to achieve simultaneous imaging across the UV, visible, and NIR spectral ranges without spatial misalignment or loss of resolution. The system uses indocyanine green (ICG) as an FDA-approved NIR fluorescent probe for LN localization and UV excitation to evaluate LN status via autofluorescence. The UV fluorescence leverages endogenous biomarkers, such as tryptophan, commonly enriched in tumor-associated tissues. This dual-modality imaging approach enables real-time identification of both the anatomical location and pathological status of LNs, reducing dependence on postoperative histopathological analysis. In a clinical study involving 33 breast cancer patients, the imaging system achieved a positive predictive value of 96% and a receiver operating characteristic (ROC) area under the curve (AUC) of 89% in distinguishing metastatic from non-metastatic lymph nodes. These results were corroborated by pathology, which served as the ground truth. By providing immediate and accurate feedback to surgeons, this system has the potential to improve surgical precision, reduce unnecessary excisions, and minimize the need for follow-up procedures. Unlike traditional multispectral imaging systems reliant on mechanically rotating filters or dichroic beamsplitters, our bioinspired sensor eliminates co-registration errors and significantly reduces system complexity. Its compact design and capability to perform high-resolution imaging under challenging surgical lighting conditions make it well-suited for widespread clinical adoption. Further studies are underway to validate the system’s efficacy across different cancer types and expand its applications to other surgical scenarios. This novel imaging platform offers a significant step forward in integrating real-time molecular and anatomical imaging into intraoperative workflows, addressing critical gaps in precision oncology.

#2529 Targeted light-activable multi-agent nanoparticle for enhanced photoimmunotherapy treatment of peritoneal metastasis.

Sumiao Pang[1], Carla Arnau Del Valle[2], Robert Perttila[3], Nada Fadul[1], Dana Roque[4], Tayyaba Hasan[5], Petteri Uusimaa[3], Huang Chiao` Huang[1]

[1]University of Maryland, College Park, MD,[2]Instituto Interuniversitario de Investigacion de Reconocimiento Molecular y Desarrollo Tecnologico, Valencia, Spain,[3]Modulight Corporation, Tampere, Finland,[4]University of Maryland Baltimore, Baltimore, MD,[5]Massachusetts General Hospital and Harvard Medical School, Boston, MA

Background: Peritoneal metastasis is the result of direct shedding of tumor cells from ovarian, colorectal, and other cancers that lead to studding and growth on the peritoneal surfaces and abdominal organs. Standard chemotherapy and surgery can transiently improve symptoms, but long-term disease control and survival extension remain rare due to residual disease and treatment resistance. In the past 40 years, tremendous progress in photoimmunotherapy (PIT) has been made to treat metastasis. However, many are lost in translation due to heterogeneity in photosensitizer drug uptake and treatment response. Thus, we hypothesize that the delivery of targeted therapies with a multimodal approach for PIT and integrates well with current standards of care strategies can help overcome heterogeneous delivery and improved treatment efficacy. Our novel targeted photoactivable multi-agent liposome (TPMAL) combined with fluorescence-guided PIT was demonstrated in this newly reported study.
Methods: TPMAL consists of antibody drug conjugates (photosensitizer drug and anti-EGFR antibody) conjugated onto active-loaded liposomal surface. Female athymic nude mice (18-20 g and 4-6 weeks old) were injected intraperitoneally with 3 x 10^7 OVCAR-5 human ovarian cancer cells suspended in 2 mL of PBS. Post tumor implantation, mice were i.p. injected with TPMAL or ADC alone on Day 10. Post 24h, tumor nodules were collected and frozen with Tissue-Tek O.C.T compound at -80°C until slicing. Fluorescence and bright field imaging of whole tumor nodule slices were performed with a Lionheart™ FX Automated Microscope. The center of each tumor nodule was selected for further image analysis using ImageJ. Lastly, intraperitoneal fluorescence-guided light delivery PIT with TPMAL was performed using the ML7710 medial laser device and Modulight cloud software for survival studies.
Results: TPMAL active-loaded formulation demonstrated batch-to-batch consistency and stability was observed for up to one year. This formulation also demonstrated enhanced photosensitizer drug delivery into peritoneal tumor nodules by 1.6X and up to 616.4 µm penetration depth compared to antibody drug conjugates alone. TPMAL FGLD PIT combination therapy with adjuvant chemotherapy also demonstrated enhanced long-term survival by 240X compared to no treatment and chemotherapy alone groups.
Conclusions: Our novel targeted photoactivable multi-agent liposome (TPMAL) combined with fluorescence-guided PIT was investigated for its translational potential and therapeutic efficacy by (1) developing an active-loaded liposomal formulation, (2) studying tumor nodule penetration depth of TPMAL, (3) understanding tissue optical property via oxygenation and how it may affect PIT using the ML7710, and (4) enhancing long term therapeutic efficacy compared to monotherapy treated groups in a mouse peritoneal carcinomatosis model.

#2530 Multispectral imaging system for intraoperative molecular imaging with two near-infrared fluorescent probes.

Brianna Hajek, Zhongmin Zhu, Viktor Gruev

Electrical and Computer Engineering, University of Illinois at Urbana-Champaign, Urbana, IL

Image-guided surgery using near-infrared (NIR) fluorescent probes offers surgeons real-time guidance to locate tumors and sentinel lymph nodes. The past decade has seen a proliferation in NIR fluorophore development, with options for targeting different tumor markers and tissue types. Using multiple fluorophores could improve tumor detection sensitivity and specificity, allow simultaneous tumor imaging and lymph node mapping, or distinguish tumors from vital anatomical structures. Current imaging systems, however, are limited to detecting a single NIR probe. This has motivated the development of a novel multispectral camera, capable of simultaneously imaging multiple NIR fluorophores with similar emission spectra that are excited with a single excitation source. The camera features a unique spectral filter array, with filters to capture both visible light and nine overlapping spectral bands in the NIR, monolithically integrated with three vertically stacked photodiodes. The result is a compact instrument that can produce overlaid visible and NIR images without co-registration error, while sampling the NIR spectrum in a nuanced manner to distinguish similar NIR fluorophores. The pixelated filters are arranged in a 2x2 “super-pixel” pattern, comprising a visible filter and three NIR filters with several passbands. The NIR filters produce nine spectral features, which are used to classify fluorescent spectra using machine learning. Initial experiments were performed to demonstrate the camera’s ability to differentiate two NIR fluorophores in vials. Combinations of indocyanine green (ICG), pafolacianine, and JAS239 in 10% FBS solutions were mixed with a range of volumetric ratios. The fluorophore concentrations were chosen to have similar overall fluorescence intensity, indistinguishable by a traditional NIR camera. Gradient boosting classifiers were trained to predict the dye or combination of dyes that produced the fluorescence at each pixel in an image. Pure ICG and pafolacianine were classified with 97% accuracy and their mixtures with 77% accuracy. ICG and JAS239 were discriminated with 99% accuracy, and mixtures of these two dyes with 81% accuracy. The results demonstrate that our single-chip multispectral imager captures sufficient information to distinguish two NIR fluorescent probes, a task unachievable by current instruments. Future steps will test the discrimination capabilities in more complex samples, moving closer to clinical applications.

#2531 Novel staining method for visualization, isolation and processing of intracranial brain tumors.

Sonia Jain[1], Anders Herfindahl-Quint[1], Caroline D. Doherty[2], Wenjuan Zhang[3], Danielle M. Burgenske[1], Jann N. Sarkaria[1]

[1]Department of Radiation Oncology, Mayo Clinic Cancer Center Minnesota, Rochester, MN,[2]Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic Cancer Center Minnesota, Rochester, MN,[3]Department of Pharmaceutics, University of Minnesota, Minneapolis, MN

Background and Objective: Glioblastoma (GBM) is most common primary brain tumor with dire need of novel therapeutics. Studies with intracranial tumors are required for robust characterization and development of novel drugs for brain cancer. Tumor harvest and processing is an important aspect to study pharmacokinetics, pharmacodynamics, drug delivery, and tumor evolution. Typically, delineating and dissecting tumor from surrounding brain for varied downstream processes is dependent on the distinct morphology of the tumor and/or expression of fluorescent marker. However, genetic modification of the tumor cells for the expression of fluorescent protein is not always possible, especially for patient-derived xenograft (PDX) tumor models. Thus, we have developed a dye-based staining method to confidently visualize tumor in the brain and assessed usability of isolated tumors for drug and DNA analysis.

Methodology: Whole brains were harvested from mice with intracranial Mayo GBM PDX tumors and stored at -80°C freezer. Few days prior to staining, brains were transferred to -20°C freezer. Brain was cut into 1 mm thick coronal sections and transferred onto glass slides. Slices were covered with toluidine blue (TB) solution (0.05 to 10 mg/mL) for 45 s. Excess stain solution was removed, and slices were observed under white light. Regions of tumor became more transparent, while normal brain remained opaque. This enabled dissection of tumor from normal brain for downstream analyses.

Results: TB concentration (0.05 to 10 mg/mL) was optimized to stain 1 mm thick sections of fresh frozen brain, and the best contrast between tumor to normal brain was observed at 0.1-0.3 mg/mL. TB aided differential visualization of tumors in several PDX models - GBM12, GBM43, GBM39 and GBM108 - suggesting broad applicability. To evaluate the accuracy of TB staining, brain with PDX tumor transduced with pSINeGFP/fLuc2 was observed by both TB staining and eGFP fluorescence. This analysis demonstrated excellent concordance across 6 animals with three distinct PDX models. Genomic DNA was isolated from tumor dissected under TB guidance and analyzed by PCR for primers specific for murine vs human PTGER2. 50-70% of the DNA in tumor samples was detected to be of human origin while normal brain tissue had 90-95% of the mouse DNA highlighting the specificity of TB stain for tumor detection. Tumors from drug treated GBM108 PDX were isolated under TB guidance and comparable drug levels were detected by LC-MS/MS as analyzed in GFP-assisted tumor samples.

Conclusion: Staining fresh frozen thick brain sections with toluidine blue enables visualization of tumor from normal brain regions that is compatible with varied downstream processes. Development of such staining assays can help faster and easier tumor processing and is not dependent on genetic modification of tumor cells prior to experimentation.

#2532 Utilization of longitudinal ultrasound imaging as a novel pharmacodynamic marker of graft versus host disease progression in mice.
