Introduction: Currently, risk of recurrence in ER+ HER2- breast cancer is determined by pathological stage and histological grade, in combination with a Gene Expression Assay (GEA) including Oncotype, Prosigna, Breast Cancer Index and EPClin. Higher risk disease justifies systemic therapy beyond endocrine therapy alone. GEAs need improving as these assays can misclassify risk, i.e., recurrences still occur in patients assigned low risk. Thus, approaches to identify high-risk cases more accurately would reduce under-treatment. Herein we explore whether somatic mutation and copy number data from an established 83 gene targeted sequencing panel can improve risk stratification based on clinical factors and GEA alone.

Methods: Targeted gene-sequencing (TGS) was undertaken in the Anastrozole (A) or Tamoxifen (T) alone or Combined (C) (ATAC) adjuvant trial for estrogen receptor-positive (ER+) breast cancer to identify mutations and copy number variants that are prognostic variables independent of clinical factors and GEA-based risk assessments. Patients in the combination arm were excluded for this study. Forward Stepwise Cox Regression was applied to identify candidates, whose prognostic effects were validated in independent datasets.

Results: Investigation of prognostic interactions of gene alterations with four GEA mentioned above identified three adverse gene deletions (*del*) including: 1) MAGI3*del* at chr1p.13.2 (HR=2.43-2.86, p-value< 0.005), a newly assigned tumor suppressor, that associated with other adverse deletion events on chr1p13.2-36.22 including ARID1A/JAK1/mTOR; 2) MET*del* on chr7q.31.2 (HR=1.86-2.15; p<0.05), adjacent to the tumor suppressor CAV1; and 3) RB1CC1*del* on chr8q.11.23 (HR=3.41-4.30; p<0.05), also a putative tumor suppressor. Potential clinical impact included high-relapse risk reassignment for Oncotype/Prosigna/Breast Cancer Index (BCI)-defined low and/or intermediate-risk cases if MAGI3*del* was present, and high-risk reassignments of BCI intermediate-risk cases if any of MAGI3/MET/RB1CC1 deletions were present, with lower-risk reassignment if absent.

Conclusions: Copy number variation (CNV) analysis identified three high-risk deletion events (MAGI3, MET, RB1CC1) in ER+ HER2- breast cancer that predicted worse clinical course than predicted by diagnostic-grade gene expression assays. Thus, the incorporation of CNV-detection into prognostic algorithms has the potential to reduce under-treatment due to low/intermediate-risk mis-assignment. These data are proof-of-concept that prognostication in ER+ HER2- disease can be improved by TGS, while also identifying under-studied gene deletions underlying the highly variable relapse trajectories that typifies ER+ breast cancer.

#3372 Building precision oncology via real-world data standardization, privacy preserving infrastructures, and collaboration among IT and clinical experts: The DIGICORE network experience.

Alberto Traverso[1], Giovanni Tonon[2], Piers Mahon[3], Gennaro Ciliberto[4], Andre Dekker[5], Xose Fernandez[6], **Adriana Albini**[7]

[1]Department of Artificial Intelligence, Faculty of Medicine, San Raffaele Hospital, Milano, Italy,[2]School of Medicine, Libera Universita Vita-Salute San Raffaele, Milano, Italy,[3]DIGICORE, Bruxelles, Belgium,[4]IRCCS National Cancer Center Regina Elena, Roma, Italy,[5]Department of Radiation Oncology (Maastro, GROW School for Oncology and Reproduction, Maastricht University Medical Centre, Maastricht, Netherlands,[6]DigiONE, IQVIA Cancer Research, Zaventem, Belgium,[7]IRCCS IEO - European Institute of Oncology, Milano, Italy

Precision oncology necessitates personalized treatments maximizing efficacy while minimizing toxicity. Real-World Data (RWD) presents a powerful resource to achieve this, offering insights to clinical trials and facilitating cross-national comparisons of treatment effectiveness. However, significant obstacles persist: data sparsity, unstructured formats, and limited digitization; complex and internationally diverse data privacy regulations; heterogeneous IT infrastructures and expertise across institutions. The DIGICORE (Digital Institute for Cancer Outcome Research) consortium—a network of European hospitals and companies—directly addresses these challenges. Its initiatives, among the DIGIONE research plan, include: (1) the definition of a set of minimum data elements related to electronic health record systems required to setup RWD studies (MEDOC) (2) a standardized survey assessing the digitalization of these key cancer-related data elements; (3) AI-based tools such as natural language processing to support data digitization; (4) a federated learning infrastructure for privacy-preserving clinical research; (4) the development of standards for comprehensive cancer center infrastructure, (5) the establishment of disease-focused working groups to foster collaboration, and (6) dedicated training programs for clinicians to enhance their IT knowledge. To date, three projects have been completed, with additional 10 projects underway. DIGICORE's multi-faceted approach promises to unlock the transformative potential of RWD in advancing personalized cancer care. (https://digicore-cancer.eu/) 1. Mahon P, et al. Study Name	Initiating countries	Disease	Clinical question(s)	Sample size
Analysis of the number of new primary cancers diagnosed and 12-month survival changes during COVID-19 lockdowns	Belgium Germany Italy Norway UK The Netherlands	Pan cancer	To Investigate the impact of COVID19 lockdowns on new cancer diagnoses. To estimate 12-month survivals.	124.682 patients
A disease natural history and outcomes study with care quality assessment in metastatic non-small cell lung cancer	Germany Italy Norway UK The Netherlands	Lung cancer	To investigate the survival of patients according to the location of the metastases. To describe treatment patterns by line of therapy prescribed to patients: 1. All the cohort 2. Subgroups by locations of the metastases To benchmark care quality between centers based on ESMO recommendation.	1294 patients
A disease natural history and outcomes study with care quality assessment in HR+/HER2- metastatic breast cancer	Belgium Italy UK	Breast cancer	To Describe the demographic, clinical, molecular phenotypes, and next-generation sequencing (NGS) results for patients with HR+/HER2– metastatic breast cancer (mBC): Cohort A: HR+/HER2– de novo mBC, Cohort B: HR+/HER2– recurrence after locoregional disease. To Compare HER2-low versus HER2-zero within both cohorts. .	5k-10k patients (estimate)

#3373 Event-free survival among polycythemia vera patients treated with novel JAK inhibitors: a comparative analysis using real-world genomic data and electronic health records.

Stacy Charlerie[1], Nathan Lee[1], Jaime Smith[1], **Angela X. Qu**[2]

[1]Real World Research, PAREXEL International, Research Triangle Park, NC,[2]Translational Medicine, PAREXEL International, Research Triangle Park, NC

Known as a chronic myeloproliferative neoplasm, Polycythemia Vera (PV) is a rare blood cancer characterized by an abnormal increase in the number of red blood cells. PV is associated with increased risk of thrombotic events and mortality as well as other complications, including splenomegaly, macrovascular and microvascular events (e.g., transient ischemic attacks, erythromelalgia, ocular migraines), and aquagenic pruritus. The exact cause is unknown, but genetic mutations associated with a protein called Janus kinase 2 (JAK2) are often involved, and as such genomic testing is often part of the diagnostic journey and treatment options. Real-world data (RWD) and real-world evidence (RWE) have emerged as powerful tools for unlocking the potential of healthcare data generated in routine clinical practice. In oncology, RWD has been instrumental in multiple areas including 1) Discovering novel biomarkers by uncovering associations of genetic, molecular, and clinical outcomes that predict treatment response and disease progression; 2) Identifying comorbidities by recognizing coexisting conditions that may impact treatment outcomes and patient management 3) Optimizing treatment pathways by identifying effective treatment sequences and combinations for specific patient populations; 4) Enriching clinical trials by selecting the most appropriate patient populations for clinical trials and accelerating drug development. In this study, we aim to leverage electronic health records (EHR) data to conduct a comparative analysis of event-free survival (EFS) in PV patients on novel JAK inhibitor therapy versus other standard of care first-line treatments. By utilizing EHR data, we can identify key clinical factors associated with EFS and potentially develop predictive models to inform personalized treatment strategies. Additional exploration of real-world genetic/genomic data for insights to predict thrombotic events or mortality is forthcoming. This research has the potential to improve the management of PV patients and reduce the burden of disease. We will present our findings with some preliminary data, describe the data sources used, outline the technologies leveraged, and conclude with lessons learned.

#3375 Demographic characteristics and incidence of cardiovascular events, infections and cytokine response syndrome (CRS) in patients treated with chimeric antigen receptor (CAR) T cell therapy: a nationwide analysis.

Himil Mahadevia[1], Karnav Modi[1], Akhil Jain[2], Furha Cossor[3], Deepthi Vodnala[3], Taiyeb Khumri[3]

[1]University of Missouri - Kansas City School of Medicine, Kansas City, MO,[2]University of Iowa, Iowa City, IA,[3]Saint Luke's Hospital of Kansas City, Kansas City, MO

Introduction: CAR-T cell therapy represents a significant advancement in the management of relapsed/refractory hematological malignancies. Adverse events include cytokine release syndrome (CRS), infections, and neurological and cardiovascular events. Though real-world data from referral centers regarding the uptake of CAR-T cell therapy in different populations and the incidence of various adverse events are available, we used the National Inpatient Sample (NIS) with weighted analysis to provide contemporary data representing national estimates for patients and complications profile with CAR-T therapy.
Methods: A retrospective study was conducted by obtaining patients who underwent CAR-T cell therapy using ICD-10-PCS procedure codes (XW033C3, XW043C3, XW23346, XW24346, XW23376 and XW24376) from NIS 2021 dataset. Demographic characteristics, as well as the incidence of infectious complications and adverse cardiovascular events, were obtained using ICD-10-CM diagnostic codes. Different grades of CRS were identified using specific ICD-10 codes (Grade 1-5: D89.831-D89.835).
Results: Of 2,235 patients who underwent CAR-T cell therapy between January 2021 and December 2021, 64.2% were male, 73.5% identified as Caucasian, 12.3% as Asian and 5.5% as African American. 50.6% had private insurance, 36.5% had Medicare, and 6.7% had Medicaid. Most patients had lymphomas (64.9%), followed by myelomas (17.9%) and leukemias (13%). Acute myocardial infarction and stroke were documented in 0.4% of patients each. Notably, 21.7% of patients experienced cardiac arrhythmias, and major cardiovascular events were recorded in 4.3% of the cohort. Additionally, 4.9% of patients were diagnosed with pneumonia, while sepsis occurred in 7.6% of patients, and 3.4% experienced septic shock. Moreover, 1.1% of patients developed HLH. CRS was observed in 59.3% of the patients. Among those with CRS, grade 1 and grade 2 reactions were reported in 32% and 21% of patients, respectively, while grade 3 and grade 4 reactions were noted in 4.7% and 2% of patients, with no cases of grade 5 identified. The mean total cost of hospitalization was 324,972.8 USD. The overall in-hospital mortality rate was found to be 3.4%.
Conclusion: In our study, most patients were males, and the majority belonged to the Caucasian ethnicity. Over half of the patients had private insurance. CRS was common but mostly low-grade intensity. Infections present a considerable challenge with CAR-T therapy, making early identification and appropriate antimicrobial treatment critical. Adverse cardiovascular events were frequently reported among patients receiving CAR-T cell therapy, underscoring the necessity for close cardiac monitoring to detect such events and to implement comprehensive care strategies effectively.

#3376 Real-world cancer treatment patterns and their effects in older adults with lung cancer: a SEER-MHOS analysis.

Shuyan Qiu[1], Yueyi Xu[1], Laura Pinheiro[2], Jialin Mao[2], Yushu Shi[2], Yiwey Shieh[2], Christine Garcia[2], Eunji Choi[2]

[1]Mailman School of Public Health, New York, NY,[2]Weill Cornell Medicine, New York, NY

Introduction: Lung cancer primarily affects older adults, with a median diagnosis age of 71. Due to high competing death in older adults, the feasibility and efficacy of treatment may differ from clinical trials. This study examined treatment patterns and mortality outcomes in older adults with lung cancer using real-world analytic methods.
Methods: We used SEER-Medicare Health Outcomes Survey (MHOS) to identify adults aged ≥65 years with non-small cell lung cancer (2007-2019). The study had 2 primary outcomes: (1) uptake for first-course treatments, and (2) lung cancer survival. Treatment uptake was calculated by age, frailty at diagnosis (assessed with a cancer-specific frailty index from MHOS), and neighborhood socioeconomic status (nSES) across disease stages. We used inverse probability of treatment weighting (IPTW) and clone-censoring methods in multivariable Cox models to mitigate selection and immortal time biases.
Results: In 11,443 patients (mean age, 77.3 years; 72% White; 47% distant-stage), treatment uptake varied by age, frailty, and nSES. Surgery rates for localized-stage patients declined with age (67% vs. 16% for ages 65-69 vs. ≥85, $P<10^{-3}$), as did chemotherapy rates for distant-stage patients (58% vs. 21% for ages 65-69 vs. ≥85, $P<10^{-3}$). Patients who received surgery or chemotherapy were less frail at diagnosis ($P<10^{-3}$) compared to those who did not, while frailty score was comparable by radiotherapy. Survival benefits for all three treatments were not observed in patients aged ≥85 using both IPTW and clone-censoring models, though IPTW-only models suggested survival benefits, indicating residual bias. Conclusion: Age at diagnosis, frailty, and nSES influence treatment uptake in older adults with lung cancer. Rigorous real-world analytic methods indicate limited survival benefits from intensive treatments for patients≥85 years, underscoring the need for tailored treatment decision-making in this vulnerable population.

Table. Association between treatment and lung cancer survival

Real-world Analytics	Age at LC	Surgery (vs. no surgery)		Chemotherapy (vs. no chemotherapy)		Radiation (vs. no radiotherapy)	
		aHR	(95% CI)	aHR	(95% CI)	aHR	(95% CI)
IPTW	65-74	0.34	(0.31-0.37)*	0.74	(0.69-0.80)*	0.86	(0.81-0.92)*
	75-84	0.40	(0.38-0.43)*	0.88	(0.84-0.93)*	0.86	(0.82-0.90)*
	85+	0.62	(0.56-0.68)*	0.75	(0.67-0.83)*	0.73	(0.67-0.80)*
IPTW + Clone-censoring	65-74	0.56	(0.52-0.59)*	1.08	(1.02-1.14)*	0.84	(0.80-0.89)*
	75-84	0.61	(0.59-0.63)*	1.12	(1.07-1.16)*	0.88	(0.85-0.92)*
	85+	0.97	(0.90-1.04)	1.08	(1.00-1.16)*	1.00	(0.93-1.08)

Abbreviations: IPTW, inverse probability of treatment weighting; aHR, adjusted hazard ratio; CI (confidence interval); LC (lung cancer); * denotes *P*<0.05; Hazard ratios were adjusted for key prognostic factors.

#3377 The impact of gender and age on real-world progression-free survival (rwPFS) in patients without a smoking history with NSCLC treated with checkpoint inhibitors.

Hye Sung Kim[1], Li Zhang[2], Margie L. Clapper[2], Jill Hasler[2], Tia Nicolas[2], Hossein Borghaei[2], Martin J. Edelman[2], Joseph Treat[2], J. Nicholas Bodor[2]

[1]Temple University Hospital, Philadelphia, PA,[2]Fox Chase Cancer Center, Philadelphia, PA

Introduction: While the emergence of checkpoint inhibitors has changed the treatment landscape of non-small cell lung cancer (NSCLC), most never-smokers derive little benefit. This lack of benefit is due to many never-smokers possessing oncogene-driven cancers (e.g. EGFR, ALK, ROS1, etc.) that have “cold” tumor microenvironments (TME) that poorly respond to anti-PD-1(-L1). However, being female and young are also associated with inferior responses to immunotherapy in several cancer types, possibly due to these patients having more endogenous hormones that may be immunosuppressive. To our knowledge, the impact of gender and age on the efficacy of anti-PD-1(-L1) has not been studied in NSCLCs that occur in never-smokers. Such an investigation is particularly relevant given the frequency of this diagnosis in young women.

Methods: A nationwide de-identified EHR-derived database (Flatiron Health) was used to evaluate patients without a smoking history with advanced NSCLC treated with single-agent anti-PD-1(-L1). De-identified data originated from approximately 280 US cancer clinics (~800 sites of care). Kaplan-Meier curves estimated rwPFS (based on clinician documentation of progression) in months (m) with gender and age comparisons evaluated using the log-rank test and multivariable Cox regression.

Results: In our cohort of 1535 patients, 1029 (67%) were female, 836 (55%) had a tumor oncogene, 144 (9%) were <55 years of age (yoa), 782 (51%) were 55-75 yoa, and 609 (40%) were >75 yoa. Real-world PFS did not differ between females (2.9 m, 95% CI 2.8-3.1) and males (2.8 m, 95% CI 2.7-3.2) (p=0.52). However, among female patients, those < 55 yoa had shorter rwPFS (2.1 m, 95% CI 1.9-2.7) than females 55-75 yoa (2.9 m, 95% CI 2.7-3.2) and >75 yoa (3.2 m, 95% CI 2.9-3.6) (p=0.001). In a Cox regression model that adjusted for performance status, race, therapy line, and presence of a tumor oncogene, female patients >75 yoa (HR 0.74, 95% CI 0.58-0.95) and 55-75 yoa (HR 0.82, 95% CI 0.65-1.03) were at lower risk for disease progression as compared to females < 55 yoa (reference group). Differences by age in rwPFS were not observed in males.

Conclusion: Our analysis revealed that among women without a smoking history, young patients < 55 yoa with NSCLC experience especially poor survival with anti-PD-1(-L1). Research is needed to elucidate the biological mechanisms underlying this disparity. While data on menopausal status were not available for this analysis, most women < 55 yoa are pre- or perimenopausal. The contribution of greater levels of endogenous estrogens to immunosuppression in the lung TME warrants further study. (Supported by a Flatiron-FCCC Academic Partnership Research Grant Award)

CLINICAL RESEARCH: Real-World Data and Real-World Evidence: Clinico-Genomics
Poster Session

#3381 Patient characteristics and recommendations from a multi-institution Precision Oncology Tumor Board.

Aseem Aseem, Noor Naffakh, Michael Weinfeld, Shikha Jain, V K Gadi, Kathleen Kennedy, Nan Sethakorn, Sarah Khan, Natalie Reizine, Frank Weinberg, Ryan Nguyen

University of Illinois at Chicago, Chicago, IL

Background: The Precision Oncology Tumor Board (POTB) at the University of Illinois Chicago (UIC) advances cancer treatment through molecular profiling and personalized recommendations. Studies link molecular tumor boards to improved outcomes. POTB integrates multidisciplinary expertise across institutions to provide therapeutic and trial recommendations based on clinical and genomic data. The PROMOTE (PRecision Oncology: Measuring Outcomes and Treatment Effectiveness) study is a retrospective analysis of cases presented at the UIC POTB and here we report the patient demographics, clinical characteristics, and recommendations from the first two years of this program.
Methods**:** We retrospectively analyzed attendee specialties, patient demographics, tumor characteristics, and treatment recommendations from cases reviewed (September 2022-October 2024). Descriptive statistics captured data on age, sex, race, ethnicity, cancer type, stage, insurance, diagnosis timing, biomarker class, FDA approval status, recommendation type, and trial options.
Results: A total of 120 healthcare professionals participated across 22 POTB sessions, averaging 29 attendees per session, including medical oncologists and hematology/oncology fellows (53%), pharmacists (33%), pathologists, genetic counselors, industry partners, and trainees. Of the 81 cases presented, the mean patient age was 59 years, with 33% aged >64 years and 58% aged 40-64 years. Of the patients, 49% were female, 35% were Black, 40% White, and 19% Hispanic. The most common cancer types included lung (33%), genitourinary (19%), and gastrointestinal (14%), with 79% of cases involving stage IV disease. Treatment recommendations included clinical trial recommendations (68% of cases) and FDA-approved therapies outside their labeled indications (56% of cases). Targeted therapies were recommended in 50% of cases, followed by additional testing (16%) and immunotherapy (12%). Germline testing was completed or recommended in 62% of cases.
Conclusions: This retrospective analysis highlights one of the most racially and ethnically diverse molecular tumor board patient cohorts reported in the literature. Recommendations from UIC POTB demonstrate the feasibility of integrating precision oncology into practice, with implications for expanding access to targeted therapies and clinical trials for underrepresented populations. Future efforts will focus on linking recommendations to outcomes, refining treatment strategies, and enhancing equity in precision oncology.

#3382 The predictive effect of gBRCAs mutations on rates of pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) in Chinese breast cancer (BC) patients: a single-center study in Xijing Hospital, Northwest China.

Jing Fan[1], Ting Wang[1], Jiajun Ding[1], Yidi Wang[1], Mengxuan Li[1], Huimin Meng[1], Jing Kong[1], Haoyi Zi[1], Qingxia Li[1], Shuai Wang[1], Fei Yao[2], Changbing Zhu[2]

[1]Department of Thyroid, Breast and Vascular Surgery, Xijing Hospital, Air Force Medical University, Xi'an, China,[2]Department of Medicine, Amoy Diagnostics Co., Ltd., Xiamen, China

Background and Objective: The link between germline *BRCA* (gBRCA) mutations and the effectiveness of neoadjuvant therapy (NAC) in early-stage breast cancer (BC) is debated. It prompted us to conduct this retrospective study to determine NAC efficacies according to gBRCA variant status overall or further by BC molecular subtypes.

Methods: A cohort of 452 female patients receiving standard NAC and following surgery with gBRCAs mutational signatures were enrolled in this study. Pearson Chi-square test, continuous correction chi-square test and fisher's exact test were used to explored the association between gBRCA1/2 mutation and the response to NAC.

Results: Overall, 131 patients with triple negative breast cancer (TNBC), 215 patients with Luminal B ($HER2^-$ or $HER2^+$) BC as well as 57 $HER2^+$ patients were included. All enrolled patients classified as stageII-III. 60.6% (20/33) of gBRCA1 mutation ($gBRCA1^{mut}$) patients, 28.6% (8/28) of gBRCA2 mutation ($gBRCA2^{mut}$) patients and 39.6% (155/391) of noncarriers patients achieved pathological complete response (pCR) (p=0.049). For achieving RCB 0/I, the rates were 69.7% (23/33), 39.3% (11/28) and 50.4% (197/391) respectively (p=0.045). Among $HER2^-$ patients, $gBRCA1^{mut}$ patients were more likely to be pCR compared to non-$gBRCA1^{mut}$ carriers (53.8% vs. 25.2%, p=0.005), so as in $gBRCA1/2^{mut}$ patients compared to non-$gBRCA1/2^{mut}$ carriers (42.9% vs. 25.7%, p=0.023). In Luminal B ($HER2^-$) patients, only $gBRCA1^{mut}$ was associated with better pCR rate (57.1% in $gBRCA1^{mut}$ patients compared to 13.9% in non-$gBRCA1^{mut}$ patients, p=0.013). While in TNBC patients, pCR was more frequent in $gBRCA1/2^{mut}$ patients compared to noncarriers (60.7% vs. 37.9%, p=0.034). Additionally, in clinically node-positive patients, in spite of the difference was not statistically significant, $gBRCA2^{mut}$ patients tended to be worse response to NAC compared to non-$gBRCA2^{mut}$ patients (0.0% vs. 29.3%, p=0.077).

Conclusion: Though the outcome of a single-center study with small sample size was restricted, it could be found that $BRCA1^{mut}$ patients had better response to NAC, while $BRCA2^{mut}$ patients achieved less from NAC.

#3383 Clinical and genomic utility of smoking pack years in a real world cohort.

Tejiri E. Agbamu[1], Kelly Pekala[2], Xinran Bi[3], Xuechun Bai[1], David Ma[1], Nicholas Pickersgill[1], Michele Waters[1], Jian Carrot-Zhang[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Multicare Urology, Puyallup, WA,[3]Princeton University, Princeton, NJ

Introduction: In this work, we employ pack years (PYs) to characterize the relationship between smoking exposure and clinical and genomic features in a diverse clinical genomic cohort of lung (NSCLC) and bladder cancer (BLCA) patients.
Methods: Clinical annotations including sex, age and stage at diagnosis were extracted from electronic health records (EHR) for 6,441 NSCLC and BLCA patients who underwent clinical genomic sequencing at Memorial Sloan Kettering Cancer Center after 2014. PYs were extracted from EHR using regular expressions and manually curated. To account for the non-parameteric distribution of PYs we split PYs into four groups: 0(0), 1(0-20), 2(20-40), and 3 (>40). Age at diagnosis was split into 4 groups: Under 45, 46-65, 66-80, and Over 81. Categorical variables such as age, sex, and stage were evaluated by wilcoxon rank-sum test. While continuous variables such as tumor mutational burden (TMB) and fraction genome altered (FGA) were tested by linear regression controlling for age, sex, and stage. Overall survival (OS) was measured from time of sequencing to last follow up and evaluated with a Cox proportional hazards model (CoxPH). Genetic ancestry was determined from MSK-IMPACT sequencing data using reference populations from the 1000 Genomes project, including European (EUR), African (AFR), East Asian (EAS). Ancestry was assigned based on proportion greater than 80%
Results: Our cohort consisted of 4,953 NSCLC and 1,488 BLCA patients including 3,975 former/current smokers and 2,466 never smokers. There was a significant difference among age and PYs in groups 46-65 and 66-80 in NSCLC (Mdn=1.5 v 20;p <0.0001) and BLCA (Mdn=0 vs 6;p <0.0001). Male patients also tended to have a higher PYs in comparison to female patients in NSCLC (Mdn=9 vs 23;p<0.0001) and BLCA (Mdn=0 vs 6; p<0.05). We did not observe a significant association between FGA and PYs in NSCLC or BLCA patients. However, we did notice a positive relationship between PYs and TMB in NSCLC patients (LR:1.77; CI[1.62-1.92] ; p<0.0001). We also evaluated the relationship between ancestry and PYs where patients with EUR ancestry had a higher PYs than patients with AFR in NSCLC (Mdn=20 vs 3; p<0.0001). Interestingly, we identified a novel genomic association between PYs and STAG2 in BLCA (OR:1.21, CI[1.08-1.36],p=0.001). STAG2 which could be a potential therapeutic target. Lastly, we performed a CoxPH to investigate the relationship between smoking exposure and OS. PYs were associated with an incremental decrease in OS among NSCLC patients where those in PYs group 3 had the highest risk (HR:1.50; CI:[1.34-1.66,];p<0.0001) and outperform TMB (HR:1.17; CI:[1.06-1.28]; p=0.0012). PYs also predicted OS in BLCA (HR:1.90; CI:[1.49-2.42]; p<0.0001).
Conclusion: By utilizing PYs we were able to identify clinical and novel genomic associations such as STAG2 in BLCA and lower OS in NSCLC. PYs can serve as an alternate clinical variable to smoking history alone.

#3384 Comprehensive profiling of g*BRCA1* and g*BRCA2* variants in Hormone receptor-positive breast cancer of Chinese patients.

Jiajun Ding[1], Ting Wang[1], Jing Fan[1], Huimin Meng[1], Mengxuan Li[1], Haoyi Zi[1], Shuai Wang[1], Qingxia Li[1], Yidi Wang[1], Jing Kong[1], Fei Yao[2], Changbing Zhu[2]

[1]Department of Thyroid, Breast and Vascular Surgery, Xijing Hospital, Air Force Medical University, Xi'an, China,[2]Department of Medicine, Amoy Diagnostics Co., Ltd., Xiameng, China

Background and Objective: The identification as well as the interpretation of germline *BRCA1 (*gBRCA1*)* and germline *BRCA2* (gBRCA2) variants are becoming increasingly critical in the treatment of breast cancer (BC), particularly in cases of hormone receptor-positive BC (HR^+ BC). However, a thorough analysis of these variants within the HR^+ BC population is still insufficient.

Methods: In this single-center retrospective study, a total of 1033 female invasive BC patients getting gBRCAs mutation testing with signatures were enrolled, and 652 of them were HR^+ BC patients. Pearson chi-square test and continuous correction chi-square test were used to explored the association between gBRCAs mutation and the characteristics of BC. Then clinical and pathological characteristics related to gBRCAs mutation enrollment on univariate logistic regression were selected for multivariate logistic regression.

Results: Overall, 108 Luminal A (LA) BC patients, 411 Luminal B represented HER2 negative ($LB\text{-}HER2^-$) BC patients, 133 triple-positive BC (TPBC) patients, 109 HER2 positive ($HER2^+$) patients as well as 272 triple-negative BC (TNBC) patients were enrolled in the study. There were 5.6% (58/1033) patients, 4.7% (49/1033) patients and 10.4% (107/1033) patients carrying $BRCA1^{mut}$, $BRCA2^{mut}$ and $BRCA1/2^{mut}$ individually. As for HR^+ patients, the rates were 2.6% (17/652), 5.2% (34/652) and 7.8% (51/652) respectively. It was the most frequent to found $gBRCA1^{mut}$ in TNBC (14.7% in TNBC compared to 2.36% in non-TNBC, $p<0.001$) while for $gBRCA2^{mut}$, it was $LB\text{-}HER2^-$ BC (6.8% in $LB\text{-}HER2^-$ BC compared to 3.4% in others). Even if in HR^+ BC patients, the rate of $gBRCA1^{mut}$ was higher in ER-low patients compared that in ER-high ones (10.5% vs. 1.8%, $p<0.001$), while this phenomenon could not be found for gBRCA2 mutation. According to the multivariate logistic regression in overall patients, those with bilateral BC ($p=0.007$) and PR negative BC ($p=0.026$) were more likely to be $BRCA1^{mut}$. Though the difference without statistically significant, it seemed that patients younger than 40 (≤40) ($p=0.075$) and grade III ($p=0.056$) tended to be $gBRCA^{mut}$. While patients ≤40 ($p=0.008$), in T3 or T4 stage ($p=0.034$) with higher Ki-67 ($p=0.015$) were more frequent to be $BRCA2^{mut}$. Among $LB\text{-}HER2^-$ patients ≤40 in T3 or T4 stage, the rate of $gBRCA2^{mut}$ increased to 26.9% (7/26), no less than the rate of $gBRCA1^{mut}$ in young TNBC patients (24.7%, 20/81), who were recommended the gBRCAs testing.

Conclusion: The clinical and pathological characteristics differed in $gBRCA1^{mut}$ and $gBRCA2^{mut}$ among HR-positive BC patients**.** The screening for gBRCA2 mutation could be meaningful in young $LB\text{-}HER2^-$ patients with tumor in T3 or T4 stage.

#3385 Real-world data analysis of somatic mutations using the GenMineTOP, a dual-targeted DNA and RNA comprehensive genomic profiling panel.

Kousuke Watanabe[1], Miho Ogawa[1], Eri Habano[2], Aya Shinozaki-Ushiku[2], Masakazu Akahori[3], Toshimitsu Ichijo[3], Shuichi Tsutsumi[4], Kenji Tatsuno[4], Hiroyuki Aburatani[4], Hidenori Kage[5], Katsutoshi Oda[2]

[1]Next-Generation Precision Medicine Development Laboratory, Graduate School of Medicine, University of Tokyo, Tokyo, Japan,[2]Division of Integrative Genomics, Graduate School of Medicine, University of Tokyo, Tokyo, Japan,[3]Konica Minolta, Co. Ltd., Tokyo, Japan,[4]RCAST, University of Tokyo, Tokyo, Japan,[5]Department of Respiratory Medicine, Graduate School of Medicine, University of Tokyo, Tokyo, Japan

Introduction: In Japan, comprehensive genomic profiling (CGP) tests have been covered by insurance since 2019, and the dual-targeted DNA and RNA CGP panel, GenMineTOP, has been covered since 2023. Of the CGP tests conducted under insurance, 99.6% of cases are registered in the nationwide database: Center for Cancer Genomics and Advanced Therapeutics (C-CAT). This study aims to elucidate somatic genomic alterations detected by GenMineTOP using real-world data from C-CAT.
Method: We analyzed 1,356 cases of GenMineTOP registered in the C-CAT database by June 2024. Clinical significance was determined based on the evidence level defined by C-CAT. We examined DNA mutations, copy number alterations, fusion/exon skipping, and TMB-high cases. Additionally, we performed multivariate analysis to assess the impact of DNA mutations, copy number amplifications, fusion genes, and primary organ on RNA expression levels.
Results: The top five cancer types were bowel (15.4%), soft tissue (11.6%), CNS/brain (11.1%), pancreas (8.3%), and head and neck (5.6%). Oncogenic DNA mutations, copy number amplifications, and fusion/exon skipping were found in 1,140, 342, and 117 cases, respectively. Fusion/exon skipping was more common in cases without DNA mutations (68/1140 vs. 49/216). Frequent DNA mutations included *TP53*, *KRAS*, *APC*, *PIK3CA*, and *TERT*. Copy number amplifications were most common in *MDM2*, *CDK4*, *MYC*, *EGFR*, and *CCND1*. TMB-high was observed in 72 cases (5.3%). The RNA panel detected 105 fusion cases and 13 exon skipping cases; 17 fusions were evidence level A (Japan- or FDA-approved drug for the cancer type) and 39 were diagnostically significant. NTRK fusions were detected in 11 cases (0.8%). Exon skipping was observed in *EGFR* (exon 2-7, n=5), *CTNNB1* (exon 3, n=7), and *ERBB2* (exon 16, n=1). Gene expression was influenced by the primary organ and the presence of gene amplification, fusion genes, and/or mutations. All 27 analyzed genes showed differences in expression depending on the primary organ, with *ALK*, *NTRK2*, and *NTRK3* exhibiting particularly significant variations. These genes had the highest expression levels in the CNS/brain. The effect of gene amplification on expression levels varied by gene, with the most significant impact observed in *CDK4* and *MDM2*. Mutations in *KIT* and *TERT* were linked to increased expression. Statistically significant overexpression was observed in cases positive for ALK, FGFR3, NTRK1, NTRK3, and RET fusions.
Conclusion: GenMineTOP detected clinically significant fusion/exon skipping. Factors affecting RNA expression were quantitatively elucidated.

#3386 Clinicogenomic comparison of patients with liver-avid/lung-adverse and lung-avid/liver-adverse patterns of metastases highlights commonalities across cancer types.

John Nguyen[1], Walid K. Chatila[1], Paolo Manca[1], Henry Walch[1], Subhiksha Nandakumar[1], Pedram Razavi[2], Eileen M. O'Reilly[2], Yelena Y. Janjigian[2], Rona Yaeger[2], Karuna Ganesh[3], Michael F. Berger[4], Nikolaus Schultz[1], Francisco Sanchez-Vega[1]

[1]Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Cancer Biology and Genetics Program, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY

Background: The analysis of metastatic trajectories and their association with genomic features can provide valuable insights to improve patient stratification and prognostication. We analyzed real-world data from a large multi-cancer cohort of patients who developed metastasis to either the liver but not the lung or the lung but not the liver, and we compared their clinical and molecular profiles.

Methods: We queried a pan-cancer database of more than 85,000 patients treated at Memorial Sloan Kettering Cancer Center. All patients were profiled using MSK-IMPACT, a targeted sequencing panel that identifies somatic alterations in 341-505 genes using matched tumor and blood. Liver-avid/lung-adverse (“LiverA”) patients were defined as having developed liver metastasis but not lung metastasis, while lung-avid/liver-adverse (“LungA”) patients were defined conversely. We identified 4 cancer subtypes with at least 100 patients in each metastatic cohort: pancreatic adenocarcinoma (PAAD, n=1247, 968 LiverA/ 279 LungA), microsatellite stable colon adenocarcinoma (MSS COAD, n=905, 653/252), esophageal adenocarcinoma (ESCA, n=344,193/151), and HR+/HER2− ductal breast adenocarcinoma (HR+/HER2− BRCA, n=298,156/142). Overall survival (OS) was measured from the time of diagnosis.

Results: LiverA patients had shorter OS: MSS COAD (median 53 vs. 106 months, p<0.0001), ESCA (median 21 vs. 41 months, p<0.0001), HR+/HER2− BRCA (percentage surviving after 9 years, 22% for LiverA vs. 69% for LungA patients, p<0.0001), and PAAD (median 16 vs. 33 months, p<0.0001). LiverA patients were diagnosed at a significantly younger age in 4 cancer types: HR+/HER2− BRCA (median 54 vs. 61 years, p<0.0001), ESCA (median 63 vs. 68 years, p<0.0001), PAAD(median 67 vs. 71 years, p<0.0001), and MSS COAD (median 59 vs. 61.5 years, p=0.017). Genomic analyses of primary tumors identified significantly higher chromosomal instability in the LiverA patients quantified as the fraction of genome altered (FGA) by copy number changes in 3 cancer types: ESCA (median 0.69 vs. 0.59, p=.036), HR+/HER2− BRCA (median 0.64 vs. 0.43, p=0.001), and PAAD (median 0.28 vs. 0.18, p=1.1e-5). Among HR+/HER2− BRCA patients, LiverA patients had higher rates of 11q13 (36% vs. 11%, q=0.002), MYC (14% vs. 2%, q=0.02) and FGFR1 (21% vs. 9%, q=0.06) amplifications. TP53 alterations were more frequent in LiverA patients within PAAD cohorts (84% vs. 59%, q<0.0001). MSS COAD patients in the LiverA group had higher rates of SMAD4 (19% vs. 9%, q=0.02) and lower rates of KRAS alterations (44% vs. 56%, q=0.05).

Conclusions: Our data demonstrate distinct outcomes and clinicogenomic features associated with LiverA and LungA patients consistent across several cancer types, suggesting potential commonalities in underlying tumor biology that could be exploited to improve patient stratification.

#3388 Proteomic analysis of Latin American patients and machine learning strategies for developing a prognostic signature for prostate cancer.

Juan Bizzotto[1], Agustina Sabater[1], Pablo Sanchis[1], Pia Valacco[2], Elba Vazquez[2], Javier Cotignola[2], Geraldine Gueron[2]

[1]Departamento de Quimica Biologica, IQUIBICEN - CONICET, Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales; Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), Buenos Aires, Argentina,[2]Departamento de Quimica Biologica, IQUIBICEN - CONICET, Universidad de Buenos Aires, Facultad de Ciencias Exactas y Naturales, Buenos Aires, Argentina

Prostate cancer (PCa) is the leading cause of cancer-related deaths among males in Latin America (LATAM). While some PCa patients are classified as intermediate-risk based on histopathological characteristics, their outcomes can vary widely. There is an unmet need for biomarkers that are cost-effective, easy to implement in low-resource clinical settings, and capable of identifying patients at risk for aggressive disease to tailor treatments. These biomarkers must be developed specifically for the LATAM population to ensure their relevance and accuracy within this demographic. This study aimed to identify molecular biomarkers capable of stratifying the risk of disease progression in LATAM PCa patients, independent of histological grading and other clinicopathological variables. To this end, we performed protein extraction from formalin-fixed paraffin-embedded (FFPE) PCa and benign prostatic hyperplasia (BPH) tissue samples from patients at Buenos Aires, Argentina (n=20). Tandem mass spectrometry (LC ESI-MS/MS) analysis identified 109 proteins enriched in PCa. These proteins were subsequently analyzed through a custom made bioinformatic pipeline using publicly available transcriptomic datasets (16 datasets, n = 2,954). We designed a sequential workflow that included survival analyses to evaluate the association of each gene with disease progression, as well as machine learning algorithms to identify key predictors of PCa progression. Random forest was used for feature selection, identifying the most important genes, and LASSO regression was applied to construct a predictive model based on these genes. Our analysis yielded a 10-gene expression signature capable of identifying patients at higher risk of disease progression, independent of clinicopathological parameters, specifically within the intermediate-risk subgroup ($HR > 1$, $p < 0.05$ across datasets). We validated these findings in 4 independent PCa datasets not used in the training phase, reinforcing the robustness and generalizability of our methodology. This study leveraged experimental and transcriptomic data to develop a prognostic gene-expression signature based on genes with confirmed expression and detectability in the LATAM population, ensuring its relevance and applicability within this demographic. The signature has the potential to enable risk assessment among intermediate-risk patients, facilitating personalized treatment strategies, improving clinical outcomes, and reducing unnecessary interventions. Additionally, the small size of the gene panel makes it cost-effective and compatible with standard RT-qPCR platforms, enabling widespread implementation in decentralized settings. Our results lay the foundation for future clinical trials integrating this signature into personalized therapeutic approaches.

#3389 Genetic and clinical landscape of NUTM1 structural variants.

Sara R. Selitsky[1], **Brandon A. Price**[1], Michael Rollins[1], Adam J. Hockenberry[1], Ezra Cohen[1], Brian Piening[2], Alexander Rubinsteyn[3], Jennifer H. Choe[4], Kim A. Ely[4], Henry Kaplan[5]

[1]Tempus, Chicago, IL,[2]Earle A. Chiles Research Institute, Portland, OR,[3]University of North Carolina at Chapel Hill, Chapel Hill, NC,[4]Vanderbilt University Medical Center, Nashville, TN,[5]Swedish Cancer Institute, Seattle, WA

Introduction: NUT carcinoma is an aggressive cancer, originally described in midline structures of adolescents and young adults but now known to occur in a variety of anatomic sites with growing numbers of variant histologies being reported. As such, NUT immunoreactivity and/or demonstration of the NUTM1 fusion is required for definitive diagnosis.
Methods: We identified patients within the Tempus multimodal real-world database who had either a diagnosis of NUT carcinoma based on clinically abstracted diagnosis fields or via the presence of a NUTM1 fusion, as detected either by Tempus xT (targeted DNA panel) or Tempus xR (whole-exome capture RNA-seq).
Results: There were 59 patients in the Tempus database with NUT carcinoma annotated as their primary diagnosis. Tempus NGS testing confirmed the presence of a NUTM1 fusion for 48 (81%). Of the remaining 11 patients, none underwent RNA-seq testing at Tempus and only 2 had solid-tissue DNA-seq performed at Tempus. Additionally, there were 106 patients with a NUTM1 fusion based on NGS evidence that did not have an initial NUT diagnosis, including: non-small cell lung cancer (n=33), head and neck (n=10), cancer of unknown primary (n=10), thyroid cancer (n=11), soft tissue sarcoma (n=11), and several other cancer types. Eight out of 31 sweat gland adenocarcinomas/porocarcinomas in the cohort had a NUTM1 rearrangement. Several other NUTM1 fusion rearrangements with partners not previously associated with NUT carcinoma were identified, the clinical significance of which is unclear.Among the 154 patients where we detected a NUTM1 rearrangement, the most common fusion events were BRD4-NUTM1 (n = 55), NSD3-NUTM1 (n = 31), BRD3-NUTM1 (n = 17), SLC12A6-NUTM1 (n=11), YAP1-NUTM1 (n = 11), MXD4-NUTM1 (n=3), and CIC-NUTM1 (n=3)other fusion partners occurred in only one or two patients. The overall potential underdiagnosis rate (patients with the detected fusion but not an annotated formal NUT carcinoma diagnosis) was 69% (106/154); including BRD4-NUTM1 51% (28/55), BRD3-NUTM1 47% (8/17), NSD3-NUTM1 81% (25/31), and 91% for YAP1-NUTM1 (10/11).Some cancer types were enriched for specific fusion gene partners. Eleven of 12 patients (92%) that were diagnosed with thyroid cancer had a NSD3-NUTM1 fusion. Of the 8 sweat gland adenocarcinomas/porocarcinomas, 6 had a YAP1-NUTM1 fusion.The median overall survival was 5.29 months (n = 72) and the median age was 51 (n = 114) at diagnosis. The median age at diagnosis for patients annotated with NUT carcinoma was 41 years compared to 58.5 years for patients with a NUTM1 fusion but lacking the diagnosis.
Conclusions: NUT carcinomas may be underdiagnosed the majority of the time. Certain cancer types with a high enrichment of NUTM1 fusions, such as sweat gland adenocarcinomas/porocarcinomas, thyroid cancers, and sarcomas, may benefit from universal NGS sequencing to ensure correct diagnosis.

#3390 Impact of genomic alterations in *HMGB1*, *ROS1*, *IL6*, *FGFR1*, *FGFR2*, and *TLR4* on long-term survival outcomes in esophageal squamous cell carcinoma (ESCC).

V. C. Kok;
Kuang Tien General Hospital, Taichung, Taiwan

Background. To test the hypothesis that the genomic alterations of *HMGB1, ROS1, IL6, FGFR1, FGFR2*, and *TLR4* would be associated with long-term outcomes in patients with ESCC through disrupting normal immune surveillance and promote mechanisms that allow tumor cells to evade immune detection and destruction. These genes were also variously involved in the RTK-Ras pathway (*ROS1, FGFR1, FGFR2*), PI3K-Akt signaling (*FGFR1, FGFR2, IL6* and *TLR4*), TLR signaling (*TLR4* and *IL6*) and the SHP2 signaling (*FGFR2* and *IL6*). Methods. This study merged five datasets and sorted out pure squamous cell carcinoma for analysis. GSE53624 was used for gene expression correlating to survival analysis on the genes of interest. Disease-free survival (DFS) and overall survival (OS) were calculated in patients whose survival times were available for Kaplan-Meier analysis. The log-rank test was used for comparison. Only patients with available survival data were put into the survival modes. Hazard ratios (HR) with 95% confidence interval (CI) were derived from the log-rank test. The research was conducted via the KEGG.jp, cBioPortal (accessed November 2024), and ESCCdb/Sichuan. Results. A total of 437 patients with 437 samples were selected. Male accounted for 78.5%. The altered and unaltered group comprises 66 (15%) and 371 (85%) patients. The top 10 mutated genes in this cohort are *TP53, TTN, KMT2D, MUC16, CSMD3, PKHD1L1, ZNF804B, SYNE1, NOTCH1* and *PCLO.* Patients were assigned to either altered group (any alteration in the six genes of interest) or unaltered group. Compared with the unaltered group, the altered group has a higher nonsynonymous tumor mutational burden (TMB) [(median (IQR), 3.37 (2.07-5.23) vs 5.33 (4.32-6.3), p = 5.22e-8 by Wilcoxon test)] and higher mutation count [(median (IQR), 56 (13-117) vs 158.5 (125-187), p < 10e-10)]. DFS can be calculated in 76 patients. The altered group has a nonsignificant worse DFS with an HR of 1.171 (95% CI, 0.512-2.681). With more than 85 months of follow-up in 288 patients, compared with the altered group, the altered group shows significantly worse overall survival: median and 95% CI, 40.93 mo. (28.42 mo. - not reached) vs. 18.63 mo. (18.17 mo. - 28.13 mo.), HR = 2.16 (1.33 - 3.52)]. Gene expression versus survival analyses revealed that higher HMGB1 expression harbors a significantly worse prognosis (p < 0.008). Conclusions. These in silico and dataset experiments leveraging the genomic data from ESCC demonstrate that despite having a higher mutation count and TMB, which might elicit more tumor neoantigens for immune recognition and eradication, the altered group with genomic alterations in any of the six genes might still have a significantly worse long-term survival prognosis. The novelty of the study findings needs further investigation.

#3391 Clonality and allelic imbalance of driver genes in a large retrospective cohort of colorectal cancer patients.

Henry Walch, Paolo Manca, Jierui Xu, Christopher Fong, Justin Jee, Karl Pichotta, Adam Price, Allison L. Richards, Mark Donoghue, Jinru Shia, Efsevia Vakiani, Neil H. Segal, Andrea Cercek, Nikolaus Schultz, Francisco Sanchez-Vega, Walid K. Chatila, Rona Yaeger

Memorial Sloan Kettering Cancer Center, New York, NY

Intro: The genomic alteration landscape of colorectal cancers (CRCs) is heterogeneous, which can have implications for treatments and outcomes. In this analysis, we investigated tumor sequencing data from a large cohort of CRC patients to unpack the relevance of clonality and allelic imbalance heterogeneity.

Methods: We analyzed a cohort of 6789 CRC patients treated at Memorial Sloan Kettering Cancer Center from 2014 to 2024. Every patient had a tumor/normal pair sequenced with MSK-IMPACT, a targeted sequencing assay that profiles genomic alterations across 341-505 cancer genes. The FACETS copy number algorithm was used to determine whole-genome duplication (WGD) status, as well as assess allelic imbalance and the clonality of mutations. Of the 6789 tumors, 5520 passed FACETS QC criteria. Tumors were classified as microsatellite stable (MSS), microsatellite instable (MSI), and POLE-mutant (POLE). Overall survival was calculated from time of diagnosis to last follow up.

Results: The median age at diagnosis of our cohort was 56 years. Left-sided primary tumors were the most common (38.0%) and the majority of patients were stage IV (50.3%). The most frequent molecular subtype was MSS (87.6%), followed by MSI (11.4%) and POLE (1.0%).

Within the MSS cohort, we investigated the clonality and allelic imbalance of mutations in canonical CRC genes, such as TP53, APC, KRAS, BRAF, and PIK3CA. Across all genes, clonal mutations demonstrated significantly higher rates of allelic imbalance favoring the mutant allele relative to subclonal mutations. Consistent with the other genes, tumors with a single clonal APC mutation had higher rates of allelic imbalance favoring the mutant allele when compared to those with a single subclonal mutation (81.5% vs 63.1%, $p<0.001$). However, this difference was not seen in tumors with more than 1 APC mutation.

Tumors with a clonal TP53 mutation had higher median FGA estimates relative to subclonal TP53 mutant tumors in both WGD- (42% vs 28%, $p<0.001$) and WGD+ (77% vs 69%, $p=0.011$) tumors. TP53 clonal mutant tumors were enriched for loss across several chromosomal arms, whereas TP53 wild-type tumors were enriched for gains of chromosome 12, which contains both MDM2 and KRAS (32.4% vs 10.8%, $p<0.001$). Among patients with left-sided primary tumors and KRAS mutations, presence of KRAS gain was associated with a higher risk of death (HR=1.58, 95%CI:1.17-2.12, $p=0.003$)

Conclusions: The presence of allelic imbalance in CRC might contribute to the clonal expansion of mutations important for early tumorigenesis, particularly in the absence of multiple mutations leading to loss of the wild-type allele, as is the case with APC. Further, stratification by TP53 mutation clonality demonstrated its role in regulating genomic instability. Copy number alterations might shape CRCs fate toward a higher dependency on the TP53 or RAS pathway, with possible prognostic implications.

#3393 A pan-cancer analysis of cancer-predisposition germline pathogenic variants (gPVs) utilizing the cancer genome atlas (TCGA) reveals distinct survival trends associated with immune response pathways.

Alan Shen[1], Lin Li[2], Joshua Arbesman[3], Ying Ni[2], Pauline Funchain[4]

[1]Cleveland Clinic Lerner College of Medicine, Cleveland, OH,[2]Cleveland Clinic Center for Immunotherapy and Precision Immuno-Oncology, Cleveland, OH,[3]Department of Dermatology, Medical Specialty Institute, Cleveland Clinic, Cleveland, OH,[4]Department of Medicine, Division of Oncology, Stanford University School of Medicine, Palo Alto, CA

A family history of cancer has previously been shown to positively impact survival outcomes in various cancers. Additionally, specific cancer-predisposition germline pathogenic variants (gPVs) have also been shown to have a beneficial effect on survival across multiple cancers including colorectal cancer, ovarian cancer and melanoma. However, the impact on survival of commonly accepted cancer-predisposition gPVs across cancers has not been widely studied. Here, we examine the effect of 85 common cancer-predisposition gPVs on survival outcomes across all cancer types in the Cancer Genome Atlas (TCGA). When examining survival trends, we observed that cancers with a greater proportion of gPVs generally had improved survival ($p = 0.0088$). When examining each cancer indication separately, those with significantly improved survival amongst gPV positive patients included bladder [$HR = 0.35$, $p = 0.01$] and ovarian cancer [$HR = 0.55$, $p = 0.0003$], whereas head and neck squamous cell carcinoma had significantly worse survival [$HR = 1.43$, $p = 0.04$]. Interestingly, bladder and ovarian cancer gPV positive patients had significant upregulations in immune-stimulatory transcriptomic pathways with the majority of gPVs in the homologous recombination deficient (HRD) variant category, whereas the opposite was observed in head and neck squamous cell carcinoma. Thus, by examining a large array of cancer-predisposition gPVs in all cancer subtypes included in TCGA, we not only demonstrate the prevalence of a wider variety of gPVs across cancer indications but that specific categories of gPVs can influence survival across cancers in a beneficial manner, potentially by creating a pro-inflammatory immune response.

#3394 Impact of gBRCAs mutation on the surgery decisions of Chinese breast cancer (BC) patients: a single-center real world study in Xijing Hospital, Northwest China.

Ting Wang[1], Jing Fan[1], Jiajun Ding[1], Jing Kong[1], Mengxuan Li[1], Yidi Wang[1], Huimin Meng[1], Haoyi Zi[1], Qingxia Li[1], Shuai Wang[1], Fei Yao[2], Changbing Zhu[2]

[1]Department of Thyroid, Breast and Vascular Surgery, Xijing Hospital, Air Force Medical University, Xi'an, China,[2]Department of Medicine, Amoy Diagnostics Co., Ltd, Xiamen, China

Background and Objective: Germline *BRCA* (gBRCA) mutations complicate clinical surgery management due to a higher risk of initial breast cancer, as well as increased chances of new primary cancers or local recurrence. In this study, we examined the surgical decisions for individuals carrying gBRCA mutations.

Methods: In this real world study, 1050 female patients with unilateral operable invasive breast cancer getting gBRCA mutation test were enrolled. Pearson chi-square test, continuous correction chi-square test and Fisher's exact test were used to explored the association between gBRCA mutation and surgery choice appropriately.

Results: Germline *BRCA1* mutations (gBRCA1^{mut}), Germline *BRCA2* mutations (gBRCA2^{mut}) and gBRCA1/2^{mut} were found in 5.1% (54/1050), 4.9% (51/1050), 10.0% (105/1050) BC patients separately. Among all patients, those with gBRCAs^{mut} preferred contralateral prophylactic mastectomy than those without mutation (9.3% gBRCA1^{mut} patients compared with 2.0% gBRCA1^{wt} patients, 7.8% gBRCA2^{mut} patients compared with 2.1% gBRCA2^{wt} patients, 8.6% gBRCA1/2^{mut} patients compared with 1.7% gBRCA1/2^{wt} patients, all $p<0.05$). This tendency could also be found in early-stage BC patients (n=699). While in young (≤40) BC patients (n=346), there were no significant differences in choice between gBRCAs^{mut} cohort and gBRCAs^{wt} cohort. Though in all patients, the selection of specific surgery [breast-conserving surgery (BCS), mastectomy or reconstruction surgery] was not affected by gBRCAs mutations. In young BC patients, patients with gBRCA2^{mut} were more likely to choose mastectomy or reconstruction surgery rather than BCS (10.3% gBRCA2^{mut} patients selected BCS compared with 34.4% gBRCA2^{wt} patients, $p=0.011$). The same tendency could also be found in early-stage BC patients though the difference was not statistically significant ($p=0.074$). The gBRCA1 mutation had no influence on the specific option.

Conclusion: Northwest Chinese BC patients made their surgery choice under the influence of gBRCA1/2 mutation. gBRCA2^{mut} played an more crucial role on it.

#3395 Investigating clinical features and molecular mechanisms of long-term response and acquired resistance to immunotherapy in non-small cell lung cancer by applying real-world-data.

Si Wu, **Weilong Zhao**, Baoyi Zhang, Christy Choi, Saeed Salehin Akhand, Qu Zhang, Jack Chen, Peter Ansell, Rong Chen, Xi Zhao, Josue Samayoa

Abbvie South San Francisco, South San Francisco, CA

The introduction of immunotherapy (IO) has transformed cancer treatment, particularly for non-small cell lung cancer (NSCLC), yet molecular mechanisms of IO resistance remain elusive due to incomplete clinical and omic data. Notably, while some patients, “long-term responders” (LTR), experience lasting benefits, ~60% of initial responders develop “acquired resistance” (AR), differing from those with primary resistance (PR) who exhibit no initial response.

Our study leverages real-world data (RWD) for its comprehensive clinical data, capturing therapy lines and responses with extensive follow-up. We examined RWD from ConcertAI PT360® EHRs linked to Caris Life Science molecular data across 2,176 NSCLC patients, focusing on a filtered cohort (N = 407) to explore IO response and resistance mechanisms. Within this cohort, 43% received IO monotherapy and 57% combination therapy with chemotherapy, predominantly using pembrolizumab. Most patients initiated IO in the first line (90%) or second line (8.2%).

Responders to IO noted improved overall survival (p = 0.0037, median OS 27.6 vs. 12.6 months for non-responders) and longer treatment durations (p = 4.04E-04, median 210 vs. 99 days), compared to non-responders. Biomarker analysis highlighted significantly higher tumor mutational burden (TMB) and immunologic constant of rejection (ICR), along with more PD-L1 positive patients (p = 0.03) among responders, indicating increased immune infiltration. The RNA-seq data revealed 604 significantly differential genes; responders showed higher levels of immune biomarkers (e.g., CD274, CXCL-9, GZMK, TNFRSF9), whereas non-responders exhibited increased immunosuppressive markers such as NNMT and some antigen targets. Gene Set Enrichment Analysis (GSEA) revealed enriched pathways in lymphocyte activation and extracellular structure organization, TGF-b signaling, etc.

Integrative analyses of LTR, AR, and PR groups identified mutations, notably ARID1A, PREX2, and PRKN, enriched in the LTR group, potentially rendering tumor sensitivity to IO and potential new drug targets. Additionally, six distinct molecular patterns were identified, highlighting differences between LTR, AR, and PR groups. Notably, Immunoglobulin G, B cells, and plasma cell activity scores varied significantly between AR and PR, with AR mirroring LTR, implicating these immune cells in initial IO response, potentially linked to immature tertiary lymphoid structures (TLS) before transitioning to AR, manifested with TLS scores differing significantly across groups (p = 1.7E-04).

In summary, our study uses multi-modal RWD to establish an analytical workflow, revealing key clinical features and biomarkers while offer insights into molecular underpinnings of IO long-term response and resistance through multi-omic RWD integration.

#3396 Genomic landscape and ancestry-associated variations of gynecological cancers.

Vasily N. Aushev[1], Carly B. Scalise[1], Rebecca C. Arend[2], Avinash Ramu[1], J. Bryce Ortiz[1], Alyssa Antonopoulos[1], Faraz Salmasi[1], Alexey Aleshin[1], Adam C. ElNaggar[1], Laura Chambers[3]

[1]Natera, Inc., Austin, TX,[2]School of Medicine, The University of Birmingham, Birmingham, AL,[3]Wexner Medical Center and James Cancer Hospital, The Ohio State University, Columbus, OH

Background: Gynecological cancers are a diverse set of malignancies, each with distinct genomic alterations that influence tumorigenesis and disease progression. Here, we analyzed genomic data from endometrial, ovarian, and cervical cancer patients, stratified by genetic ancestry, to assess differences in genomic mutational landscapes.
Methods: Whole-exome sequencing (WES) data from >8,000 gynecological cancer cases in Natera's proprietary Real-World Database were utilized. WES was performed on tumor tissues for designing personalized Signatera™ circulating tumor DNA tests ordered from June 2019 - November 2024. After exclusions, 6,485 patients remained: 2,956 (46%) endometrial, 2,709 (42%) ovarian, and 820 (12%) cervical cancer. Variant calling used Mutect2 and VarScan2; only non-synonymous mutations were included in prevalence analysis. Genetic ancestry was determined using EthSeq algorithm for four groups: Africa (AFR), East Asia (EAS), Europe (EUR), South Asia (SAS).
Results: In endometrial cancer, top mutated genes were PTEN (43.2%), ARID1A (37.9%), and PIK3CA (34.5%). The most common variants being SETD1B H8X (7.6%), RNF43 G659X (6.8%), PTEN R130G (5.8%) and PIK3CA H1047R (5.8%). EUR and AFR ancestry comprised 85% and 14% of cases, respectively. The top 4 most frequently mutated genes were the same in EUR and AFR; but EUR ancestry had significantly higher ARID1A (40.7% vs 23.6%, $p<0.01$), PIK3CA (36.1% vs 23.8%, $p<0.05$), and PTEN (46.8% vs 22.5% $p<0.001$) mutations, while AFR ancestry had higher prevalence of TP53 (51.2% vs 30.5%, $p<0.01$). In ovarian cancer, TP53 (53.3%), ARID1A (10.4%), and PIK3CA (9.7%) were the top mutated genes. Common variants were KRAS G12D and G12V (each 2.9%), and PIK3CA H1047R (2.5%). EUR and AFR groups comprised 79% and 8% of cases, respectively. No significant ancestry-based differences were found. In cervical cancer, PIK3CA (26.7%), KMT2C (14.0%), and KMT2D (11.5%) were most commonly mutated. The most common variants were PIK3CA E545K (13.0%), E542K (7.1%), and E726K (2.7%). EUR and AFR comprised 75% and 13% of cases, respectively, and harbored the same top two mutated genes: PIK3CA and KMT2C. The AFR group had a lower prevalence of PIK3CA E545K mutation (7.6% vs 14.4%) but a higher E542K prevalence (10.5% vs 6.8%).
Conclusions: This extensive real-world genomic analyses of gynecological cancers revealed distinct mutational landscapes that distinguish ovarian, endometrial, and cervical cancers. The data highlight the genomic diversity of these malignancies and frequent alterations in genes and variants across ancestries, offering potential research targets. Future studies will investigate links between genomic alterations and clinical outcomes to inform disease management.

#3397 Survival stratification for *TP53*-mutated endometrial cancers under platinum-based chemotherapy.

Xiaotian Zhao, **Haimeng Tang**, Xue Wu, Qiuxiang Ou

Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Endometrial cancers (EC) with mutated *TP53* or abnormal p53 show unfavorable clinical outcomes, with high recurrence rates, and additional chemotherapy has been considered within these patients. Genomic biomarkers may be critical to increasing the precision in developing treatment strategy for *TP53*-mutated EC.

Methods: We applied an in-house developed targeted sequencing homologous recombination deficiency (HRD) assessment bioinformatic algorithm (GeneseeqPrime® HRD) on 529 the Cancer Genome Atlas (TCGA) EC samples, covering all exons and translocation-related introns of 437 cancer-relevant genes. The HRD score threshold to determine HRD status as well as to stratify survival outcomes under platinum-based chemotherapy, and associations of HRD status with signaling pathways and protein expression were investigated.

Results: Of 529 EC samples, 18.0% was determined as HRD-positive (HRD score threshold: 38), including 85 patients carrying mutated *TP53*, which was associated with increased HRD scores (p<0.001). However, pathogenic *BRCA1/2* mutations appeared to be less common in *TP53*-mutated EC (p=0.08). HRD-negative EC had higher tumor mutation burden (p=0.03), with more prevalent homologous recombination-related *ATM*, and *RAD50* mutations, whereas positive HRD status was associated with higher aneuploidy score (p<0.001) and fraction of genome altered (p<0.001). Serous and endometrioid carcinomas were enriched in HRD-positive (p<0.001) and HRD-negative EC (p<0.001), respectively. HRD-positive EC exhibited higher patient age (p<0.001), disease stage (p=0.03), and histologic grade (p=0.04) than HRD-negative EC. Under platinum-based chemotherapy, HRD-positive *TP53*-mutated EC had improved progression-free survival [adjusted hazard ratio (HR), 0.56; 95% confidence interval (CI), 0.29-1.10; p=0.09] and superior overall survival (adjusted HR, 0.49; 95% confidence interval (CI), 0.24-1.00; p=0.05) compared to HRD-negative patients, when adjusting for clinical characteristics and molecular subtypes. Suppressed p53, Hedgehog, and hippo signaling pathways were observed in HRD-positive EC with *TP53* mutations (p.adjust <0.05). Additionally, MAPK14 (p<0.001) and PIK3CA (p<0.001) expression were significantly associated with higher HRD score.

Conclusions: HRD status may identify patients with *TP53*-mutated EC who could get survival benefits from platinum-based chemotherapy. Further research is required to determine the utilization of HRD assessment in EC receiving PARP inhibitors.

#3398 Gene-level and global genomic insights into colorectal cancer ovarian metastasis: Molecular mechanisms and determinants.

Y. Fang[1], Y. Sun[1], X. Zhao[2], X. Wu[2], J. Pang[2], **H. Tang**[2], Q. Ou[2], C. Chen[3], Z. Xu[4];

[1]Jiangsu Cancer Hospital, Jiangsu Institute of Cancer Research, The Affiliated Cancer Hospital of Nanjing Medical University, Nanjing, China, [2]Nanjing Geneseeq Technology Inc., Nanjing, China, [3]Jiangsu Province Hospital of Chinese Medicine, Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, China, [4]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background: Approximately 5% of female patients with colorectal cancer (CRC) develop ovarian metastasis (OM), predominantly in young women and leading to poorer survival. As the molecular mechanisms underlying OM remain unclear, this study aimed to identify the genetic determinants of OM and to investigate the mechanisms of synchronous and metachronous metastasis.

Methods: We retrospectively enrolled 81 patients with CRC who had developed OM (28 with matched primary and metastatic lesion samples, 30 with primary lesion, 23 with metastatic samples). Treatment-naïve primary and metastatic lesion tissue samples underwent next-generation sequencing targeting 437 genes to identify gene-level and global genomic determinants of OM. Two external CRC cohorts (MSKCC cohort, N=643; TCGA cohort, N=448) were analyzed for further mechanism exploration.

Results: Among 81 included patients, copy number variations (CNVs) of *SMAD4* ($p<0.01$) and *SMAD2* ($p<0.01$) were more frequently detected in metastatic lesions than primary lesions, with similar findings in 28 pairs of matched samples (*SMAD4*, $p=0.05$; *SMAD4*, $p=0.02$). Associations of *SMAD4* ($p<0.001$) and *SMAD2* ($p=0.09$) CNV loss with unfavorable overall survival were observed in the MSKCC cohort. RNA sequencing data from the TCGA cohort demonstrated up-regulated angiogenesis pathway related to *SMAD4* ($q=0.03$) and *SMAD2* ($q<0.001$) CNV loss. Higher chromosome instability was observed in metastatic lesions than primary lesions in the study cohort ($p<0.01$; matched samples, $p=0.08$), consistent with the findings in the MSKCC cohort ($p<0.001$). The APOBEC mutational signature was related to OM synchronous metastasis, with heavier burdens in both the primary ($p=0.04$) and metastatic ($p=0.01$) lesions of synchronous metastasis than those of metachronous metastasis; however, primary lesions of metachronous metastasis exhibited higher whole-genome doubling fraction ($p=0.04$) and ploidy ($p=0.02$). Moreover, in metastatic lesions, *FLT1* (17.6%, $p=0.05$) and *ZNF217* (17.6%, $p=0.05$) CNV gains were exclusively detected of synchronous metastasis when compared to metastatic lesions of metachronous metastasis.

Conclusions: *SMAD4*/*2* CNV loss and chromosome instability may drive OM in CRC. Synchronous metastasis displays distinct gene-level and global genome features different from metachronous metastasis.

#3399 Real-world experience of the clinical correlation between ARID gene alterations /RNA expression levels and treatment benefit of immunotherapy in malignant solid tumors.

Yuliang Sun, Tobias Meissner, Rachel Elsey, Bing Xu, Crystal Hattum, Casey Williams

Avera Cancer Institute, Sioux Falls, SD

Background: Cancer immunotherapies provide durable benefits for many, but not all patients with various types of solid tumor. Accumulating research suggests that patients with ARID gene alterations of the human switch/sucrose nonfermentable (SWI/SNF) chromatin-remodeling complex are more likely to respond to anti-PD-1/ PD-L1 and anti-CTLA-4 immunotherapy. To investigate the correlation between ARID gene alterations/RNA expression levels and clinical outcomes after immunotherapies, we reviewed patients with solid malignancies seen at our Institute.

Methods: A review of patients (from 2014 to 2024) with solid malignancies from our clinical database at the Avera Cancer Institute, whose tissue DNA and RNA were analyzed by next generation sequencing (NGS) by Tempus and Foundation Medicine, Inc. Patients who have alterations in the ARID gene (ARID1A, ARID1B, ARID2 and ARID5B) and received therapeutic regimens with immune checkpoint inhibitors (ICIs, including PD-1/PD-L1 and CTLA-4 inhibitors) alone or in combination with other treatments were assembled as Cohort 1. Patients with wild-type ARID gene and received ICIs were used as Cohort 2. The outcome differences of the patients between Cohort 1 and 2 were then assessed. Furthermore, patients in Cohort 1 were stratified to subgroups by RNA levels, microsatellite instability (MSI), as well as tumor mutational burden (TMB) status, and the outcomes were analyzed.

Results: **1.** Of the 3620 patients in our database, we found 591 (16.3%) patients harboring ARID gene alterations with one of 15 types of cancer. This includes 160 (4.4% of 3620 and 27.1% of 591 patients) patients (Cohort 1) that received ICIs (excluding 10 patients unevaluable due to treatment termination per drug toxicity or lack of follow-up information), and 470 (13.0%) patients (Cohort 2) with wild-type ARID gene received ICIs. **2.** No statistical difference of RNA expression level between Cohort 1 (*N*= 50) and Cohort 2 (*N*= 135). **3.** Patients in Cohort 1 (*N*= 160), the median progression-free survival (PFS) and overall survival (OS) measured from date of the initiation of ICIs were 8.3 and 20.3 months. **4.** PFS and OS of patients in Cohort 2 appear less than in Cohort 1. Assessment for patients of Cohort 2 and subgroups is ongoing. Updated results will be presented at the meeting.

Conclusion: Improved response rates to ICIs will require the efforts of researchers and clinicians to advance our understanding of tumor immunology, biology as well as omics and to integrate them with other important components of precision oncology. Our single-center observations of real-world data provide a reference for the clinical correlation between ARID gene alterations /RNA expression levels of the SWI/SNF complex and treatment outcomes after immunotherapy in malignant solid tumors, these findings might be beneficial for cancer patients' treatment in the future.

#3400 Co-mutations in FGFR3 and CDKN2A in bladder cancer: a descriptive analysis.

Muhammad A. Shahid, Radhika Gutta, Sunita Ghosh, Nallasivam Palanisamy

Henry Ford Health System, Detroit, MI

Introduction: Bladder cancer is the 9th most common cancer worldwide. Two key genetic alterations, in Fibroblast Growth Factor Receptor (FGFR3) and Cyclin-Dependent Kinase Inhibitor 2A (CDKN2A), are known to contribute to its development. Interactions between these genes have been suggested in bladder cancer progression. However, limited data exists on patients' demographics with co-mutations in these genes.
Methods: This retrospective study evaluates the patient demographics and survival analysis in patients with co-mutated CDKN2A and FGFR3 in bladder cancer. We utilized the cBioPortal MSK Cell Reports 2022 Database for Bladder cancer for our samples. We quantified our samples based on an FGFR3 mutation, CDKN2A mutation, co-mutation in FGFR3/CDKN2A, or wild-type mutation. Further associations of these mutations were tested with race, gender, smoking status, and cancer stage. Kaplan-Meier estimates for overall survival (OS) were compared for the mutational status and log-rank tests were used to compare survival curves. Statistical analysis was performed using Chi-square tests for categorical variables, and time to event analysis was performed using log-rank test. A p-value <0.05 was used for statistical significance.
Results: We evaluated 1462 samples in our study. 139 patients had a co-mutated CDKN2A/FGFR3 (9.5%), 243 with FGFR3 alteration (16.7%), 184 with CDKN2A alteration (12.5), and 896 (61.2 %) with no alteration. There was a statistically significant difference in smoking status when stratified by mutational status: current or former smokers compiled 67.9% of the co-mutated CDKN2A/FGFR3 cohort, 59.6% in the FGFR3 group, 65.9% in the CDKN2A group, and 64.4% in the wild type group ($p=0.010$). 76% of patients were male, 26% were female, and 92% were of Caucasian race; no statistical significance was noted when stratified based on gender or race. When stratifying based on cancer stage, co-mutated CDKN2A/FGFR3 was most commonly seen in Stage I and IV bladder cancer. The 5-year survival probability for patients with co-mutated FGFR3/CDKN2A was 57.9%, compared to 60.9% in FGFR3 samples, 56.8% in CDKN2A samples, and 54.7% in the wild-type samples($p=0.261$). Median OS was only reached for the wild-type mutation.
Conclusions: Our retrospective study outlines the different population groups with aberrations in either FGFR3 or CDKN2A. Patients who were current/former smokers were more likely to have a co-mutated FGFR3/CDKN2A mutation. Patients with wild-type CDKN2A/FGFR3 fared worse when looking at median overall survival (77.4 months), and patients with co-mutated CDKN2A/FGFR3 had the best response (median OS not reached). One of the considerable limitations of this database is the homogeneity of the population, with the vast majority of patients being of Caucasian descent. We hope to evaluate further our bladder cohort of patients, where we have a diverse group of patients that may give us better insight into these alterations.

#3401 Pharmacogenomic landscape of UGT1A1 in cancer patients from the Avera Sequencing and Analytics Protocol (ASAP) registry.

Kobina A. Amoah[1], Crystal Hattum[2], Tobias Meissner[2], Cheryl P. Jones[2], Stephanie B. Hastings[1], Michelle F. Green[1], Heidi C. Ko[1], Bing Xu[2], Zachary D. Wallen[1], Neil Matthiesen[3], Richard Conklin[2], Benjamin Solomon[2], Brian J. Caveney[1], Eric A. Severson[1], Shakti Ramkissoon[1], Casey Williams[2], Rachel Elsey[2]

[1]Labcorp, Durham, NC,[2]Avera Cancer Institute, Sioux Falls, SD,[3]Avera Genetics, Sioux Falls, SD

Purpose: Pharmacogenomic (PGx) testing enables clinicians to identify patients at increased risk of adverse events after chemotherapy. Specific genomic alterations that change drug metabolism can lead to increased toxicity or decreased efficacy. Irinotecan is a chemotherapy drug used to treat solid tumors like colorectal and pancreatic cancer. The UGT1A1 gene metabolizes irinotecan, and genomic alterations can lead to significant dose-limiting toxicities like neutropenia and diarrhea. We investigated the link between UGT1A1 genotype with irinotecan treatment-related adverse events (TRAEs).

Methods: We performed a retrospective analysis of 564 patients with cancer from a prospective observational registry, termed ASAP, who had PGx testing. The ASAP registry is a multicenter precision oncology initiative in a large community-based health system. Using the ASAP registry database, we characterized the demographics, genotype-phenotype correlation, cancer diagnosis, and TRAEs after irinotecan-based chemotherapy.

Results: UGT1A1 phenotypes were classified as normal (*1/*1), intermediate (*1/*80), or poor (*80/*80) metabolizers. Within the study population, 47% (264) were normal metabolizers (57% female, 43% male); 42% (236) were intermediate metabolizers (60% female, 40% male); and 11% (64) were poor metabolizers (56% female, 44% male). Of the 564 patients analyzed, 19 underwent irinotecan-based chemotherapy. Most of the UGT1A1 results were received after the patients had been treated with irinotecan and dose adjustments were made based on other patient-specific factors. Normal metabolizers accounted 37% (7) of patients, with 43% (3) requiring dose reductions at the start of treatment, 57% (4) receiving dose reductions during therapy, and 29% (2) experiencing grade 3 TRAEs. Intermediate metabolizers accounted for 32% (6) of patients, with 33% (2) requiring initial dose reductions, 67% (4) needing dose reductions during treatment, and 33% (2) experiencing grade 3 TRAEs. One patient in this group discontinued treatment. Poor metabolizers represented 32% (6) of the patients, with 50% (3) requiring initial dose reductions, 33% (2) needing dose reductions during treatment, and 17% (1) experiencing grade 3 TRAEs. Overall, 68% (13) of patients experienced grade 1-3 adverse events, which most commonly were neutropenia, diarrhea, and fatigue with 69% (9) occurring in intermediate or poor metabolizers.

Conclusion: This study analyzes UGT1A1 pharmacogenomic profiles in patients with cancer, treated with irinotecan-based chemotherapy. Individuals with intermediate or poor metabolizer phenotypes were more likely to experience grade 1-3 TRAEs resulting in dose adjustments. These results highlight the importance of UGT1A1 testing for minimizing irinotecan toxicity. Future research is underway to explore the clinical impact of UGT1A1 polymorphisms on survival.

#3402 Number of variants of unknown significance (VUS) by next generation sequencing (NGS) and response to systemic therapies in advanced urothelial carcinoma (aUC).

Thomas L. Enright[1], Jacob B. Leary[1], Dimitra R. Bakaloudi[1], Rafee Talukder[2], Michael T. Schweizer[1], Jessica E. Hawley[1], Andrew C. Hsieh[1], Todd Yezesfski[1], Bruce Montgomery[1], Evan Y. Yu[1], Petros Grivas[1], Ruben Raychaudhuri[1], Ali R. Khaki[3]

[1]Division of Hematology Oncology, Department of Medicine, University of Washington, Seattle, WA,[2]Section of Hematology Oncology, Baylor College of Medicine, Houston, TX,[3]Division of Oncology, Deptartment of Medicine, Stanford University, Palo Alto, CA

Background: NGS is routinely used in aUC to identify clinically actionable alterations. NGS assays tier variants by the likelihood of clinical significance, reporting both pathogenic variants and VUS. The number of VUS may serve as a rough estimate for neoantigen load, e.g. tumor mutational burden (TMB). We hypothesized that the number of VUS may represent an easy-to-use biomarker associated with response and overall survival (OS) with certain therapies e.g. immune checkpoint inhibitors (ICI).
Methods: We conducted a retrospective study from patients (pts) from a single academic center with aUC and available NGS data derived from FoundationCDx using tumor tissue who had received ICI, enfortumab-vedotin (EV), and/or sacituzumab govitecan (SG) in the first line (1L) or as salvage (2L+). Patients at or above the median were defined as VUS high (VUS-H); those below were VUS low (VUS-L). We analyzed observed response rate (ORR) and OS measured from each therapy start between groups. Cox proportional hazards test was used to compare OS; Fisher's exact test was used to compare ORR. Kaplan-Meier method was used to calculate survival curves.
Results: 90 pts had available NGS data and received ICI, EV, and/or SG [VUS-H (≥9 VUS) N = 51; VUS-L (0-8 VUS) N = 39]. VUS was correlated with TMB (Pearson coefficient = 0.78). Baseline characteristics including age, sex, ECOG PS, prior extirpative surgery rate, and primary tumor site were similar between groups, except for presence of liver metastases at diagnosis (VUS-H = 10%, VUS-L = 36%; p= 0.003). Results are described in the table.
Conclusions: Higher number of VUS detected by tissue-based NGS was associated with higher ORR and OS with 1st line ICI. Limitations include retrospective nature, lack of randomization, moderate sample size and power, selection and confounding biases. Results are hypothesis-generating and need external validation.
Table: ORR and OS analyses by group

		N	ORR %	OR (95%CI)	p	mOS, months(95%CI)	HR(95%CI)	p
1L ICI	VUS-H	23	60.9%(14/23)	7.78(1.74 – 34.71)	0.009	39(24-NR)	0.30(0.14, 0.66)	0.003
	VUS-L	18	14.3%(3/18)			8.0(5.3-29)		
2+L ICI	VUS-H	16	18.8%(3/16)	1.15(0.16 – 8.27)	1.0	4.3(3.0-24)	1.74(0.73 – 4.12)	0.2
	VUS-L	12	18.2%(2/12)			11(6.7-NR)		
2+L EV	VUS-H	20	45.0%(9/20)	2.86(0.47 – 17.35)	0.41	26(12-NR)	0.63(0.24, 1.62)	0.3
	VUS-L	9	22.2%(2/9)			10(8.8-NR)		
2L + SG	VUS-H	13	7.7%(1/13)	undefined	1.0	10(6.1-NR)	0.35(0.11 – 1.13)	0.08
	VUS-L	9	0.0%(0/9)			7.1(2.5-NR)		

#3403 The landscape of TP53 Y220C mutations in cancer.

Alison M. Schram, Fatema Nagib, Mara Rao, Rogelio Velasco, Michael Gormally, Alexandra Waksmundzki, Henry Walch, Michael Berger, Nikolaus Schultz, Mark Donoghue, Walid Chatila

Memorial Sloan Kettering Cancer Center, New York, NY

Background: *TP53* encodes the critical tumor suppressor p53 and is the most commonly mutated gene in cancer. The *TP53* Y220C hotspot mutation occurs in approximately 1% of solid tumors, reduces thermal stability of *TP53*, and impairs its DNA binding. *TP53* Y220C creates a unique conformational change that is amenable to small molecules that can restore *TP53* function. Several *TP53* Y220C reactivators are in development. Despite emerging evidence that *TP53* Y220C is a therapeutic target, the clinicopathologic features of patients with these tumors remain poorly understood. We describe the landscape of *TP53* Y220C solid tumors at Memorial Sloan Kettering Cancer Center (MSK).

Methods: This retrospective study included patients with TP53 Y220C solid tumors at MSK from July 2014 to March 2024. Patients were identified using paired tumor-normal next-generation sequencing (NGS) with MSK-IMPACT, a hybridization capture-based NGS assay that detects mutations, copy number alterations, and select structural rearrangements. Clinicopathologic data including sex, age and stage at diagnosis, race, and cancer type were automatically extracted from the medical record. Allele-specific copy number analysis was performed using FACETS, which infers purity and ploidy corrected integer DNA copy number calls from sequencing data. Genomic characteristics of *TP53* Y220C solid tumors were compared to those with other *TP53* missense mutations, truncating mutations, and complex alterations involving *TP53*, in addition to *TP53* wild-type tumors.

Results: 498 patients were identified with *TP53* Y220C-mutated solid tumors. The majority were female (67%), White (71%), never smokers (52%), with a median age of 63 years-old (range 16-90, n=479). Approximately half (56%) had stage I-III disease at diagnosis, 33% stage IV, 11% unknown. The most common tumor types were ovarian (22%), pancreatic (11%), breast (11%), and non-small cell lung cancer (10%). *TP53* Y220C prevalence was highest in high-grade serous ovarian cancer (4.5%). *TP53* Y220C rarely co-occurred with other *TP53* mutations (0.07%). The co-mutational profile, tumor mutational burden, copy number profile, and fraction of genome altered of *TP53* Y220C-mutated tumors was similar to tumors with p53 non-Y220C mutations. Whole genome doubling (WGD) occurred in approximately half of *TP53* altered cases, with similar frequencies for *TP53* Y220C and *TP53* non-Y220C mutated cancer. The frequency of WGD was higher in the altered groups compared to the *TP53* wild-type group. Mutations were predominantly clonal, with subclonal alterations found in only 0.7% of cases.

Conclusion: *TP53* Y220C is a newly described clinically actionable target found across solid tumors at low frequency. The genomic features of *TP53* Y220C-mutated cancers are similar to *TP53* non-Y220C mutated cancers. Research is ongoing to determine the natural history of *TP53* Y220C mutated cancers and whether this biomarker has unique predictive or prognostic implications.

IMMUNOLOGY: Enhanced Antibodies, TCR Constructs, Cytokines and Chimeric Proteins
Poster Session

#3406 GPRC5D multispecific antibodies with potent anti-tumor activity against multiple myeloma.

Hayley Roth, Daniel Rogers, **Ileine Sanchez**, Breanna Tyrell, Amelia Snyder, Kyle Doolan, Benjamin Doranz, Ross Chambers, Joseph Rucker

Integral Molecular, Philadelphia, PA

Background: GPRC5D is a G protein-coupled receptor that is expressed on multiple myeloma cells but absent from most healthy tissues. It is an attractive target for anti-tumor modalities including T cell-engaging bispecific antibodies. Recent clinical data demonstrate that combination therapy using T cell-engaging molecules, which individually target GPRC5D and BCMA on tumor cells, offers unprecedented therapeutic benefits for patients with relapsed/refractory multiple myeloma. A trispecific antibody that simultaneously engages these molecules while activating T cells is expected to provide comparable and additional benefits as a monotherapy.
Methods: Multipass membrane proteins are valuable therapeutic targets but are largely inaccessible for antibody discovery due to structural complexity and high conservation. We developed an antibody discovery platform (MPS) tailored for membrane proteins that utilizes advanced immunization techniques including DNA, mRNA, and Lipoparticles (virus-like particles) and also utilizes evolutionarily divergent host species. From the parental antibodies isolated, we engineered panels of GPRC5DxCD3 bispecific and GPRC5DxBCMAxCD3 trispecific antibodies using multiple formats and CD3 arms that encompass different geometries and binding stoichiometries. GPRC5D multispecific antibodies were tested for target specificity using Integral Molecular's Membrane Proteome Array (MPA). Both bispecific and
trispecific antibodies were tested for *in vitro* potency and cytokine release using MM.1R and RPMI 8226 multiple myeloma cell lines. *In vivo* efficacy for a subset of antibodies was determined using xenograft models in humanized mice.
Results: We immunized chickens with GPRC5D to obtain high-titer immune responses and configured resulting antibodies as T cell-engaging bispecific molecules with a CD3 binding arm. A subset of GPRC5DxCD3 bispecific antibodies displayed potent T cell-mediated cytotoxicity with picomolar potency on multiple myeloma cell lines. Antibody specificity profiling showed high specificity binding to its intended targets, and not to other proteins across the membrane proteome. Bispecific molecules were then re-engineered as trispecific antibodies with additional binding to BCMA, a well-validated multiple myeloma target. GPRC5DxBCMAxCD3 trispecific antibodies showed improved cytotoxic activity against multiple myeloma cells. Both bispecific and trispecific antibodies demonstrated a large window between cell killing and cytokine release. GPRC5D multispecific antibodies also showed robust tumor control against multiple myeloma xenografts in a humanized mouse model.
Conclusions: GPRC5D multispecific antibodies hold promise as potent and safe therapeutics for multiple myeloma.

#3407 Development of bispecific antibodies targeting claudin-6 for precision cancer therapy.

Siret Tahk[1], Paule Hermet[1], Anu Ustav[1], Robin Pau[1], Ana Shahpazir[1], Mario Plaas[2], Gaily Kivi[1], Andres Mannik[1], Joan Teyra[1], Tanel Mahlakõiv[1], **Mart Ustav**[1]

[1]Icosagen Cell Factory OU, Kambja, Estonia,[2]Tartu University, Tartu, Estonia

Background: Claudin 6 (CLDN6), a tight junction protein, is an oncofetal antigen with limited expression in adult tissues but aberrantly overexpressed in several cancers, including ovarian, testicular, and gastric tumors. Its tumor-specific expression and critical role in maintaining cell adhesion make CLDN6 a compelling target for cancer therapy. Recent studies have linked CLDN6 to tumor progression, metastasis, and chemoresistance, highlighting its potential as both a biomarker and a therapeutic target in precision oncology. This study presents the development of bispecific antibodies for the treatment of CLDN6-positive tumors.
Methods: Monoclonal antibodies specific to CLDN6 were generated using virus-like particles (VLPs) displaying CLDN6 as immunogens. Chickens were selected for immunization due to their ability to produce antibodies against highly conserved, multi-transmembrane proteins. Antibody discovery was performed using HybriFree B cell cloning technology and phage display platforms.
Results: Bispecific antibodies that specifically recognize CLDN6 and CD3 were developed and evaluated for their effectiveness in killing CLDN6-positive cells while sparing CLDN6-negative cells. Various bispecific antibody formats were assessed, showing differences in non-specific T-cell activation. These findings underscore the importance of selecting appropriate bispecific antibody modalities to achieve maximum therapeutic potency while ensuring a favorable safety profile. The functionality and potency of these novel bispecific antibodies were further demonstrated in vivo using ovarian cancer xenograft models.
Conclusions: This study highlights the development of novel bispecific antibodies targeting CLDN6 and CD3, emphasizing their superior safety profile. The use of specifically engineered antibody modalities and highly selective CLDN6 binders ensures minimal cross-reactivity with other homologous family members. These findings support the potential of these bispecific antibodies as a promising therapeutic approach for CLDN6-positive cancers.

#3408 Cancer-specific anti-HER2 monoclonal antibodies demonstrate antitumor activities in human breast cancer xenograft models.

Yukinari Kato[1], Tomokazu Ohishi[2], Tomohiro Tanaka[1], Hiroyuki Suzuki[1], Mika K. Kaneko[1]

[1]Tohoku University Graduate School of Medicine, Sendai, Japan,[2]Institute of Microbial Chemistry (BIKAKEN), Numazu, Numazu, Japan

Monoclonal antibody (mAb) therapy represents cutting-edge strategies for cancer treatment. In contrast, safety concerns persist due to the potential targeting of normal cells that express reactive antigens. Developing cancer-specific mAbs (CasMabs) that bind to cancer-specific antigens and exhibit antitumor activity in vivo is critical for reducing the risk of adverse effects. Herein, we selected mAbs targeting human epidermal growth factor receptor 2 (HER2) and successfully established an anti-HER2 CasMab (clone H2CasMab-2; mouse IgG1, kappa). We investigated both the in vitro and in vivo antitumor efficacy using three types of H2CasMab-2: the mouse IgG2a type of H2CasMab-2 (H2CasMab-2-mG2a), the mouse-human chimeric H2CasMab-2 (H2CasMab-2-hG1), and the humanized H2CasMab-2 (humH2CasMab-2). H2CasMab-2 showed lower reactivity to HER2-overexpressed Chinese hamster ovary-K1 (CHO/HER2) and breast cancer cell lines (BT-474 and SK-BR-3) than trastuzumab in flow cytometry. Every format of H2CasMab-2 also showed lower antibody-dependent cellular cytotoxicity (ADCC) against CHO/HER2 and the breast cancer cell lines than trastuzumab. In contrast, every format of H2CasMab-2 exhibited significantly higher complement-dependent cellular cytotoxicity (CDC) in CHO/HER2 and breast cancer cells than trastuzumab. Furthermore, every format of H2CasMab-2 demonstrated compatible in vivo antitumor effects against breast cancer xenografts with trastuzumab. These findings highlight the distinct roles of ADCC and CDC in the antitumor effects of H2CasMab-2 and trastuzumab and suggest a potential direction for the clinical development of H2CasMab-2 for HER2-positive tumors.

#3409 T cell receptors and antibodies targeting shared indel-derived neoantigens.

Kazuma Kiyotani, Peng Zhao, Xiaojing Wu, Yusuke Nakamura

Center for Intractable Diseases and ImmunoGenomics, National Institutes of Biomedical Innovation, Health, and Nutrition, Osaka, Japan

T cells play a pivotal role in cancer immunotherapy by recognizing neoantigens presented on HLA molecules, which are specifically expressed by cancer cells. While neoantigens are generally unique to individual cancers, shared antigens that are common in a subset of cancer patients, represent promising immunotherapeutic targets. Since frameshift insertions or deletions (indels) are reported to generate highly immunogenic neoantigens through novel open reading frames. However, few studies have explored shared neoantigens from frameshift indels, which are shred among multiple cancer patients. In this study, we analyzed frameshift neoantigens from frameshift indels in TCGA exome sequencing data, identifying 760 recurrent frameshift mutation clusters (FSCs) that shared frameshifted open reading frames and premature stop codons. Among these, we focused on two FSCs in the APC gene, which generate potential neoantigens (AS3 and AS10) presented the HLA-A24 molecule. We successfully identified the T cell receptor (TCR) sequences for APC frameshift neoantigens from healthy donor's blood. Genetically engineered T cells expressing these TCRs demonstrated recognition and cytotoxic activity against target cells presenting these APC frameshift neoantigens. Additionally, we explored the development of an antibody targeting a complex formed by the APC shared neoantigen AS10 and the HLA-A24 molecule. Using phage display library screening, we isolated single-chain variable fragments (scFvs) that specifically recognized the AS10-HLA-A24 complex. A bispecific antibody (BsAb) was then designed to connect T cells via an anti-CD3 scFv to the AS10 neoantigen on HLA-A24. We found that the AS10 BsAb specifically recognized both the AS10-HLA-A24 complex and CD3 protein, and showed significant IFN-γ release and cytotoxicity against target cells expressing frameshift neoantigens. By focusing on recurrent frameshift mutations and shared neoantigens, this study provides compelling evidence for the development of more effective and broadly applicable immunotherapeutic strategies.

#3410 Fc engineering of CD9 antibodies mitigates platelet toxicity and retains potency against acute lymphoblastic leukemia.

Wing Hei Ng[1], Shengyu Fu[2], Kathy Yuen Yee Chan[1], Kin Yi Chung[1], Yuen Ching Tiffany Hui[1], Qi Zhao[2], Kam Tong Leung[1]

[1]Department of Paediatrics, The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Institute of Translational Medicine, Faculty of Health Sciences, University of Macau, Macau, Macao

Background: Albeit significant progress in CD19/CD22-based immunotherapies, the outcomes of patients with relapse/refractory acute lymphoblastic leukemia (ALL) remains suboptimal. Tetraspanin CD9 endows proven prognostic impact and therapeutic relevance in ALL (Leung et al, 2020/2024). Yet, lethal platelet toxicities incurred by CD9 antibodies have hampered their clinical translation. This study aims to develop a safe and effective CD9 biologics through antibody engineering.
Methods: Murine CD9 antibodies were generated by standard immunization/hybridoma technologies and humanized via complementarity-determining region (CDR) grafting. Antibody affinity and specificity were assessed against soluble CD9 antigen and CD9-expressing/depleted ALL cell lines, while efficacy was confirmed with cell line-derived and patient-derived xenograft (PDX) models. Platelet toxicity was evaluated by CD62P expression, optical aggregometry and in FcγRIIA transgenic mice. Mechanisms were explored by cell proliferation, apoptosis, imaging and antibody-dependent cellular cytotoxicity (ADCC) assays.
Results: Two isolated murine monoclonal antibodies (mAbs) displayed distinct binding affinity and specificity towards the CD9 antigen, with biophysical properties preserved following humanization (hAbs). Administration of either mAbs or hAbs in 697-transplanted NOD/SCID mice markedly suppressed leukemia progression, alongside with substantial extension of animal survival. Consistent with previous reports, platelets were fully activated within 30 minutes after exposure to hAb IgGs but not their Fab or scFv fragments, indicating that platelet activation is a Fc-dependent event. By introducing a N297A mutation to the antibody Fc domain, platelet activation and aggregation was completely extinguished compared with the non-engineered version as reflected by absence of phenotypic CD62P expression (5.1±0.9% *vs.* 89.6±4.8%, $P<0.0001$) and physical aggregation (AUC: 18.9-29.5 *vs.* 382-395, $P=0.0016$). Additionally, no thrombocytopenia was observed in FcγRIIA transgenic mice with platelet counts in the hAb arm similar to those in the human IgG control arm (929±84 *vs.* 968±118, $P=0.7935$). Notably, N297A-modified hAbs profoundly reduced leukemia burden by >98% in PDXs developed from ALL patients who relapsed from upfront immunotherapies displaying CD19 antigen loss. Underlying its potency, Fc-modified hAbs triggered direct cell death and proliferation inhibition in CD9+ ALL cell lines following homotypic aggregation, a feature associated with type II antibodies. Cytotoxicity was mediated via an ADCC-independent mechanism.
Conclusion: Fc engineering mitigates the platelet toxicity of CD9 antibodies but retains potency against refractory ALL, potentially breaking the decade-long hurdle for their clinical translation. Large animal studies are ongoing.

#3411 Transcriptional modulations of tumor microenvironment by BH3120, a PD-L1x4-1BB bispecific antibody, in patient-derived organotypic tumor spheroids (PDOTS) model.

Jun Wang, **Jiangcheng Xu**, Jing Wang, Jiawang Liu, Kyoungwoo Lee

Beijing Hanmi Pharm. Co. Ltd., Beijing, China

BH3120 is an heterodimeric IgG like bispecific antibody in clinical stage targeting PD-L1 (CD274) and 4-1BB (CD137) simultaneously. It binds 4-1BB with moderate affinity while binds PD-L1 with relatively higher affinity, with the aim to focuss PD-L1 binding dependent 4-1BB agonism in tumor microenvironment. De-coupling of immune modulation between tumor and normal tissues were confirmed in multiple non-clinical studies, and the results were consistent with favorable safety profiles. In the meantime, BH3120 shows synergistic anti-tumor efficacy with PD-1 inhibitors without systemic safety concerns in vivo.

To understand how BH3120 and the combination with a PD-1 inhibitor modulate the tumor microenvironment, ex vivo studies with patient-derived organotypic tumor spheroids (PDOTS) were generated from freshly obtained tumor tissues of non-small cell lung cancer (NSCLC) patients, and cultured in microfluidic devices containing extracellular matrix. After incubation of the test articles in the ex vivo model, anti-tumor activities and immune modulations were observed by RNA analysis as the response to BH3120, a PD-1 inhibitor, and the combination.

In responding tumor spheroids, multiple genes were significantly upregulated or down-regulated. In particular, RNAs representing $CD4^+$ T cell, $CD8^+$ T cell, NK cell, and B cell signals, and certain co-stimulators, proinflammatory cytokines, and chemokines were notably increased. Combination of BH3120 and PD-1 inhibitor resulted in the relevant genetic modulations with high magnitudes implicating potential synergism in RNA level.

#3412 Cis demasking cytokine technology improves therapeutic index of immunocytokine.

Caroline Mary, Margaux Seite, Virginie Thepenier, Geraldine teppaz, Justine Durand, Kevin Biteau, Cecile Batty, Ariane Desselle, Julien Taurelle, Virginie Aillerie, Nicolas Poirier, **Aurore Morello**

OSE Immunotherapeutics, Nantes, France

Immunocytokines are promising therapeutic approaches to enhance T cell response by delivering interleukins directly to the tumor site. The fusion of wild-type or attenuated interleukins with anti-PD-1 antibodies has shown some efficacy in preferentially cis-activating PD1+ T-cells in tumor and lymph nodes. However, for many immunocytokines (*e.g.* IL-2/IL-15/IL-21/IL-12), off-target activation of PD1-negative cells remains a significant challenge due to the high affinity of the cytokine for their receptors, leading to unwanted systemic effects, toxicity, high clearance and low tumor biodistribution, which ultimately limits their clinical potentials. To address this low therapeutic index issue, strategies have emerged to achieve localized cytokine activation using conditional masking strategies (e.g. Enzymatic cleavable linkers) but their clinical translation remains challenging due to off-tumor activation. To overcome these limitations, we developed OSE-Cytomask® Platform, a universal and non-cleavable linker technology allowing cytokine CIS-demasking upon binding of the fused antibody to its target. This platform enables precise cytokine activation on the right T cell population to minimize toxicity and improve therapeutic index of immunocytokine. A series of linkers were screened for optimal cis activation of the cytokine on PD1+ vs PD1neg T cells fused to a high-affinity anti-PD1 antibody. OSE-Cytomask® linker technology strongly decreases IL-2 or IL-15 cytokine activity on PD1neg cells while maintaining strong activation of PD1+ T cells even in a co-culture system. We confirmed OSE-Cytomask® activity on PD1+ primary T cells while very low activation has been observed in naïve T cells. OSE-Cytomask® linker technology does not induce TRANS-activation on PD1neg T-cells illustrating a strict CIS-demasking activity. Importantly, Anti-PD1/IL-15 and anti-PD1/IL-2 OSE-Cytomask® technology strongly reduced toxicity of the immunocytokine while maintaining in vivo anti-tumor in vivo efficacy. At least 10-fold higher therapeutic index for OSE-Cytomask® Anti PD1/IL2v was obtained compared to the conventional Anti PD1/IL2v. In conclusion, OSE-Cytomask® linker technology illustrates specific intrinsic property to mask cytokine on naïve peripheral immune cells not expressing the target of the antibody while allowing selective CIS-demasking and activation of the cytokine on PD1+ cells. Unlike protease-cleavable linker technologies, OSE-Cytomask® does not rely on enzymatic activity, making it a more stable and adaptable solution across different TME conditions. It has been validated with multiple cytokines (6 tested) and can be fused with various antibodies. By reducing off-tumor cytokine activity and selectively activating immune cells, OSE-Cytomask® platform offers a promising strategy for the clinical development of more effective and safer immunocytokines for cancer therapies.

#3413 Discovery of GRC 65327, a best-in-class, selective and potent Cbl-b inhibitor for the treatment of advanced solid cancers.

Venkatesha Udupa[1], Atul Akarte[1], Jiju Mani[1], Nilanjana Biswas[1], Vikas Karande[1], Murugan Chinnapattu[1], Megha Marathe[1], Akshata Virdikar[1], Sneha Pusadkar[1], Shruti Talekar[1], Anuj Singh[1], Pandurang Lambade[1], Gopal Rajput[1], Akshaya Wagh[1], Pramod Pawar[1], Ajit Jagadale[1], Dayanidhi Behera[1], Balasaheb Gavhane[1], Manoj Pawar[1], Prashant Ingle[1], Pankaj Jain[1], Amol Walunjkar[1], Pavan Payghan[1], Sachin Chaudhari[1], Vidya Kattige[1], Sravan Mandadi[1], Madhavi Mulay[1], Ramesh Senaiar[1], **Mario Perro**[2], Pratima Deshpande[1], Nagaraj Gowda[1]

[1]Ichnos Glenmark Innovation (IGI), Mumbai, India,[2]IGI Biotherapeutics SA, Epalinges, Switzerland

Casitas B-lineage lymphoma-b (Cbl-b), a key member of RING finger E3 ligases, regulates both innate and adaptive immunity by mediating the degradation of signaling transducers. Cbl-b is a master regulator downstream of TAM receptors and CD28, promoting an immunosuppressive tumor microenvironment (TME) that limits the anti-tumor functions of T and NK cells. The absence of CD28 co-stimulation has been associated with T cell exhaustion and resistance to anti-PD-1 therapy. Inhibition of Cbl-b activates T cells even without CD28 co-stimulation, offering a potential therapeutic strategy to overcome immune suppression in the TME. GRC 65327 is a potential best in class, highly active and selective Cbl-b inhibitor. It significantly potentiates IL-2 and IFN-γ production in assays across human and preclinical species, with sub-nanomolar potency. Importantly, GRC 65327 restores function in anti-PD1 resistant exhausted T cells, mimicking the immunosuppressive conditions of the TME. The compound also engages its target in vivo, modulating biomarkers such as Notch1, enhancing its expression on T cells. Additionally, GRC 65327 demonstrated potent tumor cell killing in vitro, further highlighting its therapeutic potential. Efficacy studies in CT26 and MC38 colon tumor models demonstrated significant inhibition at tested doses. When combined with anti-PD1 therapy, GRC 65327 enhanced tumor growth inhibition and immune responses. Complete tumor regression was achieved in combination treatment in approximately 50-65% of animals, suggesting a synergistic effect between GRC 65327 and anti-PD1. Importantly, no treatment-related adverse effects, including changes in body weight, clinical signs, or mortality, were observed in these efficacy models. In vitro safety receptor profiling revealed minimal off-target activity, and hERG inhibition at an IC_{50} > 10 µM. In a one-month repeat-dose study in mice, no adverse effects were observed at the maximum tested dose of 300 mpk/day. However, liver toxicity was noticed in dose-range finding studies in dogs and monkeys. Despite this, a robust pharmacological response in the tissues was observed around $AUC_{0\text{-}24}$ of 1500 ng·h/mL and an increased number of circulating immune cells were seen at the highest dose tested compared to controls and baseline levels, with no adverse findings up to $AUC_{0\text{-}24}$ of ~13,400 ng·h/mL in a one-month repeat-dose study in monkeys. Importantly, no cytokine storm and myeloproliferative effects attributed to c-cbl in the literature were observed in the same study. Additionally, unlike a previous less-selective lead which exhibited RTK-mediated toxicities in various organs during exploratory tox study in rodents, GRC 65327 did not show adverse effects, highlighting its improved selectivity and safety profile. Based on these findings, a first-in-human clinical trial of GRC 65327 is scheduled to begin in advanced solid cancers.

#3414 PD-1 targeting increases the tolerance of IL-12 while maintaining potent anti-tumor immunity.

Stephen Searles, Kritika Mohan, Wenjing Yang, Elena Galitovskaya, Lynn Wang, Haikuo Zhang, Lidia Mosyak, Changhua Ji, Javier Chaparro-Riggers, Tzu-Hsuan Huang, Gabriel Starbeck-Miller

Pfizer Oncology, San Diego, CA

Preclinical studies have shown that IL-12 is a potent immunostimulatory cytokine that is capable of directly boosting CD8 T cell and IFNγ-dependent anti-tumor immunity. However, fully potent IL-12 therapies have limited clinical safety profiles. We have designed PF-07921585 to overcome this challenge by targeting IL-12 pharmacology on PD-1^{+} immune cells, a subset of CD8 T cells often enriched in the tumor microenvironment. PF-07921585 is a fusion protein consisting of an effector null bivalent anti-human PD-1 full length IgG1 and a single, potency reduced, human IL-12 mutein. PF-07921585 was specifically designed to permit simultaneous binding of PD-1 antagonists and enable combination with PD-1/L1 agents (PDx). Combination potential was confirmed in a mixed-lymphocyte reaction assay where we observed that PF-07921585 promoted robust IFNγ-responses as a single agent and boosted PDx-dependent IFNγ responses when given in combination. These data also suggested that targeted IL-12 receptor agonism and PDx checkpoint blockade have potential to non-redundantly amplify anti-tumor immune responses. In further support of this hypothesis, we found that combining a PF-07921585 mouse surrogate with PDx therapy can elicit greater efficacy in both PDx-sensitive and resistant mouse syngeneic tumor models than when either the surrogate or PDx therapy were administered as single agents. Administration of mouse surrogate as a single-agent also elicited potent anti-tumor CD8/IFNγ-dependent efficacy in PD-sensitive/resistant models and less peripheral toxicity compared to an untargeted, fully potent IL-12. Mechanistically, single-agent surrogate treatment enhanced the effector states (including increased IFNγ production) of several PD-1^{+} exhausted CD8 T cell subsets including the most dysfunctional subset, terminally exhausted cells. This latter effect was most striking as many published studies suggest PDx therapies only elicit efficacy by affecting the least dysfunctional exhausted T cell subsets, stem-like/progenitor cells. In summary, these data suggest that PF-07921585 may be better tolerated than other IL-12 therapies and has potential to deliver efficacy in PDx-refractory patients by heightening the effector function of CD8 T cell subsets not previously achieved by existing PDx therapies.

#3415 Preclinical characterization of LG anti-LILRB1, a potent antagonist targeting LILRB1.

Seok-Joo Kim, Younghoon Kim, Han Byoul Kim, Junhaeng Cho, Minsoon Kim, JungA Kim, Suji Hong, Heehang Kim, Shin-Young Kang, Hyungjin Cho, Jeeyeon Roh

LG Chem, Seoul, Korea, Republic of

LILRB1 is an inhibitory receptor found on various immune cells, including T cells, B cells, NK cells, and monocytes. It interacts with multiple ligands, including HLA class I molecules, with the highest affinity for HLA-G, and induces inhibitory signals that allow cancer cells to escape cancer immunosurveillance, impeding clearance from immune cells such as NK cells, T cells, and macrophages. This inhibitory effect in the tumor microenvironment may lead to disease progression, tumor metastasis, and poor clinical outcomes. For this reason, the blockade of LILRB1/HLA-G interaction could be a novel therapeutic target for the treatment of cancer. Additionally, recent studies indicate that LILRB1 may play an independent role in T cell functions beyond those regulated by PD1, suggesting that anti-LILRB1 therapy could potentially help in overcoming resistance mechanisms to anti-PD1 treatments. Therefore, LILRB1 is a promising target for cancer immunotherapy in human cancers due to its potential to mediate immune suppression across a wide range of tumor-associated immune cells. The protein-based and cell-based binding affinity of anti-LILRB1 antibody was measured using SPR and FACS analysis. A competitive ligand blocking assay was used to evaluate the ability of anti-LILRB1 antibody to block the interaction of LILRB1 with HLA-G. NK cell-mediated cellular cytotoxicity was evaluated by flow cytometry against HLA-G expressing tumors. The activities of NK cells and T cells were evaluated following the blockade of LILRB1. The in vivo anti-tumor efficacy of anti-LILRB1 antibody was evaluated in the human LILRB1 transgenic mouse and MC38-HLA-G syngeneic model. The binding affinity of the anti-LILRB1 antibody against LILRB1, quantified as 60 kD, was measured using a protein-based assay, and the EC50 was determined to be 20 nM using a cell-based assay. The binding of anti-LILRB1 antibody blocked interaction with HLA-G. In studies using human NK cell line and primary NK cells demonstrated that the anti-LILRB1 antibody enhanced their killing activity against HLA-G expressing tumors. In both systems, anti-LILRB1 antibody increased expression of CD69 and CD137, which are activation markers of NK cells, and IFN-Γ secretion. In LIR-overexpressing Jurkat cell line, anti-LILRB1 antibody enhanced IL-2 secretion. Importantly, the anti-LILRB1 antibody showed tumor growth inhibition in syngeneic model of human LILRB1 transgenic mice with MC38-HLA-G tumor. Based on these preclinical data, phase 1a study is currently ongoing (NCT06332755). Blockade of LILRB1/HLA-G interaction by antibody targeting LILRB1 enhances the immuno-modulatory effect of target immune cells. Furthermore, LILRB1 blockade enhanced anti-tumor efficacy in tumor bearing LILRB1-Tg mice model. These findings suggest that LILRB1 blockade antibodies have the potential to be developed as a therapeutic agent for the cancer immunotherapy for further investigation.

#3416 Advancing cancer immunotherapy: PD-L1-targeted IFNa2a fusion protein RO7694744.

Moritz Rapp[1], Harald Duerr[1], Gabriel Schnetzler[2], Davide Bertoldo[1], Jack Bates[1], Laura Kruempelmann[1], Alexandra Baumgartner[1], Marion Lichtenauer[1], Sandra Bunte[1], Kerstin Paetzold[1], Martina Antoniolli[1], Malika Ait-Goughoulte[2], Yvonnne Kienast[1], Johannes Sam[3], Steffen Dettling[1], Martin Lechmann[1], Robert Mader[2], Daniela Willend[2], Barbara Leutgeb[2], Anja Irmisch[3], Claudia Mueller[1], Metodi Donev[4], Andreas Roller[2], Nino Gochitashvili[5], Kerstin Meier[6], Yan Li[2], **Meher Majety**[1], Marina Bacac[3], Christian Klein[3], Pablo Umana[3]

[1]Roche Innovation Center Munich, Roche Pharma Research and Early Development, Penzberg, Germany,[2]Roche Innovation Center Basel, Roche Pharma Research and Early Development, Basel, Switzerland,[3]Roche Innovation Center Zurich, Roche Pharma Research and Early Development, Zurich, Switzerland,[4]Regulatory Affairs, F. Hoffmann-La Roche AG, Basel, Switzerland,[5]Clinical Development, Roche Products Limited, Welwyn, United Kingdom,[6]Legal, Roche Diagnostics GmbH, Penzberg, Germany

Interferon alpha (IFNa) is recognized for its potential in cancer immunotherapy by activating immune responses against tumor cells. However, untargeted IFNa's application is limited by systemic toxicity and non-specific activity, affecting both tumor and healthy tissues and resulting in undesirable side effects. To overcome these challenges, we developed the novel trivalent bispecific antibody-cytokine fusion protein RO7694744 designed to provide a specific activation of IFNa on programmed cell death ligand 1 (PD-L1) positive cells, such as tumor cells and immune cells. One antibody arm binds to human PD-L1 with high affinity, whereas the other arm can bind mutually exclusive either to human PD-L1 (with lower affinity) or to IFNa2a, which is fused to the antibody via a peptide linker. Both PD-L1 binders are non-blocking. This antibody design, called DutaFlip, protects the IFNa2a moiety from interacting with IFNa receptors (IFNAR1/2) until it is activated by binding to PD-L1 on the target cells.

Our research explored the PD-L1 selective activity of RO7694744 in multiple preclinical models. Using reporter cell assays, human whole blood cell assays, and various tumor cell lines with different PD-L1 expression levels, we demonstrated that IFNa activity depends on PD-L1 expression. Cells with elevated PD-L1 expression showed significantly higher activation compared to those with low PD-L1 levels. In vivo studies further validated these findings. In MDA-MB-231 tumor-bearing mice, RO7694744 treatment resulted in significant tumor growth inhibition (TGI), accompanied by intratumoral immune cell activation, and demonstrated a synergistic effect when combined with checkpoint inhibitor (CPI) treatment. To ensure translational relevance, we confirmed these in vivo observations in patient-derived tumor explants that mimic the human tumor environment. The explant data supported our previous findings, demonstrating PD-L1 specificity and dependency of RO7694744.

Our preclinical findings illustrate that RO7694744 selectively targets and activates PD-L1 expressing tumor and immune cells. Clinical experience is needed to confirm whether this targeted strategy can enhance therapeutic efficacy while minimizing adverse effects, thus addressing the key challenge of untargeted IFNa in cancer immunotherapy.

#3417 Preclinical studies of BR-2302: A HER3xEGFR bi-specific Exd-containing ADC.

Y. Wang, B. Xia, L. Cao, J. Yang, C. Feng, F. Jiang, C. Li, L. Gu, Y. Yang, J. Tian, J. Geng, Q. Zhang, Z. Wei, Y. Zhou;
Bliss Biopharmaceutical (Hangzhou) Co., Ltd., Hangzhou, China

HER3 has emerged as a critical player in the resistance mechanisms against therapies targeting the epidermal growth factor receptor (EGFR). Its upregulation can activate alternative signaling pathways, enabling cancer cells to bypass the effects of EGFR inhibitors, which often results in treatment failure. To combat this issue, novel HER3-targeting therapies are under investigation, including antibody-drug conjugates (ADCs) such as Patritumab Deruxtecan (U3-1402), which have shown encouraging results in clinical trials, underscoring the potential of HER3 targeting to overcome resistance. The development of bispecific ADCs that target both HER3 and EGFR represents a pioneering approach that may enhance therapeutic efficacy through dual targeting. Izalonatamab brengitecan (BL-B01D1), an ADC designed for simultaneous targeting of EGFR and HER3, has demonstrated substantial clinical benefits in heavily pretreated patients with EGFR-mutant non-small cell lung cancer (NSCLC). Building on this strategy, we are advancing a novel bispecific ADC, BR-2302, which employs a human IgG1 format bi-specific antibody with high affinity for HER3 and moderate affinity for EGFR. This innovative design aims to maximize therapeutic effectiveness while minimizing on-target/off-tumor toxicity associated with the widespread expression of EGFR in normal tissues. Our comprehensive studies on BR-2302 have focused on its *in vitro* cytotoxicity and *in vivo* tumor inhibitory effects across various cancer cell lines and xenograft models expressing the target antigens. BR-2302 exhibited significant anti-tumor activity *in vitro*, achieving subnanomolar IC_{50} values against HER3-expressing cell lines regardless of their EGFR expression levels. *in vivo* experiments demonstrated remarkable tumor growth inhibition and sustained regression in human lung and colon cancer xenograft models, surpassing the tumor inhibitory effects of established benchmark ADCs. Collectively, our findings indicate that BR-2302 possesses promising anti-tumor properties. This innovative therapeutic approach has the potential to improve treatment outcomes for patients with solid tumors expressing both HER3 and EGFR, warranting further clinical exploration.

#3418 IL6/1 fusion cytokine as a novel adjuvant for manufacturing of T cells for the treatment of ovarian cancer.

Sejal Tarun Sharma[1], Rahul Das[2], Lisa Barroilhet[1], Manish Patankar[1], Jacques Galipeau[2]

[1]Obstetrics & Gynecology, University of Wisconsin-Madison, Madison, WI,[2]Department of Medicine, University of Wisconsin-Madison, Madison, WI

Background: Autologous adoptive T cell therapy (ACT) is an emerging approach for the treatment of ovarian cancer. ACT is more effective if T cells manufactured ex vivo exhibit memory phenotype rather than exhaustive. IL-6 cytokine is known to effect T cell activation, proliferation, survival, and polarization whereas IL-1β is known to augment *in vivo* expansion of antigen-primed CD8 and CD4 T cells, $CD8^+$ T cell compartmentalization, and activation of T cells by antigen presenting dendritic cells. Due to known effects of these cytokines, we developed a novel biological product, IL6/1, a chimera of IL-6 and IL-1β, for effective manufacturing of T cells for ACT against ovarian cancer. We demonstrate that manufacturing of modified T cells with IL6/1 fusion cytokine improves T cell biological properties and hope to improve success of ACT in ovarian cancer.
Methods: Media from the HEK293 cells lentivirally transduced with IL6/1 was used to purify and characterize the fusokine. T cells were isolated from healthy donor PBMCs by negative selection and activated with IL2, anti CD3 - CD28 beads in the presence IL6, IL1β, IL6 + IL1β, IL6/1, conditional media, or no treatment control. Flow cytometry was used to monitor (a) T cell proliferation, (b) expression of CD45Ra, CD45Ro, CD3, CD4 and CD8 to define T cell phenotype and (c) assess cell death by labeling with annexin V and DAPI. Western blotting was performed to study the mechanism of action of IL6/1. Two-way ANOVA was used for statistical analysis.
Results: IL6/1 enhanced human T cell survival and increased the CD4 and CD8 memory (CD45Ro+) T cells as compared to vehicle controls or T cells exposed to IL6 or IL1β. T cells exposed to IL6/1 also showed a 10-15% increase in protection from cell death and apoptosis as compared to vehicle controls and T cells exposed to IL-6 or IL1β. Western blotting showed an increase in phosphorylation of STAT3, suggesting the involvement of this key signaling molecule in IL6/1-mediated T cell activation.
Conclusion: These findings suggest that IL6/1 fusion cytokine holds promise as a novel adjuvant for increasing the efficacy of T cell manufacturing for therapy in ovarian cancer. Overall, the IL6/1 fusion cytokine represents a novel approach to promote T cell survival, and memory T cell proliferation. Ongoing studies are focusing on evaluating the efficacy of IL6/1-based adjuvants in combination with ACT for the treatment of ovarian cancer in relevant mouse models.

#3419 EPS 226, a novel HER2 targeting IgE therapeutic, delivers immune dependent anti-tumor activity in preclinical models of breast cancer.

Elizabeth Hardaker[1], Lais C. GF Palhares[2], Melanie Grandits[2], Katie Stoker[2], Jitesh Chauhan[2], Tim Wilson[1], Sophia N. Karagiannis[2], Heather J. Bax[2], Kevin FitzGerald[1]

[1]Epsilogen Ltd, London, United Kingdom,[2]Kings College London, London, United Kingdom

HER2 is expressed at low levels in approximately 30-40% of cancers, including in breast cancer patients. Therapeutic IgE antibodies have been shown to deliver robust immune-dependent preclinical anti-tumor activity across a wide range of antigen levels. To explore the potential utility of a HER2-targeting IgE for the treatment of low HER2 breast cancer, EPS 226 was profiled in two in vivo models.EPS 226 was tested in the HER2-low, trastuzumab-resistant, human breast cancer model, JIMT1, in PBMC engrafted mice and the rat metastatic breast cancer model, MTLn3, in a fully immune competent rat. Briefly, female NXG mice were implanted with JIMT1 cells subcutaneously and engrafted with PBMC in the presence of FLT3 ligand once the tumors reached 50mm3. Female Fischer rats were implanted with MTLn3 subcutaneously and once tumors reached 50mm3, they were randomized into treatment groups. Animals were dosed twice weekly with EPS 226 or appropriate controls by intravenous administration. Tumor volumes were assessed, and the tumors were formalin fixed, or snap frozen, for further analysis at the end of study.EPS 226 induced an antigen specific tumor cell killing of JIMT1 and MTLn3 cells via antibody dependent cellular cytotoxicity (ADCC) in vitro, in the presence of human or rat PBMCs respectively. In the JIMT1 model, EPS 226 resulted in a dose dependent tumor growth inhibition. At 20mg/kg, EPS 226 resulted in a 62±10% tumor growth inhibition in the presence of PBMCs. No anti-tumor activity was observed in the absence of PBMCs demonstrating this efficacy was immune dependent. To fully explore the impact of EPS 226 on the immune system a rat syngeneic model, MTLn3, was established and shown to express low levels of HER2. Across multiple experiments EPS 226 resulted in an average of 50% tumor growth inhibition. In contrast, in this model, anti-PDL1 did not statistically significantly impact tumor growth. The efficacy of EPS 226 was associated with a 1.9-fold increase in tumor resident macrophages compared to the PBS control. Histology analysis also demonstrated that EPS 226 resulted in a 2.7-fold increase in T cells, comprising of predominantly CD8+ T cells. RNA Seq analysis of the bulk tumor showed a statistically significant increase ($p\ adj < 0.05$) in the activated CD8 T cell signature, compared to PBS controls.These studies are the first to demonstrate immune dependent anti-tumor efficacy of a novel HER2-targeting IgE antibody in models that have low HER2 expression. Treatment with EPS 226 resulted in an upregulation of immune cells, including an increased level of activated T cells, within the tumor microenvironment. These findings suggest that a HER2 targeting IgE has the potential to deliver clinical efficacy, in the context of low HER2 expressing patients, via a unique mechanism of action.

#3420 Coordinated stimulation of APC and T cell functions by first-in-class, tri-specific AN8025 for next-generation cancer immunotherapy.

Youping Wang, Wenjing Yang, Wanwan Chen, Kun Zhu, Zhihong Liu, Guolong Xu, Nanhai He

Adlai Nortye Ltd., Hangzhou. Zhejiang Province, China

Background: Immune checkpoint inhibitors (ICI), the cornerstone of current immunotherapies, primarily target T cells to reinvigorate the immune system against tumors. Recently, combinatory approaches, particularly in the form of bi-specific molecules such as Akeso's PD-1/VEGF and Innovent's PD-1/IL2, have garnered significant interest for their potential to deliver superior clinical efficacy beyond the ICI era. Building on this paradigm, AN8025 emerges as a tri-specific antibody fusion protein derived from a clinically validated and approved anti-PD-L1 antibody, fused with functionally optimized extracellular domain of CD86 and LAG3 on its C- and N-termini, respectively. Here we report that AN8025 leverages the LAG3 component to stimulate the differentiation and maturation of antigen-presenting cells (APCs), while the CD86 and anti-PD-L1 components synergistically amplify tumor-specific T cell responses. Together, these actions orchestrate a multifaceted enhancement of immune function.

Method: The *in-vitro* binding activities of AN8025 to corresponding targets and targets expressed on cell lines or primary cells were assessd by BLI, ELISA, or flow cytometry. Its *in-vitro* functional activities were measured using both reporter and primary immune cells. *In-vivo* efficacy was evaluated in MC38-hPD-L1 syngeneic model and hPBMC-engrafted NOG mouse bearing the MDA-MB-231 model. The developability of AN8025 was assessed under various stress conditions, and the preliminary pharmacokinetic (PK) profile was characterized in SD rats and Cynomolgus monkeys.

Results: AN8025 exhibited low single-digit nanomolar binding affinity to PD-L1 and CTLA4, while demonstrating over ten nanomolar binding to CD28. It effectively blocked the PD-1/PD-L1 interaction and the interaction between CTLA4 and CD80 proteins. Functionally, AN8025 demonstrated superior activation of T cells compared to the PD-L1 antibody alone and the combination of individual components of AN8025 (PD-L1 antibody, CD86-Fc, and LAG3-Fc). Significantly, the heightened T cell activation, primarily driven by the interaction of CD86 and CD28, is strickly dependent on the presence of PD-L1. In addition, AN8025 promoted the differentiation and maturation of antigen-presenting cells (APCs), as indicated by morphological changes, increased secretion of cytokines and chemokines, and induced expression of APC activation/maturation markers such as CD80/CD83. *In-vivo*, AN8025 alone showed superior efficacy compared to either ICI or the combination of individual components of AN8025. Furthermore, AN8025 exhibited favorable *in-vitro* stability and *in-vivo* pharmacokinetic profiles, with a long serum half-life in rats and in monkeys.

Conclusion: AN8025 demonstrates superior *in-vitro* and *in-vivo* activities compared to ICIs, supporting its further preclinical and clinical development.

#3421 XON7, a new emerging multitarget immunotherapy against metastatic soft tissue sarcomas.

Carine Ciron, Gwenaelle Evanno, Pierre-Joseph Royer, Odile Duvaux, **Firas Bassissi**

Xenothera, Nantes, France

Context: Soft tissue sarcomas (STS) are rare and heterogeneous malignancies originating from mesenchymal tissues, comprising over 50 subtypes. While surgery and radiotherapy are effective for localized disease, advanced and metastatic STS have poor outcomes due to limited efficacy of standard treatments like doxorubicin and frequent therapeutic resistance. Advances in molecular profiling have enabled targeted therapies, such as PARP inhibitors, but their effectiveness remains limited by the diversity of STS and resistance mechanisms. In this study, we evaluate the safety and efficacy of XON7, a first-in-class glyco-humanized polyclonal antibody (GH-pAb), as a novel therapeutic approach to address these challenges.
Methods: XON7's antitumor efficacy was tested in a panel of primary patient-derived sarcoma tumors and established sarcoma cell lines using CellTiter-Glo assay. Mechanisms of action assessed included complement-dependent cytotoxicity (CDC), apoptosis, antibody-dependent cell cytotoxicity (ADCC) and antibody-dependent cellular phagocytosis (ADCP). Apoptotic pathways were explored via caspase 8/9 activation, reactive oxygen species (ROS) production, and mitochondrial membrane potential. In vitro 3D cultures, XON7's impact on tumor growth, spheroid formation, and metastasis was evaluated. In vivo XON7 efficacy was evaluated in patient-derived xenograft (PDX) models of STS, with tri-weekly treatments initiated at tumor volumes of 150-200 mm^3.
Results: XON7 acts via plural MOA (CDC, apoptosis and ADCP), it demonstrated a potent anti-tumor activity in a panel of soft tissue sarcoma cells, with cytotoxicity ranging from 60% to 100% at a concentration of 300 µg/ml. Apoptotic induction involved both intrinsic and extrinsic pathways as evidenced by caspase 8/9 activation, ROS generation and loss of mitochondrial membrane potential. In 3D culture, repeated exposure to XON7 at a concentration of 300µg/ml significantly reduced the surface and viability of spheroids (liposarcoma SW872 cell line). XON7 also demonstrated its ability to reduce tumorogenicity and metastasis in a transwell invasion assay. In a PDX mice model of dedifferentiated liposarcoma, XON7 inhibited tumor growth by 50% over 48 days.
Conclusion: XON7 characterized by its plurality of action and potent antitumor efficacy, currently under clinical evaluation, XON7 emerges as a promising immunotherapy for soft tissue sarcomas.

#3422 Targeted optimized interferon alpha demonstrates improved safety and efficacy in tumors with low PD-L1 expression.

Kristopher Steward[1], Wuyi Wang[1], Yanmei Sun[2], Chengwei Shang[2], Chun Yang[2], Tom Boone[1], Hai Yan[1]

[1]REMD Biotherapeutics, Camarillo, CA,[2]Sichuan Luzhou Buchang Biopharmaceutical Co., Luzhou, China

Introduction: Type 1 interferons (IFN), including IFN alpha, have potent antitumor and immune stimulating effects. Though approved for treatment of multiple cancers, clinical use of IFN alpha is hindered by its short serum half-life and poor tolerability due to the broad expression of the Type 1 IFN receptor (IFNAR). A systematic approach was taken to improve the therapeutic window of IFN alpha. First, site specific mutations were designed to attenuate binding to IFNAR resulting in modified interferons with optimized activity. Then, the optimized interferons were fused to tumor antigen targeting antibodies (Abs) to generate immunocytokine molecules called Tumor Activated Interferon (TAI). Behaving as agonists, TAIs exhibit improved on-target activity once bound to antigen-positive cells. Moreover, TAIs also display significantly reduced systemic toxicity due to their attenuated non-targeted IFN activity. These characteristics contribute to the improved therapeutic window of TAIs. REMD-456 is our lead candidate consisting of optimized IFN alpha fused to PD-L1 Ab.

Methods: TAIs were screened for their IFN activity by reporter assay using cells with or without PD-L1 expression. Tumor cell growth inhibition activity of TAIs was assessed by MTS and CellTiter-Glo proliferation assays. Equimolar doses of pegylated IFN alpha-2a (PEGASYS) and TAI were evaluated in human tumor xenograft models using cell lines with various levels of PD-L1 expression. A single dose non-GLP tox study was conducted in Syrian golden hamsters with both PEGASYS and TAIs to assess PK and safety. Furthermore, PK, toxicity and biomarkers of TAIs were assessed in cynomolgus monkeys.

Results: Various TAIs containing different peptide linkers and optimized IFNs fused to PD-L1 Ab were screened for their PD-L1 targeted and non-targeted IFN activity. Compared to IFN alpha, the TAIs showed up to 9000-fold reduced non-targeted activity and up to 14-fold improved targeted activity. Tumor cell growth inhibition assays showed a similar activity profile. TAIs, at doses as low as 1 ug/kg, demonstrated superior in vivo anti-tumor activity compared to PEGASYS against NCI-N87 (PD-L1 low) and NCI-H820 (PD-L1 high) human tumor xenografts. In Syrian golden hamsters, high dose TAI did not affect body weight while PEGASYS at equimolar dose caused significant body weight loss. In cynomolgus monkeys REMD-456 had an acceptable safety profile at all doses tested.

Conclusions: REMD-456 was selected for its efficacy and safety profile in vitro and in vivo and manufacturability. It showed enhanced IFN activity only on PD-L1^{+} cells, resulting in an improved therapeutic window. In vivo, REMD-456 demonstrated superior anti-tumor efficacy in human tumor xenografts. Moreover, REMD-456 displayed an improved safety profile in hamster and primate single dose toxicity studies. IND enabling studies are in progress with anticipated filing in late 2025.

#3423 A novel triple action of SLC-3010 strengthens anti-tumor immunity by *in vivo* free TCB2/endogenous IL-2 complexing.

Junhyeok Heo[1], Daeun Kim[1], Geona Kim[1], Kyungmi Han[1], Junyoung Lee[1], Sun Young Rha[2]

[1]Selecxine Inc., Pohang-si, Korea, Republic of,[2]Song-dang Institute for Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: CD122-biased signaling has arisen as a promising approach to enhance anti-tumor T cell responses. However, the limited efficacy of CD122-biased IL-2 in clinical trials suggests that a more delicate approach beyond CD8 activation is needed. The secretion of IL-2 by activated T cells following CD122-biased IL-2 eventually leads to the expansion of Tregs, which can dampen the strength of the anti-tumor immune responses. Based on prior studies that anti-mouse IL-2 antibody (S4B6) can suppress Treg survival by blocking mouse IL-2 in vivo but boost CD8 T cells when it is complex with mIL-2, we devised a strategy leveraging this mechanism. To this end, we developed SLC-3010, which is hIL-2 and an anti-hIL-2 antibody (TCB2) conjugate via antigen-antibody interaction. Since TCB2 binds with IL-2 through CD25-binding epitope on hIL-2, the SLC-3010 provides CD122-biased IL-2 signaling. Although the primary MoA, anti-tumor efficacy and crystal structure of SLC-3010 have been previously reported, the fate and therapeutic implications of the non-covalent conjugated drug are not fully understood.
Methods: PK properties of SLC-3010 and TCB2 were assessed by ELISA after SLC-3010 administration. The role of free TCB2 in augmenting anti-tumor immune responses was investigated using flow cytometry. The therapeutic impact of free TCB2 was assessed by comparing the anti-tumor efficacy of SLC-3010 in tumor-bearing hIL-2 tg and wt mice. The anti-tumor efficacy of SLC-3010 and IL-2-CD25 fusion protein, which is unable to regulate endogenous IL-2 beyond primary CD122-biased signaling, was evaluated in hIL-2 tg mice.
Results: Free TCB2 dissociated from SLC-3010 remains detectable in the bloodstream for an extended duration than SLC-3010. Circulating free TCB2 can bind with lately encountered hIL-2 and provide a CD122-biased signaling again. Tregs expansion and/or survival were significantly reduced in hIL-2 tg mice, leading to a 3.65-fold higher tumor infiltrating MP CD8/Treg ratio than in wt mice. The anti-tumor efficacy of SLC-3010 was more pronounced in hIL-2 tg mice compared to wt mice. SLC-3010 exhibited superior anti-tumor efficacy compared to IL-2-CD25 fusion protein in hIL-2 tg mice.
Conclusions: SLC-3010 exhibits a "triple action" mechanism: SLC-3010 selectively stimulates anti-tumor immunity, disrupts Treg homeostasis, and re-boosts the immune system through in vivo complexing with endogenous IL-2. Currently, SLC-3010 is undergoing evaluation in an open-label, multi-center phase I/II clinical trial with dose escalation and expansion. SLC-3010 has been well-tolerated and has showed promising clinical activity, including confirmed partial response and sustained stable diseases with tumor shrinkage in patients with advanced solid tumors. (NCT05525247)

#3424 DuoBody®-FAPαxDR4 induces tumor cell death through FAPα-dependent, DR4 transactivation-mediated apoptosis.

I. Jongerius[1], J. Laoukili[2], B. de Goeij[1], E. Souteyrand[1], G. Andringa[1], M. Paauwe[1], M. Luijten[1], D. Satijn[1], E. Breij[1], O. Kranenburg[2], M. Overdijk[1];

[1]Genmab B.V., Utrecht, Netherlands, [2]University Medical Center Utrecht, Utrecht, Netherlands

Apoptosis can be induced through activation of death receptors (DRs), which, upon binding to their natural ligands, hypercluster to initiate caspase-dependent cell death. This process can be mimicked by agonistic antibodies, making it a promising approach for anticancer therapy. However, DR-targeting cancer therapies evaluated in the clinic have shown limited success, due to insufficient clinical activity and/or safety concerns primarily related to hepatotoxicity. We hypothesize that conditional activation of DR4 in the tumor microenvironment (TME) can improve the therapeutic window of DR agonism.

Fibroblast activation protein (FAP)α-expressing cancer-associated fibroblasts (CAFs) are abundant in the stroma of many solid cancers, making FAPα an attractive target to direct DR4 agonism to the TME. Here we present the novel Fc-silenced bispecific antibody DuoBody-FAPαxDR4 (GEN1057) designed to simultaneously bind to DR4 expressed on tumor cells and FAPα expressed on CAFs, to conditionally activate DR4 on the tumor cells. Functional activity of DuoBody-FAPαxDR4 was assessed in tumor cell lines and colorectal carcinoma (CRC) patient-derived organoids (PDOs) using viability and bioluminescent reporter assays and potential hepatotoxicity was evaluated using human primary liver spheroids *in vitro*. *In vivo*, antitumor activity of DuoBody-FAPαxDR4 was evaluated in patient-derived xenograft (PDX) models from different tumor types and in a model for spontaneous multiorgan metastasis of CRC.

DuoBody-FAPαxDR4 induced dose-dependent caspase-8 activation and cytotoxicity in DR4-expressing tumor cell lines and CRC PDOs, when cocultured with FAPα-expressing cells *in vitro*. Cytotoxicity was strictly dependent on the presence of FAPα-expressing cells, with no direct effect on their viability. Furthermore, no cytotoxicity was observed in cocultures treated with monospecific control antibodies containing either the FAPα- or DR4-specific Fab arm of DuoBody-FAPαxDR4, confirming that binding to both DR4 and FAPα is required for DR4 transactivation. DuoBody-FAPαxDR4 induced caspase-8 activation and cytotoxicity in the cocultures to levels in the same range as an antibody that induced unconditional DR4 hyperclustering. Importantly, DuoBody-FAPαxDR4 did not induce cytotoxicity in human primary liver spheroids. *In vivo*, DuoBody-FAPαxDR4 showed potent antitumor activity in PDX models and against multiorgan metastases in a CRC PDO cecum transplantation mouse model.

In conclusion, DuoBody-FAPαxDR4 is a novel bispecific antibody that activates DR4 on cancer cells exclusively in the presence of FAPα-expressing cells, leading to targeted caspase activation and tumor cell death. DuoBody-FAPαxDR4 represents a promising therapeutic agent for the treatment of cancer and is currently under evaluation in a first-in-human trial in patients with solid tumors (NCT06573294).

#3425 A novel anti-EGFR × IL-10M (FP010) fusion protein for solid tumor therapy.

J. Guo, J. Ding, C. Gu, L. Ye, D. Zhu, Y. Ou, Z. Zhang, B. Ren, C. Zhou, B. Shen, X. Wu, K. Chen, D. Lu, Y. Huo;
Guangdong Fapon Biopharma Inc, Dongguan, China

$CD8^+$ T cell exhaustion has been recognized as an important factor contributing to the resistance to PD-1/PD-L1 inhibitors. Recently, IL-10 was found to reinvigorate tumor-infiltrating terminally exhausted $CD8^+$ T cells via metabolic reprogramming, and enhance their proliferation, cytotoxicity and cytokine secretion. Notably, combining IL-10 with anti-PD-1 or CAR-T therapies markedly enhanced their antitumor efficacy. In a Phase 1b clinical trial, PEGylated IL-10 showed promising therapeutic potential in NSCLC and RCC. However, severe hematologic toxicities limited its clinical applications.

To overcome this challenge, we engineered the dimeric IL-10 into a monomeric form (IL-10M) to reduce its downstream activity, thus minimizing its toxicity. We then developed FP010, an anti-EGFR × IL-10M fusion protein of which IL-10M was fused to the C-terminus of the heavy chain of an engineered anti-EGFR antibody (panitumumab Fab combined with IgG1 Fc). This design allowed FP010 to preferentially accumulate in EGFR-expressing tumors, thereby enhancing its therapeutic effect. In this study, we evaluated FP010's antitumor activity in vitro and in vivo, as well as its safety profile in cynomolgus monkeys.

FP010 showed binding and blocking activity similar to that of panitumumab on A431 cells, and could significantly inhibit their proliferation. Additionally, FP010 exhibited strong ADCC activity. FP010 exhibited much lower downstream signal activity than wild type IL-10 in a STAT3 reporter assay. However, FP010 still kept its ability in promoting IFN-γ secretion and inhibiting apoptosis in exhausted $CD8^+$ T cells, indicating its ability to reinvigorate these cells. In vivo studies demonstrated potent antitumor activity of FP010 in both MC38-cEGFR and B16-cEGFR models, better than IL-10M or anti-EGFR antibody alone. We further assessed the hematologic toxicities of FP010 in cynomolgus monkeys. No evident hematologic toxicity was observed with FP010 at a dose of 10 mg/kg IV QW. In contrast, Panitumumab × wt IL-10 caused a remarkable decrease of erythrocytes at the same dose, consistent with the adverse effects of PEGylated IL-10 observed in clinical trials.

FP010 has demonstrated significant antitumor activity in vitro and in vivo, with acceptable adverse effects observed in cynomolgus monkeys. These data indicate that FP010 has great potential for cancer immunotherapy, especially for tumors with resistance to PD-1/PD-L1 inhibitors due to T cell exhaustion.

#3426 Preclinical development of CD-001, a novel fusion protein combining PD-1 blockade with IL-21 for solid tumors.

Y. Li[1], X. Luan[2], S. Zhou[2], X. Cheng[2], J. Zhao[1], G. Sang[2], H. Shen[2], N. Yang[2], J. Yang[2], J. Xu[2], S. Wang[1];
[1]Institute of Biophysics, Chinese Academy of Scienses, Beijing, China, [2]CD (Suzhou) Biopharma Co., Ltd., Suzhou, China

Background: Immune checkpoint blockade (ICB) has revolutionized cancer immunotherapy, offering significant clinical benefits. However, these successes are unfortunately limited to a minority of patients. Meanwhile, cytokine-based therapies have shown promise in cancer treatment, but are accompanied by potential severe systemic toxicity. CD-001 is a novel fusion protein integrating anti-PD-1 antibody with mutated IL-21. This dual-targeting approach enables simultaneous blockade of the PD-1/PD-L1 axis and targeted delivery of IL-21 to PD-1$^+$ T cells, aiming to enhance tumor-specific immune responses while minimizing systemic adverse effects.

Methods: Comprehensive nonclinical studies, including pharmacology, pharmacokinetics (PK), and toxicology assessments, were conducted to evaluate the safety and efficacy of CD-001. Pharmacology studies were performed to assess CD-001's binding affinity to PD-1 and IL-21R as well as its functional targeting of PD-1$^+$ T cells. In vivo efficacy was explored in various mouse tumor models including melanoma, lung cancer, and lymphoma. Toxicology and PK were also evaluated in cynomolgus monkeys.

Results: CD-001 exhibited high affinity to both PD-1 and IL-21R, and effectively targeted PD-1$^+$ T cells to exert its biological function. In vivo, CD-001 demonstrated superior antitumor activity compared to anti-PD-1 monotherapy or its combination with IL-21. Enhanced tumor-reactive CD8$^+$ T cell responses were observed. PK studies showed dose-proportional systemic exposure of CD-001 with no significant accumulation after repeated dosing in cynomolgus monkeys, and receptor occupancy results illustrated more than 30% of target engagement within 7 days. GLP toxicity studies in cynomolgus monkeys demonstrated a favorable toxicity profile, with no significant cardiovascular or neurological dysfunctions observed. Immunotoxicity observed in the GLP study tended to resolve or was fully resolved by the end of the recovery period.

Conclusion: CD-001 exhibits a well-characterized safety profile and potent antitumor activity in preclinical models, supporting its future development as a therapeutic candidate for advanced solid tumors. The dual mechanism of CD-001, combining PD-1 inhibition with targeted IL-21 delivery, represents a novel therapeutic strategy to enhance T cell-mediated immunity in cancer patients.

#3427 HY07121, a new generation of immune oncology therapeutics overcoming tumor immune resistance.

X. Zheng, Y. Chen, G. Dong, Y. Zhang, M. Zhang, B. An, C. Li, J. Zhan, X. Chai, J. Dai, P. Yang, D. Sun, A. Fu, T. Wei;
Sichuan Huiyu Seacross Pharmaceutical Technology Co., Ltd., Chengdu, China

Objective: The majority of cancer patients develop resistance to immune checkpoint inhibitors (primary and acquired drug resistance), which may be related to immune cell exhaustion mediated by additional immune checkpoints and the immunosuppressive tumor microenvironment. Developing next-generation immunotherapy drugs to address tumor immune resistance is a pressing clinical need.
Methods: We engineered and optimized a bispecific fusion protein, HY07121, by integrating PD-1 and TIGIT-targeted antibodies with IL-15/IL15Ra fusion cytokine. The molecule utilizes steric hindrance and tumor-specific targeting of PD-1 and TIGIT to minimize IL-15 exposure to peripheral tissues and balance toxicity with efficacy. Additionally, HY07121 synergistically enhances the intratumoral targeting of stem-like CD8+ T cells through PD-1 and IL-15 co-stimulation, inducing their expansion and differentiation. This replenishes tumor-killing effector T cells, thus overcoming immune exhaustion-induced resistance. The pharmacodynamic (PD), mechanistic, pharmacokinetic (PK), and toxicological profiles of HY07121 were evaluated through in vitro, in vivo, and cynomolgus monkey studies.
Results: In vitro pharmacodynamic studies demonstrated that HY07121 significantly stimulated IFN-γ secretion from human PBMCs at levels superior to the combination treatment group, demonstrating a strong synergistic potential that went beyond additive effects. In vivo, HY07121 exhibited dose-dependent tumor inhibition in both the human bladder cancer cell derived xenograft model and the immune-resistant human melanoma cell (A375) derived xenograft model, significantly outperforming the combination of Pembrolizumab and Tiragolumab. Mechanistically, HY07121 markedly upregulated the transcription of stem-like CD8+ T cell and NKT-related gene sets. Cynomolgus monkey pharmacokinetic analysis revealed dose-dependent systemic exposure (Cmax and AUClast) in the 0.2 mg/kg, 0.6 mg/kg, and 1.8 mg/kg groups, indicating nonlinear pharmacokinetics. The half-life (T1/2) across different doses ranged from 6.25 to 13.7 hours, with an accumulation ratio of less than 1.17 after four consecutive doses. During the entire GLP toxicity study, all monkeys were in good condition, with no abnormal clinical findings, and all animals survived until the planned necropsy. The maximum tolerated dose (MTD) was determined to be 2.4 mg/kg, and the highest non-severe toxic dose (HNSTD) was 1.8 mg/kg, indicating a therapeutic safety window of approximately 10-fold.
Conclusion: The in vitro and in vivo findings suggest that HY07121 is a novel, mechanism-driven therapeutic with the potential to enhance the efficacy of immunotherapy and address both primary and acquired resistance. The pharmacological and toxicological profiles strongly support the continued clinical development of HY07121.

#3428 Mechanistic insights into IFx-Hu2.0 responses in the first human trial after prior anti-PD-1 therapy failure.

Joseph Markowitz, Vishanna Balkaran, Andrew S. Brohl, Amod S. Sarnaik, Zeynep Eroglu, Nikhil I. Khushalani, Deanryan B. De Aquino, Pei-Ling Chen, Vernon K. Sondak, Ahmad A. Tarhini, Youngchul Kim, Shari Pilon-Thomas

Moffitt Cancer Center, Tampa, FL

Introduction: IFx-Hu2.0 is a plasmid encoding Streptococcal Emm55 protein for transfection into mammalian cells. The first-in-human clinical trial of IFx-Hu2.0 for unresectable melanoma showed that intra-tumoral IFx-Hu2.0 is safe. Melanoma patients responded to anti-PD1-based treatments after IFx-Hu2.0 treatment despite being previously refractory to treatment. Antibodies to Emm55 protein were seen in patient-derived plasma (Markowitz et al., Mol Cancer Ther., 2024). We now report on TCRseq and BCRseq from patients who received IFx-Hu2.0 on study. We also report on murine studies investigating how IFx-Hu2.0 produces a systemic immune response.
Methods: Samples were available pre/post therapy from 6/6 patients who completed the dose-limiting toxicity period on trial. TCRseq from peripheral blood and BCRSeq from peripheral blood and tumors were measured on purified RNA using Adaptive Biotechnologies™ company. The B16 murine model was utilized to study IFx-Hu2.0 systemic effects. Thirteen mice had tumors implanted in both right and left flanks. The mice received weekly injections of IFx-Hu2.0 or empty plasmid vehicle control into the right flank, and tumor growth curves were constructed. Tumor growth curves were compared using the CGGC permutation test. To determine whether antibodies are developed against Emm55, we transfected an unrelated cell line (EL4) with the Emm55 plasmid (EL4-Emm55) and exposed it to murine serum obtained from mice bearing B16 tumor, treated with IFx-Hu2.0 treatment using an empty plasmid as a control. Following this, we utilized a fluorescently tagged secondary goat anti-mouse IgG to assess whether antibodies in the serum bound to the cells, with measurements taken via flow cytometry.
Results: TCRSeq and BCRSeq demonstrated unique T and B-Cell clones in melanoma patients treated with IFx-Hu2.0. Mice injected with IFx-Hu2.0 demonstrated a statistically significant reduction in tumor growth compared to control mice (mean tumor volume at Day 17; 104 ± 22 mm^3 vs 702 ± 100 mm^3, $p < 0.01$). Within mice treated with IFx-Hu2.0, uninjected tumors grew more slowly than tumors in uninjected mice ($p = 0.03$), supporting an abscopal effect in mice. Anti-emm55 IgG antibodies were measured via flow cytometry on EL4-emm55 cells pulsed with murine sera from mice treated with IFx-Hu2.0 and IgG did not bind to EL4 cells transfected with Emm55 but not pulsed with serum.
Conclusions: The expression of Emm55 in a B16 murine melanoma model induces a direct anti-tumor and abscopal effect, with antibodies to Emm55 detected in murine sera. Further research is needed to assess the role of these antibodies in anti-tumor immunity. Unique clones from TCRSeq and BCRSeq suggest that IFx-Hu2.0 may be a personalized vaccine. Ongoing studies aim to understand how patients become re-sensitized to anti-PD-1 therapy, with subsequent clinical trials in development.

#3429 Improving druggability of a promising tumor target by the novel glycosylation-dependent mAb GT-008 for treatment of solid tumors.

Johanna Gellert, **Andreas Franz**, Manon Weis, Evelyn Hartung, Stephanie Gurka, Antje Danielczyk, Lisa Wei?, Patrik Kehler

Pentixapharm AG, Berlin, Germany

Aberrant O-glycosylation is a hallmark of cancer and can be used to improve druggability of targets for cancer immunotherapy. Tumors express cell surface proteins decorated with truncated O-glycans like Thomsen-Friedenreich (TF), Thomsen-nouveau (Tn) or sialylated Tn (sTn) antigens, which are virtually absent from normal tissues. Development of therapeutic mAbs against these hapten glycotopes is often hampered by weak affinities and low specificity, whereas peptide epitope targeting mAbs usually cannot distinguish between normal and tumor tissue. Both drawbacks can be circumvented by addressing combined protein/carbohydrate epitopes with mAbs that enable high affinity binding and high tumor specificity at the same time. We generated mAb GT-008 recognizing the glycoprotein CD24 with fundamental role in tumorigenesis and tumor progression, which is expressed on solid tumors, but also on healthy immune cells and tissues. GT-008 binds CD24 only in presence of a tumor-associated glycosylation thereby leading to reduced binding of the protein expressed on healthy cells.GT-008 was generated by immunization and single B cell cloning using different on- and off-target glycoforms for selection and screening. Binding and tumor selectivity were analyzed by ELISA, flow cytometry and immunohistochemistry on healthy and tumor tissues. Functionality was investigated by *in vitro* internalization and cytotoxicity assays with tumor and healthy cells. Compared to a conventional glycosylation-independent control antibody, GT-008 binds the protein target only in presence of TF O-glycosylation, but not the non-glycosylated protein, other glycoproteins carrying TF nor a synthetic TF O-glycoconjugate. GT-008 differentiates against the sialylated glycoform present on normal tissues. This leads to reduced binding to healthy human immune cells and tissues compared to the control mAb, whereas binding to cancer tissues from different indications (e.g. endometrium, breast, ovarian, prostate, a.o.) was retained. Additionally, its glycosylation dependent binding translates into tumor-selective internalization of GT-008 *in vitro* while sparing out CD24-positive immune cells. GT-008 has the potential to overcome limitations of conventional protein-targeting mAbs currently in clinical development by circumventing immune cell depletion and on-target/off-tumor toxicities associated with target expression on healthy cells. With its improved therapeutic window due to the strong differentiation between healthy and tumor tissue, GT-008 is exceptionally suitable for different therapeutic modalities, such as drug delivery (ADC, RIT) or cellular therapies (CARs). An *in vitro* and *in vivo* proof-of-concept study as therapeutic radioimmunoconjugate has been initiated.

#3430 FP008, a novel anti-PD-1×IL-10M fusion protein for cancer therapy.

Ce Gu, Jiaojiao Ding, Baiguang Ren, Mengying Liang, Linhui Ye, Yingye Ou, Chang Zhou, Bingquan Shen, Jian Guo, Xiaodong Wu, Ke Chen, Yongting Huo, Di Lu

Guangdong Fapon Biopharma Inc., Dongguan, China

Immune checkpoint inhibitors (ICI) such as anti-PD-1/PD-L1 antibodies have achieved remarkable clinical successes in cancer therapy. However, over 70 % of patients receiving ICI treatments are not responsive or experience disease progression after an initial period of response. Terminal exhaustion of $CD8^+$ T cell was supposed to contribute to this low responsiveness. On the other hand, IL-10 could enhance the anti-tumor activity of ICI by reinvigorating and expanding terminally exhausted $CD8^+$ T cells. Encouraging efficacies have been observed in phase 1 clinical trials of IL-10 therapy, but severe hematologic toxicity and low dosage greatly hindered its efficacy in further clinical trials. We therefore developed FP008, a novel anti-PD-1 × IL-10M (IL-10 monomer) fusion protein, and demonstrated its promising potential for cancer therapy.

FP008 exhibited strong anti-PD-1 blocking performance and activity comparable to its parental anti-PD-1 antibody. More importantly, FP008 significantly decreased $CD8^+$ T cells apoptosis and promoted IFN-γ secretion when co-cultured with exhausted $CD8^+$ T cells induced in vitro. This function was mainly caused by the IL-10M moiety, which was modified into a monomer to reduce downstream signaling and the resulting hematologic toxicity. Compared with wild-type (wt) IL-10, IL-10M significantly decreased the phagocytosis of erythrocytes by macrophages in vitro. The result was consistent with the observation in the toxicity study in monkeys. FP008 induced less STAT3 phosphorylation without PD-1 crosslinking in activated $CD8^+$ T cells or reporter cells than wt IL-10. Furthermore, the STAT3 signaling was greatly enhanced after PD-1 crosslinking, indicating FP008 may have strong activity on TILs where PD-1 is highly expressed.

In both CT26 and MC38 tumor models in hPD-1 knock-in mice, FP008 dose dependently inhibited tumor growth, with stronger anti-tumor efficacy and longer survival than Keytruda. In a CT26 rechallenge model after FP008 treatment and complete tumor regression, mice were re-challenged with CT26 tumor cells but remained tumor-free without further treatment, indicating that FP008 treatment could induce immunological memory. TILs analysis showed that the number of tumor-infiltrating $CD8^+$ T cells increased, while Treg cells decreased after FP008 treatment. In a GLP toxicology study in cynomolgus monkeys, FP008 was well tolerated at the dose of 10 mg/kg, and produced minimal decrease of erythrocyte and no tissue damage.

In conclusion, FP008 showed novel characteristics such as the synergistic function of anti-PD-1 and IL-10M, cis-activation of IL-10M by PD-1 enrichment and improved safety profiles. It demonstrated promising potential for clinical therapy for the anti-PD-1 naïve or resistant patients.

#3434 Evaluation of TCR-engineered T cells specific for KRAS G12V mutant peptide presented by HLA-A*02:01.

Joshua Ferrell, Xingyue He, Hongjing Qu, Allison Drain, Monique Peyreau, Nicole Danek, Ping Zhu, Hubert Lam, Dongmei Xiao, Joshua Francis, Gary Shapiro, Loic Vincent

Affini-T Therapeutics, Inc., Watertown, MA

Adoptive cellular therapies (ACT) have had limited success in the treatment of solid tumors. Recent approvals of both Tumor Infiltrating Lymphocyte (TIL) and T cell receptor-engineered T cell (TCR-T) therapies herald the promise of autologous T cell strategies. Unfortunately, existing therapeutics face significant challenges including an existing T cell response to immunogenic tumors (TILs) or relying on targets lacking tumor dependence (TCR-T). Engineered T cell therapies utilizing TCRs specific for public oncogenic driver mutations would overcome these hurdles with the intent of driving potent durable responses. Single residue alterations in KRAS are the most frequent oncogenic driver mutations in solid tumors, with G12V arising in indications with high unmet medical need such as PDAC, CRC, and NSCLC. HLA-A*02:01 is the most frequently occurring HLA class I allele in North American and Western European populations, and thus targeting the mutant KRAS G12V peptide presented in the context of HLA-A*02:01 offers the opportunity to treat a large patient population. However, therapeutics designed to provoke immunogenic responses to the KRAS G12V peptide presented by HLA-A*02:01 have proven challenging thus far, and physical evidence of the presentation of the G12V peptide by HLA-A*02:01 has been limited. Here, we employed a non-viral knock in system to screen TCRs via delivery of a transgene cassette comprised of 1) a transgenic TCR, 2) a chimeric cytokine receptor, and 3) the CD8αβ coreceptor to the *TRAC* locus of human primary T cells. We show specific TCR-T activation by KRAS G12V exogenous peptides loaded into HLA-A*02:01. We also demonstrate the potent induction of functional responses by engineered T cells to endogenous HLA-A*02:01 cancer cell lines both 1) engineered to express tandem minigenes (TMGs) encoding the KRAS G12V peptide and 2) transiently transfected with mRNA to express full length KRAS G12V proteins. These data provide evidence for the processing and presentation of KRAS G12V peptides by endogenous HLA-A*02:01 and illustrate its immunogenicity. This finding is further supported by the recognition of HLA-A*02:01 cell lines endogenously harboring KRAS G12V mutations and the specificity of the engineered T cells as assessed by X-Scan analysis. Our work provides evidence for the processing and presentation of the KRAS G12V mutant peptide in the context of HLA-A*02:01 and demonstrates the feasibility of targeting this public tumor-specific neoantigen widely expressed in indications with high unmet medical need.

#3435 B cell TuLibs: Immortalized tumor-derived B cell libraries for the interrogation and unbiased discovery of novel therapeutic targets and antibodies from patients.

Casper Marsman, Jurgen Heinen, Kelly Maijoor, Arjen Bakker, Rob Roovers, Michael Koslowski, Stefano Gulla, **Alessandra Micaela Villa**

Kling Biotherapeutics BV, Amsterdam, Netherlands

The use of B cell repertoires for antigen and antibody discovery is on the rise due to the emergence of new techniques to tap into the human antigen-experienced B cell repertoire. Recently, many research groups have shown that the presence of tumor-infiltrating B cells or Tertiary Lymphoid Structures (TLS) at tumor sites correlate with improved survival and response to Immune Checkpoint Inhibitors. Here, we present Kling Biotherapeutic's platform that enables the discovery of novel therapeutic targets and antibody-pairs. We overcome the limited proliferative lifespan of primary human and animal B cells by transduction with a proprietary vector to express Bcl6 and Bcl-xL, which prevents both terminal differentiation and apoptosis. Through the highly efficient isolation and immortalization of tumor- or TLS-derived B cells, our approach captures the B cell diversity and all Ig-isotypes from all tissues. As opposed to the labour intensive and costly approach of ex vivo BCR sequencing and subsequent recombinant antibody production and validation, our B-cell Tumor Libraries (TuLibs) secrete antibodies into the culture supernatant while retaining indefinite expansion capabilities, allowing for immediate functional screening of antibodies and rapid identification of unique tumor-specific B cell clones. Moreover, our immortalized B cells retain the ability to undergo somatic-hypermutation, allowing for in vitro affinity maturation of immortalized B cell clones against targets of interest. Altogether, Kling Biotherapeutic's proprietary platform allows the comprehensive functional screening and affinity maturation of human and animal B cell repertoires from multiple tissues sources. TuLibs represents a significant advancement in our ability to identify new immuno-functional targets and antibodies for biopharmaceutical development of tumor targeted therapies.

IMMUNOLOGY: Inflammation and Cancer: Tumor Initiation and Progression / Metastasis
Poster Session

#3438 The CD24-SEC14L2 drives the neoplastic progression of oral squamous cell carcinoma.
S.-R. Chang, C.-H. Chou, K.-W. Chang, **S.-C. Lin**;
National Yang Ming Chiao Tung University, Taipei, Taiwan

Immune stimulation or escape are critical factors determining the survival of malignancies, including oral squamous cell carcinoma (OSCC) and head and neck SCC (HNSCC). CD24 is a glycoprotein anchoring on cell membranes, modulating macrophages' immune responses and tumor stemness. However, its roles in the neoplastic progression are still controversial. As the inhibition of multiple oncogenic miRNAs downregulates CD24 expression, but not other immune checkpoint molecules, in murine OSCC cell lines, the functional roles of CD24 are investigated using a knockdown approach and the stable *CD24* tet-off expression cell subclones. CD24 expression modulates the increase of migration and invasion and the upregulation of phosphatidylcholine/phosphatidylinositol transfer protein SEC14 Like 2 (*SEC14L2*) expression. CD24 expression enriches the orthotopic growth of syngeneic tumor grafts. This is accompanied by the slight change in the myeloid lineage of immune cell infiltration within tumors and the mild disruption of cell profile in recipient mice's neck lymph node and spleen. The shutdown of CD24 with doxycycline treatment drastically suppresses the growth of CD24 tet-off tumors. Concordance in CD24 and SEC14L2 expression is noted in murine tumors. *SEC14L2* is upregulated in TCGA-HNSCC tumors and our OSCC tumors. High *SEC14L2* expression defines the decreased B cells and myeloid cell population. The integrative analysis of combined TCGA-HNSCC and our OSCC cohort using random effect mode illustrates *SEC14L2* as an unfavorable survival predictor of tumors. The oncogenic potential of the CD24-SEC14L2 axis being elucidated in this study may signify the therapeutic efficacy of CD24 targeting for oral cancer.

#3439 Study on the mechanism of sesamin inhibiting the malignant metastasis of prostate cancer.

Y. Chen[1], A.-C. Chang[2], C.-H. Tang[1], T.-S. Hwang[2];
[1]Medicine, China Medical University, Taichung, Taiwan, [2]Shin-Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan

Purpose: Prostate cancer (PCa), a malignant tumor of the urinary tract, is one of the most common cancers in men. PCa tends to metastasize to bones and lymph nodes, resulting in increased mortality. Sasamin is a plant compound extracted from sesame seeds. Some studies suggest that sesame lignans may have the potential for antioxidative, anti-inflammatory, and anti-tumor effects. Here, we aim to investigate the inhibitory effects of sesamin on the invasiveness of PCa cells *in vitro* and tumor progression *in vivo*.
Materials and Methods: Human PCa cell lines DU145 and PC-3 were obtained from the Bioresource Collection and Research Center (BCRC). Cell survival was detected by Colony formation assay. Wound healing assay, Anoikis assay and Transwell migration/invasion assay were performed to analyze cell aggressiveness. The subcutaneous tumor model was performed to study the inhibition of tumor growth by sesamin treatment. The levels of ADAM9, PD-L1 and Ki67 protein expression in tumor tissues were detected by immunohistochemistry (IHC) staining.
Results: Firstly, PCa cells were treated with different concentrations of sesamin, revealing a dose-dependent inhibition of both cell survival rate and proliferative ability. The co-administration of sesamin with a chemotherapeutic drug (docetaxel & cabazitaxel) enhances chemosensitivity in PCa cells. Next, we found that sesamin inhibits cell motility, invasion, and anoikis resistance via ADAM9 down-regulation through the JNK and c-Jun signaling pathway in PCa cells. Interestingly, sesamin can reduce ADAM9-mediated cleavage of membrane-bound PD-L1 (mPD-L1) into its soluble form, thereby inhibiting immune escape in PCa. Moreover, subcutaneous injection of PCa cells in mice, followed by twice-weekly intraperitoneal injection of sesamin, resulted in tumor growth inhibition. IHC staining of mice tumor tissues revealed a decrease in the levels of ADAM9 and Ki67 expression, and an increase in mPD-L1 expression in the sesamin-treated group compared to the non-treated group.
Conclusion: These results suggest that sesamin exhibits inhibitory effects on cell proliferation, migration, invasion, anoikis resistance, and immune escape *in vitro*, as well as tumor growth *in vivo*. The strategy of co-administration of sesamin can benefit clinical chemotherapy treatment, highlighting the potential of sesamin as an adjunctive treatment in PCa.

#3440 Local regulatory T cell dysfunction in gut mucosa post-infection prevents colorectal cancer establishment.

L. M. Goncalves[1], L. B. da Conceicao[1], J. B. de Assis[1], G. W. da Silva[1], G. M. B. Rodrigues[1], B. d. Oliveira[1], M. V. de Araujo[1], G. d. Lima[1], A. M. Abreu[1], C. B. Alves[1], F. Moreira[2], M. S. Coelho[1], L. C. R. da Silva[1], E. A. d. Nascimento[1], R. G. Ludwig[3], M. R. Vinolo[3], S. M. Muxel[1], E. E. de Oliveira[4], A. Lepique[1], D. M. da Fonseca[1];

[1]Institute of Biomedical Sciences (ICB), University of Sao Paulo, Sao Paulo, Brazil, [2]Johannes Gutenberg University Mainz, Mainz, Germany, [3]Institute of Biosciences (IB), University of Campinas, Campinas, Brazil, [4]University of Rio de Janeiro State - UERJ, Rio de Janeiro, Brazil

Colorectal cancer (CRC) is among the most lethal intestinal diseases, claiming approximately 1 million lives globally each year, with an incidence rate of around 2 million cases annually, presenting a significant public health challenge. Investigations into the etiology of CRC and strategies to enhance patient survival have highlighted the role of infectious episodes in disrupting intestinal immune homeostasis. Our research indicates that the resolution of certain acute gastrointestinal infections, typically considered benign, leads to permanent remodeling of the immune and lymphatic systems in the gastrointestinal tract and adjacent organs, such as the mesentery and mesenteric lymph nodes. This remodeling results in chronic local inflammation, impairing specific regulatory responses in the intestinal mucosa. We have demonstrated that this chronic inflammatory environment increases susceptibility to inflammatory bowel diseases, prompting the hypothesis that a similar process could occur with CRC. To test this, we infected C57BL/6 mice with *Yersinia pseudotuberculosis* (YP) and, after bacterial clearance, we induced CRC by azoxymethane and dextran sodium sulfate treatment. On the contrary to our initial hypothesis, Mice previously infected with YP exhibited fewer countable tumors compared to naïve mice, suggesting that the prior infection might protect against cancer development. Concurrently, we observed that Treg lymphocytes in the colonic lamina propria of YP-infected mice are dysfunctional, as they fail to control inflammation in both the T cell transfer colitis model and in vitro suppression assays. We believe that Treg dysfunction post-YP infection may favor immune surveillance and support the reduction in tumor development, given that the tumor microenvironment typically recruits Tregs as an immune escape mechanism, and post-infection, these cells are unable to function correctly.

#3442 Multi-omics comparison of early vs late-onset colorectal cancer reveals distinct tumor phenotype of early-onset patients.

David Cohen[1], Aleksandar Obradovic[2], Luka Jovanovic[2], Soobeom Lee[3], Dechokyab De[4], Casidhe-Nicole Bethancourt[1], Caitlin Rogers[4], Yosuke Mitani[4], Tianxia Li[4], Viktoria Jakubikova[5], Yoanna Pumpalova[2], Beatrice Dionigi[1], Sanja Vickovic[6], Joel Gabre[2]

[1]Department of Surgery, Columbia University Irving Medical Center, New York, NY,[2]Department of Medicine, Columbia University Irving Medical Center, New York, NY,[3]New York Genome Center, New York, NY,[4]Columbia University Irving Medical Center, New York, NY,[5]Human Immune Monitoring Core, Columbia University Irving Medical Center, New York, NY,[6]Department of Biomedical Engineering and Herbert Irving Institute for Cancer Dynamics, New York Genome Center, New York, NY

Though incidence and mortality of colorectal cancer (CRC) in individuals older than 50 (late-onset, LO-CRC) have been declining over the last 30 years, they have been increasing among adults less than 50 (early onset, EO-CRC), constituting a significant public health concern. Detailed molecular comparison of EO-CRC to LO-CRC tumors has thus far been limited to whole-exome sequencing and confounded by the complex tumor immune microenvironment (TME), with significant presence of non-tumor cells. Here, we present integrated comparison of EO- and LO-CRC by single-cell RNA-Sequencing (scRNA-Seq) and multi-plex immuno-fluorescence (mIF). We combine public data with in-house clinical samples to comprise a rich resource of scRNA-Seq on 43,000 cells from 11 EO-CRC tumors and 19 LO-CRC tumors and perform mIF on a tissue microarray of 50 EO- and 50 LO-CRC samples, focusing on major immune cell subsets. Our ScRNA-Seq analysis utilizes an algorithm that leverages gene regulatory networks for Virtual Inference of Protein Activity by Enriched Regulon (VIPER) to cluster cell populations in the TME, identify cell types over-represented in EO-CRC (by Fisher's Exact Test), and characterize regulatory proteins aberrantly activated in those cell types. By this approach, we have found small, but statistically significant elevation in fibroblasts (p=0.042), endothelial cells (p=0.025), and B-cells (p=0.042) in EO-CRC compared with LO-CRC, though no difference in T-cells. Further, scRNA-Seq VIPER analysis of tumor cells demonstrates a sub-phenotype conserved across patients and significantly over-represented in EO-CRC (p=0.028), marked by up-regulation of TLR4, C5AR2, LILRB4, PTPRE, and CCR5 (proteins known to play a role in immune signaling and inflammation) – and with specific activity of druggable proteins EPHB4, FGFR4, and IKBKB. Overall, we find that EO-CRC is transcriptionally similar to LO-CRC and is composed of a similar cellular milieu. mIF validates no differences in T-cell subsets but is unable to confirm increase in endothelial cells in EO-CRC found in our scRNA-Seq data set. Our finding of similar T-cell density is of particular interest and helps dispel the notion that EO-CRC is more immune "cold" than sporadic CRC in older cohorts. Most strikingly, we find that EO-CRC is marked by a particular cluster of TLR4-high tumor cells. It has previously been found that high fat diets can lead to increased CRC growth in a TLR4-dependent manner in murine models – thus suggesting a link between a known environmental risk factor and EO-CRC. Work is ongoing to validate TLR4-high tumor cells in human tissues and patient-derived organoids (PDOs). Further studies will utilize PDO as an *in vitro* model for drug screens targeting aberrantly active druggable protein targets in EO-CRC tumors and to further explore the mechanisms that contribute to development of EO-CRC.

#3443 Bipotential role of retinoblastoma binding protein 9 in sporadic colorectal cancer and colitis-associated cancer.

Yuki Nakanishi, Kensuke Hamadaa, Yu Muta, Mayuki Omatsu, Kosuke Iwane, Munehiro Ikeda, Jiayu Chen, Yoko Masui, Naoki Aoyama, Hiroki Kitamoto, Nobuyuki Agatsuma, Go Yamakawa, Takahiro Utsumi, Makoto Okabe, Shuji Yamamoto, Akihisa Fukuda, Hiroshi Seno

Kyoto Univ. Graduate School of Medicine, Kyoto, Japan

Retinoblastoma-binding protein 9 (RBBP9) is expressed in various human cancers and has been identified as a serine hydrolase promoting cancer progression by antagonizing TGFβ signaling. While its roles in pancreatic cancer have been explored, little is known about its function in intestinal tumorigenesis. Using human samples and mouse models, we investigated the bipotential role of RBBP9 in sporadic colorectal cancer (CRC) and colitis-associated cancer (CAC).Human surgical samples revealed that RBBP9 expression is significantly lower in CAC compared to sporadic CRC. Sporadic CRC is driven by Wnt/β-catenin activation, whereas CAC involves inflammation-associated pathways such as mTORC1 and IL6/JAK/STAT3 signaling. Consistent with these findings, *Rbbp9*$^{-/-}$ mice exhibited increased colitis severity and enhanced CAC tumorigenesis in the azoxymethane/dextran sulfate sodium (AOM/DSS) model. Transcriptomic analysis of AOM/DSS-treated tumors revealed upregulation of inflammatory and proliferation-associated pathways, such as mTORC1 and IL6/JAK/STAT3, while Wnt/β-catenin and mitotic signatures were downregulated, indicating inflammation-driven tumorigenesis independent of Wnt signaling in CAC.In the *Apc*$^{Min/+}$ model of spontaneous intestinal tumorigenesis, RBBP9 loss led to fewer and smaller tumors in the small intestine, accompanied by reduced proliferative activity and downregulation of cell cycle-related pathways (e.g., Myc targets and G2M checkpoint). Interestingly, tumors from *Apc*$^{Min/+}$;*Rbbp9*$^{-/-}$ mice exhibited enrichment of inflammatory and interferon-related signatures, including “oxidative phosphorylation” and “interferon alpha/gamma response,” though these changes did not lead to increased tumor proliferation without inflammatory stimuli. However, when *Apc*$^{Min/+}$;*Rbbp9*$^{-/-}$ mice were treated with DSS, a significant increase in inflammation-mediated tumorigenesis was observed in the colon, accompanied by elevated Ki67 and pS6 staining, markers of proliferative activity.Collectively, these findings highlight the bipotential role of RBBP9 in intestinal tumorigenesis. In human CAC, reduced RBBP9 expression correlates with inflammation-driven pathways, while in sporadic CRC, higher RBBP9 expression supports tumor progression via Wnt/β-catenin and cell cycle pathways. These results demonstrate that RBBP9 functions as a context-dependent regulator, suppressing inflammation-mediated tumorigenesis while supporting spontaneous tumorigenesis through proliferative pathways. Targeting RBBP9 may offer novel therapeutic strategies tailored to distinct CRC subtypes, depending on their inflammatory or non-inflammatory origins.

#3444 Characterization of immune environment in SV40C3-tag mouse model of triple-negative breast progression.

Janvi Sandhu[1], Anjana Bhardwaj[1], Alexander Koh[1], Raniv D. Rojo[2], Rim Ouni[3], Matthew Embury[1], Roza Nurieva[3], Isabelle Bedrosian[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]College of Medicine, University of the Philippines, Manila, Philippines,[3]Department of Immunology, UT MD Anderson Cancer Center, Houston, TX

Background: Triple-Negative Breast Cancer (TNBC) is aggressive subtype and studies have reported impact of immune system on prognosis and treatment response. The role of the immune system during TNBC tumorigenesis, in the transition from precancer to cancer in unknown. We hypothesize that progression towards tumor is associated with both quantitative and functional changes to the immune microenvironment.

Methodology. SV40C3-TAg female mice, a TNBC progression model that develops tumors resembling human Ductal Carcinoma In-situ (DCIS) and Invasive Ductal Carcinoma (IDC) was used. To characterize immune population, mammary glands were harvested at 6-weeks (precancer) and 22-weeks (tumor) and immune cell population was analyzed by Fluorescence Assisted Cell Sorting (FACS). Animals were also sacrificed at multiple timepoints prior to tumor development to investigate immune cell populations and cytokine mileu during tumorigenic progression. Histopathological grades were assigned to mammary tissues: 0 for simple epithelium, 1-3 for mid to atypical hyperplasia (non-malignant low grade) and 4-5 for in-situ to invasive carcinoma (high grade lesions). Average number of $B220^+$ B cells and $CD8^+$ T cell per high-power-field (HPF) across the mammary tissue samples was determined. To understand functional characteristics of immune population mammary tissue samples were analyzed for levels of cytokines IL-4, IL-10, INF- ɣ using ELISA and Luminex Discovery Assay.

Results: The average number of $B220^+$ B cells increased from 0.73 cells/HPF in low grade (G0-3) to 1.61 cells/HPF in high grade (G4-5) mammary lesions ($p=0.0329$). Similarly in flow cytometry analysis, a 2-fold increase ($p=0.0051$) of B cell population was seen when comparing mammary tumors in 22-week animals to mammary glands from 6-week tumor free animals. Similarly, a significant infiltration of $CD8^+$ T cells from low (0.6 cells/HPF) to high (3.62 cells/HPF) grade lesions was seen by IHC ($p<0.0015$), mostly localized in peri-tumoral region, which is substantiated with 10-fold increase in $CD8^+$ T cells ($p=0.0012$) in FACS analysis of mammary tumors vs mammary tissue from 6 week animals. Furthermore, when we investigated the subpopulation of CD8+ T cells, there is an 2-3-fold increase in $CD8^+$ T FoxP3+ and $CD8^+$T $CTLA^+$ ($p=0.0004$) cells when comparing 22 week tumor bearing glands to mammary glands at the 6 week timepoint and 2-3-fold elevation in $CD8^+$ T IL-10 ($p=0.0291$). In line with FACS data, we observed increasing trend of IL-10 and IL-4 along with reduction in INF- ɣ when comparing cytokine levels in high grade mammary tissues vs low grade mammary tissues.

Conclusions: The influx of immune B cells and immune regulatory cells T cells indicate active response to tumor. The patterns of change in quantitative cell counts and immune mileu suggest changes from immune-stimulatory (Th1) to suppressive environment (Th2) with tumor progression.

#3445 Germline BRCA2 heterozygosity drives gastric lesion formation via myeloid-biased differentiation in bone marrow under chronic IL-1β overexpression and *Helicobacter felis* infection.

Feijing Wu, Quin Waterbury, Puran Zhang, Hiroki Kobayashi, Biyun Zheng, Hualong Zheng, Yi Zeng, Ruhong Tu, Jin Qian, Xiaofei Zhi, Yosuke Ochiai, Mashahiro Hata, Leah B. Zamechek, Timothy C. Wang

Columbia University Irving Medical Center, New York, NY

Background: BRCA2 plays a crucial role in DNA homologous recombination repair, and mutations in this gene significantly increase cancer risk. Previous studies have shown that heterozygous mutations in BRCA2 enhance pancreatic tumorigenesis driven by $KRAS^{G12D}$, but their impact on gastric tissues is less understood. This study investigates how knockout of a single BRCA2 allele affects inflammation-induced gastric damage under chronic interleukin-1β (IL-1β) overexpression and Helicobacter felis infection.
Methods: Mice heterozygous for BRCA2 were crossed with ATP4b-IL1β transgenic mice, which overexpress IL-1β in parietal cells to mimic chronic gastric inflammation. These $BRCA2^{+/-}$; ATP4b-IL1β mice were then infected with H. felis for three months and compared to ATP4b-IL1β control mice. Stomach histology and immune response dynamics were assessed, including a complete blood count (CBC) and flow cytometry of bone marrow to analyze hematopoietic stem cells (HSCs), myeloid-biased multipotent progenitors (MPP3), and neutrophils.
Results: We observed no significant atrophy or metaplasia histological changes in the stomachs of $BRCA2^{+/-}$; ATP4b-IL1β or ATP4b-IL1β mice at three months. However, H. felis infection significantly intensified gastric inflammation, metaplasia, dysplasia, and atrophy in $BRCA2^{+/-}$; ATP4b-IL1β mice compared to the ATP4b-IL1β mice. CBC results showed a 52.3% increase in neutrophil counts in the blood of infected of infected $BRCA2^{+/-}$; ATP4b-IL1β mice. Flow cytometry of bone marrow hematopoietic cells indicated a 72.3% reduction in HSCs and a 21.0% increase in MPP3 populations in $BRCA2^{+/-}$ mice compared to $BRCA2^{+/+}$ mice overexpressing IL-1β, suggesting a shift towards myeloid differentiation. Analysis of gastric tissue showed a 77.9% increase in neutrophil infiltration in $BRCA2^{+/-}$ mice, which correlated with the increased severity of lesions.
Conclusions: Our results indicate that heterozygosity for BRCA2 mutations can worsen gastric injuries in the context of chronic inflammation and H. felis infection, potentially due to hematopoietic imbalances and a shift towards neutrophil differentiation that exacerbates gastric pathology. This underscores the critical role of bone marrow dysfunction in driving inflammation-induced gastric damage in individuals with BRCA2 mutations. Future studies are needed to clarify the effects of BRCA2 mutations on hematopoietic progenitors and potential strategies to mitigate these effects.

#3446 Acinar to ductal metaplasia is an evolutionary dead end and does not actively contribute to pancreas regeneration after damage.

Rutvi Shah[1], I-Lin Ho[1], Er-Yen Yen[1], Charles Dyke[1], Hyuk Jean Kwon[1], Matthew Wong[1], Francesca Citron[1], Zhaoliang Liu[1], Sergio Attanasio[1], Ruparoshni Jayabalan[2], Ricardo Gonzalez Delgado[2], Luca Cecchetto[1], Elisabetta Granato[1], Ashish Damania[1], Shan Jiang[3], Haoqiang Ying[4], Giulio Draetta[1], Mauro Di Pilato[2], Nadim Ajami[1], Andrea Viale[1]

[1]Genomic Medicine, UT MD Anderson Cancer Center, Houston, TX,[2]Immunology, UT MD Anderson Cancer Center, Houston, TX,[3]Traction, UT MD Anderson Cancer Center, Houston, TX,[4]Molecular and Cellular Oncology, UT MD Anderson Cancer Center, Houston, TX

One of the major risk factors strongly associated with PDAC is pancreatitis and meta-analysis studies have revealed that inflammation of the pancreas increases the relative risk of developing pancreatic cancer by up to 13-fold. During pancreatitis, acinar cells transiently undergo metaplasia known as acinar to ductal metaplasia (ADM). It is well known that in the presence of activated oncogenes, for example mutated *Kras*, this metaplastic state can progress into PDAC with ADM being the first step towards tumorigenesis. To understand the pathophysiological role of ADM during pancreatitis and tumorigenesis, we utilized different mouse models to study the function and fate of ADM cells. We found that although ADM can effectively mitigate pancreatitis-induced tissue damage, it is not a regenerative process. Instead, cells that underwent ADM were eventually exhausted. We confirmed these findings by performing lineage tracing experiments to understand the fate of the cells and found that they were indeed not responsible for regenerating the pancreas. To better capture the dynamic process distinct sub-populations of epithelial cells undergo, during ADM induction and resolution, we are leveraging spatial transcriptomics of the entire pancreatic tissue at different timepoints after damage induction. We are also actively studying how oncogenic *Kras* activation reverts this process and contributes to tumorigenesis. This study will shed light on initiation of pancreatic cancer and how it can be prevented in the context of evolution from pancreatitis.

#3447 Neutrophil extracellular traps drive the tumorigenic potential in pancreatic ductal adenocarcinoma.

Sakshi Bansal[1], Anjali Aggarwal[1], Vinit Sharma[1], Rajesh Gupta[2], Harjeet Singh[2], Naresh Sachdeva[3], Alka Bhatia[4]

[1]Anatomy, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[2]GI Surgery, HPB and Liver Transplantation, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[3]Endocrinology, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India,[4]Experimental Medicine & Biotechnology, Postgraduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background: Tumor-infiltrating neutrophils (TINs) have been observed to be linked with poor prognosis in patients with pancreatic ductal adenocarcinoma (PDAC). In the inflammation and oxidative stress-rich tumor microenvironment, neutrophils are likely to undergo neutrophil extracellular traps (NETs) formation which have unique capability of shielding the tumor cells from anti-tumor immune response and facilitate tumor progression. However, the extent of NET infiltration in PDAC and the specific mechanisms by which NETs contribute to tumorigenesis remain unclear. This study aims to investigate NETs infiltration in PDAC and their impact on PDAC progression.

Methodology: Tumor-infiltrating neutrophils (CD15) and NETs specific markers (citrullinated histone H3, Myeloperoxidase) in the tumor tissue and blood of 15 PDAC patients and 15 healthy volunteers were determined by flow cytometry, gene expression and immunofluorescence. NETs were cocultured with Panc1 cells to assess their effect on tumor growth and behavior through various tumorigenic assays (MTT, colony formation assay, scratch assay). The gene expression analysis was done for epithelial-mesenchymal transition (EMT), extracellular matrix (ECM) modulation, stemness and dormant cell markers through qRT-PCR and further confirmation at protein level by western blot.

Results: In both blood and tissue samples of PDAC patients, relative percentage of NETs were markedly increased and the levels of citrullinated histone is positively correlated with higher tumor stage & grade. Moreover, circulating NETs shows a significant linear positive correlation with local pancreatic tumor NETs, indicates an association between NETs infiltration and disease severity. *In vitro*, NETs increased tumor migration and induced a more aggressive mesenchymal phenotype. They promoted tumor progression and invasion by downregulating epithelial markers (E-cadherin, ZO-1) and upregulating mesenchymal markers (N-cadherin, Vimentin, Snail, Twist, Zeb1, IL8, TGFβ) as well ECM-modulating markers (αSMA, Desmin, MMP, TIMP). Additionally, NETs contributed to tumor relapse by awakening dormant cancer cells (Dec2, p21, p27, p38) and increasing the expression of proliferative markers (Ki67, ERK, Bcl2) along with stemness markers (Sox2, Oct4, Nanog).

Conclusion: NETs contribute to a pro-metastatic cancer phenotype by activating EMT and reactivating dormant cancer cells. Therefore, NETs may serve as independent diagnostic biomarker and a potential therapeutic target in PDAC.

#3448 Profiling the urinary bladder cancer composition and inter-cellular proximity patterns using single-cell RNA-sequencing and spatial transcriptomics.

Alexandros Kostakis, Andrea Behanova, Iliana Kerzeli, Ramy Elgendy, Aikaterini Chourlia, Sven Nelander, Per-Uno Malmstrom, Ulrika Segersten, Milena Doroszko, Anca Dragomir, Carolina Wahlby, Martin Lord, **Sara Mangsbo**

Uppsala University, Uppsala, Sweden

Urinary bladder cancer (UBC) has shown to be difficult to treat, attributed to tumor heterogeneity and differences in response to treatment based on molecular subtypes. It is essential that we increase our knowledge the interplay between the tumor, stroma and immune system to improve our knowledge of the TME in UBC and thereby therapeutic options. Herein we employed single-cell RNA sequencing and *in situ* spatial transcriptomics on bladder samples from two UBC mouse models (model development in PMID 34232958), including in-depth immune clustering to characterize the TME during tumor progression from non-muscle invasive bladder cancer (NMIBC) to the muscle-invasive bladder cancer (MIBC) stage in a semi-spontaneous UBC model. Granulocytes and lymphoid cells were enriched in the carcinogen-induced tumors, while monocytes/macrophages were more prevalent in the reference MB49 cell line-transplantable orthotopic tumor model. Immune activation was generally increased in tumor-bearing mice overall. Lymphoid cell analysis identified NK cells and various T and B cell types, with effector CD8 T cells in carcinogen-induced tumors and scarce naïve CD4 and CD8 cells in MB49 mice. Differentially expressed genes between NMIBC and MIBC stages were predominantly linked to cell proliferation and signaling pathways. Interestingly, inferred cell interaction analysis by CellChat predicted increased *Cd6-Alcam* signaling within the lymphoid populations between T cells and basal or myeloid cells. Myeloid cell analysis displayed distinct profiles between the two models with infiltration of Ms4a7+ macrophages in the carcinogen-induced model and Iftim1+ macrophages in the MB49 model. Also, stage played a role for myeloid infiltration, with primarily Ccl8+ macrophages enriched in NMIBC, while those in MIBC were predominant of Spp1+ type. Granulocyte analysis identified eight clusters with diverse distributions in carcinogen-induced tumors, including four with strong neutrophil-like phenotypes (Isg, Retnlg, Hif-1, and SigF). Spatial transcriptomics indicated increased monocyte/macrophage tumor influx and interestingly, a significant interaction with bladder mesenchymal cells upon tumor progression. This technique also showed noticeable granulocyte tumor infiltration of penetrated tumor tissue at both the NMIBC and MIBC stages, the latter at higher levels, possibly suggesting spiraling pro-inflammatory TME. This data provide an example of that we need to further improve our knowledge of the myeloid/granulocyte role in UBC and consider how to selectively target subtypes of these cells with pharmacological interventions to improve therapeutic outcome in this severe disease, a disease that often recurs at the NMIBC stage and that presents with a high mortality in the MIBC stage.

#3449 The role of N-terminal cleavage of Trop2 in tumor progression and therapeutic resistance in triple negative breast cancer.

Andrea E. Wilson[1], Junping Wei[2], Gangjun Lei[2], Tao Wang[2], Xiao-Yi Yang[2], Melissa Gajda[2], Cong-Xiao Liu[2], Zachary C. Hartman[2]

[1]Pathology, Duke University School of Medicine, Durham, NC,[2]Surgery, Duke University School of Medicine, Durham, NC

Background: Triple negative breast cancer (TNBC) is the most aggressive subtype of breast cancer (BC), with risk factors including greater frequency of recurrence and metastasis and lower overall survival rate compared to other BC subtypes. While the drivers of TNBC are unclear, Trop2 is a transmembrane protein that has been found to be highly expressed in TNBC, whose role in tumor progression is not well understood. High expression of Trop2 has led to the development of antibody-drug conjugates (ADCs) targeting wild-type Trop2, including Sacituzumab govitecan (SG) and Datopotamab deruxtecan (Dato-dxd). However, Trop2 is an intronless gene but can be posttranslationally cleaved by ADAM10 and other proteases in malignant tissues. Cleavage of Trop2 and its effect on tumor progression and drug resistance have not been previously explored, which is becoming increasingly crucial to understand as more Trop2-targeting therapies enter clinical practice.

Experimental Methods and Results: To determine the oncogenic capacity of cleaved Trop2, our lab has generated a construct of N-terminally cleaved Trop2 ΔQ31-R87 called Trop2-ΔN and have stably transduced mouse TNBC MM3MG cells, a cell line that is not well transformed and grows poorly in immune competent mice. SCID-beige mice who lack T and B cells and have non-functional NK cells and immune competent BALB/c were injected with wild-type Trop2, an uncleavable form of Trop2 called Trop2-87/88, Trop2-ΔN, and control to find that Trop2-ΔN conferred a proliferative phenotype, which was comparable to the known oncogene HER2Δ16. Additionally, MM3MG cells were stained for SG, Dato-dxd, and their parental monoclonal antibodies and analyzed for binding via flow cytometry. We found that SG and Dato-dxd had lowered binding capacity towards Trop2-ΔN expressing cells. To determine if the killing capacity of these ADCs were altered, we transduced the human breast epithelial cell line MCF10AT with our constructs of uncleavable Trop2-87/88 and Trop2-ΔN to find that both SG and Dato-dxd to have lowered killing against Trop2-ΔN expressing cells.

Conclusions: Our studies found that N-terminally cleaved Trop2 induces a proliferative phenotype in vivo, reduce binding capacity of Trop2 ADCs, and are more resistance to ADC-induced killing in vitro. These data provide insight into the potential importance of N-terminally cleaved Trop2 in tumor progression and drug resistance that have not been explored. Future experiments will elucidate the mechanisms that underlie cleavage of Trop2 and refining Trop2-targeting therapies.

#3450 The role of NRF2-HO-1 expressing macrophages in lung cancer progression.

Ana Sofia Leal, Karen T. Liby

Indiana University School of Medicine, Indianapolis, IN

Macrophages are a highly plastic cell, in the lung they have important physiological roles, such as removing reactive oxygen species (ROS). One of the main pathways that is used by macrophages to remove ROS is the NRF2->HO-1, a detoxifying mechanism. KRAS mutated lung cancer, one of the most common diagnosed lung cancers, can deregulate the NRF2->HO-1 pathway on macrophages within the lung microenvironment, promoting cancer progression. Bone marrow derived macrophages (BMDM) from both A/J WT and full body NRF2 KO mice were used. Monocytes were differentiated into macrophages using M-CSF for 5 days. On day 5, BMDM are further stimulated with conditioned media (CM) from murine lung cancer cells (VC1 and LL2). HO-1 and NRF2 ($p<0.05$) mRNA levels are higher in BMDM of WT mice compared with NRF2 KO mice. Assuming HO-1 is a “first” response mechanism, stimulation with CM from VC-1 and LL2 was extended to 48 hours. At 48 hours BMDM from WT mice compared with NRF2 KO mice have increased mRNA HO-1 expression in both VC-1 and LL2 stimulated ($p<0.05$). Moreover, other markers, such as CCL2 and IL6 are differently expressed between WT and NFF2 KO BMDM. CCL2 appears to be predominantly expressed in NRF2 KO BMDM. To determine the evolution of HO-1 expression in macrophages in the lung after tumorigenesis initiation with vinyl carbamate (VC), lung of A/J mice were collected at 1, 2, 4, and 8 weeks after VC injection. VC is a carcinogenic compound that induces KrasQ61L mutations and consequently lung adenocarcinomas 12 weeks after administration. CD11b cells were isolated from the lungs of mice after VC administration. CD11b cells show an increase in HO-1 mRNA at week 2 post VC, and in NRF2 one week after VC. IL6 and CD206 mRNA values do not significantly change over time. CCL2 mRNA levels increase 2-fold ($p<0.001$) at 4 weeks in CD11b positive cells when compared with mice receiving saline. Zinc (II) propoporphyrin IX (ZN-IX) is an HO-1 inhibitor, that has shown anti-tumor and immune modulatory effects. A/J WT mice 6 weeks after stimulation with VC, were treated with ZN-IX for 2 weeks, every 2 days at 50mg/Kg ip. Flow cytometry of lungs of mice treated with ZN-IX showed an increase in CD4 T cells ($p=0.002$) and increase in the activation of CD8 T cells (CD107, $p=0.007$). The number of macrophages infiltrating the lungs did not change between mice treated with control-DMSO or ZN-IX, however, significant reductions ($p<0.05$) in the macrophage tumor promoting marker CD206 were observed. Moreover, the same macrophage populations showed and increased expression of IA-IE (MHC-II, $p<0.05$), an anti-tumor marker in macrophages. Immune cell-cancer cell interactions and regulation are still not fully understood. Here we show that KRAS mutated lung cancer cells can hijack the natural detoxifying process in macrophages to promote cancer. Interrupting this process can unlock new therapeutic vulnerabilities for lung cancer prevention in high-risk populations.

#3451 Exploring the impact of neoantigen expression on lung tumor development.

Jennifer Loza, Ishan Bansal, Brian Hunt, Kelli Connolly, Srividhya Venkatesan, Advait Jeevanandam, Nikhil Joshi

Yale School of Medicine, New Haven, CT

Lung adenocarcinoma (LUAD) stands as a formidable challenge in oncology, despite the emergence of immunotherapy as a promising treatment avenue. The dynamic interplay between the immune system and cancer plays a pivotal role in shaping cancer development and progression. Central to this process are neoantigens, tumor-specific antigens recognized by cytotoxic T cells, which trigger the elimination of tumor cells. It has been implicated that the presence of T cells also decreases tumor grade. However, the precise impact of neoantigen expression on LUAD development and progression remains poorly understood.

Our lab previously developed a genetically engineered mouse model with the ability to induce expression of a fluorescent neoantigen in oncogenic KRAS, P53-null, tdTomato-expressing lung adenocarcinoma cells. Using this system, we track tumor initiation, progression, and advanced LUAD development across 20 weeks in both immune-deficient and -sufficient settings. Further, tumors initiated in this system give rise to heterogeneous (neoantigen+ and -) tumors, enabling the study of T cell-driven tumor selection. Through multiplexed immunofluorescence, we identified that neoantigen+ tumors experience increased T cell infiltration and reduced volume, ultimately leading to prolonged animal survival. Surprisingly, advanced lung tumors maintain neoantigen+ cells, indicating that endogenous lung T cells are ineffective at clearing neoantigen-expressing tumor cells. Yet, we detected that infiltrated tumors exhibit reduced p-ERK expression, suggesting that T cells may slow tumor progression through non-cytotoxic mechanisms. Transferring stimulated neoantigen-specific T cells to tumor-bearing mice largely eliminated neoantigen+ tumor cells. All these data together suggest complex mechanisms for the role of endogenous T cells in controlling lung tumors.

Through molecular characterization of tumor progression and T cell-mediated tumor suppression, this study reveals specific pathways that LUAD cells undergo during the process of development and progression, providing valuable insights into the immune response against neoantigen-expressing tumors. Ultimately, by unraveling the intricate interplay between neoantigen expression, immune surveillance, and tumor progression, this project aims to contribute significantly to our understanding of how neoantigens shape the dynamics of tumor biology.

#3452 Investigating the relationship between obesity-related dyslipidemia, inflammatory myeloid cells, and cancer.

Maria D. Sanchez-Pino[1], Ramesh Thylur Puttalingaiah[2], Dorota Wyczechowska[2], Timothy Kayes[2], Julia Panov[3], Jone Garai[2], Timothy Foster[4], Jovanny Zabaleta[1]

[1]Interdisciplinary Oncology, LSU Health Science Center, New Orleans, LA,[2]LSU Health Science Center, New Orleans, LA,[3]Tauber Bioinformatics Research Center, Haifa, Israel,[4]Microbiology, LSU Health Science Center, New Orleans, LA

Background: Since people with obesity generally have altered immune responses, a high level of cholesterol, and a higher risk for cancer development and progression, it is important to investigate the relationship between cholesterol, immune cells, and cancer. The current study aims to assess the contribution of obesity-related excess lipids in priming subset of myeloid cells.
Methods: The carcinogen diethylnitrosamine (DEN) was used to induce hepatocellular carcinoma (HCC) in mice (Wild-type and liver-specific Alb-CPT1-Knockout) and diet-induced obesity (DIO) was induced to evaluate the impact of obesity compared to lean mice. Tumor burden and transcriptomic profiling were performed. *In vitro* exposure to immature myeloid cells (IMCs) from mice bone marrow with LDL-cholesterol (LDLc) was performed for molecular (protein, RNAseq, ATACseq) assessments and functionality.
Results: Obesity induced by diet increased the tumor burden on mice associated with steatosis and accumulation of myeloid-derived suppressor cells in the liver identified by flow cytometry. CPT1-KO mice showed increased gene expression of markers for immunosuppressive neutrophilic subtype and macrophages. Among different pathways, differentially expressed genes were involved in the MET and TGFb Signaling- ECM Remodeling & Metastasis, Inflammation and Epigenetic & Transcriptional Regulation. LDLc *in vitro* stimulation of IMCs increased the expression of immunosuppressive markers. Integration of RNAseq-ATACseq suggests that lipid-exposed IMCs have an epigenetically regulated activation program.
Conclusion: Excess lipids facilitate liver cancer where inflammatory neutrophilic cells and macrophages may play a major contributing role.
Funding: Pennington Research Center NORC U54-GM104940 and LSU LCMC Health Cancer Center.

#3453 TNF augments ovarian cancer metastasis in an omentum-independent manner.

R. L. Mintz[1], E. E. Erlich[2], H. S. Ruiz[1], Q. Alayo[1], M. Wohltmann[1], G. J. Randolph[1];
[1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Memorial Sloan Kettering Cancer Center, New York, NY

The mechanistic role of the inflammatory cytokine tumor necrosis factor (TNF) in ovarian cancer pathogenesis has been widely debated. The Randolph lab has developed a new mouse model, TNF^{D69Au}, in which CRISPR/Cas9 was used to target the 3' AU rich-response element of TNF mRNA transcripts in immunocompetent C57BL/6J mice, resulting in increased stability of TNF RNA and thus elevated inflammation. When TNF^{D69Au} mice and their wild-type (WT) littermate controls were intraperitoneally injected with the aggressive ID8p53$^{-/-}$Brca2$^{-/-}$ murine ovarian cancer cell line that recapitulates high-grade serous ovarian cancer, the TNF^{D69Au} mice had significantly increased tumor burden compared to their littermates as early as one-week post-injection. This discrepancy continued consistently until the endpoint when ascites accumulated. The greater omentum, a visceral fat pad along the stomach, is a well-established early and predominant metastatic niche in ovarian cancer. Yet, the TNF^{D69Au} mice demonstrate broad tumor dissemination across peritoneal organs with minimized omental preference. When TNF^{D69Au} mice were omentectomized, their tumor burden was equivalent to that of TNF^{D69Au} mice that received sham surgery, while WT mice expectedly exhibited decreased tumor burden when omentectomized. Regardless of omentectomy, the tumor burden in these TNF^{D69Au} mice was higher than in WT mice, highlighting how increased TNF production in the peritoneal cavity leads to increased tumor burden independent of the omentum. To determine if the source of TNF driving the elevated tumor burden was hemopoietic-derived, bone marrow from TNF^{D69Au} mice or WT littermates was transplanted into WT or TNF^{D69Au} mice recipients. TNF^{D69Au} mice that received bone marrow from WT or TNF^{D69Au} mice had increased tumor burden compared to WT mice that received WT bone marrow. These results suggest that the elevated TNF responsible for increased tumor burden can be stromal-derived, which is surprising given the canonical role of hematopoietic cells in TNF-signaling. Altogether, our data suggest that TNF increases peritoneal ovarian cancer spread and minimizes omental dominance, potentially through stromal signaling.

#3454 Charting single-cell metabolism co-evolution during metastasis.
Y. C. Wu;
Fudan University, Shanghai, China

Metastasis, the leading cause of cancer death, exhibits a highly heterogeneous and suppressive cancer microenvironment. Here, we sequenced 97 matched samples by using single-cell RNA sequencing and spatial transcriptomics of colorectal cancer liver metastasis. Strikingly, the metastatic microenvironment underwent remarkable spatial reprogramming of immunosuppressive cells such as MRC1+ CCL18+ M2-like macrophages. We further developed scMetabolism, a computational pipeline for quantifying single-cell metabolism, and observed that those macrophages harbored enhanced amino acid metabolic activity. Interestingly, neoadjuvant chemotherapy could block this status and restore the antitumor immune balance in responsive patients, whereas the nonresponsive patients deteriorated into a more suppressive one. In parallel, metastatic cancer cells displayed the metabolic switch from OXPHOS to glycolysis, which is dependent on the metabolic master regulator LY6E. Our work described the metabolism co-evolution of both immune and cancer cells during metastasis and uncovered the black box of how tumors respond to neoadjuvant chemotherapy.

#3455 Mesenchymal tumors direct macrophage-mediated vascular editing and premetastatic remodeling to promote PDAC metastasis.

Nicole Elizabeth Gross[1], Soren Charmsaz[1], Tiffany Chu[2], Jae W. Lee[1], Emma Kartalia[1], Yiyang Gao[3], Alexei G. Hernandez[1], Sarah M. Shin[1], Erin M. Coyne[1], Courtney Cannon[1], Xuan Yuan[1], Cheng-Chieh Huang[1], James Leatherman[1], Pei-Hsun Wu[2], Laura D. Wood[1], Elizabeth M. Jaffee[1], Won Jin Ho[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Department of Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD,[3]Johns Hopkins University, Baltimore, MD

Background: Patients with pancreatic ductal adenocarcinoma (PDAC) often have metastatic disease at diagnosis and respond poorly to therapies. High myeloid-to-T cell ratios correlate with worse prognoses, but a more detailed, integrated understanding of mechanisms by which myeloid cells regulate metastasis is critically needed. Using high-parameter spatial profiling, we recently observed that a highly metastatic tumor cell line utilizes mesenchymal invasion and harbors a tumor microenvironment with increased endothelial cell abundance, lower M1-like to M2-like tumor associated macrophage (TAM) ratios, and Arginase-1+ TAMs situated closer to tumor and endothelial cells, compared to a less metastatic model. These models were further interrogated to study the myeloid drivers of metastasis in the primary and metastatic sites.

Methods: We used two murine cell lines driven by *Kras*^{G12D} and *Trp53*^{R172H} under *Pdx1*-Cre, KPCY 2838c3 (“c3”) and KPCY 6419c5 (“c5”), which exhibit low-metastatic and high-metastatic propensities, respectively. Imaging mass cytometry was used to determine the changes in the primary tumor and pre-metastatic microenvironments. TAMs and endothelial cells from the primary site were evaluated using RNAseq. *In vitro* tube formation assays were performed to evaluate the potential factors driving vascularization.

Results: In the pancreatic site, the highly metastatic c5 model was significantly enriched for metastasis- and angiogenesis-promoting pathways, including the RANK/RANKL axis. *In vitro* tube formation assays revealed that c5-derived TAMs induce greater tube formation over those from the c3 model and that RANKL significantly promotes tube formation. Moreover, in the hepatic premetastatic site, the c5 tumors expanded Kupffer, stellate, and endothelial cells to a greater extent than c3 tumors. Finally, the c5 tumors recruit fewer lymphocytes and more granulocytes to the liver, suggesting poorer immune protection against metastasis.

Conclusions: Our study highlights multiple tumor-intrinsic and extrinsic factors responsible for metastasis, and that TAMs serve as a critical integration point. Interestingly, we found the RANK/RANKL axis, for which there is already an inhibitory agent that is clinically used, to be a potential mechanism underlying the TAM-endothelial crosstalk. Together, these data prompt further exploration of the observed TAM-endothelial relationship and the premetastatic remodeling in human PDAC, as well as the targetability of the RANK/RANKL axis for disrupting PDAC metastasis.

#3456 Differential impact of oncostatin M (OSM) on EMT and biomechanical properties of HER2+ and HER2- breast cancer.

Maria Pou[1], Kali Woods[2], Laura Bond[2], Cheryl Jorcyk[1]

[1]Boise State University, Boise, ID,[2]Biomedical Research Institute, Boise, ID

In the United States, breast cancer (BC) is projected to cause over 43,000 deaths in 2025, despite significant advances in diagnostic and therapeutic strategies. Mortality is primarily attributed to late-stage diagnosis with distant metastasis. One key mechanism that enhances the metastatic potential of breast carcinoma cells is the epithelial-to-mesenchymal transition (EMT), a process in which cells lose their apical-basal polarity and acquire a mesenchymal-like phenotype; thereby increasing their motility and invasiveness. The treatment choice for each BC patient is very complex since it depends on the presence or absence of hormonal receptors and epidermal growth factor receptor 2 (HER2) expressed by the tumor cells. This research distinguishes between patients whose cancer cells overexpress HER2 (HER2-positive; HER2+) and those who do not (HER2-negative; HER2-), representing around 30% and 70% of all BC diagnoses, respectively. Oncostatin M (OSM) is an interleukin 6 (IL-6)-family proinflammatory cytokine produced in the BC tumor microenvironment in a paracrine manner by macrophages and neutrophils, as well as in an autocrine fashion by the tumor cells. Clinical data indicates a negative correlation between elevated OSM tumor levels and patient survival. OSM plays a critical role in metastasis through multiple mechanisms, including promoting the secretion of pro-metastatic molecules such as VEGF, LOXL2, and IL-6, increasing circulating tumor cell (CTC) numbers, and facilitating metastasis to distant organs such as bone and lung as observed *in vivo*. Our laboratory has demonstrated that OSM induces EMT in HER2- BC cell lines, but little is known about its role in HER2+ BC. Thus, we aimed to investigate the differential effects of OSM on metastatic potential, focusing on EMT and cell motility in HER2+ versus HER2- BC models. Using qRT-PCR, western blot analysis, and immunofluorescent staining on HER2+ and HER2- BC cell lines, we show that OSM treatment downregulates tight junction proteins, essential for maintaining epithelial apical-basal polarity. Additionally, we detected upregulation of key EMT transcription factors, including SNAIL, and a marked rearrangement of actin filaments, which collectively promote a mesenchymal-like phenotype in these cells. By employing nanoindentation assays with atomic force microscopy (AFM) to measure biomechanical properties, we establish for the first time, a link between OSM and increased membrane elasticity, a hallmark of motile cells in breast cancer. This research aims to understand the unique role OSM plays in HER2+ and HER2- breast cancer in promoting metastasis and will provide a mechanistic understanding of how this occurs and offer a molecular framework for identifying patients who may benefit from anti-OSM therapies that are in development.

#3457 CYLD regulates cGAS-STING pathway and metastasis in HNSCC.

Shiyang Deng[1], Satoru Shinriki[1], Yasuhito Tanaka[1], Hideki Nakayama[2]

[1]Molecular Laboratory Medicine, Kumamoto University, Kumamoto University, Kumamoto, Japan,[2]Oral & Maxillofacial Surgery, Kumamoto University, Kumamoto University, Kumamoto, Japan

Chromosomal instability, a hallmark of cancer, is related to cancer progression including metastasis and known to promote the activation of the cGAS-STING pathway. Cylindromatosis (CYLD), a well-known negative regulator of NF-kappaB, is down-regulated in aggressive head and neck squamous cell carcinoma (HNSCC), correlating with reduced apoptosis, enhanced invasiveness, and poor prognosis of patients with HNSCC. However, its role in metastasis, immune responses and interaction with the cGAS-STING pathway remain unclear. We found that CYLD protein was rapidly up-regulated and phosphorylated under Poly(dA:dT) or cGAMP stimulation. In addition, by using various cancer cell lines expressing shRNA targeting CYLD, we found that CYLD was essential for sustained phosphorylation of TBK1, a main STING downstream mediator. These results suggest that modulation of the CIN-related activation of cGAS-STING pathway and hence immune responses by down-regulation of CYLD regulates HNSCC progression. Further studies focusing on possible relationship between the NF-kappaB and cGAS-STING pathways would contribute to better understanding of the molecular mechanisms underlying CIN-related metastasis. Furthermore, our preliminary data revealed that CYLD knockdown significantly enhanced metastasis of murine HNSCC cells in immunocompetent mice.

#3458 Antagonism between tumors and lymphocytes drives coevolutionary processes throughout metastasis.

Cort B. Breuer, Marcos Labrado, Nathan E. Reticker-Flynn

Otolaryngology - Head & Neck Surgery, Stanford University School of Medicine, Stanford, CA

The development of metastatic disease is a conserved feature across most solid organ malignancies and accounts for the majority of cancer-related deaths. While adaptations within the local immune microenvironment of primary tumors are well-appreciated hallmarks of tumor progression, there remains much unknown about the specific impact of metastasis on both local and systemic immune responses. Here, we present an analysis of changes in the adaptive immune response to tumors during metastasis and clonal selection. Our group previously developed a syngeneic melanoma mouse model of spontaneous lymph node metastasis, performing nine generations of in vivo serial passaging to select for metastatic phenotypes. As previous work suggests, we find that tumors undergo clonal selection during metastasis using lentivirus integration mapping to measure clonality. Even amidst reduced genomic diversity, we find that metastases exhibit comparable or increased transcriptomic diversity when compared to primary tumors. In light of this discordance between genomic and transcriptomic diversity, we ask whether the immune response, especially T cells, exhibit similar dynamics. Performing both bulk and single cell T cell receptor (TCR) sequencing, we find that T cell clonality mirrors the reduced clonal diversity of metastatic tumors both in the total T cell compartment and specifically in regulatory T cells. Through paired investigation of evolution of tumors and the responding immune cells, we develop a model of tumor-immune coevolution in which reduced tumor clonality selects for narrower T cell repertoires; yet, diverse tumor transcriptional profiles support the differentiation of a variety of T cell subsets that are advantageous for tumors including regulatory T cells and exhausted CD8+ T cells. We further perturb this dynamic by evolving new metastatic cell lines in the absence of T cell pressure, finding unique evolution of metastatic pathways when the immune system is altered, impairing metastasis when reimplanted into immunocompetent mice. This model of tumor-immune coevolution establishes the importance of ongoing, dynamic communication between the host and tumors throughout metastatic progression.

IMMUNOLOGY: Local Treatments, Novel Tools, and Delivery Systems to Manipulate Tumor Immunity
Poster Session

#3462 Novel delivery platform for temporally-controlled release of immunocytokines and immune checkpoint inhibitors to enhance cancer therapy.

Pilar O'Neal[1], Julia Lu[2], Yicheng Zhang[2], Marek Kovar[3], Hai-Quan Mao[2], Jamie Spangler[1]

[1]Biomedical Engineering, Johns Hopkins University, Baltimore, MD,[2]Department of Material Science and Engineering, Johns Hopkins University, Baltimore, MD,[3]Laboratory of Tumor Immunology, Institute of Microbiology of the Czech Academy of Sciences, Prague, Czech Republic

Interleukin-2 (IL-2) is a multifunctional cytokine that plays a critical role in the differentiation, proliferation, activation, and survival of immune cells and has been used therapeutically for over 30 years as a cancer treatment. Unfortunately, the cytokine's narrow therapeutic window and its short circulation half-life have severely limited its clinical application. Strategies designed to bias the activities of IL-2 represent emergent and promising avenues in the treatment of cancer, as they afford the opportunity to selectively target and stimulate certain immune cell subtypes. Recently, our lab has developed one such therapy, termed an immunocytokine (IC), which fuses IL-2 to an anti-IL-2 antibody that biases the cytokine towards immunostimulatory activities while also extending its persistence in the bloodstream. Additionally, we further established that the IC was able to synergize with immune checkpoint inhibitors (ICIs) to effectively clear tumors through expansion of CD8+ T cells and stimulation of their effector functions. Interestingly, it was observed that the therapeutic effects of this combination treatment were highly sensitive to dosing regimen; specifically, robust antitumor activity was observed when IC was delivered after ICI, but not when the order was reversed. Building on this observation of time-dependent anti-cancer activity, here we expand upon this work through the development of a biomaterial system that will enable further exploration of the kinetics surrounding the combinatorial delivery landscape using IC and ICIs. Our biomaterial system involves formulation of nanoparticles that encapsulate IC and ICIs using a flash nano complexation and flash nanoprecipitation system. These particles are further enclosed within a hydrogel system for protection and sustained release within the tumor environment, controlling both the temporal and spatial distribution of the encapsulated immunotherapies. We have successfully designed and characterized the delivery platform and established time-dependent release of the therapeutic cargo. In vivo immune stimulation and tumor clearance studies are ongoing to further evaluate our approach. Overall, our work introduces an innovative and highly versatile bioengineering approach that can be tuned to optimize immunotherapy strategies in a wide range of cancer types.

#3463 A novel nanobody based IL-18 surrogate cytokine agonist, used alone or combined with immune checkpoint inhibitors, demonstrated synergistic tumor suppression.

Yakun Wan[1], Min Zhu[1], Junwei Gai[1], Yanyang Nan[2], Yuping Huang[1], Xuyao Zhang[2]

[1]Novamab Biopharmaceuticals Co,. Ltd, Shanghai, China,[2]School of Pharmacy, Fudan University, Shanghai, China

IL-18 is a cytokine belonging to IL-1 family regulating both innate and acquired immune responses, acting on innate lymphocytes and antigen-experienced T cells to produce interferon gamma (IFNγ). However, clinical efficacy of IL-18 monotherapy in cancer patients has been proved to be slight, which is mainly caused by the upregulation of IL-18 binding protein (IL-18BP), a decoy protein that binds IL-18 with extremely high affinity, produced in the tumor microenvironment. In this study, we have developed an innovative approach to activate IL-18 receptors without the need for the cytokine itself. We achieved this by employing human IL-18Ra and human IL-18Rb-targeting nanobodies, which mimic the natural IL-18 cytokine. This strategy leads to the formation of functional receptor dimers and initiates the subsequent signaling cascade. IL-18Ra and IL-18Rb nanobodies with high affinity were selected out from the immune libraries constructed from PBMCs isolated from camels immunized with IL-18Ra and IL-18Rb respectively. And then IL-18Ra/IL-18Rb bispecific nanobodies were constructed and evaluated for their induction of IFNγ release in primary peripheral blood mononuclear cells (PBMCs). Modality with best IFNγ stimulation was chosen for further development. And the humanized most potent IL-18Ra/IL-18Rb nanobody was named LQ058. Compared to wild type IL-18, LQ058 demonstrated superior IFNγ stimulation from PBMCs. And $CD8^+$ T cells RNA-sequencing evaluation demonstrated that LQ058 is IL-18BP resistant. In human PK59 and H23 tumor xenograft models, LQ058 illustrated better tumor growth suppression compared with wild type IL-18. Meanwhile, LQ058 showed synergistic tumor inhibition when administrated together with anti-PD-1 or anti-CTLA4 therapies. Besides, LQ058 is designed to have extended half-life which would improve medication convenience. Overall, these positive characteristics of LQ058 make it a promising therapy possible to overcome the limitations of current IL-18 therapies for malignant tumor treatment.

#3464 Advancing antibody therapeutics: a 3D *in vitro* model for penetration assessment of immunoglobulins in human tumor spheroids.

Sue Fontaine Grepper, Maja Nedic, Charlotte Veser, Michal Rudnik, Matthias Zbinden, Irina Agarkova, Madhu Nag, Laure-Anne Ligeon

InSphero AG, Schlieren, Switzerland

The advancements in biotechnology and the successful application of monoclonal antibody therapeutics have incited the development of innovative therapeutic antibody modalities, including bi-or tri-specific antibodies, antibody fragments (e.g. Fab), and other formats (e.g. DARPin). These have transformed cancer treatments; however, monoclonal antibodies often demonstrate limited efficacy in cancer therapy due to poor tumor penetration, leaving regions of untargeted and untreated tumor areas that can escape therapy. Addressing this limitation requires the development of advanced *in vitro* culture models that accurately replicate tumor-tumor microenvironment (TME) interactions. To bridge the gap between traditional *2D in vitro* cultures and animal models, 3D human tumor spheroids offer a promising solution. In this context, InSphero has developed an *in vitro* 3D Antibody Penetration Assay. We demonstrate that 3D InSight™ Human Tumor Microtissues closely mimic the complexity and heterogeneity of the TME, while maintaining uniform composition and size across spheroids, providing reliable and reproducible models to enhance drug discovery. Using 3D InSight™ human tumor spheroids, we evaluated the efficacy, distribution, and penetration depth of a therapeutic antibody and an antibody-drug conjugate (ADC). Results showed that both modalities successfully penetrated the 3D InSight™ lung cancer tumor (A549) model. After 30 minutes of treatment, antibodies were detected at the periphery of the spheroids, while longer treatment windows resulted in progressively deeper penetration. This assay offers a robust and reliable platform for assessing the distribution and penetration of antibody therapeutics, biologics, ADCs, and other agents in solid tumor models, leveraging advanced *in vitro* 3D human tumor models to improve drug discovery and therapeutic development.

#3465 T cells on a crossroad between cytosolic and mitochondrial BCAA transamination in the lymphoma microenvironment.

Tanner Wetzel[1], Christie Adam[1], Sheila Erfan[1], Lucas Figueroa[1], Lindsey Croll[1], Anthony Diehl[1], Taha Khan[1], Alexander Martin[2], Maxwell Swain[1], Michael Boyer[1], **Elitsa Ananieva**[1]

[1]Des Moines University, West Des Moines, IA,[2]Flushing Hospital Medical Center, Flushing, NY

Neoplastic cells of the lymphoma microenvironment demonstrate substantial plasticity allowing their escape from immune surveillance and subsequent rapid growth. A distinct feature of this plasticity is the release of immunosuppressive signals that lead to T cell exhaustion. Metabolic enzymes, including the cytosolic (BCATc) and mitochondrial (BCATm) branched chain aminotransferases may contribute to the immunosuppressive repertoire of lymphoma cells as these enzymes break down and thus limit the availability of the branched chain amino acids (BCAAs) for helper and cytotoxic T cells. Because of the significant impact BCATc and BCATm have on the biosynthetic and energy demands of T cells, we hypothesized that T cell differentiation and effector function depend on a switch between cytosolic and mitochondrial BCAA transamination. Mice with a single or a combined deletion of BCATc and BCATm in T cells were subcutaneously injected with $2.5x10^5$ murine EL4-OVA lymphoma cells [n=8-9/group] for 15 days and tumor development and growth were monitored. In addition, splenic and lymphatic T cells were isolated, activated with anti-CD3/CD28, and differentiated into $CD4^+$ T cell subsets or $CD8^+$ T cells, followed by RT-PCR, Flow Cytometry and ELISA to measure lineage-specific transcription factors and effector cytokine secretion. Results showed that T cells deficient in BCATm afforded mice with a local (as seen during an in vitro cell killing assay) but not with a systemic resistance to EL4-OVA lymphoma. In contrast, T cells with a single (BCATc), or a combined (BCATc-BCATm) deletion, led to ~ 50 % reduction in tumor growth over time. This difference in response was further observed at the level of T cell subset differentiation, where a loss of BCATc caused an increased secretion of IFNγ (53 %) and upregulation of Tbet expression by 31 % in Th1 cells. In contrast, BCATm had no impact on Th1, however, in Th2 cells, a loss of BCATm expression resulted in a 50 % decrease in the secretion of IL13. A loss of both isoenzymes from Treg cells, however, favored a switch to Th1-like phenotype where Treg cells demonstrated 2.3- and 1.7- fold increases in the expression of Tbet in the absence of BCATc or BCATm, respectively. Lastly, deletion of BCATc positively affected $CD8^+$ T cell activation, while deletion of BCATm stimulated $CD8^+$ T cell expansion. The observed effects were directly bound to the transaminase activity of the BCAT enzymes as seen by the reverse effects of the leucine structural antagonist, n-acetyl-leucine amide [NALA], on T cell differentiation and function. These findings suggest that T cells switch between cytosolic and mitochondrial transamination of BCAAs during their activation and lineage commitment, a behavior that may likely impact the interactions of T cells with cancer cells in the lymphoma microenvironment.

#3466 Bubble therapy: Histotripsy ablation of pancreatic tumors in an *in vivo* murine model affects the tumor microenvironment and increases systemic anti-tumor immunity.

Tamalika Paul, Victor Lopez, Cora Youngs, Carley Elliott, K.M Imran, Tyler Moore, Manali Powar, Benjamin Tintera, Eli Vlaisavljevich, Irving Coy Allen

Virginia Tech, Blacksburg, VA

Pancreatic cancer is one of the leading causes of cancer-related deaths, highlighting the urgent need for innovative treatment strategies. Histotripsy is a non-invasive, non-ionizing, non-thermal, image-guided focused ultrasound ablation treatment method that uses high-pressure pulses to create acoustic cavitation, a “bubble cloud,” at the target. The rapid expansion and collapse of this bubble cloud ablates the tumor into an acellular homogenate. In this study, we evaluated the hypothesis that histotripsy ablation of pancreatic tumors reduces tumor burden, activates systemic immune responses, and induces an abscopal-like effect. Our *in-vivo* study is a contralateral study conducted in C57BL/6J mice, employing a specialized histotripsy setup designed for precision. This setup featured a customized 1 MHz, 8-element histotripsy transducer engineered with a tailored focal point geometry. We targeted partial ablation around 50-60% to activate the immune responses and convert the “cold” pancreatic tumor microenvironment to “hot” tumor microenvironment. Treatment parameters included a peak negative pressure (PNP) of 250 Hz, a pulse repetition frequency (PRF) of 250 Hz, and 250 pulses per focal point. Mice were harvested in 5 groups/timepoints (2 hours, 24 hours, 7 days, 14 days and 21 days), with biological assessments generally focused on ablation zone, structural effects of histotripsy, chemokines and cytokines released and immune cell populations. The study’s significance lies in understanding how histotripsy influences immune responses, particularly T cell infiltration and proliferation, from the treated tumor site to the untreated contralateral tumor site. Our data demonstrated that histotripsy effectively reduced tumor volume, with significant reductions in tumor diameter observed in both treated and contralateral untreated tumors compared to control groups. Flow cytometry analysis revealed significant changes in immune cell populations across treated and control groups. Transcriptomic analyses identified differentially expressed genes and pathways associated with systemic anti-tumor immune responses, while mass spectrometry highlighted antigens presented by antigen-presenting cells. Overall, the results indicated that histotripsy promotes a localized immune response, leading to immune system activation and substantial alterations in the tumor microenvironment. These systemic immunological changes present potential targets for adjuvant therapies, underscoring the promise of histotripsy as a therapeutic modality in pancreatic cancer treatment.

#3467 Delivery of CpG and GM-CSF in a novel silica-based scaffold leads to differentiation of AML blasts and T cell-dependent immunity in syngeneic AML tumor models.

Fernanda Langellotto, Jessica McDonough, Benjamin Seiler, Brena Barra, Edward Doherty, Robert Pierce

Attivare Therapeutics Inc., Natick, MA

Background: Acute Myeloid Leukemia (AML) has poor prognosis, however, differentiation therapy results in a high cure rate for a subset of patients with acute promyelocytic leukemia. Prior preclinical studies using a cryogel-based “antigen free” system demonstrated complete remission in AML models and a vaccine-like response. We set out to recapitulate these effects using a silica-based, biodegradable scaffold (mesoporous silica rod, MSRs) in order to capitalize on their ease of manufacturing and injectability. Building on this prior work, here we show that MSRs loaded with GM-CSF and CpG (ATT-01) can similarly induce differentiation of AML blasts *in vitro*, a significant vaccine-like T cell response, and durable remission in murine models of AML.

Methods: Syngeneic mouse models [C1498, C1498-eGFP, and WEHI-3] were conducted by injecting tumor cells into the mouse tail vein. Tumors were treated with chemotherapy (ara-C, doxorubicin) on days 7-12 and then mice were treated with a subcutaneous injection of ATT-01 on 2 flanks on day 14. For takedown studies, flow cytometry was conducted on mouse organs on day 7 and 14 post-ATT-01 treatment. In a cellular depletion experiment, mice were treated with antibodies to decrease CD8+T-cells, CD4+T-cells and NK cells prior to running the C1498 therapeutic model. *In vitro* experiments were conducted by co-culturing MSRs with THP-1 cells and tumor cells, and APC functionality of THP1 cells (no PMA) were assayed using flow cytometric phenotyping.

Results: Chemotherapy plus ATT-01 treatment resulted in complete remissions [CRs] in C1498 and WEHI-3 models, compared to chemotherapy or GM-CSF and CpG injection alone, which resulted in no CRs. The cellular depletion study demonstrated that CD8+ T cells were required for the therapeutic effect. The takedown study demonstrated that ATT-01 therapy resulted in increased CD8+ T cells in the bone marrow at day 7, compared to controls. *In vitro*, MSR and ATT-01 caused NETosis in THP-1 cells. *In vitro* studies demonstrated that Murine AML cell lines cultured with ATT-01 and MSR resulted in tumor cell death for a portion of cells. Surprisingly, a subset of murine AML cell lines expressed immune cell markers after culture with ATT-01 or MSR. In addition, THP-1 cells (human leukemic cell line, no PMA) cultured with MSR and ATT-01 differentiated into immune phenotypes.

Conclusions: Treatment of murine AML with chemotherapy and ATT-01 resulted in durable remissions. We propose that generating peripheral inflammation in AML can lead to differentiation of AML blasts into APCs and presentation of AML antigens, leading to immune-mediated tumor control. Future experiments will further elucidate the differentiation effect of ATT-01 *in vivo*.

#3468 Intratumoral interleukin-7 delivery via human iPS cell-derived neural stem cells for glioblastoma immunotherapy.

Yi Fu, **Irfaan Karim**, Hernando Lopez-Bertoni, Mingyao Ying

Neuro-Oncology, Kennedy Krieger Institute, Baltimore, MD

Glioblastoma (GBM) is the most aggressive primary brain tumor characterized by severe immunosuppression and a poor response to conventional treatments. The immunologically "cold" tumor microenvironment of GBM makes immunotherapy still challenging. Here, we studied the immunostimulatory cytokine interleukin-7 (IL7) for GBM immunotherapy. We first showed that IL7 delivery to GBM tumors effectively induced an immune-active tumor microenvironment and anti-tumor immunity. Next, we developed a therapeutic strategy based on intratumoral IL7 delivery via human iPS cell-derived neural stem cells (iNSCs). This iNSC-IL7 treatment in two mouse syngeneic GBM models (CT2A and GL261) led to robust tumor regression with a complete response rate (CR) of 40%. It also significantly extended the survival of animals with partial responses. This treatment induced an immune-active microenvironment, as evidenced by increasing cytotoxic CD8+ T cell infiltration and activity and established anti-tumor immunity. Following RNA-sequencing analysis, we defined transcriptomic changes of tumors in response to iNSC-IL7 treatment, including various tumor microenvironment modulators and the upregulation of immune checkpoint pathways (e.g., PD-1 and CTLA4). This discovery guided the combination regimens using iNSC-IL7 and immune checkpoint inhibitors (anti-PD1 or anti-CTLA4 monoclonal antibody). These two combination regimens led to CR of 80% (iNSC-IL7 + anti-PD1) and 60% (iNSC-IL7 + anti-CTLA4), more effective than monotherapies (iNSC-IL7: 40%; anti-PD1: 40%; anti-CTLA4: 30%). Our results demonstrate that IL7 is a potent immunostimulatory cytokine for GBM immunotherapy. They support iNSC-IL7 treatment for future clinical translation as an autologous cellular immunotherapy for GBM and likely other solid tumors based on human iPS cell-derived cell progenies. The transcriptomic analysis dataset will facilitate the future development of an optimal iNSC-IL7 therapy through combination strategies with other immunotherapy regimens, such as immune checkpoint inhibitors.

#3470 Intratumoral cytokine delivery combined with checkpoint blockade improves immunotherapy responses in immune-infiltrated oral cancers.

A. H. Molina[1], G. M. Sunga[1], N. Dharmaraj[1], N. I. Hussein[1], A. G. Sikora[2], S. Young[1];

[1]The University of Texas Health Science Center at Houston, Houston, TX, [2]The University of Texas M.D. Anderson Cancer Center, Houston, TX

Cytokine therapies improve antigen priming, increase effector immune cells in the tumor immune microenvironment (TIME), and enhance cytolytic activity. There is strong interest in the interleukin (IL) family to activate effector immune cells in the TIME. Interleukin-12 (IL-12) is known for its pro-inflammatory effects, T-cell differentiation properties, regulation of natural killer (NK) cell responses, and production of interferon-gamma (IFNγ). The TIME in head and neck squamous cell carcinoma (HNSCC) impairs tumor-infiltrating lymphocyte function, decreases the production of effector cytokines, and contains suppressive immunocytes. Immune checkpoint inhibitors (ICIs) have shown promise in several solid cancers with similar mutation burden and immune infiltration as HNSCC. However, most HNSCC patients do not respond to treatment with single-agent immunotherapy, in large part due to the immunosuppressive TIME. Therefore developing strategies to mitigate the suppressive tumor immune microenvironment and elicit a robust anti-tumor immune response through combinatorial treatments is key. Herein, we combined anti-programmed cell death protein-1 (α-PD-1) with IL-12 to reverse exhausted phenotypes and activate effector immune cells in the HNSCC TIME. We hypothesize that the combination of IL-12 and α-PD-1 therapy will stimulate anti-tumor effector immunocytes to target immune-infiltrated and immune-excluded TIME in the preclinical oral cancer models, MOC1 and MOC2. Continuous treatments of intratumoral IL-12 and systemic α-PD-1 either as monotherapies or in combination were administered to MOC1 tumor-burdened mice. We observed tumor regression in the MOC1 tumor-burdened mice with IL-12 + α-PD-1 combinatorial treatments, IL-12, and α-PD-1 monotherapies. Mice that rejected the primary tumor challenge were rechallenged with MOC1 cells. We observed complete responses in IL-12 + α-PD-1 treatment groups and tumor regression in IL-12 monotherapy groups. Additionally, in the more aggressive HNSCC preclinical model, MOC2, IL-12 treatments led to prolonged survival. Overall, our results demonstrate the effectiveness of IL-12 + α-PD-1 combinatorial treatments in an immune-infiltrated HNSCC preclinical model. Future studies will include the addition of small molecules, such as Stimulator of Interferon Genes (STING) agonists, to enhance antigen presentation and activate anti-tumor effector cells to combat an aggressive TIME.

#3471 CD47 blockade-based local immunotherapy for endometrial cancer.

Kerem Yucebas[1], Sooah Ko[1], Omair Khan[2], Irving Weissman[2], **Shiying Jin**[1]

[1]University of Missouri - Columbia, Columbia, MO,[2]Stanford University, Stanford, CA

Endometrial cancer (EC) incidence and mortality have been persistently increasing, indicating the limitations of current therapeutic measures. We have developed an immunotherapy for EC targeting the immune checkpoint molecule CD47. CD47 is a transmembrane protein that serves as a ligand for receptor signal regulatory protein-α (SIRPα) expressed on macrophages. When CD47 on tumor cells and SIRPα on macrophages interact, phagocytosis of malignant cells is inhibited. We found that macrophage phagocytosis of human EC cells is enhanced by an anti-CD47 monoclonal antibody (mAb). Our preclinical studies revealed the anti-CD47 mAb effectively reduces tumor burden without displaying overt signs of toxicity when administered through transvaginal local treatment in *PR-cre*$^{+/-}$*;Pten*$^{flox/flox}$ female mice with endometrial carcinoma. Thus, our findings provide rationale for the clinical application of anti-CD47 local immunotherapy to benefit women at risk for endometrial cancer development.

#3472 STX-003: cancer immunotherapy with systemic delivery of mRNA utilizing programmable genetic circuits for precise regulation of IL-12 expression and reduced toxicity.

Gautam N. Shenoy, Wen Allen Tseng, Emily A. Clinton, Ryan A. Patenaude, Wuhbet Abraham, Zhijun Su, Madhuri Dey, Justin H. Letendre, Maeve M. Pattie, John T. Sexton, Emily Tjon, Nandita S. Nambiar, Jacob R. Becraft, Tasuku Kitada

Strand Therapeutics, Boston, MA

Introduction: Immunotherapies have revolutionized the treatment of solid tumors, which represent 90% of adult human cancers. Therapeutic delivery of IL-12, a potent immunostimulatory cytokine, is robustly effective in preclinical models. However, systemically delivered IL-12 is poorly tolerated potentially due to its off-target activity. To overcome this challenge, we developed an mRNA platform that utilizes programmable genetic circuits to regulate the expression of an encoded protein in response to microRNAs (miRNAs), enabling precise control of payload expression in the target tissues. Using this platform we developed STX-003, a systemically delivered self-replicating mRNA encoding IL-12 which bears programmable genetic circuitry to limit the expression of payload in off-target tissues while preserving expression in the tumor. Here, we tested the activity of the genetic circuitry as well as its effects on the efficacy and tolerability of systemically delivered IL-12 using preclinical models.

Methods: To reduce payload expression in (i.e., detarget) healthy tissues, we first identified unique miRNA signatures using in silico modeling and high-throughput in vitro screening. We then selected candidate circuits, characterized their effectiveness and formulated them in LNPs. Payload expression was tested in vitro using the human cancer cell lines and patient-derived breast cancer organoids. Proof-of-concept studies were conducted in non-human primates and naive mice (with a murine surrogate) to demonstrate successful detargeting of the off-target tissues and its impact on tolerability following systemic delivery. Efficacy was tested in the B16.F10 syngeneic mouse model of melanoma. Tolerability was assessed by monitoring body weights and clinical signs, while efficacy was tracked by measuring tumor volumes over time.

Results: STX-003 as well as the uncircuited control expressed the IL-12 payload when transfected into patient-derived tumor organoids and cancer cell lines. Intravenous injection of a murine surrogate of STX-003 improved tolerability and induced anti-tumor responses in a syngeneic mouse model. While STX-003 yielded similar levels of mIL-12 in tumors compared to an uncircuited control, markedly lower levels of mIL-12 were observed in off-target tissues. In healthy non-human primates, systemic administration of STX-003 demonstrated a substantial reduction in circulating IL-12 levels compared to a control without genetic circuitry.

Conclusion: These data demonstrate the potential of STX-003, our programmable RNA circuit platform, for expanding the therapeutic index of potent drugs that are limited by systemic toxicities associated with off-target expression.

#3473 iPS-derived MSC secreting IL7 and IL15 exert immune mediated anti-tumor activities.

Sandeep Singh[1], Andrea Bedoy[1], Dipmoy Nath[2], Kyung Hee Chang[1], Lauren B. Ostermann[1], Ivo Veletic[3], Christopher D. Pacheco[3], Po Yee Mak[1], Edward Ayoub[1], Muharrem Muftuoglu[1], Mahesh Basyal[1], Taeyun Kim[4], Raven Dance Hinkel[4], Kyle M. Garland[4], Matthew Angel[4], Sanjeev Luther[2], Christopher B. Rohde[4], **Michael Andreeff**[1]

[1]Section of Molecular Hematology & Therapy, Department of Leukemia, UT MD Anderson Cancer Center, Houston, TX,[2]Eterna Therapeutics, Inc., Cambridge, MA,[3]Leukemia, UT MD Anderson Cancer Center, Houston, TX,[4]Factor Bioscience, Inc., Cambridge, MA

We previously discovered that BM-derived Mesenchymal stromal cells (BM-MSCs) are migrating to the stroma of numerous cancers and their metastasis, forming TAFs and secrete proteins intra-tumorally. MSCs have not been used in cancer therapy because of their immune suppressive properties, limited replicative capacity, source dependent quality and controversial roles in cancer biology. Here, we report the characterization of novel MSCs (iMSCs), which were generated from adult skin fibroblast-derived induced pluripotent stem cells (iPSC). These iPSCs were generated via a unique, transient mRNA transfection technique and subsequently differentiated into iMSCs. Notably, iMSCs displayed contact inhibition and significantly enhanced proliferative capacity under both normoxic and hypoxic conditions, outperforming bone marrow-derived MSCs (BM-MSCs) while fully retaining trilineage differentiation potential. Comprehensive molecular profiling, including RNA sequencing, single-cell mass cytometry (CyTOF), and Luminex assays, revealed strong phenotypic and functional resemblance between iMSCs and BM-MSCs. Crucially, no sarcoma formation was detected in NSGS mice following intraperitoneal, subcutaneous, or intravenous administration of iMSCs, underscoring their safety profile. We further engineered a DNA cassette into these cells to enable IL-7 and IL-15 cytokine production, expressed as either individual molecules (P2A) or a single fused molecule (FUS). Both P2A and FUS cells demonstrated the capacity to drive T cell proliferation autonomously in co-culture. Cytokine secretion from these modified iMSCs enhanced tumor cell death in a triple co-culture system comprising iMSCs, the ovarian cancer cell line ID8, and human PBMCs. In a syngeneic mouse model of ovarian cancer (ID8 in C57BL/6 mice), administration of P2A or FUS MSCs resulted in reduced tumor growth and extended survival. Immunohistochemical and flow cytometric analyses revealed massive infiltration of T cells, macrophages, NK cells, and other immune cells into the tumor microenvironment (TME) in both FUS or P2A groups, but not in control, unmodified MSC, or PBS injected animals. Moreover, the TME in P2A- and FUS-treated mice showed enrichment in M1-type macrophages, with no detection of any of the T cell exhaustion markers tested, in contrast to the control groups (PBS or GFP-iMSC). In conclusion, our findings indicate that IL7-IL15-secreting iMSCs migrate into solid tumors, induce massive immune cell infiltration into the TME and enhance antitumor immunity in a syngeneic mouse model of cancer. These cytokine-producing iMSCs represent a promising therapeutic strategy for modulating the immune response against tumors and advancing anticancer immunotherapy by converting “cold” into “hot” tumor microenvironments.

#3474 Breast cancer control and increased TIL with intratumoral TLR2 agonist and IFNγ.

Ileana Soto Mauldin, Elaheh Najafianashrafi, Kelly T. Smith, Marya E. Dunlap-Brown, Chengli Shen

Surgery, University of Virginia, Charlottesville, VA

Background: High densities of tumor-infiltrating lymphocytes (TILs) in triple-negative breast cancer (TNBC) are associated with better outcomes and response to anti-PD-1 checkpoint blockade therapy. CXCL10 is a critical chemoattractant for activated T-cells and is lowly expressed in breast cancers, thus, approaches to increase CXCL10 may boost TIL, and enhance TNBC control. We have previously found that a TLR2 agonist (FSL-1) plus IFN-gamma enhances the production of CXCL10 by human melanoma cells. We hypothesized that intratumoral therapy with these agents would enhance CXCL10 production, TIL, and tumor control in TNBC.
Methods: Chemokine production and TNBC cell viability were evaluated in vitro after treatment of TNBC cell lines with PBS, FSL-1, IFNγ, or FSL-1+IFNγ. In vivo, changes in TIL, tumor outgrowth, and murine survival were evaluated after intratumoral therapy of E0771 tumors grown in the mammary fat pad of C57BL/6 mice.
Results: CXCL10 production by 12 human and 3 murine TNBC cell lines was evaluated by flow cytometry and ELISA assay. FSL-1+IFNγ stimulation synergistically enhanced CXCL10 production by human and murine TNBC cell lines when compared to IFNγ, FSL-1, or PBS alone ($p \leq 0.03$). Luminex assay revealed that CXCL10 was the most abundant chemokine produced by murine TNBC cells in response to FSL-1+IFNγ (1185 pg/ml), while human TNBC cells dominantly produced CXCL10 (36498 pg/ml) and CXCL9 (31480 pg/ml) and produced low levels of CXCL11, (341 pg/ml) CXCL12 (8 pg/ml), and CCL5 (391 pg/ml). Intratumoral therapy with FSL-1+IFNγ treatment increased overall survival when compared to those receiving PBS, FSL-1, or IFNγ alone (58 vs 34 days $P<0.0001$). FSL-1+IFNγ induced visible tumor necrosis and induced sustained full tumor regression in 2 of 11 mice evaluated for long-term survival. Gene signatures associated with T-cell infiltrates and T-cell activation were elevated in FSL-1+IFNγ treated tumors evaluated by Nanostring analysis. $CD8^+$ T-cell infiltrates, evaluated by multiparameter immunofluorescence histology (mIFH), were increased in FSL-1+IFNγ treated tumors (117 cells/mm^2) compared to those treated with PBS, FSL-1, IFNγ (52, 29, 33 cells/mm^2 respectively, $p \leq 0.02$). Additionally, in flow cytometric assays, FSL-1+IFNγ treated tumors had increased percentages of $CD8^+$ T-cells (27% $p \leq 0.001$) relative to control groups treated with PBS 12%, FSL-1 8%, and IFNγ 5%.
Conclusions: FSL-1+IFNγ treatment increases TIL, murine survival, and tumor growth control, and promotes the complete regression of a subset of tumors. Thus, further studies are warranted to identify the mechanisms that modulate response to this treatment to improve treatment efficacy and to evaluate whether FSL-1+IFNγ can drive immunogenic cell death of TNBC and impart a systemic benefit for tumor control.

#3475 KGX103, a conditionally active prodrug of PD-1-targeting IL-15 induces antitumor activity by preferentially activating PD-1+ intratumoral T cells in cis.

Jiangfeng Fan, Zhiqiang Bai, Jing Wang, Shumin Yang, Yucheng Luo, Jie Huang, Hui Chen, Haixiang Wu, Yi Wu, **Weidong Jiang**

Shanghai KangaBio Co., Ltd., Shanghai, China

Interleukin-2 (IL-2) and IL-15 have both similar and contrasting functional roles in the proliferation and regulation of lymphocytes. They share the β/γ heterodimeric receptors while having distinct α-receptors. IL-15 is thought to be superior to IL-2 for the treatment of cancer in the aspects of lower vascular endothelium associated toxicity, much weaker Treg-stimulating activity and stronger expanding NK and CD8+ T cells abilities. However, the application of IL-15 in tumor immunotherapy remains challenging due to short half-life and severe adverse events caused by excessive and systemic immune activation.

To address these challenges, we have developed KGX103, a PD-1-targeting non-α attenuated IL-15 prodrug fused with anti-HSA antibody. The IL-15 mutein is concealed by an inactivation domain linked with tumor-specific protease cleavable peptide, to prevent systemic immune activation. Once mask is cleaved in tumor microenvironment (TME), KGX103 could effectively stimulate intratumoral antigen-experienced CD8+ T cells with elevated PD-1 expression. With PD-1 targeting and tumor-specific activation, KGX103 could greatly potentiate tumor-specific T cell proliferation and function while ameliorating systemic immune activation. The pSTAT5 activation of either fresh or pre-activated peripheral blood mononuclear cells (PBMCs) were tested with KGX103 and unmasked KGX103. KGX103 showed almost no pSTAT5 activation signal in fresh PBMCs with low PD-1 expression and weak activation in pre-activated PBMCs with elevated PD-1 expression. Meanwhile, KGX103 showed significantly reduced potency of >3000-fold than the unmasked KGX103, which could be recovered after tumor-specific protease cleavage. Then we evaluated KGX103's *in vivo* antitumor efficacy in xenograft models using B-NDG β2m KO mice plus. Mice were subcutaneously implanted with a mixture of A375 tumor cells and hPBMCs. After grouping, mice were treated with vehicle or KGX103. Compared to the vehicle group, KGX103 demonstrated its antitumor efficacy and safety as evidenced by significant tumor growth inhibition while no obvious body weight change during the dosing period. The pilot toxic study to evaluate the safety and toxicokinetics of KGX103 is ongoing in *Cynomolgus* monkeys.

#3476 A single intratumoral injection of IL-12 bound to mesoporous silica rods generates effective anti-tumor immune responses and tumor growth control in multiple syngeneic tumor models.

Fernanda Langellotto, **Jessica McDonough**, Everton Mandley, Benjamin Seiler, Brena Barra, Edward Doherty, Robert Pierce

Attivare Therapeutics Inc., Natick, MA

Background: Interleukin-12 (IL-12) is a potent inflammatory cytokine, which demonstrated anti-tumor activity in both experimental model systems and in a number of clinical trials. Unfortunately, the development of IL-12 as a therapeutic is hampered by severe toxicity in the event of significant systemic exposure. Therefore, intralesional IL-12 therapy has been actively pursued for intratumoral therapy. When delivered into the TME, IL-12 increases intratumoral interferon-γ expression leading to conversion of myeloid cells from an immunosuppressive state into an immunogenic one, recruits $CXCR3^+$ NK and effector T cells, upregulates antigen presentation/processing machinery, and generates anti-tumor immunity. Mesoporous silica rods [MSRs] are currently in development as a modular localized therapeutic platform, due to their large payload capacity, slow-release kinetics, high biocompatibility and intrinsic proinflammatory nature. In this study, we evaluated the anti-tumor effect of MSR plus IL-12 [ATT-02] as an “in situ” (“antigen-less”) vaccine and characterized the immune effects of MSR alone and in in combo with IL-12.

Methods: Syngeneic mouse models [B16F10, B16-OVA, CT26, and EMT-6] were conducted by challenging the mice with tumor cells on one flank. Tumors were treated one time with ATT-02 i.t. [Murine IL-12, MSR] when tumors reached the target size. Abscopal models were conducted by injecting tumor cells [CT26, B16F10, and B16-OVA] on both flanks at day zero. The tumor on one flank was treated when it reached the target size. Lymph nodes and spleens were collected at day 7 and analyzed by flow cytometry. *In vitro* work was conducted by co-culturing MSRs with THP-1 cells that had been initially polarized to an “M2” like phenotype. Repolarization (“M2 to M1”) and APC functionality of THP-1 cells were assayed using flow cytometric phenotyping and proliferation of co-cultured antigen-specific T- cells.

Results: ATT-02 i.t. generated potent anti-tumor immunity compared to PBS and IL-12 alone in 3 single tumor syngeneic models and 3 abscopal syngeneic models. Complete responses [CRs] were observed in the CT26 and EMT-6 model after a single dose of ATT-02. Upon rechallenge no tumor growth was observed. In the B16-OVA group, SIINFEKL+ T cells and CD86+ macrophages were observed at a higher level than controls in the draining lymph node of ATT-02 treated mice. Interestingly, MSR i.t. alone resulted in delayed tumor progression the B16F10 model. *In vitro*, we demonstrated that MSR alone results in a repolarization of macrophages to an immunogenic phenotype capable of driving T cell activation. Addition of IL-12 enhances this effect.

Conclusions: I.t. injection of ATT-02 (MSR_IL-12) leads to significant anti-tumor immune responses, antigen-specific responses, and tumor growth inhibition in multiple syngeneic tumor models.

#3477 Direct in vivo activation and expansion of tumor infiltrating lymphocytes using multifunctional immunotherapy nanoengager.

X. Wen[1], L. Ruan[1], M. Wang[1], K. Au[1], L. Zhang[2], T. Zhang[1], A. Wang[1];

[1]The University of Texas Southwestern Medical Center, Dallas, TX, [2]Xuzhou Medical University, Xuzhou, China

INTRODUCTION: TILs (Tumor infiltrating lymphocytes) therapy has been shown to be highly effective in melanoma and holds great potential for improving cancer immunotherapy in other cancers. The key limitation for TIL therapy is the complex process to activate and expand TILs. Thus, there is a strong need for refining strategies to enable TIL immunotherapy. To address this challenge, we hypothesized that we can directly activate and expand TILs *in vivo*, thereby eliminating the complex production process. We took advantage of a multifunctional nanoparticle (NP) platform to engineer NPs with multiple co-stimulatory molecules. We aimed to show that our in *vivo* approach can effectively stimulate TILs.

METHODS: Co-stimulatory molecules functionalized NPs (TIL-NPs) were synthesized through reacting Azide-functionalized NP cores with DBCO-functionalized molecules. TIL-NPs were injected intratumorally to promote the expansion and activation of TILs *in vivo*. The MC38 colorectal tumor model was used for evaluating the effects of TIL-NPs on TILs activation. For the *in vitro* experiment, TILs from tumors of MC38-bearing mice were incubated with MC38 cells following various stimulation strategies. For the *in vivo* experiment, a bilateral tumor model was established, with only the right flank receiving TIL-NP injection.

RESULTS: We successfully engineered NPs containing anti-CD3, anti-41BB and IL-2. These NPs were 126.2 nm in size. Per miligram NP conjugated with approximately 50μg immune activating molecules. TILs from MC38 tumors were incubated with TIL-NPs. Free antibodies were used as control. We found TILs stimulated by TIL-NPs demonstrated greater cytotoxicity against MC38 cells compared to the groups treated with free antibodies or unstimulated TILs (Figure 1A). IFN-γ levels were elevated in all treatment groups, with the most significant increase observed in the TIL-NPs group (Figure 1B).To determine if TIL-NPs increased T-cell activation *in vivo*, we evaluate the antitumor effects of TIL-NPs in a bilateral tumor model. One tumor received TIL-NPs while the other tumor was used to assess systemic treatment responses. Intratumorally injected TIL-NPs were highly effective in eradicating the injected tumor when compared to that of control and free antibodies groups (Figure 2A-B). All of the tumors on the right flank/injected completely regressed, achieving a 100% complete response (CR) rate. Importantly, the TIL-NPs also provided a robust systemic response, providing 60% CRs in the contralateral flank tumors. Overall, TIL-NPs significantly prolonged survival of mice (Figure 2C). Functionalizing these molecules on NPs also induced clustering of their respective receptors and improved signaling.

CONCLUSION: TIL-NPs engineered with multiple co-stimulatory molecules can directly stimulate TILs *in vivo*, providing a systemic immunotherapy response against cancer.

#3478 Pre-clinical characterization of AZD0240, a CRISPR-engineered autologous TCR-T cell product targeting KRAS-G12D/HLA-A*11:01 that is multi-armored to increase epitope sensitivity.

Lianne Kok[1], Sander Eshuis[1], Xiangjun Kong[1], Jennifer Ma[2], Michelle Mojadidi[2], Paula Kroon[1], Vanessa Tubb[1], Ton Schumacher[3], Arianne Perez[1], Carsten Linnemann[1], Mark Cobbold[4], Jeroen van Heijst[1], Gavin Bendle[1]

[1]Neogene Therapeutics / AstraZeneca, Amsterdam, Netherlands,[2]Neogene Therapeutics / AstraZeneca, Santa Monica, CA,[3]Netherlands Cancer Institute, Amsterdam, Netherlands,[4]AstraZeneca, Boston, MA

KRAS is one of the most commonly mutated genes in human cancer, with the G12D mutation having the highest frequency, occurring in 33% and 28% of colorectal cancer (CRC) and pancreatic cancer (PDAC), respectively. KRAS G12D-containing peptides are presented by the common HLA allele HLA-A*11:01, making this cancer neoantigen a highly attractive target for the development of adoptive TCR-T cell therapy. However, the levels of cancer neoantigen presentation are typically low and combined with the immunosuppressive tumor microenvironment this compromises the activation and reactivity of TCR-engineered T cells, posing a major hurdle for these cells to eradicate tumor lesions. To establish a TCR-T cell therapy clinically intended for the treatment of solid cancers, including CRC and PDAC, we developed AZD0240, a CRISPR-engineered autologous TCR-T cell product targeting KRAS-G12D/HLA-A*11:01. To improve the reactivity of AZD0240 to the KRAS-G12D neoantigen, we developed a novel multi-armoring strategy, involving the combined disruption of a key negative regulator of T cell function and the introduction of a positive enhancement of TCR signaling. Employing this multi-armoring strategy, we observed enhanced cytokine production in responds to low levels of exogenously loaded KRAS-G12D peptide, as well as HLA-A*11:01$^+$ tumor cells that express the KRAS-G12D mutation. Moreover, assessment of the *in vitro* and *in vivo* proliferative and cytotoxic capacity revealed that the AZD0240 armoring strategy can profoundly increase both the proliferative capacity and the anti-tumor efficacy of TCR edited T cells. Notably, the armored AZD0240 T cells were unable to respond to the KRAS G12 wild-type epitope, and no signs of increased TCR cross- or allo-reactivity, or malignant transformation were detected, derisking the clinical use of this armoring strategy. Taken together, AZD0240 is a KRAS-G12D/HLA-A*11:01 targeted TCR-T cell therapy that employs a novel multi-armoring strategy and is currently in preparation for clinical testing, with encouraging signs of pre-clinical efficacy and safety.

#3479 iPSC-derived γδT with novel combinatorial KO demonstrated significant anti-tumor activity and extended longevity without cytokine support.

Jhang-Sian Yu, Ming-Chin Ko, Chia-Hung Lin, Yi-Han Dai, Ke-Hsun Hsu, I-Ting Chen, Ting-Yi Wu, Jin-Yi Lu, Ying-Tsen Tung, Edward Po-Fan Chu, Yuan-Yu Hsia, Yo-Chuen Lin, Chieh-Teng Cheng, Tzu-Chien Kuo, Yi-Ting Lai, Wei-Ting Chen, Darien Zhing Herr Chan, Lee-Yieng Lim, Chih-Lung Chen, Chun-Yu Lin, Lin-Yu Liao, Wan-Chen Tsai, Lien-Szu Wu, Ching-Ying Huang, De-Kuan Chang, Alex Shih-Min Huang

BeiGene, Ltd., Grand Cayman, Cayman Islands, United Kingdom

Induced pluripotent stem cell (iPSC)-derived cell treatment offers several competitive benefits, including consistency, homogeneity and unlimited dosage, in contrast to autologous and allogeneic donor-derived cell therapies. These attributes improve affordability and accessibility of medicines worldwide. Noteworthy, the effectiveness of T cell therapy is constrained by factors such as cell potency and persistence. Our research on iPSC-derived gamma-delta T (γδT) cells has identified a novel combinatorial KO to overcome these challenges. IL-2 administration has been approved by FDA for durable, complete, and apparently curative regressions in cancer patients. Previous studies demonstrated that IL-2 receptor beta (IL-2Rβ) chain-mediated signaling pathway is critical for killing potency and cell persistence. The suppressor of cytokine signaling (SOCS) family helps control cytokine signaling by blocking the JAK/STAT pathway. For example, cytokine-inducible SH2-containing protein (CISH) is a member of the SOCS protein which is essential for managing cytokine signaling, cell growth, differentiation, and immune system activities. Our findings indicated that iγδT cells deficient in both CISH and another SOCS family protein exhibited increased persistence and enhanced cytotoxic capabilities compared to cells with only one of the knockouts. Notably, we demonstrated the proliferative advantage of double SOCS protein KO by using a humanized mouse model. Cytokine withdrawal- and activation-induced cell death were key factors that diminish effector cell persistence post infusion. For prolonging cell survival, we identified a mediator of mitochondrial apoptotic pathway and found that this proapoptotic protein is necessary for extending the survival of iγδT cell post IL-15 withdrawal. In addition, FAS-FASL signaling was recently identified as auto-regulatory circuit for CAR-engineered lymphocyte persistence. We presented biochemical data and performed gain-of-function experiments to elucidate the mechanisms by which this proapoptotic protein contributes to the extended survival of effector cells. Furthermore, we demonstrated FAS deficiency protects functional enhanced iγδT cells from FASL-induced apoptosis and then enhances its durable killing ability against HepG2 cells. Altogether, we identified a novel combination of gene knockouts that extends longevity and profound anti-tumor efficacy without cytokine support. We achieved the goldilocks signaling balance could strengthen the efficacy and longevity of iγδT cell, while avoid the possible dysfunction, such as exhaustion, caused by introducing constitutively active cytokine receptors as many others have attempted. Building on this engineering platform, we could incorporate tumor-targeting receptors for treating different indications in the near future.

#3480 Gene electrotransfer in cancer: different immunomodulatory profiles and cell death pathways depend on different electric pulse protocols.

Mariangela De Robertis[1], Tim Bozic[2], Iva Santek[2], Flaviana Marzano[3], Bostjan Markelc[2], Domenico Alessandro Silvestris[1], Apollonia Tullo[3], Graziano Pesole[1], Maja Cemazar[2], Emanuela Signori[4]

[1]Department of Biosciences, Biotechnology and Environment, University of Bari Aldo Moro, Bari, Italy,[2]Department of Experimental Oncology, Institute of Oncology Ljubljana, Ljubljana, Slovenia,[3]Institute of Biomembranes, Bioenergetics and Molecular Biotechnologies, Consiglio Nazionale delle Ricerche, Bari, Italy,[4]Laboratory of Molecular Pathology and Experimental Oncology, Institute of Translational Pharmacology, CNR, Roma, Italy

Gene electrotransfer (GET) is an excellent strategy for delivering therapeutic genes and vaccines into the target cell using electric pulses. In view of the insights gained during the last COVID-19 pandemic, it is widely acknowledged that genetic vaccines represent a safe and affordable option with considerable promise for addressing a range of diseases, including infectious diseases and cancer. Growing evidence from preclinical studies and clinical trials, which include both intramuscular and intratumoral immunotherapy, suggests that GET-based methods could be adapted for application in veterinary and clinical treatment protocols. At present, a key focus of research is on enhancing plasmid DNA (pDNA) electrotransfer techniques to reduce tissue damage and improve gene transfection efficiency. However, the molecular effects of electroporation (EP)-assisted DNA delivery in vivo are still not well understood. We assessed two GET protocols for the intratumoral administration of pDNA: Short and High Voltage (SHV) electric pulses or an adapted High Voltage - Low Voltage (HV-LV) pulses protocol, both of which are used for reversible electroporation. We investigated the ability of these two electric pulse conditions to trigger immune and tissue responses in murine CT26 colorectal tumors treated with intratumoral non-coding pDNA EP, instead of using an antigen or immunostimulatory agent. Immune cell infiltration in the tumors was assessed after both treatments, and a transcriptomic analysis through RNA sequencing was conducted to examine the gene expression changes induced by GET, with a particular focus on immune and cellular signaling pathways. We observed no significant differences between the two GET protocols in counteracting tumor development in the absence of immunomodulatory molecules. However, important variations in intratumoral macrophage, CD4+ T cells and even higher CD8+ T cells recruitment were reported between the two treatment methods. Transcriptomic analysis revealed that apoptosis is a predominant mode of cell death after GET by SHV pulses, whereas, GET by HV-LV pulses is associated with immunogenic necrotic pathways as well as a prominent activation of both innate and adaptive immune response. We showed that varying pulse parameters can trigger different immunomodulatory profiles within the tumor microenvironment, emphasizing the significance of choosing the right pulse settings in EP-based therapies. This analysis could provide valuable insights for selecting the most effective EP method or for developing new EP-based strategies to enhance the success of GET protocols used for vaccination or gene therapy.

#3481 Transarterial embolization for HCC: how embolic agents shape tumor immunity and systemic responses.

Andrea C. Cortes[1], Simone Anfossi[2], Kiyoyuki Minamiguchi[1], Rony Avritscher[1]

[1]Interventional Radiology, UT MD Anderson Cancer Center, Houston, TX,[2]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX

Transarterial embolization (TAE) is an effective therapy for hepatocellular carcinoma (HCC). Effects of the treatment on tumor immune microenvironment are poorly understood. Different TAE agents induce varying degrees of tumor and peritumoral hypoxia and nutrient-depletion. The purpose of this study is to investigate the immunological effects of the most commonly used embolic agents. Using a preclinical rat HCC model, tumors treated with oil or microspheres were compared to untreated controls. Tumor and serum samples collected at 7 and 14 days post-treatment were analyzed by flow cytometry, cytokine assays, and gene expression profiling using nanoString CodeSet. Ethiodized oil significantly altered the TME, reducing exhausted CD8+Tcells and PD-1+regulatory T cells while increasing CD45+CD3+immune cell infiltration ($P \leq 0.05$). Microsphere-treated tumors showed less pronounced effects. Serum cytokine analysis revealed a shift from Th2- to Th1-dominated immunity in the Ethiodized oil group, with elevated Th1 cytokines (IL-12,IL-18,IFNγ) and reduced Th2 cytokines (IL-4,IL-5,IL-10) at 14 days ($P \leq 0.05$). Both embolic agents reduced pro-inflammatory cytokines (IL-1α,IL-1β, TNFα,G-CSF), indicating a dampened systemic inflammatory response. Gene expression analysis showed significant downregulation of Th2-associated pathways, in tumors treated with Ethiodized oil. This treatment promoted a Th1-dominant immune response, contrasting with the Th2-skewed signaling seen in microsphere-treated tumors. Pathway analyses further demonstrated a reduced activity of Th2-associated chemokine receptors and cytokine pathways in Ethiodized oil-treated tumors compared to microspheres, highlighting distinct immunological modulations driven by embolic agent choice. The findings demonstrate how embolic agents impact the tumor microenvironment and systemic immunity. Ethiodized oil exhibits superior immunomodulatory effects, promoting a Th1 phenotype and reducing pro-tumoral factors. This information is critical for devising new combinatorial immunotherapy strategies in HCC that consider the distinct effects of different embolic agents.

#3482 Enhanced targeting of HPV positive cancers using gamma delta 1 T cells armored with an HPV E7-specific TCR: a novel approach to overcome HLA downregulation.

Andres Mosquera[1], Diego F. Chamorro[1], Paul Shafer[2], Lauren K. Somes[1], Emily Madaras[1], Valentina Hoyos[1]

[1]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX,[2]Lester and Sue Smith Breast Center, Baylor College of Medicine, Houston, TX

T-cell receptor (TCR) engineered T cells have emerged as a promising cancer therapeutic. While the clinical trial using ab T cells targeting the HPV E7 protein showed promise, it also highlighted a concerning issue: tumor escape due to the acquisition of defects in peptide-HLA presentation. As an alternative cellular platform, Gamma Delta One T cells (DOT) offer several advantages over alpha/beta T cells. These include their tissue-homing abilities, their use as allogeneic cells without GVHD risk, and their potential to target cells through both TCR and NK-like receptors (which can kill HLA Class-I deficient cells). *The overall purpose of this study is to establish DOTs as an effective platform for TCR-T therapy targeting solid tumors, demonstrating enhanced therapeutic efficacy in overcoming tumor escape through mutations in the antigen-processing machinery (APM).* We developed a novel protocol to isolate and expand DOTs from peripheral blood using a Delta 1 TCR-specific antibody and EasySep positive selection. By day 4, DOTs reached 37.3% (SD ± 10.3%) enrichment, increasing to 91.85% (SD ± 2.15%) by the end of culture. From transduction day, cells expanded over 100-fold by day 15, demonstrating scalability for therapeutic use. Efficiently transduced with an E7-specific TCR engineered to minimize mispairing (murine constant alpha and beta chains), we achieved transduction levels comparable to alpha/beta T cells. DOTs expressed high levels of NK-like receptors, including NKG2D (94.85% SD ± 0.55%), DNAM-1 (99.1% SD ± 0.3%), and NKp30 (76% SD ± 11%), crucial for targeting HLA-negative tumors. Using HPV+ E7+ SCC90 and CaSki cell lines with varying NKG2D ligand expression, we performed CRISPR/Cas9-mediated B2M knockout to generate HLA class I-deficient variants. Cytotoxicity was evaluated using in vitro chromium release (short-term) and IncuCyte (long-term) assays, where DOTs consistently outperformed alpha/beta T cells in killing HLA-heterogeneous tumors. DOT TCR-T cells exhibited comparable cytotoxicity to alpha/beta TCR-T cells against HLA-A*02:01+ E7+ targets while excelling against HLA-negative variants. These findings establish DOTs as a robust platform for TCR-engineered therapies, capable of overcoming tumor immune evasion across diverse HLA settings. We are currently validating these results in vivo using murine models. In summary, DOTs offer a promising platform for TCR-engineered therapies, excelling in targeting HLA-heterogeneous tumor populations through their dual recognition mechanisms. This work highlights their potential for developing off-the-shelf TCR-T therapies to overcome HLA downregulation and tumor heterogeneity in solid tumors.

#3483 MyT^{TM}platform-identified PRAME TCRs for T cell therapy demonstrate superior efficacy and best-in-class potential compared to clinical benchmarks.

Lia Walcher, Lena Immisch, Mira Heichenko, Alexei Leliavski, Robert Hoeltzel, Sharesta Khoenkhoen, Niklas Fellmer, Elisa Kieback, Lorenz Knackstedt, **Lucia Poncette**

T-Knife GmbH, Berlin, Germany

Introduction: PRAME is a clinically validated target for T cell receptor-modified T cell (TCR-T) therapy with high prevalence in multiple solid tumor indications. T-knife's MyT^{TM} platform generates best-in-class, high-affinity and high-specificity PRAME-directed TCRs for use in next-generation TCR-T therapy.

Methods: We identified PRAME-directed TCRs using the MyT platform, a TCR discovery engine based on transgenic mice expressing the human TCR repertoire with the ability to overcome central tolerance. Reactive TCR candidates were identified by rapid throughput screening using an indicator cell line. Selected TCR candidates were subsequently expressed retrovirally in primary T cells in combination with a CD8αβ coreceptor and characterized for peptide dose-response, cytokine release and cytotoxicity. We performed in-depth TCR safety profiling by rapid alloreactivity screening of single-HLA-transfected cells and by deep mutational cross-reactivity scans (X-scans). Finally, we supercharged TCR-modified T cells by co-expression with an activating CD8 coreceptor with built-in co-stimulation and a FAS-CD40/OX40 switch receptor using CRISPR-Cas9 gene editing combined with knockout of the endogenous TCR.

Results: PRAME was highly immunogenic leading to a 100% response rate in mice after immunization. We identified 85 TCRs reactive to the immunodominant HLA-A*02:01 PRAME epitope SLLQHLIGL. Peptide dose-response assays as well as co-cultures with a panel of PRAME-expressing cancer cell lines from a broad range of tumor indications demonstrated high avidity, high cytokine secretion and high cytotoxicity of T cells expressing MyT TCRs. Three lead TCR candidates were selected, which showed no alloreactivity against 149 tested HLA-subtypes covering 98% of class-I HLA alleles. Furthermore, testing over 300 putative off-target peptides predicted *in silico* or experimentally in X-scans, revealed that MyT TCRs show no off-target recognition. Importantly, benchmarking showed that the selected lead TCR candidate displays higher *in-vitro* efficacy compared to publicly disclosed clinical-stage TCRs, which was particularly evident at low E:T ratios and retained during multiple rounds of tumor cell restimulation. Finally, as part of the development of a Supercharged PRAME TCR-T product, TCR expression and functionality was further enhanced, by dual T cell armoring and using gene editing combined with endogenous TCR knockout, without impacting safety.

Conclusions: Our data demonstrate that the MyT platform delivers best-in-class, high-affinity/high-specificity PRAME TCRs. Administration of Supercharged PRAME-TCR-T cells incorporating these MyT TCRs, a single-chain co-stimulatory CD8 coreceptor and a switch receptor in a non-viral process, provides potential to induce deep and durable responses in hard-to-treat solid tumor indications.

#3484 Lipid nanoparticle-mediated *in vitro* transfection of microbubble-activated T cells.

Seeta Nyayapathy[1], Paige Gronevelt[1], Erin Holcomb[2], Julie M. Rumble[1]

[1]Cayman Chemical Company, Ann Arbor, MI,[2]Medical School, University of Michigan, Ann Arbor, MI

Immunotherapy of cancer has revolutionized approaches to controlling and curing cancer, with adoptive transfer of chimeric antigen receptor T cells (CAR-T cells) representing a potentially curative treatment for previously unresponsive tumors. CAR-T cell therapy consists of ex vivo expansion of autologous T cells, transfection with the chimeric antigen receptor (CAR) and transfer into the patient. The CAR allows those T cells to identify and kill any cells expressing the antigen of interest, typically a surface protein expressed abundantly and primarily by the tumor. While these methods are extremely effective in a subset of patients, there is opportunity for improvement that may broaden the efficacy of this type of therapy. First, the application of selection, activation and expansion microbubbles has been shown to result in a less “exhausted” phenotype of the T cells at the end of the expansion phase, resulting in better overall T cell responses. In addition, alternative methods of transfection such as lipid nanoparticles (LNPs) may improve both transfection efficiency and viability. LNP lipid components can be tuned to optimally encapsulate different cargo types and transfect different cell types. Therefore, we formulated a variety of different LNPs to encapsulate either mRNA or pDNA encoding a reporter gene and assessed the relative transfection efficiency in microbubble-activated T cells. Additionally, we evaluated the final activation/exhaustion profile of the transfected cells to determine how uptake of different LNPs may affect the killing effectiveness. These results may ultimately suggest process improvements that have the potential to expand the number of CAR-T recipients who have improved responses to therapy.

#3485 T cell receptor (TCR)-Based cellular therapy for Fibrolamellar HCC.

Kayla J. Bendinelli[1], Allison M. Kirk[2], Paul G. Thomas[2], Mark Yarchoan[1]

[1]Johns Hopkins University, Baltimore, MD,[2]St. Jude Children's Research Hospital, Memphis, TN

Background: Fibrolamellar carcinoma (FLC) is a rare and often lethal liver cancer that primarily affects children and young adults without cirrhosis. There is no standard systemic treatment for FLC and the median survival for patients with advanced, unresectable FLC is approximately 12 months. The FLC transcriptome is characterized by an in-frame fusion of exon 1 of DNAJB1 with exons 2-10 of PRKACA, the catalytic subunit of protein kinase A (PKA), leading to expression of a chimeric protein, DNAJ-PKAc that has thus far been “undruggable” due to unacceptable on-target toxicity. Our overall goal is to target this “undruggable” oncogenic driver using T Cell Receptor (TCR)-Based cellular therapy.
Methods: We are performing a clinical trial of a peptide-based therapeutic vaccine targeting DNAJ-PKAc, in combination with the immune checkpoint inhibitors nivolumab and ipilimumab. We analyzed PBMCs from a subset of patients who demonstrated a clinical response to this immune-based combination therapy to identify TCRs with specificity for DNAJ-PKAc.
Results: To identify fusion specific T cell receptors (TCRs) generated in response to the vaccine patient peripheral lymphocytes were expanded and 10x single cell transcriptomic with paired TCR sequencing was performed. Candidate TCRs were reconstructed and expressed in T cells prior to co-culturing with HLA matched antigen presenting cells that were pulsed with DNAJ-PKAc peptides to verify fusion specificity via flow cytometry for T cell activation. We reconstructed and verified fusion specificity for multiple TCRs from several patients, and characterized them functionally by HLA specificity, affinity, and killing capacity in vitro. We identified TCRs recognizing DNAJ-PKAc-derived peptides in the context of class II HLAs, including HLA-DRB1*13:01 and HLA-DRB3*01. The TCRs that were identified recognize distinct DNAJ-PKAc-derived epitopes, with variable HLA specificity, TCR affinity, and cytokine response profiles after DNAJ-PKAc antigen stimulation. In general, TCRs with specificity for DNAJ-PKAc presented in the context of HLA-DRB1*13:01 were higher affinity than those recognizing HLA-DRB3*01, even when obtained from the same original patient.
Conclusion: This work identifies and characterizes multiple TCRs with specificity for DNAJ-PKAc. Our data provides evidence that the therapeutic efficacy of a peptide-based therapeutic vaccine may be mediated by a CD4 T cell response, and provides potential candidates for off-the-shelf TCR therapy for FLC.

#3486 Click-to-release for controlled immune cell activation: tumor-targeted unmasking of an IL-12 prodrug *in vivo*.

Martijn H. den Brok[1], Kim E. de Roode[1], Luc M. J. Zijlmans[1], Laurens H. J. Kleijn[1], Marleen H. M. van Stevendaal[1], Ron M. Versteegen[2], Lieke W. M. Wouters[1], Raffaella Rossin[1], Marc S. Robillard[1]

[1]Tagworks Pharmaceuticals B.V., Nijmegen, Netherlands,[2]SyMO-Chem, Eindhoven, Netherlands

Immunotherapy utilizing immune stimulating cytokines such as IL-12 holds great promise for the treatment of cancer. However, clinical use of IL-12 is hampered by severe toxicity following systemic administration resulting in a narrow therapeutic window. Tagworks is pioneering the use of *in vivo* click chemistry (Click-to-Release platform) to enable effective on-tumor activation of prodrugs, with the aim to increase the therapeutic index and application scope of potent anticancer drugs. We here present a novel treatment strategy in which IL-12 is inactivated by lysine conjugation to *trans*-cyclooctene(TCO)-linked PEG masks that can be released through the Click-to-Release reaction between the TCO linker and a tetrazine molecule (the trigger), restoring the native cytokine. Selective activation in the tumor microenvironment is achieved by pre-targeting the trigger to the tumor by i.v. injection of a tetrazine-protein conjugate, triggering local activation of the masked IL-12 when it is given in a subsequent i.v. injection. Evaluation of several Click-to-Release designs *in vitro* resulted in the selection of an IL-12-TCO-PEG construct with 9 conjugated lysines, exhibiting superior masking (>100 fold attenuated) combined with instantaneous and complete re-activation upon reaction with tetrazine. Next, we developed a tumor-targeted tetrazine based on a diabody against TAG72, a pan-carcinoma marker in the tumor microenvironment, modified with 4 tetrazine moieties. The diabody-tetrazine showed good tumor uptake in mice bearing colorectal (LS174T) xenografts combined with rapid blood clearance (< 0.5 %ID/g 24h p.i.). Also IL-12-TCO-PEG showed nearly complete clearance in 24 hours (< 0.5 %ID/g 24h p.i.). Administration of diabody-tetrazine to tumor-bearing mice followed by IL-12-TCO-PEG 24 hours later afforded selective IL12 unmasking in tumors and not in blood, demonstrating the feasibility of locally activating systemically administered immune stimulating cytokines with the versatile Click-to-Release platform.

#3487 Mechanistic role of CD70 in UV exposed keratinocytes and cutaneous squamous cell carcinoma (cSCC).

Asad Khan[1], Qiushi Wang[1], Chengcheng Hu[2], Emannuel Petricoin[3], Rebecca Morris[1], Georg T. Wondrak[2], Ann M. Bode[1], Clara Curiel-Lewandrowski[2], **Tianshun Zhang**[1]

[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]The University of Arizona Cancer Center, The University of Arizona, Tucson, AZ,[3]Center for Applied Proteomics and Molecular Medicine, College of Medicine, George Mason University, Fairfax, VA

The incidence of cutaneous squamous cell carcinoma (cSCC) is rising due to limited prevention strategies. Significant gaps persist in understanding the mechanisms of UV-induced DNA damage and immune modulation in skin cancer development. By analyzing expression data from sun-exposed and sun-protected skin in the Genotype-Tissue Expression (GTEx) database and the Gene Expression Omnibus (GEO), we identified CD70 as a key gene linking solar UV exposure, immune responses, and photocarcinogenesis. Reverse Phase Protein Microarray Analysis (RPPA) revealed a significant upregulation of CD70 in sun-damaged skin compared to sun-protected skin. CD70 expression was also markedly higher in actinic keratosis (AK) and cSCC compared to normal tissue. In this study, we investigated the mechanistic role of CD70 in solar simulated light (SSL,149 kJ/m^2 UVA & 7.2 kJ/m^2 UVB)-exposed keratinocytes and cSCC. CD70 expression was found to increase in keratinocytes following SSL irradiation in a dose- and time-dependent manner. Deletion of CD70 effectively suppressed cSCC cell growth in both 2D and 3D culture models. RNA sequencing (RNA-seq) analysis (shCon vs. shCD70) revealed that CD70 regulates gene expression changes induced by solar UV exposure through multiple oncogenic pathways. CD70-associated genes are strongly linked to AK and cSCC and involve critical signaling pathways, including MAPK, Rap1, and others. Additionally, CD70 deletion inhibits NFkappa B nuclear translocation, as demonstrated by luciferase assays and immunofluorescence analysis. In summary, these findings underscore the pivotal role of CD70 in SSL-induced skin damage and photocarcinogenesis. The CD70 inhibition may offer a novel targeted strategy for preventing and treating cSCC.

#3488 MERTK inhibition regulates tumor-associated myeloid cell phenotypes and potentiates host-versus-lung cancer immunity.

Dan Yan[1], Xiaodong Wang[2], Stephen V. Frye[2], H. Shelton Earp[3], Deborah DeRyckere[1], Douglas K. Graham[1]

[1]Pediatrics, Emory University, Atlanta, GA,[2]Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC

The TAM (TYRO3, AXL, MERTK) family receptor tyrosine kinases are important for clearing apoptotic cells and maintaining tissue homeostasis. They promote an immunosuppressive environment during cell clearance, which can be hijacked by tumor cells to promote immune evasion. This study aimed to determine how MERTK inhibition affects immune cells within the tumor microenvironment (TME) in lung cancer using a subcutaneous *Kras*-mutant murine lung cancer tumor model in wild-type (WT), *Axl* knock-out (KO), or *Mertk* KO mice. Tumor growth was inhibited in *Mertk* KO mice compared to WT mice, while *Axl* KO mice had no significant change in tumor growth. The anti-tumor effect observed in *Mertk* KO mice was lost in Mertk KO *scid* mice, which lack functional T and B cells, suggesting MERTK as an immunotherapeutic target in *Kras*-mutant lung cancer. MRX-2843 is a novel first-in-class MERTK-selective inhibitor that is currently being tested in phase 1/1b clinical trials. The murine cancer cell line used in this study did not express detectable MERTK and was unresponsive to MRX-2843 *in vitro.* However, *in vivo* treatment with MRX-2843 led to dose-dependent inhibition of tumor growth. Conditional knockout of *Mertk* in LysM expressing (i.e. myeloid) cells resulted in reduced tumor growth compared to tumors in WT mice. These data suggest that MERTK functions in myeloid cells to inhibit anti-tumor immunity, although contributions of homozygous LysM KO could not be eliminated in this study. Additionally, MERTK was only expressed in WT tumor myeloid cells ; myeloid cell MERTK was not detected in the TME in conditional *Mertk* KO mice. Furthermore, tumors from *Mertk* KO mice had evidence of increased antigen-presenting capacity with significantly increased numbers of tumor-associated macrophages expressing high levels of MHC-II and increased incidence of dendritic cells. Together these findings suggest that MERTK inhibits anti-tumor immunity by regulating myeloid cell functions and implicate MERTK as an immunotherapeutic target in *Kras*-mutant non-small cell lung cancer.

#3489 Functional enhancement of hypoxia-activated chimeric antigen receptor T-cells by a chimeric switch receptor recognizing TGF-β.

Zhihong Huang, Deping Han, Jean-Paul Thiery, **Xi Zhang**

Biosyngen Pte Ltd, Singapore, Singapore

Background: We have previously demonstrated that hypoxia-activated chimeric antigen receptor (CAR) T-cells could execute robust anti-tumor efficacy with controllable on-target, off-tumor (OTOT) toxicities in the clinical setting. However, some normal tissues or organs, such as bone marrow, rectum, stomach, gallbladder, and epidermis, also exhibit hypoxic microenvironment, which might lead to potential side effects or constraints for the clinical use of hypoxia-responsive CAR T-cells. TGF-β is a significant immunosuppressive factor that impedes immune response in the tumor microenvironment, while its expression in the hypoxic normal tissues is limited. We optimized the construct by introducing an AND-gated circuit complementing the hypoxia-driven conditional activation to reduce OTOT toxicities further.

Methods: The AND-gated CAR, BTRPTB001L, consisted of a hypoxia-activated CAR and a constitutively expressing TGF-β chimeric switch receptor (CSR). T-cells isolated from human peripheral blood mononuclear cells were stimulated with anti-CD3/CD28 beads, lentivirally transduced, and expanded *ex vivo*. CAR/CSR expression was assessed by flow cytometry. IncuCyte was used to analyze the *in-vitro* cytotoxicity in the presence of TGF-β. The TGF-β sponging capability was assessed by ELISA. Anti-tumor efficacy was evaluated in subcutaneously inoculated xenograft mouse models. Safety evaluation was performed using the AND-gated CAR T-cells targeting the murine orthologous antigen (BTRPTB001L') in immunocompromised mice.

Results: In BTRPTB001L, the fold change of CAR expression level in 1% O_2 compared to 21% O_2 was 6.33 ($P < 0.05$), while the CSR expression remained unaffected under either condition. BTRPTB001L showed significantly reduced cytotoxicity under normoxic conditions compared to second-generation (2nd-gen) hypoxia-activated CAR T-cells by co-culturing with target cells. Interestingly, in the presence of TGF-β and under hypoxic conditions, BTRPTB001L showed enhanced cytotoxicity, indicating that the CSR could reverse the inhibitory signal and be specifically activated by the soluble TGF-β in the tumor microenvironment. Notably, the CSR could also sponge TGF-β in the culture supernatant. The improved anti-tumor efficacy of BTRPTB001L was also demonstrated in a xenograft mouse model of pancreatic cancer. Moreover, while the constitutively expressing 2nd-gen CAR recognizing the murine orthologous TAA caused a lethal weight loss phenotype in mice, the BTRPTB001L'-treated group showed no prominent adverse events.

Conclusion: BTRPTB001L demonstrated robust anti-tumor potential and improved safety profile compared to hypoxia-responsive 2nd-gen CAR T-cell, supporting its further clinical development.

IMMUNOLOGY: T Cell Engagers
Poster Session

#3493 A novel T cell engager antibody for the treatment of HLA-A*01/KK-LC-1-positive tumors.

Athanasia Dasargyri, **Melissa Vrohlings**, Stephanie Jungmichel, Blaz Pavlovic, Martina Priola, Zoi Barou, Hannes Merten, Philip Knobel, Luca Scheu, Fabian Scheifele, Gonzalo Acuna, Matteo Morotti, Christian Leisner, Swethajit Biswas, Leonardo Borras

CDR-Life Inc., Horgen, Switzerland

Kita-Kyushu lung cancer antigen-1 (KK-LC-1) is a cancer-testis antigen prevalently expressed in multiple tumors including lung and gastric cancers but not in normal tissues. Here, we describe CDR505, a novel antibody-based T cell engager (TCE) for the treatment of KK-LC-1-expressing solid tumors. Since most HLA-restricted TCEs currently in clinical development are targeted against peptides presented on HLA-A*02, there is a high unmet need to develop TCEs for other HLA-A patient subpopulations. CDR505 is the only TCE to date, which is being developed against an intracellular target presented on HLA-A*01$^+$ tumors. CDR505 is a humanized, affinity-matured, and stability-engineered TCE that binds with one Fab arm to CD3 on T cells and with two scFv arms to the HLA-A*01-restricted KK-LC-1 peptide NTDNNLAVY on cancer cells. With a molecular weight of 100 kDa, this format is predicted to achieve a favorable PK likely allowing Q2W or Q3W dosing. CDR505 shows very efficient cancer cell killing as demonstrated with KK-LC-1$^+$/HLA-A*01$^+$ cancer cell lines NCI-H1703 and EKVX in co-cultures with human PBMCs. Upon CDR505-mediated cancer cell killing, increased expression of activation (CD69, CD25) and proliferation (Ki67) markers were observed on CD3$^+$ cells. T cell activation was further confirmed by the presence of cytokines detected in culture supernatants, including IFNγ, IL2, TNFα, IL6, and granzyme B. KK-LC-1 is a highly challenging target due to high levels of similar off-target peptides presented in healthy tissues. Extensive assessments for binding specificity and cross-reactivity in normal human cells were performed with CDR505. The binding profile of CDR505 was determined using surface plasmon resonance (SPR). This binding profile was used to identify potential off-target peptides in mass-spectrometry databases containing peptides presented in healthy tissues. None of the peptides identified caused relevant T cell activation in presence of CDR505 when presented on TAP-deficient, (empty) HLA-A*01-expressing T2 cells. Furthermore, CDR505 did not induce relevant T cell reactivity towards a panel of HLA-A*01 positive normal human cells from different organs and tissues. These results support a low risk for CDR505 off-target reactivity and a favorable safety profile. Collectively, CDR505 potently activates T cells and induces efficient cytotoxicity against KK-LC-1$^+$/HLA-A*01$^+$ cancer cells. It shows high specificity for KK-LC-1/HLA-A*01 and shows an overall safe profile in the presence of normal human cells. Future studies will include in vivo efficacy testing and a broader range of cellular assays using tissues and cultured cells as part of the preclinical studies that will be included in the IND application.

#3494 Durable and potent in vitro T cell activity with repeated exposure to CDR404, a potential best-in-class T cell engager targeting MAGE-A4.

Alessio Vantellini, Nora Wettstein, **Melissa Vrohlings**, Stephanie Jungmichel, Andre Luis Fonseca da Silva, Alice Langer, Anna Howald, Zoi Barou, Daniel Lenherr-Frey, Matteo Morotti, Christian Leisner, Swethajit Biswas, Leonardo Borras

CDR-Life Inc., Horgen, Switzerland

T cell engagers (TCEs) targeting the melanoma antigen gene A4 (MAGE-A4) have entered first-in-human trials for HLA-A*02:01+ patients with MAGE-A4 expressing solid tumors. CDR404 is a bispecific antibody-based TCE that binds bivalently to the MAGE-$A4_{230-239}$ peptide on HLA-A*02:01 and monovalently to CD3. The safety, tolerability and preliminary therapeutic efficacy of CDR404 are currently being evaluated in a dose-finding Phase 1 trial in multiple solid cancers including NSCLC (NCT06402201). The only other MAGE-A4 targeting TCE currently in clinical trial is a TCR-based TCE with a low affinity T cell recruiter, bearing an Fc region (TCR-TCE-Fc). Therefore, there are fundamental differences in format, functionality and pharmacology between these two TCE molecules. This preclinical study provides novel mechanistic insights into the persistence of cancer cell killing with repeated dosing of CDR404, comparing it to the TCR-TCE-Fc molecule. Since upregulation of PD-1 is an obligate immunosuppressive brake to T cell activation, we additionally investigated the in vitro killing activity of a CDR404 and Pembrolizumab combination compared to CDR404 alone. In co-culture assays of MAGE-A4+/HLA-A*02:01+ NSCLC cells (NCI-H1755) and human PBMCs, CDR404 induced higher levels of T cell activation, reflected by activation (CD69, CD25) and proliferation (Ki67) markers, and more potent tumor cell killing compared to the TCR-TCE-Fc. Higher potency of CDR404 was confirmed on different MAGE-A4+ cell lines from various cancer types. CDR404 also showed more efficient cancer cell killing than the TCR-TCE-Fc at low E:T ratios (down to 1:1), indicating that it has the potential to achieve higher efficacy in tumors with low T cell infiltration (“cold tumors”). Strikingly, potency of CDR404 was efficiently maintained over multiple rounds of serial killing of NSCLC cells (NCI-H1755), in contrast to the TCR-TCE-Fc molecule. In this experiment, CDR404 induced significantly less upregulation of T cell exhaustion markers than the TCR-TCE-Fc. These results highlight the potential of CDR404 to achieve more durable responses in solid tumors. Since T cell engagers treatment is accompanied by upregulation of PD-1/PD-L1 axis, we evaluated CDR404 in combination with the anti-PD-1 therapy pembrolizumab, showing enhanced potency of in vitro exhausted T cells on a PD-L1 overexpressing NSCLC cell line compared to CDR404 alone. In conclusion, these results demonstrate the potential of CDR404 to achieve improved efficacy and more durable responses for HLA-A*02:01+ patients with MAGE-A4+ tumors. The combination with an anti-PD-1 therapy may have additive anti-tumor activity in patients, and could potentially allow a transition into earlier, anti-PD-1/PD-L1 containing lines of treatment for multiple solid cancers including NSCLC, thus benefiting a larger patient population.

#3495 QL535, A novel CD2-costimulating T cell engager targeting PSMA-positive prostate cancer matching CD28 trispecific antibody in cytotoxicity, minimizing cytokine release and T-cell exhaustion.

Xiao Liu[1], Shenda Gu[1], Ke Liu[2], Joshua Morrissette[1], Jiantao Kong[3], Guangjie Guo[1], Yuxia Wang[2], Xin Zhang[2], Jiaming Cao[3], Moyan Hu[2], Min Sun[3], Ruixue Ma[2], Jane Chen[1], Nathan Ngo[1], Hejie Zhu[3], Liwei Wang[3], Yan Fang[3], Hao Liu[3], Shuyong Zhao[2], Shihao Chen[1]

[1]QLSF Biotherapeutics, South San Francisco, CA,[2]QILU Pharmaceutical Co., Ltd., Jinan, China,[3]QILU Pharmaceutical Co., Ltd., Shanghai, China

Prostate cancer is a leading cause of cancer-related mortality in men, highlighting the resistance to current treatments and need for new therapeutic options. PSMA (Prostate-Specific Membrane Antigen) is overexpressed in prostate cancer tissues compared to normal prostatic tissue, rendering it an ideal target for prostate cancer therapies, enabling precise delivery of therapeutic agents to cancer cells. We evaluated PSMA expression in 77 Chinese prostate cancer patients using immunohistochemistry (IHC), confirming its high expression in Chinese malignant prostate tissues. Due to the lack of clinical activity from T cell targeted therapies in solid tumors, recent developments in the field have focused on providing a co-stimulatory signal via CD28 or more recently, CD2. Analysis of single-cell RNA sequencing data from 2,170 cells across 14 mCRPC patients revealed that CD2 expression on tumor-infiltrating lymphocytes (TILs), particularly $CD8^+$ T cells, exceeds that of CD28, underscoring the potential for CD2 targeting in enhancing antitumor immunity. We developed QL535, a novel trispecific antibody in a 2+1+1 format designed to bridge tumor cells via PSMA and activate T cells through CD3 (signal 1) and CD2 (signal 2) via its ligand CD58. This design aims to stabilize the immune synapse and enhance T-cell cytotoxicity. Additionally, this combination overcomes T-cell exhaustion, with fine-tuned CD3 affinity to improve safety and reduce the risk of cytokine release syndrome (CRS). Comparative analysis was conducted with three trispecific antibody formats targeting CD28, and three formats targeting CD2, resulting in a lead CD2 trispecific antibody, QL535, alongside a CD28 trispecific antibody as a control. QL535 demonstrated superior tumor-specific killing both *in vitro* and *in vivo* compared to bispecific CD2-deficient antibodies, and exhibited a favorable safety profile, characterized by low IL-6, TNFα, IFN-γ and IL-8 levels compared to the CD28 trispecific control, which achieved comparable cytotoxicity. Further evaluation using repeated stimulation assays of prostate cancer patient-derived PBMCs showed that QL535 outperformed the CD28 trispecific control, an analog of the clinical benchmark PSMA targeted T cell engager, and our bispecific antibody control in overcoming T-cell exhaustion. Whereas other agents showed diminished cytotoxicity, potentially due to T-cell exhaustion, QL535 maintained durable tumor-specific lysis. Favorable manufacturing (CMC) studies further support QL535's developability for clinical applications. In conclusion, QL535 is a novel trispecific T cell engager with improved anti-tumor efficacy and safety profile. These findings warrant further clinical investigation to evaluate its safety and efficacy in patients.

#3498 Generation of an NG2 targeting bispecific antibody for induction of T cell immunity against melanoma.

Nisha Prakash, Sebastian Horner, Ilona Hagelstein, Gundram Jung, Helmut R. Salih

Clinical Collaboration Unit Translational Immunology, German Cancer Consortium (DKTK), University Hospital Tubingen, Tubingen, Germany

Analysis of mRNA levels using The Cancer Genome Atlas (TCGA) identifies high expression of neuron-glial antigen 2 (NG2) in several tumor tissues, particularly in melanoma, where it is selectively overexpressed in 90% of cases. NG2, also known as Melanoma-associated Chondroitin Sulfate Proteoglycan (MCSP) was originally identified on the surface of cutaneous melanoma. Due to its tumor-restricted expression, NG2 is an attractive target for immunotherapeutic approaches. Strategies that aim at the direct and specific lysis of malignant cells are needed in melanoma treatment despite the advent of immune checkpoint inhibiting antibodies. The latter lack tumor-specific activity and the capacity to directly recruit T cells to the tumor site. As a consequence, a considerable proportion of patients do not respond to immune checkpoint inhibitors, or for a limited time only.
Here we report on the generation and characterization of two NG2 bispecific antibodies (bsAbs) with differing T cell binding properties. NG2xUCHT-1 contains a CD3 binder with high affinity, whereas NG2xM18 was generated using a modified UCHT-1 with approximately 100-fold lower CD3 affinity. The purity and integrity of the generated bsAbs were biochemically confirmed using SDS-PAGE and size exclusion chromatography. Dose titration of the two bsAbs on NG2 expressing cell lines documented dose-dependent binding with similar EC_{50} values of ~0.5nM. Functional analysis in-vitro revealed that both bsAbs potently induce T cell activation and proliferation, resulting in strictly target-dependent tumor cell lysis. Of note, despite the significantly reduced binding affinity to T cells, NG2xM18 mediated comparable antitumor efficacy as NG2xUCHT-1, but induced substantially lower secretion of cytokines like IL-2, IFN-γ, and TNF, pointing to an optimized ratio of efficacy and potentially dose limiting side effects caused by cytokine release syndrome (CRS).
Our findings indicate that NG2xM18 is a promising therapeutic compound that may allow for effective clinical dosing with reduced side effects.

#3499 Engineering and construction of anti-B7-H3 antibody-based T cell engagers (TCEs) and antibody-drug conjugates (ADCs) for cancer therapy.

Chuan Chen, Yue Wu, Liang Tian, Chenpeng Su, Xiaoou Xu, Xiaoqian Chen, Dandan Liu, Yang He, Jiyuan Tian, Jian Peng, Zhenping Zhu

Helixon US Inc., New York, NY

B7-H3 (CD276), an immunomodulatory protein of the B7 superfamily, is overexpressed in a wide range of solid tumors. Various antibody-based therapeutic modalities targeting B7-H3 have shown antitumor response in preclinical and clinical studies. Ifinatamab deruxtecan (I-DXd), a B7-H3-directed DXd antibody drug conjugate (ADC) has demonstrated promising efficacy in patients with pretreated ES-SCLC in phase II clinical study. Further, several bispecific T-cell engagers (TCE) targeting B7-H3 and CD3 have also entered early phase clinical trials. In this study, leveraging our streamlined AI-guided antibody engineering platform, we generated several biparatopic TCEs targeting B7-H3 and CD3 as well as a number of biparatopic anti-B7-H3 ADCs constructed with various linkers and cytotoxic payloads. Our biparatopic TCEs were designed to simultaneously target two distinct epitopes on B7-H3 and with monovalent binding to CD3 on T cells with moderate to low affinity, in an attempt to enhance T cell-mediated specific cytotoxicity while mitigating the risk of cytokine release syndrome (CRS). The lead biparatopic TCE molecule demonstrated a robust B7-H3-specific T cell-dependent cellular cytotoxicity towards multiple B7-H3-positive tumor cells with various B7-H3 expression levels. The biparatopic ADCs demonstrated high avidity-driven binding activity to B7-H3 positive cancer cells and were capable of mediating strong internalization activity with higher tumor cell killing efficiency compared to their counterpart ADCs targeting to a single binding epitope. Further in vitro assays and in vivo efficacy studies for the lead biparatopic TCE and ADC molecules in xenografted tumor animal models are being investigated. Taken together, our studies provide support for the further development of the biparatopic B7-H3-targeting ADCs and TCEs for the treatment of B7-H3-expressing solid cancers.

#3500 LBL-054-CD3: An anti-CDH17 and CD3 bispecific antibody for the treatment of CDH17-positive gastrointestinal cancer.

Xingxing Fang, Yurong Qin, Xiaoya Liu, Chengze Ni, Tingtng Li, Peng Zhang, Chao Chu, Mi Ye, Guojin Wu, Jianming Sun, Yue Zhao, Xiao Huang, Jordan Zhu, Shoupeng Lai, Xiaoqiang Kang, **Hong Ling**

Nanjing Leadsbiolabs Co., Ltd., Nanjing, China

Background: CDH17 is a member of the cadherin superfamily, a group of calcium-dependent cell adhesion molecules critical for organ development, tissue integrity, and cancer progression. In normal tissues, CDH17 is highly restricted to the lateral membrane and concealed within intestinal tight junctions, making it inaccessible and blocking immune cell infiltration. In contrast, it is overexpressed and redistributed in 50% to 90% of gastrointestinal cancers, leading to its exposure on the cancer cell surface, therefore becoming more accessible to target. This unique feature makes CDH17 a promising target for T cell engager based immunotherapy for GI cancer. Here, we have developed a novel bispecific antibody, LBL-054-CD3, targeting CDH17 and CD3 to selectively kill CDH17-positive tumor cells by engaging T cells.
Methods: LBL-054-CD3 was developed using our proprietary LeadsBody™ T-cell engager platform, comprising high-affinity arms targeting CDH17 and one finely tuned arm targeting CD3, engineered to balance efficacy and safety characteristics. The binding affinity of LBL-054-CD3 to CDH17 and CD3 was assessed using Fortebio, while its biological activity was evaluated through several cell-based assays, including reporter gene assay, TDCC to various levels of CDH17 expressing tumor cells, and T cell activation. The anti-tumor activity of LBL-054-CD3 antibody was evaluated in PBMC-humanized mice bearing GI tumor cell line xenograft models.
Results: LBL-054-CD3 was shown potent binding affinity for CDH17 with no cross-reactivity to other family proteins. In vitro cytotoxicity assays revealed that LBL-054-CD3 mediated tumor cell killing was dependent on CDH17 expression level, inducing moderate cytokine release and cell proliferation while exhibiting no cytotoxic effects on CDH17-negative cells. In a PBMC-humanized mouse CDX model, LBL-054-CD3 demonstrated significant antitumor activity.
Conclusions: The study demonstrates that LBL-054-CD3 has potent binding affinity to the membrane-proximal region of CDH17 and mediates T-cell cytotoxicity against various levels of CDH17 expressing tumor cells. Further, the bispecific antibody is shown excellent antitumor activity in both in vitro and in vivo experiments.

#3501 A novel CD2-targeted costimulatory bispecific antibody platform for enhancing CD3 T cell engager-based cancer immunotherapy.

Gerhard J. Niederfellner[1], Welbeck Danquah[2], Melanie Pichery[3], Thomas Eden[4], Aurelien Boyance[3], Lise Pasquet[3], Virginie Roure[1], Alice Marchand[3], Marion Mars[3], Ellen Gumz[4], Mylene Gador[3], Lou Valente[3], Marion Contini[3], Lukas Czernecki[4], Sanjit Shanmuganathan[4], Markus Dangl[1]

[1]Evotec International GmbH, Gottingen, Germany,[2]Evotec International GmbH, Hamburg, Germany,[3]Evotec France SAS, Toulouse, France,[4]Evotec SE, Hamburg, Germany

CD3-based T cell engagers (TCEs) are a clinically successful class of bispecific antibodies that has delivered 11 approved agents to date, albeit primarily for treatment of blood cancers. These agents provide a strong signal 1 for redirecting polyclonal T cells, regardless of their native specificity, to kill cancer cells. However, when only receiving signal 1 for prolonged periods of time without a costimulatory signal, T cells become anergic and exhausted. In part due to the lack of costimulatory signals in the tumor microenvironment, TCEs have had limited therapeutic success in solid tumor indications so far. Interestingly, single cell RNA sequencing data from multiple solid tumor types revealed that a high percentage of tumor infiltrating T cells express high levels of CD2 but not CD28 or other costimulatory receptors. Based on a proprietary antibody that binds a unique epitope on the costimulatory T cell receptor CD2, we have developed a novel bispecific antibody platform (BiTco) that provides costimulation to T cells via CD2 in the context of a tumor-associated antigen. Using primary human T cells as effectors *in vitro*, we found that CD2 and CD28 costimulation potentiated T cell activation and T cell-mediated tumor cell killing to a comparable extent. However, the CD2 BiTco format triggered less pronounced cytokine release making it a potentially safer clinical option. Moreover, we demonstrated that, unlike CD28, our CD2 BiTco format also provides robust costimulation to CD28-negative CD8 T cells that possess high cytotoxic capacity and constitute the majority of CD8 T cells found in elder patients. Further, by using a fixed sub-efficacious dose of CD3 TCE we simulated *in vitro* a clinical setting where reduced expression of tumor antigen can result in loss of CD3 TCE monotherapy efficacy. When adding increasing doses of CD2 BiTco in this setting we could fully restore optimal anti-tumor cytotoxicity and T cell activation. In addition, we knocked out CD58 on tumor target cells to mimic loss of expression of this primary ligand of CD2, which is another known mechanism of immune escape by tumors. We showed that BiTco treatment allows to recover and even enhance TCE-mediated T cell cytotoxicity in the absence of tumor-expressed CD58. Finally, we established a BT474 clone 5 xenograft model using immunodeficient mice, in which a human T cell compartment was reconstituted by injection of human PBMCs. In this in vivo model we showed that combination treatment of CD2 BiTco with a sub-efficacious dose of a CD3 TCE resulted in highly effective control of tumor growth by human T cells. In summary, combination therapy with our differentiated CD2 BiTco platform can improve CD3 TCE response and limit acquired resistance mediated by loss of tumor antigen and/or CD58.

#3502 Preclinical development of an mRNA-encoded T cell engager targeting Glypican-3 with tissue- and tumor-specific enrichment in hepatocellular carcinoma.

Yan Huang, Shaoli Liu, Xiaoju Zhang, Bingxu Zhang, Hongya Han, Andong Liu, Xiaoyun Ma, **Wei Xu**

METiS Pharmaceuticals, Hangzhou and Beijing, China

Background: T cell engagers (TCEs) have been clinically validated but are mostly limited to hematological cancers. Developing BiTEs for solid tumors faces hurdles such as T cell penetration into tissue, suppressive nature of the tumor microenvironment and systemic toxicity, etc. This study aims to tackle these challenges by delivering an mRNA-encoded TCE targeting the hepatocellular carcinoma antigen Glypican-3 (GPC3) directly to liver tissue, thus enhancing the local TCE concentration to promote anti-tumor activity and exhibiting a favorable pharmacokinetics (PK) profile.
Methods: The BiTE was engineered by fusing single-chain variable fragments (scFvs) targeting GPC3 and CD3, separated by a flexible peptide linker. The mRNA encoding the BiTE was engineered using a combinatorial approach to optimize codon usage and enhance translational efficiency and stability, balancing the Codon Adaptation Index (CAI) and Minimal Free Energy (MFE). The mRNA was encapsulated in a novel lipid nanoparticle (LNP) for efficient liver-tropic delivery, forming the complex named MTS105. BiTE's cell-killing activity was tested using human GPC3-expressing cell lines and human PBMC. Anti-tumor efficacy was evaluated in liver orthotopic tumor-bearing mouse models. GLP Tox studies including PK and biodistribution were assessed in rodents and cynomolgus monkeys.
Results: Mechanistic studies demonstrated that MTS105-translated TCE mediated specific killing of GPC3-positive cells, T cell activation and proliferation *in vitro* and *ex vivo*. In the two liver orthotopic tumor-bearing mouse models, MTS105 achieved complete tumor regression in a dose-dependent manner, accompanied with intra-tumoral T cell activation. In mice, rats and cynomolgus monkeys, MTS105-translated TCE consistently exhibited higher exposure levels in the liver than the plasma. The sustained release of MTS105-translated TCE resulted in higher functional protein exposure in liver/tumor, while showing lower peripheral TCE Cmax (maximum concentration) and AUC (area under the curve) than the Fc-domain containing antibody-based TCE. In the cynomolgus monkeys, MTS105 displayed favorable and linear plasma PK profiles including mRNA, lipid and translated TCE in the up to 100 μg/kg following a single and 4-time repeat dosing weekly. The time to peak (Tmax) was 6 to 12 h in both periphery and targeting tissues, which correlated with the observation of fast Intra-tumoral T cell activity in mice. All monkeys tolerated well to a dose up to 100 μg/kg, with no sever adverse effects and gross pathology observed.
Conclusion: The mRNA-encoded TCE demonstrated optimal tissue/tumor-specific PK, safety and potent anti-tumor activity in preclinical models. These preclinical studies enabled a first-in-human study to assess its safety and preliminary efficacy which is currently ongoing.

#3503 ZW171, a differentiated 2+1 T cell-engaging bispecific antibody with antitumor activity in a range of mesothelin-expressing cancers.

Nicole J. Afacan, Patricia Zwierzchowski, Wingkie Wong, Maya Poffenberger, Chayne Piscitelli, Thomas Spreter von Kreudenstein, Nina E. Weisser

Zymeworks Inc., Vancouver, BC, Canada

Mesothelin (MSLN) is a tumor associated antigen overexpressed in many cancer indications and is an attractive target for immunotherapies including bispecific T cell engagers (TCE) and chimeric antigen receptor T (CART) cells. While MSLN-targeting immunotherapies have shown signs of clinical activity, their success has been hindered by dose-limiting toxicities associated with on-target off-tumor effects and cytokine release syndrome (CRS). To overcome these issues, we engineered ZW171, a MSLN-targeting TCE, with enhanced safety and antitumor activity. ZW171 is a 2+1 IgG1-like antibody, built with Azymetric^{TM} and EFECT^{TM} technologies, consisting of two MSLN binding domains and one low affinity CD3ε binding domain. We previously showed that the unique geometry and 2+1 design of ZW171 facilitates tumor selective binding and potent preferential killing of MSLN-mid and -high target cells, while sparing MSLN-low expressing target cells, and enhanced antitumor activity compared to other 2+1 TCE formats and the clinical benchmark HPN536 in MSLN-expressing PBMC-engrafted CDX models. To address the evolving clinical landscape and assess antitumor activity in additional indications and more translationally relevant models, we assessed ZW171 activity in advanced patient-derived organoid and xenograft models and benchmarked to other MSLN-targeting TCE including AMG 305, JNJ-79032421 and CT95. Additionally, activity in expanded MSLN-positive indications including pancreatic, endometrial, and gastric cancer, and the in the presence of soluble MSLN (sMSLN), which is observed in the serum of patients and can impede MSLN-targeted antibody-based therapies, was assessed in vitro. *Ex vivo*, ZW171 mediated potent tumor cell killing and T cell activation in patient-derived ovarian cancer organoid models. ZW171 induced complete tumor regressions in established patient-derived *in vivo* MSLN-positive non-small cell lung cancer and pancreatic cancer models. Comparison of ZW171 to AMG 305, JNJ-79032421 and CT95 showed reduced binding to T cells and equivalent or greater antitumor activity against MSLN-overexpressing cells. *In vitro*, ZW171 demonstrated potent MSLN-dependent killing in MSLN-positive indications including pancreatic, endometrial, and gastric cancer, and maintained activity in the presence of clinically relevant sMSLN concentrations observed in patient serum. Overall, ZW171 demonstrates differentiated and potent antitumor activity in a range of MSLN-expressing cancers. ZW171 is being evaluated in a Phase 1 clinical trial in MSLN-expressing solid tumors (NCT06523803).

#3504 Evaluation of T cell-engaging bispecific antibody using perfusable three-dimensional model.

R. Tsumura[1], R. Singh[2], N. Mori[3], Y. Kida[3], R. Asano[4], H. Takashima[1], H. Fuchigami[1], N. Sakamoto[1], M. Yasunaga[1], Y. Koga[1]; [1]National Cancer Center, Kashiwa, Japan, [2]University of Tsukuba, Tsukuba, Japan, [3]National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan, [4]Tokyo University of Agriculture and Technology, Tokyo, Japan

Introduction The development of T cell-engaging bispecific antibody (T-BsAb) has been an attractive field in cancer research due to its clinical success, especially in the treatment of hematologic cancer. In recent years, several T-BsAbs have been investigated for treating solid cancers. To improve T-BsAbs in treating solid cancers, it would be important to develop a robust *in vitro* evaluation system that mimics *in vivo* tumors. A conventional two-dimensional (2D) model is often used to evaluate *in vitro* efficacy of T-BsAb. However, T cells can directly contact cancer cells without any obstacles in this assay, resulting in a limited correlation with their *in vivo* efficacy. Although a three-dimensional (3D) model using the extracellular matrix such as matrigel can also be applied for drug evaluation, the lack of a perfusable vascular network may be a limitation for evaluating some therapeutic modalities, including T-BsAb. Here, we established the novel perfusable 3D *in vitro* model and compared the efficacy of T-BsAb in several *in vitro* and *in vivo* models, in order to determine which *in vitro* model best mimics *in vivo* in the evaluation of T-BsAb.

Material and Method We used three colorectal cancer cell lines, DiFi (EGFR+++), HT29 (EGFR++) and SW620 (EGFR-), and T-BsAb (named hEx3) targeting EGFR and CD3. As the conventional models, 2D and 3D *in vitro* models were adopted to evaluate the efficacy of hEx3. In the 3D model, T cells were applied on the matrigel with cancer cells. The perfusable 3D tissue is formed from a collagen gel composed of cancer cells and human umbilical vein endothelial cells (HUVECs). The tissue has a main blood vessel in the center through which the culture medium flows. The HUVECs in the gel have the self-organizing activity of a capillary-like structure from the main vascular vessel. To investigate *in vivo* efficacy, the cell line-derived xenograft (CDX) models were used.

Results In the conventional 2D model, hEx3 exerted high cytotoxicity against DiFi and HT29 cells but not SW620 cells. On the other hand, in the conventional 3D model, the cytotoxicity of hEx3 was limited even for EGFR-positive cells. In addition, hEx3 treatment showed anti-tumor effects in only DiFi CDX model but not in HT29 and SW620 CDX models. These results suggested that the efficacy of T-BsAb in the CDX model is not reflected by the conventional 2D and 3D *in vitro* models. We attempted to perform T cell perfusion in the perfusable 3D *in vitro* model. T cells were distributed near the capillary-like blood vessels, indicating that T cells infiltrated into the tissue through the blood flow. We are currently using this model to evaluate the efficacy of hEx3 *in vitro.*

Conclusion The conventional *in vitro* models would not be suitable to evaluate the efficacy of T-BsAb because their results were inconsistent with those in CDX models. Therefore, it would be necessary to develop an *in vitro* evaluation system that mimics *in vivo* blood vessel structures.

#3505 AM105, first-in-class T cell engaging bispecific antibody for metastatic colon cancer, demonstrates strong anti-tumor activity by both neutralizing EGFR activity and engaging T cells.

Hyun-Jong Lee, Dong-Wook Kim, Seong-Yeol Kim, Min Yoon, Young-ha Lee, In-Sik Hwang, Yoon Lee, Jong-Hoon Kim, Jong-Seo Lee

AbClon, Inc., Seoul, Korea, Republic of

Globally, colorectal cancer is a significant health concern. In 2020, there were over 1.9 million new cases and more than 930,000 deaths attributed to this disease and 5 year survival rate for distant colorectal cancer is 14.7 percent. Cetuximab, an approved anti-EGFR antibody, is effective in treating metastatic colorectal cancer with wild-type KRAS, improving survival. However, about 80% of patients develop resistance, leading to disease recurrence. To address this high recurrence rate, ongoing research focuses on developing bispecific antibodies that can overcome this resistance, aiming to improve long-term outcomes in metastatic colorectal cancer patients.AM105, a novel T cell-engaging bispecific antibody comprising a newly developed monoclonal antibody (15E3) and an affibody targeting EGFR and 4-1BB respectively. Characterized by its 2+4 architecture, it enhances selective binding to cancer cells by creating a difference in affinity between TAA and 4-1BB. It includes four Affibodies targeting 4-1BB, thereby increasing the likelihood of binding with T cells. Additionally, by enhancing the “clustering of CD137” on T cells, the T cell response is significantly amplified. In addition, AM105 was found to efficiently induce tumor cell death in CRC cell lines, even at very low effector-to-target cell ratio, in a target expression dependent manner. In vivo experiment using humanized 4-1BB mice have demonstrated excellent tumor cell elimination effects, and this therapeutic effect was still observed after newly introduction of tumor cells even in the absence of AM105 in the blood, suggesting the induction of T-cell memory function. Taken together, these results strongly suggested that AM105, a novel 4-1BB based bispecific antibody, exhibits potent anti-tumor T cell activity and could be promising therapeutic agent.

#3506 Clinic enabling development of a TCR-Ab half life extended T cell engager against a novel solid tumor target.

Sarah Leonard[1], Hemza Ghadbane[1], Dominic Hine[1], Samantha Drennan[1], Peter Cain[1], Louise Holland[1], Eleanor Bagg[1], Jana Rundle[1], Helena Horvatic[1], Christos Gavriel[1], Sophie Wells[1], Samhita Rao[1], Mathew Veal[1], Michela Marongiu[1], Juan Bolivar[1], Xiaoyan Pan[1], Maria Busz[1], David Cook[1], Wilawan Bunjobpol[1], Alexander Stephens[1], Sophie Johnson[1], Oleksandr Dudchenko[1], Jong Fu Wong[1], Sophie Richard[1], Samuel Ward[1], Simon Wright[1], On Kan[1], Amalia Martinez[1], Dzmitry Batrakou[1], Mitchell P. [1]T-Cypher Bio, Oxford, United Kingdom,[2]Department of Dermatology, University of Zurich, Zurich, Switzerland,[3]University of Oxford, MRC Translational Immune Discovery Unit, Oxford, United Kingdom

Introduction: T cell engagers (TCEs) are a promising class of targeted therapies with recent clinical successes in solid tumors. A unique advantage of HLA-presented targets is that they can be derived from any part of the human genome providing an opportunity to build next generation TCEs against novel targets. We here present our discovery and development of a half-life extended TCE against a novel tumor-target towards clinical candidate selection. Our proprietary TCE drug format is based on a solubilized TCR, engineered as an Fc-based bispecific, showing high potency and safety in pre-clinical evaluation.
Experimental Procedures: We have performed T cell repertoire analysis on billions of T cells to identify the most potent TCRs from CD8 T cells against 100s of targets. This has resulted in isolation of specific TCRs against multiple novel targets. We have then taken the most potent TCRs (low micromolar affinity) through affinity engineering using a proprietary approach that combines machine learning-guided mutagenesis with high-throughput functional screening. A library of proprietary TCE formats with engineered TCRs and an anti-CD3 engager arm were optimized for yield, stability and function. The novel target in focus was selected based on high copy number on cancer tissue determined using epitope staining approaches. Finally, lead TCEs were assessed for efficacy, safety, longevity & biodistribution in ex vivo primary human cell assays and humanized xenograft models.
Results: We have developed a half-life extended TCE in a unique format with specific picomolar binding affinity against a novel tumor target. Our machine learning guided affinity engineering process progressed a set of uM wild-type TCR molecules to pM affinity, enhancing TCR:target binding >100,000 fold. High yielding TCRs were formatted into TCR-Ab TCE engagers and tested on primary tumor cells taken from patients. The TCEs showed activation of primary T cells and subsequent killing of these novel target positive cancer patient cells. We observed no T cell activation or killing of primary normal cell panels. Selected TCEs tested in humanized mouse models showed long circulating properties and efficacy. We have identified a novel TCE lead candidate which is potent, specific and safe in ex vivo human samples with a large therapeutic window.
Conclusions: We have developed a half-life extended T cell engager against a novel solid tumor target utilizing machine learning-guided TCR engineering that allows for the formation of an Fc-based anti-CD3 TCE. Currently, we are finalizing the preclinical evaluation and will enter IND enabling development mid 2025.

#3507 Discovery and preclinical characterization of novel TCR-mimetic T-cell engagers targeting TERT peptide-HLA complex for the treatment of solid and hematologic malignancies.

Yu Huang, Bhupal Ban, Jessica Jimenez, Preethi Sankaran, Christine A. Devlin, Melissa Bikowitz, Qunyan Yu, Ricard Masia, Delainey O'Connor, Emily McNally, Sarah Jaffe, Tanzila Rahman, Jennifer Helble, Alona Kulesha, Andrew Wolpert, Brendan Whalen, Shawn O'Malley, Yue Li, Michael Jennings, Galina Gabriely, Amanda Mak, Tao Wang, Benjamin Lee, Michi Schebesta, Michael Princiotta, Geraldine L. C. Paulus, Dmitri Wiederschain

Crossbow Therapeutics, Inc., Cambridge, MA

TERT (telomerase reverse transcriptase) is highly expressed in 85-95% of all tumors, making it a compelling target for cancer therapy. Although several TERT-targeting approaches are being investigated in clinical trials, only one therapeutic (RYTELO®, imetelstat) has received FDA approval for the treatment of low-risk myelodysplastic syndrome. Targeting HLA-restricted peptides (pHLA) derived from intracellular cancer antigens allows for broader exploration of the cancer proteome. The HLA-A*02:01-restricted $TERT_{540}$ peptide is presented by human tumors and can be a target for T cell-mediated tumor lysis. TCR mimicking (TCRm) antibodies recognize pHLA complexes and are capable of re-directing T cells once incorporated into a T Cell Engager (TCE) format. Here we report the preclinical characterization of potent and specific TCRm-based TCEs targeting $TERT_{540}$ pHLA. $TERT_{540}$-targeted TCEs consist of a single humanized CD3 binding domain and either one or two fully human TCRm domains, thus recognizing $TERT_{540}$/HLA-A*02:01 in either monovalent or bivalent forms. Monomeric affinity for $TERT_{540}$ pHLA was found to be in sub-nM range, and target binding was greatly enhanced through avidity effects in the presence of two TCRm binding domains. Alanine/glycine scan identified multiple amino acid residues in the $TERT_{540}$ peptide sequence that are required for TCE binding. Extensive specificity profiling revealed no meaningful activity of $TERT_{540}$ TCEs against cells pulsed with supra-physiological levels of computationally predicted HLA-A*02:01 cross-reactive peptides or multiple unrelated HLAs (alloreactivity). Furthermore, both $TERT_{540}$ TCEs showed no interactions with a large panel of normal primary cells from multiple vital tissues and organs *in vitro*. A modest IFNγ response was noted against bone marrow (BM) CD34+ hematopoietic stem cells at high concentrations of $TERT_{540}$ TCEs. In contrast, both compounds induced potent, target-dependent T cell activation and T cell-mediated killing of multiple TERT- and HLA-A*02:01- positive leukemia, lung, and ovarian cancer cell lines, achieving sub-nM EC50 values *in vitro*. Consistent with the specificity profile of $TERT_{540}$ TCEs, no activity was observed against TERT-negative or HLA-A*02:01-negative cells. *In vivo* efficacy studies with $TERT_{540}$-targeted TCEs are currently in progress. Comprehensive analytical and biophysical assessments revealed favorable developability profiles for both TCEs. In summary, these data provide strong preclinical evidence of potency, specificity, safety, and developability of novel, TCRm-based TCEs for TERT-targeted cancer therapy.

#3509 ATG-110, a novel “2+1” LY6G6D-targeted T-cell engager (TCE) for the treatment of MSS colorectal cancer.

Gang Bian[1], Jiahui Hua[1], Ge Lin[1], Xueli Chen[1], Huiling Liu[2], Peng Chen[1], Jay Mei[3], **Bing Hou**[3]

[1]Shanghai Antengene Corporation Limited, Shanghai, China,[2]Antengene (Hangzhou) Biologics, Hangzhou, China,[3]Antengene Corporation, Shaoxing, China

Background: Colorectal cancer (CRC) is one of the most common cancers worldwide and requires more effective and safer therapies to improve its poor survival outcome. LY6G6D is a GPI-anchored cell surface protein with expression that is particularly specific to colorectal cancer (CRC). LY6G6D exhibits significantly elevated expression levels in colorectal cancer (CRC) tissue comparing to normal tissue, particularly in pMMR/MSS CRC, which demonstrates primary resistance to immune checkpoint inhibitor (ICI) therapy. T cell engagers have shown encouraging efficacy in treating hematological malignancies, while exhibiting suboptimal performance in solid tumors. The potential of cytokine release syndrome (CRS) remains significant issues. We present a novel 2+1 LY6G6DxCD3 T cell engager, ATG-110, which demonstrated LY6G6D-dependent CD3 binding and significant anti-tumor activity with reduced cytokine release.

Methods: ATG-110 was constructed by introducing a novel conformational epitope-targeted anti-CD3 single chain fragment variable (scFv) to the hinge region of one of the heavy chains of a LY6G6D monoclonal antibody. It was evaluated in a series of preclinical *in vitro* studies for binding affinity, T cell activation and cytokine release, T cell dependent cytotoxicity (TDCC), and drug developability. The *in vivo* anti-tumor efficacy was evaluated in PBMC-humanized immunodeficient NDG mice engrafted with LY6G6D^{medium}-expression HT55 or LY6G6D$^{very\ low}$-expression SW480 MSS CRC cells.

Results: ATG-110 bound to LY6G6D-positive cell lines, LY6G6D-overexpression 293T, HT55, LS1034, with the nanomolar grade EC50. The CD3 binding site of ATG-110 is concealed by the LY6G6D Fab arm before binding to LY6G6D, due to the steric hindrance. Therefore, ATG-110 demonstrated limited binding capability to CD3+ cells before LY6G6D crosslinking. It activated T cells and induces cytokine release only in the presence of LY6G6D+ cells. *In vitro*, ATG-110 resulted in potent T cell dependent cytotoxicity with single-digit pM IC50 values on HT55 and SW480 cells. ATG-110 also showed potent anti-tumor activity in PBMC-humanized SW480 xenograft model and exhibited complete response (CR) in PBMC-humanized HT55 xenograft model. ATG-110 demonstrated good drug developability.

Conclusion: ATG-110 demonstrated LY6G6D-dependent CD3 binding and activation with low risk of CRS. It showed powerful *in vitro* and *in vivo* anti-tumor efficacy against colorectal cancer, which warrants further clinical evaluation.

#3510 A 2+1 format MUC16 targeting T cell engager induces MUC16-dependent T cell activity and superior anti-tumor efficacy.

Jinyang Li, Yang Li, Nan Gao, Yi Wang, Mengqiang Di, Min Wu, Yiyi Li, Ran Xue, Shiyu Hao, Weiwei Wu, **Xiguang Zhang**, Li Li, Shuaixiang Zhou, Huizhong Xiong

Innovent Biologics (Suzhou) Co. Ltd, Jiangsu, China

T cell engager (TCE) therapies targeting specific tumor associated antigens (TAAs) have shown clinical efficacy in multiple types of solid tumors. Indeed, TCE has been approved to treat melanoma and small cell lung cancer. Nevertheless, it remains necessary and challenging to improve the efficacy and safety profile of TCE to deliver benefits to more cancer patients. Recurrent and chemotherapy resistant ovarian cancer remains an urgent global unmet medical need. These is limited therapeutic options for this highly lethal and refractory disease. Recently, a MUC16 TCE demonstrated promising and durable clinical efficacy against heavily pretreated MUC16-high ovarian cancer, with acceptable safety profile. This underlines the potential to develop a MUC16 TCE with favorable safety profile and enhanced anti-tumor efficacy to possibly expand the benefits to MUC16-medium and MUC16-low ovarian cancer patients. MUC16 is a glycoprotein overexpressed in several types of solid tumors, especially in the majority of ovarian cancer. Here, we developed a 2+1 format MUC16 TCE, with improved tumor cell binding affinity, enhanced tumor cell killing potency, and MUC16-dependent T cell binding and activation. This MUC16 TCE targets membrane-proximal domains of MUC16 and achieves avidity-driven tumor cell binding in the presence of soluble CA125. Moreover, this MUC16 TCE elicited limited T cell binding and activation in the absence of MUC16, compared to benchmark molecule, to minimize off-target activity. This 2+1 format MUC16 TCE also showed favorable pharmacokinetics profile in mice. Functionally, systemic administration of this MUC16 TCE showed superior anti-tumor efficacy, with undetectable toxicity, in xenograft tumor models. Importantly, this MUC16 TCE demonstrated potent and synergistic anti-tumor efficacy in combination with clinically validated therapeutic strategies for ovarian cancer in pre-clinical tumor models. This provides rationale to develop combination therapies in future clinical trials. Indeed, combination of TCE with other therapies, e.g. ADC, chemotherapy, PD1/PDL1 mAb, are being tested clinically. Together, our pre-clinical data demonstrated that a 2+1 MUC16 TCE elicits potent anti-tumor efficacy and minimized off-target T cell activation, with potential to deliver benefits to ovarian cancer patients and patient with other MUC16-positive cancer.

#3511 A T cell engager (TCE), HB134, targeting LILRB4 and CD3, exhibits potent anti-tumor activity with a favorable safety profile for monocytic AML.

Juan Liu, Fangfang Ren, Chunmei Liu, Jing Shao, Fang Yang, Jianhe Chen, **Bin Ye**, Jianhua Sui

Huahui Health, Ltd., Beijing, China

Background: Acute myeloid leukemia (AML), is a heterogeneous and highly aggressive malignancy, characterized by poor prognosis and limited treatment options. Monocytic AML, including M4 and M5 subtypes, presents a significant clinical challenge due to its dismal prognosis and high relapse rates post-transplant. The leukocyte immunoglobulin-like receptor B4 (LILRB4) is overexpressed in monocytic AML but is absent in normal hematopoietic stem cells, highlighting its potential as a therapeutic target. Here, we report the development of a novel TCE targeting LILRB4 and CD3, HB134, for the treatment of monocytic AML.
Methods: The HB134 TCE was generated by fusing an anti-LILRB4 nanobody and an anti-CD3 Fab to a human IgG1 with a silent Fc region. Surface plasmon resonance, enzyme-linked immunosorbent assay, and flow cytometry were used to measure HB134's binding activities to LILRB4 and CD3. Luciferase-based cellular reporter assays and a primary T cell-dependent cellular cytotoxicity (TDCC) assay using peripheral blood mononuclear cells (PBMCs) were employed to assess HB134's T cell activation activity. Additionally, *in vivo* anti-tumor efficacy and pharmacokinetic (PK) profile were evaluated in mouse models.
Results: HB134 exhibited sub nanomolar high binding affinity for human LILRB4 and low binding affinity to human CD3. In the cellular luciferase reporter assays, in the presence of LILRB4-positive monocytic AML cells (THP-1 or MOLM-13 cell line), HB134 induced robust T cell activation; in contrast, no T cell activation was observed in the presence of LILRB4-negative cells, indicting HB134 can specifically induce T cell activation in a LILRB4-engagement-dependent manner. In the TDCC assays using PBMCs, HB134 induced potent cytotoxicity against LILRB4-positive THP-1 and MOLM-13 cells with limited induction of cytokine release syndrome-related proinflammatory cytokines, including IL-6 and TNF-α. In an immunodeficient mouse model engrafted with human PBMCs and LILRB4-positive THP-1-luciferase cells, HB134 showed potent anti-tumor efficacy. Additionally, HB134 demonstrated a favorable PK profile in BALB/c mice.
Conclusions: HB134, a TCE designed to engage T cells via CD3 and specifically target LILRB4, exhibits potent anti-tumor activity and favorable PK and safety profiles, positioning HB134 as a promising therapeutic candidate for treating LILRB4-positive monocytic AML.

#3512 Development of a novel T cell engager for solid tumors presenting KRAS G12V mutant peptide in HLA-A*11:01.

Lauren Pitt, Rasika Premaratne, Rebecca Wood, Ruban Kannan, Shereen Jabar, Dylan James, Brendan Eames, Kal Gunarathne, Nicole Church, Zac Rosenes, Fiona Gracey, Idris Bello, Eleanor Leung, Brad McColl, Ben Kiefel, Matt Beasley

Myrio Therapeutics Pty Ltd, Blackburn North, Australia

Background: KRAS neoantigens present on the surface of tumors as peptide-HLA complexes are promising targets for immunotherapy. Here, we describe preclinical development of a half-life extended T cell engager, MA022-2037, designed to redirect T cells to kill solid tumors driven by KRAS G12V mutation in HLA-A*11:01-positive patients.
Methods: The antibody discovery platform, Retained Display (ReD), was used to isolate fully human single chain variable fragments (scFv) selectively recognizing a 10-mer peptide derived from KRAS G12V in the context of HLA-A*11:01, while avoiding the corresponding wildtype KRAS peptide differing by a single amino acid. Target selectivity was assessed in bead-based binding assays involving arrays of irrelevant peptide-HLA-A*11:01 complexes and HLA-A*11:01-restricted peptides with sequence homology to the target peptide. Scanning mutagenesis was used to map specific binding motifs for prediction of cross-reactive peptides. Following conversion to T cell engager format, activity was assessed in co-cultures of *in vitro* expanded T cells isolated from donor PBMC with HLA-A*11:01-positive tumor cell lines with or without KRAS G12V mutation. The pharmacokinetics of half-life extended MA022-2037 was assessed in animals prior to evaluation of efficacy in tumor-bearing mice engrafted with donor PBMC.
Results: MA022-2037 binding was restricted to KRAS G12V/HLA-A*11:01, with no binding observed to any other HLA-A*11:01-restricted peptide examined, including those with similarity to the target peptide. No cross-reactive peptides from the known human proteome were predicted to bind MA022-2037 based on analysis of its specific binding motif. MA022-2037 mediated robust killing of HLA-A*11:01-positive, KRAS G12V mutant tumor models in the presence of donor T cells *in vitro*, while KRAS wildtype or KRAS mutation-mismatched tumors were spared. As a half-life extended T cell engager, MA022-2037 displayed a favorable pharmacokinetic profile with a half-life of ~20 days, enabling *in vivo* evaluation of efficacy.
Conclusions: Our preclinical data support continued development of MA022-2037 for HLA-A*11:01-positive patients with KRAS G12V mutant tumors and IND-enabling studies are in progress. We anticipate delivery of a new precision immunotherapy for patients whose high unmet need is not currently addressed by molecularly targeted inhibitors.

#3513 CC312, a trispecific CD19-targeting co-stimulatory T cell engager, for the treatment of B cell malignancies and autoimmune diseases.

Yingfeng Huang, Ruixia Zhang, Xiaofang Zhang, Zhen Jing, Caizhi Zhao, Fangfang Pan, Beibei Zheng, Ruixue Dai, **Li Zeng**

CytoCares (Shanghai) Inc., Shanghai, China

Background: B cell depletion therapy (BCDT), such as monoclonal antibodies, bispecific T cell engagers(TCE) and CAR-T,has an extensive history of effectively treating B cell malignancies. Certain BCDT monoclonal antibodies,e.g. rituximab,are also approved to treat autoimmune diseases(ADs), however demonstrate poor B cells depletion in deep tissue which may limit the long-term disease control or remission in patients. Recently, anti-CD19 CAR-T, through thorough depletion and “resetting” of B cell populations, have achieved multi-year drug-free remission in systemic lupus erythematosus (SLE),idiopathic inflammatory myopathy(IIM)and systemic sclerosis(SSc). Here, we developed a trispecific TCE CC312, targeting CD3 and CD28 on T cells and CD19 on B cells. Consistent with CAR-T, CC312 showed potent T cell activation and B cell depletion in a prior study in B cell malignancies. In the current study, the potential of CC312 in treating ADs was explored in translational models and in the clinical setting.

Methods: B cell killing of CC312 was assessed in *ex vivo* cytotoxicity assays using PBMC isolated from AD patients. T cell activation, proliferation and differentiation were also evaluated with patient PBMC. The *in vivo* efficacy for SLE was investigated in mice engrafted with SLE patient PBMC. In addition, clinical safety, tolerability, and efficacy of CC312 in refractory SLE, IIM, SSc, and other B cell-related ADs was evaluated in an ongoing investigator-initiated clinical trial.

Results: *In vitro*,CC312 induced a concentration-dependent potent depletion of B cells in PBMCs derived from donors with ADs, with EC_{50} in pM range across donors and disease types. Compared with anti-CD3/CD19 bispecific benchmark, CC312 significantly enhanced T cell activation, proliferation, and memory T cell differentiation due to CD28 co-stimulation. *In vivo*, CC312 thoroughly depleted peripheral B and plasmablast cells,as well as eliminated IgG and anti-dsDNA in serum. At the end of this study, neither IgG deposits nor CD20+B cell infiltrates were observed within kidney tissues. In the ongoing clinical study of ADs, CC312 is well-tolerated, with no Grade 3+ CRS or ICANS. Even at the lowest dose level(5 μg/dose), peripheral B cells and B cell subgroups can be comprehensively depleted, accompanied with improvement or remission of disease.

Conclusion: CC312’s capacity to potently and thoroughly eliminate B cells has been demonstrated in *in vitro* and *in vivo studies* as well as in the clinical setting, indicating the potential benefit in treating B cell-related ADs. As the first CD28 co-stimulatory TCE to be explored in ADs, additional clinical studies will be conducted to further evaluate the efficacy and safety in autoimmune patients.

#3514 AZD6621: Improving the therapeutic index for prostate cancer T cell engagers with a next-generation CD8-guided format.

Suzanne Sitnikova[1], Natalie Burrows[1], Nikolaos Ioannou[1], Even Walseng[2], Chunning Yang[2], Nadia Luheshi[1], Yariv Mazor[2], Mark Cobbold[2], Saso Cemerski[2], Simon Dovedi[1]

[1]AstraZeneca, Cambridge, United Kingdom,[2]AstraZeneca, Gaithersburg, MD

Prostate cancer is the second most common malignancy in males with a 5-year survival rate for metastatic castration-resistant prostate cancer of only 37%. Six-transmembrane epithelial antigen of the prostate 2 (STEAP2) is a metalloreductase with plasma membrane expression that is restricted to the prostate but is highly overexpressed across all stages of prostate adenocarcinoma. This expression profile makes STEAP2 an ideal target for a T cell engager (TCE). Despite promising efficacy, the toxicity profile of current TCEs remains challenging with patients often experiencing cytokine release syndrome and on-target, off-tumor adverse effects. This dose-limiting toxicity profile restricts their therapeutic window and with it the potential for combination therapy. We sought to improve this therapeutic index in 3 ways: 1) targeting the tumor-restricted STEAP2 antigen, 2) affinity-optimizing the CD3 binding domain and 3) integrating a CD8 binding domain to preferentially engage $CD8^+$ T cells over $CD4^+$ T cells, as the latter have been shown to contribute to the risk of cytokine release syndrome. Here we provide preclinical *in vitro* and *in vivo* evidence demonstrating that this design can potentially increase the therapeutic index when compared to a conventional TCE. We demonstrate that AZD6621 mediates potent, STEAP2-dependent cytotoxicity *in vitro* with cytotoxicity EC50 values below 10 pM. AZD6621 also induces preferential activation of $CD8^+$ T cells over $CD4^+$ T cells, with an approximately 5-fold increase in maximal activation of $CD8^+$ T cells, as well as significantly reduced cytokine release compared to a conventional TCE. AZD6621 mediates complete anti-tumor regressions as a monotherapy in the STEAP2-expressing 22Rv1 subcutaneous xenograft model in humanized mice. Anti-tumor activity of AZD6621 *in vivo* was also observed in a C4-2 intratibial xenograft model. Furthermore, when matched for anti-tumor activity in an intravenous 22Rv1 xenograft model, systemic cytokine levels were significantly reduced in AZD6621-treated mice compared to a conventional TCE. These data provide reason to believe that AZD6621 can improve the therapeutic index of conventional TCEs via CD8-guided, affinity-optimized CD3 engagement of STEAP2 on prostate cancer cells and support a first-in-human clinical trial planned to start in 2025.

#3516 TriNKETs®: trispecific immune cell engager therapies exhibit potent preclinical in vivo anti-tumor activity and broad combinability in diverse cancer models.

Colin LaCroix, Adam Stockmann, **Mitchell Bigelow**, Cornelis van der Poel, Jolanta Dubauskaite, Jeremy Beech, Samia Khan, Eva Gutierrez, Nathan Felix, Stuart W. Hicks, Nicolai Wagtmann, Ann F. Cheung

Dragonfly Therapeutics, Inc., Waltham, MA

The trispecific immune cell engager TriNKET® platform is designed to direct the activity of cytotoxic immune cells against cancer cells through simultaneous engagement of a tumor-associated antigen and the activating receptors CD16a and NKG2D (natural killer group 2 member D), a receptor expressed on natural killer (NK) cells, γδ T cells, and CD8+ T cells. To evaluate the preclinical efficacy of the TriNKET platform, a TriNKET targeting the murine Tyrosinase-related protein 1 (TYRP1), a melanocyte protein expressed on melanomas and normal melanocytes, was developed and evaluated using TYRP1-expressing immunocompetent syngeneic models. The TYRP1-TriNKET model system bridges the gap between in vitro studies and potential clinical activity, providing a robust system to validate the immune-based activities of TriNKETs, and their ability to be combined with standard-of-care therapies, such as checkpoint blockade or chemotherapy.

The anti-tumor activity of the TYRP1-targeting TriNKET was evaluated in the B16F10 melanoma model, which endogenously expresses TYRP1, as well as in MC38 and CT26 colon tumor models that were engineered to express TYPR1. Immunological changes within the tumor microenvironment were characterized using flow cytometry. In addition, the potential for enhanced activity was explored by testing the TYRP1-TriNKET in combination with anti-PD1, Abraxane, and various chemotherapy regimens.

The TYRP1-TriNKET demonstrated strong binding to TYRP1+ cell lines and robustly activated NK cells in vitro when co-cultured with tumor cells. TYRP1-TriNKET monotherapy showed superior in vivo anti-tumor efficacy compared to a TYRP1-targeting monoclonal antibody in all tumor models tested. TYRP1-TriNKET increased infiltration of NK cells and CD8+ T cells, promoted immune cell activation, and increased levels of pro-inflammatory cytokines and chemokine within the tumor microenvironment without inducing peripheral immune activation or cytokine release. Depletion of immune cells prior to treatment confirmed that the observed anti-tumor responses are mediated through both NK cells and CD8+ T cells. Furthermore, TriNKET efficacy was enhanced when combined with standard-of-care therapies, including anti-PD-1, Abraxane, cyclophosphamide, gemcitabine, and 5-FU, with no evidence of antagonism in combination treatments.

TriNKETs display potent preclinical in vivo anti-tumor responses driven by NK cell and CD8+ T cell effector functions. These findings highlight the potential of TriNKETs as promising immunotherapeutic agents, demonstrating their potential both as standalone treatments and as components of combination strategies with standard-of-care therapies.

#3517 A bispecific pan-γδT cell engager with IL-15 fusion that activates both δ1 and δ2 types of γδT cells for the treatment of acute myeloid leukemia.

Mingcan Yu[1], Peng Chen[2], Ying Jin[2], Fulai Zhou[2], Honglei Bi[2], Mark Chiu[1], **Di Zhang**[1]

[1]Tavotek Biotherapeutics, Lower Gwynedd, PA,[2]Tavotek Biotherapeutics, Suzhou, China

Background: Bispecific T cell engagers redirecting pan $CD3^+$ T cells for tumor immunotherapy have demonstrated clinical promise in treating mainly hematologic cancers but are often accompanied with severe toxicity due to cytokine storms. An alternative approach involves engaging innate-like γδ T cells instead which possess inherent antitumor activity but are less prone to toxicity. Unfortunately, most γδ T cell-based therapeutics reported so far exhibit suboptimal clinical efficacy due to subtype-specific engagement, limited quantity, and poor durability of γδ T cells in cancer therapy.

Methods and Results: We characterized a pan γδ T cell receptor antibody capable of binding and activating γδ T cell receptors from both δ1 γδ T cells (mainly resident in mucosal tissues and tumors) and δ2 γδ T cells (predominantly found in blood circulation). When paired with an antibody targeting the acute myeloid leukemia (AML) associated target CD123, this bispecific pan γδ T cell engager, TAVO317A, mediated tumor cell dependent activation and degranulation of both δ1 and δ2 γδ T cells and redirected them to potently kill antigen-specific hematologic cancer cells. To enhance the durability of bispecific pan γδ T cell engagers in tumor therapy, we engineered an attenuated IL-15 along with the IL-15 receptor α sushi domain as a fusion component on the CD123 bispecific pan γδ T cell engager. The addition of the IL-15 domain further boosted the ability of the engager to promote the activation and proliferation of γδ T cells. In humanized AML cell xenograft models, the CD123 bispecific pan γδ T cell engager effectively recruited γδ T cells to control AML tumor growth. Moreover, the CD123 engager with IL-15 fusion exhibited even better efficacies in tumor cell elimination and sustained γδ T cell activity without requiring IL-2 supplementation.

Conclusions: By recruiting both δ1 and δ2 γδ T cells, our bispecific pan γδ T cell engager can mobilize more γδ T cells that may otherwise be of limited quantity for tumor therapy. In addition, the engineered IL-15 domain for immune modulation can facilitate enhanced durability of γδ T cells in tumor cytotoxicity. Our novel proprietary bispecific pan γδ T cell engager platform has the potential to serve as a potent and efficacious alternative to CD3-based therapy by offering enhanced liquid and solid tumor immunotherapy with a better safety profile.

#3519 EVOLVE104, a differentiated T cell engager targeting the novel antigen ULBP2/5/6, exhibits potent preclinical efficacy for the treatment of squamous tumors.

Oksana A. Sergeeva, Jennifer Zeiger, Colleen Brown, William DeMaria, Donal Ryan, Antonio Ward, Guixian Jin, Martin Preyer, Yanhuai Ding, Bruce Andrien, Mark Aimone, Agnes Meade, Jay S. Fine, Jeremy S. Myers, Stella Martomo

EvolveImmune Therapeutics, Inc, Branford, CT

EVOLVE104 is the first CD3 T cell engager (TCE) being developed for solid tumors which utilizes integrated CD2 T cell co-stimulation. EVOLVE104 is a trispecific molecule which targets ULBP2/5/6 on the tumor cell and uses affinity-tuned CD3 engagement together with a CD2-selective fusion protein to deliver coordinated costimulatory signal integration to the T cell to optimize its effector function. ULBP2/5/6 are closely related proteins of the UL16 binding protein family which are recognized by the NKG2D receptor and induced on tumor cells while maintaining restricted expression on normal human tissues.

In patient tumor samples, at both the RNA and protein level, ULBP2/5/6 expression is higher in carcinomas of squamous pathology as compared to adenocarcinomas. For example, squamous non-small cell lung cancer (NSCLC), squamous head and neck, and squamous urothelial cancer demonstrate > 70% ULBP2/5/6 positivity. In addition, transitional urothelial cancer, which encompasses most bladder cancers, also shows 70% ULBP2/5/6 positivity. We have verified that matched primary and metastatic urothelial, head and neck, and NSCLC tumors retain ULBP2/5/6 expression, and that standard of care treatments as late as post-third line do not decrease ULBP2/5/6 expression levels. These observations support the positioning of EVOLVE104 in squamous tumors and transitional urothelial cancers in initial clinical trials.

Using a variety of indication-specific tumor cell lines, we show an in vitro T-cell directed cell cytotoxicity EC50 of ~100 pM for EVOLVE104 with concomitant T cell activation, proliferation, and cytokine release. EVOLVE104 demonstrates a minimal efficacious dose of 0.25 mg/kg in indication-specific human cell line derived in vivo xenograft models in NSG mice engrafted with human PBMCs. In non-human primates, EVOLVE104 was well tolerated at doses up to 24 mg/kg, with no adverse findings or organ-specific toxicities at supra-pharmacologic levels compared to predicted human efficacious exposures. We show binding of EVOLVE104 in vivo on more than 95% of peripheral T cells for at least 168 hours post dose and no evidence for cytokine excursions throughout the duration of the study. Thus, preclinical data demonstrate safety and efficacy of EVOLVE104 and support the upcoming Phase I clinical study.

EVOLVE104, a trispecific TCE with integrated affinity-tuned CD3 binding and CD2 co-stimulation, optimizes effector T cells for anti-tumor activity. The enriched expression of its tumor antigen target, ULBP2/5/6, in primary and metastatic squamous tumors and transitional bladder cancers, together with its compelling in vitro and in vivo pharmacology and nonclinical safety profile, position EVOLVE104 as a first-in-category immunotherapy to address underserved patient populations with high unmet needs.

#3520 EM1031, a novel KLK2 x CD3 bispecific T-cell engager with highly effective efficacy in preclinical models.

Z. Ma, B. Shi, Z. Wei, W. Guo, L. Hu, Y. Li, X. Wu, S. Gong, D. Wu, C. Wu;
EpimAb Biotherapeutics Inc, Shanghai, China

Therapeutic options for metastatic castration-resistant prostate cancer (mCRPC) are limited within hormonal therapies, taxane-based chemotherapies and palliative radiotherapy. Currently available targeted therapies or immunotherapies have limited efficacy and can only benefit a small population of mCRPC patients. Human kallikrein 2 (KLK2) is a membrane-bound trypsin-like serine protease that shares 78% homology with prostate specific antigen (PSA). Directly regulated by androgen receptor (AR), KLK2 is specifically expressed in epithelial cells of prostate and prostate cancer cells and was considered as a promising tumor associated target. In this case, we have developed EM1031, a novel KLK2 x CD3 bispecific T-cell engager (TCE) based on EpimAb's proprietary CD3 antibody and bispecific antibody platform, adopting optimized CD3 affinity and binding arm valency to achieve potent redirected tumor cell lysis while maintaining minimal cytokine release. *In vitro* T-cell activation and cytokine release assay showed that EM1031 activates T cells only in the presence of KLK2 positive target cells. A clinical stage reference KLK2 TCE was also generated with published sequences for comparison. In preclinical studies, EM1031 showed less cytokine release against KLK2 positive prostate cancer cell lines than the reference KLK2 TCE, while it maintained comparable *in vitro* tumor cell killing activity. In xenograft models derived from KLK2 positive prostate cancer cell lines, EM1031 completely eradicated tumors with lower cytokine release compared to the reference TCE. Taken together, these data suggest that EM1031 has the potential in the treatment of prostate cancer.

#3521 A novel T cell engager targeting HLA-A02:01 TP53-R175H for cancer immunotherapy.

Mark Ng, Emily Zygiel, Alexander McQuown, Jinsheng Liang, Luhua Shen, Joshua Francis, Xingyue He, Hubert Lam, Gary Shapiro, Loic Vincent

Affini-T Therapeutics, Inc., Watertown, MA

Background: The tumor suppressor protein p53 (TP53) plays a pivotal role in preventing tumor formation by inducing cell cycle arrest and apoptosis in response to DNA damage. However, TP53 mutations are prevalent across various cancer types, and these mutations not only result in loss of tumor suppressive functions but also confer gain-of-function properties that drive oncogenesis. Among these mutations, HLA-A0201 TP53-R175H represents the largest TP53 population with >34,000 cases per year in the US and EU across all solid tumor indications, with no therapies explicitly targeting this mutation in the clinic. Leveraging Affini-T's TETHER™ platform, we present the development of a novel TCR-based T cell engager designed to redirect the cytotoxic potential of T cells against mutant TP53-expressing cancer cells.

Methods: A bispecific T cell engager was engineered to simultaneously engage T cells via CD3 and target TP53-R175H-expressing cancer cells by an affinity-matured specific TCR. Affinity maturation of the TCR was performed to increase its specificity and binding affinity towards the mutant peptide. Tumor co-culture assays were conducted to evaluate T cell-mediated cytotoxicity. T cell activation was assessed by measuring cytokine production. The tolerability profile of the engagers was established by X-scan, evaluating T cell activation by normal tissue.

Results: The data demonstrate successful affinity maturation of the TCR, resulting in enhanced recognition of the HLA-A0201 TP53-R175H peptide with high specificity. Tumor co-culture assays revealed potent T cell-mediated killing of mutant TP53-R175H-expressing cancer cells by the engager, accompanied by robust T cell activation characterized by cytokine production. Importantly, the engager exhibited favorable tolerability profiles, demonstrated by minimal off-target activation via X-scan and with minimal T cell activation towards normal tissue.

Conclusions: These findings highlight the promising activity and tolerability profile of a novel T cell engager targeting HLA-A02 TP53-R175H for cancer immunotherapy. Harnessing the cytotoxic potential of T cells against mutant TP53-expressing tumors presents a promising approach for the development of innovative cancer treatments.

Poster Session

#3525 Neo20 mRNA vaccine induces neoantigen-specific T cell immunity in humanized patient-derived xenograft mouse models of triple-negative breast cancer.

Maria F. Chervo[1], Chiara Mancino[2], Raghav Shroff[3], Wei Qian[1], Jenying Deng[1], Karina A. Ortega-Martinez[1], Jianying Zhou[1], Fotis Nikolos[4], Liliana Guzman-Rojas[1], Francesca Taraballi[2], Keith S. Chan[4], John P. Cooke[5], Jimmy D. Gollihar[3], Jenny C. Chang[1]

[1]Breast Oncology Department, Dr. Mary and Ron Neal Cancer Center, Houston Methodist Research Institute, Houston, TX,[2]Center for Musculoskeletal Regeneration, Houston Methodist Research Institute, Houston, TX,[3]Department of Pathology and Genomic Medicine, Houston Methodist Research Institute, Houston, TX,[4]Department of Urology, Dr. Mary and Ron Neal Cancer Center, Houston Methodist Research Institute, Houston, TX,[5]Department of Cardiovascular Sciences, Center for Cardiovascular Regeneration, Houston Methodist Research Institute, Houston, TX

Triple-negative breast cancer (TNBC) is the most aggressive breast cancer subtype, carrying a higher risk of recurrence and metastasis within 3 years, with poor prognosis. Neoadjuvant chemotherapy and immune checkpoint blockade are the standard of care. However, many patients still do not benefit from these treatments. Here we developed an mRNA lipid nanoparticle (LNP) vaccine (Neo20) as a potential therapeutic strategy for TNBC. We aimed to test the preclinical efficacy of Neo20 vaccine in humanized patient-derived xenograft (hu-PDX) mouse models of TNBC expressing HLA class I. Tumor neoantigens were identified in the TNBC PDX model MC1 using a proprietary algorithm that prioritizes vaccine candidates on their likelihood to elicit neoantigen-specific T cells and associated antitumor responses. mRNA encoding 20 HLA-A2-restricted neoantigens was synthesized and encapsulated into LNPs for in vivo administration. Human immunity was reconstituted in female HLA-A2 transgenic NSG mice through I.V. transplantation of CD34+ hematopoietic stem cells (HSCs) from HLA-A2+ cord blood donors. Mice showing efficient human CD45+ (hCD45+) cell engraftment were implanted with MC1 tumors into the mammary fat pad. Once the tumors were established, hu-PDX mice received Neo20 vaccine (10 μg mRNA/mouse) or vehicle/empty LNPs as control by intramuscular (I.M.) injection. Animals were treated every three days for one week, and splenocytes were harvested 7 days after the last dose for restimulation with vaccine peptides followed by IFN-γ ELISpot assay. Flow cytometry analysis of hCD45+ cells showed human reconstitution with T cells, B cells, myeloid cells, and NK cells in blood, spleen, and bone marrow (BM) collected from humanized mice at 12 weeks post-HSCs injection. Within the human T cell fraction, we identified naive, central memory and effector memory CD8+ subsets in the recipient spleen. We also confirmed the ability of T cells to produce IFN-γ, TNF-α, and granzymes A and B, demonstrating their potential to drive effective antitumor responses. Human dendritic cells differentiated into plasmacytoid and conventional subsets in the recipient BM, further supporting this model for the study of acquired immunity post-vaccination. When treated with Neo20 vaccine, hu-PDX mice mounted HLA-A2-restricted immune responses against multiple vaccine peptides as measured by ex vivo IFN-γ production. Luminex analysis of mouse serum demonstrated an increased secretion of proinflammatory cytokines and T cell activation markers in the Neo20-treated group. Overall, our findings provide evidence associated with mRNA vaccines against TNBC and support the use of hu-PDX mice as a model to preclinically validate vaccine candidates. Ongoing studies are directed to evaluate the antitumor response to Neo20 vaccine in hu-PDX mice upon repeated I.M. administration.

#3526 A novel strategy to treat advanced, late-stage tumors with real-time tumor vaccination “Online Vaccine”.

Piotr Jachimczak[1], Paul Jachimczak[2]

[1]RealTVac, Piotr Jachimczak (Individual), Wuerzburg, Germany,[2]MD Program, Gustaw Herling-Grudzinski University of Cracow, Cracow, Poland

Malignant cells acquired immunoevasive properties by numerous mechanisms allowing them to form locally invasive and metastatic tumors resistant to current therapeutic strategies. TGF-beta overexpression in tumor cells correlates with malignant progression by induction of “immune-escape phenomenon” in cancer bearing patients. Real-Time approach to generate a Tumor Vaccine *in vivo* (“Online Vaccine”) aims at avoiding this ,,immune-escape phenomenon“ by intratumoral inhibition of TGF-beta function while simultaneously and synergistically inducing an efficient anti-tumor immune response. The synergistic effects of the proposed combination of a TGF-beta inhibitor with immunostimulating cytokines IL-2 and GM-CSF (RealTVac®) upon human immune cell activation has been demonstrated *in vitro* and *in vivo*. This, four-dimensional (4D)-approach to treat advanced, late-stage, malignant tumor by use of repetitive spacio (intratumoral) - temporal (real-time) combination therapy allow the host immune system to scan in real-time all Tumor Associated Antigens (TAAs) being currently expressed by those tumor cells that are exposed to sufficient TGF-beta inhibition. The repetitive administration of the RealTVac® approach is furthermore expected to provide a continuous update of the immune response, reflecting the changing pattern of TAAs related to the dynamic intratumoral heterogeneity in malignant tumors. Thus, intratumoral immunization as applied for RealTVac® may create a new paradigm for cancer therapy in the future.

#3527 Low-intensity pulsed focused ultrasound, with microbubbles and immune adjuvants, promotes CNS epitope spreading, improving CAR T cell therapy for heterogeneous brain tumors.

Marco Gallus[1], Akane Yamamichi[1], Victor Andres. Arrieta[2], Atsuro Saijo[1], Lan Phung[1], Pavlina Chuntova[1], Su Phyu[1], Jeffrey Haegelin[1], Aishi Zhao[1], Haoyu Long[1], Senthilnath Lakshmanachetty[1], Takahide Nejo[1], Kaori Okada[1], Li Chen[2], Karl Habashy[2], Andrew Gould[2], Christina Amidei[2], Catalina Lee Chang[2], Roger Stupp[2], Michael Canney[3], Adam M. Sonabend[2], Hideho Okada[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Northwestern University, Chicago, IL,[3]Carthera, Lyon, France

While chimeric antigen receptor (CAR) T-cell therapies present novel therapeutic opportunities, their clinical success has been limited when targeting malignant brain tumors, such as malignant gliomas. Marked antigenic heterogeneity of those tumors underlies their treatment resistance. Ultimately, it is crucial to promote endogenous T cell responses against tumor cells not targeted by the CAR ("epitope-spreading"). However, natural anatomical barriers and an immunosuppressive environment allow neoplasms within the brain to evade detection by the endogenous immune system. We identified that low-intensity pulsed focused ultrasound combined with microbubbles (LIPU/MB)-mediated transient blood-brain barrier (BBB) opening enables the trafficking of antigen-presenting cells from the central nervous system (CNS) into the periphery utilizing intravital two-photon microscopy, multiparametric spectral flow cytometry, bone marrow chimera mice and blood samples from glioblastoma patients treated with LIPU/MB. Because mouse glioma models do not allow us to study the immune response with the intact BBB, we created a novel transgenic mouse model in which MHC class I- or II-presented T-cell epitopes are restrictedly expressed in glial cells. A combination of LIPU/MB with immune adjuvants poly-ICLC and interleukin-2 promoted priming, activation and homing of CNS-antigen-specific naïve T cells into the brain. Genetic depletion of β2 microglobulin in systemic hematopoietic cells by bone marrow chimera showed that this phenomenon was independent of antigen presentation by peripheral bone marrow-derived cells. Furthermore, T cell activity in the brain also induced MHC-I and MHC-II epitope spreading, shown as significantly increased endogenous epitope-specific T cells in the deep cervical lymph nodes and spleen. Ultimately, the combination of LIPU/MB with poly-ICLC and IL-2 significantly enhanced the efficacy of EGFRvIII CAR T cell therapy in mice harboring heterogenous (CAR+ and CAR-) SB28 tumors. Therapeutic efficacy was associated with the presence of endogenous immune cells targeting other tumor antigens within the CNS. Collectively, our findings suggest that LIPU/MB, in combination with poly-ICLC and Interleukin-2, can overcome the inherent limitations of CAR T cell therapy by promoting CNS antigen presentation to the peripheral immune system inducing endogenous tumor-tumor-specific immune responses that enhance the efficacy of CAR T cell therapy.

#3528 Combination therapy with HIF1α/c-MET peptide vaccine and bone-modifying agents is a promising strategy for suppressing bone metastases though a synergistic effect in mouse model of metastatic triple-negative breast cancer.

JinHwa Hong, Soon Young Lim, Hye Yeon Rho, Dong Ge Ra Mi Moon, Ju Won Kim, Jiwon Lee, Kyong Hwa Park

Korea University College of Medicine, Seoul, Korea, Republic of

Metastatic triple-negative breast cancer (mTNBC) remains incurable due to its aggressiveness and high metastatic potential, particularly to bones. Bone metastases activate osteoclasts, resulting in severe pain and bone destruction. While bone-modifying agents such as denosumab (anti-RANKL) and bisphosphonate (zoledronic acid; ZA) have been commonly used to inhibit the activity of osteoclasts, they have limitations such as high cost and jaw osteonecrosis. Due to the high immunogenicity and hypoxic tumor microenvironment (TME) of TNBC, immunotherapies such as immune checkpoint inhibitors (ICIs) and cancer vaccines are widely explored as treatment options. In our previous study, we demonstrated that HIF1α/c-MET peptide vaccine combined with anti-PD-1 effectively inhibited bone metastases. However, in clinical practice, many patients exhibit low response rates due to the heterogeneity of TNBC and its diverse immune evasion mechanism, highlighting the need for new strategies to reverse the TME. The synergistic effects of bone-modifying agents, such as denosumab or ZA have not yet been explored. This study aimed to evaluate whether the combination therapy of HIF1α/c-MET peptide vaccine with bone-modifying agents will provide a synergistic effect for suppressing bone metastases. We established the bone metastatic model by intracardiac inoculation of M6-bone cells in C3(1)Tag mouse. Mice were vaccinated with HIF1α/c-MET peptide vaccine weekly for three times and treated anti-PD-1 or anti-RNAKL or ZA. Control group received PBS vaccination and treated with IgG. Weekly In vivo imaging showed that combination therapy with HIF1α/c-MET peptide vaccine and bone-modifying agents reduced metastases. Through micro-CT and bone volume-to-total volume analysis, bone metastasis and destruction were reduced in the combination therapy of peptide vaccine with bone-modifying agents compared to the anti-PD-1 combination group. To understand the TME changes more comprehensively, immunofluorescence staining of HIF1α and c-MET is ongoing to confirm the inhibitory effects of the peptide vaccine on targeted oncogenic protein. Osteoclast activity is also being quantitatively assessed by analyzing the ratio of osteoclast surface to bone surface using tartrate-resistant acid phosphatase (TRAP) staining. To determine whether combination therapy can modulate the TME, tumor infiltrating lymphocytes (TILs) are being evaluated by assessing the expression of CD4 and CD8. Although further analysis of TME is necessary, we propose that the combination therapy of HIF1α/c-MET peptide vaccine with bone-modifying agents may provide a promising strategy for suppressing bone metastases in mTNBC.

#3530 Utilizing a humanized HLA-A2.1 mouse model for non-clinical studies of mRNA vaccines.

Leila Kokabee, Zhenlan Niu, Jing Guo, Shuaiqiang Zhang, Zhiyuan Shen, Hui Xu

Biocytogen, Waltham, MA

Substantial genetic discrepancies exist between the major histocompatibility complex (MHC) systems of animals and the human leukocyte antigen (HLA) system. The utilization of HLA humanized mouse model systems constitutes a superior methodology for examining fundamental mechanisms associated with HLA-A-related vaccine development and HLA-A-restricted immune responses against diseases such as infections and cancers in humans.

To study both *in vitro* and *in vivo* the requirements for shaping an effective T cell response against clinically relevant cancer targets such as NY-ESO-1, WT1 and other newly discovered targets, Biocytogen generated a C57BL/6 background HLA-A2.1 humanized mouse model that is restricted to the human HLA-A2. This humanized mouse model was utilized to evaluate immune responses to a variety of cancer peptide and mRNA vaccines, including analyses of immune cell populations, cytokine production, and *in vivo* anti-tumor efficacy.

Immunoprofiling analysis of this novel humanized HLA-A2.1 mouse strain revealed that the introduction of the HLA-A2.1 gene significantly influences the immune cell composition in these humanized mice. Following vaccination with various cancer-specific epitopes, HLA-A2.1-restricted, epitope-specific cytotoxic T lymphocytes (CTLs) were induced in the B-HLA-A2.1 mouse model. Furthermore, we established an mRNA vaccination treatment model in B-HLA-A2.1 mice, demonstrating a synergistic antitumor effect when combined with the mRNA vaccine. These findings indicate that the B-HLA-A2.1 mouse model serves as a powerful research tool, not only for investigating HLA-A2.1-restricted CTL responses but also for the preclinical evaluation of vaccines.

We have established a promising preclinical research model using HLA-A2.1 humanized mice. This model could accelerate the identification of novel HLA-A2.1-restricted epitopes and facilitate vaccine development, while also supporting the study of HLA-A2.1-restricted responses against cancers in humans.

#3531 Development of a mRNA-LNP vaccine for Lynch syndrome.

Yuri Koboziev[1], Ligia A. Pinto[2], Robert H. Shoemaker[3], **Jason D. Marshall**[1]

[1]NCI-Frederick/Leidos Biomed. Research, Inc., Frederick, MD,[2]Vaccine, Immunity and Cancer Directorate, NCI-Frederick/Leidos Biomed. Research, Inc., Frederick, MD,[3]Division of Cancer Prevention, NCI-Frederick, Frederick, MD

Lynch syndrome (LS) is a genetic disorder in which colorectal cancer is caused by mutations in DNA mismatch repair enzymes. Prophylactic mRNA vaccines have become the subjects of increasing interest as platforms for the potential prevention of such disorders. Several neoantigen sequences caused by defective mismatch repair were identified as expressed in a GEMM model of Lynch Syndrome, VCMsh2, and were also confirmed to be immunogenic for T and B cell responses in the background strain C57BL/6, as measured by IFN-g ELISPOT and ELISA in peptide/adjuvant-vaccinated mice. Vaccine mRNA constructs coding for 3 neoantigen peptides were designed with the HA signal peptide sequence and BioNTech 3' and 5' UTR regions and synthesized on the BioXp 3250 platform using pseudouridines. Monovalent mRNA vaccines were generated by encapsulating LS neoantigen mRNA into lipid nanoparticles (LNPs) on the NanoAssemblr Spark platform. High mRNA encapsulation efficiency was verified, and LNP size, polydispersity index, concentration, and zeta potential passed vaccine specifications. In vitro translation of vaccine mRNAs in transfected HEK-293 and RAW 264.7 cells were confirmed by FLAG Western Blot and mass spectrometry. The mRNA vaccines were administered 2X monthly via IM route to C57BL/6 mice. Substantial splenic CD4 T cell responses to the LS neoantigen peptides Nacad, Maz, and Senp6 were detected although lower than T cell responses to the corresponding peptide/adjuvant vaccine. In an attempt to adjuvant the mRNA vaccine, the TLR9 agonist CpG-2395 was encapsulated into LNPs via methods identical to mRNA packaging. In vitro testing on cell lines revealed that the CpG-LNPs enhanced Luciferase mRNA expression in RAW264.7 macrophages, triggered TLR9 signaling in mTLR9-HEK Blue reporter cells, and promoted IL-12 production by transfected RAW264.7. When LS neoantigen mRNA-LNPs were co-vaccinated with CpG-LNPs in C57BL/6 mice, T cell responses were augmented to be comparable to peptide-vaccinated T cell responses. Our current efforts involve optimizing the LNP lipid composition for uptake efficiency, optimizing the in vivo trafficking of the LNPs, and determining a suitable method for adjuvanting mRNA vaccines to boost T and B cell responses before evaluation in the VCMsh2 Lynch Syndrome GEMM model.

#3532 Development of mouse models for preclinical evaluation of cancer mRNA vaccines.

Hongyan Sun[1], Jialu Fan[1], Yunlong Jiang[1], Jianming Xu[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Since the successful development of vaccines against COVID, mRNA vaccine strategy showed superior efficacy and lower manufacturing costs compared to conventional vaccine approaches. The broad usage of mRNA vaccines was initially hampered by the early degradation before reaching to the target tissues. With the development of improved delivery systems to overcome the aforementioned problems *in vivo,* mRNA vaccine has become a promising strategy against various diseases including cancer. However, wild type mouse models are not suitable for the evaluation of cancer mRNA vaccines due to the fact that effective MHC-restricted antigen presentation is critical for mRNA vaccines to work *in vivo* in order to trigger a robust cellular and humoral immune response.

GemPharmatech has developed a series of MHC-humanized mouse models to better evaluate the *in vivo* immunogenicity, efficacy and safety of mRNA vaccines, eliminating the inconsistencies in antigen peptide recognition and immune response due to the MHC structural discrepancies between humans and mice.

Human immune cells can be reconstituted in immunodeficient mice (NCG) engrafted with human hematopoietic stem cells (HSC). However, since the species differences that murine cytokines provide limited support to human immune cells, HSC-NCG mice lack sufficient numbers of functional DC cells and the T cells are functionally defective because they are educated by murine MHC molecules. To address these two issues, we have introduced human HLA-A2 molecules into HSC-NCG-M mice, which is the ideal model for human myeloid cell reconstitution. HSC-NCG-M-hHLA-A2 mice have been developed to better reconstitute DCs and functional T cells educated by human MHC I molecules. An improved quantity of DC cells can be detected in HSC-NCG-M-hHLA-A2 mice. In addition, HLA-A2-restricted immune responses can be observed in HSC-NCG-M-hHLA-A2 mice. The HSC-NCG-M-hHLA-A2 mouse model is an ideal mouse model for the evaluation of *in vivo* immunogenicity and anti-tumor efficacy of mRNA cancer vaccines.

In addition to the humanized models, the adoptive cell transfer mouse model, in which splenocytes from immunocompetent MHC-humanized mice are injected into tumor-bearing (HLA matched) immunodeficient mice, is also an excellent choice, utilizing the complete immune system of immunocompetent mice and the susceptibility of immunodeficient mice to human tumor cells. This is the ideal model for the evaluation of TAA targeting mRNA vaccines, which is time and cost efficient without the need for cell line modification.

In conclusion, we have developed a series of MHC-humanized mouse models to provide more options for preclinical evaluation of tumor vaccines.

#3533 Claudin 6 vaccines effectively inhibit tumor growth in a syngeneic mouse colon cancer model.

N. Wang, M. Toh, H. Wang;
CK Life Sciences Development Limited, Hong Kong, China

Human Claudin 6 (CLDN6) is a member of the Claudin family of proteins, which play a crucial role in the structure and function of tight junctions. The expression of CLDN6 is restricted to stem cells and embryonic tissues. In human adults, CLDN6 mRNA is only detected at very low levels in testis, pancreas, and placenta. However, several types of cancers have been found to express CLDN6 at high levels, suggesting that CLDN6 is an ideal tumor-associated antigen and target for immunotherapy, albeit its precise role in cancer remains to be defined. Here, we designed and produced vaccine proteins consisting of multiple human B- and/or T-cell epitopes of CLDN6, which were selected from computer-predicted sequences, fused with an immune enhancer/carrier, and investigated their immunogenicity and anti-cancer activities in mice. First, C57BL/6 mice were vaccinated subcutaneously once a week for 5 times with the different vaccine proteins. CpG oligodeoxynucleotides were used as the vaccine adjuvant. Using the IFNγ ELISpot assay, we found that splenocytes collected from mice vaccinated with vaccine proteins containing T-cell epitopes displayed potent IFNγ release activity after stimulation with T-cell epitope peptides, suggesting that these CLDN6 vaccine proteins may inhibit the growth of CLDN6-expressing cancer by activating specific cytotoxic T-cells to destroy cancer cells. To explore this potential, we investigated the anti-cancer activity of the vaccine proteins by monitoring the tumor growth of CLDN6-humanized MC38 mouse colon cancer cells inoculated subcutaneously in vaccinated C57BL/6 mice for 4 weeks. We found that the growth of tumors was inhibited 98-100% (compared to the adjuvant-only control group) in two groups of mice (N=8 in each group) vaccinated with proteins containing multiple T-cell epitopes. In the first group, all 8 tumors disappeared within 4 weeks. In the second group, 7 of 8 tumors disappeared within 3 weeks and the last tumor stopped growing after the second week. In mice treated with adjuvant only, all tumors (N=8) displayed the same growth rate and reached an average of ~1,000 mm^3 in volume, similar to mice treated with PBS. Collectively, our results demonstrate that CLDN6 vaccines effectively inhibited the growth of CLDN6-expressing cancer cells in mice. These findings suggest that CLDN6 protein vaccines hold promise for treating CLDN6-expressing cancers in humans, and this potential will be further explored in future studies.

#3534 TPIPE, a pipeline for the identification and functional assessment of therapeutic cancer vaccine candidates.

C. Schifflers[1], M. Vlaming[1], E. Sidot[1], J. Lefevre[1], E. Pepermans[2], E. Boelen[1], S. Pattyn[1];
[1]IQVIA, Gosselies, Belgium, [2]Immunespec, Niel, Belgium

Therapeutic vaccination is a promising strategy for personalized cancer therapy. Using this approach, anadaptive T cell mediated immune response can be mounted against peptides presented by cancer cells,allowing for a systemic cancer cell eradication and immune memory formation.A key challenge for this approach is the identification of target peptides that are ubiquitously presented bycancer cells and capable of eliciting a cytotoxic T cell response. In this context, IQVIA Laboratories, In Vitro Immunology (formerly known as ImmunXperts) developed a pipeline for the Target Peptide Identification and the (functional) Peptide Evaluation (*TPIPE*) using *in vitro* generated peptide-specific T cells. This approach can be customized to be applicable to various therapeutic vaccine platforms. In brief, *in silico* prediction tools are used for the identification and pre-selection of candidate peptides.Peptide presentation is assessed by immunopeptidomics/MHC-associated peptide proteomics (MAPPs) in collaboration with *ImmuneSpec*. Upon identification of relevant targets, peptide-specific T cells aregenerated *in vitro* by co-culturing T cells with peptide-loaded/transfected dendritic cells. Peptide-reactivityis monitored over time by assessing the ability of the antigen-specific T cells binding to multimers via flowcytometry and in peptide re-stimulation FluoroSpot assays. The cytotoxic functionality of *in vitro* enriched peptide-specific T cells is subsequently evaluated in live-cell imaging, flow cytometry or colorimetry-based killing assays. Taken together, the *TPIPE* pipeline provides a customizable approach of the identification and functionalevaluation of therapeutic vaccines. TPIPE relies on high-quality pre-screened PBMCs, as provided by IQVIA Laboratories, In Vitro Immunology's own biobank, covering a wide range of 4-digit HLA-typed healthy donor preparations.

#3535 Targeting cervical cancer: VC-2 as a vaccine and treatment for HPV infections.

Mohammed T. Hussain, Robert Ellis, Kiran Fida, Mariano Carossino, Brent A. Stanfield

Department of Pathobiological Sciences, Louisiana State University, Baton Rouge, LA

Cervical cancer is a major cause of mortality worldwide and has been attributed to long-lasting (persistent) infections with the human papillomavirus (HPV). Although more than 50 types of HPVs are known the infect the genital tract, fewer than a dozen of them are regularly linked to cervical cancers leading to these types being designated as “high risk” HPVs. The infectious nature of HPVs procures the need for preventative vaccines against cervical cancer, and current vaccines such as Gardasil-9 and Ceravix achieve high efficacy in protection. However, once infections are established, preventative vaccines are inefficient in treating the malignancies. In HPV-associated tumors, the E7 oncoprotein is an ideal target for immunotherapeutic strategies and has been shown to be a likely target to treat cervical cancer. HSV, particularly HSV-2, often coexists with HPV due to similar transmission routes. Studies suggest that HSV infections may enhance the oncogenic effects of HPV by increasing inflammation, immune system modulation, and promoting a more favorable environment for HPV persistence and progression to cancer. Engineered Herpes Simplex Virus Type-1 (HSV-1) has been a promising candidate in treating established cancers and has been shown to be efficacious in improving anti-tumors responses and controlling tumor metastasis. Therefore, in this study, we aim to utilize the engineered HSV-1 strain (VC-2) to treat established cervical cancers and evaluate its efficacy as a prophylactic vaccine. The mice inoculated with the Tal-3 cervical cancer cell line show metastasis in the lungs and formation of large tumors. Moving forward, we would like to conduct therapeutic and prophylactic studies evaluating the reengineered VC-2 towards treating cervical cancer.

#3536 Synergistic effects of combined PD-L1 and B7-H3 fusion protein vaccination in a mouse model of pancreatic cancer.

Kenneth Nansheng Lin, Melvin Toh, Hong Wang

CK Life Sciences Limited, Hong Kong, Hong Kong

Background: Expressing immune checkpoint ligands is a mechanism for cancer cells to escape immune surveillance. Inhibiting these checkpoints effectively disrupts their escape mechanisms, improving cancer treatment outcomes. Various strategies have been developed to induce immune checkpoint inhibition. In this study, we developed cancer vaccines targeting checkpoint regulators, PD-L1 and B7-H3, and studied the anti-cancer activity in a syngeneic mouse cancer model using Panc02 cancer cells, known for their expression of both PD-L1 and B7-H3.
Methods: Vaccines targeting PD-L1 and B7-H3 were recombinant proteins consisting of immune enhancers fused with mouse PD-L1 and B7-H3 extracellular domains, respectively, and produced in E.coli. C57BL/6 mice were vaccinated multiple times with vaccine protein(s) adjuvanted with Poly(I:C) and Freund's Adjuvant. Vaccine-induced humoral responses were measured by ELISA using serum samples collected from the mice. Anti-cancer activity was investigated using mice vaccinated four times followed by subcutaneous implantation of Panc02 cells and additional four vaccinations. Tumor growth was recorded. Tumor-infiltrated immune cells were characterized by immunofluorescence staining.
Results: PD-L1 and B7-H3 vaccines induced specific antibodies against PD-L1 and B7-H3. Serum samples collected from PD-L1-vaccinated mice displayed neutralizing activity, blocking the binding of PD-L1 to PD-1. In mice inoculated with Panc02 cells, vaccination with PD-L1, B7-H3, and PD-L1/B7-H3 mixture inhibited tumor growth by 10%, 30%, and 66%, respectively. In the tumors, vaccination with the PD-L1/B7-H3 mixture increased CD4+ T cells significantly, indicating that vaccine-induced immune cell infiltration plays a critical role in tumor inhibition.
Conclusions: Our results demonstrate that vaccination is an effective strategy for inducing neutralizing antibodies that inhibit immune checkpoints in cancer treatment. The most significant tumor growth inhibition observed with the combination of PD-L1 and B7-H3 vaccination underscores the necessity of simultaneously targeting multiple checkpoint regulators in cancers that express these proteins.

#3537 Development and validation of humanized HLA-A11.1 mouse model for preclinical evaluation of novel peptide vaccines.

Dong Han, Leila Kokabee, James Jin, Zhenlan Niu, Ying Zhao, Shuaiqiang Zhang, Zhi Zhang, Hui Xu

Biocytogen, Waltham, MA

The Major Histocompatibility Complex (MHC) is responsible for presenting diverse antigenic peptides and initiating T cell-mediated immune responses. Given the significant genetic differences between animal MHC systems and the human leukocyte antigen (HLA) system, HLA humanized mouse models offer an efficient *in vivo* system for HLA-A-related vaccine development and for studying HLA-A-restricted response mechanisms in humans.

In this study, we present a novel B-HLA-A11.1 mouse model and have thoroughly investigated its phenotypic and immunological attributes. Our findings indicate that the blood routine and biochemistry of B-HLA-A11.1 mice are comparable to those of wild-type mice, suggesting that the humanization of HLA-A11.1 does not adversely alter blood cell composition or morphology, nor does it affect the health status of organs such as the heart, liver, or kidneys. Collectively, these data demonstrate that B-HLA-A11.1 mice develope normally and do not exhibit any evidence of spontaneous pathology due to the humanization of HLA-A11.1. To gain a deeper understanding of the role of MHC molecules, we extended our research using a humanized mouse model to assess immune responses against various cancer target peptides.

In summary, our data indicate that humanized HLA-A11.1 mice provide a powerful preclinical model for *in vivo*/*ex vivo* evaluation of novel peptide and mRNA vaccines.

#3538 The development of neoantigen-derived peptide vaccine driven by AI epitope design and computer assisted epitope enhancement.

Chi Han Samson Li[1], Hong Wang[1], Kin Tak Chan[1], Genwei Zhang[2], Jiewen Du[2], Lipeng Lai[2], Melvin Toh[1]

[1]CK Life Sciences Development Limited, Hong Kong, Hong Kong,[2]Xtalpi, Beijing, China

Background and objective: Neoantigens are the ideal targets for developing cancer vaccine for cancer treatment. However, the development of cancer vaccines is often hindered by poor antigen presentation of the vaccine peptide by major histocompatibility complex (MHC) molecules. Our AI epitope prediction model showed prediction accuracy superior to several state-of-the-art algorithms for MHC-I antigen presentation. As studies showed that amino acid substitution in key positions of MHC-I epitope provides strong activating signals to cytotoxic T cells, we aimed to develop MHC-I restricted neoantigen vaccines by coupling our AI model with computer-assisted modification of neoantigen-derived epitopes to improve their HLA presentation probability and immunogenicity.
Methods: The AI model was used to analyze some common TP53 neoantigen sequences and predict epitopes for HLA-A*02:01. The epitopes underwent computer-assisted saturation mutagenesis that simulated single amino acid substitutions to obtain the associated presentation score changes. Peptide sequences with improved presentation scores were synthesized, and their binding affinities with HLA-A*02:01 were analyzed by surface plasmon resonance (SPR). The peptides were immunized into the HLA-A*02:01-humanized C57BL/6 mice, and their immunogenicity was determined by mouse interferon γ (mIFNγ) ELISpot assay and intracellular cytokine staining (ICS) using splenocytes of the mice.
Results: Our AI model predicted epitopes from common TP53 neoantigens that showed high HLA-A*02:01 presentation probability. Through saturation mutagenesis, dominant mutations with at least 5% increase of presentation probability were screened out. Seven novel modified peptides were synthesized and showed high binding affinity with HLA-A*02:01/ß2-microglobulin heterodimer. After these peptides were pooled to immunize HLA-A*02:01-humanized mice, mIFNγ ELISpot assay showed that 6 out of the 7 modified peptides reactivated splenocytes from the peptide-immunized mice, while mIFNγ ICS showed that $CD8^+$ cytotoxic T-cells were activated. The splenocytes were then restimulated with the native neoantigen peptides corresponding to the modified peptides. One native neoantigen peptide reactivated T-cells from the immunized mice, suggesting that immunization of the modified peptides could induce cytotoxic T-cell response against the native neoantigens.
Conclusion: Our study demonstrates a highly efficient approach by coupling MHC-I presentation prediction AI model and computer assisted saturation mutagenesis to design single amino acid substituted MHC-I peptides derived from neoantigens. Immunization of the peptides induced cytotoxic T-cell responses which may inhibit the growth of cancer cells carrying such a neoantigen. This novel approach to developing cancer vaccines will be further tested in future studies.

#3540 Proteolysis-targeting vaccines for robust combination immunotherapy of melanoma.

Qiyan Wang[1], Ting Su[2], Furong Chen[3], Shurong Zhou[1], Xiang Liu[1], You Xu[1], Ri Tang[1], Shimiao Liao[1], Jordan Dailey[1], Guolan Xiao[1], Guizhi Zhu[1]

[1]University of Michigan, Ann Arbor, MI,[2]State Key Laboratory for Modification of Chemical Fibers and Polymer Materials, College of Biologica, Donghua University, Shanghai, China,[3]School of Life Sciences, Shanghai University, Shanghai, China

Introduction: Protein/peptide vaccines show great promise for combination tumor immunotherapy with immune checkpoint blockade (ICB). However, conventional protein/peptide vaccines often elicit insufficient antitumor T cell responses, resulting in suboptimal therapeutic outcomes. Here, we introduced proteolysis-targeting vaccines (PROTAVs), which integrate melanoma protein/peptide antigens, E3 ligase-binding ligands, and linkers. This design enhances antigen proteolytic processing and cross-presentation, resulting in robust activation of T cell responses. By co-delivering PROTAVs with a bi-adjuvant system through lipid nanoparticles (LNPs), we aim to significantly improve the quantity and quality of specific $CD8^+$ T cells, thereby enhancing the efficacy of ICB-based combination therapies.

Method: Ovalbumin (OVA) was employed as a model antigen, with pomalidomide serving as the E3 ligase ligand, conjugated via a series of linkers. Linker optimization was conducted using an in vivo T-cell response assay. Protein degradation and antigen presentation efficiency were assessed using Western blotting, co-immunoprecipitation, and flow cytometry. Leveraging these findings, PROTAV-TgT (Trp2-gp100-Trp1), incorporating melanoma-specific antigens, was strategically developed to enable a comprehensive evaluation of its immunological mechanisms and therapeutic potential.

Result: A series of PROTAV-OVA constructs incorporating linkers of varying water solubility and lengths were synthesized, eliciting robust $SIINFKEL^+$ T cell responses in mice, with the EG_4 linker achieving superior immunogenicity, inducing up to 18% $SIINFKEL^+$ T cells. Mechanistic studies demonstrated that PROTAV-OVA facilitated enhanced antigen degradation, as evidenced by increased DQ-OVA fluorescence and OVA-ubiquitin colocalization in dendritic cells. Additionally, it significantly improved antigen presentation, as shown by elevated H_2K^b-SIINFEKL staining both in vitro and in vivo. Based on these, the PROTAV-TgT was designed, incorporating melanoma-specific antigens and co-delivery with CpG using SM-102 LNPs. Immunization with PROTAV-TgT induced 4-fold increasing gp100-$specific^+$ T cell responses, compared with TgT alone. In the B16F10 model, PROTAV-TgT combined with ICB resulted in complete tumor regression (CR) in 50% of mice treated. Remarkably, in the aggressive SM1 $Braf^{V600E}$ melanoma model, this combination therapy achieved 100% CR by day 24, an outcome not observed in other group at the time point.

Conclusion: PROTAVs effectively elicit robust $CD8^+$ T cell responses and alleviate tumor immunosuppression, enhancing the efficacy of ICB combination immunotherapy for melanoma. These findings highlight the potential of PROTAVs as a versatile platform for developing cancer therapeutic vaccines, offering broad applicability for robust immunotherapy across various cancer types.

#3541 A novel chimeric RNA as a source of neoantigens in CRC.

Sarah A. Lynch[1], Amanda M. Lulu[2], Samir Lalani[3], Justin Elfman[3], Craig L. Slingluff[4], Hui Li[1]

[1]Pathology, University of Virginia, Charlottesville, VA,[2]Pediatrics, University of Virginia, Charlottesville, VA,[3]Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA,[4]Surgery, University of Virginia, Charlottesville, VA

Colorectal cancer (CRC) is the second-leading cause of cancer-related death worldwide, affecting over 100,000 men and women in the United States every year. There is an unmet need for early biomarker discovery and the identification of novel therapeutic targets in CRC. Chimeric RNAs and their protein products are well-established as ideal biomarkers and drug targets for malignant cancers. Additionally, cancer-specific fusion proteins present attractive targets for neoantigen vaccines. Using RNA-seq from The Cancer Genome Atlas (TCGA) database, we have identified a chimeric RNA prevalent in approximately 50% of CRC samples, but absent in non-cancer colon tissue. This transcript correlates with worse overall survival, is expressed as early as stage I CRC, and is present in both microsatellite stable and instable disease. This chimeric RNA arises from readthrough transcription and cis-splicing between adjacent genes, producing a previously unidentified chimeric protein. Importantly, this protein includes a splice variant of the 5' gene, leading to a frameshift in the 3' gene and resulting in a novel 101 amino acid peptide sequence. This sequence is not detected by mass spectrometry in any healthy tissue but is present in multiple CRC cases within the Clinical Proteome Tumor Analysis Consortium (CPTAC) data portal. Using an antibody generated against the frameshift sequence, we have confirmed this protein is expressed in patient CRC samples, regardless of disease stage, sex, age, race, or microsatellite instability status. Finally, we have demonstrated that T cells from healthy donors and patients with CRC exhibit activation following co-culture with autologous dendritic cells pulsed with peptides derived from this protein. Additionally, these T cells display cytotoxicity against HLA-matched CRC cell lines. These findings highlight the potential of chimeric RNAs and their protein products as both biomarkers and therapeutic targets, presenting a previously unexplored class of tumor antigens as an innovative strategy for improving patient outcomes.

#3542 Nanofilament immunotherapy as an antigen-agnostic cancer vaccine.

Kevin Neil[1], Samuel Genier[1], Marie-Eve Poisson[1], Hugo Giguere[2], Lauren Daniel[2], Julie Douchin[1], Lee-Hwa Tai[2], Sebastien Rodrigue[3], Jean-Francois Millau[1]

[1]TATUM Bioscience, Sherbrooke, QC, Canada,[2]IRCUS, Universite de Sherbrooke, Sherbrooke, QC, Canada,[3]Biology, Universite de Sherbrooke, Sherbrooke, QC, Canada

Checkpoint inhibitors revolutionized cancer treatment by potentiating antitumor immune responses. However, many patients do not respond to these therapies, often due to a lack of pre-existing immune response against cancer cells. Personalized cancer vaccines promote cancer cell antigen recognition and mount antitumor immune responses, thus helping to improve response rates. However, personalized cancer vaccine interventions imply complex and costly procedures that make the technology difficult to scale. As an alternative to personalized cancer vaccines, we established multimodal nanofilament immunotherapy as an antigen-agnostic *in situ* cancer vaccine modality. Through genetic engineering of the M13 bacteriophage, nanofilaments displaying combinations of therapeutic agents were generated to steer the immune system against cancer cells. TAT003, a multimodal nanofilament combining the natural adjuvant properties of M13 with the display of anti-PD-L1 and IL-2 molecules, was developed to bind the surface of cancer cells and transform them into immunological targets. After validation of TAT003 biological activities *in vitro* and assessment of biodistribution, the potency of the candidate was evaluated upon intratumoral administration in syngeneic mouse models both as a single agent as well as in combination with PD-1 blockade therapy. The mode of action of TAT003 was also characterized using cytokine paneling, immune profiling, and T-cells activation assays. TAT003 nanofilaments simultaneously displayed biologically active anti-PD-L1 and IL-2 molecules. Upon intratumoral injection, TAT003 anchored durably in the tumor, which limited systemic exposure to the drug. TAT003 profoundly remodeled the tumor microenvironment of injected lesions, where it sparked a strong myeloid cell infiltration, and promoted the infiltration of T-cells in non-injected contralateral lesions, promoting T-cells infiltration. This translated into potent tumor regression of both lesions in multiple cancer models, and potentiated PD-1 blockade therapy. TAT003 treatment induced the expansion of cancer-cell specific effector T cells systemically, providing a long-lasting antitumor vaccine response. Multimodal nanofilament immunotherapy is a novel approach to mount systemic antitumor immune responses *in situ* by physically coupling large immunostimulatory molecules to cancer cells. TAT003 induced marked tumor regressions by leveraging synergies between the therapeutic agents displayed on its surface while offering a favorable tolerability profile. These results establish multimodal nanofilaments as an innovative and versatile immunotherapy platform for developing *in situ* cancer vaccines.

#3543 Combinatorial mRNA-LNP vaccines for triple-negative breast cancer.

Sara L. Woessner[1], Xiaolei Cai[2], Caroline Kellogg[3], Jun Huang[2]

[1]Committee on Cancer Biology, University of Chicago, Chicago, IL,[2]Pritzker School of Molecular Engineering, University of Chicago, Chicago, IL,[3]University of Chicago, Chicago, IL

Breast cancer is the most commonly-diagnosed tumor in women, and there remains a need for effective treatment options for metastatic disease. mRNA-lipid nanoparticle (LNP) vaccines targeting tumor neoantigens are a potential avenue for treating triple-negative and basal-like breast cancers. Using established whole-exome and RNA-sequencing data, we identified a combination of neoantigens that induce CD4 and CD8 T cell responses. Administration of mRNA-LNPs encoding 4 neoantigens significantly delayed growth of 4T1 murine syngeneic tumors. When the vaccine is combined with IV injection of engineered IL7 and IL12, the median overall survival is increased by 14 days. Taken together, these improvements to current breast cancer vaccination approaches may represent a way to induce tumor regression and clearance in treatment-refractory disease.

#3544 Synergistic efficacy of a PSMA DNA vaccine and PD-1 inhibition in anti-tumor immunity against prostate cancer.

Perry Ayn Mayson Maza, Leslie Flores, Dana Rae Cyril-Ramirez, Dafei Chai, Delana Bui, Dan Zhao, Junhao Wang, Yifei Wang, Haiwei Ni, Xiaohui Xie, Xinfang Yu, Yong Li

Baylor College of Medicine, Houston, TX

Prostate cancer (PCa) remains one of the leading causes of cancer-related morbidity and mortality in men. A promising target for immunotherapy is prostate-specific membrane antigen (PSMA), a transmembrane protein predominantly overexpressed in PCa, with expression levels correlating with tumor aggressiveness and invasiveness. In this study, we evaluated the prophylactic and therapeutic potential of a plasmid DNA vaccine targeting PSMA for the treatment and prevention of prostate cancer using the RM-1 mouse PCa cell line engineered to overexpress human PSMA. A DNA plasmid which encoded the human PSMA antigen, was administered prophylactically, prior to tumor challenge, or therapeutically, following tumor establishment using electroporation. In the prophylactic approach, vaccination resulted in significant tumor volume reduction and marked tumor growth inhibition. Moreover, the immune response was robust, characterized by increased infiltration of tumor-infiltrating lymphocytes (TILs), including CD8+ cytotoxic T cells, CD4+ helper T cells, B cells, NK cells, neutrophils, macrophages, and dendritic cells within the tumor microenvironment. Immune cell activation was also observed in the spleens, indicating systemic immune priming. Peptide-MHC tetramer staining revealed a significant increase in PSMA-specific CD8+ T cells in the spleen of vaccinated mice, confirming the induction of a targeted immune response against PSMA-expressing tumor cells. Additionally, PSMA-specific antibodies were significantly increased in the serum of vaccinated mice, suggesting humoral immunity in response to the vaccine. In the therapeutic approach, vaccination with the PSMA DNA vaccine alone slowed tumor growth. Like the prophylactic approach, therapeutic vaccination resulted in increased TILs and immune activation in the spleen. Upon the addition of PD-1 antibody, tumor growth was significantly inhibited, resulting in a greater reduction in tumor volume. The combination of PSMA vaccination and PD-1 blockade led to a more potent anti-tumor immune response, characterized by further activation and expansion of PSMA-specific CD8+ cytotoxic T cells, increased production of PSMA-specific antibodies, and enhanced infiltration of immune cells. These findings underscore the potential of PSMA-targeted DNA vaccines in combination with immune checkpoint blockade (e.g., anti-PD-1) as a promising preventive and therapeutic strategy for PCa, highlighting their ability to enhance immune surveillance and induce more effective anti-tumor immunity

#3545 Enhancing anticancer immunity with SARS-CoV-2 B cell epitope-guided neoantigen nanovaccines.

Chengyi Li, **Fang Ke**, Shuai Mao, Zera Montemayor, Mohamed Dit Mady Traore, Alejandra Duran Balsa, Mahamadou Djibo, Neha Karekar, Hanning Wen, Wei Gao, Duxin Sun

University of Michigan, Ann Arbor, MI

Background: Current neoantigen cancer vaccines primarily rely on dendritic cell- and macrophage-mediated antigen presentation to activate T cell immunity. However, the potential of incorporating B cell-mediated antigen presentation into these vaccines to enhance CD4 and CD8 T cell responses has not been fully explored.

Methods: We developed $B_{SARS}T_{NeoAg}$Vax, a SARS-CoV-2 B cell epitope-guided neoantigen peptide or mRNA cancer nanovaccine, designed to leverage B cell-mediated antigen presentation. $B_{SARS}T_{NeoAg}$Vax was tested in three mouse cancer models (melanoma, pancreatic cancer, and breast cancer) using two types of T cell tumor neoantigens (peptide or mRNA) and two types of nano delivery systems (I or lipid nanoparticles, LNP). SARS-CoV-2 B cell epitopes were conjugated on the surface of I or LNP to facilitate crosslinking with the B cell receptor (BCR) on SARS-CoV-2-specific B. Immune responses and therapeutic efficacy of $B_{SARS}T_{NeoAg}$Vax were compared with existing neoantigen vaccines.

Results: $B_{SARS}T_{NeoAg}$Vax enabled SARS-CoV-2 B cell-mediated antigen presentation to tumor-specific CD4 T cells, significantly enhancing the activation of tumor-specific follicular and non-follicular CD4 T cells. This interaction also promoted B cell-dependent tumor-specific CD8 T cell immunity, resulting in robust antitumor responses. Importantly, the efficacy of $B_{SARS}T_{NeoAg}$Vax was independent of antibody production, as the SARS-CoV-2 B cell epitopes on the vaccine generated anti-SARS-CoV-2 antibodies that lacked anticancer efficacy. In the mouse cancer models, $B_{SARS}T_{NeoAg}$Vax demonstrated superior efficacy, showing improved tumor control and enhanced immune activation compared to current neoantigen vaccines.

Conclusion: Our findings establish a universal platform for cancer immunotherapy, utilizing SARS-CoV-2 B epitope-guided neoantigen nanovaccines to enhance CD4 and CD8 T cell antitumor immunity through viral-specific B cell-mediated antigen presentation. This approach holds significant promise for improving the efficacy of neoantigen-based cancer vaccines across diverse tumor types.

#3547 Therapeutic efficacy of genetically modified CD34-derived allogeneic dendritic cell cancer vaccine platform in a pancreatic tumor model.

Jose Dominic Gonzalez[1], Sara Huerta-Yepez[2], Neha Sheik[1], Senay Beraki[1], Elango Kathirvel[1], Ariel Rodriguez Frandsen[1], **Saleemulla Mahammad**[1], Lu Chen[1], Francois Binette[1], David Weinstein[1], Anahid Jewett[2]

[1]Renovaro Biosciences, Los Angeles, CA,[2]Division of Oral Biology and Medicine, School of Dentistry, University of California, Los Angeles, CA

Background: Pancreatic cancer is the fourth leading cause of all cancer-related deaths. Dendritic cells are the primary antigen presenting cells that have the capacity to activate both innate and adaptive immune systems. Although peripheral blood derived mature dendritic cell (DC)-based vaccines have shown the potential to activate multiple anti-tumor immune responses *in-vitro* and in animal studies, they have yielded disappointing results in clinical trials. Here we report on a novel allogeneic dendritic cell cancer vaccine (DCCV) platform derived from CD34+ Hematopoietic Stem Cells (HSCs) that are transduced with lentiviral vector encoding CD93, CD40L, and CXCL13. We are reporting therapeutic efficacy of such allogeneic dendritic cell cancer vaccine therapy platform in a pancreatic tumor bearing humanized mouse model.

Methods: We have developed a robust manufacturing method to generate large numbers of engineered allogenic DCs overexpressing CD93, CD40L, and CXCL13. A tri-cistronic lentiviral vector was constructed to co-express these genes. The engineered DCs were evaluated for the expression of transgenes and functionality via flow cytometry, PCR, and ELISA. Antigen education of engineered DCs was performed via coculturing them with whole tumor lysate. *In vivo* therapeutic efficacy was tested in Bone-Liver-Thymus (BLT) and PBMC humanized NOD-SCID gamma (NSG) mouse models with Mia Paca-2 (MP2) orthotopic pancreatic tumors. Chromium release assay, E-sight and IHC methods were employed to quantify the cytotoxicity and cell proliferation of T cells and infiltration of immune cells into the tumors upon treatment with the engineered DC.

Results: We have investigated the therapeutic efficacy of our engineered DCCV in curtailing pancreatic tumor growth. Tumor-bearing Humanized mouse models treated with engineered DCCV demonstrated significant tumor regression compared to untreated controls. This is accredited to DCCV's ability to activate the host immune system, proliferation of CD4+, CD8+, and NK cells in the peripheral blood and subsequent infiltration of these immune cells into the tumor tissue.

Conclusion: These results demonstrate the potency of our allogeneic DCCV expressing CD93, CD40L, and CXCL13, in controlling pancreatic tumor growth by stimulating the immune system and therefore could provide an effective therapeutic opportunity for the treatment of various solid tumors. We report on a DCCV platform to treat multiple solid tumors such as triple negative breast cancer (TNBC), hepatocellular carcinoma, pancreatic, head and neck, oral and prostate cancers.

#3548 Systemic antitumor immunity stimulated by intratumoral CD40 agonist in combination with PD1 therapy in immune-cold melanoma.

Barbara Pazdrak, Heather M. Sonnemann, Barbara M. Nassif, Salah E. Bentebibel, Greg Lizee, Adi Diab

UT MD Anderson Cancer Center, Houston, TX

Agonistic CD40 antibodies in combination with checkpoint inhibitors have shown beneficial outcomes in clinical trials for the treatment of malignancies. We demonstrated that intratumoral injection of CD40 agonist in combination with systemic anti-PD1 therapy activates innate immune responses and promotes selective expansion of effector CD8 T cells while decreasing immunosuppressive Treg and M2 populations in melanoma tumors. However, the mechanisms of systemic antitumor immune responses driven by this combination therapy in patients are not well defined. Therefore, the aim of this study was to evaluate the impact of this combination therapy on systemic antitumor immunity using a bilateral, immunologically “cold” tumor model. Mice bearing bilateral B16-F10 melanoma tumors were injected with anti-CD40 Ab into right flank tumors, either alone or in combination with anti-PD1 Ab on day 8 post-tumor implantation. Mice were received treatment every 3 days for a total of 5 doses. Our results demonstrated that intratumoral CD40 Ab alone or in combination with anti-PD1 therapy inhibited the growth of both treated and distant (non-treated) tumors. The combination therapy showed superior efficacy compared with single Ab treatments. CD40 Ab-injected tumor weights measured at day 17, were ~9-fold reduced in mice treated with the combination therapy as compared to PD1 Ab alone (0.09±0.02g vs 0.83±0.17g). Importantly, similar antitumor efficacy of the combination therapy was observed in non-treated tumors (0.09±0.02g vs 0.74±0.23g) on the left flanks of these mice, demonstrating an abscopal treatment effect that was associated with enlargement of spleen and TdLNs. Flow cytometry analysis showed that CD40 agonist stimulated the proliferation of CD4 and CD8 T cells, and B cells in TdLNs and spleen. Furthermore, CD40 Ab treatment increased the frequency of blood circulating effector (40% vs 7% CTR) and central memory (25% vs 15% CTR) CD8 T cells as determined at day 21. Our data indicated that intratumoral CD40 agonist in combination with anti-PD1 therapy stimulated systemic antitumor immunity resulting in inhibition of distant tumor growth in a “cold” melanoma model, which was accompanied by increased proliferation of T cells and B cells in lymphoid organs and frequency of effector and memory CD8 T cells in the circulation. The results provide new insights about the mechanisms of systemic antitumor responses induced by intratumoral CD40 agonist.

#3549 Engineering an artificial antigen presenting system: A novel immunotherapeutic strategy for lung cancer.

Sindhu Yalavarthi[1], Li Wang[1], Yusif-Abdul Rashid[1], Kiki Parker[2], I'yanah Gunter[1], Ethan Li[3], Emily Cao[3], Jianjun Wei[1], Zhenquan Jia[4], Kounosuke Watabe[5], Kerui Wu[1]

[1]Nanoscience, Joint School of Nanoscience and Nanoengineering, University of North Carolina Greensboro, Greensboro, NC,[2]Nanoenigneering, Joint School of Nanoscience and Nanoengineering, North Carolina Agricultural and Technical State University, Greensboro, NC,[3]Nanoscience, Joint School of Nanoscience and Nanoengineering, Greensboro, NC,[4]Department of Biology, University of North Carolina Greensboro, Greensboro, NC,[5]Department of Cancer Biology, Wake Forest University School of Medicine, Winston Salem, NC

Lung cancer continues to be the major cause of cancer-related deaths worldwide, indicating the urgent need for innovative and effective treatment strategies. Immune checkpoint inhibitors (ICIs) have demonstrated great promise as a new therapy, offering new hope for patients with advanced lung cancer. However, resistance to ICIs is frequently observed in cancer patients, with many failing to achieve durable responses. One of the very important factors contributing to ICI resistance is the dysfunction of antigen-presenting cells (APCs), especially dendritic cells (DCs), which are key initiators of the anti-tumor immunity. In lung cancer patients, DCs are compromised with a low capability of generating cytotoxic T cells, which are indispensable for the effectiveness of ICIs. To overcome this challenge, we have designed an artificial antigen-presenting system (aAPS), a new bioengineered platform that enables the direct stimulation of anti-tumor T cell responses independent of host APCs. The platform comprises specifically engineered nanostructures presenting membrane-bound IL-2, co-stimulatory molecules (4-1BBL and CD40L), and major histocompatibility complex (MHC)-bound antigens. aAPS thus efficiently performs direct antigen presentation to lymphocytes, leading to a robust and specific adaptive immune response. By mimicking these three necessary signals—cytokine stimulation, co-stimulatory activation, and MHC-antigen presentation—aAPS can elicit and amplify T cell activation independently of dysfunctional host APCs. The membrane-bound IL-2 on aAPS is extensively oriented toward highly targeted T-cell engagement, improving immune cell activation and lowering the systemic toxicity usually linked with the administration of free cytokines. Our preliminary studies have shown that aAPS potently induces an antigen-specific T cell response, which is superior to the effects seen in conventional dendritic cell-based approach. The efficacy profile of aAPS has been quite promising in preclinical murine lung cancer models, showing a huge reduction in tumor growth, enhancement of tumor-infiltrating lymphocytes, and augmentation of the efficacy of ICIs. Such data indicate that aAPS may overcome one of the major immune suppressive barriers to ICI therapy in lung cancer, paving the way for potentially potent new tools to enhance anti-tumor immunity and improve patient outcomes. Further studies will confirm these results and move aAPS toward clinical application in advanced lung cancer by transforming the bioengineering strategies to reduce technical barriers, enabling high-yield and high-purity production of this innovative therapy.

#3550 Dendritic cells pulsed with cancer stem cell antigen showed profound anti-tumoral efficacy in ovarian cancer.

Haixi Liang, Tong Xiang, Lin Zhou, Zhiwen Xie, Mao Ye, Chunyan Lan

Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Background: Ovarian cancer serves as the first leading lethally gynecologic cancer, of which around 70% of patients would relapse soon even have undergone standard treatment. Several mechanisms work together attributing to the early relapse. Among these, cancer stem cells (CSCs) act as the root of metastasis and relapse in the early reports. However, limited methods directly targeting these rare populations have been developed so far. Here we develop DC vaccine directly targeting CSCs by loading DCs with enriched cancer stem cell antigen (CSC-Ag) in vitro.

Methods: Freshly dissected ovarian tumors are digested into single cell suspension with digestive enzymes. Subsequently, fluorescence-activated cell sorting (FACS) is used to isolate CD44CD133 double-positive cells, previously reported surface markers of CSCs. Basic medium supplied with several cytokines is used to maintain and enrich CSCs. Suspension of enriched stem cell spheres is repeated five freeze-thaw cycles in liquid nitrogen and 37-degree Celsius water bath, and the supernatant after centrifugation is regarded as CSC-Ag. CD14+ cells of patients' PBMCs are isolated using CD14 microbeads according to manufacturer's instruction. IL-4 and GM-CSF are added to induce DC. Immature DC are loaded with previously prepared CSC-Ag. Meanwhile, CD14- cells are cultured with the supplement of anti-CD3, anti-CD28 antibodies, and rhIL-2. T cells are soon co-cultured with mature DC for further antigen-presenting. In vitro cytotoxicity against OC cell lines are tested. Additionally, we developed a peritoneal metastatic ovarian cancer cell model by injecting OVCAR8 transfected with luciferase into NSG mice. IVIS system is used later to monitor tumor growth twice a week.

Result: Both CD44 and CD133 were highly expressed in ovarian cancers compared with normal tissue in matched TCGA and GTEx datasets. CD44CD133 double-positive cells ranged from 0.00% to 59.10% in our OC cohort (n=21). CSCs were successfully isolated and enriched, confirmed by the expression of stem cell markers, including SOX2, OCT4, and NANOG. CSC-Ag also expressed those markers comparable to freshly cultured CSC. DC-CSC+T showed remarkable efficacy both in vitro and in vivo against ovarian cancer, with more cancer cell apoptosis.

Conclusion: Dendritic cells pulsed with cancer-stem cell antigen (DC-CSC+T) could significantly lower the growth rate of OC, and may serve as a potential adjuvant therapy for improving OC disease-free interval.

#3551 Signal 1 boosters that address the antigen-access problem for solid tumor cell therapy.

Diane Manry, Kelly Radecki, Alexander Partin, Charles Kirsh, Anagha Krishnagiri, Navneet Kumar, Aaron D. Flynn, Yuta Ando, Jon Torres, Breanna DiAndreth, Timothy P. Riley, Alexander Kamb

A2 Biotherapeutics, Inc, Agoura Hills, CA

Background: Access to tumor antigens in solid tumors is one of the major impediments to progress in oncology, exemplified by the stark difference between the success of cell therapies for blood cancers vs. solid tumors. To overcome this obstacle, cell therapy research and development has explored a wide range of methods to enhance potency without worsening toxicity. Special attention has been paid to onboard potency boosters expressed by engineered immune cells, because they more readily avoid systemic toxicity. Investigation has focused primarily on signals 2 (co-stimulatory factors) and 3 (cytokines), but other mechanisms have also been considered, including expression of transcription factors, anti-apoptotic proteins, and TGFβ pathway inhibitors. Despite the magnitude and range of these efforts to boost potency, little attention has been directed at enhancers of signal 1, beyond designs intended to improve acute sensitivity of chimeric antigen receptors (CARs) and t-cell receptors (TCRs).
Methods: Three different small-molecule-regulated systems were explored as inducible modules to regulate tonic signaling by CARs and TCRs. Acute and long-term behavior was examined, with an emphasis on inducer-dependent activation of immune function. Fusions of known members of the TCR signaling pathway were compared to identify modules with different functional properties; for example, background signaling level and ligand-induced induction ratio.
Results: A variety of constructs, including fusions to LAT, SLP76, CD3ε, and CD3ζ were shown to affect tonic signaling in a fashion that could be controlled by small-molecule inducers. Acute effects measured in Jurkat cells were also observed in primary T cells. Three clinically-tested classes of small molecule were able to act with their cognate ligand-binding fusion proteins as signal 1 boosters, demonstrating flexible small molecule control of the booster. This tunable-booster approach was extended to Tmod^{TM}, a dual-receptor NOT gate based on the LIR-1 inhibitory receptor (Hamburger AE, et al. *Mol Immunol*. 2020).
Conclusions: We have developed an approach to mitigate a major challenge for solid tumor cell therapy—access to tumor antigens in the blood. The system utilizes signal 1 agonists and is tunable, flexible, and modular. These signal 1 booster constructs can be added to CARs, TCRs, and other receptor systems to mimic an antigen stimulus with a small molecule, thereby triggering tonic (antigen-independent) signaling that reversibly activates the cells in the absence of antigen.

#3552 An mRNA-encoded adjuvant-enzyme activates STING to enhance the immunogenicity of vaccines targeting human papillomavirus positive cancers.

Jonathan Chow, Kelsey Finn, Anastasia Nikiforov, Dahlia Alkekhia, Stephan Matissek, Saisha Nalawade, Angela O'Neil, Carolyn MacFarlane, Philip Coblentz, Milap Chokshi, Colin Kelly, Brenna Sherbanee, Nicolina Lamberti, Evan Kennedy, Andrew Cornforth, Sivan Elloul, Jonathan C. Kagan

Corner Therapeutics, Watertown, MA

Despite the clinical success of prophylactic vaccines against human papillomavirus (HPV), vaccines administered post-infection are unable to prevent HPV-associated cancers. Therapeutic HPV vaccines that can treat pre-malignant and established oropharyngeal and anogenital tumors therefore represent an unmet clinical need. Using a novel mRNA-encoded catalytic vaccine adjuvant, Corner Therapeutics is developing a therapeutic vaccine against HPV.The cyclic GMP-AMP synthase/stimulator of interferon genes (cGAS/STING) signaling pathway is a robust inducer of inflammation and protective immunity. No effective means to activate this pathway in the context of mRNA-based vaccines is known. Towards this end, we engineered an mRNA construct encoding a self-DNA reactive form of the enzyme cGAS (hereafter cGASΔN) to use as a catalytic vaccine adjuvant. Herein we show that cGASΔN mRNA was successfully formulated into lipid nanoparticles (LNPs) of a size and consistency matching LNPs used clinically, and that the cGASΔN mRNA is translated into a functional protein allowing for downstream STING signaling in primary human dendritic cells. When treated with cGASΔN mRNA-LNPs, human dendritic cells produced cytokines, chemokines and interferons, and expressed cell surface activation markers associated with T cell co-stimulation. The immunostimulatory activities of cGASΔN-LNPs resulted in robust ability of DCs to activate HPV-specific human T cells in *in vitro* cocultures. In contrast, DCs stimulated with LNPs encoding non-stimulatory proteins (akin to those used clinically), were ineffective inducers of T cell activation. In murine vaccination studies, intramuscular injection of LNPs encoding cGASΔN and HPV16 E6 and E7 antigens enhanced antigen-specific T cell responses to both viral proteins. These results establish cGASΔN mRNA-LNPs as a potent adjuvant to enhance the immunogenicity of mRNA-based HPV antigens, and that this promising approach could be utilized to develop therapeutic cancer vaccines.

#3553 Bria-OTS+: A versatile therapeutic platform for inducing anti-cancer immunity.

Miguel A. Lopez-Lago[1], Vikas Bhardwaj[2], Pravin Kesarwani[2], Xiaoyi Zheng[2], sagarika Pachhal[2], Patience Cournoo[2], Renee Cortez[1], George Woodfield[1], Charles Wiseman[2], William Williams[3]

[1]BriaCell, Philadelphia, PA,[2]BriaCell Therapeutics Corp., Philadelphia, PA,[3]BriaCell Therapeutic Corp., Philadelphia, PA

Background: Despite advances, achieving curative cancer therapies remains challenging due to the complex, multi-stage nature of the disease. Recently, therapeutic cancer vaccines have shown promising efficacy, driven by advances in immune profiling, antigen selection, immunotherapy combinations, mRNA technology, and delivery platforms. However, challenges persist, including identifying highly immunogenic tumor antigens, overcoming T-cell immune escape, and achieving scalable, cost-effective manufacturing. To address these, BriaCell is developing a gene-modified allogeneic tumor cell platform to stimulate both innate and adaptive immunity. This platform provides a broad range of tumor antigens and includes immune-stimulatory factors to induce a comprehensive immune response. Initial results with the SV-BR-1-GM (Bria-IMT) breast cancer cell line, expressing GM-CSF, have shown promise. Bria-OTS+ further enhances immune activation by expressing additional cytokines, co-stimulatory factors, and HLA alleles across tumor cells, offering a personalized, adaptable immunotherapy platform.
Methods: Bria-OTS+ cell lines are derived from various cancer lines, including breast, prostate, lung, and melanoma. The cells are modified to express co-stimulatory molecules, cytokines and a range of HLA alleles through lentiviral transduction. To assess Bria-OTS+'s therapeutic potential, we developed an in vitro vaccination assay. Briefly, peripheral blood mononuclear cells (PBMCs) from healthy donors were co-cultured with Bria-OTS+ cells in a four-phase assay—priming, resting, boosting and effector phases—to evaluate immune activation, memory formation, exhaustion, and cytotoxicity.
Results: Bria-OTS+ robustly activated innate and adaptive immune responses in vitro. Co-culture with PBMCs led to T and NK cell activation, marked by increased activation markers and cytokine production. The platform induced immune memory, with enhanced cytokine release, cytotoxicity and memory marker expression upon re-stimulation. Cytotoxicity assays confirmed effective tumor cell targeting, and blocking antibody studies identified key activation pathways.
Conclusions: Bria-OTS+ is an adaptable cancer immunotherapy platform with strong clinical potential. It expresses a broad range of cancer antigens, including Tumor-Associated Antigens and Post-Translational Modifications, to stimulate robust immune responses. The platform activates both adaptive and innate immunity, overcoming immune escape by engaging NK cells in cases of HLA deletion. Bria-OTS+ is flexible, easily updated with new innovations, and suited for both personalized and ready-to-use applications. Its simplified administration and anticipated favorable side effect profile support broad clinical potential and patient tolerance.

#3559 Racial and ethnic disparities in medication adherence between Black and Caucasian cancer survivors using oral anticancer medications: A Blinder-Oaxaca decomposition analysis.

Meng-Jung Wen[1], Olayinka O. Shiyanbola[2]

[1]Health Services Research in Pharmacy, School of Pharmacy, University of Wisconsin-Madison, Madison, WI,[2]Department of Clinical Pharmacy, College of Pharmacy, University of Michigan, Ann Arbor, MI

Background: About half of cancer survivors do not adhere to prescribed oral anticancer medications (OAMs), leading to higher relapse rates, hospitalizations, and healthcare costs. Nonadherence disproportionately impacts Black cancer survivors, often due to barriers such as limited healthcare access, healthcare mistrust and health literacy challenges. However, limited research has examined adherence among Black cancer survivors using OAMs, highlighting the need to explore factors contributing to nonadherence for future interventions. This study aimed to (1) assess disparities in medication adherence among Black and Caucasian cancer survivors on OAMs, and (2) examine the extent to which these disparities may be attributed to patient demographics and psychosocial factors.
Methods: A total of 335 cancer survivors currently taking OAMs were recruited through two online panels. Participants completed a survey on medication adherence, psychosocial factors, and demographics. Medication adherence was measured with the 12-item Adherence to Refills and Medications Scale, designed to assess the extent of adherence to OAMs. Independent t-tests and multiple linear regression analyses examined differences and predictors of nonadherence between Black and White patients. A two-fold Blinder-Oaxaca decomposition analysis was used to further decompose the disparities in medication adherence identified within the regression model.
Results: Compared to Caucasian patients, Black patients had significantly lower adherence (-2.06 points, $p = .04$) to OAMs. The model attributed a total of 2.77 points (SE = .64) of adherence disparities to socio-demographic and psychosocial factors. Specifically, age and metropolitan residence explained 1.18 points (51.5%) and 0.18 points (7.9%) of the variance, respectively. Health literacy emerged as the most significant psychosocial factor, accounting for 1.24 points (54.2%) of the observed disparities in medication adherence.
Conclusion: Blinder-Oaxaca decomposition analysis offered a nuanced way to assess disparities in medication adherence and their contributing behavioral factors. The results indicate that younger Black cancer survivors and those who live in metropolitan areas showed lower engagement in medication use. Future interventions should adopt a multi-faceted approach to address modifiable factors, such as enhancing health literacy and providing support for OAM adherence among Black cancer survivors.

#3560 Understanding health-seeking delays for post-menopausal bleeding among subpopulations of Black women.

Maurice J. Chery, LaShea D. Rolle, Wilmar Belizaire, Alejandra Casas, Sara M. St. George, Sophia HL George, Matthew Schlumbrecht

University of Miami Miller School of Medicine, Miami, FL

Background: Black women face disproportionate risks of endometrial cancer (EC). They more often present with advanced stage and high-grade histologies, and have lower survival rates compared to White women. Subpopulations of the Black community have been shown to have variable risks of disease and poor outcomes; the underlying causes for this observation are unknown. Without specific screening tests for EC, timely diagnosis relies on recognizing postmenopausal bleeding (PMB), the most common symptom. Our objective was to explore perceptions of PMB and factors influencing care-seeking behavior when PMB occurs among subpopulations of healthy Black women to determine if these factors influence observed intra-racial disparities.

Methods: We utilized a community based participatory research approach guided by the Safer and Anderson model of Total Patient Delay. We conducted focus groups with three subpopulations of healthy Black women (US-born [USB], Caribbean-born English speaking [CBB], and Haitian-Creole speaking [HC]) who were ≥50 years old. We collected demographic information and queried participants about their perceptions of PMB if they were to personally experience it, including its meaning, disclosure of the symptoms to others, and strategies to self-appraise and engage the healthcare system. We transcribed, thematically coded, and analyzed each session using Dedoose software.

Results: Fifty-four women (median age 60 [54-65]) participated (USB 40%; HC 40%, CBB 20%). Over 60% were non-USB, and 90% had at least a high school education. Cultural and religious beliefs significantly shaped health management across all groups. HC prioritized prayer and divine guidance over immediate medical care, preferring to use natural remedies aligned with traditional health practices. USB integrated spiritual beliefs with conventional medical approaches but expressed concerns over stigma, leading to selective sharing of health concerns within families. CBB highlighted hereditary factors, linking PMB symptoms to family history and genetics. Across all groups, family dynamics shaped health-seeking behaviors, with non-USB preferring to rely more heavily on familial networks for guidance. Information-seeking behaviors varied, from strong reliance on digital resources (USB) to direct validation from healthcare professionals (CBB) or community networks (HC). Despite differences, all groups highlighted delays in seeking care, often attributed to symptom misconceptions and normalization of PMB.

Conclusion: In the hypothetical setting of PMB, cultural beliefs, familial dynamics, and information-seeking behaviors shape health perceptions and care-seeking actions among Black women. Culturally tailored interventions to address knowledge gaps, promote timely recognition of PMB, and encourage early engagement with healthcare providers are needed to reduce EC disparities.

#3562 Associations between premature aging and cancer among middle-class Black and White women in the US: A case-control NHANES analysis.

Kayla S. Ingram[1], Brittany Jenkins-Lord[1], Kassandra L. Alcaraz[2], Avonne E. Connor[1]

[1]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD,[2]Johns Hopkins School of Medicine, Baltimore, MD

Although overall cancer mortality rates have decreased, Black women in the U.S. continue to have higher mortality rates from cancer than their White counterparts. Recent studies reveal that both genetic and environmental factors combine to contribute to these racial disparities in cancer, and may be modulated by differences in tumor biology. With cancer being an aging-related disease, it has previously been hypothesized that racial disparities in cancer outcomes are exacerbated by prolonged exposures to social and economic stressors that lead to premature aging. Our study aims to explore these effects on cancer status among U.S. Black and White women with annual household incomes of > $75K/year. Using data from the National Health and Nutrition Examination Survey (NHANES) from 1999 to 2021, we quantified social and economic stressors using three factors: (1) allostatic load (AL) score to predict confounding stress factors on an individual's health, (2) telomere length to predict premature aging, and (3) validated epigenetic aging markers from NHANES methylation data. We calculated the total AL score by summing the individual components for a score ranging from 0 to 9. Participants with high AL have a score ≥3. Mean telomere length was measured continuously. All aging metrics represent different aspects of accelerated epigenetic aging (Horvath Age and Hannum Age), phenotypic age (PhenoAge), pacing of aging (DunedinPoAm), and predicted age of mortality (GrimAge2Mort). Adjusted regression models were used to identify associations between these metrics, any cancer status, and race. We restricted our study sample to women with annual household incomes >$75K/year, resulting in a final NHANES cohort of 3,690 women (cancer cases, n=302; controls, n=3,388). In this cross-sectional study of Black (n=850) and White (n=2,840) women, increasing allostatic load was associated with decreased odds of cancer case status overall (odds ratio (OR)=0.89, 95%CI=0.81,0.98, p=0.02) and specifically for White women (OR=0.89, 95%CI=0.80,0.99, p=0.03). Increasing Horvath Age was associated with a 20% increased odds of cancer case status overall (OR=1.20, 95%CI=1.01,1.43, p=0.04) and significantly for White women (OR=1.36, 95%CI=1.11,1.166, p=0.003), but not Black women. We also found that AL and telomere length were both associated with several accelerated aging metrics in cases and controls. Our results suggest that increasing allostatic load had a protective effect in this cohort of high-earning women, specifically among White women. Increasing epigenetic aging metrics correlated to odds of a cancer diagnosis overall and with race specific implications. Some differences by race may be attributed to the low sampling of Black women in this cohort with corresponding telomere and methylation data, emphasizing the need for future epigenetic studies to include more Black populations.

#3563 Racial and ethnic disparities in mental health care and psychotropic medication utilization and expenditure among cancer survivors with serious psychological distress.

Hyunjung Lee[1], So-Yeon Kang[2], Alexandre Chan[3], Jason Zheng[1], Ahmedin Jemal[1], Farhad Islami[1]

[1]American Cancer Society, Atlanta, GA,[2]Department of Health Management and Policy, Georgetown University School of Health, Washington, DC,[3]School of Pharmacy & Pharmaceutical Sciences, University of California, Irvine, CA

Background: Although National Comprehensive Cancer Network provides the standardized guideline for mental health screening and treatment during cancer care, mental health care has been still underutilized among cancer survivors. Cancer survivors may experience stress and mental health issues for many reasons, including the unexpected diagnosis; cancer treatment; and fear of reoccurrence and premature death. Access to mental health care is critical to improve their quality of life and avoid unnecessary costs due to mental illness. Although previous research has shown racial and ethnic inequities in mental health services and medication utilization in the general population, few studies have examined these disparities among cancer survivors with serious psychological distress (SPD).
Method: Nationally-representative pooled 2012-2021 Medical Expenditure Panel Survey was used. The key outcomes included 1) the total number of each type of office-based visits (psychiatrist, psychologist, and psychotherapy/mental health counseling), 2) expenditures related to these visits, 3) whether medication was prescribed during these visits, and 4) psychotropic medication utilization (purchased). Zero-inflated negative binomial model for count outcomes, two-part regression models for cost outcomes, and logistic regression model for a binary outcome, adjusting for multiple individual socioeconomic factors and health status.
Results: Approximately 5% of cancer survivors in 2012-2020 MEPS data had SPD (N=1,016). Compared with non-Hispanic White (NHW) survivors with SPD, non-Hispanic Black (NHB) with SPD were less likely to receive counseling (−1.74 visit, 95%CI=−2.70, −0.79) and non-Hispanic other (NHO) were less likely to visit psychiatrist (−1.74 visit, 95%CI=−2.70,−0.79). Among cancer survivors who visited office-based mental health professionals, psychotropic medications were more likely to be prescribed to NHB survivors than NHW survivors by 22.2 percentage points (95%CI=9.22,35.21). The expenditure on mental health visits was lower among NHB survivors than NHW survivors (total cost: $−226, 95%CI=−384,−68; out-of-pocket cost: $-75, 95%CI=−110, −40). Compared with NHW survivors, antidepressants utilization was lower among NHB (−15.0%, 95%CI=−24.8,−5.2) and Hispanic (−9.6%, 95%CI=−18.8,−0.5) and anxiolytics utilization was lower among NHB (−12.5%, 95%CI=−19.8,−5.2) and NHO (−14.9%, 95%CI=−24.7,−5.1) survivors.
Conclusions: We found that Black-White disparities existed in number of counseling visits, total and out-of-pocket expenditures, and antidepressant and anxiolytic utilization, and Hispanic or NHO were less likely to utilize antidepressant or anxiolytics, calling for improvements in adherence of mental health treatment and access to psychotropic medication among racial and ethnic minorities.

#3564 Analyzing state policies that impact cancer care access for individuals with intellectual and/or developmental disabilities.

Esha Mathur[1], Carly Camplain[2], Freya Abraham[1], Erin Vinoski[3], Julie Armin[1]

[1]University of Arizona, Tucson, AZ,[2]Indiana University, Bloomington, IN,[3]Georgia State University, Atlanta, GA

Background: Almost 2 million people in the US are diagnosed with some form of cancer, with a large proportion due to environmental, occupational, or lifestyle factors. People with intellectual and/or developmental disabilities (IDD) have the same risks for cancer as the general population, and are diagnosed with cancer at similar rates to the general population; however, they may experience worse cancer-related outcomes. Studies show the life expectancy of people with IDD has improved, largely due to better health management. As this population ages , it is important to address diseases of age, like cancer. There has been little exploration into how health-promoting federal and state policies influence the cancer outcomes of people with IDD. To understand how policies may affect cancer-related experiences of those with IDD, our team is conducting in-depth analysis of state programs and Medicaid waivers of two states: Kentucky, a state that expanded Medicaid eligibility with the Affordable Care Act; and Georgia, a state that chose not to expand.
Methods: We compiled every Kentucky and Georgia Medicaid waiver (vehicles states use to deliver and pay for health care services in Medicaid) and health-focused program (17 for Georgia, and 14 for Kentucky). Our team also conducted in-depth interviews with policy advocates in each state (N=4), where we gained insight into the effectiveness of these policies in practice. We thematically coded each waiver with 3 broad categories-overall health promoting, disability-specific, and cancer-specific initiatives-and with 6 social determinants of health (SDoH) categories- economic stability, education, social context, living conditions and physical environment, health care system, and food.
Results: For both Georgia and Kentucky, we found that every waiver/program (100%) addressed health care access. In Georgia, waivers and programs were coded as follows: food (4, 23.5%), economic stability (1, 5.8%), living conditions/physical environment (4, 23.5%), education (0), social context (6, 35.3%). In Kentucky, waivers and programs were coded: food (3, 21.4%), economic stability (2, 14.3%), living conditions/physical environment (7, 50%), education (1, 7.1%), social context (5, 35.7%). In interviews, advocates mentioned transportation, health literacy, and provider education as major barriers to health care.
Conclusions: While most Medicaid waivers address access to health care, there is a need for waivers to address the other SDoHs that create significant accessibility barriers and may affect cancer outcomes.

#3565 Personalized Drug Discovery Process (PDDP): An AI-driven, sustainable, and equitable solution for cancer drug discovery.

Pietro Veronesi[1], Adekunle Odunsi[2], Marciano Siniscalchi[3], **Marina Chiara Garassino**[2]

[1]Booth Business School, University of Chicago, Chicago, IL,[2]University of Chicago, Chicago, IL,[3]Economics, Northwestern University, Chicago, IL

Background: Personalized medicine has improved survival rates for lung cancer patients with common targetable alterations. However, developing drugs for rare or ultra-rare molecular alterations is likely to become economically unsustainable, potentially creating unequal access to personalized therapies for patients with these mutations.
Methods: We formulate a new mathematical model and use Monte Carlo simulations to calculate pharma companies' projected profits from targets that affect an increasingly smaller fraction of the world population, considering the costs of R&D and Randomized Clinical Trials (RCTs) and the probability of drug approval. We then use similar methods to calculate projected profits for an alternative, feasible, AI-driven approach called the Personalized Drug Discovery Process (PDDP), which has four steps: target identification, protein synthesis, drug matching or repurposing, and bioassay synthesis.
Findings: At the current annual price for targeted therapies of around $200,000/patient and RCT costs of $100,000 per subject, the financial incentives for further drug discovery under the current approval paradigm evaporate for targets affecting less than 0.5% of the lung cancer population, even if Phase 0 and I R&D costs are as low as $100 million/target. To ensure proper incentives for Pharma companies to innovate even for targets affecting less than 0.5% of lung cancer patients, targeted therapies would require margins of over $828,000/year per patient over manufacturing costs, implying global societal costs of over $1.45 trillion/year. PDDP is instead projected to be sustainable, even accounting for the required investments in infrastructure. At peak, we calculate PDDP will cost $1,250 per lung cancer patient, net of drug manufacturing costs. Pharma companies will invest in PDDP and hence foster further research if successful personalized drugs yield margins between $25,000 - $90,000/year per patient.
Conclusions: PDDP is already a feasible and sustainable drug discovery process. This can create a paradigm shift in drug discovery by testing the process instead of specific drugs. By contrast, under current regulatory agency requirements, the drug discovery and development process is unsustainable for targets with a frequency of less than 0.5%. This approach promotes innovation and equity in access for all patients with any identifiable target mutation

#3566 OncoPSM as a tool for cost-effectiveness analysis in oncology trial using Kaplan Meier curve data.

Baohui Han[1], Feilong Zhao[2], Ding Zhang[2]

[1]Shanghai Chest Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China,[2]3D Medicine, Shanghai, China

Introduction: Cost-effectiveness analysis (CEA) is a key tool for evaluating the economic viability of new treatments compared to current standards of care. However, many CEA methodologies are not specifically designed to address the intricate cost structures in oncology trials.

Methods: We employed a public image recognition tool to extract data from Kaplan-Meier (KM) curves published in clinical trials. Using an iterative algorithm based on the iKM method, we reconstructed individual patient data (IPD). A partitioned survival models (PSM) were then fitted to the IPD data. Under this model, we estimated the probability of each survival state for each model-cycle and combine these probabilities with utility values to calculate both the effect per model-cycle and the incremental effect for the experimental group. For cost analysis, we performed a treatment-cycle-specific cost evaluation, accounting for cost uncertainty through a gamma distribution. By setting model-cycle equals to the treatment-cycle, we could calculate the state-weighted cost, applied a discount rate, and determined the incremental cost for the experimental group. The Incremental Cost-Effectiveness Ratio (ICER) was then calculated based on the incremental effect and incremental cost.

Results: The OncoPSM application, available at (https://zhaofeilong.shinyapps.io/app_oncopsa/), was validated with real-world data from the CHOICE-01 trial. OncoSPM accurately reconstructed IPD from KM curve data, with root mean square error (RMSE) values below 0.004 across all curves. Log-rank p-values for the experimental and control groups (PFS: <0.0001; OS: 0.0104) closely aligned with those reported in the original publication (PFS: <0.0001; OS: 0.0108). Hazard ratios (HR) from the reconstructed IPD data (PFS: 0.504, 95%CI: 0.4-0.63, OS: 0.731, 95%CI: 0.57-0.93) were consistent with the original study (PFS: 0.49, 95%CI: 0.39-0.61, OS: 0.73, 95%CI: 0.57-0.93). The log-logistic model provided the best fit for both PFS and OS curves, based on the Akaike Information Criterion (AIC). Extrapolating the survival curve to a 10-year horizon, we created the PSM, deriving the average state probabilities per treatment-cycle to calculate state-weighted costs. The incremental cost for the experimental group was ¥42,291, with an incremental quality-adjusted life year (QALY) of 0.35, yielding an ICER of 122,319 ¥/QALY, which is well below the willingness-to-pay (WTP) threshold of 268,200 ¥/QALY. Uncertainty analysis showed a 99.6% probability that the experimental group was cost-effective at the WTP threshold.

Conclusions: OncoPSM offers an accurate and user-friendly treatment-cycle-based cost analysis tool that addresses the complexities of costs in oncology research. By integrating and visualizing the entire CEA process, OncoPSM supports decision-makers in making well-informed choices based on both statistical and intuitive insights.

#3567 Immunotherapy combined with chemotherapy versus biomarker-guided immunotherapy: A cost-effectiveness analysis.

Fubing Wu[1], Feilong Zhao[2], Ding Zhang[2], Wen Huang[3]

[1]Sir Run Run Hospital, Nanjing Medical University, Nanjing, China,[2]3D Medicine, Shanghai, China,[3]The Fourth Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background. PD-L1 and TMB are established biomarkers for predicting immunotherapy efficacy. However, with the substantial reduction in the cost of domestic PD-L1 testing, the value of expensive genetic testing compared to its limited benefits has become a pertinent question.

Methods. Data from 309 NSCLC receiving immunotherapy and 156 NSCLC undergoing chemotherapy in CHOICE-01 clinical trial were analyzed. Using a decision tree model, patients were categorized into All-in group receiving immunotherapy combined with chemotherapy, and two control groups guided by TMB and PD-L1, respectively. Cost-effectiveness was assessed using Incremental Cost-Effectiveness Ratio (ICER).

Results. The decision tree comprised three chance nodes: All-in combinational therapy, TMB-guided, and PD-L1-guided strategies (Table 1). The TMB-H group exhibited the highest response rate, followed by the PD-L1 positive group, both exceeding an overall response rate of 65.7%. Utility values for partial response (PR), stable disease (SD), and progressive disease (PD) were retrieved from previous studies, then adjusted by weighted average of SD and PD distribution and adverse reaction-related disutility. After model evaluation, the All-in, TMB-guided, and PD-L1 guided strategies yielded utility of 0.653, 0.638, and 0.628, respectively. Corresponding costs were ¥3,202, ¥3,833, and ¥11,395. Given the decreasing utility and increasing cost across the strategies, calculating the ICER was deemed unnecessary.

Conclusion. The All-in strategy demonstrated the highest utility and lowest cost, indicating it as the most cost-effective option for patients considering immunotherapy combined with chemotherapy. However, as this study focused on ORR, it only reflects short-term cost-effectiveness. Further investigation into long-term cost-effectiveness regarding survival outcomes is warranted.

Table 1. Structure and parameters of the decision tree.

Decision	Probability, %	Regimen	ORR mean, %	ORR Distribution	Adjusted mean utility
All-in	100	Comb	65.70	Beta(203,106)	R: 0.698 NR: 0.567
TMB	TMB-H: 30.96	Comb	72.73	Beta(56,21)	R: 0.698 NR: 0.567
	TMB-L: 69.04	Chemo	45.88	Beta(39,46)	R: 0.690 NR: 0.547
PD-L1	Pos: 65.16	Comb	68.00	Beta(136,64)	R: 0.698 NR: 0.567
	Neg: 34.84	Chemo	39.62	Beta(21,32)	R: 0.690 NR: 0.547

#3568 Evaluating recent drug approvals for hematologic malignancies utilizing the New European Society of Medical Oncology Magnitude of Clinical Benefit Scale for Hematology (ESMO-MCBS:H).

Ryan Hirsh[1], Justin Moyers[2], David Benjamin[3], Aysche Stern[4]

[1]University of Kansas Medical Center, Kansas City, KS,[2]Cedars-Sinai The Angeles Clinic and Research Institute - West Los Angeles, Los Angeles, CA,[3]Hoag, Newport Beach, CA,[4]Department of Internal Medicine - Temecula Valley Hospital, Temecula, CA

Introduction: Over the last decade, the US Food and Drug Administration (FDA) and the European Medicines Agency (EMA) have steadily leaned towards granting regulatory approval based on earlier phase trials and surrogate endpoints. Despite obtaining regulatory approval, many countries hold additional standards to assess the value of a new drug approval. The ESMO-MCBS is a tool created to evaluate the values and reduce bias or hype of drug approvals using various metrics: efficacy, quality of life, and duration of response. In 2023, the ESMO-MCBS:H was created for hematological malignancies. We aimed to evaluate recent drug approvals using the new ESMO-MCBS:H criteria for hematologic malignancies.

Methods: We included all drugs approved for a hematologic malignancy between 2019 and 2024. Drugs were assessed using ESMO-MCBS:H forms 2a, 2b, 2c, or 3 depending on the trial type and primary endpoints leading to drug approval. Approvals were independently scored by two reviewers with a third reviewer to adjudicate scoring differences.

Results: 66 drugs were approved by either FDA or EMA during this time. 88% (n=58) were approved by both EMA and FDA, 12% (n=8) by FDA alone. No drugs were approved by the EMA alone without preceding or subsequent FDA approval. 4 drug approvals were for pediatric indications. 36 approvals (n=35/66, 53 %) were based on early phase 1 and/or 2 trial data. Approvals were for leukemias (n=16; 24%), lymphomas (n=25, 38%), myeloma (n=18, 27%), or CLL/SLL (n=6; 9%). 13% of approvals (n=9/66) were for drugs with a biomarker matched indication. Substantial benefit criteria were met by 15 of 66 approvals (23%). Substantial benefit criteria were met by 0% (N=0/8) of drug indication by approved by FDA alone versus 26% of drugs approved by both the FDA and EMA (n=15/58).Approvals based on early phase (phase 1 and/or 2) trials met criteria in 17% (n=6/35) of trials and 29% of later phase (phase 3) trials met criteria (n=9/31) without statistical significance (p=0.25).

No significant difference in approvals meeting substantial benefit were seen for biomarker matched therapies (33%; n=3/9) versus unmatched therapies (21%; n=12/57) (p=0.41). No therapies approved for a pediatric indication met criteria for substantial benefit (n=0/4).

Conclusion: Few drugs approved by both agencies met the rigorous ESMO-MCBS:H criteria for substantial benefit. Recent approvals meeting substantial benefit criteria were not statistically correlated with approval agency, phase of trial utilized for approval, or biomarker selection of therapies. Drug approvals must balance proven benefit to access to innovative and new therapies.

#3569 Patient characteristics, treatment complications, and factors associated with inpatient outcomes and treatment burdens among CAR-T recipients: Insights from the 2021 National Inpatient Sample.

Simo Du[1], Yuqing Wang[2], Jiahao Peng[2], Junmin Song[1], Roha Memon[1], Hasiya Yusuf[1], Ruirong Yuan[3], Abhishek Kumar[1]

[1]Internal Medicine, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY,[2]Internal Medicine, Montefiore Medical Center, Bronx, NY,[3]Medical Oncology, East Orange VA Medical Center, Bronx, NY

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has transformed cancer treatment since FDA approval, with increasing utilization. Despite its potential, however, inpatient CAR-T therapy remains costly and is often complicated by cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS), leading to longer hospital stays and higher costs. Identifying factors influencing outcomes is critical for optimizing care and targeting therapy to appropriate populations.
Methods: We conducted a cross-sectional study using the 2021 National Inpatient Sample (NIS). CAR-T recipients and associated complications including CRS, ICANS, and hemophagocytic lymphohistiocytosis (HLH) were identified using ICD-10 codes. The Elixhauser comorbidity index was derived from 31 comorbidities. Weighted analyses were used to provide national estimates. Generalized linear models were used to assess factors influencing length of stay (LOS) and costs, and logistic regression was employed to evaluate mortality predictors.
Results: Among 6,666,752 weighted discharges, 525 CAR-T cases were identified, with 468 adult admissions analyzed, representing 2,340 national encounters. The mean age was 56.1 years; most patients were White (72.4%), male (64.1%), and admitted electively (76.1%). Non-Hodgkin lymphoma (NHL) was the most common diagnosis (65.6%), followed by Multiple Myeloma (19.7%). Hospitals were predominantly large (76.9%), private (78.6%) and teaching institutions (100%). Complications included CRS (61.3%), ICANS (8.3%), and HLH (1.1%). Median LOS was 14 days (IQR: 9-19) and median charges were $980,000 (range: $180,000-$1,700,000).Higher Elixhauser comorbidity scores were associated with increased mortality (OR 1.21 per point, $p < 0.01$), longer LOS (+1.6 days/10-point increase, $p < 0.01$), and higher costs (+$91,192/10-point increase, $p < 0.01$). CRS added 2.1 days to LOS ($p < 0.01$) and $255,634 to costs ($p = 0.003$). ICANS added 2.6 days to LOS ($p = 0.05$) but did not significantly affect mortality. Non-Hodgkin lymphoma increased LOS by 3.5 days ($p < 0.01$) and costs by $1,368,424 ($p < 0.01$). Medicaid patients experienced 4.1 more days of LOS ($p < 0.01$). Medium-sized hospitals increased LOS by 4.2 days ($p < 0.01$), and large hospitals by 2.0 days ($p = 0.02$).
Conclusions: Inpatient CAR-T therapy is associated with substantial complications, prolonged LOS, and high costs. Comorbidities, diagnosis and treatment-related complications, particularly CRS and ICANS, are primary drivers of resource utilization. Additionally, hospital size and insurance type also significantly influence outcomes. These findings highlight the need to address both clinical and non-clinical factors to optimize care delivery and patient outcomes for CAR-T therapy.

#3570 Impact of private equity ownership on quality of cancer care in U.S. hospitals.

Megan Worthington[1], Ruth Carlos[2]

[1]Touro College of Osteopathic Medicine, Middletown, NY,[2]Radiology, Columbia University, New York, NY

Introduction: This study examined the potential impact of private equity (PE) acquisitions on patient satisfaction in U.S. hospitals with cancer care centers. Given the growing trend of PE involvement in healthcare, we hypothesized that ownership changes could correlate with measurable declines in perceived quality of care.

Methods: From a national dataset of 5,395 Medicare-participating hospitals, we filtered to 2,405 facilities that met criteria for dedicated oncology services and comprehensive cancer care, including defined treatment facilities and national program affiliations. Using Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey data (2016-2023), which provides patient satisfaction scores on a 1-to-5-star scale, we analyzed satisfaction ratings for 118 hospitals acquired by PE to identify changes pre- and post-acquisition. Pitchbook provided insights into deal type, deal frequency, and financing status. Julius AI was utilized for analysis, with particular attention to deal structures and rating trends.

Results: Over half of the hospitals studied (51.7%) experienced declines in satisfaction ratings post-acquisition, with an average decrease of 0.061 stars. Bankruptcy and debt-related deals corresponded with more substantial declines (-0.318 and -0.095 stars, respectively), suggesting that financial pressures may directly or indirectly impact patient experiences. Comparatively, single-deal hospitals showed a mean decrease of 0.061 stars, with 56.7% reporting declines, versus 44.9% for multiple-deal hospitals, which showed a more stable rating profile. Although a weak negative correlation (-0.101) existed between multiple deals and rating stability, hospitals with three or more deals showed minimal fluctuation, possibly reflecting stronger organizational adaptation over time.

Conclusion: This analysis reveals a consistent trend: patient satisfaction ratings tend to decrease in a considerable portion of PE-owned hospitals, with variations based on deal type and structure. The findings underscore the need for ongoing evaluation of PE ownership models in healthcare, particularly as financial motivations intersect with patient-centered care priorities. These preliminary trends merit deeper investigation into the mechanisms through which PE acquisitions may influence hospital service quality, especially in oncology-focused settings where patient care and continuity are critical. This abstract was prepared with the assistance of generative AI (Julius AI) for data analysis.

#3571 Drivers of cancer genomics research productivity in high income countries (HICs) versus lower middle income countries (LMICs): Which interventions can help close the gap?.

R. Chown[1], G. Curtis[2], C. Quigley[2], N. Jansler[2], R. Jacome[2], R. G. Bristow[2], G. F. Njoroge[3], E. Njoki Mwangi Maina[4], D. C. Wedge[2]; [1]The Christie NHS Foundation Trust and The University of Manchester, Manchester, United Kingdom, [2]The University of Manchester, Manchester, United Kingdom, [3]Kenyatta University Teaching Research and Referral Hospital, Nairobi, Kenya, [4]The University of Nairobi, Nairobi, Kenya

Purpose: Productivity disparity exists in cancer research systems between High Income Countries (HICs) versus Lower-Middle-Income-Countries (LMICs). Capacity and productivity for cancer genomics research is an exemplar metric for overall cancer research capacity. Kenyan cancer genomics research capacity was used as a case study for an LMIC benchmarked against the HIC countries of the UK and USA. A conceptual framework was used to analyse drivers of productivity of cancer genomics research within institutions based on research environment resources. Preliminary recommendations which can help close the research productivity gap were then made.
Methodology: This research study was carried out by conducting sixteen semi-structured interviews with researchers based across the United Kingdom, United States, Australia, South Africa, and Kenya, and analysis of this qualitative data was then conducted via NVivo. Further primary research data was sought via surveying of genomics researchers and specific institutions based in case study countries. Secondary research was conducted through online and database searches, and in-depth literature reviews on cancer genomics research and global disparities in cancer research. We applied and considered 'The Matthew Effect', that relates to cumulative advantage, and theories of productivity.
Results: This study found that drivers of the productivity gap between national cancer research systems across HICs and LMICs can be attributed to interrelated factors within three key areas: Data and Technology, Funding and Partnerships, and Knowledge and Capacity Build. These are critical to the productivity and eventual impact of cancer research in a particular environment. This study identified that external context factors are as important as the drivers of research productivity, and that research needs to be context relevant and designed to be relative to the local environment.
Conclusions: This study concludes that The Matthew Effect is clearly observable within cancer research systems. Whilst this has amplified global disparity to date, the correct application of stated recommendations can change this trajectory and help close the gap to ultimately improve global progress and outcomes for comparative cancer research.

POPULATION SCIENCES: Cancer Disparities: Environmental, Microbiome, and Tumor Biology
Poster Session

#3576 Socio-environmental exposure leads to disparities in colorectal cancer mortality and tumor biology in metropolitan Detroit.

Natalie Gail Snider[1], R. Blake Buchalter[2], Theresa Hastert[1], Gregory Dyson[1], Carina Gronlund[3], Elena Stoffel[4], Laura Rozek[5], Ann Schwartz[1], Kristen Purrington[1]

[1]Oncology, Wayne State University School of Medicine, Detroit, MI,[2]Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH,[3]University of Michigan, Ann Arbor, MI,[4]Internal Medicine, University of Michigan Health System, Ann Arbor, MI,[5]Oncology, Georgetown University School of Medicine, Washington, DC

Non-Hispanic Black (NHB) patients face the highest colorectal cancer (CRC) mortality rates in the US, heavily influenced by social determinants of health (SDOH). Neighborhood quality, a key SDOH, impacts both socioeconomic factors and exposure to cancer-related environmental contaminants which has direct implications in tumor biology. Thus, in studying the role of environmental justice on health outcomes it is crucial to account for the separate and combinatory effects of environmental and socioeconomic burden. We expect socio-environmental exposures to increase the risk of CRC mortality among NHB patients, as well as alter tumor biology among those with the highest exposure. We utilized the Centers for Disease Control and Prevention's (CDC) comprehensive socio-environmental variable available at the census tract level called the Environmental Justice Index (EJI) to first compare social vulnerability (SVM), environmental burden (EBM), and their combined Social Environmental Score (SER) to the risk of CRC mortality by race. Patient data including census tract at diagnosis, demographics, and clinical features were obtained from the Metropolitan Detroit Cancer Surveillance System population-based cancer registry for 9727 Non-Hispanic White (NHW) and 3778 NHB invasive CRC cases. EJI variables were converted to quartile-level variables, and mortality risk was evaluated for quartile 4 (highest burden) compared to quartile 1 (lowest burden). Associations were tested via Cox Proportional Hazards regression. In nearly all models, EJI variables increased the risk of mortality. SVM showed stronger effects overall compared to EBM, and most models showed similar effects among race and age groups in both overall and cancer-specific mortality. A notable exception to this was that NHB early onset (EO) patients showed an elevated risk of cancer-specific mortality due to EBM (HR=1.98, 95% Confidence Interval (CI)=1.20-3.26, p=0.0071) compared to SVM (HR = 1.10, 95% CI = 0.61-2.00, p=0.75), and also compared to NHW EO EBM (HR=1.40, 95% CI=0.88-2.25, p=0.16) and NHW EO SVM (HR=2.12, 95% CI = 0.97-4.61, p=0.059). Additionally, we have noted that NHB patients are more likely to have KRAS mutations than BRAF, and comparative analyses are underway to compare molecular subtypes to exposure level. Our results suggest that environmental burden may play a role in racial disparities by age, and further analyses investigating the molecular implications of these exposures are needed to better understand the molecular mechanisms driving tumor progression and mortality disparities.

#3579 Racial disparity in microbial risk score for predicting subsequent risk of head and neck squamous cell cancer.

Soyoung Kwak[1], Chan Wang[1], Mykhaylo Usyk[2], Feng Wu[1], Steve C. Moore[3], Wen-Yi Huang[3], Caroline Y. Um[4], Martha J. Shrubsole[5], Qiuyin Cai[5], Huilin Li[1], Jiyoung Ahn[1], Richard B. Hayes[1]

[1]NYU Grossman School of Medicine, New York, NY,[2]Albert Einstein College of Medicine, Bronx, NY,[3]National Cancer Institute, Bethesda, MD,[4]American Cancer Society, Atlanta, GA,[5]Vanderbilt University Medical Center, Nashville, TN

Background: The association between oral bacteria and head and neck squamous cell cancer (HNSCC) risk has been investigated in recent years. Traditional approaches often explore individual microbes, overlooking the interaction and compositional profiles within microbial communities. We propose the use of a Microbial Risk Score (MRS) to examine the collective effects of bacterial communities in predicting HNSCC risk, with a focus on racial disparities.
Method: We conducted a prospective nested case-control study within 3 large US cohorts: the ACS-Cancer Prevention Study-II Nutrition Cohort, the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial, and the Southern Community Cohort Study. Among 159,840 cohort participants who provided oral wash samples, we selected HNSCC cases and their matched controls (2:1 frequency matching on cohort, age, sex, race/ethnicity, and time since oral wash sample collection) during a mean of 5.1 years of follow-up. Our study population included 440 White participants (149 HNSCC cases and 291 controls) and 222 Black participants (76 HNSCC cases and 146 controls). We characterized the oral bacterial microbiome using whole-genome shotgun sequencing. We explored the probability of MRS to predict HNSCC risk across different racial groups and at different p-value(p) thresholds for bacterial community selection. The MRS was calculated as a weighted sum of relative abundance of the selected bacterial species, with weights assigned according to their effect size determined via Analysis of Compositions of Microbiomes with Bias Correction. The association between MRS and HNSCC risk was estimated using logistic regression after adjusting for age, sex, cohort, smoking, drinking, and oral human papillomavirus 16 status.
Results: The MRS derived from Whites at $p<0.01$ yielded an OR in Whites of 1.38 (95% CI: 1.07-1.80) per 1 SD increase in the MRS, while this MRS yielded a weaker OR of 1.23 (0.86-1.75) in Blacks. The MRS derived from Blacks at $p<0.01$ yielded an OR of 1.54 (1.01-2.33) in Blacks, while it yielded a weaker OR of 1.19 (0.92-1.53) in Whites. Decreasing the stringency of bacterial community selection (e.g., to $p<0.20$) tended to yield overall stronger associations which were also more closely comparable for the counterpart racial groups; MRS derived from Whites at $p<0.20$ showed an OR of 1.74 (1.20-2.52) in Blacks, and the MRS derived from Blacks showed an OR of 1.39 (1.07-1.79) in Whites. These associations between MRS and HNSCC tended to hold for oral cavity, pharynx, and larynx, and were unrelated to tobacco and alcohol use.
Conclusion: Our findings suggest that while the MRS tends to perform better within racial groups, race-specific MRS do associate with disease risk in another racial group, particularly under less stringent selection of bacteria that comprise the score. The MRS offers a promising approach for HNSCC risk prediction across diverse racial groups.

#3580 Contemporary neighborhood redlining and racial mortgage lending bias and disparities in prostate cancer survival.

Wayne R. Lawrence[1], Neal D. Freedman[1], Jennifer K. McGee-Avila[1], Hyokyoung G. Hong[1], Scarlett L. Gomez[2], Andrew P. Loehrer[3], Kirsten M. M. Beyer[4], Yuhong Zhou[4], Jared W. Magnani[5], Harold W. Neighbors[6], Jarrett A. Johnson[7], Ziqiang Lin[8], Amy J. Davidoff[1], Adana A. M. Llanos[9], Meredith S. Shiels[1]

[1]National Cancer Institute, Bethesda, MD,[2]University of California San Francisco, San Francisco, CA,[3]Dartmouth-Hitchcock Medical Center, Lebanon, NH,[4]Institute for Health & Equity, Medical College of Wisconsin, Milwaukee, WI,[5]Department of Medicine, University of Pittsburgh School of Medicine, Pittsburgh, PA,[6]School of Public Health, University of Michigan, Ann Arbor, MI,[7]Division of Community Health and Population Science, National Institute on Minority Health and Health Disparities, Bethesda, MD,[8]School of Medicine, Jinan University, Guangzhou, China,[9]Department of Epidemiology, Columbia University, New York, NY

Introduction: Mortgage lending bias (based on property location or applicant's race) is a critical driver of residential segregation and may contribute to inequities in cancer survival. We investigated the association between contemporary redlining and racial mortgage lending bias and prostate cancer survival among Medicare-insured men.
Methods: This cohort study used the Surveillance, Epidemiology, and End Results (SEER)-Medicare database that included 34,163 non-Hispanic Black (13%) and White (87%) men diagnosed with prostate cancer between 2010-2013 and followed-up through 2019. Home Mortgage Disclosure Act data (2010-2017) were used to calculate census-tract (1) redlining index (odds of a mortgage application denial for a property in a local area, compared with all properties within the same metropolitan statistical area) and (2) racial lending bias index (odds of a mortgage application denial for a Black applicant, compared to a White applicant for a property in the local area). Both indices were assessed continuously and categorically (low (<1), moderate (1-<2), or high (≥2)). Multivariable-adjusted Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (95%CIs) for prostate cancer-specific and all-cause mortality.
Results: 44.6% of Black and 7.4% of White men lived in high redlined neighborhoods; 60.3% of Black and 63.7% of White men lived in neighborhoods with high racial lending bias. In the overall cohort, as the redlining index increased, men experienced poorer prostate cancer survival. Compared to those residing in low redlined neighborhoods, those in high redlined neighborhoods had an increased risk of prostate cancer-specific (HR=1.21; 95%CI 1.03-1.42) and all-cause (HR=1.25; 95%CI 1.17-1.34) mortality. Associations between redlining and all-cause mortality were observed among both Black (HR=1.14; 95%CI 1.03-1.26) and White (HR=1.30; 95%CI 1.19-1.43) men. Among White men, compared with those residing in low racial lending bias neighborhoods, those in high racial lending bias neighborhoods had an increased risk of all-cause mortality (HR=1.11; 95%CI 1.03-1.21).
Conclusions: Neighborhood redlining was associated with poorer prostate cancer survival in the overall population. However, the association between neighborhood racial lending bias and elevated mortality was only observed among White men. Findings suggest mortgage lending discrimination may contribute to inequities in prostate cancer survival through shaping neighborhood health conditions.

#3581 Psychosocial factors associated with lung cancer incidence and survival among individuals with low income in the Southeastern U.S..

Anna Junkins[1], Jennifer Richmond[2], Douglas DeMoulin[1], Xijing Han[1], Heather Munro[1], Martha J. Shrubsole[1], Wei Zheng[1], Xiao Ou Shu[1], Melinda C. Aldrich[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Wake Forest University School of Medicine, Winston-Salem, NC

Background: Lung cancer is the leading cause of cancer-related mortality in the U.S. and significant racial inequities exist. Psychosocial factors, including stressful life experiences, have been linked to increased incidence and poorer outcomes. The purpose of this study was to identify psychosocial factors associated with lung cancer incidence and survival among a low-income, racially diverse population in the U.S. South.

Methods: We utilized data from the Southern Community Cohort Study (SCCS), a large, prospective study across 12 Southeastern states, enrolling participants from 2002-2009, to examine psychosocial factors and lung cancer incidence and survival. Incident cancers and deaths were identified by linkage with state cancer registries and the National Death Index, respectively. Individual-level social, behavioral, and medical history information was ascertained at baseline via questionnaire. We examined depression, spirituality, attendance at faith-based services, social support, and use of anti-depressant/anxiety medication. We also analyzed data from a subset of participants who responded to psychosocial questions collected on a follow-up survey. We used Cox regression analyses to identify factors associated with lung cancer incidence and survival overall and by race.

Results: Among 74,295 SCCS participants, approximately 69.8% self-reported as Black persons, 58.4% female, and 56.3% had an annual household income below $15,000. There were 1,569 incident lung cancer cases identified, of whom, almost half (49.2%) were diagnosed at distant stage. Overall, lower spirituality was associated with a reduced risk of lung cancer. Among Black participants, identifying as “fairly” vs. “very” spiritual was associated with a 15% lower risk (HR: 0.85; 95% CI: 0.74-0.97); a similar pattern was observed among White participants but was not statistically significant. Similar patterns were observed with mortality. In subset analyses among 367 participants with lung cancer, depression and less frequent attendance at faith-based services were associated with greater mortality. Among Black participants, those with depression had 2.75-fold greater mortality (95% CI:1.11-6.84) compared to those without depression, and those who attended faith-based services at least once per week had 50% lower mortality compared to those who attended less than once per week (HR: 0.50; 95% CI: 0.30-0.83). Among White participants, identifying as “slightly/not at all” vs. “very” spiritual was associated with 4.31-fold greater mortality (95% CI: 1.47-12.66).

Conclusions: Psychosocial factors and spirituality may play a role in inequities observed in lung cancer outcomes. Future research should investigate how psychosocial factors may impact lung cancer outcomes.

#3582 Lung cancer screening in breast cancer survivors: a comparison of the USPSTF guidelines and risk-based criteria.

Baitong Wang[1], Marissa Michael[1], Justin Lee[2], Yiwey Shieh[1], Lauren Groner[1], Leah M. Backus[2], Allison W. Kurian[2], Rulla M. Tamimi[1], Summer S. Han[2], Eunji Choi[1]

[1]Weill Cornell Medicine, Cornell University, New York, NY,[2]Stanford School of Medicine, Stanford University, Palo Alto, CA

Introduction: Improved survival rates among breast cancer survivors highlight the need to address long-term health risks, including second primary cancers. Second primary lung cancer (SPLC) is the second most common second primary cancer among breast cancer survivors and is associated with high mortality. However, the optimal approach for identifying high-risk breast cancer survivors to be surveilled for SPLC remains uncertain. This study seeks to fill this gap by comparing the US Preventive Services Task Force (USPSTF) criteria for lung cancer screening vs. a risk-based criteria leveraging a SPLC risk prediction model tailored for breast cancer survivors.

Methods: We analyzed 5,563 patients diagnosed with initial primary breast cancer (IPBC) in 1993-2014 from the PLCO Cancer Screening Trial. SPLC was defined as a primary lung cancer occurring at least six months after the IPBC. We utilized cause-specific Cox regression to build a prediction model for 5-year SPLC risk in breast cancer survivors, informed by existing literature and the Bayesian information criterion for model parsimony. Predictive accuracy was assessed through discrimination using the area under the curve (AUC) and calibration via plots derived from 200 bootstrapped samples. We compared the risk-stratification ability of the USPSTF and risk-based criteria for SPLC screening using the Aalen-Johanssen estimator.

Results: In a cohort of women with breast cancer (mean age at diagnosis: 71 years; stages: in situ [20.7%], localized [58.8%], regional/distant [18.5%]), 91 individuals (1.6%) developed SPLC over 108,783 person-years of follow-up. The SPLC risk model exhibited strong discrimination (AUC: 0.86 [95% CI, 0.79-0.92]) and good calibration in internal validation. Key model features included risk-decreasing factors (hysterectomy, menopausal hormone therapy, BMI, ibuprofen use) and risk-increasing factors (prior cancer, liver comorbidities, smoking-related factors). The stratification by a predicted risk threshold of ≥2% (90th percentile) showed that the observed incidence of SPLC was higher in high vs. low-risk groups (8.7% vs. 0.8%), surpassing the stratification performance of the USPSTF criteria (6.6% vs. 0.7%) when comparing eligible and ineligible subgroups.

Conclusions: We developed an SPLC risk model tailored for breast cancer survivors. Although the USPSTF criteria showed reasonable risk stratification in SPLC risk, the risk-based approach provided superior performance. This method provides a promising strategy for identifying high-risk breast cancer survivors for SPLC who may benefit from low dose computed tomography screening. Given the potential value of integrating breast cancer screening with effective lung cancer screening strategies, breast cancer survivors could serve as a model to advance early detection of lung cancer during routine surveillance.

#3583 The Breast Cancer Risk Prediction Project: a resource of 1.8 million women with diverse backgrounds from 20 prospective cohorts to improve breast cancer risk prediction and advance breast cancer epidemiology.

Peter Kraft[1], Laura Beane-Freeman[1], Julie Palmer[2], Ellen O'Meara[3], Jeanine Genkinger[4], James Lacey[5], Thomas Rohan[6], Lauren Teras[7], Marian L. Neuhouser[8], Kala Visvanathan[9], Celine Vachon[10], Roger Milne[11], Christopher Haiman[12], Yu Chen[13], Heather Eliassen[14], Cari Kitahara[1], Katie O'Brien[15], Emily White[8], Garnet Anderson[8], I-Min Lee[14], Archie Campbell[16], Renee Fortner[17], Ylva Lagerros[18], Sven Sandin[18], Mia Gaudet[1], Montserrat Garcia-Closas[19], Nilanjan Chatterjee[9]

[1]National Cancer Institute, Rockville, MD,[2]Boston University, Boston, MA,[3]Kaiser Permanente Washington Health Research Institute, Seattle, WA,[4]Columbia University, New York, NY,[5]City of Hope, Duarte, CA,[6]Albert Einstein College of Medicine, Bronx, NY,[7]American Cancer Society, Atlanta, GA,[8]Fred Hutchinson Cancer Center, Seattle, WA,[9]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[10]Mayo Clinic, Rochester, MN,[11]Cancer Council Victoria, Melbourne, Australia,[12]Keck School of Medicine of the University of Southern California, Los Angeles, CA,[13]NYU Grossman School of Medicine, New York, NY,[14]Harvard T.H. Chan School of Public Health, Boston, MA,[15]National Institute of Environmental Health Sciences, Research Triangle, NC,[16]University of Edinburgh, Edinburgh, United Kingdom,[17]Cancer Research of Norway, Oslo, Norway,[18]Karolinska Institutet, Stockholm, Sweden,[19]Institute of Cancer Research, Sutton, United Kingdom

Breast cancer risk assessment tools are widely used in clinical practice to guide decisions regarding screening timing and modality, lifestyle interventions, genetic testing, preventive therapy, and risk-reducing surgery. Although a number of tools designed for the general population are used in practice, they face a series of challenges including: (i) modest discriminatory ability due to lack of a unified model that flexibly incorporates a comprehensive set of risk factors; (ii) inability to produce subtype-specific risk estimates, relevant for tailoring screening and/or preventive strategies (e.g. prophylactic endocrine therapy that is effective only for hormone receptor positive tumors); (iii) lack of data from diverse populations to build models that work well for all women; and, (iv) scarcity of opportunities for comparative validation of different models. The Breast Cancer Risk Prediction Project (BCRPP), a collaboration currently including 20 prospective cohorts from the National Cancer Institute's Cohort Consortium, is addressing these challenges by harmonizing, sharing, and analyzing data on over 1.8 million women, over 115,000 of whom have developed breast cancer. The BCRPP is developing a comprehensive tool that will predict breast cancer risk, overall and by subtypes, across major racial and ethnic groups in the United States. This tool incorporates known and emerging risk factors (e.g. reproductive history, anthropometry, smoking, alcohol intake, medication use, mammography, family history, and measured genotypes). In parallel to model building and validation efforts, BCRPP investigators are developing privacy-preserving web and mobile interfaces to deliver the risk tools to patients and clinicians. Here we present descriptive data on participating cohorts (e.g. dates of enrollment, ages at enrollment, length of follow up, numbers of cases by subtype), summarize missing data patterns and our approach to model development and validation that accounts for heterogeneity in missingness patterns across cohorts, and describe data governance procedures and data sharing infrastructure (including pooled and federated analyses, to account for policy limitations on sharing individual data). Descriptive information and procedures for requesting and accessing data are available via the BCRPP data platform (https://epidataplatforms.cancer.gov/bcrpp/). Although originally assembled for risk model development, these data on a large and diverse sample of women with extensive harmonized risk factors and covariates can be a resource to address other outstanding questions in breast cancer epidemiology across time, the lifecourse, and diverse populations.

#3584 Artificial intelligence-derived body composition measurements reveal sex- and metformin-specific predictors of overall survival in non-small cell lung cancer.

Xinan Wang[1], Akinori Hata[2], Noriaki Wada[3], Yi Li[4], Mark Schiebler[5], Hiroto Hatabu[3], David Christiani[6]

[1]Harvard T.H. Chan School of Public Health, Boston, MA,[2]Radiology, Osaka University, Osaka, Japan,[3]Radiology, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[4]Biostatistics, University of Michigan, Ann Arbor, MI,[5]Radiology, University of Wisconsin, Madison, WI,[6]Pulmonary & Critical Care Medicine and Cancer Center, Massachusetts General Hospital, Boston, MA

Background: Body composition (BC) is emerging as a prognostic factor in cancer, with metformin showing potential anti-tumor effects in overweight/obese patients with non-small cell lung cancer (NSCLC). However, the sex-specific impact of BC on overall survival (OS), its underlying mechanisms, and relationship to metformin's beneficial effects remain unclear.
Methods: A total of 1,275 patients with NSCLC were included. Six AI-derived BC measurements were extracted from chest CT scans: muscle density and volume, visceral (VAT) and subcutaneous adipose tissue (SAT), VAT/SAT ratio, and intra-muscular adipose tissue (IMAT). Clinical data included age, sex, histology, stage, smoking status, diabetes, metformin use, and BMI. Multivariable Cox proportional hazard model was used to assess the associations with OS. Correlations between BC and eight circulating inflammatory cytokines were evaluated in a subset of 93 patients and BMI-related mutation profiles were compared in an independent cohort of 5,363 patients with NSCLC.
Results: Sex-specific distributions showed significantly higher muscle volume, density, VAT, and VAT/SAT ratio in males, while females had higher SAT and IMAT. Higher muscle volume is associated with prolonged OS (HR = 0.71, T3 vs. T1 and HR = 0.78, T2 vs. T1, $P < 0.01$). In females, higher muscle density was associated with prolonged OS (HR = 0.76, T3 vs. T1, $P = 0.04$), while higher IMAT correlated with shortened OS (HR = 1.39, T3 vs. T1, $P = 0.01$). In males, increased VAT and SAT tended to associate with prolonged OS. Higher SAT (HR = 0.48, 0.42 for T3 and T2 vs. T1, $P = 0.02$ and 0.01) and IMAT (HR = 0.52, 0.42 for T3 and T2 vs. T1, $P = 0.04$ and 0.01) predicted prolonged OS specifically in metformin users, but not in diabetic non-metformin users. Cytokine analysis showed positive correlations between VAT, SAT, IMAT and leptin in both sexes, while IMAT positively correlated with IL-8 and MCP-1, and muscle density negatively correlated with leptin and IL-8 in females. *EGFR* mutation was significantly less frequent and *KRAS* mutations more frequent in patients with BMI > 25, particularly in females. Mutation analysis revealed lower EGFR and higher KRAS mutation frequencies in patients with BMI > 25, particularly in females. Mutations in metabolism and immune response genes (STK11, NF1, ATM, and SMARCA4) showed reversed sex-specific trends related to BMI, suggesting obesity may drive distinct mutation selection and immune responses between sexes.
Conclusions: AI-derived BC measurements revealed sex-specific associations with OS in NSCLC, supported by distinct patterns in circulating cytokines and somatic mutations. Metformin's beneficial effects were specifically associated with adipose tissue measurements, suggesting its anti-tumor activity may be mediated through metabolic and immunomodulatory pathways.

#3585 Persistent poverty and late-stage breast cancer diagnosis in the United States: Impacts of rurality, race, and time within Surveillance, Epidemiology, and End Results (SEER) registries, 2004 to 2021.

H. R. Sherr[1], A. Soliman[2], K. A. Bertrand[3], K. A. Hirko[4];

[1]Boston University School of Public Health, Boston, MA, [2]City University of New York School of Medicine, New York, NY, [3]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, [4]Michigan State University College of Human Medicine, Traverse City, MI

Background: County-level poverty is associated with late-stage breast cancer (BC) diagnosis, though the effects of persistent poverty (>20% residents in poverty for 30+ years) are unclear. Persistent poverty's role may also vary by rurality, race, and over time.

Methods: We analyzed county-level data from the Surveillance, Epidemiology, and End Results (SEER) Program for females (ages 20-74 years) diagnosed with late-stage (regional and distant) BC from 2017-2021 (excluding 2020). We estimated mean rate differences (RDs) in late-stage BC between persistently poor (n = 156) and non-persistently poor (n = 923) counties using multivariable linear regression. Models were adjusted for age, current poverty, race, lack of insurance, unemployment, and educational attainment using data from the American Community Survey (ACS) between 2017 and 2021. We stratified results by rurality (rural vs. urban based on Rural-Urban Continuum Codes) and race (≥ 5% vs. < 5% Non-Hispanic Black). Joinpoint regression was used to estimate annual percent change (APC) in BC stage at diagnosis rates from 2004-2019 according to persistent poverty status and rurality.

Results: Age-adjusted late-stage BC rates were higher in persistent poverty compared to non-persistent poverty counties (RD = 5.78 per 100,000 person-years, 95% CI = 2.46, 9.10). Differences in late-stage BC rates by persistent poverty status were similar in rural and urban counties but elevated in counties with larger non-Hispanic Black populations. Associations were attenuated in adjusted models (overall RD = 3.22, 95% CI = -1.13, 7.56). However, fully adjusted late-stage BC diagnosis rates were higher in persistently poor counties with small non-Hispanic Black populations (RD = 8.32, 95% CI = 1.39, 15.26).

Overall rates of breast cancer diagnosed at the distant stage increased from 2004 to 2010 (APC = 2.01, 95% CI = 1.09, 4.87) and have remained constant since (APC = 0.04, 95% CI = -1.65, 0.52). The rise in distant BC was driven by counties characterized by persistent poverty (APC = 1.79, 95% CI = 0.95, 2.62) and rurality (APC = 1.78, 95% CI = 0.68, 2.87). Regional breast cancer rates declined from 2004-2017 (APC = -1.05, 95% CI = -2.04, -0.74), but have been rising since (APC = 1.57, 95% CI = -0.93, 3.02).

Conclusions and Implications: Late-stage BC diagnosis rates were elevated in persistent poverty counties, but the difference was reduced after adjusting for current poverty. Rates of distant BC have risen over time, particularly in persistent poverty and rural counties. Efforts to alleviate the burden of poverty and address barriers to screening are needed to promote early BC detection, particularly in medically underserved areas.

#3586 Fusobacterium nucleatum presence and colorectal cancer-specific mortality in a racially and ethnically diverse patient population.

Nicole C. Lorona[1], Scott D. LaBrie[2], Claire E. Thomas[2], Hang Yin[2], Jeroen Huyghe[2], Conghui Qu[2], Sushma Thomas[2], Sosun Nayemi[2], Hamza Ammar[2], Orsalem Kahsai[2], Li Hsu[2], Diana Redwood[3], Li Li[4], Christopher I. Li[2], Ulrike Peters[2], Timothy K. Thomas[3], Amanda I. Phipps[2], Jane C. Figueiredo[1], Meredith Hullar[2]

[1]Department of Medicine, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]Alaska Native Tribal Health Consortium, Anchorage, AK,[4]Ochsner Clinic Foundation, New Orleans, LA

Purpose: There are persistent racial and ethnic disparities in colorectal cancer (CRC) mortality. We examine the association between prevalence of *Fusobacterium nucleatum* (Fn) in tumor tissue and CRC-specific mortality in a diverse population.
Methods: The present study includes 569 African American, Alaska Native, Latinx, and non-Hispanic White adults with stage I-III CRC who were part of the Translational Research Program in Colorectal Cancer Disparities (TRPCD). 188 patients with CRC who died of CRC were matched to 381 patients with CRC who did not die of CRC. Genomic DNA was extracted from colorectal tumor tissue samples. Droplet digital polymerase chain reaction (ddPCR) was used to analyze 1) the nusG gene from Fn (Fn(nusG)), and 2) the SLCO2A1 gene as a housekeeping (HK) gene reference from the human genome. Fn(nusG) positive droplet counts were normalized by HK gene positive droplet counts for each duplicated assay, and then averaged. Fn(nusG) prevalence was analyzed as a dichotomous variable in primary analyses (not present, present) and as a categorical variable (not present, low prevalence, high prevalence). The median normalized average Fn(nusG) count among those with Fn(nusG) present was the cut-point between low and high prevalence. We fit logistic regression models for the association between Fn(nusG) presence and CRC-specific mortality, adjusted for matching factors (age at diagnosis, year of diagnosis, sex, stage, tumor site, race and ethnicity). Effect modification by age, sex, stage, tumor site, and racial and ethnic group was assessed using a likelihood ratio test.
Results: Fn(nusG) was present in tumors for 24% of patients with CRC who died of CRC (N=46) and 16% of patients with who did not die of CRC (N=61). Presence was lower in patients who were Alaska Native (14%), with stage I CRC (12%), and with rectal cancer (16%), and higher in those diagnosed in 2011-2017 (22%). Presence of Fn(nusG) was associated with a higher odds of CRC-specific mortality (OR: 1.76; 95% CI: 1.12-2.74), relative to no presence of Fn(nusG), after adjustment for matching factors. Estimates for the association between low prevalence (OR: 1.77; 95% CI: 0.97-3.21) and high prevalence (OR: 1.74; 95% CI: 0.95-3.14), relative to no presence of Fn(nusG), and CRC-specific mortality were similar. Further analysis is underway.
Conclusions: These findings provide evidence of an association between presence of fusobacterium in CRC tumor tissue and CRC-specific mortality in a diverse population. As the association did not differ by low or high prevalence of fusobacterium, any amount of fusobacterium in CRC tumor tissue may confer poorer prognosis. Fusobacterium may contribute less to CRC-specific mortality in Alaska Native patients with CRC. Identifying microbiota associated with CRC mortality can inform targeted interventions to address racial and ethnic disparities in this disease.

#3587 Identifying clinical and lifestyle factors which mediate the association between socioeconomic status and colorectal cancer mortality.

Shaneda Warren Andersen[1], Thomas Lawler[1], Oluwatoyosi Ogunmuyiwa[1], Rida A. Khatri[1], Mark Steinwandel[2], Martha Shrubsole[2]

[1]University of Wisconsin-Madison, Madison, WI,[2]Vanderbilt University Medical Center, Nashville, TN

Background: Higher socioeconomic status (SES) is associated with lower mortality risk for people with colorectal cancer (CRC) and contributes to geographic and racial disparities for CRC. However, the factors that mediate the association between SES and CRC mortality have not been comprehensively investigated. We performed a mediation analysis to identify clinical and lifestyle- factors that may mediate the association between household income as a proxy for SES with overall, and CRC-specific mortality in a longitudinal cohort where most participants are non-Hispanic Black with lower SES.

Methods: Data arise from 1,038 participants of the Southern Community Cohort Study (SCCS) who developed incident CRC after enrollment. Participants were aged 40-79 years at enrollment between 2002-2009; 73% self-identify as having Black racial identity. Annual household income was assessed via questionnaire at enrollment and 59% of the cohort had household income < $15,000/year. Overall and CRC-specific mortality were determined via linkages to the National Death Index through December 31, 2020. Proportional hazards models were used to estimate hazard ratios (HRs) with 95% confidence intervals (CIs) for mortality outcomes by income level, adjusted for age, sex, and marital status. Mediation analysis was used to estimate the indirect effect of stage, healthcare-related factors (CRC screening, insurance, and surgical resection) and lifestyle-related factors (smoking status, pack years smoked, alcohol consumption, diabetes duration, diet, and physical activity) on mortality, expressed as a percentage of the association between income and mortality attributable to the mediator.

Results: Income ≥ $15,000/year was associated with lower risk for mortality, however associations were more apparent in White participants (all-cause: mortality HR 0.44, CI: 0.29-0.67; CRC-specific HR: 0.43, CI: 0.24-0.76) than Black participants (all-cause: HR 0.76, CI: 0.62-0.94; CRC-specific: HR: 0.81, CI: 0.62-1.05). Stage at diagnosis and completing surgical resection were the largest mediation factors accounting for 35% of the association between income and CRC-specific mortality among white participants and 20% of the association among Black participants. Results were similar for overall mortality. For participants identifying as Black, history of and pack-years of smoking mediated an additional 28% of the association. For White participants, smoking and the other lifestyle-related factors did not mediate the association between income and mortality outcomes.

Conclusions: Higher income is associated with lower risk for mortality after CRC diagnosis. However, the factors that mediate the association may differ by self-reported race. Interventions to promote early detection of CRC and equitable access to curative surgery may help to mitigate CRC disparities related to SES.

#3588 Modifiable factors associated with survival among a racially diverse and low-income population with prostate cancer.

Sobia T. Siddiqui[1], Martha J. Shrubsole[1], Heather Munro[1], Xijing Han[1], Francesca Kolitsopoulos[2], Julia S. Perkins[3], Leo J. Russo[4], Loren Lipworth[1], Wei Zheng[1]

[1]Epidemiology, Vanderbilt University Medical Center, Nashville, TN,[2]Pharmacoepidemiology and Safety, Gilead Sciences, New York, NY,[3]Oncology and Hematology, Pfizer, New York, NY,[4]Epidemiology, Pfizer, New York, NY

Background: Prostate cancer is the most diagnosed cancer among men in the United States and is the second leading cause of cancer-related deaths. Black men have the highest incidence and mortality rates compared to all other racial or ethnic groups and these disparities are not fully understood.
Objective: In this study, we aim to investigate various sociodemographic, lifestyle, health and dietary factors that might be associated with survival in men diagnosed with prostate cancer within a study designed to evaluate cancer health disparities.
Methods: The Southern Community Cohort Study is a prospective cohort study of 34,313 adult men recruited between 2002 and 2009, with a focus on Black individuals and those with low socioeconomic status. At recruitment, a baseline questionnaire was administered to assess sociodemographic and lifestyle factors. Participants were followed over time by linkages to state cancer registries for cancer diagnosis and the National Death Index for death. Chi-squared and ANOVA tests examined associations between baseline characteristics and racial group. Cox proportional hazards regression models were used to assess relationships between covariates and survival, calculating hazard ratios for overall survival with 95% confidence intervals.
Results: Our study included 1,367 men with prostate cancer of whom 350 died, including 291 Black and 59 White men. Only current cigarette smoking was associated with increased risk of mortality among both Black (HR= 2.22, 95% CI=1.57-3.14) and White (HR= 4.09, 95% CI=1.56-10.75) men in comparison to never-smokers and only higher intake of added sugars was associated with reduced risk among both Black (HR=0.66, 95% CI=0.46-0.96) and White men (HR=0.31, 95% CI: 0.13-0.89). Among Black men only, diabetes history (HR=1.58, 95% CI=1.17-2.14) was associated with an increased risk of mortality and hypercholesterolemia (HR=0.74, 95% CI=0.55-0.99) was associated with decreased risk. Among White men only, living in an area of highest deprivation (HR=3.12, 95% CI=1.18-8.27) and consuming higher quantities of red meat (HR=3.66, 95% CI=1.37-9.73) were associated with increased risk of death and higher intake of whole grains (HR=0.34, 95% CI=0.15-0.76) was associated with a decreased risk.
Conclusion: Our study identified an increased risk of mortality in men with prostate cancer associated with several modifiable lifestyle, health and dietary factors. Although not all these factors were associated with increased risk among both Black and White men, differing lifestyle behaviors based on race highlight the need for studies to better understand mortality risk. However, cigarette smoking was strongly associated with risk for all groups, thus, tobacco cessation should be considered for men with prostate cancer. These findings highlight the need for targeted interventions to address disparities in outcomes in men with prostate cancer.

#3589 Serum organochlorine insecticide concentrations and risk of aggressive prostate cancer.

D. A. Tadesse[1], L. M. Hurwitz[1], R. B. Biritwum[2], Y. Tettey[2], A. Adjei[2], E. Tay[2], A. Sjodin[3], R. Jones[3], M. Davis[3], F. Menegaux[4], M. Abubakar[1], E. A. Akpakli[5], K. Klufio[5], J. E. Mensah[2], S. Berndt[1], S. Koutros[1];
[1]National Cancer Institute, Rockville, MD, [2]University of Ghana Medical School, Accra, Ghana, [3]Centers for Disease Control and Prevention, Atlanta, GA, [4]Universite Paris-Saclay, Villejuif, France, [5]Korle Bu Teaching Hospital, Accra, Ghana

Introduction: Prostate cancer is one of the leading causes of cancer morbidity and mortality among men worldwide, with heightened rates in Western, Central and Southern Africa, and the Caribbean. Although few risk factors have been identified, studies have shown positive associations with exposure to persistent organochlorine pesticides (OCPs) and aggressive prostate cancer. Few studies have yet been conducted in Africa despite the greater burden of prostate cancer and continued OCP use for vector control. Here we described predictors of serum levels of OCPs in 300 prostate cancer cases and 300 population-based controls from Ghana.
Methods: Serum concentrations of three DDT (dichlorodiphenyltrichloroethane) metabolites were measured: p,p'-dichlorodiphenyldichloro-ethylene(pp'-DDE), p,p'-dichlorodiphenyltrichloroethane(pp'-DDT), and o,p'-dichlorodiphenyltrichloroethane(op'-DDT). Chi-Square tests were used to examine the relationship between quartiles of DDT and demographic/lifestyle factors in controls. Levels were reported in cancer cases by clinical factors, including high-grade (Gleason≥8) and advanced stage (T3 or T4) disease.
Results: Among 300 controls, the geometric means (and percent detected) of pp'-DDE, pp'-DDT, and op'-DDT were at 737.6 ng/g lipid (99.7% detect), 48.4 ng/g lipid (95.6% detect), and 16.7 ng/g lipid (45.3% detect), respectively. Increasing BMI was associated with higher serum levels of pp'-DDE and pp'-DDT (chi-square p-value=0.064 and 0.002, respectively). Among prostate cancer cases, higher mean levels of pp'-DDE were observed in men with high-grade compared to low-grade disease (1109.3 ng/g lipid vs. 760.4 ng/g lipid, p-value=0.038) and in men with advanced disease (1139.2 ng/g lipid vs. 838.7 ng/g lipid, p=value=0.028).
Conclusion: OCPs are a class of insecticides that are banned in most countries due to their slow degradation and ability to bioaccumulate. Measurable levels of DDT were abundant in serum samples in men from Ghana (pp'-DDE =737.6 ng/g lipid vs. 262 ng/g lipid and nondetectable op'-DDT in Black men in the U.S. as reported by the 2003-2004 National Health and Nutrition Examination Survey), suggesting ongoing exposure. Consistent with reports that DDT is highly fat soluble, higher BMI was associated with higher serum concentrations. Serum levels of pp'-DDE were higher for those with aggressive prostate cancer, offering evidence of a plausible link between exposure and aggressive prostate cancer risk in Africa. Results from the ongoing case-control analysis will be presented.

#3590 Survival among individuals diagnosed with cancer during the COVID-19 pandemic in the United States.

Chenxi Jiang, Xuesong Han, Ahmedin Jemal, Hyuna Sung

American Cancer Society, Atlanta, GA

Background: The COVID-19 pandemic has impacted cancer outcomes, but research on its impact on survival outcomes, especially cause-specific death across different cancer types and socioeconomic factors, is limited.
Methods: Individuals diagnosed in 2019 and 2020 with one of 14 types of cancer at ages 20-89 in 17 Surveillance, Epidemiology, and End Results registries were included. We used Cox proportional hazards model to compare the risk of death from all causes, cancer, and COVID-19 within the first year of diagnosis between cases from 2020 vs 2019, adjusting for demographic factors and socioeconomic status. Additionally, for 2020 cases, Cox models were used to identify risk factors for COVID-19, cancer, and all causes death.
Results: Compared to 2019 cases (N=274,605), 2020 cases (N=248,840) had a higher risk of death from all causes and COVID-19 for each of the 14 types of cancer, while increased risks of cancer-specific death were limited to cases with 8 of 14 cancer types. Highest hazard ratios (HRs) were estimated among those with cancers of the thyroid (HR=1.57, 95%CI: 1.42-1.72) and prostate (HR=1.51, 95% CI:1.44-1.58) for all-cause death; among those with leukemia (HR=11.42, 95%CI: 6.31-20.64) and lung (HR=6.58, 95%CI:5.02-8.62) cancers for COVID-19 death; and among those with colorectal (HR=1.15, 95%CI:1.10-1.20) and breast (HR=1.12, 95%CI:1.04-1.21) cancers for cancer-specific death. Among 2020 cases, cancer-specific death and Covid-19 death showed distinct patterns in racial/ethnic and urban/rural disparities (Table 1). Specifically, individuals living in large metropolitan areas and those identifying as Hispanic were found to be at higher risk of death from COVID-19, but not from cancer.
Conclusion: The Covid-19 pandemic's impact on survival of individuals with cancer varied by cause of death, cancer type, and socioeconomic factors, highlighting the need for targeted healthcare interventions to ensure equitable care and reduced mortality.

Table 1: Association of patients characteristics with the risk of death from all-cause, cancer-speci

Risk factors (reference group)	All-cause Adjusted HR (95% CI)	cancer-specific Adjusted HR (95% CI)	covid-related Adjusted HR (95% CI)
Age (ref: 20-39 y)			
40-49 y	1.35 (1.25-1.45)	1.71 (1.50-1.96)	1.51 (0.74-3.09)

#3591 Global burden and trends in cancer incidence and mortality among young adults.

Kieran Patrick Kelly[1], Yejun Son[2], Nikita Sandeep Wagle[1], Dong Keon Yon[2], Ahmedin Jemal[1], Hyuna Sung[1]

[1]Surveillance & Health Equity Science, American Cancer Society, Atlanta, GA,[2]Kyung Hee University College of Medicine, Seoul, Korea, Republic of

Background: Increasing cancer incidence among young adults has been reported for several types of cancers, primarily in certain high-income countries. However, there is a lack of comprehensive examination of the global burden and trends in cancer incidence and mortality among young adults.

Methods: We presented estimated numbers of cancer cases, cancer deaths, age-standardized incidence, and mortality rates per 100,000 people among young adults (YAs, ages 25-49 years) for all cancers combined and 35 cancer sites in 185 countries and 20 UN regions using GLOBOCAN 2022. We further quantified trends in age-standardized incidence (ASIR; 52 countries) and age-standardized mortality (ASMR; 62 countries) for the top five incident cancers (female breast, cervix uteri, thyroid, colorectum, and trachea, bronchus and lung cancers) among YAs over the most recent decade by estimating average annual percent change (AAPC), using the Cancer Incidence in Five Continents (CI5; 2008-2017) and WHO mortality data (2011-2020; thyroid mortality data was not available), respectively.

Results: In 2022, an estimated 2.9 million cancer cases and 962,000 cancer-related deaths occurred in YAs worldwide, corresponding to 108.1 cases per 100,000 people per year and 35.9 deaths per 100,000 people per year. Globally, ASIR and ASMR were higher in women than men (143.7 vs. 73.5 for incidence; 40.0 vs. 32.0 for mortality). By UN region, ASIR per 100,000 people was highest in Australia-New Zealand (185.7) and lowest in South Central Asia (72.5), while ASMR per 100,000 was highest in Eastern Africa (55.9) and lowest in Northern Europe (21.9). For the most recent 10 years, increases in ASIRs were observed for thyroid cancer (AAPC, 2.5-19.6%) in 27 countries, for colorectal cancer (AAPC, 1.2-11.5%) in 20 countries, for female breast cancer (AAPC, 0.7-5.9%) in 17 countries, and for cervix uteri cancer (AAPC, 1.8-15.7%) in 4 countries. Increases in ASMR were observed for colorectum cancer (AAPC, 0.6-8.0%) in 13 countries, for female breast cancer (AAPC, 0.9-4.8%) in 11 countries, and for cervix uteri cancer (AAPC, 2.1-4.7%) in 6 countries. Incidence and mortality both increased in YAs for female breast cancer in Czechia, ovarian cancer in the Republic of Korea, cervix uterine cancer in the Netherlands, and colorectum cancer in Australia, Canada, Chile, and the USA. Trachea, bronchus and lung cancers ASIR and ASMR decreased in 24 (AAPC, -1.5 to -11.3%) and 47 (AAPC, -2.0 to -11.4%) countries among YAs, respectively.

Conclusions and Relevance: The burden and trends in cancer among young adults vary significantly by sex and region. Rising incidence and mortality rates for multiple cancer types across the world underscore the need for renewed attention to cancer prevention efforts and improvements to cancer surveillance systems targeting this often overlooked age group.

#3592 Hospital-treated infectious diseases and pancreatic cancer risk: Findings from a large population-based cohort.

K. R. Murison[1], R. J. Hung[2];
[1]University of Toronto, Toronto, ON, Canada, [2]Sinai Health, Toronto, ON, Canada

Rationale: Inflammation has been established as a mechanism for pancreatic cancer development. The longitudinal relationship between infection, and the resulting inflammation, and pancreatic cancer risk has yet to be elucidated. A large population-based cohort, such as the United Kingdom (UK) Biobank, offers a unique opportunity to assess these relationships with long follow-up time and a large number of infections.
Objectives: Estimate the effect of hospital-treated infection on pancreatic cancer risk by infection type and infection burden.
Methods: UK Biobank participants with no record of pancreatic cancer at cohort entry were included. Follow-up was to February 29, 2020 and January 31, 2021 for participants from England and Wales, and Scotland, respectively. Hospital-treated infection status was obtained through linkage to hospital inpatient data and allowed for characterization of exposure to over 900 infectious diseases using the International Classification of Diseases and Related Health Problems 10th Revision. Incident pancreatic cancer diagnosis was obtained through linkage to national cancer registries. Relative risk (RR) and associated 95% confidence intervals (CI) were estimated for infectious disease groups and infectious disease burden categories using negative binomial regression models.
Results: From cohort entry to the end of follow up, 502,219 people were included in the cohort. 93,123 participants had at least one recorded exposure to hospital-treated infection preceding pancreatic cancer diagnosis and 1,255 were diagnosed with pancreatic cancer throughout the follow up period. Exposure to any hospital-treated infection was associated with increased risk of pancreatic cancer (aRR 2.56 [95% CI 2.27, 2.88]). When considering infection burden, a dose-response relationship was seen ($p_{trend} < 0.001$) where a greater number of infections was associated with a greater risk of pancreatic cancer. When compared to those with no infection, participants had increasing risk with 1 infection (aRR 1.99 [95% CI 1.69, 2.35]), 2 infections (aRR 2.84 [95% CI 2.34, 3.43]), and $\geq$3 infections (aRR 3.21 [95% CI 2.72, 3.78]).
Conclusions: Infections which require treatment in hospital are associated with risk of pancreatic cancer. This association was strongest when considering bacterial infection and its impact on longitudinal risk of pancreatic cancer. Further, the dose-response relationship observed when investigating infection burden may suggest a cumulative risk of pancreatic cancer conferred with severe infections.

#3593 Effect of regular antidepressants use on cancer morbidity and mortality: A propensity score matched cohort study.

Jing He[1], **Yue Ma**[1], chenyang Li[1], Fubin Liu[1], Yaogang Wang[2], Fengju Song[1]

[1]Department of Epidemiology and Biostatistics, Key Laboratory of Molecular Cancer Epidemiology, Key Laboratory of Prevention and Control of Major Diseases in the Population, Ministry of Education, National Clinical Research Center for Cancer, Tianjin's Clinical Research Center for Cancer,Tianjin Medical University Cancer Institute & Hospital, Tianjin, China,[2]School of Public Health, Tianjin Medical University, Tianjin, China

Background—Antidepressant use is rising globally and has shown potential anticancer properties in vitro, but findings from observational studies have been inconsistent. We aimed to investigate the association between regular antidepressant use and cancer risk in a large prospective cohort with long-term follow-up.
Methods—A total of 421,529 participants without cancer or cardiovascular disease at baseline were obtained from the UK Biobank, recruited between 2006 and 2010 from 22 assessment centres across the UK. Regular antidepressant users were matched to nonusers using propensity score matching (PSM), adjusting for 21 key covariates, including age, sex, race, socioeconomic status, lifestyle factors, and medical history. The primary outcomes were overall cancer morbidity and mortality, with site-specific cancer morbidity as a secondary outcome. The association between different antidepressant subtypes and cancer risk was also examined.
Findings—The median follow-up was 13.6 years. Of the participants, 26,796 were regular antidepressant users and 394,733 were nonusers. After 1:1 PSM, 26,372 matched pairs were identified. Regular antidepressant use was associated with a reduced risk of overall cancer morbidity (HR 0.83, 95% CI 0.79-0.88), particularly for colorectal cancer (HR 0.75, 95% CI 0.65-0.86), and lower cancer-related mortality (HR 0.91, 95% CI 0.84-0.99) compared with nonusers. Among antidepressant subtypes, selective serotonin reuptake inhibitors (SSRIs) were associated with a 17% reduced risk of overall cancer morbidity (HR 0.83, 95% CI 0.79-0.88), especially for fluoxetine, citalopram, and sertraline. SSRIs were also associated with a 23% reduced risk of cancer-related mortality (HR 0.77, 95% CI 0.70-0.85), particularly with fluoxetine and citalopram. However, tricyclic antidepressants (TCAs) were linked to an increased risk of cancer-related mortality (HR 1.19, 95% CI 1.07-1.32), especially for amitriptyline.
Interpretation—These findings provide important evidence for the potential repurposing of antidepressants in cancer prevention and treatment. However, TCAs, such as amitriptyline, were associated with an increased risk, warranting caution. Further research is needed to confirm these findings.

#3594 Performance of common general-population breast cancer risk prediction models in 14 cohorts.

Kristen D. Brantley[1], **Thomas U. Ahearn**[2], Emily Norton[3], Julie Palmer[4], Gary Zirpoli[4], Matt Barnett[5], Marian L. Neuhouser[5], Lauren Teras[6], James Hodge[6], Thomas E. Rohan[7], Roger Milne[8], A. Heather Eliassen[9], Hongyan Huang[9], Yu Chen[10], Katie M. O'Brien[11], Cari Kitahara[12], Garnet Anderson[5], I-Min Lee[13], Nilanjan Chatterjee[3], Montserrat Garcia-Closas[14], Peter Kraft[2], Breast Cancer Risk Prediction Project

[1]Dana-Farber Cancer Institute, Boston, MA,[2]National Cancer Institute, Bethesda, MD,[3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD,[4]Slone Epidemiology Center at Boston University, Boston, MA,[5]Fred Hutchinson Cancer Center, Seattle, WA,[6]American Cancer Society, Atlanta, GA,[7]Albert Einstein College of Medicine, Bronx, NY,[8]University of Melbourne, Melbourne, Australia,[9]Harvard TH Chan School of Public Health, Boston, MA,[10]New York University Langone Medical Center, New York, NY,[11]National Institute of Environmental Health Sciences, Durham, NC,[12]Radiation Epidemiology Branch, National Cancer Institute, Bethesda, MD,[13]Harvard Medical School, Boston, MA,[14]Institute of Cancer Research, London, United Kingdom

Background: Several breast cancer (BC) risk prediction models are used in clinical practice to identify women eligible for enhanced screening or prevention strategies. While these models have been independently validated in specific and often separate contexts, their performance has not been systematically evaluated and compared across a wide range of populations or age ranges.
Methods: We collected individual-level baseline questionnaire data and incident cancer diagnoses from 14 cohorts participating in the Breast Cancer Risk Prediction Project (BCRPP), representing the United States (N=12), Canada (N=1) and Australia (N=1). After harmonizing data across cohorts, five-year absolute risk estimates for invasive breast cancer were derived using four models: BCRAT, iCARE-Lit, Tyrer-Cuzick (all estimating risk in women aged ≥20-75 years) and the Black Women's Health Study (BWHS) calculator (estimating risk in Black women aged ≥30-70 years). Using the iCARE-calibrate function in R we estimated the area under the curve (AUC) and 95% confidence intervals (CI) within each cohort, using absolute risk designations to incorporate age. Expected to observed (E/O) absolute risks were estimated on average and within expected absolute risk deciles for each cohort. To align with its intended use in clinical practice, calibration of the BWHS calculator (and comparison to other models) was performed within the subset of Black women pooled from all cohorts.
Results: A total of 1,041,708 women, enrolled in studies between 1976-2015, were included. Within five years of baseline cohort entry, 116,113 invasive breast cancer cases were diagnosed. Mean age at baseline ranged from 34 to 62 years. Within cohorts, discrimination was similar across models but varied substantially across cohorts. Age-incorporated AUCs ranged from 0.55-0.77, with most cohort-specific AUCs under 0.65 and higher AUCs observed among younger cohorts. Calibration, measured by E/O ratios, differed substantially by both cohort and risk prediction model. For the majority of cohort-model combinations, risk was overestimated in the upper risk deciles. In general, E/O ratios were more similar for BCRAT and Tyrer-Cuzick models compared to iCARE-Lit, which tended to overestimate risk more on average. In the subset of Black women aged ≥30-70 years (N=84,594, N=824 invasive cases in 5 years), age-incorporated AUCs ranged from 0.61 to 0.64. While risk was overestimated in the upper risk deciles for all models, overestimation was 13-118% lower for the BWHS calculator.
Conclusion: The discrimination and calibration of existing risk prediction models varied across studies. Future model development including additional risk factors (e.g., genetic and mammographic information) should leverage diverse training data and flexible models to ensure risk estimates perform well across different regions, countries, and ethnicities.

#3595 Estimating excess mortality due to cancer during the COVID-19 outbreak in South Korea.

Linh Thi My Bui[1], Jinwoo Cho[2], Yun-Chul Hong[3], Yoon-Jung Choi[1]

[1]Cancer Control and Population Health, National Cancer Center Graduate School of Cancer Science and Policy, Goyang, Korea, Republic of,[2]Department of Statistics, University of Pittsburg, Pittsburgh, PA,[3]Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Excess mortality serves as a valuable metric for evaluating the comprehensive health impact of healthcare systems worldwide during the COVID-19 pandemic, particularly affecting vulnerable populations, including cancer patients. This study aims to estimate excess mortality attributable to all causes and cause-specific mortality, including cancer, during the COVID-19 pandemic in South Korea. ***Methods:*** Monthly mortality data from January 2000 to December 2022 was obtained from Statistics Korea. Using the World Health Organization International Classification of Diseases and Related Health Problems (ICD-10), we identified deaths due to neoplasia (C00-D48), infectious diseases (A00-B99, U07.1, U07.2, U10), cardiovascular diseases (I00-I99), and respiratory diseases (J00-J98, U04). Excess mortality during 2020-2022 was calculated by subtracting the predicted monthly number of deaths from the observed deaths from January 2020 to December 2022. The predicted number of deaths in 2020-2022 was estimated by using exponential smoothing, specifically, Error-Trend-Seasonal (ETS) models based on the death in 2000-2019. AIC, BIC and Log likelihood criteria were used to evaluate the different models of ETS, which showed that (additive, additive, additive) model was the most well-fitting. ***Results:*** All-cause excess mortality was highest in March 2022, with a total of 44,616 observed deaths (predicted deaths: 26,874, 95% confidence interval (CI): 22,271 - 31,476 deaths, statistically significant). There was significant excess mortality due to infectious and parasitic diseases in every month from 2021 to 2022, peaking at March 2022 (1367.75%), which corresponded to 11,893 observed deaths (predicted deaths: 810, 95% CI 676 - 945). The number of deaths attributable to cardiovascular or respiratory diseases was not statistical different from predicted values. Notably, excess mortality attributable to cancer was significantly associated with the COVID-19 pandemic, peaking in February 2022 at a rate exceeding 4.45%, equating to 6,740 observed deaths (predicted deaths: 6453, 95% CI 6212 - 6704). Among those deaths, males experienced a higher excess mortality rate of 3.91%, compared to 1.74% among females. ***Conclusion:*** We observed a significant overall increase in all-cause excess mortality during 2022 in South Korea related to the COVID-19 outbreak. Although cancer deaths remained relatively stable and closely aligned with predicted values during the study period, there was 4.45% increase of cancer death in 2022 February which exceeded the upper limit of 95% CI. Our study provides valuable insights into the resilience of cancer-related mortality patterns in South Korea amidst the challenges posed by the pandemic in accessing healthcare services and medical resources.

#3596 Risk of gastrointestinal cancer by sex and age in U.S. veterans with new-onset iron deficiency anemia.

Andrew J. Read[1], Sarah L. Krein[1], Tony Van[2], Kennedy Dubose[2], Jennifer Burns[2], Akbar K. Waljee[3], Sameer D. Saini[1]

[1]Internal Medicine, University of Michigan, Ann Arbor, MI,[2]VA HSR&D Center for Clinical Management Research, Ann Arbor, MI,[3]Learning Health Sciences, University of Michigan, Ann Arbor, MI

Background: New onset iron deficiency anemia (IDA) may indicate undiagnosed gastrointestinal (GI) cancer. Current guidelines strongly recommend colonoscopy and upper endoscopy (bidirectional endoscopy) for new onset IDA in men and postmenopausal women. In younger women, guidelines conditionally recommend bidirectional endoscopy, as IDA can occur from benign menstrual blood loss. Given rising rates of GI cancers in younger individuals, disregarding IDA in premenopausal women could inadvertently lead to delayed diagnoses of GI cancer. We assessed the likelihood of GI cancer in a national cohort of Veterans with new onset IDA by age and sex, using common clinical cutoffs.

Methods: We conducted a retrospective cohort study in the Veterans Health Administration (VA). We identified regular users of VA primary care (≥1 primary care visit every 2 years over a 5-year period) who developed a new anemia (hemoglobin <12 g/dL for women, <13 g/dL for men), and who had a ferritin within 1 year. We defined IDA as ferritin <45 ng/ml and varied this definition in sensitivity analysis. We identified luminal GI cancers (esophageal, gastric, small intestine, colon, rectum) diagnosed within 1 year of incident anemia by the VA cancer registry. We calculated the odds ratio (OR) of IDA and a GI cancer diagnosis in the overall cohort, stratified by age and sex.

Results: 308,250 individuals met inclusion criteria, with 18,672 (6.1%) women and 289,578 (93.9%) men. 94,713 (30.7%) had IDA, and 33,711 (10.9%) were <50 years old. 3,035 GI cancers were diagnosed within 1 year of incident anemia (0.98%), the majority of which were colon cancers (n=1835, 60.5%). The odds of cancer were significantly higher in those with IDA versus non-IDA (OR 4.47, 95% CI: 4.14-4.82). For women with IDA age ≥ 50 compared to those < age 50, the OR of GI cancer in 1 year was 6.62 (95% CI: 3.54-12.36). In those < age 50 with IDA, men had an OR of GI cancer in 1 year of 9.74 compared to women (95% CI: 5.45-17.40). In those age ≥ 50 with IDA, men had an OR of GI cancer of 2.24 compared to women (95% CI: 1.64-3.05). In sensitivity analysis, lowering the ferritin cutoff to 10 ng/ml did not change the directionality of these relationships.

Conclusions: Women age < 50 with new onset IDA were substantially less likely to develop GI cancer than comparable age men and older women. These findings support current guidelines, which strongly recommend bidirectional endoscopy in men and postmenopausal women and conditionally recommend endoscopy in premenopausal women. At the same time, clinicians should carefully assess for the presence / absence of symptoms that point to GI tract blood loss in premenopausal women. Additionally, future work should explore the role of computational methods and the electronic health record to leverage data from longitudinal complete blood counts (CBCs), moving beyond simple ferritin cutoffs.

#3597 Tumor bacteria, tumor-infiltrating T cells, and colorectal cancer survival outcomes.

Tomotaka Ugai[1], Jennifer Borowsky[2], Yuxue Zhong[1], Satoko Ugai[3], Mai Chan Lau[4], Kota Arima[5], Koichiro Haruki[6], Marios Giannakis[7], Jonathan Nowak[7], Shuji Ogino[1]

[1]Brigham and Women's Hospital, Boston, MA,[2]The University of Queensland, Brisbane, Australia,[3]Harvard T.H. Chan School of Public Health, Boston, MA,[4]A*STAR's Bioinformatics Institute, Singapore, Singapore,[5]Kumamoto University, Kumamoto, Japan,[6]The Jikei University School of Medicine, Tokyo, Japan,[7]Dana-Farber Cancer Institute, Boston, MA

Background: Colorectal cancer (CRC) is a heterogeneous tumor with complex interactions between tumor cells, immune cells, and microbiota in the tumor microenvironment. We hypothesized that T cell infiltrates might differ by colorectal tumor tissue bacteria. We also hypothesized that the presence of T-cell-associated tumor bacteria might be associated with worse clinical outcomes.
Methods: We used a prospective cohort tumor biobank database of 831 incidence CRC cases with available tissue data in the Nurses' Health Study and the Health Professionals Follow-up Study. To identify the tumor microbiota, we developed 16S rRNA gene sequencing and validated the data using quantitative PCR assays. We assessed tumor-infiltrating T-cell subsets using multiplexed immunofluorescence assays with digital image analyses and machine-learning algorithms. Spearman correlation test was performed to examine the correlation between the abundance of tumor microbiota and $CD3^+CD4^+$ or $CD3^+CD8^+$ T-cell densities. Multivariable Cox proportional hazards regression model was used to calculate hazard ratios (HRs) and 95% CIs for CRC-specific mortality. P values <0.005 were considered statistically significant.
Results: Strong negative correlations were observed between $CD3^+CD4^+$ T-cell density and the abundance of *Bacteroides fragilis* (rho=-0.12, P<0.001), *Fusobacterium canifelinum* (rho=-0.11, P=0.001), *Fusobacterium nucleatum* (rho=-0.10, P=0.003), and *Moryella indoligenes* (rho=-0.08, P=0.007). We observed similar strong negative correlations between $CD3^+CD8^+$ T-cell density and *Bordetella trematum* (rho=-0.10, P=0.004), and *Prevotella salivae* (rho=-0.075, P=0.023). We further evaluated whether T-cell-associated bacteria were associated with poor prognosis. Among identified $CD3^+CD4^+$ T cell-associated bacteria, the presence of *Moryella indoligenes* [HR (95% CI), 2.82 (1.40-5.66); P=0.004]*, Campylobacter gracilis* [HR (95% CI), 2.10 (1.22-3.61); P=0.008], and *Fusobacterium nucleatum* [HR (95% CI), 1.56 (1.17-2.30); P=0.004] were associated with higher CRC-specific mortality. We did not observe significant associations of $CD3^+CD8^+$T-cell-associated bacteria with poor prognosis.
Conclusions: We identified immune-suppressive bacteria that were correlated with lower $CD3^+CD4^+$ and $CD3^+CD8^+$T cell densities in the tumor microenvironment. Among these immune-suppressive bacteria, *Fusobacterium nucleatum*, *Moryella indoligenes,* and *Campylobacter gracilis* were associated with both lower $CD3^+CD4^+$T cell density and worse survival. Our findings indicate that certain tumor microbiota, such as *Fusobacterium nucleatum,* suppresses anti-tumor T cell response, leading to the development and progression of CRC. By contrast, other tumor bacteria, such as *Bacteroides fragilis,* may suppress anti-tumor T cell response and have a key role in tumor initiation, but may not strongly affect clinical outcomes.

#3598 Environmental circadian misalignment and cancer prevalence in the United States.

Seigi Karasaki[1], Matthew D. Weaver[2], Amanda I. Phipps[3], Trang VoPham[1]

[1]Epidemiology, Fred Hutchinson Cancer Center, Seattle, WA,[2]Medicine and Neurology, Brigham and Women's Hospital, Boston, MA,[3]Epidemiology, University of Washington, Seattle, WA

PURPOSE: Circadian disruption (e.g. from shift work) is associated with increased risk for certain cancers. Emerging evidence suggests that sources of environmental circadian misalignment, such as solar jetlag (due to differential light exposure based on time zone position) and polycyclic aromatic hydrocarbons (PAHs; from combustion of compounds such as gasoline, damaging the transcription translation feedback loop that drives circadian rhythms at the cellular level) may impact cancer development. We examined the associations between solar jetlag, PAHs, and cancer prevalence.

METHODS: We examined cancer prevalence (proportion of adults in 2022 ≥18 years diagnosed with cancer, excluding non-melanoma skin cancer) in the United States at the census tract level using Population Level Analysis and Community EStimates (PLACES). We estimated solar jetlag exposure (unitless) using a high-resolution geospatial model incorporating data on time zone position, sunrise and sunset times, and elevation. We estimated exposure to PAHs using data on smoking prevalence from PLACES; benzo[a]pyrene (BaP) and residential wood combustion from chemical transport and atmospheric dispersions models; black carbon (BC), carbon monoxide (CO), nitrogen dioxide (NO_2), particulate matter <10 microns in diameter (PM_{10}), and $PM_{2.5}$ from land-use regression; and traffic volume from averaged traffic counts. We used geographic information systems to aggregate and join these data to census tracts with areal weighting. We used Poisson regression with robust variance estimation to calculate prevalence ratios (PRs) and 95% confidence intervals (CIs) for associations between solar jetlag, PAHs, and cancer prevalence adjusting for census tract-level sociodemographics, health conditions, behaviors, socioeconomic status, and light at night.

RESULTS: This analysis included 77,494 census tracts with an average cancer prevalence of 8.0%. There were no independent associations of solar jetlag or PAHs with cancer prevalence. However, there were statistically significant interactions between solar jetlag and BC, NO_2, PM_{10}, $PM_{2.5}$, and traffic volume in associations with cancer prevalence. The strongest associations were observed within $PM_{2.5}$ exposure strata, in which higher solar jetlag exposure was associated with increased cancer prevalence in areas with relatively higher $PM_{2.5}$ levels (adjusted PR per interquartile range [45.33] increase in highest quintile of $PM_{2.5}$ [8.62-35.40 μg/m^3]: 1.05, 95% CI 1.04-1.07 vs. adjusted PR in lowest quintile of $PM_{2.5}$ [2.05-5.89 μg/m^3]:1.01, 95% CI 0.99-1.03; p interaction <0.01).

CONCLUSIONS: We observed interactions between solar jetlag and PAHs on cancer prevalence, suggesting that these sources of environmental circadian disruption may jointly act to impact cancer. Future research should utilize geocoded addresses, examine other sources of PAHs such as from diet, and data on cancer incidence.

#3599 Proteomic risk factors for prostate cancer: A case-cohort study in EPIC.

Zhe Huang[1], Mahboubeh Parsaeian[1], Vivian Viallon[2], Ziqiao Wang[3], Keren Papier[1], Trishna Desai[1], Stephanie Chan[1], Antonio Agudo[4], Carlotta Sacerdote[5], David C. Muller[6], Domenico Pali[7], Giovanna Masala[7], Nicholas Wareham[8], Raul Zamora-Ros[9], Roel C. H. Vermeulen[10], Rosario Tumino[11], Ian G. Mills[12], Nilanjan Chatterjee[3], Elizabeth A. Platz[13], Pietro Ferrari[2], Marc Gunter[6], Elio Riboli[6], Tim J. Key[1], Joshua R. Atkins[1], Karl Smith-Byrne[1], Ruth C. Travis[1], The EPIC SomaLogic Working Group

[1]Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom,[2]International Agency for Research on Cancer, Lyon, France,[3]Department of Biostatistics, Johns Hopkins University, Baltimore, MD,[4]Institut Catala d'Oncologia, Barcelona, Spain,[5]University of Turin, Turin, Italy,[6]School of Public Health, Imperial College London, London, United Kingdom,[7]Institute for Cancer Research, Prevention and Clinical network, Florence, Italy,[8]University of Cambridge, Cambridge, United Kingdom,[9]Unit of Nutrition and Cancer, Cancer Epidemiology Research Program, Catalan Institute of Oncology (ICO), Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain,[10]Division of Environmental Epidemiology and Veterinary Public Health, Institute for Risk Assessment S, Utrecht University, Utrecht, Netherlands,[11]Iblea Association, Epidemiological Research (AIRE-ONLUS), Ragusa, Italy,[12]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom,[13]Department of Epidemiology, Johns Hopkins University, Baltimore, MD

Background: Prostate cancer (PCa) is the most prevalent cancer among men in Europe, yet its aetiology is poorly understood. Proteins contribute to the development of carcinogenesis and are also the target of most pharmacological interventions. The examination of associations between plasma proteins and PCa may enhance understanding of the aetiology of the PCa.
Aim: Identify proteins associated with PCa risk within a large European prospective cohort, with emphasis on associations with aggressive subtypes of the disease.
Methods: We conducted a case-cohort study in the European Prospective Investigation into Cancer and Nutrition (EPIC) study, with data for a sub-cohort of 1,573 individuals and for 982 incident PCa cases. The SomaLogic® 7K panel was used to measure 7,363 aptamers (representing 6,412 unique proteins) in plasma samples drawn at recruitment. PCa diagnosis was ascertained by linkage to cancer and death registry data, and was further stratified into aggressive subtypes based on histological grade, tumour stage and mortality information. The Prentice-weight Cox regression model was applied to estimate associations between individual proteins and PCa risk, with adjustment for body mass index, smoking, alcohol intake and education level. Subgroup analyses examined associations with high-grade, advanced-stage, aggressive and extended lag-time (diagnosis more than 15 years after blood draw) PCa risk. We sought external replication for our significant findings in an independent multi-ancestry cohort, the Atherosclerosis Risk in Communities (ARIC) study (SomaLogic® 5K).
Results: Following a median follow-up period of 16.2 years, the sub-cohort developed 79 cases of PCa. ACP3, FLT4, and KLK3 [HRs (95% CI): 1.20 (1.10, 1.31), 1.26 (1.13, 1.40) and 2.28 (1.96, 2.65), respectively] were associated with overall PCa risk in EPIC at FDR (false discovery rate) <0.05. In the subgroup analyses, 12 proteins were associated with high-grade, 9 with advanced stage, and 7 with aggressive PCa risk. Among these, ANKRD1 was associated with approximately a 25% higher risk of all three of these clinically relevant subtypes per SD increase. Twelve proteins were associated with PCa risk diagnosed more than 15 years after blood draw, including ANXA2, OSCAR, and SAT2. Two well-established biomarkers of PCa (ACP3 and KLK3) were replicated in ARIC, together with two novel proteins (ANXA2 and APOC2).
Conclusion: Multiple novel circulating proteins were associated with PCa risk, particularly with risk for aggressive subtypes. While some proteins may serve as early biomarkers of PCa, those with evidence from long-lag time highlight underlying aetiological mechanisms in the development of PCa.

#3600 Methylation-based biological age and risk of colorectal cancer recurrence: Findings from the ColoCare Study.

A. Richards[1], E. Jean-Baptiste[1], T. Barrow[2], S. Hardikar[3], B. Gigic[4], J. Figueiredo[5], C. Li[6], D. Shibata[7], A. T. Toriola[8], D. A. Byrd[1], C. M. Ulrich[3], P. Stewart[1], E. M. Siegel[1], **J. K. Kresovich**[1];

[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]University of Essex, Essex, United Kingdom, [3]Huntsman Cancer Institute, Salt Lake City, UT, [4]Heidelberg University Hospital, Heidelberg, Germany, [5]Cedars-Sinai Medical Center, Los Angeles, CA, [6]Fred Hutchinson Cancer Center, Seattle, WA, [7]University of Tennessee Health Science Center, Memphis, TN, [8]Washington University School of Medicine, St. Louis, MO

Introduction: Approximately 20% of colorectal cancer (CRC) patients experience disease recurrence, contributing significantly to CRC-specific mortality in those with non-metastatic disease. Recurrence risk is typically assessed after treatment, potentially delaying interventions for high-risk patients. Assessing recurrence risk earlier could enable personalized therapy strategies that balance remission potential with treatment side-effects. Although tumor characteristics provide some predictive value, they are insufficient for accurately identifying patients at high risk of recurrence. Biological age metrics derived from blood DNA methylation (DNAm) data, called “epigenetic clocks,” integrate information from known recurrence risk factors and are attractive targets for improving risk assessment. However, the relationship between epigenetic clocks and CRC recurrence risk has not been examined in detail.

Methods: The ColoCare Study is an international, multi-center, prospective cohort of newly diagnosed CRC patients. For this study, we selected a nested case-control sample of 137 patients enrolled at Moffitt Cancer Center, with recurrence cases matched 1:3 to recurrence-free controls by age, sex, body mass index, stage, and follow-up time. Pre-treatment whole blood DNAm profiles were assayed and used to calculate seven epigenetic clocks (Hannum, Horvath13, Horvath18, PhenoAge, GrimAge, DunedinPACE, DNAm Frailty). Logistic regression models, adjusted for matching factors and tumor location, estimated odds ratios (ORs) for associations between each epigenetic clock (per 1-standard deviation [SD] increase) and risks of CRC recurrence and all-cause mortality.

Results: Patients had a mean age of 62.7 years at diagnosis (SD= 13), with a majority being male (57%), overweight (78%), and White (90%). During follow-up, 35 (25%) patients experienced CRC recurrence, and 47 (34%) died. Higher GrimAgeAccel, DunedinPACE, and DNAm Frailty were associated with higher recurrence risk (GrimAgeAccel, OR: 1.60, 95% CI: 1.02, 2.50, P= 0.04; DunedinPACE, OR: 1.47, 95% CI: 0.91, 2.36, P= 0.12; DNAm Frailty, OR: 2.13, 95% CI: 1.17, 3.85, P= 0.01). PhenoAgeAccel, GrimAgeAccel, DunedinPACE, and DNAm Frailty were also positively associated with all-cause mortality (PhenoAgeAccel, OR: 1.52, 95% CI: 0.99, 2.35, P= 0.06; GrimAgeAccel, OR: 1.78, 95% CI: 1.15, 2.76, P= 0.01; DunedinPACE, OR: 1.43, 95% CI: 0.91, 2.23, P= 0.12; DNAm Frailty, OR: 1.69, 95% CI: 0.97, 2.95, P= 0.06).

Conclusions: Several epigenetic clocks measured in pre-treatment blood samples are associated with CRC recurrence risk and mortality. These findings suggest epigenetic clocks are novel risk factors for CRC recurrence that may be useful for enhancing risk assessment before treatment initiation.

#3601 Elevated short-chain fatty acid level and increased risk of hepatocellular carcinoma in a prospective cohort study.

Sindhu Karnam[1], Wei Jia[2], Renwei Wang[3], Jennifer Adams-Haduch[3], Woon-Puay Koh[4], Jian-Min Yuan[1]

[1]UPMC Hillman Cancer Center, University of Pittsburgh School of Public Health, Pittsburgh, PA,[2]The University of Hong Kong, Hong Kong, China,[3]UPMC Hillman Cancer Center, University of Pittsburgh Medical Center, Pittsburgh, PA,[4]Yong Loo Lin School of Medicine, National University of Singapore, Kent Ridge, Singapore

Background: Hepatocellular carcinoma (HCC) makes up 80-90% of primary liver cancers and is typically detected at an advanced stage because of its silent nature of progression and a lack of effective non-invasive early detection biomarkers. Gut-derived metabolites such as short-chain fatty acids (SCFAs) play a key role in liver health and may impact the progression of early non-malignant stages of liver disease to malignant transformation to HCC. Although most of studies have shown that SCFAs including acetate, butyrate, and propionate have been associated with lower risk of intestinal disease, some experimental studies have shown dysregulated metabolism of SCFAs may induce proinflammatory milieu for liver disease progress. The goal of this study is to investigate whether metabolomic profiling of SCFAs in baseline serum is associated with risk of HCC development.
Methods: We performed a nested case-control study with 100 incident HCC cases and 100 individually matched healthy controls within the Singapore Chinese Health Study, a cohort of 63,257 men and women aged 45-74 years at enrollment in 1993-1998. The incidence of HCC among cohort participants was annually surveilled using the nationwide Singapore Cancer Registry. Serum acetic, butyric, propionic, and valeric acids were quantified using ultra-performance liquid chromatography triple-quadrupole mass spectrometry assays. The conditional logistic regression was used to evaluate the association between SCFAs and HCC risk using odds ratios (ORs) and their 95% confidence intervals (CI).
Results: Cases and controls were comparable in distributions by age, body mass index (BMI), alcohol consumption and smoking status. Individuals with HCC were more likely to be HBsAg positive and had a history of diabetes than controls. Among controls, the summed all SCFAs and total butyric acid and its metabolites were positively associated with BMI (P trend < 0.05). The summed and most of individual SCFAs measured were significantly elevated in HCC compared with controls. Compared to the lowest tertile, the OR (95% CI) of HCC for the highest tertile of summed all SCFAs and total butyric acids was 3.24 (1.45-7.24) and 2.78 (1.27-6.12) after adjusting for age, sex, BMI, alcohol consumption, smoking status, type 2 diabetes, and HBsAg status (both P's for trend < 0.01).
Conclusion: The present analysis demonstrated a statistically significant association between elevated SCFA levels and increased risk of HCC in a prospective cohort of Singaporean Chinese. These results align with increased risk of HCC within this cohort with elevations in other metabolites such as bile acids. Mapping metabolic profile changes in liver disease progression to cancer will provide clinicians with a novel biomarker for risk stratification and early detection.

#3602 The association between longitudinal lipid trajectories and all-cause mortality in breast cancer survivors: A population-based study.

Shana Jean Kim[1], Vanessa De Rubeis[2], Brendan T. Smith[3], Husam Abdel-Qadir[4], Jennifer D. Brooks[1]

[1]University of Toronto, Toronto, ON, Canada,[2]McMaster University, Hamilton, ON, Canada,[3]Public Health Ontario, Toronto, ON, Canada,[4]Women's College Hospital, Toronto, ON, Canada

Background: Given breast cancer is the second leading cause of cancer-related death in women, it is important to identify breast cancer patients at high risk of mortality. Lipid levels before and after diagnosis may be key indicators for overall health and prognostic outcomes for breast cancer patients. This study aimed to identify distinct lipid trajectories in those diagnosed with breast cancer and examined their association with all-cause mortality.

Methods: This population-based retrospective cohort study included females diagnosed with incident breast cancer who survived at least five years after diagnosis (i.e., breast cancer survivors). Total cholesterol, low-density lipoprotein (LDL), high-density lipoprotein (HDL), and triglycerides (mmol/L) were used to develop trajectory patterns for each lipid through group-based trajectory modelling. Cox proportional hazards models estimated hazard ratios (HR) and 95% confidence intervals (CI) of all-cause mortality by lipid trajectories.

Results: The study included 32,537 female breast cancer survivors. Approximately 30% of the study population lipid levels within recommended ranges before and after a breast cancer diagnosis (moderate-stable trajectory). Nearly 10% of the population had very low lipids before and after a breast cancer diagnosis (very low-stable trajectory); this pattern was associated with an increased risk of all-cause mortality for total cholesterol (HR 1.38, 95%CI 1.16, 1.66), LDL (HR 1.24, 95%CI 1.04, 1.49), and HDL (HR 1.20, 95%CI 1.02, 1.40), compared to the moderate-stable trajectory. Approximately 5-6% had very high total cholesterol or LDL that rapidly declined after a breast cancer diagnosis (very high-declining trajectory); this pattern was associated with an increased risk of all-cause mortality compared to a moderate-stable trajectory (HR 1.59, 95%CI 1.23, 2.05; HR 1.40, 95%CI 1.09, 1.81, respectively). The association between lipid trajectories and all-cause mortality did not significantly differ by lipid-lowering agent use, suggesting pharmacologic management did not impact the findings. However, those not on a lipid-lowering agent had a mortality risk of higher magnitude than those on pharmacologic intervention.

Conclusions: Breast cancer patients with very low lipids before and after diagnosis, and patients with very high lipids that rapidly decline to low levels after diagnosis were identified as subgroups at high risk of mortality. These findings highlight the importance of considering longitudinal, repeat lipid measures to improve long-term outcomes in this population.

#3603 Racial and ethnic disparities in colorectal cancer-specific mortality: The Multiethnic Cohort.

Wei (Melody) Xiong[1], Adelynn Paik[1], Iona Cheng[2], Anna H. Wu[1], Ugonna Ihenacho[1], Lynne R. Wilkens[3], Loic Le Marchand[3], David V. Conti[1], Christopher A. Haiman[1], Brian Z. Huang[1]

[1]Center for Genetic Epidemiology, Department of Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA,[2]School of Medicine, University of California, San Francisco, San Francisco, CA,[3]Epidemiology Program, University of Hawaii Cancer Center, Honolulu, HI

Background: Colorectal cancer (CRC) is a leading cause of cancer-related mortality in the United States. However, few studies have investigated the racial and ethnic disparities of CRC-specific mortality in multiethnic populations of adults with CRC while accounting for detailed individual- and neighborhood-level data.
Methods: We evaluated racial and ethnic disparities in CRC-specific mortality among 5,738 (2,911 men, 2,827 women) invasive colorectal adenocarcinoma cases (1993-2019) from the Multiethnic Cohort Study (MEC). Cases included African American (n=1,166), Latino (n=1,178), Native Hawaiian (N=358), Japanese American (n=1,960), and non-Hispanic White (NHW) (n=1,178) adults. Using Cox regression with age since diagnosis as the time metric, we estimated hazard ratios (HRs) for CRC-specific mortality, adjusting for sex, CRC grade/stage, treatment (surgery, chemotherapy, radiotherapy), family history of CRC, history of polyps, education, neighborhood SES (accounting for census block group), BMI, smoking, alcohol, physical activity, diabetes, NSAID and multivitamin use, daily calories, intake of red/processed meats, folate, fiber, and number of comorbidities (0, 1, ≥2). Stratified analyses were performed by sex, tumor stage, and site (colon, left colon, right colon, rectum).
Results: Over a mean follow-up period of 7.5 years, 1,695 (29.5%) CRC cases (874 men and 821 women) died of colorectal adenocarcinoma. Compared to NHW CRC cases, Japanese American (HR=0.74, 95% CI: 0.61, 0.89) and Latino (HR=0.65, 95% CI: 0.51, 0.82) cases had significantly lower CRC-specific mortality. These associations were significant in men (Japanese American: HR=0.74, p=0.02; Latino: HR=0.62, p<0.001), but not in women (HRs = 0.72-0.77, p<0.10). Across stage, Japanese American cases had 36% lower CRC-specific mortality for localized tumors (HR=0.64, 95% CI: 0.43-0.97), while Latino cases had >50% reduced mortality for distant tumors (HR=0.46, 95% CI: 0.31-0.69). For colon cancer specifically, both groups showed significant lower CRC-specific mortality (Japanese American: HR=0.67, 95% CI: 0.41-0.77; Latino: HR=0.65, 95% CI: 0.50-0.85). Results were similar by colon tumor site but were stronger for Japanese American cases for left-sided colon cancer (HR =0.57, 95% CI:0.41-0.77), and for Latino cases for right-sided colon cancer (HR =0.57, 95% CI: 0.41-0.80). There were no significant differences in CRC-specific mortality among African American or Native Hawaiian cases compared to NHWs overall and by subgroups.
Conclusions: Japanese American and Latino CRC cases had significantly lower CRC-specific mortality compared to NHWs in the MEC adjusting for prognostic factors. These findings were consistent across CRC stage, tumor site, and among males. Further research is needed to explore the structural, social and biological factors underlying these disparities in CRC-specific mortality.

#3604 Diabetes and prostate cancer-specific mortality in the Multiethnic Cohort Study: Looking deeper into diagnostic timing and disease duration.

Wei (Melody) Xiong[1], David Bogumil[1], Peggy Wan[1], Gertraud Maskarinec[2], David V. Conti[1], Lynne R. Wilkens[2], Loic Le Marchand[2], Christopher A. Haiman[1], Fei Chen[1]

[1]Center for Genetic Epidemiology, Department of Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA,[2]Epidemiology Program, University of Hawaii Cancer Center, Honolulu, HI

Background:Diabetes is found to be associated with higher cancer-specific mortality for several cancers, but the findings have been conflicting for prostate cancer (PCa). The goal of this study was to evaluate the association between diabetes and PCa-specific mortality (PCSM) in a racial/ethnically diverse population of PCa patients.
Methods:The association between diabetes and PCSM was assessed in 10,464 African American (20.9%), Latino (23.6%), Native Hawaiian (5.4%), Japanese American (28.2%), and non-Hispanic White men (21.9%) diagnosed with incident PCa in the Multiethnic Cohort (MEC). Based on questionnaires and administrative data, diabetes status was defined as non-diabetic, pre-diagnostic diabetic, and post-diagnostic diabetic (relative to PCa diagnosis). In a subsequent analysis, diabetes status was further categorized given the timing of diabetes diagnosis (0-5 or > 5 years pre- or post-diagnosis of PCa). Sub-hazard ratios (SHRs) and 95% confidence intervals (CIs) were estimated using the Fine and Grey subdistribution hazards models, with time since PCa diagnosis as the time metric and adjustments on potential confounders. All analyses were performed in all PCa patients and stratified by tumor stage (localized, advanced) and Gleason score (high-grade, low-grade).
Results: During an average follow-up of 8.5 years, 1,311 (12.5%) men with PCa died of the disease. Compared to men without diabetes, men with pre-diagnostic diabetes had a significantly lower PCSM (SHR=0.73, 95% CI: 0.62-0.86) and the reduction in PCSM appeared to be greater for men with post-diagnostic diabetes (SHR=0.58, 95% CI: 0.48-0.70). Similar trends of the associations for pre- and post-diagnostic diabetes were observed among patients with high-grade (SHR 0.72 vs. 0.51) or advanced (SHR 0.72 vs. 0.56) disease. Among patients with low-grade or localized disease, the inverse associations with PCSM were similar for men with pre- (SHR 0.70-0.76) or post-diagnostic diabetes (SHR 0.65-0.75). Further categorization given the timing of diabetes diagnosis did not lead to differences in trends of the associations for pre- and post-diagnostic diabetes on PCSM among all, high-grade and advanced PCa cases. Among low-grade or localized cases, the inverse association was more evident among those with 5+ years of diabetes before cancer diagnosis and those who became diabetic within 5 years of cancer diagnosis (SHR 0.48-0.69 vs. 0.81-0.91). Statistical significance was defined as $P < 0.05$.
Conclusions:We found that both pre- and post-diagnostic diabetes were significantly associated with a lower PCSM among PCa patients, and the association appeared to be stronger for post-diagnostic diabetes. Further studies are needed to confirm these findings in other multiethnic populations and to understand the mechanisms driving these associations.

POPULATION SCIENCES: Environmental, Immunological, and Tumor Microenvironment Drivers of Cancer Disparities Poster Session

#3608 Non-smoking lung cancer: The impact of cooking-related household air pollution.

B. J. McAllister, K. Brown, S. Cai, S. Khan;
UNIVERSITY OF LEICESTER, Leicester, United Kingdom

Lung cancer is increasingly prevalent in the non-smoking population, with Household Air Pollution (HAP) recognised as a major contributor, and some evidence that women of South-Asian backgrounds are at greater risk than other demographics. A systematic review of available literature was performed to explore the risks of lung cancer posed by HAP for never-smokers in high-income countries. We identified three papers fulfilling our criteria, two conducted in Taiwan, and one in Hong Kong, with no identified studies fitting the criteria in Western countries. The review found that cooking-related HAP increases the risk of LCINS in Chinese women. There is a clear research gap regarding the impact of HAP on LCINS in high-income countries outside Taiwan and Hong Kong. Building on this evidence, the aim of this project is to determine whether South Asian households are exposed to higher levels of cooking-related HAP compared to households of White British ethnicity, leaving them at a greater risk of non-smoking lung cancer.
Methods: Twenty households have been recruited, with White British, and South-Asian families equally represented among participants. Kitchen air quality is monitored for pollutants including PM_1, $PM_{2.5}$, PM_{10}, gases including NO_x, CO, and O_3, VOCs and mould, using active and passive methods. Air sampling is conducted over a week, once in winter and once in summer to account for seasonal variation. Participants complete a daily diary noting activities related to cooking, cleaning and ventilation. A home survey is completed noting structural features e.g., age and style of house, layout of living spaces, floor coverings and renovation work.This study is ongoing, with the first round of data collection complete in January 2025. This data will include accurate, real time air quality measurements allowing for direct comparison with the daily activity diaries to assess the impact of cooking on kitchen air quality, as well as initial analysis of the impact of ethnicity and cultural practices on the quality of household air in non-smoking households.To date, data from eight houses has been collected, with 12 more scheduled. Initial Findings have shown that the use of gas cookers and hobs increases PM_1, $PM_{2.5}$, PM_{10}, while also raising concentrations of NO_x and O_3. Homes using gas appliances frequently breached recommended NO_x exposure levels. While air fryers and electric hobs also increase levels of PM_1, $PM_{2.5}$, PM_{10} during use, there is no corresponding increase in NO_x or O_3.To the best of our knowledge, this is the first UK study to explore how cooking practices affect the presence and concentrations of PM, VOCs and mould in household environments, with a focus on ethnicity and cultural practices. It will provide valuable data on how household air quality affects the risks of non-smoking lung cancer in a high-income country.

#3610 Healthcare segregation experienced by colorectal cancer patients residing in high-poverty areas and its impact on health outcomes.

X. Zheng[1], L. C. Pinheiro[1], P. Tehranifar[2], E. Phillips[1], R. M. Tamimi[1], S. Y. Chao[1], M. Pisu[3], C. Gao[1], A. G. Rundle[2], **J. Mao**[1]; [1]Weill Cornell Medicine, New York, NY, [2]Columbia University Mailman School of Public Health, New York, NY, [3]The University of Alabama at Birmingham School of Medicine, Birmingham, AL

Background: Existing evidence indicates that colorectal cancer (CRC) patients from high-poverty areas (HPA), defined as areas with 20% or more residents living below federal poverty level, are more likely to receive surgery at low-volume, non-accredited hospitals than those from low-poverty areas (LPA). The systematic difference in surgical care location between patients from HPAs and LPAs, healthcare segregation, could represent a structural equity through which disparities in health outcomes arise. We sought to determine the existence of healthcare segregation and assess its impact on patient health outcomes.

Methods: We identified patients undergoing surgery for non-metastatic CRC diagnosed in 2009-2019 from SEER-Medicare. Patients living in a county which had been an HPA for at least 30 years were classified as living in a persistent-poverty area (PPA). Patients living in a county which was an HPA during the year of cancer diagnosis but not a PPA were classified as living in a current-poverty area (CPA). Otherwise, they were classified as living in an LPA. Experiencing healthcare segregation was defined as being treated at a poverty-area-serving (PAS) hospital where ≥50% of the patients were from HPAs. We examined the association between area-level poverty, treatment at PAS hospitals, and health outcomes (postoperative adverse events, 30-day readmission, long-term all-cause mortality (ACM), and cancer-specific mortality (CSM)) using logistic and Cox regression. We performed a subgroup analysis for metropolitan, urban, and rural areas.

Results: We included 81,767 patients (7.5% from PPAs, 8.4% from CPAs) with a median age of 78 (IQR: 73-84) years. 53.9% of patients were females, 14% were non-White, and 1.5% lived in rural areas. 81% of the hospitals (180/991) were PAS hospitals, which treated 64% of patients from PPAs and CPAs vs. 3% from LPAs. Compared with patients from LPAs treated at non-PAS hospitals, those treated at PAS hospitals who were from PPAs (ACM HR=1.17(1.08-1.26), CSM HR=1.23(1.11-1.37)) and CPAs (ACM HR=1.15(1.08-1.22), CSM HR=1.23(1.13-1.35)) had worse short and long-term outcomes. Patients from CPAs treated at non-PAS hospitals also had worse outcomes, to a lesser degree (ACM HR=1.12(1.05-1.19), CSM HR=1.16(1.06-1.28)). Among rural residents, being treated at PAS-serving hospitals but not area-level poverty was independently associated with worse outcomes.

Conclusions: Patients living in HPAs experience healthcare segregation in CRC treatment, contributing to their worse health outcomes. Healthcare segregation reflects systemic inequities and structural barriers limiting access to resources that patients from HPAs may deploy to mitigate consequences of cancer. Understanding healthcare segregation and factors shaping it can help identify areas for intervention to reduce associated health disparities.

#3611 Association of ambient air pollution with hypertension among cancer survivors.

Da-eun Lee[1], Juyeon Hwang[2], Seohyun Ahn[2], Kyounghyeon Kim[1], Kyeezu Kim[1], Hyun-Jin Kim[2]

[1]Sungkyunkwan University, Seoul, Korea, Republic of,[2]National Cancer Control Institute, National Cancer Center, Goyang, Korea, Republic of

Introduction: Hypertension is one of the leading risk factors for cardiovascular disease and premature death worldwide. Ambient air pollutants such as particulate matter (PM) and toxic gases have been linked to an increased risk of hypertension. Cancer survivors are more susceptible to the adverse effects of air pollution and tend to have a higher prevalence of hypertension compared to cancer-free individuals, potentially due to shared intrinsic and extrinsic factors that contribute to both oncogenesis and elevated blood pressure. This study aimed to investigate the association between long-term exposure to ambient air pollution and blood pressure in cancer survivors.

Methods: This study utilized data of 2,492 cancer survivors obtained from the Korea National Health and Nutrition Examination Survey between 2007 and 2021. Five air pollutants, $PM_{2.5}$ (μg/m3), PM_{10} (μg/m3), SO_2 (ppb), NO_2 (ppb), and CO (ppb), were included, and moving average concentrations over 1 to 3 years prior to the survey date were calculated using air quality models and satellite data. We adopted multivariable regression models adjusting for socio-demographic and lifestyle factors to assess the association of air pollution with hypertension status and high blood pressure. We further conducted age- and sex-stratified analyses to examine the potential differences in hypertension.

Results: Greater exposure to air pollution was associated with high blood pressure in cancer survivors, particularly among females and individuals older than 65 years. In male cancer survivors, higher 1-year exposure to SO_2 was associated with greater odds of hypertension (OR= 1.08, P= 0.05). In female cancer survivors, higher exposure to $PM_{2.5}$, PM_{10}, NO_2, and CO over 1- to 3-year periods was associated with elevated diastolic blood pressure (β ranged 0.47 1.09, all $P < 0.05$). Cancer survivors aged 65 or older had greater odds of hypertension ($PM_{2.5}$: OR= 1.27, P= 0.01; PM_{10}: OR= 1.14, P= 0.04) and elevated systolic/diastolic blood pressure (β ranged 0.68 1.56, all $P< 0.05$) per 1-unit increase in PM exposure over 3-years. In cancer survivors aged under 65, 3-year exposures to PM_{10}, NO_2, and CO were associated with higher diastolic blood pressure (β ranged 0.64 0.98, all $P< 0.05$).

Conclusions: Our findings suggest that long-term exposure to air pollution may impact high blood pressure among cancer survivors, across diverse air pollutants. These results underscore the potential health risk posed by air pollution particularly for female cancer survivors and those aged 65 or older.

#3612 Three aging biomarkers differentially mediate cardiotoxicity after irradiation to the heart or exposure of anthracyclines in survivors of childhood cancer.

Xiaoxi Meng, Tiffany Eulalio, Noel-Marie Plonski, John Easton, Heather Mulder, Emily Walker, Geoffrey Neale, Kyla Shelton, Deo Kumar Srivastava, Stephanie B. Dixon, Jinghui Zhang, Melissa M. Hudson, Kirsten K. Ness, Gregory T. Armstrong, Zhaoming Wang

St. Jude Children's Research Hospital, Memphis, TN

Background: Childhood cancer survivors experience accelerated aging, largely due to treatment toxicity. We investigated how aging biomarkers, which quantify accelerated aging and capture multifaceted mechanisms, differentially mediate treatment-related cardiotoxicity.

Methods: Peripheral blood samples from survivors in the St Jude Lifetime Cohort were profiled with EPIC BeadChip to generate DNA methylation (DNAm) data, from which three established aging biomarkers were subsequently derived: epigenetic age (EA, reflecting epigenetic alterations), leukocyte telomere length (LTL, reflecting cellular senescence), and C-reactive protein (CRP, reflecting chronic inflammation). EA (Levine's PhenoAge) and LTL were calculated with the methylCIPHER R package, while CRP was computed as a weighted (regression coefficients from a prior study) sum of serum CRP-associated CpGs. Cardiomyopathy (CMP) with a CTCAE (Common Terminology Criteria for Adverse Events) grade ≥2 and myocardial infarction (MI) with a CTCAE-grade ≥3 were analyzed. Multivariable logistic regression assessed associations of CMP or MI with each biomarker (standardized sample age adjusted residuals), adjusting for sex, attained age, age at primary cancer diagnosis, and cardiotoxic exposures including mean heart irradiation (heart-RT) dose and cumulative anthracycline dose. Linear regression evaluated associations between each biomarker and cardiotoxic exposures, adjusting for sex, age at blood draw and other treatments.

Results: Among 3,059 survivors (all of European ancestry; 46.85% female; mean [SD] = 29.35 [0.22] years of age at blood draw), the incidence of CMP and MI was 8.0% and 1.6%, respectively. Biomarker correlations ranged from moderate to high (r^2 = 0.32 to 0.67). CRP was associated with increased risk of CMP (Odds ratio [95% CI] = 1.28 [1.11-1.47], P = 8.30×10^{-4}) and MI (1.43 [1.09-1.88], P = 1.08×10^{-2}). EA was associated with MI risk only (1.76 [1.30-2.38], P = 2.45×10^{-4}), and LTL was associated with risk of CMP (1.23 [1.05-1.42], P = 7.86×10^{-3}) and MI (1.71 [1.26-2.31], P = 1.19×10^{-3}). Furthermore, CRP specifically mediated the cardiotoxicity of heart-RT (13.87%, P < 2.00×10^{-16}) and anthracyclines (3.07%, P = 1.20×10^{-2}) on CMP, whereas EA specifically mediated the cardiotoxicity of heart-RT on MI (24.36%, P = 2.00×10^{-3}). In contrast, LTL mediated the cardiotoxicity of heart-RT on both CMP (15.06%, P = 8.0×10^{-3}) and MI (20.77%, P = 4.00×10^{-3}), albeit less significantly.

Conclusion: These findings suggest specific aging biomarkers are more informative for certain outcomes, potentially driven by various underlying aging mechanisms. There is no one-fits-all biomarker to identify survivors with greater accelerated aging and hence higher risk of particular adverse outcomes, emphasizing the need for integrative approaches in future clinical research.

#3613 Association between cumulative lifetime exposure of reproductive hormones and TILs among women with breast cancer.

Yidan Zhang[1], Rand Akasheh[1], Bo Qin[2], Angela Omilian[3], Nur Zeinomar[2], Song Yao[3], Elisa V. Bandera[2], Christine Ambrosone[3], Thaer Khoury[4], Ting-Yuan David Cheng[1]

[1]Department of Internal Medicine, The Ohio State University Wexner Medical Center, Columbus, OH,[2]Cancer Epidemiology and Health Outcomes, Rutgers Cancer Institute, New Brunswick, NJ,[3]Department of Cancer Prevention and Control, Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]Department of Pathology & Laboratory Medicine, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Tumor-infiltrating lymphocytes (TILs) within the tumor and its surrounding microenvironment reflect an active immune response and are regarded as a prognostic marker for breast cancer. However, host factors that affect TILs remain less explored. The study investigated the association between lifetime hormone exposure and TILs.
Methods: The study included newly diagnosed invasive breast cancer cases in the Women's Circle of Health Study. Lifetime endogenous hormone exposure (LHEendo) was defined as the sum of reproductive years and cumulative pregnancy duration, minus cumulative breastfeeding duration. The reproductive years were defined as the duration between age at menarche and age at diagnosis for premenopausal women, and as the duration between age at menarche and age at menopause for postmenopausal women. Lifetime exogenous hormone exposure (LHEexo) was estimated by summing the years of oral contraceptive (OC) use and hormone replacement therapy (HRT) use. TILs were scored as 0% to 100% of stromal tissue based on established guidelines. Generalized linear models with Gamma distribution and log link function were used to assess the associations between LHEendo or LHEexo and TILs. Directed acyclic graphs (DAGs) were used to select covariates. When assessing the association between LHEendo and TILs, we adjusted for race, family history of breast cancer, and duration of OC use. For the association between LHEexo and TILs, adjustments included race, BMI at enrollment, age at diagnosis, and menopausal status.
Results: A total of 1315 patients (920 Black and 395 White women) were included in the study. Overall, we did not observe a significant association between either LHEendo or LHEexo and TILs. However, when analyses were stratified by race, shorter LHEendo or LHEexo was associated with higher TILs among White women (exponentiated (exp) beta=0.98, 95% CI=0.96 to 0.99 for LHEendo, and (exp) beta= 0.98, 95% CI=0.97 to 1.00, respectively; P-interaction=0.042 for LHEexo and 0.15 for LHEendo), but not among Black women. When stratifying the analyses by breast cancer molecular subtype, a shorter LHEendo was associated with higher TILs in hormone receptor (HR)+/HER2- patients ((exp) beta=0.99, 95% CI=0.97 to 1.00), while a shorter LHEexo was associated with higher TILs in HR+/HER2+ patients ((exp) beta=0.97, 95% CI=0.95 to 1.00). The interactions between LHEendo or LHEexo and molecular subtype were not significant (P>0.05).
Conclusions: The associations of lifetime endogenous and exogenous hormone exposure with TILs may vary by race and breast cancer molecular subtype. These findings contribute to our understanding of the roles of hormonal factors in the breast tumor microenvironment.

#3614 Examining social networks within public housing to better direct cancer screening interventions for Pacific Islanders.

Mark L. Willingham[1], Kevin Cassel[1], Ian Pagano[1], Grazyna Badowski[2]

[1]University of Hawai'i Cancer Center, Honolulu, HI,[2]College of Natural & Applied Sciences, University of Guam, Mangilao, Guam

Background: Social networks and social interactions play an important role in an individual's health and cancer screening behaviors. We examined the relationship between types of social interactions to better understand where to direct efforts for cancer screening interventions for Pacific Islanders (PIs) in Hawai'i (Native Hawaiians, Chuukese, and Marshallese adults) in public housing communities where PIs are often overrepresented.

Methods: We utilized a mixed methods research design, examining an existing survey dataset of 1,010 PIs and 16 semi-structured interviews from the same sites where we surveyed individuals, to determine the role of social networks on health outcomes within PIs living in public housing. As a measure of social networks, we formed a social network index from three survey items, including, the number of individuals a person knows personally, interacts with, and discusses personal matters with utilizing a range of 0-9 for each item. Findings from the 16 semi-structured interviews regarding social networks used by individuals for information sharing and with whom participants discussed personal health matters provided qualitative data used for examining the social network index. We applied means testing between the groups (515 Native Hawaiians, 305 Chuukese, 180 and Marshallese) to determine if there were differences in the groups' social networks, and grounded theory to extract the major themes from the narratives.

Results: Interviewees discussed the role of small social circles consisting of their families and households for information and health resource sharing. Within the dataset, Chuukese had significantly smaller personal networks ($\bar{x}$= 4.05, p=.003); however, they had significantly more individuals ($\bar{x}$= 4.90, p=.04) with whom they would discuss personal matters, more than Native Hawaiian and Marshallese adults. Marshallese indicated significantly more individuals ($\bar{x}$= 5.10, *p*=.04) that they have interacted with over the past two weeks.

Conclusions: Chuukese adults have small personal networks; however, their small social circles used to discuss personal and important matters is larger than the other groups, Marshallese and Native Hawaiian. This thus indicates more meaningful social networks for this group. Marshallese adults may interact with more people; however, they did not indicate more close relationships than Chuukese to discuss personal matters. These findings indicate social networks and the type and frequency of social interactions have meaningful roles in health and cancer information sharing for PIs. Future interventions must recognize the frequency and types of meaningful social networks within PIs to potentially change cancer screening behaviors by increasing resource sharing within the most valuable networks.

#3615 Clonal hematopoiesis in ovarian cancer survivors: Correlation with carboplatin and PARP inhibitor exposure.

Marc R. Radke, Nithisha Khasnavis, Carly Mondoy, Mayumi Rubin-Saika, Enna Manhardt, Jennifer Ochoa, Melanie R. Dillon, Roseanne J. Gamboa, David Wu, Sioban Keel, Sergei Doulatov, **Elizabeth M. Swisher**

University of Washington, Seattle, WA

Background: Ovarian cancer (OC) survivors have high rates of therapy-related myeloid neoplasia. We characterized clonal hematopoiesis (CH) in OC survivors and its relationship to therapeutic exposures.
Methods: We sequenced peripheral blood mononuclear cell (PBMC) DNA from 121 OC survivors treated with carboplatin +/- PARP inhibitors and 71 controls: 37 cancer-free females and 34 with OC prior to treatment. Our BROCA-MY sequencing panel identifies all classes of mutations in 72 susceptibility genes for gynecologic cancer, bone marrow failure, and leukemia and genes frequently altered in CH or myeloid malignancies. To accurately detect CH pathogenic variants (CHV) at ≥1% variant allele frequency (VAF), unique molecular identifiers (UMIs) were used to construct duplex consensus reads. CHVs were included if present in at least three consensus reads, had a VAF ≥1%, had a QUAL score (VarDict) ≥100, and were predicted to be pathogenic.
Results: Of the 121 PBMCs collected post treatment from OC survivors, 57 (47.1%) had no CHVs, 36 (29.8%) had 1 CHV, and 28 (23.1%) had ≥2 CHVs, not significantly different than controls: 37 (52.1%) with no CHVs, 26 (36.6%) with 1 CHV, and 8 (11.3%) with 2 or more (P=0.14). However, there was a trend (P=.055) for more cases with ≥2 CHVs in cases vs controls. Within treated OC cases, PARP inhibitor exposure was significantly associated with CHV detection: 14 (34.1%) with 0 CHV, 11 (26.8%) with 1 CHV and 16 (39.0%) with ≥2 CHVs vs cases without PARP inhibitor exposure: 43 (54.1%) with 0 CHV, 24 (30.4%) with 1 CHV, and 12 (15.2%) with ≥2 CHVs (P=0.0045). CHVs were significantly more common in cases than controls for *CHEK2* (11.8% vs 1.4%, P=0.006) and *PPM1D* (19% versus 0, P< 0.0001) while CHVs in *DNMT3A* (17.4% vs 11.6%) and *TET2* (9.1% vs 5.6%) were similarly frequent in cases and controls. *TP53* CHVs were more common in case (8.3%) versus controls (1.4%) but this did not reach statistical significance (P=0.057). In 2 patients with paired PBMC samples collected 6 months apart, CHVs detected in the second sample were not detectable in the baseline (*ATM* and *TET2* in one case and *TP53* in the other). A third case had a baseline blood sample with 5 CHVs (2 in *TP53*, 2 in DNMT3A and 1 in *SMC3)* that were detectable 6 years prior to TMN diagnosis. At the time of TMN diagnosis, the same 5 CHVs were identified with 2 additional CHVs in *PPM1D* and *CHEK2.*
Conclusions: The gene distribution and number of CHVs differed in PBMCs from ovarian cancer survivors treated with platinum chemotherapy compared to controls, although the overall frequency of CHVs was similar. CHVs in *PPM1D* and *CHEK2* were significantly more common in cases, while *DNMT3a* and *TET2* CHVs were present at similar frequencies. Within OC survivors, PARP inhibitor exposure was significantly associated with the presence of a CHV. We are following OC survivors prospectively and will present additional sequential data on CHVs in patients undergoing varying treatments.

#3616 Cultural racism as a driver of health disparities.

O. L. Osazuwa-Peters[1], T. Brown[2], N. Krieger[3], T. Akinyemiju[1];
[1]Duke University School of Medicine, Durham, NC, [2]Duke University, Durham, NC, [3]Harvard T.H. Chan School of Public Health, Boston, MA

Background: Cultural racism (CR), which refers to ideologies, values, belief systems, and tangible manifestations that enable racial oppression, is a distinct component of systemic racism with hypothesized links to health disparities. However, relative to other more widely recognized components of systemic racism— interpersonal and structural racism— CR is poorly studied with sparse epidemiological evidence on its direct relationship with health outcomes and contributions to disparities.
Methods: To bridge this gap, we developed the cultural racism factor (CRF), a latent measure derived using confirmatory factor analysis to model interrelationships among seven indicators that are hypothesized to reflect CR: i) anti-immigrant sentiments, ii) racial resentment, iii) online racial animus, iv) number of public symbols of the confederacy/100,000, v) aggregate implicit racial bias for White residents, vi) lack of White support for Medicaid expansion, and vii) lack of community-oriented policing. These indicators were quantified at the state level, given that data was consistently available at this level, and states are influential political actors that shape population health and allocate resources. Associations between the CRF and a variety of health outcomes (four mortality outcomes, life expectancy at birth, and two mental health outcomes) were evaluated using demographics-adjusted regression models.
Results: In analysis of US mortality data between 2018 and 2021 obtained from CDC Wonder, each unit increase in the CRF was associated with ~136 (95% confidence interval (CI): 90-182) all-cause deaths per 100,000, ~40 (21-59) cardiovascular-specific deaths per 100,000, ~6 per 100,000 (3-9) diabetes-specific deaths per 100,000, and ~11 per 100,000 (5-17) cancer-specific deaths per 100,000. Also, the CRF was associated with a one-year decline in life expectancy at birth (~ -1 (-2 - -1); National Center for Health Statistic data). Overall, these associations were consistent for both Black and White adults. Also, CRF's association with all-cause mortality appeared to be independent of structural racism. Further, CRF showed significant associations with mental health outcomes including a higher risk for depression history ranging from 3% overall to 25% among Native Hawaiian/PI and higher risk for poor mental health days ranging from 3% overall to 14% among Hispanics, in CDC's Behavioral Risk Factor Surveillance System data (2018-2021).
Conclusion: In sum, CRF was adversely associated with numerous health outcomes, overall and by racialized groups. These findings highlight cultural racism's role as a contemporary, consistent, and universally harmful social exposure for US adults that critically needs to be addressed. Further, the CRF makes it possible to advance the science of racism and health and provides an empirical basis for efforts to address US health inequities that result from cultural racism.

#3617 Distinct immune signature and regulated genes in prostate cancer disparity.

Shiv Shankar Verma[1], Pingfu Fu[1], Gregory T MacLennan[2], Lee E Ponsky[3], Chen-Han Wilfred Wu[4], Jonathan E Shoag[1], Sanjay Gupta[1]

[1]Urology, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Department of Pathology,, Case Western Reserve University School of Medicine, Cleveland, OH,[3]Department of Urology, Case Western Reserve University School of Medicine, Cleveland, OH,[4]Department of Genetics and Genome Sciences,, Case Western Reserve University School of Medicine, Cleveland, OH

Prostate cancer is a biologically and clinically diverse disease, with incidence and mortality rates varying significantly among different racial and ethnic groups. In African American (AA) men, the incidence of prostate cancer is approximately 60% higher, and the mortality rate is two to three times greater compared to Caucasian American (CA) men. These disparities are complex and encompass various biological and social determinants, including genetic predisposition, comorbid conditions, socioeconomic status, and environmental influences. The interplay of these elements has a clear association with disease outcomes. Recent research highlights the role of the tumor immune landscape and its associated genes in regulating prostate cancer biology at every stage of progression, ultimately impacting patient outcomes. We hypothesize that variations in immune cell gene signatures within tumors across different racial groups may influence prostate cancer outcomes. To investigate this, we analyzed transcriptomic data from 35 radical prostatectomy specimens obtained from treatment-naive patients, comprising 20 AA men and 15 CA men with prostate cancer. This analysis focused on the gene expression profiles of primary prostate tumors and adjacent normal tissues. We specifically selected immune-related genes to assess the immune-oncological differences between AA and CA prostate tumors, utilizing bioinformatics platforms such as EPIC, xCell, and IPA. To evaluate race-specific differential gene expression, we employed a rank test, and the effect of each gene's expression on overall survival was further analyzed using a univariate Cox regression model. Prostate tumors in AA patients exhibit significant enrichment in the tumor microenvironment and a distinct gene immune profile compared to those in CA men. In AA patients we observed elevated z-scores in pathways such as CREB signaling, Th1 and Th2 pathways, dendritic cell maturation, IL-17 signaling, TREM1 signaling, and cytokine production in macrophage and T Helper cells mediated by IL-17A and IL-17F. We also noted increased cytokine levels in epithelial cells influenced by IL-17A and IL-17F. Conversely, pathways like PD-1, PD-L1, ILK, IL-3, chemokine signaling, adrenomedullin, erythropoietin signaling, IGF-1, VEGF, and B-cell receptor signaling exhibited low z-scores in AA prostate tumors. Additionally, our analysis identified 13 major immune cell types, and 27 genes significantly associated with immune cell infiltration in AA prostate cancer. The expression levels of ARSL, BAALC, CCL23, EPHA2, IGFL2, KRT5, NTM, and NDP ($p < 0.05$) were linked to overall survival in AA prostate cancer patients. Taken together, prostate cancer in AA patients demonstrates a unique immune repertoire and gene profile, characterized by significant enrichment in pro-inflammatory immune pathways that correlate with poorer outcomes.

#3618 Biosocial determinants of health disparities among racial/ethnic minorities with chronic liver disease and liver cancer.

Tagari Samanta, Jun Hyoung Park, Panagiotis Katsonis, Benny Abraham Kaipparettu

Baylor College of Medicine, Houston, TX

Background: Metabolic disorders and chronic liver disease (CLD) play crucial roles in the development and progression of liver cancer (LC) like hepatocellular carcinoma (HCC). Previous studies suggest that the ethnic minority population increasingly suffers from CLD and LC. Thus, the impact of biosocial factors contributing to CLD and LC among minority populations requires further investigation. Using the All of Us database, this study aimed to understand the biosocial factors contributing to CLD and LC among racial subgroups.
Methods: Using All of Us Researcher Workbench, we analyzed in a cohort of 33767 CLD [non-alcoholic fatty liver disease (NAFLD), alcoholic liver disease (ALD), and Hepatitis B and C] patients among different ethnic groups. We investigated the impact of various social determinants of health (SDOH) factors and genetic variations in key liver disease genes (PNPLA3, TM6SF2, MBOAT7, GCKR, and HSD17B13). Additionally, we explored metabolic pathways contributing to LC progression were analyzed using MACdb, GENT2, and TCGA databases and publicly available RNASeq data.
Results: Several confounding factors associated with CLD in Hispanic (HA) and African American (AA) populations compared to the non-Hispanic White (NHW) populations were identified in this study. HA and AA CLD patients suffer more from high socioeconomic status (SES) barriers. While genetic variations in the aforementioned genes were associated with CLD risk, their impact varied across ethnic groups. Metabolomic data of urinary metabolites from LC patients and healthy volunteers suggest hypoxanthine is upregulated in LC patients. TCGA analysis of hypoxanthine-related genes in the LC tumors confirmed that xanthine dehydrogenase (XDH), which converts hypoxanthine to uric acid, is down-regulated in the tumors of Asian patients. Survival analysis confirmed poor overall survival among the Asian and AA LC patients with lower XDH expression in their tumors.
Conclusions: Our study highlights the complex interplay of social, genetic, and metabolic factors in CLD and LC disparities. Further research is needed in a larger cohort to eliminate the root causes of these SES and cancer signaling disparities to obtain a more equitable survival outcome from CLD and LC in minority populations.

#3619 Urban-rural variations in racial/ethnic differences in time to treat among individuals newly diagnosed with cancer in the United States 2015-2021.

Hui Cheng, Oxana Palesh, Susan Hong

Virginia Commonwealth University - VCU, Richmond, VA

Timely treatment is crucial for effective cancer care. Studies have shown longer durations from diagnosis to treat among non-white racial/ethnic groups in the United States. In this study, we assessed whether racial/ethnic differences in the time to treat vary across urban/rural residents. We conducted a retrospective cohort study of over 3.5 million individuals newly diagnosed with cancer from 2015 to 2021, using data from the Surveillance, Epidemiology, and End Results (SEER) program. We estimated the median number of days from diagnosis to treatment by five racial/ethnic groups (non-Hispanic [NH] white, NH black, NH American Indian/Alaskan Native, NH Asian and Pacific Islander, and Hispanics) and five strata of urban/rural classifications of residence (large, mid-sized, small, adjacent, and non- metropolitan areas). NH black individuals living in large metropolitan areas experienced the longest median duration from diagnosis to treatment initiation (33 days), which was 8 days (95% CI=7.8, 8.2) longer than NH white individuals in large metropolitan cities. Longer durations among NH black were also present among those who live in mid-sized (6 days difference, 95% CI=5.6, 6.4), small (6 days, 95% CI=5.4, 6.6), adjacent (4 days, 95% CI=3.4, 4.6), and non-metropolitan areas (5 days, 95% CI=3.9, 6, .1), albeit smaller in size. Among Hispanic individuals newly diagnosed with cancer, those in large to small metropolitan cities also experienced longer duration from diagnosis to treatment when compared to NH white individuals in those areas (coef.=3 days [95% CI=2.8. 3.2], 2 days [95% CI=1.7, 2.3], and 3 days [95% CI=2.4, 3.6] for large, mid-sized, and small metropolitans); those in adjacent and non-metropolitan areas had slightly shorter duration from diagnosis to treatment (coef.=-1 day [95%=-1.7, -0.3] and -1 day [95% CI=-1.9, -0.1] respectively). NH American Indian/Alaskan Native also experienced longer duration from diagnosis to treatment compared to NH white individuals, and there were no variations across urban/rural areas. Similarly, NH Asian and Pacific Islander individuals had an estimated 3 days longer duration from diagnosis to treatment regardless of their residential areas, except that those who lived in non-metropolitan areas experienced even longer delays (coef.= 7 days [95% CI=5.7, 8.3]) compared to NH white individuals. This study highlights significant racial/ethnic disparities in time to cancer treatment, particularly for NH black individuals in large metropolitan areas. Addressing these disparities is essential for improving cancer care equity.

#3620 A weighted multi-modal transfer learning model for alleviating racial disparities in breast cancer.

Min-jeong Baek[1], Lusheng Li[1], Jieqiong Wang[2], Vimla Band[1], Shibiao Wan[1]

[1]Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Department of Neurological Sciences, University of Nebraska Medical Center, Omaha, NE

Breast cancer (BC) is the second leading cause of cancer-related death among women in the United States. Previous studies have shown that African American (AA) women have disproportionately high mortality rate in BC compared to European American (EA) women in the United States. Existing studies have suggested that transfer learning could reduce health disparities in BC by transferring information from a majority group (e.g., EA women) to a minority group (e.g., AA women). However, their performance may be decreased due to limited training patient samples and using single-omics data only. We recently presented a transfer learning method by integrating two multi-omics data for reducing cancer disparities. However, the integration model was not optimized, and its performance in reducing disparities was not robust. To address these concerns, we propose a novel weighted multi-modal transfer learning model that can optimize the integration of multi-omics data to alleviate racial disparities in BC. Specifically, we first calculated the patient-patient similarity by using the Pearson Correlation Coefficient (PCC), based on which we performed weighted integration of multi-omics data. Then, we performed a nested grid search method to find the optimal weights for each type of omics data, which were subsequently fed into a transfer learning model. To demonstrate the effectiveness of our model, we performed the tasks of predicting Disease-Specific Survival (DSS) prognosis for the 1098 female BC patient samples from The Cancer Genome Atlas (TCGA) database. Results suggested that our model with optimized weighted integration of three multi-omics (including mRNA, miRNA and methylation) data significantly outperformed previous multi-omics transfer learning models in terms of AUC. In addition, our multi-modal transfer learning model performed remarkably better than single-omics and two-omics-integration transfer learning models, suggesting that the inclusion of more diverse omics data contributes to a better reduction of racial disparities in BC. Furthermore, the performance of our transfer learning model was also superior to that of conventional mixed models and independent models. In summary, our proposed weighted multi-modal transfer learning model achieves far better performance than existing state-of-the-art methods for reducing health disparities in BC. We expect that our proposed model will provide a new way to reduce health disparities in BC diagnosis, prognosis, and treatment, and it can be extensible to alleviate health disparities in other types of cancer.

#3621 Geographic and racial disparities in bladder cancer care in the U.S..

Atreyee Majumder[1], Daniel Erim[1], Arveen Kaur[2], Lisa Dwyer Orr[1]

[1]Johnson & Johnson, Titusville,, NJ,[2]Johnson & Johnson, Horsham, PA

Introduction: This study aims to elucidate variations in bladder cancer health outcomes and social determinants of health across diverse geographic regions in the US. It specifically investigates racial disparities in care delays among patients with bladder cancer, identifying critical intervention areas to enhance health equity.
Methods: A retrospective database analysis was conducted utilizing Medicare fee-for-service data for patients with bladder cancer diagnosed between January 1, 2021, and December 31, 2022, to measure and compare rates of diagnosis, interventions (surgical or pharmacological), specialist visit, time-to-specialist visit, and diagnosis-to-treatment initiation across US racial and ethnic groups. The reference group for rates was White patients. For example, the diagnosis rate ratio for Black patients was the quotient of diagnosis rates among Black residents and diagnosis rates among White residents diagnosed with bladder cancer during the study period. Diagnosis claims with ICD-10 code C67 and ICD-9 code 188 were used. Medicare patients with at least one year of enrollment were included. Patients were excluded if their first bladder cancer diagnosis was outside the study period.
Results: Diagnosis rate ratios were 0.5 for Black patients and 0.4 for Hispanic patients. Intervention rate ratios were 0.9 for Black patients and 0.8 for Hispanic patients. Specialist visit rate ratios were 0.9 for both Black patients and Hispanic patients. Median time-to-specialist visit was 21 days for all patients, while mean (standard deviation) times were 89 (162) days for Black patients, 77 (128) days for Hispanic patients, and 85 (148) days for White patients. Mean (standard deviation) diagnosis-to-treatment initiation were 29 (91) days for Black patients, 33 (94) days for Hispanic patients, and 27 (90) days for White patients; the corresponding 95% confidence interval was (29,36) and (26,28) for Hispanic and White patients, respectively.
Conclusion: At the national level, diagnosis-to-treatment initiation for bladder cancer was significantly delayed for Hispanic patients and disparities in intervention were identified for Black and Hispanic patients in hotspots of economic inequity. Stakeholders, including population health decision makers, healthcare providers, payers, advocacy groups and policymakers, can use the study findings to design and implement strategies to reduce geographic and racial disparities, foster collaboration among key stakeholders, and improve overall healthcare quality.

#3622 Racial disparities in second primary cancers in stomach cancer survivors: a comparative study of US and Korea cancer registries.

Yuntong Wang[1], Dong-Woo Choi[2], Minjin Kim[2], Jialin Mao[1], Art Sedrakyan[1], Kui Son Choi[2], Heejung Chae[2], Eunji Choi[1]

[1]Weill Cornell Medicine, New York, NY,[2]National Cancer Center, Goyang-si, Korea, Republic of

Background: Stomach cancer shows racial disparities in incidence and mortality, influenced by biological, lifestyle, and healthcare factors globally. With improved survival rates, stomach cancer survivors face an elevated risk of second primary cancer (SPC). However, racial differences in SPC risk and post-SPC survival remain unclear. We examined these disparities, leveraging disaggregated racial data from the U.S. and Korea SEER Registries.

Methods: Data from 47,627 U.S. stomach cancer survivors (stage I-III, diagnosed 2000-2021, survival ≥1 year) were analyzed. SPCs were defined as primary cancers diagnosed >1 year after the initial stomach cancer. The cumulative SPC incidence (stomach vs. other SPCs) were estimated using the Aalen-Johansen estimator, accounting for competing death. Cox regression evaluated the impact of SPC development on overall survival by treating SPC as a time-varying factor. Comparative analysis included 200,456 stomach cancer survivors in Korea (2012-2020).

Results: Among 47,627 U.S. stomach cancer survivors (49% localized-stage), 4,918 developed SPC (996 stomach SPC and 3,911 non-stomach SPC) over 238,135 person-years. The cumulative incidence of stomach SPC increased over time, with Hispanic survivors having the highest 15-year incidence (3.6%, CI: 3.1-3.6%). While grouped Asian data suggested a moderate stomach SPC incidence (3.0% CI: 2.4-3.5), disaggregated analysis revealed heterogeneity (1.4%-3.3%), highest in Korean and lowest in Filipino survivors. The cumulative incidence of non-stomach SPC, however, showed less variability among Asian subgroups. Survival analysis found that any SPC development (vs. those without SPC) was associated with 2.2 (CI: 2.07-2.29) times higher mortality risk. In race-specific subgroup analyses, the mortality impact of SPC development was more pronounced in Asians (adjusted hazard ratio, HR=3.2) vs. in Whites (HR=1.9; Interaction *P*<.1). Among Asian subgroups, the mortality impact of SPC was highest in Koreans and Chinese (HR=3.5 vs. 1.8 in Filipinos). Data from the Korean SEER Registry, including 200,456 survivors (75.1% localized stage [vs. 50.7% in Korean Americans]), showed that SPC incidence was half of that observed in Korean American patients. The post-SPC mortality risk was lower in Korea (HR: 2.0) than in Korean Americans in the US (HR: 3.49).

Conclusions: SPC incidence and post-SPC survival in stomach cancer survivors vary by race, with marked heterogeneity among disaggregated Asian subgroups. Patient groups with a better prognosis from initial stomach cancer, such as Asians and Koreans, experience a higher incidence of SPC and greater post-SPC mortality, possibly due to the longer survival time allowing for SPC development. Comparative studies linking US and Korean SEER with claims data could advance understanding of SPC patterns and post-treatment surveillance outcomes.

#3623 Racial disparities in front-line use of novel agents and stem cell transplants among patients with multiple myeloma.

Phyu Thin Naing[1], Anthony Corsi[2], Kelvin Zheng[2], Divya Chukkalore[1], Richa Thakur[1], Juliet Meir[1], Jessica Caro[1]

[1]Hematology and Oncology, Northwell Health Cancer Institute, New Hyde Park, NY,[2]Internal Medicine, Northwell Health, New Hyde Park, NY

Background: Racial disparities in incidence, mortality, and access to care persist in multiple myeloma (MM). Black/African Americans remain underrepresented in pivotal clinical trials, such as MAIA and PERSEUS, that led to the approval of novel agents like daratumumab (Dara). Dara received FDA approval for frontline use for transplant-ineligible (2018) and transplant-eligible (2019) patients. This study aims to analyze the disparities in the utilization of novel agents and autologous stem cell transplants (ASCT) in MM patients.

Methods: We conducted a single-center retrospective study of MM patients diagnosed between January 2022 and December 2023 at Northwell Health, the largest healthcare system in New York. Patients without confirmed MM or complete diagnostic data were excluded. Demographics, MM risk (cytogenetics and Revised International Staging System), time to treatment, time to ASCT, and treatments received were collected and analyzed.

Results: A total of 115 patients were included, of which 40 (34.8%) were Black/African American (AA), 46 (40%) White, 9 (7.8%) Asian, and 17 (14.8%) other races; 2.6% had missing race data. The median age at diagnosis was 68.8 years, with no significant difference across racial groups (p=0.21). High-risk cytogenetics, marked by t(4;14), t(14;16), t(14;20), 17p deletion, or 1q amplification, were identified in 22 patients. Stage 2 or 3 disease was observed in 76 patients. At a median follow-up of 13.6 months, 18 patients had died. Only 33.9% of patients received Dara as initial therapy. White patients had the highest proportion of recipients (17/46, 37%), whereas AA patients had the lowest (10/40, 25%). The median time to first treatment was 15 days, with no significant differences by race (p=0.08) or gender (p=0.6). The median time to ASCT was 259 days, with only 23 patients (20%) undergoing ASCT. White patients had the highest transplant rate (30.4%), followed by AA (15%), other races (11.8%), and Asians (11.1%). Non-White patients experienced a longer time to ASCT.

Discussions: Despite its demonstrated efficacy and widespread FDA approval, Dara use in frontline treatment remains low, particularly among Black/African Americans, who continue to have disproportionately limited access to novel agents. Similarly, access to ASCT remains inequitable, with lower utilization and longer times to transplant among non-White patients. Barriers such as delayed clinician adoption, drug accessibility, referral patterns, and systemic inequities should be addressed through education, streamlined access pathways, and targeted interventions to ensure equitable care for all MM patients.

#3625 Urban-rural and racial disparities in the utilization of immune checkpoint inhibitor (ICI) treatments for non-small cell lung cancer (NSCLC).

Mary T. Davis[1], Nikita Nikita[1], Krupa Gandhi[2], Scott W. Keith[2], Sarah Gordon[1], Rebecca Hartman[2], Swapnil Sharma[1], Amy Shaver[1], Grace Lu-Yao[1]

[1]Medical Oncology, Sidney Kimmel Comprehensive Cancer Center at Jefferson, Philadelphia, PA,[2]Biostatistics, Sidney Kimmel Comprehensive Cancer Center at Jefferson, Philadelphia, PA

Background: While ICIs have revolutionized NSCLC management, studies regarding real-world ICI uptake are limited. Before ICIs became the standard of care, NSCLC research uncovered inequities in treatment outcomes by race and other social determinants, like rurality. It is unclear if similar disparities exist for ICI treatment. This population-based study aims to investigate differences in ICI treatment uptake by race and rurality among late-stage NSCLC patients.

Methods: Patients ≥ 66 years diagnosed with stage III or IV NSCLC, with continuous Medicare coverage ≥ 12 months prior to diagnosis, were identified using the SEER-Medicare database. ICI treatment uptake was analyzed between January 1, 2014 and December 31, 2019. A multivariable logistic regression model was used to assess the likelihood of receiving ICI treatment, adjusting for age, year of diagnosis, sex, race, rurality, Charleson comorbidity index, cancer histology, dual eligibility for Medicaid, and state buy-in to Medicaid. Race was self-reported. Rurality was identified using SEER's Rural-Urban Continuum Codes 04-09.

Results: Of the 18,083 patients identified with NSCLC, 1,316 (7.38%) were Black and 15,972 (88.34%) were White; 3,230 (17.86%) lived in rural areas and 14,853 (82.14%) in urban areas. ICI treatment uptake increased from 8.70% of patients diagnosed in 2014 to 31.35% in 2017. ICI treatment rates were 15% lower in Black patients compared to White patients, and 25% lower for rural residents compared to urban residents (Table 1). No significant difference was found comparing patients of other races to White patients. (Table 1).

Conclusion: This population-based study documented increasing ICI usage over time, with significant rural-urban and racial disparities in treatment. These findings highlight the need to implement initiatives addressing rural and racial differences in both accessing ICI treatment for NSCLC and improving overall treatment equity.

Adjusted Odds Ratios (aOR) and 95% Confidence Intervals (CI) of Receiving Immunotherapy Treatment

Effect	aOR (95%CI)	P-value
***Metropolitan Status*: Rural vs Urban**	0.75 (0.68–0.83)	<0.001
***Race:* Black vs White**	0.85 (0.73–0.99)	0.040
***Race:* Other vs White**	1.03 (0.86–1.23)	0.245

#3626 Deoxycytidine kinase (dCK) gene expression patterns and racial disparities: Findings from the Multiethnic Cohort study.

Saunjoo Yoon[1], Sherise Rogers[2], David Bogumil[3], Edward Agyare[4], Renee Reams[4], Mariana Stern[3], Seth Ablordeppey[4], Diana J. Wilke[1], Bo Han[3]

[1]University of Florida, Gainesville, FL,[2]Yale Universtiy, New Haven, CT,[3]University of Southern California, Los Angeles, CA,[4]Florida Agricultural and Mechanical University, Tallahassee, FL

Background: Significant disparities exist in pancreatic cancer outcomes across different racial and ethnic groups, with African Americans experiencing disproportionately higher incidence and mortality rates than other ethnic groups. The genetic underpinnings of these disparities, particularly concerning drug metabolism and treatment response, remain poorly understood. Deoxycytidine Kinase (dCK) plays a crucial role in activating nucleoside analogs for pancreatic cancer treatment. Our study aim was to characterize dCK expression patterns across different racial/ethnic groups and evaluate the association between genetic variations in dCK and survival outcomes.

Methods: Germline genetic variation was analyzed on a subset of 756 cases in the Multiethnic Cohort (MEC) study. Incident pancreatic cancer cases were identified using SEER state cancer registries. Samples were genotyped across various arrays and imputed to the 1000 genomes reference panel using the Minimac4 algorithm. Imputed data was filtered to SNPs and short indels within the dCK gene coding region. Genetically determined dCK gene expression was estimated using imputed data. Associations between genetic variation and mortality among cases were estimated using Cox proportional hazards regression.

Results: Sample characteristics are shown in Table 1. Nine variants from the dCK gene with an imputation quality score of $R^2 \geq 0.8$ across all samples were highly correlated within each self-reported ethnic group—the highest correlation was among African Americans. There was no association between any variants and pancreatic cancer survival nor interactions between dCK variants dosage and chemotherapy treatment on mortality rate.

Conclusions: To further evaluate the potential influence of the variants on survival and mortality, we are testing the protein levels using Immunohistochemistry (IHC) staining and Western blot.

Table 1. Sample Characteristics: (N =756)

Race/Ethnicity	African-American	Japanese-American	Latino	Native Hawaiian	White
Cases (n)	129	266	152	76	133
Females (%)	60.5%	59.4%	45.4%	55.3%	47.4%
Deaths	122	238	136	67	127
Pancreatic Cancer Deaths	101	207	112	59	111
Person-Months Total	1253	3778	1921	1201	2488
Mean Age at Dx (years)	79.4	79.0	78.4	75.8	77.0
Mean Survival (months)	9.7	14.2	12.6	15.8	18.7
Median Survival (months)	4.1	4.9	5.2	5.5	5.0

#3627 Looking beyond the aggregate: uncovering ethnic-specific differences in breast cancer among young Asian American women.

Alice W. Lee[1], Diana Aguilar-Cruz[1], Cindy Do[1], Peyton Fisher[2], Aleah La Flair[2], Mojgan Sami[1], Nicole Wells[2]

[1]California State University, Fullerton, Fullerton, CA,[2]The Young Breast Cancer Project, Chula Vista, CA

Background: Emerging data suggest that breast cancer incidence rates in Asian American women are on the rise, and this has also been observed specifically among young women (i.e., under age 40). However, most breast cancer studies often aggregate data across all Asian Americans, overlooking the distinct sociodemographic features and health disparities that may characterize each Asian ethnic subgroup. Therefore, it is unclear if the observations noted in young Asian American breast cancer patients as a single group translate to each Asian subgroup as well. This is especially important when it comes to young women since they do not have established breast cancer screening guidelines and are more likely to be diagnosed with advanced stage tumors.
Methods: We analyzed the Surveillance, Epidemiology, and End Results Program's (SEER's) specialized Asian groups database, which includes cancer incidence data from 13 population-based registries. Overall, 33,960 female breast cancer cases who were diagnosed under age 40 and between the years of 1990 and 2014 were identified; the 1990-2014 time period for our analysis reflects the available data in this database. We calculated incidence rate ratios (IRRs) and 95% confidence intervals (CIs) comparing young breast cancer incidence by stage for seven Asian subgroups relative to Non-Hispanic Whites (NHWs). Joinpoint regression models were also run to determine annual percent change (APC) using 5-year grouping intervals for the racial/ethnic groups.
Results: Most Asian ethnic subgroups showed lower incidence rates of regional/distant breast cancer when compared to NHWs with the only exception being Hawaiian/Pacific Islanders (IRR=1.14, 95% CI 0.98-1.31). Regional/distant breast cancer incidence had also been trending upwards for most racial/ethnic groups; it increased 2.72% for Asian Indian/Pakistanis (95% CI -0.52 to 7.61) and 1.97% for Koreans (95% CI 0.79 to 3.18). Japanese constituted the only Asian subgroup to be significantly more likely to receive a localized breast cancer diagnosis relative to NHWs (IRR=1.21, 95% CI 1.09-1.35). In addition, significant increasing trends of localized tumors were observed for Asian Indian/Pakistanis (APC=3.35, 95% CI 1.20 to 6.71) and Chinese (APC=1.18, 95% CI 0.23 to 2.23).
Conclusions: Breast cancer in young women is understudied, particularly in Asian Americans who have historically been thought to be at lower risk of the disease. With the growing literature highlighting the increasing incidence of breast cancer in Asian Americans, including young women, our findings highlight important disparities in which specific ethnic subgroups appear to be at higher burden of advanced stage breast cancer. This type of work is essential for developing targeted preventive strategies to address the needs of young Asian females.

#3628 Associations between per and polyfluoroalkyl substances (PFAS) and inflammatory markers in a racially diverse cohort of breast cancer patients.

Alicia Arredondo Eve[1], Ashlie Santaliz Casiano[2], Haihley Connors[1], Oana Danciu[3], Garth Rauscher[4], Natalie Pulliam[5], Elona Liko-Hazizi[5], Sarah Friedewald[6], Seema Khan[6], Julie Kim[6], William Gradishar[6], Kent Hoskins[3], Zeynep Madak-Erdogan[7]

[1]Food Science and Human Nutrition, University of Illinois Urbana-Champaign, Urbana, IL,[2]Division of Nutritional Sciences, University of Illinois Urbana-Champaign, Urbana, IL,[3]Division of Hematology/Oncology, University of Illinois at Chicago, Chicago, IL,[4]School of Public Health, University of Illinois at Chicago, Chicago, IL,[5]Northwestern Memorial Hospital, Chicago, IL,[6]Northwestern University Feinberg School of Medicine, Chicago, IL,[7]Cancer Center at Illinois, University of Illinois Urbana-Champaign, Urbana, IL

Background: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental pollutants known for their resistance to degradation and their potential to accumulate in biological systems. These compounds have been associated with various adverse health effects, including promoting cancer progression.
Aim: This study aimed to examine the associations between plasma PFAS levels and inflammation-related proteins identified through targeted proteomics in a racially diverse cohort of menopausal women and breast cancer patients.
Methods: Three PFAS compounds—perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), and perfluorobutane sulfonic acid (PFBS)—were quantified in plasma samples from both cancer-free individuals and breast cancer patients using targeted liquid chromatography-mass spectrometry (LC-MS).
Results: We found higher levels of PFBS in African American patients with breast cancer compared to Non-Hispanic White patients. Analysis of variance (ANOVA) revealed marginal differences in PFAS levels between racial groups for PFBS ($p=0.056p$) with no significant differences for PFOA or PFOS ($p>0.05$). Logistic regression models showed no significant associations between normalized PFAS levels (PFOA, PFOS, and PFBS) and health outcomes (tumor grade or status) in the overall cohort or within racial subgroups. Lastly, Among African American patients, PFBS levels were strongly associated with inflammatory and cancer-related markers including CASP8, CCL3, MMP10 and TRANCE, which are implicated in immune regulation tissue remodeling and cancer progression. These findings highlight the potential role of PFAS in contributing to inflammation and cancer progression, particularly among African American breast cancer patients, emphasizing the need for further research on PFAS exposure and its impact on cancer disparities.

#3630 First-line therapies and subjective cognitive function trajectories among international metastatic hormone-sensitive prostate cancer survivors.

H. Chan School of Public Health, Boston, MA

Introduction: The standard of care for metastatic hormone-sensitive prostate cancer (mHSPC) has evolved with the expanded approval of androgen receptor pathway inhibitors (ARPIs) alongside androgen deprivation therapy (ADT). ADT alone has been shown to affect cognitive function. However, the cognitive impact of distinct treatment combinations remains unclear. We investigated the association between first-line systemic treatments and the trajectory of subjective cognitive function among mHSPC survivors in the International Registry for Men with Advanced Prostate Cancer (IRONMAN).

Methods: This analysis included 2435 newly diagnosed mHSPC patients enrolled across 15 countries between July 2017 and August 2024. Treatments were reported by site personnel and physicians. For this analysis, we focused on first-line systemic treatment and classified treatment groups at enrollment as ADT monotherapy (referent), ADT + ARPIs, or ADT + chemotherapy. Subjective cognitive function was assessed via the EORTC QLQ-C30 Cognitive Function subscale, with patient-reported scores (range 0-100) collected at enrollment and every 3 months for up to 5 years; higher scores reflect better cognitive function. Associations were estimated using linear mixed effects models with clustering by study site and country to examine differences at enrollment and across trajectories of subjective cognitive function by first-line treatment, adjusting for demographic and clinical factors.

Results: Median age at enrollment was 70 years, with a median follow-up of 1.7 years. 724 (30%) participants were treated with ADT monotherapy, 1317 (54%) with ADT + ARPIs, and 394 (16%) with ADT + chemotherapy. Mean cognitive function scores at enrollment were 85.4 (Standard Deviation [SD] 19.5) for participants treated with ADT monotherapy, 86.7 (SD 17.3) for ADT + ARPIs, and 86.7 (SD 18.0) for ADT + chemotherapy. Cognitive function scores decreased by -0.60 points (95% Confidence Interval [CI] -0.72, -0.48) per year among those treated with ADT monotherapy, with similar rates observed for those treated with ADT + chemotherapy. Participants treated with ADT + ARPIs had a slower decline in cognitive function, with scores decreasing by -0.36 points (95% CI -0.60, -0.08) per year.

Conclusion: In this international cohort of mHSPC survivors, subjective cognitive function scores were generally high at enrollment but declined over time. There was no evidence of worse cognitive function in those treated with ADT + ARPIs nor ADT + chemotherapy over time compared to ADT monotherapy. Cognitive functioning is a key component of survivorship, and defining cognitive trajectories associated with first-line treatment can inform supportive interventions, patient treatment decision-making, and clinical guidelines.

#3631 The role of distress-related metabolic dysfunction in ovarian cancer development.

Nan Lin[1], Raji Balasubramanian[2], Heather A. Eliassen[1], Britton Trabert[3], Mary K. Townsend[4], Shelley S. Tworoger[4], Oana A. Zeleznik[1]

[1]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[2]Department of Biostatistics and Epidemiology, University of Massachusetts, Amherst, MA,[3]Department of Obstetrics and Gynecology, University of Utah, and Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT,[4]Division of Oncological Sciences, Oregon Health & Science University, Portland, OR

Background: Ovarian cancer has few known risk factors and most of them are not easily modifiable on a population level. Thus, there is an urgent need to identify novel and modifiable risk factors for ovarian cancer. Growing evidence suggests chronic stress and subsequent distress influence ovarian cancer etiology. Metabolites represent the end-products of metabolism, reflect genetic and environmental influences, and are associated with chronic distress. Here, we evaluated the association of a 20-metabolite distress score (MDS) and its constituting metabolites with ovarian cancer risk.
Methods: Our study includes two 1:1 matched case-control studies, one (N=594) nested within the Nurses' Health Studies (NHS and NHSII) and another (N=348) nested within the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial (PLCO). Metabolites were measured 3-27 years before diagnosis using liquid-chromatography tandem mass spectrometry in two batches. We calibrated and pooled metabolite values across two studies. Of the 20 MDS metabolites, we aligned 19 across batches, which were used in calculating the MDS. We estimated odds ratios (OR) and 95% confidence intervals (CI) for ovarian cancer corresponding to a one standard deviation (SD) increase in MDS and the individual metabolites using unconditional logistic regression, adjusting for matching factors and menopausal status, race, tubal ligation, oral contraceptive use, and family history of breast/ovarian cancer.
Results: A 1-SD increase in MDS was not associated with ovarian cancer risk, however, point estimates were consistent across studies and in the expected directions (Overall: OR 1.07; CI 0.97-1.19, p=0.17; NHS: OR 1.07; CI 0.94-1.21, p=0.31; PLCO: OR 1.09; CI 0.90-1.31, p=0.39). We observed heterogeneity in the MDS-ovarian cancer association by menopausal status, where a 1-SD increase in MDS was associated with a 19% (OR 1.19; CI 0.98-1.14, p=0.08) increased ovarian cancer risk in pre-menopausal women and 3% (OR 1.03; CI 0.91-1.17, p=0.62) increased risk in post-menopausal women.
Conclusion: Pooling two independent studies, higher circulating MDS levels were associated with a modest increase in ovarian cancer risk, consistent with our hypothesis. Further, the MDS-ovarian cancer association was more pronounced among pre-menopausal women, consistent with the previously reported association between depression and ovarian cancer risk. Additional analyses investigating heterogeneity in the MDS-ovarian cancer association by lifestyle and behavior factors is ongoing. Our findings suggest that metabolic dysregulation associated with chronic distress may represent a novel risk factor for ovarian cancer.

#3632 Analysis of supportive care medication use in metastatic colorectal cancer across racial and ethnic groups using SEER-Medicare.

Olga Trejos Kweyete[1], Yi Guo[2], Sherise Rogers[2], Lisa Scarton[2], David Deremer[2], Diana Wilkie[2], John Allen[3]

[1]University of Florida, Orlando, FL,[2]University of Florida, Gainesville, FL,[3]Purdue University, Indianapolis, IN

Background: This study investigates disparities in the use of adjunctive supportive care medications (SCM) among metastatic colorectal cancer (CRC) patients across different racial and ethnic groups. SCMs are central to symptom management and improving health-related quality of life in cancer treatment. Our goal was to identify potential disparities in medication use for neurological symptoms that may impact quality of life and symptom management in end-of-life care for metastatic colorectal cancer patients.

Methods: Data were acquired from Surveillance, Epidemiology, and End Results (SEER)-Medicare-linked database covering 2005-2017. We included patients diagnosed with metastatic CRC who died between 2005-2017 with more than one year of Medicare enrollment. Logistic regression models evaluated the relationship between SCM use and race while adjusting for various covariates, including sex, race, age, marital status, education, income, residence, and Charlson Comorbidity Index. Non-Hispanic White (NHW) CRC patients served as the reference group for all comparisons. Results are reported as the adjusted Odds Ratio and 95% Confidence Interval.

Results: After applying the inclusion/exclusion criteria, 28,212 patients were included in the final analysis (NHW:72.81%, Black 12.67%, Hispanic 9.51%, Asian/Pacific Islander 4.65%). Racial and ethnic disparities in the use of multiple SCM drug classes were identified. The results are summarized in Table 1.

Conclusion: Black CRC patients had significantly lower use of multiple SCM drug classes than NHW patients. Hispanic and Asian CRC patients' results were more heterogeneous, demonstrating both increased and decreased use for various SCM drug classes than NHW patients. These findings suggest varying patterns in medication use across racial and ethnic groups and require further investigation to understand further the causes and potential consequences of these differences in use

#3633 Exploring racial and ethnic disparities in supportive medication use for nonmetastatic colorectal cancer: a SEER-Medicare database analysis.

Olga Trejos Kweyete[1], Yi Guo[2], Sherise Rogers[2], Lisa Scarton[2], David Deremer[2], Diana Wilkie[2], John Allen[3]

[1]University of Florida, Orlando, FL,[2]University of Florida, Gainesville, FL,[3]Purdue University, Indianapolis, IN

Background: Colorectal cancer (CRC) is a devastating disease with CRC patients experiencing physical disease and treatment-related symptoms that seriously impact the quality of life and psychological health. These symptoms often require supportive care medications (SCM) to manage and improve health-related quality of life throughout the illness trajectory. This study explores racial and ethnic differences in using SCMs in nonmetastatic CRC, aiming to uncover barriers and promote equitable care.
Methods: Data from the SEER-Medicare-linked database (2005-2017) were analyzed for metastatic CRC patients who died during this period and had over a year of Medicare enrollment. Logistic regression assessed the relationship between SCM use and race, controlling for variables like sex, age, marital status, education, income, residence, and Charlson Comorbidity Index, with non-Hispanic White patients as the reference group. Results are presented as the adjusted Odds Ratio and 95% Confidence Interval.
Results: After applying the inclusion/exclusion criteria, 81784 patients were included in the final analysis (White:72.6%, Black: 10.0%, Hispanic: 7.9%, Asian/Pacific Islander: 4.2%). Racial and ethnic disparities in the use of multiple SCM drug classes were identified. The results are summarized in Table 1.
Conclusion: Black patients tended to have lower odds of supportive care medication use across several SCM classes, particularly anti-emetics, headache aids, steroids, and sleep aids, while showing higher use of anti-epileptics and cognitive aids than White patients. Hispanic patients showed higher odds than White patients of using anti-emetics, cognitive aids, and appetite stimulants but had lower odds for muscle relaxants and steroids. Asian patients displayed higher odds for using anti-emetics and appetite stimulants but lower odds for using anti-epileptics, muscle relaxants, and sleep aids.

#3634 Short-term outcomes of breast cancer surgery by race-ethnicity in the Military Health System.

Yvonne Eaglehouse[1], **Sarah Darmon**[1], Matthew Nealeigh[1], Tracey Koehlmoos[2], Craig D. Shriver[1], Kangmin Zhu[1]

[1]Surgery, Uniformed Services University of the Health Sciences, Bethesda, MD,[2]Preventive Medicine and Biostatistics, Uniformed Services University of the Health Sciences, Bethesda, MD

Background: Racial-ethnic differences in receiving breast cancer treatment in the U.S. are well documented and have been partly attributed to access to care. However, little is known about possible disparities in short-term outcomes following breast cancer surgery. This study aimed to compare racial-ethnic groups in experience of post-operative outcomes following breast cancer surgery in the equal access U.S Military Health System.

Methods: We identified a cohort of women aged 18 and older diagnosed with stage I-III breast cancer between 2001 and 2014 who received mastectomy without reconstruction for their cancer in the MilCanEpi database. Information on 30-day complications, reoperation, and inpatient admission were captured. Multivariable logistic regression estimated the adjusted odds ratios (AORs) with 95% confidence intervals (CIs) in association with race-ethnicity for the outcomes.

Results: Among 886 Asian or Pacific Islander (API), 1,246 non-Hispanic Black (NHB), 497 Hispanic, and 4,898 non-Hispanic White (NHW) women receiving mastectomy for stage I-III breast cancer, the odds of 30-day complications were lower for API (AOR=0.63, 95% CI=0.47, 0.86) and similar for NHB (AOR=0.79, 95% CI=0.62, 1.02) and Hispanic (AOR=0.97, 95% CI=0.70, 1.34) compared to NHW women. The likelihood of reoperation was similar between the racial-ethnic groups. Hispanic women had higher odds of 30-day inpatient admission (AOR=1.55, 95% CI=1.10, 2.17) and the likelihood was statistically similar for API and NHB compared to NHW women.

Conclusions: In the equal access Military Health System, API women were less likely and NHB and Hispanic women as likely as NHW women to experience 30-day complications following primary surgical treatment without reconstruction for non-metastatic breast cancer. This highlights the importance of access to care in providing quality surgical care regardless of a patients' racial or ethnic background. The reason for higher likelihood of 30-day inpatient admission despite similar likelihood of complications among Hispanic women warrants further research.

#3635 Racial-ethnic comparisons in surgical treatment and outcomes of non-metastatic renal cell cancer in an equal access system.

Yvonne L. Eaglehouse, **Sarah Darmon**, Craig D. Shriver, Kangmin Zhu

Surgery, Uniformed Services University of the Health Sciences, Bethesda, MD

Background: Access to care has been implicated in racial-ethnic disparities in surgical treatment and survival for patients with renal cell carcinoma (RCC) in the United States. We assessed whether there were racial-ethnic disparities in surgery receipt and clinical outcomes of RCC in the U.S. Military Health System (MHS), which provides equal access to care for beneficiaries.
Materials and Methods: We used the MilCanEpi database to study a cohort of patients aged 18 and older who were diagnosed with stage I-III RCC between 1998 and 2014. Treatment with nephrectomy was evaluated in logistic regression models expressed as adjusted odds ratios (AORs) with 95% confidence intervals (CIs). Risk of recurrence and all-cause death were estimated using multivariable Cox regression models.
Results: The study included 1,371 non-Hispanic White, 362 non-Hispanic Black, and 177 Hispanic patients. Black patients were less likely to receive nephrectomy as non-Hispanic White patients overall (AOR=0.69, 95% CI=0.47, 1.00) and in strata for stage I (AOR=0.62, 95% CI=0.41, 0.95) or clear cell subtype (AOR=0.46, 95% CI=0.22, 0.96). Hispanic patients were as likely to receive nephrectomy as non-Hispanic White patients overall (AOR=1.13, 95% CI=0.49, 2.62) and in strata by stage or histologic subtype. There were no statistically significant differences in risk of recurrence or all-cause death for Black or Hispanic patients compared to non-Hispanic White patients in multivariable models.
Conclusion: In the equal access MHS, nephrectomy receipt was similar for Hispanic patients compared to non-Hispanic White patients while Black patients, especially with stage I or clear cell RCC, were less likely to receive nephrectomy. Nevertheless, there were no differences in recurrence or survival for non-Hispanic Black or Hispanic patients compared to non-Hispanic White patients with non-metastatic RCC. Further research on factors other than access to care that may explain the lower likelihood of receiving nephrectomy for Black patients is needed.

#3639 A generative AI architecture integrates molecular, clinical and functional data to develop explainable predictive models and therapeutic strategies for multiple myeloma.

Praneeth Reddy Sudalagunta, Rafael Renatino Canevarolo, Daniel DeAvila, Rachel Howard, Maria Coelho Siqueira Silva, Alexandra Achille, Angel Perez, Robert Gatenby, Mark B. Meads, Kenneth H. Shain, Ariosto Siqueira Silva

H. Lee Moffitt Cancer Center, Tampa, FL

We present a novel Generative AI pipeline designed to integrate molecular, clinical, and functional data, specifically tailored to develop explainable predictive models and therapeutic strategies for Multiple Myeloma (MM). MM is an incurable, biologically complex, and a heterogeneous disease characterized by multifactorial progression and therapy-resistant phases, driven by genetic, cytogenetic, epigenetic, and transcriptomic alterations. These alterations exhibit patient-specific variability but converge on conserved biological pathways. The lack of consensus in treating pre-malignant, high-risk, or therapy-refractory MM patients underscores the need for innovative approaches like the one described here.
Our AI architecture leverages the Mistral 7 Large Language Model (Mistral AI), fine-tuned using Low-Rank Adaptation (LoRA), and incorporates a Retrieval-Augmented Generation (RAG) layer to enhance contextual understanding and decision-making. The pipeline was trained on a unique cohort of 2419 MM patient samples (PMRC DB), spanning the disease spectrum from pre-malignant to late-refractory stages, using integrated data from molecular (RNAseq - 1175, whole exome sequencing - 1232, cytogenetics - 2008), clinical (treatment history and response - 1413), and ex vivo functional assays (986), and validated in CoMMpass cohort (MMRF).
The RAG framework integrates a literature database curated from PubMed abstracts relevant to MM biology and clinical trials through the R library easy PubMed. The documents were embedded into dense vector representations using the sentence-transformers/all-MiniLM-L6-v2 model. These embeddings were indexed using FAISS's IndexFlatL2, for fast similarity-based retrieval of relevant documents for a query run on structured PMRC DB. The pipeline retrieves the top-k relevant documents based on proximity to the query's embedding, providing essential context. Retrieved documents and the user query are combined into a structured prompt, which is passed to the model for contextually aware text generation. The model uniquely combines an MM patient's features and biological/clinical context from published literature to generate text output that provides patient-specific insight from published literature.
The AI system provided explainable insights into MM treatment strategies and can potentially aid in therapeutic decision-making. Its accuracy as a predictive biomarker and capacity to elucidate underlying biology require further validation, especially for clinical cohorts with sparse or missing data. This work represents a proof-of-concept for the integration of generative AI with domain-specific biological and clinical datasets, setting the foundation for more precise and explainable AI-driven therapeutic strategies in MM.

#3640 Mapping drug-gene interactions in cancer with large language models.

Ying-Ju Lai[1], Li-Ju Wang[2], Yufei Huang[2], Yu-Chiao Chiu[2]

[1]Department of Biostatistics and Health Data Science, University of Pittsburgh, Pittsburgh, PA,[2]UPMC Hillman Cancer Center, Pittsburgh, PA

Understanding drug-gene relationships is critical for advancing targeted cancer therapies, identifying opportunities for drug repurposing, and improving patient outcomes. However, the vast and growing volume of biomedical literature presents significant challenges for researchers attempting to efficiently extract relevant insights. To address this, we developed an automated pipeline that integrates state-of-the-art large language models (LLMs) with up-to-date literature to reliably infer drug-gene interactions. By seamlessly interfacing PubMed with LLMs, the pipeline generates efficient, evidence-based inferences, effectively overcoming the limitations of static LLMs, including outdated knowledge and the potential for inaccurate conclusions. We systematically validated the pipeline using curated collections of drug-gene pairs from established knowledgebases. Comparative performance evaluations of various LLMs, including GPT-4o (OpenAI), Gemini 1.5 Pro (Google), and several open-source models, revealed that GPT-4o slightly outperformed Gemini 1.5 Pro, with both achieving an area under the ROC curve (AUROC) exceeding 90%. These proprietary models demonstrated substantial performance advantages over open-source alternatives. Using this pipeline, we analyzed hundreds of key oncogenes and FDA-approved drugs to construct a comprehensive pan-cancer drug-gene interaction network. This network identifies therapeutic targets and drug repurposing opportunities. The highest density of drug-gene pairs was observed in breast, colorectal, and lung cancers, reflecting significant therapeutic development and research interest in these prevalent cancer types. Additionally, our analysis of liver cancer, the third leading cause of cancer-related deaths worldwide, uncovered intricate multi-target effects of approved drugs such as sorafenib and lenvatinib. Beyond cancer-type-specific findings, the analysis also revealed numerous drug-gene associations spanning multiple cancer types. In summary, our pipeline integrates real-time literature retrieval with advanced LLMs and offers a robust and accessible resource for anti-cancer drug development. Designed with user accessibility in mind, the pipeline has the potential to enable cancer researchers to analyze drug-gene relationships without requiring programming expertise or extensive computational resources. This work provides a foundation for advancing therapeutic exploration and supporting innovation in oncology.

#3641 Predicting treatment outcomes using cross-modality correlations in multimodal oncology data.

Aakash Gireesh Tripathi[1], Asim Waqas[1], Yasin Yilmaz[2], Matthew B. Schabath[1], Ghulam Rasool[1]

[1]H. Lee Moffitt Cancer Center, Tampa, FL,[2]University of South Florida, Tampa, FL

Accurate prediction of treatment outcomes in oncology requires modeling the intricate relationships across diverse data modalities. This study investigates cross-modality correlations by leveraging imaging and clinical data curated through the Multimodal Integration of Oncology Data System (MINDS) and HoneyBee frameworks to uncover actionable patterns for personalized treatment strategies. Using data from over 10,000 cancer patients, we developed a machine learning pipeline that employs advanced embedding techniques to capture associations between radiological imaging phenotypes and histopathological features, aiming to predict survival outcomes and treatment efficacy.

The HoneyBee framework played a key role in preprocessing and feature extraction, using foundation models for imaging and text data. Radiological imaging, such as computed tomography (CT) and magnetic resonance imaging (MRI), was transformed into high-dimensional embeddings with vision transformers and convolutional neural networks. Clinical data, including electronic health records and pathology reports, was structured into embeddings using biomedical language models. These embeddings ensured standardization and cross-modal alignment while capturing modality-specific features. HoneyBee also applied data augmentation and preprocessing, such as stain normalization and tokenization, to maintain data quality. MINDS provided a scalable, metadata-driven architecture for integrating datasets like patient demographics and treatment histories, supporting seamless ingestion, harmonization, and storage. Together, these frameworks created a unified, multimodal dataset optimized for predictive modeling and resilient to missing data.

In training, embeddings were combined through late-stage fusion techniques to generate unified patient-level representations in latent space. These representations were used to train machine learning models, including gradient-boosted trees and neural networks, for survival analysis and treatment response prediction. Testing was conducted using stratified cross-validation to ensure generalizability across cancer subtypes and demographic groups. Results demonstrated significant predictive correlations, such as imaging-derived phenotypes linked to histopathological indicators of treatment response. The machine learning pipeline achieved a 12% improvement in concordance indices over unimodal approaches, underscoring the enhanced accuracy of cross-modality learning.

#3642 TLSL: Transfer learning for synthetic lethality (SL) experiment design and SL prediction.

Birkan Gokbağ, Lijun Cheng, Lang Li

Department of Biomedical Informatics, The Ohio State University College of Medicine, Columbus, OH

Introduction: In a synthetic lethality (SL) gene pair, the cell dies when the function of both genes is disrupted but remains viable when the function of only one of the genes is compromised. While carrying strong therapeutic potential in the treatment of cancer, SL interactions are context specific and sparse. CRISPR-Cas9 based gene combination double knockout (CDKO) experiments are purposely designed to discover novel SL gene pairs. However, none of the published CDKO studies have considered how to use existing SL data to choose gene pair targets and cell lines for new experiments. In this project, for the first time, we present a transfer learning framework for SL prediction, namely TLSL. We anticipate TLSL can illustrate whether and how existing SL data can assist in gene and cell line selection for new CDKO experiments.
Methods: Signature-iSL is the foundation model for TLSL. It is designed to be interpretable, perform cell line specific SL prediction, and incorporate pathway-based co-membership of gene pairs and multi-omics signatures. In transfer learning, Signature-iSL shall transfer information from source data (i.e. existing CDKO experiment data) to target data (i.e. data from new CDKO experiment). Our transfer learning covers four different CDKO experiment design scenarios: (1) experiment keeps the same genes, but on a new cell line; (2) experiment keeps the same cell line, but selects different genes; (3) experiment targets a similar mechanism, but selects different cells and genes; and (4) big data (i.e. all other existing SL CDKO experiments in Synthetic Lethality Knowledge Base (SLKB)) to small data (i.e. targeted genes in a cell). TLSL was applied to all datasets under four scenarios in SLKB. It covers 11 studies, 22 cell lines, 6,127 genes, 16,059 SL, and 264,424 non-SL gene pairs. Each computational experiment was repeated five times and evaluated in out-of-sample gene pair prediction; 20% of genes and their gene partners were held out from training.
Results: As a standalone model, Signature-iSL outperformed two previous state-of-the-art methods, MVGCN-iSL and MLEC-iSL. While MVGCN-iSL achieved 0.62 and MLEC-iSL achieved 0.65 AUC-ROC, Signature-iSL reached 0.75. On average, across all four scenarios, TLSL improved accuracy, AUC-ROC, and F-1 metrics by 15%, 9%, and 10% respectively. The most successful scenario was big data to small data transfer learning, where accuracy, AUC-ROC, and F-1 metrics improved by 23%, 18%, and 15% respectively.
Conclusion: The proposed transfer learning approach, TLSL, is shown to be highly informative and beneficial for selecting genes and cells in new CDKO experiments by borrowing SL data from existing CDKO experiments. Under all four transfer learning scenarios, TLSL has significantly improved SL prediction model performance.

#3643 AI driven discovery of novel synthetic lethal gene pairs for targeted cancer therapy.

Amalia Soenens[1], Daniel Miller*[2], Oliver Vipond[2], Florencia Skuras[2], Alfie Brennan[2], Anna Hercot[2]

[1]EditCo Bio, Redwood City, CA,[2]Evariste Ltd, London, United Kingdom

Synthetic lethality (SL) offers a promising avenue for cancer therapy by exploiting vulnerabilities unique to tumor cells and minimizing off-target effects on normal tissue. However, the application of SL-based therapies remains constrained by a limited repertoire of validated targets and biomarkers. Using data from the Cancer Dependency Map (DepMap) and advanced in silico modeling, Evariste's Frobenius Target platform identified 50 potential SL gene pairs with druggable nodes and rational mechanisms linking targets and biomarkers. From this set, 24 gene pairs were prioritized for validation based on translational relevance and impact on the patient population.

Validation was achieved through a collaborative high-throughput workflow with EditCo Bio, leveraging their CRISPR-based cell line engineering platform to generate 72 knockout pools in under three weeks. Validation studies in multiple cell lines demonstrated >10 high-confidence SL pairs, including a novel SL relationship involving focal adhesion kinase (FAK). To further substantiate this relationship, novel inhibitors were developed with best-in-class selectivity over the SL partner gene. Functional assays confirmed these inhibitors' effectiveness in biomarker-low cell lines, with promising implications for clinical translation.

This study highlights the potential of AI-driven approaches to uncover the next generation of SL targets, expanding the therapeutic landscape in cancer research. By focusing on biomarker-low gene expression as a predictor of SL, our work establishes a robust framework for the discovery and validation of clinically actionable SL relationships.

#3644 Mechanistically explainable AI model for predicting synergistic cancer therapy combinations.

H. Si[1], S. Kumar[1], S. Lata[1], A. Ahmad[1], S. Ghosh[1], K. Stephansen[1], D. Nagarkar[1], E. Zhou[2], B. W. Higgs[1];
[1]Genmab US, Inc., Plainsboro, NJ, [2]Lamini, Menlo Park, CA

Background: Resistance to single-agent cancer therapies often arises through complex mechanisms such as genetic mutations, compensatory signaling, and tumor microenvironment changes. These adaptive strategies make multi-drug combinations essential to effectively target canonical pathways simultaneously. However, common *in vitro* and *in vivo* models often fail to capture these complexities, resulting in limited translational success to human clinical settings. This highlights the need for predictive frameworks that not only identify synergistic drug combinations from human clinical trials, but also provide mechanistic insights to inform clinical application. This study presents a novel Large Language Model (LLM)-based framework that integrates extensive drug combination data with a knowledge graph to predict drug combinations with biological explainability.
Methods: A retrieval-augmented generation (RAG) approach was employed to enhance predictive specificity and reduce hallucinations. *In vitro* data on drugs, targets, cell lines, tumor types, and synergy scores were compiled from over 50,000 cell line results from the DrugComboDb database. Using NCBI's APIs, BeautifulSoup, and GPT-4, biomedical information was extracted from 1,092 phase I-III clinical trials covering 700+ drug combinations across 22 tumor types. This RAG corpus, combined with targeted prompts, fed into the LLM Mistral v0.2 for prediction generation, while a knowledge graph - PrimeKG provided mechanistic insights. Model validation included unseen cases (N=42) across various drug modality combinations (N=8), including 34 immuno-oncology therapies (IO) combined with an IO, chemo, or targeted therapy, 1 targeted therapy combination and 7 antibody drug conjugate (ADC) combinations.
Results: The model achieved an F1 score of 0.80 on the entire validation set, with accuracy at 0.74, precision at 0.71, and recall at 0.92. Among drug modalities, combinations of ADC agents with IO/targeted/chemo/other ADC agents performed best (F1 score: 100%), while IO-IO combinations scored the lowest (F1 score: 62%). Each prediction included detailed mechanistic explanations, highlighting whether the drug combination was supported or unsupported with biological rationale.
Conclusions: This study presents a novel framework integrating LLMs with biological knowledge graphs to predict the efficacy when combining 2-3 oncology drugs across a range of indications. By linking generative AI with explainability tools, we address two critical challenges in AI-driven drug discovery: predictive accuracy and mechanistic transparency. Such predictive models can accelerate the discovery of synergistic therapies, thereby reducing costly experiments, and improve overall patient outcomes. Specific test cases with explainable results will be presented.

#3645 Pathway-informed deep learning enhances cancer dependency prediction using multi-source CRISPR screening data.
Chien-Hung Shih, Yu-Chiao Chiu

UPMC Hillman Cancer Center, Pittsburgh, PA

Precision cancer therapy relies on identifying tumor-specific genetic dependencies, which are genes critical for cancer cell survival and proliferation that can be leveraged as therapeutic vulnerabilities. The Cancer Dependency Map (DepMap) datasets from the Broad and Sanger Institutes provide a comprehensive resource for systematically uncovering these dependencies through genome-wide loss-of-function CRISPR screens. These datasets have enabled the development of predictive models for cancer cell lines or tumors that cannot be directly screened. Recent machine and deep learning approaches have utilized gene expression data, with or without the integration of other omics profiles, to predict such dependencies. However, existing methods often fall short in capturing pathway-level interactions among genes and in effectively integrating insights from both Broad and Sanger DepMap datasets due to limitations in model design and training strategies. To address these challenges, we present a novel deep learning model that integrates pathway-level information and both DepMap datasets to predict the dependency of individual genes in cancer cell lines. In our approach, each cancer cell line is represented by activity scores across thousands of biological pathways and functions, while each gene is modeled based on its involvement in these pathways. This design enables the model to comprehensively capture functional interactions and dependencies within the cellular context, rather than treating genes in isolation. To further enhance the representation of genes targeted for knockout, we implemented a contrastive learning framework. This framework was pretrained on the Sanger CRISPR screens to classify whether two genes exhibit similar dependency profiles and was subsequently fine-tuned on the Broad CRISPR screens to predict the dependency score of each gene in a specific cell line. The final deep learning model demonstrated strong predictive performance, achieving a median correlation coefficient of 0.86 between actual and predicted dependency scores across genes in individual cell lines. The model significantly outperformed baseline configurations that excluded pathway integration or contrastive learning. Notably, cell lines from lung, head and neck, esophageal, and gastric cancers exhibited particularly high prediction accuracy, potentially due to shared biological characteristics within these tumor types. Further investigation is warranted to identify factors contributing to this performance. In summary, our novel deep learning model improves cancer dependency prediction by leveraging pathway-level insights and integrating multiple DepMap datasets. Ongoing efforts include further model refinement, expanded validation experiments, and systematic model interpretation to uncover the underlying mechanisms captured by the model.

#3646 DeepSynBa: A deep learning method to improve drug combination predictions using full dose-response matrices and contextual features of cell lines and cancer indications.

Marta Milo[1], Haoting Zhang[2], Halil ibrahim Kuru[3], A. Ercument Cicek[4], Oznur Tastan[5], Carl Henrik Ek[6], Magnus Rattray[7]

[1]Oncology Data Science, AstraZeneca, Cambridge UK, United Kingdom,[2]The Computer Laboratory, University of Cambridge, Cambridge UK, United Kingdom,[3]Computer Engineering, Bilkent University, Ankara, Turkey,[4]Computational Bilogy, Carnegie Mellon University, Pittsburg, PA,[5]Faculty of Engineering and Natural Sciences, Sabanci University, Istanbul, Turkey,[6]The Computer laboratory, University of Cambridge, Cambridge UK, United Kingdom,[7]Division of Informatics, Imaging and Data Sciences, University of Manchester, Manchester, United Kingdom

Introduction: Many cancer monotherapies have limited activity in clinic, making combinations a relevant treatment strategy. The number of possible combinations is vast, and the responses can be context-specific, making it challenging to predict combination effects. Existing computational models typically predict a single aggregated synergy score, i.e. Bliss or Loewe, for a given drug combination. However, these approaches exhibit high prediction uncertainty and limited actionability because they fail to differentiate between potency and efficacy by oversimplifying the drug-response surface using a single synergy score.

To address these limitations, we introduce DeepSynBa, which models the full dose-response matrix of drug pairs rather than an aggregated synergy score. DeepSynBa formulates this task as a regression problem and uses cell line-specific features and drug embeddings to predict the entire drug-response matrix within a deep learning framework. Following SynBa's approach of modelling the dose-response surface [1], DeepSynBa includes an intermediate layer that estimates pharmacological parameters, which are then used to predict dose-response values across dosages. This design also enables post-hoc calculation of traditional synergy scores like Loewe and Bliss, maintaining compatibility with existing synergy predictors.

Results: We evaluated DeepSynBa on the NCI-ALMANAC dataset, which contains 104 FDA-approved cancer drugs, 60 cell lines, and nearly 300,000 drug pair-cell line combinations. DeepSynBa outperforms comboFM [2] and comboLTR [3], two state-of-the-art methods for direct dose-response matrix prediction across multiple evaluation scenarios, such as novel drug combinations, cell lines, and drugs. DeepSynBa achieves RMSE values of 7.72 and 7.71 in the new drug combination and new cell line settings, respectively, which is an improvement of approximately 65% compared to comboFM, the next-best model.

DeepSynBa also consistently attained lower RMSE and higher Pearson and Spearman correlations across nine tissue types including breast, colon, and leukemia.

Conclusions: DeepSynBa provides a more accurate framework for predicting the full dose-response matrix than existing methods. Additionally, DeepSynBa supports experimental design by providing detailed predictions of drug combination responses across dosages. For untested combinations, by utilizing the parameter layer which separates efficacy from potency, biologists can select dosage ranges that optimize efficacy while limiting off-target toxicity, hence increasing the likelihood of identifying optimal therapeutic dosages.

#3647 Validation of a computational reasoning model for precision oncology with large-scale patient-derived xenograft data.

Robert Doczi[1], Akos Takacs[1], Anna Dirner[1], Dora Lakatos[1], Maria Kocsis-Steinbach[1], Barbara Vodicska[1], Dora Tihanyi[1], Eniko Kispeter[1], Reka Szalkai-Denes[1], William T. Beck[2], **Petak Istvan**[1]

[1]Genomate Health Inc, Cambridge, MA,[2]University of Illinois Chicago, Chicago, IL

Comprehensive tumor molecular testing is key in precision oncology. However, interpretation of complex molecular profiles in clinical practice can be challenging and subjective. The Digital Drug Assignment (DDA) system is a computational reasoning model that scores treatment options based on full tumor genomic data. This approach was predictive of relative benefit of the agents as used in the SHIVA01 trial (DOI: 10.1038/s41698-021-00191-2). Here, we analyzed patient-derived xenograft (PDX) data from Gao et al. (DOI: 10.1038/nm.3954). Molecular profiles of 179 solid tumors were processed by DDA, the resulting personalized drug scores were evaluated with treatment outcome data in PDX models for 1151 molecularly targeted agent (MTA) monotherapies, using 23 MTAs, targeting key oncogenic signaling pathways. In the PDX avatar system, multiple treatments can be tested for the same tumor, and outcomes can be measured in clinical metrics, enabling direct evaluation of drug ranking. To this end, cohorts were formed based on DDA ranking positions for each MTA-tumor pair. DDA ranking position was predictive of relative treatment benefit (Table, upper panel). Because the difference between neighboring ranks is probably minor, and to increase group sample sizes, larger cohorts were formed by combining neighboring rank groups. Here, a clear pattern of gradual decrease of treatment benefit with ranking distance from the top cohort was demonstrated (Table, lower panel). In this study, utilizing the unique advantages of the PDX system, we could demonstrate the predictive power of DDA treatment ranking. Digital drug assignment can serve as a practical and economic in silico avatar system for treatment planning and can potentially address challenges with complex molecular profiles in routine clinical settings.

#3648 AI-enabled 3D multimodal integration platform reveals subcellular architecture of tumor immune microenvironment for therapeutic target and biomarker discovery and patient selection.

Inyeop Jang[1], Yoonho Choi[1], Minji Kim[1], Jeonghwan Park[2], Jiyeon Sung[3], Byungsoo Ann[4], Clemenceau R. Jean[1], TaeHyun Hwang[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Seoul National University College of Medicine, Seoul, Korea, Republic of,[3]KyungHee University, Seoul, Korea, Republic of,[4]Severance Hospital Yonsei University College of Medicine, Seoul, Korea, Republic of

Background: Tumor immune microenvironment (TIME) organization fundamentally shapes cancer progression and immunotherapy outcomes. Traditional 2D spatial molecular approaches inadequately capture the complex three-dimensional architecture and cellular interactions within TIME. We developed an AI-driven platform integrating multiple spatial molecular datasets, enabling comprehensive 3D visualization for therapeutic discovery and patient selection.
Methods: Our platform combines holotomography imaging, providing 3D refractive index maps, with diverse spatial molecular data: in situ molecular imaging, spatial proteomics, multiplex immunohistochemistry, and spatial transcriptomics. AI algorithms align datasets within a unified 3D coordinate system, while Poisson implicit surface reconstruction generates subcellular-resolution models. Platform validation used clinical samples from immunotherapy-treated patients.
Results: The platform integrated multimodal spatial data into high-resolution 3D TIME representations, revealing novel relationships between protein expression, transcriptional patterns, and cellular architecture. 3D surface protein analysis with subcellular morphology identified patients with target protein expression outside tight junctions, indicating higher risk for adverse effects from antibody-drug conjugates and cellular therapies. This insight, unavailable through 2D analysis, enabled precise patient selection.
Conclusions: This platform provides detailed subcellular-resolution TIME architecture analysis, offering actionable insights for therapeutic targeting, biomarker discovery, and patient selection . AI-driven 3D spatial multimodal TIME analysis advances precision medicine across multiple therapeutic approaches, including immunotherapy, targeted therapy, and drug delivery optimization.

#3649 Artificial intelligence accelerates shared neoantigen peptide cancer vaccine development.

Genwei Zhang[1], Jiewen Du[1], Xiangrui Gao[1], Zhenghui Wang[1], Qingxia Zhang[1], Tongren Liu[1], Dong Chen[1], Chi Han Samson Li[2], Kin Tak Chan[2], Hong Wang[2], Melvin Toh[2], **Lipeng Lai**[1]

[1]XtalPi, Beijing, China,[2]CK Life Sciences Development Limited, Hong Kong, China

Background: Many cancers remain intractable despite the recent breakthroughs in immune checkpoint inhibitors and gene and cell therapies, making the pursuit of novel, efficacious, and safe treatment options critical. Recently, there is a renewed interest in cancer vaccines as a promising cancer immunotherapy approach. Nevertheless, precisely predicting the immune response elicited by cancer vaccines continues to be a significantly hurdle.

Methods: From published literature and available datasets, we collected over 17 million peptide entries ranging from 8 to 11 amino acids, and approximately 4 million peptide entries ranging from 13 to 21 amino acids to train models predicts the probability of a given peptide to be presented by MHC-I or MHC-II, respectively. Those peptides were restricted to 150 unique MHC-I alleles and 19 unique MHC-II alleles. Overall, both MHC-I and MHC-II presentation models were constructed with about 30 million parameters. In addition, we developed algorithms to specifically introduce single point mutations to further enhance binding to MHCs, and in the meanwhile, not influence cognate recognition. To validate the model prediction accuracy, automated peptide synthesis and surface plasmon resonance (SPR) technologies were applied. We then examined the presentation of designed peptides using MHC allele-engineered cell line, and further validated the peptide immunogenicity in mice by assessing T cell activation and tumor cell killing capabilities.

Results: Our advanced AI models has outperformed the state-of-the-art prediction algorithms, including NetMHCpan and MixMHCpred, in predicting antigen presentation for both MHC-I and MHC-II. To validate our model accuracy, 28 novel peptides based on mutated TP53 protein were predicted and their binding to corresponding HLA alleles were measured using SPR. >80% of the peptides displayed stronger binding affinities than the positive controls, demonstrating a significantly improved algorithm accuracy for peptide neoepitope design. In the cellular presentation study, one out of six designed neoepitope peptides were validated by mass spectrometry to be presented by HLA-A*02:01 expressing cell line. Importantly, to further evaluate the immunogenicity, we immunized mice with several mouse-derived neoepitope peptides . *Ex vivo* ELISpot assay showed that >20% mouse-derived neoepitope peptides could elicit strong immune responses.Moreover, the activated T cells demonstrated potent (>50%) tumor cell killing capability in the *ex vivo* cellular experiment.

Conclusions: We crafted sophisticated AI algorithms capable of rapidly designing shared neoantigen T cell epitopes that exhibit strong immunogenicity. We believe that our AI technology has substantial promise for propelling the development of ready-made cancer vaccines, and will eventually improve patient outcomes when successfully applied in clinical settings.

#3650 AI-based MTB assistant in cancer personalized treatment: Analysis from a real-world, multi-center retrospective study.

Minghui Wang[1], Yanhong Shang[2], Zhengang Yuan[3], Xin Huang[4], Qing Hao[4], Shaohua Yuan[4], Guobang Shi[4], Hui Chen[4], Wenjin Liu[4], Lili Wang[5], Shiwang Wen[6], Huilai Lv[6], Zhizheng Wang[4], Dong You[4], Yang Liu[4], Fei Pang[4], Wei Rao[7], Haitao Wang[5], Leilei Lu[4], **Kai Wang**[4]

[1]Sun Yat-sen University, Guangzhou, China,[2]Affiliated Hospital of Hebei University, Baoding, China,[3]Eastern Hepatobiliary Surgery Hospital, Shanghai, China,[4]OrigiMed Co., Ltd, Shanghai, China,[5]The Second Hospital of Tianjin Medical University, Tianjin, China,[6]Fourth Hospital of Hebei Medical University East, Shijiazhuang, China,[7]The Affiliated Hospital of Qingdao University, Qingdao, China

Background: Developing personalized treatment plans in cancer care is a complex and time-intensive process. The multidisciplinary Molecular Tumor Board (MTB) approach offers a promising solution for tailoring precision treatments but is often limited by the manual analysis of vast molecular data, which is laborious and error-prone. To address these challenges, we developed SmartMTB, an artificial intelligence (AI)-based assistant, designed to support clinicians in formulating cost-effective and efficient personalized treatment plans.
Methods: SmartMTB leverages a medical-field-customized large-language model and a database tailored to the Chinese population. It integrates patient-specific tumor types and gene variation data to suggest personalized treatment strategies. In a real-world, multi-center retrospective study on the precision medicine platform, we included clinical data of 1032 Chinese cancer patients and asked SmartMTB for treatment plan suggestions.
Results: The study cohort included 1,032 patients spanning 13 major tumor types, with a median age of 58 years (range: 7-87 years). Clinical stages ranged from I to IV (stage I: 11.4%, stage II: 10.3%, stage III: 21.9%, stage IV: 51.6%, unknown: 4.8%). Among them, 92% of the patients got treatment plan suggestions from SmartMTB. Eventually, 39.4% of the patients received SmartMTB-recommended treatment plans, while 52.5% did not. Patients who received SmartMTB-recommended treatment plans exhibited higher partial response rate (PR, 31.4% vs. 11.3%), objective response rate (ORR, 34.1% vs. 12.3%) and longer median progression-free survival (mPFS, 163 vs. 92 days, $P < 0.0001$) than those who did not. Similar benefits were observed across cancer types, including lung cancer (PR: 31.9% vs. 10.2%; ORR: 35.2% vs. 11.9%; mPFS: 185 vs. 92 days, $P < 0.0001$) and hepatobiliary tumors (PR: 28.6% vs. 13.3%; ORR: 31.4% vs. 15%; mPFS: 121 vs. 87 days, $P = 0.024$). Excluding lung cancer patients treated with EGFR-TKI, SmartMTB's recommendations maintained efficacy for the remaining lung cancer patients (PR: 31.7% vs. 8.9%; ORR: 35% vs. 10.7%; mPFS: 153 vs. 90 days, $P < 0.0001$). Furthermore, SmartMTB took about 2.5 h to analyze data from 1032 patients and provide treatment suggestions, which was much more efficient than the traditional manual MTB.
Conclusion: In this study, patients using treatment strategy SmartMTB recommended had much better clinical treatment results than those who didn't. This study highlights the clinical utility of SmartMTB in enhancing treatment outcomes for cancer patients. By providing timely, accurate, and personalized treatment recommendations, SmartMTB addresses critical gaps in traditional approaches, reducing time and cost burdens. Its potential for widespread clinical adoption could transform precision oncology practices and improve patient care globally.

#3651 AI-derived immune cell knowledge graphs to advance immunotherapy.

Shan (Chloe) He, Yukun Tan, Vakul Mohanty, Hind Rafei, Katy Rezvani, Ken Chen

UT MD Anderson Cancer Center, Houston, TX

Immune cells are critical units in human immunity, yet our current understanding of their roles remains limited. A critical barrier is a lack of human natural language in describing the complex molecular roles of immune cells in diverse contexts. Current descriptors of molecular features such as genes and pathways are limited by biological terms available in the functional annotation databases, which were not created specifically to describe immunity, lacking granularity and completeness. Although richer language exists in biological literature, they require labor-intensive curation. We hypothesize that by applying cutting-edge AI techniques such as large language models (LLMs), we can curate a knowledgebase specific for describing human immunity, consisting of rich molecular-cellular relationships and functional descriptors not available in current databases. Querying this knowledgebase can substantially enrich our language in describing and understanding the complex roles of immune cells, and generate novel, verifiable hypotheses for discovery and development of immunotherapy. To address these challenges, we have constructed immune cell type-specific knowledge graphs (KG) for T cells, NK cells, B cells, and macrophages by parsing 9,995, 3,665, 7,503, and 3,615 relevant published abstracts since 2020, respectively. We have fine-tuned BioBERT models to perform named entity recognition (NER) on genes, diseases, and cell types, formulated rule-based algorithms to extract pathways and biomedical concepts. We then employed the LLaMA3-70B model to infer relationships between the extracted entities based on abstract using carefully designed prompts. We present the first immune cell type-specific KGs. Using LLMs, we overcome limitations in immune vocabularies, extracting concise biomedical phrases to expand vocabularies and better characterize immune cell biology beyond existing knowledge bases. These enriched vocabularies can annotate gene sets, providing annotations that reflect recent literature. The KGs, represented as directed networks of biomedical entities, support hypothesis generation and experimental design. By querying relationships among genes and concepts, researchers can identify genes linked to specific phenotypes and predict phenotypic changes following interventions such as gene silencing or cytokine stimulation. These KGs enable dynamic queries to explore immune cell complexity, identify therapeutic targets, and design experiments to investigate signaling pathways. To enhance accessibility, we provide a web application for exploring genes and phenotypes in a cell type-specific manner: https://kchen-lab.github.io/immune-knowledgegraph.github.io/.

#3652 OCTO-virtual cell: a Foundation Model of Cell and Tissue Spatial Biology with Application to Patient Stratification and Target Discovery.

Yubin Xie, Eshed Margalit, Tyler Van Hensbergen, Dexter Antonio, Jake Schmidt, Yu Phoebe Guo, Jeremie Decalf, Maxime Dhainaut, Lucas Cavalcante, Hargita Kaplan, Rodney Collins, Francis Fernandez, Rob Schiemann, Eric Siefkas, Michela Meister, Joy Tea, Carl Ebeling, Anastasia Mavropoulos, Nicole Snell, Shafique Virani, Ron Alfa, Lacey Padron, Jacob Rinaldi, Daniel Bear

Noetik Inc, South San Francisco, CA

Background: Understanding cellular behavior within the context of the tumor-immune microenvironment is essential to developing next-generation cancer therapies and advancing precision medicine. The inherent challenges of this problem reflect the complexity of human biology - patient and tissue heterogeneity, a multitude of interacting signaling pathways, dynamic short- and long-range interactions between the tumor and the immune system, and the intrinsic limitations of measurement techniques. Machine Learning foundation models trained on multimodal patient data present an opportunity to grapple with this complexity and push the field forward leveraging recent advances in spatial biology.

Method: A custom multimodal transformer was trained on 1399 primary resections from lung cancer patients profiled via H&E, CosMx spatial transcriptomics, whole-exome sequencing, and a custom multiplex immunofluorescence panel. To our knowledge this is the largest extant spatial transcriptomics dataset, comprising more than 40 million cells. The transformer was trained via self-supervised learning to predict expression of each CosMx panel gene for a single cell, conditioned on both spatially proximal and patient-level data from all modalities. This training task induces the model to learn fundamental rules that govern cell state and cell-cell interactions within the context of disease. The resulting model, Celleporter, can generate gene expression in a “virtual” cell at a particular location within real or simulated patient tissue. Counterfactual simulations with modified patient data can be used to predict the effects of genetic alterations, gene expression changes, or external interventions on the tumor-immune microenvironment.

Result: Celleporter accurately predicted spatial gene expression patterns from sparsely sampled data, resolving the limitations of traditional experimental approaches. Virtual cell simulations reproduced distinct biological states, such as cytotoxic and naïve transitions of CD8+ T cells within and outside tumor regions and reproduced foundational immunology, including the relationship between MHC-I and T cell activation. Comparative analyses across patient cohorts identified immune-suppressive mechanisms in STK11-mutant tumors resistant to immunotherapy. Perturbation simulations highlighted therapeutic targets predicted to restore cytotoxic activity in STK11-mutant tumor microenvironments.

Conclusion: This study demonstrates that a self-supervised foundation model trained on large-scale multimodal patient data can learn fundamental aspects of cancer immunology, and accurately reproduce the impact of the tumor-immune microenvironment on cell state in a patient-specific manner. This flexible system for interrogating cell and tissue biology has direct application to patient stratification and target discovery.

#3653 Comparison between rule-based, AI-powered and manual clinical trial matching using OncoSolver, a newly-developed clinical decision support tool.

Edoardo Crimini[1], Matteo Repetto[2], Tommaso Fougier[3], Giuseppe Curigliano[1]

[1]Division of New Drugs and Early Drug Development, IEO - European Institute of Oncology, Milan, Italy,[2]Memorial Sloan Kettering Cancer Center, New York, NY,[3]Independent researcher, Milan, Italy

This study compared OncoSolver (OS), a novel clinical decision tool for matching oncologic patients to clinical trials (CTs), with the manual matching (MM) process at European Institute of Oncology (IEO) Phase I Unit. Twenty volunteer investigators screened for suitable CTs 100 advanced cancer patient profiles (PP) comprehensive of treatment history, pathological, genomic and clinical characteristics, modeled on publicly available precision oncology cohorts. OS used rule-based (RB) and AI modalities to match PP concurrently. AI matching used GPT4 as large language model. Results were compared for accuracy, precision, and recall, with discordant matches reviewed for eligibility assessment. Time spent and correlation between experience and performance were analyzed for MM. Analyses were performed with R version 4.3.3 and RStudio. Neuroendocrine, breast and biliary tract were the most represented cancer types (n=19, 11 and 11, respectively). Seventy-one PP had molecular alterations of interest for at least one of the 25 CTs active during the study period. *PIK3CA* and *KRAS* mutations were the most common alterations of interest (n=21 and 17). The concordance among the 3 methods was 2350/2500 (94.0%), between MM and RB 2395/2500 (95.8%), between MM and AI 2388/2500 (95.5%), and between RB and AI 2418/2500 (96.7%). The review of the discordances across the 3 methods led to the definition of 100 correct CT-PP matches, with 57 PP eligible for at least one CT. The number of false positive was 17, 26 and 46 for MM, RB and AI, while false negatives were 68, 2 and 33, respectively. Accuracy was 96.6, 98.8 and 96.7, precision 65.3, 78.2 and 57.5 and recall 32.3, 98.0 and 65.7 for MM, RB and AI. RB had the highest AUC (0.98), followed by AI (0.82) and MM (0.66). Median time for OS matching was 2 minutes per PP (range 1-4), significantly shorter than MM (4 minutes, range 1-17, $p < 0.001$). Recall showed a significant positive correlation with the increase of experience in MM (range 1-5 years, $p=0.04$). MM process is inefficient and carries the risk of missed therapeutic opportunities for cancer patients, which could negatively affect their outcomes. As a proof of concept, OS has the potential to improve patient enrolment in CTs and to reduce physician workload. Both RB and AI modalities outperformed MM in terms of recall, the most important metric in this context, and time efficiency. RB matching relies on rules derived from actual CT characteristics, requiring costly updates and maintenance to sustain performance. In contrast, AI has the advantage of continuous learning, potentially enhancing its effectiveness over time and offering more scalability. Clinical validation of OS is necessary before its integration into routine practice. To the best of our knowledge, this study is the first to compare CT matching performance of human, RB and AI approaches on the same cohort of PP.

#3654 Comparative efficacy of FOLFIRINOX versus gemcitabine plus nab-paclitaxel in metastatic pancreatic cancer: computing IPTW estimator while limiting patient data exposure with federated learning across 3 institutions.

Quentin Klopfenstein[1], Jean Ogier du Terrail[1], Honghao Li[1], Imke Mayer[1], Nicolas Loiseau[1], Mohammad Hallal[1], Michael Debouver[1], Thibault Camalon[1], Thibault Fouqueray[1], Jorge Arellano Castro[1], Zahia Yanes[1], Laetitia Dahan[2], Julien Taieb[3], Pierre Laurent-Puig[4], Jean-Baptiste Bachet[5], Shulin Zhao[4], Remy Nicolle[6], Jerome Cros[7], Daniel Gonzalez[8], Robert Carreras-Torres[9], Adelaida Garcia Velasco[10], Kawther Abdilleh[11], Sudheer Doss[11], Felix Balazard[1], Mathieu Andreux[1]

[1]Owkin, Paris, France,[2]Department of Digestive Oncology, Hopital la Timone, Marseille, France,[3]GI oncology department Georges Pompidou European Hospital, Universite Paris Cite, CARPEM CCC, APHP, Paris, France,[4]Centre de Recherche des Cordeliers, Sorbonne Universite, Inserm, Universite Paris Cite, Paris, France,[5]Hepatogastroenterology and digestive oncology department, Sorbonne University, Pitie Salpetriere hospital, APHP, Paris, France,[6]Universite Paris Cite, Centre de Recherche sur l'Inflammation (CRI), INSERM, U1149, CNRS, ERL 8252, Paris, France,[7]Department of Pathology, Universite Paris Cite - FHU MOSAIC, Beaujon Hospital, Clichy, France,[8]Federation Francophone de Cancerologie Digestive, Dijon, France,[9]Institut d'Investigacio Biomedica de Girona (IDIBGI), Girona, Spain,[10]Department of Medical Oncology, Catalan Institute of Oncology, Doctor Josep Trueta, University Hospital, Girona, Spain,[11]Pancreatic Cancer Action Network, Manhattan Beach, CA

Background: Two first-line treatments are commonly used for metastatic pancreatic cancer: FOLFIRINOX and gemcitabine plus nab-paclitaxel. However, a direct head-to-head comparison in a randomized clinical trial has not yet been conducted. Collecting enough data for this comparison requires collaboration among multiple partner institutions. Herein we use a privacy enhancing technology called federated learning combined with a novel algorithmic methodology: FedECA. This method aims to facilitate collaboration by enabling institutions to retain ownership of their data, sharing only aggregated information across a network.
Methods: We deployed a federated network across three cancer centers: the Fédération Francophone de Cancérologie Digestive (FFCD) hosting data from two past clinical trials (PRODIGE 35 - NCT02352337, PRODIGE 37 - NCT02827201), the Institut d'Investigació Biomèdica de Girona (IDIBGI) and the Pancreatic Cancer Action Network (PanCAN) that hold data from clinical practice. Patients with metastatic pancreatic adenocarcinoma, a performance status eastern cooperative oncology group (ECOG) no larger than 2, and receiving one of the two treatments as first-line were included. To compare the efficacy of the two treatments, we applied FedECA, the federated version of Inverse Probability of Treatment Weighting (IPTW). The following covariates were used as confounders to estimate the propensity score: age, biological gender, liver metastasis and ECOG score. Missing covariates were imputed using the MissForest algorithms independently on each center. The hazard ratio computed with a propensity score-weighted Cox Model is the estimand of the treatment effect on overall survival. The bootstrap variance estimator is used as advised when using IPTW. The entire analysis was performed without data leaving the servers of the corresponding institutions.
Results: 514 patients were included for the treatment effect estimation (215 FOLFIRINOX and 299 gemcitabine plus nab-paclitaxel). The estimated hazard ratio output by our method, FedECA, is 0.75 (95% CI=0.63-0.92, p=0.005) in favor of FOLFIRINOX over gemcitabine plus nab-placlitaxel. These results show the survival benefit of using FOLFIRINOX over gemcitabine plus nab-paclitaxel. The same analysis conducted in each center independently failed to demonstrate a significant effect likely due to the statistical tests being underpowered.
Conclusion: In this observational study leveraging historical trial data and real-world data, we find that FOLFIRINOX is superior to gemcitabine plus nab-paclitaxel. FedECA is the first method to allow performing IPTW in a federated setting i.e. without pooling data on a central server, facilitating collaboration across institutions and countries while ensuring data privacy.

#3655 Leveraging alternative AIML technologies to identify predictive biomarkers for chemotherapy selection: An analysis of the COMPASS trial evaluating chemotherapy response in advanced PDAC.

Joseph Geraci[1], **Bessi Qorri**[1], Mike J. Tsay[1], Christian Cumbaa[1], Paul Leonchyk[1], Larry Alphs[2], Luca Pani[3]

[1]Netramark Corp., Toronto, ON, Canada,[2]Larry Alphs, Consulting, Princeton, NJ,[3]Miller School of Medicine, University of Miami, Miami, FL

Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal malignancy with limited effective therapeutic options. Gemcitabine plus nab-Paclitaxel (GnP) and FOLFIRINOX (FFX) are commonly used first-line chemotherapies for advanced PDAC. However, disease heterogeneity and late-stage diagnosis remain to result in a poor prognosis. There is a need for predictive biomarkers for selecting patients likely to respond to either regimen. Here, we analyzed data from the COMPASS trial to identify predictive mutational and transcriptional features that can guide treatment selection between GnP and FFX in advanced PDAC patients.

We utilized NetraAI, an alternative artificial intelligence/machine learning (AI/ML) technology to analyze 87 PDAC patients. NetraAI identifies explainable patient personas characterized by a set of 2-4 variables that favor a specific treatment outcome and is capable of learning from smaller data. By focusing on uncovering causal high effect size subpopulations, this approach avoids overfitting and the reinforcement of biases about PDAC. The patient population was categorized into two groups: GnP responders or FFX non-responders (GnPR/FFXNR; n=45) and GnP non-responders or FFX responders (GnPNR/FFXR; n=42). Tumor responses were assessed according to standard criteria (stable disease, partial response, and complete response).

NetraAI identified specific variables that characterize preferential response to either GnP or FFX. A key FFX preferential responder persona (n=26; 16 FFXR/GnPNR, 10 GnPR/FFXNR) was characterized by low expression levels of C3AR1 (<3), MIEF1 (<8), and HOXB6 (<20), demonstrating a significant effect size (Cohen's D=1.086, p=0.00799). A key GnP preferential responder persona (n=28; 17 FFXR/GnPNR, 11 GnPR/FFXNR), was characterized by TRIM25 expression between 22-25, low expression levels of RAB40B (<10), and NUTF2 (<35), with a significant effect size (Cohen's D=1.2, p=0.00294). Additionally, lower levels of Major Vault Protein (MVP) were found to be associated with response to chemotherapy in both regimens, particularly favoring GnP response when combined with other variables.

Our findings suggest that specific transcriptional and mutational biomarkers can predict preferential response to GnP or FFX in advanced PDAC patients. The use of NetraAI enables the identification of patient subpopulations characterized by a small set of variables, paving the way towards personalized treatment selection. These results highlight the potential of AI/ML modeling approaches in enhancing precision medicine for PDAC and could inform clinical decision-making to improve patient outcomes.

#3657 Optimal prescriptive treatments for ovarian cancer with genetic data.

A. Mertzios[1], M. Gjika[1], X. Xu[1], S. Guha[2], N. M. Bardhan[1], S. Kumar[3], A. Belcher[1], G. Perakis[1];
[1]Massachusetts Institute of Technology (MIT), Cambridge, MA, [2]Florida International University, Miami, FL, [3]Temple University, Philadelphia, PA

Among the cancers affecting the female population, Ovarian Cancer (OC), while being relatively rare, is the leading cause of gynecological cancer-related deaths, with overall 5-year survival rates of approximately 50% for all stages combined. This is because of the challenges associated with the diagnosis, resulting in detection at advanced stages of OC, coupled with the slow progress in effective treatment options since the approval of platinum-based chemotherapy in the late 1970s. There has been a relative lack of sophisticated methods based on Machine Learning (ML) models that use genetic data for better prediction of Ovarian Cancer outcomes and result in more effective treatment recommendations. Therefore, there is an unmet clinical need to create models that allow physicians to make informed decisions based on all available data, including patient demographic, social, health, and genomic data. Hence, we develop new techniques for leveraging genetic information in prescribing optimal treatments for patients with OC, using a publicly available dataset from the Prostate, Lung, Colorectal and Ovarian Cancer (PLCO) trial. Our approach is able to transform genotype sequencing information into a simple tabular form that can then be used as the input to any ML model. Coupled with the recorded treatment regimen and clinical parameters of matched patients from the genetic dataset, we estimate the treatment effect in terms of mortality prediction and use it to prescribe the optimal treatment for any given patient. By including the genetic features engineered through our proposed method, our models have a higher accuracy than the models without genetic information embedded. The increase in predictive accuracy demonstrates the improved efficacy of our method in the predictive setting. Furthermore, in the prescriptive setting, the models including genetic features output different treatment choices for patients, showing the impact of their inclusion. This is further highlighted by the feature importance of the genetic features such as mutations in the FAT3, BRCA1, BRCA2, and NF1 genes, where they rank highly with a tighter aggregation of the top features, relative to the sharp drop-off in feature importance after the top feature in the models without genetic data. Taken together, in summary, our models will allow oncologists to make more informed and accurate decisions, incorporating a patient's genetic data with all other available clinical information, which has the potential for improved prognosis and better long-term survival outcomes for Ovarian Cancer patients.

#3658 LINE1 ORF1P is a druggable target for early onset colorectal cancer and cancer prevention.

Dan Zhao[1], Yifei Wang[1], Praveen Neeli[2], Yong Li[1]

[1]Baylor College of Medicine, Houston, TX,[2]University of Texas MD Anderson Cancer Center, Houston, TX

Colorectal cancer is the second most common cause of cancer deaths in the United States. In recent years, there has been a surprising increase in early-onset colorectal cancer, making it the leading cause of cancer-related death in young men under 50 years old. With aging as the primary risk factor for human cancers, we argue that anti-aging agents are a viable option for cancer prevention. One common scientific approach in anti-aging is partial cell reprogramming using Yamanaka factors. However, there is concern that activation of stem cell-specific transcription factors may promote tumor formation. Transposable element LINE1 ORF1p expression has been reported to be elevated in both aging and cancer across multiple species and cancer types, making it a promising target to address both aging and cancer simultaneously. Interestingly, we discovered that LINE-1 expression is higher in the serum of early-onset colorectal cancer patients and hypothesize that ORF1p activation accelerates aging and promotes cancer progression. Using artificial intelligence-based small molecule drug screenings from 10 million compounds, we identified two LINE1 ORF1p targeting drugs, B7 and C1, that significantly kill cancer cells but not normal cells in vitro. A surface plasmon resonance (SPR) assay confirmed high binding affinity of B7 and C1 to the ORF1p protein. Consistently, B7 and C1 inhibited retrotransposition using a LINE1-specific retrotransposition reporter assay. When we transplanted ORF1p high-expressing human cancer cells into NSG mice, treatment with B7 or C1 significantly inhibited tumor growth by 57% (C1) and 75% (B7) and improved survival of tumor-bearing mice compared to vehicle control. Additionally, we designed an antibiotic-free nanoplasmid DNA vaccine targeting ORF1p. We confirmed its high expression level in vitro and then performed electroporation of the DNA vaccine using Ichor's TriGrid™ intramuscular electroporation technology. In a prophylactic model, we vaccinated the mice three times before inoculating them with syngeneic mouse colon tumor cells. The vaccination significantly delayed tumor onset and inhibited tumor growth by more than 50%. In conclusion, our data suggest ORF1p as a druggable target and a promising DNA vaccine target for both cancer prevention and treatment in human early-onset colorectal cancer.

#3659 Biology-driven, machine learning-based development of a biomarker to predict response to WEE1 inhibitor Debio 0123.

Jeannette Fuchs[1], Luke Piggott[1], Kristian Urh[2], Matjaz Zganec[2], Eva Lavrenčič[2], Mark Uhlik[2], Carolina Haefliger[1]

[1]Debiopharm International S.A., Lausanne, Switzerland,[2]Genialis Inc., Boston, MA

Introduction: The WEE1 kinase is a central regulator of G2/M and S phase cell cycle checkpoints which is potently activated in response to DNA damage. To date, a number of biomarker candidates have been proposed for WEE1 monotherapy sensitivity, including TP53 alterations, however, there is currently limited clinical evidence that biomarker-positive patient populations are significantly enriched in response to WEE1 inhibitors. Debio 0123 is a WEE1 inhibitor that has previously shown significant preclinical efficacy as a single agent and is currently being investigated in phase 1 clinical studies either as a monotherapy or in combination with different therapies. Herein we present a first-generation digital biomarker utilizing the ResponderID™ framework and the Genialis™ Supermodel to configure a model capable of predicting responders from non-responders to the Debio 0123 WEE1 inhibitor.

Methods: The initial model is based on an extra-trees regression algorithm spanning five biological pathways related to DNA damage response as features. It was primarily trained on public and proprietary datasets to build a foundation DDR biology model, prior to further training on Debio 0123 patient-derived organoid RNA-seq datasets. The model was then tested on Debio 0123 datasets to measure model performance utilizing leave-one-out cross-validation.

Results: The first-generation DDR biomarker showed potential to predict Debio 0123 IC50 values for viability (prediction accuracy of 0.7). Further refinement of optimal activity thresholds, tuning of features by tissue transferability, and establishment of a classifier-based model yielded an improved prediction accuracy (0.8 vs. null model accuracy of 0.5). Furthermore, this optimized model accurately predicted independent PDX model responses. Specifically, the model accurately predicted a non-responder (tumor growth inhibition <5%) in vivo and strikingly, an in vivo responder that was considered a non-responder by ex vivo organoid IC50.

Conclusion: This biology-driven, machine learning-based classifier predicts response to Debio 0123 in patient derived organoid and xenograft models at an accuracy significantly greater than that of a dummy model and serves as a basis for further optimization and retrospective analyses of Debio 0123 clinical studies.

#3660 Machine learning-based combination prediction for Wee1 inhibitor.

Tianduanyi Wang[1], Juho Rousu[2], **Lin Tang**[3]

[1]Aalto University & University of Helsinki, Espoo, Finland,[2]Aalto University, Espoo, Finland,[3]Schrodinger Inc., San Diego, CA

Motivation: Wee1 is the gatekeeper gene that allows proper DNA damage repair (DDR) during the G2/M cell cycle transition. Inhibiting the Wee1 gene will abrogate the DDR mechanism and lead cancer cells with high replication stress to premature catastrophic mitosis and eventually apoptosis. Several Wee1 inhibitors (Wee1i) are under active development in both preclinical and clinical studies. They have shown efficacy in multiple cancer types as monotherapy or as a combination with chemotherapies or targeted therapies. These studies suggest that a broader combination potential for Wee1i should be explored. Machine learning-based methods are promising and efficient approaches to model drug combination in a broader combination space. Here we have integrated two large combination studies and applied a tensor reconstruction based polynomial regression (comboLTR) method to predict the combination effects for Wee1i in expanded combinations. This work supports a machine learning approach in generating novel combination hypotheses in an expanded space from existing experimental data.

Method: Two large published screening studies containing the Wee1i were normalized and integrated. This resulted in a combined screening study of 131 drugs and 53 cell line models. ComboLTR was applied to train drug combination response prediction models using collected known drug combination responses, drug molecular fingerprints, and model genomic features. The model performance was evaluated under different prediction scenarios, including the prediction of missing entries in a dose-response matrix and the prediction of entire dose-response matrices in new cell lines or with unknown drugs. The hyper-parameters were tuned separately for different prediction scenarios to reach the best performance. Three different synergy scores (HSA, Bliss, Loewe) were used to summarize the synergy effects of the predicted drug combinations. The average of the synergy scores was used to evaluate the combination partners for Wee1i.

Results: We integrated drug combination response data from two publications and trained LTR models based on the data. In 5-fold cross-validations for the different prediction scenarios, new entry, new matrix, new drug combo, the model achieved a Pearson correlation of above 0.8 between predicted and measured response data. The final model was trained to predict responses of drug combinations between Wee1i and 130 other drugs in 53 cell lines. Based on these predictions, we calculated synergy scores for each drug combination and cell line triplet and ranked the synergy effect within each cancer type. Several compounds reported to be synergistic with Wee1i in selected cancer types were reproduced in the prediction, including dasatinib in ovarian cancer, SN38 in breast cancer, and CHK1i in ovarian cancer. The model also predicted these compounds as having synergistic effects with Wee1i in potential new cancer types which may be of future interest.

#3661 TeloPred: A machine learning classification webserver for prediction of small molecules as telomerase inhibitors for anti-cancer drug development.

Divpreet Kaur[1], Daman Saluja[2], Madhu Chopra[3]

[1]Medical Biotechnology Lab and Laboratory of Molecular Modeling and Anti-Cancer Drug Development, Dr. B.R. Ambedkar Ctr. for Biomedical Res., Delhi, India,[2]Medical Biotechnology Lab, Dr. B.R. Ambedkar Ctr. for Biomedical Res., Delhi, India,[3]Laboratory of Molecular Modeling and Anti-Cancer Drug Development, Dr. B.R. Ambedkar Ctr. for Biomedical Res., Delhi, India

Introduction: Telomerase activity is upregulated in 85-90% of cancers, making it a critical therapeutic target. However, the development of small-molecule inhibitors targeting telomerase is hindered by structural complexity and limited resources for three decades since its discovery. To bridge the gap, we present TeloPred—a pioneering structure-activity machine learning classification model for predicting small-molecules as telomerase inhibitors, advancing anti-cancer drug discovery.
Methodology: TeloPred was developed using a curated dataset of telomerase inhibitors with IC_{50} values from ChEMBL. After preprocessing, key molecular properties (e.g., molecular weight, TPSA) were calculated using RDKit, and compounds were classified as active/inactive based on a pIC_{50} cutoff of 5.2 nM. Informative features were selected using variance thresholding and Recursive Feature Elimination (RFE) from each of the 12 molecular fingerprints generated with PaDEL software. The dataset was split (80% training, 20% testing), and six machine learning algorithms (e.g., Random Forest, SVC, XGBoost, AdaBoost) were trained, fine-tuned, and evaluated using metrics like accuracy, F1 score and AUC-ROC. The best model underwent external validation with a decoy set, SHAP analysis for interpretability, and screening of a natural compound library. TeloPred will be soon available on a public webserver for global use.
Results: Data preprocessing reduced 388 compounds to 281. Exploratory analysis showed distinct clustering of active/inactive compounds based on properties like molecular weight, aromaticity, TPSA and H-Bond donor and acceptors. Among tested models, Support vector classifier performed best, achieving 87.2% accuracy on the test set and 89% on training, with low false positives/negatives. External validation yielded an enrichment factor of 21, indicating strong predictive strength of model. SHAP analysis revealed aromatic groups, amide linkage, and carbonyl groups as critical for telomerase inhibition. Screening a natural compound library narrowed the search space by 83%, identifying 10 leads with high predicted probabilities and QED scores which are under experimental validation.
Conclusion: TeloPred is the first ML classification model designed to effectively distinguish telomerase inhibitors, enabling efficient virtual screening of large libraries. It minimizes attrition rates compared to traditional high-throughput screening (HTS) methods, offering a powerful tool to accelerate telomerase-targeted drug discovery for cancer treatment. Its availability as a publicly accessible resource further amplifies its impact on global research efforts to drive precision medicine.

#3662 DNA-encoded chemical library screening and machine-learning for hit identification for WD40 repeat targets including oncology targets such as DCAF1, WDR5 and WDR12.

Anthony D. Keefe, Arrash J. Baghaie, Paolo A. Centrella, Matthew A. Clark, Marie-Aude Guie, John P. Guilinger, Jenny Liu, Ryan T. Walsh, Ying Zhang

X-Chem Pharmaceuticals, Waltham, MA

Training machine-learned models using DNA-Encoded Chemical Library screening data “DEL-ML” and using these models to rank compounds in virtual catalogs has been successful for hit identification for a range of individual oncology targets including ER alpha and c-KIT [McCloskey et al 2020]. Here we describe the importance of library quality and diversity, protein quality, screen design, appropriate profile choice, training set preparation and evaluation, promiscuity labeling, chemical representations, modeling algorithms and their tuning in the context of a systematic target class-based evaluation for a range of oncology targets including DCAF1, WDR5 and WDR12. This approach yielded first-in-class, drug-like ligands for multiple targets that were characterized using a range of biophysical approaches including x-ray crystallography.

#3663 A digital health solution for monitoring skin toxicities in cancer treatment.

Ramya sita Palacholla[1], Ali Soltani[1], Josep A. Pous[1], Monika Dutkiewicz-piasecka[2], Debra Carter[3], Elisabeth Piault-Louis[4]

[1]Digital Science, Evinova (AstraZeneca), Durham, NC,[2]Clinical Development, Astrazeneca, Warsaw, Poland,[3]Astrazeneca, Gaithersburg, DC,[4]Digital Science, Evinova (AstraZeneca), San Fransisco, CA

Introduction: Skin toxicities such as maculo-papular rash, xerosis, or pruritis, can hinder the optimal dosing of immunotherapy, chemotherapy, and targeted therapies1-4. Their management is primarily palliative and prompted by patients' report of skin symptoms or impact on their activities of daily living (ADL). A digital product for the collection, transfer and visualization of data relevant to skin toxicities could contribute to early identification and palliative management and ultimately decreased morbidity for patients between clinic visits

Methods: A review of the published literature and clinical expert interviews (n=8) informed the content of a digital product. Behavioral psychology, measurement and data science drove the design of the interfaces and functionalities with a focus on user-engagement and on supporting diversity. Patients (n=20) receiving anticancer therapies and clinicians (oncologists and nurses, n=8) participated in qualitative user testing of the instructions, question flow, response options, educational material and disclaimers to document comprehension and usage.

Results: Key determinants in identifying and reporting skin symptoms include the actual hue of the skin and the body location and surface affected by the skin manifestation(s). The app supports selection of the closest match to the user skin tone; then the patients access tone-matched pictures from an AI-generated library of skin lesions as relevant references to report and rate symptoms severity. A 3D interactive body avatar allows participants to zoom, record and annotate the symptom(s) location and extent. Patient-captured pictures of the skin lesions are automatically anonymized by an AI- photo processing to ensure patient privacy. The HCP portal provides an easy visualization of patient-reported symptoms and pictures within context of ADL impact and patient's skin history. The digital solution includes a symptom-worsening alert to nudge a discussion between the patient and clinician. In addition, patients receive non-medical tips to self-manage non-severe symptoms to prevent higher morbidity. Most patients appreciated personalizing the app based on their skin tone. Content was easy to understand yet adapted on rewording suggestions. Tracking skin symptoms was seen as enabler of more precise discussions with clinicians and the main intrinsic usage driver. Clinicians were positive of the potential for useful insights into patients' skin status. HCPs reflected on a positive tradeoff between lower risk of significant morbidity and additional workload.

Conclusion: The digital solution features several innovative components for reliable and sustained data capture of the onset and evolution of skin symptoms providing relevant insight for the remote monitoring of patient at risk of skin toxicities; Further research will inform its clinical validity and utility.

#3664 SafetyNet: a knowledge graph framework for toxicity management and safety profile prediction.

Miguel Goncalves[1], Mark O'Donoghue[1], Abigail Morrison[1], Heidi Lloyd-Williams[1], Sanjana Singarayer[1], Neki Patel[1], Samad Jahandideh[2], Ken Twomey[1], Krishna C. Bulusu[1]

[1]AstraZeneca UK Limited, Cambridge, United Kingdom,[2]AstraZeneca US, Gaithersburg, MD

Background: Anti-cancer treatments can range from systemic therapy, like chemotherapy, to targeted approaches, such as antibody-drug conjugates. In any case, such therapies cause adverse events (AEs) in cancer patients. In this study, we have developed a dedicated knowledge graph (KG) for AE risk factor prediction - SafetyNet. Specifically, this study aims to deliver class-specific risk factors, inform toxicity management guidance, and elicit a strategy for risk mitigation and monitoring. Ultimately, we aim to devise a standardized framework to monitor AEs in clinical trials.

Methods: SafetyNet was built from synthetic data of 21 oncology trials, which was created from and follows the same distribution as AstraZeneca trial data and is therefore a suitable interim substitute. Real ADC trial data will replace the synthetic data in the near future. In addition, SafetyNet includes biomedical entities and relationships from AstraZeneca's internal Biological Insights Knowledge Graph, with prior knowledge from literature as well as safety intelligence data from OFF-X. We find trends in the data by querying SafetyNet via the personalized PageRank (PPR) method. Briefly, PPR works by simulating multiple random walks in the graph, from which we count the number of visits to each node. Nodes that are visited more often have higher PPR, meaning they are more important to the starting node.

Results: There are different strategies that can be employed to obtain insights. We can, for example, focus on a given AE: for patients that had nausea as an AE of the primary treatment, we found hypertension to be the most frequent comorbidity, with 367 patients affected. To complement this observation, we found that there are 543 concomitant medications that have both nausea and hypertension as a known AE. We can also analyze trends between serious and non-serious cases of a given AE: serious vomiting was more tightly linked to the use of tinzaparin sodium, an antithrombotic drug. Accordingly, pulmonary embolism and deep vein thrombosis were more frequent in patients experiencing serious vomiting vs non-serious. We can equally analyze patients that had a particular concomitant medication: diarrhea, nausea and vomiting were all higher ranked in patients that were taking cisplatin concomitantly with the primary treatment.

Conclusions: By utilizing SafetyNet, we can identify the risk factors associated with AEs for a given ADC as well as their relationship with concomitant medications. By doing these analyses across ADC trials, we gain generalized insights that can help our understanding of AEs in the ADC space. In turn, these insights can be used to create standardized guidelines for ADC toxicity guidance and AE monitoring. Furthermore, SafetyNet brings considerable time saving and human error reduction relative to manually analyzing all the clinical, literature and OFF-X data.

#3665 Insilco evaluation of multiple ubiquitin-specific protease 1 (USP1) inhibitors and selectivity profiling over other USPs using Alphafold.

Prashant Kashinath Bhavar[1], Uday Kumar Surampudi[1], **Appaji Baburao Mandhare**[2], Rupesh Chikhale[3]

[1]VRise Therapeutics Inc., Cambridge, MA,[2]VeGen Therapeutics, Hyderabad, India,[3]Department of Pharmaceutical and Biological Chemistry, School of Pharmacy, University College London, London, United Kingdom

DNA damage triggers cell signaling cascades that mediate repair. This signaling is frequently dysregulated in cancers. The proteins that mediate this signaling are potential targets for therapeutic intervention. Ubiquitin-specific protease 1 (USP1) is one such target, with small-molecule inhibitors already in clinical trials. Here, we used USP1 crystal structures (PDB: 7ZH4 and 9FCJ) to study the comparison of multiple novel USP1 inhibitors alongside the clinical USP1 inhibitor KSQ-4279 and a well-established tool compound, ML323. Our findings indicate that each of these novel USP1 inhibitors binds to the same cryptic site on USP1 as ML323/KSQ4279, yet they induce subtle variations in the protein structure. Notably, one of the novel compounds exhibit additional interactions with D751 and D752 which we hypothesize may contribute to the unique structural disruptions associated with this novel inhibitor. This binding would likely enhance the thermal stability of USP1 significantly, potentially due to the inhibitors occupying a hydrophobic tunnel-like pocket within the USP1 structure. Furthermore, we have successfully employed AlphaFold structures of various USP proteins to demonstrate the selective binding of these novel compounds to USP1, setting them apart from all other known USP's. Our results advance the in silico understanding of the binding modes of these novel ligands and underscore their selective potential. We aim to utilize this data for the design of new USP1 inhibitors.

#3666 Proteomic-based drug sensitivity prediction algorithms: generation, optimization, and assessment.

Robert F. Gruener

University of Minnesota, Minneapolis, MN

Personalized medicine uses genomic information to inform therapeutic decisions. In the past decade, much effort has been made to develop machine learning models to link drug response with large “-omics” expression patterns in pursuit of personalizing medicine. However, until recently, large-scale proteomic datasets have not been widely available and therefore have not often been incorporated into these machine learning methods. Proteomics has the advantage of directly assaying the functional molecular machinery of cells, leading to better understanding of pathway dynamics and quantifying the targets of small molecule inhibitors. Thus, we hypothesize that proteomic data in drug response modeling could offer distinct advantages and better performing drug response models.
In this study, we sought to determine if drug response models built on proteomics data can outperform other transcriptomic or multi-omic based models. To this end, we developed and tested a novel framework to predict drug response using only proteomic data. We leveraged several recent large-scale cell line proteomics datasets from DepMap (CTRP) and Sanger (GDSC) to build machine learning models trained on baseline protein expression and drug sensitivity data. We used robust testing to determine optimal parameters, drug sensitivity processing, while comparing performance across multiple machine-learning methods. Our optimized framework demonstrated strong predictive power across multiple drug classes and cancer types. Moreover, our approach successfully predicted clinical outcomes in independent, publicly available datasets, illustrating its translational potential. It was worth noting that across most therapies, our models performed similarly to gene expression-based approaches in identifying responders to both cytotoxic and targeted therapies. The work to improve and optimize these models are on-going with the intent that these tools will be made available to all proteomic researchers looking to directly develop drug response hypotheses from their proteomic data.

#3667 AI-based models integrating serum proteomics and clinical features to predict immune-related adverse events in NSCLC patients undergoing immunotherapy.

Junho Song[1], Leeseul Kim[2], Donghoon Shin[3], Jongwoo Kim[1], Taegyu Um[1], Allen Cho[4], Jieun Park[1], **Liam IL-YOUNG Chung**[1], Jeeyeon Lee[5], Young Kwang Chae[1]

[1]Northwestern University, Chicago, IL,[2]University of Chicago, Chicago, IL,[3]Metrowest Medical Center, Framingham, MA,[4]Weiss Memorial Hospital, Chicago, IL,[5]Kyungpook National University, Daegu, Korea, Republic of

Background: Immune checkpoint inhibitors (ICIs) improved outcomes in NSCLC treatment, but causing irAEs. Serum proteomic biomarkers combined with clinical data may offer a better approach for toxicity risk prediction.
Methods: To predict five irAE types (pneumonitis, rash, arthritis, thyroiditis, and other adverse events) at multiple time points, pre-treatment serum samples and clinical data (age, gender, smoking history, cancer stage, performance status, and treatment regimen) were analyzed from consecutive 173 NSCLC patients treated with ICI monotherapy or ICI-chemotherapy combination. Serum proteomics was performed via mass spectrometry, and three machine learning models (XGBoost, HistGradientBoosting, and logistic regression) were evaluated using 5-fold cross-validation. Primary outcomes were five toxicity types evaluated at 1, 3, 6 months, and 1 year. Model performance was assessed using the area under the receiver operating characteristic curve (AUC).
Results: The median age was 70.7 years, with 50.9% female and 66.5% adenocarcinoma. 16.2% had never smoked, 68.2% former smokers, and 15.0% current smokers. Performance status (PS) was 0 in 17.9%, 1 in 55.5%, 2 in 20.2%, and 3 in 5.2%. The median tumor mutational burden (TMB) was 5.4 mut/Mb, with PD-L1 negative in 30.1%, positive in 58.4%. Treatment regimens included mono-ICI (35.3%), dual ICI (12.7%), and ICI + chemotherapy (52.0%). 91.3% received palliative treatment. Median overall survival (OS) was 20.9 months, progression-free survival (PFS) was 7.1 months, and toxicity-free survival was 35.2 months. The multimodal analysis demonstrated distinct predictive patterns across toxicity types and timepoints. At 30 days, combined modality approaches performed best: Logistic Regression for pneumonitis (AUC=0.60), HistGradientBoosting for rash (AUC=0.60), and XGBoost for arthritis (AUC=0.60). Feature importance analysis identified KRAS mutation status and smoking history as primary predictors for pneumonitis, ECOG status and histology type for rash, disease stage and treatment regimen for arthritis, and PD-L1 expression for other adverse events. Proteomics-based models performed best at 3 months for pneumonitis (AUC=0.60) and thyroiditis (AUC=0.57). Notably, the HistGradientBoosting model achieved superior performance (AUC=0.75) for overall irAE prediction at 9 months using both proteomics and clinical features, demonstrating the value of integrated multimodal analysis.
Conclusions: The models showed moderate discrimination, with AUCs ranging from 0.556 to 0.75, particularly excelling in early toxicity prediction. These findings support multimodal machine learning for personalized toxicity risk assessment and proactive management.

#3668 AI-based models integrating serum proteomics and clinicopathologic features to predict survival outcomes in NSCLC patients undergoing immunotherapy.

Junho Song[1], Leeseul Kim[2], Donghoon Shin[3], Jongwoo Kim[1], Taegyu Um[1], Allen Cho[4], Jaeyoung Bae[1], **Liam IL-YOUNG Chung**[1], Jeeyeon Lee[5], Young Kwang Chae[1]

[1]Northwestern University, Chicago, IL,[2]University of Chicago, Chicago, IL,[3]Metrowest Medical Center, Framingham, MA,[4]Weiss Memorial Hospital, Chicago, IL,[5]Kyungpook National University, Daegu, Korea, Republic of

Background: Responses to immune checkpoint inhibitors (ICIs) vary among patients with NSCLC. Combining serum proteomics with clinical data offers a novel approach to individualized outcome prediction.
Methods: This study analyzed 148 consecutive NSCLC patients treated with ICI monotherapy or ICI-chemotherapy combinations. Serum proteomics quantified via mass spectrometry were integrated with clinicopathological data (age, gender, smoking history, cancer stage, performance status, tumor mutational burden (TMB), PD-L1 IHC, and treatment regimen). Machine learning models(XGBoost, logistic regression, and multilayer perceptron) were used with single and multimodal approaches and were evaluated using 5-fold cross-validation. Primary outcomes were progression-free survival (PFS) and overall survival (OS) at 90, 180, 270, and 360 days. Performance was assessed using the area under the receiver operating characteristic curve (AUC).
Results: The cohort's median age was 71 years, with 52.0% being female. 14.2% never smoked, 71.0% former smokers, and 14.2% current smokers. Histologically, 68.2% had adenocarcinoma, 27.7% squamous cell carcinoma, and 4.1% other types. Performance status was 0 in 20.3%, 1 in 54.7%, 2 in 17.6%, and 3 in 6.1%. Most patients had stage IV disease (82.1%). Median TMB was 5.4 mut/Mb; PD-L1 >1% in 56.8%, <1% in 29.7%. Treatment regimens included mono-ICI (35.8%), dual ICI (14.2%), and ICI + chemotherapy (50.0%). Median OS and PFS were 19.5 and 7.1 months, respectively. Proteomics-based models outperformed other approaches for PFS prediction, with XGBoost achieving a peak AUC of 0.67 at 3 months and maintaining strong performance through 6 months (LogReg, AUC=0.65) and 9 months (XGBoost, AUC=0.64). For OS prediction, model performance improved over time, reaching the highest AUC of 0.61 with XGBoost using proteomics at 360 days. Risk groups were stratified at 9 months OS using XGBoost regression, leveraging 4,000 highly variable proteomic features identified by mass spectrometry (m/z). Significant differences in PFS between high- and low-risk groups were confirmed by a log-rank test ($p < 0.01$) and Cox proportional hazards analysis (HR = 1.72, 95% CI: 1.18-2.51, $p < 0.01$), with median PFS of 166 days for the high-risk group and 297 days for the low-risk group.
Conclusions: The AI-based models demonstrated moderate to strong discrimination, with AUCs ranging from 0.70 to 0.77 for the best-performing models. These results highlight the potential of multimodal machine learning approaches for personalized prediction of outcomes with immunotherapy in NSCLC.

#3672 High-sensitivity CRISPR-Cas12a detection of prostate-specific antigen based on computationally optimized aptamers.

Peizhi Ma[1], Jing Wu[2], Yichen Zhang[3], Fangyue Guo[1], Mengying Liu[1], Shuying Sun[1], Shize Xiao[1], Shanfeng Zhang[4], **Pei Li**[1]

[1]Zhengzhou University School of Basic Medical Sciences, Zhengzhou, China,[2]Department of the First Clinical Medicine, Zhengzhou University, Zhengzhou, China,[3]Henan Institute of Medical Sciences, Zhengzhou, China,[4]Practice Base of Basic Medical Innovation and Entrepreneurship Education in Henan Province, Zhengzhou, China

Background: Prostate cancer (PCa) is one of the most common malignant tumors worldwide. Early detection of PCa via Prostate-Specific Antigen (PSA) blood testing is essential for efficient and accurate screening. However, current diagnostic approaches are costly, labor-intensive, require large sample volumes and have relatively low interference capability. Additionally, the limitations of Systematic Evolution of Ligands by Exponential Enrichment (SELEX) technology often result in PSA aptamers with insufficient affinity, compromising the sensitivity of some aptamer-based detection methods.
Methods: In this study, we developed a PSA detection strategy based on the trans-cleavage mechanism of the CRISPR-Cas12a-aptamer system, integrating computationally optimized PSA aptamers with CRISPR-Cas12a-based technology. A series of experiments were conducted, including the optimization of PSA aptamers, the design of crRNA, the optimization of aptamer concentration, the establishment of the CRISPR-Cas12a-aptamer detection system, and the validation of clinical samples.
Results: Through sequence alignment and structural analysis of existing PSA aptamers, we identified conserved and potential binding sequences, enabling the construction of optimized aptamers. Molecular docking revealed aptamers with lower ΔG values and higher ZDOCK scores, which were selected as candidates. Optimal aptamer concentrations were identified experimentally, and the system's sensitivity and specificity were assessed using PSA standards and non-specific controls. Comparative studies demonstrated enhanced detection sensitivity with optimized aptamers, exhibiting a linear PSA detection range of 1.44-23 ng/ml with steeper slopes and higher R^2 values compared to original aptamers. In the validation of clinical samples, the detection values of this method showed good consistency with the data provided by hospitals.
Conclusions: This study demonstrates the ultrasensitivity and rapidity of the CRISPR-Cas12a-aptamer detection system and presents a robust strategy for improving aptamer affinity through sequence analysis and molecular docking, offering significant potential for diagnostic applications.

#3673 Identifying druggable target in medulloblastoma.

Dongxue Mao[1], Li Zhao[1], Ying Zhu[1], Chunjie Jiang[1], Kyle Smith[2], Paul Northcott[2], Bissan Al-Lazikani[1]

[1]Genomic Medicine, Institute for Data Science in Oncology, The University of Texas MD Anderson, Houston, TX, [2]St. Jude Children's Research Hospital, Memphis, TN

Background: Approximately 15,000 children in the United States are diagnosed with cancer annually. While pediatric cancers boast a 10-year survival rate of approximately 80%, they present unique challenges in drug discovery due to the low frequency of recurrent mutations and limited therapeutic targets. Brain cancers in children, including medulloblastoma, remain the leading cause of cancer-related deaths in this age group. Certain subtypes, such as group 3 medulloblastoma, are still associated with poor outcomes despite advances in therapy. Current treatment strategies, while effective at increasing survival, frequently lead to severe long-term toxicities, emphasizing the critical need to identify drug targets that can reduce toxicity and enhance outcomes.

Method: Our lab has previously demonstrated that AI-based models can successfully facilitate drug discovery in common adult cancers by identifying and prioritizing key druggable molecular vulnerabilities (Zhu Y et al, *Probabilistic graph-based model uncovers previously unseen druggable vulnerabilities in major solid cancers*, bioRxiv 2024.06.04). Building on this success, we applied this approach to medulloblastoma by analyzing 491 whole-genome sequencing and 167 RNA sequencing to identify potential druggable targets, and systemically evaluated the predictions.

Results: A total of 120 genes were identified as significantly recurrently altered in the cohort, including *TERT*, *PTCH1*, *DDX3X*, *KMT2D*, *CTNNB1*, and *KMT2C*. These genes were used to seed our AI-based model to generate patient network and predict molecular vulnerabilities. Predictions were validated using DepMap medulloblastoma cell lines, confirming 15 of the top 50 ranked genes as dependencies, despite no cell line data being used as input or for model training. Unsupervised clustering of the patient data revealed four distinct molecular clusters consistent with the established medulloblastoma subtypes. Differential expression analysis and elastic net regression were employed to identify representative subtype-specific genes. By combining DNA and RNA data, we constructed subtype-specific molecular networks and identified dependencies unique to each subtype.

Conclusions: This study is the first to apply an AI-based model to identify druggable targets in medulloblastoma. By amplifying weak signals within cancer molecular networks, the model successfully prioritized key vulnerabilities and revealed subtype-specific therapeutic opportunities. These findings provide a framework for advancing precision oncology in pediatric brain cancers, with the potential to reduce treatment-related toxicity and improve outcomes for medulloblastoma patients.

#3674 Predicting chromatin organization from cell-free DNA fragmentation patterns.

Ravi Bandaru[1], Zhihan Zhou[2], Hailu Fu[1], Weimin Wu[2], Haizi Zheng[3], Rashmi S. Hegde[4], Li Wang[1], Han Liu[2], Yaping Liu[1]

[1]Department of Biochemistry and Molecular Biology, Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Department of Computer Science, Northwestern University, Chicago, IL,[3]Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH,[4]Division of Developmental Biology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Epigenetic regulation, including the three-dimensional (3D) architecture of the genome, plays a critical role in gene expression and cellular function. Aberrations in chromatin organization are implicated in various diseases, particularly cancer. While Hi-C is the gold standard for mapping chromosomal conformations, it has significant limitations: it requires fixed cells, limiting its capacity for longitudinal monitoring of dynamic chromatin changes. Cell-free DNA (cfDNA), which consists of short DNA fragments released into circulation through apoptosis and necrosis, offers a promising alternative. CfDNA fragmentation patterns are non-random and influenced by underlying epigenetic features, providing a window into chromatin organization *in vivo*.

Here, we hypothesize that the correlation of cfDNA fragmentation patterns between two genomic regions can potentially reflect the 3D chromatin architecture. Since cfDNA fragments *in vivo* are released from multiple cell types, we generated *in situ* Hi-C and matched cfDNA whole-genome sequencing data from a xenograft mice model as the training dataset. We trained a contrastive deep learning model to infer Hi-C contact maps directly from cfDNA fragmentation data. The model demonstrated high accuracy in predicting chromatin compartments and topologically associating domains (TADs) from cfDNA fragmentation patterns, outperforming conventional machine learning approaches. These findings suggest that cfDNA fragmentation can enable the non-invasive and longitudinal monitoring of 3D genome aberrations *in vivo*.

#3675 An integrated approach for simultaneous detection of genomic and epigenetic alterations in blood-based ctDNA analysis.

Qin Tang, Becky Wong, Varahenage Namali Perera, Yu Sun, Nafisa Bulsara, Brian Giacopelli, James Yu, Jason Close, Peter George, Andy Eang, Ashley Linares, Andrew S. Lee, Neil Peterman, Alex Robertson, Nicole Lambert, Yexun Wang

Foundation Medicine, Inc., San Diego, CA

Cancer harbors abnormalities in the genome and the epigenome, and both can serve as biomarkers to facilitate its detection. We developed an integrated multi-omic approach to identify genomic and methylation alterations simultaneously from blood-based circulating tumor DNA (ctDNA) analysis. In contrast to traditional methods of separated lab workflows for each signal modality, our lab workflow generates both genomic and methylation sequencing libraries from the same input sample. During the workflow, a cytosine conversion-resistant analog of the original cell-free DNA (cfDNA) molecule is synthesized such that its genomic sequence is preserved. Following cytosine conversion of the original cfDNA and its analog in a single reaction, methylation and genomic libraries are respectively derived. A new signal modality identification design is used for separation of genomic and methylation libraries during data processing. Our strategy has the benefit of reducing operational complexity while maximizing ctDNA capture efficiency from small quantities of analyte. Our results show that the multi-omic library is efficiently synthesized (52.8% of genomic reads and 47.2% methylation reads after parsing signal modality identifier), and that the genomic library is effectively protected from cytosine conversion (99.98% protection efficiency). Filtered conversion efficiency exceeds 99.9% in CH (where H corresponds to A, T or C) context from the methylation library, supporting high signal integrity in the methylation workflow. Genomic variant calling detected known cancer variants in FFPE tissue and plasma samples (>96% variants in FFPE tissue samples from stage II and III cancers). In a small clinical cohort study, the methylation signal modality detected 40% of stage I, 95% of stage II and 87% of stage III lung cancer plasma samples at 100% specificity without requiring matching tissue. Taken together, our integrated multi-omic approach provides a versatile tool for combined sensitivity and actionability in blood-based ctDNA detection.

#3676 Ultrasensitive protein detection using proximity initiated nucleic acid target amplification with digital biosensing.
Skye Shepherd, Weinan Liu, Brian T. Cunningham

University of Illinois at Urbana-Champaign, Urbana, IL

Proteins are vital biomarkers and provide a real-time dynamic look into cancer progression and disease states. Point-of-care simple diagnostics for rapid, ultrasensitive testing is necessary to study longitudinal changes of protein biomarkers for treatment monitoring, prognosis, or early detection. Proximity assays are a solution-based protein assay using antibody pairs that can achieve high sensitivity, specificity, and be used for high-throughput or multiplexing applications. However, standard proximity assays require complicated design, enzymatic amplification such as polymerase chain reaction (PCR), and thermocycling with expensive laboratory equipment and specialized laboratories. This limits the use for longitudinal monitoring or liquid biopsies. We demonstrate here the Proximity Initiated Nucleic Acid Target Amplification (PINATA) assay, a novel proximity immunoassay for protein detection that can be performed completely at room temperature in a single step using a small, portable, point-of-care benchtop detection instrument. The PINATA assay implements linear amplification using toehold-mediated strand displacement reactions of antibody-oligonucleotide conjugates along with digital detection of individual gold nanoparticle tags for ultrasensitive, rapid protein quantification in the femtomolar range, allowing detection in less than two hours for sub picogram per milliliter concentrations of human interleukin 6, a cytokine biomarker of inflammation that has been linked to certain cancers. These results showcase the promise of entropy-driven strand displacement proximity assays for fast and ultrasensitive point-of-care applications and disease diagnostics.

#3677 Early detection of pancreatic cancer using methylated circulating cell-free DNA of *ZFP30* and *ZNF781*genes.

Ruo-Kai Lin[1], Yao Yu Hsieh[1], Hsieh-Tsung Shen[2]

[1]Taipei Medical University, Taipei, Taiwan,[2]EG BioMed Co. Ltd., Taipei, Taiwan

Background:
Pancreatic cancer (PC) is often diagnosed at advanced stages, leading to limited treatment options and poor survival rates. Current biomarkers, such as CA19-9, have high false-positive rates, with only 4 out of 1,000 abnormal cases confirmed as cancer. Aberrant DNA methylation, a stable and early epigenetic event in tumorigenesis, has emerged as a promising biomarker for early detection and disease monitoring.
Objective:
This study presents a novel blood test analyzing methylated cell-free DNA (mcfDNA) of *ZFP30* and *ZNF781*genes for the early detection of pancreatic cancer. Functional assays were also performed to explore the tumor-suppressive roles of *ZFP30* and *ZNF781* in pancreatic cancer cell lines.
Methods:
ZFP30 and *ZNF781* were identified through analyses of plasma samples from Taiwanese pancreatic cancer patients combined with data from The Cancer Genome Atlas (TCGA). A novel test was developed to assess methylation levels in cfDNA extracted from plasma. Clinical validation was conducted on PC patients and healthy controls, while functional studies assessed the effects of exogenous *ZFP30* and *ZNF781* expression on cancer cell proliferation and migration.
Results:
The methylation levels of *ZFP30* and *ZNF781* were significantly elevated in 87% of pancreatic cancer (PC) tumor tissues compared to adjacent normal tissues in PC patients. Furthermore, these methylation markers were detected in circulating cell-free DNA (cfDNA) in 99% of plasma samples from PC patients, demonstrating an area under the curve (AUC) of 0.96, with a sensitivity of 99% and a specificity of 93.9%. Methylation signals were nearly undetectable in plasma from healthy subjects, and the test accurately identified PC patients across all stages. Comparative analysis demonstrated superior performance over traditional biomarkers such as CA19-9 and CEA. Functional studies showed that exogenous expression of *ZFP30* and *ZNF781*significantly inhibited pancreatic cancer cell proliferation and migration, supporting their roles as tumor suppressor-like genes.
Conclusion:
The methylated cfDNA of *ZFP30* and *ZNF781* offers a highly sensitive and specific biomarker for the early detection of pancreatic cancer. Integrating this blood test into clinical practice could greatly enhance diagnostic accuracy. Additionally, the tumor suppressor-like functions of *ZFP30* and *ZNF781* highlight their potential as therapeutic targets, providing further avenues for pancreatic cancer management and treatment.

#3678 Liquid biopsy fragmentomics approach for the diagnosis of uterine tumors.

Meagan S. Cobb[1], Philippe Jolivet[2], Kristen N. Ganjoo[3], Deirdre A. Lum[3], Matt van de Rijn[3], Joanna Przybyl[4]

[1]Department of Pathology, McGill University, Montreal, QC, Canada,[2]Research Institute of the McGill University Health Centre, Montreal, QC, Canada,[3]Stanford University, Stanford, CA,[4]Department of Surgery, McGill University, Montreal, QC, Canada

Background: Leiomyomas (LM), also known as fibroids, are common benign tumors of the smooth muscle of the uterus that can cause pain, infertility, and abnormal menstrual bleeding. Diagnosing LM is challenging using clinical indications alone, as they share symptoms with leiomyosarcoma (LMS), a rare, aggressive uterine malignancy with a ~50% disease-specific survival. Pre-operative distinction between LM and LMS is difficult because these tumors are rarely biopsied before surgery. We hypothesize that a non-invasive circulating tumor DNA (ctDNA) test based on LMS- and LM-specific molecular markers will provide accurate pre-operative diagnosis and guide appropriate surgical treatment.

Methods: We previously analyzed point mutations and copy number alterations (CNAs) in ctDNA using deep targeted sequencing and shallow whole-genome sequencing (WGS) from plasma specimens of 7 LMS and 12 LM patients (PMIDs: 29463554, 32232185). To build on this, we performed a new analysis of the first 4 nucleotide sequences (4-mer motifs) on the 5' end of the cell-free DNA fragments using shallow WGS data. The frequency of 256 possible 4-mer motifs was calculated using R programming and normalized to total reads in each specimen. Two-class differential analysis identified motifs enriched in LM and LMS (false discovery rate < 0.05).

Results: Our previous studies demonstrated the feasibility of ctDNA detection in LMS and LM patients. In LMS patients, ctDNA was detected in 6 of 7, with >98% specificity; in LM patients, ctDNA was detected in 6 of 12, with 76% specificity. To increase ctDNA detection sensitivity, we incorporated fragmentomics as a new ctDNA marker. Our new analysis identified 66 significantly enriched and 21 significantly decreased motifs in cell-free DNA from LMS patients compared to LM patients. Motifs associated with DNASE1L3 nuclease activity (e.g., CCCA) were significantly decreased in LM compared to LMS patients.

Conclusion: We identified new tumor-specific fragmentomic markers in cell-free DNA from LMS and LM patients. Combining detection of point mutations, CNAs, and fragmentomic patterns could enable a highly sensitive ctDNA assay for accurate pre-operative distinction between LM and LMS. Next, we will validate DNASE1L3 and other nucleases in tissue microarrays of 100+ LM and 200+ LMS specimens by immunohistochemistry, and validate distinct fragmentomic patterns using expanded plasma collections. This research addresses an unmet clinical need for accurate pre-operative diagnosis of uterine tumors.

#3679 Plasma-based multimodal profiling of urothelial carcinoma to characterize tissue-based subtypes.

A. Cauwels[1], E. Levy[1], A. D. Tang[1], V. Cheung[1], R. Gupte[1], A. Tseng[1], T. Qing[1], K. Walter[1], Z. Assaf[2], S. Mariathasan[2], R. Banchereau[2], E. Tabari[1], J. C. Lin[1];

[1]Freenome, Inc., Brisbane, CA, [2]Genentech, South San Francisco, CA

Background

Urothelial carcinoma (UC) is a molecularly and clinically heterogeneous malignancy with notable diversity in patient outcomes and response to treatment such as immune checkpoint blockade. There have been various efforts to identify and enrich for patient populations which benefit most from these immunotherapies. Cell-free DNA (cfDNA) can be utilized as a non-invasive method to detect the extent of residual tumor, and also provide molecular characterization through indirect measures of gene expression. Here, we use a multimodal plasma-based platform on samples from the IMvigor130 trial to explore biomarkers associated with tissue-based UC subtypes, which have been previously shown to have differing responses to checkpoint blockade.

Methods

Plasma samples from baseline metastatic and locally advanced UC patients with known tissue-defined subtypes (n=120) were evaluated with a targeted sequencing approach that characterizes chromatin accessibility and cfDNA methylation. Fragment length and positioning around each transcription start site were used to indirectly infer gene expression. We also identified UC subtype-associated CpG hypermethylation patterns. We trained binary and multinomial regression models utilizing the individual plasma analytes as well as the combined multimodal features to predict the tissue-based subtypes.

Results

The luminal marker KRT20 and basal marker CXCL6 were previously observed to be subtype markers in tissue data; here we show similar associations with subtype using cfDNA inferred gene expression. An analysis of differentially methylated promoters revealed many other subtype-specific genes that show potential in plasma cfDNA for UC classification. We observed concordance in predicted gene activity from both inferred gene expression and methylation for the majority of genes (>75%). We compared these signals to subtypes previously identified by tissue RNA expression, which featured luminal, stromal, immune, or basal characteristics. The classes with the strongest classification performance were luminal, with an AUC of 0.66, and basal, with an AUC of 0.72. These groups are characterized by tumor-intrinsic features, as opposed to the stromal and immune-driven subtypes. Notably, the basal subtype is known to be enriched for responders to PD-L1 inhibition.

Conclusions

Here, we show a proof-of-concept for how a non-invasive multimodal cfDNA assay can be used to interrogate and recapitulate subtypes of UC. Our findings are aligned to the known biology of tissue transcriptomics-defined subtypes and reveal additional insight into potential plasma biomarkers. Finally, the capacity to subtype UC from a blood-based multiomics approach can be leveraged for the longitudinal monitoring of subtype and disease characteristics over the course of treatment.

#3680 Plasma DNA methylome profiling predicts response to olaparib and durvalumab in recurrent IDH-mutant gliomas: Results from a phase II trial.

Yosef Ellenbogen, Xin Wang, Vikas Patil, Alexander Landry, Justin Wang, Jeffrey Zuccato, Mathew Voisin, Andrew Ajisebutu, Leeor Yefet, Farshad Nassiri, Eric Chen, Gelareh Zadeh

University of Toronto, Toronto, ON, Canada

Background: Combing PARP and Immune Checkpoint inhibition has been proposed as a potentially synergistic strategy in IDH mutant glioma, targeting dysregulated homologous recombination repair pathways. We analyzed the cell-free DNA (cfDNA) methylome of patients in a phase 2 trial using the PARP inhibitor olaparib and the PD-1 inhibitor durvalumab. The primary objective was to evaluate cfDNA methylome as a non-invasive biomarker of response.
Methods: Patients with recurrent IDH-mutant gliomas were enrolled in a phase II open-label study (NCT03991832). Blood samples were collected at baseline and monthly while on treatment. Cell-free methylated DNA immunoprecipitation and high-throughput sequencing (cfMeDIP-seq) was performed. Samples were separated into 50 random discovery and validation sets with an 80:20 split. Binomial regularized regression models were developed for each response class versus others using the discovery set and model performance was assessed using the validation set. Area under receiver operating characteristic (ROC) curve (AUROC) values were calculated for each model in the validation set.
Results: 29 patients (median age 40.5; 41% female) enrolled between January 2020-February 2023. The initial tumor grade was 2 (n=9), 3 (n=8), and 4 (n=12). Patients received olaparib 300 mg twice daily and durvalumab 1500 mg IV every 4 weeks. The overall response rate was 10% (95% CI 2.2-27%) via RANO criteria. 144 plasma samples (from 29 patients) were profiled with cfMeDIP-seq along with 30 healthy controls. The circulating tumour DNA methylome was enriched by normalizing to differentially methylated regions not found within the normal controls. The enriched circulating tumour DNA methylome during response periods exhibited a highly specific signature, accurately discriminating response versus failure (AUC 0.98 ± 0.02). Additionally, on-treatment samples were able to be discriminated from samples off therapy (AUC 0.74 $\pm$ 0.11). Lastly, the specific differentially methylated gene pathways between groups were comprehensively examined in both plasma samples and baseline tumor tissue.
Conclusions: Plasma cfDNA methylome exhibits highly specific signatures that enable accurate prediction of response to olaparib and durvalumab in recurrent IDH-mutant glioma.

#3681 A tumor-naive method for estimating tumor fraction using 5-hydroxymethylation cytosine in cell-free DNA.

Ceyda Coruh[1], Onur Sakarya[2], Yuhong Ning[2], Yuan Xue[2], Michael Cipriano[2], Kyle Hazen[2], Alexander W. Wyatt[3], David Quigley[4], Felix Feng[4], Martin Sjostrom[4], Gulfem Guler[2], Wayne Volkmuth[2], Samuel Levy[1]

[1]ClearNote Health, San Diego, CA,[2]ClearNote Health, San Mateo, CA,[3]Department of Urologic Sciences, Vancouver Prostate Centre, University of British Columbia, Vancouver, BC, Canada,[4]Helen Diller Family Comprehensive Cancer Center, University of California at San Francisco, San Francisco, CA

Accurate measurement of the tumor fraction (TF) in circulating cell-free DNA (cfDNA) allows estimation of tumor burden non-invasively, potentially useful in guiding treatment decisions, monitoring treatment response, and detecting minimal residual disease. 5-hydroxymethylation of cytosine (5hmC) marks activation of cancer drivers and downstream gene targets, and has been shown to positively correlate with gene expression and gene regulation. Here we trained a machine learning (ML) model to predict TF in a tumor-naive way from 5hmC-enriched sequencing data together with low-pass whole genome sequencing data. In cross-validation the ML model showed excellent performance, showing high correlation ($R > 0.8$) and low composite absolute error (CAE < 5%) compared to copy-number variation (CNV) based estimates. The high correlation was confirmed in an independent test set which also showed $R > 0.8$, with only a modest increase in CAE (<10%) using targeted point mutation-based TF estimates as an external reference comparator. Using in silico cancer mixtures that created contrived cfDNA samples targeting concentrations below 10%, our 5hmC-based TF prediction method achieved detection sensitivity of approximately 90% with a specificity of 97%. Finally, we observed that 5hmC-based predicted TF was significantly associated with overall survival ($HR = 1.04$, $p < 0.001$) in an independent prostate patient cfDNA cohort when controlling for other covariates. In summary, we find that the 5hmC-based TF estimate is a reliable metric of tumor burden irrespective of tumor mutational status. The 5hmC-based TF estimate may be used either alone or in conjunction with mutation and CNV-based estimates to provide more accurate measures of survival risk and therapy response during treatment.

#3682 Body mass index impacts blood-based markers signatures in advanced colorectal cancer.

Gabriela Felix[1], Jun Gong[2], Francesca Aguirre[1], Lisa Zhou[1], Aaron Denmark[1], Rocio Ramirez[1], Hayan Lee[3], Megan Hitchins[1]

[1]Department of Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Department of Medicine, Cedars-Sinai Medical Center, Los Angeles, CA,[3]Department of Medical Genetics and Molecular Biochemistry, Fox Chase Cancer Center, Philadelphia, PA

Background: In the USA it is estimated that more than half-million cancer cases are associated with obesity. Colorectal Cancer (CRC) is one of the most common types of cancer, and rising death rates underscores the need for a feasible and tailored algorithm to aid in disease management such as a blood-based test, i.e., liquid biopsy. Here, we investigate a multimodal assessment of blood-based markers, cell-free DNA (cfDNA) methylation signatures, levels of Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), and Carcinoembryonic Antigen (CEA), and the impact of Body Mass Index (BMI) in CRC cases at presentation.
Method: A multimodal assessment was conducted on sixteen treatment-naive CRC cases. The evaluation consisted of a review of clinical records to collect (i) blood levels of CEA, AST, and ALT, and (ii) BMI data. Additionally, cfDNA methylation analysis was performed by Whole Genome Bisulfite Sequencing (WGBS), and methylated *SEPTIN9* (mSEPT9) by Real-Time PCR. Statistical analysis was conducted on GraphPad and SPSS.
Results: All CRC cases were advanced stages (III and IV), and most had a familial history of cancer. The mean age of diagnosis was 51.50 years (SE ± 3.42). Healthy BMI was observed in most cases (56.3%), followed by overweight/obese (31.3%) and underweight (12.5%). ALT, AST, and CEA levels were abnormal in 25%, 31.3%, and 56.3% of the cases, respectively. Overall cfDNA analysis showed aberrant methylation patterns in all cases, and 75% were mSEPT9 positive. Principal component analysis (PCA) showed a significant correlation among AST (0.93), CEA (0.89), ALT (0.83), mSEPT9 positivity (0.80), and cfDNA overall methylation (0.50) (Kaiser-Meyer-Olkin score 0.60, Bartlett's test $p<0.05$) but negative correlation with BMI (-0.33) (Kaiser-Meyer-Olkin score 0.50, Bartlett's test $p<0.05$).
Conclusion: Blood-based multimodal assessment could be a valuable method for managing CRC clinically. However, there is an inverse correlation BMI and blood markers. This highlights the importance of considering BMI when evaluating liver function and tumor markers in advanced CRC cases.

#3683 AI assisted MRI volumetrics improve recurrent glioblastoma patient stratification following immunotherapy treatment.

Alexander L. Ling[1], Joshua D. Bernstock[1], Erickson Torio[2], Naoyuki Shono[3], Junfeng Liu[4], Ana Montalvo Landivar[5], Nafisa Masud[1], Ethan Chen[1], E. Antonio Chiocca[1]

[1]Neurosurgery, Brigham and Women's Hospital, Brookline, MA,[2]Neurosurgery, Medical College of Wisconsin, Milwaukee, WI,[3]The University of Tokyo, Tokyo, Japan,[4]Neurosurgery, Tongji Hospital, Wuhan, China,[5]Stanford University, Stanford, CA

Background: MRI-based monitoring of tumor progression after treatment plays a critical role in patient care decisions and clinical trial monitoring for glioblastoma patients. However, traditional MRI assessments of glioblastoma tumor burden (i.e. RANO-based criteria) can be significantly confounded by inflammatory pseudo-progression—especially in the context of immunotherapy treatment.
Methods: In an effort to improve MRI assessments of tumor burden in glioblastoma patients, we performed volumetric tumor segmentation of >1000 MRI timepoints from 41 recurrent high-grade glioma patients who underwent oncolytic herpesvirus treatment. Volumetric assessments were correlated with patient outcomes and clinical covariates to assess their utility in stratifying patient outcomes relative to RANO analysis. Furthermore, to reduce the cost and time required for tumor segmentation, we leveraged our dataset and the Brain Tumor Segmentation (BraTS) 2023 challenge dataset to train a convolutional neural network to automate glioblastoma tumor segmentation. Automated segmentation volumes were validated against manually segmented tumor volumes and optimized for high-throughput processing.
Results: While routine RANO assessment of tumor progression in the months following therapy failed to separate short- and long-surviving patients, volumetric assessment enabled clear stratification of patients into short, medium, and long-surviving groups using only a few months of post-treatment imaging follow up. Furthermore, automated segmentation volumes showed a high-concordance with manual segmentation volumes in most patients, with deviations between the two being largely restricted to misclassification of resection cavities. In most cases, such errors could be easily detected and corrected, enabling rapid and accurate segmentation.
Conclusions: Volumetric tumor segmentation significantly improves stratification of recurrent glioblastoma patients following immunotherapy treatment versus traditional RANO classification. While such segmentation is time and skill intensive when performed manually, AI assisted segmentation can result in accurate segmentation volumes with greatly reduced time and skill. Surgical artefacts remain challenging for automated segmentation approaches; however, we expect these limitations to be overcome as we improve our training datasets. We expect this to enable rapid and cheap volumetric analyses capable of improving glioblastoma patient monitoring and, ultimately, providing clinicians with more accurate information when making patient care decisions.

#3684 Integrating multiparametric MRI with spatial transcriptomics to identify "Radio-Spatial Genomic" features of prostate cancer using artificial intelligence..

Thineskrishna Anbarasan[1], Sandy Figiel[1], Sophia M. Abusamra[1], Wencheng Yin[1], Nithesh Ranasinha[1], James T. Grist[2], Dan J. Woodcock[1], Richard J. Bryant[1], Ruth McPherson[1], Freddie C. Hamdy[1], Bartlomiej Papiez[3], Ian G. Mills[1], Alastair D. Lamb[4]

[1]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom,[2]Department of Academic Radiology, University of Oxford, Oxford, United Kingdom,[3]Big Data Institute, University of Oxford, Oxford, United Kingdom,[4]Barts Cancer Institute, Queen Mary University of London, London, United Kingdom

Introduction: Risk stratification remains a key challenge in prostate cancer (PCa) management involves risk stratification, and identification of the subgroup of patients at highest risk of progressing from localised to metastatic disease is critical. Multiparametric MRI (mpMRI) is key in the PCa diagnostic pathway. By integrating clinical parameters, mpMRI radiomics and spatial transcriptomics (ST), this novel "Radio-Spatial Genomics" platform offers an exciting opportunity to identify mpMRI radiomic features associated with important biological aspects of PCa linked to an aggressive disease phenotype.
Methods: Multi-regional spatial transcriptomics (Visium 10x Genomics) was performed on archived formalin-fixed paraffin-embedded prostatectomy sections from patients recruited to a local trial (ISRCTN10046036). Axial sections were sequenced using ST (8 per patient) from 2 patients with Gleason 4+4 PCa and preoperative mpMRI available was used for this study. Anatomical landmarks on mpMRI were segmented by a radiologist. Using a proportional size algorithm and a convolutional neural network (ProsRegNet), T2-axial MRI slices were aligned and registered to histopathology sections. An application, SpatialStitcher, was developed on Python 3.7.0 to digitally stitch separate ST sections for image registration.
Results: Using the prostatic capsule and urethra as landmarks, histopathology sections from 2 patients were co-registered to corresponding T2-axial MRI slices. In total, a median of 114670 whole transcriptome sequenced barcoded ST spots were co-registered to 30424 pixels on MRI per patient. A median DICE correlation score of 0.942, 0.738 and 0.756 was achieved for capsule, tumour and BPH nodules respectively. AMACR (marker for PCa) expression inversely correlated with T2 MRI intensity-based radiomic features ($r = -0.763$), consistent with the tumour being hypointense. Differential gene expression analysis between hyperintense peri-tumoural and hypointense tumour regions revealed enrichment for genes involved in mucosal immune response.
Conclusion: In this study, we report preliminary results of mapping MRI with ST using machine learning to identify genotypic changes based on radiomics. This novel "Radio-Spatial Genomics" model may allow the detection of clinically relevant genotypic features from diagnostic prostate mpMRI imaging.

#3685 Virtual Gleason score: Towards personalized predictive identification of prostate cancer risk via integration of clinical and imaging data into spatiotemporal, biomechanistically-informed classifiers.

Guillermo Lorenzo Gomez[1], Chengyue Wu[2], Joshua P. Yung[2], John F. Ward[2], Hector Gomez[3], Thomas E. Yankeelov[4], Aradhana M. Venkatesan[2], Thomas J. R. Hughes[4]

[1]University of A Coruna, A Coruna, Spain,[2]The University of Texas MD Anderson, Houston, TX,[3]Purdue University, West Lafayette, IN,[4]The University of Texas at Austin, Austin, TX

The Gleason score (GS) is a fundamental predictor of prostate cancer (PCa) behavior and cancer-specific survival. The GS is determined by analyzing the tumor cell architecture in tissue samples. As PCa exhibits significant heterogeneity within any single tumor, whole-prostate tissue specimens enable a comprehensive assessment of the tumor's GS. However, a biopsy, upon which treatment decisions are made, is inherently prone to sampling bias. Thus, a more accurate method to predict tumor biology and clinical disease progression is needed. To address this unmet critical demand, we propose the concept of virtual Gleason Score (vGS).
The vGS consists of a personalized prediction of the local map of GS over the 3D tumor morphology extracted from MRI and informed by biomechanistic markers that characterize spatiotemporal tumor dynamics. The vGS is obtained through a three-step pipeline hybridizing physics-driven and data-driven models. First, we personalize a biomechanistic model of PCa growth using MRI and serum PSA data collected as part of routine management of the disease. Second, we calculate a panel of biomechanistic biomarker maps probing quantities and mechanisms included in the model that have shown strong correlation with GS. Finally, a machine learning algorithm leverages the local values of these biomechanistic markers to render a spatiotemporally-resolved map of vGS over the tumor geometry.
Here, we present preliminary results in a cohort with 16 PCa cases that were longitudinally monitored with PSA and MRI in the context of active surveillance. The underlying biomechanistic model was the Fisher-Kolmogorov equation, and we used logistic classifiers to build the vGS. Our study shows that local proliferation activity and tumor cell density weighted by the ratio of tumor to prostate volume achieve an AUC of 0.96 as well as optimal sensitivity and specificity of 86.4% s and 90.7% for predicting GS. Despite the coarse nature of the vGS predictions obtained from the biomechanistic model used herein, these forecasts accurately anticipated the emergence of higher GS more than one year earlier than standard PCa monitoring. Future work will seek to advance the biomechanistic and data-driven models to enhance local vGS forecasts, as well as leveraging them to optimize disease management on a patient-specific basis.

#3686 Multi-tensor AI/ML uniquely able to identify mechanistically interpretable and actionable predictors from small-cohort and noisy high-dimensional multi-omic clinical data.

Orly Alter[1], Marissa Coppola[2], Tessa O. House[2], Jessica W. Tsai[2]

[1]University of Utah and Prism AI Therapeutics, Inc., Salt Lake City, UT,[2]Children's Hospital of Los Angeles and University of Southern California, Los Angeles, CA

Two decades after the human genome, prediction in cancer remains limited. The entire multi-ome affects the disease. And, unlike typical artificial intelligence and machine learning (AI/ML), e.g., neural networks and deep learning, our multi-tensor AI/ML is uniquely able to identify predictors from multi-omic clinical data. We have been developing the algorithms, i.e., the “multi-tensor comparative spectral decompositions,” to extend the mathematics that underlies quantum mechanics to overcome the limitations of typical AI/ML. We demonstrated the algorithms in the discovery and validation of novel predictors of survival and response to treatment in, e.g., astrocytoma, including glioblastoma (GBM), brain, lung, nerve, ovarian, and uterine cancers.

The algorithms, first, blindly, i.e., without any assumptions or a-priori knowledge, removed batch effects and separated demographic variations from the data. This enabled identifying, e.g., a predictor in ovarian cancer, which is encompassed within the normally varying X chromosome. Second, the algorithms identified the predictors repeatedly, in federated and imbalanced public datasets from as few as 50-100 patients each, showing that the algorithms are batch- and demographics-agnostic, and the predictors are actionable in the general population. Third, the predictors were interpreted in terms of known and new disease mechanisms and drug targets and combinations of targets to sensitize the tumors to the treatment. The predictors are independent from all standard-of-care indicators, additionally showing that this information that they contain was missing from the understanding and management of cancer. Fourth, the GBM predictor, which is the first biomarker to encompass the whole genome, was prospectively and retrospectively experimentally validated to be the most accurate and precise. All other attempts to associate a GBM tumor’s DNA copy numbers with the patient’s outcome failed. For 70 years, the best indicator has remained age at diagnosis, establishing that the algorithms find what all others miss, and the predictors outperform all others where they exist.

Here, we present recent experiments demonstrating that, fifth, the GBM predictor correctly identified previously unrecognized drug targets, i.e., genes that are required for the tumor’s cell proliferation and viability, further validating the mechanistic interpretability of the multi-tensor AI/ML. Guide RNAs were designed and a lentiviral CRISPR-Cas9 all-in-one vector was harnessed to knock out the candidate genes. Knockout validation at the protein level was performed using Western blot. Knockout in patient-derived GBM cell lines resulted in significantly attenuated cell viability and proliferation.

We conclude that our multi-tensor AI/ML is uniquely suited for personalized medicine.

#3687 Multi-tensor AI/ML discovery and validation of whole-transcriptome predictors of survival in response to immunotherapy from multi-omic clinical data.

Orly Alter[1], David B. Oberman[2], Asaf Zviran[2]

[1]University of Utah and Prism AI Therapeutics, Inc., Salt Lake City, UT,[2]Prism AI Therapeutics, Inc., Salt Lake City, UT

Prediction in cancer remains limited, and drugs continue to fail clinical trials and post-market validation. The entire multi-ome affects the disease, but typical artificial intelligence and machine learning (AI/ML) cannot generate predictors from multi-omic clinical data. Because, first, the data are “skinny,” with orders of magnitude more features than samples. Neural networks and deep learning, e.g., would require ≥3B-patient sets to generate models from the 3B-nucleotide genome alone. Second, batch and demographic variations mask the disease-specific patterns. Third, unavoidable imbalances and unavailable labels obscure the distinctions among subpopulations. Fourth, accuracy and interpretability are usually traded off, but (pre)clinical models need to accommodate both. Fifth, the data are of different types, numbers, and dimensions.

Our multi-tensor AI/ML is uniquely able to identify accurate, precise, actionable, and mechanistically interpretable predictors from multi-omic clinical data. We have been developing the algorithms, i.e., the “multi-tensor comparative spectral decompositions,” to extend the mathematics that underlies quantum mechanics to overcome the limitations of typical AI/ML. We demonstrated the algorithms in the discovery and validation of predictors in, e.g., astrocytoma, including glioblastoma (GBM), brain, lung, nerve, ovarian, and uterine cancers. The algorithms identified the predictors repeatedly, in federated and imbalanced public datasets from as few as 50-100 patients each. The GBM predictor, the first to encompass the whole genome and the first to associate a GBM tumor’s DNA copy-number alterations with the patient’s outcome, was additionally prospectively and retrospectively experimentally validated to be the most accurate and precise predictor of survival and response to treatment. Recent experiments also show that the GBM predictor correctly identified previously unrecognized drug targets, i.e., genes that are required for the tumor’s cell proliferation and viability.

Here, we demonstrate the multi-tensor AI/ML in the discovery and validation of whole-transcriptome predictors of survival in response to atezolizumab PD-L1 inhibitor immunotherapy. The predictors were discovered in pre-treatment metastatic disease profiles from an open-source clinical trial, and validated in primary disease profiles from the Cancer Genome Atlas (TCGA). One predictor is additionally correlated with the response to the treatment, and the other - with the tissue of metastasis. Kaplan-Meier survival analyses and Cox proportional hazards models show that the two predictors outperform the best indicator of response to atezolizumab to date, i.e., tumor mutation burden (TMB).

We conclude that our multi-tensor AI/ML is uniquely suited for personalized medicine.

#3688 Correlation between natural killer cell sensitivity and epithelial mesenchymal transition morphology: A cell morphology based screening for NK cell susceptible tumor cells.

Yin Zou[1], Harrison Ball[1], Yuru Chen[2], Nithya Ramnath[3], Venkateshwar Keshamouni[4], Sunitha Nagrath[1]

[1]Chemical Engineering, University of Michigan, Ann Arbor, MI,[2]Biomedical Engineering, University of Michigan, Ann Arbor, MI,[3]Veteran Affairs, Ann Arbor Healthcare system, Ann Arbor, MI,[4]Internal Medicine, University of Michigan, Ann Arbor, MI

Natural killer (NK) cell-based immunotherapy has demonstrated promising anti-tumor efficacy and safety in multiple early clinical trials against hematological and solid tumors. However, intrinsic NK resistance in tumors has resulted in a variable response to adoptively transferred NK cells. To enhance the treatment efficacy, a personalized approach must be adopted. Current methods for screening NK cell sensitive tumors using transcriptomic or proteomic techniques can be costly and often biased by the limited markers detected. Studies showed that cancer cells undergoing the process of epithelial mesenchymal transition (EMT) increase their vulnerability to NK mediated cytotoxicity. We hypothesize that by utilizing image-based analysis to quantify EM morphology change we can correlate EMT morphology with NK cell sensitivity. To analyze EM morphology, we trained a machine learning model based on cell morphological features using the A549 cell line treated with transforming growth factor-β (TGF- β), which depicts various cell morphology across the EMT spectrum. We optimized an organelle specific and live cell compatible staining panel that targets the nucleus, nucleic acid, cell membrane, and F-actin, which does not rely on antigen presentation. The images were processed via a Cell Painting cell segmentation and feature extraction pipeline. In parallel, we conducted a NK cell cytotoxicity assay on cells undergoing the same treatments and confirmed the EMT status via transcriptomic analysis. Our machine learning model successfully identified the EM status of A549 cells treated with TGF- β for different durations (0, 24, 48, and 72 hours) by assigning each cancer cell a quantitative EM score (zero be most epithelial and one be most mesenchymal). We identified a correlative trend between higher EM scores and increased NK cell sensitivity. The same trend was observed when we evaluated the workflow on various non-small lung cancer (NSCLC) cell lines, including two in-house patient derived CTC cell lines. In conclusion, we have established a quantitative measurement for EM status in NSCLC cancer cell lines and observed a correlation between EM score and NK cell sensitivity. We will extend this work by transferring our EM score model to process clinic patient tumor samples, paving the way for developing a rapid screening method for personalized NK cell therapy.

#3689 Hydrogel-based specimen transfer method enhances compatibility and integration of spatial omics.

Amos Chungwon Lee[1], Sumin Lee[1], **Changhee Lee**[2], Sunghoon Kwon[2]

[1]Meteor Biotech, Seoul, Korea, Republic of,[2]Seoul National University, Seoul, Korea, Republic of

Spatial omics technologies have revolutionized our understanding of biological systems by enabling the molecular mapping of RNA, DNA, and proteins within their tissue context. Despite these advancements, a major limitation of spatial omics tools is their lack of compatibility with traditional methods and with each other. Traditional gold-standard methods such as Hematoxylin and Eosin (H&E) staining on formalin-fixed paraffin-embedded (FFPE) tissue sections and Wright-Giemsa (W&G) staining on hematological smears mounted on standard glass slides are fundamental to routine medical practice, and their widespread use highlights the significant challenge posed by the incompatibility of advanced spatial omics tools with these established protocols. To overcome these challenges, there is a growing practical need for technology that can transfer specimens from one substrate to another while preserving both spatial and molecular information. For tools where extremely fine spatial information, context, and morphology are crucial markers, existing sample transfer techniques such as floating techniques are largely primitive, leading to inadequate preservation of critical data and hampering the effectiveness of spatial omics analyses. Here, we present a novel hydrogel-based technique for transferring samples from standard slides to spatially omics-compatible slides. By comparing the spatial information of samples before and after transfer, as well as consecutive samples, we show that the technique preserves spatial information extremely finely. In addition, we compared proteomics, genomics, and transcriptomics analyses according to the number of transfers, showing that the integrity of molecular information is maintained even after multiple transfers. Furthermore, we demonstrated that it is possible to transfer multiple samples from diverse slides onto a single spatially omics compatible slide. To showcase its applicability, we applied SLACS (Spatially resolved laser-activated cell sorting) to an archival slide containing a rare co-occurring multiple myeloma and acute myeloid leukemia (AML) sample. After transferring the sample to a Cosmoslide, cells were identified using W&G and fluorescent staining, isolated, and sequenced. Whole-genome sequencing linked cytogenetic profiles to clonal variations, uncovering critical changes leading to myeloma and AML cell formation. This hydrogel-based specimen transfer technology bridges the gap between traditional methods and spatial omics tools, enabling seamless integration into clinical and research workflows. It offers a transformative solution for studying rare samples and complex diseases, unlocking new opportunities for spatial omics applications in biomedical research.

#3690 Biomarker Navigator - empowering the augmented scientist in biomarker discovery.

Ioannis Kagiampakis[1], Mishka Gidwani[2], Iaroslav Korkodinov[2], Georgiy Ponomarev[2], Sun Gerald[3], Etai Jacob[3], Damian Bikiel[4]

[1]Oncology Data Science, AstraZeneca US, South San Francisco, CA,[2]Oncology Data Science, AstraZeneca US, Gaithersburg, MD,[3]Oncology Data Science, AstraZeneca US, Waltham, MA,[4]Oncology Data Science, AstraZeneca US, New York, NY

The advent of large language models (LLMs) is poised to revolutionize every domain of the pharmaceutical industry, from early-stage drug development to clinical trial design. By harnessing both public datasets and scientific literature, LLMs offer unparalleled access to critical knowledge for researchers, while proprietary datasets provide a unique competitive edge, enabling organizations to derive exclusive insights and drive innovation. To excel in biomarker development within large organizations, two critical goals must be prioritized: maximizing the extraction of insights from proprietary datasets and ensuring the seamless dissemination of knowledge across the organization. Large Language Models (LLMs) facilitate these goals by connecting expertise across diverse scientific domains and delivering knowledge in natural language. This enables the creation of an “augmented scientist” empowered to make data-driven decisions and generate hypotheses through the integration of cross-disciplinary knowledge. The Biomarker Navigator program exemplifies AstraZeneca’s commitment to this augmented scientist vision through three core components: 1) an automated analysis framework for biomarker identification. 2) a comprehensive repository of standardized, detailed biomarkers insights. 3) an intuitive interface for fast, seamless knowledge access.

AstraZeneca is expanding the Biomarker Navigator by integrating public datasets to make it accessible to the broader scientific community, with an initial focus on renal cell carcinoma (RCC) and melanoma. This dataset expansion includes whole exome sequencing (WES), copy number alterations (CNA), RNA sequencing (RNA-seq), and clinical metadata. The resulting system empowers researchers to seamlessly transition from a high-level overview of the biomarker landscape—within or across datasets—to detailed insights about a single biomarker, ensuring no information is lost. By combining an intuitive user interface with LLM-driven insights, this platform showcases the transformative potential of AI in biomarker discovery, paving the way for a robust, open-source framework for the scientific community in the near future.

#3691 Integrated multiomics unlocks holistic phenotypic insights allowing for deep molecular exploration.

Andrea J. O'Hara[1], Tom Cohen[2], Ethan Stancliffe[2], Adam Richardson[2], David Corney[1], Laure Turner[1], Haythem Latif[1], Ginger Zhou[1]

[1]GENEWIZ from Azenta Life Sciences, South Plainfield, NJ,[2]Panome Bio, St Louis, MO

The omics era has greatly expanded the repertoire of approaches available for researchers and clinicians to unravel the complexity underpinning human health: Next Generation Sequencing (NGS) approaches can characterize genomes, epigenomes, transcriptomes, and proteomes. The analyses are critical to assess in individuals both pre- and post-treatment during therapeutic development and early-stage clinical trials. Peripheral blood mononuclear cells (PBMCs) offer a non-invasive approach that, when combined with omics tools, can provide a near holistic view of immune processes across patient cohorts. For fresh blood draws, this starts with automated sample handling and processing to ensure high viability and yield of PBMCs, along with simultaneous plasma separation and collection, which is then aliquoted for downstream analysis. These PBMC and plasma aliquots were then processed such that whole exome sequencing, whole genome methylation sequencing, single cell and bulk RNA sequencing, Olink Explore HT and Seer proteomic analysis, and metabolomic analysis can all be collected from patient blood draw. Integrated analysis across multiple data modalities allows for holistic views of pathways and processes that are highly impacted, with increased statistical significance than any one modality alone. Inclusion of dual proteomics assays provided a greater breadth of downstream functional results, revealing complementarity between assays. While genomics, transcriptomics, and proteomics provide information about genetic and functional potential, inclusion of metabolomics grants deeper phenotypic insights within and across individuals within a patient cohort. Ultimately, this approach reduces the need for repeated patient collections and lowers bio-storage requirements, making it a more patient-friendly and cost-effective solution, while rapidly producing a diverse set of multiomics results and allows for deep exploration of the molecular underpinnings of cancerous tissue.

#3692 Computational modeling of human microbiome evolution in the context of esophageal adenocarcinoma progression.

C. E. Guccione[1], I. Sfiligoi[1], A. Gonzalez[1], J. Shaffer[2], M. Kazachkova[1], Y. Weng[1], D. McDonald[1], S. Shah[1], S. S. Minot[3], T. Paulson[3], L. Alexandrov[1], R. Knight[1], K. Curtius[1];

[1]University of California San Diego - UCSD, San Diego, CA, [2]Fresno State, Fresno, CA, [3]Fred Hutchinson Cancer Center, Seattle, WA

Elucidating the role of microbes in precancer evolution could transform clinical risk prediction and management strategies. In the case of esophageal adenocarcinoma (EAC) progression, microbial communities have been detected across precancerous and neoplastic stages. However, unlike prior studies that statistically compare microbial abundances at single time-points, we employed mathematical modeling of microbial population dynamics within human hosts to determine likely modes of evolution that drive changes in microbial composition over time.

We first aggregated whole genome sequencing (WGS) datasets from esophageal tissue samples taken across stages of EAC progression, which included healthy esophagus, gastroesophageal reflux disease (GERD), Barrett's esophagus (BE), and EAC. In particular, we analyzed baseline WGS data from a case-control study of patients with BE who later progressed to EAC ("progressors") versus those patients with BE who did not progress to cancer within 5 years ("non-progressors"). We employed a robust bioinformatics host filtration pipeline to remove human DNA reads, mapped remaining reads to a human-scrubbed Web of Life microbial database, and filtered out taxa with low genomic coverage. After extracting occurrence and abundance data for taxa in each disease stage, we applied mathematical models of both neutral and non-neutral microbial evolution. We found evidence of neutral dynamics across stages of normal to pre-cancer (goodness-of-fit to the neutral expectation $R^2 > 0.85$ for normal esophagus and GERD, $R^2 > 0.65$ for BE non-progressors and BE progressors) but not for EAC ($R^2 = 0.14$ in EACs from the International Cancer Genome Consortium, and $R^2 = 0.34$ in a validation set of 19 EACs who also had surrounding BE).

We also found that *Helicobacter pylori* (*H. pylori*), a bacterium inversely associated with EAC risk, deviated significantly from the expected neutral model in BE non-progressor patients but not in BE progressor patients. To test hypotheses that accounted for potential selection effects, we performed simulations for both neutral and non-neutral processes. Using simulated data for the EAC cohorts, we found that assuming widely varying growth rates best reflected the data, implying that selection pressures likely influence largely niche-based population dynamics in the tumor microenvironment. For the BE non-progressor cohort, we found that assuming a lower death rate for *H. pylori* compared to other taxa recapitulated the data. This implies that *H. pylori* may have a selective advantage in non-progressing BE (as it does when present in the stomach), and further studies are needed to understand the impact on EAC progression. Overall, considering metagenomic data as the result of a dynamic process within a human host will enhance our understanding of the human microbiome's role in precancer and cancer evolution.

#3693 Modeling VEGF dynamics in cancer: An evolutionary game theoretic approach.

Ranjini Bhattacharya[1], Anuraag Bukkuri[2], Joel S. Brown[3]

[1]Department of Integrated Mathematical Oncology, Moffitt Cancer Center, Tampa, FL,[2]Department of Computational & Systems Biology, University of Pittsburgh, Pittsburgh, PA,[3]Cancer Biology and Evolution Program, Moffitt Cancer Center, Tampa, FL

Cancer cells in rapidly growing tumors often experience nutrient deprivation and hypoxia. They adapt by upregulating pro-angiogenic factors such as VEGF, which promote blood vessel formation within the tumor. Targeting angiogenesis, therefore, aims to starve cancer cells and inhibit tumor growth. This was the driving principle behind the development of anti-angiogenics like bevacizumab and sunitinib. While anti-angiogenics have shown modest improvements in progression-free survival, patients often relapse within the first year of treatment. This underscores the need to understand “why” and “how” VEGF expression evolves in cancer to better inform therapy.

Empirical, conceptual, and mathematical models of angiogenesis often assume that VEGF expression by cancer cells represents cooperative behavior towards a shared public good. To evaluate this assumption, we develop an evolutionary game theoretic model to explore how nutrient sharing among cancer cells influences VEGF expression. We find that habitats with high nutrient sharing—where nutrients redirected from blood vessels are evenly distributed among cells—support larger cell population sizes. In contrast, in habitats with low nutrient sharing—where nutrients are distributed in proportion to each cell’s investment in VEGF—cells over-invest in VEGF expression in an attempt to outcompete their neighbors. Individual cancer cells are incentivized to increase VEGF expression not to enhance overall blood supply but to pre-empt the blood supply that otherwise would have gone to others. This over-expression of VEGF comes at the cost of lower cell population sizes. This phenomenon, where individual cells prioritize their own fitness over collective welfare, is known as the tragedy of the commons (TOC).

Using the model we evaluate the efficacy of different dosing regimens of anti-angiogenics, glucose transporter (GLUT) inhibitors, and chemotherapy. We find that the TOC diminishes the effectiveness of therapy in habitats with proportional nutrient sharing. Moreover, anti-angiogenic drugs that neutralize VEGF are ineffective at controlling the tumor size. Instead, combining anti-angiogenic drugs with GLUT inhibitors shows greater promise. We are using patient-derived histology samples to observe these trends *ex vivo* and validate the relevance of our findings in a clinical setting. Our modeling efforts highlight: 1) how mathematical models can provide fresh insights into well-studied biological phenomena, 2) how testing alternative hypotheses about the interactions in the tumor microenvironment is important, and 3) how understanding cancer cell traits as adaptations to selective pressures in the tumor microenvironment aids in developing effective therapeutic strategies.

#3694 Clinical validation of a quantitative systems pharmacology (QSP) model of ISB 2001 used for deriving first in human (FIH) dose and efficient phase 1 dose escalation design in relapsed refractory multiple myeloma (RRMM) patients.

Vinu Menon[1], Beata Holkova[1], Lida Pacaud[1], Sunitha GN[2], Andrew Garton[1], Maria Pihlgren[3], Tomomi Matsuura[4], Piet H. van der Graaf[4], Mario Perro[3], Cyril Konto[1]

[1]Clinical Development, Ichnos Sciences Inc, New York, NY,[2]DMPK, Glenmark Pharmaceuticals Ltd, Mumbai, India,[3]Research, Ichnos Sciences Biotherapeutics SA, Lausanne, Switzerland,[4]Applied BioSimulation, Certara UK Limited, Canterbury, United Kingdom

Background: ISB 2001 is the first trispecific antibody that simultaneously targets BCMA and CD38 on MM cells, and CD3 to engage T-cells, forming tumor/immune cell synapses (TICS) that cause tumor cytotoxicity. Since ISB 2001 lacks cross-reactivity to common preclinical toxicology species including monkeys, no preclinical toxicology studies were conducted to inform the FIH dose calculation. The conventional minimal anticipated biological effect level (MABEL) approach for FIH dose derivation for T-cell engagers (TCE) often results in exposing patients to non-therapeutic doses. Instead, we developed a QSP model to predict an optimal FIH dose and efficacious dose range. This informed the design of the ongoing phase 1 dose escalation study of ISB 2001 in RRMM patients (NCT05862012), starting at 5 µg/kg subcutaneously with the initial three single-patient cohorts followed by standard 3+3 cohorts beginning at 150 µg/kg.
Method: A QSP model utilizing binding affinities, target expressions, cell counts, and preclinical pharmacokinetic (PK) data was developed to characterize TICS profiles in the tumor compartment. Normalized TICS formation was linked to tumor cytotoxicity, and the model was calibrated with ISB 2001 *in vivo* efficacy data to enable efficacy predictions. This QSP model was benchmarked with teclistamab's clinical data to derive the minimal pharmacologically active dose (MPAD) of ISB 2001[1]. The MPAD was further adjusted using *in vitro* cytokine secretion data to establish the FIH dose, which was preceded by fractionated step-up doses to mitigate potential cytokine release syndrome concerns. Serum concentration of ISB 2001 across doses up to 1200 µg/kg were quantified using a validated electrochemiluminescence assay and compared with the model predictions.
Results: No CRS was observed in the FIH cohort, and only one grade 1 case was reported at doses up to 15 µg/kg in third cohort, supporting the QSP model-based FIH dose selection while acknowledging the limited sample size. As predicted, objective tumor responses were observed at dose levels as low as 50 µg/kg, just 10-fold higher than the FIH dose. Measured ISB 2001 serum concentration time profiles across multiple dose levels up to 1200 µg/kg (n=20) aligned well with model simulations.
Conclusion: Despite the absence of monkey PK and toxicology data, this QSP-guided approach successfully predicted an optimal FIH dose, clinical PK, safety, and efficacy, while minimizing patient exposure to non-therapeutic doses. With this method, TCEs can be optimized solely for activity against human tumors without requiring cross-reactivity to animal species. Overall, the QSP based FIH calculation approach offers an effective pathway for designing phase 1 studies for future TCEs. References: [1] Lancet. 2021;398(10301):665-674.

#3695 A mechanistic model of ctDNA shedding and its relevance for clinical interpretation.

Thomas Rachman[1], Patrick Wagner[2], William LaFramboise[2], David Bartlett[2], Russell Schwartz[1], Oana Carja[1]

[1]Ray and Stephanie Lane Dept. of Computational Biology, Carnegie Mellon University, Pittsburgh, PA,[2]Allegheny Health Network, Pittsburgh, PA

Circulating tumor DNA (ctDNA) in plasma is a key biomarker of tumor dynamics, yet the quantitative relationship between ctDNA levels and clinical variables—such as tumor volume, vascularization, and cell death—remains unclear. The release of ctDNA is thought to depend on cell death mechanisms and the transport of extracellular tumor DNA (excDNA) to blood vessels. We hypothesized that ctDNA concentrations are modulated by the interplay between proximity to blood vessels and excDNA transport kinetics. To test this hypothesis, we develop a spatial mechanistic model to first predict hypoxia-mediated cell death based on blood vessel distribution and then assess the amount of excDNA reaching blood vessels after release, incorporating diffusion and degradation parameters within empirically plausible ranges. In our model, we find that ctDNA concentration in plasma depends on both vascularization and transport dynamics. For example, when diffusion dominates, ctDNA yield is high, and increasing hypoxic cell death from 0 to 80% leads to a tenfold increase in ctDNA. When degradation dominates, ctDNA yield is much lower and the same change in hypoxia results in a tenfold decrease. When both terms are relevant, ctDNA depends nonlinearly on vascularization. These findings suggest that the relationship between blood vessel proximity and ctDNA is highly sensitive to excDNA transport dynamics, underscoring the importance of experimental validation of key parameters, which may vary significantly according to site and release mechanism.

#3696 Evolutionary immunotherapy in NSCLC: identifying optimal dosing strategies in TIL therapy using agent-based modeling.

Sandhya Prabhakaran[1], Mark Robertson-Tessi[1], Kimberly Luddy[2], Rafael R. Bravo[1], Taylor M. Bursell[2], Julian Pineiro[2], Jeffrey West[1], Megan Johnson[1], Jhanelle A. Gray[3], Amer A. Beg[3], Scott J. Antonia[4], Robert A. Gatenby[5], Alexander R. A. Anderson[1]

[1]Integrated Mathematical Oncology, Moffitt Cancer Center, Tampa, FL,[2]Clinical Science lab, Moffitt Cancer Center, Tampa, FL,[3]Departments of Immunology and Thoracic Oncology, Moffitt Cancer Center, Tampa, FL,[4]School of Medicine, Duke University, Raleigh, NC,[5]Department of Radiation Oncology, Moffitt Cancer Center, Tampa, FL

Purpose: Our study examines tumor growth dynamics and immunosuppression under the presence of immune attack to identify optimal immune pulsing treatment strategies.

Motivation: While immunotherapy has shown remarkable success in treating many cancers like non-small cell lung cancer (NSCLC), not all patients respond well to immunotherapy. This mixed response can be attributed to the complexity of the tumor-immune system dynamics. TIL therapy is an emerging immunotherapy where activated T cells are injected into the patient. This therapy can fail due to tumor-induced immunosuppression, for example via the PDL1/PD1 axis. PDL1 expression has been studied and can increase under IFN-γ, released by activated T cells, but PD-L1 relaxation is not understood. We hypothesize that a) the regimen of TIL therapy administration should impact the dynamics of PDL1, and that b) there may be better strategies of therapy delivery that maximize tumor kill while minimizing immune suppression. We investigate these complex PD-L1 driven dynamics through a unique combination of *in vitro* studies and mathematical modeling.

Methods: We have collected *in vitro* and temporal confocal microscopy images of PD-L1 expression on NSCLC cells, which were either untreated or treated for 48 hours with high dose IFN-γ followed by chronic low dose IFN-γ for 21 days. To reinforce our *in vitro* experiments and findings, we developed a hybrid agent-based model (ABM) to study PD-L1 dynamics. The agents in the ABM are tumor cells having variable PD-L1 expression, and immune cells that secrete IFN-γ and can kill tumor cells. Tumor cells can be randomly- or cluster-seeded. IFN-γ is modeled as either a binary well-mixed pulse (to simulate the *in vitro* experimental setup), or as a diffusible via a reaction-diffusion process (to simulate the tumor-immune cell interactions in an *in vivo* spatial manner). We model the TIL therapy as a pulse of immune cells, given at regular or irregular intervals and with different quantities of cells.

Results: Our ABM is calibrated to capture *in vitro* data dynamics. Under certain combinations of spatial configurations of the tumor and intermittent immune dosing schedules, we observe the presence of ‘sweet spots’ where tumor extinction is possible and immune exhaustion is avoided. This indicates that an appropriate pulsing of TIL therapy may lead to better overall immune efficacy than a bolus injection or continuous immunotherapy, by preventing sustained suppression that increases immune cell exhaustion, despite the potential for tumor regrowth between pulses.

Conclusion: We have built an ABM to study tumor-immune evolution under various pulsing strategies of TIL therapy. Our novel findings can potentially benefit clinical cancer research by giving multiple insights related to the tumor extinction, equilibrium and escape phenomena, and lead to improved schedules in patients receiving immunotherapy.

#3697 Cell-free DNA fragmentome dynamics as a biomarker for immune-checkpoint inhibition in advanced carcinoma.

Linh Nguyen Phuong[1], Frederic Fina[2], Romain Zakrajsek[3], Laurent Greillier[4], Pascale Tomasini[4], Jean-Laurent Deville[5], Audrey Boutonnet[6], Frederic Ginot[6], Jean-Charles Garcia[6], Sebastien Salas[4], Sebastien Benzekry[3]

[1]Aix-Marseille University, Marseille, France,[2]ID-Solutions, Marseille, France,[3]INRIA, Marseille, France,[4]Assistance Publique - Hopitaux de Marseille - Aix-Marseille University, Marseille, France,[5]Assistance Publique - Hopitaux de Marseille, Marseille, France,[6]Adelis Technologies, Labege, France

Background: Immune-checkpoint inhibitors (ICIs) have revolutionized cancer treatment, but a large proportion of patients is resistant to the treatment. Genome-wide cfDNA fragmentation profiles (fragmentome) represent a promising non-invasive approach able to monitor and predict response.
Methods: The SChISM (Size cfDNA Immunotherapies Signature Monitoring) enrolled 128 advanced pan-cancer ICI-treated patients. Using Adelis technologies (France), based on the patented BIABooster system, pre- and on-treatment cfDNA size profiles were generated from the plasma, without prior DNA extraction. First, associations of pre-treatment fragmentome-derived metrics (e.g., concentration within multiple size ranges, position of peaks in the distribution) with early progression (EP, defined as progression at the first imaging evaluation) and progression-free survival (PFS) were assessed using logistic/Cox proportional hazard regression models. To assess predictive performances, data were split into training (n=90) and test (n=38) sets. Then, a mechanistic model for the joint dynamics of cfDNA and tumor lesions at the systemic level was developed. It relies on the following biological hypotheses: 1), wild-type cfDNA is primarily released through the apoptosis of hematopoietic cells, 2) cancer cells can be either resistant or sensitive to treatment, 3) cancer cells release a higher amount of DNA fragments due to the chaotic apoptosis-proliferation cycle characteristics of tumor cells, 4) cfDNA fragments are continuously cleared by liver and kidneys, with half-life ranging from 15min to 2h, 5) immunotherapy induces apoptosis in cancer cells, leading to the release of short cfDNA fragments, and 6) in the tumor microenvironment, cells undergo necrosis as the tumor grows, resulting in the release of longer fragments.
Results; The ratio of long fragments (≥ 1650 base pairs (bp), LF) - normalized by total concentration - was significantly associated with non-EP (odds ratio = 0.3 (95%: 0.16-0.55), $p < 0.001$) and longer PFS ($p<0.001$, hazard ratio 0.44 (95%: 0.31 - 0.64)). It also showed the best predictive performances of EP, on the test set: AUC = 0.74 (95% (CI): 0.65-0.82)), accuracy = 0.71 (95% CI: 0.62-0.77), positive predictive value 0.58 (0.46-0.69). The mechanistic model was able to accurately describe cfDNA-cancer dynamics under ICI, including steady decrease/increase of cfDNA concentration in either the long- or short-size ranges, but also non-trivial patterns, such as initial cfDNA concentration bumps.
Conclusions: High-molecular-weight fragments are associated with early progression in ICI-treated patients. Mechanistic modeling offers biological insights for the interplay between cfDNA and tumor kinetics.

#3698 A longitudinal investigation of temporal/intratumoral heterogeneity by plasma NGS profiling of mutation clones in metastatic colorectal cancer.

Petra Kroupova, Barbora Minarikova, Andrea Chmelarova, **Marek Minarik**

Elphogene, Inc., Prague, Czech Republic

Intratumoral tumor heterogeneity characterized by the presence of genetically and phenotypically distinct cell populations (clones) within the same lesion, represents a significant obstacle to accurate diagnosis, prognosis, and therapeutic targeting based on molecular investigation, when biopsy may yield incorrect results due to insufficient representation of all tumor clones in the sample. Liquid biopsy, defined as the detection and quantification of somatic aberrations of circulating tumor DNA (ctDNA) in blood plasma, has long been considered an approach that can be effectively applied to obtain full spectrum of mutations without any bias. This assumption based on condition that the release of ctDNA fragments occurs quantitatively from all present cell populations.
Our study aims to verify this hypothesis based on continuous liquid biopsies in patients undergoing treatment for advanced solid tumors. In the field of liquid biopsy, the use of ctDNA detection for continuous monitoring of ongoing therapy has recently come to the forefront. The so-called "tumor informed" approach, in which somatic mutations found in tumor tissue are subsequently detected in ctDNA. The procedure is characterized by relatively low costs, which allows repeated examinations based on frequent sampling for continuous monitoring of the disease and treatment. In ctDNA-positive patients, we subsequently perform broad-spectrum longitudinal profiling of mutational clones in ctDNA using an NGS panel based on the principle of hybrid capture of a panel covering a total of 127 genes. This method is used to monitor mutation profiles in ctDNA from plasma of patients with metastatic colorectal cancer undergoing multimodal treatment including surgical resection of metastatic tissue and chemotherapy.
The results indicate that the response to treatment, which is manifested by a decrease or increase in ctDNA represented by different mutations, may not occur homogeneously in all present mutational clones. In fact, some clonal populations appear to indicate earlier response than others, characterized by shifts in mutation fraction dynamics.

#3702 Unraveling the mechanism of action for research of cancer therapies using AVITI24.

Vivian Dien, Connor Thompson, Daniel Honigfort, Tristin Rammel, Grace Yeo, Marielle Krivit, Ramreddy Tippana, Jane Yao, Sinan Arslan, Matthew Kellinger, Amirali Kia, Michael Previte

Element Biosciences, Inc., San Diego, CA

For decades, the mechanism of action towards research of cancer therapies have been deciphered by the isolated analyses of transcriptomics, proteomics, or cell morphology to resolve heterogeneous responses in a series of assays requiring multiple biological samples which limit the ability to capture the full picture of the biological response. Integrating these readouts through multiplexed analysis enables a comprehensive understanding of how gene expression relates to functional outcomes and phenotypic effects, offering a holistic view for research of cellular processes impacted by treatment. Tyrosine kinase inhibitors (TKIs) have significantly advanced the treatment of non-small cell lung cancer (NSCLC) yet achieving consistent and durable patient responses remains a challenge. In this research study, we utilized AVITI24 Teton CytoProfiling, a platform that enables spatial co-detection of RNA, protein, phospho-proteins, and cell morphology at subcellular resolution within a single biological sample. This approach allowed us to resolve complex systemic responses to TKIs in three NSCLC cell lines. Specifically, three NSCLC cell lines were treated with Gefitinib or Osimertinib to investigate therapy-induced molecular and morphological changes in both TKI-sensitive and TKI-resistant cells. Single-cell analysis uncovered significant heterogeneity in RNA and protein expression, with distinct patterns emerging between drug-sensitive and drug-resistant cells. For example, in Gefitinib-treated A549 cells, we observed notable pathway inhibition, including reductions in phosY1068-EGFR (Log2FC -0.108) and phosTY-ERK12 (Log2FC -0.237). Conversely, the resistant cell line NCI-H1975 showed minimal changes alongside other distinct responses within the MAPK pathway. Drug-specific morphological changes further highlighted how these therapies influence cellular architecture in ways that correlate with functional outcomes. And by resolving cellular heterogeneity at the single-cell level, these insights—often obscured by bulk analyses—shed light on the intricate mechanisms of both therapeutic effects and resistance development. Our findings demonstrate the potential of multi-omics platforms like AVITI24 Teton CytoProfiling to address critical challenges in cancer research. By consolidating transcriptomic, proteomic, and morphological data in a single assay with subcellular spatial resolution, this platform facilitates the resolution of multidimensional mechanisms underlying tumor responsiveness and drug resistance. By bridging molecular and morphology insights, our study provides a powerful framework for studying the intricate dynamics of targeted therapies in NSCLC, paving the way for innovative strategies to enhance cancer treatment and personalize patient care.

#3703 Cell identity revealed by precise cell cycle state mapping links data modalities.

Saeed S. Alahmari[1], Andrew Schultz[2], Jordan Albrecht[2], Vural Tagal[2], Zaid Siddiqui[3], Sandhya Prabhakaran[2], Issam El Naqa[2], Alexander Anderson[2], Laura Heiser[4], Noemi Andor[2]

[1]Department of Computer Science, Najran University, Najran, Saudi Arabia,[2]Moffitt Cancer Center, Tampa, FL,[3]Baylor College of Medicine, Houston, TX,[4]Oregon Health and Science University, Portland, OR

Purpose: Despite advances in single-cell technologies, integrating multimodal data to capture both the genetic and phenotypic dynamics of tumor cells in their microenvironment remains a challenge.
Approach: We leverage variations in cell cycle state as a natural barcode to link data across different modalities. We have demonstrated the feasibility of this method in a gastric cancer cell line (NCI-N87)using two widely different technologies: single-cell RNA sequencing and live-cell imaging. Our approach begins with the transfection ofFUCCI probes into cells, followed by acquisition of 3D images using a Leica microscope. These images are then utilized to train a label-freeU-Net-based prediction model (FNet)to infer subcellular organization, specifically for the nucleus, mitochondria, and cytoplasm. FNet achieved correlation coefficients of 0.76, 0.70, and 0.78 for these compartments, respectively. Segmentation masks generated by CellPose enabled cell statistics calculations. We further applied deep learning methods, including a customized convolutional neural network (CNN)and a truncated ResNet50, to distinguish between cells in G1, S and G2M phases of the cell cycle. The CNN achieved an accuracy of 90.67% when using the nucleus alone and 91.63% when using all three compartments (nucleus, mitochondria, and cytoplasm).
Deep features were extracted by removing the classification layer and flattening the convolutional layer feature maps. These features were then employed for cell cycle pseudotime inference. When projecting the features onto pseudotime, we observed a strong correlation between the inferred pseudotime and FUCCI-derived cell cycle states (Pearson r =-0.899, p-value < 1E-6). This finding demonstrates the ability to assign continuous cell cycle states directly from imaging data. Comparing imaging- and sequencing-derived cell cycle pseudotime obtained for the same cell line, we assigned 449 imaged cells to their corresponding 693 sequenced cells, achieving an average resolution of 3.4 cells per sequencing profile and 2.4 cells per imaging profile.
Conclusion: This integration has opened new possibilities for linking genotype (from sequencing)and phenotype (from imaging), providing a forward-looking approach to genotype-phenotype mapping at single-cell resolution. Assigning the transcriptome of a sequenced cell to its closest living relative (still actively growing and expanding), will enable tracing the cellular trajectory in real-time, enabling a deeper understanding of how tumor cells adapt to their microenvironment and evolve over time.

#3704 A semiconductor-based biosensor for sensitive T cell detection and common neoantigen identification in cancer immunotherapy.

Po-Yuan Chen[1], I-Fen Ko[1], Kuan-Hsing Chen[1], Wai-Shan Chung[2], Che-Ming Lin[1], Yuh-Shyong Yang[1], **Tai-Ming Ko**[1]

[1]National Yang Ming Chiao Tung University, Hsinchu, Taiwan,[2]Chang Gung Memorial Hospital, Taipei, Taiwan

Background: Identifying common neoantigens and detecting T cell responses to these antigens are critical for providing therapeutic targets and monitoring treatment efficacy. However, current cancer targeted sequencing panels miss up to 95% of genes corresponding to immunogenic neoantigens, limiting treatment options. Detecting specific T cells responsive to these neoantigens is also challenging due to their low abundance and limitations of existing detection methods.
Objective: We developed an innovative extended-gate field-effect transistor (EG-FET) biosensor for sensitive detection of T cells within heterogeneous immune populations and a comprehensive common neoantigen database to identify widely shared tumor antigens, addressing limitations in molecular profiling and aiding generalized treatment design.
Methods: The EG-FET biosensors leverage semiconductor technology for label-free, real-time detection with high sensitivity. Antibodies targeting T cell surface markers were immobilized on the chip, enabling antigen-antibody interactions to differentiate T cells from other immune cells. Its capability to detect multiple samples simultaneously was assessed, maximizing throughput. We developed a common immunogenic neoantigen database using a pipeline that predicts neoantigens from TCGA data and quantifies their prevalence.
Results: The biosensor detected and differentiated T cells with high sensitivity and specificity. The platform detected as few as 1,000 T cells, significantly reducing sample requirements compared to traditional methods needing 100,000 cells. Detection was completed in under 30 minutes, decreasing processing time and costs. The ability to detect multiple samples simultaneously enhanced efficiency. The common neoantigen database aids in identifying widely shared tumor antigens, improving generalized treatment strategies and expanding coverage of immunogenic targets missed by current sequencing panels.
Conclusion: Combining EG-FET biosensors with a common neoantigen database offers a transformative approach in cancer immunotherapy. By enabling sensitive detection of T cells within heterogeneous immune populations and identifying common neoantigens, the platform addresses tumor heterogeneity and limited treatment options. These advancements pave the way for scalable, efficient, and more effective cancer immunotherapy, offering promising strategies to overcome drug resistance and improve patient outcomes.

#3705 *In silico* modeling of ctDNA shedding using a novel computational pipeline which models tumorigenesis, progression, and metastasis.

Jasmine R. Alvarez[1], Ajay Subramanian[2], Everett J. Moding[2], Erik S. Blomain[3]

[1]Department of Pharmacology, Physiology, and Cancer Biology, Thomas Jefferson University, Philadelphia, PA,[2]Department of Radiation Oncology, Stanford University, Stanford, CA,[3]Department of Radiation Oncology, Thomas Jefferson University, Philadelphia, PA

Introduction: Liquid biopsies are shifting the paradigm for diagnosis and treatment of many types of cancer. Circulating tumor DNA (ctDNA), defined as small fragments of tumor DNA shed into circulation from tumor cells, represents a major analyte for liquid biopsy approaches. ctDNA has potentially wide translational applications, including early detection of cancer, monitoring disease response, detection of minimal residual disease (MRD), and biological-sampling of tumor biology noninvasively. Although there is significant interest and a growing body of work in applying ctDNA to the clinic, existing studies are generally limited by the access to patient plasma samples. Importantly, computational models are often useful to simulate data in contexts where actual experiments require such precious resources; however, there are currently no existing computational models of tumor ctDNA shedding. In that context, the current study overcomes this limitation and describes a novel bioinformatic pipeline which is able to model ctDNA shedding during tumor initiation, growth, progression, and metastasis.

Methods: We developed a novel method for generating simulated ctDNA next-gen sequencing (NGS) data in a variety of tumor scenarios. To accomplish this, we enhanced a previously-characterized spatial model of tumor growth which generates simulated whole exome sequencing data *in silico* to also generate ctDNA data. Outputs from this spatial model include a list of variants called from the simulated exome data. To generate the simulated ctDNA data, the distribution of these variant allele frequencies (VAF) were split into quantile bins with an associated scale factor. All variants had their mean tumor VAFs divided by their respective scale factors to determine corresponding ctDNA VAFs utilizing a validated “downsampling” technique.

Results: First we utilized the novel pipeline to generate simulated ctDNA in the setting of both a non-metastatic primary tumor and a metastatic tumor. We next validated the fidelity of simulated ctDNA data to real-world biologic data using published datasets of ctDNA from both metastatic and nonmetastatic sarcomas. In that validation analysis, we demonstrated a high degree of similarity between the simulated and published ctDNA data.

Conclusions: Here we demonstrate a novel computational approach to model the paradigm-shifting technology of liquid biopsy completely *in silico*. Our ability to generate simulated data with validated biologic fidelity has potential to augment discovery-based ctDNA studies. Furthermore, the potential of this technology is underscored by the emerging potential of AI-based approaches, digital twin technologies, and simulated clinical trial data as viable synergistic approaches to conventional clinical studies.

#3706 Identifying first-in-class targets for anti-cancer therapy in KRAS mutant NSCLC using the systems biology-based drug discovery platform.

Namhee Kim, Jae Il Joo, Sea Rom Choi, Kwang-Hyun Cho

biorevert Inc., Daejeon, Korea, Republic of

Background: Activating mutations in KRAS are the most common oncogenic drivers, occurring in approximately 30% of non-small cell lung cancer (NSCLC). The G12C mutation, a glycine-to-cysteine mutation at residue 12, is particularly prevalent in NSCLC patients. Developing KRAS inhibitors has long been challenging, but recent FDA approvals of sotorasib and adagrasib for treating KRAS G12C-mutant NSCLC patients represent significant breakthroughs, establishing a new treatment paradigm. However, they are still limited in their clinical applications by low efficacy, side effects, and resistance. Moreover, it is currently unclear how to predict responsive patient subsets and suggest effective therapeutic strategies for clinical application.
Methods: For this, we used our drug discovery platform, MObyDiCK (Mechanistic target Optimization by Discovering and Controlling networK), which incorporates systems biology and AI-based computational analysis to identify first-in-class targets and their regulatory mechanisms. MObyDiCK includes (a) analysis of single-cell omics data, (b) construction of simulation-capable network models, (c) identification of first-in-class targets, and (d) elucidation of their mechanisms based on network control technologies. In addition, we predicted the efficacy and side effects of the identified targets using different public data, and experimentally validated that regulating the identified targets can effectively overcome KRAS inhibitor resistance.
Results: In this study, we utilized public patient single-cell datasets of NSCLC with KRAS mutations to construct corresponding network models using our MObyDiCK platform. We explored specific pseudo-time trajectories to understand the dynamics of KRAS inhibitor resistance, tailoring the analysis to the distinct cancer subpopulations exhibiting resistance potential in each patient. Next, we binarized single-cell transcriptome data by examining the distribution of gene expression values for each individual. We then inferred gene regulatory networks and constructed their mathematical models. Finally, by analyzing dynamic changes within the mathematical models of NSCLC, we identified the combinatorial targets and their mechanisms to overcome KRAS inhibitor resistance in NSCLC. We further predicted the effectiveness of the targets in NSCLC with public data analysis and validated their efficacy through in vitro experiments.
Conclusions: By analyzing single-cell datasets of NSCLC patients with the MObyDiCK platform, we gained a comprehensive understanding of the dynamics of regulatory interactions in KRAS inhibitor-resistant cells and ultimately identified the prominent target genes. With these findings, we will further expand this study on how these targets are related to the normal developmental processes or immune system in NSCLC and other cancer types.

#3708 Targeting the ATG101 And ULK1 complex in pancreatic ductal adenocarcinoma: computational approach.

Raasil R. Basha[1], Vaishnavi Kuppala[2], Ganji Purnachandra Nagaraju[2]

[1]Missouri Southern State University, Joplin, MO,[2]The University of Alabama at Birmingham, Birmingham, AL

Introduction: Pancreatic Ductal Adenocarcinoma (PDAC) is an aggressive malignancy with poor prognosis (five-year survival rate around 13%). PDAC progression mainly depends on autophagy signaling for cell homeostasis. The current study holds significant importance in this context as it aims to identify the interaction between ULK2 and ATG101 and evaluate hydroxychloroquine's effect on the ULK2 and ATG101 complex.

Methods: The proteins ULK2 (Q9QY01, MOUSE) and ATG101 (Q9D8Z6, MOUSE) were retrieved from the UniProtKB database. The domain region of the protein structures was carefully trimmed using BIOVIA Discovery Studio 4.5 Visualizer, and the interacting residues were identified with precision using HawkDock. The ULK2-ATG101 complex was then imported into DimPlot to recognize and display the presence of intermolecular hydrogen bonds. To validate the complex structure, we employed the Desmond Program, Molecular Dynamic (MD) Simulations, Principal Component Analysis (PCA), Root Mean Square Deviation (RMSD), and Root Mean Square Fluctuation (RMSF). To confirm the functional activity of the interaction, we conducted an *in vitro* pulldown assay. All samples were lysed with RIPA buffer, and the lysate (500 µg) was added to 30 µL of agarose beads and anti-ULK2. The samples were resolved on the SDS page and transferred to the PVDF membrane. The membrane was probed with ATG101, and the intensity of protein bands was quantified using the Image J program. Unpaired t-tests were conducted to acknowledge the difference between treated and untreated samples.

Results: The formation of hydrogen bonds between these complexes are Arg19 vs. Glu146 and Glu150; Gln67 vs. Ser160; Arg4 vs. Thr63. Among the top 10 scoring ATG101-ULK2 PPI complex models, the highest binding energy was found at -48.13 kcal/mol. The RSMD graph displayed a stable trajectory, following 80 ns of simulation time using RMSD values ~3.1A to ~3.7A, depicting stabilization during 100 ns for the PPI complex. The pulldown assay results indicated hydroxychloroquine reduced the interaction between the ATG101 and ULK2, suggesting a potential impact on PDAC treatment.

Discussion/Conclusion: Results suggested that the interaction of ATG101-ULK1 was strong, and hydroxychloroquine reduced this interaction. Site-directed mutagenesis is essential to understanding the molecular interaction (ATG101-ULK2) and the role of residues in PDAC.

#3709 Ezekiel: a simulated digital twin for virtual diagnostic biomarker screening.

Aaron Chevalier, Maciej Pacula, Gabrielle N. Barcaskey, MacKenzie S. King, Lauren Cuoco, Brittany Grimes, Lukasz Kornilowicz, Katherine S. Yang, Daniel Salem, Anthony Couvillon, Toumy Guettouche, Troy B. Hawkins

Mercy Bioanalytics, Waltham, MA

Background: Extracellular vesicles (EVs) are released from all stages of tumors and are highly abundant in blood, making them an attractive analyte for cancer screening diagnostics. However, background noise from non-tumor cells presents a significant challenge to cancer-specific signal detection. We have developed a novel assay platform for measuring combinations of surface biomarkers co-localized on EVs that are highly specific for tumor-associated EVs and a computational platform to simulate individual patient EV profiles for the purpose of nominating candidate biomarkers for use in this assay.

Discovery Pipeline: Because the EV-based assay is a multi-marker test, combinatorial expansion of biomarkers presents a significant challenge to experimental validation. To discover biomarker candidates, we simulate performance using a virtual assay of simulated patients using a novel digital twin platform called Ezekiel. In these simulated patients, tumor gene expression profiles from multi-center cancer genomic consortia (e.g. TCGA) are combined with background gene expression from healthy tissue using tumor size and EV abundance estimates to generate a virtual analyte pool. Initial candidate biomarkers are selected based on a carefully curated set of quantitative and qualitative features, and pairs and triplets of biomarkers are ranked by signal-to-noise ratio in a simulated assay to refine a library of targets for screening.

Validation: Biomarkers and biomarker combinations identified by this computational approach are validated experimentally. Individual biomarkers and immunoaffinity capture reagents are first validated using Western blotting and an abbreviated version of the EV-based assay in pooled plasma. Pairs or triplets of biomarkers are then evaluated in the full assay to select top candidates for development. We have confirmed co-localization of these biomarkers using Single Molecule Localization Microscopy (SMLM) and tumor gene co-expression in matched patient tissue and plasma.

Results: We present a novel computationally driven discovery workflow for a single representative cancer indication. Starting from a pool of 4,782 biomarkers, we virtually screened 11,431,372 combinations resulting in 435 candidates, down selected to 145 biomarkers following manual review. 24 biomarkers were selected based on availability of high-quality antibodies, from which 13 biomarkers were identified that show activity with our assay platform. Representative orthogonal validation data is presented demonstrating the computationally-nominated biomarker’s success in enabling discrimination of cancer samples from healthy controls.

#3711 An RNA-binding phosphoprotein twist with BRCT domains in DNA damage repair: computational modeling of nucleolin.

Nitu Farhin, Andriele S. Eichner, Anjana Saxena, Shaneen Singh

Brooklyn College, Brooklyn, NY

Nucleolin (NCL), an RNA binding protein (RBP), and BRCA1, a tumor suppressor protein linked to breast and ovarian cancer susceptibility, colocalize at the sites of DNA damage and collaborate in homologous DNA repair pathways. Even so, the underlying mechanism where NCL and BRCA1 function together during DNA damage repair (DDR) remains unexplored. We utilized in silico approaches to unveil and characterize the shared interactome of BRCA1 and NCL. Our analysis revealed 49 common proteins interacting with BRCA1 and NCL, potentially influencing their functions. These proteins were systematically categorized into five distinct Gene Ontology (GO) annotation classes: DNA repair, RNA-binding, chromatin remodeling, DNA damage, and cell cycle regulation. Here, we predict interaction scenarios between full-length NCL and five BRCT-containing proteins crucial for DNA repair: BRCA1, MDC1, NBN, PARP1, and TP53BP1, to provide molecular insights into the interface. We strongly predict that the N-terminal acidic region of NCL which is also a site of several CK2 and CDK1 phosphorylation sites is involved in interaction with these five BRCT-containing proteins. Our computational models predict that RNA binding domains (RBDs) of NCL remain free to bind RNA or DNA, potentially facilitating its role in DDR. We further present the mutational landscape of the BRCT regions of these five proteins using the COSMIC database and identify the sites that might affect their interactions with NCL. Identifying the common interactome that associates with NCL and BRCA1 duo will facilitate our understanding of the intricate molecular interplay during the DDR. These protein-protein interactions potentially provide targetable interfaces, especially to combat aggressive triple-negative breast cancer where the DNA-repair pathway is predominantly deregulated.

#3712 A computational method for quantifying circulating tumor DNA (ctDNA) in plasma using methylation profiling data.

Ping Lan[1], Xiaowen He[1], Ying Mei[2], Yangjunyi Li[3], Nina Guanyi Xie[3], Liyuan Zhao[3], Zhihui Xu[3], Chen Zhu[3], Yujie Chen[3], Min Li[3], Baoliang Zhu[3], Xiaohui Wu[3], Xueguang Sun[3]

[1]The Sixth Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[2]Health Medical Center, The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China,[3]Shanghai Weihe Medical Laboratory Co., Ltd, Shanghai, China

Background: Abnormal DNA methylation is a hallmark of tumorigenesis and cancer development, where patients exhibit distinct methylation patterns compared to healthy individuals, referred to as tumor-specific methylation haplotypes. These haplotype markers are widely used for cancer screening and diagnosis. Accurate quantification of ctDNA in cell-free DNA (cfDNA) is important in evaluating the analytical performance of clinical assays. Conventional methods generally employ 120-nt DNA probes to capture both the Watson and Crick strands, assuming that CpGs are either fully methylated or fully unmethylated, and therefore are unbiased. With sufficient sequencing depth, ctDNA quantification can be performed by calculating the proportion of tumor-related methylation haplotype reads. However, in enrichment-capture methods, where DNA probes are designed to specifically target tumor-related signals, quantification of ctDNA can be challenging due to varying enrichment efficiencies across numerous probes. Here, we present a novel computational method for precise quantification of ctDNA in plasma based on methylation profiling data, where tumor-related methylation signals were enriched experimentally.
Methods: We constructed an Enrichment Factor Model (EFM) based on the thermodynamic characteristics of probes that target methylation haplotypes from a panel. The enrichment factor is determined by comparing the true values and observed values generated from multiple reference samples with different haplotype frequencies captured by that panel. This enrichment factor remains stable when applied to unknown samples captured by the same panel, and therefore the model can be used to predict the ctDNA amount in any unknown clinical samples.
Results: 16 reference samples with a variety of haplotype frequencies were generated by mixing the 0% and 100% HCT116 at different ratios. Using 12 reference samples, we were able to calculate the enrichment factor. The remaining 4 samples were used to validate the EFM, accurately predicting their values with an R^2 of 0.99 and a mean squared error (MSE) of 0.0011. We further applied the model to 59 colorectal cancer (CRC) cases and 103 healthy control clinical plasma samples. The estimated ctDNA fraction closely aligned with clinical tumor stages, with higher fractions consistently observed in late-stage patients. Additionally, a clear distinction was observed between cases and controls with a p-val of $4.73\ E^{-6}$.
Conclusion: We developed a computational method to accurately quantify ctDNA fractions using methylation profiling data, specifically optimized for experimental methods that enrich tumor-related signals. Our method offers a reliable tool for ctDNA quantification in cancer detection and monitoring applications.

#3713 Immunoengineering by design: generative AI and high throughput cell screening to develop therapeutic TCR-guided bispecifics against multiple targets.

Alex S. Powlesland, Aaron Sim, Dubravka Pezic, **Valerie Coppard**, Victoria Koullourou, Joshua Meyers, Lewis Cornwall, James Day, Neil Dalchau, Lilly Wollman

Synteny Biotechnology, London, United Kingdom

T cell receptors (TCRs) are a unique class of targeting molecule. Through highly specific interactions with peptide:HLA complexes present on the cell-surface, they offer a means of therapeutically targeting any protein, with this specificity highlighted by their ability to selectively recognize cancer-associated single amino acid mutations. However, identifying TCRs that have the desired specificity toward a target peptide has traditionally been challenging; often screening large numbers of peripheral T cells to find only a handful of potential molecules. Even when a target peptide-specific TCR has been identified, its selectivity becomes crucial in developing a successful therapeutic, with reactivity toward off-target peptides having potentially serious safety implications. To increase the speed and success of TCR discovery, we have developed a in silico TCR design process leveraging recent advances in machine learning for protein sequences combined with high-throughput, rapid cell-based screening, where both specificity and selectivity are considered at the point of design.

Targets for TCR generation are assessed for potential off-target reactivity through a combination of immunopeptidomic data, sequence similarity, and machine learning predicted binding similarity. Large protein language models are fine-tuned on experimental data which captures binding specificities between known TCRs and their peptide ligands, learning meaningful latent representations of both sequences. These trained models are then used to generate TCRs in silico that are optimized for selective target binding, leveraging an energy-based diffusion process that has been specially adapted to handle multiple conditioning. In this way, we can guide the model towards TCR sequences that bind to multiple target peptide-HLA sequence(s), enabling reactivity to heterogeneous neoantigens, cross-HLA recognition and off-target (self-peptide) avoidance. Designed sequences are then synthesized and expressed in a cell-based high throughput screen, providing binding data on up to a million TCR sequences per cycle, enabling further model refinement based on desired binding properties. Our pipeline has been applied to design novel TCRs against public neoantigens derived from the common KRAS mutations at the position 12. We show how a generative model produces TCRs optimized for multiple-antigen specificity, binding to one or more of the target peptide(s) but not self-peptides including the unmutated wild type KRAS protein. The TCRs are optimized for high-affinity interactions to drive development of TCR-guided bispecific therapies.

Combining state of the art generative AI with high throughput screening empowers a TCR design process that considers both selectivity and specificity, opening up the next generation of rapid development of TCR-based therapeutics.

#3714 Microscopic mayhem: Serial killing and other immune cell dynamics captured in situ.

W. Gregory Sawyer[1], Diego Pedro[1], Alfonso Pepe[1], Reginald Atkins[2], Chandler Gatenbee[2], Luis Felipe[2], Carlos Garcia Fernandez[2], Soraya Zorro Manrique[2], Said Cifuentes Maury[2], Athena Tsingelis[2], Duy Nguyen[2], Alexander Anderson[1], Erin George[2], Gilmer Valdes[2], Fredrick Locke[2], Patrick Hwu[2]

[1]Moffitt Cancer Center, Gainesville, FL,[2]Moffitt Cancer Center, Tampa, FL

Critical to advancing immunotherapy and cell therapy in cancer is developing a deeper understanding pf the dynamics of immune cell-mediated cytotoxicity. The results from the multidisciplinary effort reported here include numerous movies of immune cell-mediated cytotoxicity with striking examples of serial killing, foraging, path-tracking, cytokine gradients at tumor margins, and killing dynamics, in some cases revealing peak apoptotic signatures just minutes after T Cell engagement.

In vitro studies of immune cell killing are traditionally performed using time-lapse imaging and biochemical assays, but these methods are often limited by spatial and temporal resolution, throughput, and the ability to extract the dynamics of cellular interactions. This study integrates high-resolution and high-speed laser scanning confocal microscopy with artificial intelligence (AI), and machine learning (ML) approaches to provide a high-resolution data-driven analysis of immune cell killing dynamics in vitro.

We have engineered a perfusion-enabled 3D culture system integrated microscopy to assess cellular dynamics for extended periods of time. Perfusion culture maintains the interstitial flow of liquid culture media, clearing the microenvironment of toxic metabolites and reactive oxygen species. This platform uses a Liquid-Like Solids (LLS) to mimic the transport dynamics of a capillary bed. Integrated microscopy allows in situ quantification of spatiotemporal cytokine concentrations, immune cell tracking, immune cell killing dynamics, and invasion dynamics.

In one example, we used Human CAR T cells with an anti-cd19.28z CAR that included a fluorescent mCherry protein fused to the carboxy terminus of the CAR vs. target cancer cells (Burkitt lymphoma) that express GFP. The media contained a 0.1% concentration of Propidium Iodide as a terminal maker of cell death. Such multi-channel data highlights the critical stages of immune-mediated cytotoxicity; however, the complexity and volume of confocal imaging data necessitates advanced computational tools for analysis.

The ML algorithm used in this study comes from computer vision using object detection, which is a cornerstone technique in medical imaging. We utilized the YOLOv8X model, which is distinguished by its high accuracy and efficiency in object detection tasks. The YOLO (You Only Look Once) architecture is designed to predict both bounding boxes and class probabilities in a single forward pass, making it exceptionally fast and suitable for real-time applications.

Finally, by integrating robotics, imaging, and AI/ML detection we are able to capture immune cells of interest in situ. This integrated analysis of complex imaging data from confocal microscopy has been significantly accelerated, enabling the identification of subtle patterns and dynamic interactions between immune cells and their targets, and the actual collection of cells of interest.

#3715 Disrupting the effects of KRAS in colorectal cancer: Investigation of protein pathways linking KRAS and PRMT5.

Isaac Silverman[1], Aaron Shaykevich[2], Netanel Louloueian[1], Danbee Chae[1], Sanjay Goel[3], Radhashree Maitra[1]

[1]Biology, Yeshiva University, New York, NY,[2]Public Health and Preventive Medicine, SUNY Upstate Medical University, Syracuse, NY,[3]Medical Oncology, RWJBarnabas Health Rutgers Cancer Institute, New Brunswick, NJ

Introduction: Numerous therapeutic methods have been explored to inhibit the oncogenic effects of mutant KRAS. Previous in-vitro and in-silico research in our lab indicated that PRMT5 (Protein arginine methyltransferase), a well studied transcription regulator, is a possible surrogate target through which the negative effects of mutant KRAS can be mediated. Our previous preliminary in-silico data developed potential protein pathways linking KRAS and PRMT5 utilizing digital protein models and molecular dynamics simulations. Our current study expands on the preliminary molecular dynamic simulation results, enhancing the understanding of structural and kinetic components of the proteins' interactions and the strength of the theorized pathways.
Methodology: In-silico: The STRING database was used to determine two complementary pathways connecting KRAS and PRMT5. AlphaFold protein structure files downloaded from UniProt were docked with the ClusPro server. Using PyMOL, proteins were separated by chain identities. The Molecular Dynamics Simulation software GROMACS was used to simulate interactions between proteins in a computational topology regulated by Newton's Laws. GROMACS, gmx_MMPBSA, and XmGrace softwares were used to analyze kinetic and structural components.
In-vitro: 4 cell lines, HCT116 and SW620 (KRAS mutant), and Hke3 and LIM420 (KRAS wild-type), were used in this study. Cells were treated with the PRMT5 inhibitor, GSK, for either 6, 9, 24, or 48 hours. Subsequently, quantitative polymerase chain reaction (qPCR) was performed to determine mRNA expression of (HRAS, SNRPE, CLNS1A, WDR77). The difference in fold change between untreated and treated was calculated at each time point.
Results: The proteins HRAS, SNRPE, CLNS1A, and WDR77 were found to be significant interactors between KRAS and PRMT5, forming two possible pathways abbreviated: K-H-S-C-P and K-H-S-W-P. RMSD data confirmed complex stability. RMSF data of each protein per complex displayed regions of significant interaction. qPCR data indicated altered expression of pathway mRNA in mutant cells as compared to in wild-type.
Conclusion: Targeting the crosstalk between KRAS and PRMT5 may be a suitable method of inhibiting mutant KRAS' oncogenic effects. Inhibition of PRMT5 has confirmed distinct retroactive effects on the pathway proteins' gene expression in mutant vs. wild-type cell lines. Therapeutic advances can be made against KRAS using this surrogate target approach with detailed information of pathway interactions.

#3716 Discovery of macrocyclic peptides TTA-121 as insulin receptor modulators with anticancer potential: An integrated *in-silico* and *in-vitro* investigation.

Veera Chandra Sekhar Reddy Chittepu[1], Poonam Kalhotra[2], Tzayhri Osorio-Gallardo[3], Tzayhri Gallardo-Velazquez[4], Guillermo Osorio-Revilla[5]

[1]Medicine, Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Medical Oncology, Jerome Lipper Multiple Myeloma Disease Center, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA,[3]Departamento de Microbiologia e Immunologia, Facultad de Medicina Veterinaria Y Zootecnia, Universidad Nacional Autonoma de Mexico, Mexico City, Mexico,[4]Departamento de Biofisica, Escuela Nacional de Ciencias Biologicas, Instituto Politecnico Nacional, Mexico City, Mexico,[5]Departamento de Ingenieria Bioquimica, Escuela Nacional de Ciencias Biologicas, Instituto Politecnico Nacional, Mexico City, Mexico

Insulin receptor (INSR), and Insulin-like growth factor (IGF-1R) are significantly similar to each other, and upon activation by ligands increases cell proliferation, differentiation and metastasis. In addition, for the cancer cells to acquire resistance to existing FDA approved one or downstream of it signaling pathways. So, identification of peptides to participate in the INSR/IGF-1R signaling pathway and possess anticancer is one of the upcoming strategies to treat cancer, and diabetes. In this study, we applied bioinformatics tools to analyze structure-activity relationships (SAR) of chemicals or peptides as insulin receptor (INSR) modulators to identify and gain the molecular insights into structural features responsible for INSR modulators. Later, commercially available cyclic peptide libraries are screened to possess the INSR modulator features, followed by molecular docking simulations/molecular dynamics revealed the binding mode, flexibility, and interacting residues of cyclic peptides which were similar to the binding of insulin-to-insulin receptor. To further validate our *in-silico* predictions, we conducted an intrinsic fluorescence assay, that demonstrated peptides like TTA-121 changed emission levels like insulin, mimicking insulin function or participating in insulin signaling pathway. Further, we carried out cancer cell proliferation assays in different cancer models like breast, lung and prostate cancer models to validate the potential of chosen peptides as anticancer agents. Our findings establish TTA-121 as a promising anticancer agent. On going studies are aimed to understand further TTA-121, its derivatives and in combination with standard drugs in clinical care are synergistic or additive and elucidating the mechanism of action. Overall, this study highlights the potential of cyclic peptides and its derivatives as INSR modulators and supports their use as standalone treatments or in combination with existing anticancer drugs would ultimately help in development of new cancer therapeutics to benefit cancer care.

#3718 Characterization of chromosomal instability-related dependencies through cell-specific metric for gene dosage compensation potential.

Peter Szikora, Ivan Fekete, Maria Victoria Ruiz-Perez, Dora Kallai, Csilla Hegedűs, Bence Szalai, **Daniel Veres**

Turbine Simulated Cell Technologies Ltd., Budapest, Hungary

Numerical chromosomal instability (n-CIN) is a defining characteristic of most human cancers with serious implications of large-scale alterations of the genome - such as chromosome arm level copy number changes. These kinds of somatic alterations are frequently targeting oncogenes and tumor suppressors, enriched in cancer driver events in order to shape the transcriptome in favor of tumor progression and proliferation. While oncogenes are mostly associated with copy number gains and tumor suppressors are more frequent in chromosome arm losses, neighboring genes are also affected in both cases. This collateral damage may be able to create synthetic lethal relationships and context-specific dependencies. Cancer cells might be able to avoid partial loss and gain-related lethal effects by triggering different dose compensation mechanisms, occurring at the genomic, epigenetic and post-translational levels, which leads to deviations across copy number and expression profiles.

To propose a metric for dose compensation potential, we analyzed copy number and gene expression profiles of the Cancer Cell Line Encyclopedia in order to characterize cancer cell lines with the ability to compensate dependencies arising from chromosomal losses and gains. Our metric consists of the sum of gene expression residuals from linear model fits, describing how much a cell line tends to under or overexpress genes compared to what we expect from copy number counts. By comparing other publicly available datasets with our results, such as perturbation transcriptomics data from the LINCS-L1000 project and the DepMap genome-wide gene essentiality measurements, we aim to identify CIN-related therapeutic vulnerabilities associated with chromosome arm losses and gains. Besides finding potential target candidates, we show that our method is capable of finding well-known pathway-specific compensation mechanisms. As an example, we show a significant correlation between the activity of the Nonsense mediated decay (NMD) pathway and our proposed compensation potential score (CPS) of cancer cell lines.

We propose our method to be used to detect context-specific dependencies associated with gene dosage compensation, and also able to provide pathway-level evidence - both novel and previously known from the literature.

#3719 Docking analyses of miR-21 with RNA-binding proteins that interact with BRCA1..

Yelyzaveta Khayman, Shaneen Singh, Anjana Saxena

Brooklyn College, Brooklyn, NY

RNA binding proteins (RBPs) are key post-transcriptional regulators that predominantly control gene expression through RNA metabolism. Dysregulation of RBPs is implicated in therapy resistance of breast cancer and targeting key RBPs can be a promising therapeutic approach to reverse this resistance. However, the RBP-related mechanisms in breast cancer are complex, influencing the critical proteins involved in cellular DNA damage response (DDR) at one end and modulating the processing of primary miRNA (pri-miRNA) structures to precursor forms on the other end. Studies strongly demonstrated that a stress-responsive RBP, namely nucleolin (NCL) co-localizes with the tumor suppressor breast and ovarian cancer susceptibility gene (BRCA1) during DDR and regulates the expression of a specific subset of miRNAs (miR-21, miR-221, miR-222, and miR-103) that are causally involved in breast cancer initiation, progression, and drug resistance. Earlier we generated docking scenarios with this subset of miRNAs to demonstrate a role of NCL-RNA-binding domain (RBD) 3 and 4 playing a significant role in such interactions. We also identified a group of RBPs as common interactors of BRCA1 and NCL, namely heterogeneous nuclear ribonucleoprotein A1 **(**HNRNPA1), heterogeneous nuclear ribonucleoprotein D (HNRNPD), polyadenylate binding protein cytoplasmic 1(PABPC1), and TAR DNA-binding protein 43 (TDP-43). Interestingly, miR-21 is revealed as a known predicted target of this subset of RBPs. In this study, we therefore focus on modeling docking scenarios of miR-21 with these four RBPs and assessed NCL-binding to miR-21. In this study, we utilized complete RBD regions of these RBPs to predict models for RBP-miR-21 interactions, to highlight the conserved motifs participating in such an interaction. Next, we propose models of competitive versus synergistic binding of miR-21 with the different RBPs. The computational models generated in this study will provide key insights about the RBP- miR-21 interacting interfaces. Additionally, RBP-BRCA1 collaborations further provides insights about how miR-21 regulation by RBP play a role in defective DNA repair mechanism in breast cancer that could serve as potential for therapeutic intervention.

#3720 Histone dynamics and minor groove width: structural drivers of mutations in *KRAS* and *NRAS*.

Yisrael Wiener[1], Isaac Silverman[1], Sanjay Goel[2], Radhashree Maitra[1]

[1]Biology, Yeshiva University, New York, NY,[2]Medical Oncology, RWJ Barnabas Health Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Introduction: Cancer development is driven by genetic mutations, particularly in genomic hotspots, which are sequences prone to mutations. This study seeks to understand the structural properties of DNA in these regions, focusing on the minor groove width (MGW), helical parameters (ProT, HelT, roll, EP), and DNA-histone interactions.

Methods and Materials: An expanded hotspot database was developed by including additional information about mutation-associated sequences and structural properties. A control group of random exon sequences was established to serve as a baseline for analysis. Structural differences were assessed using statistical tests to quantify clustering of hotspot sequences with higher mutation counts around specific MGW values. The *KRAS* and *NRAS* genes were selected for molecular dynamics simulations due to their role in oncogenesis. Several simulations were conducted: one each for both the normal *KRAS* and *NRAS* sequences and others representing the most common mutations. The simulations, lasting 100 ns each and using the AMBER99SB-ILDN force field.

Results and Discussion: The average minor groove width (MGW) values observed in the hotspots revealed structural differences that may impact stability. The normal *KRAS* and *NRAS* sequences exhibited a narrower MGW of 5.4 Å, while sequences with common mutations displayed wider MGW values. This variation in MGW may influence stability. Molecular dynamics simulations indicated that the normal *KRAS* and *NRAS* sequences exhibited greater fluctuations compared to its mutated counterparts. The root mean square fluctuation (RMSF) showed that the normal sequence had higher fluctuations around the guanine-containing regions in *KRAS* or the adenine-containing region in *NRAS*. This instability may be linked to the enhanced mutation rates observed in *KRAS* and *NRAS* hotspot regions. Figures illustrating RMSF plots of *KRAS* demonstrated that the normal sequence's interaction with histone proteins was more unstable than that of sequences with common mutations. The presence of guanine appears to introduce significant strain in the DNA-histone interaction, further correlating with the narrower MGW values. This strain may lead to increased mutational frequency, contributing to the oncogenic potential of *KRAS* mutations. For *NRAS*, the introduction of the adenine nucleotide contributed to the instability of the DNA-histone interaction, particularly when the DNA curved closer to the histone.

Conclusion: The simulations provide valuable insights into the dynamics of the *KRAS* and *NRAS* gene, revealing how specific mutations affect DNA stability and interaction with histones. By focusing on the structural factors that predispose certain regions to mutations, this research contributes to a greater understanding of cancer biology.

#3721 The transcriptional signature of KSHV infection in the guinea pig host.

Kiran Fida, Mohammed Tanvir Hussain, Robert Ellis, Brent A. Stanfield

Pathobiological Sciences, Louisiana State University, Baton Rouge, LA

Introduction: Kaposi's sarcoma-associated herpesvirus (KSHV) is a human oncogenic virus implicated in various malignancies, including Kaposi's sarcoma, primary effusion lymphoma, and Multicentric Castleman disease. The study investigates the similarities in gene expression profiles during KSHV infection of human and guinea pig lung cell lines, aiming to uncover conserved host responses and viral mechanisms across species.

Methods: The human lung cell line MRC5 and guinea pig lung cell line JH4 are infected with KSHV and analyzed against non-infected cell lines as controls. RNA sequencing will be done using Illumina NovaSeq6000 platform. Raw data will be applied to the bioinformatic pipeline, which includes quality control with FastQC and MultiQC, adapter and quality trimming with Cutadapt, filtering to the genome of KSHV with STAR, transcript quantification with Salmon tool. Differential expressed genes will be identified using R package DESeq2 with FDR-adjusted p-value < 0.001 and absolute value of log2(FC) >1. Gene Ontology (GO) for functional annotation of genes and KEGG pathway analysis to determine difference in responses of intracellular pathways will be done.

Expected Results: The RNA sequencing and transcriptome comparison between MRC5 and JH4 is expected to produce significant similarities in immune response and viral manipulation of cellular pathways. RNA sequencing should reveal an upregulation of interferon-stimulated genes (ISGs), and antiviral cytokines. Comparative transcriptomic analysis is expected to show a common pattern of dysregulation in genes related to cell cycle arrest, and apoptosis. Species-specific differences in the transcriptional regulation of metabolic pathways, as well as differences in cell-type-specific transcription factors are anticipated. This may influence the overall magnitude and nature of response to KSHV. Overall, this comparative study will enhance our understanding of KSHV-host interactions and could suggests the use of guinea pig as a viable model for KSHV research offering insights into conserved and species-specific antiviral defense mechanisms.

Conclusion: Both human and guinea pig lung cell lines expected to exhibit similar activation of innate immune response genes, particularly interferon-stimulated genes and pro-inflammatory cytokines, highlighting a conserved antiviral defense response across species during KSHV infection. The similarity in gene expression profiles between human and guinea pig cell lines would be able to suggest that JH4 cells may serve as a viable model for studying KSHV infection, with minor species-specific differences providing additional insights into host-virus interactions.

PREVENTION / EARLY DETECTION / INTERCEPTION: The Role of Physical Activity, Diet, Microbiome, Obesity, and Energy Balance in the Cancer Continuum
Poster Session

#3725 Long-term leisure-time physical activity and digestive system cancer risk and mortality.

Yiwen Zhang, Edward L. Giovannucci

Harvard School of Public Health, Boston, MA

Introduction: Accumulating evidence indicates physical activity (PA) protects against digestive system cancer (DSC) risk. However, less is clear about its optimal amount, intensity, joint association with sedentary behavior, or its role in DSC mortality.
Methods: A total of 231,067 adults from 3 prospective US cohorts (Health Professionals Follow-up Study, 1988-2020; Nurses' Health Study [NHS], 1988-2020; NHS II, 1991-2021) were analyzed. Leisure-time PA was assessed biennially via validated questionnaires and expressed in MET-h/week. Time spent sitting watching TV, a widely used surrogate of sedentary behavior, was assessed biennially. DSC encompassed the digestive tract (mouth, throat, esophagus, stomach, small intestine, colon and rectum) and accessory organs (pancreas, gallbladder, and liver).
Results: Over up to 32 years of follow-up, we documented 6537 incident DSC and 3789 DSC deaths. Higher PA levels were associated with lower DSC risk (≥45 vs. <3 MET-h/week: HR [95% CI], 0.82 [0.74-0.92]; P-trend<0.001) and mortality (0.72 [0.62-0.84], P-trend<0.001). The inverse association was evident for both digestive tract and digestive accessory organ cancers. The maximum benefit appears to be reached at approximately 50 MET-hours/week for DSC risk (P non-linearity=0.01) and mortality (P non-linearity<0.001). Moderate and vigorous PA was independently associated with lower DSC risk and mortality. Consistently meeting the PA guidelines was further associated with lower risk of DSC. Participants who were highly active and less sedentary had a 22% lower DSC risk (95% CI, 0.69-0.87) than those who were highly sedentary and less active.
Conclusion: Higher PA, whether moderate or vigorous, was associated with lower DSC risk and mortality. The optimal benefit was observed at approximately 50 MET-hours/week of total PA. Being consistently physically active may further reduce DSC risk. Increasing PA and reducing sedentariness may be strategies for preventing DSC risk and mortality.

Table 1. Association between total physical activity and digestive system cancer risk and mortality.

	Total physical activity, MET-hour/week						
	<3	3 to <7.5	7.5 to <15	15 to <30	30 to >45	≥45	P-linear
Total digestive system cancer risk

#3726 Physical activity levels are associated with transcriptomic pathways in colon tumors and tumor-adjacent visceral adipose tissue: Results from the ColoCare Study.

V. M. Bandera[1], C. Himbert[1], E. M. Glenny[2], T. Lin[1], S. Hardikar[1], A. Tan[1], J. Ose[3], V. Damerell[4], P. Erickson[1], R. Viskochil[5], C. Warby[1], O. Aksonova[1], C. Stubben[6], D. Nix[6], K. Boucher[1], P. Schirmacher[4], I. Strehli[1], A. Sanchez[1], J. Jedrzkiewicz[1], L. C. Huang[1], V. Florou[1], J. N. Cohan[1], A. Brobeil[4], H.-U. Kauczor[7], C. Kahlert[4], M. Karchi[8], E. H. Wood[8], D. A. Byrd[9], E. M. Siegel[9], A. T. Toriola[10], D. Shibata[8], C. I. Li[11], J. C. Figueiredo[12], B. Gigic[4], J. Roper[13], S. D. Hursting[2], C. M. Ulrich[1];

[1]University of Utah Huntsman Cancer Institute, Salt Lake City, UT, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of Applied Sciences and Arts, Hannover, Germany, [4]Heidelberg University Hospital, Heidelberg, Germany, [5]University of Massachusetts Boston, Boston, MA, [6]Huntsman Cancer Institute, Salt Lake City, UT, [7]University Hospital Heidelberg, Heidelberg, Germany, [8]University of Tennessee Health Science Center, Memphis, TN, [9]Moffitt Cancer Center, Tampa, FL, [10]Washington University School of Medicine, St. Louis, MO, [11]Fred Hutchinson Cancer Center, Seattle, WA, [12]Cedars-Sinai Medical Center, Los Angeles, CA, [13]Duke University, Durham, NC

Physical activity has consistently been associated with improved colon cancer survival, yet the biological mechanisms for this association are not yet fully understood. We investigated the transcriptome of colon tumors and tumor-adjacent visceral adipose tissue (VAT) in relation to colon cancer patients' physical activity levels.

Methods: Fresh-frozen tumor and VAT samples were collected from 134 stage I-III colon cancer patients recruited at Huntsman Cancer Institute, Utah, and Heidelberg University Hospital, Germany, and profiled with bulk RNA sequencing. Habitual physical activity levels were self-reported by the International Physical Activity Questionnaire and patients were classified as either active (≥7.5 metabolic equivalents per week (MET hrs/week), or 150 minutes/week of moderate to vigorous activity) or as inactive (≤ 2.5 MET hrs/week or ≤1 hour of light activity). To evaluate robustness and consistency of findings, patients were also categorized as ≥7.5 MET hrs/week vs. ≤ 3.5 MET hrs/week. Normalized differentially expressed genes were identified (DESeq2 R package) and analyses were adjusted for age, sex, body mass index (BMI), study site and tumor stage. Gene set enrichment analysis identified enriched pathways within the 2024 Hallmark gene sets. Significance was assessed using false discovery rate *padj* <0.05.

Results: Active patients (n=57) were on average younger (61±14 years vs. 64±14 years), with less disease severity (84% Stage II/III, 95% Stage II/III), lower BMI (26.8±5 kg/m^2 vs. 32.1±7 kg/m^2) compared to inactive patients (n=55). There were 21 and 27 significant gene sets (*padj* <0.05) in colon tumor tissue and VAT, respectively, when comparing active to inactive patients. Colon tumors of active patients displayed downregulation of oncogenic pathways relative to the inactive patients, including epithelial mesenchymal transition and angiogenesis (|Normalized Enrichment Score (NES)|≥1.5, *padj* < 0.05). Tumors from active patients also exhibited downregulation of oxidative phosphorylation (|NES|≥1.5, *padj* < 0.05) relative to inactive patients. VAT of active patients had significantly upregulated oxidative phosphorylation, fatty acid metabolism and glycolysis relative to inactive patients (|NES|≥1.4, *padj* ≤ 0.05). These tumor and adipose gene set results were consistent across the comparison of ≥7.5 MET hrs/week vs. ≤ 3.5 MET hrs/week.

Conclusions: Colon tumors from patients meeting or exceeding physical activity guidelines displayed significant downregulation of oncogenic pathways relative to tumors from inactive patients. Similarly, VAT of active patients had transcriptional profiles promoting metabolic pathways. These findings suggest that physical activity levels meeting or exceeding the current guidelines are associated with favorable gene expression both in tumors and tumor-adjacent VAT.

#3727 Physical activity patters according to demographic, social, and clinical correlates among breast cancer survivors.

M. Kebede[1], C. E. Matthews[2], M. R. Dunn[1], N. R. Burse[1], A. G. Howard[1], K. R. Evenson[1], M. A. Troester[1];
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]National Cancer Institute, Rockville, MD

INTRODUCTION: Moderate to Vigorous Physical Activity (MVPA) after breast cancer diagnosis is associated with improved survivorship, suggesting the need for interventions to increase MVPA. However, differences in MVPA by race and age among breast cancer survivors are not well described in population-based studies.
METHODS: We analyzed data from Carolina Breast Cancer Study Phase 3 (CBCS3, n=2994, 50% Black) participants to evaluate the trajectory of MVPA up to 18-month post-diagnosis. Participants were classified as having Any MVPA (and Sufficient or Insufficient according to national guidelines) or No MVPA. Associations between MVPA and demographic, social, and clinical variables were estimated using multivariable logistic regression.
RESULTS: At baseline, 84.0% of participants reported Any MVPA pre-diagnosis, which dropped to 55.4% at 6-month post-diagnosis, then rebounded to 85.1% by 18-month post-diagnosis. Among those who had No MVPA pre-diagnosis, 32.5% and 71.0% became active at 6- and 18-month post-diagnosis, respectively. Race was not significantly associated with Any MVPA [OR=1.12, 95%CI (0.90,1.39) Non-black vs. Black], but higher income [OR=1.33, 95%CI (1.02, 1.74) >$30K vs. <15K], lower Body Mass Index (BMI) [OR= 1.30, 95%CI (1.00, 1.73) <25 vs. >30], low area deprivation [OR= 1.35, 95%CI(1.08, 1.67) vs. high], high area assets [OR=1.54, 95%CI (1.23, 1.93) vs. low], and stage I [OR= 1.72, 95%CI(1.22, 2.43) vs. 3 or 4], were associated with Any MVPA at 18-month post-diagnosis.
CONCLUSION: Individual and community-level socio-economic status (SES) are strong predictors of Any MVPA, and together with established clinical correlates (such as late disease), these factors may contribute to breast cancer disparities.

#3728 Extracellular vesicle dynamics in alternate-day fasting combined with low-carbohydrate weight loss intervention.

Faiza Kalam[1], Kalpana Deepa Priya Dorayappan[1], Rand T. Akasheh[1], Zhipeng Tao[2], Ting-Yuan David Cheng[1], Krista Varady[3], Selvendiran Karuppaiyah[1]

[1]The Ohio State University, Columbus, OH,[2]Texas Woman's University, Denton, TX,[3]University of Illinois at Chicago, Chiago, IL

Background: Obesity is associated with systemic metabolic dysregulation and chronic inflammation, which are reflected in alterations in extracellular vesicles (EVs) that mediate intercellular communication. EVs, marked by CD9 and CD63, may also play a critical role in cancer risk by mediating pro-inflammatory and metabolic signaling. This study investigates how an alternate-day fasting and low-carbohydrate (ADF-LC) intervention impact EV secretion and subpopulation dynamics, exploring their potential as candidates for further protein-level investigations to delineate functional roles in inflammation and metabolic dysfunction.
Methods: Serum samples were analyzed from 10 participants with obesity enrolled in a 24-week ADF-LC intervention, comprising of a 12-week weight loss phase and a 12-week weight maintenance phase. EVs were isolated from serum collected at baseline (Week 0), after weight loss (Week 12), and after weight maintenance (Week 24). EV quantification and characterization were performed using ImageStream flow cytometry, focusing on EV surface markers CD9 and CD63. Fluorescent antibody labeling was used to detect these tetraspanins, allowing precise measurement of EV subpopulations. Total EV concentrations and subpopulation dynamics were assessed, while protein cargo consistency was evaluated to identify functional shifts.
Results: Body weight significantly decreased during the weight loss period (-5.5 ± 0.5%; $p < 0.001$) and stabilized during the weight maintenance phase ($p = 0.57$). Net weight loss by Week 24 was -6.3 ± 1.0%, accompanied by a significant reduction in fat mass ($p < 0.01$). Total EV concentrations significantly declined from baseline to Week 24 ($p < 0.05$), with notable reductions in CD9+ EV populations at Weeks 12 and 24 ($p < 0.05$) and CD63+ EV populations at Week 24 ($p < 0.05$). Despite these changes, EV protein cargo remained consistent, suggesting shifts in specific EV populations and EV-mediated signaling rather than alterations in total protein load. These findings support the need for further investigation into protein changes within EVs to better understand their functional roles in inflammation and metabolic dysfunction.
Conclusions: This study highlights significant changes in EV dynamics and subpopulations during ADF-LC, providing novel insights into metabolic adaptations associated with obesity and weight loss interventions. EVs, particularly CD9+ and CD63+ subpopulations, emerge as potential candidates for further exploration of protein-level changes to better delineate their functional roles in mediating inflammation and metabolic dysfunction, and potential involvement in the obesity-cancer connection.

#3729 The BE FIT study: feasibility of an exercise intervention on the microbiome and immune function in a high-risk cohort for lung cancer.

Marisa A. Bittoni[1], Angela Lontoc[2], Matt Soileau[3], Jennifer Moon[2], Liliana Marin[2], Victoria Hockenhull[2], Amoni Lewis-Hughes[2], Daniel Spakowicz[1], David A. Carbone[1], Zachary Chaplow[3]

[1]Division of Medical Oncology, The Ohio State University, Columbus, OH,[2]Comprehensive Cancer Center, The Ohio State University, Columbus, OH,[3]Department of Human Sciences, The Ohio State University, Columbus, OH

Background/Objective: Modifiable lifestyle risk factors, including diet and exercise, have shown to be associated with reduced lung cancer risk. We previously implemented the BEWELL diet study, which assessed the effects of a black raspberry beverage on bodily inflammation and the microbiome in high-risk smokers. We recently launched the BEFIT exercise study with similar outcomes and objectives which are to: a) confirm the feasibility of an exercise intervention in high-risk smokers, and b) examine the intervention impact on the microbiome and inflammatory biomarkers. This report will describe trial progress, including participant characteristics, recruitment challenges and adherence in this ongoing study.

Methods: Consenting enrollees from The Ohio State University Lung Cancer Screening Clinic (OSULCSC) were randomized to one of two arms: (a) Exercise/Behavioral Support Intervention - an ACSM-approved 12-week virtual resistance training plus aerobic program, or (b) Standard of Care - an information-only, control condition (e.g. light walking). Eligibility criteria include: ages 40-80 years, exercise<150 minutes/week, 20 pack-year smoking history and computer/internet access. Blood draws, stool samples, physical activity measures and behavior change predictors will be evaluated at baseline and intervention completion, with 1-year follow-up to assess adherence.

Results: We have consented 47 out of 115 eligible participants, with 23 randomized to the intervention arm and 24 to the control arm (5 and 6 withdrew from each group, respectively). Individuals have primarily been recruited through the OSULCSC and social media ads. Our goal is to recruit 40 participants who complete the 12-week study (20 per arm). Common reasons for withdrawal include too busy, changed mind and no longer interested. Participant characteristics include mean age 64, 75% female, 89% white, 45% current smokers and mean BMI of 35 (obese). Adherence to the intervention has been high with 90% of sessions attended and no adverse events reported. Biospecimen collection and social cognitive intermediates are currently underway.

Discussion: We have successfully launched the BEFIT exercise intervention study for smokers at high risk for lung cancer with high adherence and no adverse events reported. Due to initial recruiting challenges and dropout, with many being ineligible initially, we adjusted the eligibility criteria (lower age and exercise levels) and increased the study compensation. Our BEWELL study showed statistically significant improvements in the gut microbiome with a few non-significant changes in inflammation. We will assess similar outcomes in the BEFIT study and look forward to reporting these when completed. These lifestyle studies provide unique strategies for lung cancer prevention, which are greatly needed.

#3730 Oral microbiome and breast cancer risk in the NIH-AARP Diet and Health Study.

Giovanny A. Herrera Ossa[1], Xing Hua[2], Linda M. Liao[1], Yunhu Wan[1], Casey L. Dagnall[2], Kristine Jones[2], Belynda D. Hicks[2], Amy Hutchinson[2], Mitchell H. Gail[1], Jianxin Shi[1], Gretchen Gierach[1], Rashmi Sinha[1], Emily Vogtmann[1]

[1]NCI Div. of Cancer Epidemiology & Genetics, Bethesda, MD,[2]Frederick National Laboratory for Cancer Research/Leidos Biomedical Research Laboratory, Inc., Frederick, MD

Introduction: Breast cancer is the most commonly diagnosed cancer and leading cause of cancer death among women worldwide, with approximately 310,720 new cases and 42,250 deaths in 2024 in the US. The oral microbiome has been observed to be associated with breast cancer in case-control studies, but few studies have evaluated whether the oral microbiome may influence the risk of breast cancer. It has been hypothesized that the oral microbiome may be related to breast cancer risk through multiple mechanisms, including periodontal disease-related systemic inflammation or bacterial translocation. We evaluated the prospective association between the oral microbiome and breast cancer risk in the NIH-AARP Diet and Health Study cohort.

Methods: The NIH-AARP cohort recruited 566,398 participants aged 50 to 71 from 1995 to 1996. In 2005, 34,262 oral wash specimens were collected by mail from a subset of living participants who had never been diagnosed with cancer and participants who had previously developed colorectal, breast, or prostate cancer. Within the women with an oral wash specimen without a prior cancer diagnosis, 348 women who later developed breast cancer were matched to a control using incidence density sampling by age at sample collection, race, and smoking history. DNA was extracted from the oral wash using the PowerSoil Pro, and shotgun metagenomic sequencing was conducted on the Illumina NovaSeq. After host filtering, the taxonomy of the unmapped reads was assigned using MetaPhlAn3, and functional profiling was performed using HUMAnN3. Relative abundances of the taxa from phylum to species level and the functional data of genes and pathways were calculated. Conditional logistic regression was conducted for alpha diversity, beta diversity, species-, and genes-level metrics to calculate odds ratios (OR) and 95% confidence intervals (CI) with adjustment for potential confounders including demographic and lifestyle characteristics, and reproductive factors.

Results: The average age of participants was 61.5 (SD 5.2). The cases developed breast cancer an average of 3.4 years after the oral wash sample collection. There were no significant differences between cases and controls by education level, age at menarche, or menopausal status. Results from the first two batches of samples (44 cases and 44 controls) suggested that alpha diversity was inversely, but not statistically significantly, associated with breast cancer risk (e.g., OR observed species=0.79; 95% CI=0.45-1.40). Similarly, the presence of some periodontal pathogens was inversely, but not significantly, associated with breast cancer risk (e.g., OR *Porphyromonas gingivalis*=0.62; 95% CI=0.21-1.80).

Conclusions: There are some indications that the oral microbiome may be prospectively associated with breast cancer risk. However, results from the complete dataset will provide better statistical power to adequately investigate potential associations.

#3731 The role of dietary patterns and microbiome composition in colorectal cancer survival: The ColoCare Study.

Biljana Gigic[1], Tian Jin[1], Mmadili N. Ilozumba[2], Victoria Damerell[1], Doratha A. Byrd[3], Tengda Lin[2], Maria Gomez[3], Van Manh H. Le[1], Alireza Shamsian[1], Farzaneh Malekian[1], Jennifer Ose[2], Sheetal Hardikar[2], Jane C. Figueiredo[4], Christopher I. Li[5], David Shibata[6], Adetunji T. Toriola[7], Gianni Panagiotou[8], Ute Nothlings[9], W. Zac Stephens[2], June L. Round[2], Cornelia M. Ulrich[2], Caroline Himbert[2], Christoph Kahlert[1]

[1]Department of General, Visceral and Transplantation Surgery, Heidelberg University Hospital (UKHD), Heidelberg, Germany,[2]Huntsman Cancer Institute, Salt Lake City, UT,[3]Department of Cancer Epidemiology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[4]Department of Medicine, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA,[6]Department of Surgery, University of Tennessee Health Science Center, Memphis, TN,[7]Department of Surgery, Washington University St. Louis, St. Louis, MO,[8]Microbiome Dynamics, Leibniz Institute for Natural Product Research and Infection Biology- Hans Knoll Institute, Jena, Germany,[9]Institute for Nutrition and Food Sciences, University of Bonn, Bonn, Germany

Introduction: Diet plays a crucial role in shaping the gut microbiome, which in turn can influence cancer progression and patient outcomes. Specific dietary patterns - such as those rich in fiber, protein, and healthy fats - can promote a balanced microbiome, support immune function, reduce inflammation, and improve treatment response. In contrast, diets high in processed foods and unhealthy fats may disrupt the microbiome, potentially leading to poorer outcomes. Understanding the impact of dietary patterns on the microbiome and cancer progression could provide valuable insights into personalized nutrition strategies aimed at improving colorectal cancer (CRC) survival. This study explores the relationship between nutrient-based dietary patterns, microbiome composition, and overall survival (OS) among CRC patients.

Methods: Pre-surgery fecal samples were collected from 129 stage I to IV CRC patients in the ColoCare Study, a prospective cohort of newly diagnosed CRC patients, in Utah, US and Heidelberg, Germany. To characterize the gut microbiome, we performed 16S rRNA sequencing. We calculated estimates of alpha and beta diversity, relative abundance, and *a priori* selected bacterial presence or absence. DESeq2 was used to quantify differential abundance. Principal component analysis was applied to identify nutrient-based dietary patterns, including 23 *a priori* selected macro- and micronutrients from Food Frequency Questionnaires. Nutrients were log-transformed and adjusted for total energy intake. OS was assessed in 117 stage I to III CRC patients, using multivariate Cox proportional hazards regression.

Results: We identified two major dietary patterns: a “Western diet” characterized by e.g. high intake of protein, fats, and carbohydrates, and a “vitamins & minerals diet” with high intake of vitamins and minerals, especially vitamin B_6, potassium, and calcium. Alpha diversity was significantly higher in stage I patients compared to stage IV (Shannon index, $p=0.04$) and significantly different between study centers (Shannon index, $p<0.01$). Beta diversity was significantly different comparing patients adhering to a low *vs.* high “Western diet” (Bray Curtis distance, $p=0.02$). We did not observe statistically significant differences in relative abundance among patients following a “Western diet” or a “vitamins & minerals diet”. Additionally, no significant association was found between microbiome composition and OS.

Conclusion: While dietary patterns were linked to gut microbiome diversity, no significant association was observed between microbiome composition and OS in CRC patients. To further substantiate these findings, examining dietary patterns at the food group level may provide additional insights. Additionally, metagenomic sequencing is essential to investigate species, gene, and functional profiles in larger patient populations.

#3732 Associations between gut microbiome changes and quality of life in colorectal cancer patients: a pre- and post-surgery comparison.

Hyeree Park[1], Donghyeok Seol[1], Ji Won Park[2], Min Jung Kim[2], Seung-Yong Jeong[2], Aesun Shin[3], Eun Sung Jung[4], Sunyoung Lee[4]

[1]Seoul National University Bundang Hospital, Seongnam, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of,[3]Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]HEM Pharma Inc., Suwon, Korea, Republic of

With the increasing number of colorectal cancer (CRC) survivors, understanding how treatment impacts health-related quality of life (QoL) and microbiome composition is critical. This study investigated the relationship between QoL metrics and microbiome changes before and after surgery in CRC patients, utilizing the EORTC QLQ-C30 and QLQ-CR29 questionnaires alongside clinical metadata. Additionally, the study explored how persistent symptoms, weight changes, and physical activity levels post-surgery influence QoL and microbiome diversity.
Survey data were collected from 38 patients who completed pre- and post-surgery QoL assessments and provided matched fecal samples. Part I of the survey assessed health and lifestyle habits, including exercise levels quantified by MET-minutes, while Part II evaluated QoL using functional and symptom scales. Patients were classified as high-risk based on functional (≤33.32) or symptom scale scores (>66.66). Matched fecal samples were analyzed by sequencing the V3-V4 regions of the 16S rRNA gene, with taxonomy assigned using a besttax approach and processed via the QIIME pipeline. Microbiome analyses included differential abundance testing (using ALDEx2 and DESeq2) and diversity metrics (alpha and beta diversity). Significant changes were reported in functional scales, including body image and weight concern, and in symptom scales, such as blood and mucus in stool and stool frequency, between baseline and follow-up surveys.
Microbiome analysis identified significant differences in taxa such as *Peptostreptococcus, Parvimonas,* and *Prevotella* pre- and post-surgery. While trends toward higher microbial diversity were observed in patients with increased physical activity or weight gain, these were not statistically significant. Symptom severity was associated with distinct microbial profiles: patients with frequent symptoms like blood and mucus in stool exhibited higher levels of *Collinsella* and *Senegalimassilia,* alongside lower abundances of beneficial genera like *Ruminococcus* and *Dialister.*
By integrating QoL survey data with microbiome profiles, this study highlights the potential for personalized symptom management based on distinct microbial patterns linked to specific symptoms. Such insights enable tailored interventions to address both colorectal cancer-related symptoms and broader QoL concerns in survivors. A nuanced understanding of these relationships can guide targeted strategies to improve symptom control, enhance quality of life, and support comprehensive recovery through optimized microbial diversity.

#3733 Increased risk of EOCRC after multiple exposures to antibiotics in A/J mice.

Niti Jani, Maredith Richardson, Kristen Hogan, Maria M. Pena

University of South Carolina, Columbia, SC

Colorectal cancer (CRC) is the fourth most common cancer and the second leading cause of cancer-related deaths in the United States and globally. When diagnosed in individuals under 55 years of age, it is referred to as early onset colorectal cancer (EOCRC). EOCRC has been increasing in incidence and mortality since the 1990's with an 11% to 20% increase from 1995 to 2019 and projected to rise by 140% by 2030. Although EOCRC has been associated with known risk factors for CRC, the exact causes and mechanisms remain unclear. Based on current knowledge, we propose that EOCRC may be driven by exposure to internal and external factors (collectively known as exposomes) that have been on the rise over the past four decades, potentially affecting the microbiome and leading to dysbiosis and inflammation in the distal colon and rectum. One significant contributing factor may be the use of antibiotics (Abx), especially in infants and young children. In this study, we hypothesized that early life exposure to Abx could lead to dysbiosis and inflammation in the distal colon and rectum, which in turn may cause increased mutations and epigenetic changes that promote development of EOCRC. To test this hypothesis, we investigated the impact of commonly prescribed pediatric Abx on the gut microbiota and inflammatory environment in the colon, and their potential role in tumor development when exposed to a carcinogen. A/J mice were treated with several rounds of Abx and then exposed to azoxymethane (AOM), a known carcinogen, to assess their effect on tumor formation. The results revealed that Abx exposure induced dysbiosis and inflammation in the colon, along with systemic inflammation in the treated mice. When AOM was introduced in the presence of Abx-induced dysbiosis, this led to increased tumor burden in the distal colon. These findings suggest that Abx may play a role in elevating the risk of EOCRC. Future studies are aimed at examining age-dependent effects of Abx on EOCRC risk and in combination with other common exposomes.

#3734 Associations between microbiota-derived indoles and inflammation markers among colorectal cancer patients.

Victoria Damerell[1], Doratha A. Byrd[2], Sheetal Hardikar[3], Mmadili N. Ilozumba[3], Christoph Kahlert[1], Jane C. Figueiredo[4], Christopher I. Li[5], David Shibata[6], Adetunji T. Toriola[7], Cornelia M. Ulrich[3], Gianni Panagiotou[8], Biljana Gigic[1]

[1]Department of General, Visceral and Transplantation Surgery, Heidelberg University Hospital (UKHD), Heidelberg, Germany,[2]Department of Cancer Epidemiology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL,[3]Huntsman Cancer Institute, Salt Lake City, UT,[4]Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA,[6]Department of Surgery, University of Tennessee Health Science Center, Memphis, TN,[7]Department of Surgery, Washington University St. Louis, St. Louis, MO,[8]Leibniz Institute for Natural Product Research and Infection Biology, Leibniz Institute for Natural Product Research and Infection Biology - Hans Knoll Institute, Jena, Germany

Introduction: Gut microbiota-derived indole metabolites, produced from dietary tryptophan, play significant roles in modulating inflammation and intestinal immune responses. However, despite emerging interest, still little is known about the roles of indoles in the context of colorectal cancer (CRC). Given the microbiome's potential impact on CRC progression, understanding the associations between indoles and inflammatory markers may reveal novel therapeutic insights for CRC management.
Methods: Pre-surgery serum samples from 77 stage I-IV CRC patients participating in the ColoCare Study, Heidelberg, have been contributed to the German PerMiCCion Consortium to measure circulating levels of indoles and cytokines using untargeted metabolomics analyses and LEGENDPLEX Cytokine Array, respectively. Multivariable linear regression models were conducted to quantify associations between Indole-3-Acetic Acid (IAA), Methyl-IAA (mIAA), 5-Hydroxyindoleacetic Acid (5-HIAA), Indole-3-Propionic Acid (IPA), Indole-3-Acetamide (IAM), Indole-3-Lactic Acid (ILA), Indole-3-Aldehyde, Indole-3-Carboxylic Acid (ICA) and 44 inflammation markers. Models were adjusted for age, sex, tumor stage, tumor site, and circulating creatinine levels. Sensitivity analyses with false discovery rate (FDR) correction were conducted to adjust for multiple testing.
Results: We found mixed associations for indoles with inflammation markers. For example, IAM was positively associated with IL-6 (β=0.23, p=0.04), CD25 (β=0.68, p=0.01), Tim-3 (β=0.29, p=0.03) and Angiopoietin-2 (β=0.31, p=0.04). In contrast, IPA and ICA showed inverse associations with IL-6 (β=−0.37, p=0.01; β=−0.07, p=0.02, respectively). Strong associations between IPA and CD68 (β=1.01, p=0.02) and PDGF-AA (β=0.62, p=0.03) were observed. Additionally, IAA, 5H-IAA, and ILA were positively correlated with chemokines CXCL9, CXCL11, and CCL4 (β=0.30, p=0.02; β=0.19, p=0.01; β=0.17, p=0.03, respectively). Weak associations of ILA and mIAA with PD-L1 were found (β=0.14, p<0.01; β=0.14, p<0.01, respectively). In sensitivity analyses, associations did not remain statistically significant after FDR adjustment.
Conclusion: This study highlights the varied roles of indole metabolites in CRC. Metabolites like IAM appear to foster a pro-tumor immune landscape via inflammation, immune exhaustion, and angiogenesis. While IPA and ICA may counteract these processes through anti-inflammatory effects, IPA may also have pro-angiogenic properties. IAA, 5H-IAA, and ILA seem to be involved in immune cell recruitment to the tumor site and ILA and mIAA may play a role in suppression of anti-tumor immune responses. Larger cohort studies are needed to gain a deeper understanding of the interplay between indoles and inflammatory processes during colorectal carcinogenesis which may ultimately help identify therapeutic targets for CRC.

#3735 A prospective study of excess weight and weight change in adulthood and risk of colorectal cancer incidence and mortality.

Wen-Yi Huang[1], Steven C. Moore[1], Kathryn Hughes Barry[2], Sonja I. Berndt[1]

[1]Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD,[2]Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD

Obesity is a rising public health problem in the U.S. and worldwide and excess body mass index (BMI, kg/m^2) is a recognized risk factor for colorectal cancer (CRC). However, the role of weight change over the adult life course and timing of the excess BMI in relation to the incidence and mortality of CRC is not well understood. With >15 years of follow-up, we prospectively evaluated the risk of CRC incidence (n=3,092) and mortality (n=931) in association with adult weight change among men and women (n=131,814) recruited in the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial at ages 55 to 74 between 1993 and 2001. At baseline, participants filled out a questionnaire reporting their weight and height at ages 20 years, 50 years, and baseline, allowing us to assess weight change from early to middle, middle to late, and early to late adulthood. Hazard ratios (HRs) and 95% confidence intervals (CI) were computed using multivariable-adjusted proportional hazard regression models. Higher BMI at all ages was associated with an increased risk of CRC incidence (*p*-trend=0.05, 0.0003 & 0.0001 for ages 20, 50 and baseline, respectively). Compared with individuals whose BMI never exceeded 25 kg/m^2 over their lifetime, those who first exceeded a BMI of 25 kg/m^2 in early adulthood had a slightly higher risk of CRC (HR=1.3, CI:1.1-1.4) than those whose BMI did not exceed 25 kg/m^2 until middle age (HR=1.2, CI:1.1-1.3) or later (HR=1.2, CI: 1.0-1.3). Moreover, compared with stable weight, weight gain >4 kg per 5 years from early adulthood to middle or late adulthood was associated with an increased risk of CRC (HR=1.2, CI: 1.1-1.4 for both periods). The increased risks for weight gain >4 kg/5 years between early to middle adulthood appeared more pronounced for those with normal BMI at age 20 (HR=1.3, CI: 1.1-1.5). For CRC mortality, higher BMI at age 50 and baseline, but not age 20, was associated with increased risk (*p*-trend = 0.0002, 0.0002, and 0.3, respectively). Compared to those whose BMI never exceeded 25 kg/m^2, those who first exceeded a BMI of 25 kg/m^2 in early adulthood had an increased risk of mortality (HR=1.2, CI: 1.0-1.5), but no association was found for those whose BMI did not exceed 25 kg/m^2 until middle adulthood or later. A higher risk of CRC mortality was observed for weight gain >4 kg/5 years from early adulthood to middle or late adulthood (HR=1.5, CI: 1.1-1.9 and HR=1.7, CI:1.4-2.1, respectively), especially among those with normal BMI at age 20 (HR=1.5, CI: 1.1-2.0 and HR=1.7, CI:1.3-2.2, respectively). Exceeding normal weight in early adulthood and weight gain from early to middle or late adulthood were associated with increased risks of both CRC incidence and mortality. These findings highlight the harms of excess BMI in early adulthood, the importance of maintaining healthy weight throughout the adulthood, and the potential benefit of weight control programs for CRC prevention.

#3736 Persistent threat: The role of modifiable risk factors in US cancer mortality.

Kyle Edwards[1], Chinmay Jani[2], Aysswarya Manoharan[1], furkan bahar[3], Samuel Kareff[4], Gilberto Lopes[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]University of Miami Miller School of Medicine, Doral, FL,[3]Mount Auburn Hospital, Cambridge, MA,[4]Baptist Health, Boca Raton, FL

Objectives: Cancer is the second leading cause of death globally, with many cases linked to modifiable risk factors. It is crucial to improve our preventive strategies and screening guidelines to reduce preventable cancer. Our study analyzes trends in modifiable risk factors linked to cancer-related mortality in the US over past 30 years..

Methods: The Global Burden of Disease (GBD) database was utilized to extract the overall and risk factor-associated Age-Standardized Mortality Rate (ASMR) for all cancers, as well as for 23 specific cancer in the US, from 1990 - 2021. Our analysis involves the stratification and sub-stratification of modifiable risk factors, encompassing behavioral, environmental/occupational, and metabolic categories, to define risk factor-outcome pairs. Joinpoint Trends were analyzed.

Results: In 2021, 44.1% of cancer-related deaths (315,572) in the US were due to risk factors, with the top five proportional risk factors being smoking (21.4%), high BMI (6.6%), high plasma glucose (6%), occupational carcinogens (5.1%), and high alcohol use (3.4%). From 1990-2019, metabolic risk factors saw the highest associated increase in cancer mortality (+66.4%), especially plasma-glucose (+87.2%) and high BMI (+At 51.5%), contributing to 9 of top 10 increases in ASMR for risk factor-outcome pairs. The greatest reduction was from household air pollution (-81.9%). The highest ASMR among risk factor-outcome pairs was for smoking- trachea-bronchi-lung cancer (TBLC) overall (17.2), in males (21.6), and in females (13.8). Other common pairs included dietary risks (low whole grain, high red meat) - colorectal cancer (CRC), asbestos-TBLC, high fasting glucose-pancreatic cancer, and high BMI-CRC. For males, the top five remained the same except for smoking-esophageal cancer, while for females, the top five also included unsafe sex-cervical cancer and dietary risks-breast cancer replacing asbestos-TLBC and high BMI-CRC. The highest proportional ASMR for risk factor-outcomes pairs included unsafe sex-cervical cancer (99%), occupational carcinogens-mesothelioma (m:96.1%; f:89%), smoking-larynx (m: 72%; f:67%), smoking-TBLC (m;62%; f:56%).

Conclusions: A substantial proportion of cancer-related mortality in the US is linked to modifiable risk factors, particularly smoking, high BMI, and high plasma glucose. Notably, over 50% of the mortality in cancers like cervical, mesothelioma, larynx, TBLC, and liver is associated with modifiable risk factors. Despite a significant decline, smoking remains the leading risk factor for cancer mortality. While mortality associated with environmental and occupational risk factors has improved, that linked to metabolic risk factors has increased both proportionally and absolutely for certain cancers. These findings underscore the urgent need for targeted prevention and screening strategies to address these risk factors and reduce preventable cancer mortality.

#3737 Effect of a potential cancer preventive nutraceutical derived from olive oil processing on hematological, and metabolic parameters.

Adriana Albini[1], Luana Calabrone[2], Anna Aiello[3], Paola Corradino[1], Sara Nofri[4], Simone Cristoni[2], Giulia Accardi[3], Giuseppina Candore[3], Angelo Zinellu[5], Calogero Caruso[3], **Douglas M. Noonan**[6]

[1]IRCCS IEO - European Institute of Oncology, Milano, Italy,[2]ISB-Ion Source & Biotecnologie Srl, Rho, Milan, Italy,[3]Department of Biomedicine, Neuroscience and Advanced Diagnostics, University of Palermo, Palermo, Italy,[4]University of Florence, Florence, Italy,[5]Department of Biomedical Sciences, University of Sassari, Sassari, Italy,[6]Unit of Molecular Pathology, Biochemistry and Immunology, IRCCS MultiMedica, Milano, Italy

Introduction: Extra virgin olive oil is a basic component of the Mediterranean diet; it contains several molecules with antioxidant, anti-inflammatory, anti-angiogenic anti ageing, and pro-apoptotic properties. Olive mill waste water (OMWW), a liquid residue produced in vast amounts during olive oil extraction, represents an environmental issue but on the other side it is a rich source of phytochemicals particularly, phenolic compounds, that show promise in preventing the development of several disease disorders, including cancer. We performed in vitro and in vivo experiments and in a pilot study we measured hematochemical, anthropometric, and metabolomic parameters in volunteers after dietary supplementation of an OMWW purified nutraceutical preparation.
Experimental procedures: OMWWs ability to affect cell proliferation and survival on different cancer cell lines was analyzed by MTT, and by gene expression analysis. The supplementation of OMWW-OL (Oliphenolia) 25 mL twice daily for 30 days was tested, upon ethical committee approval, on a pilot cohort of volunteers with characteristics close to metabolic syndrome. Hematochemical, anthropometric, serum biomarkers and serum metabolomic parameters were analyzed before the intervention, at 30 days, and 30 days after.
Results: OMWW extract shown a potent inhibitory effect inhibiting cells proliferation of cancer cell lines and HUVECs. We analyzed sera from volunteers with pre-metabolic syndrome, and we assessed several biological parameters before and after nutraceutical intervention with Oliphenolia. Body mass index, slightly decreased, particularly in the women. Also, hydration increased, especially in women, while blood pressure, glycemia, and insulin decreased. Cholesterol, high-density lipoproteins, and triglycerides were stable, and LDL levels decreased, while vitamin D levels, alongside calcium, perceptibly increased. Albumin also increased. All the values were in support of a trend towards a beneficial effects. By mass spectrometry analysis, we also found favorable changes in the vitamin D.
Conclusions: OMWW extract has shown stronger anti-angiogenic and anti-tumor properties in vitro and in vivo, with potential cancer preventive potential. A small pilot study, with limited potency, suggested that Oliphenolia extract represents a promising dietary supplement, that can could be potentially valuable for people at risk of metabolic syndrome and relevant in supporting healthy ageing and in cancer prevention

#3738 Triangulating the metabolic crossroads: understanding the complex interplay between metabolic dysregulation and obesity cancer risk.

Marinella Temprosa[1], Bing Li[2], Liza Makowski[3], James Hebert[4], Cornelia Ulrich[5]

[1]The George Washington University, Rockville, MD,[2]University of Iowa, Iowa City, IA,[3]University of Tennessee, Memphis, TN,[4]University of South Carolina, Columbia, SC,[5]University of Utah, Salt Lake City, UT

Obesity is on the verge of surpassing tobacco use as the leading modifiable cause of cancer in the U.S., contributing to over 40,000 new cancer cases annually. With obesity rates rising, especially in younger populations, its association with increased cancer risk is becoming more evident. There is an urgent need to understand the mechanisms underlying the relationship between obesity related metabolic dysregulation and cancer risk, including factors that may mitigate health disparities. Recent advances in molecular oncology and metabolic research provide opportunities in understanding the intricate connections between metabolic dysregulation, obesity, and cancer. This session will describe a novel triangulation approach, synthesizing evidence from randomized controlled trials, mechanistic animal studies, and large-scale secondary data analyses to build a comprehensive understanding of these relationships from the NCI-sponsored Metabolic Dysregulation and Obesity Cancer Risk Consortium (MeDOC). MeDOC is guided by team science and transdisciplinary approach to advance our understanding of the underlying mechanisms that connect obesity, metabolic dysregulation, and cancer risk to identify markers that will enhance cancer risk prediction and identify targets for intervention. Both obesity and metabolic dysregulation contribute to a cascade of derangements in adipocyte function, growth factors, inflammation, gut microbiome, immune function, sex hormones, lipid and glucose metabolism which, in turn, can disrupt several downstream signaling pathways related to cancer initiation and progression. These derangements occur systemically and within the tumor microenvironment itself. Through 5 individual projects and 6 collaborative projects in human and animal studies, we are currently evaluating the role of A-FABP (adipocyte fatty acid binding protein), ceramides, inflammation, gut mediated metabolites, gut microbiome dysbiosis in cancers of the colon, breast, and liver, facilitated by the coordinating center. Methodological triangulation will be emphasized throughout, demonstrating how randomized trials provide causal inference, animal studies reveal mechanistic insights, and secondary data analyses establish population-level patterns and clinical relevance. Experts from the MeDOC Consortium will review current understanding, describe the ongoing human and animal studies and big data analytic methods to establish robust causal frameworks. Open discussion will include our early career members to engage the community to identify emerging areas.

Chairperson: Marinella Temprosa
Hallmarks of metabolic dysregulation and their role in obesity cancer risk: Bing Li
Harmonization of Animal Studies: Liza Makowski

#3767 Enhanced anti-tumor efficacy through prolonged plasma membrane retention of a novel anti-CCR8/IL2 mutein fusion antibody.

Andres Zucchetti[1], Benjamin Pelletier[1], Fabien Delisle[1], Bere Diallo[1], Anupama Karnam[1], Marco Pretti[1], Erica Russo[1], Caroline Janot-Sardet[1], Yann Courbebaisse[1], Elsa Lheriteau[1], Charlotte Muller[1], Marine Dubois[1], Reno Winter[1], Mercedes Tkach[1], Alvaro Lladser[2], Jonathan Back[1], Bernard Vanhove[1], Sebastien Lemoine[1], Monica Gostissa[1], Eliane Piaggio[3], Ilgar Mamedov[1], **Fiorella Kotsias**[1]

[1]EGLE THERAPEUTICS, Suresnes, France,[2]Centro Cientifico y Tecnologico de Excelencia Ciencia & Vida, Fundacion Ciencia & Vida, Santiago, Chile,[3]Institut Curie, INSERM U932, PSL Research University, Institute Curie Research Center, Paris, France

Background: Infiltrating regulatory T cells (Tregs) are part of the tolerogenic microenvironment of tumors and key players in resistance to immune checkpoint inhibitor (ICI) therapy. Selective depletion of Tregs within the tumor microenvironment has the potential to overcome this resistance and to increase the proportion of patients responding to immunotherapy. The CCR8 chemokine receptor, which is preferentially upregulated on tumor-resident Tregs, represents an attractive and specific target for antibody-dependent cell cytotoxicity (ADCC)-mediated Treg depletion. Several ADCC-enhanced anti-CCR8 antibodies are currently being evaluated in clinical trials to assess their therapeutic potential. Our findings suggest that rapid internalization of anti-human CCR8 antibodies upon receptor binding significantly hampers their ADCC efficacy. To address this limitation, we engineered EGL-002, a novel anti-CCR8 antibody fused to an IL2 mutein designed to preferentially block the CD25 receptor and to prevent CCR8 internalization.
Methods: Retention of EGL-002 on the plasma membrane was assessed through microscopy and flow cytometry using in vitro-expanded and tumor-infiltrating human Tregs. ADCC and antibody-dependent cellular phagocytosis (ADCP) potency were evaluated in reporter assays and confirmed using donor-derived natural killer (NK) cells and macrophages, respectively. Pharmacodynamics, biodistribution, and anti-tumor activity were evaluated in tumor-bearing mice genetically engineered to express the human target receptors. Treg-depleting activity and specificity were further confirmed in human tumor samples.
Results: EGL-002 demonstrated prolonged retention on the plasma membrane of Tregs across in vitro, ex vivo, and in vivo models, compared to the parental antibody. This resulted in enhanced ADCC and ADCP potency, leading to complete Treg depletion in tumors while sparing other tumor-infiltrating effector T cell populations as well as Tregs in the periphery. In mouse models, EGL-002 effectively depleted tumor Tregs, achieving robust anti-tumor efficacy as single-agent and in combination with anti-PD-1 therapy.
Conclusion: Preclinical data highlight EGL-002 as a highly effective tumor Treg-depleting agent with potent anti-tumor activity. Its unique design positions it as a best-in-class therapeutic candidate for solid tumors, either as a standalone treatment or in combination with ICIs.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: DNA Damage Response and Modulation of DNA Repair 1
Poster Session

#4198 Unraveling the molecular interactions between DDR and autophagy in response to oxidative stress.

Kavya Ajit Pandya, Neeru Singh

Institute of Advanced Research, Gandhinagar, India

The DNA damage response (DDR) is essential for maintaining genomic integrity by detecting and repairing DNA damage. In conjunction with autophagy, DDR functions as a critical protective mechanism under oxidative stress, mitigating the risk of cancer development. Our study investigates the link between oxidative stress and DDR, particularly focusing on ATM kinase's role in reactive oxygen species (ROS)-mediated genotoxic stress for double-strand break (DSB) repair. Cancer cells' heightened reliance on DDR, due to high proliferation and genomic instability, underscores their susceptibility to DDR inhibitors. However, the effectiveness of DDR inhibitors is often limited by the evolution of resistance in tumors. Resistance mechanisms can include the restoration of DNA repair pathways or activation of compensatory pathways. This adaptability limits the long-term efficacy of DDR-targeted therapies, emphasizing the need to understand the molecular drivers underlying resistance to enable the development of more effective strategies. Our study focuses on the potential interaction between Mediator of DNA damage checkpoint 1 (MDC1), a key DDR protein, and Beclin-1, a vital autophagy inducer. We have employed a comprehensive approach using the HeLa cell line, including wild type, MDC1 knockdown (KD), and MDC1 overexpressing (MDC1-Ov) variants. Oxidative stress was induced using hydrogen peroxide (H_2O_2), and we conducted co-immunoprecipitation, immunofluorescence, and immunoblotting to investigate the interactions between MDC1 and Beclin-1 under these conditions. Our results demonstrate that MDC1 interacts with Beclin-1, with the interaction enhanced over time, indicating its essential role in cellular responses to oxidative stress. We also show that oxidative stress prompts the relocation of Beclin-1 from the cytoplasm to the nucleus, suggesting that Beclin-1 may be involved in regulating DDR in response to oxidative stress-induced DNA damage. Given the central role of MDC1 in recruiting various effector proteins at the site of DNA repair, we hypothesized that MDC1 may facilitate the nuclear translocation of Beclin-1. Consistent with this hypothesis, we found that nuclear localization of Beclin-1 was significantly reduced in MDC1 knockdown cells compared to wild type when treated with H_2O_2. These findings underscore the critical role of MDC1 in modulating the nuclear localization of Beclin-1 in response to oxidative stress. The significance of our study lies in its potential implications for chemotherapy. Given the prevalence of oxidative stress in various cancers and the therapeutic reliance on chemotherapy-induced oxidative stress, understanding this novel interplay between DDR and autophagy pathways may provide insights for developing constructive therapeutic strategies.

CHEMISTRY: High-Throughput Screening Assays and Libraries

#615 The effect of novel natural compounds on papillary thyroid cancer cell viability.
Michelle Carnazza[1], Nan Yang[1], Robert Werner[1], Raj K. Tiwari[2], Jan Geliebter[2], Xiu-Min Li[2]

[1]General Nutraceutical Technology, LLC, Elmsford, NY,[2]New York Medical College, Valhalla, NY

Thyroid cancer (TC) is the most common endocrine malignancy and has been increasing in incidence in the United States over the last few decades. Incidence and mortality rates are largely owed to papillary TC (PTC), as they constitute approximately 80% of TC cases. PTC is usually contained within the thyroid gland and has an excellent prognosis, with a 5-year survival rate of more than 90% following surgery. Many survivors still need ongoing surveillance, continued treatment, and lifelong thyroid hormone supplementation, while also undergoing the consequences of current therapeutics including hormone fluctuations, surgical complications, and radioactive iodine side effects. Therefore, novel treatments, including herbal medicine, have been suggested. General Nutraceutical Technology, LLC. has a library of over 300 compounds and we screened twenty from different herbs including *Glycyrrhiza glabra* and *Phellodendri chinensis*, to name a few. Literature has supported their immunomodulatory effects and therefore we determined their dose-dependent effects at 40 ug/mL, 20ug/mL, 10ug/mL, 5ug/mL, and 2.5ug/mL on PTC cells, K1 and TPC1. Cell viability was assessed with an XTT assay over three days. Those with the lowest IC_{50} were further screened for synergy through the calculation of an interaction index. Initial screening demonstrated dose-dependent reductions in cell viability over three days in several of the single-blind coded compounds, plateauing at 48 hours. Compounds C35L, C7Q, and C3I were among the lowest IC_{50} for K1 cells at 4.4ug/mL, 9.5ug/mL, and 23 ug/mL respectively. These compounds also had the most pronounced effects on TPC1 cells with determined IC_{50} of 8ug/mL, 9.8ug/mL, and 23 ug/mL, respectively. Synergistic interactions were evaluated and concluded that in K1 a combination of all three compounds reduced the IC_{50} to 4.565ug/mL after 72 hours of treatment (II=0.57). This data warrants further investigation, including the mechanism of cell viability reduction upon treatment using Trypan Blue Exclusion, Western Blot and Flow Cytometry. Apoptosis can be assessed through the protein expression of apoptosis markers by Western Blot and Annexin V/Propidium Iodide staining by Flow Cytometry. Flow Cytometry can also determine effects on the cell cycle. Natural compounds have demonstrated long-lasting effectiveness that is safe and able to regulate multiple targets at once with advantages to Western medicine being more readily available, more convenient, and affordable. Therefore, these novel natural compounds, especially in combination, may provide safe and inexpensive relief to PTC survivors.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Therapeutic Approaches to Attack the Tumor Microenvironment

#6391 OMTX705: A dual-mechanism ADC targeting FAP-positive CAFs, to overcome chemo and immunotherapy resistance in solid tumors.

Patricia Gonzalez[1], Isabel Egana[1], Cristina Ferrer[1], Roland Kontermann[2], Oliver Seifert[2], Klaus Pfizenmaier[2], Wolfgang Richter[1], Laureano Simon[1], **Myriam Fabre**[1]

[1]Oncomatryx Biopharma, S.L., Derio, Spain,[2]Institute of Cell Biology and Immunology, Stuttgart University, Stuttgart, Germany

ADCs targeting the tumor stroma offer a promising strategy to address tumor heterogeneity. Traditional tumor-targeting ADCs face limitations, as intratumor and interpatient variability in target protein expression can result in incomplete targeting. In contrast, the tumor stroma is more genetically stable and consistent across patients. CAFs, the predominant stromal cell type within the tumor microenvironment, play a critical role in cancer progression and immune evasion in multiple cancers. OMTX705, a clinical-stage ADC, targets FAP-positive CAFs in the tumor microenvironment. OMTX705 presents an optimized and highly stable linker and it is quickly internalized and transported to late endosomal compartments in FAP-expressing cells. Its novel cytolysin-based payload demonstrates strong cell killing activity upon specific ADC internalization in FAP positive cells. Indeed, enhanced cytotoxicity was observed when compared to MMAE, particularly in cells with high PgP expression, offering a potential solution for tumor drug resistance. OMTX705 has demonstrated preclinical robust efficacy, achieving 100% tumor growth inhibition and even regression, in PDX murine models for pancreatic, gastric, ovarian, triple negative breast and lung cancers, with or without humanized immune systems, and showing no significant toxicity. Higher anti-tumoral effect was evidenced over both classical chemotherapy and modern immunotherapy drugs, as a single agent or in combination therapies with Gemcitabine/Abraxane or immune checkpoint inhibitors. OMTX705 even displays superiority compared to other FAP-targeted ADCs bearing different payloads such as deruxtecan in pancreas cancer models. Moreover, it exhibits high plasma stability and excellent safety profile, with no adverse effects observed in non-human primates at doses up to 100 mg/kg. OMTX705 operates through a dual mechanism of action. First, upon ADC internalization, the bystander effect of the payload released from FAP-positive CAFs leads to efficient killing of neighboring tumor cells. This effect has been validated through different experimental techniques *in vitro* and in preclinical tumor samples. The second mechanism involves immune cell infiltration within the tumor microenvironment, further strengthening its therapeutic potential. This dual effect, combined with a favorable safety profile, positions OMTX705 as a promising candidate among cancer therapeutics, targeting the stroma in solid tumors and enhancing antitumor immune responses.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Antitumor Agents 2
Poster Session

#861 N17350 outperforms cytotoxic agents in killing tumors of treatment-naïve and chemotherapy-treated ovarian carcinoma patients.

Chang Cui[1], Ravindra Gujar[1], Maria Fumagalli[1], Nicole Martinez[1], Peter Haberz[1], Afshin Bahador[2], Alain Algazi[3], Lev Becker[1]

[1]Onchilles Pharma, Inc., San Diego, CA,[2]South Coast Gynecologic Oncology, Inc, San Diego, CA,[3]UCSF Head and Neck Medical Oncology, San Francisco, CA

Background: Tumor heterogeneity leads to suboptimal responses to chemotherapy as well as primary and acquired resistance. Advanced ovarian cancer (OvCA) patients with chemotherapy resistant disease have significantly poorer prognosis and limited treatment options and thus there is an urgent need for new therapies. N17350 is a novel therapeutic modality that kills cancer cells independent of anatomical locations, tumor genetics, and tumor immune status while preserving normal cells. N17350's broad efficacy and specificity are mediated by elevated levels of histone H1 isoforms in cancer cells. A single intra-tumoral injection of N17350 induces tumor regression and triggers anti-tumor immunity in a wide range of pre-clinical models [1 - 4]. Here, we compared tumor killing by N17350 to standard-of-care chemotherapies *in vitro* and *in vivo* in OvCa patients that had not received chemotherapy or received neoadjuvant chemotherapy (NACT) prior to cytoreductive surgery.
Methods: Cytoreductive surgery tissue specimens were collected from 27 consecutive patients treated by author AB. Cancer cells and $CD45^+$ immune cells were isolated, treated with N17350 24h post-isolation, and cell viability was quantified by calcein-AM and immunogenic cell death markers. *In vitro* tumor killing by N17350 was compared to carboplatin, paclitaxel, doxorubicin, or oxaliplatin in chemotherapy naïve and NACT patients. OvCa cells from 3 patients were injected into nude mice to create cell-derived xenograft (CDX) models. Mice were treated with N17350 (400µg/100mm^3, intratumoral) or carboplatin (100mg/kg, intraperitoneal) and tumor growth was assessed.
Results: Of 27 patients, 18 had OvCa, 9 had peritoneal carcinoma, 1 had fallopian carcinoma, 1 had high-grade invasive squamous cell carcinoma and 1 had sarcoma. 15 were chemotherapy naïve prior to cytoreduction, 11 received 3-7 cycles of NACT, and 1 had recurrent disease. N17350 induced immunogenic cell death in cancer cells and preserved immune cells in all tested patients, whereas chemotherapies were toxic to both cell types equally. N17350 was more effective at killing cancer cells than chemotherapy in patients with NACT. Additionally, N17350 showed robust tumor killing in primary, metastatic, and recurrent tumors whereas chemotherapy was inferior in killing metastatic and recurrent tumors. N17350 rapidly regressed tumors in all OvCa CDX models and exhibited markedly improved efficacy over carboplatin.
Conclusions: Our data demonstrate that, compared to standard chemotherapy, N17350 yields superior and more selective tumor killing, particularly following exposure to NACT. Tumors that are resistant to chemotherapy retain sensitivity to N17350, and N17350 could improve clinical outcomes in OvCa, including patients with chemotherapy resistant disease.

#ADV01 Hereditary cancer, beyond BRCA mutations..
Debbie Denardi

FORCE (Facing our Risk of Cancer Empowered), Tampa, FL

Hereditary cancers or inherited cancers are caused by a genetic mutation that can be passed from one generation to the next; mothers and fathers can pass these mutations to sons and daughters. A person who inherits a genetic mutation from their parent will have a higher lifetime risk for certain types of cancer. A family with hereditary cancer may have many family members who have been diagnosed. Many different genes have been identified that can increase the risk for different types of cancer. Genetic testing on blood or saliva can tell if a person has inherited a gene mutation that increases cancer risk. Inherited mutations have been linked to many different types of mutations. Some types of cancer are more likely to be hereditary. Below is a list of common cancers, and the most common genes that have been linked to increased risk for each. Breast Cancer in women: gene mutations ATM, BARD1, CHEK2, CDH1, PALB2, PTEN, RAD51C, RAD51D, TP53 (Besides BRCA1, BRCA2). Breast Cancer in men: gene mutations CHEK2, PALB2 (Besides BRCA1, BRCA2). More research is needed to help patients manage their care based on their predisposition to many cancer types.

#ADV02 Results of a Patient Survivorship and Supportive Services Needs Assessment.

Alique Topalian

University of Cincinnati Cancer Center, Cincinnati, OH

A cancer patient needs assessment focuses on patients' needs, how well they are being met, and how to best support them. The purpose of this project is to understand the knowledge cancer patients have of support services, their satisfaction with those services, and what additional services patients desire.

We hypothesize that patients: (1) have a lack of knowledge regarding supportive services offered to them, (2) would like more services than the current offerings, and (3) and face a variety of barriers to accessing services.

We collected data from over 500 patients seen at urban midwestern academic cancer center and satellite hospital. We found that 56.57% of patients were not receiving any supportive services, 27.68% of patients were receiving services from the health system, 4.85% were receiving services outside of the health system, and 10.91% were receiving services from a combination of the health system and outside agencies. Of patients who are receiving supportive services the most common services accessed are individual counseling (9.69%), Cancer Survivorship (9.44%) Nutrition (8.96%), and the Exercise program (7.99%). Of patients surveyed 39.42% said they received the right amount of information on supportive programs, 26.97% were unaware of any supportive programs for cancer patients, and 24.91% were aware of some programs but would have wanted more information. Symptoms most patients would like supportive services for are fatigue (20.39%), fear of recurrence (18.42%), sleep (17.11%), anxiety/distress (17.32%), nutrition (15.57%) and weight (15.35%). Patients said the supportive services they are the most interested in are the exercise program (19.42%), individual counseling (17.86%), cancer survivorship (16.07%), nutrition (14.73%), cancer wellness clinic (11.83%), and group support for cancer type (11.61%). Most patients were interested in alternative services such as massage (33.98%), relaxation/meditation (24.24%), yoga (17.10%), acupuncture (17.10%), and culinary classes (16.45%). The greatest barriers to accessing these services are cost (29.77%), programs not happening during availability (29.53%), fatigue (24.88%), lack of knowledge (22.56%), distance from home (20.70%), and lack of time (20.23%).

Patients need more information about services that are available to them. Majority of patients said that they would like to learn about supportive services from their My Chart Portal. Patients would also like their health care professionals to know more about services available to them to provide referrals. Supportive services are a crucial part of healing and wellness during the cancer journey, and we need to equip our patients with the best programs possible.

#ADV03 Sarcoma Patient Community Data Collaboration to Advance Research.

Brandi Felser

Sarcoma Foundation of America, Damascus, MD

The sarcoma community data project is a collaboration among sarcoma patient advocacy organizations to combine data collected across organizations through registries and other mechanisms. Ethical data sharing, especially in a rare cancer like sarcoma with many different subtypes is beneficial to patients as it allows for the opportunity for more research across the sarcoma landscape. Only by pooling data from many patients, across different institutions, and from studies can there be enough statistical power to derive meaningful conclusions and insights in sarcoma, and importantly rare and ultra-rare subtypes of sarcoma where very few patients exist. Currently, sarcoma organizations and individual patients are housing data in some data platforms not tied to sarcoma, and most of which do not collaborate or work together. Even if the sarcoma community wanted to look across subtypes for specific research questions, it would be difficult because sarcoma data is so fractured. A central repository allows the sarcoma advocacy community to monitor, be collaborators in sharing and providing access to data, and become integrated in outcomes research utilizing patient donated data. This is an opportunity for sarcoma patient advocacy organizations to work collaboratively to combine health records, patient experience data, and genomics and other information in one location across subtypes. Essentially creating a leading registry for sarcoma to advance research.

#ADV04 Youthful Patients and the Importance of Early Detection .

Colt J. Blunt

Debbie's Dream Foundation, Fort Lauderdale, FL

This poster will highlight recent trends of younger people being diagnosed with stomach cancer. It will discuss the need for better education regarding younger stomach cancer patients and highlight the importance of early detection.

#ADV05 Empowering Underserved Communities: Bridging the Gap in Clinical Research.

Valarie Traynham

HealthTree, Lehi, UT

Black, Hispanic, and Rural communities face significant health disparities, often rooted in a lack of awareness, historical mistrust, and systemic inequities in clinical research. This abstract highlights a targeted educational initiative designed to empower those communities with accurate, culturally relevant information about clinical research.

The poster focuses on addressing barriers to participation, such as mistrust stemming from historical injustices, limited access to research opportunities, and misconceptions about clinical trials. Through community workshops, faith-based partnerships, and tailored educational materials, the initiative fosters trust, transparency, and engagement.

Key outcomes include increased awareness of the importance of clinical research in improving health outcomes, growth in participant trust, and higher levels of interest in trial enrollment. By amplifying the voices of advocates within the underrepresented communities and providing resources that resonate culturally, the program lays the foundation for equitable representation in clinical research.

This abstract emphasizes the critical role of education in dismantling systemic barriers and achieving health equity for underserved populations.

#ADV06 Influence of peer support on patient decision-making.

Ben Nathanson

AnCan Foundation, Tumacacori, AZ

We're currently undertaking a survey of those who participate in AnCan -- we have more than 370 responses already and plan to get 500. One goal is to make AnCan better, but another is precisely to demonstrate to medical professionals the importance of organizations like ours.

#ADV07 Comparing base LLMs vs. RAG-enhanced systems in Rare Cancers Such as Chromophobe RCC.

Katie Coleman

Independent Advocate, Buda, TX

This poster outlines the development and goals of the Chromophobe Renal Cell Carcinoma (chRCC) Patient Registry, an initiative led by my nonprofit, the Chromophobe and Oncocytic Tumor Alliance (COA). As one of the most underrepresented and rare subtypes of kidney cancer, chRCC requires dedicated efforts and champions to bridge gaps in research and patient care. The registry aims to collect patient-reported outcomes, medical records, and treatment data in a secure, anonymized format to empower research and improve understanding of this rare cancer.

With a flexible survey design and strong focus on data privacy, the registry enables patients to share their experiences while ensuring their personal information remains protected. By fostering collaboration among patients, researchers, and clinicians, this initiative aims to uncover actionable insights, identify trends in treatment efficacy, and build a foundation for future studies. This poster will also highlight the technical infrastructure and the critical role of patient advocacy in shaping a registry that serves the community's unique needs.

#ADV08 The Influence of Mentorship and Social Media on the Journey of Cholangiocarcinoma (CCA) patients.

Lisa Craine

Cholangiocarcinoma Foundation, Akron, OH

My research will be surveying cholangiocarcinoma patients and how social media, and mentoring impacted their cancer journey, both medically and emotionally. The survey link will be posted on social media sites, emailed, and texted to CCA patients. My goal is to evaluate the role of mentoring and social media and the importance of community, mentoring and social media.

#ADV09 Bridging the Gap: Collaborative Strategies to Advance Molecular Profiling in Brain Tumor Care - Insights from the 3rd Annual Leadership Fly-In.

Georgia Pinner

The Sontag Foundation, Ponte Vedra Beach, FL

This poster will provide an overview of the 3rd Annual Brain Tumor Organization's Leadership Fly-In and its outcomes. This event was dedicated to advancing the understanding and implementation of molecular profiling in the treatment of brain tumors. This event brought together leaders in the field - clinicians, researchers, advocates, and nonprofit leaders to foster collaboration and accelerate the adoption of molecular profiling as a standard practice at diagnosis.

#ADV10 Moving Abroad After Cancer: Is It a Good Idea?.

Carmen Montero

Youth Cancer Europe, Cluj-Napoca, Romania

For many young people, traveling the world and experiencing new cultures is a natural desire. But after a cancer diagnosis, is this still an option? Adolescent and young adult (AYA) cancer survivors face unique challenges beyond medical treatment, including mental health struggles, stigma, and long-term effects on employment and relationships. For migrants, there are extra challenges such as healthcare disparities, cultural barriers, and systemic inequities. Drawing from my lived experience as a migrant cancer survivor across seven countries, this poster explores cancer care and migration, highlighting both the barriers and opportunities encountered along the way. My journey has shaped my role as an advocate and researcher, leading efforts such as the Equitable, Diverse, and Inclusive (EDI) Cancer Carerecommendation for the European Parliament, the Right to Be Forgotten policy proposal in Costa Rica, the Can-Can book series to reduce childhood cancer stigma, and MANO Beyond Cancer, a global platform sharing survivor stories. My experience meeting survivors worldwide underscores the urgent need for culturally sensitive, equitable, and psychologically supportive survivorship care. By fostering collaboration among healthcare professionals, researchers, and patient advocates, we can build a more inclusive cancer care system that supports all survivors, regardless of where they come from.

#ADV11 Patient-centered education in genitourinary malignancies.

Darrell Nakagawa

SWOG Cancer Research Network, Portland, OR

This is a program designed to increase effectiveness in patient facing material to achieve multiple aims: (1) clarify trial eligibility, identify barriers to enrollment, and effective methods of distribution, especially in the community setting; (2) increase understanding of documents related to the trial while ensuring adherence to established regulatory requirements; and (3) quantify the impact of the material in trial accrual.

Patients have expressed great frustration in understanding different clinical trials, and the underlying science beneath them. This project is intended to increase that understanding to stimulate enhanced accrual for our trials. Our intent is to develop new templates for patient communication that are easy to understand, assimilate, and facilitate informed choice.

#ADV12 Engaging Patients to Transform Experience: Building ACCESS.

Adrienne Co-Dyre

ACCESS: Advancing Childhood Cancer Experience, Science & Survivorship, Toronto, ON, Canada

In Canada, roughly 1,500 children and adolescents are diagnosed with cancer each year. Advocacy for enhanced childhood cancer research and care in Canada by patients, families and the academic community led to a $23M investment through the Canadian Institutes of Health Research to establish a national pediatric cancer consortium (termed ‘ACCESS’). ACCESS’ mission is to ensure every child with cancer in Canada has access to the latest scientific advances, diagnostic tools, therapies, and supportive care leading to better outcomes and quality of life. ACCESS is a unique collective of scientists, healthcare providers, industry leaders, partner organisations, advocates, patients, and their families who are conducting research, changing policy, and developing new tools to ensure better lives for children who experience cancer in Canada and for their loved ones. ACCESS is driven and led by people with lived experience of pediatric cancer and framed by the patient journey. To date, ACCESS has unified a national community of more than 750 people and stimulated a culture of open communication in which diverse viewpoints, including those of people with lived experience (PWLE) of cancer, are sought and valued. The inclusion of the diverse perspectives and insights of people who have been directly affected by pediatric cancer drives meaningful improvements through research, policies, practices, processes and programs at all levels of ACCESS. Over 70 persons with lived experience guide and contribute to ACCESS’ 50+ projects. They hold leadership positions in all governance bodies of ACCESS, including as: PWLE Co-Chair of ACCESS; representatives on the ACCESS Senior Leadership Committee; co-leads of major projects and thematic areas; members the PWLE Advisory Committee; engage together in the ACCESS PWLE Community group; and participate in the national PWLE network. Together we will improve outcomes and quality of life for all children who experience pediatric cancer.

#ADV13 Survivor Turned Advocate: Importance of Advocacy and How to Prepare.

Lauren Bendesky

St Baldrick's Foundation, Monrovia, CA

After a diagnosis with stage IV neuroblastoma, Lauren turned to advocacy, using her voice to support others. Through her efforts, she identified gaps in training for advocates, with little integration of medical knowledge. Motivated by this, she worked to help establish the Creating Advocates through Research Education (CARE) Training Program, empowering others to make a meaningful impact.

#ADV14 Bridging the gap in pancreatic cancer: A perspective from a stage IV survivor on the importance of words, testing, and collaboration.

Elise Roth Tedeschi

Independent Advocate, Smyrna, GA

I'm a stage IV pancreatic cancer survivor who was given just a 1% chance of surviving five years. I beat those odds—and that experience shaped my mission: to ensure that patients are not only heard, but meaningfully involved in shaping the future of cancer care and research. In this poster, I emphasize the crucial need for enhanced collaboration among survivors, researchers, and oncologists. Far too often, patients are left confused, overwhelmed, and underinformed due to communication gaps within the healthcare system. In pancreatic cancer specifically, the rates of genetic and molecular tumor testing are still too low, especially in community practices compared to academic centers. Many patients are not receiving care that aligns with NCCN guidelines, which highlights a deeper issue of inconsistency and missed opportunities in treatment.

Survivors offer something that clinical data and textbooks can't: lived experience. When we're included in research design, clinical trials, and medical education, we help shape more relevant studies, build better support systems, and foster more compassionate care. Our perspectives bring humanity to the science, and that leads to better outcomes for everyone.

We are not just stories. We are not just statistics. We are experts in what the system often overlooks. By bringing survivors to the table as true partners, we can close critical gaps and create a future where care is not only scientifically sound but also deeply personal.

#ADV15 Long-term side effects of platinum-based chemotherapy drugs among people treated for colorectal cancer.

Michael Holtz

Fight Colorectal Cancer and Man Up to Cancer, St Louis, MO

Drugs like Oxaliplatin are commonly used in the treatment protocol for colorectal cancers. While the short-term side effects of these drugs are explained to patients, including cold sensitivity, fatigue and neuropathy, the long-term side effects are only now being understood. Long-term side effects can include permanent neuropathy, hearing loss, dental issues, cognitive issues, mental distress, heart problems. fatigue and more. My poster would examine the current research into long-term side effects and the potential gaps in research.

#ADV16 Addressing Colorectal and Anal Cancer Disparities in the LGBTQ+ Community.

David Russo

Cheeky Charity Inc., Palm Springs, CA

This poster will highlight Cheeky Charity's efforts to reduce health disparities in colorectal and anal cancer prevention, screening, and survivorship care for the LGBTQ+ community. It will showcase key initiatives, including the LGBTQ+ Community Cancer Needs Survey, which identifies barriers and motivators to cancer screening, and the PrideCare program, which provides culturally competent support services for patients, survivors, and caregivers.

The poster will also describe how data collected through the survey is used to inform education campaigns, foster partnerships with Federally Qualified Health Centers (FQHCs) and LGBTQ+ clinics, and advocate for health equity. By combining data-driven strategies with community engagement, Cheeky Charity is addressing stigma, mistrust of healthcare providers, and other systemic barriers to improve early detection and outcomes for LGBTQ+ individuals affected by colorectal and anal cancers.

#ADV17 Prevention Is the Cure: Many Paths to Wellness.
Judith A. Fitzgerald

Judith Fitzgerald (Individual)

My poster will represent the issues I am most passionate about in my advocacy work. It will reflect my passion for diet and lifestyle strategies to help with healing, whole body wellness, and prevent recurrence. I developed my “Wheel of Wellness” when I was invited to present in an online webinar hosted by NIH/NCI. The message is that there are many paths to wellness and it’s acceptable to take small steps to avoid feeling overwhelmed. I also advocate for less toxic treatments and better quality of life for patients. By participating in the FDA’s “Project Optimus” I endorsed the paradigm of “individualized oncology” where one size does not fit all. My hope for the future is that we achieve the primary prevention of breast cancer, so the disease never has a chance to start. My role as an advocate on the Phase I clinical trial of the alpha-lactalbumin breast cancer vaccine invented by Dr. Vincent Tuohy at Cleveland Clinic has been one of the greatest honors of my life. The greatest gift I can give my three granddaughters is a world without breast cancer.

#ADV18 The AYA Cancer Experience: A Qualitative Exploration of Quality of Care.
Rebecca Munoz

Independent Advocate, Austin, TX

Adolescents and Young Adults (AYAs) with cancer face unique challenges in navigating their cancer journey. This qualitative multiple case study aimed to explore the quality of care experienced by AYA patients across pediatric and adult oncology settings. Through semi-structured interviews, I investigated the AYA experience across three key domains of the Donabedian model: Structure, Process, and Outcome. Findings revealed a complex landscape of care, highlighting the importance of patient advocacy, effective communication, and comprehensive support services. This research underscores the need for tailored interventions and policies to improve the quality of care for AYA cancer patients.

#ADV19 Hope For People Living With Metastatic Breast Cancer..

Aditya Manna

MAS Clinic and Hospital, Purba Medinipur, India

As in any developing countries state of West Bengal in India has a huge burden of metastatic breast cancer patients in advanced stage coming from rural area where awareness regarding the usefulness of palliative care in rather poor. Our goal is to give a pain free good quality of life in these advanced stage breast cancer patients.

#ADV20 Survivor Advocacy: Using Social Media to Break Stigma, Raise Awareness, and Empower Change in Cancer Care.

Aisha McClellan

Independent Advocate, Snow, NC

In this poster, I will explore how social media platforms, particularly TikTok, can be used to drive awareness, reduce stigma, and advocate for better cancer care. By sharing my personal journey as a cancer survivor, I've created a space to foster open conversations around the importance of early screening, treatment options, and support for those affected by cancer.

#ADV21 From Guidelines to Action: A Personalized Screening Intervention to Address Breast Cancer Disparities.

Tara Latta

My Density Matters, Hawthorn Woods, IL

The stark reality is that Black women have a 38% higher breast cancer mortality rate than White women, despite a 5% lower diagnosis rate (ACS, 2024-2025). This disparity is, in part, driven by later-stage diagnoses, which primarily result from inequities in breast cancer screening access and quality (ACS, 2024-2025).

To address the need for earlier surveillance, the American College of Radiology® (ACR®) updated its guidelines in 2023, recommending universal breast cancer risk assessments by age 25, with a particular focus on Black women, and early surveillance for high-risk individuals. However, there is no clear evidence of the implementation of these crucial guidelines.

To bridge this gap, I developed the Breast Cancer Screening Guide (BSCG) in 2023, guided by the 2023 ACR® guidelines. Designed to empower women of color in medically underserved areas of Chicago's South Side, the BSCG provides personalized recommendations, facilitates informed screening discussions with physicians, and includes a follow-up questionnaire to evaluate effectiveness and identify barriers.

To ensure the BSCG's ongoing optimization, we will employ a data-driven approach, analyzing pilot data to derive actionable insights for the next iteration of the BSCG. Future development will prioritize refining the questionnaire, enhancing the infographic, and actively engaging community members for feedback on cultural relevance and usability. These efforts will create a powerful tool to promote early detection and reduce breast cancer disparities.

#ADV23 Patients Make a Difference!.

Angus Pratt

Independent Advocate, Surrey, BC, Canada

Lung cancer remains the leading cause of cancer-related deaths in Canada, underscoring the urgent need for a unified approach to improve outcomes. The Canadian Action Plan for Lung Cancer represents a groundbreaking effort to incorporate patient perspectives into national cancer strategy development. This initiative, co-designed by patient advocates, researchers, clinicians, and policymakers, emphasizes the value of lived experience in shaping evidence-based solutions.

The development process began with a nationwide survey using open-ended questions. Patients, caregivers, clinicians, and policymakers shared their priorities, challenges, and unmet needs. Key themes emerged: reducing stigma, enhancing early detection, improving access to treatment, and investing in research for innovative therapies. These insights informed a second survey, in which a select group of constituents were asked to prioritize these themes.

The plan culminated in a one-day summit, during which Patient advocates worked alongside scientific and medical experts to cocreate actionable goals. The day included a mix of panels and workshops presenting specific issues and viewpoints.

To ensure inclusivity, special focus was given to engaging underrepresented groups, such as Indigenous communities and rural populations, whose experiences with lung cancer often differ. The resulting Action Plan integrates patient-centered recommendations with measurable objectives, such as increasing lung cancer screening participation rates, funding research on targeted therapies, and implementing supportive care programs.

This initiative exemplifies the transformative potential of patient-researcher partnerships in addressing complex health challenges. The Canadian Action Plan for Lung Cancer sets a precedent for future cancer strategies globally by amplifying patient voices and prioritizing equitable access.

#ADV24 Implementation and evaluation of a 365-day global cancer podcast for patients and survivors delivering research-backed strategies and comedy content daily in 131 countries..

Saranne Rothberg

The Comedy Cures Foundation, Tenafly, NJ

Cancer patients and survivors (CPAS) commonly report elevated levels of depression, stress, anxiety, loneliness, overwhelm, confusion plus unique stressors compared to other adults. This study tested the feasibility and efficacy of a free, global, on-demand, daily supportive podcast with comedy content.

The Beating Cancer Daily Podcast is streamed on the web and on major podcasting sites, delivering a free audio-guided intervention for those 18+ years old. Before launching, The ComedyCures Foundation sent out a press release, posted graphics on social media, and mentioned the podcast in several emailed newsletters. No listener compensation was provided. The program is designed to provide daily support, humor, and evidence-based strategies to individuals navigating a cancer diagnosis and survivorship. Hosted by stage IV cancer survivor, researcher, and humorist Saranne Rothberg, the podcast aims to empower listeners worldwide through the fusion of expert insights and clean comedy. Recognizing the emotional and informational gaps faced by cancer patients, survivors, and caregivers, the podcast provides 365 original daily episodes, creating a trusted, accessible, and uplifting global resource.

Beating Cancer Daily episodes have achieved remarkable organic global reach without paid advertising or marketing. The podcast has grown monthly by word-of-mouth, eventually helping listeners in 131 countries on 7 continents: North America, Europe, South America, Asia, Africa, Oceania, and recently in Antarctica - including listeners in regions experiencing major conflict, e.g., Ukraine, Russia, Middle East, Syria, Taiwan, Democratic Republic of Congo, Sub-Saharan Africa. Over 80% of listeners are on mobile devices with an average daily listen-through rate of 90% to 94%. Presently, over 8500+ websites are organically linking to podcast's main website. Enthusiastic public and private testimonials are received from listeners, including tennis star and recent survivor Gaby Dabrowski, highlighting the impact on improved mood, reduced isolation, and actionable takeaways. Other recognitions include: Rated 'Top 5 Cancer Podcast for Patients' 2024 & 2025 and '#1 Cancer Survivor Podcast' 2024.

Beating Cancer Daily demonstrates that accessible audio content, combining humor with research-backed strategies, can be a cost-effective and meaningful way to support CPAS globally every day. This podcast's rapid expansion by word-of-mouth, positive ratings and listener feedback validate its unique approach and the effectiveness of the host and survivor, Saranne Rothberg. Extensive audience surveys and examination of advanced listener demographics will bring enhanced understanding of the needs of CPAS.

#ADV25 Survivorship Science: A Call to Expand Pediatric Cancer Research Beyond Treatment.

Sarah Rostock

Independent Advocate, Norfolk, VA

Discuss the need for research into long-term survivor care, including addressing late effects, mental health, and quality of life. Advocate for a holistic approach to childhood cancer research that goes beyond just curing the disease.

#ADV26 Fostering positive and productive interactions between patients and researchers.

Terlisa Sheppard

Independent Advocate

To bring together a diverse audience to create a collaborative research environment with a long-term goal of developing curative approaches for metastatic breast cancer.

#ADV27 Why I left Cancer Advocacy, and Why I Came Back.

Sharon Batt

Independent Advocate, Halifax, NS, Canada

My poster uses my 35-year journey through cancer advocacy to explore how values and advocacy are intertwined. Following a breast cancer diagnosis in 1988, I spent a decade of intense involvement in the breast cancer movement in Canada and internationally. Disturbed by the commercialization of cancer advocacy, I disengaged to study, teach and write about health policy and the rise of “patient power.” My central concern is that corporate partners can shape patient perspectives on health policy to the detriment of patients. With a clearer understanding of what’s at stake, I have reengaged in health advocacy with like-minded patients, citizens, physicians and policy researchers. I co-founded the non-profit organization Independent Voices for Safe and Effective Drugs, became a research fellow at PharmedOut, a project to advance evidence-based prescribing based at Georgetown University's Medical Center, and began working with Common Sense Oncology, a cancer research and advocacy organization based in Kingston Ontario.

#ADV28 Empowering Underserved Communities: Bridging the Gap in Cancer Awareness and Support from Africa to the Diaspora.
Edith Meto'o

Independent Advocate, Longueuil, QC, Canada

Educational Outreach in Africa: Plans and initiatives to bring cancer awareness programs to African communities, focusing on early detection, prevention, and treatment options tailored to local cultural and healthcare realities.
Building Global Bridges: How collaboration between African and diaspora communities can improve access to care, knowledge sharing, and resource mobilization.
Survivorship Support Across Borders: Initiatives like wig donations, mental health resources, and wellness kits designed to support women undergoing treatment in Africa and the diaspora.
Advocacy for Equity in Healthcare: Using training from the Parole-Onco program at CHUM, the organization advocates for patient-centered care while addressing the challenges of stigma, limited resources, and access disparities in Africa.

#ADV29 Chemo at the Edge of the World: Caring for my Mom through Pancreatic Cancer on Haida Gwaii.

Dana Bellis

Canadian Institutes of Health Research, Ottawa, ON, Canada

This poster will feature the lived experience of providing cancer care through chemotherapy on Haida Gwaii, a remote northern archipelago off the coast of BC. By sharing my firsthand experience of caring for my mom through her pancreatic cancer, I will highlight the challenges and opportunities faced by a northern, rural, remote, and largely Haida community. The poster will address key issues related to accessing care, services, and supplies in a community setting, especially through the changing seasons and weather conditions. Key focus areas include barriers to travel, particularly the differences between winter and summer, and the personal costs involved in accessing care and supplies. The poster will overview our current chemo program on island, how chemo is flown in on a 1950's float planes each week, and how our two-seat chemo room provides service to our island of about 4,500 people. It will explore how mail is redefined as an essential service for basic needs, how continuity of care is supported during hospital diversions, and how a telepharmacy programs work to support people going through chemo. Finally, the poster will highlight the importance of leaning into community support and resilience to provide the best care possible.

The presentation of the poster will be done through using photos for visual understanding and impact, written text, and brief charts/graphs as needed to quantify relevant information.

This poster will share my lived experiences with the cancer research community, offering insight into what accessing chemotherapy and cancer care is like in Haida Gwaii. This goal is to help inform future research and foster reciprocal relationships, where researchers feel comfortable reaching out to ask questions and learn more about life on the edge of the world.

#ADV30 Integrating the Patient Voice in Training the Next Generation of Scientists.

Megan Sewell

Canadian Institutes of Health Research, Dollard-des-Ormeaux, ON, Canada

Inform and inspire junior cancer researchers on the advantages of patient partners and how the bi-lateral relationship will shape impactful research.

- Both researchers and patient partners learn from each other
- Patient partners feel empowered and valued
- Early engagement lays the groundwork for long-term collaborations

#ADV31 Community-led efforts examining the quality of life over time in young adults diagnosed with cancer..

Carolyn Van

Canadian Institutes of Health Research, Ottawa, ON, Canada

The Recover Study is a mixed-method and longitudinal study that seeks to engage young adults with lived/living experience with cancer to understand the holistic quality of life (e.g. physical, mental, social, and financial) over time and to identify recommendations (e.g. policy, practice, research, and programming) to support their recovery. The Recover Study is a Pan-Canadian 5-year cohort study that is informed by participatory action research (PAR) and patient-oriented research (POR).

Candidly is a podcast that sheds light on everyday scenarios and circumstances of those living life with and after cancer. From changes in work and finances, to friendships and dating, to fatigue and brain function, Candidly is a space for listeners to ask questions, gain diverse perspectives and food for thought from those with shared experiences and professional practitioners, and listen in on authentic human conversations to relate and connect with.

The Recover Study is led with Young Adult Cancer Canada (YACC), a national, non-profit organization dedicated to helping Young Adults (YAs) live better with, through and beyond cancer through various online and in-person services, including online groups, social events, intensive retreats, and survivor conferences designed to address the unique needs of this population.

Candidly is hosted by non-hodgkin lymphoma cancer survivor and health equity advocate, Carolyn Van and is available across all major podcast platforms. It is committed to shedding light on how various aspects of life are impacted by cancer while prioritizing the voices and perspectives of those living through it. Candidly addresses topics that are not always discussed amongst friends, family members, and in the public discord and calls those with various cultural, ethnic, sexual, educational and financial backgrounds into the conversation.

Carolyn Van hopes that through The Recover Study and Candidly, cancer futures will represent and function with a broadened, more nuanced and holistic understanding of recovery.

#ADV32 Smart Decisions about Breast Cancer.

Martina Wood

Canadian Institutes of Health Research, Ottawa, ON, Canada

My “Smart Decisions about Breast Cancer - choices, risks, living well, preventing recurrence” book helps patients navigate their BC journey proactively. Written in an easy to read format, with decision charts (if this, then⋯ - real steps for real people), practical tips, pathology report understanding, and research citations, this book is essential reading for anyone who wants to understand and participate in decision making, cope better, and achieve a sense of control over what happens to them.

I started my research when I was asked to make a treatment decision without any oncology knowledge, because it was so upsetting. This uncovered so much relevant information that I wanted to share it with other women and resulted in a 200+ page book. My advocacy started with supporting other women as I sat in waiting rooms, developed further when I was writing my book, and continued when I became an admin for a Facebook survivor group (12,000+ strong), and joined Canadian Cancer Trials Group (CCTG) as a patient representative. I recently also became a patient partner at Trillium Health Group (THP) in Mississauga for both the hospital group generally as well as the oncology group.

Both at CCTG and THP I’ve been involved in specific patient facing communications initiatives, and helped train other patient reps in how to review such documents when developed for new trials. I reviewed and scored cancer study proposals for funding approval on a one-year term of four sessions as a full member of the Clinical Trials Committee at CCTG. I have written letters of support for a young investigator and research proposals and supported numerous letters of support written by other patient reps at CCTG.

In 2024 I participated in workshops to identify the research priorities most important to patients, first with the CCTG Patient Rep Committee, which resulted in the August 2024 report “CCTG Patient Representative Priorities in Cancer Research”, and the second with the Canadian Cancer Society in November, which will be compiled in 2025 into a report that will contain recommendations of voices heard on the challenges associated with clinical trials in Canada. I have also had a video made by the College of American Pathologists, about my story, and CCTG about my role as a patient rep and the importance of clinical trials.

#ADV33 EmPOWERing Research that leverages scientist-survivor collaboration.

Marsha Biven

Powell-Drescher Ovarian Cancer Research Foundation, Seattle, WA

The goal of the Powell-Drescher Ovarian Cancer Research Foundation is to foster breakthrough ovarian cancer research that will meaningfully improve ovarian cancer outcomes. We believe that this breakthrough research requires close collaboration between individuals who experience the disease and scientists who are trying to address the problem. A major obstacle is that advocates - ovarian cancer survivors, patients, family members, caregivers, previvors, or other persons touched by ovarian cancer - who bring the experience of living with ovarian cancer do not typically interact with the scientists who are working on its prevention, detection, treatment and/or cure. We intend to address this obstacle through a range of innovative programs and projects as by working together, the physician and the patient, the scientist and the survivor, have the power to change the statistics.

#ADV34 Patient Advocate Advisors for ISPY 2.

Jan Tomlinson

University of California, San Francisco Carol Franc Buck Breast Care Center, San Francisco, CA

Dedicated Patient Advocate Advisors for the I-SPY 2 breast cancer clinical trial, bring the patient voice to the forefront of research design and implementation. Their work focuses on enhancing patient-centered communication, informed consent processes, and trial accessibility. Through close collaboration with researchers and trial participants, patient advocates help ensure that the lived experiences and priorities of patients shape the future of breast cancer treatment.

Tuesday, April 29, 2025

IMMUNOLOGY: CAR-T Cells
Poster Session

#1219 CAR-T migration and cytotoxicity in a vessel-cancer co-culture.
Luuk de Haan, Johnny Suijker, Todd Burton, Michel Ziegler, **Nick Saites**, Pleun Hombrink, Job komen, Karla Queiroz

Mimetas B.V, Oegstgeest, Netherlands

Several CAR-T therapies have been approved for hematologic malignancies. However, despite starting hundreds of clinical trials in solid tumors, no CAR-T therapy has been successful against solid tumors.[1] Efficacy in solid tumors is hampered by various factors such as antigen variation, lack of infiltration of T-cells in tumors from blood vessels, and an immune suppressive tumor micro-environment (TME)[2]. These factors lack in current *in vitro* and preclinical animal models. Therefore CAR-T cells are not evaluated on their efficacy with these critical parameters in place, which makes it impossible to select promising candidates for the clinic. This study aims to reduce the *in vitro-in vivo* gap by introducing these parameters in our vascularized tumor models. In earlier work we evaluated T-cell infiltration from a vessel towards chemotactic gradients and tumor cells[3]. In our organ-chip platform we now have created a model which contains a blood vessel, through which CAR-T cells can be perfused, and an adjacent co-culture of cancer tissue. The adjacent co-culture can consist of cancer cell lines, cancer cells and stroma, or primary tissue containing cancer cells and stroma to recapitulate the TME. With an EPCAM targeting second generation CAR-T, extravasation and migration into the tumor compartment could be quantified. Furthermore, after 72h the CAR-T cells reduced tumor volume in the EPCAM-positive HT29 colorectal cancer cell line, while volume of the EPCAM-negative A375 melanoma cell line grew. There was a clear dose response. The vasculature was shown to be intact at most concentrations of CAR-T cells, while being destroyed at highest concentrations. Ultimately there was a ‘therapeutic window’ in which the CAR-T cells reduced tumor mass but left a viable vessel. With the model the effects of modifications to the CAR-T cells or stimulatory cytokines could be evaluated. Changing the co-stimulatory domain from CD28 to 4-1BB reduced the potency of CAR-T, whereas increasing IL-2 concentrations in the expansion or treatment phase enhanced the potency of CAR-T. Hence, we created a co-culture of a vessel and cancer tissue for evaluating CAR-T functionality. In the future the system will be used for testing novel cell therapy variants in panels of patient cancers to support drug discovery and translational medicine by evaluating the efficacy and therapeutic index of different CAR-T variants and identifying responders.

IMMUNOLOGY: Epigenetic Regulation of Tumor Immunity
Poster Session

#2226 Combined inhibition of MEK and HDACs improves the cytotoxicity of CD4 and CD8 T cells in NRAS;ASXL1-driven acute myeloid leukemia mice.

M. Bolisetti[1], J. Li[1], B. Jia[2], E. Keewan[1], E. A. Ranheim[3], K. V. Nadiminti[4], H. Zheng[2], X. You[1], J. Zhang[5];
[1]University of Wisconsin-Madison, Madison, WI, [2]Penn State Cancer Institute, Hershey, PA, [3]University of Wisconsin School of Medicine and Public Health, Madison, WI, [4]University of Wisconsin - Madison, Madison, WI, [5]University of Wisconsin Carbone Cancer Center, Madison, WI

Acute myeloid leukemia (AML) is a heterogeneous malignant blood cancer that occurs mainly in the elderly. Its treatment outcome is greatly influenced by leukemia-driving mutations. Oncogenic *NRAS* mutations are associated with both AML progression and multi-drug resistance and treatment failure in AML. We have previously developed a NRAS; ASXL1-driven secondary AML (NA-AML) mouse model, which is characterized by a suppressive immune microenvironment resulting in reduced leukemia killing activities of T cells. Targeting hyperactive RAS/MEK signaling via trametinib (T, a MEK inhibitor) attenuates the exhaustion of CD8 T cells and prolongs the survival of NA-AML mice. To further boost the efficacy of T, we performed a re-purpose screen of ~2,500 drugs, either approved by FDA for treating various human diseases or currently under clinical evaluation, in the absence or presence of T. We identified that quisinostat (Q), a 2nd generation of HDAC inhibitor, potently inhibited the growth of both mouse and human NA leukemia cells and significantly synergized with T in vitro. In addition, combined T and Q (TQ) downregulated AP-1 transcription factors and expression of immune checkpoint ligands (PD-L1/L2, CD80, and CD86) while upregulated expression of MHC I/II in mouse NA-AML cells. We further validated our results in NA-AML mice. Vehicle (Veh) - treated mice rapidly succumbed to AML and died within 4-5 weeks post-treatment. T alone and Q alone slowed down AML progression and prolonged the survival of leukemia mice, while all TQ-treated mice remained alive ~22 weeks post-treatment. Surprisingly, TQ only provided moderate survival benefits in immunodeficient NSG mice engrafted with NA-AML cells, suggesting an important role of cytotoxic T cells in TQ-mediated AML alleviation. We then analyzed CD4 and CD8 T cells from moribund vehicle-treated mice and age-matched drug-treated mice. TQ decreased the exhaustion of CD4 and CD8 T cells and expanded the activated effector/memory T (Tem) cells. Single-cell RNA-Seq analysis showed increased expression of gene signatures associated with cytotoxicity of Tem cells, including CXCR3 and CXCR5. Consistent with these findings, leukemia: T cell co-culture experiments demonstrated significantly enhanced cytotoxicity of TQ-treated CD4 and CD8 T cells, which appeared to be mediated by increased expression of MHC I and II in AML cells. We are currently pursuing the underlying molecular mechanisms. Our data provide a strong rationale to develop immunotherapies via epigenetic modulation of both leukemia and leukemia-associated T cells.

TUMOR BIOLOGY: Angiogenesis
Poster Session

#3836 Discovery of a highly potent fully human VEGF VHH antibody from RenNano transgenic mice that exhibits a superior blocking activity on VEGF function.

Yi Yang, Weiqiu Lan, Baihong Liu, Yang Chen

Biocytogen, Waltham, MA

Background: VEGFA (or VEGF hereafter) is the prototypic member of a family that also includes placental growth factor (PLGF, also known as PGF),VEGFB,VEGFC,VEGFD . **VEGFR2** is the major mediator of the physiological and pathological effects of VEGF. VEGFR2 mediates EC proliferation, migration and arterial fate specification [1]. VEGFA monoclonal antibodies have significant therapeutic effects in the treatment of tumors and macular degeneration [2]. In this study, we evaluated a fully human anti-VEGFA mAb generated from our fully human antibody RenNano^{TM} mice.
Methods: Blocking activity of the anti-VEGFA mAb against VEGF/VEGFR2 interaction was assessed using ELISA. The affinity to human VEGFA165 was measured by surface plasmon resonance (SPR). At the same time, we conducted relevant physicochemical property tests on the obtained nanobodies, including purity, Tm value, Tagg, and hydrophobicity assessment. To evaluate the in vitro inhibitory effect of anti-VEGFA on endothelial cell proliferation, we used human umbilical vein endothelial cells (HUVEC) for the experiment.
Results: We identified an anti-VEGFA nano-antibody with high affinity to human VEGFA165,and it was able to block the interaction of VEGFA and VEGFR2 in vitro. Our antibody molecule exhibits desirable physicochemical properties, as we found that the purity is above 95% after one step of affinity chromatography. Furthermore, our anti-VEGFA nano-antibody exhibited a strong inhibitory activity on the proliferation of HUVEC cells compared to Bevacizumab analog.

#3837 Defining the mechanism of semaphorin4D tumorigenesis in prostate cancer models.

Kavin Velur Ganesan, Maolake Aerken, Renyuan Zhang, Kent L. Nastiuk

Cancer Genetics and Genomics, Roswell Park Comprehensive Cancer Center, Buffalo, NY

Background: Advanced and recurrent prostate cancer exhibits a “cold” immune phenotype characterized by an influx of immunosuppressive cells and fewer tumor-infiltrating lymphocytes (TILs), limiting the efficacy of checkpoint inhibitors. Semaphorin4D (SEMA4D/CD100), via the PlexinB receptors, regulates cell-cell interactions and migration in the nervous system, also responsible for cancer metastasis. Further, SEMA4D affects angiogenesis and immune regulation in other cancers. We hypothesize that SEMA4D promotes the recruitment of immunosuppressive cells via tumor blood vessels, further impairing TIL activity and anti-tumor immunity. Loss of SEMA4D function could disrupt vascularization, creating hypoxia that induces tumor cell apoptosis.
Methods: Two mouse models—subcutaneous Myc-CaP allografts in immunocompetent mice and Hi-Myc prostate cancer GEMM were treated with a SEMA4D blocking mAb (pepinemab) to inhibit SEMA4D signaling. Tumor volume changes, vascularity, and oxygen saturation were assessed during treatment using high-frequency ultrasound, Power doppler, and photoacoustic imaging followed by FACS and IHC analyses on tumor tissues to evaluate immune cell phenotypes, hypoxia, apoptosis, and microvascular damage. To further elucidate genotypic changes in the tumor immune microenvironment, RNA sequencing gene expression changes associated with SEMA4D inhibition, including signaling pathways and Immune cell constituents.
Results: Blocking SEMA4D significantly arrested tumor growth and reduced vasculature in Hi-Myc mice, with no prominent changes in immune phenotype by FACS after 4 weeks pepinemab treatment. IHC will test for changes in hypoxia, apoptosis, and microvascular damage. Allografts of prostate tumor cells similarly demonstrated tumor growth arrest. Effects on vasculature and microvascular integrity, leading to hypoxia and apoptosis, in this more tractable imaging environment, are anticipated. Transcriptomically, gene ontology and enrichment analyses may reveal pathways related to vessel formation, immune regulation, and metastasis.
Conclusion: Our findings suggest that SEMA4D inhibition effectively arrests tumor growth by disrupting angiogenesis and potentially regulating immune activity, alongside inducing hypoxia and apoptosis. Ongoing transcriptomic analyses will further explore molecular mechanisms, including pathways involved in angiogenesis and immune regulation.

#3838 KRAS dependency and thrombospondin-1 levels are inversely associated with TIMP1.

Ilamathi M. Thirusenthilarasan[1], Bilal Siddiqui[2], Pankaj Ahluwalia[3], Ravindra Kolhe[4], Amyn M. Rojiani[5], Mumtaz V. Rojiani[6]

[1]Pathology, Penn State Health Milton S. Hershey Med. Ctr./Penn State Cancer Institute, Hershey, PA,[2]Pathology, Penn State Health Milton S. Hershey Med. Ctr./Penn State College of Medicine, Hershey, PA,[3]Pathology, Medical College of Georgia, Augusta University, Augusta, GA,[4]Pathology, Medical College of Georgia/Augusta University, Augusta, GA,[5]Pathology, Penn State Health Milton S. Hershey Med. Ctr., Hershey, PA,[6]Pharmacology and Pathology, Penn State College of Medicine/Penn State Cancer Institute, Hershey, PA

Beyond its role as an inhibitor of matrix metalloproteinases, tissue inhibitor of metalloproteinase 1 (TIMP1) has been associated with poor prognosis in many cancer types including non-small cell lung cancer (NSCLC), and substantial evidence suggests it plays a role in tumor progression. The most frequent mutation identified in NSCLC is KRAS. Recently, we described an inverse relationship between expression of KRAS and TIMP1 in NSCLC cell lines. These cells fall into two distinct categories, KRAS dependent and KRAS independent, depending upon their need for sustained expression of KRAS or if the cells have become independent of KRAS expression. We have shown that KRAS-dependent cells with high levels of KRAS, exhibit lower levels of TIMP1. Inversely, KRAS-independent cells with low levels of KRAS show high levels of TIMP1. We have demonstrated that modulation of TIMP1 using knockdown clones or TIMP1 overexpressing cells, alters KRAS dependency features. In the present study, based on preliminary observations on TIMP1 and angiogenesis, we postulate a similar inverse relationship between KRAS-dependent cells expressing high levels of Thrombospondin-1 (TSP1), whereas the independent cells expressing low levels of TSP1. Overexpression of TIMP1 led to a decrease in thrombospondin (TSP1) levels, while TIMP1 knockdown resulted in an upregulation of TSP1. Furthermore, serum-free conditioned media (SFCM) from TIMP1 overexpressing (OE) cells significantly enhanced capillary networking tube formation of HUVEC cells in Matrigel, indicating increased angiogenic potential. By contrast, SFCM from TIMP1 knockdown (KD) clones reduced capillary networking and tube formation compared to parental cells. Additionally, CDH5 (VE-cadherin), a marker of endothelial cells, was upregulated in TIMP1-OE cells and downregulated in the TIMP1-KD clone relative to parental cells. These findings suggest that TIMP1 modulates endothelial cell behavior, likely through regulation of TSP1 and CDH5. In KRAS dependent cells, we also observed the upregulation of VEGFα secreted in the SFCM of TIMP1-OE cells. Furthermore, we investigated the clinical significance of TSP1 and TIMP1 in the TCGA LUAD dataset. Immune deconvolution analysis revealed that TIMP1 expression is associated with a higher infiltration of immune cells, along with a significant enrichment of exhausted immune phenotypes compared to TSP1. These findings highlight the dichotomy between TIMP1 and TSP1, demonstrating both quantitative and qualitative impacts on immune infiltration, with crucial therapeutic implications. Future studies will be directed at investigating the underlying mechanisms linking KRAS dependency and TIMP1 in angiogenesis along with the complex interplay of TSP1, which could provide novel insights into therapeutic strategies targeting TIMP1 to impair angiogenesis and tumor progression in NSCLC.

#3839 MIG-6 plays as a tumor suppressor to inhibit angiogenesis by downregulating HDAC1 in PTEN-deficient endometrial cancer.

Shamsun Nahar[1], Jiyoung Yu[2], Haeam Lee[1], Rong Li[1], Jin-Seok Jung[3], Tae Hoon Kim[1], Kyunggon Kim[2], Jung-Yoon Yoo[3], Jae-Wook Jeong[1]

[1]Univ. of Missouri School of Medicine, Columbia, MO,[2]Asan Medical Center, Seoul, Korea, Republic of,[3]Yonsei University Mirae Campus, Wonju, Korea, Republic of

Endometrioid endometrial cancer (EEC) is the most prevalent gynecological malignancy. Metastatic and recurrent endometrial cancer is incurable with currently available standard therapies. While *Mig-6* mutation develops distant metastasis and recurrence of EEC with *Pten* deficiency, *Mig-6* overexpression ($Pten^{d/d}Mig\text{-}6^{over}$ mice) suppresses tumor development. Therefore, there is an urgent need to explore the mechanisms of tumor metastasis and recurrence to further elucidate the progression of EEC. We performed RNA-seq analysis to identify targets of *Mig-6* in $Pten^{d/d}$ and $Pten^{d/d}Mig\text{-}6^{over}$ mice. The transcriptomic analysis identified 104 and 518 genes significantly increased or decreased transcripts in $Pten^{d/d}Mig\text{-}6^{over}$ mice compared to $Pten^{d/d}$ mice. The pathway analysis of these dysregulated genes showed significant inhibition of immune, inflammatory, and angiogenesis pathways in $Pten^{d/d}Mig\text{-}6^{over}$ compared to the $Pten^{d/d}$ mice group, where the key regulator was hypoxia-inducible factor-1 (HIF1A). Immunohistochemical analysis of HIF1A and PECAM1 validated a significant reduction of angiogenesis in $Pten^{d/d}Mig\text{-}6^{over}$ mice. Moreover, combined interactome and immunoprecipitation analyses revealed that MIG-6 directly binds with histone deacetylase 1 (HDAC1) in the EEC of $Pten^{d/d}Mig\text{-}6^{over}$ mice. Our double immunofluorescence results confirmed colocalization of two proteins in EEC. Finally, we evaluated the therapeutic effect of Panobinostat, a HDAC inhibitor, in EEC of $Pten^{d/d}$ mice. Our results demonstrate the tumor suppressor role of MIG-6 as an HDAC1 interacting protein in angiogenesis of EEC. Our findings highlight potential molecular targets of EEC that could significantly enhance therapeutic strategies for endometrial cancer.

#3841 Unique and redundant roles of Notch1 and Notch4 in retinal angiogenesis.

Nivedha G. Krishnan, Christie Kang, Taliha Nadeem, Braulio Aguilar, Krishna Thakkar, L.A. Naiche, Jan K. Kitajewski

Physiology and Biophysics, University of Illinois College of Med. at Chicago, Chicago, IL

Angiogenesis plays a vital role in the progression of cancer: the proliferation and metastasis of tumor cells relies on extending the vascular network that supplies oxygen and nutrients necessary for growth. Understanding the modulators and regulators of angiogenesis thus allows us insight into the mechanisms of a developing cancer. Notch signaling plays a critical role in the mediation of angiogenesis. Of the four Notch genes, the mechanisms of the Notch1 pathway are most well-understood, whereas the impact of Notch4 regulation on the vasculature is poorly studied and has shown contradictory phenotypes. In recent work, we have shown that an anti-Notch4 antibody, E7011, reduces tumor growth in multiple tumor models that express Notch4 in tumor endothelium and changes the number and phenotype of tumor associated macrophages. To better understand the role of Notch4 in angiogenesis, we have examined endothelial-specific loss of Notch4 during developmental retinal angiogenesis and determined that loss of Notch4 has substantially different effects than loss of Notch1. Loss of Notch4 is anti-angiogenic, characterized by reduced radial outgrowth of vessels and decreased vessel density, in contrast to the loss of Notch1, which results in hypersprouting and increased density. However, the structural similarity and common transcriptional targets of Notch1 and Notch4 suggest they have overlapping functions that are not evident until both genes are removed. To investigate the distinct and overlapping roles of Notch1 and Notch4, we generated mice with endothelial-specific knockouts of Notch1 (Notch1ECKO), Notch4 (Notch4ECKO), or both genes (Notch1Notch4ECKO). We harvested retina from mice at postnatal day (P)5, P10, and P12 timepoints to analyze vascular growth in the superficial and deeper plexus of the retina. Harvested retina were stained for Isolectin B4 to identify vasculature and Iba1 to identify microglia and analyzed for vascular growth measurements, including density, outgrowth, and tip cell counts. Quantitative analysis of the postnatal day 5 timepoint showed a highly abnormal double-mutant Notch1Notch4ECKO phenotype characterized by a significant reduction in radial outgrowth and a significant increase in tip cell density at the vascular front. Qualitative analysis suggested diminished vascular density near the center of the retina. Ongoing analysis is defining changes unique to Notch4ECKO, Notch1ECKO, and Notch1Notch4ECKO to clarify each gene’s individual function in angiogenesis.

#3842 ZNF217 promotes breast tumor progression by facilitating angiogenesis.

Ann Dharshika Shangaradas, Parinda Tennakoon, Margaret A. Schwarz, Laurie E. Littlepage

Department of Chemistry and Biochemistry, University of Notre Dame, South Bend, IN

The transcription factor ZNF217 is amplified in 20-30% of breast cancers and is identified as a putative oncogene. Its overexpression accelerates tumor progression, metastasis, and chemoresistance *in vivo* and correlates strongly with poor prognosis in patients. To identify growth factors that are released from mammary epithelial cells that overexpress ZNF217, we analyzed the conditioned media from MCF7 cells with or without knockdown of ZNF217 using a 71-Plex Discovery assay. Conditioned media from MCF7 cells deficient for ZNF217 showed a significant downregulation in the secretion of VEGF-A, PDGF-AA, and PDGF-AB/BB and was validated by ELISA in conditioned media from both MCF7 cells and in MDA-MB-231 cells that overexpress ZNF217. VEGF-A, PDGF-AA, and PDGF-AB/BB are key components in promoting angiogenesis, a key hallmark of cancer. RNA sequencing data and qRT-PCR revealed no significant difference in the transcriptional expression of VEGF-A and PDGF-AA/AB/BB after ZNF217 knockdown. To evaluate if the secretion of the identified angiogenic factors promotes endothelial cell sprouting, we co-cultured endothelial progenitor cells with the conditioned media from MCF7 cells ± siZNF217. Endothelial cells treated with media from MCF7 ± siZNF217 induced a sprouting phenotype in endothelial cells grown in conditioned media from ZNF217 expressing cells compared to knockdown cells. Together, these data suggests that ZNF217 is a promotor of VEGF-A secretion and promotion of angiogenic phenotypes in endothelial cells. We also evaluated the role of ZNF217 in the expression of the VEGFR-2 signaling. Knockdown of ZNF217 also decreased the expression of KDR (VEGFR-2 receptor for VEGF-A) in MCF7 cells, suggesting a potential autocrine signaling role for VEGF-A in the cancer cells. Single cell RNA sequencing data of mammary tumors derived from orthotopic injection of PyMT±Zfp217 revealed an increased population of endothelial cells in FVB mice injected with Zfp217 overexpressing cells compared to vector expressing control cells. These findings highlight a novel role for ZNF217 as a promoter of angiogenesis during breast cancer progression. Thus, unravelling the mechanisms of ZNF217-mediated angiogenesis will be an instrumental step in determining if anti-angiogenic therapies are an effective and novel strategy used to overcome metastatic growth in breast cancer patients with tumors that overexpress ZNF217.

#3844 Tumor endothelial cell lines and their use for the identification of new tumor vascular targets during dysbiosis.

Samir V. Jenkins, Mohammad Alimohammadi, Kieng B. Vang, Robert J. Griffin, **Ruud P. Dings**

UAMS Winthrop P. Rockefeller Cancer Institute, Little Rock, AR

The overall use of antibiotics has increased by more than 30% in recent years according to the centers of disease control and prevention (CDC). Moreover, many cancer patients are prescribed antibiotics, as a prophylactic or to treat infection, a frequent complication during cancer progression and treatment. Yet, tumor endothelial cell lines are scarce at best and tumor endothelial cell lines derived under dysbiotic pressure non-existent. In order to address this we generated ‘normal’ or orthobiotic and dysbiotic tumor endothelial cell lines. After validating their endothelial cell origin on a genomic, proteomic and functional level, we found that tumor endothelial cells derived from dysbiotic mice (TEC-Dys) were more sensitive to hypofractionated radiation doses (i.e. 6 Gy) as compared to tumor endothelial cells derived from orthobiotic mice, TEC-Ortho. In order to identify relevant tumor vasculature drug targets during dysbiosis, we used tandem mass tag mass spectroscopy and focused on the extracellular proteins significantly overexpressed in TEC-Dys, as compared to TEC-Ortho. C-Met fulfilled these criteria and we validated this histologically by comparing tumors with or without dysbiosis. Moreover, c-Met inhibitors Foretinib, Crizotinib, and Cabozantinib were significantly more effective against TEC-Dys than TEC-Ortho. Foretinib inhibited tumor growth to a greater extend during dysbiosis as compared to orthobiotic conditions. Thus, we surmise that tumor response in dysbiotic patients may be greatly improved by targeting dysbiosis-induced pathways, such as c-Met, as compared to the targets suppressed due to dysbiosis. These matched tumor endothelial cell lines generated under orthobiotic and dysbiotic conditions can now be used in in vitro and in vivo cell-based models, and provide an improved and specialized platform for current and next-generation anti-cancer drug discovery and development.

#3845 A matching panel of tumor organoids and patient derived orthotopic xenograft mouse models (PDOX) of high-grade gliomas in EGFP-based SCID mice.

Xin (Alice) Zhai, Milagros Suarez Palacios, Zilu Huang, Jinnan Chen, Tongchao Jiang, Nitin Wadhwani, Michael DeCuypere, Yuchen Du, Xiaonan Li

Northwestern University - Chicago, Chicago, IL

Background: High grade glioma, also known as glioblastoma multiform (GBM) a highly aggressive brain tumor, requires advanced systems to study tumor-stroma interactions. Paired in vitro and in vivo model systems such as 3D organoids and PDOX models derived from EGFP-SCID mice offered a unique opportunity to precisely and rapidly differentiation of mouse (EGFP positive) from human tumor cells, thereby facilitating the visualization and analysis of tumor/normal cell interactions in vitro and in vivo.
Methods: EGFP-SCID mice received intra-cranial implantation of pediatric (n=6) and adult (n=6) GBM tumors to form PDOX. Tumor-bearing mouse brains were dissected, and tumor cells were cultured to generate organoids by seeding at cell densities of 1250, 2500, 5000 cells/well and monitored for size and count over 1-21 or 28 days. Immunohistochemistry (IHC) tracked the distribution of EGFP-positive mouse cells and GBM markers, including GFAP, Nestin, Ki67, GFP, $CD276^{+}$ and so on. Additional staining for lysosomes and nuclei (Hoechst/DIPA) confirmed cellular localization and interactions.
Results: Hybrid organoids were successfully generated, integrating mouse and human GBM cells in 12 PDOX models. Organoid size and count varied by cell density and culture duration, with similar growth patterns between pediatric and adult samples. IHC confirmed expression of cellular proliferation (Ki67), glial cells (GFAP), differentiation (SYN), stem cell (Nestin) as well as normal mouse cells (GFP) that were in and surrounding tumor cells. In organoids, EGFP fluorescence revealed dynamic tumor-stroma interactions, with changing proportions of mouse cells and GBM cells over time, reflecting the organoid's developmental complexity.
Conclusion: This EGFP-based organoid and PDOX model system offers a robust platform for studying tumor-stroma interactions and characterizing cellular dynamics in GBM. The system's integration of IHC provides a detailed view of tumor and stromal components, making it a valuable tool for biological and translational GBM studies.

#3846 BNIP3-dependent muscle atrophy in cancer cachexia promotes PDAC progression.

Alexandra Sophia Ware[1], Elizabeth C. S. Foster[2], Kay F. Macleod[2]

[1]University of Chicago, Chicago, IL,[2]Ben May Department for Cancer Research, University of Chicago, Chicago, IL

Cancer cachexia is a debilitating effect of several human cancers, including pancreatic ductal adenocarcinoma (PDAC), that involves involuntary body weight loss due to wasting of skeletal muscle (with or without loss of adipose tissue). Cancer cachexia negatively affects the long-term survival of cancer patients, partly due to reduced tolerance of and response to therapy, and increased mortality due to cardiac and respiratory failure. Here, we present new data demonstrating a role for the mitochondrial cargo receptor BNIP3 in driving muscle atrophy during cachexia caused by PDAC in genetically engineered mouse models. Muscle-specific deletion of BNIP3 in CB mice (Mck-Cre;Bnip3$^{fl/fl}$) inhibited muscle atrophy in the KPF (FSF-KRas^{G12D};p53 $^{Frt/+}$;p48-FlpO) mouse model of PDAC such that skeletal muscle in age-matched compound KPFCB mice (FSF-KRas^{G12D};p53 $^{Frt/+}$;p48-FlpO; Mck-Cre;Bnip3$^{fl/fl}$) exhibited increased weight, increased myofiber cross-sectional area, and decreased expression of muscle atrogenes MuRF1 and Atrogin1, compared to KPF mice. Orthotopic injection of KPF and KPC PDAC lines and sub-cutaneous injection of LLC lung tumor lines similarly revealed key differences in muscle atrophy between WT and CB mice. The sustained health of myofibers in KPFCB mice compared to KPF mice was associated with increased mitochondrial mass, increased mTOR activity, and decreased autophagy markers. In addition to limiting muscle atrophy, loss of BNIP3 in muscle attenuated PDAC tumorigenesis with tumors exhibiting delayed progression from pre-malignant pancreatic intra-epithelial neoplasia (PanINs) to PDAC, and muscle-specific loss of BNIP3 extended lifespan of KPF mice. These findings indicate that degradation of muscle driven by BNIP3-dependent mitophagy is “feeding” the PDAC tumor via factors circulating in plasma. Steady state metabolomics revealed that purines were amongst the most down-regulated metabolites in muscle and plasma of cachectic mice consistent with a model in which BNIP3-dependent mitophagy in muscle is limiting 1C metabolism due to decreased mitochondrial mass. Together, our findings identify BNIP3 as a molecular target in muscle for therapeutic intervention to limit both cancer cachexia and tumor progression.

#3847 APE1 mediates angiogenesis by stabilizing SMAD3 and blocking its ubiquitin induced degradation in esophageal adenocarcinoma.

Farah Ballout, Heng Lu, Nadeem Bhat, Lei Chen, Dunfa Peng, Zheng Chen, Alexander Zaika, Oliver McDonald, Wael El Rifai

University of Miami Miller School of Medicine, Miami, FL

Background: The incidence of esophageal adenocarcinoma (EAC) is rapidly rising in the United States and Western countries. Unfortunately, EAC has one of the lowest survival rates due to limited treatment options. Identifying disease drivers through functional studies is crucial for improving treatment options. This study aimed to explore the role of APE1 in regulating SMAD3 and promoting EAC progression.

Methods and Results: Analysis of publicly available datasets revealed that APE1 and SMAD3 are upregulated and positively correlated in EAC compared to normal samples. Immunofluorescence staining of esophageal cancer progression tissue arrays confirmed significantly higher levels of APE1 and SMAD3 in EAC than in normal tissues. Western blot analysis showed that silencing APE1 reduced SMAD3 nuclear expression, which was also confirmed by immunofluorescence staining showing a loss of nuclear SMAD3 accumulation following APE1 knockdown. Immunoprecipitation and proximity ligation assays indicated a direct interaction between APE1 and SMAD3 in the nucleus. Further analysis revealed that APE1 binds to the C-terminal MH2 domain of SMAD3, protecting it from ubiquitin-mediated proteasomal degradation by preventing its interaction with the RING finger protein, ROC1. Notably, inhibiting APE1's redox or endonuclease activity with pharmacological inhibitors or mutants disrupted APE1-SMAD3 binding, suggesting a conformational regulation. Interestingly, knocking down APE1 reduced angiogenesis in tube formation assays and 3D co-cultures; however, this effect was reversed by overexpressing SMAD3, suggesting that APE1 regulates angiogenesis through SMAD3.

Conclusion: The findings establish the role of APE1 in regulating SMAD3 in EAC and suggest a potential therapeutic approach for treating EAC patients.

#3848 Smoking promotes angiogenesis and epithelial to mesenchymal transition in breast cancer.

V. Katkoori[1], S. R. Kandukuri[1], M. V. Burra[1], J. E. Trosko[1], D. M. Tamkus[2], C. Leece[1], L. R. Kareti[1], G. S. Abela[1], H. L. Bumpers[1];
[1]Michigan State University, East Lansing, MI, [2]John H. Stroger, Jr. Hospital of Cook County, Chicago, IL

Introduction: Nicotine, the addictive component of cigarettes, induces tumor progression via the α7-nicotine acetylcholine receptor (α7-nAChR) subtype in lung cancer. However, the molecular mechanisms by which nicotine impacts tumor progression of breast cancer (BC) remain unclear. In this study, we evaluated the effects of nicotine/smoking on tumor angiogenesis, and epithelial-mesenchymal transition (EMT) signaling mechanisms that are involved in BC progression.
Experimental Design: BC cell spheroids from the MCF7, a non-invasive cell line was treated with nicotine (0.3 to 3μM) for 14 days. Sections of tumor tissue from the human BC (smoking vs. never smoking) were assessed for phenotypic expressions of α7-nAChR, and vimentin by immunostaining (IHC). CD31 staining was used to evaluate tumor angiogenesis, as measured by microvessel density (MVD). Western blot (WB) analyses were also performed on lysates of both cell lines and tumors to assess the effect of nicotine on the signaling pathways that promote BC progression.
Results: The present study revealed that nicotine treated spheroids have increased expression of Ki67, Mdr1, Oct4 signatures that are indicative of BC progression. IHC analysis indicated that tumor from patients that smoked displayed increased expression of α7-nAChR. Furthermore, the expression of Oct4 (marker for cancer stem-cell), and vimentin (marker for EMT) that correlates with advanced disease and metastasis were found to be higher in smokers. However, tumors from non-smokers had low expression of Oct4 and vimentin. It was also found that tumors from patients who smoked had well established vascularity, while tumors from non-smokers had very little vascularization. Indeed, the mean MVD was lower in tumors from non-smokers compared to tumors from smokers.
Conclusions: These findings offer significant novel insights into the mechanism by which nicotine contributes to the increased aggressiveness of BC. This work was supported in part by NIH/NCI Workforce Diversity Grant R21-CA171251.

#3849 Pygo2 deletion stimulates tertiary lymphoid structure formation and forms the cornerstone for a quadruple combination immunotherapy of prostate cancer.

Yan Liu, Ziyu Zeng, Yini Zhu, Xin Lu

Department of Biological Sciences, University of Notre Dame, South Bend, IN

Introduction: Advanced prostate cancer (PCa) shows overwhelming *de novo* resistance to immune checkpoint blockade (ICB). We previously identified Pygopus 2 (Pygo2) as a critical epigenetic regulator in PCa to orchestrate the Pygo2/p53/Sp1/Kit/Ido1 pathway to foster a microenvironment hostile to cytotoxic T lymphocytes (CTLs), and inhibiting Pygo2 genetically or pharmacologically sensitized PCa mouse models to ICB and adoptive CTL transfer therapy (Sci Immunol. 2023; PMID: 36897957). Here, we continued this line of research and examined the effect of Pygo2 targeting on castration (androgen deprivation therapy), anti-MDSC therapy and ICB in genetically engineered mouse models.

Methods: We crossed Pygo2 conditional null allele to the PB-Cre/Pten/Smad4 (DKO) mice and generated PB-Cre/Pten/Smad4/Pygo2 (TKO) PCa mouse model. Using this model, we performed a series of combination treatments including ICB, surgical castration, and anti-MDSC therapy SX682 (Cxcr1/2 inhibitor). Various immune-phenotyping techniques (single-cell RNA-seq, bulk RNA-seq, flow cytometry and immunohistochemical staining) were performed on treated tumors.

Results: The best tumor protection phenotype came from the combination of Pygo2 deletion, castration, ICB and SX682 treatment. This quadruple combination regimen led to nearly curative outcome, rendering the mouse tumors extensively necrotic. scRNA-seq and IHC revealed that Pygo2 deletion promoted the formation of tertiary lymphoid structures (TLS) within the tumor microenvironment. The quadruple combination demonstrated the highest level of infiltration of B cells and CTLs. Emerging data suggest that Pygo2 loss instigates cancer-cell-intrinsic signaling distinct from the previously identified Kit/Ido1-dependent pathway and connects an antiviral mimicry state of the cancer cells to adaptive tumor immunity that culminates in TLS formation and maturation.

Conclusions: Our study further consolidates Pygo2 as a valid and promising therapeutic target in combination immunotherapy of prostate cancer. The quadruple combination immunotherapy composed of Pygo2 inhibition, androgen deprivation therapy, SX682 and ICB demonstrates superior preclinical efficacy and should be further investigated for its clinical implications.

#3850 Aberrant tumor pericytes in pancreatic ductal adenocarcinoma-a barrier and opportunity for therapeutic advances.

Vikneshwari Natarajan, Sangdeuk Ha, Jiha Kim

North Dakota State Univ., Fargo, ND

There is a lack of effective treatment for PDAC, often due to abnormal and leaky blood vessels and a lack of proper pericyte coverage, contributing to the inability of the drugs to reach the tumor. We and others showed that pericyte (PC) coverage significantly correlates with vascular integrity, function, and intratumoral hypoxia. However, in PDAC, the PC-endothelial (EC) cell communication is decreased or non-existent, thereby affecting drug delivery and immune function. We propose to re-program tumor-associated pericytes to normalize the tumor blood vessels and revert them to an optimal functional state. We previously showed that tumor-associated pericytes in PDAC exhibit ectopic αSMA expression up to ten times higher than normal pericytes, correlating strongly with vascular instability and hypoxia. Due to significant involvement of αSMA in cellular morphology and structure, tumor-associated pericytes presented biomechanical abnormalities, which diminished intimate association with endothelial cells during tube formation assay. We employed scRNA sequencing to define the pathological signature of tumor-associated pericytes and identify therapeutic targets for vascular normalization. Our analysis revealed considerable heterogeneity in lung pericytes compared to PDAC pericyte clusters, indicating a disrupted vessel hierarchy. Additionally, we identified a distinct pericyte subpopulation characterized by elevated expression of αSMA, MCT1, and gap junction proteins. Alterations in basement membrane gene expression and smooth muscle markers further emphasized the disrupted vascular architecture and impaired pericyte-endothelial cell adhesion within the tumor microenvironment. Our data reveals consistently upregulated monocarboxylate transporters in vascular cells. Therefore, we investigated lactate transporters as a potential target for improving PC-EC adhesion. We have shown that in PDAC, MCT1 lactate exporters are upregulated in EC and PCs. The high amount of lactate produced by PCs decreases the pH in the basement membrane. So, we knocked down MCT1 transporters in PCs to increase basement pH, leading to improved PC-EC attachment and pericyte homeostasis. In conclusion, our study indicates that tumor-associated pericytes undergo phenotype switching and disturbed metabolic communication under the influence of pancreatic cancer cells. These aberrant pericytes might contribute to non-optimal vascular integrity and function. Single-cell RNA sequencing helped understand the molecular signature of the PDAC pericyte, providing a powerful tool to develop novel targeting strategies for vascular normalization. Future work includes exploring the vascular normalization approach by suppressing pericyte phenotype switching to enhance vascular function and chemo- and immunotherapeutic efficacy.

#3851 Vascular regulation of immune exclusion in melanoma.

Ha-Ram Park[1], Nika Kozolv[1], Shawn Jaeha Kim[2], Eugene Son[1], Sungsoo Kim[1], Hee Won Yang[1], Minah Kim[1]

[1]Columbia University Irving Medical Center, New York, NY,[2]Columbia University, New York, NY

The infiltration of immune cells into the tumor is as crucial as their activity in determining the responses to immune checkpoint inhibitors (ICIs). Immune cell exclusion from tumors has been linked to poor responses to ICIs across various cancers, including melanoma; however, the underlying biological mechanisms remain poorly understood. Abnormal tumor vasculature, characterized by leakage and instability, represents a key barrier to immune cell infiltration, but the mechanisms underpinning these vascular changes and their impact on immune exclusion development remain poorly understood.To address this, we utilized a syngeneic mouse melanoma model to investigate the role of vascular changes in regulating immune cell positioning and exclusion during tumor progression. Spatial distribution of various immune cell populations and vascular integrity were assessed through multiplexed immunofluorescence staining across whole tumor cross-sections. While early-stage tumors exhibit well-infiltrated $CD8^+$ T cells and neutrophils throughout the tumors, these immune cells became confined to the tumor periphery as tumors grew, leaving the core devoid of infiltration. This immune exclusion development correlated with vascular instability and leakage, particularly observed at the tumor periphery. Transcriptomic analysis of endothelial cells, sorted from the tumor periphery and core revealed increased gene expression of chemotaxis and immune migration in endothelial cells at the tumor periphery. Through multi-omics approaches including single-cell and spatial transcriptomic analysis, we aim to unravel the molecular mechanisms by which vascular abnormalities shape immune cell exclusion. These findings will guide us in building strategies to restore vascular integrity, enhance immune cell infiltration, and improve the efficacy of ICIs, addressing critical unmet needs for melanoma patients resistant to current immunotherapies.

#3852 The role of endothelial cell remodeling in driving immunotherapy resistance of hepatocellular carcinoma.

Baoyi Yin[1], Shufen Chen[1], Zhewen Xiong[1], Patrick Wong[1], Zhuo Yu[2], Stephan Chan[1], Alfred Sze-Lok Cheng[1]

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]Shanghai University of Traditional Chinese Medicine, Shanghai, China

Introduction: Hepatocellular carcinoma (HCC) is the most common liver cancer and a leading cause of cancer-related deaths globally. Immune checkpoint blockade (ICB) therapy has shown promise but has yielded limited responses in HCC patients. Combining anti-vascular endothelial growth factor (VEGF) with ICB enhances therapeutic efficacy, however, a deeper understanding of endothelial cell (EC) remodeling is crucial for further improving ICB effectiveness. Our integrated analyses identified a transcription factor-4 (TCF4)-driven transcriptional program, coupled with elevated BRD4 expression, associated with EC remodeling in ICB-resistant HCC. Emerging studies have shown that TCF4 functions depend on BRD4 through recruitment to a specific enhancer region, and BRD4 inhibitors can reduce TCF4 expression. We aim to delineate the microenvironmental cue and transcriptional network that direct EC remodeling for tumor immunosuppression and their role in promoting ICB resistance.

Methods: Single-cell transcriptomic profiling was performed on samples from a Phase II trial of pembrolizumab (anti-PD-1) in hepatitis B-related HCC patients (NCT03419481). An ICB-resistant HCC mouse model generated via iterative selection was used for validation. The BRD4 inhibitor AZD5153, administered in oral and nanoparticle formulations, was used to suppress BRD4 and TCF4 expression in systemic and endothelial cells. Quantitative immunofluorescence assessed ECs and detected TCF4 and BRD4 levels.

Results: scRNA-seq analysis revealed that tumor vessels from ICB non-responders were enriched with disorganized macrovascular-like endothelial cell (MaVEC), which further increased upon ICB. RNA velocity analysis predicted that MaVEC in non-responders likely originate from liver sinusoidal endothelial cell (LEC), indicating LEC-to-MaVEC trans-differentiation during ICB resistance acquisition. TCF4 was identified as the top regulon in MaVEC, with increased activity along the LEC-to-MaVEC trajectory and association with BRD4. Using AZD5153, we observed that TCF4 can be suppressed in ECs, which caused a significant intra-tumoral reversal from MaVEC to LEC phenotypes, resulting in tumor cell apoptosis and regression. Additionally, nanoparticle-delivered EC-targeted AZD5153 achieved similar tumor-suppressive effects at a lower dosage.

Conclusions: Our study reveals that the dynamic trans-differentiation from LEC to MaVEC is associated with ICB resistance in HCC, which can be reversed by BRD4 inhibition and possibly mediated by TCF4 transcriptional regulation, targeting their expression in ECs showed improved therapeutic outcomes.

#3853 Plasma activin A levels are significantly elevated for a month after minimally invasive colorectal resection (MICR) for cancer and may support early growth of residual tumor.

Chandana S. K. Herath Mudiyanselage[1], Yi-Ru Chen[1], Neil Mitra[1], Hiromichi Miyagaki[2], Elizabeth Nilsson Sjolander[1], Xiaohong Yan[1], Vesna Cekic[1], Richard L. Whelan[1]

[1]Department of Surgery, Colorectal Division, Lenox Hill Hospital, Northwell Health, New York, NY,[2]Department of Surgery, Otemae Hospital, Osaka, Japan

Introduction: Activin A (ActA) is a cytokine from the TGF-β family. ActA has a wide range of effects in different tissues and plays a role in inflammation, fibrosis, and wound healing. Its actions are mediated mainly via SMAD signaling. A variety of tumors express ActA which has been associated with increased MMP levels and tumor invasion. ActA is also found in the tumor microenvironment (fibroblasts, EC's, and immune cells). ActA mediates the development of cancer-associated fibroblasts that facilitate tumor invasion. Higher tumor ActA levels are associated with worse outcomes. Surgery's impact on ActA levels is not understood. This study's purpose was to determine plasma ActA levels before and after MICR for colorectal cancer (CRC).

Method: CRC patients (pts.) undergoing MICR enrolled in an IRB approved data/tissue bank for whom periop plasma samples were available were eligible. Clinical and pathological data was collected prospectively. Blood samples were obtained preoperatively (PreOp) and on various postoperative days (POD) including POD 1, 3, and at least one late postoperative day (POD 7 to 41). Late samples were grouped into 7-day bundles and used as single time points. Plasma ActA levels were measured in duplicate via ELISA and results expressed as mean ±SD. The Wilcoxon paired t-test was used (sig. $p<0.05$). Correlation between plasma ActA levels and incision length, surgical length, etc was determined using Spearman's rank correlation (rs.). Plasma Act A levels between Laparoscopic and hand-assisted groups were compared by Mann-Whitney U test.

Results: A total of 83 CRC MICR patients met inclusion criteria (48 males: 35 females mean age 65.31± 14.09; rectal, 32%/colon, 68%). The mean incision length was 8.21± 3.63 cm and mean length of stay was 7.9± 6.9 days. The cancer staging (STG.) breakdown was; STG I, 40%, STG II, 29%, STG III, 28% and STG IV, 3%. The mean PreOp ActA level (pg/ml) was 235.8±119.8 (n=83). Elevated mean plasma levels were noted on POD 1(300.4±150.1, n=82, $p< 0.001$), POD3 (325.0±217.4, n=72, $p< 0.001$), POD7-13 (314.9±245.4,n=57,p=0.03), POD14-20 (316.0±144.8,n=29, p=0.003),POD 21-27 (279.3±115.7,n=15, p=0.03) and on POD 28-41(246.4±86.86,n=18, p=0.02) when compared to PreOp levels. Postop ActA levels correlated with the duration of surgery on POD1 ($rs = 0.3$, $p= 0.002$). The mean ActA levels in the hand group were elevated at all Postop time points (9-26%) with (sig. only POD1;P=0.02).

Conclusion: Plasma ActA levels remained significantly elevated from preop levels for 6 weeks after CRC MICR. The increases were 37-39% over Preop levels. The source of the increase may be linked to inflammation associated with wound healing and angiogenesis. Elevated plasma ActA concentrations could potentially facilitate metastasis or the proliferation of remaining cancer cells during the initial month post-surgery.

#3854 Lymphatic endothelial progenitors promote tumor lymphatic formation through cell-cell fusion.

S. Athaiya[1], L. Volk-Draper[1], E. Cox[1], N. Zinkevich[2], S. Ran[1];
[1]Southern Illinois University School of Medicine, Springfield, IL, [2]University of Illinois, Springfield, IL

Introduction: Bone marrow (BM) derived myeloid-lymphatic endothelial cell progenitors (M-LECP) promote formation of tumor lymphatics and metastasis to lymph nodes. Regenerative capacity of BM progenitors to many other lineages is mediated through cell-cell fusion, a process that efficiently inserts a pro-mitotic message directly into damaged or division-restricted cells. We aimed to determine whether M-LECP use a similar mechanism to induce division of tumor lymphatic endothelial cells (LEC) which is an essential step towards the formation of new sprouts.

Methods: Fusogenic markers were determined in M-LECP differentiated by Th2 and TLR4 ligands as well as in RAW264.7 macrophages by qPCR, flow cytometry, and immunohistochemistry (IHC) applied to mouse and clinical breast cancers. Fusion of myeloid and lymphatic cells stably expressing GFP and mCherry tags, respectively, was quantified using flow cytometry and microscopy by determining the percent of yellow cells resulting from merging of green- and red-colored cell partners. Fusion of lymphatic progenitors *in vivo* was determined in female chimera mice bearing MDA-MB-231 or EMT6 breast tumors that have been grafted with male BM prior to tumor implantation. Staining for LEC-specific markers in combination with probes for Y-chromosome quantified tumor lymphatic vessels fused with BM progenitors.

Results: 10% to 25% of myeloid cells fused with co-cultured LEC quantified by two independent methods. M-LECP and RAW264.7 macrophages expressed a variety of fusogenic markers such as SIRP-a, CD36, DAP12, Stabilin-1, and DC-Stamp. These proteins were also expressed in M-LECP residing in human and mouse breast tumors. *In vivo* models showed up to 48% of tumor lymphatic vessels containing nuclear Y-chromosome indicating fusion. Supporting the hypothesis, Y-chromosome in LEC nuclei correlated with mitotic markers, nuclei doubling, lymphatic formation, and metastasis to nodes. Both *in vitro* and *in vivo* assays showed dependency of fusion on Th2 and TLR4 pathways.

Conclusion: We show for the first-time using *in vivo* and *in vitro* assays that bone marrow derived myeloid-lymphatic progenitors induced by Th2 or TLR4 ligands are able to fuse with LEC. This event correlated with LEC proliferation and ultimately, metastatic behavior. These findings suggest a fundamentally novel mechanism of generating new lymphatic sprouts triggered by fusion with lymphatic endothelial cell precursors.

TUMOR BIOLOGY: Approaches for Metastasis Inhibition
Poster Session

#3858 Therapeutic targeting of cofilin-1 phosphorylation by peptidomimetics inhibits lung cancer metastasis.

M.-Y. Lin[1], J.-D. Leu[2], C.-Y. Wu[1], **Y.-J. Lee**[1];
[1]National Yang Ming Chiao Tung University, Taipei, Taiwan, [2]Division of Radiation Oncology, Taipei City Hospital RenAi Branch, Taipei, Taiwan

Background: The main challenges in the clinical management of lung cancer are distant metastasis and recurrence. Targeting the destabilization of actin dynamics has become a critical approach to slowing the rapid proliferation of tumor cells. However, a specific class of anti-metastatic drugs is still being uncovered.
Methods: The analysis of gene expression of ADF/cofilin family by public database in clinically relevant. Combination of the endogenous protein level of CFL-1, its phosphorylation status, and cellular invasion activity in various lung cancer cell lines. We used synthetic peptide to interfere LIMK/CFL-1 regulatory pathway to produced anti-metastatic and survival benefits in a xenograft lung cancer model. Furthermore, the biological characteristics of peptide labeled with metal radionuclide both *in vitro* and *in vivo* were also be evaluated.
Results: Over-expression of cofilin-1 (CFL-1) gene was associated with the incidence and survival rate of lung adenocarcinoma using the in-silico analysis. CFL-1 proteins were also differentially elevated in various NSCLC cell lines. Notably, we found that the phosphorylation level of CFL-1 at serine 3 (Ser3), rather than the total CFL-1, was better correlated with the invasion potential of NSCLC cells. Here, we developed synthetic CFL-1 mimetic peptides (CMP) to inhibit endogenous CFL-1 phosphorylation and evaluated their effects using highly metastatic NSCLC cells. The SPECT/CT imaging demonstrated that CMP labeled with ^{99m}Tc can be detected in an orthotopic lung tumor. Furthermore, CMP can act as a competitive decoy of cofilin kinase, demonstrating anti-metastatic effects and prolonged survival in a xenograft model, with no significant toxicity observed.
Conclusion: This study demonstrates that the phosphorylation level of CFL-1 at serine 3 is strongly correlated with the metastatic potential of lung cancer, and interfering with its phosphorylation could be a promising strategy for lung cancer treatment.

#3859 Ephrin inhibition disrupts stromal-cancer crosstalk and reduces metastasis in pancreatic cancer.

C. L. Bolton[1], R. O'Sullivan[1], S. Menezes[1], A. J. M. Cameron[1], G. Marin[1], J. F. Marshall[1], E. P. Carter[2], M. Henkemeyer[3], R. P. Grose[1]; [1]Queen Mary University of London, London, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]UT Southwestern Medical Centre, Dallas, TX

Pancreatic Ductal Adenocarcinoma (PDAC) is the 10th most common cancer in the UK but has devastating mortality rates world-wide. Reasons underpinning this include delays in diagnosis and treatment resistance, where the desmoplastic nature of the disease hampers treatment efficacy. One of the most influential cell types within the PDAC stroma is the cancer associated fibroblast (CAF). CAFs are known to have both pro- and anti-tumoral roles, making them an attractive cell type to target for re-programming. To investigate CAF-cancer cell crosstalk we developed a 3D *in vitro* model of CAF-led invasion using heterocellular spheroids of cancer cells and CAFs. RNA sequencing of chimeric mouse/human versions of these spheres identified complementary expression of ephrin family receptors (Eph-B2) and ligands (EFNB2) between cancer and CAFs respectively, implicating their involvement in invasion. Part of the receptor tyrosine kinase superfamily, the ephrin family are unique in that both the ligand and receptor can signal, with implications of this having been well described in vasculogenesis and axon guidance. Utilising CAFs expressing either EFNB2 knockout or a gain-of-function mutation in EFNB2, we have found that both forward and reverse signalling is required for invasion, suggesting that disruption of both elements could be beneficial therapeutically. Using first-in-class inhibitors of this pathway, we observed a significant decrease in PDAC invasion in our 3D spheroid invasion model. Extending this *in vivo*, we have utilised a KPC-derived PDAC orthotopic mouse model that recapitulates human biology through the formation of both primary and metastatic disease. We found that tumour growth and size were not affected by ephrin blockade. However, eph-ephrin signalling inhibition did cause a significant decrease in metastatic tumour presence across multiple organ sites. This highlights a potential for this treatment to halt disease progression and reverse disease severity. We hope to extend these results further to test the potential clinical applications of this compound as a treatment option for both early and late-stage PDAC patients.

#3860 Metastasis score: A powerful tool to determine the metastatic potential and the appropriate adjuvant therapy of melanoma.
K. Shen, C. Wei, J. Gu;
Fudan University, Shanghai, China

Metastasis is the onerous challenge in the prognosis of melanoma patients. Accurately predicting the metastatic potential of non-metastatic melanoma (NMM) and determining effective postoperative adjuvant therapy for inhibiting metastasis remain uncertain. In this study, we conducted comprehensive analyses of melanoma metastases using bulk and single-cell RNA sequencing data, enabling the construction of a metastasis score (MET score) through multiple machine-learning algorithms. The reliability and robustness of the MET score were validated by various in vitro and in vivo assays. Our findings revealed a distinct molecular landscape in metastatic melanoma summarized by the enrichment of metastasis-related pathways, complex cell-cell communication, and heightened infiltration of pro-angiogenic tumor-associated macrophages compared to NMM. Importantly, patients of the high MET score group exhibited poorer prognoses and immunosuppressive microenvironment, featuring increased infiltration of regulatory T cells and decreased infiltration of CD8+ T cells, compared to the low MET score patient group. Expression of PD-1 was markedly higher in patients of low MET scores. Anti-PD-1 (aPD-1) therapy profoundly affected antitumor immunity activation and metastasis inhibition in these patients. In summary, our study demonstrates the effectiveness of the MET score in predicting melanoma metastatic potential. For patients with low MET scores, aPD-1 monotherapy may be a potential treatment strategy to inhibit metastasis. Patients with high MET scores may benefit from combination therapies.

#3862 OC201 and OC202e, potential inhibitors of cancer metastasis, suppress EMT in pancreatic cancer.

Youngjin Kim, Dong Sub Jung, Sewon Kim, So Jung Sung, Yenny Kim, Yi Rang Kim, **Jihoon Kang**

Oncocross Co., Ltd, Seoul, Korea, Republic of

Objective: Pancreatic cancer is among the most aggressive malignancies, associated with a very poor prognosis due to its rapid progression and resistance to conventional therapies, underscoring the urgent need for novel treatment approaches. Epithelial-mesenchymal transition (EMT) is a key process that enhances the migration and invasion capabilities of cancer cells and is recognized as a pivotal mechanism driving malignancy in pancreatic cancer. Inhibiting EMT is therefore a critical therapeutic strategy. This study aimed to evaluate the anti-metastasis efficacy and define the mode of action of OC201 and OC202e in EMT-induced pancreatic cancer cells.
Method: EMT was induced in Panc-1 and MIA PaCa-2 cells through treatment with TGF-β1 (5 ng/ml) and TNF-α (10 ng/ml). Cell migration and invasion were assessed through functional assays, while EMT-related markers (E-cadherin, ZEB1, Snail, Vimentin, and MMP-2) were analyzed via qPCR and Western blot. The cells were subsequently treated with OC201 and/or OC202e, and changes in expression of EMT-related signaling proteins were evaluated. An *in vivo* hepatic metastasis model was also established using MIA PaCa-2 cells to evaluate the effects of OC201 and/or OC202e treatment on metastasis following four weeks of therapy.
Results: Treatment with TGF-β1 and TNF-α significantly increased migration and invasion in both Panc-1 and MIA PaCa-2 cells, accompanied by decreased E-cadherin expression and increased expression of ZEB1, Snail, and Vimentin. Treatment with either OC201 or OC202e reduced cell migration and invasion, suppressed the expression of EMT markers (ZEB1, Snail, Vimentin, and MMP-2), and increased E-cadherin expression. Both compounds inhibited the activation of key EMT signaling proteins, AKT and IκBα, with combination treatment resulting in a stronger inhibition of AKT and IκBα activation and an enhanced E-cadherin expression compared to monotherapy. OC202e alone inhibited autophagy, while OC201 showed no significant effect. In the hepatic metastasis model, both OC201 and OC202e monotherapy significantly reduced liver metastatic nodules in mice compared to control, with combination therapy yielding a more substantial reduction, confirming the efficacy in reducing metastasis to the liver.
Conclusion: This study demonstrated that OC201 and OC202e effectively inhibited TGF-β1- and TNF-α-induced EMT via the AKT and NF-κB signaling pathways, highlighting their potential to target critical mechanisms underlying pancreatic cancer metastasis. Both compounds effectively suppressed EMT while maintaining cell viability, with combination therapy exhibiting superior efficacy. These findings suggest that the combined use of OC201 and OC202e may serve as a promising therapeutic strategy for pancreatic cancer.

#3863 Targeting TACC3 inhibits metastasis in breast cancer with centrosome amplification.

Mustafa Emre Gedik[1], Ozge Saatci[1], **Kubra Calisir**[1], Metin Cetin[1], Burge Ulukan Altun[1], Ozlem Sener Sahin[1], Rony Hull[2], Lauren Ball[2], Elizabeth Hill[3], Chaemin Lim[4], Sridhar Vempati[4], Burcu Caliskan[5], Erden Banoglu[5], Ioulia Chatzistamou[6], Ozgur Sahin[1]

[1]Department of Biochemistry and Molecular Biology, MUSC Hollings Cancer Center, Charleston, SC,[2]Department of Cell and Molecular Pharmacology and Experimental Therapeutics, MUSC, Charleston, SC,[3]Department of Public Health Sciences, MUSC, Charleston, SC,[4]A2A Pharmaceuticals, Inc., New York, NY,[5]Department of Pharmaceutical Chemistry, Gazi University, Faculty of Pharmacy, Ankara, Turkey,[6]Department of Pathology, Microbiology & Immunology, University of South Carolina, Columbia, SC

Centrosome amplification (CA) is highly prevalent in cancer. It is strongly associated with tumor progression and worse prognosis in a variety of different cancers. Preclinical studies have demonstrated that CA can trigger tumor initiation as well as cancer cell invasion. Thus, CA is known to be a promising therapeutic target. We have previously identified Transforming Acidic Coiled-Coil Containing Protein 3 (TACC3) as being overexpressed in tumors with CA. TACC3 forms distinct functional interactomes regulating spindle stability, clustering extra centrosomes and transcription of key tumor suppressors in mitosis and interphase to ensure proliferation and survival of cancer cells with CA. Despite the known mechanisms in tumor growth inhibition, the molecular mechanisms by which TACC3 drives tumor invasion and metastasis in cancers with CA remain underexplored. Here, we aim to test TACC3 targeting as a novel strategy to block invasion and metastasis and to elucidate the underlying mechanisms. We found that higher TACC3 levels are strongly associated with worse metastasis-free survival in breast cancer patients with CA. Using a combination of *in vitro* assays, transcriptomics, proximity labeling (APEX2-TACC3), and mass spectrometry, we demonstrate that TACC3 promotes cancer cell migration and invasion. In addition, we provide evidence that targeting TACC3 via a small-molecule inhibitor or CRISPR-Cas9-mediated knockout significantly reduces cell migration and invasion. Furthermore, TACC3 inhibition reduces the number of circulating tumor cells and spontaneous metastasis to the lungs in the MMTV-PyMT transgenic mouse model and lung-tropic breast cancer xenografts without any toxicity. Overall, our findings demonstrate the potential for TACC3 as a therapeutic target to inhibit metastasis in breast cancer with CA. This work offers new insights into the molecular underpinnings of TACC3's role in metastatic breast cancer, particularly in CA-driven tumors and underscores its therapeutic relevance.

#3864 AOH1996: A multi-faceted inhibitor of metastasis via PCNA and tumor microenvironment targeting.

Robert G. Lingeman[1], Robert Hickey[1], Linda Malkas[1], Mustafa Raoof[1], Jacob Cawley[2]

[1]Beckman Research Institute of The City of Hope, Duarte, CA,[2]Case Western Reserve University, Cleveland, OH

Metastasis remains the leading cause of cancer-related mortality, emphasizing the urgent need for therapies to prevent and treat this process. AOH1996, a selective inhibitor of proliferating cell nuclear antigen (PCNA), has emerged as a promising agent with anti-metastatic properties. AOH1996 disrupts critical pathways such as angiogenesis, cancer cell migration, and tumor microenvironment modulation. Through bulk RNA-seq analysis of cancer cells, AOH1996 was found to downregulate genes involved in angiogenesis and migration, processes essential for metastasis. Functional assays using highly metastatic osteosarcoma cell lines revealed that AOH1996 inhibited cell proliferation and migration in both 2D monolayer and 3D spheroid models. In 3D cultures, which closely mimic the tumor microenvironment, AOH1996 significantly suppressed cell invasion and growth, demonstrating its efficacy in a more physiologically relevant context. The anti-metastatic potential of AOH1996 was further validated using an ex vivo Pulmonary Metastasis Assay (PuMA), where osteosarcoma cells implanted into mouse lungs were effectively killed by AOH1996. This highlights its ability to directly target metastatic cells in the lung. Complementary cell invasion assays using Matrigel showed that AOH1996 altered the morphology of invadopodia—structures critical for tissue invasion—rendering them non-functional and significantly reducing invasive capacity. Preliminary data from a Phase I clinical trial (NCT05227326) in patients with advanced, chemo-refractory solid tumors demonstrated AOH1996's clinical potential. In one patient with pancreatic cancer, AOH1996 reduced the size of two liver metastases by 50%, underscoring its efficacy in a clinical setting. Tumor-associated macrophages (TAMs) facilitate immune evasion, angiogenesis, and metastasis. Oncogenic MYC influences the tumor microenvironment (TME) by recruiting TAMs to the TME. We have found that AOH1996 inhibits MYC expression in cancer cells, but not in non-malignant cells. We hypothesize that this suppression of MYC by AOH1996 disrupts the formation of a supportive metastatic niche through reduced TAM recruitment. Thus, AOH1996 may enhance immune responses and impede angiogenesis and metastasis. Together, these findings establish AOH1996 as a multi-faceted therapeutic with significant anti-metastatic potential. By targeting both PCNA-dependent processes and the tumor microenvironment, AOH1996 could provide a unique approach for combating metastatic cancers.

#3865 Targeting MYC high osteosarcoma through EYA2 modulation.

Ryota Shirai, Sydney Hakim, Avery Bodlak, Masanori Hayashi

University of Colorado Anschutz Medical Campus, Aurora, CO

Osteosarcoma is the most common bone cancer in children, adolescent and young adults. Recent large scale genomic studies have started to reveal that Osteosarcoma (OS) patients who have tumors that highly express the transcription factor MYC, are significantly at high risk of treatment failure. However, MYC has long been known to be extremely difficult to target with drugs. The EYA protein is an evolutionarily conserved transcriptional co-activator of the SIX1 family of homeobox proteins, which also has phosphatase activity. Multiple studies have shown that EYA is involved in the initiation and progression of various cancers. EYA Tyrosine Phosphatase has been shown to regulate MYC expression and protein stability in Brain tumors. In OS cells, EYA2 is highly expressed and has been indicated to be involved in tumor progression and invasion, but the interaction between EYA2 and MYC is unknown. The major goal of our study is to clarify the effect of EYA2 on the expression of MYC in OS cells, and evaluate it as a therapeutic target.
First, EYA2 and MYC expression in various OS cell lines were confirmed using western blotting. Next, we established EYA2 shRNA knock-down in 143B cells and CHCO-OS1 cells, which highly express both EYA2 and MYC. Interestingly, in these cells, EYA2 knock-down led to decreased MYC expression, decreased clonogenicity and proliferation. Furthermore, EYA2 knock-down led to decreased cell migration in 143B cells when measured by a scratch assay using the Incucyte live cell imaging. Next, we also tested 9987, an allosteric EYA2 phosphatase inhibitor. Here, 9987 was shown to inhibit the clonogenicity, proliferation and migration compared to DMSO control.
These results indicate that in MYC-high OS cells, EYA2 knockdown leads to decreased MYC expression, decreased proliferation, clonogenicity, and migration, and EYA2 phosphatase inhibition is a promising therapeutic strategy for this tumor. We are currently confirming whether the EYA2 inhibitor 9987 can reduce metastatic rate and extend overall survival in our orthotopic-implantation-amputation mouse model, and further identifying the mechanisms of how EYA2 regulates MYC activation in OS.

#3866 A new approach to suppress triple-negative breast cancer metastasis by blocking apurinic/apyrimidinic endonuclease 1 interaction with G-quadruplex.

Yingling Chen[1], Suravi Pramanik[1], Mason Tarpley[1], Achyuth Kalluchi[1], Sutapa Ray[2], Bhopal Mohapatra[1], Kyle Hewitt[1], Jordan Rowley[1], Vimla Band[1], Kishor K. Bhakat[1]

[1]Department of Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Department of Pediatrics, University of Nebraska Medical Center, Omaha, NE

Triple-negative breast cancer (TNBC) has a relatively high metastasis rate as compared to other breast cancer subtypes. Metastasis and tumor recurrence remain major challenges for TNBC patients, resulting in poor prognosis. Therefore, it is imperative to identify and elucidate the molecular mechanisms that drive metastasis to allow the development of new therapeutic agents to inhibit TNBC metastasis and improve patients' outcomes. Herein, we uncovered a new mechanistic connection between a multifunctional DNA repair protein APE1 and G-quadruplex (G4), a secondary DNA structure present in many metastasis-related signature genes promoters in TNBC. We found that APE1 is highly enriched at the G4 regions on the promoters of metastasis related genes and APE1 knockout or knockdown impairs the tumorigenic and pro-metastatic traits of TNBC cell lines in vitro. Intriguingly, we found that G4 is required for APE1's enrichment at these promoters and APE1 promotes transcription factors (TFs) binding to these promoters, thereby promoting the expression of these metastasis-related genes. Deletion of APE1 impeded TFs' binding to promoters and downregulated expression of these genes. In addition, we found that G4 deletion in some target gene promoters exerted similar inhibitory effects as APE1 knockout on cell migration, cell invasion and tumor sphere formation. We discovered that a small molecule which disrupts APE1: G4 interaction significantly disrupted APE1's enrichment to G4 on promoters, thereby blocking TFs binding, gene expression, cell migration, invasion and tumor sphere formation in vitro. We generated orthotopic TNBC metastasis mouse model using an aggressive TNBC cell line, MDA-MB-231 and found that disrupting G4-APE1 axis either by APE1 knockout or G4 deletion or small molecules significantly inhibited the primary tumor growth and impeded TNBC distant metastasis to lungs. Overall, our study uncovered a novel functional axis of G4-APE1 in regulating TNBC growth and metastasis and identified that this regulatory axis has the potential to serve as a new therapeutic target to prevent metastasis in TNBC patients.

#3867 Small molecule inhibitors targeting TG2 in ovarian cancer and identification of drug escape pathways.

Monica Tudor[1], Cristian Munteanu[1], Gabriela Chiritoiu[1], Stefana Orobeti[1], Alexandra Bran[2], Florin Jipa[2], Felix Sima[2], Gary E. Schiltz[3], Daniela Matei[3], **Livia Elena Sima**[1]

[1]Molecular Cell Biology, Institute of Biochemistry of the Romanian Academy, Bucharest, Romania,[2]Cetal, National Institute of Laser Plasma and Radiation Physics, Magurele, Romania,[3]Northwestern University, Chicago, IL

Ovarian cancer (OC) is the 8th most common cancer in women. Most patients with high-grade serous OC present with intraperitoneal disseminated disease when diagnosed, due to mild symptoms in earlier disease stages. They respond efficiently to cisplatin or taxol-based compounds in the front-line treatment; however, resistance emerges in the majority of cases, which allows tumors to progress. There is an urgent need for improved treatment to increase patients' survival. Tissue transglutaminase (TG2) is a protein overexpressed in many solid tumors, including ovarian; it interacts with fibronectin (FN) in the extracellular matrix and promotes OC intraperitoneal dissemination. This makes TG2 a promising target for treatment. We previously identified MT4 as a promising small molecule inhibitor (SMI) able to disrupt TG2-FN protein-protein interaction, prevent cancer cell adhesion and spheroid formation, and sensitize OC cells to chemotherapeutic drugs, such as paclitaxel (*Sima LE et al., Mol Cancer Ther., 2019*). We recently investigated the effect of 5 new MT4 analogues on OC cells behavior. We found that compound #3011 completely prevented spheroids formation, similar to *Tgm2* gene excision, while #3002 decreased cell adhesion onto FN. We used phosphoproteomics to analyze the adaptive signaling of OC cells treated with MT4 that escape treatment. New promising molecular TG2 co-targets for OC treatment have been identified as effectors of MT4 escape pathways: sirtuins and p21-activated kinases (PAKs). Combination of signaling inhibitors and TG2-directed SMIs induce OC cell death in both 2D and 3D conditions, with potential for future therapeutic use. Our multiplex IHC data shows that in OC tumors TG2 is expressed by cancer cells, as well as by α-SMA$^+$ CAF subset. Therefore, we next sought to test the effect of TG2 drug targeting on OC cells-fibroblasts 3D co-cultures. Our results showed that MT4 prevents heterospheroid self-assembly *in vitro*, which indicates potential disruption in tumor-stroma communication using TG2-directed therapies. In parallel, we developed new tools to test drug combinations, as well as radiation therapy regimens for their potential to inhibit cancer spreading. We produced a new glass microfluidic chip and adapted a miniaturized mesothelial clearance assay for live cell imaging. We obtained new SKOV3 and SKOV3-TG2KO LifeAct$^+$ stable cell lines to allow real time imaging measurements of OC cell behavior. Subpopulations were sorted based on actin-GFP expression level and characterized by cell motility quantification. Cell lines with behavior similar with parental cells were selected for further use. We currently use these tools to investigate the potential of TG2 targeting to enhance response of cancer cells to new FLASH radiation sources (*Orobeti S et al, Sci. Rep., 2024*), such as very high energy electrons generated with a high-intensity laser plasma accelerator system.

#3868 Decreased metastatic burden in a spontaneous metastatic melanoma model by inhibiting myeloid-derived suppressor cell function.

Kaitlyn M. Landreth[1], Angisha Basnet[1], Mary Garland-Kledzik[2], Brian A. Boone[2], Tracy W. Liu[1]

[1]Department of Microbiology, Immunology, and Cell Biology, West Virginia Univ. Health Sciences Ctr., Morgantown, WV, [2]Department of Surgery, West Virginia Univ. School of Medicine, Morgantown, WV

Metastatic melanoma is the leading cause of skin cancer-related deaths, with a five-year survival rate of only 30%. Myeloid derived suppressor cells (MDSCs) are considered a driver of metastatic progression, supporting pre-metastatic niche formation, facilitating tumor cell migration, invasion, and extravasation and promoting immune evasion. This study evaluates the contribution of myeloperoxidase (MPO) and extracellular trap formation in melanoma metastasis. Using a spontaneous melanoma metastasis model, we demonstrate metastases in the lungs, bone, and lymph node approximately 4 weeks post surgical resection of primary subcutaneous B16F10 tumors. Tumor growth and metastatic burden were quantified using a bioluminescent reporter stably expressed in B16F10 cells. Syngeneic myeloperoxidase-deficient and peptidyl arginine deiminase 4 (PAD4)-deficient mice, as well as C57BL/6J wild-type mice treated with an MPO-specific inhibitor or hydroxychloroquine (an extracellular trap inhibitor), exhibited significantly reduced lung and bone metastases compared to untreated wild-type controls. PAD4, a critical enzyme in extracellular trap formation, was essential for these effects. Targeting myeloperoxidase or extracellular traps significantly reduced MDSC populations while increasing B cells in the metastatic microenvironment, as assessed by flow cytometry. Ex vivo assays revealed diminished MDSC-mediated suppression of T and B cells when myeloperoxidase or extracellular trap formation was inhibited. Notably, depletion of B cells abrogated the anti-metastatic effects of targeting myeloperoxidase or extracellular traps, highlighting B cells as central mediators of metastasis suppression. These findings demonstrate that targeting myeloperoxidase or extracellular trap formation reduces metastatic burden and mitigates MDSC-mediated pro-metastatic and immunosuppressive functions. This work underscores the therapeutic potential of targeting myeloperoxidase and extracellular trap formation in combating melanoma metastasis.

#3869 Targeting anoikis resistance in ovarian cancer via metabolic enzyme inhibition.

Geeta Rao, Pallab Shaw, Shailendra Dwivedi, Priyabrata Mukherjee

University of Oklahoma Health Sciences Center, Oklahoma City, OK

Ovarian cancer (OvCa) is the deadliest gynecologic malignancy, with poor prognosis largely due to late-stage diagnosis and metastasis, which limit treatment options and contribute to high mortality. Anoikis resistance, a key mechanism enabling metastatic spheroids to survive in the peritoneal cavity, drives both metastasis and therapy resistance. Therefore, understanding the regulation of anoikis is critical for identifying novel therapeutic targets. Recent studies, including work from our group, have identified overexpression of cystathionine beta-synthase (CBS)—an enzyme that produces hydrogen sulfide (H2S)—as a contributor to OvCa progression. CBS has been shown to promote cancer progression through enhanced lipogenesis and mitochondrial fusion. Based on these findings, we hypothesize that CBS plays a central role in anoikis resistance in OvCa and propose that targeting CBS could inhibit metastasis and improve sensitivity to chemotherapy. To investigate the functional role of CBS in anoikis resistance, we utilized OvCa cell lines (COV318, OVCAR8, OVCAR4, and A2780_CP20) and achieved CBS silencing via siRNA-mediated knockdown. Cells were cultured in both monolayers (2D) and spheroids (3D) to better mimic in vivo tumor conditions. Our findings reveal that: (i) High CBS expression is associated with poor median survival in stage 3 and stage 4 high-grade serous ovarian cancer (HGSOC) patients, (ii)CBS expression directly correlates with elevated expression of stemness and epithelial-to-mesenchymal transition (EMT) markers, (iii) CBS silencing induces anoikis in both COV318 (ascites-derived) and A2780_CP20 (drug-resistant) OvCa cell lines, (iv) CBS silencing disrupts integrin-mediated downstream signaling through focal adhesion kinase (FAK) in both 2D and 3D cultures. These findings establish CBS as a critical regulator of anoikis resistance in ovarian cancer, underscoring its potential as a therapeutic target to suppress metastasis and enhance the efficacy of existing chemotherapy regimens.

#3870 Ruxolitinib diminishes cell proliferation and invasiveness in BRAF mutated metastatic melanoma.

Raza Ahmed[1], Jayesh Menon[2], Rishka Raj[3], Rakesh Singh[1], Philip Friedlander[4], Omar Aljitawi[1]

[1]University of Rochester Wilmot Cancer Institute, Rochester, NY,[2]University of Rochester School of Medicine and Dentistry, Rochester, NY,[3]IMC University of Applied Sciences Krems, Krems, Austria,[4]Icahn School of Medicine at Mount Sinai, New York City, NY

Introduction: Treatment with a BRAF inhibitor of unresectable or metastatic melanoma with a BRAF V600E or V600K mutation has an estimated 5-year survival rate of 34%, with 19% being progression free. To improve outcomes, we hypothesize that the blocking of the JAK/STAT pathway via the use of Ruxolitinib, a direct JAK2 inhibitor, may decrease proliferation and invasiveness in BRAF mutated melanoma in vitro.

Methods: *BRAFV600E* mutated melanoma cell line, SK-MEL-1, was obtained from ATCC. The effect of Ruxolitinib of proliferation was measured via a proliferation assay. Cells were treated with 0nM Ruxolitinib and 10nM Ruxolitinib for 24 hours, then counted with a hemocytometer. The effect of Ruxolitinib on invasiveness was evaluated through an invasion assay. After 24-36 hours, cells that invaded through a Matrigel coated membrane were fixed and stained with crystal violet, and then subsequently imaged by an inverted microscope. The number of invaded cells was quantified, and the total number of invaded cells was calculated by averaging the cell density (cells/um^2) for each image and then multiplying that by the total membrane area. All data was normalized to their respective controls and analyzed using the appropriate statistical analysis.

Results: In cells containing a BRAF mutation, Ruxolitinib caused a decrease in erythropoietin (EPO) induced proliferation. Modulation of *EPOR* with EPO, 10nM Ruxolitinib, and 10nM Ruxolitinib with EPO yielded a mean fold change over control in proliferation of 1.55 (95% CI: 1.16-1.94), 0.96 (95% CI: 0.84-1.09), and 1.24 (95% CI: 0.77-1.72), respectively (p=0.0254). In metastatic melanoma cells, Ruxolitinib significantly reduced invasiveness by a 0.48-fold change over control in proliferation. Additionally, Ruxolitinib blocked EPO induced increase in invasion, as EPO caused a 2.2-fold increase over control in invasiveness, however with the addition of Ruxolitinib there was a -0.04-fold change over control in invasion.

Discussion: Here we show that *JAK2* inhibition with Ruxolitinib diminishes erythropoietin (EPO) induced cell proliferation in an in-vitro model of invasive *BRAF*-mutated melanoma. We also show that Ruxolitinib decreases the invasive nature of metastatic melanoma, at baseline and when induced by EPO. Erythropoietin Receptor (EPOR) transduces signal through JAK/STAT and potentially contributes to a more aggressive phenotype. This provides initial evidence for future studies exploring the therapeutic role of Ruxolitinib in *BRAF* mutated melanoma. We further hypothesize that Ruxolitinib can be used in conjunction with BRAF inhibitors, such as Dabrafenib, to improve outcomes in metastatic melanoma.

#3871 Methyl jasmonate reduces proliferation and migration of head and neck cancer cell lines.

Jorge Viera-Vera[1], Maria M. Sanchez-Vazquez[1], Nicole J. Sariego-Hassan[2], Adianez Rosario-Vazquez[3], Magaly Martinez-Ferrer[1]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Inter American University of Puerto Rico, Bayamon, Puerto Rico,[3]University of Puerto Rico, Mayaguez, Puerto Rico

Head and neck squamous cell carcinomas (HNSCC) arise from the mucosal lining of the oral and nasal cavities, pharynx, and larynx. The 2022 Global Cancer Statistics identify HNSCC as the sixth most common and seventh most lethal cancer globally, with 891,453 new cases and 458,107 fatalities. Over half of patients with HNSCC are diagnosed at an advanced stage, this has been associated with difficulties in early diagnosis, tumors with significant local invasion, and metastases in regional nodes. The Surveillance, Epidemiology, and End Results Program (SEER) estimates about 54,000 new HNSCC cases and 11,230 deaths in the United States during 2022, contributing to approximately 2% of all cancer deaths. The 5-year survival varies by stage at diagnosis, fluctuating from 86.3% for localized disease to 40.4% for metastatic disease. Current treatments for HNSCC include surgery, radiation, and chemotherapy, which can lead to serious side effects and may offer limited efficacy. Researchers have recently focused on exploring new complementary therapies. This study aims to analyze how methyl jasmonate (MeJa) affects HNSCC cell lines A-253 and SCC9 with special emphasis on cell migration. Methyl jasmonate is a plant-derived hormone that has been proven to exhibit highly selective cytotoxicity toward cancer cells that may prove to be a potentially less toxic therapeutic agent. The half maximal effective concentration (EC50) for MeJa was determined employing the MTS Assay Colometric Kit (Abcam, USA) and following the manufacturer instructions. Wound healing assays using the scratch method were performed and image data was collected with an Olympus LC35 camera attached to an CKX53 microscope. All experiments were performed in triplicates and data was analyzed using GraphPad Prism. MeJa inhibited the proliferation of A-253 and SCC9 HNSCC cell lines in a dose-dependent manner with estimated IC_{50} values of 2.23µM and 2.05µM respectively. Furthermore, the wound healing assay showed that MeJa significantly decreased cell migration in the A-253 cell lines at 12 and 24 hours after treatment. Our findings support the potential effects of methyl jasmonate on cellular events such as cell proliferation and migration during tumor progression of head and neck squamous cell carcinomas.

#3872 Fatty acid synthase inhibition to prevent metastatic colonization by pancreatic neuroendocrine tumor cells.

Piotr Rychahou[1], Benjamin M. Evers[1], Yekateriza Zaytseva[1], Courtney M. Townsend[2], B. Mark Evers[1]

[1]University of Kentucky, Lexington, KY,[2]University of Texas Medical Branch, Galveston, TX

Introduction: Pancreatic neuroendocrine tumors (pNETs) are among the most frequently occurring neuroendocrine neoplasms. At the time of diagnosis most patients have extensive metastatic disease and are not candidates for curative surgical resection. Therefore, identification of pathways that promote pNET metastasis is critical for developing targeted therapies to prevent cancer cells from colonization of parenchymal organs. The purpose of this study was to determine whether fatty acid synthase (FASN) inhibition can be used as a target against metastatic spread of pNETs.

Methods: Expression of FASN was evaluated in pancreatic neuroendocrine primary and metastatic tumors and scored by a pathologist. Neutral lipid droplet levels in BON, QGP-1 and NT-3 cell lines were determined with BODIPY 493/503 staining. Clonogenic and SRB assays were used to evaluate cytotoxic effects of FASN inhibition by TVB-3664 in QGP-1 and BON pNET cell lines. Western blot analysis was used to determine levels of cleaved PARP and cyclin D1 after FASN inhibition. FASN knockdown was used to delineate the effects of FASN downregulation on proliferation and lipid synthesis. Intravenous (iv) and intraperitoneal (ip) injections of BON GFP-Luc cells were used to establish lung metastasis and peritoneal carcinomatosis, respectively.

Results: FASN expression was determined at the maximum scores of 6 and 5 in 98% of patient samples. Highest levels of neutral lipid droplets were observed in the BON cell line. BON and QGP-1 cells were treated with TVB-3664 in either complete media with fatty acids (FA+) or complete media prepared with fatty acid depleted (FA-) FBS. Treatment with TVB-3664 resulted in significant inhibition of QGP-1 cell proliferation and cyclin D1 expression in both FA+ and FA- conditions. Depletion of extracellular FA enhanced the effect of TVB-3664 therapy on NET cells. FASN inhibition with TVB-3634 suppressed pNET cell proliferation and colony formation. Knockdown of FASN resulted in over 90% suppression of lung metastasis colonization. Pretreatment of BON GFP-luc cells with FASN inhibitor TVB-3664 before iv or ip injections also significantly suppressed lung metastasis colonization and peritoneal carcinomatosis.

Conclusions: Our study demonstrated high expression levels of FASN in pNET patient samples and cell lines. QGP cell viability was significantly decreased with FASN inhibition even in the presence of extracellular lipids. FASN inhibition alone in BON cells had only a minimal effect on cell viability and required depletion of extracellular lipids to achieve a significant decrease in cell viability. Despite minimal effects on BON cell viability, pretreatment with TVB-3664 in FA+ conditions had a pronounced effect on lung colonization and peritoneal carcinomatosis. These data demonstrate an essential role of de novo lipid synthesis in the pNET metastatic cascade - colonization of parenchymal organs.

#3873 Uncovering key regulators of OSCC invasion: A pathway to novel therapeutic strategies.

G. Flores[1], S. Uaroon[1], J. A. Raygoza Garay[1], M. R. Buchakjian[2];
[1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]University of Michigan, Ann Arbor, MI

Recurrence and metastasis are the primary drivers of poor prognosis in patients with Oral Squamous Cell Carcinoma (OSCC), even after aggressive surgical interventions. To uncover the genetic regulators of OSCC invasion and migration, we conducted a first-of-its-kind genome-wide CRISPR screen. This screen identified several key players involved in epithelial-mesenchymal transition (EMT), a critical process in tumor progression and metastasis. Among the top hits was *EDIL3*, a gene that codes for a secreted protein that promotes EMT and chemotherapy resistance by interacting with integrin receptors in the extracellular matrix. Though previously implicated in other cancers, EDIL3's role in OSCC has not been described. Additionally, our screen highlighted NISCH as the top anti-invasion hit, a gene whose expression is positively correlated with survival in head and neck cancers, including OSCC. NISCH appears to inhibit EDIL3-driven invasion by interfering with integrin-mediated signaling, potentially via a FAK and WNT5a-dependent mechanism. Current work is focused on characterizing *EDIL3* and *NISCH* knockouts to validate their roles in OSCC migration and invasion. Functional assays such as spheroid formation and wound healing experiments are being performed to assess the impact of these knockouts on tumor cell behavior. Additionally, we are investigating FDA-approved drugs targeting these pathways to explore immediate translational potential. This research represents a novel approach to identifying genetic drivers of cancer metastasis and offers promising avenues for the development of targeted therapies for OSCC to reduce recurrence and improve patient outcomes.

TUMOR BIOLOGY: Cancer Cell Heterogeneity, Evolution, and Trajectory Profiling

Ewing sarcoma (EwS) is a highly aggressive pediatric cancer driven by the EWS::FLI1 (EF) fusion oncoprotein. Emerging evidence suggests that variations in EF expression levels may contribute to tumor cell plasticity, promoting treatment resistance and relapse. Both tumor intrinsic and extrinsic influences such as microenvironmental and therapy related factors, may influence EF thresholds. However, the phenotypic consequences of EF fluctuations at different amplitudes and intervals remain poorly understood. To address this, we engineered a EF threshold modulation system in A673 cells by tagging endogenous EF with a fluorescent mNeonGreen (mNG) and a degron tag (dTAG). Using mNG fluorescence as a quantitative proxy for EF levels, we established a stable and highly reproducible EF gradient through treatment with graded concentrations of the dTAG^V-1 ligand, ranging from 3 hours to 4 weeks. Phenotypic assays revealed that partial EF depletion (35-65%), but not near-complete loss (90-95%), significantly enhanced migratory and invasive behaviors in vitro, while minor reductions (15-35%) were sufficient to impair anchorage-independent growth. In vivo studies corroborated these findings, as partially EF-depleted cells upon EF restoration exhibited increased extravasation in zebrafish models and enhanced lung metastasis in immunocompromised mice. To elucidate the molecular basis underpinning EF threshold-dependent phenotypes, we integrated acute transcriptional changes from nascent RNA sequencing (SLAM-seq) with EF chromatin occupancy (CUT&RUN) data following 3 hours of dTAG^V-1 gradient treatment. A 15% reduction in EF resulted in immediate downregulation of EF-activated genes enriched for GGAA microsatellites in enhancers and upregulation of EF-repressed genes associated with monomeric ETS binding sites in EF-bound promoter regions. Interestingly, the largest group of EF repressed genes, associated with epithelial-to-mesenchymal transition (EMT), showed graded upregulation in response to increasing dTAG^V-1 concentrations. For these genes, EF binding was predominantly localized to promoter regions enriched for Krüppel-related zinc finger protein binding sites, implicating novel EF coregulators in mediating the migratory phenotype. Strikingly, transient EF depletion (3 weeks) followed by rapid EF restoration led to sustained upregulation of EMT-related genes and migratory behavior for up to 2 weeks after dTAG^V-1 ligand washout. Supporting these observations, approximately 20% of these genes correlated with poor prognosis in a cohort of 196 EwS patients. Our findings underscore the importance of EF expression dynamics in driving EwS cell plasticity and highlight therapeutic challenges posed by insufficient direct EF inhibition. These insights provide a foundation for exploiting oncogene dynamics to uncover therapeutic vulnerabilities in single oncogene driven cancers.

#3880 Functional dissection of the highly plastic basal cell state in pancreatic cancer.

Anupriya Singhal[1], Hannah Styers[1], Jonathan Rub[1], Kate Ryan[1], Jung Yun Kim[1], Zeynep C. Tarcan[1], Jill Hallin[2], Olca Basturk[1], Rona Yaeger[1], James G. Christensen[1], Yan Yan[1], Elisa de Stanchina[1], Tuomas Tammela[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Mirati Therapeutics, San Diego, CA

Pancreatic ductal adenocarcinoma (PDAC) is a treatment-refractory malignancy with a dismal prognosis. Targeting cancer cell plasticity—the capacity to adapt to cell-extrinsic pressure via non-genetic mechanisms—is a promising therapeutic strategy, yet cell states within PDAC harboring high plasticity remain poorly understood. Using genetically engineered mouse models driven by oncogenic KrasG12D and loss of p53 (“KPC” model), we profiled primary PDAC tumors using single-cell RNA sequencing and single cell ATAC sequencing. We find that the KPC model harbors a basal state, which harbors transcriptional signature that aligns with the "basal" signature in human PDAC and is linked to poor prognosis and chemoresistance. The basal state co-expresses both epithelial and mesenchymal programs and has a distinct epigenetic landscape with accessible chromatin across gene sets that mark cancer cell states with divergent phenotypes, suggesting that this cell state is primed for cell state switching. To functionally interrogate the basal state in PDAC progression, we developed a novel lineage-tracing and ablation system. Lineage-tracing experiments revealed that the basal state has a robust capacity for differentiation into epithelial and mesenchymal states, indicating that the basal state is functionally plastic and acts as a source of fixed malignant states. Strikingly, targeted elimination of the basal state over short time periods resulted in tumor collapse, underscoring a critical role in tumor maintenance. Further, we found that the basal state is highly dependent on KRAS activity, with acute KRAS inhibitor treatment leading to a selective depletion of the basal state. Taken together, our data indicates that PDAC harbors a striking dependency on the basal state and encourages therapeutic approaches aimed at eradicating this critical subset of cancer cells.

#3881 Comprehensive analysis of somatic mutagenesis in normal tissues across 19,643 samples reveals insights into clonal evolution and tumorigenesis.

Leonie Stockschlader[1], Eldar Abdullaev[1], Siddharth Annaldasula[1], Ino de Bruijn[2], Baby Anusha Satravada[2], Ritika Kundra[2], Rima Madupuri[2], Manuela Benary[3], Dieter Beule[3], Tim H. H. Coorens[4], Regine Armann[1], Nikolaus Schultz[2], Chris Sander[5], Kirsten Kubler[1]

[1]Department for Functional Diagnostics, Berlin Insitute of Health, Berlin, Germany,[2]Marie-Josee & Henry R. Kravis Center for Molecular Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Core Unit Bioinformatics, Berlin Insitute of Health, Berlin, Germany,[4]Broad Institute of MIT and Harvard, Cambridge, MA,[5]CompBio Collaboratory, Harvard Medical School, Boston, MA

The detection of somatic mutagenesis in normal tissues has transformed our understanding of clonal evolution, revealing a mosaic of somatic mutations, including those in cancer driver genes, that influence cellular behavior and tissue homeostasis. However, key questions remain about how these mutational patterns contribute to tumorigenesis and the role of cancer driver mutations in the transition from normal to malignant states. To address this, we performed a combined computational analysis of the largest normal-tissue DNA-sequencing and clinical dataset to date, spanning 21 published datasets, 37 tissue types, 521 patients, and 19,643 samples, and integrated these with precancer and cancer tissue data to identify tissue-specific mutational changes potentially critical for tumorigenesis. We identified tissue-specific differences in mutation burden, with epithelial tissues exhibiting significantly higher mutation rates than other tissue categories ($p<2x10^{-16}$). These differences were further reflected in the mutational signatures: UV-light signatures dominated sun-exposed epithelial tissues, while gastrointestinal epithelial tissues showed mutation burden driven by intrinsic factors. Regression analysis revealed that, alongside aging, mutations in specific driver genes (e.g., *ARID2*, *ATM*, *TP53*), but not others, were selectively associated with higher mutation rates, highlighting nuanced contributions to tissue mutagenesis. Further MutSig2CV and dN/dS analyses identified positively selected driver genes with distinct patterns based on tumorigenic pathways: tumors that develop through normal-to-dysplastic sequences (e.g., colon cancer) shared driver genes across all progression stages, reflecting clonal evolution within the same tissue lineage. In contrast, tumors arising from metaplastic processes (e.g., esophageal adenocarcinoma) shared mutated driver genes between cancer and precancer metaplastic tissues, but not normal tissues, suggesting selective pressures emerge during metaplasia. Across the cohort, most driver genes were highly mutated in cancer and present at lower mutation frequency in normal tissues. In contrast, similar to *NOTCH1* mutations, *CHEK2* mutations were significantly enriched in the normal esophagus but absent in cancer, hinting at potential tumor-suppressive effects. Taken together, our large-scale analysis has allowed us to detect previously unrecognized phenomena through increased statistical power. The analysis of normal tissue mutagenesis underscores its potential for predicting tissue-specific cancer risks. In addition, our integration of normal tissue data into the cBioPortal platform provides an important resource to support and advance future cancer research.

#3882 Patterns of genomic patient-model conservation and evolution in the Human Cancer Models Initiative (HCMI) next-generation cancer model resource.

Background: Patient-derived cancer models advance therapeutic development and are essential to studies of treatment resistance mechanisms. The Human Cancer Models Initiative (HCMI) has created 665 patient-derived models, including organoids, neurospheres, and conditionally reprogrammed cells, all paired with patient tumors and clinical annotations. This resource provides an opportunity to study genomic conservation and divergence during model development at scale in a large pan-cancer cohort of matched tumor-model pairs.
Methods: We characterized the genomes of models and parent tumors, computing allele specific Copy Number Variation (CNV), Single Nucleotide Variants (SNV), small Insertions and Deletions (InDels) and Structural Variations (SV) from bulk whole genome and whole exome Sequencing. We used pyclone to study changes in clonal abundances between tumor and model, MutationTimeR to understand the timing of model specific CNVs and Whole Genome Doubling (WGD), and AmpliconArchitect to identify ecDNA.
Results: HCMI models exhibited high concordance with matching tumors when evaluated on SNVs, SVs, InDels and CNVs, with 69% of SNV/InDel drivers and 43% of CNV drivers conserved between tumor and model. Only 2% of investigated models (9/405) showed significantly divergent patterns of aneuploidy and presence of distinct clonal outgrowth in the model. This included two pancreatic cancer models with oncogenic KRAS point mutations that differed from those in the parent tumor. The cohort included models and tumors with ecDNA affecting known oncogenes including EGFR in GBM samples, CCNE1/KRAS in esophageal cancer and MYC in pancreatic cancer. ecDNA were the least conserved aberration type; 20% (50/254) of tumor-detected ecDNA were retained in an associated model while 35% (50/143) of model-detected ecDNA were found in their parent tumors. While the tumors and models generally showed similar WGD states, 10% of models exhibited WGD private to the model, and this model specific WGD generally occurred later in estimated mutational evolution time than models for which the tumor and model were both WGD. Surprisingly, not all models were pure for cancer cells with 19 models, enriched for melanomas, containing more than 20% diploid presumably non-tumor cells.
Discussion: HCMI models exhibited high genomic concordance with their matching tumors across all cancer types. We catalogued classes of genomic divergence representing either selection of subclones or evolution during model development. SNVs and InDels exhibited greater conservation compared to CNVs, with ecDNA showing the highest variability between the tumor and the model. Our results provide full visibility into the genomic fidelity of each HCMI model, and enable researchers to select the most relevant HCMI model for their study.

#3883 Evolution of genomic and epigenomic heterogeneity in prostate cancer from tissue and liquid biopsies.

Marjorie Roskes[1], **Alexander Martinez-Fundichely**[1], Weiling Li[1], Sandra Cohen[1], Hao Xu[2], Shahd ElNaggar[3], Anisha Tehim[4], Metin Balabin[5], Chen Khuan Wong[6], Yu Chen[6], Ben Raphael[5], Ekta Khurana[1]

[1]Weill Cornell Medicine, New York, NY,[2]McGill University, Montreal, NY, Canada,[3]Barnard College, New York, NY,[4]Cornell University, Ithaca, NY,[5]Princeton University, New Jersey, NY,[6]Memorial Sloan Kettering Cancer Center, New York, NY

Castration resistant prostate cancer (CRPC) is an aggressive, highly plastic, late-stage disease. We previously showed that the two histological subtypes, adenocarcinoma (CRPC-Adeno) and neuroendocrine (CRPC-NE), show four epigenetic and transcriptomic subtypes: CRPC-AR depends on the androgen receptor pathway, CRPC-SCL is stem-cell like, CRPC-WNT is dependent on the WNT pathway, and CRPC-NE has high expression of neuroendocrine markers. Here, by analyzing data from 500 patients with tissue and/or liquid biopsies, we uncover the landscape of molecular heterogeneity in patient tumors. Analysis of whole-genome sequencing revealed genomic variants associated with CRPC-SCL and allowed development of a computational classifier which can predict presence of CRPC-SCL in patient tumors solely using genomic alterations with 81% accuracy. In particular, analysis of matched chromatin conformation data (Hi-C) showed a complex rearrangement on chromosome 4 disrupts enhancer - promoter contacts leading to downregulation of *MOB1B*, which can lead to upregulation of the *YAP/TAZ* pathway that is characteristic of CRPC-SCL. Joint computational inference of epigenomic state and genomic variants from cell-free DNA collected at multiple points during the evolution of resistance to AR signaling inhibitors allowed investigation of genomic and epigenomic co-evolution at an unprecedented resolution. We discuss the current limits of detection for tumoral epigenomic and genomic states using cell-free DNA for clinical application. Importantly, our study demonstrates the utility of liquid biopsies for discovery of basic biological mechanisms leading to treatment resistance, beyond their use for biomarkers.

#3884 Uneven inheritance and functional heterogeneity derived from extrachromosomal DNA enable rapid adaptation of cancer cells.

Shu Zhang[1], Aditi Gnanasekar[1], Ellis J. Curtis[1], Jun Tang[1], Vishnu Shankar[1], Ivy Tsz-Lo Wong[1], Xiaowei Yan[2], Rui Li[2], Lu Yang[1], Howard Y. Chang[2], Paul S. Mischel[1]

[1]Department of Pathology, Stanford University, Palo Alto, CA,[2]Department of Dermatology, Stanford University, Palo Alto, CA

The amplification of oncogenes on extrachromosomal DNA (ecDNA) is common in cancer and associated with poor outcomes. Uneven inheritance of ecDNA during cell division leads to intratumoral ecDNA copy number heterogeneity. However, the relationship between shifts in ecDNA copy number and the rapid environmental adaptation of cancer cells remains unclear. In this study, we utilized imaging and single-cell multi-omics analyses to demonstrate that the transcript and protein expression of ecDNA oncogenes, along with functional heterogeneity, correlate with ecDNA copy number heterogeneity. Using fluorescence-activated cell sorting (FACS) and live-cell imaging, we found that cells with “middle” ecDNA copy numbers display the highest growth rates compared to cells with the lowest or highest copy number statuses, indicating greatest fitness is achieved by the balance of promoting cell proliferation while minimizing heightened replication stress arising from increasing copy numbers of ecDNA oncogenes. Through simulations based on random segregation and optimal copy number models, we found that ecDNA-bearing cells can rapidly adjust their copy numbers to achieve optimal growth in new environments. Notably, compared to chromosomally amplified cells, those with ecDNA exhibited superior growth following xenograft injection and treatment with single drugs targeting replication stress or oncogenes, aligning with our simulation findings. Our results reveal that functional heterogeneity resulting from uneven ecDNA inheritance enhances cancer cells' adaptability to tumor microenvironments and rapid acquisition of drug resistance, warranting that the development of combinatorial therapies that synergistically target a wide range of copy numbers is critical for effectively treating ecDNA-containing cancers.

#3886 Decoding pediatric adrenocortical tumor heterogeneity through multimodal molecular profiling - pathways to improved risk stratification and therapy.

Victoria E. Fincke[1], Maurice Lo?ner[1], Marina Kunstreich[1], Irmengard Sax[2], Marlena Mucha[1], Felix Dorn[1], Maria D. Hernandez Ramirez[1], Stefan Wudy[3], Christian Vokuhl[4], Christoph Slavetinsky[5], Jorg Fuchs[5], Michael C. Fruhwald[1], Matthias Schlesner[2], Antje Redlich[6], Rainer Claus[7], Michaela Kuhlen[1], Pascal D. Johann[1]

[1]Pediatrics and Adolescent Medicine, Swabian Children's Cancer Center, University Hospital Augsburg, Augsburg, Germany,[2]Biomedical Informatics, Data Mining and Data Analytics, University of Augsburg, Augsburg, Germany,[3]Pediatric Endocrinology and Diabetology, University Hospital Giessen, Giessen, Germany,[4]Department of Pathology, Section of Pediatric Pathology, University Hospital Bonn, Bonn, Germany,[5]Department of Pediatric Surgery and Urology, University Children?s Hospital Tuebingen, Tuebingen, Germany,[6]Pediatric Hematology and Oncology, University Hospital Magdeburg, Magdeburg, Germany,[7]Molecular Oncology, University Hospital Augsburg, Augsburg, Germany

Pediatric adrenocortical tumors (pACTs) are rare neoplasms with significant mortality, presenting diagnostic challenges in distinguishing benign from malignant tumors. Here, we employed a comprehensive multimodal molecular profiling approach to delineate and characterize molecular subgroups and investigated their potential for risk stratification.

We profiled 109 pediatric adrenocortical tumors using Illumina methylation arrays and analyzed them together with 105 published samples. For 29 of the 109 tumors, fresh-frozen samples were analyzed with single-nucleus RNA sequencing and seven of these also with single-nucleus ATAC sequencing.

Our analysis revealed four molecularly distinct subgroups with differences in clinical presentation, cellular composition and molecular signatures. Importantly, the herein identified high-risk subgroup demonstrated substantially reduced overall survival, with a 5-year survival rate of merely 27% compared to 81-95% in other subgroups. Notably, these tumors showed increased CpG island methylation and aberrant activation of the canonical WNT signaling pathway in gene expression profiling.

Additionally, through integration of scRNA-Seq and scATAC-Seq, we uncovered complex transcriptional networks driving tumor biology. Tumor cells resembling the physiological adrenocortical zones exhibited unique gene expression patterns, with the high-risk subgroup characterized by an increased proportion of zona glomerulosa-like cells.

These zona glomerulosa-like cells showed dysregulated WNT/CTNNB1 signaling and a proliferative and cell cycle activation signature, which emerge as a critical driver of malignancy. In particular, the glomerulosa-like tumor cells seem to fuel tumor proliferation by a crosstalk with fasciculata/reticularis-like tumor cells, which is unique for the high risk pACT subgroup. Further key molecular alterations include upregulation of cancer associated genes like *PVT1* and *MDM2*, suggesting potential therapeutic vulnerabilities. Moreover, our analysis uncovered transmembrane glycoprotein BAMBI to be specifically upregulated in the high-risk tumors, highlighting its potential as a prognostic indicator.

This comprehensive characterization provides a robust framework for risk stratification in pACTs. Specifically, we have unraveled a previously undescribed molecular hub using canonical WNT signaling to drive proliferation in high risk tumors. These changes may open an avenue towards integrating WNT-directed therapies in the clinical setting.

#3887 Clonal expansion in the bile duct associated with primary sclerosing cholangitis.

Hirona Maeda[1], Nobuyuki Kakiuchi[2], Takashi Ito[3], Eri Ogawa[4], Masahiro Shiokawa[5], Norimitsu Uza[5], Koichi Watanabe[1], Yasuhito Nannya[6], Yuzo Kodama[7], Tatsuki Kataoka[8], Hatano Etsuro[3], Seishi Ogawa[1]

[1]Department of Pathology and Tumor Biology, Kyoto University, Kyoto, Japan,[2]The Hakubi Center for Advanced Research, Kyoto University, Kyoto, Japan,[3]Department of Surgery, Kyoto University, Kyoto, Japan,[4]Department of Pediatric Surgery, Kyoto University, Kyoto, Japan,[5]Department of Gastroenterology and Hepatology, Kyoto University, Kyoto, Japan,[6]Department of Hematology/Oncology, The University of Tokyo, Tokyo, Japan,[7]Division of Gastroenterology, Kobe University, Kobe, Japan,[8]Department of Pathology, Iwate University, Iwate, Japan

[Introduction] Chronic inflammation has been implicated in cancer development in many tissues and has recently been shown to promote clonal expansion in non-cancer tissues. Primary sclerosing cholangitis (PSC) is a chronic progressive disease of unknown etiology that affects the bile ducts and has been associated with an increased risk of cholangiocarcinoma. However, clonal dynamics in the normal bile duct and PSC epithelium remain poorly understood due to the limited accessibility to normal/inflamed bile ducts. In this study, we investigated somatic clonal events in the chronically inflamed bile duct epithelium and identified clonal expansions with and without cancer-associated driver mutations.

[Methods] Single cell-derived organoids were established from the bile and subjected to whole genome sequencing to estimate the mutation accumulation rate in the normal bile duct epithelium. Next to evaluate clonal expansion in the bile duct in PSC, we performed whole exome sequencing in bile duct-derived organoids and samples from the bile duct epithelium obtained from PSC patients using laser-capture microdissection (LCM) and detected somatic mutations and copy number alterations therein.

[Results] In total, 14 single cell-derived organoids were established from 2 PSC patients and 3 control donors. Based on the whole genome sequencing of these organoids, the number of mutations found in non-PSC bile duct epithelium increases with age at an estimated mutation rate of 34.3 mutations per genome per year. The mutation rate did not significantly differ from the rate in the PSC epithelium, suggesting that the inflammatory process in PSC does not substantially affect the mutation rate in the biliary epithelium. We next investigated the effect of chronic inflammation on clonal expansion in the biliary epithelium, in which we analyzed 120 bulk organoid samples from 3 PSC patients and 304 LCM samples from histologically normal bile duct and biliary intraepithelial neoplasia (BilIN) from 7 PSC patients. Excluding a case with hypermutation, we detected the presence of clones in 20 (16.7%) and 105 (47.1%) of organoid and LCM samples, where a median of 13 [1-30] and 19 [5-41] somatic mutations per exome were detected in organoid and LCM samples, respectively. Most mutations were detected in a single sample, but some were shared between multiple samples. In total, 51 clones were detected across multiple samples. These clones were observed regardless of the presence or absence of BilIN lesions and found in the samples separated up to 40mm. Mutations in known cancer drivers, such as ARID1A and KRAS, and chromosomal instability were detected in 11 clones in 64 samples, suggesting their roles in the clonal expansion in PSC bile ducts.

[Conclusions] Clonal expansion in the bile duct from PSC patients are common and accompanied by known cancer driver mutations, suggesting their role in biliary carcinogenesis associated with PSC.

#3888 Exploring intra-tumor heterogeneity in malignant peripheral nerve sheath tumors through single-cell multi-omics.

Yidan Pan[1], Yixiao Cheng[1], Chunxu Gao[1], Haixi Yan[2], Zhihui Zhang[1], Leah Weber[1], Tom Lesluyes[2], Cristina Cotobal Martin[3], Isidro Cortes-Ciriano[4], Nischalan Pillay[5], David T. Miller[6], Adrienne M. Flanagan[5], Maxime Tarabichi[7], Peter Van Loo[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]The Francis Crick Institute, London, United Kingdom,[3]Wellcome Sanger Institute, Cambridge, United Kingdom,[4]EMBL's European Bioinformatics Institute, Hinxton, United Kingdom,[5]University College London, London, United Kingdom,[6]Boston Children's Hospital, Boston, MA,[7]Universite Libre de Bruxelle, Brussels, Belgium

Malignant peripheral nerve sheath tumors (MPNSTs) are a rare subtype of sarcomas arising from peripheral nerves, occurring either sporadically or in association with neurofibromatosis type 1 (NF1). Although comprising only 5-10% of soft tissue sarcomas, MPNSTs are highly aggressive and have limited treatment options, with 5-year survival rates of 34%-60%. Intra-Tumor Heterogeneity (ITH) is a key driver of tumor evolution and treatment resistance. However, prior genomic analyses of MPNSTs are often limited to a single sample per patient and have not explored ITH in detail. To fill this gap, we developed a multi-omics and single-cell integration pipeline to analyze bulk Whole-Genome Sequencing (WGS), single-nuclei DNA (snDNA) and RNA (snRNA) sequencing, and multi-regional shallow-coverage WGS derived from multiple Laser Capture Microdissection (LCM) spots within tissue sections. We applied this integrative multi-omics approach to analyze 63 samples collected from 17 patients. Somatic mutations were called in WGS using a two-out-of-three consensus approach (MuSE2, Strelka2, Mutect2), and Copy Number Aberrations (CNA) were analyzed using the Battenberg algorithm. Phylogenetic trees were reconstructed using Dirichlet Process-based methods and PyClone. We identified low-to-moderate mutational burden (median = 1.23 mutations/Mb, range: 0.52–2.34 mutations/Mb) but significant chromosomal aberrations and varied levels of genome instability. Whole genome doubling was highly prevalent (47/63 samples; 14/17 patients) and many samples showed widespread loss of heterozygosity (median = 26%, range: 4%-93%). Among the 17 patients, 5 exhibited a linear evolution pattern, while the majority demonstrated branching evolution. Cross-referencing CNA profiles across bulk WGS, snDNA (ASCAT.sc), LCM, and snRNA (inferCNV) data validated WGS-derived CNAs and demonstrated subclonal CNA co-occurrence within individual cells or subclones. Genotyping WGS-derived mutation clusters in snDNA revealed that co-occurrence of mutation pairs within single cells was exclusively observed when mutations belonged to the same cluster or lineage, further validating our bulk WGS-derived phylogenetic trees. Our findings reveal that MPNSTs are primarily driven by chromosomal instability, with ITH further elucidated through cross-referenced and refined phylogenetic tree reconstruction at single-cell resolution. Future work would focus on 3D phylogenetic tree reconstruction using spatial-genomics information derived from LCM and integrating single-cell transcriptomics. Additionally, incorporating spatial transcriptomics could provide deeper insights into the tumor microenvironment and its role in driving ITH. These efforts will further advance the understanding of MPNST biology and evolution, with potential implications for targeted therapeutic strategies.

#3889 Access and selection shapes peritoneal metastasis evolution in colorectal cancer.

Whether metastasis in humans can be accomplished by most primary tumor cells or requires the evolution of a specialized trait remains an open question. To evaluate whether metastases are founded by non-random subsets of primary tumor lineages requires extensive, difficult-to-implement sampling. We have realized an unusually dense multi-region sampling scheme in a cohort of 26 colorectal cancer patients with peritoneal metastases, reconstructing the evolutionary history of on average 28.8 tissue samples per patient with a microsatellite-based fingerprinting assay. To assess metastatic randomness, we evaluate inter- and intra-metastatic heterogeneity relative to the primary tumor and find that peritoneal metastases are more heterogeneous than liver metastases but less diverse than locoregional metastases. Metachronous peritoneal metastases exposed to systemic chemotherapy show significantly higher inter-lesion diversity than synchronous, untreated metastases. Projection of peritoneal metastasis origins onto a spatial map of the primary tumor reveals that they often originate at the deep-invading edge, in contrast to liver and lymph node metastases which exhibit no such preference. Furthermore, peritoneal metastases typically do not share a common subclonal origin with distant metastases in more remote organs. Synthesizing these insights into an evolutionary portrait of peritoneal metastases, we conclude that the peritoneal-metastatic process imposes milder selective pressures onto disseminating cancer cells than the liver-metastatic process. Peritoneal metastases' unique evolutionary features have potential implications for staging and treatment.

#3891 Integrative single-cell tracking of genome evolution and tumor cell plasticity in small cell lung cancer (SCLC).

Marcel Schmiel[1], Laura Kaiser[2], Julie George[2], Roman K. Thomas[2]

[1]Pathology, University Hospital of Cologne, Cologne, Germany,[2]Translational Genomics, University Hospital of Cologne, Cologne, Germany

SCLC is the deadliest type of lung cancer, which is mostly diagnosed at late stages and accounts for 15% of pulmonary tumors. Chemotherapy is initially effective, but SCLC patients relapse quickly and develop resistant tumors. Large-scale studies uncovered key molecular patterns in SCLC, which include universal loss of TP53 and RB1, as well as transcriptional patterns based on the expression of 4 lineage transcription factors (TF). We aimed to dissect how genomic cues impact transcriptional phenotypes, and the dynamics of tumor and immune cell interactions, to thus decipher molecular mechanisms of phenotypic divergence in SCLC.

We performed genome and single cell transcriptome profiling on 56 SCLC patient tumors, including primary tumors, metastases and paired relapse tumors, including a patient sample after treatment with DLL3-targeted immunotherapy. Single cell RNA-seq was performed with the 10x Genomics platform to study cancer cells and the tumor micro-environment (TME), and tumor cell intrinsic heterogeneity. Data were processed with an in-house pipeline.

Single cell expression profiles were determined for > 200000 cells from 56 tumors. Transcriptome profiling at single cell levels revealed co-expression of at least two of the lineage TF *ASCL1*, *NEUROD1* or *POU2F3* for each SCLC tumor. Transcriptional profiles pointed to a marked intra- and interpatient, as well as to inter-metastatic heterogeneity. Cell-cell-interaction analysis across all samples uncovered recurrent patterns of intra-tumoral receptor-ligand interactions. The integrative analysis of genome and single cell transcriptome data pointed to somatic alterations and copy number alterations shaping transcriptional heterogeneity. Specifically, tumors with gene amplifications of *MYC* family members share similar expression profiles. We performed multi-regional and longitudinal studies of matched patient cases to project genomic patterns of clonal evolution to transcriptional profiles at single cell level, thus analyzing the effect of genome diversity on the transcriptional landscape. Additionally, tumor intrinsic profiles of heterogeneity were mapped to single cell data of patient tumors to elucidate the effects on tumor-immune cell interactions.

Altogether we provide a first comprehensive framework for the study of underlying genetic alterations that shape the transcriptional landscape and phenotypic plasticity in SCLC. Our data points to a concerted regulation of a multitude of factors including lineage TF, transcriptional programs and interaction networks in SCLC.

#3892 Multi-sample whole genome sequencing unveils complex mutational dynamics and clonal evolutionary patterns in young onset breast cancer from Nigeria.

Ajan[3], Ayodele Sanni[4], Atara Ntekim[5], Abayomi Odetunde[6], Elisabeth Sveen[2], Jeffrey Mueller[7], Galina Khramtsova[2], Sulin Wu[2], Dorothy Nyamai[1], Mihai Giurcanu[8], Dezheng Huo[8], **Yonglan Zheng**[2], David C. Wedge[1], Olufunmilayo I. Olopade[2]

[1]Division of Cancer Sciences, School of Medical Sciences, University of Manchester, Manchester, United Kingdom,[2]Center for Clinical Cancer Genetics and Global Health, Department of Medicine, The University of Chicago, Chicago, IL,[3]Department of Pathology, University of Ibadan, Ibadan, Oyo, Nigeria,[4]Department of Pathology and Forensic Medicine, State University Teaching Hospital, Ikeja, Lagos, Nigeria,[5]Department of Radiation Oncology, Faculty of Clinical Sciences, College of Medicine, University of Ibadan, Ibadan, Oyo, Nigeria,[6]Institute for Advanced Medical Research and Training, College of Medicine, University of Ibadan, Ibadan, Oyo, Nigeria,[7]Department of Pathology, The University of Chicago, Chicago, IL,[8]Department of Public Health Sciences, The University of Chicago, Chicago, IL

Background: Breast cancer (BC) is a heterogenous disease, and the rising global epidemic of premenopausal BC remains poorly understood. Mutational landscape and evolutionary dynamics of BC from diverse geography and populations are largely unknown, preventing the global acceleration of progress towards precision prevention.

Methods: To examine etiology and heterogeneity of BC in indigenous Africans, 43 multi-region tumor samples and blood samples from 18 Nigerian women with BC (mean age 53 +/-12.7) were analyzed. Whole Genome Sequencing (WGS) was performed to identify somatic single nucleotide variants, insertions and deletions (ID), copy number alterations (CN), and structural variants (SV). Five mutational signature types (single base substitutions (SBS), double base substitutions (DBS), ID, CN, and SV), were analyzed and compared to COSMIC human cancer signatures. Multi-DPclust was used to classify mutations to clonal and subclonal cluster and create mutational phylogenetic trees.

Results: Driver gene analysis highlighted key driver genes, such as *TP53*, *GATA3*, and *PIK3CA*, corroborating prior findings. The most common signature was clock-like (CL) SBS5, followed by APOBEC-related SBS2 and SBS13. Other notable signatures included hypoxia-linked SBS18 and HRD-related DBS13. Signature profiles showed moderate heterogeneity across samples, with distinct patterns observed across mutational clusters. Intra-cluster correlation coefficients for signatures within samples from same patient range from 0.37 to 0.99 (median 0.84). *TP53* and *GATA3* mutations are common in clonal (early) clusters, with GATA3 often appearing in consecutive subclones. The CL SBS5 signature was prevalent early, while SBS18, linked to hypoxia, became prominent late, highlighting evolving mutational processes across disease progression. Distinct BC subtypes also displayed unique mutational profiles. HR+/HER2+ tumors exhibited higher levels of signature SBS91, while HR-/HER2- tumors exhibited higher levels of the HRD signature SBS3 compared to the rest of the tumors. HR-/HER2- tumors demonstrated lower levels of the mismatch repair-related signature ID1 but higher levels of the HRD signature ID6 and TOP2A signature ID8. Significant differences were observed in SV signatures, with higher SV9 signature activities in HR+/HER2+ tumors and elevated *BRCA*-related SV3 signature activities in HR-/HER2- tumors. Heterogeneity was also evident in the DBS and CN mutational signatures, further highlighting tumor complexity.

Conclusion: This analysis sheds light on the diverse mutational dynamics within and across molecular subtypes, providing insights into the mutational evolution of BC in a non-screen detected young onset population. Ongoing work integrating WGS and transcriptome data will be presented at the conference.

#3893 Enhanced detection of molecular subtypes in prostate cancer using saturation biopsy: Insights into tumor heterogeneity and racial disparities.

Wei Zhao[1], Pin Li[2], Shannon Carskadon[3], Jessica Ryba[3], Hristina Trpevski[3], Vishnav Ramesh[3], Dhananjay Chitale[4], Firas Abdollah[3], Wooju Jeong[3], Craig Rogers[3], Daniel Isaac[5], Nilesh Gupta[4], Nallasivam Palanisamy[3]

[1]Hematology/Oncology, Henry Ford Health System, Detroit, MI,[2]Public Health, Henry Ford Health System, Detroit, MI,[3]Urology, Henry Ford Health System, Detroit, MI,[4]Pathology, Henry Ford Health System, Detroit, MI,[5]Hematology/Oncology, Kamanos Cancer Institute at McLaren Greater Lansing, Lansing, MI

Prostate cancer is characterized by remarkable molecular heterogeneity associated with disease progression and clinical outcomes. We have identified distinct molecular subtypes between CA and AA in biomarker expression associated with altered clinical outcomes. This study compares the effectiveness of standard 12-core biopsy and saturation biopsy in identifying molecular subtypes of prostate cancer and evaluating biomarker expression patterns across racial groups. We analyzed 104 cases that underwent saturation biopsies (median min, max 23 [14, 27], cores with cancer (median 11 [5, 25] and compared them with 130 cases with standard 12-core biopsies (median min, max 12 [12, 16]; cores with cancer median min, max 4 [1, 16] using ERG, ETV1, ETV4 and SPINK1 by combined multiplex IHC and RNA ISH. Saturation biopsy demonstrated superior detection of molecular subtypes, identifying higher rates of SPINK1- and ETV4-positive tumor foci than standard biopsy ($p < .001$). It also reduced the frequency of negative cases for all four biomarkers, indicating a higher prevalence of ETS gene fusions in prostate cancer (94%) than was reported previously. Caucasian American (CA) patients exhibited higher frequencies of ERG- and ETV1-positive tumor foci, while African American (AA) patients showed higher frequencies of SPINK1- and ETV4-positive foci and presented with higher Gleason Grade Groups at the time of biopsy. ERG positivity was associated with lower Gleason Grade Groups in both racial groups (CA $p=.004$; AA $p < .001$), and ETV1 positivity was linked to higher Gleason Grade Groups (CA $p<.001$; AA $p<.001$). These findings concord with our previous observations on the association of ETV1 And ETV4 with worse recurrence-free survival in CA and AA, respectively, underscoring significant racial variations in prostate cancer biology and the prognostic implications of biomarker expression. Saturation biopsy identified 16 distinct molecular subtypes with one or more than one ETS gene fusion, compared with 13 detected by standard 12-core biopsy. By uncovering a greater diversity of tumor subtypes, saturation biopsy highlights the extent of complex tumor heterogeneity and prostate cancer biology. It reveals fewer cases classified as ETS fusions compared with standard biopsies. This study demonstrates that saturation biopsy is a more effective diagnostic tool for detecting molecular subtypes and evaluating tumor heterogeneity in prostate cancer. The enhanced detection of subtype diversity and its ability to identify biomarker expression patterns associated with racial disparities underscores the potential of saturation biopsy in guiding precision oncology. These findings have profound implications for improving diagnostic accuracy, addressing racial inequality, and informing tailored treatment strategies for prostate cancer patients.

#3894 Three-dimensional whole tumor genomic analysis redefine intratumor heterogeneity of gliomas, with implications for early tumorigenesis.

Lee H. Chen, Nicholas O. Stevers, Chibo Hong, Ivan V. Smirnov, Nadia R. Grishanina, Joshua S. Wu, Anny Shai, Susan M. Chang, Mitchel S. Berger, Shawn L. Hervey-Jumper, Joanna J. Phillips, Joseph F. Costello

Neurological Surgery, UCSF - University of California San Francisco, San Francisco, CA

Intratumor heterogeneity and evolution underlie treatment failures but are poorly understood due to a limited number of tumor biopsies. In this study, we examine IDH mutant gliomas, utilizing a 3D whole tumor sampling approach and exome sequencing (32 patients, 345 samples), along with RNAseq (12 of the 32 patients, 88 samples). We investigate and redefine intratumoral heterogeneity and evolution of insertion/deletion (indel) and single nucleotide variant (SNV) in driver genes on a whole tumor scale.

In the tumor suppressor capicua transcriptional repressor (CIC), a canonical driver in IDH mutant 1p/19q co-deleted (IDHmut-Codel) tumors, our exome and RNAseq data analysis highlights a wide spectrum of heterogeneity and inactivation by SNVs and indels in independent subclonal expansions. For instance, in nine samples from one patient's recurrent tumor, five showed distinct CIC SNVs and eight exhibited indels. Notably, all samples showed one or more CIC SNVs or indels. Among five samples harboring SNVs, three had 2 to 3 co-occurring SNVs, and among the 8 samples with indels, three had 2 and one had 5 indels. None had the same combinations of indels and SNVs, indicating extreme heterogeneity and subclonality. Additionally, TA-cloning of a long-range PCR from one sample suggested that each individual SNV and indel were in different tumor cells, raising the possibility of early diversification of subclonal expansions driven by independent CIC alterations. Similar patterns were observed in IDH-mutant and 1p/19q non-codeleted tumors involving tumor suppressor ATRX.

These findings demonstrate that lower grade IDH-mutant gliomas (LGGs) exhibit significant intratumoral heterogeneity, a trait typically associated with glioblastoma. To determine if CIC alterations were inactivating or simply passengers, we analyzed gene expression in those spatially mapped samples. Within the ETS-domain transcription factor family, ETS1, ETV1, ETV4, and ETV5 were upregulated in CIC mutant samples versus wild type samples. We also identified novel candidate genes potentially regulated by CIC, suggesting possible mechanisms contributing to tumorigenesis and new treatment targets for IDHmut-Codel tumors.

This study elucidates the substantial intratumor heterogeneity and evolutionary dynamics in the drivers of LGGs on a whole tumor scale, highlighting their important role in tumorigenesis. By utilizing spatially mapped samples within the same tumors, our research reveals convergence on CIC loss of function through many mutually exclusive SNVs and indels in IDHmut-Codel tumors. Our findings demonstrate the critical nature of CIC inactivation across entire tumors, emphasizing the importance of indels and SNVs in tumor progression. This research also identifies candidate genes upregulated by CIC inactivation as possible treatment targets for IDHmut-Codel tumors.

#3895 Clonal expansion in normal endometrium and its association with endometriosis-associated ovarian cancer.

Koichi Watanabe, Nobuyuki Kakiuchi, Kosuke Ieiri, Hirona Maeda, Tomonori Hirano, Mana Taki, Koji Yamanoi, Ryusuke Murakami, Ken Yamaguchi, Junzo Hamanishi, Masaki Mandai, Seishi Ogawa

Kyoto University, Kyoto, Japan

[Introduction] Recent studies have revealed pervasive mutations affecting cancer-related genes in many normal tissues, including the endometrium, suggesting their role in cancer development. Endometriosis-associated ovarian cancer (EAOC) is thought to develop from endometriosis lesions seeded from endometrium to the ovary, although no solid evidence supports this. In this study, we sought to identify the clonal origin of EAOC by demonstrating ancestral clones of EAOC in the endometrium by detecting shared mutations between EAOC and endometrial clones.
[Methods] We performed high-density sampling of endometrial tissues from 5 patients diagnosed with EAOC (5-32 sample/patient, 78 samples in total) and performed whole exome sequencing, and compared the somatic mutations with those of the EAOC tumors from the same patients.
[Results] The median number of somatic mutations in endometrial samples was 29/sample (range 6-74). In 74 of 78 endometrial samples (95%), one or more of known driver gene mutations such as *PIK3CA, PIK3R1, KRAS, PPP2R1A, ARHGAP35* and *FBXW7* were identified, with an average of 2.3/sample (range 0-6). *PIK3CA* mutations were the most common, identified in 42 of 78 samples (54%), followed by *ARHGAP35* mutations (25/78, 32%). Some of the adjacent endometrial samples shared multiple mutations, including driver mutations, indicating large clonal expansion over several millimeters. In one case with clear cell carcinoma in a 74-year-old woman, one of 32 endometrial samples shared 16 somatic mutations, including those affecting *PTEN, PIK3CA, KRAS* and *FOXA2* , with the ovarian tumor, indicating that this ovarian tumor originated from the endometrium. We confirmed that this endometrial tissue was histologically normal. Based on the phylogenetic analysis using whole genome sequencing, the most recent cancer founder was estimated to have diverged from the normal endometrial clones at approximately 20 years of age. No additional driver alterations were acquired in the main trunk except for multiple copy number alterations, suggesting their role in the progression from precancer to cancer.
[Conclusion] We demonstrated that at least some EAOC tumors originate from an ancestor in the endometrium, in which a number of driver events are acquired to contribute to carcinogenesis. Our findings provide new insight into early events during the development of EAOC.

#3896 Multi-omic and multi-region profiling of uterine leiomyoma reveals intra- and inter-tumor heterogeneity.

Chelsea De Bellis[1], Sujay Vennam[2], Christopher Eeles[3], Philippe Jolivet[1], Deirdre Lum[2], Benjamin Haibe-Kains[3], Matt van de Rijn[2], **Joanna Przybyl**[1]

[1]McGill University, Montreal, QC, Canada,[2]Stanford University, Stanford, CA,[3]Princess Margaret Cancer Centre, Toronto, ON, Canada

Objective: Molecular heterogeneity has been well-documented in malignant tumors but has yet to be thoroughly studied in benign non-metastasizing tumors. Uterine leiomyomas (LM) (fibroids) are benign tumors originating from the myometrium, commonly affecting women of reproductive age. Approximately half of patients present with multiple tumors, termed multifocal LM. LM are thought to be monoclonal proliferations based on their pattern of X chromosome inactivation. Mutations of the *MED12* gene are the genetic hallmark of LM. Treatment of LM includes surgery and hormone therapy. It is unknown whether multifocal LM exhibit inter-tumor heterogeneity, contributing to variable response to hormone therapy. Anecdotal reports suggest that LM may occasionally transform into malignant metastasizing tumor called leiomyosarcoma (LMS). Better understanding of intra-tumor heterogeneity of LM may identify cell clones that may contribute to oncogenic transformation. In this study, we sought to perform a comprehensive multi-omic investigation of the possible intra- and inter-tumor heterogeneity of uterine LM.
Methods: We performed multi-omic analysis of 62 specimens from 21 LM patients (median of 3 tumors per patient, range: 2-8). We analyzed multiple regions of a single tumor, and multiple concurrent LM from patients with multifocal disease. We profiled DNA methylation (EPIC microarrays), point mutations (whole exome sequencing) and gene expression (whole transcriptome RNA-seq) in these specimens.
Results: Multi-omic profiling showed a remarkable intra- and inter-tumor heterogeneity of genomic, epigenomic and transcriptomic patterns. Through reconstruction of phylogenetic trees based on single nucleotide variants, we identified novel clonal and subclonal somatic mutations in LM. We detected for the first time different *MED12* mutations in co-existing nodules in the same patient. DNA methylation and transcriptomic profiles appeared to have a similar degree of variability within individual tumors and between different tumors from the same patient. We also observed a significant enrichment of different molecular pathways between distinct regions of the same tumor.
Conclusion: Molecular heterogeneity is well-established in malignant tumors, and we report it here for the first time in histologically bland lesions like LM. Our study reveals that in multifocal LM, distinct tumors can acquire unique molecular alterations, meaning that single-tumor analysis may not capture the full spectrum of molecular changes. This highlights the importance of considering molecular heterogeneity in diagnosis and evaluation of response to hormonal treatment in LM. We also demonstrate for the first time the presence of intra-tumor heterogeneity of LM. It remains to be further investigated whether clonal evolution may contribute to occasional oncogenic transformation of benign LM into malignant LMS.

#3897 Investigating the prevalence of ecDNA in breast cancer.

Georgia Stavrou[1], Chris Bailey[2], Jeanette Kittel[1], Mariam Jamal-Hanjani[1], Charles Swanton[2], Nnennaya Kanu[1]

[1]University College London (UCL) Cancer Institute, London, United Kingdom,[2]Francis Crick Institute, London, United Kingdom

Extrachromosomal DNA (ecDNA) has been described in multiple cancer types. ecDNAs are circular and are usually greater than 500 base pairs in size. ecDNA structures lack centromeres and thus do not follow the Mendelian mode of inheritance, segregating unequally during mitosis. This can subsequently result in high copy number gene amplifications and enhance tumor heterogeneity, promoting tumor evolution. ecDNA structures have a dynamic nature whereby they can be maintained extrachromosomally in their circular form but can also reintegrate randomly back into the genome, in the form of Homogeneously Stained Regions (HSR). Earlier studies using TCGA reported that approximately 25% of breast samples contained ecDNA. We have recently reported that over 46% of HER2+ breast cancers have ecDNA amplifications. Moreover, ecDNA have been found in both pre-cancerous lesions, such as in tissues obtained from patients with Barret's esophagus, but also following both targeted treatment and chemotherapy. This highlights the ability of the structures to be detected at any disease stage and treatment phase although exact mechanisms of ecDNA formation and maintenance have not been described fully. In the present study we use a tumor-informed *in silico* approach in conjunction with *in vitro* readouts to elucidate these mechanisms. 2981 Whole Genome Sequencing data from the Genomics England breast cancer cohort and cell line data from the Cancer Cell Line Encyclopedia were analyzed using Amplicon Suite. In parallel, a panel of eight *ERBB2* amplified breast cancer cell lines was used to detect *in vitro* presence of ecDNA by metaphase FISH and Optical Mapping. Genes that were found to be differentially mutated according to the presence of *ERBB2* focal amplifications were silenced *in vitro*, then gene expression of *ERBB2* and target genes was evaluated using qPCR and the effect of *ERBB2* signal was assessed using FISH. In the cohort analyzed, 22.8% of breast tumors had ecDNA amplifications. Enrichment analysis was conducted to assess the presence or absence of specific mutations in *ERBB2*-amplified vs non-amplified tumors. Several genes were identified as being positively or negatively enriched in the cohort. Similarly, we identified 9 breast cancer cell lines containing up to 5 different species of ecDNA. In a subset of cell lines computationally predicted to harbor *ERBB2* on ecDNA, *ERBB2* amplification was in the form of HSR. We selected HCC1569 as our candidate model and silenced candidate epigenetic regulators. Our preliminary data suggests this leads to a measurable and significant change on *ERBB2* signal. At present, we highlight the propensity of *ERBB2* to be amplified on ecDNA in both breast cancer patients and breast cancer cell lines. These cell lines can serve as models for the further study of the mechanisms of maintenance of ecDNA *in vitro* which will shed light on some of the key unresolved questions in the field.

#3898 Integrating structural variants and single nucleotide variants to uncover evolutionary trajectories in melanoma.

Xiwen Cui[1], Ayse G. Keskus[1], Salem Malikic[1], Yuelin Liu[1], Anton Goretsky[1], Chi-Ping Day[1], Farid R. Mehrabadi[1], Mikhail Kolmogorov[1], Glenn Merlino[2], S. Cenk Sahinalp[1]

[1]Cancer Data Science Laboratory, Center for Cancer Research, National Cancer Institute, Bethesda, MD,[2]Laboratory of Cancer Biology and Genetics, Center for Cancer Research, National Cancer Institute, Bethesda, MD

Melanoma, a highly heterogeneous cancer, evolves through a complex interplay of genetic alterations, including both single nucleotide variants (SNVs) and structural variants (SVs). To study the evolutionary trajectory of melanoma, we established a model system composed of 24 single-cell-derived clonal sublines (C1-C24) from the M4 melanoma model, developed in a genetically engineered hepatocyte growth factor (HGF)-transgenic mouse. While SNVs have been extensively used to construct phylogenetic trees using Trisicell (Triple-toolkit for single-cell intratumor heterogeneity inference), a tool that analyzes intratumor heterogeneity and single-cell RNA mutations, the role and timing of SVs in melanoma evolution remain less well understood. This study integrates SV data with an SNV-driven phylogeny to investigate whether SV patterns align with SNV-based evolutionary trajectories in the mouse melanoma model, providing insights into the functional impact of SVs during tumor progression. We performed long-read sequencing on the 24 clonal sublines and detected SVs using Severus, a tool optimized for phasing in long-read sequencing. The SVs were mapped to the SNV-driven phylogeny using R and classified as either concordant (aligning with the SNV-based tree) or discordant (deviating from the SNV phylogeny). Gene ontology enrichment analysis revealed that concordant SVs were significantly enriched in genes associated with the hepatocyte growth factor receptor signaling pathway and the negative regulation of peptidyl-threonine phosphorylation, both of which represent core drivers of tumor progression. In contrast, discordant SVs were associated with a broader range of functional pathways, including the positive regulation of antigen receptor-mediated signaling and the regulation of natural killer cell-mediated cytotoxicity, though the exact mechanisms underlying these associations remain unclear. By integrating these SVs with an established SNV-driven phylogeny, this study highlights the distinct and critical roles SVs play in melanoma evolution. Concordant SVs appear to drive core oncogenic processes, while discordant SVs may contribute to other aspects of tumor evolution. These findings underscore the importance of considering SVs alongside SNVs to fully capture the complexity of melanoma evolution. Ongoing investigations will continue to explore the functional implications of these SVs and how the gene disruption patterns they cause shape the evolutionary trajectory of melanoma, offering potential targets for future therapeutic strategies.

#3899 Genetic insights into clonal evolution from normal prostate epithelium to cancer via HGPIN.

Kohsuke Hishiki[1], Nobuyuki Kakiuchi[2], Yuki Teramoto[3], Koichi Watanabe[4], Kosuke Ieiri[4], Hirona Maeda[4], Tomonori Hirano[4], Yuki Kita[5], Takashi Kobayashi[5], Seishi Ogawa[4]

[1]Department of Urology / Dept. of Pathology; Tumor Biology, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[2]Dept. of Gastroenterology; Hepatology, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[3]Department of Diagnostic Pathology, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[4]Dept. of Pathology; Tumor Biology, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[5]Department of Urology, Kyoto Univ. Graduate School of Medicine, Kyoto, Japan

<Backgrounds> Prostate cancer (PC) is one of the most prevalent cancers in the developed world, where its incidence is still increasing. Most PCs are thought to arise from high-grade prostatic intraepithelial neoplasia (HGPIN), a well-recognized precursor lesion. However, the genetic landscape of HGPIN and its relationship with normal prostate epithelium (NPE) and PC remains to be fully explored.
<Methods> To address these issues, we collected prostate tissue samples from five patients who underwent radical prostatectomy. Prostate tissue sections (3 mm thick) were fixed with an alcohol-based solution and prepared for dual immunostaining using AMACR/p63, in addition to hematoxylin-eosin staining, and subjected to laser-capture microdissection (LMD). Then, PC (n = 35), HGPIN (n = 71), and normal epithelium (n =244) samples were dissected and subjected to whole-exome sequencing (WES). Variant pathogenicity was assessed based on COSMIC and ClinVar databases. Furthermore, to investigate the mutation acquisition rate in the prostate epithelium, single cell-derived prostatic organoids established from three patients were analyzed using WES. Somatic single nucleotide variants (SNVs), indels, and copy number variations (CNVs) were identified.
<Results> A total of 10,047 somatic SNVs and indels were detected. The mutation rate was estimated to be 0.28 mutations/year/exon. Shared mutations were observed between NPE and HGPIN as well as between HGPIN and PC in some cases, suggesting a common clonal origin. Pathogenic *FOXA1* mutations were frequently identified in both HGPIN and PC. While pathogenic *FOXA1* mutations were also observed in NPE, none of these mutations were shared with HGPIN or PC, indicating that they likely represent independent mutational events. In one case, spatially separated multifocal cancers exhibited distinct *FOXA1* mutations, each of which was shared with the adjacent HGPIN. In other cases, mutations were also shared between PCa, HGPIN, and NPE samples, although no known driver mutations were detected therein. These observations suggest that these cancers were derived from their precancer lesions with apparently normal histology, which progressed through HGPIN and PC. Phylogenetic analysis of these samples revealed that HGPIN and PCa diverged recently from a common ancestor.
<Conclusions> We successfully characterized somatic mutations and CNVs in apparently normal prostate epithelium, which were shared between HGPIN and adjacent PC in some cases. These findings provide new insights into the early genetic events driving PC development. Further studies are needed to fully elucidate the clonal evolution from NPE to PC, which may offer novel targets for early detection and intervention.

#3900 Integrating single-molecule localization microscopy and computational pipelines to elucidate ecDNA dynamics.

Mesut Unal[1], Jessica Alsing[2], Gabrielle S. Dewson[2], Guy Nir[2], Kadir C. Akdemir[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]University of Texas Medical Branch, Galveston, TX

Extrachromosomal DNA (ecDNA) is prevalent across various cancer types, notably Glioblastoma Multiforme (GBM), where it facilitates the rapid acquisition of high oncogene copy numbers by cancer cells. These ecDNAs exhibit self-replication and are randomly distributed to daughter cells during mitosis, resulting in uneven segregation. This leads to variations in oncogene copy numbers among subclones, contributing to significant intratumoral heterogeneity. Traditional sequence-based analyses are insufficient for addressing spatial heterogeneity. To overcome this limitation, we propose utilizing sequential OligoSTORM imaging combined with single-molecule localization microscopy (SMLM), an innovative hybridization technique, and a computational pipeline. Our hybridization method significantly enhances imaging speed: whereas imaging approximately 40 loci with typical sequential OligoSTORM requires 11 days to obtain data from about 20 cells, this method enables imaging of 10^4 loci within the same time frame. Additionally, we developed a computational pipeline to complement this technique. Together, these tools enable 3D imaging of chromosomes with a high resolution of 20 kb. Our hybridization approach allows imaging at both 100-kb and 20-kb resolution steps, organized hierarchically in a Matryoshka-like structure. Our pipeline incorporates advanced computational algorithms, including iterative closest point (ICP) and space-partitioning data structures, to precisely align each 20-kb sub-step to its corresponding 100-kb step. Using this methodology, we target the *EGFR* gene locus with high resolution. To validate our approach, we are applying it to a non-cancerous microglial cell line (HMC3) as a control and a patient-derived glioblastoma stem-like cell (GSC) line as our GBM model. The GSC line, rich in ecDNA content with an average of 18 ecDNAs per cell, demonstrates pronounced tumor heterogeneity, including significant *EGFR* amplifications among subclones. Through this methodology, we can elucidate the structural organization of ecDNAs containing oncogenes and their regulatory elements with fine precision. Furthermore, our approach seamlessly integrates these structural insights with matched single-cell genomic data. This combined strategy offers a comprehensive understanding of ecDNA dynamics in cancer, shedding light on tumor heterogeneity at both spatial and genomic levels and paving the way for novel insights into oncogene-driven cancer biology.

#3901 Charting copy number gain histories from mutational divergence among multi-samples.

Yunong Xia, Ruping Sun

Department of Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, MN

In cancer, a somatic copy number gain (SCNG) on a tumor chromosomal region is often assumed to result from a series of minimum number of copy number events, but this parsimonious-trajectory assumption may be violated in reality. For example, an SCNG could develop through a complex trajectory involving a combination of gain and loss events, rather than exclusively through gains. While prior efforts have been made to infer the SCNG trajectories from patient data, the presence of complex trajectories remains to be validated. Furthermore, these methods are limited by either only utilizing SCNG profiles, or inferring trajectories from only a single sample. Here, we hypothesize that SCNG trajectories can be reflected by somatic single nucleotide variants (SSNVs) shared between samples from the same patient. By analyzing multi-regional whole genome sequencing data of tumor specimens, we found evidence where the multiplicities of shared SSNVs between samples pinpoint complex SCNG trajectories. Here, the SSNV multiplicity refers to the number of alleles harboring the corresponding SSNV in the dominating clone of a tumor sample. We also define the joint multiplicity distribution as the proportion of shared SSNVs that occur at different allelic states (multiplicities) across distinct tumor samples. We developed a probabilistic computational pipeline to automate the identification of non-parsimonious multi-sample SCNG trajectories utilizing shared SSNV multiplicities. Extending an existing method GRITIC from single sample to multi-sample setting, this pipeline enumerates all trajectories leading to SCNGs states in multiple samples, and characterizes the probability of observing the joint multiplicity distribution in the real patient data given each possible trajectory. We applied the method on prostate cancer and breast cancer datasets, and identified conclusive cases of complex trajectories on genomic regions affected by SCNGs. On regions showing different copy number states in multiple samples, we identified cases experiencing both gains and losses. On regions showing the same copy number states in multiple samples, we also identified a few of them experiencing independent acquisition of SCNGs in different samples. Our findings call for a stochastic modeling of SCNGs dynamics during tumor evolution.

#3902 Evolution of esophageal adenocarcinoma from precursor lesion stem cells.

Wa Xian[1], Frank McKeon[2], Jaffer Ajani[2], Caycel Desales[1], Ashley Hoffman[1], Amber Su[1], Crystal Nguyen[1], Rick Russell[3], William Bachovchin[4]

[1]University of Houston, Sugar Land, TX,[2]University of Houston, Houston, TX,[3]TractBio, Sugar Land, TX,[4]Tufts University, Boston, MA

Metastatic cancers arise from a decades-long succession of increasingly virulent precursor lesions, each of which represents prospective targets for therapeutic intervention. This evolutionary process has been particularly vivid in esophageal adenocarcinoma (EAC), as this cancer and associated precursor lesions, including Barrett's esophagus (BE), low-grade dysplasia (LGD), and high-grade dysplasia (HGD), co-exist in an accessible, two-dimensional pattern in esophageal mucosa. Given the durability of these precursor lesions, it is likely that they, like EAC, rely on stem cells for their regenerative growth. To assess the role of stem cells in the evolution of EAC, we applied technology that selectively clones stem cells from the gastrointestinal tract to patient-matched endoscopic biopsies from each of the precursor lesions implicated in EAC. Histologically validated, endoscopic biopsy series including EAC, HGD, LGD, BE, and normal esophageal mucosa were obtained from patients presenting with early (T1) EAC. Rare (1:1,000) cells from each of these lesions proved clonogenic and were assessed by *in vitro* differentiation, tumorigenicity in mice, and by molecular genetics. Each of the lesions in the evolution of EAC possess a discrete set of clonogenic cells marked by immaturity, enormous proliferative potential, and lesion-specific differentiation fate. DNA sequencing of these clones reveal intralesional heterogeneity and clonal resolution of the mutation progression within a given patient from BE, LGD, HGD, and EAC. High-throughput chemical screens against BE stem cells reveal drug combinations that are similarly effective against stem cells of LDG, HGD, and EAC.

#3903 Multi-omics and histological assessment to identify patient derived xenograft models of invasive lobular carcinoma.

Jagmohan Hooda[1], Jennifer M. Atkinson[2], Osama Shah[1], Megan Yates[1], Daniel D. Brown[3], Morgan DeBerry[4], Rohit Bhargava[4], Paolo Schiavini[5], **Stefano Cairo**[5], Mara Gilardi[5], Marianna Zipeto[5], Steffi Oesterreich[1], Adrian V. Lee[1]

[1]Hillman Cancer Center (HCC), Magee-Women's Research Institute, Women's Cancer Research Center, University of Pittsburgh Medical Center (UPMC), Pittsburgh, PA,[2]Department of Pharmacology & Chemical Biology, University of Pittsburgh, Pittsburgh, PA,[3]Institute for Precision Medicine, University of Pittsburgh, Pittsburgh, PA,[4]Department of Pathology, University of Pittsburgh, Pittsburgh, PA,[5]Champions Oncology, Inc., Hackensack, NJ

Breast cancer is a heterogeneous disease with various histological subtypes. Invasive Lobular Cancer (ILC) is the most common special subtype, accounting for 10-15% of all breast cancers. The pathognomonic feature of ILC is the loss of E-cadherin (CDH1), which leads to a unique single-file growth pattern of discohesive ILC cells. Although ILCs show better prognostic factors than No Special Type (NST), patients with ILC have worse long-term outcomes, which is not well understood. ILC has historically been understudied, in part due to the lack of appropriate research models. Since ILC affects "only" 10-15% of all breast cancers, most models have been generated from the more frequent subtype, NST. In this study, we characterized Patient-Derived Xenograft (PDX) models for Invasive Lobular Cancer (ILC) research. We collaborated with Champions Oncology and utilized the genomic data from their LUMIN portal to perform genomic characterization of PDX models. We identified potential ILC PDX models based on CDH1 mutation, low E-cadherin mRNA expression, or clinical annotation of ILC. We analyzed whole-exome sequencing (WES) and RNAseq data on the LUMIN portal to characterize these models. We also performed Immunohistochemistry (IHC) analysis for E-Cadherin, p120, ER, PR, and Her2 to further assess the PDX models. Our study characterized a total of 10 PDX models and identified 7 ILC models and 3 NST models. We showed that the identified ILC PDX models exhibited lower levels of CDH1 mRNA expression compared to NST, which is consistent with the characteristics of ILC. We also found that the top gene alterations in ILC PDX models included P53, CDH1, PIK3CA, FOXA1, and PTEN. The frequency and type of alterations varied between ILC and NST PDXs. Our study provides valuable tools for studying ILC biology and testing targeted therapies. The identification of potential ILC PDX models could provide insights into the molecular characteristics of ILC and provide tools for research for the development of new treatment strategies.

#3904 Clonal analysis of classical subtypes of pancreatic cancer stem cells in ascites.

Wa Xian[1], Frank McKeon[1], Paul Daniel[1], Saeed Khan[1], Caycel Desales[1], Ashley Hoffman[1], Jaffer Ajani[2]

[1]University of Houston, Houston, TX,[2]MD Anderson Cancer Center, Houston, TX

It is now established that pancreatic cancer often displays an intratumor heterogeneity at the levels of epithelial cell types, stromal activation, and immune signaling that is likely germane to therapeutic resolution. While the extent of epithelial subtypes is under investigation, there is general agreement that pancreatic ductal adenocarcinoma (PDAC) is comprised of p63+ "basal" and GATA6+ "classical" subtypes, as well as various "intermediate", hybrid, and immune subtypes. In this initial report, we have applied technology that clones stem cells of the human gastrointestinal tract (Wang et al., 2015) and of esophageal adenocarcinoma and its precursors (in review) to ascites samples from patients with PDCA. Libraries of clonogenic cells were sorted to CEACAM6+ and CEACAM6- populations that were cloned by single cell sorting. The majority of CEACAM6+ clones form colonies with morphologies distinct from the CEACAM6- clones, and yet both form aggressive tumors in immunodeficient mice. Both CEACAM6+ and CEACAM6- clones express high levels of GATA6 and LGALS4, suggesting their general inclusion into the classical subtype seen in PDCA. However, gene expression profiling and tumor histology indicate that the CEACAM6+ clones display an intestinal fate (high CDH17, CDX2, MUC17) whereas the CEACAM6- clones show a gastric profile (TFF1, TFF2, AQP5, EGR1, EGR2, SOX21, MUC5AC). In addition, the CEACAM6- clones showed high levels of interferon signaling and high levels of chemokine expression including CXCL1, 2, 3, and 8, CCL20. The stromal properties of tumors generated from CEACAM6+ and CEACAM6- clones were also distinct, with the CEACAM6- clones marked by tumors with a highly cellularized extracellular matrix including αSMA+ and FAP+ CAFs, and the intestinal CEACAM6+ clones largely devoid of these CAF subpopulations. Consistently, CEACAM6- clones expressing high levels of pro-fibrotic genes, including PLAU, FN1, and CCN1. Importantly, exome sequencing of the CEACAM6+ and CEACAM6- clones from the same patient reveal shared mutant alleles of the p53 and KRAS genes, suggesting that these phenotypically distinct classical subtypes arose from a post-transformation stage likely by epigenetic mechanisms. Ongoing studies aimed at cloning basal subtypes from ascites and resolving the epigenetic control of CEACAM6+ and CEACAM6- classical subtypes should help to define the stem cell heterogeneity in PDAC.

#3908 Exploring CAR-T cell killing dynamics through live-cell fluorescence microscopy.
Skylar Dewees[1], Nathalie Opdam - van de Laar[2], Stacie Chvatal[1], Danielle Califano[1], Ben Streeter[1]

[1]Axion BioSystems, Atlanta, GA,[2]Axion BioSystems, Eindhoven, Netherlands

Introduction: Harnessing the potent cytotoxicity of chimeric antigen receptor T (CAR-T) cells has revolutionized cancer immunotherapy. A key factor influencing CAR-T cell efficacy is target antigen density on cancer cells. Human epidermal growth factor receptor 2 (HER2), overexpressed in various cancers like ovarian and lung carcinomas, is a promising target for CAR-T cell therapy. Traditional cytotoxicity assays generally provide only static endpoint measurements and often rely on 2D cell culture models, which fail to capture the structural complexity of tumors in vivo—a factor crucial to CAR-T cell efficacy. Live-cell imaging offers a solution by enabling non-invasive, real-time monitoring of cytotoxicity. Therefore, this study aims to explore the dynamics of CAR-T cell-mediated cytotoxicity against cancer cells with varying HER2 expression levels, comparing outcomes between 2D and 3D cell culture models using the Omni platform.
Methods: Monolayers and spheroids of SKOV3 (ovarian carcinoma) and A549 (lung adenocarcinoma) cells, tagged with GFP, were exposed to HER2 CAR-T cells at different Effector : Target (E:T) ratios. Using the Omni platform, hourly brightfield and fluorescent images were captured over 72 hours assess cancer cell growth and cytotoxicity and quantify the cytolysis of the fluorescent target cells. Percent cytolysis of the target cells was calculated by comparing the green fluorescent intensity of treated wells to no treatment control wells.
Results: The study demonstrated a dose-dependent cytotoxic effect of HER2 CAR-T cells that correlated with increasing amounts of CAR-T cells. Comparing SKOV3 cells with A549 cells showed higher sensitivity and earlier response for all E:T ratios. At 72 hours post HER-2 CAR T-cell addition, the 5:1 group demonstrated approximately 82.4% cytolysis of SKOV3 cells, while it demonstrated 40.3% cytolysis of A549 cells. In comparing the cytotoxic effect of HER2 CAR-T cells on SKOV3 spheroids versus monolayers, the 3D spheroid model exhibited a more rapid and efficient dose-dependent response. At 72 hours post HER-2 CAR T-cell addition, the 5:1 group demonstrated approximately 82.4% cytolysis of SKOV3 cells in spheroid, while it demonstrated 61.1% cytolysis of SKOV3 cells in monolayer.
Conclusion: This study underscores the importance of target antigen density in determining CAR-T cell efficacy, as SKOV3 cells, with higher HER2 expression, were more prone to CAR-T cell killing compared to A549 cells. Additionally, it also highlights the critical role of the assay model type, 2D versus 3D, in accurately assessing cytotoxicity. The Omni platform provided dynamic, real-time insights into cell viability and cytotoxicity, highlighting its potential to optimize immunotherapy strategies.

#3909 Defining Docetaxel's antitumor effects on Calu3 lung cancer cells using high-throughput live-cell imaging.

S. Dewees[1], L. Boekestijn[2], B. Streeter[1], S. Chvatal[1], D. Califano[1];
[1]Axion BioSystems, Atlanta, GA, [2]Axion BioSystems, Eindhoven, Netherlands

Introduction: Oncology focuses on understanding cancer's cellular mechanisms and developing effective treatments, with a key emphasis on evaluating drug toxicity to identify potential chemotherapies. Various assays, including cell viability, migration, and clonogenic assays, are used to assess the sensitivity and resistance of cancer cells to these drugs and define the drug's profile. Docetaxel, a chemotherapeutic agent inhibiting microtubule depolymerization, involved in migration and proliferation, is studied using these assays to evaluate its impact on cell proliferation, survival, and migration. The results of toxicity studies can vary significantly depending on the type of assay used, and combining multiple assays enhances the accuracy of drug profiling. In this study, the Omni Pro 12 high-throughput live-cell imaging platform was used to simultaneously perform multiple assays on Calu3 lung cancer cells.

Method: By conducting the assays simultaneously using the Omni Pro 12, variability was minimized, ensuring that differences in experimental conditions cannot affect the results. The aim was to evaluate the effects of Docetaxel on three key aspects of cancer progression: cell viability, migration, and colony-forming potential. These aspects were investigated using the cytotoxicity, scratch, and colony assay with Docetaxel concentrations between 0 - 1000 nM.

Results: First, real-time cell confluence measurements indicated that higher Docetaxel concentrations (500 nM to 1000 nM) significantly suppressed cell proliferation. Secondly, a wound-healing assay revealed a dose-dependent inhibition of cell migration, with higher drug concentrations resulting in slower and an overall decrease in scratch closure. A significant 70% decrease in scratch closure was seen when comparing the control group to 1000 nM Docetaxel. Lastly, a clonogenic assay showed a dose-dependent decrease in colony formation at 324 hours post-treatment, the time point was chosen right before the control group colonies clustered, with higher concentrations (100 nM and 250 nM) leading to inhibition of colony growth with less than 10 colonies formed compared to approximately 110 in the control groups.

Conclusion: These results demonstrate that Docetaxel effectively inhibits Calu3 cancer cell viability, proliferation, and migration in a dose-dependent manner. A comprehensive toxicity profile was obtained with the use of multiple 2D in vitro assays, which offers valuable insights into the potential therapeutic efficacy of Docetaxel in lung cancer treatment. This study underscores the importance of integrating multiple assays to better predict drug responses, helping to reduce the incidence of failures during in vivo and preclinical studies. Utilizing the Omni Pro 12 reduced the variance between assays as they are all performed simultaneously with similar experimental conditions.

#3910 Patient-derived conditionally reprogrammed cells in prostate cancer research.

A. Elbialy, A. Sood, S.-J. Wang, P. Wang, J. Li, **X. Liu**;
The Ohio State University, Columbus, OH

Prostate cancer (PCa) remains a leading cause of mortality among American men, with metastatic and recurrent disease posing significant therapeutic challenges due to a limited comprehension of the underlying biological processes governing disease initiation, dormancy, and progression. The conventional use of PCa cell lines has proven inadequate in elucidating the intricate molecular mechanisms driving PCa carcinogenesis, hindering the development of effective treatments. To address this gap, patient-derived primary cell cultures have been developed and play a pivotal role in unraveling the pathophysiological intricacies unique to PCa in each individual, offering valuable insights for translational research. This review explores the applications of the conditional reprogramming (CR) cell culture approach, showcasing its capability to rapidly and effectively cultivate patient-derived normal and tumor cells. The CR strategy facilitates the acquisition of stem cell properties by primary cells, precisely recapitulating the human pathophysiology of PCa. This nuanced understanding enables the identification of novel therapeutics. Specifically, our discussion encompasses the utility of CR cells in elucidating PCa initiation and progression, unraveling the molecular pathogenesis of metastatic PCa, addressing health disparities, and advancing personalized medicine. Coupled with the tumor organoid approach and patient-derived xenografts (PDXs), CR cells present a promising avenue for comprehending cancer biology, exploring new treatment modalities, and advancing precision medicine in the context of PCa.

#3912 Transcriptional heterogeneity between hemangiosarcoma and nodular hyperplasia using patient-derived cell lines and orthotopic xenograft model revealed new therapeutic targets.

Y. Liu, H. Yamamoto, M. Elbadawy, A. Abugomaa, T. Usui, K. Sasaki;
Tokyo University of Agriculture and Technology, Tokyo, Japan

Human angiosarcoma (AS) is a rare and aggressive subtype of soft tissue sarcoma of endothelial cell origin with a propensity for local recurrence and metastasis. The optimal treatment of metastatic AS is unclear and is associated with a generally poor prognosis unless diagnosed early. The lack of insight into the pathogenesis always causes treatment failure in the clinic. To discover new treatment strategies for AS, it is necessary to develop new and relevant preclinical models for AS. Dogs commonly suffer from a similar neoplasm, called hemangiosarcoma (HA), with breeds like the golden retriever carrying heritable genetic factors that put them at high risk. Angiosarcomas and HA were reported to share pathology, immunohistochemical characteristics, and molecular signatures. Therefore, HA is considered a closer preclinical model for advancing AS research than rodent models. In veterinary clinic, malignant HA always occurs with nodular hyperplasia (NH), a kind of benign tumor. However, the AS orthotopic xenograft mouse still needs standard guidelines for validation. In this study, we successfully generated 5 canine HA cell lines from fresh patient tumor tissues. We compared the RNA sequencing data between HA and NH patient-derived cell strains (5:5). Data revealed that pathways related to autophagy and lysosomal membrane were found upregulated in HA compared to NH. Additionally, *PIK3IP1*, *HIP1*, *PLAAT3*, and *MARVELD3* can be considered potential pharmacological targets and biomarkers for HA. Furthermore, we established an orthotopic xenograft model on mouse spleen using canine patient-derived HA cell lines by splenic injection. The results of xenograft spleen mass and drug screening test of toceranib, carboplatin, doxorubicin and cyclophosphamide using xenograft mouse HA cells showed corresponded sensitivity, supported that our model could maintain the original features of the patient tumor. In conclusion, the transcriptional difference between HA and NH might provide a better understanding of the progress of blood vessel sarcoma, and new pharmacological targets and biomarkers for diagnosis. Also, the xenograft model study may provide a reference for both AS and HA therapeutic predictions in basic medical science.

#3914 Leveraging canine osteosarcoma as a model to advance precision medicine and targeted therapies in human osteosarcoma.

Lucas Rodrigues[1], Kevin Wu[2], Garrett Harvey[1], Gerald Post[1], Aubrey Miller[1], Lindsay Lambert[1], Christina Lopes[1], James Zou[2]

[1]FidoCure, Palo Alto, CA,[2]Stanford University, Stanford, CA

Osteosarcoma (OS) is the third most prevalent tumor in adolescence, histologically characterized by the proliferation of abnormal osteoid-producing mesenchymal cells. Surgery remains the primary approach for OS treatment, but outcomes are poor without chemotherapy. Combining surgery, radiotherapy, and chemotherapy has improved results, yet 5-year survival rates persist at 60-70%.

Despite advances in molecular medicine, progress in the treatment of OS has been limited, no significant breakthroughs have been achieved in systemic therapy, particularly for relapsed OS. Additionally, there is no consensus on the optimal treatment for these cases, leaving a substantial unmet need for effective therapies.Precision medicine trials (PMTs) have gained traction due to the ability to map the genomic profiles of individual tumors and match them to targeted therapies, but is still a challenge for OS due to limited efficacy and low enrollment rate. This low enrollment rate is due to several challenges, including tumor heterogeneity, limited molecular targets, and logistical in conducting trials. These barriers hinder the full realization of the potential benefits of PMTs to improve patient outcomes.

One promising avenue is the use of naturally occurring canine OS, which share strong biological and molecular similarities with humans. Canine OS is estimated to be 10 times more common in pet dogs than in humans. Moreover, dogs develop these tumors spontaneously, with an intact immune system and comparable environmental exposures to humans, making them a valuable model for studying OS and improving the design of human trials.

This study leverages data from 202 spontaneous canine OS, aiming to bridge the gap between preclinical investigations and clinical application. We utilized real-world clinical-genomic data from the FidoCure® platform, a canine precision medicine initiative that uses next-generation sequencing (NGS) to screen for cancer-associated genomic alterations. We identified that the most common genomic alterations occurred in tumor suppressor genes TP53, SETD2, PTPRJ, PTEN, RB1, DMD, BRCA1/2, and oncogene PIK3CA. These findings are consistent with the genomic profile seen in humans, reinforcing the value of the canine model.

We also analyzed the correlation between small-molecule targeted therapies and genomic alterations. Through FidoCure®, veterinarians can leverage insights from the NGS panel to apply any of 11 human-approved therapies. Our analysis identified significant benefits from small-molecules when used as adjuvant treatment alongside chemotherapy with median survival of 354 days compared to 194 days when just chemotherapy is used (P=0.0011).

Our study demonstrates the potential of combining small-molecule targeted therapies with traditional treatments, emphasizing the value of cross-species models in advancing osteosarcoma research and treatment.

#3915 An orthotopic model for murine urothelial carcinoma with response to standard of care checkpoint inhibitor treatment.

E. Rainbolt, A. Wong, N. Ansari, I. Mick, E. Dubis, J. Crews, J. Neil, **P. Fadden**;
Charles River Laboratories, Inc., Durham, NC

MB49 is a commercially available cell line used to evaluate bladder cancer for syngeneic growth and potential therapeutic response in preclinical studies. Subcutaneous implantation provides a convenient and accessible location to monitor tumor growth and response to therapy; however, an orthotopic approach may provide a more clinically relevant model. Bladder cancer is the fourth most common cancer in men and current research is focusing on immunotherapy to reduce toxicity while improving efficacy. Current orthotopic bladder implant models include time consuming intralumenal installation methods, however we will focus on a faster more direct implant approach in the intramural space (for implant characterization and evaluation see Bitaraf 2022). To establish the orthotopic model, we implanted cells directly into the bladder wall or intramural space in syngeneic C57BL/6 mice. Two cell inoculums were evaluated: $2.5x10^5$ based on subcutaneous implant standards and $1x10^5$ after initial testing proved rapid tumor progression. Individual animals were evaluated for disease progression based on body weight and bladder palpation performed at regular intervals with the frequency increased as needed based on clinical observations. If enlarged, bladders were expressed to confirm bladder function and urine color. Humane endpoint was met if the bladder was unable to be expressed or if pigmenturia was present. Necropsies were performed to evaluate bladders for tumor and any abnormal observations were recorded. Both cell inoculums had fast growth with median time to endpoint at nine to twelve days post implant. The lower cell inoculum ($1x10^5$) was chosen to proceed with efficacy data. Responses to the checkpoint inhibitors anti-CTLA-4 and anti-PD-1 RMP1-14 are described in the poster figures and tables. For comparison, the anti-CTLA-4 and anti-PD-1 response data is provided for the MB49 subcutaneous model. In summary, the development of the MB49 bladder orthotopic model will provide a sensible alternative that recapitulates the difficulties of treating bladder tumors in addition to establishing a more clinically relevant model to evaluate cancer therapies compared to standard subcutaneous implanted models. Future testing with a luciferase labeled cell line will provide imaging capabilities to monitor tumor growth via in vivo bioluminescence imaging (BLI). Bitaraf , M., Muhammadnejad, S., Azimzadeh, A., Tanourlouee, S.B., Amini, E., Zolbin, M.M., Kajbafzadeh, A.M. Evaluation of direct intramural injection to the bladder wall as a method for developing orthotopic tumor models, Animal Model Exp Med (2022) Nov30; 5(6): 575-581.

#3916 Breast cancer brain metastasis development induced by intracarotid injection of MDA-MB 231 human breast cancer cells in mice.

Romain Roth Dit Bettoni, Nicolas Hoffmann, Jordan Longin, Peggy Provent, Ismahene Benzaid, **Marc Hillairet De Boisferon**

Oncodesign Services, Dijon, France

Breast cancer is the most common malignancy in women worldwide. Breast cancer can be divided into four types based on molecular subtypes: luminal A, luminal B, human epidermal growth factor receptor 2 (Her2) positive, and triple negative breast cancer (TNBC). These subtypes have very different prognoses and treatment methods.
Herceptin, a treatment specifically directed against Her2 (overexpressed in 20–25% of breast cancers), has been widely used and improves the prognosis for Her2-positive breast cancer. TNBC accounts for only 15–20% of breast cancers and is considered as the most aggressive breast cancer. This subtype does not express estrogen receptor (ER), progesterone receptor (PR), and Her2. Additionally, it is usually identified at an advanced stage of cancer progression and often results in metastases to the brain, bones, lungs, and liver.
Human subcutaneous tumors represent a small fraction of cancers that are easy to treat by surgery and chemotherapy and are technically easy to recapitulate in animals. In contrast, high grade breast cancer and metastases represent a leading cause of cancer-related mortality for which more relevant animal tumor models are required. Additionally, the poor prognosis of metastases is badly increased in the brain, particularly due to the difficulty for novel therapies to overcome the blood brain barrier. There are very few animal models exclusively focused on the development of brain metastases, and most are based on stereotactic intracranial inoculation of cells. This injection mode rather mimics the onset of primary tumors than metastases, as it leads to the formation of single tumors and does not recapitulate the extravasation and seeding events of the metastatic cascade.
In this poster we show a new TNBC mouse model of brain metastasis. We induced brain metastases by intracarotid injection of TNBC cells, thus recapitulating the tumor cells' pathway to the brain. We evaluated the metastases progression by morphological T2 weighted MRI imaging. In parallel, we assessed the blood brain barrier integrity by T1 weighted imaging after Gd-DOTA injections and followed edema formation by FLAIR MRI.

#3917 A functional precision medicine assay for immunotherapy and combination therapy testing in liver and pancreatic cancers (PEAR-PAL).

Eleonora Peerani[1], Farah Sangkolah[1], Niamh A. Leonard[1], Yann Bouremel[1], Demi Wiskerke[1], Thomas D. L. Richardson[1], Magda B. Martinez Espuga[2], Diana Visan[1], George R. T. B de Fraine[1], Jay Kearney[1], Francesco Iori[1], Duleek N. B. Ranatunga[1]

[1]Pear Bio, London, United Kingdom,[2]Biodiscovery Institute, University of Nottingham, Nottingham, United Kingdom

The PEAR-PAL study was aimed at developing a novel ex vivo 3D immune-tumor model with integrated AI-based image analysis to optimize precision therapies in hepatocellular carcinoma (HCC) and pancreatic ductal adenocarcinoma (PDAC). Both indications currently lack effective biomarkers to guide combination treatment clinical decision-making. Fresh samples from 46 patients (30 HCC, 16 PDAC) were analyzed to evaluate the feasibility of functional precision medicine (FPM) in high-unmet-need cancers.
The platform isolates viable tumor and immune cells, co-culturing them in a cancer-specific 3D hydrogel matrix, allowing subsequent testing of FDA-approved immunotherapies, chemotherapies, and tyrosine kinase inhibitors (TKIs) using a patented microphysiological immuno-oncology plate. After isolation, the 3D immune-microtumors were exposed to various drug combinations and monitored daily over five days through confocal imaging and a computer vision pipeline. Key metrics (e.g., immune cell infiltration, tumor cell viability, and microtumor volume) were evaluated to capture inter- and intra-patient variability in response to clinical treatment regimens. Therapies included chemotherapies (e.g., gemcitabine, nab-paclitaxel), TKIs (e.g., cabozantinib, sorafenib), and immunotherapies (e.g., pembrolizumab). In PDAC, further optimization focused on testing multi-drug chemotherapeutic combinations such as FOLFIRINOX.
Tumor processing was optimized, achieving mean viability of 73±19% for HCC and 80±17% for PDAC (N=36 and 12). Live/Dead and CyQuant assays determined the optimal hydrogels to maintain 3D cell viability over the five-day assay. PBMC infiltration in the optimized hydrogel formulation increased PBMC counts from 272 to 1,485 by day 4 compared to Matrigel. Dosing for each therapeutic class was optimized via 2D and 3D dose-response assays in cell lines, through molecular readouts (in-cell western, pRTK arrays, Live/Dead, CTG) and validated in primary samples. A microphysiological plate was developed for sequential treatment addition/removal and imaging without disrupting the 3D immune-microtumor. Functional assays showed patient-specific variability in responses to treatments, with pembrolizumab decreasing microtumor volume, enabling CD8- PBMC infiltration, and increasing T-cell infiltration 3-fold compared to controls (n=2).
Future trials will correlate ex vivo findings with clinical outcomes, positioning the PEAR-PAL platform as a promising tool for individualized treatment in liver and pancreatic cancers. This approach exemplifies the potential of FPM to address current limitations in precision oncology for complex cancers lacking actionable biomarkers.

#3918 Development and validation of a systemic human multiple myeloma model utilizing luciferase expressing H929 tumor cells.

B. John[1], D. Harris[1], S.-C. Chou[1], T. Rowe[2], N. Westrick[1], N. Nightenhelser[1], A. Wong[1], E. Rainbolt[1], Z. Ward[1], J. Neil[1];
[1]Charles River Laboratories, Inc., Durham, NC, [2]Charles River Laboratories, Inc., Durahm, NC

Multiple Myeloma (MM) is the second most common hematological malignancy of clonal plasma cells that originates in the bone marrow (BM). Despite significant advancements in the treatment of MM, this disease remains incurable with a poor prognosis in relapsed/refractory patients. MM has complex disease dynamics due to the genetically diverse clonal population of myeloma cells. Thus, pre-clinical models are needed to translate tumor heterogeneity for appropriate risk assessment and the development of safe and effective treatment regimens. We established a Multiple Myeloma in vivo model by systemic implantation of the luciferase-expressing tumor cell line H929 (H929-luc) into immunodeficient NCG mice. First, we generated a H929-luc monoclonal cell line from a polyclonal pool of stable luciferase-expressing cells by limiting dilution cloning. Single cells from the stable pool were expanded in selection medium and based on in vitro growth properties and bioluminescence intensity H929-luc monoclonal lines were selected for in vivo evaluation. The in vivo tumor growth profile was determined by testing the monoclonal lines at two different cell inoculums, and disease progression was monitored by in vivo serial bioimaging. For validation of the H929-luc in vivo model, we determined the efficacy and survival benefit in response to various clinically relevant standard of care agents including dexamethasone, daratumumab, cyclophosphamide, and vincristine. The quantification of tumor burden by bioluminescent imaging showed reduced tumor burden and prolonged survival with cyclophosphamide and vincristine. Taken together, we have developed a well characterized and robust systemic H929-luc model that recapitulates the disease dissemination and invasiveness of multiple myeloma for evaluating novel therapeutic approaches to treatment.

#3919 Identifying dual inhibitions of kinases to treat pancreatic ductal adenocarcinoma.

Masahiro Sonoshita

Hokkaido University, Sapporo, Japan

Significant advancements have been achieved in elucidating the pathogenesis of pancreatic ductal adenocarcinoma (PDAC) through the development and application of mammalian models. To accelerate drug discovery by identifying novel therapeutic targets on a systemic level, we established a *Drosophila* model recapitulating the genetic signature of PDAC, characterized by alterations in *KRAS*, *TP53*, *CDKN2A*, and *SMAD4*, which are associated with the poorest patient prognosis. The '*4-hit*' flies manifested tumorigenic phenotypes, such as epithelial transformation and reduced animal viability. Comprehensive kinome-wide genetic screening using this model identified potential therapeutic targets, including MEK, AURKB, and GSK3β. Notably, combined inhibition of these targets effectively suppressed the growth of human PDAC xenografts in mice. Moreover, the activity of these kinases correlated with adverse outcomes in PDAC patients. This *Drosophila*-based platform offers a robust whole-body assay to complement existing methodologies to determine therapeutic targets in PDAC.

#3920 The role of humanized monoclonal antibody ALT-100 in reducing cancer-induced bone pain: A murine animal model study.

N. C. Mathur[1], E. Villarroel[2], I. Villarroel[2], E. Bahramnedjad[2], S. Dickinson[1], J. G. N. Garcia[3], T. Largent-Milnes[1], T. W. Vanderah[1]; [1]University of Arizona College of Medicine, Tucson, AZ, [2]University of Arizona, Tucson, AZ, [3]The Herbert Wertheim University of Florida Scripps Institute for Biomedical Innovation and Technology, Gainsville, FL

Breast cancer commonly metastasises to the bone promoting a combination of inflammatory and neuropathic mechanisms. This leads to different perceptions of pain with a reported 30-50% of all cancer patients and 75-90% of late-stage patients having cancer-induced bone pain (CIBP). Thus, there is a need for therapeutic interventions to decrease pain caused by the mechanisms of CIBP. Extracellular Nicotinamide Phosphoribosyltransferase (eNAMPT) is a cytokine overexpressed in metastatic breast carcinoma that binds to Toll-like Receptor 4 (TLR4), triggering a signaling cascade through Nuclear Factor kappa beta (NFk-B) and resulting in inflammation, osteoclastogenesis, and severe bone pain. To assess the impact of eNAMPT on CIBP, ALT-100, a monoclonal antibody neutralizing eNAMPT, was tested in a murine CIBP model. The left femur of C57BL/6J female mice was inoculated with EO771 breast cancer cells and allowed 7 days for recovery from tumor growth and the development of cancer-induced pain. Behavioral data were collected to evaluate ALT-100's effectiveness in reducing pain. Four groups were used: sham + saline, sham + ALT-100, cancer + ALT-100, and cancer + saline, with ALT-100 dosed at 4 mg/kg. Pain was assessed on days 0, 7 (pre- and 2 hours post-injection of ALT-100), 10, and 14 using flinching and guarding behavior tests. A two-way ANOVA and Tukey's multiple comparisons test indicated that ALT-100 significantly reduced pain compared to the cancer + saline group. Bone scoring on days 0 and 14 showed no significant differences in bone lesions and fractures between cancer + ALT-100 and cancer + saline groups. To test ALT-100's efficacy in inhibiting osteoclastogenesis in vitro, RAW 264.7 macrophage cells were plated in five groups exposed to different drug combinations: media, eNAMPT, ALT-100, 1:1 eNAMPT + ALT-100, and 1:2 eNAMPT + ALT-100. After 5 days a marker for osteoclastogenesis, Tartrate-Resistant Acid Phosphatase staining, was measured demonstrating that cells treated with ALT-100 + eNAMPT had significantly fewer osteoclasts than those treated with eNAMPT alone. Together these results indicate that ALT-100 inhibits metastatic breast cancer pain and eNAMPT-induced osteoclast differentiation.

#3921 Development of a KRAS-G12C-driven pancreatic cancer mouse model.

Yongkun Wei, Minghui Liu, Er-Yen Yen, Jun Yao, Phuoc T. Nguyen, Xiaofei Wang, Zecheng Yang, Dean N. Pan, Jangho Park, Yiming Cai, Andrea Viale, Huamin Wang, Dan Zhao, Ronald A. DePinho, Wantong Yao, Haoqiang Ying

UT MD Anderson Cancer Center, Houston, TX

$KRAS^{G12C}$ inhibitor (G12Ci) has produced encouraging, albeit mild clinical benefit in pancreatic ductal adenocarcinoma (PDAC). Identifying and targeting resistance mechanisms to G12Ci treatment remains the major challenge due to the lack of faithful preclinical models. To better understand the tumor biology of the $KRAS^{G12C}$ allele, we established a mouse model engineered with the *LSL-*$Kras^{G12C}$, conditional *p53* knockout ($p53^{L}$), and pancreatic-specific *p48-Cre* alleles. The resulting *p48-Cre LSL-*$Kras^{G12C}$ $p53^{L/+}$ ($K^{C}PC$) mice exhibit decreased number and area of PanIN/ADM lesions compared to age-matched $Kras^{G12D}$-driven controls ($K^{D}PC$). The decreased neoplastic activity of $Kras^{G12C}$ aligns with decreased downstream signaling (phospho-ERK and phospho-AKT) and cell proliferation (Ki67) in premalignant epithelial cells, suggesting that $KRAS^{G12C}$ is a less potent oncogenic allele compared to $KRAS^{G12D}$. Compared to $KRAS^{G12D}$, $KRAS^{G12C}$ failed to induce complete ADM which is characterized with the transdifferentiating of acinar cells into progenitor-like ductal cells. The tumor microenvironment of $K^{C}PC$ mice is less immunosuppressive than that of $K^{D}PC$, which may partially explain the slower progression of $K^{C}PC$ tumor. The relatively weak tumor development in $K^{C}PC$ model results in significantly prolonged median overall survival compared to $K^{D}PC$ model. Histopathology analysis of advanced tumors from the $K^{C}PC$ model revealed similar histological features of ductal adenocarcinoma compared to $K^{D}PC$ model or human PDAC. As for KRAS downstream signaling, PDAC lesions from the $K^{C}PC$ and $K^{D}PC$ models exhibited similar phospho-ERK, phospho-MEK and phospho-S6K1. Both the total KRAS level and the amount of active form of KRAS are also comparable between the two groups. Interestingly, phospho-AKT level was lower in $K^{C}PC$ than in the $K^{D}PC$ tumor cells. Together, our data indicates that, while $KRAS^{G12C}$-driven PDAC premalignant lesions exhibit distinctive molecular features compared to the $KRAS^{G12D}$-driven ones, there is no obvious cellular or molecular difference between the two KRAS genotypes once the tumor progresses to an advanced stage.

#3922 A p53-deficient, PTK2/cMyc-driven ovarian cancer mouse model for preclinical drug discovery.

Ziping Liu[1], Wenjing Zhang[1], Xinxin Zhao[1], Yongshuai Li[1], Xiaoya Hou[1], Satyanarayana Pochampally[1], Shelby Waddell[1], Shiji Song[1], Yaohong Wang[2], Lawrence M. Pfeffer[1], Duane D. Miller[1], Junming Yue[1], **Wei Li**[1]

[1]University of Tennessee Health Science Center, Memphis, TN,[2]MD Anderson Cancer Center, Houston, TX

Background: Ovarian cancer (OC) remains a significant health issue for women due to its late diagnosis and chemoresistance. Currently, there is no relevant mouse OC model for preclinical drug screening and treatment.
Methods: We established a mouse OC cell line model, PC53K, by transforming primary ovarian surface epithelial cells through CRISPR/Cas9-mediated TP53 knockout and simultaneous overexpression of human PTK2 and cMyc. We further developed the paclitaxel-resistant PC53K/TxR cell line. PC53K and PC53K/TxR cell lines were validated in vitro and in vivo in an orthotopic mouse model. We also evaluated the efficacy of two novel tubulin inhibitors, the clinical drug VERU-111 and the preclinical compound SB-216, using the PC53K/TxR model in vitro and in vivo.
Results: Mice intrabursally injected with PC53K cells exhibited bloody ascites, aggressive primary tumor growth and widespread metastasis, which faithfully recapitulates the phenotypes of human ovarian serous adenocarcinoma. Additionally, the paclitaxel-resistant PC53K/TxR cell line shows significant higher IC50 for paclitaxel than PC53K cell line, indicating it is a valuable tool for studying OC chemoresistance. Compounds VERU-111 and SB-216 significantly inhibited tumor growth and metastasis in orthotopic OC mouse models by overcoming chemoresistance. This study demonstrates the effectiveness of the PC53K and PC53K/TxR models for preclinical drug screening and validates the potential of VERU-111 and SB-216 in overcoming chemoresistance and treating OC.
Significance: The development of the PC53K and PC53K/TxR mouse models represents a significant advancement in OC research. By mimicking the genetic profile, aggressive behavior and chemoresistance of human OC, these models provide a robust platform for preclinical drug discovery and development.

#3923 Lung cancer autochthonous model gene expression database.

Ling Cai

UT Southwestern Medical Center, Dallas, TX

Lung cancer, the leading cause of cancer mortality, exhibits diverse histological subtypes and genetic complexities. Numerous preclinical mouse models have been developed to study lung cancer, but data from these models remain disparate, siloed, and difficult to compare centrally. To address this, we established the Lung Cancer Autochthonous Model Gene Expression Database (LCAMGDB), an extensive repository encompassing 1,354 samples from 77 transcriptomic datasets, including 974 from genetically engineered mouse models (GEMMs), 368 from carcinogen-induced models, and 12 from a spontaneous model. Importantly, 85% of the data were reprocessed through standardized pipelines tailored to each platform, including RNA-seq and five microarray platforms, enhancing comparability across studies. LCAMGDB aligns 859 GEMM tumors with human lung cancer mutations, revealing the need to expand the diversity of genetic aberrations modeled. Our analysis highlights underrepresentation of key alterations such as ROS1, RET, and MET, which are pivotal in human cancers. Furthermore, we are actively updating LCAMGDB to include 989 additional samples from 44 studies, augmenting the current collection of RNA-seq data by nearly 80%. Complementing the database, we developed a web application at https://lccl.shinyapps.io/LCAMGDB/ offering researchers data review and download, as well as intuitive tools for dynamic gene expression analysis and cross-study comparisons. Future iterations aim to integrate pathology data through engagement with the lung cancer mouse model community, potentially complementing transcriptomic insights. LCAMGDB bridges gaps between mouse models and human lung cancer, laying the groundwork for translational research and collaborative advancements. By standardizing and expanding this resource, we aim to improve the fidelity and relevance of preclinical studies for understanding lung cancer biology and developing therapies.

#3924 *in vitro- in vivo* model correlations and cross-species comparisons in osteosarcoma.

Emma N. Vanderboon, Geoffrey A. Wood, Courtney R. Schott

Pathobiology, University of Guelph, Guelph, ON, Canada

Osteosarcoma (OS) is the most common primary malignant bone cancer of both humans and dogs, characterized by its high rate of metastasis. Despite decades of research, treatment strategies for OS have seen limited advancements in over 40 years. This stagnation highlights the critical need for accurate preclinical models to investigate metastasis and develop relevant therapeutic approaches. Understanding the utility and limitations of *in vitro* and *in vivo* OS models is paramount to deriving meaningful conclusions that can guide future research and inform clinical strategies. This study aims to develop an *in vitro* assay pipeline to investigate mechanisms of metastasis and to characterize a panel of human OS cell lines previously characterized using orthotopic amputation and intravenous murine metastasis models, allowing us to examine *in vitro- in vivo* correlations. Furthermore, the study seeks to characterize a diverse panel of canine OS cell lines, enabling cross-species comparisons since canine OS serves as an important model for human disease and vice versa. By correlating findings between species and *in vitro* and *in vivo* models, this investigation seeks to bridge gaps in understanding how metastatic behaviors observed in the laboratory translate to the complexities of metastasis in living organisms. The human panel includes eight patient-derived xenograft (PDX)-derived cell lines (5 primary, 3 metastatic) and two commercial OS cell lines (MG63, SJSA). The canine panel includes commercial cell line D17 and 13 primary cell lines (11 primary, 2 metastatic). The *in vitro* pipeline comprises six assays designed to mimic key steps of the metastatic cascade: migration (via scratch and transwell assays), invasion (using a spherical invasion assay), anchorage-independent survival (anoikis assay), and colony formation (clonogenic assay). Additionally, doubling-time will be measured to assess proliferation. Results show differences between *in vivo* and *in vitro* metastatic behavior for individual cell lines. By establishing a robust and reproducible cross-species *in vitro* assay pipeline, this study aims to enhance our understanding of OS metastasis and provide a platform for future mechanistic studies. The ultimate goal is to facilitate the accurate interpretation of *in vitro* and *in vivo* findings, ensuring that conclusions drawn from these models are relevant and actionable in the context of future OS research and therapeutic development.

#3925 *In vitro* and *in vivo* characterization of *Cdh1* CRISPR knockout in syngeneic ER+ SSM3 mouse mammary tumor cells.

Insa Thale[1], Dixcy J. S. John Mary[1], Sarah Wang[2], Lora Rigatti[3], Jagmohan Hooda[4], Peter Lucas[5], George C. Tseng[2], Adrian V. Lee[4], Steffi Oesterreich[4]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Department of Biostatistics, University of Pittsburgh, Pittsburgh, PA,[3]Division of Laboratory Animal Resources, University of Pittsburgh, Pittsburgh, PA,[4]University of Pittsburgh, Pittsburgh, PA,[5]Mayo Clinic College of Medicine and Science, Rochester, MN

Invasive lobular carcinoma (ILC) accounts for 10-15% of all breast cancers, making it the most common special histological subtype of breast cancer. Initially, ILC is associated with a better response to adjuvant hormonal therapy compared to invasive ductal breast cancer (IDC). However, patients with ILC often experience a worse long-term outcome. Over 90% of ILCs are estrogen receptor positive (ER+) and do not express functional E-cadherin (CDH1). There are limited studies aimed at improved understanding of the tumor microenvironment (TME) in ILC. Therefore, we set out to generate and characterize a syngeneic mouse cell line model that mimics the genetic loss of *CDH1* seen in ILC.

We created an ER+ ILC-like mammary cancer model using the syngeneic SSM3 cell line, derived from an ER+ mouse mammary tumor in STAT1-deficient mice. To mimic the hallmark feature of ILC, we used CRISPR-Cas9 to knock out *Cdh1*.

In vitro assays were performed to evaluate the effects of *Cdh1* knockout (KO) in both 2D and 3D environments, focusing on cell proliferation and estrogen sensitivity. These experiments demonstrated increased growth of *Cdh1* KO SSM3 cells in both 2D and 3D environments, together with altered cell morphology and increased sensitivity to estrogen.For *in vivo* characterization, we focused on tumor growth and metastasis. SSM3 Scr and *Cdh1* KO cells were injected into the mammary fat pad of mice. Initial findings revealed increased tumor growth in mice injected with SSM3 *Cdh1* KO cells, while metastasis studies are ongoing.

RNA-seq analysis of both SSM3 cells grown *in vitro*, and *in vivo* tumor tissues is ongoing and will help to identify distinctive gene expression changes in the *Cdh1* KO model. We will also analyze changes in the TME, such as immune cells, ECM and fibroblasts.

In summary, we have successfully generated an ER+ syngeneic ILC model, and we expect that growing the cells *in vitro* and *in vivo* represents a valuable tool for studying ILC and holds promise for advancing the development of targeted immunotherapies and endocrine therapies for this breast cancer subtype.

#3926 The effect of *Pten* haploinsufficiency on genomic and transcriptomic profiles in combined genetically-engineered mouse models for colonic neoplasia based on *Apc* inactivation.

Haruki Sada[1], Hiroaki Niitsu[2], Hikaru Nakahara[2], Naoya Sakamoto[3], Hirotaka Tashiro[1], Hideki Ohdan[4], Takao Hinoi[2]

[1]Surgery, Kure Medical Ctr. & Chugoku Cancer Ctr., Kure, Japan,[2]Clinical and Molecular Genetics, Hiroshima University Hospital, Hiroshima, Japan,[3]Molecular Pathology, Hiroshima University, Hiroshima, Japan,[4]Gastroenterological and Transplant Surgery, Hiroshima University, Hiroshima, Japan

Background and Aim: We have reported genetically-engineered mouse models for colonic neoplasia by using our novel *CDX2P-Cre* mice, in which Cre is restrictedly expressed in colonic epithelial cells. Although colonic tumors are generated in *CDX2P-Cre;Apc$^{flox/+}$* (*CPC;Apc*) mice with highly penetrant rate, greater number and deeper invasion of colonic tumors were observed in *CDX2P-Cre;Apc$^{flox/+}$;Pten$^{flox/+}$* (*CPC;ApcPten*), possibly resulting from haploinsufficiency of *Pten* gene. We have also confirmed shorter lifespan in *CPC;ApcPten* than that in *CPC;Apc* (AACR Annual Meeting 2018). Here, we test if these phenotypes come from one copy loss of *Pten* itself or secondary genetic and/or transcriptomic alterations induced by *Pten* loss by using whole genome sequence (WGS) and RNA sequence from macroscopically-dissected colonic tumors (bulk RNA-seq).

Methods: WGS for five tumors and five livers as counterpart controls in each mouse model was performed by DNBSEQ platforms. Bulk RNA-seq was performed for three tumors in each model.

Results: In the analysis using B-allele frequency, copy-neutral LOH occurred in chromosome 18 including *Apc* loci specifically in colonic neoplasia in both *CPC;Apc* and *CPC;ApcPten* mice. In contrast, LOH was not observed in chromosome 19 including *Pten* loci in *CPC;ApcPten* mice. We also confirmed remarkably decreased coverage of reads in reference mapping in *Apc* locus, and there was a slight decrease of coverage in *Pten* locus. There were no additional driver gene mutations in *CPC;Apc* or *CPC;Apc+Pten* in WGS. All these results suggested just one copy loss of *Pten* resulting in aggressive tumor phenotype in *CPC;ApcPten* mice. In RNA-seq and subsequent GSEA comparing colonic tumors in *CPC;ApcPten* with those in *CPC;Apc* revealed upregulation of some signal pathways including mTORC1. Supporting this observation, number of colon tumors, especially adenocarcinomas, were decreased by rapamycin administration to *CPC;Apc+Pten*. Similarly, rapamycin was more effective in tumoroids from *CPC;Apc+Pten* those from *CPC;Apc*.

Conclusion: WGS reveals one copy loss of *Pten* locus is the only genetic alteration *in CPC;Apc+Pten* when compared with *CPC;Apc*. One copy loss of Pten is sufficient to upregulate mTORC1 pathway in a *CPC;Apc+Pten* mouse model, resulting in promotion of tumor formation and invasion.

#3927 Bone Metastasis Technology Platform: Establishing clinically relevant bone metastasis models for breast and prostate cancer and multiple myeloma.

Tiina E. Kahkonen[1], Jie Wen[2], Ru Yang[2], Yuyang Xu[2], Michael Zhang[2], Jussi M. Halleen[1]

[1]OncoBone Ltd, Kiviniemi, Finland,[2]PharmaLegacy LLC, Shanghai, China

Bone metastases are a significant clinical problem in many major cancers, especially in breast and prostate cancer where 70-90% of advanced patients develop bone metastases. Myeloma bone disease is associated with similar clinical problems than bone metastases, including increased risk of fractures and bone pain that decrease the quality of life. Current cancer therapies can only partially decrease tumor growth, resulting in only 5% of bone metastatic patients being alive 5 years after the diagnosis. Bone metastases are therefore a high unmet medical need with a high demand for effective therapies. Lack of appropriate preclinical bone metastasis models that would exhibit the same clinical features that are observed in bone metastatic patients has made it difficult to advance therapy development at early stages. This study describes the establishment of three preclinical bone metastasis models, a breast cancer model using 4T1 mouse triple-negative breast cancer cells in BALB/c mice, a prostate cancer model using RM-1 mouse androgen-insensitive prostate cancer cells in C57BL/6 mice, and a multiple myeloma model using human RPMI 8226 cells in immunodeficient NPG mice. The cancer cells were inoculated intratibially into the bone marrow to model tumor growth in bone. Tumor growth was monitored by bioluminescence imaging (BLI), cancer-induced bone changes by X-ray imaging, and bone pain by Von Frey filaments (mechanical allodynia).

In the 4T1 breast cancer model, 100% of the mice had bone metastases at day 7, and maximum study duration was 21 days. Osteolytic bone lesions were clearly observed and bone pain was detected at day 7. In the RM-1 prostate cancer model, 83% of the mice had bone metastases at day 7, and 100% of the mice at day 14, and maximum study duration was 28 days. Bone pain was observed at day 7, and osteolytic-mixed bone metastases were visible at day 14. In the RPMI 8226 multiple myeloma model, 100% tumor take rate was detected at day 7. Osteolytic bone metastases were visible at day 21, and maximum study duration was 100 days.

We have established a clinically relevant Bone Metastasis Technology Platform (BMTP©) that currently includes preclinical bone metastasis models for breast and prostate cancer and multiple myeloma. These models have clinical features that are similar to those observed in bone metastatic patients. In preclinical models established in BMTP, tumor burden is monitored by BLI, the type and extent of cancer-induced bone loss is visualized by X-ray imaging, and bone pain is analyzed to provide a clinically relevant readout about the quality of life. We conclude that BMTP is a clinically relevant translational tool for evaluating efficacy of cancer therapies on bone metastasizing cancers.

#3928 Analyzing treatment effects of chemo- and immunotherapy in the context of the TME in an *ex vivo* model of HNSC.

Mareike S. Haarmann, Philipp Zimmermann, Malte Suchan, Dominik Funken, Jens Peter Klu?mann, Johannes Bragelmann

University Hospital of Cologne, Cologne, Germany

Head and neck squamous cell carcinoma (HNSC) accounts for 450.000 deaths worldwide each year. Rising cases of HNSC have been predicted.

Understanding the tumor biology in patients is crucial to developing more efficient treatment strategies against HNSC. Especially in the context of immunotherapy, the interplay of immune, cancer and stroma cells in the tumor microenvironment (TME) strongly influences the biological characteristics and behavior of the tumor and its response to therapy. However, most HNSC *in vitro* models such as patient-derived cell lines and organoids do not recapitulate TME complexity.

Patient-derived tumor fragments (PDTFs) are a novel pre-clinical model to bridge this gap. Isolated directly from patients, they preserve the spatial and cellular tumor composition, allowing analysis of tumor behavior and reaction to treatment in the context of the TME. In this study, we adapted the PDTF methodology to study the effects of combined chemo- and immunotherapy on HNSC.

To generate PDTFs, tumors from patients with HPV-negative HNSC were extracted in routine surgery and immediately transferred to the lab. The tumors were mechanically dissected into 1 mm^3 fragments, termed PDTFs. Several PDTFs per tumor were distributed across wells of a cell culture plate and subjected to different treatments with cisplatin, nivolumab or caspase inhibition as well as combinations. After short-term *ex vivo* culture of max. 72h, we performed gene expression analysis via qPCR and RNA-seq as well as histological analysis of PDTFs. In total, PDTFs from 14 different HNSCs could be subjected to treatment, including 2 longitudinal biopsies from the same patient.

Histological analysis of freshly extracted PDTFs showed the intact TME *ex vivo*.

Transcriptomic analysis revealed a significant reaction to treatment that was consistent with previous *in vitro* results. HALLMARK gene sets involved in cell cycle progression (Mitotic spindle, G2M Checkpoint, E2F Targets), EMT as well as glycolysis were downregulated, while inflammatory signaling-related gene sets were enriched, especially in the combined treatment with immunotherapy. Additionally, increased IFNγ expression indicates specific effect of the immunotherapy on leucocytes in the TME.

Matched PDTFs from the same patient showed strong correlation of transcriptomic behavior.

Overall, we could show treatment-specific reaction of the PDTFs to both chemotherapy and immunotherapy, that included effects on cell cycle, metabolism and inflammation. The measurable reaction of the leucocytes within the TME sets this model apart from other *ex vivo* models.

Together with the patient-specific differences in transcriptomic behaviour, evident in the matched PDTFs, this makes PDTFs an interesting *ex vivo* model whose application for patient-specific treatment prognosis will be the subject of further studies.

#3930 Preclinical models of cancer cachexia: Bridging the gap to clinical applications.

Hongyan Sun[1], Dan Zhou[1], Yunlong Jiang[1], Jianming Xu[1], Jing Zhao[1], Xiang Gao[1], Jun Wang[2]

[1]GemPharmatech Co., Ltd, Nanjing, China,[2]GemPharmatech Co., Ltd, San Diego, CA

Cancer cachexia (CC) is a multifactorial syndrome affecting up to 80% of advanced cancer patients. Characterized by unintentional weight loss, skeletal muscle wasting, and fat depletion, CC significantly impairs quality of life, treatment tolerance, and survival. Despite its prevalence, effective therapeutic options remain limited, underscoring the urgent need for preclinical models that closely mimic clinical symptoms to support drug development.

Towards this end, we developed and validated a CC preclinical model with HT-1080 xenograft in NCG mice, which demonstrated hallmark CC features, including body weight loss, fat and muscle loss, as well as impaired physical performance. The tumor-bearing mice also displayed elevated hGDF15 levels (undetectable in non-tumor-bearing (NTB) mice), and significantly reduced cumulative food intake. In this study, we used Ponsegromab (anti-GDF15 monoclonal antibody) as a positive treatment for CC starting when mice had lost ~7% body weight. At the end of the study, mice in hIgG1-treated control group suffered over 15% body weight loss, while the Ponsegromab treatment restored body weight to baseline levels. Although Ponsegromab treated mice remained lighter than NTB PBS controls, our data suggested that Ponsegromab treatment could significantly improve food intake and increase survival rates. Fat and muscle tissue weights, including gonadal, peri-renal, and inguinal subscapular white fat, as well as gastrocnemius and soleus muscles, were significantly reduced in the hIgG1-treated control group compared to baseline controls. Ponsegromab treatment preserved fat and muscle weights to levels similar to the baseline group. Motor function assessed via rotarod performance, and grip strength showed coordination and strength impairments in tumor-bearing mice, while Ponsegromab significantly improved grip strength and physical performance in comparison to the hIgG1-treated control group.

In conclusion, our validated preclinical cachexia models closely align with clinical CC manifestations, providing a robust platform for the evaluation of novel therapeutic strategies. These models enable detailed exploration of CC mechanisms and support the development of effective interventions to mitigate cachexia and improve patient outcomes.

#3931 Establishment of an orthotopic intracranial luciferase labelled patient derived xenograft of glioblastoma in immunocompromised mice model.

Seth Hannah, Fu-Ju Chou, Ksenia Vulikh, Mara Gilardi, Stefano Cairo, Paul Heverly

Champions Oncology, Inc., Hackensack, NJ

Glioblastoma multiforme (GBM) is the most aggressive and fatal form of brain cancer, with a median survival time of less than 15 months. Currently, GBM patients have limited treatment options and poor efficacy outcomes, underscoring the urgent need for innovative research methods and more effective therapeutic strategies. Patient-derived xenografts (PDX) offer a promising approach to evaluate the side effects and potency of drugs in vivo. By implanting GBM patient tumor samples into immunocompromised mice, we gain invaluable insights into the unique mutations and genetic profiles of individual GBM models. PDX models provide a more accurate and personalized approach compared to traditional cell line-based studies. Intracranial xenograft techniques emulate the interaction of brain tumors with complex brain microenvironment and the blood-brain barrier, offering significant advantages for testing new regimens for brain tumors. Non-invasive imaging techniques like MRI and in vivo imaging systems (IVIS) have traditionally been used to monitor intracranial tumor growth and treatment response. However, challenges such as achieving the expected resolution with mouse MRI, long scan times, high costs, and technical barriers in labeling PDX material limit their application. This study aims to establish a pre-clinically relevant platform for the development and validation of potential pharmaceutical treatments for glioblastoma, utilizing patient-derived cells within an appropriate tumor microenvironment. To create this model, U87 and patient-derived glioblastoma cells were labeled with luciferase and cultured ex vivo to confirm bioluminescent signal integrity. Using a stereotaxic apparatus and established skull-to-brain mapping techniques, cell suspensions were implanted into predetermined cortical coordinates. The bioluminescent signal from the proliferating tumor was monitored, revealing consistent exponential growth of the orthotopically implanted tumor without adverse health effects over a 28-day period. Our findings demonstrate that this method allows for the orthotopic implantation of human patient-derived glioblastoma in immunocompromised mice, fostering tumor development within a relevant microenvironment. This model provides a robust platform for the accurate testing and development of glioblastoma therapeutics. Preliminary IVIS data indicate that the intensity of the U87-Luc tumor increased significantly over a designated time period. Similarly, the PDX-GBM Luc showed a remarkable increase as well. This new orthotopic intracranial platform enables us to monitor tumor growth through bioluminescent measurements, offering a valuable tool for advancing glioblastoma research and treatment.

#3932 Elucidating mechanisms of metastatic progression in bladder cancer with novel GEMMs and systems biology approaches.

Siyue Lin[1], Soonbum Park[1], Alexander Chui[1], John R. Christin[2], Andrea Califano[3], Michael M. Shen[4], Cory Abate-Shen[1]

[1]Department of Molecular Pharmacology and Therapeutics, Columbia University Irving Medical Center, New York, NY,[2]Department of Medicine, Columbia University Irving Medical Center, New York, NY,[3]Department of Systems Biology, Columbia University Irving Medical Center, New York, NY,[4]Herbert Irving Comprehensive Cancer Center, Columbia University Irving Medical Center, New York, NY

Metastasis is the leading cause of bladder cancer deaths. Despite recent advances in treatment, metastatic bladder cancer remains incurable. One of the major challenges in studying metastasis has been the lack of suitable *in vivo* models that recapitulate the natural evolution of metastatic progression within the native tumor microenvironment. To address this, we have generated genetically-engineered mouse models (GEMMs) of bladder cancer that have highly penetrant metastatic phenotypes. In particular, our new metastatic GEMMs build on our previously established GEMM, in which bladder-specific co-inactivation of *Pten* and *p53* (double knockout, DKO), leads to muscle-invasive bladder cancer (MIBC) with a low incidence of metastasis. By introducing loss-of-function mutations in *Arid1a*, an epigenetic regulator that is frequently mutated in high-grade human bladder cancer, we generated triple knockout (TKO) mice. These mice develop highly lethal MIBC with over 80% incidence of regional and distant metastasis. Histopathological characterization of TKO tumors revealed aggressive features, including aberrant differentiation and enhanced invasiveness, and demonstrated strong conservation with human MIBC, as shown by the expression of basal and luminal subtype markers. We implemented a systems biology approach to identify mechanistic determinants, or master regulators (MRs), of metastasis. To identify drivers of metastatic progression, we first performed RNA sequencing to compare metastatic tumors with pre-tumor bladder urothelium from TKO mice. Gene signatures from TKO tumors were highly conserved with human MIBC. Cross-species analysis integrating TKO mouse data with human bladder cancer datasets identified conserved MRs predictive of adverse outcome in several independent patient cohorts. Key regulators of bladder cancer, such as *Pparg* and *Shh*, and lineage plasticity drivers, like *Sox11*, emerged as candidates. To prioritize these MRs, we performed CRISPR-based functional screening, which highlighted promising targets that are now being evaluated in our mouse models. In summary, we developed GEMMs that faithfully model metastatic bladder cancer. Our cross-species analysis identified a panel of conserved MRs, including *Pparg*, *Shh*, and *Sox11*, as key drivers of lineage plasticity and metastatic progression. These findings offer insights into the mechanisms of bladder cancer metastasis and suggest novel therapeutic opportunities.

#3933 Modeling treatment naïve and castration-resistant metastatic prostate cancer in genetically engineered mouse models.

Jeannine Turgeon, Florencia Picech, Jie Zheng, Cory Abate-Shen

Department of Molecular Pharmacology and Therapeutics, Columbia University Irving Medical Center, New York, NY

Metastatic prostate cancer, the major cause of prostate cancer lethality, presents as several distinct subtypes. Treatment naïve metastatic prostate cancer, often called oligometastatic disease, develops within an androgen-intact context and, given its low frequency in the population, remains understudied. The more prevalent type of metastatic disease arises from castration-resistant prostate cancer (CRPC) as a consequence of treatment failure in response to androgen deprivation therapy (ADT). Both types of prostate cancer metastases have eluded curative treatments, and the lack of accurate molecular and phenotypic in vivo models has been a roadblock to developing effective treatments. We have developed genetically engineered mouse models (GEMMs) that recapitulate advanced prostate cancer through disruption of molecular processes that are typically altered in late-stage human prostate cancer. In particular, we have generated GEMMs that carry loss of function of the tumor suppressors, Nkx3.1, Pten and p53 alone or together with loss of DNA damage repair (DDR) genes Brca1, Brca2, or Atm. We have studied these GEMMs in parallel with mice that have both Nkx3.1 and Pten loss and gain of function of oncogenic Kras. The phenotype of these GEMMs were evaluated in androgen intact and deprived conditions to recapitulate treatment naïve and castration resistance contexts. Each of these GEMMs develop prostate cancer with distinct characteristics in the presence or absence of androgens. GEMMs with Pten loss displayed a non-metastatic indolent phenotype of prostatic intraepithelial neoplasia. When paired with p53 knockdown or mutation, the GEMMs showed phenotypic variety (adenocarcinoma, squamous cell, sarcomatoid) and had moderate metastasis incidence (~50%). GEMMs that additionally have loss of function of DDR genes developed more aggressive prostate cancer with increased penetrance to organs and bone, modeling the metastatic tropism observed in human patients. Most notably, the Brca GEMMs that underwent castration revealed higher metastatic incidences overall, with increases in the lung, liver, and bone, indicating increased CRPC penetrance. Additionally, constitutive activation of Kras resulted in an aggressive adenocarcinoma phenotype with fully penetrant metastatic disease and the highest incidence of bone metastasis (~40%). Interestingly, castration of Kras GEMMs led to a significant reduction in liver and bone metastases. To summarize, through the loss of function of tumor suppressor genes, DDR genes, and gain of function of Kras in murine models, we have successfully modeled treatment naïve and castration-resistant metastatic prostate cancer. These GEMMs are a valuable resource to identify therapeutic targets in advanced prostate cancer for various subtypes of metastatic prostate cancer in androgen intact and castrated contexts.

#3934 Establishing a non-invasive direct injection method to achieve an orthotopic murine model of cervical cancer in immunocompetent mice.

Marlene L. Campos Guerrero, Liyun Chen, Lori Strong, Stephanie Markovina

Washington University In St. Louis, St. Louis, MO

Current cervical cancer murine models consist of transgenic genetically engineered mouse models (GEMMS) that require multiple genetic mutations and/or hormone induction for spontaneous cervical cancer development. Other techniques used for studying cervical cancer in mice consist of subcutaneous injection of tumor cells and surgical implantation of tumor cells into the lower portion of the uterus. These approaches are useful for studying tumor cell behavior - growth and progression but are limited to their location and the use of immune-compromised mice models, and/or survival surgery. Attempts for tumor cell deposit into mice cervix have consisted of pretreating mice with hormones and irritating the cervix and vaginal canal prior to depositing tumor cells. Here, we focused on establishing a reproducible, reliable, non-surgical approach to orthotopic establishment of tumors directly into cervix of the immunocompetent mice. We hypothesized that this technique will not require hormone pre-treatment of mice and reliably establishes tumor cells within the cervix epithelium in mice. To test this hypothesis, we used TC1 murine cell line expressing E6 and E7 oncogenes and engineered to express luciferase to inject the cervix of mice through the urovaginal opening. We confirmed establishment of tumor cells in the cervix 3-hours post injection through bioluminescence imaging (BLI) and monitored tumor growth with BLI imaging every 3 days. Additionally, we confirmed tumor growth through micro-CT imaging every 7 days post injection. We identified that mice with cervix injection can be monitored up to 24-31 days post injection. Tumor histologic images confirm tumor establishment in cervix submucosa with local-regional spread, and lung metastasis, similar to the pattern of spread seen in human cervical cancers. While existing methods of orthotopic tumor establishment achieve a similar model of spread, this approach is minimally invasive and does not require breeding. Additional studies are ongoing to determine the success rate of desired cervical tumor establishment using this method and to discern molecular mechanisms of invasion and metastasis in cervical cancer.

#3935 Durable inhibition of ERK phosphorylation is required for tumor regression in novel human and mouse models of NF1-inactivated melanoma.

Olvania-Danyca Hilaire[1], Alexis M. Jones[1], Moriah H. Nissan[1], Sebastien Monette[1], Jordan Eichholz[1], Sandra Misale[2], Isabell Schulze[3], Naresh Vasani[1], Cailian Liu[1], Xia Yang[1], Elisa De Stanchina[1], Nikolaus Schultz[1], Michael F. Berger[1], Neal Rosen[1], Taha Merghoub[3], David B. Solit[1], Aphrothiti J. Hanrahan[1]

Inactivating mutations in Neurofibromin 1 (*NF1*), a RAS-GTPase, have been identified in a significant subset of melanomas, both concurrent with and exclusive of oncogenic *BRAF* and *RAS* mutations. However, FDA-approved therapies targeting the MAPK pathway have been largely inactive in this molecular cohort. To address the underlying biology, we first leveraged sequencing data from 1,912 melanoma tumor/normal pairs generated as part of the MSK-IMPACT sequencing initiative and identified oncogenic mutations in *TP53* as the most significant event common to *NF1*-inactivated melanoma, with oncogenic *BRAF* mutations frequently co-occurrent. Given the lack of models for studying NF1 loss, we next generated a cohort of genetically engineered mice harboring conditional alleles for $Nf1^{fl/fl}$, $Trp53^{fl/fl}$, and/or oncogenic BRAF V600E ($Braf^{CA}$) and the transgene $Tyr::CreER^{T2}$, restricting induction to melanocytes. While melanocyte-specific, homozygous knockout of *Nf1* induced hyperpigmentation, it was insufficient for melanomagenesis. Combined *Nf1/Trp53* knockout induced tumor formation with an incidence of 55.56%; tumor onset and hyperpigmentation were hastened upon the addition of oncogenic BRAF V600E. Other genetic cohorts induced tumors with variable penetrance and latency ($Braf^{CA}$*/Nf1,* $Braf^{CA}$*/Trp53*). All tumors displayed features of human melanoma including pigmented melanocytic and amelanotic spindle-shaped neoplasms, with most staining positive for S100. To facilitate preclinical and functional studies, we generated 22 mouse tumor-derived, syngeneic cell lines. As anticipated, loss of *Nf1* conditioned the response to treatment with a BRAF monomer inhibitor (vemurafenib), while *Nf1*-inactivated cells retained sensitivity to MEK inhibition (trametinib) or the combination. Combined inhibition of BRAF/SHP2 inhibited ERK phosphorylation and cell proliferation in $Braf^{CA}$*/Nf1/Trp53*-mutant cells; however, inhibition of ERK signaling was transient. Combination treatments that resulted in more durable inhibition of ERK, including the triple combination of RAF/MEK/SHP2 inhibitors, achieved tumor regression in mice with established $Braf^{CA}$*/Nf1/Trp53*-null tumors as well as in a genetically similar human PDX of melanoma (SK-MEL-1273A). Overall, we find that addition of SHP2 to MEK or RAF inhibitors resulted in more durable MAPK pathway inhibition and greater tumor regression in mice bearing NF1-null tumors. The testing of additional combinations of novel agents that selectively target the MAPK pathway and other parallel pathways contributing to resistance and survival are ongoing.

#3936 CDK12 tumor suppressor function and therapeutic targeting in newly developed mouse models of serous ovarian cancer.

Jean Ching-Yi Tien, Yali Zhai, Rong Wu, Yuping Zhang, Yu Chang, Yunhui Cheng, Abigail J. Todd, Christina Wheeler, Shuqin Li, Rahul Mannan, Caleb Cheng, Somnath Somnath Mahapatra, Xuhong Cao, Yuanyuan Qiao, Lanbo Xiao, Marcin Cieslik, Ding Ke, Kathleen R. Cho, Arul M. Chinnaiyan

University of Michigan, Ann Arbor, MI

Adenocarcinoma of the ovary is the fifth leading cause of cancer death among American women. Most mortality results from high-grade serous ovarian carcinoma (HGS-OvCa)—a disease type resistant to conventional chemotherapy, and therein requiring urgent preclinical modeling for pharmaceutical testing. We generated a novel serous ovarian carcinoma model by employing *Ovgp1*-driven Cre recombinase to catalyze CRISPR-Cas9-medicated ablation of the *Trp53*, *Rb1* and *Nf1* tumor suppressor genes in the mouse ovary (sgPRN mice). The gene encoding cyclin dependent kinase 12 (CDK12) is among the most frequently inactivated in HGS-OvCa. Its loss corresponds with increased mortality, DNA damage (including tandem duplications) and tumor immunogenicity. Co-ablation of *Cdk12* in the sgPRN model ("sgPRN-C*dk12KO* mice") accelerated tumor progression leading to *bona fide* HGS-OvCa, and early mortality. In a conventional (Cre-lox-medicated) *Trp53*/ *Nf1*/ *Rb1* triple knockout model, *Cdk12*ablation ("PRN-*Cdk12KO* mice") effected immune infiltration characterized by CD3, CD8, CD4, and Granzyme B positivity like that seen in clinical HGS-OvCa. We observed recapitulation of this immunogenic phenotype—with corresponding sensitivity to immune checkpoint blockade—in a novel syngeneic allograft model derived from these animals. To screen for synthetic lethal interactions with *Cdk12* loss, we conducted a CRISPR-Cas9 screen in PRN-*Cdk12KO* cell lines. The gene encoding CDK12 paralog CDK13 emerged as the most depleted, suggesting CDK13 could be targeted to promote paralog-induced synthetic lethality as previously demonstrated in *CDK12*-mutant prostate cancer. Indeed, sgPRN-C*dk12KO* and PRN-*Cdk12KO* -derived cell lines exhibited enhanced sensitivity to the CDK13/12 degrader YJ1206. Our work defines CDK13-targeting as a novel treatment modality for *CDK12*-inactive HGS-OvCa while establishing biological resources for the *in vivo* modeling of this disease.

TUMOR BIOLOGY: Pediatric Cancer Models
Poster Session

#3940 Development of immunocomplex pediatric tumor organoids for onco-immunotherapy research.

Naiara Martinez Velez[1], Roel Polak[1], William Wang[1], Maria Fernanda Henao Echeverri[1], Diane Cruz Manjarrez[1], Moksha Desai[1], Yiyun Cheng[1], Peng Xu[1], Cara Coleen Rada[1], Bita Sahaf[1], Hiroyuki Yoda[2], William Weiss[2], Elena Sotillo[1], Calvin J. Kuo[1], Crystal L. Mackall[1]

Aggressive pediatric solid tumors urgently require effective and specific therapies. In the clinic, promising new therapies, including immunotherapies, have shown limited efficacy against pediatric solid tumors. One challenge is the lack of reliable preclinical models for the evaluation of new therapies. While patient-derived organoids recapitulate primary tumor heterogeneity, and some structural properties, they fail to preserve immune cells, limiting their utility to evaluate antibody-based or cell-based immunotherapies. To address this limitation, we aimed to generate tumor immune organoids (TIOs) using an air liquid interface culture system. By optimizing the media and matrix conditions, we successfully developed osteosarcoma (OS), medulloblastoma (MB) and neuroblastoma (NBL) TIOs from mouse models that mimic the architecture and composition of human primary tumors. Flow cytometric and confocal microscopy analyses demonstrated that TIOs were viable and preserved not only tumor cells but stromal cells including immune cells for more than 130 days in NBL, 14 days in MB and 30 days in OS. Singe-cell RNA sequencing of primary tumors and TIOs after several days in culture showed preservation of the immune landscape, including T cells, myeloid cells and NK population, as well as their specific phenotypes. To evaluate the feasibility of using TIOs to test onco-immune agents, we treated NBL TIOs with anti-CD47 and anti-GD2 antibodies alone or in combination, hoping to replicate our previous work showing that blockade of GD2 and CD47 exerted a synergistic antitumor effect (Theruvath et al, Nat Med 2021). Importantly NBL TIOs responded to single agents with less tumor cell killing than the combination treatment, confirming that the immune compartment within the TIOs is biologically functional, enabling the study of tumor-immune interactions. Next, we tested chimeric antigen receptor T-cell (CAR-T) targeting GD2 in NBL, GPC2 in MB and B7H3 in OS. First, we optimized the delivery of the CAR-T cells to the culture without disrupting the architecture of the TIOs, facilitating the study of CAR-T interplay with TME populations and CAR-T antitumor evaluation. Notably, we successfully established patient-derived MB TIOs from a pediatric patient, that preserved neoplastic, stromal and immune compartments, and co-cultured them with GD2.BBz CAR-T cells. Using confocal live imaging we tracked the antitumor activity of CAR-T cells in the native 3D MB microenvironment. Our findings highlight the invaluable potential of using patient-derived TIOs as a platform to predict clinical responses to immunotherapies. In the context of cellular therapies, co-culture with autologous CAR-T cells provides a unique opportunity to study the mechanisms of resistance and efficacy in pediatric solid tumors, facilitating the development and testing of more effective and personalized treatments.

#3941 CRISPR screen of human stem cell derived MYC-driven medulloblastoma tumors reveal the mitochondria as a vulnerability.

Kenya Pleitez Valle[1], Miriam Velez[1], Yang Zhao[1], Bo Cheng[1], Sophia Estrada[1], Linwei Li[1], Tom O'Loughlin[2], Balaraman Kalyanaraman[3], Ming You[4], Luke A. Gilbert[2], David M. Hockenbery[5], David B. Shackelford[6], Peter J. Mullen[7], Miller Huang[1]

[1]Pediatrics, Children's Hospital Los Angeles, Los Angeles, CA,[2]University of California San Francisco, San Francisco, CA,[3]Medical College of Wisconsin, Milwaukee, WI,[4]Houston Methodist Research Institute, Houston, TX,[5]Fred Hutch Cancer Center, Seattle, WA,[6]University of California Los Angeles, Los Angeles, CA,[7]University of Southern California, Los Angeles, CA

Background: Medulloblastoma (MB) is the most common malignant pediatric brain tumor and is derived from neuroepithelial stem cells (NESC). Amplification of each member of the MYC family of oncogenes (MYCN, CMYC, MYCL) has been found in MB tumors and amplified-MYCN or CMYC correlates with poor prognosis. Since transcription factors such as MYC are difficult to drug with small molecules, more druggable targets need to be identified. While genetic screens can be performed on human MB cell lines, there is a lack of a proper isogenic control to distinguish targets that also negatively affect healthy non-tumor cells. Here, we show the utility of a human induced pluripotent stem cell (iPSC) based model of MB to find therapeutic vulnerabilities.
Methods: Human iPSC derived from a healthy adult were differentiated towards NESC and transduced with empty vector (EV), MYCN, CMYC or MYCL. We analyzed how each MYC protein influences the molecular profile (RNAseq and methylation), proliferation in vitro (EdU assay), and transformation in vivo (orthotopic implantation into the hindbrain of immunocompromised mice) compared to EV in NESC. Whole genome CRISPR interference (CRISPRi) screen was performed on MYCN and CMYC NESC-derived tumors and EV NESC. Viability in response to 72 hours of inhibitor treatment was analyzed qualitatively by transmitted light images of cells and quantitatively by LIVE/DEAD stain followed by flow cytometry.
Results: MYCN and CMYC induced a higher percentage of NESC in S-phase (46%, 40%) compared to MYCL (35%) and EV (31%). Molecularly, MYCN and CMYC NESC had similar transcriptomic and methylation profiles compared to MYCL and EV. Gene ontology revealed the most enriched pathway in NESC with either MYCN or CMYC, but not MYCL, was mitochondria gene expression. In vivo, MYCN and CMYC were both 100% penetrant by day 98 while MYCL was only 30% penetrant and EV did not develop tumors. CRISPRi screen demonstrated MYCN and CMYC NESC-derived tumors, but not EV NESC, were dependent on subunits of Complex I, III, IV and V of the electron transport chain (ETC) in the mitochondria. In support of this, treatment with two different inhibitors of Complex I (Metformin, Mito-HNK) showed stronger toxicity against both MYC NESC-derived tumors than EV NESC. Strikingly, treatment with Mito-HNK resulted in higher cell death in CMYC-expressing MB cell lines D283 (30%), D425 (83%) and MB004 (82%) compared to healthy NESC (<10%).
Conclusion: MYCN and CMYC induce molecular changes distinct from MYCL in NESC that lead to upregulation of mitochondria gene expression, faster growth and transformation. Both MYCN and CMYC driven MB tumors are more dependent on the ETC for viability than non-tumor NESC suggesting MYC tumors could be specifically targeted by disrupting their metabolism. Thus, we show the combination of human iPSC-based model of MB and CRISPR screening can uncover vulnerabilities in MB cell lines.

#3942 3D models reveal novel drug synergies and mevalonate pathway activation in Ewing sarcoma.

Branka Radic Sarikas[1], Marica Markovic[2], Mathias Ilg[1], Caterina Sturtzel[1], Martha Zylka[1], Didier Surdez[3], Martin Metzelder[4], Martin Distel[1], Aleksandr Ovsianikov[2], Florian Halbritter[1], Heinrich Kovar[1]

[1]St. Anna Children's Cancer Research Institute, Vienna, Austria,[2]Institute of Materials Science and Technology, Technical University of Vienna, Vienna, Austria,[3]ZInserm U830, Equipe Labellise INCC, PSL Universite, Siredo Oncology Centre, Institut Curie, Paris, France, Paris, France,[4]Department of Pediatric Surgery, Medical University of Vienna, Vienna, Austria

Ewing sarcoma (ES) is a rare but aggressive cancer, with survival rates of only about 30% in metastatic cases. Its rarity and severity highlight the need for focused research, yet progress is limited by scarce patient samples, few animal models, and minimal preclinical testing platforms. Conventional 2D cell cultures often fail to replicate primary tumor gene expression and drug sensitivity, while patient-derived xenografts (PDXs), though more accurate, require extensive resources and tend to lose tumor-specific traits when cultured in 2D. We established and standardized a spheroid culture system for ES and developed a semi-automated drug-screening platform for tumor spheroids. This platform enables drug testing in a 3D environment, offering more relevant insights than 2D models and helping to define drug concentration ranges for testing on tumoroids and patient samples. Bulk RNA sequencing revealed significant transcriptional differences between 3D cell line models (including spheroids and encapsulated 3D constructs) and traditional 2D cultures. The 3D constructs were created using extrusion bioprinting, which ensures uniform cell distribution and high density. Notably, the mevalonate pathway was activated in all 3D models used. ES is among the tumors with the highest expression of mevalonate pathway genes, making its activation in 3D models a promising replication of *in vivo* tumor characteristics. This activation underscores the pathway's importance in ES metabolism and its potential as a therapeutic target. Building on these findings, we validated the encapsulated 3D models using PDX-derived cells, confirming consistent mevalonate pathway upregulation across these constructs. These models further demonstrated the spheroid platform's capacity to accurately predict effective drug concentration ranges, which proved optimal for testing PDX-derived cells and may extend to other primary materials. Next, we conducted synergy tests using concentration matrices in both spheroid and 2D cultures, systematically exploring different drug concentration combinations. Based on transcriptional data and earlier studies, we opted to test interactions between mevalonate pathway inhibitors (statins), and apoptosis inhibitors, specifically BCL2 family inhibitors. Remarkably, we observed a strong synergy between BCL-xL inhibitors and statins, but only within the physiologically relevant 3D environments. These findings underscore the value of 3D models as potent tools for uncovering therapeutic combinations missed by conventional approaches. By more accurately reflecting key aspects of tumor behavior, these models enhance the reliability of drug response predictions and enable targeted treatment strategies. Advanced 3D models could accelerate the translation of preclinical discoveries into clinical treatments for Ewing sarcoma, offering new possibilities for tackling this aggressive cancer.

#3943 SFPQ-TFE3 gene fusion reciprocally regulates mTORC1 activity and induces lineage plasticity in a novel mouse model of renal tumorigenesis.

Kaushal V. Asrani[1], Adrianna Amaral[1], Juhyung Woo[1], Sanaz Abadchi[1], Thiago Vidotto[1], Kewen Feng[1], Hans B. Liu[1], Mithila Kasbe[1], Masaya Baba[2], Yuichi Oike[2], Patricia Outeda[3], Terry Watnick[3], Avi Z. Rosenberg[1], Laura S. Schmidt[4], Marston Linehan[4], Pedram Argani[1], Tamara L. Lotan[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Kumamoto University, Kumamoto, Japan,[3]University of Maryland School of Medicine, Baltimore, MD,[4]National Cancer Institute, National Institutes of Health, Bethesda, MD

The MiT/TFE family gene fusion proteins, such as SFPQ-TFE3, drive both epithelial (eg, translocation renal cell carcinoma, tRCC) and mesenchymal (eg, perivascular epithelioid cell tumor, PEComa) neoplasms with aggressive behavior. However, no prior mouse models for SFPQ-TFE3-related tumors exist and the mechanisms of lineage plasticity induced by this fusion remain unclear. Here, we demonstrate that constitutive murine renal expression of human SFPQ-TFE3 using Ksp Cadherin-Cre as a driver disrupts kidney development leading to early neonatal renal failure and death. In contrast, post-natal induction of SFPQ-TFE3 in renal tubular epithelial cells using Pax8 ERT-Cre induces infiltrative epithelioid tumors, which morphologically and transcriptionally resemble human PEComas. As seen in MiT/TFE fusion-driven human tumors, SFPQ-TFE3 expression is accompanied by the strong induction of mTORC1 signaling, which is partially amino acid-sensitive and dependent on increased SFPQ-TFE3-mediated RRAGC/D transcription. Remarkably, SFPQ-TFE3 expression is sufficient to induce lineage plasticity in renal tubular epithelial cells, with rapid down-regulation of the critical PAX2/PAX8 nephric lineage factors and tubular epithelial markers, and concomitant up-regulation of PEComa differentiation markers in transgenic mice, human cell line models and human tRCC. Pharmacologic or genetic inhibition of mTOR signaling downregulates expression of the SFPQ-TFE3 fusion protein and rescues nephric lineage marker expression and transcriptional activity in vitro. These data provide evidence of a potential epithelial cell-of-origin for TFE3-driven PEComas and highlight a reciprocal role for SFPQ-TFE3 and mTOR in driving lineage plasticity in the kidney, expanding our understanding of the pathogenesis of MiT/TFE-driven tumors.

#3944 Deciphering retinoblastoma indolence-malignancy transition with *RB1* knockout cone reporter retinal organoids.

Jinlun Bai[1], David S. Koos[1], Kayla Stepanian[1], Kevin Stachelek[1], Bhavana Bhat[1], Scott E. Fraser[2], Rex A. Moats[1], David Cobrinik[1]

[1]Children's Hospital Los Angeles, Los Angeles, CA,[2]Viterbi School of Engineering, University of Southern California, Los Angeles, CA

Purpose: This study aims to elucidate the molecular mechanisms driving the transition from pre-malignant lesions to malignancy using a human retinoblastoma retinal organoid (RBRO) model that faithfully recapitulates the cell-of-origin and multi-step retinoblastoma genesis.

Background: Retinoblastoma originates from maturing cone photoreceptor precursors with biallelic *RB1* inactivation. In explanted fetal retinae, pRB-depleted post-mitotic cone precursors proliferate, followed by a 3-5 month premalignant indolence phase before retinoblastoma-like masses emerge at tissue ages mirroring in vivo disease. Research on this transition is limited by fetal tissue availability, but CRISPR engineered retinal organoids (ROs) provide a promising alternative. This study introduces a robust organoid platform to model and investigate the retinoblastoma indolence-malignancy transition.

Methods: We generated cone-reporter iPSC lines through CRISPR knock-in of EGFP-P2A at the *GNAT2* locus. A second round of CRISPR editing produced homozygous *RB1* knockout. Chimeric $RB1^{+/+}$ ROs and $RB1^{-/-}$ RBROs were generated from edited iPSCs mixed with unedited parental iPSCs. ROs and RBROs were embedded in hydrogel and live-imaged episodically to track EGFP+ cone proliferation dynamics. Deep full-length scRNA-seq was carried out on FACS isolated EGFP+ $RB1^{+/+}$ and $RB1^{-/-}$ cones at key developmental and tumorigenesis stages, with results validated by immunofluorescent staining.

Results: In *RB1* WT ROs, EGFP specifically, robustly and innocuously labeled immature and mature cones. In RBROs, bi-weekly live confocal imaging revealed initial EGFP+ $RB1^{-/-}$ cone proliferation followed by a pre-malignant indolence phase starting at ~d150. The majority of the initially proliferating cones were Ki67-negative with some adopting mature cone morphology. Nascent retinoblastoma-like foci co-expressing EGFP, cone markers, and Ki67 formed after ~d280, a tissue age that equates to the first post-natal month when early retinoblastomas typically emerge. Single cell transcriptomics of $RB1^{-/-}$ cones from multiple tumorigenesis stages showed distinct molecular signatures of proliferation, differentiation and stress cell states and suggest a role of p53 pathway in indolence entry and escape. Immunofluorescent staining suggested post-transcriptional silencing of p14ARF underlying indolence escape.

Conclusion: We established a human retinoblastoma organoid model that recapitulates the cell-of-origin and timing of multi-step retinoblastomagenesis. This model revealed distinct molecular signatures at each tumorigenesis stage and highlighted altered expression of a p53 pathway regulator during the retinoblastoma indolence-malignancy transition.

#3946 VGLL2::NCOA2 structure-function analysis reveals domain requirements for fusion-driven infantile rhabdomyosarcoma.

C. S. Sankhe[1], D. Calderon[1], C. Taslim[1], M. Sammons[1], L. Ryan[1], A. C. Gross[1], O. Delattre[2], R. D. Roberts[1], G. C. Kendall[1];
[1]Center for Childhood Cancer Research, The Abigail Wexner Research Institute, Nationwide Children's Hospital, Columbus, OH, [2]Institut Curie, SIREDO Pediatric Center, Paris, France

Rhabdomyosarcoma (RMS) is the most common pediatric soft-tissue sarcoma and is associated with impaired skeletal muscle differentiation. RMS has significant diagnostic and therapeutic challenges, and the presence of fusion oncogenes contributes to the aggressiveness of the disease. There exists lack of mechanistic understanding of fusion-oncogene driven tumorigenesis. As a result, more efforts need to be directed towards defining fusion-oncogene biology to identify novel therapeutic strategies and improve clinical outcomes in patients. A new family of fusion-oncogenes, including VGLL2::NCOA2, has been identified in the infantile RMS subtype. Normally, vestigial-like family member 2 (VGLL2) and nuclear receptor coactivator 2 (NCOA2) independently regulate skeletal muscle differentiation as transcriptional co-activators. We found the VGLL2::NCOA2 fusion is sufficient for tumorigenesis in multiple systems. Here, we elucidate whether protein domains contribute to this activity. VGLL2::NCOA2 retains the vestigial (TDU) domain of VGLL2 and activating domains (AD1 and AD2) of NCOA2. We hypothesize that TDU, AD1 and AD2 domains of VGLL2::NCOA2 contribute to fusion-driven tumorigenesis. We implemented our C2C12 mouse myoblast cell culture model and a structure-function analysis of VGLL2::NCOA2 to define domain requirements for transformation. We transfected mouse myoblast cells with the full-length human VGLL2::NCOA2 fusion construct and truncated mutant constructs containing deletions of TDU, AD1, and AD2 domains. Using biochemical approaches, we found higher nuclear localization of VGLL2::NCOA2 in cells transfected with the full-length fusion and AD2 domain deleted mutant fusion; however, deletion of either the TDU and AD1 domain resulted in decreased nuclear localization. Furthermore, in testing the oncogenic potential of transfected cells via soft agar colony formation assay, we found higher number of colonies in cells transfected with the full-length fusion and the AD2 domain deleted construct. In the mutants with the TDU and AD1 domains deleted, there is a significant reduction in colony formation. We complemented our cell culture strategies with a mouse allograft approach. Compared to the full-length VGLL2::NCOA2 fusion, mice allografted with myoblast cells containing the VGLL2::NCOA2 deleted TDU and AD1 domains form significantly delayed tumors, with onset beginning 40 days after the full-length fusion. Overall, our results suggest that TDU and AD1 domains are required to drive oncogenic mechanisms. Targeting these domains will facilitate identification of novel molecular targets that can suppress VGLL2::NCOA2 activity, and potentially be used as therapeutic opportunities.

#3947 Defining VGLL2::NCOA2 and ARF6 cooperation in infantile rhabdomyosarcoma.

Delia Calderon[1], Chinmay Sankhe[1], Cenny Taslim[1], Olivier Delattre[2], Genevieve Kendall[1]

[1]Nationwide Children's Hospital, Columbus, OH,[2]Institut Curie, Paris, France

Rhabdomyosarcoma (RMS) is most common pediatric soft tissue sarcoma, is aggressive, and has characteristics of arrested skeletal muscle differentiation. Infantile RMS, a subtype of RMS, is genetically driven by a family of fusion-oncogenes involving key proteins essential for skeletal muscle development. One example is the fusion between transcriptional coactivators, VGLL2 and NCOA2. Recent VGLL2::NCOA2-driven RMS cases have shown that this fusion-oncogene can be lethal; however, there is a lack of significant knowledge surrounding the biological mechanisms of the fusion and an unmet need of effective targeted therapies. To assess VGLL2::NCOA2 tumorigenic mechanisms and therapeutic vulnerabilities, we generated two new VGLL2::NCOA2 driven tumor models, a C2C12 mouse allograft and transgenic zebrafish model. Both of these models histologically and transcriptionally recapitulate the human disease. Shared transcriptional features between patient data, mouse allograft, and transgenic zebrafish tumors revealed suppression of skeletal muscle specific genes and either reactivation or inappropriate developmental persistence of the small GTPase, ADP ribosylation factor 6 (ARF6). ARF6 is important for myogenic development and was significantly overexpressed across all cross-species tumors and is being pursued as a therapeutic opportunity in other cancer contexts. Knockout of *Arf6* in our C2C12-VGLL2::NCOA2 cell culture model suppressed VGLL2::NCOA2 colony formation and restored the expression levels of critical muscle differentiation specific genes. To define the role of ARF6 *in vivo,* we used CRISPR/Cas9 to generate a zebrafish arf6b germline knockout. Although arf6 is duplicated in the fish, the Arf6b homozygous null fish have a significant reduction in Arf6 protein levels and are viable as adults and fertile. We then injected wildtype and arf6b knockout fish with mosaic human VGLL2::NCOA2 to determine genetic cooperation in the disease. We found arf6b knockout fish still developed VGLL2::NCOA2 tumors; however, transcriptional analysis showed that these tumors downregulated VGLL2::NCOA2 expression and were more differentiated with a concomitant upregulation of skeletal muscle specific pathways. Given that infantile RMS displays features of arrested skeletal muscle differentiation, these results highlight the contribution of ARF6 with VGLL2::NCOA2 for oncogenesis. Our findings are consistent with our data that C2C12-VGLL2::NCOA2 cell models are unable to terminally differentiate, but that removing Arf6 ameliorates that suppression. We are also performing mouse allograft studies, to continue to delineate the *in vivo* oncogenic mechanisms of ARF6 cooperation in infantile RMS. We will assess tumor morphology and genetic features, and tumor incidence. Overall, our findings underscore the cooperative role of ARF6 in VGLL2::NCOA2 driven tumor highlighting its potential as a therapeutic target.

#3948 Enhancing immune checkpoint delivery to diffuse midline glioma (DMG) using focused ultrasound.

Amelia Claxton[1], Paul Cressey[1], David Thurston[1], Esther Hulleman[2], Antonios Pouliopoulos[3], Darren Hargrave[4], Maya Thanou[1]

[1]Institute of Pharmaceutical Sciences, King's College London, London, United Kingdom,[2]Pediatric Oncology, Princes Maxima Center, Utrecht, Netherlands,[3]Biomedical Engineering and Imaging Sciences, King's College London, London, United Kingdom,[4]Developmental Biology and Cancer Department, University College London, London, United Kingdom

Brain tumors, such as diffuse midline glioma (DMG), remain the leading cause of cancer-related death in pediatric oncology due to their universal fatality and limited treatment options. Treatment of DMG is hindered by the blood-brain barrier (BBB) presenting a roadblock in the clinical translation of therapies, particularly for larger therapeutic agents such as antibodies (e.g., immune checkpoint inhibitors). Focused ultrasound (FUS) and cavitating microbubbles provide a solution to this by transiently disrupting the BBB in a controlled and safe manner, allowing significantly enhanced drug delivery to a brain tumor whilst avoiding healthy tissue.

In this study, we investigated the use of immune checkpoint inhibitors in in vitro and in vivo (orthotopic murine) DMG models. An in vitro transwell model in combination with FUS was used to determine if immune checkpoint inhibitors can pass through an endothelial layer (BENd3) following FUS blood-brain barrier opening (BBBO) at therapeutic concentrations, using fluorescence imaging and flow cytometry. We further tested our immune checkpoint inhibitors in an in vivo orthotopic murine DMG model (mDMG-3.3). Uptake enhancement following FUS was determined using fluorescence imaging.

The results demonstrated a significant increase in the delivery of antibodies across the BBB following FUS in vitro. We also showed that FUS BBBO had no significant effect on endothelial cell viability. FUS-induced BBBO was performed in tumor-bearing mice using systemically administered SonoVue microbubbles (2 mL/kg), and FUS (peak-negative pressure = 320 kPa, cycle number = 500, pulse repetition frequency (Hz) = 5, number of pulses = 600). T1-weighted MRI was used immediately after FUS-induced BBB opening to confirm that the BBB had opened. Real-time passive cavitation detection was also used to record the harmonic signals of the cavitating microbubbles to control BBB opening, and for post-experiment analysis of microbubble behavior. Immediately following BBBO, mice were dosed with fluorescently labelled antibody (10 mg/kg) i.v., and then FUS BBBO was shown to cause a significant enhancement in uptake of the labelled antibody into the sonicated region.

These results suggest that FUS-BBBO is a suitable technology to safely enhance the uptake of immune checkpoint inhibitors into DMG tumors. Future work will include evaluation of the survival benefits of immune checkpoint inhibitors in our mouse DMG models.

#3950 Novel scaffold free method to establish 3D spheroid and 2D adherent primary neuroblastoma cell lines with adrenergic and mesenchymal-like phenotypes.

Min Huang, Robbie G. Majzner, Nathan Chiang, Alejandro Solis, Bill Chiu, Serena Tan, Emon Nasajpour, Kathleen M. Sakamoto, Norman J. Lacayo, Claudia K. Petritsch, Sheri L. Spunt, Raya Saab

Pediatrics, Stanford University, Stanford, CA

Neuroblastoma (NB) is the most frequent extracranial childhood tumor. The majority of NB tumors arise in the adrenal gland with bone marrow (BM) metastases present in 70.5% of Stage IV disease. A recent study using 23 most commonly used two-dimensional (2D) adherent NB cell lines found that expression of GD2, a target for immunotherapy, is significantly correlated with adrenergic (ADRN) and mesenchymal (MES) cell lineages through epigenetic regulation of ganglioside synthesis enzyme ST8SIA1. We aimed to establish primary NB patient cell line from adrenal NB or BM metastasis to determine whether ADRN and MES lineage specific phenotypes exist in primary NB patient cells and are also associated with distinct GD2 and ST8SIA1 expression. Using our *in vitro* primary cell culture conditions, all NB cells derived from four individual patients' BM metastases spontaneously assembled into three-dimensional (3D) spheroids in scaffold-free regular culture plates with a predominant GD2 high ADRN cell type as determined by flow cytometric and immunofluorescent analysis of ADRN marker genes. Cells maintained self-assembling ability for multiple passages (up to 30) within 5-8 months of prolonged *in vitro* cultures at a sustainable growth rate. In contrast to the BM-derived NB cells, a majority of the adrenal tumor-derived NB cells became 2D adherent within 7-10 days and displayed marked changes in immuno-phenotypes after several weeks, shifting from predominantly GD2-high to a mixture of high and low GD2 expression. Forcing the adherent NB cells with mixed GD2 level into suspension cultures using Corning's 3D Ultra-Low Attachment (ULA) plate resulted in a marked enrichment of NB spheroids with GD2-high, which regrew as 2D-adherent cells after re-seeding into regular culture plate, and retained the GD2-high and ST8SIA1-high ADRN phenotype for several months. In contrast, the NB adherent cells cultured in parallel without ULA-selection showed predominant GD2-low, ST8SIA1-low and vimentin (VIM)-high MES-like phenotype as characterized by GD2 flow and Real-time quantitative PCR of ADRN and MES marker gene expression. Our novel primary cell culture conditions allows long term *in vitro* spheroid growth of patient-derived NB cells from BM in regular culture plate, which is scaffold-free, faster, less expensive, less labor intensive, and mimics the *in vivo* NB cell clusters or aggregates seen in NB patient's BM aspirates with NB infiltration. Our culture conditions in combination with the 3D ULA-selection strategy enabled us to establish paired ADRN and MES-like NB sublines from two primary NB tumors derived from adrenal and BM sites. These patient-matched, paired NB cell lines in ADRN and MES-like cell states will be useful to study NB lineage specific biology and implications of cell states on an individual patient's response to targeted immunotherapy.

#3951 AKT inhibitor capivasertib combines with dexamethasone and venetoclax to enhance anti-tumor responses in the preclinical models of childhood acute lymphoblastic leukemia.

Brandon Willis, Nadezda Bryan, Justine Roderick-Richardson, Alan Rosen, Lori Chan, Simon T. Barry

AstraZeneca, Waltham, MA

Acute lymphoblastic leukemia (ALL) is the most common blood cancer of children and the most frequent cause of cancer related death before 20 years of age. Although the survival rate of pediatric patients with ALL is approximately 90% due to innovative chemotherapy regimens, finding treatment options for patients with relapsed/refractory ALL continues to be challenging. The PI3K/AKT/mTOR axis is often constitutively activated in relapse/refractory ALL. For example, loss of the tumor suppressor PTEN leads to hyperactivation of AKT signaling. Despite the importance of PI3K-AKT signaling in ALL, clinically effective treatment strategies to target PI3K-AKT signaling have had limited success. Inhibiting AKT signaling with capivasertib, a first in class pan AKT-inhibitor recently approved for the treatment of ER+ breast cancer, exhibits monotherapy anti-proliferative activity in pediatric T-ALL and B-ALL cell lines. However, only partial anti-proliferative activity was observed from monotherapy capivasertib treatment. To address if the activity of capivasertib in ALL could be improved by combining with other agents, we explored whether addition of the glucocorticoid, dexamethasone, and the Bcl-2 inhibitor, venetoclax could provide better therapeutic benefit in preclinical models of ALL. We conducted a capivasertib centric *in vitro* combination screen across a panel ALL cell lines. In contrast to monotherapy activities, the combination of capivasertib with dexamethasone and venetoclax showed greater cell killing in 4/5 B-ALL and 3/3 T-ALL cell lines. Interestingly, the combination enhanced antitumoral activity in most ALL cell lines regardless of the presence or absence known PI3K/AKT mutational pathway drivers. Importantly, capivasertib enhanced response to dexamethasone in a subset glucocorticoid refractory ALL cell line models that were insensitive to monotherapy glucocorticoid treatment. To further investigate whether the combination *in vitro* activity can translate *in vivo,* combinations of capivasertib, venetoclax and dexamethasone were evaluated in ALL CDX models and a disseminated pediatric PDX of T-ALL harboring known drivers of AKT hyperactivation. Using a clinically relevant dose and schedule of capivasertib, treatment combination groups led to 60% and 70% TGI in the MOLT4 and Karpas-231 xenograft models respectively. Whereas a 20% increase in survival relative to the vehicle group was observed in a disseminated T-ALL PDX model. Taken together, our results provide preclinical evidence for the rational combination of capivasertib, venetoclax and dexamethasone in the treatment of pediatric patients with relapsed/refractory ALL.

#3952 Noncoding elements within *MYCN* mRNA are autonomous drivers of oncogenesis in neuroblastoma.

Vishwaben Patel[1], Lorraine-Rana E. Benhamou[1], Dr. John T. Powers[2]

[1]The University of Texas At Austin, Austin, TX,[2]Department of Pediatrics, Dell Medical School at The University of Texas at Austin, Austin, TX

Neuroblastoma (NB) is a highly metastatic pediatric cancer originating from neural crest cells. Progression is frequently driven by *MYCN* amplified (*MA*) disease, a marker of poor prognosis presented in approximately 20% of cases. While *MA* NB is associated with increased *MYCN* protein expression, recent results suggest that non-coding RNA (ncRNA) elements within the *MYCN* mRNA independently contribute to its oncogenic potential. The *let-7* microRNA (miRNA) family, which targets the 3′ UTR of *MYCN*, is sequestered by *MYCN* mRNA itself in *MA* disease, thus impairing its function and establishing that ncRNA elements can contribute to disease pathology. To further explore the role of these ncRNA elements, we engineered cells expressing either *MYCN-ORF* (MYCN protein-coding region only), *MYCN-GL* (full-length *MYCN* mRNA from the intact genetic locus), and *Null-GL* (where *EGFP* replaces MYCN protein coding sequence but retains all ncRNA elements). *In vitro* growth analyses showed that *MYCN-GL*-expressing cells exhibited the most robust growth, followed by *Null-GL* and *MYCN-ORF*. *In vivo*, the *Null-GL* construct induced the highest incidence and largest tumors of all constructs, followed by *MYCN-GL* and then *MYCN-ORF*. Next-generation sequencing revealed that *MYCN-GL* and *Null-GL* cells were enriched for targets of microRNAs that also target *MYCN*, including *let-7*, *miR-101*, and *miR-34a*. This suggests that the *MYCN* 3'UTR may interact with these microRNAs, thus protecting other mRNA targets. Additionally, *MYCN-GL* and *Null-GL* constructs exhibited more dynamic differential gene expression than *MYCN-ORF* and *EGFP*-expressing cells. Gene ontology analysis showed that *MYCN-GL* and *Null-GL* cells were more enriched in cancer-related pathways, such as RNA metabolism and microRNA processing. Non-coding *MYCN* mRNA elements may thus regulate broader cellular functions that enhance oncogenesis. Exon usage analysis revealed that *MYCN-GL* and *Null-GL* constructs influenced splicing patterns, with increased exon inclusion and exclusion events observed across multiple chromosomes. KEGG pathway analysis of differentially spliced genes further confirmed non-coding RNA element influence on critical oncogenic pathways, including PI3K signaling, TNF signaling, viral carcinogenesis, cell survival, proliferation, and immune evasion. Whole genome sequencing revealed significant similarities in copy number variation (CNV) patterns between *MYCN-GL* and *Null-GL* constructs. These results demonstrate that non-coding elements within *MYCN* mRNA are potent drivers of tumorigenesis, influencing microRNA interactions, splicing patterns, genetic patterning, and overall activation of oncogenic pathways. Our findings provide new insights into the oncogenic mechanisms of *MA* NB, with broad implications for the genetic contribution of noncoding RNA elements in other oncogene-driven human malignancies.

#3953 FGF8 promotes non-canonical KRAS/MAPK pathway in favorable histology Wilms tumor.

Yongdong Su, Garrett Cooper, Katie Skinner, Hong Yin, Jason Yustein, Sumin Kang, Andrew Hong

Emory University School of Medicine, Atlanta, GA

Favorable Histology Wilms tumor (FHWT) is the most common pediatric kidney cancer and those with relapsed FHWT continue to have poor prognoses. A challenge in the field of FHWT research is the lack of faithful preclinical *in vitro* models for both primary and relapsed tumors. This prevents us from understanding the biology of FHWT and introducing new targeted therapies into FHWT clinical trials. We recently established 10 FHWT cell lines, including one from a relapsed case, which faithfully recapitulated the genome and transcriptome of the primary tumor. However, challenges persist in maintaining the long-term growth of these cell lines, limiting our insight into the functional study of FHWT.

Through comparison of the transcriptome of the FHWT primary tumor samples to their respective cell lines, we identified upregulation of fibroblast growth factor 8 (FGF8) expression in primary tumors. We then performed functional genomics to study the role of FGF8 in FHWT. We found that the splice variants, FGF8b or FGF8f, are required for the maintenance of FHWT cells. Re-introducing these two splice variants using either exogenous addition or endogenous overexpression led to increased viability and passaging of FHWT cell line models by an average of 100% and 30%, respectively. Further, we found that overexpressing FGF8b or FGF8f led to increased clonogenicity and invasion *in vitro* and led to tumor formation *in vivo*. Our mechanistic studies suggest that FGF8 drives a stemness and proliferation program through a non-canonical KRAS/MAPK pathway: FGF8b and FGF8f overexpression activates MEK1/2 without activating Erk1/2 while still promoting ETV1 and ETV4, leading to increased cell proliferation. Abrogation of MAPK pathway *in vitro* using MEK inhibitors led to decreased viability in cells overexpressing FGF8b and FGF8f.

Together, our study highlights the oncogenic effect of FGF8 in FHWT and links FHWT to an unexpected non-canonical MAPK pathway.

TUMOR BIOLOGY: The Tumor Immune Interplay as a Driver of Progression
Poster Session

#3957 Surface protein heterogeneity of acute myeloid leukemia is associated with distinct CD8 T cell landscape alterations.

Justin A. Cartailler, Y. Emily Chu, Chad R. Potts, Brent Ferrell

Department of Medicine, Vanderbilt University Medical Center, Nashville, TN

Acute myeloid leukemia (AML) is a heterogenous, aggressive hematologic malignancy with a poor response to immunotherapy. We applied non-negative matrix factorization (NMF) to cytometry by time-of-flight (CyTOF) data to classify AML into subtypes based on surface protein expression. We hypothesized that the resulting protein-defined subtypes of AML correlate with alterations to the CD8 T cell landscape, providing insight into the ineffectiveness of immunotherapy in AML.

Primary healthy and AML human bone marrows were stained with two CyTOF antibody panels to identify myeloid and T cell proteins. We performed NMF on the cell-protein counts matrix of the myeloid panel to determine latent protein factors present among AML samples, identifying five factors (NMF1 to NMF5) each enriched for proteins commonly associated with distinct phenotypic states. To compare to a supervised approach, the data were also clustered using the Leiden algorithm and annotated based on similarity to healthy phenotypes resulting in ten myeloblast clusters (HSC-like, monocyte-like, etc). This revealed an association among NMF factors and clusters identified through manual annotation. For example, NMF3 was defined by a primitive pattern whereas NMF5 had a pattern associated with mature AML cells. Thus, protein-defined NMF factors showed biological differences and correlated with myeloid differentiation states, allowing us to categorize AML protein heterogeneity into its predominant protein patterns.

We then used the Leiden algorithm to cluster CD8 T cells. Differential abundance analysis showed an enrichment of effector memory T cells re-expressing CD45RA (TEMRAs) in AML along a gradient with only some samples being significantly different (sFDR < 0.1). Suspecting this range was related to AML heterogeneity, we correlated each T cell subset with the respective sample's dominant AML NMF factors. We found several associations among NMF factors and enrichments of CD8 T cell subsets compared to healthy. NMF4, composed primarily of monocyte-like and dendritic-like cells, was significantly associated with an enrichment of CD57+ TEMRAs ($p = 2.8e-05$). These showed significantly increased expression of activation markers (CD95, $p_{adj} = 5.53e-39$; CD69, $p_{adj} = 1.5e-73$) and a significant reduction in GZMB ($p_{adj} = 1.3e-62$). We also observed significant marker differences among factors: CD57+ TEMRAs associated with NMF3 significantly upregulated activation markers (HLADR, $p_{adj} = 1.7e-73$; GZMB, $p_{adj} = 9.3e-39$) compared to those associated with NMF4. There was no significant difference in the abundance of naive T cells between healthy and promonocyte-like factor NMF1 ($p = 0.81$).

These data suggest that AML phenotype may directly or indirectly influence T cell phenotypes and function, which could hold implications for immunotherapeutic use in AML.

#3958 Targeting HSP70 enhances immunotherapy efficacy in triple-negative breast cancer by modulating tumor intrinsic and immunosuppressive pathways.

Ahmet B. Caglayan[1], Fulya Koksalar Alkan[1], Hilmi K. Alkan[1], Cordarryl Jones[1], Sukran Ozdatli Kurtulus[2], Elana Ishaya[1], Mahassen Elboraii[3], Hasan Korkaya[1]

[1]Oncology, Wayne State University, Detroit, MI,[2]Pharmaceutical toxicology, University of Health Sciences, Istanbul, Turkey,[3]University of Michigan-Dearborn, Dearborn, MI

Triple-negative breast cancer (TNBC) is an aggressive subtype characterized by resistance to cytotoxic therapies and immunotherapies due to the overexpression of survival proteins such as A20 and HSP70, which sustain the epithelial-to-mesenchymal transition (EMT) and cancer stem cell (CSC) phenotypes. We previously demonstrated that TNF-α stimulation in TNBC cell lines induces A20 expression, which upregulates HSP70 and protects cells from apoptosis. Luminal cell lines (MCF7 and ZR75-1), by contrast, exhibit approximately 70% apoptosis upon TNF-α treatment, and overexpression of A20 confers resistance and promotes aggressive metastatic properties in xenograft models. In vitro studies revealed that HSP70 secretion into the conditioned media is TNF-α-dependent in the EMT6 TNBC cell line, but no secretion was observed in the 4T1 TNBC cell line. LIMBO chaperone-binding assays confirmed A20 as a potential client protein of HSP70, and inhibition of HSP70 with the specific inhibitor JG-231 suppressed A20 expression in TNF-α-treated TNBC cells, reducing EMT/CSC phenotypes. Moreover, the A20/HSP70 axis was found to attract tumor-infiltrating lymphocytes (TILs) while promoting immunosuppressive myeloid-derived suppressor cells (MDSCs), as shown by increased Ly6G-positive cells in syngeneic mouse models. In vivo experiments using the EMT6 syngeneic mouse model demonstrated that JG-231, a small molecule HSP70 inhibitor, alone did not reduce primary tumor weight or metastasis after mammary fat pad injection. However, when combined with anti-PD-L1 therapy, tumor weight was significantly reduced, accompanied by a decrease in Ly6G-positive MDSCs in the tumor microenvironment. These findings suggest that the combination of JG-231 and immune checkpoint inhibitors reprograms the immunosuppressive tumor microenvironment and enhances therapeutic efficacy. In the 4T1 syngeneic model, JG-231 in combination with anti-PD-L1 and cyclophosphamide (CTX) achieved a greater than 10-fold reduction in primary tumor growth and complete elimination of metastases, while single-agent treatments showed no significant effect. Our study highlights the role of the A20/HSP70 axis in driving resistance to immunotherapy and shaping an immunosuppressive TME. By targeting HSP70, we demonstrate dual benefits: direct suppression of tumor-intrinsic survival pathways and reprogramming of the TME to reduce MDSCs and enhance TIL activity. These findings establish a strong preclinical rationale for combining HSP70 inhibitors like JG-231 with immune checkpoint inhibitors and standard chemotherapies to achieve durable therapeutic responses in TNBC. Further investigations are warranted to evaluate the clinical potential of this combinatorial strategy in aggressive breast cancers.

#3959 GAS-Luc2 reporter cancer cell lines demonstrating superior performance to the industrial standard interferon-gamma ELISA in 2-D and 3-D ex vivo immune activation and drug screening.

Hyeyoun Chang, John Foulke, Luping Chen, Catherine McManus, Fang Tian, Zhizhan Gu

American Type Culture Collection (ATCC), Manassas, VA

Interferon-gamma (IFN-γ), a cytokine critical for activating cellular immunity and facilitating anti-tumor responses, has become a key cytokine for assessing the efficacy of cancer immunotherapy drugs. While enzyme-linked immunosorbent assay (ELISA) is widely employed for the detection of IFN-γ, it has shown significant limitations in detecting low levels of IFN-γ during early-stage immune activation. Moreover, it presents serious challenges in accurately quantifying paracrine signaling of IFN-γ secreted by immune cells within 3-D co-culture models. To address the rapidly growing demand for more effective monitoring of immune activation for cancer immunotherapy research and better assessment of immunotherapy drug candidates, we developed immune activation reporter cancer cell lines engineered with a gamma-interferon activation site (GAS)-response element positioned upstream of luciferase gene. Upon activation of IFN-γ signaling pathway, these cells express luciferase, allowing for simple detection and quantification to measure immune activation. The cell lines were selected based on a comprehensive protein profiling to ensure endogenous expression of immune checkpoint ligands, such as PD-L1, CD155, or B7-H3, for additional benefit in application in immune checkpoint research. To evaluate the system, the reporter cells were stimulated with varying concentrations of IFN-γ, treated with conditioned media from primary T cells, or co-cultured with IFN-γ-producing primary immune cells. Additionally, the reporter cells were co-cultured in 2-D or 3-D systems for the comparison with ELISA. Our data revealed that bioluminescence intensity from the reporter cells increased by approximately 100- to 250-fold in a dose dependent manner following IFN-γ stimulation. Primary T-cell conditioned media stimulation resulted in a 50- to 100-fold increase in bioluminescence intensity. In co-culture assays with primary T cells or NK cells in the presence of immune checkpoint inhibitors, the reporter cell lines exhibited a 3- to 12-fold increase in bioluminescence intensity. Notably, in both 2-D and 3-D co-culture systems, the reporter cells generated a robust bioluminescent signal even at the IFN-γ concentrations below the detection range of conventional ELISA, highlighting their superior sensitivity and versatility. These reporter cell lines can serve as a valuable standard for early-stage monitoring of immune activation and offer a convenient and highly sensitive platform for evaluating cancer immunotherapy drug candidates.

#3960 Genome-wide CRISPR screens for genes inhibiting T cell-tumor cell interactions identify complex N-glycans.

Adriaan F. H. de Groot, Zowi R. Huinen, Juan Simon Nieto, Daniel S. Peeper

The Netherlands Cancer Institute, Amsterdam, Netherlands

The efficacy of immunotherapy fundamentally depends on effective T cell-tumor cell interactions, yet the molecular determinants orchestrating this engagement are not fully understood. Here, we systematically mapped and perturbed key regulators of the T cell-tumor cell interactome using innovative cell-cell interaction assays. We performed genome-wide CRISPR screens to identify genes critically required for physical and functional interactions between T cells and tumor cells. Using TurboID proximity labeling and T cell-tumor cell conjugates, we identified the complex N-glycan biosynthesis pathway as a crucial regulator of T cell-tumor cell interactions. Recognizing the role of N-glycans in protein trafficking and surface retention, we subsequently performed cell surface proteomics and TurboID-based interactome profiling on complex N-glycan-deficient T cells, revealing increased expression of cell adhesion and co-stimulatory molecules. T cells with perturbed N-glycans show a shift towards an effector memory phenotype with elevated granzyme and integrin expression. *In vivo*, both genetic and pharmacological interventions that decrease the number of complex N-glycans on the surface of T cells enhanced intra-tumoral infiltration. Our findings provide a comprehensive functional atlas of molecules modulating T cell-tumor cell interactions and position the complex N-glycan biosynthesis pathway as a potential therapeutic target to strengthen T cell-mediated cytotoxicity in cancer immunotherapy.

#3961 CBFβ-SMMHC directly activates immune regulatory genes to establish a global immune suppression in mouse AML model.

Hui Fang[1], Xiaocui Lu[1], Chang Liu[1], Xuexiu Fang[1], Stephanie Fay Mori[1], Bo Cheng[2], John K Cowell[1], Tianxiang Hu[1]

[1]Augusta University, Augusta, GA,[2]Zhongnan Hospital of Wuhan University, Wuhan, China

A recurrent inversion involved in chromosome 16 leads to the fusion of genes CBFB and MYH11, which encodes CBFβ-SMMHC fusion protein acting as a driving factor of acute myeloid leukemia (AML). Though breakthroughs have been made in the treatment of leukemia, drug resistance and relapse post treatment are still major causes of adverse prognosis of AML patients. It's found that an immune suppressive microenvironment usually affects the treatment response of cancer patients, therefore, a better understanding of the immune microenvironment holds the promise of developing novel therapy to improve outcomes. We investigated dynamic shifts in the immune landscape as leukemia progresses in the conditional Cbfb-MYH11 knockin mouse model. Accompanying the continuous increase of cKit+ leukemia cells, all the other immune cells dramatically dropped with the progression of AML. Notably, a significant reduction occurred in the levels of immune effector T, B, and NK cells. The presence of myeloid-derived suppressor cells (MDSCs) also decreased during leukemogenesis. This immune suppression phenomenon was consistently observed in both primary leukemia induction and following leukemia cell transplantation. When co-cultured with CD4 T cells, the cKit+ leukemia cells significantly inhibited the division of T cells. Mechanistically, RNA-Seq profiling revealed a global activation of the immunosuppressive pathway genes including PDL1, Tgfβ1, and Nfkb1 in these leukemia cells. Consistently, Cbfb-MYH11 inhibitor treatment can attenuate the inhibitive effects of AML cells on T cell proliferation, due to the reduced expression of immune suppressive genes. Correlative analysis in AML patient samples also confirmed the positive correlations between the immune suppression genes and MYH11. Furthermore, flow cytometry revealed that PD-L1 was exclusively upregulated in cKit+ leukemia cells, accompanied by increased CD4 and CD8 T cell exhaustion, suggesting that the PD-L1/PD1 pathway at least partially contributes to this global immune suppression. Indeed, transplantation of the same leukemia cells into PD1 KO mice led to delayed AML progression. Taken together, our results reveal the establishment of a global immune suppression in this AML mouse model by the immune suppressive AML cells expressing CBFβ-SMMHC, and immune suppressive pathways including PD-L1/PD1 are involved, justifying a combinational treatment of immunotherapy with current "7+3" regimen for treatment of AML carrying CBFβ-SMMHC.

#3962 Pan-cancer spatial characterization of tertiary lymphoid structures.

Kyung Serk Cho[1], Yunhe Liu[1], Guangsheng Pei[1], Jianfeng Chen[1], Tieling Zhou[1], Khalida M. Wani[1], Alejandra G. Serrano[1], Sharia D. Hernandez[1], Akshaya S. Jadhav[1], Daiwei Zhang[2], Hannah C. Beird[1], Jiahui Jiang[1], Diana Shamsutdinova[1], Xinmiao Yan[1], Yibo Dai[1], Enyu Dai[1], Ashley L. Wilson[1], Anne Waldrep[1], Fuduan Peng[1], Wei Lu[1], Yang Liu[1], Jimin Min[1], Paola A. Guerrero[1], Idania C. L. Julio[1], Tong Yin[3], Shin Hsu Shi[3], Sabitha Prabhakaran[1], Scott E. Kopetz[1], Dipen M. Maru[1], Alexander Lazar[1], Amir A. Jazaeri[1], Michael Green[1], Mingyao Li[4], Catherine Sautes-Fridman[5], Wolf H. Fridman[5], Andrew Futreal[1], Luisa M. S. Soto[1], Humam Kadara[1], Anirban Maitra[1], Suet Yi Leung[3], Jianjun Gao[1], Linghua Wang[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]The University of North Carolina at Chapel Hill, Chapel Hill, NC,[3]The University of Hong Kong, Hong Kong, Hong Kong,[4]University of Pennsylvania, Philadelphia, PA,[5]University of Paris, Paris, France

Tertiary lymphoid structures (TLS) are frequently observed in various solid tumors, where they play a pivotal role in regulating anti-tumor immune responses. Despite their importance, our understanding of TLS and their interactions with cancer cells within complex tissue environments remains limited. Recent advances in spatial transcriptomics (ST) technology offer new possibilities for investigating the spatial and phenotypic heterogeneity of TLS.

We developed TLSphenotyper, a computational framework for automatic TLS segmentation, labeling, extraction, and comprehensive profiling of TLS using spot-level ST data. It enables reproducible and efficient large-scale analysis of TLS. To accurately map TLS and characterize their cellular composition, we created a robust TLS-specific gene signature and enhanced the resolution of spot-level ST data to near-single-cell resolution. TLSphenotyper computes cell type-specific gene signature scores to generate a detailed cell type probability map across the tissue section. This map facilitates segmentation of key cellular components within TLS, enabling precise spatial mapping and colocalization analysis of major cell types and their transcriptomic states. Additionally, TLSphenotyper automatically analyzes and classifies TLSs based on their maturation stages, offering insights into their phenotypic and functional heterogeneity. Its accuracy and precision were validated using single-cell ST data generated from adjacent tissue sections. Further benchmarking against established deconvolution methods demonstrated superior accuracy and granularity in spatial cell type inference, cell organization and co-location analysis within TLS regions.

To further investigate TLS and their interactions with cancer cells in a pan-cancer setting, we curated a comprehensive dataset of publicly available and in-house spot-level ST data, encompassing 340 tissue sections from 12 distinct cancer types. This represents the largest collection of ST data on human cancer assembled to date. Using TLSphenotyper, we identified and characterized 695 TLSs across 340 tissues. Our analysis revealed substantial variation in TLS presence, size, location, density, cellular composition, and maturation stage across cancer types. TLSs at different maturation stages exhibited distinct transcriptomic profiles. Notably, cancer cells in proximity to TLS demonstrated significantly different activity across key signaling pathways compared to those farther away, suggesting that TLS interaction can shape cancer cell expression profiles and cellular states. Additionally, patients classified based on the maturation stages of TLS demonstrated distinct survival outcomes. Together, this study provides novel insights into the spatial dynamics and phenotypic heterogeneity of TLS, identifies potential targets for modulating TLS, and establishes a valuable resource for the research community.

#3963 Tumor-intrinsic impact of PIP4K2C degradation drives preclinical efficacy in colorectal cancer.

Eva d'Hennezel[1], Morgan O'Shea[1], Guosen Ye[1], Kristin Brown[1], Andrew Good[1], Melvyn Chow[1], Julie Arnold[1], Lilly Ein[1], Vincent Giacalone[1], Robert Prenovitz[1], Sebastian Hayes[1], Sydney Alnemy[1], Erica Dube[1], oluwatimileyin A. Adigun[1], Kirti Khardenavis[2], Alyssa Martin[2], Michael Perricone[2], Krista Goodman[1], Emily Corse[1], Catherine Sabatos-Peyton[1]

[1]Larkspur Biosciences, Inc., Cambridge, MA,[2]Xsphera Biosciences, Boston, MA

Phosphatidylinositol 5-phosphate 4-kinase, type II, gamma (PIP4K2C) is a lipid kinase with critical roles in vesicular trafficking, autophagy-dependent catabolism and modulation of the immune system. PIP4K2 kinases regulate membrane localization and clustering of $PI(4,5)P_2$ and thus govern multiple aspects of receptor trafficking and signaling at the plasma and vesicular membranes, independently of their catalytic function (Wang et al.). Cancer cells maintain their fitness by developing survival adaptations that foster escape from intrinsic and extrinsic mechanisms of cell death in conditions of stress. Through its ability to modulate membrane lipid dynamics, PIP4K2C plays an important role in cancer fitness and has the potential to modulate key signaling pathways and cellular responses to exogenous and endogenous stress, in turn increasing the immunogenicity of the tumor. As germline PIP4K2C knockout mice develop subclinical autoinflammatory signs with age (Shim et al.), systemic modulation of PIP4K2C both enhances anti-tumor immunity and disrupts cancer cell fitness, both impacts synergizing to reduce tumor growth in cancer patients. Achieving potent targeting of PIP4K2C while sparing other family members or other lipid kinases has so far precluded the exploration of its potential as a therapeutic target. LRK-A was developed as a bifunctional degrader of PIP4K2C causing rapid and exclusive degradation of PIP4K2C in vivo and in vitro. Degradation of PIP4K2C in tumors leads to modulation of key pro-tumorigenic pathways and upregulation of immune activating cytokines, chemokines, and stress-associated receptors. Subsequently, tumors are more susceptible to immune cell killing by NK cells and phagocytosis by dendritic cells. Concurrently, PIP4K2C degradation in phagocytes increases PIP2 production and mediates an increased uptake of dead tumor material, enabling a synergistic, dose-dependent amplification of the immune response to cancer. Dosing of LRK-A as a single agent significantly reduces tumor growth including full regressions in a mouse syngeneic model of colorectal cancer. We further demonstrate that treatment of human primary spheroids derived from tumor resections of MSS-CRC patients leads to increased tumor cytotoxicity and upregulation of key immune activation markers. Collectively, our results show that PIP4K2C is a novel cancer fitness target at the critical convergence of tumor-intrinsic and tumor-immune pathways, and which can be specifically and effectively targeted in vivo using a bifunctional degrader. The reduced tumor growth we observed both in vivo in mice and ex vivo in human MSS-CRC patient samples upon targeting PIP4K2C alone suggests that PIP4K2C is a highly promising target for therapeutic intervention. Further explorations are ongoing to enable the development of PIP4K2C-targeted therapeutic strategies.

#3964 HLA typing and its association with TMB in a pan-cancer Chinese cohort study.

Ran Shu[1], Li Bian[2], Ying Yang[1], Jian Shen[1], Xiaoyu Tuo[1], Yanxi Li[1], Shiyue Liu[1], Feilong Zhao[3], Ding Zhang[4], Zhe Yang[1]

[1]The First Affiliated Hospital of Kunming Medical University, Kunming, China,[2]The First Affiliated Hospital of Kunming Medical University, Shannxi, China,[3]3D Medicine, Shannxi, China,[4]3D Medicine, Shanghai, China

Background: Previous studies have linked HLA-I heterozygosity to immunotherapy efficacy. Given that tumor mutational burden (TMB) is a well-established biomarker for immunotherapy, this study explores the relationships among HLA-I heterozygosity, HLA-I subtypes, and TMB.
Methods: Whole exome sequencing (WES) was performed on all samples. HLA-I typing was identified using HLAscan and clustered with HLAClustRView. Mutation analysis was performed with Maftools.
Results: We analyzed 810 patients, covering over 20 tumor types, with 163 in the any-homozygous group and 647 in the all-heterozygous group. No significant differences were observed between groups in age, gender, or MSI status. HLA-I subtype landscape revealed a predominance of A02 and A11 for HLA-A, B15 and B40 for HLA-B, and C03 and C01 for HLA-C. Approximately 50% of patients exhibited heterozygosity for both HLA-B and HLA-C loci, while none were heterozygous across all three loci. Utilizing the similarity distances of HLA-I gene subtypes, we categorized patients into six distinct clusters. Each cluster displayed a preference for specific tumor types, and for particular HLA-I gene subtypes. All-heterozygous patient proportion was notably higher in clusters #6, #2, and #3, and lower in cluster 4. Gene mutation analysis revealed significant enrichment of ADSS1, USP8, and MYOCD in cluster 3, as well as MUC22 in cluster 6, whereas the other clusters did not demonstrate significant mutation enrichment. HLA clusters also demonstrates a potential association with TMB ($p = 0.069$), where cluster 6 exhibited significantly lower TMB than the other clusters. TMB was slightly lower in the all-heterozygous group ($p = 0.13$). Stratified by cancer type, TMB was generally higher in the all-heterozygous group, particularly in liver cancer ($p = 0.005$), but lower in gastric cancer ($p = 0.027$). In gastric cancer, the any-homozygous group ($n = 39$) exhibited a higher proportion of MSI-H patients ($p = 0.024$), suggesting that MSI-H may contribute to TMB discrepancies. This finding also posits that HLA homozygosity may promote MSI-H occurrence. Comparative analysis of gene mutations revealed significant enrichment of 41 genes, including CSF2RB, NUP210L, and NUP214, in the any-homozygous group, with enrichment analysis linking these genes to reproductive system development, lipid localization, and HIV infection. In liver cancer, the any-homozygous ($n = 14$) and All-heterozygous groups ($n = 70$) showed no significant differences in age, sex, or MSI status. However, MUC16 and EPPK1 mutations were significantly enriched in the all-heterozygous group, while DSPP mutations were notably enriched in the Any-homozygous group ($p = 0.034$).
Conclusion: This study illustrated HLA-I subtypes in a large Chinese pan-cancer cohort, identifying six clusters. HLA heterozygosity and clusters were associated with TMB, suggesting potential for HLA-based personalized therapy development.

#3965 Targeting mTORC2 in lung squamous cell carcinoma improves anti-tumor immunity through the PSGL-1-VISTA axis.

Verra Ngwa, Yoonha Hwang, Wenqiang Song, Deanna Edwards, Jin Chen

Vanderbilt University Medical Center, Nashville, TN

Lung squamous cell carcinoma (LUSC) represents 30% of non-small cell lung cancer (NSCLC) cases and has a high mortality rate with limited targeted therapies. Unlike lung adenocarcinoma (LUAD), which has seen advancements in targeted therapies, LUSC has not benefited from similar breakthroughs despite having similar genetic abnormalities. While immune checkpoint inhibitor therapies have shown promise in some LUSC patients, a significant portion does not respond effectively, leaving limited treatment options. The metabolic landscape of tumors plays a crucial role in shaping the efficacy of immunotherapies, especially adoptive T cell therapies. However, identifying actionable metabolic vulnerabilities involved in T cell therapy is poorly understood. In this study, we investigated vulnerabilities in NSCLC and found that a substantial number of LUSC patients have genetic alterations in the PI3K-mTORC2-AKT signaling pathway. By using CRISPR/Cas9, we showed that disrupting mTORC2 function in LUSC cells reduced glycolysis and lactate secretion, which in turn reduced tumor growth in vivo. Remarkably, the loss of mTORC2 also enhanced the activity of cytotoxic T cells within the tumors. To further understand the metabolic and immune changes associated with mTORC2 loss of function, we performed RNA sequencing comparing wild-type (WT) and mTORC2-deficient cells. Our results confirmed a link between mTORC2 and HIF-2α, while regulating PSGL-1, a ligand of the VISTA/PD-1H checkpoint receptor. Furthermore, introducing a stable, non-degradable form of HIF-2α in mTORC2-deficient tumor cells restored PSGL-1 expression in vitro and in vivo. These results suggest that the interaction between PSGL-1 and VISTA plays a role in suppressing the anti-tumor immune response in LUSC tumors. Indeed, anti-VISTA treatment inhibited the growth of LUSC WT tumors in vivo, suggesting that mTORC2 plays a role in regulating PSGL-1 expression in the tumor microenvironment. Together, these data demonstrate that targeting mTORC2 or inhibiting VISTA checkpoint receptor may serve as a potential therapeutic strategy for improving immunotherapy in LUSC. Experiments are underway to perform an in vivo CRISPR screening to uncover metabolic genes that can modulate the immune response in lung squamous cell carcinoma (LUSC) while sensitizing this tumor subtype to T cell therapy.

#3966 Divergent immune responses in pancreatic cancer driven by KRAS mutations.

Andrew Wenger, Katherine Bacchi, Huanhuan Sun, Adrian Vega, Whitney Sisso, Erika Hissong, Lukas Dow, **Despina Siolas**

Weill Cornell Medicine, Queens, NY

Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive malignancy with abysmal survival rates. The highly immunosuppressive microenvironment of PDAC poses a major barrier to effective therapy. KRAS mutations are near-ubiquitous in PDAC, and studies indicate clinical outcomes vary depending on the specific KRAS genotype. Given that tumor genotype can shape the immune cell composition of tumors, we examined the immune cell composition of pancreatic tumors with specific KRAS mutations, focusing on $KRAS^{G12D}$ mutations (representing 40% of PDAC cases which have the worst prognosis) and $KRAS^{G12R}$ mutations (which make up 20% of PDAC cases and have a better prognosis). Orthotopically implanted $Kras^{G12R/+}$;$Trp53^{KO}$ mouse pancreatic tumors have a distinct immune profile in comparison to $Kras^{G12D/+}$;$Trp53^{KO}$ tumors, characterized by an influx of intratumoral $CD3^{+}$ T cells and mature dendritic cells. Selective depletion of CD4+ T cells induces a rapid progression in KRASG12R, but not KRASG12D mouse tumors. RNA sequencing of $KRAS^{G12R}$ tumor cells revealed enrichment of Type I interferon (IFN) pathways accompanied by related chemokines, CXCL9 and CXCL10 in comparison to $KRAS^{G12D}$ tumors. Analysis of publicly available and real-world human PDAC datasets an enrichment of dendritic cells and other immune related cell pathways in $KRAS^{G12R}$ tumors. Collectively, these data link the $KRAS^{G12R}$ mutation to an unique immunogenic role.

#3967 Targeting Siglec-10 interactions enhances macrophage-mediated phagocytosis of pancreatic cancer.

P. Saini[1], G. Mirji[2], S. A. Bhat[2], R. S. Shinde[2], M. Abdel-Mohsen[1];
[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL, [2]The Wistar Institute, Philadelphia, PA

Background: Pancreatic ductal adenocarcinoma (PDAC) is one of the most aggressive and immunotherapy-resistant cancers. Tumor-associated macrophages (TAMs) contribute to this resistance by failing to phagocytose cancer cells. Cancer cells evade immune detection by upregulating sialic acid on surface glycoproteins like CD24, which bind to inhibitory Siglec receptors such as Siglec-10 on TAMs, triggering signals that block phagocytosis. While blocking Siglec-10/CD24 interactions with αCD24 antibodies has improved phagocytosis in ovarian and breast cancers, the role of Siglec-10 interactions with CD24 or other glycoproteins in PDAC immune evasion, as well as targeting Siglec-10 to enhance macrophage phagocytosis in PDAC, remains unexplored.
Methods: Flow cytometry with Siglec-10 protein and affinity pulldown, followed by mass spectrometry, were used to identify glycoprotein ligands interacting with Siglec-10 on various human PDAC cell lines (PANC-1, MIAPaCa-2, Hs766T, and AsPC-1). Surface plasmon resonance (SPR) assay validated binding of these ligands to Siglec-10. To assess the role of Siglec-10 interactions in PDAC cells' evasion of macrophage-mediated phagocytosis, live-imaging immune-killing assays were performed in vitro with αCD24 or Siglec-10 blocking antibodies. Finally, the efficacy of Siglec-10 blockade in enhancing TAM-mediated killing of PDAC cells in vivo was evaluated using a subcutaneous PDAC xenograft model in immunodeficient mice injected with human monocyte-derived TAMs and treated with an isotype control or Siglec-10 blocking antibody.
Results: Most PDAC cells (~95%) bind Siglec-10, indicating sialic acid ligands. However, unlike ovarian and breast cancers, most PDAC cells do not express CD24 (~81%), suggesting PDAC cells bind Siglec-10 through other glycoproteins. Mass spectrometry identified integrin alpha-3 (ITGA3) as a novel Siglec-10 ligand on PDAC cells. ITGA3 binds strongly to Siglec-10, as assessed by SPR, and this interaction was abrogated when sialic acid was removed from ITGA3 using sialidase enzyme. Analysis of PDAC tissue single-cell datasets confirmed that PDAC cells express significantly higher ITGA3 levels than normal cells ($p<0.0001$). Our newly developed antibodies against Siglec-10, but not αCD24, significantly increased macrophage phagocytosis of PDAC cells in vitro ($p<0.05$). In vivo, Siglec-10 blockade reduced tumor size by 36% compared to controls ($p=0.0002$).
Conclusion: We identified ITGA3 as a novel Siglec-10 ligand enabling PDAC immune evasion from macrophage-mediated phagocytosis. Glycan-based immunotherapies, such as Siglec-10 blocking antibodies, are promising for enhancing phagocytosis and countering PDAC's immunosuppressive environment.

#3968 Developing T cell and organoid co-cultures derived from breast cancer patients of African descent for drug screening.

Batoul Farran[1], Moses Kamita[1], Sylvester Antwi[1], Valerie Ofori Abohah[1], Harriet Larrious-Lartey[1], Jessica Bensenhaver[1], Haythem Ali[1], Eleonor Walker[1], Foster Amponsah[2], Josephine Nsaful[3], Rose Dampson[4], Patrick Kafui Akakpo[4], Evelyn Jiagge[1]

[1]Hematology/ Oncology, Henry Ford Health System, Detroit, MI,[2]Eastern Regional Hospital, Koforidua, Ghana,[3]Korle Bu Teaching Hospital, Accra, Ghana,[4]Cape Coast Teaching Hospital, Cape Coast, Ghana

Triple negative breast cancer (TNBC) is the most aggressive form of breast cancer. It is highly prevalent in women of West Sub-Saharan African ancestry (WSSA) and African American (AA) women, resulting in poorer survival outcomes compared to European American (EA) women. Studies have shown that immune cells in the tumor microenvironment (TME) contribute to the progression of TNBC by immune suppression, the reprogramming of macrophages into pro-tumorigenic subtypes and the release of inflammatory cytokines. A previous study by our laboratory revealed that the immune processes and markers associated with TNBC are different in TNBC patients of African ancestry compared to EA patients. We have established platforms consisting of T cells co-cultured with organoids derived from patients of diverse ancestries to investigate the interactions between immune cells and TNBC cells. Organoids from Ghanaian (GH), EA and AA patients were successfully established from PDXs and primary tumors. T cells were isolated from patient PBMCs (matched tumor and T-cell), activated and tested in co-cultures with organoids, derived from TNBC tumors. Flow cytometry was performed to assess the efficacy of T cell killing. The activated T cells successfully eradicated TNBC cells at conditions that replicate in vivo T cell infiltration in TNBC, as evidenced by decreased percentages of EpCAM+ cells. Concomitantly, we observed a reduction in the percentages of CD3+ CD137+ activated T cells, suggesting that the tumor cells in the co-culture also impacted T cells. Based on our initial results, we are evaluating the effects of co-culture on distinct populations of cytotoxic T cells as well as on markers of activation and exhaustion to determine potential differences between TNBC patients of diverse ethnicities. Characterizing the differences in tumor-immune cell interactions within the TNBC tumor microenvironment between EA and AA TNBC patients will hopefully inform the development of novel therapeutic strategies for women of African descent.

#3969 Quantitative spatiotemporal analysis of patient-derived organoid-based tumor-immune microenvironment model in lung cancer for immunotherapy response prediction.

M. Lee[1], J.-E. Lee[1], D. Lee[2], D. Kim[1], D. Kang[1], C. Chung[1];

[1]Chungnam National University Hospital, Daejeon, Korea, Republic of, [2]Chungnam National University, Daejeon, Korea, Republic of

The tumor-immune microenvironment (TiME) plays a crucial role in cancer progression and treatment response, yet establishing physiologically relevant ex vivo models that accurately recapitulate TiME remains challenging. Here, we present a novel multi-modal analytical platform using lung cancer patient-derived organoids (PDOs) and autologous lymphocytes to model TiME, aiming to predict immunotherapy responses and guide treatment strategies. We developed an integrated analytical platform combining: (1) PDO-lymphocyte co-culture system using autologous cells isolated from lung cancer patients, (2) multiplexed immunofluorescence imaging for spatial analysis of immune cell distribution, (3) label-free holotomography for real-time visualization of TiME dynamics, and (4) comprehensive genomic profiling. The formation and architecture of TiME were validated through quantitative spatiotemporal immunophenotyping. Machine learning algorithms were employed to integrate multi-modal data and identify predictive signatures for treatment responses. Our integrated platform successfully reconstituted patient-specific TiME models that maintained key molecular and cellular characteristics of original tumors. Real-time holotomographic imaging revealed distinct patterns of immune cell migration and tumor-immune cell interactions. Quantitative spatiotemporal analysis demonstrated specific immune response signatures correlating with clinical outcomes. Integration of multi-modal data through machine learning algorithms showed significant predictive value for immunotherapy responses. The platform successfully identified differential drug responses in patient-specific models, correlating with clinical treatment outcomes. We established a novel multi-modal analytical platform for studying tumor-immune interactions in patient-specific models. The integration of spatial, temporal, and molecular analyses provides comprehensive insights into TiME dynamics and treatment responses. This platform shows promise as a predictive tool for immunotherapy outcomes and could serve as a personalized drug screening system, presenting new opportunities for patient stratification and therapeutic strategy optimization in lung cancer treatment.

#3970 Advancing multiple myeloma research: patient-derived 3D Organ-on-a-Chip models to reveal immunological mechanisms influencing cancer growth and resistance.

Medbh A. Dillon[1], Kevin J. Lee[1], Cole G. Phalen[1], Aishwarya Chander[1], Imran McGrath[1], Love Tätting[2], Troy R. Torgerson[1], Melinda L. Angus-Hill[1]

[1]Allen Institute for Immunology, Seattle, WA,[2]Department of Hematology & Department of Biomedical and Clinical Sciences, Linkoping University, Linkoping, Sweden

Multiple myeloma (MM) is characterized by malignant plasma cells infiltrating the bone marrow. The standard induction therapy for MM includes combining bortezomib, lenalidomide and dexamethasone (VRd); this has recently expanded to include an anti-CD38 antibody, which has improved patient outcomes. Despite the recent advances in treatment, patients with MM commonly relapse and it is a disease that remains ultimately incurable. More advanced patient-derived 3D models would allow a greater understanding of the tumor microenvironment (TME) and how it changes during treatment. This is needed for the identification and validation of new biomarkers for this disease and could aid in predicting individual treatment responses.

Longitudinal Olink proteomic data, generated by our group, from the plasma and bone marrow interstitial fluid (BMIF) of patients undergoing VRd induction therapy, allowed us to glean key insights into the changes specific to the bone marrow tumor microenvironment (TME) throughout therapy that can be validated in our 3D MM model system.

Our longitudinal data shows elevated interleukin 16 (IL-16) in the BMIF of patients at diagnosis, which decreases following induction therapy. IL-16 is a proinflammatory cytokine that acts as a chemoattractant for CD4+ T cells, myeloid cells and eosinophils, and has also been shown to be essential for proliferation of MM cell lines. Extracellular IL-16 may contribute to tumor growth or influence immune cell recruitment to the bone marrow TME. Its increased presence in the BMIF compared to the plasma suggests a localized role within the bone marrow TME.

To further investigate the role of IL-16 in the MM TME we developed a novel, patient-derived organ-on-a-chip model of multiple myeloma bone marrow. Using bone marrow mononuclear cells (BMMC) and donor matched bone marrow stromal cells (BMSC) we developed a complex TME on-chip using primary human cells. Using this model we examined the role of IL-16 and other differentially expressed growth factors on tumor development, hematopoietic stem cell differentiation and cytokine production in the TME. Preliminary data shows an increase in proliferation of malignant MM cells in the presence of IL-16, highlighting IL-16 as a potentially promising therapeutic target.

#3971 Single-cell transcriptomic insights into tumor and immune dynamics driving resistance to sitravatinib, nivolumab, and ipilimumab in advanced clear cell renal cell carcinoma.

Kai Yu[1], Ying Yuan[1], Jianfeng Chen[1], Xinmiao Yan[1], Menuka Karki[1], Fei Duan[1], Rahul Annil Sheth[1], Priya Rao[1], Kanishka Sircar[1], Amishi Yogesh Shah[1], Amado Zurita-Saavedra[1], Giannincola Genovesa[1], Min Li[1], Chih-Chen Yeh[1], Minghao Dang[1], Guangchun Han[1], Yanshuo Chu[1], Max Hallin[2], Peter Olson[2], Rui Yang[2], Daniela Slavin[2], Hirak Der-Torossian[2], Curtis Chin[2], Nizar M Tannir[1], Linghua Wang[1], Jianjun Gao[1], Pavlos Msaouel[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Mirati Therapeutics, San Diego, CA

The combination of sitravatinib, nivolumab, and ipilimumab offers a novel approach to enhance immunotherapy outcomes in advanced clear cell renal cell carcinoma (ccRCC). To explore the immunomodulatory and resistance mechanisms underlying this triplet therapy, we performed single-cell RNA sequencing (scRNA-seq) on tumor samples collected longitudinally from 12 patients across treatment timepoints. Transcriptomic data from 70,526 cells, including 58,331 tumor microenvironment (TME) cells, revealed dynamic shifts in cellular composition and transcriptional states during therapy. Analysis of TME cells identified eight major cell types, with notable increases in T cells and reductions in myeloid and endothelial cells post-treatment. Baseline T cell abundance correlated with improved clinical response, while fibroblast enrichment predicted resistance. Tumor cells were classified into ten transcriptionally distinct clusters, including a treatment-resistant population (C8) enriched in epithelial-mesenchymal transition (EMT), hypoxia, and glycolysis signatures. These signatures correlated with shorter progression-free survival in the trial cohort and worse survival outcomes in an external TCGA ccRCC dataset. T cell states showed a transition from cytotoxic to exhausted phenotypes in non-responders and end-of-treatment samples, suggesting a role for T cell dysfunction in resistance. Similarly, myeloid cells exhibited a shift toward immunosuppressive phenotypes, characterized by M2-like macrophages and inhibitory signaling pathways. These findings elucidate resistance mechanisms to the triplet therapy, highlighting EMT-driven tumor cell states and immunosuppressive TME dynamics as key contributors. The identification of a tumor-specific C8 signature provides a potential biomarker for predicting poor responses and tailoring therapeutic strategies. Further validation in larger cohorts is needed to optimize patient selection and therapeutic outcomes.

#3972 The role of myeloid derived suppressor cells in organ-specific breast cancer metastasis.

Batul Al-zubeidy, Edgar Gonzalez, Aaron Baugh, Matt Jacobo, Evanthia Roussos Torres

USC - University of Southern California, Los Angeles, CA

The liver and lungs are the most common sites of breast cancer metastasis, associated with poor prognosis and limited response to systemic therapies. These tumor microenvironments (TMEs) exhibit distinct cellular compositions and molecular mechanisms that promote tumor growth and metastatic progression. Visceral organs differentially recruit specific immune populations that foster protumor interactions, contributing to the poor therapeutic response to immunotherapy. To explore the role of TMEs in tumor progression, immune evasion, and metastasis, we employed an orthotopic mouse model inoculated with an ERBB2/HER2-enriched breast cancer cell line. Flow cytometry analysis of primary breast tumor, and liver and lung metastases showed an early accumulation of $CD3^+$ lymphocytes in primary tumors shortly after inoculation, which significantly declined over time. Despite this overall reduction in lymphocytes within tumor microenvironments (TMEs), the lungs consistently maintained the highest levels of lymphocyte infiltration. Conversely, myeloid-derived suppressor cells (MDSCs) progressively infiltrated both primary and metastatic sites, exerting potent immunosuppressive effects that likely facilitate tumor progression and dampen immune responses. MDSCs derived from liver and lung metastases, but not from the primary tumor, suppressed $CD8^+$ T cell proliferation and significantly inhibited the production of cytotoxic cytokines, such as granzyme A. The most pronounced suppression was observed in breast-to-liver metastases. Flow cytometry analysis revealed that MDSC-mediated immunosuppression varies by microenvironment, with predominant arginase release in the liver, inducible nitric oxide synthase (iNOS) production in the lung, and interleukin-10 secretion in the primary tumor. Additionally, in the liver TME, $CD11b^+$ $F4/80^+$ tumor-associated macrophages (TAMs) exhibited higher arginase activity than MDSCs, further enhancing the suppressive microenvironment. These immunosuppressive cytokines likely impair the function of tumor-infiltrating lymphocytes (TILs) within their respective TMEs, highlighting the need to investigate organ-specific mechanisms of immunosuppression. Notably, liver metastases harbor the lowest levels of antitumor lymphocytes and the highest suppressive MDSC activity compared to lung metastases and the primary tumor. These immune alterations are likely initiated shortly after tumor seeding, emphasizing the importance of early intervention in metastatic disease.
In summary, the tissue-specific programming of MDSCs in breast-to-liver metastases, compared to primary tumors and breast-to-lung lesions, results in reduced T cell infiltration and impaired T cell function. These findings underscore the importance of developing niche-specific immunotherapeutic strategies to address organ-specific immune suppression.

#3973 Tumor-associated macrophages protect glioblastoma cells from ferroptotic stress in a sex-biased manner by inducing ferritin-bound iron release from cancer cells.

A. Sahu, K. Palsa, G. Shenoy, B. Slagle-Webb, J. R. Connor;
Penn State College of Medicine, Hershey, PA

Glioblastoma (GBM) is a highly aggressive and difficult-to-treat brain tumor originating from astrocytes. It is also sexually dimorphic, with females having a survival advantage and responding better to standard therapy. Sex-biased differences in iron metabolism play a significant role in making GBM a sexually dimorphic disease. Iron is a critical player in tumor metabolism, as cancer cells require iron to keep dividing rapidly; however, high cellular iron can make the cells vulnerable to ferroptosis. Macrophages play a pivotal role in tumorigenesis by regulating iron homeostasis in the tumor microenvironment. Here, we examine macrophage iron homeostasis as a potential driver of sex biases in glioblastoma using bone marrow-derived macrophages (BMDM) isolated from C57BL/6 mice. Immunoblot analysis shows that male macrophages have a higher storage (FTL expression) than female macrophages. We used a stable isotope of iron (Fe57) to determine macrophage iron uptake by ICPMS and observed that male BMDMs have a higher iron uptake. Flow cytometric analysis after ferro far red staining showed that male macrophages have a higher labile iron pool. These results indicate that macrophage iron metabolism is sexually dimorphic.

Next, we used a transwell co-culture system to study how macrophages regulate the iron status of GL261 cells. Immunoblot analysis showed that GL261 cells cocultured with BMDMs had a significant reduction in cellular FTH1 in a sex-biased manner. This reduction in cellular FTH1 correlated with decreased total cellular iron. Further immunoblot analysis of the condition media revealed increased secreted FTH1 levels from GL261 cells in coculture. Fe57 loading experiments showed that this increased secreted FTH1 levels correlated with an increased iron secretion. All these results indicate that macrophages induce FTH1-bound iron release in GL261 cells in a sex-biased manner. To understand if this cellular decrease in iron alters the GBM cells' susceptibility to ferroptotic stress, we induced ferroptosis by RSL3 treatment. Upon RSL3 treatment, GL261 cells in coculture with BMDMs had significantly higher cellular viability (Cell titer glo) and significantly less lipid peroxidation (Bodipy Staining). This indicates that tumor-associated macrophages protect GBM cells from ferroptotic stress in a sex-biased manner by inducing the cellular release of iron-containing FTH1.

#3974 Flexible and comprehensive phenotyping of tumor and peripheral blood mononuclear cells in endometrial carcinoma.

Deeqa Mahamed[1], **Jessica Elmore**[2], Geneve Awong[1], Gary Impey[1]

[1]Standard BioTools, Markham, ON, Canada,[2]Standard BioTools, South San Francisco, CA

Endometrial carcinoma (EC) is the most common form of uterine cancer, with increasing prevalence in developed countries due to population aging and rising obesity rates. Though prognosis is relatively good with an 80% survival at five years after diagnosis, the leading treatment is total removal of the uterus, ovaries and fallopian tubes. Thus, identifying biomarkers that may enable more personalized medicine or immunotherapy discoveries is important, both to create more treatment options as well as to tackle aggressive EC subtypes. To that end, we developed a 58-parameter mass cytometry (CyTOF™) panel that enables deep phenotyping of both immune and non-immune cells in tumors as well as in PBMC. In total, 48 markers were measured for each cell, allowing for deep profiling of cell identity, cytokine production, cytotoxicity, exhaustion and activation. This was achieved by combining pre-optimized panels for pan-immune cell phenotyping, T cell profiling and cytokine and cytotoxic mediator detection with nine drop-in antibodies selected for their relevance in EC as biomarkers or potential immunotherapy and drug targets. Cell proliferation was assessed using IdU incorporation and Ki-67 staining, while tumor cell and tumor-infiltrating leukocytes (TILs) were further defined with EpCAM, Her2, β-catenin, CD69, CD103, PD-L1 and FoxP3. Live-cell universal barcoding with a tellurium-based 7-choose-3 strategy allowed multiplexing of samples during cell staining and acquisition. Matched PBMC and dissociated tumor cells (DTCs) from EC patients and healthy donor PBMC (n=5 each) were stimulated with PMA and ionomycin, then barcoded and pooled. Cells were then stained for surface, cytoplasmic and nuclear targets before acquisition on a CyTOF XT mass cytometer. Data was normalized and debarcoded before analysis to yield sample-specific cell frequencies and marker expression. The tumor-derived T cells from EC patients exhibited a tissue residency phenotype (CD69+CD103+/-), robust staining of immune checkpoint markers TIGIT, LAG-3, TIM-3 and OX-40 and increased staining of CD95/Fas, PD-1 and 4-1BB compared with peripheral blood T cells. Intracellular cytokines were detectable on tumor-derived immune cells despite being rare, with some subsets producing IFNγ, TNFα, IL-2 and IL-17A in response to stimulation. This high-parameter panel allows for deep phenotypic and functional profiling of circulating immune cells, tissue and tumor cells and TILs. In addition to dissociated cells from tumor resections and biopsies, this panel could be used with liquid or fine needle aspirate biopsies from tumor samples when combined with live-cell universal barcoding to multiplex low-input samples. By utilizing a flexible and modular assay designed to characterize both immune and non-immune cells, this CyTOF panel can facilitate biomarker discovery and accelerate drug development in cancer therapeutics.

#3975 Regulating dendritic cells to promote mature tertiary lymphoid structures and enhance anti-tumor immunity.

Elizabeth E. Evans[1], Crystal Mallow[1], Terrence L. Fisher[1], Elaine Gersz[1], Holm Bussler[1], Maria Scrivens[1], Vuyani Matsenjwa[1], Ellen Giampoli[2], Saurabh K. Garg[3], Colin W. Snyder[3], Brian Czerniecki[3], Conor Steuer[4], Nabil Saba[4], Michael Lowe[4], Gregory B. Lesinski[4], Chrystal Paulos[4], Maurice Zauderer[1]

[1]Vaccinex, Inc., Rochester, NY,[2]University of Rochester, Rochester, NY,[3]Moffitt Cancer Center, Tampa, FL,[4]Winship Cancer Center of Emory University, Atlanta, GA

Mature tertiary lymphoid structures (TLS) characterized by the presence of germinal centers are strong predictors of response to immunotherapy. DCs play critical and decisive roles in determining the outcome of the immune responses in the TME and within TLS. Therefore, strategies to recruit and activate DC have the potential to induce TLS and enhance response to immunotherapy. Pepinemab, semaphorin 4D (SEMA4D) blocking antibody, reversed myeloid suppression and promoted infiltration of activated DC and CD8+ T cells into the TME in preclinical and clinical studies. New data demonstrates the presence of mature TLS following pepinemab treatment in combination with immune checkpoint inhibitors (ICI) in three separate clinical studies. KEYNOTE-B84 study (NCT04815720) evaluated the safety and efficacy of pepinemab in combination with pembrolizumab as a first-line treatment for immunotherapy-naïve patients with R/M HNSCC. Neoadjuvant studies in patients with surgically resectable metastatic melanoma (NCT03769155) and HNSCC (NCT03690986) received pepinemab treatment combined with nivolumab and/or ipilimumab. Screening and on-treatment tumor biopsies were evaluated using multiplex immunohistochemistry, RNAseq and spatial transcriptomics. TLS identified in biopsies of patients treated with pepinemab in combination with ICI were larger and more mature, containing high density of activated HLA-DR+ DCs, FDC, follicular B cells, and Tfh cells expressing CXCR5, characteristic of germinal centers. Importantly, comparison of matched biopsy pairs before and after treatment indicated that TLS were induced by the pepinemab combination treatment. Increased density and maturity of lymphoid aggregates, as well as significant changes in DC activation markers and the Flt3/Wnt pathway correlated with clinical benefit. We hypothesized that effects of pepinemab could be further enhanced by increasing the population of DC available in the TME. In preclinical studies, intra-tumoral vaccination with ex vivo expanded DC-1 enhanced effects of systemic treatment with SEMA4D-blocking antibody, resulting in improved DC trafficking to draining lymph nodes, and inducing tumor regression in both target and distant tumors. For in vivo expansion of DC, treatment with Flt3L improved anti-tumor activity when combined with SEMA4D-blocking antibody. Pepinemab represents a novel strategy to boost dendritic cell infiltration, activation, and organization of functional TLS to overcome limitations of immune checkpoint therapies. When combined with ICI, pepinemab induced de novo formation of TLS that correlated with clinical benefit, even in poorly immunogenic tumors that do not respond well to ICI, including HPV-negative and PD-L1 low HNSCC. When combined with modalities to further expand DC, SEMA4D blocking antibodies inhibited tumor growth in preclinical models, including in ICI-resistant models.

#3976 Disrupting CD44-SPP1 interaction between tumor cells and tumor-associated macrophages (TAMs) to overcome cisplatin resistance in muscle-invasive bladder cancer (MIBC).

Yuzhen Zhou[1], Jihyun Lee[2], Hiba Siddiqui[1], Martin Egger[1], Eliezer M Van Allen[1], Filipe De Carvalho[2], Kent Mouw[1]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Brigham and Women's Hospital, Boston, MA

Introduction: Cisplatin-based chemotherapy remains a mainstay of treatment for MIBC; however, cisplatin resistance is common and is associated with poor clinical outcomes. Tumor cells actively shape the tumor microenvironment (TME), including tumor-associated macrophages (TAMs)—which comprise 50-80% of stromal cells—to support tumor growth. While TAMs are critical determinants of pro- or anti-tumor TME characteristics, the mechanisms underlying tumor-macrophage crosstalk in cisplatin resistant tumors remain poorly understood.

Methods: We employed single-nucleus RNA sequencing (snRNA-seq) to analyze cell populations in cisplatin sensitive and resistant human bladder tumors. Spatial transcriptomic analysis was performed to assess the spatial organization of cell types within tumors. CRISPR-Cas9 was utilized to generate CD44-deficient bladder cancer cell lines and SPP1-deficient macrophages. Functional assays for tumor cells and macrophages were performed using direct and indirect tumor cell-macrophage co-culture systems. Phagocytosis was analyzed using live-cell imaging and flow cytometry. Finally, both immune-competent and immune -deficient mouse model was utilized to evaluate the therapeutic potential of targeting the CD44-SPP1 axis as a strategy to overcome cisplatin resistance.

Results: Our analysis revealed that high CD44 expression in tumor cells is positively correlated with cisplatin in human bladder cancer patients. SPP1-expressing macrophages were spatially localized near CD44 positive tumor cells in cisplatin resistant tumors. Deleting CD44 in tumor cells increased sensitivity to cisplatin, which was more significant in the presence of macrophage-conditioned media in co-culture with bladder cancer cell lines. CD44 loss also promoted the phagocytic activity of the mouse macrophage cell line Raw264.7. We are currently using an immune-competent mouse bladder cancer model to test whether genetic deletion or pharmacological blockade of CD44 sensitizes tumors to cisplatin. Furthermore, we will utilize immune-deficient nude mice to co-implant human bladder cancer cell with human macrophages with or without SPP1 expression to evaluate whether SPP1 deficient macrophage enhance cisplatin responses and promote tumor suppression.

Conclusion: Targeting the CD44-SPP1 interaction, either through genetic modification or antibody-mediated blockade, sensitizes bladder tumors to cisplatin. This approach represents a promising therapeutic strategy to overcome cisplatin resistance in MIBC.

#3977 Illuminating mesothelioma immune microenvironment in response to immune checkpoint inhibitors using spatial transcriptomics.

M. Alamgeer[1], D. Gough[1], V. Xue[1], B. Kumar[1], A. Pick[2], F. S. Yoosuf[1], S. Arulananda[2], J. Marquez[1], V. Ganju[1];
[1]Monash University, Clayton, Australia, [2]Monash Health, Clayton, Australia

Most mesothelioma patients either have primary refractory disease or develop acquired resistance to immune checkpoint inhibitors (ICIs). A more sophisticated understanding of the tissue microenvironment (TME) and intercellular communication will enable opportunities for overcoming ICI resistance. Here, we utilize the Visium 10x spatial transcriptomics (ST) technology to address this question. We conducted ST on a cohort of 12 mesothelioma patients (28 samples) treated with ICIs (Table 1). Nine patients had a response to ICIs with a median response duration of 9 months and three had primary ICI resistant disease. We show the transition from the immune infiltrated tumor in a pre-treatment sample transition to immune exclusion in the post-treatment (ICI-resistant) sample. In addition, we were able to map the immune cell sub-types in relation to cancer cells. In a responder, we identified CXCL12-CXCR4 mediated communication at the mesothelial-immune interface. We mapped a 48-gene prognostic signature to generate spatial heat maps showing specific regions within tissue with elevated poor prognosis signatures in treatment naïve samples that expanded in matched relapsed samples. We also identified remarkable heterogeneity showing pre- and post-ICI treatment samples to be transcriptionally diverse. In another patient, we assessed four samples from the primary tumor prior to treatment, two from PET-positive and two from PET-negative areas. Moreover, we complemented spatial transcriptomics with multi-region whole genome sequencing. This revealed that these sites are genomically stable but transcriptionally distinct. Further deconvolutional analysis to approximate cell composition, cell co-localization, and cell evolution/plasticity measures are underway. Together, this deep spatial investigation provides a key understanding of oncogenic communication in TME, before and after ICI therapy.

Table 1.

Patient No	Sex	Histological Subtype	Treatment	Pre-Treatment samples	Post Treatment samples	Response	Response duration
1	M	Sarcomatoid	PD-1	5	-	Yes	6
2	M	Epithelioid	PD-1	3	-	No	-
3	M	Biphasic	PD-1/CTLA-4	4	-	Yes	87
4	F	Biphasic	PD-1/CTLA-4	1	-	No	-
5	M	Epithelioid	PD-1/CTLA-4	2	1	Yes	12
6	F	Sarcomatoid	PD-1	1	-	Yes	52
7	M	Epithelioid	PD-1	1	1	Yes	17
8	M	Sarcomatoid	PD-1/CTLA-4	2	-	Yes	75
9	M	Epithelioid	PD-1/CTLA-4	1	1	No	-
10	M	Biphasic	PD-1	1	1	Yes	18
11	M	Sarcomatoid	PD-1/CTLA-4	1	1	Yes	22
12	M	Epithelioid	PD-1/CTLA-4	-	1	Yes	16

#3978 The downregulation of OGT1 reprograms tumor-associated macrophages and CD4 T cells fate in pancreatic adenocarcinoma tumor model.

Vira Chumak[1], Kuldeep Singh Attri[2], Pankaj Kumar Singh[1], Kamiya Mehla[1]

[1]Dep. of Onc. Science, University of Oklahoma Health Sciences Center, Oklahoma City, OK,[2]Baylor College of Medicine, Houston, TX

O-linked β-N-acetylglucosamine modification (O-GlcNAcylation) is a post-translational modification that plays a crucial role in development, normal physiology, and the pathophysiology of various diseases, including pancreatic cancer. This process is catalyzed by the enzyme O-GlcNAc transferase (OGT). The hexose biosynthesis pathway provides the necessary substrate, O-GlcNAc, for this reaction. However, the role of O-GlcNAcylation in tumor-associated macrophages has not been extensively studied. The hypoxic tumor microenvironment leads to increased glucose uptake and enhanced glycolysis. Additionally, macrophages undergo significant metabolic changes in this environment. The immunosuppressive nature of the tumor microenvironment promotes the polarization of macrophages toward the non-inflammatory M2-like phenotype, which is characterized by increased CD206, and Arg1 expression. To investigate the role of OGT1 in tumor-associated macrophages, we created a mouse strain, LysM-Cre; $Ogt^{fl/fl}$, which features OGT1 loss specifically in macrophages. We isolated bone marrow mononuclear cells from both mutant and control animals and differentiated them into bone marrow-derived macrophages (BMDM) in vitro. Following this, we cultured the BMDMs with pancreatic tumor cell-conditioned media (TCM) from pancreatic cancer cells and assessed arginase 1 (Arg1) levels using Western blotting. The BMDMs isolated from LysM-Cre; $Ogt^{fl/fl}$ mice expressed lower levels of arginase 1 compared to control mice after being cultured in TCM. Next, we investigated the effect of pharmacological inhibition of OGT1 using OSMI-1 on the BMDMs, which were treated with TCM or control media, and how these macrophages influenced CD4 T-cell subtypes. The BMDMs were cultured for 72 h in a medium containing 100 μM OSMI-1 under hypoxic conditions (1% O_2). Subsequently, the total CD4 T cells were co-cultured with the BMDMs for 62 h in hypoxia and stained to identify markers of Th1 and Th2 cell populations. We observed that macrophages stimulated with TCM reduced the number of IFNy+/IL-12+ CD4+ T cells compared to those treated with control media. In contrast, the inhibition of OGT1 in BMDMs resulted in an increase in the number of IFNy+/IL-12+ CD4+ T cells upon incubation with TCM. These findings suggest a potential role of OGT1 and O-GlcNAcylation in the interplay between macrophages and lymphocytes within the pancreatic adenocarcinoma TME. The data indicate that OGT1 may inhibit the immune components of the tumor microenvironment. This knowledge could pave the way for innovative strategies aimed at shifting the balance towards a more effective anti-tumor immune response.

#3979 Genomic determinants of canine tumor-associated macrophage polarization.

R. V. Brady, K. B. Farrell, E. P. Palmer, S. Das, D. L. Duval, D. H. Thamm;
Colorado State University, Flint Animal Cancer Center, Fort Collins, CO

There is poorly understood variability both between and within cancer types in their ability to maintain an immunosuppressive microenvironment and polarize tumor-associated macrophages (TAMs). Identifying genetic biomarkers of cancers that strongly polarize TAMs would enable the discovery of novel therapeutic targets and support the stratification of patients for appropriate immunotherapy. Our aim, therefore, was to correlate gene expression data from cancer cell lines with phenotypic changes in canine macrophages. We harvested standardized tumor-conditioned medium (TCM) from twenty-five canine cancer cell lines with bulk RNA-sequencing data available. Primary monocyte-derived macrophages were obtained from three canine donors and polarized with the twenty-five different TCMs. After a washout period, supernatants were collected, and polarization changes of the macrophages were assessed via secretory products using ELISA and a multiplex cytokine/chemokine assay. For each analyte measured, a modified z-score was used to rank each cell line's ability to stimulate the secretion of that analyte from macrophages. Multiple regression analysis and pairwise comparison analysis (composed of "strong" and "weak" stimulators) were performed against the full transcriptome. Many significantly differentially expressed genes were identified in the cancer cell lines with the strongest ability to polarize macrophages. For example, cell lines with MVB12A upregulated, a gene involved in selecting cargo for exosomes, had the highest ability to stimulate VEGF production from macrophages. This was subsequently confirmed by depleting the TCM of exosomes which resulted in a significant decrease in VEGF production. Multiple other genes involved in macrophage immunosuppression were upregulated, while those involved in cell adhesion and metastasis prevention were downregulated. In conclusion, canine cancer cell lines have varying abilities to polarize primary macrophages, irrespective of histologic type, as measured by secretory products. The cell lines capable of potent polarization had relevant differentially expressed genes and pathways. These are currently being explored to identify novel biomarkers and therapeutic targets.

#3980 Exploring the diversity and dynamics of the macrophage compartment in non-small cell lung cancer.

Eun Ji LEE[1], You Won Lee[2], Minyeop Kim[3], Seung Yeon Oh[1], YoungJoon Park[2], Su-Jin Choi[4], JuHyeon Lee[4], Kyoung-Ho Pyo[2], Jae Hwan Kim[5], Jii Bum Lee[6], Min Hee Hong[6], Sun Min Lim[6], Mi Ran Yun[5], Byoung Chul Cho[6]

[1]Graduated School of Medical Science, Brain Korea 21 FOUR Project for Medical Science, Yonsei University College of Medicine, Department of Biomedical Science Institute, Seoul, Korea, Republic of,[2]Yonsei New Il Han Institute for Integrative Lung Cancer Research, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]JEUK Institute for Cancer Research, JEUK Co., Ltd, Gumi, Korea, Republic of,[4]Department of Research Support, Yonsei University College of Medicine, Yonsei Biomedical Research Institute, Seoul, Korea, Republic of,[5]Severance Biomedical Science Institute, Yonsei University College of Medicine,, Seoul, Korea, Republic of,[6]Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Although immune checkpoint inhibitors (ICIs) has improved the survival rate for some cancer, EGFR mutant (MT) non-small cell lung cancer (NSCLC) patients exhibit a poor response to ICIs than those with EGFR wild-type (WT). EGFR-MT cells contribute to immunosuppressive tumor microenvironment (TME) by secreting inhibitory cytokines and recruiting pro-tumor immunogenic cells, thereby diminishing the efficacy of ICIs. Tumor associated macrophages (TAMs) represent a major component of the TME, playing complex roles in tumor progression and metastasis. While single-cell RNA (scRNA) analyses have been performed in various cell types, studies on macrophage (MØ) diversity between EGFR-WT and -MT NSCLCs are limited. Therefore, we aimed to reveal the presence of multifaceted MØ populations, using scRNA sequencing.

Methods: Using the 10x Genomics, we generated scRNA expression data from 904,174 cells in primary lung tissues of 95 patients: EGFR-WT (n=35), treatment-naïve EGFR-MT (n=55), EGFR-TKI post-treatment (n=5), and matched normal (n=22). We annotated five distinct cell lineages—lymphocytes, epithelial cells, endothelial cells, fibroblasts, and myeloid cells—using canonical marker gene expression. We focused on MØs (n=158,640 cells) in myeloid, including markers such as *APOE, FCGR1A*, and *MARCO*.

Results: We characterized 13 transcriptional states of MØs: Four clusters of alveolar MØs (AMs; *PPARG*$^{+}$), two clusters of interstitial MØs (IMs; *MERTK*$^{+}$, *LYVE1*$^{+}$) and eight clusters of MØs expressing canonical markers (*CD68*$^{+}$, *C1QA*$^{+}$) with high monocyte derived MØ (MDM) signatures. To define significant clusters, we analyzed their proportions based on sample type, tumor stage, and recurrence status. MØ cluster compartment varied among normal, EGFR-WT, -MT, and -TKI samples. AMs were primarily found in normal tissues, while IMs and MDMs predominate in tumors. Some IM and MDM clusters showed opposing trends in proportion between EGFR-WT and -MT across tumor stages, with major recurrence-associated clusters differing between the two types. Next, we defined high proportion of four major TAM clusters identified in EGFR-WT, -MT, and -TKI, expressing the representative genes *SPP1, TREM2, IL1B*, and *FOLR2*, respectively. Gene ontology pathway analyses revealed the complexity of the TME. SPP1 TAMs, predominant in EGFR-MT, were associated with cellular stress response, while IL1B TAMs, mainly in EGFR-WT, were associated with response to external stimuli. FOLR2 TAMs were associated with chemoattraction and were prevalent in both EGFR-WT and -TKI. TREM2 TAMs, associated with lipid metabolism, were evenly distributed across all sample types.

Conclusions: We characterized the heterogeneity of MØ compartments between EGFR-WT, -MT and -TKI samples. These results highlight the need for selective treatment strategies based on EGFR mutation and treatment status in NSCLCs for successful immunotherapy.

#3981 The GZMK CD8 T cells cluster defined by single-cell transcriptome profiling with innate-like functions is a predictor of survival in hepatocellular carcinoma patients.

Wei-Ting Ku[1], Chien-Hao Huang[2], Jian-He Fan[2], Cheng-Heng Wu[2], Tsung-Han Wu[3], Wei Teng[2], Po-Ting Lin[2], Chung-Wei Su[2], Yung-Chang Lin[4], Chun-Yen Lin[5]

[1]Graduate Institute of Biomedical Sciences, Chang Gung University, Taoyuan, Taiwan,[2]Division of Gastroenterology and Hepatology, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan,[3]Department of General Surgery, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan,[4]Department of Hematology-Oncology, Linkou Chang-Gung Memorial Hospital, Taoyuan, Taiwan,[5]College of Medicine, Chang Gung University, Taoyuan, Taiwan

Hepatocellular carcinoma (HCC), the sixth most common cancer globally in 2020, is closely associated with hepatitis B or C infections and non-alcoholic steatohepatitis (NASH). Despite advancements in surgical and systemic therapies for early and advanced stages, tumor relapse and poor prognosis remain significant challenges, necessitating improved therapeutic approaches. This study highlights the role of GZMK-expressing $CD8^+$ T cells in HCC, identified through single-cell transcriptome profiling. These cells exhibit transcriptional profiles similar to hepatotoxic $CD8^+$ T cells in chronic hepatitis B and innate-like $CD8^+$ T cells in chronic hepatitis C. GZMK $CD8^+$ T cells are enriched with tissue-resident memory traits and are detectable in peripheral blood and tumor tissues. Furthermore, within the tumor microenvironment, GZMK CD8 cells expressed surface receptors resembling those of NK cells, allowing them to release IFN-γ and exert non-antigen specific innate-like cytotoxic effects. These GZMK $CD8^+$ T cells could be identified as $CD38^+$HLA-DR^+ $CD8^+$ T cells by flow cytometry. These $CD38^+$HLA-DR^+ $CD8^+$ T cells increased in the peripheral blood of HCC patients and accumulated in tumor tissue. Cytokines such as IL-12, IL-15, and IL-18 were shown to stimulate the proliferation of $CD38^+$HLA-DR^+ $CD8^+$ T cells, enhancing their production of IFN-γ and granzyme B, as well as their expression of NK-like receptors and effector molecules. These bystander-activated $CD38^+$HLA-DR^+ $CD8^+$ T cells, derived from effector memory (EM) and effector memory RA (EMRA) subsets, displayed cytotoxicity against K562 and THP-1 cell lines through DNAM-1, granzyme B, and perforin. A high GZMK $CD8^+$ T cell signature was strongly associated with improved overall survival (OS) and progression-free survival (PFS) in the TCGA-HCC database. These findings suggest that GZMK $CD8^+$ T cells have a significant impact on survival in HCC, possibly through their innate-like cytotoxic functions. This unique subset may serve as a biomarker and a potential therapeutic target in HCC management.

TUMOR BIOLOGY: Tumoroids, Organoids, and Cell Culture
Poster Session

#3985 Optimizing co-culture of tumoroid and immune cells for recapitulation of the tumor microenvironment.

Shyanne Salen, Sydney Hawkins, Sylvia Beam, **Colin D. Paul**, Chris Yankaskas, Pradip Shahi Thakuri, Matt Dallas, David Kuninger

Thermo Fisher Scientific, Frederick, MD

Immunotherapies for solid cancer treatment aim to potentiate immune cell recognition of cancer cells within the tumor microenvironment or recruit peripheral immune cells (native or engineered) to the tumor. Patient-derived tumoroids, or cancer organoids, are multicellular structures that closely mimic the architecture and genetic and transcriptomic landscape of tumors. When co-cultured with immune cells, these models enable a more comprehensive investigation of the tumor-immune microenvironment than traditional cancer cell lines. However, culture conditions to prolong survival of both epithelial cancer cells and immune cells remain poorly defined. Here, we explored methods to supplement Gibco™ OncoPro™ Tumoroid Culture Medium to promote immune cell survival for better recapitulation of the tumor microenvironment. In initial experiments, healthy donor PBMCs were thawed and cultured in suspension in OncoPro medium for 5 days. Total viable cells were counted at the end of the culture period and revealed loss of 80±2% of the cells initially present. Similarly, RNA sequencing comparing freshly dissociated colorectal and endometrial tumors with cells cultured for 7 days in OncoPro medium indicated downregulation of genes related to immune cell signaling pathways, and flow cytometry of tumoroid models showed loss of immune cell populations over time compared to the initial material. Therefore, designed experiments were used to screen and optimize cytokine cocktails that maximized PBMC survival while minimizing the change in the percentage of monocytes, B cells, NK cells, helper T cells, and cytotoxic T cells between the original (day 0) donor material and in vitro PBMC cultures. Cytokine addition led to an increase in PBMC cell number after 5 days in culture of 2.2±0.8x compared to culture in non-supplemented OncoPro medium across three independent donors, with <10% change in the relative proportion of cells in the immune compartments examined over the culture period. Follow up experiments are focused on determining conditions that support the survival of immune cells present in cryopreserved dissociated tumor cell (DTC) samples using cytokines identified during PBMC screening experiments. In preliminary work, the addition of cytokines to potentiate immune cell survival did not negatively affect the culture of epithelial tumoroid cells. Co-culture of immune cells with tumoroids will facilitate the examination of immune checkpoint inhibitors and other immunotherapy strategies in vitro to enable higher throughput and more controlled screening of immunotherapy candidates. We envision that this approach will provide critical insights into the mechanisms of immune evasion and resistance and potentially lead to more effective treatment options for cancer patients.

#3987 Implementation of advanced molecular imaging to evaluate probiotic L. lactis bacterium capability to preferentially target orthotopic colorectal tumor.

J. G. Gomez-Gutierrez[1], M. Ramos-Gomzalez[1], N. Rubio-Infante[1], J. Amos-Landgraf[1], S. Rachagani[1], L. McNally[2], H. Shirwan[3]; [1]University of Missouri - Columbia, Columbia, MO, [2]University of Oklahoma Health Science, Oklahoma, OK, [3]University of Missouri, Columbia, MO

Colorectal cancer (CRC) is the third most diagnosed cancer and has the second highest mortality of all cancers. CRC treatments include surgery, chemotherapy, and radiation. However, CRC patients suffer from significant toxic side effects, develop resistance to the therapies, and experience recurrence and metastasis. A new strategy for CRC treatment is immunotherapy, which uses the patients' immune system to attack cancer cells. Unfortunately, most CRC patients do not respond to immune checkpoint inhibitors (ICIs). To better treat CRC patients with immunotherapy, it is essential to improve tumor-targeting and tumor-specific uptake. Therefore, this study used advanced molecular imaging for real-time evaluation of the capability of probiotic facultative anaerobic bacterium *Lactococcus lactis* (*L. lactis*) to preferentially target orthotopic colorectal tumors. We combined bioluminescent (BL) and fluorescent imaging to simultaneously detect CRC tumors and *L. lactis* expressing infrared fluorescent protein (*L. lactis*-iRFP), respectively. To simultaneously detect BL and iRFP signals, we subcutaneously injected a CRC cell line expressing luciferase (CT26/luc) in the right flank of 6-week-old BALB/c mice. After the tumor reached a volume of 500 mm^3, *L. lactis*-iRFP was injected intratumorally. We found that BL and iRFP signals colocalized at the tumor site without directly overlapping without interfering one with another and *L. lactis*-iRFP signal was detected at the tumor site up to 5 days post-injection. Next, we proceeded to generate an orthotopic CRC mouse tumor model in 6-weeks-old BALB/c mice using the colonoscopy guided inoculation technique. We included two control mice without tumors, one administered with non-fluorescent *L. lactis* wild type, and the other with *L. lactis*-iRFP to compare the bacterium retention between tumor bearing mice. At day 11, when the orthotopic CRC tumor was well-established, the animals were administered with $1x10^{12}$ cfu/200 µL of *L. lactis*-iRFP or wild type via oral gavage, and BL and fluorescence signals were measured. The advanced molecular imaging revealed a strong iRFP signal in the tumor-bearing animals, up to 5 days post *L. lactis*-iRFP inoculation. The colons were scanned *ex vivo* and showed BL signal in the distal location of the CRC tumor. Interestingly, only the colons with tumors showed iRFP signal, suggesting that *L. lactis*-iRFP preferentially targets the CRC tumor microenvironment. However, additional experiments are required to reproduce this data and support a conclusion. We demonstrated that simultaneous detection of BL and iRFP signals is feasible and that this imaging technology could be potentially implemented for preclinical real-time evaluation of the capability of other bacteria to preferentially target solid tumors.

#3988 Patient-specific 3D engineered microphysiological systems to model triple-negative breast cancer chemotherapy using patient-derived xenograft (PDX) tissue.

Edgar A. Borrego[1], Linjie Luo[2], Janine Hagar-Montoya[1], Jose L. Perez[1], Paula Delgado[1], Khandan Keyomarsi[2], **Sylvia L. Natividad-Diaz**[1]

[1]Metallurgical, Materials, and Biomedical Engineering Department, The University of Texas at El Paso, El Paso, TX,[2]Department of Experimental Radiation Oncology, Division of Radiation Oncology, MD Anderson Cancer Center, Houston, TX

Chemotherapy efficacy and pharmacokinetics are influenced by a patient's unique characteristics, including gender, ethnicity, age, gene expression, and disease state. Three-dimensional (3D) tissue models integrated into microfluidic devices offer a controlled and reproducible platform to study cellular responses to drugs, leveraging fluid circulation for precise quantification. These models can be tailored to individual patients through the incorporation of patient-derived xenograft (PDX) tissues, which are purified and encapsulated within biomimetic hydrogels that replicate the tumor extracellular matrix (ECM). The objective of this study was to develop a patient-specific 3D model of triple-negative breast cancer (TNBC) cultured in a self-driven, closed-capillary microfluidic device to assess chemotherapy efficacy, toxicity, and tumor microenvironment interactions in vitro. We hypothesized that integrating human TNBC PDX tissue into customized microfluidic devices would create physiologically relevant systems to study disease pathology and treatment responses in vitro. TNBC-PDX tissues were isolated to establish a cell line expressing human EpCAM with a population doubling time of 48 hours. A CC50 value of ~10 µM was determined via flow cytometry viability assays following treatment with a 10-fold dilution series of Doxorubicin (DOX). The cells were encapsulated in 3D collagen hydrogels (0.2 wt%) and cultured in transwell (TW) dishes or microfluidic devices (DwP). These 3D TNBC-PDX models demonstrated viability, elongated morphology, and tumor-like clustering within DwP, reorganizing according to device microfeatures. When treated with 10 µM DOX, the 3D cultures in both TW and DwP conditions exhibited limited cell death, reflecting the original tumor's drug-resistant phenotype. These findings highlight the feasibility of integrating PDX tissues into microfluidic systems to create patient-specific 3D models, offering a physiologically relevant platform for evaluating chemotherapy responses. This approach may advance personalized cancer treatment strategies by enabling in vitro assessment of drug efficacy and resistance mechanisms.

#3989 Patient derived cancer organoids as a model to predict clinical response and drug discovery in colorectal cancer.

Alexa E. Schmitz, Shirsa Udgata, Maggie O. Smith, Rian Engeldinger, Yousef Gadalla, Xingqi Shen, Addison T. Zick, Alec B. Cornelio, Cheri A. Pasch, Dustin A. Deming

University of Wisconsin - Madison, Madison, WI

Background: Patient derived cancer organoids (PDCOs) have shown to preserve cell morphology and better recapitulate patients' cancers. Due to these advantages, PDCOs could be used as a model to better predict how a patient will respond to drug treatments. STX-478, a *PIK3CA*^{H1047R} mutant specific inhibitor, has shown promise to circumvent severe toxicities which could aid in the tolerability of novel combinations. Here, we examine the impact of PDCOs for predicting patient response to chemotherapy and in drug discovery.
Methods: PDCO lines were acquired from surgery and biopsies following consent and approved Institutional Review Board protocols. Seven PDCOs were imaged (Day 0) and treated for 48 hours based on the patient's clinical treatment. Media was subsequently replaced and PDCOs re-imaged 48 hours later (Day 4). Diameter analysis was performed using ImageJ and percent relative change (PRC) and Glass's Delta (GD) was determined for all treatments. Based on previous data, a Glass's Delta over 1.25 has been shown to correlate with partial response, and under 0.75 correlates with progressive disease. Clinical response was determined based on MRI scans and RECIST v1.1 guidelines. In the drug screen, a CRC PDCO line with a *PIK3CA*^{H1047R} mutation, was treated with 115 different inhibitors in combination with STX-478 for 48 hours. All plates were imaged on Day 0 and Day 2; diameter analysis was performed, and GD was determined for all treatment groups.
Results: Seven PDCO lines were treated with FOLFOX or FOLFIRI and a GD range of 0.01-1.61 with a median of 0.75 were observed. Based on previously described GD sensitivity thresholds, two PDCO lines were responsive, and five were nonresponsive to treatment. The five non-responsive PDCO lines were all collected from the residual tumor after treatment with FOLFOX. FOLFIRI treatment of PDCO line CRC1 caused a significant response compared to all treatment groups (PRC= 22.4%, GD= 1.26, control: 70.3%, 5FU: 33.5%, 0.97, SN38: 43.1%, 0.71). Clinically, the patient had a 42% reduction in cancer size per RECIST v1.1, which is considered a partial response. In the STX-478 drug screen, six different combinations resulted in an enhanced response compared to single agents, including enasartinib HCl (EHCL; STX-478 single agent PRC= 29.1%, EHCL= 38.6%, and combination= -2.06%, STX-478 vs combination GD: 1.57; EHCL vs combination: 2.07). Additionally, NSC23766, a Rac1 inhibitor, also demonstrated enhanced response in combination (STX-478 single agent PRC= 29.1%, NSC23766= 38.0%, and combination= 9.2%, STX-478 vs combination GD: 1.00; NSC23766 vs combination: 1.42).
Conclusion: PDCOs show exciting potential as a predictive model for patient response and drug discovery. These findings need to be validated in further studies.

#3990 Characterization of triple negative breast cancer organoids from diverse ethnic populations.

Akakpo[4], Jessica Bensenhaver[1], Kwabena Agbedinu[5], Michael Nortey[4], Nelson Affram[6], Mohammed Sheriff[7], Cassandra Mills[1], Alex Mremi[8], Theresia Mwakyembe[8], Ijeoma Aja[9], Moses Dokurugu[6], Haythem Ali[1], Eleanor Walker[1], Evelyn Jiagge[1]

[1]Henry Ford Health System, Detroit, MI,[2]Eastern Regional Hospital, Koforidua, Ghana,[3]Korle Bu Teaching Hospital, Accra, Ghana,[4]Cape Coast Teaching Hospital, Cape Coast, Ghana,[5]Komfo Anokye Teaching Hospital, Kumasi, Ghana,[6]Ho Teaching Hospital, Ho, Ghana,[7]Tamale Teaching Hospital, Tamale, Ghana,[8]Kilimanjaro Christian Medical Centre, Moshi, Tanzania, United Republic of,[9]Eastern Regional Hospital, Ho, Ghana

Introduction: Triple negative breast cancer (TNBC) among women with African ancestry has been shown to be more prevalent than in women of European ancestry. However, the root cause for this disparity is not fully understood. We have previously shown that the gene expression in the breast cancer stem cells of TNBC tumors differs based on Western sub-Saharan ancestry. Tumor organoids are three-dimensional structures that are derived from tumor cells and are able to mimic the organization and function of the organ of origin. Organoids are, therefore, valuable tools for studying complex interactions in cancer biology. To have a better understand of how differential gene expression based on ancestry affects aggressiveness of TNBC, we are developing and characterizing patient derived xenografts (PDXs) and organoids from TNBC tumors derived from African (Ghanaian), European American and AA populations.
Objective: The objective of the study is to develop and characterize PDXs from TNBC tumors that will serve as a renewable source for studying how differential gene expression based on ancestry affects aggressiveness of TNBC among AA.
Methods: Fresh tumors from continental Africa (Ghana), European American, and African American (Henry Ford Hospital) were collected from consenting patients during surgery. The tumors were then implanted in mice and organoids developed from the resulting PDX tumors. Tissues were processed using the Miltenyi Gentle MACS dissociator. The cells were seeded in a 12-well plate coated with Matrigel. Developed organoids are characterized using, immunohistochemistry, single cell RNA sequencing and 10X spatial sequencing
Results: We have successfully developed organoids using frozen tissues from West African European American, and African American TNBC breast patients. We have successfully established five (5) PDXs and their corresponding organoid lines. The organoids are passaged after every 7-14 days, with some organoid lines attaining 20 passages. We are in the process of characterizing the developed PDXs and organoids using immunohistochemistry, single cell RNA sequencing and 10X spatial sequencing and compare their different features.
Conclusion: This is an ongoing process, and the efforts will help us have a renewable source of tumor for studying how differential gene expression based on ancestry affects aggressiveness of TNBC among AA. We also aim to use the resources to identify tumor biomarkers for treating aggressive TNBC that disproportionately affects women of western sub-Saharan ancestry.

#3993 High-throughput screening of clinically relevant patient-derived 3D cultures to inform on the efficacy of antibody drug conjugate payloads in 10 distinct cancer indications.

Annamaria Rapisarda, Kayin Chan, Mara Gilardi, Stefano Cairo, **BanuPriya Sridharan**

Champions Oncology, Inc., Hackensack, NJ

High-throughput screening (HTS) enables rapid evaluation of the efficacy of anticancer agents alone and in combinations across diverse cell-based tumor models. However, the successful translation of these findings to clinical settings necessitates the use of tumor models with high biological fidelity. By integrating tumor cell heterogeneity and three-dimensional morphological features, patient-derived 3D cultures offer enhanced in vivo relevance compared to traditional tumor cell lines grown as monolayers. Nevertheless, the growth of these cultures within an extracellular matrix material and the use of complex media formulations represent challenges for culture scale-up and automated drug screening methods. To address these challenges, we leveraged our well-characterized Patient Derived Xenograft (PDX) bank and Champions TumorGraft3D platform (CTG3D), comprising over 165 well-characterized models, to develop an HTS solution. This platform is highly representative of the patient population and enables users to evaluate the activity of test agents in (i) expandable and ex vivo amenable 3D models from indications such as Colorectal and Non-Small Cell Lung Cancer (NSCLC); as well as in (ii) models freshly derived from PDXs, which present more heterogeneous and indication-specific material such as Prostate and Glioblastoma Multiforme (GBM). Champions Oncology's PDX-derived 3D platform (CTG3D) models are low passage and preserve the molecular and phenotypic signatures of parental PDX and hence original patient-derived material maximizing translatability and minimizing clonal drift. Here, we present work that supports the translation of our assays to a 384-well plate-based high-throughput format, using models representing more than 15 cancer indications. These models were evaluated for their recovery from cryopreservation, reproducible growth, and assay performance metrics in a miniaturized 384-well format using CellTiter-Glo® 3D luciferase assay-viability endpoint. PDX-derived and patient-derived 3D cultures from varied indications were screened with a library of agents used as Antibody-Drug-Conjugates (ADC) payloads. Over 4 days, our 3D cultures were exposed to eight concentrations of each drug in a 1/2-log dilution series. Assay performance metrics (such as Z' and S:N ratio) and pharmacological data demonstrated the robust performance of this organoid screening platform. Future initiatives will focus on developing additional PDX-derived 3D culture panels to expand our high-throughput screening (HTS) capabilities.

#3994 Comparing ATP-based and image-based viability readouts for assessing treatment responses in patient-derived organoids.

Claudia Beaurivage, Tao Yang, Anna Schepers, Mayke Doorn, Sumeyra Mucuk, Merel Derksen, **Sylvia F. Boj**

HUB Organoids B.V., Utrecht, Netherlands

High-throughput viability determination often relies on quantifying intracellular Adenosine TriPhosphate (ATP) levels. While this offers a robust option for assessing the efficacy of various compounds, it poses significant challenges when assessing compounds that interfere with metabolic or differentiation pathways, which affect intracellular ATP levels. HUB Organoid Technology is built on the discovery that adult stem cells proliferate and organize into three-dimensional organotypic structures when embedded into an extracellular matrix. Patient-Derived Organoids (PDOs) are generated from normal and malignant tissues and stored as high-quality biobanks that yield highly reproducible results. HUB Organoids® recapitulate complex characteristics of the parental tissue, including molecular heterogeneity and morphological and functional traits. Notably, PDOs can differentiate when subjected to the right conditions. This study compared ATP-based and image-based viability readouts to determine the best fit for quantifying treatment response in a panel of PDOs exposed to drugs with different modes of action. Herein, we show that an ATP-based viability readout fails to detect a viability shift in organoids treated with compounds known to modulate differentiation and metabolism, which instead becomes apparent when using an image-based readout. On the other hand, both readouts are equally effective at detecting changes in organoid viability following treatment with Oxaliplatin and 5-FU, which affect DNA damage and replication, respectively. Our results reveal the importance of consulting an expert organoid service provider who has an in-depth understanding of organoid biology and who can tailor your study based on your compound's expected mode of action, thus increasing your program´s chance of success.

#3995 Investigating the role of sphingosine kinase 2 and p53 in bioprinted head and neck cancer 3D models.

Thais More Milan[1], Luda Lin[2], Sara Sartini[2], Alberto Mendoza Valderrey[2], Alice Soragni[2], Andreia Machado Leopoldino[1]

[1]Department of Clinical Analyses, Toxicology and Food Sciences, School of Pharmaceutical Sciences of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil,[2]Department of Orthopaedic Surgery, David Geffen School of Medicine, University of California, Los Angeles, CA

Head and neck squamous cell carcinoma (HNSCC) presents a high incidence of recurrences and metastasis. Alterations in sphingolipids metabolism caused by deregulation of sphingosine kinase 2 (SK2) is related to tumor progression. Additionally, the interaction between SK2 and p53 has been found to promote aggressive behavior in HNSCC (Milan et al, 2024). However, SK2 deregulation in HNSCC and SK2/p53 crosstalk remains to be fully investigated. Our goal is to explore the interaction between sphingosine kinase 2 and p53 in HNSCC cell lines and patient organoids. We leverage 3D HNSCC models generated by bioprinting HNSCC cell lines expressing different p53 and SK2 levels with extracellular matrix components in high throughput-compatible mini-ring format (Phan et al, 2019; Tebon et al, 2023; Al Shihabi et al, 2024). We then investigated metabolic activity, organoids size, and quantified both SK2 and p53 protein levels. Given that p53 misfolding and aggregation has been reported as contributing to tumor progression in several cancers, we have determined its folding status by multiplexed immunofluorescence using conformation-specific antibodies in the presence or absence of SK2 activity and p53 aggregation inhibitors. Combined inhibition of SK2 activity by Opaganib and p53 aggregation by ReACp53 (Soragni et al, 2016) decreased organoid size, ATP levels, and p53 aggregation. Single agent and combinatorial treatment with ReACp53 and Opaganib also resulted in elevated γH2AX levels. Our studies highlight a complex interplay between SK2 and p53 in HNSCC, resulting in more aggressive disease. Combinatorial targeting of these proteins could offer a potential therapeutic strategy for HNSCC.

Funding: CAPES, CNPQ and FAPESP Grant n.2023/15046-8

#3996 Organoids and immune cells co-culture for evaluating the efficacy of enfortumab vedotin and pembrolizumab combination therapy..

Anne-Sophie Bajeot[1], Celine Rouget[2], Nadege Bidan[2], Claire Beraud[2], Sarah Pericart[1], Xavier Game[1], Mathieu Roumiguie[1], Philippe Lluel[2], **Emilie Decaup**[2]

[1]Toulouse Hospital, Toulouse, France,[2]Urosphere SAS, Toulouse, France

Significant therapeutic progress have been made for advanced bladder cancer (BC) particularly with the combination of Enfortumab Vedotin (EV) and the pembrolizumab (anti-PD1). This combination has shown a manageable safety profile and superior outcomes compared to chemotherapy, leading to FDA approval for patients with advanced BC. In clinical settings, decisions regarding PD1 immunotherapy are guided by PDL1 expression levels on tumor cells. We selected two organoid models (F659 and BLOU_191) out of 18 from our biobank based on their PDL1 and nectin-4 expression. An additional organoid model (F659R) with acquired-resistance to EV was also included. The objectives of this study were to highlight the advantages of a co-culture system, which combines organoids and immune cells, to evaluate the efficacy of EV and pembrolizumab combination. Furthermore, leveraging recent developments, effectiveness of this therapy was assessed in a context of EV resistance. Transcriptome sequencing of our biobank enabled the identification of mRNA levels expression for PDL-1 and nectin-4. Peripheral blood mononuclear cells (PBMCs) from healthy donors were introduced into organoid cultures at varying effector-to-target (E:T) ratios. Co-cultures were treated with pembrolizumab (200 nM) and EV (from 0.3 to 3 µg/mL), both individually and in combination. Organoid viability was assessed using the CellTiter-Glo® assay at intervals ranging from 48 to 96 hours post-treatment. The efficacy of the combination therapy was then compared to the effects of each compound alone. We have assessed the responses of the three models to pembrolizumab and EV, and correlated treatment efficacy with PDL1 and nectin-4 expression levels, respectively. Results demonstrated that pembrolizumab efficacy was related to PDL1 expression in organoid models, while EV efficacy did not show a strict correlation with nectin-4 expression. Indeed, despite its high Nectin-4 expression, BLOU_191 presented only a low response to EV. In co-culture systems using the EV-responsive organoid model (F659), the combination of EV and pembrolizumab exhibited significant 20% enhanced efficacy compared to the individual treatments whereas it did not in the low-responder model (BLOU_191). In the resistant model, neither EV nor pembrolizumab exhibited significant efficacy when used alone, and their combination did not enhance these effects. The co-culture system involving organoids and PBMCs demonstrated its utility in evaluating the combination of pembrolizumab and EV. Notably, this study highlighted a critical finding: while the combination has shown superiority over current treatment options, it does not overcome resistance to EV. Overall, this co-culture system is highly adaptable to other immunotherapeutic agents and presents a valuable tool for developing novel therapies, particularly in addressing resistance to EV.

#3997 Advancing precision cancer medicine with patient-derived organoids: an endometrial cancer case study.

Nikolina Radulovich, Pamela P. Soberanis, Molly Udaskin, Quan Li, Kevin C. J. Nixon, Irene Xie, Nhu-An Pham, Ming S. Tsao, Stephanie Lheureux

Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

Background and Purpose: Endometrial cancer (EC) is one of the most common gynecologic cancer, comprising a group of complex, heterogeneous subtypes with distinct features and varying outcomes. While advancements in EC treatment have progressed rapidly, managing mixed endometrial carcinomas remains challenging due to the variability of subtypes and their impact on clinical and biological behavior. This study highlights the potential of patient-derived organoid (PDO) models through the case of a young patient initially diagnosed with grade 1 endometrioid endometrial cancer, treated with endocrine therapy. The disease later progressed into a biologically aggressive mixed carcinoma exhibiting three distinct patterns: grade 1 endometrioid, large-cell neuroendocrine, and undifferentiated carcinoma.
Methods: A PDO model (OPTO.85) and a corresponding organoid-derived xenograft (ODX) model were generated from the patient's surgical specimen. Patient tissue and OPTO.85 models underwent WES, RNAseq and ATACseq to profile genomic and epigenomic alterations. A high-throughput drug screen was performed using the ApexBio FDA-Approved and Epigenetic Drug Libraries, as well as the OICR Kinase Inhibitor and Tool Compound Libraries. Organoids were plated on 1536-well drug plates, drugs were added at 2.5 µM concentration, and cell viability was measured after 6 days using Alamar Blue. Drug sensitivity curves were performed on individual compounds, using a 21-point dose-response. To assess *in vivo* drug response, OPTO.85 was implanted into NOD SCID mice, and mice were treated with BKM120 (50 mg/kg) +/- Cediranib (6 mg/kg) daily via oral gavage.
Results: Histopathological and genomic analyses confirmed that the PDO model accurately reflected the tumor's biology. Sequencing revealed oncogenic alterations in PIK3CA, ARID1A, and CTNNB1 genes across patient tissue, PDO, and ODX models. OPTO.85 PDO demonstrated sensitivity to PI3K inhibitors. RNAseq and ATACseq analyses revealed enrichment in VEGF and Wnt signaling pathways, suggesting potential therapeutic vulnerabilities. High-throughput drug screening identified sensitivity to VEGF inhibition. The VEGF inhibitor Cediranib demonstrated synergy with BKM120, significantly reducing OPTO.85 organoid growth. This combination also showed *in vivo* efficacy in the OPTO.85 ODX model, where it significantly suppressed tumor growth.
Conclusion: We demonstrate the potential of PDO models in cancer research. By leveraging RNAseq, ATACseq, and high-throughput drug screening, this study identified actionable targets in the VEGF and PI3K pathways and validated the synergistic effects of Cediranib and BKM120 in an endometrial cancer with complex histology and genomic profile. These findings highlight the value of PDO models as innovative tools for personalizing cancer treatment and developing effective therapies for complex endometrial malignancies.

#3998 Exploring fibroblast's influence on chemoresistance in PDAC using patient-derived organoids.

Jonathan Barajas[1], Carolyn Ruiz[1], Zhi Yang[1], Edward Agyare[2], Saun-Joo Yoon[3], Ba Xuan Hoang[1], Bo Han[1]

[1]Surgery, University of Southern California, Keck School of Medicine, Los Angeles, CA,[2]College of Pharmaceutical Science, Florida A&M University, Tallahassee, FL,[3]Department of Behavioral Nursing Science, University of Florida, Gainsville, FL

Pancreatic adenocarcinoma (PDAC) remains one of the most lethal malignancies, with a 5-year survival rate below 13%. A critical factor in this poor prognosis is the tumor microenvironment (TME), characterized by dense stroma comprising cancer-associated fibroblasts (CAFs), immune cells, and epithelial cells. CAFs secrete inflammatory cytokines like IL-6 and TGF-β and deposit ECM components, particularly collagen, leading to immunosuppression and chemotherapy resistance. This study examines the role of fibroblasts in modulating the efficacy of gemcitabine in PDAC using patient-derived organoids (PDOs). PDOs were co-cultured with either human fibroblasts and tumor cells or tumor cells with fibroblast-conditioned medium. The PDOs were cultured in collagen based matrices, which allows for manipulation of the ECM stiffness, using either a soft or stiff gel condition to mimic the heterogeneity of in vivo environments. Conditioned Medium was collected from fibroblasts grown in either soft or stiff ECM gels. Patient-derived cells were obtained from two patients: one Black (G43) and one White (G46). Results reveal significant differences in response to treatment between the two cells used. G43 is shown to be more sensitive to treatment overall in co-culture and condition medium, when compared to G46. However, when cells are compared to themselves, either in co-culture or conditioned medium, there are differences seen. In particular, G43 cells are more responsive to treatment in conditioned medium, in soft ECM, when compared to co-cultures. However, in stiff ECM conditioned media, this effect is not seen. Indicating that the stiffness of the ECM, rather than just secreted soluble factors alone, is a key driver of tumor cell behavior. The difference between co-culture and conditioned media supports the observations that fibroblast induced mechano-stress, aids in chemotherapy resistance. The results suggest that therapeutic strategies aimed at modulating the physical properties of the tumor microenvironment, such as ECM stiffness, could potentially improve treatment responses in PDAC.

#3999 Single cell transcriptomic comparison of patient derived ovarian cancer organoids and primary tumor epithelial signatures.

Bisiayo Fashemi, Vijayalaxmi Gupta, Yukihidi Ota, Moreniola Akande, Mary Mullen, Dineo Khabele

Washington University School of Medicine in St. Louis, St. Louis, MO

High-grade serous ovarian cancer (HGSOC) is a rare but deadly disease. Platinum-based therapy along with PARPi maintenance therapy, is recommended to 80% of patients. However, acquired resistance to platinum and PARPi remains an ongoing clinical challenge, highlighting the need for the development of targeted therapies. To address this, there is a need for better in vitro models that mimic the tumor microenvironment (TME). Unlike traditional 2D culturing methods, patient-derived ovarian cancer organoids (PDOs) form 3D structures that more accurately recapitulate multilayered, multicellular tissue. The overall objective of this study is to examine how HGSOC PDOs can be used better understand tumor reprograming and how this relates to patient tumor behavior and response to therapy. Primary and metastatic tumor samples were collected from diagnosed HGSOC patients for organoid generation. Organoids were cultured for 1-5 passages before being submitted for sc-RNAseq. In addition to organoid samples, matched tumor FFPE samples were submitted for comparison. Our pilot study revealed that PDOs contain a mixture of epithelial, stromal, and immune cells. Using Monocle3, we assessed epithelial cell development and differentiation over time and identified distinct cell trajectory projections across all samples. We identified three distinct cell states: early, intermediate, and late. Our PDO sample exhibited multiple branch points within the intermediate cell state, which reflects different cell fate decisions. These findings suggest the presence of sub-populations within the intermediate cell state that are not detectable or are masked in whole tumor FFPE samples. Additionally, we examined cell-to-cell interactions using CellChat. Fibroblast cells were the most prolific producers of signaling messages across all cell types, while dendritic cells and macrophages received the highest volume of incoming signals. In conclusion, PDOs recapitulate key aspects of the TME, and can be used to investigate cell fate decisions of epithelial tumor cells, and cell-to-cell communications. This platform offers a promising tool for studying tumor behavior, therapeutic resistance, and developing more targeted and effective treatments.

#4000 The significance of GLP-1R and its agonist in neuroendocrine neoplasms.

Sophia A. Hueser, Reese E. Townsend, Casandro J. Chan, Leona Rupp, Leopaul J. Chan, Dawn E. Quelle, Joseph S. Dillon, Andrew M. Bellizzi, James R. Howe, **Po Hien H. Ear**

University of Iowa, Iowa City, IA

Neuroendocrine neoplasms (NENs) are rare cancers originating from neuroendocrine cells that are found throughout the body. NENs are subdivided into 2 categories: Well-differentiated neuroendocrine tumors (NET) and poorly differentiated neuroendocrine carcinomas (NEC). Both NET and NEC are highly metastatic and difficult to treat. NEN cases are on the rise and yet the etiology remains unclear. Commonly used drugs such as proton pump inhibitors can promote NET growth and result in poor prognosis for NET patients. Nowadays, the diabetes and weight loss drug semaglutide, a glucagon-like peptide 1 receptor (GLP-1R) agonist, has gain extensive popularity and are currently being taken by over 15 million people in the USA. Semaglutide is contraindicated for NET patients with medullary thyroid carcinoma (MTC) or multiple endocrine neoplasia syndrome type 2 (MEN2) since some of these cancers express the GLP-1R. However, this area of research remains understudied. Little is known about the expression levels of GLP-1R in NEN from different anatomical locations and their response to semaglutide since these are rare cancers and few NET models are available for drug testing. We recently identified 2 human NET cell lines (GOT1 and NT-3) that express the GLP-1R and showed that semaglutide promotes tumor cell growth both in vitro and in vivo. In this study, we aim to investigate the levels of GLP-1R expression in a large collection of NEN tissue microarrays and determine the effects of semaglutide in novel GLP-1R positive NET patient-derived spheroid cultures. We stained for GLP-1R expression by immunohistochemistry in 357 NET tissue microarrays covering 7 classes of NEN: 78 pancreas NET, 62 duodenum NET, 33 ileal NET, 42 lung NET, 10 small cell lung NEC, 12 extrapulmonary visceral NEC, 29 thyroid NET, 12 gastric NET, 6 appendix NET, 6 rectum NET, 22 pheochromocytoma, 22 paraganglioma, and 23 Merkel cell carcinoma. Furthermore, we generated GLP-1R positive pancreas, ileal, and duodenal NET spheroids for drug testing. Our data showed 45% of duodenum NET, 17% of gastric NET, and 14% of pancreas NET stained positive for GLP-1R expression. Less than 2% of other classes NET or NEC stained positive for GLP-1R expression. Using newly established NET patient-derived spheroid models, we demonstrated that 100 nM of semaglutide accelerates tumor cell growth by 1.4 to 2-fold. Surprisingly, duodenum NET is the class of NET that frequently express GLP-1R and should be highly cautioned for the semaglutide usage.

#4001 Patient avatar models for ovarian cancer: Predicting patient response to treatment.

Erin M. George[1], Yuxi Zhou[1], Alfonso Pepe[1], Athena Tsingelis[1], Angie Rivera[1], Diego Pedro[1], Katriana Johnson[1], Dominick Dag[1], Said Cifuentes Maury[1], Lucia Mazzacurati[1], Jack Famiglietti[2], Ryan Smolchek[2], Duy Nguyen[1], W. Gregory Sawyer[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]Aurita Corporation, Gainesville, FL

Background: Despite recent advances in targeted therapies, ovarian cancer (OVCA) remains the deadliest gynecologic malignancy, with approximately 80% of cases diagnosed at advanced stages and an equally high recurrence rate despite high response rates to frontline chemotherapy. Current OVCA models fail to accurately replicate the intricate biological landscape of metastatic disease. In response, we developed an innovative 3D in vitro system that preserves the unique cellular complexity of patient's original tumor. This model features key advancements, including prolonged (>21 days) culture of patient-derived microtumors, a perfusable microgel medium (Liquid-Like Solids, LLS), specialized microtiter plates for controlled "pumpless" media perfusion (Darcy Plates), and integrated high-resolution multiphoton confocal microscopy for *in situ* imaging.

Methods: Tumors were collected at the time of OVCA surgery and fragmented into 1 µl sized microtumors, which were then suspended into a 3D Liquid Like Solid (LLS) medium and cultured in a perfusion (Darcy) plate. Cell viability and proliferation were assessed over 21 days using LIVE/DEAD™ Cell Imaging Kit and EDU staining, respectively. Immunofluorescence microscopy was used to identify epithelial OVCA cells and immune cell populations. Drug screens were performed in a 48-well perfusion plate using standard of care chemotherapy and targeted therapies and compared to patient response.

Results: Optimal conditions were established using HPLM media supplemented with 10% FBS, 1% Pen/Strep, 2.5 mg/L Amphotericin B, 10 mM HEPES, 0.5 µM A83-01, and ITS, along with a perfusion flow rate of 100 µl/day per well. PAX8 nuclear expression confirmed epithelial OVCA cells. EDU staining demonstrated sustained cell proliferation and CD45 markers showed immune cell retention. Drug testing with standard of care chemotherapies like carboplatin and targeted agents revealed differential microtumor responses and was comparable to patient response.

Conclusions: OVCA's complex biology and extensive metastatic potential present significant clinical challenges. This study highlights the potential of 3D patient-derived microtumors as a robust platform for drug screening, high-throughput assays, and biomarker discovery. By retaining tumor heterogeneity and microenvironmental interactions, this model offers a promising avenue for improving therapeutic strategies and personalized treatment approaches in OVCA management.

#4002 Development of an organoid coculture model to investigate tumor immune interactions and therapeutic strategies in prostate cancer.

Kinjal Bhadresha, Jessica L. Horner, Jessica D. Kindrick, Douglas K. Price, Cindy H. Chau, William D. Figg

Genitourinary Malignancies Branch, National Cancer Institute, NIH, Bethesda, MD

While immunotherapy has demonstrated remarkable success in other malignancies, its efficacy in prostate cancer remains limited. Organoid models, capable of recapitulating patient-specific therapeutic responses, offer a promising platform for studying tumor biology and treatment responses. However, their utility in modeling immune interactions remains underdeveloped. To address this, we established an in vitro co-culture system of tumor organoids and immune cells to investigate tumor-immune interactions and identify novel therapeutic targets for aggressive prostate cancer. Using publicly available LuCaP PDX microarray datasets (GSE199596 and GSE113743), we identified the downregulation of antigen processing and presentation (APP) pathways, indicative of immune evasion mechanisms. Moreover, our analysis revealed overexpression of macrophage-polarizing factors, such as the STAT signaling pathway, ARG1, and MALAT1, which are implicated in tumor progression, metastasis, and drug resistance. To experimentally validate these findings, we developed and optimized a macrophage co-culture model utilizing organoids derived from LuCaP167 and LuCaP167CR, effectively recapitulating distinct tumor microenvironment characteristics associated with castration resistance. We further assessed for drug response using targeted and Immunotherapeutics within this system to evaluate their therapeutic potential. This proof-of-concept study highlights the potential of this sustainable and scalable co-culture platform for studying cancer-immune interactions ex vivo. The model serves as a valuable tool for evaluating the efficacy of existing therapeutics and discovering novel agents that enhance immune responses in advanced prostate cancer.

#4003 Improved drug screening and resistance monitoring using cancer organoids derived from dissociated tumor cells and circulating tumor cells.

Yi-chun Han, David Hsieh, Shian-Jiun (SJ) Shih

Cellentia Inc., Foster City, CA

Cancer is a complicated disease, and despite recent breakthroughs in cancer treatment, cancer remains the second leading cause of death globally, with metastatic cancers responsible for the large majority. To develop effective cancer drugs, we need reliable *in vitro* models that represent cancers accurately, particularly for metastatic cancers. However, current experimental models of human cancers *in vitro* face several limitations. Well-established cell lines typically emerged from long-term exposure to simple tissue culture conditions, while genomic and epigenetic instability contribute to their drift away from the characteristics of the original tumors. Because of the significant heterogeneity both within each tumor and within each type of cancer, cell lines fail to represent the diversity of the disease. Even using a very large number of cell lines still restricts the results to cancers whose cells grow on plastic in relatively uncomplex media formulations.
Aiming to overcome these limitations, we are leveraging a novel system for culturing tumor organoids. We culture tumor organoids from dissociated tumor cells (DTCs) from primary tumors, or circulating tumor cells (CTCs) from the blood of patients with solid tumors, in our proprietary culture platform. We have successfully cultured a wide range of DTC and CTC samples into tumor organoids, including samples from breast, colon, renal, lung, pancreatic, and prostate cancers, and we continue to add to the list. The successful expansion of these samples enables us to overcome the limited availability of such material and to apply methods typically reserved for cell line-based drug screening. We tested the drug sensitivity of these organoids to standard-of-care chemotherapeutics and other approved anticancer drugs, by cell viability assay. We also monitored organoid morphology longitudinally by brightfield microscopy during the treatment period. To evaluate drug resistance, we plated tumor organoids into Corning Elplasia plates, separating organoids into individual microcavities and enabling longitudinal tracking of each organoid throughout treatment. We continued culturing the surviving drug-resistant organoids after the treatment period and evaluated their changes in phenotype, morphology, mutation status, and gene expression. To characterize the resistance of individual organoids, we tested whether single-organoid RNA-Seq could provide more useful insights than bulk RNA-Seq.
DTC- and CTC-derived organoids typically exhibit differing sensitivities in our drug sensitivity screening. Since CTC-derived organoids resemble metastatic cancers, this platform enables the evaluation of anti-metastatic cancer drug efficacy, representing a major improvement over the current system.

#4004 Identification of predictive biomarkers of USP1 inhibitor sensitivity using ovarian cancer organoid models.

Ozge Somuncu, Nicholas Ashton, Alexandre A. B. A. da Costa, Sirisha Mukkavalli, Ramya Ravindranathan, Benjamin Lamarre, Huy Nguyen, Lisa Moreau, Joyce Liu, Geoffrey I. Shapiro, Kalindi Parmar, Alan D. D'Andrea

Dana-Farber Cancer Institute, Boston, MA

BRCA1-deficient tumors are unable to efficiently perform DNA repair by homologous recombination (HR) and are dependent on alternative DNA damage response pathways. PARP inhibitors have improved the progression-free survival of HR-deficient ovarian cancer patients in clinical settings. However, PARP inhibitor (PARPi) resistance often develops, and new therapies are required for these patients. USP1 is a deubiquitinating enzyme that controls DNA repair pathways through the deubiquitination of PCNA-Ub and the activation of Translesion DNA Synthesis (TLS). Inhibitors of USP1 result in a strong upregulation of PCNA-Ub levels and a dysregulation of TLS repair. Importantly, USP1 is synthetically lethal in BRCA1-deficient tumors (Lim et al., Mol Cell, 2018), and USP1 inhibitors (USP1is) are currently undergoing clinical development for the treatment of these cancers as monotherapy or in combination with a PARPi. USP1is kill *BRCA1*-mutated patient-derived ovarian cancer organoids (PDOs) and overcome PARPi resistance in *BRCA1*-WT PDOs (da Costa et al, Cancer Research, 2024). Sensitivity to USP1i strongly correlates with the accumulation of single strand DNA (ssDNA) gaps in both PARPi-sensitive and PARPi-resistant PDOs. Moreover, knockdown of RAD18, the E3 ubiquitin ligase required for PCNA ubiquitination, results in a reduction in PCNA-Ub levels and a corresponding reduction in ssDNA gaps, and in USP1i resistance. These findings suggest that ssDNA gaps and RAD18 levels in the tumors can predict the sensitivity to USP1 inhibitors. As *BRCA1*-mutated tumors express high levels of USP1 mRNA, we also investigated the relevance of this biomarker in predicting the sensitivity to USP1 inhibitors. Interestingly, the USP1i sensitivity correlated with increased USP1 mRNA expression, at baseline, in ovarian cancer PDO and patient-derived xenograft-derived organoid (PDXO) models. Similar results were obtained in *BRCA1*-deficient breast cancer cell line models with acquired PARPi resistance. USP1i sensitive ovarian cancer organoid models retained high USP1 mRNA levels upon PARPi treatment. The specific organoid models that were resistant to PARPi or USP1i monotherapy exhibited up to 40-fold increase in expression of USP1 mRNA and they were sensitive to a combination of USP1i plus PARPi. Taken together, in addition to the accumulation of ssDNA gaps and RAD18 levels, the relative expression of USP1 mRNA is a useful prognostic biomarker for patients who may respond to USP1 inhibitors, either as monotherapy or in combination with PARP inhibitors. These predictive biomarkers will be useful in monitoring the response of ovarian cancer patients enrolled in USP1i plus PARPi clinical trials.

#4005 Integrative clinical and molecular characterization of an international community resource of organoid models of human cancer.

[1]Department of Oncologic Pathology, Dana Farber Cancer Institute, Boston, MA,[2]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA,[3]Computational Oncology, Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY,[4]Department of Bioinformatics and Computational Biology,, University of Texas MD Anderson Cancer Center, Houston, TX,[5]Department of Epigenetics, Van Andel Institute, Grand Rapids, MI,[6]Broad Institute, Cambridge, MA,[7]Department of Systems Biology, Vagelos College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, NY,[8]Wellcome Sanger Institute, Cambridge, United Kingdom,[9]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY,[10]Frederick National Laboratory for Cancer Research, Frederick, MD,[11]Center for Cancer Genomics, National Cancer Institute, Bethesda, MD,[12]Information Management Services, Inc, Rockville, MD,[13]American Type Culture Collection, Manassas, VA,[14]Department of Medicine, Division of Hematology, Stanford University School of Medicine, Stanford, CA,[15]Institute for Computational Biomedicine, Weill Cornell Medicine, New York, NY,[16]Department of Biomedical Engineering, Oregon Health & Science University, Portland, OR,[17]Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC,[18]New York Genome Center, New York, NY,[19]Departments of Medicine and Human Genetics, University of California Los Angeles, Los Angeles, CA

The discovery of novel cancer therapeutics requires evaluation in representative laboratory models. However, existing model collections do not represent the full spectrum and scale of molecular diversity required to support biological discovery and drive pre-clinical research. Recent technologies have enabled more efficient derivation of cell-based models (e.g., organoids). However, systematic pan-cancer comparisons of the integrity of genomic, transcriptomic and epigenomic states following long term ex vivo expansion remain elusive. Here, we report on a large-scale international program—the Human Cancer Models Initiative (HCMI), consented more than 2,500 donors resulting in the production and subsequent characterization of 665 organoid, neurosphere and cell line models by whole genome, exome, methylome, and transcriptome analysis. Critical properties of the donors and tissues included 71 derived from populations beyond European ancestry, primarily African (54%), Asian (45%) and Indigenous American (1%); 448 have therapeutic treatment profiles from donor medical records, and 45 represented rare cancers. Integrative analysis between models and source tumors shows that 92-96% of 417 analyzed models were highly concordant by molecular characterization. The small number of discordant behaviors were associated with either cell culture media influences in glioblastoma or stromal infiltration or rare cell differentiation state shifts, which were validated by single cell RNA sequencing. We validate the utility of the resource studying therapeutic resistance to chemo-, targeted-, and immuno-therapies by integrative analysis of extrachromosomal DNA-based gene amplification and post-treatment mutational signatures. This internationally accessible community resource, including data and accompanying integrative software tool packages, provides a roadmap for capturing an increasing spectrum of cancer diversity in preclinical models.

#4006 HER2-positive patient-derived xenograft organoids (PDXOs) as a novel preclinical tool to evaluate new therapies against HER2-driven cancers.

Fu-Ju Chou, Yamini Nallana, Hsiu-Wen Tsai, Mara Gilardi, Stefano Cairo, BanuPriya Sridharan

Champions Oncology, Inc., Hackensack, NJ

The human epidermal growth factor 2 receptor (HER2) is a key member of the receptor tyrosine kinase superfamily. Alterations in HER2 have been identified in various malignancies, including approximately 20% of non-small-cell lung cancer (NSCLC) and about 30% of breast cancer (BRCA). These HER2 alterations encompass gene mutations, gene amplification, and protein overexpression, all of which are associated with tumorigenesis and contribute to enhanced cancer cell proliferation. Cancers with HER2 alterations often exhibit more aggressive behavior, a higher recurrence rate, and a poorer prognosis. The introduction of HER2-directed therapies has significantly improved therapeutic outcomes. FDA-approved therapeutic options for HER2-positive cancers can be categorized into three major groups: tyrosine kinase inhibitors (TKIs), antibodies, and antibody-drug conjugates (ADCs). These treatments specifically target the HER2 receptor or its downstream signaling pathways. However, many studies show that nonselective TKIs and HER2 naked antibodies demonstrate limited therapeutic effectiveness in HER2-positive cancers. In contrast, HER2-directed ADCs selectively deliver cytotoxic compounds to HER2-positive tumor cells, resulting in better responses and fewer adverse effects, as evidenced by numerous preclinical and clinical studies. In our current work, to showcase our well-characterized PDX-O platform BRCA and NSCLC models were selected and assessed to be HER2 positive as evidenced by complete and intense membrane staining identified in patient-derived xenograft organoids (PDXOs) tissue blocks. Furthermore, from early low passages, assay-ready cells were seeded in a 96-well plate high throughput format at a density of 5000 cells per well. Well-defined 3D structures formed after 3 days, and the models were evaluated for morphology and proliferation assessment. Cytotoxicity controls: 10 µM Staurosporine and 0.1% DMSO were added to each plate to serve as plate controls and used in determining the Z factor of the assay. The models were tested for efficacy of Lapatinib (TKI); and Enhertu and Kadcyla (ADC) and their corresponding Isotypes. All models demonstrated a classic 3D morphology with > 150 µm diameter formed 72 hrs. after seeding; and were then dosed. The duration of drug incubation was 6 days after which Cell-Titer-Glo® reagent was added to all wells to determine half-maximal inhibitory concentration (IC50). The assay was robust with a Z factor > 0 and a high Signal: Noise ratio. Specifically for one model, the IC50 of Lapatinib was 69.15 µM. Both ADCs: Kadcyla and Enhertu, exhibited greater specificity and efficacy compared to their isotype controls. The ex vivo HER2-positive CTG3D platform represents a reliable and powerful tool for screening newly designed HER2 treatment regimens.

#4007 Building 3D ex vivo models as a powerful platform for anti-cancer drug and biomarker discovery.

Fu-Ju Chou, Annamaria Rapisarda, Mara Gilardi, Stefano Cairo, BanuPriya Sridharan

Champions Oncology, Inc., Hackensack, NJ

Patient-derived models have increasingly been adopted into target validation, lead-optimization and secondary screening campaigns to move translation ahead in drug discovery. While 2-dimentional cell line in vitro models continue to play a pivotal role in early screening studies, new advanced in 3D patient derived organoids (PDO) and patient derived xenograft organoids (PDX-O) technology have made it suitable to meet the rigor and reproducibility of traditional screening metrics. At Champions Oncology, we have built a successful pipeline of ex vivo models from pre-treated, metastatic, and genetically diverse cohorts across varied indications. PDX-derived cell cultures serve as (i) physiologically relevant high throughput platforms for early or clinical hypothesis testing, (ii) cellular systems to gain mechanistic and phenotypic insights into drug mode of action in 3D tumor microenvironment, and (iii) cost-effective translational bridge to well-informed in vivo studies. Ex vivo models have been widely established and characterized for non-small cell lung cancer (NSCLC), colorectal (CRC), and other epithelial tumor types. Indications such as renal cell carcinoma (RCC), Diffuse large B-cell lymphoma (DLBCL), gastric and bladder cancer, glioblastoma multiforme (GBM), prostate cancer, and sarcoma are less common and often a size-able cohort size rarely exists. In this poster, we showcase our recent efforts on the iterative media optimization process, growth kinetics, and morphology of models from these rare indications and characterization data that establish them front and center as valid preclinical screening tools. Through careful media formulation, the appropriate standard of care controls (SoC), and vigorous assay development criteria we show the versatility of these models for both efficacy and complex mechanistic readouts when probed with various modalities including antibody-drug conjugates (ADC) and anti-sense oligos (ASO). Our experience establishing 3D microstructures from various indications by iterative optimization of culture conditions is further validated by our comprehensive quality control (QC) procedures and deep molecular and pharmacological characterization. In summary, through a series of examples, we highlight the application of Champions TumorGraft3D Ex vivo models in enhancing the biological and clinical fidelity of novel modalities of drugs and/or novel drug combinations.

SCIENCE AND HEALTH POLICY: Cancer Survivorship and Patient Communication / Patient Advocacy and Engagement Poster Session

#4011 Health maintenance reframed: Insights from Black prostate cancer survivors on prioritizing wellbeing.

D. Fullwood, M. Young, F. Odedina;
Mayo Clinic Jacksonville, Jacksonville, FL

Background: Prostate cancer continues to disproportionately affect Black men, who face notonly higher incidence, but also more severe outcomes compared to other racial and ethnicgroups. While advancements in survivorship care have been made, significant disparities remain, highlighting the critical need for research that addresses the distinct challenges faced by Black men during their survivorship journey. In the face of these ongoing inequities, understanding the advocacy, resilience, and lived experiences of Black men post-treatment is essential. By exploring these factors, our study aims to uncover actionable strategies to enhance survivorship care and support, driving the development of targeted interventions that can close the gap in outcomes for this underserved population.
Methods: We conducted a secondary analysis of qualitative interviews with 31 Black prostatecancer survivors participated in the CaPCaS study, aiming to explore their perspectives onsurvivorship and advocacy. A Grounded Theory approach was employed to rigorously analyze the participants' narratives. Through open and axial coding, we systematically identified key themes from the transcribed, verified, and deidentified audio recordings, ensuring a comprehensive exploration of their post-treatment experiences.
Results: Our analysis revealed four central themes that highlight the evolving health behaviors and coping mechanisms of participants. First, Self-care and Health Management emerged, showcasing empowered decision-making around exercise, dietary improvements, and hydration. Second, Increased Awareness and Prioritization underscored the shift toward heightened health consciousness, with participants emphasizing the importance of personal health and prioritizing food quality. Third, the theme of Emotional and Social Support illustrated how shared experiences fostered comfort and perspective, reinforcing ongoing health maintenance. Finally, participants reframed Health Challenges, viewing them as minor nuisances rather than deterrents, bolstered by medical reassurance and a strong survivor mindset.
Conclusion: These findings emphasize the importance of holistic health strategies in improving the quality of life for Black men during their post-treatment prostate cancer survivorship journey. By fostering empowered self-care, prioritizing health awareness, and leveraging emotional and social support, survivors can navigate ongoing health challenges with resilience and confidence. The reframing of health issues as manageable aspects of their lives further underscores the potential for interventions to enhance long-term well-being and reduce disparities in prostate cancer survivorship.

#4012 Patient perspective on the prevalence and severity of adverse psychosocial outcomes amongst those treated for lymphoma or chronic lymphocytic leukemia: An analysis of the Lymphoma Coalition's 2024 Global Patient Survey.

Steve E. Kalloger[1], Amanda Watson[2], Shawn Sajkowski[3], Lorna Warwick[4]

[1]Lymphoma Coalition, Mississauga, ON, Canada,[2]Amanda Watson, Mississauga, ON, Canada,[3]Shawn Sajkowski, Mississauga, ON, Canada,[4]Lorna Warwick, Mississauga, ON, Canada

Patients who have received treatment for lymphoma or chronic lymphocytic leukemia (CLL) experience numerous side effects which can have a profound impact on health-related quality of life (HRQoL). Some of the most underreported are adverse psycho-social outcomes (APSO). We explored the prevalence and severity of APSO's amongst a globally derived sample from this patient population. Patient reported outcomes (PRO's) were collected from an anonymous global survey directed at patients with lymphoma and CLL. Nineteen different APSO's were pre-specified in the survey. Prevalence was captured with severity assessed using a 5-part Likert scale. Latent class analysis (LCA) was used to cluster patients with a propensity for experiencing multiple APSO's. Resultant clusters were investigated to determine if they were enriched for selected demographics. Responses were received from 5984 patients who had received treatment for lymphoma or CLL where the median age was 64, ranging from 18 - 94 years. Sixty percent were female. Fear of progression/relapse was the most prevalent APSO (49%; Table 1). Most APSO's had severity scores above 3 indicating a moderate level of severity (Table 1). LCA identified a cluster comprising 12% of the patients who experienced all APSO's at a higher rate than the remaining patients. Both younger age and female sex were significantly enriched in this cluster ($p<0.0001$). The results suggest that a segment of patients experience multiple APSO's which can compound to create a significant overall degradation in HRQoL. While younger age and female sex are enriched in this segment, further exploration is needed to identify those with heightened risk for multiple APSO's. The application of mitigation strategies in those suffering from APSO's may help to improve patient's HRQoL during treatment, recovery and rehabilitation.

Psychosocial Outcome	Prevalence (N = 5984)	Severity Score (N)
Fear of progression/relapse	49%	3.2 (2904)
Concern relating to being immunocompromised	38.4%	3.2 (2281)
Anxiety/nervousness	35%	3.1 (2067)
Worry	33%	3.2 (1939)
Concerns about physical appearance	27.4%	3.2 (1619)
Depression/sadness	26.6%	3.1 (1567)
Fear of dying	21.7%	3.3 (1279)
Isolation of loneliness	21.5%	3.3 (1273)
Loss of interest in usual activities	19.1%	3.3 (1125)
Anger	18.5%	2.8 (1087)
Loss of Self-Esteem	18.1%	3.2 (1071)
Changes in relationships	16.8%	3.2 (994)
Feelings of worthlessness	16.2%	3.3 (962)
Grief or loss	15.7%	3.2 (929)
Fear of being incapacitated	14.6%	3.4 (885)
Loss of sense of purpose	12.2%	3.4 (719)
PTSD	9.1%	3.2 (536)
Changes in faith or beliefs	4.4%	3.3 (257)
Conflicts between beliefs and cancer treatments	2.4%	3.3 (139)
Other	2.4%	3.6 (132)
None	18.4%	N/A

#4014 Prognostic evaluation of breast cancer long-term survival outcomes: contributions from a Brazilian hospital-based cohort.

Alessandra B. de Souza[1], Daniely R. Freitas-Alves[1], Taiana S. L. da Silva[2], Vanessa Indio-do-Brasil[1], Rosane Vianna-Jorge[3]

[1]Oswaldo Cruz Foundation, Rio de Janeiro, Brazil,[2]National Cancer Institute, Rio de Janeiro, Brazil,[3]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Breast cancer is currently the second most common neoplasm worldwide and the leading cause of death by cancer among women. Treatment advances based on molecular classification of tumors have contributed to reduce mortality in many developed countries. Nevertheless, the growing incidence worldwide poses additional challenges to adjust prognostic evaluation to changing epidemiological profiles in distinct populations. In this regard, the present study evaluates a current prospective cohort of Brazilian women with primary unilateral and non-metastatic breast carcinoma, who were diagnosed and started treatment between 2009 to 2013 at the Brazilian National Cancer Institute (INCA #129/08). The study aims to characterize the contribution of well-known histopathological characteristics, in combination with clinical and sociodemographic aspects, for prognostic evaluation of survival outcomes. Here, we present the first analyses after completing ten years of follow-up. Survival curves were estimated using the Kaplan-Meier method, and the impact of individual variables on disease-free or overall survival rates was estimated by calculation of their hazard ratios (HR) and 95% confidence intervals (95% CI). Multivariate Cox proportional hazards regression models were used to calculate the adjusted HR (HRadj) and respective 95% CI. Total patient follow-up was 152,832 person-months, with a median follow-up time per person of 12.5 years (y). Disease-free survival (DFS) was 80.2% (5y) and 64.8% (10y), with a median of 99 months (95% CI 97.8 - 102.0). Overall survival (OS) was 83.1% (5y) and 69.6% (10y), with a median of 98 months (95% CI 96.0 - 100.7). Tumor staging ≥ IIb and molecular classification as HER-2 or triple-negative were prognostic of both DFS and OS, either for 5y- or 10y- models. In addition, obesity was significantly associated with worse DFS (HRadj = 1.554; 95% CI 1.021 - 2.365) and marginally contributing for OS (HRadj = 1.545; 95% CI 0.998 - 2.391), but only in 5y-models. In contrast, the 10y-models indicated worse outcomes for patients who self-reported as black or brown: HRadj = 1.365 (95% CI 1.048 - 1.777) for DFS or HRadj = 1.511 (95% CI 1.051 - 2.171) for OS. It is not clear how color/race is affecting survival in our cohort, as no significant differences were found for clinical or histopathological characteristics at diagnosis. We are currently including data from gene polymorphisms as an attempt to find new molecular biomarkers that might improve prognostic evaluation of breast cancer.

#4015 Mitigating Financial Toxicity b legal and financial navigation for individuals diagnosed with cancer, caregivers, and health care professionals.

Laura Beilke, Melanie Grant

Triage Cancer, Chicago, IL

Background and Purpose: After a cancer diagnosis, individuals are faced with a variety of legal and financial issues that leave individuals diagnosed with cancer and their caregivers with complex questions about insurance coverage, accessing government benefits, and employment. Without accurate information, individuals are unable to make educated decisions, which results in financial consequences, often referred to as financial toxicity. Triage Cancer's Legal & Financial Navigation Program (LFN) offers free expert guidance to individuals coping with cancer, their caregivers, and health care professionals on a wide range of legal and practical issues. The LFN provides the accurate information and resources needed within the patient's own community to help mitigate financial toxicity.

Methods: The LFN provides one-on-one guidance on practical strategies and referral resources that can empower individuals and caregivers facing cancer-related legal and financial challenges. Also, the LFN provides this information to health care professionals to guide their patients through these difficult decisions. Practical strategies are provided to help individuals understand complex legal and financial matters, enabling them to make informed decisions tailored to their unique circumstances. The efficacy of the program is measured through voluntary survey response. Callers receive a follow-up email with a one question survey within a day of the initial call. After three weeks, the caller also receives a detailed survey.

Results and Outcomes: In 2023, the LFN had 1,759 callers from 49 states, the District of Columbia, US territories, and other countries. After the call, individuals are provided with a one question survey asking if they feel better prepared after speaking with Triage Cancer. 95% of respondents say they "feel better prepared" after speaking with Triage Cancer. Callers receive a follow up email with a link to the survey three weeks after our initial email, which includes six follow up questions to measure the efficacy of the program. • 91% of callers strongly agreed or agreed that Triage Cancer answered their questions. • 88% of callers agreed or strongly agreed that they would use the program again in the future. • 88% of callers agreed or strongly agreed that they had actionable next steps. • 90% of callers agreed or strongly agreed that the follow up resources and materials were helpful. • 89% of callers agreed or strongly agreed that they were better prepared. • 85% of callers agreed or strongly agreed that their stress and/or anxiety levels decreased.

Conclusions: The LFN provides tailored education around cancer-related legal issues in order to improve the quality of life of individuals coping with cancer. The LFN provides individuals with the knowledge they need to address the practical and financial issues they encounter when faced with a cancer diagnosis.

#4016 Understanding clinician level barriers and facilitators to managing cancer survivors with chronic conditions at community health centers.

M. Museitif[1], B. Balasubramanian[1], G. H. Walton[1], L. A. Shay[1], H. Ma[2], S. Lee[3];
[1]University of Texas Health Science Center, Houston, TX, [2]MD Anderson Cancer Center, Houston, TX, [3]University of Kansas Medical Center, Kansas City, KS

Background: Primary care clinicians (PCCs) play a critical role in delivering comprehensive care to patients with chronic conditions, including cancer survivors. Community health centers (CHCs) serve as primary healthcare facilities, providing accessible and affordable care to underserved and vulnerable populations, including cancer survivors. Despite the essential role of CHCs, significant gaps remain in knowledge and research training regarding survivorship care within these settings. Given the rising population of cancer survivors in the United States, addressing these gaps is crucial to ensuring high-quality survivorship care. This study aimed to assess the barriers and facilitators PCCs encounter when providing survivorship care to cancer survivors with chronic conditions at CHCs.
Methods: Qualitative in-depth interviews were conducted with PCCs from two healthcare systems, encompassing four urban CHCs in Texas during two phases. The research team developed semi-structured interview guides to explore barriers and facilitators in survivorship care. Interviews were conducted via phone or WebEX, a virtual platform, and were audio-recorded and transcribed verbatim by a certified transcription service. A team member reviewed the transcripts to ensure accuracy. Data were analyzed using an adapted immersion and crystallization approach, guided by the Chronic Care Model (CCM), to identify key themes related to survivorship care.
Results: Ten PCCs participated in the study. Qualitative analysis identified five key barriers to delivering high-quality survivorship care: (1) role ambiguity between PCCs and specialists, (2) inaccessibility of survivorship clinical guidelines, (3) limited communication between PCCs and oncologists, (4) inconsistent documentation of medical history, and (5) patient socioeconomic challenges, including financial difficulties. Pragmatic solutions were proposed to mitigate these barriers, and a patient-centered approach emerged as a key facilitator in improving care delivery.
Conclusions: These findings highlight valuable opportunities to enhance survivorship care within CHCs by addressing identified barriers and leveraging facilitators to foster patient-centered, high-quality care for underserved cancer survivors. The utilization of the CCM framework provided deeper insights into the specific gaps and challenges PCCs face in CHCs.

#4017 The prevalence of comorbid chronic conditions among cancer patients in the All of Us Research Program.

Sue E. Kim, Crystal Rubalcava, Jennifer Tsui

Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA

Cancer survivors in racial/ethnic minority, low socioeconomic status, and aging populations are more likely to have other chronic conditions, including 30% of cancer survivors who have diabetes or cardiovascular disease, many of which were pre-existing before cancer diagnosis. We examined the prevalence of comorbid chronic conditions among cancer patients in the All of Us Research Program (AoURP) cohort (2016-2024) and disease code identification from the National Library of Medicine and compared demographic, social determinants, and health-related social needs across specific cancer diagnosis sites. Comorbidities were self-reported data from the personal health history survey and found in electronic health records. We assessed the socioeconomic status (SES) barrier as a composite score (0-5) that combined education (≤ high school), income (≤ 35K), uninsured, housing (rent/other), and employment status (unemployed).

We identified 12,415 breast cancer, 4,047 colorectal cancer (CRC), 3,126 lung cancer, and 7,951 prostate cancer cases among 574,000+ AoURP participants, as of Nov 2024. 54% of breast, 65% of colorectal, 76% of lung, and 57% of prostate cancer patients reported having at least 1 comorbid condition. About 20% had at least 2 comorbidities. Obesity and diabetes were the two most common conditions for breast and colorectal cancer, chronic pulmonary disease (CPD) and diabetes were the most common for lung cancer, and diabetes and moderate/severe kidney disease for prostate cancer. Among the other top 5 common comorbid conditions were rheumatoid arthritis, liver disease, and congestive heart failure.

About a quarter of lung cancer patients with diabetes had 3 or more SES barriers, compared to 23% of colorectal, 20% of breast, and 12% of prostate cancer patients. Also, about 28% of lung cancer patients with liver disease had 3 or more SES barriers. A smaller proportion of CRC patients (19%) with obesity had 3 or more SES barriers, compared to 18% of lung, 13% of breast cancer, and 8% of prostate cancer patients.

The highest proportion (>40%) of Black patients reported having diabetes for all cancer types, except prostate cancer (where Hispanic patients reported the highest rate). A higher proportion of Black patients with breast and colorectal cancer had obesity while similar proportions were reported between Hispanic and Black lung and prostate cancer patients.

Understanding comorbidity prevalence in this national sample of cancer survivors provides insight into care coordination, disease management, and team-based care strategies needed to improve cancer survivorship care quality and address inequities in cancer survivorship outcomes. Further assessment of All of Us Research Program data, including patterns of care through EHR data and lab and self-reported survey data, may provide opportunities to comprehensively assess and intervene in survivorship care improvements.

#4018 Primary gallbladder cancer association with cardiovascular mortality: A 20 year population-based retrospective study.

Oboseh J. Ogedegbe[1], Olanipekin Ntukidem[1], Asfand Y. Cheema[2], Sakshi Bai[3], Kai He[4], Utkarsh Acharya[4]

[1]Internal Medicine, Trinity Health System, Ypsilanti, MI,[2]Internal Medicine, Taussig Cancer Center, Cleveland, OH,[3]Internal Medicine, Henry Ford Health System, Jackson, MI,[4]Hematology/Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH

Introduction: Primary gallbladder cancer (PGC) is the most common cancer of the biliary system. It is often late presenting, leading to a poor prognosis. While evolution and progress in medicine have resulted in reduced mortality rates in PGC, non-cancer deaths are at an increasing trend. Cardiovascular mortality (CVM) plays a significant role in this trend. We holistically evaluated the CVM risk in patients with PGC.

Methods: We utilized the Surveillance, Epidemiology, and End Results (SEER) database to retrieve PGC patients with CVM from 2000-2021. CVM was defined as death from diseases of the heart, hypertension without heart disease, cerebrovascular diseases, atherosclerosis, aortic aneurysm and dissection, and other diseases of arteries, arterioles and capillaries. We then obtained the standardized mortality rates (SMR) and absolute excess risk (AER).

Results: Total number of PGC patients who died from cardiovascular diseases was 706. Patients with non-cardiovascular causes of death and patients with unknown age, race and cancer stage were excluded. We compared the cardiovascular disease (CVD) mortality risk of each group to the general US population and noted significantly increased CVD SMRs. Regarding race, Asians or Pacific Islanders had the highest risk of CV mortality (SMR 6.80, CI 5.10-8.87, $p < 0.05$), followed by Blacks (SMR 6-15, CI 4.88-7.66, $p < 0.05$), then American Indians/Alaska Natives (SMR 5.89, CI 1.60-15.08, $p < 0.05$) and Whites (SMR 3.99, CI 3.67-4.33, $p < 0.05$). Based on cancer stage, distant had the highest risk of CV mortality (SMR 17.79, CI 14.62-21.44, $p < 0.05$) while localized had relatively the lowest risk (SMR 3.10, CI 2.59-3.69, $p < 0.05$) with regional being (SMR 4.52 CI 4.00-5.08, $p < 0.05$). In terms of age, patients aged 40-59 years had an SMR of 20.89 (CI 15.65-27.33, $p < 0.05$), 60-79 years had an SMR of 5.14 (CI 4.60-5.74, $p < 0.05$), while 80 years and above had an SMR of 3.34 (CI 2.99-3.72, $p < 0.05$).

Conclusion: Our analysis examines the magnitude of CVD-related deaths in PGC patients. Compared to the general United States population, patients with PGC have a higher risk of cardiovascular mortality. Therefore, patients with PGC should be screened for CVD to provide more holistic care in this patient population.

#4019 Effect of time interval from diagnosis to treatment on mortality in colorectal cancer by stage in Korea.

Ji Yoon Baek[1], Curi Park[1], Ji Won Park[2], Aesun Shin[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of

Background: Colorectal cancer (CRC) is one of the most common cancers worldwide and a major contributor to the disease burden. Treatment delay, defined as the time interval from diagnosis to treatment initiation, is an emerging public health concern. While treatment delays in cancer may not directly cause fatal health outcomes, some studies have reported associations though the evidence remains inconclusive. Therefore, we aimed to investigate the impact of treatment delays on all-cause mortality in CRC patients in Korea, stratified by cancer stage.

Methods: A retrospective cohort study was conducted using the sample cohort of CRC patients from the Cancer Public Library Database, which integrates data from four public sources in Korea. The study included patients diagnosed with CRC (ICD-O-3: C18-C20) between 2012 and 2019, with mortality follow-up until 2021 and health service utilization data until 2022. Treatment delay was categorized using two thresholds: 3 months and 6 months. Cumulative all-cause mortality was analyzed with the Kaplan-Meier methods, and group differences were assessed with log-rank tests. Adjusted hazard ratios (aHR) and 95% confidence intervals (CI) were estimated by Cox proportional hazard models, adjusted for sex (male/female) and age at diagnosis (<50, 50-59, 60-69, 70-79, ≥80). All analyses were stratified by SEER cancer summary stage (localized, regional, distant).

Results: Of 53,485 CRC patients, 28,520 were analyzed. Most had regional stage CRC (54.7%). The proportion of patients having treatment delays of ≥3 months was highest in the localized stage (5.5%), then in the distant (3.6%) and regional (1.7%) stages, with a similar trend observed for delays of ≥6 months (localized: 2.4%; distant: 1.7%; regional: 0.8%). Longer treatment delays were significantly associated with higher 5-year cumulative mortality across all stages (<3 months vs ≥3 months vs ≥6 months; localized: 12.7% vs 21.4% vs 37.6%; regional: 22.9% vs 35.4% vs 52.2%; distant: 77.4% vs 84.0% vs 84.1%; p<0.001 for all). Treatment delays of ≥3 months, compared to <3 months, significantly increased the risk of death, with the highest risk in the regional stage (aHR: 1.69 [95% CI: 1.42-2.02]), followed by localized (1.55 [1.24-1.93]) and distant (1.29 [1.09-1.53]) stages. For delays of ≥6 months (vs <6 months), the highest risk was examined in localized stage (2.91 [2.24-3.78]), followed by regional (2.63 [2.07-3.35]) and distant (1.47 [1.15-1.89]) stages.

Conclusion: Treatment delays of more than 3 months were significantly associated with higher all-cause mortality across all stages of CRC in Korea, with a more pronounced impact in the localized and regional stages. These findings emphasize the importance of timely treatment, especially for early-stage colorectal cancer.

#4020 Review of literature on the effect of stress and anxiety among African-American breast and endometrial cancer patients.

Gabrielle Ford, Zakirah L. Abdul-Hameed, Amirah Burton, Brian M. Rivers, Desiree Rivers

Morehouse School of Medicine, Atlanta, GA

African American women face disproportionately higher rates of breast and endometrial cancer recurrence compared to their Caucasian counterparts, highlighting an urgent need to explore the role of stress in cancer progression and recurrence. This study conducts a systematic review of the literature to evaluate the efficacy of stress and anxiety interventions in reducing cancer risk among African American survivors. By analyzing 25 articles from 2014-2024, this review examines the correlation between psychological stress, biological stress markers, and cancer outcomes. The findings emphasize the significant impact of stress on health outcomes, particularly in the context of cortisol's role in metabolism and immune response. The review also explores coping mechanisms, including social support, diet, and exercise, tailored to African American women's cultural and socioeconomic needs. The results underscore the critical need for targeted interventions to address stress in this population, with implications for improving cancer survivorship and advancing healthcare equity.

#4021 Science, prevention, and fun: The educational revolution of the project Cancer School.

Altair Filho M. Souza[1], **Talita Aguiar**[2], Andreia Juliana Rodrigues Caldeira[1]

[1]Instituto Academico de Ciencias da Saude e Biologicas, Universidade Estadual de Goias, Anapolis, Brazil,[2]Columbia University Irving Medical Center, New York, NY

Introduction: Cancer remains a leading cause of mortality worldwide, necessitating innovative strategies to enhance public understanding of its biology, risk factors, and prevention. The *Cancer School* project is part of the extension program "Laboratório de Educação Científica e Popularização da Ciência (LECPOP) from the State University of Goiás and seeks to bridge this gap by integrating science communication with educational tools that present complex topics like mutations and cancer in an accessible and engaging way. Leveraging social media (@cancerschooloficial) as a dissemination platform, the initiative has amassed over 10,000 followers and achieves consistent engagement through interactive posts, stories, and videos, fostering a virtual community for cancer education.

Methods: The project developed two essential educational tools: the *Cromocel* booklet and a board game. *Cromocel* features an engaging narrative led by characters Cromo, Alê, and Karcin to introduce concepts such as chromosome structure, mutations, and cancer progression. The board game, designed in the shape of a chromosome, includes themes like cancer biology, risk factors, and prevention. The development process involved 1) Defining educational objectives, 2) Conducting a literature review, 3) Designing prototypes, 4) Writing a question-and-answer script, and 5) Establishing gameplay rules. Both tools were piloted at the XIV National Research Meeting in Science Education (2023) in Caldas Novas, Goiás. Participants were invited to engage with the tools at an interactive stand and complete a short survey assessing the pedagogical effectiveness, engagement, and usability.

Results: The pilot study included 20 participants: 2 K-12 students, five teachers, and 13 undergraduates. All participants reported enjoying the tools, with 70% identifying "prevention" as the most straightforward concept to understand, likely due to their relevance to everyday life. The project's social media presence amplified these efforts, with posts about the educational tools achieving an average engagement rate of 15%, demonstrating strong interest from a broad audience. Followers frequently interacted with content, asking questions and sharing posts, further expanding the initiative's reach.

Conclusion: The *Cancer School* project demonstrates the potential of combining traditional educational tools with digital engagement to promote cancer literacy. The initiative successfully enhances public understanding of cancer biology and prevention strategies by integrating creative methodologies like booklets and games with social media outreach. These results highlight the value of active learning and digital platforms in science communication, offering a scalable model for addressing public health challenges.

#4022 Leveraging multidisciplinary partnerships to overcome barriers to prevent cancer disparities in healthcare.

Regina M. Sharma[1], Frankie M. Palazzolo[2], Shelley G. Skinner[3], Klementina Sula[4], Evelyn M. Jiagge[5]

[1]Detroit Justice Center, Detroit, MI,[2]Detroit Innovation Hub, Detroit, MI,[3]Genentech, Plymouth, MI,[4]Jewish Federation of Detroit, Bloomfield Hills, MI,[5]Henry Ford Health System, Detroit, MI

Background: Racial disparities in funding continue to be one of the most significant barriers to Black women research scientists progressing; impacting career trajectories and access to research grants. Because of this, there is a dire need to build connections and overcome barriers for funding opportunities for research in underrepresented communities. A multidisciplinary team of fund development professionals, research scientists, and pharmaceutical professionals came together with one intended goal; transition barriers into opportunities by navigating the complexities of a large healthcare organization and successfully build a leadership-driven model that demonstrates when people come together across a variety of entities and disciplines results will follow.
Method:

1. Navigated the complexities of a large healthcare organization
2. Successfully built a leadership-driven model to produce results
3. Engaged stakeholders by overcoming obstacles by leveraging educational opportunities to help the community and prospective donors understand the complexities of inequity in healthcare.
4. Created an elevator pitch that we could utilize in various public spaces - meetings, conferences, the community
5. Translated the work into ideas non-scientists could understand
6. Made connections across US and global Biotech, Pharma, and Precision Medicine organizations

Results: Over four years we have raised over 3.5 million dollars to support basic, translational, and qualitative research in Detroit and globally. With funding we received at Henry Ford Health, through our partnership, we generated needed preliminary data on the unique aggressive biology of African breast cancers, that was used for a successful NIH grant application. Through our initiative Precision Medicine for Aggressive Breast Cancer PMABC, we have supported research in Ghana, Tanzania, Rwanda, Uganda, Botswana, Nigeria, and South Africa. We have supported researchers in these countries with the training and education needed for cancer research in the country and have helped raise seed funding for local cancer research. We have ongoing community-based research in Detroit and SE Michigan to address barriers to Black/African Americans participating in cancer clinical trials.
Conclusion: In this session, we will review a framework that will highlight how to organize stakeholders, develop a plan of engagement, and leverage the necessary resources to execute a leadership-driven model.

#4023 ACCESS: Advancing childhood cancer experience, science and survivorship in Canada.

Stephanie A. Grover[1], **Christine J. Williams**[2], Adrienne Co-Dyre[3], David Malkin[1], James A. Whitlock[1], on behalf of the ACCESS network.

[1]The Hospital for Sick Children, Toronto, ON, Canada,[2]Ontario Institute for Cancer Research, Toronto, ON, Canada,[3]King's University College at Western University, London, ON, Canada

In Canada, roughly 1,500 children and adolescents are diagnosed with cancer each year. Advocacy for enhanced childhood cancer research and care in Canada by patients, families and the academic community led to a $23M investment through the Canadian Institutes of Health Research to establish a national pediatric cancer consortium (termed 'ACCESS'). ACCESS' mission is t*o ensure every child with cancer in Canada has access to the latest scientific advances, diagnostic tools, therapies, and supportive care leading to better outcomes and quality of life.* ACCESS is a unique collective of scientists, healthcare providers, industry leaders, partner organizations, advocates, patients, and their families who are conducting research, changing policy, and developing new tools to ensure better lives for children who experience cancer in Canada and for their loved ones. The goal is to implement transformative change in the delivery of fair, fast, effective, and safe cancer care for all children. ACCESS is driven and led by people with lived experience of pediatric cancer and framed by the patient journey. To date, ACCESS has unified a national community. It has: connected a community of more than 750 people and stimulated a culture of open communication in which diverse viewpoints, including those of people with lived experience of cancer, are sought and valued; built productive and effective partnerships to connect and leverage the work of organizations working to improve childhood cancer; initiated more than 20 new innovative pan-Canadian research studies that impact all aspects of the patient journey, including new Canadian-led clinical trials; developed an educational hub for all ACCESS members, and produced accessible communications materials such as webinars, a newsletter and a comprehensive website; developed national best practice standards and tools for research and care; started to address the complex policy, regulatory and practical barriers that prevent equitable access to cancer diagnosis and treatment for all children in Canada. Future priorities include achieving organizational sustainability, supporting collaborations and inclusivity, overcoming barriers that affect the access of children to diagnostics and treatment, enhancing data connectivity and sharing, and developing and implementing a national strategy for pediatric cancer.

#4024 Cancer research advocates: satisfaction, frustration, and opportunities.

Bob Riter[1], Hillary Andrews[2]

[1]Community Cancer Partnership, Cornell University, Ithaca, NY,[2]Friends of Cancer Research, Washington, DC

Introduction: Advocates have been involved in cancer research for several decades, but little is known about their opinions regarding what is satisfying and what is frustrating. This largely qualitative study gathered feedback from a range of advocates regarding their experiences with cancer research to identify common themes and to generate hypotheses for future research.
Methods: An online survey with 14 questions about the advocates' background and experiences with research advocacy was distributed in early 2024 to cancer research advocates through multiple organizations and research advocacy networks. Thirty individuals responded, half of whom were advocates with 10+ years of experience.
Results: Breast cancer was the most common cancer site of research activity (n=18/30, 60%), and clinical trials (n=29/30, 97%), and translational research (n=25/30, 83%) were the types of research of greatest interest. Respondents were generally enthused about their work and felt like they were making a meaningful contribution. The greatest frustration was being asked for letters of support at the last minute or otherwise "checking a box" for a researcher applying for a grant. Many respondents expressed difficulty in getting connected with research activities, especially at a local level. The advocates noted that the "career path" to becoming an established advocate is not always clear nor is it easy to find opportunities
Conclusions and Recommendations: Our survey results demonstrate that research advocates are very engaged and satisfied with their experiences. While excellent training programs provide a solid foundation for new advocates, there should be a greater focus on continued engagement and mentoring for "mid-career" advocates.

#4025 Improving collaboration and well-being among patient advocates: lessons from Escape to THRIVE.

Sherri Romanoski[1], Mindy Griffith[1], **Brandi Forbes**[1], Lisa Rezende[2]

[1]Bag It Cancer, Tucson, AZ,[2]Molecular and Cellular Biology, University of Arizona, Tucson, AZ

Background: Patient advocates play a crucial role in supporting individuals with cancer, but advocates often face challenges related to collaboration, work-life balance, and burnout. Professional development opportunities, such as conferences, may help address these challenges, yet limited research exists on their long-term impact on patient advocates.

Purpose: To evaluate changes in patient advocates' practices in three areas: 1) collaboration with other advocates, 2) work-life balance, and 3) self-care following participation in *Escape to THRIVE*, a leadership conference.

Methods: Patient advocates attending the *Escape to THRIVE* conference in three different years (2020 (n=27), 2023 (n=21), and 2024 (n=25)) were surveyed at three time points: pre-conference, immediately post-conference, and six or more months post-conference. Questions focused on collaboration with other advocates, workload management, and self-care behaviors. Responses were analyzed using both quantitative and qualitative methods.

Results: Following conference participation, advocates demonstrated meaningful changes in collaboration and personal well-being management. A trend toward increased collaboration, with advocates more frequently partnering with those supporting patients with different cancer types. Participating advocates also reported improved workload management and self-care behaviors.

Conclusion: Results suggest that targeted professional development at conferences can effectively promote positive changes in patient advocates' collaborative behaviors and personal well-being management practices, with benefits sustained over time. These findings support the value of professional development opportunities for patient advocates that promote professional collaboration and personal well-being management.

#4026 The Bench with Bedside Initiative™: an unconventional collaborative approach between scientists and research participants.

Audrey Saghian[1], Alex J. Kalfa[2], Robel Dagnew[2], Navid Golshan[1], Raed Jaffal[2], Dayanara Ruiz[3], Mary K. Falcone[4], Caryn Lerman[4], Bodour Salhia[1]

[1]Department of Translational Genomics, Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA,[2]Department of Translational Genomics, Keck School of Medicine, University of Southern California, Los Angeles, CA,[3]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, CA,[4]Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA

Translational research (TR) relies on human specimens, yet traditional models often fail to engage diverse populations with ambiguity between researchers and research participants (RPs). This disconnect can hinder trust, diminish inclusivity, and reduce generalizability. To address this, we developed *The Bench with Bedside Initiative (TBBI)*, a trans-relational model of TR that integrates scientists at the bench with RPs at the bedside. TBBI fosters bidirectional communication, enabling researchers to understand invaluable RP perspectives while enhancing RP understanding of research to offer empowerment and inclusion. TBBI uses social media to expand regional recruitment, connect with underrepresented populations, promote researcher-RP rapport, and disseminate findings. TBBI also employs culturally tailored community engagement through webinars and in-person events to foster trust and participation among historically marginalized groups. We are currently using TBBI to recruit 1000 diverse RPs to validate a novel test for detecting minimal residual disease (MRD) in breast cancer survivors at the Norris Comprehensive Cancer Center (NCCC). RPs complete measures on social determinants of health, provide blood samples, and permit collection of clinical data. TBBI has attracted 2,723 entries via web-based eligibility surveys, primarily through social media advertising and email outreach. Of these, 63% met eligibility, and 1,357 RPs advanced to secondary screening. To date, 554 RPs have consented using TBBI. Concurrently, 135 RPs were recruited from the NCCC and Los Angeles General Medical Center clinics, representing 20% of recruitment. RP demographics include 66.3% White, 16.5% Hispanic, 6.7% Asian, 4.6% Black, 4.5% Multiracial, 0.4% Native Hawaiian, 0.4% American Indian or Alaskan Native, and 0.4% declined to disclose. Given NCCC catchment, 53.8% of RPs recruited in clinic identified as Hispanic and 21.9% identified as Asian. TBBI is transforming RP recruitment and the researcher-RP relationship by promoting transparency and collaboration to connect laboratory science and patient care. While long-term outcomes are being evaluated, TBBI demonstrates that trans-relational approaches to TR can diversify participant pools, improve recruitment efficiency, and foster sustained researcher-RP collaboration. By leveraging social media and community engagement, TBBI is paving the way for an inclusive and impactful future in translational science.

#4027 Self-confidence as a driver of community impact: Outcomes of the Community Genetic Navigation Engagement Specialist (CoGENES) train-the-trainer program.

Bianca Rosales[1], Janet Rodriguez[1], Joel Sanchez Mendez[1], Yaneth L. Rodriguez[1], Charite Ricker[2], Rosa Barahona[1], Heinz Joseph Lenz[1], John Carpten[3], Mariana C. Stern[1], **Lourdes A. Baezconde-Garbanati**[1]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]Department of Medicine, Division of Medical Oncology, Keck School of Medicine of USC, Los Angeles, CA,[3]Beckman Research Institute of City of Hope., Duarte, CA

Hispanic/Latino (H/L) populations are disproportionally affected by colorectal cancer (CRC). This disparity is driven by a lack of awareness about CRC prevention, genetic testing, and access to culturally appropriate resources. A CoGENES train-the-trainer program was develop for a workforce of community health workers (CHWs*)* as part of COPECC, a Cancer Moonshot NCI funded PE-CGS network program at USC. After development and testing with community input, the program was implemented in three phases. Phase 1: Twelve CHWs participated in six in-person sessions over three weeks in Spanish/English, which provided knowledge on CRC/genetic testing, and community education strategies. Phase 2: the trained CoGENES replicated the sessions within their respective H/L communities training 30 more CoGENES. Phase 3: all 42 CoGENES are disseminating information through community events using the CoGENES training manual, to sustain long-term community impact. Data was collected on the number of individuals educated, events attended, and CRC/genetic testing information disseminated. Demographic and acculturation information was collected through surveys. Self-confidence to train others was measured at baseline, after training completion, at a 6 and 12 month follow-up, using a team-developed nine-item tool. All p-values are two-sided from paired t-tests. Majority of the participants were female (phase 1 = 75%, phase 2 = 79%) Mexico-born (92% & 75%), and very Latino oriented (67% & 71%). We saw a statistically significant increase in the “self-confidence to train others” in 8/9 items and 7/9 items of the survey for Phase 1 and Phase 2 CoGENES after they received the training (p-values <0.05). The level of self-confidence was sustained at 6 and 12 months, with no difference in the mean values of the items when compared to post-training values in Phase 1 CoGENES (p-values >0.05). In Phase 2 CoGENEs, we saw a decrease in the mean values for 5/9 items in the survey for the 12-month follow-up when compared to after training (p-values <0.05). Despite this, all the values remained higher at 12-months than at baseline. The difference between baseline and 12-month follow-up was the confidence to “describe what genetic tumor testing is” (p = 0.016) in Phase 1 CoGENES, and the confidence to “describe what genetic counseling is” (p = 0.017) in Phase 2 CoGENES. The CoGENES train-the-trainer program, a culturally tailored linguistically specific approach to address disparities in CRC prevention and genetic testing within H/L communities. Results show a lasting increase in the self-confidence of participants to empower other individuals in their communities to disseminate CRC prevention knowledge. The CoGENES CHWs partnered with 20 community-based organizations, reaching over 3 million people through community events, media interviews, podcasts, and workshops.

#4028 Establishing optimal care coordination in localized bladder cancer in the United States: A modified Delphi consensus study.

Gautam Jayram[1], Monika Baskin[2], Gordon Brown[3], Mollie Deshazo[4], Michael Fabrizio[5], Balaji Hiremalagur[6], Angela Hunter[7], **Mukul Singhal**[6], Arveen Kaur[6], Michael Lattanzi[8], Lynn Redmond[9], Guru Sonpavde[10]

[1]Urology Associates, Advanced Therapeutics Center, Nashville, TN,[2]Department of Medicine, University of Pittsburgh, Pittsburgh, PA,[3]Department of Urologic Oncology, Summit Health, Moorestown, NJ,[4]Department of Hematology Oncology, University of Alabama, Birmingham, AL,[5]Department of Urology, Eastern Virginia Medical School, Nashville, VA,[6]Johnson and Johnson, Horsham, PA,[7]The Urology Group, Cincinnati, OH,[8]Department of Genitourinary Oncology, Texas Oncology, Austin, TX,[9]Pharmacy, Urology Associates, Advanced Therapeutics Center, Nashville, TN,[10]University of Central Florida, Orlando, FL

Introduction: Care for localized Bladder Cancer (BC) primarily begins with a urologist and generally requires multidisciplinary management. With emerging novel treatments and evolving standards, effective communication and coordination across specialties is crucial. This project aimed to build consensus among clinicians and supporting staff with expertise in managing bladder cancer care, to propose an outline for the optimal management and coordination of care in localized BC originating from the urology clinic.
Methods: The project used a modified Delphi method. A steering committee (SC) experienced in BC care coordination (including urologists, medical and radiation oncologists, advanced practitioners and administrators) convened to discuss issues in BC care, developing a series of consensus statements. A finalized set of 46 statements were used in a 4-point Likert scale survey, disseminated by a third-party to healthcare practitioners with active roles managing localized BC in the USA. A consensus threshold was set at 75% agreement. The SC then reconvened to discuss the results and formulate recommendations based the consensus achieved.
Results: 300 responses were received across the nation, 102 (34%) from urologists, 79 (26.3%) from medical oncologists, 31 (10.3%) from nurse/nurse navigators, 32 (10.7%) from radiation oncologists, 30 (10%) from advanced practitioner providers, and 26 (8.7%) from administration roles. Of the statements, 38/46 (83%) achieved ≥90% agreement, and 8 (17%) attained ≥75% but <90%. No statements fell below the consensus threshold. Sub-analyses showed there was disagreement between urologists in different practice settings, although there was overall concordance in agreement levels between responder roles. 95% agreed multidisciplinary teams and tumor boards need to be created to facilitate bladder cancer care. 97% agreed clear and ongoing provider to provider communication during care is essential to maximize outcomes. 98% agreed patients need to be educated on all treatment options to facilitate informed decision making. From the statements with highest agreement, a series of 10 recommendations were developed.
Conclusions: These consensus recommendations from 300 experienced healthcare practitioners and allied healthcare professionals from all major localized BC treating specialties provide a roadmap toward improving the quality of care of these patients.

#4029 Project Cure CRC: advancing colorectal cancer research and personalized treatment through a CRC platform clinical trial.
Kimberly Lynn Newcomer, David Fenstermacher

Colorectal Cancer Alliance, Washington, DC

Background: The Colorectal Cancer Alliance (Alliance) established Project Cure CRC to support critical research breakthroughs in colorectal cancer (CRC), driving advancements in treatment and improving patient outcomes. CRC is among the most prevalent and fatal cancers worldwide, accounting for over 1.9 million new cases and 935,000 deaths annually. A significant challenge in treating CRC is its high genetic variability among patients, leading to differing responses to standard therapies and underscoring the urgent need for personalized approaches. Many cases involve mutations linked to resistance to conventional treatments, resulting in poor prognoses and limited options for these patients.
Methods: Project Cure CRC initiated a targeted Request for Proposals (RFP) informed by insights from the previous Cure CRC Summit. This effort received 250 submissions, many aiming to fund clinical trials testing novel therapies targeting CRC directly or enhancing the tumor microenvironment to improve immunotherapy effectiveness. The Alliance intends to invest $100 million in research over the next three years; funding individual trials was deemed insufficient for achieving the desired impact. After extensive exploration of various strategies, the Alliance is establishing a multi-center colorectal cancer platform trial to focus on curative research in four key areas: Neoadjuvant therapy for CRC, Minimal residual disease-positive patients with no radiographic evidence of disease, Perioperative surgery of metastatic disease, Metastatic and oligometastatic disease.
Results: To advance treatment options, accelerate regulatory approvals, and increase the 5-year survival rate for metastatic CRC from 13% to 35%, the Alliance is leading an adaptive, multi-site platform trial tailored to high-risk CRC cases. Modeled after successful trials for breast cancer, AML, multiple myeloma, and PDAC, this innovative trial design enables researchers to test multiple therapies simultaneously through multiple trial arms. The trial will use real-time data and Bayesian statistical approaches to adaptively select and refine effective treatments. A synthetic cohort will also be created in collaboration with the FDA, minimizing the need for some patients to receive only standard-of-care therapies. By integrating cutting-edge biomarker research, the platform trial will identify the most effective treatments for specific CRC tumor molecular subtypes.
Conclusions: The CRC platform trial will establish a collaborative, data-driven framework to accelerate the translation of research into clinical application. By incorporating ongoing adjustments and emphasizing targeted therapies, the trial aligns with the Alliance's mission to deliver impactful research and offer personalized, effective treatments to CRC patients with limited options under current care standards.

#4030 Uncovering psychosocial and physical challenges in colorectal cancer: findings from a comprehensive patient and survivor survey.

Kimberly Lynn Newcomer, David Fenstermacher

Colorectal Cancer Alliance, Washington, DC

Background: Colorectal cancer (CRC) is the third most diagnosed cancer and the second leading cause of cancer-related deaths globally among men and women combined. While survival rates for CRC have improved, limited knowledge exists about the specific unmet needs of CRC patients and survivors. These needs include emotional support, information on treatment options, and strategies for coping. CRC significantly impacts patients' emotional well-being, quality of life (QoL), and healthcare experiences. Beyond the stress of a cancer diagnosis, patients endure the physical and emotional toll of rigorous treatments, even in cases where no signs of the disease remain. Methods: The Colorectal Cancer Alliance conducted a comprehensive survey of CRC patients, survivors, and caregivers to better understand their experiences and needs. This IRB-approved, cross-sectional study included over 150 questions addressing patient profiles, diagnosis, access to care, treatment experiences, resources, and QoL. The survey was distributed through the Alliance's social media, email, and web-based platforms, reflecting a collaborative effort to address the multifaceted challenges faced by the CRC community. Results: Insights from 283 CRC patients and survivors highlighted critical unmet needs. The median age group of respondents was 46-55. Key findings included 74% struggling to find someone who shared similar experiences, 41% reporting reduced support after treatment, 54% feeling fatigued, and 51% experiencing stress. Cancer significantly disrupted personal and social aspects of life: 64% reported adverse effects on careers, 51% on dating, 43% on family planning, 58% on spousal relationships, 80% on sexual health, and 65% on social participation. Although patients felt well-informed pre-treatment, 46% identified gaps in knowledge about complementary or alternative therapies. These findings underscore the importance of addressing psychosocial and physical needs to improve care outcomes. Conclusions: CRC patients and survivors face profound psychosocial and physical challenges that reshape their lives. By identifying these needs, healthcare providers can develop more personalized treatment plans and support systems, offering hope for better patient experiences and outcomes. The Alliance aims to use these findings to guide clinical practices, care programs, and survivorship support, driving transformative improvements in CRC care.

#4031 Project Cure CRC: advancing precision medicine in colorectal cancer through innovative research and targeted therapies.

Kimberly Lynn Newcomer, David Fenstermacher

Colorectal Cancer Alliance, Washington, DC

Background: The Colorectal Cancer Alliance founded Project Cure CRC to support breakthrough research in colorectal cancer (CRC) and advance precision medicine to improve patient outcomes. CRC remains one of the most common and deadly cancers, with over 1.9 million new cases and 935,000 deaths annually. A significant challenge in CRC treatment is the genetic variability among patients, leading to different responses to standard therapies and highlighting the need for personalized approaches. Many CRC cases involve mutations that resist conventional treatments, resulting in poor prognosis and limited options for affected patients.
Methods: Project Cure CRC launched a targeted Request for Proposals (RFP) to address these challenges based on insights from last year's Cure CRC Summit. The RFP attracted 250 proposals centered on novel precision medicine strategies, and nearly $7 million in funding has been allocated to support 18 high-impact research projects.
Results: Funded projects employ diverse and innovative strategies to tackle CRC. Critical approaches include enhancing intratumoral mRNA vaccines that target immune checkpoints to boost anti-tumor responses and combining targeted radiation with immunotherapies to create synergistic effects in advanced CRC. Additional studies focus on new drug combinations for BRAF-mutated CRC, which has low response rates to existing treatments. Other projects investigate ProAgio, a protein targeting cells that support cancer survival, with the potential to improve therapies for hard-to-treat tumors. Further research examines how fat tissue influences CRC growth and metastasis, particularly in patients with obesity, and leverages technology to target multiple genes simultaneously, identifying cancer cell vulnerabilities and enhancing immune response. The Alliance has also funded a theranostic project that is able to use the same drug molecule to determine the location of tumors and a target therapeutic approach, and the development of a drug pipeline platform that will accelerate the development of new targets and therapies.
Conclusions: These initiatives demonstrate the Alliance's commitment to advancing precision medicine and addressing key gaps in CRC care, particularly for patients with treatment-resistant profiles. By funding high-impact research and fostering collaboration, Project Cure CRC aims to accelerate the development of personalized, effective treatments for CRC patients, transforming the landscape of colorectal cancer care.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Gene Regulation and Transcription Factors 1

#4035 Elucidating the DNA binding dynamics of EWSR1::FLI1 using biochemical methods.

Jack Tokarsky[1], Blanche Chen[2], Michael G. Poirier[2], Emily Theisen[1]

[1]Nationwide Children's Hospital, Columbus, OH,[2]The Ohio State University, Columbus, OH

Importance: This work signifies a breakthrough in our ability to study Ewing sarcoma by developing a protocol to purify functional WT EWSR1::FLI1. This development changes the level of detail to which we can study EWSR1::FLI1 and potentially other difficult to purify fusion oncoproteins.
Objective: Ewing sarcoma is a pediatric bone and soft tissue sarcoma that arises in adolescents and young adults. The mutation that causes >85% of Ewing sarcoma cases is caused by the fusion oncoprotein, EWSR1::FLI1. Efforts to purify recombinantly expressed EWSR1::FLI1 have proven challenging for decades due to aggregation caused by the low complexity domain (LCD) of EWSR1. Our goal was to purify recombinantly expressed and functional EWSR1::FLI1 to quantitatively understand the nature of binding dynamics to various DNA sequences.
Methods: We successfully expressed and purified EWSR1::FLI1 using a newly developed protocol. We performed electrophoretic mobility shift assays (EMSAs) to test binding of EWSR1::FLI1 on naked- and nucleosome-wrapped DNA. Binding constants were determined with DNA containing either a canonical high affinity (HA) ETS DNA binding sequence or a 2X GGAA microsatellite repeat.
Results: Our laboratory has successfully developed a protocol to consistently achieve highly pure and functional EWSR1::FLI1. EWSR1::FLI1 has approximately 7-fold tighter binding to a 2X GGAA repeat, than to HA ETS sequence. For comparison, the minimal FLI DNA binding domain proteins (ETS85 and ETS102) bind to HA ETS sequences and GGAA microsatellites at similar affinities. These experiments suggest that the EWSR1 LCD alters the binding dynamics of the ETS DBD domain and that EWSR1::FLI1 preferentially binds to GGAA microsatellites. We tested the pioneer function of EWSR1::FLI1 by performing EMSAs with nucleosome-wrapped DNA. EWSR1::FLI1 bound to nucleosome-wrapped DNA containing GGAA repeats with only 3-fold less affinity than naked DNA. For comparison, when ETS85 and ETS102 bound nucleosome-wrapped DNA, this affinity was ~30-fold less, showing potentially weak pioneering function of the FLI DBD.
Conclusions & Relevance to Pediatric Care: These studies allow us to understand the physical nature of fusion oncoproteins such as EWSR1::FLI1 and will be the foundation for therapeutics that could be used to treat Ewing sarcoma patients.

#4036 Selective inhibition of the transcription factor Brachyury in chordoma and non-small cell lung cancer.

G. Mercenne, Y. Gao, B. McEllin, A. Gutierrez, J. Robbins, B. Hueffmeier, E. Broderick, D. Canzani, W. Fondrie, L. Pino, A. Federation; Talus Bioscience, Inc., Seattle, WA

Chordoma is a rare and slow-growing cancer arising from remnants of the notochord, a structure present during embryonic development. It most commonly affects the sacrum and cervical spine, accounting for about 20% of primary spinal tumors and 3% of all bone tumors. While surgery and radiation are the primary treatments, the tumor's location often makes complete removal challenging, and recurrence is common. There are no approved therapies at this time. A hallmark of chordoma is the aberrant expression of the transcription factor (TF) Brachyury (TBXT) which plays a key role in notochord development but is normally silenced in adult tissues. In chordoma, Brachyury is reactivated and contributes to tumor initiation and progression, making it both a diagnostic marker, and a potential therapeutic target.
Talus Bio has developed a groundbreaking technology, TF-Scan, the first cell-based global screening platform specifically designed to target TF. TF-Scan integrates functional proteomics, automated cell processing, and machine learning to evaluate a drug’s ability to modulate the activity of DNA-bound proteins in live human cells. Using our platform, we identified compounds that target TBXT. Hit validation and hit-to-lead optimization led to the development of a covalent small molecule, TAL61, that effectively modulates TBXT activity. In preclinical studies using a patient-derived xenograft (PDX) model for chordoma, TAL61 demonstrated significant efficacy in reducing tumor burden. TBXT has also been shown to be overexpressed in different cancers particularly lung cancer and breast cancer. We tested our lead compound in a model of NSCLC and were able to significantly decrease tumor burden by more than 50% and visualize additive effects while doing combination with a chemotherapy agent.
We are conducting other studies to further characterize TAL61 and uncover new cancer indications where TBXT plays a key role. The development of TF-Scan represents a paradigm shift in drug discovery, enabling the identification of compounds capable of disrupting targets that were previously inaccessible to conventional approaches.

#4037 Epigenetically-controlled CEBPB regulates kidney cancer tumorigenesis via GPD1L-mediated ether lipid synthesis.

Thi Ha Nguyen, Xuan Linh Mai, Tin Tin Manh Nguyen, Hoonsik Nam, Sunghyouk Park, **Ji Yun Lee**

Seoul National University College of Pharmacy, Seoul, Korea, Republic of

The VHL-HIF axis has been recognized as a major regulator of lipid accumulation and tumorigenesis in clear cell renal cell carcinoma (ccRCC), but a growing number of VHL-HIF-independent pathways suggests possible alternative regulators. By screening epigenetic drivers and transcription factors, we identified CCAAT/enhancer-binding protein beta (CEBPB) as a key VHL-independent transcription factor crucial to lipid-related ccRCC progression, which was confirmed through *in vitro/vivo* experiments. CEBPB levels, regulated by H3K27ac and H3K4me, were also correlated with various poor prognostic factors in ccRCC patients. Mechanistically, CEBPB transcriptionally repressed glycerol-3-phosphate dehydrogenase 1-like (GPD1L), causing substrate (dihydroxyacetonephophate) accumulation for ether lipid synthesis. This enhanced Akt activation through membrane recruitment, and the subsequent downregulation of carnitine palmitoyltransferase 1A (CPT1A) led to lipid accumulation. Connecting multiple elements of the Hallmarks of Cancer in an unbranched path, the CEBPB-GPD1L-ether lipid-Akt-CPT1A axis is proposed as a new VHL-independent mechanism of lipid-related ccRCC tumorigenesis.
Significance: The identification of CEBPB as a VHL-independent regulator of lipid metabolism and tumorigenesis shows how major cancer hallmarks (epigenetics, metabolites, and signaling) can be orchestrated by single factor. The proposed CEBPB-GPD1L-ether lipid-Akt-CPT1A axis provides new insights and therapeutic potentials for the regulation of lipid-related tumorigenesis in ccRCC

#4038 Oncogenic ETS transcription factors in prostate cancer and Ewing sarcoma are interchangeable when avoiding repression by a PRC2/FOXO1 complex.

Nicholas Frederick Downing[1], Katelyn M. Mills[1], Peter C. Hollenhorst[2]

[1]Indiana University Bloomington, Bloomington, IN,[2]Medical Sciences, Indiana University Bloomington, Bloomington, IN

ETS transcription factors play roles throughout development, aiding in hematopoiesis, blood vessel formation and cell fate. The ETS family is composed of 28 members, all of which share an ETS DNA-binding domain. Chromosomal rearrangements that lead to the overexpression of specific ETS promote oncogenic transformation and tumor development. More than half of prostate tumors are driven by aberrant expression of an ETS protein. Our lab has demonstrated that oncogenic ETS form essential interactions with a ubiquitous RNA-binding protein, EWS, to promote prostate tumorigenesis. A similar mechanism exists in Ewing sarcoma (ES). ES tumors are driven by the expression EWS/ETS fusion proteins. This project focuses on how ETS and EWS/ETS act as oncogenic transcription factors; furthermore, we identify a novel ERG/PRC2/FOXO1 regulatory complex that may be exploited for therapeutic benefit. We compared biological functions of oncogenic ETS found in prostate cancer (ERG, ERG(S96E), ETV1, ETV4, ETV5) and EWS/ETS fusions in ES (EWS/FLI1, EWS/ERG). All oncogenic ETS promoted migration and clonogenic survival in normal prostate epithelial cell lines, RWPE1 and PNT2. Knockdown of endogenous EWS/FLI1 in the ES cell line, A673, reduced anchorage-independent colony formation in soft agar. Exogenous expression of EWS/FLI1, ETV1, ETV4, and ETV5 rescued A673colony formation, however ERG and EWS fused to full-length ERG were unable to rescue this phenotype. Our lab has established that ERG can act as a transcriptional repressor through the formation of an ERG/PRC2 complex. Pulldown assays using purified proteins and A673 lysates revealed that ERG and EWS fused to full-length ERG interact with EZH2, a subunit of the PRC2, and FOXO1, a tumor suppressor that is thought to repress ERG transcriptional activity. Both the N-terminal truncation of ERG and phosphorylation of ERG at S96 disrupted these interactions and rescued colony formation in A673. Further immunoprecipitation assays suggest that a FOXO1/PRC2 complex can exist independent of ETS expression. ERG is thought to cooperate with mutations that promote prostate tumorigenesis through activation of the PI3K/AKT pathway. Our lab has observed increases in clonogenic survival and tumorigenesis upon expression of both ERG and a constitutively- active mAKT in RWPE1. AKT negatively regulates FOXO1 expression. We aim to evaluate the effects of FOXO1 expression in facilitating ERG/PRC2 interactions. Furthermore, we aim to explore the effects of Ipatasertib, an AKT inhibitor in clinical trials, on the ERG/PRC2/FOXO1 complex and ERG-dependent phenotypes in prostate cancer cell models.

#4039 An isogenic CRISPR screen identifies novel MYC-driven vulnerabilities.

P. Lin[1], C. Lourenco[1], J. Cruickshank[2], L. Palomero[3], J. E. van Leeuwen[1], A. H. Y. Tong[1], K. Chan[1], S. El Ghamrasni[2], M. Pujana[3], D. W. Cescon[2], J. Moffat[1], L. Z. Penn[2];

[1]University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain

c-MYC (MYC) is a central regulatory protein that is dysregulated in >50% of all human cancers and is linked to aggressive disease. Developing MYC inhibitors would revolutionize cancer treatment; however, efforts to target MYC directly using small molecular inhibitors have historically failed. A promising approach is to identify and inhibit critical MYC partner proteins to inactivate MYC and trigger cancer cell death. Inhibiting these targets therapeutically can result in synthetic lethality (MYC-SL), which can be exploited in MYC-dysregulated cancers. To identify MYC-SL targets, we performed a genome-wide CRISPR knock-out screen using an isogenic pair of non-transformed and MYC-driven breast cancer cells. In contrast to other screens, this model is both dependent on MYC and recapitulates human disease at pathological and molecular levels *in vivo*. Finally, these hits were cross-referenced with our MYC protein-interactome data to reveal putative MYC partner proteins that are critical for MYC activity.

From our screen results, we performed gene set enrichment analysis to identify biological activities that may represent core functional dependencies in MYC dysregulated cancer cells. Using this approach, we identified and validated topoisomerase 1 (TOP1) as an actionable vulnerability that can be targeted with clinically approved inhibitors. Genetic and pharmacological inhibition of TOP1 in multiple orthogonal assays resulted in MYC-driven cell death. Finally, drug response to TOP1 inhibitors correlated with MYC levels and activity across panels of breast cancer cell lines and patient-derived organoids, highlighting TOP1 as a promising target for MYC-driven cancers.

The recent accessibility of large-scale datasets detailing functional dependencies across hundreds of cancer cell lines offers an unprecedented opportunity to prioritize targets with greater translational relevance, which is a major limitation of the synthetic-lethal approach for target discovery. As a secondary analysis of our hits, we utilized DEPMAP data to classify cancer cell lines as relatively MYC-dependent or MYC-independent, enabling the *in silico* evaluation of each MYC-SL hit's differential essentiality. MYC-SLs that exhibited selective essentiality in MYC-dependent cell lines were prioritized for further investigation. Results from this strategy revealed critical MYC cofactors that have been validated by us and others (e.g., CDK9), providing confidence in this approach. Excitingly, previously underexplored targets were identified with promising validation to-date. Together, this work features two successful strategies to prioritize hits from hundreds of synthetic-lethal genome-wide CRISPR screens to identify novel MYC-driven vulnerabilities in cancer.

#4040 p63 represses metabolic pathways in aggressive bladder cancer.

Artem Smirnov[1], Mariacristina Franzese Canonico[1], Damiano Barnaba[1], Maurizio Fanciulli[2], Alessandro Mauriello[1], Gerry Melino[1], Eleonora Candi[1]

[1]Departement of Experimental Medicine, University of Rome Tor Vergata, Rome, Italy,[2]Dept. of Research, Advanced Diagnostics, and Technological Innovation, IRCCS Regina Elena NCI, Rome, Italy

Over half a million of people get bladder cancer (BLCA) each year worldwide with a third of all cases leading to death. Recent breakthroughs significantly improved early detection of BLCA, however little progress has been done to manage advanced invasive cancers since 1980s. Regulation of gene expression by key transcription factors governs multiple molecular pathways determining tumour evolution and selection. Here, we screen the transcription factors based on changes of their essentiality throughout bladder cancer evolution and identify p63 is a key factor. p63 is an oncogene in multiple epithelial tumours, however its expression is dramatically reduced in advanced BLCA, furthermore the loss of p63 is associated with a worse prognosis. Yet, little is known about p63 targetome in bladder cancer. In this work, we use transcriptomics, genome occupancy and chromatin accessibility assays to characterise global p63 targetome in BLCA in vitro along with bioinformatic analyses of gene expression in BLCA patients. We identify metabolism as a key pathway repressed by p63 during BLCA evolution and we show that activation of this pathway is associated with poor prognosis. In vitro, targeting of specific metabolic pathways induces cell death. Altogether, we identify an unexpected tumour-suppressive role for p63 in bladder cancer and propose novel therapeutic strategies for treatment of invasive BLCA.

#4041 Overexpression of HMGA1 in gastric cancer cells is associated with reduced tumor cell malignant behavior and decreased YAP-TEAD signaling.

Dipti Athavale, Yan-ting Yann Zhang, Xiaodan Yao, Shumei Song

Coriell Institute for Medical Research, Camden, NJ

Background: The High Mobility Group A1 (HMGA1) is an architectural transcription factor and facilitates the interaction between transcriptional regulatory proteins and DNA in different cancers by remodeling chromatin structure. Hippo/YAP1 pathway is an evolutionary conserved signaling consisting of up-stream kinases, transcriptional co-activators and scaffold proteins. Unphosphorylated YAP and TAZ translocate to the nucleus, bind with TEAD transcription factor family and induce expression of a wide range of genes involved in cell malignant behavior. Silencing of HMGA1 downregulated YAP activity in breast cancer however, the functional role of HMGA1 and its interaction with Hippo/YAP1 signaling in mediating gastric cancer (GC) progression and metastasis remains unknown. We hypothesize that HMGA1 is essential to promote YAP activity in gastric cancer.
Methods: TCGA dataset and our own bulk RNAseq and single cell RNA sequencing (scRNAseq) will be analyzed to understand the expression pattern of HMGA1 in normal, primary tumors and metastatic tissues. HMGA1 will be overexpressed in GC cells; and YAP activity will be measured by its nuclear translocation, transcription of target genes (CTGF, CyR61, Birc5, Sox9) upon genetic modulation of HMGA1. *In vitro* functional assays such as proliferation, migration, colony formation and tumor sphere as well as *in vivo* tumorigenicity of GC cells with HMGA1 overexpression will be performed in SCID mice.
Results: HMGA1 expression was significantly increased in GC tissues compared to normal in TCGA datasets. Moreover, HMGA1 transcripts showed positive correlation with YAP1 and TEAD4 mRNA level. scRNAseq data from advanced GC patients indicated HMGA1 mRNA is upregulated in primary tumor, peritoneal and liver metastasis compared to normal in stomach. Tissue microarray of more than 200 GC indicated that HMGA1 is highly expressed in tumor tissue and associated with poor survival. Increased expression of HMGA1 was detected in cancer cells as compared to normal gastric epithelial cells by Western blot. Unexpectedly, overexpression of HMGA1 in GC cell lines (AGS, GA0518 and GT-5) reduced colony formation, and tumor-sphere size and number as compared to vector control. Invasion of AGS, GA0518 and GT-5 was significantly reduced upon HMGA1 overexpression. Mechanistically, nuclear localization of YAP, TAZ and SOX9 (YAP target) was decreased while Tead1-4 did not change in GC cells upon overexpressing HMGA1 compared to vector. Furthermore, YAP-TEAD luciferase reporter activity was significantly reduced along with transcript level of YAP target genes upon HMGA1 overexpression *vs.* vector in GC cells.
Conclusion: Although, endogenous expression of HMGA1 was increased in GC cells and tissues as compared to normal, its overexpression reduced tumor cell malignant behavior, migration and inhibited YAP-TEAD signaling.

#4042 Mitochondrial electron transport chain inhibition suppresses NRF2 expression in NSCLC.

Chang Jiang[1], Ryan Martin[1], Yun Huang[1], Nicolas Prieto[2], Yun Pyo Kang[3], Mingxiang Teng[1], Gina DeNicola[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]University of South Florida, Tampa, FL,[3]Seoul National University, Seoul, Korea, Republic of

Lung cancer is the leading cause of cancer-associated death in the US. Non-small cell lung cancer (NSCLC) accounts for 85% of all diagnosed lung cancer cases, which has a high frequency of mutations in the KEAP1/NRF2 circuit (15-34%). NRF2 is a stress-responsive transcription factor that regulates transcriptional programs in response to oxidative stress. KEAP1 directs NRF2 degradation, and accordingly, disruption of KEAP1 increases the abundance and activity of NRF2. KEAP1/NRF2 mutations result in constitutive NRF2 activation and chronic induction of a battery of NRF2 target genes, which confer profound resistance to chemo/radiation therapy. Although direct inhibition of NRF2 holds great therapeutic potential, NRF2 inhibitors have not yet existed in the clinic. Instead, our attempt to address this challenge focuses on targeting upstream NRF2 regulators in NSCLC. To this end, we leveraged CRISPR/Cas9-based genetic screening approaches. We found that electron transport chain (ETC) complex I/III component deletion or pharmacological inhibition results in complete loss of NRF2 protein expression in KEAP1 mutant NSCLC cells. Our results indicate that NRF2 destruction by ETC inhibition is associated with post-translational ubiquitination and degradation facilitated by an alternative E3 ligase within the Cullin complex and is controlled by AMPK. We also translate these findings *in vivo* using novel NRF2 active genetically engineered lung tumor mouse models LSL-$Kras^{G12D}$; $Lkb1^{flox/flox}$; $Nrf2^{D29H}$ that mimic the common co-occurrence of KRAS and Lkb1 loss-of-function mutations in human lung adenocarcinoma. This work establishes the link between the mitochondria and NRF2 regulation in NSCLC and, more importantly, will lead to the discovery of novel mediators of this signaling, which can be targeted as a therapeutical strategy for NRF2 inhibition. Overall, our research has great implications in reversing the profound resistance of NSCLC with KEAP1/NRF2 mutations to chemo/radiotherapy, which can significantly improve treatment efficacy and patient survival.

#4043 MYB/AKT3 axis is a key driver of ovarian cancer growth and aggressiveness.

Kunwar Somesh Vikramdeo[1], Orlandric Miree[2], Shashi Anand[1], Sanjeev Kumar Srivastava[2], Seema Singh[1], Rodney P. Rocconi[3], Ajay Pratap Singh[1]

[1]Cell and Molecular Biology, University of Mississippi Medical Center, Jackson, MS,[2]University of South Alabama, Mobile, AL,[3]University of Mississippi Medical Center, Jackson, MS

Ovarian cancer (OC) is the most common and lethal gynecologic malignancy in the United States, primarily due to late-stage diagnosis and limited treatment options for the advanced disease. It disproportionately affects Black women at every stage, from initial diagnosis to treatment, resulting in higher mortality rates compared to non-Hispanic White women. In an effort to identify novel biomarkers and therapeutic targets for improved clinical management, we discovered *MYB* as a differentially-expressed gene in OC, exhibiting a race-specific prognostic association. *MYB* encodes for a transcription factor protein that drives oncogenesis by regulating the expression of a wide array of gene targets. We also found that MYB is expressed in OC cell lines, having elevated levels in aggressive (SKOV3-ip) and chemo-resistant (A2780-Cip) variants compared to their parental counterpart (SKOV3 and A2780) cell lines. Gain- and loss-of-function studies suggested that MYB plays a role in growth, aggressiveness, and chemoresistance. Gene expression profiling of low (SKOV3-Neo) and high (SKOV3-ip-Scr) MYB-expressing cells along with their forced MYB-expressing (SKOV3-MYB) and MYB-silenced (SKOV3-ip-shMYB) derivative lines using the nCounter® PanCancer Progression panel on a nanoString nCounter system, revealed several MYB-driven differentially expressed genes (DEGs). With a 1.5-fold-change cutoff, we identified 164 DEGs in the SKOV3-ip (Scr vs. shMYB) comparison and 87 DEGs in SKOV3 (Neo vs. MYB) comparison. Notably, the majority of DEGs were distinct between these comparisons, suggesting that MYB alters gene expression in a cell-specific manner. Validation of commonly altered genes in additional paired MYB-overexpressing and silenced cell lines by qRT-PCR identified *AKT3* as a significant downstream target of MYB. Moreover, KEGG pathway analysis of DEGs in MYB-modulated cells highlighted PI3K pathway as commonly altered. *In silico* analysis of *AKT3* promoter identified seven putative MYB binding regions (P1-P7), and chromatin immunoprecipitation confirmed strong MYB binding to P4 region of the AKT3 promoter. Inhibition of AKT3 through RNA interference resulted in reduced cell proliferation, clonogenicity, migration and invasion, and increased apoptosis in OC cells. These findings suggest that AKT3 serves as a key mediator in driving the oncogenic actions of MYB in ovarian cancer.

#4044 Hypomethylation and overexpression of transcription factor AP2B promote growth in ILC via cell cycle modulation.

Abdalla M. Wedn[1], Hunter Waltermire[2], Haley Arbore[3], Daniel Brown[4], Osama Shah[5], Fangyuan Chen[6], Sanghoon Lee[7], Jagmohan Hooda[2], Adrian Lee[2], Steffi Oesterreich[2]

[1]Department of Pharmacology and Chemical Biology, University of Pittsburgh School of Medicine, Pittsburgh, PA,[2]Women's Cancer Research Center, Magee Women's Research Institute, UPMC Hillman Cancer Center, Pittsburgh, PA,[3]University of Pittsburgh School of Medicine, Pittsburgh, PA,[4]Institute for Precision Medicine, University of Pittsburgh, Pittsburgh, PA,[5]University of Nebraska Medical Center, Omaha, NE,[6]Dana-Farber Cancer Institute, Boston, MA,[7]New York University Langone Health, New York, NY

Invasive lobular carcinoma (ILC) is responsible for 10%-15% of all invasive breast cancers and is associated with worse long-term outcomes compared to the most common no special type (NST). Despite known differences between ILC and NST, the treatment for ILC is the same as stage matched NST. Therefore, identifying the biological molecules that are specific for ILC and can be therapeutically targeted is an urgent need. In this context, we recently identified the transcription factor AP2b (TFAP2B) as one of the most hypomethylated genes in ILC compared with NST and normal mammary tissues. Consistently, differential gene expression analysis in TCGA, METABRIC and SCAN-B datasets confirmed the upregulation of TFAP2B expression in ILC. Methylation of CG island in the first exon possesses the highest correlation with mRNA expression levels. Here, we examined the role of this transcription factor in ILC using various models including cell lines, patient derived organoids (PDOs) and tumor samples. Immunoblotting and RT-qPCR confirmed the specific upregulation of TFAP2B in ILC compared with NST cell lines and PDOs. Immunofluorescence showed a clear nuclear localization of TFAP2B and immunohistochemistry revealed a strong and uniform expression in tissues isolated from ILC patients. TFAP2B knockdown (using siRNA and inducible shRNA) significantly reduces the growth of ILC cell lines and PDOs in anchorage dependent and independent conditions as well as colony formation assay. The actions of TFAP2B seem to be mediated, at least in part, through cell cycle as knockdown of this factor decreases and increases the percentage of cells in S and G0/G1 phase, respectively. CDH1 knockout or inducible expression in NST or ILC cell lines failed to affect TFAP2B levels indicating that changes in E-cadherin levels, in the transformed cells, are not sufficient to alter TFAP2B expression. Preliminary data from CUT and RUN sequencing indicate possible binding sites for TFAP2B in growth factors and cell cycle related genes. Collectively, the data support the specific enhancement of TFAP2B in ILC and its importance for cell proliferation. Future studies will be conducted to uncover the interaction partners and pathways regulated by TFAP2B. This could serve as a basis for the development of novel therapeutic approaches that can be tailored specifically to patients with ILC tumors.

#4045 Leiomyosarcoma is characterized by two distinct subtypes driven by NFI or AP1 transcription factors.

Ryan A. Denu, Zhao Zheng, Yingda Jiang, Veena Kochat, Emre Arslan, Danh D. Truong, William Padron, Davis R. Ingram, Khalida M. Wani, Diana Shamsutdinova, Ravin Ratan, Neeta Somaiah, Christina L. Roland, Pamela T. Soliman, Larissa A. Meyer, Alexander J. Lazar, Elise F. Nassif Haddad, Emily Z. Keung, Kunal Rai

The University of Texas MD Anderson Cancer Center, Houston, TX

Objective: Leiomyosarcoma (LMS) is a smooth muscle-derived tumor documented to display significant heterogeneity. Although bulk transcriptome studies have been reported in LMS, single-cell characterization has been lacking to assess intra-tumoral cellular heterogeneity. We aimed to characterize heterogeneity, create a single-cell atlas, define molecular subtypes, and identify gene regulatory networks underlying the heterogeneity of LMS.
Methods: We performed single nucleus multiome sequencing with concurrent RNA sequencing (snRNA-seq) and assay for transposase-accessible chromatin (snATAC-seq) using 16 fresh frozen, untreated LMS samples (9 retroperitoneal/vascular, 4 uterine, and 3 extremity). We delineated malignant cells from benign cells using InferCNV and CytoTRACE analyses. Spatial transcriptomic analysis was performed on 12 LMS tissue microarrays (~250 total tissue cores, mostly pre-treated tumors) using 10x Xenium and a custom 480-gene panel informed by snRNA-seq data. Human LMS cell lines were employed to functionally validate findings from these data.
Results: We obtained high-quality data from 94,439 nuclei for snRNA-seq and 89,702 nuclei for snATAC-seq. Malignant cells were characterized by a less differentiated state by CytoTRACE and higher CNVs. UMAP analysis identified 15 different cell clusters including 12 malignant cell clusters and 3 non-malignant cell clusters. Some malignant cell clusters showed signs of aberrant differentiation with enrichment of osteoblastic and neural pathways. Malignant cells fell almost exclusively into 2 distinct subtypes: a dedifferentiated subtype with mesenchymal features (MES) and a differentiated subtype with enrichment of smooth muscle cell markers (SMC). Integration of chromatin accessibility data showed enrichment of nuclear factor I (NFI) transcription factor (TF) motifs in the MES and AP-1 (BACH2, FOSB, and FOSL2) motifs in the SMC group. Whole genome sequencing did not reveal an obvious genomic etiology for these subtypes. Expression of these TFs was observed in LMS cell lines. Depletion of NFI TFs, namely NFIX, reduced proliferation and invasion of LMS cell lines. Spatial transcriptomics identified spatial relationships between these subtypes and infiltrating immune cells. This revealed a greater tendency for immunosuppressive macrophages to cluster around MES cells compared to SMC cells.
Conclusion: We produced an atlas of the LMS single-cell transcriptome and epigenome. We demonstrate the presence of two predominant malignant cell clusters with dedifferentiated/mesenchymal or smooth muscle cell-like properties, a novel finding in LMS, and implicate NFI and AP-1 TFs in driving this heterogeneity.

#4046 Role of kaiso in androgen receptor signaling and castration resistance.

Oceane Kircha Nana[1], Huixian Lin[1], Isra Elhussin[1], Md. Abu Siddique[2], Omna Hayyat[1], Moray Campbell[3], Clayton Yates[1]

[1]Johns Hopkins University School of Medicine, Baltimore, MD,[2]Tuskegee University, Tuskegee, AL,[3]Cedars Sinai, Los Angeles, CA

Metastatic PCa patients are treated with androgen deprivation therapy (ADT) alone or ADT together with antiandrogens such as enzalutamide (Enza). ADT/Enza targets AR-expressing PCa cells; therefore, the mechanisms underlying ADT/Enza resistance involve AR genomic alterations, AR splice variants, and persistent AR signaling even under castrated conditions. Our lab recently identified Kaiso, a BTB-POZ methyl-binding transcriptional regulator, as a crucial player in AR signaling networks. However, it is known how Kaiso potentially influences progress and treatment outcomes. Firstly, we established that Kaiso expression levels increased, as well as a cytoplasmic to nuclear localization occurred during Enza treatment. Additionally, utilizing ChIP and Cut-n-Run assays we observed that Kaiso directly binds to the methylated regions within the AR promoter. Utilizing AR-specific methylation-sequencing, we further observed that CGCG-rich regions in the AR promoter can be modulated utilizing both Kaiso depleted (sh-Kaiso) and Kaiso (overexpression) OE cell lines. Furthermore, modulation of Kaiso expression levels influences both AR and PSA. RNA-seq of Kaiso OE cells demonstrate significant AR and PSA overexpression, as well as GSEA enrichments highlight that androgen receptor signaling, epithelial to mesenchymal transition, and MYC signaling as the most significant pathways. Finally, sh-Kaiso cells displayed increased sensitivity to both Enza and ABi, while Kaiso OE cell lines displayed a complete lack of response to both compounds. In summary, our findings suggest that Kaiso levels may significantly influence androgen sensitivity and highlight Kaiso as a therapeutic target to improve conventional AR-directed therapies.

#4048 The circadian gene Dec2 promotes pancreatic cancer dormancy by regulating tumor cell antigen presentation to facilitate immune evasion.

Lan Wang[1], Chris Harris[2], Orjola Prela[2], Wade Narrow[2], Jennifer L. Becker[3], Juliana Cazarin de Menezes[4], Darren R. Carpizo[2]

[1]Pathology, University of Rochester Wilmot Cancer Institute, Rochester, NY,[2]Surgery, University of Rochester Wilmot Cancer Institute, Rochester, NY,[3]Center of Advanced Research, University of Rochester Wilmot Cancer Institute, Rochester, NY,[4]Biomedical Genetics, University of Rochester Wilmot Cancer Institute, Rochester, NY

The mechanisms that regulate cancer dormancy remain poorly understood. Using an orthotopic mouse model of resectable pancreatic adenocarcinoma (PDAC), we identified the transcriptional repressor factor Dec2 (*Bhlhe41*) as a gene that was upregulated in metastatic dormant tumor cells from the liver. To understand how Dec2 regulates dormancy, we deleted it from the murine pancreatic cancer cells and implanted them in the model. Following resection, mice implanted with Dec2 KO cells demonstrated a striking improvement in survival compared to the mice with Dec2 WT cells. This difference in survival was abrogated when nude mice were used as hosts indicating the survival difference is from an immune mediated mechanism. Pancreatic cancer is a highly immunosuppressive tumor due to both a relatively low expression of major histocompatibility complex class I (MHC-I)-dependent antigen presentation and an abundance of myeloid-derived suppressor cells that lead to poor T cell trafficking and activation. We found that deletion of Dec2 overcame both of these mechanisms to restore anti-tumor immunity that inhibited tumor growth not only in primary tumors as well as metastases. Dec2 suppresses MHC-I antigen presentation by repressing multiple genes in the antigen presentation pathway including H2-k1, H2-d1, Tap1, and B2m as well as the source of tumor antigens from the proteosome by repressing multiple proteasome genes. Loss of Dec2 repolarized the tumor immune microenvironment by decreasing expression of multiple immunosuppressive cytokines such as Cxcl1, Ccl2 and Csf2 in tumors. We conclude that Dec2 facilitates both pancreatic tumor growth and dormancy by regulating tumor cell MHCI antigen presentation. Dec2 is known to function as part of a negative accessory arm of the molecular circadian clock. We found several components of the antigen presentation pathway oscillated in a circadian manner that was lost upon deletion of Dec2. Moreover, T-cell mediated tumor cell killing varied depending on the time of day. We suggest that lowered MHC-I presentation of antigens during rest phase is a natural effect of the circadian clock.

#4049 Transcriptional regulation of FOXA1 by GATA2/3 attenuates the antitumor effects of histone deacetylase (HDAC) inhibitors in basal-like breast cancer.

Congcong Tan, Hui Lyu, Yakun Wu, Margaret E. Larsen, Shou-Ching Tang, Bolin Liu

LSU Stanley S. Scott Cancer Center (SSSCC), New Orleans, LA

Introduction: Basal-like breast cancer (BLBC), an aggressive subtype of triple-negative breast cancer (TNBC), exhibits a high risk of recurrence and resistance to conventional treatments. Histone deacetylase inhibitors (HDACis), such as panobinostat and romidepsin, are approved for hematopoietic malignancies and have shown effectiveness against TNBC cells. Our study demonstrated that HDACis inhibited BLBC cell growth and induced apoptosis by suppressing HER3 expression via transcriptional downregulation of forkhead box protein A1 (FOXA1). However, the mechanisms by which HDACis regulate the expression of FOXA1 remain unclear.
Methods: Cell viability was evaluated using colony formation, MTS, and LIVE/DEAD cell staining assays. Apoptosis was assessed by flow cytometry. Gene and protein expression levels were analyzed via qRT-PCR, Western blotting, and immunohistochemistry (IHC). Co-immunoprecipitation was used to evaluate protein interactions. Lentiviral vectors carrying cDNA or shRNAs enabled overexpression or knockdown of target genes. Chromatin immunoprecipitation-quantitative PCR elucidated transcriptional regulatory mechanisms. *In vivo* experiments were conducted to examine therapeutic effects. Kaplan-Meier analysis evaluated clinical outcomes.
Results: FOXA1 was highly co-expressed with HER3 in BLBC specimens and cell lines, and FOXA1 induced HER3 expression. Panobinostat and romidepsin inhibited BLBC cell growth and induced apoptosis by suppressing FOXA1 expression and HER3 signaling. Gene expression profiling revealed a significant positive correlation between FOXA1 and transcription factors GATA2/3. High GATA2/3-FOXA1 expression correlated with poorer relapse-free survival (RFS) in BLBC patients. Mechanistic studies confirmed that GATA2/3 transcriptionally regulated FOXA1 by directly binding to its promoter. Overexpression of GATA2 in BLBC cells restored FOXA1 expression downregulated by HDACis and reduced their antitumor effects. Importantly, *in vivo* experiments showed that HCC1806 xenografts overexpressing GATA2 were less sensitive to panobinostat treatment. Consistent with these findings, IHC analyses revealed higher FOXA1 and HER3 expression in GATA2-overexpressing tumors.
Conclusion: HDACis exhibit potent antitumor effects in BLBC by suppressing the GATA2/3-FOXA1-HER3 axis. Our study highlights the critical role of GATA2/3 in transcriptionally regulating FOXA1 and mediating resistance to HDACis. These findings suggest that targeting the GATA2/3-FOXA1-HER3 axis may represent a promising therapeutic strategy for BLBC.

#4051 STK11-dependent NFkB localization drives characteristic transcriptional signatures in lung cancer.

Allison R. Racela[1], Sean M. Lenahan[2], Paula B. Deming[1], David J. Seward[1]

[1]University of Vermont, Burlington, VT,[2]Dana-Farber Cancer Institute, Boston, MA

Lung cancer is responsible for more deaths annually in the U.S. than any other cancer. Despite recent advances in lung cancer detection and treatment, the overall prognosis for patients remains poor since many are diagnosed at an advanced stage where the 5-year survival rate is less than 25%. Immune checkpoint inhibitors (ICI) have dramatically improved outcomes in patients with lung cancer by targeting mechanisms of immune evasion. Unfortunately, only ~30% of lung adenocarcinomas (LUADs) respond to anti-PD-1 therapy and we cannot reliably identify this group prior to treatment with ICIs. This underscores the need to identify which patients will respond to ICI therapies, while simultaneously highlighting the ~70% non-responder rate. Recent clinical studies have identified a subgroup of patients with KRAS-driven lung adenocarcinoma (LUAD) who exhibit anti-PD-1 therapy resistance. This group is characterized by tumors with the loss of function (LoF) of Serine/Threonine kinase 11 (STK11). STK11 operates in a heterotrimeric complex with the pseudo-kinase STRADα and the scaffolding protein MO25 where it regulates numerous intracellular signaling networks impacting metabolism, proliferation, transcription, and cell morphology. Why STK11 LoF correlates with anti-PD-1 resistance in the context of KRAS-driven LUAD remains unknown and represents a critical question in lung oncology. We performed whole transcriptome and pathway enrichment studies comparing KRAS-driven/STK11-compentent LUAD cell lines with KRAS-driven/STK11-null lines and identified STK11-loss-dependent differential gene expression profiles consistent with activation of the NF-kappa B (NF-kB) signaling pathway. Based on this analysis, we hypothesize that STK11 LoF leads to constitutive NF-kB-mediated transcriptional activation, including the upregulation of tumor-intrinsic, immune-evasion promoting cytokines, thereby connecting LUAD genotype with a putative mechanism explaining anti-PD1 resistance. Our ongoing studies aim to identify the downstream transcriptional effects of NF-kB activation and reveal the mechanism(s) linked to STK11 activity. To that end, we have established that NF-kB functions downstream of STK11. We demonstrate this relationship using the IKKB inhibitor PS1145. PS1145 blocks IKKB activation leading to NF-kB cytosolic sequestration and rescuing the STK11-loss-dependent transcriptional phenotype. In summary, our work highlights potential interventions to reduce ineffectiveness of immune-checkpoint inhibitor therapy by preventing tumor-intrinsic, genotype-dependent transcriptional changes contributing to immune-evasion. Understanding these molecular mechanisms could inform targeted therapies to overcome resistance and improve survival rates.

#4052 Biological Variations in NRF2 Hotspot Mutants.

Syed A. Ashraf[1], Anh Thi Thai[1], Jinghai Wu[1], McKenzie Kreamer[1], Katarina Benejova[2], Terry M. Williams[3], Martin Benej[2], Ioanna Papandreou[1], Nicholas C. Denko[1]

[1]Department of Radiation Oncology, The Ohio State University Comprehensive Cancer Center, Columbus, OH,[2]Department of Molecular Medicine and Therapeutics, The Ohio State University Wexner Medical Center, Columbus, OH,[3]Department of Radiation Oncology, City of Hope Cancer Center, Duarte, CA

Background: NRF2 is a transcription factor that is a master regulator for the cell's antioxidant response. Under normal conditions, NRF2 is rapidly degraded by cytoplasmic association with KEAP1 and subsequent ubiquitination and proteasomal degradation. Activating mutations in NRF2 contribute to lung cancer transformation. D29H, R34G, and E79Q are the most common mutations found in lung squamous cell carcinoma.
Methods: H520 lung cancer cells harbor an intact NRF2/KEAP system. H520 mutant cell lines were generated using lentivirus transduction of either WT or mutant NRF2 and confirmed by Western blot. Immunofluorescence was used to examine the effect of mutations on NRF2 levels and subcellular localization. Cells were tested for ROS levels by DCFFA fluorescence and subcellular NRF2 localization before and after treatment with tert-butyl hydroperoxide. Colony forming ability was tested after radiation with 0, 2, 4, or 6 Gy.
Results: D29H and R34G mutations result in increased NRF2 levels and stress-independent translocation to the nucleus compared to wild type NRF2. These mutant cells also showed higher expression of the NRF2 target gene G6PD. E79Q has little difference compared to wild type. All mutants showed decreased DCF fluorescence. With regards to colony formation ability, mutant cell lines were not statistically different from WT cells.
Conclusion: Our findings identified D29H and R34G as having increased nuclear levels and transactivation compared to WT cells. Despite the increased activity of NRF2 in these two mutations, there was little evidence for increased radiation resistance. These results indicate differential biological response of common NRF2 mutations.

#4053 Dynamic combinatorial p53 post-translational modifications regulate temporal transcription program and cell fates.

Dan Lu

Harvard Medical School, Boston, MA

The tumor suppressor p53 is activated by a range of cellular stresses including DNA damage, oncogenic signals, and nutrient deprivation. Upon activation, p53 transcriptionally upregulates an extensive repertoire of genes including those affecting cell fates such as cell cycle arrest, senescence, and apoptosis. What remains unclear is how information is conveyed through p53 to elicit the appropriate downstream responses according to the nature of the upstream stress. Changes in p53 temporal expression dynamics as well as specific p53 post-translational modifications (PTMs) are known to differentially regulate target gene induction. However, with over 100 known PTMs possible on p53, technical limitations have restricted the ability to detect the combinations of modifications on whole p53 molecules.
Using a state-of-the-art mass spectrometry method (I2MS) which enabled the first measurement of individual intact human p53 proteins, we have begun to uncover the landscapes of combinatorial PTMs from different p53 activation regimes in cancer cell lines. Together with complementary p53 modification specific antibodies we identified changes in PTM patterns which were both stimuli and time dependent. For example, we found that in response to double-strand DNA breaks, p53 exhibits pulses of expression. Furthermore, p53's post-translational modification state is altered between successive pulses, which we ascertained the most prominent temporal change in p53 PTMs in response to DNA damage to be a reduction of multiple p53 lysine acetylations. Inhibition of the deacetylase HDAC1, but not SIRT1, prevented the reduction in p53 acetylation, causing overexpression of senescence and apoptotic genes, and corresponding cell fates. Finally, we abrogated lysine acetylation by generating KR (lysine to arginine) mutations at single or multiple sites on p53, and found that acetylation sites are functionally non-redundant, with specific combinations exerting unique transcriptional effects on p53 target gene inductions. These results demonstrate an interplay between dynamics and modifications as a mechanistic strategy for cellular hubs like p53 to temporally organize multiple processes in individual cells. In addition, it highlights the importance of accounting for dynamical combinations of p53 PTMs in order to achieve the desired cellular response and efficacy of p53-mediated cancer therapies.

#4054 Heme oxygenase 1 and its nuclear interactors: a novel perspective on neuroendocrine prostate cancer.

Rocio A. Seniuk[1], Agustina Sabater[2], Juan Bizzotto[3], Gaston Pascual[1], Julia Lechuga[4], Estefania Labanca[5], Nicolas Anselmino[5], Elba Vazquez[1], Javier Cotignola[1], Pia Valacco[1], Geraldine Gueron[1], Ayelen Toro[1], Pablo Sanchis[2]

[1]IQUIBICEN (UBA-CONICET), Buenos Aires, Argentina,[2]Department of Genitourinary Medical Oncology, IQUIBICEN (UBA-CONICET), Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), The University of Texas MD Anderson Cancer Center, Buenos Aires, Argentina,[3]IQUIBICEN (UBA-CONICET), Universidad Argentina de la Empresa (UADE), Instituto de Tecnologia (INTEC), Buenos Aires, Argentina,[4]University of Buenos Aires, Buenos Aires, Argentina,[5]MD Anderson Cancer Center, Houston, TX

Heme-oxygenase 1 (HO-1), the rate-limiting enzyme for heme degradation, has been implicated with a non-canonical antitumor role in prostate cancer (PCa). This study addressed the hypothesis that HO-1 exerts its antitumor effects through its protein interactome, aiming to identify HO-1's nuclear interactors and their potential association with specific PCa phenotypes. PCa cells were treated with hemin (80 µM, 24 h), a specific pharmacological inducer of HO-1, followed by HO-1 immunoprecipitation (IP) and LC-ESI MS/MS analysis, leading to the identification of 42 HO-1 interactors. Since we were interested in the nuclear functions of HO-1 we continue this work focusing in the 11 interactors that appeared only in the nucleui of hemin treated cells. Based on our hypothesis that nuclear HO-1 influences the activity of various transcriptional regulators, ChIP Atlas analysis identified four of 11 interactors—ILF3, DDX17, BCLAF1, and SAFB—as DNA-binding factors with regulomes significantly linked to neurological disorders. To explore the relevance of these interactors in PCa, we analyzed RNA-seq data from the MDA-PCa-PDX series (PCa Patient-Derived Xenografts Program, MD Anderson Cancer Center), which reflects the heterogeneity of PCa. Unsupervised clustering based on the expression of HO-1 interactors revealed that samples with high expression of these genes were predominantly associated with neuroendocrine prostate cancer (NEPC). Further bioinformatics analysis, comprising transcriptomic and clinical data from NEPC patients, demonstrated that the expression of HO-1 interactors distinctly clustered a subgroup of large cell neuroendocrine carcinoma samples characterized by elevated levels of *ILF3, DDX17, SAFB, BCLAF1,* and low expression of *HMOX1.* To functionalize these results *in vitro*, we established a protocol to transdifferentiate C4-2B cells to neuroendocrine (NE) cells using Forskolin (Fsk). Fsk (10uM, 48h) treated cells showed increased expression levels of NE markers namely *NSE, EZH2* and *SOX2.* Also, treatment with Fsk increased neurite-like processes formation, branch points formation and neurite-like processes length, consistent with a NE-like phenotype. In line with the previous bioinformatics analyses, we observed a significant suppression of *HMOX1 ($p<0.05$)* expression in NE-like C4-2B cells. Strikingly, this phenotype was accompanied by a significant induction of *BCLAF1 ($p<0.05$)* levels, reinforcing its implication in NEPC. Moreover, we confirmed by IP-Western blot HO-1/BCLAF1 physical interaction. In conclusion, our findings suggest that HO-1 exerts its non-canonical antitumor role in PCa by negatively regulating key nuclear interactors, including BCLAF1, ILF3, DDX17, and SAFB. This regulatory mechanism appears to suppress aggressive neuroendocrine phenotypes, particularly in NEPC samples, highlighting its potential as a therapeutic target.

#4055 Estrogen receptor beta suppresses melanoma progression through modulation of melanocyte master regulator activity.

Jocelyn Treneff, Amanda McCrary, Craig Burd

The Ohio State University, Columbus, OH

Female sex is associated with lower overall melanoma incidence and mortality, with estrogen signaling thought to protect against disease progression. Genomic estrogen signaling is mediated by estrogen receptors alpha (ERα) and beta (ERβ), which function as ligand-activated transcription factors. Notably, ERβ expression shows an inverse correlation with tumor thickness in the skin and is often lost in advanced melanomas, suggesting that ERβ activity may repress melanoma development. Here, we demonstrate that germline ERβ knockout leads to reduced melanoma-free survival in a murine model of $NRAS^{Q61R}$ spontaneous melanomas. While this implicates ERβ as a tumor suppressor, little is understood about the molecular activities of ERβ in melanomas and in melanocytes prior to transformation. To elucidate the genomic actions of the receptor, we performed ChIP-Seq in immortalized human melanocytes. We found that ERβ binding regions significantly overlap with those of MITF, a transcription factor that acts as a master regulator of melanocyte development. Changes in melanoma cellular phenotypes, such as increased proliferation, dedifferentiation, or invasiveness, are thought to be driven by differences in MITF activity. Therefore, we hypothesize that ERβ modulates MITF transcriptional activity in a way that suppresses melanoma progression. Using a reporter construct with activity driven by the tyrosinase (TYR) promoter, we showed that ERβ activation coincided with altered MITF regulation of reporter activity. As we have characterized overlapping ERβ and MITF recruitment in the TYR promoter, this result supports the hypothesis that ERβ co-binding can influence MITF transcriptional programs. Additionally, transcriptome analysis revealed that estrogen-responsive genes in melanocytes are enriched for migration and differentiation, biological processes that are directed by MITF and dysregulated in melanomas. Taken together, these findings indicate that ERβ functions as a tumor suppressor in melanoma by reprogramming MITF activity, identifying a new avenue through which melanoma may be better understood at the molecular level.

#4056 Determining the role of ZNF687, an uncharacterized zinc finger transcription factor, in lung adenocarcinoma (LUAD).

Xingyu Liu[1], Yixuan Xie[1], Zongtao Lin[1], Patrick Pribil[2], Benjamin Garcia[1]

[1]Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Sciex Canada, Concord, MO, Canada

Introduction: ZNF687, a relatively understudied ZnTF, has been identified as a potential biomarker for lung adenocarcinoma (LUAD) through bioinformatic analysis of The Cancer Genome Atlas (TCGA) database, revealing its frequent upregulation in early-stage LUAD patients. This study aims to elucidate the molecular mechanisms that explain the role of ZNF687 in LUAD using liquid chromatography-mass spectrometry (LC/MS)-based proteomics approaches.

Methods: LUAD cell lines NCI-H1437 and Hcc2935 were obtained from ATCC. lentiviral system was employed to deliver shRNA targeting ZNF687 into the LUAD cells. An inducible expression system for tagged ZNF687 was generated in LUAD cells using the PiggyBac transposon system. Proteomics samples were processed with S-Trap and analyzed with LC/MS.

Results: We began by analyzing protein interactions of ZNF687. Compared to a control purification, several interaction candidates were significantly enriched in ZNF687 purifications. Among the top candidates identified were ZMYND8 and ZNF592, two ZnTFs previously reported to form the co-regulatory "Z3" complex with ZNF687. Other notable candidates included TSPYL2, a nucleosome assembly protein; KDM5C, a histone H3 lysine 4-specific demethylase; and the casein kinase 2 (CK2) complex.

Next, whole proteome profiling was conducted for each LUAD cell line, with or without ZNF687 knockdown via shRNA. Using a data-independent acquisition and label-free quantification approach, we quantified over 5,000 proteins. With a fold-change cutoff of 2 and a Q-value threshold of 0.05, more than 500 proteins showed significant abundance changes upon ZNF687 knockdown in Hcc2935 cells, while over 700 proteins were significantly altered in NCI-H1437 cells. Notably, the whole proteome analysis revealed an upregulation of epithelial-mesenchymal transition (EMT)-associated proteins following ZNF687 knockdown in both cell lines, suggesting an unexpected repressive role of ZNF687 in EMT. Further examination of common EMT markers, CDH1 and CDH2, in cells overexpressing ZNF687 revealed changes opposite to those observed with ZNF687 knockdown.

Conclusions: Given that both LUAD cell lines used in this study were derived from stage I patients and primarily exhibited epithelial characteristics, these findings suggest that the upregulation of ZNF687 in early-stage LUAD may play a role in preventing disease progression. Based on the identification of KDM5C as a potential ZNF687 interactor, we proposed the following model: ZNF687 recruits KDM5C to EMT related genes; subsequently, the expression of EMT genes are down regulated due to the loss of H3K4me3 from those chromatin regions, resulting in suppression of the EMT process.

#4057 Mechanism of TAL1 activation by alterations in the downstream enhancer in childhood T-lineage acute lymphoblastic leukemia.

Nadezhda V. Terekhanova[1], Xiaolong Chen[1], Wentao Yang[1], Ying Shao[1], Li Dong[1], Bensheng Ju[1], Yu Liu[1], John Easton[1], A. Thomas Look[2], Jinghui Zhang[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]Dana-Farber Cancer Institute, Boston, MA

The transcription factor (TF) TAL1 is a master regulator expressed at the early stages of normal thymocyte development. It is one of the major drivers in childhood T-lineage acute lymphoblastic leukemia (T-ALL) and is aberrantly activated in 30-40% of T-ALL. While somatic alterations in upstream and intronic cis-regulatory regions of *TAL1* are known mechanisms of activation, the role of downstream enhancer alterations (DEAs) remains less understood. We investigated somatic alterations in an intergenic region 11Kb downstream of *TAL1*, identifying a complex indel that created a *de novo* MYB transcription factor binding site (TFBS), and a 2.4Kb internal tandem duplication (ITD) encompassing a MYB TFBS. Alterations in this region were found to be present in 2% of the samples in a recent T-ALL landscape study involving 1,335 cases. Using the patient-derived xenograft (PDX) mouse models of the two T-ALLs harboring the complex indel and ITD DEA, we performed multi-omic profiling, including H3K27ac, H3K4me1, H3K27me3 and MYB chromatin immunoprecipitation sequencing (ChIP-seq); assay for transposase-accessible chromatin using sequencing (ATAC-seq), Hi-C, RNA-seq and full-length transcriptome sequencing (Iso-seq). Enhancer activity by DEA was validated by presence of H3K27ac peaks and cis-activation of *TAL1* which exhibits mono-allelic expression in both the primary tumors and PDX models. Involvement of MYB in enhancer activity is validated by MYB ChIP-seq peaks centered around the *de novo* and existing MYB TFBSs. Interestingly, we found that *TAL1* activation via DEA led to preferential initiation of transcription from the promoter located at the exon 4, resulting in predominant expression of the *TAL1*-short isoform in cases with DEA. Indeed, *TAL1*-short expression accounted for 78% of the *TAL1* expression in T-ALLs harboring DEA in contrast to the 37% frequency in other *TAL1*-activated T-ALLs (Wilcoxon two-sided test P=0.001). Furthermore, using the full-length transcripts generated by PacBio Iso-seq platform on the PDX samples, only *TAL1*-short transcripts were detected. By comparing Hi-C data generated from our PDX samples with those from Jurkat (TAL1+, with upstream enhancer region) and DND41 (TAL1-) cell lines, we identified a re-organization of chromatin looping structure showing distinct interaction between DEA region and *TAL1* promoter at exon 4. This study provides a detailed view of the regulatory mechanism of *TAL1* activation by DEA, indicating that preferential expression of *TAL1*-short isoform, protein product of which is known to bind more strongly to TAL1 E-protein partners than that of *TAL1*-long isoform, is active in initiating and maintaining the TAL1 core regulatory circuit in the transformation of pre-T cell progenitors in T-ALL.

#4058 CUT&RUN reveals E2F7 as a key transcriptional regulator of oncogenic functions in neuroendocrine small cell lung cancer.

Meijun Du[1], Jessica Schmeling[1], Angela Mathison[2], Victor Jin[3], Hui-Zi Chen[1]

[1]Division of Hematology & Oncology, Department of Medicine, Medical College of Wisconsin, Waukesha, WI,[2]Linda T. and John A. Mellowes Center for Genomic Sciences and Precision Medicine, Medical College of Wisconsin, Waukesha, WI,[3]Data Science Institute, Medical College of Wisconsin, Medical College of Wisconsin, Waukesha, WI

Small cell lung cancer (SCLC) is a molecularly heterogeneous disease, classified into neuroendocrine (NE) and non-neuroendocrine (non-NE) subtypes. The NE subtypes, including ASCL1 and NEUROD1, account for approximately 80% of SCLC cases. E2F7, a non-canonical E2F transcription factor family member, regulates cell cycle progression, and its dysfunction has been linked to cancers. A recent study identified E2F7 as a cofactor of ASCL1, enhancing its neurogenic activity. However, the role of E2F7 in SCLC subtypes is not yet clearly defined. The objective of this study is to profile both common and subtype specific E2F7 target genes and pathways that contribute to pathogenesis and may serve as targets for therapeutic intervention. To identify E2F7 targets in NE SCLC subtypes, we performed CUT&RUN (Cleavage Under Targets & Release Using Nuclease) in ASCL1 (DMS79, H146) and NEUROD1 (H82, H446) cell lines. Two antibodies against E2F7 and one against histone H3K4me3, marks of active gene promoters, were used in each cell line, with IgG as a negative control. Total 32 CUT&RUN next generation sequencing libraries (NGS) were generated and sequenced. NGS data was analyzed with a custom bioinformatics pipeline, using SEACR for peak calling and ChIPseeker for annotation. The identified E2F7 targets were then correlated with RNA-seq data from the CCLE database. In both ASCL1 and NEUROD1 cell lines, ~95% of E2F7-bound peaks were within 1 kilobase (kb) of gene promoters, most co-localizing with H3K4me3 peaks. Combining peaks from two E2F7 antibodies, we identified 872 E2F7 target genes in H146 (ASCL1) cell line, 818 in DMS79 (ASCL1) and 754 in H446 (NEUROD1). Fewer E2F7 peaks were called for H82 (NEUROD1) due to higher background. These targets included common and subtype-specific genes. Notably, E2F1 (regulator of G1/S transition) and EZH2 (mediator of the repressive H3K27me3 mark) were common targets, while DLL3 (target of multiple therapeutics in clinical development for SCLC) was ASCL1-specific, and CD82, a cell surface glycoprotein involved in cancer cell signaling, was NEUROD1-specific.Pathway analysis of E2F7-bound genes in ASCL1 and NEUROD1 cell lines revealed several shared pathways: cell cycle, spliceosome, ATP-dependent chromatin remodeling, and the Polycomb repressive complex. ASCL1-specific pathway was related to endocytosis, while NEUROD1 was linked to the HIF-1 signaling pathway. Correlation of E2F7 target genes with RNA-seq data revealed distinct gene expression patterns, specific to both the cell line and the subtype. These results offer new insights into E2F7-mediated transcriptional regulation in SCLC subtypes, providing a foundation for targeted therapeutic strategies. Our results support E2F7 as a master transcriptional regulator in SCLC and an important therapeutic target. Further analysis is needed to extend these findings to other subtypes, including POU2F3 and YAP1

#4059 CDK1-dependent hyperphosphorylation of NFIB governs its pro-metastatic function in SCLC.

Pawel Nowialis, Lina Song, Thi Na Nguyen, Thi Kim Ngan Bui, Wenjing Na, Ryan Clay, Kunyang Li, Lingtao Jin

UT Health Science Center at San Antonio, San Antonio, TX

Small cell lung cancer (SCLC) is a highly aggressive type of lung cancer. Its ability to form a metastatic spread in the early stages of disease accounts for high morbidity rates. Despite initial high rates of response to the most common line of treatment - conventional chemotherapy, majority of SCLC patients suffer from chemoresistant recurrence. Lack of full understanding of molecular basis driving metastasis and resistance are main obstacles in developing more efficient treatments. Several recent studies reported that nuclear factor I/B (NFIB) plays a role in promoting metastasis of SCLC through modulating chromatin accessibility. Moreover, NFIB is frequently found to be overexpressed or amplified in human SCLC and its high levels correlate with poor overall survival. Although oncogenic properties of NFIB have also been reported in studies on melanoma and triple negative breast cancer, other research, involving non-small cell lung cancer, glioblastoma, osteosarcoma and cutaneous squamous cell carcinoma suggest, that NFIB may also function as a tumor suppressor. The nature of this contradictions remains elusive and implies that the function of NFIB might depend on tissue specific regulation, e.g. post-translation modification (PTM). In this study we demonstrate that NFIB undergoes hyperphosphorylation during M-phase. Utilizing kinase specific inhibitors, siRNA and *in vitro* assays with recombinant proteins, we identified cyclin-dependent kinase 1 (CDK1) as a specific enzyme responsible for phosphorylation of NFIB during M-phase. Using Mass Spectrometry analysis of PTM of NFIB protein, we discovered specific amino acid targets of CDK1 and generated a quadruple NFIB mutant (Ser->Ala) construct, unable to undergo hyperphosphorylation during M-phase. qPCR analysis revealed that expression of phospho-incompetent form of NFIB in human SCLC cell lines resulted in altered expression of EMT-related genes in the fashion similar to NFIB knock-down. Altogether, these results suggest that phosphorylation of NFIB by CDK1 regulates its pro-metastatic function in SCLC. It also underlines the value of further research on targeting phosphorylation state of NFIB in aiding standard chemotherapeutic regimes.

#4060 The role of paraspeckles in EWS activated cancers.

Renee A. Kinne, Peter C. Hollenhorst

Medical Sciences, Indiana University School of Medicine, Bloomington, IN

The ETS family of transcription factors become aberrantly activated in multiple cancers. This activation is dependent on the co-activator EWS in both prostate cancer and Ewing sarcoma, an adolescent bone cancer. In prostate cancer, EWS is a binding partner necessary for oncogenic ETS, primarily ERG, activation. In Ewing sarcoma, the intrinsically disorder region (IDR) of EWS is fused to ETS members, primarily FLI1, and promotes aberrant expression and activation. The IDR of EWS promotes liquid-liquid phase separation (LLPS) and acts as a transcriptional activation domain. Current studies link LLPS with oncogenesis, making the LLPS ability of EWS a potential mechanism for oncogenic co-activation. In cells, EWS is found in phase separated bodies such as paraspeckles. Paraspeckles are nuclear bodies that have a role in transcriptional regulation, but their role in cancers is not well understood. I have shown that ERG and EWS/FLI1 colocalize with EWS granules in a purified protein droplet assay. This suggests that oncogenic ETS can participate in EWS LLPS. NEAT1, the essential RNA scaffolding of the paraspeckle, has a role in tumor progression in prostate cancer and I have shown that both ERG and EWS/FLI1 interact with NEAT1 through RIP. However, the potential role of paraspeckles in Ewing sarcoma or prostate cancer has not been further investigated. ETS positive prostate cancer and Ewing sarcoma lines showed paraspeckle presence through NEAT1 RNA-FISH. Knock down (KD) of two necessary paraspeckle components, NEAT1 or FUS, in Ewing sarcoma cells reduce paraspeckle presence, colony growth, and EWS/FLI1 activity at the transcriptional level. KD of FUS and NEAT1 also increased migration, which is consistent with EWS/FLI1 loss. Taken together, these data suggest that the paraspeckle has a role in EWS/FLI1 activity in Ewing Sarcoma and that components of the paraspeckle interact with ERG. Because ERG and FLI1 are homologous, there is potential that the paraspeckle acts as a mechanism of oncogenic transcription in prostate cancer as well as Ewing sarcoma.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: High-Throughput Sequencing / Microarrays / Next-Generation Sequencing Poster Session

#4064 Transcriptome-Wide Association Study of Alternative Polyadenylation Identifies Susceptibility Genes in Non-Small Cell Lung Cancer.

Xiaohang Xu, Sicong Wang, Hanyi Zhou, Qilong Tan, Zeyong Lang, Yun Zhu, Huadi Yuan, Zixiang Wu, Ling Zhu, Kejia Hu, Wenyuan Li, Dan Zhou, Ming Wu, Xifeng Wu

Zhejiang University, Hangzhou, China

Alternative polyadenylation (APA) plays a crucial role in cancer development and prognosis. However, the molecular characteristics of APA related to non-small cell lung cancer (NSCLC) susceptibility remain understudied especially in East Asian populations. In this study, we constructed an atlas of APA-regulated 3' untranslated region (3'UTR) and profiled its genetic regulation in 747 lung tissue samples (including tumors and paired normal tissues) from 417 Chinese NSCLC patients. We verified a significant global shortening of 3'UTRs in tumor samples compared to normal samples and underscored the value of APA-regulation as prognostic markers. The 3'UTR APA quantitative trait loci (3'aQTL) was identified by regressing the percentage of distal poly(A) site usage index (PDUI) value on genetic variants. We found that a significant proportion 3'aQTL are independent of genetic regulation of expression and are specific in Chinese. We also conducted a 3'UTR APA transcriptome-wide association study (3'aTWAS) by integrating the APA regulation atlas with a genome-wide association studies (GWAS) for NSCLC involving 7,035 cases and 185,413 cancer-free controls. We identified NSCLC-associated genes. Combining the consistent results from colocalization analysis, differential APA analysis, and survival analysis, we provide novel evidence for the role APA regulation in NSCLC and identified potential upstream regulators. Overall, our study profiled the APA regulation and highlighted the substantial role of APA in NSCLC carcinogenesis and prognosis.

#4065 Unveiling drivers of esophageal adenocarcinoma with CRISPR pooled screening and single-cell RNA-sequencing.

Ebtihal H. Mustafa, Julia Milne, Ka Meng Wu, Katherine Papastratos, Niko Thio, Wayne Phillips, Nicholas Clemons

Peter MacCallum Cancer Centre, Melbourne, Australia

Esophageal adenocarcinoma (EAC) is an aggressive malignancy with a rising incidence and limited treatment options. It develops from Barrett's esophagus, a pre-cancerous metaplastic condition, yet the molecular mechanisms driving its progression remain poorly understood. Genomic studies have identified ~76 candidate genes as potential drivers of EAC. In our previous work, we demonstrated that in the context of mutant TP53, the inactivation of one such candidate tumour suppressor, SMAD4, was sufficient to drive tumorigenesis in non-tumorigenic CP-B Barrett's esophagus xenografts. Building on this, we combined our EAC tumorigenesis model with Perturb-Seq (CRISPR-mediated gene editing coupled with single-cell RNA sequencing (scRNA-Seq)) to enable high-throughput functional characterization of EAC driver genes. The study specifically aimed to: (i) identify the molecular perturbations driving tumorigenesis in EAC, (ii) understand the transcriptional changes underlying the oncogenic effects of these perturbations, and (iii) tackle the genetic heterogeneity of EAC by categorizing driver genes according to shared transcriptional phenotypes. *In vivo* loss-of-function CRISPR screen was conducted using a boutique pooled CRISPR/Cas9 sgRNA library (6 sgRNAs per gene) targeting 57 known and putative tumour suppressor genes. To analyze the gene knockout-specific effects on the transcriptome at single-cell resolution, capture sequences compatible with 10X Feature Barcoding were incorporated into the sgRNAs. The library was transduced into two independent esophageal pre-malignant cell models, CP-B and CP-D, followed by xenotransplantation in NSG immunodeficient mice. We established that the knockout of 40 out of the 57 candidate tumour suppressors were independently sufficient to induce tumour formation in vivo. By integrating the scRNA-Seq data corresponding to each tumour suppressor knockout, we found that depletion of these tumour suppressor genes inhibited the proteasomal degradation of oncogenes and anti-apoptotic proteins, such as cyclin E, c-Myc, and Mcl-1. Additionally, this depletion led to the upregulation of genes involved in cell cycle progression, DNA repair, and lipid and carbohydrate metabolism. Perturb-seq also showed that driver-dependent transcriptional changes can be categorized into a smaller number of functional pathways allowing us to potentially consider groups of drivers as functional units. Collectively, the findings of this study enhance our understanding of the molecular events driving EAC tumorigenesis and offer a comprehensive view of the transcriptional phenotypes that can be targeted in future research. These insights lay the foundation for the development of novel therapeutic strategies for this highly heterogeneous disease.

#4066 High throughput single-cell TCR sequencing method identifies cancer-specific TCR clonotypes.

Efthymia Papalexi[1], Crina Curca[1], Bryan Hariadi[1], Alexa Suyama[2], Simone Marrujo[1], Gary Geiss[1], Charles Roco[1], Alexander Rosenberg[1]

[1]Parse Biosciences, Inc., Seattle, WA,[2]OHSU, Portland, OR

Cancer cells produce tumor-specific antigens and neoantigens that can be recognized by T cells and induce their clearance. Single cell profiling of T cell receptors (TCRs) and gene expression enables the identification and characterization of tumor infiltrating T cells that have antigen recognition and killing capabilities. Existing microfluidic-based single cell sequencing methods have limited cell and sample throughput making it hard to perform longitudinal studies to capture changes in TCR repertoire dynamics during tumor progression and therapeutic interventions. Understanding these dynamics will be key in designing the next generation of immunotherapies. To overcome these limitations, we developed a combinatorial barcoding approach to simultaneously characterize the TCRs alongside the full transcriptomes of up to 1 million fixed T cells from up to 96 unique samples in a single experiment. To demonstrate this approach, we profiled 1 million human T cells stimulated with a variety of antigens including the tumor antigens MART-1, NY-ESO-1, HER2/Neu, MAGE-A10, WT-1 and Tyrosinase. Using our technology, we recovered paired TCR alpha and beta clonotype information in 82% of all T cells. We estimated the clonotype diversity and found that the tumor antigen-stimulated samples had lower diversity than the controls. Specifically, when looking at the top three most expanded clonotypes for each sample we show that they account for 8-99% of all detected clonotypes. Next, we searched publicly available databases and showed our method not only detects previously annotated disease-specific CDR3 sequences but also uncovers previously unknown ones. Finally, we ran multiple sequence alignments and identified CDR3 sequence motifs unique to each antigen-stimulated population. In summary, we present a highly flexible and scalable method to single cell TCR profiling to allow researchers to profile up to 1 million T cells and up to 96 samples in a single experiment. We envision our approach to be invaluable in investigating T cell functional responses during infection, cancer, autoimmunity, or therapeutic interventions and pave the way for the development of new immune-based therapies.

#4067 Covaris truCOVER library prep kit: A streamlined PCR free WGS workflow for enhanced NGS library performance and data quality.

Vanessa Process[1], Martina Werner[1], **Madan Ambavaram**[1], Thuy Dao[1], Heidi Giese[1], Sushant Khanal[1], Luca Beker[1], Sameer Vasantgadkar[1], Maura Berkeley[2], Zachary Herbert[2], Greg Endress[1], Eugenio Daviso[1], Ulrich Thomann[1]

[1]Covaris, Woburn, MA,[2]DFCI, Boston, MA

Whole-genome sequencing (WGS) has become an indispensable tool in genomic research and clinical diagnostics, offering unprecedented insights into the underlying mechanisms of genetic diseases, cancer evolution, pharmacogenetics and pharmacology (1). As WGS increasingly transitions from research to routine clinical use, optimization of workflows for precision, scalability, and efficiency is essential. Addressing key challenges - including inconsistency in DNA fragmentation precision, suboptimal library conversion rates, cumbersome optimization to address sample input variation and its resulting sequencing biases - is essential for ensuring high-quality sequencing data. To this end, Covaris recently launched the truCOVER WGS PCR-free Library Prep Kit, a unique solution designed to streamline the whole-genome sequencing (WGS) library preparation process. This innovative, single-vessel workflow integrates Covaris Adaptive Focused Acoustics (AFA)-based DNA shearing, followed by end-repair and adaptor ligation, and adds a post-library size selection (2) that results in optimized fragment sizes. By optimizing fragment sizes for sequencing, this approach significantly reduces workflow complexity and turnaround time from sample to ready-to-pool libraries while lowering overall costs. The truCOVER library prep kit consistently delivers superior library conversion rates across diverse sample types, including DNA isolated from blood, saliva, and FFPE tissues. Sequencing analysis conducted in-house and in collaboration with leading institutions like the Dana-Farber Cancer Institute demonstrated improved genome coverage and enhanced variant detection accuracy with the Covaris workflow as compared to leading competitor workflows.

#4068 Development and evaluation of standardized samples for multiomic ctDNA assays across multiple cancer types.

Qiancheng You, Jiayue Xu, Jing Su, Xingyu Yang, Sa Zhang, Zeliang Deng, Xiaoling Li, Guangyou Li, Xinyue Kang, Si Zhang, Meifang Wu, **Bingsi Li**

Innovation Center, Burning Rock Biotech, Shanghai, China

Background: Multiomic circulating tumor DNA (ctDNA) assays offer several benefits over tumor-dependent ones, including being more rapid, less invasive, and cost-effective for monitoring tumor recurrence or therapy response through serial testing. Despite these advantages, identifying ultra-low frequency ctDNA alterations, whether genetic or epigenetic, from limited input material is highly challenging. Furthermore, complex assays are often more susceptible to experimental and computational variables and artifacts. This poses a pressing need for standardized samples to assess the analytical performance and enable unbiased comparisons between different technology platforms.

Methods: We have developed contrived standards using cell line, tissue, plasma, and PBMC samples that were either commercially purchased or provided with informed consent. The 'ground truth' for tumor fraction (TF) was defined by the dilution ratios and validated through *in silico* reads-mixing simulations. Subsequently, estimates of tumor allele fraction (TAF) using different biomarkers were analyzed and compared. (i) Mutation-based TAF: Both tumor-agnostic (somatic variants allele frequency, SVAF) and tumor-informed (circulating tumor allele fraction, cTAF) ones were characterized by a validated 520-/168-gene panel (10,000-35,000X) or an individualized mutation tracking panel (100,000X depth) following a WES scan on paired tumors. (ii) Methylation-based TAF: Both tumor-agnostic (tumor methylated fraction, TMeF) and tumor-informed (methylated tumor allele fraction, mTAF) ones were characterized by a validated targeted methylation assay.

Results: We have tested >400 contrived and clinical samples across different cancer types. Sample dilutions at pre-determined levels of TAF (0.001%-1%) are suitable for evaluating the limits of detection (LoDs) for most mainstream tumor-informed/-agnostic ctDNA assays. Samples with TAF near the LoD and background plasma were tested with replicates for precision and accuracy studies. Overall, reliable estimates of TAF were observed across different biomarkers, although the measurement of ultra-low fractions (i.e. TAF<0.01%) still remains a challenge. Notably, the number of unique patients/healthy donors is crucial for generating methylation-based standards, as demographic factors such as age, sex, and ethnicity have been shown to influence DNA methylation patterns.

Conclusions: With clinical adoption underway, it is critical to understand and evaluate the variables that impact the analytical performance of complex multiomic ctDNA assays. Here, we report a systematic evaluation of the analytical features and clinical relevance of standardized samples, thereby providing a versatile tool for assay optimization, validation, and cross-platform comparison.

#4069 Transcriptome-wide splicing analysis reveals changes in transcript usage of *MDM2* and *ESR1* in uterine leiomyomas.

Vilja Jokinen[1], Niko Valimaki[1], Kristiina Rajamaki[1], Auli Karhu[1], Emma Siili[2], Ralf Butzow[2], Oskari Heikinheimo[2], Annukka Pasanen[2], Lauri A. Aaltonen[1]

[1]University of Helsinki, Helsinki, Finland,[2]University of Helsinki and Helsinki University Hospital, Helsinki, Finland

Uterine leiomyomas (ULs) are smooth muscle tumors of the uterus. ULs are the most common tumors in women affecting up to 70% by the age of 50. ULs are often divided into molecular subtypes based on genetic driver alterations that are usually mutually exclusive. Transcriptome-wide aberrations in messenger-RNA (mRNA) splicing have been reported in many cancer types due to disturbed regulation of splicing. In addition, splice site mutations of individual driver genes, especially tumor suppressor genes, are common in cancer. Splice mutations of a few driver genes have been identified also in ULs. However, to our knowledge transcriptome-wide changes in splicing have not been studied in ULs.

Our aim was to study the potential role of mRNA-splicing alterations in UL genesis. We generated RNA-sequencing (RNAseq) data from 410 ULs and 151 corresponding normal myometrium samples and used LeafCutter for running splicing analyses.

The preliminary results suggest that splicing patterns differ between UL subtypes. Unsupervised hierarchical clustering based on splicing separates normals and molecular UL subtypes to their respective clusters. The different UL subtypes shared many splicing alterations compared to normal myometrium. mRNAs for components of extracellular matrix and contractile muscle fibers were enriched among differentially spliced transcripts in tumors compared to normals.

The only differentially spliced gene shared by all molecular UL subtypes was *MDM2*, a well-known oncogene that plays a role in the regulation of p53. Interestingly, *ZMAT3*, which is the third most overexpressed gene in ULs, is known to regulate *MDM2* splicing. Earlier GWAS studies have revealed a UL predisposition locus close to *MDM2*, affecting *MDM2* expression levels in ULs but not normal myometrium.

The UL subtypes with driver alterations in *MED12* or SRCAP complex genes showed differential usage of *estrogen receptor 1 (ESR1)* transcript isoforms. It is well known that excessive estrogen promotes UL genesis. The differential expression of *ESR1* isoforms may play a role in estrogen sensitivity of ULs.

ULs almost never progress to leiomyosarcoma. However, ULs share common driver genes and dysregulated signaling pathways with many cancer types. Better understanding of UL genesis broadens our knowledge on the common and distinguishing characteristics of benign and malignant tumors, perhaps shedding light on mechanisms preventing malignant degeneration in a benign neoplastic lesion.

#4070 Demonstrating analytical performance of Agilent Avida Duo utilizing novel multiomic reference standards.

Michael Ruvolo, Yingmin Wang, Grace Zhao, Heng Wang, Kyeong-Soo Jeong, Yun Bao, Shengrong Lin, Bram Herman, Mistuni Ghosh

Agilent Technologies, Inc., Santa Clara, CA

Measuring both genetic and epigenetic status by target enrichment NGS workflows is critical for high-sensitivity oncology applications using cell-free samples (cfDNA). Conventional workflows accomplish this by splitting a sample into multiple tests, potentially limiting sensitivity. The Agilent Avida target enrichment technology enables high-efficiency enrichment of native DNA fragments, preserving epigenetic markers such as methylation. This method, termed Avida Duo, measures both mutation and methylation status, maximizing the information that can be obtained from any single cfDNA sample. Multiomic assays have become increasingly important in research applications and determining their analytical performance is key to ensure they are fit for purpose. Currently, standards with known variants or methylation levels are available, however, there is a lack of multiomic standards for evaluation of more advanced dual modalities. We utilized commercially available mutation and methylation standards to create a combined reference to assess the performance of the Avida Duo workflow. To create this reference, the mutation status of the methylation-specific reference and the methylation profile of the mutation-specific reference was determined. We blended these fully characterized references in defined ratios to achieve known variant allele frequencies and methylation levels similar to real-world cfDNA samples. Using this combined reference standard, we demonstrated the analytical performance of the Avida Duo technology across an input range of 5-20ng using a 55.2kb mutational panel that combines hotspot and full-gene enrichment and a 173.9kb methyl panel that covering relevant differentially methylated regions (DMRs). From this, we were able to demonstrate robust detection of variants down to <0.5% VAF and 1% methylation of DMRs. The Avida Duo technology offers a single workflow for a combined interrogation of genetic and epigenetic information of cfDNA and as such, requires new tools to appropriately characterize the performance. Here we demonstrate an approach for generating reference samples for assay development, QC, and benchmarking the analytical performance of multiomic assays.

For Research Use Only. Not for use in diagnostic procedures.

#4072 Functional screen to optimize logic gate potency and selectivity.

Sara Martire, Michele Mcelvain, Vasantika Suryawanshi, Mark Daris, Tanveer K. Gill, Timothy P. Riley, Alexander Kamb, Chawita Netirojjanakul

A2 Biotherapeutics, Inc, Agoura Hills, CA

Background: Logic-gated cell therapy systems are considerably more complicated than conventional therapeutics and, therefore, more challenging to optimize. One type of logic gate, the NOT gate, responds to two inputs: the presence of antigen A and absence of antigen B. Perhaps the best studied NOT gate is called Tmod which consists of an activator (eg, a chimeric antigen receptor [CAR]) that is co-expressed with an inhibitory receptor, or blocker (DiAndreth B, et al. *Clin Immunol*. 2022). However, the complexity of the system limits the amount of structure-activity information that can readily be obtained. If further modules (eg, potency boosters) are added to the system, the behavior of these synthetic circuits can be even more complex.
Methods: A fluorescence-activated cell sorter (FACS)-based screening system was designed to rapidly select functional inhibitory receptors and inducible boosters from a pooled library of candidates. This screen incorporates an NFAT-responsive reporter cell line for iterative selection of reporter (+) and (-) cell populations by FACS after exposure to different stimuli. The selected populations were analyzed by sequencing to identify candidate blocker or booster sequences enriched during the process.
Results: Proof-of-concept experiments using a library of blocker variants demonstrated enrichment of active blockers. Moreover, selected features were used to successfully predict the blocker behavior with 70-80% accuracy by machine-learning algorithm. In another set of experiments, a library of almost 30,000 variants of a signal 1 booster that activate signaling in the presence of a small molecule (rimiducid) was screened. Signal 1 boosters with specific domain structures were enriched and validated in subsequent experiments.
Conclusions: The screening system described here identifies active blocker receptors and boosters from large libraries of variants. Its throughput is sufficient to generate large datasets and train machine learning models to better predict and optimize the function and control of logic-gated cell therapeutics.

#4073 Massively parallel barcoding as an alternative to genetic demultiplexing in large cohort scRNA-Seq studies.

Sanika Khare, Dominic Skinner, Austin Holmes, Felix Schlesinger, Keith Jackson

Scale Biosciences, Inc., San Diego, CA

Single-cell RNA sequencing (scRNA-Seq) studies with large sample cohorts are expensive, and prone to batch effects. Genetic demultiplexing allows for pooling of distinct samples beforehand and then using bioinformatic tools post sequencing to identify individual samples based on their genetic makeup. This allows for super-loading conventional scRNA-seq runs while reducing costs and batch effects. However, these strategies often lead to up to 30% doublets and are limited by the quality of the reference genome used, and the genetic diversity of the input. Additional bulk sequencing and computational analyses add on costs and times to identify individual samples. This problem becomes more acute in diseases with heavy mutational burden like cancer - tumor-driven mutations might overshadow natural genetic variation between samples and extra sequencing and analyses might be warranted. Scale Bio has pioneered the use of massively parallelized barcoding and novel multiplexing strategies (ScalePlex) to boost throughput and circumvent the need for additional sample demultiplexing strategies to identify individual samples. Typical doublet rates in a Scale Bio scRNA-Seq library are around 5% and the protocol allows for simultaneous profiling of up to thousands of samples with Scaleplex, with significantly lower per sample inputs and no additional bulk sequencing required. Here we demonstrate the utility of the Scale Bio scRNA-Seq with and without Scaleplex in sample demultiplexing 12 samples from diseased and non-diseased individuals with similar genetic backgrounds when compared to super loading a conventional scRNA-seq run. Furthermore, we compare our data with current on market, publicly available computational tools for genetic demultiplexing with ScalePlex readouts as the ground truth. We observe low doublet rates in the Scale Bio data along with maximum utilization of possible sequencing reads, and clear, unambiguous sample identification when compared to conventional scRNA-seq techniques and analyses tools. Thus, the Scale Bio scRNA-seq platform offers a viable, low cost and effort platform for conventional genetic demultiplexing techniques with better resolution and higher sample multiplexing capacity. Furthermore, ScalePlex provides an alternative to easily, distinctly barcode and multiplex samples without genetic demultiplexing where researchers can gain the same benefits of reduced cost and batch effects while removing sample heterogeneity considerations and bioinformatics barrier of genetic demultiplexing.

#4074 A 10 million cell atlas of cytokine-stimulated PBMCs via high-throughput combinatorial single cell RNA sequencing.

Joey Pangallo, Efthymia Papalexi, Simone Marrujo, Bryan Hariadi, Crina Curca, Alexa Suyama, Maria Nigos, Oliver Sanderson, Hoai Nguyen, Vuong Tran, Ajay Sapre, Olivia Kaplan, Sarah Schroeder, Alec Salvino, Ryan Koehler, Gokhan Demirkan, Gary Geiss, Charles Roco, Alexander Rosenberg

Parse Biosciences, Inc., Seattle, WA

Cytokines, secreted by immune cells, are essential for coordinating immune responses against pathogens and abnormal cells, such as those found in cancer. Despite their critical role, a comprehensive understanding of how many different types of immune cells respond to individual cytokines remains elusive. To begin to address this challenge, we created a comprehensive single cell atlas of immune responses to 90 cytokines, profiling the single cell transcriptomes of 10 million PBMCs from 12 donors after 24 hours of treatment. We identified 18 cell types, resulting in the analysis of 19,440 experimental conditions. Our analysis revealed gene expression changes that are both cell type- and donor-specific, uncovering responses even in rare immune cell populations that are difficult to capture in smaller datasets. Furthermore, we also identified a small number of cytokines that induced changes in cell type proportions after cytokine treatment. Given the limited number of publicly available large-scale single cell studies, we also provide an updated, detailed analysis workflow to encourage researchers to produce similarly scaled-up datasets. By sharing this comprehensive dataset and methodology, we aim to empower the scientific community to scale single cell experiments and drive advancements in immunology, immuno-oncology, cancer biology, and beyond.

#4075 GEM-X Flex: scalable and cost-effective whole transcriptome single cell analysis for cancer marker detection from FFPE tissue section slides.

Tingsheng Y. Drennon, Jawad Abousoud, Ryan T. Stott, Juan Pablo Romero, Paul Lund, Nico Sponer, Sarah Taylor, Peter Smibert, Andrew Kohlway

Biology, 10x Genomics, Inc., Pleasanton, CA

Formalin-fixed paraffin-embedded (FFPE) tissue blocks are the most widely used sample type in clinical research for preserving tissue morphology and supporting long-term storage. These samples can be particularly valuable for studying rare cancers or when sample procurement is challenging. The growing demand for comprehensive single cell gene profiling calls for methods that require less sample input, reduce costs and enable high-throughput analysis for large clinical studies.

Large-cohort studies are often limited by financial constraints. To overcome this challenge, we performed a cost-effective, high-throughput experiment with eight different FFPE blocks (glioblastoma, colorectal, lung, breast, skin, endocervical cancers, normal kidney, and reactive lymph node), with two replicates per sample. Using the 16-barcode multiplexing approach of GEM-X Flex, we processed 320,000 cells pooled from all 16 samples in a single lane (20,000 cells per sample). The distinct barcodes allowed us to obtain high quality single cell sequencing data from each individual sample with ~< 8% undetected multiples. We identified tumor markers specific to each cancer, including *PROM1* (glioblastoma), *BRCA1* (colorectal), *KRT19* (lung), *MUC1* (breast), *GPC3* (breast), and *MUC16* (endocervical). This method allows processing up to 2.56 million cells per chip across 8 lanes, reducing the cost per sample to just one cent per cell, making large-scale studies more cost-efficient.

We also extended this approach to tissue sections already mounted on slides and subjected to histological analysis, enabling the extraction of the most information from precious clinical samples. Using the GEM-X Flex assay, we generated whole transcriptome profiles from as few as 25,000 nuclei isolated from 5 µm FFPE tissue sections on standard superfrost slides. Gene expression profiles, cell type proportions, and assay sensitivity from these thin sections were comparable to those from 25 µm tissue scrolls from the same FFPE block, demonstrating that high-quality single cell RNA sequencing is achievable with minimal sample input. The ability to work with 5 µm tissue sections expands options for universal sample preparation across various assays. It also broadens sample procurement opportunities by using tissue sections instead of whole FFPE blocks, significantly lowering costs.

In summary, the GEM-X Flex assay enables whole-transcriptome gene profiling at single cell resolution from 5 µm FFPE tissue sections. By combining H&E image analysis with RNA sequencing data from sequential sections of the same cancer block, pathologists can achieve more precise diagnostics. The assay's multiplexing capability significantly lowers costs and supports high-throughput studies, enabling large-scale tumor marker screening for early detection, progression monitoring, and therapeutic target development.

#4077 Preserving and contextualizing in situ transcriptomes of hormone receptor-negative breast premalignancy.

Russell B. Hawes[1], Kristen A. Atkins[2], David R. Brenin[3], Kevin A. Janes[1]

[1]Biomedical Engineering, University of Virginia, Charlottesville, VA,[2]Pathology, University of Virginia, Charlottesville, VA,[3]Surgical Oncology, University of Virginia, Charlottesville, VA

Triple-negative breast cancer (TNBC) is a poor-prognosis molecular subtype of breast cancer that is thought to begin as an estrogen receptor-negative ductal carcinoma in situ (ER- DCIS). ER- DCIS is much less common than other types of DCIS, suggesting that it is a transient premalignant state before invasion begins. To better characterize the premalignant transcriptome, we use laser capture microdissection-guided stochastic 10-cell RNA sequencing to profile the transcriptome of ER- DCIS cases that present to the University of Virginia (n = 10 cases thus far). In early cases, RNA integrity was poor with RNA integrity numbers (RIN) near zero. To improve RNA integrity in future samples, we began transporting surgical excision material on ice to minimize RNase activity, and coordinated the pathological processing to minimize time to cryoembedding. We have reduced time to cryoembedding to 26 minutes on average and obtained usable RNA for 10-cell RNA sequencing, though RIN remains case dependent. We also optimized proteinase K and inhibitor concentrations during RNA extraction to ensure maximal reverse transcriptase activity after cell digestion. 10-cell transcriptomes will be combined with RNA sequencing data from the Human Tumor Atlas Network — a large, multisite patient dataset that includes ER- DCIS profiles acquired from whole lesions isolated by laser capture microdissection (LCM). These external LCM samples have been filtered to remove samples with low read counts across all genes. These additional samples in combination with our own will allow us to distinguish whether differences in handling and sample preservation give rise to tangibly higher quality transcriptomes when compared to existing archival samples.

#4078 Enabling single-cell RNA analysis of hundreds of samples and millions of cells through automated library preparation.

Rosary Nguyen, Swarnagowri Vaidyanathan, Zorine Hlathu, Xueying Zhao, Jamie Moskwa, Ricelle A. Acob, Chelsea Gordon, Larry Wang, Aruna Ayer

BD Biosciences, Milpitas, CA

Single-cell RNA-seq is a powerful method for studying complex cell populations. As opportunities grow for single-cell multiomics methods in translational research, there is an increased need for high-throughput approaches capable of efficiently capturing and analyzing large numbers of cells and samples simultaneously. Current assays on scRNA-seq platforms have limited throughput due to the low cell recovery and tedious hands-on library preparation steps.

Here we demonstrate the feasibility of automating single-cell RNA-seq library preparation with BD Rhapsody cell capture bead libraries on the Hamilton NGS STAR system. To show the range of cell input capabilities of the NGS STAR system, we input BD Rhapsody Cell Capture Beads containing captured molecules from 6,000 to 20,000 cells. To evaluate the repeatability and reproducibility of the platform, we generated a large pool of BD Rhapsody cell-captured beads to test the same sample library across multiple wells, instruments, and runs. Using in-process quality control and sequencing, we confirmed equivalent biological output in terms of library quality, sensitivity, and gene expression correlation ($R^2 > 0.9$) compared to manual bench controls. In addition, we loaded several BD Rhapsody HT Xpress lanes with 100,000 cells and used automated library preparation to compare with manual bench controls. This study demonstrates that BD Rhapsody cell captured beads can be utilized on the Hamilton NGS STAR to generate high quality libraries for sequencing and increase throughput of samples, while reducing hands on time. Processing 48 samples with 100K cells each allows users to prepare libraries for over 4 million cells in a single run. When combined with upstream sample multiplexing, hundreds of samples can be analyzed together, offering significant time savings and reducing variability between samples. This application could be readily extended to other existing multiomics single-cell technologies such as CITEseq assay.

#4080 A novel integrated target capture and rapid sequencing workflow for myeloid malignancy mutation detection within 12 hours.

Kyle S. Metcalfe, Benjamin J. Krajacich, Xiaodong Qi, Kelly Wiseman, Marina McCowin, Shawn Levy, Junhua Zhao

Element Biosciences, Inc., San Diego, CA

Hybrid capture technology is a powerful and cost-effective tool in precision oncology research to detect somatic mutations in hematologic malignancies. While target capture is important for efficient mutation detection, obtaining rapid sequencing results is critical for research in this field. Traditional hybrid capture workflows involve several time-consuming steps prior to sequencing, including post-hybridization capture, washes, and amplification, which can delay results. Here, we combine Trinity™ hybrid capture and a rapid AVITI™ sequencing protocol to deliver targeted sequencing results within 12 hours. We applied this rapid Trinity™ workflow together with a custom myeloid panel based on a design used by Genomics Medicine Sweden to detect mutations in reference DNA and patient blood/bone marrow/fresh frozen tissue. This custom panel builds on an earlier design, targeting genes included in contemporary guidelines and those with strong or potential clinical impact as well as genes reported in the literature but with less established clinical relevance. The final 7,901-probe panel spans a target region of 0.73 kb and provides uniform coverage across all targets, including challenging GC-rich regions. We were able to detect myeloid malignancy mutations between 0.5%-70% VAF in Horizon's Mimix™ Myeloid DNA Reference Standard, including internal tandem duplications observed in some patients with acute myeloid leukemia (AML). In sum, the Trinity™ workflow on the AVITI™ sequencer provides a rapid, accurate, and robust solution for targeted sequencing, offering significant advancements in turn-around time for hematology malignancy research.

#4081 Analysis of low-grade serous ovarian cancer by long-read full length transcripts sequencing.

Kwong-Kwok Wong, Yvonne Tsang, David M. Gershenson

UT MD Anderson Cancer Center, Houston, TX

Low grade serous ovarian carcinoma is a rare epithelial ovarian cancer that occurs more frequently in younger women. RNA sequencing (RNAseq) has been playing a pivotal role in understanding the molecular pathogenesis of the low-grade ovarian serous carcinoma (LGSOC). The quantification of gene expression with enough sequencing depth can be fairly accurate. However, the current short-read RNAseq approach is not very accurate in measuring individual transcript activity. This is because multiple transcripts from the same gene share high sequence similarity, which complicates the transcript mapping. As the accuracy of long-read sequencing technology is improving, long-read full transcript RNA sequencing is becoming an important tool for interrogating alternative transcripts and the discovery of gene fusion transcripts. In this study, we compare short-read RNAseq and long-read RNAseq from the same LGSOC patient samples. The RNA-Seq analysis for long-reads were performed by mapping sequencing reads to annotated reference human genome GrCh38 with minimap2. First, all annotated transcripts or genes were extracted including any annotated splice variants. Subsequently, the reads were mapped against all the transcripts as well as to the whole genome using minimap2. The distributing and counting the reads across genes and transcripts were calculated. We found that the expression level of transcripts in short-read in general is higher than that that of long-read. It is because short reads frequently could not be accurately mapped to the correct alternative transcripts from the same genes. When a read mapped to multiple transcripts, the short reads were randomly assigned to a transcript from the same gene. As a result, more than 100,000 transcripts had at least one assigned read in the short-read RNAseq analysis, but less than 50,000 transcripts had at least one assigned read in long-read RNAseq analysis. Long read with greater read-depth had better quantification accuracy for detecting specific transcripts. To identify potential gene fusions, the raw Oxford Nanopore long-read RNA-seq fastq files were corrected and polished with high sequencing quality short-read RNA-seq data by racon assembly tool. Those long-reads with unaligned ends of reads from a mapping generated by RNA-Seq analysis were re-mapped to the reference using the unaligned ends of reads. In this study, we identified several gene fusions including a gene fusion between *NSUN4* and *FAAH* genes with at least seven long reads covering the breakpoint. *FAAH* encodes the enzyme fatty acid amide hydrolase and has been shown to be a metastasis suppressor in breast cancer previously. It is possible that the truncated FAAH protein because of gene fusion is involved in the metastasis of the LGSOC that we have analyzed. This could be another mechanism involved in the progression of LGSOC. Additional analysis of the long-read full transcript sequencing of LGSOC is in progress.

#4083 Ancestral background and germline mutations in head and neck cancer: An analysis of disparities in genetic risk factors using the All of Us database.

Mayra S. Haedo-Cruz, Grace E. Velez-Crespo, Natalie Alamo-Rodriguez, Vivian Colon-Lopez, Julie Dutil, Josue Perez-Santiago

University of Puerto Rico Comprehensive Cancer Center, San Juan, PR

Background: Head and Neck Cancer (HNC) ranks as the seventh most common cancer globally, yet significant disparities persist in mortality rates across ethnic groups, especially in the United States (US). Hispanic and Non-Hispanic (NH) Black men exhibit higher cancer-specific mortality rates for HNC compared to NH White men, indicating gaps in cancer prevention, early detection, and genetic risk profiling for these groups. The influence of genetic ancestry on HNC risk remains understudied, particularly within Hispanics, who have a diverse ancestral composition. This study aims to elucidate the association between genetic ancestry and HNC, while also analyzing mutations in four genes associated with HNC: FAT1, POLB, TP53, and CDKN2A.
Methods: Demographic information, electronic health records, and microarray data for this study was sourced from the All of Us Research Program. A cohort of 2,552 individuals was identified, where half were of HNC cases, and half were demographically matched controls without a cancer diagnosis. Mann-Whitney U test was performed to analyze the differences between ancestry percentages within cancer and non cancer groups. Associations of genetic variants with cancer status or ancestral genetic makeup were assessed with Chi-square tests.
Results: Self-reported Hispanic or Latino participants in our cohort had an approximate average of 83% Indigenous American ancestry, 8% European ancestry, 6% African ancestry, 1% Eastern Asian ancestry, 0.6% Southern Asian ancestry, and 0.5% Middle Eastern ancestry. We identified that individuals with a higher percentage of Indigenous American ancestry were more likely to have a negative cancer diagnosis ($p<0.05$). Conversely, individuals with a higher percentage of European ancestry were more likely to have a positive HNC diagnosis ($p<0.01$). We did not identify significant results relating African ancestry to the diagnosis of HNC. Six single nucleotide polymorphisms (SNPs) within the four genes studied had a significant association to cancer diagnosis ($p<0.05$). There was a significant association in two of these SNPs between genotypes and predominant ancestry. Individuals with predominant Indigenous American ancestry were more likely to have the CT genotype for rs3136719 in the POLB gene ($p<0.05$). For rs3218009 in the CDKN2A gene, individuals with predominant European ancestry were associated with the CG genotype ($p<0.05$).
Conclusions: We identified that a high percentage of Indigenous American ancestry was linked to reduced HNC risk, while a high percentage of European ancestry was associated with increased risk, suggesting ancestry-related germline mutations may influence susceptibility. These findings indicate that the increased mortality rate related to HNC in Black and Latino populations in the US could be more significantly affected by social determinants of health.

#4085 Assessing RNA integrity in FFPE samples with the DV200 quality metric for automated electrophoresis systems.

I. Priester[1], A. Dorn[1], T. Butler[2];
[1]Agilent Technologies, Waldbronn, Germany, [2]Agilent Technologies, Ankeny, IA

Introduction:
Formalin-fixation and paraffin-embedding (FFPE) is a pivotal technique in pathology, enabling the long-term preservation of tissue specimens. This method not only maintains the cellular structure but also allows repeated analyses of the same sample without the need for additional collection. Despite its benefits, FFPE poses significant challenges for nucleic acid extraction and analysis, particularly for RNA, which is essential for gene expression studies. The fixation process can lead to RNA degradation and fragmentation, creating obstacles for researchers who require high-quality RNA for sequencing purposes. Implementing a quality control system to evaluate RNA integrity post-FFPE extraction is crucial for determining the viability of a sample for downstream analyses like next-generation sequencing.
Methods:
FFPE RNA samples extracted from different sources were analyzed on the Agilent 2100 Bioanalyzer system with the Agilent RNA 6000 Nano kit and the Agilent RNA 6000 Pico kit, and on the 4200 TapeStation system with the Agilent RNA ScreenTape and High Sensitivity RNA ScreenTape with corresponding reagents. Data analysis on the Agilent 2100 Bioanalyzer Expert software was completed using the DV_{200} assay configuration file. Analysis using the TapeStation was performed with the region mode, setting a region of 200 to 10,000 nucleotides to obtain the DV_{200} metric.
Results:
The obtained electropherograms from both systems exhibited similar overall patterns, with slight differences. Despite these differences in electropherogram appearance, the comparison of DV_{200} values demonstrated highly comparable results. The Bioanalyzer and TapeStation systems showed consistent DV_{200} scores across different FFPE RNA samples, demonstrating their interchangeability and reliability.
Conclusions:
The results demonstrate that each system is capable of similarly assessing the quality of FFPE RNA samples. Additionally, the data points out that a consistent measurement can be obtained regardless of the assay or kit being used within each system. This comparison allows users for confident use of the DV_{200} quality metric in their workflows.
For Research Use Only. Not for use in diagnostic procedures.
Keywords: RNA, DV200, quality control, FFPE, TapeStation system, Bioanalyzer system

#4086 A streamlined and modular workflow solution enhances coverage uniformity and achieves high library complexity from genomic DNA/total RNA using both short and long read sequencers.

Bahram Arezi[1], Adam Janssen[1], Nikki Liu[1], Sergey Shiryaev[1], Keith Chen[1], Bilan Hsue[1], Brandyn Clark[1], Jeff fox[1], Nedda Saremi[2], Inlora Jingga[2], Kyeong-soo Jeong[2], Khine Win[2], Gilbert Amparo[2], Neelima Mehendale[2], Jayati Ghosh[2], Cindy Hon[2]

[1]Agilent Technologies, Inc., La Jolla, CA,[2]Agilent Technologies, Inc., Santa Clara, CA

The application of NGS-based assays can be limited by the availability and quality of genomic DNA from certain sample sources. Practical factors such as turnaround time, workflow simplicity, target enrichment capability, and overall performance are crucial in determining whether NGS is the preferred method for germline or somatic mutation detection. In addition, due to certain short read sequencer limitations (e.g., mapping rate, repetitive regions, etc.), enabling long read capture and sequencing allows for better detection of structural variations, complex rearrangements, and variants in highly repetitive or polymorphic regions. To address these challenges, we have developed a flexible and automation-compatible workflow solution that supports both WGS (PCR-free and PCR-based, depending on the application) and target enrichment sequencing. Our modular workflow accommodates a wide range of DNA and RNA inputs (10-500 ng), standard and in-line molecular-barcoded adaptors, enzymatic and mechanical shearing methods, fast or overnight probe hybridization, and up to 384 unique dual sample indices to eliminate index hopping. Our enzymatic library preparation method combines fragmentation, end repair, and dA-tailing in a single step, allowing the use of samples with low concentrations. We demonstrate high base coverage uniformity and minimal bias across all GC content (Fold 80 of 1.12-1.13) using three bacteria of varying GC content (30%-67%) and human gDNA. Finally, our novel fast hybridization buffer formulation provides maximum complexity while maintaining high uniformity and base coverage, specifically addressing the issue of complexity loss when multiple libraries are pooled during bait hybridization. As we demonstrate, with small changes in the protocol, efficient long read capture (>5kb) and sequencing can be successfully accomplished. For Research Use Only. Not for use in Diagnostic procedures.

#4087 Panel-adjustable and user-friendly hybridization-capture technology delivers high performance demonstrated by different exome probe panels.

Alexandra Wang, Daniel Saatman, Ekaterina Star, Jinglie Zhou

R&D, Integrated DNA Technologies, Inc., Redwood City, CA

Targeted sequencing by hybridization-capture is a versatile and powerful way to interrogate selected regions of interest in large and complex genomes. However, the performance of a given hybridization-capture workflow is often optimized only towards a specific approach to probe panel design. Here we demonstrate a hybridization-capture enrichment system that delivers high performance on three commercially available Exome panels with short and overnight hybridizations. This is achieved using our new xGen Hybridization and Wash v3 (xGen v3), which features a simple user-friendly workflow without any pre-heating, hot-liquid handling, or time-and-temperature sensitive steps. Human genomic reference libraries were constructed with xGen™ cfDNA & FFPE DNA Library Preparation Kit using Coriell NA12878 gDNA. These equivalent libraries are hybridized to xGen™ Exome Hyb Panel v2, xGen™ Exome Hyb Panel v1, or a double-stranded-probe Exome panel. Hybridization incubations from 1-hour to overnight were compared, spanning total inputs from 100ng to microgram quantities per hybridization-capture. xGen v3 delivered consistent performance for all three Exome panels, without the increase in GC-bias that typically occurs for short hybridizations. Benchmarking using a currently available commercial kit is presented for performance comparison. Non-biased sampling reveals properties of the library as directed by the panel design. The demonstration here displays a panel-directed enrichment workflow that is reliable for wide range of total capture inputs and hybridization times for each given Exome panel, spanning different panel design approaches as well as single- and double-stranded probes. This behavior can be extrapolated to applications that requires multiplexing, low-pass or deep-sequencing needs, and custom panels. The panel-directed consistency over a large range of inputs and hybridization times makes xGen v3 adaptable to a large variety of applications, from quick surveys to high-throughput and/or in-depth interrogations as directed by the panel design.

#4088 Optimized workflow for isolating nuclei from FFPE tissue sections for snRNAseq.

Lea Eich, Svetlana Khorkova, Nojan Jelveh, Lilian Martinez Carrera, Olaf Hardt, Carsten Poggel, **Benjamin Theek**

Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany

Background: Formaldehyde fixed and paraffin embedded (FFPE) tissue sections are a valuable resource in cancer research due to the long-term preservation of clinical samples. However, these tissues present significant challenges for molecular analysis due to fixation-induced crosslinking. This study describes an optimized workflow that enables efficient isolation of nuclei from FFPE tissues, compatible with the Chromium Single Cell Gene Expression Flex Assay for downstream gene expression analysis.
Methods: FFPE tissue sections from different tissue types (i.e., breast-, lung-, and colon-cancer) were subjected to a deparaffinization and rehydration process, followed by a combined gentleMACS based mechanical dissociation and enzymatic digestion to obtain nuclei. Our new dissociation protocol was benchmarked against a Liberase TH based dissociation. Key modifications of our protocol include the selection of an optimized enzyme mix and a digestion buffer composition to enhance nuclei yield and purity. Nuclei purity and yield were quantified using flow cytometry and an automated cell counter, respectively, while RNA metrics, such as DV200, were assessed via the Agilent TapeStation. The isolated nuclei were then processed using 10x Genomics Chromium Single Cell Gene Expression Flex Assay to validate their suitability for RNA profiling.
Results: The optimized protocol successfully isolated nuclei from a variety of FFPE tissue types, often yielding sufficient nuclei from a single 25um FFPE tissue scroll. The following Chromium Single Cell Gene Expression Flex Assay confirmed the superior performance of our new dissociation workflow for RNA profiling. Cell Rangers QC metrics for median UMI counts, median genes, and median reads per cell were improved on average by 61%, 53%, and 59%, respectively. Furthermore, mitochondrial gene expression was reduced on average by 63% compared to the control, suggesting a cleaner nuclei sample.
Conclusion: The optimized workflow provides a significant advancement for utilizing FFPE samples in single-cell gene expression studies. By enabling efficient nuclei isolation from FFPE sections, this protocol allows for comprehensive transcriptomic analysis using the Chromium Single Cell Gene Expression Flex Assay, with minimal background, unlocking the potential of archived tissues in retrospective and translational research.

#4089 A novel NGS-based sample tracking system for robust sample chain of custody and quality control in fresh frozen and FFPE tumor samples.

Katherine Milligan, Yu Qiu, Andrea O'Hara, **Carrie Ziemniak**, David Corney, Haythem Latif

Azenta Life Sciences, South Plainfield, NJ

When processing large cohorts of samples, sample identity and functional quality are key to ensure the derived data is accurate and attributed to the appropriate sample. This is especially critical when working with precious and degraded material such as formalin-fixed paraffin-embedded (FFPE) samples. A potential sample swap or poor sample quality may result in incorrect data or delays due to re-processing. While traditional methods such as qPCR can be used for quality control, they may not be an effective predictor of sample success in Next-Generation Sequencing (NGS) based assays due to differential susceptibility to inhibitors and interfering substances. Performing a functional quality control assessment using the same methodology for data generation allows for a more accurate prediction of performance as it would be similarly affected by interfering substances or sample degradation. We have created a scalable, cost-effective sample tracking and functional quality control assay that may be assessed prior to performing more expensive downstream sequencing assays. This assay was designed to confirm consistency in sample identity during processing and confirm identity when multiple samples are submitted from the same subject. This amplicon panel targets autosomal SNPs with varying minor allele frequencies in different ethnic populations, limiting a bias towards variation in European ethnic populations. The average minor allele frequency for the panel developed for the general population is 0.45, more specifically 0.46 for European background, 0.44 for African background and 0.46 for Asian background based on data from the Allele Frequency Aggregator (ALFA) database. Most amplicons were designed to be less than 150 base pairs to increase the likelihood of success for samples with degraded DNA. Targets were included on the X and Y chromosome for sex determination. Tumor-normal paired samples were processed on the sample tracking assay, targeting regions throughout the exome to allow tracking of sample identity. When comparing “normal” samples extracted from blood to their paired FFPE tumor tissue, known matches had an average of 98.0% concordance, while known mismatches had an average of 40.4% concordance, with the highest known mismatch showing 61.9% concordance. Additionally, when comparing well-characterized samples to their corresponding data from the 1000 Genomes Project, samples had 99.4% concordance. This exemplifies a robust sample tracking assay that can ensure sample identity is correct. A strong quality control assay enables NGS laboratories to identify poor sample quality or degradation, allowing for re-extraction or new sample collection before processing on a more expensive assay. This newly developed sample tracking assay ensures both sample integrity and identity, leading to an overall increase in data quality for cancer research studies.

#4090 Analytical validation of PanTracer LBx performance, a comprehensive pan-solid tumor liquid biopsy assay.

Christodoulos Pipinikas[1], Faqiang Wu[2], Daniel Whang[2], Rebecca Hong[2], Samuel Koo[2], Qinqin Zha[2], Jieying Chu[2], Rachel Schell[2], Jiannan Guo[2], Giovanni Marsico[1], Tim Forshew[1], **Amber Chevalier**[3], Andrew Lukowiak[3], Heng Xie[2], Gregory Jones[4]

[1]NeoGenomics, Cambridge, United Kingdom,[2]NeoGenomics, Aliso Viejo, CA,[3]NeoGenomics, Fort Myers, FL,[4]NeoGenomics, Durham, NC

Introduction: Pan-solid tumor comprehensive genomic profiling (CGP) assays have gradually replaced single gene and smaller, tumor-specific panels to identify actionable somatic mutations in patients with advanced cancer. While tissue-based CGP remains important for clinical decisions, invasive biopsies can be challenging in terms of material quantity/quality and/or risk to patients. Plasma-based CGP assays provide the potential for rescuing cases where tissue fails, providing faster results to enable treatment decisions, monitoring treatment through repeated sampling, or capturing tumor heterogeneity. As such, CGP via liquid biopsy (LBx) represents an asset to patients and the options for such testing spans several to hundreds of genes. Here we describe initial results of the analytical validation (AV) process of a large deep sequencing panel aiming to establish the initial performance characteristics of the PanTracer LBx CGP assay. We also provide initial preliminary comparison data to an established highly sensitive targeted panel.

Methods: PanTracer LBx, a next-generation sequencing (NGS) assay based on TSO500 chemistry, is designed to detect key classes of somatic alterations across solid tumors, such as SNVs and small InDels (517 genes), CNVs (59 genes), fusions (23 genes) and key immune signatures. AV was performed in a CAP/CLIA certified laboratory across the above mutation classes to determine key assay performance characteristics: limit of detection (LoD), limit of blank (LoB), precision and analytical sensitivity/specificity using clinical samples with orthogonal data.

Results: LoD90, was assessed by measuring the detection of somatic variants present in SeraSeq complete ctDNA reference material at different %VAF levels (0.1%-2%) and DNA concentrations. Using a Probit regression model, LoD90 for SNVs and InDels was determined as 0.17% and 0.31%, respectively, and 1.23x for CNVs. LoB for SNVs/InDels and CNVs, assessed by calculating the cumulative per gene specificity across 21 healthy donors subjected to sequencing, was 0%. Analytical sensitivity and specificity were determined by sequencing late-stage cancer samples and comparing results to those obtained with an amplicon-based assay (InVisionFirst^{TM}-Lung). Positive and negative percent agreement with the orthogonal method was 96.9% and 99.3%, respectively. Precision (inter-assay, -lot and -operator) was >95%.

Conclusions: Performance evaluation of PanTracer LBx assay met all pre-specified AV acceptance criteria. Fusion LoD90 analysis is ongoing and will be presented during the meeting with additional results including input metrics and preliminary clinical validation. Based on a large panel targeting different classes of somatic variants across multiple genes, it offers results consistent with a smaller, established targeted panel with the addition of more biomarkers that may be informative or actionable.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Integrating Chromatin, Oncogenes, DNA Repair, and Biomarkers for Therapeutic Advancements
Poster Session

#4094 Allosteric chromatin activity transition mechanisms drive epigenetic dosage compensation in essential genes triggered by oncogene activation in TRACERx.

Francisco Gimeno-Valiente[1], Carla Castignani[2], Xiaohong Liu[1], Georgia Stavrou[1], Nana E. Mensah[1], Elizabeth Larose Cadieux[2], Ozgen Deniz[3], Mariam Jamal-Hanjani[1], Stephan Beck[1], Jonas Demeulemeester[4], Miljana Tanic[1], Charles Swanton[2], Peter Van Loo[5], Nnennaya Kanu[1]

[1]University College of London, London, United Kingdom,[2]Francis Crick Institute, London, United Kingdom,[3]Queen Mary University of London, London, United Kingdom,[4]Katholieke Universiteit Leuven, Leuven, Belgium,[5]MD Anderson Cancer Center, Houston, TX

Lung TRACERx is a prominent study employing multi-region and longitudinal multi-omics sequencing to unravel the evolutionary trajectories of cancer. While aberrant DNA methylation is described in most cancers, its interplay with genomic alterations and chromatin remodeling in non-small cell lung cancer (NSCLC) is less understood. We propose Allosteric Chromatin Activity Transition (AllChAT) as a framework to elucidate epigenetic dosage compensation mechanisms, focusing on essential genes impacted by oncogene-driven DNA methylation changes. The study utilized multi-region sampling from 59 NSCLC patients, encompassing 217 tumor regions and 59 adjacent normal tissue samples. RRBS was performed to profile DNA methylation patterns, with tumor-specific methylation rates determined using the CAMDAC tool. WES was conducted to identify somatic mutations and copy number alterations via ASCAT. Additionally, ChIP-seq for H3K4me3 and H3K27me3 was carried out on TRACERx patient-derived cell lines (PDCs) to investigate chromatin state changes associated with epigenetic transitions.We identified oncogenes such as RAC1, EGFR, and CDK4, whose expression scales with amplification and exhibited lower methylation levels in tumour regions where amplified compared to non-amplified tumor regions. We also discovered oncogene-proximal genes under dosage compensation by DNA methylation associated with amplification of CCND1 in LUSC and LUAD, as well as CDK4, KRAS, and GNAS, specifically in LUAD. These dosage-compensated genes were enriched for essential genes. Using chromatin immunoprecipitation on TRACERx patient derived cell lines (PDCs) from 2 tumors and one normal sample, we observed that oncogenes such as CDKN1B, FGFR1, and JAK2 were co-amplified and associated with chromatin opening and hypomethylation at amplified loci compared to non-amplified loci. Additionally, we found essential passenger genes, including NOP2, DCTN6 and FOXD4, were associated with closed chromatin and increased DNA methylation at the respective loci when amplified compared to when not amplified in tumor PDCs compared to the normal PDC. As observed in TRACERx tumor tissues, we observed evidence for AllChAT around LRRC34 when co-amplified with the PI3KCA oncogene in both tumor PDCs. Conversely, as expected, no evidence of AllChAT was observed in non-amplified control regions such as for the essential passenger genes TOMM40 and RPS9 located proximal to the ERCC2 oncogene when not amplified nor for the essential gene ECT2 located proximal to PIK3CA. Taken together, these data suggest that copy number alterations around amplified oncogenes might trigger an allosteric chromatin transition and DNA hypermethylation of co-amplified passenger genes, which might be crucial to the regulation of essential genes during tumor evolution.

#4095 Advancing cancer prognosis: FFPE-CUTAC for comprehensive and affordable transcription profiling in oncology.

Y. Zheng[1], K. Ahmad[2], S. Henikoff[2];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Fred Hutchinson Cancer Center, Seattle, WA

RNA-seq has been the method of choice for profiling patient samples. However, it predominantly detects genes expressed at moderate-to-high levels and is limited by the fragility of RNA, especially in Formalin-Fixed Paraffin-Embedded (FFPE) sections. We introduce Cleavage Under Targeted Accessible Chromatin (CUTAC) with an antibody to RNA Polymerase II (RNAPII) as a sensitive, cost-effective alternative for directly profiling transcription in FFPEs. Our findings reveal that FFPE-CUTAC libraries are significantly more comprehensive than RNA-seq libraries from both frozen and FFPE clinical sections, capturing low-level transcription of most active genes often missed by RNA-seq. Integrating RNAPII FFPE-CUTAC data from meningioma tumor samples with RNA-seq data from 1,298 patients, we demonstrate that RNAPII occupancy correlates strongly with transcriptional output. Embedding RNAPII FFPE-CUTAC datasets within a meningioma RNA-seq UMAP enhances the prediction of poor clinical outcomes, offering a powerful and economical replacement for RNA-seq in general cancer diagnosis.

Moreover, we observed widespread hypertranscription in human cancers, which correlates with poor prognosis. Using FFPE-CUTAC, we demonstrated genome-wide hypertranscription in transgene-driven mouse gliomas and various human tumors at active regulatory elements. Notably, hypertranscription challenges most normalization strategies that assume equal fragment volumes across samples. Tumor burden varies greatly across patients and tumor types, with significantly more cells in tumors compared to their corresponding normal samples. Within tumor cells, hypertranscription results in substantially higher FFPE-CUTAC fragment count. Assuming equal reads between tumor and normal samples can obscure hypertranscription signals. To address this, we developed a background-driven normalization strategy for FFPE-CUTAC data, accounting for the variations of cell numbers and fragment volumes to ensure accurate comparison across tumor and normal samples. We validated this strategy using both single-cell simulated data and specially designed experiments with known cell proportions and signal fold changes.

Our experimental and computational results affirm that FFPE-CUTAC provides a sensitive and affordable approach for detecting hypertranscription and classifying tumors using small tissue sections, advancing genome-wide strategies for personalized medicine.

#4096 Altered epigenetic aging in leukocytes with detectable mosaic chromosomal alterations.

Corey D. Young, Derek W. Brown, Charles Breeze, Rebecca L. Kelly, Kara M. Barnao, Aubrey K. Hubbard, Weiyin Zhou, Amy A. Hutchinson, Belynda D. Hicks, Aurelie L. Vogt, Wen-Yi Huang, Steven C. Moore, Stephen J. Chanock, Mitchell J. Machiela

NCI Div. of Cancer Epidemiology & Genetics, Rockville, MD

Background: Mosaic chromosomal alterations (mCAs), including autosomal mCAs, mosaic loss of chromosome X (mLOX), and mosaic loss of chromosome Y (mLOY) are types of age-related detectable clonal hematopoiesis (CH) in the blood and are associated with hematologic cancer risk. Epigenetic age, measured by DNA methylation-based clocks, can be used to estimate epigenetic age acceleration and could offer insights into the etiology of hematologic cancer; however, the relationship between mCAs and epigenetic age acceleration remains poorly understood.

Methods: DNA methylation was analyzed in 482 blood-derived samples from the Prostate, Lung, Colorectal and Ovarian (PLCO) Cancer Screening Trial using the Illumina EPIC array. Quality control and normalization were implemented using the Chip Analysis Methylation pipeline (ChAMP) and epigenetic aging metrics were derived using the DNA Methylation Age Calculator. T-tests were conducted to evaluate differences in age acceleration and age-adjusted logistic regression was used to investigate differences in estimated abundance of immune cells by mCA type.

Results: In total, 115 analyzed PLCO participants had autosomal mCAs, 68 had mLOX, 38 had mLOY, and 261 were mCA-free. Participants with mLOY exhibited the highest mean chronologic age (67.50 years) and the highest smoking prevalence (68.52% ever smokers). Across all samples, DNA methylation age demonstrated a moderate correlation with chronologic age ($r=0.57$, $p\ 8.38\times10^{-43}$, 95% CI:0.51-0.63). A trend toward higher epigenetic age acceleration was observed in individuals with detectable mCAs compared to mCA-free individuals (mean difference=1.17, p=0.05), with females having detectable mLOX displaying the highest age acceleration (mean difference=1.82, p=0.031). Notable alterations in methylation-estimated immune cell abundance were observed in individuals with detectable mCAs including elevations in CD4 T cells, natural killer cells, monocytes and granulocytes. Additionally, 2 probes, were differentially methylated in individuals with mCAs relative to mCA-free individuals, both located near the FOXI2 gene.

Conclusion: We observe epigenetic age acceleration in individuals with detectable mCAs, indicating epigenetic age acceleration could be a contributor to or consequence of mCAs in the hematopoietic compartment. Methylation-based evaluation of immune cell abundance identified increases in both lymphoid and myeloid cell types in individuals with mCAs, supporting prior findings of altered immune function in individuals with mCAs.

#4097 The ATAC histone acetyltransferase complex is a key oncogenic driver in sarcomas.

Souradip Sinha, Krishnendu Ghosh, Ali Khan, Yuliia Drebot, Gillian DeWane, Nicholas Scalora, Samuel Yu, Keith Garcia, Munir R. Tanas

Department of Pathology, University of Iowa, Iowa City, IA

Background: Sarcomas are heterogenous neoplasms originating in mesenchymal tissues such as muscles, fat, nerves, blood vessels, etc. Our lab has previously shown that the Hippo signaling pathway is perturbed in sarcomas, and TAZ/YAP, the end effectors of the Hippo pathway, are key oncoproteins driving sarcomagenesis. Epithelioid hemangioendothelioma (EHE), a vascular sarcoma, is predominantly driven by the fusion protein TAZ-CAMTA1, which promotes cancer hallmarks and alters gene expression patterns by interacting with YEATS2 and ZZZ3, which are key scaffolds of the Ada2A-Containing (ATAC) histone acetyltransferase (HAT) complex. YEATS2 is a histone reader and binds H3K27-acetyl, and ZZZ3 binds the histone H3 tail, and both YEATS2 and ZZZ3 are necessary for the proper assembly of the ATAC complex, which subsequently acetylates H3K9, a key histone modification necessary for gene transcription. Previously, we have utilized RNA-sequencing data from The Cancer Genome Atlas and shown that high YEATS2/ZZZ3 RNA levels correlate with a worse overall survival in multiple histological subtypes of sarcomas.

Methods: We performed western blot analysis to measure YEAST2/ZZZ3 protein levels in human sarcoma cell lines. We utilized siRNA/shRNA to knockdown YEATS2/ZZZ3 and measured H3K9-acetyl protein levels via western blot analysis. Apart from genetic inhibition, we utilized HAT-inhibitors and performed several *in vitro* cancer hallmarks, such as 3D soft agar assays and poly-HEMA assays to measure anchorage-independent growth and MTT-based assays to measure 2D proliferation. We also performed a cell-line-derived xenograft experiment where we injected immunocompromised NSG mice with SW872 cells expressing TAZ-CAMTA1 with or without stable knockdown of YEATS2.

Results: We observed that YEATS2/ZZZ3 protein levels are upregulated in multiple human sarcoma cells. We also observed that genetic and pharmacological inhibition of the ATAC complex in both fusion protein-positive (SW872 cells expressing TAZ-CAMTA1) and -negative (SKLMS; leiomyosarcoma and HT1080; fibrosarcoma) sarcoma cells decreases H3K9-acetyl protein levels. In the xenograft experiment, knockdown of YEATS2 significantly decreased tumor initiation and progression in NSG mice as compared to non-targeting cells. In SKLMS, YEATS2 knockdown significantly reduced 2D proliferation and colony formation on soft agar.

Conclusion: Our data show that in both fusion protein-positive and -negative sarcomas, the ATAC complex is a key histone acetyltransferase for H3K9. We show that the ATAC complex promotes tumorigenesis *in vivo* in a xenograft mouse model. In the leiomyosarcoma cell line SKLMS, the ATAC complex promotes 2D proliferation and anchorage-independent growth *in vitro*, which are key cancer hallmarks. Overall, our studies show that the ATAC complex is a potential therapeutic target in multiple sarcomas, such as EHE and leiomyosarcoma.

#4098 PARP1 and EZH2 independently limit 5'-3' end resection to promote rapid DNA repair after radiation.

Elena Efimova[1], Yue Liu[1], Sera Averbek[1], Isabelle Lomeli[1], SeokGyeong Choi[2], Sojung Ha[2], Woo-Young Kim[2], Stephen J. Kron[1]

[1]Ludwig Center for Metastasis Research and Department of Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL,[2]Department of Pharmacy, Sookmyung Women's University, Seoul, Korea, Republic of

Cellular metabolism and epigenetic regulation have overlapping roles in cancer cell responses to radiation, with dynamic, reversible post-translational modifications including poly-ADP-ribosylation, O-GlcNAcylation and methylation emerging as key targets. This study explored crosstalk between poly-ADP-ribose polymerase 1 (PARP1), O-GlcNAc transferase (OGT), and the PRC2 subunit and histone methyltransferase EZH2 in the context of DNA double-strand break (DSB) repair. We focused on 5'-3' end resection, which determines repair pathway choice during S and G2 via guiding DSB repair away from non-homologous end joining (NHEJ) and toward homologous recombination (HR). DSB repair was examined in the human breast cancer cell line MCF7 using neutral comet assay and immunofluorescent detection of γH2AX, 53BP1, and BRCA1 foci. 5'-3' end resection was followed by tracking BrdU, RPA and RAD51 foci. We used CRISPR RNP to form pools of PARP1 and EZH2 knockout (KO) cells. After irradiation, both PARP1 KO and PARP inhibitor veliparib-treated cells displayed persistent DSBs and increased ssDNA, each restricted to S/G2 cells. While increased 5'-3' end resection may result from NHEJ defects, deregulation of resection may divert DSBs away from NHEJ to saturate cellular capacity for HR. Indeed, PARP inhibition enhanced HR repair based on a repair pathway reporter. Increasing protein O-GlcNAcylation in PARP1 KO or veliparib-inhibited cells restored DSB repair and suppressed hyper-resection, suggesting an independent, OGT-regulated determinant of pathway choice. Prior studies had implicated EZH2 and resulting histone H3 K27 trimethylation in promoting NHEJ and as a mediator of O-GlcNAcylation effects. Much like PARP1 KO, irradiated EZH2 KO cells displayed an S/G2 DSB repair defect associated with increased ssDNA. Hyper-resection in EZH2 KO was enhanced by PARP inhibition but modulating O-GlcNAcylation had no effect. Interestingly, along with increased nuclear BrdU foci, irradiated PARP1 KO and EZH2 KO each displayed cytosolic ssDNA foci. We infer that limiting NHEJ repair and/or promoting 5'-3' end resection in S/G2 can overwhelm HR, leading to hyper-resection, cytosolic DNA, and inflammation. Toward overcoming resistance to PARP inhibitors, O-GlcNac metabolism, OGT activity and its downstream mediator EZH2 offer attractive targets for therapeutic intervention. Overall, strategies aimed at deregulating 5'-3' end resection may help focus effects of genotoxic stress on proliferating cells and potentiate combinations with immunotherapies.

#4099 Leveraging the cell-free DNA hydroxymethylome as a prognostic biomarker in small cell lung cancer.

Janice J. N. Li, Dangxiao Cheng, Danielle B. Sacdalan, Luna J. Zhan, Sami Ul Haq, Vivek Philip, Gregory Schwartz, Scott V. Bratman, Geoffrey Liu, Benjamin H. Lok

UHN Princess Margaret Cancer Centre, Toronto, ON, Canada

Purpose: Small cell lung cancer (SCLC) is a highly aggressive neuroendocrine carcinoma characterized by rapid growth, early treatment resistance, and a dismal 5-year overall survival rate of <10%. Despite a high mutation burden, identifying robust biomarkers for SCLC remain a challenge due to the lack of actionable driver mutations and the scarcity of tumor tissue. Exploring DNA 5-hydroxymethylcytosine (5hmC) in plasma cell-free DNA offers a promising, minimally invasive opportunity for genome-wide profiling, however this remains understudied in SCLC. In this study, we hypothesize that the SCLC cell-free hydroxymethylome is distinct from healthy non-cancer controls and that it controls biological pathways that mediate prognosis.

Methods: Blood plasma samples were collected from a cohort of 49 de novo SCLC patients at pretreatment timepoints and 55 healthy non-cancer controls. Cell-free DNA (cfDNA) was isolated from plasma and examined using the 5hmC-selective chemical labeling (HMe-SEAL) assay, followed by next generation sequencing, to generate genome-wide 5hmC profiles. Global and gene-feature specific 5hmC patterns were compared between SCLC and control cfDNA to delineate SCLC-specific differentially hydroxymethylated regions (DhMRs). KEGG pathway analysis was performed on global DhMRs significantly enriched in SCLC. Kaplan-Meier and log-rank analyses were performed to determine the relationship between global DhMRs and survival outcomes. Overall survival (OS) was anchored from the time of SCLC diagnosis and progression-free survival (PFS) was anchored from the start of first-line treatment.

Results: Among the 49 SCLC patients, 69% had extensive-stage (ES-SCLC, n=34) and 65% were male (n=32). Global enrichment of 5hmC was observed in SCLC cfDNA compared to controls, particularly at intronic regions ($p<0.001$). Differential analyses revealed that global and gene feature-specific DhMRs, such as enhancer regions, could distinguish between SCLC and controls by principal component analysis. Pathway analysis of global DhMRs enriched in SCLC highlighted genes involved in cell proliferation (e.g. cAMP, Hippo, Wnt signaling pathways), axonal guidance, and stemness, which are commonly altered in cancer ($p<0.001$ for all mentioned pathways). When correlating 5hmC levels with survival data, SCLC patients presenting with high global 5hmC levels trended towards worse OS and PFS compared to those with low global 5hmC levels (median OS of 10.5 months vs 15.3 months, $p=0.13$; median PFS of 5.27 months vs 7.18 months, $p=0.07$).

Conclusion: Global cell-free 5hmC patterns distinguished between patients with SCLC and non-cancer controls and mapped to cancer-related pathways. Global 5hmC levels could also be leveraged for patient prognostic stratification, presenting a novel, minimally invasive biomarker for SCLC.

#4100 Aberrant translation regulated by METTL1/WDR4-mediated Val-AAC tRNA N7-methylguanosine modification promotes gastric carcinogenesis.

Yuan Li, Silei Sui, Rui Su, Ajay Goel

City of Hope Comprehensive Cancer Ctr., Duarte, CA

Background: Dysregulated epigenetic modifications in RNA are closely associated with the onset and progression of human tumors. Among cellular RNA modifications, transfer RNAs (tRNAs) are the most frequently modified type; however, the role of tRNA modifications in cancer remains largely unexplored. The RNA methyltransferase METTL1, which catalyzes N7-methylguanosine (m7G) modification of tRNAs, is often amplified and overexpressed in cancers and correlates with poor patient survival. In this study, we aimed to investigate the function and underlying mechanisms of m7G modification in tRNAs driving the development and progression of gastric cancer (GC).
Methods: We conducted a series of mechanistic studies to investigate the physiological functions of tRNA m7G modifications in GC tumorigenesis. Using tRNA modification and expression profiling, mRNA translation profiling, and rescue assays, we identified the molecular mechanisms underlying m7G modification in GC. Additionally, we analyzed the expression levels of the tRNA m7G methyltransferase complex components, methyltransferase-like 1 (METTL1) and WD repeat domain 4 (WDR4) in human GC samples.
Results: METTL1/WDR4 promoted GC progression and metastasis in cell-based and xenograft mouse models. Mechanistically, the loss of METTL1 reduced tRNA m7G levels, particularly in Val-AAC tRNAs, leading to decreased translation of mRNAs enriched with m7G tRNA codons and impairing the synthesis of a subset of oncogenic transcripts. Moreover, the tRNA m7G methyltransferase complex components METTL1 and WDR4 were found to be upregulated in GC and correlated with poor patient prognosis.
Conclusion: The tRNA m7G methyltransferase METTL1 was identified as a key driver of GC development and malignancy by regulating global mRNA translation through tRNA modifications. Our findings highlight METTL1 as a promising therapeutic target for GC patients.

#4101 Blood based biomarkers of DNA methylation associated with platinum resistance in high grade serous ovarian cancer.

Daniela Matei[1], Horacio Cardenas[1], **Elnaz Abbasi Farid**[2], Zhen Fu[3], Collin M. Coon[2], Adam Vieth[1], Kenneth P. Nephew[2]

[1]Feinberg School of Medicine, Northwestern University Chicago, Chicago, IL,[2]Indiana University School of Medicine, Bloomington, IN,[3]Van Andel Institute, Grand Rapids, MI

High grade serous ovarian cancer (OC) is initially a responsive tumor to platinum (Pt)-based therapy. Tumor suppressor genes (TSGs) are implicated in OC initiation and progression and can be inactivated through genetic or epigenetic events. DNA methylation has been shown to silence TSGs and other cancer-related genes and is detectable in cancer cells and in blood. Here we aimed to develop a blood-based methylation assay associated with cancer and cancer recurrence in OC. We evaluated genome-wide DNA methylation in de-identified peripheral blood mononuclear cells (PBMCs) from women: without cancer (controls, n=20), newly diagnosed OC (prior to treatment, Pt-sensitive, n=50), and platinum-resistant recurrent HGSOC before and after treatment with a hypomethylating agent (HMA, Pt-resistant, n=31). The Pt-resistant patients were enrolled on NCT02901899 clinical trial testing guadecitabine and pembrolizumab. DNA extracted from PBMCs was analyzed by using Infinium MethylationEPIC BeadChips. DNA methylation analysis used R package SeSAMe to derive beta (β) values and identify differential methylated loci (DMLs) and differential methylated regions (DMRs) between groups. Bioinformatics analysis was conducted to identify biological pathways and processes, determined using Ingenuity Pathway Analysis (IPA) and KEGG, GO:BP, REAC databases. Deconvolution analyses used the HEpiDISH algorithm to determine the cellular make-up of the samples. Comparing controls vs. Pt-sensitive groups, there were 30,369 DMLs (adj. $p<0.05$, $\beta>10\%$), with most loci being demethylated. Enriched pathways related to presence of cancer included: mechanisms of cancer, neutrophil degranulation, and cancer-related signaling pathways (PI3K/AKT, STAT3, HGF, interleukins). The number of DMLs was greater (880, adj. $p<0.05$, $\beta>10\%$) in Pt-resistant vs Pt-sensitive and enriched pathways associated with Pt-resistant OC included: pathways in cancer, metabolic pathways, platelet activation, ABC transporters and signaling pathways (calcium, PI3K/AKT, MAPK, Ras, ErbB, Hippo, Wnt). Massive genome-wide hypomethylation 5 days after treatment with the HMA was seen (13,742, adj. $p<0.05$, $\beta>10\%$), consistent with observed LINE1 hypomethylation in PBMCs, and genome-wide hypomethylation persisted 30 days after end of HMA treatment. Enriched pathways among hypomethylated genes included: Th17 cell differentiation, virus infection, focal adhesion, signaling (chemokine, cGMP-PKG, Rap1) and hormone (thyroid, parathyroid, oxytocin, growth hormone) pathways. Deconvolution analysis identified decreased B and NK cells, monocytes, and eosinophils and a trend towards decreased $CD4^+$ and $CD8^+$ cells in Pt-sensitive OC vs controls. In contrast, neutrophils were increased in cancer vs control patients. We propose new DMLs associated with Pt-sensitive vs. Pt-resistant OC. These findings can lead to new biomarkers for HGSOC.

#4102 N6-methyladenosine modification of FZR1 mRNA promotes gemcitabine resistance in pancreatic cancer.

Ziming Chen

Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly aggressive cancer with a 5-year survival rate of less than 10% and limited treatment options. Gemcitabine, a pyrimidine nucleoside analogue, is the standard first-line treatment for pancreatic cancer. However, drug resistance to gemcitabine remains a major challenge in PDAC. Dysregulation of N6-methyladenosine (m6A) modification has been linked to human disease regulation, and targeting aberrant m6A modifications or their key regulators may be beneficial to overcome drug resistance. However, the potential role and precise mechanism of m6A modification in the development of gemcitabine resistance in PDAC have not been fully elucidated.

Methods: In this study, we screened gemcitabine-insensitive and -sensitive PDAC cells through exposure to time- and dose-gradient gemcitabine. We then performed m^6A-sequencing analysis on these cells and identified the hyper-m^6A modification of FZR1 as a key molecular event contributing to gemcitabine insensitivity in PDAC. Additionally, we examined human PDAC samples using m^6A-qPCR assays and reaved that FZR1 m^6A modification had a significant clinical PDAC diagnosis and therapeutic value for PDAC.

Results: We found that PDAC cells with distinct gemcitabine sensitivity showed different m^6A profiles and that FZR1 had the most upregulated m^6A modification in gemcitabine-insensitive cells compared with gemcitabine-sensitive cells. Mechanistically, we discovered that RNA m^6A modification enhanced FZR1 translation in a GEMIN5-dependent manner, leading to a gemcitabine-insensitive phenotype by inducing a quiescent state. Importantly, targeting the m^6A modification of FZR1 increased the sensitivity of PDAC cells to gemcitabine both in vitro and in vivo.

Conclusions: This study identified the m^6A-FZR1 axis as an underlying mechanism contributing to gemcitabine treatment resistance in pancreatic cancer. The m^6A-FZR1 axis may serve as a predictor of gemcitabine treatment response in patients with PDAC. Overall, our discoveries interestingly link the dysregulated m^6A modification to gemcitabine insensitivity in PDAC, and provide new insights into the molecular mechanisms of gemcitabine resistance in this cancer type.

#4103 MLL4/COMPASS dysfunction in cancer and treatment.

Zibo Zhao[1], Sarah Gold[1], Yuki Aoi[1], Khyati A. Meghani[1], Luke St John[1], Rukkia Liaqat[1], Carolyn Moloney[1], Yanni Yu[1], Jun Qian[1], Issam Ben-Sahra[1], Rintaro Hashizume[2], Devalingam Mahalingam[1], Joshua Meeks[1], Ali Shilatifard[1]

[1]Biochemistry and Molecular Genetics, Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]Pediatrics, University of Alabama at Birmingham, Birmingham, AL

Epigenetic status-altering mutations in chromatin-modifying enzymes are a feature of human diseases, including many cancers. We investigated cellular dependencies, or vulnerabilities, that arise when enhancer function is compromised by loss of the frequently mutated COMPASS family members MLL3 (KMT2C) and MLL4 (KMT2D). We performed a CRISPR dropout screen that revealed a targetable metabolic dependency arising from epigenetic factor deficiency, identifying potential therapies for cancers with epigenetic alterations secondary to MLL3/4-COMPASS dysfunction. We identified strong evidence that there is an internal balance between promoter and enhancer usage dictated by MLL1- versus MLL4-COMPASS, and this equilibrium is subject to disruption during cancer. Using an autochthonous carcinogen model of bladder cancer, we demonstrate that truncated, cytoplasmic MLL4 predicts response to targeted metabolic inhibition therapy for bladder cancer and could be developed as a biomarker for KMT2D-mutated cancers. We also highlight the broader potential for prognosis, patient stratification and treatment decision-making based on KMT2D mutation status in MLL4 truncation-relevant diseases, including human cancers and Kabuki Syndrome. Due to the high prevalence of loss-of-function mutations affecting MLL4 or its COMPASS partner UTX (KDM6A) in bladder cancer, we hypothesized that KMT2D mutation status may predict responsiveness to purine-targeting therapy, including methotrexate and pemetrexed. Our study found that KMT2D mutant bladder cancer cells were selectively dependent on TYMS and showed heightened sensitivity to pemetrexed, a drug that inhibits TYMS, DHFR, and GART. This suggests that targeting multiple enzymes within the one-carbon metabolism and de novo purine synthesis pathway could be promising for the treatment of MLL4/UTX-COMPASS mutant bladder cancer. Based on our previous and current findings, a clinical trial using pemetrexed in MLL4/UTX-COMPASS mutant solid tumors is being launched at Northwestern Medicine.

#4104 Adapter-anchored methylation specific amplification on genomic DNA using proximity primers (aMAPP).

F. Darbeheshti*[1], H. Zeggar*[1], H. Salmani[1], Y. Liu[2], V. A. Adalsteinsson[3], G. Makrigiorgos[1];
[1]Dana-Farber Cancer Institute, Boston, MA, [2]Wuhan University, Wuhan, China, [3]Broad Institute of MIT and Harvard, Cambridge, MA

Purpose: The epigenetic deregulation of CpG islands (CGIs) plays a crucial role in cancer initiation and progression. Genome-wide analysis of aberrant methylation patterns in CGIs offers a promising approach for the early cancer detection. However, the clinical utility of whole genome bisulfite sequencing is limited by the need for high sequencing coverage to achieve sensitive detection. To address this challenge, we have developed aMAPP, a method that enriches hypermethylated and/or hypomethylated CGIs. This approach enables the detection and tracing of aberrant methylation patterns, achieving high coverage in CGIs with ultra-low depth sequencing.
Methods: NEBNext Ultra II Library Prep. was used for adapter ligation. DNA was then subjected to APOBEC-mediated deamination and/or TET-Assisted Pyridine Borane Sequencing (TAPS) and pre-amplified. Methylation-specific amplification was then conducted using novel, customized proximity primers composed of an anchor, binding to the adapter, and a 6-10 bp probe, designed to bind tandem CpG dinucleotides downstream of the adapter. These primers amplify selectively DNA fragments containing methylated CpGs that remain intact after APOBEC deamination or unmethylated CpGs that remain intact after TAPS. Following Proximity Primer-PCR, MiSeq was conducted, generating approximately 500,000 reads per sample.
Results: Proximity primers were shown to amplify APOBEC-treated DNA fragments containing CpGs that match the primer probes, even if these CpGs are 100 bases downstream the adapter. While unmethylated fragments lack CpGs and are not amplified ($\Delta Ct_{meth\text{-}unmeth} \approx 18$). Applying aMAPP to APOBEC-treated methylated gDNA provided large amplification footprint of genome-wide methylated CGIs with remarkable efficiency, yielding 355-fold and 746-fold more CGIs with coverage of ≥5 and ≥10, respectively, compared to standard EM-Seq. Depending on conditions applied, aMAPP captures >80% of all CGIs with high coverage using ultra-low sequencing depth. Similarly, aMAPP applied to TAPS-treated unmethylated DNA captured selectively the unmethylated CGIs. aMAPP can be applied with very low starting material (10-100pg). Upon application to clinical samples, aMAPP detected thousands of CGIs and identified CpG island methylator phenotype (CIMP) and the top 20 hypermethylated CGIs in colorectal cancer. aMAPP could trace differentially methylated CGIs (DMR) in tumor samples present at 0.01% levels within adjacent normal tissue, or within circulating DNA of normal volunteers.
Conclusion: aMAPP enriches methylated and/or unmethylated portions of the genome with a unique efficiency, simplicity and flexibility that supersedes previously reported methylation enrichment approaches, enabling focused methylation sequencing at high coverage. Multiple applications in biomarker tracing and discovery can be envisioned in cancer, and beyond cancer.

#4105 ADAR1-high tumor-associated macrophages induce drug resistance and are therapeutic targets in colorectal cancer.

Kazuya Moriwake, Kunitoshi Shigeyasu, Hibiki Umeda, Toshiaki Takahashi, Masashi Kayano, Kaori Nitta, Shunsuke Nakamura, Masafumi Takahashi, Yuya Sakurai, Yuki Matsumi, Yoshitaka Kondo, Fuminori Teraishi, Hiroshi Tazawa, Toshiyoshi Fujiwara

Okayama Univ. Graduate School of Med., Dentistry & Pharm. Sci., Okayama, Japan

Background: Colorectal cancer (CRC) is one of the most prevalent cancers. In case of CRC with distant metastasis, it is initially treated by chemotherapy, and oxaliplatin is often used in first-line regimen. However, chemoresistance often becomes an issue and it remains unclear. We previously reported that RNA editing enzyme ADAR1 causes stemness (JCI Insight, 2018) and induces the poor prognosis in the liver metastasis of CRC (Scientific Reports, 2023). In this study, we cleared the role of RNA editing in chemoresistance of CRC.
Methods: We performed immunohistochemistry (IHC) of ADAR1 in 151 cases of CRC with distant metastasis. In vitro, we analyzed ADAR1 expression and RNA editing levels in both cancer cells and macrophages with the CRC cell lines and differentiated THP-1(dTHP-1). RNA-sequence was performed to compare wild type and ADAR1 knockdown dTHP-1 co-cultured with CRC cells respectively. In vivo, xenograft mouse models were made by mixing CRC cells and macrophages, and treatment experiment was conducted using oxaliplatin.
Results: IHC scoring showed that high expression of ADAR1 in CRC cancer cells relates the poor prognosis ($p<0.01$). Moreover, high expression of ADAR1 in the stromal mononuclear cells relates the poor prognosis ($p=0.032$) and resistance to oxaliplatin ($p<0.01$). Additionally, there was a positive correlation between the expression levels of ADAR1 in macrophages in tumor tissue and cancer cells ($\rho=0.74$, $p < 0.001$). In vitro, macrophages increased the intensity of ADAR1 expression when indirectly co-cultured with CRC cells ($p<0.01$). These results suggested that ADAR1 might be supplied from CRC cells to macrophages through some liquid factors. We focused on extracellular vesicles (EVs). Western blotting revealed that EVs from CRC cells contained ADAR1. When these EVs were added to macrophages, ADAR1 expression increased in the macrophages. ADAR1 increased RNA editing levels in macrophages, including AZIN1 and GLI1. Next, RNA-sequence analysis showed an enrichment of pathways associated with distant tumor metastasis in macrophages with high ADAR1 expression ($p<0.05$). Additionally, an increase in SPP1 gene expression, which is involved in tumor immune suppression, was observed. In vivo, xenograft mouse models were made, knockdown of ADAR1 in macrophages enhanced the effect of oxaliplatin to inhibit tumor growth ($p<0.01$). Treatment model mouse was made using oxaliplatin in combination with filgotinib, JAK inhibitor that reduces ADAR1 expression. The results showed a significant inhibition of tumor growth in the oxaliplatin plus JAK inhibitor group ($p=0.0197$).
Conclusions: We showed that ADAR1-high macrophages are induced by stimulation from CRC cells via EVs and it may cause chemoresistance. Cancer cells and macrophages dual-targeted RNA editing suppression therapy was considered a promising treatment option.

#4106 Glutamine deficiency drives epigenetic silencing of *GLS2* to promote survival and metastasis from the core region of colorectal cancer.

J.-Y. Lee[1], S. Kwon[1], S. Park[1], T. Yoon[1], J. Kim[1], H. Kim[1], E. Park[2], J. Lee[1];

[1]Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of

Rapid, uncontrolled proliferation is one representative hallmark of cancer. As tumor masses grow, the core regions receive inadequate blood supply, leading to severe nutrients and oxygen deprivation. Glutamine—regarded as non-essential for normal cells—has emerged as a critical nutrient that supports cancer cell metabolism. While glutamine deprivation typically induces cell death in the tumor core, some cancer cells survive by leveraging adaptive epigenetic mechanisms. However, the molecular mechanisms underlying this adaptation remain poorly understood. Using ATAC-seq and RNA-seq analyses, we revealed that glutamine deprivation induces the epigenetic silencing of *GLS2,* an enzyme that converts glutamine to glutamate, in colorectal cancer cells through increasing H3K27Me3 histone modification. This epigenetic silencing suppresses ferroptosis, an iron-dependent form of cell death, that enables cancer cells to survive and proliferate under glutamine-scarce conditions. With patient-derived colorectal cancer sample, we further confirmed a significant downregulation of *GLS2* within the tumor core, specifically in regions that remained actively proliferative despite nutrient deprivation. Additionally, tumor core cells deprived of glutamine exhibited increased invasion and migration abilities, indicating an enhanced metastatic potential towards nutrient-rich compartments or distal sites. Treatment with histone methylation inhibitors successfully reversed *GLS2* silencing, restored ferroptosis sensitivity, and suppressed metastatic behavior, which together emphasizes the potential of targeting epigenetic dysregulation as a therapeutic strategy. Combining epigenetic therapies to restore *GLS2* expression with ferroptosis-inducing drugs offers a promising, integrative approach to target resilient cancer cells in nutrient-deprived tumor cores. This strategy holds significant clinical potential for improving outcomes in patients with aggressive colorectal cancer, particularly those exhibiting resistance to ferroptosis-targeting anticancer drugs due to metabolism reprogramming.

#4107 CircZFR-YTHDF3 complex drives lymph nodes metastasis in cervical cancer via facilitating FASN translation.

Mingyi Zhou[1], Yong Zhang[1], Lian He[1], Bo Gao[1], Francois Claret[2], George Calin[2], Danbo Wang[1]

[1]Cancer Hospital of China Medical University, Liaoning Cancer Hospital & Institute, Shenyang, China,[2]the University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Lymph node metastasis is a key driver of poor outcomes in cervical cancer. Our study reveals that elevated fatty acid synthase (FASN) protein is closely linked to metastasis and reduced survival in cervical cancer, yet its regulatory mechanisms remained unclear.
Methods: We compared the expression of FASN in the cervical cancer samples with or without lymph nodes, long or short disease-free survival (DFS) via qRT-PCR, western blot assay, and tissue array. We investigated and validated the combination between circZFR and YTH N6-methyladenosine RNA binding protein F3 (YTHDF3) protein via circRNA pulldown assay, mass spectrometry, and RNA immunoprecipitation (RIP) assay. The m^6A sites on FASN mRNA were tested via MeRIP-qPCR. Protein co-immunoprecipitation (Co-IP) assay was used to validate the combination between YTHDF3 and eukaryotic translation initiation factor 4A3 (eIF4A3) protein. The siRNAs for YTHDF3 or FASN were transfected into HeLa, C33A, and Caski cells. Proliferation ability of cells was tested via CCK-8 and EdU assay. Migration and invasion ability of cells were tested via transwell assay. The function of circZFR on promoting lymph nodes metastasis was validated by animal assay.
Results: The test in clinical samples showed that the overexpression of circZFR and FASN is associated with lymph nodes metastasis and shorter DFS of cervical cancer patients. The results of circRNA pulldown and RIP assay demonstrated the combination between circZFR and YTHDF3 protein. The results of MeRIP-qPCR assay validated the m6A sites in FASN mRNA. The results of Co-IP assay showed that upregulated circZFR could increase the combination between YTHDF3 and eIF4A3 proteins. The results of proliferation, migration, and invasion assay suggested that knocking down FASN will inhibit the proliferation, migration, and invasion of cervical cancer cells. The results of animal assay validated the promotion of lymph nodes metastasis by circZFR.
Conclusions: We identified circular RNA circZFR as a crucial regulator, significantly enhancing FASN protein expression. CircZFR overexpression accelerates lymph node metastasis and shortens DFS in patients. Mechanistically, circZFR binds to the m^6A reader protein YTHDF3, facilitating m6A recognition on FASN mRNA and recruiting the translation initiator eIF4A3, thereby boosting FASN translation. These findings establish circZFR as a pivotal driver of cervical cancer progression and highlight its inhibition as a promising therapeutic strategy.

#4108 SMARCA4-driven oncogenic enhancer and transcriptional reprogramming in non-small cell lung cancer.

Hye-Ju Yang, Eun-Ju Kim, Sang-Hyeon Song, Tae-You Kim

Seoul National University, Seoul, Korea, Republic of

SMARCA4, an ATPase subunit of the SWI/SNF complex, is frequently mutated in cancers and plays a crucial role in chromatin remodeling and gene regulation. However, the mechanisms by which SMARCA4 drives oncogenesis in non-small cell lung cancer (NSCLC) remain poorly understood. In this study, we show that SMARCA4 restoration in SMARCA4-deficient NSCLC cells significantly enhances cell proliferation and migration. ATAC-seq and ChIP-seq analyses revealed that SMARCA4 restoration induces extensive epigenetic reprogramming, including altered chromatin accessibility, histone modifications, and activation of enhancers near genes linked to proliferation and migration. These changes were accompanied by increased expression of these genes, suggesting that SMARCA4-mediated enhancer reprogramming promotes oncogenic pathways. Motif analysis identified FOSL1 as a key transcription factor that collaborates with SMARCA4 by physically interacting with SWI/SNF subunits to activate enhancers. Enhanced FOSL1 binding correlated with the upregulation of proliferation- and migration-associated genes. Notably, FOSL1 knockout reduced the expression of these genes and suppressed cell growth, highlighting its critical role in SMARCA4-driven tumorigenesis. Furthermore, targeting SMARCA4 with small molecules such as BRM014 and ACBI1 selectively impaired cell viability in SMARCA4-restored cells, underscoring their potential as therapeutic agents for SMARCA4-dependent cancers. These findings reveal a central role for SMARCA4 in epigenetic regulation and enhancer activation, driven by the SMARCA4/FOSL1 axis, and offer insights into potential therapeutic strategies for NSCLC.

#4109 Accelerated aging in breast cancer survivors: the role of therapy-induced epigenetic modifications.

Nikita Nikita[1], Zhengyang Sun[2], Swapnil Sharma[2], Amy Shaver[2], Victoria Seewaldt[3], Ana Maria Lopez[2], Grace Lu Yao[2]

[1]Sidney Kimmel Comprehensive Cancer Center at Jefferson, Philadelphia, PA,[2]Thomas Jefferson University, Philadelphia, PA,[3]City of Hope Comprehensive Cancer Center, Duarte, CA

Breast cancer affects over 300,000 individuals annually in the United States, with survival rates improving due to advances in chemotherapy, radiation, hormonal, and targeted therapies. However, these treatments may inadvertently accelerate biological aging through epigenetic modifications, including DNA methylation, histone alterations, and changes in non-coding RNAs. This review explores how breast cancer therapies impact aging-related epigenetic pathways. Chemotherapy induces cellular senescence by altering DNA methylation patterns and histone modifications, potentially leading to the early onset of age-related diseases. Targeted therapies also affect epigenetic regulation, influencing gene expression related to cell cycle control, apoptosis, and DNA repair. Non-coding RNAs, such as microRNAs and long non-coding RNAs, are essential gene expression regulators affected by cancer treatments. They play significant roles in cellular senescence and therapeutic resistance, adding complexity to the aging phenotype observed in survivors. Clinical manifestations like cardiovascular dysfunction, endocrine disorders, and systemic inflammation are linked to therapy-induced epigenetic changes and in turn accelerated aging. Emerging epigenetic therapies targeting DNA methylation and histone modifications offer potential strategies to mitigate treatment-induced aging effects. DNA methyltransferase inhibitors and histone deacetylase inhibitors show promise in reactivating silenced genes and enhancing therapy sensitivity. Non-pharmacological approaches, including exercise, dietary modifications rich in bioactive compounds, and gut microbiota modulation, may also counteract therapy-exacerbated aging processes. In conclusion, existing evidence shows that cancer therapies are associated with decreased cardiorespiratory fitness, increased risk of cardiomyopathy, osteoporosis, and metabolic dysregulation, contributing to accelerated biological aging via diverse epigenetic mechanisms. Recognizing these changes is crucial for developing interventions that survivor’s health and quality of life. Further research is needed to fully understand therapy-induced epigenetic alterations and their long-term impacts, facilitating personalized survivorship care that addresses this population’s aging complexities.

#4110 Non-classical HLA epigenetic biomarkers associated with concordant cervical and oral HPV infection.

Y. Zheng[1], I. Morhason-Bello[2], Y. Qu[1], J. Wang[1], A. Fowotade[2], A. Daniel[2], A. Adisa[2], O. Awolude[2], J. Ogunbiyi[2], M. Pavon[3], R. Murphy[1], I. Adewole[2], D. Watson-Jones[4], L. Hou[1];

[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]University of Ibadan, Ibadan, Nigeria, [3]Catalan Institue of Oncology, L'Hospitalet, Spain, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: Human papillomavirus (HPV) is prevalent in mucocutaneous surfaces, with the persistence of infections causing approximately 5% of human cancers. While HPV presence at one site increases the risk at others and, possibly, increases the risk of cancer(s) in other anatomical sites, this risk varies among individuals despite similar sexual behaviors. Identifying women with high-risk cervical HPV who are also at risk for high-risk oral HPV could help reduce HPV-associated cancers. This study aims to identify methylation biomarkers explaining the risk of concordant high-risk oral HPV in women with cervical high-risk HPV infections.

Methods: As part of the Sexual Behavior and HPV Infections in Nigerians in Ibadan study, we conducted a cross-sectional analysis of sexually active women aged 18-45 years in Ibadan, Nigeria. Participants had interviews and clinical examinations and provided oral rinse and cervical swab samples. DNA was extracted and genotyped for HPV using the Anyplex™ II HPV28 assay. An epigenome-wide association study compared DNA methylation patterns between women with high-risk HPV types 16, 18, or 35 detected in both oral and cervical samples (concordant group) and those with high-risk HPV only in cervical samples (control group), matched by age, sexual behaviors, and lifestyle factors. Genome-wide DNA methylation profiling was performed on both sample types (total n=32) using the Infinium Methylation EPIC v2.0 BeadChip.

Results: We identified 61 differentially methylated CpG sites in the concordant group, with consistent associations in both cervical and oral samples (Pearson's $r = 0.91$, $p<0.001$). Notably, cg11201654 in the promoter region of a non-classical human leukocyte antigen (HLA) gene, *HLA-F,* was one of the top significant CpGs and showed approximately two-fold hypermethylation in the concordant group in cervical ($p = 0.00080$) and oral samples ($p = 0.00005$). Similarly, cg27020253 in the promoter of another non-classical HLA gene, *HLA-L*, exhibited ~1.7-fold hypermethylation in both cervical ($p = 0.00039$) and oral samples ($p = 0.00025$). These epigenetic modifications suggest that HPV may facilitate immune evasion and persistent infection by suppressing non-classical HLA genes, which are known for modulating immune responses through interactions with natural killer cells.

Conclusion: Hypermethylation of non-classical HLA genes may serve as novel biomarkers for identifying women at elevated risk for persistent high-risk HPV infections and related malignancies, offering insights into HPV-mediated immune evasion mechanisms. The consistent methylation patterns across oral and cervical tissues highlight the capacity of HPV to broadly influence host gene regulation. These epigenetic biomarkers could have applications in broader contexts of immunogenetics and cancer risk prediction, potentially refining the stratification of high-risk women.

#4111 Whole-genome methylation profiling enhances cancer detection and tumor fraction quantification in liquid biopsies.

Hang Dong, Shuang Gan, Haoran Tang, Yue Zhang, Feng Xie

Huidu (Shanghai) Medical Sciences, Ltd., Shanghai, China

Circulating tumor DNA (ctDNA) is a critical biomarker for non-invasive cancer diagnosis, prognosis, and therapeutic monitoring. However, accurately quantifying ctDNA content in liquid biopsy samples remains challenging due to its low abundance and interference from non-tumor DNA. Current approaches, such as targeted sequencing and mutation-based quantification, are limited by their dependence on known mutations and reduced sensitivity to low ctDNA fractions. Next-generation sequencing (NGS)-based methylation profiling offers a promising alternative by leveraging the distinct methylation patterns between tumor-derived and normal cell-free DNA (cfDNA). We developed a robust algorithm for the whole-genome methylation sequencing assay, PredicineEPIC^{TM}, as a multi-cancer detection solution enabling the quantification of ctDNA content in blood, urine, and cerebrospinal fluid samples. This approach focuses on comprehensive cancer-specific methylation markers to distinguish ctDNA fragments from background cfDNA molecules. We characterized methylation profiles of 800 simulated liquid biopsy samples with titrated tumor fractions (0.01%-50%) and applied machine learning models for analysis to evaluate ctDNA amounts. An independent set of 93 real-world samples from patients with lung, prostate, colorectal, ovarian, and bladder cancers was collected to validate the accuracy of the model. Performance was benchmarked against mutation panel-based reference tumor fractions. In the simulated dataset, our method achieved high accuracy ($R^2 = 0.92$) and sensitivity in detecting ctDNA at tumor fractions as low as 0.05%. The tumor fractions estimated by this approach correlated strongly with variant allele frequency (p-value < 0.01). Compared to conventional mutation-based methods, our approach achieved a higher detection rate in liquid samples with low tumor burden. Notably, the whole-genome strategy offered deeper insights into epigenetic alterations and fragmentomics features associated with gene expression activity, which remain undetectable by mutation-based assays. This study highlights the potential of whole-genome methylation profiling as a highly precise and comprehensive tool for tumor fraction quantification in liquid biopsy samples. The demonstrated accuracy and clinical relevance underscore its applicability for early cancer detection and real-time disease monitoring.

#4112 The epigenetic landscape identified through ATACseq reveals the NCAM1/FYN pathway as a potential therapeutic target in p53-/PTEN- transformed breast cancer stem cells.

Abigail G. Weatherford[1], Margaret V. Leonard[1], Maria Ouzounova[2], Hasan Korkaya[3], **Austin Y. Shull**[1]

[1]Department of Biology, Presbyterian College, Clinton, SC,[2]Cancer Research Center of Lyon, Lyon, France,[3]Karmanos Cancer Institute, Detriot, MI

Metastatic potential in basal-like breast cancers typically correspond with increased enrichment of aggressive progenitor-like populations called cancer stem cells (CSCs), typically identified by the loss of epithelial markers EpCAM and CD49f. In our MCF10A breast cell line model, deletion of p53 and PTEN lead to tumorigenic transformation and cancer stem cell expansion. With these observations that reflect cell dedifferentiation as a mechanism of oncogenic transformation, it was important to better detail the epigenetic events that correspond with breast CSC progression. With this in mind, we performed Assay for Transposase-Accessible Chromatin sequencing (ATACseq) on our isogenic panel of MCF10A breast cell lines where tumor suppressor genes TP53 and PTEN were silenced to drive breast CSC expansion. Furthermore, we performed gene expression analysis of isolated EpCAM-/CD49f- CSCs from MCF10A p53-/PTEN- cells to determine which genes differentially upregulated in CSCs corresponded with open chromatin in our ATACseq analysis. Based on this analysis, we identified 96 genes with open chromatin that were also significantly overexpressed within our isolated CSC populations. Several transcripts identified were potential metastatic drivers, including genes involved in signal transduction (PDE4B, PDE3B), cellular adhesion (MDGA2), transcriptional regulation (NPAS2), and oxidative stress responses (SMOX). Furthermore, many of these genes were also significantly upregulated clinically in basal-like breast cancers from The Cancer Genome Atlas (TCGA) breast cancer dataset. One key pathway of interest identified was the NCAM1/FYN pathway, which showed increased chromatin opening in the promoter regions of these two genes that are a part of the same signal transduction pathway and are of clinical relevance. Comparative analysis demonstrated that NCAM1/FYN pathway components were overexpressed in breast cancer samples, with statistically significant increased protein phosphorylation of MAP2K1 and RAF1 in the CPTAC proteogenomic TCGA samples. Collectively, this work provides an overview of open chromatin sites that contribute to oncogene overexpression in breast cancer and provide rationale for targeting these transcripts via chromatin targeting-based therapies (ex: BET bromodomain inhibition) to prime these CSC populations toward specific drug sensitivities.

#4113 α7 integrin is a critical co-regulator of chromatin accessibility and gene expression in HPV-negative head and neck cancer.
O. Borodins, A. Vehlow, N. Cordes;
Technische Universitat Dresden, Dresden, Germany

Epigenetic regulation and gene transcription, which are mainly restricted to the nucleus, are dynamically modulated by extracellular signals. In HPV-negative head and neck squamous cell carcinoma (HNSCC), genetic mutations and epigenetic alterations promote a complex and heterogeneous tumor microenvironment, often characterized by extensive remodeling of the extracellular matrix. This process affects the expression and function of integrins, making integrins central signaling mediators and key regulators of cancer progression and therapy resistance. While the 12 heterodimeric α/β1 integrin receptors are known to be key factors for therapy resistance in various malignancies, their direct influence on chromatin accessibility and gene transcription remains to be elucidated. Here, we systematically investigated 24 HNSCC cell models physiologically cultured in a 3D matrix for nuclear morphology (3D super-resolution microscopy), whole exome sequencing, euchromatic and heterochromatic markers, transcriptome (RNA sequencing), DNA accessibility (ATAC sequencing), and phosphoproteome (protein microarrays). Integrative, multiomic bioinformatic analyses, including random forest algorithms, provided comprehensive insights into integrin-mediated epigenetic and transcriptomic regulation. The HNSCC model panel showed substantial variability in nuclear architecture and protein-altering mutations. An RNAi screen for all integrin receptors identified α7 integrin as the most potent modulator of the selected histone modification markers. Mechanistically, α7 integrin depletion increased spatial aggregation of nuclear DNA. RNA- and ATAC-seq showed that knockdown of α7 integrin alters the expression of 3,257 genes, reducing chromatin accessibility at transcription start sites by 65%. This resulted in downregulation of genes involved in survival and chromatin regulation, while motifs for transcription factors such as JUN, FOSL1, and RELA were enriched in differentially accessible regions. Phosphoproteomics combined with artificial intelligence-based analyses showed significant inhibition of MAPK-dependent cell cycle progression, resulting in impaired proliferation, chromatin condensation, and reduced cell viability in all HNSCC models. In summary, this study provides substantial evidence that α7 integrin is an important co-regulator of gene transcription and chromatin accessibility. The discovery of the role of α7 integrin in these molecular mechanisms fundamentally supports the paradigm that cell adhesion dictates epigenetics and transcription. By increasing our understanding of these complex interactions, we may gain exploitable insights for the development of new, molecularly targeted drugs to treat patients with HNSCC.

#4115 Gene expression and bioinformatics profiles of four different cancer cells following treatment with HDAC inhibitor SAHA.

Umamaheswari Natarajan, Appu Rathinavelu

Rumbaugh Goodwin Institute for Cancer Research, Barry and Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL

Background: Epigenetic modifications of chromatin play a crucial role in regulating gene expression and are often dysregulated in cancer. This study aimed to investigate changes in gene expressions following HDAC (Histone Deacetylase) inhibition in breast, ovarian, and lung cancer cells.
Aim: Our goal was to determine and compare the epigenetic alteration related gene expressions that may serve as diagnostic and/or predictive biomarkers for human cancers. To achieve this, we evaluated the effect of SAHA treatment on histone and DNA modification related gene expressions in human breast (MCF7), ovarian (A2780), and lung (HCC827 & H460) cancer cell lines.
Method: Using RT^2 Profiler PCR Array, we identified the differential expression of genes (DEGs) in four different human cancer cells following SAHA treatment in comparison to untreated controls. Independent quantitative real-time PCR (qRT-PCR) verified some of the most significant DEGs. We constructed a protein-protein interaction (PPI) network using STRING and Cytoscape to analyze the interactions of these DEGs.
Results: Our results showed that SAHA exposure significantly impacted histone and DNA modification related methyltransferases in the above listed human cancer cells. We identified three differentially expressed genes, including two commonly down-regulated (DNMT3A, NSD1) and one significantly up-regulated (HDAC3) genes in these cancer cells that were treated with SAHA. qRT-PCR and Western blot analyses confirmed the array results of DNMT3A, NSD1 and along with USP21, PAK1, and NEK6. All levels of all these five proteins were significantly down regulated following treatment with SAHA.
Conclusion: Our study demonstrates some commonality in the DEGs and the impact of HDAC inhibition with SAHA in four different human cancer cells compared with normal cells. Our findings provide new insights into the network and the interactions of significantly altered gene expressions that may eventually impact the growth abilities of cancer cells. Our findings also highlight some of the potential molecular targets and related signaling pathways. Altogether, these results may also contribute to our better understanding of the HDAC inhibition related mechanisms that may underly the growth regulation of breast, ovarian, and lung cancer cells.

(Ft. Lauderdale, FL, USA) for their financial support in conducting this research.

#4116 A multi-omics study reveals an epigenomic subtype shapes a pro-metastatic niche in Epstein-Barr virus-associated nasopharyngeal carcinoma.

Kazi Anisha Islam, Larry Ka-Yue Chow, Kiu Wai Cheng, Dittman Lai-Shun Chung, Zhaozheng Hou, Yingpei Zhang, Anne Wing-Mui Lee, Wai Tong Ng, Roger Kai-Cheong Ngan, Dora Lai-Wan Kwong, Wei Dai

University of Hong Kong, Hong Kong, Hong Kong

Nasopharyngeal carcinoma (NPC) is a unique form of cancer that originates in the epithelial lining of the nasopharynx. It is often associated with Epstein-Barr virus (EBV) infection. NPC's etiology involves various factors, including genetic predispositions, environmental influences and particularly, epigenetic dysregulation. In an earlier study, it was discovered that there are two methylation subtypes with global hypermethylation (HyperNPC) and hypomethylation (HypoNPC) in NPC, representing 80% and 20% of patients, respectively. This study further investigates HypoNPC to characterize its biological features, association with EBV life cycles and to evaluate its clinical impact. Whole exome sequencing (WES), RNA-sequencing (RNAseq), and targeted bisulfite sequencing (BS) using the customized panel targeting the EBV genome and 23 selected human regions were performed for the tumor biopsies from 82 NPC patients. Patients were characterized as the HypoNPC subtype based on their methylation ratios across 13 selected regions using linear discriminant analysis (LDA). The WES data was utilized to evaluate the mutational profiles of the subtypes, while the RNAseq data was used to identify differentially expressed genes in both host and EBV. Chromosome instability (CIN) was quantified based on the extent of allelic imbalances in NPC tumors. The patients were stratified as metastatic (MET) NPC if they developed distant metastasis within 3 years post-treatment, and as non-metastatic (nonMET) NPC if they did not develop distant metastasis within the same time period. This multi-omics study revealed that HypoNPC patients are more likely to develop metastasis within 3 years post-treatment (OR=5.60, 95% CI=1.29-38.89) compared to HyperNPC patients. HypoNPC is enriched for loss-of-function mutations of KDM6A, which could lead to the hyperactivation of the mTORC1 signaling pathway. These patients also display elevated CIN, heightened DNA damage responses, replication stress and mitotic spindle assembly, alongside increased MYC activation. We found that pro-metastatic genes like SKP2 and PHF8 are upregulated, while anti-metastatic genes like PTPRD and ZNF154 are suppressed in these patients. Interestingly, the EBV genome in HypoNPC has a larger variation of DNA methylation levels, suggesting less stringent control of EBV gene transcription through DNA methylation. In addition, HypoNPC has a distinctive immunosuppressive tumor microenvironment, marked by a significant reduction in plasma B cells and suppressed complement function through macrophages. HypoNPC exhibits distinctive cancer cell features and the tumor microenvironment, which may form a pro-metastatic niche leading to early development of distant metastasis in these patients. This study highlights the needs for molecular subtyping in NPC to improve patient management and treatment.

#4117 ADAR1-mediated RNA editing of KCTD13s promotes pancreatic cancer metastasis by impeding RhoA ubiquitination.

Lingxing Zeng, Xiaoyu Wu, Ziming Chen, Jian Zheng

Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China

Background: Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal disease with limited therapeutic options and a poor prognosis. Adenosine-to-inosine (A-to-I) RNA editing, a crucial post-transcriptional modification, introduces nucleotide changes in RNA sequences. However, few protein-recoding editing targets with functional significance have been identified. In this study, we propose that the ADAR1-KCTD13s-RhoA/ROCK1 signaling axis plays a critical role in PDAC progression.
Methods: We performed an in-depth analysis of A-to-I RNA editing using RNA-sequencing, validated by Sanger sequencing. In vitro phenotypic assays, including proliferation, colony formation, migration, and invasion tests, were conducted. In vivo studies included an orthotopic pancreatic tumor growth model and a lung metastasis model. Protein interactions were evaluated using immunoprecipitation, protein stability was assessed with cycloheximide (CHX) treatment, and ubiquitination was examined with MG132 treatment.
Results: Our analysis of A-to-I modifications in PDAC tissues and cell lines identified KCTD13s as a novel protein-recoding RNA editing target. Increased KCTD13s editing levels, driven by the overexpression of adenosine deaminase acting on RNA 1 (ADAR1), were associated with poor survival in PDAC patients. Functional experiments demonstrated that KCTD13s editing promotes pancreatic cancer metastasis. Mechanistically, this amino acid alteration stabilizes the KCTD13s protein by preventing its ubiquitination. The stabilized KCTD13s competes with KCTD13 for binding to CUL3, inhibiting RhoA ubiquitination. This results in elevated RhoA protein levels and activation of the RhoA/ROCK1 signaling pathway.
Conclusion: Our findings illuminate the malignancy-promoting role of the ADAR1-KCTD13s-RhoA/ROCK1 signaling axis in PDAC. This study reveals an epigenetic regulatory mechanism mediated by A-to-I RNA editing and highlights the potential of targeting epitranscriptomic pathways for therapeutic intervention in PDAC.

#4118 Decoding the noncoding: An insight into the noncoding genome of breast cancers.

A. Cuy Saques[1], A. White[1], K. Rabab[2], P. Scarry[3], F. Matra[4], C. Monger[5], A. Bracken[6], J. Crown[7], A. Eustace[1];
[1]Dublin City University, Dublin, Ireland, [2]Dundalk Institute of Technology, Dundalk, Ireland, [3]Bristol Myers Squibb, Dublin, Ireland, [4]ICON, Dublin, Ireland, [5]Pfizer, Dublin, Ireland, [6]Trinity College Dublin, Dublin, Ireland, [7]St. Vincent's University Hospital, Dublin, Ireland

Introduction: The PI3K/AKT pathway, a key oncogenic signalling pathway, is mutated in 70% of breast cancers (BC). PI3K/AKT coding mutations promote BC progression and are associated with poor survival. However, coding mutations represent <1% of the whole genome. Non-coding mutations (NCMs) can promote oncogenic gene expression in several cancers, including BC. Further study on NCMs can enhance our understanding of BC and help identify novel treatments targets.
Experimental procedure: NCMs surrounding kinome genes were identified from whole genome sequencing of 915 BC tumours. NCMs were prioritised based on recurrence and analysed with the Activity by Contact (ABC) bioinformatic model, which estimates their likelihood to interact with transcription start sites (TSS) and indicates their enhancer potential. Epigenetic data (Hi-C and H3K27ac, ChIP Seq) from BC cell lines (n=12) was screened to identify BC subtype-specific epigenetic changes surrounding the prioritised NCMs. The NCMs' regulatory effect over gene expression was confirmed by luciferase reporter assays.
Results: We identified 3,546 recurrent NCMs surrounding kinome genes in BCs and observed an enrichment of NCMs in gene loci of PI3K/AKT pathway members (p=0.005). We discovered subtype-specific enrichment of NCMs around oncogenes, like AKT2 in HR+ BCs (29/398, 7.2%) or AKT3 for TNBC (21/444, 4.7%). Of the 152 NCMs analysed, 17 (11.2%) reported positive by ABC analysis. 6/17 NCMs were identified in the gene loci of AKT2 or AKT3 (ABC scores 0.023-0.1) and were predicted to interact with genes up to 75kb from the NCM. Epigenetic analysis of ER+ and TNBC cell lines reported peaks of enhancer activity near the AKT2 and AKT3 NCMs, thus supporting the ABC analysis. Luciferase assays confirmed a 1.6-fold increase in luciferase expression for an AKT2 gene loci NCM (AC_A, chr19:41858248) and a 3-fold increase in luciferase expression for an AKT3 gene loci NCM (-_AT, chr1:244065861), whilst we observed a 3-fold decrease for a NCM in AKT2 gene loci (CAG_C, chr19:39686510).
Conclusions: We have identified that BCs have an enrichment of NCMs surrounding PI3K/AKT pathway genes. NCMs in the gene loci of AKT2 and 3 were predicted to interact with distal genes and luciferase reporter assays confirmed their regulatory effects *in vitro*. These results highlight the potential of NCMs to drive BC oncogenesis and potentially act as targets for drug development.

#4119 Epigenetic age as an early tumor biomarker for breast cancer.

Su Yon Jung

Translational Sciences Section; Department of Epidemiology, Fielding School of Public Health, UCLA - University of California Los Angeles, Los Angeles, CA

DNA methylation (DNAm)-based marker of aging, referred to as ‘epigenetic age’ or ‘DNAm age’ is a highly accurate multi-tissue biomarker for aging, associated with age-related disease risk, including cancer. Breast cancer (BC), an age-associated disease, is associated with older DNAm age and epigenetic age acceleration (age accel) at tissue levels. But this raises a question on the predictability of DNAm age/age accel in BC development, emphasizing the importance of studying DNAm age in pre-diagnostic peripheral blood (PB) in BC etiology and prevention. We included postmenopausal women from the largest study cohort and prospectively investigated BC development with their pre-diagnostic DNAm in PB leukocytes (PBLs). We estimated Horvath’s pan-tissue DNAm age and investigated whether DNAm age/age accel highly correlates with risk for developing subtype-specific BC and to what degree the risk is modified by hormones and lifestyle factors. DNAm age in PBLs was tightly correlated with age in this age range, and older DNAm age and epigenetic age accel were significantly associated with risk for developing overall BC and luminal subtypes. Of note, in women with bilateral oophorectomy before natural menopause experiencing shorter lifetime estrogen exposure than those with natural menopause, epigenetic age accel substantially influenced BC development, independent of obesity status and exogeneous estrogen use. Our findings contribute to better understanding of biologic aging processes that mediates BC carcinogenesis, detecting a non-invasive epigenetic aging marker that better reflects BC development, and ultimately identifying the elderly with high risk who can benefit from epigenetically targeted preventive interventions.

#4120 A systematic design of multiplex methylation-specific qPCR for CRC biomarkers.

Michelle Y. Lee[1], Joy Wang[2], Brian B. Lin[2], Katelyn Y. Chao[3], Annie X. Wu[4]

[1]Irvington HIgh School, Fremont, CA,[2]Basis Independent, Fremont, CA,[3]Menlo-Atherton High School, Atherton, CA,[4]Biochemistry and Biophysics, Rensselaer Polytechnic Institute, Fremont, CA

Analysis of circulating cell-free DNA (cfDNA) methylation abnormalities has emerged as a promising strategy for detecting various diseases, including cancer. While single-biomarker approaches may lack sensitivity, comprehensive next-generation sequencing (NGS) can be cumbersome and expensive. Multiplex methylation qPCR assays offer a practical intermediate solution by providing accurate, accessible, and affordable methylation biomarker detection. In this study, we demonstrated a process for developing a multiplex methylation-specific qPCR assay using colorectal cancer (CRC) methylation biomarkers as a case study. Starting with a set of CRC methylation biomarkers, we developed the Multiplex Methylation-specific qPCR (MMqPCR) algorithm to scan differentially methylated regions (DMRs) for methylation-specific PCR primer and probe design. We then established a systematic process to eliminate assay cross-reactions, reduce background noise, and assess multiplex compatibility. Using a low concentration of hypermethylated DNA (0.1%) in a digital analysis, we demonstrated a 95.8% detection rate with the multiplex strategy, significantly outperforming the singleplex approach (47.9%). The multiplex qPCR development principles and automated primer design algorithm presented here provide valuable tools for developing disease screening, detection or monitoring methods based on methylation analysis.

#4121 Correlation, interaction, and prognostic impact of SMC4 and NIPBL phosphorylation in endometrial carcinoma.

Jie Zhang[1], Qin Yang[1], Feilong Zhao[2], Ding Zhang[2], Yantao Li[1]

[1]The First People's Hospital of Yunnan Province. The Affiliated Hospital of Kunming University of Science and Technology, Kunming, China,[2]3D Medicine, Shanghai, China

Background: Uterine Corpus Endometrial Carcinoma (UCEC) poses treatment challenges due to limited options. Protein phosphorylation, a dynamic reversible process, emerges as optimal targets. Methods: We analyzed phosphoprotein, protein, and mRNA data of UCEC in the CPTAC dataset (PDC000126). Correlation network and hierarchical clustering were employed to identify core phosphoproteins and proteins. Protein-Protein Interaction network was constructed using the STRING database. Results:Data from 95 UCEC patients, mainly FIGO stage I, included 73,212 phosphoprotein sites (8,450 genes) and 9,099 protein expressions. Only genes expressed in ≥80% of samples were included. Generally, protein-mRNA expression correlation was high (median 0.51), while phosphoprotein-protein and mRNA correlations were weaker (median: 0). Using a correlation coefficient >0.4, we identified 259 phosphorylation sites that correlated with 91 proteins. Clustering identified 11 core phosphorylation sites that universally correlated with proteins and 15 core genes that universally correlated with phosphorylation sites. Further analysis found the phosphorylation sites that strongly associated with these core genes located at 72 genes. The interaction networks between the 14 core genes and 72 co-expressed genes revealed RFC4, TPX2, SMC4, and NCAPD2 as central nodes regulating at least 10 co-expressed genes. Survival analysis linked the 4 core genes to UCEC patient PFS and OS. By setting experimentally determined interactions >0.5, we identified previous confirmed phosphorylation counterparts of core genes: NCAPD2-NCAPG, RFC4-RFC1, SMC4-NCAPG, SMC4-NCAPD3, and SMC4-NIPBL. Notably, NIPBL harbored two phosphorylation sites (NIPBL_T599 and NIPBL_T592). Intriguingly, SMC4, NCAPG, and NCAPD3 are condensin complex subunits, while NIPBL is a cohesin-loading factor, suggesting coordinated regulation between the two protein complexes. Conclusion: The gene expression and protein phosphorylation network offer potential UCEC treatment targets. The SMC4-NIPBL interaction implies a harmonization between cohesin and condensin complexes, potentially impacting UCEC prognosis.

#4122 Epigenetic biomarker identification of each stage during the progression of prostate cancer.

S. Logotheti[1], K. Mesiakaris[1], K. Lazaros[2], E. Kontogianni[1], E. Panopoulou[1], S. Kontogiannis[1], M. R. Estecio[3], R. Soundararajan[3], C. J. Logothetis[3], A. G. Vrahatis[2], V. Tzelepi[1];

[1]University of Patras, Rion-Patras, Greece, [2]University of Ionion, Corfu, Greece, [3]UT MD Anderson Cancer Center, Houston, TX

Prostate cancer (PCa) heterogeneity is observed both across different patients and within the same patient during the progression of his disease. Although genetic profiling alone has not fully captured these complexities, epigenetic modifications may better characterize changes in bidirectional gene regulatory programs during PCa progression. In this study, we aimed to identify epigenetic biomarkers that may distinguish each stage of the disease. We thus focused our efforts on DNA methylation, the most extensively studied epigenetic mechanism, because it enables dynamic shifts in gene expression without altering the DNA sequence, often as a result of environmental and therapeutic pressures. To achieve our goal, we selected 24 formalin-fixed paraffin-embedded (FFPE) archival PCa specimens encompassing the full disease spectrum, from normal prostate tissue to aggressive states. This cohort includes indolent (N=8), high-grade non metastatic disease (N=4), aggressive/lethal disease (N=8), and adjacent normal tissues (N=4). DNA extracted from representative tissue sections was analyzed using the Infinium Methylation EPIC v2.0 array, followed by bioinformatic analyses: following standard beta-value calling and normalization, we applied unsupervised hierarchical clustering and found that the samples of each cohort clustered together. Then, differential methylation analysis identified 629 uniquely methylated CpG sites across the disease stages (Normal: 3 hypermethylated, 214 hypomethylated; Indolent: 4 hypermethylated, 1 hypomethylated; High-grade non-aggressive: 181 hypermethylated, 51 hypomethylated; Aggressive: 22 hypermethylated, 153 hypomethylated). We next took advantage that 422 of these identified differentially methylated sites (representing 67.1%) are also represented in previous versions of the bead array platforms (Illumina 450k and EPIC v1.0 arrays) and leveraged publicly available retrieved from TCGA and GEO databases to refine our pipeline, focusing on CpG sites consistently differentially methylated across disease stages. Based on our discovery set of well-characterized PCa specimens, ongoing analyses aim to incorporate over 100 additional public datasets to identify markers that reflect disease continuum. We anticipate that functional enrichment analysis of these datasets will also reveal candidate mechanisms involved in disease progression. Ultimately, this research seeks to lay the groundwork for a marker-informed approach to monitor PCa progression, establishing a basis for proactive strategies to manage and combat prostate cancer.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Kinases/Phosphatases, Ubiquitin, and Ubiquitin-like Proteins
Poster Session

#4126 Illuminating the dark kinome using proximity labeling and phosphoproteomics analysis.
I. Plutzer, D. P. Bhatt, E. M. Wilkerson, R. Williamson, D. Goldfarb, M. Major;
Washington University School of Medicine in St. Louis, St. Louis, MO

Kinases are highly druggable targets for cancer therapy due to their control over a variety of oncogenic processes via protein phosphorylation. While, large clinical phosphoproteomics datasets have expanded our understanding of how the phosphoproteome is altered in cancer, annotation of the phosphoproteome is significantly lacking. 95% of phosphorylation sites in the PhosphoSitePlus database have no associated kinase, and 80% of annotated substrates are assigned to just 20% of the most well-studied kinases. Of the ~650 kinases in the human genome, 162 are designated by the NIH as ‘dark kinases’ due to lack of information on their function and substrates. The primary aim of my research is to define the functions and substrates of the dark kinome and identify kinases with therapeutic potential.My lab has collected mass spectrometry (MS)-based proximity labeling data for 137 of the dark kinases. Probabilistic scoring of raw data yields functionally relevant proximity networks for each kinase that defines its cellular localization and protein complex membership. Enrichment analysis identifies functional protein domains and protein sequence motifs that drive kinase localization and substrate specificity via protein-protein interactions. Additionally, clustering of this data highlights the prevalence of kinase signaling hubs – distinct locations within the cell harboring diverse kinase populations – that regulate extracellular signal processing, protein trafficking, transcription, and translation.As a second branch of my work, I have developed kinase gain-of-function (GOF) phosphoproteomics experiments to identify substrates and pathways regulated by dark kinases. This medium-throughput method uses multiplexed deep phosphoproteomic profiling to measure changes in protein phosphorylation levels following transient overexpression of a kinase. Analysis of this data reveals signaling pathways regulated by a kinase, which can be validated using low-throughput western blots. When combined with proximity data, I am able to define high-confidence putative substrates that are both proximal to the kinase and significantly hyperphosphorylated following overexpression of the kinase. As an example of this workflow, I highlight the dark kinase BRSK2. In my BRSK2 GOF experiment, I identify 584 candidate sites that are significantly upregulated. Enrichment analysis of these sites reveals that BRSK2 is a positive regulator of AMPK and negative regulator of mTOR signaling. This is validated by western blotting of key AMPK and mTOR substrates. Mapping upregulated sites onto the proximity network for BRSK2 yields a small list of 39 high-confidence proximal substrates, an improvement on the 4 substrates in the PhosphoSitePlus database.

#4127 Oncogenic BRAF suppresses p53 function in melanoma through direct protein protein interaction.

Kayla T. O'Toole, Adamaris Martinez, Brandon Murphy, Deevya Baral, Anastasia Proveyeka, Fatima Al-Sudani, Joshua Andersen, Robert Judson-Torres, Martin McMahon

University of Utah Huntsman Cancer Institute, Salt Lake City, UT

Oncogenic BRAF is a driver of approximately 8% of all cancers, with a particular prevalence in lung cancer, thyroid cancer, and cutaneous melanoma. $BRAF^{V600E}$ is the most common oncogenic alteration, accounting for about 50% of cutaneous melanoma cases. Combined inhibition of $BRAF^{V600E}$ plus MEK1/2 is the current targeted therapeutic option approved for the treatment of $BRAF^{V600E}$-driven melanoma and lung cancer. Unfortunately, many patients only experience short-term therapeutic benefit with a mean progression-free survival of 7 to 14 months in non-small cell lung cancer and melanoma, respectively. Thus, this highlights the need to identify better therapeutic targets for BRAF-driven cancers. $BRAF^{V600E}$ is often referred to as a monomer as $BRAF^{V600E}$ signals independent of RAS-GTP and RAF dimerization. However, oncogeneic BRAF may still be dependent on other scaffolding proteins for optimal signaling. Thus, to evaluate this, we used gel filtration chromatography and immunoblotting analysis to visualize BRAF signaling complexes. These data revealed that $BRAF^{V600E}$ exists in a large multiprotein complex. Pharmacological inhibition of $BRAF^{V600E}$ shifted the elution of $BRAF^{V600E}$ complexes into lower molecular weight fractions. We further investigated this $BRAF^{V600E}$ signaling complex by implementing the proximity labeling technique, TurboID. Coupled with mass spectrometry, this technique enabled the unbiased identification of novel BRAF interactors and helped us understand how targeted therapy impacts this BRAF interactome. Here, we identified a multitude of unique wild-type BRAF and $BRAF^{V600E}$ interactors, with the tumor suppressor p53 being of particular interest. Intriguingly, TP53 alterations are infrequent in melanoma, prompting the hypothesis that by interacting with p53, $BRAF^{V600E}$ may influence p53 function. We show that $BRAF^{V600E}$ expression alters p53 subcellular localization, significantly reduces native p53 activity, and prevents p53 activation following UVB radiation and MDM2 inhibition. Ultimately, these findings provide unique mechanistic insight into the mechanisms by which $BRAF^{V600E}$ drives cancer development and may clarify why TP53 is infrequently altered in melanoma.

#4128 Mapping the hypoxic regulation of IFNγ and TNFα-mediated kinase pathways in melanoma.

Simar Pal Singh[1], Alex Miranda Rodriguez[2], Russell W. Jenkins[2]

[1]PamGene International B.V., 's-Hertogenbosch, Netherlands,[2]Department of Medicine, Massachusetts General Hospital, Harvard Medical School, Mass General Cancer Center, Krantz Family Center for Cancer Research, Boston, MA

Introduction: Hypoxia can promote immunologic, transcriptomic, and metabolic alterations in the tumor microenvironment that contribute to immune evasion. Activation of hypoxia signaling pathways has been linked to cancer cell-intrinsic immune evasion and resistance. Hypoxic tumor cells show less susceptibility to direct killing by cytotoxic T lymphocytes and NK cells through several mechanisms, including upregulation of immune checkpoint ligands. IFNγ and TNFα are immune cell-derived effector cytokines critical for tumor immunity. However, the effect of these cytokines in the hypoxic tumor microenvironment is less well studied. Since, kinase signaling pathways are directly activated downstream of cytokine receptor, we explored the functional activity of kinases downstream of IFNγ and TNFα.
Methodology: Murine B16F10 melanoma cells were treated with 40 ng/ml of IFN-gamma and TNF-alpha under normoxia (21 % oxygen) and hypoxia (1% oxygen) conditions for 6 or 24 hours. Following treatment, cells were lysed with M-PER Mammalian Extraction Buffer supplemented with Halt Phosphatase Inhibitor Cocktail and Halt Protease Inhibitor Cocktail EDTA free and protein quantification was determined using Pierce Coomassie Plus (Bradford) Assay Kit. Tyrosine and Serine/threonine kinase activity profiles were generated using PamChip® comprising 340 different phosphosites that are known downstream substrates of kinases. Peptide phosphorylation and Upstream Kinase Analysis was performed with PamGene's tercen analysis pipeline.
Results: We found a global reduction of the cytokines induced kinome activation when cells were treated under hypoxia for 6h. However, after 24h a group of kinases associated mainly with the MAPK, RAS and Calcium signaling were increasingly activated in the hypoxia condition. A dynamic activation of the PI3K/AKT pathway was observed when comparing cells exposed to cytokines in normoxia or hypoxia conditions. At 6 h after IFNγ and TNFα treatment under normoxia, we observed an increased PI3K/AKT activity that decreased and became undetectable after 24h. However, when cells were exposed to the cytokines under hypoxia the reduced PI3K/AKT kinase activity at 6 h is reverted after 24h of treatment. Interestingly, the downstream mTOR pathway is predicted to have lower activity in the hypoxia conditions across both time points evaluated.
Conclusions: In the present work we unveil strong diversity on the kinome of melanoma cells when exposed to the inflammatory cytokines IFNγ and TNFα under different oxygen levels. These results provide deeper insight into the mechanisms by which hypoxia contributes to immune evasion and response to cytokines. Our data can help inform future therapeutic strategies targeting these pathways to enhance immune-mediated tumor suppression.

#4129 Phosphorylation of AMPKβ by EDIL3/Del-1 regulates the progression of triple negative breast cancer.

Seolhwa Jeong[1], Soo Jung Lee[2], Jeeyeon Lee[2], In Hee Lee[2], Byeongju Kang[2], Ho Yong Park[2], Eun Ae Kim[1], Jieun Kang[2], Yee Soo Chae[2]

[1]Kyungpook National University, Daegu, Korea, Republic of,[2]Kyungpook National University Chilgok Hospital, Daegu, Korea, Republic of

Background: Developmental Endothelial Locus-1 (Del-1), also known as EGF Like Repeats and Discoidin Domains 3 or Edil-3, is a secreted glycoprotein enriched in extracellular vesicles circulating in the plasma of breast cancer patients. Various papers have suggested that Del-1 might be important in Triple Negative Breast Cancer (TNBC), the subtype with the highest mortality rate, even though it only accounts for 15%-20% of all breast cancers. However, the precise role of Del-1 in TNBC regulation remains poorly characterized. AMP-activated protein kinase (AMPK), a heterotrimeric energy sensor, is composed of α (catalytic), β (scaffolding), and γ (nucleotide-binding regulatory) subunits. AMPKβ subunits, characterized by their carbohydrate-binding modules (β-CBM), facilitate glycogen binding and are often amplified in tumor cells. Although AMPKβ has been extensively studied for its metabolic functions, its contributions to oncogenic signaling pathways in TNBC remain poorly understood.
Methods: RNA sequencing of Del-1-suppressed MDA-MB-231 cells revealed reduced expression of AMPK subunits. Western blot assays confirmed that AMPKβ protein levels were significantly elevated in TNBC cell lines, and RT-PCR analysis further verified increased AMPKβ mRNA levels in breast cancer patient samples. CRISPR/Cas9 genome editing Del-1 knockout cell lines and pharmacological activator of AMPKβ, and tumor progression assays (MTT, MTS, BrdU and Matrigel transwell assays) were used to evaluate the effects of Del-1 and AMPKβ on TNBC cell proliferation, invasion, and survival. To understand how Del-1 positively activates AMPKβ, genetically mutated phospho-mimetic AMPKβ was overexpressed, and assessed the progression of TNBC cells.
Results: In TNBC cells (particularly TNBC mesenchymal stem-like cells), the expression levels of Del-1 and AMPKβ were significantly upregulated. While AMPKα remain unchanged, β subunit of AMPK was increased. Both overexpression of Del-1 and pharmacological activation of AMPKβ stimulated proliferation and invasion, whereas CRISPR/Cas9 genome editing Del-1 knockout inhibited AMPKβ and blocked proliferation and invasion. Notably, overexpression of Del-1 upregulated AMPKβ, but AMPKβ activation did not affect Del-1. Furthermore, DEL-1 phosphorylates AMPKβ at S108, and phosphor-mimetic AMPKβ overexpression significantly enhanced TNBC cell progression.
Conclusions: Our findings identify AMPKβ as a novel downstream target of Del-1 in TNBC mesenchymal stem-like cells. Elevated Del-1 and AMPKβ levels accelerate proliferation, invasion, and survival. These
results uncover a previously unrecognized Del-1-AMPKβ axis, offering new insights into the molecular mechanisms of TNBC progression and potential therapeutic targets.

#4130 Atypical protein kinase C iota (PKC-ι) regulates an oncogenic positive feedback loop between the MAPK/JNK signaling pathway, AP-1 complex and TNF-α in triple negative breast cancer.

Nuzhat Nowshin Oishee, Mahfuza Marzan, Khandker Mohammad Khalid, Abiral Hasib Shourav, Abigail Olatunji, Radwan Ebna Noor, Mildred Acevedo-Duncan

Chemistry, University of South Florida, Tampa, FL

Breast Cancer is the second most common cancer in the United States and consists of about 30% of all new female cancers each year. The average risk of a women developing breast cancer in her lifetime is about 13%. Atypical Protein Kinase C iota (PKC-ι) is over expressed in 88 of the 110 breast cancer cases (80.0%) and is highly active in the invasive progression of the disease. Therefore, considering PKC-ι as a novel therapeutic target is crucial. c-Jun is a Basic leucine zipper (bZIP) transcription factor and crucial component of activator protein-1 (AP-1) complex, which is also overexpressed in breast cancer and its oncogenic function regulates proliferation, apoptosis, metastasis and angiogenesis in breast cancer. c-Jun sits at the crossroad of the signaling network; hence, understanding the relationship between PKC-ι and c-Jun is fundamental. c-Jun is activated by the JNK pathway, which itself has its own oncogenic function and plays vital role in malignant transformation and metastasis in different cancer including breast cancer. In addition, the upstream markers of JNK are MKK7 and Tak1, which are part of the MAP2K and MAP3K families, respectively and these markers also play a pro-oncogenic role in breast cancer. The activation of these upstream markers further stimulates the phosphorylation and activation of JNK, which in turn activates c-Jun. Activated c-Jun forms homodimers and heterodimers in Activator Protein-1 complex (AP-1) complex, which also have oncogenic activity in cancer cell proliferation and apoptosis. The AP-1 complex further stimulates the pro-inflammatory cytokine TNF-α, which again stimulates the activation of the MAPK/JNKpathway. This indicates that there is an oncogenic positive feedback loop between these biomarkers, and it is hypothesized that PKC-ι regulates this positive feedback loop.This study examines the role played by PKC-ι in regulating the positive feedback loop between the MAPK/JNK pathway, AP1 complex, and TNF-α. Using ICA-1S, an inhibitor specific to PKC-ι, BT549 breast cancer cells were treated for 5 days (10μM dosage), and SDS-PAGE was conducted. Our results indicate that in BT549 cells, inhibition of PKC-ι with ICA-1S has significantly reduced the levels of Tak1, p-JNK, JNK, m-MKK7, MKK7, p-c-Jun, c-Jun, and TNF-α. These findings indicate that inhibiting PKC-ι can reduce the phosphorylation and activation of JNK and its upstream and downstream targets, and that inhibition of PKC-ι inhibits the oncogenic role of this positive feedback loop in breast cancer. Hence, it can be concluded that in BT549 triple negative breast cancer cells, PKC-ι regulates the oncogenic loop between MAPK/JNK pathway, AP-1 and TNF-α via the phosphorylation and activation of c-Jun, which further stimulates the activation of the entire loop.

#4131 Expanding the roles of 14-3-3 and Smad2/3 as coordinators of PKC-ι activity in medulloblastoma: a study based on PKC-ι specific inhibitor ICA-1S.

Luke Lajmi, Wishrawana Sarathi Ratnayake, Sloan Breedy, Aaron Todman, Mildred Acevedo-Duncan

Chemistry, University of South Florida, Tampa, FL

Medulloblastoma is one of the most aggressive and common pediatric cancers, second only to leukemia, and the most common childhood brain tumor, comprising 20% of all pediatric brain cancers. Current treatment options involving radiation and chemotherapy as well as surgical resection are extremely invasive and often lead to patients living with long term neurological and endocrinological consequences. This study focuses on exploring the PKC-ι specific small-molecule inhibitor 5-amino-1-((1R,2S,3S,4R)-2,3-dihydroxy-4-methylcyclopentyl)-1H-imidazole-4-carboxamide (ICA-1S) and its effects on medulloblastoma cell lines Daoy and ONS-76. Using the previously established IC_{50} values for both cell lines, this study demonstrates that PKC-ι inhibition by ICA-1S leads to significant downregulation of both 14-3-3/c-Raf/Erk and TGF-β/Smad2/3/β-catenin pathways. Our results showing the association and localization of PKC-ι with 14-3-3, Smad2/3, and Erk1/2 are likely driving this cross-talk communication between these two pathways. We also show that ICA-1S simultaneously induces apoptosis and pyroptosis in addition to reducing the migratory and invasive capabilities of medulloblastoma. Finally, as a proof of concept, we demonstrated that *in-vivo* treatment of ICA-1S decreased tumor volume in nude mice by approximately 50%. In summary, PKC-ι is likely an important oncogenic target in medulloblastoma and ICA-1S appears to be a promising potential medulloblastoma therapeutic that merits further research.

#4132 PTPRF negatively regulates c-MET signaling to inhibit cell migration in colon cancer.

Carolina Galeano-Naranjo[1], Haley Stanczyk[1], Warren Van Nort[2], Tianyan Gao[2]

[1]Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY,[2]Markey Cancer Center, University of Kentucky, Lexington, KY

The spatiotemporal control of cell signaling requires a balancing act of protein kinases and phosphatases. Hyperactivation of signaling downstream of receptor tyrosine kinases (RTKs) is one of the most common mechanisms leading to oncogenic transformation in numerous cancer types. Although the activation process of RTKs has been extensively studied, the inactivation mechanisms mediated by tyrosine phosphatase are less understood. Previously, we have determined the molecular mechanisms by which protein tyrosine phosphatase receptor type F (PTPRF) regulates the Wnt pathway. In this study, we investigated the functional importance of PTPRF in controlling c-MET signaling in colon cancer. Downregulation of PTPRF in colon cancer cells using CRISPR-mediated gene deletion or shRNA-mediated gene silencing activates c-MET signaling at the level of GAB1 scaffolding protein upon HGF-induced receptor activation. Co-immunoprecipitation experiments indicate that PTPRF interacts with the c-MET receptor/GAB1 complex. In addition, PTPRF downregulation prolongs the phosphorylation of GAB1 in colon cancer cells treated with c-MET inhibitor. Functionally, PTPRF-loss markedly increases cell migration. Moreover, bioinformatics analysis of TCGA colon cancer patient data reveals that the expression of PTPRF gene is significantly decreased in tumor samples compared to normal controls. Taken together, these results identify PTPRF as a novel phosphatase of GAB1 that negatively regulates c-MET signaling. Decreased expression of PTPRF may play an important role in promoting tumor progression in colon cancer.

#4133 Cyclin-dependent kinase signaling in oncology: assessing the effectiveness of a CDK9-targeting using no-wash immunoassays.

Jennifer Old[1], Najim Douayry[2], Milind Rajopadhye[3], Olivia J. Kelada[3]

[1]Revvity Inc., Waltham, MA,[2]Revvity Inc., Codolet, France,[3]Revvity Inc., Hopkinton, MA

Cyclins are regulatory subunits that bind to a cyclin dependent kinase (CDK), thus activating the kinase and controlling its activity. Most CDKs form a complex with a particular cyclin and are involved in the regulation of either cell cycle or cell transcription. Dysregulation of CDKs has been found to be a primary driver in tumorigenesis. Thus, CDK9 is an attractive target for cancer therapeutics due to its crucial role in transcription regulation, particularly of short-lived anti-apoptotic proteins such as MCL-1 and XIAP. Among the investigated CDK9-based therapeutic strategies, the degradation of CDK9 using specific compounds like proteolysis targeting chimera (PROTAC) is of high interest.

The purpose of our study was to determine whether homogeneous time-resolved fluorescence (HTRF) and a bead-based homogeneous immunoassay platform (AlphaLISA Surefire Ultra, ALSU) assays are effective solutions for identifying and characterizing PROTAC degradation of CDK9. Both assays were used to monitor the expression levels of CDK9 or GAPDH in cell lysates from HeLa or MCF-7 cells. Assessing CDK9 levels allowed the identification of a PROTAC degradation of CDK9 while the determination of GADPH levels was used as an internal control for potential changes to global protein levels in drug treatment.

Cells were treated for 4h either with 1µM of a reference CDK9 degrader, Thal-SNS-032 or with the same concentration of its two individual chemical components, Thalidomide and SNS-032 (as negative controls). Cells were then lysed, and the corresponding lysates were assessed in either CDK9 or GAPDH assays. Thal-SNS6032 induced a robust degradation of CDK9 (80 to 95%) while Thalidomide and SNS-032 did not affect the expression level of CDK9. Moreover, none of the tested compounds affected the GAPDH expression level suggesting that the changes of CDK9 levels is not due to changes in the global protein concentration. To further characterize the effect of Thal-SNS-032, a dose-response treatment was carried out on HeLa and MCF-7 cells. CDK9 and GAPDH levels were assessed in the corresponding cell lysates and a dose-dependent degradation of CDK9 was observed with half-maximal degradation values (DC50) ranging from 60 to 166nM while GADPH levels remained unchanged. These data suggest that HTRF and ALSU assays are efficient solutions to identify and characterize PROTAC targeting of CDK9. Results obtained for CDK9 can be translated to other CDK targets of interest in oncology research as a broad portfolio of total CDK detection kits is available using the two assay platforms.

#4134 An inhibitor of the atypical protein kinase C-ζ impede the growth of gastric cancer cells by inducing apoptosis.

Abiral Hasib Shourav, **Abigail Olatunji**, Mahfuza Marzan, Radwan Ebna Noor, Mildred Acevedo-Duncan

Chemistry, University of South Florida, Tampa, FL

The global statistics on gastric cancer suggest that it is the fifth most common type of cancer in terms of prevalence and third-most common type in terms of death rate. The considerably high mortality of gastric cancer is mainly because of the fact that it is mostly diagnosed when the disease has progressed to the advanced stage. While the bacterium Helicobacter pylori is known to be the most common cause of gastric cancer, other notable risk factors also include high salt intake, age and diets lacking in fruits and vegetables. Demographic data have revealed that the regions of East Asia, Eastern Europe and South America are notable hotspots of this type of cancer. Endoscopic resection is considered as the major treatment procedure for early detected gastric cancer while those diagnosed in later stages are treated with surgeries such as D2 lymphadenectomy. Previously, the Atypical Protein Kinases C (aPKCs) - ζ and ι - have been documented to play significant roles in elevated cell proliferation in various cancer types. Here, an inhibitor of the aPKC-ζ, known as ζ-stat (8-hydroxy-1,3,6-naphthalenetrisulfonic acid), that specifically inhibits the aPKC-ζ on a gastric cancer cell line (i.e., AGS) was used to observe its effects on cell proliferation. In separate trials, AGS cells were treated with ζ-stat for 72 hours (about 3 days). An assortment of drug concentrations for the inhibitor was tried and the analysis of the cell count demonstrated that the cell proliferation decreases were statistically significant for the drug in all concentrations. The highest decrease was observed at 10 μM ($P < 0.0001$) as the number of cells diminished to approximately 44%. Our previous research has revealed that ζ-stat downregulates the aPKC-ζ by interfering with established cancer pathways to cause cell deaths. Henceforth, Western Blot analysis of AGS cells treated with ζ-stat have shown evidence of apoptosis. There have been considerable decreases in the levels of total PARP, Caspase 3 and Survivin. Likewise, levels of cleaved-Caspase 3 and cleaved-PARP have also increased along with the mitochondrial apoptotic marker Cytochrome C. Current investigations include how ζ-stat play into some of the well-established gastric cancer pathways to lead to cell deaths with techniques such as Western Blot analysis, Immunoprecipitation Assays and Flow cytometry.

#4135 AKT1 mediates PTEN-loss induced intrahepatic cholangiocarcinoma development in mice.

Ielyzaveta Slarve, Yining Ding, Yushan Wang, Qi Tang, Zifei Xu, Lina He, Bangyan Stiles

USC - University of Southern California, Los Angeles, CA

Introduction: Liver cancer is the third most common cause of cancer-related mortality worldwide. Mice with liver-specific *Pten* loss (*Pten*$^{loxP/loxP}$; albumin [*Alb*]-*Cre*$^{-/+}$; LiPten) develop predominantly intrahepatic cholangiocarcinoma (ICC) and some hepatocellular carcinoma (HCC) by 12 months of age. *Pten* loss results in activation of the serine/threonine kinase AKT. Of the three AKT isoforms identified to date, AKT1 isoform is implicated in regulation of cell growth, proliferation, and survival. The present study investigated the role of AKT1 in mediating PTEN-loss induced liver cancer development.

Methods: To generate mice with liver-specific *Pten* and *Akt1* deletion (*Pten*$^{loxP/loxP}$; *Akt1*$^{loxP/loxP}$; *Alb-Cre*$^{-/+}$; LiPtenA1), LiPten mice were crossed with mice that have liver-specific *Akt1* loss (*Akt1*$^{loxP/loxP}$; *Alb-Cre*$^{-/+}$; LiA1). Whole livers from 12-month-old WT, LiA1, LiPten, and LiPtenA1 mice were analyzed for tumor prevalence and morphology via hematoxylin and eosin staining, and for markers of HCC and ICC via qPCR and immunofluorescence.

Results: All male LiA1 mice displayed WT-like phenotype. Like LiPten mice, all male LiPtenA1 mice develop steatosis followed by tumors by 12 months of age. Compared to LiPten mice, LiPtenA1 animals displayed predominantly HCC phenotype based on morphology, increased HCC markers (*Hnf4a*, *Alb*), and decreased ICC markers (*Sox9*, *Spp1*, *Hes1*, *Ck19*).

Conclusions: AKT1 loss in LiPten mice did not prevent development of steatosis and liver tumorigenesis but resulted in predominantly HCC rather than ICC phenotype, suggesting the role of AKT1 in mediating ICC development. These results contribute to the understanding of the role of AKT isoforms in regulating liver tumorigenesis, and further investigation into signaling mechanisms underlying these observations is required.

#4136 The causes and consequences of off-target activation of the GCN2-eIF2a-ATF4 axis in cancer therapy.

C. Ryland III[1], Nasreen Marikar[1], Vu Nguyen[2], Varuna Nangia[1], Alicia Darnell[3], Stacey Bagby[2], Kasey Couts[2], Matthew G. Vander Heiden[3], Philip Reigan[2], Sabrina L. Spencer[1]

[1]University of Colorado Boulder, Boulder, CO,[2]University of Colorado Anschutz, Aurora, CO,[3]Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Cambridge, MA

Kinase inhibitors are notorious for their promiscuity and off-target effects. We discovered that multiple clinical inhibitors used in the treatment of cancer, including dabrafenib and encorafenib, activate the GCN2 kinase at patient-relevant concentrations in an off-target manner via direct interaction. GCN2 is an activating kinase of the integrated stress response (ISR) that leads to induction of the transcription factor ATF4. Cotreatment with a GCN2 inhibitor in BRAF-V600E melanoma cells significantly alters the rate of drug resistance and cell outgrowth. We thus propose that off-target activation of GCN2 affects development of drug-resistant and metastatic phenotypes. Finally, we perform an *in silico* inhibitor screen, identifying dozens of FDA-approved inhibitors used in the treatment of cancer that appear to share this off-target GCN2 interaction.

#4137 Investigating VRK1 inhibition as an anti-cancer therapy for pancreatic ductal adenocarcinoma.

K. Chu, Y. Xi, S. Schwarz, K. T. Vaughan;
University of Notre Dame, Notre Dame, IN

Pancreatic ductal adenocarcinoma (PDAC) is a aggressive and often a lethal form of exocrine pancreatic cancer with a 5-year survival rate of 12%. Current PDAC therapeutics are ineffective and highly toxic, leading to a variety of harsh side effects that greatly reduce patient quality of life. This low quality of life highlights the need for new approaches. This study investigates the potential of inducing nuclear envelope instability in PDAC cells through inhibition of Vaccinia-Related Kinase 1 (VRK1). Previous studies in the Vaughan lab have demonstrated that the knock down of VRK1 reduces BAF phosphorylation, reduces BAF/Lamin A interaction, and leads to nuclear blebbing. Evidence also suggests that nuclear blebbing leads to DNA leakage and activation of the cGAS-STING pathway and cellular senescence. However, it remains unclear what stage of the cell cycle is inhibited by VRK1 inhibition. To determine when this phenomenon occurs, we synchronized Cos7 cells using a thymidine and nocodazole block and treated with VRK1-IN-1, a potent VRK1 inhibitor. To determine if VRK1 inhibition affects a certain stage of mitosis, cells were synchronized and stained for tubulin and Lamin A. We observed that VRK1-IN-1 does not affect a specific stage of the cell cycle. Here we developed a protocol for measuring the effect of VRK1 inhibitors on mitosis and the cell cycle. This protocol will serve as a launching point to validate the discovery of VRK1 inhibitors from a 12,000-compound kinase assay screen. Elucidation and understanding of when VRK1 inhibition activate/induces the cGAS-STING pathway and cellular senescence, may provide the rational for to pursuing of VRK1 inhibitors as novel therapeutics for the treatment of PDAC.

#4138 Investigating the relationship between DUSP12 and ZPR9 in cell division and death.

Mai Abdusamad[1], Xiao Guo[1], Ivan Ramirez[1], Whitaker Cohn[2], Erick Velasquez[1], Ankur Gholkar[3], Julian P. Whitelegge[2], Jorge Z. Torres[1]

[1]Department of Chemistry and Biochemistry, UCLA - University of California Los Angeles, Los Angeles, CA,[2]Pasarow Mass Spectrometry Laboratory, UCLA - University of California, Los Angeles, Los Angeles, CA,[3]UCLA - University of California Los Angeles, Los Angeles, CA

Protein phosphatases regulate essential processes in human cells and have critical roles in many human diseases, including cancer. The dual-specific phosphatases (DUSPs) are a subset of protein phosphatases that have become increasingly implicated in human cancers over the past decade. DUSP12 is a poorly characterized atypical DUSP widely conserved throughout evolution. While DUSP12 has been shown to possess pro-survival attributes, it is unclear if this is related to its potential role in cell division. Specifically, DUSP12 has been shown to play a role in both cell death and proliferation, acting in a protective capacity against stressful conditions in both hepatic and myocardial ischemic-reperfusion injury. Interestingly, several studies have also linked aberrant expression of DUSP12 to the development of a wide range of cancers, highlighting the importance of investigating the biological activities of DUSP12 as it appears that dissecting its functions in detail can provide insight into new mechanisms supporting uncontrolled cell growth. More recent evidence further suggests that DUSP12 affects cell cycle progression by regulating DNA content at the G1/S and G2/M checkpoints, likely through its unique zinc binding domain. However, the lack of known DUSP12 targets has hindered our understanding of the biological significance of this unique enzyme. From preliminary proteomic analyses of DUSP12 using affinity- and proximity-based approaches coupled to mass spectrometry, we identified ZPR9 as a potential interactor of DUSP12 which has been validated by in-cell and *in-vitro* immunoprecipitation assays. Previous studies have shown that ZPR9 may play a role in apoptosis, but it is unclear if and how ZPR9 participates in cell division and, more so, how it promotes cell death. Using cancer cell lines as a model system and leveraging advanced imaging techniques, I am performing follow-up functional studies to determine if and how ZPR9 is modified by DUSP12 and, further, if modification of ZPR9 by DUSP12 is important in influencing improper cell division. Collectively, this work will provide insights into the mechanism and regulatory role of the phosphatase DUSP12 during cell division as well as form the basis for designing novel therapeutic approaches to address diseases associated with abnormal proliferation.

#4139 Targeting USP10 to enhance chemotherapy and immunotherapy in NSCLC.

S. Dorandish, K. Bhayekar, A. Samarbakhsh, B. Kushwaha, P. Parajuli, Y. Ge, N. S. Gavande;
Wayne State University, Detroit, MI

Non-small cell lung cancer (NSCLC) remains a leading cause of death from cancer. While platinum-based chemotherapy is initially effective for early-stage NSCLC, drug resistance often limits its long-term success. Combining platinum-based chemotherapy with immunotherapy has emerged as a first-line treatment for metastatic NSCLC. However, many patients still experience limited benefits due to various resistance mechanisms. One critical mechanism underlying drug resistance is the increased capacity of DNA damage response (DDR). The deubiquitinase USP10 plays a crucial role in regulating the DDR by stabilizing oncogene proteins such as HDAC6. Inhibition of USP10 disrupts the USP10-HDAC6 axis, leading to enhanced DNA damage and cell death. Further, HDAC6 inhibition enhances immunogenic cell death-inducing radiotherapy-induced immune responses. Furthermore, HDAC6 inhibition leads to decreased expression of CD47 that acts as a "don't eat me" signal to prevent immune cells from phagocytosing tumor cells. Based on these findings, we hypothesize that targeting USP10 leads to HDAC6 degradation and DNA damage, resulting in sensitization of NSCLC cells to chemotherapy. Additionally, we propose that USP10 inhibition can sensitize NSCLC cells to immune checkpoint inhibitors and immunotherapy targeting CD47. Our extensive computational and structure-activity-relationship (SAR) studies led to the discovery of potent USP10 inhibitors. Our preliminary data show that the lead compound, GL-320, selectively inhibits USP10 activity, as confirmed by in vitro deubiquitinase (DUB) and cellular thermal shift assays. GL-320 dose-dependently inhibited the in vitro cell proliferation of H1299, a p53 null lung cancer cell, whereas it was significantly less effective against A549 cells with w/t p53. We also show that by inhibiting USP10, we can disrupt the DDR pathway, leading to increased DDR and cell death, as confirmed by western blotting and flow cytometry analyses. Our preliminary data show that USP 10 is a validated drug target to enhance the efficacy of existing chemotherapy and immunotherapy in NSCLC.

#4140 Non-proteolytic regulation of oncogenic transcription factors by deubiquitinases.

Yunsik Choi

Sogang University, Seoul, Korea, Republic of

Oncogenic transcription factors (TFs) such as ETS2 and TEAD4 are critical regulators of genes driving cancer progression, including those involved in proliferation, survival, and metastasis. Despite their importance, the mechanisms modulating their activity through ubiquitination remain poorly understood. This study investigates deubiquitinases (DUBs) that interact with and regulate ETS2 and TEAD4, aiming to uncover novel insights into their transcriptional control.A DUB sub-library screening identified USP39 and OTUD6A as regulators of ETS2 and TEAD4, respectively. USP39 interacts with ETS2 via their amino-terminal regions, independent of the zinc finger and PNT domains, and deubiquitinates ETS2. This interaction reduces ETS2's nuclear localization and transcriptional activity without affecting its stability, indicating a negative regulatory role. In contrast, OTUD6A interacts with TEAD4 at its YAP-binding domain and deubiquitinates TEAD4. OTUD6A further enhances TEAD4 transcriptional activity and cofactor interactions, notably by promoting YAP binding. Similar to USP39 and ETS2, OTUD6A does not influence TEAD4 stability but positively regulates its activity.These findings highlight the distinct, non-proteolytic roles of USP39 and OTUD6A in modulating transcriptional activity of ETS2 and TEAD4, respectively. Our findings underscore the functional diversity and opposing regulatory mechanisms of DUBs in oncogenic transcriptional control.

#4141 PDE3A promotes ER positive beast cancer progression by preventing ERα ubiquitination degradation.

Shengyu Pu, Heyan Chen, Bohong Chen, Jianjun He, Na Hao

The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Background: ER+ breast cancer (ER+BC) is the most common subtype, which characterized by high risk of recurrence and metastasis after treatment. ERα is considered to be a key driver in the malignant progression of ER+BC, and it is necessary to understand the signaling mechanism of ERα. PDE3A, a member of the phosphodiesterases (PDEs) family, can hydrolyze the cAMP and cGMP, and is an important regulator of intracellular signaling. However, there are few studies on the effect of PDE3A on the malignant progression of ER+BC, and the specific mechanism is still unclear.
Aim: (i) To investigate the prognostic role of PDE3A in ER+BC and its links with breast cancer proliferation and metastasis; (ii) to explore the regulatory mechanism of PDE3Ain ER+BC biological process; (iii) to screen effective molecule inhibitor targetingPDE3A.
Methods: The expression level of PDE3A in ER+BC was determined by immunohistochemical staining and the mRNA expression profiles from the TCGA database. Roles of PDE3Ain cancer cell growth, metastasis were determined by molecular and cell biology methods. Co-Immunoprecipitation (CO-IP) was used to examine the binding of PDE3Aand ERα. Chromatin immunoprecipitation (ChIP) and promoter luciferase reporter assay were included for detecting the transcription of PDE3A in ER+BC. ER+BC xenograft mice were used to study the inhibition of tumor development.
Results: PDE3A is a novel ER+BC target, which is overexpressed in ER+BC tissues and significantly associated with clinical pathology of advanced TNM stage and poor prognosis of patients. In vitro and in vivo studies have demonstrated that PDE3Apromotes ER+BC proliferation and metastasis. Mechanically, PDE3A regulates ERαproteasome degradation through competitive binding to ERα with its E3 ligase SPOP, independently of the catalytic activity of PDE3A. In addition, ERα directly facilitates the transcription of PDE3A and up-regulate the expression level of PDE3A.Furthermore, we screened out brequinar, a small molecule inhibitor targeting PDE3A, can inhibit breast cancer cell proliferation and metastasis, and reverse endocrine resistance.
Conclusion: We identified an important role of PDE3A-ERα feedback loop in the ER+BC progress and resistance to endocrine therapy, representing a future biomarker and therapeutic target of ER+BC.

#4142 Modulation of kinase signaling by APLP2 in pancreatic cancer cells.

Kenadie Doty[1], Kaitlin J. Smith[2], Gabrielle L. Brumfield[1], Joyce C. Solheim[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]College of Saint Mary, Omaha, NE

Pancreatic cancer is a highly aggressive malignancy with few effective treatment options, highlighting the importance of understanding its underlying molecular mechanisms. The overexpression of amyloid precursor-like protein 2 (APLP2) in pancreatic cancer suggests that it may promote cancer progression. However, mechanisms by which APLP2 may influence critical signaling pathways in pancreatic cancer remain undefined. To address this, a membrane-based sandwich immunoassay was used to determine the relative phosphorylation levels of 37 kinase sites in S2-013 pancreatic cancer cell lysates following siRNA-mediated APLP2 knockdown. The results demonstrated that the downregulation of APLP2 led to significant changes in the phosphorylation of several key kinases, including a pronounced increase in the phosphorylation of the proline-rich Akt substrate of 40 kDa (PRAS40), which is involved in mTORC1 function, and decreases in the phosphorylation of CREB, ERK1/2, and JNK 1/2/3. Qiagen Ingenuity Pathway Analysis (IPA) identified that the pathways most affected by APLP2 knockdown involved MAPK targets and nuclear events mediated by MAP kinases. Together, these findings suggest that APLP2 may regulate key signaling pathways driving pancreatic cancer progression and provide insights into the molecular mechanisms by which APLP2 contributes to pancreatic cancer's aggressive nature. Our future studies will utilize chemical inhibitors, knockout experiments, and western blot analysis to validate and extend these new findings.

#4143 Analyzing BRAFV600E signaling complexes to better understand BRAF driven melanoma.

Adamaris M. Martinez, Kayla T. O'Toole, Martin McMahon

Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT

In approximately 8% of all cancers, mutational activation of BRAF is an oncogenic driver, with a particular prevalence in lung cancer, thyroid cancer, and melanoma. Mutations in BRAF account for about 50% of the cutaneous melanoma cases in patients. The most common mutational alteration is the *BRAF*^{T1799A} encoding the BRAF^{V600E} oncoprotein kinase. Combined inhibition of BRAF^{V600E} and MEK 1/2 has been approved to treat BRAF^{V600E}-driven melanoma and lung cancer. There are several mechanisms of resistance to inhibitors of BRAF^{V600E} signaling, with one of the most intriguing being the emergence of tumors expressing p61-BRAF^{V600E} that is encoded by a variant mRNA that is aberrantly spliced to remove exons 4-8. Consequently, p61-BRAF^{V600E} is missing amino acid sequences that promote association with RAS.GTP (RBD) and the cysteine rich domain (CRD). Moreover, while full-length BRAF^{V600E} is widely considered to signal as a monomer, p61-BRAF^{V600E} is thought to require dimerization for activation. Here, we use gel-filtration chromatography and immunoblotting to show that both forms of BRAF^{V600E} are detected in a large molecular weight complex of 450-500 kDa. However, p61-BRAF^{V600E} containing complexes are smaller than those with full-length BRAF^{V600E}, which may reflect the difference in size of the BRAF^{V600E} proteins or subtle differences in the signaling complexes. Interestingly, the addition of a BRAF^{V600E} inhibitor, vemurafenib, shifted the elution of complexes with full-length BRAF^{V600E} into lower molecular weight fractions. In addition, we have utilized the proximity labeling technique, TurboID, to uncover more of the BRAF interactome.

#4144 PTPTF negatively regulates c-Src kinase through the dephosphorylation of the activation loop.

Haley Stanczyk[1], Carolina Galeano-Naranjo[1], Tianyan Gao[2]

[1]Department of Molecular and Cellular Biochemistry, University of Kentucky, Lexington, KY,[2]Markey Cancer Center, University of Kentucky, Lexington, KY

Kinases and phosphatases play a dynamic role in the regulation of signaling propagation. c-Src is an oncogenic kinase that plays multifunctional roles in the initiation and progression of many cancers, including breast, colorectal and lung cancers. The activity of c-Src kinase is tightly regulated by the phosphorylation status of two key tyrosine residues (Tyr419 and Tyr530 in human c-Src) that controls its propensity for entering an active conformation. Phosphorylation of Tyr530 at the C-terminus of c-Src locks the kinase in an inactive confirmation whereas phosphorylation of Tyr419 in the activation loop is required to activate c-Src. A number of tyrosine phosphatases have been identified to activate c-Src by dephosphorylating Tyr530. However, the phosphatases controlling the Tyr419 site remain elusive. In this study, we investigated the role of protein tyrosine phosphatase receptor type F (PTPRF) in regulating the phosphorylation of c-Src. PTPRF is characterized by an extracellular domain, a single transmembrane motif, and two tandem intracellular phosphatase domains (including a catalytically active D1 domain and a catalytically inactive D2 domain). We show that overexpression of PTPRF, but not a phosphatase inactive mutant, results in a decrease in Tyr419 phosphorylation of both wild-type and Y530F constitutively active c-Src in 293T cells. On the other hand, CRISPR-mediated knockout of PTPRF increases the phosphorylation of c-Src and signaling downstream. Co-immunoprecipitation experiments indicate that PTPRF interacts with c-Src through its D2 pseudo phosphatase domain. Consistent with the notion that the kinase activation reduces c-Src protein stability, we find that the expression of c-Src is increased when co-expressed with PTPRF, suggesting that PTPRF-mediated dephosphorylation stabilizes c-Src protein. Taken together, this study identifies PTPRF as a novel phosphatase that negatively regulates c-Src kinase activity through the dephosphorylation of Tyr419 in the activation loop.

#4145 TRIM21 functions as an oncogene in glioblastoma by transactivating FOSL1 and promoting the ubiquitination of p27 transactivating FOSL1 and promoting the ubiquitination of p27.

Vanajothi Ramar, Rajveer Sidhu, Osei Pako, Cheyenne R. Cisse, Shanchun Guo, **Mingli Liu**

Morehouse School of Medicine, Atlanta, GA

Background: Our previous studies demonstrated that FOSL1 promotes glioblastoma (GBM) progression and stemness through multiple pathways such as STAT3 and NF-κB signaling. Recently, we identified that FOSL1 physically interacts with the E3 ligaseTRIM21, which is localized in the nucleus of glioma cells. This study investigates the role of TRIM21 in GBM, its relationship with FOSL1, and its regulation of the TRIM21 ubiquitination target gene p27.
Methods: 1) Protein interaction: Immunoprecipitation assays were conducted to examine the physical interaction between TRIM21, FOSL1, and p27. 2) Regulation of p27: TRIM21 overexpression and knockdown (via siRNA) were used to analyze the effects on p27 protein levels. 3) Ubiquitination assay: TRIM21 knockdown followed by p27 immunoprecipitation and anti-ubiquitin probing was performed to assess ubiquitination. 4) Clinical data analysis: TCGA datasets were analyzed to correlate TRIM21 expression with glioma subtype and patient survival. 5) Functional assays: Glioma cell growth (MTT, colony formation) and invasion (transwell assay) were measured following TRIM21manipulation. 6) Histopathology: IHC was performed to evaluate TRIM21 expression in glioma patient tissues and its relationship with FOSL1 expression. 7) Nuclear TRIM21: The effects of nuclear-localized TRIM21 in regulating FOSL1 was assessed, including its ability to stimulate FOSL1 promoter activity via AP-1 binding sites.
Results: 1) TRIM21 physically interacts with FOSL1 and p27. 2) TRIM21 promotes p27 degradation through ubiquitination in a dose-dependent manner. 3) TCGA analysis reveals high TRIM21 expression in GBM patients, particularly in the mesenchymal subtypes. 4) TRIM21 enhances glioma growth and invasion in short-term and long-term assays. 5) IHC data show elevated TRIM21 levels in grade IV GBM tissues, correlating with FOSL1 expression. 6) nuclear-localized TRIM21 promotes FOSL1 transactivation via AP-1 sites and simultaneously mediates p27 degradation.
Conclusion: TRIM21 functions as an oncogene in GBM by driving FOSL1 transactivation and degrading the tumor suppressor gene of p27, thereby promoting GBM progression and aggressiveness.

#4146 USP36 associates with the rixosome complex and promotes ribosome biogenesis.

Yanping Li, Xiao-Xin Sun, **Mushui Dai**

OHSU, Portland, OR

Eukaryotic ribosome biogenesis is a highly regulated multistep process to generate the ribosome, including transcription of pre-ribosomal RNA (pre-rRNA), rRNA processing, ribosome subunit assembly and export. Dysregulation of ribosome biogenesis has been associated with development of various diseases, including ribosomopathies and cancer. Therefore, it is crucial to understand how ribosome biogenesis is regulated during normal cell homeostasis and how it is deregulated in human diseases. We previously reported that the ubiquitin-specific protease USP36 acts as a SUMO ligase to promote nucleolar protein SUMOylation. Using affinity purification, we found that USP36 associates with a number of nucleolar and ribosome biogenesis-related proteins, including the rixosome complex that consists of Las1L, Nol9, MDN1, Pelp1, WDR36, Tex10 and SENP3 and plays a critical function in ribosome maturation. We confirmed that that USP36 interacts with all the components of the rixosome complex. We further showed that USP36 promotes the SUMOylation of Las1L, Nol9 and Pelp1, suggesting that USP36 promotes rixosome protein group SUMOylation. As USP36 is a ubiquitin specific protease, we also test whether the stability of these rixosome proteins is regulated by USP36. We found that the levels of MDN1 and Las1L, Nol9 are reduced upon USP36 knockdown. Abolishing Las1L SUMOylation impaired rRNA processing and inhibited cell growth. Together, these results suggest that USP36 plays an important role in regulating ribosome biogenesis by post-translationally regulating the function of rixosome complex.

#4147 Role of MLK3-mediated phosphorylation of β-catenin in regulating cellular senescence and osteopontin expression in hepatocellular carcinoma.

Tanushree Kashyap, Rong Ke, Deepti Srivastava, Sunil K. Singh, Subhasis Das, Piush Srivastava, Sandeep Kumar, Ajay Rana, **Basabi Rana**

University of Illinois at Chicago, Chicago, IL

The canonical Wnt/β-catenin signaling pathway is important for normal liver growth and development, abnormal activation of which can lead to various liver pathologies, including hepatocellular carcinoma (HCC). Usually, β-catenin signaling is regulated by a degradation complex that includes adenomatous polyposis coli, Axin, Glycogen Synthase Kinase β, and Casein kinase 1α. Mutations of β-catenin itself and other genes regulating this pathway can cause aberrant activation of this axis. We have reported earlier that Mixed Lineage Kinase 3 (MLK3), a member of the MAPK kinase Kinase (MAP3K) family, can phosphorylate β-catenin and regulate its downstream pathway. The current studies were aimed to elucidate the biological consequences of MLK3-induced β-catenin phosphorylation in HCC. The experimental procedures included creating stable cell lines, RT^2 Profiler PCR Arrays, qPCR analysis, Immunofluorescence (IF), ELISA, IHC, MTT and β-Galactosidase (β-Gal) assays. Using Mass Spectrometry, we identified that MLK3 can phosphorylate the N-terminal region of β-catenin at Serine 129 amino acid residue. To understand the significance of β-catenin S129 phosphorylation, stable HCC cell lines overexpressing β-catenin-WT or its phospho-mutants (S129A, S129D) were generated. While MTT assays showed no significant differences between β-catenin-WT or mutant overexpression, β-Gal assays revealed that overexpression of β-catenin WT and S129D can promote a senescence phenotype, which was inhibited in the S129A mutant. These cells also showed increased expression of a set of unique senescent genes including COL1A1, COL3A1, and IGFBP7 which were dependent on S129 phosphorylation. Analysis by RT^2 Profiler PCR Array for cytokine and chemokine genes showed an increased expression of SPP1 (Osteopontin gene) in the WT compared to S129A cells. Further validation by qPCR, IF, and ELISA confirmed the induction and secretion of Osteopontin by β-catenin WT and S129D but not by S129A, suggesting a senescence-induced secretory phenotype (SASP) mediated by β-catenin-S129 phosphorylation. TMA analysis showed significant increase in Osteopontin expression in HCC patient samples compared to normal. Database analysis suggested that the SPP1 gene is induced in HCC, and high expression of SPP1 is associated with poor prognosis. In addition, there was a strong correlation between CTNNB1 (β-catenin gene) and SPP1 expressions in HCCs. Considering a well-established role of Osteopontin in HCC and other liver pathologies, these results suggest a potentially novel paracrine signaling network operating in liver cells mediated via a crosstalk of MLK3-β-catenin-Osteopontin axis. These also suggest MLK3 to be a viable drug target for antagonizing this axis and in clinical management of HCC.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Metabolic Pathways
Poster Session

#4151 Creatine and GAMT promote tumor stemness and malignancy and can be used as biomarkers for colorectal cancer recurrence.

Zhengran Zhou, Peishan Hu, Zerong Cai, Yufeng Chen, Xiaojian Wu, Xuanhui Liu

The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

BACKGROUND: The role of creatine, a common nutritional supplement, in tumorigenesis and development has gained increasing attention. Previous studies have shown that it has a dual effect on tumorigenesis and recent studies suggested that it promotes colorectal cancer (CRC) metastasis. However, the role creatine metabolism plays in tumor malignancy and recurrence is still unclear and identifying the mechanism could provide new strategies for the treatment of CRC.
METHODS: Targeted metabolomics analysis of creatine was dynamically performed on plasma samples of 160 CRC patients including 30 relapse cases. GAMT, the key enzyme in creatine synthesis, was investigated in TCGA and ICGC-ARGO database (a large multi-omics study of CRC in China conducted by the sixth affiliated hospital of Sun Yat-sen University). The effect of creatine and GAMT on CRC stemness and its mechanism were investigated in CRC cell lines, patient-derived organoids, and patient-derived xenografts. Limited proteolysis-mass spectrometry (LiP-MS) and RNA-sequencing was performed to illustrate creatine-protein interaction and the regulation of relative signal pathways.
RESULTS: In recurrent CRC cases, creatine level gradually increased over time after the first radical surgery until recurrence. Meanwhile, GAMT expression was found significantly higher in patients who were going to relapse, both in TCGA and ICGC-ARGO database. Patients with higher GAMT expression had worse prognosis. The addition of creatine inhibitor can effectively restrain CRC activity and proliferation both in vitro and in vivo. GAMT knockdown significantly reduced the self-renewal ability of CRC cells, and tumor stemness pathways were up-regulated, which can be reversed by adding creatine to the culture.
CONCLUSIONS: Creatine is associated with CRC recurrence through promoting tumor stemness and malignancy. Therapeutic strategies targeting creatine metabolism have the potential to reduce CRC recurrence.

#4152 Disrupting lipid elongation impairs prostate cancer progression in c-MYC driven mouse models.

Silvia D. Rodrigues[1], Isadora F. Teixeira[1], Giuseppe N. Fanelli[1], Caroline F. Ribeiro[1], Fabio Socciarelli[1], Jeanne Jiang[1], Debora C. Bastos[2], Hubert Pakula[1], Filippo Pederzoli[1], Pier V. Nuzzo[1], Alessandro Barberis[3], Lisa M. Butler[4], Johannes V. Swinnen[5], Massimo Loda[1]

[1]Pathology and Laboratory Medicine, Weill Cornell Medicine, NEW YORK, NY,[2]Departamento de Patologia, Faculdade Sao Leopoldo Mandic, Campinas, Brazil,[3]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, United Kingdom,[4]South Australian Immunogenomics Cancer Institute, University of Adelaide, Adelaide, Australia,[5]Department of Oncology, KU Leuven, Leuven, Belgium

Background: Altered lipid metabolism is a hallmark of prostate cancer development and progression. Key pathways affected include *de novo* fatty acid synthesis and downstream fatty acid elongation, which are both activated by androgens and oncogenic signaling, including c-Myc, a downstream target of Fatty Acid Synthase. One of the enzymes that is upregulated in clinical PCa is ELOVL5 (Elongation of Very Long-Chain Fatty Acids Protein 5), a target of the androgen receptor (AR), which catalyzes the initial step of fatty acid elongation. However, its role in cancer progression remains unknown.

Methods: Prostate tumors from HiMyc transgenic mice were evaluated for growth, histopathological progression and lipidomics changes up to 48 weeks and compared to HiMyc mice with ELOVL5 homozygous deletion. 3D organoid model derived from the ventral prostate of these GEMMs were assessed for changes in cell proliferation, size, and response to anti-androgen therapy (Enzalutamide). Rescue experiments were performed by supplementation with cis-vaccenic acid, a key fatty acid product of ELOVL5 activity.

Results: ELOVL5 KO significantly inhibited progression from prostatic intraepithelial neoplasia to invasive adenocarcinoma in comparison to HiMyc mice. Lipidomic profiling confirmed reduced levels of ELOVL5 elongation products, characterized by shortened acyl chains in phosphatidylethanolamine (PE) and phosphatidylcholine (PC) species, in both serum and prostate tissues. The growth effect was recapitulated in organoids derived from these mice, was further enhanced by Enzalutamide and partially rescued by supplementation with cis-vaccenic acid. Gene expression profiling confirmed downregulation of fatty acid biosynthesis pathways and androgen receptor in HiMyc: ELOVL5 KO models.

Conclusion: ELOVL5 curtails c-Myc-driven prostate cancer, providing a direct link between fatty acid elongation and prostate cancer progression.

#4153 Biomarker-driven polyamine pathway targeting as a treatment approach for TNBC.

Chloe White, Caroline Liang, Thomas Velenosi

Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada

Triple negative breast cancer accounts for about 15% of all breast cancer diagnoses and represents the most aggressive breast cancer subtype. This study aims to use a polyamine biomarker-driven approach to treat TNBC. Polyamines are small cationic molecules important for cancer cell growth and spermidine/spermine N^1-acetlytransferase (SAT1) is the rate-limiting catabolic enzyme in the pathway. Our previous work demonstrated that doxorubicin induces SAT1 expression in moderate-SAT1 expressing TNBC models. We hypothesize that the effectiveness of using an SAT1 agonist to treat TNBC is dependent on baseline SAT1 expression and function. TNBC cell lines and patient-derived xenografts with low, moderate, and high baseline expression levels of SAT1 were used to evaluate the hypothesis. Cell lines were treated with TNBC standard-of-care doxorubicin, the SAT1 agonist N1, N11-diethylnorspermine (DENSpm), combination DENSpm-doxorubicin, or vehicle control. Adding DENSpm to sub-therapeutic doxorubicin treatments further decreased cell viability in moderate and high baseline SAT1 expressing cells ($p<0.05$). DENSpm depleted spermidine in moderate-SAT1 expressing TNBC-PDX ex vivo tumours slices, which was further depleted by combining with doxorubicin. In vivo, the addition of DENSpm to doxorubicin treatment further attenuated tumour growth in moderate-SAT1 expression TNBC-PDX, which corresponded to an increase in urine diacetylspermine as an indicator of treatment effectiveness. In conclusion, the results of this study suggest that combination doxorubicin and DENSpm treatment may be an effective treatment option for TNBC tumours with moderate baseline SAT1 expression, and that urine diacetylspermine production may be indicative of treatment effectiveness.

#4154 Cancer cells exhibit novel metabolic vulnerabilities when exposed to low lipid environments.

D. L. Ramesh[1], K. L. Abbott[1], R. Ferreira[2], M. G. Vander Heiden[1];

[1]Massachusetts Institute of Technology, Cambridge, MA, [2]Wyss Institute for Biologically Inspired Engineering and Harvard Medical School, Harvard University, Boston, MA

Cancer cell metabolism is significantly influenced by microenvironmental factors such as nutrient availability, which can vary across different tissues and introduce exploitable therapeutic vulnerabilities. Notably, lipid availability is particularly low in the brain compared to other tissues. To identify metabolic vulnerabilities of cells in lipid-poor environments, we performed a CRISPR/Cas9 screen of metabolic synthesis genes in human cancer cells cultured in lipid-rich versus lipid-poor media. Through this screen, we observed a novel metabolic dependency in the cells when grown in lipid-depleted conditions. We verified this differential dependency by knockout (KO) of this target gene, which resulted in slower cell proliferation in lipid-depleted media. Additionally, wild-type cells displayed heightened sensitivity to inhibitors of other proteins in the pathway in lipid-depleted conditions, thereby phenocopying the KO. Polar metabolomics analyses by LC-MS revealed depletion of several nucleotide species in the KO cells cultured in lipid-depleted conditions, and supplementation with purine nucleotides rescued the proliferation of KO cells cultured in lipid-depleted media. We hypothesized that this nucleotide depletion could in turn result in nucleotide imbalance and DNA damage, and Western Blot analyses confirmed elevated DNA damage levels in the KO cells in lipid-depleted media. Our model is that in low-lipid environments, the KO redirects metabolic resources toward lipid synthesis, causing nucleotide imbalance, DNA damage, and cell death. Overall, our findings indicate that cancer cells exhibit novel metabolic vulnerabilities when exposed to lipid-depleted environments, which could be leveraged for treating tumors growing in lipid-poor organs such as the brain.

#4155 Catabolism of extracellular glutathione supplies amino acids to support tumor growth.

F. Hecht[1], M. Zocchi[1], E. T. Tuttle[1], N. P. Ward[2], B. Smith[1], Y. P. Kang[2], J. Cazarin[1], Z. G. Soares[1], M. Emir Ozgurses[3], H. Zhao[3], C. Sheehan[4], F. Alimohammadi[1], L. Munger[1], D. Trivedi[1], G. Asantewaa[1], S. Blick-Nitko[1], J. Zoeller[5], Y. Chen[6], V. Vasiliou[6], B. M. Turner[1], A. Muir[4], J. L. Coloff[3], J. Munger[1], G. DeNicola[2], I. Harris[1];

[1]University of Rochester Medical Center, Rochester, NY, [2]Moffitt Cancer Center and Research Institute, Tampa, NY, [3]University of Illinois College of Medicine, Chicago, IL, [4]University of Chicago, Chicago, IL, [5]Harvard Medical School, Boston, MA, [6]Yale School of Public Health, New Haven, CT

Restricting amino acids from tumors is an emerging therapeutic strategy with significant promise. While typically considered an intracellular antioxidant with tumor-promoting capabilities, glutathione (GSH) is a tripeptide composed of cysteine, glutamate, and glycine that can be catabolized, yielding amino acids that could support tumor metabolism. However, the extent to which GSH-derived amino acids are essential to cancers is unclear. Here, we find that catabolism of extracellular GSH provides critical support for tumors by supplying cysteine. We show that disrupting the tumor's ability to synthesize intracellular GSH does not perturb its growth, highlighting the potential importance of extracellular GSH. Notably, we find GSH to be abundant in the tumor interstitial fluid, the primary environment surrounding cancer cells in vivo, where it far exceeds cystine levels. Our findings reveal that cancer cell survival and growth can be restored in cystine-deprived conditions through GSH supplementation. This process was dependent on the catabolic activity of γ-glutamyl-transferases (GGT) enzymes, which can break down GSH, yielding glutamate and cysteinylglycine, which can be further brown down to cysteine and glycine. GGT1 overexpression further facilitates this rescue by lowering the amount of GSH required for cell survival. Metabolomic analysis shows that GSH catabolism replenishes cysteine-related products depleted by cystine deprivation. Additionally, pharmacological screening revealed that when cancer cells acquire their cysteine from GGT-mediated GSH breakdown, they become resistant to inhibitors of cystine uptake and utilization. Finally, the systemic treatment of mice bearing breast tumor xenografts with a potent GGT inhibitor prevented circulating GSH breakdown, reduced tumor cysteine levels, and slowed down tumor growth. This effect was reversed by restoring cysteine levels with N-acetyl-cysteine, indicating that cysteine depletion drives the observed reduction in tumor growth. Our findings indicate a non-canonical role for GSH in supporting tumors by acting as a reservoir of amino acids. Depriving tumors of extracellular GSH or inhibiting its breakdown represents a potentially tractable therapeutic approach for cancer patients, as it could restrict tumors' access to critical amino acids. These findings offer a mechanistic explanation for the pro-tumorigenic role of GSH and reshape our understanding of how amino acids, including cysteine, are supplied to cancer cells, unveiling a novel therapeutic avenue for targeting cancer metabolism.

#4156 Differential effects of tumor metabolites on T cell activation and effector function.

D. Hua, S. Budhu, A. Assouvie, S. Verma, M. Bah, J. D. Wolchok, T. Merghoub;
Weill Cornell Medicine/Sandra and Edward Meyer Cancer Center, New York, NY

Over the past decade, immunotherapies have significantly improved clinical outcomes in cancer patients. The FDA approval of ICB for cancer treatment represents a clinical milestone, however, durable responses are observed in only ~20-40% of patients. The immunosuppressive nature of the tumor microenvironment (TME) presents a major challenge for effective anti-tumor responses. Tumor cells are highly metabolically active compared to other cells in the TME. Processes such as glycolysis and oxygen consumption (OXPHOS) lead to tumor hypoxia and the accumulation of metabolites in the TME. Metabolites found in the TME play key roles in immunosuppressive pathways including the adenosine-A2A receptor (A2AR) signaling pathway, and the Tryptophan-kynurenine-aryl hydrocarbon receptor (AHR) axis. Here we investigated how these metabolic pathways directly affect activation and effector function of T cells. In addition, we examined whether these pathways overlap functionally. To explore how TME metabolites affect T cell function, naïve mouse T cells were activated in the presence of metabolites including lactic acid (Lac), adenosine (Ado), kynurenine (Kyn). After 72 hours, T cells were analyzed via flow cytometry for proliferation and activation. We found that lactic acid decreased T cell frequencies and proliferation, but increased expression of CD39 and CD73, key enzymes involved in the conversion of ATP to Ado. Intriguingly, the combination of Kyn and Ado uniquely promoted T cell activation, showing markedly elevated expression of classical activation and effector markers such as CD44, CD25, and Granzyme B along with reduced CD39 and CD73 levels. Similar findings were observed in a clonogenic killing assay using tumor-specific T cells co-cultured with metabolites corroborating the functional relevance of our observations. Lactate negatively affected T cell killing function and the combination of Kyn and Ado showed the largest increase in killing efficiency. These findings suggest potential synergy between Kyn and Ado pathways in enhancing T cell function within the TME possibly through complementary pathways that bypass or counteract typical immunosuppressive signals. Further mechanistic investigation could unlock new strategies to overcome TME-induced immunosuppression and enhance existing immune based therapies.

#4157 Prodrug development of Cyclo-Creatine: Enhancing permeability and reducing toxicity for HER2+ breast cancer treatment.

Y. Li, Y. Huang, P. Dey, S. Hitosugi, S. Buhrow, J. Reid, T. Hitosugi;
Mayo Clinic College of Medicine and Science, Rochester, MN

HER2+ breast cancer is an aggressive subtype of cancer that often develops resistance to the current first-line therapy, Trastuzumab. In our previous work, we demonstrated that HER2 signaling activates mitochondrial creatine kinase 1 (MtCK1), which enhances mitochondrial energy metabolism for rapid proliferation of breast cancer cells. However, pharmacological blockage of MtCK1 with a creatine analog, Cyclo-Creatine (CCr), requires millimolar concentration to inhibit breast cancer cell proliferation and is associated with brain toxicity, limiting its clinical application. This brain toxicity may result from the inhibition of the creatine transporter SLC6A8 by CCr, which decreases to transport creatine into brain.

In this study, we took a prodrug development approach to identify and optimize protection groups for CCr, designed to bypass the SLC6A8 transporter, enhancing bioavailability and reducing toxicity. Liquid chromatography-mass spectrometry (LC-MS) was utilized to analyze drug uptake and creatine metabolites in cells treated with the prodrugs. Prodrug C, which is our lead prodrug candidate, demonstrated a seven-fold increase in cellular uptake and more than a hundred-fold improvement in cell-killing effects as compared to CCr in an MtCK1 specific manner in breast cancer cells. This approach offers a promising therapeutic strategy to inhibit HER2+ breast cancer cell by disrupting mitochondrial energy metabolism. Future investigations will focus on validating this prodrug's pharmacokinetics (PK) and pharmacodynamics (PD) through further preclinical studies.

#4158 PIKfyve inhibition drives lipogenic adaptation and reveals metabolic vulnerabilities in PDAC.

Ruya Pakkan[1], Caleb Cheng[1], Jasmine Wisniewski[1], Sydney Peters[1], Pietro Morlacchi[2], Li Zhang[1], Yuanyuan Qiao[1], Costas A. Lyssiotis[1], Arul M. Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]Agilent technologies, Inc, Lexington, MA

PIKfyve plays a key role in autophagy and lysosomal functions, which are critical for pancreatic ductal adenocarcinoma (PDAC) cell metabolism and survival. Consistent with this, we found that PIKfyve perturbation suppresses autophagy and reduces PDAC cell viability. Prior studies show that autophagy and lysosomal processes are critical for maintaining iron homeostasis and mitochondrial respiration in PDAC. However, PIKfyve inhibition did not seem to significantly affect oxygen consumption rate (OCR) compared to other lysosomal inhibitors such as chloroquine and bafilomycin, suggesting that PIKfyve also regulates other metabolic demands in addition to iron homeostasis. To understand the role of PIKfyve in PDAC and detect genes essential for metabolic compensation to PIKfyve loss, we performed a CRISPR screen using the PIKfyve inhibitor apilimod as a selective pressure. This revealed that the most depleted sgRNAs targeted genes involved in de novo fatty acid synthesis, insinuating that de novo fatty acid synthesis acts as a functional adaption to loss of PIKfyve function. Consistent with these results, cells upon disruption of fatty acid synthesis were sensitized to PIKfyve inhibitors, confirming that PIKfyve perturbation makes cells more reliant on fatty acid synthesis for survival. Moreover, PIKfyve inhibition activated key lipogenic transcriptional factor SREBP1 and upregulated fatty acid synthesis genes such as FASN and ACACA. We further discovered that PIKfyve inhibition in PDAC cells changed cellular metabolism, with initial decreases in citrate levels and subsequent recovery, along with a decrease in upstream glycolytic metabolites. Targeted lipidomics and isotope tracing showed that PIKfyve inhibition rerouted glucose-derived carbon into de novo lipid synthesis, specifically sphingolipids, dependent on SREBP1 activity. An additional CRISPR screen using a more potent degree of PIKfyve inhibition further identified sphingolipid synthesis genes (SPTLC1, SPTLC2, and KDSR) as essential for cell survival under PIKfyve inhibition. These results suggest that PIKfyve inhibition drives an adaptive increase in lipid synthesis, specifically sphingolipid synthesis through the activation of SREBP1 as a survival mechanism for PDAC cells. These results show a metabolic vulnerability in PDAC, suggesting that PIKfyve inhibitors, in combination with the inhibition of fatty acid synthesis and specifically sphingolipid synthesis, represent promising therapeutic strategies.

#4159 Investigating the role of Akt isoforms in hepatocellular carcinoma and liver fibrosis.

Manahil Ghazi, Ahmed Abd El Razek, Nissim Hay

University of Illinois at Chicago, Chicago, IL

Liver fibrosis and hepatocellular carcinoma (HCC) are major global health issues, with HCC being the most common primary liver cancer and a leading cause of cancer-related death. Metabolic dysfunction-associated steatohepatitis (MASH) is an emerging risk factor for HCC. Theserine/threonine protein kinase Akt plays a central role in cell survival, growth, and metabolism, and its hyperactivation via the PI3K/Akt pathway is implicated in many cancers. Mammalian cells express three Akt isoforms, but the effects of isoform-specific Akt inhibition remain poorly understood. We previously showed that global deletion of Akt2 along with hepatic deletion of Akt1 surprisingly leads to early onset of spontaneous HCC. The current study investigates the mechanisms underlying spontaneous HCC in these mouse models and examines the roles of Akt1 and Akt2 in MASH-induced liver fibrosis and HCC. Two mouse strains were generated: $Akt2^{-/-}$; $Akt1hep^{-/-}$ and $Akt1^{-/-}$; $Akt2hep^{-/-}$. $Akt2^{-/-}$ mice survived hepatic Akt1 deletion, but all developed early onset HCC with elevated insulin and glucose levels, increased lipid droplet accumulation, and CD36 expression. In contrast, $Akt1^{-/-}$ mice survived hepatic Akt2 deletion without tumor development and had normal glucose levels. These findings suggest that HCC development in $Akt2^{-/-}$; $Akt1hep^{-/-}$ mice occurs despite the loss of Akt activity, likely due to compensatory mechanisms or alternative pathways in hepatocarcinogenesis. Given the high insulin and glucose levels in $Akt2^{-/-}$; $Akt1hep^{-/-}$ mice, we hypothesize that reducing insulin levels may prevent HCC. Additionally, we are examining whether CD36 is essential for HCC development in these mice. The second part of this study explores the impact of Akt isoforms on MASH-induced liver fibrosis and HCC. We have generated five mouse groups ($Akt1^{-/-}$, $Akt2^{-/-}$, $Akt1hep^{-/-}$, $Akt2hep^{-/-}$, and$Akt1hep^{-/-}$; $Akt2hep^{-/-}$), and these are fed with Western diet and subject to weekly CCl4 injections for MASH induced HCC. This model will help to understand the role of Akt1 or Akt2 upon hepatic versus systemic deletion and its effect on liver fibrosis and HCC progression in the MASH-induced model. Together, these studies will provide insights into the isoform-specific roles of Akt in liver carcinogenesis and fibrosis, with implications for targeted therapies in HCC.

#4160 Lipid metabolism is a metabolic vulnerability in LKB1 mutant, KRAS driven non-small cell lung cancer.

S. Flanagan[1], R. Stanley[2], B. Malacrida[3], D. O'Reilly[2], J. Naidoo[4], P. Murray[1], C. M. Dowling[2];
[1]University of Limerick, Limerick, Ireland, [2]Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland, [3]Barts Cancer Institute, Queen Mary University of London, London, Ireland, [4]Beaumont Hospital, Dublin, Ireland

Non-small cell lung cancer (NSCLC) accounts for 80-85% of all lung cancers worldwide, with KRAS-driven NSCLC representing 30% of these cases. The introduction of immunotherapy has improved outcomes in advanced lung cancer, however, many patients with lung cancer do not respond to this treatment, and some develop severe side effects. Patients with KRAS-driven NSCLC harbouring a co-mutation in the LKB1 gene (KL), have a significantly poorer response to immunotherapy compared to patients harbouring a KRAS and TP53 co-mutation (KP). However, the reason for this difference in response to immunotherapy is largely unknown. Recent studies demonstrate that metabolic vulnerabilities in KL genotypes can influence therapeutic response. Our research aims to identify and target these vulnerabilities in KL NSCLC, with the aim to enhance response to immunotherapy. Moreover, we will focus on creating a novel three-dimensional (3D) NSCLC co-culture model to study immunotherapy response. Using the cBioPortal mRNA database and publicly available patient protein data, we completed a bioinformatic analysis of key genes, proteins, and metabolites in major metabolic pathways. Notably, lipid metabolism pathways displayed significant differences between KP and KL genotypes, specifically the beta-oxidation of fatty acids and fatty acid synthesis pathways. Proteins involved in the beta-oxidation pathway showed significant upregulation in KL patients such as Acetyl-CoA Acetyltransferase 1, Acyl-CoA Dehydrogenase, Hydroxyacyl-CoA Dehydrogenase and Enoyl-CoA Hydratase, and proteins involved in fatty acid synthesis also displayed upregulation in KL patients. We conducted a drug screen using a series of inhibitors targeting proteins in the fatty acid synthesis and beta oxidation pathway, and observed strong efficacy in KL NSCLC cell lines. Moreover, we observed a reduction in cell migration, colony formation and 3D spheroid formation in response to fatty acid synthesis inhibitors in KL NSCLC. Separately, we have successfully established 3D co-culture models of NSCLC cell lines and human T-cells isolated from patient samples. We found the optimum NSCLC cell number to be 50,000 cells per gel. Using immunohistochemistry, we also observed positive Ki67 staining confirming cell proliferation within the cultures and low cleaved-caspase 3 staining indicating minimal cell death. In conclusion, we have identified fatty acid synthesis as a potential metabolic vulnerability in KL NSCLC, and targeting this pathway could be a potential therapeutic option for patients with this genotype of NSCLC. Further analysis, supported by our novel 3D co-culture model, aims to analyse the consequences of targeting this specific pathway in combination with immunotherapy in the KL genotype of NSCLC.

#4161 Hiding in plain sight: Understanding the role of tryptophan metabolism in hepatocellular carcinoma.

Shivani Krishnamurthy[1], Bavani Gunasegaran[1], Sharron Chow[1], Vincent Lam[1], Ken Liu[2], Fiona Guan[3], Joo-Shik Shin[4], Avik Majumdar[5], Geoffrey McCaughan[6], Seong Beom Ahn[1], Benjamin Heng[1]

[1]Macquarie Medical School, Faculty of Medicine, Health and Human Sciences, Macquarie University, Sydney, Australia,[2]AW Morrow Gastroenterology and Liver Centre, Royal Prince Alfred Hospital and Central Clinical School, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia,[3]AW Morrow Gastroenterology and Liver Centre, Royal Prince Alfred Hospital, Sydney, Australia,[4]Central Clinical School, Faculty of Medicine and Health, The University of Sydney and Tissue Pathology and Diagnostic Oncology, Royal Prince Alfred Hospital, Sydney, Australia,[5]AW Morrow Gastroenterology and Liver Centre, Royal Prince Alfred Hospital, Central Clinical School, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia,[6]AW Morrow Gastroenterology and Liver Centre, Royal Prince Alfred Hospital, Central Clinical School, Faculty of Medicine and Health, The University of Sydney and Centenary Institute, Sydney, Australia

Introduction: Tumour immune suppression has been identified as an emerging hallmark of cancer that facilitates cancer progression, including hepatocellular carcinoma (HCC). Studies suggest that cancer cells can remain undetected and proliferate by evading local immune surveillance. A major pathway in tryptophan metabolism, the kynurenine pathway (KP), has been suggested to be one of the key mechanisms mediating tumoral immune evasion. In a pro-inflammatory tumour microenvironment, the KP is highly activated which can suppress activation of tumour-targeting immune cells and enhance cancer cell growth. To elucidate the mechanisms underlying KP activation and its contribution to tumour progression in HCC, this study aims to characterize the KP profile and tumour secretome, including cytokines and proteins in HCC patients, to examine the relationship between changes in plasma KP activity and the inflammation-associated secretome.
Methods: We have acquired plasma samples collected from patients with HCC (n=30), cirrhosis only (n=30), and healthy control (n=30). The KP metabolomic analysis was carried out using high pressure liquid chromatography (HPLC), Ultra-HPLC and Gas-chromatography Mass-spectrometry. The cytokine and proteomics analysis was performed using flow cytometry and data-independent acquisition mass-spectrometry respectively.
Results/Discussion: Our findings demonstrate that the KP is highly activated in HCC, as inferred by the elevated enzymatic activities of indoleamine-2,3-dioxygenase/tryptophan-2,3-dioxygenase and kynurenine 3-monooxygenase in HCC patients. Activation of these KP enzymes implies that HCC patients have a suppressed immune profile to facilitate the progression of cancer. Cytokine profiling revealed a more inflamed systemic profile in HCC patients compared to controls and cirrhotic patients. Given that the KP is induced by inflammation, this provides a potential explanation for the elevated KP activity measured in HCC patients. Proteomics analysis further identified differentially expressed proteins linked to inflammation and immune system activation, highlighting that the immune system plays a major role in HCC pathophysiology, potentially driving inflammation and the observed KP profile in HCC patients.
Conclusion: Collectively, these results suggest that KP activation may potentially be one of the mechanisms used by HCC tumour to create an immune-tolerant environment, facilitating tumour progression and development.

#4162 Development of low-toxic targeted therapies for KRAS-mutant tumors: Harnessing synergistic effects of fasting-mimicking diet (FMD) and ascorbate.

Anastasiya Shmahala[1], Valter D. Longo[2]

[1]IFOM ETS - The AIRC Institute of Molecular Oncology, Milan, Italy,[2]Longevity Institute and Davis School of Gerontology, University of Southern California, Los Angeles, CA

Pharmacological doses of vitamin C (ascorbate) have been proposed as a potential anticancer therapy, according to several preclinical and clinical studies. However, the exact mechanisms of its function in cancer cells remains controversial. Our laboratory demonstrated that fasting and fasting-mimicking diet (FMD) delay tumor progression and sensitize a wide range of tumors to various types of treatment, such as chemotherapy, immunotherapy and tyrosine kinase inhibitors (TKIs). In addition, FMD can enhance the therapeutic effects of pharmacological doses of vitamin C across different cancer cell lines bearing mutations in KRAS oncogene. Namely, combination of pharmacological doses of ascorbate and FMD in preclinical models has displayed a significant anticancer activity on KRAS-positive colorectal carcinomas, delaying tumor progression, but not achieving cancer free survival because of cellular resistance mechanisms. According to our latest findings FMD has been shown to activate specific starvation-induced escape pathways (SEPs) in triple-negative breast cancer (TNBC) cells that can be identified and targeted by specific targeted treatments. For this reason, this study not only investigates the synergistic effects of short-term starvation (STS) and high-dose ascorbate on cancer cell viability, but aims as well at disentangling the resistance mechanisms of the cells not responsive to the proposed treatment. To unravel these resistance mechanisms, we performed bulk RNA-sequencing analysis on vitamin C and STS/FMD resistant cancer cells. Results unveiled a significant upregulation of different signaling pathways in pancreatic, colorectal and non-small cell lung cancer cell lines non responding to vitamin C and STS. Namely, targeting these pathways by specific inhibitors reactivated sensitivity to ascorbate and STS causing cell death in the resistant cell population. In this study we also highlighted the mechanism through which STS and ascorbate, if combined with inhibitors, induces cancer cell death. Reactive oxygen species (ROS) mediated the cytotoxicity of the combinatorial treatment, as antioxidants were able to reverse the cell death. Next, we also assessed the impact of FMD and ascorbate treatment on the tumor microenvironment: we observed a reshaping of collagen deposition and a normalization of vasculature inside the tumor stroma, which could improve drug delivery and immune cell infiltration. To conclude, this project provides evidence that FMD and ascorbate synergize to cause toxicity in different cancer cell lines. Furthermore, we identified a common escape mechanism toward the abovementioned treatment. All these data together suggest so far that a combinatorial low-toxicity treatment can be developed, thus possibly improving clinical outcomes for cancer patients.

#4164 Targeting glycogen metabolism as a potential therapy for Ewing sarcoma.

Yueying Liu[1], Pankaj K. Singh[1], Lyndsay E. A. Young[2], Harrison A. Clarke[1], Tara R. Hawkinson[1], Meagan L. McCall[3], Elias Sayour[1], Craig W. Vander Kooi[1], Li Chen[3], Ramon C. Sun[1], Matthew S. Gentry[1]

[1]University of Florida College of Medicine, Gainesville, FL,[2]Medical University of South Carolina, Charleston, SC,[3]University of Florida, Gainesville, FL

Ewing sarcoma (EWS) is a malignant bone tumor or soft-tissue tumor that mainly affects children, adolescents, and young adults. We recently demonstrated that the PAS+ accumulations in EWS indicate extensive deposits of glycogen, a macro-metabolite that provides an immediate source of glucose to support cellular energy needs. In this study, we sought to elucidate the role of glycogen and its related enzymes in EWS tumorigenesis and metastasis. Though complex carbohydrates like glycogen are traditionally difficult to study due to their biochemical and biophysical properties, the Gentry and Sun laboratories recently developed a robust workflow of matrix-assisted laser desorption/ionization (MALDI)-imaging of complex carbohydrates (MICC), a spatial technique to visualize glycogen *in situ*. Leveraging this technique, we profiled glycogen accumulation in a cohort of EWS patient tumors. This analysis revealed glycogen levels were dramatically higher in the intra-tumoral regions across all EWS samples. Additionally, through our comprehensive pan-cancer study encompassing 12 different cancer classes, we revealed that glycogen accumulation varies among tumor origins, signifying its unique role in EWS.

Lysosomal glycogen degradation is catalyzed by acid α-glucosidase (GAA). Preliminary data from our laboratory demonstrates that glycogen colocalizes with GAA in EWS patient tumors and that small-molecule inhibition of GAA significantly impairs EWS cell proliferation and migration. Transcriptomic analyses revealed a strong correlation between GAA expression and known EWS metastasis regulators, including TGF-β and Wnt/β-catenin signaling pathways. Further experiments revealed that while glycogen synthase 1 inhibitor reduced glycogen levels and impaired EWS cell viability, a small molecule promoting lysosomal glycogen degradation reduced glycogen but paradoxically enhanced cell viability. These findings highlight the critical role of lysosomal glycogen utilization in EWS cell viability, suggesting a potential link between GAA-regulated glycogen degradation, energy homeostasis, and apoptotic pathways in EWS.

Moving forward, we are defining the efficacy and mechanism of GAA*i* in the treatment of EWS preclinical models both as a single agent and in additive therapy with other chemotherapies. To assess the efficacy of GAA*i* in metastatic EWS, spontaneous lung metastatic mice models will be established by subcutaneous implantation of EWS patient-derived tumor in NSG mice. Our state-of-the art integrated spatial analysis of metabolome, lipidome, and glycome followed by high dimensionality reduction and spatial clustering, annotation, pathway enrichment analysis will provide in-depth spatial insights into tumor and stromal metabolism profile of EWS. Future potential of GAA*i* study is to conduct clinical trial to identify when and how to add GAA*i* to current standard care EWS therapy and improve survival outcomes.

#4166 The RNA demethylase FTO promotes glutamine metabolism in clear cell renal cell carcinoma through the regulation of SLC1A5.

M. Zhao[1], D. Zhang[1], H. Jiang[1], N. Kuganesan[1], S. Natarajan[1], L. Pu[1], K. N. Thakkar[1], H. Zhao[1], J. D. Brooks[1], D. M. Peehl[2], J. Ye[1], E. B. Rankin[1];

[1]Stanford University, Stanford, CA, [2]University of California, San Francisco, CA

Glutamine reprogramming is a hallmark feature of clear cell renal cell carcinoma (ccRCC). However, the regulation of glutamine reprogramming in ccRCC is incompletely understood. Here we demonstrate that the RNA demethylase enzyme, FTO, promotes glutamine reprogramming in ccRCC cells to support growth and survival. Genetic and pharmacologic inhibition of FTO reduced glutamine-derived reductive carboxylation, de novo pyrimidine synthesis and glutathione biosynthesis. FTO inhibition resulted in increased DNA damage and reduced growth and survival that were rescued by the administration of pyrimidines and the antioxidant N-acetylcysteine. Mechanistically, FTO demethylates the glutamine transporter SLC1A5 mRNA transcript to promote SLC1A5 expression and glutamine reprogramming in ccRCC cells. In FTO knockdown cells, restoration of SLC1A5 expression was sufficient to rescue glutamine-derived reductive carboxylation, glutathione levels, DNA damage as well as growth and survival. Further, we observed that the FTO inhibitor FB23-2 enhanced the efficacy of the PARP inhibitor talazoparib *in vitro* and *in vivo*. Our study reveals a novel role for FTO in glutamine reprogramming of ccRCC, highlighting the therapeutic potential of targeting the epitranscriptomic regulation of metabolic reprogramming in ccRCC.

#4167 CK2 inhibition restores IKAROS-mediated metabolic control and induces cell death in acute lymphoblastic leukemia.

Diwakar Bastihalli Tukaramrao[1], Arati Sharma[2], Dhimant Desai[2], Sinisa Dovat[1]

[1]Pediatrics, Penn State College of Medicine, Hershey, PA,[2]Pharmacology, Penn State College of Medicine, Hershey, PA

The transcription factor IKAROS functions as a critical metabolic gatekeeper in B cells by regulating glucose metabolism and the pentose phosphate pathway (PPP). In lymphoid leukemias, casein kinase 2α (CK2α) overexpression impairs IKAROS function, leading to dysregulated cellular metabolism. This study investigated the metabolic consequences of CK2α inhibition in B- and T-cell acute lymphoblastic leukemia (ALL). Treatment of ALL cell lines with the CK2 inhibitor CX4945 resulted in significant cell death, with IC50 values ranging from 4-10 μM. In NALM6 cells, CK2α inhibition led to increased reactive oxygen species (ROS), decreased NADPH/NADP+ ratio, and reduced glucose consumption by 40%. Additionally, CX4945 treatment significantly decreased both glycolytic activity and mitochondrial respiration in ALL cell lines (NALM6, 697, MOLT4 and CEM). Metabolomic analysis revealed 64 differentially expressed metabolites between CX4945-treated and vehicle-treated NALM6 cells, with notable reductions in glycolytic intermediates. These findings demonstrate that CK2α inhibition effectively restores IKAROS-mediated metabolic control, leading to energy deficiency and increased oxidative stress in ALL cells. This work provides evidence that targeting the CK2-IKAROS axis represents a promising therapeutic strategy for ALL through metabolic modulation.

#4168 NMN supplementation enhances proliferation and aggressiveness in UV-induced skin cancer.

Niti Kumari, Brian J. North

Creighton University School of Medicine, Omaha, NE

Nicotinamide adenine dinucleotide (NAD^+) is an important redox cofactor and substrate for key enzymes and is involved in several cellular processes such as, energy metabolism, cell signaling, and DNA repair. Disturbance in NAD^+ homeostasis is associated with multiple human diseases. NAD^+ boosting agents, such as, nicotinamide mononucleotide (NMN) is under investigation in clinical trials and is a subject of active research in various pathological conditions associated with declining NAD^+ levels including, Alzheimer's disease, diabetes, heart failure and overall health in aging. NMN administration in mice improved age-associated changes in body weight, energy metabolism, insulin resistance, mitochondrial respiration, and reversed gene expression changes. In human trials, NMN improved insulin sensitivity in pre-diabetic women, aerobic capacity in amateur runners and physical performance in older people. Although many diseases are negatively impacted due to a decline in NAD^+ levels, cancer cells are known to upregulate NAD^+ biosynthesis to support their growth and progression. For example, NAMPT, a rate limiting enzyme of NAD^+ salvage pathway, is frequently upregulated in cancer and is associated with cancer progression and stemness. As safety of prolonged NMN supplementation in humans are being evaluated, it is equally important to explore its potential impact, adverse or beneficial, in relation to cancer pre-disposition conditions. To evaluate the impact of NMN in skin tumorigenesis, SKH-1 mice (~11-17 weeks old) were supplemented with NMN in drinking water (vehicle) at 300mg/Kg/day. Mice were either sham treated or treated with UV at 18Kj/m^2 five times a week for spontaneous development of cutaneous squamous cell carcinoma (cSCC). Number of tumors per mice (tumor multiplicity) was evaluated once a week starting at week 23 post UV irradiation. Tumors from both groups, vehicle UV and NMN UV, were harvested on week 37 and were subjected to exome sequencing, bulk RNA-sequencing, and Ki67 immunofluorescence for assessment of differences in mutation burden, gene expression and proliferation, respectively. Effect of NMN and nicotinamide (NAM) on cell proliferation and cell migration of cSCC cells, Colo-16, and SRB12, was assessed *in vitro* via MTT assay and scratch assay, respectively. NMN supplemented group exhibited increase in tumor multiplicity upon UV treatment in male and female SKH-1 mice. NMN supplemented tumors had relatively high mutation burden and Ki67 expression. Additionally, increase in extracellular matrix organization, epithelial mesenchymal transition, and angiogenic gene signatures were also elevated in NMN UV group. Colo-16 and SRB12 exhibited increased proliferation and migration in the presence of NMN or NAM. Overall, this study indicates that continuous NMN supplementation in cancer pre-disposition conditions might enhance development and progression of skin cancer.

#4169 Coordination of malic enzyme 2 and the malate-aspartate shuttle supports growth and survival in triple-negative breast cancer.

Mark Daniel Slayton[1], Jin Heon Jeon[1], Zackariah Farah[1], Abhinav Achreja[1], Ben Krinkel[2], Yi-Hsien Eu[1], Alyssa Rosenfeld[1], Kerslee Kohagen[1], Liwei Bao[1], Xu Cheng[1], Kerry Loomes[2], Deepak Nagrath[1], Sofia Merajver[1]

[1]University of Michigan, Ann Arbor, MI,[2]University of Auckland, Auckland, New Zealand

Background & Hypothesis: Triple-negative breast cancer (TNBC) presents therapeutic challenges due to the lack of hormone-targeted treatments. Malic enzyme 2 (ME2), crucial for pyruvate and NADPH production, regulates cancer metabolism and redox balance. Elevated ME2 expression correlates with poor outcomes in multiple cancers. We hypothesized that ME2 knockdown (ME2kd) would impair TNBC growth by disrupting metabolic homeostasis, with the malate-aspartate shuttle (MAS) playing a complementary role.
Methods: TNBC cell lines (MDA-MB-468, HCC70, HCC1806, Hs578T, BT20) and a control line (MCF10a) were analyzed under ME2kd using siRNA and shRNA. Growth, migration, and metabolic flux were assessed in vitro. Metabolite profiling was performed using GC-MS and Metabolite-Glo assays. Xenograft models of MDA-MB-468 and HCC70 evaluated tumor growth in vivo. ME2kd effects on mitochondrial function were measured via Seahorse XF96 assays. Growth under serine, glycine, and glucose deprivation was also assessed. The role of MAS in supporting ME2kd cells was evaluated with double knockdown experiments.
Results: ME2kd reduced proliferation by over 50% in MDA-MB-468 and HCC1806 cells with minimal effects on MCF10a. Tumors derived from MDA-MB-468 ME2kd cells grew significantly slower, with extended survival in vivo. In contrast, ME2kd had no impact on HCC70 growth or migration. Metabolite profiling revealed elevated malate and reduced NADH/NADPH levels under ME2kd, with compensatory upregulation of serine biosynthesis genes. Deprivation of serine, glycine, or glucose with or without ME2kd impaired growth in 4 of 5 TNBC lines, with minimal effects on MCF10a. Combined ME2 and MAS knockdown further suppressed growth across TNBC lines, emphasizing MAS's role in maintaining cytosolic NAD+/NADH balance under ME2kd.
Conclusions: ME2 is essential for supporting the metabolic and proliferative demands in TNBC. Loss of ME2 disrupts key metabolic pathways, leading to significant reductions in cellular proliferation and migratory capacity. The observed increase in malate levels and altered NADH/NADPH ratios under ME2kd highlight its central role in maintaining metabolic homeostasis. Our data shows that ME2, de novo serine synthesis, and glycolysis are closely co-regulated in TNBC cell lines. The ability of the cell lines to compensate for ME2kd correlated with their inherent de novo serine synthesis capacity. Furthermore, the interdependence of MAS and ME2 suggests that MAS may act as a bridge between ME2 and de novo serine synthesis via regulation of cytosolic NAD+/NADH ratio. These findings confirm that ME2 is involved in TNBC metabolism and establish it as a compelling target for therapeutic intervention. Future studies could explore synergistic strategies combining ME2 inhibition with interventions targeting complementary metabolic pathways.

#4170 Glucose transporter 2-transported glucosamine inhibits glycolysis in cancer cells through competition with glucose for hexokinase 2.

Se Yong Park[1], Ki-Hoon Song[2], Ju-Hee Kang[1], Jung Ho Hwang[3], Seung Hyun Oh[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]ViroCure, Seoul, Korea, Republic of,[3]Gachon University, Incheon, Korea, Republic of

Anticancer effects of glucosamine, a glucose derivative with a similar structure to glucose, have been discovered, but the molecular mechanisms are not yet fully understood. Since glucosamine and glucose not only have similar structures but also are catalyzed by the same enzyme, hexokinase (HK), in this study, we delved into determining whether the anticancer effect of glucosamine involves the inhibition of glycolysis by competition with glucose. Whole-genome screening analysis showed that many of the gene pathways controlled by glucosamine were directly and indirectly involved in glycolysis. *In vitro* experiments revealed that as more glucose was added, the anticancer effect of glucosamine decreased. Also, we found that glucosamine was transported into cells mainly through glucose transporter (GLUT) 2 which was responsible for the anticancer effects of glucosamine. In addition, we found that cancer cells with low expression level of HKII show high sensitivity to glucosamine, and a HK inhibitor, 3-bromopyruvate, enhanced the anticancer effect of glucosamine. Under hypoxic conditions, activated hypoxia-inducible factor 1α (HIF-1α) inducing glucose uptake and glycolysis hampered glucosamine-induced cell death, and *HIF1A* knockdown or HK inhibitors restored glucosamine's anticancer effects. These findings demonstrate that glucosamine is an efficient glycolysis inhibitor and that GLUT2 and HKII play important roles as biomarkers for determining sensitivity to glucosamine. Moreover, our results suggest that the anticancer effect of glucosamine may be more efficient when administered in combination with other glycolytic agents or inhibitors targeting HIF-1α.

Keywords: glucosamine, cancer, glycolysis, GLUT2, HKII, HIF-1α

#4171 ADRM1 inhibitor, Up284 induces replication stress and suppresses cell proliferation in triple-negative breast cancer.

Iffat Jahan[1], Shacoya Mack[2], Ravi Anchoori[3], Balasubramanyam Karanam[2], Komaraiah Palle[1]

[1]Texas Tech University Health Sciences Center, Lubbock, TX,[2]Tuskegee University, Tuskegee, AL,[3]Up Therapeutics LLC, Frederick, MD, MD

Triple-negative breast cancer stands as the most aggressive and deadliest subtype of breast cancer associated with poor prognosis and limited treatment options due to the lack of important receptors; estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2) used for targeted therapy. Relying exclusively on chemotherapy enhances the chances of resistance and recurrence and leaves TNBC challenging to treat. Thus, it mandates the need for novel drug compounds and combination therapies. Adhesion-regulating molecule 1 (ADRM1/RPN13), a ubiquitin receptor of 26S proteasome that supports recognition of polyubiquitinated substrates and their subsequent deubiquitination and degradation by unique deubiquitinase UCH37/UCHL5.Its inhibition causes a rapid and toxic accumulation of its substrate polyubiquitinated proteins in very high molecular weight (HMW) aggregate; disrupting the protein homeostasis. In response to that, the cancer cells halt the cell cycle and induce replication stress. Consequently, cells signal the survival mechanism by signaling the DNA damage repair (DDR) pathway activation. Using the Cancer Gene Genome Atlas and GEO datasets, our primary analysis demonstrated that ADRM1 is overexpressed in all types of breast cancer including TNBC. Higher expression in tumor cells compared to normal cells strengthens the stands for ADRM1 as a potent target for therapy. In vitro analysis has been performed in TNBC cell lines MDAMB 453 and MDAMB 231. The dose dependency assay demonstrated that the UP284 compound showed activation of CHK1 (Checkpoint kinase1) mediated DNA damage response and γH2AX foci formation confirms the double-stranded DNA breakage. Clonogenic assay confirms the suppression of cell proliferation and colony formation in a concentration-dependent manner in both BRCA positive and BRCA mutant cell lines. Up284 treated cells also showed cell cycle arrest at the G2/M phase. Together, our results indicate that ADRM1 is a promising target for TNBC therapy and suggest that this ADRM1 inhibitor, Up284, has the potential for clinical application in the treatment of TNBC. Our analysis will unravel the novel mechanistic insight into the therapeutic potential of this compound and provide preclinical evidence to develop further combination therapy.

#4172 Carnitine metabolism regulates ovarian cancer metastasis.

Medine Tasdemir[1], Shree Bose[1], Jason Locasale[2], Ernst Lengyel[1], Abir Mukherjee[1]

[1]University of Chicago, Chicago, IL,[2]North Carolina State University, Durham, NC

Ovarian cancer (OvCa), the most lethal gynecological malignancy, is often detected late when the cancer cells have metastasized throughout the peritoneal cavity. OvCa cells are readily shed into the abdominal cavity from the ovary or the fallopian tube and are disseminated throughout the peritoneal cavity via the peritoneal or ascetic fluid. Therefore, ascites function as a liquid tumor microenvironment intermediary between primary tumor and metastasis. It is unclear if the ascites is a mere vehicle for disseminating cancer cells or if it alters the metabolic machinery of OvCa cells to increase their metastatic capacity. Here, we performed systematic multi-site metabolomic analyses to characterize the metabolic milieu of ascites and identified the mechanisms that augment the metastatic capacity of OvCa cells. We analyzed patient-matched samples (comprised of primary, metastatic omental tumors, ascites, and plasma) collected from a cohort of 25 high-grade serous ovarian cancer patients using liquid chromatography-mass spectrometry. By performing multidimensional scaling, we show that each sample site has a characteristic metabolic profile. The metabolome of the ascites is unique, and a higher abundance of acylcarnitines distinguishes its metabolome from patient-matched tumor and plasma. Conjugation of fatty acids to carnitine (generating acylcarnitines) aids in transfer of fatty acids across the mitochondrial membrane for their oxidation and subsequent ATP generation. We found that ascites-driven growth of OvCa cells correlates with methionine uptake and accumulation of N^6-trimethyl-L-lysine (a key metabolite in the biosynthesis of carnitine). We also observed increased levels of acylcarnitines in metastatic tumors from the omentum compared to primary ovarian/fallopian tube tumors. Therefore, increased carnitine synthesis is a metabolic phenotype of OvCa cells growing in ascites and is associated with progression through the metastatic cascade. Gamma-butyrobetaine hydroxylase 1 and 2 (BBOX1 and BBOX2), are enzymes that regulate the rate-limiting steps of carnitine synthesis. Stable knockdown of BBOX1 and BBOX2 reduced the growth rate, and migratory and invasive capacities of OvCa cells in vitro. Colonization of the omentum (a visceral adipose tissue covering the bowel) marks an essential step in OvCa progression. We and others have shown that heightened fatty acid oxidation capacity in cancer cells aids in omental metastasis. We now show that increased carnitine biosynthesis in the OvCa cells precedes omental colonization and is a potential metabolic vulnerability.

#4173 Compensatory interactions between tryptophan catabolism and serine metabolism highlight potential vulnerabilities in TNBC cells with dysregulated *de novo* serine synthesis.

Jin Heon Jeon, Abhinav Achreja, Mark Slayton, Olamide Animasahun, Minal Nenwani, Fulei Wuchu, Sofia D. Merajver, Deepak Nagrath

University of Michigan, Ann Arbor, MI

Background: Despite the major advances people have achieved in treating breast cancer, triple-negative breast cancer (TNBC) remains a difficult cancer to conquer. TNBC is one of the most heterogeneous and aggressive forms of breast cancer and is characterized by the loss of ER, PR, and HER expression. Due to the lack of these receptors, TNBCs are especially hard to treat with traditional methods that target these receptors, necessitating a more targeted approach to tackling these cancers. Serine and tryptophan are both metabolites that play crucial roles in the production and balance of nucleotides, energy and redox. These overlaps in metabolic functions make it likely that these two metabolites play compensatory roles under certain conditions. Different TNBCs have been shown to have vastly varying levels of de novo serine synthesis capacity and IDO1 expression. In our study, we attempt to uncover the role of tryptophan catabolism, in relation to serine metabolism in TNBC cells.

Methods: LC-MS with [U-13C11]-Tryptophan and [U-13C3]-Serine were used to analyze their contributions to nucleotide synthesis, and energy metabolism via the tryptophan catabolism pathway and the folate/methionine cycle, respectively. [U-13C6]-Glucose was used to analyze its contribution to de novo serine synthesis under disrupted serine and tryptophan metabolism conditions. IDO1 inhibitor (Epacadostat), PHGDH inhibitor, and SHMT inhibitor (SHIN1) were used to inhibit tryptophan catabolism, de novo serine synthesis, and folate cycle, respectively. Cell growth was assessed via cell count imaging and changes in protein expression in relevant pathways were evaluated via western blot.

Results: IDO1 inhibition showed varying levels of efficacy in different TNBC cells relating to their ability to synthesize serine and the availability of extracellular serine. Growth was most affected in cell lines with dysfunctional de novo serine synthesis indicating a compensatory effect between tryptophan catabolism and serine synthesis. This was further corroborated with the changes observed in IDO1 and PHGDH expression under enzymatic inhibition and metabolic deprivation. LC-MS analysis on IDO1, PHGDH, and SHMT inhibition showed different methods of compensation in different cell lines, with some exhibiting larger changes in nucleotide synthesis, while others in energy (NAD/H and ATP) and redox metabolism (NAD(P)/H).

Conclusion: Our findings show serine and tryptophan metabolism are tightly co-regulated in TNBC cells. It also highlights the heterogeneity and complexity of how these cells utilize varying metabolic pathways to achieve these compensatory interactions. Our data supports that certain TNBC cells with dysfunctional de novo serine synthesis may be vulnerable to strategies that leverage their limited capacity to compensate between these pathways.

#4174 Regulation of metabolic programming in esophageal cancer by transcription factor p63.

Niamh McNamee[1], Keene Abbott[2], Aya Tal-Mason[1], Matthew G. Vander Heiden[2], Uma M. Sachdeva[1]

[1]Massachusetts General Hospital, Boston, MA,[2]David H. Koch Institute for Integrative Cancer Research, Massachusetts Institute of Technology, Boston, MA

Background: Esophageal adenocarcinoma (EAC) and squamous cell carcinoma (ESCC) exhibit markedly different responses to treatment regimens, including chemotherapy, chemoradiation, and immunotherapy. The transcription factor TP63 is expressed in ESCC and notably absent in EAC and is associated with squamous differentiation and expression of the GLUT1 glucose transporter in squamous cell cancers. Given its homology to p53, a known tumor suppressor and regulator of cell metabolism, we sought to determine whether p63 expression may confer a distinct and targetable metabolic program in ESCC relative to EAC.

Methods: p63 and GLUT1 expression levels were established in ESCC (TE11, TE14) and EAC (OE19, OE33, and FLO-1) cell lines by immunoblot and qPCR. Associated metabolic programs in EAC vs ESCC cells were assessed using the Seahorse XF bioanalyzer, 2-(*N*-(7-Nitrobenz-2-oxa-1,3-diazol-4-yl) Amino)-2-Deoxyglucose (2-NBDG) uptake, and cell viability in the setting glucose deprivation. Genetic knockdown of p63 was performed by siRNA transfection in ESCC cells and resulting effects on mitochondrial metabolism and expression of squamous and glandular differentiation markers were evaluated. The fate of glucose-derived carbon was tracked in ESCC cells with or without genetic knockdown of p63 by incubation with ^{13}C-glucose followed by gas chromatography mass spectrometry and correlated with metabolic gene expression by immunoblot.

Results: ESCC cells exhibited higher glycolytic metabolism and glucose uptake and reduced viability in response to glucose starvation, in the setting of increased p63 and GLUT1 expression, relative to EAC cells. ESCC cells also demonstrated lower mitochondrial respiration, intracellular ATP levels, and respiratory spare capacity. Genetic knockdown of p63 in ESCC cells resulted in increased mitochondrial respiration, ATP production, and respiratory spare capacity, as well as reduced sensitivity to glucose deprivation. This was associated with reduced expression of squamous differentiation markers and increased expression of glandular differentiation markers. Furthermore, knockdown of p63 expression increased glucose flux through the tricarboxylic acid (TCA) cycle and towards fatty acid synthesis. This was associated with enhanced pyruvate dehydrogenase activity, and as increased activation of acetyl-CoA carboxylase and fatty acid synthase.

Conclusions: Our data suggest that ESCC and EAC represent different metabolic programs, with ESCC more dependent on glucose and glycolytic metabolism and EAC exhibiting greater mitochondrial respiration and respiratory spare capacity. These differences are dependent on transcription factor p63, as loss of p63 in ESCC increased glucose shunting into mitochondrial metabolism and fatty acid synthesis pathways. These data suggest that differential metabolic targeting may be an effective approach for both ESCC and EAC.

#4175 Momordicine-I modulates head and neck cancer growth by altering key metabolic pathways.

Ellen T. Tran, Debojyoti Bandyopadhyay, Ruchi A. Patel, **Ratna B. Ray**

Saint Louis University, St. Louis, MO

One of the hallmarks of cancer is metabolic reprogramming which controls cellular homeostasis and therapy resistance. Here, we investigated the effect of momordicine-I (M-I), a key bioactive compound from *Momordica charantia*, on metabolic pathways in human head and neck cancer (HNC) cells and a mouse HNC tumorigenicity model. We found that M-I treatment on HNC cells significantly reduced the expression of key glycolytic molecules at the mRNA and protein levels. We further observed reduced lactate accumulation, suggesting glycolysis was perturbed in M-I treated HNC cells. Metabolomic analyses confirmed a marked reduction in glycolytic and TCA cycle metabolites in M-I-treated cells. M-I treatment significantly downregulated mRNA and protein expression of essential enzymes involved in *de novo* lipogenesis, including *ACLY*, *ACC1*, *FASN*, *SREBP1*, and *SCD1*. Using shotgun lipidomics, we found a significant increase in lysophosphatidylcholine and phosphatidylcholine loss in M-I treated cells. Subsequently, we observed dysregulation of mitochondrial membrane potential and significant reduction of mitochondrial oxygen consumption after M-I treatment. We further observed M-I treatment induced autophagy, activated AMPK and inhibited mTOR and Akt signaling pathways. However, blocking autophagy did not rescue the M-I-mediated alterations in lipogenesis, suggesting an independent mechanism of action. M-I treated mouse HNC MOC2 cell tumors displayed reduced *Hk1, Pdk3, Fasn,* and *Acly* expression. In conclusion, our study revealed that M-I inhibits glycolysis, lipid metabolism, induces autophagy in HNC cells and reduces tumor volume in mice. Therefore, M-I-mediated metabolic reprogramming of HNC has the potential for important therapeutic implications.

#4176 Targeting KRAS selectively induce metabolic reprogramming in pancreatic cancer.

Matthew Cheung, Laiba Shiekh, Don-Gerard Conde, Chiamaka Ezeh, Zeribe Nwosu

Department of Molecular Biology and Genetics, Cornell University, Ithaca, NY

Pancreatic ductal adenocarcinoma (PDAC) is a lethal disease largely due to the lack of effective treatments that overcome the tumor drug resistance. Oncogenic KRAS mutations contribute to most PDAC and drive multiple metabolic pathways to promote tumor growth. Despite this predominant role of KRAS, the inhibition of KRAS/MAPK pathway often leads to resistance via mechanisms that remain unclear. Pharmacological inhibition of the KRAS/MAPK pathway produces varying and context-dependent responses in different phenotypes of pancreatic cancer cells. Specifically, while KRAS/MAPK inhibition using drugs such as MRTX1133 and Trametinib suppresses growth in some cell lines, the same treatment induces or does not alter the growth of other cell lines, and selectively impacted cell migration. Metabolic activity was suppressed in cells with inhibited growth but accelerated in cells where KRAS/MAPK inhibition promoted growth. Analysis of gene expression profile of human PDAC and KRAS-driven mouse tumors identified nutrient transporters that are upregulated upon KRAS induction, but further upregulated by KRAS inhibition. Our study reveals context-dependent response to KRAS inhibition in PDAC and suggests targeting nutrient transporters to overcome therapeutic resistance. Laiba Shiekh and Matthew Cheung contributed equally to this work.

#4177 Integrated assessment of alterations in coenzyme Q biosynthesis genes impacting cancer metabolism leading to critical vulnerabilities in tumors.

Nischal Mahaveer Chand, Eric M. Grund, Poornima K. Tekumalla, Gregory M. Miller, Niven R. Narain, Vijay Modur, Michael A. Kiebish

BPGbio, Framingham, MA

Coenzyme Q10 (CoQ) is critical in governing mitochondrial bioenergetics as a pivot point regulating the efficiency of the electron gradient, while balancing electron slippage leading to reactive oxygen species (ROS) generation. Alterations in cancer metabolism are a hallmark of oncogenesis and central is the Warburg Effect, which reflects a dependence on glycolysis due to inefficient mitochondrial function in the presence of oxygen. Alterations in CoQ biosynthesis can disrupt cellular respiration and energy homeostasis, leading to various metabolic disorders. In cancer, restoring proper CoQ function, by correcting its biosynthetic pathway and the levels of CoQ, could offer therapeutic benefits. Targeting CoQ alterations may enhance mitochondrial function and potentially inhibit the proliferation of cancer cells, presenting a novel avenue for cancer treatment. To understand the extent of CoQ biosynthesis imbalance in cancer, gene expression and mutation data for 33 cancers in the TCGA were analyzed. RNA-seq gene expression and SNP mutation data were evaluated for 13 genes in the CoQ biosynthesis pathway: COQ10A, COQ10B, COQ2, COQ3, COQ4, COQ5, COQ6, COQ7, COQ8A, COQ8B, COQ9, PDSS1, and PDSS2. The median expression level of transcripts was examined and 4 genes critical in the biosynthesis pathway demonstrated low median expression across cancers: PDSS1, PDSS2, COQ2, and COQ3. SNP mutations were aggregated across cancers and normalized to gene length for each of the 13 genes. Mutations were low across the 13 genes, with an average of 0.875 SNP mutations observed per 1000 base pairs. Additionally, COQ8A and COQ8B had no observed mutations in any TCGA samples. Kaplan-Meier analysis was performed for each cancer based on low expression (below 25th percentile) and high expression (above 75th percentile) for each CoQ gene. Low Grade Glioma was observed having 6 of 13 genes (COQ10B, COQ2, COQ8A, COQ8B, COQ9, PDSS1) with a significant change in overall survival based on expression levels (logrank test p-value < 0.001). Additionally, 3 genes (COQ5, COQ7, PDSS2) were identified with a significant difference in Kidney Renal Clear Cell Carcinoma, 2 genes each in Adrenocortical Carcinoma (COQ8A, PDSS1), Papillary Renal cell Carcinoma (COQ4, COQ9), and Uveal Melanoma (COQ2, COQ6). In conclusion, this comprehensive analysis of CoQ biosynthesis genes across multiple cancer types reveals critical insights into their expression and mutation profiles, as well as their potential impact on patient survival. The low mutational rates across the 13 genes underscore their importance in maintaining cellular energy homeostasis. Furthermore, the significant survival differences associated with the expression levels of these genes in specific cancers highlight the potential of restoration of CoQ pool as a therapeutic strategy for mitigating dysfunctional energy metabolism.

#4178 Investigating glucose utilization in cancer and immune cells using bioluminescent metabolite and enzyme assays.

Donna Marie Leippe, Natasha Karassina, Mike Valley, Kayla Sylvester, Anthony Lauer, Jolanta Vidugiriene

R&D, Promega Corporation, Madison, WI

Glucose metabolism is fundamental to the function and survival of both cancer cells and immune cells within the tumor microenvironment. Cancer cells often exhibit altered metabolic pathways to meet the elevated energy and anabolic demands of rapid proliferation, including increased glucose uptake for enhanced glycolysis and glycogen storage. This can deplete glucose availability for infiltrating immune cells, restricting their ability to execute an effective anti-tumor response and promoting an immunosuppressive environment. Understanding glucose metabolism in cancer cells and T cells is important for elucidating the role of nutrient competition in immunotherapy effectiveness. To investigate these dynamics, we developed sensitive bioluminescence assays capable of measuring multiple aspects of glucose metabolism in both cancer and immune cells, including glycogen synthesis and utilization. Glycogen serves as a glucose reservoir that can rapidly respond to glucose supply and demand to maintain cellular functions under fluctuating nutrient conditions. Changes in glycogen levels (both increases and decreases) were observed in cancer cell lines in response to medium composition (e.g., glucose concentration) and drug treatments. Glycogen was also measured in T cells upon activation, providing a useful method for studying requirements for glycogen synthesis in these cells and its relevance for T cell function. The increased sensitivity of the glycogen assay required low cell numbers and was amenable to reduced volumes, in 384-well plates, further facilitating these studies. In addition to glycogen synthesis and degradation, other glucose metabolic pathways, including glycolysis, oxidative phosphorylation, and the pentose phosphate pathway, were analyzed. We used assays to measure intermediates and products in these pathways, including lactate, pyruvate and malate, as well as assays for measuring dehydrogenase enzyme activity. Dehydrogenases representing all three pathways exhibited increased activity upon T cell activation, indicating enhanced engagement of these pathways. These assays should provide a valuable method for studying the impact of limited glucose on T cell activation and suggesting approaches to address it. To better understand the role of glucose availability and implications of nutrient competition in the tumor microenvironment for anti-tumor immune responses, we used sensitive bioluminescent assays to investigate metabolic profiles of cancer and immune cells. The assays can facilitate identification of potential approaches and targets to eliminate limited access to glucose and other nutrients as a barrier to efficient immunotherapies.

#4179 ADCK1 expression modulates pro-cancerous characteristics of hepatocellular carcinoma.

Noel A. Jacquet, Yunfeng Zhao

Pharmacology, Toxicology and Neuroscience, LSU Health Sciences Center - Shreveport, Shreveport, LA

The incidence of hepatocellular carcinoma (HCC) has steadily increased over the past few decades, with minimal progress in developing effective therapeutic agents. As the most common form of primary liver cancer, HCC is currently the third leading cause of cancer-related deaths. HCC originates from hepatocytes, the primary liver cell type responsible for vital metabolic functions, including the processing of amino acids, lipids, carbohydrates, and xenobiotics. Dysregulation of cellular metabolism can drive malignancies and lead to tumorigenesis. AarF Domain Containing Kinase 1 (ADCK1), a putative kinase, is implicated in regulating mitochondrial functions, which are essential for cellular metabolism. Defects in mitochondrial function are known to contribute to tumorigenesis. Although ADCK1 remains poorly studied in humans, early research suggests its involvement in the tumorigenesis of parathyroid, colon, and osteosarcoma cancers. Our lab aims to elucidate the role of ADCK1 in cellular metabolism and the behavior of HCC cells. Bioinformatics analysis conducted by our group revealed that high ADCK1 expression correlates with worse overall survival rates in HCC patients compared to those with low ADCK1 expression. To investigate the impact of ADCK1 loss, we generated ADCK1 knockout (KO) clones in HCC cells. Our findings indicate that the loss of ADCK1 modulates several malignant characteristics associated with HCC tumorigenesis, including alterations in cellular proliferation, cell cycle regulation, programmed cell death, colony formation, and mitochondrial respiration. Future studies will explore the mechanisms underlying these processes, to establish ADCK1 as a promising therapeutic target for HCC treatment. This abstract has been proofread and enhanced for clarity through the assistance of Grammarly and ChatGPT AI.

#4180 Insights into HuR as a modulator of aerobic glycolysis in triple-negative breast cancer.

Arundhathi Dev J R[1], Ajay Gogia[1], Sandeep R. Mathur[2], Ashutosh Mishra[3], Chandra Prakash Prasad[1]

[1]Medical Oncology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[2]Pathology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[3]Surgical Oncology, All India Institute of Medical Sciences (AIIMS), New Delhi, India

The RNA-binding protein Human Antigen R (HuR/ELAVL1) is ubiquitously expressed and plays a pivotal role in post-transcriptional gene regulation by stabilizing and enhancing the translation of mRNAs containing U/AU-rich elements. Its overexpression, particularly in the cytoplasm, has been implicated in various cancers, where it drives critical processes such as proliferation, survival, angiogenesis, and metastasis. As a key modulator of oncogenic pathways, HuR represents a significant target for understanding cancer progression and developing novel therapeutic strategies. The present study investigates the oncogenic role of HuR in TNBCS, an aggressive subtype of breast cancer. Meta-analysis with TNBC dataset (Liu-2014) correlated high HuR protein expression with reduced patient survival (p=0.028). Immunohistochemistry performed in 40 TNBC patient tissue showed an overexpression of HuR (77%) and its downstream target MMP9(55%). Disrupting the RNA binding activity of HuR with the HuR specific inhibitor CMLD2 resulted in the downregulation of HuR and its downstream targets CDK2, MMP9, and β-catenin in TNBC cell lines MDA-MB-231 and MDA-MB-468. Inhibition of cytoplasmic HuR was validated via immunofluorescence and cell fractionation followed by immunoblotting. HuR inhibition compromised proliferation, migration, invasion, extracellular acidification, clonogenicity (2D and 3D), and EMT (downregulated E-Cadherin, N-Cadherin, and Vimentin) in TNBC cells. Exploratory transcriptomics via nCounter XT showed that HuR inhibition in MDA-MB-231 altered the profile of glycolytic genes in addition to other pathways such as cell cycle, DNA damage repair, amino acid synthesis etc. In accordance, the expression of the glycolytic genes LDHA, PFKP and MCT4 was reduced upon CMLD2 treatment at mRNA and protein level in both the TNBC cell lines. Pretreatment with CMLD2 impaired the tumor forming ability of 4T1 *in vivo*. Consistent results were obtained on HuR siRNA knockdown. To our knowledge, this is the first report that explores HuR as a positive regulator of aerobic glycolysis in TNBCs. Inhibition of HuR by CMLD2 provides a rationale to consider it as a potential anticancer agent for TNBCs.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: DNA Damage Response and Modulation of DNA Repair 2
Poster Session

#4184 Development of a homogenous poly(ADP-ribose) assay for screening and profiling PARP inhibitors.

Mahbbat Ali, Ha Pham, Anibal Ramos-Martinez, **Robert Lowery**

BellBrook Labs, Madison, WI

Poly(ADP-ribose) polymerases (PARPs) initiate DNA damage repair (DDR) by binding to double strand breaks and creating a scaffold of poly(ADP-ribose) (pADPr) chains for assembly of other DDR proteins. The use of PARP inhibitors for ovarian tumors with BRCA-1 mutations was the first clinical exploitation of synthetic lethality, and PARP inhibitors are now used for breast, prostate, pancreatic, and ovarian cancers. New types of PARP inhibitors are being sought to broaden the scope of indications. To facilitate this effort, we developed a high throughput screening (HTS) assay for PARPs that enables quantitative detection of pADPr formation in a homogenous format. The assay relies on enzymatic conversion of pADPr to AMP, which is then detected using the Transcreener AMP/GMP assay with a fluorescence polarization (FP) or time-resolved Förster resonance energy transfer (TR-FRET) readout. To minimize interference from screening compounds, we first optimized the concentration of coupling enzymes to ensure that the pADPr will be completely converted to AMP even if the conversion reaction is inhibited by as much as 80%. Using this optimized system, the assay generated a robust signal (Z' > 0.8) using 0.8 nM PARP1 with sub-saturating NAD (100 µM) and saturated sheared salmon sperm DNA (0.25 mg/mL) under initial velocity conditions. The assay was validated for HTS using a 1,280 compound bioactive library, resulting in 18 hits, 5 of which proved to be interference. We also screened a 3,200 compound diversity library, resulting in 44 hits, 3 of which were identified as interference. Four known PARP1 inhibitors, Olaparib, PJ 34 HCl, Veliparib, and Rucaparib Camsylate, were detected in the bioactive screen and tested in dose response mode with both FP and TR-FRET readout; the measured IC_{50} values (0.45 nM, 29 nM, 1.4 nM and 0.4 nM, respectively) were consistent with published values. By enabling sensitive, quantitative detection of pADPr formation in a simple, mix-and-read format, the Transcreener pADPr assay should facilitate efforts to develop more effective PARP inhibitors.

#4185 A novel USP1 inhibitor enhances PARP inhibitor efficacy in elevated replication stress tumors: Evidence from BRCA-mutant and CCNE1-amplified models.

Ho-Jeong Lee, Hyerim Yoo, Jihye Kim, Sunkyu Kim, Sejeong Park, Sanghoon Lee, Kiwoong Yoo, Jin Kwan Kim, Kwang-Ok Lee, Jaewoo Kang

AIGEN Sciences, Seoul, Korea, Republic of

Synthetic lethality offers a promising strategy for cancers with elevated replication stress, including BRCA-mutant and CCNE1-amplified tumors. USP1, a deubiquitinating enzyme, stabilizes replication forks by regulating ubiquitinated PCNA (Ub-PCNA). Using the AIGEN ChemTailor AI platform, we developed a novel USP1 inhibitor, which exhibited selective anti-proliferative effects in BRCA-mutant cancer cells and enhanced efficacy when combined with PARP inhibitors *in vitro*. We evaluated the USP1 inhibitor's *in vivo* efficacy in BRCA-mutant breast cancer models and CCNE1-amplified ovarian cancer models.

In MDA-MB-436 breast cancer xenografts, the combination of the USP1 inhibitor with PARP inhibitor demonstrated significant tumor suppression in both subcutaneous and orthotopic models, with the orthotopic model better reflecting the cross-talk between tumor cells and the tumor microenvironment. In OVCAR3 ovarian cancer orthotopic metastasis models, the USP1 inhibitor enhanced PARP inhibitor's anti-tumor activity. Elevated Ub-PCNA expression in tumor tissues from MDA-MB-436 models further supports its potential as a pharmacodynamic marker.

These findings highlight the USP1 inhibitor's potential to enhance PARP inhibitor efficacy in BRCA-mutant and CCNE1-amplified cancers, with Ub-PCNA serving as a promising PD marker. IND-enabling studies, including GLP toxicology, are ongoing, with completion expected by late 2025.

#4186 Discovery of novel PARP1-selective inhibitors for treatment of brain tumors using artificial intelligence.

Sarah Truong[1], Beibei Zhai[1], Louise Ramos[1], Mona Marzban[1], Fariba Ghaidi[1], Fuqiang Ban[1], Jason Smith[1], Mohit Pandey[1], Ekaterina Manskaia[1], Kally Singh[2], Hans Adomat[1], Xiaoqi Chen[2], John Langlands[2], Dennis Brown[2], Jeffrey Bacha[2], Colin Collins[3], Artem Cherkasov[3], Mads Daugaard[3]

[1]Vancouver Prostate Centre, Vancouver, BC, Canada,[2]Rakovina Therapeutics, Vancouver, BC, Canada,[3]University of British Columbia, Vancouver, BC, Canada

Introduction: Brain tumors, including primary brain tumors and central nervous system (CNS) metastases, remain among the most challenging malignancies to treat, with therapeutic options often limited by the inability of drugs to penetrate the blood-brain barrier (BBB). Poly(ADP-ribose) polymerase (PARP) is a key enzyme in DNA repair, and inhibition of PARP1 specifically drives synthetic lethality in BRCA-mutated disease. While they have achieved commercial success, first generation PARP inhibitors are limited in their utility as they cannot readily pass through the blood-brain barrier and produce adverse side effects, likely driven by the collateral inhibition of PARP2. Development of a PARP1-selective CNS penetrant inhibitor could reduce toxicity, while providing a new therapeutic option for brain tumors. Traditional drug discovery methods are time-consuming and costly, necessitating innovative approaches. Here, we describe the application of Deep Docking combined with generative artificial intelligence (AI), to discover a novel, PARP1-selective inhibitor for use against brain tumors.
Methods: Deep Docking utilizes deep learning to accelerate the prediction of the binding affinity of a large number of compounds to target proteins, streamlining the virtual screening process and allowing for rapid docking of billions of compounds against the PARP1 protein. Additionally, state-of-the-art generative algorithms and deep learning techniques for predicting CNS penetrance can be combined with Deep Docking to rapidly perform hit-to-lead optimization of a CNS-penetrating PARP1-selective inhibitor.
Results: We will present Deep Docking screening results from billions of compounds. Validating in vitro and in vivo data, including PARP1 inhibition and selectivity, BBB permeability, metabolic stability, pharmacokinetic profile, and CNS penetration will be described.
Conclusion: The Deep Docking platform is being used in concert with generative AI approaches to discover and finetune a selective PARP-1 inhibitor for brain tumors. This approach will not only improve the efficiency of drug discovery but also enhance the specificity and efficacy of potential therapeutics.

#4187 Enhancing doxorubicin DNA-damaging therapy in neuroendocrine cancer via DNA-PK inhibition.

Subin Kim[1], Allisa Pack[1], Nathan L. Vanderford[1], Courtney M. Townsend[2], B. Mark Evers[1], Piotr Rychahou[1]

[1]University of Kentucky, Lexington, KY,[2]University of Texas Medical Branch, Galveston, TX

Introduction: Gastroenteropancreatic (GEP) neuroendocrine tumors (NETs) are neoplasms originating from the gastrointestinal track and pancreas. Unfortunately, most patients at the time of diagnosis have extensive metastatic disease and are not candidates for curative surgical resection of metastatic tumors. In such cases, chemotherapy can slow the progression of metastatic disease, but eventually tumors develop resistance to genotoxic agents through DNA repair pathways activation. Therefore, targeting DNA repair pathway can increase the tumor sensitivity to cancer therapies. In this study, we examined whether DNA-PK inhibition could sensitize pancreatic NETs to DNA damaging chemotherapy.
Methods: DNA double-strand break damage was induced with topoisomerase II inhibitor doxorubicin. DNA-PK activity was inhibited with peposertib. Clonogenic and proliferation assays were used to evaluate the efficacy of peposertib in combination with doxorubicin in BON and QGP-1 neuroendocrine cell lines. DSB-induced DNA repair was visualized with confocal laser scanning microscopy using γ-H2AX immunofluorescence. Induction of apoptosis in chemotherapy combination groups was visualized with confocal laser scanning microscopy using cleaved caspase-3 immunofluorescence and with western blot using cleaved PARP bands. To further validate the role of DNA-PK in the response to treatments, DNA-PK knockdown cell lines were established, and confocal microscopy and western blotting were used to assess DNA damage and apoptosis. Data was analyzed using GraphPad Prism and expressed as a mean ± standard deviation.
Results: DNA-PK inhibition resulted in enhancement of doxorubicin cytotoxic therapy (BON IC50 DOX = 194.73± 26.52 nM, DOX+Pep = 89.87± 17.6 nM; QGP IC50 DOX = 108.37± 23.97 nM, DOX+Pepo = 30.27± 4.80 nM) in both BON and QGP-1 cell lines. Immunofluorescence analysis detected γH2AX foci increase in the doxorubicin and peposertib combination groups. DNA-PK inhibition in combination with doxorubicin treatment significantly increased caspase-3 cleavage and PARP cleavage in BON and QGP-1 cell lines. Similar trends in DNA damage and apoptosis were observed across both drug combination and knockdown groups.
Conclusions: High DNA repair activity is commonly associated with cancer drug resistance. The combination of DNA-PK inhibition with DNA-damaging therapies impaired DNA damage response and enhanced neuroendocrine cancer cells apoptosis. These findings demonstrate that selective DNA-PK inhibition provides a potent therapeutic strategy for disruption of non-homologous end joining DNA double-strand break repair and may offer a novel therapeutic approach in advanced NET chemotherapy.

#4188 The role of NHEJ/HR mediated DSB repair in cancer cell sensitivity to payload of T-DXd ADC.

Len Katsumata[1], Manabu Abe[1], Misa Ikuta[1], Fumitaka Suto[2], Kumiko Koyama[1]

[1]Daiichi Sankyo Co., Ltd., Tokyo, Japan,[2]Daiichi Sankyo Inc., Basking Ridge, NJ

Introduction: Trastuzumab deruxtecan (T-DXd) is an innovative HER2-targeting antibody-drug conjugate comprising a HER2-specific antibody linked to an exatecan derivative (DXd) payload. This therapeutic agent has demonstrated substantial clinical efficacy across various HER2-expressing malignancies. The DXd payload functions as a topoisomerase I inhibitor, stabilizing the topoisomerase-DNA cleavage complex. This stabilization inhibits the re-ligation of DNA, leading to the accumulation of DNA double-strand breaks (DSBs) and ultimately inducing apoptotic cell death. DNA DSBs are primarily repaired through two distinct mechanisms: Non-Homologous End Joining (NHEJ) and Homologous Recombination (HR). However, the contributions of these DNA damage repair pathways to the sensitivity of cancer cells to T-DXd/DXd remain poorly understood.

Methods: In this *in vitro* study, we investigated the roles of NHEJ and HR in modulating the sensitivity of the HER2-expressing breast cancer cell line, MDA-MB-453, to T-DXd/DXd. This was achieved through siRNA-mediated knockdown of key components of the respective repair pathways, specifically TP53BP1 for NHEJ and BRCA1 for HR. Drug sensitivity was assessed through cell growth inhibition assays and caspase-3/7 activity assays. DNA repair machinery was evaluated using immunofluorescence to quantify RAD51 foci formation. Additionally, cell cycle dynamics in response to DXd treatment and the modulation of NHEJ/HR-mediated repair pathways were analyzed using flow cytometry and live cell imaging of MDA-MB-453 cells transduced with a Fluorescent Ubiquitination-based Cell Cycle Indicator.

Results: Our results demonstrated that the suppression of TP53BP1 led to a decrease in T-DXd/DXd sensitivity, which was associated with an increase in HR-mediated DSB repair, as evidenced by a higher incidence of RAD51 foci formation in the nuclei. Conversely, knockdown of BRCA1, which inhibits HR, substantially enhanced sensitivity to T-DXd/DXd. Notably, the alteration in DNA repair pathway balance resulted in distinct cell cycle phase shifts upon T-DXd/DXd treatment; specifically, BRCA1 knockdown increased the G2/M phase population while concurrently reducing DNA damage response (DDR)-related cell cycle arrest. Furthermore, the combination of Wee1 inhibitor with T-DXd and DXd enhanced cytotoxicity via aberrant cell cycle arrest.

Conclusions: Collectively, these findings point to the role of the mode of DNA damage repair pathways in modulating the activity of the DXd payload, suggesting the possibility of improved efficacy by the combination with DDR inhibitors. Further investigations are warranted to elucidate the contextual factors influencing these outcomes and to validate our findings in clinical samples.

#4189 CRISPR-edited cell lines targeting key molecular pathways: Accelerating the development of synthetic lethal therapeutics beyond PARP inhibitors.

Yue Huang, Yunpeng Zhai, Yan Feng, Xinyue Jia, Xiaohuan Zhang, Jinying Ning, **Feng Hao**

Kyinno Biotechnology Co., Ltd, Beijing, China

Synthetic lethality (SL) has emerged as a highly promising therapeutic strategy, gaining significant attention in the field of cancer treatment in recent years. The principle behind SL is that the simultaneous loss or inhibition of two genes results in cell death, while the inhibition of only one gene does not. SL drugs exploit this mechanism by targeting the partner gene of an already inactivated or mutated gene in cancer cells, inducing their death. This approach allows for the precise targeting of genetic vulnerabilities specific to cancer cells, sparing normal tissues from damage. Additionally, SL therapies expand the range of druggable targets, including proteins that are difficult to inhibit with traditional small molecules. By affecting both enzymatic and non-enzymatic protein functions, SL therapies reduce the risk of developing drug resistance, providing an effective option for treating cancers that are resistant to conventional therapies.Kyinno offers an extensive collection of knockout cell lines targeting a range of genes associated with synthetic lethality, including SHLD2, P53, T53BP1, AQR, ATRX, SETD2, ATM, WRN, BRCA1, and BRCA2. These cell lines, developed using the CRISPR/Cas9 genome editing technique and validated through sequencing and western blot analysis, are crucial for investigating the complex mechanisms underlying synthetic lethality and for identifying novel therapeutic strategies in cancer treatment. For example, our knockout lines for BRCA1 and BRCA2 enable researchers to investigate vulnerabilities in homologous recombination repair, paving the way for the development of innovative PARP inhibitors and targeted therapies. Additionally, lines with deletions in ATM and WRN provide essential insights into DNA damage response pathways, which can enhance the effectiveness of DNA-damaging agents. The diverse range of gene knockouts, including those involved in cell cycle regulation, DNA repair, and apoptosis, allows for comprehensive studies into the synergistic effects of dual gene inhibition. By utilizing our extensive library of synthetic lethality cell lines, researchers can effectively validate hypotheses, screen novel drug candidates, and optimize combination therapies to improve outcomes for patients with resistant cancers. We highly recommend these resources for advancing research in synthetic lethality and targeted cancer therapies.

#4190 CRISPR-CAS9 library screening identifies novel vulnerabilities in CRC drug-tolerant persister cells.

Martina Miotto[1], Simona Lamba[1], Gaia Grasso[1], Giorgio Corti[2], Julie Bonetto[1], Alberto Sogari[1], Alberto Bardelli[1], Mariangela Russo[1]

[1]Department of Oncology, Universita degli Studi di Torino, Turin, Italy,[2]Candiolo Cancer Institute, FPO-IRCCS, Candiolo, Italy

Introduction: Efficacy of targeted therapies in metastatic colorectal cancer (mCRC) is hindered by onset of resistance, therefore novel strategies are needed. A subpopulation of drug-tolerant persister cells (DTPs) survives to targeted therapies and initiates adaptive mutability response. DTPs experience an increased DNA damage and a shift to error-prone DNA damage repair, thus promoting mutability and resistance.

Aim: The purpose of this project is to explore key players modulating adaptive mutability to prevent DTPs' evolution to resistance, thus preventing tumor recurrence.

Methods: CAS9-expressing CRC cells were infected with a custom CRISPR library targeting over 500 DNA damage response (DDR) genes, divided in 12 subpopulations, and grown either for 4 weeks in normal cell culture conditions (untreated) or treated with specific oncogenic inhibitors until the development of resistance in a Time-To-Progression (TTP) assay. CAS9-expressing clones infected with empty library were grown in parallel, in absence or presence of targeted therapies, as control. Next Generation Sequencing-based analysis of sgRNA (single guides RNA) was then performed on resistant subpopulations grown in the presence of targeted therapies.

Results: We initially isolated CAS9-expressing clones from a microsatellite stable (MSS) CRC cell line and selected clones with growth rate and drug-sensitivity comparable to that of parental population. The selected CAS9-expressing clone was then infected with the CRISPR DDR library or empty library and, after the selection with puromycin, the selected populations were divided in 12 subpopulations, to exclude the possibility that pre-existing resistant cells might outgrow and interfere with the effect of DDR genes knock-outs (KO) on the development of drug-resistance. The subpopulations were then grown in absence or presence of oncogenic inhibitors for several weeks until the onset of resistance. Notably, while the 12 subpopulations infected with the empty library simultaneously developed resistance, the development of resistance in the DDR library-infected cells was spread over multiple weeks, thus highlighting that KO of DDR genes might either accelerate or delay the onset of resistance. sgRNA of resistant population were then analyzed by next-generation sequencing. A negative selection analysis will be applied to identify sgRNA that are lost in the resistant populations, thus targeting DDR genes whose depletion is potentially synthetical lethal with targeted therapies in mCRC.

Conclusion: A DDR CRISPR screening identified novel vulnerabilities of CRC DTPs able to improve efficacy of targeted therapies and prevent tumor relapse in mCRC.

#4191 Combining artificial intelligence and human expertise in pursuit of novel PolQ inhibitors.

Allan M. Jordan[1], Ageo Miccoli[2], Annabelle Charnock[2], Alexis Denis[3], Euan Fordyce[2], Cameron Franklin[2], Ennys Gheyouche[3], Ian Henderson[2], Christopher Housseman[3], Maxime Laugeois[3], Jean-Christophe Meillon[3], Stuart Onions[1], Quentin Perron[3], Clementine Pescheteau[3], Emilie Pihan[3], Mark Reeves[2], Kirsty Rooney[2], Hannah Rowlands[2], Kamaldeep Sumal[1], Franck Le Vaillant[3], Graeme Walker[2]

[1]Sygnature Discovery, Nottingham, United Kingdom,[2]Sygnature Discovery, Macclesfield, United Kingdom,[3]Iktos, Paris, France

DNA polymerase theta (POLθ or POLQ) recently emerged as a new promising drug target for the treatment of homologous recombination (HR) deficient tumours. This unique fusion protein comprises both DNA polymerase (Pol) and DNA helicase domains that function together to facilitate multiple DNA repair mechanisms. Small molecule approaches to target both domains have been described throughout the last decade and have shown potent and selective HR-deficient tumor cell death in vitro and in vivo. Despite the growing number of advanced PolQ polymerase inhibitors reported in the literature, significant ADME liabilities remain associated with the current reported scaffolds. To address this issue, machine-based learning methodologies were envisioned to act as a potential aid for medicinal chemistry efforts and help drive identification of chemical matter that might reside outside of the typical toolbox of small molecule design ideas.
Using the Makya generative AI platform, synergistically with traditional knowledge-based approaches, we have identified novel small molecule PolQ polymerase domain inhibitors. One chemotype, with an embedded oxime motif, has demonstrated potent biochemical activity and comparable cell activity to known tool compounds. A follow-up library of functionalised oxime derivatives, with varying compositions of donor and acceptor motifs, was synthesized to probe the chemical space further which demonstrated improved biochemical potency on the original hit matter. Initial ADME profiling suggests that these ligands possess properties that represent a good starting point for a lead optimisation campaign. Herein, we report key findings from the initial phase of development of our small molecule PolQ inhibitors.

#4192 Preclinical characterization of LAE122, a novel, potent and selective WRN inhibitor for the treatment of MSI-H tumors.

Ming Li[1], Minhua Zhang[1], Junyan Chen[1], Chaojun Cai[2], Xiaofen Lin[2], Justin Gu[2]

[1]Laekna Therapeutics Shanghai Co., Ltd., Shanghai, China,[2]Laekna Pharmaceutical Ningbo Co., Ltd., Ningbo, China

DNA mismatch repair (dMMR) deficiency could induce damage of genome, resulting Microsatellite instability (MSI-H), which is frequently observed in various tumor types, including colorectal, gastric, endometrial, and ovarian cancers. Although immune checkpoint inhibitors (ICI) have been approved for the treatment of MSI-H tumors, significant unmet medical need remains across several tumor types that fail to respond or relapse with ICI therapies. Werner syndrome ATP-dependent helicase (WRN) is a RecQ family helicase that plays important roles in DNA repair and in the maintenance of genome integrity. Recent studies have identified WRN as a promising synthetic lethal drug target for MSI-H cancers. LAE122 is a novel, potent and selective WRN inhibitor developed by Laekna through structure-based drug design strategy. LAE122 has highly differentiated structure from bench-mark molecules and displayed single digit nanomolar IC_{50} values in biochemical assay and cell anti-proliferation assay on MSI-H cells but had no effect on Microsatellite stability (MSS) cells up to 10 μM. LAE122 demonstrated favorable drug-like properties, including good in vitro ADMET and in vivo PK with low plasma clearance and high oral bioavailability across animal species. In SW48 and HCT116 CDX models, LAE122 showed robust anti-tumor growth effect at lower doses than bench-mark molecules with strong evidence on biomarker change. LAE122 didn't have off-target liability in in vitro assays and demonstrated good tolerability in preclinical toxicology studies. In conclusion, LAE122 is a novel, potent and selective WRN inhibitor for the treatment of MSI-H tumors.

#4193 Novel APE1 endonuclease inhibitors as precision oncology therapeutics in high grade serous ovarian cancers discovered and developed from crystallography-based fragment library screening.

D. Das[1], A. Deacon[1], M. Duncton[1], D. M. Wilson III[1], M. Algethami[2], A. Leshan[2], E. A. Rakha[2], C. Tosun[2], S. Madhusudan[2];
[1]XPose Therapeutics, San Carlos, CA, [2]University of Nottingham, Nottingham, United Kingdom

Our preclinical data show APE1 could be a synthetic lethality (SL) target in BRCA deficient ovarian cancers. *BRCA1*- and *BRCA2*-associated hereditary breast and ovarian cancer syndrome (HBOC) is characterized by increased risk for breast cancer, ovarian cancer (includes fallopian tube and primary peritoneal cancers) and other solid tumours (including pancreatic cancers and prostate cancers). About 10-20% of TNBC patients harbor germline BRCA mutations resulting in homologous recombination deficiency (HRD), and even amongst wild-type BRCA patients, somatic mutations occur more frequently producing a range of HRD phenotypes collectively termed as “BRCAness”. In epithelial ovarian cancers, germ-line BRCA mutations can be detected in up to 20% of high serous ovarian cancers, and up to 50% of somatic tumours can also manifest a HRD phenotype. PARP1 inhibitor (Niraparib, Olaparib, Rucaparib) maintenance therapy improves progression-free survival in BRCA germline deficient ovarian cancer or platinum sensitive ovarian cancers. Olaparib and Talazoparib are approved for use in BRCA germ-line deficient breast cancers. A response rate to PARPi of up to 60% has been described in clinical studies. Routine clinical use has shown that not all patients with BRCA deficient cancers respond to PARPi either due to intrinsic or acquired resistance. The search is on for other SL targets in BRCA/HRD deficient cancers that either bypass PARPi resistance or are more effective than PARP blockade. We evaluated APE1 protein expression in human epithelial ovarian cancers, correlated with clinicopathological features and survival outcomes and compared APE1 transcript levels in a panel of solid tumours and normal tissue. APE1 transcripts were evaluated in publicly available ovarian cancer clinical datasets (n=1257) for clinical outcomes. Highest levels of transcripts were observed in ovarian cancers compared to other solid tumours. When compared to normal ovarian tissue, there was striking elevation of transcripts in ovarian cancer tissues. High mRNA expression was associated with poor progression free survival (PFS) ($p=0.00019$). High nuclear APE1 protein expression was seen in 64% of tumours, a feature associated with high grade serous ovarian cancer, poor PFS and poor overall survival. XPTx-91 and XPTx-387 have biochemical IC50s of 250-500 nM. Optimized compounds were screened for selective toxicity in PEO1 (BRCA2 deficient, platinum sensitive, PARPi sensitive) and PEO4 (BRCA2 proficient, platinum resistant, PARPi resistant) cell lines. Several compounds screened in MTS cell proliferation assay showed preferential cytotoxicity in PEO1 cells compared to PEO4 cells. Further cell based (clonogenics, 3D spheroids) and functional assays (DNA double strand break accumulation, cell cycle progression and apoptosis) are ongoing.

#4194 Inhibiting PELP1 signaling enhances the therapeutic effectiveness of topoisomerase inhibitors in triple-negative breast cancer.

Khaled Mohamed Nassar[1], John R. Sanchez[2], Durga Meenakshi Panneerdoss[3], Behnam Ebrahimi[3], Xue Yang[2], Uday P. Pratap[3], Megharani Mahajan[3], Salvador Cardenas Alejo[3], Abhi Katabathina[3], Panneerdoss Subbarayalu[4], Daohong Zhou[5], Rajeshwar R. Tekmal[3], Gangadhara Reddy Sareddy[3], Manjeet K. Rao[4], Suryavathi Viswanadhapalli[3], Ratna K. Vadlamudi[3]

[1]Obstetric and Gynecology, UT Health Science Center at San Antonio, San Antonio, TX,[2]MD Anderson Cancer Center, Houston, TX,[3]Obstetric and gynecology, UT Health Science Center at San Antonio, San Antonio, TX,[4]Cell Systems and Anatomy, Greehey Children's Cancer Research Institute, UT Health Science Center at San Antonio, San Antonio, TX,[5]Biochemistry and Structural Biology, Greehey Children's Cancer Research Institute, UT Health Science Center at San Antonio, San Antonio, TX

Background: Triple-negative breast cancer (TNBC) is an aggressive tumor with a poor prognosis and high metastasis, accounting for 15-24% of breast cancer deaths. Proline-, glutamic acid-, and leucine-rich protein 1 (PELP1), an oncogene, is commonly deregulated in TNBC and serves as a biomarker of poor survival rates. The objective of this study is to establish the molecular mechanism of action of PELP1 in the progression of TNBC using IPTG-inducible PELP1 knockdown (PELP1-iKD) models and develop a novel combination therapy targeting PELP1.

Methods: TNBC models (MDA-MB-231, BT-549, HCC-1806, SUM-149) with PELP1-iKD were generated through lentiviral transduction. PELP1 signaling was further inhibited with the pharmacological inhibitor SMIP34. SMIP34's effectiveness was tested with 140 FDA-approved drugs using an MTT assay-based screen, and combination therapy was evaluated using colony formation and Annexin V/PI apoptosis assays. Mechanistic studies were conducted using RT-qPCR, Western blotting, and comet assays. The utility of SMIP34 + Topoisomerase inhibitors (TIs) combination therapy was assessed in cell line-derived xenografts (CDXs), patient-derived organoids (PDOs), and patient-derived xenografts (PDXs).

Results: Western blotting analysis confirmed that IPTG induction reduces PELP1 expression in a dose-dependent manner in all four TNBC PELP1-iKD cells. PELP1 KD significantly decreased cell proliferation and colony formation in TNBC cells while enhancing apoptosis. PELP1-iKD cells showed a delayed DNA damage response, characterized by elevated γ-H2AX levels and impaired activation of phospho-ATM, ATR, and DNA-PKcs following DNA damage. Treatment with SMIP34 also resulted in a delayed DNA damage response and accumulation of γ-H2AX, similar to the genetic approach. In an MTT-based screen, SMIP34 enhanced the sensitivity of TNBC cells to TIs. These results were validated in PELP1-iKD cells, where PELP1-iKD further increased sensitivity to TIs, providing genetic evidence of PELP1's role in the synergy between SMIP34 and TIs. The ability of SMIP34 to enhance the efficacy of TIs was confirmed in additional TNBC cell lines, with synergistic effects observed in cell proliferation, colony formation, and apoptosis assays. Mechanistic investigations demonstrated elevated levels of γ-H2AX in cells treated with the PELP1-iKD+TIs and SMIP34+TIs combinations, compared to monotherapy with TIs. Comet assay results indicated heightened DNA damage with these combination treatments. Furthermore, Combined SMIP34 and Mitoxantrone treatment significantly suppressed PDO proliferation *in vitro* and reduced CDX and PDX tumor growth compared to monotherapies or controls.

Conclusion: Collectively, these findings establish a robust preclinical foundation for the development of PELP1-targeted combination strategies for the treatment of TNBC.

#4195 Efficacy of tumor treating fields (TTFields) applied with cisplatin and paclitaxel in cervical cancer cells.

Roni Frechtel-Gerzi[1], Daria Gerasimova[1], Einav Zeevi[1], **Helena Mumblat**[1], Yara Eid Mutlak[1], Yuval Shmueli[1], Roni Monin[1], Hila Fishman[1], Inbar Schlachet-Drukerman[1], Naama Flint-Brodsly[1], Eyal Dor-On[1], Itai Tzchori[1], Adi Haber[1], Moshe Giladi[1], Uri Weinberg[1], Yoram Palti[1], Greg M. Palmer[2], Angeles Alvarez Secord[3]

[1]Novocure Ltd, Haifa, Israel,[2]Department of Radiation Oncology, and Duke Cancer Institute, Duke University Medical Center, Durham, NC,[3]Duke Cancer Institute and Division of Gynecologic Oncology, Department of Obstetrics and Gynecology, Duke University Medical Center, Durham, NC

Introduction: Most cervical cancer patients with advanced disease receive first-line cisplatin-based chemotherapy. For late-stage and recurrent cervical cancer, a second chemotherapy may be added, e.g. paclitaxel. Tumor treating fields (TTFields) are electric fields that disrupt cellular processes critical for cancer cell viability and tumor progression. TTFields concomitant with cisplatin or paclitaxel have shown benefit in several tumor types. This study explored the effects of TTFields together with cisplatin and paclitaxel in cervical cancer cells and the underlying mechanism of action of TTFields.

Methods: Ca Ski, HeLa and SiHa human cervical cancer cell lines were exposed to TTFields (0.5 or 1 V/cm RMS; 200 kHz; 72 h), in the presence or absence of cisplatin and/or paclitaxel. Cell count, colony formation, and apoptosis were evaluated; and overall effect was calculated as the product of the reductions in cell count and colony formation. TTFields-treated cells were also examined for formation of DNA damage using fluorescent microscopy for γH2AX and for reduced capacity to repair DNA damage via Western blot for proteins from the Fanconi Anemia (FA)-BRCA pathway. The abundance of mitotic spindle defects and chromosome miss-localization was determined by fluorescent staining for α-tubulin and phospho-histone 3 (PH3).

Results: TTFields treatment reduced cell count and colony formation in all cervical cancer cell lines tested and augmented the efficacy of cisplatin and paclitaxel. Cells treated with TTFields demonstrated increased levels of DNA damage, reduced expression of DNA repair proteins, and formation of abnormal mitotic figures and chromosome miss-segregation.

Conclusions: The preclinical findings suggest benefit for co-treatment of TTFields together with the DNA-damaging agent cisplatin and the anti-mitotic agent paclitaxel. The effects of TTFields are mediated via anti-mitotic and DNA repair impairment mechanisms. Downregulation of the FA-BRCA pathway, required for the repair of cisplatin induced DNA damage, creates conditional vulnerability of the cells that may account for the enhanced efficacy for application of TTFields together with cisplatin.

#4196 Alt-NHEJ inhibition leads to cGAS/STING-dependent immunogenic cell death in multiple myeloma.

Giada Juli[1], Domenica Ronchetti[2], Sara Squillacioti[1], Nicoletta Polera[1], Anna Maienza[1], Michelangelo Vocaturo[1], Emanuela Altomare[1], Katia Grillone[1], Maria Gaetano[1], Stefania Signorelli[1], Antonio Galvano[3], Niccolo Bolli[2], Pietrosandro Tagliaferri[1], Pierfrancesco Tassone[1], **Daniele Caracciolo**[1]

[1]Magna Graecia University of Catanzaro, Catanzaro, Italy,[2]Department of Oncology and Hemato-Oncology, University of Milan, Milan, Italy,[3]Department of Precision Medicine in Medical, Surgical and Critical Care (Me.Pre.C.C.), University of Palermo, Palermo, Italy

Background: Alternative Non Homologous End Joining (Alt-NHEJ) DNA repair is considered a major player in cancer genomic instability. Here, we investigated cGAS-STING pathway as crucial node in the interplay between Alt-NHEJ repair and immune response, in the aim to discover novel therapeutic vulnerability in Multiple Myeloma (MM).

Methods: *In silico* analyses were performed by consulting public MM dataset CoMMpass. Anti-proliferative activity was evaluated by CellTiter-Glo, while flow cytometry analysis was used to determine the apoptotic process, cell cycle, phagocytosis, micronuclei detection, Calreticulin and T-cell activation markers. Protein expressions were detected by western blot of whole or fractioned protein extracts.

Results: We first examined the prognostic role of a cGAS-STING signature described by Sokac et al, by interrogating public MM database. 767 MM patients were selected from CoMMpass dataset and divided into 4 groups according to cGAS-STING signature groups (CSG 1-4). Interestingly, 130 patients were classified into CSG2 group with non functional cGAS-STING pathway, 105 into CSG3 with active cGAS-STING and 532 patients into CSG4 group with abnormal activation of cGAS-STING pathway; no patients where classified as CSG1 with inactive cGAS-STING. Importantly, CSG3-4 groups showed significantly reduced PFS and OS as compared to CSG2, supporting the idea that cGAS-STING has a pivotal role in the progression of MM. Indeed, Gene Set Enrichment Analysis (GSEA) of CSG3 versus CSG2 revealed differential involvement of several pathways such as DNA repair, TNFA signaling, oxidative phosphorylation and MYC targets. In addition, gene expression analysis showed a higher mRNA expression DNA Ligase 3 (LIG3) and PARP1 in CSG3 and CSG4 group as compared to CSG2. On this basis, we evaluated the activity of Alt-NHEJ inhibitors Talazoparib (PARP1-inhibitor) and L67 (LIG3 inhibitor) on MM cell lines, focusing in their capability to modulate cGAS-STING pathway. We first detected a significant reduction of cell proliferation and the induction of apoptosis following Talazoparib and L67 treatment, which in turn induced DNA damage response and cell cycle blockade, and finally cGAS-STING pathway activation. Finally, by performing co-culture experiments with healthy donor's peripheral blood mononuclear cells (PBMCs), we demonstrated the increase of *i)* CD80 and CD83 maturation markers on dendritic cells, *ii)* CD69 and CD25 activation markers on T cells and *iii)* phagocytosis of tumor cells. Importantly, these results were confirmed also in HR-defective breast and ovarian cancer cell lines, further suggesting the onset of an immunogenic cascade upon Alt-NHEJ inhibition.

Conclusion: Taken together, our findings indicate that Alt-NHEJ inhibitors are potential immune-stimulating agents for MM with hyperactivation of cGAS-STING pathway, coherently with our working hypothesis.

#4197 Synergic antioxidant effect of cord blood stem cells derived exosomes and sulforaphane on CML.

Banan Majid Alkhatabeh[1], Shohreh Jafarinejad[1], Mohammad Isreb[1], Farshid Sefat[1], Saeed Heidari[1], Adi Baumgartner[2], Mojgan Najafzadeh[1]

[1]University of Bradford, Bradford, United Kingdom,[2]York St John University, York, United Kingdom

Despite the promising advances in the diagnostics and therapeutics of Chronic Myeloid Leukaemia in recent years, they are still the disease of the era. Conventional treatments cause severe side effects, including death. Investigating novel drugs and combination therapies is essential for improving and advancing leukaemia and treatment. In the context of haematological cancers, elevated levels of reactive oxygen species (ROS) can induce oxidative stress. This oxidative stress may be mitigated by the administration of increased antioxidant levels. sulforaphane (SFN) is an antioxidant compound found mainly in cruciferous vegetables. Many studies demonstrated that the biological properties of SFN make it a suitable candidate for blood cancer treatment, including the activation of several metabolic processes and induction of apoptosis in cancer cells. Also, In the last few years, the ability of human cord blood stem cells (CBSC)-derived exosomes to mediate cellular communication has been extensively investigated. CBSC exosomes have proved beneficial in treating various diseases. This study aimed to investigate the impact of CBSC exosomes and SFN *in vitro* on haematological disease in general and CML in particular, compared to healthy controls. The Comet assay was used to assess the impact of SFN and CBSC exosomes on DNA damage, as well as to evaluate the potential genoprotective effects of these treatments at the presence of H_2O_2 exposure. A high level of DNA damage was observed in blood cancer (such as lymphoma and multiple myeloma) PMBCs compared to healthy controls. In this study involving PMBCs from cancer patients (N=20) and healthy controls (N=20), treatment with two concentrations of sulforaphane (SFN) (10 and 15μM), along with the application of 12% v/v CBSC exosomes, demonstrated a significant reduction in DNA damage induced by hydrogen peroxide (H_2O_2), with a p-value($p<0.001$). The doses employed in this study had a minimal impact on the viability of healthy cells while demonstrating a noticeable reduction in cell viability among CML cells, as assessed by the CCK-8 assay. In this research we utilised qPCR and Western Blotting techniques to investigate the influence of SFN and hCBSC-derived exosomes, as well as SFN-CBSC exosomes, on the gene and protein expression related to the apoptosis pathway in CML cells. This study focused on key markers such as p53, p21, Bcl-2 genes and proteins, and Caspase-3, in addition to examining the BCR-ABL gene associated with tumorigenicity. We found that all previous treatments were able to induce apoptosis and reduce the oncogenicity of CML compared to negative control.

#4199 Defining roles of telomerase reverse transcriptase in DNA damage response.

Leon L. Zhou, Stephen J. Kron

University of Chicago, Chicago, IL

Telomerase Reverse Transcriptase (TERT), the catalytic subunit of telomerase, is essential for telomere maintenance, elongating the G-strand of telomeric DNA using its associated RNA template (TR). Recruitment of TERT to telomeres is mediated by the shelterin component TPP1. While TERT is highly expressed in cancer cells, efforts to target its telomeric function have shown limited clinical efficacy. Recent studies have identified noncanonical roles for TERT, particularly in the DNA damage response (DDR), suggesting alternative therapeutic opportunities. Notably, TERT inhibitors sensitize cancer cells to radiotherapy, though the mechanisms underlying this effect remain unclear. To address this gap, we established a mutant TERT phenotyping system to study how TERT variants affect the DDR. Using a tetracycline-inducible shRNA-miR knockdown system in MCF7 and HeLa cells, we targeted endogenous TERT and complemented with transfected wildtype or mutant TERT, validating expression by Western blot. Cells expressing only transfected TERT were irradiated with 6 Gy to induce double-strand breaks (DSBs), and DDR effects were assessed by 53BP1 or γH2AX foci resolution, cell survival, and senescence onset. Knockdown of TERT led to persistent DNA damage foci, confirming a role for TERT in DSB repair. Foci resolution was restored by WT TERT but not by the catalytic mutant TERT D712A, V713I. Similarly, the TERT R132E, K78E mutant, defective in TPP1 binding, exhibited persistent foci, implicating TERT-TPP1 interactions in DDR. Supporting this, TPP1 mutants unable to bind TERT also caused persistent DNA damage foci. Combined with evidence that shelterin complexes, including TPP1, localize rapidly to nontelomeric DSBs after DNA damage, these results suggest that TPP1 recruits TERT to DSBs, analogous to its role at telomeres. Ongoing studies aim to elucidate how TERT's catalytic activity promotes DSB repair and to explore TERT as a target for sensitizing cancer cells to therapy.

#4200 Elevated dNTP pools impair homologous recombination-mediated repair, promoting apoptosis in therapy-resistant glioblastoma.

Dominique Monroe, Mercy Kehinde-Ige, Apeksha Anand, Arilyn Williams, Edidiong Usoro, Matthew Kededa, Aman Kalsi, Christian Fahmy, Ramsha Khanam, Huidong Shi, Waaqo Daddacha

Medical College of Goergia, Augusta, GA

Glioblastoma (GBM) is a deadly brain tumor that often develops resistance to DSB-inducing therapeutics due to dysregulated DNA repair. Ionizing radiation (IR) targets these cancer cells by causing DNA double-stranded breaks (DSBs). However, GBM often has overactive genes involved in the error-free DSB-repair process known as Homologous Recombination (HR). This results in therapy resistance and poor patient outcomes. Here, we provide an alternative approach to target DSB-resistant GBM by modulating the dNTP pool instead of solely targeting DNA-repair proteins. Through a comet assay, we found that increasing the dNTP pool prior to IR resulted in impaired DSB-repair. Immunofluorescence analysis of key HR proteins revealed significant disruptions in end resection, a necessary phase of HR. Our RNA-seq results show that increasing the dNTP pool prior to IR treatment caused significant changes in gene expression when compared to IR or dN treatment alone. Pathways most affected include apoptosis and cell cycle arrest. Flow cytometry analysis confirmed the significant increase in apoptosis in irradiated cancer cells with elevated dNTP pools. Not only do these data suggest that HR efficiency is reduced due to end resection impairment, but they also show that as a result, cell viability is destabilized due to prolonged DNA damage, resulting in apoptosis. The identification of this impairment may be essential in finding novel therapeutic approaches to sensitize therapy-resistant GBM.

#4201 Combination of the PARP1-selective inhibitor saruparib with androgen receptor pathway inhibition provides combination benefit in preclinical models of prostate cancer with or without homologous recombination repair deficiency.

Mark R. Albertella, Giuditta Illuzzi, Anna D. Staniszewska, Sophie Cooke, Mark J. O'Connor, Josep V. Forment

AstraZeneca, Cambridge, United Kingdom

Recent phase 3 clinical trial readouts have shown benefit of the combination of poly(ADP-ribose) polymerase inhibitors (PARPi) with androgen receptor (AR) pathway inhibitors (ARPi) in metastatic, castration-resistant prostate cancer (mCRPC). While benefit was particularly evident in patients with tumors harboring mutations in homologous recombination repair (HRRm) genes, improved outcomes were also observed in patients with no such alterations in their cancers (non-HRRm). We evaluated the activity of the PARP1-selective inhibitor and trapper saruparib (AZD5305) in combination with the ARPi enzalutamide in a range of preclinical models in vitro and in vivo. Combination treatment of clinically relevant doses of 1mg/kg saruparib and 60mg/kg enzalutamide led to regressions or tumor control in BRCA2-mutant PDX models of prostate cancer, C901 and G266, and in the CDK12-mutant HRRm model PCU-012. Importantly, enhanced in vivo combination efficacy was also observed in non-HRRm prostate models LNCaP and C4-2, on treatment with saruparib and enzalutamide. Saruparib led to enhanced DNA damage after treatment in these models. We explored the mechanisms of action contributing to this observed combination benefit, focusing on the non-HRRm models where this was observed. The cell line C4-2 was not sensitive to saruparib alone, as expected, but showed enhanced sensitivity to the combination of enzalutamide with saruparib. Strikingly, this was not observed with the weaker PARP1 trapper veliparib, suggesting a requirement for trapping-induced DNA damage. The combination of enzalutamide and saruparib led to increased DNA double strand break formation, and enhanced accumulation of micronuclei, suggesting that this combination benefit is driven by an increase in unrepaired DNA damage. Enzalutamide treatment of C4-2 cells reduced the soluble nuclear fraction of the AR, as expected. Importantly, inhibition of PARP1 by saruparib reduced AR recruitment to chromatin in the presence of DNA damage. Combined treatment led to maximal reduction in AR recruitment, which may help explain the increased efficacy. These preclinical data demonstrate combination activity of saruparib and ARPi in HRRm as well as non-HRRm prostate cancer models and provide mechanistic evidence that combination benefit is driven by PARP1 trapping inducing DNA damage, and PARP1 inhibition and ARPi inhibiting the repair of this damage, leading to accumulation of cytotoxic genomic instability to the cancer cells. A clinical study ASCERTAIN (NCT05938270) has been initiated, where the focus is on collection of pre- and post- treatment biopsies from monotherapy and combinations of saruparib, and the ARPi darolutamide, with the aim of increasing further understanding of mechanisms of action between PARPi and ARPi.

#4202 PD-L1 promotes DNA double-strand-break repair and radioresistance in cancer.

Zhen Shu[1], Bhakti Dwivedi[2], Jeffrey Switchenko[3], David Yu[1], Xingming Deng[1]

[1]Radiation Oncology, Winship Cancer Institute, Emory University, Atlanta, GA,[2]Bioinformatics and Systems Biology Shared Resource, Winship Cancer Institute, Emory University, Atlanta, GA,[3]Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, GA

Resistance to radiotherapy is a major barrier during cancer treatment. Using genome-scale CRISPR/Cas9 screening, we identified that the *CD274* gene, which encodes PD-L1, confers lung cancer cell resistance to ionizing radiation (IR). Depletion of endogenous PD-L1 retarded the repair of IR-induced DNA double-strand breaks (DSBs). Treatment of lung cancer cells with IR or glycosylation inhibitor tunicamycin resulted in translocation of PD-L1 from the membrane into nucleus in a manner that is dependent on deglycosylation of PD-L1 at N219. CMTM6 transports PD-L1 from the cytoplasm into the nucleus via direct interaction. PD-L1 loss downregulated non-homologous end joining (NHEJ) while overexpression of PD-L1 upregulated NHEJ. Mechanistically, after IR exposure, PD-L1 was recruited to DSB sites to form foci, and to interact with Ku in the nucleus. PD-L1 not only enhanced Ku binding to DSB DNA but also facilitated binding of Ku to other NHEJ factors. PD-L1 deglycosylation and its interaction with Ku occurred in a cell cycle-dependent manner. Interaction between the IgC domain of PD-L1 and the core domain of Ku is required for PD-L1 to accelerate NHEJ-mediated DSB repair and produce radioresistance. Thus, PD-L1, in addition to its immune inhibitory activity, also acts as a mechanistic driver for NHEJ-mediated DSB repair in cancer. Specifically targeting this novel function of PD-L1 may represent an attractive strategy for cancer therapy.

#4203 Discovery and development of a potent and highly selective ATR inhibitor IMP9064.

S. Cai, N. Ma, X. Wang, Y. Jiang, M. Guo, R. Zhou, M. Chen, Y. Tian;
IMPACT Therapeutics (Shanghai), Inc., Shanghai, China

The ataxia telangiectasia and RAD3-related (ATR) kinase is a crucial component of the DNA damage response (DDR) and functions in conjunction with ataxia telangiectasia mutated (ATM). Loss or functional deficiency of ATM may lead to increased reliance on ATR signaling pathways. Preclinical and clinical studies have indicated a potential synthetic lethality between ATR inhibition and ATM deficiency. We have identified a novel, potent, and highly selective ATR inhibitor IMP9064. Herein we present its discovery and IND enabling *in vitro* and *in vivo* studies. IMP9064 is highly activity inhibiting ATR, and is highly selective among kinases. IMP9064 also shows potent cytotoxicity to a wide range of cancer cell lines. In addition, IMP9064 has a desirable PK profile in preclinical species. IMP9064 has demonstrated anti-tumor efficacy in human colorectal cancer CDX animal models with good dose-response tumor growth inhibition and tolerability. The results of *in vitro* and *in vivo* studies suggest that used alone or in combination with PARP inhibitor, WEE1 inhibitor, PKMYT1 inhibitor or HER2 ADC, IMP9064 has good anti-tumor activity and synergistic effect. IMP9064 has entered a phase 1/2 study to evaluate the safety and efficacy either as monotherapy or in combination with PARP inhibitor Senaparib in patients with advanced solid tumors (ClinicalTrials.gov Identifier: NCT05269316). The recommended phase 2 dose (RP2D) has been determined and IMP9064 is currently in expansion studies for selected tumors.

#4204 A novel triple combination therapy in small cell lung cancer targeting DNA damage repair as a mechanism of resistance.
Ashley Sanchez Sevilla Uruchurtu, Kevin Kwon, Shengliang Zhang, Tyler Roady, Wafik S. El-Deiry

Brown University, Providence, RI

Small cell lung cancer (SCLC) accounts for approximately 15% of new lung cancer cases in the US every year. Treatment options remain limited and 5-year survival rates have languished at around 7% for the past decade. SCLC is notorious for its response to standard etoposide-platinum doublet therapy; initially responsive, it almost always relapses and no longer responds to first-line treatments. The DNA damage response (DDR) has been credibly posited as a targetable mechanism of resistance to DNA-damaging agents. For our experiments, we added prexasertib to our prior combination of imipridone ONC201 (dordaviprone) and small molecule lurbinectedin, previously shown to be synergistic. Prexasertib is a dual inhibitor of Chk1 and 2, protein kinases in the DDR pathway that regulate downstream cell cycle checkpoint (CCC) proteins particularly implicated in G1/S transition and G2 entry. Synergy scores and western blot data from experiments in four cell lines (H1048, H1882, H1105, H1417) point to the role of the DDR-CCC pathway in SCLC treatment resistance and offer a novel treatment modality for testing in vivo, with the ultimate view to progress into the clinic.

#4205 Direct measurement of TA repeat expansions significantly outperforms MSI-H status as a predictor of sensitivity to the novel WRN inhibitor MOMA-341.

Anthony Tubbs[1], Javad Golji[1], Meredeth McGowan[1], Theresa Baker[1], Giulia Bottoni[1], Erin Brophy[1], Xin Cindy Yang[1], Haley Amemiya[1], Momar Toure[1], John R. Butler[1], Haoxuan Wang[2], Cen Gao[1], Timothy Guzi[1], Peter Hammerman[1], Erica Evans[1], **Allison Drew**[1]

[1]MOMA Therapeutics, Cambridge, MA,[2]Insitro, South San Francisco, CA

MOMA-341, first disclosed herein, is a novel, potent, and selective clinical stage small molecule inhibitor of the Werner RecQ like helicase (WRN) that acts through an allosteric, ATP-competitive binding mechanism and covalent ligation of WRN at cysteine 727. Consistent with WRN genetic depletion in MSI-H models, MOMA-341 induces DNA damage, cell death, and tumor regressions in mismatch-repair deficient (dMMR)/microsatellite instability high (MSI-H) models but has no effect in MSS tumor models or cell lines derived from normal tissues. MSI-H status, defined by loss of MMR proteins or using short read sequencing algorithms, correlates with MOMA-341 single agent activity in preclinical models but is an imperfect predictor, with a 62% Positive Predictive Value (PPV) and a 38% False Positive Rate (FPR) (N=40 MSI, 8 MSS), consistent with rates reported with other WRN inhibitors. In contrast, direct measurement of genome-wide TA repeat expansions, the substrate of WRN helicase and a feature of many MSI-H tumors, by long read sequencing produces a near-perfect prediction of sensitivity to WRN inhibition across a large cohort of preclinical tumor models spanning colorectal, gastric, and endometrial lineages (N= 36 MSI-H, 8 MSS). Long-read sequencing provides optimal insight across the genome for this purpose as it can discriminate the location, total length, and allelic heterogeneity of TA repeat expansions, whereas the TA repeat expansions that dictate WRN sensitivity are largely invisible to commonly used short read sequencing methods. While MSI-H tumors with highly expanded TA repeat regions were quite sensitive to MOMA-341, incomplete single agent antitumor activity was observed in tumors with lower levels of TA repeat expansion. However, these tumor responses could be converted to regressions when MOMA-341 was combined with chemotherapies such as irinotecan. This work demonstrates clearly that direct and specific measurement of the TA repeats that serve as a WRN helicase substrate is feasible, quantifiable and results in near perfect prediction of MOMA-341 anti-tumor activity in preclinical models, thereby successfully matching the relevant biology with pharmacologic response. Guided by this work, TA repeat expansions will be assessed in patient tumors within the upcoming Phase 1 clinical trial of MOMA-341 in dMMR/MSI-H tumors to better inform patient selection and the choice of single agent or combination dosing regimens.

#4206 Investigation into the mechanisms and therapeutic potential of R-loop-induced DNA damage in ER+ breast cancer.

Alyssa Roberts[1], Nicole Traphagen[1], Anneka Johnson[1], Eugene Demidenko[2], Patricia Muskus[3], Xiaofeng Wang[1], Todd W. Miller[3]

[1]Dartmouth College, Hanover, NH,[2]Biomedical Data Science, Dartmouth College, Hanover, NH,[3]Medical College of Wisconsin, Milwaukee, WI

A potential therapeutic vulnerability of endocrine-resistant estrogen receptor alpha (ER)-positive breast cancer is R-loop-mediated DNA damage induced by 17b-estradiol (E2). This study aims to elucidate the mechanism of DNA damage and test combination therapies to exacerbate the anti-cancer effects of E2. ER+ breast cancer cells overexpressing exogenous ER, which induces sensitivity to the growth-inhibitory effects of E2, were exposed to E2 and inhibitors of DNA damage repair proteins including poly-ADP ribose polymerases (PARP) and CHK1/2. Experimental endpoints included immunoblotting, flow cytometry, immunofluorescence, DNA fiber analysis, and growth assays using cell lines and patient-derived xenografts (PDXs). Cells overexpressing ER showed R-loop-dependent DNA damage in replicating cells. Combination therapy of E2 and the PARPi olaparib increased DNA damage in replicating cells without negatively impacting the elevated replication rates induced by E2. E2 significantly increased single-stranded DNA in ER-overexpressing cells; ssDNA is known to be susceptible to damage. These effects of E2 were exacerbated by PARPi. E2 increased the proportion of cells replicating DNA, but E2 paradoxically interfered with replication fork progression as shown by DNA fiber analysis. These findings suggest that replication interference contributes to DNA damage and eventual cell death but does not impair the ability for the cell to replicate. An alternative therapeutic approach is combination therapy with E2 and Chk1/2 inhibitor. This combination successfully inhibits growth of both parental and ER overexpressing cells indicating that E2 and Chk1/2 inhibition may have clinical potential. E2 induced DNA damage mediated by R-loops can be amplified using combination therapies targeting DNA damage repair or cell cycle inhibition. While it is clear that replication conflicts plays an important role in DNA damage, the mechanism in which the DNA damage is occurring has yet to be elucidated.

#4207 Discovery of WRN helicase inhibitors that covalently engage a novel, induced allosteric site.

Francis W. Hunter[1], Lindsey DeRatt[1], Kenneth Maksimchuk[1], Tatsuya Maehigashi[1], Seong Joo Koo[2], Liesbeth Micholt[2], Ranjeet P. Dash[1], Faraz Kazmi[1], Zhengyu Jiang[1], Albi Francis[1], Neetu Shukla[1], Aaron Patrick[1], Trpta Bains[1], Romy Perez-Abraham[1], Nikit Kumar[1], Zhijie Liu[1], Brian Reiss[1], Caitlin Morgan[1], Inha Heo[2], Werner Eyckmans[2], Gerald Chu[1], Anna Kuhn[1], Lorraine Angelillo[1], Lin-Chien Huang[1], Yu Sun[1], Ashley M. Rouleau[3], Yongkang Kim[3], John J. H. Shin[3], Harris Bell-Temin[3], Victoria Wong[1], Ruth Steele[1], Paul Shaffer[1], Kurtis E. Bachman[1], David Pocalyko[1], Scott Kuduk[1]

[1]Johnson & Johnson Innovative Medicine, Spring House, PA,[2]Johnson & Johnson Innovative Medicine, Beerse, Belgium,[3]Johnson & Johnson Innovative Medicine, Cambridge, MA

The RecQ helicase WRN is a synthetic lethal dependency in microsatellite instability-high (MSI-H) cancer and a therapeutic target of interest in that context. The two clinical-stage WRN inhibitors, HRO761 and RO7589831, both bind in an allosteric pocket near the interface of the two helicase domains (D1 and D2). To discover novel WRN inhibitors, we conducted a high-throughput phenotypic screen using γH2AX immunofluorescence imaging in MSI-H HCT116 colorectal cancer cells and identified a singleton hit, Compound A. Compound A phenocopied WRN siRNA knockdown in multiparametric analysis and was confirmed to engage and inhibit purified WRN protein. X-ray co-crystal structures with and without ATP revealed that Compound A binds to a novel allosteric site in the D1 domain which is absent in apo-WRN. The allosteric site was induced by localized rearrangement, including displacement of the DEAH-box upon ligand binding. Electron density was indicative of covalent bond formation via addition of Cys672 to the imine C=N bond of Compound A. Mechanistically, Compound A was ATP-noncompetitive, exhibited time-dependent inhibition of WRN ATPase and helicase activity, and did not inhibit the paralogous RecQ helicases BLM, RECL and RECQL4. Exploration of structure-activity relationships resulted in Compound B and Compound C that were characterized for therapeutic pharmacology. Both Compounds B and C demonstrated high potency and selectively induced γH2AX phosphorylation, cell cycle arrest, apoptosis, and clonogenic killing in MSI-H cells. The cytotoxicity of Compound C in HCT116 cells was unaffected by isogenic, CRISPR-mediated knockout of *BLM*, *RECQL*, *RECQL4*, *RECQL5* or *BRIP1* (*FANCJ*). In global proteomics and cell signaling studies, Compound C caused concentration-dependent degradation of WRN and upregulation of DNA damage response pathways in HCT116 but not microsatellite stable (MSS) SW620 colorectal cancer cells. Compound B was highly selective for MSI-H models and recapitulated the profile of sensitivity to WRN perturbation in a PRISM screen of 906 cell lines. Co-administration of Compound C with a CYP inhibitor to mice bearing HCT116 xenografts produced dose-dependent γH2AX phosphorylation in tumor tissue. Whole-genome CRISPR modifier screens with Compound C and a close analog of HRO761 in HCT116 and KM12 cells showed generally concordant functional genomic profiles, with perturbations in *SMARCAL1*, *HELLS*, and *WDR76* enriched and *POLQ* and *RBM6* depleted by WRN inhibition. In conclusion, we report a series of WRN inhibitors that engage a novel cryptic binding site and show a distinct mechanism of inhibition to WRN inhibitors currently in clinical development.

#4208 Azenosertib is a potent and selective WEE1 kinase inhibitor with broad antitumor activity across a range of solid tumors.

Wen Liu[1], Jianhui Ma[1], Jiali Li[1], Daehwan Kim[1], Sangyub Kim[1], Alexandra Levy[1], Kimberly Blackwell[1], Alejandro Recio-Boiles[2], Jennifer M. Segar[3], Shirai Sen[4], Deborah Doroshow[5], Danielle Jandial[1], Olivier Harismendy[1], Stephan K. Grant[1], Ahmed Samatar[1], Mark R. Lackner[1], Kimberlee M. Fischer[1]

[1]Zentalis Pharmaceuticals, San Diego, CA,[2]Department of Medicine, Hematology and Medical Oncology, The University of Arizona Comprehensive Cancer Center, Tucson, AZ,[3]Department of Medicine, Hematology and Medical Oncology, University of Arizona Comprehensive Cancer Center, Tucson, AZ,[4]NEXT Oncology, Dallas, TX,[5]Thoracic Oncology, Early Phase Trials Unit, Icahn School of Medicine at Mount Sinai, New York, NY

Due to high proliferative rate, cancer cells experience significant stress during DNA replication and mitosis, leading to DNA damage and increased genomic instability. To mitigate this, cancer cells rely on checkpoint kinases like WEE1, which halt cell cycle progression and allow damaged DNA to be repaired before cells enter mitosis. Damage that is too extensive leads to apoptosis. Targeting WEE1 can exploit vulnerabilities created by replicative stress and genomic instability. Given these features are common in cancer, we hypothesized a WEE1-targeted therapeutic would have broad antitumor activity across various cancer types. Azenosertib (ZN-c3) is a novel, selective, orally bioavailable WEE1 inhibitor with optimized pharmacokinetic and pharmacodynamic properties. Preclinical studies demonstrate Azenosertib inhibits cancer cell proliferation through a WEE1-dependent mechanism, marked by a reduction of pY15-CDK1 levels and increases in DNA damage markers. Herein, we evaluated its antitumor activity in 54 mouse xenograft models representing 9 solid tumor subtypes and observed robust tumor growth inhibition (> 60% TGI) in 24 of these models, including breast, colorectal, lung, ovarian, pancreatic, prostate, soft tissue sarcomas, and endometrial cancers. We also explored various dosing schedules for Azenosertib, identifying regimens that maintain efficacy with minimal toxicity in preclinical models. To further understand the mechanisms underlying Azenosertib's antitumor activity, we analyzed cell cycle changes in four cancer cell lines with variable sensitivity to Azenosertib. Treatment with Azenosertib caused accumulation of EdU-negative cells in the S-phase, reduced cells in the G1 phase, and promoted premature entry into mitosis. These effects suggest Azenosertib bypasses the G1/S and G2/M checkpoints, leading to immature S-phase and Mitosis entry, consistent with WEE1 inhibition of CDK1 and CDK2. Further analysis of DNA repair revealed an increase in γH2AX-positive cells, primarily in G1, EdU-negative S, and G2/M, and the co-localization of mitotic marker pHH3 and DNA damage marker γH2AX. Notably, WEE1 plays a critical role in safeguarding the integrity of the cell cycle, and this regulation is disrupted by Azenosertib. As a result, cells with unresolved DNA damage are driven into premature mitosis, exacerbating DNA damage and leading to mitotic catastrophe. Azenosertib is currently being investigated as a single agent in a dose escalation Phase I clinical trial (NCT04158336) evaluating safety, tolerability, and efficacy in cancer patients with previously treated, advanced solid tumors. Early clinical data from heavily pretreated patients with different types of cancer show promising signs of activity. Our findings highlight the potential of WEE1 inhibition as a broad therapeutic strategy, for gynecological cancers and various malignant indications.

#4209 Targeting RNase H2: a dual mechanism strategy to elevate replication stress, DNA damage, and antitumor immunity in triple-negative breast cancer.

Thai Quynh Anh Nguyen[1], Daniel J. McGrail[2], Hui Dai[1], Aysegul Cifci[1], Yong Du[1], Funda Meric-Bernstam[3], Shiaw-Yih Lin[1]

[1]Systems Biology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Center for Immunotherapy and Precision Immuno-Oncology, Cleveland Clinic, Cleveland, OH,[3]Department of Investigational Cancer Therapeutics, The University of Texas MD Anderson Cancer Center, Houston, TX

The inhibition of Ribonuclease H2 (RNase H2) activity offers a promising therapeutic approach for suppressing tumor growth in triple-negative breast cancers (TNBCs) by elevating DNA replication stress, inducing DNA damage, inducing cell death, and enhancing sensitivity to immunotherapy. RNase H2, a key enzyme responsible for removing misincorporated ribonucleotides from the genome, plays a pivotal role in maintaining genomic integrity. Overexpression of the RNASEH2A gene, which encodes the catalytic subunit of the RNase H2 complex, has been observed in breast tumors, with the highest levels detected in TNBC tumors and cell lines, making it a potential target for therapeutic intervention. This study explores the impact of RNase H2 inhibition on tumor proliferation, antitumor immunity, and its potential synergy with other DNA replication stress inhibitors. Our findings demonstrate that silencing RNASEH2A expression or pharmacologically inhibiting RNase H2 activity with the R14 inhibitor significantly increased levels of pRPA32 and γH2AX, indicating elevated DNA replication stress and DNA double-strand breaks. This was associated with substantial suppression of tumor growth and prolonged survival in TNBC models, while non-tumorigenic mammary epithelial cells remained unaffected. RNA sequencing analysis revealed that knockout of RNASEH2A in TNBC cell lines activated immune system signaling pathways, including increased production of T-cell-attracting chemokines such as CCL5, CXCL10, and CXCL11. This increase in immunostimulatory cytokine expression was attributed to the accumulation of cytosolic single-stranded DNA, which enhances innate immune responses. Moreover, pharmacological suppression of RNase H2 by the R14 inhibitor improved the efficacy of immune checkpoint blockade by promoting the infiltration of antitumor immune cells into the tumor microenvironment. This indicates that RNase H2 inhibition not only directly suppresses tumor growth but also modulates the tumor immune landscape, rendering TNBCs more responsive to immunotherapy. Additionally, the R14 inhibitor exhibited synergistic effects when combined with DNA replication stress inhibitors, including ATR inhibitors, PARP inhibitors, and their combination, consistent with the known role of RNase H2 deficiency in sensitizing cells to these therapeutic strategies. In conclusion, targeting RNase H2 activity represents a novel and dual-faceted therapeutic strategy in TNBCs, combining direct tumor growth suppression through increased DNA damage with enhanced antitumor immunity. This approach offers a promising avenue for combination therapy with immune checkpoint inhibitors and DNA replication stress modulators. These findings provide a rationale for the clinical development of RNase H2 inhibitors as part of an integrated treatment strategy for TNBC.

#4210 Replication stress detection using STRIDE technology platform.

Karolina Stępień, Kamila Schirmeisen, Jakub Lechowski, Magdalena Bartyńska, **Magdalena Kordon-Kiszala**, Kamil Solarczyk

intoDNA, Krakow, Poland

Replication stress, characterized by the slowing or stalling of replication forks, is a hallmark of many cancers and a key driver of genomic instability. Therapeutics targeting the ATR kinase, a central regulator of the replication stress response, have emerged as promising strategies for selectively exploiting the vulnerabilities of cancer cells. A reliable marker of replication stress is essential to better understand its dynamics and to optimize the development and application of DNA damage response (DDR) inhibitors. Such markers can provide critical insights into therapeutic mechanisms and enhance the precision of targeted treatments. Single-strand DNA breaks (SSBs) are both a cause and a consequence of replication stress, making them a potential biomarker. However, their occurrence during normal metabolism requires additional specificity, which can be provided by detecting replication stress-associated proteins. Here, utilizing our STRIDE technology platform, we combined direct *in situ* detection of SSBs with protein markers leading to the development of an assay aimed at measuring replication stress levels. The assay combined the detection of single-strand DNA breaks (SSBs) with replication stress-associated proteins: RPA, RAD17, and RAD9, evaluated separately in distinct assay variants. Each variant was assessed for steady-state readouts, negative control signal levels, and sensitivity to replication stress induced by known compounds. All variants effectively informed on replication stress induction, and baseline readouts of the assays correlated with the cellular response to replication stress-inducing agents. Importantly, the assays were also tested on FFPE tissue sections, demonstrating their feasibility for application to this type of material. The data collected thus far suggests that all assay variants hold potential as effective replication stress markers. Additional studies are required to further refine these assays, determine their optimal use in different contexts, and confirm their utility in identifying high replication stress backgrounds to predict responses to drugs targeting proteins involved in the replication stress response.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: HDAC and Methyltransferase Inhibitors
Poster Session

#4215 Targeting TNBC with a novel vorinostat conjugate that selectively inhibits and degrades HDAC3 and HDAC6.

Ping Gong[1], Min Huang[1], Haoling Wang[1], Xin Li[1], Linxiang Zhao[1], Samuel Waxman[2], Yongkui Jing[1]

[1]Shenyang Pharmaceutical University, Shenyang, China,[2]Icahn School of Medicine at Mount Sinai, New York, NY

Triple-negative breast cancer (TNBC) once metastatic is often a fatal disease with few molecular targets. HDAC3 is highly expressed in TNBC and regulates metastatic and cell death genes. The clinically approved pan-HDAC inhibitors exhibit limited efficacy with side effects in clinical trials. We have reported that the semisynthetic 18β-glycyrrhetinic acid analogues (10a-10e) bearing the 1-en-2-cyano-3-oxo substitution degrade HDAC3/6 proteins without direct enzymatic inhibition. We constructed AH3 to produce both HDAC 3/6 degradation and enzyme activity inhibition by 10a conjugation with the HDAC inhibitor vorinostat. AH3 has increased selectivity to HDAC3 and HDAC6 inhibition as compared to vorinostat. TNBC (MDA-MB-321, MDA-MB-468 and BT-459 cells) are more growth inhibited by AH3 (GI_{50}:0.6-1 μM) comparing to vorinostat (GI_{50}:1.9-2.9 μM) and exhibits selectivity for TNBC compared to normal mammary epithelial cells. Modification of the hydroxamic acid of AH3 with a methyl group (AH3-OCH3) loses HDAC inhibition and cell growth inhibition, confirming that HDAC3 and HDAC6 are the targets of AH3. AH3 inhibits colony formation, cellular invasion and migration in TNBC cells. AH3, but not AH3-OCH, induces apoptosis with downregulation of c-FLIP and upregulation of NOXA, associated with upregulation of acetyl-H3 and acetyl-tubulin as well as down-regulation of HDAC3 and HDAC6 proteins. AH3 has better tumor growth inhibition ability than verinostat in MDA-MB-231 xenograft model. AH3 is novel since both degrades and acts as an HDAC3/HDAC6 selective inhibitor with enhanced selectivity and antitumor ability against TNBC.

#4216 Advancing cancer immunotherapy through the development of a novel selective HDAC6 inhibitors.

Nithya Gajendran[1], Manasa Suresh[1], David Quiceno[1], **Sonia Sebaoui**[1], Xintang Li[1], Marie Durr[1], Sebastian J. Marquez Rodriguez[2], Mario A. Noboa[3], Sruthi Mohan[3], Barbora Havlinova[4], Julia Kudlacova[4], Annie Heuer[5], Satish Kumar Reddy Noonepalle[5], Cyril Barinka[4], Duncan J. Wardrop[2], Alejandro Villagra[1]

[1]Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC,[2]Department of Chemistry, University of Illinois at Chicago, Chicago, IL,[3]University of Illinois at Chicago, Chicago, IL,[4]Laboratory of Structural Biology, Institute of Biotechnology of the Czech Academy of Sciences, Czech Republic, Czech Republic,[5]Department of Oncology, Georgetown Lombardi Comprehensive Cancer Ctr., Washington, DC

Immune cells can significantly influence the therapeutic outcomes of anti-cancer therapies. Particularly, tumor-associated macrophages (TAMs) mainly exhibit an anti-inflammatory M2-like phenotype and are well recognized for their pro-tumoral activity, which supports tumor growth and suppresses anti-tumor immune responses. Nonetheless, TAMs exhibit remarkable plasticity, allowing for their reprogramming toward an anti-tumoral M1-like phenotype through targeted epigenetic modulations. Our group has previously reported several highly selective histone deacetylase 6 inhibitors (HDAC6is) that promote the polarization of TAMs toward the M1-like phenotype while suppressing the M2-like pro-tumoral phenotype. Despite this promising discovery, the current HDAC6is face several drawbacks, including efficacy at micromolar concentrations, which results in poor isoform selectivity and potential off-target effects. To address these limitations, we developed an advanced screening pipeline for HDAC6is on macrophage functions, and the antitumor benefits associated with their treatment, alone or in combination with anti-PD1 in the immunocompetent SM1 murine melanoma model. Based on an *in silico* screening of 980 HDAC6is derivatives and a macrophage-based screening described previously, we identified two candidates, SM-05-947 and SM-06-09, that showed superior properties compared to their parent molecules. The screening included the determination of cytotoxicity, specificity of HDAC inhibition, and the modulation of macrophage phenotype. Using bone marrow-derived macrophages, the treatment-associated changes in macrophage functions were characterized. Following dose determination, we studied their antitumor effects on SM1 melanoma tumors when administered as a single agent or combined with anti-PD1 antibodies. The tumor microenvironment was further characterized by immunotyping using flow cytometry, CyToF, and sc-RNA sequencing. The functional assays provided further evidence of increased phagocytosis of tumor cells and improved antigen cross-presentation with HDAC6 inhibition. Specifically, the presence of SIINFEKL peptide in the context of MHC class I in macrophages treated with HDAC6is showed a significant increase in antigen presentation by M1 macrophages. Administration of SM-06-09 and SM-05-947 as a single agent significantly reduced tumor growth when compared to the vehicle group. The two combination groups of HDAC6is and anti-PD1 antibodies further significantly improved these antitumor effects, as observed by flow cytometry, CyToF, and sc-RNA sequencing analysis. In conclusion, these findings provide valuable insights and pave the way toward the development of next-generation HDAC6is with maximum efficiency, minimal toxicity, and enhanced anticancer potential of TAMs.

#4217 Effect of HDAC3 targeting on endometrial cancer progression and therapeutic potential.

Keun Cheon Kim, Dunston Krystina, Hall Amanda, Hunter I Mark, Tae Hoon Kim, jaewook Jeong

University of Missouri, Columbia, MO

Endometrial cancer (EC) exerts a considerable burden on women's health worldwide. Epigenetic dysregulation is often reported in the development and progression of various cancers. A negative regulator of PI3K signaling and frequently found to be mutated in human EC is *PTEN* whereas *HDAC3* is critical in cell survival, proliferation, differentiation, and cancer development. HDAC inhibitors are being explored as an epigenetic treatment option, but their effects in EC are not well characterized. $Pgr^{cre/+}Hdac3^{f/f}Pten^{f/f}$ ($Hdac3^{d/d}Pten^{d/d}$) mice were generated and histopathologic analysis was performed to examine the effect of *Hdac3* ablation on EC with *Pten* deficiency. $Hdac3^{d/d}Pten^{d/d}$ mice revealed remarkably delayed tumorigenesis of EC compared to $Pten^{d/d}$ mice. To evaluate the effect of HDAC3 inhibitor (RGFP966), 6-week-old $Pten^{d/d}$ (Stage I EC) mice were treated with vehicle (sunflower oil) or RGFP966 (10mg/kg) twice per week for 5 weeks by intraperitoneal injection. The effect of EC progression was examined by immunohistochemistry using proliferation and apoptosis markers. In RGFP966-treated $Pten^{d/d}$ mice, uterine/body weight ratio (average 22.56 ± 2.99) was significantly ($p< 0.05$) decreased compared to vehicle-treated $Pten^{d/d}$ mice (66.78 ± 10.11). Immunohistochemistry revealed a significant reduction of proliferation marker and a significant increase of apoptosis marker in RGFP966 treatment compared to vehicle. Furthermore, the level of pAKT and pERK1/2 was substantially reduced in RGFP966 treatment group. These results demonstrate that HDAC3 targeting impedes the pathogenesis of EC and RGFP966 delays EC progression.

#4218 Discovery and in vitro characterization of FGFR/HDAC dual inhibitors for FGFR-driven cancer.

Chang-Hyun Yun[1], Sang-Heon Kim[1], Seunghwan Shim[1], Dongkyu Shin[2], Seonggu Ro[2], **Byoung-Gon Moon**[1]

[1]Handok Inc., Seoul, Korea, Republic of,[2]Pimedbio, Inc., Seongnam, Korea, Republic of

Gene alterations of Fibroblast growth factor receptors (FGFR) are frequently found in various solid tumors and are known as oncogenic drivers, particularly in bladder cancer and cholangiocarcinoma. Currently, pan-FGFR inhibitors are used for the treatment of FGFR2-driven intrahepatic cholangiocarcinoma and FGFR3-driven urothelial carcinoma. However, their efficacy is often limited by primary and acquired resistance mechanisms, including secondary FGFR mutation and alternative pathway activations. Secondary FGFR mutations are predominantly reported as an acquired resistance mechanism to pan-FGFR inhibitors. Additionally, substantial preclinical evidence suggests that alternative pathway activations, including EGFR, ERBB2, ERBB3, and c-MET, may significantly contribute to resistance. Interestingly, numerous preclinical studies have demonstrated that HDAC inhibitors can down-regulate their expression in certain tumor cell lines, suggesting the possibility of overcoming resistance through bypass activations. Furthermore, recent reports suggest that combining HDAC and FGFR inhibition may exhibit synergistic anti-tumor activity in both FGFR2 and FGFR3-driven tumors. Here we report the discovery and in vitro characterization of FGFR/HDAC dual inhibitors and their potential to overcome resistance via bypass activations. These compounds inhibited FGFR2 with an IC50 in the low nanomolar range in biochemical assay while sparing FGFR4. They also inhibited the proliferation of cancer cells harboring FGFR2 amplification with an IC50 in the low nanomolar range. Additionally, they inhibited HDAC1 with an IC50 in the low nanomolar range in biochemical assays and the HCT116 cell proliferation with an superior potency compared to vorinostat. To mimic drug resistance through bypass activations, SNU-16 cells were treated with EGF, HGF, or NRG1. In this model, the inhibitory efficacy of pemigatinib (an FDA approved FGFR 1-3 inhibitor) was significantly attenuated, whereas vorinostat (an FDA approved pan-HDAC inhibitor) maintained its efficacy. The greatest attenuation of efficacy was observed with EGF treatment, under which conditions some FGFR/HDAC dual inhibitors exhibited superior inhibitory efficacy compared to pemigatinib, correlating with their HDAC inhibition activity. In summary, these in vitro studies have resulted in several compounds that warrant further development for lead optimization. They also suggest that FGFR/HDAC dual inhibitors may be an option for overcoming bypass resistance in FGFR-driven tumors.

#4220 Anticancer effects of GEM144, a novel POLA1-HDAC11 dual inhibitor, on colorectal cancer models.

Rana Abdel-Samad[1], Susanna Noonan[1], Aileen Benitez[1], Teagan Mattox[1], Berthe Hayar[2], Sabrina Dallavalle[3], Claudio Pisano[4], Nadine Darwiche[2]

[1]Biology Depratment, Saint Mary's College, Notre Dame, IN,[2]Department of Biochemistry and Molecular Genetics, American University of Beirut, Beirut, Lebanon,[3]Department of Food, Environmental and Nutritional Sciences, Universita degli Studi di Milano, Milano, Italy,[4]Biogem, Institute of Molecular Biology and Genetics, Ariano Irpino (AV), Italy

Background and Objectives: Colorectal cancer (CRC) is the third most occurring cancer and the second cause of cancer-related deaths. Despite decades of research fighting the progression of CRC and the development of many therapeutic compounds, the 5-year survival rate remains at around 64%, with worse prognosis at advanced stages of the disease. The search for a fully efficacious treatment for CRC thus endures, in light of these suboptimal prognostic figures. GEM144 is a novel compound that was recently synthesized as a dual inhibitor of the DNA polymerase alpha (POLA1) and the histone deacetylase 11 (HDAC11). Initial investigations showed pronounced anti-proliferative potential of GEM144 when screened on a panel of hematological and solid cancer cells. Our study aims at examining the anticancer properties of GEM144 on CRC models.
Methods: We used two human CRC cell lines, HCT116 and HT29, derived from human colorectal carcinoma and adenocarcinoma, respectively, and one colon cell line, CCD-841-CoN, derived from the colon of a healthy subject. MTT assay [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide] was used to assess cell growth, and trypan blue dye exclusion assay to evaluate cell viability. A wound healing assay was performed to investigate the effect of GEM144 on cell migration ability. Finally, the *in vivo* effect of GEM144 on tumor growth inhibition was analyzed in CRC xenograft nude mouse models.
Results: GEM144 decreased the growth of HCT116 and HT29 cells at 1 μM and 5 μM, respectively, starting at 24 hours post-treatment. This inhibition was more pronounced after 72 hours of treatment, where growth rate was less than 10% compared to control cells for both cell lines. Trypan blue exclusion assay showed comparable results for both cell lines, suggesting a reduction in cell viability. Interestingly, up to 10 μM of GEM144 had no effect on the growth of the normal-like CCD-841-CoN cells. GEM144 had an inhibitory effect on the migration of the HCT116 cells, evident by the reduction of wound healing in GEM144-treated cells compared to control ones. Finally, GEM144 showed around 20% relative decrease in the tumor volume of HCT116 xenograft mice treated with oral GEM144 compared to mice receiving the vehicle, without affecting body weight. Remarkably, GEM144 sensitized the tumor to cisplatin, a standard drug in the treatment of CRC. In fact, while cisplatin reduced tumor volume by 46%, a combination of cisplatin and GEM144 reduced tumor volume by 58%.
Conclusion: Our data show promising effects of GEM144 as an anti-cancer compound in the treatment of CRC cell lines and in mouse models. Our study will now further focus on understanding the mechanisms of action of GEM144 on cell cycle progression and on the expression of major players in colorectal carcinogenesis.

#4221 Precision targeting of HDAC3 in ovarian cancer.

Vijayalaxmi G. Gupta[1], Bisiayo Fashemi[1], Reni Akande[1], Preedia Babu[1], Yukihide Ota[1], Yufeng Xaio[2], Guangrong Zhang[3], Francisca Nathalia Vitorino[1], Benjamin Garcia[1], Mary Mullen[1], Dineo Khabele[1]

[1]University of Washington, School of Medicine, St. Louis, MO,[2]College of Pharmacy, University of Florida, Gainsville, FL,[3]University of Florida, Gainsville, FL

Introduction: Addressing chemo-resistant homologous recombination-proficient (HRP) ovarian cancers and CCNE1-amplified tumors, while minimizing treatment-related side effects, remains a significant clinical challenge. Our research demonstrated that HDAC inhibition suppresses tumors in PARP inhibitor (PARPi)-resistant ovarian cancers and enhances PARPi sensitivity in preclinical models. However, pan-HDAC inhibitors (HDACis) have shown high toxicity in clinical trials. To overcome this, we focused on selectively targeting specific HDACs, particularly HDAC3 and HDAC8, which have unique structures and co-repressor complexes. HDAC3 is frequently upregulated in ovarian cancers, making it a promising therapeutic target. Here, we explore HDAC3 genetic depletion/knockout (KO) and precision targeting using HDAC-PROTACs in five cell lines.

Methods: We employed siRNA-mediated depletion and CRISPR-Cas9 KO to study the impact of HDAC3 inhibition on CCNE1-amplified OVCAR3 cell proliferation, clonogenicity, and protein expression. Histone modifications were analyzed via mass spectrometry. The anti-proliferative efficacy of HDAC3 (XZ9002), HDAC8 (YL352), and dual HDAC3/8 (YX968) PROTACs was evaluated in OVCAR3, COV318, HRP and HRD mouse fallopian tube cells, and patient-derived primary cell lines.

Results: HDAC3 siRNA treatment in OVCAR3 cells led to dose-dependent reductions in HDAC3 protein levels and PCNA expression. HDAC3-KO cells exhibited increased histone acetylation and decreased histone methylation. PROTACs showed differential efficacy across cell lines. In OVCAR3 cells, IC50 values were 1.82 µM for HDAC3-PROTAC, 1.98 µM for HDAC8-PROTAC, and ~0.67 µM for HDAC3/8 dual PROTAC, indicating superior potency with dual targeting. In COV318 cells, the dual HDAC3/8 PROTAC exhibited an IC50 of 2.5 µM. HRD mouse fallopian tube cells were more sensitive to HDAC8 and HDAC3/8 PROTACs (IC50 ~6 µM), while HRP cells were less sensitive (IC50: 8 µM for HDAC3/8 PROTAC, 10 µM for HDAC8 PROTAC, >10 µM for HDAC3 PROTAC). Patient-derived primary cell lines demonstrated the highest sensitivity to the dual HDAC3/8 PROTAC (IC50 ~7 µM), with reduced response to single HDAC PROTACs. Pharmacodynamic analyses via Western blot and qPCR are ongoing.

Conclusion: Selective targeting of HDAC3, HDAC8, and HDAC3/8 using PROTACs provides a promising therapeutic strategy to address toxicity limitations of conventional HDACis. These agents hold potential for low-dose applications in ovarian cancers and broader therapeutic use in other malignancies and diseases.

#4222 N-acetyl-L-cysteine (NAC) sensitizes psammaplin A induced DNA damage in malignant hematologic cells by enhancing HDAC inhibition.

Bao Yu[1], Yumei He[1], Dan Liu[1], Ping Gong[1], Samuel Waxman[2], Yongkui Jing[1]

[1]Shenyang Pharmaceutical University, Shenyang, China,[2]Icahn School of Medicine at Mount Sinai, New York, NY

Psammaplin A (PsA) is a symmetrical bromotyrosine-derived disulfide dimer isolated from the *Psammaplysilla sponge*. PsA is a selective natural Class I HDAC inhibitor, that requires reduction into monomer with glutathione (GSH). Cell growth inhibition and apoptosis was determined in 12 malignant hematologic cell lines revealed 8 lines sensitive (more than 50% inhibition at 1 μM) and 4 lines insensitive (less than 20% inhibition at 1 μM). PsA induces acetylation of H3 and DNA damage detected with γ-H2A.X in the sensitive lines, but not in the four insensitive cell lines. The sensitivity of PsA in these lines correlates with HDAC inhibition and reduced GSH levels. The insensitive cell lines have lower GSH levels without HDAC inhibition. N-acetyl-L-cysteine (NAC) acts as a precursor of GSH synthesis and is used as an antioxidant. Pretreatment with 5 mM NAC following by PsA enhances cell growth inhibition 10 fold. NAC plus PsA is more effective than the HDAC inhibitor SAHA, which is not enhanced by NAC, to inhibit cell growth in vitro. Western blot analysis shows that NAC sensitizes PsA effect by increasing HDAC inhibition as measured by acetylated H3 and by DNA damage marker γ-H2A.X with upregulation of GSH. Chemical studies reveal that GSH, but not NAC, reduces PsA into a monomer. PsA is enhanced by NAC to inhibit tumor growth in MOML13 xenograft models without causing toxicity. These data support that NAC enhances PsA effect by increasing intracellular GSH which reduces PsA into a HDAC inhibiting monomer with increased cancer cell growth inhibition.

#4223 Mouse clinical trials (MCT) and other comprehensive pharmacology approaches highlight protein arginine methyltransferase 1 (PRMT1) targeting in various solid tumors with promising efficacy and combined mode-of-actions (MoAs) beyond epigenetic regulation.

Hui Shi, Xingnian Fu, Yilin Liu, Qiugeng Ouyang, Jiaxin Huang, Long Wang, Shuning Xing, Youzhen Wang, Yuan Mi, Haiping Wu

CytosinLab Therapeutics, Hangzhou, China

Arginine methylation is the most abundant post-translational modifications which provide docking site for protein binding and interaction (e.g. with the aromatic cage of the Tudor domain proteins), triggering a series of downstream epigenetic regulation and cellular functions or processes. PRMT1 is the major type-I PRMTs responsive for monomethylation and asymmetric dimethylation of arginines in histone tails or non-histone protein substrates. Highly expressed in various lineages of cancers with poor survival such as non-small cell lung cancer (NSCLC), pancreatic adenocarcinoma (PAAD), triple-negative breast cancer (TNBC), esophageal squamous cell carcinoma (ESCC), gastric cancer (GA), PRMT1 has been extensively reported for targeting in cancer with profound and broad tumor-intrinsic/extrinsic modulation to repress cancer growth, metastasis or refractory immunity. Here we showed that CTS2190, the only clinically active investigational drug of PRMT1 currently in phase I/II study (NCT06224387), could drive cancer specific mode-of-actions combining epigenetic gene expression, DNA damage response (DDR), cell cycle arrest, signal transduction and immunity activation. We applied an innovative, well-designed, patient-derived xenograft (PDX)-based mouse clinical trial (MCT) approach to evaluate CTS2190 efficacy in an all-comer solid patient panel. CTS2190 demonstrated excellent tumor growth inhibition and regression in GA, NSCLC, PAAD, ESCC, etc. We also explored and validated the efficacy and proposed MoAs of CTS2190 in multiple cellular or *in vivo* pharmacology approaches as well as the synergistic effects of CTS2190 in a couple of MoA-driven and biomarker-guiding combinatorial approaches with chemo-, targeted-, radio- and/or immune-therapies. These results indicate the comprehensive anti-cancer mechanisms of CTS2190 in targeting PRMT1. CTS2190 not only demonstrates synthetic lethality with epigenetic instability, DDR, or RNA splicing (RS) dysregulation, but also as an ideal partner for a wide range of cancer therapies, including combinations with PRMT5i, a type-II PRMT member in both *MTAPnull* and *wild-type* genetic context. Ongoing clinical and translational studies for CTS2190 will pioneer the breakthrough and pave the way for developing more next-generation epigenetic therapies in solid tumors.

#4224 The pharmacological intervention of protein arginine methyltransferase 1 (PRMT1) leads to metastatic castration-resistant prostate cancer (mCRPC) repression through unique and significant androgen receptor (AR) downregulation and epigenetic modulation.

Hui Shi, Yang Han, Xingnian Fu, Jiaxin Huang, Xinyue Duan, Yilin Liu, Youzhen Wang, Yuan Mi, Haiping Wu

CytosinLab Therapeutics, Hangzhou, China

AR based mechanisms drive resistance to first-line AR pathway inhibitor (ARPI) therapy and lead to poor survival in mCRPC, including AR amplification/mutations, and the emergence of novel splice variants such as AR-V7. The heterogeneity of AR genetic context and reactivation of AR-independent downstream genes, largely driven by cancer intrinsic epigenetic dysregulation further complicate mCRPC treatment. While AR degradation therapies such as proteolysis-targeting chimeras (PROTACs) show promise, they remain unsatisfied due to limited response and progression free survival (PFS) benefits in mCRPC patients with AR-V7 mutations or heterogeneous AR-resistant backgrounds. PRMT1 is the major type-I PRMT responsible for the asymmetric dimethylation of arginine residues on substrates such as H4R3 of histones or RG/RGG in proteins other than histones. Pharmacological intervention of PRMT1 can lead to cancer repression and benefit for long-term survival in multiple solid tumors in clinical trials, owing to its comprehensive mode-of-action (MoA) utilizing both epigenetic regulation of cancer gene expression and synthetic lethality to cancer intrinsic hallmarks such as DNA damage repair (DDR) and cell cycle arrest. Here we showed that PRMT1 is overexpressed in prostate cancer, particularly in advanced metastatic cases, well correlating with poorer prognosis of mCRPC. Inhibition of PRMT1 with CTS2190, a first-in-class (FIC), orally bioavailable, small molecular clinical investigational drug specific to PRMT1, results in significant AR degradation and tumor repression in various prostate cancer models, especially in AR-V7-positive mCRPC. CTS2190 not only decreases AR and asymmetric dimethylarginine (ADMA) levels, but also expression of prostate-specific antigen (PSA), MYC, and many downstream genes in AR signaling pathway in 22RV1 model, more effectively than docetaxel, enzalutamide, or even PROTAC targeting AR degradation. By co-modulating AR degradation and inducing DDR/cell cycle arrest, PRMT1 inhibition with CTS2190 shows promise as a potent monotherapy and as an ideal partner for combination with standard-of-care (SoC) treatments with different MoAs such as ARPI, chemo- or radio-therapies for mCRPC patients. CTS2190 could enhance antitumor activity with ARPI, docetaxel, topoisomerase I (TOP1) inhibitor or radiation, suggesting improved outcomes in enzalutamide-resistant mCRPC. Taken together, our findings highlight CTS2190 as a therapeutic agent, either alone or in combination, for a broader range of patients with ARPI-resistant mCRPC. CTS2190 is currently under evaluation in a phase I/II clinical trial, with an expansion cohort including mCRPC patients.

#4225 Targeting RNA splicing sensitizes MTAP-deleted cancers to MTA-cooperative PRMT5 inhibitors.

Katherine K. Slemmons[1], Chun Su[2], Siyuan Liu[1], Po-Wen Yu[1], Michele McEntee[2], Eric Yuan[2], Jasper Lee[2], Jiamiao Lu[2], Aaron Horning[2], Antreas Hindoyan[1], Brian Belmontes[1], Paul E. Hughes[1]

[1]Amgen, Thousand Oaks, CA,[2]Amgen, South San Francisco, CA

AMG 193, currently in Phase 1/2 trials, is an MTA-cooperative PRMT5 inhibitor that is showing promise as a targeted therapy in MTAP-deleted tumors. *MTAP* deletion, which occurs in ~10-15% of cancers, results in the accumulation of its substrate MTA leading to the partial inhibition of the arginine methyltransferase PRMT5. AMG 193, and its representative analog AM-9747, selectively bind PRMT5 in the presence of MTA resulting in preferential growth inhibition of MTAP-deleted tumor cells while sparing normal WT cells. Mechanistically, AMG 193 treatment induces DNA damage, cell cycle arrest, and a change in alternative splicing. We previously showed that in a large tumor cell line panel, elevated baseline levels of intron retention positively correlated with sensitivity to AMG 193 suggesting alternative splicing could potentially be utilized as a biomarker (Belmontes & Slemmons et al, 2024). As a result, we hypothesized that co-targeting pre-mRNA splicing could sensitize MTAP-deleted cells to PRMT5 inhibition.

To identify modulators of response or resistance to MTA-cooperative PRMT5 inhibitors, we performed a series of drug anchored genome-wide CRISPR knockout screens in engineered MTAP-deleted cell lines (HAP1, HCT116) and endogenous MTAP-deleted cell lines (A549, MIAPACA2). In line with our previous data that PRMT5 inhibition induces alternative splicing and intron retention is associated with AMG 193 sensitivity, these screens identified components of pre-mRNA splicing and RNA processing as modulators of AMG 193 response. One exemplary hit, AKAP17A, is involved in the regulation of alternative splicing. Here we demonstrate that AKAP17A knockout drives sensitivity to MTA-cooperative PRMT5 inhibition resulting in a 3-4X IC50 decrease in HAP1 MTAP-deleted cells and a 30% increase in max effect in A549 and MIAPACA2 cells. In the MIAPACA2 xenograft model, which has moderate sensitivity to PRMT5 inhibition (average tumor growth inhibition of ~50%), the addition of AKAP17A knockout drives tumor regressions. Knockout of other components of the spliceosome or splicing regulators similarly sensitizes MTAP-deleted cells to AM-9747 treatment in vitro. In a complementary pharmacologic approach, treatment with spliceosome inhibitors synergizes with PRMT5 inhibition in MTAP-deleted cell lines but not in MTAP WT cells.

In summary, our data suggests that alternative splicing is a vulnerability in MTAP-deleted cell lines that can be perturbed to augment the activity of MTA-cooperative PRMT5 inhibitors. Additional resistance and sensitization pathways identified from the CRISPR screens are currently being evaluated using in vitro and in vivo assays. Furthermore, clinical biomarker datasets from the ongoing early phase trials will be utilized to validate these preclinical findings.

#4226 Genome-wide CRISPRi screening identifies histone modification as a synergistic partner with JAK/STAT inhibition for enhancing anti-tumor activity in CTCL, validated in PDX-derived tumor cells.

Yan-Jin Liu[1], Haitao Wang[2], Laura Pincus[3], Frank McCormick[4], Weiyun Z. Ai[1]

[1]Department of Medicine (Hematology/Oncology), UCSF, San Francisco, CA,[2]Thoracic Surgery Branch, Center for Cancer Research, NCI, NIH, Bethesda, MD,[3]Department of Dermatology, UCSF, San Francisco, CA,[4]Helen Diller Family Comprehensive Cancer Center, UCSF, San Francisco, CA

Cutaneous T-cell lymphoma (CTCL) is a subtype of non-Hodgkin lymphoma and a counterpart to the nodal form of T-cell lymphomas, peripheral T-cell lymphoma (PTCL). Patients with advanced-stage CTCL have a median survival of 3-5 years, a result that has not significantly improved for decades, highlighting an unmet medical need. The JAK/STAT pathway is frequently dysregulated in PTCL and CTCL through point mutations and copy number changes. These genetic aberrations lead to uncontrolled signaling, cell proliferation, and disease progression. The JAK/STAT pathway has been established as a suitable therapeutic target in PTCL and CTCL, with several inhibitors, including ruxolitinib, demonstrating clinical activity. However, response rates remain modest, and the clinical benefits are often transient. To identify synergistic partners for ruxolitinib, we conducted a genome-wide CRISPRi screening in CTCL cell lines, HH and Hut78. The screen identified histone modification, particularly acetylation and methylation, as a key mechanism involving the sensitivity of CTCL cells to ruxolitinib. To validate these findings, we assessed the anti-tumor activities of ruxolitinib in combination with histone-modifying agents already in clinical use, such as romidepsin and 5-azacitidine. Combination studies demonstrated that romidepsin and 5-azacitidine synergistically enhanced the growth-inhibitory and apoptotic-inducing effects of ruxolitinib in CTCL cell lines, HH and Hut 78, as well as in primary tumor cells from CTCL patient-derived xenograft (PDX) models. Notably, similar synergy was observed with golidocitinib, a novel JAK1 inhibitor that demonstrated promising clinical activity in PTCL, indicating an on-target class effect of synergy between JAK/STAT inhibition and histone-modifying agents. Using primary human CTCL cells derived from PDX models, we observed synergistic induction of apoptosis with ruxolitinib or golidocitinib in combination with either romidepsin or 5-azacitidine, as demonstrated by caspase activation assays. In conclusion, histone modification agents significantly enhance the anti-tumor activity of JAK/STAT inhibitors, promoting both growth inhibition and apoptosis induction. Synergy was observed with two distinct JAK/STAT inhibitors, ruxolitinib and golidocitinib, both already in clinical use. These findings demonstrated in primary human CTCL cells from the PDX models—a clinically relevant experimental system—highlight the translational significance of this approach. Ongoing therapeutic trials with PDX animals will further investigate these promising findings.

#4227 Chromatin remodeling enhances the anti-cancer effects of estrogen therapy in ER+ breast cancer.

Anneka L. Johnson[1], Alexa Warren[1], Nicole Traphagen[1], Alyssa Roberts[1], Patricia Muskus[2], Barbara Karakyriakou[1], Eugene Demidenko[1], Fred W. Kolling[1], Owen Wilkins[1], Kimberly Birmingham[2], Brock Christensen[1], Todd W. Miller[2]

[1]Dartmouth College, Hanover, NH,[2]Medical College of Wisconsin, Wauwatosa, WI

Resistance to endocrine therapies in estrogen receptor alpha (ER)-positive breast cancer can be driven by ER amplification or overexpression. We hypothesized that the anti-cancer effects of the estrogen 17b-estradiol (E2) could be enhanced through combination with chromatin remodeling agents. We evaluated the effects of E2 and the histone deacetylase inhibitor (HDACi) entinostat in long-term estrogen-deprived (LTED) ER+ breast cancer cells, cells engineered to overexpress exogenous ER, and mice bearing endocrine-resistant patient-derived xenografts (PDX). Assayed endpoints included apoptosis, growth, DNA damage (gamma H2AX), histone post-translational modification, ER-inducible transcripts and proteins, cell cycle and replication status, chromatin accessibility by ATAC-seq, and transcriptomic changes. HDAC inhibition with entinostat increased histone H3 acetylation (H3K27ac) in cell lines and PDX models. Combination treatment with E2 and entinostat induced higher levels of apoptosis compared to single-agent treatments in LTED cells. In ER-overexpressing cells, single-agent E2 or entinostat inhibited growth that was increased with combination treatment. Entinostat and E2 each induced DNA damage and ER target gene expression. Pre-treatment with entinostat halted cell cycling while addition of E2 stalled cells in S-phase. ATAC-seq showed entinostat increases chromatin accessibility in regions containing ER target genes. In mice, entinostat slowed tumor growth rate, while single-agent E2 and the combination of E2/entinostat induced complete tumor regression. The drug combination synergized to promote more rapid tumor regression than E2 alone, and the combination delayed time to tumor recurrence compared to single-agent E2. We conclude that combination therapy with chromatin remodeling agents and E2 synergistically inhibits ER+ breast cancer cell growth and induces tumor regression in mice. Efficacy is a result of increased DNA damage, elevated chromatin accessibility, treatment-induced ER activation, cell cycle stalling, and subsequent cell death. The novel combination of an HDACi and E2 has the potential to be an effective therapy for patients with endocrine-resistant ER+ breast cancer.

#4228 PRISM cancer cell viability profiling enables insights into clinical candidate target selectivity: A case study revealing the most selective PRMT5 inhibitors for cancers with MTAP loss.

Laura Doherty, Colleen Harrington, Mustafa Kocak, Anthony Fazio, John Davis, Emily Reeves, Rachael Barry, Claudine Mapa, Dennie Frederick, Alvin Kalathungal, Jillian Eskra, Tenzin Sangpo, Melissa Ronan, William Sellers, Matthew Rees, Jennifer Roth

Broad Institute, Cambridge, MA

PRISM is a highly multiplexed, genomic barcode-based cell line viability technology of nearly 1000 solid tumor and hematopoietic cell lines, which enables profiling of cellular responses to small molecules or biologics to discover biomarkers of sensitivity and resistance and generate mechanistic hypotheses. In addition to the genomic characterization of PRISM cell lines, we have generated large pharmacologic perturbation reference datasets such as the ever-growing PRISM Oncology Reference dataset, in which hundreds of clinical stage agents are systematically profiled for cell viability effects. To highlight the capability of PRISM to uncover novel insights regarding agent selectivity, here we describe the results of profiling seven unique protein arginine methyltransferase 5 (PRMT5) targeting agents (six inhibitors and one degrader). PRMT5 is a methyl transferase capable of methylating arginines on histones and non-histone protein substrates involved in important cellular processes such as growth and migration. Homozygous deletions of the PRMT5 regulator, methylthioadenosine phosphorylase (MTAP) occur in 10% of all cancers, including 40% of glioblastomas, 25% of pancreatic adenocarcinomas, and 15% of NSCLCs. Loss of MTAP leads to accumulation of methylthioadenosine (MTA) and partial inhibition of PRMT5, creating a potential therapeutic window for further inhibition of PRMT5. Our results reveal that the MTA-cooperative PRMT5 targeting agents are more selective for this target patient population (cancers with MTAP loss) compared to earlier classes of PRMT5 inhibitors. Additionally, our results suggest the PRMT5 degrader we tested does have on-target activity, but its effectiveness may be dampened by MDR1-mediated efflux. Taken together, these results showcase the capabilities of the PRISM assay to characterize clinical candidates for selectivity within the patient population of interest and uncover potential liabilities (such as drug transporter efflux).

#4229 GTA182: A potentially best-in-class, MTA-cooperative PRMT5 inhibitor for MTAP-deleted advanced solid tumors.

[1]Apeiron Therapeutics, Burlingame, CA,[2]Department of Orthopaedic Oncology, Shanghai General Hospital, Shanghai, China

Background: GTA182 is a second-generation, MTA-cooperative PRMT5 inhibitor developed to selectively target MTAP-null tumors, where MTAP deletion (often co-occurring with CDKN2A loss) creates a synthetic lethal vulnerability. Unlike first-generation inhibitors, GTA182 is optimized for high selectivity in MTAP-deleted versus MTAP wild-type cells, dose-proportional exposure, and CNS penetration, positioning it as a potential best-in-class treatment. GTA182 is currently in phase 1 clinical trials for advanced solid tumors with homozygous MTAP deletion.

Methods: Using structure-based design and advanced molecular modeling, GTA182 was optimized for enhanced ADME-PK properties, achieving broad systemic and CNS exposure. Preclinical selectivity and anti-tumor efficacy were evaluated in both MTAPwt and MTAP-null tumor models, with comparisons made against existing second-generation PRMT5 inhibitors.

Results: GTA182 demonstrated over 100-fold selectivity for MTAP-null cells, with strong anti-tumor efficacy at 3 mg/kg, substantially outperforming competitor compounds. Additionally, GTA182's optimized dose-proportional exposure profile resulted in a 30-fold multiple of exposure, with a therapeutic index up to 23-fold in murine mouse models, supporting its favorable safety margin and once-daily dosing. Effective blood-brain barrier penetration, exemplified by high Kp,uu and robust activity in the orthotopic U87 glioblastoma model, further supports its potential to treat CNS malignancies. Preliminary combination data with PD-1 inhibitors in MTAP-null osteosarcoma models suggest promising synergy, reinforcing GTA182's versatility and potential best-in-class status.

Conclusion: GTA182 represents a highly selective, MTA-cooperative PRMT5 inhibitor with significant preclinical efficacy and a broad therapeutic window. GTA182 is now advancing through phase 1 trials with the aim to establish safety, pharmacokinetics, and efficacy in MTAP-deleted advanced tumors. With the potential to safely address both CNS and non-CNS malignancies, GTA182 is positioned to emerge as a differentiated therapeutic in precision oncology.

#4230 Preclinical characterization of ATG-042, a novel MTAP ^{null}-selective PRMT5 inhibitor.

Ya Kong[1], Ge Lin[1], Ming Zhang[1], Peng Chen[1], Jay Mei[2], **Bing Hou**[2]

[1]Shanghai Antengene Corporation Limited, Shanghai, China,[2]Antengene Corporation, Shaoxing, China

Background: Targeting the PRMT5-MTA complex has become a promising strategy for treating MTAP^{null} cancer in a synthetically lethal manner, avoiding on-target-off-tumor hematological toxicity when using first-generation, non-selective PRMT5 inhibitors. The MTAP gene is deleted in around 10-15% of all human malignancies and the top3 human cancers with the highest frequency of MTAP deletion are GBM, pleural mesothelioma and bladder cancer with high unmet medical need (TCGA data). Herein, we report the preclinical feature of ATG-042, a novel MTAP^{null}-selective PRMT5 small molecule inhibitor with good brain penetration.

Methods: The in vitro activity and MTAP selectivity of ATG-042 on cell proliferation were profiled using HCT116 MTAP wild type (wt) cells, HCT116 MTAP knock out (ko) cells and multiple endogenous MTAP^{null} cell lines. The in vivo efficacy was tested in cell derived xenograft (CDX) mouse models with HCT116 MTAP wt cells, HCT116 MTAP ko cells, LU99 cells (MTAP^{null}) and U87MG-luc (MTAP^{null}). The pharmacokinetic and toxicological properties were assessed with corresponding assay methods.

Results: ATG-042 demonstrated potent and selectively inhibitory effect on HCT116 MTAP ko cells' proliferation (IC_{50}=52nM) and SDMA expression (IC_{50}=0.06nM), but very weak effect on HCT116 MTAP wt cells. Consistently, ATG-042 showed excellent anti-proliferative activities on multiple endogenous MTAP^{null} cell lines with IC_{50} values between 10nM and 100nM. ATG-042 demonstrated high permeability (Caco2 assay, A to B, P_{app} =12.2 x10^{-6}cm/s;ER=0.9), good metabolic stability, and low risk of drug-drug interaction. In vivo PK study shows that ATG-042 is well absorbed, with a dose-dependent increase in plasma distribution and high oral bioavailability in mice, SD rats and beagle dogs. Furthermore, ATG-042 is brain-penetrable (B/P ratio=51% in mice; $KPuu_{brain}$=0.73 in rats). ATG-042 showed robust in vivo efficacy in both subcutaneous CDX models (HCT116 -MTAP ko, LU99) and orthotopic CDX model (U87MG-luc) as a single agent. In addition, ATG-042 also exhibited the potential in combination with other drugs for antitumor therapy. ATG-042 was well tolerated in both SD rats and beagle dogs after four weeks of continuous administration.

Conclusions: In summary, ATG-042 is an oral MTAP ^{null}-selective PRMT5 inhibitor with potent efficacy against MTAP^{null} tumor. It also demonstrated good tolerability and brain penetrability.

#4231 Preclinical candidate RVU305, an MTA-cooperative PRMT5 inhibitor, shows activity in MTAP-deleted tumors resistant to immune checkpoint treatment.

Anna Bartosik, Adam Radzimierski, Aneta Bobowska, Aleksandra Więckowska, Kamil Kuś, Jacek Faber, Bożena Winnik, Agata Stachowicz-Wałaszek, Agnieszka Ludwig-Słomczyńska, Kamila Kozłowska-Tomczyk, Marta Wadowska, Szymon Woroszyło, Mateusz Stoszko, Aniela Gołas, Paulina Podkalicka, Adrian Zarębski, Agnieszka Piątek, Maciej Kujawa, Beata Kowalska, Julia Wirkijowska, Stefan Chmielewski, Jacek Stępniewski, Mateusz Ogorek, Lika Osugui, Agnieszka Szymula, Agnieszka Dorman, Kamila Białkowska, Marcelina Chmiel, Milena Mazan, Tomasz Rzymski, Karolina Gluza, Joanna Krawczyk, Marcin Kowiel, Adam Marciniak, Michał Combik, Oleksii Bryzghalov, Mateusz Nowak, Didier Pez, **Krzysztof Brzozka**

Ryvu Therapeutics, Krakow, Poland

Homozygous deletions of methylthioadenosine phosphorylase (MTAP), located on chromosome 9p21 are observed in 10 to 15% of all human tumors. This deletion leads to a substantial methylthioadenosine (MTA) build-up within cells. At high concentrations, MTA acts as a highly selective inhibitor of the PRMT5 methyltransferase, specifically competing with its substrate, S-adenosylmethionine (SAM). Hence, selectively targeting of residual PRMT5 levels, which are essential for survival of cancers, represents a promising strategy for eliminating cancer cells with homozygous MTAP deletion. There is growing evidence that MTA accumulation enhances immunosuppressive tumor microenvironment. Moreover, tumor-specific PRMT5 inhibition has been shown to enhance antitumor immune responses, opening the possibility of combining MTAP-deletion specific MTA-cooperative PRMT5 inhibitors with cancer immunotherapy. Ryvu has developed RVU305, a potentially best-in-class MTA-cooperative PRMT5 inhibitor, characterized by favorable drug-like physicochemical properties, low nanomolar potency, and differential efficacy in MTAP-null cancer cells. To evaluate the immunomodulatory activity of RVU305, we developed an MC38 syngeneic colon cancer model with homozygous deletion of MTAP and CDKN2A genes. The tumor growth inhibitory activity of RVU305 was assessed following oral administration, both alone and in combination with anti-PD-1 antibody. Effects on tumor-infiltrating lymphocytes were analyzed using flow cytometry. Changes in IFN-γ-secreting T cells were evaluated using ELISpot. PRMT5 inhibition in MTAP-null cancer cells, as well as in stromal and infiltrating lymphocytes, was assessed via SDMA IHC staining. RVU305 demonstrated robust tumor growth inhibition (TGI) in MC38 tumors with MTAP loss, with confirmed target engagement, while the growth of the MC38 variant with an intact MTAP gene was unaffected at pharmacologically active doses. Furthermore, co-treatment with RVU305 and anti-PD-1 antibody was well tolerated and resulted in antitumor activity. Immunomodulatory effects of RVU305, both alone and in combination with anti-PD-1, were supported by pharmacodynamic changes observed in tumor tissue. Taken together, these studies confirm that MTA-cooperative PRMT5 inhibitors induce a strong synthetic lethal phenotype in MTAP-deleted cancers, offering an exciting therapeutic opportunity for a large patient population and potentially addressing an unmet clinical need when combined with immunotherapy.

#4232 DW91170B: A novel potent EZH1/2 dual inhibitor for adrenocortical carcinoma treatment.

Doc-Gyun Jeong[1], **Yeonkyung Oh**[1], Woon Heo[1], DongHyuk Shin[1], Jung Hee Kim[2], Emilia Moonkyung Youm[2], Jihyun Youm[1], Kiyoon Kim[1], Sangho Lee[1], Yun-Ha Hwang[1]

[1]Dongwha Pharma, Yongin, Korea, Republic of,[2]Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea, Republic of

Adrenocortical carcinoma (ACC) is an aggressive cancer that occurs in the adrenal cortex with a poor prognosis, and its 5-year survival rate is less than 60%. Previous studies have characterized molecular and cellular alterations in ACC, including changes in p53, the WNT-β-catenin pathway, PKA, and chromatin remodeling pathways. EZH2 (Enhancer of zeste homolog 2), a catalytic subunit of PRC2 (polycomb repressive complex 2), also exhibits abnormal characteristics in ACC. EZH2 has been reported to be overexpressed in ACC patients and is associated with disease progression and survival rates. Here, we present DW91170B, a novel and potent dual inhibitor of EZH1/2, as a candidate for the treatment of adrenocortical carcinoma. DW91170B induces histone modification by reducing the trimethylation of H3K27, suppresses cell viability, and induces apoptosis in adrenal cancer cells. Additionally, DW91170B affects the molecular and cellular characteristics of adrenal cancer cells. Specifically, treatment with DW91170B reduces the expression of HSD3B2 and CYP11B1, genes involved in steroidogenic process. As a result, aldosterone and cortisol secretion induced by forskolin is inhibited by DW91170B. Long-term treatment with DW91170B decreases the expression of transcription regulators such as β-catenin and SF-1. These changes in transcriptional complex were confirmed through RNA sequencing, revealing alterations in gene expression. Among the differentially expressed genes, those related to epithelial-mesenchymal transition (EMT) and apical junctions were notably affected. Functional changes were further confirmed by EMT marker protein expression and a wound healing assay. The in vivo efficacy of DW91170B was assessed in two adrenal cancer models. NCI-H295R cells, which have high expression EZH2, and SW13 cells, which carry a SMARCA4 mutation that is susceptible to synthetic lethality from EZH2 inhibition, were used. DW91170B effectively inhibited tumor growth in both models. In summary, the novel EZH1/2 inhibitor DW91170B exhibits anti-tumor efficacy in adrenocortical carcinoma. These effects appear to be mediated by alterations in cancer cell characteristics and the inhibition of cell survival.

#4233 Ovarian cancer treatments: Using HSF1 and MYC gene amplification as a biomarker.

Matthew S. O'Malley[1], Imade Williams[1], Haddie DeHart[1], Bobby Walker[2], Vrushabh Ulhaskumar[2], Haimanti Ray[2], Pranav Jothirajah[3], Joe R. Delaney[4], Kenneth P. Nephew[5], Richard Carpenter[6]

[1]Medical Sciences, Melvin and Bren Simon Comprehensive Cancer Center, Indiana University School of Medicine - Bloomington, Bloomington, IN,[2]Medical Sciences, Indiana University School of Medicine - Bloomington, Bloomington, IN,[3]Medical Sciences, Indiana University Bloomington, Bloomington, IN,[4]Biochemistry and Molecular Biology, Medical University of South Carolina, Charleston, SC,[5]Melvin and Bren Simon Comprehensive Cancer Center, Anatomy, Cell Biology & Physiology, Indiana University School of Medicine - Bloomington, Bloomington, IN,[6]Melvin and Bren Simon Comprehensive Cancer Center, Biochemistry and Molecular Biology, Indiana University School of Medicine - Bloomington, Bloomington, IN

Ovarian cancer is one of the deadliest gynecological malignancies as approximately 1 in 87 women will die from this disease. One of the reasons for such a dismal prognosis for the disease is due to the limited treatment options and high rate of relapse from the first line treatment of platinum-based chemotherapy and taxanes. Therefore, patients with ovarian cancer would greatly benefit from new treatment options. To find new treatment options for ovarian cancer, we looked for ideal targets by analyzing the biology of high-grade serous ovarian cancer (HGSOC), the most common and most deadly form of ovarian cancer. This type of ovarian cancer is classified by high rates of amplification of oncogenes such as MYC, KRAS, and CCNE1, however this knowledge of oncogene amplification has been understudied as a genetic biomarker for efficacy of various treatments. Approximately 30% of ovarian cancers carry amplifications of both the MYC and Heat-shock Factor 1 (HSF1) oncogenes, which have both been shown to contribute to worse survival in multiple cancer types through mechanisms such as increased proliferation, metastasis, and immune evasion. Many drugs have been developed to directly bind to and inhibit these targets, however none have had success in clinical trials in part due to the difficulty in designing drugs to potently and specifically target transcription factors. To inhibit the activity of the MYC and HSF1 transcription factors in HGSOC, we tested alternative mechanisms of MYC and HSF1 inhibition through targeting a shared activating kinase, Polo-like Kinase 1 (PLK1), with the PLK1 inhibitor Volasertib (BI-6727). Since HSF1 and MYC are both transcription factors, we also aimed to find an epigenetic method of inhibiting their transcriptional activity. We performed a drug screen of epigenetic inhibitors in the background of HGSOC cells that carried the HSF1 and MYC co-amplification and a counter-screen of HGSOC cells that did not carry these amplifications. Results from this screen show that cells that are coamplified for the HSF1 and MYC oncogenes are more sensitive to treatment with class I HDAC inhibitors than HGSOC cells without this amplification. We show that treatment with the class I HDAC inhibitor Entinostat decreases the HSF1 and MYC expression at the mRNA and protein level. We show that loss of HSF1 and MYC decrease proliferation and colony formation ability of ovarian cancer cells using knockdown siRNAs and that the Volasertib and Entinostat inhibitors are more effective in treating ovarian cancers that carry amplifications of HSF1 and MYC than those with other driver amplifications. Work with both Volasertib and Entinostat aim to show that amplifications of oncogenes in high-grade serous ovarian cancer can be used as a biomarker for new treatment strategies in ovarian cancer.

#4234 Synergistic anti-proliferative effects of JIN-001, a novel HSP90 selective inhibitor, in combination with platinum-based drugs in ovarian cancer cell lines.

Jue Young Kim[1], Ha-Yeon Shin[1], Anna Jo[2], Ethan Seah[2], Choonok Kim[2], Jae-Hoon Kim[1]

[1]Gangnam Severance Hospital, Seoul, Korea, Republic of,[2]J INTS BIO Inc., Seoul, Korea, Republic of

Introduction: Heat shock proteins (HSPs) have been considered as a promising therapeutic target for ovarian cancer (OC), the most lethal gynecologic malignancy. HSPs facilitate tumor cell adaptation to short-term stress, promoting the development of more malignant phenotypes and the acquisition of resistance to therapeutic treatments over time. To date, Clinical trials of HSP90 inhibitors have shown modest benefits in advanced cancer patients, with no sufficient efficacy as monotherapy. Here, We investigated the anti-proliferative effects of JIN-001, a selective HSP90i, combined with platinum-based drugs in OC cell lines.

Material and methods: We examined the co-treatment effects of JIN-001 and paclitaxel (PTX) or cisplatin (Cis, platinum-based) on viability in OC cell lines (OV90, TOV21G, and OVCAR3) and drug-resistance sublines (OV90/PTX200, TOV21G/PTX100, and OVCAR3-CisR). Drug-resistant OC sublines were generated by gradually exposing OC cells to increasing concentrations of PTX or Cis. Each drug was tested either for monotherapy or in 1:1 ratio combination. Also, we assessed the synergistic anti-proliferative effects of JIN-001 (0.1 or 0.05 μM) with Cis on OVCAR3 and OVCAR3-CisR.

Results: Co-treatment of JIN-001 with PTX or Cis reduced IC_{50} in drug-resistant OC sublines compared to PTX or Cis alone. The IC_{50} of JIN-001 at a fixed dose in combination with Cis were lower in the OVACAR3 and OVCAR-CisR, compared to the single treatment. IC_{50} (μM) are shown below.

	Cell line					
Treatment	**OV90**	**OV90/PTX200**	**TOV21G**	**TOV21G/PTX100**	**OVCAR3**	**OVCAR3-CisR**
PTX	0.021	0.204	0.002	0.235	-	-
Cis	-	-	-	-	1.886	9.643
JIN-001+PTX	0.011	0.043	0.001	0.031	-	-
JIN-001+Cis	-	-	-	-	0.070	0.142
JIN-001 (0.1 μM)+Cis	-	-	-	-	0.022	0.282
JIN-001 (0.05 μM)+Cis	-	-	-	-	0.149	0.606

Conclusion: The combination of JIN-001 with PTX or Cis enhanced anti-proliferative effects and reduced IC_{50} in OC cell lines and drug-resistant sublines compared to monotherapy. This suggests JIN-001's potential as a combination therapy with platinum-based drugs in OC patients. Further studies are needed to examine whether the combination therapy of JIN-001 and the conventional drugs decelerates the tumor's ability to adapt and develop drug resistance.

#4235 PCNA and histone deacetylase targeted inhibitors in cutaneous T-cell lymphoma.

Caroline M. Li, Robert G. Lingeman, Long Gu, Robert J. Hickey, Linda H. Malkas

Beckman Research Institute of The City of Hope, Duarte, CA

AOH1996, a small molecule designed to bind proliferating cell nuclear antigen (PCNA), demonstrates selective inhibition of cancer cell growth across the NCI60 cell line panel with a mean GI50 of 300 nM, while exhibiting minimal toxicity to nonmalignant cells. Mechanistic studies reveal that AOH1996 influences DNA replication, cell cycle progression, DNA damage response, and transcription-replication conflicts. Inspired by phosphoproteomic analyses of AOH1996-treated cells, we investigated its potential in combination therapy with the histone deacetylase inhibitors (HDACi) vorinostat and belinostat. Notably, vorinostat, an FDA-approved treatment for cutaneous T-cell lymphoma (CTCL), exhibited synergistic effects with AOH1996 in cell viability assays with three CTCL derived cell lines. To better understand enhanced cell killing, we show combination drug effects on apoptosis, DNA damage and PCNA protein expression. Enhanced growth inhibition was also observed when AOH1996 was combined with other HDACi, such as domatinostat and panobinostat. These findings highlight the therapeutic potential of AOH1996 in combination with HDACi, particularly for CTCL, and pave the way for further exploration of this approach in cancer treatment.

#4236 Effects of a DNMT1-selective inhibitor on T-cell activity and tumor cells intrinsic pro-inflammatory response.

S. W. O'Brien, S. Rajapurkar, A. Della Pietra III, H. Sun, A. Fedoriw, M. McCabe, M. Pappalardi;
GSK, Collegeville, PA

Previous studies indicate that while combinations of DNA methyltransferase inhibitors, such as decitabine or 5-azacytadine, with immunotherapies has shown potential in activating anti-tumor activity, their limited clinical success could be attributed to the systemic delivery and toxic effects on the immune cells in the microenvironment, which may explain the lack of activity in clinical trials. To explore the potential of combining an epigenetic inhibitor with an immunomodulatory agent, the effects of a DNMT1 inhibitor on T-cell activity and intrinsic pro-inflammatory responses in tumor cells were examined. Human and mouse cancer cell lines or isolated T-cells were treated with DNMT1-selective inhibitors and assessed for gene expression, global DNA methylation, mass cytometry, fluorescent cytometry, and chemokine ELISA. DNMT1-selective inhibitors triggered a pro-inflammatory transcriptional response in human cancer cell lines similar to decitabine. In human T-cells, DNMT1 inhibition reduced proliferation and increased markers of both anti-inflammatory and pro-inflammatory phenotypes, with these changes being reversible upon compound removal. Mouse T-cells similarly exhibited temporary loss of proliferation and increased anti-inflammatory and pro-inflammatory phenotypes. Additionally, DNMT1 inhibition elevated the expression of anti-inflammatory cytokines IL-10 and IL-4 in both human and mouse T-cells. Notably, DNMT1 inhibition resulted in a lasting pro-inflammatory transcriptional response in malignant cancer cell lines, whereas the effect on normal cells was reversible. In summary, DNMT1-selective inhibitors may boost the efficacy of immuno-oncology therapies by inducing a pro-inflammatory response in cancer cell lines while minimizing impact on T-cells through alternative dosing schedules. Further research is required to compare DNMT1-selective inhibitors with traditional HMAs and to study the interaction between immune and cancer cells in vivo. Identifying biomarkers for patient stratification could help optimize treatment strategies. This study highlights the importance of evaluating the impact of small molecule inhibitors on both tumor characteristics and immune responses to optimize conditions for effective anti-tumor responses.

#4237 Homogenous detection of O-Acetyl-ADP-ribose as a generic HTS assay method for SIRTs.

Ha Pham, Mahbbat Ali, Anibal Ramos-Martinez, Robert Lowery

BellBrook Labs, Madison, WI

Sirtuins (SIRTs) are deacetylases that catalyze removal of acetyl groups from histones and other proteins; they are important components of the epigenetic regulatory landscape and have been targeted for diverse indications, including cancer. SIRTs deacetylate in an NAD-dependent reaction that yields O-acetyl-ADP-ribose (OAADPr) and nicotinamide as products along with the deacetylated protein. Screening and hit-to-lead efforts targeting SIRTs has been hampered by a lack of robust HTS assays methods for detection of SIRT enzymatic activity, a situation that is exacerbated by the diversity of deacetylated protein products and the inherent instability of the OAADPr product. To address this unmet need, we developed a generic activity assay for SIRTs based on enzymatic conversion of OAADPr to AMP in real time, which is then detected using the Transcreener AMP/GMP assay with a fluorescence polarization (FP) or time resolved Förster resonance energy transfer (TR-FRET) readout. Using recombinant full length Sirt1 and Sirt2, we determined optimal NAD, acetylated peptide substrate, and enzyme concentration for initial velocity detection of deacetylase activity. For both enzymes, a robust signal was observed using concentrations in the nanomolar range, and there was good concordance in activity measured using FP and TR-FRET readouts. The assays were validated for HTS using a 1,280 collection of bioactive compounds. Selected hits were further profiled in dose-response assays. The assay Z' value was above 0.7, supporting its robustness for screening and hit-to-lead/SAR for Sirt1 and Sirt2 antagonists. To our knowledge, the Transcreener OAADPr assay is the first SIRT activity assay that relies on detection of OAADPr rather than the deacetylated protein product. By enabling homogenous detection of SIRT activity with native acetylated substrates, it should simplify screening and profiling of inhibitors and facilitate drug discovery efforts targeting SIRTs.

#4238 DNMT1 inhibition by SGI-1027 promotes neuroblastoma cell death through a p53-independent pathway.

Farah Naz, Shyam Sundar Jaganathan, Umamaheswari Natarajan, Appu Rathinavelu

Rumbaugh Goodwin Institute for Cancer Research, Barry & Judy Silverman College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL

Introduction: Neuroblastoma is an aggressive childhood cancer originating from neural crest cells, accounting for 700-800 new cases annually and cuases15% of pediatric cancer deaths in the U.S. Treatment for high-risk neuroblastoma includes chemotherapy, stem cell transplants, radiation, and immunotherapy. Recent evidence suggests that DNMTs inhibitors such as SGI-1027 and CM-272 can potentiate apoptosis *via* epigenetic modulation of critical regulatory pathways in cancers. Hence, we hypothesized that SGI-1027 can induce apoptosis in SK-N-SH neuroblastoma cells by upregulating p21 through DNMT1 inhibition. Our study aimed to elucidate the underlying mechanisms and assess the potential of using SGI-1027 for treating high-risk neuroblastoma.

Methods: SK-N-SH cells were treated with 2 µM of SGI -1027 for 24 hrs. The cell viability was evaluated using Trypan Blue Dye Exclusion method, while apoptotic activity was quantified through a fluorescence assay using DEVD-*amc* substrate for measuring caspase-3/7 activation. qRT-PCR and Western Blot analyses were conducted to assess expression levels of the cell cycle, apoptotic, and epigenetic pathway-related markers such as p53, p21, PARP, BAX, BCL-XL, and DNMT1. Apoptotic changes in cells were further confirmed through Immunofluorescence studies.

Results: Our study results confirmed that SK-N-SH cells treated with SGI-1027 showed significant cell death and enhanced fluorescence in the DEVD-*amc*, indicating activation of apoptotic activity. Consistent with our hypothesis, we observed an elevation in p21 levels, an increased BAX/BCL-XL ratio, and a downregulation in the levels of DNMT1, suggesting that SGI-1027 may be facilitating neuroblastoma cell death through a p21-driven mechanism that is independent of p53 pathway.

Conclusion: This study highlights the potential of DNMT1 inhibitor SGI-1027 to induce apoptosis in neuroblastoma cells through upregulating p21 and modulating the BAX/BCL-XL ratio. Our findings suggest that targeting DNMT1 using SGI-1027 may offer an effective pathway for inducing cell death and controlling neuroblastoma growth. We are in the process of validating DNMT1 targeted therapies as a powerful addition for treating aggressive neuroblastoma.

Acknowledgments: This project was supported by the National Pediatric Cancer Foundation (NPCF) and the Royal Dames of Cancer Research Inc., Fort Lauderdale, Florida.

#4239 Effect of MTAP expression on PRMT5 inhibitor sensitivity in bladder urothelial carcinoma models.

Connor Purcell[1], Leiqing Zhang[1], Maryam Ghandali[1], Maximilian Pinho-Schwerrman[2], Paola Gyuliane[1], Brian K. Baker[3], Lanlan Zhou[1], Dinara Ryspayeva[1], Benedito A. Carneiro[1], Wafik S. El-Deiry[1]

[1]Legorreta Cancer Center at Brown University, Providence, RI,[2]Brown University Health, Providence, RI,[3]Morehouse School of Medicine, Atlanta, GA

Introduction: Methylthioadenosine phosphorylase (MTAP) is a metabolic enzyme integral to the methionine/adenine salvage pathway, whose expression is lost in 30% of bladder cancer (BCa). The cellular changes associated with MTAP loss, such as accumulation of its substrate, MTA, increase the dependence of cancer cells on other metabolic enzymes, opening opportunities for synthetically lethal targeted therapy. One such target is protein arginine methyltransferase 5 (PRMT5), which relies on the methionine-cycle intermediate SAM to methylate proteins. An emerging class of PRMT5 inhibitors exploits the increased dependence of MTAP-deficient tumors on PRMT5 to induce tumor-specific death. The present study investigates the sensitivity of genetically engineered BCa cell lines and patient-derived organoids (PDOs) to the PRMT5 inhibitor AZ14209703.
Methods: MTAP was knocked out of BCa cell line 5637 (MTAP+) by 48h reverse transfection with recombinant Cas9 and MTAP or CTRL sgRNAs. MTAP was overexpressed in MTAP-null BCa cell lines RT4 and UM-UC-3 and a patient-derived organoid by lentiviral transduction with a stable MTAP overexpression (OE) plasmid or empty vector (EV). Protein expression was determined by western blot (WB). For viability assays, cells were plated at 1000 cells/well in a 96 well plate and allowed to adhere overnight before treatment. Viability was assessed 7d after AZ14209703 treatment by Cell-TiterGlo® assay, and IC50 and area under the curve (AUC) were computed.
Results: WB analysis showed no detectable MTAP in 5637 cells transfected with the MTAP sgRNA-Cas9 complex and, conversely, robust overexpression in RT4, UM-UC-3, and the PDO following lentiviral transduction. In viability assays, MTAP expression conferred protection from PRMT5i in all models tested. 5637 MTAP-/- cells exhibited reduced area under the curve (AUC) and IC50 compared to the sgCTRL. MTAP OE in UM-UC-3 and RT4 increased the AUC and IC50 versus the EV.
Conclusions: The present findings suggest that PRMT5i is highly selective to MTAP-deficient BCa models. Future work involving these models will characterize the sensitivity of the MTAP-OE PDO to PRMT5i, study the effects of MTAP and PRMT5i on T and NK cell killing, and determine whether MTAP status affects the potency of PRMT5i in combination with other therapies.

#4240 Combining belinostat with red grape seed extract effectively inhibits cell proliferation, induces apoptosis, and reduces tumor resistance to doxorubicin by targeting mutant KRAS and p-ERK in human breast cancer.

Mariam Shaker Kerema, Sara Hassan Deghedy, Sofia Khalil, Ahmed Samir Sultan

Biochemistry, Alexandria University, Alexandria, Egypt

Breast cancer ranks as the second most prevalent type of cancer worldwide. Despite significant advancements in various therapeutic approaches, the incidence rates continue to rise due to the resistance caused by elevated levels of histone de-acetylating enzymes (HDACs). The current study aims to investigate a combination therapy involving red grape seed extract (GSE) and Belinostat (PXD101), a hydroxamate-type inhibitor of histone deacetylase (HDAC), as a novel treatment to overcome resistance in breast cancer. *In vitro*, Two breast cancer cell lines spanning from poorly to highly differentiated cell lines, MDA-MB-231 and ZR-75-1, were tested with PXD101, GSE, and their combined treatment with or without Doxorubicin treatments. The WST-1 assay was utilized to evaluate the potential synergies of this combination in reducing proliferation and inducing apoptosis in the tested cells. Additionally, the underlying molecular mechanisms responsible for cancer cell death were explored through western blotting, histone release assays, assessment of caspase-3 levels, and immunohistochemistry (IHC) to determine the localization of oncogenic markers. The Wst-1 combination assay revealed that the viability of PXD101/GSE treated cells significantly varied in a concentration-dependent manner compared to the control untreated cells or each compound after 48 h of treatment. The calculated combination index indicated a synergistic effect in MDA-MB-231 cells, although this was not observed in ZR-75-1 cells. Moreover, the combination treatment for up to 48h triggered apoptosis in both cell lines, as evidenced by morphological changes, histone release alterations, increased caspase-3 activity, and significant inhibition of mutant KRAS and p-ERK expression levels. Immunohistochemical analysis of β-catenin localization indicated its presence at cell-cell contacts and in the cytoplasmic compartment, contrasting with its localization in the nuclei of untreated control cells. In an *in vivo* study utilizing the MDA-MB-231 orthotopic xenograft model, the combined treatment exhibited remarkable anticancer activity compared to the control and individual drugs. Importantly, our findings demonstrated that the combination treatment had significant inhibitory effects on tumor growth and metastatic potential, with minimal toxicity relative to untreated control tumors. Additionally, this combination enhanced efficacy, reduced toxicity, and decreased tumor resistance to Doxorubicin after 48h of treatment. Overall, our findings propose a PXD101/GSE combination as a potential non-toxic fingerprint that exhibits promising anticancer activity against Doxorubicin resistance. This combination warrants further exploration in combination therapy for human breast cancer.

InduPro, Cambridge, MA

Despite advances in cancer therapeutics, there remains a critical need to identify new protein targets and targeting approaches for drug development, particularly those with improved efficacy and safety profiles. To address these challenges, InduPro leverages a high-resolution proximity proteomics technology that uses photocatalyst-generated reactive probes to label cell surface protein microenvironments (1,2). Combining this technology with quantitative mass spectrometry, we achieve high-throughput characterization of the plasma membrane protein interactome at an unprecedented detail. The integration of this specialized proximity proteomics data with clinical protein expression profiles through computational graphs and graph convolutional neural networks (GCNNs) provides powerful opportunities for surface protein target analysis and unique biological insight.

This approach enables the identification of surface antigens in close proximity to tumor associated antigens (TAAs) within tumor microenvironments. Here, we refer to these proximal antigens as tumor associated proximity antigens (TAPAs). The co-localization and interrelated biological functions of these antigens facilitate precise dual-targeting of malignant cells, while sparing healthy tissues. This approach addresses existing limitations in cancer therapeutics, particularly the off-target effects associated with TAAs expressed on normal cells, and the poor efficacy of some tumor-specific antigens as standalone targets. Through leveraging these TAPAs, we can explore a diverse range of bispecific therapeutic modalities, including but not limited to antibody-drug conjugates (ADCs), T-cell engagers (TCEs), and radioligand therapies (RLTs).

By applying our MInt platform to cancer cell lines, patient-derived tumor samples, and animal model xenografts, we have generated a database of protein interaction networks for many TAAs comprising millions of data points. This has resulted in the identification of novel TAA x TAPA bispecific pairings across multiple indications. This platform has led to multiple preclinical programs, including IDP-001, a bispecific ADC targeting EGFR and CDCP1 in solid tumors.

Here, we showcase our discovery engine for novel target identification as a powerful method for uncovering druggable protein targets with improved therapeutic windows. This approach has the potential to expand the repertoire of cancer targets and enable the next generation of bispecific therapeutics.

#4245 Targeting ERalpha disorder-function mechanisms in ER-positive breast cancer.

Zhanwen Du, Shuqi Luo, **Sichun Yang**

Case Western Reserve University School of Medicine, Cleveland, OH

Background: The estrogen receptor (ER or ERalpha) is commonly activated by phosphorylation at serine 118 (Ser118) within its intrinsically disordered N-terminal transactivation domain (NTD), enabling estrogen-independent function in breast cancer. While kinase inhibitors targeting this modification are in clinical trials, understanding the molecular mechanism of activation is essential for developing direct therapeutic strategies.
Methods: We combined small-angle X-ray scattering and NMR spectroscopy with functional assays to characterize conformational changes in the ER-NTD. We then conducted activity-guided screening to identify small molecules directly targeting the disordered NTD.
Results: Ser118 phosphorylation triggers an unexpected conformational expansion by disrupting specific hydrophobic clusters between aromatic-rich regions within the NTD - a mechanism extending beyond simple electrostatic effects (Nature 2024, in press). Leveraging this insight, we developed selective small molecules that directly bind the disordered NTD and potently inhibit growth of hormone-independent breast cancer models.
Conclusions: Our work establishes both the mechanistic basis of ER regulation and a therapeutic framework for targeting intrinsically disordered regions in treatment-resistant breast cancer. These findings open a new avenue for first-in-class drugs that modulate protein disorder in cancer.

#4246 Degradation of the ETS transcription factor ERG by stabilized helical peptide (Helicon™) degraders enables pharmacological validation in ERG-fusion prostate cancer models.

Amelia K. Luciano, Brian White, Graeme Lambert, Aaron Fulgham, Ian Wallace, Shelagh Fluharty, Miroslaw Lech, Dakota Hawkins, Pevindi Jayasuriya, Tara Travaline, Paula Ortet, Mallika Iyengar, Julia Bowers, Yusuf Vohra, Santosh Choudary, John Santa Maria, Jason Hoki, Claire May, Mark Ator, Brandon Nicolay, Diwakar Pattabiraman, Alexander W. Hird, Markus Haeberlein, Jonathan Hurov

Parabilis Medicines, Cambridge, MA

Approximately 300,000 new prostate cancer patient diagnoses and 35,000 deaths due to prostate cancer are documented annually in the United States. An estimated 40-50% of all prostate cancers harbor the TMPRSS2-ERG fusion, leading to androgen receptor (AR)-driven expression of the oncogene ERG. As a transcription factor, ERG induces tumorigenesis by increasing cell proliferation and both invasion and migration of tumor cells, promoting their metastatic ability. ERG and AR have interconnected functions in prostate cancer, where together they strike a balance between proliferative potential and luminal differentiation. ERG also enhances the stemness of prostate cancer cells by interacting with epigenetic modifiers such as EZH2, MAT2A, and the SWI/SNF complex, which may lead to increased therapeutic resistance after treatment with AR targeted therapies. While genetic deletion or knockdown demonstrates tumor dependence on ERG, the lack of small molecule ligandable pockets on ERG has limited preclinical target validation and pharmacological proof of concept. Using the Helicon™ (stabilized helical peptides) drug discovery platform, we can efficiently discover binders of traditionally undruggable targets lacking small-molecule binding pockets, like transcription factors. An example Helicon™ is our inhibitor of the β-catenin-TCF4 interaction, FOG-001, which is currently being evaluated in a Ph1/2 clinical trial (NCT05919264). ERG is a well-suited candidate for a Helicon™-based approach to targeting. Here we demonstrate the discovery of molecules that induce targeted ubiquitin-proteosome degradation of ERG by appending E3-ligase ligands to ERG Helicon™ binders. We demonstrate that ERG-degrader Helicons™ bind selectively and with high affinity to ERG in biochemical assays. In cells, ERG is potently degraded via an E3-ligase-dependent mechanism, reducing downstream expression of its target genes. Using both human cell line- (CDX) and patient-derived xenograft (PDX) models, we demonstrate deep and durable degradation of ERG with our Helicon™ degraders and have confirmed for the first time that pharmacological reduction of ERG protein levels leads to substantial tumor growth inhibition. Collectively these data demonstrate preclinical proof of concept for this therapeutic target and mechanism of action. Ongoing optimization of these Helicons™ may allow clinical application of ERG degraders in a patient population with high unmet need.

#4247 Discovery of GH3595: a novel allosteric DHX9 inhibitor for cancer therapy.

Faridoon Faridoon, Jiapeng Li, Jiyue Zheng, Xiang Wang, Guiping Zhang

Suzhou Genhouse Pharmaceutical Co., Ltd., Suzhou, China

DExH-Box helicase 9 (DHX9), also known as RNA helicase A (RHA), belongs to the DExD/H-Box superfamily II of helicases. Due to its fundamental roles in processes such as transcription and maintenance of genomic stability, DHX9 has emerged as a key regulator in various cancer types. Specifically, microsatellite instable (MSI) cancers, such as MSI-high (MSI-H) colorectal cancer, and tumors with defective homologous recombination exhibit a strong dependency on DHX9, suggesting that targeting DHX9 could offer a significant therapeutic opportunity. Employing fragment-based drug design, we have discovered GH3595, a novel allosteric DHX9 inhibitor that selectively targets the DHX9 protein. *In vitro*, GH3595 displayed a low nM potency in ATPase and helicase activity assays, which translated to specific low nM inhibition of MSI-H colorectal cancer and BRCA loss of function breast cancer proliferation. *In vivo*, GH3595 demonstrated favorable pharmacokinetic properties in different species and showed an acceptable safety profile. Furthermore, daily oral dosing of GH3595 led to the regression of MSI-H xenograft tumors without adverse effects on body weight. More importantly, GH3595 induced dose-dependent intra-tumoral circular RNA induction, showing a well-correlated PK/PD/Efficacy relationship. In summary, we report the discovery and characterization of GH3595, a potent and selective inhibitor of DHX9, which effectively disrupts DHX9-mediated signaling pathways. These findings highlight its significant therapeutic potential for the treatment of malignancies characterized by microsatellite instability or deficiencies in homologous recombination.

#4248 Statin-derived small-molecule inhibitors of metastasis (SIM) for high-risk epithelial cancers.

Moe Ishihara, Junhui Hu, Glen Brodie, Elizabeth Bowen, Shannon Shams, Diana Vaca, Jimin Kim, Stuart Conway, Robert Damoiseaux, Lily Wu

UCLA David Geffen School of Medicine, Los Angeles, CA

Background: Metastasis is the deadliest cancer stage, and there is no universal treatment. Different tumors have distinct tissue-specific signatures, but as cancer progresses, they follow a common evolutionary trajectory toward invasiveness and metastasis. Targeting this shared vulnerability in metastatic tumors holds significant translational potential. Recent insights from kidney cancer reveal a novel metastatic mechanism, leading to the discovery of small-molecule drugs, SIMs, that selectively inhibit metastasis across cancers. By understanding SIMs, we aimed to create safer, more effective treatments, potentially saving over 500,000 lives annually in the U.S.
Methods & Results: 1) New concept: Metastasis requires cooperation between VHL+ and VHL- cells, with VHL- cells driving growth and migration in VHL+ cells. 2) SIM candidates: In high-throughput screening of 2,530 FDA-approved drugs, small-molecule compounds selectively inhibiting VHL cells were identified, with fluvastatin being the most potent ("SIM-1"). Subsequent SAR studies identified SIM-2, four times more potent than fluvastatin (IC50 < 0.1uM). 3) Older statins (fluvastatin, simvastatin) were more cytotoxic than newer statins (e.g., atorvastatin and rosuvastatin) despite a lower affinity for their known target, HMG-CoA reductase (HMGCR). Thus, SIMs target a pathway distinct from cholesterol-lowering or HMGCR.4) Transcriptomics and proteomics analyses suggest that older statins may target a non-HMGCR molecule in their anti-metastatic activities, possibly explaining mixed clinical trial results regarding statin use as antineoplastics.5) SIMs are effective in treating various cancers, including kidney, breast (TNBC), and prostate (NEPC).
Conclusions: Critical steps to advancing SIM development toward clinical translation are (i) target identification and (ii) target and therapeutic validation. While our focus is on metastatic renal cell carcinoma (mRCC) to identify SIM's drug target, strategic findings from this project will be directly relevant to other high-risk urological cancers. By investigating this further, we could develop a novel pan-cancer anti-metastatic drug.

#4249 IBI3019, a first-in-class EGFR/CDH17/CD16A tri-specific antibody, demonstrated potent efficacy against CRC and an excellent safety profile in preclinical studies.

Tiongsun Chia, Weiwei Wu, Li Li, Shuaixiang Zhou, Jia Lu, Shuming Lin, Ming Wu, Jia Liu, Feifei Wang, Ya Liu, Chenjuan Zhu, Ying Zhang, Yayao Yan, Huisi Liu, Jian Guan, Junjie Deng, Ninghuan Li, Zhihai Wu, Bin Li, Enhong Zhong, Bingliang Chen, Kaijie He

Innovent Biologics (Suzhou) Co. Ltd, Jiangsu, China

Inhibition of EGFR signaling is clinically effective in colorectal cancer (CRC) as evidenced by the approval for Cetuximab in combination with chemotherapy or Encorafenib, a BRAF inhibitor, and the promising clinical results when combined with KRAS inhibitors, such as Adagrasib or Sotorasib. This underscores the clinical versatility of EGFR antibodies. However, these strategies are inevitably associated with high target-related toxicities, which limit the maximal potential of the drugs. Here, we designed IBI3019, a next-generation EGFR blocker that targets EGFR, CDH17 and CD16A. By targeting CDH17, an adhesion molecule overexpressed in CRC, we enhanced EGFR inhibition capabilities of the tri-specific antibody on the tumor while sparing normal tissues, particularly skin tissues, which are commonly associated with severe toxicities from EGFR blockers. Additionally, IBI3019 incorporates a high affinity CD16A single domain antibody that mediates stronger antibody-dependent cell cytotoxicity (ADCC) than IgG1 used in Cetuximab or the low fucosylated Fc of Amivantamab, a bispecific antibody targeting c-MET and EGFR, both in vitro and in vivo. IBI3019 demonstrated more potent in vitro efficacy than Cetuximab and Amivantamab in CRC cell lines, regardless of KRAS mutation status or the expression of CDH17, c-MET and EGFR. It exhibited strong synergy with Fulzerasib, a KRAS G12C inhibitor and MRTX1133, a KRAS-G12D inhibitor. In NCI-H508 and CCK81 CRC cell line-derived xenograft (CDX) models, IBI3019 suppressed tumor growth more effectively than Cetuximab and Amivantamab. Importantly, in a CRC patient-derived xenograft (PDX) model that is insensitive to Cetuximab, IBI3019 achieved near complete eradication of tumors in all mice. In pre-toxicity studies, cynomolgus monkeys were administrated 4 weekly doses of 50 mg/kg or 150 mg/kg of IBI3019 intravenously, and no mortality or serious toxicity was observed in either group. The highest non-severely toxic dose (HNSTD) of IBI3019 is 150 mg/kg and the calculated therapeutic index is 66. In contrast, previous reports indicated that 5 out of 10 monkeys treated with 75 mg/kg/week of Cetuximab exhibited early mortalities associated with excessive dermatologic toxicities. These results underscore the high safety profile of IBI3019. IBI3019 is a highly optimized FIC molecule with enhanced EGFR blocking capability and ADCC, maximizing tumor inhibition while minimizing toxicity. Its superior efficacy and safety profile support further clinical evaluation.

#4250 Tumor-wide RNA splicing aberrations generate immunogenic public neoantigens across cancers.

Darwin Kwok[1], Nicholas Stevers[1], Inaki Etxeberria[2], Takahide Nejo[1], Maggie Colton Cove[1], Lee Chen[1], Jangham Jung[1], Kaori Okada[1], Senthilnath Lakshmanachetty[1], Marco Gallus[1], Abhilash Barpanda[1], Chibo Hong[1], Gary Chan[1], Jerry Liu[1], Samuel Wu[1], Emilio Ramos[1], Akane Yamamichi[1], Payal Watchmaker[1], Hirokazu Ogino[1], Atsuro Saijo[1], Aidan Du[1], Nadia Grishanina[1], James Woo[1], Aaron Diaz[1], Susan Chang[1], Joanna Phillips[1], Arun Wiita[1], Christopher Klebanoff[2], Joseph Costello[1], Hideho Okada[1]

[1]UCSF - University of California San Francisco, San Francisco, CA,[2]Memorial Sloan Kettering Cancer Center, New York City, NY

Background: High tumor heterogeneity and low mutational burden in cancers pose significant challenges for immunotherapy. To address this, we developed a novel *in silico* pipeline to characterize cancer-specific splicing events (neojunctions; NJs) expressed ubiquitously across ten cancer types. This approach successfully identified tumor-wide, public, alternatively splicing neoantigens (ASNs) that elicit CD8+ T-cell-mediated cytotoxicity across multiple cancers.

Methods: Our SSNIP pipeline identified recurring public NJs expressed in TCGA RNA-seq data (positive sample rate (PSR) > 10%) but not in GTEx normal tissue RNA-seq data (PSR < 1%) across 10 cancer types. We utilized multi-site RNA sequencing data to characterize intratumorally conserved NJs. Our in-house glioma dataset included 56 patients with approximately 10 spatially distinct intratumoral biopsy sites per patient (n=535). In vitro sensitization (IVS) of CD8+ T-cells from healthy donors against high-confidence ASN candidates, followed by 10x VDJ scRNA-seq, identified ASN-specific TCR sequences. TCR-transduced donor-derived CD8+ T-cells were cultured against NJ-expressing glioma and melanoma cell lines to evaluate tumor-specific killing. CRISPRi KD of disease-specific splicing factors was performed to assess NJ modulation.

Results: Our pipeline identified 789 public NJs, with 32 NJs concurrently identified in transcriptomic and proteomic data and predicted to be presented by HLA-A*02:01 with high confidence. We captured TCR clonotypes reactive against NJs in *RPL22* (*n*=7) and *GNAS* (*n*=1), the latter being highly intratumorally-conserved (detected in > 90% of spatially-mapped biopsies across 17/56 patients (26.78%)). Mutant GNAS-derived ASN-specific CD8+ T-cell clones were detectable from glioma patient PBMC by IVS. TCR-transduced T-cells demonstrated recognition and tumor-specific killing against endogenously processed and presented ASNs in multiple glioblastoma and melanoma cell lines. Furthermore, *IDH1*-mutant oligodendroglioma samples demonstrated significantly elevated expression of NJs over *IDH1*-mutant astrocytoma and *IDH1*wt subtypes. Differential gene expression identified decreased expression of splicing factors due to oligodendroglioma-specific co-deletion of Chromosomes 1p/19q. CRISPRi KD of these splicing factors (e.g. *SF3A3*, *SNRPD2*) in *IDH1*wt glioma cells resulted in significantly increased expression of corresponding NJs. Performing DESeq2 on the remaining cancer types revealed similar splicing gene set-associated differences.

Conclusions: SSNIP identified novel public tumor-wide splice-derived neoantigen candidates and ASN-specific TCRs, offering a promising off-the-shelf immunotherapy approach for diverse cancer types. Characterization of intratumorally conserved neoantigens addresses the critical challenge of intratumoral heterogeneity in immunotherapy resistance.

#4251 Drugging of ACOD1 is associated with tumor regression in syngeneic tumor models.

Adonia E. Papathanassiu[1], Weixing Li[1], Yajie Zhong[2], Carmen Chak-Lui Wong[2]

[1]Ergon Pharmaceuticals, Washington, DC,[2]Department of Pathology, The University of Hong Kong, Hong Kong, Hong Kong

Aconitase decarboxylase 1 (ACOD1, also known as Immune Response Gene or IRG1) is a mitochondrial enzyme responsible for the synthesis of the metabolite itaconate in the TCA cycle of pro-inflammatory macrophages. Utilizing Acod1$^{-/-}$ mice and Acod1 KO cells, recent studies have assigned a cancer-promoting role for ACOD1 and demonstrated its expression in immunosuppressive macrophages, found in the TME of syngeneic tumors (Chen et al, Sci. Adv 2023), and in anti-PD-1 (aPD1)-resistant prostate cells (Schofield et al., Cell Rep 2024). To explore the druggability of ACOD1, we synthesized a series of small MW inhibitors and selected two compounds (ERG344 and its derivative ERG350) for further study. Here, we report that, while both compounds suppress synthesis of itaconate in vitro, ERG350 exhibited a 1000-fold improvement in inhibiting ACOD1 enzymatic activity (IC_{50} of ~200 nM) compared to ERG344. Furthermore, both molecules exhibited acceptable pharmacokinetic profiles with half-lives of 8h for ERG344 and 11h for ERG350. Administration of 3 mpk ERG344 as a monotherapy in mice bearing CT26 colon tumors led to complete tumor regression in ~20% of the animals and partial tumor regression in ~40% of the animals. Immunophenotyping of ERG344-treated CT26 tumors revealed an increase in the frequency of tumor infiltrating lymphocytes (TILs), especially those expressing the CX3C chemokine receptor 1 (CX3CR1), and an increase in the frequency of mature dendritic cells DC ($CD3^{-}CD11b^{+}F4/80^{-}MHCII^{+}CD206^{-}$) suggesting that ACOD1 inhibition promotes initiation of an anti-tumor immune response. Increased probability of survival was also observed in the CT26 colon cancer model after daily administration of ERG350 in doses ranging from 0.25 to 3 mpk. The study further reports the effect of ACOD1 inhibition in additional syngeneic models including models of hepatocellular carcinomas

#4252 Genetic and pharmacological disruption of the HBS1L/PELO complex impairs mRNA homeostasis and leads to in vivo tumor regressions in FOCAD-deleted cancers.

Lauren Catherine M. Martires, Matthew Tonini, Hongxiang Zhang, Minjie Zhang, Chengyin Min, Charlotte B. Pratt, Katherine Lazarides, Frank J. Bruzzese, Douglas A. Whittington, Patrick McCarren, Teng Teng, Madhavi Bandi, Shanchuan Zhao, Stephen Paik, Eden Gordon, Shangtao Liu, Alvin Lu, Maria Dam Ferdinez, Binzheng Shen, Hannah Stowe, Yi Yu, Samuel R. Meier, Ashley H. Choi, Lauren Grove, Alan Huang, Alice Tsai, William D. Mallender, Wenhai Zhang, Jannik N. Andersen, Ed Wu, **Hilary E. Nicholson**

Tango Therapeutics, Boston, MA

Loss of tumor suppressor genes in cancer often results in the co-deletion of nearby genes around the chromosomal locus, creating potential collateral damage contexts for targeted therapy. One such example is the loss of *MTAP*, which is frequently co-deleted with the tumor suppressor genes *CDKN2A/B* and creates a synthetic lethal dependency on PRMT5 and susceptibility to MTA-cooperative PRMT5 inhibitors. To identify additional novel drug targets for patients with chromosome 9p21 loss, we first conducted unbiased, combinatorial CRISPR screens evaluating the pairwise knockout of 'context' genes lost on Ch9p21 against a focused library of ~5,000 'target' genes. We identified loss of FOCAD, the gene encoding the SKI complex interacting exonuclease, as synthetic lethal with loss of PELO, a ribosome rescue factor. To expand on this genetic interaction, we conducted genome-wide CRISPR screens in FOCAD isogenic cell lines discovering both PELO and its binding partner HBS1L as synthetic lethal targets in FOCAD-null cells. In FOCAD-deleted xenografts, knockout of HBS1L eliminates tumor growth and results in protein loss of PELO, likely through destabilization of the HBS1L/PELO protein complex. The dependency of FOCAD-null cells on HBS1L/PELO could be rescued by exogenous cDNA expression of FOCAD, and conversely, knockout of FOCAD in WT cells rendered them dependent on HBS1L, demonstrating the robustness of this interaction and validating the HBS1L/PELO protein complex as a promising target for drug discovery. Through cellular phenotypic screens and a medicinal chemistry campaign, we identified pharmacological disruptors of the HBS1L/PELO complex that selectively kill FOCAD-deleted, but not FOCAD-proficient, cells across diverse models. Oral dosing of mice harboring FOCAD-deleted xenografts with our leading compound led to dose-dependent tumor regression and modulation of PD biomarkers. Mechanistically, HBS1L and PELO form a complex responsible for resolving stalled elongation complexes during protein translation. We propose a model in which loss of FOCAD (and/or other SKI complex members) leads to accumulation of aberrant mRNAs on which ribosomes become stalled, leading to hyperdependence on HBS1L/PELO for ribosome rescue. This model is supported by the observation of translational arrest and activation of the unfolded protein response upon HBS1L/PELO inactivation. Clinically, FOCAD loss occurs in ~30% of all MTAP deleted tumors, representing ~3% of all solid tumors (including ~7% of NSCLC). Our lead molecule provides preclinical validation for targeting the HBS1L/PELO complex as a novel strategy for the potential treatment of a large population of patients with FOCAD-deleted tumors.

#4253 Turning pro-tumor inflammation into target opportunity: Development of an IL1RAP ADC for solid tumor treatment.

Yufei Chen, Marlena Gray, Piper Meigs Treuting, Craig Miller, Sara Carbonetti, Katie Snead, Kaleb Smith, Robert Lawrence, Alyson J. Smith

Pfizer Inc, Bothell, WA

Chronic and dysregulated inflammation caused by activation of interleukin-1 (IL-1) signaling supports tumor growth and helps establish an immunosuppressive microenvironment. Interleukin 1 receptor accessory protein (IL1RAP, IL-1RAcP, IL1R3) serves as a co-receptor for interleukin 1 receptor type 1 (IL1R1) at the cell membrane and plays a key role in mediating IL-1 signaling. By combining multi-omics and immunohistochemistry analysis, we identified the upregulation of IL1RAP on many solid tumor indications, including melanoma, non-small cell lung cancer (NSCLC), head and neck squamous cell carcinoma (HNSCC) and esophageal cancer, while normal tissue expression is mainly restricted to the bone marrow. This expression pattern and tumor-supporting biological function makes IL1RAP an attractive target for an antibody-drug conjugate (ADC) therapy approach. Through a hybridoma antibody campaign, we generated a pool of candidate anti-IL1RAP monoclonal antibodies (mAbs) to evaluate as ADC candidates. The candidates all exhibited ability to disrupt the IL-1 signaling cascade but demonstrated variable potency to do so. All of the clones had similar ability to drive drug delivery and direct cytotoxicity to tumor cells as ADCs. These in vitro activities translated into strong in vivo anti-tumor activity in several CDX and PDX human tumor models, with clonal separation only apparent in low expressing models. While strong activity was seen in all CDX models with various IL1RAP expression levels, primary human sample PDX models demonstrated a much stronger expression:response correlation. To evaluate any potential normal tissue liabilities of an IL1RAP ADC, and assess how clone selection may impact this, a primary human bone marrow colony formation unit assay was employed. While several of the anti-IL1RAP antibodies demonstrated on-target myeloid progenitor cell lethality, not all clones were equipotent, despite all driving similar in vivo anti-tumor activity. Collectively this data demonstrates the potential to leverage IL1RAP as an effective and well tolerated ADC and how appropriate antibody selection could potentially aid in increasing the therapeutic index.

#4254 Development of DEM201, a blocking antibody against SMAGP, a novel "Don′t Eat Me" signal overexpressed in cancer.

Sarah E. Carden, Agnieszka Denslow, Mary Baumel, Jing Zhu, Lissette Garcia, Sarah Nesti, Kayla Belanger, Meghan Davis, Carmen Adriaens, Sandeep Kumar, Christophe Queva, Loise Francisco

DEM BioPharma, Inc., Cambridge, MA

Small Cell Adhesion Glycoprotein (SMAGP), a poorly characterized glycoprotein thought to function in cell adhesion, is highly expressed in gastrointestinal (GI) cancers and overexpressed in bladder cancer, hepatocellular carcinoma, kidney papillary cell carcinoma, pancreatic adenocarcinoma, thyroid carcinoma, and endometrial carcinoma. SMAGP was recently identified as a novel “Don’t Eat Me” (DEM) signal, and overexpression of human SMAGP suppresses tumor cell phagocytosis by primary human macrophages. Unlike the canonical DEM signal CD47, SMAGP is not detected in platelets or erythrocytes. Two cellular receptors for SMAGP have been identified, PILRα, an ITIM-containing transmembrane receptor broadly expressed in the myeloid lineage, and CD177, a GPI-anchored neutrophil marker also expressed in some epithelial cells and tumor-associated regulatory T cells (Tregs). To investigate the role of SMAGP in regulating anti-tumor responses, monoclonal antibodies were raised against SMAGP and humanized. DEM201 was selected as a clinical candidate and is specific for human SMAGP with sub-nanomolar (nM) affinity. DEM201 binds cell-associated SMAGP on cancer cell lines derived from GI, pancreatic and lung cancer and elicits potent ADCP and ADCC with sub-nM EC50. *In vivo*, DEM201 significantly inhibited the growth of SMAGP-expressing RKO tumor xenografts. To assess the potential of SMAGP inhibition in regulating both innate and adaptive immunity in vivo, we tested mAb255-mIgG2a, a SMAGP mAb with sub-nanomolar affinity to mouse SMAGP, in immunocompetent syngeneic tumor models. mAb255-mIgG2a potently inhibited the growth of H22 and Hepa1-6 liver cancer. A significant increase in CD8 T cells and macrophages was observed in H22 tumors after treatment with mAb255-mIgG2a. All SMAGP mAb treatments were well-tolerated, clearing the way for DEM201 IND-enabling activities.

#4255 Membrane interactomics (MInt) platform identifies EGFR and CDCP1 as effective co-targets for bispecific antibody drug conjugate IDP-001.

Clare F. Malone[1], Anna de Regt[2], Chris May[1], Lydia Vignale[1], Kendall Johnson[1], Cody Scandore[1], Kalee Hansen[1], Sohpia Romero[2], Hayley Ma[2], Brian Woodruff[2], Ben Setter[1], Hengyu Xu[2], Carol L. Farr[2], Noah Dephoure[1], Heath Klock[1], Ertan Eryilmaz[1], Rob Oslund[1], Niyi Fadeyi[1], Pamela Holland[2], Scott Lesley[2]

[1]InduPro, Cambridge, MA,[2]InduPro, Seattle, WA

EGFR is a biologically validated target which is overexpressed and activated in many human cancers and associated with poor prognosis. However, most current EGFR targeting therapies encompassing multiple modalities have shown limited therapeutic efficacy, frequently due to on-target toxicity in non-malignant tissues where EGFR is expressed. To improve selectivity via co-localization targeting over co-expression alone, we utilized InduPro's proprietary MInt platform across multiple cancer cell systems to identify CDCP1 as a tumor associated proximity antigen to EGFR on tumor cells. Like EGFR, CDCP1 is over-expressed in multiple cancers and plays key roles in oncogenic signaling and malignant transformation (1). Moreover, EGFR signaling induces upregulation and cell surface localization of CDCP1 as well as inhibition of its degradation (2-3). We further demonstrate that EGFR and CDCP1 are co-expressed in many cancer types by immunohistochemistry, including high levels of co-expression in lung squamous cell carcinoma. IDP-001 is a novel MMAE-conjugated EGFR-CDCP1 bispecific antibody with low DAR. We find that bispecific EGFR x CDCP1 antibodies display enhanced selective internalization and cell killing through co-binding. IDP-001 is effective in vitro against a panel of cancer cell lines of varying target expression levels, including Osimertinib resistant EGFR mutant NSCLC. Importantly, IDP-001 has minimal activity against normal cells expressing both targets. CDCP1 is known to undergo cleavage in some settings, and we present data that confirms IDP-001 binds both intact and cleaved isoforms. Finally, we demonstrate in vivo efficacy of IDP-001 in a subcutaneous xenograft model. Collectively, our data supports that EGFR and CDCP1 are inherently proximal to each other in cancer cell lines and that IDP-001 shows pre-clinical efficacy in a variety of cancer settings and warrants further development. Introduction: Current ADC development focus on a small number of tumor-associated antigens (TAA). In recognizing heterogeneity of cancers and acquired resistance evolved in response to therapies, we have strategized our ADC development by focusing on discovering and develop novel TAAs.
Methods: Integrative mining of large-scale omics databases was carried out to discover TAA. In-house antibody discovery and engineering platforms were employed for antibody discovery. In vitro assays were used to screen antibodies of high affinity, high specificity, efficient internalization and developability. A MMAE based ADC was evaluated *in vitro* for stability, cytotoxicity and bystander effect and *in vivo* in CDX models for anti-tumor efficacy. PK/TK and GLP toxicology studies were carried out in monkeys.
Results: CDCP1 was identified to be significantly up-regulated in large proportions of cancer cells across many solid tumors, which was comparable to or higher expression than targets of the marketed ADC drugs. It is associated with cancer progression, metastasis and contributed to resistance to cancer therapies. We discovered and humanized a CDCP1-binding antibody (HY0001) which shows high affinity and specificity, and displays high efficiency of internalization and yet no agonist activity. We developed an ADC preclinical candidate (HY0001a) by conjugating HY0001 with vcMMAE at a DAR=4. HY0001a was rapidly internalized upon binding to CDCP1+ cancer cells and colocalized with lysosomes in 1~2 hours after endocytosis. *In vitro* cytotoxicity assays with CDCP1+ cancer cell lines, HY0001a showed high cytotoxicity activities (IC50 = 0.05~10 nM) in a target- and dose-dependent manner with strong bystander effect. HY0001a demonstrated strong anti-tumor efficacy in a target- and dose-dependent (1-5 mg/kg) manner when tested across multiple CDX models, including prostate, breast, pancreatic, colon, ovarian and bladder cancers. Like MMAE, HY0001a, but not HY0001, could arrest proliferative cancer cells in their G2M phase and significantly increase the number of apoptotic cells. HY0001a significant induced the apoptotic pathway in the tumor tissue of MDA-MB-231 CDX model. HY0001a is stable in biomatrix and possesses desired PK profiles (T1/2= 2-4 days in the CDX models and 2-3 days in cynomolgus monkeys). HY0001a showed toxicity profiles, similar to the marketed MMAE-based ADC drugs. We have completed development of the CMC processes and production of lots to enable the IND submission and early clinical trials.
Conclusions: We identified CDCP1 as an excellent ADC TAA with great potential against multiple cancers. We discovered an antibody (HY0001) of high affinity, cancer cell-specific and efficiently internalization, and completed development of a preclinical candidate MMAE based ADC (HY0001a), which showed a great rationale for further clinical investigation to provide a novel cancer therapy.

#4257 Discovery of small molecules to target DDX5 unfolding of MYC promoter G-quadruplex for MYC inhibition.

Sarah D. Washburn, Danzhou Yang

Borch Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN

c-MYC (MYC) is one of the most deregulated oncogenes in human cancers and encodes a master regulator of cell proliferation. Direct targeting of MYC protein has proven to be challenging due to its disordered structure and lack of clear drug binding pocket. G-quadruplexes (G4s) are globular DNA secondary structures that form in guanine-rich regions of the genome with important regulatory roles. The G4 formed in the proximal promoter of the MYC gene (MycG4) acts as a transcriptional silencer. Our lab has previously discovered the DDX5 helicase, a founding member of the DEAD-box RNA helicase family, actively unfolds the MycG4 and transactivates MYC in human cancer cells. Therefore, the DDX5-MycG4 interaction and unfolding represents a promising target for effective MYC downregulation and anti-cancer therapeutics. Previously, our lab has shown for proof-of-principle that G4-ligand TMPyP4 can inhibit the DDX5-MycG4 interaction and downregulate MYC expression in cancer cells. However, TMPyP4 is not a good drug candidate due to its phototoxicity. Further, no inhibitors are available that directly bind DDX5 and specifically inhibit its G4 unfolding activity. Here, we report a high-throughput screen of ~20,000 diverse drug-like compounds to identify specific inhibitors of the DDX5-MycG4 interaction for MYC downregulation in human cancers. We adapted a FRET-based G4 unfolding assay for high-throughput screening in a 384-well plate format. Briefly, a 6-fluorescein fluorophore and a Black Hole Quencher 1 FRET pair is attached to the 3'- and 5'-end of the MycG4 DNA sequence, respectively, whose fluorescence is quenched in a formed G4. Unfolding of the G4 by DDX5 increases the fluorophore distance and increases the detected fluorescence. The Z' score of the adapted FRET assay was ~0.5 which provides sufficient assay range for screening inhibitors. Compounds that reduce DDX5 unfolding by more than 40% were defined as a hit. Out of 20,000 screened compounds, 31 initial hits were identified. Significantly, we identified five different classes of hit compound chemical structures. Several hits are substantially structurally different from classic G4 interacting compounds, suggesting a different mechanism of action for inhibition of the DDX5 protein-DNA interaction. We conducted hit validation and tested the identified compounds for DDX5 G4 and RNA unfolding, to better understand the mechanisms of action of different compound classes. The hits that specifically inhibit DDX5-MycG4 interaction were tested against MYC expression levels in cancer cells. In summary, we have developed a high-throughput screening method to discover inhibitors of the DDX5-MycG4 interaction and have identified several hit compounds with different structure classes. Our goal is to identify lead compounds to target this interaction for MYC downregulation for future anti-cancer therapeutics.

#4258 FL-501 is a potential best in class GDF-15 inhibitor with extended half-life and potent anti-cachexia activity in preclinical models.

Kelly Foster, Michael S. Haas, Walter Newman, Jason Baum, **Roma Kaul**

Leap Therapeutics, Inc., Cambridge, MA

Cancer cachexia is a devastating syndrome characterized by unintentional weight loss, muscle wasting, fatigue, and severely reduced quality of life. This condition affects up to 80% of cancer patients and represents a major contributor to cancer-related mortality. Despite its significant clinical impact, there are currently no approved therapies for cancer cachexia in most of the world. However, recent pre-clinical and clinical studies have identified Growth Differentiation Factor-15 (GDF-15) as a promising therapeutic target for treating this debilitating condition.FL-501, a novel GDF-15 antibody, was designed to neutralize GDF-15 with high affinity and extended half-life. FL-501 was engineered with specific mutations designed to optimize its pharmacokinetic and safety profiles. In studies using humanized FcRn mice, FL-501 demonstrated a 2-fold increase in half-life and 0.5-fold decrease in clearance compared to both ponsegromab and a wild-type precursor of FL-501.MC38 colorectal cancer (CRC) cells engineered to overexpress human GDF-15 (MC38_hGDF15) were used to assess the role of GDF-15 in driving cancer cachexia. Mice inoculated with these tumor cells exhibited significantly greater body weight loss compared to those bearing wild-type MC38 tumors. The weight loss was attributed to substantial reductions across multiple tissue types, including skeletal muscle mass, fat deposits, and cardiac muscle mass. Importantly, treatment with FL-501 fully restored body composition in mice bearing MC38_hGDF15 tumors to an extent similar or greater than other clinical stage antibodies including visugromab and ponsegromab. To further validate these findings in a clinically relevant setting, non-small cell lung cancer (NSCLC) patient-derived xenografts (Crown Bioscience, Model LU5176) were inoculated in immunocompromised mice. In this therapeutic model, mice were treated with cisplatin (5 mg/kg) alone or in combination with either FL-501 or ponsegromab. While untreated mice and those receiving cisplatin monotherapy experienced significant decreases in weight, the combination with either FL-501 or ponsegromab effectively restored their body weight. Moreover, the addition of anti-GDF-15 therapy significantly improved survival of the mice compared to cisplatin treatment alone. These results support GDF-15 as a key driver of cachexia. Further, the targeted inhibition of GDF-15 with FL-501 was able to effectively reverse characteristics of cancer cachexia in multiple pre-clinical models. Taken together, these findings support the continued evaluation of FL501 and its progression into the clinic.

#4259 Peroxiredoxin 3 is a key regulator of mesothelioma progression and a target for therapeutic intervention.

Victoria Gibson[1], Jan Rogel[2], Joanna Dzialo,[2], Terri Messier[1], Aida Habibovic[1], Charlotte Poile[2], Apostolos Nakas[3], Kudzayi Kutywayo[2], Aleksandra Bzura[2], George Naumov[4], Dean Fennell[2], **Brian Cunniff**[1]

[1]Larner College of Medicine at The University of Vermont, Burlington, VT,[2]University of Leicester, Leicester, United Kingdom,[3]University Hospitals of Leicester, Leicester, United Kingdom,[4]RS Oncology, Cambridge, MA

Tumor cells generate increased levels of reactive oxygen species (ROS) that promote tumor cell growth. To survive under elevated ROS levels, tumor cells must increase antioxidant expression, activity, and reliance on ROS scavenging pathways, including the mitochondrial matrix hydrogen peroxide (H_2O_2) scavenging enzyme peroxiredoxin 3 (PRX3). PRX3 expression is elevated in many cancers, including mesothelioma, and is associated with increased cell proliferation, resistance to apoptosis and chemotherapy. PRX3 is a novel molecular target of the first-in-human covalent inhibitor RSO-021. Recent phase 1 data demonstrated a favorable RSO-021 safety profile with early efficacy in patients with pleural mesothelioma, warranting transition to the ongoing phase 2 portion of the MITOPE trial (NCT05278975). RSO-021 inactivates PRX3 by covalently crosslinking active site cysteines, leading to increased levels of mitochondrial ROS, resulting in tumor cell death. In contrast normal cells remain unaffected by the same treatment. Tumor cells are vulnerable to pharmacological PRX3 inhibition; however, the specific role of PRX3 in tumor biology, particularly in mesothelioma, remains unclear. To investigate this, two PRX3 knockout (PRX3 KO) human mesothelioma cell lines were generated using CRISPR/Cas9 and compared to a mock CRISPR/Cas9 control cell line. In vitro characterization of the PRX3 KO clones showed that proliferation was significantly reduced, suggesting that PRX3 plays a critical role in promoting tumor cell growth. Assays using HyPer7, a genetically encoded H_2O_2-responsive fluorescent biosensor targeted specifically to the mitochondrial matrix, revealed a significant increase in HyPer7 oxidation in the mitochondrial matrix of PRX3 KO cells compared to control cells. Additionally, measurement of mitochondrial respiration by the Seahorse XF96 Cell Mito Stress Test showed PRX3 KO cells have a decrease in basal and maximal oxygen consumption further highlighting the role PRX3 plays in mitochondrial function. When injected into SCID mice PRX3 KO cells did not develop tumors, while the control mice presented with significant tumor burden over a four-week period. RNA-sequencing of PRX3 KO cells showed reduced expression of epithelial-to-mesenchymal transition (EMT) associated genes and TGFB signaling genes compared to controls. This correlates with RNA-sequencing run on 22 patient-derived primary mesothelioma explants following treatment with RSO-021. Results showed that the most sensitive explants had a reduction in EMT gene expression, a key signature associated with tumor cell migration and metastasis. Our results show that PRX3 supports mesothelioma tumor progression and survival through regulating redox metabolism and signaling while maintaining gene expression signatures supporting tumor aggressiveness, highlighting PRX3 as an important therapeutic target in oncology.

#4260 ADV-101: a novel ADC targeting IL-1RAP, leveraging tumor cell and the tumor microenvironment vulnerabilities for enhanced anti-tumor efficacy.

Edouard De Dreuzy, Soha El Sayed, Lucie Bouquet, Stephane Lameynardie, Delphine Genin, Amandine Barberot, Lucas Bourhis, Lucas Demontrond, Clementine Primus, Christophe Ferrand, Marina Deschamps, Alexis Delabriere, Laura Demolis, Erik Rutjens, Jens Hasskarl, Ksenija Pavletic, **Richard Charles Alfred Sainson**

Advesya, Paris, France

IL-1RAP is the common co-receptor of all IL-1-related cytokines, and constitutes a novel type of ADC target due to its strong expression on both tumor cells and immunosuppressive cells within the tumor microenvironment (TME). The increased value of this target is complemented by the dependency of certain tumors on IL-1RAP-dependent signaling arguing for a lower chance of antigen loss in response to anti-IL-1RAP therapies. IL-1RAP overall low expression in healthy tissues, also minimizes the risk of on-target off-tumor effects. While healthy tissues exhibit minimal plasma membrane IL-1RAP expression, tumoral tissues demonstrate high IL-1RAP expression, particularly in cancers with squamous histology such as HNSCC and ESCC, as well as other tumor types such as GBM, PDAC, Ewing Sarcoma (EWS) and AML.We developed ADV-101, an ADC consisting of a humanized anti-IL-1RAP IgG1 mAb conjugated to a clinically validated topoisomerase I inhibitor via a cleavable linker (DAR of 8). The anti-IL-1RAP antibody of ADV-101 was shown to be highly specific and selective to IL-1RAP, binding to both human and cynomolgus recombinant protein with EC_{50} values of 0.095 nM and 0.072 nM, respectively (ELISA), and with an EC_{50} of 6.47 nM to human IL-1RAP (by SPR). The antibody was also demonstrated to bind IL-1RAP-expressing cells from different cancer indications, with EC_{50} values ranging from 0.35 to 2.1 nM, and showed specific internalization in a panel of IL-1RAP-expressing cell lines, with EC_{50} values ranging between 0.34 and 4.44 nM. Notably, this binding and internalization were unaffected by the presence of excess IL-1β ligand. There was no impact of payload-linker conjugation on the ADC binding affinity to IL-1RAP protein and expressing cells. The ADC effectively killed IL-1RAP-positive cells *in vitro*, with IC_{50} values ranging from 0.02 to 78.5 nM. *In vivo*, ADV-101 demonstrated strong anti-tumor efficacy in established tumors derived from CDX models (including large tumors) and PDX models. An *in vivo* efficacy study in six EWS PDX models with varying levels of IL-1RAP expression and derived from both metastatic and primary disease demonstrated high anti-tumor efficacy in 5 out of 6 models, including full tumor regression, even in tumors known to be resistant to topoisomerase I/II inhibitors. ADV-101 safety was further established in a non-human primate (NHP) dose-range finding toxicity study, showing no severe adverse events up to the highest dose tested (50 mg/kg), together with robust pharmacokinetics data confirming exposure. Altogether, these findings warrant further development to bring ADV-101 to the clinic.

#4261 Synthetic lethality of targeting thymine DNA glycosylase (TDG) in p53-deficient lung cancer.

Jiaxin Zhou[1], Zhenyu Shao[1], Jiannan Guo[2], Yiqin Wang[1], Qing Xu[1], Yarui Du[1], Haiping Wu[2], Guoliang Xu[1]

[1]Center for Excellence in Molecular Cell Science, Chinese Academy of Sciences, Shanghai, China,[2]CytosinLab Therapeutics, Hangzhou, China

TP53 stands as the most frequently mutated gene in human cancers, with a strong correlation to poor prognosis across various cancer types. This makes it a critical target, representing the largest patient population and a substantial tumor drug market, with a pressing unmet medical need. Directly targeting p53 remains highly challenging, leaving a significant therapeutic gap. However, synthetic lethality presents a promising approach for developing treatments targeting tumors with *TP53* mutations. Thymine DNA glycosylase (TDG) is a multifaceted enzyme involved in DNA base excision repair (BER), transcriptional regulation, and DNA demethylation, playing critical roles in both embryonic development and tumor progression. In this study, we identified TDG as a synthetic essential effector in p53-deficient cancers. This identification was facilitated through an *in vitro* CRISPR-Cas9 screening assay conducted in *Trp53* knockout cells. Our finding reveals that knocking out *Tdg* selectively kills p53-deficient cells while sparing wild-type cells. Conversely, knocking out *Trp53* selectively kills Tdg-deficient cells. Furthermore, elevated TDG expression was observed to correlate with p53-deficiency in human cancers. TDG knockout significantly reduced the viability of the p53-deficient lung cancer cell line NCI-H1299, an effect was rescued by ectopic expression of wild-type p53, but did not affect the viability of p53 wide-type cell line A549. Using a genetically engineered mouse model of lung adenocarcinoma (LUAD), we further demonstrated that genetic inactivation of *Tdg* specifically suppressed tumor growth in the context of p53-deficiency. Mechanistically, TDG and p53 cooperate to regulate the transcription of the RNA helicase *DHX9*, which facilitates the resolution of double-strand RNA (dsRNA). Inhibition of TDG in p53-deficient cancer cells downregulated DHX9, leading to aberrant accumulation of dsRNA derived from SINEs (short interspersed nuclear elements). This accumulation triggered an anti-viral response via the RIG-I/MDA5-MAVS axis, resulting in tumor growth inhibition and an enhanced anti-tumor immune response. Notably, the dsRNA-mediated antiviral response induced by *Tdg* depletion facilitated the recruitment of tumor-infiltrating lymphocytes (TILs), enhancing response to immune checkpoint blockade (ICB) treatment. These findings reveal a novel therapeutic vulnerability in p53-deficient lung cancer and suggest that targeting TDG could synergize with immunotherapies to improve patient outcomes. Our study highlights the function of TDG in transcriptional regulation, extending beyond its proposed roles in active DNA demethylation and mismatch repair, and unveils TDG as a promising therapeutic target for p53-deficient lung cancer.

#4263 QX-001352 is a novel and specific inhibitor of PARG with potentially BIC in vitro and in vivo anti-tumor efficacy.

Dafydd Thomas, Xianhai Huang, Vijay Reddy, Wayne Tang

QuantX Biosciences Limited, Princeton, NJ

When DNA is damaged one of the critical steps is the addition of Poly-ADP-ribose (PAR) chains to target proteins. Poly ADP-ribose polymerase 1 (PARP1) is an enzyme that adds PAR chains to target DNA repair proteins including itself. This serves as a recruitment signal for other DNA repair enzymes to localize to the site of DNA damage. Poly ADP-ribose glycohydrolase (PARG) has a crucial role in DNA repair. This role is by virtue of its intrinsic enzymatic activity to catalyze the removal of PAR chains from target proteins. This removal leads to the resolution of DNA strand breaks. When PARG is inhibited or its expression is abrogated, PAR chains go unresolved and therefore DNA lesions also. This leads to genomic instability and cell death. Therefore, there is a critical balance of PAR chains which is reciprocally regulated by PARP1 and PARG and perturbing this balance may negatively affect tumor cell growth. This makes PARG a rational drug target in oncology, against which the compound QX-001352 has been developed as a potentially best in class (BIC) inhibitor.
QX-001352 is a potent inhibitor of PARG. QX-001352 was shown to inhibit the removal of PAR chains from PARylated PARP1 with an IC50 of 0.2 nM in a biochemical assay. This suggests QX1352 is a potent inhibitor of PARG.QX-001352 was able to inhibit the growth of two ovarian tumor cell lines as well as a breast and gastric tumor cell line. The IC50's ranged from 1.5 nM to 11.9 nM indicating potent cell growth inhibition which represents around 10 folds more potent activity than a benchmark compound in the clinic. QX-001352 blocked the removal of PAR chains in Kuramochi cells in dose dependent manner with an IC50 of 0.1 nM indicating excellent target engagement. In vivo in a Kuramochi cell xenograft model, QX-001352 caused robust tumor regression. Both low and high doses of QX-001352 were fully efficacious whereas no effect was seen with vehicle treated animals. QX-001352 was well tolerated in all the treated groups.
In conclusion, QX-001352 is a potent and specific inhibitor of PARG. This inhibition leads to PAR chain accumulation and prevents tumor cell growth both in vitro and in vivo. QX-001352 possesses highly desirable physicochemical properties and demonstrated favorable off-target profiles. Thus QX-001352 may be an effective PARG inhibitor in the clinic.

#4264 A novel, potent DNA polymerase theta inhibitor, QX-001280, demonstrates anti-tumor activity in combination with a PARP1 inhibitor.

Dafydd Thomas, James Duan, Xianhai Huang, Vijay Reddy, Wayne Tang

QuantX Biosciences Limited, Princeton, NJ

Microhomology-mediated end joining (MMEJ) is a repair mechanism that resolves double strand DNA breaks. It is considered a secondary double strand break repair mechanism behind homologous recombination (HR) but is often utilized by tumors that have lost the ability to perform HR. Critical to this process is DNA polymerase theta (Pol θ). Pol θ is a heterobifunctional protein that consists of an N-terminal helicase domain, a disorder central region and a C-terminal polymerase domain. Following DNA resection by the MRE11-RAD50-NBS-1 (MRN) complex Pol θ is recruited to the site of the double strand break where it adds the missing bases. The bases are then ligated to resolve the double strand break. The central role of Pol θ in MMEJ is highlighted by the fact that inhibition of Pol θ can be synthetic lethal with BRCA mutation and PARP-1 inhibitor treatment, with loss of BRCA1 or 2 resulting in non-functional HR. This loss was exploited with the development of the novel Pol θ inhibitor, QX-001280, and combining with a PARP inhibitor to elicit anti-tumor effect.
QX-001280 is a potent inhibitor which binds to the Pol θ Helicase domain. In vitro, QX-001280 had an IC_{50} for the inhibition of Polθ of 0.84 nM, indicating potent inhibition of the helicase domain of Pol θ. Potent inhibition was also observed in DLD-1 BRCA2 null cells with an IC_{50} of 1.03 nM. Combination with a PARP inhibitor, Olaparib, led to significant increase in phosphorylated H2AX indicating that double strand breaks are not being resolved inferring that Pol θ and MMEJ are being inhibited. In addition, cell viability was significantly reduced in DLD-1 BRCA2 null cells treated with increasing doses of PARP inhibitor in combination Pol θ inhibitor, with a reduction in IC_{50}. In vivo, single agent PARP inhibitor or Pol θ inhibitor had a modest effect on tumor growth. However, when Olaparib and QX-001280 are combined robust tumor regressions were observed. QX-001280 was well tolerated in all the dose groups.
In conclusion, QX-001280 is a potent and specific inhibitor of Polθ which exhibits anti-tumor activity both in vitro and in vivo. It is a high-quality candidate for clinical investigation in combination therapy with PARP inhibitors for cancer treatment.

#4265 The role of the mevalonate pathway in post-translational modifications of PD-L1.

Ruoheng Zhang[1], Emily J. Koubek[2], Jessie L. Reed[3], Jeffrey D. Neighbors[1], Joel M. Reid[4], Raymond J. Hohl[1]

[1]Penn State Hershey Cancer Institute, Hershey, PA,[2]USA Department of Neurology, University of Michigan, Ann Arbor, MI,[3]Department of Biology, Texas A&M University, Penn State Hershey Cancer Institute, College Station, TX,[4]Department of Oncology, Mayo Clinic, Rochester, MN

Introduction: The binding of Programmed Death-Ligand 1 (PD-L1) on the surface of tumor cells to PD-1 on T cells prevents T-cell-mediated anti-cancer immune responses. Immune checkpoint blockades that target the PD-L1/PD-1 interaction have improved survival rates but have several critical limitations. Post-translational modifications (PTMs) of PD-L1, such as glycosylation, are crucial for its stability and engagement with PD-1. Thus, targeting PD-L1 PTMs may be a novel method to improve immune checkpoint blockade efficacy. The mevalonate pathway (MVP) generates various substances involved in PTMs process. Here, we explore the effect of MVP in altering the PTMs of PD-L1 and its impacts on cell surface PD-L1 function.

Methods: The triple-negative human breast cancer (TNBC) cell lines MDA-MB-231 and BT549 were treated with the HMG-CoA reductase inhibitor lovastatin (LOV) with or without the addition of IFN-γ and/or MVP intermediates for 48 hours. PD-L1 transcription was evaluated by qPCR. Alterations in PD-L1 size were detected by Western blotting. PD-L1 surface levels were measured by flow cytometry. HMG-CoA reductase (HMGCR) knockdown was performed to validate the non-off-target effect of LOV. The binding of PD-1 protein to the cell surface PD-L1 was measured by PD-1/PD-L1 binding assay. PD-L1 glycosylation levels were measured by Concanavalin A (Con A) lectin binding assay with immunoprecipitated PD-L1 protein.

Results: LOV treatment caused a significant molecular weight shift of PD-L1 from approximately 45 kDa to 40 kDa and reduced the cell surface PD-L1 levels. However, PD-L1 transcription was not affected by LOV. HMGCR knockdown produced similar changes, indicating LOV's impact on PD-L1 was not due to off-target effects. The addition of MVP intermediates mevalonate (MEV) or geranylgeraniol, but not farnesol prevented LOV-induced changes in PD-L1 molecular weight and surface levels. Interestingly, the addition of 25-hydroxycholesterol, but not dolichol, partially prevented LOV-induced decreases in PD-L1 surface levels. Geranylgeranyl transferase inhibitor GGTI-286, which prevents protein geranylgeranylation, also altered PD-L1 molecular weight and decreased surface levels. In addition, LOV impaired the binding of PD-1 protein to tumor cells' surface PD-L1, which was reversed by the addition of MVP substrate MEV. Con A lectin-binding of immunoprecipitated PD-L1 showed that the LOV did not reduce the N-glycosylation level of PD-L1.

Conclusions: This study reveals the involvement of the MVP in regulating PD-L1 PTMs and highlights the MVP as a potential therapeutic target to modulate PD-L1’s molecular weight and function and improve the efficacy of immunotherapy interventions, presenting a promising avenue for further investigation.

#4266 Discovery and characterization of a novel LRRC15-targeting antibody drug conjugate (ADC) for the treatment of solid tumors.

Shanshan Yan[1], **Bing Wan**[1], Donghui Li[2], Yue Ge[1], Wilson Peng[2], Jiaqing Yi[2], Ziruo Wen[1], Xinchuan Dai[1], Leo Xu[2], Lina Wang[1], Qiuping Ye[2], Peter Huang[2], Linda N. Liu[2]

[1]Zai Lab (Shanghai), Co. Ltd, Shanghai, China,[2]Zai Lab (US) LLC, Cambridge, MA

Leucine-rich repeat-containing protein 15 (LRRC15) is a type I transmembrane protein involved in cell-cell and cell-extracellular matrix (ECM) interactions. It is overexpressed in various mesenchymal tumors such as sarcoma, glioblastoma and melanoma, where it promotes tumor metastasis. Additionally, LRRC15 is upregulated in cancer-associated fibroblasts (CAFs) across various cancer types, contributing to immune-excluded and immune-suppressive tumor microenvironment (TME). This makes LRRC15 an appealing target for cancer therapy. ZL-6201 is an innovative antibody-drug conjugate (ADC) targeting LRRC15, developed using the TME-activable linker-payload (TMALIN®) platform. This ADC comprises a humanized anti-LRRC15 antibody, a protease-cleavable linker, and a novel camptothecin derivative payload. It achieves a high drug-to-antibody ratio (DAR 8) with homogeneously conjugated, hydrophilic linker-payload combinations. ZL-6201 demonstrated strong and specific binding to human and cynomolgus LRRC15 without cross-reactivity to other LRRC family members. Its high affinity and specificity for LRRC15 on the cell surface led to target-mediated internalization and subsequent cytotoxicity in tumor cells upon payload release. Additionally, it exhibited potent bystander killing of LRRC15 negative tumor cells in an in vitro co-culture system. In in vivo efficacy studies, ZL-6201 was well-tolerated and effectively suppressed the growth of established human tumors in a dose-dependent manner in both tumor cell line-derived (CDX) and sarcoma patient sample-derived xenograft (PDX) models. In a human chondrosarcoma SA4109 PDX model, a significantly higher concentration of payload and ADC were detected in the tumors compared to mouse serum, indicating targeted delivery of the ADC. Collectively, these findings support advancing ZL-6201 into IND-enabling studies as a potential treatment for patients with sarcoma and other LRRC15-positive solid tumors.

#4267 Cancer cell-extrinsic effect of immune checkpoint IGSF8.

Xiangyang Wu[1], Flavian D. Brown[2], Jin Wang[1], Yixuan Tang[1], Chao Liu[1], X. Shirley Liu[2], **Xingfeng Bao**[2], Tengfei Xiao[1]

[1]Shanghai Xunbaihui Biotechnology Co., Shanghai, China,[2]Gv20 Therapeutics LLC, Newton, MA

Background: We recently discovered IGSF8 (Immunoglobulin superfamily member 8) as a novel innate immune checkpoint on cancer cells by interacting with KIR3DL2 on natural killer (NK) cells (Cell, 2024). Anti-IGSF8 antibody enhanced NK cell-mediated cancer cell killing and suppressed tumor growth in multiple syngeneic tumor models. In Phase 1 clinical trial, anti-IGSF8 antibody showed favorable safety profiles and promising monotherapy activities. While IGSF8 is overexpressed on cancer cells, it is also expressed on various immune cells within the tumor microenvironment. In this study, we investigated the cancer cell-extrinsic effects of IGSF8 in tumor immunity.
Methods: We generated germline IGSF8 knockout (KO) C57BL/6 mice using CRISPR-Cas9 technology. To evaluate the impact of IGSF8 deficiency on tumor immunity, we inoculated these KO mice with various syngeneic tumors and analyzed immune cell populations in tumor tissue and tumor draining lymph nodes by flow cytometry. To investigate antigen (Ag)-specific anti-tumor immunity, we implanted OVA-expressing B16-F10 melanoma in the KO mice, and quantified the Ag-specific CD8+ T cells with OVA257-264 tetramer and Ag-specific dendritic cells with antibodies specific for H-2Kb/SIINFEKL complexes. We also treated tumor-bearing wild-type (WT) mice with anti-IGSF8 antibody to compare the anti-tumor and immunoregulatory effects of IGSF8 blocking to those observed in IGSF8 KO animals.
Results: IGSF8 KO C57BL/6 mice were viable and fertile. Tumor growth was significantly suppressed in IGSF8 KO mice compared to WT controls across multiple syngeneic models, including B16-F10 melanoma, RM1 prostate cancer, MC38 colon cancer, and LLC non-small cell lung cancer. After tumor challenge, KO mice had a significantly higher frequency of activated $CD44^+$, $PD\text{-}1^+$ T cells from both tumor tissue and tumor draining lymph nodes. In the OVA-expressing tumor model, we observed elevated levels of $OVA_{257\text{-}264}$ $tetramer^+$ $CD8^+$ T cells and $H\text{-}2K^b$ bound $SIINFEKL^+$ dendritic cells in KO mice. Treatment of WT mice with anti-IGSF8 antibody recapitulated these findings, demonstrating enhanced activated T cell frequencies comparable to those observed in KO animals.
Conclusion: Genetic ablation of IGSF8 or its therapeutic blockade with anti-IGSF8 antibody significantly suppressed syngeneic tumor growth, associated with enhanced antigen-specific T cell and dendritic cell responses. These findings reveal a previously unknown cancer cell-extrinsic function of IGSF8 in regulating tumor immunity, further supporting IGSF8 as a promising target for cancer immunotherapy.

#4268 The allosteric MAT2A inhibitor IDE397 uniquely exploits metabolic liabilities associated with MTAP deletion to perturb DNA replication and repair.

Damien Garbett, **Arjun A. Rao**, Marcus M. Fischer, John Vivian, Khristina Magallanes, Natalie Bresnahan, Pari Lanham, Atul Rathore, Austin Li, Rebeca M. Choy, J. Carl Schultz, Scott R. Tyler, Angelica Gonzalez-Sanchez, Zhipeng Fang, Kelly Trego, Briana Marinoni, Yuchen Bai, Peter Teriete, Christian R. Frey, Michael A. White, Claire L. Neilan

Ideaya Biosciences, South San Francisco, CA

Methylthioadenosine phosphorylase (MTAP) is co-deleted with the tumor suppressor CDKN2A in approximately 15% of solid tumors. Loss of MTAP blocks cellular 1-carbon salvage pathway activity due to an inability to convert MTA into adenine and methionine. Accumulation of MTAP's substrate, MTA, and coincident depletion of the MTAP's products, adenine and methionine precursors, results in two distinct targetable vulnerabilities: direct S-Adenosyl methionine (SAM)-competitive inhibition of the essential methyltransferase Protein arginine methyltransferase 5 (PRMT5), and reduced capacity for sufficient nucleotide synthesis required to support tumor cell DNA replication and repair. MAT2A is the rate-limiting enzyme for SAM synthesis in tumor cells, and its position at the intersection of methyltransferase activity and 1-carbon metabolism indicates pharmacological suppression of MAT2A has the unique potential to exploit both vulnerabilities conferred by MTAP deletion (MTAPdel). IDE397 is an allosteric MAT2A inhibitor designed to deliver anti-tumor activity selectively in patients harboring MTAPdel tumors and has demonstrated clinical activity. Here, we have deployed label and label-free profiling of IDE397-dependent effects on tumor cell metabolism paired with genome-wide assessments of cellular methyltransferase activity to evaluate key determinants of IDE397 anti-tumor activity. IDE397 selectively perturbed de novo nucleoside/nucleotide biosynthesis in MTAPdel cells via depletion of homocysteine pools and disruption of methionine cycle/folate cycle integration. Global analyses of RNA splicing, chromatin accessibility, and DNA methylation indicated that IDE397 effectively suppressed PRMT5 methyltransferase activity, while other essential SAM-dependent processes were maintained. These observations indicate that MTAP loss confers a dual dependency on MAT2A activity for sufficient SAM biosynthesis to both support 1-carbon metabolism-associated DNA repair capacity in the absence of MTA recycling, and to ameliorate direct inhibition of PRMT5 by MTA. Furthermore, broad preservation of SAM-dependent methyltransferase activity in the presence of IDE397 suggests a hierarchy among methyltransferases for SAM consumption. Observations of adaptive compensation within distinct methyltransferase pathways, such as polyamine synthesis, suggest this hierarchy is dynamic and orchestrated. The metabolic liabilities arising from MAT2A inhibition in MTAP deleted cancer cells provide a mechanistic rationale for unique therapeutic opportunities for IDE397 as a single-agent and in combination which are now being evaluated in patients (NCT04794699 and NCT05975073).

#4269 Defining the impact of autophagy blockade on triple negative breast cancer and remodeling of the tumor-immune microenvironment in primary and lung metastatic settings.

Tao Li, Hatem Soliman, Ernst Schonbrunn, Andrij Marusyk, Marilyn Bui, **Conor C. Lynch**, Marilena Tauro

Moffitt Cancer Center, Tampa, FL

Background: Triple negative breast cancer (TNBC) cells have high basal rates of autophagy to meet metabolic demands. Our emerging *in vitro* data demonstrates that ULK3 is an important initiator of the autophagy program and is especially important in enhancing TNBC cell survival in response to stressors such as chemotherapy. Inhibiting autophagy can lead to TNBC cell death and potentially the subsequent induction of immunogenic cell death pathways. Here, we interrogate the effect of ULK3 ablation on TNBC migration, invasion and metastasis and whether there is an impact on the surrounding immune landscape.

Methodology: We investigated the impact of autophagy impairment on TNBC cells viability and migration by using CRISPR-Cas9 ULK3 knockout in MDA-MB-231Luc and 4T1Luc cells, halting downstream autophagic machinery. Cell proliferation, migration, and ATP metabolism were monitored using advanced imaging tools such as Incucyte and Opera Phenix. The effects of ULK3 ablation on the metastatic process were examined *in vivo* by injecting parental 4T1Luc and ULK3 knockout (KO) cells into syngeneic BALB/c mice (500,000 cells/mouse, n=10/group) and tracing metastasis to various organs (liver, bones) using bioluminescent imaging (BLI). Tissues were subsequently analyzed using 10x Genomics HD Visium Spatial Transcriptomics. Additionally, multiplex immunofluorescent analysis was performed on TNBC patient's tissue microarrays.

Results: Our *in vitro* data demonstrate that CRISPR-Cas9 ULK3 KO cells (MDA-MB-231Luc, 4T1Luc) exhibit reduced cell proliferation and migration, along with lower ATP metabolite levels, after 96 hours of incubation, compared to their parental counterparts. Our *in vivo* data confirmed reduced primary tumor growth and metastatic dissemination in BALB/c mice injected with 4T1Luc ULK3 KO cells compared to parental control. *Ex vivo* tissue analysis using spatial transcriptomics revealed distinct differences in the tumor microenvironment and immune infiltration between metastatic organs (liver vs bones), correlating higher tumor cell proliferation and higher T regulatory cell infiltration with poorer overall survival. Ongoing analysis of TMAs from Moffitt TNBC patients correlated similar immune e infiltration profiles with worse outcomes. Further analysis of autophagy markers in TNBC cells, along with their correlation to treatment regimens received, will help clarify the metabolic status of cells in patients.

Conclusions: Our experimental approach highlights the potential of targeting the autophagy metabolic pathway to influence TNBC progression. These findings support the use of pharmacological autophagy inhibitors at specific disease stages and offer insights into how patients might respond to immunomodulatory agents based on the localization of their metastases.

#4270 Targeting CNTN4 with exatecan-based antibody-drug conjugate for the treatment of solid tumors.

Mi Young Cha, **Mira Kim**, Seungmin Byun, Youngeun Ha, Kitae Park, Bu-Nam Jeon, Hyunuk Kim, Hyunkyung Yu, Hyunjin Yoo, Soojung Moon, Gyeong-Jin Cheon, Boeun Ju, Hansoo Park

Genome & Company, Suwon-si, Gyeonggi-do, Korea, Republic of

As a novel immune checkpoint, we previously confirmed that contactin 4 (CNTN4) expressed on tumors negatively regulates T cell activity by binding to amyloid precursor protein (APP) on T cells. Immunohistochemistry analysis revealed high expression of CNTN4 in various tumors, including gallbladder, pancreatic, gastric, endometrial, hepatic, prostatic, bladder cancers, melanoma, and others, while its expression remains low in normal tissues, including immune cells. Based on the tumor-specific expression profile of CNTN4, we have developed an antibody-drug conjugate (ADC) targeting CNTN4. This ADC utilizes GENA-104A16.hIgG1 (A16.1), an anti-CNTN4 antibody with reduced effector function of human IgG1, conjugated via cysteine-maleimide linkage to linker including hydrophilic moiety and the topoisomerase I inhibitor (exatecan) with high drug-to-antibody ratio (DAR)(A16.1-Exa). To evaluate its potential, the internalization performance of A16.1 was compared with trastuzumab (anti-HER2) using SK-BR3 cells engineered to overexpress CNTN4, which exhibited a higher HER2 target count than CNTN4 target count. A16.1-Exa demonstrated potent and highly specific cytotoxicity in CNTN4-positive cancer cells, accompanied by a robust bystander effect comparable to the Dxd conjugate. Additionally, A16.1-Exa exhibited high plasma stability and retained its immune checkpoint-blocking function, supporting T cell-mediated cytotoxicity alongside payload delivery. Treatment with A16.1-Exa demonstrated a very promising anti-tumor effect in a fibrosarcoma xenograft mouse model (HT1080/CNTN4). Investigation of the anti-tumor efficacy in a PDX model was conducted with GENA-104A16 (human IgG4 S228P) antibody in the IND-approved stage, conjugated with MMAF (low DAR) in a pancreatic cancer model. Once the tumor volume reached 195 mm^3, mice were randomly divided, and the A16-MMAF conjugate (5 mg/kg) was administered intravenously twice post-grouping. The treatment showed strong anti-tumor activity, leading to tumor regression. Future studies will expand the PDX models and optimize the therapeutic potential of exatecan conjugates to advance the development of CNTN4-targeted therapies, offering a promising approach for treating diverse cancers.

#4271 Discovery of NNC 05-2090, a small molecule antagonist of the neuromedin U receptor 2 for glioma treatment.

Yuna Roh, Taesang Son, Jang-Seong Kim, Tae-Su Han, Hyun Seung Ban, Seon-Kyu Kim

Korea Research Institute of Bioscience and Biotechnology, Daejeon, Korea, Republic of

Gliomas account for approximately 30% of all brain and central nervous system tumors, and 80% of all malignant brain tumors. Despite their high frequency, the causes of gliomas remain largely unknown. Temozolomide is the standard treatment for glioma, but its efficacy is limited due to the high rate of recurrence and the development of drug resistance in glioma patients. Therefore, discovering novel therapeutic targets and drugs is crucial to improving survival rate for glioma patients. This study aims to investigate the functions of neuromedin U receptor 2 (NMUR2) as a novel target for glioma and to identify NMUR2-specific regulatory drugs. NMUR2 is highly expressed in glioma tissue, and its overexpression promotes cell proliferation and migration, while its knockdown suppresses these effects. RNA sequencing analysis revealed that NMUR2 knockdown downregulates cell cycle-related genes. STAT5, a transcription factor, mediates the link between NMUR2 and cell cycle regulation. To discover an NMUR2-specific antagonist, we performed cell-based drug screening with 6,331 repurposing drugs and finally identified NNC 05-2090. The NNC 05-2090 treatment in glioma cells reduced cell cycle progression through its downstream signaling pathway. Additionally, we observed a synergistic effect between NNC 05-2090 and temozolomide in both in vitro and in vivo. In conclusion, this study suggests that NMUR2 is a promising novel target, and its antagonist, NNC 05-2090, combined with temozolomide, might offer a promising strategy to improve glioma treatment.

#4272 Cirtuvivint inhibits Ewing sarcoma (ES) growth by suppressing EWS-FLI-1 expression and inducing alternate EWS-FLI1 splice variants.

Sergei Vatolin, Gary K. Schwartz

Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH

Background: The transcription factor EWS-FLI1 is responsible for malignant transformation and ES cell survival. The breakpoints observed typically occur within introns of EWSR1 or FLI1, and expression of EWS-FLI1 requires the splicing machinery to generate an in-frame transcript. Cirtuvivint (SM08502, Biosplice Therapeutics Inc) has been shown to disrupt spliceosome activity by inhibiting Cdc2-like (CLK) and dual-specificity tyrosine phosphorylation-regulated (DYRK) kinases that regulate pre-mRNA splicing. In view of this, we elected to test its effect on ES cell growth, EWS-FLI-1 expression, and whether it would generate alternate splice variants that could suppress ES cell growth.
Results: Treatment of ES cells (A673, CHP100, and MHH ES1) with increasing concentrations of cirtuvivint, as well as its analog SM09419, significantly reduced cell viability (LD_{50} ~250 nM) both in vitro and in vivo, This treatment suppressed EWS-FLI-1 expression and generated multiple alternative EWS-FLI-1 variants within 4-6 hours, marked by the loss of whole exons. Mechanistic studies showed reduced β-catenin and c-myc expression, however, siRNA experiments targeting these genes did not affect cell growth. To investigate the role of these alternative EWS-FLI1 splice variants, transcripts generated by cirtuvivint treatment were cloned, sequenced, and inserted into eukaryotic expression vectors, including a Tet-inducible system and vectors for cell-free protein expression. A luciferase reporter vector containing the EWSR1-FLI1 binding site (GGAAx20) was constructed to assess the impact of wild-type and variant EWSR1-FLI1 on downstream gene expression. Results showed that the expression of specific alternative EWSR1-FLI1 variants in ES cells significantly reduced cell viability, whereas others had no effect. Moreover, cirtuvivint-treated cells transfected with the luciferase reporter exhibited decreased luciferase expression, indicating a loss of gene expression regulated by the oncogenic fusion protein. Comprehensive transcriptome analysis (RNAseq) 4-6 hours post-treatment exhibited significant changes in gene expression, including those associated with alternate splicing, offering new insights on the molecular shifts induced by splicing modulation in these cells.
Conclusion. These findings suggest that cirtuvivint, as a novel CLK/DYRK inhibitor, offers a new therapeutic strategy for targeting EWS-FLI-1 in ES. The induction of specific alternative splice variants has the ability to inhibit cell growth with the associated suppression of gene expression. A clinical trial in recurrent or refractory ES is planned.

#4273 Discovery of first in class, polyphenolic inhibitors of CKAP4 and their antitumor activity in ovarian and endometrial cancer.

Eugenio Gaudio[1], Viktor Ivasishin[2], Paulina Biniecka[1], Christian Kleusch[3], Cosimo Kropp[3], Benjamin Zimmer[3], Kamilla Pawlicka[4], Helena Almqvist[5], Alexey Chernobrovkin[5], Janneke Melis[6], Guido Zaman[6], **Dan F. Stoicescu**[1]

[1]Floratek Pharma, Aubonne, Switzerland,[2]Symeres B.V., Groningen, Netherlands,[3]2Bind GmbH, Regensburg, Germany,[4]Carcinotech Ltd, Edinburgh, United Kingdom,[5]Pelago Bioscience AB, Solna, Sweden,[6]Oncolines B.V., Oss, Netherlands

While some plant-derived polyphenolic compounds exhibit anticancer activity, their complex mechanism of action is generally hindering the efforts to produce clinically useful derivatives. Here we present several compounds that are, to the best of our knowledge, the first known inhibitors of cytoskeleton associated protein 4 (CKAP4) a transmembrane protein associated with resilient forms of cancer. Since CKAP4 is overexpressed in ovarian cancer the compounds were evaluated in the experimental models below as proof of concept.
Target deconvolution using CETSA was followed by spectral shift binding, TRIC and ITC validation. *In vitro* studies assessed anti-proliferative activity (ATPLite, Revvity), with Oncolines Profiler analysis comparing the IC_{50} fingerprints with those of 213 pre-profiled reference drugs. *Bioprinted* human tissue organoids tested the efficacy of the new chemical entities. Tumor microenvironment characterization was performed using immunofluorescence imaging.From our proprietary physical library of 400 new chemical entities SND 106, 108, 562, 581, 584 and 586 were selected based on their strong binding to CKAP4. They were highly active in the ovarian and endometrial cell lines: PA-1, ES-2, AN3-CA, OVCAR-3 with IC_{50}s in the low nanomolar range. Furthermore, the results of the organoid assays showed a significantly improved efficacy of the new compounds compared with the standard of care drug carboplatin.Novel, first-in-class small molecules inhibitors of CKAP4 were discovered, showing strong antitumor activity in ovarian and endometrial cancer. Future studies will determine whether they can be developed into new drugs.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Novel Cancer Therapeutic Targets 1
Poster Session

#4277 EP601: Agonism of GPR84 activates myeloid cells and augments the response to anti-CTLA4 to promote tumor growth inhibition and prolong survival in a syngeneic (CT26) tumor model.

Graeme L. Fraser, Catherine Sorlet, Nicolas Parmentier, Sarah Rorive, Guillaume Dutheuil

EPICS Therapeutics, Gosselies, Belgium

GPR84 is a G-protein coupled receptor predominantly expressed on myeloid cells such as macrophages, NK cells, monocytes and neutrophils. It has previously been reported that GPR84 expression is induced by acute inflammatory stimuli and furthermore that GPR84 may be an interesting target to reverse the immunosuppressive tumor microenvironment[1]. In the current study, induced expression of GPR84 is confirmed as it is demonstrated that there is a 5-fold (or greater) expression of GPR84 on human (M1) macrophages polarized with either IFN-gamma or muramyl dipeptide-and-LPS ("MDP+LPS"). Compound A (CpdA) is a proprietary, selective, small-molecule agonist at GPR84 with similar potency at both the human and mouse GPR84 receptor orthologs (cAMP assay, EC_{50} = 13 nM and 9 nM, respectively). CpdA promotes TNF-alpha secretion from MDP+LPS-activated human macrophages in a concentration-dependent manner and this response is blocked by the GPR84 antagonist GLPG1205. The pharmacokinetic profile of CpdA has been established in rodents ($t_{1/2}$ = 1h, oral bioavailability = 25%) and the compound is appropriate for *in vivo* testing. In the CT26 mouse tumor model, CpdA (30 mg/kg, PO, BID) significantly increased the response to anti-CLTA4 (2 mg/kg, IP, BIW) to >80% tumor growth inhibition and improved survival corresponding to altered immune cell infiltration into the tumor. These results demonstrate the potential of pharmacological activation of GPR84 as a novel approach relevant to cancer immunotherapy.[1]Li et al., Cancer Immunol Immunother (2024)

#4278 Targeting tumor pericyte-specific transcription factor heterodimer for anti-metastasis cancer therapy.

Junqiu Zhang[1], Wenqian Yin[1], Minfeng Chen[1], Yi Xue[2], Wencai Ye[1], Dongmei Zhang[1]

[1]State Key Laboratony of Bioactive Molecules and Druggabity Assesment, Jinan University, Guangzhou, China,[2]Tsinghua University, Beijing, China

Pericytes, mural cells that envelop capillaries, play a critical role in tumor metastasis. While current therapies targeting tumor pericytes (TPCs) effectively suppress tumor angiogenesis and growth, they paradoxically promote metastasis, highlighting the need for improved TPC-based strategies. In this study, we identified a TPC-specific transcription factor heterodimer, TCF21-TCF3, which is positively associated with hematogenous metastasis. TCF3 is essential for TCF21-mediated collagen hydroxylation, facilitating extracellular matrix deposition and accelerating tumor metastasis. Using hydrogen-deuterium exchange mass spectrometry (HDX-MS), transverse relaxation-optimized spectroscopy (TROSY) NMR, and mutational analysis, we characterized the interacting residues of the TCF21-TCF3 heterodimer. A peptide designed to disrupt the TCF21-TCF3 interaction inhibited the formation of the heterodimer, downregulated TCF21/TCF3-dependent gene expression, and suppressed malignant behaviors, effectively reducing metastasis. This study proposes that targeting TPC-specific transcription factor heterodimers offers a promising therapeutic approach to combat tumor metastasis.

#4279 FAK inhibitor APG-2449 induces immunogenic cell death and enhances anti-tumor immunity in cervical cancer through the PERK-eIF2α pathway.

Lin Zhang[1], Mingyue Zhang[1], Weihan Kang[2], Jing Xiao[1], Maple Tse[3], Yong Du[1], Dajun Yang[4]

[1]Sun Yat-sen University Cancer Center (SYSUCC), Guangzhou, China,[2]The First Clinical Medical College of Lanzhou University, Lanzhou, China,[3]University of Sheffield, Sheffield, United Kingdom,[4]Sun Yat-sen University Cancer Center (SYSUCC)/Ascentage Pharma (Suzhou), Guangzhou/Suzhou, China

The focal adhesion kinase (FAK) inhibitor APG-2449, a multi-target tyrosine kinase inhibitor that also targets ALK and ROS1, has demonstrated significant potential for inducing anti-tumor immunity. In this study, we explored the effects of APG-2449 on cervical cancer, emphasizing its capacity to induce immunogenic cell death (ICD) and stimulate immune responses via the PERK-eIF2α pathway. Our findings indicate that APG-2449 enhances ATP release and calreticulin (CRT) exposure on the surface of tumor cells, which are key indicators of ICD. Moreover, treatment with APG-2449 led to a notable increase in dendritic cell (DC) maturation and promoted their differentiation into classical dendritic cells (cDCs), which are essential for antigen presentation and the subsequent activation of T-cells.In vitro co-culture models, APG-2449 effectively boosted the activation of DCs and increased the frequency of tumor-specific CD8+ T cells. These observations underscore that APG-2449 elicits a robust immunogenic response, suggesting that inhibition of FAK/ALK/ROS1 could be a promising therapeutic approach for enhancing anti-tumor immunity in cervical cancer.These results highlight the potential of APG-2449 as an innovative therapeutic agent capable of modifying the tumor microenvironment to foster an effective anti-tumor immune response via the FAK/PERK-eIF2α axis. Future studies are needed to determine the clinical efficacy of APG-2449, particularly in combination with other immunotherapies.

#4280 DWP216, a novel TEAD1 selective inhibitor for NF2 mutant tumors and drug-tolerant persister cells.

Bora Yoo, YoungKu Kang, Won An, Seul Lee, Inyoung Lee, Ahreum Kwon, Eunji Ha, Hyoungrok Bak, Ji-Duck Kim, Joon Seok Park

Daewoong Pharmaceutical Company Ltd., Yongin-si, Korea, Republic of

Neurofibromatosis type 2 (NF2) controls the Hippo pathway signaling through YAP and TEAD axis. NF2 mutation leads to YAP and TEAD activation and is reported in malignant mesothelioma with 30-40% and meningioma with 50%. Furthermore, drug-tolerant persister cells to EGFR inhibitor or KRAS inhibitor show up-regulation of YAP and TEAD. Four isoforms of TEAD (1-4) are highly conserved and each TEAD isoform has the different biological function depending on organ and co-factors. DWP216, a TEAD1 selective inhibitor, shows the excellent in vitro activities. DWP216 also inhibits TEAD1 activity, TEAD1 palmitoylation and interaction between TEAD1 and YAP1 by binding to palmitate binding pocket of TEAD1. Pharmacokinetic parameter of DWP216 present good druglike properties with blood-brain barrier penetration. DWP216 has the superior in vivo efficacy compared to TEAD1 selective inhibitor and pan-TEAD inhibitor. Moreover, we found that TEAD1 is a key regulator for drug-tolerant persister cells to targeted therapy. Combination of DWP216 and EGFR inhibitor or KRAS inhibitor show synergistic anti-cancer effect in vitro and in vivo. In conclusion, DWP216 is a promising TEAD1 selective inhibitor for NF2 mutant tumor and may be a proper option for drug-resistance of targeted therapy. DWP216 is preparing toward to IND filing for Phase 1 in 2025.

#4281 Pharmacological inhibition of thymine DNA glycosylase (TDG) triggers an anti-tumor immunity to suppress p53-deficient cancer.

Jiannan Guo[1], Meng Wang[1], Jiaxin Zhou[2], Yao Cao[1], Yiqin Wang[2], Yilin Liu[1], Youzhen Wang[1], Yuan Mi[1], Yarui Du[2], Guoliang Xu[2], Haiping Wu[1]

[1]CytosinLab Therapeutics, Hangzhou, China,[2]Center for Excellence in Molecular Cell Science, Chinese Academy of Sciences, Shanghai, China

As the most frequently mutated or silenced tumor suppressor, *TP53* mediates cell-cycle arrest, apoptosis, and senescence in cancer development. Although patients with *TP53* alterations are unfortunately poor in prognosis and survival, targeting p53 directly is still largely difficult to activate or restore p53 normal function specifically in cancer. Recently, synthetic lethality approach has been successfully applied to treat patients with mutations in tumor suppressor genes (TSGs) like PARPi in BRCA1/2 mutated tumors, potentiating the future direction of next generation p53 therapies. However, it remains a huge challenge to identify the *bona fide* synthetic lethal partners to *TP53* mutations in cancer. In this study, we demonstrated that pharmacological inhibiting thymine DNA glycosylase (TDG), a multifunctional DNA modifying enzyme with essential roles in DNA base excision repair (BER), transcriptional regulation, and DNA active demethylation, can induce synthetic lethality specifically in various p53-deficient solid tumors including lung, breast, and skin cancer, etc. This offers a novel strategy to target mutated *TP53* for cancer therapies. We discovered and developed from CytosinLab's EpigenPLUS platform a series of small-molecule inhibitors that binds specifically and directly to TDG and disrupts its DNA-binding and modifying activities. Among the series, C-271 is an orally bioavailable front-runner with excellent pharmacokinetics (PK) properties and druggabilities and exhibits profound efficacy in suppressing growth of p53-deficient lung cancer cells both *in vitro* and *in vivo*, with minimal repression on p53 wide-type cells. In p53-deficient cancer cells, treatment with C-271 reduces transcription of the RNA helicase *DHX9*, thereby leading to the accumulation of SINE (short interspersed nuclear element) -derived dsRNA and subsequent activation of the anti-tumor immunity pathways. Additionally, TDG inhibition enhances anti-tumor immunity and displays significant synergy with anti-CTLA-4 antibody, the immune checkpoint blockade (ICB). Furthermore, we explored and validated the sensitivity of other p53-deficient cancer types to TDG inhibition, broadening the potential of TDG inhibition to treat a larger patient population. In conclusion, we identified inhibition of TDG as a brand-new synthetic lethality approach and an innovative synthetic immune activation anti-cancer mechanism in *TP53*-mutant tumors. It underscores the promise of profiling and developing C-271 or other preclinical candidate molecules of TDG into clinic study and extending the breakthrough first-in-class (FIC) therapy to be viable and beneficial for treating p53-deficient cancers. CytosinLab Therapeutics holds full intellectual property (IP) rights to C-271 and its series of TDG-targeting small molecules.

#4283 PLK4 inhibition: A therapeutic strategy to treat patients with TRIM37 amplified tumors.

Kristen Wong, Debashish U. Menon, Weichao Zhang, Boris Wilson, Jared Spletstoser

GlaxoSmithKline, Collegeville, PA

TRIM37 is a breast cancer oncogene and crucial regulator of pericentriolar matrix (PCM) components. Tumors with amplified TRIM37, an E3-ubiquitin ligase, undergo mitotic catastrophe when Polo-like kinase 4 (PLK4) is inhibited. PLK4 is essential for centriole duplication, a key process in cell division. While several PLK4 kinase inhibitors have been identified, their selectivity and in vivo pharmacokinetic properties are suboptimal. In this study, cellular proliferation and pharmacodynamic assays were developed to optimize the activity and selectivity of PLK4 inhibitors. PLK4 inhibition more effectively inhibited cell proliferation in TRIM37-amplified breast and neuroblastoma cell lines. Conversely, TRIM37 knockout breast cancer cells showed reduced sensitivity to PLK4 inhibition. Mechanistically, PLK4 stability is controlled by its auto-phosphorylation, which triggers rapid degradation via the proteasomal pathway. Tool compounds confirmed that inhibition of PLK4 leads to its stabilization, establishing PLK4 stabilization as a pharmacodynamic biomarker for PLK4 inhibition. These assays will enable evaluation of PLK4 inhibitor activity and selectivity in TRIM37 amplified cells.

#4285 Modulation of spliceosomal protein hnRNPH1 in BRAF, NRAS, and triple-wild type melanoma induces immunogenicity and in vivo immune response.

Maab Sultan[1], Sadeeshkumar Velayutham[1], Vladimir Beljanski[2], Keiran S.M. Smalley[3], Nhut Minh Nguyen[1], Shweta Shah[4], Tulsi Desai[4], Aveta Singh[5], Jun Yong Choi[5], Dmitriy Minond[1]

[1]Nova Southeastern University, College of Pharmacy, Fort Lauderdale, FL,[2]Cell Therapy Institute, Dr Kiran C. Patel College of Allopathic Medicine, Nova Southeastern University, Fort Lauderdale, FL,[3]Department of Tumor Biology, Moffitt Cancer Center, Tampa, FL,[4]Keiran Patel College of Osteopathic Medicine, Nova Southeastern University, Fort Lauderdale, FL,[5]Department of Chemistry and Biochemistry, Queens College, Flushing, NY

Background: We previously reported that treating WM266-4 with H1 siRNA, followed by RNAseq, resulting in increased immune related pathways. Additionally, we reported novel melanoma leads, 2155-14 and 2155-18, which act via downregulation of spliceosomal heterogenous nuclear ribonuclear proteins hnRNPH1/H2 (H1/H2) and demonstrated efficacy in an in vivo model of A375 BRAF mutation. This study aimed to determine the effect of H1 modulation on immune-related genes in vitro across melanoma cell lines with diverse mutational backgrounds and in vivo using a syngeneic mouse model.
Methods: To assess in vivo immune response, 2155-14 and 2155-18 were tested in the B16F10 C57BL/6J syngeneic mouse model (n=5). In vitro, we knocked down H1/H2 in BRAF-mutant, NRAS-mutant, and triple-wild type melanoma cell lines and treated BRAF and NRAS cell lines with both compounds to evaluate immune responses to spliceosomal modulation. Data from in vivo experiments were analyzed using one-way ANOVA to compare means, followed by Sidak's multiple comparisons for significant differences. Statistical significance was set at $p < 0.05$. For NanoString experiments, a 1.4-fold change and p-value <0.05 (n=3) were used as thresholds.
Results: Treatment of B16F10 syngeneic melanoma mouse model with 2155-14 and 2155-18 resulted in increased tumor infiltration of macrophages (p-value <0.01), dendritic cells (p-value <0.05), B cells (p-value <0.05), and CD4+ T cells (p-value <0.05) as determined by flow cytometry analysis. Moreover, NanoString gene expression analysis of both transfected and treated samples confirmed upregulation of interferon signaling and cellular immune responses, processes known to enhance cellular immunogenicity.
Conclusion: These findings highlight the therapeutic promise of targeting spliceosomal proteins H1 and H2, and they underscore the potential of 2155-14 and 2155-18 as promising drug candidates for melanoma treatment. Furthermore, the results suggest that spliceosomal inhibition can enhance immune system activation, presenting an opportunity to combine these therapies with FDA-approved immunotherapies to achieve improved treatment outcomes.

#4286 CHK1 as a novel therapeutic target for pleural mesothelioma.

K. Akagi[1], H. Taniguchi[1], H. Tomono[1], M. Matsuo[1], H. Gyotoku[1], S. Takemoto[1], Y. Nakao[1], S. Yano[2], K. Ashizawa[1], H. Mukae[1];
[1]Nagasaki University, Nagasaki, Japan, [2]Kanazawa University, Ishikawa, Japan

Background: Pleural mesothelioma (PM) is a rare thoracic malignant tumor with poor prognosis. First line nivolumab plus ipilimumab prolonged overall survival compared to standard chemotherapy, however its clinical benefit is limited and development of therapeutic strategy with novel mechanisms is strongly desired. In this study, we focused on CHK1, one of the major molecules involved in the DNA damage repair, as a candidate for novel therapeutic target since one of the hallmarks of PM is DNA damage repair, such as BAP1 loss or TP53 mutation.
Method: The prognostic impact of CHK1 mRNA expression on PM was analyzed using RNAseq data of The Cancer Genome Atlas (TCGA). The anti-tumor effect of CHK1 inhibitor using human PM cell lines were evaluated by MTT assay and annexin V assay. The protein expression was evaluated by Western blotting and the mRNA expression was evaluated by qRT-PCR. The anti-tumor effects of CHK1 inhibitor in vivo were evaluated with subcutaneous tumor model that was established by injecting mouse PM cells subcutaneously in immunodeficient Balb/c nu/nu mice, and the pleural carcinomatosis model that was also established with injecting the mouse PM cells into the intrapleural space of immunocompetent Balb/c mouse.
Results: The low CHK1 expression group demonstrated significantly longer overall survival than the high CHK1 expression group in PM cases of TCGA. CHK1 inhibitor had anti-tumor effect and induced apoptosis in a dose-dependent manner. CHK1 inhibitor increased micronuclei formation, activated STING pathway, and induced mRNA expression of type I and II interferons, CCL5, and CXCL10, suggesting CHK1 inhibitor activated anti-tumor immune response. PD-L1 expression was also increased by CHK1 inhibitor. CHK1 inhibitor demonstrated significantly suppressed tumor growth combined with cisplatin compared to CHK1 inhibitor alone in the subcutaneous mouse model. Furthermore, CHK1 inhibitor combined with anti-PD-L1 antibody significantly prolonged overall survival in the pleural carcinomatosis model.
Conclusion: The CHK1 inhibitor showed immunostimulatory effect on PM in addition to direct anti-tumor effect. Furthermore, the therapeutic benefit was enhanced when combined with cisplatin or anti-PD-L1 antibody.

#4287 GBC-11004: an AI-driven novel kinase target with potential to overcome osimertinib resistance in NSCLC.

Hat Nim Jeon, Ji Young Bae, Hyunsun Na, Ji Hwan Park, Seung Hyun Ahn, Bada Pyo, **Jihye Ryu**, Jinguen Rheey
