Osimertinib resistance poses a significant clinical challenge in the treatment of non-small cell lung cancer (NSCLC), with diverse mechanisms complicating patient outcomes. Conventional next-generation sequencing (NGS) analysis methods often fall short in identifying effective therapeutic targets due to the complexity and heterogeneity of resistance mechanisms. To address this issue, we have developed an artificial intelligence (AI)-driven target discovery platform designed to identify novel and effective drug target genes capable of overcoming Osimertinib resistance in NSCLC, thereby surpassing the capabilities of traditional NGS analysis. Our platform integrates three key components: deep learning (G-TAC), statistical significance testing (G-SET), and a large language model (G-LAT). G-TAC and G-SET evaluate and rank genes according to their responsiveness to Osimertinib and tumor-specific expression. G-LAT assesses these genes based on publications and clinical trials to ensure novelty and efficacy of the identified targets. We identified a novel kinase target named GBC-11004, as one of the top-ranked target genes that were found to be overexpressed in patient-derived organoids (PDOs) resistant to Osimertinib. To ascertain the functional impact of GBC-11004, target validation was conducted using PDOs and CRISPR/Cas9-based gene editing. Gene editing in Osimertinib resistant PDOs resulted in a significant decrease in cell viability corresponding to increased indel frequency. Furthermore, we have initiated lead compound optimization by preliminary IC50 analyses using compounds targeting GBC-11004 and observed significantly enhanced sensitivity in the combination therapy group (Osimertinib + GBC-11004 inhibitor) compared to the Osimertinib monotherapy group in resistant PDO models. Our results demonstrate the potential of GBC-11004 as a novel therapeutic target for overcoming Osimertinib resistance in NSCLC treatment and emphasize the capability of our PDO-based AI-driven target discovery platform in identifying high-priority novel targets.

#4288 Discovery of a small molecule inhibitor of ADAR1 for cancer immunotherapy.

Zijun Chen, Liqiang Shen, Qi Zhao, Jing Lu, Weiliang Li, Wen Jin, Xiang Ji, Mengchao Shi, Haowei Zhu, Lin Wang, Leduo Zhang, Xianqi Kong, Dawei Chen, **Tianlun Zhou**, Jiasheng Lu

Risen Pharmaceuticals Private Ltd., Shanghai, China

Adenosine deaminase acting on RNA 1 (ADAR1) is a critical enzyme that catalyzes the conversion of adenosine to inosine in double-stranded RNA (dsRNA). By modifying endogenous dsRNA, ADAR1 prevents erroneous recognition by cytoplasmic dsRNA sensors, including MDA5, PKR, and ZBP1. Inhibition of ADAR1's deaminase activity can activate MDA5-mediated innate immune responses and stimulate interferon production, while blocking ADAR1's RNA-binding activity can induce PKR-mediated translational shutdown and cell death. Emerging evidence suggests that silencing ADAR1 enhances tumor responsiveness to immune checkpoint inhibitors, highlighting ADAR1 as a promising target in cancer immunotherapy. In this study, we aimed to develop small-molecule inhibitors of ADAR1 as potential therapeutic agents for ADAR1-dependent cancers. A primary RNA-editing assay was established to screen a library of 265,000 compounds, leading to the identification of 505 initial hits. These hits underwent triage validation involving target engagement studies, cell-based editing assays, and selectivity profiling. Among the validated compounds, RP05129 emerged as a lead candidate for further investigation. RP05129 effectively inhibited ADAR1's RNA-editing activity in both biochemical and cellular assays. Treatment with RP05129 activated downstream interferon-β signaling in an MDA5-dependent manner, confirming its immunostimulatory potential. Detailed point mutation studies revealed the binding site of RP05129 on the ADAR1 protein, providing insight into its mechanism of action. The identification of RP05129 as a selective ADAR1 inhibitor underscores its potential to enhance immune-based therapies for cancers reliant on ADAR1 activity. Further preclinical evaluation of RP05129 may pave the way for novel therapeutic strategies in cancer immunotherapy

#4289 Discovery of potent RAD51 inhibitors with anticancer activity in preclinical models of non-small cell lung cancer.

Yifan Yu[1], Morgan Black[2], Nikolina Radulovich[1], Peter Ferguson[2], James Koropatnick[2], Ming Tsao[1], Mark D. Vincent[2], Geoffrey Liu[1], Samir H. Barghout[1]

[1]University Health Network, Toronto, ON, Canada,[2]Schulich School of Medicine & Dentistry, Western University, London, ON, Canada

RAD51 is a protein that plays a key, canonical role in double-strand break (DSB) repair through homologous recombination (HR) and is biologically important for maintaining genome stability. Given its additional, non-canonical role in mitigating the replication stress characteristic of tumor cells, RAD51 has emerged as an attractive therapeutic target in several malignancies including non-small cell lung cancer (NSCLC). Nonetheless, drug discovery endeavors for developing direct RAD51 inhibitors have had limited success. Here, we describe a series of novel RAD51 inhibitors and their cytotoxic activity in preclinical models of NSCLC. We accessed and improved upon a previously discovered series of phenylsulfonyl indolyl isoquinoline derivatives that bind to the hydrophobic pocket of RAD51 preventing its multimerization and interaction with BRCA2. Of these, JKYN-1 and its mesylate salt (patent application # CA3204011A1) displayed potent and selective RAD51 inhibition in cell-free assays. Given the biological importance of replication stress in a subset of NSCLC, we assessed the cytotoxicity of these RAD51 inhibitors in preclinical models of NSCLC. Using the CellTiter-Glo assay, JKYN-1 displayed cytotoxicity in A549 and H1975 cell lines with lower IC_{50} values compared to the classical RAD51 inhibitor B02 (A549, 4.9 vs >10 μM; H1975, 3.2 vs 8.3 μM). We subsequently assessed the cytotoxicity in a panel of 7 patient-derived organoids (PDOs) of NSCLC with diverse molecular, genetic, and clinical profiles (LPTO308, XDO137, LPTO357, LPTO318, LPTO366, LPTO362, LPTO221). In these models, JKYN-1 and JKYN-1-mesylate displayed a highly potent cytotoxicity with sub-micromolar IC_{50} values between 0.1-0.87 μM as opposed to B02 that had IC_{50} values between 3.7 to >10 μM. In conclusion, our data identify JKYN-1 and its mesylate salt as potent and selective RAD51 inhibitors with superior cytotoxic activity compared to classical inhibitors such as B02. These findings highlight the potential of these novel compounds as promising therapeutic agents in a subset of NSCLC.

#4290 Long chain fatty acid elongase 6 is a novel therapeutic target for breast cancer.

Linxiang Gong, Susumu Kohno, Chiaki Takahashi

Kanazawa University Cancer Research Institute, Kanazawa, Japan

Cancer cells alter the quality of lipids to grow and survive. De novo synthesized fatty acids need to be elongated to provide numerous varieties to lipids. Despite the critical functions of lipid metabolism in cell function, how specific elongase contributes to tumor progression remains incompletely understood. In breast cancer (BRCA), retinoblastoma 1 (RB1) mutation or deletion is considered as one of the key factors promoting tumor progression. We previously reported that loss of RB1 transcriptionally upregulates the elongation of long chain fatty acid family member 6 (ELOVL6). We observed that BRCA cells with lower RB1 expression tend to show high ELOVL6 expression. ELOVL6 inhibition reduced cell proliferation in all subtypes of BRCA cells in vitro and in vivo. Moreover, RB1 loss sensitized these cells to undergo apoptosis following ELOVL6 depletion. These data indicate that ELOVL6 may have synthetic lethal relationship with RB1. We tried to elucidate the mechanism whereby ELOVL6 inhibition causes anti-tumor effects from a metabolic perspective. We noticed that ELOVL6 depletion reduced p-AKT levels in BRCA cells. Using a lipidomic approach, we observed that ELOVL6 depletion caused significant increase in the amount of intracellular ceramide and glycosphingolipids and decrease in sphingomyelin. Cell death associated with enhanced accumulation of ceramide was observed in cells in which both RB1 and ELOVL6 depletion. Inhibition of serine palmitoyltransferase 1 (SPTLC1) restored the p-AKT level and cell proliferation. These results suggest that ELOVL6 inhibition reduces p-AKT level by enhancing ceramide accumulation thereby suppressing cell proliferation. Taken together, our observations suggest that ELOVL6 is a promising therapeutic target in BRCA.

#4291 Inhibition of FANCM helicase activity confers synthetic lethality in alternative lengthening of telomeres (ALT) positive cancers.

Youyou Zhang, Raghuvar Dronamraju, Tom Berrodin, Kevin Coleman, Benjamin Schwartz

GSK, Collegeville, PA

FANCM (Fanconi anemia, complementation group M) is a human gene that encodes a protein that plays a key role in DNA repair and genome maintenance. Alternative lengthening of telomeres (ALT) is a mechanism that allows cancer cells to maintain telomere length without using telomerase. A synthetic lethal relationship between ALT status and FANCM levels was uncovered by analyzing CRISPR Screens in DepMap database. By using telomerase (TERT) as a biomarker which is negative in ALT positive tumors, cell lines without TERT or ALT+ were found to be sensitive to FANCM knockdown. This synthetic lethal relationship was validated in cell lines with different status of ALT by targeting FANCM with siRNA pool and CRISPR-Cas9. Knock-in of K117K silent mutation, but not K117A/R mutations in catalytic domain of FANCM “rescued” the growth of ALT positive FANCM KO SAOS2 cell. Depletion or deletion of FANCM using siRNA/ CRISPR Cas9 led to the increase in the intensity/distribution of PML and TRF foci. ALT positive cell lines have significantly higher amount of C circle DNA compared to telomerase positive or ALT negative cell lines. Loss of FANCM leads to increase in the levels of C circles. Our results further validate FANCM as a target for ALT cancers and suggest inhibiting its helicase activity as a strategy to treat ALT cancer.

#4292 Targeting YB-1 as a treatment strategy for high-grade serous ovarian carcinoma.

D. Tailor[1], F. J. Garcia-Marques[2], A. Bermudez[2], W. Li[1], A. Dheeraj[1], A. Rolig[1], C.-F. Tsai[3], T. Liu[3], T. Pejovic[4], S. J. Pitteri[2], S. V. Malhotra[1];

[1]Knight Cancer Institute, Oregon Health & Science University, Portland, OR, [2]Stanford University, Palo Alto, CA, [3]Pacific Northwest National Laboratory, Richland, WA, [4]Providence OB/GYN Health Center, Medford, OR

Background: High-grade serous ovarian carcinoma (HGSC) is an aggressive type of ovarian cancer, accounting for 75% of ovarian epithelial cancers. It is often diagnosed at advanced stages and frequently develops treatment resistance, resulting in poor survival rates. A key protein associated with this resistance is Y-box binding protein 1 (YB-1), which binds to both RNA and DNA. We hypothesize that pharmacological inhibition of YB-1 may enhance HGSC treatment effectiveness and reduce the development of treatment resistance.
Method: We collected tumor tissue and adjacent normal tissue samples from HGSC patients whose disease relapsed after receiving four to six different therapies. These tissues were used for proteomics, multiplex immunohistochemistry (mIHC), and to create patient-derived xenograft (PDX) models. In mice, the PDX tumors were subjected to treatment with a combination therapy of YB-1 inhibition and chemotherapy agents. Additional proteome analysis was conducted on mouse HGSC cells.
Results: Proteome profiling of patient HGSC samples revealed that malignant tissues significantly overexpress YB-1 and related mRNA processing pathways in comparison to adjacent normal tissues. mIHC analysis of patient HGSC tissue indicated high YB-1 expression correlated with low infiltration of CD45-positive immune cells. *In vivo* mouse studies using the PDX models derived from HGSC samples indicated that treatment with a YB-1 inhibitor (monotherapy with SU056) slowed tumor progression and enhanced sensitivity to cisplatin and paclitaxel. Consistent with the analysis of patient tissues and PDX models, both *in vitro* and *in vivo* studies of mouse cell lines indicated that treatment with SU056 hindered tumor growth and the development of treatment resistance. Furthermore, proteome profiling of mouse HGSC cells treated with SU056 corroborated the patient tissue observations, demonstrating that YB-1 inhibition resulted in the downregulation of mRNA processing-associated pathways.
Conclusions: Combination therapy using a YB-1 inhibitor with chemotherapy enhances chemotherapeutic responses in HGSC PDX models.

#4294 SMCHD1 is a synthetic lethal strategy for cancers with a cancer-testis antigen gene expression signature.

V. Quereda[1], Y. Zhang[1], D. Klimaszewska[2], S. Tonin[2], T. Groth[1], Y. Rao[1], M. T. McCabe[1], B. Schwartz[3], M. Queisser[2], R. Buxton[2], T. J. Berrodin[1], S. Peace[2];

[1]GSK, Collegeville, PA, [2]GSK, Stevenage, United Kingdom, [3]GSK, Cambridge, MA

SMCHD1 is a component of the structural maintenance of chromosomes (SMC) protein family involved in epigenetic gene silencing of the X chromosome and other autosomal chromosome regions. SMCHD1 encodes an ATPase domain and binds chromatin at both N- and C-term domains to facilitate long-range chromatin interactions. However, the exact mechanism by which it elicits transcriptional silencing remains unknown. We have identified a selective dependency on SMCHD1 in cell lines exhibiting a gene expression signature characterized by high expression of multiple cancer testis antigen (CTA) genes. This CTA signature is observed in multiple cancers with >60% prevalence in Chronic Myeloid Leukemia. Importantly, SMCHD1's effect on cell growth was independent of its ATPase activity, and a knock-in degron tag phenocopied SMCHD1 KO indicating that the proliferative advantage offered by SMCHD1 might be due to structural SMCHD1 function unrelated with its enzymatic ATPase role. Finally, SMCHD1 depletion led to the upregulation of multiple genes, including a cluster of CTA genes, in sensitive cell lines with the CTA-positive signature, while CTA-negative cell lines remained unaffected. These data confirm that SMCHD1 is a potential therapeutic target for patients with elevated CTA expression, and provides insight to what therapeutic modality would be most effective.

#4295 Discovery of a novel class of androgen-competitive AR inhibitors that can combat drug resistance due to AR gene amplification.

A. Szempruch, T. Scott, J. Ernst, J. Hoffman, A. Klova, A. Liu, N. Lu, A. Milik, S. Niessen, G. Packard, J. Remsberg, R. Sipos, T. Soriano, G. O'Neill, S. Buchanan;
Belharra Therapeutics, Inc., San Diego, CA

In metastatic prostate cancer, most cases of resistance to direct AR inhibitors (ARi) are associated with a rebound in serum PSA implying AR reactivation. Resistance to first generation ARi, like bicalutamide, has been linked to AR amplification and is thought to be caused by increased levels of AR protein favoring the drug's partial agonist activity. This agonism counteracts inhibition with a net effect of incomplete antagonism. The phenomenon of anti-androgen withdrawal syndrome documented with early ARi supports this hypothesis and presumably reflects net agonist activity. Enzalutamide ushered in the current generation of approved ARi and was identified using prostate cancer cell line models of bicalutamide resistance with increased AR protein. It has recently become clear that a large majority of cases of mCRPC resistance to enzalutamide is associated with even higher copy number amplification of AR. Enzalutamide, and other latest generation ARi, including AR degraders in clinical development, all share a closely related ('lutamide) core chemical structure with the earlier generation partial agonists implying a similar mechanism of binding AR. This raises the possibility that high copy AR amplification-driven resistance to enzalutamide is due to an antagonism-to-agonism switch mechanistically identical to that of bicalutamide but requiring higher AR levels. However, AR levels exceeding those required to confer bicalutamide resistance are detrimental to standard cancer cell lines growing in culture. Here we describe new mechanistic models of androgen-stimulated AR activation across a wide range of AR levels. In these models early generation 'lutamides, but not enzalutamide, show a switch to agonist like behavior at moderate levels of AR overexpression. At higher levels of AR, enzalutamide, apalutamide, and darolutamide show the same agonist conversion and corresponding evidence of incomplete antagonism in enzalutamide-resistant prostate cancer cells with high copy AR amplification. We employed these assays in concert with a novel, in-cell, chemoproteomic screening approach to identify non-lutamide ARi capable of complete antagonism. We discovered a novel chemotype of ARi that lacks any propensity for an agonism switch, even at high levels of AR protein. These compounds completely suppress viability of VCAP prostate cancer cells with high copy AR amplification, have no effect on the viability of AR-independent cell lines, and show activity against all clinically common AR point mutants. These observations suggest that the potential for a switch to agonism is inherent, in the 'lutamide scaffold, and is exacerbated by increased AR levels leading to incomplete antagonism and resistance. This resistance can be effectively combated with a new class of complete AR antagonists.

#4297 Targeting metabolic dysfunction in prostate cancer: the anti-proliferative effects of ql47 through inhibition of dlat.

Grace Nirmala Jesuthankaraj, August John, Huanyao Gao, Arun Kanakkanthara, Richard Weinshilboum, Liewei Wang

Molecular Pharmacology and Experimental Therapeutics Department, Mayo Clinic Hospital-Rochester, Rochester, MN

Background: Prostate cancer is the most common cancer in men in the United States with an estimated 288,300 new cases diagnosed in 2023. The treatment strategies include androgen deprivation therapies (ADTs) for metastatic prostate cancer (mPC) but 10-20% of patients eventually progress to castration-resistant prostate cancer (CRPC). However, nearly all patients develop primary and acquired resistance overtime, and developing therapies and identifying novel molecular targets are essential in enhancing the clinical outcomes of patients with prostate cancer. In this study, we report a small molecule that belongs to a class of tricyclic quinolones, QL47 that was previously screened among various other compounds in prostate PDX organoid models and showed a potent anti-proliferative activity.
Methods: QL47 was tested on prostate cancer cell lines (22Rv1, 22RV1 abiraterone-resistant and DU145) for its anti-proliferative potential. Further, we used the biotinylated QL47 (QL47B) to pulldown its potential targets and we identified the targets through immunoprecipitation-mass spectrometry (IP-MS) technique followed by Western blot analysis. Cell cycle and cell death analyses were performed after staining the cells with propidium iodide and Annexin V followed by flow cytometry analysis. Oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) was investigated using the Seahorse assay.
Results: The initial screening of QL47 in prostate cancer cell lines showed that it inhibits the proliferation at an IC50 of 50-200 nM. Through IP-MS and Western blot analysis, we identified a member of the pyruvate dehydrogenase complex dihydrolipoamide S-acetyltransferase (DLAT) as a direct target of QL47. Mechanistically, we found that QL47 does not increase cell death or affect cell cycle, but inhibits metabolic function, with a decrease in both oxygen consumption rate (OCR) and extracellular acidification rate (ECAR).
Conclusion: We have identified a novel mechanism of action of QL47 on the pyruvate dehydrogenase complex, and we plan to further validate the safety and efficacy for the treatment of prostate cancer.

#4298 Investigating the potential of EO3001 as a therapeutic agent for clear cell ovarian cancers harboring ARID1A mutations.

Yuchen Ding[1], Tsz Yin (Jacky) Lam[2], Yuting (Shary) Chen[1], Longyijie (Grace) Wei[1], Yuqin (Lucy) Li[1], Yuhan (Joyce) Zhang[1], Farhia Kabeer[1], Forouh Kalantari[1], **Jeffrey Bacha**[3], Dennis Brown[3], Sarath Kanekal[3], Neil Sankar[3], Michael Lizardo[4], Michelle Woo[4], Amal M. EL-Naggar[1], David Huntsman[1]

[1]Pathology and Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada,[2]Interdisciplinary Oncology, University of British Columbia, Vancouver, BC, Canada,[3]Edison Oncology Holding Corp, Menlo Park, CA,[4]Molecular Oncology, BC Cancer Research Centre, Vancouver, BC, Canada

Introduction: Clear cell ovarian cancer (CCOC) is a histological subtype of ovarian cancer that is resistant to standard chemotherapies. Although it accounts for only around 6% of all ovarian cancer cases, it is the second leading cause of mortality among ovarian cancers. ARID1A loss-of-function mutations have been identified as a hallmark (~65%) of CCOC. ARID1A, a key component of the SWI/SNF chromatin remodeling complex, plays a critical role in regulating gene expression. Loss of ARID1A disrupts the expression of SLC7A11, leading to decreased glutathione (GSH) levels and elevated reactive oxygen species (ROS) levels, while making cancer cells highly dependent on oxidative phosphorylation (OXPHOS). EO3001, a synthetic small molecule, can selectively transport extracellular Cu(II) to mitochondria, increasing mitochondrial ROS and inducing cuproptosis. Recent studies suggest that ARID1A-deficient CCOC cells are more vulnerable to EO3001. In this study, an ex vivo model, the pulmonary metastasis assay (PuMA), along with other in vitro models, was employed to assess the effectiveness of EO3001 in CCOC. PuMA enables the study of cancer cell growth in a more physiologically relevant microenvironment. In PuMA, fluorescently tagged cancer cells are inoculated into mouse lungs, which are then inflated with agarose gel, sectioned, and treated under different conditions. The growth of cells is quantified by fluorescence intensity from lung sections.
Methods: Isogenic ARID1A wild-type and mutant CCOC cell lines (RMG-1, OVCA429, and JHOC-5) were generated using CRISPR-Cas9. The effects of EO3001 were evaluated using in vitro assays and PuMA. Cell viability, proliferation, ROS levels, glycolysis and OXPHOS activity, migration, and invasion were measured with and without EO3001 treatment under various stress conditions. Drug efficacy was validated in both short- and late-harvest PuMA models.
Results: EO3001 demonstrated significant differential effects against ARID1A-deficient CCOC cells in both in vitro and ex vivo models. However, hypoxic conditions significantly diminished its efficacy, likely due to a metabolic shift between OXPHOS and glycolysis. Furthermore, Cu(II) concentration in the microenvironment remarkably impacts the efficiency of EO3001. Overall, EO3001 presents a promising therapeutic strategy for ARID1A-mutant CCOC as a single agent. Targeting the OXPHOS dependency in ARID1A-mutant CCOC cells and enriching Cu(II) concentration could further enhance the efficacy of EO3001.

#4299 Validation of the antitumor compound 3797 in human and murine glioblastoma models.

Lara Gonzalez-Rendo[1], David Moreiras-Alvarez[2], Martin Baleiron-Rodriguez[3], Laura Porres-Ventin[1], Jose A. Zumalave[1], Maria Isabel Loza-Garcia[3], **Victor M. Arce**[1], Jose A. Costoya[1]

[1]Molecular Oncology Laboratory, CIMUS, Departamento de Fisioloxia, IDIS, Universidade de Santiago de Compostela, Santiago de Compostela, Spain,[2]Kaertor Foundation, Santiago de Compostela, Spain,[3]Biofarma Research Group, CIMUS, Universidade de Santiago de Compostela, Santiago de Compostela, Spain

Multiple studies have highlighted the critical role of the RB-E2F pathway in the control of cell proliferation, therefore, decreasing E2F hyperactivity could be a valuable therapeutic strategy in cancer. Based on this, we propose a therapeutic approach in which E2F transcriptional activity is specifically reduced in cells that show hyperactivation of this pathway, in other words, tumor cells. Preliminary data obtained in the group show that poly (ADP-ribose) polymerase-1 (PARP1) is a transcriptional co-activator of E2F1 and, because of this, loss of PARP results in cell cycle regulation and reduced tumor growth. Furthermore, taking into consideration that most oncogenic processes are associated with cell cycle dysregulation, disruption of the PARP1-E2F1 interaction could provide a new therapeutic target for various tumor types. By searching for compounds that can interfere with the PARP1/E2F1 interaction, our group has obtained a library of 85 compounds generated by *in silico* screening of millions of commercially available compounds using a drug discovery platform. After initial *in vitro* screening, we have identified 12 molecules capable of inhibiting this interaction. The one that performed best was selected for validation using 2D and 3D models of human and murine glioblastoma. For this purpose, we carried out cell viability and migration assays to assess the effect of the compound on two murine and one human glioma cell lines. In all cell lines, cell growth was decreased by treatment, as revealed by violet crystal staining. In addition, wound closure response was inhibited in treated cells as compared with controls. Finally, the therapeutic efficacy of compound 3797 was tested in organoids originated from those tumor cell lines, using the lactate dehydrogenase (LDH) assay, which assess the cell metabolic activity. In keeping with results obtained in 2D cultures, LDH assay showed that compound 3797 decreases the growth rate in organoids derived from glioblastoma cell lines. This work was supported by Agencia Estatal de Investigación (AEI/10.13039/501100011033), Xunta de Galicia (GPC GI-1862, ED431B 2020/26; ED431G 2019/02) and European Regional Development Fund-ERDF. #4300 AT1965, a novel mRNA cap 2′O methylation inhibitor, exerts potent antitumor activity and enhances chemotherapy efficacy.

Arshit Narang, Vinay S. Mahajan, Shiladitya Sengupta

Harvard Medical School/Brigham and Women's Hospital, Cambridge, MA

Cellular messenger RNA (mRNA) of higher eukaryotes and many viral RNAs are methylated at the N-7 and 2′-O positions of the 5′ guanosine cap by specific nuclear and cytoplasmic methyltransferases. N-7 methylation is essential for RNA translation and stability. Recent studies have highlighted the critical role of 2′O methylation of the cap in enabling the innate immune system to distinguish self-RNA from foreign RNA through pattern recognition receptors, such as RIG-I. Despite advances in understanding RNA modifications, the therapeutic potential of targeting RNA capping enzymes remains unexplored. Here, we report that AT1965, a novel mRNA cap 2′O methylation inhibitor, exhibits potent antitumor effects and significant synergy with cabazitaxel, an FDA-approved anticancer agent. Subcutaneous Lewis Lung Carcinoma (LLC) tumors were established in C57BL/6 mice, divided into three groups: untreated controls, those treated with cabazitaxel alone, and those treated with cabazitaxel in combination with AT1965. The combination therapy resulted in a mean tumor size reduction of 23.6%, while tumors in the other groups increased in size. Mechanistically, AT1965 impairs mRNA stability and translation of key oncogenic transcripts, sensitizing tumors to cytotoxic agents. These findings underscore the potential of RNA capping enzymes as therapeutic targets in cancer. Future studies should explore the application of AT1965 in other tumor models and its potential to synergize with diverse chemotherapeutics.

#4301 ENO1 as a potential target for anti-cancer therapy: Insights into its role in neuroendocrine prostate cancer cell growth and survival.

Krystal Rubi Santiago Torres, Alfonso Duran, Kristen Whitley, Shriya Roy, Frankis Almaguel, Carlos A. Casiano

Loma Linda Univ. School of Medicine, Loma Linda, CA

Prostate cancer (PCa) is the second most commonly diagnosed cancer and the leading cause of cancer-related death among men in the United States. Taxane-based chemotherapy with docetaxel (DTX) and cabazitaxel is used as last-line treatment for metastatic castration-resistant prostate cancer (mCRPC). However, these drugs often fail due to the development of chemoresistance. The prostate-specific membrane antigen (PSMA) has emerged as a critical target for theranostics (imaging + therapy) in mCRPC. Nonetheless, around 30% of patients show a limited response, particularly those with low or absent PSMA expression. Given the limitations of targeting PSMA in certain patients, exploring alternative molecular targets such as Enolase (isoforms ENO1 and ENO2) could enhance therapeutic options for patients with mCRPC. ENO1, an enzyme involved in glycolysis, demonstrates potential as an alternative target for mCRPC treatment as it is found on the surface of various tumors. We hypothesized that ENO1 is abundant on the surface of neuroendocrine-like prostate cancer (NEPC-L) cell lines, and that targeting this protein will disrupt key metabolic pathways, resulting in significant anti-cancer effects and reduced tumor growth. Western blot analysis revealed that DTX-sensitive PCa cell lines expressing NEPC markers also express both ENO1 and ENO2. In contrast, DTX-resistant NEPC-L cells expressed ENO1, with limited ENO2 expression, indicating a potential metabolic vulnerability in these cells due to ENO2 downregulation. Additionally, we observed that the cell surface localization of ENO1 in DTX-resistant NEPC-L cell lines varied according to glucose levels. High glucose levels, common in metabolically active metastatic tumors, promoted the cell surface localization of ENO1. By contrast, cells cultured in normal glucose conditions demonstrated lower levels of ENO1 cell surface abundance, likely due to inhibition of the c-MYC oncogene and upregulation of MBP1, a small variant of ENO1 that suppresses c-MYC mediated transcriptional induction of ENO1. We also determined if genetic silencing of ENO1 affects the proliferation and clonogenic ability of NEPC-L cells. Preliminary results following MTT and Clonogenic Assays indicated that ENO1 knockdown with specific siRNAs significantly reduced cell proliferation and clonogenic ability and altered cellular morphology, while preserving cell viability, compared to scramble negative control siRNA. This indicated that while genetic targeting of ENO1 may not necessarily impact tumor cell survival, it could have a dramatic inhibitory effect on tumor growth. Future experiments will explore if ENO1 knockdown re-sensitizes NEPC-L cells to DTX treatment, inhibits tumor-sphere formation, and modifies the stemness properties of these cells, supporting its potential as a novel therapeutic target in patients with drug-resistant NEPC.

#4302 Loss of carnitine acyl-carnitine carrier induced tumor regression by mTOR inactivation.

J. Kang[1], H. Lee[1], S. Woo[2], W. Choi[2], S. Sim[2], J. Chun[1], S.-Y. Kim[2];

[1]National Cancer Center Graduate School of Cancer Science and Policy, Goyang-si, Gyeonggi-do, Korea, Republic of, [2]National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic of

Purpose: We found that most ATP production in cancer cells depends on fatty acid oxidation (FAO). However, the direct link between FAO and cancer promotion has not been interpreted. Therefore, we propose that blocking FAO in cancer may prevent pancreatic cancer growth promotion by blocking its ATP production.

Experimental Design: To block FAO, CAC (carnitine-acylcarnitine carrier, gene: *SLC25A20*) in the mitochondria inner membrane was knocked down in cancer cells, which was implanted for xenograft in mice. To compare cancer development, survival rates and histopathological differences were analyzed with KPC mice (*Kras*$^{G12D/+}$; *Trp53*$^{R172H/+}$; *Pdx1-Cre*) and KPC/Cac$^{+/-}$ mice.

Results: By CAC knockdown, the cancer cells reduced ATP production and decreased cell growth. Proteomic analysis showed that CAC knockdown significantly reduced cancer cell growth following mTOR inactivation by reduced ATP production, consequently leading to cell death. Xenografts using CAC knockdown PDAC cells showed up to 80% decrease of tumor growth compared to the control. Furthermore, the median survival of KPC/Cac$^{+/-}$ mice was increased by 3.1 weeks compared to KPC mice.

Conclusion: Blocking FAO by CAC knockdown significantly suppressed tumor growth by mTOR inactivation through ATP depletion in pancreatic cancer cells. mTOR inactivation by CAC knockdown, consequently, decreased levels of cyclin D and PARP, which were followed by cell cycle arrest and cell death. Thus, even if signal transduction is induced by various growth receptors, mTOR cannot be activated when ATP levels fall below the *Km* value.

Funding source: This research was supported by the Basic Science Research Program through the National Research Foundation of Korea (NRF), funded by the Ministry of Science and ICT to SK (NRF-2019M3A9G1104345) and by a grant from the National Cancer Center of Korea to WC (NCC 2410891-1) and JWC (NCC 2410892-2).

#4303 AZD2284: A novel, alpha-particle emitting radioconjugate targeting STEAP2 in metastatic castration-resistant prostate cancer.

Background: AZD2284 is a novel, targeted alpha therapeutic directed against six-transmembrane epithelial antigen of prostate-2 (STEAP2), a receptor highly overexpressed in prostate cancer. AZD2284 is comprised of a humanized, STEAP2-targeting rodent cross-reactive IgG1 monoclonal antibody conjugated with a DOTA chelate and radiolabeled with the alpha-particle emitting radionuclide, actinium-225 [^{225}Ac]. Leveraging high STEAP2 expression in prostate cancer and the high linear energy transfer of the alpha emitter, AZD2284 is presumed to deliver the radioisotope to targeted tumor cells, generating clustered DNA double strand breaks and other cellular damage that ultimately leads to cell death.

Methods: Preclinical pharmacological assessments were conducted with the lutetium-177 [^{177}Lu] labeled analog of AZD2284, FPI-2281. In vitro binding and internalization assays with FPI-2281 were performed in STEAP2-positive prostate cancer cell lines with varying levels of target expression. In vivo biodistribution and uptake were evaluated ex vivo across multiple timepoints following FPI-2281 administration to tumor-bearing cell-line derived xenograft (CDX) models. To assess the radiotherapeutic efficacy of AZD2284, a single dose was administered intravenously to prostate cancer CDX and patient-derived xenograft (PDX) models.

Results: Binding and internalization studies demonstrated FPI-2281 effectively binds to the STEAP2-positive prostate cancer cell line models (LNCaP, C4-2, and 22Rv1) with over 30% cellular retention at 24 hours. Corresponding in vivo biodistribution profiles showed sustained tumor uptake in xenograft models, with peak tumor uptakes of 60% ID/g in the 22Rv1 model and 83% ID/g in the C4-2 model at 14 days, respectively, with limited normal organ uptake observed at all timepoints. AZD2284 elicited target- and dose-dependent anti-tumor efficacy and sustained tumor regressions in CDX and PDX models with varying levels of STEAP2 expression.

Conclusions: In preclinical models, AZD2284 effectively binds to and internalizes in prostate cancer cells, thereby delivering the radioisotope, [^{225}Ac]. Biodistribution studies confirm sustained tumor uptake of AZD2284 with low normal organ uptake. Single-dose administration of AZD2284 leads to durable anti-tumor efficacy in xenograft models. These data suggest AZD2284 is a promising therapeutic candidate in prostate cancer and support the initiation of clinical trials.

#4304 Novel small molecule targeting cancer metabolism by inhibiting SCAP/SREBP pathway.

Jeffrey N. Lindquist[1], Michael Green[2], Ravi K. Muttineni[3], Hirdesh Uppal[4]

[1]Research, Capulus Therapeutics LLC, San Francisco, CA,[2]Chemistry, Capulus Therapeutics, LLC, San Francisco, CA,[3]Immunocure Discovery Solutions Pvt Ltd, Hyderabad, India,[4]Capulus Therapeutics LLC, San Francisco, CA

Background: A critical component of oncogenesis and cancer progression is metabolic re-programming of cells to enable continuous growth. Oncogenic activated signaling pathways can drive *de novo* lipogenesis to provide ample lipids, e.g. cholesterol and fatty acids, to support the tumor cells heightened metabolic needs. The transcriptional regulation of lipogenesis is mediated by the sterol regulatory element-binding protein (SREBP) transcription factors, that are controlled by the regulatory SREBP cleavage activating protein (SCAP). Dysregulation of the SCAP/SREBP pathway has been documented in many tumor types, including breast, liver, and prostate cancer (Reviewed in Peck & Shulze, 2019). Activation of this pathway is inversely correlated with PFS and OS across tumor types, implicating the SCAP/SREBP pathway as a critical mediator of tumorigenesis and making it a good anti-cancer target. Historically, small molecule targeting of the SCAP/SREBP pathway has been difficult given the complexity of the pathway regulation and protein-protein interactions.
Results: Utilizing an integrated drug discovery AI (Artificial Intelligence)-based platform to model SCAP/SREBP complex interactions and identify druggable domains to target with small molecules. Screening a total of ~400 compounds across multiple scaffolds identified compounds with low nano-molar IC50 inhibition of SREBP pathway, and a pan-cancer cell line screen identified “responders” across cancer indications and subtypes. A comprehensive screening and SAR of *in vitro* ADME properties (LM stability, solubility) led to candidates for in vivo pharmacokinetics analysis. Several chemotypes with low clearance, long T1/2 in mice and good bioavailability were identified. Further testing of several Research Leads demonstrated robust tumor growth inhibition in breast (MCF7, 84.15%) and liver (HepG2, 45.5%) as a single agent, and synergistic activity with SoC in the HepG2 model (Sorafanib combination 76.1%). Probing publicly available datasets for glycolytic/lipogenic phenotypes across tumor types reveals heterogeneity across tumor types and the ability to stratify patients and indications by Glyco-/Lipo-genic score that may allow for patient selection in future clinical trials.
Conclusion: We report here a novel small molecule that interacts with SCAP to prevent activation of SREBP pathway that was identified by computational modeling of a multi-protein complex of SCAP/SREBP. This molecule, CAP-1628987 specifically targets SCAP/SREBP pathway, has good drug-like properties, robust efficacy in multiple tumor models and favorable CMC properties.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Oncogenes, Tumor Suppressor Genes, and Gene Products as Targets for Therapy 1
Poster Session

#4305 Targeting the exonuclease domain of POLE to induce synthetic lethality in highly aneuploidic tumor cells.

Meng He, Eun Jung Kim, Yangmeng Wang, Alejandro Chibly, Kristel Dorighi

Genentech, Inc., South San Francisco, CA

Aneuploidy is a hallmark of cancer evolution, it is associated with fast disease progression and drug resistance across many tumor types. The underlying molecular aberration that causes aneuploidy remains largely unknown. Currently, there are no established therapeutics for tumors with high levels of aneuploidy. We propose that inhibition of the exonuclease domain of the DNA polymerase, POLE, could induce synthetic lethality in tumor cells with high levels of aneuploidy. We observed that loss of function mutations in the exonuclease domain of POLE are mutually exclusive with high levels of aneuploidy in the Foundation Medicine database, the Cancer Genome Atlas (TCGA) as well as the cancer Dependency Map (DepMap). Our analysis and statistical modeling showed that the number and unique spectrum of mutations induced by loss of POLE's exonuclease activity have a high probability of hitting an essential gene with hemizygous loss in aneuploidic tumor cells, therefore leading to a synthetic lethality phenotype. Experimentally, we showed that specific inhibition of the exonuclease domain through genetic mutations can cause strong cellular fitness effects in highly aneuploidic cell lines. In summary, our data suggest that a specific inhibitor targeting the exonuclease domain of POLE might bring therapeutic benefits to patients with highly aneuploidic tumors.

#4306 KMT2A rearranged acute myeloid leukemia is vulnerable to the combinatorial inhibition of menin and MYC protein degradation.

Shreya Nair[1], Shayaun Khazaei[1], Lauren B. Ostermann[1], Hideaki Mizuno[1], Po Yee Mak[1], Bing Z. Carter[1], Steffen Boettcher[2], Liandong Ma[3], Miriam B. Garcia[4], Branko Cuglievan[4], Michael Andreeff[1], Yuki Nishida[1]

[1]Leukemia, UT MD Anderson Cancer Center, Houston, TX,[2]Medical Oncology and Hematology, University of Zurich, Zurich, Switzerland,[3]Oncobio Therapeutics, Radnor, PA,[4]Pediatrics, UT MD Anderson Cancer Center, Houston, TX

Background: Menin is the scaffolding protein part of the mixed lineage leukemia (MLL) histone methyltransferase complex and uniquely acts as both a tumor suppressor and oncogenic cofactor. KMT2A or MLL rearranged (KMT2Ar) leukemias are a distinct group with poor prognosis and a median overall survival of 0.9 years (Issa, 2021). This interaction has been targeted by menin inhibitors revunemib and ziftomenib with promising results in clinical trials (Aldoss & Issa, 2023; Erba, 2022), and revumenib is now FDA-approved. Menin directly interacts with the TAD domain of c-MYC (MYC) and amplifies MYC's transcriptional activities (Wu, 2017). We have investigated GT19715, the first-in-class MYC/GSPT1 degrader in MYC-driven hematological malignancies (Nishida, ASH 2022, 2023, 2024). We hypothesized that combined menin inhibition and MYC degradation induces synergistic cytotoxicity in KMT2Ar AML.
Methods: MOLM-13 CRISPR-generated isogenic cells with wild-type (WT), knockout (KO), or mutant TP53 (R175H, Y220C, M237I, R248Q, R237H, and R282W), MV411 and OCI-AML2 cell lines were exposed to menin inhibitor SNDX-50469 (SNDX) (selleckchem) in combination with GT19715 (GT). Cell death was determined by annexin V/DAPI assays. Time course experiments were conducted in MOLM13 WT, KO, Y220C and R282W cells. Bliss synergy scores (BSS) > 10 are considered synergistic. MOLM-13 cells WT and Y220C mutation labeled with GFP/luciferase were injected into NSG mice and SNDX and/or GT were administered.
Results: The combination treatment (100 or 400 nM SNDX and 2 or 4 nM GT) significantly induced cell death and reduced cell numbers by > 99% (> log10^2 difference), starting at day 2 (WT and KO) or 3 (Y220C and R282W) compared to SNDX or GT monotherapy. SNDX + GT induced synergistic cell death (BSS > 10) in all cell lines tested with BSSs up to 80, suggesting substantial synergistic effects by menin inhibition combined with MYC protein degradation. We injected MOLM-13 TP53 WT GFP/Luc and MOLM-13 TP53 Y220C GFP/Luc cell lines (0.5 e6/mouse through tail veins) into NSG mice. After confirming engraftment determined by bioluminescence imaging (BLI), we treated mice with vehicle, GT (3 times a week, every other day by IP injections), SNDX (PO, QD) or GT + SNDX combination for 6 weeks. The combination treatment reduced the total BLI signals at week 2 by 10^4, 10^4 and 10^2 compared to vehicle, GT or SNDX alone. The data suggest the combinatorial treatment of SNDX with GT synergistically reduced leukemia burden in vivo.
Conclusion: Combinatorial approach of menin inhibition and MYC degradation results in a profound synergistic reduction of KMT2Ar AML cells in vitro and in vivo, validating the underlying premise. Further mechanistic studies and efficacy in PDX models are ongoing.

#4307 A first-in-class EGFR-directed KRAS G12V selective inhibitor.

Lyla Stanland[1], Hayden Huggins[1], Alessandro Porrello[2], Yogitha Chareddy[2], Salma Azam[2], Jillian Perry[2], Pradeep Pallan[3], Kristina Whately[2], Lincy Edatt[2], Matthew Fleming[4], Jonah Im[2], Christina Gutierrez-Ford[2], Imani Simmons[2], Vandanaa Jayaprakash[1], Rani Sellers[5], Gabriela de la Cruz[5], Albert Wielgus[5], Martin Egli[3], Albert Bowers[2], Chad V. Pecot[2]

[1]EnFuego Therapeutics, Morrisville, NC,[2]UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]Vanderbilt Ingram Cancer Center, Nashville, TN,[4]UNC Eshelman School of Pharmacy, Chapel Hill, NC,[5]UNC Department of Pathology and Laboratory Medicine, Chapel Hill, NC

The KRAS proto-oncogene encodes a small GTPase that is crucial for the activation of intracellular signaling pathways that control cell proliferation, survival and differentiation. *KRAS* is frequently mutated in cancer resulting in its constitutive activation and dysregulation of downstream signaling pathways that drive oncogenic transformation. KRAS G12V is the second most common KRAS mutation in cancer, and occurs frequently in lung, colon and pancreatic cancers. However, while significant advancements have been made in developing KRAS G12C, G12D and pan-KRAS inhibitors, there remain no direct KRAS G12V inhibitors in the clinic. Due to challenges targeting oncogenes with traditional small molecule approaches, RNA interference (RNAi) has become an attractive therapeutic approach for many oncogenes. RNAi has faced many obstacles as an effective cancer therapeutic, including the lack of cancer-specific tissue targeting, rapid oligonucleotide nuclease degradation and clearance from circulation, the need for endosomal escape, and unwanted immune stimulation. However, recently, the use of targetable ligands conjugated to chemically modified siRNAs have shown promise in circumventing these barriers. Here, we describe the development of EFTX-G12V, a fully-modified, mutant-selective siRNA conjugated to an EGFR ligand that shows improved tumor delivery and significant anti-tumor activity in lung and colon cancer models. We used a structure-activity relationship screening approach to identify a highly mutant-selective fully chemically modified siRNA that inhibits KRAS G12V expression at both the mRNA and protein level while completely sparing KRAS WT. Furthermore, this siRNA inhibited cancer cell growth *in vitro* and showed no off-target effects. To address the issue of tumor-specific delivery, we conjugated a non-mitogenic EGFR ligand to the siRNA and found enhanced delivery to tumors with varying levels of EGFR expression. EFTX-G12V significantly inhibited KRAS G12V mRNA and protein *in vivo* and showed significant anti-tumor activity in lung and colon xenograft models. Importantly, EFTX-G12V showed no off-target effects on WT KRAS in somatic tissues including kidney, skin and bladder. Unexpectedly, we found that mutant-selective targeting showed improved efficacy in comparison to a pan-KRAS siRNA. EFTX-G12V significantly inhibited tumor angiogenesis while pan-KRAS targeting had inconsistent effects suggesting that mutant-selective targeting has advantages within the tumor microenvironment. Together our findings represent a technologic advance in ligand-directed, mutant-selective oncogene targeting using RNAi and reveal new biologic insights in KRAS targeting that may have broader implications with regards to safety and efficacy.

#4308 BRD8 is a therapeutic vulnerability for overcoming resistance to dual ER/HER2 blockade therapy in HR+/HER2+ breast cancer.

Ang Gao[1], Parth Khatri[1], Gui Ma[1], Peng Liu[1], Mark Burkard[1], Kari Wisinski[2], Charles Perou[3], Huy Dinh[1], Wei Xu[1]

[1]Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI,[2]Univ. of Wisconsin Madison, Department of Medicine, Madison, WI,[3]University of North Carolina, Chapel Hill, Chapel Hill, NC

Hormone receptor (HR)-positive, HER2-positive breast cancers often develop resistance to endocrine and anti-HER2 therapies due to the heterogeneous expression of estrogen receptor (ER) and HER2 and the crosstalk of these growth-promoting pathways. However, how anti-HER2 agents activate ER and other growth-promoting pathways remains unknown. Single-cell RNA sequencing of BT474 breast cancer cells identified Bromodomain Containing Protein 8 (BRD8), an acetyl-lysine reader protein in the histone acetylase EP400 complex, as a pivotal mediator to activate ER in response to neratinib treatment. BRD8 expression was rapidly induced by various anti-HER2 agents (neratinib, lapatinib, and trastuzumab), and its depletion disrupted the crosstalk between ER and HER2 signaling pathways and rendered HR+/HER2+ cells and PDxOs more sensitive to anti-HER2 agents. BRD8, ER, and ER target genes are co-induced by neratinib in single-nucleus RNA and ATAC sequencing of a patient-derived xenograft (PDX). SnATAC-seq also reveals that the activated genes share open chromatin regions enriched in ER, forkhead box (FOX), and ETS family transcription factors (TF) binding motifs. FOX family TFs are well-known for regulating estrogen signaling, and ETS proteins have been shown to promote tumorigenesis. Since EP400 enhances H2AZ deposition and acetylation on chromatin, we performed H2AZ and H2AZac ChIP-sequencing in the presence or absence of BRD8 and neratinib treatment. We found that, in response to neratinib treatment, BRD8 activates ER, FOX, and ETS target genes through modulating H2AZac deposition and chromatin decompaction. This finding coincides with RNA-sequencing where BRD8 promotes cell growth in an ER-dependent and -independent manner. In line with these findings, patients who responded poorly to the anti-HER2 therapies exhibited higher levels of BRD8 target gene signature as compared to the responders. Furthermore, BRD8 knockout ablates the ER and HER2 signaling crosstalk and re-sensitizes neratinib-resistant HR+/HER2+ cells to neratinib. In summary, this work not only explains why ER signaling is activated upon anti-HER2 therapies but also identifies BRD8 as a druggable vulnerability for treating HR+/HER2+ breast cancer.

#4310 Novel analogues of indanone and tetralone-keto oximes as potent estrogen receptor beta agonists for treating GBM.

Uday P. Pratap[1], Michael Tidwell[2], Annabel Maciolek[2], Luca De Angelis[2], Sridharan Jayamohan[1], Jessica D. Johnson[1], Khaled Mohamed Nassar[1], Karinel Nieves-Merced[2], Henriette U. Balinda[1], Peter LoCoco[2], Joseph Boerma[2], Suryavathi Viswanadhapalli[1], Gangadhara Reddy Sareddy[1], Nicholas Clanton[2], Stanton McHardy[2], Andrew Brenner[1], Ratna K. Vadlamudi[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]UTSA, San Antonio, TX

Background: Glioblastoma (GBM) is the most common and aggressive brain tumor, with a poor 5-year survival rate. Epidemiological studies suggest that estrogen receptor beta (ERb) may inhibit brain tumor growth, highlighting the potential therapeutic role of ERb. However, the lack of potent, selective, and brain-permeable ERb ligands has limited the clinical application of ERb-based therapies. We recently identified indanone and tetralone-keto oximes as promising ERb agonists. To further optimize these compounds, we employed a structure-based drug design strategy, utilizing existing X-ray structural data to guide the development of novel ligands targeting the ERb-ligand-binding domain. The objective of this study is to design and develop a new class of ERb agonists that can cross the blood-brain barrier and offer an effective treatment option for GBM.

Methods: To improve CIDD-0149897 potency and comprehend pharmacophores, we designed and synthesized 99 more analogues. The selectivity of CIDD-0149897 analogues was determined using ERb and ERa reporter assays. CIDD-0149897 analogues were examined for cell viability using CellTiter-Glo and apoptosis using Annexin V and Western blotting, ionizing radiation, RT-qPCR, comet assays, and mass spec analysis were used for mechanistic research. UTSA's Center for Innovative Drug Discovery (CIDD) pre-clinical pharmacology core performed in vitro ADME studies. The ERb agonist was tested *in vivo* using orthotopic patient-derived xenografts.

Results: Our analysis of new CIDD-0149897 analogues identified four optimized ERb agonists with improved specificity and potency. ADME studies showed these agonists have 20-50-times better aqueous solubility than CIDD-0149897, with excellent plasma stability. Microsomal and hepatocyte stability varied, with alcohol analogues being more stable. The MDCK-hMDR1 KO cell line shows low to moderate mono-directional permeability and minimal pGP efflux. Treatment with optimized ERb agonists dramatically reduced neurosphere formation, stemness marker expression, and promoted apoptosis in patient-derived GSC model cells. Mass spec data analysis showed that ERb binding proteins are involved in DNA repair and damage response, replication, and G1 checkpoint. In combination with Temozolomide, ERb agonists sensitized GSCs, increased DNA damage, and inhibited neurosphere formation. Comet assay demonstrated enhanced DNA damage in the combination group compared to single agent treatment. The lead compound CIDD-0169124 significantly reduced tumor volume in orthotopic model compared to the vehicle. CIDD-0169124 also improved TMZ-treated GSC tumor-bearing mouse survival relative to vehicle or TMZ monotherapy in an orthotopic GBM model.

Conclusion: These findings showed that CIDD-0169124 is a potent ERb agonist that can be used with existing chemotherapies to improve GBM patients' survival.

#4311 Exploiting the spontaneous intrahepatic cholangiocarcinoma mouse models to uncover MRTX1133's dual role in directly inhibiting KRAS^{G12D}-driven tumor progression and modulating the immune landscape.

X. Li, G. Wu, Z. Song, J. Xue, H. Zhang, C. Liu;
Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Purpose: Mutations in the KRAS gene, particularly the G12D variant, are prevalent in intrahepatic cholangiocarcinoma (iCCA) and correlate with unfavorable patient outcomes. Currently, there is an urgent need for targeted therapeutic strategies against KRAS^{G12D} iCCA. This study aims to investigate the impact and mechanisms of KRAS^{G12D} mutation on iCCA progression and to conduct a preclinical evaluation of MRTX1133, a non-covalent inhibitor of KRAS^{G12D}.

Methods: We developed spontaneous tumorigenesis mouse models of iCCA harboring KRAS^{G12D} mutation (YAP^{S127A}+AKT+KRAS$^{WT/G12D}$ model and AKT+NICD+KRAS$^{WT/G12D}$ model) using hydrodynamic tail vein injection, aiming to study the oncogenic role and mechanisms of KRAS^{G12D} in iCCA. The impact of MRTX1133 on KRAS^{G12D} iCCA was investigated using human iCCA cell lines, patient-derived organoids (PDOs), cell line xenografts, patient-derived xenografts (PDXs), and spontaneous tumorigenesis mice. Single-cell RNA sequencing (scRNA-seq) and multiplex immunofluorescence were utilized to assess changes in the tumor microenvironment following KRAS^{G12D} mutation and MRTX1133 treatment.

Results: The KRAS^{G12D} mutation significantly increased oncogenicity in several iCCA mouse models, characterized by increased tumor proliferation, reduced survival, and robust activation of downstream ERK pathway, along with elevated Ki67 expression. MRTX1133 demonstrated potent antitumor activity against human KRAS^{G12D} iCCA cell lines, PDOs, and *in vivo* models, including PDX and iCCA spontaneous tumorigenesis mice, exhibiting inhibited tumor proliferation, suppressed ERK and AKT pathway activation, and extended mouse survival. The scRNA-seq analysis revealed a reduction in CD8$^+$ T cells and an increase in M2-type macrophages in the tumor microenvironment of KRAS^{G12D} iCCA mice, while these alterations were reversed by MRTX1133 treatment, as validated by multiplexed immunofluorescence. Notably, MRTX1133 showed a more pronounced antitumor effect in immunocompetent C57 mice compared to immunodeficient NSG mice (68% tumor volume reduction versus 36%), suggesting that immune system engagement enhances the efficacy of MRTX1133. The *in vivo* studies combining MRTX1133 with immune checkpoint blockade (ICB) are underway to determine their potential synergistic effects.

Conclusion: This study is the first to validate the oncogenic role and therapeutic vulnerability of the KRAS^{G12D} mutation in iCCA. It also suggests the potential benefits of combining KRAS^{G12D} inhibitor MRTX1133 with ICB immunotherapy with synergistic effects.

#4312 CTR9 controls the mammary luminal lineage and susceptibility to carcinogen/hormone-induced breast tumors.

Gui Ma, Ang Gao, Mingshan Hu, Ngai Ting Chan, Yidan Wang, Wei Xu

Univ. of Wisconsin Madison Sch. of Med. & Public Health, Madison, WI

CTR9 encodes a key component of the human RNA polymerase II (RNAPII)-associated factor complex (hPAFc). CTR9 loss-of-function variants are predisposed to rare myeloid malignancies and Wilms tumors. Although CTR9 promotes the growth of estrogen receptor (ER)-positive breast cancer cells and controls the expression of 90% of ER-target genes, the roles of CTR9 in mammary gland development and breast cancer etiology *in vivo* remain unknown. About 0.1 % of breast cancer patients were found to harbor loss of function CTR9 mutations based on TCGA data. Analyzing normal mouse mammary gland scRNA-seq data reveals that CTR9 is highly expressed in luminal cells, which is confirmed by immunofluorescence staining in human breast tumors. To study the effects of the loss-of-function of CTR9 on mammary gland development, we generated a mammary gland-specific CTR9 knockout (KO) mouse using MMTV-Cre and CTR9 loxP system. CTR9 depletion from mammary epithelial cells was validated using qPCR, Western blot, and IHC. Loss of CTR9 in C57B/6 female mice led to increased duct branching and elongation during puberty and increased alveologenesis during pregnancy. This observation coincides with the detection of expanded mammary stem cells by flow cytometry in the 6-week-old mouse mammary glands. When treated with DMBA and progestin (MPA) to induce mammary tumors, both wild-type (WT) and CTR9 null mice began to develop tumors 6 weeks after the last DMBA treatment, but CTR9 null mice exhibited a markedly enhanced susceptibility to carcinogen/hormone-induced mammary tumors as compared with the WT counterparts. To detect changes during the early stage of tumorigenesis, we profiled the stem and luminal progenitor cell populations in the mammary gland 4-week after the last DMBA treatment. Remarkably, CTR9 depletion enhanced the stem cell and luminal progenitor populations while decreasing the mature luminal cells. CTR9 KO mammary gland had elevated Ki67 levels, decreased ER and PR, decreased mature luminal cells, and increased expression of KRT15, a luminal progenitor marker. The CTR9 null mammary gland expressed lower levels of KDM5A and higher levels of H3K4me3 as compared to the wild-type mice. Taken together, our findings establish that CTR9 depletion blocks the terminal differentiation of luminal cell lineage possibly through epigenetic regulation of histone methylation, and renders the mammary glands more susceptible to carcinogen/hormone-induced tumors.

#4313 COPS5 inhibition synergizes the antitumor effect of trastuzumab by PTEN upregulation in HER2 amplified gastric cancer.

Sung-Hyun Hwang[1], Ji-Won Kim[1], Kuijin Kim[1], Haseseong Park[2], Andrew Aguirre[3], Keun-Wook Lee[1]

[1]Seoul National University Bundang Hospital, Seongnam-si, Korea, Republic of,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA

COP9 Signalosome Subunit 5 (COPS5), a deubiquitinating enzyme, contributes to chemoresistance, and its expression is closely correlated with poor prognosis in patients with solid tumors. However, the role of *COPS5* amplification in patients with gastric cancer (GC) and its inhibition in *HER2*-amplified GC models has never been elucidated. In the curated stomach adenocarcinoma cohort (n=294) from The Cancer Genome Atlas datasets, *COPS5* amplification significantly co-occurred with *HER2* amplification (10.5% vs. 2.7%, P=0.040) and was associated with worse disease-free survival (median 12.6 vs. 45.2 months, P=0.012) and overall survival (median 21.4 months vs. not reached, P=0.004) after surgery. In *HER2*-amplified GC cell lines, NCI-N87, SNU216, and OE19, COPS5 inhibition using CSN5i-3, a selective COPS5 inhibitor, synergistically enhanced the antiproliferative effect of trastuzumab. After CSN5i-3 treatment, *COPS5* knock-out (KO) cell lines demonstrated a uniform increase in *PTEN* transcription and translation levels. This effect was mediated by SNAIL ubiquitination, suppressing the AKT downstream signaling pathway. However, in *PTEN* KO cell lines, the synergistic effect of CSN5i-3 and trastuzumab was not apparent. Similarly, reduced PTEN expression caused by SNAIL overexpression also decreased the responsiveness of CSN5i-3 treatment. Moreover, *COPS5* KO cells exhibited increased sensitivity to the proliferative effect and downstream signaling inhibition of AKT inhibitors MK2206 and capivasertib compared to control cells. In a mouse xenograft model of NCI-N87 cells, CSN5i-3 treatment combined with trastuzumab yielded a synergistic anti-tumor effect compared to monotherapy without notable changes in body weight. This effect was accompanied by enhanced apoptosis and reduced SNAIL and AKT downstream signaling activity. In conclusion, the synergistic antiproliferative effect of COPS5 inhibition and trastuzumab was attributed to increased PTEN expression via SNAIL ubiquitination, resulting in the AKT downstream inhibition. These findings highlight the potential of COPS5 as a therapeutic target in combination with trastuzumab for *HER2*-amplified GC, warranting further clinical studies.

#4314 Understanding the mode of action and development of resistance towards HER2 targeting agents in preclinical in vivo models.

Eva Oswald[1], Philipp Meyer[1], Loreen Weichert[1], Roxana Redis[2], Dan Rocca[2], Louise Brackenbury[2], Justin Bryans[3], **Julia B. Schueler**[1]

[1]Charles River Laboratories, Inc., Freiburg, Germany,[2]Charles River Laboratories, Inc., Portishead, United Kingdom,[3]Charles River Laboratories, Inc., Saffron Walden, United Kingdom

Treatment options for HER2 positive cancer types have advanced significantly over recent years, focusing on targeted therapies that inhibit HER2 signaling and more recently using HER2 as the anchor-signal to bring tumor killing moieties or effector immune cells near the cancer cell. In our recent study we compared in vivo efficacy in tumor bearing immune-compromised mice using four different modalities in a proof-of-concept format in a HER2+ ovarian cancer xenograft model, SKOV-3. We then tested a panel of HER2 targeting agents in a broader range of clinically relevant PDX models of breast, ovarian and gastric cancer and correlated these results with different characteristics of the PDX models, such as HER2 expression (by IHC) and molecular phenotype (by WES and RNAseq). The range of modalities that were tested in this study comprised small molecules, antibodies, antibody-drug conjugates (ADC) and mRNA-LNP encoded antibodies. Antitumoral activity was measured as tumor growth inhibition (TGI) based on twice weekly tumor volume measurements. The sensitivity of SKOV-3 was heavily influenced by the modality of the respective drug. Whereas small molecule Lapatinib showed only mild efficacy (TGI 40%), Trastuzumab was moderately active (TGI 57%) compared to Trastuzumab-emtansine (TGI 68%). An mRNA-LNP encoding for trastuzumab was the most efficacious treatment with a TGI of 88%. Despite this, none of the treatments induced complete remission. The ongoing analysis of tumor tissue from these studies suggests an escape mechanism via epithelial-mesenchymal transition (EMT) as Vimentin is upregulated and E-Cadherin is downregulated in tumors after re-growth. The superior activity of the mRNA-encoded trastuzumab compared to the clinically approved therapeutic is likely to be due to the elevated and sustained trastuzumab protein levels in the serum of the tumor bearing animals. Broader screening across 33 PDX models revealed ADCs (trastuzumab-emtansin and trastuzumab-deruxtan) as the most efficacious modalities leading to higher TGI values with prolonged persistence of tumor remission. Two therapeutic antibodies (trastuzumab and pertuzumab) showed similar activity patterns despite their slightly different modes of action. HER2 expression correlated with the sensitivity of the PDX model, although this relationship was not strictly linear. HER2 has provided oncologists a tractable target for some cancer types. However, clinical as well as preclinical data indicate the further untapped potential of HER2 as a therapeutic target. Screening studies like those described are important tools to deconvolute sensitivity and possible mechanisms of resistance in a preclinical setting. This provides opportunities to discover biomarkers to better enable patient selection and to provide a better understanding of HER2 biology, further maximizing its therapeutic potential.

#4315 PELP1 oncogene targeted therapy for the treatment of ovarian cancer.

Gaurav Sharma[1], Behnam Ebrahimi[1], Arhan Rao[1], William C. Arnold[1], Hariprasad Vankayalapati[2], Rajeshwar R. Tekmal[1], Suryavathi Viswanadhapalli[1], Ratna K. Vadlamudi[1]

[1]UT Health Science Center at San Antonio, San Antonio, TX,[2]Biolexis Therapeutics, INC., Lehi, UT

Background: Ovarian cancer (OCa) is the most lethal of all gynecologic malignancies in the United States. Despite the initial responses observed in OCa patients to standard combinations of surgical and cytotoxic chemotherapy, roughly 80% of these patients will develop recurrence and ultimately succumb to chemotherapy-resistant disease. Novel targeted therapies for the treatment of OCa are needed. The oncogene PELP1 is highly expressed in a variety of cancers including OCa. The suppression of PELP1 is shown to reduce the proliferation of cancer cells and renders therapy-resistant cells more susceptible to chemotherapy. We have recently developed a novel inhibitor SMIP34 that binds and degrades PELP1. The purpose of this study is to evaluate the efficacy of SMIP34 in the treatment of OCa.
Methods: We have used multiple established and patient-derived OCa models that represent all 4 types of OCa. SMIP34 was used for the inhibition of PELP1 oncogenic functions. The effect of SMIP34 on OCa cell viability was examined by MTT assays. The efficacy of SMIP34 on cell survival and apoptosis was determined using clonogenic assays, Annexin V/PI labelling and caspase 3/7 assays respectively. Mechanistic studies were performed using western blotting, RTq-PCR and RNA-seq analyses. The effect of SMIP34 on STAT3 signaling was examined using reporter gene assays. The efficacy of PELP1 inhibitor on tumor growth was examined using *ex vivo* patient derived explants (PDEX), patient-derived organoids (PDO), and *in vivo* patient-derived xenograft models (PDX).
Results: Utilizing several established and primary OCa cells, we found that SMIP34 decreased cell viability, impaired colony formation capacity, and induced apoptosis. SMIP34 markedly diminished the viability of OCa cells resistant to carboplatin, cisplatin, and taxol. SMIP34 therapy reduced STAT3 reporter activity. Western blot analysis confirmed that treatment with SMIP34 decreased the phosphorylation of PELP1 regulated survival pathways including STAT3, mTOR and AKT. Mechanistically, SMIP34 interaction with PELP1 facilitates its degradation along with its associated protein complex, which includes TEX10, LAS1L, and SENP3. Biochemical analysis confirmed that SMIP34 decreased ribosome biogenesis and new protein synthesis. RT-qPCR demonstrated that SMIP34 therapy decreases the expression of PELP1 target genes. RNA-seq analysis indicated that SMIP34 therapy downregulated cell cycle genes and induced apoptosis. Utilizing PDEX and PDO *ex vivo*, assays we show that SMIP34 markedly reduced tumor proliferation as assessed by Ki67 staining. Moreover, SMIP34 (20 mg/kg/IP) administration *in vivo* markedly inhibited tumor progression in patient-derived xenografts.
Conclusions: Collectively our results using *in vitro*, *ex vivo*, and *in vivo* models suggest that SMIP34 may serve as potential therapeutic for treating OCa by inhibiting PELP1 oncogenic signaling.

#4316 Co-alterations in *PIK3CA* and *ARID1A* lead to greater sensitivity to PI3K pathway inhibition.

Xingqi Shen, Shirsa Udgata, Jordan N. Stoecker, Cheri A. Pasch, Dustin A. Deming

University of Wisconsin-Madison, Madison, WI

Introduction: Co-alterations in *PIK3CA* (PK*)* and *ARID1A* (AD) occur in ~1% of all cancers. Previously we have shown that patients with mutations in both genes are more sensitive to copanlisib (cop) treatment than those with just *PIK3CA*(PK) mutation. Here we evaluate the efficacy of PI3K/AKT and PI3K/mTOR dual inhibitors, compared to that of cop using PKAD patient-derived cancer organoids (PDCOs).
Methods: RSEM files from NCI repository were obtained for endometrial cancer (EC) PDCOs with PK, AD, PKAD and wild type for PK and AD. Expression data in RSEM format were processed using the tximport package in RStudio to import data into data frames. The DESeq2 package was used to create differential gene expression (DGE) files. Additionally, bulk-RNA sequencing was done by UW Bioinformatics Research Core on 2D colorectal cancer (CRC) cell lines, SW48 and SW48$^{PIK3CA\text{-}H1047R}$ (SW48PK), from which AD was deleted with CRISPR (SW48AD; SW48PKAD). Gene Set Enrichment Analysis was run to identify hallmark pathway alterations (| -log10(FDR q-val) | >= 1). PDCOs were obtained following surgery with consent and following UW IRB protocol. PDCOs were generated as described previously. AD was deleted from a CRC PDCO line, with a *PIK3CA*^{H1047R} mutation (CRC-PK) using CRISPR (CRC-PKAD). PDCO lines were treated with PI3K inhibitors (alpelisib (alp), pictilisib (pict), cop, capivasertib (cap), sapanisertib (sap) and everolimus (eve)). Relative change in diameter (ΔD) was measured at day 0 and day 2 using ImageJ. Normalized ΔD (nΔD) was calculated as the ratio of median ΔD of treatment and control.
Results: Bulk-RNA-seq analysis of EC PDCO samples showed significant downregulation in immune signature pathways like epithelial-mesenchymal-transition, Interferon-γ, and IL6-JAK9-STAT3 signaling, along with a significant upregulation in the WNT-beta catenin signaling pathway when comparing PKAD and PK. Comparison between PKAD and AD showed upregulation in p53, apoptosis, and WNT-beta catenin signaling pathways. RNA-seq of 2D CRCs showed significant downregulation of the p53 (-log10FDR = 10), MYC target v2 (2.366), and apoptosis (1.826) pathways when comparing SW48PKAD and SW48PK. PKAD CRC PDCO lines had greater sensitivity to cop treatment than those with PK alterations alone (PK: nΔD=0.175; PKAD: nΔD =-0.12; $p < 0.005$). An enhanced response was observed with some other PI3K inhibitors, including sapanisertib (PK=0.13; PKAD=0.014; $p < 0.005$) everolimus (PK=0.66, PKAD=0.36; $p < 0.005$) and capivasertib (PK=0.85; PKAD=0.47; $p < 0.05$). An enhanced response was not observed with alpelisib (PK=0.54; PKAD=0.61; $p = 0.77$) nor pictilisib (PK=0.64, PKAD=0.76; $p < 0.005$).
Conclusions: Cancers with PK and AD alterations have enhanced efficacy to PI3K pathway inhibition, especially those inhibitors with downstream activity against AKT or MTOR. Further mechanistic and in vivo studies are warranted in addition to further clinical validation.

#4317 Targeting KRAS in appendiceal cancer: promising results with MRTX1133 and RMC-6236 in organoids and PDX models.

Saikat Chowdhury[1], Ichiaki Ito[1], Vinay K. Pattalachinti[2], Abdelrahman MG Yousef[1], Mahmoud MG Yousef[1], Mohammad Mahdi Fanaeian[1], John Paul Shen[1]

[1]Department of Gastrointestinal Medical Oncology, The UT MD Anderson Cancer Center, Houston, TX,[2]The Joe R. and Teresa Lozano Long School of Medicine, University of Texas Health Science Center San Antonio, San Antonio, TX

Oncogenic *KRAS* mutations are frequent in mucinous appendiceal adenocarcinoma (AA) (63.4%), with G12D accounting for just over half (50.9%) and G12V representing 23.0%. There remains a significant unmet need for effective targeted therapies of AA. The advent of novel RAS inhibitors, such as $KRAS^{G12D}$ inhibitor MRTX1133 and Pan-RAS inhibitor RMC-6236, offer a promising opportunity to address this therapeutic gap by directly targeting this oncogene. Here, we investigate the therapeutic impacts of these two new inhibitors in preclinical models of AA tumors.

One AA organoid model with $KRAS^{G12D}$ and one with $KRAS^{G12V}$ mutation were each treated with MRTX1133 and RMC-6236. Additionally, the orthotopic AA PDX model TM00351 (Jackson Laboratory) harboring $KRAS^{G12D}$ was treated intraperitoneally (IP) with MRTX1133 (15 mg/kg) (N=5) or vehicle (N=5), administered BID for 4 weeks.

MRTX1133 was highly effective for $KRAS^{G12D}$ but not $KRAS^{G12V}$ organoids (IC50 4.1 nM vs 1.8 uM, sum-of-squares F test $p < 0.0001$). In contrast, both $KRAS^{G12D}$ and $KRAS^{G12V}$ organoids were sensitive to RMC-6236 (IC50 4.4 nM vs 0.5 nM, respectively). Both inhibitors significantly increased Caspase-3/7, consistent with induction of apoptosis (p-value < 0.01). IP treatment with MRTX1133 led to a marked decrease in tumor volumes (measured by MRI) at 4 weeks after treatment in orthotopic $KRAS^{G12D}$ PDX models (MRTX1133: 1.15 fold change from baseline vs Control: 2.39, $p = 0.04$). Furthermore, MRTX1133-treated mice showed better PFS than mice in the control group (median: 5 weeks vs unreached, p-value = 0.005). Pathologic evaluation showed that MRTX1133 treatment significantly reduced cellularity in tumor tissues, with only a few cells showing positive for Ki-67. pAKT expressions did not change. pERK expressions were reduced considerably in $KRAS^{G12D}$ mutant tumor cells but did not change in $KRAS^{WT}$ stromal cells, indicating MRTX1133 mediated RAS-MEK-ERK pathway inhibition is specific to tumor cells only. Gene Set Enrichment analysis revealed significant downregulations of hallmark gene set ‘E2F targets (NES = -1.9, p-adj = 0.06)’ and the newly developed ‘RAS/ERK upregulated (NES = -2.3, p-adj = 0.06)’ gene set after MRTX1133 treatment. Also, downregulations of RAS-MEK-ERK pathway proteins, such as pMEK (logFC = -3.3, p-adj = 2.9 X 10-5) in RPPA, confirmed robust inhibition of this pathway by MRTX1133.

This is the first report demonstrating the therapeutic efficacies of G12D and pan-KRAS inhibitors in preclinical models of AA. This data is consistent with the oncogenic effect of KRAS, which is mediated by RAS-MEK-ERK pathway, not by PI3K/AKT pathway. Single-agent MRTX1133 was highly potent and specific to $KRAS^{G12D}$ AA tumors, whereas pan-RAS inhibitor RMC-6236 inhibited both $KRAS^{G12D}$ and $KRAS^{G12V}$ organoids at nanomolar concentrations. MRTX1133 demonstrated robust suppression of the RAS-MEK-ERK pathway and prolonged survival in vivo models of AA.

#4318 Genome-wide in vivo CRISPR screen identifies the role of SRSF9 in immunotherapy response regulation in hepatocellular carcinoma.

Nanzhou Yu[1], Jie Luo[1], Beibei Ru[2], Renyue Ji[1], Lanqi Gong[1], Peng Jiang[2], Xinyuan Guan[1]

[1]Department of Clinical Oncology, The University of Hong Kong, Hong Kong, Hong Kong,[2]National Institutes of Health, Bethesda, MD

Hepatocellular carcinoma (HCC) is a leading malignant tumor globally and the second-highest cause of cancer-related mortality. The insidious nature and high recurrence rates of HCC largely necessitate systemic therapies for many patients, particularly those based on immune checkpoint inhibitors. For advanced HCC, the combination of atezolizumab and bevacizumab (Atezo+Beva) has become the preferred first-line treatment, providing superior survival benefits compared to sorafenib. However, the response rate to this therapy remains under 30%, with the underlying resistant mechanism still unclear. Therefore, identifying and characterizing predictive biomarkers associated with the response to Atezo+Beva therapy is essential for improving clinical prognosis in patients with advanced HCC. Here, we performed an in vivo genome-wide CRISPR screen model after anti-programmed death ligand 1 (anti-PD-L1) and anti-vascular endothelial growth factor a (anti-VEGFa) treatment to investigate genomic modulators of the immunotherapy response in HCC. Our screening identified serine and arginine rich splicing factor 9 (SRSF9) as a critical gene involved in the anti-immunotherapy regulation. Knockout of SRSF9 in mouse tumor cells significantly enhanced the sensitivity of primary tumors and the lung metastasis to anti-PD-L1 and anti-VEGFa treatment. This finding was further validated using SRSF9-overexpression mouse model. Functional assays indicated that without immunotherapy SRSF9 had a minimal direct effect on the proliferation of multiple HCC cell lines, aligning with the analytical results derived from the DepMap database. Clinically, SRSF9 expression was increased in multiple cancer types compared to normal counterparts and was positively correlated with poor survival in HCC patients following Atezo-Bev therapy. Furthermore, high SRSF9 expression could negate the prognostic advantage typically seen in patients with strong CD8+ T cell function. In addition, SRSF9 could decrease the secretion of interferon-gamma (IFN-γ) and tumor necrosis factor-alpha (TNF-α) in tumor environment. These suggested a potential role for SRSF9 in downregulating CD8+ T cell activity. The underlying mechanism of how SRSF9 inhibits the response of HCC patients to Atezo+Beva therapy still needs further investigation. In conclusion, our study reveals the significant role of SRSF9 in modulating the response to immunotherapy in HCC, indicating its substantial potential for expanding the cohort of patients who may benefit from Atezo+Beva therapy and enhancing their prognosis. Further exploration of the underlying mechanisms will be undertaken in the future.

#4319 Loss of Golga7 suppresses oncogenic Nras-driven leukemogenesis without detectable toxicity in adult mice.

B. Jiao, L. Yan, R. Zhang, W. Huang, X. Wang, P. Liu, R. Ren;
Ruijin Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

NRAS mutations are prevalent in human hematological malignancies and are also common in certain solid tumors, including melanoma and colon cancer. Despite their crucial role in oncogenesis, no effective therapies targeting NRAS have been developed. Inhibiting NRAS localization to the plasma membrane (PM) represents a promising strategy for cancer therapy, as its oncogenic signaling relies on PM localization. Knocking out *Golgin subfamily A member 7 (Golga7)*, an accessory protein of RAS palmitoyltransferases, through a conditional gene editing approach drastically suppresses the development of myeloid leukemia induced by the activation of $Nras^{G12D/G12D}$ knock-in alleles in mice. The loss of *Golga7* disrupts $NRAS^{G12D}$ PM localization in bone marrow cells without altering the level of $NRAS^{G12D}$ palmitoylation. Notably, *Golga7* is dispensable for normal hematopoiesis in adult mice. While constitutive Golga7 knockout leads to embryonic lethality, the ubiquitous knockout of *Golga7* induced in adult mice does not manifest any measurable toxic effects. These findings indicate that GOLGA7 is an effective and safe therapeutic target for NRAS-driven leukemias.

#4321 Selective targeting of TBXT with DARPins identifies regulatory networks and therapeutic vulnerabilities in chordoma.

C. S. Umbaugh[1], M. Groth[1], C. Erkut[1], K.-S. Lee[1], J. Marinho[2], F. Iser[1], J. N. Kapp[2], P. Schroeter[1], S. Dolaner[1], A. Kayserili[1], J. Hartmann[1], P. Walch[1], T. F. E. Barth[3], K. Mellert[3], B. Dreier[2], J. V. Schafer[2], A. Pluckthun[2], S. Frohling[1], **C. Scholl**[1];
[1]German Cancer Research Center (DKFZ), Heidelberg, Germany, [2]University of Zurich, Zurich, Switzerland, [3]Institute of Pathology, Ulm University, Ulm, Germany

Aberrant expression of the embryonal transcription factor TBXT (also known as brachyury) drives chordoma, a rare spinal neoplasm with no effective drug therapies. The gene network regulated by TBXT is poorly understood, and strategies to disrupt its abnormal activity for therapeutic purposes are lacking. We developed TBXT-targeted designed ankyrin repeat proteins (T-DARPins) that selectively bind TBXT and inhibit its binding to DNA. In chordoma cells, T-DARPins reduced cell cycle progression, spheroid formation, and tumor growth in mice. Combining T-DARPin-mediated TBXT inhibition with transcriptomic and proteomic analyses, we determined the TBXT regulome in UM-Chor1 chordoma cells, which comprises in particular networks involved in cell cycle regulation, DNA replication and repair, embryonal cell identity, metabolic processes, and interferon response. The analysis of selected TBXT regulome components provided new insights into chordoma biology, such as the strong upregulation of IGFBP3 upon TBXT inhibition to fine-tune part of TBXT's downstream effectors. Finally, we assigned each TBXT regulome member a druggability status to create a resource for future translational studies and found high interferon response signaling in chordoma cell lines and patient tumors, which was promoted by TBXT and associated with strong sensitivity to clinically approved JAK2 inhibitors. These findings demonstrate the potential of DARPins to interrogate the function of nuclear proteins to understand the regulatory networks of cancers driven by aberrant transcription factor activity, including novel entry points for targeted therapies that warrant testing in patients.

#4322 NSC59984 is a radiosensitizer and cytotoxic agent in *in vitro* and *in vivo* models of *TP53mut* endometrial cancer.

Camilla Yu, Aaron Petty, Theresa D'Silva, Roberto Vargas

Cleveland Clinic, Cleveland, OH

Background: Endometrial cancer (EC) mortality is associated with high grade histologies harboring *TP53* mutations. NSC59984 is a small molecule drug hypothesized to restore p53 signaling in *TP53mut* cancers, but has not been explored in EC. We aimed to evaluate the cytotoxic and radiosensitizing potential of NSC59984 in *TP53mut* EC cell lines *in vitro* and *in vivo* and elucidate its mechanism of action.
Methods: *In vitro* experiments used 2 EC cell lines with differing *TP53* status: JHUEM2 (WT *TP53*) and Hec1B (homozygous R248Q). Dose response curves were generated by treating cells with NSC59984 for 24hrs and assessing viability with CellTiter-Glo after 9 days. To assess for mutation specific effects, we used CRISPR/Cas9 modified variants of JHUEM2 cells lacking WT p53 and harboring 1 of 5 *TP53* mutations (R248Q, R248W, R273C, R273H, Y220C). Western blot analysis assessed p53, p21, PUMA, GADD45, and NOXA signaling using whole cell lysates after treatment with 25μM of NSC59984 for 24hrs. Radiosensitizing effect was assessed using JHUEM2 *TP53* variants and Hec1B treated with increasing doses of NSC59984 and a single fraction of RT (0, 0.5, 1, 2, 4 and 8Gy.) *In vivo* experiments used HEC1B xenograft tumors generated in female NSG mice. 2 $x10^6$ cells were injected SQ in the flanks of 6 week old mice. 2 mice (4 tumors) were included in each arm: vehicle, RT, NSC59984, and NSC59984 + RT. Once tumors were 150mm^3, mice were treated with a 2Gy fraction of RT and NSC59984 (45mcg/kg) every 5 days for 23 days via IP injection. Synergy was tested using HSA and BLISS modeling.
Results: NSC59984 had a negative, dose dependent effect on cell viability. IC50s for JHUEM2 and Hec1B were 4.2μM and 5.7μM. IC50s for NTC, *TP53* KO and variants were similar (4.2-6.1μM). In Western blot analysis, NSC59984 restored p53 signaling via p21, PUMA, and NOXA with decreased mutant p53 signal across all variant cell lines. Radiosensitization assays demonstrated synergy of NSC59984 + RT in all cell lines with maximum synergy at 5μM of NSC59984 and 2Gy ($p<0.05$) based on HSA modeling. *In vivo* pilot experiments confirmed *in vitro* findings, showing tumor growth suppression with NSC59984 + RT compared to vehicle or single agent treatment. On day 20, mean tumor size in the NSC59984 + RT group was 103.4mm, significantly smaller than vehicle (384.5mm, $p=0.004$), RT (506.2mm, $p=0.03$), and NSC59984 (394.8mm, $p=0.02$) groups. Tumor growth inhibition synergy analysis using the Bliss model demonstrated synergy of NSC59984 + RT on days 20-23 with a mean synergy score of 101.6.
Conclusions: NSC59984 has cytotoxic and radiosensitizing effects in *in vitro* and *in vivo* models of *TP53mut* EC. These effects are independent of specific *TP53* mutations, suggesting it bypasses inactive p53 to drive p21, PUMA, and NOXA signaling. The synergistic effect is within biologically relevant doses and supports the need for further preclinical investigation in a disease with significant unmet need and poor outcomes.

#4323 CARM1-mediated methylation of ZNF703 regulates its oncogenic functions in estrogen receptor positive breast cancer.

Jingjing Zhou, Eui-Jun Kim, Gui Ma, Ang Gao, Wei Xu

UW Madison, Madison, WI

ER-positive (ER+) breast cancer, characterized by estrogen receptor expression on tumor cells, constitutes approximately 70% of all breast cancer cases. Identifying specific oncogenes and elucidating relevant oncogenic mechanisms are critical for developing effective therapies. *ZNF703*, a NET/N1Z family transcription factor, drives 8p12 locus amplification found in 10-20% of ER+ breast tumors. *ZNF703* has been reported as an oncogene that promotes ER+ breast tumorigenesis in vitro. However, its regulation and *in vivo* oncogenic function remain unclear. We showed that *ZNF703* expression is induced by estradiol in ER+ cell lines. ShRNA-mediated ZNF703 knockdown significantly reduced cell proliferation in MCF7 and BT474 cells. ZNF703 is post-translationally modified, which may affect its nuclear localization as well as its functions. Using mass spectrometry, we identified two asymmetrically di-methylated arginine residues (R544 and R580) on ZNF703 in human breast tumors. Protein arginine (R) methylation is catalyzed by protein arginine methyltransferases (PRMTs), which are classified into Type I, II, and III based on the type of methyl-R they produced. Among these, CARM1, a Type I PRMT, catalyzes asymmetric di-methylation of arginine residues. We showed that ZNF703 is methylated by CARM1 in *in vitro* methyltransferase assay. Furthermore, ZNF703 protein levels were reduced in CARM1 knockout MCF7 cells, accompanied by an increased degradation rate, suggesting that ZNF703 may be stabilized by CARM1. Given the lack of an ER+ breast cancer mouse model, we derived an ER+ MG1 rat cell line from estrogen-induced rat breast tumors. Consistent with our findings in human ER+ cell lines, ZNF703 was validated as an estrogen-induced gene in MG1 cells. ZNF703 knockout in MG1 cells impaired cell proliferation and colony formation. Functional rescue experiments demonstrated that re-expression of wild-type ZNF703 fully restored cell growth, whereas the methylation-deficient mutants ZNF703 R580K and R544K only partially rescued the proliferation defect. Our results implicate that CARM1-mediated ZNF703 methylation may regulate its stability and oncogenic functions. Given that patients diagnosed with 8p12 locus amplification caused by *ZNF703* typically have poor prognosis, our MG-1/ACI rat syngeneic model would enable the investigation of *ZNF703*'s oncogenic functions in vivo.

#4324 Inhibition of ERK reactivation by FGTI-2734: A strategy to overcome sotorasib resistance in KRAS G12C lung cancer.

Aslamuzzaman Kazi[1], Hitesh Kumar Kantilal Vasiyan[2], Deblina Ghosh[1], Dipankar Bandyopadhyay[3], Rachit D. Shah[4], Vignesh Vudatha[4], Jose Trevino[5], Said M. Sebti[1]

[1]Pharmacology and Toxicology, VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]VCU Massey Comprehensive Cancer Center, Richmond, VA,[3]Biostatistics, Virginia Commonwealth University, Richmond, VA,[4]Surgery, Virginia Commonwealth University, Richmond, VA,[5]Pharmacology and Toxicology, Virginia Commonwealth University, Richmond, VA

Discovery of sotorasib is a major breakthrough for KRAS G12C targeted therapies. However, overall response rates of patients with KRAS G12C lung cancer treated with sotorasib are modest due to resistance mediated by adaptive reactivation of ERK, which requires wild-type (WT) RAS membrane localization. In this study, we demonstrate that the dual farnesyltransferase (FT) and geranylgeranyltransferase-1 (GGT-1) inhibitor FGTI-2734 inhibits WT RAS membrane localization, and overcomes sotorasib adaptive resistance through inhibition of sotorasib-induced ERK feedback reactivation. The combination of FGTI-2734 and sotorasib is synergistic at inhibiting the viability and inducing apoptosis of lung cancer cell lines with KRAS G12C mutation, including those that are highly resistant to sotorasib. Anti-tumor activity of sotorasib is enhanced by FGTI-2734, leading to significant tumor regression of a patient-derived xenograft (PDX) from a KRAS G12C lung cancer patient as well as several xenografts from highly sotorasib-resistant KRAS G12C human lung cancer cells. Importantly, *in vivo*, FGTI-2734 inhibited sotorasib-induced ERK reactivation in the KRAS G12C PDX, and combinations of FGTI-2734 and sotorasib were also significantly more effective at suppressing the levels of P-ERK in sotorasib-resistant human KRAS G12C lung cancer xenografts. This study provides a rational strategy for overcoming sotorasib resistance in KRAS G12C lung cancer.

#4325 FXYD5 plays diverse roles in immune evasion and tumor progression in prostate cancer.

Ru Wen[1], G Edward W. Marti[1], Neeladrisingha Das[1], Zhengyuan Qiu[1], Nathan Lam[1], Eric E. Peterson[1], Zenghua Fan[2], Aram Lyu[2], Fernando Jose Garcia Marques[1], Abel Bermudez[1], Hongjuan Zhao[1], Lawrence Fong[3], Guillem Pratx[1], Donna M. Peehl[2], Sharon J. Pitteri[1], James D. Brooks[1]

[1]Stanford University, Stanford, CA,[2]UCSF, San Francisco, CA,[3]Fred Hutch Cancer Center, Seattle, WA

FXYD5 is involved in various biological processes, including inflammation, tumor progression, drug resistance, and hypertension. It has been suggested as a potential biomarker for several cancers, with elevated levels found in ovarian and colon cancer. However, the role of FXYD5 in prostate cancer has not yet been elucidated. Here, we found that the FXYD5 was expressed in tumor cells by sc-RNA sequencing of human metastatic prostate tumor tissues. The expression levels of FXYD5 were higher in androgen receptor (AR)-negative prostate cancer cells compared to AR-positive prostate cancer cells. Intrinsically, FXYD5 knockout promoted PC3 cell proliferation, migration, and invasion. *In vivo* studies showed that FXYD5 knockout promoted PC3 tumor growth, while overexpression of FXYD5 inhibited PC3 tumor progression. However, in AR-positive 22Rv1 cells, overexpression of FXYD5 promoted tumor progression. In vitro assays indicate that overexpression of FXYD5 in PC3, C42B, and 22Rv1 cells reduces mitochondrial membrane potential and reactive oxygen species. Additionally, FXYD5 overexpression reduces lactate dehydrogenase activity and lactate levels in PC3 cells but has no effect on these parameters in 22Rv1 cells. In PC3 cells, FXYD5 overexpression promotes the formation of tight cell-cell interactions, accompanied by downregulation of membrane markers and nuclear enlargement. In contrast, these effects are not observed in 22Rv1 or C42B cells. Further, FXYD5 is identified as a potential Siglec-7 ligand by CRISPRi screen. FXYD5 knockout decreased Siglec-7 Fc binding capacity and enhanced the NK-cell mediated cytotoxicity in prostate cancer cells. In a humanized mouse model, 22Rv1 tumor growth was inhibited with human immune cell modulation. However, when FXYD5 was overexpressed in 22Rv1 cells, tumor growth was not impacted by immune cell-based therapy. This was due to the interaction of FXYD5 on cancer cells with Siglec-7 on immune cells, thereby inducing immunosuppressive signals. These findings suggest potential therapeutic strategies targeting FXYD5-based mechanisms.

#4326 KRB-456: A novel KRAS G12D switch-I/II allosteric pocket binder that thwarts pancreatic cancer patient-derived tumors.

Aslamuzzaman Kazi[1], Alok Ranjan[1], Vasanth M. V. Kumar[2], Bogos Agianian[3], Martin Garcia Chavez[4], Vignesh Vudatha[1], Rui Wang[1], Rajani Kanth Vangipurapu[5], Liwei Chen [5], Perry Kennedy [5], Karthikeyan Subramanian[1], Quirke Jonathan Charles Kenneth [4], Francisca Beato[5], Patrick W. Underwood,[1], Jason B. Fleming,[5], Paul Hergenrother [4], Jose Trevino[1], Evripidis Gavathiotis[3], Said M. Sebti[1]

[1]VCU Massey Comprehensive Cancer Center, Richmond, VA,[2]Department of Biochemistry,, Albert Einstein College of Medicine, Richmond, NY,[3]Department of Biochemistry,, Albert Einstein College of Medicine, New York, NY,[4]University of Illinois, Champaigne Urnbana, IL,[5]Moffitt Comprehensive Cancer Center, Tampa, FL

Currently, there are no clinically approved drugs that directly thwart mutant KRAS G12D, a major driver of human cancer. Here, we report on the discovery of a small molecule, KRB-456, that binds KRAS G12D and inhibits the growth of pancreatic cancer patient-derived tumors. Protein nuclear magnetic resonance studies revealed that KRB-456 binds the GDP-bound and GCP-bound conformation of KRAS G12D by forming interactions with a dynamic allosteric binding pocket within the switch-I/II region. Isothermal titration calorimetry demonstrated that KRB-456 binds potently to KRAS G12D with 1.5-, 2-, and 6-fold higher affinity than to KRAS G12V, KRAS wild-type, and KRAS G12C, respectively. KRB-456 potently inhibits the binding of KRAS G12D to the RAS-binding domain (RBD) of RAF1 as demonstrated by GST-RBD pulldown and AlphaScreen assays. Treatment of KRAS G12D-harboring human pancreatic cancer cells with KRB-456 suppresses the cellular levels of KRAS bound to GTP and inhibits the binding of KRAS to RAF1. Importantly, KRB-456 inhibits P-MEK, P-AKT, and P-S6 levels *in vivo* and inhibits the growth of subcutaneous and orthotopic xenografts derived from patients with pancreatic cancer whose tumors harbor KRAS G12D and KRAS G12V and who relapsed after chemotherapy and radiotherapy. These results warrant further development of KRB-456 for pancreatic cancer.

#4327 Disruption of aggregated oncogenic mutant p53 as a novel therapeutic strategy for gynecologic cancers.

Geneva L. Williams[1], Jamie L. Padilla[1], Lane E. Smith[1], Jun-yong Choe[2], Doris M. Benbrook[3], Kimberly K. Leslie[1]

[1]University of New Mexico Health Sciences Ctr., Albuquerque, NM,[2]Chemistry, University of New Mexico, Albuquerque, NM,[3]School of Medicine, University of Oklahoma, Oklahoma City, OK

High grade serous ovarian and endometrial cancers possess *TP53* missense mutations that result in loss of the central tumor suppressive functions of wild type p53 (WT p53). In normal unstressed cells, p53 protein is regulated through ubiquitin-tagging and shuttling to the 26S proteasome by the E3 ubiquitin ligase MDM2 (Murine Double Minute 2). In cancer cells with mutant forms of p53, MDM2 is not adequately expressed in such cells to perform its regulatory role, thus leading to mutant p53 aggregates. Understanding mechanisms to target mutant p53 proteins for degradation in cancers has tremendous therapeutic potential. Recent discoveries in p53 refolding agents to reinstate WT p53 functionality for the treatment of gynecologic malignancies have shown promise. Treatment of cancer cells harboring p53 mutations with p53 reactivators HO-3867 and our novel curcumin analogue AKT-100 displayed an upregulated expression of *heat shock protein 70 (HSP70)* family member genes, as well as the autophagy-inducing co-chaperone *BAG3* (*Bcl-2-associated athanogene 3*) by RNA sequencing analysis. Western blot analysis showed a decrease in p53 protein expression after treatment with the curcumin analogues, while MDM2 levels were unchanged, indicating an alternative mechanism of mutant p53 degradation. *We hypothesize that the BAG3-HSP70 interaction varies with different mutations in p53 as well as the various HSP70 family members involved and can be therapeutically normalized to restore WT p53 regulation.* Using our cell models of high grade serous ovarian and endometrial cancer, we have determined through co-immunoprecipitation and mass spectrometry that p53 binds HSPA6 and BAG3 upon treatment only with AKT-100 in KLE (p53 R175H) and COV362 (p53 Y220C) cells. Furthermore, co-treatment of curcumin analogue AKT-100 plus HSP inhibitor SHetA2 (sulfur heteroarotinoid A2, NSC 726189) highly increased the expression of BAG3, HSPA1A, HSPA6 and ubiquitination while decreasing mutant p53 expression in KLE cells. Confocal microscopy in KLE cells also displayed a shift of mutant p53 and HSPA6 from nuclear to mostly cytoplasmic upon treatment with AKT-100. Co-treatment with AKT-100 and SHetA2 highly increased HSPA6 expression throughout the cell, while p53 returned to the nucleus to perform normal apoptotic functions based on CyQuant proliferation data. Our data indicates a novel mechanistic insight into therapeutically intervening to re-establish normal p53 levels and regulation to treat women with advanced, mutant p53 gynecologic malignancies.

#4328 Preclinical development of SCR-A008: A CDH17-targeted ADC for gastrointestinal cancer.

Guangcun Cheng, Hui Zheng, Zhiyong Yu, Chunlei Xia, Huipeng Guo, Xiyuan Wang, **Yayuan Fu**, Renhong Tang

Simcere Zaiming, State Key Laboratory of Neurology and Oncology Drug Development. Simcere Pharmaceutical Group, Shanghai, China

Background: Cadherin is a superfamily of cell adhesion molecules that depend on Ca^{2+} and play an important role in maintaining tissue architecture. Abnormal expression of Cadherins is often associated with malformation of tissues, tumor formation, and metastasis. Cadherin-17 (CDH17) also known as hepatocyte-enterocyte cadherin, is a non-classical member of the calcium-dependent cadherin superfamily. Unlike classical cadherins, the CDH17 sequence is formed by seven extracellular calcium-dependent cadherin domains and a very short cytoplasmic domain. CDH17 is a calcium-dependent transmembrane glycoprotein that mediates cell-cell adhesion in intestinal epithelial cells. Studies have found that CDH17 expression is limited to the intestinal and pancreatic duct epithelial cells in human normal tissues. However, in tumor tissues, CDH17 is highly expressed in various digestive tract tumors, such as gastric cancer (73%), colorectal cancer (100%) and pancreatic cancer (31%). Some studies have also reported positive staining for CDH17 in about 6% of lung cancer patients, 11% of ovarian cancer patients, and 2% of liver cancer patients. These results suggest that CDH17 may be a potential therapeutic target in related tumors, especially digestive tract tumors.

Methods & Results: We developed a novel CDH17-targeting antibody-drug conjugate (ADC) called SCR-A008, which is comprised of an anti-CDH17 humanized monoclonal antibody conjugated with novel topoisomerase 1 inhibitor (CPT116) via a hydrophilic cleavable linker at DAR 8. SCR-A008 specifically recognizes human and cyno CDH17 with high affinity. In vitro cytotoxicity experiment demonstrated that SCR-A008 induced tumor cell lysis in various tumor cell type. Compared to MMAE-based CDH17-ADC, SCR-A008 exhibits significantly stronger anti-tumor activity in colorectal cancer cells. Additionally, we utilized CDX and PDX model to evaluate the *in vivo* efficacy of SCR-A008. The results showed that SCR-A008 inhibited tumor growth of various tumors in a dose dependent manner. SCR-A008 also have good stability and favorable developability. Pharmacokinetics and tolerability were assessed in mouse and cynomolgus monkey. The pharmacokinetics experiment in mice showed better PK characteristic than the reference ADC.

Conclusion: These findings suggest that SCR-A008 is a potential Best-in-Class therapeutic drug for CDH17-positive solid tumor.

#4329 Developing oncogenic mutant-selective antisense oligonucleotide to treat PIK3CA-mutated cancers.

Peng Ning[1], Yamu Li[1], Clemens Burda[2], Zhenghe Wang[1]

[1]Department of Genetics and Genome Sciences, Case Comprehensive Cancer Center, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Department of Chemistry, Case Western Reserve University, Cleveland, OH

Phosphatidylinositol 3-kinases are heterodimers consisting of a p110 catalytic domain and a p85 regulatory domain. PIK3CA, which encodes the p110α catalytic subunit, is frequently mutated in human cancer. The FDA approved a WT p110-specific inhibitor, alpelisib, to treat PIK3CA-mutant breast cancer patients a few years ago. However, alpelisib and other WT p110α inhibitors could cause severe hyperglycemia in patients because WT p110α inhibitors block the intracellular action of insulin on the liver and skeletal muscle, thereby creating a transient state of insulin resistance. Most PIK3CA/p110α oncogenic mutations occur at two hot spot regions, one in the helical domain and the other in the kinase domain. Recently, a couple of PIK3CA/p110α kinase domain mutant-specific inhibitors have been developed. Early-phase clinical trials showed that the kinase domain mutant-specific inhibitors did not cause severe hyperglycemia in patients. Half of all p110α mutations are in the helical domain, and the E545K is the most frequent recurrent helical domain mutation. However, developing small molecule inhibitors against the PIK3CA/p110α helical domain mutations remains challenging. To this end, we have developed antisense oligonucleotides (ASOs) that preferentially degrade PIK3CA/p110α helical domain mutant mRNAs. In a cell-based assay, our lead ASO (ASO18) potently and preferentially degraded the PIK3CA E545K mutant allele at low nM concentrations. In multiple subcutaneous xenograft models, intra-tumor injection of ASO18 significantly inhibits the growth of tumors that harbor a PIK3CA E545K mutation but not a PIK3CA WT tumor. Based on our previous findings that p85β dissociates from PIK3CA/p110α E545K mutant protein and translocates into the nucleus to stabilize EZH2, we further demonstrated that a combination of ASO18 with an EZH2 inhibitor tazemetostat synergistically suppress xenograft growth of tumors harboring a PIK3CA E545K mutation. To deliver the ASO systematically, we used an FDA-approved D-Lin-MC3-DMA lipid nanoparticle (LNP) formulation to load the ASO, showing that ASO capsulated efficiently (over 95%). Moreover, the dose of LNP-ASO in the nanomolar range could achieve the same potency as the micromolar level of free ASO in tissue culture cells. Experiments assessing the efficacy of the LNP-ASO in xenograft models are ongoing. To our knowledge, our study represents the first mutant-selective ASO against an oncogenic mutation, which may lead to the development of a mutant-selective ASO to treat patients whose tumors harbor a PIK3CA E545K mutation.

#4330 Employing synthetic mRNA therapeutic platform to restore p53 function to suppress growth of p53 mutant cancer.

Yong Ho Heo, Seung-Hyun Shin, Youngjin Han, Chang Gyu Lim, Innah Kim, Ji Hee Lee, Sol-Bi Shin, Soye Jeon, Aran Park, Jooyun Byun, Daejin Kim, In Young Choi

Hanmi Pharmaceutical Co., Ltd., Gyeonggi-do / Hwaseong-si, Korea, Republic of

TP53, a gene encoding p53, is a critical tumor suppressor gene, and its mutation serves as a major driver in various cancer types, deeply influencing tumor progression and patient prognosis. Efforts to restore wild-type p53 function have included targeting specific p53 mutants with small molecules, preventing p53 degradation through inhibition of its negative regulators, and employing adenoviral vectors to deliver wild-type p53. However, these strategies face challenges, including limited efficacy and the heterogeneity of p53 mutations. In this study, we present an optimized mRNA-based approach to restore p53 functionality, utilizing both in vitro and in vivo models of cancers with high p53 mutation frequencies. To enhance therapeutic efficacy, we optimized key elements of p53 mRNA, including the 5' and 3' untranslated regions (UTRs), the open reading frame (ORF), and Hanmi's 5' capping reagent. Using cancer cell lines derived from lung, ovarian, pancreatic, and head and neck cancers harboring p53 mutations, we evaluated the therapeutic potential of our p53 mRNA therapy. Selectivity was assessed by examining its effects on both normal and p53 wild-type cancer cells. Our findings demonstrate that Hanmi's p53 mRNA therapy selectively inhibits the proliferation of p53-mutant cancer cells by inducing apoptosis and cell cycle regulators such as PUMA, BTG2, and p21. Importantly, in vivo studies revealed significant tumor growth inhibition in xenograft models of lung, ovarian, and pancreatic cancers, with no notable impact on mouse body weight. Additionally, we tested the efficacy of our p53 mRNA therapy in a cancer orthotopic model, confirming its potent antitumor activity in a clinically relevant setting and demonstrating the selective efficacy against tumor. These results underscore the promise of p53 mRNA as a novel and efficient therapeutic strategy for selectively targeting p53 mutant cancers, paving the way for improved outcomes in precision oncology.

MOLECULAR/CELLULAR BIOLOGY AND GENETICS: Gene Regulation and Transcription Factors 1
Poster Session

#4331 Collaboration between p63 and ZNF148 in regulating squamous cell carcinoma progression.

Artem Smirnov, Eleonora Candi

University of Rome Tor Vergata, Rome, Italy

p63, a member of the p53 family of transcription factors, is essential for the development and maintenance of squamous epithelium. In squamous cell carcinomas, including head and neck squamous cell carcinoma (HNSCC), p63 is the most frequently amplified transcription factor at the genomic level and is often overexpressed. HNSCC is a prevalent and aggressive form of cancer and treating advanced stages of the disease remains a significant challenge. Using a proteomics-based approach, we identified new binding partners of the oncogenic variant DNp63. Among these, the zinc finger protein ZNF148 was found to be co-expressed with DNp63 and to physically interact with it in carcinoma cells. Genome-wide binding studies revealed a functional enhancer-derived RNA (eRNA) located upstream of the *CCND1* gene, which is bound by both DNp63 and ZNF148. This interaction regulates the transcription of the eRNA, leading to increased cyclin D1 expression, thereby promoting tumor cell proliferation. Notably, this pathway is specific to cancer cells and remains inactive in normal epithelial cells. The expression levels of DNp63, ZNF148, and the eRNA are positively correlated in cancer, with higher levels linked to advanced disease and metastasis. Furthermore, ZNF148 also independently influences cell migration and inflammatory responses in HNSCC by regulating genes involved in actin cytoskeleton remodeling and type I and II interferon signaling pathways. Together, these findings uncover a novel molecular mechanism driving HNSCC progression and highlight potential targets for selective cancer therapies.

#4332 Concomitant therapy leveraging antibody-pan-*KRAS*^{mt} siRNA conjugate for PDAC and LUAD harboring *KRAS* mutations.

Aiyun Wen, Jing Guo, Zengyan Mu, Chengang Zhou, Junhao Wang, Tongtong Hu, Haibo He, Meijun Xiong, Cong Liu, Paul H. Song, Gang Qin

GeneQuantum Healthcare (Suzhou) Co., Ltd., Suzhou, China

Background: *RAS* is the most frequently mutated oncogene, with *KRAS* being the most mutated *RAS* isoform and accounting for 85% of *RAS* mutations observed in human cancers. *KRAS* mutation plays a crucial role in cancer initiation and progression and confers resistance to treatment. *KRAS* mutation is present in 90% of pancreatic ductal adenocarcinoma (PDAC) and 35% of lung adenocarcinoma (LUAD). With FDA's approval of the first-in-class *KRAS*^{G12C} inhibitor LUMAKRAS® for the lung cancer in 2021, the emergence of secondary mutations continues to pose challenges in the clinical treatment of *KRAS*-mutant (*KRAS*^{mt}) cancers via inhibition of the single mutations. The goal of the current study was to investigate the impact of *KRAS* oncogene silencing by antibody-pan-*KRAS*^{mt} siRNA conjugates (AOCs) on the pancreatic and lung tumor growth. A series of pan-*KRAS*^{mt} siRNA sequences that target a wide range of *KRAS* mutations were selected and ligated to a tumor targeting antibody utilizing GeneQuantum's (GQ) proprietary iGDC™ conjugation platform. The therapeutic potential of these AOCs with and without gemcitabine was examined in the cancer cell lines/patient derived organoid (PDO) models and subcutaneous CDX/PDX mouse models.

Results: GQ's iGDC™ conjugation process yielded unprecedented pure DAR1 pan-*KRAS*^{mt} AOCs, with over 98% purity confirmed by HPLC analysis. These candidate AOCs achieved potent target knockdown with reduced phosphorylation level of downstream effectors and significantly inhibited cell proliferation in multiple *KRAS* mutant cell lines/PDOs. The lead AOCs selected from the *in vitro* testing achieved enhanced tumor exposure compared to non-targeting isotype AOC in the CDX/PDX mice, and pharmacological reduction of oncogenic *KRAS* mutations suppressed the growth of tumor xenografts. Combined treatment of the lead pan-*KRAS*^{mt} AOC with gemcitabine demonstrated synergistic effects with prolonged survival rate and dramatically reduced mean tumor volume.

Conclusion: GQ's pan-*KRAS*^{mt} AOC demonstrated the benefit of the tumor enrichment and the positive impact on the tumor regression. The additive tumor reduction outcome via combining with gemcitabine suggested the potential sensitization effect of pan-*KRAS*^{mt} AOC on the conventional chemotherapy. Our findings in the present study unveiled a new path toward addressing *KRAS*-driven refractory cancers with tumor targeting siRNA therapy covering multiple *KRAS* mutations.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Pharmacokinetics and Pharmacodynamics of Cancer Therapeutics Poster Session

#4336 Translational PK/PD modeling of MEK inhibitors: Trametinib, cobimetinib and binimetinib.

Jake Dickinson, Hitesh B. Mistry

Seda Pharmaceutical Development Services, Stockport, United Kingdom

We propose a translational PK/PD framework that enables human dose estimation (HDE), compound ranking and to assess the clinical applicability of cancer cell-line-panels. Translational PK/PD simulations were performed to estimate the efficacious doses in humans. The translational approach was first calibrated using an approved therapy, Trametinib. Cobimetinib and Binimetinib were then used as test compounds. Translational simulations for Cobimetinib and Binimetinib were performed and benchmarked against the Trametinib simulations to aid in HDE. The modelling approach was qualified against reported efficacious doses for Binimetinib and Cobimetinib. The reported population PK (PopPK) models were used to simulate clinical PK. Drug effect was described by an E_{max} model. *in vitro* efficacy data for Trametinib, Cobimetinib and Binimetinib, were extracted from the PRISM screen within DepMap Public Access Portal which contained the results of pooled-cell line chemical-perturbation viability screens for 1448 compounds screened against 489 cell lines. EC50 distributions were derived from the PRISM screening for each compound. Only cell-lines that had the same biological profile as the target population, V600E mutated BRAF patients, were included in the EC50 distribution. We have developed a PopPK/PD model structure to simulate the dose-response, where response is the average drug effect (E_{avg}), by integrating in vitro efficacy cell line data and published PopPK models for MEK-inhibitors Trametinib, Cobimetinib and Binimetinib. Trametinib E_{avg} at the approved dose, 2mg once daily (QD), was simulated using the developed PopPK/PD model. The simulated median E_{avg} was 31% and 25th and 75th percentile were 13% and 57% respectively. Dose-response curves, where E_{avg} was the response, were simulated for Binimetinib and Cobimetinib. A dose that resulted in an E_{avg} that was matched to the median Trametinib E_{avg} was identified for both compounds. Expected, efficacious dose was predicted to be 10 mg QD 21/7 (50% Prediction Interval (PI); 6 - 15 mg QD 21/7) for Cobimetinib and 40 mg BID (50% PI; 15 - 95 mg BID) for Binimetinib. To qualify the modelling approach the predicted efficacious doses were compared to the reported maximum tolerable dose (MTD). The predicted efficacious dose for Binimetinib was similar to the reported MTD, 45 mg BID. The predicted efficacious dose for Cobimetinib was slightly lower than MTD, 60 mg QD 21/7. The translational PK/PD framework highlighted that the routine cancer cell-line-panels, in this instance the PRISM assay, may well be suitable for making HDE. The predictions may be improved further by using multiple different *in vitro* systems and more complex assays. Additionally, the translational framework enables compound ranking and selection and aids in quantifying a clinical therapeutic window. We are thankful for fruitful discussions with Heinrich Huber of Boehringer Ingelheim.

#4337 SYS6051, a next-generation tissue factor-targeted antibody-drug conjugates for the treatment of TF-expressing malignancies.

X. Wu[1], M. Shen[2], **M. Dan**[1], X. Hui[2], B. Yao[2], Y. Li[1], W. Yang[1], H. Xu[1], C. Yuan[2], Y. Sun[1], B. Kang[1], Y. Zhang[1], L. Xiao[1];
[1]CSPC Pharmaceutical Group Ltd., Beijing, China, [2]CSPC Megalith Biopharmaceutical Co., Ltd., Shijiazhuang, China

Tissue factor (TF) is an integral membrane protein, normally separated from the blood by the vascular endothelium, which plays a key role in the initiation of blood coagulation. However, TF is aberrantly expressed in solid tumors and its expression associated with poor prognosis. The first TF targeting antibody-drug conjugate (ADC) , a microtubule inhibitor based ADC(MTI-ADC), is approved for the treatment of cervical cancer. It had several prespecified adverse effects (AEs) including bleeding risks, ocular toxicity and perpheral neuropathy, the last two of which were known MMAE related AEs. In order to mitigate the safety concerns, we developed a novel ADC, SYS6051. It was composed of a humanized TF-targeting lgG1 antibody site-specifically conjugated to a topoisomerase I inhibitor (Exatecan) at a drug-to-antibody ratio (DAR) of 6 via a protease-cleavable linker. In addition, SYS6051 had improved resistance towards retro-Michael elimination reactions, resulting in improved stability compared to cysteine thiol-maleimide conjugated ADCs. The naked SYS6051-mAb did not interfere with the interaction among TF, Factor FVII and Factor X, and had no impact on coagulation cascade. SYS6051-mAb could quickly enter cells through endocytosis 3 hours after treatment, faster than the antibody of the MTI-ADC. Treatment with SYS6051 resulted in significant tumor growth inhibition in a panel of TF-positive cell line derived xenografts (CDXs), including pancreatic and cervical cancer xenografts. Furthermore, SYS6051 was well tolerated in a toxicity study in cynomolgus monkey at dosages ≤30 mg/kg. A stable PK profile of SYS6051 was also observed in NHP. Neither coagulation disorder nor skin rash was observed, superior to the historical toxicity data in NHP of the MTI-ADC. Taken together, SYS6051 has a wide therapeutic window because of promising efficacy, higher tolerability, stable PK profile, and could potentially provide benefits for the patients carrying TF positive malignancies.

#4338 SYS6042, a novel anti-TROP2 pH-sensitive antibody-drug conjugate (ADC) with improved therapeutic window.

Y. Wang[1], X. Gao[2], M. Dan[1], **X. Hui**[2], B. Yao[2], Y. Zhang[1], C. Niu[1], C. Yuan[2], X. Zhu[1], Z. Sun[2], B. Kang[1], M. Wei[1];
[1]CSPC Pharmaceutical Group Ltd., Beijing, China, [2]CSPC Megalith Biopharmaceutical Technology Shijiazhuang) Co., Ltd., Shijiazhuang, China

TROP2 is a ubiquitously expressed tumor-associated antigen. Its expression in normal tissues such as skin, oral mucosa, esophagus, liver, and cornea severely limits the development of anti-TROP2 ADCs. It is difficult to balance the efficacy and toxicity to obtain a larger therapeutic window. In clinical, Dato-DXd, Trodelvy and SKB264 showed obvious on-target toxicity or off-target toxicity, which affect clinical development and patient benefit. To address the unmet needs, we developed the SYS6042, an ADC composed of an anti-TROP2 pH-sensitive antibody, a tetrapeptide-based stable linker, and a topoisomerase I inhibitor payload, with a drug-to-antibody ratio (DAR) of 8. It binds TROP2 with nanomolar affinity at pH 6.0 but hardly binds the target at pH 7.4, thereby reducing on-target toxicity. In several cell line-derived xenografts (CDX) models, a single dose of SYS6042 at 0.4 - 4.0 mg/kg exhibited remarkable tumor growth inhibition. Notably, the antitumor activity of SYS6042 was superior to homemade Dato-DXd and SKB264. In exploratory toxicology study, SYS6042 showed favorable PK and good safety profiles with toxic findings unrelated to on-target toxicity(hematotoxicity) despite high levels of TROP2 expression in normal tissues of cynomolgus monkey. The highest non-severely toxic dose (HNSTD) for monkeys was defined as 30 mg/kg for repeating dosing. Based on these results, it demonstrates that the novel design of SYS6042 leads to an improved therapeutic window, which would help address unmet needs in the treatments of TROP2-positive tumors.

#4339 Glucosinolates selectively target cancer cell types and exhibit antineoplastic effects.

K. Carrozzi[1], A. Aggarwal[1], **K. W. Yip**[2];
[1]University of Toronto, Toronto, ON, Canada, [2]Anticancer.ca, University of Toronto, Toronto, ON, Canada

Introduction: Glucosinolates are organic compounds found in high concentrations within cruciferous vegetables. Plant tissue damage initiates the release of myrosinase, which breaks down glucosinolates into the biologically active compounds indole-3-carbinol (I3C) and sulforaphane. *In vitro* studies have suggested that I3C and sulforaphane can mitigate cancer progression via hormone regulation and antioxidant mechanisms, respectively. However, there has yet to be a systematic analysis of these two glucosinolates against a wide range of human cancer cell lines. We hypothesized that I3C would differentially affect cancer cell growth depending on cell line of origin, and that sulforaphane would induce a genetic signature similar to compounds and genetic perturbations with anticancer properties.

Methods: Cell survival data was obtained from the NCI-60 human tumor cell lines screen. 59 tumor cell lines were seeded into 96-well microtiter plates. 100 µL of 5 different I3C 10-fold dilutions (0.01 - 100 µM) were added to the wells and incubated for 48 hours. After staining with sulforhodamine, absorbance was measured, and percent growth was calculated relative to the no-drug control and number of cells at baseline. Genetic profiling data was obtained from the Broad Institute's L1000 assay. Sulforaphane was added to 9 cell lines in 384-well plates. mRNA was extracted and expression levels of 978 landmark genes were measured. This provided a transcriptomic signature that was compared to signatures from other compounds and genetic perturbations. A Connectivity Score was then developed to measure the similarity of each signature to the one induced by sulforaphane.

Results: I3C was most potent in the KM12 cell line (IC_{50} = 14.9 µM; colon cancer) where it inhibited ~90% of growth at a 100 µM concentration. Cancers of the colon and skin were most sensitive to I3C (median IC_{50} values of 28.3 µM and 36.1 µM, respectively), while breast and myeloid tissue cancers were least sensitive. Gene expression induced by sulforaphane was most similar to that induced by isoliquiritigenin, a flavonoid compound that exhibits antiproliferative and anti-inflammatory effects. Transcriptomic changes caused by sulforaphane were highly similar to NFE2L2 overexpression (tau score = +97.87), and SLC7A5 knockdown (tau score = +97.16). The NFE2L2 gene encodes a transcription factor (NRF2) that regulates antioxidant enzymes, and the SLC7A5 gene encodes an amino acid transporter that is often overexpressed in many cancer types.

Conclusion: Glucosinolates, specifically I3C and sulforaphane, demonstrate anticancer properties by inducing cell survival and gene expression changes in several cancer cell lines. In the future, identifying the genes and proteins targeted by I3C, as well as the pathway through which sulforaphane acts, will be crucial to further elucidate the effects of glucosinolates on cancer.

#4340 DM1 pharmacokinetics in combination with tucatinib in patients with HER2+ LA/M breast cancer.

Ariel R. Topletz-Erickson[1], Diqiong Xie[1], Flavia Storelli[1], Julie Meyer[1], Shawna Hengel[1], Wentao Feng[1], Lauren Farr[1], Amit Garg[2]

[1]Pfizer Oncology, Bothell, WA,[2]Pfizer Oncology, San Fransisco, CA

Background: HER2CLIMB-02 (NCT03975647) is a randomized, double-blinded, placebo-controlled, global phase 3 study designed to evaluate the efficacy and safety of tucatinib in combination with T-DM1 (ado-trastuzumab emtansine) in patients with HER2+ locally advanced/metastatic breast cancer (LA/mBC) who received prior treatment with trastuzumab and a taxane in any setting. Tucatinib is a strong cytochrome P450 3A4 (CYP3A4) inhibitor. The T-DM1 unconjugated payload DM1 is primarily metabolized by CYP3A4. Though T-DM1 is contraindicated for concomitant use with strong CYP3A4 inhibitors, no clinical drug-drug interaction studies have been conducted in patients to assess the impact of strong CYP3A4 inhibitors on DM1 PK. Thus, DM1 PK with and without tucatinib was characterized in HER2CLIMB-02.

Methods: Patients in HER2CLIMB-02 were randomized to either tucatinib+T-DM1 or placebo+T-DM1 arms. PK samples were collected on Days 1, 2, 3, and 5 in Cycle 2 (intensive PK substudy) and Day 1 of Cycles 3-6 (all patients). DM1 plasma concentrations were analyzed using validated mass spectrometry methods. DM1 PK parameters following T-DM1 administration, including plasma area under the concentration-time curve up to the last time point (AUC_{last}, Cycle 2 only) and maximal concentrations (C_{max}, end of T-DM1 infusion), were calculated using Phoenix (WinNonlin v8.2). Statistical summaries were produced using SAS version 9.4 or later.

Results: PK data were available for 196 (substudy: n=27) and 206 (substudy: n=20) patients in the tucatinib and placebo arms, respectively. Geometric mean (GM, CV%) Cycle 2 DM1 AUC_{last} values were 4.93 (34%) and 4.37 (23%) day*ng/mL in the tucatinib (n=11) and placebo (n=11) arms, respectively. Cycle 2 GM (CV%) DM1 C_{max} values were 2.38 (26%) and 2.75 (24%) ng/mL in the tucatinib (n=23) and placebo (n=20) arms. Geometric mean ratios for Cycle 2 DM1 AUC_{last} and C_{max} were 1.13 ($CI_{90\%}$ 0.92-1.4) and 0.86 ($CI_{90\%}$ 0.76-0.98), respectively, in the tucatinib versus placebo arms. Likewise, DM1 C_{max} GM values for Cycles 3-6 in all study patients were similar between tucatinib and placebo arms.

Conclusions: DM1 plasma PK was not impacted by tucatinib in patients with HER2+ LA/mBC.

#4341 Association of *HapB3 1129-5923C>G* and *1236G>A* with severe fluoropyrimidine toxicity: A systematic review.

Samantha J. Embley[1], Jaime L. Natoli[2], Pang F. Xiong[3], **Ryan S. Nelson**[1]

[1]ARUP Laboratories, Salt Lake City, UT,[2]SCPMG Department of Clinical Analysis, Kaiser Permanente Southern California, Pasadena, CA,[3]Children's Hospital of Colorado, Aurora, CO

Introduction: The *DPYD HapB3* haplotype includes a decreased-function intronic variant (*1129-5923C>G*) as well as a benign variant (*1236G>A*). Although it was thought that the variants were in complete linkage disequilibrium and testing for only *1236G>A* was an accurate proxy, new evidence suggests otherwise. In addition, evidence suggests that drug-related toxicity associated with *HapB3* may be less likely compared to no-function *DPYD* variants. The primary objective of this study was to evaluate the association between *HapB3* variants and severe fluoropyrimidine toxicity and to compare this to associations for other variants with functional impact.

Methods: We conducted a systematic review (date: Nov 2024) to identify studies that evaluated the association between *DPYD* variants and severe (grade ≥3) toxicity among patients undergoing fluoropyrimidine-based chemotherapy. Direct comparisons were made for each *HapB3* variant (*1129-5923C>G* and/or *1236G>A*) vs wild-type (WT) as well as for other decreased-function (*2846A>T*) and no-function variants (e.g., **2A*) vs WT. Findings were quantitatively combined using Excel to calculate an odds ratio (OR). Indirect comparisons of ORs made across variants using WT as a common comparator.

Results: *HapB3 vs WT:* Each *HapB3* variant was compared to WT data with results summarized in the included table. *Direct Comparison: HapB3* variants were directly compared to other decreased-function or no-function alleles within the same studies with results summarized in the included table. *Indirect Comparison: HapB3* variants were indirectly compared to other decreased-function or no-function alleles from populations outside of *HapB3* studies as summarized in the included table.

Conclusions: *HapB3* variants *1129-5923C>G* and *1236G>A* were not strongly associated with increased toxicity compared to wild-type. Both *HapB3* alleles showed less risk of grade 3 or higher toxicity compared to other decreased-function and no-function variants.

Association of DPYD variants with any fluoropyrimidine-related severe toxicity (grade ≥3)

Comparison Type	Variant	Studies	n	Odds Ratio	95% CI	P Value
Decreased Function vs WT	*1129-5923C>G* (*HapB3* Intronic Variant)	5	4315	1.28	0.99-1.65	0.06
	1236G>A (*HapB3* Benign Variant)	4	991	1.03	0.59-1.78	0.92

#4342 The lymphatic system plays a major role in the absorption of subcutaneously administered trastuzumab in a lymph-duct cannulated rat model.

Junyi Pei[1], Xiaoxuan Fei[1], Luojuan Hu[1], Huimin Zhang[2], Sifei Han[1]

[1]China Pharmaceutical University, Nanjing, China,[2]the First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China

Introduction: The lymphatic system plays a key role in the metastasis of a number of cancers, such as certain types of breast cancer, lung cancer, and colorectal cancer. Drug delivery to the lymphatics may co-localize high concentrations of therapeutic agents and the biological targets (cancer cells or immune cells) in a relatively confined area, thereby providing opportunities for the inhibition of lymphatic metastasis. However, such targeted delivery is usually difficult to achieve since drug molecules mainly circulate via the blood stream instead of the lymphatics. A number of preliminary studies on the pharmacokinetic behaviors of subcutaneously administered biologicals suggested that the lymphatic system served as a main conduit for the absorption of large molecule drugs. The current study aims to examine the absorption pathways (blood vs lymph) after subcutaneous administration of two marketed products of the same anti-HER2 monoclonal antibody drug trastuzumab (Herceptin for IV and Herceptin for SC).

Method: In vivo pharmacokinetic studies were conducted using a rat model with cannulas in thoracic lymph duct, carotid artery and jugular vein. Herceptin IV (intravenous formulation) and Herceptin SC (subcutaneous formulation) were administered to two groups of animals to the footpad at a dose of 2.5 mg/kg trastuzumab (both diluted to a concentration of 21 mg/ml using saline before injection). Lymph fluid from the thoracic duct and blood from the carotid artery were collected, with fluid loss compensated through jugular vein using saline.

Results: More than 70% of the subcutaneously administered dose was recovered in thoracic lymph for both formulations of trastuzumab in rats over 36 hours. Notably, trastuzumab concentration in the lymph of the cannulated group was approximately ten times higher than that in the plasma collected from the same animals. Furthermore, following subcutaneous administration, Herceptin SC formulation demonstrated faster absorption profile compared to the IV formulation, with trastuzumab $C_{max\ in\ lymph}$ 3 times higher (~150 μg/ml for Herceptin SC vs 50 μg/ml for Herceptin IV), and $T_{max\ in\ lymph}$ 1 hour earlier (1h for Herceptin SC vs 2h for Herceptin IV). The faster absorption and higher lymphatic transport are potentially due to the presence of rHuPH20 in the SC product that facilitated disperse of the antibody molecules in the subcutaneous interstitial spaces.

Conclusion: The study confirms the lymphatics is the main absorption pathway following subcutaneous administration of trastuzumab, regardless of the formulation type (IV or SC). This results in markedly high concentrations of trastuzumab in the draining lymphatics, and the co-localization of the drug molecules with potentially disseminated tumor cells and immune cells within the tumor-draining lymphatics may provide an opportunity for enhanced therapeutic outcomes.

#4343 Characterization and comparison of inhibitors of GPR68.

Piotr Stepien[1], Duncan Bellamy[1], Alice E. Berizzi[1], Alex Ceroni[1], Elena Fonfria[1], Major Gooyit[2], Mizuho Horioka[1], Katherine Lansu[1], Sam R. Lawrence[1], Manisha Naik[1], Maninder Panesar[1], Kostantinos Papachristos[1], Martin Redhead[1], Simon Richards[1], David A. Smith-Parkin[1], Jake Swadling[1], Diogo M. R. Tomaz[1], Bojan Vilagos[1], Andrew S. Walker[1], Michael Prime[1], Reid H. J. Olsen[3]

[1]Recursion Pharmaceuticals, Oxford, United Kingdom,[2]Recursion Pharmaceuticals, Chicago, IL,[3]Recursion Pharmaceuticals, Boston, MA

Background: GPR68 is a proton-sensing GPCR reported to play a role promoting tumor aggressiveness and immune-evasion, as well as in inflammatory disease. Most data supporting these findings come from genetic studies, and disclosed small molecule compounds targeting GPR68 are scarce. Nevertheless, two distinct chemical entities have recently been reported as GPR68 inhibitors. They have been used to define *in vitro* mechanisms by which GPR68 may affect disease biology. One of these, FT011, has completed a Phase 2 trial for scleroderma and is described as a GPR68 antagonist, however no pharmacological characterization at GPR68 has been reported to date. A chemical probe, ogremorphin, identified through a chemical genetic screen, is described as a GPR68 antagonist with anti-cancer efficacy *in vitro*.

Methods: Here we describe the identification of three series of novel, drug-like GPR68 antagonists from a screening campaign, which were further optimized via our proprietary generative AI design methods. We present the pharmacological characterization of these series and compare representative examples to FT011 and ogremorphin in primary pharmacology assays and benchmark their activity in fibroblast and glioblastoma (GBM) cell lines.

Results: Three unique chemical series were identified as potent antagonists of GPR68. Detailed characterization using the TRUPATH system suggests that all three scaffolds act as negative allosteric modulators. In comparison, in our hands, FT011 does not inhibit GPR68 activation when evaluated with classical signaling technologies, nor in TRUPATH. Ogremorphin does weakly antagonise GPR68 as reported, with the potency of these effects dependent on the assay technology. All three of our designed GPR68 antagonist series potently inhibit the release of GPR68-stimulated cytokines in a GPR68-expressing cancer associated fibroblast line, as does ogremorphin to a lesser degree. In our hands, FT011 does not antagonise GPR68-mediated cytokine release. We confirm the reported inhibition on GBM lines by ogremorphin, but this effect is absent in our three unique GPR68 antagonist series.

Conclusions: Here we describe multiple highly-potent chemical scaffolds targeting GPR68 as negative allosteric modulators with our data strongly supporting the characterization of our drug-like molecules as first-in-class antagonists of GPR68. In contrast, our profiling of FT011 does not support its purported activity at GPR68. Ogremorphin is confirmed as a weak antagonist of GPR68 which inhibits GBM cell proliferation but it is possible the effect of ogremorphin is due to activity against other targets, or polypharmacology not represented in our GPR68 antagonists. Our first-in-class compounds are currently in development for oncology indications.

#4344 Broader therapeutic window via combining sodium ascorbate for protecting radioactive antibodies from radiolysis and sodium perchlorate for blocking sodium iodide symporter in radioimmunotherapy with astatine-211.

Hiroki Takashima[1], Shino Manabe[2], Ryo Tsumura[1], Yoshikatsu Koga[1], Takahiro Anzai[3], Hiromitsu Haba[4], Anri Inaki[1], Masahiro Yasunaga[1]

[1]National Cancer Center, Kashiwa, Japan,[2]Hoshi University, Shinagawa-ku, Tokyo, Japan,[3]National Institute of Technology (KOSEN), Gunma College, Maebashi, Japan,[4]RIKEN, Wako, Japan

Background: Increasing attention has been paid to developing new cancer treatments with alpha particles characterized by a high linear energy transfer (LET) and a range of 50-100 µm in tissue, which is equivalent to 5-10 cells. Due to the short path length, tumor-selective accumulation of alpha particles is pivotal for achieving a reasonable therapeutic window. Previously, we demonstrated that reactive oxygen species (ROS) generated via the radiolysis of water in storage solution denature antibodies labeled with astatine-211, an alpha emitter, which results in disrupted specific binding activity of astatinated antibodies. On the other hand, free radical scavengers such as sodium ascorbate (SA) can quench ROS and protect radioactive antibodies from astatine-211-induced denaturation. The antibody denaturation significantly attenuates tumor accumulation and the antitumor activity of antibodies labeled with astatine-211, whereas SA protection successfully maintains them. On the other hand, stabilization with SA has no impact on distribution to normal organs, including the uptake in the stomach and thyroid caused by free astatine-211 released from antibodies. Thus, in this study, to reduce the accumulation in these organs, we combined sodium perchlorate (SP), a sodium iodide symporter (NIS) inhibitor, with SA protection and evaluated antitoxic activity. Although it is well known that NIS blockade can reduce halogen radionuclide accumulation in these organs, the antitoxic effect and tolerability in radioimmunotherapy (RIT) with astatine-211 under SA protection remain unclear.

Methods: Mice bearing tumor were pretreated with PBS or 1.2 µmol/g SP and intravenously administered 1 MBq of antibody labeled with astatine-211. We evaluated the impact of the NIS blockade on biodistribution. The accumulation in the thyroid was visualized by single-photon emission computed tomography/computed tomography (SPECT/CT). Toxicity after RIT was evaluated by body weight change and blood tests.

Results: Pretreatment with SP significantly reduced the percentage of injected dose per gram of tissue (%ID/g) for stomach and stomach contents without decreasing tumor accumulation (stomach, $P = 0.020$; stomach contents, $P = 0.013$). SPECT/CT images showed that the pretreatment resulted in lower signals in the thyroid and stomach contents. NIS blockade contributed to significantly more rapid recovery from body weight loss after the injection of astatine-211-labeled antibody ($P = 0.002$). Findings in blood tests were comparable between these groups, showing the tolerability of the combination.

Conclusion: Combining SA protection against radiolysis and NIS blockade with SP is tolerable in RIT with astatine-211, leading to a broader therapeutic window.

#4345 BH3120, a PD-L1x4-1BB bispecific antibody, exhibits favorable safety profiles in distinct in vivo and ex vivo liver toxicity evaluations.

Jing Wang, **Jiangcheng Xu**, Jun Wang, Jiangwang Liu, Kyoungwoo Lee

Beijing Hanmi Pharm. Co. Ltd., Beijing, China

BH3120 is a novel bivalent PD-L1/4-1BB bispecific antibody targeting both inhibitory (PD-1/PD-L1) and co-stimulatory (4-1BB clustering) signaling. In multiple non-clinical safety evaluations, BH3120 consistently showed minimal modulation of T cell functions in the blood or normal tissues resulting in favorable safety profiles. Clinical evaluation of BH3120 as a monotherapy and in combination with a PD-1 inhibitor is underway (NCT06234397).

While early stage clinical evaluations of 4-1BB agonists as a monotherapy or in combination with PD-1/PD-L1 inhibitors are generally associated with certain level of liver abnormalities, the potential biomarkers or patient's backgrounds that can pre-determine the risk of liver toxicity have not been discussed in details. In the meantime, treatment discontinuation or disruption, and administration of corticosteroid due to liver toxicity would be the limitations of 4-1BB agonists in tumor management, and the mode of action and impact of 4-1BB agonists on liver inflammation need to be further investigated. To understand potential risks of liver toxicity with BH3120, sensitive in vivo and ex vivo models for liver toxicity evaluations were established: a mice model with mild liver inflammation induced by Concanavalin A, and human liver organoids co-cultured with immune cells to mimic the histological and physiological changes in patient's liver tissues.

In both models, BH3120 was not associated with significant elevation of liver inflammation markers, indicating minimal risk of liver toxicity that is in line with the safety results we previously reported. The property of BH3120 to minimize systemic immune modulation enables de-coupling of anti-tumor efficacy from systemic toxicities, and would provide flexibility in combination with different anti-tumor treatments.

#4346 Improved pharmacokinetic properties of the purified S-enantiomer of the alkylphospholipid Edelfosine compared to the racemic mixture: Potential orally available novel anticancer agent active against pancreatic cancer.

Michael Ahrweiler, Wolfgang Meyer, Daniel Perrissoud, Axel Zander

RDP Pharma AG, Romanshorn, Switzerland

Edelfosine, an alkylphospholipid anticancer drug, has been extensively investigated, but the racemic mixture used in these studies has not been approved for human commercial use. This drug acts by integrating into lipid rafts in cell membranes, including mitochondria and the ER. The mechanism of action involves CD95-mediated apoptosis, AKT3/PI3K inhibition, phospholipase C and protein kinase C inhibition, as well as interference with cholesterol and phosphatidylcholine metabolism. Edelfosine is preferentially taken up by malignant cells, its efficacy in numerous xenograft studies, including metastatic breast and prostate cancer models, as well as in phase 2 clinical trials has been convincingly demonstrated. In patients, it is generally well-tolerated; the reported main adverse event was dose-dependent, but reversible gastrointestinal toxicity. We purified the S and R enantiomers from the racemic mixture and assessed the pharmacokinetic (PK) and pharmacodynamic (PD) differences between them (R-CP201 and S-CP201) in rodents using a validated LC-MS/MS bioanalytical method. Following a single-dose i.v. administration (20 mg/kg) in male rats (N=5), S-CP201 showed a favorable half-life ($t_{1/2}$ alpha and beta: 1.8 and 8.0 hours) vs R-CP201 (2.1 and 18.2 hours). C_{max} values were similar (~42 µg/mL); but AUC_{last} was higher for S-CP201 (172.6 µg*h/mL vs. 149.3 µg*h/mL for R-CP201). This trend persisted with oral administration (150 mg/kg), where AUC_{last} was 54.2 µg*h/mL for S-CP201 compared to 46.3 µg*h/mL for R-CP201. In another study, single doses of each enantiomer (10 mg/kg orally, 2.5 mg/kg i.v.) were given to male rats (N=8). Systemic exposure, expressed as AUC_{last}, was lower for R-CP201 (i.v.: 43.0 µg*h/mL; oral: 49.4 µg*h/mL) than S-CP201 (i.v.: 50.6 µg*h/mL; oral: 63.7 µg*h/mL). Absolute oral bioavailability (F) was 33.2% for S-CP201 and 29.1% for R-CP201. Daily doses of 10 mg/kg S-CP201 or R-CP201 were given to male rats (N=4) for 5 days. After 5 days, AUC_{last} values were 115.5 µg*h/mL for R-CP201 and 159.0 µg*h/mL for S-CP201, with respective C_{max} values of 1.9 µg/mL and 2.6 µg/mL. A single-dose PK study of Edelfosine (20 and 40 mg/kg orally; 5 mg/kg i.v.) and its enantiomers (10 and 20 mg/kg orally; 2.5 mg/kg i.v.) in male mice showed comparable relative bioavailability for Edelfosine and S-CP201 (~45%), but lower for R-CP201 (~35%). Also, no interconversion between the enantiomers was observed in rat plasma. S-CP201 demonstrated in vitro efficacy across diverse tumor cell lines and showed superior tumor reduction in a PDX pancreatic cancer study in mice (57% vs. 33%). No major toxicity was detected for S-CP201 in rats and mice. These results confirm PK and PD advantages and acceptable tolerability of S-CP201 and support its further development as an anticancer agent is warranted.

#4347 Preclinical evaluation of pharmacokinetic interactions among nebivolol, dasatinib and devimistat in mice.

Airong Li, Mikayla Skillman, Fatima Dagher, Amir Mohammad Gholizadeh, Emanuel Baltrip, Junghwa Park, Meghana Trivedi, Diana S.-L. Chow

University of Houston, College of Pharmacy, Houston, TX

Breast cancer ranks as the most frequently diagnosed cancer in 157 of 185 countries. It accounts for 30% of all new female cancers annually, with triple-negative breast cancer (TNBC) comprising 10-15% of the cases. TNBC is particularly aggressive, with rapid growth and spread, limited treatment options, and a worse prognosis. Due to the lack of markers, TNBC is challenging to treat, and monotherapies are often ineffective; instead, combination therapies with drugs with different mechanisms of action may offer more effective options. In the previous study, G protein-coupled receptor-targeting drugs were evaluated using high throughput screening. Nebivolol (NBV), a third generation β-blocker, was identified as a potential inhibitor against TNBC metastasis. This study investigated the pharmacokinetics (PK) of NBV in combination with dasatinib (DAS), a multi-kinase inhibitor, and devimistat (CPI), a mitochondrial tricarboxylic acid cycle inhibitor, respectively, in FVB healthy mice, focusing on the potential drug-drug interaction (DDI). In this study, FVB mice were randomly assigned to 5 groups (NBV, DAS, CPI, NBV+DAS and NBV+CPI, n=5 each). The compounds were administered via intraperitoneal injection at single doses of NBV at 4 mg/kg, DAS at 10 mg/kg, and CPI at 12 mg/kg, for each group. Blood samples were collected at 20 min, 1 h, 3 h, 6 h, 8 h, and 23 h post dose and quantified using LC-MS/MS assay (Sciex 5500). Data was analyzed using Phoenix (8.5.1) and GraphPad Prism (10). Statistical analysis of PK parameters was performed using ANOVA followed by Tukey post hoc test or t-test, for significance at $p<0.05$. The results indicated, in the NBV and DAS combination group, the half-life of NBV (Mean±SD) significantly increased to 5.32±1.72 hours, from 3.11±0.27 hours in NBV alone group, likely due to a higher distribution volume (V) and lower clearance (CL), which were not statistically significant due to large variations. The area under curve (AUC) remained comparable in combination treatment. The PK of DAS was unaffected by NBV. In the combination of NBV and CPI, the PK parameters of NBV were unaffected, whereas the CL of CPI significantly decreased in the combination group (70.29±30.32 L/h), from that in CPI alone group (142.32±49.35 L/h). CPI distribution volume decreased (124.51±90.18 L) in the combination group versus 1107.11±1379.40 L in the alone group. However, this change in V was not statistically significant due to a large variation. The AUC of CPI significantly increased to 201.72±92.25 h*ng/mL, compared to 87.62±22.21 h*ng/mL in CPI alone group. In summary, DDIs were observed among NBV, DAS, and CPI. Co-administration with DAS slowed the NBV elimination, suggesting that NBV accumulation would be considered when used alongside DAS. Additionally, CPI exposure significantly increased in the presence of NBV, indicating that dose adjustments may be necessary in combination therapies.

#4348 A translational pharmacokinetic-pharmacodynamic (PKPD) modeling framework of novel, highly selective, next-generation allosteric cyclin-dependent kinase 2 (CDK2) inhibitors.

Andrea Gruber[1], Sven Christian[2], Carsten Schmeck[3], Antje Rottmann[1], Hongyu Xue[2], Marine Garrido[4], Mariya Pavlyuk[4], Bart Ploeger[1], Peter N. Morcos[5]

[1]Bayer AG, Berlin, Germany,[2]Bayer AG, Cambridge, MA,[3]Bayer AG, Wuppertal, Germany,[4]Bayer AG, Basel, Switzerland,[5]Bayer AG, Whippany, NJ

Background: CDK2 plays a crucial role in regulating multiple oncogenic signaling pathways, and its activity is essential for the loss of growth control during cancer development. The amplification and overexpression of the CDK2 binding partner Cyclin E1 (CCNE1) is a key mechanism in various cancers. Selective CDK2/CCNE1 inhibition therefore offers a promising treatment for patients with CCNE1 overexpressing tumors. CDK2/CCNE1 inhibition has been shown to reduce phosphorylation of the retinoblastoma protein (pRB), a direct downstream target, which is associated with decreased tumor growth in preclinical *in vitro* and *in vivo* models. Reduced levels of pRB have also been observed in patients treated with CDK2 inhibitors. We have developed a pharmacokinetic-pharmacodynamic (PKPD) model for CDK2 inhibitors and examine the relationship between dose, exposure, pRB and tumor growth, using published and in-house *in vitro* and *in vivo* data from several compounds, to support preclinical and clinical phases.

Methods: Our PKPD model framework consists of *in vitro* and *in vivo* components. The *in vitro* model evaluates the relationship between compound concentrations and pRB levels as well as cell proliferation in CCNE1-overexpressing cell lines for multiple CDK2 inhibitors. The *in vivo* model describes compound exposure in plasma and tumor and the modulation of pRB, which is associated with changes in tumor growth. Model building and validation was informed by published literature on CDK2 inhibitors, *in vitro* data showing modulation of pRB and proliferation, and *in vivo* mouse data in CCNE1-overexpressing OVCAR3 xenografts, including plasma and tumor exposure, pRB measurements, and tumor growth inhibition data for different CDK2 inhibitors and dose levels. The model was developed using the MonolixSuite (Lixoft) software.

Results: For the investigated CDK2 inhibitors a direct nonlinear model quantitatively characterizes the association of compound exposure and pRB levels, allowing the derivation of an IC50 from *in vitro* data for use in the *in vivo* model. The *in vivo* model describes plasma PK by a two-compartment model and tumor PK by an additional tumor compartment. The modulation of pRB levels by compound concentration in the tumor is described using an indirect response model and the *in vitro* derived IC50. Further, the reduction of pRB is linked to tumor growth inhibition using a Simeoni model. Diagnostic plots and model parameter estimates show that the *in vitro* and *in vivo* models well capture the complete data of the investigated CDK2 inhibitors, increasing confidence in the established model and applied hypotheses.

Conclusion: We have established a translational PKPD modelling framework to support preclinical candidate selection, which will be evaluated in the clinical development of novel, next-generation CDK2 inhibitors.

#4349 Translational pharmacokinetic/pharmacodynamic (PK/PD) modeling for VVD-130037, a novel, first-in-class covalent small molecule Kelch-like ECH-associated protein 1 (KEAP1) activator.

Conrad Housand[1], Nil Roy[1], Tine Wyseure[1], Christie Eissler[1], Hauke Ruehs[2], Christoph Niederalt[2], Carsten Zieschang[3], Marielena Mata[1], Ramin Samadani[1], John Bothos[1], Lawrence Lu[1], Jenna Goldberg[1], **Peter N. Morcos**[4]

[1]Vividion Therapeutics, San Diego, CA,[2]Bayer AG, Wuppertal, Germany,[3]Bayer AG, Berlin, Germany,[4]Bayer AG, Whippany, NJ

Introduction: The KEAP1-nuclear factor erythroid 2 (NRF2) pathway provides homeostatic mechanisms for oxidative stress response which can be activated in cancers. Vividion Therapeutics has developed novel allosteric molecular glues of the Keap1-CUL3 E3-ligase complex. Preclinically, these agents covalently target KEAP1-CUL3 E3 ligase and allosterically increase the affinity between KEAP1 and CUL3, promoting the formation of active KEAP1-CUL3 E3 ligase complexes and enhancing NRF2 degradation (*Mol Cancer Ther* (2023) 22 (12_Suppl): PR011). We established a translational PK/PD model for KEAP1 target engagement (TE) for the clinical candidate, VVD-130037.

Methods: VVD-130037 PK/PD modeling leveraged an initially developed framework (*Mol Cancer Ther* (2023) 22 (12_Suppl): C126). Compartmental PK models are used to describe VVD-130037 plasma and tumor exposure and are coupled to a mechanistic TE model capturing intracellular covalent binding to KEAP1 and KEAP1/NRF2 synthesis, degradation and complex formation. The PK models were parameterized using mouse experiments; the predicted tumor concentration provided the input to the TE model. Predictive accuracy of the TE model was made by comparison to experimental TE. A physiologically-based PK (PBPK) model incorporating human physiology was linked to the TE model for human PK-TE predictions.

Results: The PK model captures mouse plasma and tumor PK across dose levels. Similarly, the mechanistic TE model adequately predicts in vitro and in vivo TE profiles at various drug concentrations. Sensitivity analyses reveal KEAP1 turnover as a key parameter influencing VVD-130037 TE. Biologically plausible ranges facilitate predictions of efficacious dose regimens to saturate TE. The VVD-130037 human PBPK model predicted a rapid plasma half-life, however when coupled with the TE model predict sustained peripheral and tumor TE with once and twice daily dosing regimens.

Conclusions: A translational PK/PD model is developed for VVD-130037; supporting efficacious doses during clinical development.

#4350 Pharmacodynamic biomarker modulation by OMX-0407, a novel, spectrum-selective kinase inhibitor for the treatment of angiosarcoma and renal cell carcinoma.

Marisa Stebegg-Wagner[1], **Ilona Petra Maser**[1], Bettina Bauer[1], Andreas Schirmer[1], Moritz Zulley[1], Carmen Amerhauser[1], Thorsten Meyer[2], Tiantom Jarutat[1], Hannes Loferer[1], Stefan Bissinger[1]

[1]iOmx Therapeutics AG, Martinsried/Munich, Germany,[2]Granzer Regulatory Consulting & Services GmbH, Munich, Germany

Background: OMX-0407 is an orally available spectrum-selective kinase inhibitor targeting a set of oncology-relevant tyrosine kinases (TK) as well as the salt-inducible kinase (SIK) family, demonstrating a dual mode of action (MoA) in cancer. This involves OMX-0407-induced cell cycle arrest in tumor cells by de-phosphorylation and inactivation of TKs such as Src family kinases (SFK) and the SIK family, and increased sensitivity of the tumor microenvironment to immune-mediated tumor cell killing. OMX-0407 is currently undergoing early clinical testing for the treatment of angiosarcoma (AS) and clear cell renal cell carcinoma (ccRCC) (NCT05826600).

Methods: Kinase activity profiling using the PamChip® kinase array was used to quantify OMX-0407 treatment effects. Moreover, a flow-cytometry-based “phosFlow” assay was developed to assess the phosphorylation status of SFKs. Both assays revealed dose-dependent inhibition of SFK phosphorylation and activity in peripheral blood mononuclear cells (PBMCs). Hence, they were implemented as pharmacodynamic biomarkers in the ongoing first-in-human trial (NCT05826600) of OMX-0407 in patients with previously treated unresectable solid tumors.

Results: As of 30th of October 2024, 24 patients have received continuous treatment with OMX-0407 administered orally in 28-day cycles in a dose escalation study at dose levels of 10, 30, 60, 90, 100, and 140 mg twice daily (BID). Treatment was well tolerated with the main safety finding being gastro-intestinal adverse reactions. One patient with secondary radiation-induced angiosarcoma achieved a complete response at doses of up to 60 mg BID, which remains ongoing at 14 months.

PhosFlow analysis confirmed OMX-0407 effects on the phosphorylation of SFKs in PBMCs at doses of 60mg and above. This was associated with the inhibition of oncology-relevant TKs as determined by functional kinase activity profiling. Treatment effects were significantly correlated with PK exposure. This confirms that both phosFlow and kinase activity profiling successfully resolve dose-dependent OMX-0407 activity in peripheral patient blood as pharmacodynamic biomarkers.

These findings, together with safety findings and PK profiling, contributed to the selection of 100mg BID as the recommended phase 2 dose (RP2D) for the dose expansion.

Conclusions & Outlook: OMX-0407 is a promising therapeutic candidate for the treatment of angiosarcoma and RCC with a potential dual MoA combining direct anti-tumor effects with modulation of the immune cell compartment towards a pro-inflammatory state. In September 2024, Ph1b expansion cohorts of the first-in-human trial (NCT05826600) were initiated for patients with unresectable/metastatic AS or ccRCC who have received at least one prior line of therapy, evaluating OMX-0407 at a dose of 100mg BID.

#4351 Clinical indenoisoquinolines strongly inhibit the global *MYC* transcriptional pathway.

Yichen Han[1], Sheng Liu[2], Mark Cushman[1], Jun Wan[2], Danzhou Yang[3]

[1]Borch Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN,[2]Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN,[3]Borch Department of MCMP, PICR, PIDD, Department of Chemistry, Purdue University, West Lafayette, IN

MYC, one of the most validated driver cancer oncogenes, is overexpressed in a majority of human cancers. However, the MYC protein is intrinsically disordered and considered “undruggable”. The *MYC* gene promoter forms G-quadruplex, a globular non-B DNA secondary structure. *MYC* G-quadruplex (MycG4) is a transcription repressor that silences *MYC* expression upon stabilization by small molecules. Targeting MycG4 for transcriptional inhibition is a promising approach for cancer therapeutics. Indenoisoquinolines were designed as topoisomerase I inhibitors with better physicochemical and biological properties than the clinical camptothecin drugs, with three compounds in phase I/II clinical trials. Recently, we found that indenoisoquinolines can bind and stabilize MycG4 and downregulate *MYC* expression in cancer cells, which significantly correlates with anticancer activities. Herein, we investigate the effects of the three clinical indenoisoquinolines on MYC downregulation and MYC gene pathways, with comparison to other well-known G4-ligands and the topoisomerase I inhibitor camptothecin (CPT). The clinical indenoisoquinolines strongly bind and stabilize MycG4, whereas CPT shows little binding and stabilization. We assessed global changes in gene expression by RNA sequencing in the MYC-dependent B-lymphoma Raji cells. We treated the tumor cells with the three clinical indenoisoquinolines (LMPs), other G4-ligands, and CPT, at subtoxic doses across various timepoints. Our enrichment analysis on gene ontology and pathway identified the primary cellular responses and pathways altered with MYC expression modulation. We also evaluated the treatment-induced effects on all hallmark biological pathways from the Molecular Signature Database using Gene Set Enrichment Analysis. The RNA-seq results indicate that the MYC pathway is the major cellular response of the clinical LMP compounds. We further examined the treatment-induced suppression of MYC-regulated genes and observed significant and durable inhibition of MYC-regulated gene pathways. Notably, we found that the clinical LMPs, especially LMP400, exhibited significantly stronger MYC suppression compared to other G4-ligands. We speculate that dual MYC-targeting and topoisomerase I inhibition is critical to the exceptional MYC inhibition and anticancer efficacy of indenoisoquinolines. In conclusion, we demonstrate that the clinical indenoisoquinolines effectively and persistently inhibit the global MYC transcriptional pathway, serving as a major mechanism of action. Because MYC is a common and essential oncogene, our study provides critical mechanistic understanding and a molecular basis for the future clinical developments and therapeutic applications of indenoisoquinolines in MYC-dependent cancers.

#4352 Safety and pharmacokinetics of tinengotinib monotherapy in different doses and dosing schedules in advanced solid tumors.

Sarina A. Piha-Paul[1], Sanjay Goel[2], Chih-Yi Liao[3], Nashat Y. Gabrail[4], Farshid Dayyani[5], Syed Kazmi[6], Sayeh Lavasani[7], Shumao Ni[8], Caixia Sun[8], Katie Hennessy[9], Hui Wang[8], Peng Peng[8], Jean Fan[9], Milind Javle[1]

[1]University of Texas MD Anderson Cancer Center, Houston, TX,[2]Rutgers Cancer Center Institute of New Jersey, New Brunswick, NJ,[3]The University of Chicago Medicine and Biological Sciences, Chicago, IL,[4]Gabrail Cancer Center Research, Canton, OH,[5]University of California, Irvine, Irvine, CA,[6]University of Texas Southwestern, Dallas, TX,[7]City of Hope National Medical Center, Duarte, CA,[8]TransThera Sciences (Nanjing), Inc., Nanjing, China,[9]TransThera Sciences (US), Inc., Gaithersburg, MD

Background: Tinengotinib is a novel multi-kinase inhibitor that targets cell proliferation, angiogenesis, and immune-oncology pathways by inhibiting Aurora kinases A/B, Janus kinases (JAK) and receptor tyrosine kinases (FGFRs and VEGFRs). Here we present the safety and pharmacokinetics (PK) of tinengotinib monotherapy in different doses and dosing schedules from a multicenter, open label phase Ib/II study in patients (pts) with advanced solid tumors.

Methods: Eligible pts received tinengotinib monotherapy in Arm A (12 mg once daily (QD)) and Arm C with QD doses of 5, 8, 10 and 12 mg, and twice daily (BID) doses of 4 mg and 6 mg every 28-day/cycle. Safety was assessed based on CTCAE v5.0. PK samples (plasma) were analyzed by liquid chromatography-tandem mass spectrometry. Preliminary efficacy including Objective Response Rate (ORR) was evaluated per RECIST 1.1.

Results: 197 pts were enrolled and received tinengotinib monotherapy at the following doses and schedules: 4mg BID (n=18), 6mg BID (n=18), 5mg QD (n=14), 8mg QD (n=18), 10mg QD (n=21), and 12mg QD (n=108). Treatment-related Adverse Events (TRAE) were reported in

81.7% (161/197) pts: 46.2% were Grade (G) 3-4, 0% G5. The most common G3-4 TRAE (>10%) was hypertension. Increased G3-4 TRAE rates were seen at higher dose exposures, but no significant differences were noted between the BID and QD schedules. The maximum concentration (T_{max}) was reached at ~2-4 hr. The terminal elimination half-life ($t_{1/2}$) was similar across all QD dose groups in the PK-run-in of Arm C, at ~26-34hr. The apparent volume of distribution (Vz/F) is much larger than 100L. Steady state was reached at C1D15, with mean accumulation ratios of approximately 2-5. Exposure of tinengotinib increased with increasing dose up to 10mg QD, reaching potential saturation of absorption between 10mg and 12mg QD. No notable difference in AUC was observed in QD vs. BID schedules. Sensitivity analyses were like those of the main analysis. Among 159 efficacy evaluable subjects (n=15 in 4 mg BID; n=18 in 6 mg BID; n=10 in 5 mg QD; n=13 in 8 mg QD; n=19 in 10 mg QD; n=84 in 12 mg QD), the best overall response was 13.2% (21/159) including PRs in 2 (11.1%) pts in 6 mg BID, 1(10.0%) in 5 mg QD, 4 (21.1%) in 10 mg QD, and 13 (15.5%) in 12 mg QD. 1 CR was achieved in 12 mg QD. The dose level demonstrating superior efficacy was 10mg QD, with an ORR of 21.1%.

Conclusions: There were no discernable trends in safety or PK between the BID and QD dose schedules. Although there was an increase in TRAEs with overall dose increase, the 10mg QD dose was shown to have an optimal PK profile and demonstrated superior efficacy as compared to the other dose levels. These results suggest that the combination of known PK and safety predictability with promising efficacy provides a basis of dose selection for further clinical development of tinengotinib.

Clinical trial Information: NCT04742959

#4353 A phase I open-label positron-emission tomography study to determine brain exposure of [^{11}C]savolitinib in healthy volunteers.

Kowser Miah[1], Zsolt Cselenyi[2], Jonas Svensson[3], Aurelija Jucaite[2], Ike Igwegbe[4], Caitlin Muldoon[5], Miriam Zanuy Porquet[6], Kenneth Dahl[2], Peter Johnstrom[2], Miguel A. Cortes Gonzalez[3], Antonia Hognasbacka[3], Andrea Varrone[3], Karthick Vishwanathan[1], Magnus Schou[2]

[1]Clinical Pharmacology and Quantitative Pharmacology, CPSS, AstraZeneca, Waltham, MA,[2]PET Imaging Centre, AstraZeneca, Stockholm, Sweden,[3]Department of Clinical Neuroscience, Centre for Psychiatry Research, Karolinska Institutet and Stockholm County Council, Stockholm, Sweden,[4]Global Clinical Program, AstraZeneca, Gaithersburg, MD,[5]Late Oncology Statistics, AstraZeneca, Cambridge, United Kingdom,[6]Patient Safety Oncology, AstraZeneca, Barcelona, Spain

Introduction: Savolitinib is a potent, oral highly selective small molecule MET kinase inhibitor and is capable of inhibiting tumor growth *in vivo* when used as a monotherapy or in combination therapy for multiple indications harboring MET aberrations (MET amplification or MET overexpression). The use of savolitinib in combination with osimertinib is currently being evaluated in NSCLC patients with EGFR mutations and MET amplification. Patients with EGFR mutations appear to have a higher incidence (50-60%) of brain metastasis[1]. Preclinical data suggest that savolitinib penetrates the blood-brain barrier (BBB) which is important to prevent or treat brain metastasis. This study was conducted to determine brain distribution and exposure of a microdose of carbon-11 labelled savolitinib using positron emission tomography (PET), in healthy adult volunteers under physiological conditions (i.e. when the BBB is intact).

Methods: This was an open-label, non-randomised, single-center study. The study was comprised of two site visits and follow-up call. The first visit included screening, the second visit involved two PET examinations. For the first PET examination (PET1), a single microdose (≤10 µg) of [^{11}C]savolitinib was administered. The second PET examination (PET2) using [^{11}C]savolitinib took place the same day, approximately 2 hours after the administration of a single oral 300 mg dose of savolitinib. Radioactivity in brain and arterial blood were measured. Kinetic PET parameters describing brain distribution and exposure were quantified: percent injected dose entering the brain, $\%ID_{max_brain}$; time to maximum concentration in brain, T_{max}; free brain to free plasma partition coefficient $K_{p,\,uu}$.

Results: Seven participants, 2 males, 5 females, 51-64 years of age were examined. [^{11}C]savolitinib entered the brain at a mean 0.80 $\%ID_{max_brain}$ (range: 0.65% to 0.93%, n = 7) and uniformly distributed in all brain regions. When the participants were pre-treated with a 300 mg oral dose of savolitinib the $\%ID_{max_brain}$ values were found to be similar (mean: 0.81 $\%ID_{max_brain}$, range: 0.69% to 0.99%, n = 6). The median T_{max_brain} values at PET1 and PET2 examination were 1.45 minutes (range: 0.22 to 10.95 minutes) and 1.72 minutes (range: 0.17 to 11.03 minutes) and the mean±SD for $K_{p,\,uu}$ was 0.29±0.08 (range: 0.21 to 0.46) and 0.35 ± 0.04 (range: 0.30 to 0.41), respectively.

Conclusion: PET brain imaging in healthy volunteers showed that savolitinib penetrates the BBB and distributes to the brain following IV injection of a microdose of [^{11}C]savolitinib. #4354 Safety and tolerability of NPX372, a novel B7-H7:CD3 bispecific T cell engaging antibody.

Silvia Ferrati, Matthew Rausch, Katalin Kis-Toth, Bijan A. Etemad-Gilbertson, Leena Gandhi, Tatiana Novobrantseva

NextPoint Therapeutics, Cambridge, MA

BACKGROUND: B7-H7 is a B7 family member upregulated on tumor cells of many histologic subtypes with a very restricted normal tissue expression and is, therefore, being explored as a novel tumor targeting antigen. NextPoint Therapeutics has developed a T cell engager bispecific antibody, NXP372, which simultaneously recognizes B7-H7 and CD3 from both human and non-human primates, providing T cell activation in the proximity of B7-H7. NPX372 induced T cell activation and T cell-mediated killing of B7-H7^{+} tumor cells *in vitro* and B7-H7 levels correlated with cytotoxic potency. In addition, NPX372 induced cytokine production in primary T cell cultures with B7-H7+ tumor cells. Finally, NPX372 demonstrated dose-dependent anti-tumor activity in a B7-H7+ tumor model in vivo at clinically relevant doses (1).
METHODS: Affinity to human and monkey B7-H7 and CD3 was evaluated by cell binding using flow cytometry and an Octet binding assay, respectively. Immunohistochemistry was used to evaluate human and monkey B7-H7 tissue expression. To evaluate the tolerability of NPX372, we performed a dose escalation toxicokinetic study in cynomolgus monkeys. Animals were evaluated for 4 weeks after a single or step-up intravenous dose(s) of NPX372. Clinical observations, hematology, chemistry, cytokine, immunophenotyping, and PK samples were collected. At completion, pathology evaluation of selected tissues was performed.
RESULTS: Expression of B7-H7 is predominant in the luminal epithelium of the gastrointestinal tract (GI) in both monkey and human. NPX372 affinity to NHP and human B7-H7 is similar as measured by on-cell binding. Octet binding confirmed cross-reactivity to NHP CD3. NPX372 was well tolerated up to 100 µg/kg after single IV dose and up to 300ug/kg in a step-up dosing. On-target GI toxicity was observed at the highest dose of 1000 µg/kg, lasting ~5 days. Pathological assessment of small and large intestinal epithelium was normal at time of scheduled evaluation 28 days after dosing, supporting reversibility of the adverse effects. Clinical chemistry, coagulation, and hematology lab parameters were normal, with minor increases in C-reactive protein in one animal each treated at 300 and 1000 µg/kg. No evidence of cytokine release syndrome was observed, although small increases in G-CSF, IL-1RA, IL-8, MCP-1 and MIP-1β cytokines were noted. One animal dosed at 1000 µg/kg showed a transient increase in IFNγ. Immunophenotyping data showed dose-proportional activation of T cells (by upregulation of CD25). PK exposure was also dose-proportional.
CONCLUSION: These data demonstrate on-target activity of NXP372 in monkeys, with doses tolerated up to 1000 µg/Kg, which covers a dose range that is effective in preclinical models. The totality of the data suggests that NXP372 may be a safe and effective drug to further develop toward human clinical studies. References 1) Rausch et al. Abstract SITC 2024

#4355 Investigating the role of CXCR6 signaling in sorafenib resistance in HCC.

Morgan Reeves, Satyamaheshwar Peddibhotla, Siobhan Malany

Department of Pharmacodynamics, University of Florida, Gainesville, FL

Introduction: Hepatocellular carcinoma (HCC), one of the most common liver cancers and a leading cause of cancer-related deaths globally, is often diagnosed at late stages limited to systemic treatment. Sorafenib, an FDA-approved first in line treatment, efficacy is hindered due to innate or developed resistance in patients. Hyperactivation of CXCR6/CXCL16 signaling has been detected and shown to contribute to a proinflammatory and pro-survival tumor microenvironment driving drug resistance in HCC. Wnt/β-catenin signaling pathway is dysregulated in 50% of HCC and has shown to be involved in sorafenib resistance due to accumulation of its core component, β-catenin. Our hypothesis posits that CXCR6 antagonism will restore potency of sorafenib in HCC cell lines via inhibition of β-catenin-mediated signaling.
Experimental Procedure: Basal sorafenib sensitivity assessed via MTT assay, and β-catenin and CXCR6 protein expression via western blot were compared across five HCC cell lines. An orally bioavailable small molecule antagonist, SBI-457, was used to probe CXCR6 signaling. We evaluated sorafenib-, SBI-457- and combination-induced modulation of β-catenin expression via western blot and IF imaging in SKHep1. CXCL16- and SBI-457-induced modulation of pCREB protein expression post forskolin activation in both SKHep1 and CXCR6-overexpressed CHOK1 cells were compared. Secretion of soluble CXCL16 was measured via ELISA in SKHep1 cells.
Results: Sorafenib dose-dependently increased β-catenin protein expression via immunofluorescence imaging and whole cell lysates of SKHep1 cells. SBI-457 in combination showed trends towards attenuating sorafenib-induced increases, yet lacked significance. We demonstrate that high CXCR6 protein expression levels match sorafenib growth inhibitory (GI50) values across all five HCC cells tested. 200ng/ml CXCL16 significantly attenuated forskolin-induced increase in pCREB expression and SBI-457 dose-dependently restored in a CXCR6 overexpressed CHOK1 cell line. However, both CXCL16 and SBI-457 were unable to clearly modulate forskolin-induced pCREB in CXCR6 endogenously expressed HCC cell lines. SKHep1 cells significantly cleave increasing levels of soluble CXCL16 as measured up to 24h, of which was blocked by ADAM 10 and 17 inhibition.
Conclusion: Sorafenib treatment increased total β-catenin levels in SKHep1 cells. Though we show clear CXCR6-mediated signaling in an overexpressed cell line, it is inconsistent in HCC cells, despite CXCR6 expression. SKHep1 cells secrete significantly increasing CXCL16 and this was attenuated by combined inhibition of ADAM10and17. This data suggests SKHep1 cleave soluble CXCL16 from its transmembrane form and potentially alter traditional forward signaling. Future studies aim to evaluate tmCXCL16 expression levels across HCC cells and evaluate the role this plays in CXCR6-mediated signaling via our small molecule inhibitor to further understand the therapeutic potential of CXCR6 inhibition in HCC.

#4356 OBI-902, a novel TROP2 targeted antibody-drug conjugate via GlycOBI® platform, has favorable pharmacokinetics and sustained antitumor activities in challenging solid tumors.

Ren-Yu Hsu, Chi-Huan Lu, Chi-Sheng Shia, Hsin-Shan Wu, Lu-Tzu Chen, Jhih-Jie Yang, Jyy-Shiuan Tu, Hui-Wen Chang, Shih-Ni Wen, Ming-Tain Lai, Ya-Chi Chen

OBI Pharma, Inc., Taipei, Taiwan

Trophoblast cell surface antigen 2 (TROP2) is overexpressed in a variety of solid tumors, including non-small cell lung cancer (NSCLC), pancreatic cancer (PC), gastric cancer (GC), and colorectal cancer (CRC), where high expression levels of TROP2 correlate with poor prognosis. OBI-902 is a novel site-specific antibody-drug conjugate (ADC) consisting of a humanized anti-TROP2 monoclonal antibody linked to a topoisomerase I (TOP1) inhibitor payload with drug-to-antibody ratio of 4 via OBI's proprietary glycan conjugation platform (GlycOBI®) and dual-action enzymatic technology (EndoSymeOBI®). This unique linker-payload design is expected to enhance the ADC stability and improve the efficiency of payload delivery in tumors. This study aimed to evaluate the therapeutic potential of OBI-902 in challenging solid tumors. *In vitro* linker-payload stability was evaluated in human serum albumin via LC-MS. Pharmacokinetics (PK) was assessed in the serum and tumor of NSCLC xenograft mouse model. The antitumor activity studies of OBI-902 were conducted in NSCLC, PC, GC, and challenging CRC xenograft mouse models with Dato-DXd, SG, or MK-2870 as benchmarks. The antitumor activities were evaluated in both tumor volumes of 200-250 mm^3 and 500-550 mm^3 (large tumor burden). Survival was analyzed with the log-rank (Mantel-Cox) test with *$p<0.05$, **$p<0.01$. Humane endpoint: Tumor volume was larger than 1500 mm^3. OBI-902 showed superior in vitro linker-payload stability than the Dato-DXd. In addition, OBI-902 exhibited favorable PK profiles with excellent ADC stability in circulation and efficient payload release in NSCLC xenograft model. The tumor-to-serum ratios of payload C_{max} and AUC_{0-t} were 33 and 86, respectively. OBI-902 achieved 4.2-fold higher intra-tumor payload exposure than that of MK-2870 at the same dosage. OBI-902 exhibited potent and durable antitumor activities. In the GC xenograft model, tumor volume reductions of OBI-902 were 3.6- to 6.2-fold better compared to benchmarks, by day 57. In the challenging CRC model, OBI-902 showed a sustained suppression of tumor growth by day 56 (329 ± 110 mm^3) compared to benchmark ADCs which reached over 1000 mm^3 before day 18. In the large-tumor NSCLC xenograft model, OBI-902 achieved superior antitumor activity, with 40% of treated mice surviving beyond day 70. In contrast, all mice treated with benchmarks were sacrificed early (tumor volume >1500 mm) at days between 29 and 42. Similarly, in the large-tumor PC xenograft model, OBI-902 prolonged survival beyond day 50, while all mice in the benchmark groups were sacrificed by day 28. OBI-902 can efficiently deliver payload to the site of action (tumor) to achieve desirable drug exposure and sustainable antitumor activities in various challenging solid tumors, pointing to its potential to be the best-in-class TROP2 ADC.

#4357 Disparities in neurotoxicities in cisplatin-treated cancer patients: a population pharmacogenomics approach.

Swetha Nakshatri[1], Paul C. Dinh[2], Darren R. Feldman[3], Robert J. Hamilton[4], David J. Vaughn[5], Chunkit Fung[6], Christian Kollmannsberger[7], Robert Huddart[8], Lawrence H. Einhorn[2], Nancy J. Cox[9], Lois B. Travis[2], M. Eileen Dolan[10]

[1]University of Chicago, Chicago, IL,[2]Indiana University School of Medicine, Indianapolis, IN,[3]Memorial Sloan Kettering Cancer Center, New York, NY,[4]Princess Margaret Cancer Centre, Toronto, ON, Canada,[5]Department of Medicine, University of Pennsylvania, Philadelphia, PA,[6]University of Rochester Medical Center, Rochester, NY,[7]BC Cancer - Vancouver Cancer Centre, Vancouver, BC, Canada,[8]Institute of Cancer Research and Royal Marsden NHS Foundation Trust, London & Sutton, United Kingdom,[9]Vanderbilt University Medical Center, Nashville, TN,[10]Department of Medicine, University of Chicago, Chicago, IL

Background: Disparities in peripheral sensory neuropathy (PSN) have been studied in taxane-treated breast cancer and vincristine-treated leukemia survivors, but not addressed in cisplatin. Both platinum compounds and environmental heavy metals are associated with vascular toxicity, and there is genetic variation in single nucleotide polymorphisms (SNPs) associated with metal burden, which may be due to adaptation to exposures across geographies. We hypothesize that disparities may exist in cisplatin-induced neurotoxicities related to differences in population allele frequency and variants' impact on gene expression.
Methods: In a study of 1663 genotyped testicular cancer survivors, logistic regression between multidimensional scaling-calculated geographic ancestry and neurotoxicities (400-450 mg/m^2 cisplatin) and clinical/lifestyle factors was assessed. SNPs with Fst > 0.25 in 1000 Genomes were filtered using GTEx and LDmatrix to find independent expression/splicing trait loci (eQTL/sQTL) in nerve/brain tissue or cisplatin-associated genes. Logistic regression was conducted between genotype and toxicity with age and 10 genetic principal components as covariates. Spearman correlation between gene expression (DepMap) and cisplatin sensitivity (GDSC) in cell lines was calculated for genes of interest from association analysis.
Results: Survivors of African (AFR) ancestry had significantly higher PSN incidence versus European (EUR) ($p=0.049$) and Asian (ASN)-axis ($p=0.034$) ancestry and higher vertigo incidence versus EUR ($p=5.2\times10^{-3}$) and ASN-axis ancestry ($p=0.04$), with significant differences in self-reported health. Clinical factors did not show disparities, although ASN-axis survivors were significantly less likely to be on antihypertensives. 19,992 SNPs passed filtering. While genotype-toxicity associations did not hit Bonferroni threshold, six SNPs had suggestively significant $p<1.0\times10^{-4}$. One SNP had increased frequency of the risk allele in the AFR population for PSN and four SNPs for vertigo. rs34904346 ($p=2\times10^{-5}$) was a RNF24 eQTL in the nerve, with 3 other RNF24 eQTLs also associated with PSN ($p<0.05$). For vertigo, rs3777909 ($p=3.1\times10^{-5}$) was an eQTL for MFSD4B in the nerve and REV3L in the brain, with other independent eQTLs associated with vertigo ($p<0.05$) and MFSD4B (3) and REV3L (4). For vertigo, rs56819906 ($p=7.6\times10^{-5}$) and rs73626678 ($p=1.8\times10^{-4}$) were DDX25 eQTLs in the nerve. MFSD4B ($p=0.0058$) and REV3L ($p=5.1\times10^{-5}$) expression in cancer cell lines were significantly correlated with cisplatin sensitivity, matching direction of effect in toxicity association analyses.
Conclusions: We show evidence for the contribution of differential risk allele frequencies to disparities in cisplatin-induced PSN and vertigo. If results are confirmed, genotyping risk alleles to identify at-risk patients may benefit cisplatin-treated populations.

#4358 Single nucleotide polymorphisms located in PK/PD pathway genes of standard AML chemotherapy regimen predicts outcome in pediatric AML.

Aneesha Nath[1], Richard Marrero[1], Xueyuan Cao[2], Jeffrey E. Rubnitz[3], Stanley Pounds[4], Jatinder K. Lamba[1]

[1]Pharmacotherapy and Translational Research, University of Florida, Gainesville, FL,[2]Health Science Center, University of Tennessee, Memphis, TN,[3]Department of Oncology, St. Jude Children's Research Hospital, Memphis, TN,[4]Department of Biostastics, St. Jude Children's Research Hospital, Memphis, TN

Acute Myeloid Leukemia (AML) is an aggressive hematologic cancer with poor treatment outcomes in pediatric patients, particularly due to high relapse rates and drug resistance. Standard treatment involves cytarabine (Ara-C), daunorubicin, and etoposide (ADE) but resistance to these drugs remains a significant challenge. To better understand the genetic factors influencing drug resistance and treatment outcomes, we conducted a pharmacogenomic analysis of genetic variants in AML-related and drug-metabolizing genes within the context of (ADE) chemotherapy regimen. We extracted SNPs in genes involved in pharmacological pathways of ADE as well as genes representative of myeloid panel from an existing set of genome-wide Illumina 2.5 Omni microarray data obtained from genomic DNA of 400 patients treated on multi-site AML02 [NCT00136084, n=167] and AML08 [NCT00703820, n=233] clinical trials. SNPs within +/-10 kb region of the gene locus were evaluated for associations with multiple clinical endpoints such as minimal residual disease after induction 1 (MRD1), event-free survival (EFS), and overall survival (OS), adjusting for genetic ancestry. Our analysis results showed that at a p value of <0.01,215 SNPs in 52 genes were predictive of at least one of the outcomes. SNPs in solute carrier (SLC) transporters, including SLC22A1, SLC28A1, and SLC28A3, were linked to increased MRD1 positivity, indicating poor prognosis. SLC28A1 and A3 have been implicated in uptake of nucleoside analogs such as Ara-C. In contrast, SNPs in SLCO1B1 were predictive of better EFS and OS, suggesting that variations in drug uptake influences treatment outcomes. Five SNPs within the cytidine deaminase (CDA), involved in inactivation of Ara-C were associated with poorer EFS and OS. These SNPs were linked to higher CDA mRNA expression in blood, as per the GTEx database, and showed regulatory potential in chromatin states. SNP rs1048977 has been associated with reduced CDA enzyme activity, further corroborating its role in poor treatment outcomes. Among the myeloid panel genes SNPs in the AML-related gene RUNX1, CSF3R and CDKN2A were associated with poor clinical outcomes. SNPs in CSF3R and CDKN2A genes were predictive of poor EFS and OS. RUNX1 is a critical factor for myeloid differentiation, CSF3R is involved in neutrophil biology and activates the JAK/STAT pathway, while CDKN2A functions as a tumor suppressor and regulates the cell cycle. Dual mutations in CSF3R and CEBPA have been linked to high relapse rates in pediatric AML. In conclusion, our comprehensive pharmacogenomic analysis of genes involved in drug metabolism and AML pathogenesis has identified key genetic variants that influence treatment outcomes. These findings, once validated in larger cohorts, could offer new opportunities for personalizing chemotherapy and improving prognosis prediction in pediatric AML patients.

#4359 Comprehensive pharmacokinetics of Re-phenformin as an anticancer agent for pancreatic cancer therapy in mice: a comparative study with phenformin.

Amir Mohammad Gholizadeh[1], Fatima Dagher[1], Chiyi Xiong[2], Chun Li[2], Diana S-L Chow[1]

[1]Department of Pharmacological and Pharmaceutical Sciences, College of Pharmacy, University of Houston, Houston, TX,[2]Cancer Systems Imaging, The University of Texas M.D Anderson Cancer Center, Houston, TX

Re-phenformin (Re-$(CO)_3$-phenformin, Re-phen (MW=476.07)), a derivative of phenformin (MW= 206.24), was previously synthesized, purified, and characterized to explore its anticancer potential in comparison to phenformin, a biguanide medication. It has demonstrated enhanced *in vitro* anticancer efficacy compared to phenformin with significantly lower IC_{50} values in MiaPaca-2 (0.75 mM) and Kras* cells (0.410 mM) versus phenformin (4.02 mM and 2.36 mM, respectively). The primary aim of this study is to compare the pharmacokinetic (PK) characteristics of Re-phenformin, with phenformin to evaluate their PK parameters. We conducted a PK study in healthy male FVB mice, administering equimolar intravenous doses of Re-phenformin (25 mg/kg, n = 5) and phenformin (12.69 mg/kg, n = 4) using a Saline: Ethanol: Cremophor EL (8:1:1) vehicle. Blood samples were collected at six time points (0.33-24 hours), and organs were harvested at 24 hours post-dose. Quantification was performed using a validated LC-MS/MS method with a Kinetex® 1.7 µm XB-C_{18} column (LLOQ: 0.25 ng/mL) following liquid-liquid extraction of 10 µL blood spiked with 10 µL internal standard (D_5-phenformin) and 200 µL acetonitrile (0.1% formic acid). The mixture underwent vortexing, sonication, centrifugation, and reconstitution in 100 µL mobile phase (ACN: water, 35:65, with 0.1% formic acid). The method yielded 93.91% recovery (CV = 2.10%, N=3) and minimal matrix effects (86.38%-90.96%). The PK profiles of Re-phen and phenformin were modeled using a two-compartment model in Phoenix® WinNonlin (version 8.0) for comparison. Statistical significance was evaluated using a two-tailed unpaired t-test at $p < 0.05$. Re-phen showed smaller systemic exposure (AUC = 15.9 hr.µg/mL, $p = 0.02$*) and lower peak concentration (C_{max} = 5.3 µg/mL, $p = 0.0062$**) than phenformin (AUC = 40.2 hr·µg/mL, C_{max} = 30.4 µg/mL). Despite its faster clearance rate (CL = 1.7 L/hr/kg vs. 0.3 L/hr/kg, $p = 0.0019$**), Re-phen exhibited a prolonged half-life (11.1 hours vs. 7.8 hours), primarily attributed to its significantly larger volume of distribution (Vss = 17.1 L/kg vs. 1.3 L/kg, $p < 0.001$ ****). These findings highlight distinct distribution and elimination differences between the two compounds. Ongoing co-modeling aims to elucidate the *in vivo* conversion of Re-phen to phenformin and their PK interplay. This first PK comparison in healthy mice extends previous research and supports further evaluation in an orthotopic PDAC model to explore therapeutic potential in pancreatic cancer.

#4360 Development of a novel mithramycin analogue with improved pharmacokinetics and therapeutic window for targeted inhibition of EWS-FLI1 in Ewing sarcoma.

Rajesh Yetirajam[1], Srijan Acharya[1], Kumar Kuldeep Niloy[1], Yasuda Kazuto[1], Jamie Horn[1], Thomas Prisinzano[2], Jon S. Thorson[2], Oleg Tsodikov[2], Jurgen Rohr[2], Markos Leggas[1]

[1]St. Jude Children's Research Hospital, Memphis, TN,[2]University of Kentucky, Lexington, KY

Background: Ewing Sarcoma (EWS) is characterized by aberrant activity of the oncogenic EWS-FLI1 transcription. Mithramycin (MTM) has been identified to be a specific inhibitor of transcription mediated by the EWS-FLI1. A phase I/II trial and PK study in Ewing sarcoma patients demonstrated that MTM had poor PK and dose-limiting hepatic and hematologic toxicities at subtherapeutic concentrations. Here, we are presenting a novel MTM analogue with significantly improved PK and a wider therapeutic window for targeted inhibition of.
Results and Discussion: MTMSA-Trp was prepared by chemical conversion of MTM to the MTMSA analogue and the subsequent conjugation of a tryptophan amino acid. This substitution appears to shift the ionization properties of the two hydroxy groups on the tricyclic core and to increase protein binding, which significantly improves PK. The cytotoxicity of MTMSA-Trp is in the order of low nM across several cell lines expressing EWS-ETS fusions, and the compound disrupts the expression of positively regulated proteins (NR0B1, ID2) and induces expression of negatively regulated ones (PHLDA1, LOX). MTMSA-Trp mediates apoptosis during which upstream caspases proteolytically processes for Caspase-7 activation. This effector caspase drives the cleavage of downstream substrates PARP and high secondary DNA damage (gH2A.X). Luciferase reporter assay demonstrates a dose-dependent effect of MTMSA-Trp on the attenuation of EWS-FLI1 transcription and DNA binding, and based on CETSA evidence, there is physical interaction between MTMSA-Trp and EWS-FLI1. MTMSA-Trp was found to modify the prototypical activity of EWS-FLI1 by disrupting R-loops. Evaluation of MTMSA-Trp effect on EWS-FLI1 mediated transcriptional activity by RNA Seq highlighted 287 genes among overlapping DEGs. ATAC seq analysis revealed that TEAD, ETS, CEBP, and NFKB TF families have divergent TF binding profiles between Ewing and non-Ewing cells treated with MTMSA-Trp. EWS-FLI1 modulation persists longer when cells are exposed to GI90 concentration for a short time compared to the GI50 for longer times, suggesting that daily dosing or continuous exposure is not required. MTMSA-Trp has improved PK in athymic nu/nu mice with a greater than 10-fold reduction in clearance and significantly reduced partition in the liver compared to MTM. Initial efficacy studies in TC32 EWS cells demonstrated tumor regression and improved survival at the maximum tolerated dose (MTD) and at of the MTD on a daily x 5 intravenous bolus injection. Significantly, a more protracted dosing schedule, which allowed higher doses every 3 days for 6 doses, led to an impressive reduction of tumors whose initial size was 1200-1600 mm3.
Conclusions: MTMSA-Trp demonstrate that improving the pharmacologic properties of mithramycin may lead to the development of an EWS-FLI1 inhibitor.

#4361 Development and application of a mechanistic pharmacokinetic pharmacodynamic (PKPD) model to predict anti-chronic myeloid leukemia (CML) effects of tyrosine kinase inhibitors.

Qi Wang[1], Andrew Santulli[2], Haili Ping[1], Scott van Wart[2], Damiette M. Smit[1], Donald Mager[2], Helen Collins[1], Samuel Kintz[1], Joseph P. Lyssikatos[1]

[1]Enliven Therapeutics Inc., Boulder, CO,[2]Enhanced Pharmacodynamics, Buffalo, NY

Introduction: Chronic myeloid leukemia (CML) is driven by BCR::ABL1 fusion resulting from t(9;22)(q34;q11) chromosomal translocation. Although tyrosine kinase inhibitors (TKIs) for BCR::ABL1 like imatinib, dasatinib, nilotinib, bosutinib, asciminib and ponatinib are available for CML treatment, novel treatments are needed for CML that is resistant or patients who are intolerant to available therapies. The objective of this study was to develop a mechanistic PKPD model to assess anti-CML activity of TKIs in patients with newly-diagnosed CML.
Material and Methods: The PKPD model consisted of 3 parts; Population PK (popPK), leukemic stem cell (LSC) PD, and TKI effect on PD. PopPK models and PK data for TKIs were obtained from the literature. The PD model was adapted from Fassoni et al. In vitro TKI potency was measured using a CRKL assay in the presence of 100% human serum and a STAT5 assay in the presence of 10% fetal bovine serum. Effects of TKIs on LSC growth were modeled using a hyperbolic model ($I = Imax*Cp^H/(IC_{50}^H+Cp^H)$). Key model parameters, Imax and H, were determined and fixed, and IC_{50} was fixed for each TKI. A virtual patient population using all key covariates and common demographic data was created to mimic patients with CML. The model was applied to simulate the BCR::ABL1 transcript values for patients with CML following TKI treatments over time, followed by calculating corresponding molecular response rates (MR2, MR3 [MMR], MR4, and MR4.5).
Results: PopPK models for TKIs were reproduced and validated using literature data. The relationship between plasma concentrations of each TKI and BCR::ABL1 transcript levels was described by the mechanistic population PKPD model. PD model parameters, their inter-individual variability, and inhibition parameters I_{max} and H were constant for all TKIs, with only IC_{50} values varying. The model-simulated mean BCR::ABL1 levels following imatinib 400 and 800 mg QD, nilotinib 400 mg BID and dasatinib 100 mg QD agreed with observed data over a treatment period of 60 months. Further, the model-estimated MMR agreed well with the observed data from Phase 3 studies of imatinib, nilotinib, dasatinib and bosutinib over a 60-month period. For example, the MMR rates by 24- and 48-month of dasatinib and imatinib were predicted to be 66% and 45 %, and 74.5% and 53% vs. observed 64% and 46%, and 73% and 56%, respectively. Interestingly, the model a priori predicted the asciminib12-month MMR rate of 72% in patients with newly-diagnosed CML agreed with the Phase 3 reported rate of 67.7% at week 48.
Conclusion: This generalizable PKPD model, using available PK and in vitro potency data, was developed and accurately predicted outcomes of five approved BCR::ABL1 TKIs in patients with newly-diagnosed CML, suggesting the mechanistic PKPD model may be used to predict efficacy for novel TKIs.

#4362 Body mass index influences imatinib exposure in CML patients: Evidence fromTDM with adaptive dosing in real-world patients.

P. Maroselli[1], R. Fanciullino[2], J. Colle[2], L. Farnault[2], P. Roche[2], G. Venton[2], R. Costello[2], **J. Ciccolini**[3];
[1]Aix-Marseille University, Marseille Cedex 05, France, [2]Assistance Publique Hopitaux de Marseille, Marseille Cedex 05, France, [3]Inserm and Aix Marseille Univ, Marseille Cedex 05, France

Imatinib remains a mainstay of treatment for elderly or frail patients with chronic myeloid leukaemia (CML). Trough levels of around 1000 ng/mL are associated with a major molecular response with acceptable tolerability. We present data from 60 adult CML patients treated with imatinib on therapeutic drug monitoring (TDM) and adaptive dosing. Mean trough levels after treatment initiation were 994.2 ±560.6 ng/mL and a large inter-patient variability was observed (CV: 56%). Only 29% of patients were in the therapeutic range. All parameters associated with corpulence (i.e. body weight, height, body surface area, body mass index (BMI)) and age were significantly associated with imatinib plasma levels on univariate analysis. Age and BMI remained the only parameters associated with trough levels on multivariate analysis. As severe toxicities have been previously reported in patients with low BMI treated with standard imatinib, we evaluated the extent to which low BMI may lead to plasma overexposure. We found a statistically significant difference in trough imatinib levels in patients with BMI<18.5, with exposure +61.5% higher than in patients with 18.5<BMI<24.9 and +76.3% higher than in patients with BMI>24.9 ($p<0.05$, ANOVA). After TDM with adaptive dosing, a statistically significant difference in dosing between patients was observed, with doses ranging from 200 to 700 mg ($p<0.001$, ANOVA). No difference in toxicity or efficacy was observed regardless of BMI after adaptive dosing ($p>0.05$, Chi-2 test). Our data suggest that low BMI has a significant impact on imatinib exposure, but that pharmacokinetically-guided dosing limits its clinical impact in patients.

#4363 Establishment of plasma inhibitory kinase assays (PIA) to detect functional drug levels in patient plasma.

Lena Pilgermayer, Eva M. Egenter, Katharina Schaich, Daniel Feger, Jan E. Ehlert

Cellular Pharmacology, Reaction Biology Europe GmbH, Freiburg, Germany

Anticipation of the in vivo activity of an investigational new drug (IND) is challenging. In the context of the living body, compounds are subjected to degradation, metabolic modification or binding to plasma proteins - mechanisms that are well described to potentially compromise the in vivo activity seen in the patient compared to its predicted potential to inhibit its target in specific in vitro assays. As such assays are performed in artificial cell-culture media, we had previously modified our proprietary cellular FLT3 kinase phosphorylation assay to measure the activity of FLT3 inhibitors directly in and from human plasma, similar as described by Levis et al. 1. We hence established a method to analyze the activity of kinase inhibitors in human or rodent plasma (plasma inhibitory activity assay, PIA) in ELISA-based cellular kinase assays. We have successfully applied this methodology to determine the pharmaco-kinetics of a newly developed inhibitor of FLT3 in the context of a clinical trial targeting FLT3. We have now expanded this methodology for the detection of further kinase targets of potential clinical relevance. We were able to compile in vitro PIA assay data for further kinases such as VEGFR2 and BCR-Abl which will allow us to better predict the in vivo effect of specific inhibitors of these kinases and to determine the amount of freely available active test substance in the blood/sera of treated cancer patients. 1: Levis et al. Blood. 2006; 108 (10):3477-3483

#4364 Preclinical pharmacokinetics and pharmacodynamics of MK-4464, a novel NK cell engager targeting CEACAM5.

T. Nayak[1], Y. Zheng[2], L. Li[2], S. Li[2], S. Mauze[2], M. Cai[3], R. Mangadu[2], K. Riffel[1], X. Meng[1], S. Hseih[2], K. Dobrenkov[4], A. Beebe[2]; [1]Merck & Co., Inc., West Point, PA, [2]Merck & Co., Inc., South San Francisco, CA, [3]Merck & Co., Inc., Boston, MA, [4]Merck & Co., Inc., Rahway, NJ

MK-4464 is a bispecific, trifunctional antibody designed to direct NK cells to a tumor with a CEACAM5-specific scFv arm, and to activate the NK cells to kill tumors by simultaneously binding to NK cell costimulatory receptors NKG2D and CD16A. To support clinical translation, preclinical pharmacokinetics and pharmacodynamics studies were performed. In-vitro characterization was performed using cell-based assays, in-vivo efficacy was performed in B16F10-hCEACAM5 tumor-bearing hCEACAM5 transgenic mice. PET imaging studies were performed with ^{89}Zr-labeled MK-4464 in CEACAM5+ve and CEACAM-ve tumor bearing hIL-15 transgenic NSG mice engrafted with CD34+ human hematopoietic stem cells. In vitro cytolytic activity assay demonstrated the ability of MK-4464 to kill CEACAM5-expressing tumor cell lines. The EC50 values for cytolytic activity in tumor cell lines MKN-45, SK-CO-1, and BxPC3 were 0.61 nM, 0.61 nM, and 4.45 nM, respectively. The cytolytic activity was higher in cell lines with higher CEACAM5 expression. MK-4464-mediated NK-cell activation was demonstrated by increased IFNγ production and CD107a expression. The activation was shown to be dependent on the binding to CEACAM5, NKG2D, and CD16A. The cytolytic activity of MK-4464 increased with a higher effector/target cell ratio. A mouse surrogate of MK-4464 induced significant tumor growth inhibition in B16F10-hCEACAM5 tumor-bearing hCEACAM5 transgenic mice, number of remaining animals was significantly greater in mice treated with murine MK-4464 at 15 mg/kg ($p<0.0001$), at 5 mg/kg ($p=0.0004$), and at 1.5 mg/kg ($p=0.0274$) compared with the isotype control group. PET imaging studies demonstrated high target-mediated localization in the tumor with relatively low uptake in normal tissues. [^{89}Zr]MK-4464 demonstrated 2.5-fold greater tumor uptake than ^{89}Zr-labeled control antibody in CEACAM5+ve tumors, while no significant difference was observed in CEACAM5-ve tumors. Dose-dependent tumor saturation was observed in CEACAM5+ve tumors with near complete saturation at 10 mg/kg. Accumulation in spleen and lymphoid tissues were significantly lower than CEACAM5+ve tumors. After IV bolus administration of MK-4464 on Study Days 1 and 15, mean AUC and Cmax values were approximately dose-proportional from 1 to 10 mg/kg/week and slightly greater than dose-proportional from 10 to 100 mg/kg/week. The MABEL approach was used to determine the first-in-human starting dose. These findings collectively demonstrate the potent and specific activity of MK-4464 in targeting and killing CEACAM5-expressing tumor cells through NK cell activation and cytokine release. These preclinical studies facilitated the clinical translation of MK-4464 and [^{89}Zr]MK-4464 (ClinicalTrials.gov ID NCT05514444).

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: RAS Inhibitors
Poster Session

#4367 ERAS-4001 is a pan-KRAS inhibitor with robust anti-tumor activity in KRAS altered solid tumors.

Jae Hyun Bae, Bingzhen Lin, Erin D. Lew, Alexei Brooun, Joanne Oh, Taylor Sullivan, Corine Holub, Alex Stromitis, Brian Qua, Robert F. Shoemaker

ERASCA, Inc., San Diego, CA

KRAS is one of the most frequently mutated proteins in cancer (approximately 16% of all cancers), including non-small cell lung (~30%), pancreatic (~90%), colorectal (~40%), and other cancers. Targeting both wild type (WT) KRAS and oncogenic KRAS mutant proteins within the tumor cell is a potentially more promising therapeutic strategy than targeting the mutant KRAS protein alone since WT KRAS activity can act as a resistance mechanism to mutant selective KRAS inhibition. Pan-KRAS inhibitors enable simultaneous mutant/WT KRAS inhibition and have the potential to show improved tolerability relative to pan-RAS inhibitors by sparing NRAS and HRAS. ERAS-4001 is a novel pan-KRAS inhibitor that binds to WT KRAS and KRAS G12X mutants and prevents KRAS from signaling downstream via effector proteins, such as the RAF protein family, with single digit nanomolar potency. ERAS-4001 was selective for KRAS G12X mutants and WT KRAS over WT HRAS and WT NRAS in surface plasmon resonance (SPR) studies, possibly providing an expanded therapeutic index. In the biochemical KRAS G12D-RAF1 RBD (RAS-binding domain protein) assay, ERAS-4001 inhibited complex formation when KRAS G12D was either in the active state (i.e., GMPPNP-bound) or inactive state (i.e., GDP-bound) with single digit nanomolar IC_{50}s. ERAS-4001 showed potent cellular activity in a panel of KRAS WT amplified and KRAS G12X mutant NSCLC, PDAC, and CRC cell lines in both ERK1/2 phosphorylation (pERK) inhibition and 3-dimensional Cell-Titer Glo (3D-CTG) assays with IC_{50}s in the range of 0.7-56 nM. In vivo, oral administration of ERAS-4001 at 100 mg/kg BID resulted in significant tumor growth inhibition in KRAS G12D and G12V mutant subcutaneous xenograft models from 77% TGI to 83% tumor regression. ERAS-4001 achieved a dose dependent increase in plasma concentrations and significant concomitant reduction in pERK. We hypothesize that the potency and selectivity profile of the pan-KRAS inhibitor ERAS-4001 will provide efficacy and tolerability for patients with tumors driven by oncogenic KRAS alterations. An IND submission is intended for the first quarter of 2025.

#4368 Selective targeting of oncogenic KRAS G12D using complementary peptide nucleic acid oligomers.

Jayati Mondal[1], Dennis Lam[1], Mary E. Gerritsen[2], Tilmann M. Brotz[3], Jodi G. Kennedy[4], Bruce Rehlaender[3], Arthur J. Ross[5], Daniel E. Levy[6], Christopher A. Bonagura[7], William Lanzilotta[8], Frank McCormick[9], Jeffrey H. Rothman[10], Andrew L. Wolfe[1]

[1]Biological Sciences, Hunter College, The City University of New York, New York, NY,[2]Gerritsen Consulting, San Mateo, CA,[3]PharmaDirections, Boston, MA,[4]Oncogenuity, Inc, New York, NY,[5]Fortress Biotech, Waltham, MA,[6]DEL BioPharma, LLC, San Mateo, CA,[7]Art Robbins Instruments, Sunnyvale, CA,[8]University of Georgia, Athens, GA,[9]Helen Diller Family Comprehensive Cancer Center, University of California San Francisco, San Francisco, CA,[10]Department of Medicine, Ichan School of Medicine at Mount Sinai, New York, NY

KRAS is a proto-oncogene that has activating mutations in ~15-30% of all cancers. Conventional therapies non-selectively target tumor and normal cells which may cause high toxicities, and programmable mutant-selective targeted inhibitors are lacking. Peptide nucleic acids (PNAs) have base sequences analogous to DNA, except they have modified peptide backbones instead of sugar-phosphate backbones, allowing them to hybridize with DNA with high avidity to suppress transcription. Here, we developed KRAS G12D-selective PNA oligomers with novel cell-penetrating peptides (CPP) flanking regions. Immunofluorescently labeled PNA-CPP oligomers had high uptake rates in cells and nuclei. Complementary PNA-CPP treatment resulted in repression of KRAS G12D RNA and protein expression within 2 hours, lasting up to 48 hours. Alternative end modifications and lengths of complementary KRAS sequence were tested using dose-response cell viability assays. These experiments identified modifications to PNA oligomer sequence composition and length that were most effective at selectively preventing growth of on-target KRAS G12D cells, while relatively sparing off-target KRAS G12C cells. These PNA-CPPs were effective against a panel of pancreatic ductal adenocarcinoma cell lines and patient derived xenografts *in vivo*. These results indicate that PNA-CPPs show promise as both a tool for studying tumors driven by oncogenic point mutations, and as a possible therapeutic strategy capable of sparing normal cells while selectively targeting mutant cancer cells.

#4369 Preclinical characterization of a dual-state pan-KRAS Inhibitor.

Kevin Gaida, Tao Osgood, Ying-Chu Chen, Deanna Mohn, Anne Y. Saiki, Gilbert Diaz, Monica Leavitt, Upendra Dahal, Amit Vaish, Jason DeVoss, Karen Rex, Ryan Wurz, Brian A. Lanman, Paul E. Hughes, **Rati Verma**

Amgen Oncology, Thousand Oaks, CA

Activating mutations in *KRAS* occur in greater than twenty percent of all cancers encompassing several solid tumors with significant unmet medical need, including lung, colon, pancreatic, endometrial and stomach cancers. While mutations of codon 12 of *KRAS* (encoding glycine) are the most common, activating missense mutations are also observed at codons 13 and 61. Guided by our experience in the successful development of the covalent *KRAS* G12C mutant-selective inhibitor, sotorasib, we leveraged structure-based design to identify a new class of reversible, pan-KRAS inhibitors capable of targeting an expanded set of hot spot mutations prevalent in the above tumor types (e.g., *KRAS* G12D, G12V, G13D and Q61H). These reversible inhibitors potently inhibit both the GDP(OFF)- and GTP(ON)-states of KRAS while sparing H/NRAS. Dual ON/OFF-state activity facilitates the inhibition of mutant alleles that rapidly cycle between ON and OFF states (e.g., *KRAS* G12C) as well as those demonstrating slower cycling (e.g., *KRAS* G12V & *KRAS* Q61H), which predominantly reside in the GTP-bound state. Mechanistically, these inhibitors block the interaction of KRAS with its downstream effectors, such as c-RAF, and potently inhibit ERK phosphorylation. In vivo profiling demonstrated promising preclinical efficacy in *KRAS* G12D and *KRAS* G12V xenograft models, and good tolerability, illustrating the potential of pan-KRAS inhibitors to extend therapeutic benefit to tumors beyond those with *KRAS* G12C mutations.

#4370 Synthetic cell penetrating RAS-binding peptide for the treatment of RAS mutated cancer.

Gookjin Yoon[1], Beom Soo Jo[2], Dong Woo Lee[2], Moonsil Choi[2], Eui Kyun Jeong[2], Hoo Cheol Lee[2], Yu-Bin Kim[2], Sanghui Seok[2], Yoon Shin Park[3], Jue-Yeon Lee[2], Chong Pyung Chung[2], Yoon Jeong Park[1]

[1]Seoul National University, Seoul, Korea, Republic of,[2]Nano Intelligent Biomedical Engineering Corporation (NIBEC), Seoul, Korea, Republic of,[3]Chungbuk National University, Cheongju, Korea, Republic of

The RAS-RAF-ERK1/2 signaling pathway plays a critical role in cancer progression and is a primary target for anticancer drug development, given its frequent activation in various human cancers. MAPK, a key molecule within this pathway, is vital for eukaryotic cells to process external stimuli, leading to cancer cell proliferation. The MDA-MB-231 cell line, which represents triple-negative breast cancer, carries a G13D KRAS mutation, rendering it resistant to numerous treatments. This mutation drives abnormal MAPK pathway activation, fueling tumor progression. To address this, a synthetic cell-penetrating peptide called RAS-binding peptide (RBP) was designed to selectively bind RAS with high affinity in MDA-MB-231 cells. Experimental results revealed that RBP effectively inhibited RAS-RAF interaction, leading to reduced cell proliferation and suppression of ERK1/2 phosphorylation in MDA-MB-231 cells. Additionally, RBP significantly decreased cell migration and invasion, indicating potential anti-metastatic properties. In both chicken egg and mouse xenograft models, RBP treatment markedly inhibited tumor growth and metastasis. Histopathological analysis further demonstrated enhanced immune cell infiltration, while immunohistochemistry confirmed reduced expression of Ki-67, a marker for tumor cell proliferation. Collectively, these findings highlight RBP as a promising therapeutic candidate for targeting RAS-driven cancer by inhibiting tumor growth and metastasis.

#4371 PHI-501 as a potent pan-RAF/DDRs inhibitor suppresses lung cancer cell proliferation and overcomes KRAS G12C inhibitor resistance.

An-Na Moon[1], Ji Young Kim[2], Hee-sun Hwang[1], Gi-Jun Sung[1], Jinsun Kwon[1], **Ky-Youb Nam**[1], Kyu-Tae Kim[1], June Han[1], Jeong Hyeok Yoon[1], Ki-Young Lee[2]

[1]Pharos iBio Co., Ltd., Anyang, Korea, Republic of,[2]Sungkyunkwan University School of Medicine, Suwon, Korea, Republic of

Background: Mutations of the KRAS are one of the most commonly mutated oncogenes in cancer. Oncogenic mutations in KRAS typically occur at hotspots in the protein, increasing the steady-state levels of KRAS proteins in the GTP-bound state that are capable of driving oncogenic signaling through downstream effector pathways, such as the MAPK and PI3K pathways. The recent development of direct $KRAS^{G12C}$ inhibitors(G12Ci) has improved outcomes in KRAS mutant cancer. Mechanisms of acquired resistance to G12Ci are heterogeneous including both on-target and off-target resistance. On-target acquired resistance includes secondary codon 12 KRAS mutations, but also acquired codon 13 and codon 61 alterations, and mutations at drug binding sites. Off-target acquired resistance can derive from activating mutations in KRAS downstream pathways including $NRAS^{Q61K}$ and $BRAF^{V600E}$, acquired oncogenic fusions, gene level copy gain, or oncogenic alterations in other pro-proliferative and anti-apoptotic pathways. PHI-501 is a potent and dual kinase inhibitor for pan-RAF and discoidin domain receptor (DDR). In this study, we investigated the anti-tumor effect of PHI-501 as monotherapy and addressed the molecular mechanism underlying overcoming G12Ci resistance.
Methods: RAF family kinase profiling was performed. Cell viability was measured using the WST assay in human lung cancer cell lines and Ba/F3 cell lines expressing $BRAF^{V600E}$, DDR1 and $BRAF^{V600E}$/DDR1. Western blot was used to investigate the effects of down-stream signals. In vivo anti-tumor activities of PHI-501 were evaluated in the A549 mouse xenograft model.
Results: In Ba/F3 cells carrying $BRAF^{V600E}$/DDR1, PHI-501 displayed 70-fold higher cellular potency (IC_{50} 0.012 μM) over control cells. PHI-501 demonstrated potent anti-proliferative activity (IC_{50} < 0.2 μM) in 7 lung cancer cell lines harboring KRAS wild-type, KRAS or NRAS mutation. PHI-501 profoundly inhibited the phosphorylation of MEK, ERK, and AKT proteins as the downstream signaling of EGFR and DDR1 in KRAS mutant lung cancer cells. The growth inhibitory activity of PHI-501 in $KRAS^{G12V}$, $KRAS^{G12S}$, $KRAS^{Q61H}$ and $NRAS^{Q61K}$ lung cancer cells was superior to that of G12Ci (sotorasib and adagrasib) and BRAF inhibitors (encorafenib and avutometinib). PHI-501 considerably suppressed the reactivation of both pERK and pAKT by inhibition of pDDR1 expression in lung cancer cells. Consistently, treatment of A549 ($KRAS^{G12S}$) with PHI-501 in mice resulted in dramatic tumor regression superior to control groups.
Conclusion: The treatment of PHI-501 alone showed robust growth inhibition in lung cancer cells harboring KRAS wild-type or KRAS and NRAS mutation. Our results suggest that PHI-501 as the pan-RAF/DDRs dual inhibitor is beneficial for the treatment of lung cancer and even helps overcome the resistance of previous G12Ci treatments.

#4373 Discovery and characterization of BAY 3498264: a small molecule inhibitor targeting the RAS-SOS1 interaction.

Nils Guthof[1], Hongyu Xue[1], Isabel Jerchel-Furau[1], Christoph Hethey[2], Jan-Erik Busse[2], Karsten Denner[2], Matthias Voemel[3], Marc Kunze[4], Yunlong Shi[1], Zebin Wang[1], Volker Schulze[2], Sangeeta Jethwa[5], **Shinghu Cheung**[1]

[1]Bayer U.S. LLC, Cambridge, MA,[2]Bayer AG, Berlin, Germany,[3]Bayer AG, Wuppertal, Germany,[4]Pharmaceuticals, Bayer AG, Berlin, Germany,[5]Bayer, Basel, Switzerland

RAS proteins are GTPases cycling between the active GTP-bound on-state and inactive GDP-bound off-state. *KRAS* is among the most frequently mutated genes in cancers including non-small cell lung cancer, colorectal cancer and pancreatic cancer. Recent regulatory approvals of KRAS G12C selective inhibitors (KRAS G12Cis) including sotorasib and adagrasib have offered clinical advances to patients with cancer harboring the *KRAS G12C* mutation. However, monotherapy with these inhibitors showed modest response rate with median duration of response of less than one year for both. It has been shown preclinically that there is a feedback activation of the MAPK pathway when the pathway is being suppressed. This on-treatment feedback reactivation of the MAPK pathway is hypothesized to play an important role in limiting the clinical efficacy of KRAS G12Cis. Therefore, rational combination approaches are needed to address the feedback reactivation.

The MAPK pathway is intricately regulated by negative feedback mechanisms, including ERK-mediated inactivation of SOS1. As a guanine nucleotide exchange factor, SOS1 interacts with RAS to promote the exchange of GDP for GTP, thus facilitating RAS activation. Inhibiting SOS1, a crucial node within the MAPK pathway negative feedback loop, could block the feedback reactivation of MAPK pathway via RAS, akin to the effect seen with SHP2 inhibitors as reported, yet potentially with better tolerability. Indeed, our preclinical data have demonstrated that inhibiting SOS1 enhances the duration and depth of response of KRAS G12Cis, suggesting that SOS1 inhibitors could improve the therapeutic outcomes of KRAS G12Cis in patients.

Here, we report on the preclinical characterization of BAY 3498264, a potent and selective small molecule oral inhibitor of the SOS1 and RAS interaction. In *KRAS G12C* mutant cells, BAY 3498264 inhibits the rebound of phospho-ERK induced by sotorasib, achieving a more prolonged ERK phosphorylation inhibition when combined. Additionally, in *in vitro* proliferation assays, combining BAY 3498264 with various MAPK pathway inhibitors demonstrates marked combination effect as compared to single agent MAPK inhibition. The combination of BAY 3498264 with sotorasib in *KRAS G12C* mutant CDX and PDX models *in vivo* is well tolerated and exhibits combination benefit, enhancing both the depth and duration of response over sotorasib alone. Furthermore, we have assessed combination of BAY 3498264 with additional MAPK pathway directed therapies *in vivo* and have demonstrated combination effect with multiple molecules in addition to KRAS G12Cis. Our findings support the clinical exploration of BAY 3498264 in combination with KRAS G12Cis, and other therapies targeting the MAPK pathway, potentially offering a more durable blockage of the pathway and greater benefit for patients. BAY 3498264 is now in the early stages of a novel phase I study (NCT06659341).

#4374 Discovery of a highly potent and efficacious SOS1 inhibitor targeting KRAS-driven cancers.

Yang Li[1], Yang Zang[1], Wenbing Hu[1], Yuan Zhou[1], Lifei Liu[1], Xuejun Zhang[1], Shaohua Chang[2]

[1]Humanwell Healthcare (Group) Co.,Ltd, Wuhan, China,[2]KinoTeck Therapeutics Co., Ltd, Guangzhou, China

SOS1 is a crucial protein that activates RAS by promoting its conversion from the inactive GDP-bound state to the active GTP-bound state, triggered by growth factor receptor signals. This process is further enhanced by a feedback mechanism between SOS1 and RAS, increasing the strength and duration of RAS signaling, making SOS1 a significant therapeutic target in the RAS-MAPK pathway. Genetic alterations in the RAS-MAPK pathway are frequently observed across a spectrum of cancer types. While therapies targeting KRAS G12C mutations has been approved for certain types of lung cancers, there remains a need for treatments addressing other mutations (e.g. KRAS G12D, G12V etc.). Inhibiting SOS1 has shown potential in reducing proliferation of cancer cells dependent on KRAS signaling. Here, we report the discovery of a highly potent and efficacious SOS1 inhibitor HW071021. It demonstrates an IC50 of 8.5 nM in SOS1 binding assay and modulates ERK1/2 phosphorylation (pERK) in DLD-1 cell assay. Oral administration of HW071021 as a monotherapy in mouse MIA PaCa-2 xenograft models harboring KRAS G12C mutations results in significant tumor growth inhibition (TGI:~78%). Additionally, HW071021 combination with the EGFRi Osimertinib demonstrated much greater antitumor activity than Osimertinib monotherapy (TGI: 97% vs 33%) in mouse NCI-H1975 (EGFR L858R/T90M) xenograft model. HW071021 has excellent ADME and physical properties with low risks of hERG-related cardiotoxicity and drug-drug interactions . These data support the clinical utility of HW071021 as a single agent or combination partner of Osimertinib for the treatment of human Kras-driven cancers. IND application in China has been approved in September.

#4375 LY4066434, an oral small molecule pan-KRAS inhibitor, demonstrates robust anti-tumor activity in KRAS-mutant models, including in the CNS.

H. Gao[1], Y. Zhang[1], C. Yu[2], W. Xu[2], B. Li[1], H. Bian[1], M. Tandon[1], T. Wang[1], T. R. Stewart[1], M. H. Bender[1], W. Ming[1], M. A. Johnson[1], L. M. Kays[1], M. Leonard[1], M. A. Castanares[1], A. Capen[1], A. You[3], W. Bian[2], L. Prieto[4], T. Kercher[5], L. LeBrun[5], A. Klippel[6], C. Iyer[1], X. Gong[1];

[1]Eli Lilly and Company, Indianapolis, IN, [2]Lilly (China) Research and Development Center, Shanghai, China, [3]Lilly (China) Research and Development, Shanghai, China, [4]Eli Lilly and Company, Alcobendas, Spain, [5]Eli Lilly and Company, Louisville, CO, [6]Eli Lilly and Company, New York, NY

KRAS is altered in ~16% of all cancers and is an oncogenic driver in NSCLC, pancreatic, colorectal, and other cancers. Next generation KRAS inhibitors, designed to target multiple oncogenic KRAS mutations, have the potential to improve outcomes for the large burden of KRAS-mutated disease. Importantly, preclinical data suggest that a pan-KRAS approach that spares wildtype HRAS and NRAS may avoid the skin toxicities associated with pan-RAS inhibition.[1] This is particularly important in the context of treating KRAS-mutated colorectal cancer in combination with EGFR inhibition, which also carries skin toxicity. Next generation KRAS inhibitors could treat a wide range of patients including the approximately 35% of those with NSCLC who are at increased risk of developing CNS metastases. LY4066434 is an orally bioavailable, highly potent pan-KRAS inhibitor that has high selectivity over HRAS and NRAS.[2] Here, we report the antitumor activity of LY4066434 in patient-derived xenograft (PDX) and intracranial cancer models. We evaluated the activity of LY4066434 in PDX models harboring different KRAS mutations (both common and less frequent) and representing diverse histologies. LY4066434 showed robust anti-tumor activity, ranging from significant tumor growth inhibition to strong regression, in KRAS-driven PDX models of NSCLC, pancreatic, colorectal, and gastric cancers. Furthermore, we analyzed the activity of LY4066434 in combination with standard-of-care therapies. LY4066434 when combined with cetuximab showed enhanced antitumor activity in PDX models of NSCLC, pancreatic, and colorectal cancers with various KRAS mutations. Additionally, the combination of LY4066434 with chemotherapies also demonstrated greater efficacy in KRAS-mutant PDX models of endometrial and ovarian cancers. Finally, evaluation of LY4066434 activity in two KRAS-mutant orthotopic brain tumor models of NSCLC showed that LY4066434 inhibited tumor growth and promoted survival in these brain tumor models. Taken together, these results demonstrate the potential of LY4066434 as a promising therapeutic option for a range of cancer types driven by KRAS mutations including NSCLC, pancreatic, and colorectal cancers. LY4066434 is currently being investigated clinically (NCT06607185).

#4376 Preclinical characterization of SGR-4174, a potent and selective SOS1 inhibitor for the treatment of pan KRAS mutant cancers in combination with KRAS pathway inhibitors.

Hui Wang, Felicia Gray, Christian Atsriku, Adam M. Levinson, Andrew Placzek, Evelyne M. Houang, Abba E. Leffler, Anatoly Ruvinsky, Leah Frye, Jeremy Greenwood, Mats Svensson, Jeff Bell, Zhijian Liu, Roman Shimanovich, Matt Liu, Shaoxian Sun

Schrodinger, Inc., New York, NY

KRAS is the most frequently mutated oncogene in many tumor types including pancreatic (90%), colorectal (50%) and lung cancers (30%). KRAS mutation typically impairs the conversion of active GTP-bound KRAS to the inactive GDP-bound form, resulting in constitutively active KRAS. SOS1 is a predominant guanine exchange factor (GEF) that binds the inactive GDP-KRAS form and catalyzes conversion to the active GTP-KRAS. SOS1 inhibition has thus been described to be an effective approach for suppressing the KRAS signaling pathway and inhibiting tumor cell proliferation in KRAS mutant-driven cancers. Combination of SOS1 inhibitor with KRAS G12C inhibitor could be an attractive therapeutic approach to enhance the efficacy and overcome the resistance to KRAS G12C inhibitors driven by the reactivation of the RAS pathway observed in the clinic.

SGR-4174 is a potent and selective inhibitor of the SOS1-KRAS complex that was rationally designed using Schrödinger's computational platform. SGR-4174 binds to the catalytic domain of SOS1 (KD = 11 nM), disrupts the SOS1::KRAS interaction (SOS1::KRAS G12C FRET IC50 = 13 nM), and inhibits ERK activation (pERK IC50 = 28-61 nM) and KRAS mutant-driven tumor cell viability (3D CTG IC50 = 42-107 nM). SGR-4174 is effective in broad cancer types harboring KRAS G12C/D/V mutations and KRAS WT/EGFR mutations in drug sensitivity profiling of 49 tumor cell lines. In KRAS G12C tumor xenograft mouse models, SGR-4174 monotherapy demonstrated dose-dependent tumor growth inhibition and a decrease in the tumor PD biomarker pERK.

SGR-4174 was examined in combination with KRAS G12C inhibitor sotorasib and MEK inhibitor trametinib in vitro and in vivo. When combined with sotorasib, SGR-4174 demonstrated deeper and more sustained inhibition of the KRAS signaling pathway, stronger suppression of cell proliferation in 3D cell culture, and tumor regression in xenograft models compared to single agent activity. In addition, when combined with trametinib, SGR-4174 suppressed KRAS pathway reactivation by MEK inhibition and led to robust tumor cell death and tumor stasis. Compared to other published SOS1 inhibitors (BI-3406, MRTX0902), SGR-4174 is more potent, and demonstrated similar anti-tumor activity and target engagement at a lower dose both in monotherapy and combination therapy studies in xenograft tumor models. SGR-4174 was well tolerated as monotherapy and in combination with sotorasib or trametinib.

SGR-4174 demonstrated favorable PK properties across preclinical species and toxicity profile was well characterized. Our comprehensive preclinical efficacy and safety data support progressing SGR-4174 to clinical development to treat KRAS mutant cancers.

#4377 AN9025, an orally bioavailable pan-RAS(ON) inhibitor with potent, broad-spectrum anti-tumor activity.

Shuaishuai Liu, Meng Lv, Xiangyu Fu, Chenchen Zou, Hannah Yan, Tanya Yang, Feifan Li, Zhao Sun, Xiaoli Zhu, Hongyang Zhu, Meng Chen, Junying Li, Zhiyong Yu, Nanhai He

Adlai Nortye Ltd, Hangzhou, China

RAS mutations drive approximately 30% of human cancers, representing a critical unmet clinical need. AN9025, an oral RAS (ON) inhibitor, with best-in-class potential, demonstrates picomolar potency against RAS-dependent tumor cell lines, showing greater potency than a benchmark molecule. AN9025 binds to cyclophilin A (CypA) to form a binary complex which then engages the RAS (ON) protein to create a tri-complex that effectively inhibits downstream signaling pathways such as MAPK and PI3K/AKT. Preclinical characterization shows that AN9025 binds to CypA with high affinity (K_D=3.2 nM) and selectively engages with GMPPNP-bound RAS (ON), rather than RAS (OFF), to form a tri-complex with single-digit nanomolar affinity (K_D=8.8 nM). Consistent with its high binding affinity, cell-based assays showed that AN9025 disrupts the KRAS-RAF1 interaction and downregulates phospho-ERK1/2 levels in $KRAS^{G12D}$- and $KRAS^{G12V}$-mutated cells, with IC_{50} values of 0.068 and 0.013 nM, respectively. AN9025 also exhibited potent antiproliferative effects across a range of RAS-dependent tumor cell lines with various mutations ($KRAS^{G12C}$, $KRAS^{G12D}$, $KRAS^{G12V}$, $KRAS^{G12R}$, $KRAS^{G12A}$, $KRAS^{G13C}$, $NRAS^{Q61H}$, $NRAS^{Q61L}$, $NRAS^{Q61K}$), achieving IC_{50} values between 0.001 and 0.1 nM. Additionally, AN9025 demonstrated cytotoxic activity in cell models resistant to KRAS(OFF) G12C inhibitors sotorasib and adagrasib, while showing no cytotoxicity in BRAF-mutant, RAS-independent cell lines. In the $KRAS^{G12D}$-bearing HPAC xenograft model, oral administration of AN9025 at a dose of 0.125 mg/kg QD achieved ~95% intratumoral pharmacodynamic (PD) inhibition of DUSP6 and induced deep tumor regression compared to vehicle. Notably, AN9025 demonstrated sustained PD inhibition, with 60% inhibition persisting 14 days post-treatment cessation, suggesting extended therapeutic efficacy. In summary, AN9025 is a highly potent pan-RAS(ON) inhibitor that forms a tri-complex with CypA and RAS, effectively blocking downstream signaling and demonstrating robust antitumor efficacy, including in models that are resistant to mutant-selective RAS(OFF) inhibitors. Preclinical studies support its advancement into clinical development as a promising targeted therapy for RAS-driven cancers.

#4378 BBO-11818, an orally bioavailable, highly potent and non-covalent pan-KRAS inhibitor demonstrates robust anti-tumor activity in KRAS-mutant preclinical models.

C. E. Stahlhut Espinosa[1], K. Singh[1], Z. Zhang[1], K. Sullivan[1], N. Gitego[1], M. Rigby[2], R. Ma[2], P. Alexander[2], S. Setoodeh[1], J. Shu[1], K. Lin[1], D. Rabara[2], E. Larsen[2], A. Sharma[2], A. Chan[2], B. P. Smith[2], A. Stephen[2], Y. Yang[1], J. Pei[3], F. C. Lightstone[3], D. Simanshu[2], R. Xu[1], C. Ji[1], K. Wang[1], B. Wang[1], K. Sinkevicius[1], D. V. Nissley[2], E. Wallace[1], F. McCormick[2], A. E. Maciag[2], P. J. Beltran[1];
[1]BridgeBio Oncology Threapeutics, South San Francisco, CA, [2]Frederick National Laboratory for Cancer Research, Frederick, MD, [3]Lawrence Livermore National Laboratory, Livermore, CA

KRAS is the most commonly mutated oncogene, altered in approximately 15% of human cancers. While inhibitors of $KRAS^{G12C}$ have shown promising clinical efficacy, there are currently no approved targeted therapies against other KRAS variants, resulting in a significant underserved patient population across several major cancer types, including pancreatic carcinoma (PDAC), colorectal cancer (CRC), and non-small cell lung cancer (NSCLC). To address this unmet clinical need, we have developed BBO-11818: a potent, selective, orally bioavailable non-covalent pan-KRAS inhibitor with activity against multiple KRAS mutants, including $KRAS^{G12D}$ and $KRAS^{G12V}$, in both their inactive GDP-bound and active GTP-bound states. BBO-11818 binds mutant KRAS with high affinity and selectivity in its active and inactive conformations, locking it in the inactive State 1 to disrupt the association of GTP-bound KRAS with its key effector RAF1. Cell-based assays confirm that BBO-11818 potently inhibits several driver KRAS mutants, resulting in the suppression of MAPK signaling and inhibition of cell proliferation with low nanomolar EC_{50} values. The selectivity of BBO-11818 for KRAS is demonstrated by its >1000-fold lower potency against NRAS- and BRAF-mutant cell lines. BBO-11818 exhibits favorable pharmacokinetic (PK) and pharmacodynamic (PD) properties in mouse models of cancer. Single dose, oral administration results in strong dose- and time-dependent inhibition of pERK in $KRAS^{G12D}$ and $KRAS^{G12V}$ cell-derived xenograft (CDX) models. Importantly, BBO-11818 monotherapy induces strong anti-tumor responses, including regression at well-tolerated doses in CDX models of KRAS-mutant pancreatic, non-small cell lung, and colorectal cancer. In combination with either BBO-10203, a selective RAS:PI3Kα breaker that blocks RAS-mediated activation of AKT; or cetuximab, an anti-EGFR monoclonal antibody, BBO-11818 shows significantly enhanced efficacy in models harboring $KRAS^{G12D}$ or $KRAS^{G12V}$ mutations. BBO-11818 also shows a combination benefit with anti-PD-1 treatment, resulting in complete tumor regressions in the CT-26 syngeneic tumor mouse model. BBO-11818 is a potent pan-KRAS inhibitor with activity against both GTP and GDP forms of KRAS, presenting the opportunity to address, as monotherapy or combination, a large fraction of KRAS mutant tumors currently lacking targeted therapeutic options.

#4379 BPI-572270: An orally bioavailable and highly potent RAS (On) multi tri-complex inhibitor.

X. Yang, X. Zhu, **H. Han**, W. Wu, Y. Zhou, X. Kong, Y. Zhao, X. Liu, Y. Liu, T. Zhang, H. Chen, S. Li, C. Yang, J. Guo, Q. Zhou, H. Lan, L. Ding;
Betta pharmaceuticals, Co., LTD., Hangzhou, China

KRAS mutations are oncogenic drivers occur in approximately 20%-30% of all cancers with particularly high frequencies observed in pancreatic cancer (~90%), non-small cell lung cancer (~35%), and colorectal cancer (~45%). While approved $KRAS^{G12C}$ inhibitors have demonstrated clinical benefits in patients with $KARS^{G12C}$ mutation, other prevalent KRAS mutations, such as $KRAS^{G12D/G12V/G13D/Q61H}$, remain a significant therapeutic challenge. Here we present BPI-572270, a highly potent Cyclophilin A-dependent $RAS(On)^{multi}$ inhibitor with favorable oral bioavailability designed to target those difficult-to-treat RAS mutations. *In vitro,* BPI-572270 demonstrated exceptional potency by disrupting the GTP bound $RAS^{WT/Mut}$ and cRAF interaction in a cell-free assay, and by inhibiting tumor cell proliferation with sub-nanomolar IC_{50} values in a range of tumor cell lines harboring mutant KRAS, NRAS, or HRAS, as well as wild type RAS cell lines. *In vivo*, BPI-572270 achieved significant tumor regression in $KRAS^{G12V}$ human pancreatic Capan-2 xenograft mouse model at 0.3 mg/kg (PO, QD), and in $KRAS^{G12D}$ human pancreatic KP-4 xenograft model at 3 mg/kg (PO, QD), demonstrating potent efficacy. BPI-572270 also showed outstanding pharmacokinetic properties in mouse, rat and beagle dog. Safety evaluations in repeated-dose studies in rats and beagle dogs indicate a promising safety profile, reinforcing its potential for further clinical development. In conclusion, BPI-572270 emerges as a highly potent, orally bioavailable $RAS(On)^{multi}$ inhibitor, with favorable efficacy, pharmacokinetics, and safety profiles in pre-clinical studies.

#4380 HBW-016-K, a novel orally available pan-KRAS inhibitor targeting both “ON” and “OFF” states, is potent, selective, efficacious, safe, and high tissue-penetrant.

N. Lee, Y. Li, G. Liu, J. Li, M. Yang, z. Song;
Hyperway Pharmaceutical, Chengdu, China

Purpose: This study aimed to develop a novel, orally available pan-KRAS inhibitor capable of targeting both the “ON” and “OFF” states of KRAS, addressing drug resistance and expanding treatment options for KRAS-mutant cancers.
Methods: Through medicinal chemistry efforts, we designed and optimized a pan-KRAS inhibitor that selectively targets various KRAS mutant subtypes while sparing wild-type KRAS, NRAS, and HRAS. The lead compound was further evaluated for its pharmacokinetic (PK) properties and safety profile. Its anti-tumor efficacy was assessed in multiple KRAS mutant mouse models following oral administration.
Results: HBW-016-K demonstrated potent inhibition of various KRAS mutant cell lines with excellent selectivity for KRAS wild-type and other RAS isoforms. This compound effectively targets both the “ON” and “OFF” conformations of KRAS G12D. Additionally, HBW-016-K exhibits favorable PK properties and significant tissue penetration, particularly in lung, intestine, and pancreas. In a KRAS G12V mouse xenograft model, HBW-016-K exhibited dose-dependent anti-tumor activity. At the highest dose of 30 mg/kg (BID, PO), tumors shrank by 84.1% compared to baseline, with sustained tumor regression. HBW-016-K also demonstrated potent anti-tumor activity in KRAS G12D and G12C mouse models. Preliminary toxicity studies revealed a favorable safety profile for HBW-016-K, including minimal off-target effects, negative mutagenicity, and excellent tolerability in a 14-day rat toxicity study.
Conclusion: HBW-016-K is a promising novel pan-KRAS inhibitor with superior potency, selectivity, and efficacy. Its favorable PK profile and safety profile support its advancement into clinical development. HBW-016-K has the potential to significantly impact the treatment of KRAS-driven cancers, particularly those with limited therapeutic options, such as lung, colorectal, and pancreatic cancer.

#4381 Preclinical studies of HEC211909, an orally bioavailable, high potent pan-KRAS inhibitor.

H. Liu, H. Xie, F. Tan, N. Kang, M. Li, Y. Zhang;
Sunshine Lake Pharma Co. Ltd., Dong Guan Shi, China

Background: KRAS is the most commonly mutated oncogene, which is the driver in nearly 23% human cancers, and are especially prevalent in colorectal, lung, and pancreatic tumors. The KRAS signaling pathway is often hyperactivated in cancer cells due to KRAS gene mutations. This hyperactivation leads to uncontrolled cell proliferation, ultimately leading to the development and progression of cancer. There has been an urgent and unmet need to target KRAS mutations in KRAS-driven cancer.
Methods: Biochemical HTRF assay was used to measure the inhibition of HEC211909 to both GDP-bound and GTP-bound state of various KRAS mutant. CellTiter-Glo assay was performed to determine the effects on proliferation of tumor cell lines. Several KRAS dependent tumor models were employed to study the in vivo pharmacodynamic and anti-tumor effects.
Results: HEC211909 is a potent and orally bioavailable small molecule inhibitor of the KRAS oncogene, such as KRAS G12D, KRAS G12C, KRAS G12V, KRAS Q61H, KRAS G13D and KRAS wild-type amplifications. HEC211909 inhibits both active (GTP-bound) and inactive (GDP-bound) forms of multiple KRAS mutant protein with single-digit nanomolar IC50 values. HEC211909 has a strong anti-proliferative activity in a panel of KRAS mutant cancer cell lines and KRAS wild-type amplifications cancer cell lines in vitro with sub-nanomolar IC50 values, as well as significant inhibition of ERK1/2 phosphorylation with sub-nanomolar IC50 values. HEC211909 is highly selective for KRAS vs HRAS or NRAS, and is expected to be well-tolerated in normal tissues. In vivo, HEC211909 demonstrated dose-dependent anti-tumor activity with tumor regressions at 30 or 60 mg/kg given orally twice daily in KRAS-mutant xenograft models, such as PK59(KRAS G12D), HPAC(KRAS G12D), H358(KRAS G12C) xenograft models, and shows good tolerability during 21 days of treatment.
Conclusions: HEC211909 is a highly potent and selective orally pan-KRAS(ON/OFF) inhibitor against KRAS G12D, KRAS G12C, KRAS G12V, KRAS Q61H, KRAS G13D mutations and also displays high selectivity over WT HRAS and NRAS, thus providing an expanded therapeutic index.

#4382 Discovery and characterization of potent and orally bioavailable KRAS G12D inhibitors with therapeutic potential for KRAS G12D-mutated solid tumors.

Mijin Moon, Jiyoung Song, Soyoung Ki, Beomjin Hong, Ilkyoo Koh, Hyunho Cho, Seona Lim, Chuneung Park, Eunsung Jang, Gyeong Hi Cho, Hoiyun Jung, Minchang Cho, Sook-Kyung Park

Drug Research Division, SK Biopharmaceuticals Co., Ltd., Seongnam-si, Korea, Republic of

Background: KRAS G12D is the most prevalent KRAS mutation commonly found in pancreatic ductal adenocarcinoma (PDAC) and colorectal adenocarcinoma (CRC). This mutation drives tumorigenesis through aberrant downstream signaling, making it a critical therapeutic target. Tens of KRAS G12D inhibitors are currently under development, however many encounter challenges related to drug-likeness. Here, we present orally bioavailable KRAS G12D inhibitors designed to overcome these barriers.
Methods: Binding affinity to KRAS-mutant proteins was evaluated using thermal shift assays (TSA). The inhibitory effects on cancer cells were assessed by measuring ERK phosphorylation levels via ELISA. Cell proliferation assays were performed across various KRAS wild-type (WT) and mutant cell lines to determine compound selectivity and potency. *In vivo* efficacy was assessed using PDAC and CRC models harboring KRAS G12D mutation. Combination studies were evaluated using *in vitro* cell proliferation assays, and synergistic effects were confirmed with Combenefit software.
Results: A series of KRAS G12D inhibitors with novel and differentiated structures were identified through optimization of physicochemical properties to maintain inhibitory potency while achieving high plasma exposure following oral administration. These compounds exhibited strong binding affinity to KRAS G12D with remarkable selectivity over other KRAS mutant proteins. In KRAS G12D-driven cancer cell lines, our compounds demonstrated potent inhibition of pERK and cell proliferation at low nanomolar concentrations. In contrast, proliferation inhibition in cell lines expressing WT or other KRAS mutations was 50- to 1000-fold lower, highlighting exceptional KRAS G12D selectivity and minimal impact on normal cells. Additionally, our compounds exhibited favorable metabolic stability. Following oral administration at 30 mg/kg in mice, selected compounds achieved a C_{max} exceeding 1 μg/mL, surpassing plasma exposure levels reported for other KRAS G12D inhibitors. High plasma and tumor exposure led to robust inhibition of pERK in tumor tissues. In KRAS G12D-driven pancreatic (PDAC) and colorectal (CRC) cancer xenograft models, oral administration of the lead compound resulted in potent, dose-dependent tumor growth inhibition without notable body weight loss.
Conclusion: Our potent and selective KRAS G12D inhibitors demonstrate favorable ADME properties and significant antitumor activity in KRAS G12D-mutant xenograft models, addressing a critical unmet need for patients with KRAS G12D-driven cancers.

#4383 Discovery of ID12241161, an oral KRAS^{multi} inhibitor demonstrating potent and selective anti-cancer effects in KRAS-dependent cancers.

J. Kim[1], S. Lee[2], J.-H. Lee[3], C. Hong[4], Y. Song[4], D. Kim[4], W. Lee[1], M. Lee[1];

[1]Idience, Seoul, Korea, Republic of, [2]Chung-Ang Uviversity, Seoul, Korea, Republic of, [3]Korea Institute of Toxicology, Daejeon, Korea, Republic of, [4]Yunovia, Hwaseong, Korea, Republic of

Kirsten rat sarcoma virus (KRAS) gene mutations are prevalent in multiple cancers, contributing to approximately 89%, 44%, and 30% of pancreatic, colorectal, and lung adenocarcinomas, respectively. These mutations are associated with poor prognosis, and limited treatment options for all KRAS mutations, except for G12C, highlights the urgent need for oncogene targeted therapies. Despite ongoing development of KRAS pathway-targeting drugs, balancing safety and efficacy remains challenge owing to its essential role in cellular functions across various tissues. Through extensive computational analysis and structure-based drug design, we developed ID12241161, a novel, potent, and orally available small molecule inhibitor that favorably positions within the KRAS switch II pocket to target both “ON” and “OFF” states of diverse KRAS mutants. In this study, we demonstrated that ID12241161 exhibited robust anti-proliferative effects *in vitro* at picomolar to nanomolar concentrations (most IC50 values were lower than 10 nM) across a range of cancer cell lines with KRAS mutations or amplifications. Significant pharmacodynamic modulation of biomarkers was observed, including the inhibition of ERK1/2 phosphorylation, in these KRAS-dependent cell lines. In KRAS-independent cells, minimal cytotoxicity was observed, even at micromolar concentrations, suggesting that ID12241161 selectively targets KRAS-driven cancers. In mice, the pharmacokinetic profile of ID12241161 is characterized by a half-life of 6 hours with a high volume of distribution, which allows sustained effects for over 24 hours following once-daily dosing. Furthermore, *in vivo* studies demonstrated that a daily oral dose of 5-15 mg/kg ID12241161 was well tolerated and effectively induces tumor regression in KRAS-dependent xenograft models representing various cancer types. Our data indicated that ID12241161 possesses potent anticancer effects in KRAS-dependent cancers, with a wide safety margin and favorable pharmacokinetics, allowing for once-daily dosing. These findings support the potential use of ID12241161 as a viable treatment option for patients with KRAS-driven cancers.

#4384 SYNB021225: a potent oral pan-KRAS peptide inhibitor that can address unmet needs of small molecule inhibitors.

Michael Poss[1], Caihong Zhou[2], Cheng Lu[2], Ruochi Zhang[3], Yu Wang[3], Yuanpeng Xiong[3], Xin Gao[3], Xiao Zhang[3], Yan Degenhardt[4]

[1]Syneron Tech, Lawrenceville, NJ,[2]Syneron Tech, Shanghai, China,[3]Syneron Tech, Beijing, China,[4]Syneron Tech, Wynnewood, PA

KRAS mutations are present in 30% of cancer patients, underscoring the importance of KRAS as a critical target for drug development. Despite the advancements in small molecule inhibitors targeting specific KRAS mutations, such as G12C and G12D, significant challenges persist in addressing other prevalent mutations such as G12V. Furthermore, small molecule inhibitors predominantly target the GDP-bound form of KRAS due to accessibility of the SWITCH II pocket, even though most mutant KRAS proteins in cancer cells are in the activated GTP-bound form. Peptide drugs have emerged as promising alternatives due to their exceptional binding affinity and specificity, along with their reduced dependency on the presence of a well-defined binding pocket. Utilizing Syneron's innovative technology, we have successfully developed cyclic peptides capable of cell penetration and oral bioavailability, to overcome some of the limitations associated with small molecule KRAS therapeutics. SYNB021225 is a potent pan-KRAS inhibitor effective against multiple KRAS mutations, including G12V. With sub-nanomolar potency in both binding and *in vitro* cell killing, SYNB021225 induces tumor regression at oral doses of 10-20 mpk administered once daily. Besides expanding the treatable patient population, its broad targeting profile can also potentially address tumor heterogeneity and mitigate resistance. SYNB021225 inhibits both KRAS-ON and KRAS-OFF forms, directly disrupting the interaction between GTP-bound KRAS and RAF. Given that most mutant KRAS proteins in cancer cells are in the activated GTP-bound form, comparing to small molecules that mainly target the GDP-bound KRAS, this dual action offers potential advantage in enhancing efficacy as well as overcoming resistance from activated Receptor Tyrosine Kinases like EGFR. Indeed, in the *in vitro* proliferation assay, the potency of SYNB021225 remained unaffected when treated with EGF. Furthermore, SYNB021225 demonstrates efficacy against KRAS wild-type amplified tumors, which are resistant to KRAS-ON only molecular glue inhibitors. Current small molecule inhibitors often fail to maintain sustained p-ERK inhibition, impacting overall survival. In preclinical studies, SYNB021225 has shown prolonged tumor retention and p-ERK suppression lasting up to 72 hours, that may translate to improved clinical efficacy. Unlike small molecules, peptides such as SYNB021225 are metabolized by proteases and excreted via the kidneys, minimizing liver toxicity. This profile makes SYNB021225 more suitable for combination therapies, such as with anti-PD1 agents, without exacerbating the liver inflammation as seen in the clinic with small molecule inhibitors. Currently, SYNB021225 is being prepared for clinical development.

#4385 Preclinical evaluation of RAS pathway inhibitors in gastroesophageal adenocarcinoma.

Zachary Hammer[1], Jack Rifkin[2], Ralph Fleuranvil[1], Babita Pokharel[3], Stella Savone[4], Sandra W. Ryeom[1], Mariam El-Ashmawy[1]

[1]Surgical Sciences, Columbia University Irving Medical Center, New York, NY,[2]Sidney Kimmel Medical College, Philadelphia, PA,[3]Broad Institute, Cambridge, MA,[4]Greens Farms Academy, Westport, CT

Gastric cancer is the 4th leading cause of cancer-related deaths worldwide and up to 25% are driven by alterations in the RAS pathway. RAS activation in cancer is commonly a result of a mutation locking the protein in the ON state. However, KRAS amplification (KRAS^{AMP}), defined as >6 copies of wild type KRAS allele, occurs more frequently in gastroesophageal adenocarcinoma (GEA). Western blot analysis revealed differences in MAPK signaling amplitude between KRAS^{AMP} and KRAS^{MUT} cell lines after synchronization. KRAS^{AMP} cells show a sharp spike in signaling upon stimulation, followed by attenuation, we speculate due to negative feedback. Historically KRAS^{AMP} has been difficult to target due to adaptive signaling requiring MAPK inhibition at multiple signaling nodes, yet these combinations are clinically limited by toxicity. Here we test novel RAS pathway inhibitors in KRAS$^{AMP/MUT}$ GEA cell lines, to investigate toxicity, synergy with drug combinations, and efficacy of MAPK pathway target inhibition by quantifying levels of p-ERK. KRAS^{AMP} GEA cells ranged in copy number from 8-68; while all GEA mutant cell lines harbored KRAS^{G12D} mutations. GEA cells were seeded in 96 well plates, treated with drug for 5 days then assessed for viability via Cell titer glo. The half-maximal effective drug concentration (EC50) for p-ERK inhibition was determined by Western blot analysis after 24 hours of drug treatment. The pan-KRAS (OFF) Inhibitor, BI-2865 inhibits KRAS altered GEA cell viability with an IC_{50} ranging from 0.2 - 1.4 μM in KRAS^{AMP} and KRAS^{G12D} mutant cell lines. The RAF/MEK clamp VS-6766 demonstrated an IC_{50} range from 0.81 μM in KRAS^{AMP} in cell lines, while mutant KRAS^{G12D} lines exhibited 40-fold lower sensitivity. The allosteric SHP2 inhibitor RMC-4550 demonstrated an IC_{50} of 0.08-6.67 μM in KRAS^{AMP} and KRAS^{G12D} lines. BI-2865 suppressed p-ERK protein expression with an EC50 of 16 and 45 nM in KRAS^{AMP} and KRAS^{MUT} GEA cells respectively. There was no adaptive signaling through PI3K pathways based on suppressed p-AKT levels, in comparison to trametinib which resulted in increases in pAKT. The RAF/MEK clamp VS-6766 also inhibits signaling through MAPK as evidenced by decreased p-AKT, and an EC50 for p-ERK of 131.83 nM (KRAS^{AMP}) and 10.4725 nM (KRAS^{MUT}) GEA cells. Our data indicates a positive correlation between KRAS copy number and the IC50 of RAS-MAPK pathway inhibitors, suggesting cells with more KRAS copies require higher doses to achieve cytotoxicity; this is also reflected in the dose required for target engagement. This highlights the differential sensitivity of KRAS^{AMP} versus mutant cell lines, emphasizing the complexity of KRAS^{AMP} tumors and their reliance on high copy numbers. Our results suggest that combination strategies will be essential to overcome adaptive resistance and maximize therapeutic benefit in KRAS^{AMP} cells. Future *in vivo* studies will validate the potential of these inhibitors and combination approaches.

#4386 HJ-099, a novel, orally bioavailable pan-KRAS (ON) non-covalent inhibitor, demonstrates significant antitumor activity in multiple preclinical models with KRAS mutations.

Xiangyu Yang, Fengtian Du, Na Guo, Huiqiao Ling, Shuai Luo, Xiaorong Yu, Qingqing Qian, Ruisi Wu, Jingyu Tian, **Jianxin Ji**, Li Zhang

Chengdu Huajian Science Co., Ltd., Chengdu, China

Background: KRAS is one of the most common mutated oncogenes in cancer, which primarily stimulates tumor growth by activating the MAPK pathway. Tumors with non-$KRAS^{G12C}$ mutations, such as $KRAS^{G12D}$, $KRAS^{G12V}$, and other codon mutation subtypes, currently lack compelling precision medicines. Therefore, the development of pan-KRAS inhibitor is an unmet and pressing clinical need.
Methods and Results: Here, we report a novel, orally bioavailable pan-KRAS (ON) inhibitor HJ-099, designed to treat various KRAS mutation-driven tumors. HJ-099 exhibited significant anti-proliferative activity against multiple KRAS mutated cancer cell lines, including SW620, MAI PaCa-2, NCI-H358, AsPC-1, and NCI-H441, with IC_{50} <1.5 nM. In multiple KRAS mutated xenograft mouse models, HJ-099 showed significant inhibition on tumor growth. Tissue distribution study in tumor-bearing murine model showed that HJ-099, after oral administration, were mainly detected in the tumors, and the long-lasting accumulation of HJ-099 in tumor tissues resulted in more potent and durable antitumor activity in vivo.
Conclusions: The study indicates that HJ-099 is a novel, highly active pan-KRAS (ON) inhibitor that shows significant tumor suppression activity against major KRAS mutation subtypes, and merits clinical evaluation.

#4388 Novel small molecule on state inhibitor for GTP bound pan-KRAS (G12) mutations.

C. Gajendran, N. M. Sadhu, R. Gosu, M. Zainuddin, D. Sivanandhan, **S. Rajagopal**;
Jubilant Therapeutics Inc, Bedminster, NJ

Introduction: KRAS is part of the RAS family of small GTPases. They act as molecular switches by cycling between an active GTP-bound (ON) state and an inactive GDP-bound (OFF) state in response to extracellular signals. KRAS is frequently mutated in nearly 30% of cancers, with the G12, G13, and Q61 hotspots being the most common [1]. Among these, G12 mutations account for 83% of KRAS mutations, being one of the most prevalent drivers of cancers [2]. Active KRAS triggers effector pathways like MAPK and PI3K, promoting cellular proliferation and survival. Oncogenic KRAS remains constitutively active due to defective GTP hydrolysis [3]. Therefore, inhibitors that target the “ON” state can effectively interrupt the signaling pathways that promote cancer cell growth and survival. Recently pan-KRAS tricomplex inhibitor, which inhibits KRAS ON state, has entered the clinic. Therefore, targeting the KRAS in ON state could be of high clinical value in cancers with defects in G12 mutations and in overcoming resistance. In this regard, we are developing a series of novel pan-KRAS ON state inhibitors.

Methods: Fragment screening with SPR and structure-based drug design were used to identify novel pan-KRAS (G12) mutant “ON” state inhibitors. Over 20 scaffolds were synthesised and screened using the AlphaLISA and Nucleotide exchange assay. Binding was assessed using thermal shift assay. To assess *in vitro* potency and to drive the structure-activity relationship, an AlphaLISA assay that measures the disruption of active KRAS:C-Raf interaction and for the inactive GDP bound state Nucleotide exchange assay was used. The cell-based activity of these inhibitors was assessed by measuring the pERK levels and 2D/3D cell proliferation assays. PK-PD assessment was performed in A427 lung cancer and AGS gastric cancer xenograft models in mice.

Results: Based on in vitro screening, we identified a novel series of potent pan-KRAS ON inhibitors targeting (G12) mutations. These early hit compounds demonstrated differential anti-proliferative activity between wild type and G12 mutant KRAS cell lines under 2D and 3D culture conditions. Accordingly, significant reductions in PD biomarker, pERK was demonstrated in KRAS mutant cell lines. PK-PD correlation was also established in a tumor bearing mice models, showing dose-dependent reductions in pERK level. The early data with these compounds show good ADME properties, and oral bioavailability, making them suitable for in vivo profiling and further SAR exploration.

Conclusion: Our findings highlight the potential of these novel pan-KRAS ON state inhibitors as promising therapy approach for cancers harbouring KRAS (G12) mutations. Further SAR optimization, mechanistic studies, in vivo studies and toxicity evaluations are warranted to fully establish their efficacy and safety.

#4391 A novel dual inhibitor of RAS and β-catenin signaling with advantages over mutant-specific KRAS inhibitors to escape resistance has robust antitumor efficacy and activates antitumor immunity.

Gary A. Piazza[1], Dhana Sekhar Reddy Bandi[2], Ganji Purnachandra Nagaraju[2], Kristy L. Berry[1], Khalda Fadlalla[1], Md Yeashin Gazi[3], Upender Manne[2], Xi Chen[1], Jeremy B. Foote[2], Adam B. Keeton[1], Yulia Y. Maxuitenko[1], Donald B. Buchsbaum[2], Bassel F. El Rayes[2], Gang Zhou[3]

Aberrant activation of RAS signaling due to oncogenic RAS mutations, constitutive activation of receptor tyrosine kinases, or gene amplifications are key drivers/dependencies of most human cancers. Co-occurring mutations in the APC/β-catenin pathway that often occur in gastrointestinal and other cancers also play a crucial role in tumorigenesis and likely contribute to resistance to KRAS inhibitors. Phosphodiesterase 10A (PDE10) is overexpressed in certain cancers compared with normal tissues, while known inhibitors or gene silencing selectively inhibit proliferation and induce apoptosis of PDE10-expressing cancer cell lines. In contrast, normal cells lacking PDE10 were remarkedly insensitive. A novel orally bioavailable PDE10 inhibitor, ADT-030, was identified by screening a proprietary indene library followed by chemical optimization with delivery advantages over conventional PDE10 inhibitors. PDE10 inhibition by ADT-030 was confirmed with enzymatic assays using recombinant PDE10 and in cancer cells by cellular thermal stability assays, as well as the ability of ADT-030 to activate cGMP/PKG signaling at concentrations that inhibit and bind PDE10. ADT-030 blocked RAS-MAPK/AKT signaling and destabilized β-catenin, suppressing the transcription of genes essential for cancer cell proliferation and survival (e.g., MYC, Cyclin D, Survivin). Cancer cells resistant to $KRAS^{G12C}$ and $KRAS^{G12D}$ inhibitors retained complete sensitivity to ADT-007. Oral administration of ADT-030 strongly inhibited tumor growth at doses without discernable toxicity in mouse tumor models of colon, lung, breast, and pancreatic cancer. Notably, ADT-030 caused tumor regression in patient-derived xenograft mouse models of pancreatic cancer and increased survival in orthotopic mouse models of lung cancer. ADT-030 also inhibited metastasis in the 4T1 orthotopic model of breast cancer and synergized with anti-PD1 in the CT26 mouse model of colon cancer to enhance survival. In addition, ADT-030 inhibited tumor formation in chemical-induced models of lung cancer and the MMTV/neu mouse model of breast cancer. Finally, deep immunophenotyping studies revealed a significant impact of ADT-030 treatment on the tumor immune microenvironment characterized by selective induction of apoptosis in myeloid-derived suppressor cells (MDSC) while increasing tumor infiltration of CD8+ T cells and natural killer cells. Together, these results support IND-enabling studies of ADT-030 as a monotherapy or in combination with immunotherapy for a broad range of KRAS-driven/dependent cancers.

#4392 A 1st in class pan-RAS inhibitor with robust antitumor activity in PDAC models and advantages over other RAS inhibitors to escape resistance.

Gary A. Piazza[1], Dhana Sekhar Reddy Bandi[2], Ganji Purnachandra Nagaraju[2], Kristy Berry[1], Junwei Wang[1], Sindu Ramesh[1], Chung-Hui Huang[1], Upender Manne[2], Xi Chen[1], Jeremy B. Foote[2], Adam B. Keeton[1], Yulia Y. Maxuitenko[1], Donald J. Buchsbaum[2], Bassel F. El Rayes[2]

[1]Drug Discovery and Development, Auburn University Harrison College of Pharmacy, Auburn, AL,[2]O'Neal Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, AL

ADT-007 is a novel reversible pan-RAS inhibitor with ultra-high potency and unique selectivity to inhibit the growth of cancer cells with mutant or activated RAS by blocking GTP activation of RAS. ADT-1004, an orally bioavailable prodrug of ADT-007, displayed robust antitumor activity in multiple mouse models of pancreatic ductal adenocarcinoma (PDAC), including PDX models harboring $KRAS^{G12D}$, $KRAS^{G12C}$, $KRAS^{G12V}$, and $KRAS^{G13Q}$ mutations, at dosages approximately 9-fold below the maximum tolerated dose. Analysis of treated tumors revealed that ADT-1004 suppressed GTP-RAS and p-ERK levels and activated antitumor immunity. As evidence of target selectivity for mutant RAS, ADT-1004 suppressed the growth of $KRAS^{G12C}$ MIA PaCa-2 tumors without affecting $KRAS^{WT}$ BxPC-3 tumor growth. ADT-1004 displayed superior antitumor activity over sotorasib and adagrasib in a PDAC model involving MIA PaCa-2 cells that developed resistance to mutant-specific KRAS inhibitors. *In vitro* experiments show that ADT-007 potently inhibited the proliferation of cancer cell lines harboring mutations in K/N/H RAS without affecting the proliferation of cells with downstream BRAF mutations or cells from normal tissues. Cancer cell lines with RAS^{WT} but amplified RAS or upstream mutations in RTK or NF-1 were also highly sensitive to ADT-007 with low nM potency. ADT-007 reduced GTP-RAS levels from mutant KRAS and co-expressed RAS^{WT} isoforms under serum-free and EGF-stimulated conditions while inhibiting MAPK/AKT signaling to suppress MYC levels. Growth assays involving direct comparison of ADT-007 with mutant-specific $KRAS^{G12C}$ inhibitors (sotorasib), pan-KRAS inhibitors (BI-2865), or other pan-RAS inhibitors (RMC-6236) revealed more complete cancer cell killing by ADT-007. In addition, colony formation assays showed near complete inhibition by ADT-007 but only partial inhibition by sotorasib, BI-2865, and RMC-6236. ADT-007 also inhibited the growth of RAS^{WT} cancer cells harboring amplified RAS with more extensive killing compared with BI-2865 and RMC-6236. Finally, cancer cell lines resistant to $KRAS^{G12C}$ and $KRAS^{G12D}$ inhibitors retained complete sensitivity to ADT-007 but showed resistance to MRTX849 and MRTX1133, respectively. These results show the unique advantages of ADT-1004 over mutant-specific KRAS, pan-KRAS, and other pan-RAS inhibitors to escape resistance that limits the efficacy of RAS inhibitors FDA-approved or in clinical trials.

#4393 RAF/MEK clamp avutometinib combined with a pan-RAF inhibitor induces nearly complete MAPK pathway inhibition with deep tumor regressions in NRAS or BRAF class III mutant models.

Silvia Coma[1], Poulikos I. Poulikakos[2], **Jonathan A. Pachter**[1]

[1]Verastem Oncology, Needham, MA,[2]Department of Oncological Sciences, Icahn School of Medicine at Mount Sinai, New York, NY

Although there are targeted therapies currently approved for cancers with KRAS G12C and BRAF V600E (class I) mutations, there is still significant unmet medical need for patients harboring NRAS or BRAF class II/III alterations which are found in a range of cancers including melanoma and lung cancer. Avutometinib is a first-in-class orally available RAF/MEK clamp that potently inhibits MEK1/2 kinase activities and induces formation of dominant negative RAF/MEK complexes thereby blocking compensatory activation of MEK by RAF. The combination of avutometinib with the focal adhesion kinase (FAK) inhibitor defactinib has shown clinical activity for patients with low-grade serous ovarian cancer and is currently being investigated in a Phase 3 confirmatory study (RAMP 301; NCT06072781). Here, we tested the combination of avutometinib with a pan-RAF inhibitor (pan-RAFi) in cancer models harboring NRAS or BRAF class III mutations. In 3D proliferation assays, avutometinib inhibited cell proliferation across multiple MAPK pathway alterations including NRAS, and BRAF class II and III. Combination strategies of avutometinib with inhibitors of upstream MAPK pathway signaling, including pan-HER, SOS1 and pan-RAF inhibitors, were explored and striking synergy was observed between avutometinib and pan-RAF inhibitors in reducing viability of tumor cells *in vitro*. In a BRAF class III non-small cell lung cancer patient-derived xenograft (PDX) model (LU3057), the combination of avutometinib with the pan-RAFi exarafenib induced strong tumor regressions in all the mice, whereas avutometinib alone induced tumor stasis. In an NRAS mutant melanoma PDX model (ME9518), the combination of avutometinib and exarafenib showed deep tumor regression, whereas avutometinib or exarafenib single agents did not induce tumor regression. In contrast to the tumor regressions induced by avutometinib plus exarafenib in this ME9518 model, the combination of the MEK-only inhibitor binimetinib with exarafenib caused substantial body weight loss and failed to show tumor regression. Strong tumor regressions in all mice were also observed with the combination of avutometinib and the pan-RAFi belvarafenib in an NRAS mutant xenograft model (SKMEL2). Mechanistically, the deep tumor regressions observed with the combination of avutometinib plus exarafenib corresponded with virtually complete elimination of MAPK pathway markers such as pMEK, DUSP4 and pS6 in the tumors relative to avutometinib or exarafenib alone which conferred less complete inhibition. These results demonstrate that the combination of avutometinib with a pan-RAFi is especially efficacious and is well tolerated, indicating that clinical evaluation of avutometinib in combination with a pan-RAF inhibitor for treatment of patients with NRAS or BRAF class III mutations may be warranted.

#4394 GFH375 (VS-7375): An oral, selective KRAS G12D (ON/OFF) inhibitor with potent anti-tumor efficacy as single agent and in combination with other anticancer therapies in preclinical models.

Jonathan A. Pachter[1], Feng Yan[2], Silvia Coma[1], Cristina Caffarra Malvezzi[3], Xiuting Liu[4], Emilia Berardelli[3], Tao Jiang[2], Siyuan Le[2], Nathan Sanburn[1], Fusheng Zhou[2], Jiong Lan[2], David G. DeNardo[4], Chiara Ambrogio[3], Qiang Lu[2]

[1]Verastem Oncology, Needham, MA,[2]GenFleet Therapeutics, Shanghai, China,[3]Department of Molecular Biotechnology and Health Sciences,, University of Torino, Torino, Italy,[4]Department of Medicine, Washington University School of Medicine, St Louis, MO

KRAS G12D is the most prevalent KRAS mutation in human cancers, present in 37%, 12.5%, 8% and 4.9% of pancreatic, colorectal, endometrial and lung cancers, respectively. Currently there are no FDA approved KRAS G12D-selective inhibitors and thus, cancers with KRAS G12D mutations represent a significant unmet medical need. GFH375 (also known as VS-7375) is an orally available KRAS G12D-selective small molecule inhibitor that binds KRAS G12D in the active (ON; GTP-bound) and inactive (OFF; GDP-bound) states. By blocking the activities of the ON and OFF states of KRAS G12D, GFH375 has the potential to inhibit KRAS G12D signaling and tumor growth more completely than compounds that block KRAS G12D only in the OFF state or only in the ON state. Here we show that among a panel of human cancer cell lines, GFH375 potently and selectively inhibited proliferation of tumor cells bearing a KRAS G12D mutation relative to cell lines bearing wild-type KRAS or non-G12D KRAS mutations. Similarly, in a panel of mouse embryonic fibroblasts (MEFs) engineered to express various human KRAS mutation variants, GFH375 selectively inhibited proliferation of KRAS G12D mutant MEFs relative to MEFs expressing other KRAS G12X or Q61X mutations. Furthermore, GFH375 was more potent than other KRAS G12D inhibitors (e.g. RMC-9805, MRTX1133) in reducing the level of RAF1-bound active KRAS G12D-GTP (ON) and inhibiting cell proliferation in MEFs expressing human KRAS G12D. GFH375 also reduced pERK and pCRAF more potently than these other KRAS G12D inhibitors corresponding with greater increase in pro-apoptotic BIM. In vivo, oral administration of GFH375 single agent induced strong tumor regressions in multiple KRAS G12D colorectal and pancreatic cancer tumor models, including xenograft models and a transplanted pancreatic cancer model derived from KPC genetically engineered mice. GFH375 also demonstrated potent anti-tumor activity in an intracranial GP2D tumor model, suggesting potential to use for treatment of brain metastases. Combination of GFH375 with the anti-EGFR antibody cetuximab induced complete responses in all mice in a colorectal cancer xenograft model, and cetuximab also augmented the antitumor efficacy of GFH375 in pancreatic and lung cancer models. Combination with the RAF/MEK clamp avutometinib also enhanced the anti-tumor efficacy of GFH375. Additional combinations with GFH375 are currently being explored. Altogether, GFH375 is a potent and selective orally active inhibitor of KRAS G12D (ON/OFF) and demonstrated promising anti-tumor activity in multiple KRAS G12D tumor models in vivo as single agent and in combination with other anticancer therapies including cetuximab. These results support the ongoing clinical evaluation of GFH375 for treatment of patients with KRAS G12D mutant cancers (NCT06500676).

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Regulation of Gene Expression in Drug Resistance
Poster Session

#4398 Dysregulating transcription and epigenetic remodeling using dual BRD4 and CDK9 inhibition in pancreatic ductal adenocarcinoma.

Lucas J. Koeppel[1], Austin Stram[2], Robert J. Millikin[3], Md Shahadat Hossan[2], Ron Stewart[3], Jeremy D. Kratz[2]

[1]Department of Medicine, University of Wisconsin-Madison, Madison, WI,[2]Center for Human Genomics and Precision Medicine, Madison, WI,[3]Morgridge Institute for Research, Madison, WI

Background: Pancreatic ductal adenocarcinoma (PDAC) is the most common cause of mortality for pancreatic cancers with a five-year survival rate of only 13%. These malignancies acquire resistance to therapeutics through dysregulation of epigenomic and transcriptional signals, however few investigations have considered combination therapies to disrupt these pathways. BRD4 and CDK9 are both promising targets playing key roles in epigenomic and transcription regulation and are both upregulated in PDAC. Here, we evaluate the potential of dual BRD4 and CDK9 inhibition as a strategy to disrupt global transcriptional and epigenomic regulation in PDAC.
Methods: PDAC patient-derived cancer organoids (PCOs) were established from live tissue samples. PCOs were treated with single agents, VIP152 and ZEN3694, or the combination. ZEN3694 was treated continuously while VIP152 was removed after 24 hours to mimic *in vivo* pharmacokinetics. Western blotting was used to analyze phosphorylation of RNA polymerase II at serine 2 (pRPB1-s2) and anti-apoptotic proteins after 24 hours of treatment. Differential expression and peak calls were made on bulk mRNA and CUT&Tag sequencing (RNA-seq and CUT&Tag) performed on treated PCOs. PCOs were collected after 144 hours of treatment for RNA-seq and 48 hours for CUT&Tag. gProfiler was used for pathway analysis for both sequencing sets.
Results: Western blot analysis revealed combination therapy achieved downregulation of pRPB1-s2 and anti-apoptotic proteins compared to single agents. RNA-seq yielded no pathway dysregulation for VIP152 treated PCOs across 2 unique PDAC lines. The number of dysregulated pathways increased in the combination treated group compared to ZEN3694 in PDAC2 (ZEN3694 n=156, combination n=235), however this was not seen in PDAC1 (ZEN3694 n=69, combination n=37). Pathway analysis from CUT&Tag of PDAC1 for pRPB1-s2 revealed significant pathway dysregulation in the combination (n=186) with no single agent disruption. These pathways included biologically relevant gene sets such as ‘Pancreatic Cancer Subtypes’ (adj $p<0.001$), ‘response to stimulus’ (adj $p<0.001$), and ‘signal transduction’ (adj $p<0.001$) across both sequencing sets. CUT&Tag also revealed a significant decrease in pRPB1-s2 binding across all matched significant differential peak calls (VIP152=-0.21, ZEN3694=-0.23, combination=-0.74 $p<0.001$), and a decrease in open chromatin markers (H3K4me3=-0.64 $p<0.001$ and H3K27ac=-0.56 $p<0.001$) compared to both single agents (VIP152=-0.15 and -0.20; ZEN3694=-0.15 and -0.14).
Conclusion: Here, we show preclinical evidence that combination treatment of VIP152 and ZEN3694 synergistically dysregulates PDAC transcription and remodels the epigenomic landscape. Future directions will include exploring *Myc* amplified subtype specific selectivity and *in vivo* validation of toxicity and efficacy.

#4399 Systematic interrogation of cell states that drive inflammation tolerance and therapy resistance in cancer.

Srivatsan Raghavan[1], Evelyn Y. Tong[2], Aswanth H. Mahalingam[1], Zixin Chen[1], **Jacob Smigiel**[3], Tsukasa Shibue[3], Andrew Navia[3], Alex K. Shalek[2], Lorin Crawford[4], Ava Amini[4], Peter S. Winter[3]

[1]Dana-Farber Cancer Institute, Boston, MA,[2]Massachusetts Institute of Technology, Cambridge, MA,[3]Broad Institute of MIT and Harvard, Cambridge, MA,[4]Microsoft Research, Cambridge, MA

Cancers develop and evolve by overcoming numerous selective pressures including cell-intrinsic growth-inhibitory mechanisms, microenvironmental stresses, and therapeutic interventions. In addition to mutational mechanisms, cancer cell adaptation via transcriptional plasticity remains an important but poorly understood driver of cancer cell fitness. Specifically, when disease progression occurs after targeted therapy treatment, genomically-defined mechanisms of resistance are only identified in approximately 50% of patients, suggesting that non-genomic mechanisms play an equally important role. Thus, there is a pressing need to devise systematic and scalable methods to determine essential drivers of prognostically-relevant cancer cell states, and to engineer state-relevant models that can be applied to discover new therapeutic approaches that overcome these modes of resistance. Here, we present a strategy to systematically identify transcriptional drivers of inflammation- and therapy-resistant cancer cell states. We have successfully established a high-throughput screening pipeline to 1) over-express human transcription factor (TF) isoforms in a pooled format within cancer models; 2) perform positive-selection screens under a variety of selective pressures to define transcriptional mechanisms of inflammation tolerance and therapy resistance; 3) perform single-cell RNA sequencing to define families of TFs that drive specific cell state transitions and resistance phenotypes; and 4) conduct mechanistic studies to examine the downstream signaling networks that facilitate cancer cell growth in the setting of these selective pressures. We uncover TFs and states that drive resistance in a tissue- and perturbation-specific manner, as well as states that are robust to multiple different selective pressures. A subset of TFs and associated gene programs induce tolerance to chronic interferon exposure in our screens and are reflected *in vivo* in the setting of immunotherapy resistance. We also identify distinct TF families that drive resistance to pharmacologic KRAS inhibition. Notably, cancer cell states that confer resistance to KRAS inhibition also exhibit cross-resistance to other MAPK pathway inhibitors, suggesting that cell state adaption may contribute to multi-drug resistance as cancers progress. More broadly, our strategy enables the systematic identification and mapping of cell states that drive cancer cell fitness to *in vivo* clinical atlas datasets, providing a framework for interpretation of clinical phenotypes and potential predictive modeling of cell state evolution. Furthermore, the cell state-defined models developed here provide a substrate for new therapeutic discovery using cancer cell states as biomarkers, a key next step to developing combination strategies that overcome therapeutic resistance and improve outcomes for patients.

#4400 SRPK1: The dominant power of alternative splicing in tumor chemoresistance.

D. Duzgun, S. Oltean;
University of Exeter, Exeter, United Kingdom

Introduction: Abnormal pre-mRNA alternative splicing (AS) is critical in shaping tumor chemoresistance by modulating the function of genes involved in resistance mechanisms. The serine arginine protein kinase 1 (SRPK1) is a major regulator of AS by phosphorylating an important group of splice factors named SR-proteins. Our study aims to elucidate the molecular mechanisms by which SRPK1 promotes resistance to chemotherapeutic drugs.
Methods: Two cell lines resistant to cisplatin (CDDP) (breast cancer MDA-MB-231-CDDP-R and colon cancer HCT-116-CDDP-R) and one cell line resistant to docetaxel (DTX) (prostate cancer PC-3-DTX-R) were established by derivation from their parental using the pulse selection method. The CDDP and DTX resistance and the expression of SRPK1 of cells were verified by the IC_{50} measurements, MTT assay and western blotting (WB). The molecular mechanisms were determined using WB, siRNA, immunoprecipitation, the JC-10 apoptosis assay, and RT-PCR.
Results: The MTT assay revealed that resistant cell lines were about 5-17 times more resistant to chemotherapeutic agents than parental cell lines. SRPK1 protein was upregulated in MDA-MB-231-CDDP-R and PC-3-DTX-R cells; however, its expression in HCT-116-CDDP-R cells was markedly lower than that in parental cells. Using siRNA to knockdown SRPK1 expression lead to the re-sensitization of the MDA-MB-231-CDDP-R and PC-3-DTX-R cells to CDDP and DTX, respectively, but this effect was not observed in SRPK1-downregulated HCT-116-CDDP-R cells. Both WB and JC-10 assay demonstrated that co-treatment with CDDP, DTX and SRPK1 specific inhibitor, SPHINX31, remarkably upregulated pro-apoptotic markers (cleavage of caspase-8, caspase-3, and PARP) in MDA-MB-231-CDDP-R and PC-3-DTX-R cells, compared with CDDP, DTX and SPHINX31 alone conditions. Notably, in SRPK1 down-regulated HCT-116-CDDP-R cells, transient transfection of SRPK1 increased the sensitivity of the cells to the cytotoxicity of CDDP. JC-10 assay results also indicated an increase in apoptosis upon CDDP or a combination treatment with SPHINX31 in HCT-116-CDDP-R cells transfected with SRPK1. Moreover, immunoprecipitation assay showed that the level of SRSF1, phosphorylated by SRPK1, was elevated in CDDP and DTX-treated MDA-MB-231-CDDP-R and PC-3-DTX-R cells. Mechanistically, SRSF1 modulates various cancer-related splicing events, particularly the splicing of BCL2L1 and MCL-1. SPHINX31 dramatically promoted the pro-apoptotic Bcl-xS and Mcl-1S isoforms in MDA-MB-231-CDDP-R and PC-3-DTX-R cells as compared to control.
Conclusion: Our research reveals a key role for SRPK1 in chemoresistance by modulation of apoptotic genes splicing, suggesting a potential therapeutic avenue for alleviating challenges posed by chemoresistance.

#4401 Dual regulation of frizzled receptors (FZD1/7) by IGF2BP3: A novel oncogenic event promotes stem-like properties and reduces carboplatin chemosensitivity in Triple-negative breast cancer.

M. Cai, P. Yin, Z. Wang, Y. Huang, Y. Wang, K. Wu, X. Zhang, L. Shi, J. Wei, Q. Ding;
The First Affiliated Hospital with Nanjing Medical University, Nanjing, China

Background: Triple-negative breast cancer (TNBC) is primarily driven by cancer stem cells (CSCs), resulting in treatment resistance after chemotherapy. Emerging evidence suggests that TNBC-CSC transformation is strongly dependent on m6A modification. We aim to characterize the specific m6A regulatory factor in TNBC-CSCs and its underlying mechanism.
Methods: Transcriptome-based screening was used to determine the main m6A regulator in TNBC-CSCs. Mammosphere formation assay and flow cytometry were used to evaluate the role of insulin-like growth factor 2 mRNA-binding protein 3 (IGF2BP3) in regulating stemness in TNBC *in vitro*. Limiting dilution assay was used to assess the CSC frequency *in vivo*. Multi-omics data, including RNA immunoprecipitation sequencing (RIP-seq), Methylated RIP sequencing ((MeRIP-seq) and RNA sequencing data, were integrated to investigate the mRNA targets of IGF2BP3. RNA probes and IGF2BP3 truncations were generated to detect the direct binding location of IGF2BP3 and its target FZD1/7 mRNAs. Comet assay and homologous recomination (HR) assay were used to assess the effect of IGF2BP3 knockdown and FZD1/7 inhibitor, Fz7-21 in combination with carboplatin (CBP).
Results: We demonstrated that IGF2BP3 was the dominant m6A regulator in TNBC-CSCs. Its knockdown increased chemosensitivity and reduced tumor recurrence rate after CBP therapy *in vivo*. Furthermore, IGF2BP3-m6A-FZD1/7 axis might act as a pivotal oncogenic event in TNBC. Stem-like properties, including higher homologous recombination repair (HRR) efficacy and chemoresistance to CBP driven by frizzled receptors 1/7 (FZD1/7), were pharmacologically targeted by a small-molecule inhibitor, Fz7-21. Mechanistic studies unveiled that the RNA-recognition motif (RRM) domain of IGF2BP3 was the functional site to recognize m6A modification on the 3'-terminal of FZD1/7 mRNAs, leading to increased RNA stability. Enhanced stability elevated the expression levels of these two transcripts, leading to FZD1/7 heterodimerization and the activation of β-catenin pathway. This was marked by the nuclear translocation of non-phosphorylated (Ser37 and Thr41) β-catenin.
Conclusions: Our study highlights the critical oncogenic role of IGF2BP3 in promoting stem-like properties and reduces the TNBC sensitivity to CBP treatment. Targeting IGF2BP3 and FZD1/7 with inhibitors has the therapeutic potential to disrupt cancer stemness and reduce clinical drug dosage of CBP in TNBC patients.

#4402 A whole genomic CRISPR-Cas9 screen identifies the LAT3 neutral amino acid transporter as a major determinant of oxaliplatin resistance in colorectal cancer cells.

Nisha R. Pawar, Heidi M. Wade, Allison V. Mitchell, Connor Jewell, Lisa M. Jenkins, Robert W. Robey, Michael M. Gottesman

Center for Cancer Research, Laboratory of Cell Biology, NIH-NCI, Bethesda, MD

Colorectal cancer (CRC) is the second leading cause of cancer deaths, with a five-year survival rate of 65%. Oxaliplatin, developed as a derivative of the DNA-damaging agent cisplatin, is used as an adjuvant therapy for advanced CRC, yet 90% of patients develop resistance. Several mechanisms of oxaliplatin resistance have been proposed, but few are widely accepted. Genome-wide CRISPR activation and knockout screens were conducted to identify genetic changes that confer resistance to oxaliplatin in two CRC cell lines with distinct molecular backgrounds (SW620 and RKO). Guide RNA libraries covering approximately 18,000 human genes were utilized to identify several potential mechanisms of resistance. Guide RNAs corresponding to SLC43A1 (LAT3) were the most significantly enriched in knockout screens and depleted in activation screens, suggesting a potential role for the amino acid transporter LAT3 in oxaliplatin resistance. In vitro CRISPR knockout and overexpression of LAT3 in SW620 and RKO cell lines confirm increased resistance or sensitivity to oxaliplatin, respectively, and this correlated with levels of intracellular accumulation of oxaliplatin, suggesting its potential role as a novel transporter. Further studies to investigate the specificity of this mechanism of resistance to oxaliplatin in CRC and other cancers are ongoing to clarify the molecular basis of oxaliplatin resistance and uncover potential targeted therapeutic strategies for advanced CRC.

#4403 Enhancing chemotherapeutic activity against triple-negative breast cancer cells using induced electric fields.

G. Sarathy[1], S. Dhekni[1], A. M. Roy[1], M. Gatti-Mays[1], V. Subramaniam[2], **E. Shankar**[1];
[1]The Ohio State University Wexner Medical Ctr., Columbus, OH, [2]EMBioSys, Inc, Massachusetts., OH

Triple-negative breast cancer (TNBC), comprising approximately 15% of breast cancers, is particularly aggressive, often metastasizing to organs such as the lungs, brain, and bone marrow, leading to poor prognosis and resistance to therapy. Distant metastasis is responsible for most cancer-related deaths. Anthracyclines and taxanes remain the most active chemotherapeutic agents to treat TNBC, often in combination with immunotherapy. Of the taxanes, paclitaxel is widely used. In this abstract, we describe a novel, non-pharmacological, non-contact (i.e. electrode-free) approach that employs low-intensity, non-ionizing electromagnetic (EM) fields that potentiates standard of care (SOC) chemotherapeutic agents' paclitaxel and capecitabine. Using time-varying magnetic fields to penetrate cell interiors, these induced electric fields (iEFs) selectively alter the actin cytoskeletal machinery in TNBC cells, and significantly reduce their energy required for migration by hampering mitochondrial oxidative phosphorylation through the inhibition of succinate dehydrogenase activity. Importantly, this iEF treatment does not adversely affect normal breast epithelial cells. We show here that iEFs enhance the activity of paclitaxel and capecitabine in inhibiting TNBC growth. Furthermore, combination of anti-migration iEF with cytotoxic paclitaxel or capecitabine is found to hinder migration while also reducing cell viability. Moreover, iEF treatment was instrumental in significantly reducing the IC50 values (half-maximal inhibitory concentration) for paclitaxel (from 13 nM to 6 nM) and for capecitabine (from 1 mM to 0.7 mM) thus potentiating inhibition of cell viability by these cytotoxic agents. RNA sequencing was also performed in the presence and absence of iEF to determine the effect of paclitaxel or capecitabine on gene regulation. The sequencing data revealed that paclitaxel treatment in the presence of iEF upregulated 1058 genes and down regulated 1126 genes when compared to TNBC cells treated with paclitaxel in the absence of iEF. Collectively, our results show that iEF enhances the efficacy of chemotherapeutic agents' paclitaxel and capecitabine in inhibiting TNBC growth, viability, migration in addition to affecting the gene expression pattern. This work represents a critical step in improving current SOC for patients with TNBC for whom there are limited options. (This work is supported by DOD: W81XWH2010065, and Division of Medical Oncology award, OSU for Eswar Shankar)

#4404 BRPF1 inhibition restores chemosensitivity in triple negative breast cancer via ribosomal pathway modulation.

Triple-negative breast cancer (TNBC) is an aggressive cancer subtype lacking targeted therapies, leaving chemotherapy as the primary treatment option. However, acquired resistance to drugs like paclitaxel (Taxol) poses a significant challenge, often driven by complex genetic and epigenetic changes. Our study identifies bromodomain and PHD finger-containing protein 1 (BRPF1) as a critical epigenetic regulator of Taxol resistance in TNBC cells, linking it to ribosome biogenesis and ABCB1-mediated drug resistance. We developed Taxol-resistant TNBC cell lines using an escalating dose protocol. These cells exhibited sustained resistance to high doses of Taxol, accompanied by significantly elevated expression of ABCB1. Epigenome-wide CRISPR/Cas9 screens revealed that BRPF1 is required for the survival of Taxol-resistant cells. Genetic depletion or pharmacological inhibition of BRPF1 using small-molecule inhibitors sensitized resistant cells to Taxol. RNA sequencing and functional assays demonstrated that BRPF1 loss led to the downregulation of ribosomal biogenesis and translation-related genes, impairing global protein synthesis. Notably, BRPF1 was found to directly bind the ABCB1 promoter, regulating the elevated ABCB1 levels. These findings highlight BRPF1's dual role in maintaining translation machinery integrity and modulating ABCB1-driven chemoresistance. In conclusion, our work identifies BRPF1 as a novel therapeutic target for combating Taxol resistance in TNBC. Targeting BRPF1 disrupts ribosome biogenesis and reverses ABCB1-mediated drug resistance, offering a promising strategy to overcome chemotherapy failure in aggressive breast cancers. This work was supported by The Scientific and Technological Research Council of Turkey (TUBITAK) 1003-216S461 and 1001-221S419.

#4405 Annexin A1 regulates lenvatinib resistance through mediating STAT3/S100A6 signaling cascade and M2 macrophage polarization in hepatocellular carcinoma.

Carmen Oi Ning Leung, Catherine Yu Jia Gu, Terence Kin Wah Lee

Applied Biology and Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, China

Hepatocellular carcinoma (HCC) is the sixth most commonly diagnosed cancer and third leading cause of cancer-related deaths worldwide. Lenvatinib has been approved by the FDA for front-line treatment of HCC patients at advanced stages. However, the survival benefit of lenvatinib is modest due to the development of acquired drug resistance. To understand its underlying mechanism, we have established lenvatinib resistant (LenR) HCC patient derived xenograft model (PDTX) via administration of four rounds of lenvatinib and the corresponding tumors from LenR and mock counterparts were analyzed by single cell RNA-sequencing (scRNA-seq). SCENIC analysis revealed that Annexin A1 (ANXA1) is enriched in LenR tumor. This finding was similar in patients with LenR HCC when compared to the sensitive group. An *in vitro* hepatocyte differentiation model showed that the expression of *ANXA1* peaked during the intermediate stages of liver development but was absent in mature hepatocytes but upregulated in HCC tumor tissues, indicating its role in the regulation of cancer stemness in HCC. Further functional analysis showed that ANXA1 drives cancer stem cell-driven lenvatinib resistance, as evidenced by *the in vitro* and *in vivo* limiting dilution and apoptosis assays. Through *in silico* analysis, SOX2 was predicted to be an upstream regulator of *ANXA1*, which was further validated using chromatin immunoprecipitation-qPCR and luciferase promoter assays in LenR and *SOX2*-silenced cells. To investigate potential downstream targets of ANXA1, differential gene expression (DEG) analysis was conducted on *the* $ANXA1^{High}$ and $ANXA1^{Low}$ groups within the LenR tumors. The results revealed S100A6 was the most significantly upregulated gene in the $ANXA1^{High}$ subpopulation, suggesting a possible regulatory relationship between ANXA1 and S100A6 expression. Further GESA analysis of DEGs of *the* $ANXA1^{High}$ to $ANXA1^{Low}$ group further showed that ANXA1 transcriptionally regulates S100A6 mediated through STAT3 activation. Consistently, a positive correlation between *STAT3* and *ANXA1/S100A6* levels was observed in the TCGA-LIHC cohort. Interestingly, ANXA1 secreted from HCC cells also drives cancer stemness and drug resistance in an autocrine manner. Analysis of the same set of scRNA-seq data revealed that tumor microenvironment (TME) in LenR tumors was altered by increasing the M2/M1 ratio of tumor-associated macrophages (TAM). Likewise, enhanced infiltration of M2 macrophages was observed in LenR PDTX and mouse HCC tumors. Using an *in vitro* assay with conditioned media, LenR-HCC-derived ANXA1 induced macrophage polarization towards the M2 phenotype. In conclusion, ANXA1 may regulate lenvatinib resistance intrinsically via the promotion of cancer stemness and extrinsically via reshaping immunosuppressive TME by inducing M2 macrophage polarization.

#4406 Temozolomide-resistant glioblastoma cells promote proteolytic activities of MMPs and PAI-1 to manifest invasive potentials.

H. T. Duong[1], T. H. Nguyen[1], S. Jeong[1], K.-S. Moon[2], C. Jung[1];
[1]Chonnam National University Medical School, Gwangju, Korea, Republic of, [2]Chonnam National University Hwasun Hospital and Medical School, Hwasun, Jeollanam-do, Korea, Republic of

Glioblastoma (GBM) is the most lethal and treatment-resistant tumor among brain cancers. Temozolomide (TMZ) is the standard chemotherapeutic agent for GBM, but the majority of patients experience recurrent tumors, leading TMZ-resistant cells to evade the cytotoxic effects of TMZ and continue to invade surrounding tissues. We have recently reported that transient treatment of high-dose TMZ in GBM cells upregulates matrix metalloproteinases 9 (MMP9), resulting in increased tumor cell migration and invasion through the activation of p38 and JNK MAPK pathways. To confirm potential adverse effects caused by TMZ, in this study, we constructed TMZ-resistant GBM cells through repeated culturing of cells by gradually doubling the TMZ concentration (12.5-300 μM). TMZ-resistant cells were analyzed for proteome profiling, revealing altered expression of several proteases including MMP2/9 and PAI-1. Compared to parental cells, resistant cells showed a significant increase in migration and invasion in vitro and either inhibition of JNK or suppression of MMP9 and PAI-1 dramatically counteracted the invasive potential of resistant cells. At the same time, media collected from TMZ-resistant cells significantly activated the migration and invasion potentials of normal fibroblasts. Further mechanistic studies demonstrated that TMZ-resistant cells retain higher promoter activities of MMP9 and PAI-1 through the regulation of MAPKs and β-catenin/TCF pathways. Since resistance to TMZ in GBM tumors leads to poor treatment outcomes and low survivability for patients, results from our study about potential adverse effects from ensuing TMZ-resistant cells may contribute to these malignant processes of GBM cells.

#4407 Taurine's potential role in tamoxifen resistant MCF-7 cells.

Yazan I. Hamadneh[1], Mohammad Alwahsh[2], Aya Hasan[2], Ala A. Alhusban[2], Osama M. Younis[1], Roland Hergenroder[3], Lama Hamadneh[4]

[1]School of Medicine, University of Jordan, Amman, Jordan,[2]Faculty of Pharmacy, Al-Zaytoonah University of Jordan, Amman, Jordan,[3]Leibniz-Institut fur Analytische Wissenschaften-ISAS-e.V., Dortmund, Germany,[4]Department of Basic Medical Sciences, Faculty of Medicine, Al-Balqa Applied University, Amman, Jordan

Taurine is a non-proteinogenic amino acid synthesized from cysteine. Although taurine does not contribute to protein synthesis, it regulates glutathione metabolism, upregulates proliferative and anti-oxidative pathways, downregulates pro-apoptotic pathways, and improves mitochondrial function in normal tissues. However, the role of taurine in tumorigenesis and resistance development in cancer, especially breast cancer, is not widely understood. We aim to study metabolic and cellular changes associated with the taurine metabolism pathway in tamoxifen resistant (TAM-R) MCF-7 breast cancer cell lines. Methods: Three TAM-R MCF-7 models were developed using two strategies. The first was achieved by incrementally increasing the dose until reaching a predetermined dose (TAM-P). The second was achieved by taking cell lines from the first method and continuously treating them with 1μM of tamoxifen (TAM-C). NMR was used to quantify the levels of intracellular metabolites, and HPLC/MS-MS was used to calculate taurine uptake by the cells from media. Gene expression levels of *ESR1, PI3KCA* and *PTEN* were measured by RT-PCR. GSCA: Gene Set Cancer Analysis platform was used to check the association of a gene set consisting of taurine metabolism pathway genes (*CDO1, ADO, GAD1, GAD2, CSAD*) with the regulation of cancer related pathways. Results: Taurine, choline, and glutathione concentrations were significantly higher in TAM-C compared to tamoxifen-sensitive control and TAM-P, while cystine was lower in TAM-C. Taurine uptake from the media in TAM-C and control were slightly higher than TAM-P. *ESR1* was 40 folds overexpressed in TAM-C and down regulated in TAM-P, while *PI3KCA* was overexpressed and *PTEN* was down regulated in both TAM-C and TAM-P. Moreover, there was a positive correlation between taurine metabolism pathway gene set and activation of ER pathway. Conclusion: The significant increase in taurine and decrease in cysteine in the TAM-C group cannot be explained by the marginal increase in taurine uptake alone, which necessities increased synthesis of the taurine. Overexpression of *ESR1* in TAM-C could be caused by upregulation of the taurine synthesis pathway. However, overexpression of PI3KCA and down regulation of PTEN indicates reliance on *PI3K/AKT/PTEN* pathway instead of estrogen signaling pathway. Moreover, increased glutathione and choline concentrations increased antioxidative capacity, mitochondrial function, and resistance to oxidative stress.

#4408 CRISPR/Cas9 knockout and AI-based drug screening for novel gene targets in ovarian cancer chemoresistance.

Jinjiang Wang[1], Jiaxi Li[2], Jiao Liu[1], Kit-Ying Chan[1], Ho-Sze Lee[1], Zhewei Zhang[1], Joseph Kwong[3], Tat-San Lau[1], Chi-Chiu Wang[1]

[1]The Chinese University of Hong Kong, Hong Kong, Hong Kong,[2]The University of Hong Kong, Hong Kong, Hong Kong,[3]Keele University, Keele, United Kingdom

Introduction: Ovarian cancer, characterized by its heterogeneity and resistance to conventional therapies such as cisplatin (CDDP), presents a significant clinical challenge. To address these challenges, we combined genome-scale CRISPR/Cas9 knockout screening, single-cell-CRISPR Purterb RNA sequencing (scRNA-seq), and AI-driven virtual screening to identify novel chemoresistance mechanisms and evaluate potential therapeutic strategies. This integrated approach aims to reveal genetic determinants and actionable therapeutic targets to improve treatment outcomes.

Methods: We performed genome-scale CRISPR/Cas9 knockout screening in ovarian cancer cell lines treated with CDDP, erastin, and a combination of elesclomol and copper (ES+Cu), identifying genes involved in drug resistance mechanisms. Differential gene candidates will be prioritized based on its strong association with resistance across the drug treatments. AI-based virtual screening will be employed to identify novel drugs targeting the candidates. Additionally, surviving cells from drug treatments will be subjected to scRNA-seq to reveal distinct cell cluster harboring resistance-related gene signatures. We also established ovarian cancer cell lines resistant to CDDP, erastin, and ES+Cu to validate the therapeutic targets and efficacy of the repurposed drugs in both resistant and wild-type cell lines.

Results: CRISPR screening identified several key genes associated with drug resistance, with YTHDC2 emerging as a central target. Pathway analysis highlighted its role in regulating survival and proliferation in the context of drug-induced stress. AI-driven virtual screening pinpointed Proguanil, Calcipotriol, and Sildenafil as high-affinity binders to YTHDC2, suggesting their potential as targeted therapeutics. scRNA-seq analysis of resistant cancer cells identified key gene cluster with GADD45A and ZFAS1 associated with cisplatin resistance. Gene Ontology and STRING pathway analyses revealed their involvement in DNA damage response and apoptosis regulation. Drug-response assays demonstrated that Proguanil, Calcipotriol, and Sildenafil effectively suppressed cell proliferation in the resistant cell lines. These findings support their potential to overcome the chemotherapy resistance.

Conclusion: This study integrates CRISPR-based screening, scRNA-seq, and virtual screening to provide the first comprehensive framework for addressing drug resistance in ovarian cancer. The identification of YTHDC2 as a key resistance-related gene and the validation of Proguanil, Calcipotriol, and Sildenafil as potential therapeutics underscore the translational potential. These findings offer new avenues for precision oncology, with the goal of improving outcomes for ovarian cancer patients.

#4409 Exploring PBX1's role in enzalutamide resistance in advanced prostate cancer.

Ephraim J. Gardner[1], Surendra Gulla[2], Leslie McClinton[2], Jonathan E. Bard[3], Remi Adelaiye-Ogala[2]

[1]Department of Pharmacology and Toxicology, University at Buffalo, Buffalo, NY,[2]Department of Medicine, University at Buffalo, Buffalo, NY,[3]Department of Biochemistry, University at Buffalo, Buffalo, NY

Aggressive prostate cancer (PCa) is often driven by upscaled activity of the androgen receptor (AR), and second-generation AR antagonists such as Enzalutamide have become standard therapeutics for men with advanced PCa. While patients initially respond to treatment, many develop resistance, with disease progression and poor prognosis. We have focused on a mechanism involving an AR cistrome switch from a canonical to a non-canonical cistrome as PCa becomes Enzalutamide-resistant. As collaborating protein partners drive transcriptional activity, we employed core regulatory circuitry analysis in Enzalutamide-resistant PCa cell line models to identify novel Transcription Factor (TF) candidates that may be involved in non-canonical AR cistrome reprogramming. One identified candidate is Pre B-Cell Leukemia Homeobox 1 (PBX1), a TALE homeodomain TF involved in embryonic development and cellular differentiation. PBX1 is known to work with other TFs to modulate gene expression and has been implicated as an oncogenic driver in hematologic and solid cancers, including PCa. Our group has shown that PBX1 is highly expressed in prostate cancer cell line models of castrate- and Enzalutamide-resistance compared to Enzalutamide-sensitive models. Through multi-ome single-cell ATAC + gene expression analysis of a heterogenous patient-derived xenograft (PDX) model, we identified clusters of cells that are enriched for PBX1, AR, and non-canonical AR target CREB5, while simultaneously expressing low levels of KLK3, a prominent canonical AR target. Based on these findings, we hypothesize that PBX1 works in tandem with AR to drive non-canonical AR cistrome and mediate Enzalutamide resistance in advanced PCa. To test this hypothesis, we first determined the impact of silencing PBX1 activity in Enzalutamide-resistant PCa models. By targeting PBX1 pharmacologically in our cell lines and PDX models, we have observed an anti-proliferative effect specifically in a castration-resistant, Enzalutamide-resistant cell line model. This effect was not observed when treating an Enzalutamide-sensitive cell line model, which has low PBX1 expression. Our observations were consistent across several models and our ongoing mechanistic studies will provide further insight into PBX1’s exclusive role in Enzalutamide-resistant CRPC. In addition, we are currently assessing the impact of inhibition or perturbation of PBX1 in Enzalutamide-resistant PCa cell lines and PDX models on canonical and non-canonical AR cistrome activity using multi-omic approaches.

#4410 Targeting MEIS2 in platinum resistant ovarian cancer.

Yinu Wang[1], Natalia Obrochta[2], Junzui Li[3], Daniela Matei[4]

[1]Northwestern University - Chicago, Chicago, IL,[2]Department of Neurobiology, Northwestern University, Chicago, IL, Northwestern University - Chicago, Chicago, IL,[3]Department of Obstetrics and Gynecology, Feinberg School of Medicine, Northwestern University, Northwestern University - Chicago, Chicago, IL,[4]Department of Obstetrics and Gynecology, Northwestern University - Chicago, Chicago, IL

Introduction: Ovarian cancer has the highest mortality rate among gynecological cancers. Relapse of the disease accompanied by chemoresistance is common; however, the biological causes are still unclear. Although initial chemotherapy succeeds in debulking the burden of OC, it promotes emergence of cancer stem cells (CSCs), which are responsible for driving tumor relapse and developing chemo-resistant tumors in OC. *Myeloid Ecotropic Insertion Site 2 (MEIS),* is a homeobox transcription factor (TF), deregulated in various cancers, which plays critical roles in regulating stem cell identity and cell fate decision. Here, we examined the role of MEIS2 in regulating stemness features that promote chemoresistance of OC, and the impact of a MEIS2 blockade on OC initiation and progression.
Methods: Paired isogenic OC cell lines (OVCAR4/5 and COV362 platinum sensitive (Pt-S) and resistant (Pt-R)) were used. MEIS2 expression level in these cells were assessed by q-RT-PCR and Western Blotting. The effects of MEIS2 inhibition (by using a pharmacological inhibitor MEIS2i and biological knockdown (KD) on OC cell survival were assessed using colony formation and cell proliferation assays, and on stemness features by flow cytometry for analysis of ALDH+ cancer stem cell (CSC) population and measurement of stemness-related gene expression. MEIS2 direct binding targets in OC cells, were examined using ChIP-seq. The anti-tumor effects of MEIS2 inhibition on Pt-R OC cells were tested in vivo.
Results: MEIS2 expression levels were increased in Pt-R vs. Pt-S OC cells at mRNA and protein levels. Treatment with MEIS2i (500nM-1μM) reduced the number of colonies in OC cells by at least 2-fold change ($p<0.001$); however, proliferation of cells was not diminished. Treatment with MEIS2i (250nM-1μM, 48 hours) decreased ALDH+ CSCs population by at least ~2-fold ($p<0.05$), and inhibited the expression of stemness associated genes ALDH1A1, ALDH1A3, and Sox2 ($p<0.05$), compared to vehicle control. Knock down of MEIS2 decreased the CSC population from 29.4% to 14.3% ($p<0.05$) and inhibited stemness gene expression ($p<0.05$). MEIS2 knockdown inhibited tumor initiating capacity in vivo. OC xenografts derived from MEIS2 knockdown OVCAR5 cells were more responsive to carboplatin in vivo ($p<0.05$) compared with control xenografts. By integrating ChIP seq and RNA seq, we identified stemness-associated genes, ALDH1A2 and CD44 as direct MEIS2 targets contributing to maintaining stemness and chemo-resistance.
Conclusions: Overexpression of MEIS2 contributes to stemness in OC. MEIS2 blockade inhibited stemness traits that contribute to chemotherapy resistance and tumor relapse. Our results put forward MEIS2 as a potential new target.

#4412 Characterization and targeting of an androgen receptor pre-mRNA stem loop structure to inhibit AR-V7 splicing in prostate cancer.

Marek D. Zorawski, James P. Falese, Riley S. Spingler, Jason A. Somarelli, Andrew J. Armstrong, Amanda E. Hargrove

Duke University School of Medicine, Durham, NC

Alternatively spliced mRNAs can contribute to aggressiveness and resistance to androgen receptor pathway inhibitors (ARPIs) in castration-resistant prostate cancer (CRPC). Among these spliced mRNAs, the androgen receptor (AR) splice isoform AR-V7 participates in AR signaling independent of androgen levels or ARPIs, such as enzalutamide. AR-V7 detection correlates strongly with ARPI treatment resistance and poor patient outcomes in CRPC. AR-V7 incorporates cryptic exon 3 (CE3) within the *AR* gene that prematurely terminates the full-length transcript. While several proteins have been described that may promote splicing of CE3, the impact of the pre-mRNA structures in this region is unknown. Using selective 2′-hydroxyl acylation analyzed by primer extension with mutational profiling (SHAPE-MaP), we developed the first experimentally informed pre-mRNA secondary structure model of the CE3 3′ splice site from cellular RNA. In this structural model, we observe a novel stem loop structure, which we hypothesized could inhibit AR-V7 biogenesis. We used an AR-V7 minigene assay to evaluate structure-modulating mutations in AR-V7 biogenesis and observed concordant changes in AR-V7 abundance in response to stabilization of this repressive structure, leading us to term this structure the cryptic exon 3-splicing inhibitory stem loop (CE3-SISL). Protein binding site identification of the region through the Δ-SHAPE pipeline suggests a repressive protein interaction that may be lost in androgen independence and ARPI resistance. Together, these data suggest the importance of RNA structure in AR-V7 biogenesis and indicate a potentially targetable interface for the development of AR-V7-depleting agents, as we have exemplified using structure-guided antisense oligonucleotides (ASOs) that are able to inhibit AR-V7 splicing during enzalutamide treatment. These ASOs would represent the first RNA structure-targeted splicing modulators being developed for patients with AR-V7-driven CRPC.

#4414 Targeting CCL5 signaling pathway in endocrine resistant breast cancer therapy.

Dominick Lomonaco, **Kideok Jin**

Albany College of Pharmacy & Health Sciences, Albany, NY

Estrogen receptor (ER) is the primary transcription factor driving ~75% of all breast cancers and serves as the target for endocrine therapies. However, resistance to endocrine therapy remains a critical clinical challenge, particularly in metastatic ER-positive breast cancers harboring ESR1 point mutations in the ligand-binding domain, such as Y537S and D538G. These mutations are frequently identified in metastatic tumors and circulating tumor DNA (ctDNA) from patients undergoing endocrine treatment. Despite the efficacy of endocrine therapies combined with CDK4/6 inhibitors, resistance mechanisms and therapeutic vulnerabilities in ESR1-mutated metastatic breast cancer remain poorly understood. Our preliminary studies explored the crosstalk between endocrine-resistant breast cancer (ERBC) cells and stromal cells. By co-culturing seven ERBC cell lines, including genome-edited models of ESR1 mutations, with four stromal cell types, we screened 28 secretome combinations using cytokine antibody arrays. This analysis identified significant upregulation of CCL5 and endoglin in the tumor-stromal microenvironment. We hypothesize that CCL5 mediates endocrine therapy resistance and facilitates the metastatic transition of ERBC cells through interactions with stromal components. To test this, we used CRISPR-Cas9 to generate CCL5 knockout EO771 cells and validated the loss of CCL5 expression via qRT-PCR and ELISA. Functional assays revealed significantly reduced proliferation and migration in CCL5 KO cells compared to wild-type cells. In vivo studies using an orthotopic mouse model demonstrated decreased CCL5 KO tumor growth and metastasis, and treatment with maraviroc (a CCR5 inhibitor) selectively reduced wild-type cell viability. These findings establish CCL5 as a critical regulator of ERBC growth and metastasis, supporting its potential as a therapeutic target. This research provides a foundation for designing clinical trials targeting CCL5-mediated resistance mechanisms in endocrine-resistant breast cancer.

#4415 Nuclear receptor liver receptor homolog-1 (LRH-1) contributes to enzalutamide-resistance in castration-resistant prostate cancer.

Tiantian Gao, Franky Leung Chan

School of Biomedical Science, The Chinese University of Hong Kong, Hong Kong, Hong Kong

Introduction: Prostate cancer is the most common cancer in males worldwide and the second leading cause of cancer-related deaths. Targeting androgen signaling through androgen deprivation therapy (ADT) is an important treatment option for prostate cancer, although the majority of patients eventually progress to castration-resistant prostate cancer (CRPC). Several second-generation anti-androgen drugs including enzalutamide are conventionally used for CRPC patients. However, resistance to potent anti-androgen treatments inevitably develops in prostate cancer patients. Liver receptor homolog-1 (LRH-1, NR5A2) is a member of nuclear receptor super family, which is characterized to be involved in the regulation of steroids, bile acid and cholesterol homeostasis, glucose metabolism and cell proliferation. Our previous study has found that LRH-1 can promote the intratumoral androgen biosynthesis to support the growth of CRPC cells. Meanwhile, our unpublished results showed that LRH-1 was negatively regulated by androgen receptor (AR) signaling pathway, suggesting that LRH-1 expression may play roles in anti-androgen drug resistance, especially in enzalutamide-resistant prostate cancer.
Methods: Prostate cell line 22Rv1 is characterized as an enzalutamide-resistant prostate cancer cell line. CCK8 assay was performed to measure the viability of cells treated with enzalutamide and LRH-1 antagonist (ML180). ChIP-qPCR was performed to validate the potential binding sites of LRH-1 in AR promoter. Luciferase reporter gene assay using constructed reporters driven by different lengths of AR promoter and various LRH-1 variant mutants was performed to validate the activation of AR promoter by LRH-1.
Results: Public dataset analysis revealed that high LRH-1 expression was associated with poor disease-free survival rate. LRH-1 expression was elevated after long-term enzalutamide treatment. We found that knock-down of LRH-1 attenuated cell viability of enzalutamide-resistant cells and LRH-1 antagonist ML180 could reverse the drug resistance in prostate cancer cells. Furthermore, we demonstrated that LRH-1 could bind to and activate AR promoter region and induce AR expression, suggesting a possible mechanism on the occurrence of enzalutamide resistance in CRPC.
Conclusion: LRH-1 could contribute to the induction of enzalutamide resistance in prostate cancer via specific regulation of AR gene. Our results also indicated that targeting LRH-1 could be a potential therapeutic management for enzalutamide resistance in CRPC. (This work is supported by RGC-Granted Research Fund (Project number: 14107623), Hong Kong Research Grants Council.)

#4416 Impact of vaping on FoxM1-mediated chemoresistance mechanisms in lung adenocarcinoma.

Rizwana Begum[1], Shilpa Thota[1], Naveen Chintala[1], Biplov Sapkota[1], Dayanidhi Raman[2], Joseph Francis[1]

[1]Louisiana State University, Baton Rouge, LA,[2]University of Toledo, Toledo, OH

Background and Purpose: E-cigarette usage among students and adolescents is increasingly popular, attributed to appealing flavors, discreet usage, and the perception of being a safer alternative to traditional tobacco. However, this perception is misleading as e-cigarettes carry significant health risks, especially concerning cancer development due to the presence of carcinogenic compounds like formaldehyde, acrolein, nitrosamines, and polyaromatic hydrocarbons found in flavored e-liquids and their aerosols. These xenobiotics may impact DNA repair and cell cycle. FoxM1, a pivotal transcription factor within the forkhead box protein family, regulates genes crucial for DNA repair and cell cycle progression, such as BRCA1, BRCA2, and XRCC1. These genes are instrumental in mediating chemoresistance across various cancers via drug transporters, Wnt/β-catenin, and NOTCH signaling pathways. However, the specific impact of e-cigarette aerosol exposure on FoxM1 activity and subsequent chemoresistance is not well understood. Hence, we hypothesized that exposure to menthol-flavored e-cigarette aerosol would increase FoxM1 expression in lung adenocarcinoma cells, thus enhancing chemoresistance through Wnt/β-catenin and NOTCH signaling pathways.

Methods: The human lung adenocarcinoma cell line Calu-3 was exposed to menthol-flavored e-cigarette aerosol using a Vitrocell® VC10 system, following the CORESTA recommended method No. 81. We quantitatively assessed changes in FoxM1 and its downstream effectors in the Wnt/β-catenin and NOTCH pathways using qPCR, immunoblotting, and immunohistochemistry.

Results: Our results demonstrated a significant upregulation of FOXM1 at both mRNA (> 3-fold) and protein (> 1.5-fold) levels. This upregulation was correlated with increased expression of β-catenin (> 1.5-fold) and enhanced transcriptional activity of c-MYC (> 3-fold) and Cyclin D1 (> 2-fold), critical mediators of Wnt signaling. Furthermore, activation of the NOTCH signaling pathway was confirmed by the upregulation of Mastermind-like (MAML) protein (1.5-fold). Notably, siRNA-mediated knockdown of FOXM1 resulted in the downregulation of Wnt 3a (> 2-fold) and β-catenin (> 1.5-fold) levels, highlighting FoxM1's critical role in mediating the signaling pathways affected by vaping that are intricately linked to chemoresistance.

Conclusion: Our findings suggest that vaping can enhance cancer chemoresistance through the activation of FoxM1 and its downstream signaling pathways. This study contributes to a deeper understanding of how lifestyle choices like vaping can impact cancer treatment outcomes, underscoring the necessity to reevaluate the perceived safety of e-cigarettes.

#4417 Identification of signaling and apoptotic pathway alterations in oxaliplatin resistant HCT116 colorectal cancer cells.

Aliza Jafri[1], Sheerien Rajput[2], Areeb Ahmed[2], **Azhar Hussain Rajabali**[3], Kulsoom Ghias[3]

[1]University of Karachi, Karachi, Pakistan,[2]Centre for Regenerative Medicine and Stem Cell Research, Aga Khan University Hospital - Karachi, Pakistan, Karachi, Pakistan,[3]Biological and Biomedical Sciences, Aga Khan University Hospital - Karachi, Pakistan, Karachi, Pakistan

Background: Chemoresistance remains a significant barrier in colorectal cancer (CRC) treatment, particularly with oxaliplatin, a key first-line chemotherapy agent. This study is therefore aimed to develop an *in vitro* model of oxaliplatin-resistant HCT116 cells and investigate the associated morphological and molecular adaptations to identify potential dysregulated survival and apoptotic pathways that are playing a role in developing chemoresistance.
Methods: HCT116 CRC cells were cultured, and resistance was induced by stepwise oxaliplatin exposure, with recovery phases between treatments. Morphological changes during resistance development were observed using phase-contrast microscopy. Flow cytometry was performed to analyze cell cycle distribution and apoptotic cell populations. Gene expression of key survival pathways, including Wnt/β-catenin, NFκB, and PI3K/Akt, was assessed using qPCR to identify molecular alterations associated with resistance.
Results: Parental HCT116 cells displayed cuboidal morphology, high proliferation (Ki-67 positivity), and epithelial characteristics (moderate E-cadherin and ALDH1 expression). Resistant cells exhibited increased morphological heterogeneity, cell detachment, and features of epithelial-mesenchymal transition (EMT). Flow cytometry revealed a significant reduction in the sub-G1 population and an increase in the G2/M phase, suggesting diminished apoptosis and cell cycle dysregulation in oxaliplatin resistant HCT116 cells as compared to wild type. Gene expression analysis showed a marked upregulation of β-catenin, NFκB, and PI3K/Akt pathway components, coupled with increased expression of EMT markers (Snail, Vimentin) and drug efflux genes (ABCG2, ABCC1) in oxaliplatin resistant cells as compared to wild type HCT116 cells suggesting a role of these survival pathways and genes in induction of resistance.
Conclusion: Oxaliplatin resistance in HCT116 CRC cells is characterized by morphological plasticity, altered cell cycle regulation, and activation of survival pathways, including Wnt/β-catenin, NFκB, and PI3K/Akt. These findings highlight the complexity of chemoresistance and provide a basis for identifying novel targets to enhance treatment efficacy in CRC.

#4418 Epigenetic reactivation of estrogen receptor for treatment of triple-negative breast cancer.

Jer-Yen Yang, Chia-Hua Cheng, Wan-Chi Lu, Yu-Wa Lei, Alice CJ Chang

China Medical University, Taichung City, Taiwan

About 12% of breast cancers are invasive breast cancers, including triple negative breast cancer (TNBC), which manifest early metastasis and recurrence with limited treatment options. Therefore, a better understanding of the molecular mechanisms of TNBC holds the key for effective treatment of TNBC. Tamoxifen, a first line treatment for estrogen receptor (ERα) positive breast cancer, serves as an ERα antagonist by binding to ERα and blocking estrogen receptor signaling to suppress estrogen receptor dependent cancer cells. It is known that estrogen receptor gene (ESR1) is hypermethylated and hence ERα expression is deficient in TNBC. As a result, TNBC cells are highly resistant to tamoxifen, and the strategy used to resensitize tamoxifen response in TNBC has yet to be established.

We have discovered that a DNA demethylation enzyme tet methylcytosine dioxygenase 2 (TET2) plays a critical role in reversing DNA methylation of estrogen receptor gene (ESR1) and thereby enables to reactive estrogen receptor expression in TNBC, resulting re-sensitization of TNBC cells to tamoxifen. It is also reported that a clinically used anti-diabetic drug, metformin, can enhance TET2 protein stability and expression. Therefore, we hypothesize that through TET2-mediated reactivation of estrogen receptor, metformin combined with tamoxifen can synergistically suppress TNBC growth.

To test the hypothesis, we first investigated the effects of vehicle, metformin, tamoxifen, and the combination therapy (metformin + tamoxifen) on cell growth and migration/abilities of TNBC cell lines, MDA-MB-231 and BT549. We then analyzed the effects of the combination therapy on tumor growth and metastasis using a TNBC xenograft mouse model. Furthermore, immunohistochemical staining was used in patient tissue samples to analyze the correlation of TET2 and estrogen receptor expression levels to clinicopathological characteristics. Our data has revealed that metformin-tamoxifen combination therapy significantly inhibits TNBC cell growth compared to the single drug and vehicle treatment groups. Metformin-tamoxifen combination therapy more effectively suppresses TNBC cell migration compared to the single drug and vehicle treatment groups. Furthermore, using Combination Index (CI) and Dose Reduction Index analysis, we have demonstrated that metformin-tamoxifen combination therapy can synergistically inhibit TNBC cell growth compared to the single drug and vehicle treatment groups, where the metformin dose could be reduced by approximately 5-fold, and tamoxifen dose could be reduced by approximately 20-fold.

Together, these findings suggest that metformin-tamoxifen combination therapy could produce a significant synergy, allowing for lowered drug doses and thus reduced toxicity, and provide clinical implications for a novel, effective, and safe TNBC treatment regimen.

#4419 Cancer exosomal microRNAs promote global mRNA 3' end shortening, multidrug chemoresistance, and cancer stemness.
Kenneth K.W. To

School of Pharmacy, Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong

Background and Aim: Multidrug resistance (MDR) is a major cause of failure in cancer chemotherapy. It is commonly caused by efflux of anticancer drugs by ABC transporters including ABCG2. ABCG2 is also a cancer stem cell survival factor to drive cancer recurrence. Preferential production of mRNA isoforms with shortened 3'untranslated region (3'UTR) in cancer is associated with poor drug response. We previously reported that mRNA 3'UTR shortening could trigger ABCG2 overexpression in MDR cancer. Exosomes are cell-derived vesicles that are present in various biological fluids. Tumor-derived exosomes are emerging as important cell-to-cell couriers of oncogenic materials to mediate tumorigenesis. This study investigated the enrichment of specific microRNAs in MDR colon cancer derived exosomes to promote global mRNA 3'UTR shortening and spread chemoresistance.
Method: Exosomes were isolated from a sensitive (S1) or resistant (S1M1-80) colon cancer cell lines conditioned medium by differential centrifugation, denoted as exo/S and exo/R, respectively. The transfer of microRNAs from exo/S or exo/R to a few sensitive colon cancer cell lines was evaluated. The shortening of ABCG2 mRNA 3'UTR in the exosome-donor and -recipient cancer cells was investigated by 3'RACE assay. MicroRNA microarray was conducted to identify differentially expressed microRNAs in drug sensitive cells after incubation with exo/R. Western blot and qPCR analysis were conducted to measure relevant protein and transcript expressions.
Result: By 3'RACE assay, the shortening of ABCG2 3'UTR observed in the exosome donor resistant cells was also detected in the exosome recipient sensitive cells. MicroRNA profiling was conducted on 3 drug-sensitive and ABCG2^{low} colon cancer cell lines (HCT116, SW480, and SW620) incubated with exo/S or exo/R. MiR-1260b was found to be remarkably upregulated in all 3 sensitive cell lines after incubation with exo/R. Intriguingly, the polyadenylation factor PABPN1 was found to be remarkably downregulated in exo/R-treated cells, which was accompanied by higher expression of ABCG2 and a few cancer stem cell markers (DCLK1, LGR5 and BMI1), and shortening of their mRNA 3'UTR. PABPN1 was subsequently confirmed to be a miR-1260b target. MiR-1260b inhibitor was able to reverse the downregulation of PABPN1 in HCT116 cells treated with exo/R, which subsequently suppressed ABCG2 level and reversed the MDR phenotype. Furthermore, while exo/R treated HCT116 form tumorspheres readily *in vitro*, miR-1260b inhibitor effectively reduced tumorsphere formation.
Conclusion: MDR cells-derived exosomes may spread chemoresistance by transferring a miR-1260b/PABPN1/ABCG2 regulatory machinery to sensitive cells. We will set the stage to develop novel therapies aimed at interfering with the master regulators that mediate the microRNA sorting into exosome and mRNA 3'UTR shortening during MDR development.

#4420 Identification of a novel marker gene predicting recurrence after chemotherapy with DNA-damaging agents by using drug-resistant gastric cancer organoids.

Kenji Harada[1], Naoya Sakamoto[1], Shingo Sakashita[1], Motohiro Kojima[1], Kazuaki Tanabe[2], Hideki Ohdan[3], Kohei Shitara[4], Takahiro Kinoshita[5], Genichiro Ishii[6], Wataru Yasui[7], Atsushi Ochiai[8], Shumpei Ishikawa[1]

[1]Division of Pathology, National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Kashiwa, Japan,[2]Department of Perioperative and Critical Care Management, Hiroshima University, Hiroshima, Japan,[3]Department of Gastroenterological and Transplant Surgery, Hiroshima University, Hiroshima, Japan,[4]Department of Gastroenterology and Gastrointestinal Oncology, National Cancer Center Hospital East, Kashiwa, Japan,[5]Division of Gastric Surgery, National Cancer Center Hospital East, Kashiwa, Japan,[6]Department of Pathology and Clinical Laboratory, National Cancer Center Hospital East, Kashiwa, Japan,[7]Department of Molecular Pathology, Hiroshima University, Hiroshima, Japan,[8]Research Institute for Biomedical Sciences, Tokyo University of Science, Noda, Japan

Despite recent advances in gastric cancer therapy, chemotherapy resistance and lack of methods for selecting combination regimens remain major problems. Organoids, which recapitulate the *in vivo* micro-environment, can be established from surgical specimens with a high success rate, and are widely used for drug sensitivity assays. Cancer organoids are also known to contain abundant amounts of cancer stem cells (CSCs), a subpopulation of tumor cells with self-renewal and differentiation capabilities. CSCs are thought to contribute to tumor initiation, metastasis, and acquiring resistance to chemotherapy by altering their phenotype during the treatment.In this study, we aimed to discover a novel biomarker for predicting multidrug resistance using gastric cancer organoids (GCOs), which provide *in vivo*-like culture system that more closely resembles tumor cell organization than traditional cell lines, to understand the mechanism of multidrug resistance in cells, including CSCs, under *in vivo* conditions and to identify novel biomarkers to predict chemoresistance.We evaluated 5-fluorouracil or oxaliplatin-resistant GCOs to find novel biomarkers that reflect multidrug resistance in gastric cancer. To examine the resistance mechanisms, RNA-seq analysis and *ex vivo* drug sensitivity testing were performed. The association of biomarkers with patient prognosis and chemotherapy efficacy was evaluated using three original cohorts with a total of 230 cases. The results were also validated with two independent public cohorts and a single-cell RNA sequence data. Increased expression of *PI3*/Elafin was detected in all 5-fluorouracil or oxaliplatin-resistant GCOs. Our findings suggest a potential association of *PI3*/Elafin expression with ribosome biosynthesis and RNA metabolism under organoid conditions. We also found that *PI3*/Elafin overexpression promotes 5-fluorouracil/oxaliplatin/cisplatin resistance but not paclitaxel resistance. Immunohistochemical evaluation of Elafin expression revealed that the Elafin-positive gastric cancer group had a poorer outcome, especially in terms of time-to-recurrence. Elafin positivity was also an independent predictor of relapse after chemotherapy with DNA-damaging agents. *PI3*/Elafin promotes DNA-damaging drug resistance through multiple downstream regulations related to RNA and ribosomal metabolism. We demonstrated that *PI3*/Elafin contributes to the acquisition of resistance to 5-fluorouracil and platinum drugs in *in vivo*-like environments and identified GOs related to ribosome and RNA metabolism as novel *PI3*/Elafin downstream targets. Our results provide new insights into multidrug resistance mechanisms and highlight *PI3*/Elafin as a novel tool for precise stratification of patients with gastric cancer.

#4421 Chemotherapy-induced DNA damage triggers caspase-dependent degradation of N^6-methyladenosine reader YTHDF proteins, reshaping the cancer transcriptome.

S. Lee, S.-Y. Cho;
Seoul National University College of Medicine, Seoul, Korea, Republic of

N^6-methyladenosine (m6A) modification plays a crucial role in DNA damage response (DDR), which is the primary mechanism targeted by most chemotherapeutic agents. Here, we investigated the dynamic regulation of m6A-related molecules during chemotherapy-induced DNA damage. Anthracycline treatment led to a significant reduction in protein levels, but not mRNA levels, of m6A readers YTHDF1, YTHDF2, and YTHDF3. It was consistently observed with other chemotherapeutic agents, including 5-fluorouracil (5-FU) and oxaliplatin. Notably, this reduction occurred independently of p53 status, as YTHDF proteins remained unchanged upon p53 overexpression alone, while their reduction was still observed in p53-knockout cells treated with doxorubicin. Mechanistic studies showed that the decrease in YTHDF proteins was primarily associated with topoisomerase II inhibition rather than reactive oxygen species (ROS) generation, which are both known mechanisms of doxorubicin. Further investigation revealed decreased protein stability of YTHDFs upon doxorubicin treatment, which was primarily attributed to activated caspase-mediated degradation during apoptosis rather than proteasomal degradation or autophagy. RNA sequencing analysis of YTHDF2-overexpressing cells showed differential enrichment of MYC targets V1, V2 pathway upon doxorubicin treatment, indicating a potential role for YTHDF2 in modulating oncogenic pathways during chemotherapy response. Collectively, our findings unveil mechanisms of m6A reader regulation during chemotherapy and suggest potential therapeutic implications for cancer treatment through manipulation of m6A-mediated gene regulation.

#4422 Targeting MLK4 in herceptin-resistant breast cancer.

Subhasis Das[1], Jingjing Sun[2], Song Li[2], Basabi Rana[3], Ajay Rana[3]

[1]University of Illinois at Chicago, Chicago, IL,[2]Department of Pharmaceutical Sciences, University of Pittsburgh School of Pharmacy, Pittsburgh, PA,[3]Department of Surgery, University of Illinois at Chicago, Chicago, IL

Mixed Lineage Kinases play a significant role in cancer biology, including breast cancer, by influencing key cell proliferation, survival, and metastasis signaling pathways. Targeting MLKs offers a promising therapeutic strategy, especially in cancers with dysregulated MLK activity. We have reported that one of the members of the mixed lineage kinase (MLK) family, MLK3 kinase activity, was necessary to mediate the cytotoxic effect of anti-HER2 therapies (i.e., Herceptin and Lapatinib). Activation of MLK3 using C6-ceramide nanoparticles caused massive cell death and apoptosis in Herceptin-resistant breast tumors. Recently, we observed that another MLK family member, MLK4, was overexpressed in human HER2^{+} breast cancer Herceptin-resistant breast tumors and Herceptin-resistant cancer cell lines, suggesting that MLK4 could play a functional role in developing HER2-therapy resistance. Interestingly, MLK4 gene knockdown in Herceptin-resistant breast cancer cell lines significantly caused cell death and apoptosis. Knockdown of MLK4 in Herceptin-resistant SkBr3 & BT474 cell lines downregulated p-HER2 (Y1221/1222, Y1248), p-AKT (S473), pCDC2 (Y15) and arrested cells in G2-M phase suggesting MLK4 regulates HER2 activation, and cell cycle progression. Overexpressing MLK4 in Herceptin-sensitive cells further activated the HER2-PI3K-Akt pathway, leading to Herceptin resistance. Surprisingly, MLK4 and HER2 endogenously interacted, and an in vitro kinase assay showed that MLK4 phosphorylates the intracellular domain of HER2 at Tyrosine 1221 and 1222 sites (Y1221/2), indicating that MLK4-induced phosphorylation could activate HER2 downstream signaling. Finally, MLK4 knockdown using siMLK4-loaded nanoparticles in an *in vivo* mouse PDX model demonstrated significant tumor regression and apoptosis. These results suggest that MLK4 upregulation is necessary for Herceptin resistance in HER2-positive breast tumors. Considering our *in vitro* and *in vivo* data, we plan to develop a specific inhibitor of MLK4, which could be used clinically to treat Herceptin-resistant HER2^{+} metastatic breast cancer.

#4423 CLL drug resistance- A multifaceted mechanism.

Sutapa Sinha[1], Weiguo Han[1], Zhiquan Wang[1], Brianna M. Finke[1], Heather C. Darby[1], Kari G. Rabe[2], Susan L. Slager[3], Chantal E. McCabe[2], Daniel R. O'Brien[2], Sameer A. Parikh[1], Esteban Braggio[4], Yi Chen[5], Fenlai Tan[5], Stephen P. Anthony[5], Yu Chen[5], Bing Dai[5], Yue Shen[5], Neil E. Kay[6]

[1]Hematology, Mayo Clinic, Rochester, MN,[2]Computational Biology, Mayo Clinic, Rochester, MN,[3]Hematology & Computational Biology, Mayo Clinic, Rochester, MN,[4]Hematology and Oncology, Mayo Clinic, Phoenix, AZ,[5]Newave, Alameda, CA,[6]Hematology / Immunology, Mayo Clinic, Rochester, MN

Despite the advent of novel targeted therapies with high overall response rates, chronic lymphocytic leukemia (CLL) is still largely incurable due to the development of resistance. The bone marrow microenvironment (BMME) plays an important role in the survival and drug resistance in CLL. BM stromal cells (BMSCs) are considered a key component of BMME. Our long-term goal is to gain further insights of BMSCs-CLL crosstalk influencing both survival and drug resistance in CLL. To understand the global biologic changes that occur in leukemic CLL cells when in contact with BMSCs, we assessed RNA-seq in paired CLL cells isolated from untreated blood and BM and in untreated patients' CLL cells cultured alone or with BMSCs. CLL cells from blood/BM and cultured alone/with BMSCs were also examined by Immunoprecipitation (IP), Western blot (WB), untargeted metabolomics (LCMS+GCMS), and preclinical drug sensitivity assays. We detected only 13 upregulated genes that overlap between CLL cells from BM and cocultured with BMSCs (p<0.05, fold change >1.5). When we analyzed the expression of these 13 genes in CLL cells from a cohort of 162 untreated patients by RNA-seq, we found associations between 4 genes (*PNP*, *C16orf54*, *MOB3A*, *CDK2AP2*) and clinical outcomes including overall survival (OS), progression free survival (PFS), and time to first treatment (TTFT) [multivariable Cox proportional hazards models, p<0.05]. Of the 4 genes, purine nucleoside phosphorylase (*PNP*), an enzyme in the purine pathway, had the most significant association with OS, PFS, and TTFT. Metabolomic profiling indicated an increased level of purine pathway metabolites adenosine, adenine, inosine, and hypoxanthine in cocultured CLL cells. WB analysis showed variable baseline PNP protein expression with 2 cohorts: low /no (L) and high (H) PNP using CLL blood cells. An induction in PNP protein levels were noticed in CLL cells expressing only LPNP when cocultured. Given the association of HPNP with adverse clinical outcomes, we tested for L vs. HPNP cohorts drug sensitivity to known BTK inhibitors(is) or Bcl2is. Treatment of CLL cells from untreated patients with Bcl2is venetoclax, S55746, and LP-118 (Bcl2-Bclxli, Newave) showed increased sensitivity to the Bcl2/Bclxlis in HPNP but not in LPNP cells. In addition, BTKis showed no difference in drug sensitivity associated with CLL PNP levels. To explain this discrepancy, WB and IP analyses were conducted in L vs. HPNP leukemic cells for apoptotic profiles, where we found increased phosphorylated-Bcl2(S70) and an increased association of Bcl2 with Bax in LPNP-expressing CLL cells compared to HPNP. These findings support increased resistance to apoptosis afforded by inhibiting Bcl2 for LPNP vs. HPNP-expressing CLL cells. Our future goals are to continue to understand the prognostic significance of the 4 genes with adverse clinical outcomes and to investigate how best to exploit the peculiar, enhanced sensitivity to Bcl2/Bclxlis found in the HPNP CLL cells.

#4424 Heterogeneity in resistance mechanisms found in *KRAS* mutant and wild-type patient-derived organoids with anti-EGFR therapy panitumumab.

Jordan N. Stoecker, Shirsa Udgata, Xingqi Shen, Cheri A. Pasch, Dustin A. Deming

University of Wisconsin-Madison, Madison, WI

Introduction: Tumor heterogeneity plays a major role in the development of resistance to therapies in colorectal cancer (CRC). The epidermal growth factor receptor (EGFR) antibodies, panitumumab (pani) and cetuximab are commonly used for the treatment of CRC. At resistance, very low frequency *KRAS* mutations can be detected by circulating tumor DNA (ctDNA). This raises the question if rare *KRAS* mutant clones can lead to EGFR inhibitor resistance. Here we utilized patient-derived cancer organoids (PDCOs) to investigate the impact of low frequency *KRAS* mutant clones on the development of pani resistance.
Methods: PDCOs were obtained after surgery with patient consent under UW institutional review board protocol. Tissue samples were processed as described previously for PDCOs. Two CRC PDCO lines, with $KRAS^{G12V}$ mutation (KR) and without (WT) were mixed in culture at multiple concentrations (v/v) (100% KR, 100% WT, 20% KR+80% WT, 10% KR+90% WT, 5% KR+95% WT, 1% KR+99% WT, 0.5% KR+99.5% WT, 0.25% KR+99.75% WT). Diameter analysis from day 0 to 4 was completed with increasing concentrations of pani. Once complete resistance to treatment was reached (>20% median growth in diameter under treatment at 100% physiologic C_{max} for two consecutive weeks), PDCOs were collected for bulk RNA-Seq. Differential expression analysis was prepared by UW Madison Bioinformatics Research Core using edgeR. Gene Set Enrichment Analysis (GSEA) was performed on hallmark gene sets.
Results: Despite ≤1% of KR PDCOs present in some populations, mixed conditions escalated to ≥ 40% C_{max} within 10 weeks and reached complete resistance to pani by week 16, while 100% WT culture remained at 20% C_{max} for 22 weeks. GSEA revealed 0.5% KR+99.5% WT condition resulted in ($p < 0.05$) up and downregulation of eight and 22 hallmark pathways (HP), respectively, compared to 100% WT at baseline. Upregulated HP of interest include MYC Targets V1/2 and MTORC1 Signaling, while downregulated HP of interest were KRAS Signaling Up, Apoptosis, and P53 Pathway. Comparing baseline mixed populations to resistant counterparts, the significant upregulation in HP was heterogenous across conditions. Some HP of note were KRAS Signaling Up and Apoptosis. In contrast, the significantly downregulated HP ($p < 0.001$) was relatively homogenous across only the three HP of E2F Targets, G2M Checkpoint, and MYC Targets V1.
Conclusion: PDCO lines containing very low concentrations of resistant clones can lead to significant changes in HP regulation and treatment response. The heterogeneity in HP upregulation in fully resistant mixed populations indicate differing mechanisms of reaching resistance. To confirm these observations, further studies will evaluate the response of more PDCO lines to pani treatment and utilize patient ctDNA collected before and after treatment in clinic to see the effect of the presence of *KRAS* subclones on outcomes.

#4425 Quantum-inspired computing analysis of spatial omics uncovers immune pathways relevant to T-DXd resistance in metastatic breast cancer.

Glori Das[1], Wenjuan Dong[1], Matthew Vasquez[1], Ji-hoon Lee[2], Yuan Gao[3], Jenny Chang[1], Xiaoxian Li[3], Hong Zhao[1], Stephen T. C. Wong[1]

[1]Houston Methodist Neal Cancer Center, Houston, TX,[2]David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA,[3]Department of Pathology and Laboratory Medicine, Emory University School of Medicine, Atlanta, GA

Purpose: Trastuzumab deruxtecan (T-DXd) is a key therapy for HER2+/HER2-low metastatic breast cancer (mBC), but up to 50% of patients develop resistance. Resistance mechanisms have implicated dysfunctions in DNA repair, lysosomal activity, and immune responses. This study combines spatial omics and quantum-inspired regulatory network analysis to investigate tumor-immune-extracellular matrix interactions contributing to T-DXd resistance.

Methods: Using NanoString GeoMX, spatial proteomics were analyzed in 29 metastatic tissue sections from 15 responsive (R) and 14 non-responsive (NR) patients. Across 6-8 regions of interest per section, immune and stromal components were quantified. Additionally, a subset of samples (n = 2R, 2NR) underwent GeoMX whole transcriptomics profiling and analysis using both classical and quantum-inspired algorithms.

Results: NR tumors consistently exhibited immunosuppression, disorganized immune responses, upregulated fibronectin, and poor infiltration of granzyme B-producing cells. Organ-specific findings included:•NR bone and brain mets showed increased spatial correlations between dendritic cells and T-cell exhaustion markers (PD-L1, CTLA4), suggesting niches of immune suppression.•NR bone mets showed increased spatial correlation of fibronectin correlated with immune markers, indicating that stiffer ECM physically blocks immune infiltration. •R chest wall mets showed upregulated smooth muscle actin (SMA), possibly reflecting vascular remodeling and enhanced immune infiltration.

Additionally, spatial transcriptomics analysis revealed the following::•Tumor-associated B cells were identified in NR samples, interacting with exhausted T cells and the Wnt-catenin pathway. •QuantumGRN revealed interactions in immune cells involving RBPP4 with DNMT3A and TAF4, linked to altered chromatin remodeling and transcription regulation, respectively.

Conclusions: This work shows that T-DXd response is heavily influenced by microenvironment remodeling and immune infiltration. This work highlights the value of spatial omics for uncovering ADC-resistance mechanisms, as well as the value of quantum-inspired computing for identifying novel therapeutic targets. In addition to collecting more spatial and single-cell omics data, future directions include pathway validation in animal models and computationally simulating quantum and molecular dynamics of ADC resistance.

#4426 Chromatin constraints underpin adeno-to-squamous cell state transitions during acquired resistance to KRAS inhibition.

Ayushi S. Patel, Samuel Greene, Arianne Parvaresh-Rizi, Gustavo S. Franca, Kwok-Kin Wong, Itai Yanai

NYU Langone Health, New York, NY

The advent of single-cell RNA-seq has permitted a global view of the transcriptomic variation across cancer cells in individual tumors and revealed functionally-related sets of genes - a gene module - underpin a cancer cell state. While single-cell transcriptomic atlases have provided a descriptive characterization of cancer cell states across tumor types, we lack a mechanistic framework on the constraints of tumor heterogeneity. Therefore, we propose a 'developmental constraint' model - where *cancer cell state transitions are restricted by the organism's developmental map, wherein* from the cell-of-origin the malignant cells traverse states that are accessible by its developmental trajectory, both toward progenitor-like states and differentiated-like states of adjacent lineages. Our model posits a constraint on the emergence of states, even under evolutionary pressures such as therapeutic intervention. To test this framework, we modeled non-genetic mechanisms of acquired resistance to KRAS inhibitors - histological adeno-to-squamous transition (AST). Multi-omic analysis of 68 patients enrolled in the KRYSTAL-1 clinical trial revealed a squamous gene signature correlated with a poor response specifically in patients with co-occurring *KRAS*^{G12C};*STK11* (K_CL) mutations. We recapitulated AST upon resistance to KRAS^{G12C} inhibition in K_CL genetically engineered mouse models and tumor-derived organoids. Single-cell transcriptomic and epigenomic of tumor-derived organoid revealed that AST is mediated by a two-step transition - from adeno-like states to an intermediate highly plastic cell state expressing markers of mixed-identity to enriched for squamous-like states. These findings support the developmental constraint model where cell state transitions are mediated by progenitor states in contrast to a trans-differentiation model. Furthermore, we hypothesized that cancer cell state transitions are restricted by the cell's chromatin context and specific chromatin modifiers are required for cell state transitions analogous to development. Therefore, we leveraged a time-course Perturb-seq approach against 191 chromatin modifiers to identify functional requirements for the adeno-to-intermediate and intermediate-to-squamous transition. Using a module-based method, we found cells with perturbations of the SWI/SNF complex (Arid1a, Smarca4 and Smarce1) did not transition to the squamous cell state but were restricted to the intermediate highly plastic cell state, suggesting that the SWI/SNF complex is required for the intermediate-to-squamous transition. Together, we have showed evidence that cell state transitions in cancer may be explained by the developmental constraint model and revealed that these constraints may act at the chromatin level where chromatin modifiers and chromatin states enable AST plasticity during adaptation to KRAS inhibitors.

EXPERIMENTAL AND MOLECULAR THERAPEUTICS: Reversal of Drug Resistance 2
Poster Session

#4430 Combination of IGF1R/InsR and proteasome inhibition shows strong antitumor activity in proteasome inhibitor resistant multiple myeloma.

Andrej Besse[1], Tiberiu Totu[2], Marianne Kraus[3], Max Mendez Lopez[3], Jana Veprkova[1], Ondrej Slaby[1], Marija Buljan[2], Leo Rasche[4], K. Martin Kortum[4], Christoph Driessen[3], **Lenka Besse**[1]

[1]Masaryk University, Brno, Czech Republic,[2]Swiss Federal Laboratories for Materials Science and Technology, St. Gallen, Switzerland,[3]Cantonal Hospital St. Gallen, St. Gallen, Switzerland,[4]University Hospital Wurzburg, Wurzburg, Germany

Background: Overcoming proteasome inhibitor (PI) resistance remains an unmet medical need in multiple myeloma (MM) therapy. Anaplastic Lymphoma Kinase (ALK) inhibitors co-target related tyrosine-kinases, such as InsR and IGF1R. Ceritinib, a second-generation ALK inhibitor, has anti-MM activity in monotherapy or in combination with PI carfilzomib (CFZ). MM cells do not express ALK, but are dependent on InsR/IGF1R to sustain their high metabolic demand. Here, we aimed to identify the mechanism of action of ceritinib and the mechanism of synergy between ceritinib and CFZ in MM cells in vitro, in vivo, and ex vivo.
Methods: PI-naïve and PI-resistant MM cell lines and primary cells were used. Genome-wide CRISPR/Cas9-based screening was performed to identify ceritinib resistance candidate genes. A pam-kinase screening, RNA sequencing and untargeted LC-MS/MS were used to elucidate mechanism of action of treatment combination. RNA-seq data from patients included in the CoMMpass study and from patients treated at the Wurzburg University Hospital were analyzed for InsR and IGF1R expression. An orthotopic in vivo mouse model with PI-resistant cells was used to determine the effect of the drug combination in vivo.
Results: Among several approved ALK inhibitors tested, ceritinib shows the highest synergistic cytotoxicity in combination with CFZ in MM cell lines and primary cells. The combination of ceritinib and CFZ is active in PI-resistant MM in vivo. MM cell lines and primary cells are negative for ALK but positive for InsR and IGF1R expression, which is increased in the relapsed/refractory MM cohort. Kinase screening identified InsR and IGF1R as major kinases inhibited by ceritinib in MM. CRISPR/Cas9-screening identified transcription factor FOXO1, a downstream target of InsR/IGF1R/Akt, as the top resistance candidate to ceritinib. Subsequently, FOXO1 inhibition protected MM cells from ceritinib-induced cytotoxicity. Ceritinib in combination with CFZ caused rapid translocation of FOXO1 to the nucleus, suggesting its activation. Consistently, ceritinib induced the expression of genes related to cell cycle arrest, which are regulated by FOXO1. Ceritinib, by targeting the InsR/IGF1R, impaired glycolysis and amino acid homeostasis, observed as an accumulation of aromatic amino acids. Collectively, ceritinib decreases Akt activity via InsR/IGF1R inhibition, leading to metabolic and proliferative shut-down. In combination with proteasome inhibition, this has a detrimental effect, impairing protein homeostasis and inducing starvation in MM cells.
Conclusion: Ceritinib in combination with carfilzomib represents a promising treatment option for MM to be tested in the clinic.
Support: Supported by the project National Institute for Cancer Research (Programme EXCELES, ID Project No. LX22NPO5102) - Funded by the European Union - Next Generation EU.

#4431 RRM2-driven dNTP biosynthesis: a therapeutic vulnerability in temozolomide-resistant glioblastoma.

Atique U. Ahmed, Karan Dixit, Ella N Perrault, Jack M Shireman, Priya Kumthekar, Roger Stupp. David C James,

Northwestern Univ. Feinberg School of Medicine, Chicago, IL

Glioblastoma (GBM) remains one of the most aggressive and fatal cancers, with a median survival of only 12-18 months despite standard treatments, including surgical resection, temozolomide (TMZ) chemotherapy, and radiotherapy. Tumor recurrence and therapy resistance are significant barriers to improving patient outcomes. To address this, our lab investigated the molecular mechanisms driving resistance during TMZ therapy using a single-cell RNA-sequencing screen on a patient-derived xenograft (PDX) model. This approach enabled us to study tumor evolution pre-, during, and post-therapy. Our analysis identified 149 unique genes expressed during TMZ therapy, with the ribonucleotide reductase (RNR) family, particularly Ribonucleotide Reductase Regulatory Subunit 2 (RRM2), emerging as critical players. During TMZ treatment, GBM cells preferentially utilize RRM1-RRM2 interaction to support deoxynucleoside triphosphate (dNTP) biosynthesis, whereas post-therapy recurrent GBM shifts to RRM1-RRM2B complexes. Functional studies demonstrated that RRM2 knockdown sensitized GBM cells to TMZ, reducing DNA repair capacity, as evidenced by increased yH2AX fluorescence, while RRM1 or RRM2B knockdown conferred resistance ($p<0.001$). Metabolomic profiling revealed that RRM2 mediates dCTP and dGTP production during TMZ treatment, critical for chemoresistance. Supplementation with these dNTPs rescued TMZ susceptibility in RRM2-deficient cells, highlighting its pivotal role in DNA repair and therapeutic resistance. Recognizing the limitations of first-generation RNR inhibitors, we explored the second-generation inhibitor Triapine (3-AP). Preclinical studies showed that 3-AP effectively inhibits RRM2 activity, enhancing TMZ sensitivity and extending survival in PDX models ($p<0.0001$). Mice treated with a combination of 3-AP and TMZ demonstrated significantly longer survival compared to TMZ alone. These findings underscore the potential of targeting RRM2-mediated dNTP biosynthesis to overcome chemoresistance in GBM. We are conducting a Phase 1/1b clinical trial to assess the safety, toxicity, and maximum tolerated dose (MTD) of combining 3-AP with TMZ in recurrent GBM patients.

#4432 mRNA-based restoration of pomalidomide sensitivity in multiple myeloma.

J. U. Ogbede, M. S. Rogers, R. J. D'Amato, B. R. Zetter;
Boston Children's Hospital, Harvard Medical School, Boston, MA

Multiple myeloma (MM) remains an incurable hematologic malignancy, and immunomodulatory imide drugs (IMiDs) have been used as an effective treatment option. A significant challenge with IMiDs such as pomalidomide, as with other treatment options, is the development of drug resistance. This has become a substantial impediment to extending patients' lives. Currently, no effective strategy exists for overcoming IMiD resistance in MM patients. Exploring alternative approaches that could improve the efficacy of pomalidomide might help myeloma patients live longer. Genetic alterations in cereblon (CRBN) contribute to more than one-third of clinical cases of pomalidomide resistance. This study aims to restore sensitivity to pomalidomide-resistant cells through mRNA-based wildtype CRBN restoration. First, we repeatedly exposed multiple myeloma cell lines (MM1.S) to pomalidomide at increasing doses, starting from 2 nM to 10 μM. Following six months of pomalidomide exposure, we generated MM1.S cells that are resistant to pomalidomide and confirmed the absence of CRBN with RNA sequencing and western blotting. Through in vitro transcription, we synthesized CRBN mRNA and electroporated it to the resistant cells. We found restoration of wildtype cereblon and subsequent pomalidomide sensitivity compared to cells without CRBN mRNA treatment. As electroporation is impractical beyond laboratory studies, we are designing a polymer-lipid hybrid nanoparticle to efficiently deliver the mRNA to the cells. Additionally, to ensure targeted delivery of the nanoparticle-coated CRBN mRNA to plasma cells, we applied phage display peptide library screens and identified a cyclic peptide with a high affinity for B-cell maturation antigen (BCMA), a protein known to be almost exclusively expressed by plasma and myeloma cells. This peptide is being validated for BCMA binding, and will be conjugated with the nanoparticle-coated CRBN mRNA for targeted delivery to the malignant plasma cells. Findings from this work will advance mRNA-based therapeutics for overcoming drug resistance caused by genetic alterations in target proteins.

#4433 Effectiveness of USP1 inhibitor (VRTX531) in gynecological cancers with diverse BRCA mutation status.

Uday Kumar Surampudi[1], Prashant Kashinath Bhavar[1], Partha Pratim Sarma[2], Rishi Rahangdale[1], Anuj Ramesh Kshirsagar[2], Appaji Baburao Mandhare[2]

[1]VRise Therapeutics Inc., Cambridge, MA,[2]VeGen Therapeutics, Hyderabad, India

Triple-negative breast cancer and Ovarian cancer are aggressive malignancies often associated with poor prognoses due to their high recurrence rates and limited targeted treatment options. TNBC, which lacks expression of estrogen, progesterone, and HER2 receptors, accounts for 10-15% of breast cancers and disproportionately affects younger women, those with BRCA1 mutations, and certain ethnic groups, such as Black women. Similarly, ovarian cancer is often diagnosed at advanced stages and includes subtypes like high-grade serous carcinoma, which is strongly linked to BRCA1/2 mutations and homologous recombination deficiency. Both cancers share vulnerabilities in DNA damage repair pathways, making them promising candidates for treatments like PARP inhibitors and novel agents targeting DDR mechanisms. However, only 20-40% of the patients benefit from PARPi and are alive 5-years after diagnosis from these gynecological cancers. Ubiquitin specific protease 1 belongs to a group of deubiquitinating enzymes and is a key regulator in the DNA damage repair (DDR) pathway. A deficiency in USP1 results in compromised genomic stability, making it a potential therapeutic target in tumors that exhibit defects in the DNA damage repair mechanism. VRTX531 is a potent, selective, and allosteric oral inhibitor of USP1, specifically designed to target HRD Tumors. Treatment with VRTX531 resulted in decreased viability in cell lines with BRCA1/2 mutations and HRD+ tumors. USP1 inhibitors are anticipated to induce cell death via a pathway distinct from PARPi, and thus have the potential to overcome resistance to PARPi. The synergistic effect of VRTX531 combined with PARPi was demonstrated in cell-based assays representing these gynecological cancers representing BRCA mut, HRD+, MDA-MB-436 and BRCA null, HRD+, UWB1.289. Moreover, VRTX531 exhibited a significant synergistic effect in vitro when used in conjunction with a PARP inhibitor. These results indicate that VRTX531 not only provides substantial monotherapy benefits but also improves the effectiveness of PARP inhibition. The cell viability assay revealed a dose-dependent reduction in cell proliferation, with VRTX531 demonstrating potent anti-proliferative effects which was further confirmed by clonogenic assays. DNA damage was evaluated by γH2AX foci formation which showed a marked increase in DNA damage upon treatment with VRTX531. Our Previous work demonstrated that treatment with PARPi alone led not only to a delayed onset of response but also showed statistically significant variability between subjects, in contrast the combination of VRTX531 and PARPi led to rapid onset of response, followed by complete tumor regression with an TGI >98%, in a TNBC Xenograft of MDA-MB-436. USP1 inhibitor VRTX531, exhibits best-in-class pharmacokinetics, with exemplary safety profile, that supports its further development.

#4434 Ficerafusp alfa reverses acquired resistance to the KRAS-G12C inhibitor sotorasib in KRAS-G12C-mutated lung tumors.

Veena Somasundaram[1], Shiv Ram Krishn[1], Reshmi Nair[1], Pradip Nair[1], **Rachel L. Salazar**[2]

[1]Syngene International Ltd., Bengaluru, India,[2]Bicara Therapeutics Inc., Boston, MA

Approximately 15% of non-small cell lung cancer patients present with a KRAS-G12C mutation and do not respond to anti-Epidermal Growth Factor Receptor (anti-EGFR) therapy[1]. Recent approvals of KRAS-G12C inhibitors (G12Ci) such as sotorasib (AMG510) and adagrasib have improved treatment responses and overall survival rates[2]. One of the mechanisms associated with acquired resistance and subsequent relapse after prolonged treatment with G12Ci is linked to overexpression of TGF-β[3]. Increased TGF-β is associated with immune suppression and epithelial-mesenchymal transition (EMT), contributing to increased metastasis[3,4]. Ficerafusp alfa, a bifunctional antibody targeting EGFR and TGF-β within the tumor microenvironment, may enhance treatment efficacy when combined with G12Ci by overcoming drug resistance.

Lung cancer cell lines NCI-H1792 (KRAS-G12C$^{+/-}$) and NCI-H1373 (KRAS-G12C$^{-/-}$), both characterized by high EGFR and TGF-β levels, were cultured with sotorasib for over 6 weeks to induce resistance. Resistant NCI-H1792 cells were treated with sotorasib, cetuximab (anti-EGFR antibody), ficerafusp alfa, or their combinations. Treatments were assessed in 2D culture and 3D spheroid-PBMC co-cultures, measuring cytotoxicity and gene expression changes via Nanostring analysis (in 2D model). Additionally, sotorasib-resistant NCI-H1373 cells were used in a subcutaneous xenograft model to evaluate treatment efficacy *in vivo*.

Results demonstrated that combining sotorasib with ficerafusp alfa showed better efficacy over sotorasib alone and sotorasib in combination with cetuximab in sotorasib-resistant NCI-H1792 tumor cells *in vitro*. Additionally, in the 3D spheroid-PBMC co-culture assay, our combination reduced overall spheroid area. Nanostring analysis showed downregulation of TGF-β signalling, EMT, and metastatic pathways in the sotorasib and ficerafusp alfa group compared to sotorasib plus cetuximab. *In vivo*, TGF-β ELISA analysis revealed higher TGF-β levels in sotorasib-resistant NCI-H1373 tumors compared to the parental tumors. The combination of sotorasib with ficerafusp alfa resulted in a significant reduction in sotorasib-resistant NCI-H1373 tumors over sotorasib in combination with cetuximab.

This study reinforces the hypothesis that TGF-β plays an important role in acquired resistance to G12Ci. Our findings suggest that combining G12Ci with ficerafusp alfa could overcome G12Ci drug-resistance in KRAS-G12C-mutated lung cancer.

#4435 PRAME-mediated retinoid resistance is overcome by EZH2 inhibition in keratinocyte carcinoma.

Brandon Liam Ramchatesingh[1], Ivan V. Litvinov[2]

[1]Research Institute, McGill University Health Centre, Montreal, QC, Canada,[2]Division of Dermatology, McGill University Health Centre, Montreal, QC, Canada

Retinoids have exhibited efficacy as treatments and prophylactics for both types of keratinocyte carcinoma (KC): basal cell carcinoma (BCC) and cutaneous squamous cell carcinoma (cSCC). However, the practical efficacy of these compounds is limited by retinoid resistance mechanisms. Preferentially Expressed Antigen in Melanoma (PRAME) is a cancer-testis antigen ectopically expressed in a subset of BCC and cSCC tumors. In gametes, PRAME binds Enhancer of Zeste Homologue 2 (EZH2), an epigenetic silencer, selectively targeting transcriptional repression to retinoic acid response elements (RARE) in gene promoters. The functions and therapeutic relevance of PRAME expression in KC tumors have not been investigated. A combination of transcriptomic analyses, 2D and 3D cell culture approaches were undertaken to evaluate the contributions of PRAME to KC pathogenesis and treatment response. Pharmacological retinoid sensitization strategies were also investigated. Epidermal differentiation and cytokine signaling pathways were downregulated in high PRAME-expressing tumors and in PRAME overexpressing (OE) cell lines. Conversely, low-PRAME tumors and PRAME depleted cell lines exhibited an enrichment of epidermal differentiation and cytokine signaling gene signatures. PRAME OE impaired epidermal differentiation in 3D organotypic skin culture models. Additionally, PRAME OE impaired RARE activation and conferred resistance to retinoid-induced growth suppression. PRAME depletion restored RARE activation and restored retinoid-induced growth suppression. Mechanistically, PRAME was determined to abrogate the anti-keratinization effect of retinoid treatment in SCC cells and organoid models. PRAME also abrogated the cell death promoting effect of retinoid treatment in BCC cells. Targeting of EZH2, using pharmacological or genetic strategies, in combination with retinoid treatment, resulted in a selective repression of cell growth in KC cell lines. Similar effects were observed when performing co-treatments using cell lines representative of cutaneous melanoma and lung squamous cell carcinoma. This study illustrates potential roles for PRAME in modulating differentiation programs and demonstrates a role for PRAME in conferring resistance to retinoid-based therapeutics. Furthermore, this study offers a preclinical demonstration of a drug repurposing strategy including retinoid compounds and EZH2 inhibitors to suppress the growth of PRAME-expressing cells.

#4436 Mechanistic insights into CXCR7 activation and resistance pathways in EGFR-Mutant NSCLC with mesenchymal phenotype.

Kaajal Rengaraj[1], Laura C. Gunder[1], Ines Pulido[1], Jeffery H. Becker[1], Frida Pantoja[1], Jennifer Graeber[2], Malek G. Massad[2], Takeshi Shimamura[2]

[1]University of Illinois Chicago, Chicago, IL,[2]Surgery, University of Illinois Chicago, Chicago, IL

EGFR tyrosine kinase inhibitors (TKIs) have significantly improved outcomes for NSCLC patients with EGFR mutations. However, resistance inevitably develops, with the T790M mutation identified in over 50% of resistant tumors, alongside mechanisms like MET amplification, SCLC transformation, and Epithelial Mesenchymal Transition (EMT). Osimertinib, a third-generation EGFR TKI approved for first-line treatment, specifically targets the T790M mutation and mitigates T790M-related resistance. Despite this, non-T790M resistance mechanisms, including mesenchymal transformation, are increasingly prevalent. Our group previously reported that the atypical GPCR CXCR7 is critical for EGFR TKI resistance associated with a mesenchymal phenotype. CXCR7 activates the MAPK and PI3K pathways when mutant EGFR receptors are inhibited, offering alternative survival pathways. Although CXCR7 plays a pivotal role in drug resistance with a mesenchymal phenotype, the precise mechanisms underlying its activation remain unclear. Profiling cytokine-chemokine secretion from gefitinib-resistant HCC4006GeR cells identified elevated levels of CXCL12, MIF, and chitinase-3 like-protein-1 (CHI3L1). Exposure of HEK293 cells ectopically overexpressing CXCR7 to canonical CXCR7 ligands, CXCL12 and MIF, activated the MAPK pathway within 30 minutes. We found that CRISPR depletion of CXCR4 in HEK293 cells abrogated MAPK activation following exposure to CXCL12 and MIF. In contrast, HCC4006-CXCR7 cells lacking CXCR4 required eight hours for CXCL12 and MIF to activate MAPK in the presence of osimertinib. Notably, exposure of HCC4006-CXCR7 cells to CXCL12 and MIF in the absence of EGFR TKI failed to augment the MAPK signal. We discovered that CXCR7 co-immunoprecipitated with constitutively active mutant EGFR in NSCLC cells, and this association ceased upon EGFR inhibition. Thus, dissociation of CXCR7 from mutant EGFR appears to be a prerequisite for MAPK activation. Additionally, we identified CH3L1 as a previously unrecognized chemokine capable of activating MAPK in HCC4006-CXCR7 more effectively than CXCL12 or MIF. CXCR7 activation increased the expression of TWIST, ZEB1, and ZEB2, essential for maintaining the mesenchymal phenotype. Depletion of CXCR7 in HCC4006Ge-R cells with a mesenchymal phenotype led to the attenuation of these transcription factors, a mesenchymal-to-epithelial transition, and restoration of EGFR TKI sensitivity. Collectively, these findings reveal a unique ligand-induced mechanism of CXCR7 activation and downstream MAPK pathway modulation by putative ligands. This complex CXCR7 activation mechanism in EGFR-mutant NSCLC suggests that preventing receptor-ligand binding may not be a viable strategy for overcoming EGFR TKI resistance.

#4437 Pimitespib (TAS-116), an HSP90 inhibitor, overcomes resistance to androgen receptor pathway inhibitors in prostate cancer by simultaneously targeting several key resistance mechanisms.

Hiromi Muraoka, Kazuhisa Minamiguchi, Akihiro Hashimoto, Hiroshi Sootome, Shuichi Ohkubo

Taiho Pharmaceutical Co., Ltd., Tsukuba, Japan

Background: Resistance to androgen receptor pathway inhibitors (ARPIs) poses a significant challenge in the treatment of metastatic castration-resistant prostate cancer (mCRPC). Key mechanisms driving ARPI resistance include androgen receptor (AR) overexpression, AR mutations, AR splice variants such as AR-V7, alternative glucocorticoid receptor (GR) signaling, and activation of the AKT pathway. Heat shock protein 90 (HSP90), a molecular chaperone essential for stabilizing several of the key proteins involved in these resistance-related mechanisms, has emerged as a compelling therapeutic target. Pimitespib (TAS-116), an HSP90 inhibitor approved in Japan for the treatment of gastrointestinal stromal tumors, holds potential for addressing ARPI resistance by disrupting these mechanisms through the inhibition of nuclear translocation and protein destabilization of AR and related factors.
Materials and Methods: The effects of pimitespib were assessed in four human prostate cancer cell lines (LNCaP, VCaP, 22Rv1, and SAS MDV No.3). Cell proliferation was assessed using intracellular ATP measurements. Western blotting and quantitative reverse transcription polymerase chain reaction were used to analyze protein and gene expression levels of resistance markers, including AR, AR-V7, GR, AKT, as well as their downstream transcriptional targets. Subcellular localization of AR and GR was examined using Western blotting. Antitumor efficacy was evaluated in two castration-resistant prostate cancer (CRPC) xenograft models (LNCaP-Xeno-IL-6 and VCaP).
Results: Pimitespib enhanced the efficacy of three ARPIs (enzalutamide, darolutamide, and abiraterone) in the four prostate cancer cell lines. Mechanistic analysis revealed that pimitespib rapidly inhibited nuclear translocation of AR and GR within 1 h of treatment. Additionally, pimitespib reduced the protein levels of AR, GR, AR-V7, and AKT, effectively reversing ARPI resistance. Gene expression analysis showed that pimitespib downregulated AR, AR-V7, and GR target genes. In the CRPC xenograft models, pimitespib potentiated the antitumor effects of the ARPIs, resulting in enhanced inhibition of tumor growth. Combination therapy using pimitespib with enzalutamide was well-tolerated, with no significant increase in toxicity.
Conclusion: Pimitespib effectively addresses ARPI resistance in mCRPC by rapidly inhibiting AR and GR nuclear translocation and reducing the protein levels of AR, GR, AR-V7, and AKT. In addition, our findings highlight the potential of combining pimitespib with ARPIs for the treatment of mCRPC patients who have progressed on ARPI therapy.

#4438 Role of USP1 in overcoming chemoresistance Independent of BRCA mutation status.

Uday Kumar Surampudi[1], **Prashant Kashinath Bhavar**[1], Partha Pratim Sarma[2], Anuj Ramesh Kshrisagar[2], Rishi Rahangdale[1], Appaji Baburao Mandhare[2]

[1]VRise Therapeutics Inc., Cambridge, MA,[2]VeGen Therapeutics, Hyderabad, India

The efficacy of chemotherapeutic agents like Cisplatin is often limited by DNA repair mechanisms, including the PARP and USP1, that regulates DNA damage response proteins. In this study, we explore the effects of USP1 inhibition, both alone and in combination with a PARP inhibitor, on DNA repair and cell survival following Cisplatin treatment. Our experiments were conducted in a variety of cell lines, irrespective of their BRCA mutation status, to understand the broad applicability of this therapeutic strategy. Cells were treated with Cisplatin to induce DNA damage, followed by treatment with VRTX531 a USP1 inhibitor and/or a PARP inhibitor assessed by in vitro cell based assays such as cell viability, γH2AX foci formation, and comet assay. Inhibition of USP1 resulted in impaired repair of Cisplatin-induced DNA damage, leading to increased sensitivity to subsequent PARP inhibition, regardless of BRCA mutation status. The combination treatment synergistically enhanced cell death, as evidenced by a significant reduction in cell proliferation and an increase in DNA damage markers. These findings suggest that targeting USP1 in combination with PARP inhibition may be a promising therapeutic strategy to overcome chemoresistance, providing a potential treatment approach for tumors with or without BRCA mutations. Further investigation into the mechanistic underpinnings of this combination therapy is warranted to optimize its clinical application.

#4439 Adaptive rewiring after prolonged KRAS inhibition sensitizes PDAC cells to sequential targeting with ferroptosis inducers.

Tina Kos, Christian Schneeweis, Shinjini Bandopadhyay, Birgit Prinker, Chen Zhao, Dieter Saur

Chair of Translational Cancer Research and Institute of Experimental Cancer Therapy, Klinikum rechts der Isar, School of Medicine, Technische Universitat Munchen, Munich, Germany, Munich, Germany

Recent advances in direct targeting of oncogenic KRAS necessitate the need to understand and overcome intrinsic and extrinsic resistance mechanisms of cancer cells, especially in pancreatic ductal adenocarcinoma (PDAC) with KRAS as the main oncogenic driver. To investigate time-dependent KRAS resistance, we created a dual-recombinase PDAC mouse model that allows for inducible genetic deletion of $Kras^{G12D}$ *in vivo* and *in vitro*. A drug screen on primary PDAC cell lines derived from the model that were resistant to $KRAS^{G12D}$ inhibition identified a strong RSL3-induced ferroptosis sensitivity of $Kras^{G12D}$-depleted cell lines compared to their $Kras^{G12D}$-proficient counterpart. Inhibitors MRTX1133 and RMC-6236 also conferred ferroptosis sensitization in various mouse and human PDAC cell lines. Interestingly, ferroptosis sensitization was stronger after 7-day treatment with KRAS inhibitor, compared to acute inhibition of 1-3 days, indicating that exhaustive rewiring of cellular pathways is needed for complete sensitization. This was also evident in the transcriptome analysis of cells at different time-points after $KRAS^{G12D}$ depletion revealing temporary and chronic adaptations spanning various metabolic, proliferative and stress-associated pathways, several of which were previously linked to ferroptosis. $Kras^{G12D}$-depleted cells exhibited higher ROS, higher iron ion content, and lower capacity to reduce ROS based on redox ratio of intracellular glutathione. Intriguingly, the sensitized phenotype was maintained in resistant cells treated with MRTX1133 over a period of 30-45 days, suggesting a stable phenotype that could be exploited in a clinical setting using sequential therapy approach. To better understand which genes are essential for viability of $Kras^{G12D}$-depleted cells, we performed a whole-genome CRISPR knock-out screen on cell line with $Kras^{G12D}$-depletion (genomic and inhibitor-based), as well as with additional RSL3 treatment. Kras-depletion screen identified several ferroptosis-associated regulators among the top depleted and enriched genes, including redox balance regulators (Slc7a11, Txnrd1, Keap1, Nadk), iron homeostasis (Ttc7, Glrx5) and KRAS-resistance-associated pathways (Taz, Map3k7). Machine learning algorithm applied on RNAseq of differentially sensitized cell lines revealed a signature of genes whose expression is altered based on sensitivity to RSL3. These, together with global changes in transcriptome, suggest that multiple pathways likely contribute to ferroptosis sensitization, including KEAP-NRF2 redox balance pathway, iron and lipid metabolism, and also hint at involvement of TGFβ-EMT signaling axis. Our results suggest that a sequential two-hit therapeutic approach with KRAS inhibition followed by subsequent ferroptosis induction could efficiently mitigate resistance to KRAS-inhibitor based therapies in PDAC.

#4440 The efficacy of NST-628, a non-degrading pan-RAF/MEK molecular glue, and MEK inhibitors for overcoming acquired osimertinib resistance mediated by TRIM24-BRAF fusions in EGFR mutant NSCLC.

Alvaro Guimaraes Paula, Ximeng Liu, David Molkentine, Monique Nilsson, Junqin He, John V. Heymach

UT MD Anderson Cancer Center, Houston, TX

In patients with EGFR-mutant non-small cell lung cancer (NSCLC), acquired resistance to EGFR tyrosine kinase inhibitors (TKIs) can be driven by novel gene fusions. Among these, acquired fusions in the BRAF gene occur in approximately 2% of osimertinib resistant cases. Based on paired molecular profiling of biopsies from a patient with classical EGFR exon 19 deletion (del19) NSCLC, taken pre and post osimertinib treatment, we identified a novel BRAF fusion, TRIM24-BRAF, and hypothesized that this aberration played a causal role in osimertinib resistance. To test this hypothesis, we transfected HCC827 and HCC4006 EGFR mutant NSCLC cell lines to express TRIM24-BRAF fusion variants using lentivirus vectors and performed a 3 day cell viability assay to assess the impact of these fusions on sensitivity to osimertinib. Expression of TRIM24-BRAF fusions resulted in an IC50 of at least 100 times higher as compared to the parental cell lines, confirming that TRIM24-BRAF fusions are sufficient to induce EGFR TKI resistance. To further evaluate the mechanism, we performed Western blot analysis, which revealed that that osimertinib blocked EGFR phosphorylation in both parental cell lines and cells expressing the TRIM24-BRAF fusion variants. However, osimertinib inhibited MEK phosphorylation only in the parental cell lines, but not in those expressing the TRIM24-BRAF fusions, indicating that cells expressing the TRIM24-BRAF fusion had sustained activation of signal transduction pathways downstream of EGFR after osimertinib treatment. Next, we utilized a panel of compounds targeting the RAS/RAF/MAPK pathway including agents targeting pan-RAS (RMC-6236 and RMC-7977), SHP2 (RMC-4550), BRAF (dabrafenib, encorafenib, tovorafenib and vemurafenib), pan-RAF (TAK-632), MEK (binimetinib, cobimetinib, selumetinib and trametinib), pan-RAF/MEK (NST-628) and assessed whether targeting signal transduction molecule downstream of EGFR could overcome this adaptative resistance mechanism. Our data indicated that trametinib, a MEK inhibitor, and NST-628, a non-degrading pan-RAF/MEK molecular glue, were the most effective against cells expressing TRIM24-BRAF fusions. Moreover, cell viability assays combining osimertinib either with trametinib or with NST-628 showed an addictive effect among all the different TRIM24-BRAF variants and a synergistic effect in some. TRIM24-BRAF expressing cells showed minimal sensitivity to BRAF, SHP2 or RAS targeting single agents. Taken together, our findings indicate that expression of TRIM24-BRAF fusion induce osimertinib resistance in EGFR mutant NSCLC and targeting the MEK pathway using trametinib or NST-628 can overcome osimertinib resistance in this setting.

#4441 Specific OXPHOS inhibitors can overcome chemoresistance of triple negative breast cancer.

C. Uslu[1], E. Kapan[1], E. Abad[2], A. Lyakhovich[1];
[1]Sabanci Universitesi, Istanbul, Turkey, [2]Universitat Pompeu Fabra, Barcelona, Spain

Recently, we and others have shown that drug-resistant malignancies are characterized by higher levels of mitochondrial oxidative phosphorylation (OXPHOS) compared to chemotherapy-responsive tumors. Specifically, we used cisplatin- and cyclophosphamide-resistant triple-negative breast cancer cells and corresponding xenograft models to show that the chemoresistant phenotype is characterized by a higher oxygen consumption rate and higher metastatic potential compared to its chemosensitive counterpart. We hypothesized that OXPHOS inhibitors may resensitize chemoresistant cells to anticancer therapy. Given the endosymbiotic origin of mitochondria from alphaproteobacteria, we analyzed OXPHOS inhibitors among hundreds of antimicrobial agents and selected several that specifically target chemoresistant cancer cells. Experiments in nude mice confirmed the efficacy of these compounds against tumors derived from chemoresistant cells. In addition, we performed proteomic profiling and identified several mechanisms of action of these chemicals, including enhancement of oxidative stress, induced mitophagy, and suppression of metalloproteinase activity. Furthermore, we confirmed the synergistic effects of individual antibactericidal drugs and chemotherapeutic agents and suggest that this alternative approach should be considered for the treatment of OXPHOS-dependent chemoresistant tumors.

#4442 Drug resistant humanized PDX platform: Clinically relevant *in vivo* modeling of innate and acquired resistance within human immune environment.

Jie Wen, Hao Cheng, Cheng Zhang, Bingrui Han

PharmaLegacy LLC, Shanghai, China

Cancer treatment has been facing many hurdles, drug resistance is one of the most significant one among them. Over the years, treatment strategies have been evolving. A complex interaction between intrinsic (innate) and extrinsic (acquired) factors enables the survival of selected cancer cells, through progression under unfavorable conditions, ultimately develop resistance. Although numerous prospective drugs against cancer have been shown promising therapeutic efficacy on preclinical *in vitro* and *in vivo* models, only a few have been proven safe and effective in clinical validations. These problems are largely due to the lack of precise research tools to reveal the genuine status of cancer especially to recapitulate cancer resistance development in real-world patients. Patient derived xenograft (PDX) models have been shown superiority in reflecting the characteristics of cancer patients by retaining genomic information, diversified treatment backgrounds and clinical behaviors, all of these features make PDX an excellent *in vivo* system to study drug resistance, evaluate drug sensitivity and better treatment regimens. However, due to the low tumor engraftment rate and difficulty to reconstitute proper human immune system, only a few studies published about drug resistant humanized PDX model. The current study describes the successful establishment and validation of two drug-resistant humanized PDX models: a HER2 ADC resistant gastric PDX demonstrating clear innate resistance, and a multidrug resistant (MDR) melanoma PDX showing acquired resistance to targeted therapies, immune check point inhibitors (ICIs) and ionizing radiation. The gastric PDX model with HER2 expression confirmed by IHC (2+) shown limited response (TGI <10%) to trastuzumab deruxtecan and no response to Dxd, demonstrating a clear intrinsic resistance. In a separate study in hPBMC mice, significant tumor growth inhibition was achieved (TGI > 60%) when treating with anti-hPD1, implicating the clinical benefit of combining ICIs with ADC treatments. The MDR melanoma PDX model was derived from a patient with treatment history of initial surgical resections, followed by targeted therapies (VEM+COB) then ICIs when recurrence happened. The tumor shown limited response to BRAF inhibitor (TGI <15%) and completely abolished response to anti-hPDL1, anti-hPD1 and ionizing radiation in humanized mice with averaged hCD45% > 30%. We have successfully established and characterized several drug resistant PDX models particularly in humanized mice, making it possible to study interactions between human tumors and immune system, identify biomarkers and better clinical strategies to overcome drug resistance. This platform can be used to achieve personalized medication management, which is the ultimate translational goal.

#4443 Targeting the mutual regulation between EZH2 and FADS2 to suppress ovarian cancer by synergistic inhibition of Notch signaling and mitochondrial function.

Zhengyang Guo, Xiao Huo, Ying Song, Jiagui Song, Yang Bai, Tong Liu, Lixiang Xue

Peking University Third Hospital, Beijing, China

Ovarian cancer (OC) is the most aggressive and lethal gynecological cancer associated with abnormal lipid metabolism. Enhancer of zeste homolog 2 (EZH2), the catalytic subunit of the polycomb repressive complex 2, is overexpressed in OC and other various cancers. It functions as a tumor promoter through canonical H3K27me3 modification and non-canonical ways, and is considered as a potential anticancer target. Although numerous EZH2 inhibitors have been developed and tested in clinical trials, the therapeutic effect of EZH2 inhibitors on solid tumors is still very limited. Here, we report that EZH2 bi-directionally regulates transcription of fatty acid desaturases 2 (FADS2) transcript variant 1 (v1) and 2/3 (v2/3) in canonical and non-canonical ways respectively. FADS2 is considered the rate-limiting enzyme in the synthesis of long chain polyunsaturated fatty acids (PUFAs). The transcript v1 encodes the full-length isoform, and v2/3 encodes the shorter protein predicted to lack the desaturase activity. EZH2 deficiency increased FADS2 v1 and decreased v2/3 at mRNA and protein level. In fact, the transcriptional start site for FADS2 v2/3 is located about 12 kb upstream of v1. EZH2 occupied at the promoter of FADS2 v1 and v2/3, but the enrichment of H3K27me3 at v2/v3 promoter was significantly lower than that at v1 promoter. These data indicate that EZH2 inhibits FADS2 v1 transcription by catalyzing H3K27me3, and promotes FADS2 v2/v3 transcription in a non-canonical way. In most OC cell lines tested, FADS2 v2/3 was dominant at the protein level compared to v1, which may be due to the advantage in protein stability of v2/3. EZH2 inhibitors reversed the FADS2 expression pattern by especially upregulating FADS2 v1, and increased PUFA abundance in OC cells. In reverse, targeting FADS2 by shRNA or inhibitor impaired EZH2 level and Notch signaling, resulting in suppressed cell proliferation and increased sensitivity to EZH2 inhibition. Proteomics analysis revealed that SDHD (succinate dehydrogenase complex subunit D, a subunit of mitochondrial complex II) was one of the most down-regulated protein under the combined treatment of FADS2 and EZH2 inhibitors. The combined treatment suppressed mitochondrial function and activated AMPK signaling, leading to inhibition of protein synthesis and cell cycle arrest. Furthermore, we found that combined targeting EZH2 and FADS2 induced synergistic inhibition of Notch signaling and mitochondrial function, and enhanced the therapeutic effect of OC in vitro and in vivo. In conclusion, this study reveals the regulation between EZH2 and FADS2, and provides a novel potential therapeutic strategy for ovarian cancer.

#4444 Targeting eIF4F-mediated translation to reduce T cell exhaustion and enhance PD-1 blockade efficacy in melanoma.

Samad Muhammadnejad[1], Monireh Kazemimanesh[1], Naima Benannoune[1], Sandrine Agoussi[1], Cecile Badoual[2], Louis Vaquier[2], Helene Lecourt[1], stephan Vagner[3], **Caroline Robert**[1]

[1]INSERM U981 (Gustave Roussy), Villejuif, France,[2]Pathology, Gustave Roussy, Villejuif, France,[3]Institut Curie, Orsay, France

Background: The eukaryotic initiation factor 4F (eIF4F) complex is essential for the selective translational control of protein expression enabling cells to rapidly adapt to diverse stimuli. We previously identified an eIF4F/STAT1/PDL1 axis in melanoma cells. The effectiveness of cancer immunotherapy, particularly immune checkpoint inhibitors (ICIs) or tumor-infiltrating lymphocytes (TILs)-based adoptive therapy, is hindered by resistance mechanisms associated with the terminal exhaustion of T cells. Here, we investigate the role of eIF4F in the translational control of immune checkpoints (ICs) and associated transcription factors in both circulating T cells and TILs from melanoma patients, aiming to reveal potential connections between eIF4F-mediated translational regulation and T cell exhaustion.
Methods: Polysome profiling was conducted on both circulating lymphocytes and TILs isolated from 10 melanoma specimens. We examined the expression of various activation/exhaustion markers by FACS, assessed T cell functions and determined cytokine secretion profiles. These experiments were performed with and without inhibition of the eIF4F-dependent translation using three different inhibitors of the eIF4A helicase (eIF4A-i: silvestrol, EFT226 and RBX0901). The effects of eIF4A-i combined with PD1 blockade were assessed in ex-vivo co-cultures, organotypic models and three syngeneic murine cancer models of melanoma and colon cancer.
Results: Key negative immune checkpoints and transcription factors including TOX, NFAc2, CTLA-4, LAG3, and TIM3 are regulated by eIF4F in TILs and can be efficiently downregulated by eIF4A-i.. Notably, the factors controlled by eIF4F in circulating $CD8^+$ T cells differ from those in TILs emphasizing the importance of patients' tumor-derived samples. TILs proliferation is increased by eIF4A-I in vitro. Co-culture experiments with TILs and syngeneic melanoma cells along with organotypic melanoma models, showed enhanced melanoma killing by TILs when anti-PD1 was combined with eIF4A-i. Additionally a synergistic effect of eIF4A and anti-PD1 was observed in the three immunocompetent murine models tested.
Conclusion: Our findings unveil a previously unrecognized role of eIF4F in orchestrating the translational regulation of key proteins driving T cell exhaustion. This study is the first to demonstrate that targeting eIF4F with eIF4A inhibitors not only downregulates exhaustion markers but also synergistically enhances the efficacy of anti-PD-1 therapy across multiple models, including human TILs and murine cancer systems. This novel insight underscores the immense therapeutic potential of combining eIF4A inhibitors with ICIs to overcome resistance mechanisms and reinvigorate anti-tumor immunity.

#4445 Super-enhancers reorganization controls re-sensitization of oxaliplatin-resistant FBXW7-mutated colorectal cancer.

V. Tolotto[1], N. Gualandi[1], R. Picco[1], Y. Cortolezzis[1], F. D'Este[1], M. Colitti[1], W. W. Hancock[2], C. Brancolini[1], L. Xodo[1], E. Di Giorgio[1]; [1]University of Udine, Udine, Italy, [2]University of Pennsylvania, Philadelphia, PA

The resistance of cancer to therapies remains an unresolved issue. It may result from tumor evolution, which is characterized by epigenetic plasticity and large-scale chromatin remodeling. Catalytically inactive class IIa HDACs (HDAC4, HDAC5, HDAC7, HDAC9) control the targeted recruitment of chromatin remodeling complexes, making them attractive therapeutic targets in oncology. Recently, we have described the role of HDAC4 in monitoring the assembly of the end resection complex involved in homologous recombination (HR) repair. In cells defective for HR repair, HDAC4 is proteasomally degraded. Here, through *in silico* and *in vitro* screenings we identified FBXW7 as the E3 ligase involved in proteasomal degradation of HDAC4, and its role was confirmed by means of ubiquitin co-immunoprecipitation experiments and *in vitro* ubiquitylation assays. FBXW7 is a tumor suppressor gene encoding the substrate recognition component of an SCF ubiquitin ligase complex. It is one of the most frequently mutated genes in colorectal cancer (CRC), and loss of function of FBXW7 has been reported to induce resistance to chemotherapeutic agents such as oxaliplatin (OxPt), which is commonly used in adjuvant therapy for CRC. We confirmed that *FBXW7-/-* CRC cells were resistant to OxPt treatment and HDAC4 was not degraded under these conditions. Silencing or forced degradation of HDAC4 using a PROTAC-based compound restored OxPt sensitivity in *FBXW7*-mutated CRC cells, in patient-derived organoids (PDOs) and in a xenograft model in mice. By evaluating the transcriptomic landscape and super-enhancer (SE) repertoire status in FBXW7-mutated PDOs, we demonstrated the relevance of epigenetic resetting in controlling OxPt resistance. In particular, forced downregulation of HDAC4 resulted in dramatic loss of SEs in FBXW7-deficient tumors and restoration of certain SEs found in OxPt-sensitive tumors. Furthermore, patient profiling based on the epigenetic state of SEs controlled by HDAC4 identified a priori CRC patients resistant to OxPt. This study supports HDAC4 as a key mediator of OxPt resistance in FBXW7-mutated CRC and highlights the remodeling of a well-defined repertoire of SEs as part of the process of successful re-sensitization.

#4446 Collateral drug screening throughout the evolution of osteosarcoma drug resistance.

Gabriel Mandel, **Elizabeth Nowak**, Jarrel Imamur, Kristi Lin-Rahrdja, Mina Dinh, Masahiro Hitomi, Jacob Scott, Zachary Burke

Cleveland Clinic, Cleveland, OH

Introduction: Osteosarcoma is the most common primary malignant bone tumor in childhood. Advancements in therapy have been stagnant for over 40 years and the prognosis for osteosarcoma remains challenging. The 5-year relative survival rate of localized osteosarcoma is 75%. If disease is metastatic upon diagnosis or first line therapy fails, survival rate falls to approximately 25%. First line therapy consists of alternating cycles of methotrexate with doxorubicin and cisplatin (MAP). In contrast, second line therapy is not standardized, and outcomes after salvage therapy remain poor. Identifying better second line agents may be an avenue to successful salvage therapy. Cancer is a dynamic state and can be viewed through an evolutionary framework. When cancer cells are exposed to chemotherapy, resistant cells may be selected for and proliferate. These resistant cells may exhibit a different resistance/sensitivity profile to other therapy options, termed collateral changes. By correlating these collateral changes with genomic and transcriptomic data, we can theoretically develop a library of gene/gene expression markers that correlate with resistance or sensitivity to a panel of drugs.

Methods: We have exposed an osteosarcoma cell line, MG63.3, in cell culture to a clinically relevant sequential therapy that models MAP. 5 evolutionary replicates were exposed to combination cisplatin and doxorubicin, followed by methotrexate. 3 control replicates were exposed to solvent without drug. Once cells returned to confluency after each exposure to chemotherapy, we performed drug assays to a panel of 16 second-line drugs and drug combinations, in addition to radiation therapy, and extracted DNA/RNA from each replicate.

Results: As a result of this work, we created a heatmap displaying the development of sensitivity and resistance to this treatment panel, based on the change in half maximal effective concentration (EC50) over time and have found variable collateral changes indicating timepoints in which cells are significantly more sensitive or resistant to second line agents as our evolutionary replicates evolved resistance to frontline therapy.

Conclusions: This heat map can serve as a springboard for transcriptomic and genomic analyses to correlate the changes with resistance and sensitivity. This may allow future researchers to correlate our findings with patient derived genomics and transcriptomics to ultimately choose better second line therapeutics for patients who do not respond to MAP therapy.

#4447 Autophagy inhibition overcomes resistance to FLT3 inhibitors in *FLT3*-ITD acute myeloid leukemia models.

Manuela Albuquerque de Melo[1], Diego A. Pereira-Martins[2], Brunno G. S. Macedo[1], Priscila S. Scheucher[1], Joao A. Machado-Neto[3], Fabiola Traina[1]

[1]Department of Medical Images, Hematology, and Oncology, University of Sao Paulo at Ribeirao Preto Medical School, Ribeirao Preto, Brazil,[2]Department of Experimental Hematology, Cancer Research Center Groningen, University Medical Center Groningen, Groningen, Netherlands,[3]Department of Pharmacology, Institute of Biomedical Sciences, Sao Paulo, Brazil

Autophagy has recently been postulated as a potential mechanism that may contribute to the development of resistance to FLT3 inhibitors (FLT3i). Our aim was to investigate the role of pharmacologic autophagy inhibition in enhancing the efficacy of FLT3i in the *FLT3*-ITD acute myeloid leukemia (AML) resistant model and its impact on the survival and molecular response to FLT3i. In MOLM13 and MV4-11 (*FLT3*-ITD mutated cell lines), the administration of FLT3i first (midostaurin) or second (quizartinib) generation significantly elevates autophagic flux by inducing the formation of acidic vesicular organelles visualized by flux cytometry. We also observed a reduction in negative autophagy regulators, evidenced by the inhibition of AKT (p-Ser473), mTOR (p-Ser2448), and its downstream protein p70S6K (p-Thr421/Ser424), as well as a reduction of ULK1 (p-Ser757) by western blot assay. FLT3i treatment resulted in the conversion of LC3B-I to LC3B-II, accompanied by the degradation of LC3B-II and p62, indicating autophagy induction. The combination of FLT3i with autophagy inhibitors chloroquine (CQ), bafilomycin A1 and ROC-325 significantly reduced cell viability and survival in comparison with vehicle and monotherapies in vitro in MOLM13 and MV4-11 cells and ex vivo in primary cells from bone marrow of FLT3-ITD AML patients. To elucidate the role of inhibition of autophagy in FLT3i-resistant cells, we generated MV4-11 cells resistant to quizartinib (MV4-11 QR) trough selective pressure and we noted that MV4-11 QR cells exhibited a higher basal level of autophagy compared to conventional MV4-11 cells, as indicated by the increased formation of acidic vesicular organelles, and confirmed by the reduced expression of LC3B and p62 proteins. In MV4-11 QR cells, we observed that CQ effectively reduced the IC50 of quizartinib and increased FLT3i-induced apoptosis, suggesting its use to mediate resistance to FLT3i in AML. We also observed an increased molecular effect of quizartinib when associated with CQ, manifested by a significant increase in Cleaved-Caspase3 and a reduction of STAT5 (p-Tyr694) and P70S6K in comparison with vehicle and quizartinib monotherapy. The combination of quizartinib with CQ showed a strong synergistic effect in the resistant lineage demonstrated by a ZIP score value = 10.8, while in the non-resistant lineage it demonstrated an additive effect (ZIPscore = 8.4), suggesting that CQ is autophagy-dependent and has its effect potentiated in conditions of high autophagic flux, as observed in MV4-11 QR, being effective, mainly, in conditions of resistance generated by the induction of autophagy. In conclusion, FLT3i induces autophagy flux, limiting drug inhibitory activity, and autophagy inhibition can enhance the antileukemic effect of FLT3i and reverts cellular resistance. Analysis of the autophagic profile in AML can play a crucial role in individualized treatment.

#4448 Novel tyrosine kinase/MEK inhibitor combinations impair the viability and invasive potential of TNBC cell lines.

Celia Asdih[1], Ariane Lehmann[2], Jasmin Traichel[1], Eva Oswald[3], Julia Schueler[3], Rhena Klar[4], Patrick Metzger[4], Melanie Boerries[4], Tilman Brummer[1], Ricarda Griffin[1]

[1]Institute of Molecular Medicine and Cell Research, University of Freiburg, Freiburg, Germany,[2]Institute of Medical Bioinformatics and Systems Medicine, University of Freiburg, Freiburg, Germany,[3]Charles River Discovery Research Services Germany GmbH, Freiburg, Germany,[4]Institute of Medical Bioinformatics and Systems Medicine, Faculty of Medicine, Medical Center-University of Freiburg, Freiburg, Germany

This study demonstrates that the tyrosine kinase inhibitors ALW-II-41-27 and ponatinib enhance the efficacy of MEK inhibition in multiple TNBC cell lines, suggesting potential for combination therapy. This project aimed to identify compensatory mechanisms triggered by MAPK inhibitors (MAPKi) in TNBC and to develop novel treatment strategies to effectively block these mechanisms. To this end, we performed a conditioned medium (CM) experiment in which we identified secreted cytokines as potential mediators of drug resistance. We then performed a cytokine array and receptor tyrosine kinase (RTK) array to identify the cytokines and RTKs implicated in this process. Finally, we targeted some of these previously identified RTKs in combination with trametinib and tested the efficacy of the combination on the viability of 11 TNBC cell lines. Two combinations were tested for further experiments to characterize their efficacy and mechanism of action, including colony forming assay, transcriptomic analysis and wound healing assays. We identified several cytokines secreted in response to the pan-Raf inhibitor CCT196969, the MEK inhibitor (MEKi) trametinib and the ERK inhibitor (ERKi) ulixertinib such as FGF-basic, FGF-19, MIF and angiogenin. CM from drug treated cells induced the activation of several RTKs such as FGFR1, FGFR3, Insulin-R, ALK and DTK in untreated TNBC cells. To validate the significance of these upregulated RTKs, we used a panel of kinase inhibitors. This led us to identify two synergistic combinations: trametinib with the EPHA2 inhibitor ALW-II-41-27 and trametinib with ponatinib, which targets multiple RTKs, including EPHA2. These combinations demonstrated efficacy in other TNBC cell lines over a longer period and, notably, prevented cell re-growth even after an additional eight days without treatment. This was in contrast to trametinib single treatment, where cells resumed growth under similar conditions. Our transcriptomic analyses of the combination treatment with trametinib and ALW-II-41-27, either singly or in combination, across a panel of cell lines revealed significant pathway alterations. Notably, we observed increased *HER2* and *HER3* transcription following trametinib treatment, which we could confirm at the protein level by Western blotting. Lastly, the trametinib/ALW-II-41-27 combination revealed a significant reduction in cell migration and invasion compared to trametinib treatment alone. These findings indicate that ponatinib and ALW-II-41-27 combined with MAPKi could be a promising novel therapeutic approach for TNBC.

#4449 SIRT5 promotes chemoresistance through metabolic rewiring for nucleotide replenishing in refractory triple negative breast cancer.

Z. Ren[1], K. Kurmi[2], T. Bernasocchi[1], E. Zaniewski[1], S. Joshi[2], G. Lam[1], C. Guo[1], I. Smidt[1], P. Dave[1], A. Maccio[1], J. Kreuzer[1], G. E. Gioia[1], V. I. Bossuyt[1], B. N. Dontchos[1], G. X. Wang[1], S.-H. S. Chou[1], M. Lawrence[1], E. Rheinbay[1], L. M. Spring[1], W. Haas[1], R. Mostoslavsky[1], M. C. Haigis[2], L. W. Ellisen[1];

[1]Massachusetts General Hospital/Harvard Medical School, Boston, MA, [2]Harvard Medical School, Boston, MA

Drug resistance is the leading cause of neoadjuvant chemotherapy (NAC) failure to achieve pathological complete response (pCR) in more than 40% of patients with triple negative breast cancer (TNBC). Thus, understanding the potential drug resistance mechanisms in TNBC patients is a critical unmet clinical need. Using quantitative high-throughput metabolomic and proteomic approaches, we systematically analyzed clinicopathological, metabolic, and proteomic data profiled from NAC treatment-naive biopsy samples derived from primary TNBCs. Particularly, we identified that non-pCR TNBC primary tumors are uniquely and highly enriched in metabolic pathways for the TCA cycle and oxidative phosphorylation (OXPHOS) along with nucleotide metabolism relative to pCR TNBC tumors. In addition, sirtuin 5 (SIRT5) as a master regulator of mitochondrial metabolism is dramatically increased in non-pCR TNBC primary tumors. Of note, we found that SIRT5 is frequently overexpressed in TNBC tumors due to copy number gain and amplification. Furthermore, metabolomics and ^{13}C-glucose tracing uncovered that SIRT5 gain of function promotes chemoresistance by diverting TCA cycle intermediates into the pentose phosphate pathway (PPP) for nucleotide replenishing. Moreover, SIRT5 knockout restores chemosensitivity to TNBC cells. We anticipate that blocking SIRT5-mediated metabolic rewiring may reverse chemoresistance in refractory TNBC patients.

#4450 Targeting KEAP1/NRF2 signaling sensitizes KRAS-driven NSCLC to KRAS inhibitors.

Xianwen Yang, Peiling Ren, Guiping Li, Ying Yu, Guangxiu Dai

HUTCHMED, Shanghai, China

The emergence of KRAS G12C inhibitors has paved the way for new therapeutic approaches in NSCLC patients with KRAS mutations. However, the efficacy of these inhibitors has been limited in NSCLC based on clinical trial results. Numerous studies have uncovered that the co-occurrence of additional mutations, particularly in KEAP1 and STK11, is associated with a poorer prognosis for KRAS G12C-mutated NSCLC patients. KEAP1 is a negative regulator of the NRF2 signaling pathway. KEAP1 mutations lead to constitutive activation of NRF2, thus promoting tumor growth and drug resistance. In this study, we employed siRNA technique to specifically target NRF2, and found that targeting NRF2 could be a promising therapeutic approach to improve the efficacies of KRAS inhibitors in NSCLC. Firstly, we compared the basal mRNA and protein levels of NRF2 between cell lines with and without KEAP1 mutation. The results showed that the basal mRNA levels were comparable across 5 cell lines including A549, H2122, HEK293, H292 and LoVo. Only A549 and H2122, two cell lines with KEAP1 mutation, expressed high NRF2 protein levels. This observation aligns with the established mechanism that KEAP1 mutation leads to the accumulation of NRF2 through a protein degradation-repression manner. Furthermore, luciferase reporter assay demonstrated that NRF2 transcription was activated in A549 and H2122 in comparison to HEK293. Accordingly, the expression of NRF2 downstream genes, such as *AKR1B10* and *AKR1C1*, was relatively higher in KEAP1-mutated A549 and H2122 cells than in KEAP1-intact cells. To investigate the impact of NRF2 knockdown on cell proliferation, siRNA was performed in A549 and H2122 cells. The knockdown efficiency was verified through qRT-PCR and western blot analysis. The results revealed that knockdown of NRF2 could significantly inhibit cell growth in both A549 and H2122 cells. To ensure that the inhibitory effects of NRF2 knockdown were not limited to the two cell lines, we conducted an analysis of NRF2 dependency in NSCLC using the Depmap database. The results indicated that KEAP1/NRF2 pathway-activating mutations could predict NRF2 dependency in NSCLC, even in the broader context of lung cancer. Moreover, two downstream genes of NRF2, *AKR1B10* and *AKR1C1*, were observed down-regulated in A549 and H2122 cells post NRF2 knockdown. Finally, we assessed the combined effectiveness of NRF2 knockdown and KRAS inhibitors in the A549 and H2122 cells. The results demonstrated that silencing NRF2 could significantly improve the responsiveness of both the pan-KRAS inhibitor RMC-6236 and the KRAS G12C inhibitor Sotorasib in A549 and H2122 cells. Taken together, our study demonstrates that knockdown of NRF2 can enhance the effectiveness of KRAS inhibitors in treating NSCLC patients with KEAP1 mutations. This finding provides the scientific foundation for developing combination therapy strategies that target both NRF2 and KRAS to improve patient outcomes.

#4451 Stabilization of checkpoint kinase 1 by the lncRNA HOTAIR promotes PARP inhibitor resistance in high-grade serous ovarian cancer.

Yanchi Zhou, Kenneth P. Nephew

Indiana University Bloomington, Bloomington, IN

Poly (ADP-ribose) polymerase inhibitors (PARPis) are an important treatment modality for homologous recombination deficient (HRD) cancers, including high grade serous ovarian cancer (HGSOC). PARP mediates DNA single-strand break (SSB). PARPis trap PARP at the site of SSB and prevent DNA SSB repair, which eventually leads to double-strand DNA breaks (DSBs). DSBs are normally repaired through the HR pathway, and PARPis are highly efficient in HRD disease. However, the majority of HGSOC are HR proficient (HRP), and the use of PARPis for patients with HRP tumors represents an unmet therapeutic need. The long non-coding RNA (lncRNA) HOX transcript antisense RNA (HOTAIR) is frequently over-expressed in HGSOC and contributes to chemoresistance. We examined the role of HOTAIR in the response to PARPis in HRP and HRD HGSOC cell lines. Knockout or siRNA knockdown of HOTAIR sensitized ($p<0.05$) HGSOC cell lines to PARPis (olaparib, talazoparib). HOTAIR upregulated the expression of checkpoint kinase 1 (CHK1), a key kinase involved in DNA damage response. Treatment with talazoparib (5μM, 72hrs) increased ($p<0.05$) expression of CHK1, while HOTAIR depletion with paired CRISPR gRNAs decreased ($p<0.05$) CHK1 activation by PARPi. In contrast, overexpression of HOTAIR enhanced ($p<0.05$) talazoparib-induced activation of CHK1. It has been reported that CHK1 inhibition converted PARPi-insensitive cells to PARPi-sensitive cells and, furthermore, that CHK1 interacts with the DNA repair protein RAD51 which was necessary to promote the reversal of stalled replication forks and protect the reversed fork from degradation. Thus, we hypothesized that HOTAIR contributes to PARPi resistance in HGSOC cell lines by regulating CHK1 and CHK1-mediated replication forks stabilization and DNA damage response. We demonstrated that RAD51 expression was reduced ($p<0.05$) in HOTAIR depletion cells treated with talazoparib, while overexpression of HOTAIR increased ($p<0.05$) talazoparib-induced activation of RAD51. In addition to a role in replication stress, CHK1 and RAD51 contribute to DNA damage repair through the HR repair pathway. To further examine the role of HOTAIR in DNA damage repair, we examined the effect of PARPi on DNA damage using the comet assay. In HOTAIR overexpressed HGSOC cells, PARPi-induced DNA damage was reduced ($p<0.001$), based on comet tail moment. As no effect of HOTAIR on CHK1 transcription was observed, we investigated the mechanism of HOTAIR regulating CHK1 by using the cycloheximide chase assay and assessing CHK1 protein stability. HOTAIR depletion increased ($p<0.05$) degradation of CHK1, and HOTAIR overexpression stabilized CHK1 protein. Collectively, these findings suggest that HOTAIR contributes to CHK1 stabilization, promotes replication fork protection and DNA damage repair in HGSOC and in turn HOTAIR contributes to PARPi resistance, regardless of HR status.

#4452 Targeting matrix metalloproteinase-3 to reverse chemotherapy resistance in high-grade serous ovarian cancer.

Victor G. Reyes-Burgos[1], Marienid Flores-Colon[1], Eliud Hernandez-O'Farrill[2], Luis E. Vazquez-Quinones[3], Pablo E. Vivas-Mejia[1]

[1]Biochemistry, University of Puerto Rico School of Medicine, San Juan, Puerto Rico,[2]University of Puerto Rico School of Pharmacy, San Juan, Puerto Rico,[3]Sciences and Technology, Interamerican University, Arecibo, Puerto Rico

High-Grade Serous Ovarian Cancer (HGSOC) remains the most aggressive and lethal gynecological malignancy, with most patients developing resistance to platinum-based chemotherapies. Matrix Metalloproteinase-3 (MMP3), an enzyme involved in extracellular matrix remodeling, has been implicated in this resistance. Prior work in our lab demonstrated that MMP3 is overexpressed in chemotherapy-resistant ovarian cancer cell lines, including the cisplatin resistant cells, OVCAR3CIS and A2780CP20, compared to their sensitive counterparts, OVCAR3 and A2780, respectively. Our team previously showed that knockdown of MMP3 with small interference RNA (siRNA) reduce cell growth and invasion of cisplatin-resistant ovarian cancer cells. We have progressed toward therapeutic applications by developing small molecule inhibitors (SMIs) to target MMP3. Bioinformatics was used to select potential MMP3 inhibitor candidates starting with a library of 370,000 compounds. Cell viability assays showed that four out of 30 preselected SMIs significantly reduced cell viability in cisplatin resistant cell lines. Further evaluation in combination therapy revealed promising results, as pre-treating cisplatin-resistant HGSOC cells with SMIs resensitized the cells to cisplatin treatment. These findings provide compelling evidence that MMP3 inhibition can restore chemotherapy sensitivity in resistant HGSOC cells, offering a promising dual-therapy approach. This research represents a significant advancement in developing novel therapeutic strategies to overcome chemotherapy resistance and improve outcomes for HGSOC patients.

#4453 Glucagon-like peptide-1 receptor agonists target the HIF1α-PFKFB3 pathway to enhance Lenvatinib efficacy and overcome resistance in hepatocellular carcinoma through the reversal of the Warburg effect.

Takayuki Noma[1], Yuan Li[1], Yuma Wada[2], Katsuki Miyazaki[2], Yuji Morine[2], Mitsuo Shimada[2], Ajay Goel[1]

[1]Molecular Diagnostics and Experimental Therapeutics, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Department of Surgery, Tokushima University, Tokushima, Japan

Background: Glucagon-like peptide-1 receptor agonists (GLP1RAs), originally developed for diabetes and obesity treatment, have recently gained attention for their potential anti-tumor effects. However, the mechanisms underlying these effects remain largely unexplored. Given their emerging role in improving metabolic conditions such as fatty liver disease and liver cirrhosis, we hypothesized that GLP1RAs could also target cancer-specific metabolic pathways, a potential that is yet to be fully understood. Hepatocellular carcinoma (HCC), characterized by metabolic reprogramming, including enhanced glycolysis, consequently contributes to chemotherapy resistance and malignancy. This study evaluates the anti-tumor potential of GLP1RAs in HCC, focusing on their ability to reverse the Warburg effect by inhibiting key glycolytic pathways, thereby improving therapeutic outcomes.
Methods: A comprehensive series of experiments was conducted using GLP1RAs and Lenvatinib, including cell proliferation, apoptosis, and glycolysis assays. Genes involved in metabolic pathways were screened using PCR analysis, with key targets identified and validated through Western blotting. Metabolic reprogramming was assessed using Seahorse XF analysis and lactate assays to measure extracellular acidification rate and lactate production. Additionally, the synergistic effects of GLP1RAs and Lenvatinib were evaluated to determine their combined therapeutic potential.
Results: The combination of GLP1RAs and Lenvatinib demonstrated synergistic effects, suppressing cell proliferation and enhancing apoptosis in Lenvatinib-resistant cell lines. PCR screening and subsequent validation revealed that Lenvatinib resistance was associated with enhanced glycolysis via the HIF1α-PFKFB3 pathway. GLP1RAs treatment significantly inhibited the HIF1α-PFKFB3 pathway, reducing ECAR and lactate production. By reversing the Warburg effect, GLP1RAs suppressed glycolysis and exerted potent anti-tumor effects.
Conclusion: GLP1RAs target the HIF1α-PFKFB3 pathway and significantly enhance the anti-tumor efficacy of Lenvatinib by reversing the Warburg effect in Lenvatinib-resistant HCC cells. These significant findings, which suggest that GLP1 can potentially overcome Lenvatinib resistance and improve therapeutic outcomes in advanced HCC, are a testament to the potential of GLP1RAs in cancer treatment.

#4454 Cancer cell permeability induced by tumor treating fields (TTFields) improves chemotherapy uptake and requires cells to transverse through the G2/M phase under TTFields application.

Bella Koltun, Tali Voloshin, Cfir David, Tal Kan, Yiftah Barsheshet, Alexandra Volodin, Shay Cahal, Catherine Tempel-Brami, Mai Shai, Sara Jacobovitch, David Lancry Abittan, Boris Brant, Noa Kaynan, Lilach Koren, Anat Klein-Goldberg, Efrat Zemer Tov, Rom Paz, **Naama Flint-Brodsly**, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti

Novocure Ltd, Haifa, Israel

Background: Multidrug resistance (MDR) poses a significant challenge in cancer treatment, and efforts to overcome it have not yet resulted in meaningful improvements in survival rates. Tumor Treating Fields (TTFields), a cancer treatment based on the application of electric fields, have recently been shown to increase the membrane permeability of glioblastoma cells. The current study aimed to characterize this phenomenon and examine whether it can be leveraged to facilitate uptake of anticancer agents and overcome MDR.
Methods: 4T1 breast mammary carcinoma cells were treated with TTFields (300 kHz; 1.7 V/cm). Intracellular 7-aminoactinomycin D (7-AAD) accumulation was measured by flow cytometry, adding the agent before or after treatment cessation. Cell cycle analysis using the Hoechst reagent was performed with or without G1/S blockage using thymidine. 4T1-MDR (doxorubicin (DOX)-resistant) cells were generated by repeated DOX exposure of the parental 4T1 (DOX-sensitive) cells. TTFields together with DOX were applied to the 4T1 and 4T1-MDR cells, followed by analysis of DOX accumulation and cell count. For testing drug accumulation in vivo, mice were orthotopically inoculated with 4T1 cells or with lung carcinoma LL/2 cells, followed by TTFields treatment and injection of DOX or paclitaxel (PTX), respectively. Drug accumulation was measured in single-cell tumor suspension and whole tumors, using flow cytometry or an in vivo imaging system (IVIS) for DOX, and LC-MS/MS for PTX. For the latter, accumulation was also measured in the healthy lung. For the efficacy studies, mice were orthotopically inoculated with 4T1 or 4T1-MDR cells. The mice were treated with TTFields or sham-heat continuously for 8 days, with DOX (1 mg/kg for 4T1 cells; 5 mg/kg for 4T1-MDR cells) or vehicle injections on days 2 and 6 of treatment. Tumor volumes were measured using caliper.
Results: 7-AAD accumulation tests demonstrated that TTFields-induced cancer cell permeability is reversible and requires that cells transverse through the G2/M phase under TTFields application. The application of TTFields allowed DOX accumulation to the same extent in both DOX-resistant and DOX-sensitive cells and sensitized both cell types to DOX cytotoxicity. Enhanced drug accumulation was observed in vivo, with DOX in breast tumors and PTX specifically in lung tumors. The application of TTFields concomitantly with DOX significantly decreased tumor growth in both 4T1 and 4T1-MDR tumor-bearing mice.
Conclusions: TTFields reversibly and in a G2/M dependent manner increased cancer cell permeability, allowing enhanced intracellular accumulation of chemotherapy, in vitro and in vivo. TTFields treatment concomitant with DOX improved treatment efficacy, in DOX-resistant and DOX-sensitive cells, in vitro and in vivo.

#4455 Involvement of the PI3K/AKT signaling pathway in the cancer cell response to tumor treating fields (TTFields).

Anat Klein-Goldberg, Tali Voloshin, Efrat Zemer-Tov, Rom Paz, Lilach Koren, Kerem Wainer-Katsir, Alexandra Volodin, Bella Koltun, Boris Brant, Yiftah Barsheshet, Tal Kan, Cfir David, Tharwat Haj Khalil, **Naama Flint-Brodsly**, Adi Haber, Moshe Giladi, Uri Weinberg, Yoram Palti

Novocure Ltd, Haifa, Israel

Introduction: Tumor treating fields (TTFields) therapy is an approved treatment for glioblastoma (GBM), pleural mesothelioma and non-small cell lung carcinoma (NSCLC), and is under investigation for the treatment of other solid tumors. The current study aimed to uncover cellular response mechanisms of cancer cells to TTFields treatment.
Methods: Changes in signaling pathways following TTFields application (150 or 200 kHz; 1.7 V/cm RMS) were analyzed using the Luminex multiplex assay and validated by protein expression in three cancer cell lines: A2780 ovarian cancer cells, H1299 lung cancer cells, and U87-MG GBM cells. The mechanism of action was tested with various tools, including immunofluorescence microscopy, inhibition assay, antibody neutralization assay, and immunoprecipitation. The efficacy of concomitant treatment with TTFields and a potential inhibitor were tested in cell lines and in an orthotopic LL/2 lung cancer mouse model.
Results: Increased PI3K/AKT and Focal Adhesion Kinase (FAK) phosphorylation were observed in the cancer cells following short term (2h) treatment with TTFields. Accordingly, FAK inhibition abrogated TTFields-induced AKT phosphorylation. For long term (72h) treatment, the PI3K/AKT pathway was activated via N-cadherin, as evident by the increased cell surface levels and reversal of the AKT phosphorylation when a neutralizing antibody was used to inhibit the N-cadherin-mediated cell-cell contacts. Additionally, pull-down assays with an anti-N-cadherin antibody demonstrated increased recruitment of the p85 regulatory subunit of PI3K to N-cadherin complexes. In accordance with the identified involvement of the PI3K/AKT axis in the response to TTFields, co-treatment with the PI3K inhibitor alpelisib enhanced the effectiveness of TTFields in vitro and in vivo.
Conclusions: These findings provide a molecular understanding of the cellular response to TTFields, with early PI3K/AKT activation through FAK cell-surface interactions, and late activation via N-cadherin cell-cell interactions. PI3K inhibition presents a potential therapeutic strategy to sensitize cancer cells to TTFields treatment.

#4459 Molecular docking and drug virtual screening of novel small molecule inhibitors of anti-apoptotic proteins for cancer treatment.

J. Shin[1], Y. Chen[2], B. Feldmeier[3], E. Lee[1], Q. Zhao[1];
[1]University of the Pacific, Stockton, CA, [2]The Quarry Lane School, Dublin, CA, [3]Amador Valley High School, Pleasanton, CA

Bcl-2, an anti-apoptotic protein, is involved in cancer development and progression and has been considered as a promising target in cancer therapy. ABT-199, a Bcl-2 inhibitor, has been approved, as a single agent or in combinations, for the treatment of adult patients with chronic lymphocytic leukemia (CLL), small lymphocytic lymphoma (SLL), or newly diagnosed acute myeloid leukemia (AML) patients with age of 75 years or older. Although most patients can initially benefit from ABT-199 treatment, patients eventually develop resistance majorly due to BCL2 mutations, such as G101V and D103Y, or overexpression of Bcl-xL. Therefore, inhibitors that can target both wild-type and mutant Bcl-2 as well as Bcl-xL have the potential to overcome the resistance mechanisms to ABT-199. LP-118 is a novel inhibitor targeting wild-type Bcl-2, Bcl-2^{G101V} and Bcl-2^{D103Y} mutants, and has moderate activity against Bcl-xL. In preclinical and clinical studies, LP-118 had excellent anticancer activity in animal models and patients with CLL or SLL. However, there is no co-crystal structure information available to show exactly how LP-118 binds to Bcl-2, Bcl-2^{G101V}, Bcl-2^{D103Y}, or Bcl-xL. Molecular docking is one of the most frequently used methods in drug design and discovery, due to its ability to predict the binding-conformation of small molecule ligands to the appropriate target binding site. Using the molecular docking Software ICM-Pro, we are the first to illustrate how LP-118 binds to Bcl-2, Bcl-2^{G101V}, Bcl-2^{D103Y}, and Bcl-xL proteins in 3D. The molecule LP-118 is tightly tugged in the reception pocket of each protein where the interactions, including hydrogen bonding, electrostatic and π-stacking interactions, slightly vary in each case. These knowledge enables a better understanding of the mechanism of actions of LP-118 and provides a foundation for the rational design of future generations of Bcl-2/Bcl-xL inhibitor that will overcome the Bcl-2 mutation resistance. Based on the docking result, we designed over 1,000 analogues of LP-118 by fine-tuning the backbone and substituents on the molecule, used ICM-Pro/VLS software to virtually screen these analogues against Bcl-2, Bcl-2^{G101V}, Bcl-2^{D103Y}, or Bcl-xL, and successfully identified and prioritized 10 top-ranked analogues for chemical synthesis and anticancer activity testing.

#4460 OpencanSARchem: chemistry registration and standardization pipeline for FAIR integration of bioassay data.

Rezvan Chitsazi, Phillip W. Gingrich, James P. Long, Chong Wu, Bissan Al-Lazikani

UT MD Anderson Cancer Center, Houston, TX

Introduction: The rapid growth of medicinal chemistry and bioactivity data has driven AI advancements but inconsistencies in chemical representation across databases make bioactivity-focused data integration challenging. Tautomerism, a key challenge, complicates chemical registration due to the existence of multiple interchangeable molecular forms, significantly impacting database uniqueness and separating bioactivity data across tautomeric forms. We previously developed a standalone, fully deployable solution to address these challenges (Dolciami et al. 2022), now a core component of the canSAR (https://cansar.ai) knowledgebase. However, our solution fell short of achieving FAIR (Findable, Accessible, Interoperable, Reusable) data integration due to its reliance on commercial software. In addition, it was computationally intensive limiting the size of data and rapidity of analysis. We present OpencanSARchem, a fully open-source, RDKit-based, and computationally efficient tool for the drug discovery community. It is 100-fold faster, enabling analysis of larger databases, eliminates reliance on commercial software, and enhances scalability to advance data integration.
Methods: OpencanSARchem pipeline involves five steps: (1) assessing input structure for physical consistency, (2) removing irrelevant fragments, solvents, and counter-ions, (3) tautomerically canonicalizing compounds, (4) removing stereochemistry and isotopic labels, and (5) generating abstract representations for hierarchical generalization and grouping of related data across disparate data sources. Tautomeric canonicalization is the key difference between RDKit (OpencanSARchem) and ChemAxon (canSARchem), potentially leading to variations in canonical tautomer selection. We use quantum chemical methods to calculate the Gibbs free energy of tautomer pairs generated by both pipelines, followed by statistical analysis to evaluate the energetic consequences of our utility selection.
Results: The new pipeline can process 2.3 million compounds for standardization and generation of canonical tautomers in ~3 hours. We found that 20% of compounds resulted in different tautomers between ChemAxon and RDKit. The median difference in Gibbs free energy between ChemAxon and RDKit tautomers was found to be approximately 2 kcal/mol. In the context of drug discovery, small free energy differences allow tautomers to coexist in equilibrium, making either structure potentially available for therapeutic activity.
Conclusion: To our knowledge, OpencanSARchem is the only fully open-source pipeline addressing all aspects of chemical standardization, including tautomerization, and enabling FAIR data integration, democratizing this method to address the needs of the broader community.

Dolciami et al., *J. Cheminformatics, 2022,* 14, 28.

#4461 Utilizing steered molecular dynamics simulations for enhanced virtual screening: Active pharmacophore search by dynamic corrections to target MKK3-MYC interactions.

Muhammet Eren Ulug[1], Saima Ikram[1], Ehsan Sayyah[1], **Serdar DURDAGI**[2]

[1]Lab for Innovative Drugs (Lab4IND), Computational Drug Design Center (HITMER), Bahcesehir University (BAU), Istanbul, Turkey,[2]Molecular Therapy Lab, Department of Pharmaceutical Chemistry, School of Pharmacy, Bahcesehir University (BAU), Istanbul, Turkey

The complex interplay between mitogen-activated protein kinase 3 (MKK3) and the MYC proto-oncogene protein is critical for cancer progression, especially in triple negative breast cancer (TNBC). Despite substantial advancements, effective MYC-targeted drug discovery remains a challenge, underscoring the need for innovative approaches to manage MYC-dependent malignancies. One promising strategy involves disrupting the protein-protein interactions (PPIs) between MKK3 and MYC, as MKK3-mediated activation of MYC is pivotal in multiple cell types, highlighting a new target for therapeutic interventions in MYC-driven cancers. In this study, we employed a novel *in silico* approach to screen small molecule libraries targeting the MKK3-MYC interaction. Dynamic structure-based pharmacophore models were created to screen these libraries, identifying compounds that effectively aligned with the specified pharmacophore features. Physics-based simulations were then conducted on the selected hits. Steered molecular dynamics (sMD) simulations were employed to evaluate the correlation between the force required to dissociate the candidate ligands from the binding pocket and their corresponding average binding free energies. Comparative analysis of the average binding free energies of these identified hits, relative to the reference compound SGI-1027, indicates that the selected molecules have promising predicted binding affinities. These findings may represent a significant step forward in our ability to modulate MYC activation for cancer therapy.

#4462 Covalent inhibition of eIF4E: A computational approach.

X. Ma;
Portsmouth Abbey School, Portsmouth Abbey School, RI

Covalent docking has emerged as a promising strategy for targeting challenging protein residues. Specifically, lysine residues, which are often overlooked due to their lower nucleophilicity compared to cysteines, have shown potential in the development of covalent inhibitors for eukaryotic translation initiation factor 4E (eIF4E), a critical regulator of protein synthesis implicated in breast cancers. Leveraging aryl sulfonyl fluorides, recent studies had successfully docked to K162 within eIF4E and shown reduced protein activity, but the molecules had faced significant specificity and instability. In this study, I improved the molecules in the following aspects: specificity and stability. Regarding specificity, I found additional lysine residues, such as K106 and K108, as promising targets for covalent inhibition through structural analyses of eIF4E. I also designed bivalent molecules that covalently bind to both lysine residues simultaneously. This bivalent binding increases the specificity as there are only two regions of two lysine residues in three amino acids, whereas there are a total of 15 lysine residues. The differences in binding affinity and docking score between the bivalent and control groups were insignificant, suggesting that the potency of the bivalent molecule didn't drop. Finally, through molecular dynamic simulations, I verified that there is conformational changes at the cap-binding site after covalent inhibition, demonstrating the biological efficacy of the drug molecules.

#4463 A novel method for constructing diverse cyclic peptide libraries for efficient screening of PPI inhibitors.

Zhenyu Wu[1], Xiaoli Hou[2], Hongbo Zhang[3]

[1]The Ohio State University, Columbus, OH,[2]Beijing University of Chemical Technology, Beijing, China,[3]Nankai University, Tianjin, China

Cyclic peptides drug design and discovery has experienced a resurgence of interest due to their target specificity and metabolic stability. In this study, we developed a novel methodology for generating extensive, structurally diverse, and synthesizable virtual libraries of cyclic peptides. Such libraries are essential for the identification of hit compounds against a spectrum of therapeutic targets through screening assays. We introduce an innovative strategy for the creation of diverse cyclic peptide libraries leveraging a “hierarchical generation” approach combined with artificial intelligence (AI)-driven sampling. Our approach begins with the generation of a library of representative linear peptides which are subsequently subjected to cyclization via an array of cyclization reactions. The generation of linear peptides is executed via a hierarchical generation method wherein amino acids are initially categorized according to their physicochemical properties. Next, a sequence of these properties is formulated, and the similarity of these property sequences is calculated through sequence alignment algorithm. Low-similarity property sequences are then processed by AI models to generated multiple sequences of amino acids, while high-similarity sequences are judiciously excluded. The iteration of this process yields a set of representative linear peptides, which are then cyclized to produce the desired cyclic peptides. Employing this novel methodology, we have successfully generated a virtual cyclic peptide library encompassing nearly 6 million molecular cyclic peptides (covering approximately 4 thousand trillion peptides) within a single week. Over 1000 representative cyclic peptides were selected for synthesis via the solid-phase peptide synthesis (SPPS) technique, and a cyclic peptide library with high structural diversity was obtained. In conclusion, the structural diversity of our library, combined with the successful screening results, highlights the robustness of our method in designing diverse cyclic peptides, particularly for hit identification against traditionally undruggable targets. Our findings underscore the utility of this cyclic peptide library in discovering potential PPI inhibitors.

#4464 A large language model for diverse 2D molecular generation (2DMG) and its application in focused library generation and rational design.

Zihao Liu[1], Qingbo Xu[2], **Zhenyu Wu**[1], Hongbo Zhang[3]

[1]The Ohio State University College of Medicine, Columbus, OH,[2]China Agricultural University, Beijing, China,[3]Nankai University, Beijing, China

AI-driven large language models for molecular generation are gaining significant interest in structure-based drug design. However, challenges such as dataset quality, molecular diversity, and synthesizability still persist. To address these challenges, we introduce StoneWise 2DMG, an advanced model that sparks creativity in medicinal chemistry experts, accelerating the drug discovery process by generating diverse 2D molecular structures. The model is pre-trained on a vast dataset comprising 30 million commercial compound structures (covering most global commercial compounds), 8 million patent-derived compound structures (spanning from the 1960s to 2023), 11 million building block structures, and billions of easily synthesizable molecular structures. This large-scale training enables the generation of drug-like molecules suitable for focused library generation and rational design. The 2DMG model can be utilized for focused library generation. By analyzing the structures of molecular glues that have been published or advanced into clinical trials, we selected glutarimide as a seed molecule for focused library design. Utilizing the 2DMG model, we are able to rapidly generate a diverse, rational, synthesizable, and drug-like molecular library. This molecular glue library is currently under synthesis in the laboratory and will be employed for high-throughput screening in the future. We then extended the application of our model to tackle a more advanced challenge in rational drug design. In a case study involving ABBV-CLS-484 (a molecule targeting both tumor and immune cells; PDBID: 7UAD), we analyzed the key binding fragment, thiadiazolidin-3-one, in the crystal structure. The model then used this critical fragment as a seed to generate a focused library of over 100,000 compounds, which were docked and further selected by medicinal chemistry experts. Ten compounds were chosen for synthesis, and four showed acceptable activity, making them suitable for lead optimization. In summary, StoneWise 2D Molecular Generation model, trained on billions of data points, offers a robust platform for generating diverse and structurally rational molecules. The model supports focused library design for high-throughput or virtual screening and facilitates rational design to explore and expand chemical space, thus accelerating the drug discovery process.

#4465 Molecular docking studies on the factors affecting histone deacetylase inhibition: Design, rigidity, and chirality of the inhibitors.

Q. Zhao, J. A. Tang, K. Artero, A. Huang, R. Bosri;
University of the Pacific, Stockton, CA

Histone deacetylase (HDAC) has become one of the targets for cancer therapy since it was found overexpressed in cancer cells. New HDAC inhibitors were designed and investigated to demonstrate how the molecules interact with HDAC enzymes, using the molecular docking software ICM-Pro. Multiple families of HDAC inhibitors, derivatized from the FDA-approved HDAC inhibitors, were constructed and optimized for *in silico* screening. Detailed analyses of the docking results showed that the addition of an aromatic ring on the linker domain could boost or diminish the interactions of the molecules with the enzyme, depending on the location and size of the aromatic ring. The rigidity of the molecules was tuned by installing heterocyclic rings of various sizes at different positions. Molecules of specific rigidity could greatly enhance the dock scores and binding affinity, thus theoretically the enzyme inhibition. Modification of protein recognition and zinc-binding domains and chirality of the molecules were also explored to seek inhibitors for specific HDAC inhibitions. Drug candidates with the desired binding affinity and selectivity were selected for chemical synthesis and biological activity examination in the lab.

#4466 Machine-learning-driven optimization of kinase inhibitors to overcome CNS efflux and target breast cancer brain metastases.

Eneye D. Ajayi, Mostafa M. A. Aref, Rokaia Abdullah, Md Emran Hossain, Hamed I. Ali

Pharmaceutical Sciences, Texas A&M University, College Station, TX

Breast cancer (BC) is the most prevalent form of malignancy and the leading cause of cancer mortality in women. The fatality of BC is highly attributed to BC brain metastases (BCBM) which represent 30%, with a 1-year survival rate of 20%. About 15-20% of BC demonstrates significant overexpression of HER2, hence the development of anti-HER2 targeted therapies such as tucatinib which have prolonged survival rates and improved patient quality of life. Despite the improvements in HER2 targeted therapy to rapidly target BCBM, tucatinib and other quinazoline HER2 inhibitors (dacomitinib and gefitinib) possess poor CNS penetration due to P-gp and BCRP efflux. *In vitro,* BBB permeability assays such as the BBB-PAMPA are cost-intensive prompting the need for computational methods that can rapidly predict the BBB permeability potential of small molecules in the early phase of drug discovery. Herein, we used quantitative and qualitative machine learning (ML) algorithms trained with experimental data to direct structural optimization of in-house KIs to improve BBB penetration. We employed qualitative and quantitative ML models to identify the most promising compounds from our in-house library of 120 KIs previously designed for dual HER2/VEGFR targeting. The core of our approach lies in the structural simplification of starting compounds to drastically reduce molecular weight and topological surface area and the appropriate substitution of solubilizing residues to modulate pKa. Furthermore, we developed a benchmark of optimal physiochemical properties of molecules intended as CNS therapeutics using an approved CNS drug dataset. Optimized analogs possessing physicochemical properties within the benchmark range and a favorable ML prediction of BBB permeability were synthesized and tested on a kinase panel. BBB-PAMPA was also used to evaluate BBB penetration of both starting KIs and optimized analogs. Optimized analogs demonstrated HER2 kinase inhibitory activity alongside a significant increase in BBB permeability compared to the starting compounds. Our results suggest that structural optimization to modulate the physicochemical properties of small molecules is key to identifying potential drug candidates for targeting BCBM. *In vivo* studies using animal models will be conducted to validate these findings.

#4467 Receptor targeted delivery of the multi-kinase inhibitor F7/PIK-75 by organic-core templated lipid nanoparticles as cancer therapy.

Jonathan S. Rink[1], Andrea E. Calvert[1], David Kwon[2], Xu Hannah Zhang[3], Hongwei H. Yin[2], David Horne[3], SonBinh T. Nguyen[4], Adam Y. Lin[1], Steven T. Rosen[3], Leo I. Gordon[1], C Shad Thaxton[1]

[1]Northwestern Univ. Feinberg School of Medicine, Chicago, IL,[2]High Throughput Screening Core, City of Hope, Duarte, CA,[3]City of Hope, Duarte, CA,[4]Chemistry, Northwestern University, Evanston, IL

Introduction: PIK-75 is a potent multi-kinase inhibitor, targeting p110α, p38γ and DNA-PKs. We and others have demonstrated that PIK-75 is effective against a diverse range of malignancies, including prostate cancer, cutaneous T-cell lymphomas, acute myeloid leukemia (AML) and pancreatic cancer, among others. However, PIK-75 is hydrophobic and difficult to deliver to target tissues, which has limited clinical development. To address these limitations, we developed a bio-inspired delivery platform for PIK-75 that has some features of natural high-density lipoproteins (HDL). We employed an organic core (oc) template to synthesize HDL-like nanoparticles (ocHDL NP) with size, shape, surface composition and targeting functions similar to mature, spherical, naturally occurring HDLs. The ocHDL NPs target and bind to the high-affinity HDL receptor scavenger receptor class B type 1 (SR-B1). SR-B1 is often over-expressed in cancer, making it an ideal target for drug delivery. Therefore, we hypothesized that ocHDL NPs can deliver PIK-75 via SR-B1 to cancer cells to induce cell death in vitro and in vivo.

Methods: PIK-75 ocHDL NPs were synthesized by combining an oc with PIK-75, phospholipids and the HDL-defining apolipoprotein A-I. Following spontaneous self-assembly the PIK-75 ocHDL NP were purified by dialysis. PIK-75 ocHDL NPs were characterized for size, surface charge and drug loading. In vitro efficacy was assessed in prostate cancer cell lines (CWRR1, LnCaP), AML cell lines (HEL, KASUMI-1, BDCM, KG1a), and the NCI-60 panel + 6 pancreatic cancer cell lines. An SR-B1 blocking antibody and small molecule inhibitor of SR-B1 were used to demonstrate SR-B1-mediated delivery of PIK-75 by ocHDL NPs. In vivo efficacy was assessed in a prostate cancer tumor xenograft model.

Results: PIK-75 was successfully incorporated into the ocHDL NP platform. Data demonstrate PIK-75 ocHDL NP had 20 ± 1 PIK-75/ NP. PIK-75 ocHDL NPs specifically target SR-B1 and deliver PIK-75 to inhibit its kinase targets, as measured by flow cytometry and western blotting. PIK-75 ocHDL NPs potently induced cell death in all cell lines tested, with average IC50s for prostate cancer (1.58 nM), AML (2.50 nM), pancreatic cancer (10.56 nM) and NCI60 panel (3.09 nM) in the low nanomolar range. PIK-75 ocHDL NPs significantly reduced tumor growth in a murine model of castrate resistant prostate cancer and there were no obvious untoward side effects.

Conclusions: ocHDL NPs can be successfully loaded with hydrophobic drug cargo, such as PIK-75, to enable SR-B1 targeting and delivery of PIK-75 to cancer cells. PIK-75 ocHDL NPs potently induced cell death across a wide array of malignancies in vitro, and in an in vivo prostate cancer xenograft model. These results provide proof-of-principle that ocHDL NPs can be successfully leveraged to deliver hydrophobic small molecule drugs in a receptor targeted manner.

#4468 Modified 5-FU immunoliposome targeting EGFR-expressing pancreatic tumors: *In vitro* and *in vivo* evaluation.

Esther Frimpong[1], Raviteja Bulusu[1], Joy Okoro[1], Xue Zhu[1], Renee Reams[1], Bo Han[2], Saunjoo Yoon[3], Edward Agyare[1]

[1]Florida A&M University College of Pharmacy & Pharmaceutical Sciences, Tallahassee, FL,[2]Department of Surgery, Keck School of Medicine, University of Southern California, Los Angeles, CA,[3]Department of Biobehavioral Nursing Science, College of Nursing, University of Florida, Gainesville, FL

Purpose: Epidermal growth factor receptor (EGFR) is vital in tumor growth, invasion, and metastasis. Many pancreatic tumors express EGFR, making it important in targeted therapy. XYZ-I-73, a novel 5-Fluorouracil (5-FU) analog formed from conjugating lauroyl chloride to 5-fluorocytosine from our previous study, has shown cytotoxicity against pancreatic cancer (PCa) cells. The study aimed to develop an immunoliposome by conjugating pegylated XYZ-I-73 liposomal nanoparticles to EGFR monoclonal antibody and determining in vitro and in vivo anticancer effects in PCa.

Methods: EGFR expression in PCa cells was determined via Western blot analysis. XYZ-I-73 liposomes were prepared from dipalmitoyl phosphatidylcholine (DPPC),1,2-Distearoyl-sn-glycero-3-phosphoethanolamine-Polyethylene glycol (DSPE-PEG 2000), and Labrasol as surfactant using a thin-film hydration method. We conjugated EGFR monoclonal antibody to XYZ-I-73 PEGylated liposomes (XYZ-I-73LnP) to produce an antibody-conjugated PEGylated liposome (Ab-XYZ-I-73LnP). Immunoliposomes conjugation was confirmed and characterized for size, entrapment, and stability. The in vitro cytotoxicity and apoptotic effects were determined in MIA PaCa-2 cells and PANC-1 cells. Pharmacokinetics and biodistribution studies were conducted on KPC mice.

Results: Characterization of XYZ-I-73LnP showed a mean particle size of 105±2.1nm, PDI (0.24), zeta potential of -34.3±0.9mV, and entrapment efficiency (EE) of 84.3±3.8%. Ab-XYZ-I-73LnP mean particle size was 143nm±2.3, PDI (0.37), and zeta potential -46.2±1.3mV. The coupling efficiency and conjugation of the antibody to the liposomes were confirmed by Bicinchoninic Acid Assay (BCA) and Fourier Transform Infra-Red (FTIR). The in vitro cytotoxicity of Ab-XYZ-I-73LnP treated MIA PaCa-2 cells (IC_{50} (2D) = 2.5±0.9μM and IC_{50} (3D) = 8.1±1.1μM) was significantly higher than 5-FU-treated cells (IC_{50} (2D) = 7.4±1.3μM; IC_{50} (3D) = 26.7±1.1 μM). Ab-XYZ-I-73LnP inhibition in PANC-1 culture was significantly higher (IC_{50} (2D) = 2.9±1.1 μM; IC_{50} (3D) = 11.6±1.9 μM) than 5-FU-treated culture (IC_{50} (2D) = 26.7±1.1 μM; IC_{50} (3D) = 37.1±0.9 μM). Ab-XYZ-I-73LnP showed a remarkable apoptotic effect as concentration increased (12.5, 25, and 50μM) in MIA PaCa-2 and PANC-1 3D spheroids compared to 5-FU. MIA PaCa-2-treated Ab-XYZ-I-73LnP showed a significantly reduced expression of EGFR than 5FU. The pharmacokinetic profile of Ab-XYZ-I-73LnP showed a longer half-life than 5-FU ($t_{1/2}$ = 1.62±0.03h vs 0.49±0.01h, $p < 0.001$). The area under the curve (AUC) of Ab-XYZ-I-73LnP was 2.5-fold higher than 5-FU. Ab-XYZ-I-73LnP demonstrated a significantly higher tumor accumulation than 5-FU.

Conclusion: The study demonstrated that modified 5-FU immunoliposome nanoparticles may enhance the therapeutic activity of 5-FU in treating PCa.

#4469 Multimodal liposomal organic nanoparticle for immunomodulation and photodynamic combinatorial therapy for triple negative breast cancer.

Sayantan Sinha[1], Dhruv Bhatnagar[2], Anne Frei[3], Heather Himburg[3], Amit Joshi[2]

[1]Biomedical Engineering, Medical College of Wisconsin, Wauwatosa, Milwaukee, WI,[2]Biomedical Engineering, Medical College of Wisconsin, Milwaukee, WI,[3]Radiation Oncology, Medical College of Wisconsin, Milwaukee, WI

Background: IL-12 is a potent cytokine with promising pre-clinical efficacy in solid tumors, including triple-negative breast cancer (TNBC), by enhancing anti-tumor immunity through Treg reprogramming and boosting $CD8^+$ T cell function. However, its clinical use is limited by systemic toxicity and challenges in targeted tumor delivery. Combining IL-12 with photodynamic therapy (PDT) represents a potential solution to these issues, optimizing therapeutic outcomes.

Concept & Novelty: We developed a cationic tetra-lipid organic nanoparticle to co-encapsulate IL-12 and HPPH (a photosensitizer; λ_{max} = 658 nm). Efficient IL-12 encapsulation has been challenging due to steric hindrance and hydrophilic nature. To overcome this, we employed a bipolar solvent system ($CHCl_3$:CH_3OH, 2:1), achieving 98% IL-12 loading. The self-assembly of IL-12 in methanol enables its complexation with chloroform, forming hydrogen-bonding through synergistic solvation that enhances encapsulation efficiency.

Methodology: (a) Liposomal nanoparticle (LNP) Synthesis: The cationic core lumen for IL-12 encapsulation in LNP was achieved by dissolving DPPC, cholesterol, and DOTAP in a 13:5:1 molar ratio in $CHCl_3$. IL-12 (2 mg/mL in CH_3OH) was added and stirred for 1 hour. Subsequently, DSPE-PEG-2000-NH_2 conjugated with HPPH and DiR in $CHCl_3$ added dropwise and stirred under inert conditions. Solvent removed to form lipid cake (15 mg/L total lipid concentration), and hydrated with PBS. LNP achieved with sonication and multiple freeze/thaw cycles. Purified with centrifugation-dialysis. (b) In-Vivo: 4T1 murine model of breast cancer was developed with 20 Balb/c mice. Double-blind segregation in 5 groups (1 test + 4 control) was done. The test group received intravenous (i.v.) injections of IL-12 and HPPH-loaded LNP (IL-12@LNP-DiR@HPPH) and treated with laser. The control groups received either/or free IL-12/IL-12@LNP-DiR/LNP/No treatment. The biodistribution of LNP was monitored through time-dependent IVIS imaging.

Results & Discussion: We synthesized 92 nm IL-12@LNP-DiR@HPPH nanoparticles with surface charge of 0-0.4 mV, indicating stability for biological use. After intravenous injection, maximum DiR fluorescence was observed at tumor site at 6 hours. At this time point, photodynamic therapy with IL-12@LNP-DiR@HPPH resulted in 80-94% tumor volume regression and increased cytolytic T cell presence in the tumor, compared to controls. No toxicity, ulceration, or metastasis was observed in the treatment group during the therapeutic window.

Conclusion: We present a novel platform that addresses the challenge of multiple drug loading including efficient loading of IL-12 and successful delivery to the tumor site. A crosstalk between IL-12-mediated immune response and photo-triggered ROS generation promises a potential therapeutic strategy for TNBC with interventions.

#4470 Development of a nanoparticle formulation of an MMP-activated, tumor-specific prodrug with an enhanced therapeutic index for the treatment of breast cancer.

Zubeda Khatoon, Hannah L. M. Spencer, Huw S. Jones, Goreti R. Morais, Amalia R. Estrada, Robert A. Falconer

University of Bradford, Institute of Cancer Therapeutics, Bradford, United Kingdom

Triple-negative breast cancer accounts for 20% of all breast cancer cases and has a poor prognosis due to the lack of targetable expression of specific hormone and growth factor receptors. Therefore, systemic chemotherapy is one of the main therapeutic options. However, a lack of tumor specificity results in systemic toxicity. A tumor-selective prodrug, such as ICT2588[1], could enhance the therapeutic index of the active drug. ICT2588 comprises a colchicine analogue as the active drug, which is conjugated to an MMP14-specific peptide sequence and an endcap to prevent non-specific degradation. MMP14 is widely expressed and functionally active in the tumor tissues and neo vasculature compared to healthy tissues where it is largely absent, thereby facilitating specific release of the active drug within the tumor microenvironment. Despite the therapeutic potential of ICT2588, a lack of aqueous solubility is a limitation. In this study we aim to optimize a nanoparticle formulation of ICT2588 using a lactic and glycolic acid (PLGA) based approach, to increase the aqueous solubility of ICT2588, while offering a controlled release system without additional toxicity.[2] ICT2588 was synthesized and purified by semi-preparative HPLC. Nanoparticles were synthesized via nanoprecipitation and the formulations were optimized in terms of hydrodynamic diameter, zeta potential, and encapsulation efficiency. The evaluation of the ICT2588-PLGA formulations in an MDA-MB-231 triple negative breast cancer model will be reported, with the MMP14 overexpression validated by SDS PAGE and western blotting. The improvements in aqueous solubility will increase the therapeutic potential of ICT2588 and facilitate its translation towards clinical evaluation. 1.Atkinson JM, Falconer RA, Edwards DR, et al. Development of a novel tumor-targeted vascular disrupting agent activated by membrane-type matrix metalloproteinases. #4472 Self-assembly of CD38-binding peptides into nanofibers for imaging multiple myeloma.

Jacqueline Godbe, Amit Kumar Sharma, Rui Tang, Han Jing, Alexander Zheleznyak, Monica Shokeen

Radiology, Washington University in Saint Louis, Saint Louis, MO

CD38 is overexpressed in multiple myeloma (MM) and the target of clinically approved therapeutic antibodies daratumumab and isatuximab. Our lab has previously developed a peptide-based radiotracer (LS1209) that targets CD38 for specific and sensitive imaging in MM. In this study, we demonstrate that the addition of lipid tails to LS1209 templates self-assembly of this peptide into multivalent nanofibers with morphology controlled by the length of the lipid tail. Morphology of the nanofibers was assessed via conventional and cryo-electron microscopy. Internal packing of the peptides was assessed via fluorescence. As the length of the lipid tail increases, the average spacing between residues increases. Additionally, there is a distinct morphologic change between cylindrical nanofibers and helical nanofibers as the lipid tail increases in length from a hexanoic acid tail to an octanoic acid tail. These nanofibers effectively multimerize LS1209 in order to take advantage of multivalent and cooperative binding to CD38, which was assessed via surface plasmon resonance (SPR) and cell surface binding. We demonstrate that binding activity is related to nanofiber morphology and the packing density/availability of peptides for binding interactions. Additionally, the nanofiber design co-localizes radiotracers to the site of interest without CD38 binding events, leading to additional increases in signal. The nanofibers demonstrate high efficiency radiolabeling with 64Cu and are stable at 24h in serum when assessed by radio thin layer chromatography. Preliminary animal experiments demonstrate no toxicity at expected imaging and high concentration (20x) doses.

#4473 Liposomal nanoparticle mediated gene modulation for the treatment of melanoma in murine models.

Poonam Yadav[1], Santosh K. Mandal[1], Bill Tang[2], Rahul A. Sheth[1]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Texas Tech University Health Sciences Center, El Paso, TX

Background: The Wnt/β-catenin pathway plays a significant role in melanoma progression, including the suppression of tumor-specific immunity. Inhibition of this pathway represents a promising therapeutic strategy. Our study investigates the potential of liposomal nanoparticles (LNPs) for delivering Wnt/β-catenin signaling pathway-inhibiting mIR-124 plasmids to melanoma cells.
Materials and Methods: Cationic liposomes were synthesized using the thin-film hydration method. Liposomes were mixed and incubated with a full-length cloned miR-124 plasmids vector (pDNA) at a 10:1 lipid-to-pDNA ratio to allow nanoparticle (NPs) formation referred to as lipoplex or (miR-124-NP). The size distribution and zeta potential of the LNPs were measured using dynamic light scattering (DLS). Nanoparticle morphology was assessed using transmission electron microscopy (TEM). B16-N2 melanoma cells were seeded and treated with miR-124-NP and blank liposomes (10 µg lipid). Cytotoxicity and transfection efficiency were evaluated at 24- and 48-hours post-treatment using immunofluorescence and flow cytometry. Female C57BL/6 mice, bearing B16-N2 tumors in both flank regions, were assigned to 1) Blank Liposomes B-NP, 2) miR-124-NP (n=12 tumors per group). On day 13 post-tumor inoculation, the mice received three intratumoral injections of miR-124-NP (40 µg DNA per injection) at 3-day intervals. Tumor volume was measured daily using caliper measurements. The delivery of nanoparticles to the tumors was monitored by an in vivo imaging system (IVIS), detecting GFP signals at multiple time points. At 24 hours post-injection, mice were euthanized, and tumors were harvested for further analysis via flow cytometry and RT-PCR to assess transfection efficiency.
Results: DLS and TEM analysis confirmed that the miR-124-NP exhibited proper size (180 nm), charge (16.66 mV), and structure. The miR-124-NP formulation (1:10 µg plasmid: lipid ratio) successfully transfected B16-N2 melanoma cells without causing toxicity. Immunofluorescence and flow cytometry data verified the transfection was successful, with 40% efficiency. In vivo imaging using IVIS demonstrated successful delivery of the plasmid to tumor cells. In vivo, miR-124-NP treatment significantly reduced tumor volumes compared to the blank liposome control, with the tumor growth curve showing a marked decreased total tumor burden to up to 50% through day 20 post-inoculation. RT-PCR analysis revealed that miR-124-NP treatment led to decreased expression of SLUG and SNAIL, along with a reduction in vimentin levels, indicating a modulation of epithelial-mesenchymal transition (EMT) processes.
Conclusion: LNPs showed high retention in B16-N2 cells and were non-toxic in vitro. In vivo miR-124-loaded LNPs effectively transfected tumor cells, modulating beta-catenin signaling and EMT gene expression, leading to reduction in tumor burden in C57BL/6 mice.

#4474 Turning up the heat: nanoimmunotherapy transforming outcomes in breast cancer treatment.

Ana I. Matos[1], Barbara Carreira[1], Liane I. F. Moura[1], Rita C. Acurcio[1], Ronit Satchi-Fainaro[2], **Helena F. Florindo**[1]

[1]Universidade de Lisboa, Lisboa, Portugal,[2]Tel Aviv University, Tel Aviv, Israel

Immune checkpoint blockade reaches remarkable clinical responses. However, even in the most favorable cases, half of these patients do not benefit from these therapies in the long term. This work hypothesized that the activation of host immunity by co-delivering peptide antigens, adjuvants, and regulators of the transforming growth factor (TGF)-β expression using a polyoxazoline (POx)-poly(lactic-co-glycolic) acid (PLGA) nanovaccine, while modulating the tumor-associated macrophages (TAM) function within the tumor microenvironment (TME) and blocking the anti-programmed cell death protein 1 (PD-1) can constitute an alternative approach for cancer immunotherapy. Nanoparticles (NP) prepared by the double emulsion solvent evaporation method were modified with mannose to target the mannose receptor (CD206) expressed at the dendritic cells (DC) surface, thus promoting receptor-ligand interaction and subsequently improving payload delivery. NP physicochemical properties were characterized, and the loading of antigens, adjuvants, immune modulators was quantified by fluorescence. The synergistic immunotherapeutic potential of our multifunctional nanovaccine, isolated and in combination with the TGF-β downregulation and Pexidartinib (colony-stimulating factor 1 receptor (CSF-1R) inhibitor that modulates TAM), was assessed in the immune-competent MC38 colorectal (CRC) mouse model. The added value of combining the immune checkpoint inhibitor anti-PD-1 monoclonal antibody to control the CRC (MC38 and CT26) and the highly aggressive melanoma (B16F10) growth and survival was also evaluated.NP presented a mean diameter close to 200 nm, low polydispersity index, neutral surface charge, homogenous spherical shape, and high loadings for antigens, immune adjuvants, and modulators. POx-Mannose (Man) nanovaccines generated stronger antigen-specific T-cell responses, which led to significant tumor growth inhibition when compared with poly(ethylene glycol) (PEG)-Man nanovaccines. This anti-tumor effect induced by the POx-Man nanovaccines is mediated by a $CD8^+$-T cell-dependent mechanism, in contrast to the PEG-Man nanovaccines. POx-Man nanovaccine combined with Pexidartinib restricted the MC38 tumor growth and synergized with PD-1 blockade, controlling MC38 and CT26 tumor growth and survival. This data was further validated in B16F10-bearing mice, a highly aggressive and poorly immunogenic melanoma mouse model for immunotherapy studies.This innovative approach discloses the synergy among the targeted cancer nanovaccine and immune modulatory and checkpoint therapies (αCSF-1R and αPD-1) within the immunosuppressive TME, which overall outcome may constitute a promising nanotechnology-enhanced immunotherapy for solid cancer patients.

#4475 Evaluation of targeted immunoliposomes encapsulating 4-N-hydroxylgemcitabine in EGFR-positive pancreatic cancer.

Joy Okoro[1], Raviteja Bulusu[1], Esther Frimpong[1], Saunjoo Yoon[2], Bo Han[3], Renee Reams[1], Xue Zhu[1], Edward Agyare[1]

[1]Florida A&M University, Tallahassee, FL,[2]University of Florida, , Gainesville, FL,[3]University of Southern California, Los Angeles, CA

Purpose: Pancreatic cancer (PCa) is a deadly malignancy that is challenging to treat. Gemcitabine (Gem) is a standard therapy in PCa treatment. Epidermal growth factor receptor (EGFR) is commonly overexpressed in PCa and contributes to tumor progression and metastasis. Gem is limited by its short half-life and metabolic instability. Our previous studies demonstrated that our modified Gem analog (GemAGY) had improved metabolic stability and anticancer activity compared to Gem. Targeted immunoliposomes have been developed to increase cellular uptake and accumulation in PCa. This study seeks to develop an EGFR-targeted immunoliposome with improved antitumor activity of Gem against PCa.
Methods: EGFR antibody (cetuximab) was conjugated to a liposome encapsulating 4-N-hydroxylGemcitabine hydrochloride (GemAGY) called GemAGY-LnP. Fourier-transform infrared spectroscopy (FTIR) was used to confirm the conjugation of the EGFR antibody to the liposome. GemAGY-LnP was characterized using the dynamic light scattering technique. MiaPaCa-2 spheroid cultures and patient derived xenograft (PDX) pancreatic tumor mouse models were treated with GemAGY-Lnp and Gemcitabine Hydrochloride (GemHCl). 3D cell viability assay was conducted using MiaPaCa-2 spheroids to evaluate the anticancer effects of GemAGY-LnP. Pharmacokinetics, biodistribution, and in vivo antitumor efficacy studies were conducted using PDX mouse models.
Results: FTIR confirmed the successful conjugation of the EGFR antibody to the liposome. The mean particle size and zeta potential of GemAGY-LnP were 141.6 ± 40nm (Poly Dispersity Index = 0.15± 0.01) and -25.2 ± 0.04mV, respectively. The entrapment efficiency of GemAGY-Lnp was 66%. The half-maximal inhibitory concentration (IC_{50}) value was significantly lower (6-fold lower) in GemAGY-LnP-treated MiaPaCa-2 spheroids (3.75±0.3μM) when compared to GemHCl-treated spheroids (24.12 ± 4.8μM) indicating that GemAGY-Lnp exhibited a higher cytotoxic effect when compared to GemHCl. The pharmacokinetics profile revealed that the area under the curve (AUC) of GemAGY-Lnp (52.70 ±0.05 μghr/mL) was over 15-fold higher than that of GemHCl (3.09±0.04) μghr/mL) while half-life of GemAGY-LnP (1.93 hr) was almost 4-fold higher than that of GemHCl (0.50 hr). In vivo studies showed that tumor growth inhibition in PDX pancreatic tumor mice treated with GemAGY-Lnp was significantly higher than in PDX mice treated with GemHCl (GemAGY-LnP vs GemHCl; $p < 0.0001$). The biodistribution studies revealed a significantly higher GemAGY-Lnp accumulation in tumor relative to GemHCl.
Conclusion: Our findings suggest that GemAGY-Lnp significantly increases the tumor accumulation of Gem, enhances the anticancer activity and improves Gem's pharmacokinetic profile compared to GemHCl. GemAGY-LnP may potentially inhibit tumor growth when treating EGFR-positive pancreatic cancer.

#4476 Curcumin gold nanoparticles significantly boost the effectiveness of docetaxel-induced apoptosis in breast cancer.

Santosh K. Singh, Rajesh Singh

Microbiology, Biochemistry & Immunology, Morehouse School of Medicine, Atlanta, GA

Breast cancer (BrCa) is the most diagnosed cancer in women; it develops locally and then metastasizes to other organs. Due to tumor heterogeneity, the prevalence of drug resistance, and disease recurrence, current therapy options are proving less effective for specific BrCa subtypes, such as triple-negative breast cancer (TNBC). Therefore, BrCa treatment has shifted from a one-size-fits-all strategy to a more focused approach. In this study, we demonstrated folate receptor-based targeted delivery of either curcumin (Cur), a natural compound isolated from *Curcuma longa*, or docetaxel (DTX), a chemotherapeutic drug, or a combination of the two, using gold nanoparticles (AuNPs) for successful BrCa therapy. We synthesized AuNPs coated with folic acid (FA)-conjugated with poly (ethylene glycol) copolymer, encapsulated with DTX and Cur, and then characterized these NPs for size, charge, shape, conjugation, and distribution using various techniques, including a Zetasizer, scanning electron microscope (SEM), transmission electron microscope (TEM), nuclear magnetic resonance (NMR), and nanoparticle tracking analysis (NTA). The results confirmed the successful conjugation of both drugs. To evaluate whether Cur enhanced the efficacy of DTX-AuNPs on BrCa cell lines (MCF-7 and MDA-MB-231), we treated the cells with Cur- or DTX-alone or in combination -AuNP followed by cell viability assessment using MTT assay and apoptosis assays. The live/dead cells immunofluorescence test confirms the effectiveness of combined drugs, showing an increase in dead nuclei in MCF-7 and MDAMB 231 cells treated with the combination (FA-Cur+ DTX-AuNP) for 48 hours. The combination was most effective in inducing apoptosis, inhibiting EMT (epithelial-mesenchymal transition), and BrCa cell proliferation. It showed the downregulation of the anti-apoptotic Bcl-xL and the upregulation of pro-apoptotic markers Bak and Bid. The EMT markers, E-cadherin, were upregulated, and the N-cadherin and Snail markers were downregulated in western blots and RT-PCR. Further, the combination of NPs increases the expression of $p27^{KIP1}$, inhibiting the CDK4, Cyclin D1 complex and the transition of cells into G_0/G_1 to the S phase in both cell lines. The NPs internalization, colony formation, and migration assays further confirm the synergistic effect of both NPs. These findings indicate that Cur may serve as a therapeutic contender for enhancing the effectiveness of DTX, representing a promising advancement in breast cancer treatment.

#4477 Biological evaluation of EGFR- conjugated liposomal drug delivery system for enhanced targeting of pancreatic cancer.

Raviteja Bulusu[1], Joy Okoro[1], Esther Frimpong[1], Saunjoo Yoon[2], Bo Han[3], Renee Reams[1], Zhu Xue[1], Edward Agyare[1]

[1]Florida A&M University, Tallahassee, FL,[2]University of Florida, Gainesville, FL,[3]University of Southern California, Los Angeles, CA

Purpose: The purpose of this study is to entrap and characterize a potential lead compound (heptyl (5-fluoro-2-oxo-1-(tetrahydrofuran-2-yl)-1,2-dihydropyrimidine-4-yl) carbamate (AGY_2) into antibody-conjugated liposomal drug delivery system (AGY_2-EGFR LDDS) to target pancreatic cancer.

Methods: The monoclonal antibody (Cetuximab) conjugated AGY_2 loaded liposome drug delivery system (AGY_2-LDDS) using DPPC, MPPC, and PEG_{-2000} lipids. The conjugation was confirmed by Fourier Transform Infrared Spectroscopy (FTIR) spectra. The particle size (PS), zeta potential (ZP), polydispersity index (PI), and entrapment efficiency (EE) of the formulation were determined. 3D cytotoxicity studies were performed on MiaPaCa-2 (MP-2) and PANC-1 (P-1) cells. Stability study was performed at different temperatures (4°C, 25°C, and 40°C). Pharmacokinetic (PK) and biodistribution studies were conducted. A tumor efficacy study was conducted by inoculating the KPCY PDX mice.

Results: The variations in the peaks for AGY_2, AGY_2 LDDS, and AGY_2-EGFR LDDS in the FTIR spectra confirmed the successful conjugation of EGFR to the lipids. The PS of the formulation was 115±7 nm with a ZP of -35 ±8 mV, and the EE was 80%, as analyzed by Stat-Ease360. In MP-2 spheroids, the IC_{50} values were as follows: AGY_2-EGFR LDDS at 7.7 ± 2.3 μM ($p < 0.0001$), AGY_2 LDDS at 16.5 ± 3.7 μM ($p < 0.001$), and AGY_2 at 27.5 ± 4.2 μM ($p < 0.0328$), compared to 5-Fluorouracil (5-FU) at 36.6 ± 4.8 μM. Similarly, in P-1 cells, the IC_{50} values were: AGY_2-EGFR LDDS at 9.6 ± 0.9 μM ($p < 0.0001$), AGY_2 LDDS at 18.5 ± 5.7 μM ($p < 0.0003$), and AGY_2 at 35.4 ± 5.2 μM, compared to 5-FU at 40.8 ± 5.9 μM. In MP-2 organoids, the IC_{50} values were: AGY_2-EGFR LDDS at 10.8 ± 3.3 μM ($p < 0.0001$), AGY_2 LDDS at 25.1 ± 3.9 μM ($p < 0.0004$), and AGY_2 at 35.2 ± 3.7 μM ($p < 0.0154$), compared to 5-FU at 47.9 ± 4.4 μM. Similarly, in P-1 organoids, the IC_{50} values were: AGY_2-EGFR LDDS at 12.2 ± 3.9 μM ($p < 0.0001$), AGY_2 LDDS at 29.09 ± 4.9 μM ($p < 0.001$), and AGY_2 at 41.56 ± 5.1 μM, compared to 5-FU at 45.96 ± 4.8 μM. Stability studies showed that at 4°C and 25°C, the formulations remained stable over 30, 60, and 90 days, with no significant changes in PS and EE. However, at 40°C, the formulations were stable for 30 and 60 days, but the 90-day samples showed reduced EE and increased PS. The PK study demonstrated that AGY_2-EGFR LDDS had a threefold increase in half-life (1.54±0.06 vs. $0.49±0.03_{5\text{-}FU}$ h), AUC (428±10 vs. $125±12_{5\text{-}FU}$ μg/L*h), and clearance (0.73 vs. $2.5_{5\text{-}FU}$ L/h). The biodistribution study showed a higher AGY_2-EGFR LDDS tumor accumulation compared to 5-FU. In the tumor efficacy study, the AGY2-EGFR LDDS treated group showed significant tumor growth inhibition compared to the 5-FU treated group.

Conclusion: This study shows that AGY_2-EGFR LDDS improves the anticancer activity 5-FU and may have the potential to significantly reduce tumor growth in EGFR-positive pancreatic cancer.

#4478 Persistent luminescent nanoparticles for autofluorescence-free tumor imaging: A novel approach to enhanced cancer diagnostics.

Bhupendra B. Srivastava[1], Swati Mohan[1], Murali M. Yallapu[2], Subhash C. Chauhan[2]

[1]School of Integrative Biological and Chemical Sciences, The University of Texas Rio Grande Valley, Edinburg, TX,[2]School of Medicine, The University of Texas Rio Grande Valley, Edinburg, TX

Background: Persistent luminescent nanoparticles (PLNs) represent a significant advancement in tumor imaging by providing autofluorescence-free imaging capabilities. Unlike conventional fluorescent probes, PLNs emit light for an extended period after excitation, enabling high-sensitivity imaging without interference from surrounding tissue autofluorescence. Despite their potential, commonly used PLNs suffer from low photoluminescence quantum yield (PLQY), limiting their brightness and imaging efficiency. This challenge necessitates the development of novel materials and synthesis strategies to enhance PLNs' optical properties and stability for bioimaging applications.
Method: PLNs were developed Mn^{2+}-doped Zn_2GeO_4 (ZGOM) nanorods through a modified hydrothermal synthesis method. The approach was designed to optimize crystal structure, doping efficiency, and luminescent properties. The nanorods were characterized using dynamic lightscattering (DLS), transmission electron microscopy (TEM), X-ray diffraction (XRD), andphotoluminescence spectroscopy to evaluate particle size, morphology, crystallinity, and opticalperformance. Their photoluminescence quantum yield (PLQY) was measured, and stability studies were conducted in biologically relevant media. Additionally, in vitro studies were performed to assess biocompatibility and imaging efficacy in cancer cell models.
Results: The synthesized ZGOM nanorods exhibited a highly uniform rod-like morphology with an average size below 100 nm. Under UV irradiation, the nanorods displayed intense green luminescence with a quantum yield exceeding 50%, demonstrating significant improvement over conventional PLNs. Stability studies confirmed excellent photostability and minimal degradation in aqueous and biological media. In vitro experiments showed efficient cellular uptake and bright, sustained luminescence, enabling high-resolution imaging of cancer cells. Furthermore, the absence of autofluorescence interference in surrounding tissues highlighted the potential of these nanorods as precise imaging agents for tumor targeting and cell tracking.
Conclusion: The Mn^{2+}-doped Zn_2GeO_4 nanorods synthesized in this study exhibit enhanced optical properties, including high PLQY and photostability, making them a promising candidate for autofluorescence-free tumor imaging. The combination of improved synthesis methods and superior material properties addresses the primary limitations of conventional PLNs, paving the way for their application in advanced bioimaging. These findings establish ZGOM nanorods as aviable platform for cancer diagnosis, with potential for further optimization and translation intoclinical imaging applications.

#4479 Optimization of ultrasound-responsive nanoparticles encapsulating cancer cells for enhanced immunotherapy.

Omer Aydin[1], Gizem Kursunluoglu[2], Munevver Akdeniz[1]

[1]Biomedical Engineering, Erciyes University, Kayseri, Turkey,[2]Drug Development and Research Center, Erciyes University, Kayseri, Turkey

Due to the limited effectiveness of current cancer treatment methods, numerous innovative therapeutic strategies are being developed. Among these, immunotherapy, which leverages the patient's immune system, has emerged as a highly investigated and promising approach for cancer therapy. Nanotechnology-based treatments enhance the efficacy of therapies, enabling innovative and advanced technological applications. Within these innovative systems, ultrasound therapy stands out as a technology particularly effective in eliciting and strengthening immune responses against cancer. Using ultrasound-active materials can enhance the mechanical ablation effect in ultrasound therapies, leading to more effective treatments. This study aims to develop biomimetic nanoparticles by synthesizing ultrasound-active gold nanocones (AuNCs), which facilitate tumor size reduction through mechanical ablation under therapeutic ultrasound. This process also releases tumor-specific molecules into the cancer microenvironment, promoting an increase in immune cells. The AuNCs were subsequently coated with B16F10 melanoma cancer cell membranes to create biomimetic nanoparticles (CCM@AuNCs). The membrane-coated nanoparticles were optimized using three distinct techniques: extruder, sonication, and microfluidizer methods. The CCM@AuNCs prepared by these methods were characterized using a Zetasizer (Malvern, Nano ZS, UK) to measure zeta potential, nanoparticle tracking analysis (NTA, Malvern, Nanosight NS300, UK) to determine size distribution, and scanning transmission electron microscopy (STEM) to examine their morphology. All methods produced nanoparticles approximately 200 nm in size with a zeta potential of -40 mV. STEM images clearly showed membrane coating around the particles. The efficiency of membrane coating on CCM@AuNCs prepared via the three methods was evaluated using the BCA Assay Kit (Thermo Scientific-23227). The extruder method demonstrated the highest coating efficiency (43.49%) and protein concentration in 100 µL (120 µg). Based on coating efficiency and characterization results, CCM@AuNCs prepared via the extruder method were selected for further studies. Anti-gp100 (Abcam, ab137078) antibodies were used to confirm membrane coating, and the fluorescence images of CCM@AuNCs were obtained. Cytotoxicity studies performed using the Resazurin assay demonstrated no cytotoxicity for CCM@AuNCs. The biomimetic nanoparticles exhibited homologous targeting, showing increased accumulation in melanoma cancer cells. Cellular uptake studies using fluorescence microscopy and flow cytometry revealed that CCM@AuNCs were internalized more efficiently by B16F10 melanoma cells than by 4T1 breast cancer cells. The study will be further extended to in vivo B16 murine models. This work is supported by the TÜBİTAK 2247-D program (#121C221).

#4480 Novel targeting API@API nanomedicines for synergistic molecular signaling modulation in head and neck cancer and the microenvironment.

Li-Xing Yang, Ru-Fen Chen, Yan-Wei Wu, Pei-Wen Wang, Chih-Chia Huang, Dar-Bin Shieh

National Cheng Kung University, Tainan City, Taiwan

Head and neck cancer (HNC) has become a prominent health concern in Taiwan, particularly among young males, with rising socioeconomic implications due to traditional treatments' limited success in preventing recurrence and metastasis. Our study introduces a novel API@API nanoformulation strategy that combines multiple active pharmaceutical ingredients (APIs) to synergistically target signaling pathways, aiming to overcome limitations of current HNC therapies and reduce toxicity. The API@API nanoformulation leverages natural nanoparticles derived from *Cordyceps sinensis*, incorporating key drugs such as FTY720 and Perifosine. The formulation optimizes amphipathic drug properties, allowing for higher bioavailability and targeted therapeutic action. By evaluating API@API nano cocktails in preclinical HNC models, we observed increased efficacy, with enhanced cytotoxicity and downregulation of critical pathways in HNC cells. The formulation demonstrated selective cytotoxicity across cancer stages, effectively targeting the tumor microenvironment (TME) through dual-drug-loaded nanoparticles. We also accessed the *in vitro* and *in vivo* efficacy of API@API nano cocktails in suppressing tumor growth, modulating immune responses, and reducing cancer cell migration. The platform demonstrated improved pharmacokinetics, enhanced tumor accumulation, and prolonged retention at tumor sites. Further immunological analyses indicated an immunosuppressive-to-immunomodulatory shift within the TME, with increased dendritic and M1 macrophage activity and reduced immunosuppressive cell populations. Spatial proteomic analyses confirmed enhanced immune cell distribution with reducing tumor associate neutrophiles, indicating that API@API formulations may improve HNC sensitivity to immunotherapy. In conclusion, the API@API nanoformulation platform has shown potential as an effective therapeutic strategy for HNC, offering significant advantages in efficacy, reduced side effects, and TME modulation. This platform supports broader biopharmaceutical applications, aligning with the global need for advanced cancer treatments.

#4481 Targeting Xkr8 via nanoparticles-mediated codelivery of siRNA and chemotherapy drugs for cancer immunochemotherapy.
Yuang Chen

Massachusetts Institute of Technology (MIT), Cambridge, MA

Activation of scramblases is one of the mechanisms that regulate the exposure of phosphatidylserine to the cell surface, a process that plays an important role in tumor immunosuppression. Here we show that chemotherapeutic agents induce overexpression of Xkr8, a scramblase activated during apoptosis, at the transcriptional level in cancer cells, both *in vitro* and *in vivo*. Given this finding, we developed a nanocarrier for co-delivery of Xkr8 siRNA and the FuOXP pro-drug to tumors. Intravenous injection of our nanocarrier led to significant inhibition of tumor growth in colon and pancreatic cancer models along with increased antitumor immune response. Targeting Xkr8 in combination with chemotherapy may represent a novel strategy for the treatment of various types of cancers.

#4482 Development of a stable and efficient therapeutic mRNA cancer vaccine utilizing RNA-plex technology.

Yongbin Liu, Dongfang Yu, Lingyi Huang, Junhua Mai

Department of Nanomedicine, Houston Methodist Research Institute, Houston, TX

Background: Therapeutic mRNA vaccine is a promising approach for cancer immunotherapy. However, one of its major challenges is the inherent instability of mRNAs, as it is highly sensitive to ambient environments. Consequently, current mRNA vaccines require production, shipping, and storage at ultra-low temperatures, limiting their global application and increasing costs. Thus, enhancing mRNA stability is essential to develop stable mRNA-based therapeutic vaccines.
Methods: In this study, we developed a novel mRNA stabilization technology termed "RNA-plex", which prevents mRNA from hydrolytic degradation using polymeric macromolecules known as “carrier-base”, composed of a poly-glutamic/aspartic acid backbone conjugated with nucleobases.
Results: We demonstrated that unprotected (naked) mRNA was completely degraded after incubation at 95°C in only 5 minutes, while mRNA complexed with carrier-base remained intact, showing resistance to hydrolytic degradation at high temperatures. Additionally, RNA-plex stabilized mRNA in water at room temperature (RT) for over two weeks and at 4°C for more than two months, whereas naked mRNA degraded within 3 days at RT and within one month at 4°C. Moreover, the protective effect of carrier-base is independent of RNA sequence and structure, effectively safeguarding various linear mRNAs, circular RNAs, and single guide RNAs, and being compatible to commonly used RNA delivery systems. In addition to mRNA protection, RNA-plex effectively boosts mRNA translation in 293T cells and antigen presentation in dendritic cells, making it a potent tool for enhancing cellular responses. We prepared mRNA vaccines by encapsulating either naked OVA mRNA or OVA RNA-plex within *in vivo*-jetRNA (jetRNA), a liposomal *in vivo* mRNA transfection reagent, and tested its effectiveness in cancer immunotherapy in an ovalbumin (OVA) engineered B16 melanoma model (B16-OVA). The jetRNA-RNA-plex formulation demonstrated robust efficacy in inhibiting melanoma growth compared to the formulation containing naked mRNA only ($p<0.01$).
Conclusion: Our findings demonstrate that the RNA-plex technology effectively stabilizes mRNA, offering impressive potential for long-term storage in ambient environment. Moreover, RNA-plex enhances mRNA translation and significantly improves anti-cancer efficacy in cancer vaccines by eliciting a robust anti-tumor immune response. These promising results suggest that RNA-plex holds substantial potential for advancing mRNA-based therapeutics for cancers.

#4483 Photodynamic therapy in breast cancer by photosensitizer-chitosan particles inducing ferroptosis.

Marek Feith[1], Abhilash D. Pandya[1], Astrid Hyldbakk[2], Anders Hogset[3], Kirsten Sandvig[4], Tore Skotland[4], Tore-Geir Iversen[4], Gunhild Mari Malandsmo[1]

[1]Department of Tumor Biology, Oslo University Hospital, Institute for Cancer Research, Oslo, Norway,[2]Department of Biotechnology and Nanomedicine, SINTEF AS, Trondheim, Norway,[3]PCI Biotech AS, Oslo, Norway,[4]Department of Molecular Cell Biology, Oslo University Hospital, Institute for Cancer Research, Oslo, Norway

Triple-negative breast cancer (TNBC) is a subtype of breast cancer associated with poor prognosis and limited treatment options. While chemotherapy has traditionally been the main treatment, resistance frequently emerges, reducing its effectiveness. Recently, a range of immunotherapy strategies, including combinations of chemotherapy and immunotherapy, have expanded treatment possibilities. To further enhance the therapeutic efficacy, there is a desire to combine chemotherapy with other currently used modalities such as photodynamic therapy (PDT) or to encapsulate drugs into nanoparticles (NPs).

Ferroptosis has been described as a highly immunogenic type of cell death, characterized by increased ROS and lipid peroxidation. Mesenchymal cancer cells have been reported to be more sensitive to ferroptosis than epithelial cells. We have previously shown that tetraphenylchlorin-conjugated chitosan nanoparticles (TPC-CS NPs) loaded with mertansine and cabazitaxel induce ferroptosis in TNBC.[1] In this project, we investigated the effect of TPC-CS NPs together with free RSL3, a ferroptosis inducer. We show that such treatment induces cell death in a mesenchymal breast cancer cell line but not in an epithelial one. The combined treatment also significantly affects lipid peroxidation and mitochondrial function. Based on these results, we encapsulated RSL3 into TPC-CS NPs and used them in two different breast cancer cell lines. We explored the photodynamic effect of empty and RSL3 loaded TPC-CS NPs upon illumination on cell viability by using an MTS assay. Since we have not observed any beneficial effect of TPC-CS NPs-RSL3, we explored the uptake of only empty TPC-CS NPs by using fluorescence microscopy and flow cytometry in these two cell lines. Currently, a biodistribution study in immunocompetent animals bearing 4T1 tumors is being performed. We will perform the maximum tolerable dose experiments for illumination to determine the light dose for further experiments. Moreover, we will perform efficacy studies of TPC-CS NPs and investigate the immune cell composition of tumors and tumor microenvironment using a flow cytometry panel of 25 markers.

This project has received funding from the Europe Union's Horizon 2020 research and innovation program under the Marie Sklodowska-Curie grant agreement 956544.

#4484 Targeting DNA repair mechanism that leverages current standard of care interventions with a novel agent in glioma.

Meser M. Ali[1], Hamid Suhail[1], Mahesh Yadab[1], Ataur Rahman[1], James Snyder[2]

[1]Wayne State University School of Medicine, Detroit, MI,[2]Henry Ford Hospital, Detroit, MI

Glioblastoma (GBM) is a malignant glioma characterized by molecular heterogeneity and poor prognosis. GBM remains a uniformly lethal malignancy, with patient survival rarely exceeding two years despite the best available treatments. In clinical practice, about 60% of GBM patients have shown overexpression of O^6-methylguanine-methyl-transferase (MGMT), an enzyme responsible for DNA repair, were found to receive little benefit from TMZ and represent a group of great unmet need with no chemotherapeutic agents that significantly improve survival. A key factor contributing to treatment resistance and disease relapse is the overexpression of MGMT. MGMT overexpression reduces the efficacy of standard therapies like temozolomide (TMZ) and radiotherapy (RT), leaving patients with active MGMT expressions in urgent need of new treatment strategies. The depletion of MGMT in tumors has been investigated as a strategy to increase TMZ and RT efficacies in resistant, MGMT-positive GBMs. Chemical depletion using O^6-benzylguanine derivatives as MGMT inhibitors have been actively tested, but these compounds are associated with high hematologic toxicity. Recent studies have shown that disulfiram (DSF), an alcohol aversion drug, combined with copper (Cu), can inhibit MGMT and improve the response to TMZ in GBM. However, phase II clinical trials using oral Cu/DSF demonstrated no survival benefit, primarily due to the instability of DSF *in vivo*. To address this limitation, we developed a novel delivery system using 2-hydroxypropyl beta cyclodextrin (HPßCD) encapsulating the Cu complex of DSF's active metabolite, diethyldithiocarbamic acid (DDC). This HPßCD-Cu$(DDC)_2$formulation stabilizes the complex, preventing degradation and reducing non-specific interactions in the bloodstream. *In vitro* studies revealed that HPßCD-Cu$(DDC)_2$ inhibited MGMT through the ubiquitin-proteasome pathway. Inhibition of MGMT activity in cell cultures vastly increased the alkylation-induced DNA double-strand breaks (gama-H2AX), that are hallmark of TMZ effectiveness as supported by cytotoxicity and the increased levels of apoptotic markers, like JNK-P and cleavage of PARP-1. Systemic delivery of HPßCD-Cu$(DDC)_2$ in MGMT overexpressed patient derived orthotropic xenograft resulted in depletion of MGMT with tumor size regression. Tumor burden has been evaluated within patient derived orthotropic rat models that represent high expression of MGMT followed by oral vs intravenous treatments.

#4485 Resistance to ferroptosis in high grade diffuse large B-cell lymphoma is mediated through the Nrf2 signaling pathway.

Meiying Yang[1], Jonathan S. Rink[1], Adam Y. Lin[1], Shuo Yang[1], Colby S. Thaxton[2], Leo I. Gordon[1]

[1]Medicine, Hematology/Oncology, Robert H. Lurie Comp. Cancer Ctr. of Northwestern Univ., Chicago, IL,[2]Urology, Robert H. Lurie Comp. Cancer Ctr. of Northwestern Univ., Simpson Querry Research Institute, Chicago, IL

Introduction: High-grade B-cell lymphomas (HGBCL) with *C-MYC* and *BCL-2* rearrangements are aggressive and resistant to standard treatment. Some B cell lymphomas, including HGBCLs and diffuse large B cell lymphomas (DLBCL), are susceptible to ferroptosis, a cell death pathway marked by toxic lipid peroxides. We have shown that some DLBCLs are sensitive to ferroptosis induced by gold high-density lipoprotein (HDL)-like nanoparticles (Au-HDL NPs), while others, including some HGBCLs, are more resistant. Differential gene expression (DEG) analysis of RNAseq data suggests that resistance to Au-HDL NP-induced ferroptosis correlates with increased expression of *Nrf2* associated genes. We hypothesized that *Nrf2* protects HGBCL cells against ferroptosis induced by Au-HDL NPs and other reactive oxygen species (ROS)-inducing chemotherapy agents and tested this by generating *Nrf2* knockout OCI-ly1 cells (*Nrf2*$^{-/-}$).
Methods: DLBCL (SUDHL-4) and HGBCL (RC, OCI-ly1, OCI-ly8, OCI-ly18) cell lines were studied. Au-HDL NPs were synthesized as previously described. RNA from RC and SUDHL4 cells treated with Au-HDL NPs or vehicle were subjected to RNA-seq. DEGs were validated by RT-qPCR and Western blot. *Nrf2* $^{-/-}$ OCI-ly1 cells were generated using CRISPR/Cas9. Viability was assessed by MTS and Annexin V-FITC/PI staining, while lipid peroxidation was quantified by C11 BODIPY.
Results: HGBCL cell lines (RC, OCI-ly1, OCI-ly8, OCI-ly18) were less sensitive to Au-HDL NP-induced ferroptosis (IC_{50} = 31.4, 27.2, 58.2, and 26.0 nM, respectively) compared with the DLBCL cell line SUDHL4 (8.1 nM). RNAseq, RT-qPCR and western blot revealed higher expression of *Nrf2* regulated genes, particularly *NQO1* in Au-HDL NP-treated RC (19.9-fold), OCI-ly1 (9.0-fold), and OCI-ly8 (36.5-fold) cells compared with SUDHL4 (4.2-fold). *Nrf2* $^{-/-}$ OCI-ly1 cells were less viable after treatment with Au-HDL NPs than SUDHL4 (30%, 14%, 6% vs. 104%, 75%, and 41% at doses of 10, 20, and 40 nM Au-HDL NPs, respectively). Annexin V^+/PI^+ was increased in *Nrf2* $^{-/-}$ OCI-ly1 cells (58%) compared to OCI-ly1^{wt} cells (32%), and lipid peroxidation levels were also higher in *Nrf2* $^{-/-}$ cells, suggesting that *Nrf2* mediates resistance to Au-HDL NPs by reducing oxidative burden. Compared to OCI-ly1^{wt} cells, *Nrf2* $^{-/-}$ cells increased sensitivity to other ferroptosis inducers, such as erastin (IC_{50} 1.1 vs 5.7 μM) and RSL3 (IC_{50} 26.5 vs 57.3 nM). *Nrf2* $^{-/-}$ cells exhibited increased sensitivity to ROS-related chemotherapy agents compared to OCI-ly1^{wt} cells, including doxorubicin (IC_{50} 1.2 vs 2.6 nM) and venetoclax (IC_{50} 21.5 vs 52.3 μM).
Conclusion: *Nrf2* signaling plays a crucial role in conferring resistance of aggressive lymphomas to ROS-dependent cell death mechanisms, including ferroptosis. Targeting *Nrf2* could be a promising strategy to overcome resistance to ferroptosis and enhance the efficacy of ROS-inducing chemotherapy agents.

#4491 HSP70 leverages STUB1 to modulate N-Myc protein turnover in lethal prostate cancer.
P. Xu, J. C. Yang, B. Chen, C. Nip, S. Ning, A. C. Gao, **C. Liu**;
UC Davis, Sacramento, CA

Background: Imbalances in protein homeostasis (proteostasis) are associated with a wide range of diseases, including neurodegeneration and tumorigenesis. Prostate cancer has proven to be a key model for understanding how proteostasis regulates tumor progression. Neuroendocrine prostate cancer (NEPC) is the most aggressive type of prostate cancer with no effective treatment. The amplification of N-Myc (encoded by *MYCN*) is a key modification of NEPC. However, it has proven challenging to identify therapeutic strategies that reduce N-Myc transcriptional activity or levels owing to the presence of intrinsically disordered functional domains and lack of enzymatically active sites. In this study, we sought to take a different approach and identify the molecular chaperones involved in N-Myc proteostasis.
Methods: N-Myc was knocked down by siRNA. Cell proliferation and N-Myc expression were assessed using cell viability assays and Western blotting, respectively. Rapid immunoprecipitation pull-down assays followed by label-free mass spectrometry were used to identify N-Myc-binding proteins. Co-immunoprecipitation (Co-IP) and Proximity Ligation Assay (PLA) were performed to detect the interaction between HSP70 and STUB1 with N-Myc. In vitro ubiquitination assays were conducted to detect the ubiquitination of N-Myc. Site-directed mutagenesis (SDM) was used to construct N-Myc, STUB1, and ubiquitination deletion or point mutation plasmids. Cycloheximide (CHX) chase assays were employed to examine the half-life of N-Myc.
Results: Knockdown of N-Myc by siRNA significantly inhibited the growth of H660, UCDCaP-CR, and CWR22Rv1 cells. A total of 779 proteins were identified as N-Myc-binding proteins. Among them, several HSP70 family proteins, such as HSPA1B (HSP70), HSPA6, and HSPA8 (HSC70), were the most enriched. The HSP70/STUB1 complex interacted with N-Myc and regulated N-Myc protein turnover. This interaction appeared to occur at a degron ‘SELILKR’ in N-Myc. The K416 and K419 of N-Myc seem to be sites for ubiquitination by STUB1, where it added K11-linked polyubiquitin chains for further proteasome degradation.
Conclusions: The HSP70 interacts with N-Myc at a conserved binding motif and regulates N-Myc protein turnover through STUB1.

#4492 Covalent ligands that selectively disrupt CDK4-CDC37/HSP90 interactions in cancer cells.

Z. E. Potter[1], B. Melillo[1], K. E. DeMeester[2], B. F. Cravatt III[1];
[1]The Scripps Research Institute, La Jolla, CA, [2]Lafayette, Easton, PA

The Heat-Shock family of Proteins (HSPs)—which are conserved in prokaryotic and eukaryotic organisms—are molecular chaperones that regulate protein folding and stability, and in turn cellular homeostasis. In human cancers and hematological malignancies, HSPs are often upregulated. Additionally, many oncogenic proteins are HSP90 client proteins. Thus, decades of research have focused on inhibiting HSP90's function as a potential anti-cancer therapeutic strategy. However, the clinical application of HSP90 inhibitors has been hampered by dose-limiting toxicity due to the systemic disruption and subsequent dysregulation of HSP90 client proteins. Hence, the selective targeting of individual cancer-relevant client:chaperone interactions could represent a more tractable therapeutic strategy. Using activity-based protein profiling (ABPP), we have identified a stereoselective and site-specific covalent liganding event at an isotype-restricted cysteine on CDK4 located in proximity to the interface for binding the HSP90 co-chaperone CDC37. Alterations to the CDK4/CDK6/Rb signaling pathway are common in almost all tumors, and typically arise via the overexpression of CCND1, or loss of the CDK4/CDK6-specific inhibitor p16INK4a—either event increases CDK4/CDK6 activity and leads to uncontrolled cell proliferation. Importantly, CDK4 stability is highly dependent on interactions with CDC37 and HSP90. We show that the covalent ligands selectively disrupt the CDK4:CDC37:HSP90 chaperone complex while sparing other kinase:CDC37:HSP90 interactions; the selective disruption of this chaperone complex leads to the partial degradation of CDK4 in breast cancer cells. The ligand-induced disruption of CDK4-chaperone interactions and CDK4 stability are both stereoselective (not observed with an inactive enantiomeric compound) and site-specific (not observed with a C135S mutant CDK4 protein). Given CDK4's validated role in regulating the growth of hormone-sensitive cancer cells, compounds that can selectively disrupt chaperone regulation and stability of this kinase may have therapeutic potential as precision medicines.

#4493 Exploring APE1-G4 interactions and FACT complex inhibition to overcome therapy resistance in pediatric medulloblastoma.

Ritesh Dey[1], Yingling Chen[1], Sutapa Ray[2], Kishor Bhakat[1]

[1]Genetics, Cell Biology and Anatomy, University of Nebraska Medical Center, Omaha, NE,[2]Pediatrics Hematology/Oncology, University of Nebraska Medical Center, Omaha, NE

Medulloblastoma or MB is the most common malignant brain tumor in children. Tumor recurrence and therapy resistance remain critical obstacles for the treatment of MB. Although surgical resection followed by high doses of chemotherapies and ionizing radiation IR has considerably improved the survival rates. Resistance of residual tumor to IR and chemotherapies often leads to tumor recurrence. Despite advances in standard therapies, survival rates for relapsed MB patients have remained stagnant for over three decades, leaving clinicians and families with limited options. Previous reports have demonstrated that APE1, a key protein involved in repairing AP sites and single-strand breaks SSBs in DNA, is overexpressed in MB, and its activity is associated with tumor progression. Knockdown of APE1 enhances sensitivity of MB cells to radiation and chemotherapy, suggesting that APE1 mediates IR/chemo resistance. We have recently demonstrated that IR or cisplatin treatment induced APE1 interaction which Facilitates Chromatin transcription FACT complex, and treatment with CBL0137, a FACT targeted small molecule, improves the potency of cisplatin and radiation in vitro and in intracranial orthotopic MB xenograft model. Our current study discovered that recombinant APE1 binds to non-canonical four stranded DNA secondary structure called G quadruplexes or G4 DNA in the genome of MB cells and interacts with G4 in cells. Inhibition of APE1 binding to G4 by small molecules affects damage repair in cells. Treatment with these small molecules dose-dependently affects MB tumor cell growth in vitro. Further, we have delineated a mechanistic link of G4 with APE1 mediated drug resistance. Our project unraveled a novel mechanism by which APE1 and G4 promote therapy resistance and identify a promising strategy to improve the efficacy of IR and cisplatin and prevent tumor recurrence.

#4494 Structure, dynamics and therapeutic potential of fatty acid synthase.

Naimul Hasan[1], Alexander Keszei[2], Matthew Waas[2], Thomas Kislinger[2], Razq Hakem[2], Mohammad Mazhab-Jafari[2]

[1]Medical Biophsysics, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[2]Medical Biophysics, Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada

De novo lipid synthesis is facilitated by the multifunctional enzyme fatty acid synthase (FASN), a hallmark of cancer associated with chemotherapeutic resistance and poor prognosis. Human FASN (hFASN) is a dynamic protein that undergoes significant conformational changes during catalysis, posing challenges for structural characterization. To date, no structural information is available for full-length hFASN, hindering our understanding of its catalytic mechanism and complicating rational drug design.Here, we report the structure of hFASN resolved using electron cryo-microscopy (cryoEM). The modifying region of hFASN was determined at near-atomic resolution using a recombinant expression system bound to the first-in-class inhibitor Denifanstat, enabling structure-based small molecule discovery. Additionally, we solved the full-length structure of endogenous hFASN from MCF7 cells, revealing an interaction with the small heat shock protein HSP27. In some 2D classes of hFASN from cryoEM data, we found partial unfolding of the modifying region, evidence of potential protein degradation. However, HSP27 knockdown in breast cancer cell lines did not alter overall hFASN levels, indicating that this interaction may be transient or involve additional partners.Mass spectrometry-based post-translational modification analysis further identified dihydroxylation of proline, arginine, and tyrosine residues in hFASN from MCF7 cells, likely reflecting oxidative stress. These modifications may play a role in protein stabilization or regulation under stress conditions, highlighting a potential mechanism for hFASN activity modulation. Together, these findings provide critical structural and regulatory insights, paving the way for targeted therapeutic development.

#4495 Inhibition of OTUD4/CD73 proteolytic axis by novel small molecule inhibitor ST80 reinvigorates tumor immune response.

Kevin Li, Yueming Zhu, Yong Wan

Emory University, Atlanta, GA

Despite the widespread utilization of immunotherapy, the poor clinical response by immune-suppressive tumors is an emerging challenge in the use of current immune checkpoint inhibitors. Recent research has revealed that CD73, or Ecto-5′-nucleotidase, is an enzyme overexpressed in many cancers, and works in concert with CD39 to produce immunosuppressive extracellular adenosine, subsequently inhibiting CD8+ T cell responses. Our multi-omics analysis identified CD73 and OTUD4, a deubiquitinase that stabilizes CD73 by counteracting its that counteracts its E3 ligase-mediated ubiquitination and degradation, as potential targets for enhancing anti-cancer immune responses.

Using druggability and pharmacophore simulations, we developed ST80, a novel small molecule inhibitor that disrupts the OTUD4-CD73 interaction by binding to the hydrophobic OTUD4 binding site on CD73. Within in vitro models of triple-negative breast cancer, EGFR-mutant lung cancer, ovarian cancer, and colorectal cancer, ST80 demonstrates significant potential in overcoming immune evasion by reducing adenosine production in the tumor microenvironment, subsequently reinvigorating the tumor immune responses by enhancing CD8+ T cell proliferation and IFN-γ production. By targeting the CD73/OTUD4 proteolytic axis, ST80 presents a promising strategy for treating cancers with immune-suppressive properties, potentially enhancing the efficacy of current immunotherapies.

#4496 Small molecule inhibition of previously “undrubbable” transcription factors with AI-guided functional proteomics.

Alexander J. Federation, Daniele Canzani, Andrea Gutierrez, Julia Robbins, Brian McEllin, Anastasiya Prymolenna, Lillian Tatka, Bodhi Hueffmeier, Yang Gao, Tonibelle Gatbonton-Schwager, Erin Broderick, Gaelle Mercenne, William Fondrie, Lindsay Pino

Talus Bioscience, Inc., Seattle, WA

Transcription factors (TFs) are central regulators of gene expression and key drivers of diseases such as cancer, autoimmune disorders, neurological disease, and metabolic conditions. Despite their critical role, TFs have long been considered “undruggable” due to their intrinsic disorder outside of native cellular environments, complex multiprotein assemblies, and the absence of traditional binding pockets suitable for small molecule targeting.

To address these challenges, Talus Bio has developed TF-Scan, a live-cell platform that provides a proteome-wide view of drug-induced changes in TF DNA-binding activity. This technology integrates high-resolution functional proteomics with advanced machine learning to measure TF:DNA engagement directly in unmodified human cells. Data from TF-Scan feeds into Strategian, a deep tensor factorization model trained on Talus Bio’s proprietary TF-Scan database, enabling AI-driven discovery of novel small molecule modulators.

Strategian evaluates a chemical universe of billions of drug-like molecules to predict their effects on TF activity, prioritizing candidates by potency and selectivity. These predictions are validated experimentally using TF-Scan, which further refines lead selection. This approach has enabled the identification of novel scaffolds for TFs including TBXT, ARv7, and STAT3, demonstrating the ability to generate drug-like compounds tailored to specific TFs.

By combining live-cell proteomics with AI-driven modeling, TF-Scan and Strategian create a powerful, scalable platform for targeting TFs and other challenging regulators within the regulome. This work establishes a new paradigm for drug discovery, transforming previously intractable targets into actionable opportunities to address critical unmet medical needs.

#4497 Discovery and optimization of a covalent AKR1C3 inhibitor for evaluation in hormone-dependent cancers.

Robert J. Grams[1], Robert J. Seal[2], James Veccia[2], **Ku-Lung Hsu**[1]

[1]The University of Texas At Austin, Austin, TX,[2]The University of Virginia, Charlottesville, VA

Aldo-keto reductase family 1 member C3 (AKR1C3) is a member of the AKR superfamily of enzymes that metabolizes androgen, estrogen, and prostaglandin substrates to produce potent drivers of proliferation in hormone-dependent cancers. Interest in developing selective inhibitors have produced tool compounds for inactivation or degradation of AKR1C3 with varying degrees of selectivity among the 15 known AKR proteins. Selectivity of AKR1C3 inhibitors across the AKR family is critical since a clinical candidate failed due to hepatotoxicity from off-target inhibition of AKR1D1. Here, we report development of a sulfonyl-triazole (SuTEx) covalent AKR1C3 inhibitor (RJG-2051) that site selectively engages a non-catalytic tyrosine residue on AKR1C3 in cells. Importantly, RJG-2051 exhibited negligible cross-reactivity with detectable AKRs or other proteins across thousands of tyrosine and lysine sites quantified by chemical proteomics. The disclosure of a covalent and proteome-wide selective inhibitor for potent AKR1C3 inactivation in cells will expedite cell biological studies for testing the therapeutic potential of this metabolic target.

#4498 Drug screens identify new therapeutic targets that synergize with EZH1/2 inhibition in adult T-cell leukemia/lymphoma.

Noorhan Ghanem, Carman K.M. Ip, Kit Tong, Mehran Bakhtiari, Michael Y. He, Aaron Schimmer, Robert Kridel

University of Toronto, Toronto, ON, Canada

Adult T-cell leukemia/lymphoma (ATLL), a rare form of non-Hodgkin lymphoma, affects approximately 2-5% of individuals infected by the retrovirus Human T-cell Lymphotropic Virus- 1 (HTLV-1). The disease has a dismal prognosis and resistance to chemotherapy is commonly seen in most patients. A significant characteristic of ATLL pathogenesis involves the disruption of normal epigenetic regulation, which results in transcriptional repression of tumour suppressors, mediated by the polycomb repressor complex 2 protein. Within this protein complex, the histone methyltransferases EZH1 and EZH2 play vital roles in catalyzing the excessive trimethylation of histone 3 lysine 27 (H3K27me3). In light of these mechanisms, a phase II clinical trial evaluated the efficacy of Valemetostat (VAL), a dual EZH1/2 inhibitor, in ATLL patients. Half of the patients responded to VAL; however, the median progression-free survival was only 7 months.To address these challenges and unbiasedly identify agents that could synergize with VAL, we conducted extensive high-throughput drug screens across four ATLL cell lines (ATL1K, ATL43T-, ATL55, and ED41214+). We initially screened 3,113 FDA-approved drugs to assess their pharmacological relevance in the presence of VAL. Additionally, given the important role of epigenetic deregulation in the pathogenesis of ATLL, we also tested 68 epigenetic chemical probes (ECPs) from the Structural Genomics Consortium with and without VAL. From these screens, we narrowed down the top 98 candidates from the FDA-approved drugs, based on the average cell viability minus two standard deviations, and the top five synergistically effective ECPs based on Bliss syngery score calculated by Synergy Finder across all four cell lines. We next screened these hits from FDA-approved drugs and the synergistically effective ECPs along with the corresponding negative non-functional probes across a wider ten-point dose range(2.5nM to 1uM for FDA-approved drugs and 10nM to 5uM for ECPs), both in the presence or absence of VAL. Based on the observed synergy, we identified our top nine hits that included bromodomain and methyltransferase inhibitors. Finally, we tested these nine hits in 6x6 combination matrices to precisely determine the optimal dosing with VAL.Currently, we are expanding our validation across additional ATLL cell lines and optimizing dosage schedules for *in vivo* testing on our established ATLL models to ensure synergistic effective.This research aims to identify novel targets that will sensitize resistant ATLL to epigenetic therapies. These findings may contribute to developing strategies to address drug resistance and offer additional treatment opportunities for this difficult-to-treat disease.

#4499 Drug target ID and binding site mapping in complex cellular environments using LiP-MS.

M. Soste[1], P. Shichkova[1], R. Bruderer[1], M. Stefancic[1], D. Redfern[1], F. Cavallo[2], K. Bhalla[2], H. Burston[3], P. S. Baruah[3], R. Hjerpe[2], S. Thomson[2], A. Jordan[2], **Y. Feng**[1];

[1]Biognosys AG, Schlieren, Switzerland, [2]Sygnature Discovery, Nottingham, United Kingdom, [3]Sygnature Discovery, Saint-Laurent, QC, Canada

Identifying drug targets within cellular contexts is critical to advancing both target-based and phenotypic drug discovery, particularly for small molecule degraders, such as molecular glues (MG). In most common cases of MG, target identification involves two key mechanism of actions (MoA): determining specific protein target(s) that are engaged by the E3 ligase when a drug binds the E3 ligase, and, conversely, identifying the E3 ligase (adaptor) that is recruited to form the ternary complex when the drug directly targets the protein itself. Limited proteolysis combined with mass spectrometry (LiP-MS) has emerged as a robust, label-free method for deconvoluting small molecule and peptide targets directly within cell lysates, avoiding the need for compound modification or cell line manipulation. This approach leverages a non-specific protease under controlled conditions to detect conformational changes or steric hindrance induced by drug-protein interactions or protein-protein interactions.

Using quantitative MS, LiP monitors over 250,000 peptides, representing more than 8,000 proteins in a mammalian cell line, allowing for proteome-wide profiling of drug-target interactions. A comprehensive concentration-response study spanning seven concentrations, combined with machine learning-based LiP-scoring, provides a precise ranking of targets and predicts binding sites with peptide-level resolution. Beyond global target identification, we also established a high-throughput HR-LiP workflow that offers detailed peptide-level insights into small molecule-protein interactions directly in cell lysates from cell lines overexpressing target proteins or complexes. This workflow bypasses the need for protein purification, mitigating risks of protein truncation or misfolding.

To evaluate LiP-MS' performance on molecular glue MoAs, we performed global target ID experiments using two well-characterized models: the cyclin K degraders CR8 and SR-4835 and the GSPT1 degraders MRT-2359 and Eragidomide. While the cyclin K degraders bind directly to CDK12, inducing its interaction with DDB1 and leading to the degradation of cyclin K within the CDK12 complex, the GSPT1 compounds engage CRBN, which in turn recruits and degrades GSPT1 as a neosubstrate. Applying HR-LiP, we mapped the binding site of the BRD4 inhibitor JQ1 on full-length BRD4, a large protein challenging to study via standard methods, using a mammalian transient overexpression system. Similarly, we located binding sites for EGFR inhibitors gefitinib and afatinib on the membrane-bound EGFR protein. Additionally, we pinpointed the SMER28 binding site on the hexameric ATPase VCP, an autophagy enhancer, demonstrating the method's applicability to large protein complexes.

In conclusion, LiP-MS provides a versatile toolbox for identifying drug targets and mapping binding sites within complex cellular environments.

#4500 Exploring site-specific activation of kinase inhibitors via AKR1C3-mediated prodrug strategy.

Esther Elonga, Zhengnian Li, Michael Martinez, Anuradha Tathireddy, Stephen M. Hinshaw, Nathanael S. Gray

Chemical and Systems Biology, Stanford University School of Medicine, Stanford, CA

Targeted therapies such as kinase inhibitors have significantly advanced cancer treatment. However, targeting pan-essential kinases remains challenging due to the side effects associated with a narrow therapeutic window. To address this issue, we propose developing prodrugs that can be site-specifically activated by Aldo-keto reductase 1C3 (AKR1C3). Specifically, a kinase inhibitor prodrug will be selectively activated by AKR1C3 to release the active parent compound in tissues with overexpression of AKR1C3. In this study, we designed prodrugs of the kinase inhibitor OTS964, a potent inhibitor of the pan-essential kinase CDK11, modeled after the AKR1C3-activated prodrug OBI3424. Using rational design principles, our prodrugs were engineered for selective activation by AKR1C3. Enzymatic assays confirmed AKR1C3-mediated reduction of the prodrugs, liberating the parent compound OTS964. Subsequent in vitro assays demonstrated that these prodrugs retained comparable activity to the parent compound in cell viability, immunoblotting, and NanoBRET assays. This study introduces a promising strategy to enhance the therapeutic window of pan-essential kinase inhibitors by concentrating their effects in affected tissues while sparing normal cells.

#4501 Temporal Validation of Novel Therapeutic Targets in Non-Hodgkin Lymphoma.

Tudor I. Oprea[1], Mohammed Quazi[1], Suman Sirimulla[1], Cristian G. Bologa[2], Ruben Karapetian[1], Alexey Pushechnikov[1], Bill Farley[1], Nikolay Savchuk[1]

[1]Expert Systems, Inc., San Diego, CA,[2]Internal Medicine, University of New Mexico, Albuquerque, NM

In 2024, we reported the development of knowledge graph machine learning (KGML) models focused on 41 blood cancers (1), using several public resources. Our disclosure identified 19 drug targets that are likely to be druggable and fall into the "Tchem" category—that is, targets perturbed by small molecules (2). These 19 genes had limited or no known blood cancer associations, when evaluated via the DISEASES platform (3). Upon re-evaluation a year later, five genes (BLK, FCER2, FRK, CAMK2D, and EPHB1) were no longer investigated due to a growing body of literature. Of the remaining 14 genes (see Table 1), only two (IRAK3 and ITPKB) have marginally relevant associations with lymphoma, leukemia, or myeloma, according to the DISEASES platform (3).

Table 1 summarizes cytotoxicity assays for the 14 targets, using compounds specific for each target. Non-Hodgkin lymphoma cell lines were: Toledo (CL1), SU-DHL-6 (CL2), TMD8 (CL3), and JeKo-1 (CL4). CC50 (50% cytotoxic concentration) values, measured in micromolar concentrations, were collected at 3 (_3d) and 7 days (_7d), respectively; "nd" - not determined; "gt" - greater than value.

Except for GRM8, all targets exhibited at least one micromolar CC50 value. Five kinases (IRAK3, ITPKB, PRKCE, ACVR2B, and PIM1), one enzyme (ADCY1), and one ion channel (TRPV4) have at least one sub-micromolar CC50 value (25 values total). Some targets (e.g., GPR18, a G-protein coupled receptor; and ITPKB, a kinase) show low micromolar CC50s at 7 days, with gt 20 CC50 after 3 days, suggesting target engagement. Confirmatory target engagement experiments are in progress. Although preliminary, these data validate our KGML approach (1), as they implicate at least seven targets in non-Hodgkin lymphoma disease biology, with potentially novel therapeutic applications.

#4503 Analyzing and expanding the druggable proteome from predicted models.

Phillip W. Gingrich, Ansuman Biswas, Bissan Al-Lazikani

Genomic Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: The number of experimentally solved protein structures is ever-growing. These are vital for informing early drug discovery, yet only 40% of the human proteome is structurally characterized experimentally. Newmodelling tools such as AlphaFold are heralded to plug the gap in structural knowledge for the drug discoverer. Importantly, what part of the human proteome is available to drug discovery using the collective data? Here, we report analyses at the residue, protein, and cluster levels to understand how much of the proteome is structurally enabled for drug discovery, and we present the first comprehensive, reliable druggability map of the human proteome.
Methods: We mapped experimental structures and AF models to canonical forms in the human proteome, mapping experimental coverage and pLDDT scores to each residue. As a proxy for useful domain-sized structures, the presence of at least 100 consecutive residues with experimental coverage or high prediction confidence was annotated per protein. MMSeqs2 clustering was used to explore proteins where AF struggled, both with and without experimental coverage in the PDB. Finally, protein pockets were found using SURFNET and classified by our draggability classifier.
Results: The PDB covers 2.9 million residues across the proteome. AF affords 4.2 million additional confident predictions, yielding 68% of the proteome as structurally enabled at the residue level. 7100 proteins of those in the PDB have >= 100 consecutive residues with experimental coverage. AF provides 7600 more proteins with >= 100 consecutive confident residues, resulting in 72% of the proteome being structurally enabled with a domain-sized structure. AF makes low confidence predictions for the last 5700 proteins, most of which no experimental coverage. Likewise, low confidence predictions are made for proteins typically in complex with other macromolecules, despite 75% of them having at least 50% experimental coverage. In total, 40% of the proteome was classified as druggable using experimental structures or high confidence models, with as much as 60% being druggable with loosened confidence criteria. We provide a detailed map and guidelines on the utility of AF for drug discovery.
Conclusion: Roughly 70% of the proteome has been made accessible and suitable for in silico drug discovery efforts based on experimental coverage and prediction uncertainty. This has expanded the druggable fraction of the proteome significantly over previous estimates. This is the first comprehensive analysis on the suitability of predicted models, highlighting where predicted models are practically useful to the drug discoverer.

#4504 The impact of metabolite kinetics on dysregulation of essential enzymes in cancers with MTAP deficiencies.

Oscar Aubi, Shannon Faris, Daniel M. Walden, Kai Yang, Zhipeng Fang, Mason J. Appel, Angelica M. Gonzalez-Sanchez, Kelly S. Trego, Briana E. Marinoni, Brittany Cruzan, Pari Lanham, Khristina Magallanes, Damien Garbett, Ivan G. Shabalin, Rebeca M. Choy, **Peter Teriete**

Ideaya Biosciences, South San Francisco, CA

Background: Methylthioadenosine phosphorylase (MTAP) deletion is a common genetic alteration in various cancers, leading to accumulation of methylthioadenosine (MTA) and dysregulation of protein arginine methyltransferase 5 (PRMT5), an essential enzyme that utilizes the MAT2A product S-adenosylmethionine (SAM). This study investigates the complex interplay between metabolite kinetics and enzyme inhibition in MTAP-deficient cancers, focusing on the efficacy of MTA-cooperative PRMT5 inhibitors and their combination with the MAT2A inhibitor IDE397.

Methods: We employed a multi-faceted approach including molecular mutagenesis, surface plasmon resonance (SPR), X-ray crystallography, molecular dynamics simulations, NanoBRET assays, and cell-based studies to elucidate the mechanisms of metabolite exchange and inhibitor binding in PRMT5. The effects of MTA/SAM ratios on PRMT5 inhibitor efficacy were examined, and combination studies with IDE397, an allosteric MAT2A inhibitor, were conducted.

Results: Our findings revealed that metabolite exchange in PRMT5 is possible even in the presence of MTA-cooperative inhibitors. Crystallographic and molecular dynamics studies identified a second access channel to the metabolite binding pocket, gated by Lysine 393, allowing for metabolite exchange in the presence of substrate-binding inhibitors. The efficacy of MTA-cooperative PRMT5 inhibitors in cell-based assays was significantly influenced by the ratio of MTA to SAM, not just by absolute MTA concentration. Co-treatment with IDE397 lowered SAM levels in cells, substantially enhancing the efficacy of MTA-cooperative PRMT5 inhibitors.

Conclusions: This study provides novel insights into the metabolic vulnerabilities of MTAP-deficient cancers and the mechanisms underlying the efficacy of targeted therapies. The discovery of the metabolite exchange channel in PRMT5 and the impact of MTA/SAM ratios on inhibitor efficacy offer new avenues for drug design and combination strategies. The synergistic effect observed with concurrent MAT2A and PRMT5 inhibition presents a promising approach with the potential to profoundly alter the treatment landscape for patients with MTAP deleted cancers.

Our novel findings in this study provide mechanistic support for the importance of understanding metabolite exchange in PRMT5, the crucial impact of MTA/SAM ratios on the potency of MTA-cooperative PRMT5 inhibitors, and the benefit of combination therapy with the MAT2A inhibitor IDE397.

#4505 Differential protein expression in platelets collected from glioma patients and healthy controls: A comparative study.

Vibecke Markhus[1], Katarina Fritz-Wallace[1], Olav Mjaavatten[1], Einar Kleboe Kristoffersen[2], Rupavathana Mahesparan[3], Hrvoje Miletic[4], Frode Selheim[1], Dorota Goplen[5]

[1]Institute of Biomedicine, University of Bergen, Bergen, Norway,[2]Immunology and Transfusion Medicine, Haukeland University Hospital, Bergen, Norway,[3]Neurosurgical department, Haukeland University Hospital, Bergen, Norway,[4]Experimental Neuro-oncology and Neuropathology, Haukeland University Hospital, Bergen, Norway,[5]Oncology, Haukeland University Hospital, Bergen, Norway

Background: Glioblastoma (GBM) is the most aggressive type of primary brain tumor in adults. Standard treatment fosters event free survival for approximately 7 months and extends overall survival to only 15 months. Due to the risk of biopsy complications, the verification of the tumor is not always possible. Therefore, in many cases the treatment is based on MRI findings and exclusion of other malignancies. A confirmative liquid biopsy would provide additional and useful support for clinical decision making and patient counselling. To date no liquid biopsy for GBM is available.
Platelets interact with tumor cells in multiple ways, including direct contact, release of cytokines, and uptake of tumor-derived extracellular vesicles. These interactions cause modifications in platelet RNA and protein profiles, yielding tumor educated platelets that reflect specific tumor characteristics.
Our study aimed to use proteomic analysis to identify differential protein expression in platelets collected from glioma patients compared to healthy controls, identifying potential biomarkers for glioma diagnosis and therapeutic monitoring
Methods: Platelet samples were collected from 14 glioma patients and 14 matching healthy controls. Platelets were isolated using differential centrifugation to minimize contamination with other blood components. Protein extraction and quantification were performed, followed by analysis using mass spectrometry-based proteomics. Protein identification and quantification were conducted with Label-Free Quantification techniques, and differentially expressed proteins were statistically validated. Bioinformatic tools were employed to analyze pathways and functional annotations related to identified proteins.
Results: In total 3444 proteins were identified and quantified. Of these, 463 proteins were differentially expressed between platelets in glioma patients and healthy controls.
Reactome Pathway, gene ontology enrichment and protein protein interactions analyses revealed proteins associated with pathways linked to Vesicle-mediated transport, Apoptosis, Metabolism of Lipids, Cell Cycle Checkpoints, Glutathione synthesis/recycling, Platelet Activation and Signal transduction.
Conclusion: The study identifies a distinct proteomic profile in platelets from glioma patients compared to healthy individuals, suggesting that platelets in glioma may harbor unique proteins characteristics related to tumor biology. These findings support the potential of platelets as a source of biomarkers for glioma detection, confirmation of diagnosis and monitoring. Future studies with larger cohorts are warranted to validate these proteins as diagnostic markers and explore their mechanistic roles in glioma progression.

#4506 Plasma proteomics reveals biomarkers of lung cancer in non-smoking women.

Guojin Si, Zhangyan Lyu, Ximin Gao, **Fengju Song**

Tianjin Medical Univ. Cancer Inst. & Hospital, Tianjin, China

Background: Lung cancer is the most prevalent cancer among women in China. The incidence of lung cancer in women is increasing, despite the fact that traditional risk factors such as smoking have decreased. The investigation of new protein markers may enhance the etiological network and further elucidate the pathogenesis of lung cancer in non-smoking women.
Methods: We selected three non-smoking female lung cancer patients from the Chinese Colorectal, Breast, Lung, Liver, And Stomach Cancer Screening Trial (C-BLAST) cohort. Three healthy controls were matched based on age (±3 years), sex, year of screening, and smoking status. The proteomic assays were conducted on the Somascan Assay 11k platform, utilizing plasma that had been collected at baseline. The differential proteins between lung cancer patients and healthy controls were analyzed using paired t-tests ($P < 0.05$). The Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) platforms were employed to investigate the functions and pathways enriched by differential proteins. The STRING platform was utilized to develop the protein-protein interaction (PPI) network of these proteins, and the core proteins were determined based on their degree.
Results: The average age of the participants in the study was 55.8 years. Through the comparison of plasma proteomics between lung cancer patients and healthy controls, 224 differential proteins were discovered, including 116 up-regulated and 108 down-regulated proteins. GO analysis revealed these proteins were associated with some biological functions, including the response to hydrogen peroxide, nuclear-transcribed mRNA catabolic process, exonucleolytic, fatty acid homeostasis, immune effector processes, and T-helper 2 cell differentiation. KEGG analysis revealed that these proteins are enriched in pathways such as glycerolipid metabolism, aldosterone-regulated sodium reabsorption, transcriptional dysregulation in cancer, and NOD-like receptor signaling pathway. We constructed the PPI network based on these 224 proteins and identified the top ten core proteins: CD4, INS, MYD88, IFNA1, APOE, BECN1, CD86, MPHOSPH10, NLRP3, and C3. These core proteins are involved in biological processes, including immunology, inflammation, and antiviral responses, and may contribute to the development of lung cancer.
Conclusions: We found several plasma proteins by plasma proteomics that may assist in identifying lung cancer patients and offer new insights into the etiological network of non-smoking lung cancer in women.

#4507 Circulating plasma proteins and risk of multimorbidity of cancer and cardiometabolic diseases.

Heinz Freisling[1], Michael Stein[2], Vivian Viallon[1], Karl Smith-Byrne[3], David C. Muller[4], Antonio Agudo[5], Giovanna Masala[6], Salvatore Panico[7], Carlotta Sacerdote[8], Ruth C. Travis[3], Rosario Tumino[9], Martijn Kolijn[10], Roel Vermeulen[11], Monique Verschuren[12], Adam Butterworth[13], Nicholas Wareham[13], Marc J. Gunter[4], Elio Riboli[4], **Pietro Ferrari**[1]

[1]International Agency for Research on Cancer, Lyon, France,[2]University of Regensburg, Regensburg, Germany,[3]University of Oxford, Oxford, United Kingdom,[4]Imperial College London, London, United Kingdom,[5]Institut Catala d'Oncologia, Barcelona, Spain,[6]Institute for Cancer Research, Prevention and Clinical Network, Florence, Italy,[7]University of Naples Federico II, Naples, Italy,[8]University of Turin and CPO Piemonte, Turin, Italy,[9]Provincial Health Authority (ASP) Ragusa, Ragusa, Italy,[10]Erasmus MC, Rotterdam, Netherlands,[11]Utrecht University, Utrecht, Netherlands,[12]University Medical Center Utrecht, Utrecht, Netherlands,[13]University of Cambridge, Cambridge, United Kingdom

Background: Cancer, type 2 diabetes (T2D), and cardiovascular diseases (CVD) are the leading causes of death worldwide. These chronic conditions can also co-occur within individuals, a phenomenon known as multimorbidity. Other than exposure to common risk factors, multimorbidity could be the result of shared biologic pathways. Leveraging large-scale proteomic data, we investigated whether specific patterns of circulating proteins were common to the occurrence of combinations of cancer, T2D, and CVD, as well as to multimorbidity of these conditions.

Methods: In a case-cohort study of the European Prospective Investigation into Cancer and Nutrition (EPIC), participants from the sub-cohort (n=4,063), as well as pre-selected cases of cancer (n=5,577) were included. The SomaScan 7k Assay was used to acquire aptamer measurements on pre-diagnostic samples. Using Prentice-weighted multivariable-adjusted Cox regression, we assessed single aptamer associations with cancer, T2D, CVD, and multimorbidity. We also sought to showcase the potential of proteomic profiling to study exposure-disease associations by investigating a proteomics signature of weekly leisure-time physical activity and its association with disease outcomes.

Results: Common patterns of aptamers across multiple diseases (3,612 incident cancers, 435 T2D, 503 CVD, and 403 multimorbidity cases) are identified in ongoing statistical analyses. Weekly leisure-time physical activity was inversely associated with 6 proteins (e.g., sorbitol dehydrogenase and leptin) and positively with 10 proteins (e.g., COMP and laminin-2) after multiple-testing correction. After multivariable- and physical activity adjustment, the signature of those proteins per 1 SD increment was inversely associated with overall cancer (HR: 0.93, 95% CI: 0.86 to 0.99) and T2D (HR: 0.54, 95% CI: 0.45, 0.66), but not with CVD (HR: 0.91, 95% CI: 0.76, 1.09). Results of associations with multimorbidity will be presented.

Conclusions: Candidate biological pathways common to cancer, T2D, and CVD as well as to multimorbidity, and their link with major lifestyle factors, will be comprehensively investigated in this large-scale proteomics dataset.

#4508 Quantitation of PD-1, PD-L1, and CTLA-4 in human melanoma using SMC® high sensitivity immunoassays.

Anthony J. Saporita, Joseph Hwang, Matthew Lippold, Laila Faramarzi, Raad Gitan, Wen-Rong Lie, Brooke Gilliam, Rick Wiese

MilliporeSigma, Saint Louis, MO

Immune checkpoint proteins such as PD-1, PD-L1, and CTLA-4 play a central role in neoplastic cell immunosurveillance. Soluble forms of these cell surface proteins are currently being evaluated as potential biomarkers in the diagnosis, prognosis, and pathogenesis of several forms of cancer, such as melanoma. For this study, we first wanted to compare human plasma samples from 12 healthy donors and 12 individuals with melanoma using MILLIPLEX® Human Immuno-Oncology Checkpoint Protein Panel 1, a 17-plex immunoassay. Three immune checkpoint proteins (CD27, CD40, and TIM-3) exhibited statistically significant increases in melanoma samples versus healthy controls, despite the small sample size. While PD-1, PD-L1, and CTLA-4 trended toward increases in the disease state, differences were below the threshold of statistical significance when assessed by MILLIPLEX®. CTLA-4, in particular, was present in low abundance in circulation, with fifty percent of healthy plasma samples near the lower limit of quantification (LLoQ) for the MILLIPLEX® assay. To achieve greater sensitivity for this critical immune checkpoint protein, we developed a novel SMC® CTLA-4 high sensitivity immunoassay. SMC® technology delivers ultrasensitive biomarker measurements for low abundant proteins in comparison to the limits of traditional sandwich ELISA immunoassays. The SMC® assays for PD-1, PD-L1 and CTLA-4 consistently achieved LLoQs of 1.74 pg/mL, 0.78 pg/mL and 0.1 pg/mL, respectively. More importantly, these ultrasensitive SMC® kits allowed quantitation of these cell surface proteins in all plasma samples tested from both healthy donors and melanoma patients. Statistical differences in CTLA-4 (p-value <0.01) and PD-1 (p-value < 0.005) were observed with the SMC® kits in the melanoma cohort compared to the healthy samples. The integration of MILLIPLEX® multiplex assays and SMC® high sensitivity assays in a comprehensive workflow enables profiling of multiple analytes and a deeper understanding of immune response dynamics by accurately measuring low abundant proteins, thereby providing a powerful non-invasive tool for evaluating disease conditions.

CLINICAL RESEARCH: Biostatistics in Clinical Trials / Surgical Oncology
Poster Session

#4512 Impact of clinical response and treatment tolerability on HRQoL in patients treated with ponatinib or imatinib for newly diagnosed Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL).

Ajibade Ashaye[1], Ling Shi[2], Ibrahim Aldoss[3], Pau Montesinos[4], Pankit Vachhani[5], Vanderson Rocha[6], Cristina Papayannidis[7], Jessica T. Leonard[8], Maria R. Baer[9], Jose-Maria Ribera[10], James McCloskey[11], Yanyu Wu[1], Meliessa Hennessy[1], Alexander Vorog[1], Shien Guo[2]

[1]Takeda Development Center Americas, Inc., Cambridge, MA,[2]Evidera Inc., Bethesda, MD,[3]City of Hope National Medical Center, Duarte, CA,[4]Hospital Universitari i Politecnic La Fe, Valencia, Spain,[5]University of Alabama at Birmingham, Birmingham, AL,[6]Instituto do Cancer do Estado de Sao Paulo, University of Sao Paulo, Sao Paulo, Brazil,[7]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Istituto di Ematologia "L. e A. Seragnoli,", Bologna, Italy,[8]Oregon Health and Science University, Portland, OR,[9]University of Maryland Marlene and Stewart Greenebaum Comprehensive Cancer Center, Baltimore, MD,[10]ICO - Hospital Germans Trias i Pujol, Josep Carreras Leukaemia Research Institute, Badalona, Spain,[11]Hackensack University Medical Center, Hackensack, NJ

In the PhALLCON trial (NCT03589326), ponatinib demonstrated superior minimal residual disease (MRD)-negative complete remission (CR) rate, patient-reported treatment tolerability, and health-related quality of life (HRQoL) over imatinib in combination with reduced intensity chemotherapy in adults with newly diagnosed Philadelphia chromosome-positive (Ph+) acute lymphoblastic leukemia (ALL). To further substantiate the effect of treatment benefits on HRQoL, we assessed the effect of clinical response and treatment tolerability on changes in HRQoL over time in PhALLCON trial patients. HRQoL was assessed using prespecified primary domains from the Functional Assessment of Cancer Therapy-Leukemia (FACT-Leu) questionnaire and the EQ-5D-5L. Treatment tolerability was assessed using the FACT-GP5 item "bothered by treatment side effects". Linear mixed-effects regression models were used to examine changes in HRQoL over time, with CR status and treatment tolerability as time-varying predictors, while controlling for significant covariates. The analysis included 238 patients (ponatinib 159, imatinib 79). Achieving CR was linked to significant HRQoL improvement in all FACT-Leu domains and the EQ-5D visual analogue scale (EQ-VAS), with clinically meaningful improvements in the FACT-Leu Trial Outcome Index, FACT-G Total Score, and FACT-Leu Total Score domains (Table). Treatment-related side effects led to significant and clinically meaningful deterioration in all scales. Higher levels of "bother" were associated with greater worsening in HRQoL. Given the 2-fold higher MRD-negative CR rate of ponatinib compared to imatinib, these analyses further support the HRQoL benefit of ponatinib over imatinib in patients with Ph+ ALL.

#4513 Impact of patient safety regulatory considerations on early oncology clinical investigations.

Baisong Huang[1], Cindy Lu[1], Danny Lu[2], Daniel Slade[3], Hazel Kurz[3], Thomas Jahn[4], Sergio Vicente[5], Bruno Medeiros[4], Jayne Marshall[3]

[1]AstraZeneca, Waltham, MA,[2]AstraZeneca, Mississauga, ON, Canada,[3]AstraZeneca, Cambridge, United Kingdom,[4]AstraZeneca, South San Francisco, CA,[5]AstraZeneca, Barcelona, Spain

Introduction: Model assisted approaches such as mTPI2 designs are widely applied in early phase oncology trials to guide dose escalation decisions. Recent health authority interactions have highlighted the importance of design parameters such as the target dose limiting toxicity (DLT) rate and the equivalence interval (EI), in situations where lower toxicity is desired. As the dose escalation strategy may vary with different parameter configurations, the shift of target DLT and EI motivated us to explore the optimal cohort size for a given design.
Methods: We simulated thousands of escalation trials using the mTPI2 design with five dose levels under five common scenarios with monotonal dose toxicity relationship, maximum total N=36-48 and maximum cohort size of n=12 in each simulated trial. The target DLT was set at 25% with an EI of (20%, 33%). Using simulation, we compared the mTPI2 performance with cohort sizes of three, four, and five, evaluating: 1) Reliability: Probability of identifying the true MTD; 2) Safety: Proportion of patients experiencing DLT or overdosed (receiving MTD or higher doses); 3) Dose Escalation Efficiency (DEE): Reliability adjusted by number of patients treated; and 4) Incorrect Dosing Decisions: Proportion of decisions escalating above or de-escalating below the true MTD.
Results: Preliminary results show that a cohort size of four increased the sample size by 1.4-4.9 but improved reliability by 4.6%-10.8% in absolute value compared to a cohort size of three, resulting in the highest DEE among all cohort sizes tested in all scenarios. A cohort size of five also increased reliability but marginally diminishing. A cohort size of four had the lowest likelihood of incorrect dosing decisions (an average ~4% absolute reduction) compared to a cohort size of three in all scenarios, which indicated that cohort size four generates the shortest dose escalation/de-escalation pathway to estimating MTD that ensures the highest DEE among the three cohort sizes tested. The simulation also indicated that, generally, safety performance improved when cohort size increased. When cohort size increased from three to four, the proportion of patients experiencing DLT reduced by 1-2% and proportion of overdosed patients reduced by 2.9-5.0% both in absolute values.
Conclusions: When using the mTPI2 dose escalation design in early clinical trials, we strongly recommend that trial statisticians conduct simulations to assess various configurations across all potential scenarios. This approach optimizes the dose escalation process, increasing the likelihood of identifying the true MTD and minimizing patient exposure to toxicity. Increasing cohort size can offer operational benefits, such as reducing the need to replace non-evaluable participants. Enhanced reliability may also mitigate risks in further development, at the cost of a small number of additional patients treated at early stages.

#4514 The impact of Project Optimus and FDA guidance on study design of early-phase clinical trials.

Deepak Bhamidipati[1], Suzanne Jones[2], David Spigel[1], Gerald Falchook[3], Manish Patel[4], Howard Burris[1], Vivek Subbiah[1]

[1]Sarah Cannon Research Institute at SCRI Oncology Partners, Nashville, TN,[2]Sarah Cannon Research Institute, Nashville, TN,[3]Sarah Cannon Research Institute at HealthONE, Denver, CO,[4]Sarah Cannon Research Institute at Florida Cancer Specialists, Sarasota, FL

Background: In recent years, the FDA has issued guidance on the design and conduct of clinical trials such as dose optimization (Project Optimus), increasing enrollment of participants in underrepresented communities, and reporting patient-centered outcomes. Specifically, the FDA recommends examination of multiple doses to determine the optimal dose but how this guidance affects the design of early-stage oncology clinical trials remains uncertain. The goal of this study was to evaluate trends in early phase trial design and incorporation of dose optimization into early phase protocols over time.

Methods: All early phase protocols activated at Sarah Cannon Research Institute between 2021-2023 were reviewed (n=286 protocols). Information such as class of therapy, study design, and dose optimization plan (if applicable) were extracted from review of each protocol. Fisher's exact test was used to compare proportions across categories and a p-value <0.05 was considered statistically significant.

Results: 268 unique protocols including 215 first in human trials (80%) were initiated with 179 different sponsors between 2021 and 2023. Trial classification by mechanism of action included 114 targeted therapies (43%), 109 immunotherapies (41%), 29 antibody drug conjugates (11%), 12 Immune effector cellular therapies (4%), and 4 chemotherapies (1%). Most trials employed a Bayesian dose escalation design (53%) versus rule-based (3+3), and this did not vary significantly year-over-year. 32% of trials (N=86) had a dose optimization plan. 47 trials (18%) included a dose optimization plan with randomization while 39 trials (14%) discussed optimization without randomization. The percentage trials with a dose optimization plan increased annually from 2021-2023 (22%, 29%, and 47% respectively; $p=0.002$). There was an increase in the proportion of trials which included backfill cohorts from 2021 (60%) to 2022-2023 (76%) ($p=0.007$) in addition to the proportion of protocols which allowed intra-patient dose escalation (45% in 2021 versus 57% in 2022-2023, $p<0.001$). The number of additional patients required in the trials with a dose optimization plan ranged from 12 - 200 with a median of 40. The inclusion of patient reported outcomes in early phase protocols was low at 12% from 2021-2023 and only 3 protocols (1%) addressed enrollment of underrepresented groups in the protocol.

Conclusion: Overall, there has been a trend towards increased implementation of a dose optimization plan within early phase protocols since the announcement of the FDA's Project Optimus initiative in 2021. Moreover, Bayesian designs, backfill cohorts, and intra-patient dose escalation are common in contemporary dose escalation studies. However, patient-centered outcomes and underrepresented populations are not routinely addressed in these protocols. Updated analysis including early phase clinical trials activated in 2024 is planned.

#4515 Epidemiological factors associated with breast density in Guam.

Gian M. Paras[1], **Rodney S. Teria**[1], Su Bin Jin[1], Grazyna Badowski[1], John Shepherd[2], Rose Grino[3]

[1]Pacific Island Partnership for Cancer Health Equity (PIPCHE), University of Guam, Mangilao, Guam,[2]Pacific Island Partnership for Cancer Health Equity (PIPCHE), University of Hawaii Cancer Center, Honolulu, HI,[3]FHP Health Center, Tamuning, Guam

Guam's breast cancer incidence is lower than the U.S. (86.6 vs. 126.8 per 100,000), but mortality rates are higher (27.3 vs. 20.3). This disparity underscores the importance of improving screening and understanding risk factors. Breast density, categorized using the Breast Imaging Reporting and Data System (BIRADS), complicates tumor detection and correlates with malignancy risk. This study investigates the demographic and reproductive factors associated with breast density in Guam. Data from 1,940 women undergoing mammography at FHP Health Center (Nov 2023-Aug 2024) in the HIPIMR study were analyzed. Associations between demographic factors (ethnicity, BMI) and reproductive factors (family history, age at menarche, menopausal status, parity, age at first live birth) with BIRADS categories were tested using chi-square tests. Reproductive factors were categorized by risk level. Multinomial logistic regression, adjusted for age and BMI, examined associations. Missing data (e.g., BMI, age, parity) were imputed using series means/medians. Women with extremely dense breast tissue (BIRADS D) were younger (mean age 57.13 vs. 58.32, $p<0.001$) and had lower BMI (74% vs. 37%, $p<0.001$). They more often experienced menarche after age 12 (58% vs. 51%, $p=0.002$), had fewer than two births (64% vs. 53%, $p<0.001$), and gave birth after age 30 (65% vs. 51%, $p<0.001$). Premenopausal (32%) and early menopause women (51%) had higher BIRADS D proportions ($p<0.001$, $p=0.005$). Regression showed BMI inversely associated with BIRADS D (OR = 0.815, 95% CI: 0.787-0.844), BIRADS C (OR = 0.875, 95% CI: 0.842-0.908), and BIRADS B (OR = 0.937, 95% CI: 0.907-0.968) ($p<0.001$). Family history increased odds of BIRADS D (OR = 1.64, 95% CI: 1.041-2.584, $p=0.033$) and BIRADS B (OR = 1.674, 95% CI: 1.042-2.69, $p=0.033$). Nulliparous women were 2.66 times more likely in BIRADS B (OR = 2.66, 95% CI: 1.157-6.114, $p=0.021$). Micronesians were less likely to belong to BIRADS D (OR = 0.419, 95% CI: 0.19-0.924, $p=0.031$) or BIRADS C (OR = 0.265, 95% CI: 0.092-0.766, $p=0.014$). BMI, parity, and childbirth age significantly influence breast density in Guam. Women with lower BMI, fewer births, or later childbirth were more likely to have extremely dense breast tissue, potentially complicating tumor detection. Ethnicity also played a role, with Micronesian women less likely in BIRADS D. While imputation mitigated missing data, bias remains possible. Future research should expand sample sizes and include malignancy risk via BIRADS outcomes for deeper insight. This research was funded by the National Cancer Institute: The University of Guam/University of Hawaii Cancer Center Partnership to Advance Cancer Health Equity (PIPCHE), Grant U54CA143728 (University of Guam, YCP)/Grant U54CA143727 (University of Hawaii Cancer Center).

#4516 Prognostic value of PET/CT in newly diagnosed multiple myeloma: A Bayesian analysis with missing data imputation.

E. A. Gonzalez Artunduaga[1], N. A. Cruz Gutierrez[2], S. Sandoval Alvarez[3], K. M. Galvez Cardenas[4];
[1]Universidad Nacional de Colombia, Bogota, Colombia, [2]University of the Balearic Islands, Balearic Islands, Spain, [3]Universidad de Antioquia, Medellin, Colombia, [4]Hospital Pablo Tobon Uribe, Medellin, Colombia

Introduction: PET/CT assessment in newly diagnosed patients with multiple myeloma is a significant predictor of long-term clinical outcomes. Incorporating this imaging technique into a Bayesian analysis that addresses data gaps allows for more accurate prognostic estimates. This methodology enhances our understanding of the disease and guides informed clinical decisions, ultimately improving patient care.
Objective: This study aims to evaluate the prognostic value of PET/CT in newly diagnosed patients with multiple myeloma, using Bayesian analysis to manage missing data imputation. We seek to determine how PET/CT findings predict long-term clinical outcomes, thereby enhancing treatment personalization.
Hypotheses:

1. A positive PET/CT at diagnosis may correlate with poor prognosis, indicating lower survival rates and worse disease control.
2. A negative PET/CT at diagnosis may be associated with better prognosis, suggesting higher treatment response rates and longer survival.

Study Design: An analytical study based on clinical and imaging data from PET/CT.
Study Population: Patients diagnosed with multiple myeloma between 2017 and 2024 at an institution in Medellín, Colombia, approved by the ethics committee of Pablo Tobón Hospital.
Variables of Interest:

- Clinical Variables: Age, sex, type of treatment.
- PET/CT Variables: Positive (+), negative (-).
- Other Variables: Cytogenetics, Beta 2 Microglobulin (B2M), Bone Marrow Biopsy, Albumin, Hemoglobin.
- Outcome Variables: Overall Survival, Progression-Free Survival, Treatment Response.

Data Imputation Methodology: Using advanced R tools, including:

- MCMC: For parameter estimation despite incomplete data.
- SMC: To optimize sequential inferences and improve precision.

Statistical Analysis:

- Kaplan-Meier survival curves for visualizing survival rates.
- Significance of covariates evaluated through 95% credibility intervals.

Results: The Bayesian model highlights PET/CT and cytogenetics as key outcome variables. A negative PET/CT correlates with better survival and more accurate treatment response prediction, while a positive PET/CT is linked to higher disease progression rates.
Limitations:

- Generalizability may be limited due to single-institution data.
- Missing data could introduce bias despite imputation methods.
- Short follow-up may restrict long-term outcome assessment.
- Variability in imaging protocols may affect result consistency.

Conclusions:

1. Prognostic Value of PET/CT: The study indicates that PET/CT evaluation is a significant predictor of long-term outcomes in multiple myeloma. A negative PET/CT is linked to better prognosis and treatment response.
2. Clinical Decision Making: Integrating Bayesian analysis and data imputation into PET/CT assessment enhances prognostic accuracy, providing clinicians with valuable insights for personalized treatment and optimized patient care.

#4517 Comprehensive intraoperative imaging of surgical margins with AI-driven open-top light-sheet microscopy.

D. Brenes[1], Q. Han[1], R. Wang[1], R. Kareem[1], M. C. Topf[2], E. L. Rosenthal[2], E. Marchiano[1], E. Palmquist[3], F. Mahmood[4], S. H. Javid[3], S. M. Dintzis[3], J. T. C. Liu[1];

[1]University of Washington, Seattle, WA, [2]Vanderbilt University, Nashville, TN, [3]University of Washington School of Medicine, Seattle, WA, [4]Harvard Medical School, Boston, MA

Surgeons rely on subjective visual and tactile feedback to differentiate tumors from adjacent normal tissue, which lacks accuracy and may make complete resection challenging. Over 20% of breast and 40% of head & neck cancer surgeries yield positive margins—cancerous cells at the edge of the resected specimen—requiring costly additional treatments with inferior outcomes. When pathologists assess margins, they quantify the tumor's proximity to the margin surface, where a margin of several millimeters is often desired. This is done by viewing formalin-fixed, paraffin-embedded (FFPE) tissue sections oriented perpendicularly to the specimen surface. FFPE sections are typically ~5 µm thick and are obtained at 3 - 5 mm intervals, meaning that < 0.1% of the specimen surface is evaluated. We propose that for solid continuous tumors, comprehensive surface microscopy — though unable to measure the tumor's proximity to the specimen surface — could more accurately identify positive margins and could be performed rapidly in the operating room to maintain specimen orientation. We are developing an intraoperative open-top light-sheet (OTLS) microscopy system that comprehensively assesses fresh specimen surfaces through an artificial intelligence (AI)-driven, time-efficient, multi-resolution workflow. The system resembles a flatbed scanner and images the bottom face of a specimen placed on a glass plate. Fresh specimens are rapidly stained (< 1 min) with a fluorescent agent for nuclear and stromal contrast. A profilometer quickly (< 1 min) obtains a height map of the specimen's bottom surface to guide the OTLS microscope as it captures a thin volume (50 – 100 µm in depth) encompassing the specimen's surface. The OTLS microscope operates at two resolution modes: low (~5 × 5 × 5 µm xyz) and high (~1 × 1 × 3 µm xyz). First, a comprehensive low-resolution scan is acquired rapidly (< 3 min per 10 x 10 cm area). An AI model then identifies high-risk regions to re-scan at high resolution for diagnosis. Our 3D AI-driven imaging strategy mimics the time-efficient workflow of pathologists, who first examine FFPE slides at low magnification before zooming into localized regions at high magnification. The ability to acquire a shallow amount of volumetric data (up to ~ 100 microns deep) can improve positive margin detection over a single 2D surface due to the greater amount of cellular information and the ability to avoid artifacts from surgical damage (e.g. cautery). To develop our 3D AI algorithm, we are building a dataset from freshly excised breast and head & neck specimens, with ground-truth diagnostic labels provided by pathologists. The model will be weakly supervised, using pre-trained models for 3D feature extraction.In summary, AI-guided multi-resolution OTLS microscopy has the potential to enable rapid, comprehensive intraoperative margin assessment, reducing positive margin rates and improving patient outcomes.

#4518 The use of surgical staging of inguinal lymph nodes in penile squamous cell carcinoma in the HIV era.

Victor Mapulanga, Owen Ngalamika, Edford Sinkala, Mumba Chibamba

University of Zambia, Lusaka, Zambia

Penile cancer is quite common in developing countries such as sub-Saharan Africa (SSA) and this high incidence in SSA has been attributed to high prevalence of Human Papilloma Virus (HPV). Additionally, Human Immunodeficiency Virus (HIV) prevalence is high in SSA and considering that HIV affects lymph nodes, this may potentially affect the clinical manifestation of draining lymph nodes in penile cancer. These lymph nodes are staged surgically by inguinal lymph node disection which is associated with high complications rates. Data on surgical staging of lymph nodes in penile cancer in SSA are scanty. We set to explore the use of surgical staging of inguinal lymph nodes in penile squamous cell carcinoma (PSCC) in a high HIV endemic setting.A prospective study was conducted from November, 2022 to January, 2024 at the University Teaching Hospital, Lusaka, Zambia. Patients with PSCC with surgically resectable tumor undergoing surgical treatment of primary tumor and inguinal lymph node dissection were recruited into the study. The questionnaire was administered to capture relevant information.Blood was collected pre operatively for HIV testing and viral load determination. The disected lymph node tissue and resected tumor were sent to the pathologist for histological determination of tumor involvement of lymph node and histopathological staging. Immunohistocehmistry was done on tumor tissue using p16 for HPV determination.Forty (40) were enrolled in the study with a median age was 53 years. Thirty-five (88%) were HIV seropositive with most HIV positive patients being virologically suppressed with antiretroviral therapy at the time of surgery. The prevelence of HPV among the participant was 65% with HPV types 16 and 35 being the most common. The prevalence of pathological lymph node metastasis (LNM) was 37.5% (12/32) in patients with clinically palpable (cN+) inguinal lymph nodes. In conclusion surgical staging of inguinal lymph nodes in patients with PSCC in the era of HIV has low yield of positive lymph node involvement with most being reactive adenopathy due do HIV infection and not the cancer

#4519 Lung carcinoma with air lucency: Possible classification and their prognosis.

Kazuya Hisamatsu[1], Kazuhiko Shien[2], Shuta Tomida[3], Daisuke Mizuno[1], Ryota Fujiwara[1], Kousei Ishimura[1], Ryunosuke Fujii[1], Atsushi Matsuoka[1], Ryo Yoshichika[1], Tomoaki Higashihara[1], Naohiro Hayashi[1], Yuma Fukumoto[1], Kazuhiro Okada[1], Fumiaki Mukohara[1], Mao Yoshikawa[1], Ken Suzawa[2], Shinichi Toyooka[2]

[1]General Thoracic Surgery, Okayama Univ. Graduate School of Med., Okayama, Japan,[2]Thoracic, Breast and Endocrinological Surgery, Okayama University Hospital, Okayama, Japan,[3]Center for Comprehensive Genomic Medicine, Okayama University Hospital, Okayama, Japan

Background: Lung cancer with air lucency (LCAL) represents a group of lesions in which a primary lung cancer manifests on CT images with a cyst or cystic airspaces. NSCLCs with adjoining cystic airspaces have been reported an increased risk of poor prognosis after surgical resection. However, the detailed classification of LCALs based on diagnostic imaging have not yet been established. We aim to classify LCALs into emphysematous and non-emphysematous groups objectively, and then analyze the prognosis of each group.
Methods: A total of 101 surgically resected LCAL cases in our institution between 2015 and 2022 (including all cancer stages and histological subtypes) were collected. Cases were separated into emphysematous and non-emphysematous groups based on Goddard's score, derived from LAA% (Low Attenuation Area percentages) analyzed in CT scans. A Goddard's score of 1 or more was considered emphysematous in this study. Then, clinicopathological features and prognosis for each group were analyzed.
Result: Sixty (59%) cases were classified as emphysematous, and forty-one (41%) cases as non-emphysematous. Higher pathological stages (worse than IIB) were more common in the emphysematous group (p-value<0.01). For respiratory performance (FEV1%), the emphysematous group had worse outcomes compared to the non-emphysematous group (p-value=0.01). Kaplan-Meier analysis revealed that the emphysematous group had a significantly worse overall survival (p-value=0.02). In multivariate analysis, a Goddard score of 1 or more, advanced TNM staging, and tumor histology subtypes other than adenocarcinoma were identified as independent risk factors for poor prognosis in LCAL patients.
Conclusion: LCALs can be categorized using Goddard's score into emphysematous and non-emphysematous groups, with the emphysematous group showing poorer overall survival. This result suggests that patients with emphysematous LCALs should be considered at high risk for poor outcomes following surgery. This classification may help identify patients who require alternative therapeutic strategies and/or more cautious post-operative management.

#4520 Assessing treatment strategies in high-risk metastatic nephroblastoma: A trinetx-based comparison of chemotherapy with surgery vs. primary nephrectomy.

Zayan Musa, **Javier Prieto**, Fatemeh Adabifirouzjaei

UC Riverside School of Medicine, Riverside, CA

Introduction:
Wilms Tumor, or nephroblastoma, is the most prevalent kidney cancer in pediatric populations. With a survival probability nearing 90%, the disease carries a 15% risk of recurrence. Wilms Tumor has a developmental origin, frequently involving mutations in genes such as WT1, WTX, CTNNB1, and TP53, which correlate with a poorer prognosis. The tumor can present unilaterally or bilaterally, often due to excess metanephric tissue cultures. Despite favorable survival rates, the potential for recurrence and malignancy calls for continuous evaluation of treatment strategies.
Methods:
A retrospective analysis was conducted on patients aged 0-18 diagnosed with Wilms Tumor and treated either by chemotherapy followed by surgery (Cohort 1) or surgery alone (Cohort 2). Cohort 1 included 289 patients who underwent chemotherapy prior to nephrectomy, while Cohort 2 consisted of 84 patients who received only a partial or full nephrectomy. Outcomes were compared over a 10-year follow-up period, focusing on secondary malignancies and survival rates.
Results:
Over the 10-year follow-up, Cohort 2 (surgery-only) demonstrated a significantly higher survival probability compared to Cohort 1 (chemotherapy plus surgery). The risk of a secondary malignancy was 97.23% in Cohort 1, compared to 73.8% in Cohort 2, indicating a 12.4% increase in malignancy risk with the addition of chemotherapy ($p < 0.0001$). This data suggests that chemotherapy prior to surgery may not be the safest option in terms of long-term outcomes for nephroblastoma patients.
Conclusion:
Current nephroblastoma treatment involves chemotherapy followed by surgical resection. Our study suggests that surgery alone may provide better outcomes, reducing the risk of secondary malignancies by 12.4% and significantly improving long-term survival. While surgical excision alone may not be feasible in all cases, it warrants consideration as an individualized treatment option. Further research should investigate nephrectomy-only treatment as a potentially safer and more effective alternative for pediatric Wilms Tumor patients.

#4521 Quilting of flaps reduces drain effluent without significantly increasing duration of surgery in mastectomy a low resource setting.

AbdulRazzaq O. Lawal, Jimoh O. Hassan, Adewumi Alabi, Oluwole A. Atoyebi

Lagos University Teaching Hospital, Lagos, Nigeria

Introduction: Mastectomy is the most common surgical procedure for breast cancer in low- and middle-income countries. Following mastectomy, patients usually require a drain to be inserted to prevent seroma formation. Several strategies are used to reduce the both the quantity of effluent and the duration a patient has to have the drain inserted.
Methods: We did a prospective trial where patients were randomized to either use of quilting with 2-0 vicryl sutures or lack of quilting in order to reduce the post operative drain volume and the post operative period during which the drain will be in situ. Consecutive patients who are scheduled for mastectomy were randomized to either quilting or non-quilting of the skin to the pectoralis muscle. Duration of surgery was recorded. Consecutive daily volumes of drain effluent were documented until removal of the drain. Number of days before drain removal as well as body mass index and other parameters were recorded.
Results: A total of 63 patients were recruited. Forty patients were randomized to non-quilting whilst 23 patients were randomized to quilting. The demographic data, stage of the disease and body mass index of the patients in the two categories were similar. The age range was 22 to 82 years. With mean age of 49.8 and median age of 48 years. The number of days before removal of drain ranged from 3 to 10 days with mean of 6.62 days and mode of 6 days. Mean daily drain effluent was 55 to 237mls with a mean of 134.5mls and median of 136mls while total drain effluent ranged between 166 to 2,173mls with mean of 938.1mls and median of 846 mls. Independent t-test revealed that there was a statistically significant difference in duration of drain insertion, mean daily drain effluent and total drain effluent between the two groups. There was however no statistically significant difference in the duration of surgery between the two groups.
Conclusion: It is recommended that surgeons should quilt between the skin and pectoralis muscle in order to reduce the duration of drain insertion, daily drain effluent and total drain effluent following mastectomy in patients with breast cancer.

#4522 Old dog, new tricks: The role of capecitabine in HPV-negative head and neck cancer.

Marco Antonio Mascarella, Nisha Suarez, Keith Richardson, Alex Mlynarek, Michael Hier, Nader Sadeghi, Khalil Sultanem, Derin Caglar, Marc Pusztaszeri, Livia Florianova, Nathaniel Bouganim, Khashayar Esfahani

McGill University Health Centre, Montreal, QC, Canada

Objective: Treatment for HPV-negative head and neck squamous cell carcinoma (HNSCC) has seen little innovation, particularly in advanced-stage disease, where outcomes remain suboptimal. The public healthcare system's delays in access to care can exacerbate this issue, allowing tumors to progress prior to treatment initiation. This study explores the use of capecitabine, an oral chemotherapy agent, in both preoperative and recurrent settings for HPV-negative HNSCC.
Study Design: We conducted a prospective cohort study of patients with stage III/IV HPV-negative HNSCC at two academic centers in Montreal, Canada. The study evaluated clinical and pathological responses in patients receiving capecitabine in a preoperative setting, with radiological and clinical outcomes assessed for those with unresectable recurrent disease.
Results: Among the 34 patients included in the study (23 oral cavity, 1 oropharynx, 5 skin, 5 larynx), 31 received capecitabine preoperatively, while 3 had recurrent, unresectable disease. Of the 31 patients undergoing surgery, 16 exhibited clinical tumor reduction, 13 remained stable, and 2 experienced tumor growth. Pathological responses were observed in 15 patients, including 1 complete response (skin) and 6 major responses based on the modified Ryan criteria. Two non-responders developed recurrences within one year. The mean follow-up for surgical patients was 6 months. In the non-surgical cohort, all three patients showed reduced pain and radiological improvements, with a mean follow-up of 8 months. No significant toxicity related to capecitabine was reported.
Conclusion: Capecitabine, used either in a preoperative window of opportunity or in the recurrent setting, demonstrated measurable clinical and pathological responses in patients with HPV-negative HNSCC. Given its efficacy and low toxicity, further investigation of this oral agent is warranted, particularly in resource-constrained settings where timely access to treatment may be a challenge.

#4523 Personalized risk prediction for treatment intolerance in operable HPV-negative head and neck cancer: Beyond the eyeball test.

Marco Antonio Mascarella[1], Keith Richardson[1], Nader Sadeghi[1], Alex Mlynarek[1], Michael Hier[1], Khalil Sultanem[1], Christina Tsien[1], Khashayar Esfahani[1], Marie-Jeanne Kergoat[2]

[1]McGill University Health Centre, Montreal, QC, Canada,[2]University of Montreal, Montreal, QC, Canada

Introduction: Head and neck cancer (HNC) treatment is highly complex, with substantial toxicity risks from curative therapies, often including surgery, radiation, and chemotherapy. Poor treatment tolerance can hinder optimal recovery, impacting patient outcomes. Current predictive tools lack precision in forecasting treatment intolerance for HNC patients undergoing curative surgery. Frailty and sarcopenia, especially muscle quantity biomarkers, are increasingly recognized as crucial predictive factors. This study aims to develop a comprehensive risk index incorporating sarcopenia, frailty, and patient-specific factors to better predict intolerance.
Methods: An ambispective observational study was conducted with 542 patients undergoing curative-intent HNC surgery from 2015 to 2024. Patient data on demographics, frailty, sarcopenia (via cervical paraspinal muscle index or CPSMI), tumor staging, and planned adjuvant therapy were collected. Using logistic regression, we evaluated predictive factors for treatment intolerance, defined as major adverse events (MAEs) or incomplete treatment. Risk model performance was validated internally and externally and compared against ASA, mFI, and RAI.
Results: In 542 patients, lower CPSMI (first tertile) correlated significantly with intolerance (OR 1.85, 95% CI 1.10-3.13). High-density muscle was protective, while low-density muscle predicted intolerance (OR 1.88, 95% CI 1.18-2.99). Sarcopenia and frailty were independently predictive, with the mFI also strongly correlating with intolerance (OR 4.92, 95% CI 1.88-12.9). The new risk index demonstrated superior predictive accuracy, showing a 0.04 increase in the C-statistic compared to existing indices (p=0.02).
Conclusion: The multimodal risk index effectively predicts treatment intolerance in HNC surgery patients. By integrating sarcopenia, frailty, and patient-specific factors, the tool enables better preoperative counseling and intervention planning, with particular utility for high-risk individuals. Further research on prehabilitation strategies may enhance treatment tolerance in vulnerable patients, supporting a proactive approach to HNC care.

#4524 The independent prognostic nomogram models for primary and recurrent retroperitoneal liposarcoma: A population-based cohort study.

Huan Deng, Zhenhau Lu, Binrui Wang, Yisheng Pan

Huan Deng (Individual), Beijing, China

Purpose: The aim of this study was to establish independent prognostic models for primary and recurrent retroperitoneal liposarcoma (RLS).
Experimental design: A total of 2429 patients confirmed to have RLS were extracted from the Surveillance, Epidemiology and End Results (SEER) database. The 245 patients collected from the same period at First Medical Center, Chinese People Liberation Army General Hospital (CPLAGH), were used for external validations. Nomogram were built on the basis of clinical practicability, univariate and multivariate Cox analyses.
Results: The simplified predictive models for primary RLS was mainly based on tumor size (median size, 162 mm [range, 90-230], $P < 0.001$) and pathological subtypes (WDL vs DDL, hazard ratio[HR]=2.11; 95% confidence interval [CI]=1.71-2.61; $P < 0.001$), which can be acquired in the outpatient clinics. However, TNM stage (Stage 1 vs Stage 2, HR=2.18; 95% CI=1.49-3.20; $P < 0.001$) as an extremely important postoperative indicator was enrolled in the model for recurrent RLS. The area under the time-dependent receiver operating characteristic curve (time-dependent AUC) and concordance index (C-index) of models almost approach 0.75 in the training and validation cohorts. These results indicated favourable discrimination of the models. The calibration curves of the model illustrated good consistency between the predicted and observed survival probabilities in both the training and two validation cohorts. Furthermore, decision curve analysis (DCA) revealed that the nomogram models were clinically useful and had considerable practicability.
Conclusion: Efficient and independent models for primary and recurrent RLS will providing clinical guidance for both prognostication and individualized therapeutic decision-making.

#4526 Safeguarding parathyroid glands during thyroidectomy using a real-time imaging agent.

Jing Huang, Jialun Ding, Zhishan Guo, Kuan Liu

Aisee Biotechnology, LLC, Hangzhou, China

Parathyroid gland (PG) inadvertent damage or removal is a frequent complication of thyroidectomy, largely due to the difficulty of distinguishing PGs from surrounding thyroid gland (TG) during surgery. To address this challenge, we developed a novel imaging agent (IO-100) for real-time intraoperative PG visualization. Our study demonstrates that locally administered dark-colored IO-100 preferentially diffuse into TG while remaining excluded from tissue-dense PGs, creating a visually distinct contrast observable by surgeons. Through systematic in vivo optimization, intraoperative PG/TG contrast has been significantly enhanced, and PGs have been well identified and preserved. Importantly, local IO-100 administration was well-tolerated, showed no adverse toxicities exploiting the unique biodegradable property. These findings establish IO-100 as a promising safe and effective imaging agent for enhancing PG identification and minimizing damage/removal risk during thyroidectomy, providing a valuable tool for improving surgical outcomes.

CLINICAL RESEARCH: Immune Responses to Therapies Including Chemotherapy and Radiotherapy
Poster Session

#4530 mTOR inhibition augments antitumor T cell response by modulating the expression of immune regulatory molecules.

Priyatosh Nath, Alok Khandelwal, Ivan Alvarez, Chun Li, Srivatsa Vasudevan, Tara Moore-Medlin, Cherie-Ann Nathan

Department of Otolaryngology- Head & Neck Surgery, LSU Health Sciences Center - Shreveport, Shreveport, LA

The mechanistic target of rapamycin (mTOR) is a protein kinase that plays a critical role in regulating immune responses by modulating the growth, differentiation, activation and migration of various immune cells. Dysregulation of mTOR signaling, which is common in various cancers, can potentially disrupt the immune cell function, leading to weakened immune surveillance. This study evaluates the antitumor activity of an mTOR inhibitor drug, everolimus, focusing on its impact on antitumor immunity. Treatment with everolimus inhibited the growth of PD-1 resistant and poorly immunogenic ROC-1 syngeneic grafts, potentially through the activation of T cell-mediated immunity. Flow cytometry analysis of single cell suspension of tumor cells revealed increased CD8+ T cell infiltration and increased expression of class-I MHC in tumor cells in mice treated with everolimus when compared to vehicle. Moreover, everolimus reduced the number of exhausted (PD1+) CD4+, CD8+ T cells in tumors, indicating a more potent immune response against the cancer cells. The CD8+ tumor infiltrated lymphocytes (TILs) magnetically sorted and cocultured with the tumor cells showed significantly higher T cell cytotoxicity for the group of mice who received everolimus in comparison to vehicle. These findings suggest the potential of everolimus in boosting anti-tumor immunity, providing a rationale for further investigation.

#4531 The effects of MRTX1133 on antitumor immunity in KRAS^{G12D}-mutant lung cancer.

K. Shono[1], S. Watanabe[1], T. Masuda[2], T. Wakabayashi[1], R. Yamazaki[1], Y. Ando[1], R. Suzuki[3], S. Tanaka[1], T. Tanaka[1], K. Nozaki[1], Y. Saida[1], N. Yanagimura[1], M. Arita[1], M. Sato[1], R. Ohashi[1], K. Shima[1], Y. Kimura[1], N. Aoki[1], Y. Ohshima[1], T. Koya[1], T. Kikuchi[1];
[1]Niigata Univ. Grad. School of Medical & Dental Sci., Niigata, Japan, [2]Niigata City General Hospital, Niigata, Japan, [3]Sado General Hospital, Niigata, Japan

Background: There is no effective treatment for KRAS^{G12D}-mutant tumors. Immune checkpoint inhibitors (ICIs) have improved survival rates for lung cancer patients, but they are less effective in non-small cell lung cancer (NSCLC) with KRAS^{G12D} mutations. MRTX1133 is a selective inhibitor of KRAS^{G12D} undergoing early clinical trials. This study aimed to investigate the immune landscape of a KRAS^{G12D}-mutant lung cancer mouse model and evaluate whether MRTX1133 could induce antitumor immunity. We also assessed whether MRTX1133 has anti-proliferative effects and can promote antitumor immunity in human KRAS^{G12D}-mutant lung cancer cell lines.
Methods: We generated conditional KRAS^{G12D}-mutant mice by crossing CCSP-rtTA/TetO-Cre and LSL-KRAS^{G12D} knock-in mice, inducing lung-specific tumors with doxycycline-containing food. MRTX1133 was administered intraperitoneally at 10 mg/kg once daily for 4, 8, or 12 days. After treatment, lungs and spleens were collected for flow cytometry analysis, and lung cells from the 4-day treatment group underwent RNA sequencing. Human KRAS^{G12D}-mutant lung cancer cell lines (A427 and SK-LU-1) were treated with MRTX1133 for RNA-Seq, differential gene expression analysis, and gene set enrichment analysis (GSEA). CCL20 protein levels were further validated by Western blotting and ELISA.
Results: Longer doxycycline exposure increased regulatory T cell (Treg) infiltration in lung tumors. Additionally, immune checkpoint molecules (ICMs) such as PD-L1, PD-1, TIGIT, TIM-3, and LAG-3 were upregulated in CD4+ and CD8+ T cells. MRTX1133 treatment inhibited KRAS^{G12D} tumor progression, reduced Treg percentages, and decreased PD-1 expression in CD4+ and CD8+ T cells. It also increased tumor-specific CD8+ effector T cell infiltration in lung tumors, and interferon-gamma was enriched in MRTX1133-treated lung cells. In human KRAS^{G12D}-mutant lung cancer cells, MRTX1133 increased immune-related gene expression and decreased cell division-related genes in both cell lines. GSEA showed enrichment of interferon-gamma and interferon-alpha in MRTX1133-treated SK-LU-1 cells, while DMSO-treated cells showed enrichment of cell division genes. Elevated CCL20 levels were confirmed in the SK-LU-1 MRTX1133-treated group.
Conclusion: KRAS^{G12D}-mutant lung tumors in mice exhibited T cell exhaustion. MRTX1133 showed therapeutic efficacy in the preclinical KRAS^{G12D}-mutant lung cancer model, possibly by enhancing antitumor immune responses along with oncogenic signaling inhibition. In human KRAS^{G12D}-mutant lung cancer cell lines, MRTX1133 reduced cell proliferation and increased antitumor cytokine expression, especially in SK-LU-1 cells. These findings may support the development of new immunotherapeutic strategies for patients with KRAS^{G12D}-mutant lung cancer.

#4532 Investigating the effects of radiation and anti-PD1 therapy on immune cell tumor infiltration in head and neck cancer.

Katelyn Jansen[1], Maria Lehn[1], Nicolas Nassar[2], Alexis Redmond[2], Mathieu Sertorio[3], Vinita Takiar[3], Dalia El-Gamal[1], Trisha Wise-Draper[1]

[1]Hematology and Oncology, University of Cincinnati College of Medicine, Cincinnati, OH,[2]Cincinnati Children's Medical Center, Cincinnati, OH,[3]Radiation Oncology, University of Cincinnati College of Medicine, Cincinnati, OH

Head and neck cancer (HNC) is predominantly comprised of head and neck squamous cell carcinoma (HNSCC), ranking as the 6th most common cancer worldwide. There are roughly 450,000 documented annual fatalities with predictions of annual increases in incidence. Despite advances in these intensive anticancer techniques, patient survival remains low. The current standard of care for local recurrence of HNSCC tumors is salvage surgery (SS) or combined modality with adjuvant re-irradiation using (X-ray)-based therapy (XRT). However, due to critical structure dose limits of the head and neck region, adjuvant XRT can cause excess morbidity. Proton radiation (PT), although less researched, may be advantageous to minimize the risk of injury to highly critical structures and minimize the radiation dosage outside of the tumor volume due to its energy course of the Bragg's Peak, which is thought to also have a higher relative biological effectiveness. While there may be high clinical relevancy of PT, there is currently a lack of translational and clinical data to confirm advantages of its use in HNSCC. Patients with HNSCC have impaired immune surveillance, and higher levels of inhibitory checkpoints such as PD-L1 permitting tumors to evade the immune system. Immunotherapy targeting PD-1, receptor to PD-L1, has greatly enhanced survival rates in these patients, but many patients fail to respond due to other immunosuppressive factors. Here we investigate the immune response effects of RT, with either XRT or PT combined with anti-PD1 antibody (αPD1) *in vivo* using an established murine oral cavity tumor model. Wild-type C57BL/6 mice were injected into the buccal region with 1.5 x 10^6 mouse oral cavity (MOC-1) cells. Once tumors reached 50-150mm^3, mice were treated over one week with XRT (3 treatments of 5 Gy) or sham. The following week the mice received αPD1 or IgG isotype control antibody. Here we present effects of XRT vs PT on immune infiltration by flow cytometry and immunofluorescence in three independent studies. Growth curves in the studies indicated that proton therapy and αPD1 in combination may be advantageous over αPD1 or PT alone with increased CD8 T cell infiltration, suggesting that PT in combination with αPD1 may offer significant advantages in eliciting a strong anti-tumor immune response.

#4533 Lymphotoxin-mediated tumor immunosuppressive regulation in ovarian cancer recurrence.

Zhewei Zhang[1], Kit Ying Chan[1], Ho Sze Jacqueline Lee[1], Joseph Kwong[2], Tat San Lau[1], Chi Chiu Wang[1]

[1]The Chinese University of Hong Kong, Shatin, Hong Kong,[2]Keele University, Keele, United Kingdom

Background: Recurrence is the major leading cause of death in patients with ovarian cancer. We previously report that inflammatory cytokine, lymphotoxin, derived from ovarian cancer cells, stimulates chemokine expressions in stromal fibroblasts via lymphotoxin-beta receptor, LTBR. These lymphotoxin-driven reciprocal tumor-stromal interactions in turn promote ovarian cancer progression via chemokine receptor CXCR3. However, the role of lymphotoxin in tumor immune microenvironment (TIME) and its contribution to recurrence remain poorly understood. This study aims to investigate the immunosuppressive regulation mediated by tumor-derived lymphotoxin in relation to ovarian cancer recurrence.

Methods: We determined the expression of a panel of immunosuppressive genes in a cohort of 202 primary ovarian cancer tissues, which included both high-risk (n=132) and low-risk (n=70) recurrence, using qPCR. Findings were validated by TCGA data analysis. Cell lines and syngeneic mouse models were used.

Results: Using multiplex immunofluorescence staining (mIF), we identified IFN-γ+ CD8+ T cell infiltration in ovarian tumors from patients following neoadjuvant chemotherapy with paclitaxel. While paclitaxel did not directly affect PD-L1 expression, IFN-γ significantly upregulated both PD-L1 gene expression and surface protein expression in most of ovarian cancer cell lines (14/17) as demonstrated by qPCR and flow cytometry. Primary tumors from high-risk recurrence patients showed elevated expression of IFN-γ signature genes (IFNG, STAT1, CCL5, CXCL9, CXCL10, HLA-DRA, CD8A, LAG3) and lymphotoxin-associated genes (LTA, LTB, CCL5, CXCL10, CXCL11). In our mouse models, lymphotoxin (Lta/Ltb) overexpression activated the NF-κB pathway and significantly reduced survival (p=0.0018). In situ immune profiling and mIF revealed that lymphotoxin overexpression specifically enriched regulatory B cells and LAG3+CD3+CD8+ exhausted T cells in the tumor microenvironment. Analysis of TCGA data confirmed that patients with high lymphotoxin expression showed significantly elevated levels of IFN-γ signature genes (IFNG, STAT1, CXCL9), lymphotoxin-stimulated chemokines (CCL5, CXCL10, CXCL11), and immunosuppressive cell markers (CD244, LAG3, FOXP3, TGFB1, EOMES, GZMB, ICOS, IL10, CCL2). These findings were further validated at the protein level using mIF in patient samples, which showed increased LAG3+CD3+CD8+ T cells and CD20+ B cells in recurrent tumors.

Conclusions: Our findings reveal that an immunosuppressive tumor microenvironment contributed to primary tumors from ovarian cancer patients with high recurrence risk. A distinct set of immunosuppressive regulators orchestrated by cancer-derived lymphotoxin through recruitment of B-regs and exhausted T cells suggests new therapeutic strategies targeting ovarian cancer recurrence.

#4535 Targeting YAP1 and DKK1 pathways to suppress peritoneal carcinomatosis in gastric adenocarcinoma.

Y. Fan[1], S. Song[2], G. Zou[1], L. Huo[1], A. Scott[1], R. Wang[1], E. Dai[1], S. Shao[1], L. Wang[1], S. Dhar[1], J. Ajani[1];
[1]UT MD Anderson Cancer Center, Houston, TX, [2]Coriell Institute for Medical Research, Camden, NJ

Peritoneal carcinomatosis (PC), characterized by malignant ascites cells or implants, affects approximately 45% of advanced gastric adenocarcinoma (GAC) patients and is associated with a poor prognosis, with survival rates often less than six months. Despite its prevalence and severe impact, the molecular mechanisms underlying PC in GAC remain poorly understood, highlighting a significant unmet need for targeted therapies. Our previous studies demonstrated that YAP is highly expressed in PC cells, promoting cancer stem cell (CSC)-like properties and correlating with decreased patient survival. Here, we observed that high YAP1 expression is inversely correlated with $CD8^+$ T cell infiltration in GAC. RNA sequencing analysis revealed a significant reduction in *DKK1* expression upon *YAP1* depletion, and both YAP and DKK1 were highly expressed in PC cells. High expression of these markers is significantly associated with poor survival outcomes in GAC patients. Further experiments showed that ectopic DKK1 expression in YAP1 knockout cells restored cell proliferation, tumor sphere formation, cell invasion, and impaired $CD8^+$ T cell function. Dual inhibition of YAP and DKK1 markedly reduced tumor growth and enhanced $CD8^+$ T cell responses within the TME. Combination therapy with YAP antisense oligonucleotides (ASO), DKN1 antibody, and anti-PD-1 further extended overall survival and bolstered immune response. Our findings reveal a critical role of YAP1 in maintaining an immunosuppressive microenvironment through DKK1 in GAC with PC. This combined inhibition approach holds promise and warrants further investigation as a therapeutic strategy for GAC patients with PC.

Key words: YAP1, DKK1, Immune response, Peritoneal metastasis, Gastric adenocarcinoma

#4536 Dissecting tumor-immune microenvironment in response and resistance to immune checkpoint blockade in metastatic melanoma.

Xinyu Cui[1], Giuseppe Tarantino[2], Yiwen He[3], Priyanka Solanky[1], Kathleen Pfaff[2], Aaron R. Thorner[2], Tyler J. Aprati[2], Boyang Zhang[4], Timothy Blosser[1], Emily Robitschek[4], Jiajia Chen[2], Junko Tsuji[5], Elliot Boblitt[5], Allison Frangieh[2], Hannah M. Faulkner[2], Marta Holovatska[2], Aleigha Lawless[6], Michael Manos[2], Karla Helvie[2], Tatyana Sharova[7], Dennie Frederick[8], James L. Fahey[9], Diego Villamarin[10], Sachi Krishna[5], Chanell Mangum[5], Ajit J. Nirmal[1], Domenic Abbondanza[11], Cai McCann[5], Bruce Johnson[2], Alex K. Shalek[12], Eliezer Van Allen[2], Xiaowei Zhuang[1], Ryan Sullivan[6], Barbara E. Engelhardt[4], Samouil L. Farhi[5], Scott Rodig[13], F. Stephen Hodi[2], Genevieve M. Boland[6], David Liu[2]

[1]Harvard Medical School, Boston, MA,[2]Dana Farber Cancer Institute, Boston, MA,[3]Northwestern University, Chicago, IL,[4]Stanford University, Stanford, CA,[5]Broad Institute of MIT and Harvard, Cambridge, MA,[6]Massachusetts General Hospital, Boston, MA,[7]Massachesetts General Hospital, Boston, MA,[8]Broad Institute of MIT and Harvard, Boston, MA,[9]Loyola University Chicago, Chicago, IL,[10]University of Rochester School of Medicine and Dentistry, Rochester, NY,[11]University of Chicago, Chicago, IL,[12]Massachusetts Institute of Technology, Cambridge, MA,[13]Brigham and Women's Hospital, Boston, MA

Background: Immune checkpoint inhibitor (ICI) therapies have markedly improved the prognosis for patients with stage III & IV metastatic melanoma by prolonging progression-free and overall survival rates. However, the variability in immune evasion and resistance mechanisms presents significant challenges to the clinical efficacy of ICIs. This project aims to define drivers of immunotherapy response and resistance by employing advanced genomic, single-cell mRNA analyses, and spatial profiling techniques on tissue biopsies from metastatic melanoma patients.

Methods: In this study, we developed a framework to analyze response and resistance, both intrinsic and acquired, via immune features in the tumor microenvironment in a standardized, uniformly processed, and deeply clinically annotated cohort of metastatic melanoma patients (n=61) treated with ICB as part of the human tumor atlas network (HTAN) initiative. From the tumor samples, we conducted single-nucleus RNA sequencing, and for a subset of the samples high-resolution spatial imaging (including protein mIHC, CODEX, and transcriptomics MERFISH). Standardized processing and data pipelines allowed for integrating genomic, transcriptomic, and spatial features to elucidate characteristics and mechanisms in tumor microenvironment and their relationships with resistance.

Results: Studies of the pretreatment samples demonstrated that CD4 and CD8 T cells, particularly TCF7+ CD8 T cells, are significantly more prevalent in responders to immunotherapy. Conversely, macrophages, especially Angio-TAMs, show higher levels of enrichment in non-responders. Moreover, the presence of B cells and follicular dendritic cells in non-lymph node biopsies supports the presence of tertiary lymphoid structures within the TME. Three levels of immune enrichment were identified through spatial analysis, and samples with more immune enrichment tend to have better responses. We also identified 10 recurrent cellular neighborhoods (RCNs) and found that RCN2,4, and 7 with high lymphocyte infiltration are significantly more enriched in responders than non-responders. In addition, RCN4 is associated with immune infiltration while RCN7 is TLS-like.

Conclusions: Our findings indicate that patients with low immune infiltration exhibited enrichment of macrophages associated with the hypoxia and angiogenesis phenotypes, while patients with high immune infiltrates displayed enrichment in lymphocytes, particularly TCF7+ CD8+ T cells, confirming previous findings and indicating a robust T cell-mediated immune response. This project integrates genomic, transcriptomic, and spatial features to elucidate shared tumor and microenvironmental states and their relationships with resistance, and guide more personalized and effective treatment strategies for metastatic melanoma.

#4537 Dynamics of B-cell repertoires following CAR-T and bispecific antibody therapy in multiple myeloma.

F. Jacob, **R. Garza-Morales**, J. Hentz, A. Wonnaparhown, J. Wiedmeier-Nutor, M. Arribas, G. Alatorre, S. Best, J. Poulignot, U. Yadav, S. Chhabra, P. Bergsagel, R. Fonseca, T. Hilal;
Mayo Clinic Arizona, Phoenix, AZ

Introduction: Multiple myeloma (MM) is a B-cell-derived malignancy associated with immune dysregulation. Anti-CD38 monoclonal antibodies (mAbs) therapies have shown improved outcomes in patients with MM. Silbermann *et al.* showed that anti-CD38 mAb-containing therapies lead to profound hypogammaglobulinemia and reduction in Ig gene repertoire. The effect of modern therapies such as CAR-T and bispecific antibodies (BsAbs) on B-cell repertoire has not been well described. In this study, we sought to investigate the effect of these therapies on B-cell repertoire in patients with MM.

Methods: This is a single-institution retrospective observational study evaluating MM patients treated with anti-BCMA CAR-T and BsAbs. Baseline characteristics, laboratory data, treatment history, were extracted from medical records. Total unique sequences (TUS) and total sequences of IgH, IgK, and IgL were identified and quantified using clonoSEQ. Patients were classified in two groups: CAR-T and BsAbs. The primary objectives were (1) characterize changes in TUS and total sequences within IgH, IgK, and IgL before and after treatment, and (2) examine how the sequences evolve over time following CAR-T.

Results: 76 MM patients received CAR-T or BsAbs. Among those, 22 CAR-T and 5 BsAbs patients had pre- and post-treatment sequences available. Median age at initiation of treatment was 66 years in the CAR-T group (42-81 y) and 65 years in the BsAbs group (48-71 y). Based on mSMART v3 criteria, 72% of CAR-T and 60% of BsAbs recipients were classified as high-risk. Median number of prior lines of therapy was 5 (2-8) in the CAR-T group and 6 (5-13) in the BsAbs group.CAR-T recipients were classified into early (<40 days) and late (>40 days), based on when the post-CAR-T treatment clonoSEQ assay was performed. Changes in TUS and total sequences of IgH, IgK, and IgL were calculated, and the averages were assessed independently. The mean early and late change in total unique IgH sequences were (-75,586 and 131,038, p=0.052), unique IgK (-57,797 and 52,586, p=0.020), and unique IgL (-22,354 and 25,056, p=0.011). A subgroup of 8 patients with sequential MRD reports post-CAR-T therapy were identified, six patients showed improvement in B-cell sequence dynamics and two patients showed a decrease over time. For patients who received BsAbs, results indicated a similar pattern, with an early decrease in B-cell repertoires, characterized by reductions in sequence diversity and quantity.

Conclusions: Our analysis of B-cell repertoires following CAR-T revealed changes before and after treatment. Patients receiving CAR-T therapy showed a decline in the number of TUS and total sequences of IgH, IgK, and IgL, likely due to the lymphodepletion regimen, followed by a gradual restoration reflecting immune recovery. Longer follow-up and a larger cohort will be necessary to assess the implications of these B-cell repertoire changes on patient outcomes.

#4538 T-cell immunogenicity and biomarker profiling in advanced melanoma patients receiving the personalized vaccine EVX-01 in combination with pembrolizumab.

Mads Lausen[1], Michail A. Pavlidis[1], Rasmus Ohrt Andersen[1], Thomas Trolle[1], Nikolas Thuesen[1], Christian Garde[1], Nicholas Willumsen[2], Morten Asser Karsdal[2], Nadia Viborg[1], Adnan Khattak[3], Georgina V. Long[4], Paolo A. Ascierto[5], Carolina Cimminiello[6], Michael J. Chisamore[7], Stine Friis Thorsen[1], Birgitte Rono[1], Daniela Kleine-Kohlbrecher[1]

[1]Evaxion Biotech A/S, Hoersholm, Denmark,[2]Nordic Bioscience A/S, Herlev, Denmark,[3]Hollywood Private Hospital, One Clinical Research, Nedlands, WA, Australia,[4]The University of Sydney, Royal North Shore & Mater Hospitals, Melanoma Institute Australia, Sydney, Australia,[5]Melanoma Cancer Immunotherapy and Development Therapeutics Unit, Instituto Nazionale Tumori IRCCS Fondazione "G. Pascale", Napoli, Italy,[6]Sarcoma e Tumori Rari, Divisione di Oncologia Medica del Melanoma, Milano, Italy,[7]Oncology Early Clinical Development, Merck & Co., Inc., New Jersey, NJ

Patients with advanced melanoma were treated with a personalized neoantigen vaccine, EVX-01, in combination with pembrolizumab in a phase 2 clinical study (NCT05309421). The peptide-based EVX-01 vaccine consists of multiple tumor-specific neoantigens (neoAg) identified by Evaxion Biotech's target discovery AI-Immunology™ platform. As reported in September 2024 at the one-year follow-up, the treatment was well tolerated, neoAg specific T-cell responses were observed, and the objective response rate was 11/16 (68.8%) in the overall cohort.To investigate potential markers associated with the immunogenic and therapeutic effect, several biomarker analysis technologies were applied. Baseline tumor biopsies as well as longitudinal blood samples before, during and after treatment were collected. Vaccine-specific T-cell responses were analyzed by ELISpot of peripheral blood mononuclear cells (PBMCs). Treatment-induced changes of circulating immune cell subsets were characterized using spectral flow cytometry.Baseline tumor samples were analyzed by genomic and transcriptomic analyses, immunohistochemistry (IHC), and AI-assisted digital pathology to understand the characteristics of the tumor and the immunological landscape of the tumor microenvironment (TME).Longitudinal plasma and serum samples were assessed for treatment-induced changes of circulating markers using the Olink proteomics technology and Nordic Bioscience's ProteinFingerPrint Technology™.
Immunogenicity analysis demonstrated vaccine-specific T-cells in all patients after EVX-01 priming (n=15) and repeated booster immunizations lead to sustained magnitude and broadness of T-cell responses. Overall, the analysis showed that 78% of the AI-Immunology™ selected neoAgs were immunogenic and 93% of the immunogenic peptides induced *de novo* responses.Quantification of functionally diverse immune cell subsets in patient PBMCs will further increase our understanding of the immunological changes induced by EVX-01. Immunohistochemistry analysis of baseline tumor biopsies showed PD-L1 expression and T-cell infiltration in 66% and 75% of tumor specimens, respectively. Additional analyses are being conducted to evaluate relevant features of TME, such as fibrosis and spatial distribution of different cell types in the TME.
Olink proteomic analysis and ECM turnover marker analysis of serum samples will provide further insights into tumor- and immune-related interactions during EVX-01 treatment. The immune and biomarker analyses enhance our understanding of the complex interactions between the immune and tumor compartments, while also shedding light on treatment induced adaptations. This new understanding can aid in refining therapeutic strategies and identifying predictive biomarkers that may guide treatment decisions in the future.

#4539 A new and standardized method to isolate viable, high-quality PBMCs from patient blood samples.

Eleonora Naimo, **Lotta Raty**, Stefanie Niehues, Migena Kodra, Svetlana Khorkova, Konstantina Kostadinovska, Gregor Winkels

Miltenyi Biotec, Bergisch Gladbach, Germany

With the rise of immunotherapy, monitoring patient immune responses during clinical trials has become increasingly critical. Peripheral blood mononuclear cells (PBMCs) serve as a reliable analyte for various cellular analyses, including flow cytometry, ELISpot, and transcriptomics. However, acquiring high-quality PBMCs is traditionally challenging due to long shipment times that compromise cell integrity. Reports indicate that a significant number of patient samples are rendered unsuitable for downstream applications due to these delays. Additionally, traditional gradient centrifugation methods are manual, time-consuming, and require skilled personnel. In this study, we present a novel, standardized, and automation-friendly method for generating PBMCs from whole blood samples. This innovative approach consistently yields high-quality, viable PBMCs, even from older samples, overcoming the limitations of traditional methods. Our method minimizes the need for extensive hands-on training and produces cells ready for immediate use in downstream applications. By streamlining the PBMC isolation process, our method enhances the reliability and efficiency of immune monitoring and biomarker discovery in clinical and research settings. This advancement holds significant potential for improving the quality and consistency of PBMC samples, thereby facilitating more accurate and reproducible immunological analyses.

#4540 Longitudinal analysis of multiple myeloma: Therapeutic response and immune microenvironment dynamics in the context of tumor heterogeneity.

[1]Allen Institute for Immunology, Seattle, WA,[2]Department of Hematology in Linkoping, and Department of Biomedical and Clinical Sciences, Linkoping University, Linkoping, Sweden,[3]University of Washington, Seattle, WA,[4]Immunotherapy Integrated Research Center, Fred Hutchinson Cancer Center, Seattle, WA,[5]Immunotherapy Integrated Research Center, Immunology, Medicine,, Fred Hutchinson Cancer Center, University of Washington, Seattle, WA,[6]Translational Science and Therapeutics, Fred Hutchinson Cancer Center, Seattle, WA,[7]Clinical Research Division, Fred Hutchinson Cancer Center, Seattle, WA,[8]BKV, Linkoping University, Linkoping, Sweden

Multiple myeloma (MM) is a hematological malignancy characterized by an expansion of malignant plasma cells in the bone marrow. For newly diagnosed MM (NDMM), standard three-drug treatment regimens—such as the combination of bortezomib, lenalidomide, and dexamethasone (VRd)—and the more recent inclusion of a fourth drug, anti-CD38 antibody immunotherapy, have significantly improved patient outcomes by targeting multiple mechanisms of tumorigenesis. This treatment approach typically involves several cycles of VRd induction therapy, followed by high dose melphalan (HDM) and autologous stem cell transplant (ASCT), and maintenance therapy. Treatment responses vary widely, with some patients requiring longer and more intense therapy and others exhibiting more rapid responses and longer relapse-free remission. Relapse or treatment refractory multiple myeloma (RRMM) is driven by clonal evolution of malignant cells and tumor-supportive changes in the stromal and immune microenvironment. This cycle of remission, maintenance, and eventual relapse persists despite advancements in treatment modalities, including immunotherapy, leaving MM incurable. This study characterizes the tumor state and immune microenvironment in MM patients across variable graded patient responses. Using a multimodal, longitudinal approach, we investigate immune and microenvironmental cellular changes during treatment in NDMM patients and in a second cohort of RRMM patients. For the NDMM cohort, longitudinal blood and bone marrow aspirate samples were collected at diagnosis, throughout induction therapy, following ASCT, and at post-transplant intervals of 1 and 2 years. In the RRMM cohort, longitudinal blood and bone marrow samples were collected from patients who relapsed and were subsequently treated with anti-CD38 antibody in combination with a personalized three-drug regimen over a 2-year timeframe with regular collection of blood and bone marrow aspirate samples across timepoints. Multi-omic profiling of these samples magnifies the individual heterogeneity between tumor and therapeutic response. The longitudinal aspect of the study allowed us to focus on individual-level longitudinal responses instead of cross-patient effects, enabling detailed insights into tumor and microenvironment dynamics. Using Olink proteomic analysis of plasma and bone marrow interstitial fluid (BMIF), and single-cell analyses of peripheral blood mononuclear cells (PBMC) and bone marrow mononuclear cells (BMMC) we longitudinally characterized tumor, the immune microenvironment, and therapeutic responses. This revealed distinct immune states and pathways associated with therapeutic response, tumor survival, and relapse, highlighting potential targets and therapeutic strategies to improve patient outcomes.

#4542 B cells mediate antitumor immune response and predict pathological response in locally advanced NSCLC patients treated with perioperative chemoimmunotherapy (NADIM trials).

Belen Sierra-Rodero[1], Cristina Martinez-Toledo[1], Marta Molina-Alejandre[1], Angeles Gil-Gonzalez[1], Ernest Nadal[2], Alex Martinez-Marti[3], Bartomeu Massuti[4], Amelia Insa[5], Joaquin Casal[6], Javier de Castro[7], Rosario Garcia Campelo[8], Jose Luis Gonzalez-Larriba[9], Reyes Bernabe[10], Santiago Ponce[11], Manuel Domine[12], Noemi Reguart[13], Carlos Camps[14], Guillermo Lopez Vivanco[15], Manuel Cobo[16], Virginia Calvo[1], Ana Collazo-Lorduy[1], Mariano Provencio[1], Alberto Cruz-Bermudez[1]

[1]Medical Oncology, Instituto de Investigacion Sanitaria Puerta de Hierro-Segovia de Arana (IDIPHISA), Hospital Univ. Puerta de Hierro Majadahonda, Madrid, Spain,[2]Institut Catala d'Oncologia (ICO), IDIBELL, L'Hospitalet de Llobregat, Barcelona, Spain,[3]Vall Hebron Institute of Oncology (VHIO), Hospital Universitari Vall d'Hebron, Barcelona, Spain,[4]Hospital General Dr. Balmis de Alicante, ISABIAL, Alicante, Spain,[5]Fundacion INCLIVA, Hospital Clinico Universitario de Valencia, Valencia, Spain,[6]Hospital Universitario de Vigo, Pontevedra, Spain,[7]Hospital Universitario La Paz, Madrid, Spain,[8]Hospital Universitario A Coruna, A Coruna, Spain,[9]Hospital Universitario Clinico San Carlos, Madrid, Spain,[10]Hospital Universitario Virgen del Rocio, Sevilla, Spain,[11]Hospital Universitario 12 de Octubre, Madrid, Spain,[12]Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain,[13]Hospital Clinic and Translational Genomics and Targeted Therapies in Solid Tumors, Institut de Investigacions Biomediques, Barcelona, Spain,[14]Hospital General Universitario de Valencia, Universidad de Valencia and Centro de Investigacion Biomedica en Red Cancer, Valencia, Spain,[15]Hospital Universitario Cruces, Barakaldo, Spain,[16]Regional and Virgen de la Victoria University Hospitals, Instituto de Investigacion Biomedica de Malaga, Malaga, Spain

Perioperative chemoimmunotherapy (ChIO) has become a paradigm shift in the treatment of patients with locally advanced non-small cell lung cancer (NSCLC), considerably increasing complete pathological response (CPR) and survival rates. The role played by B lymphocytes in the antitumor response emerges as a crucial factor in the fight against cancer, although mechanisms remain to be elucidated. Therefore, the main objective of this study is the identification of B lymphocyte-related mechanisms and biomarkers of response to perioperative chemoimmunotherapy treatment in patients with locally advanced NSCLC. For this purpose, tumor tissue B-cell receptor (BCR) repertoire, gene expression profile by bulk RNA sequencing, and qualitative localization by spatial transcriptomics have been characterized in 110 NSCLC patients receiving ChIO from NADIM and NADIM II trials (NCT03081689 and NCT03838159). Results of this work show an association between CPR and neoadjuvant treatment with a more diverse (p=0.069) and less even (p=0.030) BCR repertoire in pre-treatment tissue, which appears to be dominated by a set of more frequent clones (top 10, p=0.043). In addition, neoadjuvant chemoimmunotherapy induced overexpression of B lymphocyte-related genes in surgical tissue, mainly localized at tertiary lymphoid structures (TLSs) identified by spatial transcriptomics. Those tumors with low BCR repertoire evenness (CPR response) exhibited a different gene expression profile compared to highly even tumors (non-CPR). TLSs area and density were higher in CPR/low evenness sample compared to NCPR/high evenness; and functional T helper lymphocytes, defined as T CD4 lymphocytes colocalized with antigen presentation genes, were detected only in CPR/low evenness sample. In conclusion, tumor BCR repertoire clonality is associated to CPR after neoadjuvant ChIO. Neoadjuvant ChIO induces expression of B cell related genes in the context of TLS, being their area and functionality dependent on baseline BCR repertoire clonality.

#4543 Low dose radiation enhanced antitumor immune response by reprogramming T cell and CAR-T cell metabolism in a tumor immune microenvironment.

Zahid Rafiq[1], Puebla Nahum Osorio[1], Weiqin Lu[2], James Welsh[1]

[1]Radiation Oncology, UT MD Anderson Cancer Center, Houston, TX,[2]Department of Pharmaceutical Sciences, School of Pharmacy, The University of Texas at El Paso, El Paso, TX

Background: The infiltration of T cells and chimeric antigen receptor T (CAR-T) cells into solid tumors is essential for robust antitumor response and therapeutic outcomes. While cell therapies succeeded in hematologic malignancies, their efficacy in solid tumors is limited due to poor tumor penetration and the immunosuppressive tumor immune microenvironment (TIME). Our previous studies showed that combining low-dose radiotherapy (LDRT) with T-cell therapy synergistically enhanced tumor control and survival. Nanostring metabolic gene analysis indicated that LDRT modulates T-cell metabolism within TIME. Therefore, we hypothesized that LDRT enhances T-cell metabolism, favoring anticancer potency.

Methods & Results: To investigate the role of LDRT in T-cell metabolism, we established a TIME using co-culture of cancer cells and PBMCs in xenograft NSG mice, followed by LDRT. Using nCounter Metabolic Pathways, we quantified the expression of genes associated with core metabolic and immune metabolic processes in intratumoral T cells. Nanostring analysis revealed key pathways and genes that regulate T-cell effector functions, further underscoring LDRT's impact on T-cell metabolism. Seahorse assays highlighted that LDRT positively influenced the oxygen consumption rate (OCR) and extracellular acidification rate (ECAR), favoring improved metabolic and effector functions in T/ CAR-T cells. Mitotracker analysis revealed that LDRT-treated T/ CAR-T cells exhibited enhanced mitochondrial membrane potential (Mitotracker Deep Red) and mitochondrial mass (Mitotracker Green), suggesting robust mitochondrial health and functionality. Transmission electron microscopy (TEM) showed improved mitochondrial morphology of T cells following LDRT. Additionally, Incucyte live-cell analysis demonstrated that CAR-T cells treated with LDRT exhibited significantly enhanced cancer cell killing ($P \leq 0.001$) compared to controls. CAR-T cells conditioned with LDRT showed increased tumor cell killing in vivo, further validating the potentiating effect of LDRT on cell-based therapies. These findings collectively highlight the pivotal role of LDRT in modulating T-cell metabolism and enhancing antitumor immune responses.

Conclusion: The study highlights the translational potential of combining LDRT with cell therapies in solid tumors. By reprogramming T-cell metabolism within TIME, LDRT significantly enhanced tumor control and improved survival outcomes, establishing a promising foundation for metabolism-targeted therapies. These findings provide compelling evidence to support further exploration and clinical investigation of this synergistic approach, aiming to optimize the efficacy of cell-based immunotherapies and improve outcomes for patients with challenging solid tumor malignancies.

#4544 Immunotherapy with chemotherapy provides superb pathologic complete response rate in chemotherapy-resistant metaplastic carcinoma of breast.

I-Chun Chen[1], Shang-Hsuan Peng[2], Tsung-Che Wu[3], Ching-Hung Lin[4], Diana Hui-Min Lin[5], Li-Wen Huang[6], Chi-Han Cheng[7], Yen-Shen Lu[8]

[1]National Taiwan University Cancer Center (NTUCC), Taipei, Taiwan,[2]Department of Oncology, National Taiwan University Hospital Yunlin Branch, Huwei, Taiwan,[3]Department of Oncology,, National Taiwan University Biomedical Park Hospital, Hsinchu, Taiwan,[4]Department of Medical Oncology, National Taiwan University Cancer Center (NTUCC), Taipei, Taiwan,[5]Medical Solution Cluster, Roche Products Ltd., Taipei, Taiwan,[6]7. Medical Solution Cluster, Roche Products Ltd., Taipei, Taiwan,[7]University of Minnesota, Minneapolis, MN,[8]National Taiwan University Hospital, Taipei, Taiwan

Background: Metaplastic carcinoma of breast (MCB) is a rare subtype of breast cancer (BC) accounting for <1% of newly diagnosed BC. It is composed of co-existing sarcomatous and carcinomatous components. Because of its sarcomatous components, the response rate of chemotherapy in MCB is low both in early BC and advanced BC. The pathologic complete response rate (pCR%) after neoadjuvant chemotherapy in MCB is as low as 10%. Neoadjuvant immunotherapy plus chemotherapy is a new standard of care for early triple-negative BC providing improved pCR%, event-free survival, and overall survival. Pembrolizumab was also approved by the FDA in 2021 for neoadjuvant treatment in TNBC. We aim to examine the modern pCR% of immunotherapy and chemotherapy in MCB patients.
Methods: MCB patients and treatment regimens, including neoadjuvant immunotherapy, were retrospectively selected from Flatiron Health, a nationwide electronic health record database. Demographic data and neoadjuvant regimens were collected. pCR% was calculated for patients treated with neoadjuvant chemotherapy versus neoadjuvant immunotherapy plus chemotherapy.
Results: A total of 87 early stage MCB patients diagnosed between January. 2011 and May 2024 were included from the Flatiron Health. 20 and 5 of the MCB patients received neoadjuvant chemotherapy alone and neoadjuvant immunotherapy plus chemotherapy, respectively. 2 in the neoadjuvant chemotherapy group (pCR%=10%) and 3 in the neoadjuvant immunotherapy/ chemotherapy group (pCR%=60%) achieved pCR. The pCR% of neoadjuvant chemotherapy is as low as previously reported in MCB patients.
Conclusion: Neoadjuvant immunotherapy and chemotherapy provide comparably high pCR% in MCB patients as compared to other TNBC patients. We are validating the findings from additional cohorts from Taiwan. The high pCR% makes immunotherapy and chemotherapy an attractive strategy that worth further investigation in MCB patients.

#4548 The association between tissue genomic alterations and ctDNA shedding in non small cell lung cancer.

Robert Cameron[1], Anna Di Lello[1], Faith Abodunrin[1], Sulin Wu[1], Alessandra Esposito[1], Apameh Pezeshk[1], Valter Torri[2], Christine Bestvina[1], Marina Garassino[1]

[1]UChicago Medicine, Chicago, IL,[2]Institut Mario Negri, Milan, Italy

Introduction: Tumor burden, stage and metastatic extent are associated with the presence of circulating tumor DNA (ctDNA). However, the association between genomic alterations and the presence of ctDNA remains unclear.
Methods: We retrospectively analyzed patients with non-small cell lung cancer (NSCLC) with available Next-Generation Sequencing (NGS) analysis on both tissue and blood treated at the University of Chicago. NGS on tissue biopsies was conducted using the internal Oncoplus assay (168 genes). NGS on blood samples was conducted using the Guardant360 assay. Plasma ctDNA concentration was measured by the Variant Allele Frequency (VAF). Spearman rank correlation coefficient was used to assess the relationship between increasing number of mutations and VAF. Wilcoxon rank-sum test was used to compare the distribution of VAF between subgroups.
Results: A total of 221 patients were identified. Adenocarcinoma was the predominant histological subtype, accounting for 89.6% (n=199) of cases. The cohort was predominantly Caucasian (55.4%) and female (66.2%). The median age at diagnosis was 65 years. At the time of index liquid biopsy, 85.1% of patients had metastatic disease. Among the 221 patients, 129 (58.6%) harbored actionable mutations, with EGFR exon 19 or 21 mutations being the most prevalent (n=80, 36.2%). This study found a weak but significant association between VAF and mutation count in the tissue biopsy: for total mutations including both significant alterations and variants of unknown significance ($r = 0.146$, $p=0.032$) and for significant mutations only ($r = 0.160$, $p=0.018$). These associations were stronger in the KRAS G12C mutated sub-cohort for both total ($r=0.471$, $p=0.036$) and significant mutations ($r=0.573$, $p=0.008$). Significantly higher ctDNA VAF was observed in TP53 ($p=0.006$) and STK11 ($p=0.05$) mutant tumors.
Conclusions: Our results showed a correlation between increasing number of alterations and ctDNA shedding. The association was stronger for KRAS G12C mutated tumors. The relationship between genetic changes and ctDNA release is supported by the increased ctDNA VAF seen in TP53 and STK11 mutant tumors.

#4549 Impact of an ultrasensitive ctDNA test on MRD detection in real world clinical patient testing.

Rachel Marty Pyke[1], Steven Dea[1], Fabio C.P. Navarro[1], Charles W. Abbott[1], Sherif El-Refai[1], Yi Chen[1], Janet Lai[1], Gabor Bartha[1], John M. Lyle[1], Jason Harris[1], Georges Azzi[2], Sean M. Boyle[1], Richard O. Chen[1]

[1]Personalis, Inc., Fremont, CA,[2]Holy Cross Medical Group, Fort Lauderdale, FL

Circulating tumor DNA (ctDNA) is a non-invasive biomarker increasingly used to detect residual or recurrent disease and to monitor patient response to therapy. However, there is a need for more sensitive tests that can achieve earlier detection of disease. The NeXT Personal® Dx (NPDx) ctDNA MRD test uses paired tumor and normal whole genome sequencing (WGS) to design a bespoke panel of up to ~1800 variants and relies on advanced noise suppression to achieve ultrasensitive detection down to ~1 part per million (PPM) of ctDNA (1x10-6 tumor fraction) with high analytical specificity (>99.9%). Here, we describe the real world performance for a set of cancer patients (>15 cancer types) profiled using the NPDx test. For this study we have included 1693 plasma timepoints from 700 patients (range of 1 to 21 timepoints per patient), with the highest proportion of patients having breast, lung or colorectal cancer. The plasma timepoints have a median LOD of 1.93 PPM (IQR:1.55-2.78 PPM). Notably 41.6% of MRD+ samples were detected at low traces of ctDNA below 100 PPM, in the ultrasensitive range; moreover, a majority (50.4%) of the ultrasensitive detections are at or below 15 PPM, further highlighting the impact of a highly sensitive assay for MRD profiling.

We also examined performance in specific challenging situations. NPDx tests performed well with challenging FFPE tumor samples (low tumor DIN <=3 indicating some sample degradation or low tumor fraction <=30%), achieving low LODs (median = 2.97 and 2.56 PPM, respectively). The WGS-based panel design allowed NPDx to achieve ultrasensitivity on low TMB tumors (<=2 mutation/MB, median LOD = 2.90 PPM) through utilization of variants from intergenic regions (95% MRD panel variants were from non-exonic regions) that would largely be unavailable to exome-based tests. Testing was performed across a wide range of cell free DNA (cfDNA) inputs (range 2-30 ng, median = 14 ng). Even with low cfDNA inputs (<=3ng, 5.25% of cohort), NPDx still achieved a low median LOD of 2.63 PPM.

Two case studies demonstrate the impact of ultrasensitive MRD testing with patients. A 50-year-old woman with stage 1B endometrial cancer was monitored using NPDx following hysterectomy and brachytherapy, and ctDNA was detected in the ultrasensitive range (<50 PPM in this case). Reflex imaging revealed a new nodule leading to additional therapy and ctDNA clearance. In a second case, a woman in her 70s with stage 1 HER2+ breast cancer who underwent standard lumpectomy and adjuvant treatment was found with persistent low levels of ctDNA (between 25-30 PPM) detected with NPDx over a period of five months. Reflex imaging revealed a new nodule leading to additional radiation therapy, with plans for chemotherapy. These cases illustrate how NPDx's ultrasensitive detection capabilities can impact patient management in a real world setting.

#4550 Dried blood sot sampling as a minimally invasive and accessible method for investigating circulating tumor DNA in diverse cancer settings.

Amit Roshan[1], Fazlur R. Talukdar[1], Angela An[1], Emma-Jane Ditter[1], Ze Zhou[1], Paulius D. Mennea[1], Linfang Wu[1], Maria C. Neofytou[1], Anita Balakrishnan[2], Claire M. Connell[1], Gabriel Funingana[1], Giovanni Codacci-Pisanelli[2], Girma Mulisa[3], Tamrat Abebe[4], Constanza Linossi[5], Hui Zhao[1], Wendy N. Cooper[1], Huiqi Yang[2], Rajesh Jena[5], James D. Brenton[5], Pippa Corrie[2], Rebecca C. Fitzgerald[5], Simon Pacey[5], Richard Baird[5], Nitzan Rosenfeld[6]

[1]CRUK Cambridge Institute, Cambridge, United Kingdom,[2]Cambridge University Hospitals NHS Trust, Cambridge, United Kingdom,[3]Adama Hospital Medical College, Adama, Ethiopia,[4]Addis Ababa University, Addis Ababa, Ethiopia,[5]University of Cambridge, Cambridge, United Kingdom,[6]Queen Mary University of London, Lomdon, United Kingdom

Background: Proof-of-principle studies have identified circulating tumor DNA (ctDNA) in small volumes of whole blood, even dried blood spots (DBS) collected by finger-prick sampling from patients with advanced cancer. This minimally invasive sampling method offers ease, frequency and low cost of collection, simplified shipping and long-term room temperature stability. Adopting DBS for ctDNA collection and whole genome sequencing (WGS) analysis may support novel clinical trial design and increase real-world utility of liquid biopsies, especially where traditional phlebotomy is a barrier.

Methods: We collected sample quartets comprising serial DBS, and matching plasma, tumor, and buffy coat from ~125 patients with multiple cancer types including oesophageal, lung, head & neck, melanoma, ovarian, colorectal and pancreatic cancer. Collections were in diverse settings at hospitals in the UK and Ethiopia, and by patients at home in the UK. DNA isolated from DBS was size-selected using bead-based enrichment to remove genomic DNA. Libraries were generated from DBS size-selected DNA, and DNA extracted from plasma, tumor and buffy coat samples had paired-end WGS at depth of ~1X, 10X, and 50X respectively. Using bioinformatic pipelines for tumor-informed and tumor-agnostic detection, WGS data was analyzed for somatic copy number aberrations (SCNAs), fragment length, and tumor-specific single nucleotide variants (SNVs).

Results: We detected SNVs and SCNAs in DBS reflective of genomic changes in matching tumor DNA and plasma, from patients with Stage II-IV cancers. We observed concordant changes to the levels of those SNVs and SCNAs in plasma and DBS samples collected before and after systemic treatment compared with clinical and radiological measures. With tumor-informed analysis, utilizing patient-specific lists of 5,930-51,927 SNVs identified from tumor DNA, limit of detection for ctDNA was 34 ppm in plasma, and 95 ppm in DBS, comparable to commercially available assays for ctDNA. DBS collected in hospital by healthcare professionals, remotely in Ethiopia and at-home by patients in the UK with transportation at room temperature showed ctDNA can be extracted for analysis from diverse settings.

Conclusion: Our data highlights the promising role of DBS in advancing non-invasive cancer diagnostics and monitoring. The versatility of DBS in capturing ctDNA from various cancer types, coupled with its accessibility for collecting samples, is a significant step forward in blood-based cancer detection. This offers potential to enhance cancer monitoring and early detection strategies in both tumor-informed and tumor-agnostic settings. DBS is a cost-effective, user-friendly sampling strategy allowing at-home collection, enabling large-scale research and development programs needed to bring biomarker methods into widespread use.

#4551 Increased blood draws for ultrasensitive ctDNA and CTCs detection in early breast cancer patients.

I. Comino-Mendez[1], M. Quiros-Ortega[1], J. Velasco-Suelto[1], C. Gaona-Romero[1], A. Alba-Bernal[1], A. Godoy-Ortiz[1], M. Dominguez-Recio[1], B. Jimenez-Rodriguez[2], E. Lopez-Lopez[1], J. Peralta-Linero[1], M. Ortega-Jimenez[3], E. Bellagarza-Garcia[2], L. Troyano-Ramos[2], G. Garrido-Ruiz[3], A. Garrido-Aranda[1], R. Lavado-Valenzuela[1], M. Alvarez[1], N. Ribelles-Entrena[1], J. Pascual[1], E. Alba[1];
[1]Inst of Biomedical Investigation, Malaga., Malaga, Spain, [2]Hospital Regional Universitario de Malaga, Malaga, Spain, [3]Hospital Universitario Virgen de la Victoria de Malaga, Malaga, Spain

Relapse due to residual disease (RD) is a significant concern for early breast cancer (BC) patients following initial treatment. Liquid biopsy offers a non-invasive approach to detect tumor-derived components in blood; however, detection sensitivity remains limited at early disease stages due to low target concentrations. To improve this, we evaluated 282 high-volume plasma and blood-cell samples for the dual detection of circulating tumor DNA (ctDNA) and circulating tumor cells (CTCs) using droplet-digital PCR. In pre-treatment samples, ctDNA and/or CTCs were detected in all cases. Post-treatment, positive samples achieved enhanced sensitivity, with a minimum variant allele frequency of 0.003% for ctDNA and a minimum CTCs concentration of 0.069 cells/mL, surpassing detection limits of prior studies. Dynamic ctDNA monitoring allowed accurate prediction of pathological response in the tumor, achieving an area under the ROC curve of 0.92. Moreover, blood detection of disease markers preceded clinical relapse by up to 34.6 months in relapsing patients, providing a significant lead time for intervention. This methodology was also applied to a study of 38 additional BC patients treated solely with surgery to further evaluate its capacity for RD detection in a surgically managed cohort. The findings and implications for RD detection are detailed and presented, underscoring the potential of this sensitive, high-volume approach for real-time monitoring in early-stage BC.

#4552 Quality assessment of cfDNA from urine and plasma using fragment size analysis.

Thorsten Voss, Daniela Mancarella, Christina Goebel

QIAGEN GmbH, Hilden, Germany

INTRODUCTION: The majority of liquid biopsy approaches are based on cell-free DNA (cfDNA) from plasma. In recent times, urine cfDNA is getting more attention as it has been shown to provide complementary information to blood cfDNA, which could increase sensitivity with respect to detection of pathogenic genetic variants. However, cfDNA degradation and genomic DNA (gDNA) contamination can impact the cfDNA profile and prohibit reliable molecular analysis of these analytes. Therefore, quality assessment of cfDNA eluates from both body fluids before use in sensitive downstream assays is essential. In this study, we present quality assessments based on capillary electrophoresis using samples stabilized and isolated with verified and standardized preanalytical workflows using the PAXgene Urine Liquid Biopsy Set (RUO) and the PAXgene Blood ccfDNA Tube (CE-IVD).

METHODS: Urine and blood samples from apparently healthy, consented individuals were collected and stabilized in the PAXgene Urine Liquid Biopsy Set and the PAXgene Blood ccfDNA Tube (PreAnalytiX). Unstabilized samples from the same individuals were collected and processed in parallel. The samples were stored for several days on the lab bench at room temperature (15-25°C) or incubated at varying temperatures mimicking real world storage and/or transport scenarios. After storage, urine and blood samples were centrifuged to remove cells and cfDNA was isolated from the urine supernatant or plasma either using automated or manual methods. The concentration of cfDNA was measured using the Qubit dsDNA HS Quantification Assay Kit on the Qubit Fluorometer (Thermo Fisher Scientific). Fragment profiles were analyzed using the QIAxcel DNA High Sensitivity Kit on the QIAxcel Connect instrument (both QIAGEN). For analysis of cfDNA from urine, the maximum fragment size shown was manually set to 5000 bp in the ScreenGel software (QIAGEN).

RESULTS: cfDNA isolated from the PAXgene Blood ccfDNA Tube showed the typical, predominantly mononucleosomal fragment length independent of whether the blood was stored or processed directly, while unstabilized blood showed contamination with gDNA. Urine cfDNA isolated from samples stabilized with the PAXgene Urine Liquid Biopsy Set showed that in addition to mono- and di-nucleosome DNA, longer fragments could be detected with and without storage. In unstabilized urine, DNA degrades rapidly, resulting in reduced fragment sizes compared to stabilized urine already on the day of urine collection without storage. After storage of unstabilized urine for three days, only degraded cfDNA could be detected.

CONCLUSIONS: In this study we could demonstrate that stabilization of cfDNA in urine and blood are essential to preserve the native profiles of this analyte. Standardized preanalytical workflows provided by PreAnalytiX and state of the art quality control via the QIAxcel instrument should be considered for development of reliable downstream analysis.

#4553 Evaluation of cfDNA release profiles in colorectal cancer patients during surgery.

Mailson Alves Lopes[1], Maria Elvira Ribeiro Cordeiro[1], Flavio de Alencar Teles Barreto[1], Lara de Souza Moreno[2], Andre Araujo de Medeiros Silva[3], Mayra Veloso Ayrimoraes Soares[2], Mariana Braccialli de Loyola[1], Joao Batista de Sousa[3], **Fabio Pittella-Silva**[1]

[1]Laboratory of Molecular Pathology of Cancer, University of Brasilia, Brasilia, Brazil,[2]Department of Radiology, Brasilia University Hospital, Brasilia, Brazil,[3]Department of Colorectal Surgery, Brasilia University Hospital, Brasilia, Brazil

Surgical intervention is one of the most employed treatments for colorectal cancer, especially in patients with localized disease. However, the dynamics of circulating cell-free DNA (cfDNA) release during surgical procedures remain poorly understood. This lack of understanding underscores a significant gap regarding the biological processes underlying tumor response to surgery. Here we examined surgical cfDNA release from 30 colorectal cancer patients. cfDNA was extracted from plasma samples at three key points: preoperative (just before surgery), intraoperative (during surgery), and postoperative (at the end of surgery). Automated electrophoresis was used to analyze cfDNA concentrations and fragment sizes, which were then correlated with different clinical variables. Our findings show a significant increase in cfDNA release during and after surgery in comparison to preoperative time (2.8- and 2.2-fold higher, respectively). cfDNA fragments of <400 bp were predominant at all surgical stages, with no significant release of genomic DNA detected in any stage. We found that cfDNA concentrations increase on an average of 2 to 3-folds during and after surgery in patients over 60 years old, in patients with comorbidities and in patients with CEA levels > 5 ng/mL. Importantly, cfDNA release during surgery was significantly higher in patients with adverse clinical characteristics. Patients with locally advanced tumors or metastasis had a 3.1-fold increase in cfDNA release intraoperatively and a 2.4-fold increase postoperatively ($p < 0.01$). cfDNA concentrations also increase intraoperatively in patients with high tumor bud scores (2.6-fold higher, $p < 0.02$), perineural invasion (3.4-fold higher, $p < 0.02$), and lymphovascular invasion (3.1-fold higher, $p < 0.05$). Overall, our findings indicate that factors such as advanced physiological age, existing comorbidities, adverse clinical characteristics, and extensive surgical manipulation may contribute to increased tissue damage and enhanced cfDNA release.

#4554 Advanced detection of *TMEM240* hypermethylation in circulating cell-free DNA as a novel biomarker for colorectal cancer monitoring.

Yao-Yu Hsieh[1], Ruo-Kai Lin[2]

[1]Taipei Medical University Shuang Ho Hospital, Ministery of Health and Welfare, New Taipei City, Taiwan,[2]Taipei Medical University, Taipei, Taiwan

Background: Carcinoembryonic antigen (CEA) is currently the most widely utilized biomarker for monitoring colorectal cancer (CRC) progression and treatment efficacy. With a sensitivity of approximately 80% and specificity of 70% at a cutoff level of 5 μg/L, CEA has demonstrated clinical utility in many cases. However, 20-30% of CRC patients fail to benefit from CEA monitoring due to its limited dynamic range and clinical irrelevance in specific cases, underscoring the urgent need for more accurate and reliable biomarkers. Recent advancements have identified the hypermethylation of the *TMEM240* gene as a promising biomarker for CRC detection, prognosis, and progression.

Results: We developed an advanced detection technology to analyze methylated circulating cell-free DNA (mcfDNA) specific to the *TMEM240* gene. A cohort of 30 colorectal cancer patients, including 5 with stage I and II, 3 with stage III, and 22 with stage IV, was monitored every 1-3 months over a follow-up period exceeding six months. The results revealed that elevated levels of *TMEM240* mcfDNA could be detected 1-3 months before image progression. Notably, patients with good prognoses exhibited no detectable *TMEM240* mcfDNA in their plasma, suggesting and good predictive marker of treatment response. In contrast, metastatic colorectal cancer patients with detectable *TMEM240* mcfDNA in plasma were identified as having a higher risk of cancer progression. Furthermore, high levels of *TMEM240* mcfDNA were strongly associated with the development of multiple metastases within three months, emphasizing its prognostic value in advanced disease stages. The method exhibited outstanding accuracy in predicting cancer progression, achieving an area under the curve (AUC) of 0.986, a sensitivity of 92.3%, and a specificity exceeding 99.0%. These results highlight the superiority of *TMEM240* mcfDNA as a biomarker compared to CEA, particularly in its ability to provide earlier and more precise detection of disease progression. Unlike CEA, which often fails to reflect subtle or early changes in CRC dynamics, *TMEM240* mcfDNA levels demonstrated robust applicability across all stages of CRC, from early detection in stages I and II to advanced monitoring in stage IV cases. *TMEM240* mcfDNA levels also provided real-time insights into treatment efficacy, particularly in metastatic colorectal cancer patients.

Conclusion: The hypermethylation of *TMEM240* mcfDNA in plasma represents a highly sensitive and specific biomarker for CRC monitoring, addressing the limitations of traditional markers such as CEA. The integration of this innovative assay into clinical practice could revolutionize CRC management by enabling earlier detection of progression, more accurate prognosis, and real-time evaluation of therapeutic efficacy.

#4556 Postoperative minimal residual disease detection using tumor-informed circulating tumor DNA analysis in stage II-III gastric cancer.

Background: Circulating tumor DNA (ctDNA) analysis enables the detection of minimal residual disease (MRD), offering potential for improved risk stratification and guidance on decisions regarding adjuvant chemotherapy (ACT). We investigated the clinical utility of tumor-informed ctDNA analysis for postoperative MRD assessment in stage II-III gastric cancer (GC).

Methods: We plan to enroll 100 patients from the 976 expected in the ongoing EXODOX study (NCT04787354), a phase III randomized trial comparing reduced-duration XELOX with the standard 6-month regimen as ACT in patients with pathologic stage II-III GC after curative resection. In this sub-study, ctDNA MRD was assessed using the CancerDetect^{TM} assay (IMBdx, Inc.), a targeted sequencing method with a tumor-informed bespoke panel (BSP). To create the BSP, whole exome sequencing of tumor tissue and paired white blood cells identified up to 100 patient-specific variants. Whole blood (20 mL) was collected at five postoperative time points: 3-10 weeks (P0), 6 months (P1), 12 months (P2), 18 months (P3), and 24 months (P4). CtDNA MRD positivity was defined as the detection of two or more BSP variants in plasma.

Results: This analysis includes 42 patients enrolled from May 2022 to August 2024, with ctDNA MRD assessed at three time points: P0 (n = 42), P1 (n = 27), and P2 (n = 17). The median age was 66 years (range, 39-96); 27 patients (64.3%) were male, all had adenocarcinoma, and 30 patients (71.4%) had stage III disease. Overall, postoperative ctDNA (P0) positivity was 45.2% (19/42), with a median of 8 somatic mutations per patient (range, 2-94). CtDNA positivity was significantly higher in stage III than in stage II patients at P0 (56.7% vs. 16.7%, P = 0.037). CtDNA MRD clearance after ACT was achieved in 46.2% (6/13) of patients who were ctDNA-positive at P0. One initially ctDNA-negative patient converted to positive, resulting in an overall ctDNA positivity rate of 29.6% (8/27) at 6 months (P1). Twelve months postoperatively, ctDNA positivity (P2) was 35.2% (6/17). After a median follow-up of 12.0 months, 7 patients experienced recurrence. CtDNA positivity at P1 and P2 was significantly associated with worse recurrence-free survival (RFS) (P = 0.003 and P = 0.038, respectively), whereas it was not significantly associated at P0 (P = 0.101). RFS differed significantly based on changes in ctDNA positivity from P0 to P1 (P = 0.010), with the persistent ctDNA-positive group showing the poorest RFS. Notably, patients who achieved ctDNA clearance after ACT had RFS similar to those who were ctDNA-negative at both P0 and P1 (P = 0.480).

Conclusions: In patients with stage II-III GC, postoperative MRD was associated with recurrence risk. Temporal changes in ctDNA MRD status during monitoring reflect the response to ACT and may guide treatment decisions. To fully understand the impact of ctDNA MRD monitoring, further follow-up is planned.

#4557 Genome-wide cfDNA hypo-methylation landscape of 500 patients, a real-world study.

Chao Dai, Giancarlo Bonora, Kemin Zhou, Shidong Jia, Pan Du

Predicine Inc., Hayward, CA

Background: Liquid biopsies analyzing cell-free DNA (cfDNA) from plasma and urine can offer clinical diagnostic information in a non-invasive way. One major application of DNA methylation in liquid biopsies focuses on targeted panel regions, aiming to detect hypermethylation in cancer related regions. Recent studies have revealed that the loss of DNA methylation is significantly enriched in late-replicating loci compared with early-replicating loci in cancer cells. In this study, we profiled genome-wide DNA methylation of plasma and urine samples from various of cancer indications to detect DNA methylation loss in tumor DNA.
Methods: We used the PredicineEPIC assay for genome-wide DNA methylation profiling at 20× coverage. Unlike traditional differential methylation region (DMR) analysis, we identified fragment-level DNA methylation changes in CpG-rich genomic regions. For each fragment, we calculated the probability of the fragment being unmethylated versus methylated. This calculation is specific to genomic positions, with the background distribution built upon more than 100 healthy plasma samples.
Results: Compared with genome-wide DNA methylation profile of healthy plasma samples, we observed two distinct types of methylation loss in cancer patient samples. In the first case, hypomethylation occurs at fragments with significant methylation loss, where the methylation status of all CpG sites transitions from methylated to unmethylated. We observed that the magnitude of methylation loss is positively correlated with tumor fraction. Based on wet-lab titration experiment results, we can achieve tumor fraction detection limit of 0.1% for prostate, breast, and lung cancers. In the second case, hypomethylation at the fragment level is more subtle, with only a portion of CpG sites becoming unmethylated. We found that many samples in this category had CHIP mutations or other methylation enzyme deficiencies detected, with DNMT3A, which encodes DNA methyltransferase, being the most frequent. The same method can also be applied to urine cfDNA data for the detection of bladder cancer. We analyzed over 500 whole-genome methylation samples across different cancer indications, including prostate, colon, pancreatic, lung, breast and bladder cancers. Overall, genome-wide DNA methylation loss is highly prevalent in cancer samples and varies across cancer types. Some chromosome regions are consistently hypo-methylated across samples and cancer indications.
Conclusions: Our results indicate that global nuclear organization might be disrupted by methylation loss at closed chromatin compartments. The genome-wide methylation profile of circulating tumor DNA can measure cancer genome abnormality in terms of DNA methylation loss, CHIP mutations and copy number variations. Combination of all these features can provide a robust utility for cancer detection and estimating tumor fraction in liquid biopsies.

#4558 Comparative analysis of blood- and tissue-informed MRD studies in SCLC.

Haoran Tang[1], Wei Tan[2], Pu Sun[2], Yang Shi[2], Cancan Jia[1], Feng Xie[1], Yue Zhang[1], Qin Luo[1]

[1]Huidu Shanghai Medical Sciences, Ltd., Fengxian District, Shanghai, China,[2]BeiGene (Shanghai) Co., Ltd., Jing'an District, Shanghai, China

Introduction: Minimal residual disease (MRD) reflected by specific genetic alterations in ctDNA was considered to be closely related to disease status in solid tumors. MRD detection was reported to be promising to monitor therapeutic effects and identify recurrence risks. Next-generation sequencing (NGS) based MRD assays usually require tissue samples to identify tumor-specific mutations for subsequent monitoring (tissue-informed MRD). However, baseline tissue samples were not always available in clinical settings, limiting their applications. In this study, we explored using baseline blood samples to identify mutations for post-treatment ctDNA MRD detection (blood-informed MRD) as well as tissue-informed MRD in 62 limited-stage small cell lung cancer (LS-SCLC) patients receiving CRT combined with IO treatments (NCT04952597).

Methods: 62 patients with LS-SCLC underwent MRD testing using both tissue-informed and blood-informed PredicineBEACON assays during CRT treatment, either alone or in combination with IO. The assays utilized enhanced whole-exome sequencing (PredicineWES+) on initial tissue and blood samples to identify somatic mutations. Personalized MRD panels were developed for each patient, incorporating up to 50 mutations identified through bioinformatics analysis from either baseline tissue or blood, along with a standard panel of 500 key tumor mutations. The study conducted ultra-deep sequencing at 100,000X coverage using these tailored panels to detect MRD at two critical time points: cycle 1 day 1 (C1D1) and cycle 3 day 1 (C3D1).

Results: In this study, 62 patients were subjected to both tissue-informed and blood-informed MRD testing. PredicineWES+ at baseline identified 13,542 somatic mutations in tissue samples and 12,133 in plasma samples, with medians of 181 and 155 mutations per patient, respectively. There was a notable overlap where 10,503 mutations were recognized by both methods, resulting in a median concordance rate of 86.4% per patient, highlighting the WES assay's reliability in mutation detection across biopsy types. Upon MRD assessment at C3D1, a high concordance in MRD status was observed between the two methods: 35 patients tested MRD-positive and 26 MRD-negative in both assays. One patient displayed discordant results, being MRD-positive in the tissue-informed but negative in the blood-informed assay. Additionally, the study found a significant correlation in tumor fractions between the MRD tests at both C1D1 and C3D1 (R^2=0.96, p<2.2e-16), as established by linear regression, underscoring their robustness in evaluating tumor dynamics.

Conclusions: This study demonstrated high concordance of tumor-informed and blood-informed MRD assay in LS-SCLC patients treated with IO and CRT. These outcomes highlight the potential clinical applicability of using baseline ctDNA NGS assays for personalized MRD detection.

#4559 Paired liquid biopsies analysis reveals resistance mechanisms and prognostic factors in patients treated with KRASG12C inhibitors.

Kristi Beshiri, Damien Vasseur, Julieta Rodriguez, Smolenschi Cristina, Francesco Facchinetti, Antoine Italiano, Nicotra Claudio, Maud Ngo-Camus, Anas Gazzah, Capucine Baldini, Luc Friboulet, Yohann Loriot, Fabrice Barlesi, Christophe Massard, Antoine Hollebecque

Gustave Roussy Institute, Villejuif, France

Background: KRASG12C inhibitors (G12Ci) represent an emerging class of therapeutics. We aimed to explore resistance mechanisms and prognostic factors using liquid biopsy (LB) analyses.
Methods: We retrospectively assessed LBs from patients (pts) treated with G12Ci (February 2022 - November 2024), under the STING trial (NCT04932525). Paired LBs (baseline and progressive disease (PD)) were analyzed using the FoundationOne Liquid CDx assay. Survival outcomes were calculated, and univariate/multivariate analyses performed with R packages “survival” and “survminer” (v 3.3-1 and 0.4.9).
Results: A total of 18 pts treated with one or more G12Ci were included: NSCLC (n=9), colon cancer (n=8), and pancreatic cancer (n=1). All pts had a confirmed KRASG12C mutation in tissue samples. Three pts received two G12Ci sequentially. Overall, 21 LBs pairs were available: 13 included co-treatments (e.g., EGFR inhibitor (n=5), immunotherapy (n=4), and another small molecule (n=3)). At baseline LBs, KRASG12C was detected in 18/21 pairs (85.7%), and in 15/21 pairs at PD (71.4%). In three pairs the mutation was not detected at any timepoint. Overall response rate was 42.8% (9/21). At progression, acquired genomic alteration that may be associated with treatment resistance were identified in 6/21 pts (28.6%). All six pts exhibited at least one on-target KRAS alteration: KRAS amplification (n=2), KRAS R68S mutation (n=1), KRAS G12V (n=1), or KRAS mutations at G12A/D/F/S/Y, G13D, Q61H, R68S, Y96D (n=1). EGFR mutations (n=3),primarily associated with anti-EGFR resistance, a MET amplification (n=1), an ETV6 fusion (n=1), and a CDKN2A mutation (n=1) were also observed. Impact of the baseline variant allelic frequency (VAF) of the KRASG12C mutation on progression free survival (PFS) was assessed. The median PFS for pts with a VAF lower than the median (2.5%) was 7.5 months (95% CI: 5-NA), vs 4 months (95% CI: 2-NA) for those with a VAF higher, which was associated with worse PFS (p=0.0097). Univariate analysis revealed that the number of metastatic sites at baseline (HR: 2.00, 95% CI: 1.30-3.00, p = 0.0013) was associated with worse PFS, as well as higher baseline VAF (HR: 3.40, 95% CI: 1.30-8.90, p = 0.015). Multivariate analysis confirmed higher VAF at baseline as a predictor of worse PFS (HR: 2.79, 95% CI: 1.01-7.75, p = 0.0049), as did the baseline number of metastatic sites (HR: 1.84, 95% CI: 1.09-3.11, p = 0.022). The correlation between Tumor Fraction (cut-off 10%) and PFS was no statistically significant (p=0.081).
Conclusion: Paired LBs represent a potential method for idenfying up to 28.6% of the resistance mechanisms to G12Ci. Complementary molecular methods, such as tissue biopsy molecular analysis, are needed to comprehensively identify resistance mechanisms. Higher VAF at baseline LBs and a greater number of metastatic sites were both associated with worse PFS.

#4560 Use of ctDNA fragmentomics as a predictive biomarker in locally advanced non-small cell lung cancer.

Kishen R. Patel[1], Anisha Mistry[2], Robert Monfries[3], Florent Mouliere[4], John R. Conibear[3], James Wilson[5], Karim Keshwani[5], Wing K. Liu[6], Crispin Hiley[1]

[1]Hiley Lab, University College London (UCL) Cancer Institute, London, United Kingdom,[2]Cancer Research UK RADNET, London, United Kingdom,[3]Clinical Oncology, Barts Cancer Centre, London, United Kingdom,[4]Mouliere Lab, Cancer Research UK Manchester Insitute, Manchester, United Kingdom,[5]Oncology, University College London Hospital, London, United Kingdom,[6]Jamal-Hanjani Lab, University College London (UCL) Cancer Institute, London, United Kingdom

Introduction: Locally advanced non-small cell lung cancer (NSCLC) is a serious condition with a poor 5-year survival rate of approximately 30%. Standard treatment involves chemoradiotherapy (CRT) followed by immunotherapy (IO). However, predicting benefit prior to CRT and monitoring response post treatment are areas of unmet need. Cancers, like many tissues, release fragments of DNA into the bloodstream, which can be detected using whole genome sequencing (WGS). Research has shown that cancer cells tend to release shorter DNA fragments, typically between 90-150 base pairs, at higher rates than normal tissues. This study aims to analyze cell-free DNA fragment sizes (fragmentomics) as a predictive tool for assessing treatment response in patients with LA NSCLC. This tumor-uninformed approach is cost-effective and can be implemented using routine blood samples.
Methods: Low-pass WGS at 0.1x coverage was performed on 40 pre-treatment plasma samples from patients LA NSCLC obtained from the UCL biobank. The median follow-up for the cohort was 33 months. To investigate the cancer origin of short DNA fragments (90-150 bp), mutation calling was conducted using Mutect2. Mutation density was defined as the number of mutations per million bases (MPM). Tumor volumes were obtained using CT imaging, and the percentage quantity of short DNA fragments was plotted against tumor volume. Enrichment of short fragments (SFE) <20% was assessed and correlated with clinical outcomes, including relapse and overall survival.
Results: Short DNA fragments (90-150 bp) had a significantly higher mutation density (973.8 MPM) compared to unselected fragments (381.7 MPM; $p<0.0001$). This elevated mutational burden supports the hypothesis that shorter fragments are of cancer origin. Linear regression analysis showed no significant relationship between tumor volume and the percentage of short DNA fragments for the entire cohort ($R^2 = 0.035$, $p = 0.35$). However, in lung squamous cell carcinoma (LUSC), a strong positive correlation was observed ($R^2 = 0.6787$, $p = 0.003$). Suggesting a potential quantitative link between tumor burden and ctDNA quantity in this subtype. SFE was observed in 31 of 40 patients (78%) prior to treatment. SFE was found in similar proportions in LUSC (78%; 15/19) and lung adenocarcinoma (75%; 15/20). Mortality occurred in 45% (14/31) of patients with SFE, compared to 11.1% (1/9) of those without enrichment. Among patients for whom consolidation IO was indicated, relapse rates were higher in those with SFE (44%; 7/16) than in those without enrichment (25%; 1/4). Findings of the research were limited by sample size; however further centers have been recruited to address this issue. These findings suggest that fragmentomic patterns represent a cost-effective, non-invasive prognostic biomarker for LA NSCLC, with particular potential in LUSC. Ongoing research is exploring patterns following treatment.

#4561 ShieldingUltra: A novel approach for enhanced minimal residual disease detection through the integration of mutation, copy number variation, and fragmentomics.

Hao Zhang, Ningyou Li, Wanxiangfu Tang, Jinfeng Zhang, Xunbiao Liu, Peng He, Baihan Zhu, Shuang Chang, Zilin Wang, Zhili Chang, Dongqin Zhu, Rui Liu, Xiaoxi Chen, **Haimeng Tang**, Hua Bao, Xue Wu, Yang Shao

Geneseeq Research Institute, Nanjing Geneseeq Technology Inc., Nanjing, China

Introduction: Minimal Residual Disease (MRD) detection using circulating tumor DNA (ctDNA) has significant clinical value in cancer therapy. However, existing methods primarily focus on mutations, restricting their broader applicability. Personalized panels, while targeted, are limited by prolonged turnaround times (TAT) and reliance on central labs. Fixed-panel approaches provide standardized, efficient solutions with strong potential for in vitro diagnostic kit development.
Method: We present ShieldingUltra, a fixed-panel MRD solution targeting hotspot mutations across 2,365 genes using ultra-deep unique molecular identifier sequencing. Using over 1,000 clinical plasma samples, cutting-edge AI-driven models were designed to reduce sequencing background error and clonal hematopoiesis interference, and improve sensitivity by integrating mutations, copy number variations, and fragmentomics. ShieldingUltra demonstrates exceptional performance validated across diverse clinical settings.
Result: ShieldingUltra demonstrated exceptional performance, achieving over 70% and 90% presurgical plasma positivity in early- and late-stage pan-cancer samples, respectively, with >99% specificity in healthy plasma. We further evaluated ShieldingUltra in a few most challenging clinical scenarios, rarely studied before with poor outcomes, and achieved unparalleled performance. In a cohort of lung cancer patients, ShieldingUltra achieved the most sensitive MRD detection with 1-week postsurgical landmark plasma (61.5%, 16/26), with sensitivity rising to 96% (25/26) using longitudinal plasma. In another challenging and unresolved scenario aimed at further stratifying advanced non-small cell lung cancer (NSCLC) patients who exhibited a partial response upon completion of immunotherapy (IO), as well as identifying those unable to maintain prolonged progression-free survival, ShieldingUltra successfully identified over 50% (18/34) of individuals who quickly relapsed. This highlights ShieldingUltra's potential to pinpoint patients most likely to ultimately benefit from IO, which marks an innovative frontier in MRD research. Additionally, ShieldingUltra was explored for perioperative MRD tracking and the potential to guide the treatment strategies in an advanced stage ovarian cancer cohort, including evaluating neoadjuvant therapy for surgical decisions, assessing the need for adjuvant therapy post-surgery, and monitoring treatment efficacy and MRD status after surgery.
Conclusion: ShieldingUltra combines a fixed panel with multiple genomic features and AI modeling for exceptional MRD detection. Its standardized design minimizes TAT, eliminates custom setup delays, and ensures reliable, cost-effective results, making it ideal for time-sensitive clinical decisions and broad clinical adoption.

#4562 Bespoke sequencing of enriched and normalized amplicons increases on-target rate and reduces background noise for circulating tumor DNA detection and quantification.

Tania Contente-Cuomo[1], Devin Dinwiddie[1], Mojca Stampar[1], Adriana Marshall[1], Michael E. Berens[1], Stephanie J. K. Pond[1], Jeffrey M. Trent[1], Muhammed Murtaza[2]

[1]Translational Genomics Research Institute, Phoenix, AZ,[2]Surgery/Center for Human Genomics and Precision Medicine, University of Wisconsin-Madison, Madison, WI

Background: Analysis of circulating tumor DNA (ctDNA) using tumor-guided bespoke sequencing can achieve high accuracy for minimal residual disease detection. However, bespoke laboratory workflows are often complex, difficult to scale, and costly. Multiplexed PCR methods have lower costs and preserve input DNA but instill higher background noise, variable on-target rates and unpredictable relative representation of amplicons. Locus- and mutation-specific hybrid capture can overcome these challenges but with higher costs of patient-specific custom baits and greater loss of input DNA. Here, we describe a workflow that combines targeted amplification with fixed content exome-wide hybrid capture to overcome these challenges.

Methods: We performed tumor-guided plasma DNA analysis using a novel method based on enrichment and normalization of amplicons and targeted sequencing. Using tumor and germline exome sequencing, we identified somatic founder mutations, and designed primers for multiplexed amplification. Targeted sequencing libraries were prepared using a combination of single-stranded adapter ligation, targeted PCR and hybrid capture. Sequencing reads were grouped in read families based on fragment size and unique molecular identifiers, and analyzed to improve specificity for detection of known mutations. We evaluated assay performance using reference samples (Seracare Life Sciences) as well as plasma samples from patients with cancer.

Results: We analyzed 8 replicates of reference samples at 10 ng input each for variant allele fractions (VAFs) of 0.5%, 0.25% and 0.125%, using an 18 mutation panel, and detected mutated DNA in 8/8 samples for all VAFs. In addition, we prepared a dilution at 0.01% VAF and analyzed 16 replicates of this sample at 40 ng input each, and detected mutated DNA in 15/16 samples. Using the same analytical thresholds, 1/8 wild-type reference samples were called positive. A comparison of observed and expected tumor fractions across all samples showed a correlation coefficient of 0.97 ($p<0.001$, $n=48$). In addition, we developed 44 patient-specific panels targeting a median of 30 mutations per patient (range 5 to 125 mutations) for patients with pancreatic cancer, breast cancer and glioblastoma. Using a median input of 6.7 ng (range 1.1 to 24 ng), we analyzed 112 plasma DNA samples across 44 panels and observed a median on-target rate of 89% using the first round of panel design. ctDNA was detected in 62 plasma samples (55%) at a median tumor fraction of 0.013% (range 0.009% to 5.8%).

Conclusion: Our results demonstrate analytical performance and assay stability across 44 patients using bespoke sequencing of enriched amplicons for circulating tumor DNA (enACT-DNA) analysis. On-going studies are evaluating the clinical relevance of perioperative ctDNA detection using enACT-DNA in patients with cancer.

#4563 Tumor fraction estimation and tissue copy number inference using copy number signal from a liquid biopsy assay.

Patrick D. Cherry, David Tsao, Wen Zhou

BillionToOne, Menlo Park, CA

Purpose: Estimating tumor fraction and inferring copy number alterations (CNAs) from cell-free DNA (cfDNA) liquid biopsy is challenging due to SNV heterogeneity and occasional lack of SNV signal. About 90% of solid tumors exhibit chromosome arm level gains or losses [1-2], and this effect on copy number could potentially be used as a tumor load biomarker. This study aims to use aneuploidy signal in cfDNA to estimate tumor fraction and infer tissue copy number, addressing a limitation of variant-based cfDNA assays and providing a robust method for benchmarking against gold-standard techniques like FISH.

Methods: We employed Northstar Select for copy number quantification, BillionToOne's treatment-selection liquid biopsy assay, which is optimized for accurate plasma copy number measurement of genes and is resistant to technical and biological noise. A Gaussian mixture model (GMM) was applied to quantify liquid aneuploidy signal on measured genes. The periodicity pattern was used to estimate tumor fraction independently of SNV signal. From a databank of 3180 clinical samples, we analyzed 92 clinical samples (from 20 patients) for concordance with SNV-based methods over multiple timepoints, and 136 clinical samples (from 128 patients) with homozygous copy number loss calls for concordance with the tissue copy number estimate.

Results: Aneuploidy-based tumor fraction estimates showed robustness above 2% tumor fraction. GMM tumor fraction estimates demonstrated concordance with samples exhibiting clear SNV alterations (Pearson r = 0.65 across multiple accessions and patients), and the correlation can be as good as r = 0.96 in samples from patients with longitudinally trackable SNVs. In the retrospective analysis, 141 homozygous copy number losses were called by Northstar Select assay, and among those, aneuploidy-based tissue copy number estimation identified homozygous losses in 126 samples (89%). The algorithm also identified additional homozygous losses (both inside of and outside of the reportable gene set of Northstar Select). Analysis of serially tested clinical plasma samples revealed that—despite large tumor fraction fluctuations (≤5% to ≥50%)—tissue copy number estimates for the same patient remained stable.

Conclusions: Our aneuploidy-based approach provides a reliable alternative to SNV-based methods for tumor fraction estimation and tissue copy number inference from liquid biopsy data. These findings suggest potential improvements in the utility of liquid biopsy for cancer diagnostics and monitoring, particularly in cases with low/mixed SNV signals. The ability to accurately infer tissue copy number is crucial for predicting amplification levels, identifying driver mutations, and anticipating therapeutic responses.

#4564 Enhancing circulating tumor DNA recovery and liquid biopsy sensitivity with precision liposomal priming agents.

Kasturi Chakraborty[1], Carmen Martin-Alonso[1], Daniel Kim[1], Savan Patel[1], Sahil Patel[1], Zhenyi An[2], Shervin Tabrizi[2], Claire Sullivan[2], Lily Gao[2], J. Christopher Love[1], Viktor A. Adalsteinsson[2], Sangeeta N. Bhatia[1]

[1]Koch Inst. for Integrative Cancer Research at MIT, Cambridge, MA,[2]Broad Institute of MIT and Harvard, Cambridge, MA

Liquid biopsies offer the potential for early cancer detection as well as a non-invasive, real-time window into the evolving tumor as the cancer progresses (*Turabi+, 2024 PMID: 39001494*). In this context, circulating tumor DNA (ctDNA) - the fraction of cell-free DNA (cfDNA) shed by tumor cells into the bloodstream, has emerged as a promising candidate. It carries the genetic and epigenetic alterations specific to the originating tumor, making it an essential source of information for cancer diagnosis and monitoring. While in patients with advanced cancer and a higher tumor burden the proportion of ctDNA is >10%, and can even exceed 40% of the total cfDNA, this fraction is less than 1% in early-stage tumors making early detections challenging. We hypothesized that manipulating ctDNA biology could improve its recovery and developed a SPE-liposomal “priming agent" which transiently inhibit macrophage mediated clearance (Martin-Alonso/Tabrizi/Xiong+, 2024 PMID: 38236959). The targeting of SPE liposomes to liver macrophages was predominantly size-dependent, utilizing particles with the average hydrodynamic diameter between 230 and 260 nm. This range was designed to match the size of murine liver capillary fenestrae, such that the nanoparticles would preferentially target liver-resident macrophages over hepatocytes. However, effective macrophage priming still required a significant lipid load to increase cfDNA levels in circulation. To improve on our priming agents, we developed three distinct SPE-modified nanoparticles to target macrophage subpopulations in the liver and tumor. These next-generation priming agents enabled a 60-fold reduction in lipid dose while achieving a more than 1500-fold higher recovery of cfDNA compared to untreated mice. Additionally, we show that these nanoparticles provided a marked increase in the detection of mutant duplexes in a transplantation model of colon cancer lung metastases, Luc-MC26 tumor-bearing mice. In summary, we optimized macrophage-targeted nanoparticle-based strategies that significantly improved the recovery of cfDNA, and that enhanced early tumor detection rate. These technologies have the potential to improve the accuracy and sensitivity of liquid biopsies, as well as to extend our fundamental understanding of the in vivo dynamics of circulating nucleic acid structures.

#4565 CANARy-TF: an improved copy number and tumor fraction estimator for liquid biopsy applications.

Diego Almanza, Takeshi Sugio, Emily Hamilton, David Kurtz, Maximilian Diehn, Mohammad Shahrokh Esfahani, Ash A. Alizadeh

Stanford University, Menlo Park, CA

Background: Accurate detection of copy number alterations (CNAs) and reliable estimation of tumor fraction from liquid biopsies are crucial for effectively triaging patient samples in large clinical trials. This is particularly vital in scenarios where variant allele frequency (VAF) data is unavailable, yet an estimation of tumor fraction remains necessary. We hypothesize that specific characteristics of circulating free DNA (cfDNA) can enhance the performance of algorithms aimed at detecting CNAs and estimating tumor fraction.
Methods: We introduce CANARy-TF (Copy number ANomaly Assessment and RecoverY Tumor Fraction), a novel algorithm designed to accurately identify CNAs and estimate tumor fraction from low-pass whole-genome and off-target sequencing. CANARy-TF utilizes sequencing coverage data to pinpoint amplifications and deletions by comparing samples against a panel of normals. Additionally, it incorporates unique cfDNA features, such as fragment size and shifts in the distribution of wildtype/mutant fragments, to improve tumor fraction estimation.
Results: The performance of CANARy-TF was evaluated on a cohort of 23 cfDNA samples from patients with non-small cell lung cancer (NSCLC), alongside 149 cfDNA samples from healthy individuals as a background population. For all samples, tumor-informed VAF data were available. Analysis revealed a strong correlation between true VAF and the estimated tumor fraction by CANARy-TF, with a Spearman's rho of 0.86 (p-value = 1.38e-07). In silico mixtures representing tumor prevalence from 0.001% to 5% were generated, demonstrating a limit of detection for the algorithm at around 1%.
Conclusion: CANARy-TF effectively estimates CNAs and tumor fraction from plasma cfDNA samples. Notably, this algorithm is robust when applied to low-pass whole-genome sequencing, offering an efficient solution for triaging samples in both clinical settings and liquid biopsy studies.

#4566 A methylation-based, tissue-independent blood test for recurrence monitoring and treatment assessment.

Jiayue Xu, Xingyu Yang, Qiancheng You, Jing Su, Zeliang Deng, Xinyue Kang, Guangyou Li, Si Zhang, **Bingsi Li**

Innovation Center, Burning Rock Biotech, Shanghai, China

Background: Circulating tumor DNA (ctDNA) has emerged as a promising biomarker of minimal residual disease (MRD) detection and therapy response assessment. However, the low tumor burden in early-stage cancer and interference from non-tumor variants (e.g. clonal hematopoiesis) often necessitate tumor tissue to achieve the desired sensitivity and specificity. This requirement can limit the clinical application, particularly in situations where tissue biopsy is challenging or rapid turnaround times are critical. We previously validated an tissue-free assay (OverC) that combines a novel methylation sequencing method and machine learning for sensitive detection of low-frequency ctDNA in multiple cancer types. Here we describe the expansion of this assay for recurrence monitoring and treatment assessment.

Methods: DNA extracted from 139 formalin-fixed paraffin-embedded tumor/normal tissues and 249 plasma samples subjected to whole-genome methylation sequencing (5-30X depth) for single-molecule pattern recognition. The targeted methylation panel of the refined version, known as OverC Monitor, covered 70, 546 CpGs (~1.0 Mb), representing promoters, introns and other epigenetic regulatory elements. The classifier was developed with a larger THUNDER training set and independently validated with 506 pre-treatment plasma samples from patients with cancer and age-matched non-cancer controls. A positive call is made upon the identification of a cancer signal exceeding a locked threshold. In addition, a quantitative measure of tumor allele fraction (TAF) was developed and reported for each sample to assess its prognostic and monitoring potential.

Results: The assay performance was tested using plasma samples from 104 patients with lung cancer (LC), 48 colorectal cancer (CRC) and 74 liver cancer (HCC) and 280 age-comparable non-cancer donors. For LC, the sensitivity was 69.2% (Stage I: 30.3%, Stage II: 60.0%, Stage III: 86.7%, Stage IV: 91.7%) at a specificity of 98.6%. The sensitivity for CRC was 81.3% (Stage I: 41.7%, Stage II: 90.0%, Stage III: 95.0%, Stage IV: 100%) at a specificity of 98.9%. For HCC, the sensitivity reached 95.9% (Stage I: 89.5%, Stage II: 100.0%, Stage III: 95.0%, Stage IV: 100.0%) at a specificity of 98.9%. Further validation with larger cohorts and additional tumor types is underway, and updated data will be presented as it becomes available.

Conclusions: By leveraging cancer-derived methylation signatures and machine learning, we have developed and validated a highly sensitive assay (OverC Monitor) for detecting trace amounts of ctDNA in blood. This innovative, tissue-free approach has demonstrated performance on par with cutting-edge tissue-dependent mutation tracking methods for certain cancer types, highlighting its potential for broader clinical use in recurrence monitoring and treatment efficacy assessment.

#4567 Circulating tumor DNA-based molecular residual disease guides treatment in metastatic colorectal cancer patients with no evidence of disease: An open-label, prospective, interventional phase II study.

Yaqi Li[1], Chengcheng Li[2], Peng Cui[2], Xiang Hu[1], Fangqi Liu[1], Wenhua Li[3], Guoqiang Wang[2], Kunli Zhao[2], Qi Pan[4], Jing Wang[2], Bing Li[2], Shangli Cai[2], **Junjie Peng**[1]

[1]Department of Colorectal Surgery, Fudan University Shanghai Cancer Center, Shanghai, China,[2]Burning Rock Biotech, Guangzhou, China,[3]Department of Medical Oncology, Fudan University Shanghai Cancer Center, Shanghai, China,[4]Department of Hepatic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China

Patients with metastatic colorectal cancer (mCRC) can achieve no evidence of disease (NED) after curative treatment. However, the survival benefit of adjuvant chemotherapy (ACT) for these patients remains uncertain. Circulating tumor DNA (ctDNA)-based molecular residual disease (MRD) detection has shown to help predict recurrence risk in CRC. Recent retrospective studies have indicated that ACT offers no clinical benefit in surgically resected mCRC with negative ctDNA. In this study, we conducted a prospective, interventiaonal clinical trial (NCT05635630) to evaluate the efficacy of ctDNA-guided ACT in patients with mCRC who achieved NED. Eligible mCRC patients who achieved NED after curative treatment were enrolled. Surgical tissues or puncture tissues were sequenced by whole-exon sequencing, and up to 50 highly ranked patient-specific variants were selected for the personalized panel design. Post curative treatment blood samples was sequenced by the personalized panel to determine the MRD status. Patients with positive MRD post curative treatment were offered investigator-determined ACT, while those with negative MRD were under surveillance. During surveillance, blood samples were collected every 3 months and patients whose MRD turned positive would receive intensive image surveillance every 2 months. A total of 104 eligible patients were included in the current analysis, among them 7 patients did not receive assigned treatment strictly adhered to the study protocol and were excluded from the per protocol set (PPS). In the PPS, as date cutoff of October 2024, the median follow-up was 14 months with 58 patients (58/97, 59.8%) who experienced recurrence. MRD was detected in 53 patients (54.6%, 53/97) post curative treatment. The median recurrence-free survival (RFS) was 8.5 months and not reached for patients with positive or negative MRD post curative treatment, respectively (HR: 4.28, 95% CI: 2.36-7.77; P<0.001). Six patients with negative MRD received ACT and had non-superior RFS than those who did not receive ACT (HR: 1.60, 95% CI: 0.46-5.58; P = 0.46). During surveillance, the median RFS was 6.1 months, 11.8 months, 16.8 months and not reached in patients with persistently positive ctDNA, converted positive ctDNA, converted negative ctDNA, and persistently negative ctDNA, respectively (log-rank P for trend <0.0001). All recurrent patients had at least one positive ctDNA detection before imaging confirmed recurrence, and the median lead time interval of ctDNA positivity to radiographic recurrence was 7.8 months (range, 0-20.2 months). Our results demonstrated the feasibility of using ctDNA to guide ACT in mCRC patients with NED. Future randomized clinical trials are needed to further demonstrate the utility of ctDNA-guided ACT in mCRC patients with NED. The follow-up is still on-going.

#4568 Biochemical mitigation of technical artifacts improves performance of a ctDNA methyl sequencing assay.

James Yu, Peter George, Jason Close, Andy Eang, Neil Peterman, Yu Sun, Nafisa Bulsara, Eileen Dimalanta, Alexander Robertson, Yexun Wang, Nicole Lambert

Foundation Medicine, Inc., San Diego, CA

In addition to accumulating mutations that may drive tumor growth, cancer cells also show broad changes in DNA methylation patterns genomewide. For example, a colorectal cancer sample may have fewer than 10 driver mutations, fewer than 100 passenger mutations, but may have nearly 800 differentially methylated regions. In contrast to the traditional method of using sequencing to find these scarce mutations in the genome, probing for these relatively abundant aberrantly methylated regions in the genome can be a powerful alternative approach for the detection of cancer.

However, assessing DNA methylation via methyl sequencing is complicated by artifacts introduced during the traditional NGS library prep process. In vivo, CpG sites in mammals are typically methylated on both strands of the double stranded DNA; however, we observe that the majority of read fragments display some level of hemimethylation (only one strand displays methyl modifications), and roughly 10% of all reads are hemimethylated across the read. Furthermore, we observe that the fraction of methylated bases gradually decreases over the course of a sequencing read; the methylation state of DNA should not be expected to be impacted by the cycle number of a sequencing run. These artifacts are collectively known as M-bias and can be mitigated computationally, but these methods are an incomplete solution and may sacrifice valuable base coverage.

We have devised a strategy to correct M-bias biochemically, using a custom formulated end repair mix. We show that this novel library prep workflow reduces M-bias by ~50% in diverse ctDNA assays. This reduction in M-bias results in more accurate methylation status calls and reduces the number of reads needed to confidently cover a CpG region of interest. Finally, we show that biochemical M-bias mitigation methods lower healthy hypomethylation background signal by ~10x. These changes increase robustness of hypomethylation biomarker quantitation and utility in ctDNA detection assays.

#4569 MiRNA signatures in liquid biopsy for early detection of non-small cell lung cancer.

Alessandro Pascon Filho[1], Giovana M. Stanfoca Casagrande[1], Rodrigo Sampaio Chiarantano[2], Fabiana de Lima Vazquez[2], Rui Manuel Reis M. Reis[1], Leticia Ferro Leal[1]

[1]Molecular Oncology Research Center, Barretos Cancer Hospital, Barretos, Brazil,[2]Department of Medical Oncology, Barretos Cancer Hospital, Barretos, Brazil

Background: Liquid biopsy-based biomarkers present a promising approach for non-invasive risk assessment and early detection of lung cancer.
Aim: To identify a miRNA signature in sputum and plasma samples as a non-invasive biomarker for early detection of non-small cell lung cancer (NSCLC).
Methods: A case-control study was conducted within the Barretos Cancer Hospital Screening Program, utilizing a low-dose CT mobile unit. Sputum and plasma samples were collected from high-risk controls (NLST and/or PLCO criteria; n=61) and NSCLC patients (n=62), matched for age, sex, and smoking history. MiRNA expression was analyzed using the nCounter HumanV3 miRNA panel (Nanostring™). Counts were normalized by the top stable miRNAs, followed by differential expression analysis ($p<0.05$). MiRNA selection was conducted using Boruta and LASSO. Dataset was partitioned into training and validation sets (85/15 split). Machine learning models (ML) were conducted (Azure) and performance was assessed using AUC (Table 1).
Results: In plasma, 68 miRNAs were identified as differentially expressed, and 8 miRNAs were retained following filtering. Among the all-tested models (Table 1), the best ML (Voting Ensemble) for the 8-miRNA plasma signature showed a high accuracy in both training (80.3%, AUC = 0.931) and validation set (73.3%, AUC = 0.892). In sputum, 46 miRNAs were identified as differentially expressed, and 7 miRNAs were retained. The best ML (SVD,Logistic Regression) for the 7-miRNA sputum signature showed a high accuracy in both training (81.42%, AUC = 0.943) and validation set (78.57%, AUC = 0.916). The two defined signatures exhibited no overlap in miRNAs between fluids.
Conclusion: This study identified two distinct miRNA fluid-specific signatures in sputum and plasma as potential non-invasive biomarkers for the early detection of lung cancer, underscoring their potential to advance precision-based screening and improve clinical decision-making in lung nodules management.

#4570 ESR1-mutant circulating tumor DNA is associated with plasma interleukin-2 (IL-2) leading to circulating tumor cell proliferation in metastatic breast cancer.

Q. Zhang[1], J. W. Zhang[2], J. Jiao[3], A. A. Davis[4], L. Gerratana[5], Y. Zhang[1], X. Wang[1], P. D'Amico[6], W. Qin[7], L. Flaum[1], A. Chawla[1], J. Lu[1], L. C. Platanias[1], W. J. Gradishar[1];

[1]Robert H. Lurie Cancer Center, Feinberg School of Medicine, Northwestern University - Evanston, Chicago, IL, [2]Northwestern University and Whitney Young High School, Chicago, IL, [3]Xijing Hospital, Innovation Center for Tumor Immunocytology Therapy Technology, Xijing Innovation Research Institute, Fourth Military Medical University, Xi'an, Shaanxi, China, [4]Washington University in St. Louis, St. Louis, MO, [5]University of Udine, Udine, Italy, [6]Merck, Rahway, NJ, [7]Xijing Hospital, Innovation Center for Tumor Immunocytology Therapy Technology, Xijing Innovation Research Institute, Fourth Military Medical University, Chicago, China

Introduction: Immune suppression is one of the most important causes of metastasis in metastatic breast cancer (MBC). Monitoring circulating tumor DNA (ctDNA) and circulating tumor cells (CTCs) in patients with MBC is predictive of a worse prognosis. We previously reported that ctDNA *ESR1* alterations are associated with disease resistance in MBC (2022-ASCO #1057). Here, we sought to examine if ctDNA *ESR1* mutations correlated with plasma IL-2 level, a key cytokine in the MBC immune microenvironment, leading to changes in CTCs levels following systemic treatment.

Methods: Whole blood samples (7.5ml/each) were collected from 50 ER^+ (12 HER^+ and 38 $HER2^-$) patients with MBC before (base line, BL) and 3 months (follow-up evaluation, FE) after systemic therapy at Northwestern Memorial Hospital (IRB-NU16B06). Plasma ctDNA was analyzed using the Guardant360 NGS-based assay and CTC enumeration was performed in the FDA-approved CELLTRACKS System (Menarini). The CTCs were classified as $CK^+/DAPI^+/CD25^-$. ELISA (Fisher) for IL-2 was analyzed by using patients' plasma. Kruskal-Wallis test was used for statistics.

Results: Of the 50 patients, CTCs were found in 26 patients at BL level and in 24 patients at the follow-up FE level, respectively. *ESR1* mutations were identified in 12 hotspots from 10 patients ($ESR1^{Mut}$, 20%), while 40 patients had no mutations ($ESR1^{WT}$, 80%). The median number of total CTCs (/7.5 ml) was significantly higher in the $ESR1^{Mut}$ group compared to the $ESR1^{WT}$ group, CTCs were 23.2 vs. 10.3 (P=0.006) at the BL level and 27.8 vs. 14.7 (P=0.014) at the FE level, respectively. Meanwhile, the corresponding IL-2 levels were significantly lower in the $ESR1^{Mut}$ group compared to the $ESR1^{WT}$ group, with levels of 71.9 pg/ml vs. 81.3 pg/ml (P<0.01) at the BL level and 68.3 pg/ml vs. 77.1pg/ml (P<0.01) at the FE level. In the $ESR1^{Mut}$ group after treatment, patients with decreased IL-2 levels (median decrease of 17.38 pg/ml) showed an average increase of 9.4 CTCs, while those with increased IL-2 levels (median increase of 19.8 pg/ml) showed an average decrease of 3.3 CTCs. The results indicate that *ESR1* mutations correlated with lower IL-2 levels and higher CTC counts both before and after treatment, and changes in IL-2 levels were inversely correlated with changes in CTC counts.

Conclusions: ctDNA *ESR1* mutations were associated not only with lower plasma IL-2 levels but also with significantly higher CTC counts, even after systemic treatment. Our new findings demonstrate that, in addition to contributing to endocrine therapy resistance, *ESR1* mutations may also suppress plasma IL-2 and weaken the immune environment in MBC, leading to an increase in CTCs escaping immune surveillance and promoting metastasis. The synergy between ctDNA *ESR1* mutations and IL-2 expands the predictive role of ctDNA monitoring in assessing metastatic prognosis for clinical decision-making.

#4572 Preliminary results of perioperative minimal residual disease monitoring using a tumor-informed ctDNA assay in stage II-III breast cancer.

Jongseong Ahn[1], Jiwoong Jung[2], Yongjun Cha[1], Sunghoon Heo[1], Eunhye Kang[3], Woosung Chung[4], Hwang-Phill Kim[1], Duhee Bang[5], Sang-Hyun Song[1], Han-Byeol Lee[6], Wonshik Han[6], Tae-You Kim[1]

[1]IMBdx, Inc, Seoul, Korea, Republic of,[2]Department of Surgery, Uijeongbu Eulji Medical Center, Eulji University, Uijeongbu, Korea, Republic of,[3]Department of Surgery, Seoul National University College of Medicine, Seoul, Korea, Republic of,[4]DCGen Co. Ltd., Seoul, Korea, Republic of,[5]Department of Chemistry, Yonsei University, Seoul, Korea, Republic of,[6]Department of Surgery, Biomedical Research Institute; Cancer Research Institute; Seoul National University College of Medicine, Seoul, Korea, Republic of

Background: Detection of minimal residual disease (MRD) via circulating tumor DNA (ctDNA) is a promising biomarker for risk stratification and treatment guidance in cancer. This study evaluated the clinical impact of tumor-informed ctDNA MRD monitoring during the perioperative period in stage II-III breast cancer (BC).

Patients and Methods: Patients with stage II-III BC were prospectively enrolled at Seoul National University Hospital (Feb 2023 - Jul 2024). In the neoadjuvant systemic therapy (NST) arm, 20mL of whole blood (WB) was collected at eight perioperative time points: baseline (N00), after one cycle of NST (N01), after completion of NST (N03), and at 1, 6, 12, 24, and 36 months post-surgery. In the adjuvant chemotherapy (AC) arm, WB was collected at seven postoperative time points: 1, 2 months post-AC, and at 6, 12, 24, 36, and 48 months post-surgery. Plasma samples were analyzed using the CancerDetect^{TM} assay (IMBdx, Inc), a personalized tumor-informed MRD detection test. Samples with ≥2 detected mutations were classified as ctDNA+.

Results: A total of 231 female patients were enrolled, and 189 met eligibility criteria. This analysis included 111 patients with analyzable WES data, focusing on 103 NST patients. Number of patients analyzed were 103 at N00, 100 at N01, 94 at N03, and 46, 52, 10 at 1, 6, 12 months post-op, respectively. Median age was 51 years (25-72). There were 48 (46.7%) HER2-positive (HER+), 31 (30.1%) triple-negative (TNBC), and 24 (23.3%) hormone receptor (HR)-positive/HER2-negative (HR+/HER2-) BCs. 58 (56.3%) were stage II and 45 (43.7%) were stage III. Median number of target variants from WES was 53 (8-100) and higher in TNBC (67) and HER2+ BC (55) than HR+/HER2- BC (31.5, $p = 0.006$). Baseline ctDNA positivity was 81.6% (84/103), and ctDNA+ rates by subtype were as follows: 87.1% for TNBC, 83.3% for HER2+ BC, and 70.8% for HR+/HER2- BC ($p = 0.281$). The positive rate by stage were 77.6% and 86.7% for stage II and stage III, respectively ($p = 0.356$). Median ctDNA fractions were higher in TNBC (0.186) than HER2+ BC (0.020) or HR+/HER2- BC (0.018, $p = 0.031$), and higher in stage III (0.125) than stage II (0.012, $p = 0.003$).After NST completion, the overall pathologic complete response (pCR) rate was 57.3% and ctDNA positivity dropped to 20.2% (19/94), and ctDNA negativity at N03 was associated with higher pCR rates (62.7% vs. 26.3%, $p = 0.010$). Among N00 ctDNA+ patients, 79.7%
achieved clearance after NST, which correlated with higher pCR rates (66.1% vs. 12.5%, $p < 0.001$). In this subpopulation (median follow-up 13.6, 6.7-19.9), only 4.9% (2/41) of the pCR patients were ctDNA+, no recurrences were reported.

Conclusions: Tumor-informed ctDNA assays correlated with NST response in stage II-III BC. Variations in target variants recovered from WES may explain differences in ctDNA positivity by subtype, which should be considered for clinical interpretation and application.

#4573 Verified preanalytical workflow for urine cfDNA including the PAXgene Urine Liquid Biopsy Set allows transport and storage at varying temperatures and is unaffected by blood interference.

Daniela Mancarella, Laura Sofie Witthaus, Moritz Meyer, Julia Rutsch, Moritz Rath, Lisa Erkelenz, Thorsten Voss

QIAGEN GmbH, Hilden, Germany

INTRODUCTION: Urine has become an important standalone source for biomarkers research using cell-free DNA (cfDNA). In addition, urine cfDNA has been shown to provide complementary information to blood cfDNA. However, cfDNA degradation, dilution by genomic DNA (gDNA) released from body cells and bacteria can impact the cfDNA profile and prohibit transport and storage of urine, making reliable urine molecular analysis impossible. Furthermore, interfering substances, such as blood, could affect the preanalytical workflow including the cfDNA isolation and hence, affect the research outcome. In this study, we tested the PAXgene Urine Liquid Biopsy Set (RUO) for urine collection and cfDNA stabilization in a standardized preanalytical workflow with challenging sample conditions and show that it enabled reliable analysis of cfDNA.

METHODS: Stabilized urine from apparently healthy, consented individuals was collected in the PAXgene Urine Collection Cup. Female urine specimens were spiked with cell-free male urine supernatant and, where indicated, with 1% v/v female blood. Urine was stabilized using the PAXgene Urine Liquid Biopsy Tube or was left unstabilized. Urine samples were stored for 3 days or 10 days at room temperature (RT, 15-25°C) on the lab bench or incubated for up to 10 days at varying temperatures mimicking real-world transport scenarios. Two temperature profiles were tested: Cold profile (4 hours (h) at RT , followed by 3 days (d) at 5°C, followed by 6 d at 12°C and 8 h at RT) and warm profile (3 d at 25°C, followed by 12 h at 37°C, followed by 1 d at 25°C, followed by 5 d at 5°C and 10 h at RT). Additional urine samples were transported via air from Germany to the USA. Where indicated, transported samples underwent dropping and vibration testing. cfDNA was isolated from the urine supernatant either using automated or manual QIAGEN kits. Autosomal and male-specific targets were quantified by qPCR on the QIAGEN RGQ instrument.

RESULTS: Stabilization with the PAXgene Urine Liquid Biopsy Tube increased the cfDNA yield isolated from urine. Furthermore, it minimized the loss of the cfDNA target of interest, minimized the dilution of the cfDNA target of interest by gDNA release and minimized bacterial growth during urine storage at challenging warm and cold weather temperature profiles and real-life urine transport. Blood concentration of 1% v/v in urine did not affect the yield of cfDNA isolated from the PAXgene Urine Liquid Biopsy Tube.

CONCLUSION: The optimized and standardized preanalytical workflow for cfDNA analysis from urine using the PAXgene Urine Liquid Biopsy Set enabled urine storage and transport and reliable analysis of urine cfDNA under challenging research settings. Furthermore, 1% v/v blood in urine did not interfere with cfDNA isolation and detection, underlining the robustness of the verified preanalytical workflow.

#4574 Epigenetic comparison of colorectal cancer tumors and patient-matched cfDNA.

Seeta Rajpara[1], Chris Gooden[1], Dan Weisenberger[1], Raed Jaffal[1], Hanna Jaynes[1], Carmen Chavez[1], Mariana Stern[1], Heinz-Josef Lenz[1], David Craig[2], John Carpten[2], Bodour Salhia[3]

[1]Keck School of Medicine of USC, Los Angeles, CA,[2]City of Hope, Duarte, CA,[3]Translational Genomics, Keck School of Medicine of USC, Los Angeles, CA

Colorectal cancer (CRC) is the third leading cause of cancer-related deaths in the U.S., with Hispanic/LatinX (HL) populations facing disproportionately higher mortality rates. Despite advancements in CRC screening and treatment, racial disparities in outcomes persist, partly due to limited access to early and precise detection tools. This study addresses these inequities by developing an innovative cfDNA methylation-based liquid biopsy for detecting minimal residual disease (MRD), a critical predictor of cancer recurrence that could improve outcomes in underrepresented populations. In this study, we performed methylation profiling using the EPIC v2 array on tumor tissue samples and cfDNA whole-genome bisulfite sequencing (WGBS) on 27 (16 females, 11 males; mean age 51.7 years) patient-matched blood plasma samples collected after tumor resection. Clinical data was abstracted to annotate each sample with tumor characteristics and the patient's disease status. Disease status was determined as either no evidence of disease (NED) for over 2 years or active disease (AD). Next, to identify markers potentially associated with recurrence, we performed differential DNA methylation analysis between patients with AD (N = 14) and who have been NED (N = 13) for greater than 2 years and examined the overlap of differentially methylated regions (DMRs) between tissue and cfDNA. These markers would essentially represent tumor burden in patients with AD. We identified 175 DMRs in tissue, (88% hypermethylated and 12% hypomethylated) and 350 DMRs in cfDNA (94% hypermethylated and 6% hypomethylated) between patients with AD versus NED status. Tissue DMRs were significantly more promoter-enriched (78.3% tumor vs. 55.1% cfDNA, $p=1.87x10^{-7}$) and had fewer gene body DMRs compared to cfDNA DMRs (10.9% tumor vs. 27.4% cfDNA, $p=1.03x10^{-5}$). Enhancer regions were notably more frequent in tissue than cfDNA (10.9% tumor vs. 0% cfDNA, $p=4.34\ x10^{-10}$), while intergenic regions were more enriched in cfDNA than tumors (17.4% tumor vs. 5.1% cfDNA, $p=5.94x10^{-5}$). Unsupervised clustering of showed clear separation of samples by disease status in both cfDNA and tissue samples. Furthermore, correlation analysis of beta values between matched tumors and cfDNA showed stronger correlations for AD samples ($R^2=0.68$) compared to NED ($R^2=0.61$), suggesting that tumor burden of AD samples are detectable in circulation to a higher degree and can have utility in biomarker development. The distinct methylation patterns observed between CRC tissue and cfDNA highlight the potential of liquid biopsies to capture tumor burden in circulation, particularly in active disease cases.

#4575 mRNA expression in paired saliva and blood samples from different cancer indices.

Srinivas V. Koduru, Mark Kidd, Abdel Halim

Wren Laboratories, LLC, Branford, CT

Introduction: Liquid biopsies have become gradually accepted, as a non-invasive alternative to traditional tumor biopsies in the field of oncology. The FDA and other regulatory bodies have already approved blood-based tests and researchers are working on validating urine, saliva and buccal swabs as alternative sample sources. This study's main goal was to compare mRNA expression levels, in matched blood and saliva samples from cancer patients, as well as apparently healthy individuals.
Methods: We collected matched saliva and blood samples from 35 individuals, including 27 patients diagnosed with cancers including Breast (4), Lung (4), Colon (5), Melanoma (3), Pancreatic (4), Prostate (7) cancer along with 9 healthy participants. The samples were collected in Wren's proprietary buffer kit and RNA was extracted via TRIzol-based method. RNA sequencing was carried out on an Illumina Novaseq 6000. The data was analyzed using high performance computing (HPC) through PartekFlow software with the BWA aligner (hg38).
Results: Nearly 94% of the genes found in saliva and 60% of the genes in blood were matched across all cancer types, with the exception of pancreatic cancer in blood, which showed only about 30% matching. We further evaluated both groups based on housekeeping genes (1003 genes) and the known cancer-associated genes as listed in the OncoKB database (1154 genes) for each cancer type. In addition, we investigated the expressions of 412 and 241 cancer genes priorly validated and used in IVD assays, respectively, in our lab. We found that 78-80% of the genes in blood were common across all cancer types, while saliva samples showed 64-73% commonality. Only 43% of genes detected in saliva from pancreatic cancer matched other cancer types. Out of the 241 internally validated cancer genes 68-71% genes were detected in blood and 57-65% in saliva in this cohort except pancreatic cancer where only 30% was detected. Out of the 412 genes, we found 67-69% in blood and 51-58% in saliva, again with the exception of pancreatic cancer, exhibits only 26% of genes. Additionally, 98% of housekeeping genes from blood and 71-87% of housekeeping genes from saliva were consistent, except for pancreatic cancer, which showed only 35%.
Conclusion: Our study indicates that the majority of mRNA (94%) detected in saliva from various cancer types was also detected in blood, compared to healthy controls. This suggests that exploring mRNA-based biomarkers development in saliva could be even a more convenient alternative to blood.

#4576 Sequential purification of cfDNA and cfRNA from blood stabilized in Nucleic Acid BCT using an automated workflow.

Nicholas M. George, Lisa Bartron, Jordan LaRue

Streck Laboratories, Inc.R, La Vista, NE

Liquid biopsies, which interrogate body fluids in search of analytes released by healthy or diseased cells, have become increasingly common in oncology. Foremost among the technologies used are those that employ nucleic acids, such as cfDNA and cfRNA. While cfDNA remains the primary choice for mutation detection, cfRNA is also informative, as it is released by both live and dying cells and represents the true disease state-mediated transcriptional output. Further, gene fusion events, which may be expressed at high levels in tumors, are easier to detect using cfRNA. As such, combined analysis of both cfDNA and cfRNA could provide a more comprehensive analysis. However, if blood samples are not stable, cell death or activation could lead to spurious increases in both analytes. To address this issue, Streck developed Nucleic Acid BCT (NAC), a stabilizing blood collection tube formulated to minimize changes to cfDNA and cfRNA concentrations during storage and shipping. To determine whether a combined cfDNA and cfRNA isolation protocol is compatible with NAC, blood from self-proclaimed healthy donors was drawn into EDTA and NAC and stored at ambient temperature for up to 7 days, plasma was isolated, and cfDNA and cfRNA were sequentially isolated using the Promega Maxwell RSC System with applicable kits. To mimic mutational events observed in lung cancer, synthetic 170-mer oligonucleotides encoding the EGFRL858R or EGFRdel19 events were spiked to an anticipated 1% MAF. Likewise, an RNA Ultramer encoding the EML4-ALK fusion was spiked at a copy number representative of that observed in clinical samples. Samples were then analyzed using ddPCR to determine concentrations of EGFRL858R and EGFRdel19 relative to the wildtype allele and EML4-ALK copy number relative to the housekeeping gene UBB. Our data support the combined use of the Promega Maxwell system with applicable extraction kits with plasma isolated from NAC. As expected, samples collected into NAC had minimal increases in cfDNA and cfRNA concentrations during storage compared to blood samples stored in EDTA. Baseline MAF of the spiked mutant cfDNA alleles was completely lost in samples stored in EDTA, while equivalent blood samples stored in NAC maintained MAFs reflective of draw time levels. A similar trend was observed when plasma RNA expression was investigated where samples collected in NAC had similar concentrations of cfRNA at draw and after storage, but those collected into EDTA did not. Specifically, EML4-ALK copy number relative to the UBB housekeeping gene fell precipitously in EDTA but maintained draw-time frequencies in blood samples stored in NAC. Taken together, these data indicate that the combined use of NAC and the sequential nucleic acid extraction protocol described herein can provide the liquid biopsy community with a robust workflow for both blood sample stabilization and multianalyte extraction and downstream analysis.

#4577 Ultra-sensitive detection of circulating tumor DNA using methylation anchor probes to enhance hepatocellular carcinoma (HCC) detection.

Nan Lin[1], Ying Mei[2], Nina Guanyi Xie[3], Yangjunyi Li[3], Liyuan Zhao[3], Zhihui Xu[3], Chen Zhu[3], Yujie Chen[3], Yalong Zhang[3], Bingqiang Fu[3], Jinlei Song[3], Min Li[3], Xiaohui Wu[3], Xueguang Sun[3]

[1]Department of Hepatobiliary Surgery, The Third Affiliated Hospital, Sun Yat-sen University, Guangzhou, China,[2]Health Medical Center, The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China,[3]Shanghai Weihe Medical Laboratory Co., Ltd, Shanghai, China

Background: Hepatocellular carcinoma (HCC) is one of the leading causes of cancer-related death worldwide. Circulating cell-free DNA (cfDNA) methylation markers offer a promising approach for early cancer detection and therefore improve patient outcomes. Among the many CpG sites with altered methylation status, only specific methylation patterns (haplotypes) are disease-related and are often rare in clinical samples. Current cfDNA-methylation signal-based methods lack sufficient sensitivity, particularly in detecting low-abundance tumor-derived DNA with limited sequencing reads. Here, we introduce an experimental method to address this issue by using short hybrid capture probes specifically designed to bind tumor-derived DNA methylation haplotypes, while minimizing binding to wild-type fragments. This approach reduces the number of sequencing reads required and improves assay sensitivity.
Methods: Methylation haplotypes were selected based on in-house whole-genome bisulfite sequencing (WGBS) data from tumor tissue and paired normal tissues adjacent to the tumors (NATs) of HCC patients. Further filtering was applied using cfDNA data from a group of healthy individuals. Short hybrid capture probes were then rationally designed to specifically target HCC-related methylation haplotypes. The panel was tested on 118 clinical samples (57 HCC patients and 61 controls). Data processing included the quantification of haplotype frequencies, followed by mutual information-based feature selection to identify the most distinctive markers in the training data to enhance classification performance. Finally, a boosted tree model (XGBoost) was applied to predict cancer.
Results: All samples were divided into a training set (75%) and a test set (25%), ensuring a balanced distribution of controls and cancer stages. The top 128 features were selected for both early (Stage I & II) and late (Stage III & IV) HCC. Across all stages of HCC, the panel achieved 97.6% specificity and 97.2% sensitivity in the training set, and 94.7% specificity and 95.2% sensitivity in the test set.
Conclusions: We developed a novel and cost-effective method to specifically enrich HCC-related methylation haplotypes, enabling accurate and ultra-sensitive detection of HCC. In the future, we will test more HCC cancer, precancer, and benign samples to further assess our assay performance. Also, our method is versatile and holds potential for the early detection and monitoring of other cancer types, paving the way for broader applications in precision oncology.

CLINICAL RESEARCH: Molecular Diagnosis, Molecular Characterization and Theranostics of Tumors
Poster Session

#4582 Molecular and clinical characterization of claudin-18 expression in pancreatic cancer.

Ikeda[1]; [1]National Cancer Center Hospital East, Kashiwa, Japan, [2]National Cancer Center Hospital, Tokyo, Japan, [3]Kanagawa Cancer Center, Yokohama, Japan, [4]Kansai Medical University Hospital, Osaka, Japan, [5]National Hospital Organization Kyushu Cancer Center, Fukuoka, Japan, [6]Saitama Cancer Center, Saitama, Japan, [7]Hokkaido University Hospital, Sapporo, Japan, [8]Saitama Medical University International Medical Center, Hidaka, Japan, [9]Gifu University Graduate School of Medicine, Gifu, Japan, [10]Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [11]Kyorin University Faculty of Medicine, Tokyo, Japan, [12]Kansai Rosai Hospital, Amagasaki, Japan, [13]Kanazawa University Hospital, Kanazawa, Japan

Background: Claudin-18 (CLDN18) is a major component of tight junctions located on the cell membrane surface. CLDN18.1 and CLDN18.2 are specifically expressed in normal lung tissues and gastric mucosa, respectively. However, CNDN18.2 is known to be frequently expressed in gastric cancer, and also overexpressed in pancreatic cancer (PC) in 30-60% of cases. Clinical features of PC due to CLDN18 expression have been reported in a limited number of cases, and molecular features remain unknown. Here, we evaluated molecular and clinical characterization of *CLDN18*expression in advanced PC.

Methods: This study used data from the MONSTAR-SCREEN-2 study, a nationwide molecular profiling project targeting solid tumors. Patients with advanced PC who received first-line systemic therapy and underwent tissue whole exome/transcriptome sequencing by Caris Life Sciences (Phoenix, AZ, USA) were included. Transcripts per million (TPM) for *CLDN18* expression were categorized into high and low groups based on the median value. The clinical and molecular characteristics of these groups were compared. Gene ontology and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment studies were carried out in R language using the programs clusterProfiler, enrichplot, and ggplot2. Differentially expressed genes identified based on log2 fold change greater than 1 and p-values less than 0.05 were used for pathway analysis. Only results with p-values and q-values no more than 0.05 were deemed significantly enriched.

Results: A total of 104 patients were enrolled in the study. In the *CLDN18*-high and -low groups, the median age was 69 years/67.5 years; female was 57.7%/34.6%; tumor stage was recurrence 51.9%/30.8%, locally advanced 7.7%/9.6%, and metastatic 40.4%/59.6%; metastatic site was liver 48.1%/61.5%, lymph node 9.6%/11.5%, lung 17.3%/11.5%, and peritoneum 19.2%/9.6%; treatment regimens were FOLFIRINOX 21.2%/36.5% and gemcitabine + nab-paclitaxel 63.5%/51.9%, respectively. Objective response rate was 17.3%/19.2%, and disease control rate was 75.0%/63.5% (P = 0.29). The median overall survival was 16.5 and 18.7 months; hazard ratio (HR) 0.9 (95% confidence interval [CI] 0.5-1.7); P = 0.81. The median progression free survival was 7.3 and 5.3 months; HR 1.3 (95%CI 0.8-2.1); P = 0.28. The frequent gene alterations were *KRAS*, *TP53*, *SMAD4*, and *CDKN2A*, regardless of *CLDN18* high and low groups. Gene expression such as *GATA6* and *CTSE*, known as the characteristics of the classical type of Moffitt's classification, was significantly higher in *CLDN18*-high group, and gene expression such as *S100A2* and *KRT6A*, known as the characteristics of the basal-like type, was significantly higher in *CLDN18*-low group.

Conclusion: There was no significant difference in treatment efficacy and prognosis of systemic therapy between the *CLDN18*-high and -low groups. *CLDN*-high and -low were associated with known classical and basal-like molecular profiles.

#4583 *In-situ c*haracterization of small blue round cell tumor proteome and N-glycome.

C. Bollwein[1], K. Schwamborn[1], T. Tran[2], **A. Ly**[2], N. H. Patterson[2], J. P. L. Goncalves[1];
[1]Technical University of Munich, Munich, Germany, [2]Aspect Analytics, Genk, Belgium

Background: Small blue round cell tumors (SBRCT) is an umbrella term for different tumor types with similar histological presentation that can originate from entirely different tissues. Correct diagnosis is crucial, though challenging, as treatment strategies and prognosis vary significantly between tumor entities. Matrix-assisted laser desorption/ionization (MALDI) mass spectrometry imaging (MSI) is a label-free analytical technique to analyze and visualize the spatial distribution of different classes of molecules, like peptides, glycans, lipids, and metabolites. In this study, MALDI-MSI was used to profile tryptic peptides and N-glycans from archival SBRCTs samples. The data was used to create classification algorithms to reliably distinguish the different entities and to identify discriminatory features between the tumor types.
Methods: SBRCT cases (n = 26) were assembled in a tissue microarray: Ewing sarcoma (n = 5), rhabdomyosarcoma (n = 5), neuroendocrine carcinoma (n = 5), acute lymphoblastic leukemia/lymphoma (n = 5), nephroblastoma (n = 3), and neuroblastoma (n = 3). Every case was represented by 3 to 4 tissue cores to account for tumor variability. One TMA section was subjected to on-tissue N-glycosidase F enzymatic digestions, and a second section with trypsin, followed by matrix application and measurement on a mass spectrometer (rapifleX, Bruker). Afterwards, the sections were H&E stained, digitized and underwent histopathological annotation (QuPath, version 0.4.3)Data analysis was performed using SCiLS Lab (Bruker, v.2024a), Weave (v.1.0, Aspect Analytics), and Python (v.3.9). Weave was used to co-register all datasets, combining the peptide and glycan data into a single dataset for comparison of analytes and histology, and interactive assessment of data analysis.
Results: MSI data was employed for the training and validation of different classification algorithms (gradient boosting, support vector machine, k-nearest neighbor, and linear discriminant analysis) using 10-fold cross-validation on pixel level. Multiclass classification was implemented as a one vs. rest (one entity vs. all other entities) and one vs. one (one entity vs. every other entity) approach. For the one vs. rest strategy, mean accuracy of all classifiers was 90.5 % with a mean accuracy of 88.7 % for peptide analysis, 92.4 % for glycan analysis and 95 % for the combined dataset. For the one vs. one approach, mean accuracy of all classifiers was 92.4 % with a mean accuracy of 88.8 % for peptide analysis, 96.1 % for glycan analysis and 97 % for the combined dataset.
Conclusions: Peptide and N-glycan mass spectrometry imaging, particularly in combined form, has huge potential to aid in distinguishing between different SBRCT entities. Future work will aim to expand the patient cohort and explore alternative statistical methods to further improve classification performance.

#4584 Advancing non small cell lung cancer detection and subtyping by MasSpec Pen technology.

Yasmin Shanneik[1], Bryan Burt[2], Maheshwari Ramineni[3], Livia S. Eberlin[1]

[1]Surgery, Baylor College of Medicine, Houston, TX,[2]Surgery, University of California, Los Angeles, CA,[3]Pathology, Baylor College of Medicine, Houston, TX

Introduction: Non-small cell lung cancer (NSCLC) is the most aggressive and frequently diagnosed form of lung cancer. Histological and molecular subtyping are critical in lung cancer treatment-decision making. However, despite recent advances, the 5 year survival rate remains low. Within the field of mass spectrometry (MS), the MasSpec Pen (MSPen) technology stands out as a nondestructive technique employed intra-operatively for cancer detection. The MSPen deploys a single droplet of sterile water onto tissue, facilitating the extraction of molecules upon contact in real-time within seconds. Here, we employ the MSPen for NSCLC diagnosis based on molecular signatures, with a specific focus on classifying major histological subtypes and identifying key proteogenomic markers. Furthermore, we tested the reproducibility of the MSPen, using samples collected across multiple centers and analyzed by different personnel.
Methods: 319 frozen human lung tissues (n=177 normal lung and n=142 NSCLC) were analyzed in negative ion mode using the MSPen coupled to a Q Exactive Orbitrap MS (Thermo Scientific). Following analysis, the analyzed region was marked with a surgical pen, frozen, and sectioned at 10µm. It was then histologically stained and evaluated by a pathologist to confirm diagnosis and subtype. Proteogenomic markers for lung cancer samples, such as EGFR and PD-L1, were obtained from clinical data or determined using biomarker and sequencing analysis. Mass spectra were processed and subjected to statistical classification using the least absolute shrinkage and selector operator (Lasso).
Results: MSPen analyses enabled the detection of hundreds of biomolecules in seconds with high sensitivity, specificity, and accuracy. Negative ion mode mass spectra presented rich molecular profiles characterized by multiple cancer-specific markers. Normal lung tissue showed high relative abundances of phosphatidylglycerol (PG)(34:1) and PG(36:2). Mass spectra of NSCLC showed a different profile with high relative abundances of phosphatidylethanolamine (PE)(38:4) and phosphatidylinositol (PI)(38:4). Samples with high PD-L1 expression also presented a distinct lipid pattern with a high relative abundance of PG lipids, whereas samples with high EGFR expression were enriched with PE lipids. Histological staining confirmed no macro- or microscopic tissue damage, highlighting the potential of the MSPen in clinical settings. Lasso classification of MSPen data allowed for the predictive performance of the molecular evaluation and diagnosis of the NSCLC samples. Lasso classification yielded exceptional performance, with an AUC=0.9 in the training set and an overall accuracy of 93% across training and test sets of samples compared with the pathological evaluation.
Conclusion: Our results highlight the robustness of MSPen technology and its utilization for lung cancer detection and subtyping in clinical procedures.

#4585 Exploiting intrinsic bioelectrical signatures for label-free immune cell sorting.

Dean E. Thomas[1], Ilyssa E. Ramos[2], Kyle S. Kinskie[1], Kyle M. Brown[1], James M. Cherry[3], **Alexandra R. Hyler**[1]

[1]CytoRecovery, Inc., Blacksburg, VA,[2]Miller School of Medicine, University of Miami, Miami, FL,[3]Center for Human Immunology, Autoimmunity, and Inflammation (CHI), National Institute of Allergy and Infectious Diseases (NIAID), Bethesda, MD

Immune cell separation from heterogeneous samples is crucial for various downstream research applications. Standard methods for cell purification are laborious and require additional fluorescent or magnetic labels to identify cells of interest. Approaches contingent upon the use of labels may interfere with downstream testing and analysis, like single cell sequencing or downstream oncology research. Label-free cell sorting by electrokinetic dielectrophoresis (DEP) has recently been used to characterize and separate target subpopulations from complex samples. Available literature describes the use of DEP for isolation and enrichment of limited cell types. However, technical challenges and uncertainty have restricted DEP's commercialization and widespread implementation for biological use. To address this pitfall, we have exploited the strength of the CytoR1 platform for label-free sorting of T-cells, B-cells, and monocytes from bulk sample preparations. Characterization and isolation of these cells will support the CytoR1 platform's capabilities. Variables like frequency, voltage, and flow rate are incorporated in the profiling of target cells, facilitating the development of custom workflows to enrich individual immune cell populations from heterogeneous samples without labels. Platform validation will involve downstream fluorescence-activated cell sorting (FACS) and potential RNA sequencing to confirm the accuracy of label-free sorting. Here, we introduce a workflow implementing a microfluidics-based, benchtop cell-sorting technology, the CytoR1, for precise enrichment and capture of unlabeled target cell populations.

#4586 Multi-scale multi-omic assessment of matched synchronous colorectal cancer liver metastases using multiple spatial transcriptomic tools.

Colin Wood, Luke McNickle, Andrew Cameron, Ritupam Sarma, Vaidehi Pandya, Joao Da Silva Filho, Colin steele, John Cole, Joanne Edwards, Paul Horgan, Campbell Roxburgh

University of Glasgow - Institute of Cancer Sciences, Glasgow, United Kingdom

Background: Primary colorectal cancer (CRC) is manageable with surgical and non-surgical therapies. However, high affinity for distant spread to the liver (CRLM) and lack of subsequent therapeutic options has maintained CRC as one of the most lethal malignant diseases worldwide. Tumors consist of malignant cells as well as a complex micro-environment (TME) of stromal and immune components, all of which have been implicated in disease severity and treatment resistance. Spatial transcriptomics (ST) is novel technology which allows molecular profiling of tissue while preserving tissue architecture. By studying matched CRC and CRLM with modern ST tools which allow scrutiny of the malignant cells and TME we aim to learn more about mechanisms of metastasis and why CRLM are resistant to treatment.
Methods: 41 patients (29 untreated) underwent synchronous resection of CRC and CRLM within our institution between April 2002 and June 2010 (64% 5 year mortality). Paired CRC and CRLM from 4 patients underwent single-cell ST assessment on the Nanostring CosMx Spatial Molecular Imager (23 fields of view (FOV)). Paired CRC and CRLM from 4 patients underwent regional ST assessment (PanCk+,PanCk-,aSMA+ comprtments) on the Nanostring GeoMx Digital Spatial Profiler (116 FOV). Paired CRC and CRLM from 2 patients underwent regional ST assessment on the Visium 10X Genomics platform (4 FOV).
Results/Conclusions: GeoMx offers entire slide visualization with bespoke and convenient FOV selection with reliable segmentation of TME components with whole transcriptome available. Visium 10X offers high resolution ST assessment of large pieces of tissue but slide preparation is difficult without specific tools. CosMx offers single-cell in-situ allowing the highest resolution with neighborhood and cellular interaction analysis possible but at lower plex and increased complexity. All technologies demonstrated differences between CRLM and their matched CRC. CRLM were generally more collagenous and chemokine rich. Furthermore, transcriptomic and morphological differences exist between CRLM from different patients. Specifically, CosMx demonstrated that epithelial cells and fibroblasts in CRC express MZTA compared to COL9A2, NEAT1 and IGF2 in CRLM. Neutrophils in CRLM under-express CXCL8. Desmoplastic CRLM were chemokine high whereas replacement CRLM over-expressed IGF2, DUSP5 and COL9A2. GeoMx identified MET and IL17 as potential drug targets in CRLM. These data suggest that CRLM evolve once metastasis is established and the immune response of the host to the metastasis is pivotal. Future therapeutic goals should emphasize personalized medicine and molecular staging of CRLM with specific targeted therapies.

#4587 Retrospective analysis of claudin-18.2 expression in ethnically diverse patients with gastroesophageal adenocarcinoma.

Sara Wallam, Jimyung Park, Ryan H. Moy

Department of Medicine, Columbia University Irving Medical Center, New York, NY

Background: Claudin-18.2 (CLDN18.2), a tight junction molecule, is a novel therapeutic target for patients with advanced gastroesophageal adenocarcinoma. Recent phase III trials demonstrated improved survival with the addition of an anti-CLDN18.2 antibody (zolbetuximab) to first-line chemotherapy. However, expression of CLDN18.2 and its association with other biomarkers, especially in racial and ethnic minorities, remains poorly defined. We evaluated CLDN18.2 expression, its association with demographic and clinicopathologic characteristics, and its prognostic potential in a small cohort of ethnically diverse patients.
Methods: We conducted a single-center retrospective cohort study among patients with gastroesophageal adenocarcinoma in whom CLDN18.2 immunohistochemistry had been performed. Positivity was defined as moderate-to-strong expression in ≥75% of tumor cells. We extracted demographic and clinicopathologic data from the electronic medical record. Associations with CLDN18.2 were investigated using the t-test and chi-square test. Survival curves were calculated using the Kaplan-Meier method and compared using the log-rank test. P-value <0.05 was considered statistically significant.
Results: Among 75 evaluable patients, 42.7% were CLDN18.2 positive. Mean age was 66.2 years (SD, 13.2 years), 34.7% were female, and 62.7%, 18.7%, and 18.7%, had primary gastric, gastroesophageal junction, and esophageal tumors, respectively. At diagnosis, 32% were metastatic. The cohort was 49.3% White, 12% Black, 8% Asian, and 30.7% Other/Unknown, and 20% identified as Hispanic. By ethnicity, 53.3% of Hispanic patients were CLDN18.2 positive compared to 38.2% of non-Hispanic patients. By race, 37.8% of White, 44.4% of Black, and 50% of Asian patients were CLDN18.2 positive. In univariate analyses, CLDN18.2 positivity was significantly associated with female sex (p=0.002) and HER2 negativity (p=0.040). TP53 mutations were found in 65.2% of patients with available next generation sequencing data, but there was no association with CLDN18.2. CLDN18.2 was also not associated with response to neoadjuvant therapy in non-metastatic patients, progression-free survival in metastatic patients, or overall survival in the total population.
Conclusions: This study provides new information on CLDN18.2 expression in an ethnically diverse population and suggests that Hispanic patients may have higher rates of CLDN18.2 positivity than non-Hispanic patients. However, this finding lacks statistical significance, likely due to the small sample size. We also demonstrate the association between CLDN18.2 and female sex and lack of association with survival, consistent with published data. Future research should further investigate differences in CLDN18.2 expression and identify subpopulations of patients who may benefit from CLDN18.2 targeted therapies.

#4588 Cell states and resistance in colorectal cancer: What can we learn from patient-derived organoids?.

M. Norkin[1], P. Hernandez Lopez[2], C. Esposito[3], G. Ramzy[4], M. A. Carbo[4], P. Ordonez-Moran[5], P. Nowak-Sliwinska[4], S. Piscuoglio[3], K. Homicsko[1], J. Huelsken[2];

[1]CHUV Lausanne University Hospital, Lausanne, Switzerland, [2]EPFL, Lausanne, Switzerland, [3]University Hospital Basel, Basel, Switzerland, [4]University of Geneva, Geneva, Switzerland, [5]University of Nottingham, Nottingham, Switzerland

Colorectal cancer (CRC) is among the three most commonly diagnosed cancers and one of the major causes of cancer-related morbidity and mortality. Despite the discovery of several predictive biomarkers, the 5-year survival rate for metastatic CRC is 15%. A hallmark of CRC is inter- and intra-patient heterogeneity. Moreover, chemo-radiation and targeted therapies often result in producing resistant clonal populations that are unresponsive to the ongoing treatment. Revealing a comprehensive landscape of primary and metastatic CRC cell states and their evolution during chemotherapy treatment provides the potential for tackling this problem. Patient-derived organoids are a valuable research tool to study the biology of the disease as well as for drug screening in personalized medicine. To that end, we have collected a biobank of 90 PDOs from primary and metastatic CRC patients, as well as autologous cancer-associated fibroblasts (CAFs) and tumor infiltrating lymphocytes (TILs). We have performed whole-exome sequencing (WES), scRNA-seq and bulk RNA-seq of original tumors and PDOs, with and without chemotherapy treatment. We have discovered specific and common transcriptional cell states within PDOs and tumors, as well as the multiple responses to treatment confirming high heterogeneity of CRC. Combination of these results with clinical data can predict new biomarkers.

#4589 Molecular subtypes identified in lung adenocarcinoma using a large-scale, real-world dataset.

Akul Singhania, Prerna Jain, Ezgi Karaesmen Rizvi, Radia M. Johnson, **Justin Guinney**

Tempus AI, Inc., Redwood City, CA

Introduction

Despite advances in targeted and IO therapies, lung adenocarcinoma (LUAD) remains a high unmet clinical need due to its complex molecular landscape. Previous studies have focused on early-stage disease with smaller patient populations to identify molecular subtypes in LUAD. This study characterized the molecular profiles and clinical features of LUAD patient tumors from a large real-world dataset (RWD) containing early and late-stage patients as well as primary and metastatic sites.

Methods

The analysis cohort consisted of de-identified clinical and genomic records of patients diagnosed with LUAD and profiled with Tempus' targeted DNA and whole-transcriptome RNA assays. Molecular subtyping was performed using non-negative matrix factorization on RNA-seq data from primary lung site tumors (n=3,975; Stage III and IV: 68%). A subtype classifier was trained on tumor-intrinsic features and applied to tumors from primary non-lung and metastatic sites (n=3,981; Stage III and IV: 99%). quanTIseq was used to estimate immune cell proportions. Progression free survival (PFS), defined as the time from the start of first metastatic therapy to the date of first progression or death from any cause, was assessed in LUAD patients with available data (17.6%).

Results

Six distinct molecular subtypes were identified: C1-C6. The C1 subtype (31.8%; median PFS 10.4 months, 95% CI 7.4-13.2) had the highest tumor mutation burden (22.1% with TMB≥10) and PD-L1 status (54.2% with TPS≥50), and was characterized by TP53 mutations (78.62%) with co-mutations in NF1 (log odds ratio 1.8, $p<0.05$). The C2 subtype (18.82%; PFS 8.8 months, 95% CI 6.6-10.7) showed high EGFR mutation frequency (33.31%), and lower immune cell proportion (41%). In contrast, the C3 subtype (12.63%) showed high prevalence of EGFR mutations (32.37%) with high immune activation (57%), and had the best prognosis (PFS 17.4 months, 95% CI 11.7-36). C3 comprised a large portion of primary lung samples (23%) and was overrepresented in early-stage primary tumors (Stage I and II: 61%) . The C4 subtype (7.03%; PFS 9.8 months, 95% CI 5.5-16.7) was enriched with a fibrotic tumor microenvironment (TME) and an increased proportion of immune cells (54%). The C5 subtype (23.15%) had the worst prognosis (PFS 5.6 months, 95% CI 4.3-7.4), lowest immune cell proportion (36%), and a mutational profile characterized by decreased EGFR mutations (5.6%) and increased STK11 (36.85%), KEAP1 (19.67%), and SMARCA4 (15.95%) mutations. Lastly, the smallest subtype, C6 (6.6%; PFS 9.7 months, 95% CI 6.4-15.4) was characterized with a fibrotic TME.

Conclusions

This study highlights the heterogeneity of LUAD, revealing patient states with distinct mutational landscapes, TME profiles, and clinical outcomes in a real-world setting. Future work is needed to explore how these subtypes may inform strategies for disease management and new treatment modalities.

#4590 Clinicopathological analysis of pulmonary high-grade neuroendocrine carcinoma with high expression of hepatocyte nuclear factor 4 alpha.

Kei Asayama, Ryota Matsuoka, Aya Shiba, **Daisuke Matsubara**

University of Tsukuba, Ibaraki, Japan

Pulmonary high-grade neuroendocrine carcinomas (HGNECs), including small cell carcinomas (SCLCs) and large cell neuroendocrine carcinomas (LCNECs), are highly aggressive and have a poor prognosis. The molecular subtyping of HGNECs has recently attracted attention, and Wang et al. recently proposed a cross-tissue classification framework of NECs, including the hepatocellular nuclear factor 4 alpha (HNF4A) subtype [*Cancer Cell*, 2024]. HNF4α, a transcription factor associated with gastrointestinal differentiation, and TTF-1 are mutually and exclusively expressed in lung adenocarcinomas; however, the characteristics of HNF4α-high HGNECs and TTF-1-high HGNECs have yet to be compared. We immunohistochemically examined the characteristics of HNF4α-high HGNECs in 83 surgically resected specimens (37 SCLCs and 46 LCNECs) and revealed that HNF4α-high and TTF-1-high HGNECs accounted for 15% (12/83) and 47% (39/83), respectively. Regarding morphology of HNF4α-high HGNECs, HNF4α-high SCLCs had a slightly more abundant cytoplasm and more obscured nuclear molding than HNF4α-low SCLCs, while HNF4α-high LCNECs were characterized by a coarse nuclear chromatin pattern and prominent nuclear atypia. The cytomorphological score referred to the previous study [Jimbo, *Am J Surg Pathol*. 2024] was significantly higher for HNF4α-high HGNECs than for HNF4α-low HGNECs (p<0.01). In SCLCs, HNF4α-high cases (n=3) and TTF-1-high cases (n=20) were almost confined to the neuroendocrine phenotype with high ASCL1 expression, and the expressions of HNF4α, TTF-1, and POU2F3 were mutually exclusive. Similar results were obtained for LCNECs; however, some HNF4α-high cases were positive for TTF-1 or YAP1, possibly due to the heterogeneity of LCNECs. Therefore, we investigated the heterogeneity of LCNECs and performed a spatial transcriptome analysis of one HNF4α-high LCNEC case, which revealed a mutually exclusive mixture of different subgroups characterized by *HNF4A* and *TTF-1* expression. A whole-genome analysis of 10 LCNECs showed that *NFE2L2/KEAP1* mutations were characteristic of HNF4α-positive LCNECs. A prognostic analysis revealed a significantly poorer prognosis in HNF4α-high LCNECs compared to HNF4α-low LCNECs (p<0.01). A cell line analysis showed that TTF-1-high-expressing (H446/Lu139/H889/H510A) and HNF4α-high-expressing (VMRC-LCD) lines were consistent with ASCL1-high-expressing lines. HNF4α knockdown/knock-in experiments in VMRC-LCD and SBC5 (HNF4α-negative) revealed that HNF4α promoted cell proliferation by inhibiting apoptosis. HNF4α subtype HGNECs are a unique subtype, belonging to a neuroendocrine phenotype with high ASCL1 expression and showing mutual exclusivity with the TTF-1/POU2F3 subtypes. *NFE2L2/KEAP1* mutations and HNF4α itself are potential therapeutic targets for this subtype.

#4591 Development and validation of a molecular classifier of meningiomas.

Alex Landry[1], Justin Wang[1], Jeff Liu[1], Vikas Patil[1], Chloe Gui[1], Andrew Ajisebutu[1], Yosef Ellenbogen[1], Qingxia Wei[1], Olivia Singh[1], Julio Sosa[1], Sheila Mansouri[1], Aaron Cohen-Gadol[2], Ghazaleh Tabatabai[3], Marcos Tatagiba[3], Felix Behling[3], Jill Banholtz-Sloan[4], Andrew Sloan[5], Lola Chambless[6], Serge Makarenko[7], Stephen Yip[7], Alireza Mansouri[8], Derek Tsang[1], Kenneth Aldape[4], Andrew Gao[1], Farshad Nassiri[1], Gelareh Zadeh[1]

[1]University of Toronto, Toronto, ON, Canada,[2]University of Southern California, Los Angeles, CA,[3]University of Tubingen, Tubingen, Germany,[4]National Cancer Institute, Bethesda, MD,[5]Piedmont Brain Tumor Center, Atlanta, GA,[6]Vanderbilt University, Nashville, TN,[7]University of British Columbia, Vancouver, BC, Canada,[8]Penn State, Hershey, PA

Background: Meningiomas exhibit considerable clinical and biological heterogeneity. We previously identified four distinct molecular groups (*immunogenic, NF2-wildtype, hypermetabolic, proliferative)* that address much of this heterogeneity. Despite the utility of these groups, the stochasticity of clustering methods and the use of multi-omics data for discovery limits the potential for classifying prospective cases. We sought to address this with a dedicated classifier.
Methods: Using an international cohort of 1698 meningiomas, we constructed and rigorously validated a machine learning-based molecular classifier using only DNA methylation data as input. Original and newly-predicted molecular groups were compared using DNA methylation, RNA sequencing, copy number profiles, whole exome sequencing, and clinical outcomes.
Results: We show that group-specific outcomes in the validation cohort are nearly identical to those originally described, with median PFS of 7.4 (4.9-Inf) years in *hypermetabolic* tumors and 2.5 (2.3-5.3) years in *proliferative* tumors (not reached in the other groups). Tumors classified as *NF2-wildtype* had no *NF2* mutations, and 51.4% had canonical mutations previously described in this group. RNA pathway analysis revealed upregulation of immune-related pathways in the *immunogenic* group, metabolic pathways in the *hypermetabolic* group and cell-cycle programs in the *proliferative* group. Bulk deconvolution similarly revealed enrichment of macrophages in *immunogenic* tumors and neoplastic cells in *hypermetabolic* and *proliferative* tumors with similar proportions to those originally described.
Conclusions: Our DNA methylation-based classifier, which is publicly available for immediate clinical use, recapitulates the biology and outcomes of the original molecular groups as assessed using multiple metrics/platforms that were not used in its training.

#4592 TERT expression predicts progression-free survival in meningiomas.

Chloe Gui[1], Justin Z. Wang[1], Vikas Patil[2], Andrew Ajisebutu[1], Jeff Liu[2], Zeel Patel[3], Rebeca Yakubov[4], Ramneet Kaloti[4], Yosef Ellenbogen[1], Christopher Wilson[5], Aaron Cohen-Gadol[6], Ghazaleh Tabatabai[7], Marcos Tatagiba[8], Felix Behling[8], Eric C. Holland[9], Jill S. Barnholtz-Sloan[10], Andrew E. Sloan[11], Craig Horbinski[12], Silky Chotai[13], Lola B. Chambless[13], Andrew Gao[14], Serge Makarenko[15], Stephen Yip[16], Kenneth Aldape[1], Farshad Nassiri[1], Gelareh Zadeh[1]

[1]Department of Surgery, Division of Neurosurgery, University of Toronto, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[3]Temerty School of Medicine, University of Toronto, Toronto, ON, Canada,[4]University of Toronto, Toronto, ON, Canada,[5]Oklahoma State University College of Osteopathic Medicine, Tulsa, OK,[6]Department of Neurological Surgery, Keck School of Medicine of the University of Southern California, Los Angeles, CA,[7]Department of Neurology and Interdisciplinary Neuro-Oncology, Center for Neuro-Oncology, Comprehensive Cancer Center, Hertie Institute for Clinical Brain Research, Eberhard Karls University Tubingen, Tubingen, Germany,[8]Department of Neurosurgery, Eberhard Karls University Tubingen, Tubingen, Germany,[9]Human Biology Division, Fred Hutchinson Cancer Center, Seattle, WA,[10]Central Brain Tumor Registry of the United States, Hinsdale, IL,[11]Case Comprehensive Cancer Center, Case Western Reserve University School of Medicine, Cleveland, OH,[12]Department of Pathology, Northwestern University, Evanston, IL,[13]Department of Neurosurgery, Vanderbilt University Medical Center, Nashville, TN,[14]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada,[15]Department of Surgery, Division of Neurosurgery, University of British Columbia, Vancouver, BC, Canada,[16]Department of Pathology & Laboratory Medicine, University of British Columbia, Vancouver, BC, Canada

Background: TERT promoter mutation (TPM) is a rare but established biomarker in meningiomas associated with aberrant TERT expression, reduced progression-free survival (PFS), and reduced overall survival. While TERT is highly expressed in tumors with promotor mutations, its expression has also been observed even in tumors with wildtype TERT promoters (TP-WT). This study aimed to assess the prevalence of TERT expression and its association with clinical outcome in meningiomas. Methods: Bulk RNA sequencing (n=604), Sanger sequencing of the TERT promoter (n=1095), and methylation profiling (n=1218) of a multi-institutional cohort of meningiomas (total n=1241) were performed to determine TERT expression, TERT promoter mutation status, and TERT promoter methylation. A cohort of 380 meningiomas from Toronto was used for discovery, and 861 meningioma samples from external institutions were compiled as a validation cohort. Results: TERT expression was significantly higher in meningiomas with TPMs compared to TP-WT. However, TERT was still expressed in 30.4% of meningiomas that lacked TPM. TERT expression increased with higher WHO grades and was associated with shorter progression-free survival, even among TP-WT tumors. WHO grade 1 tumors that expressed TERT had PFS similar to those of WHO grade 2, while WHO grade 2 meningiomas expressing TERT had a PFS similar to those of WHO grade 3 meningiomas. Among grade 3 meningiomas, tumors expressing TERT had PFS similar to those with TPMs. Conclusions: Our findings highlight the prognostic significance of TERT expression in meningiomas, even in the absence of TPMs. Its presence may identify patients at greater risk of rapid progression. These results support the inclusion of TERT expression in risk stratification models and management strategies, including future WHO classification and cIMPACT-NOW molecular testing criteria.

#4593 Molecular and immunohistochemical classification of extrapulmonary small cell neuroendocrine carcinomas: A study of 181 cases.

Radoslav Matej[1], Pavel Dundr[2], Klara Pavlickova[1], Marian Svajdler[3], Jan Hojny[2], Nikola Hajkova[2]

[1]Pathology and Molecular Medicine, Thomayer University Hospital, Prague, Czech Republic,[2]Pathology, General University Hospital, Prague, Czech Republic,[3]Pathology, University Hospital Pilsen, Pilsen, Czech Republic

Extrapulmonary small cell neuroendocrine carcinoma (EP-SCNC) is a rare malignancy with a poor prognosis. Most patients with EP-SCNC have metastatic disease upon presentation, and their average overall survival (OS) is less than 12 months. Our study aimed to conduct a complex analysis of EP-SCNC. One hundred and eighty-one EP-SCNC tissue samples were subjected to a complex analysis. One hundred and fifty-five tumors were pure EP-SCNC, while 26 were combined tumors. Immunohistochemistry for ASCL1, NEUROD1, YAP1, POU2F3, Rb1, p53, cyclin D1, p16, PTEN, DLL3, PD-L1, CD56, synaptophysin, chromogranin A, and INSM1 was performed, and 128 samples were analyzed molecularly using next generation sequencing (NGS), comprising DNA and RNA analysis. Detailed results on immunohistochemical and molecular analyses were provided for each primary origin of EP-SCNC separately. Median survival for the whole cohort of patients was 8.94 months. Patient age (≥ 70 years), tumor mutational burden (TMB) < 15, and *TP53* and *BRCA2* mutations were negative prognostic factors. High expression of ASCL-1 was associated with shorter OS, whereas high expression of YAP1 was associated with longer OS. Patients with genitourinary tumors had significantly better OS than those with gastrointestinal tract EP-SCNC tumors. Rb1 expression loss was detected more often in genitourinary tract SCNCs. In contrast, p16 overexpression was found more often in genitourinary tract SCNCs. POU2F3 expression was detected more often in combined tumors, whereas NEUROD1 was detected more often in pure EP-SCNC. Regarding “druggable markers,” DLL3 was expressed in 66% of tumors and PD-L1 in 17.4%.Detailed analyses of different prognostic and predictive markers are needed to better understand EP-SCNC biology and create more personalized therapy to improve patient prognosis.

#4594 EGFR PACC mutations occur more frequently as compound mutations with better responses to EGFR TKIs.

Ximeng Liu[1], Moses Stamboulian[2], Maxime Borgeaud[3], Ashwin Ravichandran[4], Caroline Weipert[2], Monique B. Nilsson[1], Erjia Zhu[1], Hong Chen[1], Courtney Lewis[2], Simon Heeke[1], Junqin He[1], John Lawson[5], Jianjun Zhang[1], Addeo Alfredo[3], John V. Heymach[1], Xiuning Le[1]

[1]UT MD Anderson Cancer Center, Houston, TX,[2]Guardant Health, Inc., Redwood City, CA,[3]University Hospital Geneva (HUG), Geneva, Switzerland,[4]KBR, Inc., Intelligent Systems Division, NASA Ames Research Center, Moffett Field, CA,[5]Intelligent Systems Division, NASA Ames Research Center, Moffett Field, CA

EGFR mutations are key oncogenic drivers in NSCLC and can occur either as single or compound mutations. The frequency of classical (Ex19del and L858R) and non-classical PACC mutations in single and compound forms is not fully characterized, and the impact of single vs. compound EGFR mutations on drug sensitivity and clinical outcomes with EGFR TKIs remains unclear. We aimed to identify the effect of single and compound EGFR mutations to improve precision treatment and outcomes for EGFR-mutant NSCLC patients. We queried a circulating cfDNA sequencing database of de-identified NSCLC patients from Guardant Health and analyzed the incidences of EGFR mutations in single and compound forms. In this dataset, after excluding samples with T790M/C797S or Ex20ins, the most frequent classical mutations were Ex19del (6,670, 38.1%) and L858R (4,700, 26.9%), and the most frequent PACC mutations were G719X (712, 4.1%), S768X (335, 1.9%) and E709X (207, 1.2%). 84.22% of classical mutations occurred as single mutations, with Ex19del in 89.5% and L858R in 76.7% of samples, respectively. In contrast, 80.12% of PACC mutations occurred as compound mutations, with G719X in 73.2%, S768X in 86.9%, and E709X in 97.1% of samples. We engineered Ba/F3 cells to express single or compound PACC mutations and evaluated sensitivity to clinically available EGFR TKIs. Compound PACC mutants showed significantly increased sensitivity to 2nd-gen compared to 1st- and 3rd-gen TKIs. Cells with compound PACC mutations exhibited a tendency towards enhanced TKI sensitivity compared to cells with single mutations.

Cells with single or compound G719X/E709X, single V769L and compound S768I/V769L were most sensitive to 2nd-gen TKIs. Cells with single S768I had the highest sensitivity to 3rd-gen TKIs. In a retrospective clinical data analysis we assessed treatment outcomes for patients with single or compound PACC mutations (n=1268). Patients with either form of PACC mutations showed the best response rates (RR) (single: 54.67%, compound: 70.34%) and longest mPFS (single: 9mo, compound: 15mo) with 2nd-gen TKIs. Compound PACC mutations were associated with better RRs and longer mPFS than single forms across all TKIs. Specifically, patients with G719X or E709X, regardless of mutation form, had the longest mPFS with 2nd-gen TKIs (single vs. compound: G719X:11.2 vs. 18.5mo, E709X: 10.9 vs. 8.9mo). Patients with single S768X showed the longest mPFS to 3rd-gen TKIs (13.25mo), differing from those with compound S768X, whose mPFS was the longest with 2nd-gen TKIs (8.9mo). Collectively, our analysis indicates that EGFR PACC mutations predominantly occur as compound mutations while classical mutations most frequently present as single mutations. Compound and single PACC mutations were associated with improved clinical responses to 2nd-gen EGFR TKIs.

#4595 Transcriptomic and tumor microenvironment alterations in microsatellite stable rectal tumors: Comparison between neoadjuvant-treated and treatment-naive patients.

E. K. Hamalainen[1], K. Ojala[2], M. Marttinen[1], M. Nykter[1], T. Seppala[3];

[1]Tampere University, Tampere, Finland, [2]Helsinki University Hospital, Helsinki, Finland, [3]Tampere University Hospital, Tampere, Finland

Neoadjuvant therapy (NAT) for rectal cancer has markedly improved survival rates and the likelihood of complete therapeutic response. However, recurrence after curative intent therapy and resistance to primary oncological therapy remain, shortening the survival. The modulation of transcriptomic profiles by NAT and its association with therapeutic response remain unclear. Methods: The preliminary analyses of observational study of 680 colorectal cancer (CRC) patients focused on a sub-cohort of 233 primary rectal cancer patients, of whom 95 received NAT (chemoradiotherapy, radiation therapy with immediate surgery or wait period, or chemotherapy) and 138 were treatment-naive. Pathological responses varied from minimal to excellent. Transcriptomic, genomic, and immunohistochemical (IHC) profiling were performed on surgical resection samples. Mutation statuses of non-synonymous variants in CRC driver genes were compared between groups. Gene expression profiles were classified into consensus molecular subtypes (CMS) and intrinsic CMS (iCMS), with differentially expressed genes analyzed for hallmark pathway enrichment. Results: Transcriptomic analysis revealed a significant shift in molecular subtypes, with 66% of NAT tumors classified as iCMS3 (CMS4), compared to 63% of treatment-naive tumors classified as iCMS2. Pathway enrichment analysis of 4,817 differentially expressed genes showed significantly higher expression of hallmark pathways, particularly epithelial-to-mesenchymal transition and p53 signaling, in NAT tumors. Treatment-naive samples classified as iCMS3 (27%) displayed expression patterns similar to NAT iCMS3 tumors. The fraction of epithelial cells was significantly lower in NAT compared to treatment-naive, as determined by IHC. No significant differences in the overall mutation statuses of key CRC driver genes were observed between groups. Although, mutations in APC and TP53 were less frequent in the NAT tumors. Notably, KRAS mutations were mutually exclusive with TP53 in treatment-naive samples (36/95), whereas TP53 mutations co-occurred with APC in NAT tumors (48/22). Conclusion: NAT potentially induces a shift in gene expression from iCMS2 to iCMS3 in left-sided MSS rectal tumors, accompanied by increased epithelial-to-mesenchymal transition and altered driver gene interactions. Further investigations are needed to confirm whether NAT drives this gene expression shift, to elucidate its effects on tumor microenvironment modulation with available IHC data of T-cell, TMA, and CAF panels and to assess their impact on therapeutic outcomes and potential to inform adjuvant therapy strategies.

#4596 Spatial transcriptomics reveals subtype heterogeneity within the tumor epithelial compartment of pancreatic ductal adenocarcinoma.

James Topham[1], Jenny Chu[2], Maya Kevorkova[1], Steve Kalloger[1], Joanna Karasinska[1], Andrew Metcalfe[1], Hassan Ali[1], Dongxia Gao[2], Christine Chow[2], Jonathan Loree[3], Daniel Renouf[1], David Schaeffer[1]

Molecular subtyping of pancreatic ductal adenocarcinoma (PDAC) has converged on basal-like and classical subtypes with the former being associated with worse prognosis. Sequencing-based tools have emerged to bring PDAC subtyping closer to incorporation into clinical practice. We sought to test the utility of PDAC subtyping using a cohort of patient tumor samples in a clinical setting. For 29 patients with resectable PDAC, two formalin-fixed paraffin-embedded (FFPE) blocks were sequenced from each patient tumor sample (total n=58 blocks) using Nanostring nCounter. 18/58 (31%) of tumors had inconsistent PurIST-based basal-like or classical labels between the two blocks. Two tumors were selected for digital spatial transcriptomics based on having either consistent or inconsistent subtype labelling. Regions of interest (ROI) were selected to capture a diverse range of cellular compartments within the tumor microenvironment including tumor, stroma, immune cells, tumor buds and neurons. ROIs were sequenced across two and three FFPE blocks from the subtype consistent and inconsistent tumors, respectively. Gene expression was segmented by PanCK positive (epithelial) and negative (non-epithelial) signal. Across all ROIs (n=35), PanCK+ segments showed higher expression of basal-like (p=1.9e-7) and classical (p=4.2e-9) genes compared to PanCK- segments. For the subtype-consistent (classical) tumor, all ROIs (n=13) across two blocks showed predominate classical gene expression in the PanCK+ segment. In the subtype-inconsistent tumor that originally had blocks labelled PurIST classical and intermediate, ROIs (n=22) taken across three blocks showed 50, 60 and 83% of ROIs having higher basal-like expression, while remaining ROIs had predominant classical gene expression, and $\log_2$ fold change basal-like vs. classical (median) gene expression ranged from -2.4 (T-cells) to 1.3 (tumor and stroma) across ROIs. Overall, the classical gene signature was positively correlated with *GATA6* expression (rho=0.40, p=3.2e-4) across all ROIs and PanCK segmentations. While these data support the notion of subtyping expression being specific to the tumor epithelial component, nearly one-third of patient samples had different subtype labels depending on which area of the tumor epithelium was captured. We demonstrate the ability for spatial transcriptomics to resolve subtype heterogeneity and the contributing cellular compartments, providing potential to better understand how aggressive disease develops and could be treated.

#4597 Globo H affects the immune tumor microenvironment in cholangiocarcinoma.

Chih Chieh Yen[1], Tzer Min Kuo[2], Chun Jung Lin[2], Hung Wen Tsai[3], Wen Lung Wang[1], Chien Jui Huang[4], Ping Jui Su[5], Ting Kai Liao[5], I Ting Liu[1], Li Chin Cheng[6], Ying Jui Chao[5], Yan Shen Shan[5], Chia Jui Yen[1], Ming Tain Lai[2]

[1]Department of Oncology, National Cheng Kung University Hospital, Tainan, Taiwan,[2]OBI Pharmaceuticals Inc., Taipei, Taiwan,[3]Department of Pathology, National Cheng Kung University Hospital, Tainan, Taiwan,[4]Division of Gastroenterology and Hepatology, Department of Internal Medicine, National Cheng Kung University Hospital, Tainan, Taiwan,[5]Department of Surgery, National Cheng Kung University Hospital, Tainan, Taiwan,[6]Department of Surgery, Chi Mei Medical Center, Tainan, Taiwan

Background: Cholangiocarcinoma (CCA), which is characterized by aberrant glycosylation on the surface, is a rapidly progressing cancer with an unsatisfactory response to chemoimmunotherapy. Globo H (GH) ceramide, a tumor-promoting glycosphingolipid, is expressed in various types of cancer and is correlated with poor prognosis. However, few studies have discussed the role of GH in CCA. Hence, the pathways involved and alterations in the immune tumor microenvironment (TME) have not been explored.
Methods: We aimed to reveal the clinical features and immune modulatory role of tumor GH and its correlation in CCA. We evaluated the signaling-associated proteins and those coexpressed with GH. Tumor-infiltrating immune cells (TIMCs) were compared between tumors with high vs. low levels of GH synthesizing enzyme (GH-se) using open-domain databases and single-cell RNA sequencing results.
Results: Surface GH expression correlated with poor prognosis and peritumor inflammation. High-GH CCA cells coexpressed GH with PD-L1, EGFR and EPCAM. While GH and its synthesizing enzymes affected immune modulation and survival, TIMCs such as neutrophils, tumor-associated macrophages, natural killer cells and foxp3 regulatory T cells were significantly altered in high-GH-se tumors.
Conclusion: Tumor GH expression correlates with a poor prognosis in patients with cholangiocarcinoma. GH modulates the immune TME by promoting an immune-evasive niche. The results provide insights for combining immunotherapy with GH-targeting therapy.

#4598 A novel systemic delivery approach for oncolytic adenovirus therapy using tumor-homing mesenchymal stem cells.

Yu Mikane, Nobuhiko Kanaya, Shinji Kuroda, Hitoshi Minagi, Makoto Matsumoto, Tetsuya Katayama, Daisuke Kadowaki, Shunya Hanzawa, Masashi Hashimoto, Yoshihiko Kakiuchi, Satoru Kikuchi, Shunsuke Kagawa, Hiroshi Tazawa, Toshiyoshi Fujiwara, Yasuo Urata

Department of Gastroenterological Surgery, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan

Oncolytic viral (OV) therapy is a promising approach for treating metastatic cancer; however, systemic delivery remains a significant challenge due to antiviral immune responses. We previously developed a telomerase-specific OV, Telomelysin (OBP-301), which utilizes the hTERT promoter to drive the expression of E1A and E1B. OBP-301 demonstrated an abscopal effect when combined with anti-PD-1 antibodies in distant metastases in vivo murine colorectal cancer (MC38) mouse models. A p53-armed variant, OBP-702, showed potent tumor-suppressive effects in mouse models of gastroenterological cancers via intratumoral injection. However, these therapies remain limited to accessible lesions. To address these challenges, we investigated three novel approaches for systemic OV delivery. First, we encapsulated the DNA plasmids of GFP-expressing OBP-301 (OBP-401) in liposomes, which effectively reduced the production of neutralizing antibodies compared to naked OVs. Second, we explored extracellular vesicles (EVs) derived from OBP-301-infected tumors as natural carriers. These EVs demonstrated the abscopal effects to non-injected metastatic lesions in preclinical models, achieving promising therapeutic efficacy. Finally, we utilized mesenchymal stem cells (MSCs), known for their tumor-homing properties, as carriers for OBP-702. When MSCs loaded with OBP-702 (MSC-OBP-702) were intraperitoneally injected into an MC38-bearing peritoneal metastasis model, they effectively migrated to metastatic sites, significantly suppressing tumor growth and improving overall survival compared to OBP-702 alone. These findings demonstrate that MSC-OBP-702 has significant potential to overcome the challenges of systemic OV therapy through the tumor-homing capability of MSCs, providing a foundation for future clinical applications.

#4599 Preclinical evaluation, and clinical translation of ^{68}Ga/^{177}Lu-JH04, a novel FAP-targeting radiolabeled agent.

Yun Yang[1], Hongfei Cheng[1], Yuxin Lai[1], Xiuting Lin[1], Yaoming Yu[2], Jian Zhan[2], Yueguan Sun[2], Eric Wang[2], Haihua Yu[2], Kevin Wang[2], Jinqiu He[2], Guochang Wang[1], Weibing Miao[1]

[1]the First Affiliated Hospital, Fujian Medical University, Fuzhou, China,[2]Bivision Pharmaceuticals, Inc, Shanghai, China

Introduction: Fibroblast activation protein (FAP) is an ideal target for tumor imaging and therapy. To enhance tumor uptake and prolong the retention of FAP-targeting agents, we developed JH04, a novel cyclic peptide composed of a FAP-targeting ligand. The objective of this study is to evaluate the specificity, biodistribution, pharmacokinetics, and dosimetry of ^{68}Ga/^{177}Lu-JH04 through preclinical and preliminary clinical investigations, and to compare these findings with those of ^{68}Ga/^{177}Lu-FAP-2286.

Methods: The FAP-positive cell line HT1080-FAP was employed in *in vitro* and *in vivo* studies. The affinity of JH04 precursor to recombinant FAP protein was measured using surface plasmon resonance (SPR) and radioligand binding assays. PET imaging with ^{68}Ga-JH04 was performed in xenograft mouse models to evaluate its *in vivo* specificity and preclinical pharmacokinetics. The tumor uptake and retention of ^{177}Lu-JH04 were assessed in xenograft mice model and compared with those of ^{177}Lu-FAP-2286. Furthermore, the biodistribution and radiation dosimetry of ^{68}Ga-JH04 were evaluated using data from five cancer patients, with head-to-head comparisons of imaging results against those of ^{68}Ga-FAP-2286. Lastly, the therapeutic efficacy of ^{177}Lu-JH04 was investigated in three patients with tumor.

Results: The dissociation equilibrium constant (K_D) of JH04 precursor to human FAP protein was 0.428 nM. The IC50 of JH04 for human FAP protein was 3.96 nM, which was superior to that of FAP-2286 (12.2 nM). ^{68}Ga-JH04 exhibited excellent stability both *in vitro* and *in vivo*. In cell binding studies, the uptake of ^{68}Ga-JH04 in HT1080 cells was approximately 2.83 times higher than that of ^{68}Ga-FAP-2286 after 30 min incubation. Small-animal PET imaging revealed that the tumor uptake of ^{68}Ga-JH04 was approximately twice as high as that of ^{68}Ga-FAP-2286. SPECT imaging demonstrated high tumor uptake and prolonged retention of ^{177}Lu-JH04, the area under the curve (AUC) for tumor uptake over 168 hours was 1.94 times higher for ^{177}Lu-JH04 compared to ^{177}Lu-FAP-2286. In a head-to-head clinical comparison with ^{68}Ga-FAP-2286, PET/CT imaging results revealed significantly higher tumor radiotracer uptake for ^{68}Ga-JH04 (SUVmax: 60 minutes, 14.58 ± 6.26 *vs.* 11.98 ± 6.43, $P = 0.025$; 150 minutes, 17.46 ± 9.07 *vs.* 12.00 ± 7.65, $P = 0.006$). Additionally, the retention of ^{68}Ga-JH04 in the kidneys and liver was 3.02 times and 3.80 times lower than that of ^{68}Ga-FAP-2286. In a preliminary clinical evaluation of ^{177}Lu-JH04 therapy, all three patients tolerated well. The mean effective whole-body dose of ^{177}Lu-JH04 was determined to be 6.18E-02 ± 6.85E-03 mGy/MBq.

Conclusion: ^{68}Ga/^{177}Lu-JH04, novel FAP-targeting agent with excellent binding affinity, high tumor uptake, prolonged retention, and robust tumor-suppressive effects. These promising results encourage us to conduct further clinical research.

#4600 Preclinical evaluation and clinical translation of ^{68}Ga/^{177}Lu-JH12, a novel CXCR4-targeting radioligand.

Tianrui Kang[1], Yuxin Lai[1], Hongfei Cheng[1], Xiuting Lin[1], Yaoming Yu[2], Jian Zhan[2], Yueguang Sun[2], Eric Wang[2], Haihua Yu[2], Kevin Wang[2], Jinqiu He[2], Guochang Wang[1], Weibing Miao[1]

[1]Department of Nuclear Medicine, the First Affiliated Hospital, Fujian Medical University, Fuzhou, China,[2]Bivision Pharmaceuticals, Inc., Shanghai, China

Introduction: C-X-C motif chemokine receptor 4 (CXCR4) is highly expressed by many kinds of tumors. Radiolabeled Pentixafor/Pentixather as typical targeting CXCR4 radioligands have been widely used in clinical practice, while there still remains barriers such as inadequate tumor uptake and high retention in blood or liver. Therefore, we designed a novel CXCR4-targeted agent, JH12. This research evaluated the specificity, biodistribution, pahrmacokinetics, and dosimetry of ^{68}Ga/^{177}Lu-JH12 in preclinical and preliminary clinical studies, using ^{68}Ga-Pentixafor/^{177}Lu-Pentixather as references.

Methods: HT1080-CXCR4 cell line was used in cellular and small animal experiments. The *in vitro* binding affinities to CXCR4 were evaluated and presented as IC50 values. The specificity of ^{68}Ga/^{177}Lu-JH12 was assessed using PET/SPECT imaging, compared with ^{68}Ga-Pentixafor/^{177}Lu-Pentixather. *Ex-vivo* biodistribution studies were performed to obtain tumor uptake of ^{177}Lu-JH12. Besides, the biodistribution and radiation dosimetry of ^{68}Ga-JH12 were evaluated in 5 patients with oligometastatic tumors. We also conducted a head-to-head comparison to assess the diagnostic performance of ^{68}Ga-JH12 and ^{68}Ga-Pentixafor PET/CT in 3 patients.

Results: ^{68}Ga-JH12 exhibited excellent radiochemical purity and stability both *in vitro* and *in vivo*. The lower IC50 values on cellular level was observed in JH12 (18.79 nM) than Pentixafor (400.3 nM) and Pentixather (148 nM). In small animal PET imaging, the tumor uptake of ^{68}Ga-JH12 was 3.29 times than ^{68}Ga-Pentixafor at 1 hour post-injection. In small animal SPECT imaging and the *ex-vivo* distribution, ^{177}Lu-JH12 showed significantly higher tumor uptake (approximately 2 times) while lower accumulation in liver (approximately 10 times) than those of ^{177}Lu-Pentixather. Furthermore, clinical PET/CT imaging of ^{68}Ga-JH12 demonstrated remarkably higher tumor radiotracer uptake than ^{68}Ga-Pentixafor (SUV_{max}: 60 minutes, 27.44 ± 14.75 *vs.* 12.98 ± 7.41, P<0.05). Ultimately, based on the results of ^{68}Ga-JH12 dosimetry in 5 patients with tumor, the mean dose of ^{68}Ga-JH12 in liver, kidney and red marrow was 2.31E-02 ± 3.25E-03 mGy/MBq, 7.57E-02 ± 2.12E-02 mGy/MBq and 3.03E-02 ± 1.34E-02 mGy/MBq respectively. The effective dose of ^{68}Ga-JH12 was 2.01E-02 ± 6.66E-03 mGy/MBq.

Conclusion: JH12 appears to perform better in tumor visualization and retention, which might be a promising biological radio-tracer in CXCR4-targeting imaging and treatment.

#4601 Development and clinical translation of a phage display derived MT1-MMP-specific bicyclic peptide for radiotheranostic applications.

Ann-Christin Eder[1], Mohamed A. Omrane[1], Anusha R. Regupathy[2], Mohamed El Fakiri[1], Nils Steinacker[1], Lisa-Charlotte Domogalla[1], Christoph-Ferdinand Wielenberg[1], Michael Mix[1], Johanna Lahdenranta[3], Ben Blakeman[2], Francesca Wood[4], Philip Huxley[4], **Gemma E. Mudd**[4], Matthias Eder[5], Philipp T. Meyer[1], Martin T. Freitag[1]

[1]Department of Nuclear Medicine, University of Freiburg Medical Center, Freiburg, Germany,[2]BicycleTx Limited, Cambridge, United Kingdom,[3]Bicycle Therapeutics, Cambridge, MA,[4]Bicycle Therapeutics, Cambridge, United Kingdom,[5]Radiopharmaceutical Development, German Cancer Consortium partner site Freiburg, Freiburg, Germany

Background: Membrane type 1 matrix metalloproteinase (MT1-MMP) is a pivotal enzyme involved in extracellular matrix remodeling, contributing to tumor invasion, metastasis, and poor prognosis in various cancers, including non-small cell lung, urothelial, pancreatic, gastric, and breast cancers. This study outlines the preclinical development and first in-human application of a phage display-derived MT1-MMP-specific bicyclic peptide, [^{68}Ga]Ga-BCY25286, as a radiotheranostic agent for PET/CT imaging.

Methods: The MT1-MMP-targeting bicyclic peptide BCY25286 was radiolabeled with either Ga-68 or Lu-177 and subsequently characterized for stability, binding affinity, and internalization. Preclinical evaluation included biodistribution and µPET/MR imaging in MT1-MMP^{+} HT1080 and MT1-MMP^{-} MCF-7 xenograft tumor-bearing nude mice. For clinical translation, a 65-year-old patient with advanced pulmonary adenocarcinoma underwent [^{18}F]FDG-PET/CT followed by [^{68}Ga]Ga-BCY25286 PET/CT imaging, with PET scans performed after 60 minutes for [^{18}F]FDG and up to 60 minutes for [^{68}Ga]Ga-BCY25286 (compassionate use).

Results: Radiolabeling achieved >99% radiochemical purity for both radionuclides. [^{68}Ga]Ga-BCY25286 demonstrated highly MT1-MMP-specific binding (7.2 ± 1.6 nM), proteolytic stability up to 72 hours, and rapid background clearance, thereby enhancing imaging contrast within 30 minutes. In mice, the tracer demonstrated high tumor uptake (10.6 ± 1.1 %ID/g at 1 h p.i.) with persistence up to 24 hours. In the clinical case, [^{68}Ga]Ga-BCY25286 PET/CT imaging revealed high uptake in both primary and biopsy-confirmed metastatic sites, corroborating the findings of [^{18}F]FDG-PET. SUV_{max}values were comparable for lymph node metastases but higher for bone metastases in MT1-MMP-PET compared to [^{18}F]FDG-PET, with significant kidney retention due to renal excretion.

Conclusion: This first-in-human application of MT1-MMP-targeting [^{68}Ga]Ga-BCY25286 demonstrates the feasibility for visualization of MT-1-MMP-expressing primary tumors and metastases, which is in line with the preclinical findings. These initial clinical results support further investigation of [^{68}Ga]Ga-BCY25286 as a diagnostic tool with potential to improve tumor characterization and patient management strategies in MT1-MMP-positive cancers.

#4602 GPRC5D alterations impact CD38 expression and provide proliferative advantage in multiple myeloma.

Umair Munawar[1], Seungbin Han[1], Elena Gerhard-Hartmann[2], Cornelia Vogt[1], Silvia Nerreter[1], Shilpa Kurian[1], Thomas Nerreter[1], Johanna Thurner[3], Julia Weingart[4], Patrick Eiring[4], Xiang Zhou[1], Nina Rein[1], Johanna Lehmann[1], Max Koeppel[1], Andreas Rosenwald[2], Ondrej Slaby[5], Michael Hudecek[1], Hermann Einsele[1], Leo Rasche[1], Markus Sauer[4], Johannes Waldschmidt[1], Bernhard Kuester[3], Klaus Martin Kortuem[1]

[1]University Hospital Wuerzburg, Wuerzburg, Germany,[2]Institute of Pathology, University of Wuerzburg, Wuerzburg, Germany,[3]Technical University of Munich, Freising, Germany,[4]University of Wuerzburg, Wuerzburg, Germany,[5]Masaryk University, Brnu, Czech Republic

Background: The treatment landscape in Multiple Myeloma (MM) shifts towards immunotherapies with the G protein-coupled receptor class C group 5 member D (GPRC5D) as a promising antigen for T cell engagers (TCE) and investigational CART constructs. Monoallelic genetic alterations in GPRC5D are present in up to 15% of MM patients prior GPRC5D directed therapy. The incidence of acquired biallelic GPRC5D events following treatment has to be determined. Recently, biallelic loss of GPRC5D was identified as the underlying mechanism for acquired resistance toward talquetamab, the first approved GPRC5D directed TCE. In this study, we modeled GPRC5D genetic alterations and studied their impact on the biology of the disease and responsiveness to anti-MM immunotherapies.

Methods: Mono- and bi-allelic *GPRC5D* knock-out (KO) cell models were created using the MM cell line OPM-2 via CRISPR-Cas9 technology. Surface receptor distribution and epitope quantification of common immunotherapeutic targets was performed via *Direct* stochastic optical reconstruction microscopy (*d*STORM). MM cells were engineered to perform cytotoxicity, functional and clonal competition assays using immunotherapeutic agents in presence of effector T cells from healthy donors.

Results: *d*STORM revealed a 2-fold reduction in GPRC5D surface expression on $GPRC5D^{Wt/Del}$ (0,16±0,02 clusters/μm^2) vs. WT cells (0,32±0,10 clusters/μm^2). $GPRC5D^{Del/Del}$ had barely detectable GPRC5D expression with 0,03±0,07 clusters/μm^2. CD38 expression was unexpectedly diminished in $GPRC5D^{Wt/Del}$ (5,74±0.43 CD38 clusters/μm^2) compared to WT parental cells (9,59±0,71 clusters/μm^2, p=0.04), with an even greater reduction detected in $GPRC5D^{Del/Del}$ clones (2,22±0.203 clusters/μm^2, p<0,0001). GPRC5D-altered cells with reduced CD38 expression depicted a significant resistance towards CD38 targeting antibodies (8.01% specific lysis in $GPRC5D^{Wt/Del}$ cells, 6.38 % in $GPRC5D^{Del/Del}$ compared to 31.50% in WT cells, p <0.0001). $GPRC5D^{Wt/Del}$cells depicted a significant resistance towards Talquetamab. Additionally, in presence of talquetamab $GPRC5D^{Del/Del}$ models showed a proliferation gain (2 fold, p<0,0001). High content chemokine profiling using the scioCyto microarray platform revealed significantly altered chemokine profiles, including growth and proliferation promoting cytokines. In addition, upregulation of MAPK and PI3K pathways involved in growth proliferation and downregulation of the RAP1 signaling pathway involved in cell adhesion was observed in GPRC5D altered cells via bulk RNA seq. To decipher potential mechanism of growth induction and a link to CD38, scRNA seq and phospho-proteomic based analysis are ongoing.

Conclusion: Our work suggest a link between CD38 and GPRC5D in MM and supports an anti-proliferative function of GPRC5D suggesting treatment over progression with talquetamab may favor tumor growth in GPRC5D deficient cells.

#4603 Monoclonal P40 antibody BC28 identifies neoplastic cells with basal-like differentiation in a subset of pancreatic ductal adenocarcinoma.

Sourat Darabi[1], Derek Cridebring[2], Daniel Von Hoff[2], Haiyong Han[2], Michael J. Demeure[1], F. Scott Heinemann[1]

[1]Hoag Cancer Institute, Newport Beach, CA,[2]Translational Genomics Research Institute, Phoenix, AZ

Background: Transcriptomic analysis of pancreatic ductal adenocarcinoma (PDAC) has identified classical and basal-like subtypes of PDAC as discrete entities with distinct outcomes that require transcriptomic analysis for accurate diagnosis. Adenosquamous carcinoma of the pancreas (ASPC) is a histologic variant of pancreatic cancer with a basal-like transcriptomic phenotype and a distinctly poor prognosis. Current guidelines for diagnosing ASPC require the presence of at least 30% squamous component. We hypothesized that classical and basal-like PDAC may exist along a spectrum with ASCP at one end. DeltaNp63 (P40) immunohistochemistry (IHC) is an excellent marker for diagnosing primary lung squamous cell carcinoma. The use of P40 IHC in pancreatic carcinoma is less well established. This study was performed to determine the percentage P40 positive cells in ASCP and PDAC.

Method: Archived tissue slides and blocks from patients with PDAC (N = 58) and ASPC (N = 3) were retrieved from the files of Hoag Hospital using Hoag tumor registry data. Tissue sections of selected blocks from each case were stained by IHC using monoclonal anti-P40 antibody clone BC28 (Abcam, Waltham, Mass). IHC staining was performed with the BOND III automated immunostainer (Leica Biosystems, Nusslock, Germany). Any neoplastic cells with strong nuclear P40 staining were considered P40+. For tumors with P40+ neoplastic cells, the percentage of tumor surface area that contained P40+ neoplastic cells was estimated and the percentage of P40+ cells within the P40 positive component was estimated. IRB approval was obtained to conduct the study with exemption for patient consent.

Results: Greater than 90% of the surface area and >90% of the tumor cells in each ASCP tumor studied were P40 positive. Within the 58 PDAC, 12 cases (21%) contained P40 positive tumor cells. The median percentage of P40 positive cells within the P40+ PDAC components was 3.5%. P40 positive cells were distributed focally in 10 cases and diffusely in 2 cases. In PDAC cases with focal P40 staining, the P40+ components represented between 5% and 50% of the total surface area of the tumor. Most P40+ neoplastic cells in PDAC were cytologically indistinguishable from P40 negative tumor cells, but a subset had a flattened shape and peripheral distribution within the neoplastic glands reminiscent of basal cells. The median length of follow-up/survival in the study cohort was 18 months. Thirty-one of the PDAC patients were alive and 24 were dead. The survival status of 3 patients was not recorded in the registry data. 42% of PDAC patients with P40+ cells were alive at the time of study whereas 60% of patients with P40 negative PDAC were alive, but this difference did not reach statistical significance.

Conclusions: These findings support the hypothesis that a subset of PDAC contains a minor population of neoplastic cells with basal-like differentiation.

#4604 Implications of genomic alterations in RNF43 and RSPO3 for the response of BRAFV600E metastatic colorectal cancer to anti-EGFR+BRAF combinatory therapy.

Jakob M. Stenersen[1], Max Z. Totland[1], Luis Nunes[1], Ina A. Eilertsen[1], Vilde C. W. Elster[1], Tuula A. Nyman[2], Ragnihild A. Lothe[1], Anita Sveen[1], Kushtrim Kryeziu[1], Edward Leithe[1]

[1]Department of Molecular Oncology, Institute for Cancer Research, Oslo University Hospital, Oslo, Norway,[2]Department of Immunology, Institute for Clinical Medicine, Oslo University Hospital, Oslo, Norway

The *BRAF*^{V600E} mutation, present in 8 - 10% of colorectal cancers (CRCs), is associated with poor patient outcome and has limited treatment options. Recent studies have shown that mutations in the E3 ubiquitin ligase RNF43 predict response to anti-EGFR/BRAF combinatory therapy in patients with *BRAF*^{V600E} metastatic CRC. Gene expression analysis of CRCs with the *BRAF/RNF43* co-mutation exhibit significantly higher expression levels of *MAP2K1* and *MAPK3* compared to their wild-type counterparts. This implies an unknown but clinically significant molecular relationship between RNF43 loss-of-function and the MAPK signaling pathway. RNF43 attenuates WNT signaling by promoting the endocytosis and lysosomal degradation of Frizzled receptors to desensitize the cells to WNT ligands. RNF43 itself is in turn negatively regulated by the R-spondin (RSPO) family of proteins. Activating fusions involving *RSPOs* and inactivating mutations in *RNF43* are found in ~2% and ~5% of CRCs, respectively. The aim of the present project is to better understand how gene alterations affecting the R-spondin/RNF43 signaling module influence the response to EGFR/BRAF inhibitor combination treatment. We use patient-derived organoids with different genomic alterations in *BRAF* and *RNF43*, *APC*, or *RSPO3* as preclinical models to elucidate signaling dynamics before and after treatment with EGFR and BRAF inhibitors alone or in combination. This analysis includes various omics approaches such as mass spectrometry, RNA sequencing and kinome profiling. Here, we present preliminary results from this study, showing how these treatments differentially affect MAPK and WNT signaling depending on the mutational profile of the organoids

#4605 Exploring resistance mechanisms in cancer using patient-derived organoids reveals replication stress and EMT as potential biomarkers.

Ruben M. Drews[1], Finnian Firth[2], Paul R. Barber[1], Anna Pasto[1], Tony T. Ng[1]

[1]Oncology Translational Research Organisation, GSK Plc, London, United Kingdom,[2]gsk.ai, GSK Plc, London, United Kingdom

Mutational processes such as chromosomal instability and replication stress are important molecular features of head and neck squamous cell carcinoma (HNSCC) and non-small cell lung cancer (NSCLC), contributing to poor patient survival. Their changing influences during cancer development creates challenges in identifying response biomarkers. Patient-derived organoid 3D cancer models (PDOs) have been shown to match their primary source material and to reflect tumour biology more faithfully than cell lines. In our companion abstract, we detail how we have built the Digital Biological Twin lab to study PDOs for drug testing and biomarker discovery. In this work, we used PDOs to investigate resistance to PARP inhibitors (PARPi), which are mechanistically linked to DNA repair and replication. 10 PDOs (6 HNSCC, 4 NSCLC) generated from untreated tumor resections were bulk RNA-sequenced and treated with Niraparib. IC50, cell viability measured by flow cytometry and protein expression levels were used to classify 3 PDOs as sensitive to treatment. Expression analysis, stratifying by PARPi sensitivity, resulted in 287 differentially expressed genes (DEGs). Enrichment analyses found involvement of the endothelial-to-mesenchymal transition (EMT) and small molecule transport pathways. Knowing that EMT is linked to multi-drug resistance, we treated the PDOs with Cisplatin and found a significant correlation to PARPi IC50 values. By examining the biology of the DEGs, we categorized them using MSigDB into five gene sets, each with 1 to 14 genes. We functionally validated the gene sets by assessing PARPi susceptibility in 45 cell lines pre and post a genome-wide CRISPR knockout, finding four significantly enriched in PARPi gene dependencies. For two replication stress-derived gene sets, we demonstrated significant concordance between PARPi sensitivity status of PDOs and cell lines from DepMap, and with progression free interval of HNSCC and NSCLC patients from TCGA. Leveraging Cox analysis on these patients, one replication stress gene set stratified the patients by showing a significant decrease in relapse probability. In summary, our results indicate that PARPi resistance is associated with the deregulation of genes related to small molecule transport, multi-drug resistance and EMT. The consistent findings around replication stress across disease models strongly suggests a conserved and central role in resistance mechanisms. We also identify a replication stress gene set that significantly correlates with resistance in cancer models and relapse in patients. Further work is needed to translate our findings into a predictive model for drugs linked to replication stress. Here we showed that PDOs can be successfully used for furthering our understanding of resistance mechanisms while improving molecular stratification of patients with direct clinical implications.

#4606 Digital biological twin platform: multiomics in patient derived organoids combined with machine learning.

[1]GlaxoSmithKline, Stevenage, United Kingdom,[2]gsk.ai, GlaxoSmithKline, Stevenage, United Kingdom,[3]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom,[4]King's College of London, Comprehensive Cancer centre KHP Cancer Biobank., London, United Kingdom,[5]King's College of London, School of Cancer and Pharmaceutical Sciences, London, United Kingdom

Patient-derived organoids (PDOs) are in vitro 3D structures that mimic the complexity of tumors, including their molecular and phenotypic features. Recently, numerous studies have demonstrated their potential as preclinical model for drug screening and tailored treatment selection for patients.Non-small cell lung cancer (NSCLC) with its rapid growth and early metastasis onset, represents the most common cause of cancer-related deaths worldwide. Current treatments offer limited long-term survival, necessitating novel approaches. Immunotherapy, specifically anti-PD1 and anti-PD-L1, has transformed NSCLC treatment, but only a small percentage of patients respond. There is an unmet need to develop novel clinically relevant models of NSCLC to improve cancer patient risk stratification as well as to predict future targeted and/or immuno-therapy susceptibilities that may be met with PDOs.We have created the Digital Biological Twin lab, a platform that performs multi-omics analysis on PDOs combining advanced cellular, genomic, and molecular techniques with machine learning models, aiming to improve cancer patient risk stratification and predict future therapy susceptibilities. This platform, part of the Oncology translational research organization at GSK, will provide proof of concept data from patient samples collected in hospital biobank-linked organoid studies. In an ongoing study we are establishing PDO models from 200 NSCLC tissues collected at the Guy's and St Thomas' Biobank in London. The PDOs are treated with standard care, then co-cultured with pre-activated immune cells in the presence of IO drugs, and subjected to assays including exosome isolation, protein and DNA content analysis, imaging assays, flow cytometry analysis of tumor markers and immune phenotype, and transcriptomic analysis. This multi-omics approach allows for simultaneous analysis of different biological parameters after treatment to understand tumour cell interaction with immune cells and drug-induced changes. The results will be used to identify potential biomarkers of treatment response and generate hypotheses for drug resistance.Initial results in a pilot study with PDOs from NSCL and head and neck cancers have shown that several factors correlate with and can be combined in a linear elastic-net or robust Bayesian regression model that predicts resistance risk, as measured by PDO cell viability or IC50. These factors include the treatment induced change in CD45+ immune cell infiltrating, changes in tumour PD-L1 and immune PD-1 expression, changes in MYC, TIGIT and CD96 expression. More details of a genomic analysis will be presented in a companion presentation at this conference.

#4607 Pharmacokinetic analysis of palbociclib and association with safety/efficacy in patients with HR-positive/HER2-negative advanced breast cancer: Result from PATHWAY trial.

Background: We recently reported that the combination of palbociclib and tamoxifen significantly extended progression-free survival (PFS) in patients with HR+/HER2- advanced breast cancer, in both pre-, peri-, and post- menopausal Asian patients versus tamoxifen alone (PATHWAY trial, NCCH1607, NCT03423199). Here, we report on palbociclib pharmacokinetic (PK) analysis results and their relationship to adverse events and PFS.

Methods: In the PATHWAY study, 184 patients were randomized to palbociclib plus tamoxifen group (91 patients) or placebo plus tamoxifen group (93 patients). Blood samples were collected to assess steady-state trough plasma concentrations of palbociclib (at C1D15 and C2D15). PK data from patients who had been administered 125 mg of palbociclib or placebo once daily for seven consecutive days before sample collection, and for whom samples were collected within 24 hours ± 10% of the dose administered the day prior to sample collection, were used in the analysis. All the PK analyses were performed using LC/MS/MS. The study has been conducted as a Clinical Research Collaboration with the National Cancer Center Hospital as the regulatory study sponsor and Pfizer providing drug and financial support.

Results: A total of 171 patients were included in the analysis: 82 in the palbociclib group and 89 in the placebo group. In the palbociclib group, 82 patients had samples collected at C1D15, and 47 at C2D15, and the median palbociclib concentration (interquartile range) was 84.8 (62.45 - 104.75) ng/mL and 67.9 (51.75 - 80.05) ng/mL, respectively. In the quartile analysis of palbociclib C1D15 PK, the lowest quartile (Q1) group tended to have a higher rate of progressive disease than the other quartile groups (Q2-4) (Q1 vs Q2-4, 14.3% vs 1.6%). In terms of adverse events, the frequency of hematological toxicities such as neutropenia and thrombocytopenia increased in both cycle one and the entire treatment period, in correlation with the quartile of palbociclib C1D15 PK. On the other hand, the frequency of dose reductions also increased in correlation with the quartile. Finally, PFS in the Q1 group was comparable to placebo but significantly shorter than in the Q2-4 group (median PFS 95% confidence interval) Placebo; 11.1 (8.5 - 14.9) months, Q1; 9.5 (5.4 - NR) months, Q2-4; 29.5 (20 - 38.2) months, p=0.033).

Conclusion: In combination therapy with palbociclib and tamoxifen for HR+/HER2- advanced breast cancer, the palbociclib PK at C1D15 correlated with the frequency of hematological toxicity. At the same time, patients with lower exposures of palbociclib may not benefit in terms of PFS. Further accumulation of real-world PK data may lead to optimization of palbociclib dosing, which in turn could potentially reduce adverse events and improve survival outcomes.

#4608 Evaluation of the impact of homozygous MTAP truncations on the clinical activity of MTA-cooperative PRMT5 inhibitors.

Homozygous deletion of the MTAP gene occurs in 10-15% of all human cancers. To benefit this large patient population, MTA-cooperative PRMT5 inhibitors, including TNG908, TNG462, and TNG456 were developed to leverage the synthetic lethal relationship between MTAP deletion and PRMT5 inhibition. Clinical trial eligibility for most MTA-cooperative PRMT5 inhibitors is restricted to patients with tumors with confirmed MTAP loss either detected by next-generation sequencing or immunohistochemistry. MTAP loss most commonly occurs as a co-deletion event with the proximal CDKN2A gene and the chromosomal 9p breakpoints are not uniform. Previously, we reported that homozygous loss of only the terminal exon (exon 8), an event reported to occur in only 0.5% of MTAP-deleted tumors, is insufficient for complete loss of MTAP activity in preclinical assays. Here, we report initial evidence for the clinical impact of MTAP truncations, as opposed to complete deletion, on the activity of MTA-cooperative PRMT5 inhibitors.

CLINICAL RESEARCH: Predictive Biomarkers 5
Poster Session

#4611 Microbiome-derived indole metabolites and response to immune checkpoint inhibitors in patients with hepatocellular carcinoma.

Background: Immune checkpoint inhibitors (ICI) represent the most promising therapy for hepatocellular carcinoma (HCC) to-date; however, responses are heterogeneous and strategies to extend survival are urgently needed. Metabolites of the essential amino acid, tryptophan (Trp) are emerging as potential targets in immune tolerance, inflammation and ICI response. Trp metabolism occurs through: (1) the kynurenine pathway, (2) the serotonin pathway, and (3) the indole pathway—the latter of which is primarily mediated by the gut microbiota. Specific indole metabolites exhibit anti-cancer properties, such as inhibiting cell proliferation and activating CD8+ T cells to target tumor cells. In unresectable, neoadjuvant and adjuvant HCC patients treated with ICI, we aimed to identify metabolite biomarkers of durable response. We further explored microbial sources of these metabolites and validated the presence of relevant gut bacteria in a separate but overlapping cohort of HCC patients prior to ICI therapy.
Methods:Ten serum indole metabolites were measured by liquid chromatography-high-resolution mass spectrometry (LC-HRMS) in 38 HCC patients treated with anti-PD1/PL1 (nivo+/-ipi, atezo+bev). Kaplan-Meier analysis assessed time-to-progression (TTP) and recurrence-free survival (RFS) in patients with non-resectable (66%) and resectable disease, with Mann-Whitney U test in landmark analysis (TTP>8 mos, RFS>2 yrs). Finally, we characterized the fecal microbiome of 8 unresectable HCC patients using 16Sv4 rDNA sequencing and compared the profiles to predictions from TrpNet, a web-based tool that uses Bayesian logistic regression to identify potential microbial sources of Trp metabolites.
Results: Among unresectable patients with elevated vs. low indolepropionic acid (IPA), 50% vs. 10% reached TTP>8 mos. According to TrpNet, IPA is most likely produced by the Peptostreptococcaceae family, which was observed in our small microbiome cohort. However, the relative abundances of bacterial families Pasteurellaceae and Lachnospiraceae—producers of the IPA precursor indole pyruvate—were the most significantly elevated in patients that initially responded to IC1. No clear associations were observed in the small subset of resectable patients.
Conclusion: Elevated IPA levels were correlated with improved outcomes among unresectable HCC patients treated with ICI. These findings further highlight the potential role of circulating indoles and other microbial-derived metabolites in ICI response, warranting further validation in larger cohorts and investigation of their influence on tumor progression and treatment efficacy.

#4612 Development of an Integrated Microfluidic Chip for CAR T-Cell Therapy: A Preclinical Trial-on-Chip Tool.

Xuejia Kang[1], Lang Zhou[1], Weiqiang Chen[2], Zongliang Yue[3], Pengyu Chen[1]

[1]Department of Mechanical Engineering, Materials Research and Education Center, Auburn University, Auburn, AL,[2]Department of Biomedical Engineering, New York University, New York, NY,[3]Department of Drug Discovery and Development, Harrison College of Pharmacy, Auburn University, Auburn, AL

Chimeric antigen receptor (CAR) T-cell therapy has demonstrated promising outcomes in treating leukemia, yet it confronts significant hurdles due to severe side effects like cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Furthermore, existing preclinical evaluation platforms often fall short in accurately replicating the human tumor microenvironment, leading to extended development durations and elevated costs. To overcome these challenges, we have developed an innovative, integrated microfluidic chip equipped with microarchitectural features that precisely mimic tumor niches, thus enhancing the modeling of CAR T-cell therapy. This chip incorporates an integrated biosensor for real-time cytokine detection, providing essential insights into cytokine dynamics throughout the therapy process. This advanced chip enables spatiotemporal monitoring of CAR T-cell functionality by observing key processes such as T-cell extravasation, target recognition, and leukemia cell destruction. Additionally, it supports the detailed examination of immune cell interactions, including those with monocytes and basophils, which are critical for understanding the side effects of CAR T therapy, particularly its impact on neuronal tolerance. By meticulously tracking these dynamics, our tool not only refines the precision of therapy modeling but also deepens our understanding of the immune response and potential toxicities associated with CAR T-cell therapy. Our investigations using the chip have yielded detailed profiles of cytokine levels across various therapy phases, including remission, resistance, and relapse. Moreover, the chip is capable of evaluating the effects of compounds in inhibiting cytokine release. This cutting-edge tool significantly shortens the development timeline, reduces costs, and enhances the physiological relevance of preclinical evaluations for CAR T-cell therapy. The implementation of this ‘(pre-)clinical-trial-on-chip’ platform is poised to revolutionize CAR T-cell therapy by facilitating the development of personalized therapies and informing clinical decision-making processes. Our findings represent a transformative step forward in the optimization and safety profiling of CAR T-cell therapies.

#4613 Differential TROP2 immunohistochemical expression between pleomorphic and classic invasive lobular carcinoma of the breast.

Elizve Barrientos-Toro[1], Harsh Batra[1], Pandurengan Renganayaki[1], Yasmeen Qamar Rizvi[2], Jason Aboudi Mouabbi[3], Funda Funda Meric-Bersntam[2], Qingqing Ding[4], Aysegul Sahin[4], Maria Gabriela Raso[5]

[1]Translational Molecular Pathology, UT MD Anderson Cancer Center, Houston, TX,[2]Investigational Cancer Therapeutics, UT MD Anderson Cancer Center, Houston, TX,[3]Breast Medical Oncology, UT MD Anderson Cancer Center, Houston, TX,[4]Anatomical Pathology, UT MD Anderson Cancer Center, Houston, TX,[5]UT MD Anderson Cancer Center, Houston, TX

Background:TROP2, a transmembrane glycoprotein implicated in tumor progression and metastasis, exhibits variable expression across breast cancer subtypes. The classic variant of invasive lobular carcinoma (ILC-C) and the pleomorphic variant (ILC-P) display distinct morphological and biological characteristics. This study aims to investigate differences in TROP2 expression between ILC-C and ILC-P, enhancing our understanding of its potential as a biomarker for aggressive subtypes.
Methods:TROP2 protein expression was evaluated in 14 samples (8 ILC-C and 6 ILC-P) using immunohistochemistry (IHC) and quantified with digital image analysis software. Samples were annotated and classified into tumor and stroma components. The percentage of TROP2-positive cells was assessed, and staining intensity was categorized as weak, moderate, or strong. H-scores were calculated to assess overall TROP2 expression. Statistical analyses included descriptive statistics and the Wilcoxon test to compare expression levels between ILC-C and ILC-P groups.
Results:TROP2 expression was significantly higher in ILC-P samples compared to ILC-C across multiple metrics. The percentage of positive cells was markedly elevated in ILC-P (mean: 73.04; median: 81.09; SD: 16.08) compared to ILC-C (mean: 17.97; median: 15.14; SD: 12.48). Similarly, H-scores were significantly higher in ILC-P (mean: 153.07; median: 146.79; SD: 54.31) than in ILC-C (mean: 24.97; median: 17.96; SD: 18.81). The Wilcoxon test for both parameters revealed statistical significance ($p = 0.002$). However, no significant difference was observed between molecular classification groups and TROP2 expression levels.
Conclusion:Our findings demonstrate distinct TROP2 protein expression profiles in ILC, with ILC-P samples exhibiting significantly higher expression levels. This elevated TROP2 expression in the aggressive ILC-P variant highlights its potential as a biomarker for identifying high-risk lobular carcinoma subtypes. Further studies are warranted to explore the clinical implications of TROP2 in ILC-P, potentially guiding targeted therapeutic strategies.

#4614 Differential PD-L1 expression by IHC between matched samples obtained from FFPE blocks versus frozen blocks.

Rebeeca Bascom[1], Paige Nelson[1], Jacob Harris[1], David Booker[2], Ken Dixon[3], Jared James Barrott[1]

[1]Brigham Young University, Provo, UT,[2]Specicare, Augusta, GA,[3]Specicare, Gainesville, GA

Introduction: Personalized cancer treatment is crucial for improving patient outcomes, yet the standard preservation methods for clinical tissue samples may not fully support this goal. Currently, most cancer tissue samples are preserved as formalin-fixed and paraffin-embedded (FFPE), which recent studies suggest compromise DNA quality and quantity. In this study, we extended previous research by comparing the protein expression of PD-L1, a significant biomarker associated with cancer cell evasion of immune response, between FFPE and cryopreserved (frozen) tissues from 37 patients with various types of cancer. We hypothesized that cryopreserved samples would exhibit higher and more accurate PD-L1 levels than FFPE samples.
Methods: The first step in our research was to confirm the presence of cancer in 37 patient tissue samples through standard hematoxylin and eosin (H&E) staining. Next, we stained both the FFPE and cryopreserved samples using immunohistochemistry (IHC) protocols to visualize PD-L1 expression. The FFPE protocol involved dewaxing, antigen retrieval, incubation with primary and secondary antibodies, and staining. The protocol for the cryopreserved tissues was similar, with slight changes by eliminating the dewaxing and antigen retrieval steps. DAB was used to stain PD-L1 (identified in brown) and hematoxylin was used to stain cell nuclei (identified in blue). Positive controls were included in each stain to ensure reliability and minimize overstaining. Once each sample was stained in both its FFPE and cryopreserved forms, samples were sent to a board certified pathologist for further analysis and comparison.
Results: Our research results indicated a trend towards increased PD-L1 expression in cryopreserved samples, supporting our hypothesis that FFPE tissue exhibits a weaker PD-L1 signal compared to cryopreserved tissue. We have seen a significant difference between the FFPE and cryopreserved tissue samples-a result that was corroborated by a board-certified pathologist. Among the FFPE samples, less than 6% were found to be positive for PD-L1. Conversely, the cryopreserved samples exhibited a 64% rate for positive PD-L1 expression.
Discussion: This study highlights the impact of tissue preservation methods on the accuracy of cancer diagnostics through an analysis of protein preservation. The personalization of treatment strategies in a clinical setting depends on data such as these, underscoring the need for more accurate analysis. This data, along with previous and future studies, will advocate for a shift towards cryopreservation in clinical settings, leading to better personalized treatment and results for the patient.

#4615 Comprehensive genomic profiling using VARIANT*Plex*™ and FUSION*Plex*™ panels along with Archer's new tumor-only homologous recombination deficiency algorithm.

Glen Bjerke, Taylor Patterson, Devin Tauber, Allison Hadjis, Ryan Rogge, Dhruti Legare, Mark Rogers, Laura Johnson, Brent Lutz

Integrated DNA Technologies, Inc., Boulder, CO

Comprehensive Genomic Profiling (CGP) for cancer research has arisen out of the need for Next Generation Sequencing (NGS) tests that can be used across tumor types and detect both discreet genomic changes and genome-wide biomarkers. Herein, we detail IDT's Archer CGP suite of assays, offering cutting-edge precision oncology research solutions designed to provide a thorough and accurate molecular characterization of tumors. This modular set of assays includes VARIANT*Plex* (DNA) and FUSION*Plex (*RNA) profiling with a full range of biomarkers that offer high concordance with established orthogonal methods, ensuring both reliability and reproducibility in genomic profiling. The newest component of Archer's CGP assays is Homologous Recombination Deficiency (HRD) analysis, which is based on Archer's tumor-only Copy Number Variation 2.0 (CNV2.0) and Allele Specific Copy Number (ASCN) calling along with an independent measure of Non-homologous End Joining (NHEJ). Archer's HRD solution comprises a modular set of chemistry targets that can be added to any VariantPlex panel and an HRD bioinformatics workflow within Archer Analysis software. Our HRD pipeline shows high concordance with orthogonal Genomic Instability Score (GIS) methods and consistent calling across various targeted panels and input masses. Additional CGP biomarkers for DNA analyses include Microsatellite Instability (MSI) and tumor mutational burden (TMB) calling. In addition to genome-wide biomarker analysis, all VARIANT*Plex* panels include Single Nucleotide Variant (SNV), Insertion/Deletion (InDel), and Internal Tandem Duplication (ITD) calling with panel sizes of up to 460 genes. The RNA components of Archer's CGP offering are FUSION*Plex* panels that allow fusion calling from low purity (>= 10% tumor cellularity) samples along with RNA variant calling, which we show to be consistent with DNA allele frequencies. Furthermore, all VARIANT*Plex* and FUSION*Plex* panels can be customized to allow users the flexibility to make a CGP solution according to their individual needs. Archer's CGP panels offer a complete end-to-end solution including automatable chemistry workflows, Archer Analysis bioinformatics software, integration with Molecular Heath's Guide Case Annotation Solution (CAS) tertiary analysis platform, and now include tumor-only HRD calling along with the full suite of biomarker testing for RNA and DNA panels.

#4616 Detection of phosphorylated biomarkers in clinical blood samples: a flow cytometry platform utilizing smart tube fixation.

Valerie Oberhardt, Philipp Metzger, Carla N. Castro, **Holger Weber**

Reaction Biology Europe GmbH, Freiburg, Germany

The identification and quantification of biomarkers in clinical blood samples play a pivotal role in personalized medicine, enabling disease monitoring and therapeutic assessment. Protein phosphorylation, a key post-translational modification, reflects cellular signaling in immune or tumor cells. To exploit this, we developed a platform detecting phosphorylation states of key signaling proteins from clinical blood samples via flow cytometry. Our approach analyzes phosphorylated STAT5 (pSTAT5), ERK1/2 (pERK1/2), and p38 (p-p38), vital components in immune regulation and cancer progression.

A major challenge in the analysis of phosphorylated proteins is the rapid degradation or change in phosphorylation state ex vivo, which requires immediate stabilization of samples after collection. To solve this problem, we use Smart Tubes, which enable rapid fixation of clinical blood samples and preserve the phosphorylation state upon collection, ensuring signal integrity and minimizing variability. Sample collection with Smart Tubes requires no technical equipment and can be easily implemented and standardized at any clinical trial site.

Our test system employs flow cytometry, enabling the analysis of linage-specific markers (e.g., T/B cells, monocytes) and phospho-specific antibodies to quantitatively detect pSTAT5, pERK1/2, and p-p38 in peripheral blood mononuclear cell (PBMCs) subpopulations. Validation experiments with specific inhibitors demonstrate sensitivity and specificity in detecting these phosphorylated targets, even in heterogeneous cell populations within blood samples. The method allows for its application across a range of clinical conditions, from cancer immunotherapy monitoring to autoimmune disease characterization.

By integrating rapid sample fixation with advanced analytical techniques, this platform addresses key challenges in analyzing phosphorylated biomarkers in clinical samples. The use of flow cytometry as the central analytical tool enables single-cell resolution, allowing detailed investigation of individual cell populations within complex samples by differential marker expression. This precision makes it possible to differentiate and study specific subpopulations of immune cells or circulating tumor cells, within a heterogeneous sample. The ability to preserve and accurately measure phosphorylation states directly in patient-derived samples provides invaluable insights into real-time cellular signaling and facilitates the optimization of therapeutic strategies targeting dysregulated signaling pathways.

In summary, our system can detect phosphorylated proteins in clinical samples, with Smart Tubes ensuring sample stability and reliable biomarker analysis, advancing translational research and precision medicine.

#4617 Blood-based biomarkers for predicting treatment response to immune checkpoint inhibitors after EGFR-TKI resistance.

Jun Hyeok Lim, Min Seok Park, Nuri Park, Yejin Cho, Sehan Kwak, Beom Seok Han, Minseo Lee, Donghyun Seo, Woo Kyung Ryu, Jeong-Seon Ryu, Soon-sun Hong, Kyung Hee Jung

Inha University College of Medicine, Incheon, Korea, Republic of

Background: Immune checkpoint inhibitors (ICIs) improve survival in advanced non-small cell lung cancer (NSCLC), but their benefits are limited in EGFR-mutant NSCLC. ICIs are often used after resistance to EGFR tyrosine kinase inhibitors (EGFR-TKIs). Since EGFR-TKI treatment alters the tumor microenvironment, predictive biomarkers for ICI response should ideally be identified post-EGFR-TKI resistance. However, obtaining re-biopsy samples is challenging. This study explores predictive biomarkers for ICI response using plasma samples collected before and after EGFR-TKI therapy.

Methods: We retrospectively analyzed 28 EGFR-mutant NSCLC patients treated with ICIs at Inha University Hospital (2016-2023). All patients received first-line EGFR-TKI therapy and transitioned to ICIs after resistance. Plasma samples were collected before EGFR-TKI initiation and post-resistance. Ninety-six plasma proteins were quantified using the Olink Immuno-Oncology panel. PD-L1 expression in tumor tissues was assessed at diagnosis with SP263 or 22C3 assays. Progression-free survival (PFS) was defined as time from ICI initiation to progression. Responders were defined as PFS ≥6 months, and non-responders as PFS <6 months.

Results: Among 28 patients, 25 had adenocarcinoma, 1 squamous cell carcinoma, 1 adenosquamous carcinoma, and 1 poorly differentiated NSCLC. EGFR mutations included exon 19 deletion (n=14), L858R (n=10), and uncommon mutations (n=4). First-line EGFR-TKIs included erlotinib (n=15), afatinib (n=9), and gefitinib (n=4). T790M mutations were identified in 11 patients, of whom 10 received osimertinib and 1 received lazertinib. ICIs included atezolizumab (n=15), pembrolizumab (n=5), and nivolumab (n=8). PD-L1 expression was evaluated in 23 patients using SP263 (5 negative, 15 with 1-49%, 3 with ≥50%) and in 22 patients using 22C3 (7 negative, 11 with 1-49%, 4 with ≥50%). Median PFS for ICIs was 2.7 months (95% CI: 1.7-3.7), with 6 responders and 22 non-responders. Plasma levels of IL-4, IL-6, GZMH, and Gal-9 differed significantly between responders and non-responders post-EGFR-TKI resistance. These findings were validated using tissue samples obtained post-resistance. Progression-free survival (PFS) showed significant differences according to plasma biomarker expression.

Conclusions: Plasma samples collected after EGFR-TKI resistance can predict ICI responses in EGFR-mutant NSCLC. Post-resistance plasma biomarker levels may serve as a minimally invasive approach to guide therapeutic decisions in this challenging patient population.

#4618 Baseline and dynamic cytokines as biomarkers for first-line therapy in advanced hepatocellular carcinoma.

X. Zhao[1], H. Wilbur[2], M. Yarchoan[2];

[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Baltimore, MD

Background: Hepatocellular carcinoma (HCC) causes significant cancer mortality. The preferred treatment for patients with advanced HCC is immune checkpoint inhibitors (ICIs), with or without the VEGF-inhibitor bevacizumab. The immune effects of bevacizumab are not well understood, and biomarkers are needed to guide therapy selection in advanced HCC. We serially evaluated circulating cytokines in patients with HCC treated with ICIs with or without bevacizumab.

Methods: Circulating cytokines were evaluated in 57 advanced HCC patients treated with ICI-based therapy as standard of care at Sidney Kimmel Cancer Center from 2000-2024. A total of 36 patients received ICIs without bevacizumab (ICI-Only group), and 21 patients received the combination of an ICI with bevacizumab (ICI+Bev group). Serum was collected prospectively at baseline and at approximately 2 months after starting therapy. Cytokines were assessed using a Luminex panel of 33 cytokines. Patients were stratified by above- or below-median baseline cytokine levels and fold-change post-treatment. We evaluated the relationship between treatment group (ICI-Only versus ICI+Bev), cytokine changes, and clinical outcomes.

Results: Across all patients, the median age was 65, 26% were female, and 60% were White. Baseline demographic characteristics were balanced between the ICI-Only and ICI-Bev treatment groups, except for a higher proportion of patients receiving prior systemic therapy in the ICI-Only group (75%) compared to the ICI+Bev group (14%). Compared to patients receiving ICI-Only, those receiving ICI+Bev exhibited reduced fold changes in multiple cytokines after 2 months of treatment, including sCD40L ($p = 0.017$), MIP-1b ($p = 0.015$), and MIG ($p = 0.049$). Across all patients, lower baseline levels of IL-8 ($p = 0.017$) and lower on-treatment levels of IL-1Ra ($p = 0.008$), IL-4 ($p = 0.049$), IL-8 ($p = 0.021$), IL-9 ($p = 0.028$), and IL-18 ($p = 0.004$) were associated with longer survival. In the ICI-Bev group, higher baseline IL-6 ($p = 0.008$) was associated with improved progression-free survival, while smaller post-treatment increases in IL-6 were associated with both improved PFS ($p = 0.028$) and objective response rate ($p = 0.010$). In contrast, in ICI-Only patients, lower baseline IL-8 ($p = 0.012$) and smaller post-treatment increases in IL-1Ra ($p = 0.021$) were associated with extended overall survival.

Conclusion: Adding in bevacizumab to ICIs in advanced HCC may influence systemic cytokines, particularly those associated with innate immune populations. These findings suggest that bevacizumab may modulate innate immune responses and highlight the potential role of specific myeloid-related cytokines as biomarkers to identify patients who could benefit from bevacizumab-based combination therapy. These exploratory results warrant prospective validation in independent patient cohorts to confirm their clinical significance.

#4619 SEPT9 isoform expression and response to neo-adjuvant taxane treatment in breast cancer patients.

Jacob Nathaniel Essif, Kate Lathrop, April Risinger

UT Health Science Center at San Antonio, San Antonio, TX

Drugs that disrupt the microtubule cytoskeleton, such as the microtubule stabilizing taxanes, are regularly used in the treatment of breast cancer in the neoadjuvant setting. However, there are currently no molecular biomarkers that are used to guide which patients will respond to taxane treatment. Septins, a class of small GTPases, interact with both microtubules and actin to functionally link these cytoskeletal components and regulate cell biological processes shown to be critical for the invasion and migration of cancer cells. Septin 9 (SEPT9) directly interacts directly with microtubules through an N-terminal domain on the longest isoform, SEPT9 isoform 1, which is sufficient to promote migration and invasion of breast cancer cells *in vitro.* Additionally, both SEPT9 isoform 1 and SEPT9 isoform 3 have been shown to play a role in taxane resistance *in vitro*, but the possible role in clinical taxane resistance had not been studied. We hypothesized that the relative expression of SEPT9 isoforms in breast tumors could play a role in their response to treatment taxanes in the neoadjuvant setting. We performed a prospective clinical trial to correlate the expression of SEPT9 isoforms in breast tumors with pathological response to taxanes in the neoadjuvant setting. Pretreatment levels of SEPT9 isoform mRNA, as well as mRNA from other genes associated with clinically relevant drug resistance mechanisms, were determined from FFPE biopsy samples by multiplexed PCR, while protein levels of SEPT9 isoforms were determined by IHC. Patients were treated in the neoadjuvant setting with either paclitaxel (dose dense or weekly), docetaxel or nab-paclitaxel. Expression was reevaluated in post-treatment surgical samples of patients who did not have a pathological complete response (pCR). We found that the expression of SEPT9 mRNA variants and drug resistance genes differed amongst the pre-treatment patient samples. Initial SEPT9v2 mRNA levels are higher in patients that have a pCR. Additionally, expression of SEPT9v4, MDR1 and ABCC11 mRNA levels are statistically significantly reduced post-taxane treatment in patients that did not have a pCR. We are currently determining the mRNA expression levels of a panel of 96 clinically relevant genes in the pre-treatment samples to identify a genetic profile of response to taxane treatment. We are performing *in vitro* studies to determine if elevated levels of SEPT9v2 correspond with response to other chemotherapeutic drugs. Overall, the data support the hypothesis that the relative expression of SEPT9v2 in breast tumors plays a role in their response to treatment with to taxanes in the neoadjuvant setting and supports the use of SEPT9v2 expression levels in determining whether to use taxane treatment or other drug treatment in the neoadjuvant setting, facilitating the use of microtubule targeted chemotherapy in a more personalized manner.

#4620 Assessing the impact of germline and somatic variants in breast cancer treatment.

Jonathan V. Wooten[1], Santiago Avila[2], Becca Pollard[3], Sheila Rajagopal[4]

[1]National Cancer Institute, Rockville, MD,[2]Pritzker School of Medicine, University of Chicago, Chicago, IL,[3]Harvard University, Cambridge, MA,[4]National Cancer Institute, Bethesda, MD

Germline genetic variants are hereditary DNA alterations, whereas cancer somatic variants originate in the tumor. For patients with breast cancer, treatment approvals focus on either germline or somatic data with no consideration of co-occurrence. As such, most clinical datasets lack either germline or somatic variant designation, and most molecular oncology datasets contain limited treatment information, focusing primarily on survival. Datasets that contain germline and somatic sequencing and treatment information are typically from single institutions, limiting their statistical power. This project seeks to aggregate datasets inclusive of germline and somatic sequencing and treatment information with the goal of starting to assess the effect of co-occurring variants on treatment response in breast cancer.

We reviewed breast cancer datasets in CBioPortal and papers published in the past 15 years for germline and somatic sequencing with reported variants, treatment information, and associated responses. We identified 3 datasets: The Cancer Genome Atlas, The Metastatic Breast Cancer Project, and Fudan University Shanghai Cancer Center (BC cohort). We evaluated a total of 7 co-occurring gene pairs obtained from literature review: *BRCA1* and *BRCA2*; *BRCA2* and *RB1*, *BRCA1* or *2* and *TP53*, *PTEN*, *PIK3CA, MYC*; and *PALB2* and *NOTCH2*. We used the NIH Integrated Data Analysis Platform to harmonize variant calls across these datasets. For early-stage disease, we assessed disease-free survival (DFS) in response to the classes of chemotherapy or hormone therapy. For metastatic disease, we assessed duration of treatment response for specific treatments.

We were able to assess one gene pair using our dataset – *BRCA1/2* and *TP53*. Other gene pairs had 0-2 patients with co-occurring variants, limiting statistical analysis. We observed statistically significant differences in DFS among early-stage patients who received chemotherapy (Kruskal-Wallis test: <0.05), but observed patients with *BRCA1/2* alone having shorter DFS relative to those with *TP53* regardless of co-occurrence:No variants (n=212): Mean=33.32 months (SD=26.7 months)*BRCA1/2* alone (n=141): Mean=18.32 months (SD=13.91 months)Co-occurring (n=10): Mean=49.17 months (SD=38.14 months)*TP53* alone (n=95): Mean=41.45 months (SD=31.88 months)

In the context of treatment, significantly more publicly available, better annotated data will be required to understand the influence of co-occurring variants, germline origin, and somatic origin on treatment response. In this preliminary analysis, we observed differential patterns of changes in treatment response based on the presence or absence of *BRCA1/2* and *TP53*. These genes commonly co-occur – where co-occurrence is less common, we lacked power for our analysis. This question is under-addressed and may potentially influence treatment response and decision-making.

#4621 Beyond tumor biomarkers: Multiparametric biophysical assessment of T cells from peripheral blood to inform checkpoint blockade therapy.

Robert Kimmerling[1], Selim Olcum[1], Mark Stevens[1], Rachel LaBella[1], Madeleine Vacha[1], Katelin Katsis[1], Reginald Aikins[1], Steven Wasserman[1], Tatyana Sharova[2], Aleigha Lawless[2], Sonia Cohen[2], Genevieve Boland[2]

[1]TRAVERA, Medford, MA,[2]MGH, Boston, MA

Clinical decisions for immune checkpoint blockade (ICB) treatment currently rely on tumor-based biomarkers such as mutational burden, microsatellite instability, and PD-L1 expression. While these markers serve as valuable proxies for tumor antigenicity and the immune status of the tumor microenvironment, they fail to account for the fitness of a patient's T cells, a critical factor in anti-tumor immunity. Direct assessment of T cell functional capacity could complement existing biomarkers to improve patient stratification and efficacy prediction for ICB therapies. Our previous work showed that single-cell mass measurements serve as a label-free means of assessing immune cell activation and ICB response. T cells from patients with various malignancies displayed significant variability in both their activation capacity and ICB response ex vivo, indicating that mass measurements capture key functional differences in T cells across patients.Here we present a next-generation platform that measures cell mass alongside linked measurements of volume, density, and morphological features. This platform incorporates fluorescence exclusion measurements to determine single-cell volume which, when combined with cell mass, enables precise determination of single-cell density. Additionally, we utilize inline brightfield imaging to capture images from individual cells and extract morphological features using an autoencoder-based reconstruction model.Our results show that multiparametric measurements significantly enhance the ability to characterize T cell functional states. In activation experiments using healthy donor T cells, these combined signatures reveal notable phenotypic changes as early as six hours after activation—changes that remain undetectable with mass measurements alone.In a cohort of peripheral blood samples from patients with advanced melanoma, we observed substantial heterogeneity in T cell biophysical signatures at baseline and following stimulation, with and without immune checkpoint blockade. These signatures were distinct from those observed in T cells derived from healthy donor PBMCs.These findings underscore the potential of a blood-based functional precision medicine assay to assess patients' baseline immune fitness. When integrated with existing clinical biomarkers, these unique functional signatures offer orthogonal insights that could improve patient stratification for immune checkpoint inhibitor therapies. Moreover, the multiparametric nature of these measurements aligns well with emerging multimodal AI approaches, paving the way for more effective identification of patients most likely to benefit from these treatments.

#4622 Proteomic insights into anti-CTLA4 therapy resistance in metastatic melanoma: Pathway-specific biomarkers for treatment response.

Katherine Bronson, Nathan Avaritt, Erin Taylor, Alan Tackett

University of Arkansas for Medical Sciences, Little Rock, AR

The current standard of care for metastatic melanoma includes immune checkpoint inhibitor (ICI) therapy that, although revolutionary for melanoma treatment, is ineffective for most patients long-term. According to clinical data, patients have a limited response to anti-PD1 and anti-CTLA4 immunotherapy treatment, with overall response rates of roughly 40% and 15% respectively, and increasing to 60% with combination therapy. However, with half of patients not responding to combination therapy or acquiring resistance to therapy as the treatment progresses, there is an evident need for identifying and vetting more reliable biomarkers for treatment response or resistance. Although up-to-date ICI treatment often includes both anti-PD1 and anti-CTLA4 effectiveness, the different treatment regimens have independent factors of patient responsiveness. Anti-PD1 therapy directly mediates tumor-immune interactions, permitting immune system activation; however, protein levels of PD1 or its ligand is a poor indicator of responsiveness. Recent data suggests an enrichment in oxidative phosphorylation and lipid metabolism in anti-PD1-responsive patients. Identifying key biomarkers for response to CTLA4 therapies is more nuanced, as its mode of action occurs outside of the tumor microenvironment. Due to this, the approach to identifying tumoral patterns or biomarkers that indicate anti-CTLA4 responsiveness is more nuanced. To identify anti-CTLA4 response-specific biomarkers, we collected metastatic melanoma tumors from patients prior to ICI treatments and sorted them as responders or non-responders depending on patient response. The tumor proteome from patients treated with anti-CTLA4 therapy was analyzed via tandem mass tag (TMT) mass spectrometry to mark differentially expressed proteins between responder and non-responder groups. Comparative pathway analyses on platforms such as Ingenuity Pathway Analysis (IPA) and GSEA found several distinct protein and pathway enrichments, including that anti-CTLA4 non-responding patient tumors were enriched for pathways such as oxidative phosphorylation and fatty acid metabolism. This anti-CTLA4-specific enrichment is distinct from anti-PD1-treated patient tumors. These differences between the ICI treatment responses could be used clinically to inform patient treatment plans and improve the likelihood for response to initial treatments. Future studies will elucidate the function of specific proteins and pathways in ICI resistance as well as identify potential novel neoadjuvant therapies to increase patient responsiveness to ICI therapies.

#4623 The relationship of KRAS mutation and clinical outcomes in patients treated with consolidation durvalumab for locally advanced non-small cell lung cancer.

W. J. Phillips, M. Pradier, D. J. Stewart, S. Moore;
University of Ottawa, Ottawa, ON, Canada

Introduction: *KRAS* G12C is associated with a favorable response to immunotherapy in patients with advanced non-small cell lung cancer (NSCLC), while other *KRAS* variants show mixed effects. In addition, there is little known on how *KRAS* mutations affect immunotherapy responsiveness in the curative setting. This study aims to evaluate the impact of *KRAS* mutations on clinical outcomes of patients treated with consolidation durvalumab for unresected locally advanced NSCLC.

Methods: Clinical data were gathered from the medical records of patients seen at The Ottawa Hospital Cancer Centre from June 1, 2019 to Mar 1, 2024. Adult patients with non-squamous NSCLC who completed chemoradiation therapy and received at least 1 dose of consolidation durvalumab were included. Patients were grouped by KRAS mutation as follows, (1) G12C, (2) non-G12C, or (3) wild type/unknown. Real world progression free survival (PFS) was the primary outcome. Univariable analysis was performed using the Cox Proportional Hazards Model.

Results: 78 patients were included. The median age was 68 years old and 64% of patients were female. PDL1 expression was <1% in 14 (18%) patients, ≥1% in 51 (65%), and missing in 13 (17%). 50 cases were tested for KRAS and 31 (62%) harbored a KRAS mutation. Of those, 16 (32%) were G12C and 15 (30%) were non-G12C. Non-G12C point mutations included G12V (n=6), G12A (n=3), G12D (n=3), G13D (n=2), and G13V (n=1). The median PFS of the entire cohort was 40.6 months (95% CI: 23.1-58.2), G12C mutated was 32.1 months (95% CI: 26.0-38.1), and non-G12C was 20.5 months (95% CI: 12.7-28.3). Compared to KRAS wild type/unknown, there was a trend to improved PFS in patients with G12C mutations (hazards ratio (HR) 0.48, p=0.17), and shortened PFS in patients with non-G12C (HR 1.47, p=0.35). Furthermore, PDL1≥1% was associated with improved PFS (HR 0.21, p<0.01).

Conclusions: This study demonstrates the potential prognostic value of both *KRAS* G12C and non-G12C mutations in locally advanced unresectable NSCLC treated with consolidation durvalumab. It also supports PDL1 expression as an established biomarker of immunotherapy sensitivity in the real world. Further studies to prospectively validate KRAS as a predictive marker are warranted.

#4624 Analysis of the characteristics of immune microenvironment in non-small cell lung cancer patients with EGFR amplification and exploration of immunotherapy.

Zhi Xian Jin, Min Chen, Xu He, Hong Bi, Chao Yang, Jing Shao, Zhaoming Huang, Yuyan Zhou, Cuilin Yang

Department of Pulmonary and Critical Care Medicine, Affiliated Calmette Hospital of Kunming Medical University and The First People's Hospital of Kunming City, Kunming, China

Background: EGFR is the most common driver gene in Asian NSCLC patients, and its association with tumors and the efficacy of targeted therapy for sensitive mutations are well-established. According to current guidelines, first-line immunotherapy is not recommended for patients with EGFR-sensitive mutations. However, the treatment strategy for EGFR variants with limited sensitivity to TKIs remains unclear. EGFR amplification has been shown to exhibit resistance to TKIs in several studies, and its relationship with immunity has yet to be definitively established. Therefore, exploring the immune microenvironment to assess the efficacy of immunotherapy in this context holds significant clinical value.

Methods: Tumor tissue samples from 210 Chinese lung adenocarcinoma (LUAD) patients were analyzed using next-generation sequencing (NGS) and multiplex immunohistochemistry (mIHC). The mIHC analysis, performed with the Akoya Detection Kit targeting 13 markers, quantified immune cell percentages among total cells, offering insights into the distribution of cell subpopulations within the tumor and stromal compartments.

Result: Among the enrolled patients, 114 had EGFR point mutations and insertion-deletion mutations (54.3%), with 83 cases of L858R and 19del mutations, and 31 cases of EGFR amplification (14.8%), which is consistent with previous studies. An analysis of the immune microenvironment characteristics among patients with EGFR wild-type (EGFRwt), EGFR-sensitive mutations (EGFRm), and EGFR amplification (EGFRa) revealed that the levels of CD8+PD-1+ cells in the tumor stroma were significantly higher in the EGFRwt (P=0.008) and EGFRa (P=0.025) groups compared to the EGFRm group. Additionally, the NK cell levels in the tumor stroma were significantly higher in the EGFRwt group (P=0.037) compared to the EGFRm group, while no significant difference was found between the EGFRa and EGFRm groups (P=0.071). Although there were no significant differences in the infiltration levels of macrophages, T cells, and B cells between the three groups in the tumor parenchyma and stroma, the numbers were generally slightly higher in the EGFRwt and EGFRa groups compared to the EGFRm group.

Conclusions: The results of this study suggest that the level of immune cell infiltration in the EGFR amplification group is higher than in the EGFR-sensitive mutation group. This may indicate that EGFR amplification patients could have better outcomes with immunotherapy compared to those with EGFR mutations. Therefore, immunotherapy as a first-line treatment may offer greater benefits for EGFR amplification patients, providing a potential mechanistic basis for the treatment strategy of this patient population.

#4625 The optimal tumor mutational burden cutoff value for predicting the efficacy of the PD-1 checkpoint inhibitor combined with chemotherapy in advanced gastric cancer.

Jaeyeon Jang[1], Youngkyung Jeon[2], Sun Young Jeong[2], Sung Hee Lim[2], Jeeyun Lee[2], Seung Tae Kim[2]

[1]Division of Hematology-Oncology, Department of Internal Medicine,, Wonju Severance Christian Hospital, Yonsei University, Wonju College of Medicine, Wonju-si, Korea, Republic of,[2]Division of Hematology-Oncology, Department of Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Purpose: Chemotherapy is associated with an increase in tumor mutational burden (TMB). When receiving the combination of programmed cell death-1 (PD-1) checkpoint inhibitor and chemotherapy, TMB can be a better option for predicting the response, especially for tumors with initially low TMB. We aimed to investigate the optimal TMB cutoff value that could predict the efficacy of PD-1 checkpoint inhibitors combined with chemotherapy in advanced gastric cancer. **Materials and Methods:** Patients with AGC who received nivolumab with capecitabine and oxaliplatin as the 1st line palliative treatment, between September 1, 2021, and July 15, 2023, at Samsung Medical Center in Korea were retrospectively analyzed. The TMB levels were measured using a next-generation sequencing assay. Based on receiver operating characteristic curve analysis, the TMB cutoff value was determined. **Results:** A total of 101 patients were analyzed. The TMB cutoff value for predicting the overall response rate (ORR) to nivolumab combined with capecitabine and oxaliplatin was defined as 10.2 mutations per megabase (mt/Mb) with 97.7% sensitivity and 22.4% specificity. Based on this definition, 14 (13.9%) patients were TMB-high (TMB-H). The ORR differed between the TMB-low (TMB-L) and TMB-H groups (51.7% vs. 92.9%, P=0.004). The progression-free survival (PFS) and overall survival (OS) for 101 patients were 11.8 (95% confidence interval [CI], 8.46-15.14) and 27.9 months (95% CI, 20.34-35.45), respectively. The median PFS tended to be longer in the TMB-H group (22.0 months; 95% CI, 11.86-32.14) than in the TMB-L group (11.1 months; 95% CI, 8.56-13.64; P=0.217). The median follow-up duration of the TMB-H group was 23.7 months, and the median OS was not reached. The median OS of the TMB-L group was 27.9 months (95% CI 20.50-35.23; P=0.241). **Conclusions:** The TMB cutoff value for predicting treatment response in AGC patients who received the PD-1 checkpoint inhibitor combined with capecitabine and oxaliplatin as the 1st line palliative treatment was 10.2 mt/Mb. When applying the programmed death ligand-1 status to TMB, patients who would benefit from PD-1 checkpoint inhibitors can be selected.

#4626 A machine learning model for predicting hyperprogressive disease risk in cancer immunotherapy: Integrating clinical and molecular data.

Haitao Wang[1], Lili Wang[1], Yu Zhang[1], Hongzheng Li[1], Nan Li[1], Qijie Jian[2], Yaxian Wang[2], Zhijian Song[2], Fei Pang[2], Kai Wang[2]

[1]The Second Hospital of Tianjin Medical University, Tianjin, China,[2]OrigiMed, Shanghai, China

Background
Immunotherapy has revolutionized cancer treatment, offering significant efficacy across various cancer types. However, hyperprogressive disease (HPD)—a severe and unexpected acceleration of tumor growth—poses a critical challenge, as some patients experience this adverse effect. Early and accurate identification of HPD risk is essential for optimizing immunotherapy strategies and improving patient outcomes. To address this, we developed a machine learning-based predictive model for HPD risk across cancer types, integrating clinical and molecular data.
Methods
This study analyzed data from 1,005 patients with solid tumors treated with at least one dose of immune checkpoint inhibitors between 2018 and 2024. After stringent data preprocessing, feature selection was performed using chi-square and Fisher's exact tests to identify significant variables associated with HPD. Logistic regression evaluated feature importance, accounting for multicollinearity, correlation, and interpretability. A random forest algorithm was then employed to construct a predictive model based on selected features.
Results
From an initial pool of 44 variables, eight features were identified as significant predictors of HPD, including HPD-associated genes, immunotherapy resistance genes, cancer type, bone metastasis, the number of metastatic sites, lactate dehydrogenase levels, neutrophil-to-lymphocyte ratio, and treatment regimen. Patients lacking pre-immunotherapy genetic and blood test data for the selected features were excluded, resulting in a final cohort of 363 patients across 17 cancer types, including 52 HPD cases and 311 non-HPD cases. The model demonstrated strong predictive performance, achieving a cross-validated AUC of 0.87, sensitivity of 0.90, and specificity of 0.78. On an independent test set, the model attained an AUC of 0.71, sensitivity of 0.70, specificity of 0.73, and overall accuracy of 73%. Using the same eight features, a traditional logistic regression model was constructed (AUC = 0.66) and found to be less effective than the machine learning model.
Conclusions
We identified eight statistically and clinically significant predictors of HPD and developed the first high-sensitivity pan-cancer predictive tool combining molecular and clinical features. This machine learning-based approach enhances HPD risk stratification, assisting clinicians in tailoring immunotherapy and mitigating risks, ultimately improving patient outcomes across cancer types.

#4627 Correlation of early circulating tumor DNA dynamics with whole body FDG PET/CT parameters during immune checkpoint inhibitor therapy in advanced stage melanoma.

Vincent T. Ma[1], Fauzia Hollnagel[2], Tomas A. Romero[3], Janmesh D. Patel[1], Alexander Birbrair[4], Robert J. Jeraj[5], Mark R. Albertini[1], Steve Y. Cho[3], Nandakumar Menon[3]

[1]Medicine; Division of Hematology, Medical Oncology, and Palliative Care, University of Wisconsin Carbone Cancer Center, Madison, WI,[2]Medicine, University of Wisconsin Carbone Cancer Center, Madison, WI,[3]Radiology, University of Wisconsin Carbone Cancer Center, Madison, WI,[4]Dermatology, University of Wisconsin Carbone Cancer Center, Madison, WI,[5]Medical Physics, University of Wisconsin Carbone Cancer Center, Madison, WI

Background: Evaluation of tumor volume change and [^{18}F]Fluoro-2-deoxy-2-D-glucose (FDG) uptake using whole-body PET/CT is frequently used to evaluate treatment response with immune checkpoint inhibitors (ICIs) in patients with advanced stage melanoma. We previously reported that early circulating tumor DNA (ctDNA) dynamics after 3-4 weeks of ICI initiation appears to be a candidate biomarker to predict treatment response. This study explores the correlation between early ctDNA dynamics and various FDG PET/CT parameters in ICI-treated patients with advanced melanoma.

Methods: A prospective study was conducted for patients with unresectable stage III/IV melanoma who underwent personalized, tumor-informed ctDNA analysis (Natera) and whole-body FDG PET/CT imaging at baseline and at 3-4 weeks after treatment initiation (prior to the second dose of ICI therapy). Assessed FDG PET/CT parameters included: largest target lesion (TaL) volume, TaL SUV_{max}, TaL SUV_{max} to liver mean ratio, total lesion (ToL) SUV_{max}, ToL SUV_{max} to liver mean ratio, ToL SUV_{mean}, and ToL SUV_{mean} to liver ratio. Correlation coefficients were calculated to evaluate the relationship between early ctDNA dynamics and FDG PET/CT parameter changes.

Results: Nine patients were evaluated, with a median age of 65 and a median baseline total number of metastatic lesions per patient of 6. Primary sites of melanoma included cutaneous (59%, 5/9), primary unknown (22%, 2/9), uveal (11%, 1/9), and mucosal (11%, 1/9). Disease stages included M1d (33%, 3/9), M1c (11%, 1/9), M1b (33%, 3/9), and M1a (22%, 2/9). Treatment regimens were split between ipilimumab/nivolumab (56%, 5/9) and nivolumab/relatlimab (44%, 4/9). All subjects with ctDNA decrease at 3-4 weeks had an overall partial response (6/9, 67%) or stable disease (1/9, 11%); and all other subjects with ctDNA increase had progressive disease (2/9, 22%) per RECIST v1.1. Strong correlations were observed between early ctDNA dynamics and changes in largest TaL volume ($r = -0.9541$), ToL SUV_{max} ($r = 0.8697$), and ToL SUV_{max} to liver mean ratio ($r = 0.8414$). Weak to moderate correlations were identified for other parameters.

Conclusions: This study demonstrates very strong correlations between early ctDNA dynamics and several FDG PET/CT parameters, including largest TaL volume, ToL SUV_{max}, and ToL SUV_{max} to liver mean ratio. These findings highlight the potential of using ctDNA and FDG PET/CT as multifaceted early biomarkers of response to assess ICI efficacy. Ongoing patient enrollment and validation efforts are essential to establish their role in response-adapted treatment studies.

#4628 Exploring the differences in immunotherapy efficacy and immune microenvironment characteristics among colorectal cancer patients with different notch receptor gene subtypes.

Junyi Chen[1], Jiahui Fang[2]

[1]Department of Gastrointestinal Surgery, Shanghai Fourth People's Hospital, School of Medicine, Tongji University, Shanghai, China,[2]General Practice, Gaojing Town Community Health Service Center Shanghai, Shanghai, China

Background: The NOTCH signaling pathway is a highly conserved signaling system regulated by close-range cell-to-cell interactions. The interaction between NOTCH receptors (NOTCH1-4) and "classical" ligands, or the activation of other non-classical pathways, is associated with the occurrence and progression of various tumors. Although some studies have confirmed a correlation between the efficacy of immunotherapy and NOTCH gene mutations, no definitive conclusion has been reached in colorectal cancer. Exploring the tumor immune microenvironment may help us find better answers.
Methods: An independent cohort (MSKCC) comprising next-generation sequencing (NGS) data from 109 pan-cancer colorectal cancer (CRC) patients on immunotherapy outcomes. Tumor tissue samples from 249 Chinese CRC patients were analyzed using NGS and multiplex immunohistochemistry (mIHC). The mIHC were stained using the Detection Kit (Akoya), targeting 13 markers Results, showing immune cell percentages of total cells, provided insights into cell subpopulation distributions in tumor and stroma.
Result: In the MSKCC cohort revealed that CRC patients with NOTCH3 mutations had significantly longer overall survival (OS) following immunotherapy (11.5 m VS 8 m; P = 0.008). In contrast, although patients with mutations in other NOTCH pathway genes showed numerically longer OS compared to the wild-type group, the differences were not statistically significant. In Chinese patients, Among the 249 Chinese CRC patients included in the study, 21.7% (54/249) carried NOTCH gene mutations, with mutation rates of 12.0% for NOTCH1, 7.6% for NOTCH2, 11.6% for NOTCH3, and 7.2% for NOTCH4. Further analysis of the immune microenvironment characteristics revealed that patients with NOTCH1 (P=0.002), NOTCH2 (P=0.003), and NOTCH3 (P=0.0192) mutations had significantly higher levels of CD8+ T-cell infiltration in the tumor parenchyma compared to the wild-type, while no significant differences were observed for the other mutations. An additional analysis of differences between the tumor parenchyma and stroma showed that the percentage of CD8+ T cells in the tumor stroma was significantly higher than in the parenchyma for patients with NOTCH3 mutations (P=0.0307), whereas no significant differences were observed for the other three mutation subtypes. Similarly, patients with NOTCH3 (P=0.0446) and NOTCH4 (P=0.0285) mutations exhibited significantly higher levels of NK cell infiltration in the tumor parenchyma compared to the stroma.
Conclusions: NOTCH pathway genes have a better immune microenvironment, which may be the reason for the better immune efficacy of patients with Notch pathway mutations. In particular, NOTCH3 has more CD8+ T cell reserves in stroma and more NK into the tumor parenchyma, which shows significantly better immune efficacy.

#4629 Plasma exosomal miRNA and disease progression in metastatic breast cancer on CDK4/6 inhibitors: A feasibility study.

Ding Quan Ng[1], Julia Trudeau[1], Casey Hudson[2], Khai Kober[1], Kord M. Kober[3], Munjal M. Acharya[2], Alexandre Chan[1], Ritesh Parajuli[4]

[1]Clinical Pharmacy Practice, University of California, Irvine, Irvine, CA,[2]Anatomy & Neurobiology, University of California, Irvine, Irvine, CA,[3]Physiological Nursing, University of California, San Francisco, San Francisco, CA,[4]UCI Chao Family Comprehensive Cancer Center, Orange, CA

Background: Treatment resistance is common among metastatic breast cancer patients receiving CDK4/6 inhibitors (CDKi). Exosomal miRNA play a key role in intercellular communication and gene regulation that may predict treatment outcomes. We hypothesize that patient's blood exosomal miRNA can uncover biological pathways critical for CDKi response and resistance.
Methods: Plasma samples from metastatic breast cancer patients were prospectively collected every 12 weeks during CDKi treatment until discontinuation. Next generation sequencing was performed on isolated plasma exosomes for miRNA profiling. MiRNA independently associated with treatment response (hazard ratio [HR] < 1) and resistance (HR > 1) after Bonferroni correction were identified with mixed-effects Cox regression with time-to-disease progression as the outcome. We generated a miRNA-gene network using miRNet and performed pathway enrichment analysis of target genes using hypergeometric test.
Results: Eleven patients provided 26 samples during CDKi treatment. Five (45%) progressed; they were more likely to be hormone receptor negative (40% vs 0%) and a race-ethnic minority (80% vs 17%). After adjustment, 54 and 18 miRNAs were associated with treatment response and resistance, respectively. A total of 48 pathways (false discovery rate [FDR] < 0.05) were identified in relation to treatment outcomes (Table 1). Of these, 25 pathways (52%, e.g. TGF-β, insulin, Jak-STAT) were associated exclusively with response, 2 (4%, long-term depression and oocyte meiosis) were associated with resistance, and 21 (44%, e.g. cell cycle, p53, neurotrophin) were shared by both. The study's feasibility is demonstrated by the identification of numerous cell-cycle and cancer-specific pathways.
Conclusion: This study highlighted the potential of exosomal miRNA as gene expression modulators to uncover key pathways underlying CDKi treatment outcomes. Findings warrant validation in independent studies.

Table 1: Select significant biological pathways († FDR<0.05)

FDR<0.5 for response, resistance, or both	Pathways	Response: P-value	Response: FDR	Resistance: P-value	Resistance: FDR
Response	Apoptosis	2.19E-02*	***4.76E-02†***	1.79E-01	2.45E-01

#4630 A novel approach to define ctDNA molecular response to immunotherapy.

John Guittar[1], Sandra Hui[1], Terri Driessen[1], Wei Zhu[1], Christine Lo[1], Akash Mitra[1], Michelle Stein[1], Halla Nimeiri[1], Rotem Ben-Shachar[1], Wade T. Iams[2]

[1]Tempus AI, Inc., Chicago, IL,[2]Tennessee Oncology, Nashville, TN

Molecular biomarkers that quantify changes in circulating tumor DNA (ctDNA) can predict clinical outcomes. However, there is no consensus on classification of molecular responders (MRs) and molecular non-responders (nMRs), who may benefit from early treatment intervention. We explored the classification of MRs vs. nMRs in a real-world pan-cancer cohort of patients treated with immune checkpoint inhibitor (ICI) therapy in two ways. (1) As previously described, a ≥ 50% decrease in ctDNA tumor fraction (TF) between baseline and on-treatment time points (MR50), and, (2) hypothesizing that consistently low TF may represent a favorable subgroup with prolonged outcomes despite small increases in TF, MRlow, we evaluated a "low TF" threshold, above the TF detection rate, classifying patients as MRlow if TF remains below the TF threshold at both timepoints, regardless of magnitude change.

The cohort consisted of advanced cancer patients from the Tempus de-identified clinicogenomic database who received a liquid biopsy at pre-treatment baseline and within 21-180 days after starting ICI therapy. TF was quantified via an ensemble algorithm, xM for treatment response monitoring, that incorporates pathogenic variant allele frequencies, copy number information, and germline information. Evaluable patients had TF ≥ limit of blank in at least one blood sample. Real-world overall survival (rwOS) was defined as the time from on-treatment testing to death or last known clinical record in event-free patients. Cox proportional hazards models were used to estimate the hazard ratio (HR) for MR status (MR vs. nMR) and tests for significance were conducted using 1-sided Wald tests at a 5% significance level.

The evaluable cohort consisted of 71 advanced pan-cancer patients with >10 cancer types; most commonly NSCLC (38.0%, n=27) and small cell lung cancer (19.7%, n=14). Twenty-five patients (35.2%) were treated with ICI monotherapy and 46 (64.8%) were treated with ICI-chemotherapy combination.

Using a definition of MR of a 50% decrease in TF alone, 44 patients were MRs and 27 patients were nMRs, with MRs having significantly longer rwOS than nMRs (HR=0.44, P=0.012). We next evaluated various low TF thresholds and found that a 1% low TF threshold further improved the association between MR and rwOS (HR = 0.32, P = 0.0008). 53 patients were classified as MRs [18 MRlow + 35 MR50] and 18 patients were classified as nMRs. Of the MRlow patients, 6 had increasing TF. Median rwOS for nMRs was seven months and not reached at 18 months for both MRlow and MR50.This study suggests that patients with consistently low TF below 1% while on ICI therapy (MRlow), regardless of TF changes, represent a unique, biologically differentiated, prognostic group. Our study suggests that MRlow patients have prolonged rw-survival, similar to molecular responders based on a 50% decrease in TF (MR50). Prospective validation for this threshold is planned.

#4631 Deciphering immunotherapy response variability and immune-related toxicities through longitudinal multimodal ctDNA analysis in advanced melanoma.

Z. Cheng[1], S. McDonald[1], H. Thomas[1], Z. Zhou[1], P. Mennea[1], H. wang[1], D. Shcherbo[1], C. Zhang[1], G. McAndrew[1], F. Talukdar[1], W. N. Cooper[1], H. Zhao[1], N. Rosenfeld[2], P. G. Corrie[1], A. Roshan[1];

[1]University of Cambridge, Cambridge, United Kingdom, [2]Queen Mary University of London, London, United Kingdom

Background: Immune checkpoint inhibitors (ICIs) have revolutionized treatment of advanced cutaneous melanoma by leveraging the host immune system to target and eliminate tumour cells. However, predictive biomarkers for clinical response to ICIs remain elusive, limiting the ability to stratify patients effectively. The heterogeneity in treatment outcomes, coupled with the limited sensitivity and timeliness of radiographic assessments, particularly in patients with stable disease, underscores the urgent need for molecularly guided, minimally invasive approaches for real-time monitoring of therapeutic efficacy. Biomarkers, such as circulating tumour DNA (ctDNA) and T-cell clonal dynamics, offer promise not only in assessing tumour burden and dynamics but also potentially in providing early indicators of immune-related adverse events (irAEs).

Methods: We analysed 70 longitudinal plasma samples from 13 patients with resectable or unresectable, Stage III melanoma from the MELResist study. These patients were treated with either pembrolizumab or a combination of ipilimumab and nivolumab. PD1/PDL1 expression in FFPE tumour samples was quantified using digital pathology, and deep whole-genome sequencing (around 30x coverage) was performed on tumour tissue to profile genomic alterations. By integrating ctDNA analysis (>10x WGS coverage) with matched tumour samples using the cfDNAPro, ichorCNA and INVAR2 pipelines, we conducted serial WGS-based monitoring to evaluate molecular response dynamics as measured by copy number alterations, fragmentomics and patient-specific tumour mutations respectively. Additionally, irAEs were assessed through longitudinal tracking of the peripheral T-cell repertoire (TCR) using TCR-sequencing of buffy coat samples, alongside with plasma protein expression profiling via the Olink Explore panel.

Results: In evaluating ctDNA molecular response, we found a copy number fraction ranging from 0 to 42% by ichorCNA analysis, with higher fractions at later timepoints correlating with poorer overall survival. Fragmentomic analysis revealed changes in 4-mer end motif frequencies and the ratio of short-to-long fragments (100-150 bp vs. 151-220 bp). Specifically, a decreased CCCA motif frequency and an increased short-to-long fragment ratio at later timepoints were associated with poorer overall survival.

Conclusion: ctDNA dynamics during immunotherapy for advanced melanoma reflect clinical outcomes. Changes in ctDNA can be identified using tumour informed methods with high sensitivity but at additional cost or tumour agnostic methods with lower logistical burden. Together with our assessment of T-cell clonal dynamics and proteomic changes, these approaches will offer valuable insights for monitoring therapeutic benefits and immune-related adverse events (irAEs) during immunotherapy.

#4632 Molecular determinants to neoadjuvant chemotherapy resistance in breast cancer patients: Insights from a Latin-American cohort.

H. M. Guevara-Nieto[1], C. A. Orozco[1], R. S. Parra-Medina[1], J. Zabaleta[2], L. Lopez-Kleine[3], A. L. Combita[1];
[1]Instituto Nacional de Cancerologia, Bogota, Colombia, [2]Louisiana State University Health Sciences Center, New Orleans, LA, [3]Universidad Nacional de Colombia, Bogota, Colombia

Neoadjuvant chemotherapy (NAC) is vital in treating primary breast cancer, yet the mechanisms behind its success are not fully understood. Understanding transcriptomic changes associated with NAC resistance is crucial for improving treatment. This study sought to identify transcriptomic alterations linked to NAC resistance, enhance comprehension of treatment resistance, and lay the groundwork for developing targeted strategies for patients unresponsive to standard NAC protocols.We analyzed the transcriptomes of 44 matched breast cancer specimens from nonresponder patients to NAC at the Colombian National Cancer Institute. Samples were collected before and after NAC, representing luminalA, luminalB/HER2-positive, luminalB/HER2-negative, and TNBC subtypes. We performed differential gene expression and enrichment analyses and compared hallmark gene sets. Furthermore, we used deconvolution algorithms to estimate tumor microenvironment (TME) infiltration and assess immune population activity within the TME. Our findings were compared with publicly available GEO database data.Gene expression patterns before and after treatment were distinct across subtypes, with FOS and NR4A1 common to all, and ZBTB16 unique to luminalB. FOSB was found in all luminal samples. ATF3, DUSP1, EGR1, and JUN were shared among HER2-negative subtypes. GEM was common to luminalA and LuminalB/HER2-negative subtypes. Pathway variations included complement and coagulation cascades, and IL-17, TNF, MAPK, and NF-κB signaling pathways among subtypes and post-NAC specimens. Post-treatment LuminalA samples had increased CD4 memory cells, Tregs, and neutrophils. The LuminalB/HER2+ group showed higher CD8+ and CD4+ memory-activated cells post-treatment. In LuminalB/HER2- post-treatment samples, B cell CD4 memory resting, Macrophages M2, and neutrophils were elevated. TNBC post-treatment samples had higher resting mast cells and CD4+ memory cells. MSIGBD comparison of gene sets linked to cisplatin, docetaxel, and doxorubicin resistance identified several shared genes. GeoDatabases confirmed FOS and NR4A1 across all groups, with other DEGs shared among subtypes.Our research indicates that NAC affects gene expression, cell function, and interactions within the TME, potentially contributing to treatment resistance. Assessing TME components is crucial for predicting NAC effectiveness and reducing the risk of recurrence. These results highlight the importance of studying diverse patient populations to gain fresh perspectives and address disparities in treatment outcomes. This investigation emphasizes the need to understand how TME influences chemotherapy resistance, paving the way for the development of more precise and efficient therapeutic strategies.

#4634 Development of novel monoclonal antibody detection of ERα36 in breast cancer.

Alexandra C. Selico Dunn[1], Hogyoung Kim[1], DeZha A. Robinson[1], Sihyoung Kim[2], Clark J. Perkins[2], Sichan Kim[2], Emily L. S. Smith[1], Emma Elkins[1], Christopher Williams[1]

[1]Division of Basic Pharmaceutical Sciences, Xavier University of Louisiana, New Orleans, LA,[2]Biology and Applied Health Sciences, Xavier University of Louisiana, New Orleans, LA

Approximately 75% of breast cancer tumors express the estrogen receptor alpha steroid receptor. Canonical estrogen receptors ERα66 and ERβ1 are the main mediators of estrogen-dependent pathophysiology in mammals. However, numerous isoforms have been identified, stimulating unconventional estrogen response pathways leading to complex cellular and tissue responses. Estrogen receptor alpha plays essential roles in the human body, such as the reproductive organs and metabolic and inflammatory systems. Recent studies suggest that a 36 kD variant of ERα (ERα36, ERα isoform 4) may play a role in endocrine therapy resistance in breast carcinoma (BCa). However, a key limitation to discovering the precise role of ERα36 in BCa is the lack of reliable, commercially available antibodies. Most ERα polyclonal antibodies show poor antigen specificity, hindering the evaluation of ERα36 as a clinical biomarker in BCa. Our goal is to develop a reliable monoclonal antibody targeting ERα36, which could facilitate its development as a clinical biomarker in BCa. Here, we describe the development of hybridoma producing an ERα36 monoclonal antibody (34F11) followed by rigorous enrichment (ultrafiltration), purification (fast protein liquid chromatography), and affinity (spectral shift assay) characterization. We assessed the utility of 34F11 antibody in several applications (immunoblot, immunohistochemistry, and fluorescence cytometry). Here, we provide the first comparative characterization of a monoclonal antibody directed toward ERα36 for the potential implementation of biomarker detection in BCa.

#4635 Reg4-induced CD44ICD expression: A potential biomarker of human pancreatic cancer.

Tashvi Anand[1], Matthew A. Ciorba[2], **Kumar S. Bishnupuri**[1]

[1]Internal Medicine - Division of Gastroenterology, Washington University School of Medicine in St. Louis, St. Louis, MO,[2]Internal Medicine - Division of Gastroenterology, Matthew Ciorba, St. Louis, MO

Background and Aims: Regerating Gene 4 (Reg4) is highly upregulated in gastrointestinal (GI) malignancies including pancreatic cancers (PC). Numerous studies have demonstrated an association between higher Reg4 expression and PC tumor aggressiveness. However, the underlying mechanism remained unknown. Our recent studies identified CD44 intracytoplasmic domain (CD44ICD), a γ-secretase-mediated cleavage product of CD44, as a key downstream mediator of Reg4-signaling to activate genes involved in the regulation of cancer cell proliferation. We accordingly aimed this study to determine a link between Reg4/CD44ICD expression and PC patient survival and define its importance as an early biomarker for metastatic PC.

Methods: A closed IRB-approved human study with PC patient linked survival and invasion data was used to construct 3 tissue microarray (TMA) slides of resected specimens. TMA slides were immunostained using Reg4-specific rabbit polyclonal and CD44ICD-specific goat polyclonal antibodies. Spearman's correlation was used to study the association between individual proteins using percent mean expression (0-100%) and mean intensity (0, 1, 2, 3) as scored blindly by the pathologist. Product-limit survival estimates were obtained to estimate survival probability and log-rank tests were used to compare survival probability between groups. Patient-linked tumor grades were used to determine correlation between Reg4/CD44ICD expression and PC tumor grades.

Results: Assessing immunostaining scores in PC specimens, cytoplasmic Reg4 (R^2 = 0.121) and CD44ICD (R^2 = 0.1168) expression along with nuclear expression of CD44ICD (R^2 = 0.0261) showed a positive correlation with increasing PC grades. Analysis of product-limit survival estimates revealed that cytoplasmic expression of Reg4 and CD44ICD, and nuclear expression of CD44ICD in PC specimen was directly associated with poor patient survival irrespective of tumor grades. To determine the association of Reg4/CD44ICD expression with PC invasiveness, we extended our study and analyzed the patient linked lymphatic, venous and perinuclear invasion data. Following analysis, we observed almost universal presence of venous and perineural invasion in most of the PC patients without a direct correlation with cytoplasmic expression of Reg4 and CD44ICD, and nuclear expression of CD44ICD. However, we observed a significantly higher expression of nuclear CD44ICD in PC patients positive for lymphatic invasion, and data demonstrated a positive correlation between nuclear CD44ICD expression and lymphatic invasion (R^2 = 0.0699).

Conclusion: These results suggest that higher expression of Reg4 and CD44ICD constitute an important event responsible for poor survival of PC patients and identify CD44ICD as a key downstream mediator of Reg4 signaling, a potential therapeutic target and a critical biomarker of metastatic PC with lymphatic invasion.

#4636 Keratin 6 and SOX2 regulate growth, stemness, basal/squamous expression, and chemotherapy response in muscle-invasive urothelial carcinoma.

N. Nargis, A. Mehus, D. A. Sens;
University of North Dakota, Grand Forks, ND

Background and purpose: Urothelial carcinoma (UC) is prevalent globally and it is well-established that arsenic exposure is associated with development of UC. Muscle-invasive UC (MIUC) is aggressive and accounts for 25% of all diagnosed UC cases. Cisplatin-based treatment is the standard treatment for MIUC. Patients with MIUC often have a dismal prognosis and frequently acquire chemoresistance, especially if the tumors exhibit squamous differentiation (SD). UC can be further subtyped as being either basal or luminal based on gene expression signatures of the tumors. The basal tumors are considered more aggressive and are enriched with expression of genes associated with SD (KRT1, KRT5, KRT6, KRT14, and KRT16). The UROtsa cell line is derived from normal human urothelium and our lab has malignantly transformed these cells using arsenite (As^{3+}). The tumors derived from As^{3+}-transformed cells resemble clinical cases of basal MIUC displaying focal areas of SD and expression of basal keratins (KRT1, 5, 6, 14, and 16). Additionally, SOX2 was found to be overexpressed in these As^{3+}-transformed UROtsa cells. SOX2 expression in UC is correlated with reduced survival and promotes malignant stemness and proliferation. SOX2 is also associated with the development of cisplatin resistance in other cancers. The goal of this study was to define the role of KRT6 and SOX2 in regulating basal/squamous expression, regulating growth, and regulating sensitivity to cisplatin.

Methods: We performed stable lentiviral knockdown of KRT6 or SOX2 in the As^{3+}-transformed UROtsa cells (basal MIUC with SD), along with the commercially available UC cell lines 5637 (basal, invasive) and RT4 (luminal, non-invasive). After successful knockdown KRT6 or SOX2 in these cells, we assessed cellular proliferation and colony formation. Additionally, the gene/protein expression of the basal keratins along with other genes/proteins involved with growth and stemness were analyzed. Migration was evaluated using a wound healing assay and drug sensitivity was tested after KRT6 or SOX2 knockdown.

Results: Knockdown of KRT6 or SOX2 in the As^{3+}-transformed cells attenuated basal keratin expression, reduced cell proliferation, decreased colony forming abilities, and increased sensitivity to cisplatin compared to control cells. Furthermore, cell migration was reduced in SOX2 knockdown cells.

Conclusion: These results indicate that both KRT6 and SOX2 play critical roles in basal/squamous expression, growth, migration, and cisplatin sensitivity in MIUC. However, further *in vivo* studies are required to confirm the impact of KRT6 and SOX2 expression on tumor growth, SD, invasion, and chemotherapy response.

#4637 Nanomechanical signatures: novel class of clinically translatable biomarkers to predict response to immunotherapy in advanced solid tumors.

Sara Nizzero[1], Nahum Puebla-Osorio[2], Gitika Srivastava[3], **Reinier Oropesa Nunez**[3], Kathleen Graham[1], Papa Diogop Ndiaye[3], Joylise Mitchell[2], Ailing Huang[2], Thomas Riad[2], Carolina Ortiz-Velez[3], Sienna Welsh[3], Philipp Oertle[3], Tobias Appenzeller[3], Vittorio Cristini[4], Marko Loparic[3], Marija Plodinec[3], James W. Welsh[2]

[1]ARTIDIS INC, Houston, TX,[2]University of Texas MD Anderson Cancer Center, Houston, TX,[3]ARTIDIS AG, Basel, Switzerland,[4]Houston Methodist, Houston, TX

Background: Advancements in immunotherapy have opened new avenues for the treatment of solid tumors. However response remains poor, especially in case of advanced tumors where resistance to immunotherapy after initial response remains a significant challenge. In recent years it has become evident that mechanical properties of tumor and immune cells as well as of the tumor microenvironment (TME) pose an upstream challenge to efficacy of a variety of therapeutics, including immunotherapy. Approaches such as pretreatment with low-dose radiation therapy (LD-RT) to remodulate the physical tumor microenvironment in combination have shown promise in clinics, reporting as effective as fully extinguishing detectable tumors in patients with previously stage IV tumors in lung and liver. Accurate prediction of benefit by such strategies is of outmost importance. In this work, we report on a novel class of predictive, tumor-agnostic biomarkers for combination immunotherapies: nanomechanical signatures.

Methods: To characterize the nanomechanical signature, the clinically-embedded, tissue-preserving AFM-based Automated and Reliable Tissue Diagnostics (ARTIDIS) platform is used. ARTIDIS multimodal analysis includes integration with available histopathological and clinical data. Two preclinical models are used: PD1-resistant lung adenocarcinoma on 129Sv/Ev mice, and gastric cancer on NSG mice, treated with anti-CTLA and anti-PD1 in combination with LD-XRT and anti-mesothelin CAR-T cell therapy in combination with LD-XRT, respectively. Case reports from patients with advanced metastatic solid cancers resistant to immunotherapy enrolled under the on-going ARTIDIS Umbrella protocol at MDACC are also included.

Results: Our preclinical studies identify the nanomechanical signature of response to low-dose radiation and immunotherapy with high sensitivity, specificity and AUC (90%-99%). Furthermore, we can identify the unique nanomechanical signature of T cell infiltration. Our clinical studies confirm that a unique nanomechanical signature reflects TME remodulation in different therapeutic regiments among similar clinical and histopathological cases.

Conclusions. In this work we demonstrated across different therapeutic strategies, preclinical tumor models and clinical cases that the nanomechanical signature can quantitatively describe the TME remodulation upon LD-XRT that mediates restored response to immunotherapy. This work supports the use of nanomechanical signature as predictive biomarker of response to immunotherapy to be used to support clinical decision making.

#4638 Investigations on association of prognostically important pan-cancer genes with disease progression and acute transformation in CML indicate involvement of diverse cellular mechanisms.

Sabreen Alanazi[1], Sarah Alfayez[1], Maryam Butuwaybah[1], Nawaf Alanazi[1], Abdulkareem Algarni[1], Kanza Adeel[1], Yaqob Taleb[1], Aamir Aleem[2], Aemir Mohammed[2], Zafar Iqbal[1]

[1]King Saud bin Abdulaziz University for Health Sciences (KSAU-HS), Al Mubarraz, Saudi Arabia,[2]King Saud University, Riyadh, Saudi Arabia

Chronic myeloid leukemia (CML) is caused by the abnormal fusion of the bcr-abl gene which leads to the overexpression of tyrosine kinase function. Tyrosine kinase inhibitors (TKI) are targetable drugs that inhibit the kinase activity of the bcr-abl oncoprotein. They have been used over the last two decades and have shown tremendous efficacy in treating CML, specifically in chronic phase (CP-CML) and accelerated phase CML patients (AP-CML). However, disease progression to advanced stages, specifically blast crisis CML (BC-CML), leads to TKI resistance, morbidities and subsequently death, with a median overall survival of less than 2 years, despite all innovations in diagnosis, risk stratification and treatment modalities. Therefore, further investigations of gene mutations associated with CML progression is primarily essential in accurate prognostic stratification and patient-tailored treatment of advanced phase CML. As cancer is a molecular disease, different types of cancers have recently reported to share many common genomic variants. Therefore, this study aimed to investigate the association of prognostically-important pan-cancer genes with advanced phases in CML patients. The study included a total of 73 CML patients at different CML Phases (CP=41, AP=20, BC=12). The study was approved by Institutional Review Board of the participating centers and was carried out per regulations of the Declaration of Helsinki. Whole exome sequencing (WES) was conducted using Illumina NextSeq500 platform using compatible kits per manufacturer's instructions. Healthy controls were included from genomic databases. All study subjects were screened for prognostically important pan-cancer gene mutations. Genes exclusively and commonly shared with each CML phase were subjected to further analyses. The data was analyzed using SSPS Ver. 26. The first data a total of 64 genes with 2531 mutations were detected in BC-CML patients that were absent in chronic phase CML (CP-CML) as well as healthy controls, indicating that these genes/mutations are exclusively associated with BC-CML. RPTOR was the most common gene mutated (7.35%) and chromosome 17 was the most encountered (16.32%) while chromosome 12 was the least involved (0.04%). The second data 55 genes in the accelerated phase while 83 genes in BC. Therefore, we conclude that many gene mutations associated with BC-CML are associated with different types of leukemias and solid tumors. Moreover, these genes were found to have resistance causing mutations with various underlying. Mechanisms in cell signaling, which could potentially impact treatment and prognosis of advanced phases CML patients.

#4639 Predictive clinical-pathological features for CDK 4/6 inhibitors: Outcomes in hormone receptor-positive, HER2-negative metastatic breast cancer patients.

Amer N. Radwi[1], Anwar Khan[1], Mohammed Essam Mahroos[2], Fares Alhejaili[1], Saleh Alsaiari[1], Ali Nasfan[1], Ahmad Almuslim[1], Mohammed Alasri[1], Yousef Alraddadi[1]

[1]King Saud University for Health Sciences, Jeddah, Saudi Arabia,[2]Oncology, King Abdulaziz Medical City-WR,NGHA, Jeddah, Saudi Arabia

Background: Breast cancer is the most common cancer among Saudi women and around the world, accounting for 30.9% of all Saudi female cancers in 2020. Metastatic breast cancer (MBC) represents a significant health burden. There has been a recent increase in hormone receptor-positive (HR+) breast cancer in young women. When used with endocrine therapy, CDK4/6 inhibitors have become a big step forward in the treatment of hormone receptor-positive breast cancer. There are sparse studies on their response prediction. We aim to determine predictive clinical-pathological features for CDK4/6 inhibitors response in HR+, Her2 negative metastatic breast cancer by getting their impact on the response rate and progression-free survival. The study looked at the medical records of women with HR+, Her2 negative breast cancer who went to the Princes Noora Oncology Centre (PNOC) in King Abdulaziz Medical City-WR between January 2016 and December 2023. The study was approved by the Institutional Review Board (IRB). We collected data for patients' demographics, clinical features, peripheral blood inflammatory cells, pathology, treatment, and follow-up details from patients' files in Electronic Medical Records. We included 18 years or older, histopathology-confirmed, advanced unresectable, and systemic therapy-naïve MBC. We excluded intracranial metastases and nonassessable responses. We cleaned and explored the data using tables, histograms, box plots, and bar charts. We applied the chi-square test, Fisher exact test, and Kaplan-Meier survival curves for survival.
Results: We found 3084 breast cancer patients and 1250 hormone receptor-positive patients. We analyzed 162 cases after applying inclusion-exclusion criteria. The median age was 51 years; PFS was 72.5 months. Menopause status, estrogen receptor positivity percentage, body mass index (BMI), tumor grade, and adenocarcinoma histology were clinical factors that could not predict the outcome. A high KI67 index of more than20%, high monocyte lymphocyte ratio (MLR), and a low lymphocyte count before the second cycle predicted the response of the CDK4/6 inhibitors, as shown by a higher response rate (RR) and better progression-free survival (PFS).
Conclusion: While clinical features were not predictive, factors such as elevated KI67 by more than 20%, elevated peripheral blood monocytes (PBMC), monocyte lymphocyte ratio (MLR), and a low lymphocyte count before the second cycle were predictive of the response to CDK4/6 inhibitors.

#4640 Identifying novel drivers of drug sensitivity using an AI-enabled composite biomarker - osimertinib sensitivity beyond EGFR.

Maayan Baron, Felicia Kuperwaser, Colin Tang, Sunil Kumar, Dillon Tracy, Zong Miao, Olena Marchenko, Sepideh Foroutan, Amy Sheide, Nathaniel Tann, Samantha Pindak, Jacob Kaffey, Jordan Wolinsky, Sean Klei, Andrey Chursov, Brandon Funkhouser, Nick Lee, Patrick Bohan, Fahad Khan, Ripple Khera, Jean Michel Rouly, George Komatsoulis, Jeff Sherman, Emily Vucic, Rachael Brake

Zephyr AI, McLean, VA

Background: Precision medicine (PM) has transformed cancer treatment but remains effective for only a subset of patients. Most tumors profiled with comprehensive genomic testing lack actionable biomarkers, and even when present, many patients fail to benefit from corresponding therapies. Some without recognized biomarkers respond in off-label contexts, highlighting the need for better biomarkers to capture drug response biology and deliver on the promise of PM. Osimertinib, a third-generation EGFR inhibitor, is used in conjunction with the single gene biomarker, EGFR. Response rates vary by EGFR variant and off-target activity has been reported. We hypothesized that integrating multi-modal data with machine learning could enhance osimertinib response predictions beyond the single-gene EGFR biomarker.

Methods: We developed an AI/ML-enabled drug response prediction model that integrates clinical and molecular features with drug structure and functional data to generate drug response predictions. The model produces an AI-enabled composite biomarker (AI-CB) based on a small amount of clinical and molecular patient input data. Each prediction is paired with a proprietary Vulnerability Network™ (VN), providing insights into biological dependencies underlying response predictions. Osimertinib response predictions were evaluated retrospectively across multiple real-world (rw) NSCLC cohorts, including clinicogenomic data from liquid biopsy. The AI-CB was also validated in EGFR-negative NSCLC patient-derived xenografts (PDX).

Results: Across multiple osimertinib-treated EGFR+ rw-NSCLC cohorts, the AI-CB accurately stratified patients by sensitivity to osimertinib, despite the presence of EGFR alterations in all patients. EGFR+ patients predicted to be insensitive showed a significant reduction in rw-overall survival compared to those predicted to be sensitive, indicating that osimertinib sensitivity may be impacted by more than just EGFR alterations. Compared to EGFR+ osimertinib insensitive patients, post-hoc and VN analysis across these two cohorts linked sensitivity to upregulation of pathways downstream of EGFR including NOTCH and TP63 and downregulation of RAS/RAF/MEK activity. The AI-CB was successfully validated in human PDX models without activating EGFR alterations. AI-CB application to AACR Project GENIE cohorts suggest that sensitivity to osimertinib could extend to a novel group of patients with NSCLC and beyond, e.g., colorectal cancer.

Conclusion: ML enables the integration of diverse data types relevant to drug response, overcoming limitations of single-dimensional approaches. Incorporating AI-driven patient stratification models into drug development and clinical practice could greatly expand the utility of targeted therapies and create effective stratification strategies for drugs lacking adequate biomarkers.

CLINICAL RESEARCH: Prognostic Biomarkers 3
Poster Session

#4643 The role of subcellular localization of interleukin-1alpha in head and neck cancer.

Ishrat Nourin Khan[1], M M Hasibuzzaman[2], Andrean L. Simons-Burnett[3]

[1]Interdisciplinary Graduate Program in Human Toxicology, University of Iowa, Iowa City, IA,[2]Free Radical and Radiation Biology Program, Department of Radiation Oncology, University of Iowa, Iowa City, IA,[3]Holden Comprehensive Cancer Center, University of Iowa, Iowa City, IA

Interleukin-1α (IL-1α) is a pro-inflammatory cytokine upregulated in multiple solid malignancies, including head and neck squamous cell carcinomas (HNSCCs) and has been associated with tumor growth, metastasis, immunosuppression, and therapy resistance. Unfortunately, targeting circulating IL-1α in clinical trials has shown disappointing results for cancer patients. Our previous research revealed that high nuclear IL-1α expression is associated with perineural invasion and poor progression free survival. However, little is known about the importance of subcellular localization of IL-1α. This study aims to explore the differences in nuclear and cytoplasmic IL-1α expression on tumor aggressiveness. Cal-27 HNSCC cells were transfected with four plasmid constructs of different forms of IL-1α: 1 - precursor/full length (FL) IL-1α (1-271 AA) which localizes in both the nucleus and cytoplasm; 2 - N-terminal/propiece (N-tern) IL-1α (1-112 AA) which localizes in the nucleus; 3 - C-terminal/matured (C-term) IL-1α (113-271 AA) which localizes in the cytoplasm; and 4 - pGenLenti control (CON) construct. Intracellular IL-1α expression was validated using PCR and western blot, subcellular localization was validated using subcellular fractionation kits prior to western blot, and secreted IL-1α and IL-1α-signaling endpoints (e.g. IL-6, IL-8) were analyzed by ELISA. Differences in cell growth and epithelial-mesenchymal transition (EMT) markers were assessed among the IL-1α-expressing cell lines. IL-1α gene expression was significantly increased in all IL-1α construct-expressing cell lines (FL, C-term, N-term) compared to CON. Whole cell lysates showed significantly increased precursor and matured IL-1α protein expression in the FL cells; and matured IL-1α in C-term expressing cells compared to CON. Subcellular fractionation showed increased precursor IL-1α in FL and matured IL-1α in C-term expressing cells in the cytoplasmic fraction; while higher precursor IL-1α was found in nuclear fraction of FL expressing cells. IL-1α secretion was significantly increased from both FL and C-term expressing cells while the IL-1 signaling endpoints IL-6 and IL-8 were increased in the FL expressing cells only. C-term expressing cells grew significantly more rapidly compared to the other cell lines and demonstrated “mesenchymal-like” morphology. To confirm, western blot revealed an increase in the expression of the mesenchymal markers N-cadherin and vimentin, and a complete loss of epithelial markers E-cadherin and claudin. Overall, these findings suggest that the subcellular localization of IL-1α may play a complex role in tumor growth and EMT. Future work is needed to understand the significance of IL-1α subcellular localization to improve more efficient targeting of the IL-1 pathway for cancer therapy.

#4644 Real-world outcomes in dual checkpoint inhibitor therapy: A single community center perspective.

Victoria Moe[1], **Rachel Elsey**[2], Tobias Meissner[2], Bing Xu[2], Yuliang Sun[2], Crystal Hattum[2], Casey Williams[2]

[1]University of South Dakota Sanford School of Medicine, Vermillion, SD,[2]Avera Cancer Institute, Sioux Falls, SD

Introduction: Immunotherapy using dual checkpoint inhibitors is used to induce an antitumor response towards cancer. The varied response in treatment outcomes for those who receive dual checkpoint may be influenced by many factors. We attempted to interrogate factors impacting response to dual checkpoint inhibitor therapies in a single-center retrospective analysis, with the primary objective of examining how these factors may influence cancer progression.

Methods: This single-center retrospective analysis examines patients with documented treatment histories of dual immunotherapy between 2015 and 2023. Additional data collected included: demographics, disease characteristics, additional treatment history, imaging, and next generation sequencing results. The primary endpoint of this study was progression free survival, with the secondary endpoint of overall survival. Patients were excluded from the study if they passed within one month of starting dual immunotherapy, were being treated for more than one form of cancer or had insufficient documentation.

Results: In this study, the median age at the start of dual immunotherapy was 65 years old (range 30 to 84). Of the 144 patients examined, 20% were diagnosed with stage II or stage III cancer, 76% were diagnosed with stage IV cancer, and 3.5% had an undetermined stage at the start of dual immunotherapy. The most common diagnoses were melanoma (42%), kidney cancer (29%), and lung cancer (9%). 47% of the patients received 4 doses of dual immunotherapy and the next most common group received 2 doses (22%). 51 of the patients had their tumor mutation burden (TMB) assessed with 31% of the patients in this subgroup determined to have a high TMB. 33 patients had PD-L1 assessed, with 69% having a positive PDL-1 status. 46% of patients had not received prior lines of immunotherapy or chemotherapy while 22% received a single line. There was no significant change in survival found for PDL1 status ($p=0.49$), TMB ($p=0.48$), or age ($p=0.68$). The relationship between doses of dual checkpoint immunotherapy to survival was found to be significant ($p < 0.001$) when assessed over 8000 days but showed insignificant ($p=0.18$) when assessed over 2500 days. The number of prior lines to survival also was found to be significant ($p=0.0014$) when assessed over 2500 days.

Conclusions: An increase in cancer survivorship was found to be higher in patients that received more doses of dual checkpoint immunotherapy which may suggest that doses of dual immunotherapy received may increase the lifespan of some individuals with cancer. The small sample size of this study is a limitation to this analysis as well as the limited results for PD-L1 and NGS testing results, including TMB.

#4645 Dynamic post-translational events designate muscle invasion of non-muscle invasive bladder cancer.

Sabir Salim[1], Sreenidhi Mohanvelu[1], Sheeja Aravindan[2], Poorvi Subramanian[1], Loganayaki Periyasamy[1], Natarajan Aravindan[1]

[1]Physiological Sciences, Oklahoma State University, Stillwater, OK,[2]OU Health Stephenson Cancer Center, Oklahoma City, OK

Bladder cancer (BC), the second most prevalent genitourinary malignancy where majority (~70%) of the patients present with non-muscle invasive BC (NMIBC) while the rest (~30%) present with muscle invasive BC (MIBC) at diagnosis. Despite the extensive clinical management, 50% of NMIBC relapses and progress to anew MIBC. Owing to the poor prognosis for progressive MIBC, it is indispensable to understand and mitigate the evolution of NMIBC to MIBC. In particular the intratumoral heterogeneity pre- and post-therapy in NMIBC, is crucial to pin the genetic, molecular and/or post-translational events and the mechanism(s) involved in this critical transformation. Studies have identified Promyelocytic leukemia factor (PML) as a defined proapoptotic protein that regulates BC cell growth and progression. Further, studies have identified that loss of PML-nuclear bodies (PML-NB) corresponds to a 'low-is-worse' association with BC clinical outcomes. Herein, we investigated the mechanism on how the PML-NB derails and its significance in disease prognosis. In this study, we identified a unique site specific post-translational modification (SSPT) in PML that leads to its destabilization and loss. Further, significance of this PML-SSPT in clinical outcomes were investigated in a test cohort of (n=112) BC patients. For this, MIBC and NMIBC tissues in triplicates were custom archived in tissue microarrays and were examined for PML-SSPT with Opal immunohistochemistry utilizing our custom synthesized antibody. The spatio-temporal PML-SSPT modification was analyzed in QuPath v 0.5.1 bioimage analysis platform with a modified fluorescence image analysis module. We observed a significantly higher PML-SSPT modification in MIBC compared to NMIBC and a relative increase in PML-SSPT modification associated with advanced disease stage defining its crucial role in cancer progression. More importantly, higher PML-SSPT in patients with metastatic disease as well as with relapsed disease highlighted its critical role in mediating disease dissemination and evolution to aggressive MIBC. Together, the outcomes identified a crucial post-translation modification event in PML that corresponds to the coordination of de novo MIBC from NMIBC. Further, these outcomes identified a novel molecular target and paves way to develop novel molecular tumor targeted maintenance therapeutic strategies for the cure of BC. Funding: This work was funded by the Department of Defense, DoD CA-210339; Oklahoma Center for the Advancement of Science and Technology, OCAST-HR19-045; and the National Institutes of Health P20GM103639 awarded to Dr. Aravindan. The work was also supported by the NCI Cancer Center Support Grant [P30CA225520], NIGMS [P30GM154635], and a grant from the Oklahoma Tobacco Settlement Endowment Trust [R23-03] awarded to the OU Health Stephenson Cancer Center.

#4646 Technical, intratumoral and interpatient variability of a novel assay that quantifies fractional occupancy of PD1 by PDL1 in clinical biospecimens.

Suresh Veeramani, Chaobo Yin, Kristen L. Coleman, George J. Weiner

University of Iowa, Iowa city, IA

Background: New biomarkers are needed to predict clinical response to anti-PD1 therapy. We have been evaluating whether quantifying fractional occupancy of PD1 by PDL1 (PD1 FO) within a tumor may be of value as a predictive biomarker. The Ligand-Receptor Complex-binding Aptamer (LIRECAP) assay used to quantify PD1 FO is based on the preferential binding of one RNA aptamer to unoccupied PD1 (P aptamer) and the other to the PD1/PDL1 complex (C aptamer). Here, we report the technical, intratumoral, and inter-patient variability of the PD1 LIRECAP assay using clinical biospecimens.

Methods: Biospecimens: Formalin Fixed Paraffin Embedded (FFPE) sarcoma biospecimens were selected based on their availability with varying expression of PDL1. All samples had significant T cell infiltration. Ten-µm-thick scrolls were cut, deparaffinized, rehydrated and used for analysis. To assess technical variability, scrolls were macerated, aliquoted, and repeat LIRECAP assays were performed on the same sample. To assess intratumoral variability, multiple scrolls were cut from the same biospecimen. To assess inter-patient variability, biospecimens from different patients with high (tumors 1, 2 and 3) or low PDL1 (tumors 4, 5 and 6) were evaluated.

PD1-PDL1 LIRECAP assay: An equimolar mix of a “P aptamer” and a “C aptamer was added to a macerated scroll. After extensive washing, bound P and C aptamers were quantified using a TaqMan-based RT-qPCR with a set of common PCR primers (against their constant regions) and two unique TaqMan probes (against their unique central regions). The ratio of bound aptamers (C:P ratio) reflected PD1 FO.

Results: Technical variability. The PD1 LIRECAP assay showed high technical reproducibility, with low coefficient of variation (CV) for C:P ratio between the aliquots from the same scroll (e.g. Tumor #1: 10%; Tumor #5: 7%).

Intratumoral variability. Intratumoral variability was greater than technical variability demonstrating regional variations in PD1 FO within an individual tumor (CV: Tumors #1 - 71%; #2=84%; #3=44%; #4=45%; #5=76%; #6=79%).

Interpatient variability. $PDL1^{high}$ tumors showed a higher C:P ratio, indicating higher PD1 FO, when compared to $PDL1^{low}$ tumors ($p=0.017$) with higher interpatient variability in $PDL1^{low}$ patients (CV: $PDL1^{high}$=15%; $PDL1^{low}$=32%).

Conclusions and Significance: Evaluation of clinical FFPE biospecimens using the PD1 LIRECAP assay is technically feasible and reproducible. There is intratumoral variability in PD1 FO indicating regional differences within a tumor. Nevertheless, PD1 FO was highest in the $PDL1^{high}$ biospecimens. Studies assessing the value of PD1 FO as a predictive biomarker as determined by the PD1 LIRECAP assay are ongoing with the understanding that further evaluation of PD1 FO as a biomarker for response to anti-PD1 therapy will need to take intratumoral variability into account.

#4647 Systematic review and meta-analysis on the prognostic value of circular RNAs in triple-negative breast cancer.

Gessika Lanzillo de Almeida Nunes[1], Thoa Thi Kim Vu[1], So-Youn Jung[2], Yoon-Jung Choi[3], Sun-Young Kong[4]

[1]Department of Cancer Control and Population Health, Graduate School of Cancer Science and Policy, National Cancer Center, Goyang, Korea, Republic of,[2]Center for Breast Cancer, National Cancer Center Hospital, Goyang, Korea, Republic of,[3]National Cancer Control Institute / Center for Cancer Prevention & Detection, National Cancer Center - National Cancer Center Hospital, Goyang, Korea, Republic of,[4]Department of Laboratory Medicine / Targeted Therapy Branch, Research Institute, National Cancer Center, Goyang, Korea, Republic of

Background: Triple-negative Breast Cancer (TNBC) is known for its aggressive nature, high recurrence rate, poor prognosis and limited treatment options. Currently, the use of non-coding RNAs as diagnosis or prognosis biomarkers or even target treatment options for TNBC are being studied. Among the non-coding RNAs, recent studies show that circular RNAs (circRNAs) levels are differentially expressed in TNBC tumor tissues, they also interact with micro RNAs and regulate multiple intracellular mechanisms involved in tumorigenesis. Furthermore, their distinct shape makes them more stable and resistant. However, the transition from laboratory research to their clinical application as biomarkers is still in progress. In this meta-analysis we compare multiple studies on prognostic values of circRNAs.
Methods: After detailed literature search on EMBASE, PubMed, and Web of Science, eligible studies were meta-analyzed to estimate the pooled hazard ratio (HR) and 95% confidence intervals for overall survival (OS) and disease-free survival (DFS) in TNBC patients based on their levels of expression of circRNAs.
Results: A total of 1991 patients had their serum or TNBC tumor samples analyzed across 15 different studies and the levels of expression of certain circRNAs were found to be upregulated or downregulated in TNBC compared to normal breast tissues. High expression of upregulated circRNAs also significantly impacts the outcomes of TNBC patients with poor OS (adjusted: HR=2.85, 95%CI: 2.02 - 4.00) and reduced DFS (HR=5.43, 95%CI: 1.82 - 16.21). Moreover, circCRIM1, circEIF6, circTRIO, circCFL1, circGNB1, circRAD18, circ_0001006, circSIPA1L3, circ_0000199, circTBC1D14, circIFI30, circSEPT9, circ_0003528 were upregulated and their high level was associated with worse outcomes. Conversely, circFBXW7 was downregulated in TNBC samples and low levels were significantly associated with bad prognosis.
Conclusion: This review showed that circRNAs are abnormally expressed in TNBC tumors, their levels significantly impact the outcome of the patients and their distinct molecular structure is more stable and less prone to degradation which makes them good candidates for prognosis biomarkers and potential therapeutic targets.

#4648 Circulating tumor DNA analysis demonstrates newly emerging alterations in previously treated IDH1 mutated cholangiocarcinoma patients enrolled in the ClarIDHy study.

Hatice Duygu Saatcioglu[1], Haley Ellis[2], Jinkai Wan[2], Sam Lubner[3], Milind Javle[4], Ghassan K. Abou-Alfa[5], James M. Cleary[6], Robin Kate Kelley[7], Mitesh J. Borad[8], Teresa Macarulla[9], Do Youn Oh[10], Camelia Gliser[1], Susan Pandya[1], Sung Chloe[1], Nabeel Bardeesy[11], Adriana Tron[1]

[1]Servier Pharmaceuticals, Boston, MA,[2]Massachusetts General Hospital Cancer Center/Harvard Medical School, Boston, MA,[3]University of Wisconsin, Madison, WI,[4]MD Anderson Cancer Center, Houston, TX,[5]Memorial Sloan Kettering Cancer Center, New York, NY,[6]Dana-Farber Cancer Center, Boston, MA,[7]University of California, San Francisco, San Francisco, CA,[8]Mayo Clinic Arizona, Phoenix, AZ,[9]Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain,[10]Seoul National University Hospital Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[11]Massachusetts General Cancer Center Harvard Medical School, Boston, MA

Background: Ivosidenib (IVO) is a first-in-class oral inhibitor of the IDH1 mutant (mIDH) enzyme. In the ClarIDHy phase 3 study of previously treated patients with mIDH cholangiocarcinoma (CCA), IVO treatment led to improved progression-free survival (PFS) and overall survival (OS) vs placebo (median PFS: 2.7 vs. 1.4 months and OS 10.3 vs. 5.1 months, when adjusted for the 70% crossover rate; HR, 0.49 [95% CI, 0.34-0.70]; 1-sided *P*<0.001. Here, we studied the dynamics of mutations emerging after 6 months of IVO treatment using ctDNA analyses.

Methods: Prior to enrollment, all subjects in ClarIDHy had *IDH1* R132 mutations confirmed by a central NGS panel utilizing tumor biopsy tissue. Since post-progression tissue samples were unavailable, discovery of emerging mutations was limited to plasma ctDNA assessments. To explore molecular changes associated with acquired resistance, an analysis was performed on 18 subjects treated with IVO for ≥6 months (4 partial response; 12 stable disease, 2 NA) using matched baseline and end of treatment (EOT) samples (PGDx elio^{TM} plasma complete, 521 gene panel). A subset of the oncogenic alterations identified were selected for confirmation by ddPCR analysis in ctDNA samples collected longitudinally. Longitudinal plasma 2HG levels were also evaluated.

Results: This analysis identified several EOT mutations not present at baseline. The most common mutations were in the MAPK pathway, including activating KRAS, NRAS, and MAP2K1 mutations and loss-of-function NF1 mutations (6/18 patients, 33%). In 2/6 patients, multiple MAPK pathway mutations were detected. There was a range of variant allele frequencies (VAFs) of RAS alterations, including some that had comparable levels to the truncal mIDH, suggesting that MAPK activation may have made a major contribution to the burden of resistant disease. ddPCR analyses from longitudinal plasma samples from selected cases confirmed these findings. In addition, 2 patients had mutations affecting transcription/epigenetics (WT1 and KMT2C). Finally, only 1 patient had acquired mutations in IDH genes (IDH2-R172K and IDH1-G131V). The WT1, KMT2C, and IDH variants had a low VAF. Accordingly, EOT plasma 2HG levels were reduced vs pre-treatment levels in the patient with secondary mIDH, indicating a limited role in the overall emergence of resistance.

Conclusion: Analyses of paired baseline/EOT samples suggest that multiple acquired mutations could contribute to IVO resistance, with oncogenic MAPK pathway alterations being the most common. Consistent with previous clinical studies conducted in AML, IDH1 second site mutations and isotype switching to IDH2, rarely emerge during IVO treatment. The lack of detectable mutations in the majority of patients could reflect the sensitivity of the NGS assay or a role for non-genetic mechanisms of resistance.

#4649 Proposal of the concept of "*p53* mutational spectrum": Its clinical implication in oral squamous cell carcinoma.

T. Hyodo[1], N. Kuribayashi[2], C. Fukumoto[1], Y. Komiyama[1], T. Hasegawa[1], K.-i. Nakashiro[2], D. Uchida[2], H. Kawamata[1];
[1]Dokkyo Medical University School of Medicine, Tochigi, Japan, [2]Ehime University Graduate School of Medicine, Ehime, Japan

The p53 gene is the most frequently mutated gene in malignant tumors. We found that p53 abnormalities were observed in most cases of oral squamous cell carcinoma (OSCC). Therefore, it is necessary to search for type of the functional abnormality (complete loss of function, partial loss of function, or gain of oncogenic function) of the p53 gene rather than the presence or absence of gene mutation. Here we would like to propose the concept "p53 mutational spectrum". In this study we performed whole-exome sequencing of p53 using clinical specimens from OSCC and attempted to clarify the implication of "p53 mutational spectrum" with clinical manifestation. Sixty-seven patients with OSCC who visited the Department of Oral and Maxillofacial Surgery, Dokkyo Medical University or Ehime University were subjected to the study. Genomic DNA was extracted from biopsy and surgical specimens, and a custom panel was created for OSCC. p53 and other driver gene mutations were analyzed by NGS. p53 mutation pattern was classified into 5 categories, wild type without p16 expression, wild type with p16 expression, missense mutations in the DNA binding domain, missense mutations out of the DNA binding domain and truncation mutations. Patients with several p53 mutational patterns were statistically analyzed in relation to biological and clinical grade, and overall survival (OS) and disease-free survival (DFS) were also analyzed. The patterns of p53 gene was wild type without p16 expression in 7 patients, wild type with p16 expression in 6 patients, missense mutations in the DNA binding domain in 31 patients, missense mutations out of the DNA binding domain in 2 patients and truncation mutations in 7 patients. Thus, the p53 gene was mutated in 54 patients, 33 with missense mutations and 24 with truncation mutations. p53 mutation distribution was concentrated in the DNA binding domain and missense mutations were common, while truncation mutations were common in other domains such as the transcriptional activation domain. In univariate analysis, p53 truncation mutations were identified as a risk factor for DFS and were associated with poorer prognosis compared with other mutation groups. p53 mutational spectrum was not significantly associated with other driver gene mutations. p53 missense mutation group. The p53 missense mutationp group was also analyzed in the same way, but the results were not statistically significant. The p53 truncation mutation (complete loss of function) was associated with poorer prognosis than other gene status, wild type with/without p16 and missense mutation. The p53 missense mutation may contain functional diversity (complete loss of function, partial loss of function, almost wild, or gain of oncogenic function). We are currently constructing a platform for p53 mutational spectrum database.

#4650 The impact of GLI3 mutations and expression on prognosis in gastric cancer.

Wanfu Zhang[1], Wendi Jin[1], Hongwei Wan[1], Chao Niu[1], Chu Yan[1], Chunxiao Wang[1], Juanjuan Liu[1], Xiaogang Li[1], Qinglan Zong[2], Ning Gao[2], Ding Zhang[2]

[1]Department of General Surgery, The Affiliated Hospital of Yunnan University, Kunming, China,[2]3D Medicines Inc., Shanghai, China

Background: GLI3, a member of the GLI zinc finger family, has been extensively investigated in various cancers, including gastric cancer. It has been observed that GLI3 is significantly upregulated in solid cancer types. These findings suggest the involvement of GLI3 in the malignant progression of different cancers. However, the precise impact of GLI3 mutations and expression on the prognosis of gastric cancer patients remains unclear. Further investigation is warranted to elucidate the prognostic significance of GLI3 alterations in gastric cancer.
Methods: This study included 269 gastric cancer patients from TCGA and 2903 patients from China. The mutation rate of GLI3 was analyzed using Excel. Additionally, the survival rates of gastric cancer patients with GLI3 mutations were compared to those with wild-type using KM survival curves in the TCGA cohort. In addition, the impact of high and low expression of GLI3 on survival was analyzed using a 50% threshold. The expression of GLI3 in tumor tissues were evaluated using Mann-Whitney analysis to compare with those in normal tissues.
Results: The mutation rate of GLI3 was 13.55% in the TCGA cohort, whereas it was significantly lower at 7.79% in the Chinese cohort. KM curve analysis demonstrated that patients with GLI3 mutations in the TCGA cohort had a significantly higher survival rate than those with the wild group ($p < 0.05$). Additionally, GLI3 expression was significantly higher in tumor tissues compared to normal tissues ($p < 0.01$). Furthermore, based on GLI3 expression analysis, patients with a 30% higher expression of GLI3 had a significantly worse prognosis compared to the remaining 70% of patients ($p < 0.05$). The analysis of GLI3 mutations and expression revealed that patients with GLI3 mutations had significantly lower RNA expression compared to those with the wild-type.
Conclusion: The mutation rate of GLI3 was found to be higher in the TCGA cohort compared to the Chinese cohort. Both GLI3 mutations and expression were closely associated with the prognosis of gastric cancer patients. These findings highlight the significance of GLI3 as a potential prognostic indicator in gastric cancer. Further research is needed to elucidate the underlying mechanisms and validate these observations in larger and more diverse patient populations.

#4651 Long non coding RNA LINC01224 is prognostic marker and regulates cancer stemness in the NSCLC.

Ji Woong Son, Wan Jin Hwang, Minhyeok Lee, Daeun Kang, In Beom Jeong, Sun Jung Kwon

Konyang Univ. College of Medicine, Daejeon, Korea, Republic of

Long noncoding RNA is also a molecule that is attracting attention these days. Only about 1.5% of the genome is protein-coding, while the other 98.5% consists of non-coding elements, which are transcribed by RNA polymerase II (polII) into non-coding RNA (ncRNA). Among them, ncRNAs with a size of 200nt or more are called long non-coding RNAs (lncRNAs). To date, lncRNA have been recognized to have regulatory roles in gene expression through various mechanisms. They are involved in diverse biological processes such as cell differentiation, apoptosis, development, inflammatory response, and immune response. Cancer stem cells (CSCs) identified in lung cancer exhibit resistance to chemotherapy, radiotherapy, and targeted therapy. Therefore, a technology for controlling CSCs is needed to overcome such resistance to cancer therapy. The authors planned this study to discover lncRNAs involved in cancer stemness. We analyzed TCGA data to search for lncRNAs that predict the prognosis of NSCLC and selected LINC01224 as a candidate lncRNA involved in cancer stemness. Treatment of LINC01224 with siRNA reduced colony formation ability in cell lines with stem cell characteristics. Next, we performed whole-genome expression in lung cancer cell line after siRNA treatment to identify gene controlled by LINC01224. This experiment revealed that lncRNA is involved in apoptosis, cell cycle, cell death, cell differentiation, cell migration, and DNA repair. LINC01224 is a prognostic factor and an attractive treatment target for non-small cell lung cancer. LINC01224 possibly regulates various biological phenomena and specific mechanism studies are needed.

#4652 Prevalence and prognostic role of KDM6A deficiency and overexpression in surgically treated prostate cancer.

Neele Heckmann[1], Natalia Gorbokon[1], Maximilian Lennartz[1], Martina Kluth[1], Eike Burandt[1], Till S Clauditz[1], Waldemar Wilczak[1], Stefan Steurer[1], Christian Bernreuther[1], Elena Bady[1], Lisa Hornsteiner[1], **Ronald Simon**[1], Hans Heinzer[1], Alexander Haese[1], Sarah Minner[1], Guido Sauter[1], Thorsten Schlomm[2], Markus Graefen[1], Florian Viehweger[1]

[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany,[2]Charite - Universitatsmedizin Berlin, Berlin, Germany

KDM6A, also known as UTX (ubiquitously transcribed X chromosome tetratricopeptide repeat protein) is a critical epigenetic regulator which is often subject to truncating mutations and subsequent expression loss in cancer. To interrogate the clinical significance of aberrant KDM6A expression, a tissue microarray containing prostate cancers from patients treated by prostatectomy was analyzed by immunohistochemistry. KDM6A immunostaining was weak in 33.5%, moderate in 52.9%, and strong in 7.3% of 13,747 interpretable tumors while 880 (6.4%) tumors completely lacked KDM6A staining (KDM6A deficiency). The KDM6A status depended on the *TMPRSS2:ERG* fusion status. Strong KDM6A staining occurred in only 4.5% of ERG IHC negative, but in 11.1% of ERG IHC positive cancers while KDM6A deficiency occurred in 10.5% of ERG negative, but in only 1.4% of ERG positive cancers ($p<0.0001$ each). High KDM6A expression was linked to advanced pT, high Gleason grade, nodal positivity, and early PSA recurrence ($p<0.0001$ each). The prognostic role of high KDM6A expression was independent of pre- (Gleason score from biopsy, cT, PSA) and postoperatively (Gleason score from prostatectomy, pT, pN, R status) available parameters in all tumors ($p<0.0001$) and in ERG negative ($p<0.0001$) and positive subgroups ($p=0.0049$). In contrast, the outcome of KDM6A deficient cancers varied substantially between ERG negative (good prognosis) and ERG positive (bad prognosis) subgroups. In conclusion, the striking independent association of high KDM6A expression with poor prognosis suggests an important role of KDM6A expression in cancer cells which may have clinical utility in prostate cancer. The reciprocal role of KDM6A expression losses in ERG positive and negative cancers indicates a variable, cancer subtype dependent clinical effect of KDM6A deficiency. The clinical effects of anti-EZH2 drugs remains may depend on the ERG status in prostate cancer.

#4653 Platelet to lymphocyte ratio and platelet count: new frontiers as prognostic factors in metastatic colorectal cancer patients receiving anti-angiogenic drugs.

Eleonora Lai, Francesco Loi, Enrico Palmas, Claudia Codipietro, Andrea Pretta, Dario Spanu, Stefano Mariani, Alessandra Pia D'Agata, Pina Ziranu, Valeria Pusceddu, Marco Puzzoni, Mattia Cucca, Andrea Cadoni, Maria Letizia Ledda, Francesca Semonella, Veronica Dell'Utri, Marta Pozzari, Daiana Rizzo, Giulia Deias, Giulia Papalexis, Giorgia Sanna, Giusy Moledda, Benedetta Congiu, Fabio Bardanzellu, Fabiana Contu, Emanuela Piseddu, Erika Cimbro, Antonio Maccioni, Elisa Aresu, Sara Murgia, Gianluca Pannella, Clelia Donisi, Giorgio Astara, Elena Massa, **Clelia Madeddu**, Mario Scartozzi

Medical Oncology Unit, University Hospital and University of Cagliari, Cagliari, Italy

Background: Anti-angiogenic drugs represent a milestone of metastatic colorectal cancer (mCRC) pts) treatment. To date, no validated prognostic biomarkers are available. Recently, hematological parameters became of particular interest in solid tumors, including mcRC. Here, we present the results of our research in order to identify potential prognostic factors among clinical and laboratory parameters in mCRC pts receiving anti-angiogenic agents at our Centre.
Patients and Methods: We retrospectively collected clinical and laboratory data of mCRC pts treated with anti-angiogenic drugs at the Medical Oncology Unit of Cagliari University Hospital (2018-04/2024) in order to identify a potential prognostic tool. Statistical analysis was performed with MedCalc (survival distribution: Kaplan-Meier; survival comparison: log-rank test; cut-off: ROC curves).
Results: Globally, 42 mCRC pts were included in our study. 25 were male, 17 female; 17 had a RAS wild-type tumor, 30 had a left-sided primary). 14 pts received anti-angiogenic agents in the the first-line, 15 in the second-line (4 bevacizumab and 11 aflibercept) and 13 in the first and further lines. Median OS was 31.4 months (95% CI: 18.3 -39.5). When assessing the correlation between clinical and laboratory parameters and prognosis of the study population, a statistically significant improvement in overall survival (OS) was found in patients with platelet to lymphocyte ratio (PLR) equal or lower than 179.23 (31.4 months [95% CI: 20.3-47.1] versus 10.5 months [95%: CI 6.8 - 39.5], p=0.0315, HR= 0.27) and platelet count equal or lower than 360/µl (31.4 months [95% CI: 20.3-41.8] versus 10.3 months [95%: CI 6.8-10.5], p<0.0001, HR=0.0002). Then, according to these findings, we separated pts in two prognostic groups: good prognostic group (no unfavorable variables) and poor prognostic group (≥1 unfavorable variables). We observed a trend for longer OS in patients belonging to the good prognostic group (31.4 months [95% CI: 20.3-41.8] versus 10.5 months [95% CI: 6.8 - 39.5], p=0.0521, HR=0.3166).
Conclusions: Our research showed a promising prognostic role of baseline platelet count and PLR in mCRC patients receiving with anti-angiogenic drugs in a limited population at our center.

#4654 Clinical significance of tumor infiltrating lymphocytes and neoadjuvant chemotherapy in colorectal cancer liver metastases.

Yasaman Rezaie[1], Kerryan Ashley[1], Janie Zhang[2], Thejal Srikumar[1], Jassim DiPalermo[1], Kurt Schalper[1], Michael Cecchini[1]

[1]medicine, Yale University, New Haven, CT,[2]medicine, UPMC, Pittsburgh, PA

Background: The effects of neoadjuvant chemotherapy (NAC) and the survival impact of tumor infiltrating lymphocytes (TILs) in the colorectal cancer liver metastases (CRCLM) tumor microenvironment (TME) remain poorly understood.
Methods: We studied the clinicopathologic characteristics and the levels of different TIL subpopulations using multiplexed quantitative immunofluorescence (mQIF) in paired primary/liver metastasis in two independent CRCLM cohorts from Yale-New Haven Hospital between 2000-2024 using tissue microarrays. The first cohort included 84 patients (Cohort 1) and the second cohort comprised 95 patients (Cohort 2). The mQIF analysis included the markers DAPI for all cells/nuclei, cytokeratin (CK) for tumor epithelial cells, CD4 for helper T-cells, CD8 for effector T-cells, and FOXP3 for regulatory T-cells (Tregs). The levels of different cell populations were measured in specific tumor tissue compartments including the CK+ cancer-cell nests, the CK-negative peritumoral stroma and the total tissue area. The association between TILs and treatment-specific overall survival (OS) were analyzed.
Results: The OS was comparable between cases treated with or without NAC with a median OS after stage 4 diagnosis in NAC treated and not treated of 84 vs. 65 months, $p = 0.31$ and 59 vs. 115 months, $p = 0.23$ in Cohorts 1 and Cohort 2, respectively). NAC was associated with significantly higher CD8+ TILs in liver metastases in all studied tumor tissue compartments ($p < 0.05$ in Cohort 1 and $p < 0.003$ in Cohort 2). Elevated CD8+ TILs in the cancer-cell compartment of CRC liver metastases were associated with significantly improved survival irrespective of NAC (Hazard Ratio (HR) = 0.39, $p = 0.022$ in Cohort 1 and HR = 0.25, $p = 0.025$ in Cohort 2), a pattern not observed in primary tumors of both cohorts. In contrast, Tregs were consistently lower in liver metastases compared to primary tumors across all compartments ($p < 0.0001$ in both cohorts). Patients who did not have disease recurrence after NAC and hepatectomy had higher levels of CD8+ T-cells in liver lesions compared to those with tumor recurrence ($p = 0.05$ and 0.04 in Cohort 1 and 2 respectively). Microsatellite instability-high (MSI-H) tumors exhibited higher CD4+ and CD8+ TILs in primary tumors, but not in liver metastases (n = 5, $p < 0.05$ and < 0.01 for CD4+ and CD8+ T cells, respectively, across all compartments).
Conclusion: NAC did not show survival benefit in CRCLM patients but was associated with increased effector TILs in liver metastases. Elevated CD8+ TILs in CRCLM are prognostic and this highlights the potential for immunostimulatory strategies to leverage TME changes induced by NAC. Liver metastatic MSI-H CRCs show prominent inter-tumor heterogeneity with increased TILs only in the primary lesion.

#4655 Identification of non-small cell lung cancer metabolic subtypes and targeting glucose pathway.

Seo-Young Lee[1], Youngjoo Lee[1], Park Seog Yun[1], Beom K Choi[2], Sohyun Park[1], Jaemin Kim[1]

[1]National Cancer Center, Goyang-si, Korea, Republic of,[2]InnoBationbio, Seoul, Korea, Republic of

Background - NSCLC accounts for approximately 80% of all lung cancer cases. Despite significant treatment efforts, overall survival rates for NSCLC patients remain low. The NSCLC microenvironment and metabolism are also not fully understood, prompting ongoing research to better understand lung cancer progression and metastasis. To address tumor heterogeneity and define precise metabolic clusters, we applied non-negative matrix factorization (NMF) and discovered that the NMF clusters were significantly associated with clinical outcomes (progression, survival).

Method - To investigate metabolic functions in 73 patients who received immunotherapy, we performed NMF clustering to identify subgroups based on significantly differentially expressed genes from NanoString data. After performing NMF, we found 5 subgroups then defined the metabolic function of each cluster using Gene Set Variation Analysis (GSVA) and identified the top 10 marker genes for each cluster using the Wilcoxon test from the Seurat package.

Result - We found that clusters 1 and 2 had a higher proportion of immune cells compared to other clusters. Interestingly, while cluster 3 showed a higher proportion of immune cells, it had a lower overall survival rate and progression-free survival rate compared to cluster 1. We identified the key difference between these two clusters as glucose uptake. Moreover, glucose-related genes (*SLC2A1, SLC2A3, SLC2A6, SLC2A14, SLC2A8*, and *SLC2A5*) were highly expressed in cluster 2, which exhibited a higher proportion of Tregs and a stronger correlation between the glucose transport pathway and Tregs. Additionally, we found that *SLC2A3* expression was significantly associated with overall survival and progression-free survival. To validate our findings and demonstrate their robustness, we corroborated them using GSE161537 data. This study may help identify metabolic pathways and biomarkers that could be targeted in precision oncology.

#4656 Fatty acid β-oxidation enzyme ECI1: a biomarker of poor survival outcome in prostate cancer patients after transurethral resection of the prostate (TURP).

Karl-Philippe Guerard[1], Elie Fadel[1], Ryan Antel[1], Fadi Brimo[2], Tarek Bismar[3], **Jacques Lapointe**[1]

[1]Department of Surgery, Divion of Urology, McGill University, Montreal, QC, Canada,[2]Department of Pathology, McGill University, Montreal, QC, Canada,[3]Department of Pathology, University of Calgary, Calgary, AB, Canada

Deregulated mitochondrial fatty acid β-oxidation is known to drive prostate cancer (PCa) pathogenesis. ECI1 (Δ3, Δ2-Enoyl-CoA Delta Isomerase 1) is a key mitochondrial fatty acid β-oxidation enzyme whose role in PCa remains to be explored. We recently showed the impacts of ECI1 on PCa phenotype by modulating its expression in cell lines and assessed the clinical implications of its expression in human prostate tissue samples. ECI1 overexpression increased PCa cell growth and enhanced colony formation, cell motility, and maximal mitochondrial respiratory capacity. PCa cells stably overexpressing ECI1 injected orthotopically in nude mice formed larger prostate tumors with higher number of metastases. Immunohistochemistry analysis of a tissue microarray representing radical prostatectomy cases revealed a stronger ECI1 staining in prostate tumors compared to corresponding benign tissues. ECI1 expression was higher in cases with high tumor grade and advanced tumor stage. ECI1 overexpression was a strong independent predictor of biochemical recurrence after adjusting for known clinicopathologic parameters. ECI1 overexpression was also associated with increased risk of distant metastasis and reduced overall survival, suggesting a key role in disease progression. The purpose of this study was to assess the prognostic value ECI1 expression in PCa tissue on overall survival of patients who underwent palliative transurethral resection of the prostate (TURP). ECI1 immunohistochemistry was performed on a tissue microarray representing 257 TURP cases. ECI1 staining of malignant epithelial cells was assessed using the H-score method and patients were dichotomized into two groups based on ECI1 expression (high vs low). ECI1 overexpression was associated with an increased risk of death, which remained significant after adjusting for age and tumor grade group (hazard ratio=1.57, P=0.01). Moreover, a subgroup of this cohort considered of favorable survival outcome according to their PTEN positive and ERG negative tumor expression statuses (n=121) were further risk stratified by ECI1 even after adjusting for age and tumor grade group (hazard ratio =2.26, P=0.004). Overall, this study supports the contribution of ECI1 to PCa progression and highlights its potential as biomarker to identify patients at high risk of death among those who underwent a palliative TURP procedure. Future studies should explore whether the ECI1 metabolic pathway may serve as therapeutic target to improve patient survival and quality of life.

#4657 Investigating the role of circulating bone cells in melanoma patients on immune checkpoint inhibitor therapy.

Nicholas Rozza, Catalin Mihalcioiu, Richard Kremer

McGill University, Montreal, QC, Canada

Bone metastasis is a frequent progression of metastatic melanoma affecting 20-40% of patients with metastatic melanoma. While immune checkpoint inhibitors have been revolutionary in the treatment of advanced melanoma, certain patient populations do not respond to immunotherapy. Clinical data from our own treated melanoma population at the MUHC has shown that patients with bone metastases respond poorly to immune checkpoint inhibitors and have worse outcomes when compared to patients without bone metastases. These findings have prompted the investigation into this observed phenomenon of treatment resistance. The bone microenvironment is known to be a key player in cancer progression and metastasis and has been shown to form a vicious cycle where cancer and bone cells interact symbiotically to promote tumor growth and enhance bone degradation. Bone cells that are released into the circulation during the dynamic process of bone metastasis can easily interact with immune cells and may disrupt the ability of the immune system to mount an effective anti-cancer response. In our cohort of 185 metastatic melanoma patients treated with immune checkpoint inhibitors, patients with bone metastasis have a 43% response rate versus 65% in patients with visceral metastases alone. In terms of the complete response (CR) rate, only 18% of patients with bone metastasis achieved a complete response compared to 52% of patients with visceral metastasis alone. The treatment resistance appears to be systemic in patients with bone metastasis; the response rate in lesions outside the bone is also reduced. In a subset of these patients with serial prospective blood collections, we profiled PBMCs to identify certain immune and bone cell populations in the circulation at a pre-treatment baseline, early on treatment 2-3 cycles and after 4-6 cycles depending on the regimen. Patients were grouped based on objective response to determine the relationship between clinical outcome and immune/bone cell profiles. Patients with bone metastasis and a poor response had reduced immune effector cells and increased osteocalcin positive bone cells in the circulation when compared to patients that achieved partial and complete responses. Immune and bone cell profiling is a novel method of evaluating melanoma patients undergoing immunotherapy and may serve as an effective predictor of response to immune checkpoint inhibitors.

#4658 Clinical characteristics, molecular subtypes, and prognosis of 176 surgically resected esophageal small cell carcinoma patients.

Ruijie Ma, Peng Wu, Chaoqi Zhang, Nan Sun, Jie He

Department of Thoracic Surgery, National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Introduction: Small cell carcinoma of the esophagus (SCCE) is an aggressive neuroendocrine gastrointestinal malignancy with poor prognosis, and accounts for 0.8%-2.4% of all histological types of esophageal malignant tumors worldwide. The pathological characteristics of SCCE are similar to those of small cell lung cancer (SCLC), and SCLC subtypes can be defined by differential expression of four key transcription regulators: ASCL1, NeuroD1, YAP1 and POU2F3. However, there is limited research on the molecular subtypes of SCCE. Here, we conducted the study to classify the molecular subtype of SCCE, and explored the relationship between SCCE molecular subtypes and patients' clinical pathological characteristics and prognosis.
Methods: Patients with surgically resected SCCE at the Cancer Hospital of the Chinese Academy of Medical Sciences between 1985 and 2019 were included in the study. Clinicopathologic data of SCCE patients were collected, including gender, age, alcohol abuse, tobacco abuse, BMI, family history, location of tumor, length of tumor, TNM stage, lymphovascular invasion, and treatment. Immunohistochemical staining was performed to calculate the H-scores of ASCL1, NeuroD1, YAP1, and POU2F3 of FFPE sample. Data processing and analyses were performed using SPSS 27, R (4.4.1), and the R package survival [3.7.0].
Results: A total of 176 patients were included in the study. The median overall survival (OS) for all SCCE patients included in the study was 21 months, and the median disease-free survival (DFS) for all SCCE patients included in the study was 13 months. Four subtypes of SCCE samples were categorized by H-score: high ASCL1 (SCCE-A), high NeuroD1 (SCCE-N), high YAP1 (SCCE-Y) and high POU2F3 (SCCE-P). Univariate Cox analysis indicated that the SCCE-P subtype, adjuvant therapy, T stage, TNM stage, lymphovascular invasion, tumor length, T stage, and TNM stage were significantly associated with patient DFS ($p < 0.05$), while adjuvant therapy, T stage, TNM stage, lymphovascular invasion, tumor length, T stage, and TNM staging were significantly associated with patient OS ($p < 0.05$). Multivariate COX analysis indicated that adjuvant therapy, tumor length, and the SCCE-P subtype were independent significant predictors of patient DFS ($p < 0.05$), while adjuvant therapy and tumor length were independent significant predictors of patient OS ($p < 0.05$). The subtypes of SCCE had no significant relationship with clinicopathologic factors of patients.
Conclusion: This study indicate that the SCCE-P subtype is an independent prognostic factor for DFS in SCCE patients, providing a reference for the molecular classification of SCCE and helping to more accurately identify the disease status and prognosis of SCCE patients. Additionally, the study observed that adjuvant therapy after surgery for SCCE patients can significantly improve both OS and DFS.

#4659 AI-powered assessment of morphologic likeness to small cell lung cancer (SCLC) predicts progression to SCLC and TKI response in EGFR-mutant NSCLC.

Soohyun Hwang[1], Hyukjung Kim[1], Yeong Hak Bang[2], Jun-Gi Jeong[3], Chang Ho Ahn[1], Seungeun Lee[1], Sanghoon Song[1], Aaron Valero Puche[1], JaeWoong Shin[1], Sehhoon Park[2], Hyun Ae Jung[2], Jong-Mu Sun[2], Yoon-La Choi[4], Jin Seok Ahn[2], Myung-Ju Ahn[2], Siraj Ali[1], Chan-Young Ock[1], Se-Hoon Lee[2]

[1]Lunit Inc., Seoul, Korea, Republic of,[2]Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Seoul, Korea, Republic of,[3]Department of Digital Health, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea, Republic of,[4]Department of Pathology and Translational Genomics, Samsung Medical Center, Seoul, Korea, Republic of

Background: A subset of *EGFR*-mutant non-small cell lung cancers (NSCLC) progresses to small cell lung carcinoma (SCLC) during tyrosine kinase inhibitor (TKI) therapy, particularly in cases with inactivating *RB1* mutations. As *RB1* mutations are likely foundational events in SCLC transformation, we hypothesize that tumors susceptible to this transformation exhibit morphologic features resembling SCLC even at the time of the initial diagnostic biopsy.

Methods: We developed a predictive model for identifying the SCLC phenotype using H&E-stained slides from cases with confirmed SCLC histological diagnosis. Morphological features of individual cells were extracted through a grid-based image retrieval method, enhanced by subcellular compartmental analysis with an emphasis on nuclear and cytoplasmic characteristics. These features were used to quantify the morphological SCLC-likeness for each case. The SCLC-like phenotype was defined as the top 25% of cases exhibiting the highest SCLC-likeness scores. The model was then applied to 106 real-world advanced-stage *EGFR*-mutant NSCLC cases to validate the extracted features and assess clinical correlations. The primary endpoints were progression-free survival (PFS) after TKI therapy according to SCLC-like phenotype versus others, along with the rate of SCLC transformation. Secondary endpoints were *RB1* mutations confirmed by targeted panel sequencing or whole exome sequencing.

Results: The SCLC-like phenotype case images correlated with pathologist-interpretable features of SCLC, including a significantly smaller nuclear area (56 μm^2 vs. 102 μm^2) and increased nuclear optical density (18.01 vs. 15.68) reflecting hyperchromasia, consistent with typical SCLC morphology. Among the 106 patients with *EGFR*-mutant NSCLC, 26 were classified as having the SCLC-like phenotype. Patients with the SCLC-like phenotype demonstrated significantly worse PFS after TKI treatment (HR 1.71, CI 1.08-2.71, P = 0.02). Among the cases with secondary tissue biopsies (n = 68), SCLC transformation was observed in 4 cases, with a numerically higher frequency in the SCLC-like phenotype group compared to others (15.8% [3/19] vs. 2.0% [1/49], P = 0.06). No significant difference in *RB1* mutation frequency was found via panel or whole exome sequencing.

Conclusion: This is the first study to demonstrate the potential of morphologic assessment in identifying features pertinent to SCLC transformation and in optimizing prognostication in *EGFR*-mutant NSCLC treated with TKI. Given the heterogeneity in advanced-stage *EGFR*-mutant NSCLCs and the need to optimize therapeutic regimens, further and prospective studies are warranted.

#4660 Epstein-Barr virus transcriptomic signatures of tumor subpopulations predict relapse in nasopharyngeal carcinoma.

Eymon Ka Chun Wu[1], Jun-Yi Chen[2], Ken Hung On Yu[2], Nelson Su[2], Esther Hyunji Won[1], Hazel Yap[1], Hin Kwok[3], Raymond King-Yin Tsang[4], Joseph Chun-Kit Chung[4], Anthony Wing-Ip Lo[5], Stephanie Nga Sze Wong[4], Jack Kuipers[6], Jeffery Yan Ho Lau[1], Horace Cheuk-Wai Choi[7], Ka-On Lam[1], Sum-Yin Chan[1], To-Wai Leung[1], Xin Yuan Guan[1], Anne Wing Mui Lee[1], Chi Ming Che[8], Joshua Wing Kei Ho[2], Victor Ho Fun Lee[1]

[1]Department of Clinical Oncology, Centre of Cancer Medicine, School of Clinical Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China,[2]School of Biomedical Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China,[3]Centre for PanorOmic Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China,[4]Department of Surgery, School of Clinical Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China,[5]Department of Pathology, School of Clinical Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China,[6]Department of Biosystems Science and Engineering, ETH Zurich, Zurich, Switzerland,[7]Division of Epidemiology and Biostatistics, School of Public Health, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China,[8]Laboratory for Synthetic Chemistry and Chemical Biology Limited, Hong Kong, China

Nasopharyngeal carcinoma (NPC), originating from nasopharyngeal epithelium and frequently metastasizes to cervical lymph nodes and distal organs, is endemic in Southeast Asia and highly associated with Epstein-Barr virus (EBV). Radiation therapy with or without concurrent chemo-radiation is the most common treatment, but 30-50% of treated patients still relapse. Plasma EBV DNA test is the gold standard in screening and monitoring relapse. However, 20-50% NPC relapse are plasma EBV DNA-negative. In situ hybridization (ISH) of EBV-encoded small RNAs (EBER) of formalin-fixed paraffin-embedded nasopharyngeal biopsy can identify EBV-positive tumors regardless of plasma EBV DNA, but remains unable to predict relapse at initial diagnosis.

Recently, single-cell RNA sequencing (scRNA-seq) technology has emerged as a long-sought solution to low resolution in bulk sequencing. We launched the largest and most comprehensive scRNA-seq NPC study. 74 patients were recruited. Matched biopsies from normal adjacent tumor, primary tumor and lymph node were scRNA-seq profiled. 1298414 cells had been successfully profiled. Our study spanned 5 years and 5 patients relapsed. By unsupervised clustering, cell type classification by canonical markers, and copy number variation, differential abundance and survival analyses, we identified a number of relapse-predicting neoplastic and non-neoplastic subpopulations. For the first time, we also attempted to unfold EBV transcriptomic signature and its association with relapse at single-cell resolution using Vulture developed by our team.

Our results confirmed EBV transcripts were highly enriched in neoplastic cells. Surprisingly, EBV transcripts could also be detected in both non-neoplastic epithelial and tumor micro-environment cells especially T cells and B cells. Neoplastic subclones carrying mutations predictive of relapse revealed by our modified Mutect2 pipeline and other relapse-predicting tumor subpopulations were also found to possess higher EBV positivity. Cox regression analysis identified both cell and tissue type-specific EBV transcriptomic signatures implicated in initial attachment and entry during infection, viral gene regulation, immune evasion and cellular transformation that predicted relapse. Receiver operating characteristic analysis suggested EBV transcriptomic signatures outperformed both nasopharyngeal EBER ISH and plasma EBV DNA in relapse prediction at initial diagnosis.

To conclude, we successfully discovered previously overlooked relapse-predicting EBV transcriptomic signatures with cell and tissue type specificity that may be implicated in (1) tumorigenic transformation and (2) progression evolution. EBV transcriptomic signatures outperforming current strategies in relapse prediction at initial diagnosis may serve as new diagnostics and therapeutic targets for relapse prevention.

#4661 PTPRT mutations in gastric cancer: prognostic implications and functional domain analysis.

Jianbiao Xu[1], Lei Zou[2], Yun Shang[1], Tongmin Wang[1], Jianlin Song[1], Wenchuan Zhu[1], Yunjun Zeng[1], Jianxun Wang[1], Chuntao Li[1], Qinglan Zong[3], Ning Gao[3], Ding Zhang[3]

[1]Department of General Surgery II, The First People's Hospital of Yunnan Province, the Affiliated Hospital of Kunming University of Science and Technology, Kunming, China,[2]Department of Gastrointestinal and Bariatric Metabolic Surgery, The First People's Hospital of Yunnan Province, the Affiliated Hospital of Kunming University of Science and Technology, Kunming, China,[3]3D Medicines Inc., Shanghai, China

Background: The PTPRT gene is recognized as a tumor suppressor in human cancers. However, prior investigations have predominantly concentrated on PTPRT mutations in colon cancer, leaving a dearth of information regarding gastric cancer. Existing studies have proposed that mutations in the PTPRT phosphatase domain are infrequent in common human cancers and have no bearing on prognosis. Conversely, our research on gastric cancer has produced conflicting outcomes, thus presenting an alternative perspective.
Methods: This study included a cohort of 369 gastric cancer patients from TCGA database and 234 gastric cancer patients from real-world settings. The mutation rate of the PTPRT gene in gastric cancer patients and the mutations at different functional domain sites were analyzed using EXEL. Furthermore, the impact of mutations in different functional domain sites on survival was assessed using Kaplan-Meier survival curves.
Results: The mutation rate of PTPRT was 10.84% (40/369) in the TCGA cohort and 11.54% (27/234) in the real-world cohort. The predominant mutations were observed in the Tyrosine-protein phosphatase domain, accounting for 52.50% (21/40) of total mutations in the TCGA cohort and 37.04% (10/27) in the real-world cohort. Additional mutations were also detected in domains such as Fibronectin type-III and HAM. Survival analysis of the TCGA cohort demonstrated that patients with PTPRT mutations had significantly higher survival rates compared to those with wild-type PTPRT ($p=0.0197$). Specifically, patients with mutations in the Tyrosine-protein phosphatase domain exhibited significantly improved survival outcomes compared to the remaining patients ($p=0.0325$). However, there were no significant differences in survival among patients with mutations in other functional domains ($p>0.05$).
Conclusion: In summary, our study elucidated a mutation rate of approximately 10.84% (TCGA cohort) and 11.54% (real-world cohort) for the PTPRT gene in gastric cancer. The Tyrosine-protein phosphatase domain emerged as the primary hotspot for these mutations. Notably, patients harboring PTPRT mutations, particularly in the Tyrosine-protein phosphatase domain, exhibited significantly improved survival outcomes compared to those without mutations in this domain. These findings underscore the potential prognostic significance of PTPRT mutations in gastric cancer and emphasize the need for further investigations to explore their therapeutic implications.

#4662 Tracking gene expression in the tumor microenvironment throughout breast cancer progression.

O. S. Ahmed[1], h. Morsy[1], H. Ateya[1], M. Medhat[2], A. Zekri[1];
[1]National Cancer Institute, Cairo University, Cairo, Egypt, [2]faculty of pharmacy- Russian university, Cairo, Egypt

Background Genetic profiling of the tumor microenvironment involves looking at a lot of genes to figure out what roles they play in the progression of cancer and in how well treatments work. The tumor microenvironment is responsible for tumor genesis, metastasis, and resistance to standard therapy. Characterizing the tumor microenvironment through gene expression, such as ABCB1, FOXA, SFRP1, EGF, and XPB1, can provide valuable insights into the mechanisms driving cancer behavior. By understanding the interactions between these genes and their surrounding environment, researchers can develop more targeted and effective therapeutic strategies that enhance patient outcomes. This study design indicates the systematic procedure of genetic profiling, including patient enrollment and data analysis, with the objective of enhancing our comprehension of the tumor microenvironment in the specific context of Egyptian patients.
Materials and Participants This study involved 60 patients, evaluating the expression levels of specific genes and identifying patterns linked to disease characteristics. RT2 Profiler PCR Arrays PASH-131Z were used to determine the gene expression of 84 genes for tumor cells and surrounding normal cells in each individual..
Results: The FOXA1 gene is up-regulated significantly ($p = 0.03$). It is involved in the laminal classification of breast cancer and the control of transcription for genes related to estrogen hormone and estrogen receptor activity. On the other hand, genes like ABCB1, ATM, BRCA1, CCNA1, CCND2, CDK2, CDKN1A, EGF, EGFR, GATA3, IGF1R, IL6, TP53, and HPRT1 show significant down-regulation ($p < 0.02$). These genes are involved in DNA damage and repair, cell cycle regulation, and apoptosis.
Conclusion :FOXA1 and XBP1 are more important for luminal A breast cancer as a connect with hormone receptor signaling. On the other hand, SFRP and ABCB1 are more important for triple-negative breast cancer because they affect Wnt pathway activation and treatment resistance, respectively. These genes underscore the unique biological pathways present in breast cancer subtypes and demonstrate the problems and potential in their therapeutic targeting.

#4663 Human papillomavirus circulating tumor DNA for risk stratification in cervical cancer.

Emma M. Collier[1], Lucas Penny[1], Jinfeng Zou[2], Zhen Zhao[2], Yangqiao Zheng[2], Pamela Soberanis Pina[3], Michelle McMullen[4], Eric Y. Stutheit-Zhao[5], Michael M. Hoffman[2], Sarah E. Ferguson[6], Kathy Han[7], Eric Leung[8], Stephanie Lheureux[2], Scott V. Bratman[5]

[1]Department of Medical Biophysics, University of Toronto, Toronto, ON, Canada,[2]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[3]Medical Oncology, UHN Princess Margaret Hospital, Toronto, ON, Canada,[4]Department of Medical Oncology, Sir Charles Gairdner Hospital, Nedlands, Australia,[5]Department of Radiation Oncology, University of Toronto, Toronto, ON, Canada,[6]Obstetrics and Gynecology, UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[7]Radiation Medicine, UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[8]Department of Radiation Oncology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

Background: Human papillomavirus (HPV) DNA is detectable in the peripheral blood plasma from patients with locally advanced and metastatic cervical cancer. Levels of HPV circulating tumor DNA (ctDNA) in pretreatment plasma have weak associations with prognosis, but the significance of detecting HPV integration into the host genome or fragmentation features within HPV ctDNA has not been explored. We hypothesized that these molecular features of HPV ctDNA may serve as prognostic biomarkers and reflect HPV biology, independent from total ctDNA abundance.

Methods: Plasma cell-free DNA was collected at baseline from 57 patients with locally advanced cervical cancer (stage IB-IVA) and 21 patients with metastatic cervical cancer. Whole viral genome sequencing was performed following hybrid capture. HPV ctDNA levels were expressed in copies/mL plasma. HPV integration sites were detected using SearcHPV. Progression-free survival (PFS) was evaluated using Kaplan-Meier analysis and log-rank tests. The normalized fragment midpoint coverage across the HPV-16 genome was calculated for individual samples and averaged across patient groups. NuPoP, was used to calculate the expected nucleosome occupancy at each base pair of the HPV-16 genome. Peaks corresponding to the observed nucleosome occupancy within our cohorts were called using pracma, and occupancy probabilities were calculated for each peak.

Results: Baseline HPV ctDNA levels were detected in 57/57 locally advanced patients (median=283 copies/mL) and 20/21 metastatic patients (median=299 copies/mL). Unique HPV integration sites were detected at varying levels in 21/57 locally advanced patients (median sites:1, range:0-23) and 12/21 metastatic patients (median sites:2, range:0-45) (Wilcoxon p=0.8). No significant differences in PFS were observed in locally advanced or metastatic patients when stratified by median ctDNA levels (p=0.7 and p=0.8 respectively). However, high confidence integration detected at baseline was associated with inferior PFS in locally advanced patients (p=0.01), but not metastatic (p=0.28). HPV ctDNA fragment coverage varied across the HPV-16 genome with the number of observed merged peaks being 32 in the locally advanced cohort (n=36) and 31 in the metastatic cohort (n=14). The median expected nucleosome occupancy probabilities across all peaks were 98.6% and 97.2%, respectively.

Conclusion: Detection of viral integration within baseline HPV ctDNA was associated with significantly inferior PFS in locally advanced patients. Peaks in the average HPV-16 ctDNA coverage profiles corresponded to high expected nucleosome occupancy in both the locally advanced and metastatic cohorts, suggesting that ctDNA may reflect chromatin accessibility of the virus. These findings suggest that quantitative and qualitative features of HPV ctDNA from baseline plasma may reflect HPV biology associated with cervical cancer.

#4664 Differential transcript usage reveals SERINC2 as a prognostic biomarker in clear cell renal cell carcinoma (ccRCC).

Chinaza Nnam, Minghui Zhang, Brock Christensen, Lucas Salas

Dartmouth College, Lebanon, NH

Background: Clear cell renal cell carcinoma (ccRCC), the most common subtype of renal cell carcinoma, accounts for approximately 75% of cases[1]. While differentially expressed gene (DEG) analyses have provided valuable insights, they often neglect alternative splicing (AS), a key driver of transcriptome diversity and functional protein complexity. AS is essential in modulating tumor biology and can impact disease progression and survival outcomes[2]. To address this gap, we performed a differential transcript usage (DTU) analysis in ccRCC to explore the role of AS in shaping survival-associated signatures.

Methods: A total of 172 tumor samples from the Dartmouth Renal Tumor Biobank were analyzed. Following quality control, transcripts expressed in > 0.1 TPM in at least 25% of tumor samples were retained, yielding 31,850 transcripts. DTU was assessed using DRIMSeq, while functionality was evaluated with IsoformSwitchAnalyzeR. Cox proportional hazards analysis and machine learning-based Cox-LASSO regression was applied to identify survival-associated features, followed by log-rank analysis to explore their prognostic relevance.

Results: DTU analysis revealed significant transcript-level changes linked to survival outcomes. Among these, *SERINC2* emerged as the most statistically significant survival-associated gene, with its transcript NM_001199039.2 exhibiting a hazard ratio (HR) of 0.5 (95% CI: 0.39-0.69). Kaplan-Meier analysis confirmed that elevated expression levels of this transcript were significantly associated with better survival outcomes ($p < 0.05$). *SERINC2* is linked to membrane lipid synthesis and may be associated with lipid metabolic reprogramming, a hallmark of ccRCC pathogenesis. Notably, isoform NM_001199039.2 has the shortest N-terminus regions compared to other validated isoforms, possibly conferring unique functionality. Finally, a prognostic model based on the Cox model demonstrated AUC values of 0.68 for 3-year survival and 0.78 for 5-year survival, indicating strong predictive potential for long-term outcomes.

Conclusions: Our findings identify the *SERINC2* splice variant (variant 5), NM_001199039.2, as a potential biomarker for favorable outcomes. We will conduct further validation in independent datasets and experimental systems to delineate the role of this splice variant on survival outcomes in ccRCC.

Key words: Differential Transcript Usage, variant, survival.

#4665 Real-world data of resected early-stage non-small cell lung cancer (NSCLC) harboring copy number variations.

Jun Wang[1], Ning Gao[2], Ding Zhang[2]

[1]Department of Thoracic Surgery, Jiangsu Province Hospital and The First Affiliated Hospital of Nanjing Medical University, Nanjing, China,[2]3D Biomedicine Science & Technology Co., Ltd., Shanghai, China

Introduction: Copy number variations (CNVs) in several genetic regions are associated with cancer susceptibility and poor clinical outcomes. Currently, the role of CNVs in Non-Small Cell Lung Cancer (NSCLC) is relatively vague. This study investigates the CNVs profile in early-stage NSCLC.

Methods: We retrospectively analyzed the next-generation sequencing (NGS) data of tumor tissue specimens from NSCLC patients over the past 3 years in our center. All samples were obtained by surgical resection, and clinical characteristics were collected for further analysis.

Results: A total of 102 early-stage NSCLC performed NGS in our study, the mean age was 60.5 years, with 51% female. Genomic analysis revealed that 85.3% (87/102) patients had driver gene mutations, predominantly *EGFR* mutations (72/102) and *ALK* fusions (6/102). CNVs were observed in 29 NSCLC patients, including 22 with *EGFR* mutations, 1 with *ALK* fusion, 1 with *BRAF* V600E, and 5 without driver gene mutations. Among patients with CNVs, 9p21 (*CDKN2A/CDKN2B*) copy number losses were most frequent (24.1%, 7/29), followed by *EGFR* copy number gains (20.7%, 6/29), *MYC* copy number gains (13.8%, 4/29), and *GATA1* copy number losses (13.8%, 4/29). There was no significant difference in age (median: 63 vs 61 years, *P*=0.504, Mann-Whitney U test) and sex (male: 66% vs 34%, *P*=0.221, chi-square test) between patients with and without CNVs. A significant trend of increased CNVs was observed in smokers compared to non-smokers (CNVs: 45.5% vs. 23.8%, P=0.046, chi-square test). Patients with small tumors accompanied by lymph node metastasis showed a significantly higher incidence of driver gene fusions than those without lymph node metastasis ($T_{1-2}N_{1-2}$ vs. $T_{1-2}N_0$ = 50.0% vs. 7.7%, P<0.001, chi-square test). However, no significant difference in CNVs incidence was found between these groups. The prognostic value of CNVs requires further validation through follow-up.

Conclusions: Our study reveals a high prevalence of copy number losses of 9p21 (*CDKN2A*/*CDKN2B*) exists in early-stage non-small cell lung cancer. And we find that NSCLC patients with a history of smoking are more likely to have copy number variations.

#4666 Unraveling the role of Nrf2 in the acute myeloid leukemia: implication for therapeutic targeting.

Avanish Kumar Pandey[1], Neha Thukral[1], Jay Singh[1], Mercilena Benjamin[1], Anmol Gaur[1], Pranay Tanwar[1], Jayantha Kumar[2], Sameer Bakhshi[3], Surender K. Sharawat[3], Deepam Pushpam[3], Akash Kumar[4], Karthikeyan Pethusamy[2], Anita Chopra[1]

[1]Laboratory Oncology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[2]Department of Biochemistry, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[3]Medical Oncology, All India Institute of Medical Sciences (AIIMS), New Delhi, India,[4]NCI Jhajjar, All India Institute of Medical Sciences (AIIMS), New Delhi, India

Background: Acute myeloid leukemia (AML) is a hematologic malignancy characterized by uncontrolled proliferation of myeloid precursor cells, presenting significant therapeutic challenges. *NRF2* (Nuclear factor erythroid 2-related factor 2) is a transcription factor that regulates cellular defense mechanisms against oxidative stress, which may contribute to AML progression and chemoresistance.
Aim: This study aims to investigate the expression and regulatory role of *NRF2* in AML, identify its downstream target genes, and evaluate its contribution to disease progression and chemoresistance.
Methods: *NRF2* expression was analyzed in de novo AML bone marrow samples, including adult (n=268) and pediatric (n=173) cases, alongside healthy controls (n=45), using qPCR. AML cell lines (MOLM13 and MV411) were also evaluated for *NRF2* mRNA and protein expression. Protein levels of *NRF2* in AML patient samples and cell lines were assessed via flow cytometry. ChIP sequencing was conducted to identify *NRF2* downstream targets, with ChIP-PCR used for target validation. The cytotoxic effects of a chemotherapeutic agent (Daunorubicin) and an *NRF2* inhibitor (Brusatol) were assessed using MTT assays to determine the IC50 values. Drug assays and inhibition studies were performed to evaluate the effects of *NRF2* inhibition on target gene expression. Statistical analyses, including univariate and multivariate Cox regression, were conducted to correlate *NRF2* expression and clinical parameters with patient survival.
Results: *NRF2* mRNA expression was significantly elevated in de novo AML samples compared to controls (p=0.0024 in adults, p=0.001 in pediatrics). Similarly, high *NRF2* expression was observed in MOLM13 and MV411 cell lines. Flow cytometry analysis revealed higher *NRF2* protein levels in CD33-positive AML blast cells than in lymphoid cells. ChIP sequencing identified 95 enriched regions associated with *NRF2*, including genes involved in the HALLMARK Reactive Oxygen Species Pathway, such as *NQO1*. ChIP-PCR confirmed the significant enrichment of *NRF2* target genes, including *NQO1, HO1, DAD1, STAT2*, and *CYP1B1*. Treatment with Daunorubicin significantly increased *NRF2* expression, while Brusatol significantly reduced *NRF2* and its target gene expression (e.g., *DAD1, STAT2, and CYP1B1*). Survival analyses showed that higher *NRF2* mRNA expression was associated with poorer overall survival (p=0.044 in adults, p=0.037 in pediatrics). Multivariate Cox regression analysis indicated that elevated *NRF2* expression (HR=1.49, 95% CI=1.10-2.12, p=0.05) and higher WBC counts (HR=1.55, 95% CI=1.06-2.25, p=0.02) were independently associated with poor survival outcomes.
Conclusion: This study underscores the role of *NRF2* in AML progression and its potential as a biomarker of poor prognosis. Targeting *NRF2* and its downstream pathways could provide a novel therapeutic approach to improve outcomes in AML patients.

#4668 Prognostic significance and therapeutic potential of TOP2A expression in rare cancers.

Jifa Li, hua Ye, xiaoqiong Bao, wenwen Yu, xiangxiang Chen, yangyang Ni, jincong Wang, yubo Shi

Yueqing People's Hospital, Yueqing, China

Background: TOP2A (Topoisomerase IIα) is a crucial nuclear enzyme involved in various processes of DNA metabolism, including replication, transcription, and chromosome segregation. Aberrant expression of TOP2A leads to chromosomal instability, increased cell proliferation and migration, and enhanced tumor invasiveness. Its high expression has been associated with poor prognosis in several common cancers, but its relationship with prognosis in rare cancers remains unclear. This study aims to investigate the expression, prognosis, and mechanisms of TOP2A in rare tumors using the TCGA (The Cancer Genome Atlas) bioinformatics database. The findings of this study will contribute to the understanding of targeted therapy and the molecular mechanisms underlying prognosis in these rare tumors.
Methods: We utilized the TCGA datasets, comprising 80 cases of ACC, 516 cases of LGG, 120 cases of THYM, and 259 cases of SARC, to investigate the expression levels of TOP2A. A comparison between normal and tumor tissues was conducted using the Mann-Whitney test. Based on the expression levels of TOP2A, the patients were categorized into two groups: high and low. The prognostic significance of TOP2A expression in these cancer types was evaluated using Kaplan-Meier Plotter. Furthermore, the correlation between TOP2A expression and BRCA1, BRCA2, and MMR genes was assessed using the Pearson correlation coefficient.
Results: Kaplan-Meier survival analysis revealed that in the overall population, the group with high expression of TOP2A exhibited significantly lower survival rates compared to the group with low expression ($p < 0.05$). This trend was consistently observed in ACC, LGG, and THYM cohorts. In the SARC cohort, when the threshold for TOP2A expression was set at 50%, there was no significant difference in survival between the two groups. However, a significant survival difference was observed between the top 25% and bottom 25% of TOP2A expression ($p = 0.022$). According to the Mann-Whitney analysis, the expression of TOP2A was significantly higher in these four cancer types compared to normal tissues. The correlation analysis between TOP2A expression and mismatch repair genes as well as homologous recombination repair genes revealed a strong association between TOP2A expression and BRCA1 and RAD51 (correlation coefficients of 0.59 and 0.8, respectively).
Conclusion: The elevated expression of TOP2A in rare cancers, along with its significant correlation with tumor progression and poor prognosis, suggests its potential as a promising therapeutic target and prognostic marker for these rare malignancies. These findings provide valuable insights and a theoretical foundation for further elucidating the mechanistic role of TOP2A in the pathogenesis of these cancer types.

#4669 Prognostic value of postoperative circulating tumor DNA in patients with resectable hepatocellular carcinoma.

Van-Anh Nguyen Hoang, Dao Nguyen Vinh, Giang Hoang Vu, Duy Sinh Nguyen, Hoa Giang, Hoai-Nghia Nguyen, Lan N. Tu

Medical Genetics Institute (Vietnam), Ho Chi Minh, Viet Nam

Background: Hepatocellular carcinoma (HCC) is endemic in Asia, particularly Vietnam due to the prevalence of hepatitis B virus infection. Liver resection is the first-line treatment but prognosis remains poor with a high relapse rate. Current methods including imaging and serum tumor biomarkers have suboptimal accuracy to monitor tumor burden and predict relapse.
Method: In this prospective study, sixty HCC patients who were eligible for curative-intent liver resection were recruited. Genomic DNA isolated from primary tumor tissues and paired white blood cells were subjected to targeted sequencing of 95 cancer-related genes to profile tumor-derived mutations. Top-ranked mutations specific to each individual were then used to track the presence of circulating tumor DNA (ctDNA) in serial plasma samples.
Results: The most frequently mutated genes in our cohort were *TP53* (42.4%), *TERT* promoter (39.0%), *CTNNB1* (23.7%), and *AXIN1* (22.0%). *TP53* R249S was the major hotspot found in 8.5% of the patients. Mutations in *TERT* promoter were significantly more prevalent in hepatitis C- than hepatitis B- infected patients, while *CTNNB1* was not mutated in those with no virus infection. On average, 4 mutations were selected to track ctDNA in plasm samples. Pre-operative detection rate of ctDNA was 96.6%, higher than AFP (57.6%). Post-operative ctDNA positivity, both at the landmark time point and during surveillance, was the strongest independent predictor of disease-free survival (HR: 17.9, 95% CI: 5.9 - 54.1, $p<0.001$). ctDNA detection could predict clinical relapse with sensitivity and specificity of 82.8% and 96.0% respectively, and the lead time of up to 7.3 months. This outperformed all serum tumor biomarkers: AFP, AFP-L3, and PIVKA-II.
Conclusion: Our simplified and cost-effective assay enabled longitudinal ctDNA monitoring for early relapse detection and predict disease-free survival in HCC patients. This study also provided the first mutation spectrum of Vietnamese HCC that could be helpful to uncover the multifactorial etiology of the disease.

#4670 The expression of HERV-K subfamilies indicated improved prognosis in small cell lung cancer.

Xingyuan Wu[1], Jingwei Zhang[2], Yan Ju[1], Xiao Li[2]

[1]Peking University Health Science Center, Beijing, China,[2]Thoracic Surgery, Peking University People's Hospital, Beijing, China

Background: The abnormal activation of human endogenous retroviruses (HERV) in tumor tissues has been proven implicated in cancer development and progression. Prior research demonstrated that antibodies against the HERV-K envelope protein could be produced by B cells in non-small cell lung cancer (NSCLC), enhancing immunotherapy efficacy. However, the role of HERV-K in small cell lung cancer (SCLC) remains largely unexplored.

Methods: Bulk RNA sequencing data from the IMpower-133 cohort (n = 271) was analyzed to detect the expression of HERV transcripts using the TELESCOPE algorithm. Single-cell RNA sequencing data from SCLC patients (n = 20) were employed for cell annotation. Carcinoma ecotypes (CEs) and cell-type proportions in SCLC were identified using EcoTyper, CIBERSORTx, and BayesPrism software. Immunohistochemistry (IHC) was performed to validate HERV-K expression in tumor samples collected at Peking University People's Hospital (n = 48). Kaplan-Meier survival analysis and multivariable Cox regression were used to evaluate clinical outcomes.

Results: By applying TELESCOPE in IMpower-133 dataset, we detected the expression of 468 HERV subfamilies and depicting the landscape of HERV subfamilies in SCLC. Survival analyses revealed that high expression of HML-2 (HERV-K), HERV-K11, and HERV-K13 subfamilies was associated with prolonged overall survival. Using CIBERSORTx and EcoTyper, bulk RNA sequencing data from IMpower-133 was deconvoluted into cell types, and five carcinoma ecotypes (CEs) were identified based on the co-occurrence of cell states. Notably, high expression of ERVK7, a locus-specific transcript of the HML-2 subfamily, was significantly correlated with higher abundance of CE1 across all samples (r = 0.43, p < 0.0001). CE1, the most prevalent ecotype in SCLC, was primarily composed of macrophages, CD38+ CD8+ T cells, CD4+ T cells, mature B cells, and plasma cells. CE1 abundance was associated with improved progression-free survival in SCLC patients receiving chemotherapy, as supported by multivariable Cox regression (HR = 0.32, CI: 0.13-0.77, p = 0.011). This finding was consistent with progression-free survival analysis based on ERVK7 expression (p = 0.036). The association between ERVK7 and macrophages was further validated through deconvolution of single-cell RNA sequencing data from SCLC using BayesPrism. Additionally, IHC of SCLC patient tumor samples confirmed HERV-K envelope protein (27/48) and ERVK7 (5/8) expression in tumor tissue. Higher HERV-K envelope protein expression was also associated with better disease-free survival, as supported by Kaplan-Meier analysis (p = 0.028).

Conclusions: The elevated expression of HERV-K indicated the better prognosis of SCLC patients, potentially due to the immune-hot tumor environment. These findings suggest that HERV-K may serve as potential biomarkers or co-stimulatory therapeutic targets for SCLC immunotherapy.

CLINICAL RESEARCH: Radiation Sciences 1
Poster Session

#4674 Pathological outcomes of short course vs. long course neoadjuvant radiation for stage II/III rectal cancer.

Alyssa Habermann, Patrick Chizek, Xiaoyan Deng, Dipankar Bandyopadhyay, Adam Khader, Stephen P. Sharp

Virginia Commonwealth University - VCU, Richmond, VA

Background: Total neoadjuvant therapy for rectal cancer has emerged as a favorable treatment plan. However, a definitive treatment algorithm has not been identified. Our study compares pathological response rates for neoadjuvant induction therapy regarding short and long course radiation across various demographic and disease-specific criteria.
Methods: Using the National Cancer Database (NCDB), data were collected for patients with clinical stage II and III rectal cancer who underwent neoadjuvant induction chemoradiation with either short or long course radiation from 2004-2021. Chi-squared test was used to compare the proportion of pathologic downstaging, pathologic compete response, positive surgical margin, and decreasing T and N stages individually for short course versus long course radiation. Logistic regression was used to perform multivariable analysis of factors impacting pathologic downstaging. Kaplan-Meier survival curves were used to compare overall survival between groups.
Results: A total of 1,470 patients underwent induction chemoradiation for stage II or III rectal cancer; 293 underwent short course radiation, while 1,177 underwent long course. Patients with stage II/III rectal cancer who underwent long course radiation were more likely to achieve pathologic downstaging (OR 1.83 [1.13, 2.97]) and decreasing T stage (OR 1.82 [1.14, 2.95]). On multivariate analysis, patients who received care at a community cancer program were less likely to achieve pathologic downstaging than those who received care at an academic program (OR 0.35 [0.14, 0.87]), patients with initial cN1 and cN2 tumors were more likely to achieve pathologic downstaging than those with cN0 tumors (OR 2.86 [1.94, 4.22] and OR 3.20 [1.80, 5.68], respectively), and patients who underwent long course radiation were more likely to achieve pathologic downstaging than those who underwent short course (OR 2.04 [1.19, 3.47]). Overall survival was improved for the long course group compared to the short course group (p=0.02). Median overall survival was 165 months for patients who underwent long course radiation and 104 months for those who underwent short course radiation.
Conclusion: Based on a retrospective review of NCDB data from 2004-2021, patients who underwent induction therapy with long course radiation for stage II/III rectal cancer were more likely to achieve pathologic downstaging than those who underwent short course radiation. Furthermore, overall survival was improved in patients who underwent long course radiation. This leads us to recommend long course over short course neoadjuvant radiation in induction therapy of patients with stage II/III rectal cancer. Given the extended median overall survival reported here, we call for long-term follow-ups from the randomized clinical trials reporting on long course vs short course radiation before the controversy can be settled.

#4675 Radiation therapy utilization and outcomes in primary and secondary central nervous system lymphoma.

Brianna Hostler[1], Jona A. Hattangadi-Gluth[2], Parag Sanghvi[2], Kathryn R. Tringale[2]

[1]Department of Psychology, San Diego State University, San Diego, CA,[2]Department of Radiation Medicine and Applied Sciences, University of California, San Diego, San Diego, CA

Background: Radiotherapy (RT) is an established consolidation strategy for primary CNS lymphoma (PCNSL). However, the role of RT in secondary CNSL (SCNSL) is unclear. Here, we describe RT doses, disease failure patterns, and survival outcomes in an RT-treated CNSL cohort.

Methods: Patients treated with CNS-directed RT for CNSL at UCSD were identified by ICD-10 codes, RT course description, or radiation oncologist. Site of CNS disease failure was local (involving initial site) or distant (outside of initial site). Overall survival (OS) and CNS progression-free survival (CNS PFS) were evaluated from time of RT start using Kaplan-Meier. Outcomes were stratified by PCNSL vs SCNSL.

Results: 30 patients (13 [43%] PCNSL, 17 [57%] SCNSL) and 39 total CNS-RT courses were included. Most received RT for relapsed/refractory disease (23, 77%) as opposed to definitive (6, 20%) or consolidative (1, 3%) intent. At the time of RT, 1 (3%) patient had CSF, 13 (43%) had ocular, and 12 (40%) had extracranial disease (6 progressive, 6 stable). Median RT dose was higher for PCNSL (40.5 Gy vs 30 Gy for SCNSL, p=.031). First course RT targets were whole-brain RT (WBRT; 17, 57%; 6 included orbits [3 electively]), orbits alone (10, 33%), focal (2, 7%), and spine (1, 3%).

17 patients relapsed, most only distantly (9 [53%] vs 5 [29%] locally). Only SCNSL patients had synchronous local and distant failures (3, 18%). 2 patients received focal RT to dura and did not progress. Of the 4 (36%) who relapsed after WBRT, 2 were local-only SCNSL failures, and 2 were distant-only PCNSL failures. Of the 4 (67%) who relapsed after WBRT + orbits, 3 failed in the parenchyma. Most of the 8 who relapsed after orbits RT alone had distant (5, 63%) failures, most (3, 60%) parenchymal. Those with ocular involvement received WBRT + orbits or orbital RT alone, most relapsing in the parenchyma (8, 62%). No ocular failures occurred in those without ocular disease at RT start.

Median OS was longer for PCNSL vs SCNSL (18.6 months [95%CI 0.0-42.4] vs 6 months [95%CI 3.0-8.9]), respectively; log-rank p=.058).

Median CNS PFS was similar between PCNSL vs SCNSL (2.83 months [95%CI 0.0-19.8] vs 4.41 months [95%CI 1.4-7.4], respectively; log-rank p=.256). 3 patients had systemic relapse preceding CNS relapse.

Conclusions: Different disease failure patterns were seen in mostly relapsed/refractory SCNSL vs PCNSL receiving CNS-RT. Only SCNSL patients failed both distantly and locally, suggesting the inclusion of more comprehensive treatments alongside RT (e.g., systemic or intrathecal). As SCNSL received a lower RT dose and most patients suffering local failure were SCNSL, further dose optimization should be considered. Future studies will examine MRI predictors of disease failure patterns.

#4676 MRI-based radiomics ensemble model for predicting radiation necrosis in brain metastasis patients treated with stereotactic radiosurgery and immunotherapy.

Yijun Chen[1], Corbin A. Helis[1], Christina K. Cramer[1], Michael T. Munley[1], Fei Xing[2], Qing Lyu[3], Christopher T. Whitlow[3], Jeffrey Willey[1], Michael D. Chan[1], **Yuming Jiang**[1]

[1]Radiation Oncology, Wake Forest University School of Medicine, Winston Salem, NC,[2]Wake Forest University School of Medicine, Winston Salem, NC,[3]Radiology, Wake Forest University School of Medicine, Winston Salem, NC

This study aims to apply an ensemble model integrating MRI-based radiomics and clinical information as a reliable tool for precisely predicting radiation necrosis, a severe consequence of radiation therapy for brain metastases that requires accurate early prediction to improve patient management. We retrospectively collected and analyzed MRI images and clinical information from 209 stereotactic radiosurgery sessions involving 130 patients with brain metastasis. Radiomic features were extracted from MRI using PyRadiomics and selected via L2 regularization and coefficient analysis. An ensemble model integrating gradient boosting, random forest, decision tree, and support vector machine as base regressors was developed using a soft voting approach to generate the final prediction of the likelihood of necrosis. Performance was assessed and compared with other machine-learning algorithms using metrics including the area under the curve (AUC), sensitivity, specificity, negative predictive value (NPV), and positive predictive value (PPV). SHapley Additive exPlanations (SHAP) and local interpretable model-agnostic explanations (LIME) analyses were applied to explain the model's prediction. The soft-voting ensemble model demonstrated strong performance in the validation cohort, achieving the highest AUC of 0.873 (95%CI: 0.672 - 1.000). It consistently outperformed individual models and the stacking ensemble model, exhibiting superior accuracy, generalizability, and reliability in predicting radiation necrosis. Both univariate and multivariate logistic regression analyses were performed and confirmed the model as the strongest predictor. SHAP and LIME analyses were employed to interpret the predictive model for radiation necrosis, identifying metastasis volume and the radiomic feature, log-sigma-1-mm_glcd_ldmn, as key predictors. Both analyses highlighted similar significant factors, enhancing the understanding of prediction dynamics. This MRI-based radiomics ensemble model exhibited high accuracy and robustness in predicting radiation necrosis. It has the potential to serve as a novel and valuable tool to facilitate radiotherapy for patients with brain metastasis.

#4677 Combating radioresistance in lung cancer: S6K1 signaling as a therapeutic target through metabolic modulation.

Ali Jose Calderon-Aparicio, Nicole L. Simone

Radiation Oncology, Thomas Jefferson University, Philadelphia, PA

Background: Locally advanced non-small cell lung cancer (NSCLC) is treated with a combination of chemotherapy, immunotherapy, and radiation but is unfortunately still associated with poor cancer survival. Improving radiation efficacy is essential to enhance tumor control and reduce resistance, ultimately improving outcomes for patients. Metabolic reprogramming could play a key role in this by targeting cancer cell metabolism to increase sensitivity to radiation and reduce tumor growth. S6K1 has emerged as a metabolic regulator that promotes chemo and radio-resistance in several cancers. However, the associated mechanisms to this phenomenon are unclear. We sought to determine if pharmacological or metabolic inhibition of S6K1 modulates radioresistance in lung cancer.
Methods/Results: The intrinsic radiosensitivity of cells lines originating from NSCLC was determined by clonogenic and proliferation assays. Four cancer cell lines of varying intrinsic radiation sensitivity were chosen as a model to investigate the role of S6K1. The A549 cells were the most resistant followed by H661, H226 and the most sensitive as H23. The phospho-activation of S6K1 and its downstream target S6 increased in more resistant cells, associating S6K1 activation with radioresistance. TCGA analysis showed that S6K1 is overexpressed in lung cancer patients compared to healthy controls ($p<0.001$). Inhibition of S6K1 by pharmacologic means using a highly specific inhibitor (PF-4708671), or by genetic deletion of S6K1 by Crispr-Cas9, in combination with radiation, significantly decreased the colony formation compared with controls. Using *in vivo* murine models, $S6K1^{-/-}$ tumors had notably decreased tumor progression than the $S6K1^{+/+}$ tumors ($p<0.001$). To determine the role of metabolic reprogramming on S6K1 activation and its effects on radioresistance, *in vitro* models of caloric restriction were tested and demonstrated a decreased S6K1 activation, and radiosensitivity trough reduction of transcriptional activation of STAT3, a target involved in radio-resistance. In NSCLC murine models, caloric restriction significatively decreased the tumor burden in mice.
Conclusion: Our findings demonstrate that targeting S6K1, through pharmacological inhibition or metabolic interventions like caloric restriction, significantly enhances the therapeutic efficacy of radiotherapy in NSCLC. Studies are underway to elucidate the detailed mechanisms linking S6K1 activity and caloric restriction to radiosensitivity, with the potential to inform novel therapeutic strategies for improving outcomes in lung cancer patients.

#4678 Identifying and exploiting a novel role of FTO in promoting cysteine metabolism for NSCLC therapy.

N. Kuganesan, S. Melemenidis, E. E. Graves, E. B. Rankin;
Stanford University, Stanford, CA

The RNA demethylase enzyme FTO is emerging as an important oncogenic factor and therapeutic target in a variety of solid tumors. However, its effect on cancer metabolism remains largely unknown. Here we show that FTO promotes cysteine metabolism, a hallmark of metabolic rewiring in non-small cell lung cancer (NSCLC) cells. Mechanistically, FTO inhibition reduces the expression of multiple targets in the cysteine metabolism pathway including the cystine transporter SLC7A11 involved in exogenous cystine uptake as well as two key enzymes cystathionine β-synthetase (CBS) and cystathionine γ-lyase (CTH) involved in de novo cysteine synthesis. Functionally, FTO inhibition reduces cystine uptake and NSCLC growth and survival in a homocysteine-dependent manner. As cysteine plays a crucial role in glutathione biosynthesis and maintenance of cellular redox homeostasis, FTO inhibition decreased glutathione levels and increased reactive oxygen species (ROS) levels in NSCLC cells. To therapeutically exploit the increased oxidative stress in NSCLC cells treated with FTO inhibitors, we combined FTO inhibition with radiation therapy. FTO inhibition enhanced the radiosensitivity of NSCLC cells. Our findings reveal a novel role for FTO in NSCLC cysteine metabolism and oxidative stress, highlighting the therapeutic potential of FTO inhibition as a strategy to enhance the efficacy of radiation therapy for the treatment of NSCLC.

#4679 FTO inhibition enhances the therapeutic index of radiation therapy in head and neck cancer.

L. Ji[1], L. Pu[1], H. Cao[1], S. Melemenidis[2], S. Sinha[2], L. Guan[1], E. E. Laseinde[1], S. Richter[1], R. Eyben[2], K. Casey[2], C. Kong[1], E. Graves[2], Q. Le[2], E. Rankin[1];

[1]Stanford University School of Medicine, Stanford, CA, [2]Stanford University, Stanford, CA

Despite the use of intensive combined modality therapy such as chemoradiation or surgery and radiation, the overall survival rate for patients with HPV-negative head and neck squamous cell carcinoma (HNSCC) remains poor. This underscores the unmet clinical need for the development of more effective drug-radiotherapy combinations to enhance the therapeutic index of radiation therapy (RT). The RNA demethylase enzyme FTO has emerged as a promising target for cancer therapy. However, its role as a radiosensitizer in HNSCC remains unknown. Here, we investigated the potential of targeting FTO to augment the effectiveness of RT in HPV-negative HNSCC. We found that genetic and pharmacologic inhibition of FTO enhanced the efficacy of RT in both human and mouse HNSCC tumor xenografts. Importantly, FTO inhibition did not increase radiation-induced oral mucositis. Mechanistically, FTO inhibition radiosensitizes HPV-negative HNSCC cells through amplifying DNA damage while reducing RAD51 foci formation, providing a molecular rationale for exploiting FTO inhibitors as radiation sensitizers in HNSCC. Collectively, our results suggest that therapeutic targeting of FTO may be an effective strategy to enhance the therapeutic index of RT for the treatment of HNSCC.

#4680 Simultaneous DDR1/FGFR inhibition elicits adaptive EGFR/MAPK pathway activation to counteract susceptibility to radiochemotherapy in preclinical glioblastoma models.

Anne Vehlow, Irina Korovina, Olegs Borodins, **Nils Cordes**

OncoRay, Dresden, Germany

GBM cell survival critically depends on cell adhesion molecules like discoidin domain receptor 1 (DDR1) and receptor tyrosine kinases like fibroblast growth factor receptors (FGFR), both of which represent potential therapeutic vulnerabilities. Based on the radiochemosensitizing potential of DDR1 mono-inhibition, we investigated the adaptive response induced by DDR1 deactivation using broad-spectrum kinome analyses. Since FGFR were identified most hyperactive, we examined the efficacy of simultaneous pharmacological DDR1/FGFR inhibition and found enhanced cytotoxicity and radiochemosensitization in a human gliomasphere panel. Subsequent evaluation of DDR1 and FGFR single and dual inhibition in orthotopic, radiochemotherapy-treated GBM mouse models revealed a profound reduction in efficacy for dual as opposed to single inhibition. This was mechanistically underpinned through RNA-seq analyses uncovering strong activation of EGFR/MAPK signaling under DDR1/FGFR deactivation relative to monotherapies. In conclusion, our data evidently show that particularly DDR1 monotherapy effectively augments radiochemotherapy in GBM, while simultaneous DDR1/FGFR inhibition requires more in-depth investigation.

#4681 Multiomic insights into mechanisms of androgen receptor-driven radioresistance in triple-negative breast cancer.

Benjamin Hauk[1], Breanna McBean[2], Anna Michmerhuizen[2], Douglas Gurdak[1], Savannah Tidmore[1], Michelle Paulsen[2], Lynn Lerner[2], Connor Ward[2], Kassidy Jungles[2], Daniel Spratt[1], Lori Pierce[2], Mats Ljungman[2], Corey Speers[1]

[1]Radiation Oncology, Case Western Reserve University School of Medicine, Cleveland, OH,[2]Radiation Oncology, University of Michigan, Ann Arbor, MI

Background: Due to the lack of molecular-targeted therapies for triple-negative breast cancer (TNBC), there have been efforts to use multimodal strategies to enhance the efficacy of existing therapies such as radiation. The androgen receptor (AR) has been identified as a radiosensitizing target and is expressed in 25-50% of TNBC tumors. The combination of AR inhibitors, such as enzalutamide (enza), and radiation therapy (RT), leads to radiosensitization in AR+ TNBC models but the mechanism by which AR mediates radioresistance is not known, and targeting this radioresistance could provide a novel strategy to improve outcomes in this aggressive breast cancer subtype. Following RT, AR is translocated to the nucleus suggesting that AR may drive transcriptional changes in response to RT.
Methods: Bulk RNA-seq with and without R1881 stimulation and RT was used to assess transcriptional changes at 24 hours. RPPA analysis evaluated protein and phophoprotein changes. AR ChIP-seq was used to identify changes in AR binding and Bru-seq to profile changes in nascent RNA. These experiments were performed in two AR+ TNBC models, MDA-MB-453 and MFM-223 cells, with and without enza and RT. Clonogenic survival assays were performed to assess for radiosensitivity.
Results: RNA-seq and RPPA analysis demonstrated numerous changes in gene and protein expression after enza-, RT-, and combination treatment. Gene set enrichment analysis (GSEA) of these changes nominated alterations of MAPK pathway genes with R1881 and R1881+RT compared to controls. To assess the MAPK/ERK pathway, constitutively active ERK was overexpressed in AR+ TNBC models which induced radioresistance, confirming this relationship. As expected, AR ChIP-seq data showed enza treatment induced a significant reduction in AR peaks compared to DMSO-treated controls. Radiation induced fewer changes in AR binding than enza treatment. Bru-seq GSEA showed significant upregulation of MYC target gene sets in response to RT in control conditions. Conversely, with enza treatment, there was no significant MYC target gene set upregulation. While there were no changes in MYC expression or AR binding to known MYC enhancers, there was increased binding of AR to known MYC binding sites in control samples in response to RT. This RT-induced binding to MYC sites was not seen in the enza-treated samples suggesting that AR inhibition may dampen the RT induction of MYC signaling leading to radiosensitization.
Conclusions: These findings provide new insights into the molecular underpinnings of AR-mediated radioresistance and identify MAPK and MYC pathways as potential therapeutic targets to enhance radiosensitivity in AR+ TNBC. Ongoing studies aim to translate these findings into clinically actionable strategies. This work expands our understanding of AR-mediated radioresistance which may uncover resistance mechanisms to combination AR inhibition and RT.

#4682 Elucidating the mechanisms of 2-deoxy-D-glucose (2-DG) and 2-deoxy-D-glucose phoaphate (2-DG-P) in maintaining gastrointestinal homeostasis.

Rao V. Papineni[1], Shahid Umar[2], Prashanthi Karyala[3], Kavya Ramesh[3], Badal Roy[2]

[1]University of Kansas Medical Center, Branford, CT,[2]University of Kansas Medical Center, Kansas, KS,[3]MS Ramaiah University, Bangalore, India

2-Deoxy-D-glucose (2-DG), a polypharmacological agent, has shown promise in treating various pathological conditions, including cancer, bacterial and viral infections, and as an adjuvant to radio-chemo-therapy. 2-DG exerts its effects by inhibiting glycolysis, disrupting protein N-glycosylation, inducing endoplasmic reticulum stress, autophagy, and apoptosis. Our recent studies demonstrated that 2-DG mitigates bacterial infection-induced inflammation and colitis, and proposed its potential as a radiation countermeasure agent. Utilizing a colonoid model, we investigated the mechanisms underlying 2-DG's maintenance of gastrointestinal homeostasis. Specifically, we explored its interaction with Doublecortin-like kinase 1 (DCLK1), a protein with two major isoforms, DCLK1-L and DCLK1-S.Here, 2-DG-Phosphate (2-DG-P), the non-metabolizable product of 2-DG, is also implicated in this process. Combining in silico molecular docking of 2-DG and 2-DG-P with DCLK1, we propose that 2-DG-P, along with 2-DG, may serve as potential candidates for radioprotection and mitigation of irradiation-induced gastrointestinal acute radiation syndrome (GI-ARS).

#4684 An in vivo comparison of ^{137}Cs and orthovoltage irradiation for murine bone marrow transplantation.

Danielle M. Burgenske, Brett L. Carlson, Matthew J. Rajcula, Michael J. Shapiro, Virginia M. Shapiro, Jann N. Sarkaria

Mayo Clinic, Rochester, MN

Total body irradiation for bone marrow transplantation (BMT) conditioning is commonly used in immunologic research. Historically, cesium-137 (^{137}Cs) irradiators were predominantly used as a radiation source for these studies. However, ^{137}Cs has a moderate half-life (30 years), is highly water soluble, and poses significant environmental and radiological safety concerns. As a result, the Department of Energy is promoting the replacement of ^{137}Cs irradiation systems with orthovoltage x-ray cabinet systems, which pose no such concerns. Because the physical characteristics of x-ray and ^{137}Cs photon beams have slightly different energy deposition characteristics, the relatively biological effectiveness (RBE) for x-rays is slightly higher than ^{137}Cs in cell survival studies. This study aims to compare the RBE of orthovoltage and ^{137}Cs irradiators with regards to BMT efficiency. Total body irradiation was performed on C57BL6 mice using ^{137}Cs or 320 kVp x-rays across six dose levels to establish a RBE for lethality. Cohorts of five mice were irradiated using split-dose radiation delivered four hours apart. Daily observations and body weights were captured over a 30-day period. Mice with poor body condition scores or weight loss ≥20% were euthanized. With x-rays, 50% lethality was observed ~750 cGy while ^{137}Cs required ~850 cGy, which results in an RBE of 750 cGy/850 cGy = 0.88. Bone marrow ablation and subsequent engraftment efficacy was compared in a parallel study. Cohorts of five C57BL6 CD45.1 recipient mice received total body irradiation with an established single dose 1000 cGy ^{137}Cs regimen or a range of x-ray doses (910-1030 cGy single-dose) and then were infused with CD45.2 donor bone marrow. Ten weeks after BMT, bone marrow, spleen, thymus, and peripheral blood were analyzed via multi-color flow cytometry and the percentage of CD45.1 and CD45.2-positive cells were analyzed to determine marrow engraftment efficiency across various immune compartments. A clear dose-response relationship with bone marrow ablation and engraftment was observed in the stem cell and progenitor compartments. LSK (Lineage$^-$ Sca-1$^+$ c-Kit$^+$) cells and other hematopoietic progenitors in the bone marrow were efficiently engrafted (>99%) except for the lowest dose of 910 cGy (around 98%). Similarly, in the spleen, B cells, myeloid, megakaryocyte/erythrocyte, and granulocyte/macrophage lineages were also efficiently engrafted similar to that of ^{137}Cs. Developing thymocytes were efficiently replaced by all radiation regimens, while replacement of peripheral T cell populations varied but were similar to traditional ^{137}Cs at the highest doses. Taken together, these data demonstrate comparable BMT efficiencies with orthovoltage irradiation after appropriate dose-optimization.

#4685 Targeting fatty acid oxidation improves radiation sensitivity in glioblastoma.

Tingting Huang[1], Kenneth Austin[1], Todd W. Miller[2], **Kelli B. Pointer**[1]

[1]Dartmouth Cancer Center, Lebanon, NH,[2]Medical College of Wisconsin, Milwaukee, WI

Background: Glioblastoma (GBM) is the most aggressive primary brain tumor, with a median survival of less than two years. A significant barrier to effective treatment is GBM's resistance to standard therapies, including radiation. This resistance is partially attributed to glioblastoma cancer stem cells (GSCs), a subpopulation with self-renewal capacity and the ability to regenerate all tumor components. Alterations in metabolic pathways, including fatty acid metabolism, are critical to GSC-mediated resistance. While fatty acid metabolism is known to be upregulated in GBM, its specific role in radiation-resistant GSCs remains poorly understood. Here, we investigated the impact of fatty acid metabolism inhibition on GSC radiation sensitivity.

Methods: Two human GBM cell lines were treated for 72 hours with perhexiline, a carnitine acyltransferase 1a/b inhibitor, or vehicle control. The IC25 was determined using the SRB assay and validated with cell counts. Cells were subsequently treated with the IC25 concentration of perhexiline and irradiated with a single dose of either 0 Gy or 8 Gy. Sphere formation assays and immunoblotting for stemness markers were performed. All experiments were conducted in triplicate for statistical rigor.

Results: The IC25 for perhexiline was determined to be 3 μM. Sphere formation assays using 3μM perhexiline combined with radiation revealed a significant reduction in both sphere number ($p < 0.0001$) and sphere size (350 μm vs. 125 μm). Immunoblotting demonstrated a decrease in stemness markers CD44 and nestin following drug treatment compared to vehicle control.

Conclusion: These findings suggest that perhexiline, an FDA-approved drug, enhances radiation sensitivity in GBM by targeting GSCs. The observed reduction in sphere formation and stemness marker expression highlights its potential as a GSC-directed therapy. Further studies are warranted to explore the therapeutic potential of perhexiline in overcoming radiation resistance and improving outcomes for GBM patients.

#4686 Efficacy and safety of efbemalenograstim alfa as primary prophylaxisfor concurrent chemo-radiotherapy induced neutropenia.

Yuanyuan Chen[1], Qiwen Li[1], Zunbei Wen[2], Yi Ouyang[1], Shuzhen Lai[3], Rong Huang[4], Minying Li[5], Xuefang Zhang[6], Yongling Ji[7], Chen Wang[8], Ming Chen[1]

[1]State Key Laboratory of Oncology in South China, Guangdong Key Laboratory of Nasopharyngeal Carcinoma Diagnosis and Therapy, Guangdong Provincial Clinical Research Center for Cancer, Sun Yat-sen University Cancer Center, Guangzhou, China,[2]Gaozhou People's Hospital Cancer Center, Gaozhou, China,[3]Department of Radiation Oncology, Yue Bei People's Hospital, Shaoguan, China,[4]The First People's Hospital of Foshan, Foshan, China,[5]Department of Oncology, Zhongshan People's Hospital, Zhongshan, China,[6]Department of Radiotherapy, Dongguan People's Hospital, Dongguan, China,[7]Zhejiang Key Laboratory of Radiation Oncology, Hangzhou, China,[8]Department of Oncology, Ganzhou People's Hospital, Ganzhou, China

Background: Concurrent chemo-radiotherapy (CCRT) occupies a pivotal position in the therapeutic management of various malignant tumors and frequently causes significant hematologic toxicity, particularly leukopenia and neutropenia. Nonetheless, granulocyte-macrophage colony-stimulating factor (GM-CSF) is not recommended for preventing CCRT, while granulocyte colony-stimulating factor (G-CSF) is seldom investigated in this setting. This study aims to evaluate the effectiveness and safety of efbemalenograstim alfa, a novel long-acting G-CSF, as a primary prophylaxis during CCRT.

Method: This multicenter, open-label, randomized controlled trial will enroll 120 patients who are scheduled to undergo definitive CCRT for malignancies, including non-small cell lung cancer, small cell lung cancer, esophageal cancer, nasopharyngeal carcinoma, head and neck squamous cell carcinoma, or cervical cancer. Patients will be randomized 1:1 to study group or control group. In the study group, patients will receive efbemalenograstim alfa approximately 48 hours post-chemotherapy. In the control group, patients will receive rhG-CSF upon an absolute neutrophil count (ANC) drop below 1.0×10^9/L. Patients who developed febrile neutropenia (FN) or dose-limiting neutropenic event in the control group will receive efbemalenograstim alfa in the subsequent chemotherapy cycles. The primary endpoint is the incidence of 3/4 grade neutropenia (ANC < 1.0×10^9/L) throughout the CCRT period.

Result: Efbemalenograstim alfa administration significantly reduced the incidence of grade 3/4 neutropenia during the CCRT period. Four patients (12.90%) in the efbemalenograstim alfa group experienced grade 3/4 neutropenia, compared to 14 (45.16%) in the control group, resulting in a difference of -32.26% (90% CI: -49.20%, -13.66%, p= 0.0035). The incidence of grade 3/4 neutropenia was 9.68% (study group) vs 45.16% (control group) (p=0.0009) across first chemotherapy cycle, and 3.23% (study group) vs 16.13% (control group) (p=0.0881) across second cycle. Efbemalenograstim alfa administration also resulted in shorter duration of grade 3/4 neutropenia, with a median duration of 0 day (IQR: 0-0) in study group and 0 day (IQR: 0-5) in control group (p=0.008). The depth of ANC nadir is higher in study group than that in control group (3.19 (0.26-8.45) $\times 10^9$/L vs 1.00 (0.06-4.43) $\times 10^9$/L, p < 0.001), the mean difference was 2.10 (1.39, 2.71) $\times 10^9$/L. Efbemalenograstim alfa was well-tolerated, as no≥3 grade treatment-related adverse event (TRAE) was reported in both group. The most common treatment-emergent AEs in study group included thrombocytopenia (48.39%), anemia (45.16%) and hypokalemia (35.48%).

Conclusion: Primary prophylaxis with efbemalenograstim alfa provide effective neutrophil support to patients undergoing CCRT, with good safety.

#4687 Clonal hematopoiesis of indeterminate potential may protect against radiation-induced toxicities in breast cancer patients.

Tirthankar Ray[1], Madison Hossack[2], Pierre-Antoine Bissey[1], Justin Williams[1], Wei Shi[1], Sagi Abelson[3], Steven Chan[4], Kenneth W. Yip[5], Fei-Fei Liu[6]

[1]University Health Network, Toronto, ON, Canada,[2]Institute of Medical Science, University of Toronto, Toronto, ON, Canada,[3]Ontario Institute for Cancer Research, Toronto, ON, Canada,[4]Medical Biophysics, University of Toronto, Toronto, ON, Canada,[5]Cell and Systems Biology, University of Toronto, Toronto, ON, Canada,[6]Radiation Oncology, University of Toronto, Toronto, ON, Canada

Introduction: Radiation therapy (RT) is administered to ~50% of all cancer patients yet can lead to toxicities such as radiation-induced fibrosis and/or lymphedema. Detailed understanding of the underlying pathogenesis of these post-RT complications remains to be elucidated. One potential factor might relate to clonal hematopoiesis of indeterminate potential (CHIP); an age-related clonal expansion of hematopoietic stem cells (HSCs) harboring characteristic somatic mutations (e.g., *Tet2*). CHIP is implicated in cardiovascular disease and leukemia progression, as well as several chronic fibrosis states. The current hypothesis is that breast cancer patients with CHIP at the time of radiation therapy (RT) are at higher risk of radiation-induced toxicities. To investigate this hypothesis, we utilized patient samples and mouse models with Tet2 mutations.

Methods: Blood samples were collected from breast cancer patients undergoing adjuvant RT prior to treatment. DNA was extracted, and CHIP mutations were identified using next-generation sequencing. We then examined the association between CHIP status and clinical data related to radiation-induced fibrosis and/or lymphedema. In addition, a CHIP mouse model was generated by transplanting myelo-ablated mice with HSCs heterozygous for *Tet2* null mutations. Mouse hindlimbs were irradiated at 20 Gy to induce fibrosis, evaluated through joint angle contracture (measured weekly), dermal thickness, and collagen. Smaller joint angles indicated increasing contracture/fibrosis. At 16 weeks post-RT, skin samples were collected to assay dermal thickness and collagen deposition.

Results: Amongst 138 breast cancer patients, 28 had CHIP mutations at baseline, of which only 1 patient developed radiation-induced fibrosis/lymphedema. Amongst the remaining 110 patients without CHIP, 24 developed fibrosis/lymphedema, demonstrating a significant association between toxicity outcomes with no-CHIP patients (Fisher's exact test, $p<0.05$). This was reflected in the *in vivo* model, wherein CHIP-positive mice (carrying *Tet2* mutant HSCs, n=9) exhibited reduced fibrosis, thinner skin (27% decrease), and less collagen (51% decrease) post-RT, compared to control mice with wild-type *Tet2* HSCs (n=9).

Conclusion: Our findings disproved the null hypothesis and unexpectedly demonstrated that breast cancer patients with CHIP displayed a lower risk of fibrosis/lymphedema compared to patients without CHIP. These findings need to be validated in other clinical cohorts and additional pre-clinical models to further understand the apparent protective effects of CHIP with development of radiation fibrosis.

#4688 Focused ultrasound for the treatment of osteosarcoma in a canine comparative oncology model: Findings from veterinary clinical trials.

Elliana Vickers[1], Alayna Hay[2], Lauren Ruger[3], Ny Luong[4], Sheryl Coutermarsh-Ott[5], Gregory Daniel[6], Steven Soliman[7], Gunjan Malhotra[7], Timothy Ziemlewicz[8], Adam Maxwell[3], Eli Vlaisavljevich[3], Joanne Tuohy[6]

[1]Virginia Tech, Blacksburg, VA,[2]Animal Cancer Care and Research Center, Virginia-Maryland College of Veterinary Medicine, Roanoke, VA,[3]Department of Biomedical Engineering and Mechanics, Virginia Tech, Blacksburg, VA,[4]Department of Biomedical and Veterinary Sciences, Virginia Tech, Blacksburg, VA,[5]Department of Biomedical Sciences and Pathobiology, Virginia-Maryland College of Veterinary Medicine, Blacksburg, VA,[6]Department of Small Animal Clinical Sciences, Virginia-Maryland College of Veterinary Medicine, Blacksburg, VA,[7]Department of Radiology, University of Michigan/Michigan Medicine, Ann Arbor, MI,[8]Department of Radiology, University of Wisconsin-Madison, Madison, WI

Osteosarcoma (OS) is the most common primary bone tumor in dogs and humans, and the similarities between human and canine OS make the dog a valuable comparative oncology model. Histotripsy, a non-invasive ablation modality using pulsed focused ultrasound to mechanically disintegrate tissue, shows promise for the treatment of bone tumors. Previous canine clinical trials have shown the safety and feasibility of ablating canine OS tumors, followed by limb amputation. The present study is the first use of histotripsy without standard-of-care tumor resection in OS, allowing for evaluation of long-term clinical outcomes. Pet dogs with spontaneous bone tumors were assessed at baseline and over time with MRI, gait analysis, pain & quality of life surveys, and lameness assessments. Histotripsy treatments were fractionated (separate treatments applied on different days) with a plan to ablate >50% of the tumor in 1-5 treatments. Additional treatments were applied if residual tumor was remaining or if untreated portions of tumor continued to grow on contrast-enhanced T1-weighted MRI. Histotripsy was delivered by a 700 kHz transducer designed for targeting musculoskeletal tumors, with coaxial ultrasound imaging to guide treatment planning and execution. 9 dogs with primary bone tumors were treated, and 6 dogs received long-term follow-up. Dogs generally tolerated histotripsy treatment well and were able to return home within 1-3 hours post-treatment. The maximum volume targeted in a single session was 29.2 cm^3. The mean total ablation volume was 35.6 cm^3, which equated to a mean percent ablation of 50.2% when compared to the pre-treatment tumor size on MRI. For each treatment, an area closely matching the targeted region was observed as a non-enhancing area on MRI. Whole tumor signal intensity as well as enhancing tumor volume decreased immediately after treatment but tended to return to baseline or increase by 6 weeks after the initial treatment. Considering clinical outcomes, 4/6 dogs with follow-up (all patients with >50% ablation coverage of their tumor) showed a clinically significant reduction in pain at the end of their follow-up period (mean 8 weeks) as compared to baseline. Across those 6 dogs, there was a significant increase in peak pressure on the tumor-bearing limb at the end of follow-up as compared to baseline. these results highlight the promise of histotripsy as a non-invasive limb salvage treatment for OS. This work also shows the potential of fractionated histotripsy treatments for the ablation of large tumors, which may expand the patient populations that can be treated with histotripsy. Ongoing studies are optimizing treatment strategies to achieve safe, rapid, and complete ablation of OS, including combination with immunotherapy.

#4689 Poly ADP ribose polymerase inhibitors potentiate proton therapy end-of-range relative biological effective dose by increasing replication stress.

Yiqun Han[1], Qin Zhou[1], Anna Olson[1], Cameron M. Callaghan[1], Bin Chen[1], Nicholas B. Remmes[1], Meng Xu Welliver[1], Zheming Wu[1], Daniel K. Ebner[1], Jake A. Kloeber[2], Zhenkun Lou[2], Robert W. Mutter[1]

[1]Radiation Oncology, Mayo Clinic, Rochester, MN,[2]Oncology, Mayo Clinic, Rochester, MN

Poly ADP ribose polymerase inhibitors (PARPi) are being investigated in combination with photon and proton radiotherapy in clinical trials of pediatric and adult malignancies. The precise mechanisms of PARPi radiosensitization, and whether differences in photon and proton-mediated relative efficacy exist, have not been fully elucidated. To study mechanisms of PARPi radiosensitization we investigated the effects of PARPi in combination with photons and two different ionizing densities of protons delivered at the entrance (ENT) or the Bragg peak (BP) of the profile (dose-averaged LET [LETd] 2.2 and 7.0 keV/µm, respectively) of a 76.8 MeV proton beam after observing an extreme tumor and normal tissue response in an 18-year-old female patient with high grade glioma treated veliparib and proton therapy in a Children's Oncology Group clinical trial. BRCA1/2 wild-type hTERT RPE-1, U2OS, and MDA-MB-231 cells were hypersensitive to the combination of veliparib and proton BP, with enhanced relative biological effectiveness (RBE) at 2 Gy values of 1.7, 1.4, and 1.3, respectively. Similar findings were observed with talazoparib and olaparib, suggesting that PARP trapping efficiency was not a major influence on the proton BP RBE. Further, we did not observe differences in transcription replication conflict between the different proton ionizing densities. Unexpectedly, DNA fiber assays revealed more elongated replication fork tracks in PARPi treated cells 60 minutes after proton BP compared with proton ENT, indicative of accelerated replication fork progression. To assess gap formation in the vicinity of nascent DNA we treated cells with the ssDNA-specific S1 nuclease and found that the lengths of CldU-labeled tracks were significantly reduced in cells treated with the PARPi/proton BP combination, suggestive of greater gap formation at replication forks. We postulated that more ssDNA gaps were being converted to DSBs during replication as we further observed that PARPi/proton BP resulted in increased γH_2AX foci at 4- and 24-hours after treatment. Consistent with increased DSB formation, a higher proportion of cells arrested in the G2/M phase of the cell cycle at 24 hours following PARPi/proton BP. Despite being arrested in G2/M when homologous recombination is active, there was a significant increase in 53BP1 and a decrease in RAD51 recruitment, indicative of upregulated repair by more error-prone non-homologous end-joining (NHEJ) repair pathway. The enhanced proton BP RBE in PARPi treated cells was abrogated upon knockdown of *XRCC4*, a critical component of NHEJ repair pathway, suggesting that toxic NHEJ may be contributing to the enhanced proton BP RBE. In conclusion, PARPi renders cells hypersensitive to high LET BP proton irradiation. Enhancing the LET in combination with PARPi warrants further investigation to overcome therapeutic resistance.

#4690 Radio-sensitizing activity in apoptosis pathway in HPV+ and HPV- head and neck squamous cell carcinoma (HNSCC).

Loren D. Lopez Rivera[1], Elizabeth Boeree[2], Kwang P. Nickel[1], Zafer Gurel[1], Randall J. Kimple[1]

[1]Human Oncology, University of Wisconsin-Madison, Madison, WI,[2]Cancer Biology, University of Wisconsin-Madison, Madison, WI

Head and Neck Squamous Cell Carcinoma (HNSCC) is the sixth most common cancer worldwide, presenting as two distinct diseases: HPV-positive HNSCC driven by high-risk human papillomavirus (HPV) infections; and HPV-negative HNSCC associated with heavy tobacco and alcohol use. Poor prognosis in HNSCC is partly attributed to therapy resistance, which differs between the two subtypes and is influenced by their underlying mechanism. Accumulating evidence points to dysregulation of the apoptotic pathway in HNSCC tumors via overexpression of Inhibitor of Apoptosis Proteins (IAPs). This results in evasion of cell death and makes these proteins critical therapeutic targets. Second mitochondria-derived activator of caspases (SMAC) mimetics, or IAP antagonists, are being explored as anti-cancer agents, especially in combination with radiation therapy. This study evaluates the efficacy of the IAP inhibitor AT406, alone and with radiation, in both HPV positive (UM-SCC47 and UD-SCC2) and HPV-negative (Cal27 and DET562) HNSCC cell lines. Preliminary findings suggest AT406 reduces cell viability in both subtypes, with HPV-positive cells exhibiting greater sensitivity, particularly in combination with radiation. On the other hand, HPV-negative cells show less pronounced reductions in cell viability, suggesting subtype-specific resistance mechanism. This trend underscores the potential of AT406 as a radio-sensitizing agent and highlight differences in therapeutic response between HPV-positive and HPV-negative HNSCC. Ongoing studies aim to confirm these findings and elucidate the molecular mechanism driving these differential responses. Apoptotic activity will be assessed through Caspase-3/7 activity, and expression of IAP proteins (cIAP1, cIAP2 and XIAP) will be evaluated using western blotting. In addition, Liquid Chromatography- Mass Spectrometry (LC-MS/MS) is being utilized to profile changes in protein expression under different treatment conditions to identify molecular contributors to resistance mechanisms. These studies aim to provide mechanistic insights into IAP inhibition and inform the development of combination therapies outcomes in HNSCC.

#4691 Concurrent EGFR inhibition and radiotherapy potentiates radioresistance in *TP53*-mutated endometrial cancer.

Gabriella Smith[1], Aaron Petty[2], Roberto Vargas[2]

[1]Division of Gynecologic Oncology, Cleveland Clinic Foundation, Cleveland, OH,[2]Department of Translational Hematology and Oncology Research, Cleveland Clinic Foundation, Cleveland, OH

Introduction: Endometrial cancers (EC) that harbor *TP53* mutations portend a worse clinical prognosis. EGFR inhibition has emerged as a potential radio-sensitizing strategy, particularly in NSCLC and HNSCC, however, its effect in *TP53*-mutated tumors is mixed. As emerging data demonstrates that *TP53* mutations may confer radioresistance in endometrial cancer, we explored the role of EGFR inhibition as a novel radio-sensitizing strategy in this disease site.

Methods: To evaluate the effect of EGFR inhibition on radiation response, we employed the parental EC cell line, Hec1B (*TP53* R248Q mutation). Cells were treated with increasing doses of the EGFR inhibitor, erlotinib, while concurrently exposed to varying doses of radiation. Cells were treated for 48 hours with erlotinib, and viability was assessed with CellTiter-Glo. IC_{50} values were determined using GraphPad Prism software. Drug synergy was determined using the Bliss independence model. A MeanR test was also used to compare the predicted response (additive) of the Bliss model to our data. All experiments were carried out in triplicate.

Results: The IC_{50} value of erlotinib alone was 14.4uM. At 6Gy of radiation, the IC50 of erlotinib was 23.1uM. Per the Bliss independence model, erlotinib was not observed to have a synergistic effect with radiotherapy. However, the MeanR test of the deviation from additivity demonstrated antagonism with an F-statistic of 6.46, $p = 0.02$.

Conclusion: Concurrent use of erlotinib potentiates radioresistance. Novel therapeutic and sequencing radio-sensitizing strategies remain to be elucidated in *TP53* mutated EC.

#4692 Multimodal cancer therapy consisting of antibody-drug conjugates and radiotherapy in cancer treatment.

Allegra Gerharz, Julian Schlegel, Christiane Rutenberg, Claudia Rittmuller, Mahmoud Moustafa, Ivana Dokic, Jurgen Debus, Amir Abdollahi

German Cancer Consortium (DKTK) Core-Center, German Cancer Research Center (DKFZ); Divisions of Molecular & Translational Radiation Oncology, Heidelberg Faculty of Medicine and Heidelberg University Hospital, Heidelberg Ion-Beam Therapy Center, Heidelberg, Germany

Targeting tumor associated antigens (TAA) with highly potent cytotoxic payloads by Antibody Drug Conjugates (ADC) technology is revolutionizing cancer treatment. Whether ADC could replace current chemotherapy as the standard partner of radiotherapy (RT) remain elusive. We sought to systematically decipher the impact of different payload classes and ADC combinations on tumor response to RT. A broad matrix of frequently targeted TAAs including EGFR, HER2, HER3, TROP2, Nectin4 and CEACAM in prototypic cancer cell lines representing different entities, including squamous cell carcinoma (A431), breast cancer (AU565, BT474, MDA-MB-361 and 231, MCF-7), lung cancer (NCI-H1975, A549), gastric cancer (NCI-N87) and pancreatic cancer (BxPC3) were evaluated. Moreover, representative payloads classes, i.e., tubulin inhibitors (MMAE and DM1/4), topoisomerase I inhibitors (DXd and SN-38), and the alkylating agent duocarmycin were examined. Accordingly, combination of RT with ADCs targeting HER2: trastuzumab emtansine/deruxtecan/duocarmazine (T-DM1/T-DXd/T-Duo) and disitamab vedotin, TROP2: datopotamab deruxtecan and sacituzumab govitecan, EGFR: depatuxizumab MMAE, HER3: patritumab deruxtecan, Nectin4: enfortumab vedotin and CEACAM5: tusamitamab ravtansine were evaluated. A broad heterogeneity in sensitivity to payload classes was found e.g., for topoisomerase inhibitor Deruxtecan a low nM (3,3 nM) IC50 was observed in sensitive A431. In contrast, 1 µM Deruxtecan led to only 20% loss of viability in resistant BT474 cells. In line, BT474 showed resistance to HER2 targeting ADC with topoisomerase inhibitor payload (T-DXd) but was sensitive to the same antibody conjugated with tubulin inhibitor payloads (T-DM1). These data indicate that not only TAA presence and density but also intrinsic payload sensitivity maybe relevant for assessment of ADC efficacy. Consequently, in tumors sensitive to both tubulin and topoisomerase inhibitors like AU565 breast cancer cell line similar ~ 65% cytotoxicity was found at 1 nM to both T-DM1 and T-DXd, regardless of the payload substance class. The relevance of TAA targeting, payload and drug antibody ratio (DAR) was further demonstrated by comparing different ADCs vs. antibody vs. payload alone. Enhanced radiosensitivity was exploited for different ADC and substance classes e.g., MMAE and SN-38 IC50 concentrations led to >2-Fold reduction of the survival fraction (SF) of A431 cells when combined with 2Gy RT. Together**,** this study demonstrates that inherent sensitivity of tumor cells to different payload classes, DAR and TAA dynamic are of relevance for the efficacy of ADC. Informed selection of ADC exhibited synergistic effects with RT providing a novel multimodal and promising strategy for efficient cancer eradication.

#4693 Impact of pelvic radiation on vaginal microbiome and pelvic health: Findings from the GEORGIA Trial (NCT04713618).

Yogita Mehra, Elizabeth LaPlante, Laura Flora, Caroline Dravillas, January Kim, Jessica Aduwo, Naa Korley, Alexandra Diaz, Eric Miller, Kenneth Pitter, Nyelia Williams, Rebecca Hoyd, Xiaokui Mo, Daniel Spakowicz, Laura Chambers, Elizabeth K. Arthur, Allison M. Quick

The Ohio State University, Columbus, OH

Radiation therapy (RT) is a common treatment for gynecological and lower gastrointestinal cancers with negative side effects on pelvic health and sexual function. These effects significantly impact patients' quality of life, yet research on mitigating such toxicities remains limited. RT has been shown to alter the vaginal microbiome, enriching opportunistic pathogens, which may contribute to vaginal toxicity and treatment resistance. This study aims to assess how pelvic health, and the microbiome change over the course of and after treatment, and whether pre-treatment microbiome composition can predict post-treatment outcomes. Here we describe the results of the GEORGIA trial (NCT04713618) a longitudinal study of women undergoing pelvic radiation for anal, rectal, cervical, endometrial, vaginal, or vulvar cancer. We assessed the effect of RT on the metatranscriptome (metaT), evaluating microbial abundance, activity, and human gene transcription by sequencing total RNA with human ribosomal depletion to a depth of >50M reads per sample on an Illumina NextSeq 2500. Samples were collected at baseline and at 1, 3, 6-, 12-, 18-, and 24-months post-treatment. Longitudinal mixed-effects models were used the assess the relationship between clinical variables and microbes, with a random intercept by patient, using lme4 in R. Vaginal length changes pre/post-treatment were analyzed via paired t-tests, while vaginal diameter changes were assessed using the Wilcoxon rank-sum test. A total of 72 patients were recruited and of those 68 (94%) participants completed the sociodemographic questionnaire. The median age was 56.5 ranging from 28 to 90 years old. Most participants were white (90%), postmenopausal before treatment (62%), and married or partnered (65%). Vaginal swab RNAseq reads aligned to human and microbe reference genomes in approximately equal numbers. Deconvolving the human reads to immune cells showed increased neutrophils following RT ($p = 0.05$). We observed a significant change in vaginal diameter over the course of treatment (Wilcoxon rank sum, $p = 0.04$). Women with *Candida*-positive microbiomes experienced a significant reduction in vaginal diameter over time, compared to women with *Candida*-negative microbiomes ($p = 0.03$). The findings suggest a potential role for fungi, and particularly *Candida,* in treatment-associated vaginal changes and sexual health. These results imply a therapeutic target to improve patient outcomes via modulation of the vaginal microbiome.

#4694 (R)evolutionary approach to predicting individual response to radiation therapy in breast cancer.

Naheel Khatri, Raafat Chalar, Saiful Samad, Alexander Stessin, **Mehdi Damaghi**

Stony Brook University, Renaissance School of Medicine, Stony Brook, NY

Despite increasing incorporation of gene panel testing into radiotherapeutic decision-making, there is no established method to tailor prescribed radiation regimens to individual tumor radiosensitivity. We propose a novel approach to assessing evolutionary determinants of radioresistance from patient-derived tumor samples. We hypothesized that pre-existing resistance to oxidative damage in tumor microenvironment (TME) can define a cell's evolutionary trajectory and its radiosensitivity. In contrast with the current genetic panels, we use a panel catered toward heterogeneity within the tumor and the TME niches, which may harbor radioresistant populations from collateral TME mechanisms of resistance. The aim is to develop an AI-based algorithm using these eco-evolutionary results to individualize radiation dose in patients, thus minimizing the percentage of non-responders. 3D spheroids of several breast cancer cell lines were grown and collected at multiple time points after 10 Gy of radiation. MALDI data was acquired in negative and positive ionization mode for spatial lipidomics and metabolomics analysis. Additionally, spatial single cell multiplexed immunofluorescence was performed on the sequential cut to MALDI using markers associated with hypoxia, acidosis, ROS, and epithelial-to-mesenchymal transition. Then we grew patient derived organoids (PDO) of breast cancer and irradiated them and analyzed them as described above. Based on a previously validated oxygen diffusion model, spheroids were categorized according to size, with those <240 micrometers in diameter designated as O-spheroids (oxygenated) and those ≥ 240 microns designated as H-spheroids (hypoxic core). While the irradiated O-spheroid growth curves plateaued upon irradiation, H-spheroids grew at the same rate as the non-irradiated controls. To investigate this phenomenon, habitats and cell phenotypes were defined using spatial multi-omics data from MALDI and multiplexed-IF, respectively. We found differential distributions of habitats in radiated spheroids as determined by the cluster size and abundance spatio-temporally. We discovered a switch in the sphingolipid metabolism pathway. Using principles of ecology and evolution, we have developed a novel approach to identifying radiosensitivity markers. Detecting these cell states and ecological niches in patients' pre-treatment biopsies can inform a more individualized approach to radiotherapy.

#4695 Post-pandemic evaluation of hypofractionated radiotherapy in preventing acute skin toxicity in multiracial/ethnic breast cancer populations.

Veronica Zhang Paley[1], Cristiane Takita[2], Isildinha M. Reis[1], Jean L. Wright[3], Jennifer J. Hu[1]

[1]University of Miami Miller School of Medicine, Miami, FL,[2]Radiation Oncology, University of Miami Miller School of Medicine, Miami, FL,[3]Department of Radiation Oncology and Molecular Radiation Sciences, Johns Hopkins University, Baltimore, MD

Background: Acute skin toxicity is a prevalent and debilitating side effect of radiotherapy (RT) for breast cancer, disproportionately impacting minority populations. Hypofractionated radiotherapy (HF-RT), which involves delivering higher doses of radiation over fewer treatment sessions, has emerged as a preferred approach during the COVID-19 pandemic due to its efficiency and convenience. This study evaluates the effectiveness of HF-RT compared to conventional fractionated RT (CF-RT) in preventing grade 2+ RT-induced skin toxicity among diverse racial and ethnic groups post-pandemic.

Objective: To investigate the severity and frequency of RT-induced skin toxicity among breast cancer patients treated with HF-RT and CF-RT, as well as the associations between toxicity and patient demographics or clinical characteristics.

Methods: A retrospective analysis was conducted using data from 105 breast cancer patients treated at the Sylvester Comprehensive Cancer Center. Patients were grouped based on RT type: HF-RT (42.5-50 Gy over 3-5 weeks) or CF-RT (50+ Gy over 5-7 weeks). Skin toxicity was evaluated using the Common Terminology Criteria for Adverse Events (CTCAE v5.0). Patients were categorized into HF-RT (n=84), CF-RT (n=15), and partial RT (n=6) groups. Patient demographics, including age, BMI, race/ethnicity, and tumor characteristics, were analyzed for their association with toxicity grades. Statistical analyses were conducted using chi-square tests and multivariate logistic regression.

Results: 12.4% of patients experienced grade 2+ skin toxicity at follow-up, with no grade 3 or higher observed. HF-RT patients showed lower grade 2+ toxicity rates (10.7%) compared to CF-RT (26.7%), although the difference was not statistically significant (p=0.143). Age was significantly associated with skin toxicity, with patients aged ≥50 years exhibiting higher rates of grade 2+ toxicity (17.4%) compared to those <50 years (2.8%, p=0.031). Other variables, including BMI, race/ethnicity, tumor stage, and treatment location, were not significantly associated with skin toxicity. HF-RT outcomes were consistent with prior studies, demonstrating safety and feasibility across all racial/ethnic groups, including 55% Hispanic and 11% Black patients.

Conclusion: Our findings suggest that HF-RT is feasible and safe for reducing acute skin toxicity in early-stage breast cancer patients across multi-racial/ethnic populations, with outcomes comparable to those reported in prior research conducted predominantly in Caucasian populations. These findings emphasize the importance of tailoring RT regimens to improve survivorship outcomes and address disparities in cancer care.

#4696 Targeting CSF1R+ macrophages to synergize immune checkpoint therapy in SCCA-mediated radioresistant cervical cancer.

Liyun Chen, Eric Liu, Victoria Shi, Marlene L. Campos Guerrero, Jasmin Yang, Abhay Singh, Matthew Inkman, Jin Zhang, Julie Schwarz, Stephanie Markovina

Washington University in St. Louis, St. Louis, MO

Tumor-associated factors released by cancer cells can promote immune suppression and tolerance to radiation or immune therapy. Squamous cell carcinoma antigen (SCCA) is a tumor-associated antigen released by cancer cells. In cervical cancer, elevated pre-treatment SCCA in the serum is seen in 28-88% of patients and these patients are more likely to experience treatment resistance and recurrence. The poor prognosis for patients with elevated SCCA shows the need for improve treatment strategies. Here, we aim to understand the mechanism of action of circulating SCCA to tumor progression and response to radiotherapy. Using sequencing analysis of paired pre- versus on-treatment biopsies, we found that patients with elevated serum SCCA had increased macrophages expressing immunosuppressive features and T-cell immune checkpoints, inversely correlated with inflammatory signaling and radiation-induced interferon-stimulated gene expression. The supplement of SCCA protein (rSCCA) to the media during in vitro macrophage differentiation promotes anti-inflammatory cytokines and gene expression. Peritoneal macrophages isolated from mice treated with intra-peritoneal rSCCA expressed high M2-associated markers and functional inhibition of T cell activation. Moreover, we found that mouse tumors engineered to express SCCA with a signal peptide promoting extracellular secretion displayed increased CSF1R+ TAM infiltration and decreased T cell activation, associated with reduced response to combined radiation and anti-PDL1 treatment. Giving the findings, we hypothesized that targeting TAMs in tumors with elevated SCCA is imperative. We further demonstrated that tumor-bearing mice showed improved response to radiation and immune checkpoint therapy when receiving concurrent CSF1R blockade, abolishing the protective effect of high circulating SCCA. Our results suggest that blockade of CSF1R signaling or other myeloid-targeting therapeutics will optimize response to radiation and PD-L1 blockade in cervical cancer, particularly those with high circulating SCCA.

#4697 FDA approved non-cardiotoxic hERG1 inhibitor ketoconazole enhances radiation sensitivity in glioblastoma.

Johnathan Rodgers Gochicoa[1], Tingting Huang[2], Kelli B. Pointer[2]

[1]Dartmouth College, Hanover, NH,[2]Dartmouth Cancer Center, Lebanon, NH

Glioblastoma (GBM) is the most aggressive primary brain tumor in adults, with a median survival of less than two years despite multimodal therapy, including surgery, radiation, chemotherapy, and tumor treating fields. GBM's dismal prognosis is largely due to its high recurrence rates. Emerging evidence implicates ion channels in promoting tumor progression and treatment resistance across various malignancies. Specifically, the potassium voltage-gated channel hERG1, encoded by the KCNH2 gene, has been associated with worse patient outcomes in GBM. However, the mechanisms underlying hERG1's contribution to treatment resistance, particularly radiation resistance, remain poorly understood. Here, we investigated the role of hERG1 in driving radiation resistance in GBM. RNA-sequencing data from 350 GBM patient tumors in The Cancer Genome Atlas (TCGA) were analyzed to assess KCNH2 expression and its correlation with overall survival. Patients were stratified into quartiles by KCNH2 expression, and Kaplan-Meier survival analyses were performed using R Studio (v4.3.1). The human GBM cell line LN-229 was used for in vitro studies. A drug screen determined the IC25 for an FDA-approved, non-cardiotoxic hERG1 inhibitor ketoconazole. Cell viability was assessed after 72 hours of drug treatment. Cells were treated with IC25 concentrations of inhibitors for three days, with radiation (0 Gy or 8 Gy) administered on day two, followed by two additional days of drug treatment. All experiments were performed in triplicate for statistical rigor. KCNH2 expression in the upper quartile was 9.7 times higher than in the lower quartile. Patients in the upper quartile exhibited worse median overall survival compared to those in the lower quartile (11.8 months vs. 12.9 months, $p = 0.00053$). The IC25 for ketoconazole was 28μM. Ketoconazole combined with radiation decreased cell viability by 54.4% compared to radiation alone ($p = 0.01$) and by 78.8% compared to vehicle control ($p < 0.0001$). High KCNH2 expression is associated with worse survival outcomes in GBM patients. FDA-approved, non-cardiotoxic hERG1 inhibitor ketoconazole decreased cell viability and enhanced radiation sensitivity in vitro. These findings suggest that combining a non-cardiotoxic hERG1 inhibitor with radiation may represent a promising therapeutic strategy to improve GBM patient outcomes.

#4698 Towards treating prostate cancer using an engineered sodium/iodide symporter (NIS) protein.

Haswitha Sabbineni[1], Alejandro Llorente[1], Todd D Giorgio[2], Nancy Carrasco[1]

[1]Molecular Physiology and Biophysics, Vanderbilt University, Nashville, TN,[2]Biomedical Engineering, Vanderbilt University, Nashville, TN

The sodium/iodide symporter (NIS) is the theranostic plasma membrane protein that mediates the active transport of iodide (I^-) ions and various clinically approved radiotracers used for imaging [such as pertechnetate ($^{99m}TcO_4^-$), radioiodide ($^{123}I^-$), and tetrafluoroborate ($[^{18}F]BF_4^-$)] and for therapeutic purposes [e.g., radioiodide ($^{131}I^-$) and preclinically approved perrhenate ($^{186/188}ReO_4^-$)]. For over 80 years, targeted internal radiation therapy (TIRT) has been used successfully to treat thyroid cancer: administered $^{131}I^-$ is selectively accumulated in the thyroid cancer cells by NIS.

NIS-mediated TIRT is a promising approach to treating prostate cancer, the second deadliest cancer in men in the United States and Europe. About 1 in 7 men will be diagnosed with prostate cancer at some point in their life. Currently available therapies, including prostate surgery and targeted irradiation are often ineffective against advanced/recurrent and metastatic prostate cancer, so new treatments are urgently needed.

In order for NIS-based TIRT to be successful, three challenges must be overcome: a) the thyroid must be protected from β-radiation; b) the immune response triggered by the viral vectors used for NIS delivery must be mitigated; and c) tissue specificity must be ensured.

To tackle these challenges, we have engineered a NIS protein (PF-NIS) by replacing two amino acids that are close to the substrate cavity (the substitutions are L253P and V254F). PF-NIS differentiates between two substrates, namely I^- and oxyanions (such as $^{186}ReO_4^-$ and $^{99m}TcO_4^-$): it transports oxyanions but virtually no I^-. We have shown in *in vitro* experiments that cells expressing wild-type NIS (WT NIS) do not die when treated with $^{186}ReO_4^-$ and saturating concentrations of non-radioactive iodide (I^-) (100 μM), because WT NIS does not transport oxyanions in the presence of excess I^-.

To decrease immunogenicity, we will use polyplexes which are nanocomplexes composed of DNA and polyvalent molecules such as polyethyleneimine (PEI). Polyplexes were formed using in vivo jetPEI and PF-NIS cDNA at an N/P ratio of 1:8. Dynamic light scattering analysis revealed an average polyplex size of approximately 100 nm. Morphological analysis using scanning electron microscopy and atomic force microscopy confirmed that the polyplexes were spherical.

Tissue specificity was achieved by suing the prostate-specific antigen (PSA) promoter, a well-characterized regulatory element that drives gene expression specifically in prostate epithelial cells and is highly active in prostate cancer cells.

We conclude that polyplexes containing the PF-NIS cDNA under the PSA promoter will render prostate cancer cells susceptible to being treated with $^{186/188}ReO_4^-$ even in the presence of non-radioactive I^-, which will protect the thyroid.

#4699 Intratumoral adenosine: Contributions from host versus tumor and interaction with radiotherapy.

Shruti Bansal, Samantha Sarti, Namita Sen, Chelsea Rahiman, Brian Ragaishis, Lindsay Caprio, Benjamin Izar, Catherine Spina

Columbia University Irving Medical Center, New York, NY

Purpose: Tumor irradiation generates high levels of extracellular ATP that is metabolized to suppressive adenosine that is implicated in cancer progression. The relative contribution of host and cancer cell-derived adenosine and downstream signaling to radioresistance is unclear.

Methods: In a murine model of breast cancer (EO771), we measured the expression of adenosine signaling proteins: CD73 that metabolizes AMP to adenosine and adenosine receptors, A2aR and A2bR by flow cytometry. We measured adenosine concentration by LC-MS in supernatants of WT tumor cells and those that lack CD73 ($CD73^{-/-}$) grown *in vitro*. To understand the non-tumor cell-derived contribution to adenosine, we measured adenosine concentration in breast EO771 tumors grown in $CD73^{-/-}$, $A2aR^{-/-}A2bR^{-/-}$ or WT mice. Tumor growth studies were performed in the untreated and irradiated (8 Gy x 3) settings. In comparison, we conducted tumor growth experiments in $CD73^{-/-}$ & WT EO771 tumors grown in WT mice to understand the contribution of tumor-derived CD73 to tumor control.

Results: In murine EO771 tumors, the proportion of viable non-immune ($CD45^{-}$) cells that express CD73 was significantly higher than in the $CD45^{+}$ immune compartment (18.3% vs 5.7%). In contrast, the proportion of viable immune ($CD45^{+}$) cells that express A2aR was significantly higher than the $CD45^{-}$ compartment (7.8% vs 4.4%), suggesting complementary roles of the two compartments. *In vitro*, adenosine production was abrogated in $CD73^{-/-}$ EO771 tumor cells compared to WT controls (0.14μM vs 2.4μM). Tumor cell irradiation caused a significant increase in adenosine in WT EO771 but not $CD73^{-/-}$ EO771. When grown in WT mice, tumor growth was delayed in $CD73^{-/-}$ tumors compared to WT controls (306 mm^3 vs 1165 mm^3 on day 22). Loss of CD73 in tumor cells significantly improved radiosensitivity and increased overall survival on 150-day by 50%. Quantification of adenosine in EO771 tumors grown in WT, $CD73^{-/-}$ & $A2aR^{-/-}A2bR^{-/-}$ mice revealed that absence of host CD73 caused 3.5-fold decrease in intertumoral adenosine, while loss of A2aR and A2bR caused no significant change. Furthermore, tumor control in both $CD73^{-/-}$ & $A2aR^{-/-}A2bR^{-/-}$ mice improved by 50% in the absence of radiation. However, after tumor irradiation, loss of host A2aR and A2bR but not CD73 improved tumor control.

Conclusions: Results suggest that tumor cell expression of CD73 is integral for production of adenosine and loss of expression significantly improves radiosensitivity. Loss of CD73 from non-tumor cells did not influence radiosensitivity, whereas expression of A2aR and A2bR does. These data suggest that tumor-derived adenosine contributes to tumor growth and radioresistance and non-tumor cells in the TME are important for A2aR/A2bR-mediated effects of adenosine. CD73 & A2aR/A2bR offer an exciting therapeutic strategy to mitigate radiation-induced suppressive changes for improved radiosensitivity and tumor control.

CLINICAL RESEARCH: Targeted Therapies and Combinations 2
Poster Session

#4703 EGFR is a promising therapeutic target in NF1 mutant melanoma.

Milad Ibrahim[1], Irineu Illa-Bochaca[1], George Jour[2], Eleazar Vega-Saenz de Miera[1], Kelly Ruggles[3], Jeffrey Weber[4], Markus Schober1[1], Iman Osman[1]

[1]The Ronald O. Perelman Department of Dermatology, NYU Langone Health, New York, NY,[2]Department of Pathology, Molecular Pathology and Diagnostics, NYU Langone Health, New York, NY,[3]Department of Medicine, New York University School of Medicine, New York, NY,[4]NYU Langone Health Perlmutter Cancer Center, NYU Langone Health, New York, NY

Background: Molecularly targeted therapies and immunotherapy improved treatment outcomes for melanoma patients. However, patients with driver mutations in the Neurofibromin 1 (*NF1*) tumor suppressor gene, which represent 20-30% of melanomas, have not benefitted from these treatment advances, underscoring an unmet clinical need.
Methods: We compared 13 *NF1* mutant ($NF1^{Mut}$) and 19 *NF1* wild-type ($NF1^{WT}$) patient-derived short-term cultures (STCs) integrating multi-omic analysis of DNA mutations (Whole Exome Sequencing), RNA expression, and gene regulation (RNA-Seq, ATAC-Seq, H3K4Me3 and H3K27Ac). Independent melanoma patients' specimens (n= 40) were used for immunohistochemical validation studies. We then used STCs for functional studies defining the role of *NF1* loss in melanoma and testing potential therapeutic targets *in-vitro* and in PDX models.
Results: Comparing $NF1^{Mut}$ to $NF1^{WT}$ uncovered gene regulatory elements (ATAC $P = 0.024$, H3K27Ac $P = 0.011$) controlling a significantly increased transcription of EGFR in $NF1^{Mut}$ ($P = 0.005$). The significant upregulation of EGFR expression was confirmed by western blotting ($P = 0.003$) and IHC in an independent melanoma patient cohort ($P = 0.0007$). Functional studies revealed that EGF rapidly activates EGFR, AKT and ERK in $NF1^{Mut}$ but not $NF1^{WT}$ melanoma cells ($P < 0.0001$). Moreover, *NF1* knockdown in $NF1^{WT}$ *in-vitro* resulted in an increased melanoma cell proliferation ($P < 0.0001$) as well as, EGFR, AKT and ERK activation. Genetic or immunological EGFR inhibition blunted cell proliferation, cell survival, and tumor growth in $NF1^{Mut}$ but not $NF1^{WT}$ melanoma STCs ($P < 0.0001$) and PDX models ($P < 0.0001$) independent of *BRAF* or *NRAS* mutation status.
Conclusion: Our study uncovers a stereotypical and transcriptionally controlled activation of the EGFR-AKT signaling axis in $NF1^{Mut}$ melanoma, with EGFR inhibition limiting tumor growth in $NF1^{Mut}$ but not $NF1^{WT}$ melanomas. Data suggest a possible role of targeting EGFR as therapeutic target in melanoma patients with $NF1^{Mut}$ tumors.

#4704 Development of a novel zebrafish patient-derived xenograft (zPDX) platform for functional precision cancer medicine for immune checkpoint (ICIs) and tyrosine kinase inhibitors (TKIs) of renal cell carcinoma (RCC).

N. Pawar, J.-S. Chung, V. Cantrell, I. Dougherty, N. Bingham, V. Margulis, P. D. Cruz, Jr., H. Hammers, K. Ariizumi;
UT Southwestern Medical Center, Dallas, TX

Predictions of cancer treatment outcomes are critical to personalized therapy. Despite extensive studies of genome-based precision medicine, we still lack reliable markers to predict patient-specific response to ICIs and TKIs for RCC. zPDX has been used to develop *in vivo* preclinical models using mouse PDX, primary cultured cells or dissociated tissues (without T cell analysis). These samples do not reflect enough of the intratumor heterogeneity. To create assays better representative of their natural state, we used freshly isolated tumor cells for zPDX and tested their ability to display patient-specific response to ICIs and TKIs. Within 24h after nephrectomy, the RCC mass (0.8-1.9 g) was extracted and purified for whole tumor cells (WTCs) via Ficoll gradient centrifugation and dead cell removal (viability >85%; yield 0.3-33 x 10^6 cells) and analyzed by FACS for % CD45+ or CD8+ cells (or PD1+CD8+). RCC-WTC was rich in CD45+ immune cells (65% ± 10, n=8) and CD8+ T cells (38% ± 10, n=5), among which PD1 expression was low (4.7% ± 2.2, n=5). WTCs were labeled with Red Cell-Tracker, mixed with Nivolumab or control IgG (0.5 ng/fish), injected into the perivitelline space (PVS) of 2dpf zebrafish embryos (~200 cells/fish, n=10/group), and zPDX cultured individually in a microwell for 2-5d at 34°C. For TKIs, WTC-injected zebrafish were cultured in media with Cabozantinib (0.1 μM) or Sunitinib (0.3 μM) (n=8/group). 2-4d post-injection, fluorescence images were taken and analyzed for tumor area (TA; procedural defined units) around PVS. % reduction in TA was recorded as response and RECIST-categorized into PR (>30% reduction), PD (>30% increase) and SD (<30% reduction). To date, we have performed zPDX assays for 8 cases (none with pre-determined treatment plans). For ICIs, 6 cases displayed PR (53% ± 1.6, $p<0.003$) and the rest (2 cases) did SD (11% ± 10) with weak association of ICI-effects with PD1 expression, but PR responders (5 out of 6) showed significant upregulation of hIL-2 mRNA (median 6.2 x10^{-5} to hGAPDH) by nested qRT-PCR of total RNA from Nivolumab-treated zPDX. This tumor inhibition was T cell-mediated, shown by co-applied anti-CD3 Ab that reversed tumor regression by ICI (n=3, 82-100% reversal) and the presence of hT-cells in zPDX treated with Nivolumab (but not with control IgG) shown by IHC staining of whole body FFPE with anti-CD3. TKIs inhibited TA, with 50% PR response rate for Sunitinib and Cabozantinib (38% ± 5.5, $p<0.05$ & 40% ± 7.7, $p<0.02$, respectively) with significant individual differences in % inhibition. We showed our zPDX model with freshly isolated WTC can quantify patient-specific responses to ICIs and TKIs before onset of actual treatments. Thus, this zPDX platform will establish a fast, accurate, and clinically relevant system for functional precision medicine for RCC immunotherapy.

#4705 FreezeO organoid biobank: A translational pipeline for precision oncology at the University Medical Center Freiburg.

The FreezeO Organoid Biobank at the University Medical Center Freiburg represents an innovative resource and an integral extension of the Molecular Tumor Board (MTB) that enables patient-specific drug testing for precision oncology. The focus of this biobank is to isolate and culture patient-derived organoids (PDOs) from fresh tumor biopsies, particularly from metastatic sites, to address an unmet need for therapy recommendations in advanced cancer. Our workflow begins when the MTB decides to obtain new tumor biopsies for whole exome sequencing (WES) or RNA sequencing (RNA-Seq). Whenever possible, PDO cultures are established in parallel to generate living tumor models. Once molecular profiling is complete, the targeted therapies recommended by the MTB are tested on the PDOs using an established semi-automated drug testing platform. Response to therapy is assessed and validated using complementary methods such as Western Blotting and transcriptomic analysis of the treated PDOs. The results will be rapidly integrated into MTB discussions and provide important data to refine and personalize treatment decisions. To date, we have successfully established and biobanked PDOs from nine different cancer types, including colorectal cancer (CRC), non-small cell lung cancer (NSCLC) and rare cancers such as jejunum carcinoma. Remarkably, 60% of our biobank consists of PDOs derived from metastatic lesions, highlighting a clear benefit for late-stage cancer patients in the future. Drug tests were carried out on the PDOs within a clinically relevant timeframe and the results were included in the MTB decision-making process. Among the cases we will present, we report a metastatic CRC case featuring a PDO from a lung metastasis harboring a KRAS G12V mutation. Based on the oncologist’s recommendation, the drug testing strategy focused on the combination of Lapatinib and Trametinib. This approach reflects the ongoing clinical interest in overcoming intrinsic and acquired resistance to EGFR-targeted treatments in CRC. The inhibitor combination demonstrated promising efficacy in the PDO model. The robustness of these findings was validated through Western Blot analysis and RNA sequencing, providing critical data to inform the MTB panel. Ultimately, this evidence was instrumental in tailoring a more informed treatment strategy. The FreezeO Organoid Biobank demonstrates the translational potential of PDOs in precision oncology, particularly in metastatic disease. By seamlessly integrating rapid organoid culture, molecular profiling and targeted drug testing, our pipeline supports the MTB in making the most informed, data-driven treatment recommendations. This approach not only reinforces therapeutic decision making, but also underscores the utility of PDOs as a bridge between research and clinical application, paving the way for broader adoption in personalized oncology.

#4706 Evaluating the efficacy of RAS(ON) inhibitor RMC-6236 combined with chemotherapy and other targeted therapies in 3D models involving patients with KRAS-mutated pancreatic cancer.

Taylor Bargenquast[1], Cherie Wesley[2], Janith Don[3], Guangfa Zhang[3], Tithi Ghosh Halder[4], Serina Ng[4], Alexis Weston[1], Trason Thode[4], Erkut Borazanci[1], Mohan Kaadige[4], Sara A. Byron[2], Nicholas Schork[3], Raffaella Soldi[4], Sunil Sharma[1]

[1]HonorHealth Research Institute, Scottsdale, AZ,[2]Bioinnovation and Genome Sciences Division, Translational Genomics Research Institute (TGen) of City of Hope, Phoenix, AZ,[3]Clinical Genomics and Therapeutics Division, Translational Genomics Research Institute (TGen) of City of Hope, Phoenix, AZ,[4]Applied Cancer Research and Drug Discovery, Translational Genomics Research Institute (TGen) of City of Hope, Phoenix, AZ

Background: RAS mutations, particularly $KRAS^{G12X}$, are critical oncogenic drivers in pancreatic cancer, with existing $KRAS^{G12C}$ inhibitors unable to target other mutations and often leading to resistance. RMC-6236, a multi-selective RAS(ON) inhibitor, demonstrates potent activity in $KRAS^{G12X}$ models, but resistance mechanisms that increase mutant RAS(ON) may reduce its effectiveness. The fibrotic tumor microenvironment in pancreatic cancer exacerbates therapy resistance, and combining RMC-6236 with other therapies could overcome both intrinsic and acquired resistances. This study evaluates RMC-6236 efficacy in patient-derived pancreatic tumors harboring KRAS mutations, and the impact of cancer-associated fibroblasts (CAFs) on its potency as a single agent and in combination with other therapies. We also assess its impact on downstream RAS signaling and apoptosis using pro-apoptotic markers.
Methods: Patient-derived tumor cells and fibroblasts were treated with RMC-6236 in 2D and 3D viability assays. Patient-derived organoids (PDOs) were generated by combining tumor and fibroblasts in a 1:1 ratio and allowing them to form in media for 72 hours. Synergy studies explored combinations of RMC-6236 with gemcitabine and abraxane chemotherapies, along with other targeted therapies, including CDK7, WNT, and mTOR pathway inhibitors. Samples were stained for α-SMA via immunofluorescence for CAF detection. Western blot analysis assessed RAS pathway inhibition and apoptotic markers.
Results: These results demonstrate the efficacy of RMC-6236 in a pancreatic cancer PDO model when combined with other therapeutic agents. Sensitivity to RMC-6236 was assessed in tumor cells, fibroblasts, and tumor-fibroblast co-cultures, yielding IC50 values ranging from 0.1 to 11 nM, 1 to 3.5 nM, and 0.2 to 5 nM, respectively. These results highlight that the presence of CAFs in KRAS-mutated pancreatic cancer PDOs does not affect sensitivity to RMC-6236 treatment. Notably, synergy studies assessing RMC-6236 in combination with chemotherapy agents (gemcitabine and abraxane), as well as WNT inhibitors (WNTi) and CDK7 inhibitors (CDK7i), revealed a significant reduction in IC50 values, with a more than 100-fold decrease (ranging from 0.0001 nM to 0.001 nM). This substantial enhancement in drug potency underscores the synergistic effects of combining RMC-6236 with these agents, particularly with WNTi.
Conclusion: The combination of RMC-6236 with standard chemotherapy and targeted therapies enhances its antitumor activity, suggesting a promising strategy for improving therapeutic outcomes in pancreatic cancer. The observed synergistic interactions, especially with WNTi, warrant further investigation in clinical trials to evaluate the potential of this combination approach in improving treatment responses.

#4707 Electrochemotherapy for the treatment of head and neck squamous cell carcinoma.

F. H. Maglietti[1], S. D. Michinski[2], L. A. Evans[3], R. Lertora[4];

[1]Instituto Universitario de Ciencias de la Salud. Fundacion HA Barcelo-CONICET, Buenos Aires, Argentina, [2]INFINA-CONICET, Buenos Aires, Argentina, [3]Mayo Clinic, Jacksonville, FL, [4]Hospital Zonal General de Agudos "Petrona V. de Cordero", Buenos Aires, Argentina

Squamous cell carcinoma (SCC) is the second most prevalent type of skin cancer after basal cell carcinoma, with the highest incidence occurring in sun-exposed regions of the body, particularly the head and neck. Approximately 300,000 new cases are diagnosed each year, imposing significant financial burdens on healthcare systems due to treatment costs and on the economy due to productivity losses. Surgery remains the primary treatment option; however, patients, particularly those with advanced-stage disease, may decline surgery due to concerns about functional and cosmetic outcomes. Other effective treatments include cryosurgery, radiotherapy, topical therapies, photodynamic therapy, and Mohs micrographic surgery. Recently, electrochemotherapy (ECT) has emerged as a novel treatment option. ECT involves administering bleomycin followed by electric pulses targeted at the tumor and surrounding margins, inducing transient cell membrane permeabilization. This enhances drug uptake and amplifies cytotoxic effects by over 1,000-fold. Since 2006, ECT has been a standard therapy in Europe and was introduced in Argentina in 2020, offering a new approach for patients who are unsuitable for or decline other treatments. In this study, we present outcomes from six patients with head and neck SCC treated with ECT on an outpatient basis. Most patients required only a single 60-minute treatment session. Observed side effects included grade 1-2 edema, pain, and flu-like symptoms per CTCAE 4.0. Tumor response was assessed using RECIST criteria, with results showing 71.4% complete response (5 of 7 lesions), 14.3% partial response (1 lesion), and 14.3% progressive disease, yielding an objective response rate of 85.7%.In conclusion, electrochemotherapy proved to be a safe and effective treatment for select head and neck SCC patients who are not candidates for surgery, providing a promising alternative in the therapeutic landscape.

#4708 FGFR gene amplification and response to HER2-directed therapy in patients with HER2+ metastatic breast cancer (MBC).

Diana Jaber[1], Natalie K. Heater[1], Sarah Marini[1], Surbhi Warrior[1], Yangruijue Ma[1], Patricia Robinson[1], Lisa Flaum[1], Regina Stein[1], Claudia Tellez[1], Huiping Liu[1], Qiang Zhang[1], Youbin Zhang[1], Massimo Cristofanilli[2], William Gradishar[1], Janice Lu[1]

[1]Robert H. Lurie Comprehensive Cancer Center, Northwestern Memorial Hospital, Chicago, IL,[2]Department of Hematology and Medical Oncology, Weill Cornell Medicine, New York, NY

Introduction: Amplification of fibroblast growth factor receptor (FGFR) signaling has been implicated in driving resistance to endocrine therapies and, more recently, HER2-directed therapies in vitro. While FGFR pathway dysregulation is well-established as a poor prognostic marker in hormone-positive BC, its impact in HER2+ BC is less clear. This study aims to investigate the association between FGFR amplification and clinical response to HER2-directed therapy in patients with HER2+ MBC.
Methods: This study retrospectively analyzed 73 patients with HER2+ MBC by IHC/FISH and/or HER2+ CTCs who received HER2-directed therapy between 2016-2024 under an IRB-approved trial (NU16B06) at Northwestern University Robert H. Lurie Cancer Center. CTC enumerations were performed via CELLTRACKS (Menarini). All patients completed NGS testing. FGFR1 and FGFR2 amplifications were identified via plasma ctDNA (Guardant 360) and tissue NGS (TempusX or FoundationOne®). FGFR gene amplification was considered positive for copy number values > 3 copies per cell.
Results: FGFR amplification was detected in 21 (28.8%) patients with HER2+ MBC. The most common co-mutations included TP53 (52.4%), MYC (33.3%), PIK3CA (28.6%), and ESR1 (28.6%). Prior to FGFR detection, 17 (80.9%) FGFR+ patients had received endocrine therapy, 13 (61.9%) had received CDK4/6 inhibitors, and 10 (47.6%) had received HER2-directed therapy. Median progression-free survival (PFS) after detection of FGFR amplification was 3.4 months (range 0.5-19.2). FGFR+ and wild-type (WT) patients did not differ in age at metastatic diagnosis (median age 50 vs 56; p = 0.8), de-novo MBC presentation (28.6% vs 25.0%; p = 0.8), or having received endocrine therapy (85.7% vs 67.3%; p = 0.2). FGFR+ patients were more likely to have ER-positive MBC (85.0% vs 50.0%, p = 0.012) and to have received a CDK4/6 inhibitor (61.9% vs 28.8%; p = 0.009). FGFR+ patients demonstrated significantly shorter median PFS in all HER2-directed therapy lines compared to WT patients, as follows: first- or second-line therapy (4.53 vs 8.25 months; p = 0.0053), third- or fourth-line therapy (3.03 vs 8.17 months; p = 0.0023), and in fifth-line or later therapies (2.20 vs 9.57 months; p < 0.0001). FGFR+ patients had significantly worse median overall survival compared to WT patients (HR: 2.13, 95% CI: 1.19-3.83; 4.47 vs 6.19 years, p = 0.011).
Conclusion: FGFR amplification in HER2+ MBC is associated with shorter PFS in all lines of HER2-directed therapies, as well as worse overall survival. These findings suggest that FGFR amplification may drive poor outcomes in patients with advanced HER2+ MBC and highlight its potential as a therapeutic target. Future studies are needed to confirm these findings and evaluate the efficacy of combining HER2 and FGFR directed therapies in this population.

#4709 Enhancing chemotherapy efficacy in pancreatic cancer synergistic effects of ONC206 and ONC212 with 5-FU through inhibition of p-ERK.

Vida Tajiknia, Claire Lin, Maximilian Pinho-Schwermann, Connor Purcell, Sean Lawler, Wafik El-Deiry

Legorreta Cancer Center at Brown University, Providence, RI

Background: Pancreatic cancer is a lethal malignancy projected to become the second leading cause of cancer deaths by 2030, with a 5-year survival rate of just 12%. Resistance to chemotherapy, particularly 5-fluorouracil (5-FU), remains a major challenge in treating pancreatic ductal adenocarcinoma (PDAC). ONC206 and ONC212, imipridone-class agents targeting DRD2/ClpP and GPR132/ClpP, show promise in disrupting tumor growth and inducing apoptosis. Phosphorylated ERK (p-ERK), a key driver of PDAC aggressiveness via the MAPK pathway, is a critical therapeutic target. We hypothesize that combining ONC206 or ONC212 with 5-FU could enhance efficacy by synergistically inhibiting p-ERK, supporting their potential in PDAC treatment.

Materials & Methods: The synergy of ONC206 or ONC212 with 5-FU was tested in PDAC cell lines (PANC1, CFPAC-1, HPAF-II, CAPAN-2, ASPAC1) using CellTiter-Glo for cell viability at 72 hours. Western blotting assessed p-ERK, ATF4, and other key proteins for pathway inhibition.

Results: Synergy between 5-FU and ONC212, or 5-FU and ONC206, was observed across all cell lines, with IC50 values for ONC206 ranging from 300-500 nM and for ONC212 from 70-100 nM. At the 48-hour time point in the HPAF-II cell line, 100 nM ONC212 significantly inhibited p-ERK levels compared to 300 nM ONC206. Both treatments as monotherapies resulted in reduced p-ERK levels compared to control. When combined with 25 µM 5-FU, ONC212 caused a more pronounced reduction in p-ERK. In the PANC-1 cell line, the strongest reduction in p-ERK was observed with the combination of ONC212 and 5-FU at 48 hours. In the ASPAC1 cell line, p-ERK inhibition occurred only in conditions containing ONC212, with a more significant effect when combined with 5-FU.

Conclusions: Our data demonstrate that combining 5-FU with ONC206 or ONC212 results in the inhibition of p-ERK, a critical node in the PDAC growth pathway. This synergy between 5-FU and the imipridone compounds ONC206 and ONC212 is a universal phenomenon in the tested human PDAC cell lines. Notably, ONC212 is more potent than ONC206, allowing for lower dosages, and in cases where ONC206 does not effectively inhibit p-ERK, ONC212 can be a more effective option Further studies are needed to elucidate the exact mechanism of this synergy, but these findings provide a promising foundation for developing novel combination therapies to improve PDAC treatment outcomes.

#4710 Heterogeneous efficacy patterns of KRAS inhibitors in digestive cancers.

Gustave Ronteix[1], Jerome Caron[1], Rafal Pietrzak[1], Gizem Altay[1], Fabiana Graziosi[1], Lelia Polit[1], Anna-Rose Gryspeert[1], Jacques RR Mathieu[2], Jerome Cartry[2], Sabrina Bedja[2], Alice Boileve[2], Michel Ducreux[2], Sophie Postel-Vinay[2], Fanny Jaulin[1]

[1]Orakl Oncology, Le Kremlin-Bicetre, France,[2]Gustave Roussy, Villejuif, France

Introduction: KRAS is a well-studied oncogenic driver in a variety of solid tumors, playing a pivotal role in cell proliferation and survival. Its involvement in digestive cancers, including colorectal cancer (CRC) has made it an attractive target for therapeutic development. However, efforts to expand KRAS-targeted assets in these cancers are hindered by the complex and heterogeneous expression patterns of KRAS in solid tumors, which complicate effective targeting and the translation of therapeutic efficacy across patient populations. Furthermore, clinical studies have shown that resistance mechanisms compensate KRAS inhibition and require the development of efficient combination therapies.

Methods: To address these challenges, we collected 24 patient-derived organoids (PDO) representing the molecular diversity of KRAS-driven CRC and PDAC with 5 KRAS G12C variants, 8 KRAS G12D variants and 6 KRAS G12R variants. In-depth molecular and transcriptomic characterization was performed with a particular focus on co-mutation patterns for each KRAS variant. Then the PDOs were screened against a KRAS drugs with and without combination with an EGFR inhibitor. The efficacy of the drugs were systematically compared among different variant populations.

Results: Our findings demonstrate that the PDO models faithfully recapitulate the KRAS heterogeneity observed in primary tumors, providing a robust preclinical platform for testing KRAS-targeted therapies. Strong synergistic effects were identified when using KRAS and EGFR inhibitors simultaneously, matching prior clinical trial results. This model system allows us to dissect the impact of KRAS expression patterns on therapeutic response and resistance mechanisms.

Conclusion: Our study emphasizes the utility of PDOs as a precision tool for advancing KRAS-targeted strategies in complex solid tumors and highlights the potential for individualized approaches in the treatment of KRAS-driven digestive cancers.

#4711 HER3 promotes triple-negative breast cancer progression by upregulating PHF8 via miR-34b-dependent mechanism.

Hui Lyu[1], Congcong Tan[1], Yakun Wu[1], Margaret E. Larsen[1], Shou-ching Tang[1], Guobin Kang[1], Qingzhao Yu[2], Bolin Liu[1]

[1]LSU LCMC Health Cancer Center, School of Medicine, New Orleans, LA,[2]School of Public Health, LSU-Health New Orleans, New Orleans, LA

Introduction: Triple-negative breast cancer (TNBC) is a highly aggressive and heterogeneous malignancy with poor prognosis and limited treatment options, presenting a significant clinical challenge. Current therapeutic strategies are insufficient to address the complexities of TNBC. In a previous study, we identified the human epidermal growth factor receptor 3 (HER3) signaling as a key driver of TNBC progression and a potential therapeutic target. However, the exact mechanisms through which HER3 signaling contributes to TNBC remain poorly understood.

Methods: To explore the molecular mechanisms underlying HER3 signaling in TNBC, we performed RNA sequencing (RNA-seq) to identify transcriptomic changes following HER3 knockdown in HCC1806 TNBC cells. Colony formation assays were used to assess cell viability, while Western blotting and quantitative real-time PCR (qRT-PCR) were employed to analyze protein and mRNA expression levels, respectively. Gene expression was modulated using lentiviral vectors carrying specific cDNAs or shRNAs. Flow cytometry was used to analyze cell cycle distribution. In vivo tumor xenograft models were established by subcutaneously inoculating HCC1806 cells into nude mice to evaluate the role of HER3-PHF8 axis in tumor progression. Immunohistochemistry (IHC) was performed to assess protein expression in both mouse tumor models and clinical TNBC specimens.

Results: RNA-seq analysis revealed a significant reduction in the expression of the histone demethylase PHF8 (also known as KDM7B) following HER3 knockdown in HCC1806 cells. Activation of HER3 by Heregulin (HRG) increased PHF8 expression, while HER3 knockdown decreased PHF8 levels and upregulated p27. PHF8 was shown to be critical for HER3-driven TNBC cell proliferation and progression. Notably, overexpression of PHF8 reversed the G1-phase cell cycle arrest induced by HER3 knockdown. In vivo, increased PHF8 expression rescued tumor growth inhibition resulting from HER3 signaling blockade. Analysis of The Cancer Genome Atlas (TCGA) data and clinical TNBC samples revealed a positive correlation between HER3 and PHF8 expressions at both the mRNA and protein levels. Further investigation identified miR-34b, which was negatively regulated by HER3 signaling, as a microRNA targeting PHF8. Luciferase reporter assays confirmed that miR-34b suppressed PHF8 expression, and MiR-34b mimics and inhibitors significantly downregulated or upregulated PHF8 protein levels, respectively, compared to the negative control in TNBC cells.

Conclusion: Our findings demonstrate that activated HER3 signaling suppresses miR-34b, leading to increased PHF8 expression and promoting TNBC progression. Targeting the HER3/PHF8 axis or restoring miR-34b levels offers promising therapeutic strategies to improve outcomes for TNBC patients.

#4712 ELVN-002; a potent, selective HER2 inhibitor with a differentiated binding mode conferring the potential for enhanced efficacy in combination with HER2-targeting antibody-drug conjugates.

A. J. Broad, M. Aujay, S. D. Gross, L. Ren, S. Kintz, J. P. Lyssikatos;
Enliven Therapeutics, Boulder, CO

Overexpression, amplification or mutation of human epidermal growth factor receptor 2 (HER2) is observed in up to 30% of solid tumors resulting in increased downstream signaling and oncogenic transformation. While trastuzumab deruxtecan (T-DXd), a HER2-targeting antibody-drug conjugate (ADC) recently approved for HER2 altered cancer types, has resulted in improved outcomes there remains a substantial unmet need for patients who either progress on T-DXd or discontinue treatment due to adverse events. The advent of small molecule HER2 inhibitors represents an opportunity to provide meaningful therapeutic benefit to these patients either as a single agent or in combination. However, given the structural similarities between EGFR and HER2, most small molecule HER2 kinase inhibitors are dual EGFR/HER2 inhibitors. These inhibitors often face significant dose-limiting toxicities related to EGFR, which hinder their clinical utility. ELVN-002 is a potent irreversible HER2 inhibitor with > 100-fold selectivity over EGFR currently undergoing clinical evaluation in patients with HER2 alterations both alone and in combination with approved standard of care therapies. We evaluated the effect of ELVN-002 and other clinically-relevant HER2 small molecule inhibitors on HER2 cell surface expression and internalization in HER2 positive cell lines derived from patients with either gastric cancer or breast cancer. We determined that ELVN-002 reduces HER2 expression on the cell surface but had no effect in total HER2 expression. Further, HER2 degradation was quantified by measuring ubiquitinated HER2. We discovered that upon ELVN-002 treatment, HER2 ubiquitination and internalization was significantly increased compared to control cells. In contrast, treatment with other clinically-relevant HER2 inhibitors did not increase HER2 internalization. Reduced cell surface HER2, in conjunction with enhanced HER2 degradation suggest that ELVN-002 induces greater HER2 receptor flux at the cell surface. ADCs bind their target and are subsequently degraded in the lysosome, resulting in the intracellular release of their toxic payload. However, some intact ADCs escape degradation via endocytic recycling. The increase in ubiquitinylated HER2 upon treatment with ELVN-002 suggests ELVN-002 enhances the amount of HER2 targeted to the lysosome and would therefore increase the amount of payload released relative to untreated cells. In contrast, treatment with other HER2 inhibitors results in increased cell surface HER2 retention and decreased internalization suggesting a decrease in cytotoxic payload deposition if combined with an ADC. The differentiated profile and mechanism of ELVN-002 has the potential to be a superior treatment in HER2 expressing cancers in combination with ADCs, other modalities, and as a single agent.

#4713 Elucidating the mechanism of clinical Teliso-v (cMet-MMAE ADC) and osimertinib combination: A CAV1 and EGFR multi-protein complex controls endolysosomal trafficking of Teliso-V.

Izhar Batth[1], Ronald Pandoy[1], Lisa Roberts-Rapp[2], Athan Vasilopoulos[2], Peter Ansell[2], Vincent Blot[2], Gregory K. Potts[2], Janice Y. Lee[2], Hua Tang[2], Jon D. Williams[2], Tamar Uziel[2], PK Epling-Burnette[2]

[1]AbbVie Inc., South San Francisco, CA,[2]AbbVie Inc., North Chicago, IL

Introduction: Telisotuzumab Vedotin (Teliso-V), a first-in-class c-Met-MMAE antibody-drug conjugate (ADC), achieved FDA breakthrough therapy designation in c-Met overexpressing (OE), 2nd Line+ EGFR wild-type, non-squamous, non-small cell lung cancer (NSCLC) patients. In addition, in a phase 1/1b trial, Teliso-V demonstrated 50% response in combination with the EGFR inhibitor, osimertinib, in *EGFR* mutant (*EGFR*-MT) NSCLC patients who had progressed on osimertinib. Here, we present mechanistic insights into the combinatorial effects of Teliso-V with osimertinib in this patient population.

Methods: EGFR-MT NSCLC cell lines were exposed to osimertinib and subjected to RNA expression, mutation, EGFR-interactome, and ADC intracellular localization and endolysosomal (EL) trafficking analysis.

Results: While no mutation gains or losses were detected, chronic and acute treatment with osimertinib enhanced Teliso-V sensitivity in *EGFR*-MT NSCLC cells. In addition to enhanced Teliso-V cytotoxicity, we observed enhanced accumulation of Teliso-V in a low pH intracellular compartment, consistent with increased endolysosome (EL) trafficking. Chronic osimertinib exposure induced gene expression changes related to increased lysosomal membranes, lytic vacuole membranes, and endoplasmic reticulum as well as reduced EGFR signaling. In addition to osimertinib, other EGFR inhibitors including erlotinib, gefitnib, or afatinib also enhanced Teliso-V EL trafficking which is consistent with the effect of *EGFR*-MT signaling in suppressing c-Met ADC EL trafficking. Cells harboring *EGFR*-MT are known to form large multimeric protein complexes to regulate EGFR trafficking and cell survival. EGFR-MT immunoprecipitation, followed by mass spectrometry analysis identified 84 proteins associated with an osimertinib-sensitive complex including c-Met, and caveolin-1 (CAV-1), a structural protein involved in signaling and trafficking. Confocal microscopy imaging showed that osimertinib treatment altered the subcellular localization of these proteins and their interaction with CAV-1. CAV-1 knockdown disrupted the multimeric protein complex, suppressed EGFR and c-Met activation, reduced downstream AKT/ERK signaling, and enhanced Teliso-V-associated EL trafficking, phenocopying osimertinib effect.

Conclusions: Chronic and acute treatment with osimertinib displaces EGFR/c-Met/CAV-1 multimeric signaling complexes leading to improved lysosomal processing of c-Met-targeted ADCs and enhanced tumor cytotoxicity. This study provides mechanistic insights into the combination of Teliso-V and osimertnib in 2L+ *EGFR*MT NSCLC patients in the clinic.

#4714 Elucidating mechanisms of acquired resistance to mobocertinib in non-small cell lung cancer harboring EGFR exon 20 insertion mutations.

G. Yamamoto[1], Y. Tanaka[1], Y. Zenke[1], J. Liu[1], T. Sakai[1], H. Izumi[1], E. Sugiyama[1], S. Umemura[1], S. Matsumoto[1], K. Yoh[1], K. Goto[1], S. S. Kobayashi[2], H. Udagawa[1];

[1]National Cancer Center Hospital East, Kashiwa, Chiba, Japan, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Mobocertinib (TAK-788) is an oral irreversible tyrosine kinase inhibitor specifically developed to target *EGFR exon 20 insertion (ex20ins)* mutant non-small cell lung cancer (NSCLC); however, acquired resistance inevitably develops, limiting its clinical efficacy. This study aims to elucidate mechanisms of mobocertinib resistance through multiple clinical and preclinical approaches. Through targeted Next-Generation Sequencing on tumor samples from a patient with *EGFR ex20ins* (A767_S768insSVD) mutant NSCLC treated with mobocertinib, we identified secondary *KRAS Q61H* mutation as a potential resistance mechanism. To recapitulate clinical resistance, we successfully established a cell line (TH937) derived from this patient's pre-treatment tumor. *In vivo* mobocertinib-resistant tumors (mobo-R) were generated by continuous oral administration of mobocertinib to TH937 xenograft nude mice. Although no actionable secondary *EGFR* or *KRAS* mutations were identified in whole exome sequencing, transcriptomic analyses revealed upregulation of MAPK and RAS-related signaling in mobo-R tumors. *In vitro* analyses also showed reactivation of ERK signaling after mobocertinib treatment, while phosphorylation of 49 major receptor tyrosine kinases (RTKs), including EGFR and other ErbB family members, was not observed. These finding indicates that RTK-independent MAPK reactivation, potentially driven by RAS signaling, may serve as a resistance mechanism. In conclusion, we found that genomic or transcriptomic alterations of MAPK/RAS signaling mediate mobocertinib resistance. Further validation and exploration are needed to improve the therapy of *EGFR ex20ins*mutant NSCLC.

#4715 Depletion of mMDSCs using a CCR2-directed cytotoxicity targeting chimera (CyTAC) leads to remodeling of the tumor microenvironment and immune mediated tumor regression.

Brandon J. Turunen[1], Beth Knapp-Reed[2], Craig Leach[1], Peiling Chen[3], Matthew Sender[4], Joseph Marino[2], Cunyu Zhang[3], Yao Chen[5]

[1]Solu Therapeutics, Boston, MA,[2]Medicinal Chemistry, GSK, Collegeville, PA,[3]Chemical Biology, GSK, Collegeville, PA,[4]AntibodyChem Biosciences, Boston, MA,[5]Merck, Rahway, NJ

mMDSCs (monocytic myeloid derived suppressor cells) are recruited to solid tumors and serve as potent inhibitors of T-cell mediated antitumor immunity. Therapeutic depletion of mMDSCs presents an exciting opportunity to increase the frequency and durability of anti-tumor clinical responses achieved with immune checkpoint inhibition. Currently, no marketed or investigational agents function by specific mMDSC depletion and no specific markers for therapeutic targeting of these cells have been clinically validated. We demonstrate that mMDSCs express high and homogeneous levels of the chemokine receptor CCR2. Because of this, we have developed a CCR2 targeting Cytotoxicity Targeting Chimera, which potently binds CCR2 on cells, and when combined with the CyTAC platform antibody, eliminates target cells via enhanced effector mediated killing. We demonstrate that the CCR2 CyTAC can deplete CCR2+ monocytes and mMDSCs from the periphery and intratumorally both ex vivo and in vivo. In the MC38 syngeneic tumor model this depletion leads to T-cell dependent anti-tumor activity and increases the levels of CD8 T-cells within the tumor microenvironment. We show across multiple additional syngeneic tumor models that depletion of CCR2+ cells remodels the tumor microenvironment causing an increase in tumor infiltrating CD8 T-Cells and a decrease in regulatory T-cells and mMDSCs. These PD changes were observed in both responding and non-responding tumor models where response can be enhanced with anti-PD1.
Significance: We have applied our CyTAC technology to specifically target CCR2 expressing cells and depletion of mMDSCs and demonstrate that this can lead to remodeling of the tumor microenvironment from a pro-tumor to pro-inflammatory phenotype. This agent has potential for treating tumors with high mMDSC content regardless of tumor type. Note: Human biological samples were sourced ethically, and their research use was in accord with the terms of the informed consents under an IRB/REC approved protocol. All studies conducted according to GSK's Policy on the Care, Welfare and Treatment of Lab Animals and reviewed by the Institutional Animal Care and Use Committee at GSK or by the ethical review process at the institution where the work was performed.

#4716 Functional precision medicine: Uncovering high actionability in rare cancers beyond genomics.

Rachele Rosati[1], Payel Chatterjee[1], Alex C. Rajewski[1], Marwah Al-Aloosi[1], Lauren R. Appleyard[1], Vaishnavi Pallem[1], Shalini Pereira[1], Robert L. Diaz[1], Christopher J. Kemp[2], Ryan Jones[3], Brady Bernard[3], Pashtoon M. Kasi[4], Kiran Turaga[5], Michael Castro[6], Tara Seery[7], Arun Singh[8], Sameek Roychowdhury[9], Melind Javle[10], Jill Alldredge[11], Soledad Jorge[12], Kathryn Pennington[12], Barbara A. Goff[12], Heidi J. Gray[12], Elizabeth M. Swisher[12], Carla Grandori[1]

[1]SEngine Precision Medicine, a Subsidiary of Tempus AI, Seattle, WA,[2]Fred Hutchinson Cancer Center, Seattle, WA,[3]Tempus AI, Inc., Chicago, IL,[4]City of Hope, Irvine, CA,[5]Yale School of Medicine, Chicago, IL,[6]Beverly Hills Cancer Center, Beverly Hills, CA,[7]Hoag Medical Group, Irvine, CA,[8]UCLA Health, Santa Monica, CA,[9]Ohio State University, Columbus, OH,[10]MD Anderson Cancer Center, Houston, TX,[11]University of Colorado, Highlands Ranch, CO,[12]The University of Washington, Seattle, WA

Background: Precision medicine relies on mutational profiling, but clinical actionability remains limited for many cancer patients. We evaluated the feasibility and actionability of ex-vivo drug sensitivity testing across solid tumors, focusing on rare cancers. This study uses the PARIS® CLIA-certified test, assessing patient-derived tumor cells (PDTCs) responses to a broad oncology drug panel.

Methods: Tumor specimens (biopsies, fluids, or surgical samples) were shipped to our laboratory to arrive within 48h and cultured in either 3D or 2D with cancer type specific protocols to generate short term tumor cell cultures. PDTCs were tested with a panel of oncology drugs (up to 42 drugs /sample), customized for each patient based on cancer type, oncologist recommendations, and genomic features. Reports, ranking drug responses, were sent to oncologists within ~3 weeks on average.

Results: 86 patients with diagnosis of rare cancers (occurring in fewer than 15 out of 100,000 people each year) were consented to the SEngine IRB protocol and had a successful PARIS® test. The overall actionability was 85%, defined by one or more drugs exhibiting exceptional/good responses based on absolute and relative metrics of drug responses in our database. The cohort included biliary tract cancers (n=26), sarcomas (n=15), low grade serous ovarian cancers (n=15), cancer of unknown primary (n=4), appendiceal cancers (n=4), esophageal and gastric cancers (n=6), brain and nervous system cancers (n=2). Notably, targeted therapies showed the strongest drug sensitivities, often revealing actionable insights beyond genomic predictions. In the LGSOC cohort in the recurrent setting the results demonstrated that the PARIS® test recapitulates the clinical resistance of LGSOC to most chemotherapies but can identify multiple targeted treatments for nearly all patients. Importantly, few of these agents wouldn't have been chosen based on standard molecular testing, and multiple patients have demonstrated months to years of disease stabilization, biomarker remission and good quality of life with PARIS® -informed therapies (Gray et al., NPJ 2023, and unpublished data). As an example, one LGSOC case, which did not present any actionable biomarkers and had progressed after standard chemotherapy, achieved disease stabilization with 29 months duration, no hospitalizations, following a PARIS®-informed therapy with regimens including Lapatinib, Everolimus, Trametinib and Letrozole. Currently, the patient has biomarker remission demonstrated by ctDNA and CA-125. Cases from other cancer types will be presented.

Conclusions: The PARIS® test offers an unbiased ex-vivo measurements of oncology-drug responses and can identify responders to targeted therapies also in cases lacking biomarker-drug matches, particularly in rare tumors with complex genomics or gene fusions without targeted drugs and limited on-label treatment options.

#4717 Glycosylation inhibition in multiple myeloma and its impact on treatment.

Heni Patel, Sharnett Riley, Hiral Kapadia, Robert B. Campbell

Department of Pharmaceutical Sciences, Massachusetts College of Pharmacy and Health Sciences, Worcester, MA

Background: Multiple myeloma (MM) is a rare and incurable blood cancer that predominantly affects older adults. It is characterized by the uncontrolled proliferation of malignant plasma cells within the bone marrow, which often exhibit abnormal glycosylation patterns that may influence their interactions with chemotherapy. Notably, MUC1-C is aberrantly expressed in MM cells, playing a pivotal role in their growth and survival, making it a promising target for therapeutic intervention. Research has demonstrated that the inhibition of MUC1-C with benzyl-α-GalNAc enhanced the susceptibility of these cells to CTL-mediated immune responses and the effects of cytotoxic drugs. Modifying the glycosylation of MUC1-C has the potential to increase the susceptibility of MM cells to clinically relevant treatment approaches. Building on this, the current study investigated the use of glycosylation inhibitors as a strategy to improve drug efficacy in MM. We hypothesized that the glycosylation levels normally observed in MM cells functions as a cellular barrier to therapeutic agents.
Method: The RPMI-8226 human plasmacytoma cell line (ATCC CCL-155) was cultured aseptically in RPMI-1640 growth medium supplemented with 10% fetal bovine serum (FBS). The cells were subsequently seeded into 24-well plates and pre-exposed to the glycosylation inhibitor, benzyl-α-GalNAc. Following a 48-hour incubation, the plates were next exposed to various agents for an additional 24-hr period. To assess the extent to which glycosylation influences drug uptake, one study involved the use of a fluorescently tagged anti-MUC1 antibody. To examine the influence of glycosylation on drug effects, the clinical agents imatinib and cyclophosphamide were also employed.
Results: The pre-exposure of RPMI-8226 to glycosylation inhibitor cells resulted in greater uptake of the anti-MUC1 antibody compared to the untreated cells ($P = 0.0008$). Furthermore, the combination of glycosylation inhibitor and imatinib improved the drug effects when compared to imatinib alone ($P = 0.0012$). A similar observation was observed with cyclophosphamide ($P = 0.0329$). These findings emphasize the promising potential of combining therapeutic agents with glycosylation inhibitors to improve the effectiveness and precision of drug therapy.
Conclusion: The application of a glycosylation inhibitor significantly enhanced drug uptake and subsequent drug effects. The promising findings suggest that the alteration of glycosylation patterns in MM may improve drug treatment efforts.

#4718 Evaluation of the potential use of glycosylation inhibitors for the treatment of chronic myeloid leukemia: A transformative approach to drug therapy.

Norymar Ayala, Binyaz Ilavia, Zein Dib, Najlaa Alsini, Robert B. Campbell

Department of Pharmaceutical Sciences, Massachusetts College of Pharmacy and Health Sciences, Worcester, MA

Background: Chronic Myeloid Leukemia (CML) is a clonal disorder of hematopoietic stem cells characterized by excessive production of neutrophils. The disease is driven by the Philadelphia chromosome (BCR-ABL1), caused by the translocation of chromosomes 9 (ABL - pro-oncogene) and 22 (BCR). The genetic alterations lead to heightened tyrosine kinase activity, thereby promoting the proliferation of myeloid cells and decreased levels of apoptosis. Leukemic cells have been shown to display aberrant glycosylation, particularly involving O-glycans, referred to as TACAs (Tumor Associated Carbohydrate Antigens). The relationship between glycosylation and drug effects has been shown for solid tumors, such as pancreatic cancer, but not yet for hematological malignant types, such as CML. For this reason, the following study investigated the influence of type O-glycosylation on drug uptake and activity against a model CML cell line (K-562-GFP) *in vitro*.
Method: The CML cell line K-562-GFP was cultured in RPMI + 10% fetal bovine serum (FBS). To assess the cytotoxic effects, the glycosylation inhibitor (benzyl-α-GalNAc) was employed to establish the maximum non-toxic concentration. In general, the K-562-GFP cells were seeded in a 24-well plate and subsequently exposed to a non-toxic concentration of Benzyl-α-GalNAc for a required length of time. A fluorescently tagged anti-MUC1(SPM533) monoclonal antibody was initially employed to evaluate the glycosylation drug barrier effect and functional activity of imatinib in the presence and absence of the glycation mesh.
Results: Preliminary studies demonstrated a significant increase in the uptake of Anti-MUC1 (SPM533) antibodies by K-562-GFP cells following exposure to the O-glycosylation inhibitor ($P < 0.0001$). Imatinib resulted in significantly higher cellular death for K-562-GFP cells pre-exposed to glycosylation inhibitor than in imatinib treatment alone ($P < 0.0001$). Early preliminary findings suggest that glycosylation may play an important role in regulating cytotoxic drug entry into target cells and in the subsequent functional activity in vitro. Additional studies involving other relevant drug agents are currently underway.
Conclusion: Initial findings support the notion that targeting glycosylation could represent a promising therapeutic strategy, as O-glycosylation may serve as a barrier limiting drug effects in CML. Ongoing studies will evaluate the potential impact of glycosylation on FDA-approved agents used for the treatment of CML.

#4719 Discovery of potential synergistic targets for PKMYT1 inhibitor through AI-assisted drug combination screening in an MPS-based vascularized metastatic gastric cancer model.

Yeongmin Choi, Sumin Kim, Yangji Kim, Youngsook Song, Jinhwan Jang, Delaney Donnelly, Bushra Rajput, Tsung-Li Liu, Kyusuk Baek, Aneesh Sathe, **Sanghee Yoo**

Qureator, Inc., San Diego, CA

Introduction: Many approvals of advanced drugs, such as Antibody-Drug Conjugates (ADCs) or immunotherapies, have not provided significant treatment benefits for patients with metastatic gastric cancer (GC). There remains an urgent need to develop novel therapies. However, the lack of well-defined oncogene targets has hindered progress in therapy development. A patient-like disease model was established using patient samples and a 3D co-culture platform, the Microphysiological System (MPS). Patient cells in this model preserved key properties and successfully replicated clinical phenotypes in the model. Promising therapeutic targets were identified through chemogenomic screening. To address resistance to single-target inhibition, potential combination targets were predicted using AI tools enhanced with target-based knowledge graphs (KG) and active learning algorithms. The top 20 combination targets were selected and tested, resulting in promising combination hits that demonstrated significant efficacy for this challenging and heterogeneous disease. The integration of AI-assisted combination discovery with the patient-like disease model has uncovered new opportunities for developing novel therapies and combination treatments.

Methods: For the vascularized GC model, patient cells, isolated from surgical specimens or ascitic fluid, were expanded and formed into spheroids. These spheroids were co-cultured with Human Umbilical Vein Endothelial Cells (HUVECs) in Curiochips by embedding them in a hydrogel. The chemogenomic library was developed based on pathway analyses of RNAseq and proteomics studies of advanced gastric cancer. Additionally, the combination library was designed by the process utilized AI for image feature extraction, supplemented by a target-based knowledge graph (KG) that integrated data from over 20 public databases, encompassing genomics, proteomics, drug interactions, and pathway information. All screens were performed using high-throughput screening (HTS) instruments, including high-content confocal microscopy, leveraging the HTS compatibility of Curiochips.

Results: Metastatic GC patient samples exhibited clinical phenotypes of aggressive migration and angiogenesis when co-cultured with endothelial cells in 3D. From pathway analysis, 200 targets were identified, and their inhibitors were screened in the vascularized model. The top targets were prioritized based on image analysis of GC phenotypic landscape. Among these, PKMYT1 was selected as a test case for identifying potential combination targets. Using the target-based KG, 20 top targets for combination with the PKMYT1 inhibitor were identified and screened in the disease model. The combination demonstrated promising efficacy and significantly delayed the onset of drug resistance.

#4720 Evaluation of lorlatinib efficacy using plasma DNA.

Yasushi Goto[1], Tadaaki Yamada[2], Akehiro Nishiyama[3], Naoko Aragane[4], Minehiko Inomata[5], Hiroki Nagai[6], Satoshi Takahashi[7], Kazuhito Miyazaki[8], Yukari Tsubata[9], Hiroaki Akamatsu[10], Tetsuya Mitsudomi[11]

[1]National Cancer Ctr. Japan, Tokyo, Japan,[2]Department of Pulmonary Medicine, Kyoto Prefectural University of Medicine, Kyoto, Japan,[3]Department of Medical Oncology, Kanazawa University Hospital, Kanazawa, Japan,[4]Takagi Hospital, Okawa, Japan,[5]Toyama University Hospital, Toyama, Japan,[6]Kobe City Medical Center General Hospital, Kobe, Japan,[7]Department of Surger, Tokyo Medical University, Tokyo, Japan,[8]Respiratory Medicine, Yokohama Municipal Citizen's Hospital, Tokyo, Japan,[9]Shimane University, Izumo, Japan,[10]Internal Medicine III, Wakayama Medical University, Wakayama, Japan,[11]Izumi City General Hospital, Izumi, Japan

Background: Lorlatinib is approved globally as a second-line treatment for ALK-positive NSCLC following resistance to alectinib, with Japan being the first country to approve its use. This study is the first to analyze lorlatinib's efficacy in such patients by integrating ctDNA analysis to explore predictive markers and resistance mechanisms.
Methods: This multi-center prospective study enrolled patients with ALK-rearranged NSCLC resistant to alectinib, with no prior exposure to ALK-TKIs other than alectinib and brigatinib. Patient eligibility required documented ALK translocations, CT imaging within 56 days, and written consent. Blood and pathology samples were collected pre- and post-treatment. Clinical data were integrated using an Electronic Data Capture (EDC) system. ctDNA analysis was conducted via Guardant Health, focusing on mutation emergence, persistence, and correlation with treatment outcomes.
Results: Among 27 evaluable patients, partial response (PR) was observed in 37% of cases, while stable disease (SD) was noted in 14.8%. The median progression-free survival (PFS) was 6.5 months (95% CI: 1.8-23.5), consistent with previously reported outcomes for lorlatinib-treated patients. Disease progression commonly involved the CNS (18.5% of cases). Genetic analysis of ctDNA revealed that patients with TP53 mutations had a reduced PFS of 2.9 months compared to 6.7 months in wild-type TP53 cases, suggesting a potential role as a poor prognostic marker. Additionally, persistent ALK fusions or new rearrangements were observed and correlated with reduced efficacy, indicating coactivation of other oncogenic pathways. Notably, two patients exhibited ALK secondary mutations (L1196M) following alectinib treatment, both of whom responded with a partial response (PR) to lorlatinib.
Conclusions: This exploratory study highlights the complexity of resistance mechanisms in ALK-rearranged NSCLC treated with lorlatinib, demonstrating ctDNA's potential as a predictive biomarker for treatment outcomes. The persistence and emergence of specific mutations, such as in TP53 and ALK, underscore the need for further investigation into combination or personalized therapeutic strategies. Despite the study's limited sample size, these findings offer critical insights into the genomic landscape influencing lorlatinib efficacy following alectinib resistance.

#4721 Glycosylation mediated cellular uptake and functional activity of conventional chemotherapy in acute lymphoblastic leukemia.

Kenny D. Pham, Ghada Alhafez, Daniel Muteba, Robert B. Campbell

Department of Pharmaceutical Sciences, Massachusetts College of Pharmacy & Health Sciences, Worcester, MA

Background: Acute lymphoblastic leukemia (ALL) is a heterogeneous hematologic disease characterized by the proliferation of immature lymphoid cells in the bone marrow, peripheral blood, and other organs. Conventional chemotherapeutic approaches are associated with toxicities leading to reduced efficacy over time due to its systemic approach to drug delivery. O-linked glycosylation patterns on lymphoid cells are common modifications on hydroxyl groups of serine or threonine residues that are associated with key functions including cell adhesion and migration. Aberrant expression of O-glycans have been associated with leukemic malignancies making it an attractive biomarker to explore in vitro. These studies aim to provide insights into the influence of O-glycosylation on cellular access of ALL target cells to model therapeutic agents, including antibody and relevant therapeutic agents currently employed for the treatment of ALL.
Methods: The target cell line employed for use in this study was CCRF-CEM. Cells were plated at 20,000 cells/mL in 24-well plates or 500,000 cells/mL in 6-well plates. Cells were exposed to Benzyl-α-GalNAc, an O-linked glycosylation inhibitor, for 48 hours prior to exposure to FITC-tagged Anti-MUC1 antibodies or conventional chemotherapy at various time points. Conventional chemotherapeutic agents were selected based on the National Comprehensive Cancer Network guidelines for the treatment of ALL. Drug agents employed were, cyclophosphamide, imatinib, and doxorubicin hydrochloride. Cell viability was assessed via electronic cell count, Caspase 3, and SRB (Sulforhodamine) assay procedures.
Results: Following inhibition of glycosylation a statistically significant decrease in the uptake of FITC-tagged Anti-MUC1 antibody by CCRF-CEM cells compared to control cells ($P<0.001$) was observed at 4 hours, with no difference reported at 24 hours. The finding suggests that the diminished glycosylation levels surrounding CCRF-CEM cells decreased the access of anti-MUC1 antibody to the membrane core protein. The studies showed that inhibition of glycosylation in CCRF-CEM cells decreased the overall effectiveness of chemotherapeutic agents compared to control *in vitro*. A diminished cytotoxic drug effect was reported for doxorubicin hydrochloride ($P<0.0001$), Imatinib ($P<0.0001$) and Cyclophosphamide ($P<0.001$), when compared to the effects of each agent alone. These findings were further supported by the cytotoxicity results from the SRB and Caspase 3 assay.
Conclusions: Our preliminary findings support the notion that the inhibition of O-linked glycosylation in ALL cells decreased, rather than increased, the entry of drug agents into ALL cells. The data are supported by diminished general effects of conventional chemotherapeutic agents against the target cells. Additional confirmation studies are currently underway.

#4722 Crucial prognostic biomarkers for resistance to KRAS-G12C inhibitors.

Y. Wang, L. Tian, C. Liu, S. Zheng, H. Shi, F. Wei, W. Jiang, Y. Dong, H. Xu, E. Yin, N. Sun, J. He;
National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China

Objective: KRAS-G12C inhibitors are promising in targeted therapeutic strategies. However, it remains uncertain to search for biological reminders of clinical outcomes and early resistance.
Methods: Systematic review has been performed up to September,2024 to evaluate treatment efficacy and beneficial patients. We constructed KEAP1 and STK11 knockout mutants with CRISPR/Cas9 technology and PD-L1 overexpression mutants with lentiviral vectors. The sensitivity of cells to different KRAS-G12C inhibitors was assessed using CCK-8 assays. Potential pathways of resistance were identified through comprehensive bioinformatics analyses.
Results: 13 clinical trials with 1,132 enrolled patients indicated remarkable clinical efficacy and benefit the senior and the female. Patients with liver and brain metastases also tends to benefit from KRAS-G12C inhibitors. KEAP1 mutation serves as a critical negative biomarker for early progression and resistance. Validation studies indicated a notable increase in IC50 values for different KRAS-G12C inhibitors after KEAP1 knockout ($P < 0.0001$). Differentially expressed genes in KEAP1 knockout cells versus contrast groups were conducted with GO, KEGG, and Reactome pathway analyses, suggested evident enrichment in extracellular matrix organization and cell adhesion processes. In addition, STK11 mutations and an increasing PD-L1 expression level reminds of worse prognosis, despite absence of significant difference.
Conclusion: This research considered KRAS-G12C inhibitors as optional therapy and selected some subgroups who are more likely gain benefits from targeted therapy. As a key adverse biomarker, KEAP1 mutation tends to affect extracellular matrix organization and cell adhesion and promotes early resistance.

#4723 Development and preclinical activity of BSI-721, a novel antibody-drug conjugate (ADC) targeting cadherin 17 (CDH17) in gastrointestinal cancers.

Xiaoyao Hao[1], Jingyu Liu[1], hongyan li[1], jun li[1], jialong wang[1], **Hui-Han Hu**[2], frank liu[1], mingjiu chen[1], Qun Lv[1]

[1]Biosion, Inc., NanJing, China,[2]Biosion, Inc., Taipei, Taiwan

Background: Cadherin 17 (CDH17) is a cell adhesion protein that belongs to the cadherin superfamily. CDH17 is highly restricted to tight junctions in normal gastrointestinal (GI) tissues. In contrast, CDH17 is frequently overexpressed and becomes accessible to targeted therapeutics in several GI malignancies, including colorectal, gastric, pancreatic, and esophageal cancers. This differential expression profile makes CDH17 a promising therapeutic target for antibody-based therapeutics, including ADCs. Here, we described the development and preclinical activity of BSI-721, a novel ADC that combines a fully humanized anti-CDH17 monoclonal antibody (mAb) with monomethyl auristatin E (MMAE) via a cleavable peptide linker.

Methods:The anti-CDH17 mAb was generated from AceMouse™ mice immunized with 293T cells overexpressing human full-length CDH17 and purified CDH17 extracellular domain recombinant protein, sequentially. Binding affinity of the anti-CDH17 mAb was assessed by surface plasmon resonance and flow cytometry. CDH17 expression as cell surface density on cancer cells was determined by quantitative flow cytometry. The anti-CDH17 mAb was conjugated to MMAE via a protease-cleavable valine-citrulline linker. Cytotoxicity of BSI-721 was evaluated in cell lines with varying endogenous expression levels of CDH17. In vivo, efficacy of BSI-721 was assessed in CDH17-high gastric and CDH17-moderate/low pancreatic CDX models.

Results: The anti-CDH17 mAb showed strong binding affinity to both human and cynomolgus monkey CDH17 and cell lines with varying expression levels of CDH17. HIC-HPLC analysis revealed that MMAE was conjugated to the anti-CDH17 mAb in a drug-to-antibody ratio (DAR) of 4 with a high yield of (among which, more than 50% conjugates carrying a DAR of 4). BSI-721 exhibited potent cytotoxicity against cell lines with varying expression levels of CDH17 (subnanomolar IC_{50}). In CDH17-high gastric cancer model (SNU-5), treatment with BSI-721 resulted in significant tumor regression (with achievement of partial response) and tumor growth inhibition (TGI). BSI-721 also demonstrated a significant TGI in CDH17-moderate/low pancreatic cancer model (AsPC1). Additionally, candidate antibodies have been identified with potential to be developed into immunohistochemistry (IHC) companion diagnostic assay.

Conclusion: These data highlight the potential of BSI-721 as an effective targeted therapy for GI malignancies with varying expression levels of CDH17. Further, pharmacokinetics, toxicity, and IND-enabling studies of BSI-721 are underway.

#4724 Evaluating immunotherapy and combination therapy efficacy in kidney cancer using a multicellular 3D immune-microtumor model.

E. Peerani[1], K. Nan[1], J. Ient[1], P. Maximchik[1], N. K. Bah[1], J. Kearney[1], J. A. Hudson[1], R. K. Hare[1], F. Sangkolah[1], G. R. T. de Fraine[1], K. L. Loughrey[1], E. Tham[1], F. Iori[1], M. H. Williams[1], M. G. B. Tran[2], D. N. B. Ranatunga[1];

[1]Pear Bio, London, United Kingdom, [2]Royal Free Hospital, University College London, London, United Kingdom

Advanced renal cell carcinoma (RCC) presents a significant treatment challenge, as response rates to immunotherapies, receptor-tyrosine kinase inhibitors (TKIs) and combination therapies remain unpredictable. A functional precision medicine approach that models tumor-immune interactions can help tailor patient-specific therapy selection, reducing ineffective treatment cycles. Pear Bio's 3D immune-microtumor platform recreates the RCC tumor immune microenvironment (TiME), retaining relevant cell subpopulations to evaluate drug efficacy.

Using fresh RCC tumor tissues and matched blood, the Pear Bio platform generates immune-microtumor cultures within a custom hydrogel optimized to sustain tumor, immune, and stromal cells (N=20). Tumor cells are co-cultured with activated peripheral blood mononuclear cells (PBMCs), with CD8+ T cells and CD8- PBMCs tracked via fluorescent dyes. FDA-approved RCC therapies, including immunotherapies (e.g. ipilimumab, nivolumab, pembrolizumab) and TKIs (e.g. axitinib, lenvatinib), are administered as monotherapies or in combination. Over 4 days, 3D confocal imaging assesses functional metrics including immune cell infiltration and tumor cell death, quantified through a proprietary computer vision pipeline.

Immunofluorescence (IF) of 3D immune-microtumors (N=20) demonstrated retention of diverse TiME cell types—including tumor, endothelial, epithelial, immune, and cancer-associated fibroblasts—at day 0 and day 4 of culture. RNAseq confirmed transcriptional similarity of cells pre- and post-culture, with cell deconvolution further supporting immune compartment retention. Therapy dosing was optimized through molecular assays (IF, Luminex, flow cytometry, in-cell western) and functional screens on immune-microtumors (N=45).

Post optimization, 3D immune-microtumors were used to test clinical treatment regimens and assess combo therapy responses in RCC in our trial (PEAR-TREE N=20 ISRCTN10001405). Pembrolizumab monotherapy increased PBMC and CD8+ cell infiltration by 26% and 14%, respectively, and boosted tumor cell death by 15% compared to controls (N=5). When combined with lenvatinib or axitinib, pembrolizumab further reduced tumor cell viability by 10% and 19%, respectively. This functional analysis reveals intra-patient response variability, underscoring the immune-microtumor model's potential to capture personalized RCC responses to combination therapies.

This 3D immune-microtumor model allows for precise ex vivo testing of combination therapies in RCC, capturing patient-specific interactions within a functional TiME. Current clinical validation in the PEAR-TREE2 RCC trial (NCT06264479) aims to further correlate ex vivo findings with in vivo outcomes, holding promise to guide optimized, personalized RCC treatment.

#4725 Engineering a novel serine-degrading enzyme for targeted cancer therapy.

Ladan Mashouri[1], Ebru Cayir[1], Sarita Bhetawal[1], Daniel J Diaz[1], Vipin Rawat[2], Jonathan Coloff[2], George Georgiou[1], Everett Stone[1]

[1]The University of Texas At Austin, Austin, TX,[2]University of Illinois at Chicago, Chicago, IL

The non-essential amino acid L-serine (serine) is the second most consumed amino acid by cancer cells, supporting their survival and proliferation by contributing to the biosynthesis of nucleotides, lipids, and proteins. Serine-auxotrophic tumors such as luminal breast cancers have compromised serine synthesis pathways, thus rely on extracellular serine, making them vulnerable to serine depletion therapies. While dietary serine restriction, the only current method to reduce serine availability for tumors *in vivo*, has shown limited success in reducing tumor growth, its application is hindered by poor patient compliance and an inadequate reduction of circulating serine. To overcome these limitations, we developed an engineered human serine/threonine dehydratase (eSDH) enzyme that irreversibly depletes over 95% of circulating serine and threonine without requiring dietary changes. Preclinical studies show that eSDH treatment significantly inhibits the growth of serine-auxotrophic tumors. To enhance the therapeutic potential of eSDH and reduce off-target effects, particularly the depletion of the essential amino acid threonine, we focused on improving the specificity of eSDH for serine. Through iterative structure-based engineering, we developed a new SDH variant with over 20 times higher selectivity for serine toward threonine. Both *in vitro* and *in vivo* studies have confirmed that this novel SDH variant depletes serine while preserving threonine in cell culture media and serum. Current efforts are focused on improving the stability of the new SDH variant to extend its half-life in serum and optimize dosing for greater therapeutic efficiency. This advancement allows us to target serine-auxotrophic cancers more precisely while minimizing the impact on normal cells. The broader impact of this work lies in establishing enzymatic serine depletion as a more effective and feasible alternative to dietary restriction for cancer therapy. This approach could provide a new therapeutic strategy for treating various serine-auxotrophic tumors, offering better patient compliance and fewer side effects.

#4726 ETC-501, a novel brain penetrant MNK kinase inhibitor, potentiates TMZ-induced senescence and sensitizes glioblastoma cells to senolytic therapy.

Giselle Nah[1], Yuk Kien Chong[2], Fatin Nasha Sulaimi[1], Kian Leong Lee[1], See Wee Lim[2], Kassoum Nacro[3], Jeffrey Hill[4], Alex Matter[1], Henry Yang[5], Beng Ti Ang[2], Carol Tang[2], Sin Tiong Ong[1]

[1]Duke-NUS Medical School, Singapore, Singapore,[2]National Neuroscience Institute, Singapore, Singapore,[3]Experimental Drug Development Centre, A*STAR, Singapore, Singapore,[4]BeiGene Innovation Center, Guangzhou, China,[5]Cancer Science Institute, National University of Singapore, Singapore, Singapore

Glioblastoma (GBM), the most lethal primary brain tumor in adults, has a median survival of only 15 months, with fewer than 10% of patients surviving beyond five years. Despite aggressive multimodal therapies, including maximal surgical resection, radiation, and temozolomide (TMZ) chemotherapy, recurrence is almost inevitable. Contributing factors include incomplete resection, elevated levels of O6-methylguanine DNA methyltransferase that repair TMZ-induced DNA damage, therapy-resistant glioma stem cells, intratumoral heterogeneity, and the restrictive blood-brain barrier. Additionally, therapy-induced senescence from chemoradiation poses further challenges, as senescent glioma cells secrete pro-tumorigenic senescence-associated secretory phenotype (SASP) factors and may escape senescence, potentially facilitating recurrence. To evaluate the clinical relevance of MNK kinases in gliomas, we analyzed data from The Cancer Genome Atlas (TCGA), showing that elevated MNK1 and MNK2 expression correlates with increased tumor aggressiveness and poor prognosis. Genetic knockdown experiments confirmed that MNK1/2 are essential for GBM growth in vitro and drive aggressive behavior in vivo. To exploit their therapeutic potential, we developed ETC-501, a potent, selective, brain-penetrant MNK inhibitor. ETC-501 inhibited critical GBM processes, including MYC-driven transcriptional programs, DNA replication, ribosome biogenesis, inflammatory responses, and coagulation. Importantly, in combination with TMZ, ETC-501 significantly enhanced TMZ-induced senescence and reduced tumor-promoting SASP factors in GBM cells, acting both as a senescence inducer and senomorphic. Leveraging this enhanced senescence, we increased the susceptibility of GBM cells to the senolytic agent navitoclax, enabling targeted clearance of residual senescent cells. This "one-two punch" therapeutic strategy effectively eradicated cells that could otherwise act as reservoirs for recurrence. Our findings underscore the therapeutic potential of MNK inhibition in GBM, advancing our approach to managing GBM and potentially other malignancies characterized by senescence and SASP.

#4727 Exploring glycosylation as a barrier to drug therapy in lymphoma: unlocking new therapeutic potential.

Shayan Mosaffa, Thao Nguyen, Nasr Issa, Robert B. Campbell

Department of Pharmaceutical Sciences, Massachusetts College of Pharmacy & Health Sciences, Worcester, MA

Background: Lymphoma, a cancer more common in younger males, poses challenges in developing treatments with precise target selectivity. Mucin, a glycosylated protein overexpressed in tumor cells, forms a barrier shown elsewhere to impede drug effects. For example, we previously demonstrated in pancreatic cancer models that the inhibition of mucin glycosylation improved treatment outcomes *in vitro* and *in vivo*. This approach remains unexplored in lymphoma. This study examines the extent to which mucin glycosylation impacts the intracellular uptake and effectiveness of lymphoma therapeutics *in vitro*. We hypothesize that glycosylation functions as a cellular barrier limiting cellular access to model agents and subsequent drug effects.
Methods: The U-937 human lymphoma cell line (ATCC CRL-1593.2) was cultured in RPMI-1640 medium supplemented with 5% fetal bovine serum (FBS). Cells were seeded in 24-well plates and exposed to a glycosylation inhibitor (benzyl-α-GalNAc). After a required incubation period, the cells were exposed to a fluorescently tagged anti-MUC1 antibody (used to probe the degree of cell access to molecular entities in the presence and absence of the glycation mesh). Antibody uptake was analyzed using a fluorescent microplate reader. The functional drug effects of pre-exposing U-937 cells to the glycosylation inhibitor were initially assessed through cell viability experiments (using Quadcount™), with follow-up studies using a fluorometric assay.
Results: At 1 hour, cells that were pre-exposed to the glycosylation inhibitor demonstrated significantly higher uptake of the anti-MUC1 antibody compared to untreated cells ($p = 0.0266$), suggesting enhanced drug delivery in the early stages. Future studies will investigate whether the uptake is time-dependent, favoring prolonged cellular exposure to the antibody. Preliminary data shows that the pre-exposure of U-937 cells to benzyl-α-GalNAc enhanced the effect of imatinib significantly when compared to imatinib alone ($P= 0.0240$). The impact of cellular glycosylation on the effect of additional therapeutic agents is currently under investigation.
Conclusions: Targeting mucin glycosylation with benzyl-α-GalNAc enhanced anti-MUC1 antibody uptake. The improved cell kill observed with the inhibitor-imatinib combination further underscores the promise of this strategy in overcoming drug resistance in lymphoma.

#4728 The selective Yap/Tead inhibitor TY-1054 re-sensitizes acquired resistance to multiple tyrosine kinase-based targeted therapies.

Shengli Dong*,#[1], Apeng Liang*,#[1], Zhengfei Guo#[1], Meihua Li[1], Huan Wang[2], Shuaibo Han[1], Hongqiang Li[1], Jing-Lan Mu[2], Yakun Qi[2], Chao Zhou[1], Yu Yu[1], Xinlong Yang[1], Lian Fang[1], Zhiyong He[1], Haoyun Li[1], Chengshan Niu[3], Mingyu Jiang[2], Xiugui Chen[2], Shaoqing Chen[2], **Jun Li**[2], Yusheng Wu[3]

[1]TYK Medicines, Inc., Changxing county, Huzhou City, China,[2]TYK Medicines, Inc. (Shanghai), Xuhui District, Shanghai, China,[3]TYK Medicines, Inc. (Zhengzhou), Zhengzhou, Henan, China

Introduction: Dysregulation of Hippo/YAP signaling is widespread in human tumors. YAP/TEAD activation is one of the major reasons for resistance in response to targeted therapies. Therefore, the Hippo/YAP signaling pathway is an emergent therapeutic target for inhibiting tumor progression and drug resistance. Small molecules that block auto-palmitoylation of TEADs, such as VT3989 (NCT04665206) and BPI-460372 (NCT05789602), have been successfully to enter the clinical trials. TY-1054 is a potent TEAD inhibitor fully developed by TYK Medicines Inc.

Results: TY-1054 had excellent efficacy in the H226 CDX and HNSCC PDX mouse models. TY-9591 is a third-generation EGFR inhibitor developed by TYK Medicines and is currently under pivotal Phase III clinical investigation in China. Our studies showed that TY-9591 had excellent efficacy in the PC9 CDX mouse model, but tumors gradually recurred, as Osimertinib did. Drug-tolerant persister (DTP) and Yap/Tead activation are believed to cause drug resistance to Osimertinib. We found that TY-1054 significantly inhibited the expansion of DTP cells that emerged in PC9 and H-1975 cells after TY-9591 treatment. To investigate whether combined YAP inhibition would result in an extension of responses to EGFR therapy, we treated EGFR-driven NSCLC cell lines with TY-1054 and TY-9591. The results showed that the combination treatment not only offered synergistic effects, but also enhanced apoptosis, compared to single-drug treatment. Furthermore, TY-1054 in combination with TY-9591 significantly delayed tumor regrowth in the PC9 CDX mouse model. The renal safety concerns associated with Yap/Tead inhibitors have attracted significant attention. Since the chemical structures of VT3989 and BPI-460372 have not yet been disclosed, we examined the renal toxicities of TY-1054 with reference compounds VT-105, an analog of VT3989, and TY-2225, which is a Tead inhibitor protected by a polymorph patent of Betta Pharma (WO2023155760A1). In a rat renal toxicity experiment, TY-1054 at a dose of 2.5 mg/kg caused much less albuminuria than VT-105 and TY-2225. To address the differences in renal toxicity between species, we performed a mouse renal toxicity study using TY-1054, VT-105, and TY-2225. In terms of preclinical efficacy and safety, the data suggest that TY-1054 is potentially the best-in-class compound compared to its major competitors.

In summary, has a favorable PK profile, good drug exposure, manageable tolerance at high drug exposure levels, and a potentially wide therapeutic window. IND clearances from the US FDA and CN NMPA have received in 2024. This study provides a strong rationale for testing TY-1054 in human clinical trials. The successful execution of the TY-1054 clinical trial will provide a powerful solution for future precision oncology. # contributed equally to this work. * To Whom Correspondence should be addressed.

#4729 The reversible and selective FGFR2/3 inhibitor CGT4859 has superior target coverage of resistance mutations missed by leading FGFR inhibitors.

John Fischer, Karyn Bouhana, Richard Brizendine, Mark Chicarelli, Brad Fell, Jennifer Fulton, Anna Guarnieri, Leyla Haygood, Ravi Jalluri, Amber Johnson, Keith Koch, Erika Koslov-Davino, Macedonio J. Mejia, Rob Rieger, John Robinson, Mareli Rodriguez, Francis Sullivan, Yang Wang, Shannon Winski, Silas Wood, Yeyun Zhou

Cogent Biosciences, Boulder, CO

FGFR2 and FGFR3 alterations are oncogenic events across many solid tumors, often through chromosomal fusion or activating mutations. FGFR2 translocations are prevalent in intrahepatic cholangiocarcinoma, while FGFR3 mutations and fusions are prevalent in bladder cancer. Both indications have approved pan-FGFR inhibitors that demonstrate responses in patients that harbor these genetic alterations, however, responses are short-lived or show reduced activity in patients with on-target resistance mutations. In addition, efficacy of these agents has been hampered by inhibition of FGFR1, which leads to dose-limiting hyperphosphatemia. To address these issues, we present our clinical candidate CGT4859, a novel reversible FGFR2/3 inhibitor with activity against clinically relevant mutations and >140-fold selectivity over FGFR1. In vivo characterization of CGT4859 demonstrates robust efficacy in target-altered models at tolerated doses. Together, these data demonstrate CGT4859 as a potential best-in-class FGFR1-sparing pan-mutant FGFR2/3 inhibitor.

#4730 The selective WEE1 inhibitor azenosertib shows synergistic anti-tumor activity with encorafenib + cetuximab in multiple BRAF^{V600E} models.

Nathan M. Jameson, **Harshit Shah**, Blake Skrable, Mona Abed, Hooman Izadi, Nam-phuong Nguyen, Olivier Harismendy, Mark R. Lackner

Zentalis Pharmaceuticals, San Diego, CA

BRAF^{V600E} is a potent oncogenic driver which results in downstream hyperactivation of MAPK signaling and unchecked oncogenic growth, while simultaneously increasing replication stress (RS) and accumulation of DNA damage. The BRAF^{V600E}-specific inhibitor encorafenib in combination with the anti-EGFR monoclonal antibody cetuximab (E + C) are approved in the second line plus (2L+) setting in metastatic colorectal cancer (mCRC) resulting in 20% overall response rate (ORR) in the confirmatory Phase 3 study. However, many patients do not respond, and alternative therapeutic options are still needed in this challenging patient population. WEE1 is a kinase involved in cell cycle progression, allowing cells to repair damaged DNA before entering the next cell cycle phase. Consequently, inhibition of WEE1 leads to premature mitotic entry, inducing replication stress (RS) and unchecked accumulation of DNA damage, ultimately resulting in mitotic catastrophe and cell death. Paradoxically, inhibition of oncogenic drivers like BRAF^{V600E} have been demonstrated to drive high levels of chromosomal instability (CIN) and RS. We hypothesized that high levels of CIN and RS in *BRAF^{V600E}*-mutant tumors before and after treatment with E + C present a vulnerability to WEE1 inhibition and provide rationale for combining azenosertib, a novel, selective, and orally bioavailable WEE1 inhibitor, with E + C. Here, we report the effectiveness of azenosertib combined with E + C as an anticancer treatment in *BRAF^{V600E}* CRC models. *In vitro* combination of azenosertib with E + C increased cell growth inhibition over monotherapy azenosertib or doublet E+ C across multiple *BRAF^{V600E}* cell lines, and was accompanied by a decrease in activity of MAPK and mediators of cell cycle checkpoints, highlighting possible mechanisms for synergy. *In vivo* treatment of *BRAF^{V600E}* CRC cell-line derived xenograft (CDX) models with azenosertib demonstrated significant monotherapy tumor growth inhibition (TGI) in the LS411N model (69%) as well as synergistic TGI and tumor regression when combining azenosertib with E + C compared against E + C alone in two CDX models (LS411N: 108% vs 63%; HT-29: 101% vs 88%). Similarly, treatment of multiple *BRAF^{V600E}* patient-derived xenograft (PDX, N=3) models of CRC resulted in synergistic triplet TGI (80%, 102%, 103%) and some tumor regression compared against monotherapy azenosertib (43%, 19%, 51%) or the E + C doublet (49%, 65%, 87%). Taken together, our results suggest that the *in vitro* and *in vivo* combination of azenosertib with E + C enhances tumor growth inhibition over single agent azenosertib or doublet E + C therapy, and may be an effective treatment option for patients with *BRAF^{V600E}* mCRC.

#4734 Alteration of tumor immune environment in metastatic and non-metastatic papillary thyroid microcarcinoma.

Rhitajit Sarkar[1], Shilpa Thakur[1], Gus Fridell[2], Noemi Kedei[3], Maria Hernandez[3], Sonam Kumari[1], Maria Merino[3], Joanna Klubo-Gwiezdzinska[1]

[1]NIH National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), Bethesda, MD,[2]Department of Biology, Johns Hopkins University, Baltimore, MD,[3]NIH National Cancer Institute (NCI), Bethesda, MD

Introduction: Papillary thyroid microcarcinomas (PTMC), defined as tumors ≤1 cm in size, are mostly indolent and warrant conservative management. However, up to 10% of PTMC present with clinically significant lymph node metastases or very rarely with distant metastases (M1). Deciphering molecular signatures of metastases-prone PTMCs may help strategize management options. Therefore, the goal of this study was to analyze the transcriptome profiles and tumor microenvironment in metastatic and non-metastatic PTMC.
Methods: Patients diagnosed with indolent non-metastatic (N0/Nx) PTMCs and with tumors metastatic to the lateral neck lymph nodes or distant sites (N1b/M1) were selected by reviewing medical records and pathology slides. RNA sequencing was done on 85 tumor samples and adjacent normal tissues. An R package pathfinder was used to do pathway enrichment analysis utilizing active subnetworks. A subset of samples (n=9) was subjected to multiplex immunofluorescence (MxIF) staining using CD8a and CD20 antibodies. Image analysis of the whole tissue, tumor, and three 400 µm regions around the tumor to count cytotoxic T cells, B-cells, and macrophages was done in a single-blinded manner using HALO (Indica Labs). Differential spatial expression was tested using t-test for normally distributed data and Mann-Whitney test for skewed data, with two-sided $p \leq 0.05$ rendered statistically significant.
Results: The study cohort consisted of 17 patients from N0/Nx group and 19 presenting with N1b/M1 disease. No difference in the clinical characteristics, viz. age (39y vs 46y, p=0.64), gender (female 82.4% vs. 94.7%, p=0.24), median tumor size (0.6cm vs 0.8cm, p=0.27) was found between the groups. There was a significant downregulation of pathways involved in the regulation of B cell activation (FDR-adjusted p-value<0.001), activation of immune response (p<0.001), antigen receptor-mediated signaling pathway (p<0.001), humoral immune response (p<0.001), B cell receptor signaling pathway (p<0.001), pathways activating and regulating cell surface receptor and signal transduction (p<0.001) in primary tumors derived from the N1b/M1 compared to N0/Nx group. However, MxIF revealed no difference in B cell ($CD20^+/CD8a$) infiltration in the primary tumors (p=0.43) nor in the tumor rims (p=0.92) between the groups. In contrast, there was a significantly higher number of cytotoxic T cells ($CD8a^+/CD20^-$) in the rims of the primary tumors from N1b/M1 group compared to N0/Nx (p=0.007).
Conclusion: Metastasis-prone PTMC is characterized by a different immune landscape as compared with the classic indolent variant, with increased cytotoxic T cell infiltration in tumor edges and decreased activation of infiltrating B-cells. GeoMx DSP experiments are undergoing to identify immune cells and their crosstalk with the cancer cells that might be involved in transducing metastatic potential for a subset of PTMCs.

#4735 In silico reconstruction of primary and metastatic estrogen receptor positive breast tumor architecture using geographic information science-augmented spatial transcriptomics.

Jin Young Yoo[1], Sabrina Akter[1], Qianying Zuo[1], Mahima Goel[1], Audrey Lam[2], Debapriya Dutta[2], Betsy Barnick[2], Maria Grosse-Perdekamp[2], Aiman Soliman[1], Zeynep Madak-Erdogan[1]

[1]University of Illinois Urbana-Champaign, Urbana, IL,[2]Carle Foundation Hospital, Urbana, IL

The tumor microenvironment consists of different cell populations, whose interactions contribute to tumor heterogeneity and plasticity and pose challenges to therapy efficacy and prognosis prediction. Breast cancer is one of the highly heterogeneous diseases, and estrogen receptor (ER) positive subtype, the most common one, shows worse prognosis once metastasized. Spatial transcriptomics (ST) is emerging as a powerful tool that offers valuable insights into spatial complexity of tumor microenvironment as well as the cell interactions underpinning tumor heterogeneity. In this study, we aimed to examine tumor heterogeneity of ER positive metastatic breast cancer by applying our geographic information science (GIS)-augmented ST analysis pipeline. Visium datasets were prepared from four metastatic liver tumors from xenograft mouse model and twelve primary and metastatic bone tumors from human patients, including three matching pairs. We integrated geospatial tools, such as multivariate spatial association analysis, with spatial omics data structures to check degree of auto-correlations and visualize localizations of single gene or gene sets. We further compensated for multi-cellular resolution of our spatial data via cell type mapping and deconvolution of cell type proportion (STdeconvolve). We identified hotspot regions displaying extensive co-localization between estrogen response gene set and lipid metabolism gene sets in the fulvestrant-treated metastatic liver tumors from xenograft mouse model. These hotspots were not concentrated in the same area within the tumor and differed by gene sets, suggesting intra-tumor metabolic heterogeneity of the endocrine responsive cells. Our primary samples from human patients showed similar pattern of co-occurrence between estrogen response and metabolic programs as well as cell-cycle related gene sets. On the other hand, mutual exclusivity was observed for estrogen response with immune-related gene sets and metastasis-related ones (epithelial mesenchymal transition, angiogenesis). Compared to primary tumors, metastatic bone tumors showed inter-tumor heterogeneity as such consistency in spatial pattern was obscured. Deconvoluting cell type proportions mapped a higher proportion of mature luminal cells in endocrine responsive hotspots, whereas cancer associated fibroblasts and pericytes were prevalent in the hotspots of metastasis-related gene sets. Our study fully utilized the potential power of ST data by delineating the tumor microenvironment in relation to intra-tumoral heterogeneity as well as cell type proportions. Findings from our study support the development of strategies to target different endocrine resistant cell populations with a combination of metabolic and metastasis-related signaling inhibitors.

#4736 A highly selective CDK4/9 dual inhibitor reverses tumor resistance to CDK4/6 inhibitors.

Jinwen Huang, Zhongyuan Li, Zeng Song, Yunli Liu, **Steve Shen**

Convalife (Shanghai) Co., Ltd., Shanghai, China

Background: CDK4/6 inhibitors have been approved for the treatment of metastatic ER+ and HER2- breast cancer. However, patients will become resistance due to various mechanisms, resulting in high unmet need. Literature suggests that CDK9 activity may be involved in the mechanism of resistance to CDK4/6 inhibitors, and targeting CDK9 could be an effective strategy to overcome breast cancer resistance.
Methods and Materials: Using the Convalife "Right 6D+AI" molecular design platform, AI-based screening and multi-angle evaluation were conducted on over 8,000 virtual molecules, ultimately yielding candidate molecule N049 with selectivity for CDK4 and CDK9 that were >30-fold and >80-fold higher than for CDK6, respectively. To explore the therapeutic potential of N049 in palbociclib-resistant tumors, effects on cell viability were evaluated in both palbociclib-sensitive and -resistant cell lines. Additionally, patient-derived organoids (PDOs) and PDX models were used to assess the impact of CDK4/9 inhibitors on cell viability.
Results: The CDK4/9 inhibitor N049 targeting CDK9 significantly impaired the viability of both palbociclib-sensitive and palbociclib-resistant LTED cell lines. Furthermore, in patient-derived organoids (PDOs) and PDX models, the CDK9 inhibitor drove tumor regression in palbociclib-resistant PDXs.
Conclusion: Our findings suggest that simultaneous inhibition of CDK4 and CDK9 may exert potential synergistic effects to overcome CDK4/6 inhibitor resistance. The use of CDK4/9 inhibitors N049 could be an effective strategy to address resistance to endocrine therapy and CDK4/6 inhibitors in ER+ breast cancer. CDK4/9 inhibitors N049 represent a promising therapeutic approach for overcoming breast cancer resistance.

#4737 IGF and insulin system in regulating hallmarks of cancer.

Bhumika Rajoria, Xihong Zhang, Rick Jansen, Deepali Sachdev, Douglas Yee

University of Minnesota, Minneapolis, MN

The Insulin-like growth factor (IGF) and insulin system is implicated in various cancers and is known to regulate cell growth, proliferation, and metabolism. Type 1 IGF receptor (IGF-1R) targeting strategies have been unsuccessful, probably due to its characteristic to form heterotetrameric hybrids with the homologous insulin receptor (IR). This introduces multiple IGF-1 binding sites and draws focus on IR and its isoforms - IR-A and IR-B, as potential therapeutic targets. A high IR-A to IR-B ratio is observed in tumors including breast cancer. IR-A regulates fetal growth and development while IR-B is predominantly found in the liver and skeletal muscle where glucose uptake is regulated via glucose transporter GLUT4. Non-specific IR targeting likely leads to metabolic imbalance and thus necessitates delineating IR isoform roles to develop efficient targeted strategies. Ideally, targeting IR-A specifically, and leaving IR-B unaffected, might be an effective IGF and insulin system targeting approach. Our group developed IR K/O MCF-7L (ER+ breast cancer cell line) and introduced IR-A or IR-B to generate isoform-specific cell lines. The real-time ATP production rates suggest IGF-1 promotes glycolytic ATP production in MCF-7L, MDA MB 231, MCF-7L IR K/O, and MCF-7L IR-B K/I while insulin at physiological concentration doesn't affect ATP production. Therefore, IR-B may maintain the metabolic demand of ER+ breast cancer cells when activated by IGF-1. Additionally, IR inactivation and metabolic stimulation via IGF-1 suggest investigating alternative fuels to glucose. Our group previously showed IGF-1 activates cystine/glutamate transporter: xC-, in ER+ cells through PI3K/Akt signaling, sequentially regulating ROS. This further supports proliferation, metastasis, and drug resistance. Glutamine is the rate-limiting step for this transporter exchange and hence a potential candidate driving the observed glycolytic phenotype. Preliminary data suggests MCF-7L maintains the metabolic demand through glucose and glutamine when stimulated with IGF-1. IGF-1 also stimulated migration in MCF-7L and MDA MB 231 cell lines while insulin promoted this phenotype in MDA MB 231 only. This suggests that the IGF and insulin system maintains the metabolic demand of cancer cells to promote cancer aggressiveness. Further investigation will elucidate IR isoform roles in cellular hallmarks of cancer.

#4738 Androgen regulation of HER3 in prostate cancer differs by duration of treatment.

Reem Belal Zalloum, Robert A. Holt, John Smetana, Candice Loitz, Lillian Perez, Larisa Nonn

Department of Pathology, University of Illinois at Chicago, Chicago, IL

Background: Prostate cancer (PCa) is the second most common cause of cancer-related death in men and occurs in 1 out of every 8 men. Normal prostate and PCa are responsive to androgens. The interplay between androgens and the ERBB3/HER3 receptor tyrosine kinase has recently been shown to differ by race. ERBB3 was higher in Black/African American patients and correlated with the androgen response pathway despite stable expression of the androgen receptor (AR) transcript. HER3 protein expression was negatively correlated with intraprostatic androgen in Black/African American men. Here we examined the effects of androgen dose and treatment duration on the HER3 pathway in vitro.

Methods: Three PCa cell lines were used; MDA-PCa-2b, derived from an African American patient bone metastasis, LNCaP and LaPC4 derived from white patient lymph nodes. Cells were treated for 48h or 6 months with low or high dose R1881 (synthetic androgen). Endpoints include proliferation (Incucyte), gene expression (RT-qPCR), and protein levels (Western blot). Neuregulin (NRG1) was used to stimulate the HER3 pathway.

Results: PCa treated for 48h with R1881 showed a biphasic effect on proliferation, whereas those treated for 6 months showed a dose-dependent increase. HER3 protein levels were increased after 48h of R1881 but decreased during the 6-month exposure. NRG1 treatment slightly increased cell proliferation. Ongoing experiments will examine NRG1 signaling in the R1881-treated cell lines.

Conclusions: The crosstalk between the HER3 pathway and androgens, two key pathways known to drive aggressive prostate cancer, has been shown to play a more pronounced role in PCa in African American men compared to their White counterparts. Moreover, short-term exposures in vitro may not mimic the effects of androgens in vivo.

#4739 Development of a prognostic ovarian cancer gene signature based on glucocorticoid receptor transcriptional activity.

A. V. Panchamukhi[1], L. Huang[2], E. P. Gray[3], Y. Liu[4], M. Taya[3], J. T. Veneris[5], X. Hou[4], S. Weroha[4], B. Győrffy[6], G. F. Fleming[7], C. Wang[4], S. D. Conzen[3];

[1]Baylor College of Medicine, Houston, TX, [2]Kite Pharma, A Gilead Company, Santa Monica, CA, [3]UT Southwestern, Dallas, TX, [4]Mayo Clinic, Rochester, MN, [5]GSK, Boston, MA, [6]Semmelweis University, Budapest, Hungary, [7]The University of Chicago, Chicago, IL

Background: Epithelial ovarian cancer (EOC), commonly known as ovarian cancer (OvCa), is the deadliest gynecological malignancy. High tumor expression of either *NR3C1* mRNA (encoding the glucocorticoid receptor or GR) or GR protein (IHC) are associated with poor overall survival (OS) in patients (pts) with advanced stage OvCa. We hypothesized that high GR expression and associated GR transcriptional activity favor OvCa cell survival and chemotherapy resistance, thereby reducing OS. Here we investigated whether a GR transcriptome-based gene signature (GR-sig) would be a better prognosticator than tumor *NR3C1* mRNA expression alone.

Methods: mRNAs up- or downregulated >1.5 fold after glucocorticoid treatment (Dex) in one or both cultured OvCa cell lines (OVSAHO and HEYA8) were defined as differentially expressed genes (DEGs). DEGs were then identified in n=1247 unique OvCa microarrays from 15 publicly available Gene Expression Omnibus (GEO) datasets with matched pt OS (training set). We then used the OS data to train a Cox proportional hazards model. The "best subset selection" (BeSS) algorithm and bootstrap sampling identified those GR-regulated DEGs whose tumor mRNA expression correlated most significantly with pt OS, creating a GR-sig "risk score." Subsequently, all n=522 microarray and n=374 RNA-seq publicly available samples from the OvCa TCGA were used as two independent validation sets. Microarray and RNA-seq data were normalized using the MAS5 and FPKM-UQ algorithms respectively. The two validation sets were independently stratified relative to the median training set risk score into low- and high-risk score groups. To examine the prognostic ability of *NR3C1* mRNA expression alone, the median training set *NR3C1* expression value was used to stratify validation set pts into low- and high-expression groups. In all cases, OS was estimated by the Kaplan-Meier method.

Results: We identified n=2288 protein-coding DEGs in one or both cell lines. Of these genes, n=1251 were expressed in each GEO microarray sample (training set). A 10-gene GR-signature (GR-Sig) was then identified using the BeSS algorithm and bootstrap sampling, yielding a median training set risk score of 1.02. In both the microarray and RNA-seq validation datasets, the 10-gene GR-sig risk score was associated with significant OS differences between low- and high-risk score groups (microarray $p = 0.018$; RNA-seq $p = 0.00049$). In contrast, the OS difference between low- and high- *NR3C1* mRNA expression groups did not reach significance (microarray $p = 0.12$; RNA-seq $p = 0.28$).

Conclusion: In this retrospective analysis, a 10-gene GR-sig derived from OvCa GR-regulated DEGs performed better as a prognosticator than *NR3C1* mRNA expression alone. Prospective application of the GR-sig may be useful in stratifying patients for treatment response with novel agents in OvCa clinical trials.

#4740 Decipher androgen receptor condensate-mediated chromatin remodeling in gastric cancer.

Ben Liu, Huahuan Liu, Mengyue Qiu, **Kexin Chen**

Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

Liquid-liquid phase separation (LLPS) is an intracellular phenomenon where biomolecules, including proteins and nucleic acids, interact to form dense complexes in the cytoplasm or nucleus. This process is crucial for regulating biological functions, including gene expression, signaling pathways, and the cell cycle. Recent studies have revealed a strong association between abnormal LLPS activity and diseases, such as neurodegenerative disorders and cancer. There is a sex difference in the incidence and mortality of gastric cancer (GC), with males exhibiting a higher incidence than females. Sex hormones are among the biological factors contributing to this difference, and the androgen receptor (AR) serves as the key mediator of androgen action. However, its role in transcriptional regulation in GC remains unclear. To address this, we conducted multi-omics assays, including ATAC-seq, CUT&Tag, HiChIP, and RNA-seq, to investigate the AR-related transcriptional regulatory network in GC. Results revealed that chromatin accessibility increased following DHT treatment, and AR target genes were predominantly enriched in pathways related to proliferation, stemness, and metabolism. Furthermore, CUT&Tag analysis indicated that AR binding peaks were primarily located in non-promoter regions, suggesting that AR might bind to enhancer regions. We identified AR-associated typical and super-enhancer (TE/SE) target genes in GC. HiChIP results further confirmed spatial proximity interactions between promoters and enhancers at AR binding sites. In this study, we further investigated the ability of AR to form condensates and observed that AR translocates into the nucleus and forms condensates in the presence of DHT. The mobility of AR-formed foci was confirmed through both in vivo and in vitro experiments. Mutational analysis of key amino acids in AR's structural domains revealed that hydrophobic amino acids, specifically proline and leucine, are critical for AR phase transition. Proximity labeling and IP-MS assays identified SWI/SNF complex subunits and transcriptional coactivators, including BRD4 and MED1, as potential components of AR condensates. To explore the relationship between AR condensation and transcriptional regulation, the AR inhibitor enzalutamide was employed. Enzalutamide disrupted AR condensation and led to the downregulation of genes enriched in proliferation- and stemness-related signaling pathways. The combination of enzalutamide and AU-15330 effectively suppressed cell proliferation, colony formation, and organoid viability. These findings suggest that AR's LLPS capacity plays a critical role in regulating its transcriptional activity. Furthermore, combining SWI/SNF inhibitors with AR antagonists showed synergistic effects in inhibiting GC cell proliferation.

#4741 HER2 status correlated with interleukin-2 (IL-2) levels after systemic therapy in hormone receptor (HR)-positive metastatic breast cancer.

Justin W. Zhang[1], **Qiang Zhang**[2], Andrew A. Davis[3], Lorenzo Gerratana[4], Jianhua Jiao[5], Weijun Qin[5], Youbin Zhang[2], Paolo D'Amico[6], zheng Cai[7], Akhil Chawla[8], Lisa Flaum[2], Janice Lu[2], Leonidas C. Platanias[9], William J. Gradishar[2]

[1]Department of Surgery, Division of Surgical Oncology, Northwestern University and Whitney Young High School, Chicago, IL,[2]Department of Medicine, Division of Hematology/Oncology, Circulating Tumor Cell (CTC) core facility, Robert. H. Lurie Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL,[3]Department of Medicine, Division of Hematology/Oncology, Washington University in St. Louis, st. Louis, MO,[4]Department of Medicine, University of Udine, Udine, Italy,[5]Department of Urology, Xijing Hospital, Innovation Center for Tumor Immunocytology Therapy Technology, Xijing Innovation Research Institute, Fourth Military Medical University, Xi'an, China,[6]Merck, Rahway, NJ,[7]Department of statistics, University of Washington, Chicago, IL,[8]Department of Surgery, Division of Surgical Oncology, Robert. H. Lurie Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL,[9]Department of Medicine, Division of Hematology/Oncology, Robert. H. Lurie Cancer Center, Feinberg School of Medicine, Northwestern University, Chicago, IL

Introduction: The immune response plays a crucial role in prognosis in metastatic breast cancer (MBC). Detecting plasma immune components, including cytokines and circulating tumor cells (CTCs), can help predict prognosis. We previously identified Interleukin-2 (IL-2) as a biomarker associated with disease progression in MBC. Similarly, HER2 is a critical tumor marker linked to therapeutic outcomes and poor prognosis in advanced breast cancer (2018-ASCO #1090, 2022-ASCO #1057). Here, we report a novel finding: HER2 status is correlated with plasma IL-2 levels following systemic therapy in MBC patients.

Methods: Whole blood samples (7.5 mL each) were collected from 42 patients with MBC, including 25 ER+, 17 ER-, 12 HER2+, and 30 HER2- patients, both before systemic therapy (baseline, BL) and 3 months after therapy (follow-up) at Northwestern Memorial Hospital (IRB-NU16B06). CTC enumeration was performed using the FDA-approved CELLTRACKS System (Menarini). Plasma Interleukin-2 (IL-2) levels were analyzed using ELISA (Fisher). Estrogen receptor (ER), progesterone receptor (PR), HER2, and Ki67 status were assessed in biopsy tissue (prior to surgery) by NU PathCore. Statistical analyses were conducted using Causal Inference with Ensemble Learning.

Results: Based on pathological diagnoses, patients were categorized into 4 groups: 17 HR+/HER2- (Group 1), 8 HR+/HER2+ (Group 2), 4 HR-/HER2+ (Group 3), and 13 HR-/HER2- (Group 4). Ki67 expression was found in 9 patients in Group 1, 6 in Group 2, 1 in Group 3, and 6 in Group 4. There was no significant difference in baseline mean IL-2 levels among the groups, with values of 82.1 pg/mL, 78.6 pg/mL, 80.5 pg/mL, and 81.2 pg/mL for Groups 1, 2, 3, and 4, respectively ($P > 0.05$). After therapy, the mean IL-2 levels changed to 80.8 pg/mL, 69.3 pg/mL, 70.2 pg/mL, and 77.6 pg/mL at follow-up. A significant difference was observed between Groups 1 and 2 ($P = 0.037$), showing that IL-2 levels were notably higher in HR+/HER2- patients compared to HR+/HER2+ patients. There was no significant correlation between IL-2 and Ki67. Additionally, 20 patients (46%) had CTCs ≥5 at baseline, with 15 having HER2-negative CTCs (Group 5) and 5 having HER2-positive CTCs (Group 6). The mean IL-2 level was significantly higher in Group 5 (88.17 pg/mL) than Group 6 (66.81 pg/mL), indicating that patients with HER2-positive CTCs had significantly lower IL-2 levels ($P = 0.02$).

Conclusion: The finding that HER2 status in CTCs correlates with lower plasma IL-2 levels, and that HER2 status in biopsy tumor tissue is associated with IL-2 levels after systemic treatment in HR-positive MBC patients, suggests that HER2 may contribute to immune suppression and weaken the immune response through its interaction with IL-2 during therapy. Exploring the HER2-IL-2 relationship could provide valuable insights into assessing therapeutic efficacy in hormone receptor-positive MBC.

#4742 Novel (Z)-endoxifen-related chemical entities exhibit potent anti-cancer activity in ERα+ breast cancer.

Lena Batoon[1], Rajeev S. Muthyala[1], Sandra S. Hammer[2], Natalie Farris[2], Steven C. Quay[2], John R. Hawse[1]

[1]Mayo Clinic, Rochester, MN,[2]Atossa Therapeutics Inc, Seattle, WA

Approximately 80% of breast cancers express estrogen receptor alpha (ERα, ESR1), which drives cancer progression. Despite the array of targeted therapies, ERα+ breast cancer exhibits the highest recurrence and late distant relapse rates among subtypes. (Z)-Endoxifen (ENDX), an active metabolite of tamoxifen, is a potent, orally bioavailable selective estrogen receptor modulator with a favorable safety profile now under development for breast health applications. Its synthesis yields endoxifen-related byproducts that are new chemical entities (NCEs), including AT416E, AT416Z, AT402E and AT402Z. This study compared the anti-estrogenic effects of these compounds to ENDX in ERα+ breast cancer cell lines (MCF7, T47D, UCD12), including those with ESR1 mutations (Y537S, D538G) linked to endocrine resistance. In 2D cultures with estrogen (E2), ENDX and all NCEs showed significant anti-proliferative effects across all lines, achieving 20-90% inhibition at 0.02-5 μM ($p<0.0001$). ENDX was the most effective in MCF7; ENDX, AT416Z, and AT402Z in T47D; and ENDX, AT416E, and AT416Z in UCD12. Under E2-deficient conditions, all NCEs had lower IC50 values than ENDX in MCF7 cells, while AT416Z and AT402Z outperformed ENDX in UCD12. In T47D D538G mutants, ENDX, AT416E, and AT402Z exhibited the highest potency, while all NCEs showed comparable efficacy in Y537S mutants. In MCF7 cells, ENDX, AT402E, and AT402Z demonstrated similar activity against Y537S mutants, while AT402Z was the most potent in D538G mutants. In 3D cultures at a clinically relevant concentration (~1 μM), all compounds significantly reduced proliferation (~75-90%; $p<0.0001$), with ENDX and AT402Z showing superior potency. AT416E outperformed ENDX in wound-healing assays ($p<0.0001$). All NCEs induced comparable G1 cell cycle arrest in MCF7 ($p<0.0001$), while AT402E and AT402Z showed stronger promotion of G1-to-S phase arrest and S/G2/M inhibition compared to ENDX in T47D cells ($p<0.05$). These NCEs also significantly induced apoptosis in MCF7 cells at 1-5 μM ($p<0.0001$), with AT416Z, AT402E, and AT402Z surpassing ENDX ($p<0.0001$). In T47D cells, apoptosis was significantly induced by ENDX, AT416E, and AT416Z ($p<0.0001$ vs. vehicle), with ENDX showing superior activity. RT-qPCR analysis at 0.1 μM revealed ENDX and AT416Z as the most potent inhibitors of E2-induced ERα target gene expression in MCF7 cells, with ENDX surpassing all NCEs in T47D cells. Synergy assays indicated that the NCEs do not synergize with ENDX, supporting their potential use as stand-alone agents. These findings highlight four NCEs with notable anti-cancer activity, with some matching or surpassing ENDX in several cancer-relevant cellular readouts, marking them as novel candidates for ERα+ breast cancer therapy. Further studies will advance one or more of these NCEs into *in vivo* models to confirm their therapeutic efficacy and potential for clinical application.

#4743 Defining the impact of anti-androgen pathway inhibitors on ABI1, dendritic spines and mouse behavior.

Anna Seidl, Kevin M. Lin, Maria A. Ortiz, Leszek Kotula

Urology, Biochemistry and Molecular Biology, Upstate Cancer Center, SUNY Upstate Medical University, Syracuse, NY

Prostate cancer (PCa) is the most commonly diagnosed cancer and the second leading cause of cancer-related deaths among American men. Following radiation therapy and surgery, patients are often treated with androgen deprivation therapy (ADT) or anti-androgen drugs to suppress tumor growth, as prostate cancer is highly androgen-dependent. However, emerging evidence highlights significant cognitive side effects, including dementia and behavioral changes, associated with anti-androgen treatments. While clinical trials are investigating these 'treatment-induced' cognitive deficits, the underlying mechanisms remain poorly understood. Our previous work revealed that the Androgen Receptor (AR) regulates Abelson Protein 1 (ABI1) expression in prostate tumors. ABI1, a key stabilizer of the WAVE complex, plays a critical role in actin polymerization and cytoskeletal reorganization. In dendritic spines, ABI1 supports the dynamic remodeling of the cytoskeleton essential for synaptic plasticity, a fundamental process underlying learning and memory. Disruption of ABI1 in hippocampal neurons results in abnormal dendritic spine morphology and impaired synapse formation, but there are no genetic studies on the role of Abi1 in cognitive performance in mouse models. Androgen deprivation, through surgical castration or ADT, has been shown to impair memory and behavior in mice. Given that ABI1 expression is downregulated by anti-AR therapy in prostate tumors, we hypothesize that ABI1 is similarly regulated by androgens in dendritic spines. We propose that AR suppression by ADT leads to reduced ABI1 expression in dendritic spines, contributing to cognitive and behavioral impairments in patients undergoing ADT. To test this hypothesis, we utilized a novel Abi1-selective knockout mouse model developed in our lab to explore the effects of ABI1 disruption on dendritic spines and behavior. Additionally, we compared dendritic spine morphology and ABI1 levels in the hippocampi of mice treated with anti-AR drugs, such as enzalutamide, or subjected to surgical castration. These results are being analyzed alongside findings from mice with genetic ABI1 disruption. This study provides critical insights into the role of ABI1 in dendritic spine dynamics and synaptic plasticity, uncovering a potential mechanistic link between ADT and cognitive dysfunction. Our findings aim to define the molecular basis of treatment-related cognitive deficits in PCa patients and may guide the development of strategies to mitigate these side effects.

#4744 State-gating cancer to prevent chemotherapy-resistance.

Christine Louise Chaffer[1], Heloisa H. Milioli[1], Beatriz P. San Juan[1], Rachel F. Dear[2], Jia (Jenny) Liu[2]

[1]Garvan Institute of Medical Research, Darlinghurst, Australia,[2]St Vincent's Hospital, Sydney, Australia

New approaches are urgently required to treat advanced-stage cancers that are therapy resistant and incurable. Furthermore, salvage treatment protocols rely on cytotoxic chemotherapies that actively induce cancer cells to transition into therapy-resistant states via non-genetic mechanisms. We show in large clinical cohorts of triple-negative breast cancer (TNBC) that chemotherapy-induced cell state changes are mediated by androgen receptor (AR) signaling and are associated with poor patient outcome. AR inhibition blocks canonical and non-canonical AR signaling to lock cancer cells in therapy-sensitive states, and synergizes with a broad spectrum of cytotoxic chemotherapies to improve survival in pre clinical TNBC models. Seviteronel, a dual CYP17 lyase and AR inhibitor, faithfully mimics genetic AR ablation and is the most effective AR inhibitor in combination with chemotherapy. A Phase 1 clinical trial (NCT04947189) confirmed the safety of combining seviteronel with taxane chemotherapies in metastatic breast cancer. Early signs of clinical efficacy in patients with advanced disease led to a Phase 2 expansion study for AR-positive TNBC. These data provide proof-of-concept for AR inhibition as a ‘state-gating’ strategy to lock cancer cells in therapy-sensitive states and prevent the emergence of chemotherapy-resistance in TNBC. This paradigm may be widely applicable to other cancers.

#4745 Comprehensive screening of drugs targeting neural signaling identifies a neuropeptide receptor as a potential therapeutic target in small cell lung cancer.

Masakatsu Tokunaga, Natsuki Nakagawa, Mirei Ka, Yuriko Sugiura, Takahiro Iida, Hiroaki Ikushima, Takahiro Ando, Kousuke Watanabe, Akiko Kunita, Hidenori Kage, **Masanori Kawakami**

Graduate School of Medicine and Faculty of Medicine, The University of Tokyo, Tokyo, Japan

Small cell lung cancer (SCLC) is characterized by poor prognosis with limited therapeutic agents. SCLC can be classified into subtypes based on the expression levels of four transcription factors: ASCL1, NEUROD1, POU2F3, and YAP1. The former two subtypes are neuroendocrine (NE)-type tumors. Recently, neural activity has been noted as a key regulator in the field of oncology. We hypothesized that some neurotransmitters and their receptors can be therapeutic targets regulating the biology of NE-type SCLC. We created a drug library consisting of 560 drugs known to target various neural signaling and examined their growth-inhibitory effects comprehensively on SCLC cells. From this library, 56 drugs exhibited more than 50% inhibition of growth of NE-type SCLC cell lines at 10 μM. After excluding drugs with possible nonspecific effects, the IC50 values of 24 drugs were examined in an expanded panel of SCLC cell lines including non-NE-type cells. The inhibitor of neuropeptide receptor X exhibited distinctly lower IC50s in NE-type SCLC cells relative to non-NE-type cells, suggesting that this receptor is potentially a specific therapeutic target for NE-type SCLC. Neuropeptide receptor X expression was high in the brain but not detectable in the lung when normal tissues were analyzed *in silico* with NCBI database. Interestingly, when cancer cells were analyzed with CCLE database, this receptor expression was substantially high in NE-type SCLC cells, compared with other cancer cells. Furthermore, the growth-inhibitory effects of the receptor X inhibitor shown in the drug screening were correlated with receptor X expression levels. Using multiple NE-type SCLC cell lines with high receptor X expression, knockdown/knockout of this receptor by siRNAs and CRISPR/Cas9 inhibited cell proliferation. Furthermore, addition of the ligand for receptor X promoted cell proliferation of NE-type SCLC cells, suggesting the significance of signaling by this neuropeptide receptor for NE-type SCLC. Inhibition of receptor X also induced apoptosis in these NE-type SCLC cells, and cell cycle assays showed an increase in sub G1 phase. These effects were not seen in non-NE-type cells. Phospho-protein array analysis followed by Gene Ontology analysis after treatment with the receptor X inhibitor suggested that MAPK and PI3K-Akt signaling pathways were involved in the antineoplastic effects of this inhibitor. Finally, *in vivo* effects of the receptor X inhibitor were examined in NCI-H146 (NE-type SCLC) xenograft mouse model. The receptor X inhibitor was well tolerated and suppressed the *in vivo* tumor growth statistically significantly. Collectively, we identified one of the neuropeptide receptors as a potential therapeutic target for NE-type SCLC. This finding warrants further exploration to establish the novel therapeutic strategy for SCLC by targeting neural signaling.

#4746 PLB-001, a novel anti-dll3 ADC with topoisomerase 1 inhibitor-based linker-payload for treatment of SCLC.

Yingdong Lu, xin li, Ganyuan Xiao, Kia J. Puan, Ling xu, Mao Yin

PrimeLink BioTherapeutics, suzhou, China

Delta-like ligand 3 (DLL3) is a promising target for antibody-drug conjugates (ADCs) in the treatment of small cell lung cancer (SCLC) due to its high expression on the cell surface of SCLC cells and minimal expression in normal tissues. With highly specific, fast internalized mAbs from antibody screening, various types of payloads including tubulin and TOPI inhibitors were conjugated with different platforms, linkers, conjugation methods available from our linker-payload arsenal to obtain the optimal ADC. Here, we present a novel DLL3 targeted ADC, PLB-001, which using a highly potent topoisomerase I inhibitor exatecan, conjugated to a humanized IgG1 antibody, through a highly hydrophilic, enzyme-cleavable linker with a DAR of 8. PLB-001 demonstrated strong *in vitro* efficacy in several different SCLC cell lines correlating with DLL3 expression levels. This ADC also exhibited potent and durable antitumor effects in cell line-derived and patient-derived xenograft models, and exhibited favorable pharmacokinetic profiles. These preclinical result support PLB-001 as a potential candidate for the treatment of DLL3-positive SCLC

#4747 Dopamine receptor D2 and dopamine antagonism modulate the progression of small cell lung cancer.

Parvez Khan[1], Aatiya Ahmad[1], Md Arafat Khan[1], Mahek Fatima[1], Asad Ur Rehman[1], Laiba Anwar[1], Sanib Chaudhary[1], Imayavaramban Lakshmanan[1], Anish Thomas[2], Surinder K. Batra[1], Varun V. Prabhu[3], Apar K. Ganti[4], Mohd Wasim Nasser[1]

[1]University of Nebraska Medical Center, Omaha, NE,[2]Developmental Therapeutics Branch, National Cancer Institute, Bathesda, MD,[3]Chimerix, Inc, Durham, NC,[4]Division of Oncology-Hematology, Department of Internal Medicine, University of Nebraska Medical Center, Omaha, NE

Small cell lung cancer (SCLC) is an aggressive neuroendocrine (NE) cancer and is one of the most lethal types of solid tumors. Although platinum-based therapy forms the backbone of systemic therapy for SCLC, resistance, and recurrence occur rapidly, and most patients die within a year of diagnosis. Despite the approval of immune checkpoint inhibitors for SCLC, the survival benefit of these combinations in an unselected patient population is modest. The majority of SCLCs (~70-75%) are initiated from pulmonary NE cells; therefore, exploiting NE drivers/modulators is crucial for developing effective therapeutic strategies. To identify novel therapeutic molecules, we performed unbiased RNA-seq expression analysis of NE modulators in SCLC gene expression datasets. Our data showed an atypical expression profile of dopamine receptor D2 (DRD2) in various cell lines of SCLC belonging to NE, non-neuroendocrine, brain metastatic (BrM), and chemotherapy-resistant phenotypes. DRD2 is a G-protein coupled receptor that governs multiple physiological functions, including modulation of the synthesis, storage, and secretion of dopamine (DA); and seems to play a role in neuropsychiatric disorders, brain tumors, and promotes oncogenesis. We studied the role of DRD2 in cell lines representing multiple subtypes of SCLC and tumor tissues compared to their matched normal controls. DRD2 expression was also high in murine SCLC cell lines derived from RPM (*Rb1*$^{flox/flox}$; *TP53*$^{flox/flox}$; *LSL-Myc*^{T58A}), a spontaneous SCLC mouse model. High expression both in murine and human cell lines derived from brain metastatic lesions (BrM), suggests that DRD2 expression may play an essential role in brain metastasis. Additionally, a substantially high expression of DRD2 was observed in chemotherapy- and immunotherapy-resistant cell lines derived from SCLC patient-derived xenografts. To assess the therapeutic potential of DRD2, we utilized ONC206, a highly specific, orally bioavailable, and blood-brain barrier penetrating DRD2 antagonist. ONC206 treatment attenuated SCLC growth and metastasis, including brain metastasis both in preclinical in vitro and in vivo models. Integrated gene expression studies coupled with pathway analysis showed that DRD2 inhibition reduces SCLC growth and metastasis by inhibiting the cholesterol biosynthesis pathway. Altogether, our study provides strong preclinical rationale for targeting DRD2 via dopamine antagonism to attenuate SCLC growth and metastasis.

#4748 Understanding the RSAD2/CMPK2 signaling axis in PVT1 exon 9 overexpressed neuroendocrine prostate cancer.

Rachel E. Bonacci, Meghan McGill, Nu Thuy Anh Le, Murtaza Barkarar, Chinedum Udekwu, Olorunseun O. Ogunwobi

Michigan State University, East Lansing, MI

Introduction/Background: Plasmacytoma variant translocation 1 (PVT1) is overexpressed in prostate cancer (PCa) and alters gene expression directly or by acting as a noncoding RNA sponge. Our group previously identified overexpression of PVT1 exon 9 in aggressive PCa tissues and cell lines and overexpression led to transformation of non-tumorigenic prostate epithelial cells to PCa with neuroendocrine prostate cancer (NEPC) phenotype when implanted *in vivo*. RNA-sequencing analysis of our PVT1 exon 9 overexpression PCa model revealed upregulation of Radical S-Adenosyl Methionine Domain Containing (RSAD2) downstream of PVT1 exon 9. We have uncovered RSAD2 overexpression as a common characteristic of NEPC and have elucidated two novel molecular pathways at play in this disease; PVT1 exon 9 independent and dependent RSAD2 upregulation. These pathways lead to differences in Type II interferon signaling, immune signaling and AR sensitization. RSAD2 is located upstream of and directly interacts with CMPK2 in a variety of cellular models and some of their functions are interdependent.
Objectives/Hypothesis: We hypothesize that RSAD2 and CMPK2 work together to contribute to NEPC pathogenesis regardless of PVT1 exon 9 overexpression status.
Methods: We tested this hypothesis with a variety of genetic and biochemical approaches.
Results: RNA-sequencing analysis of our PVT1 exon 9 overexpression NEPC model (RWPE1, RWPE1_ev, RWPE1_ex9) revealed significant (p-value < 0.05) upregulation of RSAD2 and CMPK2, in RWPE1_ex9 as compared to RWPE1_ev and RWPE1. In a second NEPC model (that also models circulating tumor cells in metastasis) derived from 22RV1 castrate-resistant prostate cancer (CRPC) parental cells implanted *in vivo* and isolated from blood, we found overexpression of PVT1 exon 9, RSAD2 and CMPK2 in isolated circulating tumor cells (C22OH) we have previously validated as having neuroendocrine features. In NEPC models that do not overexpress PVT1 exon 9, such as DU145 and NCI-H660, we found only overexpression of RSAD2 but not CMPK2. Knockdown of CMPK2 led to ~35% decreased cell viability in all models suggesting that CMPK2 may be a cancer promoting aberration in NEPC. Both RSAD2 and CMPK2 are clinically relevant and significantly overexpressed in neuroendocrine prostate cancer human cohorts. Overexpression models of CMPK2 revealed alterations in cell proliferation, colony formation and PD-L1 immune signaling and localization suggestive of a larger role in prostate cancer pathogenesis.
Discussion/Conclusions: Based on these results, PVT1 exon 9, RSAD2 and CMPK2 are promising therapeutic targets in PVT1 exon 9 overexpressed NEPC whereas RSAD2 targeting alone may be more useful in NEPC without PVT1 exon 9 overexpression. Further investigation is ongoing to understand therapeutic strategies to use alone or in combination with current clinically approved therapeutics.

#4749 Evaluating NUAK2 as a potential target in neuroendocrine prostate cancer.

Umar Mehraj, Shaista Manzoor, Julie Parks, Emily Cordova, Everardo Macias

Department of Pathology, Duke University School of Medicine, Durham, NC

Background: Neuroendocrine Prostate Cancer (NEPC) is an aggressive and lethal prostate cancer subtype. Due to Androgen Receptor-independence, NEPC lacks targeted therapeutics, with platinum-based chemotherapy serving as the primary treatment modality. This highlights the need for new molecular targets in NEPC. NUAK2, also known as sucrose non-fermenting (SNF1)-like AMPK-related kinase (SNARK) is an unstudied kinase. Yet, pan-cancer analysis shows increased expression of NUAK2 across several malignancies. Analysis of prostate cancer and NEPC datasets revealed a significant increase in NUAK2 expression levels correlating with disease progression. The objective of our study was to determine if NUAK2 is essential for NEPC tumor growth.
Methods: To investigate the therapeutic potential of NUAK2 in NEPC, we conducted genetic and pharmacological modulation of NUAK2 both in vitro and in vivo. We conducted label-free quantitative phospho-proteomic and proximity ligation interactome analyses of NUAK2 using LC-MS/MS to elucidate its role in NEPC.
Results: NUAK2 knockdown significantly decreased proliferation and 3D spheroid growth in NEPC preclinical models. CRISPR-Cas9-mediated knockout of NUAK2 in NCI-H600 cells led to reduced tumor growth *in vivo*. Furthermore, NUAK2 overexpression accelerated NEPC growth in a kinase-dependent manner. Pharmacological inhibition of NUAK2 significantly reduced the growth of NEPC cell-line and patient-derived xenografts. Phosphoproteome and interactome studies by LC-MS/MS and pathway enrichment analysis revealed the role of NUAK2 in chromatin remodeling, mRNA metabolic processes, and cytoskeleton organization.
Conclusions: Collectively, our study highlights NUAK2 is essential for NEPC tumor growth and is an actionable target in NEPC.

#4750 Epigenetic approaches to deliver a targeted radiotherapy for triple negative breast cancer.

Khalid B. Mir[1], Katie Brookes[2], Martin L. Read[2], Daniel G. Stover[3], Mathew D. Ringel[3], Christopher J. McCabe[2], Moray J. Campbell[1]

[1]Cedars-Sinai Medical Center, West Hollywood, CA,[2]University of Birmingham, Birmingham, United Kingdom,[3]The Ohio State University, Columbus, OH

The sodium iodide symporter (NIS, encoded by *SLC5A5*) is exploited in thyroid cancer to uptake radioiodide. NIS appears to function in mammary epithelial cells, being upregulated during lactation, and offers the possibility of a novel breast cancer (BrCa) radiotherapy. Unfortunately, NIS appears repressed in BrCa, and therefore we are examining mechanisms to restore its expression and function. Retinoic Acid Receptor alpha (RARα) upregulates *SLC5A5*, and pre-clinical studies suggest this is epigenetically corrupted in BrCa. To investigate RARα-dependent epigenetic control of *SLC5A5* levels we identified differentially expressed RARα coregulators in TNBC tumors in the TCGA BrCa cohort. This identified upregulation of PRAME, a known RARα co-repressor that interacts with histone deacetylase (HDAC) enzymes. We modulated PRAME expression using CRISPR methods in a panel of luminal A, luminal B and TNBC BrCa cell lines (MCF-7, T47-D, ZR-75-1, AU565 and MDA-MB-231). Elevated PRAME expression significantly repressed the antiproliferative response to ATRA (a pan-RAR ligand) and AM580 (a RARα-selective ligand). RNA-Seq confirmed that increased PRAME expression reduced by approximately half the number of significantly regulated genes in response to ATRA and AM580. For example *SLC5A5* and a significant number of RARα-canonical target genes were upregulated in MCF-7 and AU565 cells and the magnitude was significantly reduced by elevated PRAME. In MDA-MB-231 cells elevated PRAME expression led to transrepression of numerous genes including *SLC5A5* in response to ATRA and AM580. Gene set enrichment analyses also supported a significant role for PRAME to uniquely shape ATRA signaling by increasing inflammatory networks (MCF-7 and AU565) and decreasing estrogen (MCF-7) and TNFA (MDA-MB-231) signaling. Ongoing studies are repressing PRAME and examining its impact on activating and repressing histone marks. In a parallel orthogonal approach we have sought to stabilize NIS expression by targeting valosin-containing protein (VCP) that induces NIS proteolysis. We tested VCP inhibitors in combination with the HDAC inhibitor SAHA or the transcriptional potentiator, disulfiram metabolite Cu(DDC)2 in the same cell lines. Remarkably, in MDA-MB-231 cells, $Cu(DDC)_2$ combined with the VCP inhibitor CB5339, significantly increased NIS expression and radioiodide uptake leading to a prominent decrease in cell proliferation and survival. These studies, along with ongoing drug strategies in TNBC xenograft and PDX tumors, combine to support the concept that SLC5A5/NIS expression can be restored and offer the possibility of promoting radioiodide as a novel BrCa radiotherapy.

#4751 CS5005: A novel SSTR2-targeted antibody-drug conjugate (ADC) with robust antitumor activity in preclinical studies.

C. Wang, X. Zhang, N. Zhang, Y. Wang, Y. Li, X. Liu, M. Zhu, Y. Qian, Y. Yang, J. Sun, X. Dai, F. Ma, Y. Sun, J. Yang;
CSTONE Pharmaceuticals, Suzhou, China

Background: Somatostatin receptor 2 (SSTR2) is overexpressed in neuroendocrine tumors (NETs) and small cell lung cancer (SCLC). SSTR2-targeted treatment options for NETs include somatostatin analogs and radionuclide conjugates (RDCs). In SCLC, SSTR2-targeted therapies, including RAZ101 (225Ac bearing RDC), PEN221 (peptide drug conjugate) etc., have shown encouraging clinical results. Unfortunately, such therapies with peptide (SSA analogs like octreotide) suffer from short half-lives and high toxicities due to poor selectivity. Moreover, RDCs are often restricted by limited availability. To tackle these, a highly selective and potent antibody against SSTR2 could offer a promising therapeutic alternative. Here, we present CS5005, a novel SSTR2-targeted ADC developed to treat SSTR2-positive tumors, including NETs and SCLC.

Methods: SSTR2-targeted antibodies were generated from immunized mice, followed with rounds of screening, maturation and humanization. The lead antibody of CS5005 was selected based on the binding, internalization capacity, and selectivity for SSTR2. CS5005 is composed of our lead SSTR2-targeted humanized antibody, a proprietary CSL linker and a well-validated topoisomerase 1 inhibitor exatecan (EXd). The plasma-stable, hydrophilic, beta-glucuronide CSL linker enables effectively tumor-selective toxin release. The antitumor activity of CS5005 was evaluated *in vitro* and *in vivo* using cell line-derived xenograft (CDX) models originated from multiple carcinomas. Tolerability and PK were assessed in rodents and cynomolgus monkeys.

Results: The lead humanized SSTR2-targeted antibody, 221.3.1, demonstrated high-affinity binding to SSTR2-positive cells (e.g. SSTR2-overexpressing HEK, H524, and H446) and high-rate internalization on tumor cells. Importantly, 221.3.1 selectively bound SSTR2 without cross-reactivity to other somatostatin receptors. 221.3.1's cross-species recognition of SSTR2 supported the selection of cynomolgus monkey for nonclinical toxicology studies. CS5005 retained the antibody features of binding affinity, internalization and selectivity, showing excellent *in vitro* stability in serum incubation assays and a mAb-like PK profile in the *in vivo* rodent studies. *In vitro* cytotoxicity assays confirmed the ability of CS5005 to induce effective, target-dependent killing of SSTR2-expressing tumor cells. CS5005 also demonstrated robust *in vivo* antitumor activity in CDX models originated from multiple carcinomas, with minimal effective dose (MED) of 5 mg/kg. Pilot toxicity studies in non-human primates demonstrated a favorable tolerability and PK profile of CS5005.

Conclusion: CS5005 represents a promising SSTR2-targeted ADC for the treatment of advanced solid tumors. The preclinical findings support further IND-enabling studies and clinical investigations of CS5005 as a novel therapeutical option.

#4752 The combination of GLP1-R agonists and progestins enhances endometrial cancer cell killing through membrane receptor crosstalk.

Lane E. Smith[1], Jamie L. Padilla[1], Geneva L. Williams[1], Kristina Thiel[2], Kimberly K. Leslie[1]

[1]University of New Mexico Health Sciences Ctr., Albuquerque, NM,[2]University of Iowa, Iowa City, IA

Obesity is a major risk factor for endometrial cancer, and glucagon like peptide-1 receptor (GLP-1R) agonists such as semaglutide may be helpful to achieve weight loss. Conservative treatment of endometrial cancer includes hormone therapy with progestins for women who wish to preserve their uterus. Our previous work showed a significant reduction in viability of multiple endometrial cancer cell line and organoid models in response to the combination treatment of semaglutide and levonorgestrel, and identified a positive feedback loop between GLP-1R and progesterone receptor (PR) signaling. Here, we further explored mechanisms underlying the enhanced signaling, using confocal microscopy to show the co-localization of membrane PR (Progesterone Receptor Membrane Component 1; PGRMC1) and GLP1-R in response to semaglutide + progesterone combined treatment. We also found that semaglutide alone (100nM) induces the translocation of PR to the nucleus within 30 minutes. We are undergoing microarray analyses to assess specific phosphorylation events as well as RNA sequencing occurring downstream to identify the signaling molecules and transcripts activated by dual treatment. These studies highlight the potential of semaglutide to improve the anti-cancer effects of progestins, and, importantly, may reduce recurrences that can occur with progestin therapy alone.

#4753 ACSS2 inhibition alters epigenetic landscape to improve endocrine therapy outcome in ER+ metastatic breast cancer cells.

Ayca N. Mogol, Jin Young Yoo, David J. Dutton, Zeynep Madak-Erdogan

University of Illinois at Urbana-Champaign, Urbana, IL

Endocrine therapies target the hormone dependencies of the cancer cells in various ways. One primary target is estrogen receptor alpha (ERα), which is expressed in approximately 70% of human breast cancers (ER-positive or ER+). Despite treatment, recurrence and metastasis are still observed in 30-40% of ER+ patients, and the 5-year relative overall survival rate for these patients is only 24%. Local Acetyl-CoA availability plays a crucial role in regulating histone acetylation and gene expression, thereby supporting tumor progression. Our previous research demonstrated that ERα antagonist Fulvestrant (Fulv) treatment increased ACSS2 (acetyl-CoA synthetase 2) levels in vivo in metastatic breast tumors. Combining the Fulv with a highly specific ACSS2 inhibitor (ACSI) synergistically reduced cell viability in ER+ metastatic breast cancer (MBC) cells in vitro. In the present study, we employed multiple analytical approaches—including isotope tracing assay with labeled acetate, CUT&RUN sequencing, immunofluorescence, western blot, and RNA sequencing—to characterize the epigenetic and metabolic alterations induced by Fulv treatment and ACSS2 enzyme and how they contribute to endocrine resistance.

To investigate how ACSS2 drives endocrine resistance, we examined ACSS2 expression and acetate utilization in response to Fulv. We showed that the ACSS2 expression and acetate utilization by ACSS2 to synthesize Acetyl-CoA increase with Fulv treatment. Isotope tracing assay with labeled acetate indicated that Fulv treatment decreased the acetate flux to the TCA cycle and drove it toward fatty acid synthesis. However, inhibition of fatty acid synthesis did not impact Fulv-induced cell viability, suggesting an additional role for ACSS2-mediated acetyl-CoA production in metastatic breast cancer cells. Immunofluorescence assays showed that ACSS2 was almost exclusively located in the nucleus, supporting a role in epigenetic regulation. We then examined chromatin enrichment of ACSS2, ERα, and H3K27ac using the CUT&RUN sequencing method in ER+ MBC cells. Fulv treatment resulted in an increased number of global ACSS2 binding sites as well as overlapping binding sites of ERα, ACSS2, and H3K27ac. These sites were lost with the ACSI and Fulv combination. Global gene expression profiling using RNA sequencing assay showed that the gene expression is increased for genes involved in cell proliferation with Fulv treatment.

In conclusion, our findings suggest a nuclear role for ACSS2 in endocrine therapy resistance by providing a substrate for epigenetic alterations. Targeting these alterations caused by cancer cell adaptations is a novel approach that could potentially lead to new therapies. This strategy may help reduce metastasis-related mortality in breast cancer patients, offering additional opportunities for improved treatment outcomes in the future.

#4754 discovery of a casein kinase 2 small-molecule inhibitor that antagonizes wildtype and mutant estrogen receptor signaling in breast cancer.

Anil Kumar Devakrishnan, Yong Wang, Suzanne AW Fuqua, Martin Matthew Matzuk, **Murugesan Palaniappan**

Baylor College of Medicine, Houston, TX

Introduction: Activating somatic mutations in ESR1, the gene encoding estrogen receptor (ER) α, are frequently found in metastatic breast cancers. The somatic mutations Y537S and D538G mutants drive estrogen-independent activities and diminish the potency of the current standard-of-care agents. Consequently, there is an unmet clinical need to develop a novel drug that inhibits ER mutant signaling. Casein kinase 2 (CK2) is a serine/threonine protein kinase that is abnormally elevated in various cancers, including breast cancer. CK2 activates ER signaling and is considered a promising therapeutic target. Here, we seek to investigate mechanisms of CK2-mediated activation of ER signaling in breast cancer and to use DNA-encoded chemical libraries (DELs) to identify and validate potent, selective, and efficacious CK2 inhibitors that will serve as lead compounds for novel therapeutics in ESR1 mutant breast cancer.
Methods: The catalytic subunits of CK2 were screened with our in-house collection of 3.98 billion barcoded compounds. Hits enriched with CK2 were synthesized off DNA and tested in a biochemical assay. The most potent hits were analyzed for intracellular target engagement using NanoBRET tracer displacement assays. The top hit was extensively studied in WT, Y537S, and D538G mutant breast cancer cells. Metabolic stability was determined in mouse and human liver microsomes, and pharmacokinetics studies were performed in mice. Primary and metastatic tumors were harvested and used to develop ex vivo organoids and a WHIM20 patient-derived xenograft (PDX) model carrying the *ESR1* mutation Y537S. The antitumor activity of the top hit was tested in the WHIM20 PDX model.
Results: Leveraging our multibillion small molecule collection of DELs against catalytic subunits of CK2, we identified compound CDD-2007, which has low nanomolar cellular potency and good metabolic stability. CDD-2007 abolishes estrogen-induced gene programs in both wild type and mutant (Y537S and D538G) ER-positive breast cancer cell lines. In cellular assays, CDD-2007 inhibits Ser129 phosphorylation of AKT with double-digit nanomolar potency in WT and mutant breast cancer cells, but no significant loss of AKT Ser129 phosphorylation is seen in normal human breast epithelial cells (MCF10A). CDD-2007 potently inhibits primary and metastatic tumor-derived organoid growth in an *ESR1* Y537S PDX model. CDD-2007 inhibits primary tumor growth in PDX models of breast cancer and synergizes with the ER antagonist fulvestrant in the *ESR1* Y537S model without toxicity.
Conclusion: Together, our data show that CDD-2007 is a selective and potent inhibitor of CK2 with good drug-like properties that inhibit ERα signaling in endocrine-resistant metastatic breast cancer. Therefore, blocking CK2 signifies a promising therapeutic strategy for *ESR1* mutant breast cancer.

#4755 Preclinical mechanistic PK/PD-efficacy modeling for AZD9750, a novel oral androgen receptor degrader (PROTAC), to support dose selection during early clinical development.

Pablo Morentin Gutierrez[1], Ana Quiroga Campano[1], Antonio Ramos Montoya[1], Claire Crafter[1], Chrysiis Michaloglou[1], Aaron Smith[1], Nuria Galeano Dalmau[1], Jamie Scott[1], Michael Niedbala[2]

[1]AstraZeneca, Cambridge, United Kingdom,[2]AstraZeneca, Waltham, MA

Objectives: The androgen receptor (AR) is highly expressed in prostate cancers and is a clinically validated target in oncology. AZD9750 is a novel potent oral selective AR Proteolysis-targeting chimera (PROTAC) due to start clinical testing in 2025. We present here the preclinical PK/PD modeling work used to understand the required target modulation and concentration required to see anti-tumor efficacy and therefore help support the dose selection during the early clinical development of AZD9750.
Methods: We developed a novel mechanistic mathematical model applied to in vivo preclinical mouse PDX models (MR041 and C901, primary prostatic adenocarcinoma, hormone sensitive and AR-wt) linking the compound pharmacokinetics with the magnitude of target modulation expressed as relative levels of AR measured by Western Blotting. These changes at the biomarker level were subsequently linked to inhibition of tumor cell proliferation resulting in macroscopic dynamic effects on tumor size. All model parameters were derived from internal studies; some were estimated using Non-Linear Mixed Effect modeling of individual longitudinal PK, PD biomarker and tumor size data taken from several studies.
Results: The model described well the relationship between plasma concentration of AZD9750 and modulation of AR. In vivo AZD9750 concentration required to see 50% of the maximal target modulation in both animal models was on the region of 0.2-0.7 µM. Population tumor size patterns, for all treatment regimens ranging from 0 to tumour regressions across both tumor models were very well described with the model proposed. 55 - 80% reduction of AR levels was required to induce tumor regression in both models.
Conclusions: This study provides quantitative mechanistic insights into the links between compound exposure, biomarker modulation (AR) and anti-tumor responses, supporting our understanding of the required target modulation needed for maximal anti-tumor effects in these two hormone sensitive patient-derived tumor models. This mechanistic understanding is valuable to contextualize compound-induced PD modulation in patients, for given doses and schedules.

#4756 Novel anaplastic thyroid carcinoma patient-derived xenograft models and cell line.

Ahmad Abubaker[1], Ying Henderson[1], Marie-Claude Hofmann[2], Naifa Busaidy[2], Maria E. Cabanillas[2], Michelle Williams[3], Anastasios Maniakas[1], Stephen Y. Lai[4]

[1]Department of Head and Neck Surgery, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Endocrine Neoplasia and Hormonal Disorders, The University of Texas MD Anderson Cancer Center, Houston, TX,[3]Department of Pathology, The University of Texas MD Anderson Cancer Center, Houston, TX,[4]Department of Head and Neck Surgery, Radiation Oncology, Molecular and Cellular Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Anaplastic Thyroid Carcinoma (ATC) is the deadliest thyroid malignancy with a historic median overall survival of 5 months. Its highly aggressive nature limits our ability to test novel targeted therapies in patients. Patient-Derived Xenograft (PDX) models and cell lines are considered reliable preclinical models to test novel therapies as well as drug combinations.
Aim: Our group has previously reported ATC PDX model development, although certain key genetic mutations frequently found in the clinical setting are lacking. Our goal is to report our experience developing and characterizing three novel PDX models and one paired cell-line that have pathologically and clinically relevant mutations that may be used for drug development and testing.
Methods: Fresh tumor from ATC patients was harvested at the time of surgery and cut into 4x4x4 mm pieces and implanted subcutaneously in 5-8-week-old nu/nu female nude mice. Tumor was measured with a calibrated tool every 2 weeks. Mice were euthanized when the tumor reached 1000 mm3. Tumor was then harvested and transferred into a new generation of mice. Tumor samples were used to confirm genotyping by Short Tandem Repeats DNA fingerprinting as well as interspecies contamination testing to compare the fractional abundance of human versus mouse DNA. H&E staining, immunohistochemistry (IHC), and PCR were done to confirm microscopic, IHC, and genetic similarity to the original patient tumor, respectively. Successful PDX establishment was defined by successful engraftment (F0), tumor passaging through 4 consecutive generations (F1-F4), and successful tumor growth from a cryopreserved sample. A cell line was developed by collagen and extracellular DNA degradation, RBC removal, followed by incubation in RPMI medium. A total of 20 passages and at least 6 months in culture were considered adequate to deem a cell line as established.
Results/Discussion: Three novel ATC PDX models were successfully established. MDA-ATC8 is a BRAF wild type (WT) and TP53, NRAS_Q61K, TERT, ASXL2_G853S, ERBB4_D243N, INHBA_I410T mutant ATC model, from a patient previously treated with dabrafenib, trametinib and pembrolizumab (DTP). This is the only established model with a paired cell line (MDA-T317). MDA-ATC9 is a BRAF, RAS, and TERT WT tumor with TP53, FGFR2, LRP1B, and MEN1 mutations. Tumor was harvested from a previously untreated patient. MDA-ATC11 is a BRAFV600E, P53, TERT, ABL1, KMT2C, LRP1B, RICTOR mutant derived from a patient previously treated with DTP.
Conclusion: We report the development and establishment of three new ATC PDX models with one paired cell line. These models show excellent compatibility with their human tissue counterparts, making them highly reliable as preclinical models. Furthermore, with novel drugs being developed for RAS_Q61 mutation, MDA-ATC8 may play a major role in testing potential candidates for this untreatable patient population in the near future.

#4757 Elucidating novel pro-apoptotic consequences of ceramides in endocrine therapy-resistant breast cancer.

Purab Pal[1], Godwin K. Sarpey[1], G. Ekin Atilla-Gokcumen[2], Jonna Frasor[1], Jonathan L. Coloff[1]

[1]Department of Physiology and Biophysics, University of Illinois at Chicago, Chicago, IL,[2]Department of Chemistry, University at Buffalo, Buffalo, NY

Endocrine Therapy (ET)-resistant breast cancer (BC) remains a clinical problem, with approximately 40% of patients experiencing disease relapse. Previously, we demonstrated that preclinical models of ET-resistant BC have an altered sphingolipidome, which is characterized by low levels of ceramides across multiple models of ET resistance. ET-resistant models are also more sensitive to ceramide-induced death compared to their ET-sensitive counterparts suggesting a functional significance of the low levels of ceramides. This study is designed to identify mechanisms by which ceramides preferentially kill ET-resistant BC models to identify novel therapeutic strategies to improve ET-resistant BC patient outcomes.

We performed total RNA-seq of multiple ET-resistant BC cells with or without ceramides and found that ceramide exclusively induces genes associated with endoplasmic reticulum stress (EnRS), particularly in the PERK/peIF2A/ATF4 pathway, in multiple models of resistance but not in the parental ET-sensitive cells. Inhibitors of EnRS, PERK, and peIF2A partially reverse ceramide-induced cell death suggesting that ceramide-induced EnRS is lethal for ET-resistant cells. Since ceramides are well-known bioactive lipids, we hypothesized that ceramides interact with specific proteins that are instrumental in ET-resistant cell survival. To test this, we used a photoactivable-and-clickable ceramide probe and quantitative proteomics to identify differentially expressed ceramide-interacting proteins (CIPs) in ET-resistant BC cells. We found that ceramide interacts with a group of clinically relevant CIPs which are located in the endoplasmic reticulum (EnR) membrane. While most of these CIPs have yet to be implicated in ET resistance, a subset of the CIPs is known to be involved in attenuating EnRS. Knocking down one of the top CIPs, i.e., TRAM1, phenocopies ceramide treatment, suggesting that ceramides, by interacting with EnR-membrane proteins, such as TRAM1, may disrupt their function and induce a lethal level of EnRS in ET-resistant cells. Together, we find that ceramide induces preferential cell death in ET-resistant cells through interactions with a novel array of proteins leading to the inhibition of key survival proteins and a consequential activation of lethal levels of EnRS. Understanding how ceramides interact with and affect these proteins could lead to the development of novel strategies to selectively treat ET-resistant BC and to improve patient outcomes.

#4758 AZD9750, a novel androgen receptor proteolysis targeting chimera (AR-PROTAC) for the treatment of prostate cancer.

Claire Crafter[1], Antonio Ramos-Montoya[1], Chrysiis Michaloglou[1], Ziyanda Sholugu[1], Nuria Galeano-Dalmau[1], Gemma Hardman Fowler[1], Thomas Jones[2], Ana Quiroga[3], Pablo Morentin-Gutierrez[3], Andy Pike[3], Laura Evans[4], James S. Scott[4], Michael Niedbala[5]

[1]Oncology Targeted Discovery, Bioscience, AstraZeneca, Cambridge, United Kingdom,[2]Biopharmaceuticals R&D, Discovery Sciences, Cambridge, United Kingdom,[3]Oncology Targeted Discovery, DMPK, AstraZeneca, Cambridge, United Kingdom,[4]Oncology Targeted Discovery, Chemistry, AstraZeneca, Cambridge, United Kingdom,[5]Oncology Targeted Discovery, AstraZeneca, Waltham, MA

The androgen receptor (AR) is a member of the nuclear hormone receptor superfamily and a key driver of prostate tumor growth. Several androgen receptor pathway inhibitors (ARPIs) have been developed and approved for the treatment of locally advanced and metastatic prostate cancer, including the androgen synthesis inhibitor, abiraterone and the AR antagonists, enzalutamide, apalutamide and darolutamide. Despite initial success resistance does occur, often involving alterations in the receptor itself, such as AR amplification or point mutations in the ligand binding domain (LBD). Therefore, there remains an urgent need to develop alternative strategies to target the AR. Here we describe the characterization of AZD9750, a novel AR PROTAC that potently degrades AR (DC50 in LNCaP cells = 9.9nM) and shows good cross species oral bioavailability. In a panel of prostate cancer (PC) cells expressing different altered forms of the receptor, AZD9750 was shown to degrade wild type, amplified and LBD mutant AR. The reduced AR levels were confirmed to be a consequence of increased AR degradation with AZD9750 reducing the half-life of AR from 4.9 to 1.0 hr in LNCaP and from 4.6 to 0.4 hr in VCAP PC cells. Degradation was also shown to be mediated via a PROTAC mechanism that required CRBN binding and proteasomal activity. Additionally, AZD9750 decreased AR-regulated gene expression and inhibited the proliferation of AR-dependent PC cell lines with GI50s in the low nM range, which represents a 10-fold increase in potency compared to enzalutamide in the same cell lines. In vivo, in the C901 patient derived xenograft (PDX) model, AZD9750 caused a dose-dependent reduction in tumor AR levels with oral doses of 3, 10 and 30 mg/kg giving a statistically significant reduction of 72, 88 and 95%, respectively. Consistent with this, the mRNA expression of a panel of AR-regulated genes was also decreased. Anti-tumor efficacy studies demonstrated that AZD9750 reduced tumor growth and in some cases caused tumor regression in a range of AR positive PDX models that represent both hormone-sensitive and castration-resistant prostate cancer. The anti-tumor effect was dose-dependent and accompanied by reduced AR levels and AR-regulated gene expression, consistent with the observed efficacy being driven by AR degradation and inhibition of AR signaling. Furthermore, in several models, the efficacy achieved with AZD9750 was superior to the efficacy achieved with a clinical exposure matched dose of enzalutamide. These data confirm that AZD9750 is a potent oral degrader of AR that leads to anti-tumor efficacy in a range of hormone-sensitive and castrate-resistant PDX models. Through degradation of AR, including mutant and amplified forms of the receptor, it has the potential to overcome key resistance mechanisms arising to current standard of care therapies and provide benefit to patients with prostate cancer.

#4759 Novel treatment approach for efficacy outcome in androgen dependent and independent prostate cancer orthotopic mice models.

Balaji Ramachandran, Satheeshkumar Rajendiran, Rajendran Venkidusamy, Raghu Patil, Sachin Joshi, Krishnappa Haladasappa

Pharmacology, Adgyl Lifesciences Private Limited, Bangalore, India

Prostate cancer is one of the leading cause of deaths worldwide. Orthotopic injection of cancer cells into mouse prostate remains significant challenge and orthotopic mouse models resemble human pathophysiology. In the current study Androgen dependent (LNCaP VCaP and VCaP-EnzR) and Androgen independent (PC3) cells were orthotopically inoculated (1x10^6 cells) into anterior prostate of male athymic nude mice. Seven to eleven days post implantation, the preclinical efficacy of Enzalutamide (15mg/kg, PO QD x 6 weeks) and Docetaxel (DTX; 7.5mg/kg, i.p Q7D x 6 weeks) as standalone and combination treatment was evaluated. Body weight, clinicals signs, mortality was monitored up to 7 weeks. Terminally prostate was harvested, weighed, tumor volume (TV) was measured. Prostate, distant organs (lung, liver, and bone) were fixed in 10% NBF for metastatic evaluation by histopathology. In LNCaP and VCaP model standalone Enzalutamide treatment significantly reduced prostate weight and TV compared to vehicle control. However standalone DTX treatment resulted in moderate reduction of prostate weight and TV. Whereas combination of Enzalutamide with DTX demonstrated superior efficacy compared to respective standalone treatments. In the VCaP-EnzR model, docetaxel (DTX) treatment demonstrated significant antitumor activity both as standalone treatment and in combination with Enzalutamide. In contrast, Enzalutamide treatment did not reduce tumor volume and results were similar to control group. In PC3 model, the standalone DTX treatment exhibited highest antitumor activity followed by Enzalutamide therapy. The combination of Enzalutamide with DTX demonstrated superior efficacy compared with respective standalone treatments. Histopathological examination of prostate, lung, liver, and bone tissues in all treatment groups for LNCaP, VCaP & PC3 models revealed a significant reduction in organ metastasis with a clear progression of metastasis observed in the vehicle group.In conclusion, standalone hormone therapy slowed down primary tumor growth of androgen dependent prostate cancer by reducing androgen levels or blocking androgen receptors. The lack of response to enzalutamide in the VCaP-EnzR model likely reflects resistance mechanisms. In contrast, docetaxel targeting cell division, is effective regardless of AR signaling, allowing it to overcome enzalutamide resistance. In condition where prostate cancer became resistance to hormonal therapy, chemotherapy plays critical role in attacking prostate cancer cells irrespective of androgen status. This combination offers advantageous, multifaceted approach in treating metastatic resistant prostate cancer and improves treatment effectiveness, delay progression and potentially extending survival.

Key words: Prostate cancer, orthotopic, hormone therapy, metastatic

#4760 Oxysterol sulfotransferase interferes with prostate cancer progression.

Bobae Park[1], Okunola Igbekoyi[1], Mukund Bhandari[2], Bandana Chatterjee[1]

[1]Molecular Medicine, UT Health Science Center at San Antonio, San Antonio, TX,[2]Pathology, UT Southwestern Dallas, Dallas, TX

Background: Oxysterol sulfotransferase (SULT2B) mediates enzymatic sulfation of oxysterols. Oxysterols are agonist ligands for the nuclear receptor LXR (liver X receptor) and upon sulfation they become LXR inert. Poor overall survival is linked to low-SULT2B tumors in primary PC (TCGA data) and in esophageal carcinoma, evident for post-surgery patients[1]. We have shown that clinical samples of metastatic castration-resistant prostate cancer (CRPC) lack SULT2B, and it is reduced or undetectable for a subset of primary PC. In a CRPC model, SULT2B ablation led to faster xenograft growth; increased cell migration and invasion; EMT-like activation; upregulation of AKR1C3, which is a key enzyme for androgen biosynthesis; and activation of ERK - a kinase that regulates cell survival[2]. LXR is inactivated in SULT2B-overexpressed cells[3], and we observed AKR1C3 upregulation in LXRα-silenced cells. Herein we report impacts of high SULT2B on CRPC cells in culture and xenografts.

Results: PC3 cells, transduced to express SULT2B and Akaluciferase reporter (PC3-SA cells) or reporter only (PC3-VA cells) were isolated under antibiotic selection and flow sorted to >98% enrichment for the transduced genes on the basis of fluorescence from the Venus fluorescent protein. PC3-VA and PC3-SA cells showed similar proliferation rates *in vitro*. In contrast, the growth of PC3-SA xenografts showed marked and statistically significant reduction compared to PC3-VA xenografts. The reduction was calculated from differences in tumor volumes and tumor-emitted luminescence. Apoptosis, evident from caspase3 cleavage, was detected in the SA, not VA xenografts. Cleaved caspase3 in tumors was detected by Western Blot and IHC analyses. Xenograft growth was also reduced for SULT2B-high tumors of castration-resistant CWR22Rv cells which, unlike PC3 cells, express androgen receptor. The inhibition of SULT2B-high tumors is consistent with our earlier data showing escalated growth of SULT2B-null xenografts. Further, SULT2B-expressing CRPC cells showed enhanced sensitivity to an anti-cancer biologic for the inhibition of cell proliferation and invasion *in vitro*. Bioinformatic probing of single cell RNA sequences is ongoing to identify genes expressed differentially and pathways impacted in response to SULT2B expression.

Conclusion: SULT2B interferes with CRPC xenograft growth and causes enhanced sensitization of CRPC cells to an anti-cancer biologic. Factors extrinsic to cancer cells are likely to play a role in the growth suppression of high-SULT2B tumors to account for the result showing a lack of impact of SULT2B on cell proliferation *in vitro*. Our study of allograft tumors in syngeneic mice may identify extrinsic factor(s) at the tumor niche that are involved in the growth suppression of SULT2B-positive prostate tumors.

#4761 The ERBB4 exon skipping isoform JMA-CYT2 is the dominant isoform of ERBB4 gene fusions.

Shivani Jagannathan Murali, Bharath Kumar Karre, Cristina Ivan, Chao Sima, Asfetaw Abera, David Spetzler, Milan Radovich, Heather O'neill, Ravi Chakra Turaga

Department of Precision Medicine, Target and Drug Discovery, Caris Life Sciences, Inc., Chandler, AZ

Background: ERBB4, a member of the ERBB family of receptor tyrosine kinases, has received less attention than its counterparts, ERBB1 (EGFR), ERBB2 (HER2) and ERBB3(HER3), despite its established involvement in oncogenesis and its potential as a therapeutic target. While the role of ERBB4 and its isoforms in neuronal development is well understood, mutations and fusions of ERBB4 have been linked to several types of cancer, however they have not been fully explored. Further research into ERBB4 fusions and their oncogenic mechanisms is essential for advancing targeted therapies.
Methods: We performed a comprehensive analysis of ERBB4 fusions using next-generation sequencing (NGS) data from a total of 216,176 formalin-fixed paraffin-embedded (FFPE) tumor samples across various solid tumors. NGS was conducted on DNA isolated from these samples and RNA fusions were detected using whole transcriptome sequencing (WTS). We analyzed patient demographics, fusion partners, ERBB4 isoforms, and co-occurring mutations. Additionally, tumor mutational burden (TMB) was assessed, and data from public bioinformatic resources were used for comparison.
Results: ERBB4 fusions were detected in 0.25% of the 24 solid tumor types analyzed, with the highest prevalence observed in OSEC, BRCA, BLCA, UTNE, and NSCLC. Notably, 63.1% of ERBB4 fusions involved the 3' end of the gene and included various fusion partners. The most common fusion partner was IKZF2:ERBB4, accounting for 58.2% of cases. Exon 2 was identified as the most frequent breakpoint in ERBB4 fusions. As a result, 5' ERBB4 fusions retain only the signal peptide, while 3' fusions lose the signal peptide, which may impair translocation to the cell membrane. The most common isoform observed in ERBB4 fusions was the JMa-Cyt2 isoform, seen in over 83% of cases. This isoform skips exon 26, which contains a PI3K phosphorylation site critical for ubiquitination and degradation. Further analyses revealed a significant upregulation of ERBB4 expression in ERBB4 fusion positive cases in BLCA($P>0.001$), OSEC($P>0.001$), and NSCLC($P>0.001$). Pathway analyses revealed upregulation of Myc targets indicating ERBB4-ICD-STAT5A complex in promoting cell proliferation. Co-occurring mutations are enriched in TP53, PIK3CA, and TERT in ERBB4 fusions.
Conclusion: Our study highlights the frequent occurrence of ERBB4 fusions across various cancer types, with IKZF2 being the most common fusion partner. The prevalence of the ubiquitination-resistant JMa-Cyt2 isoform and the retention of cytoplasmic (kinase) domain in many fusions suggest that ERBB4 fusions may contribute to oncogenesis through a STAT5A-dependent mechanism, independent of PI3K. These findings underscore the potential of ERBB4 fusions as therapeutic targets and suggest that gamma-secretase inhibitors could be a promising treatment option for patients with these fusions.

IMMUNOLOGY: Antibodies and Antibody-Drug Conjugates

#4765 Suppression of triple-negative breast cancer metastasis by a new glyco-humanized polyclonal antibody.

Carine Ciron, Ophelie Dauphouy, Pierre-Joseph Royer, Pierre Morice, Odile Duvaux, **Firas Bassissi**

Xenothera, Nantes, France

Context: Triple-negative breast cancer (TNBC) is an aggressive subtype accounting for 15-20% of breast cancer cases, characterized by poor prognosis, high recurrence rates, and limited treatment options. The lack of hormone receptors associated with a high level of molecular heterogeneity of TNBC hinders the development of effective therapies. Chemotherapy remains the standard of care but is often compromised by resistance and toxicity, emphasizing the urgent need for innovative treatments. Here, we assess the efficacy of XON7, a first-in-class glyco-humanized polyclonal antibody (GH-pAb), in preclinical models of TNBC.
Methods: The anti-tumor efficacy of XON7 was assessed in TNBC cell lines for its capacity to induce complement-dependent cytotoxicity (CDC) and apoptosis, compared to paclitaxel and the ADC Sacituzumab Govitecan. Apoptotic mechanisms were explored by evaluating caspase 8/9 activation, reactive oxygen species (ROS) levels, and mitochondrial membrane potential. In vitro 3D cultures, XON7's ability to inhibit tumor growth, spheroid formation, and metastasis was tested. In vivo antitumor efficacy was evaluated in orthotopic and metastatic models in SRG rats inoculated with MDA-MB-231-Luc cells, using bioluminescence imaging.
Results: XON7 demonstrated potent and selective cytotoxicity across human TNBC cell lines (80-100% cytotoxicity), sparing healthy PBMCs. Apoptotic induction involved both intrinsic and extrinsic pathways, evidenced by caspase 8/9 activation, ROS generation, and mitochondrial membrane potential loss. In 3D cultures, XON7 reduced spheroid size by 50% after two treatments (300 µg/ml) and significantly decreased cancer cell viability (28% remaining). Pre-treatment with XON7 prevented spheroid formation, outperforming paclitaxel and sacituzumab govitecan. XON7 also inhibited metastasis in transwell invasion assays. In vivo, bi-weekly XON7 treatments reduced tumor growth by 50% and eliminated lung metastases in an orthotopic rat model. In a metastatic model, tri-weekly XON7 treatments reduced total metastases (lung, liver, etc.) by 90%.
Conclusion: XON7 is a multi-target antibody currently under clinical evaluation, it represents a promising candidate for advancing treatment paradigms in TNBC.

#4766 Characterization of XON9, an effective glyco-humanized polyclonal antibody against hepatocarcinoma.

Pierre-Joseph Royer, Carine Ciron, Ophelie Dauphouy, George Graur, Odile Devaux, **Firas Bassissi**

Xenothera, Nantes, France

Context: Hepatocarcinoma is the second leading cause of cancer-related death, and its incidence is increasing. Multikinase inhibitors (Sorafenib or Lenvatinib) are the conventional first line treatment for unresectable HCC, with limited response rates and serious side effects. Although immune base therapies such as checkpoint inhibitors have recently showed promising results, they remain applicable to a small fraction of patients. Thus, new treatment and strategies are desperately needed to improve the management of hepatocarcinoma. We evaluate here the in vitro and in vivo efficacy and safety of XON9, first-in-class glyco-humanized polyclonal antibody (GH-pAb) against hepatocarcinoma.

Material and methods: Cytotoxic activity of XON9 against HUH7, HepG2 and Hep3B cell lines was investigated and compared to the activity of standards of care Sorafenib and Lenvatinib. Primary hepatocytes were used as control. Mechanisms of apoptosis were further explored. Activity of caspases 8 and 9, level of reactive oxygen species (ROS) and mitochondrial membrane potential was investigated after treatment with XON9. The *in vivo* efficacy of XON9 was then assessed in NMRI nude engrafted with HUH7 cancer cells while pharmacokinetics and safety parameters were evaluated in a non-human primate after once weekly dosing at 50mg/kg over 2 weeks.

Results: XON9 shows a potent complement dependent cytotoxicity (CDC) against HUH7, HepG2 and Hep3B cells (EC50<10µg/ml). By contrast, primary hepatocytes were relatively spared by XON9 (EC50>50µg/ml). Moreover, XON9 treatment induced apoptosis of the three cell lines tested with activation of caspases 8 and 9, increase of ROS levels and drop of mitochondrial membrane potential. Overall, *in vitro* lytic activity of XON9 towards HUH7, HepG2 and Hep3B was superior to that of Sorafenib and Lenvatinib, the current standards of care for hepatocarcinoma. *In vivo,* XON9 significantly reduced tumour progression in a mouse xenograft model (40% reduction at day 25). No toxicity was observed after repeated injections of 50mg/kg of XON9 in a non-human primate.

Conclusion: Although recent immunotherapy advances have been made, hepatocarcinoma remains an incurable disease with a real need for innovative therapies. XON9 represents a promising and selective immunotherapy against refractory hepatocarcinoma.

#4767 XON11, a novel multi-target antibody in pancreas cancer.

Carine Ciron, Ophelie Dauphouy, Pierre-Joseph Royer, Gwenaelle Evanno, Odile Devaux, **Firas Bassissi**

Xenothera, Nantes, France

Background: Pancreatic cancer continues to be one of the most lethal cancer types, with a 5-year overall survival rate of only 12%. It poses one of the toughest challenges in oncology, as chemotherapy and immunotherapy have not significantly improved patient outcomes. Consequently, there is an urgent need for new therapeutic approaches. XON11 is a new polyclonal antibody targeting several pancreatic cancer antigens, including KrasG12D. The aim of these studies was to assess the tolerance and efficacy of XON11 in non-clinical pancreatic cancer models.
Material and methods: XON11 ability to induce Complement Dependent Cytotoxicity (CDC) and apoptosis compared to gemcitabine was tested in a panel of human pancreas cancer cell (MiaPaca, Aspc1, Capan, Panc1) after 24h of incubation. The capacity of XON11 and gemcitabine to impair tumorsphere formation and growth was investigated in pancreatic cancer cells for 11 days. In vivo XON11 and gemcitabine tolerance and efficacy was evaluated in NMRI nude mice after intraperitoneal dosing at 40 mg/kg tri-weekly for 4 weeks.
Results: XON11 showed potent and selective anti-proliferative activity in a panel of human pancreatic Kras muted cancer cell lines, including those resistant to gemcitabine. It induced specific tumor cell cytotoxicity (Mean EC50 = 25.85 µg/mL) without affecting healthy cells (PBMC) at this concentration. XON11 displayed significantly higher potency against pancreatic cancers compared to gemcitabine. It was able to kill up to 97% of the cancer cells, whereas gemcitabine's maximum effect reached 30%. XON11 induced both caspase 8 and caspase 9 (suggesting activation of both apoptosis pathways). Furthermore, it induced a dose- response loss of mitochondrial membrane potential and ROS generation in different pancreatic cell lines. In contrast to gemcitabine, XON11 significantly decreased Aspc1 tumorspheres viability after treatment (>75% of cytotoxicity). In addition, XON11 completely inhibited sphere formation from 33µg/ml. XON11 was significantly effective against tumor growth in two xenograft mouse models and well tolerated in mice after repeated intraperitoneal dosing at 40 mg/kg over 28 days.
Conclusion: Based on its high potency and tolerance, XON11 can provide a novel and promising therapy for fighting recurrent pancreatic cancer.

#4768 Development of fully human TCR-mimic antibodies targeting intracellular tumor antigens using humanized RenTCR-mimic transgenic mice.

Han Zhang, Wanbo Tang, Jun Du, Yue Zhang, Limin Zhao, Xin Jiao, Baihong Liu, Yi Yang

Biocytogen, Waltham, MA

T cell receptors (TCRs), a promising therapeutic strategy for targeting intracellular antigens, can specifically recognize antigen peptide presented by human lymphocyte antigen (HLA) and mediate T cell responses to eliminate tumor cells. However, the low affinity of TCRs presents a great challenge to their broader clinical application. TCR-mimic (TCRm) antibodies, with similar antigen recognition capabilities as TCRs but higher affinity, offer a solution to these limitations, enabling the targeting of previously undruggable cancer antigens. Neverthelss, specificity remains a major challenge to ensure therapeutic accuracy and patient safety, as TCRm antibodies need to precisely target a single tumor-specific peptide antigen presented by HLA rather than other similar peptides.
Using RenTCR-mimic transgenic mice, we describe the generation and preclinical evaluation of fully human TCRm antibodies by fusing them with a humanized anti-CD3 scFv to form T cell engager or assembled on T cell surface to build TCRm-T cells, further to specifically redirect T cells to lysis tumors by our proprietary RenTCR-mimic platform. We determine cross-reactive peptide sequences predicted by in silico or known off-target sequences. We further confirm the specificity and safety of TCRm antibodies. Despite low density antigen copies, TCRm antibodies elicited antibody-mediated T-cell recognition and cytotoxicity against antigen peptide-HLA complexes-restricted cell lines. Based on these methods, we perform screens to validate TCRm antibodies specificity. These experiments led us to discriminate between the target peptide and the potential off-target peptides presented by HLA and highlight the therapeutics potential of TCRm antibodies in tumor immunotherapy, offering a novel approach to expanding the repertoire of druggable cancer targets.

#4769 Characterization of novel humanized FGFR2b antibody-based ADCs site-specifically conjugated with topoisomerase I inhibitor payload in preclinical tumor models.

Fei Teng, Huanhuan Guo, Hongjun Li, Lizhi Qin, Xinlai Yao, Lei Shi, Yi Gu, Xueming Qian

Suzhou Transcenta Therpeutics Co., Ltd, Suzhou, China

Background: Fibroblast growth factor receptor 2 IIIb (FGFR2b), one of the four FGFR family members that encode transmembrane receptor tyrosine kinases, is overexpressed in a variety of cancers, such as gastric/GEJ (29%), esophageal (41%), squamous NSCLC (31%), TNBC (13%), ovarian (40%), endometrial (86%), cervical (80%), colorectal (62%), and cholangiocarcinoma (22%). We have developed a FGFR2b-targeting ADC (TST105) with a novel topoisomerase I inhibitor payload by using glycotransferase mediated site-specific conjugation and characterized its *in vitro* and *in vivo* anti-tumor activity in preclinical tumor models.

Methods: A novel anti-FGFR2b humanized antibody 38D4 was generated by hybridoma platform. The binding affinity was analyzed by Fortebio Octet, and the selectivity and species cross-reactivity were assessed by ELISA. Antibody internalization was conducted by using Fluoresence Image. Cytotoxicity of TST105 was tested in tumor cell lines with different levels of FGFR2b expression. The bystander effect was assessed in co-culture experiments with the FGFR2b-negative and -positive tumor cells. Anti-tumor efficacy was evaluated in FGFR2b-positive tumor cell line-derived xenograft (CDX) models in mice.

Results: 38D4 specifically binds to FGFR2b with a higher affinity than the Bemarituzumab-analog. 38D4 binds with comparable affinity to human, cynomolgus, rat and mouse FGFR2b. Significant internalization of 38D4 was observed after 4 hour and 24 hour-culture at 37℃. In the gastric (SNU-16) and colorectal (SW480-FGFR2b) tumor cell lines, TST105 demonstrated specific killing activity with a potency between 0.3 nM and 0.4 nM *in vitro*, which was weaker than both 38D4-MMAE and Bema-MMAE (stochastic conjugated). However, a higher potent bystander effect of TST105 than them was observed, indicating the potential to treat tumors with heterogeneous target expression. Furthermore, in SNU-16 xenograft model, which endogenously expresses FGFR2b at a high level, TST105 induced a better anti-tumor efficacy than Bema-MMAE. TST105 had a tumor growth inhibition of 91.25% and overall response rate (ORR, 50% reduction of tumor volume from baseline) of 70% at 3 mg/kg QW, while Bema-MMAE only reduced tumor growth of 48.32% with no ORR. The similar superior tumor regression efficacy of TST105 was also observed in colorectal tumor model SW480-FGFR2b. This differentiation may be contributed by the glycotransferase site-specific conjugation, which can eliminate Fc function, thus reduces the non-specific endocytosis in normal cells and leads to ADC enrichment in the FGFR2b-positive tumors.

Conclusions: FGFR2b ADC TST105 demonstrated the high potency, strong anti-tumor activity and bystander effect in the preclinical studies, which support further investigations of TST105 in FGFR2b positive solid tumors.

#4770 First-in-class anti-TRPV6 antibody as a new therapeutic agent in cancer.

Lindsay B. Alcaraz[1], Vincent Roux-Portalez[1], Aurelien Haustrate[2], Gautier Robin[1], Alexia Parmentier[1], Clement Cordier[1], Florence Boissiere-Michot[3], Amelie Gudin-de-Vallerin[3], Evelyne Lopez-Crapez[3], Gaelle Fromont-Hankard[4], Tristan Mangeat[1], Margaux Maurel[1], Marianne Le Gall[1], Thierry Chardes[5], Bruno Robert[5], Yoann Sottejeau[6], Diego Tosi[7], Natacha Prevarskaya[2], V'yacheslav Lehen'kyi[2], Bernard Pau[1], **Johanna Marines**[1]

[1]Mabqi, Montpellier, France,[2]PhyCell Laboratory, Lille, France,[3]Translational Research Unit, Montpellier Cancer Institute Val d'Aurelle, Montpellier, France,[4]Universite de Tours, Tours, France,[5]Institut de Recherche en Cancerologie de Montpellier (IRCM), Inserm U1194, Montpellier, France,[6]SATT Nord, Lille, France,[7]ICM, Montpellier, France

Context: The involvement of calcium signaling in tumor progression has been well documented in the literature. In particular, the calcium channel TRPV6 has been identified as a key player in the physiopathology of solid tumors. At the transcriptomic level, TRPV6 is overexpressed in many cancers such as prostate, pancreatic and ovarian cancers underscoring its potential as a new therapeutic target. While some TRPV6-targeting antagonistic peptides have reached clinical stage, no antibody candidate is currently in development. Leveraging its phage display technology and unique proprietary antibody libraries, Mabqi (France), in collaboration with SATT Nord and PhyCell laboratory (France), has discovered and characterized a first-in-class human anti-TRPV6 antibody "20H3" with high clinical potential.

Methods: A comprehensive series of *vitro* and *vivo* preclinical studies demonstrated the safety profile, efficacy and clinical relevance of 20H3 antibody, as a new candidate for the treatment of prostate cancer.

Results: *In vitro* studies demonstrated the high affinity and specificity of 20H3 antibody against TRPV6 target. Exploration of antigen-antibody interaction was performed through epitope and paratope mapping and antagonistic activity of 20H3 antibody was validated via calcium flux modulation assays. The excellent developability properties were also demonstrated through thermostability, aggregation and stability assays.

In vivo, the 20H3 safety profile was confirmed in mice model. After repeated doses up to 64 mg/kg, no effect on mice body weight and no sign of toxicity in main organs collected were detected. The antitumoral potential of 20H3 antibody was evaluated in three *vivo* cancer models. As initial positioning is prostate cancer indication, efficacy studies in two xenografted prostate models (LNCaP and VCaP) were performed. In both models, specific tumor targeting and tumor penetration were confirmed and a strong antitumoral efficacy was demonstrated at 4-8 mg/kg with a tumor growth inhibition superior to 60 % and an increased mice survival of 62 %. Interestingly a strong efficacy was also shown in MCA205 sarcoma model. To further elucidate antibody's mode of action, a comparison between Fc-WT and Fc-silencing format was carried out in immunocompetent and immunodeficient mice models. All together, these results demonstrated that antitumor efficacy is mediated by both paratopic region and Fc region of the antibody that potentializes the effect of the treatment. Finally, the 20H3 clinical relevance was demonstrated by immunohistochemistry studies with positive immunoreactivity in a large proportion of prostate cancer patient samples.

Conclusion: The 20H3 antibody is the first anti-TRPV6 antibody under development, with a strong potential to advance rapidly into clinic. The CMC process of 20H3 drug candidate is planned in 2025 and Phase Ia clinical trial is expected to start in early 2027.

#4771 A novel immunotherapy for metastatic prostate cancer: A monoclonal antibody that can bind both STEAP1 and STEAP2.

Minzhi Sheng, Boyang Su, Amanda Sparkes, Gobi Thillainadesan, Esther Matus, Jessica Wright, Stanley Liu, Jean Gariepy, Hon S. Leong

Sunnybrook Research Institute, Toronto, ON, Canada

Prostate cancer (PCa) is the most common cancer among Canadian men, with metastatic PCa (mPCa) patients having a 5-year survival rate of only 30%. However, the prostate-specific membrane antigen, a key target in PCa therapy, is expressed in many normal tissues and shows heterogeneity among PCa patients. Recently, Six Transmembrane Epithelial Antigens of the Prostate 1 and 2 (STEAP1 and STEAP2) have gained attention as promising therapeutic targets due to their high expression in most PCa cases compared to normal tissues and essential organs. This study aimed to develop a novel immunotherapy targeting STEAP1/2 to elicit PCa-specific immune responses in cellular and animal mPCa models. Monoclonal antibodies were generated against the extracellular region of STEAP1, which shares 60% sequence similarity with STEAP2 but has minimal homology with other human proteins. The specificity and binding strength of these antibodies were validated through techniques such as immunofluorescence, flow cytometry, immunoprecipitation, and ELISA. Results from immunofluorescence and flow cytometry using STEAP1 overexpression and knockdown PCa cell lines demonstrated the specificity of certain clones for human STEAP1. Furthermore, one antibody clone successfully pulled down STEAP2 in immunoprecipitation-mass spectrometry experiments and showed binding to STEAP2 in cell lines overexpressing the antigen. ELISA results revealed binding affinities in the low nanomolar range for STEAP1 and the low micromolar range for STEAP2.These findings highlight the potential of the monoclonal STEAP1/2 antibody developed in this study, providing a promising platform for future immunotherapy strategies and expanding treatment options for mPCa patients.

#4772 AI-guided engineering and preclinical development of biparatopic anti-DLL3 antibody-drug conjugates (ADCs).

Chuan Chen, Yue Wu, Liang Tian, Chenpeng Su, Zhaohui Chen, Jiyuan Tian, Dandan Liu, Yang He, Xiaoqian chen, Yongxin Shang, Jian Peng, Zhenping Zhu

Helixon US Inc., New York, NY

Delta-like ligand 3 (DLL3) is often overexpressed in small cell lung cancer (SCLC) and several other neuroendocrine tumors, with no or very low expression in normal issues. An anti-DLL3 x CD3 bispecific T-cell engager, tarlatamab, has demonstrated significant clinical benefits and was recently approved by the US FDA for the treatment of DLL3-expressing SCLC. On the other hand, Rova-T, the first antibody-drug conjugate (ADC) targeting DLL3 entered advanced clinical development, failed in phase III studies due to insufficient efficacy and an unfavorable safety profile. In this study, via AI-guided engineering and optimization, we produced a novel biparatopic anti-DLL3 antibody and generated a number of ADCs utilizing various linkers and cytotoxic payloads. The ADCs demonstrated efficient DLL3-mediated cell binding and rapid internalization at a much higher efficiency than the mono-epitope targeting ADCs. The ADCs showed selective cytotoxicity towards multiple tumor cell lines with varying levels of DLL3 expression in vitro, and potently inhibited the growth of several DLL3-expressing tumor xenografts in animal models. Taken together, our findings underscore the significance of AI-guided antibody engineering and optimization, and provide support for the further development of the biparatopic anti-DLL3 ADCs in patients with DLL3-expressing tumors such as SCLC and other neuroendocrine tumors.

#4773 AM E3-SG3249, a first-in-class α-CRLF2 antibody-drug conjugate for the treatment of CRLF2-rearranged Ph-like B-ALL.

Claudia Dall'Armi, Valentina Di Biasio, Chantal Paolini, Daniela Natale, Francesco Scalabri, Antonino Missineo, Nadine Alaimo, Maurizio Nuzzo, Anna Demartis, Pamela Di Pasquale, Roberto Benoni, Fulvia Caretti, Elisa Beghetto, Fabrizio Colaceci, Romina Sasso, Vincenzo Pucci, Carlo Toniatti, **Alessandro Carugo**

IRBM S.p.A., Pomezia, Italy

Background: Patients affected by Ph-like B-cell acute lymphoblastic leukemia (B-ALL) have a high mortality rate and elevated levels of disease relapse upon chemotherapy treatment. More than 60% of Ph-like B-ALL is characterized by genomic rearrangements resulting in high expression levels of the CRLF2/TLSPR receptor on the cell surface. While significant advances have been made in developing targeted agents for B-ALL treatment, the CRLF2-rearranged subpopulation is lacking selective and effective therapies. Here, we report the development and preclinical validation of AM E3-SG3249, a first-in-class α-CRLF2 Antibody-Drug Conjugate (ADC) for the treatment of CRLF2-rearranged Ph-like B-ALL.

Materials and Methods: AM E3, a fully human α-CRLF2 monoclonal antibody with single-digit nanomolar affinity for the target (5.9 ± 1.0 nM), was identified leveraging our proprietary phage display platform. Due to its rapid internalization rate by CRLF2-expressing cells, AM E3 emerged as an ideal candidate for the development of an ADC targeting CRLF2. Upon conjugation with the cytotoxic payload tesirine (SG3249), a clinically-validated cross-linking agent, AM E3-SG3249 demonstrated a potent anti-tumor effect on both CRLF2-rearranged *in vitro* cell lines and *in vivo* orthotopic xenograft models. We also developed an ADC surrogate against murine CRLF2, which has low homology with the human counterpart (<35%), to further prove tolerability of the ADC therapy in preclinical mouse models.

Results: AM E3-SG3249 was potently cytotoxic (EC_{50} = 40pM) against a panel of hCRLF2-rearranged B-ALL cell lines *in vitro*. Upon single injection in xenograft models, AM E3-SG3249 showed strong anti-tumor activity proportional to receptor density. Moreover, AM E3-SG3249 treatment extended survival of hCRLF2-rearranged B-ALL orthotopic xenografts over standard induction therapy combining vincristine, dexamethasone, and L-asparaginase (VXL). The ADC surrogate mB4 AM23-SG3249 was also efficacious and well-tolerated in xenograft models engineered to overexpress murine CRLF2.

Conclusions: AM E3 is a novel monoclonal antibody with ideal features for the development of a first-in-class α-CRLF2 ADC therapy. AM E3 conjugated with the cytotoxic agent tesirine (SG3249) demonstrated remarkable anti-tumor efficacy and a reasonable therapeutic window for the treatment of CRLF2-rearranged Ph-like B-ALL.

#4774 Synergistic enhancement of immunogenic cell death: Combining AWT020 with antibody-drug conjugates for superior anti-tumor activity.

Fan Ye, Jianing Huang, Ella Li, Wen-Chin Huang, Fang Huang, Xiaoli Cheng, Jenny Jiang, Shih Chieh Chen, Botong Hua, Hanna Lin, Joyce Kwan, Eugene Liu, Ziyang Zhong

Anwita Biosciences, San Carlos, CA

Antibody-Drug Conjugates (ADCs) are targeted cancer therapies delivering cytotoxic agents selectively to cancer cells. Despite clinical success across various malignancies, resistance to ADC therapy limits long-term efficacy. A key ADC mechanism is inducing immunogenic cell death (ICD), releasing damage-associated molecular patterns (DAMPs) and tumor antigens to stimulate an immune response. This provides a rationale for combining ADCs with immunotherapies to overcome resistance and improve survival rates.AWT020 is a novel fusion protein currently in Phase I clinical trials. It combines a humanized antibody targeting programmed cell death protein 1 (PD-1) with a potency attenuated interleukin-2 (IL-2) mutein. This design blocks the PD-1 pathway while preferentially activating IL-2 signaling on PD-1^{high} tumor-infiltrating T cells (TILs), minimizing peripheral PD-1^{low} lymphocyte activation and reducing systemic toxicity. In preclinical tumor models, a murine surrogate of AWT020 (mAWT020) demonstrated superior anti-tumor activity over a PD-1 monoclonal antibody by selectively expanding TILs.Both ADCs and AWT020 selectively target the tumor microenvironment and promote tumor cell killing through distinct mechanisms. We hypothesized that ADC-induced ICD could be further amplified by AWT020. To test this, we developed two syngeneic tumor models, $EMT6^{B7H3}$ and $EMT6^{Her2}$, expressing human B7H3 and human Her2, allowing specific ADC targeting. In the $EMT6^{B7H3}$ model, combination of B7H3 ADC (B7H3-Exa) and mAWT020 eradicated all tumors after a single dose, outperforming monotherapies. Similar synergy between Her2-Exa ADC and mAWT020 was observed in the $EMT6^{Her2}$ model. In a subsequent tumor rechallenge study, most mAWT020-treated mice rejected the replantation of $EMT6^{B7H3}$, indicating that mAWT020 had induced long-term immunological memory in these animals. As a comparison, combination of anti-mPD-1 with B7H3-Exa did not enhance the antitumor activity of ADC. Characterization of ICD markers and TIL phenotypes in the $EMT6^{B7H3}$ model showed that B7H3-Exa treatment significantly upregulated calreticulin (CRT) expression in $EMT6^{B7H3}$ tumor cells. The combination of B7H3-Exa and mAWT020 further increased CRT expression. Compared to B7H3-Exa monotherapy or the combination of B7H3-Exa and anti-mPD-1, mAWT020 treated groups significantly increased $CD3^{+}$ T cell infiltration within the tumor, as well as tumor-specific T cells, as detected by ELISpot assay.These preclinical findings demonstrate that ADC-induced ICD is amplified by AWT020, but not by anti-mPD-1, resulting in greater tumor regression and enhanced immunological memory. These results support the continued clinical development of AWT020 and to explore its potential in combination with ADCs, aiming to improve long-term survival and complete response rates in cancer patients.

#4775 Combination therapy with TB511 and anti-nectin-4 antibody drug conjugate in a human pancreatic cancer mouse model.

Ik-Hwan Han[1], Ilseob Choi[1], Soyoung Kim[1], Juwon Yang[1], Heekyung Lee[2], Geumseong Yun[1], Hyunju Lee[1], Hyunsu Bae[1]

[1]Department of Physiology, Kyung Hee Univ. College of Oriental Medicine, Seoul, Korea, Republic of,[2]R&D Center, Twinpig Biolab Inc., Seoul, Korea, Republic of

Pancreatic cancer is a type of cancer that occurs in the pancreas and occurs in the pancreatic duct in more than 90% of cases and is known as the 10th most common cause of cancer deaths worldwide. Recently, tumor-associated macrophages (TAMs) in tumor microenvironment (TME) have been known to closely associate with progression of pancreatic cancer. Among TAMs, M2 type macrophages constitute the majority within the TME and are associated with tumor progression and drug resistance. Targeting M2 macrophages represents a promising therapeutic strategy to reprogram the TME and enhance anti-tumor immunity. In our previous study, we developed TB511, a peptide drug conjugate that preferentially binds to M2 macrophages and induces apoptosis through mitochondrial targeting by conjugating with dKLA. Furthermore, in pancreatic cancer, the nectin-4 expression has been known to contribute to tumor proliferation, angiogenesis, and patient prognosis. Nectin-4 has been considered a potential new target for the treatment of pancreatic cancer. However, therapeutic efficacy of anti-nectin-4 antibody has not been established in pancreatic cancer. This study aims to evaluate the efficacy of the combination therapy of TB511 and anti-nectin-4 antibody drug conjugate (ADC) in reducing tumor growth and modulating the immune cells of tumor microenvironment in a humanized pancreatic cancer mouse model. In this study, humanized mice bearing subcutaneous pancreatic cancer using the PANC1 cell line were treated with TB511, ADC, their combination, or PBS as a control. As a result, TB511, PADCEV, and their combination significantly reduced tumor growth and Ki67 expression. EMT marker analysis revealed increased E-cadherin and decreased vimentin expression in combination therapy groups. TB511 and combination therapy reduced M2 macrophages (CD163, CD18, Kim127, CD11b) and increased CD8 T cells in the TME, while ADC alone showed no significant immune modulation. Spatial transcriptomics highlighted decreased epithelial cancer cells, increased M1 macrophages, and elevated CD8 T and NK cells in the TB511 and combination groups. Immune checkpoint markers (CTLA4, FOXP3, LAG3) were downregulated, and cytotoxic markers (GZMB, IFNG) were upregulated with TB511 and combination therapy. No significant off-target effects were observed in the spleen, liver, lung, or brain. In conclusion, combination therapy with TB511 and ADC effectively suppresses pancreatic tumor growth and reprograms the immune microenvironment by decreasing M2 macrophages and enhancing cytotoxic T and NK cell responses, offering a promising strategy for pancreatic cancer treatment.

#4776 Preclinical study of bispecific antibody drug conjugates (bsADCs) targeting DLL3 and SEZ6 demonstrated potent anti-tumor activity in small cell lung cancer (SCLC) xenograft models.

Kaiqing Zhang, Ting Yi, Liu Yang, Kunying Hao, Wenpeng Cao, Yu Qi, Jushi Gai, Luheng Du, Gao An, Chengzhang Shang, Yi Yang, Frank An

Biocytogen, Waltham, MA

Lung cancer is the most common type of cancers and the leading cause of cancer-related mortality worldwide with 2.5 million new cases and 1.8 million deaths in 2022. Small-cell lung cancer (SCLC) accounts for ~15% of all lung tumors, representing the most aggressive high-grade neuroendocrine carcinoma with a five-year survival rate less than 4%. Majority of patients are diagnosed with extensive stage SCLC (ES-SCLC) with brain metastases identified in ~80% of cases and the prognosis is dismal with 5-year survival under 2%. Patients often relapse from front line therapies and current treatments in the second-line setting are very limited.

Delta-like ligand 3 (DLL3) expression is highly restricted to SCLC, neuroendocrine tumors, and glioblastoma with minimally or no expression in normal tissues, making it a very specific and attractive tumor associated target (TAA) for SCLC. Like DLL3, seizure-related homolog protein 6 (SEZ6) is also expressed in SCLC, neuroendocrine tumors, and glioblastoma. Tarlatamab, a T cell engager targeting DLL3, was recently approved for SCLC. ADCs targeting DLL3 have shown robust anti-tumor activities in clinical trials. Similarly, anti-SEZ6 ADCs have also shown promising clinical activities.

We constructed a bispecific ADC (bsADC) that targets both DLL3 and SEZ6 (DLL3xSEZ6) for SCLC and other tumor types where both DLL3 and SEZ6 are co-expressed. We hypothesized that dual targeting of these clinically validated targets would provide more selective and more potent anti-tumor activity, help overcome tumor heterogeneity in tumoral DLL3 and SEZ6 expression levels and allow a broader patient population for treatment. The bispecific antibody (bsAb) moiety of the bsADC was 1+1 format and was conjugated to a novel TOP1 inhibitor payload with potent bystander effect (DAR 8) and a highly hydrophilic, enzyme-cleavable linker. In vitro, the bsAb showed robust internalization capability in multiple double positive SCLC cell lines. In vivo, the bsADC exhibited robust anti-tumor efficacy in SCLC xenograft models. In summary, our DLL3xSEZ6 bsADC showed promising in vitro and in vivo preclinical activities with first-in-class potential for treatment of SCLC.

#4777 GDF-15 neutralization enhances the therapeutic activity of antibody-drug conjugates.

Neha Vashist, Daniel Schatzlein, Amelie Kohler, Sabrina Genssler, Jose Medina-Echeverz, Eugen Leo, Thorsten Ross, Christine Schuberth-Wagner

CatalYm GmbH, Planegg-Martinsried, Germany

Background: Antibody-drug conjugates (ADCs) target cytotoxic payloads like microtubule and topoisomerase I inhibitors to the tumor, thereby inducing selective tumor cell death. ADCs can also trigger anti-tumoral immune responses via induction of immunogenic cell death (ICD). Recent advances in treatment of urothelial cancer demonstrate the high potential of ADCs, e.g. also in combination with PD-(L)1 immune checkpoint inhibitors (ICI). However, significant challenges still remain such as (partial) non-response, high relapse rates and notable toxicity, all highlighting the need to further improve the treatment. GDF-15 acts as a local immunosuppressant, disrupting immune cell infiltration and inhibiting myeloid cell differentiation. GDF-15 blockade in anti-PD1/PD-L1 relapsed/refractory, last-line cancer patients has shown durable anti-tumor responses when combined with PD-1 ICI (NCT04725474). Beyond tumoral overexpression, GDF-15 is also induced by various chemotherapeutic agents. Whether GDF-15 is induced by ADC payloads and could mediate resistance to therapy is currently unknown. Here, we investigated if ADC treatment can induce GDF-15 release from tumor cells and if GDF-15 neutralization may enhance ADC activity.
Methods: Human tumor cell lines were treated with ADCs or unconjugated payloads. Cell viability, induction of ICD, and GDF-15 levels were measured *in vitro* by quantifying intracellular ATP, ecto-Calreticulin (ecto-CRT), and release of HMGB1, extracellular ATP (eATP), and GDF-15 in cell culture supernatants, respectively. Induction of tumoral and serum GDF-15 levels by ADCs was assessed *in vivo* using xenograft tumor models. The effect of GDF-15 neutralization on the anti-tumoral activity of ADCs was evaluated in syngeneic tumor models by monitoring tumor growth and animal survival.
Results: ADCs and unconjugated payloads (MMAE, SN-38, calicheamicin, and PBD dimers) induced concentration-dependent lysis of tumor cells, releasing eATP and HMGB1 and translocating ecto-CRT, indicative of ICD induction. Concomitant with cell death, ADCs and their payloads induced GDF-15 release from tumor cells in vitro. ADC-induced GDF-15 release was confirmed in vivo by increase in tumoral and circulating GDF-15 levels in human tumor xenografted mice. Lastly, combining anti-GDF-15 with ADC treatment improved tumor growth delay markedly in a syngeneic tumor model, accompanied by enhanced immune cell infiltration and activation.
Conclusion: ADC treatment induces GDF-15 which contributes to reduction of ADC activity. Blockade of GDF-15 enhances ADC activity and immune cell number and activation in the tumor. Therefore, GDF-15 blockade may hold significant potential as therapeutic strategy to enhance ADC activity in cancer patients.

#4778 ADCE-T02: A first-in-class topoisomerase-1 inhibitor based antibody drug conjugate against tissue factor demonstrates excellent preclinical efficacy and tolerability.

Thomas Tuxen Poulsen[1], Yue Zhang[2], Jianjian Zhang[2], Huiyan Shi[2], Shu-Hui Liu[3], Xun Meng[2], Mette Gillberg[1], Dominik Mumberg[1]

[1]Adcendo ApS, Frederiksberg, Denmark,[2]Multitude Therapeutics, Shanghai, China,[3]Multitude Therapeutics, Redwood City, CA

Tissue factor (TF, F3, coagulation factor III, thromboplastin, or CD142) is a 47-kDa transmembrane glycoprotein. In normal tissues TF expression is limited to the perivascular compartment where it is the cell surface receptor for the serine protease factor VIIa (FVIIa). Functionally, the TF/FVIIa complex converts the inactive zymogen Factor X (FX) to FXa triggering initiation of the extrinsic coagulation protease cascade. TF is overexpressed in a wide range of solid tumors, including pancreatic, cervical, and colorectal cancer as well as non-small cell lung cancer (NSCLC) and head and neck squamous cell carcinoma (HNSCC), which in combination with efficient receptor internalization makes TF an ideal antibody-drug conjugate (ADC) target. The TF-ADC tisotumab-vedotin (Tivdak®) has been approved for treatment of cervical cancer but is associated with serious side effects including ocular toxicities, peripheral neuropathy, and bleeding. ADCE-T02 is a first-in-class Topoisomerase-1 inhibitor TF-ADC composed of a humanized anti-TF IgG1 monoclonal antibody (Ab-754), conjugated via a novel T1000 linker moiety to the Topoisomerase-1 inhibitor Exatecan payload at a drug-to-antibody ratio (DAR) of 4. ADCE-T02 binds with high affinity to human recombinant TF protein and multiple TF positive cell lines. Binding of ADCE-T02 to TF on the cell surface triggers internalization, resulting in intracellular exatecan release and cancer cell death. In addition, ADCE-T02 induces potent bystander cytotoxicity in TF negative cancer cells when cocultured with TF positive cells *in vitro*. In contrast to tisotumab, Ab-754 does not inhibit FXa activation and demonstrates reduced effect in coagulation assays *in vitro*. ADCE-T02 induces antibody-dependent cellular cytotoxicity but not antibody-dependent cellular phagocytosis or complement-dependent cytotoxicity. *In vivo*, ADCE-T02 shows strong anti-tumor activity in a wide range of solid tumor models including pancreatic cancer, esophageal squamous cell carcinoma, NSCLC and HNSCC and is well tolerated in non-human primate toxicology studies with no evidence of ocular toxicity, peripheral neuropathy, or bleeding.
In summary, ADCE-T02 constitutes a novel first-in-class Topoisomerase-1 inhibitor ADC targeting TF with a potentially enhanced therapeutic and safety profile. A phase I clinical study of ADCE-T02 in patients with advanced solid tumors is currently ongoing (Clinical Trial ID NCT06597721).

#4779 Preclinical studies of BB-1705: An EGFR-targeting eribulin-containing ADC with an affinity optimized antibody to minimize potential toxicities to normal tissues.

B. Xia[1], L. Cao[1], J. Yang[1], C. Feng[1], F. Jiang[1], C. Li[1], L. Gu[1], Y. Yang[1], J. Tian[1], J. Geng[1], L. Gong[2], T. Liu[2], Q. Qin[2], Z. Wei[1], Y. Zhou[1]; [1]Bliss Biopharmaceutical (Hangzhou) Co., Ltd., Hangzhou, China, [2]Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, China

Epidermal Growth Factor Receptor (EGFR) is a type I receptor tyrosine kinase critical for the development and normal function of epithelial cells. However, its overexpression or hyperactivity in certain cancers can lead to tumor growth and metastasis. While existing EGFR-targeting therapies can effectively inhibit tumor progression, they often cause significant toxicity due to EGFR expression in normal tissues. To mitigate these side effects, we have developed BB-1705, an antibody-drug conjugate (ADC) that utilizes eribulin as its cytotoxic agent. Eribulin is an FDA-approved treatment for metastatic breast cancer and advanced liposarcoma. BB-1705 employs an affinity-optimized anti-EGFR antibody to selectively deliver eribulin to tumor cells, sparing normal tissues by not effectively blocking the EGFR signaling pathway in those areas. This strategy aims to enhance the therapeutic index of EGFR-targeted treatments while minimizing adverse effects on normal tissues.

In vitro studies demonstrated that BB-1705 exhibits potent cytotoxicity against a range of cancer cell lines with medium to high levels of EGFR expression, while showing reduced efficacy against normal human keratinocytes, likely due to their lower EGFR expression and the antibody's affinity profile. Notably, BB-1705 also induced a significant bystander effect on EGFR-low/null cells when co-cultured or co-inoculated with EGFR-high cells.

In vivo experiments using xenograft models revealed that a single dose of BB-1705 resulted in substantial antitumor activity. When administered repeatedly via a clinically relevant route and schedule, BB-1705 demonstrated a favorable pharmacokinetic profile and safety in cynomolgus monkeys with manageable hematological side effects and minimal skin toxicity observed even at the highest tested dose (12 mg/kg, Q3W x 3).

In summary, our preclinical findings suggest that BB-1705 has the potential to optimize the efficacy and safety profile of EGFR-targeting therapies for cancers characterized by medium to high EGFR expression levels. A clinical trial evaluating BB-1705 is currently underway, aiming to assess its therapeutic potential in treatment of EGFR-expressing human cancers including TNBC, NSCLC and head and neck cancers.

#4780 Engineered ICAM-1 refractory trastuzumab improves its therapeutic activity against HER2-positive cancers in native and antibody-drug conjugate (ADC) format.

J. Bradford Kline, Luigi Grasso, **Nicholas C. Nicolaides**

Navrogen, Glen Mills, PA

The ICAM-1 protein has recently been found to bind the CH3 domain of IgG1-type antibodies and suppress their immune effector activity and internalization against ICAM-1 over-expressing cancer cells. Immune effector suppression involves reduced binding of IgG1 to CD16a Fc-γ-activating receptors on NK cells leading to reduced antibody dependent cellular cytotoxicity (ADCC), as well as binding of the complement initiating C1q protein leading to reduced complement dependent cytotoxicity (CDC) via allosteric alteration of the Fc domain. The effect of ICAM-1 on reduced antibody internalization, a requisite for ADC cytotoxicity, due to the physical interaction of the ADC antibody component with cell surface ICAM-1 has shown significant suppression of ADC activity against antigen-positive target cells. To overcome ICAM-1/IgG1 cytotoxic suppression, we identified a consensus motif within the IgG1 CH3 domain when modified leads to ICAM-1 refractory antibodies, thereby restoring maximal immune effector and ADC cytotoxicity of target cells. Here we present the development of an ICAM-1 refractory trastuzumab and its efficacy against HER2 cancer cells over-expressing ICAM-1 in native and ADC format. These data demonstrate the importance of how tumor-produced proteins may negatively impact the cytotoxic effects of tumor-targeting antibodies and offers a novel platform to improve upon the efficacy of antibody-based therapeutics in the presence of immunosuppressive proteins such as ICAM-1.

#4781 Generation and in vivo characterization of a novel antibody targeting Prostatic Acid Phosphatase (ACP-3).

Claudia Comacchio[1], Stefanie Pfister[2], Domenico Ravazza[3], Samuele Cazzamalli[2], Ettore Gilardoni[3], Emanuele Puca[2], Tobias Weiss[1], Michael Weller[1], Dario Neri[2], Roberto De Luca[2]

[1]Department of Neurology and Clinical Neuroscience Center, University Hospital Zurich, Zurich, Switzerland,[2]Philochem AG, Zurich, Switzerland,[3]Philochem AG, Otelfingen, Switzerland

Prostate cancer is the second deadliest tumor in men globally, despite the advent of novel drugs. Therapeutic modalities targeting Prostate Specific Membrane Antigen (PSMA) have provided benefit to patients but suffer from on-target off-tumor liabilities responsible for the side effects observed in clinical practice. These liabilities are a result of the expression of PSMA in healthy tissues, such as salivary glands, lacrimal glands, intestine, and kidneys. Innovative targeting ligands against better prostate cancer targets are therefore needed.
Here, we present the generation and characterization of a first-in-class fully human antibody targeting ACP-3, a tyrosine phosphatase produced by prostate epithelial cells. Compared to PSMA, ACP-3 is expressed at significantly higher levels in the majority of prostate cancer lesions (both primary and metastatic), while being nearly undetectable in most healthy organs, including salivary glands, intestine and kidneys. A novel anti-ACP3 antibody was isolated from a phage display synthetic library containing 3 billion human single chain variable fragment clones. The antibody was thoroughly characterized, and its binding properties for the cognate target were studied *in vitro* using ELISA, flow cytometry and immunofluorescence on human prostate cancer specimens. Two orthogonal *in vivo* biodistribution studies were conducted in mice bearing HT1080 tumors stably transfected with human ACP-3. The first method relied on mass spectrometry to quantify the uptake antibody in tumors and healthy organs. The second method relied on the use of the immunofluorescence imaging to evaluate the microscopic distribution of the anti-ACP-3 antibody in tumors and healthy organs. The analyses were performed 24 hours post intravenous injection of the antibody. The results confirmed that the novel anti-ACP-3 antibody can selectively bind to its target *in vitro* and can preferentially localize to the tumor when injected intravaneously in tumor-bearing mice.
In conclusion, given the exceptional binding selectivity and tumor-targeting performance, this novel anti-ACP-3 antibody promises to be an attractive scaffold for the generation of new best-in-class tumor targeted pharmaceuticals for the treatment of prostate cancer.

#4782 Inducing abscopal effect in colorectal cancer via antibody-conjugated photothermal nanoparticles in combination with immunocytokine.

Myeung Ryun Seo[1], Jinwon Park[2], Hee Geon Park[3], Jae Choi[3], Sang Moo Lee[1], Sangin Lee[3], Sae Hyung Lee[3], Hobin Yang[4], Sungyoul Hong[5], Yu-Kyoung Oh[2], Young Kee Shin[1]

[1]Department of Molecular Medicine and Biopharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of,[2]College of Pharmacy and Research Institute of Pharmaceutical Science, Seoul National University, Seoul, Korea, Republic of,[3]ABION Inc., Seoul, Korea, Republic of,[4]College of Pharmacy, Kyungsung University, Busan, Korea, Republic of,[5]Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, Korea, Republic of

Colorectal cancer is characterized by high rates of recurrence and metastasis, making it particularly challenging to manage due to multidrug resistance after treatment and/or the difficulty of detecting metastatic lesions. Photothermal therapy (PTT) has emerged as a promising strategy to overcome the drug resistance, with ongoing studies investigating its potential to induce the abscopal effect—an immune-mediated response targeting metastatic cancer. However, current research indicates that PTT alone is insufficient to trigger a significant abscopal effect and requires combination with immune modulators, such as immune checkpoint inhibitors or immune stimulating cytokines. Interferon-β (IFN-β), a cytokine capable of directly inducing tumor cell death, also exhibits anticancer effects through immune cell modulation. We hypothesized that combining PTT with IFN-β could induce a synergistic response, enhancing the abscopal effect. In a previous study, we developed antibody-conjugated polydopamine (PDA) nanoparticles targeting Claudin-3 (CLDN3), a protein overexpressed in various cancers, including colorectal cancer, to serve as a material for PTT. In addition, we utilized a CLDN3-targeting antibody-IFN-β mutein fusion protein (ABN202, αCLDN3) to enhance the abscopal effect. The objective of this study was to evaluate whether combining PTT with ABN202 (αCLDN3-IFN-β) could synergistically enhance immune cell activation compared to each treatment alone. Moreover, in human interferon receptor 1/2 knock-in mice, the combination effectively inhibited tumor growth at distant sites. It also demonstrated that the efficacy in preventing recurrence when tumor was re-challenged after the treatment. Therefore, these findings suggest that PTT in combined with ABN202 (αCLDN3-IFN-β) is a promising a novel therapeutic strategy for preventing cancer metastasis and recurrence in colorectal cancer.

#4783 Development and characterization of an antibody-drug conjugate (ADC) utilizing PB-223, a novel monoclonal antibody (mAb) specifically targeting core 2 O-glycans on human carcinomas.

Kwong Y. Tsang, Massimo Fantini, Anjum Zaki, Sharon A. Mavroukakis, Philip M. Arlen

Precision Biologics, Inc., Bethesda, MD

Introduction: The three essential components of an ADC include the mAb, the linker, and the cytotoxic payload. The mAb is designated to target specific tumor-associated antigens that are overexpressed on the surface of cancer cells. The mAb PB-223 was developed through the affinity maturation of mAb NEO-102, a chimeric human IgG1 mAb that specifically targets truncated Core-2 O-glycans, found in colorectal and pancreatic cancers. The binding affinity of PB-223 for its target was improved, compared to NEO-102, by optimizing its VH and VL sequences through Fast Screening for Expression Biophysical Properties and Affinity. PB-223 demonstrated a binding affinity (KD) at least 4-fold lower than NEO-102, indicating stronger tumor binding. IHC analysis also revealed that PB-223 binds to a wider spectrum of tumor tissues compared to NEO-102, but not to normal tissues. PB-223 can be internalized into human cancer cell lines expressing its target. The objective of this study is to develop an ADC utilizing PB-223 for treatment of various human malignancies.
Experimental Design: PB-223 was used for the development of the ADC. Monomethyl auristatin E (MMAE) was used as payload, with mc-vc-PABc serving as the linker. PB-223 was conjugated to the linker-payload through a cysteine-based conjugation method. Drug-to-antibody ratio (DAR) was measured using Size Exclusion Chromatography (SEC)-MS. Flow cytometry was used for binding assessment of the ADC using the ovarian cancer cell line OV90 as the target. Cytotoxicity of the ADC was evaluated through cell viability assays using CellTiter-Glo cell viability Kit using OV90.as target.
Results: Three ADCs were developed: PB-MMAE-2, PB-MMAE-5 and PB-MMAE-6. The DAR for these ADCs were 3.72, 3.92 and 4.15 respectively. We analyzed their target binding capabilities in comparison to PB-223. The results indicated that all three ADCs exhibit similar binding affinity to PB-223. The cytotoxicity of the ADCs was evaluated using the breast cancer cell line SK-BR-3 with Trastuzumab deruxtecan ADC (DS-8201) as positive control. At a concentration of 10nM, DS-8201 inhibited cell proliferation by 82.39%. All three PB-223 ADC effectively killed OV90 cells. At a concentration of 333nM, the percentage of cell killing for PB-MMAE-2, PB-MMAE-5 and PB-MMAE-6 was 82.91%, 84.04% and 83.16%, respectively. In contrast, both human IgG1 and naked PB-223 mAb showed no killing of OV90 cells.
Conclusions: In this study, we developed PB-223 ADCs and evaluated their anti-tumor efficacy using an *in vitro* model. We assessed three PB-223 ADCs: PB-MMAE-2, PB-MMAE-5 and PB-MMAE-6. Our findings highlight the potential of these ADCs as innovative options for treating human carcinomas expressing core 2 O-glycans. Further *In vivo* studies to evaluate the pharmacokinetics and pharmacodynamics are ongoing.

#4784 ADCE-D01: a first in class antibody drug conjugate against urokinase plasminogen activator receptor-associated protein (uPARAP) demonstrates excellent preclinical efficacy and tolerability.

Jonathan H. Wardman[1], Anne Bie[1], Christophe Come[1], Pernille Barkholt[1], Sander van Putten[1], Cecillie Lokke[1], Ida Gregersen[1], Jette Lange[1], Mette Gillberg[1], Mikkel Krogh-Madsen[1], Karen Bannister[1], Thomas Tuxen Poulsen[1], Christoffer Nielsen[1], Lars Engelholm[2], Niels Behrendt[2], Carmel Lynch[1], Pernille Hemmingsen[1], Dominik Mumberg[1]

[1]Adcendo Aps, Copenhagen, Denmark,[2]Copenhagen University, Copenhagen, Denmark

The urokinase plasminogen activator receptor-associated protein (uPARAP, endo180, CD280) is a type-1 membrane protein which acts as an endocytic receptor for collagen. uPARAP binds and internalizes both intact and partially degraded collagens. uPARAP-bound collagen is internalized via clathrin-mediated endocytosis and routed to the lysosome for further degradation, while uPARAP is rapidly recycled to the cell surface. In healthy tissues, uPARAP is expressed in a restricted number of cell types, mostly mesenchymal cell types in tissues characterized by an active matrix turnover such as skin during wound healing and in bone. In contrast, high expression levels of uPARAP are found on malignant cells of various non-epithelial cancers, including soft tissue sarcoma (STS) and osteosarcoma, glioblastoma multiforme and mesothelioma. Recent publications on immunohistochemistry (IHC)-based expression analysis with tumor samples from more than 900 patients[1,2] demonstrate that uPARAP is widely expressed at high levels across most sarcoma subtypes. The efficient internalization of uPARAP combined with the highly prevalent expression in non-epithelial tumors makes it a very attractive antibody-drug conjugate (ADC) target for the treatment of sarcomas. ADCE-D01 is a first-in-class uPARAP-ADC composed of a humanized anti-uPARAP IgG1 monoclonal antibody conjugated via a GFGG tetra-peptide linker moiety to the Topoisomerase I inhibitor P-1021 payload[3] at a drug-to-antibody ratio (DAR) of 8. ADCE-D01 binds with high affinity to human recombinant uPARAP protein and multiple uPARAP positive cell lines. Binding of ADCE-D01 to uPARAP on the cell surface triggers internalization, resulting in intracellular payload release, induction of DNA damage and cell death. In addition, ADCE-D01 induces potent bystander cytotoxicity in uPARAP negative cells. *In vivo*, ADCE-D01 shows strong anti-tumor efficacy in a range of mesenchymal solid tumor models including soft-tissue sarcoma and is well tolerated in non-human primate toxicology studies with no evidence of target-specific toxicity. In summary, ADCE-D01 constitutes a novel First-in-Class ADC targeting uPARAP with an excellent therapeutic as well as safety profile. A phase I/II clinical study of ADCE-D01 in patients with advanced STS is imminent. [1]Barkholt et al., *Cancer Res* (2024), (6_Supplement): 6355; [2]Evans et al., *Mol Cancer Ther* (2023); [3]Lin et al., J Transl Med (2024)

#4785 Preclinical characterization of the anti-tumor activity of the investigational anti-B7-H3 antibody-drug conjugate (ADC), vobramitamab duocarmazine (vobra duo), in pediatric sarcomas (pSC).

G. Bianchi, G. Rolandi, F. Pastorino, D. Segalerba, N. Pedemonte, V. Tomati, E. Ciampi, **M. Ponzoni**, C. Brignole;
G. Gaslini Children's Hospital, Genova, Italy

Background: pSC are a heterogeneous group of rare bone and soft tissue malignancies. Vobra duo (MGC018, MacroGenics, Inc., Rockville, MD, USA) is a duocarmycin-based ADC directed against B7-H3 that showed clinical anti-tumor activity in adults as well as preclinical activity in neuroblastoma.

Materials and methods: A panel of human pSC cell lines expressing B7-H3, as assessed by flow cytometry, was used. Cytotoxicity, in response to vobra duo, was evaluated in 2D and 3D models. Proliferation was assessed by using the Livecyte instrument. Apoptosis was investigated by annexin V assay. Cell signaling focused on PI3K and its downstream effectors involved in cell proliferation, AKT and S6K, was investigated by phospho-specific western blot assays. The expression of ULK-1, ATG13, LC3A-I, LC3A-II, and LAMP-1, all genes involved in autophagy and lysosomal metabolism, was also studied. An *in vivo* experiment was carried out in athymic nude mice inoculated sub cutaneously with a rhabdomyosarcoma cell line.

Results: *In vitro,* treatment with vobra duo induced a time-dependent reduction in cell viability in both monolayer and 3D cell culture models. Automated tracking of single-cell proliferation showed that vobra duo led to a significant increase in the doubling time of treated cells compared to untreated ones. A change in cell morphology, underlined by a significant increase of the cell area of vobra duo-treated cells, was observed. Following treatment with vobra duo, a down-modulation of phospho-AKT and phospho-S6K proteins was observed in both A204 (rhabdomyosarcoma) and U2OS (osteosarcoma) cells, the most treatment-sensitive and resistant lines, respectively, suggesting their potential involvement in the vobra duo-mediated anti-proliferative effect. In response to vobra duo, all cell lines underwent apoptotic cell death, although to a different extent and with different kinetics. A significant increase in executioner cleaved caspase-3 was observed, and a partial, although significant, reversion of apoptotic cell death was noted following pre-treatment with the pan-caspase inhibitor, Q-VD-OP-h. The expression of autophagic machinery's proteins involved in induction, nucleation (ULK-1 and ATG13), elongation and maturation (LC3A-I and LC3A-II) phases, was significantly down-regulated after vobra duo treatment. Moreover, vobra duo significantly affected the expression of the glycosylated form of LAMP-1 protein, a marker of lysosomal membrane integrity and functionality. A single intravenous injection of 3 mg/Kg vobra duo induced a significant tumor growth delay in a mouse rhabdomyosarcoma model.

Conclusions: Vobra duo shows anti-tumor activity toward *in vitro* and *in vivo* models of pSC. Further in depth pre-clinical assessment to support potential clinical application is warranted.

#4786 A humanized monoclonal antibody targeting the Ig-like V1-C1 domains of B7-H3 suppresses the growth of breast cancer.

Fengjuan Zhang, **Qi Zhao**

University of Macau, Taipa, Macao

Breast cancer, characterized by its heterogeneity and complexity, poses a significant threat to life. Current monoclonal antibody drugs for breast cancer primarily target HER2, which is only present in 15%-25% of all breast cancer cases. Recently, immune checkpoint therapy has emerged as a groundbreaking approach to reactivating anti-tumor immune responses. B7-H3 (CD276), a newly identified member of the B7 family, is expressed in various tumor tissues, making it an attractive candidate for therapeutic intervention. Utilizing advanced antibody discovery platforms, we have developed a humanized monoclonal antibody targeting B7-H3. This antibody exhibits specific binding affinity to epitopes in the Ig-like V1-C1 domain and demonstrates significant antibody-dependent cellular cytotoxicity effects on triple-negative breast cancer and trastuzumab-resistant HER2+ breast cells. Furthermore, both HER2+ cell-derived xenograft (CDX) and patient-derived xenograft (PDX) mouse models indicated that this antibody displayed potent in vivo anti-tumor activity. RNA-seq analysis of mouse tumor tissues revealed that the B7-H3 antibody downregulates the MAPK and NF-κB signaling pathways, leading to reduced tumor cell metabolism and migration, as well as diminished inflammation and cytokine release. Our findings indicate that B7-H3 is a viable therapeutic target, supporting the continued development of related therapeutic agents in both preclinical and clinical settings. This work is supported by FDCT/009/2023/RIC.

#4787 BGB-A3055, an afucosylated anti-CCR8 antibody, preferentially depletes intratumoral regulatory T cells and inhibits tumor growth in preclinical models.

Xitao Wang, Yannan Xu, Ming Fang, Ming Jiang, Haolan Li, Mingchao Kang, Xiaomin Song

BeiGene (Beijing) Co., Ltd., Beijing, China

Background: Regulatory T cells (Tregs) is a well-known key immune suppressive cell population enriched in tumor microenvironment (TME) that inhibits the anti-tumor immunity. Accordingly, specific depletion of Tregs in TME is considered as an attractive strategy to enhance the efficacy of immunotherapy such as PD-(L)1 treatment. C-C motif chemokine receptor 8 (CCR8), a G-protein coupled receptor, is predominately upregulated in intratumoral Tregs while CCR8 level in peripheral Tregs is relatively low. Therefore, CCR8 is widely explored as a promising therapeutic target for intratumoral Treg depletion. BGB-A3055 is a novel humanized afucosylated immunoglobulin G (IgG) 1 monoclonal antibody against human CCR8 (hCCR8). Here, we present the in vitro and in vivo data of BGB-A3055 in preclinical models.
Methods: The cellular binding of BGB-A3055 was determined by fluorescence-activated cell sorting (FACS) on 293T cells that overexpress hCCR8 or primary human Treg cells. The blocking activity of BGB-A3055 on CCL1-CCR8 induced signaling was determined by Path Hunter eXpress HuCCR8 CHO-K1ß-Arrestin GPCR Assay kit. Antibody-dependent cellular cytotoxicity (ADCC) effect was evaluated on primary Treg cells. In vivo intratumoral Treg depletion and anti-tumor efficacy was assessed in GL261 and MC38 syngeneic models using hCCR8 knock-in mice.
Results: BGB-A3055 exhibited a potent cellular binding to hCCR8 overexpressing cells and primary human Treg cells. BGB-A3055 can also efficiently block CCL1-CCR8 signaling and induce potent ADCC effect against CCR8 expressing primary Treg cells. Furthermore, in preclinical in vivo models, BGB-A3055 preferentially depleted Tregs in TME, demonstrated potent single agent and synergistic anti-tumor effect in combination with PD-1 antibody.
Conclusions: BGB-3055 is a novel fully humanized afucosylated antibody that has high binding affinity to hCCR8, strong CCL1-CCR8 blocking capacity and potent ADCC effect. BGB-A3055 demonstrated strong anti-tumor activity as single agent or in combination with PD-1 antibody. A Ph1 study evaluating BGB-A3055 alone and in combination with Tislelizumab in participants with solid tumor is ongoing (NCT05935098).

#4788 Discovery of HX035, an OX40-bi-epitope bi-specific antibody (BsAb), for the treatment of inflammatory/autoimmune diseases.

H. Ke[1], T. Yang[1], F. Peng[1], J. Li[1], C. Chen[1], P. Song[2], L. Zhang[1], F. Zhang[1], **H. Q. Li**[1];
[1]Hanx Bio, Hangzhou, China, [2]Crown Bioscience, Taicang, China

With hyperactive $OX40^+CD4^+$ T-cells implicated as the pathogenic cells in various inflammatory/autoimmune disorders, we hypothesized that OX40-antagonistic and/or depleting antibody are both important candidate therapeutics for these diseases. To test this hypothesis, we designed and tested a novel bi-specific antibody (BsAb), HX035 and a 1+1 asymmetric IgG1 mAb, against two different OX40 epitopes. Epitope-1 is featured with non-ligand blocking but strong ADCC (depleting antibody), while epitope-2 is characterized by ligand blocking and antagonistic activity. We found that HX035 binds to recombinant OX40 proteins with the similar binding affinity as the respective parental mAbs, with EC_{50} 0.056 nM (avidity) as opposed to 0.027 nM (epitope 1-mAb) and 0.036 nM (epitope 2-mAb), respectively. Although the binding avidity of HX035 to $OX40^+$ cells is similar to its parental mAbs, HX035 showed more binding to $OX40^{lo}$ and even more to $OX40^{hi}$ cells, as anticipated. HX035 is also an OX40 ligand blocker slightly less potency than the epitope 2-mAb (IC_{50} 5.0 nM vs. 2.6 nM). HX035 also showed similar extent of antagonistic activity to epitope2-mAb in an *in vitro* reporter bioassay. Remarkably, HX035 induced significantly enhanced ADCC over both parental mAbs, making it a stronger depleting antibody than both parental mAbs. We have also further engineered an ADCC-enhanced (5 times stronger) HX035 molecule, so making it an even stronger depleting-antibody. A human PBMC acute graft-versus-host disease (aGVHD) mouse model indeed confirmed the superior anti-aGVHD activities of HX035, over both parental mAbs in the preclinical setting, accompanied with significant depletion of $CD4^+$ T-cells in vivo. All these suggested that HX035 may be a potential “best-in-class” (FIC) candidate for the treatment of autoimmune diseases.

#4789 Development of IMC-002, a next-generation anti-CD47 mAb: an affinity optimized antibody with enhanced safety and therapeutic efficacy in preclinical models.

Jiyea Choi, Ji-Eun Park, A-Ra Jeon, Heewook Shin, Yeonsun Yu, HyeHyeon Jang, Hyesun Lee, Jiyoung Yoon, Sung Ho Kim, Heung Tae Kim

ImmuneOncia Therapeutics, Seoul, Korea, Republic of

CD47, a broadly expressed transmembrane glycoprotein, interacts with SIRPα to inhibit macrophage-mediated phagocytosis. Its overexpression on cancer cells is associated with poor prognosis, making the CD47-SIRPα axis a promising target for cancer immunotherapy. While blocking this pathway enhances macrophage-driven anti-tumor responses, clinical translation is hindered by challenges such as hematological toxicity and rapid drug clearance due to CD47 expression on normal cells, including red blood cells.IMC-002, a fully human IgG4 monoclonal antibody targeting CD47, was screened for an optimized affinity to balance therapeutic efficacy and safety. Comparative studies with Hu5F9 and 13H3 demonstrated IMC-002's enhanced selectivity and unique binding profile. In a tumor-RBC co-culture system, IMC-002 exhibited superior binding to CD47+ tumor cells while showing significantly reduced binding to normal cells, including RBCs, platelets, and CD3+ immune cells, compared to Hu5F9. The tumor selectivity and lack of binding to CD47 on RBCs by IMC-002 appear to result from differences in its binding site. Studies investigating the roles of CD47 clustering, Rh complex, Integrin β1, lipid rafts, and glycosylation revealed that O-glycosylation significantly influences IMC-002's selective binding to CD47. Antibody structure simulations and antigen binding docking analyses confirmed that IMC-002 engages distinct epitopes and adopts a unique binding orientation compared to Hu5F9. Supporting this mechanism, enzymatic removal of O-glycans on RBCs in vitro increased IMC-002 binding, and in-silico epitope mapping identified an O-glycosylation site within the predicted binding region. We evaluated the therapeutic potential of IMC-002 in various solid tumor models through both in vitro and in vivo studies. In vitro functional assays demonstrated that IMC-002 significantly enhanced macrophage-mediated phagocytosis of tumor cells, both as a monotherapy and in combination with standard of care (SoC) treatment. In vivo, IMC-002 exhibited dose-dependent anti-tumor activity in mouse models of triple-negative breast cancer (TNBC), hepatocellular carcinoma (HCC), and biliary tract cancer (BTC). Furthermore, in non-human primates, IMC-002 was well-tolerated, with no hematological toxicity observed at doses up to 100 mg/kg, and exhibited a pharmacokinetic profile consistent with typical therapeutic antibodies. In conclusion, IMC-002 demonstrated exceptional efficacy and safety, attributed to its unique binding site and mechanism of action. These findings provide strong support for its clinical development as a cancer therapeutic. Phase 1a trials confirmed IMC-002's superior safety profile, and ongoing Phase 1b trials are evaluating its efficacy in combination with standard-of-care therapies in patients with HCC and TNBC.

#4790 Immunostimulatory effects of GENA-104A16, a monoclonal anti-CNTN4 antibody, on tumor-infiltrating lymphocytes in a colon cancer liver metastasis model.

Hyunkyung Yu[1], Taebum Lee[2], Gyeongyeon Kim[1], Sanghoon Song[2], Youngeun Ha[1], Soo Ick Cho[2], Kitae Park[1], Hyunuk Kim[1], Mi Young Cha[1]

[1]Genome & Company, Sungnam-si, Gyeonggi-do, Korea, Republic of,[2]Lunit, Seoul, Korea, Republic of

Introduction: Immune checkpoint inhibitors (ICIs) have significantly improved response rates and survival, becoming a cornerstone in the treatments for various cancers. ICIs are effective when their target immune checkpoints, most notably PD-L1, are expressed in tumor cells, and are less effective when they are not. CNTN4 is a novel immune checkpoint expressed independently to previous targets of ICIs. GENA-104A16, a humanized anti-CNTN4 IgG4 (S228P) antibody, binds to CNTN4 on tumor cells and blocks its interaction with amyloid precursor protein (APP) on T cells. This disruption neutralizes immune-suppressive activity and enhances anti-tumor immune responses. This study aimed to further investigate the immunostimulatory effects of GENA-104A16 in a colon cancer liver metastasis model, which is known to recapitulate the resistance of ICIs.

Method: CT26 mouse colon cancer cells overexpressing mCNTN4 (CT26/Cntn4) were inoculated into the spleen. One day later, mice were treated with either isotype control (n=10), GENA-104A16 (n=10), or atezolizumab (n=9) via intraperitoneal injection (3 mg/kg) on a q3d schedule. On Day 11 post-inoculation, animals were sacrificed, and livers were harvested for formalin fixation and paraffin embedding preparation. Tumor-infiltrating lymphocytes (TILs) within hepatic tumor nodules were analyzed using an artificial intelligence (AI)-powered immunohistochemistry (IHC) analyzer applied to CD4 or CD8 stained liver sections containing tumor nodules. $CD4^+$ or $CD8^+$ TILs within the hepatic tumor area were quantified on whole slide images both as a percentage (%) of total cells and by cell density.

Results: GENA-104A16 treatment significantly increased $CD4^+$ T cells as well as $CD8^+$ T cells in both metrics ($CD4^+$ %: 17.5, $CD4^+$ density: 1470; $CD8^+$ %: 12.6, $CD8^+$ density: 1124) compared to isotype control ($CD4^+$ %: 10.0, $CD4^+$ density: 760; $CD8^+$ %: 7.0, $CD8^+$ density: 615). Meanwhile, atezolizumab treatment did not significantly increase TILs (CD4+ %: 14.0, $CD4^+$ density: 1056; $CD8^+$ %: 6.7, $CD8^+$ density: 587) in the current model, which showed similar expression levels of CNTN4 and PD-L1. Notably, an inverse correlation trend was observed between TILs quantification and tumor nodule count across all samples, regardless of the treatment group.

Conclusions: Our findings demonstrate a significant increase in $CD4^+$ and $CD8^+$ TILs following treatment with GENA-104A16 in a clinically relevant model, suggesting a potential for enhanced anti-tumor immunity. These results support the clinical evaluation of GENA-104A16 and underscore the potential of TILs quantified by an AI-powered IHC analyzer as a predictive biomarker for its therapeutic efficacy.

#4791 Immunosuppressive myeloid cells can be modulated with NRP2-targeting antibody ATYR2810 leading to enhanced anti-tumor immunity.

Christoph Burkart[1], Clara Polizzi[1], John Hyunkuk Choi[2], Max Pastenes[1], Alison Barber[1], Michael Lim[2], Leslie Nangle[1]

[1]aTyr Pharma Inc., San Diego, CA,[2]Department of Neurosurgery, Stanford School of Medicine, Stanford, CA

Introduction: A major obstacle for many cancer immunotherapies is intrinsic or acquired resistance to treatment. Myeloid-derived immune cell populations such as myeloid-derived suppressor cells (MDSCs) and tumor associated macrophages (TAMs) are promoting an immunosuppressive tumor environment. This limits the effectiveness of current cancer immunotherapies. When activated, myeloid lineage immune cells express high levels of Neuropilin2 (NRP2), a single pass transmembrane protein. NRP2 forms heterodimeric complexes with other membrane receptors such as VEGF receptors, plexins and integrins. In experimental models of immune disease, NRP2 has demonstrated anti-inflammatory effects. However, the role of NRP2 on immune cells in the context of tumor biology is largely unknown.
Results: NRP2 expression is upregulated on myeloid cells in an experimental model of acute lung injury and can be detected on myeloid cells in syngeneic tumor models. In experimental models of immune diseases like atopic dermatitis and collagen-induced arthritis, NRP2-deficient mice show a stronger immune response and worse pathology. Blocking NRP2 with a monoclonal antibody (ATYR2810) in a syngeneic, orthotopic mouse model of glioblastoma (GBM), resulted in anti-tumoral polarization of myeloid cells and a significant increase in overall survival. Additionally, in syngeneic tumor models with a large immunosuppressive myeloid population, ATYR2810 treatment improved the effectiveness of checkpoint inhibition via anti-PD-1.
Conclusions: Here we demonstrate that NRP2 is a negative regulator of the inflammatory response and is highly expressed on immunosuppressive myeloid cells in the tumor environment. Blocking NRP2 with ATYR2810 was effective as a single therapy and when combined with checkpoint inhibition in syngeneic tumor models with a high prevalence of MDSCs. This suggests that modulating NRP2 offers a new approach to targeting and reversing the immunosuppressive function of myeloid cells in the tumor microenvironment.

#4792 Highly specific GLUT-1 inhibiting antibodies for the treatment of pancreatic cancer.

Siret Tahk[1], Paule Hermet[1], Kyumhyuk Kim[2], Takefumi Morizumi[2], Anu Ustav[1], Kai Virumae[1], Robin Pau[1], Korneelia Anton[1], Alastair J. King[3], Francisca Neethling[3], Andres Mannik[1], Joan Teyra[1], Oliver Ernst[2], **Mart Ustav**[1]

[1]Icosagen Cell Factory OU, Kambja, Estonia,[2]University of Toronto, Toronto, ON, Canada,[3]Eurofins Discovery, St. Charles, MO

Background: Cancer cells often exhibit upregulated glucose metabolism to support their abnormal growth and division. Targeting the cancer-specific glucose transporter GLUT-1 offers a promising strategy to limit glucose uptake and disrupt tumor metabolism. Unlike small molecule inhibitors, monoclonal antibodies provide a unique opportunity to selectively target complex multi-pass membrane transporters. This study presents the development of highly specific antibodies that recognize GLUT-1 glycovariants, effectively blocking GLUT-1 function in cancer cells while preserving glucose transport across the blood-brain barrier.

Methods: GLUT-1-specific monoclonal antibodies were generated using GLUT-1-displaying virus-like particles (VLPs) as immunogens. Chickens were chosen for immunization due to their ability to produce antibodies against highly conserved multi-transmembrane proteins. Antibody discovery was conducted using HybriFree B cell cloning technology and phage display. Functional screens included assays for 2-deoxyglucose uptake inhibition and cancer cell proliferation.

Results: The identified antibodies bind GLUT-1 with nanomolar EC50 values and exhibit no cross-reactivity with other glucose transporters. The lead candidate, ICO-33, inhibits glucose uptake and reprograms GLUT-1-dependent cancer cells to rely on oxidative phosphorylation (OXPHOS). This metabolic shift synergizes with OXPHOS inhibitors, resulting in significant cancer cell growth inhibition at doses subtherapeutic as monotherapies. In vivo, the combination of ICO-33 and an OXPHOS inhibitor was well-tolerated and led to substantial tumor growth suppression in colorectal and pancreatic cancer models. Importantly, ICO-33 preserves glucose uptake in the brain, minimizing systemic toxicities.

Conclusions: This study highlights the discovery of GLUT-1-targeting monoclonal antibodies with high specificity and efficacy. The lead antibody, ICO-33, effectively restricts glucose uptake in cancer cells and enhances sensitivity to OXPHOS inhibitors, demonstrating its potential as a candidate for clinical development in cancer therapy.

#4793 BCG033: a first-in-class PTK7×TROP2 bispecific ADC demonstrating potent and broad efficacy in various preclinical models.

Lillian Ma, Na Zhang, Chengzhang Shang, Yi Yang

Biocytogen, Waltham, MA

TROP2 is frequently overexpressed in a number of epithelial cancers, and therapeutics targeting TROP2 has demonstrated clinical efficacy in multiple indications, including triple-negative breast cancer (TNBC), HR+/HER2- breast cancer, and non-small cell lung cancer (NSCLC). However, its broad expression in normal tissues raises the risk of on-target and off-tumor toxicity, potentially limiting the therapeutic effectiveness. PTK7 has emerged as an alternative target, exhibiting high prevalence and overexpression in a variety of tumors, such as TNBC, NSCLC, ovarian, oesophageal and colorectal cancers.

BCG033 is a bispecific antibody-drug conjugate (ADC) that targets both PTK7 and TROP2, enhancing the therapeutic efficacy while reducing the off-target effects. Developed using Biocytogen's fully human common light chain RenLite® mice, BCG033 is conjugated with BLD1102--a novel linker/payload containing a DNA Topoisomerase I inhibitor paired with a highly hydrophilic, protease-cleavable linker, achieving an optimal drug-to-antibody ratio (DAR) of 8.

Structurally, the backbone of BCG033 consists of a bivalent antibody with two monovalent components that separately target PTK7 and TROP2, which are engineered to minimize internalization and improve tumor selectivity. BCG033 backbone antibody demonstrates strong binding activity under varying PTK7 and TROP2 expression levels in tumors, and exhibits promising developability under stress force degradation.

In proof of concept studies, BCG033 AB-vcMMAE showed synergistic effect and enhanced activity compared to the parental ADCs in both cell line-derived xenograft (CDX) and patient-derived xenograft (PDX) models of TNBC, even with low PTK7 expression. When conjugated with Biocytogen's linker/payload BLD1102, BCG033 demonstrated superior efficacy across varying PTK7 and TROP2 expression levels in PDX models and consistently outperformed benchmark ADCs in multiple tumor models, including NSCLC, TNBC, gastric cancer, and colorectal cancer.

In summary, BCG033 demonstrates promising potential for delivering potent and broad anti-tumor activity across a range of solid tumors, offering broad clinical application opportunities.

#4794 Anti-VEGF x 4-1BB bifunctional AND-Body combines VEGF blockade and allosteric 4-1BB mechanism for sustained activation of adaptive and innate anti-tumor immunity.

Xiaofei Zhou, Michelle Yen, Joseph R. Brady, Oliver Yvon, Marwa Bsat, Kyriakos D. Economides, Daniel Blom

Ampersand Biomedicines, Boston, MA

Background: Bifunctional therapeutics that combine synergistic mechanisms in a single molecule (e.g., anti-PD-1/VEGF) have recently shown great promise in the clinic. The potent co-stimulatory receptor 4-1BB represents a powerful pathway to apply these bifunctional mechanisms, where growing evidence supports a unique ability to drive sustained activation of both adaptive and innate immunity. We leveraged our AND-Body platform to develop a novel anti-VEGF x 4-1BB bifunctional therapeutic, which simultaneously blocks VEGF and triggers allosteric activation of the 4-1BB pathway in the tumor, thereby increasing the therapeutic window. In preclinical models, tumor VEGF drives potent 4-1BB agonism in a cis/paracrine mechanism, enhancing tumor killing and mitigating systemic activity in tissues where VEGF levels are low. This represents a new approach to bifunctional cancer therapeutics.

Methods: The VEGF x 4-1BB bifunctional was evaluated in humanized 4-1BB transgenic mice harboring MC38 or B16F10 tumors and compared to aflibercept and urelumab. Tumor growth, survival rates, immune cell infiltration, and adverse events were assessed, including scRNA sequencing of tumor-infiltrating lymphocytes. The molecule was also tested in combination with anti-PD-1.

Results: The AND-Body robustly activated 4-1BB signaling only at high concentrations of VEGF *in vitro*. Monotherapy induced durable, localized anti-tumor immunity in MC38 and B16F10 models, leading to enhanced survival, and 90% of animals were tumor-free upon re-challenge with MC38 vs. 47% in the urelumab group. Combination therapy with anti-PD-1 showed additive benefit with 100% tumor-free survival in the MC38 model and extended survival in B16F10 tumor-bearing mice. AND-Body treatment mitigated hepatotoxicity and dermatitis compared to urelumab. Mechanistically, VEGF x 4-1BB bifunctional promoted progenitor exhausted T cell expansion and enhanced M1 macrophage differentiation distinct from other immune checkpoint inhibitors. Treatment normalized the TME, promoting aerobic respiration, preventing T cell exhaustion, and supporting sustained anti-tumor immunity.

Conclusions: Anti-VEGF x 4-1BB AND-Body represents a novel bifunctional agent, combining established benefits of VEGF blockade with an allosteric 4-1BB agonist. Potent anti-tumor activity with high therapeutic index was achieved in preclinical models by localizing immune responses via a unique mechanism of action. These studies support advancement to the clinic as a potentially first-in-class candidate for cancer immunotherapy, both as a monotherapy and in combinations.

IMMUNOLOGY: CAR-T Cells
Poster Session

#4798 In vivo generation of universal CAR T cells for targeting heterologous antigens in solid tumors.

Suilan Zheng[1], Bo Huang[1], Sudarshan R. Kasireddy[1], Yashapal Singh[1], Haiyan Chu[2], Madduri Srinivasarao[1], Laurie Beitz[2], Byoung Ryu[2], Andrew Scharenberg[2], Philip Low[1]

[1]Chemistry, Purdue University, West Lafayette, IN,[2]Umoja Biopharma Inc., Seattle, WA

The successes of autologous CAR T cell therapies in treating hematologic malignancies has spurred interest in applying the same approaches for treating solid tumors. However, challenges associated with antigen heterogeneity, CAR T cell exhaustion, cytokine release syndromes, high production costs, and manufacturing complexities have limited their use in solid tumors to date. To address these issues, we have developed a universal CAR expressing a single ScFv against fluorescein (FL) that together with fluorescein-containing bispecific adapters (tumor tags, TTs) can mediate engagement of the universal CAR T cell with multiple other cell types. The TTs that we currently use include UB-TT170 that targets folate receptors (FR) on cancer cells and tumor infiltrating myeloid cells, UB-TT4xx (prostate-specific membrane antigen [PSMA]), UB-TT2xx (carbonic anhydrase IX [CA IX]), and UB-TT5xx (fibroblast activation protein [FAP] on cancer-associated fibroblasts [CAFs]). In this study, we first test various combinations of TTs in a KB tumor model, where FRα and CA IX are expressed on the cancer cells, and FAP is expressed on CAFs. Results from these studies reveal that concurrent administration of two TTs significantly enhances tumor regression relative to injection of only a single TT. Considered together with previous data showing that optimization of TT dosing frequency and concentration can avoid problems associated with CAR T cell exhaustion and excessive cytokine release, we conclude that universal CAR T cells warrant serious consideration as viable alternatives to fixed specificity CAR T cells for treatment of solid tumors. Another challenge limiting CAR T therapies is their high cost of production. To address this limitation, we have employed a surface-engineered lentiviral particle, VivoVec^{TM}, that is currently undergoing development for production of the CAR T cells in vivo to assess whether they can be exploited to generate human CAR T cells by simple incubation in vitro. For this purpose, we have incubated the viral particles for only 1 hour with unmodified human PBMCs and then immediately injected PBMC suspension into MDA-MB-231 tumor-bearing mice. Importantly, injection of these modified PBMCs into NSG tumor-bearing mice led to eradication of their MDA-MB-231 tumors, but only when the mice were subsequently injected with an appropriate TT. Taken together, the data demonstrate that our universal anti-FL CAR T cell can be produced by brief co-incubation of a lentiviral particle with unfractionated PBMCs and that the resulting unprocessed PBMCs can be immediately exploited for eradication of MDA-MB-231 tumors in NSG mice when combined with the appropriate bispecific adapter (TT). The data further suggest that with additional improvements heterogeneous solid tumors might be treated with in vivo manufactured universal CAR T cells if they are co-administered with appropriately selected tumor tags (TT).

#4799 MSLN and MUC1 dual-targeting CAR-T with conditional activation and tumor specificity to improve clinical safety and efficacy.

Jiaguo Li[1], Yan Sun[1], Yong Xia[2], Jinxing Lou[2], Jun Guo[1], Lijie Rong[1], Dan Sun[1], Zhicai Lin[1], Yi Liu[1], Xinhao Wang[3], **Wenfeng Xu**[3], Qijun Qian[1]

[1]Shanghai Cell Therapy Group Co., Ltd, Shanghai, China,[2]Shanghai Mengchao Cancer Hospital, Shanghai, China,[3]Chantibody Therapeutics Inc., Menlo Park, California, Armenia

Background: MSLN and MUC1 are highly expressed in numerous solid tumors, presenting them as potential targets for solid tumor treatment. Nevertheless, these two targets also display varying degrees of expression in important human tissues, at risk of triggering the "on-target off-tumor" effect in CAR-T therapy. Additionally, the tumor immune microenvironment (TME) has a strong immunosuppressive impact on CAR-T cells, making them prone to exhaustion and consequently difficult to exert a long-lasting anti-tumor effect.
Methods: In this study, a dual-targeting CAR-T (designated as BZE2203) for MUC1 and MSLN was generated, validated in pre-clinical and clinical studies. The anti-MSLN VHH was engineered with a pH-dependent characteristic, endowing CAR-T cells with cytotoxicity only at acidic pH in the TME. The anti-MUC1 VHH was selected based on antigen-density dependence to ensure that it has no cytotoxic effect on cells with low MUC1 expression in normal tissues. Meanwhile, the CAR-T was armed with secreting anti-PD1 VHH to alleviate the inhibitory effect of TME on CAR-T cells and tumor infiltrating lymphocytes. Cao-V3 xenograft animal model was utilized to evaluate the safety and efficacy of BZE2203 CAR-T *in vivo*. In an investigator-initiated trial (IIT), patients including two with platinum-resistant ovarian cancer were recruited and infused with a low-dose of BZE2203 CAR-T cells to preliminarily assess the safety and efficacy of this product.
Results: *In vitro* experiments showed that BZE2203 CAR-T cells exerted cytotoxicity on MSLN-positive target cells only in the acidic pH but not neutral pH, and on MUC1-positive tumor cells in a density-dependent manner, but no cytotoxic effect on normal human primary lung cells with low MUC1 expression. After being activated by target cells, CAR-T cells secrete high level of anti-PD1 VHHs. BZE2203 CAR-T showed substantial anti-tumor effect in the Cao-V3 animal model. In the IIT clinical trial, patients did not experience severe safety issues such as cytokine storm and neurotoxicity caused by CAR-T treatment, and two ovarian cancer patients achieved partial remission.
Conclusions: Our results indicate that pH-dependent and antigen-density-dependent CAR-T can mitigate on-target off-tumor toxicities, demonstrating significant potential for improved safety and efficacy in clinical applications of solid tumors.

#4800 Modulation of Th1/Th17 axis through IFNγ-blockade alleviates Anti-CD19 CAR-T associated toxicities in a pre-clinical immune competent model.

Payal Goala[1], Marco Davila[1], Yongliang Zhang[2], Nolan Betty[1], Shannon McSain[1], Sailer Cooper[1], Muhammad Junaid Tariq[1], Showkat Hamid[1]

[1]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[2]Iovance Biotherapeutics, Tampa, FL

CD19-targeted chimeric antigen receptor T cell (CAR-T) therapy for B cell malignancies has led to tremendous improvement in patient survival, yet a subset of patients experience high-grade cytokine release syndrome (CRS) and prolonged cytopenias leading to poor clinical outcomes. Owing to IL2Rα's role in moderating inflammation and supporting Treg survival, we used IL2Rα knockout (KO) mice to emulate the inflammatory conditions that drive CAR-T associated CRS and neutropenia (NP). KO mice injected with a B cell leukemia cell line, followed by CAR-T show elevated levels of IL6 **(p=0.046),** IFNγ **(p=0.006)**, and TNFα **(p=0.048)** in serum compared to WT, which coincided with increase **(p<0.0001)** in CRS causing M1 macrophages (Mϕ) in bone marrow (BM). Onset of CRS was accompanied by a reduction in peripheral blood neutrophils (NEUT) **(p=0.004)** due to a disruption of BM NEUT homeostasis characterized by an increase in apoptotic NEUTs (**p=0.0002)**, and a decrease in proliferative (**p=0.0052)** and mature (**p<0.0001)** NEUTs. Due to the established role of IFNγ in monopoiesis (Mϕ production) over granulopoiesis (NEUTs production), we treated KO mice with IFNγ-/-CD19-CART (IFNγKO-CART) that resulted in restoration of CRS-NP symptoms. Interestingly, IFNγ-blockade restored levels of NEUT regulating cytokine IL-17. In a Th0 to Th1/Th17 in vitro differentiation assay, we noted an increase (**p=0.008**) in Th17 cells and a decrease (**p<0.0001**) in Th1 cells in the presence of IFNγKO-CART compared to CAR-T. KO mice treated with CAR-T and adoptively transferred Th17 cells displayed a significant recovery of CRS-NP symptoms with improved survival **(p=0.002)**. Conversely, KO mice treated with IFNγ KO-CART and adoptively transferred Th1 cells reversed the benefit of IFNγ blockade on CRS-NP by triggering polarization of M1 Mϕ **(p=0.048)** that significantly reduced their survival **(p<0.0001).** Serum analysis of 27 patients diagnosed with hematologic malignancies and treated with standard of care CAR-T products showed that CRS-NP patients had a decline in IL-17A levels post CAR-T therapy **(p=0.049),** compared to non-CRS-NP patients. Furthermore, CRS-NP patients had higher baseline levels of IL-17A, typical of KO mice, putatively serving as a biomarker for CRS (Area under the curve of receiver operator characteristic curve, **ROC-AUC=0.773**) and prolonged NP (**ROC-AUC=0.821**). Our study shows that Th1-Th17 imbalance under inflammatory conditions triggered by CAR-T cells drive CRS-NP in an IFNγ-dependent manner. Finding ways to fine-tune IFNγ release during CAR-T therapy will benefit B-ALL patients by reducing their chances of developing toxicities without compromising their anti-tumor efficacy. To this end, single-cell sequencing analyses are being conducted of BM mononuclear cells of KO mice treated with CAR-T, IFNγKO-CART, CAR-T+Th17, and IFNγKO-CART+Th1 to identify sources of IFNγ production.

#4801 T-bet overexpression promotes CAR T cell potency and responsiveness to low antigen density leukemia.

Jennifer M. Cimons, Kole R. Degolier, Samuel D. Burciaga, M. Eric Kohler, Terry J. Fry

The University of Colorado School of Medicine, Aurora, CO

Data from our lab and others have demonstrated that CAR T cells, contrary to canonical T cell subsets, form populations that appear to be a mixed Th1/Th2 phenotype and produce both IFNγ and IL-4. IL-4 has been shown to have immune-suppressive functions, whereas CAR T cell-derived IFNγ has been shown to promote anti-tumor responses by bolstering CAR8 cytotoxicity and promoting the activation and function of endogenous immune cells. We sought to diminish the Th2-like phenotype and boost CAR T cell potency by overexpressing T-bet, a transcription factor that is essential for Th1 differentiation of CD4 T cells and promotes effector functions in CD8 T cells. We tested overexpression of T-bet in 2nd generation CD19 CAR T cells (1928z and 19BBz) and found that T-bet reduced production of IL-4, demonstrating successful redirection to a Th1/Tc1 fate. Production of IFNγ, TNFα, and IL-2 were enhanced with T-bet overexpression, especially against leukemia cells expressing low levels of CD19 (CD19lo). T-bet overexpression also improved polyfunctional cytokine secretion from these CAR T cells. Furthermore,1928z and 19BBz CAR T cells showed increased effector functions, and degranulated and proliferated at higher rates against CD19lo leukemia when T-bet was overexpressed. To determine the impact of T-bet overexpression on CAR T cell efficacy *in vivo*, we adoptively transferred CAR+ T cells co-transduced to express a 1928z or 19BBz CAR with T-bet-EGFR or an EGFR only control into NSG mice engrafted with WT NALM6 leukemia expressing high levels of CD19. T-bet overexpression negatively impacted leukemia burden and survival of mice treated with 1928z CAR T cells. However, T-bet overexpression had no significant impact on the *in vivo* efficacy of 19BBz CAR T cells against WT leukemia. Since CD28-containing CAR T cells are known to signal with a higher intensity than 4-1BB-containing CAR T cells, we hypothesized that T-bet overexpression may be beneficial only in the context of suboptimal antigen receptor signaling. To this end, we tested the impact of T-bet overexpression on CAR T cell responses against CD19lo leukemia, as downstream CAR signaling is reduced against low-antigen target cells. We found that T-bet overexpression did not significantly affect the leukemia clearance or survival of mice engrafted with CD19lo leukemia treated with 1928z CAR T cells. However, T-bet overexpression enhanced the leukemia clearance and survival of mice engrafted with CD19lo leukemia treated with 19BBz CAR T cells. Together, this data supports a model in which the impact of T-bet overexpression on CAR T cell efficacy is dependent on the CAR signal intensity, with T-bet enhancing responses of CAR T cells receiving a low-intensity signal. Thus, we demonstrate T-bet overexpression as a viable therapeutic strategy to enhance 4-1BB- co-stimulated CAR T cell responses to low-density antigens, overcoming a well-known obstacle limiting CAR T cell efficacy.

#4802 CAR-T cell therapy workflow for discovery and development.

David Cobeta Lopez[1], Benita Quist[1], Sara Compte Sancerni[1], Sophie Vermond[1], Namrata Jayanth[1], Monika Hiller[1], Lauren Schewitz-Bowers[2], Daniel Rocca[2], Robert Nunan[2], Louise Brackenbury[2], Rhiannon Griffiths[3], Mark Aspinall O'Dea[3], Eva Oswald[4], Julia Schueler[4], Renny Feldman[5], Sabrina de Munnik[1], **Gemma Moiset**[1]

[1]Charles River Laboratories, Inc., Leiden, Netherlands,[2]Charles River Laboratories, Inc., Portishead, United Kingdom,[3]Charles River Laboratories, Inc., High Peak, United Kingdom,[4]Charles River Laboratories, Inc., Freiburg, Germany,[5]Charles River Laboratories, Inc., South San Francisco, CA

Engineered T cell therapies such as Chimeric Antigen Receptor (CAR) T cells and T cell receptor (TCR)-engineered T cells have emerged as a promising therapy. To date, seven CAR-T cell products have been approved by the FDA for the treatment of hematological malignancies and many more products are currently being explored for other therapeutic areas such as autoimmune diseases. Due to its innovative nature and the complex biology involved, CAR-T cell therapy product development can face many challenges. While most CAR programs rely on precursor molecules (scFv or VHH) affinity screening, this has proven to not always correlate best to the derived CAR-T activity observed in vivo. However, screening many CAR constructs in primary T cells is associated with lengthy timelines and high costs for their production. To overcome current limitations and streamline the lead selection, Charles River Laboratories offers alternative screening methodologies. Using Jurkat cells as a reporter cell line, plasmids encoding any number of CAR constructs can be transfected and transiently expressed. Afterwards, the CAR-Jurkat cells activation can be measured by the increased expression of CD69 upon co-culture with cells bearing the target of interest. This approach better mimics the cell-to-cell interactions critical for the CAR-T cell therapy function and allow for a more physiologically relevant ranking of the CAR constructs, aiding the selection of the lead candidate with higher success chances. Furthermore, the lack of pharmacologically relevant animal models emphasizes the need to evaluate the safety of CAR-T cell therapy products in vitro. An important step is the identification of potential off-target binders, where the Retrogenix cell microarray technology can be used for the selection and characterization of leads. Additionally, we have developed in vitro co-culture assays using a wide variety of primary or iPSC-derived human cells (representing various tissues including vital organs) to assess potential off-target and on-target/off-tumor effects. A different safety concern to take into consideration is to determine the CAR vector copy number (VCN) and insertional sites and to identify potential insertional mutagenesis effects after introducing the CAR cassette. Lastly, the cells can be tested in vivo to assess their efficacy in a more representative system and gain insights in their bio-distribution, homing sites, prevalence, and differentiation. In conclusion, we have developed a complete workflow to screen CAR candidates in a surrogate model reducing the costs and timelines for CAR-T cell therapies development funneling down the number of CARs to be tested in the in vitro safety and in vivo studies, that would support Investigational New Drug application in accordance with the regulatory agencies' requirements.

#4803 Adaptation of headless CAR T cells to tumor microenvironment induces enhance proliferation and anti-tumor activity against solid cancers.

Archana Thakur[1], Amy Schienschang[1], Sarah Whitaker Amrhein[1], Yelena Bronevetsky[2], Shannon Eaker[2], Lawrence G. Lum[1]

[1]University of Virginia, Charlottesville, VA,[2]Xcell Biosciences Inc, San Francisco, CA

Cell therapy in solid tumors faces significant challenges due to the suppressive tumor microenvironment (TME), characterized by hypoxia and high interstitial pressure. These conditions affect gene and protein expression, contributing to tumor metastasis and drug resistance. Hypoxia dampens the anti-tumor T cell response by altering immune cell activation and function by modulating metabolic activity and the presence of immune suppressive cytokines, growth factors, and immune checkpoint molecules. The success of chimeric antigen receptor (CAR) T cell therapy in treating several hematopoietic malignancies has been challenging to replicate in solid tumors, in part because of T cell exhaustion and eventual T cell dysfunction. T cell reprogramming to adapt to TME is likely to represent a novel and essential aspect of enhancing anti-tumor activity in the TME. We used the Avatar and Avatar AI incubators (Xcell Bio) to precisely control oxygen concentration and pressure to simulate TME conditions to reprogram the headless CAR T cells (hCART). Bispecific antibody armed (ahCART) or unarmed (hCARTs) headless CAR T cells were acclimated under normal environment (NE) or TME conditions before coculturing with target cells. The effect of NE or TME conditions was determined on T cell proliferation, phenotypic changes, and functional activity of hCARTs. Functional readouts were measured by real-time cytotoxicity assay and cytokine profiles under NE or TME-like conditions (1-5% O_2 + 2-5 *PSI* pressure). The phenotypic changes of ATC and hCARTs showed no changes in co-stimulatory receptor expression (41BB, CD40L, GITR, HVEM, ICOS, NFATc1, and TBET) on CD4 or CD8 T cells and co-inhibitory receptors (LAG2, LAIR, PD1, TIGIT, CTLA-4, FOXP3, GATA3 and BTLA) on CD8 T cells, except for reduced expression of certain co-inhibitory receptors on CD4 T cells under TME condition compared to NE condition. Acclimation of hCARTs under TME showed a delayed, but 100% cytotoxicity prolonged up to 7 days at low effector to target ratios of 1:1 or 2:1; non-acclimated hCART showed 100% cytotoxicity initially but declined in long-term or serial killing assays. There was no effect of TME preconditioning on cytokine profile (IL-2, GM-CSF, IFN-γ, TNF-α, and IL-6) compared to NE on hCART. These data suggest that TME reprogramming of hCARTs could be a promising approach to improve its effectiveness, especially in solid tumors. TME acclimation has the clinical potential to enhance the anti-tumor activity of cellular therapeutics.

#4804 RNA binding proteins in CAR-T armoring: Reprogramming T cells for tumor killing.

Augustin B. Biswas[1], Martin Turner[2], Romain Lara[1]

[1]Discovery Sciences, BioPharmaceuticals R&D, Astrazeneca PLC, Cambridge, UK, United Kingdom,[2]The Babraham Institute, Babraham Research Campus, Cambridge, UK, United Kingdom

Background: CAR T cell therapy uses genetically engineered T cells to express a chimeric antigen receptors (CARs) that trigger detection and killing of target tumor cells. It has been previously shown that a functional screen of mouse RNA binding proteins (RBPs) identifies genes that regulate the abundance of activated plasma cells. Deletion of specific RBP genes was shown to increase the potency of effector CD8 T cell functions. We hypothesized that these observations can be translated as an armoring approach to improve human CAR-T cell functions.
Methods: We performed cytotoxicity assays based screening using Her2 CAR T cells with or without 46 RBP knockouts in co-culture with Her2 expressing target cells. The co-culture were set up at a low E:T ratio of 1:32 to evaluate the effect of RBP KO on CAR-T cell exhaustion through engagement in multiple rounds of target cell killing. We validated the modulation of killing with time-course experiments using several Her2 cell lines as HCC-1954, SKOV-3 as well as a control Her2-KO HCC-1954 cell line. We further evaluated the relevance of these findings using patient derived organoid models co-cultured with CAR-T cells bearing specific RBP KOs.
Results: Our screen identified several RBPs which upon deletion enhanced Her2 CAR T killing similarly to Med12 deletion which was previously identified as a CAR-T cell armouring candidate. NGS sequencing and FACS analysis validated the KO efficiencies in CAR Ts used for co-culture. Intracellular flow cytometry prior to co-culturing showed that certain CAR T KOs exhibited higher expression of Interferon gamma, Granzyme B and Perforin 1. RBP KOs in CAR Ts also showed increased killing of patient derived organoids in co-culture.
Conclusion: Our findings suggest that KO of RBPs may be a good strategy to enhance CAR-T cell cytotoxic function and persistence. They suggest the importance of RBPs as a novel class of armoring targets for CAR-T cell enhancement.

#4805 Dual-target CAR-T strategy for MSLN and CLDN18.2: Advancing cancer treatment with superior efficacy and safety.

Shasha Yang, Kai Wu, Zhongjun Shi, Jiantao Wang, Xuefeng Kong, Huajing Wang, **Xiaowen He**

Oricell Therapeutics Co., Ltd., Shanghai, China

Background: CAR-T-cell therapy has achieved great success in the treatment of hematological malignancies. However, due to the characteristics of solid malignant tumors, CAR-T for solid tumors is still in the exploration stage. The restricted expression of MSLN and CLDN18.2 in normal tissues, combined with their abnormal overexpression in various tumor tissues, makes them highly promising targets for CAR-T therapy. Although targeting CLDN18.2 demonstrates significant therapeutic potential, its application in CAR-T therapy carries the risk of gastrointestinal (GI) toxicities, due to on-target/off-tumor adverse effects. MSLN and CLDN18.2 are not co-expressed in normal human tissues but are simultaneously overexpressed in various tumor tissues, including gastric and pancreatic cancers,both with limited treatment options and poor prognoses.

Methods: Considering that CLDN18.2-BBZ exhibited gastrorrhagia toxicity in our preclinical mouse models, we designed OriC613 using “AND” logic gate, aiming to improve safety while maintain anti-tumor efficacy. OriC613 employing an anti-CLDN18.2 scFv with high binding activity and an anti-MSLN V_HH with moderate binding affinity, eliciting completely activation only targeting MSLN&CLDN18.2 double positive tumor cells.

Results: OriC613 exhibits more potent *in vitro/vivo* cytotoxicity efficacy against MSLN&CLDN18.2 double positive cells than MSLN-CD3Z, and IFN-γ and IL-2 released by OriC613 were positively dependent on MSLN and CLDN18.2 expression levels. Notably, OriC613 demonstrated no cytotoxicity towards cells expressing CLDN18.2 alone, both *in vitro* and *in vivo*, indicating mitigate the toxicity toward CLDN18.2 positive normal stomach cells. OriC613 exhibited efficacy, prolonged survival and no GI toxicities in tumor stress model (NUGC-4 cells, $MSLN^{low}CLDN18.2^{med}$), even when targeting relatively large (976 mm^3) tumor sizes, indicating its potential effectiveness in patients with high tumor burden. OriC613 showed efficacy, re-enhanced production of IFN-γ and T cell expansion in a tumor re-stress model for pancreatic cancer (AsPC-1-hCLDN18.2 cells, $MSLN^{low}CLDN18.2^{high}$), with T cells homing to bone marrow and spleen (at Day 115, endpoint). These findings demonstrate that OriC613 enhance both the safety and the effectiveness and persistence of its anti-tumor activity.

Conclusions: The impressive antitumor effects and promising safety of OriC613 highlight the need for continued clinical trials in pancreatic and gastric cancer patients.

#4806 CAR binders affect CAR T cell tonic signaling, durability, and sensitivity to target.

Divanshu Shukla[1], Khatuna Gabunia[1], Shannon E. McGettigan[1], Prachi R. Patel[1], Shannon Christensen[1], Ting Jia Fan[1], Decheng Song[1], Yanping Luo[2], Yanling Wang[2], Huaishan Wang[2], Regina M. Young[1], Carl H. June[1], John Scholler[1], James L. Riley[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]Tmunity Therapeutics/Kite Pharma, Philadelphia, PA

Patients can develop human anti mouse immune responses against CD19- specific CAR T cells (CARTs) due to the use of a murine scFv to redirect T cells. To mitigate immunogenicity, a humanization process of the FMC63- based binder was undertaken that resulted in a CAR (119) that when introduced into T cells showed improved activity in a humanized mouse model. To further characterize how binding domains affect CART function, we screened a yeast display library to identify an array of fully human CD19 scFv binders. We saw significant differences in the ability of CARs employing these CD19 binders to be expressed on the cell surface, induce tonic signaling, redirect T cell function, mediate tumor killing, recognize lower levels of CD19 antigen, and maintain function upon continuous antigen exposure. From this in vitro analysis, CARTs using binders 42 and 52 were selected to be evaluated in a humanized mouse model. Here, we observed that CARTs using both 42 and 52 binders controlled the initial tumor burden and prevented tumor establishment upon rechallenge. We advanced a CAR construct using binder 42 for more advanced preclinical testing due to its greater similarity to FMC63 based binders and ability to robustly respond to tumors expressing lower levels of CD19. We found that this binder uniquely bound CD19 using distinct contact residues than FMC63 with ~40-fold lower affinity. Combined with their potential for less immunogenicity and comparable in vivo activity, CARTs using the 119 or 42 binder should be considered for clinical use.

#4807 Claudin-3-targeting CAR-T using C-terminal domain of Clostridium perfringens enterotoxin for TKI-resistant EGFR-mutated NSCLC.

O. Kwon[1], Y. Joo[1], Y. Lee[1], S. Jeon[1], J. Kim[1], H. Lee[1], M. Yun[2], B. Cho[3];

[1]Yonsei University College of Medicine, Department of Biomedical Science institute, Seoul, Korea, Republic of, [2]Severance Biomedical Science Institute, Yonsei University College of Medicine,, Seoul, Korea, Republic of, [3]Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Epidermal growth factor receptor (EGFR) mutations (MT) are oncogenic drivers in non-small cell lung cancer (NSCLC). However, acquired resistance to EGFR tyrosine kinase inhibitors (TKIs) remains a significant challenge for the treatment of NSCLC. Claudin-3 (CLDN3), a tight junction protein involved in maintaining epithelial integrity, has been reported to be overexpressed via EGFR downstream pathways or mislocalized in NSCLC, contributing to its malignant potential and making it a promising therapeutic target. The Clostridium perfringens enterotoxin (CPE), with its receptor-binding C-terminal domain (cCPE), offers a capability to specifically target CLDN3. This study aims to develop a novel CAR-T therapy utilizing cCPE to target CLDN3, focusing on overcoming resistance in post-TKI NSCLC.
Methods: CLDN3 expression was evaluated through scRNA sequencing (scRNA-seq) of primary lung tissues from 95 patients: EGFR-WT (n=35), treatment-naïve EGFR-MT (n=55), post-EGFR-TKI (n=5), and normal tissues (n=22). Protein expression was validated using ATCC and patient-derived cell lines (PDCs), including NCI-H1703 (EGFR-WT, CLDN3-negative) and EGFR-MT cell lines: HCC827 (E19del), HCC827_AR (E19del/MET amplification), YU1092 (L861Q), YU1157 (L858R), YU1162 (E19del), YU1150 (L858R/T790M), YU1182 (L858R/C797S), and YU1097 (E19del/T790M/C797S). CLDN3-overexpressing cell line (H1703Cld3) was engineered via viral transduction. CAR constructs were designed with various cCPE lengths (amino acids 116-319 [C3L], 184-319 [C3M], 194-319 [C3S]) and linked to 4-1BB and CD3ζ intracellular signaling domains via CD8α hinge and transmembrane regions. CAR expression was analyzed using flow cytometry. Antitumor activity was assessed through RTCA, LDH assays, and ELISA. In vivo efficacy was evaluated in xenograft models using H1703, H1703Cld3, and CLDN3-positive PDCs.
Results: scRNA-seq analysis revealed significantly elevated CLDN3 expression in post-EGFR-TKI patients compared to EGFR-WT and -MT. H1703 was selected as a CLDN3-, and HCC827, HCC827_AR, YU1092, YU1157, YU1162, YU1150, YU1182 and YU1097 as CLDN3+ target cells. Among the CARs, C3M showed optimal transduction efficiency (46.2%) and balanced activity, producing high IFN-γ (70,000pg/mL) against H1703Cld3 without auto-reactivity observed in C3S. C3M-CAR-T cells showed specifically higher secretion of IL-2, IFN-γ, and TNF-α against CLDN3+ target cells compared to CLDN3-. LDH assay and RTCA confirmed robust tumor lysis of CLDN3+ tumor cells than mock T cells. In vivo, C3M-CAR-T treatment led to significant tumor regression in xenografts of H1703Cld3 and PDCs.
Conclusions: This study highlights CLDN3 as a promising therapeutic target using cCPE-based CAR-T in NSCLC for overcoming resistance to EGFR-TKI. The C3M-CAR-T demonstrated robust anti-tumor efficacy across in vitro and in vivo models.

#4808 Physiological manufacturing conditions enhance in vivo efficacy of CD19 CAR T cells in mice.

Anita Zaitouna[1], **Candy Garcia**[2], Lauren Kucharczyk[1], Michael Steffey[1], Abriel Czachorowski[1], Natalie Czeryba[1], Ningchun Liu[1], Sheri Barnes[1], Yelena Bronevetsky[2], Shannon Eaker[2], James Lim[2], Scott Wise[1]

[1]Labcorp Early Development Laboratories Inc., Ann Arbor, MI,[2]Xcellbio, San Francisco, CA

Since the first chimeric antigen receptor T-cell therapy was approved in 2017, significant progress has been made in manufacturing to improve patient access to these life-saving therapies. For CD19 CAR T cells, complete response rates of 40-54% have been reported in patients with relapsed or refractory aggressive B cell lymphomas, a staggering result considering the historically poor outcomes associated with this disease. However, roughly half the treated patients did not exhibit the same profound response, owing to the complexity associated with the production of potent autologous cell therapies. In this study, we examined whether manufacturing conditions can impact the in vivo efficacy of CAR T cells in tumor-bearing mice. Utilizing the AVATAR manufacturing platform from Xcellbio, we expanded healthy donor-derived CD19 CAR T cells under physiological conditions mimicking the human vasculature system. We achieved this by tightly regulating oxygen and hyperbaric pressure levels during the expansion process. We then compared tumor-bearing mice treated with AVATAR expanded cells against conventionally manufactured CD19 CAR T cells derived from a conventional CO_2 incubator (21% O_2 + 0 PSI). CD19 expressing NALM6-Luc-mCh-Puro tumor cells were implanted intravenously in 48 mice, across 6 groups (female NOD.Cg-*Prkdc*^{scid} *Il2rg*^{tm1Wjl}/Sz*J*, Jackson Laboratories, Bar Harbor, ME), and tumor burden was measured via bioluminescence across 29 days post-implant. We report that CD19 CAR T cells manufactured under conditions mimicking the vasculature environment (15% O_2 + 5 PSI) exhibited superior tumor control compared to cells expanded in a conventional CO_2 incubator (1.8e8 vs 6.4e6 photons/second, mean BLI signal on day 29). Furthermore, we observed significant increases in plasma IFNg levels in animals treated with AVATAR expanded cells (mean: 111 pg/mL vs 32 pg.mL; day 19 post dose) indicating potent anti-tumor activity compared to animals treated with conventionally manufactured CD19 CAR T cells. Blood analysis revealed similar trends, with AVATAR expanded CD19 CAR+ cells present in higher numbers (21 cells/uL of blood vs. 7 cells/uL; mean, day 28 post dose). Also noteworthy was the increased trafficking of AVATAR-manufactured CD19 CAR+ T cells to the spleen and bone marrow compared to conventionally expanded CAR T cells. In summary, physiological culture conditions mimicking the oxygen and pressure levels of the vasculature system significantly enhanced the potency of CD19 CAR T cells in tumor-bearing mice, as measured by decreased tumor burden, higher effector cytokine production, and increased trafficking of CAR T cells to lymphoid organs. Manufacturing therapeutic cells in the AVATAR system has the promise to boost the efficacy of CD19 CAR T therapy, and may enable solid tumor-targeting cell therapy which has long suffered from poor potency.

#4809 Preclinical characterization of an iPSC-derived allogeneic CD19/CD20 CAR-T cell designed to address multiple limitations of current CAR-Ts.

Justin Yoo[1], Jen F. Lai[1], Laura Prochazka[2], Elisa Martinez[2], Chris Saxby[1], Michael H. Cadell[1], Sommer Apelu[1], Libin Abraham[1], Dylan Lee[2], Zahra Sahaf[2], Charlie Liu[1], Laxsha Thaya[2], Elizabeth Csaszar[2], Siddarth Chandrasekaran[1], Emily Titus[2], Chris Bond[1]

[1]Notch Therapeutics, Inc., Seattle, WA,[2]Notch Therapeutics, Inc., Toronto, ON, Canada

In this work, we present the differentiation and *in vitro* characterization of iPSC-derived dual antigen targeting CD19/CD20 CAR-T cells as a milestone towards enabling iPSC-derived allogeneic cell therapies. While autologous CAR-T cell therapy has become an established model in treating B cell malignancies, its application is limited by manufacturing constraints, the necessity of bridging therapy, and heterogeneity of cell product. Allogeneic CAR-T cells derived from iPSCs present an opportunity to overcome these challenges through the scalable production of homogeneous cell products that are genetically engineered and precisely differentiated. Additionally, tumor antigen loss or downregulation remains a driver of disease relapse in patients treated with CD19 CAR T-cells. Accordingly, multi-antigen targeting CAR strategies are being developed to overcome these challenges and elicit more complete and durable responses to CAR-T cell therapy. Multiple expression strategies have been employed to express CARs for multi-targeting applications, including use of bicistronic and tandem formats. We demonstrate strong functional CAR expression from both formats dependent upon the composition of the CAR hinge and transmembrane domains. Based on expression level and antigen binding of dual-targeting CAR formats and designs in Primary T cells, lead CARs were nominated for screening via iPSC-T cell differentiation and *in vitro* functional testing. These lead CARs were site-specifically integrated into the genome of iPSCs using a streamlined workflow for identification of appropriate insertion site and promoter. iPSCs engineered with CD19/CD20 CARs were successfully differentiated while preserving the anticipated CD8 T cell phenotype. The dual-targeting CAR-T cells successfully eliminate disease-relevant tumor cells expressing both or single antigen targets *in vitro*. The development of dual-targeting iPSC-derived allogeneic CD19/CD20 CAR-T cells using a readily scalable manufacturing platform represents a formidable advance in overcoming multiple hurdles faced by established CAR therapies and increasing accessibility of potent and persistent off-the-shelf treatments for cancer and autoimmune disease patients.

#4810 Metabolic reprogramming enhances IL15-GPC3-CAR T cell therapy for hepatocellular carcinoma while mitigating cytokine release syndrome.

Kevin Song[1], Yue Hu[2], Abhijit Sarkar[2], Andras Heczey[3], Xiaotong Song[2]

[1]University of Houston, Houston, TX,[2]Texas A&M University, Houston, TX,[3]Baylor College of Medicine, Houston, TX

Background: This study aims to develop a safer and more effective CAR T cell therapy for hepatocellular carcinoma (HCC). While recent clinical trials have shown promise, IL15-GPC3-CAR T cells demonstrated a 33% partial response rate but were associated with a high incidence of cytokine release syndrome (CRS), occurring in 75% of patients (9/12) compared to 8% (1/12) in GPC3-CAR T cells. Thus, strategies to mitigate CRS while enhancing efficacy are urgently needed. We previously demonstrated that inosine could serve as an alternative energy source for CAR T cells in the glucose-deprived tumor microenvironment (TME) (Nat Metabolism, 2020). More recently, we provided proof of concept that a metabolic reprogramming strategy involving adenosine deaminase 1 (ADA1) enhances T cell survival by converting adenosine to inosine while reducing pro-inflammatory cytokine production (Cell Rep Med, 2024). In this study, we aim to improve IL15-armed GPC3-CAR T cell therapy for HCC by leveraging ADA1 signaling to enhance CAR T cell persistence in the TME while mitigating inflammatory responses, potentially reducing the risk of CRS.
Methods: Human PBMCs were transduced with retroviral vectors encoding IL15-GPC3-CAR and ADA1 (designated IL15-GPC3-MRCAR). Antitumor efficacy and toxicity were evaluated in a Huh7 xenograft mouse model. Cytokine levels and mouse survival were measured to assess immune activation and CRS risk.
Results: IL15-GPC3-MRCAR T cells demonstrated enhanced proliferation and reduced exhaustion following repeated HCC stimulation in vitro. They also exhibited superior cytotoxic activity compared to IL15-GPC3-CAR or GPC3-MRCAR T cells both in vitro and in vivo. Notably, in the mouse study, IL15-GPC3-CAR T cells resulted in mortality rates comparable to the PBS-treated group, likely due to severe CRS. In contrast, IL15-GPC3-MRCAR T cells significantly extended survival, with outcomes similar to those observed in GPC3-CAR T cells and GPC3-MRCAR T cells groups.
Conclusions: IL15-GPC3-MRCAR T cell therapy enhances metabolic fitness and reduces CRS risk, representing a promising advancement in GPC3-targeted therapy for HCC. Further clinical validation is warranted.

#4811 Enhanced potency of BCMA/CD19 dual-targeting allogeneic CAR-T cells for relapsed/ refractory multiple myeloma with 4-1BB/TACI intracellular domains.

Steven Wang, Iris Pang, Claudia Chang, Michelle Burrascano, Nick DeMarco, Danny Mendoza-Reyes, Sonia Reyes, Arturo Barcenas, Pastor Nieto, Jose Diaz, Garret Arauz, Chris Lynn, Tony Nguyen, Connor Reed, Mona Connerney, Quy Le, Julia Coronella, Devon J. Shedlock

Poseida Therapeutics, Inc., San Diego, CA

B-cell maturation antigen (BCMA)-directed chimeric antigen receptor (CAR) T cell therapy has shown high initial response rates in relapsed/refractory multiple myeloma (RRMM), but most patients eventually relapse with progressive disease. Previous studies have identified a less differentiated, CD19-positive progenitor subpopulation of MM cells that contributes to resistance and poor survival. Furthermore, anti-CD19 CAR-T cells given after high-dose melphalan and stem cell transplantation have shown to improve patient survival and can eliminate MM progenitor cells that are resistant to BCMA-directed CAR-T cells.

P-BCMACD19-ALLO1 is a fully allogeneic CAR-T therapy designed to target BCMA and CD19. Additionally, P-BCMACD19-ALLO1 is a T stem cell memory (T_{SCM})-rich product derived from healthy donor T cells using a nonviral, transposon-based system for transgene delivery, with knockout of *TRBC1/2* and *B2M* to prevent graft-versus-host disease and reduce host T-cell mediated rejection, respectively. T_{SCM} -rich CAR-Ts, including our BCMA-targeting allogeneic P-BCMA-ALLO1 CAR-T for RRMM (NCT04960579), have shown favorable efficacy and safety in the clinic.

To develop P-BCMACD19-ALLO1, we constructed the BCMA CAR using two fully human, single-domain, heavy-chain variable domains (VHs) that independently bind BCMA and are joined together by a G_4S linker in tandem. The tandem anti-BCMA VHs binds to all clinical escape mutants, including teclistamab-resistant R27P mutation. The anti-CD19 CAR binder comprises of a fully human VH against CD19. Both CARs are expressed from a single, multi-cistronic transgene that also contains an inducible Caspase-9 safety switch and a dihydrofolate reductase mutein.

Herein, we show enhanced in vivo potency of P-BCMACD19-ALLO1against BCMA/CD19-double positive RPMI-8226 MM xenograft model using an optimized ICD combination that incorporates a novel co-stimulatory domain derived from the tumor necrosis factor receptor family member transmembrane activator and CAML interactor (TACI) in the CD19 CAR and the standard 4-1BB in the BCMA CAR. P-BCMACD19-ALLO1 demonstrates target-specific, in vitro cytotoxicity against tumor cells expressing BCMA, CD19, or both antigens but lacks activity against antigen-negative tumor cells. P-BCMACD19-ALLO1 also demonstrates potent, in vitro killing of tumor cells expressing R27P, P33Del, P33S and S30Del escape mutants. Lastly, P-BCMACD19-ALLO1 effectively eliminates primary bone marrow CD81+CD19+ progenitor cells as well as colony-forming cells derived from MM patient samples, suggesting that P-BCMACD19-ALLO1 may increase the depth and the durability of response.

Taken together, our data underscore the therapeutic potential of P-BCMACD19-ALLO1 and support its application for treating RRMM to be further evaluated in clinical trials.

#4812 Intracranial delivery of MC9999 CAR T-cell therapy: a novel strategy to simultaneously eliminate GBM tumors and immunosuppressive components in the tumor microenvironment.

Yan Luo, Yaqing Qie, Maria J. Ulloa-Navas, Jesus E. Sanchez-Garavito, Vanessa K. Jones, Martha E. Gadd, Mieu M. Brooks, Tanya Hundal, Andrew D. Brim, Isas K. Vazquez-Rosario, Haidong Dong, Alfredo Quinones-Hinojosa, Hong Qin

Mayo Clinic Florida, Jacksonville, FL

Immunosuppression within the tumor microenvironment (TME) poses a significant challenge to the efficacy of Chimeric Antigen Receptor (CAR) T-cell therapy in solid tumors, including glioblastoma (GBM), the most common and deadly primary brain tumor. Tumor and TME-residing immunosuppressive cells can hijack program death 1(PD1) pathway to evade antitumor T-cell immunity by upregulating its ligand, PD-L1. Thus, targeting PD-L1 emerges as a promising therapeutic strategy to simultaneously eliminate tumor cells and immunosuppressive components within the TME. We developed a novel PD-L1-targeting CAR T-cell therapy, MC9999, and investigated its therapeutic effects against GBM. The antigen-specific cytotoxicity of MC9999 CAR T-cells was firmly validated using a LN229 GBM cell line and its PD-L1-deficient variant, as well as patient-derived brain tumor-initiating cells (BTICs). Furthermore, in vivo therapeutic antitumor effects were confirmed in orthotopic GBM models through intracranial administration of MC9999 CAR T-cells. To pave the way to the translation of MC9999 CAR T-cell therapy to patient bedside, we established a unique experimental system using patient-specific CAR T-cells against their own tumor and immunosuppressive cells. High-quality, patient-specific MC9999 CAR T-cells were manufactured using T cells isolated from peripheral blood, while paired autologous BTICs were generated to serve as target cells. Autologous immunosuppressive cells include monocyte-derived M2 macrophages from patient's peripheral blood and tumor-associated macrophages (TAMs) isolated from patient's tumor. Data from multiple patients' samples consistently demonstrated that these patient-specific MC9999 CAR T-cells elicited robust cytotoxicity against autologous GBM tumor and TME-residing immunosuppressive cells, supporting our hypothesis that targeting PD-L1 effectively address both tumor and its TME. Immunohistochemistry (IHC) staining of our GBM patients' tissues showed that PD-L1 expression was restricted to tumor cells and macrophages /microglia within the tumor, with no expression detected in neurons, astrocytes, oligodendrocytes, or blood vessels. These findings suggest that MC9999 CAR T-cells can be safely delivered to the brain without compromising normal cell populations. Ongoing studies are underway to further validate the safety profile of MC9999 CAR T-cell therapy. Collectively, the data obtained from this preclinical study support the effectiveness, feasibility and safety of local administration of MC9999 CAR T-cells as a promising new approach for GBM treatment. These encouraging results have motivated us to prepare an Investigational New Drug application to initiate a phase I clinical trial.

#4813 Multi-armored allogeneic CD5 γδ CAR T cells enhance anti-tumor efficacy in T cell malignancies.

Y. Seo, H. Lee, S. Yu, H. Lee, J. Lee, H. Kim, Y. Lee;
Curocell Inc., Daejeon, Korea, Republic of

T cell malignancies, such as T cell lymphoma and leukemia (T-NHL/T-ALL), present substantial challenges to conventional first-line therapies, highlighting an urgent need for novel therapeutic approaches. CAR-T therapies targeting T-cell-specific antigens have emerged as promising strategies against these cancers. However, the risk of tumor contamination by patient-derived T cells underscores the necessity for developing allogeneic, blast-free CAR-T therapies. Healthy donor-derived γδ T cells are attractive candidates for allogeneic CAR-T cell therapy due to their blast-free nature and the minimal risk of inducing Graft-versus-Host Disease (GvHD). Nevertheless, the difficulties in large-scale expansion and limited in vivo efficacy remain substantial obstacles to clinical application. To overcome these limitations, we aimed to enhance both the expansion and *in vivo* efficacy of anti-CD5 γδ CAR-T (γδCAR5) cells by incorporating “signal-3” supplement. A membrane-bound cytokine approach was employed to ensure targeted “signal 3” supplement specifically to CAR-T cells, promoting controlled expansion and activation. Among various cytokines engineered in membrane-bound forms (IL-2, IL-12, IL-15, IL-18, IL-21, and IL-36γ), only membrane-bound IL-18 (mbIL-18) induced a more than 10-fold increase in γδCAR5 cell expansion *in vitro* and demonstrated robust anti-tumor efficacy in a T-ALL xenograft model. Furthermore, knockdown of CD5 and PD-1, which are associated with fratricide and immunosuppression, respectively, further maximized the anti-tumor activity of γδCAR5-mbIL-18. Consequently, this multi-armoring strategy, which integrates enhanced proliferative capacity, fratricide resistance, and immune checkpoint evasion, represents an innovative approach to maximizing the therapeutic efficacy of allogeneic cell therapies for T cell malignancies. This study provides a promising framework for the advancement of more effective CAR-T therapies against challenging T cell cancers.

#4814 Development of a novel claudin-6-targeting CAR-T cell.

Ana Shahpazir, Siret Tahk, Paule Hermet, Anu Ustav, Robin Pau, Gaily Kivi, Mario Plaas, Andres Mannik, Joan Teyra, Mart Ustav, **Tanel Mahlakoiv**

Icosagen Cell Factory OU, Kambja, Estonia

Chimeric antigen receptor (CAR) T cell therapies have achieved remarkable efficacy in treating B cell malignancies but have shown limited clinical success in patients with solid tumors. A key challenge in advancing these therapies lies in the identification and targeting of highly tumor-specific antigens to ensure both safety and efficacy. In this study, we employed HybriFree B-cell cloning technology and phage display to discover antibodies targeting Claudin-6 (CLDN6), an oncofetal protein selectively expressed in subsets of ovarian, lung, endometrial, and testicular cancers, with minimal or no expression in healthy adult tissues.

To generate a robust immune response, chickens were immunized with virus-like particles (VLPs) displaying a high-density presentation of transmembrane CLDN6. Monoclonal antibodies specific to CLDN6 were subsequently screened for their specificity towards CLDN6 using VLPs bearing other Claudin family members. The most promising specific binders that were able to discriminate between binding of CLDN6 and CLDN9 were humanized via the Qumanize platform and incorporated into a second-generation CAR construct with a 4-1BB costimulatory domain and CD3ζ signaling domain.

CLDN6-specific CAR T cells were then generated and evaluated for their cytotoxicity in tumor models of ovarian, lung, and gastric cancers. Two CLDN6-specific CARs exhibited highly specific recognition and efficient lysis of cancer cells endogenously expressing CLDN6. Within 24 hours of co-culture, CLDN6 CAR T cells eliminated 80% of PA-1 cells and 60% of OV-90 cells. To assess T cell immune activation, cytokine secretion was measured upon co-culture with various target cells. Notably, IFN-γ secretion was observed exclusively when CLDN6 CAR T cells were co-cultured with CLDN6-positive targets, confirming their antigen specificity.

This study underscores the utility of HybriFree technology and the Qumanize platform in generating highly specific and high-affinity CARs for tumor targeting. These findings present a promising avenue for developing next-generation immunotherapies for CLDN6-expressing solid tumors.

#4816 Enhancing the persistence of universal CAR-T against DLL3 positive small cell lung cancer using the epigenetic regulation system mediated by CRISPR.

Zichong Peng[1], Zhuoran Yao[1], Linglu Yi[2], Kai Kang[1], Ren Luo[1], Shanghai Liu[1], Yufeng Zhang[1], Shuangsi Liao[1], Feifei Na[1], Lisa Xiang[1], Ruizhan Tong[2], You Lu[1]

[1]Division of Thoracic Tumor Multimodality Treatment and Department of Radiation Oncology, West China Hospital of Sichuan University, Chengdu, China,[2]Laboratory of Clinical Cell Therapy, West China Hospital of Sichuan University, Chengdu, China

Background: Chimeric antigen receptor T-cell (CAR-T) therapy faces challenges in solid tumors. Long-term exposure of CAR-T to antigens and the immunosuppressive tumor microenvironment leads to T cell exhaustion, which impairs T cell antitumor persistence. Moreover, universal CAR-T (UCAR-T) based on knockout of TRAC, HLA or CD52 genes often has the problem of diminished function. Previous studies have shown that stem-like T cells are essential for offsetting undesirable effects of exhaustion, and both exhaustion and stemness-related genes are epigenetic regulated, which offer a safer alternative to genetic modifications in CAR-T therapy. In this study, we designed a system to turn off or turn on epigenetic regulation genes by CRISPR, named as Epi-off and Epi-on, to enhance the persistence of CAR-T and UCAR-T therapy. And the exhaustion-related epigenetic regulation gene ARID1A was chosen to test the system function.
Methods and Results: The ARID1A KO DLL CAR-T cells were constructed by an Epi-off system mediated by CRISPR using lentiviral and electrical transduction. Continuous repetitive chronic stimulation was performed to induce T cell exhaustion in vitro. The ARID1A KO DLL CAR-T cells exhibited better antitumor effects and less exhaustion, with a less exhausted T cells population (TIM3+ or LAG3+). Meanwhile, they maintained higher proportion of TCF-1+, CD62L+Slamf6+ subsets and faster expansion, which indicated ARID1A KO led to more stem-like characteristics and longer persistence. In vivo, ARID1A KO DLL CAR-T exhibited more effective and long-lasting antitumor effect. The longer survival, smaller tumor volume and more tumor infiltrating lymphocytes (TILs) were observed in tumor mice who received ARID1A KO DLL CAR-T. Moreover, we also assessed the anti-tumor effect between ARID1A KO and SUV39H1 KO CAR-T which was another epigenetic regulation gene against exhaustion. ARID1A KO CAR-T showed a comparable anti-tumor effect at reinfusion dose of 1×10^7 CAR-T cells per mouse but better than SUV39H1 KO CAR-T at comparatively low reinfusion of 5×10^6. Furthermore, ARID1A KO was implemented on UCAR-T. In vivo, ARID1A KO improved DLL UCAR-T therapy (like CAR-T) with a limited toxicity (like conventional UCAR-T) in SCLC mouse model. In addition, we also established an Epi-on system to enhance the persistence and safety of CAR-T, which had a gated structure so that the CRISPR activation component would be released into nucleus by protease to up-regulate expression of certain gene when CAR-T recognized DLL3+ SCLC.
Conclusion: We established an epigenetic regulation system (Epi-off and Epi-on) to enhance CAR-T/UCAR-T function. And the ARID1A KO DLL3 CAR-T and UCAR-T based on this system exhibited better persistence, reliable anti-tumor effects and low toxicity in both in vitro and vivo.

#4817 CAR negative T cells predominate during xenogeneic graft versus host disease after CAR T cell treatment in NSG mice.

Wahed Firoz, Michael K. Sheng, Logan Vick, Craig P. Collins, Ryan Nielsen, Sean J. Judge, William J. Murphy

UC Davis School of Medicine, Sacramento, CA

Chimeric antigen receptor (CAR) T cells are currently FDA-approved and provide a curative solution for patients with select B-cell malignancies in the relapsed or refractory setting. However, there have been multiple reports of long-term toxicities associated with CAR T cell treatment, such as second primary malignancies, highlighting the importance of assessing the long-term effects of CAR T cells on the host in preclinical models. Since the study of CAR T cell efficacy is performed in *in vivo* xenograft mouse models, long-term study is limited by xenogeneic graft-versus-host disease (xenoGVHD) in which human T cells recognize foreign murine major histocompatibility complex, leading to immune-mediated pathology and eventual death of the animal. On the other hand, allogeneic CAR T cells are being increasingly investigated in the aims of lowering cost and increasing access of treatment, though poses the risk of GVHD. In this project, we aimed to investigate the cellular dynamics of CAR T cells in mediating xenoGVHD. To accomplish this aim, we utilized a tri-specific human CAR T cell product which targets CD19, CD20, and CD22 against the Raji human B-cell lymphoma cell line in the immunodeficient NSG mouse model. During the initial tumor clearance, the CAR-positive T cells preferentially expand and constitute upwards of 90% of CD3+ T-cells in the bone marrow of treated mice. However, after approximately 40 to 180 days post tumor clearance, we observed weight loss and outward signs of xenoGVHD. We found that the variability in xenoGVHD onset and occurrence is dependent on the human T cell donor used to make the CAR T cells. Additionally, we found that the CAR-negative T cells predominated in the spleen and bone marrow of Raji-bearing NSG mice treated with human CAR T cells. Using flow cytometry, we observed upwards of 85% CAR-negative T cells of CD3+ T-cells in the spleen and bone marrow of mice experiencing xenoGVHD across multiple experiments. This was an increase from the frequency of CAR-negative T cells at both the pre-infusion baseline timepoint and during tumor clearance, suggesting a preferential expansion of CAR-negative T cells in response to xenoantigens. In addition, we observed upregulation of markers associated with T-cell activation, such as PD-1 and HLA-DR, among the CAR-negative T cells during xenoGVHD, indicating TCR-mediated activation by xenoantigens. Overall, our findings suggest that the CAR-negative T cells predominate during xenoGVHD and play a role in mediating pathology in our tested model. The occurrence of xenoGVHD in these preclinical xenograft models of CAR T cell efficacy are a limitation and prevent the study of potential long-term effects of treatment. Our findings also give insights into the generation of allogeneic CAR T cell products, especially regarding the role of CAR-negative T cells in mediating allogeneic GVHD with off-the-shelf allogeneic CAR T cell products.

#4818 CSPG4-targeting CAR-macrophages inhibit melanoma growth.

Daniel Greiner, Minna Roh-Johnson

University of Utah School of Medicine, Salt Lake City, UT

Macrophages are abundant in the tumor microenvironment of solid tumors like melanoma, and while often pro-tumorigenic, macrophages also possess inherent anti-tumor capabilities. Recent studies have highlighted the potential of CAR-Ms, or chimeric antigen receptor expressing macrophages, to recognize and kill cancer cells. As both phagocytes and antigen-presenting cells, macrophages offer a unique toolset compared to cytotoxic CAR-T cells, potentially improving efficacy in solid tumors. We engineered primary human blood monocyte-derived macrophages to express CAR constructs with an scFV targeting chondroitin sulfate proteoglycan 4 (CSPG4), an antigen commonly overexpressed in solid tumors including melanoma and glioblastoma. Using melanoma as an initial model, we evaluated the impact of CSPG4-targeting CAR-Ms on melanoma growth *in vitro* and *in vivo*. We found that CSPG4-targeting CAR-Ms lead to increased phagocytosis of melanoma cells and increased melanoma cytotoxicity compared to control CAR-Ms. Furthermore, CSPG4-targeting CAR-Ms inhibit melanoma spheroid growth in 3D and inhibit melanoma growth in mice. Interestingly, priming CSPG4-targeting CAR-Ms with CSPG4-expressing cancer cells leads to increased phagocytosis and infiltration of melanoma spheroids compared to control CAR-Ms or unprimed CSPG4-targeting macrophages. Together, these results suggest that CSPG4-targeting CAR-M immunotherapy is a promising solid tumor immunotherapy approach for treating melanoma.

#4819 Pulmonary neutrophil-CAR T cell crosstalk amplifies antigen-specific off tumor toxicity.

Robert L. Eil, Alexandra Bartlett, Matthew McWhorter, Chelsea Jenkins, Jessica Briones

Knight Cancer Institute, Oregon Health & Science University, Portland, OR

Despite the potential for tumor-specific T cells to mediate durable complete responses of advanced disease, no CAR-T cell treatment is currently approved for use against a solid cancer. While nearly all solid cancers express a tumor-associated antigen (TAA) vulnerable to CAR T cell recognition, the same TAAs are also present on healthy tissues. CAR T cells recognize and attack healthy tissues that express their target, even at low levels, provoking lethal and dose-limiting 'on-target off-tumor' toxicities, most commonly the lungs, resulting in vanishingly small therapeutic index. Genetically engineered and immunocompetent mouse models continue to inform our understanding of the immunostimulatory and inhibitory roles of myeloid populations in cancer development and antitumor immunity. However, insights into the role of myeloid populations in constraining or promoting CAR T cell function in the tumor and sites of toxicity in cancer-free organs has been limited due to the prominent use of xenograft models when evaluating CAR T cell function. CAR T cell xenograft mouse models (i.e. transfer of human T cells into immunocompromised mice bearing human tumors) fail to capture off-tumor toxicities (due to the lack of host antigen expression) and are compromised in their ability to recapitulate cytokine crosstalk between the transferred and endogenous populations (due to un-even cross-reactivity of heterologous cytokine-receptor interactions).We develop two immunocompetent murine models (C57BL/6) of CAR T cell transfer targeting TAAs abundant in multiple epithelial cancers (EpCAM and CEA). EpCAM and CEA CAR T cells affected moderate control of pancreatic and metastatic colon cancer but also infiltrated and damaged non-cancerous organs that expressed the TAA (lung & colon). The respiratory system was the site of greatest macro and microscopic pathology in both models. Flow cytometry and immunohistochemical analysis of sites of off-tumor toxicity revealed a marked accumulation of macrophages and neutrophils, along with transferred CAR T cells, in the lungs of host mice, along with immune crosstalk mediated activation and proliferation of endogenous CD4 and CD8 T cell populations. To assess their functional significance in mediating off-tumor toxicity, we depleted endogenous macrophage and neutrophil accumulation in the lungs of CEA and EpCAM CAR T cell recipients using clondronate liposomes or anti-Ly6G depleting antibodies (clone 1A8). In both CEA and EpCAM CAR T cell models, we found that depletion of host neutrophils, but not macrophages, prevented CAR T cell accumulation, activation of endogenous T cells, and pathologic tissue destruction in the lungs of host mice. These findings provide strong justification for targeting host myeloid populations for depletion or reprogramming in the setting of CAR T cell transfer to expand their therapeutic index.

#4820 Anti-CD72 nanobody-based CAR-T affinity maturation leads to improved in vitro efficacy versus low antigen density lymphoma models, but limited benefit in vivo.

Adila Izgutdina[1], Tasfia Rashid[1], Bonell Patino-Escobar[1], Sujata Walunj[1], Huimin Geng[1], Amrik Kang[1], Szu-Ying Chen[1], Haley Johnson[1], William C. Temple[2], Matthew A. Shah[10], Arun P. Wiita[1]

[1]Department of Laboratory Medicine, UCSF - University of California San Francisco, San Francisco, CA,[2]Department of Pediatrics, Division of Hematology/Oncology, UCSF Benioff Children's Hospital, UCSF - University of California San Francisco, San Francisco, CA,[3]Department of Hematology, Kanazawa University, Kanazawa, Japan,[4]Department of Hematology, Hospital Universitario 12 de Octubre, Madrid, Spain,[5]Laboratory of Pathology, Center for Cancer Research, National Cancer Institute, Bethesda, MD,[6]Department of Oncology, Blood Cancer Institute, Montefiore Einstein Comprehensive Cancer Center, Bronx, NY,[7]Arc Institute, Palo Alto, CA,[8]Preclinical Therapeutics Core, Helen Diller Family Comprehensive Cancer Center, UCSF - University of California San Francisco, San Francisco, CA,[9]Hematology and Medical Oncology, Icahn School of Medicine at Mount Sinai, New York, NY,[10]Pediatric Oncology Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD

Introduction: CD19 CAR T-cells have markedly improved the survival of patients with B-cell malignancies. However, over half of patients relapse after this therapy, many due to CD19 antigen loss. Our laboratory discovered CD72, a B cell specific surface antigen widely expressed on B-cell malignancies. We developed an effective humanized nanobody-based CAR-T (“H24 nanoCAR”) against this target (Nix et al. Cancer Discov 2021, Temple et al. JITC 2023) that we are moving to clinical translation. However, we observed reduced efficacy of H24 nanoCAR versus tumor with low CD72 antigen density. We hypothesized that affinity matured CD72 nanoCAR-Ts could target lower antigen thresholds in lymphoma models.

Methods: Affinity maturation and humanization of CAR-Ts was described in Temple et al. 2023. Humanized affinity matured NbD4.13-H24 CAR was generated by altering the framework region of clone NbD4.13 (K_D = 0.8 nM) to that in clone H24 (K_D = 33 nM). We previously described engineered JeKo1-CD72 low cell line (Izgutdina et al. ASH 2023).

Results: Flow cytometry confirmed ubiquitous CD72 expression on 20 primary B-NHL samples. Two B-ALL patient samples relapsed after CD19 CAR therapy showed downregulation of both surface CD19 and CD22, but surface CD72 was retained, raising the hypothesis that CD72 is a preferential second-line antigen after CD19 relapse. To evaluate efficacy versus CD72 antigen low model, we tested affinity matured NbD4.13 CAR and humanized affinity matured NbD4.13-H24, in comparison to H24 (clinical candidate), against an engineered JeKo1-CD72 low cell line. NbD4.13 and NbD4.13-H24 demonstrated enhanced cytokine secretion compared to H24. Upon repetitive restimulation with JeKo1-CD72 low, NbD4.13 CAR showed more rapid elimination of tumor than H24. However, NbD4.13 and H24 demonstrated equal efficacy in vivo versus mantle cell lymphoma PDX. In an in vivo experiment with JeKo1-low, NbD4.13 showed improved early tumor control than H24, but no survival benefit, while NbD4.13-H24 showed a modest survival benefit (p=0.0442 by Log-rank test). As an alternate strategy to address low antigen density, we showed that the protein kinase C inhibitor bryostatin can lead to increased surface CD72 when applied to the CD19 resistant model Nalm6-R. To understand the mechanism of action, we performed bulk RNAseq of CD72 antigen-low lymphoma cell line SC1 treated with bryostatin. GSEA showed that bryostatin broadly increases B cell lineage specific expression programs.

Conclusion: CD72 is a potential second line antigen post-CD19 relapse in B-cell malignancies. We found that affinity maturation did not demonstrably improve CD72 nanoCAR efficacy. Our results support findings demonstrated for scFv-based CARs, that moderate affinity for surface antigen may lead to optimal CAR performance in vivo, even when nanobodies are used as the recognition element.

#4821 ICAM1-specific chimeric costimulatory receptor enhances CAR T cell activity against HER2-expressing gastric cancer.

Yanping Yang, Arshiya Parveen, Yogindra Vedvyas, Sydney J. Trumper, Irene M. Min, Moonsoo M. Jin

Houston Methodist Research Institute, Houston, TX

Background: Human epidermal growth factor receptor 2 (HER2) is amplified or overexpressed in approximately 15-30% of breast and gastrointestinal cancers, leading to rapid cell proliferation and metastasis through HER2-generated cell signaling. HER2-specific chimeric antigen receptor (CAR) T cells constructed with scFv derived from the FRP5 antibody have been proven safe against advanced sarcoma and brain cancer indications but have shown limited clinical response. In this study, we engineered HER2-specific CAR T cells that co-express a chimeric costimulatory receptor (CCR) targeting intercellular adhesion molecule-1 (ICAM1). The CCR is designed to provide complementary costimulation through OX40 and CD28 endodomains, which can synergize with the 4-1BB incorporated in the CAR construct. The combination of a CAR and a CCR aims to enhance T cell activation, expansion, and persistence, particularly when CAR activation alone is insufficient due to low or heterogeneous antigen expression in target cells. ICAM1 is selected as the target for costimulation because it is highly inducible by inflammatory cytokines such as interferon-gamma, which is released by activated T cells.
Methods: HER2 CAR/ICAM1 CCR T cells (designated as HMJ01) were manufactured using the fully automated CliniMACS Prodigy system at cGMP and FACT accredited facility at Houston Methodist Research Institute. The antitumor activity and toxicity of HMJ01 were evaluated in a GLP/non-GLP hybrid study using HER2-positive human gastric cancer xenograft models.
Results: Four batches of HMJ01 CAR T cells were successfully manufactured from healthy donor leukopak, achieving a transduction efficiency of 44.0 ± 8.7%. Compared to second-generation HER2 CAR T cells, HMJ01 exhibited increased sensitivity to recognize and lyse target cells with low levels of HER2 expression. Additionally, HMJ01 CAR T cells enabled the in vivo eradication of HER2-low tumor xenografts, which were otherwise resistant to treatment with conventional second-generation HER2 CAR T cells. We also observed increased cytokine secretion and clonal expansion of HMJ01 cells in vivo compared to conventional HER2 CAR T cells. Furthermore, HMJ01 CAR T cells were found to be safe in the toxicology study, which evaluated mortality, clinical signs, hematology and clinical chemistry, and histopathology at both intermediate and final time points, warranting further clinical evaluation.
Conclusions: Our studies demonstrate the significant potential of ICAM1-specific CCR to improve the therapeutic outcomes of CAR T cells by enhancing cytotoxic efficacy and persistence. We plan to open a first-in-human phase I study to assess the safety and preliminary efficacy of HMJ01 cells in patients with HER2-positive or HER2-low unresectable or metastatic gastric cancer.

#4822 Efficacy of 4-1BB-costimulated NKG2D CAR-T cells for synovial sarcoma in comparison with CAR-T cells targeting other antigens.

Naoki Oike[1], Tomohiro Miyazaki[1], Yudai Murayama[2], Akira Ogose[3], Takashi Ariizumi[1], Hiroyuki Kawashima[1], Chihaya Imai[4]

[1]Orthopedic surgery, Niigata Univ. School of Medicine, Niigata, Japan,[2]Orthopedic surgery, Tochigi cancer center hospital, Utsunomiya, Japan,[3]Orthopedic surgery, Uonuma-kikan hospital, Minamiuonuma, Japan,[4]Pediatrics, Toyama Univ. School of Medicine, Toyama, Japan

Although the development of multimodal therapy consisting of surgery, radiotherapy, and chemotherapy has significantly improved the survival rate for patients with localized synovial sarcoma (SS), the prognosis of metastatic or recurrent SS remains poor. This has not changed over the past three decades, and a novel approach including immunotherapy is urgently needed. Clinical studies of CAR-T cell therapies against sarcomas have been performed. However, the clinical outcomes for patients with sarcomas are still limited. We have previously reported cytotoxicity of HER2-targeted CAR-T cells against SS in vitro. Here, we demonstrated that NK2GD-based CAR-T cells showed significantly higher cytotoxicity than that of HER2-targeted CAR-T cells for SS cell lines.Surface expressions of HER2 and NKG2D ligands (NKG2DLs) on three SS cell lines (SYO-I, HS-SY-II, and Yamato-SS) were evaluated by flow cytometry. Gene expression level of HER2 and NK2GDLs of SS patients were also evaluated by RNA-sequencing using public data base. Then, we generated 4-1BB-type second generation CAR-T cells targeting HER2 or NKG2DLs and examined their cytotoxicity and specific responses against SS cells. Furthermore, we compared the differences between HER2-targeted CAR-T cells and NKG2D-based CAR-T cells by co-culturing with SS cells using short-term assay (WST-8 assay), long-term assay (Real-time Cell Analysis), intracellular cytokine assay, and CD107a assay. Finaly, animal experiments were also performed to evaluate antitumor effect of CAR-T cells against SS. CAR-T cells were injected one week after the implantation of human SS cell lines.Flow cytometry revealed that surface expression HER2 and NKG2DLs were observed in all three SS cell lines. In vitro, NKG2D-based CAR-T cells showed antitumor effects against SS cells with degranulation and cytokine production. Furthermore, NKG2D-based CAR-T cells showed much stronger cytotoxicity than HER2-targeted CAR-T cells in both short- and long-term assay. Higer expression level of cytokines was found in NK2GD-based CAR-T cells than that of HER2-targeted CAR-T cells.In this study, NKG2D-based CAR-T cells demonstrated much stronger antitumor effects than HER2-targeted CAR-T cells. Although CAR-T cell therapy has been shown to be promising in blood malignancies, the efficacy in solid tumors has been disappointing due to problems such as low penetrance to tumors, the immunosuppressive microenvironment, and immune evasion of tumor cells. While further validation of clinical application of CAR-T cells against SS is necessary, we demonstrated that CAR-T cell therapy would be promising immunotherapy for SS patients.

#4823 CDH3-targeted ADC and CAR-T immunotherapies for metastatic double-negative prostate cancer and triple-negative breast cancer.

Guoqiang Liu, Shiyu Wang, Loan Duong, Xin Lu

University of Notre Dame, Notre Dame, IN

Double-negative prostate cancer (DNPC) and triple-negative breast cancer (TNBC) are two challenging malignancies characterized by frequent metastasis and resistance to current therapies. Among them, DNPC may share similar traits with basal-like prostate cancer. These aggressive cancer subtypes demand new treatment strategies. This study investigates CDH3 (P-cadherin), a cell adhesion molecule, as a new target for antibody-drug conjugate (ADC) and chimeric antigen receptor (CAR) T-cell immunotherapeutics. We conducted comprehensive in silico analysis and confirmed the enriched expression of CDH3 in DNPC and metastatic TNBC. We hypothesize that CDH3-positive ($CDH3^{+}$) prostate and breast cancer cells will be effectively targeted and eradicated using anti-CDH3 immunotherapeutics in vitro and in vivo. Both anti-CDH3 ADC and CAR-T cell therapies were developed and they both demonstrated significant target-specific cytotoxicity against $CDH3^{high}$ DU145 and MDA-MB-468 cell lines, while sparing $CDH3^{low}$ and $CDH3^{-/-}$ cell lines, highlighting their selectivity in vitro. In vivo efficacy was further validated using NOD-SCID mice engrafted with prostate and breast cancer cell lines in an experimental metastasis setting, where treatment with ADC or CAR-T therapy significantly reduced metastasis burden. Notably, CAR-T therapy, in combination with anti-PD-1 therapy, exhibited enhanced therapeutic potential.This study establishes the robust target-specific cytotoxicity of anti-CDH3 ADC and CAR-T therapies against the most virulent subtypes of metastatic prostate and breast cancers in vitro and in vivo, paving the way for potential clinical development of these therapeutic agents in patients with metastatic DNPC and TNBC.

#4826 Tyrosine kinase inhibitor combination therapies with AZD5851, dominant-negative TGFβRII armored anti-GPC3 CAR-T, for the treatment of hepatocellular carcinoma.

Nina J. Chu[1], Ashley A. Merlino[1], John Stone[2], Niresh Hariparsad[3], Scott Rata[3], Gordon Moody[1], Letizia Giardino[4]

[1]Early Oncology, Cell Therapy Unit, AstraZeneca US, Gaithersburg, MD,[2]Clinical Cell Therapy, AstraZeneca, Cambridge, United Kingdom,[3]Oncology Targeted Discovery, Drug Metabolism and Pharmacokinetics, AstraZeneca US, Waltham, MA,[4]Early Oncology, Cell Therapy Unit, AstraZeneca, Cambridge, United Kingdom

Background: AZD5851 is a glypican-3 (GPC3)-targeting CAR-T armored with a TGFβRII dominant-negative receptor that protects the CAR-T from the immunosuppressive cytokine TGFβ. AZD5851 is currently being tested in a Phase I/II clinical trial (NCT06084884) for patients with advanced/recurrent hepatocellular carcinoma (HCC). The multi-target tyrosine kinase inhibitors (TKIs) sorafenib and lenvatinib are licensed for first line treatment of advanced/recurrent HCC. Sorafenib inhibits tumor cell proliferation and angiogenesis by blocking the Ras/Raf pathway, vascular endothelial growth factor receptors (VEGFR), and platelet-derived growth factor receptor (PDGFR). Lenvatinib mediates its antiangiogenic functions by targeting VEGFR, PDGFR, and fibroblast growth factor receptors (FGFR). Additionally, lenvatinib can reduce immunosuppression in the tumor microenvironment by decreasing infiltration of tumor-associated macrophages, myeloid-derived suppressor cells, and T regulatory cells. Due to these anti-tumor and immunomodulatory effects, we evaluated whether sorafenib or lenvatinib can enhance in vivo efficacy in combination with AZD5851, and if either TKI impacts CAR-T function.
Results: Therapeutic concentrations of sorafenib and lenvatinib did not affect AZD5851 viability, antigen dependent proliferation, activation, effector cytokine secretion, and target cell killing after co-culture with GPC3+ target tumor cells in vitro. In the PLC/PRF/5 HCC xenograft model, efficacious doses of both TKIs did not impair CAR-T anti-tumor function. High efficacious dose of sorafenib in combination with AZD5851 only subtly enhanced anti-tumor efficacy, whereas coadministration of high dose lenvatinib significantly increased tumor control compared to AZD5851 alone. To further explore the combination of lenvatinib with AZD5851, pharmacokinetic modeling for lenvatinib was performed to determine doses that would achieve exposures in mice equivalent to those observed in human patients. Combination of AZD5851 with the clinically relevant dose of lenvatinib significantly enhanced the anti-tumor efficacy and survival compared to CAR-T or lenvatinib alone.
Conclusions: The TKI lenvatinib enhances TGFβRII dominant-negative receptor armored GPC3 CAR-T (AZD5851) anti-tumor efficacy in vivo without affecting acute CAR-T viability, proliferation, activation, effector cytokine production, and cytotoxicity. Therefore, combining AZD5851 with lenvatinib may be a promising combination therapeutic regimen for patients with HCC.

#4827 Cell state targeting CAR T cell therapies for glioblastoma.

Christopher Mount[1], Emily Boxer[2], Sophia Kovatsis[1], Demi Gerovasilis[1], Sydney Dumont[1], Jun Zhong[1], Jack Lu[1], Itay Tirosh[2], Mario Suva[1]

[1]Massachusetts General Hospital, Boston, MA,[2]The Weizmann Institute, Rehovat, Israel

Despite decades of concerted research and clinical efforts, patient outcomes in glioblastoma (GBM) remain dismal. The emergence of chimeric antigen receptor (CAR) T cell therapies offer great promise as immunotherapies in this disease. To date, efforts to utilize CAR T cell therapies in GBM have resulted in isolated reports of impressive efficacy in individual patients, but these have yet to generalize to larger trial populations. It is thought that inter and intra patient tumor heterogeneity contributes to the variability of these responses. Single cell RNA sequencing has demonstrated that this heterogeneity can be organized along axes representing cellular states. The ability of existing CAR T cell therapies to target these cell states is unclear, and the dynamics of this heterogeneity under the selective pressure of therapy is uncertain. We present the development of a panel of tool CAR T cells targeting cell state associated surface markers with the objective of selective targeting of these cellular states in GBM. We show that these CAR T cells have target specific activity against GBM model systems representing these cellular states. Using single cell RNA sequencing, we model the dynamics of these treatment effects, with the aim of understanding the mechanisms of GBM dynamics in response to the selective pressure of CAR T cell therapies. We demonstrate global shifts in the transcriptional landscape at the single cell level and identify state dependent and state independent effects. We anticipate that these cell state targeted CAR T cells have great potential to elucidate mechanisms of GBM adaptation to the selective pressure of CAR T cell activity and will inform foundational biology necessary for rational design of multi target constructs for therapeutic application.

IMMUNOLOGY: Epigenetic Regulation of Tumor Immunity
Poster Session

#4831 DNA methylation of immune synapse genes drives tumor immune evasion.

Imene Hamaidi[1], Anders Berglund[2], Matthew Mills[2], Ryan M. Putney[2], James J. Mule[2], Sungjune Kim[1]

[1]Mayo Clinic Florida, Jacksonville, FL,[2]Moffitt Cancer Center, Tampa, FL

Background: While cancer immunotherapies have revolutionized treatment, their efficacy remains limited for most patients, highlighting tumors' capacity to evade immune detection. Epigenetic modifications, particularly DNA methylation, play a pivotal role in silencing immune-related pathways, thereby facilitating immune escape. By modulating gene expression, methylation disrupts immune activation, contributing to reduced tumor immunogenicity. This study examines the methylation landscape of co-stimulatory and immune checkpoint genes across various cancers to elucidate how these changes influence immune responses.
Methods: Using The Cancer Genome Atlas (TCGA), we analyzed methylation and gene expression profiles across diverse cancer types. Data from 8,186 solid tumors and 745 adjacent normal tissues were processed via t-distributed stochastic neighbor embedding (t-SNE) with 247 probes targeting 20 immune-related genes. Principal component analysis (PCA) was applied to capture methylation variability across 8,931 tumor and normal samples. To explore the effects of methylation on immune gene expression, we analyzed data from 26 epithelial cancer cell lines treated with 5-azacitidine, a demethylating agent, using the GSE57342 dataset. Post-treatment changes in gene expression were assessed, and survival analyses from prior studies were used to explore clinical correlations.
Results: We identified distinct methylation patterns in immune synapse genes, differentiating tumors from adjacent normal tissues. Co-stimulatory genes such as CD40 were hypermethylated in tumors, correlating with decreased expression, whereas immune checkpoint genes like PDL1 and HHLA2 were hypomethylated, correlating with increased expression. This inverse relationship between methylation and gene expression underscores the transcriptional regulatory role of DNA methylation. Treatment with 5-azacitidine reversed hypermethylation in co-stimulatory genes, including CD40, potentially enhancing immune recognition. Methylation levels of these genes were also associated with T cell infiltration into the tumor microenvironment and predicted better outcomes in melanoma patients, underscoring their clinical relevance.
Conclusion: This study demonstrates that DNA methylation of immune synapse genes contributes to tumor immune evasion by modulating immune gene expression. Targeting these epigenetic alterations represents a promising strategy to restore tumor immunogenicity and improve immunotherapy outcomes, particularly when combined with immune checkpoint inhibitors. Reversing methylation-driven immune suppression could strengthen the immune response and enhance clinical outcomes for cancer patients.

#4832 Differential roles of histone lactylation in regulating CD8 T cell effector functions and exhaustion.

Deblina Raychaudhuri, Pratishtha Singh, Bidisha Chakraborty, Aminah Tannir, Swadhin Meher, Sangeeta Goswami

The University of Texas MD Anderson Cancer Center, Houston, TX

CD8 T cells undergo metabolic reprogramming upon activation to meet the increased energy demands associated with their cytotoxic functions. A hallmark of CD8 T cell activation is the upregulation of glycolysis, accompanied by increased lactate production. Lactylation, a post-translational modification of histones, derived from lactate, has garnered attention, though its specific role in CD8 T cell biology remains unclear. We have recently demonstrated the enrichment of histone lactylation marks, specifically H3K18-lactylation (H3K18la) and H3K9-lactylation (H3K9la), in human and murine CD8 T cells. Integrating ChIP-sequencing and RNA-sequencing data, we delineated the role of histone lactylation as transcriptional regulators of key genes essential for CD8 T cell-mediated cytotoxicity and effector functions. Importantly, our results, obtained from both *in vitro* experiments and *in vivo* disease models demonstrated that H3K18la and H3K9la exert differential effects across various CD8 T cell populations intricately tied to the metabolic profiles of distinct CD8 T cell subsets. Effector CD8 T cells, characterized by elevated glycolytic activity, exhibited correspondingly high levels of histone lactylation. In contrast, terminally exhausted CD8 T cells, where both glycolysis and mitochondrial metabolic pathways are impaired, displayed a marked reduction in histone lactylation. These cells were instead predominantly regulated by histone acetylation. Notably, co-immunoprecipitation assays revealed distinct epigenetic readers that specifically recognized histone lactylation marks, differentiating them from those binding to histone methylation or acetylation modifications. Modulating histone lactylation marks through metabolic and epigenetic interventions significantly altered CD8 T cell effector functions, including anti-tumor responses in preclinical models. Cumulatively, our findings demonstrated that histone lactylation, driven by intrinsic metabolic processes, regulates key aspects of CD8 T cell metabolism and function. Further, we identified distinct epigenetic mechanisms by which selective targeting of H3K18la and/or H3K9la can be leveraged to modulate CD8 T cell phenotype and functionality.

#4833 Targeting DOT1L to enhance the immune response in ovarian cancer.

Aisha Jamil, Shraddha Gupta, Sangeeta Kumari, Deyana Tabatabaei, Sergey Karakashev

Department of Cancer and Cellular Biology, Temple Univ. Lewis Katz School of Medicine, Philadelphia, PA

Epithelial ovarian cancer stands as the second most prevalent cause of death among all gynecological cancers. Current treatment protocols for patients incorporate platinum-based therapy regimens along with PARP inhibitors tailored for HR-deficient high-grade serous ovarian cancers (HGSOC). Despite initial efficacy, patients inevitably develop disease progression as tumor cells acquire resistance. HGSOC is characterized by low immune cell infiltration and reduced anti-tumor immune response. MHC class I mediated antigen presentation by cancer cells to the immune cells is one of the steps required to activate the anti-tumor immune response. Therefore, HGSOC often downregulates MHC class I expression to evade immune surveillance. To identify epigenetic factors negatively regulating MHC class I expression, we conducted a comparative analysis of HGSOC patient cell samples and HGSOC cell lines from the TCGA and DepMap. Our findings indicate that the epigenetic regulator DOT1L is overexpressed in ovarian cancer and negatively correlates with MHC class I expression. DOT1L is an enzyme responsible for the methylation of lysine79 on histone3 that regulates gene expression. However, the role of DOT1L in regulating MHC class I or antitumor immune response has not been previously studied. We hypothesized that DOT1L might regulate the expression of MHC class I in ovarian cancer and block the immune response. To investigate the role of DOT1L in the regulation of MHC class I, we generated a DOT1L knockout in two DOT1L-high EOC cell lines, OVCAR3 and ID8. Genetic inhibition of DOT1L led to enhanced expression of MHC class I on the surface of both cell lines. This suggests that DOT1L inhibition might be a valuable strategy to upregulate MHC class I expression, which could lead to an increased anti-tumor immune response. Importantly, a small-molecule DOT1L inhibitor, Pinometostat, is currently in late-stage clinical trials for other types of cancer. We then tested the effect of Pinometostat on MHC class I expression. In accordance with our hypothesis, DOT1L pharmacological inhibition also promoted upregulation of MHC class I expression in both cell lines. This discovery could potentially pave the way for the development of DOT1L inhibitors for HGSOC to increase anti-tumor immune response in ovarian cancer. The present research indicates that DOT1L inhibitors have the potential to be utilized in the precision medicine strategy for addressing DOT1L-high ovarian cancer patients.

#4834 Genomic and metabolic effects of KDM6A loss regulates differential responses to immune checkpoint therapy and chemotherapy in bladder cancer.

Pratishtha Singh, Deblina Raychaudhuri, Bidisha Chakraborty, Aminah J. Tannir, Swadhin Meher, Anurag Majumdar, Jessalyn Hawkins, Yun Xiong, Philip L. Lorenzi, Padmanee Sharma, Patrick G. Pilie, Sangeeta Goswami

The UT MD Anderson Cancer Center, Houston, TX

Bladder cancer often harbors driver mutations in genes regulating epigenetic processes, yet their influence on therapeutic perturbations is understudied. One key example is *KDM6A*, a gene frequently mutated in bladder cancer, which encodes a histone demethylase that confers transcription permissive chromatin state. Retrospective analysis of patient cohorts demonstrated that *KDM6A* mutations correlate with improved response to immune checkpoint therapy (ICT) and decreased sensitivity to cisplatin-based chemotherapy. Mechanistic studies reveal that CRISPR-Cas9 deletion of Kdm6a reduced expression of critical genes including *Msh2, Msh6*, and *Exo1* involved in DNA Mismatch repair (MMR) and double-stranded base repair (DSBR) in tumor cells with improved response to anti-PD-1 therapy. Further, KDM6A deficiency downregulated genes involved in cisplatin resistance and attenuated sensitivity to cisplatin-based chemotherapy *in vitro* and *in vivo*. Additionally, loss of KDM6A was associated with metabolic shift from glycolysis to oxidative phosphorylation. CyTOF analyses show decreased abundance regulatory T cells (Tregs) in Kdm6a-knockout tumors. Importantly, reduced lactate in the Kdm6a-knockout tumor microenvironment impaired histone lactylation (H3K9la/H3K18la) in Tregs with concurrent attenuation of expression of key immunosuppressive genes including *Foxp3, Tgfß1 and Pdcd1*. Collectively, this study provided insights into the role of KDM6A-mediated epigenetic regulation of DNA repair and metabolic reprogramming which could potentially govern response to chemotherapy and ICT aiding patient stratification and development of personalized treatment algorithms.

#4835 The role of ARID1A and ARID1B in melanoma.

Pei-Yu Chen, George P. Souroullas

Washington University in St. Louis, St. Louis, MO

ARID1A and ARID1B are highly homologous and mutually exclusive subunits of the chromatin remodeler SWI/SNF complex. In melanoma, *ARID1A* and *ARID1B* are mutated in about 13% and 10% of melanoma patients, respectively. Interestingly, mutations in *ARID1A* or *ARID1B* are also associated with a better response to immunotherapy in many cancers, highlighting their potential clinical relevance. The molecular mechanisms that drive this response, or their oncogenic mechanisms, remain largely unknown. What is also unknown are their unique and redundant properties within the SWI/SNF complex, and how that affects cancer progression. To study the function of ARID1A and ARID1B in melanoma, we crossed conditional knockout *Arid1a* and *Arid1b* mouse alleles to the tamoxifen-inducible tyrosinase Cre driver for melanocyte-specific deletion, in the presence of *Braf* ^{V600E} and *Pten* loss. We found that deletion of *Arid1a* or *Arid1b* did not change melanoma initiation; however, deletion of *Arid1b* accelerated nevi formation. Since melanoma initiation and progression can be two distinct processes, we next assessed the effect of Arid1a/1b deletion on melanoma progression. Using stable cell lines we generated from the primary tumors, we assessed melanoma tumor growth over time. We found that deletion of *Arid1b* dramatically decreased tumor growth compared to controls. Because deletion of Arid1a/1b did not affect *in vitro* cell growth, we hypothesized that cell extrinsic variables, like anti-tumor immunity, might be contributing to these phenotypes. Analysis of immune cell infiltration in the melanoma tumor revealed increased infiltration of CD8 T cells, particularly effector T cells in the absence of Arid1b, but not Arid1a. These results suggest that Arid1a and Arid1b are functionally distinct on regulating tumor immunity in melanoma.To mechanistically understand how Arid1a/1b affect melanoma progression, we performed gene expression profile analysis using RNA-seq. GSEA of RNA-seq data revealed enrichment in several immune-related signatures after Arid1b deletion, including IFN-α response, IFN-γ response, and MHC I antigen presentation and processing signatures. More specifically, we identified a dramatic upregulation of Stat1, an upstream regulator of MHC I antigen presentation genes that promote the cytotoxic activity of CD8 T cells. However, Stat1 remains largely unphosphorylated, so it remains unclear whether its upregulation results in increased canonical Stat signaling or whether it functions via other mechanisms. Overall, we show that Arid1a and Arid1b have distinct functions in a Braf/Pten-driven model of mouse melanoma and affect melanoma progression via alteration of pathways that control cytotoxic CD8 T cell activity. Finally, ARID1B may potentially serve as a predictive marker for immune checkpoint blockade treatment in melanoma patients.

#4837 NSD2 modulates immune surveillance in multiple myeloma.

Amin Sobh[1], Daphne Dupere-Richer[1], Emilie Bonilla[1], Guya Avshara[1], Karthik Vasan[2], Monica Clerio[1], Richard Bennett[1], Navdeep S. Chandel[2], Jonathan D. Licht[1]

[1]University of Florida, Gainesville, FL,[2]Northwestern University, Chicago, IL

Background: The histone methyltransferase NSD2 is overexpressed in 15% of multiple myeloma (MM) patients due to the translocation (4;14). NSD2 overexpression disrupts chromatin methylation promoting oncogenic gene expression. Despite advancements in MM treatments, the t(4;14) translocation remains a poor prognostic marker. Interestingly, NSD2 disruption in t(4;14) MM cell lines does not affect cellular fitness *in vitro*, suggesting its oncogenic effects might involve mechanisms beyond intrinsic cancer cell survival. Emerging evidence indicates a role of NSD2 in tumor immune response. *In vivo* CRISPR screens showed that NSD2 is selectively crucial when tumor cells are engrafted into immunocompetent mice, suggesting that NSD2 contributes to immune evasion. Targeting NSD2-mediated immune suppression shows potential therapeutic benefits in t(4;14) MM.
Aim: To investigate the role of NSD2 in modulating immune surveillance in MM.
Methods: Multi-omics analyses were performed on isogenic t(4;14) MM cell lines with varying NSD2 expression. These analyses were supported by targeted assays, including flow cytometry and multiplex immunoassays. We utilized both immunocompetent and immunodeficient MOPC315.BM myeloma mouse models to study NSD2's role in immune modulation *in vivo*.
Results: RNA-seq analysis revealed that NSD2 regulates several immune-related pathways, with a particularly strong suppression of MHC-II gene expression in NSD2-overexpressing cells. Unbiased proteomics confirmed reduced MHC-II protein levels in these cells. Flow cytometry showed that disrupting NSD2 in t(4;14) MM cells increases MHC-II expression, an effect reversed by conditioned media from NSD2-high cells. This suggests that NSD2 promotes secretion of factors that suppress MHC-II expression, reducing antigen presentation and ultimately the immune response. NSD2 inhibitor treatment increased MHC-II expression, indicating potential for immunotherapy. Cytokine and chemokine profiling revealed that NSD2 overexpression alters the secretion of CCL2, CXCL9, MCP-1, IL-16, and IL-10, with implications for immune modulation. Metabolomics showed that NSD2-high cells accumulate the immunosuppressive metabolite spermidine. Proteomics further revealed marked reduction of adenosine deaminases ADA1 and ADA2 by NSD2, suggesting an accumulation of the immunosuppressive metabolite adenosine in the tumor microenvironment.
Conclusion: NSD2 overexpression in MM suppresses immune surveillance potentially contributing to the aggressiveness of t(4;14) myelomas. These findings highlight the potential of NSD2 as a therapeutic target to enhance immunotherapy in MM.
Future directions: The effect NSD2 on MM eradication by immune cells will be investigated by immune cell killing assays. The immunocompetent MOPC315.BM MM model will be used to evaluate how NSD2 regulates immune cell composition.

#4838 Epigenetic modulation of polyamine biosynthetic pathways rectifies T cell dysfunction to enhance anti-tumor immunity in lung cancer.

Hsing-Chen Tsai[1], Yi-Chieh Wu[1], Yu-Ting Lee[1], Meng-Wei Chou[1], Shu-Yung Lin[2], Sheng-Yao Su[1], Chia-Lang Hsu[3], Nai-Wen Chang[3], Yi-Jhen Huang[1], Yi-Hsiu Juan[2], Hsuan-Hsuan Lu[2], Pei-Shan Wu[4], Miao-Hsia Lin[4], Li-Chung Hsu[5], Yen-Ling Chiu[6], Shih-Yu Chen[7], Chong-Jen Yu[8]

[1]Graduate Institute of Toxicology, National Taiwan University College of Medicine, Taipei, Taiwan,[2]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan,[3]Department of Medical Research, National Taiwan University College of Medicine, Taipei, Taiwan,[4]Department of Microbiology, National Taiwan University College of Medicine, Taipei, Taiwan,[5]Graduate Institute of Molecular Medicine, National Taiwan University College of Medicine, Taipei, Taiwan,[6]Far Eastern Memorial Hospital, New Taipei City, Taiwan,[7]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan,[8]National Taiwan University Hospital Hsin-Chu Branch, Hsinchu City, Taiwan

T cell exhaustion, a dysfunctional state caused by prolonged antigen exposure, presents a major challenge in cancer immunotherapy. While immune checkpoint inhibitors show therapeutic promise, they fail to rejuvenate T cells in a terminally exhaustion state, potentially due to epigenetic barriers. We hypothesized that targeting epigenetic regulators may provide novel therapeutic strategies to overcome these barriers, thereby rescuing terminally exhausted T cells. In this project, we used malignant pleural effusions from advanced lung cancer patients as a source of primary exhausted T cells. Through high-throughput screening of an epigenetic compound library, we identified several bromodomain inhibitors (BETis) as potent enhancers of T cell polyfunctionality in primary human T cells. Treatment with BETis, like JQ1, reduces inhibitory receptor expression and increases effector cytokine production. Transcriptomic and ATAC-seq profiling revealed that JQ1 modulates key metabolic pathways and induces chromatin accessibility changes in primary effusion-infiltrative T cells. Untargeted metabolomics showed that JQ1 expands the polyamine spermidine pool in T cells. Inhibition of ornithine decarboxylase (ODC1), a key enzyme in polyamine biosynthesis, diminishes JQ1's reinvigorating effects on these T cells. scRNA-seq analysis revealed that JQ1 reduces terminally exhausted T cells and promotes the expansion of progenitor exhausted T cells, which are more responsive to checkpoint inhibitors, by upregulating ODC1 and its upstream regulator, MYC. Notably, adoptive transfer of JQ1-treated T cells significantly reduced tumor-associated MPE in a syngeneic mouse model. Our study demonstrates that BET inhibitors enhance T cell polyfunctionality and modulate terminally exhausted T cells through metabolic reprogramming, notably by upregulating the polyamine biosynthesis pathway. These findings highlight the potential of epigenetic-based cancer immunotherapy for novel therapeutic strategies.

#4839 Harnessing the cGAS-STING signaling and immune checkpoint pathways to enhance the tumor microenvironment for breast cancer immunotherapy.

Shu-Ping Wang[1], Marvin Angelo E. Aberin[1], Saurabh Singh[2], Soumya Chatterjee[2], Guang-Zhi Sui[2], Joy Khag[1], Weng-Lang Yang[2], Chen-Yang Shen[1], Yao-Ming Chang[1], Shih-Yu Chen[1], Chandan Guha[2]

[1]Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan,[2]Department of Radiation Oncology, Albert Einstein College of Medicine, Bronx, NY

Immune checkpoint blockade (ICB) therapy has revolutionized cancer treatment, but resistance remains common with only some patients showing lasting responses. This underscores the need to understand resistance mechanisms and develop strategies to enhance responsiveness. In this study, we focus on breast cancer, particularly estrogen receptor-positive (ER$^+$) breast cancer, which is generally poorly immunogenic and responds unfavorably to ICB. Upon analyzing the METABRIC cohort's immunogenic biomarkers and tumor mutational burden (TMB), we found that relapsed ER$^+$ patients treated with endocrine therapy (ET) exhibit activated immune pathways. However, high levels of TMB and interferon-stimulated gene (ISG) expression correlated with worse outcomes in these patients, suggesting that ET modulates an active but clinically ineffective immune response. To explore the ET-dependent immune resistance mechanisms, we developed chronically tamoxifen-treated T47D and MCF7 cells (cTMX-T47D and cTMX-MCF7) and found increased type I interferon (IFN-I) signaling and innate immunity. This was confirmed in vivo with T47D xenograft showing enhanced IFN-I signaling. Further analyses revealed that tamoxifen's DNA-damaging ability modulates the TME through mitochondrial DNA (mtDNA) damage-induced STING upregulation. Depleting mtDNA in tamoxifen-treated cells reduced STING upregulation, IFN-I pathway activation, and ISG expression. Furthermore, we identified that the RACK7/KDM5C H3K4 demethylase complex is crucial for such regulation. Tamoxifen induces the reduction of RACK7/KDM5C protein stability via its ER inhibitory ability, leading to the upregulation of STING and ISG expression. Surprisingly, we discovered that tamoxifen can also induce CEACAM1 upregulation via a RACK7/KDM5C-USF1/IRF2-CEACAM1 transcriptional regulatory axis. These findings highlight the tamoxifen-RACK7/KDM5C-CEACAM1 axis's role in creating a tumor-favorable TME conducive to immune evasion and robust tumor growth. Preclinical TS/A (ER$^+$) syngeneic tumor mouse model showed that combining tamoxifen treatment with RACK7 knockdown enhances innate immunity effects compared to either treatment alone. Blocking CEACAM1-TIM3 interaction with an anti-TIM3 antibody significantly inhibited TS/A tumor growth upon the combined tamoxifen and RACK7-knockdown treatment, underscoring the CEACAM1-TIM3 pathway's role in tamoxifen resistance. In conclusion, our study provides direct evidence for tamoxifen-mediated ICB resistance mechanisms. Prolonged tamoxifen treatment reduces RACK7/KDM5C levels, increasing STING and CEACAM1 expression, creating an immunosuppressive TME via TIM3-dependent T-cell exhaustion. This fosters an immunosuppressive yet ready-to-fire TME, augmenting the efficacy of anti-CEACAM1/TIM3 immunotherapy.

#4840 Investigation of the potential immunomodulatory effect of vitamin D supplementation in vitamin D deficient cancer patients.

Alexandra Kalmar[1], Zsofia Brigitta Nagy[1], Liza Dalma Sumegi[1], Barbara Kinga Bartak[1], Sandor Spisak[2], Istvan Takacs[1], Bela Molnar[1]

[1]Department of Internal Medicine and Oncology, Semmelweis University, Budapest, Hungary,[2]Institute of Enzymology, Research Centre for Natural Sciences, Eotvos Lorand Research Network, Budapest, Hungary

Background: Advantageous effects of vitamin D supplementation have been studied in certain diseases, but the underlying chromatin remodeling processes remains to be explored in detail during the treatment of cancer patients.
Aim: We aimed to assess the molecular effects of high-dose vitamin D supplementation in patients diagnosed with various cancer types.
Methods: High-dose (30.000 NE) vitamin D per week was supplemented to 8 patients including 5 lung cancer, 2 colorectal cancer, and 1 urothelial cell carcinomas for two months. Following the blood collection before and after the supplementation period, Histopaque density gradient cell separation was applied to retrieve peripheral mononuclear cells (PBMCs). To examine alterations in the chromatin accessibility after the treatment in PBMCs, assay for transposase-accessible chromatin with sequencing (ATAC-Seq) was performed using the 10X Genomics on a NextSeq 550 instrument with a High Output Sequencing kit (Illumina Inc.). DNA integrity was assessed by the alkaline Comet-assay and telomere qPCR. To analyze further potential epigenetic alterations, global DNA methylation level was estimated on the basis of LINE-1 bisulfite-pyrosequencing experiments on cfDNA and PBMC cells.
Results: Vitamin D serum levels elevated 2,5 fold on average after 2 months of supplementation in all patients. Based on ATAC-Seq, the cellular ratio among PMBC cells altered with an elevated number of NK cells following vitamin D supplementation. DNA integrity was significantly better after treatment in mononuclear cells with decreased Comet assay DNA tail average % ($p=0.01$), but not in granulocytes. Supplemented samples showed significantly altered telomere length in mononuclear cells ($p=0.007$). However, no significant difference was observed in cfDNA levels between the sample groups. Slight, but not significant LINE-1 methylation alteration was detected in PBMCs and cfDNA after vitamin D supplementation.
Conclusion: Vitamin D supplementation caused significant changes in immune cells that might have an influence on the response to the tumors in cancer patients.

#4841 DNA methylation status classifies pleural mesothelioma cells according to their immune profile: implication for precision epigenetic therapy.

Maria Fortunata Lofiego[1], Rossella Tufano[2], Emma Bello[1], Laura Solmonese[1], Francesco Marzani[1], Francesca Piazzini[1], Fabrizio Celesti[1], Francesca Pia Caruso[2], Teresa Maria Rosaria Noviello[3], Roberta Mortarini[4], Andrea Anichini[4], Michele Ceccarelli[3], Luana Calabro[5], Michele Maio[1], Sandra Coral[1], Anna Maria Di Giacomo[1], Alessia Covre[1]

[1]Center for Immuno-Oncology - University of Siena, Siena, Italy,[2]BIOGEM Institute of Molecular Biology and Genetics, Ariano Irpino, Italy,[3]Sylvester Comprehensive Cancer Center, Miller School of Medicine, University of Miami, Miami, FL,[4]Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,[5]University of Ferrara, Ferrara, Italy

Background: co-targeting of immune checkpoint inhibitors (ICI) CTLA-4 and PD-1 has recently become the new first-line standard of care therapy of pleural mesothelioma (PM) patients, with a significant improvement of overall survival (OS) over conventional chemotherapy. The analysis by tumor histotype demonstrated a greater efficacy of ICI therapy, compared to standard chemotherapy, in non-epithelioid (non-E) *vs.* epithelioid (E) PM, although some E PM patients also benefit from treatment. This evidence suggests that molecular tumor features, beyond histotype, could be relevant to improve the efficacy of ICI therapy in PM. Among these, tumor DNA methylation emerges as a promising factor to explore, due to its potential role in driving the immune phenotype of cancer cells. Therefore, we utilized a panel of cultured PM cells of different histotype to provide preclinical evidence supporting the role of the tumor methylation landscape and of its pharmacologic modulation, to prospectively improve the efficacy of ICI therapy of PM patients.
Methods: the methylome profile (EPIC array) of distinct E (n=5) and non-E (n=9) PM cell lines was analyzed, followed by integrated analysis with their associated transcriptomic profile (Clariom S array), before and after *in vitro* treatment with the DNA hypomethylating agent (DHA) guadecitabine. The most variable methylated probes were selected to calculate the methylation score (CIMP index) for each cell line at baseline. Genes that were differentially expressed and methylated were then selected for gene ontology analysis.
Results: the CIMP index stratified PM cell lines into two distinct classes, CIMP (hypermethylated; n=7) and LOW (hypomethylated; n=7), regardless of their E or non-E histotype. Integrated methylome and transcriptome analyses revealed that CIMP PM cells exhibited a substantial number of hypermethylated, silenced genes, which negatively impacted their immune phenotype compared to LOW PM cells. Treatment with DHA reverted the methylation-driven immune-compromised profile of CIMP PM cells and enhanced the constitutive immune-favorable profile of LOW PM cells.
Conclusion: the study highlighted the relevance of DNA methylation in shaping the constitutive immune classification of PM cells, independent of their histological subtypes. The identified role of DHA in shifting the phenotype of PM cells towards an immune-favorable state supports its potential role in clinical trials of precision epigenetic therapy combined with ICI.

#4842 Inhibition of BPTF enhances the antitumor effects of doxorubicin through mitochondrial disfunction.

Manjulata Singh[1], Nasser AlAbdulaly[1], Madison Isbell[1], Dipankar Bandyopadhyay[1], Mikhail Dozmorov[1], Rebecca Martin[1], Will Pomerantz[2], **Joseph W. Landry**[1]

[1]Virginia Commonwealth University, Richmond, VA,[2]University of Minnesota, Minneapolis, MN

Epigenetics has established itself as a hallmark of cancer having essential roles in its initiation, establishment, and progression. Because of their reversibility, epigenetics has been aggressively targeted pharmacologically to correct abnormal cancer biology in the hopes of reversing cancer phenotypes. To develop novel epigenetic based therapeutic strategies for triple negative breast cancer (TNBC) we combined loss of function approaches (shRNA - KD, CAS9 - KO, and small molecule inhibitors) to the chromatin remolding protein Bromodomain PHD-finger Transcription Factor (BPTF) with standard of care chemotherapies doxorubicin (Doxo), etoposide (Eto) and paclitaxel (Pac). Using the 4T1 and E0771-LMB mouse TNBC models we show that BPTF inhibited cells are more susceptible to the anticancer effects of Doxo, Eto and Pac. However, in tumor bearing mice sensitivity to Doxo, but not Eto or Pac is observed. A 30 color spectral flow cytometry analysis of both intratumor and splenic immune cells does not observe significant differences in immune cell populations from mice bearing BPTF inhibited tumors treated with Doxo. Using immune compromised mouse backgrounds, we observe that the in vivo sensitivity to Doxo requires NK cells, but not CD8 or CD4 T cells. Ex vivo NK cell coculturing assays discovers selectivity for NK cell killing after treatment with Doxo, but not Eto or Pac. RNA-Seq analysis of genetic and BPTF small molecule inhibited cells treated with Doxo discovers the activation of several pro-apoptotic pathways including TNF signaling, apoptosis, mitophagy, and ferroptosis. In vitro analysis shows that BPTF inhibited cells increase apoptosis selectively after exposure to Doxo over Eto and Pac, and the increase in apoptosis coincides with increased mitophagy (Mitotracker QC), but not autophagy (LC3B-GFP-RFP conversion) and is preceded by enhanced cytochrome c release. Depletion of mitophagy regulators reduces the observed enhanced apoptosis in vitro and tumor growth control in vivo with the combination of BPTF KO and Doxo exposure. Analysis of NK cell receptor binding (NKG2D, NCR1, DNAM1) to control and BPTF KD Doxo treated cells did not reveal significant differences and analysis of cytokine, and eicosanoid release with Doxo, Eto and Pac show minor significant differences with BPTF KD. However, enhanced sensitivity to select pro-apoptotic molecules produced by NK cells was observed, and this sensitivity was reduced with suppression of mitophagy. These results suggest that BPTF inhibition results in enhanced mitochondrial disfunction with Doxo exposure which results in enhanced activity of NK cell proapoptotic molecules which results in enhanced tumor growth control.

#4843 TET2 oxidizes chromatin-associated regulatory RNA m^5C to potentiate anti-tumor immunity.

Ying Qing[1], Dong Wu[1], Yangchan Li[1], Keren Zhou[1], Keith Leung[1], Wei Li[1], Le Xuan Truong Nguyen[2], Lei Dong[1], Chao Shen[1], Meilin Xue[1], Zhenhua Chen[1], Kitty Wang[1], Lillian Sau[1], Mike Fernandez[1], Zhaoxu Xu[1], Yuan Che[1], Tingting Tang[1], Miao Sun[3], Li Han[1], Zhicong Zhao[1], Meiling Chen[1], Mingjiang Xu[4], Lili Wang[1], Guido Marcucci[2], Rui Su[1], Xiaolan Deng[1], Jianjun Chen[1]

[1]Department of Systems Biology and Center for RNA Biology and Therapeutics, Beckman Research Institute of The City of Hope, Duarte, CA,[2]Department of Hematologic Malignancies Translational Science, Beckman Research Institute of The City of Hope, Duarte, CA,[3]Keck School of Medicine of USC, Los Angeles, CA,[4]The University of Texas Health Science Center at San Antonio, San Antonio, TX

Current immunotherapies have shown limited success in treating acute myeloid leukemia (AML) due to immune evasion, which often stems from epigenetic dysregulation of immune-related pathways. TET2, a well-studied DNA 5-methylcytosine dioxygenase, is frequently mutated and recognized as a tumor suppressor in AML. While *TET2* deficiency in hematopoietic stem/progenitor cells (HSPCs) has been associated with elevated inflammation, TET2 has also been reported to promote inflammatory interferon (IFN) signaling in solid tumors, enhancing tumor responses to immunotherapies. Despite these findings, the precise role of TET2 in the response of established AML to anti-tumor immunity and the underlying molecular mechanisms remain poorly understood. By use of both syngeneic and xeno-transplantation AML mouse models, including patient-derived xenotransplantation (PDX) models, as well as *in vitro* co-culture systems with primary AML cells and T cells, our results revealed that TET2 sensitizes AML cells to T cell-mediated immunity by promoting the transcription of IFN-stimulated genes (ISGs). Mechanistically, we employed UHPLC-QQQ-MS/MS and optimized bisulfite-mediated 5-methylcytosine (m^5C) sequencing and demonstrated that chromatin-associated regulatory RNAs (carRNAs) are modified with m^5C and TET2 removes m^5C from target carRNAs such as LINE1, which subsequently prevents carRNA degradation mediated by SRSF2. Loss of *TET2* in AML cells leads to increased m^5C levels on carRNAs and decreased LINE1 abundance, which in turn suppresses ISG transcription, facilitating immune evasion. Collectively, this study clarifies the immune-promoting role of TET2 in established AML and elucidates a previously unappreciated molecular mechanism by which TET2 promotes ISG transcription through carRNA m^5C oxidation and thereby facilitates immune response. Our findings underscore the therapeutic potential of targeting the TET2-carRNA m^5C-ISG pathway to overcome AML immune evasion and improve immunotherapy outcomes in AML.

#4844 Epigenetic reprogramming of the STING pathway as a combination strategy in high grade serous ovarian cancer.

Saranya Rajendran[1], Elnaz Abbasi Farid[1], Kaushlendra Tripathi[2], Ishani Chattopadhayay[1], Shu Zhang[1], Stephen B. Baylin[3], Feyruz V. Rassool[2], Kenneth P. Nephew[1]

[1]School of Medicine, Indiana University, Bloomington, IN,[2]Marlene and Stewart Greenebaum Comprehensive Cancer Center, University of Maryland, Baltimore, MD,[3]Department of Oncology, The Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD

High-grade serous ovarian carcinoma (HGSOC), accounting for 70% of ovarian carcinoma cases, is often diagnosed at an advanced stage and associated with a poor prognosis. A significant clinical challenge is the lack of effective treatments for platinum-resistant OC and non-BRCA-mutated, homologous recombination proficient (HRP) tumors, which represent over 50% of HGSOC. Furthermore, although cancer immunotherapies can produce complete and durable responses, response rates in OC are modest with most patients experiencing only transient therapeutic benefit, underlining the urgent need for novel approaches to enhance antitumor immunity. Our prior research demonstrated that DNMT inhibitors (DNMTis) and PARP inhibitors upregulate ZNFX1, a zinc finger protein that facilitates STING-dependent interferon signaling and antitumor immune responses through a mechanism of pathogen mimicry. We hypothesize that in addition to upregulating ZNFX1 and immune responses, DNMTis restore STING through epigenetic reprogramming, leading to tumor cell intrinsic STING activation mediating anti-tumor response. In this study, we investigated the role of STING in HGSOC and the mechanisms underlying STING pathway activation by DNMTi. Analysis of the TCGA and GTEX database revealed reduced basal STING expression in HGSOC patient tumors, predominantly in TP53 mutant HGSOC. Furthermore, higher STING expression was linked to improved overall and progression free survival. Analysis of STING methylation in normal and HGSOC samples from TCGA database identified 6 hypermethylated sites near the promoter region/transcriptional start site. Our Infinium MethylationEPIC Array v2.0 BeadChip profiling of the HGSOC cell line OVCAR3 showed hypermethylation of these 6 sites. To determine whether this promoter-driven silencing could be reversed, we treated HRP and HR-deficient (HRD) HGSOC cell lines with increasing concentrations of DNMTi (0-100 nM decitabine, DAC). This treatment increased ($P<0.01$) STING expression in a dose-dependent manner and upregulated ($P<0.001$) downstream STING targets, CXCL10, TNFα, IL6. To further evaluate STING agonist could restore functional activation of STING signaling in addition to demethylation, HGSOC cells were treated with DAC (10nM), STING agonist (CRD3874; 1μM) and combination and evaluated for downstream STING targets by western and qPCR. The DAC-STING agonist combination increased pSTING1, pTBK1, and pIRF3 and apoptosis-dependent cell death. Additionally, combination treatment markedly reduced proliferation, colony and spheroid formation compared to single drug treatments. Together, these results demonstrate epigenetic regulation of STING expression in HGSOC, regardless of HRD status. Combining a DNMTi with a STING agonist has the potential to enhance the antitumor immune response and represents a promising therapeutic strategy for HGSOC patients.

#4845 The MLL3/GRHL2 complex modulates early malignant development and anti-tumor immunity in upper aerodigestive squamous cell carcinoma.

Chehyun Nam[1], Guowei Huang[2], Yueyuan Zheng[3], Hua Zhao[1], Ethan Pan[1], Boyan Hu[1], Talia Wenger[1], Hieu Van[4], Liyan Xu[5], En-min Li[5], H.Phillip Koeffler[3], Kai Ge[4], Yali Dou[6], Uttam K. Sinha[7], Young Min Park[8], De-Chen Lin[1]

[1]Center for Craniofacial Molecular Biology, USC - University of Southern California, Los Angeles, CA,[2]Institute of Oncologic Pathology, Shantou University Medical College, Shantou, China,[3]Cedars-Sinai Medical Center, Los Angeles, CA,[4]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD,[5]Shantou University Medical College, Shantou, China,[6]USC - University of Southern California, Los Angeles, CA,[7]Keck school of medicine, USC - University of Southern California, Los Angeles, CA,[8]Department of Medicine, Yonsei University, Seoul, Korea, Republic of

Upper aerodigestive squamous cell carcinoma (UASCC), including head and neck squamous cell carcinoma (HNSCC) and esophageal squamous cell carcinoma (ESCC), poses substantial challenges in clinical care due to its aggressive behavior and poorly understood mechanisms of early malignant transformation. This study investigates the role of MLL3 mutations as critical, clonal genomic events driving UASCC tumorigenesis. Using CRISPR-edited organoid models across species, we demonstrate that MLL3 loss facilitates early squamous neoplastic evolution. Additionally, we uncover an MLL3/GRHL2 protein complex that orchestrates epigenomic regulation, particularly influencing immune-related pathways. Strikingly, we identify a novel MLL3/GRHL2-IRF1 axis that induces the expression of Th1 chemokines, such as CXCL9 and CXCL10, enhancing anti-tumor immunity by promoting T cell infiltration within the tumor microenvironment. In syngeneic mouse models, including both subcutaneous and orthotopic settings, MLL3 was shown to modulate the efficacy of immune checkpoint blockade (ICB) therapy. Consistently, clinical data from human patients demonstrate a robust correlation between MLL3 expression and responsiveness to ICB therapy. This study underscores the pivotal role of MLL3 in UASCC pathogenesis and highlights the therapeutic potential of targeting the MLL3/GRHL2-mediated immune response pathways to improve outcomes in UASCC treatment.

#4849 MYC-mediated resistance to immune activation by SWI/SNF mutation or chemical inhibition.

Shitian Li, Diana Hargreaves

Molecular and Cell Biology Laboratory, Salk Institute For Biological Studies, La Jolla, CA

ARID1A is a critical subunit of the SWI/SNF chromatin remodeling complex, frequently mutated in several cancers. We have shown that loss of ARID1A induces an accumulation of R-loops, leading to cytosolic release of RNA:DNA hybrids and single stranded DNA (ssDNA) and cGAS/STING-dependent activation of Type I interferon (IFN-I) stimulated genes (ISGs). SWI/SNF ATPase inhibitors (FHD-286, BRD98, and BRM014) and degraders (ACBI1) similarly induce ISGs through a cGAS/STING-dependent mechanism. Consequently, ARID1A mutant tumors are more highly infiltrated with cytotoxic CD8+ T cells and exhibited enhanced tumor immunity and sensitivity to immune checkpoint blockade (ICB)[1]. These results provide a molecular mechanism for the enrichment of ARID1A mutations among ICB responders. However, co-occurring oncogenic mutations in ARID1A mutant cancers, such as MYC, KRAS, and β-catenin, have been associated with immunosuppression in some cases through suppression of IFN-I signaling and ISG expression. It is not known how such co-occurring mutations affect the ARID1A mutant ISG response or whether such mutations would counteract ISG activation by SWI/SNF inhibitors. In this study, we investigate the impact of MYC overexpression on IFN-I responses induced by ARID1A loss or SWI/SNF inhibition in cancer cells. Our data reveal that MYC overexpression impairs the ability of these cells to induce IFN-I response genes (ISGs) when cells are directly stimulated with IFN-I or treated with inhibitors targeting the SWI/SNF complex, including FHD-286 and BRM014. Through bulk RNA-seq, we characterize the molecular mechanisms underlying this resistance, with a focus on IFN-I related genes. This study highlights the suppressive effect of MYC overexpression on IFN-I responses in ARID1A-deficient cancers and suggests a potential link to therapeutic resistance in MYC-high tumors. While the precise molecular mechanisms remain to be fully elucidated, these findings provide a foundation for future studies aimed at understanding the interplay between oncogenic drivers and immune signaling pathways, with implications for developing more effective therapeutic strategies.

IMMUNOLOGY: Immune Fitness and Metabolic Regulation of Cancer Immunity
Poster Session

#4851 Disrupting redox homeostasis in pancreatic ductal adenocarcinoma initiates anti-tumor immune responses.
Vishal Pandya[1], Lucie Malbeteau[2], Emily Poulton[3], Marianne Koritainsky[2]

[1]Institute of Medical Science, University of Toronto, Toronto, ON, Canada,[2]UHN Princess Margaret Cancer Centre, Toronto, ON, Canada,[3]Medical Biophysics, University of Toronto, Toronto, ON, Canada

Immunotherapy has improved cancer treatment by ameliorating outcomes for patients with aggressive cancers. However, pancreatic ductal adenocarcinoma (PDAC) remains resistant to various immunotherapies. This resistance can be attributed to the immunosuppressive PDAC tumor microenvironment. Immunosuppressive cells populate the tumor microenvironment in the early neoplastic stages of the disease, suggesting that neoadjuvant therapies may be needed to overcome immune suppression. New therapeutic strategies that prime the immune response against PDAC are needed to improve the efficacy of immunotherapy. We aim to overcome immune suppression by leveraging redox vulnerabilities in PDAC. Our lab identified the antioxidant protein peroxiredoxin-4 (PRDX4) as essential for PDAC cell survival but dispensable in normal tissue, making it a promising therapeutic target. PRDX4 neutralizes reactive oxygen species in the endoplasmic reticulum and its depletion leads to decreased tumor growth and substantial DNA damage. From this, we hypothesize that PRDX4 depletion causes immunogenic DNA damage and initiates immune responses against PDAC. We generated stable doxycycline-inducible PRDX4 knockdown in the human PANC-1 and mouse KPC (LSL-Kras^{G12D};LSL-p53^{R172H};Pdx1-CreER) PDAC cell lines. Using immunofluorescence imaging, we show that PRDX4 depletion leads to cytosolic DNA in the form of micronuclei and dispersed DNA. We also show using RT-qPCR and ELISA that PRDX4 depletion leads to an increase in chemokine production, like CCL5, CXCL10 and CCL20. Using siRNA targeting both NF-κB and the DNA sensor cGAS, we show that this chemokine production is activated through the cGAS-STING pathway. Finally, using DNase to clear the cytosolic DNA, we show that cGAS-STING activation and chemokine production can be attributed to PRDX4 depletion-induced cytosolic DNA. To extend these findings *in vivo*, we created an immunocompetent KPC-PRDX4 mouse model by crossing KPC mice with PRDX4^{KO} mice. This model develops spontaneous and staged cancer progression, from neoplastic lesions to PDAC. It also recapitulates the immune infiltrate seen in the human disease, making it a good model to study immune dynamics in the tumor microenvironment. Based on the strong chemokine response seen *in vitro*, we are now measuring the effects of PRDX4 depletion on the immune cell composition in the tumor microenvironment. Ongoing studies include immunofluorescence imaging and flow cytometry using tumor samples from our model. The aggressive growth and treatment resistance of PDAC demand research towards novel treatment strategies. This project contributes supporting evidence for targeting cancer metabolism, particularly PRDX4, to enhance immune responses in PDAC.

#4852 Carbonic anhydrase IX and hypoxia-induced metabolic adaptations in tumor immune microenvironment: Insights into enhancing anti-PD1 efficacy in lung cancer.

Mariel Alejandra Fusco[1], Maria Florencia Mercogliano[2], Marco Aurelio Diaz Gutierrez[1], Carlos Rafael Picon[3], Paula Rosello[4], Mara Stinco[1], Flavia Piccioni[1], Constanza Paula Arriola Benitez[1], Mauricio Cesar De Marzi[5], Manglio Miguel Rizzo[3], Mariana Malvicini[1]

[1]Cancer Immunobiology Lab, Instituto de Investigaciones en Medicina Traslacional (IIMT), Universidad Austral-CONICET, Pilar, Argentina,[2]Tumor Immunology Lab, Instituto de Biologia y Medicina Experimental (IBYME-CONICET), CABA, Argentina,[3]Servicio de Oncologia, Hospital Universitario Austral, Pilar, Argentina,[4]Instituto de Investigaciones en Medicina Traslacional (IIMT), Universidad Austral-CONICET, Pilar, Argentina,[5]Universidad Nacional de Lujan - CONICET, Lujan, Argentina

In solid tumors, cancer cell survival is largely driven by hypoxia-induced metabolic changes, including the enhancement of glycolysis and extracellular acidification. This process is facilitated by enzymes such as carbonic anhydrase IX (CAIX), which is upregulated under low oxygen tension to regulate pH by exchanging H+ ions and releasing lactate. These changes contribute to an acidic tumor microenvironment (TME) that alters immune cell functionality, particularly by recruiting tumor-associated macrophages (TAMs) and stimulating immune checkpoints like PD-L1. Our analysis of The Cancer Genome Atlas (TCGA) lung cancer data reveals that CAIX and hypoxia-inducible factor 1a (HIF1a) expression levels are significantly elevated in lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC) subtypes of non-small cell lung cancer (NSCLC) ($p<0.001$), with higher CAIX expression correlating with reduced overall survival. Strong correlations between HIF1a and CAIX, HIF1a and PD-L1, and PD-L1 and TAM markers (CD68, CD163) underscore a complex hypoxia-driven immunosuppressive mechanism. As we have reported that coumarin 4-methylumbelliferone (4Mu) modifies HIF1a tumor levels, we aim to test the effect of 4Mu in vitro under hypoxia/normoxia and in vivo combined with antiPD-1 therapy, using Lewis Lung Carcinoma cells (LLC). Hypoxia induces an increase in CAIX levels compared to normoxia ($p<0.05$), reduces extracellular pH ($p<0.05$), and increases levels of lactate. However, under hypoxic conditions, 4Mu restored CAIX, pH, and lactate levels to near-baseline levels. Moreover, LLC cells conditioned under hypoxia + 4Mu induced an M1 cytokine profile in macrophages, contrasting with the M2 polarization observed with hypoxia alone. In vivo, 4Mu reduced CAIX expression, and combination of 4Mu with anti-PD1 therapy increased the infiltration of CD8+ and CD4+ T cells and significantly improved anti-tumor efficacy ($p<0.01$). These findings suggest that targeting CAIX can modulate the TME, enhancing immune responses and potentially improving clinical outcomes for NSCLC patients receiving immunotherapy.

#4853 Knockout of hypoxia inducible factor 1 subunit alpha (HIF1a) augments the antitumor activity of EGFR CAR-NK cells.

Fanxiang Gao[1], Tingting Liu[1], Qin Wang[1], Yanxue Gong[1], Chao Wang[1], Feng Zhou[2], **Zhuoxiao Cao**[1]

[1]Shanghai Simnova Biotechnology Co., Ltd., Shanghai, China,[2]State Key Laboratory of Neurology and Oncology Drug Development, Simcere Zaiming Pharmaceutical Co, Ltd., Shanghai, China

Chimeric antigen receptor T-cell (CAR-T) therapies have gained remarkable success with durable remissions in hematologic malignancies. However, the potential adverse effects, including cytokine release syndrome (CRS), graft-versus-host disease (GVHD), neurotoxicity, and off-tumor toxicity, and high production cost have limited the clinical application of CAR-T cells in oncological treatment. Recently, natural killer (NK) cells has emerged as a promising alternative immunotherapy with high biosafety and universal application. Nevertheless, the persistence and efficacy of CAR-NK cells remains to be solved. Knockout of immune checkpoint molecules (ICPs) has been proved to be an effective way to enhance the potencies of CAR-NK cells, such as cytokine inducible SH2-containing protein (CISH) and Cbl proto-oncogene B (CBLB). In solid tumors, hypoxic microenvironment can drive tumor-infiltrating NK cells dysfunction. Cellular response to hypoxia is mediated by hypoxia-inducible factors. Hypoxia inducible factor 1 (HIF1) is a master regulator and inhibits activation markers and effector molecules of tumor-infiltrating NK cells in hypoxic conditions. In this study, we disrupted HIF1a, alpha subunit of HIF1, in NK cells derived from peripheral blood mononuclear cells (PBMCs) to evaluated the anti-tumor effects. Then EGFR CAR molecules were transduced into the NK cells with retroviral vector. Successful knockout was performed by CRISPR/Cas9 and confirmed by TIDE, ICE and qPCR analysis. Our results showed that the NK cell viability was slightly affected by electroporation and gradually returned, leading to a slight reduction in knockout NK cell expansion. However, the freeze-thaw viabilities viability of knockout NK cells was comparable to that of control cells. Flow cytometry assay demonstrated that several stimulatory receptors were up-regulated in HIF1a-/- NK cells, such as CD57, CD62L, CD69, and NKp44, and some inhibitory and activating receptors were down-regulated, including NKG2A, CD38, NKp30 and NKp46. Using luciferase-based serial killing analysis, the knockout group exhibited greater in vitro cytotoxicity against HCT116 and SHP77 tumor cells compared to that of unedited CAR-NK. Moreover, HIF1a knockout significantly enhanced the anti-tumor activity of CAR-NK cells in SHP77 subcutaneously inoculated xenograft mouse model. Taken together, our data suggested that HIF1a deficiency could enhance the cytotoxicity and persistence of CAR-NK cells, and supported the further exploration for clinical application.

#4854 Alleviation of low pH induced immunosuppression through antagonism of the pH sensor GPR65 in highly glycolytic NSCLC tumors.

Prajna Behera[1], Samantha Buongervino[1], Kayla Guidry[1], Kyle Krois[1], Yanah Hossain[1], Victor Du[1], Tamara Ouspenskaia[1], Hongyu (Annie) Liang[2], Shu-Yun Zhang[2], Laura Johnston,[2], Abby Lin[2], Tolu Aweda[2], Ramona Plant[2], Paul Bojczuk[2], Marica Speranza[1], Chris Hopson[2], Charles McHugh[2], Stacey Kendrew[2], Bradley Spencer-Dene[3], Susanne Moore[3], Deon Hildebrand[3], Jonathan Lea[3], Kerena Norris[3], Antonia Lewis[3], Jacob Brett[3], Paru Rao[2], Carol Harris[3], Joseph Pero[2], Laura Ator[2], Jing Fang[2], David washburn[2], Lisa Sloan[3], Catherine Alder[3], Richard Lonsdale[3], Nick Barton[3], Sue Griffin[3], Paul Redford[3], James Smothers[2]

[1]GSK, Cambridge, MA,[2]GSK, Collegeville, PA,[3]GSK, Stevenage, United Kingdom

Out of more than 5683 clinical trials testing anti-PD1/PDL1 mAbs, on average only 20% of patients achieved an objective response, leaving an unmet need for patients who do not respond to immune checkpoint inhibitors (ICIs)(Zhao *et al*, 2020, Upadhyaya *et al*, 2022). Independent reports in NSCLC and melanoma suggest that non responders to ICI exhibit elevated levels of tumor “aerobic” glycolysis (Renner *et al*, 2019, Silva *et al*, 2022), a phenotype associated with solid and metastatic tumor cells (Hanahan, 2022). Aerobic glycolysis results in accumulation of lactate and acidification of the tumor microenvironment (TME), resulting in immune evasion through inhibition of pro-inflammatory/ anti-tumorigenic responses in surrounding immune cells (Li *et al*, 2022). GPR65 is a proton (pH) sensing GPCR, expressed on immune cells, signals via cAMP to activate anti-inflammatory pathways in multiple immune cell types (Robert and Mackay, 2018; Wang *et al*, 2023). In the context of solid tumors, GPR65 activation promotes the increase in anti-inflammatory TAMs, in addition to suppressing anti-tumor responses by NK and cytotoxic-T cell (Raker *et al*, 2016). GSK analysis of Tempus RW data conducted with TEMPUS LENS software indicated high glycolytic gene signature in NSCLC cohorts is associated with worse prognosis to both chemo and ICI therapies, providing a window of opportunity to target pH sensor GPR65. Ex vivo experiments demonstrated that low pH dampens the proinflammatory phenotype of monocyte-derived macrophages (MDMs), while knockout of GPR65 under these acidic conditions restores secretion of the proinflammatory cytokines CXCL9/10/11 in M1-like polarized MDMs. Compound A, an exemplar compound from our lead series, is a potent GPR65 antagonist with low nanomolar *in vitro* functional activity (pIC50=8.2) and excellent lipophilic ligand efficiency (6.9). It also features strong correlation between its functional and binding (nanoBRET) activities along with selectivity at GPR65 over GPR4 and GPR68. In vitro translational and cell-based assays demonstrated dose-dependent attenuation of proinflammatory cytokine release by primary CD8+T cells, M1 macrophages at pH 6.8 and in a NSCLC patient-derived tumor fragmentation assay. In vivo, compound A displays attractive pharmacokinetic (PK) properties in rodent with robust oral bioavailability. A preliminary estimate of projected human dose (PHD) is ~245 mg qd based on liver blood flow scaling of its rat PK properties and a targeted 24 h free drug coverage over functional *in vitro* IC50. Additional *In vivo* PD and/or efficacy data in translational models would further refine this calculation. In summary, we hypothesize that restricting immune cells from sensing acidification in the TME via antagonizing GPR65 will prevent the activation of anti-inflammatory programs in immune cells and promote proinflammatory anti-tumor effector mechanisms.

#4855 Metabolic and functional dynamics of T cell activation: bioluminescent assays for immune monitoring and modulation.

Kim Haupt, Kayla Sylvester, Tony Lauer, Natasha Karassina, Jolanta Vidugiriene

Promega Corporation, Madison, WI

Advancing our understanding of T cell activation and its regulatory pathways is critical for developing effective cancer immunotherapies. This study characterizes T cell health and functional dynamics under diverse activation conditions, highlighting key molecular mechanisms that influence immune responses within the tumor microenvironment. We investigate mTOR and AMPK signaling pathways, as well as the metabolic balance between glycolysis and oxidative phosphorylation, which are integral to T cell function in immunotherapeutic contexts. Using selective inhibitors, we identify modulators that regulate cytokine secretion and T cell metabolic states, revealing media composition as a significant variable affecting immune function. Our methodology leverages a suite of bioluminescent Lumit and Metabolite-Glo assays for sensitive quantification of cytokines and metabolites, enabling precise, non-invasive monitoring while preserving cell integrity. This approach is scalable and adaptable for analyzing diverse activation conditions and high-throughput screening applications. Additionally, our findings correlate these metabolic and functional profiles with cell surface markers assessed by traditional methods, providing a comprehensive framework for immune monitoring. These insights underscore the importance of metabolic and signaling interplay in T cell activation, offering a robust platform for studying immune dynamics and uncovering novel immunomodulatory targets. Our work supports the development of precision strategies to modulate T cell activity and optimize immune responses in cancer therapy.

#4856 Chronic anti-CD3/CD28 stimulation during cell expansion generates exhausted T cells with a distinct metabolic and cytotoxic phenotype.

G. Wang[1], X. Zhang[2], N. Romero[1];

[1]Agilent Technologies, Inc., Lexington, MA, [2]Agilent Technologies, Inc., La Jolla, CA

T cell exhaustion is one of the major causes of cancer immune evasion and contributes to the failure of immunotherapies targeted to solid tumors. Reversing T cell exhaustion is a promising strategy in cancer immunotherapy, as it can improve patients' responses to immune checkpoint inhibitors and adoptive T cell therapies. Recent publications showed that impairment of mitochondria function plays a critical role in developing and maintaining T cell exhaustion. This prompted us to explore the possibility of using metabolic profiling of T cells to assess relative T cell exhaustion as a tool to optimize T cell therapy product development. In our study, we induced exhaustion in previously expanded T cells via chronic stimulation with anti-CD3/CD28 Dynabeads and used briefly stimulated (24-hour) counterparts as controls. Across all three donors tested, chronically stimulated T cells exhibited reduced net proliferation, increased percentage of $PD1^{+}Tim3^{+}$ population, and decreased IL-2 secretion upon restimulation, while TNFα and IFNγ secretion varied by donor. We performed Xcelligence RTCA impedance-based, acute killing assays using Epcam-BiTEs to engage T cells to the Epcam expressing T47D cells. Surprisingly, we found that in some donors, cells exposed to chronic anti-CD3/CD28 Dynabeads, despite secrete significantly less cytokines upon antigen restimulation, display similar acute cytotoxicity compared to its non-exhausted counterparts. Importantly, when assessed using Seahorse XF assays, these exhausted T cells displayed a very distinctive metabolic phenotype, including decreased maximal respiration and spare respiratory capacity (SRC), increased glycolytic activity, and reduced capacity to further increase glycolytic activity upon acute reactivation. These findings suggest that metabolic profiling can represent a valuable tool for identifying metabolically fit T cells and is a great addition to the current matrix of parameters for assessing T cell exhaustion.

#4857 The role of tumor microenvironment lactic acid in the cancer cell resistance to anti-PD-L1 and anti-PD-1 blockade therapy.

Alyssa Kim[1], Wonkyung Oh[1], Deepika Dhawan[2], Deborah W. Knapp[2], Seung-Oe Lim[1]

[1]Borch Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN,[2]Department of Veterinary Clinical Science, Purdue University, West Lafayette, IN

Immune checkpoint blockade therapy targeting the PD-1/PD-L1 axis has shown remarkable clinical impact in multiple cancer types. However, despite its recent success, such impact has been shown to be limited to tumors encompassing specific tumor microenvironment characteristics. Furthermore, a significant proportion of initial responders eventually develop resistance. Combining PD-1/PD-L1 blockade with chemotherapy, radiotherapy, or targeted therapy have been suggested to overcome resistance, yet have been shown to be insufficient in fully accounting for resistance. Unlike normal, differentiated cells, most cancer cells produce large amounts of lactic acid. This metabolic property is often referred to as “aerobic glycolysis,” a well-known metabolic reprogramming of cancer cells to sustain cell proliferation and a hallmark of cancer. Such property as well as others of the altered metabolism of cancer cells and its byproducts affect the anti-tumor immune response. Notably, glycolytic metabolites, such as lactate, regulate T cell proliferation and function. However, the mechanism behind how such metabolic alterations impact the cancer cells’ resistance to PD-1/PD-L1 blockade therapy remains unclear. Thus, we sought to decipher the role of tumor-cell derived lactic acid in PD-1/PD-L1 therapy resistance and propose new immunotherapeutic strategies to improve the efficacy of PD-1/PD-L1 blockade therapies. Here, we found that tumor cell-derived lactic acid renders the immunosuppressive tumor microenvironment in the PD-1/PD-L1 blockade-resistant tumors by inhibiting the interaction between the PD-L1 protein and anti-PD-L1 antibody. Furthermore, we showed that the combination therapy of targeting PD-L1 with our PD-L1 antibody-drug conjugate (PD-L1-ADC) and reducing lactic acid with the MCT-1 inhibitor, AZD3965, can effectively treat the PD-1/PD-L1 blockade resistant tumors. Altogether, the findings in this study uncover a new mechanism of how lactic acid induces an immunosuppressive tumor microenvironment and suggest a potential combination treatment strategy to overcome the tumor resistance to PD-1/PD-L1 blockade therapy and improve clinical outcomes.

#4858 NKG2D co-stimulation via anti-sMIC/MIC immunotherapy reprograms intratumoral CD8 T cells toward TCF-1$^+$ stemness to enhance anti-tumor immunity.

Tyler A. Smith[1], Sizhe Liu[1], Ryan J. Brown[2], Weiguo Cui[2], Jennifer D. Wu[1]

[1]Urology, Northwestern University Feinberg School of Medicine, Chicago, IL,[2]Pathology, Northwestern University Feinberg School of Medicine, Chicago, IL

Effective co-stimulation of CD8 T cells is critical for maintenance of TCF-1$^+$ stem-like CD8 T cells necessary for long-term tumor control. NKG2D co-stimulation of CD8 T cells via binding of stress ligands such as membrane-bound MIC enhances CD8 T cell effector functions and is important for promoting memory development. Cancer cells often shed MIC into a soluble form (sMIC) that inhibits CD8 T cell activation. TRAMP prostate tumor mice expressing human MICB (TRAMP/MICB) treated with anti-sMIC/MIC antibody elicited potent anti-tumor responses with re-invigorated CD8 T cell immunity. However, mechanisms of CD8 T cell reprogramming by NKG2D co-stimulation in the tumor microenvironment are poorly understood. In this study, we used scRNA-seq of CD8 TILs from TRAMP/MICB mice treated or untreated with the anti-sMIC/MIC antibody to investigate the hypothesis that anti-sMIC/MIC therapy reprograms CD8 T cells via NKG2D pathway co-stimulation, optimizing TCR-dependent effector and memory responses. Adult male TRAMP/MICB mice were treated with 200µg anti-sMIC/MIC antibody intraperitoneally twice per week for 4-6 weeks. Prostate tumors were collected, and CD45$^+$ cells were flow sorted for scRNA-seq. scRNA-seq analyses were validated using flow cytometry. Tumors from mice treated with anti-sMIC/MIC therapy revealed enhanced functional heterogeneity of CD8 T cell subtypes. In contrast to tumors from untreated mice that were populated with primarily effector and/or exhausted CD8 T cells, tumors from treated mice were enriched in NKG2D$^+$ TCF-1$^+$ stem-like CD8 T cells. This effect of anti-sMIC/MIC therapy was then recapitulated in the syngeneic TRAMP-C2-MICB tumor model. TCF-1$^+$ CD8 T cells expressed higher levels of NKG2D compared to TCF-1$^-$ CD8 T cells, and displayed differential utilization of PI3K/Akt signaling pathways as well as upregulation of epigenetic regulators of CD8 T cell function such as *Kdm6b* and *Setd2*. Antigen-specific CD8 T cells chronically stimulated *ex vivo* with anti-sMIC/MIC antibody in complex with sMICB maintained greater proportions of TCF-1$^+$ stem-like CD8 T cells compared to antigen stimulation alone or in combination with sMICB. The results suggest that NKG2D co-stimulation via anti-MIC/sMIC therapy reprograms CD8 TILs to promote their development of TCF-1$^+$ stem-like function necessary for persistence of the anti-tumor response, and provides proof-of-concept for the translational potential of NKG2D signaling modulation in CD8 T cells to treat cancer.

#4859 TMEM33 loss improves CD8$^+$ T cell fitness and tumor control.

M. T. Jackson[1], T. Zhao[1], I. Pedroza-Pacheco[1], A. Grover[2], D. Gabrilovich[3], D. Withers[1], J. Rehwinkel[1], E. Honore[4], J. C. Christianson[1], E. E. Parkes[1];

[1]University of Oxford, Oxford, United Kingdom, [2]AstraZeneca, Cambridge, United Kingdom, [3]AstraZeneca, Gaithersburg, MD, [4]Institut de Pharmacologie Moleculaire et Cellulaire, Valbonne, France

The Endoplasmic Reticulum (ER) is a critical immunomodulatory hub governing multiple processes relating to anti-tumor immunity. TMEM33 is an ER-resident membrane protein implicated in various ER-associated functions including cholesterol metabolism, calcium oscillations, and proteostasis. We previously reported TMEM33 as a negative modulator of the innate immune signaling protein STING (STimulator of INterferon Genes). Here we identify a central role of TMEM33 in tumor immunology where its deficiency profoundly impacts infiltrating immune populations and T cell phenotype. STING-mediated ISG (interferon-stimulated gene) expression was augmented in *Tmem33*$^{-/-}$ bone marrow-derived macrophages and TMEM33-depleted Flp-In T-REx 293 cells. Strikingly, *Tmem33*$^{-/-}$ mice exhibited significantly attenuated B16F10-OVA tumor growth and enhanced CD8$^+$ T cell tumor infiltration compared to wild-type (WT) controls, while immunosuppressive immune populations including Treg cells, monocytic myeloid-derived suppressor cells and M2-like macrophages were diminished. CD8$^+$ T cell enrichment was also observed in MC38 tumor-bearing *Tmem33*$^{-/-}$ hosts. Unchallenged mice displayed no overt phenotypic or immunological differences compared to WT, however. High dimensional spectral flow cytometry was leveraged to further examine effects of *Tmem33*$^{-/-}$ on T cell compartments in B16F10-OVA tumors and draining lymph nodes (DLNs). Progenitor exhausted (Tpex) TCF-1$^+$PD-1$^+$ tumor infiltrating lymphocytes (TILs) were significantly enriched in *Tmem33*$^{-/-}$ hosts, notable given that Tpex are responsive to checkpoint blockade therapy and associate with improved patient prognosis. Compared to WT counterparts, OVA-specific *Tmem33*$^{-/-}$ TILs exhibited increased cytotoxicity and effector function, expressing elevated granzyme-B and TNF-α. Moreover, EOMES^{lo}T-bet^{hi} TILs were more frequent among TCF-1$^+$PD-1$^+$ and TCF-1$^+$ populations in *Tmem33*$^{-/-}$ hosts further suggestive of a more persistent CD8$^+$ precursor pool, while inhibitory receptor (LAG-3, TIGIT) abundance was blunted, indicating reduced exhaustion. In DLNs of *Tmem33*$^{-/-}$ mice, antigen-specific CD8$^+$ populations demonstrated enhanced effector memory (CD44$^+$CD62L$^-$) phenotypes alongside elevated CXCR3 expression compared to WT, suggesting increased tumor-migratory potential. In summary, here we identify TMEM33 as a novel immunoregulatory factor, the loss of which in hosts majorly reshapes the tumor-immune landscape and ameliorates multiple aspects of CD8$^+$ T cell fitness including stemness, exhaustion, memory, cytotoxicity and migratory capacity. Further analysis of T cell populations from tumor-bearing mice and *ex vivo* analysis will enable mechanistic refinement of the role of TMEM33. Moreover, our study supports the importance of ER-resident proteins in fine-tuning immune cell function, underlining their potential as promising targets for therapeutic intervention.

#4860 Pseudohypoxia induced by iron chelator activates tumor immune response in lung cancer.

Toshiaki Ohara[1], Yusuke Hamada[1], Yuehua Chen[1], Manato Terada[1], Hotaka Kawai[2], Masayoshi Fujisawa[1], Kazuhiro Noma[3], Hiroshi Tazawa[3], Toshiyoshi Fujiwara[3], Akihiro Matsukawa[1]

[1]Pathology and Experimental Medicine, Okayama Univ. Graduate School of Med., Okayama, Japan,[2]Oral Pathology and Medicine, Okayama Univ. Graduate School of Med., Okayama, Japan,[3]Gastroenterological Surgery, Okayama Univ. Graduate School of Med., Okayama, Japan

Hypoxia-inducible factor (HIF) plays a critical role in cellular to adaptation low oxygen levels and has been extensively studied as a biomarker of hypoxia. In cancer cells, HIF upregulation is believed to facilitate survival under hypoxic conditions, contributing to poor prognosis. However, recent studies have demonstrated that HIF signaling is crucial for immune cell function. Oxygen or iron depletion elevates HIF expression by inhibiting HIF-prolyl hydroxylase (HIF-PH) and preventing HIF degradation. Pseudohypoxia, characterized by normoxic HIF upregulation, is facilitated by iron chelators. In this study, we investigated whether pseudohypoxia induced by an iron chelator suppresses tumor growth by activating tumor immune responses, and elucidated the underlying mechanisms. Iron chelators, including Super-polyphenol 10 (SP10) and deferoxamine (DFO), were utilized to induce iron deficiency and pseudohypoxic condition. These compounds reduced the viability of human NSCLC cell lines (A549 and PC-3) but had no significant effect on murine NSCLC cell lines (LLC). Furthermore, SP10 and DFO did not impair the viability of murine CD8+ T cells isolated from normal spleen, while upregulating HIF-1α expression in these cells. Pseudohypoxia by iron chelators stimulated the secretion of IL-2, a cytokine with immunostimulatory properties, from lymphocytes (CD3+ T cells) and NSCLC cell lines (A549, PC-3, and LLC). In contrast, although hypoxic conditions promoted IL-6, a pro-inflammatory cytokine, pseudohypoxia did not induce IL-6 secretion in these cells. Oral administration of SP10 suppressed tumor growth in C57BL/6 mice with implanted tumors, a phenomenon absent in immunodeficient RAG1-deficient C57BL/6 mice. Western blot analysis revealed SP10-induced upregulation of HIF-1α expression within tumors. Immunohistochemistry and flow cytometry demonstrated that SP10 treatment enhanced IL-2 expression in both tumor and spleen tissues. Moreover, SP10 synergistically amplified the efficacy of PD-1 antibody therapy in lung cancer by increasing the infiltration of tumor-infiltrating lymphocytes (TILs). Iron chelation-induced pseudohypoxia directly upregulated HIF-1α, enhanced T cell functionality, and stimulated IL-2 secretion from CD4+, CD8+ T cells, and cancer cells, thereby enhancing the immune response and augmenting the therapeutic efficacy of PD-1 blockade in lung cancer.

#4861 INCA33890 increases CD8⁺ T-cell effector function compared with pembrolizumab as assessed by single-cell RNA sequencing in human PD-1xTGFβR2 knock-in mouse model.

Michelle Kinder[1], Jin Lu[1], Justine Carl[1], Lifeng Zhang[1], Paul Collier[1], Paul Waeltz[1], Rodrigo Hess[1], Natalia Pardo[2], Maria Terradas[2], Liang-Chuan Wang[1], Cynthia Timmers[1]

[1]Incyte Research Institute, Wilmington, DE,[2]Discovery and Translational Science (DTS), Clarivate Plc, Barcelona, Spain

INCA33890, a novel PD-1xTGFβR2 bispecific Biclonics® antibody, is designed to selectively inhibit TGFβR2 on PD-1⁺ cells, leveraging a higher binding affinity for PD-1 over TGFβR2. In preclinical studies using the MC38 colorectal tumor model in human PD-1xTGFβR2 Knock-in mice, INCA33890 had a superior antitumor efficacy compared with pembrolizumab, anti-TGFβR2 or isotype control. This study aimed to uncover the differential mechanism of tumor regression by applying single-cell TCR sequencing (scTCRseq) coupled with single-cell RNA sequencing (scRNAseq) on T cells derived from treated MC38 tumor-bearing mice. Intratumoral T cells were enriched and profiled using 10X Genomics scTCRseq and scRNAseq from MC38 tumor-bearing mice treated with INCA33890, pembrolizumab, anti-TGFβR2, or control antibodies. Results revealed that CD8⁺ T cells in INCA33890-treated mice exhibited a robust increase in RNA transcripts associated with cytotoxicity, proliferation, and T-cell exhaustion compared with pembrolizumab or control antibody treatments, signifying a potent effector response within the tumor microenvironment. Sub-grouping of CD8⁺ T cells into 13 distinct clusters based on marker expression and gene enrichment analysis demonstrated a notable expansion of proliferating, activated, and cytotoxic CD8⁺ T cell populations following INCA33890 treatment—an outcome not observed with pembrolizumab or control treatments. INCA33890 treatment also reduced the proportion of intratumoral-naïve CD8⁺ T cells, transforming their gene expression profile toward an effector-like phenotype. In intratumoral CD4⁺ T cells, treatment with INCA33890 resulted in signatures of enhanced activation, proliferation, and exhaustion compared with pembrolizumab and control treatments, suggesting broad engagement of the adaptive immune response. scTCRseq demonstrated a marked increase in the clonality of intratumoral T cells, further underscoring the impactful immune modulation induced by INCA033890. In summary, bispecific Biclonics® targeting of TGFβR2 and PD-1 with INCA33890 promotes the expansion and activation of effector CD8⁺ T-cell populations within the tumor microenvironment, driving enhanced antitumor activity in vivo.

#4862 Targeting *fli1* improves antitumor response of CD8 T cells by promoting their activation and limiting exhaustion.

Reza Alimohammadi[1], Yongxia Wu[1], Allison Pugel[1], Gustavo Leone[2], Xue-Zhong Yu[1]

[1]Microbiology & Immunology, Medical College of Wisconsin, Milwaukee, WI,[2]Cancer Center, Medical College of Wisconsin, Wauwatosa, WI

Fli-1 (Friend leukemia integration 1) is a transcription factor critical to cell proliferation and differentiation, and its overexpression has been identified in various cancers, including leukemia, Ewing sarcoma, and certain breast and prostate cancers. Emerging evidence links Fli-1 to T cell activation and exhaustion. In our recent study, we demonstrated that Fli-1 plays a key role in regulating the gene transcription for CD8 T-cell activation and their differentiation into effector and memory subsets after allogeneic hematopoietic cell transplantation. We hypothesize that targeting *fli1* in T cells will potentially improve the effectiveness of cellular immunotherapy by enhancing the persistence and function of CD8 T cells. To study how Fli-1 regulates CD8 T cell-mediated antigen-specific response, we utilized OT-I and Pmel TCR transgenic mice in which T cells are specific to ovalbumin (OVA) and melanoma-associated gp-100 antigen, specifically respectively. We generated *fli1*-deficient OT-I and Pmel mice by crossing them with $fli1^{fl/fl}$ $CD4^{cre}$ micestrain. Upon stimulation of OT-I T cells with OVA SIINFEKL peptide, $fli1^{-/-}$ OT-I T cells had increased cytolytic activity against peptide-pulsed tumor targets compared to wild-type (WT) OT-I T cells in *vitro*. Additionally, we observed enhanced cytokine secretion and reduced exhaustion in $fli1^{-/-}$ OT-I T cells after repetitive activation stimulation by OVA peptide *in vitro*. Following adoptive cell therapy *in vivo*, $fli1^{-/-}$ OT-I T cells had significantly improved ability to control $MC\text{-}38^{OVA}$ growth as compared with WT counterpart cells. Deficiency of Fli-1 also enhanced antitumor response of Pmel T cells against B16 melanoma *in vivo*. The $fli1^{-/-}$ Pmel or OT-I CD8 T cells had significantly increased effector activity, persistence, and central memory differentiation in spleen and tumor. ScRNA-seq analysis revealed that *fli1* was mainly expressed in exhausted, but not in progenitor-like subsets of CD8 T cells in tumor. Increased Granzyme B and decreased CTLA-4 gene transcription were observed in $fli1^{-/-}$ OT-I T cells compared to WT cells. To investigate the role of *fli1* in regulating human T cells, we used CRISPR/CAS9 nucleofection-based gene silencing approach to knock down *fli1* in hPBMCs. Preliminary data suggest deficiency that knock-down of *fli1* in human CD19 CAR-T cells, improve their killing ability against Raji cells human B cell lymphoma *in vitro*. In conclusion, Fli-1 plays key roles in regulating the differentiation and anti-tumor function of CD8 T cells and *fli1* silence in T cells may improve cancer immunotherapy.

#4863 IOV-5001, autologous tumor-infiltrating lymphocytes (TIL) armored with inducible membrane-tethered IL-12, shows enhanced antitumor efficacy with an improved cellular state.

Patrick Innamarato[1], Joe Dean[2], Mohammed Alkhouli[2], Marcus Machin[2], Nathan Gilbert[2], Sadie Johnson[2], Gerard Sapena[2], Nino Mtchedlidze[2], Behzad Damirchi[2], Robyn Oldham[2], Andrew Yuhas[2], Judy Fang[2], Jamie Blauvelt[3], Shari Pilon-Thomas[3], Rongsu Qi[2], Hequn Yin[2], Sean Hall[2]

[1]Patrick Innamarato (Individual), Tampa, FL,[2]Iovance Biotherapeutics, Inc., San Carlos, CA,[3]H Lee Moffitt Cancer Center and Research Institute, Tampa, FL

Introduction: Autologous tumor-infiltrating lymphocytes (TIL) engineered to secrete IL-12 have shown robust clinical efficacy in metastatic melanoma. However, systemic toxicity from elevated circulating IL-12 has limited its application. IOV-5001 is a next-generation TIL therapy engineered to inducibly express membrane-tethered IL-12 (TeIL12) upon antigen engagement, restricting IL-12 activity to the tumor microenvironment. This study evaluated the antitumor efficacy and molecular phenotype of IOV-5001.
Methods: TIL were derived from solid tumor tissues, cultured, and transduced with a lentiviral vector encoding inducible TeIL12 bicistronically with a growth factor. Antitumor activity of IOV-5001 was tested in vitro via a tumor antigen-directed TCR killing assay or against autologous patient-derived endometrial cancer organoid (PDO), and/or tumor digests. Transcriptional profiling (bulk and single-cell) was used to characterize the molecular features of IOV-5001.
Results: IOV-5001 TIL were successfully generated and effectively expressed TeIL12 upon T cell receptor (TCR) engagement. The expression of TeIL12, soluble IL-12, and IFN-gamma was lacking in the absence of stimulation, indicating that the activity of IOV-5001 TIL is dependent on TCR engagement. IOV-5001 demonstrated superior killing and effector cytokine production compared with unmodified TIL in a tumor antigen-directed TCR killing assay and against autologous tumor, irrespective of aldesleukin support. The antitumor activity was further enhanced when IOV-5001 was expanded in an optimized media. Analysis of bulk gene expression profiling revealed transcriptional profiles for IOV-5001 characterized by upregulation of genes involved in cell cycle, telomere maintenance, mitochondrial metabolism, IL-12, and TCR signaling. Downregulated genes exhibited an enrichment for IL-10 and IL-5 signaling, and prostanoid/eicosanoid ligand binding receptors. Single-cell analysis confirmed these patterns were enriched within tethered cytokine-positive TIL. Furthermore, single-cell analysis of preREP cells demonstrated that proportions of putative tumor-reactive CD8 T cells were similar in IOV-5001 TIL among tethered cytokine-positive and -negative TIL, indicating unbiased transduction.
Conclusions: These findings demonstrate that IOV-5001 with inducible and membrane-tethered IL-12 confers superior antitumor activity compared with unmodified TIL. The enhanced molecular and functional characteristics highlight IOV-5001 as a promising product for enhancing TIL efficacy in solid tumors.

#4864 The dysregulated YY1-EZH2-RKIP axis in cancer and immune evasion.

Benjamin Bonavida, **Talia Festekdjian**

UCLA - University of California Los Angeles, Los Angeles, CA

Background: The current treatment strategies for cancer have evolved with novel effective approaches, particularly immunotherapy. These have resulted in significant tumor regression and prolongation of survival in a subset of cancer patients. However, there is a subset that is initially unresponsive and a responsive subset that becomes subsequently unresponsive leading to tumor progressions and deaths.
Rationale: To develop a new immune-therapeutic approach to reverse resistance.
Hypothesis: We hypothesized that the unresponsive cancers have in common pivotal gene factors that regulate the resistance and, therefore, are amenable for targeting. These gene factors are the over-expressed Yin Yang1 (YY1) and EZH2 tumor promoters and the under-expressed Raf kinase inhibitor protein
(RKIP) tumor suppressor. Altogether, they constitute the dysregulated YY1-EZH2-RKIP axis in cancers and immune evasion.
Findings: Analyses of the regulation of expressions of these three gene products revealed that they exhibit cross-talk signaling pathways (eg the Raf/MEK/ERK, NF-kB, PI3K/Akt). YY1 and EZH2 activate pathways involved in immune resistance and evasion (e.g., inhibition of T cell effector functions, upregulation of T-cell inhibitory receptors and ligands on cancer cells, infiltration of MDSCs, etc.). In contrast, RKIP reverses YY1 and EZH2 immune inhibitory signaling pathways and enhances the anti-cancer immune response.
Conclusion: The findings revealed that the dysregulated YY1-EZH2 -RKIP axis in cancer is involved in the resistance of cancer to various immuno-therapeutics and induces an immune-suppressive TME and immune evasion. Various approaches are presented targeting each of the three gene products, individually or in combination, to reverse immune resistance and restore the effectiveness of anti-cancer immunotherapy. We suggest that further investigations are necessary to validate the targeting strategies, preclinically and then clinically. However, there remain challenges to develop agents that specifically target the cancer cells in vivo with minimal side effects.

#4865 Inhibition of PD-1 signaling during TCR stimulation promotes increased T cell activation, but upregulates compensatory inhibitory molecules and induces activation induced cell death.

Logan V. Vick[1], Michael K. Sheng[1], Wahed Firoz[1], Craig Collins[1], Lam T. Khuat[2], Bruce Blazar[3], Sean Judge[1], William J. Murphy[1]

[1]UC Davis Comprehensive Cancer Center, Sacramento, CA,[2]University of Southampton, Southampton, United Kingdom,[3]Department of Pediatrics, University of Minnesota, Minneapolis, MN

The PD1/PDL1 axis acts as a potent immune regulator for T cells. Inhibition of the PD1/PDL1 pathway has demonstrated success in the context of checkpoint immunotherapy, yet the biological consequences of the long-term effects of PD1 inhibition on T cells remain unclear. In murine models we have observed that inhibition of the PD1 signaling either through genetic ablation or PD1 checkpoint blockade results in increased activation and function. This has been demonstrated through in vitro stimulation of PD-$1^{-/-}$ T cells in which increased percentages of activation markers including CD25, CD69, and IFNγ were observed. Similar effects of increased activation markers MFI and percent were illustrated in vivo both through adoptive transfer of PD-1 -/- cells into allogeneic NSG recipients and in NSG recipients receiving allogenic wild type cells in combination with anti-PD-1. However, within both in vitro and in vivo models we observed decreases in T cells overtime. We hypothesized that due to increased early activation T cells with inhibited PD-1 signaling underwent increased apoptosis via activation induced cell death (AICD). We observed that apoptosis was increased in PD-$1^{-/-}$ T cells after culture indicated by elevated levels of Annexin V. Further, in vivo following anti-PD-1 treatment we observed increases in other inhibitory markers such as TIM3 and LAG3 via flow cytometry, and confirmed via PCR, suggesting an upregulation of other inhibitory markers following blocking of PD-1. The role PD-1 plays in CAR T cell therapy still requires additional study. Thus, to assess the role of PD-1 and its role in AICD on human cells we next implemented a CAR T xenograft model in which NSG mice were challenged with Raji cells transduced with PD-L1 and then treated with CAR T cells with and without Pembrolizumab. We observed that human CAR T cells transplanted into tumor bearing NSG mice had increased percentages of activation markers(HLA-DR and CD69) when treated with Pembrolizumab, but we also observed elevated flow percentages of inhibitory markers including TIGT, TIM3, and LAG3. These cells in addition to increased activation and upregulation of inhibitory molecules also had decreased numbers overtime and increased apoptosis identified by Annexin V staining. These data suggest a complex interplay in which PD-1 regulates T cell activation as a means of protection, but when this balance is manipulated, T cells can experience increased activation and effector function, followed by an upregulation of inhibitory molecules such as TIM3, LAG3 and TIGIT to compensate, but ultimately still resulting in AICD. Thus, targeting PD-1 unlocks a “short term gain” of activation and function of T cells at the cost of a “long term loss” in T cell numbers due to apoptosis in which cells undergo AICD.

#4867 Enhancing TCR-T with a Fas-based switch receptor boosts T cell engraftment, persistence, and anti-tumor activity in models of hard-to-treat PRAME solid tumor indications.

Laure Twyffels, Alvaro Haroun-Izquierdo, Friederike Knipping, Mikhail Steklov, Panagiota A. Sotiropoulou, **Marleen M. Van Loenen**

T-knife Therapeutics Inc., San Francisco, CA

Background: Adoptive cell therapies have shown promising efficacy in melanoma and synovial sarcoma, but success in other tumor types remains limited. A significant challenge is the hostile tumor microenvironment (TME) that restricts T cell infiltration, function and persistence. Here, we developed a switch receptor (SwR) tailored to PRAME positive solid tumors.

Methods: Analysis of TIGIT, Fas and PD1 ligand expression was performed using the Tempus^{TM} bulk RNA database and publicly available single-cell RNA sequencing (scRNAseq) data. T cells were retrovirally transduced to express different SwRs in combination with an HLA-A*0201 restricted PRAME-specific TCR and a CD8 co-receptor, and tested for proliferation, viability, cytotoxicity and cytokine secretion in models reflecting the TME of PRAME positive tumors.

Results: Analysis of the ligands of the common inhibitory receptors PD1, Fas, and TIGIT in (1) 4,622 stage III/IV patient samples across 10 PRAME-expressing indications, (2) scRNAseq of 7,000 - 176,000 cells covering 98 patients over 5 tumors, and (3) healthy tissue scRNAseq data, demonstrated high expression of TIGIT ligands in tumors and healthy tissue, raising potential safety concerns. PD-L1 and FasL had moderate expression across all target indications, with FasL having the most promising expression profile. Expression in tumors is generally stable across tumor sites and lines of treatment and increased upon CPI treatment. In healthy tissue, FasL is expressed mainly in the lymph nodes (LNs), enabling a Fas-SwR to support TCR-T engraftment and persistence during trafficking. Eight SwR candidates were designed combining the extracellular domain of Fas receptor with different intracellular activating motifs. The SwR combining CD40 and OX40 motifs (Fas-TNFR) was selected based on high cell surface expression and superior protection against FasL-induced apoptosis. When testing in models reflecting the TME of PRAME positive indications, PRAME TCR-T co-expressing Fas-TNFR showed improved T cell fitness as demonstrated by earlier memory phenotype, higher cytokine production and long-term cytotoxic capacity. Notably, Fas-TNFR significantly outperformed a Fas-41BB SwR currently in the clinic. To mimic trafficking through the draining LNs before tumor homing, PRAME TCR-T cells expressing Fas-TNFR were pre-stimulated with FasL. This led to improved T cell fitness and a trend for increased cytotoxic activity upon encountering cancer cells.

Conclusions: Extensive characterization of the TME of PRAME-expressing solid tumors guided the development of a best-in-class switch receptor. Fas-TNFR increased fitness of PRAME TCR-T cells before encountering cancer cells, and boosted long-term persistence and anti-tumor activity, indicating the potential of deeper clinical responses at lower doses.

#4868 Optimal activation of TCR T cells in solid tumors through addition of best-in-class single chain CD8 coreceptors results in CD4 engagement and improved T cell fitness and persistence.

Paul Najm, Alvaro Haroun-Izquierdo, Mikhail Steklov, Panagiota A. Sotiropoulou, Marleen M. van Loenen

T-knife Therapeutics Inc., San Francisco, CA

Background: Clinical response rates in solid tumors have been improved and/or broadened by including either CD8α or wild type CD8αβ co-receptors (CoR) in T cell receptor (TCR) T cell therapy constructs, enabling engagement of CD4 T cells. We designed a small, chimeric, single-chain CD8 CoR maintaining all functional elements of the CD8αβ CoR and used it as a scaffold to add intracellular costimulatory signaling motifs (co-stimCD8 CoR). By providing activating signals simultaneously to TCR engagement, co-stimCD8 CoR prevents TCR-T cell exhaustion caused by the lack of costimulatory molecule expression in tumors. TCR-T cells expressing co-stimCD8 CoR fully engaged CD4 T cells and mediated enhanced and durable TCR-T anti-tumor responses, superior to commonly used wild type CD8 CoRs.
Methods: The ActiviT platform consists of different single-chain CD8 CoRs designed by combining building blocks from CD8αβ and CD4 CoRs. In silico 3D modeling using the Rosetta software suite was used to model interactions between TCR-CD8CoR with HLA-I-peptide complexes. HLA-A*02:01-restricted PRAME or MAGE-A1 targeting TCR-T cells with or without different CD8 CoRs were tested for cytokine production (LEGENDplex) and long-term and serial cytotoxicity (Incucyte). Flow cytometry was used to analyze phenotype, activation and exhaustion markers.
Results: Structural evaluation by in silico 3D modeling showed that the single-chain CD8 CoR scaffold retains HLA-I binding interface identical to that of the wild type CD8 CoR. The co-stimCD8 CoR was generated by adding tumor necrosis factor receptor associated factor (TRAF) binding motifs. Assessment of cytotoxicity and cytokine secretion showed that co-stimCD8 CoR conferred higher functionality to CD4 T cells incorporating an HLA class-I restricted TCR compared to a wild type CD8 CoR. To evaluate the impact of co-stimCD8 CoR on the anti-tumor activity of TCR T therapies, functional comparison of CD4/CD8 PRAME TCR-T cells co-expressing different CD8 CoRs, including versions currently tested in the clinic, was performed. PRAME TCR-T cells expressing co-stimCD8 CoR improved T cell fitness, resulting in a less exhausted and earlier memory phenotype and enhanced functionality in serial killing experiments at low effector-to-target ratios. Notably, enhanced activity of co-stimCD8 CoR was demonstrated in 3D tumor spheroid models recapitulating hard-to-treat indications.
Conclusions: Co-stimCD8 CoR is a chimeric CD8 CoR with built-in co-stimulation. Combination of co-stimCD8 CoR with a PRAME TCR resulted in improved T cell fitness and higher functional activity compared to common PRAME TCR-T approaches, including current clinical development candidates. Inclusion of the co-stimCD8 CoR in TCR-T constructs has the potential to further deepen and broaden responses of hard-to-treat solid tumors.

#4869 Chimeric costimulatory receptor targeting ICAM1 augments functional efficacy of antitumor T cell.

Yanping Yang[1], Dessislava Stefanova[2], Yogindra Vedvyas[1], Diella S. Babu[1], Yago Alcaina[2], Maria Cristina Riascos[2], Janusz Puc[3], Kevin Chen[2], Juan Gonzalez[2], Jose Thaiparambil[1], Thomas J. Fahey[2], Rasa Zarnegar[2], Moonsoo M. Jin[1], **Irene M. Min**[1]

Background: Adoptive T cell therapy has evolved with innovations such as chimeric antigen receptor (CAR)- and engineered T cell receptor (TCR)-T cell therapies that target tumor surface antigens or tumor-associated antigens, respectively. Although remarkable antitumor response has been demonstrated in engineered T cell therapy, tumor recurrence still occurs partly due to tumor antigen escape. Low affinity of endogenous TCR for tumor antigens has been an obstacle to the success of TCR-therapy. We hypothesized that tumor-specific T cell function in an immunosuppressive tumor microenvironment could be enhanced by an expression of ICAM1-specific chimeric costimulatory receptor (ICCR). ICAM1 is overexpressed in many solid tumor cell membranes and is greatly induced by T cell cytokine IFNγ, which may enable reinforcement of specificity and efficacy of those TCRs engaged with the target tumor antigens.
Methods: We genetically engineered primary T cells with an ICCR, comprised of a single chain fragment variable sequence fused to a costimulatory molecule CD137. We first tested an ICCR in combination with CTL16, an HLA-A2-restricted, MAGE-C2-specific TCR, in cocultures with A375-MA2 melanoma cells. We measured levels of cytotoxicity and cytokine secretion when the antigen density is low or high. Next, we genetically modified allogeneic and autologous T cells with an ICCR and tested their functional efficacy in xenograft models of anaplastic thyroid cancer. Finally, TCR sequencing, signaling reporter assay, and gene expression analysis were performed to gain insights into the ICCR activity.
Results: Jurkat T cell line expressing both ICCR and CTL16 showed elevated NFκB and NFAT activities following TCR engagement when compared to cells expressing CTL16 alone. Cytotoxicity induced by the ICCR/CTL16 primary T cells were specific to target tumor cells, and functional efficacy was augmented even when antigen presentation is at a subthreshold level. The ICCR expression increased allogeneic TCR activity, leading to improved control of anaplastic thyroid cancer growth. When autologous peripheral T cells were genetically modified with the ICCR, $PD1^+$ T cells showed a superior response in controlling the growth of anaplastic thyroid cancer patient-derived tumor. ICCR expression promoted selective clonal expansion, enabling isolation of tumor-specific TCRs.
Conclusion: ICCR improves functional efficacy of the TCR activated at a subthreshold level, facilitating a robust activation of polyclonal tumor-specific T cells that may have been restricted in an immunosuppressive tumor microenvironment.

#4873 Characteristics of TIM-3 in regulating T cell activity in the brain tumor microenvironment.

mingi song[1], Su Bin Won[2], Hyung-Seok Kim[2], Dae Yeon Kim[1], Ki Sun Kim[1], Su Jeong Gu[2], Chanju Lee[2], Hee Jung Yoon[2], Eun Jung Park[2]

[1]Department of Cancer Biomedical Science, Graduate School of Cancer Science and Policy, National Cancer Center, Ilsan, Korea, Republic of,[2]Immuno-oncology Branch, National Cancer Center, Ilsan, Korea, Republic of

T-cell immunoglobulin and mucin domain-containing molecule 3 (TIM-3), a member of TIM family, has been shown to exhibit diverse characteristics in a context-dependent manner. In this study, we investigated the characteristics of TIM-3 on T cells in the brain tumor microenvironment. First, using an intracranial syngeneic mouse model, we examined the expression of TIM-3 in the brain tumor microenvironment. Immunohistochemistry (IHC) revealed that TIM-3 as well as PD-1 was expressed on various cell types, including CD3-positive cells in brain sections of tumor-bearing mice. Similar expression patterns were observed in tumor-infiltrating lymphocytes (TILs) by using flow cytometry analysis. To investigate the role of TIM-3 in T cells within the brain tumor microenvironment, we utilized T-lymphocyte specific TIM-3 conditional knock-out (TIM-$3^{fl/fl}$ Lck-cre, TIM-3 cKO). TIM-3 cKO mice exhibit a higher $CD8^+/CD4^+$ TIL ratio in the ipsilateral brain regions compared to tumor-bearing wild-type (WT) mice after GL26 cell injection into the right hemisphere. Moreover, *in-vivo* experiments with TILs demonstrated the influence of TIM-3 on T cell functional activity within the brain tumor microenvironment. Collectively, these results suggest that TIM-3 of T cells have an influence on the immune microenvironment of brain tumors.

#4874 Anti-CCR8 mediates long-lasting antitumor immunological memory and enhances anti-tumor immunity in immune-cold cancer through the combination with chemotherapy.

Shuiqing Hu[1], Minjuan Deng[2], Wei Tan[1], Rui Liu[1], Amin Zhang[1], Lu Tan[1], Mengqian Chen[1], Pu Sun[1], Li Luo[1], Wen Li[1], Juan Yang[1], Jiyuan Zhang[1], Wei Jin[2], Zhirong Shen[2]

Tumor infiltrating regulatory T cells (Tregs) suppress CD8+ T cells and facilitate tumor progression. Tumor Tregs are elevated in a variety of malignancies and have been associated with poor prognosis. Targeting Tregs presents an appealing strategy in cancer immunotherapy. Recent research has identified the chemokine receptor CCR8 is preferentially expressed by tumor Tregs and labels highly suppressive Tregs. Thus, using anti-CCR8 mAb to deplete tumor Tregs could be an efficient and safe strategy that is widely being explored. Although the anti-tumor efficacy of CCR8 mAb was reported, the dynamics and specific contributions of Tregs and CD8+ T cells to anti-tumor activity are still not fully elucidated. We found that tumor Tregs were rapidly depleted within two days, and CD8+ T cells increased after one week following treatment with anti-CCR8 in both the MC38 and CT26 tumor models, which coincided with the observed tumor growth inhibition. Tumor volume was found to have a strong negative correlation with the percentage of tumor-infiltrating CD8+ T cells, suggesting that the increased tumor CD8+ T cells may be indicative of an active anti-tumor immune response. Furthermore, treatment with CCR8 mAb has shown dose-dependent efficacy in controlling the growth of CT26 tumor. In the 1 mg/kg dosage group, 3 out of 10 mice exhibited a complete response (CR), while in the 3 mg/kg dosage group, 4 out of 10 mice achieved a CR. Rechallenging the mice with 50-fold more tumor cells on the contralateral side of the CR mice resulted in the expulsion of tumor growth without any treatment, suggesting that the use of CCR8 mAb induces a long-lasting antitumor immunological memory. This is crucial for maintaining persistent tumor immune surveillance and achieving durable responses to cancer therapy. This finding underscores the potential of CCR8 mAb not only in directly targeting tumor growth but also in bolstering the host's immune memory, contributing to a more comprehensive and enduring antitumor defense. In addition, further improved tumor growth inhibition was observed when combining anti-CCR8 with docetaxel, oxaliplatin, or gemcitabine in immune cold tumor models. PD analysis revealed that the combination of CCR8 mAb therapy with gemcitabine induced the depletion of Tregs, increase of CD8+ T cells, decrease of tumor-associated macrophages, and the activation of DCs, which are instrumental in treating immune-cold tumors. This suggests that the combined therapy may enhance the antitumor immune response by modulating the tumor microenvironment, thereby improving the efficacy of cancer treatment. Collectively, these findings advance our understanding of CCR8 as a promising target for Treg depletion in anti-cancer drug development and therapy.

#4875 B7-H3 (CD276) regulates the migration and infiltration of tumor-associated macrophages.

A-Ram Kang[1], Da Hyun Yun[1], Eun Jung Lee[1], Jong Dae Ji[2], **Serkin Park**[1]

[1]Biochemistry and Molecular Biology, Korea University College of Medicine, Seoul, Korea, Republic of,[2]Internal Medicine, Korea University College of Medicine, Seoul, Korea, Republic of

B7-H3 (CD276), a member of the B7 family of immune checkpoint proteins, is expressed on tumor cells as well as various immune cells within the tumor microenvironment (TME), including macrophages. While evidence from numerous in vitro, in vivo, and ongoing clinical studies highlights its potential as a promising therapeutic target, the function and molecular mechanisms of B7-H3 in distinct stromal cell populations within the TME remain unclear. In this study, we investigated the roles of B7-H3 in tumor-associated macrophages (TAMs) using B7-H3 knockout mice, macrophage-tumor co-culture spheroids, and in vitro experiments. B7-H3 expression was significantly upregulated during the progressive stages of bone marrow-derived macrophage (BMDM) differentiation in vitro, supporting its functional role in macrophages. For in vivo studies, we generated B7-H3 knockout mice. Immunohistochemical staining and flow cytometric analysis of B16F10 melanoma tumor tissues subcutaneously implanted in B7-H3 knockout mice revealed a significant reduction in $F4/80^+$ TAMs compared to tumors in wild-type mice. Similarly, anti-B7-H3 antibody treatment in 4T1 breast cancer-bearing mice reduced $F4/80^+$ TAMs compared to control IgG treatment. However, tumor growth and the number of $PCNA^+$ proliferating tumor cells were unaffected by either knockout or antibody-dependent inhibition of B7-H3 in vivo. Subsequent in vitro studies demonstrated that migration of BMDMs from B7-H3 knockout mice was impaired in both two-dimensional scratch-wound migration assays and a three-dimensional macrophage-tumor co-culture spheroid model. Furthermore, interferon-gamma treatment significantly enhanced the migration of BMDMs from wild-type mice, an effect that was completely blocked by a pharmacologic STAT1 inhibitor (fludarabine). Interestingly, BMDMs from B7-H3 knockout mice exhibited a significantly attenuated response to both interferon-gamma and STAT1 inhibition, indicating that B7-H3-dependent macrophage migration is mediated through the interferon-gamma and STAT1 signaling pathway. Collectively, our data indicate that B7-H3 regulates the migration and infiltration of TAMs into tumor tissues via the interferon-gamma/STAT1 signaling pathway. These findings suggest that B7-H3 is a promising therapeutic target for solid tumors such as melanoma and breast cancer.

#4876 Avidity engineered multispecific antibodies that are highly efficacious in immune cell stimulation in patient tissue and in mice: significantly improved tumor control and turning cold tumors hot.

Sophie Poznanski[1], Erik Slinger[1], Jarek Juraszek[1], Fatemeh Vahedi[2], Marcelo Pereira[3], Loreto Parga-Vidal[1], Dean Lee[3], Ali Ashkar[2], **Robert Friesen**[1]

[1]Avidicure, Oegstgeest, Netherlands,[2]McMaster University, Hamilton, ON, Canada,[3]Nationwide Children's Hospital, Columbus, OH

Introduction: Antibodies and ADCs are mainstays in the treatment of cancer. However, given difficulties in achieving a deep and sustained response, significant improvements are desirable. We report on first in class “Booster” molecules, based on clinically validated ADCC-competent antibodies, equipped with two immunomodulatory domains that are affinity engineered to be functional only when in contact with a tumor cell. We see strong expansion and increased cytotoxicity of immune cells in the presence of cancer cells *in vitro*, activation of relevant immune cell types *ex vivo*, and reduction of tumor burden *in vivo*, with significantly better activity than adoptive cell therapy or control antibody without fusion domains.

Methods: NRG mice were engrafted with luciferase expressing SKOV3 cells via intraperitoneal injection 7 days prior to treatment. Mice received 1 million NK cells isolated from healthy donors. Compounds were administered biweekly, and low dose IL2 thrice weekly. Blood was collected weekly, and tumor burden monitored weekly *via* bioluminescence. *ex vivo*: *in situ* activation of tumor infiltrating immune populations was evaluated by nanostring in freshly isolated tumor tissue. *in vitro*: cytotoxicity was measured by quantifying the number of alive tumor cells using automated microscopy. Expansion was performed by stimulating NK cells weekly with tumor cells that were opsonized with Booster or antibody, NK cells were counted weekly to determine expansion.

Results: Mice treated with a HER2 targeting Booster demonstrated superior tumor control than trastuzumab treated mice, with near tumor remission by day 35. High NK counts were observed in the blood of Booster treated mice, and no NK cells were detected in that of trastuzumab treated mice. In the peritoneal cavity, NK counts were up to 600x higher in Booster treated mice than in trastuzumab treated mice. Our Booster reprograms the immune microenvironment *ex vivo* in freshly isolated tumor tissue, transforming a cold tumor into a hot tumor. It activates multiple cytotoxic and IFN-γ pathways, stimulates CD8+ T cell activation, downregulates pro-tumor pathways in Tregs and induces a phenotypic shift in macrophages from the immunosuppressive M2 to the pro-inflammatory M1 phenotype. In separate *in vitro* assays we saw sustained expansion and enhanced cytotoxicity of NK cells for at least 6 weeks. Cells stimulated with HER2 Booster showed prolonged tumor control, whereas trastuzumab stimulated cells failed to sustain tumor control beyond 21 days.

Conclusion: In correlation with extensive *in vitro* and *ex vivo* data, we observe a prolonged and significant improvement in tumor control in mice treated with Boosters compared to mice treated with trastuzumab. Work is ongoing to develop these molecules, with the first clinical trial expected to start in 2026.

#4878 Ablation of neutrophil-specific CXCR2 and PD-L1 alters neutrophil phenotype and can reduce disease burden in a murine model of advanced colorectal cancer liver metastases.

Alistair S. McLaren, John Falconer, Sarah Ressel, Leo M. Carlin, Owen J. Sansom, Colin W. Steele

CRUK Scotland Institute, Glasgow, United Kingdom

Introduction: We have previously shown that as colorectal liver metastases (CRCLM) develop, there is a pressure that drives phenotypic development of neutrophils within the metastatic niche. Through transcriptional and protein analysis, different neutrophil transcriptional states can be delineated. Combination therapy with CXCR2 and PD-1/PD-L1 checkpoint inhibition has been shown to be a strategy to reduce disease burden in mouse models of hepatocellular carcinoma. Through loss of neutrophil-specific target proteins CXCR2 and PD-L1 in mouse models of CRCLM, we show modification of neutrophil phenotype and changes in disease burden.

Methods: *Kras*$^{G12D/+}$*, Trp53*$^{fl/fl}$*, Rosa*$^{26N1CD/+}$ (KPN) tumour cells modelling CMS4 pMMR colorectal cancer generated from murine CRCLM organoids were injected orthotopically into the spleen of male and female C57BL/6 mice with loss of neutrophil-specific proteins using the Cre-loxP system. Mrp8CreCxcr2$^{fl/fl}$ and Mrp8CrePd-l1$^{fl/fl}$ genetically engineered mouse models with neutrophil-specific loss of CXCR2 and PD-L1 respectively were sampled at 14 days and 35 days, and neutrophils isolated using MACS prior to bulk sequencing to assess the impact on neutrophil transcriptional phenotype. Neutrophil protein expression, phenotype and functional role was assessed using flow cytometry and ELISA.

Results: Loss of neutrophil-specific CXCR2 does not alter CRCLM burden at a late timepoint following intrasplenic injection but leads to an altered neutrophil phenotype with reduced PD-L1 checkpoint inhibitor expression, and increased Lactoferrin expression, a neutrophil granule protein with known anti-cancer properties. These neutrophils are strongly suppressive of T cell proliferation when co-cultured *ex vivo*. Loss of neutrophil-specific PD-L1 leads to a reduction in CRCLM tumour size but not number, suggesting an important role for neutrophil PD-L1 in growth of CRCLM without affecting tumour seeding. *Ex vivo* assays will examine the effect of loss of neutrophil-specific CXCR2 on NETosis and ROS generation, and the effect of lactoferrin upon these neutrophil functions in neutrophils with and without CXCR2 expression.

Conclusions: We speculate that inhibition of CXCR2 and PD-L1 and loss of these neutrophil proteins alters neutrophil phenotype to be more “anti-tumour”. This may be a strategy to alter the immunosuppressive microenvironment of CRCLM and allow for downstaging of CRCLM allowing for resection and preventing recurrence.

#4879 Unveiling a key obstacle to effective antitumor immunity in T-cell-restricted tumors.

D.-C. Chiu[1], X. Zhang[1], B.-L. Cheng[1], K. Hayashi[1], Q. Liu[1], B. Yu[2], R. Lee[1], C. Zhang[1], J. Rajadas[1], N. Reticker-Flynn[1], E. Rankin[1], E. Engleman[1];

[1]Stanford University School of Medicine, Palo Alto, CA, [2]ImmunEdge Inc., Mountain View, CA

Endogenous antitumor immune responses in cancer patients can lead to the formation of "inflamed" tumors, characterized by a significant infiltration of tumor-reactive T cells. However, the majority of patients fail to mount such robust immune responses, resulting in immune-evasive tumors. To explore the mechanisms underlying this failure, we established and compared spontaneous mouse models of hepatocellular carcinoma (HCC) with either an inflamed, T-cell-rich or non-inflamed, T-cell-deprived tumor microenvironment (TME). Intriguingly, non-inflamed tumor models exhibited splenomegaly and elevated plasma erythropoietin (EPO) levels despite the absence of anemia, and these effects were independent of tumor size. This finding raised the possibility that tumor-derived EPO might dictate tumor immunotype. Our investigations revealed that EPO ablation in non-inflamed HCC models led to a substantial increase in effector memory CD8 T-cell infiltration, reduced tumor burden, and even induced tumor regression. Conversely, enforced EPO expression in inflamed HCC models suppressed T-cell infiltration and promoted tumor progression. Further analysis of both human and mouse HCC tissues demonstrated that the erythropoietin receptor (EPOR) is predominantly expressed on tumor-associated macrophages (TAMs). Tumor-derived EPO interacts with EPOR on TAMs to autonomously establish a non-inflamed, immunosuppressive TME, effectively evading T-cell surveillance. Mechanistically, EPO-EPOR signaling reprograms TAMs toward an immunoregulatory phenotype via NRF2-mediated heme depletion. Disruption of this axis—through either tumor-derived EPO ablation or EPOR deletion on TAMs—transformed the TME into an inflamed, T-cell-rich TME, driving tumor regression regardless of tumor genotype. Notably, this immune reactivation synergized with immune checkpoint blockade therapy. In summary, the EPO/EPOR axis functions as a critical immunosuppressive switch, enabling tumors to escape immune surveillance. Its inactivation reprograms macrophages to foster antitumor immunity, offering a promising strategy to enhance the efficacy of immunotherapy in HCC and potentially other cancers.

#4880 A novel heparan-sulfate (HS) oligosaccharide on tumor-blood vessels is a target for anti-immune vascular therapy in renal cell carcinoma (RCC).

J.-S. Chung, N. Pawar, P. D. Cruz, Jr., H. Hammers, K. Ariizumi;
UT Southwestern Medical Center, Dallas, TX

In ccRCC, tumor cells are arranged in nests surrounded by capillary endothelial cells (EC) abundant in HS polysaccharide proteoglycan receptors (HSPGs). HS structure is highly heterogeneous, due to HS sulfotransferases (HSST) that randomly sulfate at different positions of the core disaccharides. Specific sulfation pattern determines the avidity of HS to soluble factors, which regulates the interaction between EC and leukocytes. We identified 6-*O*-highly sulfated HS 8-mer saccharides (6O-HS) to be the ligand of GPNMB receptor that inhibits T cell activation and induces angiogenesis. Using our 6O-HS-specific 1A7 mAb, we examined the expression of 1A7 epitope in RCC. IHC staining of RCC specimens (n=4) showed 1A7 mAb stained some but not all EC and nearly no staining in tumor cells. We examined this EC selectivity by identifying 6O-HS+ HSPGs using mouse SVEC line expressing HSPGs (syndecans (SD), CD44). Surprisingly FACS analysis showed very little 1A7 expression on these cells. To ask whether this is due to low expression of HS6ST1 (for 6-*O*-sulfation), HS6ST1-transfected SVEC cells were stained with 1A7 and HSPG Ab and found all HSPGs positive for 1A7. To examine whether binding of GPNMB to 1A7+ HSPG induces specific signaling, SD4/HS6ST1-transfected 293T cells were treated with GPNMB-Fc and measured Tyr-phosphorylation (p-Tyr) on SD4 protein. Western blotting showed GPNMB-Fc induced p-Tyr on SD4 in 10 min post-incubation and the signaling was completely blocked by pretreatment of transfectants with 1A7 mAb. We assayed the effects of 1A7 mAb on T cells and EC. For T cells, we assayed *in vitro* suppressor function of GPNMB+ myeloid-derived suppressor cells (MDSC from RCC patients, n=3) to autologous T cells. In coculture of T cells/MDSC, 1A7 mAb inhibited IFN-γ T cell response by 50-84% (p>0.01) and 40-60% T cells were 1A7+. For EC, we used *in vivo* angiogenesis assays: 1A7 mAb was injected into GPNMB-Fc-matrigel plugs in mice and 2 dpf zebrafish embryos. This mAb (n=5, 10 μg/ml) reversed GPNMB's angiogenic activity completely in mice and inhibited growth of the subintestinal vessels (SIV) (n=9, 50% reduction in SIV # by 2 μg/ml, p<0.001). To evaluate the efficacy of 1A7 mAb to treat RCC, BALB/c mice bearing RenCa tumor were treated with 1A7 or PD1 mAb; 200 μg *i.p.*/mouse, 2x/wk. 1A7 mAb inhibited tumor growth as greatly as PD1 Ab (64% inhibition by 1A7 vs. 61% by PD1 Ab, p<0.01, n=6) with a reduction in tumor density of microvessels and myeloid cells (50-60% reduction) and a rise in T cells (~5-fold). Similarly, 1A7 mAb inhibited human RCC growth in Caki-2-derived xenograft NSG mice injected with human PBMC (49% inhibition by 1A7 vs. 37% by Nivolumab, p=0.005). 6O-HS+ renal EC may regulate T cell activation/ trafficking into RCC and facilitates tumor angiogenesis via the high avidity to signaling factors. Thus, 6O-HS-targeting may be a promising anti-angiogenic immunotherapy for RCC.

#4881 A PD1-IFNα fusion protein, with an attenuated IFNα fused to a clinically validated PD1 mAb, elicited PD1-dependent IFNα signaling and superior anti-tumor efficacy.

Jinyang Li, Yi Wang, Mengqiang Di, Min Wu, Xueying Feng, Yiyi Li, Weiwei Wu, **Xiguang Zhang**, Shuaixiang Zhou, Huizhong Xiong

Innovent Biologics (Suzhou) Co. Ltd, Jiangsu, China

Immune checkpoint blockade (ICB) therapies blocking PD1/PDL1 signaling have shown unprecedented clinical efficacy in multiple indications. However, the overall response rate for ICB-sensitive tumors are only 10-50%. Moreover, many types of cancer, e.g. pancreatic, ovarian, and MSS colorectal cancer, remain highly refractory to ICB therapies. Thus, it remains a significant unmet medical need to improve the responsiveness and durability of current ICB therapies. Based on emerging clinical evidence, it is possible to address this challenge by combining PD1 or PDL1 mAbs with drugs targeting complementary mechanisms. Indeed, next-generation ICB therapies, e.g. PD1 x IL2 fusion protein, PD1 x CTLA4 BsAb, and PD1 x VEGF BsAb, have shown promising clinical signals and improved efficacy compared to PD1 mAb. This underlines the potential of incorporating two clinically validated anti-cancer mechanism-of-action into one drug. IFNα has shown clinical efficacy and potential synergistic anti-cancer effect with PD1 mAb. Indeed, soluble IFNα has been approved to treat cancer. Similar to the development of other cytokine-based therapies, it is necessary and challenging to overcome off-tumor activity of IFNα to achieve efficacy-safety balance, limit systemic toxicity, and improve pharmacokinetics profile and drug exposure. Here, we engineered a PD1-IFNα fusion protein composed of a functionally attenuated IFNα and a clinically validated PD1 mAb, Sintilimab, aiming to specifically stimulate PD1-positive immune cells. This PD1-IFNα fusion protein utilized bivalent PD1 binders and induced potent PD1/PDL1 blockade. To minimize systemic toxicity induced by IFNα and improve developability, we engineered human IFNα-2b to decrease the affinity between IFNα and IFNα receptors. The PD1-IFNα fusion protein elicited highly PD1-dependent IFNα signaling, selectively activated in PD1-high cells compared to PD1-low cells. Systemic administration of a mouse surrogate molecule showed superior anti-tumor efficacy compared to PD1 mAb, with undetectable toxicity, in several mouse syngeneic tumor models. This PD1-IFNα fusion protein showed favorable pharmacokinetics profile in mice and drug developability. Together, our pre-clinical data demonstrated that a bifunctional PD1-IFNα fusion protein elicits robust PD1/PDL1 signaling blockade and PD1-dependent IFNα signaling activation to achieve anti-tumor efficacy, with potential to expand the benefits of ICB therapies to more cancer patients.

#4882 LCB39, a novel systemically deliverable STING agonist with strong preclinical activity and tolerability.

Jihye Oh, Hyun Joo Bae, Ye Seul Jang, Sung Min Kim, Ho Young Song, **Sook Kyung Chang**, Chul-Woong Chung

LigaChem Biosciences Inc., Daejeon, Korea, Republic of

Direct STING activation with STING agonists is very effective in tumor control through Type I IFN responses in preclinical animal models. However, STING agonist therapeutics have faced major hurdles in clinical success due to limited bioavailability and suboptimal efficacy within tolerable doses. Here, we introduced LCB39, a novel non-CDN STING agonist small molecule currently at the preclinical development. LCB39 was intentionally generated toward the characteristics of lower cell permeability while maintaining its direct STING binding potency to improve systemic tolerability. Compared to diABZi compounds, such as GSK#3 or XMT-1616, LCB39 had about 100-fold lower THP-1 reporter activity with about 5-fold lower direct binding potency. As expected, LCB39 dramatically improved normal cell cytotoxicity to hPBMCs and HSCs. In addition, LCB39 did not induce stromal cell activation nor cell death. In contrast to the in vitro potency, LCB39 strongly promoted tumor growth suppression in a dose-dependent manner in several syngeneic mouse models. Mechanistically, LCB39 had a tumor-targeting and retention activity and promoted immune priming of tumor tissue including the activation of myeloid and lymphoid cells and induction of anti-tumor memory CD8 T cells in mice. In summary, systemically delivered LCB39 targeted tumor tissue and promoted robust anti-tumor activity with high tolerability in preclinical studies. LCB39 is a highly differentiated potent STING agonist with a safety profile, which suggested that LCB39 may have the potential to be the best-in-class STING agonist to treat solid cancers. LCB39 plans to enter first-in-human clinical study in early 2026.

#4884 Reversing immune desertification for effective cancer therapy.

Alessandra Araujo[1], Max Rodnick-Smith[2], Ranya Al-Khaledy[1], Mark Badeaux[1], **Everett Stone**[2]

[1]Chemical Engineering, The University of Texas at Austin, Austin, TX,[2]Molecular Biosciences, The University of Texas at Austin, Austin, TX

Patients with tumors that have a “cold, or “immune desert” phenotype typically have poor outcomes on immune checkpoint therapy (ICT). Aberrant sphingosine-1-phosphate (S1P) signaling in tumors and in their draining lymph nodes (TDLN) appears to causes a common form of immune desertification by disabling or stalling lymphocyte egress from the TDLN, ultimately restricting immune trafficking to tumors. Clinically, tumor expression levels of the S1P producing enzyme sphingosine kinase 1 (SPHK1) strongly and negatively correlate with survival of patients after immune checkpoint inhibitor (ICI) therapy) and pre-clinically correlate with reduced tumor infiltrating lymphocytes (TILs). While there are five known S1P receptors (S1PR1-5), the expression of S1PR1 is required for lymphocyte egress from lymphatic organs. Abnormal S1P signaling or S1PR1 agonists functionally downregulate S1PR1 levels, trapping lymphocytes in the lymph node and is the mechanism of action of certain immunosuppressants (e.g., fingolimod) used to treat autoimmune diseases such as multiple sclerosis. In preliminary studies we have demonstrated in murine cancer models treated with pharmacologically optimized S1P degrading enzymes (SGPL1), that depleting extracellular S1P dramatically increases the trafficking of lymphocytes out of TDLNs, increases tumor T cell infiltration and strongly or completely inhibits tumor growth when administered as a single agent. Data from our lab suggests that deeply lowering extracellular S1P without eliminating internal stores of S1P needed for lymphatic egress is a powerful modality for increasing the level of S1PR1 on lymphocytes, releasing tumor specific T cells from TDLNs, and ultimately increasing tumor immune infiltration. Essentially the exact opposite mechanism as observed with immunosuppressants such as fingolimod. Current small molecule inhibitors of S1P production can only lower extracellular S1P levels by ~ 50% via decreasing intracellular pools and only show limited anti-cancer activity. A cold tumor microenvironment is a common phenomenon that limits ICT efficacy and therapeutics that could enhance lymphocyte trafficking to the tumor would represent a significant advance for improving patient outcomes.

#4885 Targeting heterogeneity to improve non-small cell lung cancer treatments.

Avery Childress[1], Xiulong Song[1], Dave-Preston I. Esoe[1], Christian M. Gosser[1], Harrison Yang[1], Kassandra J. Naughton[1], Daniel R. Plaugher[1], Zhonglin Hao[2], Christine F. Brainson[3]

[1]Department of Toxicology and Cancer Biology, University of Kentucky, Lexington, KY,[2]Department of Internal Medicine, Markey Cancer Center, University of Kentucky, Lexington, KY,[3]Department of Toxicology and Cancer Biology, Markey Cancer Center, University of Kentucky, Lexington, KY

Non-small cell lung cancer (NSCLC) is currently the leading cause of cancer related death in the United States. Despite improvements in treatment, success is extremely varied due to tumor heterogeneity. Our laboratory hypothesis that targeting heterogeneity could improve treatment responses for NSCLCs. Our first method to accomplish this is to inhibit the histone methyltransferase EZH2, which tri-methylates histone 3 lysine 27 to silence genes. Using a syngeneic lung cancer model, we observed that the EZH2 inhibitor valemetostat combined with anti-PD1 immunotherapy drives tumor regression, increased activated T cells and increased antigen expression on the tumor cells. This switch to an MHC class II high state makes the tumors susceptible to immunotherapy-mediated cell killing. To closely study tumor-immune cell interactions ex vivo, our lab has optimized 3D tumoroid model that recapitulates the liquid air interface seen within the lung and immune cells. With this model, we have observed that bone marrow from valemetostat-treated mice led to a depletion of tumoroids, and an increase in CD8+ T cells. In addition to EZH2 inhibition that is currently in clinical trial, we are also exploring methionine restriction (MR) as an alternative way to alter heterogeneity. Methionine is a pre-cursor to S-adenosyl methionine, the methyl donor for EZH2. Our previous studies showed that dietary MR improved carboplatin response and slowed tumor progression in an aggressive KRAS/*Lkb1* mouse model1. Given some controversy around MR and immunotherapy, we next performed a syngeneic graft assay with the mixed lineage KRAS/*Lkb1* tumor cells. We observed that MR coupled with carboplatin and or anti-PD1 lead to improved response compared to control arms. We have also created “multi-culture” experiments that mirror the dietary intervention approach by reducing methionine within the media and treating with chemotherapy + anti-PD1. We observed that tumoroid growth in low methionine was stalled, particularly for KRAS/*Lkb1* tumoroids co-treated with chemo + anti-PD1. We also show that with the low methionine media there were significantly more T-cells present. Together these studies show that modulating EZH2 or methionine levels in NSCLC are effective ways to increase treatment efficacy. We also demonstrate use of cutting edge “multi-culture” experiments that can successfully model in vivo environments to better predict cancer response to treatment. 1 doi: https://doi.org/10.1101/2024.06.25.599795. This work was funded by: Markey STRONG Scholars Program through the American Cancer Society IRG-22-152-34 (HY), T32 CA165990 (DRP), R01 CA237643 (CFB), R01 HL170193 (CFB), P30 CA177558 (Markey Shared Resources)

#4887 TIM-3 signaling modulates brain tumor growth in an orthotopic mouse model.

Su Bin Won[1], Hyung-Seok Kim[1], Dae Yeon Kim[2], Ki Sun Kim[2], Su Jeong Gu[1], Chanju Lee[1], Hee Jung Yoon[1], Eun Jung Park[1]

T-cell immunoglobulin and mucin domain-containing molecule 3 (TIM-3) is a transmembrane protein originally identified as a T helper type 1 (Th1)-specific protein. While there is growing interest in the roles of diseases, including tumors, the properties of TIM-3 in brain tumors remain unexplored. In this study, we investigated the functional properties of TIM-3 in the brain tumor microenvironment using TIM-3 mutant mice with intracellular signaling defects (*Tim-3^{mut}*). To determine whether defects in TIM-3 signaling could affect brain tumor, we examined tumor growth using an intracranial mouse brain tumor model with glioma. EGFP-GL26 glioma cells were injected into the right hemisphere of mice with *Tim-3^{mut}* mice and WT mice, and tumor growth was monitored using MRI. Interestingly, TIM-3 singling defects lead to reduced glioma growth and improved survival in the orthotopic mouse glioma model. Next, we performed experiments to investigate how TIM-3 signaling defects influence brain tumor growth and identified alterations in several signaling molecules, including CBP35, a lectin family member in *Tim-3^{mut}* mice with GL26 tumor cells. Collectively, Our findings suggest that modulating TIM-3 signaling affects the brain tumor microenvironment, thereby influencing tumor growth and survival.

POPULATION SCIENCES: Advancing Cancer Health Equity Through Screening, Diagnostics, Genetics, and Social Determinants Poster Session

#4890 Cancer health awareness through screening and education, CHANGE: evidence of improved screening rates at 6 months post-test.

Marlo M. Vernon, **Mina Tsai**, Alma Carrillo, Ara Idun, Martha Tingen

Augusta University, Augusta, GA

Purpose: Incidence and mortality rates for breast, colorectal, and prostate cancers all exceed national rates in Georgia, and are higher among African Americans. The goal of the CHANGE initiative is to provide a sustainable model of evidence-based cancer awareness through education - with an emphasis on prevention and early detection behaviors. Thus, we examine whether participation of CHANGE initiative was related to referral follow-up rates for cancer screening and greater screening uptake for breast, colorectal, and prostate cancers.
Methos: Residents of five Augusta Housing Authority communities participated. At each site, four education sessions were provided by trained facilitators on cancer risk factors and etiology, racial disparities, eligibility for cancer screening, and participation in clinical trials. Attendance, eligibility for breast, prostate and colorectal screening were measured at baseline and 1- and 6-months post-CHANGE sessions.
Results: There were 110 residents (47.5% 65 and older years old, 45% male, 62.5% High School education, 90% AA) participated in this initiative. Around 95% completed post-intervention evaluation. Participants (n=67) were eligible for a cancer screening; breast (n=21), prostate (n=14), and colorectal screening (n=30) based on American Cancer Society guidelines. CHANGE participants who have attended 75% or above sessions had significantly higher referral rates (93.6%) and subsequent follow-up (receipt of care) (90% vs. 10% those who have attended < 75% sessions) at 6 months post-sessions. Those with higher attendance also had higher follow up with breast cancer (84.6%), colorectal, (100%), prostate cancer (100%), screening uptake when compared those without attending 75% or above sessions, respectively. Majority of those who completed follow up screening were aged 65+ years, were female, were Black, had high school or lower education, and had an insurance (either public or private).
Conclusions: Findings from our study demonstrated the participation of CHANGE initiative was related to greater referral rates and follow-up screening uptake for breast, prostate, and colorectal cancers. CHANGE participants demonstrated improved access and receipt of care/resources by attending CHANGE sessions. Participants reported being motivated and confident in seeking preventive care and satisfaction with community engagement efforts. Our study suggests that replication of this initiative in similar communities may improve knowledge for cancer risk and health equity simultaneously among underserved populations.

#4891 Genome-first approach identifies shelterin complex gene variants and associated cancers.

Akanksha Nagarkar, Hasset Nurelegne, Jung Kim, Kelvin C. de Andrade, Sharon A. Savage

NCI Div. of Cancer Epidemiology & Genetics, Rockville, MD

Telomeres, nucleotide repeats and a six-protein complex called shelterin at chromosome ends, are critical for genomic integrity. Rare heterozygous pathogenic or likely pathogenic (P/LP) germline variants in shelterin complex genes have been associated with long telomeres and risk of certain cancers, including melanoma, lymphoproliferative diseases, glioma, papillary thyroid cancer, and sarcoma. Traditional phenotype-first studies of P/LP germline variants and disease are often limited by ascertainment of the most severely affected individuals. Genome-first approaches can reduce this bias by first assessing germline variants and then evaluating the associated diseases. Since most studies, to date, have focused on variants in *POT1* and cancer, we sought to estimate associations between cancer and rare P/LP variants in the five less well studied shelterin genes (*ACD*, *TERF1*, *TERF2*, *TERF2IP*, and *TINF2)* in the UK Biobank (UKB) to understand their role in cancer etiology at the population level. Exome sequencing data on 469,578 participants were retrieved from the UKB DNA Nexus platform. Variants with minor allele frequency <1%, exonic or splice site, genotype quality >30, depth >20, and allele fraction >0.3 were retained. Variant classification used Automated Germline Variant Pathogenicity (PMID: 38426335). Logistic regression analyses adjusted for age, sex, alcohol use, smoking, and BMI were used to calculate odds ratios (OR) and 95% confidence intervals (CI). There were 177 participants (97 female, 80 male, median age = 57.0 years, range = 40.0 - 69.0) with 59 unique P/LP germline variants (30 *ACD*, 9 *TERF2*, and 20 *TINF2*). Strikingly, there were no rare variants in *TERF1* or *TERF2IP.* The population prevalence of individuals with P/LP germline variants in these five shelterin genes is estimated at 1:2,514 (174/437,486 unrelated individuals, 95% CI 2,189-2,953). Forty-eight individuals with P/LP germline variants were diagnosed with at least one cancer with a median age at first cancer of 59.3 years (range 19.4 - 80.6). Overall, P/LP variants were significantly associated with melanoma (OR 2.93, 95% CI 1.20-7.15, p = 0.018) and cancers of the urinary system (OR 2.78, 1.02-7.57, p = 0.045). By gene, P/LP variants were associated with cancers of the oral cavity/pharynx (*ACD*, OR 4.78, 95% CI 1.18-19.4, p = 0.030), soft tissue including heart (*ACD*, OR 8.90, 95% CI 1.24-63.9, p = 0.030), colon excluding the rectum (*TERF2*, OR 8.44 , 95%CI 1.05-68.0, p= 0.045), female genital system (*TERF2*, OR 12.98, 95% CI 1.43-117.8, p = 0.023), and melanoma (*TINF2*, OR 7.63, 2.35-24.75, p = 0.001).Rare P/LP germline variants in *ACD*, *TERF2*, and *TINF2* may be associated with increased risk of certain cancers in the UKB. Analyses applying the genome-first approach other population-based cohorts and assessment of telomere length are underway to better understand the extent to which variation in shelterin genes contributes to cancer etiology.

#4892 Tools for screening for social determinants of health in head and neck cancer: a scoping review.

Rebecca A. Zasloff[1], Alexandra Hunter[1], Ayush Khanna[2], Huda Haque[2], Elizabeth R. Blackwood[3], Nosayaba Osazuwa-Peters[4]

[1]Duke University School of Medicine, Durham, NC,[2]Duke University, Durham, NC,[3]Duke University Medical Center Library, Duke University School of Medicine, Durham, NC,[4]Department of Head and Neck Surgery and Communication Sciences, Duke University School of Medicine, Durham, NC

Background: Racial/ethnic disparities in head and neck cancer (HNC) outcomes are well documented. HNC has the third worst Black vs White five-year survival gap of all cancers. Despite these disparities in mortality, access to care remains an issue for minoritized individuals and lead to decreased cancer health care utilization. In recent years, there has been a growing recognition of social determinants of health (SDoH) as contributors to barriers to care and drivers of health disparities for cancer patients. Among patients with HNC, SDoH have been linked to later-stage presentation and treatment delays leading to adverse health outcomes for patients with increased social needs. Despite calls by the National Cancer Institute to address SDoH in advancing equitable cancer care delivery, there is limited research on the SDoH screening tools in the context of HNC care. This study aims to report on screening tools to assess SDoH among HNC patients.
Methods: We conducted a systematic literature search of Medline, Embase, and Web of Science databases on July 24, 2024. The included studies were US-based, written in English, and examined a validated tool to assess SDoH among HNC patients. Tools were categorized by the five primary SDoH domains as defined by the Healthy People 2030 Initiative: Economic Stability, Education Access and Quality, Social and Community Context, Health Care Access and Quality, and Neighborhood and Built Environment. Subdomains within each primary domain were used to further categorize the included tools.
Results: After screening 272 articles, 5 studies that evaluated 4 unique SDoH screening tools were included in the analysis. The number of questions in any given SDoH assessment tool ranged from 2 to 33 (mean: 16). Economic Stability (n = 3, 75%) and Health Care Access and Quality (n =2, 50%) were the only 2 SDoH domains assessed by the tools. Most tools evaluated one domain (n =3, 75%). Poverty (n = 3, 75%) and Access to Health Services (n = 2, 50%) were the most commonly assessed SDoH sub-domains. Only one study proposed a specific intervention to address SDoH.
Conclusion: This review found that most SDoH screening tools in HNC care focus on assessing Economic Stability, but do not capture several other Healthy People 2030 domains. Ultimately, the limited number of validated SDoH tools fail to assess the wide-reaching spectrum of HNC patient experiences, making it difficult to comprehensively address the social needs of HNC patients. In addition to the development of tools to screen other SDoH domains, future studies are needed to integrate adequate public health interventions in order to address social need particularly among racial/ethnic minority and marginalized populations.

#4893 Who falls through the cracks?: Characteristics of women successfully and unsuccessfully navigated to breast cancer screening from the emergency department.

Sara Heinert[1], John Hemphill[2], Gabrielle Gracias[3], Maya Iglesias[3], Jessica Kim[4], Hrithika Ravuri[5], Antonia Sames[5], Alexandra Sobocinski[5], Ana Natale-Pereira[6], Erin Muckey[7], Pamela Ohman-Strickland[8], Vince Silenzio[9], Jonathan McCoy[1], Amanda Esposito[1], Ethan Halm[2], Mary O'Dowd[2], Humaira Chaudhry[10]

[1]Department of Emergency Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ,[2]Office of Population Health, Rutgers Health, New Brunswick, NJ,[3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ,[4]Rutgers University, New Brunswick, NJ,[5]Rutgers New Jersey Medical School, Newark, NJ,[6]Division of General Internal Medicine, Rutgers New Jersey Medical School, Newark, NJ,[7]Department of Emergency Medicine, Rutgers New Jersey Medical School, Newark, NJ,[8]Department of Biostatistics and Epidemiology, Rutgers School of Public Health, Piscataway, NJ,[9]Department of Urban-Global Public Health, Rutgers School of Public Health, Piscataway, NJ,[10]Department of Radiology, Rutgers New Jersey Medical School, Newark, NJ

Screening mammography has contributed to decreased breast cancer mortality, but screening disparities exist among racial/ethnic minority populations. Emergency departments (EDs) serve in a safety net capacity for underserved patients and are a novel place for cancer screening education and navigation. We implemented an intervention at two EDs in New Jersey where students recruited patients overdue for breast cancer screening and connected them to patient navigators. This analysis describes participants who were reached by a navigator to make a mammogram appointment versus those not reached, as well as women who attended their appointment versus not. Of 415 ED patients eligible for breast cancer screening (women 40-74 years old), 152 (37%) were eligible for the study (last mammogram >1 year ago), of which 101 agreed to participate. When contacted, 14 (14%) participants were reached and made a mammogram appointment. Women reached were more likely to: be in their 40s (71% vs. 49%), Hispanic (77% vs. 47%), Spanish-speaking (64% vs. 38%), not have private insurance (33% vs. 49%), and have Medicaid (22% vs. 10%) than women not reached. Nine women (9% total, 64% of those reached) attended a mammogram appointment. Women who attended their appointment had similar characteristics as women reached but were more likely to have a primary care provider (PCP) (78% vs 64%) and Medicaid (33% vs 22%) compared to all women who made an appointment. (See table.)Follow-up care is vital to an ED cancer screening intervention. Surprisingly, English speaking and patients with private insurance were less likely to be reached for a mammogram appointment. Patients without a PCP were less likely to attend their appointment. Adapting interventions to target women who “fall through the cracks” is imperative to improving breast cancer equity. More work is needed to strengthen the follow-up process for breast cancer screening for ED patients.

Characteristics of Study Participants by Follow-Up Status					
	%	Attended Appointment (n=9)	Made Appointment (n=14)	Was Not Reached (n=87)	All (n=101)
Age	Mean (SD)	48.7 (7.4)	47.8 (6.2)	51.1 (8.1)	50.6 (8.0)
	40-49 years	67	71	49	53
	50-59 years	22	21	31	29
	60-69 years	11	7	19	17
	70-74 years	0	0	1	1
Race/ Ethnicity	Asian	0	0	6	5

#4894 Cervical cancer screening disparities among the deaf and hard-of-hearing women.

Roxana Soto-Abreu, Francisco J. Munoz-Torres, Vivian Colon-Lopez

Cancer Control and Population Sciences Division, University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Recent studies have highlighted persistent disparities in cancer screening among deaf populations[1-4]. Deaf women show lower adherence rates for cervical and breast cancer screenings compared to hearing women, with significant disparities remaining for cervical cancer screening after adjusting for correlates[1,5]. Barriers to cancer screening for deaf individuals include ineffective patient-physician communication and a lack of culturally and linguistically aligned resources[6].
Objective: Examine the association of up-to-date cervical cancer screening in deaf and hard-of-hearing women and investigate if disparities in cancer screening among this population persist.
Methods: A secondary analysis of the 2022 Behavioral Risk Factor Surveillance System (BRFSS) data set was conducted. Logistic regression was used to evaluate up-to-date cervical cancer screening, by disability status and covariates (age, race, education, income, regular provider, health insurance, and urban residency). Up-to-date cervical cancer screening was defined using the recommendation from the US Preventive Services Task Force guidelines and considered females ages 21 to 65 years who received a Papanicolaou (Pap) test in the previous 3 years to be up to date with screening[7]. The main independent variable (deafness and hard-of-hearing) was self-reported using the Guide to Disability Questions from the Centers for Disease Control and Prevention[8].
Results: A total of 13,937 females between 21 years and 65 years old reported to have a cervical cancer screening. From this sample, 3.3 % (n=455) of respondents identified as deaf and hard-of-hearing. The likelihood of being up-to-date in cervical cancer screening was lower in deaf women (AOR: 0.82; $p<0.05$) when compared to hearing women. Non-Hispanic black women have lower odds of being up-to-date with cervical cancer screening (AOR: 0.84; $p<0.05$) when compared to non-Hispanic white women. Uninsured women showed lower odds (AOR: 0.73; $p<0.001$) for being up-to-date on cervical cancer screening, compared with women with health insurance coverage. Women with an annual household income of less than $25,000 had an adjusted odds of 0.62 ($p<0.001$) being up-to-date on cervical cancer screening, compared with women with an annual household income of $75,000 or more. Additionally, those women who reported not having a personal healthcare provider had half the odds of not being up-to-date on cervical cancer screening when compared to women having 2 or more health providers (AOR: 0.50; $p<0.001$).
Conclusion: Findings from this study support that disparities among this population of deaf and hard-of-hearing women persist regarding adherence to cervical cancer screening. Social determinants of health (economic stability, healthcare access, and quality) play an important role in access to cancer care prevention, especially in people with disabilities.

#4897 Self-reported experiences of discrimination and inflammatory-related biomarkers among Black breast cancer survivors.

Nur Zeinomar[1], Marley Perlstein[1], Bo Qin[1], Hari S. Iyer[1], Jesse J. Plascak[2], Tengteng Wang[1], Kitaw Demissie[3], Christine B. Ambrosone[4], Elisa V. Bandera[1], Chi-Chen Hong[4]

[1]Rutgers Cancer Institute, New Brunswick, NJ,[2]The Ohio State University College of Medicine, Columbus, OH,[3]SUNY Downstate School of Public Health, Brooklyn, NY,[4]Roswell Park Comprehensive Cancer Center, Buffalo, NY

Purpose: Racial discrimination disproportionately affects Black individuals and is associated with adverse mental and physical health outcomes. Black individuals also exhibit higher levels of systemic inflammation compared to other racial and ethnic groups, which may contribute to disparities in cancer outcomes and comorbid conditions. Despite this, the relationship between racial discrimination and inflammatory biomarkers in cancer survivors remains understudied. This study examines the association between experiences of discrimination and inflammatory biomarker levels in a cohort of Black breast cancer survivors.
Methods: We analyzed data from the Women's Circle of Health Follow-up Study, a population-based longitudinal cohort of Black breast cancer survivors in New Jersey. Self-reported lifetime racial discrimination was assessed during baseline home visits (approximately 12 months post-diagnosis) using the validated "Experiences of Discrimination (EOD)" instrument, which captures experiences of interpersonal and institutional discrimination across nine domains, including work, education, health care, and public settings. Inflammatory biomarkers, including high sensitivity C-reactive protein, Interleukin-6 (IL-6), Tumor Necrosis Factor (TNF)-α, and IL-1β, were assayed in blood samples collected 24-36 months post-diagnosis. Multivariable linear
regression models were used to evaluate the associations between EOD (ever vs. none) and biomarker concentrations, adjusting for potential confounders.
Results: Among the 156 women included in this analysis, 74% reported experiencing any discrimination. Self-reported EOD was not significantly associated with inflammatory biomarker levels. However, women reporting discrimination had non-significant elevations in TNFα and IL-1β compared to those reporting no EOD. In age-adjusted models, the mean for TNFα among women reporting any EOD was 5.94 pg/mL (95% CI: 5.50, 6.42) compared to 5.57 pg/mL (95% CI: 4.91, 6.32) among those reporting no EOD. Similarly, the age-adjusted mean value for IL-1β was 1.37 pg/mL (95% CI: 1.21, 1.56) for women reporting any EOD versus 1.28 pg/mL (95% CI: 1.03, 1.58) for those reporting none. Fully adjusted models accounting for age at diagnosis, sociodemographic factors (marital status, income), lifestyle factors (smoking, alcohol use, physical activity, body mass index), and chemotherapy yielded comparable results.
Conclusion: While we did not observe statistically significant associations, our findings suggest a potential link between EOD and elevated levels of inflammatory biomarkers in Black breast cancer survivors, pointing to a possible biological impact of discrimination-related stress. Future studies with greater statistical power are needed to better understand these relationships and their potential relevance to cancer prognosis and survivorship.

#4898 Factors influencing implementation of a breast cancer screening intervention for women with food insecurity in a community setting: An application of the Implementation Research Logic Model.

Charlotte L. Kerber, Julie H. T. Dang, Daniel J. Pasillas-Pablo, Jocelyn T. Canty, Laura Fejerman

UC Davis, Davis, CA

Among individuals and communities with low-income, the experience of food insecurity is associated with greater delays in recommended mammography screening and late-stage breast cancer at diagnosis. Community-based interventions that address barriers to promoting breast cancer screening among diverse communities of women with food insecurity in real-world safety-net settings have been limited. In partnership with Sacramento Food Bank and Family Services (SFBFS), the largest non-profit provider of social services in Sacramento County, this study aimed to (1) identify factors influencing implementation of a breast cancer screening intervention in a food distribution setting and (2) identify mechanisms through which factors impact implementation outcomes. As part of a larger participatory-based mixed methods project with SFBFS, we conducted semi-structured interviews (n=10 staff; n=10 clients) and collected observations from direct food distribution events during the pre-implementation phase. The Consolidated Framework for Implementation Research (CFIR) guided the rapid iterative content analysis to identify barriers and facilitators of implementation. Then as part of the Implementation Research Logic Model (IRLM), we developed a matrix using CFIR, Expert Recommendations for Implementing Change (ERIC), and the Behavior Change Wheel (BCW) to identify mechanisms linked to these factors and to assess implementation outcomes of acceptability, appropriateness, and feasibility. Overall, there was consensus that promoting breast cancer screening in the food distribution setting was beneficial and welcomed by all stakeholders. Key determinants related to the general theme of sustainability were identified including financing, the availability of resources, and the process of engaging with clients while they are at the food distribution event. Characteristics of individuals, specifically the clients' capability and motivation to receive a breast cancer screening intervention in this context, must also be considered. An active and sustained partnership with food bank leaders is crucial to facilitate these outcomes. Intervention format should include tailored messaging that is culturally appropriate and empowers individuals to obtain recommended screening. Content of the intervention should provide interactive assistance that facilitates local support for screening eligibility and services. This IRLM can be adapted for future breast cancer screening interventions in novel community-based food distribution settings.

#4899 Colorectal cancer screening among deaf and hard of hearing individuals in Puerto Rico.

Francisco Munoz-Torres, Roxana Soto-Abreu, Vivian Colon-Lopez

University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico

Background: Colorectal cancer (CRC) screening rates among Deaf and Hard of Hearing (DHH) individuals are often lower than those of the hearing population. This disparity is driven by factors including communication barriers, limited access to healthcare services, and insufficient support systems. As a result, DHH individuals face unique challenges in accessing timely screening, leading to delayed diagnoses and poorer cancer outcomes.
Methods: We analyzed data from the 2022 Behavioral Risk Factor Surveillance System (BRFSS) to examine colorectal cancer (CRC) screening rates among Deaf and Hard of Hearing (DHH) individuals. The sample included 3,496 individuals aged 40 years and older, residing in Puerto Rico. Prevalence ratios (PR) for non-endoscopic colorectal cancer screening methods were calculated. Subgroup analyses were performed to assess the impact of transportation access, social and emotional support, and the ability to manage daily errands on CRC screening rates.
Results: Compared to hearing individuals, DHH individuals had an 11% lower prevalence of colorectal cancer (CRC) screening (PR = 0.89, 95% CI: 0.89, 0.90). After adjusting the model for age, sex, education, income, access to personal healthcare providers, and health insurance status, the prevalence ratio (PR) decreased further to 0.84 (95% CI: 0.83, 0.84).In subgroup analyses, the PR remained stable for individuals with reliable transportation. However, it decreased by 13% for those facing transportation challenges (PR = 0.78, 95% CI: 0.77, 0.79). The PR dropped by 15% for individuals without social and emotional support (PR = 0.76, 95% CI: 0.74, 0.77) and by 11% for those struggling with daily errands on their own (PR = 0.80, 95% CI: 0.79, 0.80).
Discussion: This study reveals a disparity in CRC screening rates between DHH individuals and the hearing population, driven by factors such as limited transportation, lack of social support, and difficulties managing errands. The lack of culturally and linguistically appropriate materials, including PRSL, worsens these barriers. Training healthcare providers to improve communication with DHH individuals is essential for increasing screening.
Conclusion: Addressing these barriers requires targeted research and interventions, focusing on accessible educational resources (including PRSL translations), improving healthcare provider training, and enhancing screening access. Future research should examine how social factors, such as socioeconomic status and geography, affect CRC screening access in DHH populations. These strategies are key to reducing disparities and improving health outcomes for DHH individuals in Puerto Rico and beyond.

#4900 Barriers and facilitators influencing the implementation of a mHealth (MeMoSA) oral cancer screening program in rural communities in a low- and middle-income country: Preliminary findings of a qualitative study.

Senthilmani Rajendran[1], Nur Dinie Junaidi[1], Davinna Satguna Rajah[1], Aliya Nabil[1], Nurshaline Kipli[2], Thaddius H. Maling[3], Roslina Mah[2], Ignatius Niap[2], Shirley Hui Hui Hu[2], Suzanne Scott[4], Rafdzah Ahmad Zaki[5], Sok Ching Cheong[1]

[1]Cancer Research Malaysia, Subang Jaya, Malaysia,[2]Ministry of Health, Malaysia, Kuching, Malaysia,[3]Ministry of Health, Malaysia, Kota Kinabalu, Malaysia,[4]Queen Mary University of London, London, United Kingdom,[5]Univeristi Malaya, Kuala Lumpur, Malaysia

Introduction: Sixty-five percent of oral cancer cases in Malaysia are detected at late stages due to poor awareness and difficulties in accessing healthcare in remote communities. The early detection of oral cancer (OC) could be overcome through teleconsultation using mHealth applications that enable remote review of clinical data and oral lesion images. We determined the feasibility of healthcare volunteers (HCVs) using a mHealth application MeMoSA for oral cancer screening in rural communities in Malaysia by identifying the barriers and facilitators of implementation.

Methods: This qualitative study was part of a larger mixed-methods single-arm feasibility study. HCVs were trained to capture oral images of villagers using MeMoSA. Dentists at the nearest public clinic reviewed images remotely to give a referral decision. Suspicious high-risk oral lesions were also reviewed by specialists via MeMoSA and where warranted, make a referral directly to the nearest tertiary center for biopsy. To identify implementation barriers and facilitators, in-depth interviews were conducted with HCVs in the Malay language, which were recorded and then transcribed and translated verbatim into English. The Consolidated Framework for Implementation Research (CFIR), was used to guide interviews, coding and data analysis.

Results: Forty-seven HCVs screened 1865 individuals in 12 rural villages with 93% uptake. Thirty-one HCVs were interviewed. Main themes related to the innovation and implementation process domains of CFIR. Barriers encountered by the HCVs included limited telecommunications infrastructure for internet access and community perceptions. For instance, the community's poor oral symptom knowledge, fear of knowing and lack of motivation to engage in preventive behaviors that influenced uptake of screening and adherence to follow-up appointments. HCVs overcame issues with internet access by traveling to areas with an internet connection to transmit information for teleconsultation. Facilitators included the avoidance of travelling long distances and incurring high transportation costs to be checked at the clinic, and the simplicity and user-friendly design of MeMoSA which motivated HCVs to conduct screening. In addition, HCVs' relationship and trust towards village leaders was a major facilitator for a well-planned implementation.

Conclusion: This novel approach to oral cancer screening has good reach, with motivated HCVs and could be feasible in low- and middle-income countries. However, strategies to improve barriers such as adherence to follow-up appointments are required and facilitators should be leveraged for sustained implementation.

#4901 Investigating whether TXNRD2 is a therapeutic target against triple negative breast cancers using African American-derived models.

Keacha Chang, Brenna Flowers, Abigail Rullo, Irida Kastrati

Loyola University Chicago, Chicago, IL

African American women are twice more likely to be diagnosed with triple negative breast cancer (TNBC) compared to Caucasian women; they are diagnosed with TNBC at a younger age and exhibit a more aggressive disease. TNBC is a heterogenous subtype of breast cancer that does not benefit from targeted therapies thus prognosis remains poor. The increased TNBC incidence and its poor prognosis exacerbate the disparate mortality experienced by African American women diagnosed with breast cancer. Thioredoxin reductases (TXNRDs) are key antioxidant enzymes within the thioredoxin pathway. Most tumors, including TNBCs, express higher levels of antioxidants to cope with higher redox stress resulting from the tumor's deregulated metabolism and mitogenic stress. This presents a therapeutic vulnerability and TXNRD1, the cytoplasmic isoform, is proposed as a cancer therapeutic target. TXNRD2 is the mitochondrial isoform; its contribution to cancer progression is understudied and unclear. Our investigation into breast cancer patient databases (Clinical Proteomic Tumor Analysis Consortium, CPTAC) demonstrated that African American patients have elevated levels of TXNRD2. Based on these observations, our goal is to (i) investigate whether TXNRD2 is a therapeutic target against TNBC using African American-derived cell models, and (ii) determine whether a new class of TXNRD inhibitors in development by us, TXNRD(i)s, can be effective drugs against aggressive TNBC. If successful, our work will set the stage for developing new drugs that are highly needed for treating TNBC in the clinic and may reduce the racial disparity gap in breast cancer. A panel of African American derived TNBC cell lines were characterized by western blot for expression levels of TXNRD1 and 2. HCC1806 cells, which had elevated levels of TXNRD2, were transfected with siTXNRD2 or control and cell growth was monitored over 5 days. Silencing of TXNRD2 significantly attenuated cell growth. Treatment of these cells with TXNRD(i)s inhibited cell viability *in vitro* and *in vivo* using a xenograft model. To determine to what extent, the inhibition of TXNRD2 vs TXNRD1 by TXNRD(i)s contributes to the anti-cancer activity we are optimizing a fluorescent probe and live cell imaging by microscopy. HCC1806 cells were incubated with TRFS-Green which fluoresces upon reduction by TXNRDs and MitoTracker-Red which stains for mitochondria where TXNRD2 is located. Colocalization between TRFS-Green and MitoTracker-Red indicates TXNRD2 specific activity. Novel TXNRD(i)s are being catalogue for TXNRD specific inhibition. Together our data support the development of TXNRD2 inhibitors to treat African American women with TNBC.

#4903 Short chain per- and polyfluoroalkyl substances associate with elevated alanine aminotransferase: cross-sectional analysis results from the STRIVE cohort.

Bojung Seo[1], Hongxu Wang[1], Rachel Maguire[2], Yukun Liu[2], Beatrice Smith[2], Kristin Haller[3], David Conti[1], Heinz-Josef Lenz[4], Antonio Planchart[2], Giorgio Roccaro[3], Lesley S. Miller[3], Andrew Muir[5], Susan K. Murphy[6], Andrew Moon[7], Melissa Troester[8], Cynthia A. Moylan[5], Joellen Schildkraut[3], Cathrine Hoyo[2], Jesse A. Goodrich[1]

[1]Department of Population and Public Health Sciences, Keck School of Medicine, University of Southern California, Los Angeles, CA,[2]Department of Biological Sciences, North Carolina State University, Raleigh, NC,[3]Department of Medicine, Emory University School of Medicine, Atlanta, GA,[4]Division of Medical Oncology, Keck School of Medicine, University of Southern California, Los Angeles, CA,[5]Division of Gastroenterology, Duke University Health System, Durham, NC,[6]Department of Obstetrics and Gynecology, Duke University Medical Center, Durham, NC,[7]Division of Gastroenterology and Hepatology, University of North Carolina, Chapel Hill, NC,[8]Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC

Background: Although long chain, high molecular weight per- and polyfluoroalkyl substances (PFAS) (≥8 and ≥6 carbons for carboxylic and sulfonic acids; molecular weight >400 g/mol) have been associated with elevated ALT, the association of short chain, low molecular weight PFAS with elevated ALT or cirrhosis, a risk factor for hepatocellular carcinoma, remains unclear.
Objectives: To examine associations of short or long chain PFAS mixtures with elevated ALT or cirrhosis and baseline factors related to PFAS.
Methods: We included 349 adults aged 40-75 years from the Southern Liver Health Study (STRIVE), an ongoing longitudinal observational study. At enrollment, 135 out of 196 participants had a confirmed diagnosis of cirrhosis. We used logistic regression to examine associations between individual PFAS serum levels and elevated ALT or cirrhosis, at baseline. Quantile g-computation was used to test the associations of short or long chain PFAS mixtures with the outcomes. Linear regression examined baseline factors associated with PFAS.
Results: Increasing all short chain PFAS by one quartile was associated with higher odds of elevated ALT (odds ratio: 2.20 [1.32-3.67]); no association was observed with the long chain PFAS mixture. Perfluoroheptanoate, a short-chain PFAS, was associated with both elevated ALT and cirrhosis (odds ratios: 1.53 [1.01-2.33]; 1.51 [1.01-2.27], respectively) at unadjusted *P*. Long chain PFAS were higher in males and linked to higher reported levels of alcohol consumption. Both long and short chain PFAS were lower in bottled water users, non-water drinkers, and current smokers compared. Perfluoropentanoic acid, a short chain PFAS, was higher in females.
Conclusions: In the STRIVE cohort, higher short-chain PFAS mixture concentrations were significantly associated with elevated ALT and varied by sex and lifestyle behaviors.

Table 1. Associations of PFAS mixtures with outcomes

	C	Molecular Weight (g/mol)	Geometric Mean (95% CI) (ng/mL)	PFAS mixture on Elevated ALT		PFAS mixture on Cirrhosis	
				Odds ratio (95% CI)	*P*	Odds ratio (95% CI)	*P*
Long-chain, high molecular weight PFAS							
PFOS	8	500.1	3.97 (3.59, 4.39)	0.84 (0.38, 1.83)	0.66	0.95 (0.86, 1.05)	0.34
PFOA	8	414.1	0.997 (0.91, 1.09)				
PFHxS	6	400.1	0.94 (0.85, 1.04)				
PFNA	9	464.1	0.40 (0.37, 0.43)				
PFDA	10	514.1	0.16 (0.15, 0.18)

Lee Moffitt Cancer Center, Tampa, FL

Background: Image based body composition is the gold standard for assessing skeletal muscle area and quality in cancer patients. In patients with pancreatic ductal adenocarcinoma (PDAC), the decrease in muscle area and quality can be particularly profound. Yet image-based muscle assessment in these patients may be impeded by the presence of edema at follow up caused by disease burden and/or treatment. Edema in superficial muscle can affect the Hounsfield units of surrounding tissue leading to overestimation of muscle area. Despite this, to our knowledge no studies have examined alternative methods of assessing muscle loss in PDAC patients in the context of edema. To address this gap, we examined the prevalence of edema in PDAC patients, its impact on change in total skeletal muscle area (SMA) between diagnosis and six month follow up, and the use of psoas muscle area (pSMA), which is less impacted by edema, as an alternative method of assessing muscle loss.

Methods: The study population included sixty-nine PDAC patients from the multi-center Florida Pancreas Collaborative study with serial computed tomography (CT) scans obtained at diagnosis and six month follow up. Using the CT scans, we assessed edema by identifying opacification in the subcutaneous fat defining those with opacification as edematous. We examined the prevalence of edema at six-month follow up in the overall PDAC population and tested for differences by race and sex using Fisher's Exact test. SMA and pSMA were quantified as surface area (cm2) at L3 with sliceOmatic software. SMA and pSMA percent change and mean change between diagnosis and follow up were calculated in the overall population and by edema status at follow up. Spearman correlation was used to test the interrelationship of SMA and pSMA according to edema status.

Results: Prevalence of edema at follow up was 53.6% and did not significantly differ by race ($p>0.76$) or sex ($p>0.05$). In the overall population, SMA increased by 0.472% between diagnosis and follow up. When stratified by edema status, SMA increased in patients with edema (+3.06%) whereas SMA in patients without edema decreased (-2.52%). Conversely, pSMA decreased by 6.32% and this was consistent across edema status (-5.69% for present and -7.05% for absent). Finally, we observed that SMA and pSMA at follow up are strongly correlated in both the presence ($r=0.72$) and absence of edema ($r=0.77$).

Conclusions: In this study, we observed that edema is prevalent in most PDAC patients at follow up contributing to an overestimation of SMA. This overestimation may introduce bias into understanding the impact of PDAC on muscle wasting, an important factor in cancer cachexia. Encouragingly, findings suggest pSMA may be a suitable proxy for total SMA and limit the impact of edema on SMA estimates. These findings have important implications for enhancing our understanding of muscle changes over the PDAC cancer care continuum and should be considered in future studies.

#4905 Mosaic chromosomal alterations overlapping hotspot and coldspot sites of somatic structural variation are associated with increased odds of hematological malignancy.

Jasmine Ryu Won Kang, Vanessa Bruat, Kimberly Skead, Mawusse Agbessi, June Kim, Elias Gbeha, Marie-Julie Fave, Philip Awadalla

Ontario Institute for Cancer Research, Toronto, ON, Canada

BACKGROUND
Clonal hematopoiesis (CH) occurs when hematopoietic cells acquire somatic mutations and proliferate to generate clones in blood. CH can be driven by mosaic chromosomal alterations (mCAs), which are large somatic structural variants, and is associated with increased risk of blood malignancy. We conducted a genome-wide search for sites significantly more or less impacted by mCA events, termed hotspots and coldspots. We tested whether the odds of blood malignancy in participants harboring mCAs overlapping hotspots or coldspots differed from the overall association between mCAs and blood malignancy.
METHODS
This study utilized two cohorts of the Canadian Partnership for Tomorrow's Health, including the Ontario Health Study (OHS; n=7070) and CARTaGENE (n=28,639). Participants were genotyped with the UK Biobank Axiom or Infinium Global Screening Array and completed a baseline cancer questionnaire. All mCA calling was performed using MoChA software. We identified hotspot and coldspot sites of autosomal mCA accumulation using binomial tests scaled by chromosome and array type. We determined whether the number of overlapping mCAs at each query site was greater or less than would be expected under the null expectation. Then, we calculated the prevalence of cancer in participants with or without mCAs overlapping hotspots/coldspots and conducted Fisher's exact tests to generate odds ratios.
RESULTS
In OHS, participants with an mCA had a significantly greater odds of having a hematological malignancy at baseline (OR=7.29, 95% CI=3.72-13.38, p=7.84e-08). They were also more likely to have a cancer diagnosis of any type (OR=1.63, 95% CI=1.14-2.30, p=5.59e-03). Participants with an mCA overlapping a hotspot site had a further increased odds of harboring hematological malignancy (OR=9.79, 95% CI=3.94-21.29, p=5.05-e06). For participants with an mCA overlapping a coldspot site, the OR reached 20.52 (95% CI=3.68-76.85, p=7.36e-04). In CARTaGENE, participants with an mCA were also at increased odds of hematological malignancy (OR=11.31, 95% CI=6.78-18.17, p=9.77e-16), and any cancer diagnosis (OR=1.93, 95% CI=1.53-2.41, p=5.95e-08). Those carrying an mCA overlapping a hotspot site were 14.6 times more likely to have a hematological malignancy (95% CI=7.94-25.29, p=3.30e-13), and those with an mCA overlapping a coldspot site were 14.2 times more likely (95% CI=5.0-32.9, p=7.63e-06).
CONCLUSIONS
These results suggest that there may be genomic locations at which somatic structural variation has a larger impact on the development of blood malignancy, relative to other regions. Further work is needed to characterize the functional consequences of somatic mutation at these key regions and explore whether these associations of hotspots, coldspots, and cancer incidence are conserved across a range of tissues.

#4906 A prospective analysis identified mismatch repair genes as predisposing for uveal melanoma.

M.-H. Stern, A. Le Ven, M.-C. Villy, A. B. Silveira, A. Houy, M. Warcoin, M. Le Mentec, F. Simaga, A. De Pauw, B. Buecher, M. Gauthier-Villars, T. Verrier, K. Merchadou, V. Renault, A. Vincent-Salomon, J. Sauge, S. El Zein, C. Dubois d'Enghien, S. Piperno-Neumann, A. Matet, D. Malaise, N. Cassoux, L. Lumbroso-Le Rouic, D. Stoppa-Lyonnet, M. R. Rodrigues, L. Golmard, C. Colas;
Institut Curie, Paris, France

Background and Aim: Uveal melanoma (UM) is the most common intraocular malignancy in adults. Thus far, germline mutations of two genes have been identified to be predisposing to UM with a high penetrance: *BAP1*, responsible for the *BAP1* tumor predisposition syndrome (*BAP1*-TPDS), and *MBD4*, which germline alterations are associated with tumor predisposition, specific tumor mutational signature and response to immunotherapy. However, only a fraction of familial and bilateral/multifocal forms of UM can be explained by these germline alterations, suggesting the existence of other predisposing factors.

Methods: We analyzed a panel of 122 candidate cancer predisposing genes by target sequencing on germline DNA from a prospective unbiased cohort of 381 patients diagnosed with UM at Institut Curie between July 2021 and February 2023.

Results: We identified 29 pathogenic variants (PVs) in genes that are relevant for patient monitoring and genetic counselling (6 in *MBD4,* 3 in *BAP1,* 3 in *BRCA2,* 1 in *ATM,* 3 in *FAN1,* 2 in *FANCL,* 3 in *FANCM,* 1 in *MLH1,* 1 in *MSH2,* 2 in *MSH6* and 4 in *PMS2*). Two patients had PVs in *MSH6*, 4 in *PMS2*, 1 in *MLH1* and 1 in *MSH2*. The frequencies of the 3 MisMatch Repair (MMR) genes *MLH1*, *MSH2* and *MSH6* were significantly higher than in the gnomAD (v2.1.1) non-Finnish European database as a matched control sub-cohort (p=0.00073, OR: 10.4 [2.8-27.5]). *PMS2* was excluded from this statistical analysis because its pseudogene prevents the interpretation of public data. One UM tumor sample was further characterized from the patient carrying the germline *MLH1* PV. This UM displayed biallelic inactivation of *MLH1,* loss of MLH1 and PMS2 expression by immuno-histochemistry, a prominent Substitution Mutational Signature 6 (SBS6) associated with MMR deficiency from whole Genome Sequencing (WGS) and an MSI-H phenotype.

Conclusions: This study confirms MMR genes as predisposing factors in UM, as suggested by two previous case reports identifying *MLH1* germline PVs and biallelic inactivation in UM cases (Lobo et al. Virchows Arch 2017;470:347; Abdel-Rahman et al. Ophthalmology 2020;127:668). Further analyses will be needed to define the risk of developing UM for patients with a Lynch syndrome.

#4907 Availability and characteristics of energy balance programs offered by NCI-designated cancer centers.

Jean Miki Reading[1], Alexandra Rich[2], Aarifah Bandealy[3], Payton Solk[4], Julia Starikovsky[4], Allegra Frank[5], Kristina Hasanaj[4], Shirlene Wang[4], Siobhan M. Phillips[4]

[1]Family and Community Medicine, University of Illinois Chicago College of Medicine, Chicago, IL,[2]Quinnipiac University, Hamden, CT,[3]Kansas City University, Kansas City, MO,[4]Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL,[5]Northwestern University, Chicago, IL

To broaden our understanding of energy balance programs (diet, physical activity, weight control available for cancer survivors in NCI-designated cancer centers across the United States, we reviewed the characteristics (program components, personalization, delivery mode) of programs using publicly available information on cancer center websites. All NCI-designated cancer centers (n=72 as of 4/24/2024) were included, and two coders reviewed their websites. Each cancer center's website was searched and reviewed from June 2023 to April 2024. We applied the RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) framework, an implementation framework used for planning and evaluation of programs, to evaluate each cancer center's energy balance programming. Information was extracted by each reviewer independently and then checked by a third study staff member for discrepancies. A total of 55 (76%) cancer centers had information on at least one energy balance program or resource posted on their website. These programs included diet/nutrition (n=41), physical activity (n=23), and weight control programs (n=3). Personalized programming was offered in 68% of diet/nutrition programs, 30% of physical activity programs, and 33% of weight control programs. Across all energy balancing behaviors, most programs offered individual sessions (76% diet/nutrition; 57% physical activity; 67% weight control). Group-based support was offered in less than half of programs across all behaviors (29% diet/nutrition; 40% physical activity; 33% weight control). In-person delivery was offered in 56% of diet/nutrition programs, 74% of physical activity programs, and 33% of weight control programs. Most of the programming for cancer survivors addressed diet/nutrition. Weight control programs were limited. Most physical activity programs were delivered in-person, which could limit reach and increase barriers to participation since the median of NCI-designated catchment areas is 26,500 square miles. There is a need for more consistency and availability of personalized support, particularly concerning exercise and weight control. Comprehensively addressing all energy balance components as part of cancer survivorship care is needed.

#4908 Exploring the role of algorithms in accessing culturally tailored nutrition information to improve survivorship in women with reproductive cancers.

Zakirah L. Abdul-Hameed, Gabrielle Ford, Amirah Burton-Obanla, Desiree Rivers

Morehouse School of Medicine, Atlanta, GA

Background/Significance: African American/Black (AA/B) women experience a 46 percent higher mortality rate from reproductive cancers compared to White women. While dietary interventions have shown effectiveness in improving survivorship, barriers such as limited access to culturally and linguistically relevant nutrition information hinder healthy dietary behaviors. Digital platforms are key sources of cancer nutrition information for AA/B women, yet algorithmic biases often limit the visibility of culturally relevant, reliable resources in underserved communities. Optimizing algorithmic frameworks to prioritize culturally tailored content could enhance survivorship outcomes for AA/B women.

Methods: An environmental scan of 25 sources evaluated the accessibility and cultural alignment of online cancer nutrition information for AA/B women. Focus groups with reproductive cancer survivors explored trust in digital health platforms and barriers to accessing culturally adapted nutrition resources. Interviews with SEO specialists, bio-nutritionists, and food industry leaders examined how algorithms impact access to culturally specific cancer nutrition information.

Results: The environmental scan revealed a gap in culturally adapted cancer nutrition content for AA/B women in national guidelines. Focus groups emphasized the reliance on digital platforms for dietary guidance but noted challenges in accessing trustworthy, culturally relevant information. Interviews revealed algorithmic biases that limit visibility of culturally tailored content, particularly in underserved areas. These findings stress the need for culturally competent nutrition education to address disparities and improve cancer survivorship outcomes.

Conclusion: Optimizing search engine algorithms and integrating trustworthy, credible, and culturally relevant nutrition content into digital platforms are essential to addressing access barriers for AA/B cancer survivors. By advancing algorithmic design and promoting reliable, culturally tailored online resources, technology can build trust and improve survivorship outcomes. This research stresses the critical role of digital innovation and health equity-focused strategies in promoting equitable access to cancer nutrition information, supporting the continuum of innovation in cancer care.

Acknowledgement of Funding: The project described was supported by Award Number CHERC-MSI-21-166-01-CHERC-MSI. from the American Cancer Society (ACS). The content is solely the responsibility of the authors and does not necessarily represent the official views of the ACS.

#4909 Artificial intelligence (AI) chatbots and their reponses to most searched Spanish cancer questions.

E. Cheng[1], J. D. Anampa[2], C. Bernabe-Ramirez[2], J. Lin[1], X. Xue[1], A. B. Moadel-Robblee[1], E. Chu[2];
[1]Albert Einstein College of Medicine, Bronx, NY, [2]Montefiore Einstein Comprehensive Cancer Center, Bronx, NY

Background: AI chatbots are predominantly trained on English contents. They perform well in answering English cancer questions, but their performance in other languages (such as Spanish) is unknown. Spanish-speaking patients are also concerned that they must use the paywall versions to get better responses, which may exacerbate existing cancer disparities.
Methods: We evaluated the responses of AI chatbots to most searched Spanish cancer questions. Using Google Trends (1/1/2020-1/1/2024), we identified the top 5 most searched Spanish cancer questions related to the top 3 common cancers in US Hispanics/Latinos. We selected 6 popular AI chatbots (free and paywall versions of ChatGPT, Claude, and Gemini) and then generated 90 Spanish responses. Board-certified oncologists speaking native Spanish assessed the quality using DISCERN Instrument (score from 1 [low quality] to 5 [high quality]), actionability using Patient Education Materials Assessment Tool (score from 0 [no clear action suggestions] to 100% [clear action suggestions]), readability using Fernández Huerta Reading Grade Level (score from 1 [1st grade] to 13 [college]).
Results: The quality of overall AI chatbot responses was moderate (mean [95% CI]: 3.5 [3.4-3.6]). The actionability was low (mean [95% CI]: 35.6% [30.8%-40.3%]), and the readability was high-school level (mean [95% CI]: 9.2 [8.8-9.6] grade). The performance of quality, actionability, and readability did not differ by free and paywall versions ($P > 0.05$).
Conclusions: AI chatbots provided moderately accurate information for most searched Spanish cancer-related questions. The responses were not readily actionable and written at the high-school level, which was not concordant with the American Medical Association's recommendation (6th grade or lower). The performance did not improve by using the paywall versions.
Relevance: To reduce cancer disparities in health literacy, AI chatbots need improvement in responding to Spanish cancer questions.

The Performance of AI Chatbots in Responding to Most Searched Spanish Cancer Questions

Performance	Overall	Free Versions	Paywall Versions	*P*
Quality (points)	3.5 (3.4-3.6)	3.4 (3.2-3.7)	3.6 (3.3-3.8)	0.22
Actionability (%)	35.6 (30.8-40.3)	36.0 (27.3-44.7)	35.1 (26.4-43.8)	0.76
Readability (grade)	9.2 (8.8-9.6)	9.2 (8.6-9.8)	9.2 (8.7-9.8)	0.99

#4911 Cancer disparities based on seven years of sexual orientation and gender identity collection at an NCI-Designated Comprehensive Cancer Center.

Shahrzad A. Zamani[1], Jaileene Perez-Morales[2], Min-Jeong Yang[1], Matthew B. Schabath[1]

[1]Moffitt Cancer Center, Tampa, FL,[2]OHSU Knight Cancer Institute, Portland, OR

Background: Sexual and gender minority (SGM) populations are underserved and minoritized. To aid in identifying real world cancer disparities among SGM patients, in 2016 our institution began collecting sexual orientation and gender identity (SOGI) on all patients. Leveraging these valuable data, this study analyzed differences between SGM and non-SGM cancer patients for clinical characteristics and quality-of-life (QoL).

Methods: Data were acquired on >118,000 patients who completed the standard-of-care Electronic Patient Questionnaire which collects self-reported SOGI. Patients were categorized as SGM or non-SGM based on SOGI. Clinical covariates were obtained from cancer registry for a subset of 51,189 patients. Descriptive statistics and survival analyses were used.

Results: ~3.2% of patients self-identified as SGM. *Cancer diagnoses*: Breast cancer was the most common diagnosis in SGM and non-SGM patients, followed by melanoma, hematologic, prostate, and lung cancers. Notably, SGM patients exhibited higher-than-expected rates of anorectal (6.8% vs. 0.7%, p<0.001) and uterine cancers (5.4% vs. 3.6%, p<0.001) compared to non-SGM patients. *Age:* Among the cancers analyzed, the mean age at diagnosis was significantly (p<0.001) lower for SGM compared to non-SGM: breast (54.8 vs. 60.5), melanoma (57.8 vs. 65.5), hematologic (62.0 vs. 67.1), prostate (65.4 vs. 68.1), lung (63.4 vs. 68.9), anorectal (55.1 vs. 64.4), and uterine (55.1 vs. 63.6). *Stage:* Among anorectal cancers, SGM were more likely to be diagnosed *carcinoma in situ* compared to non-SGM (45.8% vs. 4.8%, p < 0.001). For uterine cancers, SGM were more frequently diagnosed at stage II compared to non-SGM patients (18.2% vs. 4.8%, p = 0.008). No significant differences were observed for breast, lung, and hematologic cancers. *Survival:* Cancer site specific analysis revealed no significant differences. *QOL*: Concerns about barriers to seeking care were significantly higher (p<0.001) among SGM patients with breast (27.0% vs. 15.3%), lung (14.3% vs. 27.2%), and anorectal (35.9% vs. 15.5%) cancers. SGM patients with prostate cancer showed statistically significant lower social support (8.0% vs. 2.9%, p<0.001) and higher rates of living alone (28.4% vs. 10.8%, p<0.001), with similarly higher rates of living alone among SGM patients with anorectal cancer (33.9% vs. 16.3%, p=0.007). Worse mental health was reported by SGM patients with breast, hematologic, melanoma, prostate, uterine cancers (p<0.001), and SGM breast cancer patients had lower physical health scores (47.2% vs. 45.3%, p=0.042).

Conclusions: SGM patients were diagnosed at younger age, diagnosed at higher rates of some cancer types, experienced elevated psychosocial challenges, reported worse mental health, and higher barriers to obtaining care. These findings highlight the value of SOGI data in advancing health equity in oncology.

#4912 Assessing transcriptomic profiles of visceral adipose tissue in colon cancer patients.

Patricia A. Erickson[1], Victoria M. Bandera[1], Bettina Katalin Budai[2], Tengda Lin[1], Caroline Himbert[1], Sheetal Hardikar[1], Jeffrey T. Yap[3], Elaine M. Background: Obesity is a major risk factor for colon cancer (CC) with a number of potential biologic mechanisms. Visceral adipose tissue (VAT) has been identified as a key contributor, partly due to its secretion of adipokines and proinflammatory cytokines. VAT has also been associated with worse cancer-related outcomes. In this study, we evaluated transcriptomic differences in patients with high versus low amounts of VAT among people with CC.

Methods: Tumor-adjacent VAT was collected in 60 patients diagnosed with stage I-III CC who underwent primary surgery as part of the ColoCare Study at Huntsman Cancer Institute (HCI), University of Utah, and University of Heidelberg, Germany. Bulk transcriptomic analysis (RNAseq) was performed on VAT at the HCI genomics core. Computed tomography (CT) scans were used to measure visceral fat area (VFA) via body composition analysis performed using the Data Analysis Facilitation Suite (DAFS). The “DESeq2” R package was used to identify differentially expressed genes stratified by VFA (low VFA: <175 cm2, high VFA ≥ 175 cm2), adjusting for age at diagnosis, sex, study site, and tumor stage. Ranked/sorted genes were entered into gene set enrichment analysis (GSEA) software to identify enriched gene sets and pathways.

Results: Among the 60 patients included the study, 53% were male, the mean age at diagnosis was 63±13 years, 45% had stage III CC, and the mean VFA was 182±105 cm2. Among patients with high VFA, 173 genes were differentially expressed compared to those with low VFA. GSEA identified 17 significantly upregulated and 20 significantly downregulated gene sets (p-adj. < 0.05). Upregulated gene sets among patients with high VFA included pathways were related to extracellular matrix signaling, pyrimidine metabolism, and cytokine-cytokine receptor interactions, while downregulated gene sets included pathways related to branched-chain amino-acid degradation, propanoate metabolism, and pyruvate metabolism.

Discussion: VAT in patients with high levels of visceral adiposity was characterized by the overexpression of pathways that are thought to be associated with CRC development and progression. Our next steps involve further evaluation of these findings in a larger cohort, along with an assessment of VAT gene expression in relation to survival.

#4913 PREDICT Breast v4: Advancing equity in breast cancer prognosis for diverse populations.

Yi-Wen Hsiao[1], Gordon C. Wishart[2], Paul D.P. Pharoah[1], Pei-Chen Peng[1]

[1]Cedars-Sinai Medical Center, West Hollywood, CA,[2]Anglia Ruskin University, Cambridge, United Kingdom

Breast cancer, the most common cancer among women globally, remains a significant public health challenge. Prognosis, influenced by factors such as tumor characteristics, patient demographics, and treatment choices, is a major concern for patients. Tools like the PREDICT Breast v3 model (https://breast.v3.predict.cam/) help weigh treatment benefits against short- and long-term risks, enabling more personalised prognostic predictions. However, its performance disparities among non-Hispanic Black and non-Hispanic Asian patients in the US highlight the need for more equitable and inclusive tools. Therefore, this study aims to develop a breast cancer prognostic model that improves predictive accuracy across diverse populations and reduces disparities in prognostic outcomes. Here, we analysed data from 273,918 breast cancer patients in the Surveillance, Epidemiology, and End Results (SEER) database, each with clinical records and socioeconomic status (SES) information. The data were split 7:3 for model training and validation, with 10-fold cross-validation applied for parameter tuning. We first evaluated both conventional methods (PREDICT v3) and advanced machine learning models, including survival XGBoost, survival random forest, DeepHit, and DeepSurv, using calibration and discrimination as evaluation metrics. After comparing the models, we selected the DeepHit neural network as the best-performing approach due to its lowest calibration error and highest discrimination. We then examined whether incorporating SES improved performance by comparing SES-adjusted and unadjusted DeepHit models. Our results showed that the SES-adjusted DeepHit model achieved strong calibration (within 1.3% of observed deaths) and reduced racial disparities compared to PREDICT v3, which exhibited calibration errors of 30% for non-Hispanic Asians and 20% for non-Hispanic Blacks. These findings emphasise the importance of incorporating SES factors to enhance model accuracy and equity, underscoring the critical need for fairness in prognostic prediction. This work advances the application of machine learning in cancer prognosis and provides a foundation for addressing health disparities in clinical prediction tools.

#4914 Association of *HOXB13* G84E with prostate cancer among 592,158 men.

Taylor B. Crawford[1], Tyler Nelson[2], Roshan Karunamuni[3], Heena Desai[1], Ryan Hausler[1], Craig Teerlink[2], Hannah Carter[4], Meghana S. Pagadala[5], Patrick R. Alba[6], Scott L. DuVall[6], Morgan E. Danowski[7], Charles A. Brunette[7], Dmitry Ratner[7], Isla P. Garraway[8], Brent S. Rose[4], Kathleen A. Cooney[9], Jason L. Vassy[7], Richard L. Hauger[4], Julie A. Lynch[2], Tyler M. Seibert[4], Kara N. Maxwell[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]VA Salt Lake City Health Care System, Salt Lake City, UT,[3]University of California, San Diego, San Diego, CA,[4]University of California San Diego, San Diego, CA,[5]VA San Diego Healthcare System, San Diego, CA,[6]University of Utah, Salt Lake City, UT,[7]VA Boston Healthcare System, Boston, MA,[8]University of California, Los Angeles, Los Angeles, CA,[9]Duke University School of Medicine, Durham, NC

Background: The *HOXB13* c.G251G>A:p.G84E variant was identified as a prostate cancer (PCa) risk allele in individuals of European descent approximately ten years ago. Several studies from high-risk cohorts have demonstrated a 3-5-fold increased risk of developing PCa with this variant. However, whether this variant confers risk of more aggressive PCa remain controversial. We report age-specific PCa risks and clinical pathological associations in a population-based *HOXB13* p.G84E cohort of heterozygous individuals (n=1660) from the VA Million Veterans Program.

Methods: *HOXB13* p.G84E heterozygotes were identified by SNP genotyping in patients from the Million Veterans Program (MVP). Cox proportional hazard models were used to determine the association of the variant with patient outcomes. Multivariable logistic regression models were used to determine the association of the variant with risk of PCa diagnosis on first biopsy in a sub-cohort of Veterans diagnosed with PCa in the VA.

Results: This MVP study included a total of 592,158 males with 1,660 (0.28%) *HOXB13* p.G84E heterozygous individuals. There was a significant increase in overall incidence of PCa in *HOXB13* p.G84E heterozygous individuals (31.3% (n=519) vs 12.1% (n=71,500), p<0.001) compared to homozygous wild-type individuals. Additionally, *HOXB13* p.G84E heterozygotes were more likely to be diagnosed with PCa at a younger age group (p=0.001). In a Cox proportional hazards model, *HOXB13* p.G84E heterozygous individuals had a significantly increased risk of any PCa (HR 3.23, 95% CI 2.97-3.53, p<2.0E-16), metastatic PCa (HR 2.96, 95%CI 2.30-3.81, p<2.0E-16), and PCa related death (HR 2.65, 95% CI 1.67-4.21, p=3.8E-05). At age 60, the fraction of heterozygotes with any PCa (8.5%) and metastatic PCa (0.7%) was higher than that of wild-type individuals (any PCa: 2.8%, metastatic PCa: 0.1%). At age 90, a larger fraction of heterozygotes had any (59.5%) or metastatic PCa (12.4%) compared to wild-type individuals (any PCa: 26.9%, metastatic PCa: 5.0%). The fraction of *HOXB13* p.G84E heterozygotes who died of PCa at age 80 and 90 was 1.2% and 7.5% respectively, compared to 0.6% and 2.2% of wild-type individuals. To validate our results, we analyzed 36,321 males genotyped in MVP who underwent first prostate biopsy in the VA, among whom 202 (0.56%) were *HOXB13* p.G84E heterozygous individuals. *HOXB13* p.G84E heterozygotes were more likely to be diagnosed with PCa on first biopsy (83.2% (n=168) vs 62.7% (n=22,639), p<0.001) and had higher risk of PCa diagnosis on first biopsy (OR 2.60, 95%CI 1.94-3.52, p<0.001) compared to homozygous wild-type individuals.

Conclusions: In the largest cohort of heterozygotes with the *HOXB13* p.G84E variant to date, we report that this variant confers a 3-fold increased risk of developing prostate cancer. Further work is needed to determine if initiation of early PCa screening in *HOXB13* p.G84E heterozygous individuals would improve patient outcomes.

#4915 A multi-protein score to predict hepatocellular carcinoma occurrence.

Eleanor Watts, Steven Moore, Belynda Hicks, Wen-Yi Huang, Erikka Loftfield, Mitchell Machiela, Katherine McGlynn, Jianxin Shi, Rachael Stolzenberg-Solomon, Cody Watling

National Cancer Institute, Rockville, MD

Background: Hepatocellular carcinoma (HCC) is the most common type of liver cancer, frequently developing on a background of chronic liver disease. Our understanding of the totality of HCC etiology remains incomplete. Early detection of HCC remains a critical challenge in clinical practice as prognosis remains poor for individuals diagnosed at advanced stage. Recent advances in proteomic technologies enable systematic analysis of protein-disease associations, which has potential to improve mechanistic understanding of HCC etiology and aid in the discovery of novel biomarkers for early detection.
Aims: We aimed to investigate the associations of serum proteins with subsequent risk of HCC and create a multi-protein score to predict disease occurrence.
Methods: We conducted a nested case-control study within the PLCO cohort, analyzing 118 incident HCC cases individually matched to 118 controls (median time to HCC diagnosis:10 years). Using the Olink HT platform, we measured 5,400 proteins. Multivariable conditional logistic regression models were used to estimate protein-HCC risk associations, and we developed a multi-protein risk score using LASSO regression, which was evaluated using the area under the curve (AUC). All analyses underwent Bonferroni correction for multiple testing. We tested for replication our findings in the UK Biobank, a prospective cohort of 50,000 participants with protein data from the Olink Explore 3072 platform. During a median follow-up of 11 years, 28 participants developed HCC. We estimated protein associations using Cox proportional hazards regression and evaluated the multi-protein score's predictive performance in the overall cohort and among participants with liver disease—a population at elevated risk of HCC—by calculating the C-index.
Results: Among PLCO participants, we identified 127 proteins significantly associated with HCC risk. Of these, 126 proteins were positively associated, with the strongest association observed for TNFRSF11B (OR per 1 SD: 2.85, 95% CI 1.90-4.28). IGFBP-3 was the only protein inversely associated with risk (0.36, 0.24-0.54). Notably, 118 of the 127 proteins were available in the UK Biobank, and 117 of these associations were successfully replicated. LASSO regression revealed 8 key protein predictors. The resulting protein score exhibited high discriminatory performance in the PLCO cohort (AUC = 0.90) and generalizability in the UK Biobank (C-Index = 0.89 overall, 0.92 among high-risk individuals).
Conclusion: Our findings highlight strong potential of a multi-protein predictive score for HCC, evident years before diagnosis across 2 distinct cohorts.

#4916 Co-occurring clonal hematopoiesis in UK Biobank participants with prior cancer.

Kara Marie Barnao[1], Aubrey K. Hubbard[1], Irenaeus Chan[2], Weiyin Zhou[1], Corey D. Young[1], Rebecca L. Kelly[1], Derek W. Brown[1], Giulio Genovese[3], Duc Tran[2], Yin Cao[2], Stephen J. Chanock[1], Kelly L. Bolton[2], Mitchell J. Machiela[1]

[1]National Cancer Institute, Rockville, MD,[2]Washington Univerisity School of Medicine, St. Louis, MO,[3]Broad Institute of MIT and Harvard, Cambridge, MA

Clonal hematopoiesis (CH) describes the age-related clonal expansion of hematopoietic stem cells, driven by either acquired mutations in driver genes (referred to as clonal hematopoiesis of indeterminate potential (CHIP)), or by large-scale mosaic chromosomal alterations (mCAs). Evidence from previous studies indicate anti-cancer agents, such as chemotherapy and radiation therapy, may promote the expansion of clones with DNA damage response mutations (e.g., *TP53, PPM1D,* and *CHEK2).* However, the co-occurrence of CHIP and mCAs in participants with prior cancer has not been extensively characterized. We therefore examined the frequency of co-occurring CHIP and mCAs to further evaluate the landscape of CH within individuals with prior cancer diagnoses. We analyzed sequencing and genotyping array data from 34,339 UK Biobank participants with a prior cancer diagnosis. Among these, 2,756 CHIP events were detected in 2,470 (7.2%) of participants, at a frequency 1.5 times greater than those participants with no prior cancer diagnosis (N = 453,807). *TP53, PPM1D, MYD88, ATM, JAK2,* and *CALR* CHIP mutations in particular were detected at increased rates in those with prior cancer (ORs ranging from 1.9 for *TP53* mutations to 6.1 for *CALR* mutations, $p < 6.5 \times 10^{-4}$). Autosomal mCAs were also detected at a higher rate compared to those with no prior cancer diagnoses; 2,100 events were detected in 1,665 participants (4.8% vs 3.0% in cancer-free participants). Specifically, mCAs on 10 chromosomes (chr22, chr11, chr12, chr17, chr1, chr19, chr20, chr9, chr7, chr13, respectively) were more frequent (OR = 1.3 - 2.6, $p < 6.4 \times 10\text{-}3$). Co-occurring CH was characterized in three groups: CHIP-CHIP, mCA-mCA, CHIP-mCA. Among CHIP-CHIP events, 4 enriched co-occurrences ($p < 2.7 \times 10^{-5}$) were observed, all of which included *TET2* or *SRSF2* mutations. For mCA-mCA events, enrichment was observed for whole chromosome gains of chr3, chr12, and chr18. Approximately 1% of participants had both detectable CHIP and mCA events. A total of 12 specific CHIP-mCA co-occurrences were enriched; 3 of which were overlapping and also identified in the population with no prior cancer diagnosis (e.g., *TP53* CHIP and chr17p loss) and 4 of which were not observed in cancer-free individuals. *DNMT3A*-mLOY CH was observed less frequently than expected in prior cancer cases. These observations suggest potential instances of both mutual exclusivity and cooperation among CH types in participants with prior cancer diagnoses. The increased detection rate of some co-occurrences in this population, compared to those with no prior cancer, may reflect selective pressures of cancer treatment.

#4917 The association between MGUS and CHIP and their impact on multiple myeloma.

Nicholas J. Boddicker[1], Cristine Allmer[1], Danelle H. Moonen[1], Aaron D. Norman[1], Angelica Macauda[1], Alyssa Clay-Gilmour[2], Janet E. Olson[1], Mrinal S. Patnaik[1], Vincent Rajkumar[1], Esteban Braggio[3], David L. Murray[1], Shaji Kumar[1], Susan L. Slager[1], Celine M. Vachon[1]

[1]Mayo Clinic, Rochester, MN,[2]University of South Carolina, Columbia, SC,[3]Mayo Clinic, Phoenix, AZ

Monoclonal gammopathy of undetermined significance (MGUS) is a precursor to multiple myeloma (MM). Clonal hematopoiesis of indeterminate potential (CHIP) is a precursor to either myeloid or lymphoid malignancy, depending on whether the mutation is in a gene associated with lymphoid (L-CHIP) or myeloid (M-CHIP) outcome. Little is known about the association between CHIP and MGUS and their combined effect on risk of MM. We examined this question within Mayo Clinic Biobank cohort of participants aged 50 years or older with no prior history of hematological malignancies. Using whole blood, individuals were screened for MGUS using a matrix-assisted laser desorption/ionization-time of flight (MALDI-TOF) mass spectrometry assay. M-CHIP and L-CHIP were defined based on mutations in 56 genes associated with myeloid malignancies or mutations in 235 genes associated with lymphoid malignancies, respectively, using whole-exome-sequencing. Incident MM was identified using International Classification of Diseases (ICD) codes and confirmed via medical record review. Logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals for the association of CHIP and MGUS. Cox proportional hazards regression was used to estimate hazard ratios (HR), with time defined as date between blood sample and the first incident MM, date of death, or 12/31/2023. All models were adjusted for age and sex. Of the 16,479 individuals (median age 65 years, 45% male) screened, 12.3% were positive for MGUS, 9.8% were positive for M-CHIP, and 1.5% were positive for L-CHIP. There was no evidence of an association between M-CHIP and MGUS (OR=0.97, 95% CI:0.83-1.12) nor L-CHIP and MGUS (OR=1.12, 95% CI:0.78-1.57), including with any MGUS isotype (IgA, IgG, or IgM; P-values>0.22). Next, we investigated the association of these precursors on risk of MM. Median follow-up was 11.7 years (range 0.1-15.1), and 46 individuals developed incident MM. Both MGUS (HR=29.7, 95% CI: 14.1-62.4) and L-CHIP (HR=4.1, 95% CI: 1.3-13.2) were significantly associated with incident MM, but not M-CHIP (HR-1.0, 95% CI: 0.4-2.5). Investigating the combined effect of MGUS and L-CHIP, we found those with MGUS alone had a 27.5-fold (95% CI: 13.0-58.2) increased risk of incident MM compared to those with no precursors. No individuals with L-CHIP only developed MM, but those with both L-CHIP and MGUS had a 129.4-fold (95% CI: 34.4-486.4) increased risk of incident MM. In the largest cohort with screened MGUS and CHIP, we found no evidence of an association between either definition of CHIP with MGUS. However, individuals with both L-CHIP and MGUS were at the highest risk of developing MM.

#4918 Impact of social drivers of health on clinical trial knowledge among Hispanic/Latino and Black cancer survivors.

Hilmaris Centeno-Girona[1], Marievelisse Soto-Salgado[1], Stephanie Cameron-Maldonado[1], Arnethea L. Sutton[2], Katherine Y. Tossas[2], Robert A. Winn[2], Marcia R. Cruz-Correa[3]

[1]University of Puerto Rico Comprehensive Cancer Center, San Juan, Puerto Rico,[2]Virginia Commonwealth University Massey Comprehensive Cancer Center, Richmond, VA,[3]School of Medicine, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

Introduction: Despite significant advancements in cancer treatment, disparities in clinical trial (CT) participation persist among minority populations, such as Hispanic/Latino (H/L) and Black women (BW). Social drivers of health (SDoH) can influence health outcomes and health care decisions, like CT participation. This study assessed the association between SDoH and CT knowledge among H/L and BW cancer survivors in Puerto Rico and in Virginia, United States.
Methodology: This cross-sectional study included H/L gastrointestinal (GI) cancer survivors from Puerto Rico and BW with breast or gynecological cancers from Virginia, aged 21+ years. Participants completed an interviewer-administered questionnaire to assess their awareness, knowledge, and participation in cancer-related CTs and SDoH. A logistic regression model was used to estimate the odds ratios and 95% confidence intervals (CI) for CT knowledge and associated factors. As reported in the literature, significant variables ($p < 0.05$) and other relevant variables were included in the multivariate logistic regression model.
Results: As of November 11, 2024, 285 H/L and BW cancer survivors completed the questionnaire. Women accounted for 78% of the sample, and the mean age of study participants was 55 years (SD: 11.8). Over half of the participants (52%) had breast or gynecological cancer, whereas 47% reported GI cancer. While most study participants were aware of CTs (64%) and 80% accurately identified the correct definition, only 26% reported ever participating in a cancer-related CT. Logistic regression models showed that participants with lower educational attainment, those unemployed, and those with another type of transportation rather than their own transportation were significantly more likely to have lower CT knowledge than their counterparts ($p<0.05$). However, participants who reported an income between $20,000-$74,999 and those who perceived discrimination in medical settings were more likely to have higher CT knowledge than their counterparts ($p<0.05$). After adjusting for age, sex, educational attainment, employment, and health literacy, participants who reported an income between $20,000-$74,999 (OR: 3.43, 95%CI: 1.39-8.50) and those who perceived at least one type of discrimination in medical settings (OR: 2.44, 95%CI: 1.17-5.09) were more likely to have higher CT knowledge than their counterparts.
Conclusion: While CT awareness was relatively high, low CT participation was observed among H/L and BW cancer survivors. Understanding factors that impact CT participation is important for developing targeted interventions to improve CT participation and reduce health disparities among these underserved populations.

#4919 Evaluation of lung cancer risk and screening strategies for individuals who quit smoking more than 15 years ago.

H. A. Park, K. Alcala, J. McKay, M. Johansson, H. A. Robbins, X. Feng, Lung Cancer Cohort Consortium;
International Agency for Research on Cancer, Lyon, France

The U.S. Preventive Services Task Force (USPSTF) recommends lung cancer screening for individuals who currently or formerly smoked with at least 20 pack-years of smoking and quit less than 15 years ago. However, the number of former smokers now surpasses that of current smokers in the U.S., recently, the American Cancer Society (ACS) recommended removing the quit-year exclusion criterion for lung cancer screening eligibility. Little is known for about lung cancer risk in long-term former smokers, and the optimal criterion to identify high-risk long-term former smokers is uncertain. Our analysis included 424,483 long-term former smokers (>15 quit years) aged 40 to 80 years from the Lung Cancer Cohort Consortium (LC3) with detailed risk factors information and lung cancer incidence data from 24 prospective cohorts. We evaluated the validity of the PLCOm2012 risk model by estimating model calibration (E/O: ratio-of-expected to observed number of cases) and discrimination (AUC) in long-term former smokers. We considered individuals with six-year-risk above 1.0% as high risk, using the PLCOm2012 model. The 1.0% risk threshold was defined to identify a similar number of LDCT screening eligible individuals as the USPSTF2021 criteria. We further compared the effectiveness of the ACS criteria (i.e. USPSTF2021 without 15-year quit year exclusion) and the PLCOm2012 model in identifying future lung cancer cases and deaths in long-term former smokers. Among long-term former smokers, the PLCOm2012 model showed good risk discrimination with AUC of 0.78 (95% CI: 0.77-0.79) but underpredicted the overall lung cancer risk (E/O: 0.72; 95% CI: 0.70-0.74). The PLCOm2012 model indicated that 20.0% of long-term former smokers (N=85,041) had six-year-risk above 1.0%, which identified 62.0% (N=2,035) of lung cancers and 64.0% (N=1,169) of lung cancer deaths within 5 years in this population. The ACS criteria identified 31% of long-term former smokers as screening eligible (N=131,225), which identified 69.0% (N=2264) of lung cancers and 70.9% (N=1,294) of lung cancer deaths occurring within 5 years. When using the PLCOm2012 model to define eligibility, applying a threshold that selected a population of equal size to ACS criteria (6y risk ≥0.63%), 75.2% (N=2,469) of lung cancers and 76.4% (N=1,395) of lung cancer deaths would be identified in this group. Our findings suggest that at least 20% of long-term former smokers are at high risk and may benefit from LDCT screening. Removing the 15-year quit-year exclusion would identify over two-thirds of lung cancer cases, by screening one-third of long-term former smokers. A risk-based approach to prioritize a subset of long-term former smokers for screening may be more efficient than age and pack-year criteria. These results provide insight into the benefits of expanding current screening criteria to include long-term former smokers.

POPULATION SCIENCES: Environmental, Social, and Biological Determinants of Cancer Risk and Survival
Poster Session

#4923 The impact of HPV on oropharyngeal cancer tumor microenvironment and survival.

Esther Lam[1], Jia Y. Wan[1], Rachel Bolanos[2], Brenda Y. Hernandez[3], Charles F. Lynch[4], Robert A. Edwards[1], Anil K. Chaturvedi[5], Adrian J. Correa[2], Arjan Diepstra[6], Wendy Cozen[1]

[1]UCI Health, Orange, CA,[2]University of Southern California, Los Angeles, CA,[3]University of Hawai'i Cancer Center, Honolulu, HI,[4]University of Iowa, Iowa City, IA,[5]National Cancer Institute, National Institutes of Health, Bethesda, MD,[6]University Medical Center Groningen, Groningen, Netherlands

The increased incidence of oropharyngeal squamous cell carcinoma (OPSCC) is attributed to increased human papillomavirus (HPV) infections. HPV-positive (HPV+) OPSCC has a better prognosis than HPV-negative (HPV-) OPSCC, highlighting the need to understand the determinants of this difference. The tumor microenvironment (TME) is associated with OPSCC prognosis, but differences due to HPV infection in OPSCC and the impact on survival are not well understood. To address this, de-identified formalin-fixed paraffin-embedded (FFPE) tumor blocks from 191 multiethnic OPSCC patients diagnosed from 1984-2004 were collected from three population-based cancer registries in the Surveillance, Epidemiology, and End Results Residual Tissue Repositories (Los Angeles, Hawai'i, and Iowa). HPV16 status was extracted from an earlier study (Chaturvedi et al, 2011) using in-situ hybridization (ISH) and line probe assays (LiPA), and HPV- tumors were further confirmed using p16 INK4a immunohistochemistry (IHC). Specimens that were ISH/LiPA negative and p16 positive were excluded (n=24). Sections were stained for CD3, CD8, CD163, B2M (HLA-I), and HLA-DP/DQ (HLA-II), using IHC. Counts of positive cells (CD3+, CD8+, and CD163+) were quantified using Visiopharm digital image analysis, while HLA stains were manually scored in tumor cells and used to identify dendritic cells (DC). Analysis of HPV16 tumor status and TME biomarker positive counts were compared using the nonparametric Mann-Whitney U test, and associations between the TME biomarkers and overall survival (OS) were analyzed using multivariable Cox regression to estimate the hazard ratio (HR) of TME biomarkers adjusted for age at diagnosis, sex, race/ethnicity, and SEER stage. There were 53 HPV+ and 114 HPV- patients included in the study after exclusions. Patients were primarily non-Hispanic white (56%) and male (80%); median age at diagnosis was 60. There were significantly higher levels of CD3+ ($p<0.0001$) and CD8+ ($p<0.0001$) T-cells in HPV+ compared to HPV- OPSCCs, and HPV+ tumors had reduced HLA-I expression ($p<0.0001$). High CD8+ T-cell levels were associated with better OS in HPV+ OPSCC (HR=0.21, p=0.036) but worse OS in HPV- OPSCC (HR=2.4, p=0.035). In HPV- tumors, HLA-II expression was associated with worse survival (HR=2.4, p=0.034), but HLA-II expression on DC in HPV+ tumors was strongly associated with improved survival (HR=0.07, P=0.025). In a subgroup (n=75; 36 HPV+, 39 HPV-), CD3+ and CD8+ T-cell infiltrations were higher in both tumoral ($p<0.007$; $p<0.0001$, respectively) and stromal areas ($p=0.002$; $p<0.0001$, respectively) of HPV+ compared to HPV- tumors. Higher stromal CD163+ macrophage infiltration was associated with worse OS in HPV+ tumors (HR= 4.3, p=0.030). These findings provide evidence that HPV+ OPSCC tumors have distinct TME profiles and associations with OS compared to HPV- OPSCC tumors and that the immune cell location within the TME is also important.

#4924 Geographic and racial/ethnic differences in stage at diagnosis and survival among adolescents and young adults with thyroid cancer in the United States: An analysis of 2000-2021 SEER data.

Emma Hymel, Krishtee Napit, Josiane Kabayundo, Amelia Nichols, Shinobu Watanabe-Galloway

University of Nebraska Medical Center, Omaha, NE

Objectives: Relatively few studies have focused on thyroid cancer in the adolescent and young adult (AYA) population. The objective of this study was to examine racial and geographic predictors of thyroid cancer outcomes in the AYA population.
Methods: This population-based longitudinal study uses data from the Surveillance, Epidemiology, and End Results (SEER)-22 registries database. All primary cases of malignant thyroid cancer (including papillary, follicular, medullary, and anaplastic thyroid cancers) from 2000 to 2021 diagnosed among individuals aged 15-39 were included. Multinomial logistic regression models were used to compute the association between race/ethnicity and rurality (measured using Rural Urban Continuum codes) with stage at diagnosis (measured using SEER summary stages: localized, regional, or distant). Cox proportional hazards regression models were used to compute the association between race/ethnicity and rurality and both cancer-specific and all-cause mortality. Directed acyclic graphs were used to identify variables to adjust for in the multivariable analyses to control for confounding.
Results: Our study included 74,215 AYAs with thyroid cancer (93.04% papillary, 5.89% follicular, 1.03% medullary, and 0.04% anaplastic). Approximately 8% of the cases were diagnosed in rural counties. Compared to those diagnosed in rural counties, those in urban counties were more likely to be diagnosed with regional vs. localized cancer (aOR=1.17, 95% CI: 1.10-1.25). Compared to Non-Hispanic White AYAs, Hispanic AYAs are more like to be diagnosed with regional (aOR=1.48, 95% CI: 1.41-1.52) and distant (aOR=2.00, 95% CI: 1.74-2.30) cancer vs localized cancer. Among AYAs with thyroid cancer, living in a rural county at diagnosis was associated with an increased risk of all-cause mortality (aHR=1.41, 95% CI: 1.13-1.76). Additionally, compared to non-Hispanic White AYAs, the risk of thyroid cancer-specific mortality was highest among non-Hispanic Black (aHR=3.66, 95% CI: 2.37-5.65) and Hispanic (aHR=1.85, 95% CI: 1.32-2.60) AYAs.
Conclusion: We observed racial and geographic differences in thyroid cancer stage at diagnosis and survival among AYAs in the United States. Future research should explore the underlying causes of these disparities and identify potential opportunities for intervention.

#4925 Social determinant predictors of lung cancer incidence in diverse urban populations.

Vijeth Narra, Alex Krule, Abdul J. Zakkar, Mason Burrage-Burton, Farah Yousef, Vijayakrishna Gadi, Frank Weinberg, Mark Korpics, Yamile Molina, Sage J. Kim, Margaret Geise-Wright, Zhengjia Chen, Elisabeta Marai, Ryan H. Nguyen, Ameen A. Salahudeen

Medicine/Hematology Oncology, University of Illinois College of Med. at Chicago, Chicago, IL

Background: Lung cancer is the leading cause of cancer-related mortality globally. While screening and predictive analytics provide insights into its pathogenesis, the role of social determinants of health (SDOH), particularly in urban U.S. populations, is unexplored at the individual level. This study examines associations between SDOH factors and lung cancer within Chicago.
Methods: An IRB-approved protocol was used to build a retrospective cohort of 11,154 patients (60% African American [AA], 30% White, 10% Other) from the University of Illinois Health System. Inclusion criteria followed the U.S. Preventive Services Task Force guidelines. Twenty-three zip code-level SDOH indices (measured between 2016-2023) and patient data were analyzed using statistical analyses, including hypergeometric testing and principle component analysis. Benjamini-Hochberg correction was used for multiple hypothesis testing.
Results: Non-cancer patients had less green space access than lung cancer patients ($mean_{diff}$=0.93, P=0.048). Lung cancer incidence correlated with increased fine particulate matter (PM2.5) levels ($mean_{diff}$=0.03, P=0.030). Men with lung cancer had lower PM2.5 exposure ($mean_{diff}$=0.06, P=0.007), poverty rates ($mean_{diff}$=1.73, P=0.003), and Medicaid coverage ($mean_{diff}$=1.89, P=0.017) compared to women, suggesting increased sensitivity to these factors. Patients with low/normal BMI and lung cancer experienced higher food insecurity ($mean_{diff}$=0.64, P=0.019) compared to those with high BMI. Among non-cancer patients, low/normal BMI individuals showed lower area deprivation scores ($mean_{diff}$=1.38, P=0.001) but higher lack of vehicle access ($mean_{diff}$=1.34, P=4.202e^{-7}), lifetime inhalation cancer risks ($mean_{diff}$=0.29, P=0.003), and respiratory hazards ($mean_{diff}$=0.01, P=0.003) compared to high BMI individuals. AA patients experienced disproportionately adverse SDOH impacts, regardless of cancer status (P<0.001). AA lung cancer patients had higher PM2.5 exposure than non-cancer AA patients ($mean_{diff}$=0.03, P=0.016). AA women without lung cancer had higher PM2.5 exposure ($mean_{diff}$=0.02, P=0.010), green space access ($mean_{diff}$=1.02, P=0.001), and respiratory hazard risks (meandiff=0.004, P=0.028), but lower high school graduation rates ($mean_{diff}$=0.401, P=0.046) compared to AA men.
Conclusions: Our preliminary findings highlight the need to integrate environmental and social variables, such as PM2.5 and SDOH, into lung cancer risk frameworks.. Additional studies are also merited to investigate a mechanistic link between SDOH factors, $PM_{2.5,}$ and lung cancer disparities.
Limitations: Patient zip codes may not reflect long-term residential histories. Minimal PM2.5 variability at the zip code level warrants higher-resolution mapping. Racial comparisons were limited to AA and White patients, prompting broader demographic inclusion in future studies.

#4926 African American patients with stage III laryngeal squamous cell carcinoma have poorer survival despite similar definitive treatment and follow-up care.

Pranay Adavelly[1], Helen Gandler[1], Jessica Bauman[2], Jeremy Price[3], Curtis Miyamoto[4], Parth Anil Desai[3]

[1]Medicine, Lewis Katz School of Medicine, Philadelphia, PA,[2]Medical Oncology, Fox Chase Cancer Center, Philadelphia, PA,[3]Fox Chase Cancer Center, Philadelphia, PA,[4]Radiation Oncology, Fox Chase Cancer Center, Philadelphia, PA

Background: Laryngeal squamous cell carcinoma (LSCC) represents a significant subset of head and neck squamous cell carcinomas (HNSCC), contributing to substantial morbidity and mortality. While disparities in outcomes and care delivery for HNSCC and LSCC have been documented, there is a lack of contemporary literature exploring these disparities in the modern era of widespread chemoradiation therapy and advancements in radiation therapy (RT), chemotherapy, and supportive care.
Methods: We conducted a retrospective review of our single-institution database, identifying patients diagnosed with LSCC between January 1, 2014, and December 31, 2022. The study focused on assessing disparities in care and outcomes between African American (AA) and European American (EA) patient populations. Patients were staged according to the AJCC 8th edition criteria.
Results: Data from 251 patients with LSCC were analyzed. Focus on subgroup analysis of AA and EA ancestries (n=202) revealed a higher incidence among AA women (35% vs. 22% in EA), similar smoking rates in both groups (>94%), and a higher incidence of government insurance (Medicare/Medicaid) among AA patients(85% vs. 75% in EA). Compared to EA patients, AA patients presented with higher Stage IV disease (43% vs. 32%), predominantly due to higher rates of T4 tumors (18% vs. 9%) and more frequent N2 nodal involvement (29% vs. 21%). Rates of distant metastases at presentation were low in both groups (3.1% in EA and 3.8% in AA). For patients with Stage III/IV disease, the majority (90%) received combined modality chemoradiation therapy, with a median definitive RT dose of 7,000 cGy delivered in both populations (p=0.52). Upfront or salvage laryngectomy rates for Stage IV non-metastatic disease were similar between AA and EA patients (20%(AA) vs. 19% (EA)). Stage-specific overall survival (OS) analysis demonstrated significantly poorer survival for AA patients with Stage III LSCC (median OS = 30 months) compared to EA patients (median OS = 95 months) (p=0.01; hazard ratio [HR] 2.741, 95% confidence interval [CI] 1.229-6.116), despite similar median follow-up times for surviving patients (AA mean = 67 months [95% CI 56-79 months]; EA mean = 65 months [95% CI 54-77 months]; p=0.81). This difference in survival was not observed in Stage I, II, IV, or stage-agnostic analyses.
Conclusion: AA patients with Stage III LSCC exhibit significantly poorer survival compared to EA patients, despite receiving similar definitive treatment and follow-up care. These findings suggest that biological factors may contribute to outcome disparities beyond socioeconomic factors, highlighting the need for further research into underlying mechanisms and the development of tailored interventions.

#4927 Tumor tissue microbiome in the high-grade serous ovarian cancer: a pilot investigation within the African American Cancer Epidemiology Study.

Tengteng Wang[1], Lauren C. Peres[2], Jeffrey R. Marks[3], Courtney E. Johnson[4], Elisa V. Bandera[1], Joellen M. Schildkrau[4]

[1]Rutgers Cancer Institute, New Brunswick, NJ,[2]Moffitt Cancer Center, Tampa, FL,[3]Duke University, Durham, NC,[4]Emory University, Atlanta, GA

Background: High-grade serous ovarian cancer (HGSOC) is the most common histological subtype of ovarian cancer. Notably, Black and African American (AA) women face a ~40% higher mortality risk from this disease compared to White women. Recent studies have suggested that intratumor microbes may play a key role in shaping the tumor microenvironment and influencing the prognosis of ovarian cancer. However, to date, no studies have investigated the tumor microbiome in Black/AA women diagnosed with HGSOC using formalin-fixed paraffin-embedded (FFPE) samples and a whole metagenome sequencing approach.
Methods: We analyzed tumor FFPE samples from 20 HGSOC cases who self-identified as Black/AA and participated in the African American Cancer Epidemiology Study (AACES). Tumor DNA was extracted using a standardized protocol, and microbial profiling was performed using 2bRAD sequencing for microbiome (2bRAD-M), a high-precision, reduced-metagenome sequencing technique that enables species-level resolution. To assess tumor microbial differences by cancer stage and age at diagnosis, we compared tumor tissue microbial diversity, taxonomic composition, and functional pathways. Conventional statistical analyses (two-sample t-test and analysis of variance) were employed to evaluate significant differences across groups.
Results: 2bRAD-M sequencing successfully detected tumor microbial DNA in all 20 participants of this pilot study. A total of 285 microbial species were identified, including 160 genera and 11 phyla, from results that passed quality control assessments. The mean alpha diversity, as measured by the Shannon index, was 2.41, and the Chao1 index was 15. Compared to women with localized (stage 1 and 2, n=8) HGSOC, those with stage 3 HGSOC (n=12) exhibited higher Shannon (mean 2.45 vs. 1.57, p=0.12) and Chao1 indices (mean 21 vs. 13, $p < 0.001$). Stage 3 tumors also showed a higher relative abundance of microbial species from the phyla Pseudomonadota, Bacteroidetes, and Bacillota, compared to localized stage tumors ($p < 0.001$). Pathway analysis identified secondary bile acid biosynthesis as the most significantly enriched pathway in stage 3 tumors, with over 1.5-fold higher abundance of this pathway ($p < 0.0001$) than stage 1 and 2 tumors. Age at diagnosis was also associated with microbiome composition; women diagnosed at a younger age (<50) had higher Shannon and Chao1 indices compared to older women. Additionally, women with younger age at diagnosis vs. ≥50) were more likely to have a lower relative abundance of Bacteroidetes and a higher abundance of the prolactin signaling pathway.
Conclusion: Our pilot findings suggest that HGSOC tumor microbiome features measured among Black/AA women differ by stage and age at diagnosis, and thereby may influence the progression of HGSOC. Further studies with larger sample size are warranted as the next step.

#4929 Differences in cancer risk by environmental disparities in Puerto Rico: findings from 2016-2020 cancer data.

Nancy Raquel Cardona[1], Ana P. Ortiz[1], Carlos R. Torres[2], **Polaris Torres-Rodriguez**[3], Karen Ortiz-Ortiz[2], Noreen Michael[4], Pablo Mendez-Lazaro[5], Marievelisse Soto-Salgado[1]

[1]Cancer Control and Population Sciences, UPR - Comprehensive Cancer Center, San Juan, PR,[2]Puerto Rico Central Cancer Registry, UPR - Comprehensive Cancer Center, San Juan, PR,[3]Cancer Control and Population Sciences, UPR - Medical Sciences Campus, San Juan, PR,[4]University of the Virgin Islands, St Thomas, Virgin Islands, U.S.,[5]Environmental Health, UPR - Medical Sciences Campus, San Juan, PR

Background: Chemical contaminants have been established as risk factors for certain types of cancer including breast and prostate, which are the most commonly diagnosed cancers in Puerto Rico among women and men, respectively. By law, industries report their chemical emissions to air, water, and soil to the Environmental Protection Agency's Toxic Release Inventory Sites (TRI) program. In 2006, Puerto Rico had 148 TRI facilities across 49 of the 78 municipalities, releasing 518 chemicals, including 170 carcinogens such as arsenic, benzene, radon, and trichloroethylene. This ecological study assesses the strength of the association between cancer risk and municipalities with environmental disparities (contaminated vs. non-contaminated sites) in Puerto Rico.
Methods: Cancer incidence data from 2016 to 2020 were obtained from the Puerto Rico Central Cancer Registry. Contaminated sites, defined as municipalities with TRI facilities, were identified using data from the TRI program in 2006 (10 years before the estimation of cancer risk). To estimate cancer risk between contaminated and non-contaminated sites, we calculated the standardized incidence relative risk (RR = standardized rate of contaminated sites / standardized rate of non-contaminated sites) with 95% confidence intervals (95% CI) from 2016 to 2020 by type of cancer and sex. All analyses were conducted using SEER*Stat v8.4.4.
Results: Between 2016 and 2020, 71,814 new cancer cases were diagnosed in Puerto Rico, 37,582 among males and 34,232 among females. The RR for residents of contaminated sites showed a significant excess risk of 7% (95%CI: 1.05-1.09, p<0.0001) for all types of cancer compared to residents of non-contaminated sites; similar findings were observed in both men (9%, CI 1.06-1.12, p<0.0001) and women (6%, CI 1.03 -1.09). When evaluating the risk of female-related cancers, excesses of 6% (95%CI: 1.01-1.11, p=0.01) and 24% (95%CI: 1.04-1.49, p=0.02) were observed for breast and ovarian cancers, respectively, among residents of contaminated sites compared to residents of non-contaminated sites. For male-related cancers, an excess risk of 10% (95%CI: 1.06-1.14, p<0.0001) was observed for prostate cancer among residents of contaminated sites compared to residents of non-contaminated sites.
Conclusions: Our findings suggest a significant excess in cancer incidence among residents in municipalities with TRI facilities overall and for certain cancer types. These results underscore the need for targeted environmental interventions and public health actions to mitigate exposure to carcinogens in Puerto Rico.
Acknowledgments: This study was supported by the Caribbean Climate Change Adaptation, Cancer, and Health Disparities Research Center (CARIB-CARES) funded by the National Cancer Institute (NCI, award # 1P20CA294096-01).

#4930 Age and sex differences in the prevalence of specific comorbidities at diagnosis among pediatric acute lymphoblastic leukemia and lymphoblastic lymphoma patients.

Xin Yang[1], Maua Mosha[2], Dave Bell[1], Jennifer Dean[2], Jennifer Mayer[2], Ernest K. Amankwah[3]

[1]Medical College of Wisconsin, Milwaukee, WI,[2]Johns Hopkins All Children's Hospital, St. Petersburg, FL,[3]Department of Oncology, Johns Hopkins University School of Medicine, Baltimore, MD

Introduction: Comorbidities affect treatment outcomes in adult cancer. However, limited knowledge exists on the prevalence of comorbidity among pediatric patients diagnosed with acute lymphoblastic leukemia (ALL) or lymphoblastic lymphoma (LL). The aim of this study was to determine the prevalence of comorbidities at diagnosis among pediatric ALL/LL patients, and to examine if the prevalence varied by age, biological sex at birth, and race/ethnicity.

Methods: We analyzed data on patients diagnosed with ALL/LL at ≤21 years of age from 1/1/2005 to 6/30/2020 (n=5,455), using data from the TriNetX Research Network that has de-identified patient-level data from electronic health records. All diagnoses were identified based on ICD-9-CM and ICD-10-CM. Comorbidities were categorized as pulmonary disease; cardiac disease; developmental disorder; vascular disease; cerebrovascular disease; immune disorder; metabolic disorder; infectious disease; genitourinary disease; digestive tract disease; muscle and connective tissue disease; and nervous system disease. Only comorbidities documented within three months prior to the initial ALL/LL diagnosis were included in the analysis.

Results: Overall, 34.1% (n=1,904) of patients had at least one comorbidity at diagnosis and 4.01% of the entire cohort (n=219) had ≥4 comorbidities. Females (36.6%) had a higher prevalence of overall comorbidity than males (33.6%) (p=0.024) and Non-Hispanic White patients (37.5%) had a higher prevalence of overall comorbidity than other racial/ethnic groups (33.1%) (p< 0.001). The most common comorbidities identified were digestive tract disease (n=667, 12.2%; 95%CI:11.4%-13.1%), muscle and connective tissue disease (n=523, 9.6%; 95%CI:8.8%-10.4%), metabolic disorders (n=513, 9.4%; 95%CI:8.6%-10.2%), nervous system diseases (n=466, 8.5%; 95%CI:7.8%-9.3%), and infectious diseases (n=446, 8.2%; 95%CI:7.4%-8.9%). Analyses of specific comorbidities revealed notable patterns based on sex at birth and age at ALL/LL diagnosis. Females exhibited a higher prevalence of infectious diseases (9.7% vs. 7.0%, p<0.001), digestive tract diseases (13.7% vs. 11.1%, p=0.005), and musculoskeletal conditions (11.0% vs. 8.6%, p=0.004) compared to males. Additionally, younger patients (≤10 years) had a higher prevalence (13.8%) of digestive diseases compared to those diagnosed after 10 years (10.4%, p<0.001).

Conclusion: The overall prevalence of comorbidity among pediatric patients diagnosed with ALL/LL varies by biological sex at birth. Additionally, disparities exist for specific comorbidities, with females showing a higher prevalence of infectious diseases and younger patients having a higher prevalence of digestive tract diseases. Future studies are warranted to determine if these differences contribute to disparities in treatment outcomes.

#4931 Pan-cancer proteomic profiling of the EPIC cohort identifies novel plasma biomarkers of cancer risk.

James Yarmolinsky[1], Vivian Viallon[2], David C. Muller[3], Antonio Agudo[4], Pietro Ferrari[2], Giovanna Masala[5], Salvatore Panico[6], Carlotta Sacerdote[7], Karl Smith-Byrne[8], Ruth C. Travis[8], Rosario Turmino[9], P.Martijn Kolijn[10], Roel C. H. Vermeulen[11], Monique Verschure[11], Nicholas Wareham[12], Elio Riboli[3], Marc J. Gunter[3]

[1]James Yarmolinsky (Individual), London, United Kingdom,[2]International Agency for Research on Cancer, Lyon, France,[3]Imperial College London, London, United Kingdom,[4]Catalan Institute of Oncology, Barcelona, Spain,[5]Institute for Cancer Research, Prevention and Clinical network, Florence, Italy,[6]University of Naples Federico II, Naples, Italy,[7]University of Turin and CPO Piemonte, Turin, Italy,[8]University of Oxford, Oxford, United Kingdom,[9]Hyblean Association for Epidemiology Research, AIRE ONLUS, Ragusa, Italy,[10]Erasmus MC, Rotterdam, Netherlands,[11]UMC Utrecht, Utrecht, Netherlands,[12]University of Cambridge, Cambridge, United Kingdom

Plasma proteins play critical roles in various cancer-related processes, are frequently dysregulated in cancer, and represent a key source of druggable targets. The integration of high-throughput proteomic assays into large-scale population-based studies may provide important insights into mechanisms of cancer pathogenesis, identify biomarkers for cancer risk and early detection, and prioritize novel therapeutic targets for cancer prevention. Here, we describe initial findings from proteomic profiling of baseline plasma samples from a case-cohort of 6,073 incident cancer cases and 4,115 sub-cohort members within the European Prospective Investigation into Cancer and Nutrition (EPIC) using the SomaScan 7K assay. Participants at baseline were 53.8 (SD 8.7) years of age and 57.3% were women. Prentice weights and robust variance were used to account for the case-cohort design of the study. Models were stratified on sex, center, and age at recruitment and adjusted for education status and cancer type-specific risk factors. Pre-diagnostic plasma concentrations of 7,596 protein aptamers (representing 6,432 proteins) were evaluated for association with 24 cancer types. In total, 2,264 protein aptamer-cancer associations were observed at FDR $P < 0.05$, including 53 for overall cancer risk. The majority of aptamers (80%, 1,422/1,770) were associated with one cancer type with 11 associated with 4 or more types, including aptamers binding to GDF15, MMP12, and TNFRSF1B. Proteins represented among FDR-significant aptamers map to a diverse set of biological processes including the epithelial-mesenchymal transition, coagulation, and inflammatory signaling pathways. Around half of all aptamer-cancer associations (52%, 1,173/2,264) remained FDR-significant after excluding the first 5 years of follow-up, supporting the potential role of proteins in etiological processes, as opposed to being markers of latent/undiagnosed cancer at baseline. The number of FDR-significant associations per cancer type varied substantially, ranging from 885 for hepatocellular carcinoma and 403 for chronic lymphocytic leukemia to 3 for both pancreatic and thyroid cancer and 2 for endometrial cancer (median 23 aptamers per cancer type, IQR: 6-65). Our plasma-based proteomic profiling of a large case-cohort analysis established within the EPIC study has identified potentially novel biomarkers across a range of cancers, with evidence of both shared and distinct proteomic profiles across cancer types. Replication of findings in independent cohort studies and further interrogation of mechanistic pathways will help to validate proteins identified in this analysis and clarify their roles as potential markers for the early detection, prediction, and prevention of cancer.

#4932 Modeling uncertainty in personalised breast cancer risk prediction.

Bethan L. White, Lorenzo Ficorella, Xin Yang, Douglas F. Easton, Antonis C. Antoniou

Department of Public Health and Primary Care, University of Cambridge, Cambridge, United Kingdom

Breast cancer risk prediction models use a range of predictors to estimate an individual's chance of developing breast cancer in a given timeframe. These can facilitate risk stratification, to identify individuals who would benefit most from screening or preventive options. The BOADICEA breast cancer risk model, implemented in the CanRisk tool (www.canrisk.org), uses genetic, lifestyle, hormonal, family history and anthropometric data to estimate an individual's risk. When implementing risk prediction models, risk predictor data are often incomplete. Point-estimates calculated when some risk factor data are missing can hide considerable uncertainty.

We developed a methodological approach for quantifying uncertainty and the probability of risk-reclassification in the presence of missing data. We employed Monte-Carlo simulation methods to estimate the distribution of breast cancer risk for individuals with missing data. Multiple imputation by chained equations (MICE) with UK Biobank as a reference dataset was used to sample missing covariates. We developed a framework for estimating uncertainty, that can be applied to any given individual with missing risk factor data. We used exemplar cases to assess the probability that collecting missing data would result in a change in risk categorisation, on the basis of the 10-year predicted risk from age 40, using the UK National Institute for Health and Care Excellence (NICE) guidelines.

For example, a woman known to have a pathogenic variant in *CHEK2*, but with all other information unmeasured, will be categorised as at "moderate risk" by the BOADICEA model. Measuring lifestyle and hormonal risk factors would result in reclassification to either the "population-" or "high-risk" group in around 24% of cases (respectively 23% and 1%). Measuring only a polygenic score (PGS) would reclassify the individual about 43% of the time into either the "population-" or "high risk" group (respectively 34% and 9%); measuring a PGS and lifestyle and hormonal risk factors would reclassify the individual to the "population-" or "high-risk" group in around 51% of cases (respectively 43% and 8%).

The results demonstrate that there may be a considerable likelihood of reclassification into a different risk category after collecting missing data. The methodology presented here can identify situations where it would be most beneficial to collect additional patient information, and enable better informed clinical decision making.

#4933 Leveraging chromosome-scale length variants for ovarian cancer risk prediction.

Sarvenaz Fatapour, James P. Brody

Biomedical Engineering, University of California, Irvine, Irvine, CA

Introduction: Polygenic risk scores are tools used to predict outcomes based on germline genetics. Typically, human germline genetics are described by millions of SNPs. These scores often rely on linear combinations of SNPs to estimate risk, though nonlinear interactions may also contribute. Advanced machine learning techniques are capable of detecting non-linear patterns between groups, but they require a dataset with far more subjects than features, making it infeasible to analyze genetic differences between populations without millions of participants. To address this, we developed a genome representation using a small set of values that summarize chromosome-scale length (CSLV) variations. Using this method and machine learning, we tested whether there are genetic distinctions between women who develop ovarian cancer and those who do not.

Methods: To test our hypotheses, data from the NIH All of Us Research Program was used to determine whether CSLV can predict the occurrence of ovarian cancer among women from diverse racial backgrounds. CSLVs were computed from germline DNA for each participant, and we constructed a dataset comprising women diagnosed with at least one of the following conditions: malignant neoplasm or tumor of the ovary, malignant epithelial tumor of the ovary, cell adenocarcinoma of ovary, ovarian cystadenocarcinoma, or endometrioid carcinoma of the ovary (TRUE). An equal number of matched controls without any of these conditions (FALSE) were randomly selected using an exact matching method based on age, race, and sex at birth. Machine learning models were developed using the H2O AI platform to differentiate TRUE/FALSE groups. Model performance was evaluated by calculating the area under the receiver operating characteristic curve (AUC) on unseen test data, with scrambled labels as controls.

Results: CSLV parameters were calculated for 312,944 patients from the NIH All of Us V7 controlled tier with genetic microarray data. We then identified a study cohort that included 1,120 patients diagnosed with ovarian cancer at least once during the study period. The average age at the time of first diagnosis with ovarian cancer within the cohort is 55 years. Most ovarian cancer patients self-identified themselves as White (736), None Indicated (168), Black or African American (125), Asian (29), and multiracial (14). Using CSLV values, we evaluated the ability of our model to differentiate between patient groups by assessing the AUC. The AUC analysis provided insight into whether CSLV-based models could reliably predict ovarian cancer risk and occurrence, offering a potential tool for stratifying patients based on genetic risk.

Conclusion: A CSLV can serve as an effective genomic representation for predicting ovarian cancer risk and occurrence. By leveraging CSLV and machine learning, this approach has the potential to improve early detection and personalized risk assessment for ovarian cancer patients.

#4934 Achieving the goal of reducing cancer mortality by 50% through early detection: Insights from simulation modeling of multi-cancer screenings.

Jiheum Park[1], Stephanie Shue[1], Francesca Lim[1], Matthew Prest[1], Jenniffer Ferris[1], Jeong Yun Yang[1], Stella Kang[2], Chin Hur[1]

[1]General Medicine, Columbia University Irving Medical Center, New York, NY,[2]Radiology, New York University Langone Health, New York, NY

The Cancer Moonshot aims to reduce cancer mortality by at least 50% (~4 million cancer deaths) over the next 25 years. While cancer incidence has slightly increased from 2014 to 2018, particularly among young adults aged 15-39, cancer mortality has decreased by 33% from 1991 to 2021. This decline is largely attributed to advances in early detection, improved treatments, and reduced smoking rates, especially for lung cancer. However, the approach and feasibility of meeting the Moonshot goal remain uncertain. This study explores the potential for achieving the Cancer Moonshot goal by focusing on early detection as a primary strategy. We developed a simulation model to evaluate multi-cancer early detection/screening scenarios, using data from the NCI's SEER database. Our model focused on the five leading cancers by mortality—lung, colorectal, pancreatic, breast, and prostate—since these cancers account for the majority of cancer-related deaths in the U.S. and represent the most significant opportunity for mortality reduction through early intervention. Using a discrete event simulation model, we simulated a cohort of U.S. individuals aged 0 to 100 years in 1994 and tracked them over a 25-year period. The model was calibrated to reproduce U.S. population cancer incidence and mortality trends from 1994 to 2019, based on SEER data. To examine the impact of early detection, the model incorporated sojourn time—the period during which preclinical cancer is detectable. Sojourn times for each cancer type were randomly sampled from a triangular distribution based on values derived from a comprehensive literature review. We modeled a “perfect” scenario where cancers were detected at the earliest point in the sojourn period, at localized stages, to estimate the maximum benefit of early detection. We then compared the number of cancer deaths averted in this scenario to a natural history model with no screening. Our preliminary findings suggest that screening for all five cancers could achieve the Cancer Moonshot goal of reducing cancer deaths by 50%. Lung cancer screening provided the greatest benefit, reducing cancer deaths by ~20%, followed by breast cancer screening (~5%). Pancreatic cancer screening offered the smallest reduction, at about 2%. While these results underscore the potential of early detection in reducing cancer mortality, the model assumes perfect screening sensitivity and specificity and patient adherence, conditions that do not reflect real-world implementation. To refine these estimates and develop actionable strategies, future research should focus on addressing practical limitations, including variability in screening uptake and accuracy. Improving early detection methods, expanding access to screening, and increasing public awareness are essential to making the Cancer Moonshot goal a realistic and achievable outcome.

#4935 Disentangling the association between age and overall survival in an international cohort of patients with advanced prostate cancer.

Hannah E. Guard[1], Michelle O. Sodipo[1], Colleen B. McGrath[1], Anna Siefkas[1], Lauren E. Howard[2], Konrad H. Stopsack[1], Christopher M. Sauer[3], Robert Dreicer[4], Emilio Esteban[5], Hassan M. Introduction: Most people who die from prostate cancer are older than 75 years. However, prostate cancer diagnosed at younger ages is often more aggressive. While epidemiologic studies have examined the association between age and survival in patients with prostate cancer overall, the clinical drivers of this relationship in patients with advanced disease remain unclear. We leveraged the International Registry of Men with Advanced Prostate Cancer (IRONMAN, *NCT03151629*) to (1) quantify the association between age and overall survival and (2) explore whether this association is explained by treatments.

Methods: We included 3,734 patients enrolled from 15 countries with new diagnoses of metastatic hormone sensitive (mHSPC, N=2,642) or castration resistant prostate cancer (CRPC, N=1,092). Age at enrollment was categorized as <55, 55-59, 60-64 (reference), 65-69, 70-74, 75-79, 80-84, 85+ years. We computed age-specific death rates (95% confidence intervals [CIs]) by disease state (mHSPC, CRPC) at enrollment. To explore whether this relationship was explained by treatment, we fitted disease state-stratified Cox models and sequentially adjusted for (1) *de novo* metastatic status and country, and (2) baseline treatment (androgen deprivation therapy [ADT] alone, ADT + androgen receptor pathway inhibitors [ARPI], ADT + chemotherapy, ADT + ARPI + chemotherapy, other).

Results: Over 5.5 years of follow-up (median: 3.2 years, IQR: 1.7, 4.8), 995 patients died from any cause. Younger patients were more likely to have *de novo* metastatic disease. Among those with mHSPC at enrollment, the age-specific death rates per 1,000 person-years followed a J-shaped pattern: 80 (95% CI: 54, 117) in patients under 55 years, 58 (46, 74) in patients aged 60-64, 102 (78, 133) in patients aged 80-84, and 172 (125, 236) in patients aged 85 and older. The death rates among those with CRPC followed a similar pattern, albeit rates were higher in magnitude: 212 (95% CI: 140, 323) in patients under 55 years, 153 (115, 202) in patients aged 60-64, 200 (155, 258) in patients aged 80-84, and 204 (142, 291) in patients aged 85 and older. After adjusting for disease state, country, and the timing of diagnosis of metastases, death rates were substantially higher for ages 75-79 (HR 1.4; 95% CI 1.1, 1.7), 80-84 years (HR 1.6; 95% CI 1.2, 2.1), and 85 years and older (HR 2.0; 95% CI: 1.5, 2.7) compared to ages 60-64 years. Patients aged under 55 years had 1.4-fold higher death rates (95% CI: 1.0, 1.9) compared to those 60-64 years. After additionally adjusting for baseline treatment, overall survival remained worse for the older patients and the youngest age group with hazard ratios remaining meaningfully unchanged.

Conclusion: Age at enrollment is associated with overall survival in people with advanced prostate cancer enrolled in IRONMAN in a J-shaped pattern. This relationship is not explained by differences in baseline treatment.

#4936 The association between plasma IGFBP7 and cancer incidence, cancer mortality, and all-cause mortality in ARIC.

Vernon A. Burk[1], Michael N. Pollak[2], Corinne E. Joshu[1], Anna Prizment[3], Elizabeth A. Platz[1]

[1]Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD,[2]McGill University, Montreal, QC, Canada,[3]University of Minnesota, Minneapolis, MN

Background: Insulin-like Growth Factor Binding Protein 7 (IGFBP7) may modulate IGF signaling and influence non-IGF molecular mechanisms. We analyzed whether IGFBP7 concentration in plasma is associated with risk of cancer incidence, cancer mortality, and all-cause mortality.

Methods: We conducted a prospective cohort analysis of 10,834 participants (54.8% female, 24.3% Black) with no cancer history for cancer incidence and mortality analyses, and 11,761 participants (55.6% female, 23.6% Black) for the all-cause mortality analysis in the Atherosclerosis Risk in Communities study. The median follow-up time was 22.8, 23.5, and 25.6 years for the respective analyses. Participants were aged 46-70 years old at start of follow-up. Plasma IGFBP7 was measured using SomaScan® 5K assay, an aptamer-based technology for protein profiling. Incident cancer diagnoses were ascertained by state cancer registry linkage supplemented with medical records and death certificates. Mortality was ascertained by death certificates, including via the National Death Index. We estimated the association between IGFBP7 plasma levels (log_2transformed) and outcomes including cancer incidence, cancer mortality, and all-cause mortality using Cox proportional hazards regression models adjusting for age, sex, race, and other potential risk factors for cancer and/or mortality.

Results: The association between IGFBP7 and total cancer incidence (3,347 cases, 200,279 person-years) was null (HR=0.99, 95% CI 0.85-1.16). However, IGFBP7 was positively associated with lung cancer incidence (479 cases, 199,823 person-years; HR=1.40, 95% CI 0.93-2.10), unlike for other common cancer sites. The association between IGFBP7 and total cancer mortality (1,420 deaths, 222,320 person-years) was statistically significant (HR=1.39, 95% CI 1.10-1.76). Of the common cancers, IGFBP7 was positively associated with lung cancer mortality (HR=1.69, 95% CI 1.10-2.60) and breast cancer mortality (HR=2.09, 95% CI 0.88-4.97). The association between IGFBP7 and all-cause mortality (6,981 deaths, 262,734 person-years) was statistically significant and the strongest among the three main analyses (HR=1.72, 95% CI 1.55-1.91). Stratifying by age, the strongest association between IGFBP7 and all-cause mortality was in the youngest age quartile (ages 46.9-52.6 years; HR=2.69, 95% CI 2.01-3.59). IGFBP7 is not strongly correlated with IGF-1 and other family proteins.

Conclusions: High circulating IGFBP7 levels may be a risk factor for cancer and all-cause mortality, especially among those in middle adulthood. High circulating IGFBP7 levels may also be a risk factor for both lung cancer incidence and mortality. Additional research and laboratory testing will be necessary to determine whether IGFBP7's influence on IGF signaling or other mechanisms contribute to tumor progression and mortality, in general.

Support: NHLBI, NCI, NPCR

#4937 Circulating leukocyte composition and risk of colorectal cancer recurrence: Findings from the ColoCare Study.

A. Richards[1], E. Jean-Baptiste[1], T. Barrow[2], S. Hardikar[3], B. Gigic[4], J. Figueiredo[5], C. Li[6], D. Shibata[7], A. T. Toriola[8], D. Byrd[1], C. M. Ulrich[3], P. Stewart[1], E. M. Siegel[1], **J. K. Kresovich**[1];

[1]H. Lee Moffitt Cancer Center, Tampa, FL, [2]University of Essex, Essex, United Kingdom, [3]Huntsman Cancer Institute, Salt Lake City, UT, [4]Heidelberg University Hospital, Heidelberg, Germany, [5]Samuel Oschin Cedars-Sinai Medical Center, Los Angeles, CA, [6]Fred Hutchinson Cancer Center, Seattle, WA, [7]University of Tennessee Health Science Center, Memphis, TN, [8]Washington University School of Medicine, St. Louis, MO

Introduction: Disease recurrence occurs in approximately 20% of colorectal cancer (CRC) patients and is a major driver of CRC-specific mortality in those with non-metastatic CRC. Interactions between the immune system and malignant tumors can select for immune-resistant cell populations, increasing the risk of recurrence. Although immune cell profiles of the tumor microenvironment are associated with CRC recurrence, less is known about how recurrence risk is influenced by the composition of circulating leukocytes. Circulating leukocyte profiles reflect systemic immune activation and may provide unique mechanistic insights and predictive value for recurrence risk that can personalize treatment strategies and improve patient outcomes. However, the relationship between circulating leukocyte profiles and CRC recurrence risk has not been examined in detail.

Methods: The ColoCare Study is an international, multi-center, prospective cohort of newly diagnosed CRC patients. For this study, we selected a nested case-control sample of 137 patients enrolled at Moffitt Cancer Center, matching recurrence cases 1:3 to recurrence-free controls by age, sex, body mass index, stage, and follow-up time. Pre-treatment whole blood DNA methylation profiles were assayed and deconvolved to estimate proportions of twelve circulating leukocyte subsets (naïve and memory B cells, CD8+ T cells, and CD4+ T cells, Tregs, natural killers, monocytes, eosinophils, basophils, and neutrophils). Absolute counts were calculated by multiplying cell proportions by total leukocyte count at the time of blood draw. Logistic regression models, adjusted for matching factors and tumor location, estimated odds ratios (ORs) for associations between each leukocyte subset (count and proportion; per 1-standard deviation [SD] change) and risks of CRC recurrence and all-cause mortality.

Results: Patients had a mean age of 62.7 years at diagnosis (SD= 13), with a majority being male (57%), overweight (78%), and White (90%). During follow-up, 35 (25%) patients experienced disease recurrence, and 47 (34%) died. Higher proportions and counts of circulating memory B cells were positively associated with CRC recurrence risk (proportions, OR: 1.84, 95% CI: 1.20, 2.84, P= 0.006; counts, OR: 2.33, 95% CI: 1.33, 4.06, P= 0.003). Higher proportions and counts of circulating neutrophils were positively associated with all-cause mortality (proportions, OR: 1.52, 95% CI: 0.95, 2.44, P= 0.08; counts, OR: 1.59, 95% CI: 1.06, 2.40, P= 0.03).

Conclusions: The composition of circulating leukocyte in pre-treatment blood samples is associated with CRC recurrence risk and mortality. These findings suggest that specific leukocyte subsets may be novel risk factors for CRC recurrence, providing insights into mechanisms underlying disease progression.

#4938 Socioeconomic position and survival after lung cancer diagnosis: Comparisons in 4 continents.

Justina Ucheojor Onwuka, Karine Alcala, **Hilary A. Robbins**, Mattias Johansson, The Lung Cancer Cohort Consortium

Genomic Epidemiology Branch, International Agency for Research on Cancer, Lyon, France

Background: The incidence of lung cancer is lower among higher socioeconomic position (SEP) groups in most settings. It is important to assess whether this translates to disparities in survival by SEP after lung cancer diagnosis. We sought to describe the relationship between SEP and survival after lung cancer diagnosis across different countries.
Methods: We analyzed data from the Lung Cancer Cohort Consortium (LC3) and included 18 prospective cohorts from 14 countries in North America, Europe, Asia, and Australia. The total sample size included 48,482 lung cancer cases with pre-diagnostic risk factor information, amongst whom 37,559 died during the follow-up (median, IQR= 10.8, 6.5-15.0 years). Information on education was harmonized using the International Standard Classification of Education and then modeled as an ordinal variable in 4 categories. We evaluated the relationship between educational level and survival after lung cancer diagnosis using Cox proportional hazards models. Models were adjusted for age at diagnosis, sex, and (where applicable) cohort, smoking duration, cigarettes per day, and time since cessation.
Results: We observed a clear trend toward better survival in participants with higher educational level in lung cancer cases diagnosed in North America, Europe and Asia, but not in Australia. After accounting for detailed smoking history, the hazard ratios were partly attenuated (North America: hazard radio per 1-unit increase in educational level [HR]=0.94, 95%CI=0.93-0.96; Europe: HR=0.94, 95%CI: 0.92-0.95; Asia: HR=0.81, 95%CI=0.77-0.85), but not in Australia. When additionally adjusting for stage at diagnosis, the inverse relationship between educational level and survival was further attenuated in Asian lung cancer cases, but not in European or North American study participants. We estimated that differences in tobacco exposure mediated approximately 20% of the relationship between education and lung cancer survival, and that disease stage mediated an additional 14% of this relationship in Asian lung cancer cases.
Conclusion: Higher educational attainment is consistently associated with better lung cancer survival in North America, Europe, and Asia. Differences in tobacco exposure may partly, but not entirely mediate this relationship, and differences in stage at diagnosis may be additionally important in mediating the survival differences seen in Asian lung cancer cases. This study highlights the importance of socioeconomic position in the continuum of lung cancer disparities.

#4939 Social determinants disadvantage score and risk of liver cancer in the All of Us Research Program.

Xinyuan (Cindy) Zhang[1], Longgang Zhao[2], David Vlahov[2], Yun Chen[2], Tamar Taddei[3], Xuehong Zhang[2]

[1]Harvard Medical School/Brigham and Women's Hospital, Boston, MA,[2]Yale University School of Nursing, Orange, CT,[3]Yale University School of Medicine, New Haven, CT

Background: Social determinants of health (SDOH) are crucial in shaping health outcomes, yet comprehensive studies that span all key SDOH domains (economic stability, education, healthcare access and quality, neighborhood and built environment, and social and community context) to examine their associations with liver cancer risk are sparse. We developed and validated a Social Determinants Disadvantage Score (SDDS) to address this knowledge gap.
Methods: We conducted a cross-sectional analysis of 117,783 participants from the All of Us Research Program. The SDDS was systematically constructed using validated questionnaires covering five domains recognized by the World Health Organization and U.S. Department of Health and Human Services. Each domain was dichotomized into advantage (0) or disadvantage (1), with the SDDS ranging from 0 to 5. Prevalent liver cancer, especially hepatocellular carcinoma (HCC), was identified by the Electronic Health Record. We used logistic regression models to estimate odds ratios (ORs) and 95% confidence intervals (CIs) for the associations of SDDS with HCC, adjusting for age, sex, race, ethnicity, birthplace, marital status, smoking status, and alcohol intake.
Results: We identified 110 HCC cases in the participants who completed the SDOH questionnaires. Disadvantage in SDOH, as assessed by higher SDDS, was associated with a higher risk of HCC. Per unit increase in SDDS, the adjusted OR (95% CI) was 1.21 (1.02, 1.43) for HCC. The OR was 5.62 (1.95, 16.22) comparing the most disadvantaged to the most advantaged SDDS group. Strongest associations were observed for disadvantage in economic stability (OR = 2.37; 95% CI = 1.22, 4.63) and education (OR = 1.87; 95% CI = 1.08, 3.24).
Conclusion: The SDDS provides a comprehensive, validated tool for assessing SDOH. Our findings highlight significant associations between social disadvantage and HCC prevalence, emphasizing the need for future longitudinal studies to inform targeted interventions.

Social Determinants Disadvantage Score (SDDS) structural components and criteria for scoring.

Domain and variables	**Disadvantage level scored 1, otherwise 0**	**Total score summed up five domains**
Economic stability		Score 1 if 1 in any subdomain
Annual household income	Less than 25k	
Employed	No	
Current Home Own	Rent	
Food insecurity	Yes	
Housing quality problem	Yes	
Education		Score 1 if 1 in any subdomain
Education Year	Under twelve or GED	
Health care access and quality		Score 1 if 1 in any subdomain
Covered by health insurance	No	
Discrimination in health	≥ 80th percentile	
Neighborhood and built environment		Score 1 if 1 in any subdomain
Neighborhood physical disorder	≥ 80th percentile	
Neighborhood social disorder	≥ 80th percentile	
Neighborhood walkability	≤ 20th percentile	
Neighborhood safety	≤ 20th percentile	
Social and community context		Score 1 if 1 in any subdomain
Social cohesion	≤ 20th percentile	
Social support	≤ 20th percentile	
Loneliness	≥ 80th percentile	
Perceived discrimination	≥ 80th percentile	
Perceived stress	≥ 80th percentile	

#4940 Demographic trends in chronic myelogenous leukemia in adults in the United States between 1999 and 2020.

Saad Rashid[1], Zeeshan Muzammil[2], Taqi Khaja[1]

[1]Mercyhealth Graduate Medical Education Consortium, Rockford, IL,[2]Rosalind Franklin University of Medicine and Science, North Chicago, IL

Chronic myeloid leukemia (CML) represents about 15% of new leukemia cases annually in the United States (US), predominantly affecting older adults with a median diagnosis age of 64. Despite advances in treatment leading to a 5-year survival rate exceeding 70%, disparities in CML mortality persist. This study examines demographic differences and trends in CML mortality from 1999 to 2020 in the US.

We accessed mortality data for CML (ICD-10 code C92.1) from the Centers for Disease Control and Prevention (CDC) Wonder Database from 1999 to 2020. Age-adjusted mortality rates (AAMR) were calculated per 100,000 deaths and stratified by sex (male, female), race (White, African American), and adult age groups. Temporal trends were analyzed using Joinpoint regression software to calculate the annual percent change (APC) and average annual percent change (AAPC) to identify shifts over time. Statistical significance was set at $p < 0.05$.

Between 1999 and 2020, CML accounted for 26,329 deaths in the US, with the overall AAMR decreasing by 50%. Gender-specific trends revealed reductions in mortality for males and females. Among females, the AAMR declined from 0.5 in 1999 to 0.2 by 2007 (APC of -10.6% from 1999 to 2008, $p < 0.01$). For males, the AAMR decreased from 0.8 in 1999 to 0.4 by 2007 (AAPC of -8.9%, $p < 0.01$).

Racial comparisons show that African Americans' AAMR decreased from 0.7 in 1999 to 0.35 by 2008 (APC of -8.5%, $p < 0.01$). White Americans saw a larger reduction, with AAMR declining from 0.65 in 1999 to 0.3 by 2007 (APC -10.0%, $p < 0.01$). Age-specific analyses highlighted decreases in mortality across adult age groups. For individuals aged 45-54, AAMR declined from 0.5 in 1999 to 0.35 by 2020 (APC of -21.2% from 1999 to 2004, $p < 0.05$). For the 55-64 age group, AAMR decreased from 1.0 in 1999 to 0.4 by 2020 (APC of -11.9%, $p < 0.05$). The 65-74 age group experienced a decline in AAMR from 2.25 in 1999 to 0.8 by 2008 (APC of -11.0% from 1999 to 2007, $p < 0.05$). In contrast, the 75-84 age group initially saw an increase in AAMR from 2.4 in 1999 to a peak of 3.8 in 2006, followed by a decrease to 2.25 by 2011. This group exhibited an APC of +19.5% from 2003 to 2006 ($p < 0.05$), followed by a decline of -10.4% from 2006 to 2011 ($p < 0.05$). The oldest group aged 85 years+, had an AAMR of 5.25 in 1999, which decreased to 4.7 by 2020 but remained higher than other age groups.

While mortality from CML in the US has decreased, disparities persist among demographic groups. Older individuals, males, and African Americans exhibit higher mortality rates compared to younger individuals, females, and White Americans. These disparities may result from age-related comorbidities, differential treatment responses, and barriers to timely care among males, and limited healthcare access and socioeconomic disadvantages faced by African Americans. Addressing these disparities through targeted interventions and equitable healthcare access is crucial for further reducing CML mortality.

#4941 Psychosocial factors in association with overall survival after prostate cancer diagnosis among predominantly low-income Black and White adults.

Douglas DeMoulin[1], Loren Lipworth[1], Melinda Aldrich[1], Heather Munro[1], Ronald Fisa[2], Kabisa Mwala[2], Martha J. Shrubsole[1], Wei Zheng[1], Xiao-Ou Shu[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]University of Zambia, Lusaka, Zambia

Background: Prostate cancer is the most common cancer and the second leading cause of cancer death among men in the US. Psychosocial factors may influence prostate cancer survival, but this association has not been investigated among a low-income population, particularly in Black men.

Methods: This study used resources of the Southern Community Cohort Study (SCCS), a prospective cohort study of ~85,000 individuals aged 40-79, from predominantly low-income backgrounds, enrolled between 2002-2009 across 12 southeastern states. A total of 1,367 men (309 white and 1,058 black) newly diagnosed with prostate cancer during follow-up of 34,313 SCCS male participants were included. At recruitment, information was obtained on psychosocial variables (including depressive symptoms, religious and spiritual beliefs and practices, and social support) along with sociodemographic, behavioral, and lifestyle factors and medical history. The Kaplan-Meier method was used to generate 5-year survival rates. Statistical significance was assessed using the log-rank test. Multivariable Cox proportional hazard models were used to estimate adjusted hazard ratios (aHR) and 95% confidence intervals (CI) for mortality in association with psychosocial variables with adjustment for potential confounders.

Results: Over 18 years of follow-up among participants with prostate cancer, 291 Black (27.5%) and 59 White patients died (19.1%) (P = 0.03). White men with prostate cancer self-reporting major depressive symptoms had an 11% lower 5-year survival ($P_{survival}$ = 0.01) and were at higher risk of dying (aHR = 2.26, 95% CI = 1.02-5.03) compared to White men reporting no depressive symptoms. There was a 41% higher risk of death per standard deviation increase of depression score (95% CI = 1.05-1.88). The depression-mortality association was attenuated after adjusting for inability to control important things in life (aHR = 1.61, 95% CI = 0.62-4.23) and marital status (aHR = 1.97, 95% CI = 0.87-4.46). Additionally, White men self-reporting inability to control important things in life as "*much, most, or all of the time*" had a 12% lower 5-year survival ($P_{survival}$ = 0.01) and were at increased risk of dying (aHR = 2.30, 95% CI = 1.07-4.95) compared to White men reporting "*rarely or none of the time*". No statistically significant associations were found among Black men with prostate cancer. Testing for multiplicative interaction was significant for race-depression ($P_{interaction}$ < 0.01) and race- inability to control for important things in life ($P_{interaction}$ = 0.01).

Conclusion: The associations between psychosocial factors and mortality among prostate cancer patients are complex and may not affect all individuals equally. Programs aiming to reduce mortality for individuals with prostate cancer need to take into consideration their psychosocial needs and demographic background

#4942 Associations of smoking with the risk of second primary cancer in adults with a history of various cancer types.

H. Sung, C. C. Newton, W. Diver, E. Mitchell, E. Deubler, K. Kelly, J. Westmaas, L. Teras, A. Jemal, A. Patel, C. Bodelon;
American Cancer Society, Atlanta, GA

Importance: Smoking increases the risk of developing second primary cancers (SPCs) among individuals with a history of cancer. However, most evidence comes from survivors of smoking-related first primary cancers (FPC) with limited data available for a range of FPC types.
Objective: Examine the association between smoking and the risk of developing SPC by FPC types.
Design, Setting, and Participants: In the Cancer Prevention Study II Nutrition Cohort, we identified 28,272 participants who were diagnosed with first primary invasive, non-metastatic cancer between January 1, 1992, and June 30, 2015, and survived for 1+ year, and followed them for SPC diagnoses until June 30, 2018.
Exposures: Smoking status and years since quitting, assessed shortly (mean=1.6 years; SD=1.4) before FPC diagnosis.
Main Outcome: Self-reported SPCs (excluding those at the same site as FPC), defined as smoking-related cancers by the IARC Working Group on the Evaluation of Carcinogenic Risks to Humans
Measures: Multi-variable adjusted hazard ratio (HR) using Cox proportional hazards model
Results: Approximately 59% were male and 49% were in their 70s at their FPC diagnosis (mean=72.2; SD=7.08). The most common FPCs were prostate (32.8%), breast (18.5%), colorectal (9.0%), and non-Hodgkin lymphoma (8.3%). Smoking prevalence was highest among those with FPC of the lung (88.2%), esophagus (78.3%), and bladder (75.3%) and lowest among those with uterine corpus (38.5%) and ovarian (38.2%) cancers. During a median follow-up of 7.0 years, 1,926 individuals (7%) developed smoking-related SPCs. In multivariable models, former (HR=1.62, 95%CI=1.46-1.80) and current (HR=3.77; 95%CI=3.22-4.41) smokers were more likely than never-smokers to develop smoking-related SPCs. The HRs for current smokers varied across FPC types: 5.84 (95%CI=2.51-13.6) for uterine corpus, 4.93 (95%CI=2.60-9.33) for colorectum, 4.07 (95%CI=3.12-5.31) for prostate, 3.87 (95%CI=1.41-10.6) for melanoma, 3.27 (95%CI=2.24-4.75) for breast, 3.11 (95%CI=1.65-5.89) for non-Hodgkin lymphoma, and 2.77 (95%CI=1.50-5.15) for bladder. Among former smokers overall, HRs declined with years since quitting from 2.56 (95%CI=2.17-3.02) for <10 years to 1.30 (95%CI=1.14-1.48) for 30+ years before FPC diagnosis. The risk reduction was most marked for uterine cancer survivors after 10+ years (HR=0.80, 95% CI=0.37-1.74) and breast cancer survivors after 20+ years since quitting (HR=0.88, 95% CI=0.63-1.22), although a lower-level risk persisted for several other FPCs.
Conclusions and Relevance: Associations between smoking and the risk of SPC are evident across various FPC types, even when the first cancer is not smoking-related. The finding highlights the importance of smoking cessation efforts in reducing the burden of second primary cancers in the expanding population of cancer survivors.

#4943 A prospective study of the association between statin use and the risk of overall and advanced bladder cancer among men.

Megan R. Shanahan[1], LeeAnn Lucas[1], Colleen B. McGrath[1], Jane B. Vaselkiv[1], Chaoran Ma[2], Mark Preston[3], Edward Giovannucci[4], Eva Schernhammer[5], Lorelei A. Mucci[1]

[1]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA,[2]Department of Nutrition, University of Massachusetts Amherst, Amherst, MA,[3]Brigham and Women's Hospital, Boston, MA,[4]Department of Epidemiology and Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, MA,[5]Department of Epidemiology, Center for Public Health, Medical University of Vienna, Vienna, Austria

Background: High cholesterol has been linked to the risk of several cancers, including bladder cancer. Previous research is not consistent as to whether statin medications, which reduce cholesterol levels and have other anti-tumor effects, impact bladder cancer risk. We explored this question in a large prospective cohort study of men, for whom bladder cancer is the fourth leading cause of cancer incidence in the United States.

Methods: Our analysis included 44,116 cancer-free participants of the Health Professionals Follow-Up Study, who were followed for bladder cancer incidence from 1990 through 2018. Statin use was self-reported and updated every two years on questionnaires. Bladder cancer diagnosis was validated with medical or death records. We used multivariable Cox regression to investigate the association between statin use (ever, current, former, and never) and duration of statin use (never, less than 4 years, 4-8 years, and 8 or more years) and the risk of overall bladder cancer, bladder cancer by stage at diagnosis (localized, advanced), and fatal bladder cancer. Models estimating hazard ratios (HR) and 95% confidence intervals (CI) were adjusted for demographic, medical, and lifestyle confounders.

Results: During a median of 13.5 years of follow-up, 1,248 bladder cancers were documented, including 562 advanced and 143 fatal cancers. By mid-way through follow-up, 34% of men reported statin use. In multivariable models, there was a suggestive increased risk of overall bladder cancer comparing current statin users to former or never users (HR 1.13; 95% CI 1.00-1.27), yet no association was observed for localized, advanced, or fatal cancers. Ever use of statins (including former and current use) was not associated with overall, localized, nor advanced bladder cancer, compared to never use. However, there was a suggestive decreased risk of fatal bladder cancer (HR: 0.77; 95% CI 0.58-1.02) among ever users of statins compared to never use. Long-term statin use of 8 or more years was associated with a lower risk of advanced (HR 0.78; 95% CI 0.60-1.00) and fatal bladder cancer (HR 0.59; 95% CI 0.40-0.88), compared to never use. No association was observed for long-term statin use and overall bladder cancer (HR 0.99; 95% CI 0.85-1.16).

Conclusion: Results of this study, which investigated overall and clinical subtypes of bladder cancer incidence, suggest that long-term statin use may be protective against the development of advanced and fatal bladder cancer among men. Together with data from clinical trials supporting benefits of statins, this warrants further investigation into whether statins can be used as a preventive tool. Further research is also needed on the potential mechanism by which statins act in bladder carcinogenesis, particularly advanced forms of the disease.

#4944 Role of a planetary health diet in survival following breast cancer diagnosis.

Andrea Romanos-Nanclares[1], Michelle D. Holmes[1], Wendy Y. Chen[2], Walter C. Willett[3], Bernard A. Rosner[4], A. Heather Eliassen[1]

[1]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA,[2]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[3]Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, MA,[4]Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA

Introduction: Whilst the current trend recommendation for breast cancer survivors to follow a healthy plant-centric diet seems prudent, evidence supporting this remains limited. Furthermore, diets that address both human health and environmental sustainability remain a research priority, and the EAT-Lancet Commission's 2019 "Planetary Health Diet" has offered a framework for this approach. Our study aimed to investigate whether a Planetary Health Diet Index (PHDI), quantifying adherence to these targets, is associated with overall and breast cancer-specific mortality.

Methods: For 7,639 women with stage I-III breast cancer from the Nurses' Health Study (NHS) and Nurses' Health Study II (NHSII), we calculated the cumulative average PHDI, using repeated measures of post-diagnostic diet assessed by food frequency questionnaires (FFQ). The PHDI index included a variety of high-quality plant-based foods (whole grains, fruits, vegetables, nuts and legumes) and low amounts of animal-based foods, refined grains, added sugars, and unhealthy fats. Deaths were ascertained by report from family members or by searching the National Death Index. Hazard ratios (HRs) and 95% confidence intervals (CI) were estimated using Cox proportional hazards models and adjusted for multiple time-varying and fixed-time covariates (measured prior to or at the time of diagnosis) and clinical factors.

Results: Participants were followed up for a median of 12 years after breast cancer diagnosis. We documented 2,983 deaths, including 788 due to breast cancer. In the multivariable-adjusted model, we observed a statistically significant inverse association for cumulatively averaged post-diagnosis PHDI and all-cause mortality ($HR_{Q5vs.Q1}$ 0.85 [0.73, 0.99], p-trend <0.01), but not breast cancer specific mortality. Findings for overall mortality were similar for PHDI measured at other timings/settings, including the first post-diagnosis dietary assessment ($HR_{Q5vs.Q1}$ 0.88 [0.76, 1.01], p-trend <0.01).

Conclusions: High adherence to a diet consistent with both human and planetary health after a breast cancer diagnosis is associated with lower risk of all-cause, but not breast cancer-specific, mortality. As the number of breast cancer survivors grows and environmental sustainability becomes more urgent, strategies to reduce mortality should focus on the win-win benefits of dietary changes for both population and planetary health.

#4945 Exposure to per and poly fluoroalkyl substances and cancer risk: A systematic review and meta-analysis.

M. Seyyedsalehi, P. Boffetta;
University of Bologna, Bologna, Italy

Per- and polyfluoroalkyl substances (PFAS) are synthetic chemicals that humans can encounter through occupational or environmental exposure. Recent evidence suggests that exposure to PFAS may increase the risk of different types of cancer. In our comprehensive review and meta-analysis, we investigated the association between PFAS exposure and the risks of breast, female genital, bladder, kidney, prostate, testis, liver, esophageal, gastric, colorectal, pancreatic, head and neck, lung, thyroid, and lymphatic cancers. We systematically reviewed literature from IARC Monographs, ATSDR Reports, PubMed, and Scopus (up to January 2024) for cohort, case-control, and ecological studies. Four reviewers independently screened studies, and data extraction included study design, patient characteristics, and effect size measures. The quality of studies was assessed using the modified version of the Newcastle-Ottawa Scale (NOS). We constructed forest plots and random-effects meta-analyses of relative risks (RR) for PFAS-cancer associations with at least 3 independent risk estimates and conducted stratified, dose-response, and publication bias analyses. A total of 41 articles reported results on PFAS exposure and cancer. The pooled RR for the associations between exposure to different types of PFAS and cancer incidence and mortality are reported in Table 1. Our findings suggest that overall PFAS exposure may be associated with kidney, ovary, and lung cancer and high doses of PFAS with testicular cancer. Further prospective studies with an appropriate assessment of co-exposure with other carcinogens and detailed exposure assessment among study participants are needed to establish causality of observed associations.

Table 1: The combined relative risk (RR) of occupational and environmental PFAS exposure and various types of cancer.

Cancer type	**PFAS type**	**RR (95%CI), I2, p value**	**Number of risk estimates**	**Publication bias**
Breast	PFOA	1.08(0.97-1.20), I^2=85.2%, p<0.001	21	0.30
	PFOS	1.00(0.85-1.18), I^2=0.81.5%, p<0.001	12	
	PFNA	0.95(0.81-1.12), I^2=83%, p<0.001	10	
	PFDA	1.29(0.73- 2.25), I^2=91.3%, p<0.001	6	
Cervix	PFAS overall	0.94(0.79-1.12), I^2=0.0%, p=86	3	0.55
	PFOA	1.00(0.90-1.11), I^2=0.0%, p=0.58	4	
Ovary	PFAS overall	**1.07(1.04-1.09), I^2=99.3%, p<0.001**	12	
	PFOA	1.05(0.89-1.24), I^2=22.6%, p=0.27	4	
Kidney	PFAS overall	**1.18(1.05-1.32), I^2=52.6%, p=0.02**	11	0.31
Bladder	PFOA	0.93(0.86- 1.01), I^2=1%, p=0.43	11	0.79
	PFOS	0.94(0.78- 1.13), I^2=45.1%, p=0.14	4	
Prostate	PFOA	0.95(0.91-1.00), I^2=34%, p=0.08	17	0.71
	PFOS	1.04(0.98-1.11), I^2=34.4%, p=0.14	9	
	PFNA	0.96(0.83-1.12), I^2=92.7%, p<0.001	6	
Testis	PFAS overall	1.12(0.94-1.34), I^2=0.0%, p=0.52	8	0.53
Colorectal	PFOA	0.83(0.65-1.06), I^2=81.6%, p<0.001	6	0.37
	PFOS	0.71(0.22-2.27), I^2=81.5%, p<0.001	4	
Liver	PFAS overall	1.03(0.91-1.16), I^2=47.9%, p=0.02	16	0.51
Pancreas	PFOA	1.01(0.89-1.15), I^2=0.0%, p=0.79	9	0.44
Lung	PFAS overall	**1.20 (1.12-1.28), I^2=0.0%, p=0.95**	9	0.57
Head and neck	PFAS overall	1.15 (0.96-1.37), I^2=0.0%, p=0.72	3	0.79
Thyroid	PFAS overall	1.54 (0.86-2.78), I^2=69.0%, p=0.02	4	0.08
Hodgkin lymphoma	PFAS overall	1.23(0.90-1.70), I^2=0.0%, p=0.38	3	0.47
Non-Hodgkin lymphoma	PFAS overall	1.01(0.90-1.13), I^2=31.8%, p=0.19	6	0.64

#4946 Liver disease risk: Cyanotoxins in water and food sources in Guam.

Ella Marie Macatugal

U54 Pacific Islander Partnership for Cancer Health Equity Grant, University of Guam, Mangilao, Guam

Liver cancer is the third most common cancer among males in Guam, where incidence rates are 2.6 times higher than the U.S. average. Rates of liver cancer among Pacific Islanders are even higher in comparison with incidence among Micronesians and CHamorus at 4.6 and 2.8 times greater respectively. Chronic liver disease, including non-alcoholic fatty liver disease (NAFLD), cirrhosis, which serve as risk factors for hepatocellular carcinoma (HCC), account for a significant health burden in Guam's Asian American and Pacific Islander (AAPI) population. This health disparity has consistently plagued the community for decades and its cause remains unknown. Emerging evidence implicates microcystins (MCs), liver-damaging toxins produced by cyanobacteria, as a potential environmental contributor to liver disease and HCC prevalence. MCs are widespread in tropical freshwater and marine ecosystems and can bioaccumulate in human biospecimens (serum, saliva, and urine). In preliminary studies, MCs have been detected in residents of Guam and Hawaii. This study served to more comprehensively quantify sources of MCs in food and water sources on Guam while also examining the correlation between MC levels in human biospecimens and primary sources of drinking water and produce. This study analyzed water and produce samples from residents of Guam who participated in a previous University of Guam Liver Study and consented to follow-up research (CHRS#: IRB-21-110). Participants completed detailed surveys regarding their drinking water sources (tap, filtered, or store-bought), village of residence, and the top three fruits and vegetables they consumed. Each participant provided samples of their tap and drinking water, while produce consumption patterns guided the collection of local and imported produce. MCs in water and produce samples were quantified using the Abraxis Microcystins-ADDA SAES ELISA, a sensitive assay for detecting microcystin congeners. Tap water samples were more frequently MC-positive compared to filtered water. Detectable levels of MCs were found in both locally sourced produce and imported produce, highlighting multiple routes of exposure. A moderate positive correlation was also observed between participants' serum MC levels and the MC content of their water samples. Although MC concentrations in water and produce were generally minute, the potential for bioaccumulation is significant, particularly given the elevated levels detected in serum samples. These findings suggest that chronic exposure to MCs through tap water and produce consumption may contribute to liver disease disparities in Guam's AAPI communities. Further research is warranted to examine how these environmental toxins may contribute to the etiology of liver disease in this community, providing critical insights to inform public health interventions aimed at reducing exposure and mitigating health disparities.

#4947 Objectively measured individual light exposures and risk of colorectal cancer.

Melania Boker[1], Xiaoyu Zong[1], Jushawn Macon[1], Nick Jeschke[1], Charlie Bowe[1], Yin Cao[2]

[1]Division of Public Health Sciences, Department of Surgery, Washington University School of Medicine, St. Louis, MO,[2]Division of Public Health Sciences, Department of Surgery, Alvin J. Siteman Cancer Center, Washington University School of Medicine, St. Louis, MO

Introduction: The global rise in early-onset colorectal cancer underscores the urgent need to explore emerging risk factors like circadian disruption, which have become increasingly common in recent generations. Mechanistic studies showed that individual nighttime light exposure disrupts melatonin secretion and circadian rhythms, contributing to tumorigenesis. However, human studies are scarce and rely on proxies of personal light exposures. We assessed the prospective association between objectively measured individual nightlight and daylight exposures and colorectal cancer risk.

Methods: A total of 80,709 participants without prior history of shift-work and cancer in the UK Biobank who wore Axivity AX3 wrist accelerometers that contained a silicon photodiode light sensor for up to seven days between 2013-2015 were followed up to 2021. Nighttime and daytime light exposures (measured in lux) were quantified using factor analysis of 24-hour light profiles. Relative amplitude (RA) was calculated by the difference in mean activity during the highest 10-hour and lowest 5-hour active periods. Cox models were used to estimate relative risk (RRs) and 95% confidence intervals (CIs).

Results: During 471,456 person-years of follow-up, a total of 569 incident colorectal cancers occurred (378 colon cancer; 191 rectal cancer). Personal nighttime light exposure but not daytime light exposure was associated with increased risk of colorectal cancer (P_{trend} = 0.07), primarily driven by rectal cancer. Compared to the lowest tertile (T1), individuals in the highest tertile (T3) of nighttime light exposure had 53% increased risk of rectal cancer (RR 1.53; 95% CI: 1.05-2.22; Ptrend = 0.003). This association was independent of putative risk factors of colorectal cancer and remained robust after adjusting for daytime light exposure as well as RA, a commonly used measure of 24-hr rest-activity rhythm. In joint analysis, individuals with the highest nighttime light exposure (T3) and high level of circadian disruption (below median RA) had the highest risk of rectal cancer (RR 2.15, 95% CI: 1.20-3.86).

Conclusion: In a large prospective cohort, objectively measured individual nightlight exposure was linked to increased risk of rectal cancer, which has been rapidly increasing in younger adults. These findings underscore the need for integrative epidemiologic and mechanistic studies to validate the associations and dissect the biological pathways driving site-specific tumorigenesis, and to better inform tailored prevention and intervention strategies in younger generations.

#4949 Late-stage breast cancer risk and five-year survival by stage at diagnosis among top 5 Asian ethnic subgroups in California.

Michelle Tran, Kimberly A. Miller, Sue E. Kim, Kali Zhou, Myles Cockburn, Lihua Liu

USC - University of Southern California, Los Angeles, CA

Introduction: Breast cancer (BC) incidence over the past decade has been rapidly increasing among Asian American (AA) women compared to non-Hispanic White (NHW) women. AA women are more likely to be diagnosed with BC at an earlier stage and have better survival compared to Hispanic and Black women. However, the aggregation of AA may conceal significant population heterogeneity and health disparities among ethnic subgroups, as the risk profile in one subgroup differ from another. Thus, we aimed to understand AA ethnic disparities in BC by assessing AA subgroups and their relationship with late-stage diagnosis and all-cause mortality by stage at diagnosis using a cohort of AA BC patients from the California Cancer Registry (CCR).

Methods: We identified BC cases among NHW and among the top 5 AA subgroups (Chinese, Japanese, Filipino, Korean, and Vietnamese) diagnosed in California between 1988 to 2020 using the CCR. We conducted multivariable logistic regression to evaluate the association between the odds of being diagnosed with late-stage BC (regional and distant stages) and AA subgroups. Additionally, 5-year observed survival rates across each AA subgroup were calculated at each stage at diagnosis (in situ or localized, regional, and distant). Lastly, we conducted multivariable Cox proportional hazards regression to assess all-cause mortality by AA subgroups. All models were adjusted for year at diagnosis, age at diagnosis, nativity, socioeconomic status (SES), comorbidity, insurance status, and BC subtype. We used NHW as the reference group.

Results: Our sample contained a total of 557,551 BC cases (NHW N=493,227; Chinese N=19,380; Japanese N=8,893; Filipino N=24,938; Korean N=5,075; Vietnamese N=6,038). We found that Chinese, Japanese, Korean, and Vietnamese women were less likely to be diagnosed with late-stage BC compared to NHW ($p<0.01$ for Chinese, Japanese, and Vietnamese; $p=0.02$ for Korean), while no difference was observed for Filipino women ($p=0.72$). When comparing the 5-year observed survival rates from all causes of death by stage at diagnosis, all 5 AA subgroups had higher 5-year survival compared to NHW across all stages. However, when adjusted for year at diagnosis, age at diagnosis, nativity, SES, comorbidity, insurance status, and BC subtype, Chinese women diagnosed at the distant stage were 25% more likely than NHW women to die from all causes ($p<0.01$).

Conclusions: Most AA subgroups were at lower odds of being diagnosed with late-stage BC compared to NHW, except for Filipino women. Survival outcomes also differed by subgroups and by stage at diagnosis. Differences in AA subgroups could be due to several factors (i.e., social factors, environmental factors). Thus, different cancer strategies in terms of cancer control and care improvement for each group are needed.

#4950 Exploring the impact of neighborhood-level conditions: Geographic disparities in breast cancer mortality in Maryland, 2000-2019.

Katherine L. Ho, Kassandra Alcaraz, Avonne Connor, Michael Desjardins

Johns Hopkins Bloomberg Sch. of Public Health, Baltimore, MD

Purpose: To observe the geographic distribution of breast cancer (BC) mortality in Maryland by differences in neighborhood-level social determinants of health
Background: Cancer surveillance efforts indicate that BC mortality is unevenly distributed geographically in Maryland; however, it is unknown how area-level socioenvironmental disadvantages might be driving these neighborhood-level disparities.
Methods: Utilizing data from the Maryland Cancer Registry (MPCR), we identified women aged 18+ diagnosed with first primary, invasive BC between 2000-2019. We used census tract-level Social Vulnerability Index (SVI) as a proxy measure for neighborhood-level built and social environments. We calculated the 20-year average SVI percentile ranking and categorized each census tract as having low (least disadvantaged), low-medium, medium-high, or high (most disadvantaged) SVI. We computed age-adjusted (<50, 50+) standardized mortality ratios (SMRs) for each SVI level using the 2000 standard female population and BC-specific referent mortality rates for Maryland from 2018-2022 (age <50: 4.4 deaths/100k; age 50+ 60.8 deaths/100k). We used spatial epidemiology methods to estimate age-adjusted SMRs by census tracts among women of all ages (referent mortality rate: 20 deaths/100k). We mapped this data to visualize the geographic distribution of SVI and BC mortality.
Results: Our study population included 79,145 women (n=17,027 [2.5%] aged <50; n=62,118 [78.5%] aged 50+), of which 13,005 (16%) died from their BC diagnosis. We observed the largest differences in SMRs by age at diagnosis. Across all SVI categories, BC mortality among women diagnosed at ages 50+ was higher than expected relative to older women in the general female population (SMR range: 19.1-22.1). Results were similar for women diagnosed at ages <50 (SMR range: 48.2-53.3). Census tracts with low-medium/medium-high SVI had higher SMRs (low-med: 50.2, med-high: 53.3) than low/high SVI areas. After calculating the SMRs by census tract for all ages, we observed that census tracts in the Eastern Shore and western Maryland showed a strong spatial correlation between higher SVI and higher SMRs. Similarly, most of the Capital region and central Maryland experienced low SVI and correspondingly lower SMRs, but there was considerable spatial variation in the distribution of SVI and BC mortality around Baltimore City/County and Greater Washington region.
Conclusion: The uneven geographic distribution of BC mortality in Maryland may be due to the underlying heterogenic spatial distribution social vulnerability. Younger women diagnosed in census tracts with low-medium or medium-high SVI disproportionately experienced the highest SMRs. Our findings suggest a differential mortality impact of neighborhood-level conditions and socioenvironmental factors among younger vs. older women.

PREVENTION / EARLY DETECTION / INTERCEPTION: Health Disparities across the Cancer Continuum
Poster Session

#4954 Age- and race/ethnicity-specific values of prostate-specific antigen levels: Implications for prostate cancer screening.

Pranoti Pradhan[1], Timothy R. Rebbeck[2], William K. Oh[3], Sigrid Carlsson[4], Kevin H. Kensler[5]

[1]Harvard T.H. Chan School of Public Health, Boston, MA,[2]Dana-Farber Cancer Institute, Boston, MA,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]Memorial Sloan Kettering Cancer Center, New York, NY,[5]Weill Cornell Medicine, New York, NY

Background: A significant limitation in prostate cancer screening is the limited diversity and scope of data that have defined prostate-specific antigen (PSA) values. The use of PSA in prostate cancer screening could be enhanced with knowledge of the distribution of PSA in diverse groups of men. These data may inform triggers for clinical actionability, including biopsy.
Objective: This study aims to evaluate the distribution of PSA values among healthy men of different ethnicities and age groups to derive age- and ethnicity-specific low, middle, and upper PSA distribution values.
Methods: We meta-analyzed studies that reported PSA reference values in healthy men by age and self-identified race or ethnicity. The analysis was restricted to full text articles published in English. Participants were healthy men, aged 40-79 years with no history of prostate cancer, prostate disease, or prostate surgery. PSA values were not age-adjusted. We included data for either observed or estimated PSA values. Studies were excluded if they reported PSA in men with prostate cancer diagnosis, prostate disease, history of prostate surgery, suspicious DRE/TRUS values, age-adjusted results, or a small sample size (N<50). The primary outcomes of interest were to estimate PSA values to construct age- and race-stratified PSA values. Estimates were calculated for the upper limits of the following percentiles: 5th, 10th, 25th, 50th, 75th, 90th, and 95th for 16 race/ethnicity groups. Results were stratified by the original exclusion criteria used by the individual studies, including 1) PSA>4.0 ng/ml, Suspicious DRE/TRUS; or 2) history of prostate disease, surgery, or cancer. Forty-two studies met our criteria and were included in this report.
Results: Men of African descent had higher PSA values followed by men of Asian and European descent. Within the 95th percentile, African descent men had PSA estimates of 4.78 ng/ml, 5.47 ng/ml, 8.93 ng/ml. White men had PSA values of 1.90 ng/ml, 2.06 ng/ml, and 3.31 ng/ml respectively for 40-49 years, 50-59 years, and 60-69 years. When stratified, the distribution of PSA was overall higher among those studies which excluded based on PSA levels greater than 4.0 ng/ml compared to studies which excluded based on history or prostate disease, surgery, or cancer; for both race and age. However, Japanese men had higher a higher distribution compared to African descent men for all ages in the 95^{th}percentile among those with no history of prostate disease, surgery, or cancer.
Conclusion: We report an association of PSA levels with race and age. PSA was elevated among men of African descent and increase with age. Our data may inform the use of PSA in screening for prostate cancer in diverse populations

#4955 Somatic mutation frequency in prostate cancer patients of different ancestries and age of onset.

Tara S. K. Jennings[1], Anton N. Nguyen[1], Weiping Chu[2], Dan Mercola[1], Farah Rahmatpanah[1]

[1]Department of Pathology and Laboratory Medicine, University of California, Irvine, Irvine, CA,[2]Department of Microbiology and Molecular Genetics, University of California, Irvine, Irvine, CA

Background: Prostate cancer (PCa) varies significantly in outcomes based on age of onset and genetic ancestry. Early-onset PCa (EoPCa), diagnosed in men under 55, exhibits aggressive behavior, poor differentiation, and resistance to hormonal therapies, resulting in worse outcomes compared to late-onset PCa (LoPCa). African American (AA) men face more aggressive disease and higher incidence rates than White men with European heritage (EA), even after accounting for socioeconomic factors. Investigating somatic mutations in PCa is essential to understanding disease progression, as the biology of EoPCa remains poorly defined. Comparing mutational frequencies in AA and EA men with EoPCa and LoPCa provides key insights into these disparities and informs targeted interventions.
Methods: We analyzed the mutational status of EoPCa and LoPCa in AA and EA patients. We isolated DNA in tumor tissue from FFPE prostatectomy tissues using Qiagen's FFPE DNA Purification Plus Kit. DNA samples from three patients in each cohort (AA LoPCa, AA EoPCa, EA LoPCa, EA EoPCa) were investigated for 81 somatic mutations across 13 genes using real-time PCR. Mutational analysis was performed with Qiagen's qBiomarker Prostate Cancer Gene Panel, an assay designed to detect PCa specific sequence alterations. DNA and qBiomarker Probe Master Mix were prepared following the manufacturer's protocol. Relative fold gene expression was calculated using the 2-ΔΔCt (delta-delta Ct) method, with DNA from normal epithelial prostate tissue serving as the control. Values exceeding a threshold of 4 were considered indicative of mutations.
Results: The analysis of somatic mutation frequencies, with their position and substitution, revealed notable differences across race and the combined factors of race and age of onset. Our analysis revealed higher mutation rates in AA patients for CTNNB1 98 C>T (83.3% AA vs. 66.7% in EA) and KRAS 34 G>A (66.7% AA vs. 33.3% in EA), mutations not previously reported as elevated in AA PCa. When examining race and age of onset together, distinct patterns emerged. Among LoPCa patients, the TP53 827 C>T mutation was found in 100% of AA patients compared to 66.7% of EA patients, while the HRAS 35 G>T mutation was present in 33.3% of AA patients but absent in EA patients. In EoPCa, AA patients exhibited higher frequencies of the CTNNB1 101 G>T mutation (33.3% AA vs. 0% in EA) and KRAS 35 G>C mutation (33.3% AA vs. 0% in EA).
Conclusion: These mutations, previously unexamined in the context of race and age of onset, highlight disparities in the mutational landscape of PCa.

#4956 Exploration of sub-Saharan African immigrants' reactions to prostate cancer diagnosis.

Kaitlin Van Voorhis, Ernie Kaninjing

Georgia College & State University, Milledgeville, GA

Background: About 300,000 men will hear "you have Prostate Cancer" annually in the United States. Black men are 1.7 times more likely to be diagnosed than White men, and sub-Saharan African Immigrants (SSAIs) are 1.5 times more likely than Black men. These 4 words spark various reactions as the journey towards treatment and survivorship begins. Emotions influence the decision-making process, mental health, adherence to treatment, and treatment outcomes. An exploration of the initial reactions to diagnosis displayed by SSAI will better inform future interventions aimed at improving health outcomes.
Methods: In depth interviews were conducted with 22 SSAI Prostate Cancer (CaP) survivors, guided by Grounded Theory. Purposeful sampling was employed to ensure the study population reflected the cultural diversity among SSAIs. Interviews were transcribed, verified, and analyzed in NVivo 13.
Results: Participants expressed a range of reactions, unique to their individual experiences. These reactions were categorized into 3 over-arching categories: positive (showing signs of agreement or acceptance with the diagnosis), negative (showing signs of resistance to the diagnosis), or neutral (showing no strong pull to positive or negative, often revolving around action-based desires). Participants often experienced multiple reactions across this spectrum, but analysis showed potential correlation among various demographic variables such as age and time passed from diagnosis resulting in more neutral recollections of reactions.
Conclusions: The wide range of initial reactions to CaP diagnosis are reflective of the individual and their unique experiences as an SSAI. These common reactions and mindsets immediately following diagnosis are insightful to a patient's current headspace, focus, personal outlook, and overall mental health. All these emotions impact decision making with regards to treatment, treatment adherence, and even treatment regret as the survivorship journey continues. The National Institute of Health's Cancer Control Continuum includes focus areas for etiology, prevention, detection, diagnosis, treatment, and survivorship. However, there remains a lack of focus on the initial reaction to diagnosis. Future studies should focus on further illuminating the relationship between a patient's initial reaction to diagnosis and their treatment decisions, adherence, and overall survivorship.

#4957 Oncogenic role of stress survival gene MCM10 in colorectal cancer progression and Hispanics health disparities.

Md Zahirul Islam Khan, Urbashi Basnet, Sourav Roy

Biological Sciences, The University of Texas at El Paso, El Paso, TX

Background: Colorectal cancer (CRC) remains the second leading cause of cancer mortality in the U.S., with significant racial and ethnic disparities. This study investigates the role of a stress-survival pathway (SSP) gene MCM10 in CRC, particularly focusing on disparities between Hispanics and Non-Hispanic Whites (NHWs) in late-stage carcinogenesis. Despite comprising over 17% of the U.S. population, Hispanics face significant healthcare inequities, particularly in cancer diagnosis, leading to delayed CRC detection and reduced survival rates. Since CRC is highly treatable when identified early, addressing these disparities is therefore very crucial. Establishing MCM10 as a diagnostic biomarker and therapeutic target could significantly improve CRC management and outcomes in underserved populations.
Methods: Our in-silico analysis previously identified MCM10 as a differentially expressed SSP gene associated with CRC progression. To validate this finding, we analyzed MCM10 expression in CRC cell lines and tissue samples using qRT-PCR. The stage-specific expression patterns were further assessed through cDNA microarray analysis, while protein-level expression was confirmed via immunohistochemical assay of tissue microarrays. Functional studies were conducted in vitro after MCM10 knockdown to investigate the role of MCM10 in critical cancer-related processes such as proliferation, invasion, and survival. RNA sequencing and mass spectrometry were subsequently employed to identify the molecular mechanisms underlying MCM10-driven CRC progression.
Results: Our results showed significant upregulation of MCM10 in CRC cell lines and tissues at both transcript and protein levels. Notably, Hispanic CRC samples exhibited differential expression of MCM10 compared to NHWs, with marked upregulation of MCM10 in late-stage Hispanics. These results are in line with their traditional late-stage diagnosis. The functional study demonstrated that MCM10 knockdown in CRC cell lines significantly reduced proliferation, growth, invasion and migration of cells by inducing cell cycle arrest, apoptosis and reactive oxygen species pathways. In addition, our integrative RNA-sequencing and proteomics study reported two novel genes from zinc finger family along with 17 additional proteins which could be associated with MCM10 mediated carcinogenesis.
Conclusion: This study identifies MCM10 as a key oncogenic driver in CRC, highlighting its potential as a diagnostic biomarker and therapeutic target to enhance disease management and reduce ethnic disparities in outcomes among Hispanics and NHWs.

#4958 Mutational disparities in colorectal cancers of White Americans, Alabama African Americans, and Oklahoma American Indians revealed ANGEL2 as an African American CRC proneness candidate gene.

Hiroshi Y. Yamada[1], Madhusmita Rout[2], Chao Xu[3], Gary Sanghera[2], **Surya Singh**[4], Venkateshwar Madka[4], Farrukh Afaq[5], Katherine T. Morris[6], Dharambir K. Sanghera[7], Upender Manne[5], Chinthalapally V. Rao[4]

[1]Medicine, OU Health Stephenson Cancer Center, Oklahoma City, OK,[2]OU Health Sciences Center, Oklahoma City, OK,[3]Public Health, OU Health Sciences Center, Oklahoma City, OK,[4]Medicine, OU Health Sciences Center, Oklahoma City, OK,[5]Department of Pathology, Heersink School of Medicine, University of Alabama at Birmingham, Birmingham, AL,[6]Surgery, OU Health Sciences Center, Oklahoma City, OK,[7]Department of Pediatrics, College of Medicine, OU Health Sciences Center, Oklahoma City, OK

Introduction: The high incidence and mortality rates of colorectal cancer (CRC) in Alabama African Americans (AAs) and Oklahoma American Indians (AIs) are recognized as cancer disparities, yet the underlying causes have been poorly demonstrated. Our previous study of transcriptomic profiles of CRCs of Alabama AAs, Oklahoma AIs, and white people from both states revealed molecular disparities and differentially expressed genes (DEGs) in the racial groups.
Methods/Procedures: By evaluating CRC whole-exome sequencing and mutational profiles, we report sets of mutated genes whose frequencies differed significantly ($p<0.05$) in a race-specific manner. Secondary screening with a CRC database (cBioportal database for bowel cancer) showed 42, 38, and 35 “survival-critical genes (SCGs)” (i.e., genes whose mutations/alterations are associated with significant differences in the patients’ survival rates) among the differentially mutated genes, suggesting that the mutations have a functional impact on cancer. Notable SCGs with race-pronounced variants were different from DEGs and their involved pathways included nucleotide catabolism (GDA, NT5M, XDH) and cell cycle checkpoints (CLIP1, PSMB2, PSMD3, TP53) for AAs, and extracellular matrix organization (COL4A4, LAMA1, LAMA2, NRXN1) for AIs (Benjamini-Hochberg adjusted $p<0.05$). Most of the SCGs with race-pronounced variants (35 SCGs out of 42 in whites, 29 of 38 AAs, and 30 of 35 AI) are under-investigated with less than ten CRC-related publications in PubMed.
New results: We considered multitudes of factors to select gene(s) for further validation, such as (i) statistical significance, (ii) being a SCG, (iii) type of variant/mutation (variants occurring in open reading frame may be prioritized with an assumption of direct effects on the protein function, compared with likely indirect effects of intron variants), (iv) amount and quality of existing work, and (v) available resources, then proceeded to validate the SCGs with race-pronounced variants. Among the candidate genes, ANGEL2 with Alabama African American-pronounced variant is involved in 3'-UTR-mediated mRNA stabilization and negative regulation of mitotic cell cycle. ANGEL2 expression increases in rat colon tumor (IHC) and in human CRCs in TCGA (vs normal; <0.0001), implicating a role in regulating CRC development.
Prospective: Cancer-influencing genes with minority race-pronounced variants have evaded discovery by being diluted in all-inclusive tumor data analysis. The inclusion of these SCGs with race-pronounced variants in the clinical CRC next-generation sequencing panels and the development of targeting drugs will serve as refinements for precision medicine to overcome racial disparities in health outcomes of CRC.

#4959 Hearing Status and Colorectal Cancer Screening: Identifying Access Barriers.

Dt Bruno[1], Erika Bergeron[1], Regina Wang[2], Poorna Kushalnagar[1]

[1]Gallaudet University, Washington, DC,[2]Department of Family Medicine, University of California, San Diego, CA

Background: Early detection through colorectal cancer screening is critical for effective treatment, improved survival rates, and reduced mortality. However, adherence to screening is influenced by various factors, including education and communication barriers. These barriers can be particularly pronounced for the deaf, deafblind, and hard of hearing (DDBHH) population using American Sign Language (ASL), potentially hindering preventive care. Education is widely known to be associated with cancer screening; however, the contributory role of a person's functional ability to understand spoken language (e.g., lipreading, speechreading, combination with gestures) in a quiet room has not been explored.

Methods: Using the NCI Health Information National Trends Survey in ASL as well as USPSTF guideline for colorectal cancer screening, we surveyed 566 DDBHH adult participants between July 2023 and October 2024. Binary logistic regression was used to assess the association between functional hearing ability (understand well vs cannot understand well in a quiet room) and colorectal cancer screening adherence, after adjusting for age and education. A two-sided $p<=.05$ was considered significant.

Results: After adjusting for age and education, results did not indicate a significant association between functional hearing status and cancer screening adherence [β=1.14 (95% CI=0.75,1.73)], suggesting that a person's functional hearing ability does not independently influence screening rates. In this model, education level remained as a significant predictor, with lower educational attainment associated with a decreased likelihood of adhering to colorectal cancer screening guidelines [β =.51(95% CI=0.31,.84)].

Discussion: These findings highlight that functional hearing status alone is not a significant predictor of cancer screening adherence within the DDBHH community, underscoring the need for providers to look beyond a single moment of effective communication. While sign language interpreters ensure effective healthcare communication, they alone cannot address the educational disparities affecting DDBHH populations. Our study shows that DDBHH individuals with fewer years of education are less likely to undergo cancer screening. To achieve equitable health outcomes, providers should consider adding trained community health workers or patient navigators who have lived experience to the interpreter team. These navigators have potential to help overcome educational barriers and improve cancer screening rates among DDBHH patients.

#4960 Knowledge, attitudes, and practice patterns of primary care physicians towards cervical cancer screening in Yerevan, Armenia.

N. Chu[1], R. Shahhosseini[2], M. Hovhannisyan[3], S. Shekherdimian[4];

[1]University of California, Irvine School of Medicine, Irvine, CA, [2]Western University College of Osteopathic Medicine, Pomona, CA, [3]Yerevan State Medical University, Yerevan, Armenia, [4]University of California, Los Angeles, Los Angeles, CA

Background: In Armenia, over 60% of cervical cancer is diagnosed at stages 3 or 4. Cervical cancer screening significantly reduces mortality and has been covered by Armenia's national cervical cancer screening program since 2015. As of 2020, only 41% of women aged 30 to 60 have been screened by Papanicolaou test (Pap smear) in the past three years, which is below the screening rate of similarly resourced countries. This study aimed to understand the knowledge and practices of primary care physicians (PCPs) in Yerevan, Armenia towards cervical cancer screening.

Methods: Following institutional review board exemption from University of California, Los Angeles and Yerevan State Medical University, a survey of PCPs was administered in Yerevan, Armenia. Yerevan is the capital and largest city in Armenia. Population proportional sampling throughout all 12 administrative districts to include all 31 adult policlinics was utilized. Consenting physicians who worked as family physicians and "therapists" (internists) and practiced at least half time were included. Pediatricians, gynecologists, and specialists were excluded. A previously developed survey to assess provider knowledge and attitudes regarding cervical cancer screening was utilized and edited for local relevancy. The survey was translated to Eastern Armenian and back translated to English to assure accuracy.

Results: 140 PCPs completed the survey, of which 98% were female and 89% were internists. 91% of respondents were over the age of 40 and 86% had practiced for over 10 years. 98% of PCPs recognized human papillomavirus as a risk factor for cervical cancer. Over 85% of PCPs correctly identified foul-smelling discharge and heavy bleeding as common symptoms for cervical cancer. Almost all PCPs (99%) believed that cervical cancer screening is effective in early detection of cervical cancer. However, most PCPs (98%) disagreed that cervical cancer screening is harmless. Less than half (49%) of PCPs surveyed were trained in performing a Pap smear and only two (1%) performed the procedure. Of those PCPs who did not perform Pap smears, most (97%) believed that it was the role of the gynecologist. A majority (73%) also believed that there was no benefit for PCPs to perform Pap smears. Most respondents (65%) did not believe that patients would have Pap smears if performed by PCPs.

Conclusions: Knowledge regarding risk factors for cervical cancer and benefits of screening is high among PCPs in Yerevan. However, lack of training and hesitancy to perform Pap smears are key barriers to cervical cancer screening delivery and uptake. Inclusion of Pap smears in primary care medical curriculum and redefining the role of PCPs in providing cervical cancer screening may be useful in improving screening access. Furthermore, developing greater trust within the physician-patient relationship may encourage patients to receive Pap smears from their PCPs.

#4961 Bridging gaps in cervical cancer screening: Prevalence and key predictors among women aged 25-59 years in Eswatini.

A. M. Tafese[1], B. D. Dirbaba[2], M. T. Fentie[2], C. Zeigler-Johnson[3];
[1]Thomas Jefferson University, Philadelphia, PA, [2]Drexel University, Philadelphia, PA, [3]Fox Chase Cancer Center, Philadelphia, PA

Background: Cervical cancer is the most prevalent cancer and the leading cause of cancer-related deaths among women in Eswatini, which reported the world's highest cervical cancer incidence (95.9 per 100,000) and mortality (64.3 per 100,000) rates in 2022. Despite this significant burden, cervical cancer screening coverage was limited to 19% as per WHO's 2019 report. This study assessed progress in cervical cancer screening prevalence and identified predictors of screening uptake among women aged 25-59 in Eswatini.
Method: Data were obtained from the 2021 Eswatini Population-based HIV Impact Assessment Survey, a cross-sectional household survey designed to assess the coverage and impact of HIV services among individuals aged 15 years and older. In this study, women aged 25-59, the national target group for cervical cancer screening, were included. Survey weights were applied to adjust for the study design. Bivariate analyses identified factors associated with screening uptake, with significant variables ($p < 0.05$) entered into multivariate logistic regression models. Screening predictors were identified using stepwise backward elimination, with results reported as adjusted odds ratios (OR) and 95% confidence intervals (CI).
Result: Among 3,193 women aged 25-59, the lifetime cervical cancer screening prevalence was 48.2%. HIV-positive women had significantly higher odds of screening compared to HIV-negative women (59% vs. 39%; OR=2.22, 95%CI:1.90-2.59). Women aged 36-45 were more likely to undergo screening than those aged 25-35 (OR=1.35, 95%CI: 1.12-1.62). Higher economic status (fourth vs. lowest wealth quintile) was associated with increased screening uptake (OR=1.41, 95% CI: 1.06-1.88). Conversely, lower odds of screening were observed among women with no formal education (OR=0.58, 95%CI: 0.41-0.84), no healthcare visits in the past 12 months (OR=0.67, 95% CI: 0.55-0.83), and no use of family planning services (OR=0.81, 95% CI: 0.68-0.96). Women with no sexual partners were also less likely to be screened compared to those with two or more partners (OR=0.08, 95% CI: 0.01-0.62). Although rural women had lower odds of screening than urban women, the difference was not statistically significant (OR=0.86, 95% CI: 0.70-1.05).
Conclusion: While cervical cancer screening in Eswatini has shown significant progress, disparities persist among women with lower socioeconomic status, limited education, and fewer healthcare visits.

#4963 The role of education level in cervical cancer screening adherence among deaf, deafblind, and hard of hearing women.

Ciara Luttrell, Hiruni Hewapathiranage-Mayadunne, Erika Bergeron, Poorna Kushalnagar

Gallaudet University, Washington, DC

Background: Deaf, deafblind, and hard of hearing (DDBHH) women using American Sign Language (ASL) experience disparities in cancer screening and cancer-related health outcomes. Barriers to cancer screenings and cancer care have been well documented, owing to social determinants of health ranging from communication barriers to systemic inequalities within the healthcare system. There is a need to further clarify the roles of education status and English proficiency in DDBHH women's adherence to the U.S. Preventive Services Task Force (USPSTF) screening guidelines for cervical cancer.
Methods: Using the NCI Health Information National Trends Survey in ASL, we surveyed adult participants to assess the USPSTF guidelines' age-appropriate adherence to cervical cancer screening. Associations between pap smear adherence (screened vs not screened), self-reported English proficiency (well vs not well), and education status (HS degree or less, some college, college) were assessed using Pearson Chi-squared tests. A two-sided p<=.05 was considered significant.
Results: Over 475 DDBHH adult participants (21-65 years), recruited in-person and virtually between July 2023 and October 2024, answered screening questions for cancer screening in ASL and English. Within this group, 67% self-reported screening adherence for pap smear. In a published study, similarly aged hearing women reported 73.9% adherence in the English version of the National Health Interview Survey (NHIS). Chi-square results indicated that more years of education was significantly associated with screening adherence $[X^2 (2, 484) = 7.613, p= 0.02]$. Self-reported English proficiency was not associated with cervical screening adherence $[X^2 (1, 477) = 1.104, p= 0.30]$.
Discussion: With a 67% adherence rate, the DDBHH community has lower adherence to the recommended screening guidelines compared to the general hearing population. Within this group, those who self-report as HS graduates and/or have left college demonstrate lower adherence to cervical cancer screening guidelines. These findings show that education is key in preventive health behaviors, highlighting the need for targeted interventions to address educational gaps and achieve the Healthy People 2030 target of 79.2% screening adherence. Such research will also aid the Center for Deaf Health Equity in actively working with this DDBHH group to improve strategies for increasing cervical cancer screening adherence.

#4964 Exploring women's healthcare barriers: impacts on adolescent HPV vaccination in Latino communities.

Anju F. Kane, Lourdes Baezconde-Garbanati

Population and Public Health Sciences, USC - University of Southern California, Los Angeles, CA

Objective: This study examines how barriers to healthcare faced by women influence HPV vaccination uptake among Latino adolescents in Los Angeles.
Background: Human papillomavirus (HPV)-induced cervical cancer (CC) is a significant public health concern. Although routine HPV vaccination has been recommended in the United States for girls since 2006 and boys since 2011, disparities in vaccine initiation and completion persist, particularly among Latino adolescents in Los Angeles.
Methods: Using data from the Es Tiempo campaign (2016-2018), this cross-sectional study analyzed responses from mothers of 353 Latino adolescents aged 9 to 26 years. Crosstabs were used to examine differences in vaccine initiation and completion by child sex and birth order. Logistic regression models were used to assess the association between parental healthcare barriers, such as lack of health insurance and access to a primary care provider (PCP), and HPV vaccination initiation.
Results: Among the sample, 44% initiated the HPV vaccine, and 23% completed the series. Girls and firstborn children had higher vaccination rates compared to boys and later-born siblings. Lack of health insurance was associated with lower odds of vaccine initiation, while access to a PCP showed a modest positive effect on vaccination uptake.
Conclusion: Women's healthcare barriers significantly contribute to HPV vaccination disparities among Latino adolescents in Los Angeles. Addressing issues such as limited health insurance access and implementing targeted interventions—especially for boys—could improve vaccination rates. Future research should explore how intersecting factors, including gender, socioeconomic status, education, and healthcare access, shape vaccination behaviors and outcomes.
Keywords: HPV, cervical cancer, women's health, health equity, minority health disparities

#4965 Cooperativity of HIV and HPV co-infection contributes to cervical carcinogenesis and cervical cancer health disparity.

Vivek Kumar Kashyap[1], Namita Sinha[2], Nadeem Zafar[3], Santosh Kumar[2], Murali M. Yallapu[1], Everardo Cobos[1], Subhash C. Chauhan[1]

[1]University of Texas Rio Grande Valley, McAllen, TX,[2]University of Tennessee Health Science Center, Memphis, TN,[3]University of Washington, Seattle, DC

Clinical study show that cervical cancer is the most frequently detected cancer in women living with human immunodeficiency virus (HIV) which has been defined as an acquired immunodeficiency syndrome (AIDS). Women living with HIV are 6 times more likely to develop cervical cancer compared to the general population, and an estimated 5% of all cervical cancer cases are attributable to HIV. Studies suggests that several genes are involved in different molecular pathways which can influence vulnerability, severity, or advancement of cervical cancer in the presence of HIV and human papillomavirus (HPV) co-infection. Clinical study have also shown levels of cervical COX-2 are increased in HIV-infected and HIV/HPV-coinfected women. However, the precise molecular level interactions between HPV and HIV co-infection is not well defined. Further, smoking is well documented among HIV-positive women, but very little is known about the smoking induced molecular mechanism of HPV-HIV co infections. In this study, we investigated the interplay between smoking and HIV/HPV co-infection infectivity and their cooperativity. To check the influence of HIV-HPV co-infection at molecular level, cervical cancer cells, CaSki, were treated with U1(HIV-1-infected U937 cells) cell culture supernatant (UCS) and U937 (HIV-1 noninfected cells) culture supernatant (U9CS) every day for 4 days. To differentiate the U1 cells into macrophages, U1 cells were treated with 100 nM phorbol 12-myristate 13-acetate (PMA) for 3 days. For the treatment of smoking components, both U937 and U1 cells were treated with benzo[a]pyrene (B[a]P) at 100 nM every 24 hours for 4 days. Similarly, we treated HIV infected (U1) and noninfected (U937) cells were treated with HPV infected (CaSki) cells supernatant to determine if HPV infection can influence HIV replication related molecular pathways. Our study demonstrated that HIV-HPV-co-infection and/or B[a]P enhanced cell proliferation, colony formation, migration, and invasion as demonstrated by MTS, wound healing, boyden chamber assay respectively in CaSki cells. HIV-HPV-co-infection and/or B[a]P enhanced also induced the expression of HPV16 E6/E7, HIF-1α, COX-2 and EMT markers in CaSki cell as determined by qRT-PCR and immunoblotting. Furthermore, our qRT-PCR results demonstrated that cytokine IL-6, IL-8, IP-10, MCP-1, IL-1α, IL-10, MIP-1β TNF-α, IFN-γ and G-CSF were significantly increased in CaSki cell treated with UCS and B[a]P. We have also demonstrated that the supernatant of cervical cancer cells exacerbate HIV-1 replication in differentiated U1 cell line via transferring CYPs and HPV oncoproteins through extracellular vesicles. Taken together, our results demonstrate that a molecular link between smoking, HIV infections in HPV cooperativity in cervical carcinogenesis that might also be responsible for cervical cancer disparity among underserved populations.

#4966 Understanding social capital and health care treatment delays for cervical cancer survivors: a cross-sectional study using All of Us data.

Samantha Garcia[1], Angel Arizpe[1], Albert J. Farias[1], Brittany N. Morey[2], Brenda Y. Hernandez[3], Lawrence A. Palinkas[4], Lourdes Baezconde-Garbanati[1], Jennifer Tsui[1]

[1]USC - University of Southern California, Los Angeles, CA,[2]University of California Irvine, Irvine, CA,[3]University of Hawai'i, Manoa, HI,[4]University of California San Diego, San Diego, CA

Black and Latina women are more likely to report heath care delays when receiving treatment for cervical cancer compared to other racial and ethnic groups. Although studies have found higher social capital to be associated with higher cervical cancer screening, it is unclear if social capital is associated with health care delays among women diagnosed with cervical cancer. The purpose of this study was to examine the role of social capital (resources rooted in social networks) on treatment delays in a national sample of cervical cancer survivors from the All of Us dataset. We assessed the relationship between neighborhood social capital and healthcare delays (i.e., experienced at least one health care delay) among women self-reporting they have ever been diagnosed with cervical cancer. We conducted multivariable logistic regression to assess the association between social capital and health care delays while accounting for potential confounding variables (i.e., socioeconomic status, race, marital status, nativity status). Approximately 20% of participants (N=1,009) encountered health care treatment delays. Higher social capital was associated with lower odds of experiencing a health care treatment delay among women diagnosed with cervical cancer after adjusting for confounders (OR = 0.67, CI: 0.60, 0.79). Compared to their White counterparts, Black (OR = .63, CI: 0.50, 0.80) and Hispanic (OR = 0.74, CI: 0.60, 0.90) women had lower levels of self-reported social capital. Social capital was unrelated to nativity status among sample participants. Findings suggest that the development of social capital may help to reduce health care treatment delays among racially and ethnically diverse communities. Understanding how healthcare delays impact cancer care follow-up is an important step towards addressing cancer equity.

#4967 Identifying prognostic biomarkers and risk factors contributing to racial disparity and high mortality in pancreatic cancer at Sentara-EVMS-VOA.

Shoba Abraham[1], Fatima Chaudhry[1], Zakary Kolkey[2], Richard Hoefer[3], Amy Tang[1]

[1]Department of Biomedical and Translational Sciences, Macon & Joan Brock Virginia Health Sciences at Old Dominion University, Norfolk, VA,[2]Department of Internal Medicine, UPenn Health System, Philadelphia, PA,[3]Sentara Surgery Specialists, Sentara Healthcare, Norfolk, VA

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is the most aggressive and tthe deadliest form of human cancer. Early detection and curative intervention regimens are unmet needs in the clinic. The PDAC incidence and mortality have doubled from 1990-2017. Oncogenic K-RAS mutation is universally activated in PDAC tumors, that drive tumor malignancy, early relapse, chemo-resistance, metastasis, and dismal survival. In this study, we examine whether SIAH, an evolutionarily conserved E3 ligase that is the most downstream signaling gatekeeper of the EGFR/K-RAS pathway, has prognostic value in PDAC.
Methods: A cohort of 1,156 patients with PDAC, diagnosed at Sentara-VOA between 2001-2016 was analyzed to determine the association of SIAH expression with TNM staging, treatment efficacy, and survival prediction. SIAH expression was calculated by the average immunohistochemical (IHC) scores from two clinical pathologists in 148 operable PDAC patients, including 34 neoadjuvant chemotherapy (NACT)-treated residual tumors and 114 untreated primary tumors.
Results: Among 1,156 PDAC patients, 354 of them were operable and 802 of them are inoperable. A comparison of the 5-year survival rates showed that our local cohorts were underperforming to that of the national average from 2001 to 2016. Following the PDAC clinical procedural standardization at Sentara Cancer Network, our local 5-year survival rates have started to improve steadily, and it has approached the national standards after 2010. Analysis of the SIAH expression in 34 NACT-treated residual tumors showed that low SIAH expression (< 5%) correlated with a longer survival than those with higher SIAH expression (>5%).
Discussion: Among 1,156 PDAC patients, 32.8% of the white patients and 27.4% of Black/AA patients received surgical resection. A 5.4% difference of the two-race groups in the operable cohort suggested that Black/AA patients are more likely to present with advanced and unresectable PDAC. The narrowing of the survival gap between the local and national cohorts reflects a better PDAC management plan, treatment standardization, and timely implementation of effective treatment modalities, including the Whipple procedure, and NACT regimens for all the eligible operable PDAC patients, at Sentara Hospitals after 2010. We found that persistent high SIAH expression in residual tumors post-NACT is indicative of chemo-resistant tumor cells at the 1st-line neoadjuvant setting, and SIAH may be prognostic to identify high-risk PDAC patients who are prone to develop early relapse and suffer poor survival clinically.

#4968 Cardiovascular disparities amongst pancreatic ductal adenocarcinoma patients.

Arunima Punjala, Vignesh Vudatha, Vashti Bandy, Maria Gergoudis, Leopoldo Fernandez, Wendy Bottinor, Jose Trevino

Virginia Commonwealth University Health System, Richmond, VA

Introduction: Pancreatic ductal adenocarcinoma (PDAC) is a lethal malignancy associated with skeletal muscle cachexia which results in chemotherapy intolerance, nutritional deficiencies, physical debilitation, and increased mortality. Survival time is significantly lower for those with cardiovascular-associated mortality, and Black patients face a disproportionately higher risk of overall and cardiovascular-associated mortality. Minimal literature exists on the impact of PDAC on cardiovascular function and the implications on disease course. The aim of this study is to utilize cardiac magnetic resonance imaging (CMR) to quantify changes in cardiovascular structure and function that can potentially identify patients with PDAC who are at increased risk for cardiovascular events.

Methods: In this prospective observational study, treatment-naïve PDAC patients underwent non-contrasted CMR prior to initiation of therapy and six months after. Left ventricular mass was calculated using short axis cine images at end diastole. The maximal and minimal descending thoracic aortic areas were measured on 4-chamber cinematic sequences. Resting blood pressure was measured during the exam. Aortic distensibility (AD) was calculated using a validated equation and compared with age-appropriate reference values[1]. Variables were analyzed using a Mann-Whitney U Test with $\alpha = 0.1$.

Results: 22 patients underwent baseline CMR with 32% (7/22) receiving a follow-up scan. In total, 59% (13/22) were female, 41% (9/22) identified as Black, and 46% (10/22) were sarcopenic at baseline. Amongst all participants, 64% (14/22) demonstrated abnormal AD with Black participants demonstrating a significantly higher prevalence compared to White participants (89% vs. 50%, p=.087). Left ventricular mass index (LVMI) of 57 g/m^2 or lower is a known predictor of major adverse cardiovascular events amongst cancer patients. All participants had a low LVMI with sarcopenic patients demonstrating lower LVMI relative to non-sarcopenic patients (50.7 g/m^2 vs. 54.8 g/m^2, p=0.623). There were no significant differences between baseline and follow-up scans.

Conclusions: PDAC patients, particularly those who are Black or sarcopenic demonstrate abnormalities in cardiovascular function and structure prior to cancer therapy. These changes are known to be associated with adverse cardiac events and advocates for close cardiac monitoring, particularly in susceptible populations. Further studies are necessary to identify specific risk factors associated with these initial changes and interventions to optimize cardiovascular health.

Gender specific patterns of age-related decline in aortic stiffness: a cardiovascular magnetic resonance study including normal ranges. J Cardiovasc Magn Reson. 2015 Feb 19;17(1):20.

#4969 Ethnic disparities in breast and cervical cancer screening in Guam: a cross-sectional analysis (2012-2022).

Aurienne Cruz[1], Grazyna Badowski[1], Grace Garces Bordallo[2]

[1]University of Guam, Mangilao, Guam,[2]Guam Department of Public Health and Social Services, Mangilao, Guam

Background: In Guam, breast and cervical cancer late-stage diagnoses and mortality rates exceed U.S. averages. From 2013-2017, 30.7% of breast and 28.6% of cervical cancers were diagnosed late. Micronesians had the highest late-stage breast cancer rate (59.1%); Filipinos had the highest for cervical cancer (33.3%). Breast cancer mortality was 27.3 per 100,000 in Guam vs. 20.3 in the U.S., with Micronesians at 104.6. Cervical cancer mortality was 6.7 in Guam vs. 2.3 in the U.S., with Micronesians at 22.3.
Methods: A cross-sectional study analyzed 6,625 female adults from Guam using Behavioral Risk Factors Surveillance System data from 2012 to 2022. We examined current mammogram screenings for women aged 40 and older and Pap tests for women aged 21 to 65. Binary logistic regression models assessed trends and associations, adjusting for age, education, income, and survey year.
Results: Overall, 64.4% of women ≥40 were current with mammograms, and 67.7% of women aged 21 to 65 had recent Pap tests. White women had the highest screening rates (70.7% for mammograms; 79.7% for Pap tests), while Micronesian had the lowest (44.2% for mammograms; 49.1% for Pap tests). Mammogram rates increased by 1.4% bi-annually, with the highest increases among Filipino (2.9%) and White (1.3%) women, but declined among Micronesians (-0.8%). Pap test rates declined slightly (-0.3%), with CHamoru women having the biggest decrease (-2.1%). Despite Micronesian women having the largest increase in Pap test rates (3.7%), their screening rates (54.1%) remained significantly below the overall rate (68%). Adjusted odds ratios showed higher mammogram screening among Asians (OR = 1.3; 95% CI: 1.1-1.6) and lower among Micronesians (OR = 0.6; 95% CI: 0.6-0.8) compared to White women. Age groups 50-59 (OR = 2.2; 95% CI: 2.0-2.6), 60-69 (OR = 2.8; 95% CI: 2.6-3.0), and 70+ (OR = 2.0; 95% CI: 1.8-2.2) had higher odds than ages 40-49. Higher education and income levels were associated with increased screening. For Pap tests, Filipinos (OR = 0.6, 95% CI: 0.6-0.7), Asians (OR = 0.7, 95% CI: 0.6-0.8), and Micronesians (OR = 0.5, 95% CI: 0.5-0.6) had lower odds compared to White women. Age group 60-69 had lower odds (OR = 0.6; 95% CI: 0.5-0.7) compared to ages 18-29. Higher education and income were also associated with increased Pap test screening.
Conclusion: Despite some improvements, Guam's cancer screening rates remain below U.S. medians. Significant ethnic disparities exist, especially among Micronesian and CHamoru populations. Targeted interventions are needed to improve screening rates and reduce late-stage cancer diagnoses among these groups.
Acknowledgement: This research was funded by the National Cancer Institute: The University of Guam/University of Hawaii Cancer Center Partnership to Advance Cancer Health Equity (PIPCHE), Grant U54CA143728 (University of Guam, YCP)/Grant U54CA143727 (University of Hawaii Cancer Center).

#4970 Inpatient outcomes and racial differences in male breast cancer: insights from the 2021 National Inpatient Sample.

Raj Shah[1], Anas Alqam[1], Elie Chalhoub[2], Khalil Choucair[3]

[1]Internal Medicine, University of Kansas Medical Center, Wichita, KS,[2]Cancer Center of Kansas, Wichita, KS,[3]Medical Oncology, Barbara Ann Karmanos Cancer Institute/Wayne State University, Detroit, MI

Introduction: Male breast cancer (MBC) accounts for 1% of all breast cancer patients. In the US, 2800 MBC new cases are diagnosed yearly. MBC patients have high mortality due to late and advanced stages at diagnosis. Understanding demographics and racial disparities in MBC is crucial, and may significantly impact morbidity and mortality.
Method: We analyzed data from the National Inpatient Sample and identified patients admitted to the hospital with MBC diagnosis in 2021 using STATA BE 18.0 software. To accurately identify metastatic disease to the bone, lung, and meninges, we excluded patients with any of these concurrent diagnoses: melanoma, primary central nervous system (CNS) tumors, and prostate and lung cancer. We investigated baseline patient characteristics and stratified the results based on race. The primary endpoint was in-hospital mortality (IHM). Length of stay (LOS) and total charge (TOTCH) were secondary endpoints. Results were adjusted for age, race, insurance type, smoking, alcohol, liver disease (LD), diabetes (DM), chronic kidney disease (CKD), and congestive heart failure (CHF). Other factors including metastases to the bone, lung, meninges, history of chest radiation, protein energy malnutrition (PEM), and palliative care utilization were also assessed and adjusted for.
Results: A total of 1,915 patients met criteria for inclusion. Of those, 75% were Caucasians,16% African Americans (AA), and 9.2% of other races. AA patients were significantly younger (mean age 64 vs. 69 years in non-AA, $p<0.05$), and more commonly in the lowest income quartile (49% vs. 22% for non-AA; $p<0.05$). Clinically, 24% had estrogen receptor-positive status, 10% had prior chest radiation, and 32% had metastatic disease (24% to the bones, 16% to lung, 11% to liver, and 5.4% to CNS). Comorbidities included smoking (40%), obesity (20%), type 2 DM (35%), coronary artery disease (27%), CHF (26%), and PEM (12%), Overall IHM was 5% with a mean 6-day LOS. Compared to non-AA, AA patients had significantly higher mortality rates (11% vs. 4 %, $p<0.05$) and longer LOS (9 vs 5.4 days; $p< 0.05$). TOTCH was higher in AA ($87,937 vs. $68,852) but did not reach significance ($p=0.48$). LD, CKD, and liver metastases were independent predictors of inpatient mortality. Palliative care utilization was 10% overall, and similar in both races (AA-16% vs non-AA 10%, $p=0.15$).
Conclusion: Significant socio-economic and racial disparities impact MBC outcomes, with AA patients presenting at younger ages, experiencing longer LOS, and higher mortality rates. The high prevalence of comorbidities and metastatic disease at presentation highlights the need for earlier detection through screening and education programs, and for interventions to address racial disparities, namely in AA patients. Future research should focus on understanding potential barriers underlying these disparities, to develop strategies to mitigate them.

#4971 Predicting lung cancer screening adherence among underserved and minoritized communities using social determinants and neighborhood factors.

Kun-Han Lu, Yi Xiao, Aamna Akhtar, Jazma Tapia, Calvin Tribby, Jay Yang, Marta Jankowska, Chi Wah Wong, **Loretta Erhunmwunsee**

City of Hope National Medical Center, Duarte, CA

Purpose: Lung cancer screening (LCS) lowers cancer mortality if individuals adhere to annual scans. Minoritized communities have significantly lower adherence to LCS than non-Hispanic whites. The influence of social determinants of health (SDOH) on these disparate adherence rates are rarely evaluated. The aim of this study is to develop a machine learning (ML) model that integrates individual and neighborhood level SDOH to predict which minoritized individuals are at risk of LCS non-adherence.
Methods: A total of 168 participants with high-risk smoking histories who underwent their first low dose computed tomography (LDCT) between 2017 and 2021 were enrolled. Surveys on SDOH and perceived discrimination were completed. Participants' addresses were joined to neighborhood level SDOH data from various publicly available sources. These indices captured neighborhood socioeconomic status and segregation. Adherence rates were calculated by assessing electronic medical records to determine if participants had a second LDCT within 15 months. Participants were temporally split into training (N=125) and testing (N=43) sets with a cut-off date of June 30, 2021. A gradient boosting classifier, XGBoost, was trained to predict LCS non-adherence, incorporating variables such as sociodemographic status, perceived discrimination, previous screenings, smoking status, and geospatial indices. The SHapley Additive exPlanations (SHAP) method was used to determine the relative importance of each feature in the model's predictions.
Results: The participants represented a diverse group: Asian (26%), Black/African American (32%), and Hispanic/Latino (32%). The LCS non-adherence rates were 66% in the training set and 63% in the testing set. The XGBoost classifier achieved an Area Under the Receiver Operating Characteristic Curve (AUROC) of 0.79 and an Area Under the Precision-Recall Curve (AUPRC) of 0.90, outperforming a simple logistic regression model (AUROC=0.63 and AUPRC=0.79). The XGBoost classifier's performance metrics were Accuracy=0.77, Recall=0.85, Specificity=0.62, Positive Predictive Value=0.79, and Negative Predictive Value=0.71. The SHAP analysis indicated that participants with no prior history of colorectal cancer screening, who lived in areas with lower quality school systems, and with a higher percentage of individuals below the poverty line, were at a higher risk of non-adherence to LCS.
Conclusions: LCS reduces lung cancer survival, but LCS adherence is significantly lower in minoritized groups. Our ML model strongly predicted LCS non-adherence based on SDOH and geospatial factors. Specific neighborhood level SDOHs predicted LCS non-adherence more strongly than individual level factors. These findings support interventions that address both individual and neighborhood-level barriers to increase LCS adherence.

#4972 Changing landscape of liver cancer disparity due to the impact of social determinate of health in Georgia.

Amit Kumar Srivastav[1], Manoj Kumar Mishra[2], Shailesh Singh[1], Brian Rivers[3], James W. Lillard[1], Rajesh Singh[1]

[1]Department of Microbiology, Biochemistry and Immunology, Morehouse School of Medicine, Atlanta, GA,[2]Department of Biological Sciences, Alabama State University, Montgomery, AL,[3]Morehouse School of Medicine, Atlanta, GA

Liver cancer (LC) is one of the most devastating malignancies. Low socioeconomic status (SES), especially poverty, negatively affects HCC outcomes. Poverty is a risk factor in cancer incidence, late-stage diagnosis, and mortality for all racial/ethnic groups. This study aims to evaluate the correlation between LC incidence and Social Determinants of Health (SDOH), focusing on major ethnic groups (African American (AA) and European Americans (EA)) in Georgia (GA). We utilized Geospatial Technology (GT) to analyze the connection between SDOH and LC prevalence in AA and EA populations in GA. This study incorporated county-level LC prevalence and association with SES and health disparities. The robust data mining (All of Us, NCI Cancer Atlas, and SEER) enabled us to explore the association between SDOH and LC in the spatial context. Integrating spatial and non-spatial data on LC prevalence to SES will help predict and formulate LC prevention methods. The GT's secondary data analysis revealed that LC affects minority communities in GA. The GT analysis further demonstrates poverty, uninsured rates, and food insecurity were positively correlated with higher LC incidence, reflecting the impact of economic instability on health outcomes. Limited access to exercise and higher crime rates in some counties further compounded risks, likely through indirect effects on stress and health behaviors. Racial disparities were prominent, with AA populations experiencing a disproportionately higher burden of LC compared to EA. The analysis highlighted that GA counties with elevated poverty rates (20-33%) and higher uninsured percentages (18-26%) exhibited increased LC incidence, particularly within AA populations. In these communities, the LC rates reached 20-24 cases per 100,000 for AA males and 15-20 for AA females, which is significantly higher compared to the rates for EA males at 10-16 cases and EA females at 6-12 cases. The study underscored notable racial disparities, revealing that AA populations bear a disproportionate burden of LC, linked to a complex interplay of socioeconomic, behavioral, and systemic influences. Additionally, the findings indicated that AA individuals had lower levels of educational attainment, with 10-20% holding a bachelor's degree, alongside higher rates of smoking (20-30%) and alcohol use (15-25%). Conversely, EA populations demonstrated more favorable SES indicators, including lower unemployment rates (6-12%) and a greater percentage with higher education (20-25%). These findings underscore the intricate interplay of socioeconomic, behavioral, and systemic factors driving LC disparities. Our finding demonstrates that SES is an essential factor that modulates LC incidences in underserved minority populations in GA. Hence, understanding the association between socioeconomic disparities will help predict and prevent LC more effectively.

#4973 Assessing urban-rural differences in the outcomes of the most common cancers in Georgia: Incidence rates and stage at diagnosis.

Amelito Manuel Andaya[1], A. Miguel Andaya[2], Stanley Atencah[1], Jason Holligan[1], Chinenye Egwuonwu[1]

[1]Piedmont Athens Regional Medical Center, Athens, GA,[2]University of Santo Tomas Faculty of Medicine and Surgery, Manila, Philippines

Introduction: Lung, pancreatic, colon, prostate and breast cancers are the leading causes of cancer-related deaths in Georgia. Mortality is highest in rural counties which have higher poverty rates and larger composition of minority population. Our study aims to compare the proportion of the five most common cancers in Georgia that were diagnosed at late stages between urban and rural county locations.
Methods: The National Institutes of Health State Cancer Profiles database was examined for incidence rates of breast, colon, lung, prostate and pancreatic cancers from 2017 to 2021 in Georgia. Age-adjusted incidence rates were calculated and stratified by county name, location and percentage at late stage of diagnosis. Late stage was defined as the presence of regional or distant metastases at the time of diagnosis.
Results: Among women diagnosed with breast cancer, rural counties had a statistically significant higher percentage of late-stage diagnoses compared to urban counties. In contrast, no significant differences were observed in the incidence of late-stage diagnosis for colon, lung, prostate, or pancreatic cancers between rural and urban populations.
Conclusion: The study demonstrated a statistically significant disparity in late-stage breast cancer diagnoses between rural and urban counties in Georgia. This emphasizes the need to improve early detection of this cancer that is alarmingly becoming more common. More attention should be given to these underserved communities given these findings. While no statistically significant rural-urban differences were found for other cancer types, further observational studies with more robust methodologies are needed in order to understand the observed incongruence in stage at diagnosis of breast and the other leading cancers in Georgia.

Comparison of Mean Percentage of Late-stage Diagnosis of the Top Five Cancers in Georgia

Type of Cancer	Rural	Urban	p-value
Breast	36.43	33.45	0.0007
Colon	57.86	58.24	0.7137
Lung	70.97	70.11	0.4418
Prostate	19.31	19.86	0.6224
Pancreas	78.67	79.44	0.6217

#4974 Leveraging partnerships through a Florida Innovation Grant: A collaborative approach by the Care2 Health Equity Center.

Nazleen Del Rio[1], Brooke Hensel[1], Ileana Guzman[1], Sandra Suther[2], Fern J. Webb[3], Paul Okunieff[4], Diana Wilkie[4]

[1]University of Florida, Orlando, FL,[2]Florida A&M University, Tallahassee, FL,[3]University of Florida, Jacksonville, FL,[4]University of Florida, Gainesville, FL

The Florida-California CaRE^2 Health Equity Center advances its mission to eliminate cancer health disparities through a multifaceted approach that promotes innovation in cancer research. Funded by a Florida Department of Health Innovation Award to UF, the Florida-based CaRE^2 research team is directly collaborating to implement this innovative project. One of the first activities was to develop materials designed to increase awareness of the RadTox test - a test using small amounts of blood to assess whether one's tumor is responding to the current cancer treatment. Having educational materials in Spanish is essential for enabling Spanish-speaking individuals to consider participating in cancer-related research. Recognizing the importance of language access, CaRE^2 bi-lingual team members translated materials into Spanish with CaRE^2 tri-institutional investigators indirectly involved back-translating information to ensure accurate information transfer. The other key collaborative effort is information sharing to reach a broader community beyond clinical populations in collaboration with the industry partner, DiaCarta. The CaRE^2 Health Equity Center's is leveraging several resources to inform the community about this project, including our community contact registry, community events direct outreach, and collegial connections. With more than 1,408 adults enrolled from CaRE^2's communities, the contact registry enhances the capacity to inform more people about this test and involvement opportunities. Information also is shared at English and Spanish-speaking community events held in CaRE^2's immediate catchment areas. Additionally, CaRE^2 investigators continue to leverage institutional, community, and industry partnerships, resulting in a network filled with varying perspectives and expertise partnering on this innovative project. Since October 2024, 1,116 CaRE^2 contact registry members who are Florida residents and 20 people attending three community events received CaRE^2 and IRB approved materials about this new test. So far 1,200 individuals have responded to seek and give additional information from the study REDCap site. CaRE^2 investigators also partner to assist with sharing this information through mass media in local and statewide outlets, leading to additional opportunities to collaborate on this innovative research study. CaRE^2 continues to leverage our capacity by involving our tri-institutional team and co-investigators not directly involved with this project to review materials for population-relevance and fidelity and suggest additional strategies to inform the broader population about this novel test. Given our continued success, CaRE^2 recommends using multifaceted approaches to address cancer health disparities and create community-centered solutions that leverage existing human capacity and resources.

#4976 Examining the association between chronic inflammation, stress, and resilience factors among diverse breast cancer survivors using the NIH All of Us dataset.

Bathsheba Aklilu, Erica Tate, Cathy Samayoa

Biology, San Francisco State University, San Francisco, CA

Breast cancer disparities exist by race and ethnicity, including disparities in age at diagnosis, quality of life, and health outcomes. These disparities may be influenced by chronic stress, exacerbated by unique challenges that extend beyond disease management, such as the effects of psychosocial stress and social determinants of health (SDOH) on chronic inflammation. Elevated C-reactive protein (CRP) levels, a marker of chronic inflammation, are implicated in worse health outcomes. Understanding how stress and SDOH interact to influence CRP and other inflammatory biomarkers is critical for addressing disparities in survivorship care. However, most studies lack adequate representation of racial and ethnic minorities; thus, factors associated with chronic inflammation among diverse breast cancer survivors remain unknown. This study aims to investigate factors associated with chronic inflammation among diverse breast cancer survivors using the NIH All of Us research dataset. Using Python, a programming language available within the NIH All of Us research program dataset, we examined CRP and additional inflammatory biomarkers and their relationships with stress, economic, social, and environmental factors. Economic and environmental factors included income, housing security, and neighborhood characteristics. Social and psychological factors included social support, the Perceived Stress Scale (PSS), and the Everyday Discrimination Scale (EDS). Multivariate analyses were conducted to evaluate associations between stress, resilience, SDOH, and inflammation, with stratification by age, BMI, and allostatic load. Preliminary findings reveal significant racial and ethnic disparities in CRP levels. Black and Hispanic breast cancer survivors exhibited the highest CRP levels. We identified 3,110 participants with breast cancer in the All of Us research program dataset. Of those, 7.2% were African American or Black, 2.2% were Asian, and 6.7% were Hispanic. We hypothesize that inflammation will be higher among racial and ethnic minorities, as well as among women with higher levels of stressors, such as low income and increased PSS and EDS scores. Furthermore, we expect inflammation to be negatively associated with resilience factors, such as increased social support and greater neighborhood safety. This study will identify factors associated with chronic inflammation among diverse breast cancer survivors and provide a deeper understanding of the biological mechanisms driving breast cancer health inequities.

#4977 Knowledge and acceptance of the human papillomavirus vaccine in parents from the Colombian Caribbean.

Ines Benedetti, Laura Mendoza Carmona, Valeria Duran Cordero, Sebastian Payares Florez, Ariel Marrugo Ortiz, Luis Alvis Estrada

School of Medicine, Universidad de Cartagena, Cartagena, Colombia

Introduction: cervical cancer ranks eighth in global cancer incidence and fourth among women worldwide. Its development is strongly associated with infection by the Human Papillomavirus (HPV) making vaccination a critical preventive measure. In 2012, Colombia's Ministry of Health launched a free HPV vaccination program, positioning the country as one with the highest coverage rates globally. However, vaccination rates began to decline in 2014, with coverage for the second dose reported at 27% that year. This decline has been attributed to an incident occurred in 2014 in the municipality of El Carmen de Bolívar. The reasons behind this decrease and the current perceptions of parents regarding the vaccine remain unclear. The objective of this study was to identify factors influencing HPV vaccine acceptability among parents of girls under 13 in two Colombian Caribbean municipalities.
Methods: a cross-sectional study was conducted among parents of girls under the age of 13 residing in two Colombian Caribbean municipalities. Data were collected using a structured survey administered, focused on exploring sociodemographic characteristics and knowledge related to the HPV vaccine.
Results: a total of 238 participants were surveyed, with a mean age of 33 years old, 87.39% of whom were women. 78.1% belonged to the lowest socioeconomic stratum. All participants reported having daughters aged 13 years or younger. Vaccine acceptance was 76.8% (88% among those under 30 years old, n=84) and 70% among parents 30 years of age and older (n=154). Despite this, a significant proportion of participants lacked knowledge about how HPV is transmitted or prevented (38.6%, n= 92),and misconceptions about severe adverse effects, such as seizures, were common (between 32.79% and 35.34%).
Conclusion: vaccine acceptance was associated with knowledge about HPV, and influenced by sociodemographic factors. In both communities, distrust regarding adverse effects remains a significant barrier to vaccination. Tailored educational interventions that address the specific needs and characteristics of each community are essential to address these challenges, improve HPV vaccine acceptance, and meet coverage goals, contributing to cervical cancer prevention and enhancing women's quality of life.

#4979 Effect of allostatic load (AL) and neighborhood socioeconomic status (NSES) on cancer detection and false positive rate after screening mammography.

Niam Abeysiriwardena[1], Braelyn Wekwerth[1], Nathaniel Mercaldo[1], Sarah Bell[2], Ruth Carlos[1]

[1]Massachusetts General Hospital, Boston, MA,[2]University of Michigan, Ann Arbor, MI

Purpose: AL refers to the cumulative physiological dysregulation on the body's systems due to chronic stress. These cumulative stressors have been hypothesized to increase the risk of breast cancer (BC). AL has been associated with increased risk of high-risk benign breast pathology among women with a false positive (FP) biopsy. Separately, NSES has also been associated with BC outcomes. However, the impact of AL and NSES on cancer detection and FPs rate in a screening mammography population has not been evaluated.
Materials and Methods: We retrospectively reviewed the Mass General Brigham Biobank to identify women aged ≥40, who underwent screening mammography from Jan 1, 2021 to Dec 31, 2021. We collected age, self-reported race/ethnicity and zip code, which were geocoded to their corresponding census tract. The census tract-assigned NSES were calculated using U.S. Census Bureau American Community Survey 5-Year Estimates for 2015-2019 and summarized to the ZIP code level. We collected the following biomarkers obtained within two years before the index screen: cardiovascular [heart rate, systolic, and diastolic blood pressure], metabolic [body mass index, alkaline phosphatase, glucose, albumin], immunologic [white blood count], and renal [blood urea nitrogen, creatinine]. AL was assigned one point for each lab value in the worst quartile. The sum of all assigned points represented the composite AL, treated as a continuous variable. We collected diagnostic breast imaging and biopsy encounters that occurred in the 12 months after the index screen. To account for missing data, we performed multiple imputation. Separate multivariable logistic regression models assessed age, race, NSES, and AL associations with cancer detection and with FP rates. Rubin's rules were applied to estimate overall odds ratios, confidence intervals, and p-values for all covariates.
Results: Of 13,754 women assessed, 1.2% (n=169) women received a cancer diagnosis. Of the women, 87.6% were White, 2.6% Asian and 5.3% were Black; 1.5% self-identified as Hispanic; the mean age was 64.4±11.3 SD. AL increased risk of cancer detection after screening mammography by 16% (odds ratio OR=1.16, 95% CI:[1.06, 1.26], p=0.001). NSES was marginally associated with cancer detection (OR=1.13[0.99-1.29], p=0.067). After adjusting for AL and NSES, age and race were not significant correlates of cancer detection. We did not detect an association between FPs and either AL or NSES, after adjusting for race and age.
Conclusion: In our sample, allostatic load was associated with increased risk of cancer detection after screening mammography after adjusting for age, race, and NSES. A similar association between AL and FPs was not detected. Further work is needed to confirm these observations.
Clinical Relevance Statement: AL may represent a potential biomarker for personalized mammographic screening for BC.

#4980 Association of allostatic load (AL) and neighborhood socioeconomic status (NSES) and breast biopsy outcomes after screening mammography.

Braelyn Wekwerth[1], Niam Abeysiriwardena[1], Nathaniel Mercaldo[1], Sarah Bell[2], Ruth Carlos[1]

[1]Massachusetts General Hospital, Boston, MA,[2]University of Michigan, Ann Arbor, MI

Purpose: AL represents the physiological consequences of repeated or chronic exposure to exogenous and endogenous stressors, including NSES, which are hypothesized to increase the risk of breast cancer (BC). We showed AL correlation with BC and high-risk benign breast disease after biopsy after a palpable mass or abnormal diagnostic breast imaging. However, the effect of AL and NSES on cancer detection and false positive (FP) biopsy results after a screening mammogram has not been evaluated.

Methods: We retrospectively reviewed the Mass General Brigham Biobank to identify women aged ≥40 who underwent screening mammography between 1/1/2021-12/31/2021 and subsequent breast biopsy. We collected age, self-reported race/ethnicity, and zip code and then geocoded to their corresponding census tract. The census tract assigned socioeconomic index scores (SES) were calculated using U.S. Census Bureau American Community Survey 5-Year Estimates for 2015-2019 and summarized to the ZIP code level. We collected the following biomarkers obtained within two years before the index screen: cardiovascular [heart rate, systolic, and diastolic blood pressure], metabolic [body mass index, alkaline phosphatase, glucose, albumin], immunologic [white blood count], renal [blood urea nitrogen, creatinine]. AL was assigned one point for each lab value in the worst quartile. The sum of all assigned points represented the composite AL, treated as a continuous variable. We collected diagnostic breast imaging and biopsy encounters occurring within 12 months after the index screen. Multiple imputation accounted for missing data. Multivariable logistic regression assessed age, race, SES, and AL associations with cancer detection and FP rates. We applied Rubin's rules to estimate overall odds ratios, confidence intervals, and p-values for all covariates.

Results: Of the 418 eligible women, 59.6% had an FP biopsy, and the remainder had BC, including ductal carcinoma in situ. Women, on average, were 62 years old (SD=13), and 85.6% were White. Each unit increase in AL was associated with a 14% increase in risk of cancer detection (OR 1.14(1.01,1.30),p=0.034) after adjusting for age, race, and NSES. Both age (OR 1.21(1.11,1.321),p<0.001) and marginally NSES (OR 1.19(0.99,1.43),p=0.068), also correlated with cancer detection. We did not detect a significant association between AL and high-risk FP pathology.

Conclusion: AL, age, and NSES are associated with cancer detection after screen-indicated biopsy but not high-risk FP pathology. These results underscore the importance of considering biological markers and demographic factors in refining biopsy strategies after a positive screening mammography.

Clinical Relevance Statement: AL represents a potential biomarker for precision selection of women after screen-detected mammographic abnormalities to increase cancer yield for biopsy.

#4981 Implementation of a community-based HPV vaccination intervention supported by a cross-sector community coalition.

Ruth Rechis[1], Haley Gardiner[1], Mayra Aquino[1], Katherine Oestman[2], Efrat Gabay[3], Paula Cuccaro[3]

[1]Cancer Prevention and Control Platform, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Daybreak Consulting, Las Vegas, NV,[3]UT Health Houston, Houston, TX

Human papillomavirus (HPV) vaccination is a successful strategy to prevent HPV related infection and cancer. However, vaccination uptake remains suboptimal in the U.S., with Texas having the largest number of unvaccinated adolescents. Be Well Communities™, MD Anderson's place-based approach for cancer prevention and control, works with communities to promote wellness and address modifiable cancer risk factors. Initially, the initiative in Baytown, TX focused on healthy eating and active living interventions. Over time, the community's trust and interests expanded to more traditional cancer prevention interventions (e.g., HPV vaccination, screening). In this project, UTHealth Houston's All for Them (AFT) program was funded for three years to work with Goose Creek Consolidated Independent School District (GCCISD) to reduce adolescent vaccination barriers by providing community-based mobile vaccination clinics. GCCISD's students are 90% minority and 56% economically disadvantaged. The Be Well Communities team facilitated the relationship and supported GCCISD staff to ensure optimal implementation, assisted with mobile clinic site location, and provided educational sessions at Steering Committee meetings, of which the AFT team was a steadfast member. AFT included development and implementation of an educational messaging campaign for adolescents and their parents, school nurse continuing education to improve HPV vaccination knowledge, confidence in talking with parents about vaccination and data recordkeeping, and mobile vaccination clinics at school- and community-based venues. Program strategies resulted in increased parental engagement and trust of the team and project, improved parental acceptance of HPV vaccination, and excellent feedback from GCCISD staff about services provided. School nurses (n=31) participated in multiple professional development and training opportunities. HPV vaccines (n=1,154) were provided at 57 vaccination clinics. The number of students in GCCISD who received vaccines at multiple clinics was 37% higher than the largest school district in which AFT intervenes (outside of this initiative). With two years of available data, HPV vaccination rates increased 16.9 percentage points (46.3%) in initiation and 11.1 percentage points (77.1%) in completion among students in the participating schools. Due to their active participation on the Steering Committee, the AFT team formed relationships with all 21 organizations and fostered formal partnerships with 4 organizations. The relationships developed through participation with the Steering Committee built community collaborations in Baytown and facilitated alternative ways to bring awareness to and host vaccination-related education and activities. The project's success led to additional grant funding and sustained partnerships.

#4982 A randomized controlled trial of financial incentives to improve electronic health record (EHR)-driven recruitment among underrepresented communities.

M. A. Fiala, W. Gema, A. Davis, F. Ademuyiwa;
Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Disparities in EHR portal use have been documented based on age, race, ethnicity, and other factors. Thus, EHR-driven research recruitment may worsen representation of these groups. Monetary incentives can increase response rates, but their impact on improving inclusivity in research is unknown. In this study, we aimed to determine if a financial incentive improves response rates to recruitment messages in an equitable fashion.
Patients and Methods: A random sample of 1,200 patients with diagnoses of either breast, colorectal, prostate, or lung cancer treated at Washington University in St. Louis received a recruitment message for a fictitious cross-sectional survey study “The Social Aspects of Cancer Care” via their EHR portal. Two strata of patients were sampled, those who identify as non-Hispanic White (n = 600) and those who identify as another race or ethnicity (n = 600). Participants were randomized to receive an offer of a $20 monetary incentive (n=400) or no incentive (n=800) for their enrollment. Patients were debriefed following their participation, and all participants received the incentive regardless of randomization assignment. The primary endpoints include the comparison of response rates by 1) race and 2) financial incentive.
Results: The sample consisted of 1200 patients with a history of breast (31%), prostate (28%), lung (25%), and colorectal cancer (16%). The mean age was 65.7 years (SD 12.3) and 46% were male. Fifty percent identified non-Hispanic White, 38% African American or Black, and 12% as another race or ethnicity. Overall, 39% of participants viewed the recruitment message and 13% responded that they were interested. Incentives did not improve response rates to a statistically significant degree. The response rate for the incentive cohort was 15% compared to 12% for no incentive ($p = 0.206$). Response rates were higher ($p < 0.001$) among non-Hispanic White patients (18%) than for African American or Black (7%) and members of other racial/ethnic groups (13%). This was true for patients who did not receive an offer of an incentive (18% compared to 9% and 10%; $p <0.001$) and for those that did (19% compared to 9% and 20%; $p = 0.028$). There was a trend for greater improvement in response rate for patients of racial and ethnic minorities, but it was not statistically significant ($p = 0.129$). We performed a secondary analysis of the 471 patients who viewed the message and found similar results regarding the differences in response rates based on race and ethnicity and the lack of impact of incentives.
Conclusions: People with cancer who identify as a racial and ethnic minority are less likely to view and respond to recruitment messages for research studies through their EHR patient portal. The impact of a $20 financial incentive was modest, if any, but may be greater on people who identify as a racial and ethnic minority.

#4983 Allostatic load and prevalence of monoclonal gammopathy of undetermined significance.

M. A. Fiala, T. Lan, M. Slade, R. Vij, S.-H. Chang;
Washington University School of Medicine in St. Louis, St. Louis, MO

Background: Repeated exposure to stress can result in dysregulation of the endocrine system and excess secretion of hormones, even when stress is not present. The degree of dysregulation has been coined allostatic load (AL), and higher AL has been associated with increased risk of cancer. We explored the relationship of AL with the development of monoclonal gammopathy of undetermined significance (MGUS), the asymptomatic precursor to multiple myeloma, and the potential mediating effect of AL on racial disparities in MGUS prevalence.
Methods: Nationally representative data from National Health and Nutrition Examination Survey (NHANES) were used. In 1999-2004, MGUS testing was performed on a subtset of participants who were 50 years or older and had available serum samples. AL was scored 0-7, based on markers of metabolic, renal, and immune physiologic systems, as previously described (Obeg-Gyasi, et al, 2022). The association of AL with MGUS was assessed using multivariable odds ratio (aOR). A mediation analysis was performed to determine the relationship of AL in the observed disparities in MGUS incidence.
Results: Among the 5616 participants sampled, 2.8% had MGUS, suggesting a MGUS prevalence of 2.2% of the U.S. population above the age of 50. The characteristics of the sample with and without MGUS are compared in Table 1. African American and Blacks were twice as likely to have MGUS compared to non-Hispanic Whites (aOR 2.00; 95% Confidence Interval [CI] 1.42-3.31; *P*<0.01). After adjusting for age, race, and sex, each one unit increase in AL was associated with 30% increase in odds of having MGUS (aOR=1.30; 95% CI 1.14-1.47; *P*<0.01). AL mediated 9.6% (95% CI -1.1%-20.3%, *P*=0.08) of the disparities between African American and Black and non-Hispanic White participants.
Conclusions: Higher AL was associated with increased odds of MGUS. AL may also explain, at least in part, the higher incidence of MGUS among the African American and Black population in the US. Table 1

Characteristic	MGUS (n=155, N=1,364,360)	No MGUS(n = 5461, N= 60,016,515)	*P*
Age, mean (SD)	68.65 (1.01)	62.92 (0.22)	<0.01
Male (%)	53.2	46.8	0.20
Non-Hispanic White (%)	79.4	79.9	0.03
African American or Black (%)	13.4	7.9	
Hispanic (%)	3.6	8.2	
Other (%)	3.6	4.0	
Allostatic Load, mean (SD)	2.65 (0.11)	1.97 (0.04)	<0.01
Overweight or obese (%)	80.4	71.1	0.03
Elevated Alkaline phosphatase (%)	22.1	20.7	0.68
Elevated Creatinine (%)	29.9	20.3	0.01
Reduced Creatinine Clearance (%)	31.6	16.1	<0.01
Elevated C-reactive protein (%)	32.2	22.7	<0.01
Elevated White Blood Count (%)	23.4	24.1	0.87
Reduced Albumin (%)	45.2	22.3	<0.01

#4987 Impact of treatment on cognitive function and quality of life in head and neck cancer patients: A prospective study in Indian population.

Saravanan Sampoornam Pape[1], Delfin Lovelina Francis[2]

[1]Kalinga Institute of Industrial Technology (KIIT), Bhubaneshwar, India,[2]Public Health Dentistry, Saveetha Dental College and Hospitals, SIMATS, Chennai, Tamil Nadu, India, Chennai, India

Aim and Objectives:
•To assess cognitive function in patients with head and neck malignancies post-treatment using cognitive ability scales.
•To evaluate the impact of treatment modalities on cognitive function.
•To assess the quality of life in head and neck cancer patients post-treatment using validated QoL scales.
Study Design: A prospective observational cohort study on patients diagnosed with head and neck malignancies in the North Indian population, post-surgical and oncological treatment.
Study Population
•Inclusion criteria: 1. Age 18-70 years diagnosed with malignancies in the head and neck. 2. Undergone surgery, chemotherapy, or radiotherapy for their malignancy. 3. Follow-up of 6 months post-treatment.
•Exclusion criteria: 1. Pre-existing neurocognitive disorders. 2. Psychiatric disorders or active neurological diseases.
Cognitive Assessment
•Montreal Cognitive Assessment (MoCA)
•Mini-Mental State Examination (MMSE)
•Trail Making Test (TMT)
Quality of Life Assessment: European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30)
Data Collection and Statistical Analysis: A minimum sample size of 150 patients was selected to detect changes in cognition and QoL post-treatment with a 95% confidence level and 80% power. Changes in cognition and QoL was analyzed using paired t-tests and ANOVA. Correlations between cognitive function and QoL was analyzed using Pearson's correlation coefficients.
Results:
Cognitive Function Assessment- MoCA scores showed a mean decrease of 3.5 points in areas of memory, attention, and visuospatial functioning. Patients receiving chemoradiation experienced greatest cognitive decline, with reduction of 4.8 as assessed by the TMT. Patients receiving surgery alone showed minimal cognitive decline, with reduction of 1.2 points on MoCA. MMSE scores mirrored these findings, with a decline of 2.5 points in the chemoradiation group and 1 point in the surgery-alone group. Quality of Life (QoL) Global health score decreased by 20%, with most affected domains being emotional functioning (30% decline) and cognition (25% decline). Physical functioning was impaired, with a 15% decline, largely due to the adverse effects of treatment. The EORTC QLQ-H&N35 module revealed that pain & swallowing were prominent concerns.
Conclusion: The results of this study indicate that head and neck cancer patients experience significant cognitive decline and QoL deterioration post-treatment, with those receiving chemoradiation being most affected. Persistent cognitive deficits correlate strongly with reduced QoL, emphasizing the importance of integrating cognitive assessments and QoL evaluations into standard care practices. Future research should explore targeted interventions to mitigate these adverse effects and improve the overall survivorship experience.

#4988 Port flushes in oncology - Does frequency matter?.

Shabbir Haiderbhai[1], Julia Parrish[2], Grace Lavandowska[3], Megan Kelly[3], Aarabhi Gurumoorthy[4], Anu Gaba[4]

[1]Internal Medicine, University of North Dakota, Fargo, ND,[2]Hematology and Oncology, University of North Dakota, Fargo, ND,[3]University of North Dakota, Fargo, ND,[4]Sanford Roger Maris Cancer Center, Fargo, ND

Background: Ports, a type of central venous access device, are frequently used for the administration of intravenous medications, such as chemotherapy. These devices can remain in place for extended periods of time, from several months to years. To reduce the risk of complications, manufacturers recommend routine maintenance, often through monthly heparin flushes which leads to frequent visits to health care settings, adding to the burden and cost of care for both the patient and the healthcare system. The COVID-19 pandemic necessitated decreasing the frequency of port flushes to every 3 months when possible. The aim of this study was to evaluate if extending the interval between heparin flushes impacted safety outcomes.

Methods: A retrospective chart review study was performed utilizing patient data from a single cancer center. Medical records were abstracted for patients with the following characteristics; a diagnosis of malignancy, ≥ 18 years of age, not on current chemotherapy, port placement greater than 30 days prior to enrollment, at least 6 months of follow-up data, and at least one successful port flush within the 6-month study period. The control group (CG) consisted of patients with a standard port flush interval of 4 weeks vs the experimental group (EG) that received an extended interval of every 12 weeks. The primary outcome was port removal, and the secondary outcome was complications of any kind (discomfort, erythema, use of tPA, thrombus, and infection). Descriptive statistics were used to summarize data, with Pearson's chi-square or Fisher's exact tests utilized to calculate group differences.

Results: Of the 1,162 patients who were initially screened for eligibility, 215 patients were included in the analysis: 69 in the CG and 146 in the EG. The average port flush interval was 30.97 days in the CG and 86.21 days in the EG. In the CG, 4 patients (5.8%) required port removal due to complications, compared to 3 patients (2.05%) in the EG (p=0.21). Twelve (17.4%) patients in the CG had port-related complications as compared to 3 patients (2.05%) in the EG (p=0.001). The complications evaluated were discomfort (n=1 in CG), erythema (n=1 in CG, n=1 in EG), infection (n=1 in CG), port malfunction (n=5 in CG, n=2 in EG), thrombus (n=2 in CG), and use of tPA (n=5 in CG).

Conclusion: Our findings suggest that extending the interval between port maintenance flushes from 4 to 12 weeks may lead to lower port-related complications. While the results are promising, the study was limited by the relatively small sample size due to strict inclusion and exclusion criteria. Adopting a 12-week flushing interval may improve the quality of life of cancer patients by reducing the frequency of clinic visits and may also lower healthcare costs for patients and hospitals alike. This extended interval approach is a promising step towards patient-centered care, improving overall healthcare efficiency while maintaining safety.

#4989 Sex disparity in cancer-related fatigue, depression, and impact on quality of life among cancer survivors: Insights from NHANES.

S. Du[1], R. Memon[1], S. Han[2], Y. Wang[3], H. Yusuf[1], J. Anampa Mesias[3];

[1]Jacobi Medical Center - Albert Einstein College of Medicine, Bronx, NY, [2]Mount Sinai Hospital, New York City, NY, [3]Montefiore Medical Center, Bronx, NY

Introduction: Cancer-related fatigue (CRF) and depression are prevalent and debilitating conditions among cancer survivors, significantly impacting their quality of life (QoL). CRF affects up to 80% of patients during or after treatment, while depression affects 15-25%, often co-occurring with CRF. Female survivors are disproportionately affected due to hormonal, psychosocial, and societal factors. However, the extent of these disparities and their impact on QoL remain understudied. This study aims to address the gap by investigating sex differences in CRF and depression, with a focus on their effects on work and recreational activities as key surrogates for QoL

Methods: We analyzed data from the 2015-2016 and 2017-2020 cycles of the National Health and Nutrition Examination Survey (NHANES), including 1,555 cancer survivors representative of over 25 million U.S. survivors. Sampling weights were applied to account for NHANES' complex survey design. Three-step sequential logistic regression models were used to examine sex disparities in CRF and depression: (1) unadjusted, (2) adjusted for demographic variables (age, race), and (3) fully adjusted for demographics, socioeconomic factors (education, insurance), and comorbidities (e.g., hypertension, diabetes). CRF and depression were assessed using the validated Depression and Anxiety Screening Questionnaire (DPQ). Outcomes included vigorous or moderate work activities and recreational activities. Statistical significance was set at $\alpha = 0.05$.

Results: After adjusting for age, race, socioeconomic status (SES), and comorbidities, female cancer survivors had a 58% higher likelihood of experiencing depression compared to male survivors (OR = 1.58, 95% CI: 1.10-2.26, $p = 0.014$). Similarly, female survivors were 69% more likely to experience CRF than their male counterparts (OR = 1.69, 95% CI: 1.24-2.31, $p < 0.001$). CRF was not significantly associated with work-related activity limitations (OR = 1.17, 95% CI: 0.79-1.73, $p = 0.431$) but was strongly associated with reduced moderate recreational activities (OR = 1.83, 95% CI: 1.26-2.66, $p = 0.002$). Depression was also associated with reduced recreational activities (OR = 1.65, 95% CI: 1.05-2.58, $p = 0.02$).

Conclusion: Female cancer survivors are disproportionately affected by higher rates of CRF and depression, with both conditions reducing engagement in recreational activities and adversely affecting QoL. These findings highlight the importance of targeted interventions to address sex disparities in CRF and depression, with the ultimate goal of improving QoL among cancer survivors.

#4990 A discovery of novel methylation profiles in head and neck squamous cell carcinoma in relation to pretreatment pain by cancer subtype.

Monica A. Wagner, Yanning Wu, Naji Ayyash, Fredrick R. Schumacher, Quintin Pan

Case Western Reserve University, Cleveland, OH

Pain is the initial symptom reported by nearly 75% of individuals diagnosed with head and neck squamous cell carcinoma (HNSCC), yet effective management remains elusive, with up to 80% of patients reporting inadequate pain management despite opioid use. Pretreatment pain is a key predictor of survival and recurrence, but the molecular mechanisms underlying pain in HNSCC are not well understood. This pilot study aims to explore the epigenetic mechanisms underlying pain perception in HNSCC patients by cancer subtype and identify potential biomarkers to improve pain management strategies.

DNA methylation levels were generated for individuals newly diagnosed with HNSCC of oral cavity (OCSCC; n=18) or oropharynx (OPSCC; n=8) prior to definitive treatment using the Illumina Infinium MethylationEPIC v2.0 array. Perceived worst pain score was measured using the Brief Pain Inventory-Worst Pain item prior to treatment, categorized according to NCCN guidelines, with patients reporting no pain serving as the reference group. After quality control, M-values for 26 samples and 913,962 methylation probes were evaluated. Differentially methylated positions (DMPs) associated with pain severity were identified combining subtypes, with hypo- (fold change (FC) < -2) and hypermethylated (FC > 2) sites determined after adjusting for age. Stratified analyses were performed by cancer type. All analyses set a significance level with a false discovery rate < 5%.

Pain phenotype and blood collection occurred on the same day, after diagnosis but prior to definitive treatment. The cohort had a mean age of 65.1 ± 11.3 years, 42.3% of those reporting any level of pain were male. Pre-treatment pain was reported by 94.4% (N=17) of OCSCC and 25% (N=2) of OPSCC patients. DMP analysis revealed probe cg08573204_TC21 in *LMO1* gene was hypermethylated in OCSCC patients with mild pain versus no pain (p=0.02, Log_2FC=1.11). While *LMO1* has not been previously linked to pain, its role in adrenergic cell identity suggests potential involvement in pain pathways. In patients with moderate/severe pain, cg18566479_BC21 located in *CHDH* gene was hypermethylated in OCSCC (p=1.09E-04, Log_2FC=1.98). *CHDH*, associated with metabolic signatures in HNSCC and neuroinflammatory activation in neuropathic pain, showed significant hypermethylation, suggesting its potential as a biomarker for pain management in HNSCC.

Differential DNA methylation may be associated and predictive of the development and severity of pain in HNSCC. With future work in larger samples, this research may provide insight into the biological underpinnings of pain and guide cancer symptom management by using DNA methylation profiles to identify patients at risk for pain who may benefit from preventative measures.

#4991 Temporal trends in health-related quality of life (HRQoL) outcomes in fourth line or higher treatment for relapsed/refractory multiple myeloma (RRMM): A systematic literature review (SLR) and meta-analysis.

Ken Hasegawa[1], Xavier P. Leleu[2], Taha Itani[1], Monique Giordana[1], Enrique Granados[1], Rebecca J. Chan[3], Ana Kostic[3], Jie Ting[3], Sean P. Harrigan[4], Michael J. Zoratti[4], Rahul Banerjee[5]

[1]Kite, A Gilead Company, Santa Monica, CA,[2]Centre Hospitalier Universitaire de Poitiers, Poitiers, France,[3]Arcellx, Inc., Redwood City, CA,[4]RainCity Analytics, Vancouver, ON, Canada,[5]Fred Hutchinson Cancer Center, Seattle, WA

Background: The HRQoL of patients with RRMM is highly impacted by their disease and is typically only maintained with conventional treatments before deteriorating. We conducted an SLR and meta-analyzed temporal trends in HRQoL to contextualize findings from emerging immunotherapies for 4L+ RRMM such as chimeric antigen receptor T-cell (CAR T) therapies and bispecific antibodies (BsAb).

Methods: MEDLINE, EMBASE, CENTRAL and the grey literature were systematically searched (Jan 2012 to Mar 2024) for studies of patients with 4L+ RRMM where HRQoL was measured according to either the EORTC QLQ-C30 or QLQ-MY20. Changes from baseline were described, by treatment category (CAR T, BsAb, and Other), using fixed-effect meta-analyses over one year of follow-up. Estimates were compared to minimally important differences (MIDs) to determine clinical meaningfulness.

Results: We included 14 studies with QLQ-C30 (n=14) or QLQ-MY20 (n=11) outcomes at timepoints of interest (Table). In patients treated with CAR T, sustained clinically meaningful improvements were observed from 3 months onwards on the Physical functioning and Pain domains and from 4 months onwards on Global health status and the Social functioning, Fatigue, and Future perspective domains. Treatment with a BsAb tended to maintain baseline HRQoL over time, with some meaningful improvements in Emotional functioning, Physical functioning, Fatigue, and Pain. Meaningful deteriorations were seldom observed on any domain.

Conclusions: This evidence base is evolving, and some findings are limited by few studies and small sample sizes. Nevertheless, our study demonstrated earlier and sustained improvement in key HRQoL domains among patients with 4L+ RRMM who receive CAR T. These findings are similar to the results of CAR T in other hematological settings and reflect improved general well-being post-CAR T.

*Negative changes on symptoms show improvement; Bold: Clinically meaningful change from baseline

Domain (MID for improvement/deterioration)		Treatment category	Mean change from baseline (95% CI)							
			Month 1	Month 2	Month 3	Month 4	Month 5	Month 6	Month 9	Month 12

#4992 Results of a survey of US Ayurvedic medicine professionals regarding their work with people with cancer.

Julia T. Arnold[1], Oluwadamilola Olaku[1], Anand Dhruva[2], Gabriel Lopez[3], Bhaswati Bhattacharya[4], Manohar Gundeti[5], Anupama Kizhakkeveettil[6], Benmei Liu[7], Frank Ninivaggi[8], Sophie King[1], Jeffrey D. White[1]

[1]Office of Cancer Complementary and Alternative Medicine- OCCAM, National Cancer Institute, Bethesda, MD,[2]University of California, San Francisco, San Fransisco, CA,[3]MD Anderson Cancer Center, Houston, TX,[4]Weill Cornell Medical College, New York, NY,[5]Central Ayurveda Research Institute, CCRAS, Mumbai, India,[6]Southern California University of Health Sciences, Los Angeles, CA,[7]Division of Cancer Control and Population Sciences, National Cancer Institute, Bethesda, MD,[8]Yale University School of Medicine, New Haven, CT

INTRODUCTION: The goal of this study was to understand how Ayurveda, the traditional medicine of India, can be incorporated into the management of patients with cancer in the United States (US). Patients with cancer often seek Ayurvedic treatments to complement conventional care for prevention, to reduce symptoms/ toxicity, support recovery, improve quality of life, or palliative care. Ayurveda is a whole system personalized approach to health incorporating multiple modalities including herbal-natural products, diet, routines, behavior, detoxification, and mind/body techniques for restoring health and preventing disease. The authors surveyed the opinions of Ayurvedic professionals on the management of cancer patients using Ayurveda including its benefits for the treatment of cancer side-effects and symptoms and communications and collaborative research with allopathic practitioners.

METHODS: This Survey was a collaboration of the co-authors led by the Office of Cancer Complementary and Alternative Medicine (OCCAM), National Cancer Institute (NCI). Authors contacted key leaders of the US Ayurvedic professional community including directors of Ayurvedic colleges/academies, and leaders of state, regional and national Ayurvedic associations. An invitation letter with a web-link and QR code for the survey website was distributed by the US Ayurveda Professionals leadership (on behalf of OCCAM) to the alumni and association members of these groups. The survey had 321 respondents, of which 199 (62%) have practiced Ayurveda on patients/clients in the US. (Demographics and educational background of this population will be included in the presentation).

RESULTS: Brief highlights of the Ayurvedic professionals' responses to the 110 questions are:1- Reasons why patients sought Ayurveda care, [improve their quality of life (QoL) (94%), reduce allopathic treatment-related side effects (87%), prevent recurrence of their cancer (77%)], 2--Recommended targets of Ayurvedic consultations, [daily routine/lifestyle (97%), specific food counseling (94%), pranayama (breathing exercises; 88%), yoga and meditation (86%)], 3- The most common goals of practitioners for clients with cancer, [to improve diet and digestion (94%), increase QoL (90%), and stress reduction (90%)], 4- Practitioners agreed that combined Ayurveda and allopathic medicine is the best approach for cancer symptom and side effect management (87%), support during cancer treatment (84%), QoL (80%) cancer prevention (75%), and cancer detection (65%).

CONCLUSION: This Survey aims to increase awareness among oncologists and researchers regarding the integration of Ayurveda with conventional cancer care to enhance patient QoL and treatment outcomes. Research collaborations between oncologists and Ayurvedic professionals could support efficacy and mechanistic research on the use of Ayurveda or its components in cancer care.

#4993 A longitudinal examination of nutritional-inflammatory biomarker associations with cancer related cognition, treatment side effects and quality of life in newly diagnosed older adults undergoing chemotherapy.

Jennifer M. Crook, Michael Owings, Victoria Loerzel

Nursing, University of Central Florida, Orlando, FL

Intro: Chemotherapy-induced cognitive impairment affects 16-75% of cancer patients with neither a clear understanding of the underlying causes nor assessment guidelines for intervention. A potential consideration may be found in nutritional-inflammatory biomarker ratio panels of neutrophil-albumin ratio (NPAR), neutrophil-lymphocyte ratio (NLR), platelet-lymphocyte ratio (PLR), and monocyte-lymphocyte ratio (MLR). These calculated proportions may be obtained from readily available and normally scheduled chemotherapy labs and have been implicated for their prognostic value in cancer treatment effectiveness and/or mortality risk with sensitivity to multiple cancer types and stages. However, the relationships between these and cognitive, chemotherapy related symptoms and quality of life (QOL) evaluations have not yet been explored.

Methods: This study examined data from a RCT of 144 newly diagnosed adult participants (≥ 60 years of age) undergoing first-time chemotherapy recruited from community cancer centers in central and south Florida. Various cancer types and stages were included with treatment cycles of 1-6 timepoints captured. NPAR, NLR, MLR, and PLR were calculated and ran as continuous variables for nonparametric Friedman analysis of variance and Wilcoxon signed rank tests and categorized into three equal groups of low, medium, and high for Pearson chi-square analyses. Cognitive and symptom information were collected through Mini-Mental State Examination (MMSE), EORTC - Quality of Life (QLQ-C30), and Symptom Representation Questionnaire (SRQ) instruments.

Results: NPAR, NLR, PLR, and MLR were significantly associated with MMSE scores ($p < 0.001$). Substantial changes were identified in individuals with moderate dementia and normal cognition between baseline through final chemotherapy treatments. Cognitive and emotional assessment (EORTC-QLQ) revealed significant associations between NPAR, NLR, PLR, MLR and feeling tense ($p < 0.01$), difficulty remembering, depression, pain, nausea, and needing assistance with ADLs ($p < 0.05$). Significant treatment-related symptom associations with NPAR, NLR, PLR, MLR were identified in hair loss, numbness ($p < 0.001$), nausea ($p < 0.01$), drowsiness, lack of appetite, and hot flashes ($p < 0.05$).

Discussion: Nutritional-inflammatory lab ratios of NPAR, NLR, PLR, and MLR were significantly associated with cognitive, side effects, and QOL indicators during chemotherapy treatments of newly diagnosed older adult cancer patients. These easily obtained lab calculations may provide prognostic value in assessing and intervening in high-risk individuals to mitigate treatment-related sequalae.

Poster Session

#4997 The ROSALIND Study: Identifying multi-omic signatures in long-term cancer survivors for therapeutic target discovery.

Julieta Rodriguez[1], Olivia Le Saux[2], **Paloma Cejas**[3], David Gentien[1], Nick Riddiford[4], Naouel Zerrouk[4], Josep Tabernero[5], Olivier Elemento[6], Adrien Paix[4], Alexandre Yazigi[4], Nicolas Wolikow[4], Simon Istolainen[4], Remi Nicolle[4], Cecile Badoual[7], Elisabeth Auzias[4], Ludovic Lacroix[1], Nathalie Droin[1], Gina Dorpholz[8], Rodrigo Dienstmann[9], Jean-Yves Blay[10], Ulrich Keilhoz[11], Fabrice Andre[1]

[1]Gustave Roussy, Villejuif, France,[2]Centre Leon Berard, Lyon, France,[3]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA,[4]Cure51, Paris, France,[5]Vall d'Hebron Institute of Oncology, Barcelona, Spain,[6]Englander Institute for Precision Medicine, Weill Cornell Medicine, New York, NY,[7]Department of medical biology and pathology, Gustave Roussy, Villejuif, France,[8]Institute of Chemistry and Biochemistry, Charite Cancer Comprehensive Center, Berlin, Germany,[9]Vall d'Hebron Institute of Oncology (VHIO), Barcelona, Spain,[10]Centre Leon Berard, Lyon, France,[11]Charite, Berlin, Germany

Background: Long-term survival in cancers with poor prognosis, such as metastatic pancreatic ductal adenocarcinoma (mPDAC), glioblastoma (GBM-IDHwt), and extensive-stage small cell lung cancer (ES-SCLC), is exceedingly rare. The ROSALIND study is designed to explore the biological factors that contribute to exceptional survival in these cancers by comparing multi-omic and clinical profiles of long-term survivors (outliers) with those of patients who exhibit standard survival outcomes. By building a comprehensive clinical and molecular database, the study aims to identify novel therapeutic targets that could benefit a broader cancer population.
Methods: ROSALIND is a retrospective, multi-center, case-control study conducted across three cohorts: mPDAC, GBM-IDHwt, and ES-SCLC. Cases (long-term survivors) are defined as patients with survival exceeding 5 years for mPDAC and ES-SCLC, and 3 years for GBM-IDHwt. Controls are matched to cases based notably on tumor stage, age, sample type and treatment history, with overall survival in the control group centered around the median overall survival reported in pivotal clinical trials for each tumor type. Tumor samples from over 500 long term survivors and matched controls are undergoing multi-omic analysis, including genomics, transcriptomics, proteomics, microbiomics and radiomics, with centralized sample processing at Gustave Roussy Cancer Campus / Paris Saclay Cancer Cluster. The molecular profiling pipeline includes 10X Visium HD spatial whole transcriptomics, whole-genome sequencing (WGS) or Whole-exome sequencing (WES), bulk RNA sequencing (RNAseq), microbiomics (16s rRNA) and proteomics.
Results: As of October 2024, 135 patients have been enrolled in the ROSALIND study across three cohorts: 38 with ES-SCLC, 62 with GBM-IDHwt, and 35 with mPDAC. These patients were drawn from a global network of over 50 centers in 37 countries, and a total of 1211 outliers have been identified for potential inclusion. Molecular data collection is ongoing, with tumor and clinical data being curated into a centralized, multimodal database. The study aims to uncover key differences in molecular signatures between outliers and standard survivors, focusing on dysregulated pathways and proteins that may serve as novel therapeutic targets.
Conclusions: The ROSALIND study is pioneering the creation of an extensive, multi-omic and multimodal database of cancer outliers worldwide and at scale. By examining at the spatial and single cell level the biological underpinnings of exceptional survival in some of the most aggressive cancers, this study holds the potential to discover novel therapeutic targets. Future findings from ROSALIND could lead to the development of precision oncology treatments aimed at replicating the biology of long-term survivors, thereby improving outcomes for patients with poor-prognosis cancers.

#4998 Deriving patient similarity networks in myeloid neoplasms using multi-modal representation learning.

Georgios Asimomitis[1], Jake Sauter[1], Darin Moore[1], Himanshu Bhurtel[2], Katherine Lopez[2], Armaan Kohli[1], Kevin Boehm[1], Christopher Fong[1], Arfath Pasha[1], Luke Geneslaw[2], Anika Begum[1], Tom Pollard[1], Jacob Glass[3], Gregory M. [1]Halvorsen Center for Computational Oncology, Memorial Sloan Kettering Cancer Center, New York, NY,[2]Department of Pathology and Laboratory Medicine, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY

Myeloid neoplasms (MNs), such as Myelodysplastic Syndromes (MDS) and Acute Myeloid Leukemia (AML), are clinically overlapping hematologic malignancies. Their assessment includes the evaluation of bone marrow (BM) morphology, immunophenotyping by flow cytometry, cytogenetics, and gene mutation profiling. Established diagnostic criteria between the MN subtypes are primarily guided by empirical unimodal thresholds (i.e. 20% blasts differentiating MDS from AML) that may not always reflect the underlying disease biology. This study integrates different data modalities and produces patient-specific multi-modal views aiming to uncover associations between molecular subtypes and clinical phenotypes at the cellular and morphological level, show distinct biological and clinically relevant subgroups in MNs, and help inform future guidelines for disease classification.

The study cohort consists of 523 MSKCC patients across the spectrum of MNs. The dataset includes mutation and cytogenetic profiles, raw hematoxylin and eosin (H&E) BM whole slide images (WSIs), raw single-cell flow cytometry measurements, and differential cell type counts. Data for all modalities are present for 269 patients.

The flow cytometry and imaging data views were the products of in-house computational workflows. In flow cytometry, single cells were grouped in clusters by the Leiden algorithm. Then, the cell abundance distributions across these clusters were used to form patient-level representations. Our imaging framework first identified the cell-rich regions of the WSIs by training a tile-level vision transformer (ROCAUC: 0.95). After obtaining the encodings of the cell-rich regions from the QuiltNet foundation model (Ikezogwo et al. NeurIPS 2023), we trained a graph neural network (SlideGraph+, Lu et al. Medical Image Analysis 2022) to predict diagnostic labels (ROCAUC: 0.79), and we subsequently retrieved the WSI deep embeddings.

Different combinations of the unimodal views (genomics, flow cytometry, WSIs, differential cell types) were integrated into multi-modal embeddings through the Multiple Similarity Network Embedding (Xu et al. Methods 2021) method. Low dimensional projections and transformation of these embeddings to patient similarity graphs show the formation of homogeneous subgroups driven by somatic mutation status (i.e. TP53 mutated MNs), clusters defined by contributions of features across modalities, and the presence of out-of-group patients indicative of disease heterogeneity.

In summary, this work produces multi-modal patient embeddings in MNs and constructs patient networks indicative of both inter-patient similarity and heterogeneity. Characterizing the data-derived representations of disease profiles and the underlying inter-modality relationships will be critical for the future definition of diagnostic criteria that incorporate multi-modal measurements.

#4999 Multi-omics insights into the molecular signature and prognosis of hypopharyngeal squamous cell carcinoma.

Yanxin Ren[1], Wei Xiong[2], Chun Feng[3], Dan Yu[4], Xiaoyan Wang[5], Qing Yang[6], Siting Yu[2], Hongjiang Zhang[2], Bangyun Huo[3], Honglu Jiang[7], Zuli Li[8], Junlin Wang[4], Yu-Xiong Su[9], Ping Yang[10], Yong Liao[8], Qi Zhong[5], **Junwen Wang**[4]

Approximately two-thirds of hypopharyngeal squamous cell carcinoma (HPSCC) are diagnosed in advanced stage, with the worst prognosis among head and neck squamous cell carcinomas (HNSCCs). Identifying biomarkers for high-risk patients who need aggressive treatment is crucial. We present mutational, transcriptomic and proteomic studies of 103 Chinese HPSCC patients, observing a higher prevalence and poorer prognosis in males comparing to females. Genes in estrogen response pathways are up-regulated and proteins phosphorylated by protein kinase C (PKC) and Cyclin-dependent kinases (CDKs) are aberrantly regulated. We identify aberrant copy number regions including *SOX2* (3q26.33),*FGFR* (8p11.23), *CCND1* (11q13.3), *CDKN2A/2B* (9p21.3), and *MYC* (8q24.21). HPV status combined with highly mutated genes as predictive markers was assessed, including *SYNE1* in HPV(-), *MUC4* in HPV(+) patients. We confirm the presence of four known gene expression (GE) subtypes of HNSCC in our HPSCC cohort and present the genomic alterations, patient characteristics and survival status of each subtype. A predictive model involving clinical factors and transcriptomic expression of six genes was established and cross-site validated. The findings open new opportunities for stratifying high-risk patients and molecular targets for novel therapeutic strategies.

#5000 Single cell and spatial mapping of the fallopian tube with insight into origin of high grade serous carcinoma.

Sahar Nasr[1], Jacob Gutierrez[2], Caleb Iareau[3], Brooke Howitt[1]

[1]Pathology, Stanford University, Palo Alto, CA,[2]Cancer Biology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Memorial Sloan Kettering Cancer Center, New York, NY

High-grade serous “ovarian” carcinoma (HGSC), the most lethal gynecologic cancer, typically presents at advanced stages owing to lack of symptoms in early-stage disease. Additionally, no effective screening strategies exist. Despite the misnomer, most HGSC arise from fallopian tube epithelium (FTE). Better understanding early steps in pathogenesis of serous tubal intraepithelial carcinoma (STIC) and cell of origin for HGSC will inform early detection strategies and lead to new insights for effective screening approaches. HGSC and STIC are characterized by TP53 mutation and chromosomal instability. Earlier lesions in the FTE, such as “p53 signatures,” benign lesions harboring TP53 mutation, are less well understood. We aimed to study STIC, p53 signatures, and the benign FT at the single cell and spatial level, considering not only epithelial and lesional cells but also the surrounding stromal and immune microenvironment.
We employed single-cell RNA sequencing (scRNA-seq) in combination with single-nuclei RNA sequencing using 10x flex and single-cell spatial transcriptomics (scST), on formalin-fixed paraffin-embedded (FFPE) tissues to analyze normal and neoplastic fallopian tubes. scST data from 84 fields of view representing 8 patients (5 benign, 3 STIC) were used to define epithelial subtypes within the FTE, considering both gene expression profiles and spatial distributions correlating to histopathological findings. Furthermore, scRNA-seq data from fresh non-neoplastic FT and FFPE STIC samples were integrated to construct comprehensive atlases. The epithelial subtypes within the scST data were mapped on to the integrated atlas using gene module scores.Seven distinct epithelial subtypes were identified, with transcriptional diversity linked to HGSC precursors. Subtype-specific gene expression profiles were linked to histological features, revealing cellular heterogeneity in normal epithelium in contrast to clonal expansions and STIC. In the microenvironment, we found epithelial subtype-specific stromal and immune interactions. Furthermore, four subclusters of macrophages were identified with distinct expression programs; some subtypes were only abundant in association with STIC. We implemented scST in clinical FT samples including STIC, and integrated ST features with a large atlas of scRNA-seq data to refine single cell characterization of benign FT, p53 signatures, and STIC. Our spatially informed analyses recognized distinct subsets of epithelial, immune, and stromal cells that change over the course of STIC/HGSC development. Additionally, the trajectory of epithelial subtypes demonstrates the most likely epithelial cell subtype from which STIC may form. Our integrated FT atlas provides a critical resource for others seeking to understand early events in HGSC pathogenesis, advancing early detection and therapeutic strategies.

#5001 Multimodal topic modeling for single-cell multiomics.

Cigdem Ak, Nicole Szczepanski, Aaron Doe, Gurkan Yardimci

Oregon Health & Science University, Portland, OR

Single-cell (sc) multiomics assays simultaneously measure transcriptomic, epigenomic, and proteomic modalities in single cells. These multimodal assays enable deeper characterization of cells compared to single-omic assays by offering a more comprehensive measurement of the cell state. Additionally, they can identify cross modality associations, such as promoter-enhancer linkages. Recently, numerous computational methods for sc-multiomics data have been released; however, there is a dearth of interpretable methods While matrix factorization and deep learning approaches, such as MOFA+ and scVI, are effective at cell type clustering; however, these methods are difficult to interpret, masking the underlying biology that defines cell states. Our solution, EpiConfig, is a multimodal topic model that can accurately cluster cells based on cell types and yields biological insights by jointly modeling transcriptomic and epigenetic states combinations. Unlike other sc-multiomics topic models, EpiConfig explicitly models cross modality associations. Furthermore, we describe important cell filtering and subsetting approaches to speed up and improve the convergence of topic model. Benchmarking EpiConfig on publicly available scRNA+ATAC datasets to healthy and cancerous cell populations, we show that EpiConfig outperforms competing methods, such as Cobolt and MOFA. Furthermore, EpiConfig cross modality associations cell type capture 3D genome interactions. Modeling sc-multiomics data from lymphoma, EpiConfig identifies topics for cancerous cells. Coupled with our model interpretation R Shiny app, EpiConfig allows for the interpretation and identification of associations between transcriptomic and epigenomic features that define cell types and states.

#5002 Multi-omics insights into the role of clonal hematopoiesis in multiple myeloma.

Jeongmin Park[1], Ja Min Byun[2], Dong-Yeop Shin[2], Junshik Hong[2], Sung-Soo Yoon[2], Siddhartha Jaiswal[3], Youngil Koh[2]

[1]Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea, Republic of,[2]Seoul National University Hospital, Seoul, Korea, Republic of,[3]Department of Pathology, Stanford University School of Medicine, Stanford, CA

Multiple myeloma (MM) is a cancer involving the abnormal proliferation of malignant plasma cells in the bone marrow (BM). Clonal hematopoiesis (CH), a condition involving the clonal expansion of blood cells due to somatic mutations, is commonly observed with aging. However, its precise role in the pathogenesis of MM remains unclear. This study hypothesizes that CH influences MM cells and the microenvironment through paracrine mechanisms, thereby contributing to disease progression and treatment resistance. Using UK Biobank data, somatic CH variants were called, excluding those with a variant allele frequency (VAF) < 0.02, and analyzed them against ICD-10 codes. Hazard ratios (HR) were computed through Cox proportional regression, adjusting for covariates. Single-cell multi-omics (scDNA) sequencing was performed on BM aspirates from two MM patients, followed by cell type annotation and CH mutation subtyping using the MissionBio Mosaic pipeline. Exosomes were extracted from BM samples of 30 MM patients, and exosome small RNA sequencing was conducted. Differential expression of miRNAs was identified, and a computational tool was used to predict and integrate the target genes and pathways regulated by the differentially expressed miRNAs. Single-cell RNA (scRNA) sequencing was performed on BM sample from 12 MM patients, with data analyzed using the Seurat pipeline. Proteomics analysis using UK Biobank data was performed on a cohort of 190 MM patients identified based on ICD-10 codes. Differentially expressed protein and pathway analyses were conducted using OlinkAnalyze R package. Survival analysis conducted using the UK Biobank cohort revealed that the presence of CH was significantly correlated with MM diagnosis (HR: 1.64, CI: 1.35-2, $P < 0.001$), and CH in MM impacted EFS (HR: 1.61, CI: 1.25-2.1, $P < 0.001$). The results of the scDNA analysis revealed that approximately 88% of CH-mutated cells were distributed within myeloid cells, suggesting potential indirect effects on MM through paracrine interactions. Exosomal miRNA analysis of 30 MM patients revealed a significant reduction in miRNAs targeting the MAPK and JAK-STAT pathways (KEGG, $P < 0.005$), indicating dysregulation of oncogenic and inflammatory signaling in individuals with CH. scRNA analysis identified the activation of inflammatory pathways in CD14+ monocytes of individuals with *TET2* and *DNMT3A* mutations, including the MAPK pathway (GOBP, adj$P < 0.05$) and cytokine interactions (KEGG, adj$P < 0.05$). Proteomics analysis using Olink data from 190 MM patients in the UK Biobank further validated the activation of inflammatory and oncogenic pathways, including MAPK pathway (GOBP, adj$P < 0.05$), STAT pathway, and cytokine-cytokine receptor interactions (KEGG, adj$P < 0.05$), in CH-positive MM cases. These findings highlight the potential for CH mutations, particularly in *TET2* and *DNMT3A*, to exacerbate MM progression through inflammatory paracrine mechanisms.

#5003 Machine-learning informed multifactorial biomarkers as an approach to stratify survival outcomes among ADC treated patients.

Anna Shcherbina, Yajas Shah, Zachary McCaw, Yang Su, Serra Elliott, David Light, Angela Oliveira Pisco, Sanjana Narayanan, Chaya Wurman, Vincent Luckzow, Christopher Probert, Sacha Holland, Virginia Donovan, Peter Szabo

Insitro, South San Francisco, CA

As oncology treatments increase in molecular complexity, the need for biomarkers continues to grow. This becomes critical in treatments such as antibody-drug conjugates (ADC's), which are a promising targeted anti-cancer therapy, that not all patients respond equally well to. Though prior work suggests that patients who over-express ADC targets relative to those that do not are more likely to benefit from ADC therapy, a robust biomarker signature that predicts response has yet to be defined for most ADCs. To address this unmet need, we developed an approach to impute composite warhead-target ADC biomarkers from digitized histopathology (H&E) slides.

The first component of this biomarker signature is a machine learning model that imputes ADC target RNA expression from histopathology slides. Flash frozen and FFPE histopathology slides from 11,115 patients in The Cancer Genome Atlas (TCGA) and 2,732 patients from Aster across 32 tumor types were embedded to a lower dimensional representation via the DINO ViT model. A multilayer perceptron (MLP) was trained within each tumor type to predict transcriptome-wide gene expression (19,421 protein-coding genes) from these embedding vectors, achieving a mean spearman r = 0.20+/-0.17 across all genes (mean pearson r = 0.21+/-0.18), and a mean spearman r = 0.32 +/-0.17 across the top 1000 genes across cohorts. Improved performance was observed when imputing a weighted sum of expression for transcriptomically correlated genes (as ascertained via differential expression analysis) for a suite of 346 known candidate ADC targets.

The second component of the biomarker signature focuses on stratifying longitudinal outcomes in patients treated with topoisomerase 1 (TOP1) inhibitors. We developed a gene signature (weighted mean expression of 52 genes) based on treatment response in cell lines (GDSC2) and therapy-agnostic patient gene expression profiles (TCGA, Aster). Additional weighting based on cross-modality evidence was employed. The resulting signatures were associated with longitudinal endpoints in primary and metastatic colorectal cancer patients. An MLP was subsequently trained within the TCGA and Aster cohorts to impute the TOP1 signature from H&E datasets, achieving cross-validation spearman correlation of 0.42 within the COAD-READ cohort and a spearman R of 0.29 in a held-out MRC FOCUS test set (N=73).

In summary, the combined warhead-target imputation signature shows promise in stratifying likely ADC treatment responders from non-responders. Given that assays directly measuring gene expression at the bulk and single cell level are still seldom used in the clinic, this imputation model may provide a useful tool to leverage H&E imaging routinely performed as part of patient diagnosis as a tool to inform treatment selection.

#5004 Application of a comprehensive multi-omic immune profiling strategy achieves superior checkpoint immunotherapy response prediction in lung cancer.

Helen M. McGuire[1], Natalie Smith[1], Michael Cohen[2], Julien Hedou[3], Gregoire Bellan[3], Xavier Durand[3], Erika L. Smith-Mahoney[4], Julie Alipaz[2], Jennifer Snyder-Cappione[4], Brice Gaudilliere[3], Christina Loh[2], David King[2], Michael Hinterberg[2], Clare Paterson[2], Barbara Fazekas de St Groth[1]

[1]The University of Sydney, Sydney, Australia,[2]Standard BioTools, San Francisco, CA,[3]SurgeCare, Paris, France,[4]Boston University Chobanian, Boston, MA

Immune checkpoint inhibitors (ICIs) are currently the most effective treatment for late-stage lung cancer. However, most patients fail to mount a durable response, and the mechanisms underlying non-responsiveness remain elusive. Here, we apply a universal omics approach to identify correlates of non-responsiveness to ICIs in lung cancer. In-depth characterization of the plasma proteome was performed using the SomaScan™ platform on pretreatment and longitudinal blood samples from 40 ICI-treated patients, resulting in quantification of 10,000 unique proteins. In parallel, comprehensive immune phenotyping was achieved with matched pretreatment PBMC for 90% of patients (36/40) through CyTOF™ technology, with a 38-plex panel describing over 150 immune populations in circulation. To enhance clinical outcome predictability of cellular and plasma-based immune relationships, cross-platform data integration was achieved with Stabl, a sparse, reliable omic biomarkers analysis strategy. Stabl identified key predictive features from both CyTOF and SomaScan technology, providing insight into immune deficits present in non-responsive patients. The combined model demonstrated a stronger capability to predict non-response from a pretreatment blood sample (AUROC = 0.79, p-value = 1.7e-2, Mann-Whitney non-parametric test) compared with individual platforms alone. Additionally, this multi-omic strategy is compatible with Imaging Mass Cytometry™ technology, unlocking another layer of clinical investigation via spatial biology. This study ultimately demonstrates both the clinical impact and utility of blood- and imaging-based CyTOF technology and the benefit of combining SomaScan and multi-omic-appropriate analysis approaches. Overall, robust treatment prediction, attributed to biomarker features, provides insights into mechanisms for non-response and highlights the potential for better treatment options in lung cancer.

#5005 Integrative multi-omics characterization of syngeneic tumor models.

Zihan Xu, Binchen Mao, Wubin Qian, Xiaobo Chen, Sheng Guo

Crown Bioscience, Inc., Suzhou, China

Background: Mouse syngeneic models are widely used to study tumor-immune interactions and evaluate the efficacy of immunotherapies. Proteins serve as a link between the genetic code and phenotype, and can better reflect the dynamic state of a cell. However, the large-scale profiling of proteomics and phosphoproteomics data using syngeneic models has been limited. This study aims to reveal molecular mechanisms underlying tumor development and therapeutic response using multi-omics data generated from syngeneic models.
Methods: Untreated fresh tumor tissues (around 500 mm^3) from 12 mouse syngeneic models (H22, EMT6, Hepa16, CT26, MC38, Pan02, A20, Renca, RM1, LL2, B16F10 and B16BL6) were collected. Tissues were analyzed using RNA-seq, proteomics and phosphoproteomics. Efficacies of immune checkpoint inhibitors (ICIs) including anti-PD-1 (RMP1-14), anti-PD-L1 (10F.9G2) and anti-CTLA4 (9D9 and 9H10) were tested in each model over a period of 2-3 weeks. Tumor growth inhibition (TGI) values were calculated as: $TGI = 1 - \Delta T(t)/\Delta C(t)$, where $\Delta T(t)$ and $\Delta C(t)$ represent average changes in tumor volume from the start of experiment to time t in the treatment and vehicle group, respectively. Models with TGI>=0.45 for at least two ICIs were defined as “responder”, while models with TGI<=0.40 for all ICIs were defined as “non-responder”. Tumor purity scores were inferred with the ESTIMATE software. Differential Expressed Genes (DEGs), Differentially Expressed Proteins (DEPs) and Differentially Phosphorylated Sites (DPSs) were calculated with the limma package. Gene Set Enrichment Analysis (GSEA) was performed using the clusterProfiler package. Kinase Substrate Enrichment Analysis (KSEA) was finished using the KSEAapp package. Network analysis was performed with the STRINGdb package.
Results: Estimation of stromal and immune cells using specific genes with transcriptomics and proteomics data revealed that B16BL6 and B16F10 models had the highest tumor purity and low percentage of immune and stromal cells, while A20 model had more immune cell infiltration, and other solid tumor models had relatively higher stromal cell percentage. Next, at RNA and protein levels, genes positively correlated with the drug efficacy were enriched in interferon related pathways and immune response pathways for all ICIs. Furthermore, Dnmt3a and Igfr2 were identified as potential resistant biomarkers for immunotherapy efficacy. Finally, a user-friendly website was designed for both direct acquisition of results generated in this study and deep exploration by simply clicking to choose combinations of parameters and generate new results.
Conclusion: This study presents a comprehensive integrated multi-omics analysis using transcriptomics, proteomics and phosphoproteomics data collected from 12 widely used mouse syngeneic models, which provides insights into molecular mechanisms and pathways involved in tumor development and therapeutic response.

#5006 Multi-modal large language models for metastatic breast cancer prognosis.

Raphael Pelossof, Mark Carty, Talal Ahmed, Stanislas Lauly, Alberto Purpura, Erik Mueller, Justin Guinney

Tempus AI, Chicago, NY

Inputs into cancer prognostic models are primarily structured data such as demographic and clinicopathological features, and lack richer and temporal context often found in unstructured clinical notes. We hypothesize that creating a temporal clinical patient note from structured data that preserves longitudinal and clinical contextual information, and coupling it with a large language models (LLM) that is trained to prognosticate overall survival (OS), may improve model accuracy with an interpretable embedding space.

We developed the Patient Chronological Note (PCN), an algorithm that converts structured data elements into textual strings, mirroring physician notes of patient histories. A bidirectional large language model, was pre-trained using PCNs from breast cancer patients (N=580,000), allowing the LLM to learn a representation of the patient journey. The resulting embeddings were fed into a fully-connected 2-layer network that was fine-tuned using Cox survival loss. Fine tuning was performed on PCNs derived from mBC patients (N=28,500), where the model was trained to predict OS from the time of first metastatic diagnosis. A held-out validation dataset of mBC patients (n=28,800) was used to validate survival prediction accuracy.

Our LLM-Cox model achieved a prediction performance of 0.66 (concordance index) on the validation cohort, outperforming a standard linear cox model that achieved 0.62. A marginal effect analysis showed that features associated with metastasis, medications, and patient demographics were most important in prediction performance while hormone receptor status and sequencing information were less important.

Clustering the LLM embeddings revealed 10 distinct patient groups enriched for key mBC traits, including a high-risk cluster enriched for triple negative status, TP53 mutations, and African American race, a low-risk cluster enriched for ESR1 mutations and CDK46 treatment, and a cluster enriched for low-risk early-onset patients. The different clusters showed different prognostic risk levels.

LLM-Cox model learning from PCNs can improve prediction performance over standard models. The internal embedding representation of the LLM was interpretable, and yielded distinct clinical-molecular subtypes that also showed distinct levels of prognostic risk. Furthermore, creating LLM-based clinical-molecular groups of patients with similar journeys and similar prognostic risk presents an opportunity to identify novel stratifications within each group that are associated with treatment-specific responses and not prognostic risk.

#5007 Integrated histology-genomic multimodel deep learning to predict prognosis in non-small-cell lung cancer.

Yang Xu, **Haimeng Tang**, Xue Wu, Qiuxiang Ou

Nanjing Geneseeq Technology Inc., Nanjing, China

Background: Deep learning (DL) provokes a paradigm shift in deciphering high-dimensional data for various clinical applications, and multimodal DL approaches show significant potential to integrate diverse datasets and enhance prediction accuracy. Despite these advancements, multimodal DL remains underutilized in prognostic assessment, particularly for non-small-cell lung cancer (NSCLC) patients.
Methods: We analyzed whole-slide imaging (WSI; approximately 6,000 slides and ~40,000,000 image tiles), whole exome sequencing (WES), and overall survival (OS) data from 2,366 NSCLC patients sourced from various online databases. A Sequential-Adapted Attention (SeAttn) model was developed to process WSI data, while multiple DL models were trained to analyze WES data and clinical features. Multimodel DL was then used to combine these learned features to predict long-term OS outcomes. The model was further confirmed using a validation (N=100) and a held-out test (N=101) cohort.
Results: The SeAttn model exhibited strong predictive power for NSCLC histological subtypes, achieving an area under the curve (AUC) of 0.98 in the test cohort (P<0.0001). SeAttn-derived WSI features, baseline clinical characteristics, as well as WES-based genetic features were used individually to predict OS, yielding concordance indices (C-indices) ranging from 0.55 to 0.67. The combination of these multimodal features using a COX-based DL approach further improved the test cohort C-index to 0.71 (95% CI 0.14, P=0.002), with WSI, mutation gene-sets, and baseline clinical data as the top contributors. Notably, our multimodal DL model accurately predicted prognosis for up to 5 years post-diagnosis (P<0.05 for all time-dependent AUCs within 5 years in both validation and test cohorts), and our model could significantly stratify patients based on their OS (P=0.012 in the test cohort). Additionally, we identified and validated novel prognostic markers, including some genetic mutations, co-deletions, and amplification of two microRNA clusters.
Conclusion: Our multimodal deep learning model demonstrates substantial predictive capacity for prognosis in NSCLC patients, providing a robust framework for integrating diverse clinical, genetic, and imaging data to yield accurate survival estimates and uncovering clinically relevant biomarkers to guide risk stratification. Our findings underscore the broader promise of multimodal DL, offering a scalable and data-driven approach that can be adapted for other cancers.

#5008 A multi-dimensional vision-language deep learning model for radiology and pathology imaging.

Marta Ligero, Tim Lenz, Jakob Nikolas Kather

Technische Universitat Dresden, Dresden, Germany

Multimodal vision-language models (VLM) have shown promising biomarker classification performance in individual data modalities such as radiology and pathology. By learning joint representations of visual and textual information, these methods have shown to provide better features from medical images. However, current methods are limited to the multimodal landscape of 2D images in radiology and pathology, leaving a substantial gap for the creation of models with 3D data. In this study, we introduce a novel, multimodal VLM that can process both radiology and pathology images of varying dimensionalities. Our approach processes 3D CT reconstructions and 2D digitized hematoxylin- and eosin-stained histology slides simultaneously, learning a joint representation which is applicable for biomarker classification in either modality. Our zero-shot approach was validated using two distinct datasets, eliminating the need for model fine-tuning. The first evaluation assessed whole-body CT lesion classification across multiple organs (lung, liver, kidney, and soft tissue) in 839 patients. The second evaluation focused on distinguishing between lung adenocarcinoma and squamous cell carcinoma in 974 patients. The model achieved an average Area Under the Receiver Operating Characteristic (AUROC) curve of 0.70 for lesion detection and 0.60 for lung cancer subtyping in a zero-shot setting. Our findings demonstrate the potential of multimodal vision-language models to perform medical image analysis without task-specific training, which offers a promising direction for developing more flexible and generalizable image processing and multimodal integration towards an artificial intelligence-driven molecular tumor board.

#5010 High-resolution multi-omic dissociation of brain tumors with deep multimodal autoencoder.

Jiao Sun, Yue Pan, Tong Lin, Kyle Smith, Arzu Onar-Thomas, Giles W. Robinson, Wei Zhang, Paul A. Northcott, Qian Li

St. Jude Children's Research Hospital, Memphis, TN

Single cell technology measures multi-dimensional molecules at cellular resolution in cancer biology with challenges of low coverage and cell annotation. The inherent heterogeneity and complexity of central nervous system (CNS) tumors may hinder single-cell multi-omic profiling in large population-based studies. An alternative and efficient approach is digital dissociation, i.e., cell abundance quantification and high-resolution prediction of cell-type-specific (CTS) bulk samples. Many tools were developed to resolve mixture bulk transcriptomes by integrating scRNA-seq reference, not immediately transferable to other omics (e.g., chromatin accessibility, DNA methylation) because of ambiguous cell marker identification.

We develop MODE - a novel multimodal autoencoder neural network with parallel decoders - to purify CTS multi-omic profiles and estimate the multimodal cellular compositions. MODE is trained on the large-scale pseudo bulk multiomes constructed by probabilistic data generation with an external scRNA-seq reference and individualized non-RNA reference panel recovered from the target tumors. The CTS differentially expressed genes (ctsDEGs) in purified transcriptomes were detected by Wilcoxon rank-sum test with false discovery rate corrected, while survival analysis was performed by log-rank test.

MODE was benchmarked in an extensive simulation study generating realistic multiome from normal and tumor brain tissues, showing outperformance and superior replicability over the competing deconvolution pipelines. The purified CTS multiomes exhibited high resolution and fidelity with enhanced robustness in detecting ctsDEGs. We applied MODE to the bulk methylome-transcriptome in two independent brain tumor studies, recovering modality-specific cellular landscape for pediatric medulloblastoma (MB) and adult glioblastoma multiforme (GBM). The embryonal lineage cells for MB tumor groups were accurately recovered, i.e., Group 3 (G3) MB tumors having the origin of rhombic lip (RL) stem cells ($P < 10^{-5}$) and Group 4 (G4) arising from unipolar brush cells ($P < 10^{-5}$). Notably, hundreds of marker genes for RL or granule neuron progenitor cells identified in human fetal cerebellum were differentially expressed among (n=253) Sonic Hedgehog, G3, G4 MB patients in the corresponding lineage-specific tumor transcriptomes predicted by MODE. The results in TCGA GBM cohort showed higher abundance of myeloid cells in either methylation (P=0.002) or mRNA (P=0.019) being associated with poorer event free survival, while increased tumor purity delayed (P=0.009) the relapse or progression of GBM tumor.

Overall, the high-resolution multimodal dissociation by MODE elucidates the origins, evolution, and prognosis in pediatric and adult CNS tumors, without the need for large-scale single cell multimodal profiling. MODE is freely available at https://github.com/jsuncompubio/MODE.

#5011 Integrating multimodal data with survival-based variational autoencoders to predict recurrence-free survival in breast cancer.

Sydney Grant, Aritro Nath

Medical Oncology & Therapeutics, City of Hope, Duarte, CA

Breast cancer is the most commonly diagnosed malignancy globally and responsible for over 670,000 deaths each year. Accurate prediction of recurrence-free survival (RFS) is crucial for clinical management and personalized care in breast cancer, enabling improved surveillance, risk stratification, and optimized therapy selection. Although extensive multi-omic data from next generation sequencing tests have been collected, there is a notable gap in clinically relevant models that leverage advanced artificial intelligence-based approaches that integrate multiple data modalities. Variational autoencoders (VAEs) have been used to compress omics datasets into lower dimensionality, however the latent dimensions extracted from VAEs typically lack biological significance, hindering interpretation and the performance of downstream predictive modeling. To address this pitfall, we have developed a VAE with a built-in survival model. Our approach uses the performance of the survival model to iteratively optimize the VAE, generating latent dimensions which are relevant for predicting RFS. We developed our model by extracting latent features from approximately 800 breast cancer cases from METABRIC split into training and test datasets. Gene expression, MSigDB pathway enrichment scores, CNAs, and SNV/Indels were used to train four separate VAEs. The model's encoder compressed high-dimensional omic datasets into a set of latent dimensions, while the decoder then used the latent dimensions to reconstruct the original data; simultaneously, linear representations of the latent dimensions were used as inputs to a cox regression model. The reconstruction loss, Kullback-Leibler divergence, and negative partial log likelihood based on the survival model were used to reparametrize the VAE during each training iteration. Final models for each modality were selected based on survival prediction on the test dataset with c-index ranging from 0.61-0.65. A cox regression model was fit based on a combined dataset of the latent dimensions from each model, and clinical data from each patient. To assess the ability of our model to stratify high- and low-risk patients, an optimal cut-off was established based on the linear predictors of the cox regression model in the training dataset. There was a significant difference in survival between high- and low-risk groups in both the training ($p < 0.0001$) and the test ($p < 0.0001$) cohorts. The 5-year survival rates of high- and low-risk groups were 30.7% vs 88.9% in the training dataset and 60.5% vs 87.8% in the test dataset. Overall, our survival-based VAEs successfully extracted relevant latent dimensions for prediction of recurrence-free survival in breast cancer patients. Further implementation of our model may be used to predict treatment-specific response, helping clinicians make informed treatment decisions for cancer patients.

#5012 Multi-omics signature for estimating survival time in breast cancer patients.

Srinivasulu Yerukala Sathipati[1], Manya Reddy Elugoti[2], Rachel Tillman[3], Scott Hebbring[4], Rohit Sharma[5]

[1]Marshfield Clinic Research Institute, Marshfield, WI,[2]Edison Academy Magnet School, Edison, NJ,[3]Department of General Surgery, Marshfield Clinic Health System, Marshfield, WI,[4]Center for Precision Medicine Research, Marshfield Clinic Research Institute, Marshfield, WI,[5]Department of Surgical Oncology, Marshfield Clinic Health System, Marshfield, WI

Introduction: Predicting survival outcomes for breast cancer patients is critical for tailoring personalized treatments. However, effectively integrating multi-omics datasets for survival estimation is a persistent challenge due to the high dimensionality and complexity of the data. To address this, we developed the Multi-Omics Survival Time Estimator (MOST), a novel machine learning framework designed to accurately predict survival time by leveraging multi-omics data.
Methods: MOST employs a multi-step pipeline combining stringent feature selection, evolutionary learning, and survival estimation. Using datasets encompassing copy number variations (CNV), microRNA (mRNA), mRNA, and reverse-phase protein array (RPPA) data, the platform identifies a concise yet informative set of biomarkers that contribute to survival time prediction. Feature selection was optimized to ensure relevance and robustness, while evolutionary algorithms enhanced predictive accuracy. The model was rigorously validated to ensure reliability and generalizability.
Results: MOST identified a 38-feature multi-omics signature capable of predicting survival time with a correlation coefficient (R) of 0.90 and mean absolute error (MAE) of 1.06 year between predicted and actual survival times. The top 10 features contributing to the prediction included ENSG00000145826.7 and ENSG00000101624.9 from CNVs; hsa-miR-3928 and hsa-miR-326 from miRNAs; KIAA1199, SYT10, PSG3, ACTG1, MYPN from mRNAs; and GUSP4 from RPPA data. These results emphasize the role of integrated genetic, epigenetic, and proteomic markers in defining patient survival. MOST demonstrated superior predictive performance compared to existing methodologies.
Conclusions: MOST offers a machine learning framework for integrating multi-omics data to predict survival outcomes in breast cancer patients. Its ability to identify a robust multi-omics signature establishes a foundation for future exploration of multi-omics data across other cancers, reinforcing its clinical relevance and potential translational impact.

#5013 The interplay of genomic aberrations, transcriptional states, and therapeutic responses in lung cancer.

Hanbyul Cho[1], Noshad Hosseini[1], Yi Hsiao[1], Rahul Mannan[1], Chandan Kumar-Sinha[1], Yuping Zhang[1], Gabriel Cruz[1], Yamei Deng[1], Taiwan Cancer Moonshot Program and Clinical Proteomic Tumor Analysis Consortium, Natalie Clark[2], Shankha Satpathy[2], Gilbert S. Omenn[1], Yu-Ju Chen[3], Michael A. Gillette[2], Marcin P. Cieslik[1], Saravana M. Dhanasekaran[1], Alexey I. Nesvizhskii[1], Arul M. Chinnaiyan[1]

[1]University of Michigan, Ann Arbor, MI,[2]Broad Institute of MIT and Harvard, Cambridge, MA,[3]Academia Sinica, Taipei, Taiwan

Lung cancer leads cancer-related deaths worldwide, with 2024 estimates of 234,580 new cases in the United States. This study explores the roles of tumor driver aberrations, epithelial transcriptional states, and microenvironment composition in lung cancer outcomes using proteogenomic data from 965 patients across the Clinical Proteomic Tumor Analysis Consortium (CPTAC) and International Cancer Proteogenome Consortium (ICPC). We examined oncogenic alterations, epithelial and stromal cell type enrichment distributions, transcriptional modules activities, and drug sensitivities in lung adenocarcinoma (LUAD), squamous carcinoma (LUSC) and adenocarcinoma with no conventional drivers (NCD-LUAD).LUAD tumors displayed mutual exclusivity in RAS/Receptor Tyrosine Kinase (RTK) pathway aberrations, complemented by significant patterns of co-occurrence and exclusivity in tumor suppressor genes like TP53, STK11, RBM10, and CDKN2A. Our integrative analysis used gene expression from single-cell RNA-seq (scRNA) derived cell types reference and CPTAC bulk RNA/proteomic data for correlation-based estimation of epithelial/stromal cell type enrichment. We assembled scRNA references from 3 different studies that profiled normal tissues containing, 142 cell types from 38 tissue types, 20 stromal cell types from 11 tissues, and lastly exclusive lung cell types reference respectively. We found significant enrichment of AT2 and Club cells in LUAD tumors (p-value < 0.0001), in addition heterogeneity in epithelial cell type enrichment within each driver group. Patients enriched for AT2 and AT1 cells demonstrated better survival outcomes (p-value < 0.0001) while, secretory Goblet and Basal cells enrichment was associated with poor survival (p-value < 0.0001), underscoring the potential link between tumor transcriptional / differentiation states and prognostic implications. NCD-LUAD showed similar epithelial cell type enrichment patterns like LUADs with known drivers while LUSC tumors show predominant basal cell enrichment. Importantly we saw specific transcriptional modules (up: E2F1,MYBL2, down: NKX2-1, NFE2L2) and cell type enrichment differences in genome unstable (high copy number burden) tumors associated with poor survival. Finally, enrichment of a myofibroblast subtype associated with survival and immune infiltration status, warrants further investigation. Cell line drug sensitivity analysis showed that the RTK-altered group with poor response to targeted therapy was enriched with undetermined differentiation transcriptional status compared to more defined cell type enrichments in the good response group (p-value = 0.016). Our study underscores the importance of multi-dimensional integrative analysis approaches of molecular, cellular, and pharmacological data to understand and advance lung cancer biology, potential cell of origin, and therapeutic strategies.

#5014 Integrative molecular and spatial analysis to reveal tumor intrinsic and extrinsic drivers of immunotherapy response in mucosal melanoma.

Yingxiao Shi[1], Tuulia Vallius[2], Aikaterini Dedeilia[3], Roxanne Pelletier[2], Jia-Ren Lin[2], Mariana Lopez Leon[2], Christine Lian[4], Shishir Pant[2], Giuseppe Tarantino[5], Annette Wang[6], Jiajia Chen[5], Elizabeth I. Buchbinder[7], Peter K. Sorger[2], David Liu[1], Genevieve M. Boland[3]

[1]Computational Oncology, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA,[2]Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA,[3]Department of Surgery, Massachusetts General Hospital, Boston, MA,[4]Department of Pathology, Brigham and Women's Hospital, Boston, MA,[5]Computational Oncology, Dana-Farber Cancer Institute, Boston, MA,[6]Massachusetts General Hospital, Boston, MA,[7]Medical Oncology, Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA

Background: Mucosal melanoma (MM) is a rare subtype of melanoma that responds poorly to immune checkpoint blockade (ICB), exhibiting low response rates and few durable responses. The biological mechanisms underlying ICB response and resistance in MM remain poorly understood, highlighting the need for novel therapeutic targets and biomarkers to improve patient outcomes.
Hypothesis: While most MM patients respond poorly to ICB, a subset of durable responders (DRs) exists. We hypothesize that DRs have distinct biological and genomic features compared to rapid progressors.
Methods: We performed multimodal analysis - including whole exome sequencing, bulk transcriptomics, H&E, and multiplexed Cyclic Immunofluorescence (CyCIF) imaging - on pre-treatment and post-progression tumor samples from 126 MM patients, with a focus on a subset of 80 patients treated with ICB to identify features associated with response.
Results: Our genomic analysis of 80 MM patients revealed that DRs (PFS 1 year) had significantly fewer copy number alterations (CNAs) compared to those with progressive diseases (PFS 6 months). The most common MM driver mutations were identified including *SF3B1*, *KIT*, *NF1*, and *NRAS*. Notably, *SF3B1* mutations were primarily found in anorectal primary tumors (10/17) and had fewer CNAs, a feature also observed in DRs, suggesting it may be associated with better ICB responses in MM. Bulk RNAseq analysis (n = 67) identified a tumor cluster enriched for epithelial-mesenchymal transition and hypoxia stress pathways, suggesting increased invasiveness and potential ICB resistance. These signatures were observed in 37% of our MM primary tumors, underscoring the aggressive nature of MM. CyCIF analysis of primary and metastatic MM lesions revealed increased $CD8^+$ T cells and $CD11C^+$ myeloid cells in metastatic sites. By defining the tumor/stromal border, we found fewer antitumorigenic $CD68^+$ macrophages in the tumor center but more at the tumor border at the metastatic site compared to the primary sites, suggesting immune exclusion. In sinonasal primary tumors, non-metastatic patients had fewer protumorigenic $CD163^+$ macrophages in both tumor center and border compared to those with distant metastases. Multimodal analysis of a longitudinally sampled MM patient treated with ICB showed distinct resistance clones associated with different microenvironments. Two lymph node metastases collected simultaneously after ICB showed clonal differences, with one (harboring a *SOX17* mutation) exhibiting lower $CD8^+$ T cell infiltration, suggesting the evolution of diverse resistance mechanisms.
Conclusion: Our preliminary findings suggest that distinct genomic features, tumor states, and microenvironments differentiated ICB response and disease progression in MM, highlighting key tumor-intrinsic and microenvironmental factors associated with patient prognosis.

#5016 Enhancing prostate pelvic multimodality data generating with conditional generative models: A Pix2Pix-based approach for MRI-to-PET synthesis.

Ruobing Liu[1], Shuo Wang[2], Shibiao Wan[3], **Jieqiong Wang**[1]

[1]Department of Neurological Sciences, University of Nebraska Medical Center, Omaha, NE,[2]Department of Radiation Oncology, University of Nebraska Medical Center, Omaha, NE,[3]Department of Genetics, Cell Biology & Anatomy, University of Nebraska Medical Center, Omaha, NE

Prostate cancer remains the second leading cause of cancer-related mortality among men globally, underscoring the critical need for early detection of treatment failure and effective assessment of metastatic risk. Positron Emission Tomography (PET), particularly with prostate-specific membrane antigen (PSMA) tracers, has demonstrated superior sensitivity for identifying prostate lesions, including metastases. However, the accessibility of PET imaging is often limited by its high costs and associated radiation exposure. To overcome these challenges, we developed a deep learning model to synthesize PET images from Magnetic Resonance Imaging (MRI) image, facilitating treatment response evaluation.High-resolution T2-weighted MRI and PSMA PET images acquired within a close timeframe were retrieved from 10 prostate cancer patients, who underwent definitive radiotherapy. The PSMA-PET scans were registered to the MRI images within the Eclipse (Varian Medical Systems), and the PET images were cropped to match the same size and resolution of MRI images, resulting in 321 pairs of MRI-PET 2D images. Preprocessing included grayscale transformation, z-score normalization, and pixel value inversion to enhance model learning. A Pix2Pix framework was implemented, employing a U-Net generator and a PatchGAN discriminator. The loss function used consisted of a combination of adversarial loss, to ensure the realism of the generated images, and L1 loss, to maintain pixel-wise consistency between the generated and target images. Model evaluation was performed using leave-one-out-cross-validation (LOOCV), where all slices from one patient was used for testing and the remaining 9 patients for training.The model achieved an average Peak Signal-to-Noise Ratio (PSNR) of 14.55 and a Structural Similarity Index Measure (SSIM) of 0.648. Although these quantitative metrics were moderate, qualitative evaluation demonstrated precise and clinically meaningful localization of lesions, offering utility for aiding physician visualization of high-risk regions.This study highlighted the feasibility of leveraging Pix2Pix-based conditional generative models for synthesizing PET-equivalent images from MRI data as a cost-effective alternative to enhance prostate cancer imaging. Future efforts will focus on expanding the dataset and investigating advanced architectures, including 3D-to-3D generative models and diffusion techniques, to further improve the accuracy of prostate lesion localization and clinical applicability.

#5017 A multimodal deep learning approach to predict survival in never smoking lung cancer patients.

M. Saha[1], T. Zhang[1], P. M. Bhawsar[1], W. Zhao[1], J. Shi[1], S.-R. Yang[2], J. S. Almeida[1], M. Landi[1];
[1]National Cancer Institute, Rockville, MD, [2]Memorial Sloan Kettering Cancer Center, New York, NY

Purpose: Lung cancer in never-smokers (LCINS) is the fifth most common cause of cancer deaths worldwide. Identifying subjects who need more aggressive treatment could greatly help improve survival rates. In this study, we investigated whether a multimodal deep learning approach could be used to predict overall survival in a large cohort of never smoking lung adenocarcinoma patients from the Sherlock-*Lung* study. We leveraged multiple datasets containing different modalities, including clinical, digital pathology (WSIs: whole slide images), and genomic (driver gene mutations in EGFR, KRAS, TP53, RBM10, as well as CDKN2A deletions, ALK fusions, and mutation patterns like Kataegis) data.
Method: The sample set contained 495 LCINS cases which were randomly split into training (60%), validation (15%), and testing (25%) sets. Tiles of 256 x 256 pixels were extracted from the WSIs and processed through a customized VGG-19 convolutional neural network. The output of this network was high-dimensional feature vectors representing morphological patterns in the tiles. Genomic and clinical data were modeled separately and then concatenated with the output of the CNN to generate a shared feature space, which was then modeled using a simple densely connected neural network. The final feature vector was then used to predict the risk score using Cox partial likelihood as the loss function. The risk predictor was then validated on the held-out test set. The above procedure was conducted with and without genomic data. We also conducted a gene-specific survival study across LCINS with different driver genes as well as restricting the analysis to stage I cases only.
Results: We achieved an index of 0.86 for the concordance between predicted mortality risk and actual survival time on the test set using both approaches, with and without genomic data. The Kaplan-Meier curves for low- and high-risk groups, with the cutoff for the risk score determined by the median value, showed distinct survival patterns - patients predicted to have low risk exhibited a higher survival probability compared to those with higher scores. The log-rank test yielded a p-value of ≤ 0.05 for overall and gene-specific survival, adjusting for stage and age. Heatmaps generated using the activation map of the image model highlighted non-tumor regions as low-risk regions and tumor regions as high-risk regions.
Conclusion: The multimodal approach strongly predicted overall survival across all stages and within stage I in LCINS. Specific driver gene mutations do not significantly enhance survival prediction, highlighting the benefits of modeling on multimodal information over using only molecular data. Such approaches for LCINS prognostication could be used in the future to guide effective treatment modalities.

#5018 Multiomic integration of DNA methylation, DNA hydroxymethylation, and gene expression in clear cell renal cell carcinoma.

Yiping Li, Brock C. Christensen, Lucas A. Salas

Dartmouth College, Hanover, NH

Background

DNA methylation (5-methylcytosine -5mC) and DNA hydroxymethylation (5-hydroxymethylcytosine -5hmC) are critical epigenetic modifications for understanding gene expression in clear cell renal cell carcinoma (ccRCC). While 5mC and 5hmC modifications may influence promoter and enhancer regions differently, their distinct roles in gene regulation remain unclear. Integrating RNA sequencing (RNA-seq) data with 5mC and 5hmC analyses enables a multiomic understanding of gene regulation, revealing critical changes associated with ccRCC progression. This study integrates 5mC, 5hmC, and RNA-seq data to identify genes and transcriptional regulators driving ccRCC by comparing tumor and normal samples.

Methods

We analyzed 188 ccRCC samples from the Dartmouth Renal Tumor Biobank using the Infinium MethylationEPIC BeadChip to differentiate 5-methylcytosine (5mC) from 5-hydroxymethylcytosine (5hmC) via bisulfite and oxidative bisulfite tandem conversion. Whole RNAseq data was obtained from the same samples. Briefly, we used ENmix to process and perform quality control of the 5hmC/5mC data. RNA-seq data was processed using Nextflow rnaseq using the STAR/Salmon alignment option. The distal and proximal genomic associations between 5mC/5hmC and gene expression were analyzed using Enhancer Linking by Methylation/Expression Relationship (ELMER). The supervised mode was used because the two groups of comparisons were specified. For each differentially methylated or hydroxymethylated probes, the CpGs were mapped to nearby genes (10 upstream and 10 downstream), and enriched motifs and associated transcription factors (TFs) were identified.

Results/Discussion

Motifs associated with transcription factors ZBTB14 and ZNF148 were enriched in regions of both hypo-hydroxymethylation and hypo-methylation at enhancers, implicating their roles in kidney cancer development[1,2]. Both ZBTB14 and ZNF148 have been associated with negative regulation of transcription by RNA polymerase II, while ZNF148 has also been involved in negative regulation of gene expression[1,2].

Conclusion

The initial analysis of DNAm and DNAhydroxym after integrating RNAseq in ccRCC allows us to find the essential genes that could contribute to kidney cancer development. Next, we hope to integrate a robust analysis at the transcript level to explore the implications of epigenetic regulation on alternative splicing in ccRCC. Further research is warranted to explore additional regulatory genes and epigenetic alterations in ccRCC progression.

#5019 Genomic landscape, tumor heterogeneity and immune-related post-translational regulation in cutaneous melanoma.

Jianhui Gong[1], Gabriel Cruz[1], Yamei Deng[1], Maria Virginia Ruiz Cuevas[2], Chandan Kumar-Sinha[1], Rahul Mannan[1], Yi Hsiao[1], Francesca Petralia[3], Weiping Ma[3], Shrabanti Chowdhury[3], Noshad Hosseini[1], CPTAC Clinical Proteomic Tumor Analysis Consortium[4], Gilbert Omenn[1], Arul Chinnaiyan[1], Paul Harms[1], Raghav Jain[5], Jennifer Kyle[5], Avi Ma'ayan[3], Saravana Dhanasekaran[1], Karl Clauser[2], Hui Zhang[6], Alexey Nesvizhskii[1], Steven Carr[2], Tao Liu[5], Pei Wang[3], Marcin Cieslik[1]

[1]University of Michigan, Ann Arbor, MI,[2]Broad Institute, Boston, MA,[3]Icahn School of Medicine at Mount Sinai, New York, NY,[4]National Cancer Institute, Bethesda, MD,[5]Pacific Northwest National Laboratory, Richland, WA,[6]Johns Hopkins University, Baltimore, MD

Melanoma, the deadliest form of skin cancer, accounts for an estimated 100,640 new diagnoses and 8290 deaths in the United States in 2024. This study leverages 13 multi-omics data types from 164 melanoma samples provided by the Clinical Proteomic Tumor Analysis Consortium (CPTAC), uniquely featuring ubiquitinome and HLA peptidome profiling, to investigate the genomic aberrations, molecular subtypes, tumor microenvironment heterogeneity and post-translational modifications (PTMs).Key findings include mutual exclusivity between hotspot mutations affecting the kinase activity of BRAF and RAS, as well as between alteration types impacting TERT expression. High ultraviolet (UV) impact melanoma is characterized by NF1 loss and TERT promoter mutations. Metastatic melanoma shows higher whole genome duplication (WGD) prevalence (58% vs 46%), with early focal loss of CDKN2A and PTEN preceding WGD. A chr5-12 translocation involving CDK4 and TERT and significant clonal heterogeneity were identified, with single-clone tumors linked to better prognosis ($p = 0.029$). Transcriptional states derived from single-cell RNA sequencing (melanocytic, transitory, invasive) and proteome clustering based on immune checkpoint inhibitor (ICI) features highlight immune response as a key determinant of melanoma heterogeneity. HLA peptidome analysis identified 830 tumor antigen candidates, including 23 non-coding antigens shared across >6 patients, predominantly sourced from introns and MAGEA family genes. Metabolomic and lipidomic data provide insights into immune-metabolic interactions, while ubiquitinome and acetylome profiling are being further investigated to understand immune differences in melanoma. These findings underscore the critical role of post-translational regulation and immune regulation in melanoma progression and therapeutic targeting.

#5020 Quantum algorithms improve feature selection for multimodal cancer classification.

Siddhi Ramesh[1], Teague Tomesh[2], Ryan Robinett[3], Dmitry Karpeyev[1], Colin Campbell[2], Bharath Thotakura[2], Frederic Chong[2], Samantha Riesenfeld[3], Alexander Pearson[1]

[1]The University of Chicago Medicine Comprehensive Cancer Center, Chicago, IL,[2]Infleqtion, Chicago, IL,[3]The University of Chicago Pritzker School of Molecular Engineering, Chicago, IL

Introduction: Cancer machine learning research is often limited by overparameterization and overfitting, which arise because cancer 'omic' variables significantly outnumber patient samples. Traditional feature selection methods for multimodal cancer data fail to completely capture complex biological relationships across genomic, transcriptomic, and pathomic data due in part to computational intractability—interaction information for 3rd-order and higher terms scale exponentially, infeasible for classical methods. We developed a novel quantum-classical hybrid algorithm to identify small, informative feature sets that incorporate higher-order correlations, potentially revealing previously undetected biological signals to improve cancer classification.

Methods: We implemented a quantum-classical hybrid algorithm that frames feature selection as a polynomial constrained binary optimization problem (PCBO-Tournament). Our approach leverages quantum resources through the Recursive Quantum Approximate Optimization Algorithm to explore higher-order feature correlations. We evaluated the algorithm on The Cancer Genome Atlas (TCGA) pan-squamous cell carcinoma cohort (lung, cervical, and head and neck) (1,427 patients) with DNA mutational data, mRNA expression data, and pathomics data for tissue-of-origin classification. To reduce noise and enable efficient data loading, we binarized DNA single-nucleotide polymorphisms (2,720 loci), discretized normalized mRNA expression values into quantiles (18,879 genes), and processed pathomics data with the Slideflow platform, using the Prov-GigaPath foundation model to generate slide-level features (2,048) that we then discretized into quartiles. Feature sets were assessed in terms of the balanced accuracy of logistic regression models in cancer sub-type classification.

Results: On the TCGA pan-squamous dataset, our quantum-enhanced algorithm selected feature sets of size 14 that achieved higher balanced accuracy in cancer classification (97%, $P<0.01$), compared to both models containing all features and those with classically selected feature sets. The algorithm identified biologically relevant features, including tumor suppressor genes such as *TP53*, along expression of tissue-specific markers (*SFTPA1/A2/B*), developmental regulators (*TBX4/5*), and epigenetic factors (*HIRIP3*). The selected features demonstrated robust performance across data modalities, with a variant of our full-qubo PCBO outperforming classical approaches in the small feature set regime ($N \leq 20$).

Conclusion: Our quantum-enhanced PCBO feature selection method identifies small, biologically meaningful feature sets that outperform classical approaches, particularly in terms of incorporating higher-order correlations. This work illustrates the potential for quantum computing to advance multimodal biomarker discovery and precision oncology.

#5021 Multi-omics integration reveals interplay among intratumoral microbiome, host metabolism, and immune response in non-small cell lung cancer.

J. Yang[1], H. Woo[1], S. Yang[2], S.-i. Eyun[1];
[1]Chung-Ang University, Seoul, Korea, Republic of, [2]Sungkyunkwan University, Seoul, Korea, Republic of

The lung, constantly exposed to diverse microorganisms, harbors a microbiome that can influence disease development, including cancer, through mechanisms such as altered immune function and host metabolism. While intratumoral microbiota have been linked to cancer progression and therapy response, their specific role in lung cancer remains poorly understood. Microbial metabolites play a crucial role in mediating the host signaling and metabolic pathways. However, the precise connection between intratumoral microbiota and cancer metabolism is still unresolved. To address this, we comprehensively analyzed the relationship between intratumoral microbiota and host metabolism in 1,111 NSCLC patients using data from TCGA and single-cell RNA sequencing samples. We identified 17 microbial genera associated with host metabolism through gene set variation analysis (GSVA) and Spearman correlation, further validated these associations through survival and differential abundance analyses. To uncover key pathways associated with specific microbes, we applied gene set enrichment analysis (GSEA) and weighted correlation network analysis (WGCNA). Drug sensitivity was assessed based on microbial profiles, while Scissor method identified microbe-associated immune cell subpopulations and their functional roles within the tumor microenvironment. Our findings revealed that *Succinimonas* and *Marichromatium* act as risk factors, while *Luteibacter* serves as a protector in NSCLC patients. High abundance of *Succinimonas* was associated with upregulated glycolysis, downregulated immune responses, enhanced imuune evasion and poorer survival outcomes. Additionally, *Succinimonas* abundance was associated with mutations in key tumor progression genes, such as TP53, SPTA1, and SYNE1. Single-cell analysis demonstrated that *Succinimonas* influenced T cell subpopulations, notably by downregulating Treg Helios- cells, potentially inhibiting antitumor immunity. Furthermore, *Succinimonas* abundance was associated with sensitivity to specific cancer drugs. This study uncovers the complex relationship among intratumoral microbiota, host metabolism, and immune responses in lung cancer. *Succinimonas* emerges as a critical microbial player influencing cancer metabolism, immune evasion, and treatment responses. Our findings provide a preliminary understanding of these interactions, further in vivo and in vitro studies exploring the impact of intratumoral microbes on cancer could potentially lead to novel therapeutic strategies for cancer treatment.

#5022 iS^{3}RGs: Discriminating diverse medulloblastoma subtypes by leveraging heterogenous transcriptome data with batch effects.

M. Sun, J. Wang, S. Wan;
University of Nebraska Medical Center, Omaha, NE

As the most common malignant pediatric brain cancer, medulloblastoma (MB) accounts for around 20% of all pediatric central nervous system (CNS) neoplasms. MB includes a complex array of distinct molecular subtypes characterized by morphological, molecular, and genetic alterations, mainly including SHH, WNT, Group3 and Group4. Although the overall cure rates for MB are around 70%, the survival rate varies significantly across different molecular subtypes. Conventional experimental methods for identifying MB subtypes are usually costly, time-consuming, and labor-intensive. Accurate identification of MB subtypes enables improved downstream risk stratification and tailored therapeutic treatment design. Previous studies indicate that identifying MB subtypes based on transcriptome data is an efficient and feasible way. However, their performance may be poor due to limited cohorts and severe batch effects if combining data in different sequencing platforms and various data sources. To overcome these limitations, we propose a novel computational approach based on intra-sample subtype-specific ranked genes (iS^{3}RGs) analysis to effectively integrate heterogeneous transcriptomic data with batch effects for accurate identification of MB subtypes across diverse cohorts. For a baseline microarray dataset comprising 763 samples as training part, we specifically converted the absolute gene expression to the intra-sample rank values to capture reliable gene patterns by reducing bias from fluctuations and measurement errors. By comparing gene pairs within cohorts rather than across cohorts, we could avoid batch effects and successfully identified those gene pairs that significantly contributed to the identification of MB subtypes. Subsequently, we performed differential ranking analysis for iS^{3}RGs identification. These genes were organized into gene ranking ratios and the subtype-specific gene ratios were filtered using Fisher's exact test and LASSO regression, based on which 1035 gene ratios (corresponding to 738 unique genes) were identified. Then by testing on 14 independent datasets, our proposed method significantly outperformed state-of-the-art MB subtyping approaches with a median accuracy of 99.02%. We believe that our proposed approach has direct positive impacts on downstream MB risk stratification and tailored treatment design. We also expect that our proposed approach has great potential to address many biomedical problems with batch effects for various types of pediatric, adolescent, and young adult (AYA) cancers.

#5023 Machine learning prediction of perineural invasion in hepatobiliary cancers.

J. A. Yasin[1], A.-a. Obeid[2], L. Chen[3], M.-A. A. Tamimi[1], F. A. Qtaishat[1], O. M. Younis[1], A. E. Saeed[1], Y. A. Ateiwi[1], R. M. Odat[4], M. M. Alghaniem[1], N. Al-Awamleh[1], A. Saeed[5], A. Saeed[3];

[1]University of Jordan, Amman, Jordan, [2]World Islamic Sciences and Education University, Amman, Jordan, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, [4]Jordan University of Science and Technology, Amman, Jordan, [5]University of Vermont, Burlington, VT

Background: Hepatobiliary cancers, which affect the liver, gallbladder, and bile ducts, are aggressive malignancies with a poor prognosis. Factors such as perineural invasion (PNI) can further complicate these cancers, as it can facilitate the spread of cancer cells to distant organs, reducing treatment effectiveness and overall survival. In this study, we aimed to develop machine learning (ML) models to predict PNI in patients with hepatobiliary cancers.

Methods: After data processing and cleaning, our dataset included profiles of 433 samples of hepatobiliary cancers from the Memorial Sloan Kettering Cancer Center 2024 HCC dataset. Binary logistic regression (BLR) was used to investigate predictors of PNI. Various ML models were developed by python libraries, such as “scikit-learn” and “TensorFlow”, then trained and tested on 80-20 split. Ten classification models were built with several features including demographic, clinicopathological, and genomic variables such as fraction genome altered, microsatellite instability, and tumor mutational burden. GridSearch cross-validation was used for hyperparameter tuning. Model performance was evaluated on test sets and SHapley Additive exPlanations (SHAP) analysis was applied to interpret feature contributions.

Results: Of the 433 samples, 25.9% (n = 112) were extrahepatic cholangiocarcinoma, 24.7% (n = 107) were gallbladder cancer, 13.6% (n = 59) were hepatocellular carcinoma, 32.6% (n = 141) were intrahepatic cholangiocarcinoma, and 3.2% (n = 14) were biphenotypic tumors. Cancer subgroup was a significant predictor in BLR analysis, with extrahepatic cholangiocarcinoma having the highest proportion of PNI. Among the ML models, Decision Tree demonstrated the highest precision at 0.902. On the other hand, according to area under the curve (AUC), Logistic regression (LR), Gradient Boosting (GB), and Random Forest (RF) were the top three performing models (AUC = 0.892, 95% CI [0.845, 0.939]; AUC = 0.889, 95% CI [0.841, 0.936]; and AUC = 0.888, 95% CI [0.841, 0.936], respectively). Cancer subgroup was the most influential feature among these top three models, and primary tumor site ranked second in the RF model, according to SHAP analysis. Multilayer perceptrons were the least-performing, achieving AUC values of 0.797 (95% CI: 0.736-0.858) for the single-hidden-layer model and 0.758 (95% CI: 0.693-0.823) for the four-hidden-layer model.

Conclusion: This study demonstrates the use of ML in predicting PNI in hepatobiliary cancers, with LR, GB, and RF models achieving acceptable performance. These models can improve disease management and evaluation, allowing for personalized treatment strategies by predicting tumor aggressiveness and invasive potential.

#5024 Multiomics signature reveals network regulatory mechanisms in colorectal cancer progression: Going beyond the scope.

Juan Carlos Higareda-Almaraz[1], **Francesco Mattia Mancuso**[1], Pol Canal-Noguer[1], Kristi Kruusmaa[2], Arianna Bertossi[2]

[1]Universal Diagnostics SA, Seville, Spain,[2]Universal Diagnostics d.o.o., Ljubljana, Slovenia

Background: Colorectal cancer (CRC) progresses from normal tissue to advanced precancerous lesions (APLs) and ultimately to malignancy, driven by stepwise genetic and epigenetic alterations. A key challenge in managing CRC is the risk of overdiagnosis in APLs, which can lead to unnecessary interventions. Identifying molecular signatures that accurately distinguish between low-grade dysplasia (LGD) and high-grade dysplasia (HGD) is crucial for optimizing risk assessment and clinical decision-making. This study integrates methylation, gene expression, and mutation analyses to uncover transcription factor (TF)-driven regulatory networks, with the aim of developing signatures that could support risk-optimization scores and reduce diagnostic uncertainty.
Methods: A differentially methylated signature (DMS), previously identified from HGD and LGD samples using EM-seq and bioinformatics, was applied to the TCGA CRC methylation dataset. Unsupervised hierarchical clustering based on this DMS was performed to identify methylation-driven clusters, followed by a survival and a mutational burden analysis to assess potential associations between clusters and patient outcomes. Cluster-dependent regulatory patterns were used to construct transcription factor (TF) target networks, with hub TFs identified through network topology analysis. Functional enrichment analyses, including Gene Ontology (GO) and pathway analyses, of hub TF target genes were conducted to reveal biological processes specific to each cluster.
Results: The DMS effectively distinguished 4 Clusters (CLs), one with Normal samples and 3 tumoral CLs. A continuum in methylation patterns correlated with mutational burden ($p = 7.2e-4$) and patient survival probability, with Tumoral CL1 showing the highest impact compared to Tumoral CL3 ($p = 2.9e-2$). TF enrichment and networks analysis revealed by variations in network topology metrics ($p = 4.2e-10$), shows unique regulatory networks CLs-dependent. Functional enrichment analysis highlighted cluster-specific pathways, such as PI3K-Akt and AMPK signaling, besides cancer specific pathways in CL1; and JAK-STAT, TNF, and IL-17 signaling in Cl3.
Conclusions: This multiomics analysis reveals heterogeneity in CRC by identifying stratified regulatory mechanisms and biological processes driving progression from APLs to different CRC subtypes. By integrating these insights into risk-optimization scores, the identified signatures could enhance diagnostic accuracy, mitigate overdiagnosis, and refine patient management strategies. These findings pave the way for the development of precision diagnostic tools that optimize clinical decision-making while minimizing unnecessary interventions. Further validation is required to translate these signatures into robust clinical applications.

#5025 Applying deep learning transformers and expression quantitative trait loci to interrogate immunogenetic determinants of cancer risk.

Sophie Herszterg[1], Gustavo Arango-Argoty[2], Etai Jacob[2]

[1]Oncology Data Science, Oncology R&D, Astrazeneca PLC, Cambridge, United Kingdom,[2]Oncology Data Science, Oncology R&D, Astrazeneca PLC, Waltham, MA

The immune system plays a pivotal role in suppressing cancer development through a process known as cancer immunosurveillance. However, substantial immune variation among healthy individuals suggests that the effectiveness of the immune system in eliminating cancer is very likely to vary. This study aims to identify genetic immune characteristics that either protect against or increase cancer risk and to understand how these immune factors interact with known environmental and lifestyle-related risk factors. To achieve this, we have employed a deep learning approach, leveraging transformer models. Transformers can capture complex, non-linear interactions between features, accommodate multimodal input data and incorporate prior knowledge through self-supervised pre-training, which are all relevant properties for our application. As a discovery dataset, we have utilized the UK Biobank, a comprehensive longitudinal cohort consisting of half a million individuals with over 15 years of follow-up. Immune characteristics were derived from plasma proteomics as well as whole genomic sequencing data, in the form of immune cell-specific expression quantitative trait loci (eQTLs). Immune-cell specific eQTLs have been associated with multiple diseases and can provide mechanistic insight into the genetic basis of cancer risk. Here, we share our analysis in exploring immunogenetic factors modulating cancer risk by integrating advanced deep learning techniques with extensive genomic and environmental data. We hope this work will contribute to enhancing our understanding of individual susceptibility to cancer and thereby inform risk stratification strategies and personalized approaches to cancer prevention and intervention, leading to better health outcomes.

#5026 Discovery of oncogenic mediator genes in rectal cancer chemotherapy response using gene expression data from matched tumor and patient-derived organoids.

Hanchen Huang[1], Wini Zambare[2], Chao Wu[2], Antonio Colaprico[1], Janet Alvarez[2], Min Jung Kim[2], Aron Bercz[2], Paulina Bleu[2], Lily Wang[1], Philip B. Paty[2], Paul B. Romesser[3], J. Joshua Smith[2], X. Steven Chen[1]

[1]Department of Public Health Sciences, University of Miami Miller School of Medicine, Miami, FL,[2]Colorectal Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Department of Radiation Oncology, Colorectal and Anal Cancer Service, Memorial Sloan Kettering Cancer Center, New York, NY

Rectal cancer (RC) remains a significant clinical challenge, in part due to chemotherapy resistance encountered in neoadjuvant treatment approaches. To address this, we utilized a unique platform integrating gene expression data from RC tumor tissues and matched patient-derived organoids (PDO). Gene expression data were analyzed using the computational tool Moonlight to investigate the molecular mechanisms underlying chemotherapy response. We hypothesized that combining genomic data from RC PDOs and matched tumors would implicate molecular targets predicting chemotherapy response and clinical outcomes better than targets identified using RC tumor tissue or RC PDO input alone. We analyzed 18 tissue samples and 32 matched PDOs, capturing a comprehensive representation of tumor biology. Our integrative approach involved differential expression analyses (DEAs) and gene regulatory network (GRN) studies, identifying 5,199 genes regulating at least one potential regulon. Focusing on cancer-associated biological processes curated in Moonlight, we highlighted 2,118 regulator-regulon pairs with potential roles in oncogenic processes. Further integration with DEA results revealed 334 regulator-regulon pairs significantly enriched in both tissue and PDO samples, designating these regulators as oncogenic mediators (OMs). Among them, five genes—BTK, CDK1, LAX1, NAT2, and RAD51AP1—were associated with FOLFOX response. Survival analysis across four independent cohorts further validated CDK1, LAX1, NAT2, and RAD51AP1 as indicators of prolonged recurrence-free survival (RFS), demonstrating consistent patterns associated with good prognosis. These findings provide new insights into the molecular mechanisms of chemotherapy response in RC, and validation of these targets is ongoing. Our integrated approach underscores the translational relevance of PDOs and demonstrates the utility of Moonlight in identifying potential therapeutic targets, setting a new benchmark for precision medicine in rectal cancer.

#5031 Analyzing *CHEK2*'s role in breast cancer via *CHEK2*-specific genomic profiles.

Shuoying Qu[1], Marcel Smid[1], John Martens[1], Antoinette Hollestelle[2]

[1]Erasmus Medical Center, Rotterdam, Netherlands,[2]Amsterdam UMC, Amsterdam, Netherlands

Background: *CHEK2* is a tumor suppressor gene in multiple types of cancers, notably estrogen receptor-positive (ER+) breast cancer (BC). We previously revealed that *CHEK2*-derived BC genomes have specific genomic features that are dissimilar from *BRCA1/2*-initiated BC genomes suggesting a different underlying biology. In the study, we aimed to identify estrogen receptor-positive (ER+) samples that are wild-type for CHEK2 but which exhibit similar properties to *CHEK2* mutated tumors to reveal additional genetic drivers of this phenotype.
Methods: Using whole genome sequencing data of primary and metastatic BC from different subtypes, we categorized the size distribution of structural variants (SVs) such as inversions (INV), tandem duplications (DUP), and deletions (DEL) separately, and established *CHEK2*-specific SV profiles. We calculated cosine similarity (CS) scores for all samples comparing the SV profile of a sample to that of the baseline SV profile of *CHEK2* samples. We labeled ER+ samples without *CHEK2* mutation as ER+ *CHEK2*-like samples if their CS scores were higher than the average + 1 SD of the actual *CHEK2* samples. We also studied the location of SVs, defined CHEK2-specific sizes of SVs, and investigated the genes with SVs of these sizes. Lastly, we compared germline mutation frequencies of ER+ *CHEK2*-like and ER+ *CHEK2*-unlike tumors.
Results: The SV size distributions of 926 primary BCs were established for INV, DUP, and DELs. The INV SV profile of *CHEK2* tumors proved very similar in all ER+ tumors and was not used in the classification. Using the CS scores of ER+ tumors to the *CHEK2*-specific DUP and DEL size distributions, 31 and 47 samples, respectively, were classified as ER+ *CHEK2*-like tumors. Interestingly, DUPs in *CHEK2* and ER+ *CHEK2*-like tumors were localized, mainly on recurrently affected chromosomes 11 and 17 for ER+ BC. However, no regions or genes specific for *CHEK2* tumors were observed in the ER+ *CHEK2*-like tumors compared to ER+ *CHEK2*-unlike tumors. Evaluating germline genetic variations in ER+ *CHEK2*-like and -unlike tumors, we found 7 genes, *EBLN2, TAAR2, FAM166B, PNPLA7, IL1RAPL1, ABCC12, and SLC23A2*, with increased mutation frequency in ER+ CHEK2-likes ($p<0.05$), but none of them remained significant after correction for multiple testing.
Conclusion: Our method of selecting ER+ samples with similar SV profiles as *CHEK2* tumors appeared successful and will likely facilitate the identification of potential *CHEK2*-associated pathways. Tandem duplications in *CHEK2 and CHEK2*-like cancers mapped to specific chromosomes but did not pin-point recurrent genes. Only four potential genes with increased germline mutation frequency in ER+ CHEK2-likes (*TAAR2, PNPLA7, ABCC12, SLC23A2*) have been associated in literature with BC or its subtypes, but none of them connected to *CHEK2*-related biology.

#5032 Discovery of XPO1 as a therapeutic target in TNBC: Mechanistic insights and preclinical validation.

A. L. Paulson, R. F. Gruener, A. M. Lee, R. Huang;
University of Minnesota, Minneapolis, MN

BACKGROUND: Triple-negative breast cancer (TNBC) is an aggressive form of breast cancer with limited treatment options. The nuclear export protein XPO1 has emerged as a potential therapeutic target in cancer, but its role in TNBC hasn't been fully characterized.
OBJECTIVES: This study screens, nominates, and investigates the potential of repurposing selinexor, an FDA-approved XPO1 inhibitor, as a novel therapeutic option for TNBC.
METHODS: We utilized a computational drug repurposing pipeline to predict breast cancer patient tumor responses to hundreds of drugs. We then stratified patient tumor's predicted sensitivities by breast cancer subtype and focused on drugs preferentially sensitive towards TNBC. We identified XPO1 inhibitors as the top candidate drug and its efficacy validated in an independent patient dataset and across various TNBC cell line. Additionally, we conducted RNA-sequencing after longitudinal XPO1 inhibition in a panel of TNBC cell lines to explore the mechanism contributing to the preferential sensitivity of TNBC cells to XPO1-inhibition mediated cell death. Further mechanistic studies were conducted to validate our RNA-sequencing findings.
RESULTS: Selinexor was found to significantly reduce the viability of a variety of TNBC cell lines. Mechanistically, we reveal that selinexor induces TNBC cell death by inhibiting the NF-kB pathway through nuclear retention of *NFKBIA*, a key regulator of this pathway. This effect was consistent across multiple TNBC cell lines of differing TNBC subtypes, confirming the broad applicability of XPO1 inhibition in TNBC treatment.
CONCLUSION: This study identifies XPO1 inhibitors as a promising therapeutic candidate for TNBC patients by inhibiting the XPO1-mediated export of *NFKBIA* and blocking the NF-kB pathway. These findings pave the way for more personalized treatment strategies and provide a potential alternative to conventional chemotherapy.
IMPLICATIONS FOR PRACTICE: Repurposing selinexor for the treatment of TNBC could accelerate the availability of targeted therapies for patients with this aggressive cancer. New mechanistic insight into the causes leading to TNBC cell specific sensitivity to XPO1-inhibition mediated cell death warrant further clinical trials to evaluate the safety and efficacy of selinexor in TNBC patients.

#5033 Secondary findings from genome sequencing are prevalent in pediatric cancer patients.

Safa Majeed Grant[1], Brianne Laverty[1], Stephenie Prokopec[2], Christian Marshall[3], Trevor Pugh[2], Adam Shlien[1], Anita Villani[4], Stephen Scherer[1], Yvonne Bombard[5], David Malkin[1]

[1]Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada,[2]Princess Margaret Cancer Centre, University Health Network, Toronto, ON, Canada,[3]Division of Genome Diagnostics, Department of Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada,[4]Division of Hematology/Oncology, The Hospital for Sick Children, Toronto, ON, Canada,[5]Institute of Health Policy, Management, and Evaluation, University of Toronto, Toronto, ON, Canada

Purpose: Genome sequencing in cancer care can reveal secondary findings (SFs) - genetic variations unrelated to the primary condition - yielding potential impacts on patient health and reproductive decision-making. While the American College of Medical Genetics (ACMG) recommends investigating a specific list of actionable SFs during clinical diagnostic sequencing, the prevalence of these findings in pediatric patients with cancer remains unknown. Germline genome sequencing is becoming standard in cancer care, yet no evidence exists to guide providers on the frequency and clinical relevance of SFs in pediatrics.
Methods: To understand the landscape of SFs in pediatric cancer, we analyzed germline variants from genome sequencing across pediatric patients from the SickKids Cancer Sequencing Program (KiCS) and the Canadian COVID-19 Genomics Network (HostSeq). Germline pathogenic (P) and likely-pathogenic (LP) variants with allele frequencies <0.03 in gnomAD populations were considered SFs (including carrier status). Variants associated with primary clinical indications were removed. We compared the prevalence of SFs (including ACMG SF v3.2) across cancer and non-cancer populations of diverse genetic ancestry to inform clinical decision-making in pediatrics.
Results: The median age of KiCS participants (n=396) was 15 years (SD=10.6), compared to 7 years for HostSeq participants (SD=5.3, n=158), with 55% and 56% male participants respectively. Cancer diagnoses for KiCS participants included 51 different tumor types. On average, KiCS patients had 3.96 P or LP SFs from germline genome sequencing, similar to the HostSeq COVID-19 cohort (3.73). Across the combined cohort (n=454), P and LP variants were most common in CFTR (n=39), ABCA4 (n=32), NPHS2 (n=32), FLG (n=31) and BCHE (n=21) genes. Moreover, 5.7% of participants across cohorts had ≥1 clinically actionable ACMG SF (36 patients, n=454). Hereditary breast and ovarian cancer were the most common ACMG conditions identified from ACMG SFs in the Hostseq cohort.
Significance: Our study advances the understanding of germline variants in pediatric oncology, highlighting the potential SFs can have on cancer care in pediatrics. Ongoing work in our lab will categorize SFs by their inheritance model and reverse phenotype autosomal dominant conditions. The findings from our study will help providers understand what SFs to expect when their patients undergo genome sequencing and their clinical significance.

#5034 Comparative whole genome sequencing between matched cryopreserved and FFPE tumor samples.

Paytin Curran[1], DeLaney Anderson[1], Jeffrey Okojie[1], Ryan Miller[1], Sangmoon Lee[2], Ken Dixon[3], Jared James Barrott[1]

[1]Brigham Young University, Provo, UT,[2]Inocras, San Diego, CA,[3]Specicare, Gainesville, GA

Background & Aims: Next generation sequencing, specifically whole genome sequencing (WGS), plays a key role in precision medicine. Currently, the main source of cancer biospecimens for WGS is formalin-fixed, paraffin-embedded (FFPE) tissues. This is partly because cryopreserved (CP) tissues have not been routinely stored in real-world clinical settings. This study aimed to compare the outcomes of WGS by using matched CP and FFPE samples. We hypothesized that CP samples would demonstrate superior quality metrics before and after sequencing the DNA.

Methods: A total of 50 matched pairs of CP and FFPE tumor samples were obtained from patients with various types of cancers, primarily representing gynecological cancers. DNA was extracted and quality and quantity were determined. WGS was performed using 200 ng of DNA extracted from each sample. We conducted a comparison between CP and FFPE samples in terms of the sequencing quality control metrics and the number of identified variants.

Results: Our samples consisted of 18 ovary, 5 liver, 6 kidney, 7 uterus, 4 colon, and 10 other cancers. Metrics were obtained before sequencing, and it was found that gDNA concentration in ng/ul was significantly higher in CP (85.2) than FFPE (12.5) tissue. Additionally, DIN number (FFPE: 4.7; CP: 8.4) and fragment size in base pairs (FFPE: 444.1; CP: 644.6) were also significantly higher in CP tissue. WGS was then performed, and it was found that both mean read depth (FFPE: 34.6; CP: 54.2) and insert size (FFPE: 243.6 CP: 365.7) were significantly higher in CP than FFPE tissues. The percentage mapped over 15x was similar and not statistically different with FFPE being 99.3% and CP being 99.7%. To determine concordance between the matched samples, 94,147 variants were found in FFPE, and 80,036 variants were found in CP. The median point mutation overlap (VAP>=5.0%) was used to find a concordance percentage, with that being 43.5% between FFPE and CP tissues (shared: 51,619; FFPE: 38,690; CP:28,434). Tumer mutation burden was determined on 8 samples because germ line sequencing was performed on available blood samples. FFPE had a TMB of 13.7 and CP exhibited a TMB of 6.4, demonstrating a statistical difference with a p-value = 0.02. Lastly, structural variance was evaluated and FFPE averaged 21 and CP averaged 38.

Conclusion: WGS utilizing CP samples provides superior quality indices compared to FFPE samples. Despite matched samples, there was significant discordance in variants identified in the cancers. Therefore, CP sample collection should be prioritized when performing WGS.

#5035 Barcode-free demultiplexing of HiFi reads using natural genetic variation.

Deniz Guney Olgun[1], Simai Wang[2], Saeid Parast[3], Ali Shilatifard[3], Hani Goodarzi[4], Vijay Ramani[2]

[1]University of Virginia, Charlottesville, VA,[2]Gladstone Institute for Data Science and Biotechnology, San Francisco, CA,[3]Department of Biochemistry and Molecular Genetics, Northwestern University Feinberg School of Medicine, Chicago, IL,[4]Arc Institute, Palo Alto, CA

Cleverly exploiting the natural genetic variation among cells from unrelated individuals enables high throughput, highly parallel droplet single-cell RNA sequencing. We sought to lift this principle and bring analogous improvements to the setting of single-molecule long read sequencing. Toward this end, we present an error-robust method for matching individual long genomic reads to their genetic background based on a Naive Bayes Classifier. As a case study, we apply this to explore allele-specific splicing variation in the colorectal adenocarcinoma cell line DLD1 using Iso-Seq long-read RNA sequencing. Surprisingly, we uncover many allele differentially-expressed isoforms even across genes with no allele-specific expression bias in aggregate. Further, we investigate RNA-binding proteins and functional pathways potentially involved in mediating this allele-specific isoform expression pattern. In future work, our method will be applied to pooled single-molecule epigenomic screens of cancer cell line responses to treatment.

#5036 CAPTATe: a novel tool for enhanced artifact filtering and precise variant detection in single-cell DNA sequencing data.

Luigi Ferraro, Fulvio D'Angelo, Anna Lasorella, Antonio Iavarone, Michele Ceccarelli

Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, FL

Bulk sequencing has proven inadequate in capturing the full complexity of cancer heterogeneity, shifting focus toward cellular resolution. Single-cell DNA sequencing (scDNA-seq) technologies offer an effective approach for analyzing subclonal molecular architecture of tumor with greater granularity, facilitating the identification of somatic genetic mutations (single nucleotide variants, SNVs, and short indels) and copy number variants (CNVs) at single-cell resolution. This capability holds multiple promises, such as the characterization of timing and hierarchy of molecular events driving tumor initiation and progression. However, traditional scDNA-seq methods are hindered by significant artifacts during genome amplification, causing issues like allelic dropout and imbalance that compromise variant detection accuracy. The introduction of the Primary Template-directed Amplification (PTA) addressed these limitations by providing higher genome coverage and uniformity; however, further refinement in filtering amplification-induced artifacts remains necessary for accurate variant calling.
Here, we present CAPTATe (Characterize Artifacts in PTA Technology), a novel tool developed for improved artifact filtering and enhanced detection of SNVs, indels, and CNVs in scDNA-seq data. CAPTATe employs allele-specific CNV calling by addressing fluctuations in the read-depth ratio (RDR) through a multi-channel joint segmentation approach at the subclonal level. The tool leveraged an extension of the variational framework recently developed for single-cell RNA-seq (de Falco et al. Nature Communications 2023) and integrates both B-allele frequency (BAF) and RDR for accurate CNV detection. Additionally, SNV and indel artifact filtering are performed through a machine learning-based approach. This model accounts for allelic imbalance by evaluating the ratio between observed variant allele frequency (VAF) and expected BAF. Genetic tumor subclones can be accurately identified by clustering cells based on their genomic alteration profiles.
The increased precision and accuracy in single-cell genomic variant identification using CAPTATe overcome the main limitations of PTA scDNA-seq profiling, enabling precise characterization of genetic tumor heterogeneity at individual cell resolution.

#5037 Accelerated somatic mutation calling for whole-exome sequencing of tumor samples.

Jessica Castrillon Lal[1], Shuangxi Ji[2], Ruonan Li[2], Scott Kopetz[1], Wenyi Wang[2]

[1]Gastrointestinal Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston, TX,[2]Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Integrating next-generation sequencing (NGS) data into clinical practice faces several challenges. High-throughput sequencing generates massive amounts of data that need to be processed quickly to deliver timely clinical insights. Additionally, formalin-fixed paraffin embedded (FFPE) tissue is the primary resource for tumor molecular profiling in clinical settings. However, nucleic acids extracted from FFPE are prone to chemical alterations and technical artifacts during sequencing. Therefore, distinguishing tumor-specific variants from artifacts and germline variation with a low false discovery rate rapidly with high accuracy remains challenging.
Methods: We recently developed MuSE2, an advanced somatic mutation caller for cancer genomics that integrates a nucleotide-specific Markov substitution model for molecular evolution, a tumor-specific error model to determine tier-based cutoffs for selecting SNVs, and an optimized multi-threaded processing pipeline. It was demonstrated significantly enhanced accuracy and up to 8-80 folds faster performance compared to other common variant callers. Next, we evaluated the performance of our variant calling pipeline on FFPE derived whole exome sequencing data as part of a liquid biopsy test from patients with colorectal cancer at MD Anderson (n=808). We benchmarked our consensus calls from two out of three of the following callers, MuSE2, Strelka2, and MuTecT2, using a patient matched Medical Diagnostic Lab genetic panel sequencing as the ground truth. Our consensus calls performed well in both panel 1 (n=126 genes, F1=0.726) and panel 2 (n=146 genes, F1=0.773).
Results: MuSE2 achieves high sensitivity when combined with existing callers for both whole exome sequencing (WES, F1=0.88 0.04) and whole genome sequencing (WGS, F1=0.93 0.02). Furthermore, the calls had optimal performance when benchmarking the top driver genes in colorectal cancer (TP53, F1=0.95, KRAS, F1=0.99, PIK3CA, F1=0.74, and BRAF, F1=0.88). However, for less frequent genes the performance drops indicating additional measures are required to remove potential technical artifacts.
Conclusion: Our results suggest that a consensus mutation calling strategy including MuSE2 achieves high efficiency without compromising accuracy for clinical tumor sequencing. This is an urgent matter as genetic screening is considered a fundamental aspect of translational cancer research and is entering cancer care standard practice.

#5038 Study on acquisition timing of *KRAS* mutations in the pancreatic ductal epithelium.

Tomonori Hirano[1], Nobuyuki Kakiuchi[1], Yasuhide Takeuchi[1], Sachiko Minamiguchi[2], Takayuki Anazawa[1], Kazuyuki Nagai[1], Hiroshi Seno[1], Seishi Ogawa[1]

[1]Kyoto Univ. Graduate School of Medicine, Kyoto, Japan,[2]Fujita Health University, Aichi, Japan

Introduction: Pancreatic cancer is a highly aggressive malignancy with a poor prognosis, emphasizing the urgent need for early detection to improve outcomes. In the multistep carcinogenesis of pancreatic cancer, *KRAS* mutations are acquired at the earliest stage. However, the exact timing of acquiring *KRAS* mutations in the pancreatic ductal epithelium remains insufficiently understood.
Methods: Non-cancerous regions of the pancreas, distant from macroscopic tumors, were obtained from surgical specimens. The main pancreatic ducts were isolated, spread open manually, and excised into pieces ~1 mm in size to create pancreatic duct organoids. DNA was extracted and subjected to whole-exome sequencing (WES) with matched control DNA. Phylogenetic trees were reconstructed based on shared mutations. Single-cell-derived organoids were established from some bulk organoids and analyzed via WES to determine the mutation accumulation rate of pancreatic ductal epithelium. The timing of *KRAS* mutation acquisition was estimated based on the mutation rates and the height of the branches to which *KRAS* mutations were allocated.
Results: A total of 430 organoid samples were analyzed from 25 pancreatic cancer patients and 23 subjects without pancreatic cancer (1-21 samples per case; median: 8). A median of 33 mutations per sample (range: 8-141) was identified. 18 *KRAS* mutations were detected in 16 cancer patients, while 4 mutations in 4 non-cancer subjects, suggesting a higher prevalence of *KRAS*-mutated clones in the pancreatic ductal epithelium of cancer patients. In the phylogenetic analysis, 13 out of 22 *KRAS* mutations were allocated to the trunk, and KRAS mutant clones expanded to 6 samples on average (2-20). In contrast, *KRAS*-negative clones rarely expanded across multiple samples. We analyzed 56 single-cell-derived organoids from 19 cases, including 7 *KRAS* mutant cells. *KRAS* wild-type cells showed a positive correlation between mutation number and age, with a rate of 0.29 mutations per exome per year. *KRAS* mutant cells displayed a significantly higher mutation number compared to *KRAS* wild-type cells, suggesting an increased mutation rate of *KRAS* mutant cells. *KRAS* mutations were acquired at various ages (21-44), with some occurring as early as the early 20s.
Conclusions: In this study, we elucidated the evolutionary history of clones in non-cancerous pancreatic ductal epithelium. Our findings will contribute to a better understanding of early events of pancreatic carcinogenesis.

#5039 Machine learning enhances histology-agnostic detection of PTEN deletions in panel sequencing of advanced cancers.

Irina A. Kerle[1], Oleksandr Husak[2], Thomas Gross[3], Andreas Hartig[4], Daniela Richter[1], Sascha Bruckmann[4], Andreas Mock[5], Anja Kogler[3], Rebecca Prause[3], Alexander A. Wurm[1], **Maximilian Werner**[1], Dorothea Hanf[1], Lino Mohrmann[1], Doreen William[6], Daniela E. Aust[4], Evelin Schrock[6], Christoph Heining[1], Hanno Glimm[1]

[1]Translational Medical Oncology, National Center for Tumor Diseases Dresden, Dresden, Germany,[2]Institute of Software and Multimedia Technology, Dresden, Germany,[3]Core Unit for Molecular Tumor Diagnostics (CMTD), National Center for Tumor Diseases Dresden, Dresden, Germany,[4]Institute of Pathology, Carl Gustav Carus University Hospital, Dresden, Germany,[5]Translational Medical Oncology, Institute of Pathology, Ludwig-Maximilians-Universitat Munchen, Munich, Germany,[6]Institute for Clinical Genetics, University Hospital Carl Gustav Carus at TU Dresden, Dresden, Germany

Targeted panel sequencing of known genetic driver alterations is an established part of the initial clinical diagnostic routine for many tumors. However, exploratory sequencing for advanced and rare cancers remains experimental. MASTERsg is a prospective clinical broad panel sequencing program that utilizes the TSO500 and TST170 DNA/RNA sequencing assays to identify therapeutically relevant alterations in patients with advanced cancers. The TSO500 pipeline detects copy number variations (CNVs) by dividing the CNV caller's raw data into gene-specific bins, each consisting of 50-250 base pairs. This approach enables the detection of both amplifications and deletions through bin count averaging. However, it may miss focal CNVs that do not meet the standard caller's threshold fold change. This study aimed to enhance the CNV calling capabilities of the TSO500 pipeline to include focal CNVs. To achieve this, we developed a graphical representation of each gene's bins through plotting, enabling the visual identification of focal CNVs. Additionally, we sought to automate this identification process using machine learning, exemplified by detecting focal deletions of Phosphatase and Tensin homolog (PTEN), a tumor suppressor gene whose functional loss often serves as the basis for recommending mTOR/Akt inhibition in molecular tumor boards. For this purpose, we implemented an Extreme Gradient Boosting (XGBoost) model utilizing normalized PTEN bin counts, enhanced with feature transformations such as polynomial line fitting and derivative to capture read depth variations. Our dataset included 59 patients representing 20 advanced solid tumor entities: 29 PTEN deletions identified by the TSO500 pipeline with a gene-specific fold change cutoff of <0.65 (FC range: 0.05-0.64), five focal PTEN deletions detected only by visual bin plot analysis (FC range: 0.66-1.051), and 25 wildtype cases (FC range: 0.65-1.096). A balanced test set of 16 patients was selected for evaluation. To verify the results, all sequenced tumor samples underwent PTEN immunohistochemical (IHC) staining, with staining results quantified using the H-Score, which ranges from 0 (completely negative) to 300 (strongly positive).Our best-performing model achieved a Receiver Operating Characteristic Area Under the Curve (ROC AUC) of 0.97, accurately identifying all five focal PTEN deletions missed by the TSO500 pipeline. The biological relevance of these deletions was confirmed by IHC, with H-Scores of 0 in 4/5 cases and 35 in 1/5 cases. This study demonstrates that machine learning can enhance PTEN deletion detection in TSO500 panel sequencing, with potential applications for other genes. Prospective validation on additional tumor samples is currently ongoing.

#5040 Transformer-based foundation model for clinically relevant DNA alterations: Filling gene status gaps and enhancing classification of rare cancer types.

Dmitrii Chebanov, Quaid Morris

Computational and Systems Biology, Memorial Sloan Kettering Cancer Center, New York, NY

Differences in target panels, data collection strategies, and in data processing among clinical genomic profiling platforms, including MSK-IMPACT and FoundationOne, results in incomplete and incompatible data. For example, other GENIE panels lack the comprehensive genomic features provided by IMPACT. To address this challenge, we developed a Transformer-based foundation model, called CanBART, that generates “plausible patients” to harmonize patient profiles collected on different platforms. To illustrate the value of these generated patients, we adapted the pre-trained CanBART model for a tumor classification task to predict cancer types across 39 tumor types. The results demonstrated strong performance, showing that these plausible patients significantly enhance the robustness of classification, particularly for underrepresented cancer types.

CanBART leverages a BART-based transformer architecture to predict missing genomic data. Patient profiles were represented in a “sentence-like” format, for which they were tokenized using a word-level approach and sorted by chromosomal location, capturing clinically relevant alterations, including mutations, hotspots, copy number variations, and structural variants. We used genomic data from the MSK-IMPACT and GENIE databases, encompassing a total of 144,000 patient profiles. Missing gene statuses were addressed by generating plausible patients, producing a range of possible alterations grouped in profiles that could be sorted by their probability of presence in a particular patient. To validate these profiles, we fine-tuned the model for a classification problem to predict cancer types across the dataset. CanBART was applied to harmonize genomic profiles across patient genomic profiling platforms, producing biologically plausible patient profiles that augmented the dataset for classification tasks. Adding these patients to the training dataset improved tumor-type classification, with a notable 20% enhancement in accuracy in rare cancer predictions compared to using real patient data alone. The enriched dataset demonstrated the benefits of the proposed data representation and transformer-based architecture in addressing the challenges of cancer classification when data is scarce.

CanBART is a Transformer-based foundation model that provides an innovative solution for harmonizing patient genomic profiling platforms and generating plausible patients to train clinical prediction tools. CanBART not only addresses the challenge of incomplete data but also offers a robust method for enhancing tumor classification accuracy, particularly for rare cancers. This approach demonstrates potential for transformative advancements in genomic profiling and precision oncology, facilitating research and clinical decision-making where data scarcity has been a barrier.

#5041 OncoTagger, a novel tool for accelerated and accurate literature-based curation of cancer related genes and variants.

Chenlian Fu[1], Pia Droop[2], Xing Wang[2], Hongxin Zhang[1], Nicole Fernandez[1], Calvin Lu[1], Abhilash Anand[3], Umair Ayub[3], Saahil Jain[4], Kritik Seth[3], Debyani Chakravarty[1], Ulf Leser[2], Quaid Morris[1], Nikolaus Schultz[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Humboldt-Universitat zu Berlin, Berlin, Germany,[3]Center for Data Science, New York University, New York, NY,[4]New York University, New York, NY

Cancer is a genetic disease, and a tremendous number of papers are published each year describing the role of individual genes and specific genomic variants in different cancer types, on cancer progression, and response to therapy. Databases such as OncoKB, COSMIC, and ClinVar effectively catalogue these variants. However, building such databases currently requires laborious manual curation, which does not scale to the speed at which new findings are published: curators need to first identify relevant papers to identify novel associations, and then read through the selected papers word-by-word to ascertain such associations.

To support and accelerate this process, we developed OncoTagger, a first-of-its-kind natural language processing (NLP) powered tool that identifies cancer-related genes and variants from published abstracts and classifies them according to their oncogenicity. OncoTagger provides an abstract-level summary to identify important papers containing cancer genes and variants. Within each abstract, OncoTagger further provides a word(token)-level assessment, predicting words that are cancer genes or variants and their oncogenicity to facilitate curation.

OncoTagger consists of two BioMedBert models finetuned and evaluated on OncoKB's cancer biomarker summary data (3381 annotated abstracts with 22219 mentions of cancer genes, and 1291 abstracts with 3446 cancer variant mentions). One model performs the gene classification task: a token can be assigned to be (part of) the name of an oncogene, tumor suppressor gene, both, or none of the above; the other model carries out similar classifications for variants.

To evaluate abstract summary accuracy, we determined that OncoTagger's most frequently predicted class for each known cancer gene and variant token across the held-out test abstracts achieved 95.2% and 82.1% sensitivity, respectively. We then evaluated accuracy on the task of token classification. OncoTagger significantly outperformed LSTM and key-term matching models in identifying cancer genes and variants (overall accuracy 97.4%/99.4%, F1=72.3%/73.6%, 5.8pp/5.1pp better than the second-best model). OncoTagger achieved high sensitivity in detecting never-seen-before genes and variants (67.7%, 83.3% in oncogenes and tumor suppressor genes, respectively; 60.2% in oncogenic variants). Manual reviews of OncoTagger predictions are ongoing to further confirm OncoTagger's ability to discover new cancer genes and variants currently not included in OncoKB.

In summary, the NLP-powered OncoTagger tool accurately extracts cancer biomarkers. The scaled application of OncoTagger will help identify and curate cancer driver genes and variants from the literature, accelerating the translation of research into clinically implementable targets.

#5042 The Paipu pipeline for pan-mammalian cancer genomics.

Bria S. Smith[1], Geesa V. Daluwatumulle[1], Leslie A. Smith[1], James A. Cahill[2], Kiley Graim[1]

[1]Computer and Information Science and Engineering, University of Florida, Gainesville, FL,[2]Environmental Engineering Sciences, University of Florida, Gainesville, FL

The emerging field of comparative oncology may provide a novel solution to rare human cancer studies, as genomic resources, reference genomes, and non-human model cancer sequencing data are proliferating rapidly. Studying cancer across a diverse array of species provides a unique opportunity to interrogate factors underpinning cancer, facilitating disease modeling in the setting of spontaneous tumors complicated by comorbidities and metastases. Unfortunately, spontaneously developed tumors in non-human mammalian models have been largely overlooked, leaving a foundational resource underutilized. Several key barriers prevent the adoption of these critical data. Extensive reporting of the frequency and diversity of animal tumors has not been systematically linked to the plethora of genomic resources available. Additionally, complications in integrating data from hundreds of genomes have prevented large-scale analysis. Fortunately, recent advances in comparative genomics allowing for joint alignments of hundreds of species have bridged this gap, enabling us to integrate the rapidly expanding genetic resources for non-traditional model species and presenting an enormous potential resource for oncology.

To facilitate the transition of comparative oncology studies from human plus one or two other species to pan-mammalian analyses, we developed the Paipu computational pipeline to systematically identify and process data from hundreds of mammalian species, creating a pan-mammalian tumor compendium. Paipu consists of three phases: reference genome preparation, SRA metadata retrieval and harmonization, and FREYA for RNA-seq data processing and harmonization. Paipu identified and harmonized data from over 100,000 non-human mammalian cancer RNA-seq samples from NCBI, spanning 52 of the 241 mammalian species in the Zoonomia multi-species genome alignment. We demonstrate Paipu's potential via a comparative analysis of human cancers and a rapidly emerging model system, the dog. Using the Paipu cancer data compendium, we analyzed ten cancers in human and dog. We identified a subset of the cancers as strong models of human cancer, which we validated through literature analysis. Additionally, our comparative cancer analysis results parallel the original TCGA pan-cancer analysis findings.

Paipu's harmonization of data from numerous mammalian species facilitates downstream comparative genomics analysis. Increasing the diversity of genomes used in comparative studies can reveal shared and lineage-specific variation across species, leading to the identification of novel mechanisms of cancer risks and resistance. Our approach provides a unique opportunity to harness significant advances in the rapidly developing fields of machine learning and genomics for human cancer research by identifying reciprocal links between evolution and cancer resistance.

#5043 reVUE: repository for variants with unexpected effects.

Xiang Li[1], Ino de Bruijn[1], Thomas Y. Cong[2], Walid Chatila[1], Hongxin Zhang[1], Moriah Nissan[1], Amanda Dhaneshwar[1], Sara E. DiNapoli[3], Erika Gedvilaite[1], Bryan Lai[1], Selcuk Onur Sumer[1], Aditi Gopalan[4], Tonatiuh Gonzalez[5], Madelaine Rangel[6], Trevor J. Pugh[7], Rose Brannon[1], Michael F. Berger[1], Jianjiong Gao[1], Nikolaus Schultz[1], Debyani Chakravarty[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY,[2]Massachusetts Institute of Technology, Cambridge, MA,[3]The Melanoma Research Alliance, Washington, DC,[4]Sage Bionetworks, Seattle, WA,[5]Joan & Sanford I. Weill Medical College of Cornell University, New York, NY,[6]Cornell University, Ithaca, NY,[7]Ontario Institute for Cancer Research, Toronto, ON, Canada

Clinical sequencing of tumor samples is now a component of routine cancer care. By identifying genomic alterations that contribute to tumor initiation or progression, clinical cancer genomic sequencing may be used to identify predictive biomarkers of drug response, refine patient cancer diagnoses, assess heritable cancer risk, or inform patient prognosis. Most genomic alterations are accurately annotated with tools such as the Variant Effect Predictor (VEP) that infer the effects of these alterations on the mRNA and protein by following basic rules of transcription, mRNA post-transcriptional processing, and translation. However, a select subset of variants' effects cannot be predicted as easily by these rules. While many of these "variants with unexpected effects (VUE)" are functionally characterized and documented in the literature**,** these VUEs are often mis-annotated during routine clinical cancer genomic sequencing. Importantly, certain VUEs may have therapeutic implications, which, if mis-annotated may lead to suboptimal treatment decisions for individual patients with cancer.

To address this unmet clinical need, we created a centralized database resource, the **re**pository for **V**ariants with **U**nexpected **E**ffects (reVUE - cancerrevue.org), which curates and programmatically stores VUEs to enable the annotation of these variants during routine clinical cancer genomic sequencing. The reVUE resource consists of (1) an intuitive website listing curated VUEs with their observed effects as demonstrated by functional characterization in peer-reviewed literature and (2) an application programming interface (API) for programmatic annotation of variants.

We successfully curated 109 VUEs spanning 22 genes from 31 articles, and continue to expand this database. Several curated VUEs were associated with clinical treatment implications, including *KIT*, *MET*, *ATM*, *EGFR*, and *BRCA1/2.* The reVUE database has also been integrated into the publicly available bioinformatic ecosystem of cancer variant annotation and interpretation tools that currently includes Genome Nexus, OncoKB, and cBioPortal.

By addressing the critical challenge of the accurate annotation of genomic variants with unanticipated protein effects, reVUE enhances our understanding of complex variant interpretation and contributes directly to improved patient care. Notably, the software and all annotated variants are publicly available, allowing for community contributions, and enabling seamless integration into other genomics tools, clinical workflows, and research pipelines.

#5044 Whole-genome investigation of transcription factors that promote UV damage and mutation.

Bo Chi[1], Raluca Gordan[2]

[1]Duke University, Durham, NC,[2]Department of Biostatistics and Bioinformatics, Duke University, Durham, NC

Understanding the spatial distribution of ultraviolet light (UV)-induced damage and mutation across the genome is an important question due to their oncogenic role in melanoma and other cancers. Previous research suggests UV-induced Cyclobutane Pyrimidine Dimer (CPD) damage lesions and mutations are enriched at transcription factor (TF) binding sites, genomic locations where TFs bind to regulate gene expression. However, current studies of the links between observed enrichment and TF activity revolve around individual qualitative studies with a control sample (often naked DNA) representing sequence effects. With many TFs, damaged sites, and other contributory factors, we seek to quantitatively assess the genome-wide relationship between TF activity, damage formation, and mutagenesis. To accomplish this, we designed a distribution-free simulation pipeline to model the baseline effects of the underlying nucleotide sequence on damage and mutation accumulation by connecting TF binding sites, ATAC-seq chromatin accessibility, CPD lesions in cellular and naked DNA, and mutations from melanoma patients. This analysis reveals that CPDs exhibit varying patterns at the binding sites of TFs relative to what would be expected based on sequence context alone. While some TFs show no additional association with CPD damage, others demonstrate either an enrichment or a reduction in CPDs at their binding sites. Specifically, the top TF clusters associated with UV damage enrichment at a position are ETS, NFY, SPI, and MBD2. ETS, in particular, is consistent with previous studies as a suggested damage driver. In contrast, the top TF clusters associated with reduced damage are AP1, CCAAT_CEBP, NR (including NR1H3 and NR1I2), NFY, and IRF. Using a similar simulation approach, we identified that the most damaged positions in most of the top TF clusters had corresponding mutational enrichment. However, NFY, with damage enrichment at a non-mutagenic TT dimer, showed no mutational enrichment. These clusters can serve as a preliminary list for experimental validation of the modulation of UV-induced damage and mutagenesis driven by TF binding. Our findings and further study will reveal novel insights into the role of TFs in DNA damage accumulation and mutagenesis, which may be vital in reducing cancer incidence.

#5045 Cancer multiomics: Whole-genome DNA, methylation, RNA-seq, and direct RNA characterization of cancer genomes using Oxford Nanopore sequencing.

Sergey Aganezov[1], Philipp Rescheneder[2], Aino Jarvelin[3], Sean McKenzie[1], Ella Kennett[3], George Dodd[3], Sissel Juul[1]

[1]Oxford Nanopore Technologies Inc, New York City, NY,[2]Oxford Nanopore Technologies GmbH, Munchen, Germany,[3]Oxford Nanopore Technologies plc, Oxford, United Kingdom

Cancer progression is characterized by the accumulation of both genomic and epigenomic alterations as well as transcription changes, leading to the formation of tumors that are highly heterogeneous. This heterogeneity arises because the tumor consists of a diverse population of cells, each with distinct genomic, epigenomic, and transcriptomic profiles. These differences influence the tumor's behavior, its response to therapy, and its ability to evolve. To better understand the mechanisms driving cancer, it is crucial to adopt a multi-omics approach.

Here we describe an approach that leverages Oxford Nanopore Technologies' sequencing platform to achieve a comprehensive multi-omics analysis, enabling the detection of a wide spectrum of haplotype-specific somatic genomic variants (ranging from single nucleotide changes to large chromosomal rearrangements), epigenetic modifications such as 5mC and 5hmC, chromatin accessibility changes, and detailed transcriptomic profiles. Through both cDNA and direct RNA (dRNA) nanopore sequencing, it captures transcriptional alterations, isoform diversity, and RNA modification landscapes, providing a holistic view of the molecular changes driving cancer progression.

We highlight several notable examples of identified somatic genomic mutations in an example tumor vs matching normal sample, including loss of heterozygosity and exon deletion in PTEN gene, as well as apparent promoter 5mC hypermethylation in the tumor as well as genome wide changes in 5hmC levels. We further explore changes in isoform-level transcript expression with both cDNA and dRNA nanopore reads. We demonstrate high concordance between the two approaches with dRNA reads allowing for additional examination of RNA base modifications, including m6A and pseU. We also illustrate how the treatment with artificially induced 6mA in both normal and tumor DNA samples allows for the identification of differences in chromatin accessibility across the whole genome, while preserving the ability to detect somatic variations using a single dataset.

Lastly, we highlight the ability of Oxford Nanopore sequencing to produce telomere-2-telomere diploid assemblies of the matching normal sample enabling analyses relative to individualized assembled references, plotting a path towards truly personalized cancer genome analysis.

In summary, our approach highlights how Nanopore sequencing facilitates multi-omics analysis, providing a comprehensive characterization of diverse genomic, epigenomic, and transcriptomic alterations in tumor samples using a single platform.

#5046 Three-dimensional genome landscape of primary human cancers.

Y. Zhao[1], K. E. Yost[1], K. L. Hung[1], K. Zhu[2], D. Xu[3], R. Corces[4], S. Shams[1], B. H. Louie[1], S. Sarmashghi[5], L. Sundaram[1], J. Luebeck[2], S. Clarke[3], A. S. Doane[3], J. M. Granja[1], H. Choudhry[6], M. Imieliński[3], A. D. Cherniack[5], E. Khurana[3], V. Bafna[2], I. Felau[7], J. C. Zenklusen[7], P. W. Laird[8], C. Curtis[1], Cancer Genome Atlas Analysis Network, W. J. Greenleaf[1], H. Y. Chang[1];

[1]Stanford University School of Medicine, Stanford, CA, [2]University of California at San Diego, La Jolla, CA, [3]Weill Cornell Medicine, New York, NY, [4]Gladstone Institute, San Francisco, CA, [5]Broad Institute of MIT and Harvard, Cambridge, MA, [6]King Abdulaziz University, Jeddah, Saudi Arabia, [7]NIH, Bethesda, MD, [8]Van Andel Research Institute, Grand Rapids, MI

Genome conformation underlies transcriptional regulation by distal enhancers, and genomic rearrangements in cancer can alter critical regulatory interactions. Here we profiled the 3D genome architecture and enhancer connectome of 69 tumor samples spanning 15 primary human cancer types from The Cancer Genome Atlas (TCGA). We discovered three archetypes of enhancer usage for over one hundred oncogenes across human cancers: static, selective gain, or dynamic rewiring. Integrative analyses revealed the enhancer landscape of non-cancer cells in the tumor microenvironment at genes related to immune escape. Deep whole genome sequencing and enhancer connectome mapping provided accurate detection and validation of diverse structural variants across cancer genomes, and revealed distinct enhancer rewiring consequences from noncoding point mutations, genomic inversions, translocations, and focal amplifications. Extrachromosomal DNA promoted more extensive enhancer rewiring of oncogenes among several types of focal amplification mechanisms. These results suggest a systematic approach to understand genome topology in cancer etiology and therapy.

#5047 Enhancing germline variant calling: Adjustment with tumor samples to filter low-confidence variants from clonal hematopoiesis.

Maria Shumilova, Danil Stupichev, **Gleb Khegai**, Irina Bulusheva, Sevda Nuralieva, Miryam Spektor, Daria Melikhova, Georgy Sagaradze, Michael Goldberg, Alexander Bagaev

BostonGene, Corp., Waltham, MA

Background: High-quality germline variant calling is crucial for accurate genetic reports; yet, certain factors can lead to false identifications. Clonal hematopoiesis (CH), caused by somatic mutations in blood cells, can mimic germline variants, while pseudogenes and mosaic mutations generate low variant allele frequency (VAF) signals that can be misinterpreted. Current methods for addressing these artifacts use only non-tumor samples, limiting their use in clinical settings for generating genetic reports for tumor samples. To expand the capability of germline variant calling, we developed a filtering method to identify and eliminate low-confidence variants from CH, pseudogenes, and mosaicism within both non-tumor and tumor samples.

Methods: We analyzed whole-exome sequencing (WES) data from 2,078 patients (55.2% females and 44.8% males; mean age 58.7 years, range: 6-99) with 175 unique oncological diagnoses. From each patient, a tumor biopsy and non-tumor samples, including whole blood (71.4%), saliva (25.3%), and buccal swabs (3.3%), were obtained. Strelka v2.9.10 was used for variant calling; precise VAF values were calculated using SAMtools mpileup v1.10. The VAF values were compared between tumor and non-tumor samples. Copy number alterations (CNAs) detected with Sequenza v2.1.2 were used to evaluate expected VAF values in tumor samples adjusted for gene dosage. Mappability metrics were estimated using bigwig reference files for hg38 with various read lengths (75bp, 100bp, 150bp, 200bp) and pyBigWig v0.3.22. The binomial distribution model was calculated based on CNAs and sample purity to determine expected VAF range and identify low-confidence variants. Variants with VAFs outside the 99.9% confidence interval were flagged as potential artifacts.

Results: Overall, 3,591 unique low-confident variants were found in 1,428 patients, with about 29% being associated with low mappability (≤0.95). In total, 64 unique variants were found in 42 CH-associated genes in 121 patients (5.8%), including actionable genes *ATM*, *BRCA1*, *TP53*, and *RB1*. The mean VAF for CH mutations was 30% (standard deviation, SD 5%) in non-tumor samples, compared to 6% (SD 3%) in tumor samples. The mean patient age for filtered-out variants was 61, consistent with higher CH probability in older individuals. In non-tumor samples, CH artifacts were found mostly in whole blood (78%). Breast cancers and sarcomas were the main diagnoses with observed CH artifacts.

Conclusion: Our filtering strategy integrates WES data from both tumor and non-tumor samples, including the copy number alteration (CNA) profiles to improve the accuracy of germline reports. This unique method reduces CH-associated errors and other artifacts, consequently streamlining quality control of genetic reports for cancer patients to guide their therapeutic decision-making.

#5048 MyInformatics®: Invivoscribe's end-to-end NGS analysis software system for streamlined variant calling and reporting.

J. Burke[1], J. Wemmer[1], J. D'Angelo[1], J. Velaquez-Muriel[1], T. Johnson[1], P. Sanchez[2];
[1]Invivoscribe, San Diego, CA, [2]LabPMM, San Diego, CA

Introduction: MyInformatics® is an NGS software system that streamlines the entire sample processing workflow for Invivoscribe's CAP/CLIA-certified MyAML® and MyMRD® Assays—from data creation and entry into a laboratory information system (LIS), through comprehensive and standardized bioinformatics analyses, to annotated variant reports. The system automates processes including quality control and sample tracking through integration with LIS and web display components, enhancing data transparency, and decreasing turnaround times. These seamlessly interlinked processes also eliminate many sources of potential human error.

Methods: Following specimen accessioning and sequencing in the lab, a MyInformatics® gene-panel analysis begins when an operator executes the main NextFlow script, which orchestrates the entire workflow by calling multiple Docker containers in a single workflow. Each individual Docker container includes a bioinformatics system/tool component. Each component is responsible for a specific bioinformatics task such as variant calling, artifact identification, sample QC, or variant annotation. Different components can be used by the bioinformatics workflow via a configuration file, allowing for flexible reuse of software. Following the bioinformatic analyses, the MyInformatics® system communicates with the LIS to perform sample QC based on each panel's established quality thresholds. The system also communicates with Invivoscribe's MyInformatics Annotation Portal (MAP®), a web interface for reporting clinically significant variants. Invivoscribe's Clinical Genomics scientists use MAP® to generate final sample reports.

Results: Invivoscribe developed the MyInformatics system with a modular software architecture based on containerization and automated workflow management for bioinformatics components. This reduces code complexity, allows for efficient integration of new versions of tools, and decreases manual overhead and operator errors. The system seamlessly integrates with other software components developed by Invivoscribe, such as the LIS and a web-based annotation tool and can handle multiple assays with a single user-specified parameter.

Conclusions: MyInformatics® connects all key components of a modern NGS assay analysis workflow, from the sequencing instrument to the annotated sample reports. The containerization makes deploying the software in any computational infrastructure easier, and the automation through connecting multiple software components dramatically reduces overall turnaround times for sample reporting while improving data transparency and limiting the potential for errors. MyInformatics® also facilitates the standardization of assay workflows across our global LabPMM laboratories, promoting consistency in results.

#5050 Comparative analysis of somatic copy number variations and allelic imbalance in whole-genome bisulfite sequencing: challenges and insights.

Yiru Gu, Jian Gu, Paul Scheet, Justin Wong

Epidemiology, UT MD Anderson Cancer Center, Houston, TX

Goal: To assess the feasibility, reliability, and limitations of using Whole Genome Bisulfite Sequencing (WGBS) for detecting somatic copy number variation (SCNV) and tumor-specific allelic imbalance (AI). Background: In cancer genomics, the use of WGBS for SCNV and AI detection enables simultaneous analysis of genetic variations and methylation landscapes, potentially providing insights into the interplay between somatic alterations and DNA methylation in tumorigenesis. However, WGBS data is inherently noisier compared to whole-genome sequencing (WGS) or microarray data due to artifacts introduced during bisulfite conversion. These challenges, including difficulties in read alignment, genotype calling, and phasing, the lack of strand complementarity, and the need to distinguish true C>T SNPs from bisulfite-induced changes, collectively complicate SCNV and AI detection. *Method:* We analyzed WGBS data from The Cancer Genome Atlas (TCGA), including 39 tumor samples and 8 adjacent normal tissues across 9 tumor types. SCNV detection was performed using GATK-CNV, while AI callings were conducted with BisSNP, BISCUIT, Revelio (with Unified Genotyper), and BSsnp. Confusion matrices were used to compare GATK-CNV (WGBS) and hapLOH (microarray) at the base, gene, and arm levels. F1 score, specificity, and sensitivity were calculated to evaluate their performance across different genomic scales. Additionally, AI identified from WGBS data using BisSNP, BISCUIT, Revelio (with Unified Genotyper), and BSsnp were compared to those detected from array and WGS data using hapLOH/seq. To determine detection thresholds and refine results, sequencing data were downsampled, with filters applied to exclude low-quality data and retain high-confidence SNPs and genotypes. *Result:* GATK-CNV exhibited variable performance across samples, with most samples showing high true positives and low false positives, indicating good sensitivity for detecting SCNVs and capturing a genome burden similar to hapLOHseq data. However, for samples with a high number of events, normalization disrupts event callings, resulting in inconsistencies in SCNV identification compared to array data. For AI detection, Revelio (with Unified Genotyper) showed the best overall performance among the tools evaluated. Downsampling analysis showed that reducing sequencing coverage impaired event detection, becoming less effective at lower coverage levels. BSsnp, BISCUIT, and BisSNP produced widespread and inconsistent variant calls, and initial filtering for high-quality SNPs showed limited improvement in precision. This study highlights the potential and challenges of WGBS as a tool for analyzing SCNV/AI alongside DNA methylation with phased data, offering insights into tumorigenesis and advancements in cancer diagnostics and treatment.

#5052 Large-scale genomic analysis of mutation signatures reveals pathway alternations linked to breast cancer prognosis.

Mate Posta, **Balazs Gyorffy**

Semmelweis University, Budapest, Hungary

Introduction: Advancing breast cancer treatment demands a thorough understanding of the genetic and molecular mechanisms that drive disease progression. Our study aims to explore pathway-wide mutational patterns to uncover molecular interactions that influence survival outcomes.

Methods: We integrated mutation data from three major breast cancer databases, comprising a total of 4,586 samples and over 25,000 genes. We considered disruptive mutations for survival analysis. We applied Cox proportional hazard regression to link gene mutations and altered molecular pathways with patient outcomes.

Results: Our analysis identified 17 genes with significant associations with relapse-free survival, with the most impactful genes being TP53 (HR: 2.04, p: 4.65×10^{-33}), CARD11 (HR: 2.59, p: 1.54×10^{-5}), and PIK3R1 (HR: 2.27, p: 3.66×10^{-5}). The most significant KEGG pathways affecting relapse-free survival were *MicroRNAs in cancer* (hsa05206, HR:2.48, p: 2.69×10^{-32}), *Hepatocellular carcinoma* (hsa05225, HR: 2.39, p: 8.88×10^{-30}), and *Breast cancer* (hsa05224, HR:2.38, p: 1.78×10^{-28}). We also identified significant patterns of mutual exclusivity and co-mutation. Pairs such as *GATA3-TP53* (OR: 0.201, p: 1.42×10^{-37}), *CDH1-TP53* (OR: 0.336, p: 3.66×10^{-21}), and *AKT1-PIK3CA* (OR: 0.199, p: 4.97×10^{-13}) were mutually exclusive, while *MAP3K1-PIK3CA* (OR: 2.83, p: 4.62×10^{-23}), *CBFB-GATA3* (OR: 4.67, p: 3.37×10^{-18}), and *AHNAK2-MUC16* (OR: 3.39, p: 1.35×10^{-15}) emerged as co-mutated gene pairs. Finally, an online platform (https://server2.kmplot.com/breast) has been developed to facilitate future studies designed to validate pathway-specific results.

Conclusions: In summary, by compiling a large-scale breast cancer database, we identified disruptive mutation patterns associated with altered survival outcomes. Out new tool provides a valuable resource for future research and treatment development.

#5053 Targeted sequencing panel for comprehensive MTAP deletion detection in diverse cancer types.

Hua Bao, **Haimeng Tang**, Rui Liu, Ningyou Li, Min Wu, Xunbiao Liu, Zhili Chang, Xue Wu

Nanjing Geneseeq Technology Inc., Nanjing, China

Objective: Methylthioadenosine phosphorylase (MTAP) deletion is a prevalent genomic alteration across various malignancies, often correlated with unfavorable clinical outcomes. The detection of MTAP deletions offers opportunities for personalized therapeutic strategies aimed at exploiting specific metabolic vulnerabilities. However, existing detection methodologies are frequently costly and labor-intensive, highlighting the necessity for an efficient and economical detection panel. Developing such a tool is essential for the timely identification of MTAP deletions, facilitating prompt initiation of targeted therapies and improving patient prognoses.
Methods: We retrospectively analyzed 5,787 tissue samples from patients diagnosed with 11 distinct cancer types, including colorectal, lung, liver, gastric, bladder, pancreatic, and esophageal cancers. A targeted sequencing approach (approximately 1,000X coverage) was employed using the GeneseeqPrime™ panel, which encompasses 437 cancer-related genes. Additionally, an independent cohort of 29 cancer samples was analyzed to assess the concordance of our sequencing panel with Fluorescence In Situ Hybridization (FISH) and Immunohistochemistry (IHC).
Results: The evaluation of MTAP deletions across a spectrum of cancer types revealed significant variations in both total and homozygous deletion rates. Bladder cancer exhibited a total deletion rate of 43.43%, with homozygous deletions accounting for 11.11%. Esophageal squamous cell carcinoma indicated a total deletion rate of 46.15%, with homozygous deletions at 15.73%. Glioblastomas displayed the highest prevalence of total deletions at 58.33%, including 30.21% homozygous deletions. Furthermore, non-small cell lung cancer (NSCLC) and pancreatic cancer had total deletion rates of 35.84% and 42.55%, respectively, with homozygous deletions at approximately 8.21% and 15.55%. Our panel demonstrated perfect concordance with both FISH and IHC (100% agreement).
Conclusion: This study establishes the variable prevalence of MTAP deletions across multiple cancer types, underscoring its significance as a prognostic biomarker associated with poor outcomes. The GeneseeqPrime™ panel provides a rapid and cost-effective means for identifying MTAP deletions, facilitating timely diagnosis and personalized therapeutic strategies. Further validation in larger cohorts and clinical settings is warranted to enhance its applicability in routine oncological practice.

#5054 Understanding the genetic heterogeneity within clonal spheroids and its interaction with the tumor microenvironment.

A. Yadav, R. Chaturvedi, R. P. Singh;
Jawaharlal Nehru University, New Delhi, India

Introduction: Head and neck squamous cell carcinomas (HNSCC) exhibit significant inter- and intra-tumor heterogeneity, complicating diagnosis and treatment. Our previous work demonstrated that spheroids developed from patient-derived cells and HNSCC cell lines display distinct proliferative and migratory behaviors. We classified them as hyperproliferative and hypoproliferative spheriods. To uncover the molecular basis of this functional heterogeneity, we utilized single-cell RNA sequencing (scRNA-seq) and advanced computational tools like CellChat. Our analysis revealed key signaling pathways, cellular interactions, and surface markers defining spheroid phenotypes, offering insights into their genetic and functional diversity.

Material and Methods: scRNA-seq was performed on hyperproliferative and hypoproliferative spheroids derived from the UMSCC-22B cell line. Spheroids were cultured, dissociated into single cells, and subjected to high-throughput scRNA-seq. Bioinformatic analyses identified differentially expressed genes, signaling pathways, and cellular states. CellChat was employed to analyze intercellular communication networks within spheroids. Ligand-receptor interactions were modelled to identify pathways mediating cross-talk between distinct cell clusters.

Results: scRNA-seq revealed distinct transcriptional profiles between the two spheroids. Hyperproliferative spheroids expressed genes related to cell division and growth, while hypoproliferative spheroids expressed genes linked to migration and invasion. Pathway analysis identified differences in angiogenesis, metastasis, and tumor microenvironment interactions. Midkine signalling(MDK-SDC) through basal cells was found to be the principal contributor to the proliferative advantage in hyperproliferative spheriods, supporting their role in tumor expansion and progression. While, Desmosomal signaling (DSC2-DSG2) through keratinocytes and fibroblasts was found to play a critical role in maintaining cellular adhesion and promoting migratory capacity in hypoproliferative spheroids. TCGA data linked MDK to advanced tumor stages, poor survival, and therapy resistance, while DSG2 and DSC2 were overexpressed in metastatic tumors. These findings highlight the distinct functional states of spheroids contributing to tumor heterogeneity.

Conclusion: The balance between proliferation and migration in spheroids reflects tumor heterogeneity's dual role in cancer progression. Midkine-driven hyperproliferative spheroids anchor tumor growth, while desmosome-mediated hypoproliferative spheroids drive metastasis. Targeting Midkine or modulating desmosomal remodeling could inhibit growth and prevent dissemination, enabling patient-specific therapies.

#5055 Efficient detection of chromosomal instability in diverse cancers using a targeted sequencing approach.

Hua Bao, Rui Liu, **Haimeng Tang**, Ningyou Li, Min Wu, Xunbiao Liu, Zhili Chang, Xue Wu

Nanjing Geneseeq Technology Inc., Nanjing, China

Objective: Chromosomal instability (CIN), characterized by frequent chromosomal alterations, plays a crucial role in tumorigenesis, significantly influencing cancer progression and therapeutic resistance. Targeting vulnerabilities associated with CIN, particularly in DNA repair pathways, presents promising therapeutic strategies. However, existing CIN detection methods are often costly and labor-intensive. Thus, the development of efficient and cost-effective CIN detection panels is essential for optimizing cancer treatments and enhancing patient outcomes while reducing healthcare costs.

Methods: We conducted a retrospective study analyzing 4,941 tissue samples from patients diagnosed with 14 distinct cancer types, including ovarian, uterine, breast, pancreatic, prostate, cervical, liver, lung, colorectal, and gastric cancers. A targeted sequencing panel, GENESEEQ GENAVISTA, assessing 437 cancer-associated genes with an approximate depth of coverage of 1,000X, facilitated detailed mutational profiling. CIN assessment utilized read depth and allele frequency evaluation, alongside variant calling algorithms to identify gene duplications and genomic rearrangements. Additionally, a prospective cohort of 33 cancer patients was analyzed to compare the efficacy of our sequencing panel against the gold standard of whole genome sequencing (WGS, ~30X).

Results: Our analysis revealed significant CIN prevalence across various cancer types, particularly elevated in ovarian cancer (73.26%) and breast cancer (76.80%). Lung cancer exhibited a CIN rate of 78.57%, while melanoma demonstrated an 80.00% prevalence. Endometrial cancer presented a moderate CIN rate of 40.62%, whereas pancreatic cancer displayed an equal distribution between CIN and genomically stable tumors, each accounting for 50.00%. Prostate cancer showed a CIN incidence of 45.16%, and cervical cancer recorded a rate of 62.30%. The findings illustrate the heterogeneous nature of CIN among malignancies, suggesting its utility as a prognostic marker and therapeutic target. The panel demonstrated a high correlation with WGS results in the prospective cohort (Spearman rank correlation = 0.91), confirming its effectiveness in identifying CINs in cancer patients.

Conclusion: Our study establishes the GENESEEQ GENAVISTA targeted sequencing panel as an effective tool for accurately detecting CIN across various cancer types. The strong correlation with whole genome sequencing highlights its potential as a reliable, cost-effective alternative for CIN assessment, facilitating optimized cancer treatment strategies and improving patient outcomes while minimizing healthcare costs.

#5056 Full spectrum of somatic structural variations (SVs) detection in COLO829 with long-read sequencing.

Zishan Peng, Zechen Chong

Department of Biomedical Informatics and Data Science, University Of Alabama At Birmingham, Birmingham, AL

Somatic SVs significantly contribute to cancer development and progression. Characterizing these variations has traditionally been difficult due to the limitations of short-read sequencing technologies and the diverse types and lengths of SVs. The advent of long-read sequencing has enabled a more comprehensive analysis of germline SVs, highlighting its potential applications in cancer genomics. The melanoma cell line COLO829, along with its normal counterpart COLO829BL, is a standard reference for somatic SV detection. Valle-Inclan et al. recently validated 68 somatic SVs combining short-read, long-read, and linked-read sequencing data. However, the sensitivity may be compromised as only a limited number of alignment-based callers were employed, such as NanoSV, Sniffles (for Oxford Nanopore Technologies (ONT)), and pbsv for (PacBio HiFi). As more alignment-based SV callers are being developed, it is crucial to integrate a broader range of tools to construct a comprehensive call set of somatic SVs. Moreover, the performance of assembly-based methods in somatic SV detection within cancer remains largely unexplored. In this study, we aimed to establish a comprehensive spectrum of somatic SVs in the COLO829 melanoma cell line by employing both alignment-based and assembly-based methods with long-read whole-genome sequencing data from PacBio and ONT aligned with Minimap2, SVs were identified and integrated from 7 alignment-based callers: cuteSV, NanoVar, DeBreak, Sniffles2, Svision-Pro, NanoSV, and pbsv. In addition, genome assemblies were constructed via Hifiasm and Verkko, incorporating HiFi reads with Hi-C and ultra-long ONT integration, followed by SV detection using four assembly-based callers: Dipcall, PAV, SVIM-asm, and cuteSV. A dedicated pipeline was developed to identify and filter somatic SVs from germline events, which considers mapping quality, sequencing depth of SV regions and their flanking regions, and 50% reciprocal overlap. Compared to the truth set established by Valle-Inclan et al., we discovered 19 novel somatic SVs, including 10 deletions, 4 insertions, 3 duplications, and 2 inversions. As a comparison, assembly-based methods detected all the deletions, insertions and duplications found by the alignment-based methods. However, it missed 20 inversions and 6 translocations. Our findings highlight the superior sensitivity of alignment-based techniques in somatic SV detection and underscore the complementary nature of assembly-based approaches. This work enhances the benchmark for somatic SV characterization in cancer genomics and confirms the utility of integrated long-read sequencing analyses.

#5057 Enhancing clinical applications by evaluation of sensitivity and specificity in whole exome sequencing.

Chunghwan Hong[1], Youngbeen Moon[1], Hye Won Choi[1], Eun-Kyung Kang[1], Seo-Hyeon Ye[1], Jong-Kwang Kim[1], Young-Ho Kim[1], Hyeri Cho[1], Hana Choi[1], Dong-eun Lee[1], Yongdoo Choi[1], Tae-Min Kim[2], Seong Gu Heo[3], Namshik Han[4], Kyeong-Man Hong[1]

[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of,[2]The Catholic University of Korea, Seoul, Korea, Republic of,[3]Dana Farber Cancer Institute, Boston, MA,[4]University of Cambridge, Cambridge, United Kingdom

The cost-effectiveness of whole exome sequencing (WES) remains debated, primarily due to variability in variant calls. Evaluating the sensitivity and specificity of WES results may clarify this issue. WES was performed by three companies (AA, BB, and CC) using reference standards composed of DNA from Hydatidiform mole and individual blood at various ratios. Sensitivity was assessed by the detection rate of null-homozygote (N-H) alleles at expected variant allelic fractions, while false positive (FP) errors were counted for unexpected alleles. Sensitivity was approximately 20% for in-house results from BB and CC and around 5% for AA. Dragen analyses identified 1.34 to 1.71 times more variants, detecting over 96% of in-house variants, with sensitivity for common variants increasing to 5%. In-house FP errors varied significantly among companies (up to 13.97 times), while Dragen analyses minimized this variation. Despite Dragen showing higher FP errors for BB and CC, the increased sensitivity highlights the importance of effective bioinformatic conditions. We also assessed the potential effects of target enrichment and proposed optimal cutoff values for read depth and variant allele fraction in WES. Optimizing bioinformatic analysis based on sensitivity and specificity from reference standards can enhance variant detection and improve the clinical utility of WES.

#5058 Evaluation of false positive and false negative errors in targeted next generation sequencing.

Chunghwan Hong[1], Youngbeen Moon[1], Hye Won Choi[1], Eun-Kyung Kang[1], Jong-Kwang Kim[1], Young-Ho Kim[1], Dong-eun Lee[1], Tae-Min Kim[2], Seong Gu Heo[3], Namshik Han[4], Kyeong-Man Hong[1]

[1]National Cancer Center - Korea, Goyang-si, Korea, Republic of,[2]The Catholic University of Korea, seoul, Korea, Republic of,[3]Dana Farber Cancer Institute, Boston, MA,[4]University of Cambridge, Cambridge, United Kingdom

Background: Next-generation sequencing (NGS) has emerged as a vital diagnostic tool for various diseases; however, errors associated with NGS present significant challenges to its clinical implementation. Specifically, in cancer diagnostics, the analysis of low-level mutations is complicated by contamination from normal cells and tumor heterogeneity.
Results: In targeted NGS (T-NGS) analyses involving reference-standard samples consisting of mixtures of homozygous Hydatidiform mole DNA and blood genomic DNA at varying ratios from four certified NGS service providers, we observed considerable variability in both the lower detection limits of variants (16.3-fold difference, ranging from 1.51% to 24.66%) and false positive (FP) error rates (4280-fold difference, ranging from 5.814 × 10^-4 to 1.359 × 10^-7). The commercially available Dragen system for bioinformatics analysis reduced FP errors in results from companies BB and CC; however, inherent errors from the raw NGS data remained. Adjustments to bioinformatics parameters aimed at increasing sensitivity (by less than two times) substantially elevated FP error rates (by 610 to 8200 times). Additionally, we identified issues such as biased base calling during bioinformatics analysis and a high frequency of false negative (FN) errors in HLA regions.
Conclusion: T-NGS results from certified NGS service providers reveal considerable variability in sensitivity and FP error rates, underscoring the necessity for enhanced quality control measures in the clinical application of T-NGS. Furthermore, our study suggests that mixtures of homozygous and heterozygous DNA can serve as effective reference-standard materials for T-NGS quality control.

#5059 Self-supervised representation learning of somatic mutational data.

Marzieh Haghighi, Gustavo Alonso Arango Argoty, Etai Jacob

AstraZeneca US, Waltham, MA

Traditional approaches for learning representations from somatic mutation data often rely on the distribution of motif counts, which have limitations, including the use of small sequence contexts and the exclusion of critical information, such as mutation location and interactions among mutations. Recent efforts have leveraged advances in natural language processing (NLP) to improve representation learning from somatic mutations by incorporating larger sequence contexts into shallow networks. More recently, studies have demonstrated the feasibility of leveraging attention mechanisms to learn meaningful representations. However, these methods primarily use supervised or weakly supervised learning paradigms, which are inherently task-specific. The development of general-purpose representations, by harnessing the vast amount of somatic mutation data through self-supervised techniques, remains underexplored. Such representations could drive progress in applications including tumor subtype classification, biomarker discovery, patient stratification, drug response prediction, and pathway enrichment analysis. This study aims to develop a deep, unsupervised learning framework that leverages abundant somatic mutation data to generate robust, general-purpose representations. By adapting recent advances in self-supervised learning, the proposed approach seeks to establish a foundation model capable of capturing meaningful patterns in mutation data for diverse downstream tasks. The framework employs novel tokenization and embedding strategies to encode mutation sequences and utilizes transformer-based architectures to model contextual dependencies. The process of inputting mutation data into a transformer architecture, particularly the tokenization step, is critical for this problem, and we explore various tokenization strategies. Benchmarking these representations will include evaluating their utility across tumor subtype classification, biomarker discovery, patient stratification, drug response prediction, identification of mutational signatures. Although the model is under development, experiments from prior work—limited to mutation identifiers without leveraging sequence motifs, mutation location, or other contextual information—have demonstrated the feasibility of encoding mutational data into meaningful representations using transformer-based architectures and self-supervised learning. Building on these findings, this framework will benchmark its performance on multiple downstream tasks, including tumor subtype classification and patient stratification.

#5063 Hepatomap: An interactive shiny app for spatial transcriptomics insights in hepatocellular carcinoma.

Wei Lin Tang[1], Teresa J. Y. Tye[2], Menaka Priyadharsani Rajapakse[1], Solomonraj Wilson[1], Olaf ROtzschke[1], David Tai[3], Darren Wan-Teck Lim[3], Juha P. Vayrynen[4], Joe Poh Sheng Yeong[3], **Mai Chan Lau**[1]

[1]Singapore Immunology Network, Agency for Science, Technology And Research, Singapore, Singapore,[2]Department of Life Sciences, Imperial College London, London, United Kingdom,[3]Department of Medicine, SingHealth Duke-NUS Academic Medical Centre, Singapore, Singapore,[4]Translational Medicine Research Unit, Medical Research Center Oulu, Oulu University Hospital, Finland, Finland

Introduction: Hepatocellular carcinoma (HCC) is a heterogeneous cancer where spatial context and cellular microenvironments influence disease progression and therapeutic responses. Spatial Transcriptomics (ST) enhances immune analysis by mapping gene expression spatially, revealing cell organization and interactions. However, interpreting ST data in HCC is challenging due to high data dimensionality, unestablished bioinformatics pipelines, and fragmented knowledge in the literature. We introduce HepatoMap, a code-free interactive tool designed to streamline ST analysis for HCC research. It enables in situ visualization of expression patterns for curated HCC-associated signatures, identification of cellular interactions through cell type annotation, and uncovers molecular heterogeneity in HCC samples.
Methods: A cohort of 13 HCC patients included baseline and radiotherapy-nivolumab treated samples (with 9 pairs), 2 super responders (SRs), 2 progressors (PRs), and 9 non responders (NRs). HepatoMap (R shiny v1.9.1) supports Visium data in Seurat object and spot annotation text files. Gene enrichment scores were computed via Seurat's AddModuleScore. It includes 2 cell type annotation methods: MCP counter (marker-based) and SPOTlight (reference-based deconvolution method, with 2 pre-trained models built on TICAtlas and GSE149614 single-cell RNA references). It also provides a curated list of HCC-associated modules (cancer stem cell (CSC), driver genes), and allows users-upload gene sets , where Seurat's AddModuleScore is used to compute enrichment scores. ggplot2 (v.3.5.1) is used for box plots, pie charts, and tissue visualization; ComplexHeatmap (v2.10.0) is for heat maps. The tool offers multi-tissue visualization for cross-sample comparison and downloadable publication-ready graphics.
Results: To characterize immune response, the SPOTlight models revealed an increased T cells in treated SRs, with TICAtlas model providing finer resolution by identifying CD4 effector memory cells. SPOTlight offers resolution flexibility but assumes reference cell types represent the entire microenvironment, which may be limiting. MCP counter complements this by computing scores for predefined gene markers, revealing B cell increases in SRs and identifying additional cell types like endothelial cells and neutrophils for more comprehensive immune profiling. Additionally, contrasting to literature, SRs showed elevated CSC scores in tumor epithelium upon treatment, while a decrease was seen in NRs and PRs after treatment, adding depth to immune cell analysis.
Conclusion: We presented HepatoMap, a tool streamlining ST analysis for HCC, uncovering molecular heterogeneity and cell-type dynamics through robust cell type annotation and tumor-specific profiling. The tool is adaptable to ST technologies like Xenium and Stereo-seq, expanding its relevance in spatial immunology.

#5065 Single-cell transcriptomic profiling of longitudinal patient tumors and PDX models reveals resistance mechanisms in ALK- and EGFR-mutant LUAD.

Naomi Mfonfu[1], Floriane Braye[1], Galina Boldina[2], Matteo Cesaroni[2], Luc Fibroulet[1], Sergey Nikolaev[1], Andrey Yurchenko[1]

[1]Gustave Roussy, Villejuif, France,[2]Sanofi, Vitry-sur-Seine, France

Resistance to EGFR and ALK tyrosine kinase inhibitors (TKIs) in lung adenocarcinoma (LUAD) remains a major barrier to effective treatment. Tumor adaptation frequently involves dynamic cellular state transitions, altered signaling networks, and interactions within the tumor microenvironment (TME). Understanding the mechanisms driving resistance in EGFR- and ALK-mutant tumors is critical to developing strategies to improve patient outcomes. This study investigates transcriptomic changes underlying TKI resistance and persistance, combining patient data with functional insights from PDX models. Tumor biopsies from 11 LUAD patients were collected across three treatment stages: baseline (n=6), minimal residual disease (MRD, n=4), and relapse (n=1). Patient-derived xenograft (PDX) models were generated from pretreated tumors with EGFR and ALK mutations. Tumors were grafted into five mice per model, with three receiving treatment until stable residual disease emerged and two serving as untreated controls. Single-nucleus RNA sequencing was performed on both patient tumor samples and PDX models to comprehensively profile transcriptomic changes. Transcriptomic changes were observed in both patient tumor samples and PDX models during TKI treatment. In patients, at MRD, a novel subpopulation expressing mesenchymal and neuronal markers was identified, accompanied by altered cell-cell communication involving neuronal signaling (RELN), stromal remodeling (FGFRs), and survival pathways (MAPK). At relapse, signatures of epithelial-mesenchymal transition (EMT), ECM remodeling, and immune evasion were enriched. In PDX models, most persister cells were arrested in the G1 phase and showed suppression of canonical cancer pathways, while notable upregulation of the ciliated pathway was observed across models. This study provides a high-resolution transcriptomic map of TKI-treated LUAD tumors. Resistance mechanisms in EGFR- and ALK-mutant tumors include neuronal, EMT, MAPK signaling, ECM remodeling, and activation of the ciliated pathway. These findings offer novel therapeutic targets to combat resistance, leveraging the integration of patient-derived data and functional insights from PDX models.

#5066 Single-cell characterization of airway field alterations in patients with lung squamous premalignant lesions.

Regan D. Conrad[1], Conor Shea[1], Lukas Kalinke[2], Kitty De Jong[3], Sherry Zhang[1], Zhihan Li[1], Gang Liu[1], Erin Kane[1], Emily Siedlecki[3], Kelsey Simon[3], Kate E. J. Otter[2], Kate Gowers[2], Mark Hennon[3], Sai Yendamuri[3], Steven Dubinett[4], Avrum Spira[1], Mary Reid[3], Sam Janes[2], Marc Lenburg[1], Sarah Mazzilli[1], Joshua Campbell[1], Jennifer Beane[1]

[1]Section of Computational Biomedicine, Boston University School of Medicine, Boston, MA,[2]Lungs for Living Laboratory, University College London, London, United Kingdom,[3]Roswell Park Comprehensive Cancer Center, Buffalo, NY,[4]David Geffen School of Medicine, UCLA, Los Angeles, CA

Lung cancer is the leading cause of cancer-related mortality worldwide, and there is a critical need for early detection strategies to reduce its burden. In high-risk individuals, low-dose computed tomography (LDCT) reduces lung cancer mortality by detecting cancer at earlier stages. Gene expression obtained from bronchial and nasal brushings effectively discriminates benign from malignant lung nodules detected via LDCT. Lung premalignant lesions (PMLs), precursors to cancer, represent an opportunity for further mortality reduction, but detection methods remain underexplored. This study uses single-cell RNA sequencing (scRNA-seq) to investigate molecular and cellular alterations in the airway field of patients with PMLs.

Endobronchial biopsies from lung sites with suspect PMLs and bronchial and nasal brushes from normal-appearing epithelium were collected from high-risk patients (n=46). Epithelial and immune cells were profiled using scRNA-seq via the CEL-Seq2 protocol (n=9405 biopsy, n=3416 bronchial brush, and n=2002 nasal brush cells). Cell and gene clustering were performed via Celda. Co-expressed gene modules and cell-type abundance differences by sample type, smoking status, and lesion histology were identified with differential composition analysis and linear mixed models. Gene module associations with phenotypes were validated in independent bronchial brushes profiled by bulk mRNA-seq (n=89 samples, n=30 patients).

Clustering of epithelial cells (40 cell clusters, 70 gene modules) showed nasal brushes are enriched in cells from 9 cell clusters ($p<0.001$) with high expression of detoxification and mucous production gene modules. Nine gene modules associated with smoking status ($p<0.001$) across sample types were enriched for xenobiotic metabolism genes. The effect of smoking on these gene modules was strongest in bronchial biopsy samples, decreased in bronchial brushes and weakest in nasal brushes. This stepwise decrease was significant for each pairwise comparison ($p <= 0.001$). Five basal cell clusters enriched with carcinoma in situ lesion or tumor cells (termed high-grade basal cells) expressed 7 gene modules linked to keratinization and inflammation ($p<0.01$). Cells from a bronchial brush sample clustered with high-grade basal cells. The expression of a gene module upregulated in high-grade basal cells was associated with the worst lesion histology sampled during the procedure ($p=0.006$) in bronchial brushes profiled by bulk RNA-seq.

This study identifies smoking and lesion severity associated molecular and cellular alterations in the airway fields of patients with PMLs. These findings suggest that airway field brushings may be useful in detecting the presence of high-grade PMLs.

#5067 Concurrent spatial transcriptomics and metabolomics map differential effects of drug across brain cancer tissues.

Tuan Vo[1], Cedric Cui[1], Andrew Causer[2], Xiao Tan[2], Eunju Kim[1], Zherui Xiong[2], Hani Vu[2], Mark Hodson[2], Tianyao Lu[3], Saskia Freytag[3], Jenny Fung[1], John Lee[1], **Quan Nguyen**[2]

[1]The University of Queensland, Brisbane, Australia,[2]QIMR Berghofer Medical Research Institute, Brisbane, Australia,[3]WEHI, University of Melbourne, Melbourne, Australia

The spatial heterogeneity of tumors poses significant challenges for effective treatment, resulting in varied therapeutic responses across different regions of the same tumor. This challenge is especially pronounced in brain cancers, where uneven drug distribution—largely due to biological barriers like the blood-brain barrier—complicates treatment. Techniques that overlay drug distribution with transcriptional profiles would enable a comprehensive, unbiased investigation of drug effects.

In this study, we present a spatial multiomics approach that integrates spatial metabolomics and spatial transcriptomics within the same tissue section of mouse brain samples treated with Palbociclib, a selective CDK4/6 inhibitor with potential for targeting various cancers, including breast cancer and medulloblastoma (MB). Our high-resolution (2-55 µm) concurrent multiomics maps reveal that the differential distribution of Palbociclib results in heterogeneous effects, promoting differentiation and reducing proliferation in specific tumor regions. Through this approach, we identified tissue regions exhibiting distinct transcriptional and metabolic signatures, including areas unaffected by drug treatment, which could contribute to recurrence.

To support this analysis, we developed SpaMTP, a state-of-the-art software package providing a comprehensive pipeline for in-depth analysis of spatial metabolomics for integrating spatial multiomics data. This package bridges processing functionalities for metabolomic data from Cardinal with user-friendly cell-centric analyses implemented in Seurat. SpaMTP's comprehensive analysis pipeline covers (1) automated mass-to-charge ratio (m/z) metabolite annotation, (2) a wide range of downstream statistical analyses including differential metabolite expression and metabolic pathway analysis, and (3) integrative spatial-omics analysis. For broad implementation and interoperability, SpaMTP includes various functions for data visualisation, data object conversion and data import/export.

Overall, our work describes novel experimental and analytical methods to map drug distribution and its transcriptional impacts directly, offering critical insights into the heterogeneous effects of Palbociclib across brain tumor tissues.

#5068 Spatial architecture and epigenetic programs in IDH-mutant and wildtype glioma.

Jingxian Liu[1], Song Cao[1], Wagma Caravan[1], Xiangwei Fang[1], Preet Lal[1], Andrew Houston[1], Yuting Zhao[1], Faria Anjum Simin[1], Michael C. Jin[1], Jennifer Ponce[2], Robert Fulton[2], Michael Heinz[1], Yang Li[3], Sonika M. Dahiya[4], Dimitrios Mathios[3], Tao Liu[5], Albert H. Kim[3], Milan G. Chheda[1], Li Ding[1]

[1]Department of Medicine, Washington University in St. Louis, St. Louis, MO,[2]McDonnell Genome Institute, Washington University in St. Louis, St. Louis, MO,[3]Department of Neurosurgery, Washington University in St. Louis, St. Louis, MO,[4]Department of Pathology & Immunology, Washington University in St. Louis, St. Louis, MO,[5]Biological Sciences Division, Pacific Northwest National Laboratory, Richland, WA

Gliomas account for over 80% of primary malignant brain tumors. Among the most aggressive of these is IDH-wildtype high-grade glioma (HGG), known as glioblastoma, which is resistant to treatment and carries a median survival of 15 months. Genomic and transcriptomic characterization of HGG demonstrate strong inter- and intra-tumor heterogeneity. Distinct from IDH-mutant glioma which notably exhibit diffuse infiltrative histology with hypermethylated molecular phenotype, IDH-wildtype HGG circumferentially organize around a necrotic core with aggressive tumor expansion and macrovascular proliferation. Both IDH mutation status and tumor grade are significant prognostic factors. While IDH inhibitors have had success in IDH-mutant low-grade glioma (LGG), prognosis remains poor for HGG regardless of IDH status. Hence, a comprehensive multi-omic and spatial dataset spanning IDH status and tumor grades is crucial to further delineate similarity and heterogeneity along the disease course. In this study, we present a cohort of 85 specimens from 68 patients with high- and low-grade glioma, as well as comparisons with metastases and normal brain. To comprehensively investigate the epigenetic programs and spatial architecture of glioma driven by IDH status and tumor grade, we performed multiome single-nucleus sequencing, Xenium spatial in-situ gene expression assay, whole exome sequencing and pathological reviews. Concurrent snATAC and snRNA, in the same cell, identified differential epigenetic programs and downstream transcriptional changes. Global ATAC and RNA similarity shows IDH-mutant tumors, regardless of grade, are most closely related to oligodendroglial precursor cells (OPCs) whereas IDH-wildtype tumors show similarity to neurons, astrocytes and OPCs. To understand the spatial context differences between these tumors, we performed Xenium in-situ gene expression assays on 9 IDH-wildtype and 8 IDH-mutant HGG samples. We observe not only an increased density of OPCs in IDH-mutant HGG, but also a distinct tumor niche organized around OPCs that is more frequently observed in IDH-mutant tumors. This niche demonstrated upregulation of neurogenesis pathways and reduced hypoxia signature compared to tumor cells spatially discontiguous from OPC communities. Taken together, multimodal assessment of single-cell epigenetics, transcriptomic trajectory, and spatial organization provide further insight on glioma pathogenesis.

#5070 Tumor spatial configuration predicts pancreatic cancer recurrence risk after total neoadjuvant therapy.

Andrea V. Maraone[1], Zafar Siddiqui[1], Luis H. Cisneros[1], Merih D. Toruner[2], Mark Truty[1], Cornelius Thiels[1], Robert R. McWilliams[1], Steven R. Alberts[1], Rondell P. Graham[1], Carlo Maley[3], Qian Shi[1], Martin E. Fernandez-Zapico[1], Ryan M. Carr[1]

[1]Mayo Clinic, Rochester, MN,[2]Brown University, Providence, RI,[3]Arizona State University, Tempe, AZ

Despite advances in surgery and chemotherapy, patients with resectable pancreatic ductal adenocarcinoma (PDAC) face high recurrence rates (40-60%). Total neoadjuvant therapy (TNT) seeks to enhance margin-negative resections (R0) and address micrometastatic disease, with potential survival benefits. Yet, TNT still results in high recurrence rates, with 1-, 2-, and 3-year disease-free survival (DFS) at 65%, 48%, and 32%, respectively. Residual cancer extent is a key prognostic factor in PDAC after TNT. Tumor response scores show favorable outcomes only for patients achieving near-complete or complete pathologic response. In a cohort of 511 PDAC patients treated with TNT and surgery (2015-2022), improved DFS was only found in those with a complete pathologic response (pCR, 7.8%). This highlights the limited use of current response scoring in stratifying post-TNT patient risk, underscoring the need to better understand disease persistence and relapse. Here we developed a quantitative method to assess residual cancer. Using a digital pathology H&E library from 2180 PDAC cases (2000-2022), an AI platform segmented tissue into cancer epithelium, stroma, and normal regions. For 202 TNT-treated cases without pCR, we calculated a ratio of cancer area to stromal area from representative slides. Modeled after the histologic tumor regression grade (HTRG) system, cases were classified into <5%, 5-50%, or >50% cancer-to-stroma ratios. However, this measure alone showed no difference in DFS, suggesting tumor burden cannot fully explain differences in clinical outcomes. We hypothesized that the spatial organization of the tumor microenvironment (TME) is a determinant of patient outcomes. Drawing from landscape ecology, which studies spatial properties of ecosystems, we applied similar principles to analyze tissue architecture. Using an AI-based two-class segmentation of whole-slide images, we assessed spatial features like patch area, perimeter, density, and Shannon diversity. Python's 'pylandstats' package calculated 21 spatial metrics, reduced via stepwise Cox regression using the Akaike information criterion (AIC). The final model included mean Shannon diversity, mean and standard deviation of stromal patch areas, and stromal patch density. Kaplan-Meier analysis of 202 samples stratified model predictions into quartiles, correlating with high (mean DFS 10.85 months), medium (19.32 months), and low risk (25.92 months) groups. These findings aligned with model expectations, underscoring the potential of spatial TME analysis to predict outcomes.

#5071 Spatially resolved gene expression analysis of primary and metastatic fibrolamellar hepatocellular carcinoma (FLC).

Waqar Arif[1], Luciane Kagohara[2], Robert A. Anders[1], Kiyoko Oshima[1], Mark Yarchoan[2]

[1]Department of Pathology, The Johns Hopkins Hospital, Baltimore, MD,[2]Department of Oncology, The Johns Hopkins Hospital, Baltimore, MD

Fibrolamellar carcinoma (FLC) is a rare and aggressive malignancy of the liver that predominantly affects adolescents and young adults. These tumors are distinct from conventional hepatocellular carcinomas and are characterized histologically by thick fibrous collagen bands. The transcriptome of FLC is characterized by a recurrent oncogenic fusion between DNAJB1 and PRKACA. Liver resection is a potentially curative treatment option for early-stage FLC, but there are no standard systemic therapies available for advanced FLC. Most patients present with unresectable disease or relapse after surgery; for these individuals, outcomes are dismal with a median survival of only 12 months. This highlights the urgent need to understand the natural evolution of FLC, which in turn will support the development of effective targeted therapies. To investigate the evolution of FLC, we leveraged FLC tissue samples from n=5 patients with paired primary and distant metastatic surgical biopsies. Among these patients, 4/5 received systemic therapy including immunotherapy in the interval between primary resection and resection of the distant metastatic lesions. A histological view of the cases revealed notable morphological differences between the primary and metastatic tumors. Primary tumors showed the characteristic oncocytic tumor cells separated by thick cords of collagen fibrosis. However, the metastatic lesions exhibited reduced fibrosis or lacked it entirely, suggesting malignant progression of the tumor and loss of a key histological hallmark of FLC over time. To date, most transcriptomic analysis of FLC has been performed on bulk tissue which neglects the heterogeneity of the tumor. To capture the complexity of the lesion, we performed spatial transcriptomic analysis of our paired samples (n = 10, primary and metastatic lesions) using the VisiumHD platform by 10x Genomics. Furthermore, we succeeded in labeling the neoplastic cells using a custom-designed probe against the DNAJB1-PRKACA chimeric transcript which we included in the standard probe library. Spatially resolved gene expression analysis and neighborhood analysis using the Seurat workflow revealed marked differences in transcriptional networks coinciding with the progression of the tumor. Here we present a spatially and temporally resolved transcriptome atlas of FLC. This rich and valuable resource will be critical for understanding FLC biology and ultimately developing novel therapeutics.

#5072 Single cell-based elucidation of molecularly distinct glioblastoma states and drug sensitivity.

L. Tomassoni[1], W. Zhao[1], H. Ding[2], K. Egbuji[1], P. Laise[1], M. J. Alvarez[1], J. L. Furnari[1], M. G. Argenziano[1], M. A. Banu[1], J. N. Bruce[1], P. D. Canoll[1], P. A. Sims[1], A. Califano[1];

[1]Columbia University Irving Medical Center, New York, NY, [2]University of Arizona, Tucson, AZ

Glioblastoma (GBM) heterogeneity and plasticity represent critical challenges to the development of successful treatment options, because molecularly distinct subpopulations present different drug sensitivities, leading to resistance [Yuan et al., 2018; Neftel et al., 2019; Ding et al., 2019]. In fact, clinical outcomes for GBM, which accounts for >80% of all primary gliomas [4], have not improved over the last 20 years. Unfortunately, due to the sparse nature of single cell RNA-seq (scRNA-seq) profiles, prediction of subpopulation-specific dependencies and drugs has been difficult. To overcome this problem, we leveraged network-based algorithms, single cell versions of the ARACNe [Margolin et al., 2006], VIPER [Alvarez et al., 2016], and OncoTreat algorithms [Alvarez et al., 2018] (NY and CA Dept of Health approved, CLIA compliant algorithm, currently used in several clinical trials), to analyze a collection of scRNA-seq profiles from 16 GBM patients to elucidate Master Regulator (MR) proteins, representing molecular determinants and thus non-oncogene dependencies, of distinct, co-existing GBM cell states and to prioritize compounds capable of inverting their activity. OncoTreat prioritizes drugs by assessing their ability to invert the activity of subpopulation-specific MR proteins, based on the analysis of large-scale drug perturbation assays, thus supporting the identification of small molecule inhibitors targeting distinct tumor compartments within the same patient for potential combination therapy. Specifically, we used a library of genome-wide RNASeq profiles representing the response of proneural (PN) (HF2597 neurosphere) and mesenchymal (MES) (U87 cell line) cells at 24h following treatment with >350 clinically relevant drugs generated by the Califano Lab. The top six drugs predicted to target MES and PN subpopulations were tested in acute slices from GBM resections allowing direct characterization of the drug-mediated depletion of subpopulations predicted to be sensitive in adjacent drug vs. vehicle control treated slices [Zhao et al., 2021].Confirming our predictions, we observed statistically significant depletion of the MES and PN compartments by 3 of 3 (Dasatinib, Bexarotene and Prednisone) and 2 of 3 (Givinostat and Ixazomib) OncoTreat-predicted drugs, respectively. Given its high validation rate, this study paves the road and provides significant insight into the future development of combination trials where these drugs may be administered either concomitantly or sequentially. Moreover, the computationally inferred differential activity of subtype-specific MR proteins (CD44, OLIG2, KDM2B, EPHB3, TOP2B and others) was experimentally validated by FACS in cultured patients-derived GBM neurospheres.

#5073 Whole transcriptome spatial molecular imaging in matched pre and post treatment specimens to identify treatment-associated effects in pancreatic adenocarcinoma.

Beatrice W. Awasthi[1], Dennis Gong[1], Nicole Lester[1], Jung Woo Bae[1], Xunqin Yin[1], Ashley Heck[2], Elizabeth Stirling[2], Maximilian Walter[2], Megan Vandenberg[2], Margaret Hoang[2], Prajan Divakar[2], Joe Beechem[2], David T. Ting[3], William L. Hwang[1]

[1]Center for Systems Biology, Department of Radiation Oncology, and Center for Cancer Research, Massachusetts General Hospital, Boston, MA,[2]Bruker, Seattle, WA,[3]Mass General Cancer Center, Harvard Medical School, Charlestown, MA

Pancreatic ductal adenocarcinoma (PDAC) is among the deadliest cancer types with a poor therapeutic response. The molecular heterogeneity of PDAC has been well-studied using dissociated single-cell approaches, but clinically relevant spatial architecture remains poorly understood. Innovations in spatial profiling approaches over the years have facilitated *in situ* annotation and mapping of cell types in PDAC tumors. Nevertheless, spatial imaging at subcellular resolution has been limited to only a few thousand targets at a time, due to the challenges in attaining acceptable resolution as target panel sizes increase. Moreover, increased data sparsity with higher panel sizes greatly increases the challenges of cellular annotation. Consequently, the analysis of cellular programs has been limited to preselected targets. A whole-transcriptome (WTx; 18,985 targets) panel for spatial molecular imaging has recently been developed that enables unbiased discovery and spatial annotation of novel gene programs that may be missed with smaller panel sizes. These signatures could parse out nuanced clinically relevant transcriptional features, including subtype and intercellular interactions. We previously applied a 1000-plex (1K) spatial transcriptomics panel to evaluate post-treatment tissue remodeling in 13 unmatched primary PDAC specimens. Here, we analyzed five matched pre-treatment core biopsies and post-treatment resection specimens at subcellular resolution at both 1K panel and whole transcriptome levels on consecutive sections. This analysis provides the first direct window into treatment-induced effects in PDAC. With the WTx panel, we identified a mean of >1000 unique genes per cell, and up to 1,700 transcripts, with up to 125,000 cells analyzed per matched pair. To overcome the challenge of cellular annotation in the context of increased sparsity in the WTx data, we first annotated cells using the 1K panel, then used these labels to guide the WTx annotations. Merging our transcriptional annotations with hematoxylin and eosin-staining of FFPE sections annotated by a board-certified pathologist gave insight into the cellular composition of pre-and post-treatment samples and potential intercellular interactions around specific features and cell populations of interest. This study highlights new strategies for analyzing whole-transcriptome spatial transcriptomics at subcellular resolution and the potential thereof to identify novel treatment-associated effects.

#5074 Estimation of homologous recombination deficiency map from spatial transcriptomics.

Jeongbin Park, **Yuchang Seong**, Dongjoo Lee, Hongyoon Choi

Portrai, Inc., Seoul, Republic of Korea, Seoul, Korea, Republic of

Background: Homologous recombination deficiency (HRD) is a predictive biomarker for various anti-cancer drugs such as poly(ADP-ribose) polymerase inhibitors (PARPi) and platinum-based chemotherapeutic agents. The HRD score has been estimated using genomic and molecular assays, even though due to cancer heterogeneity, HRD could vary in the tumor microenvironment. Here, we developed a model to predict HRD score by estimating copy numbers and calculating loss of heterogeneity (LOH), large-scale state transitions (LST), and telomeric-allelic imbalance (TAI) scores resulting in exhibiting both spatial coherence and heterogeneity, making them suitable for clinical biomarkers addressing tumor heterogeneity. To estimate these scores with counts from ST data, STARCH algorithm was utilized and the copy number for each gene across spots within cancer clones was obtained. HRD scores are determined by adding together LOH, TAI, and LST. We applied these analyses to Visium and VisiumHD data from breast cancer samples and visualized the spatial distribution of the HRD score within the cancer cell map in the tumor microenvironment.
Result: This method was applied to both Visium and Visium HD data to show the heterogeneity in the HRD score. The HRD scores effectively reflected spatial patterns and demonstrated high heterogeneity, highlighting their potential as clinical biomarkers. Furthermore, when applied to direct Visium data (Visium FF), the HRD scores predicted using only gene expression data yielded similar conclusions to those calculated considering both gene expression and allele counts. Notably, the concordance between the two approaches was higher when normal spots were not separately input. Additionally, running the analyses separately or collectively produced comparable conclusions.
Conclusion: By developing a model to predict HRD scores from ST data, it becomes possible to analyze the relationship between pathophysiological mechanisms and HRD across various cancer types. This approach not only enhances our understanding of tumor biology but also enables the prediction of HRD score maps while accounting for spatial heterogeneity in predictive biomarkers. Such advancements could improve personalized treatment strategies and clinical decision-making for patients.

#5075 Detection and spatial analysis of mRNA delivered by lipid nanoparticles through spatial transcriptomics.

Jeongbin Park[1], **Yuchang Seong**[1], Dongjoo Lee[1], Jinyeong Choi[1], Hanna Jung[2], Somin Lee[3], Hongyoon Choi[1], Hyungjun Im[1]

[1]Portrai, Inc., Seoul, Korea, Republic of,[2]Department of Applied Bioengineering, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of,[3]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University, Seoul, Korea, Republic of

Background: Lipid nanoparticle (LNP) platforms are widely used for mRNA delivery, but the precise distribution of mRNA within tissues remains poorly understood. Spatial transcriptomics technologies have enabled detailed mapping of RNA localization in tissues. In this study, LNPs targeting the spleen were used to encapsulate tdTomato mRNA, and spatial transcriptomics was employed to analyze its distribution and interactions within the spleen microenvironment.
Methods: Spleen-targeting LNPs were developed to deliver codon-optimized tdTomato mRNA. Space Ranger and advanced alignment algorithms were used to distinguish endogenous and externally delivered mRNA. Overlapping sequences with mouse hemoglobin genes were excluded to ensure accurate analysis. After mapping tdTomato mRNA onto the ST data, we performed colocalization analysis with the ST data of the mouse spleen to demonstrate the precise distribution of tdTomato mRNA within the tissues.
Results: The transcriptomic analysis of mouse spleen tissues revealed distinct red pulp, white pulp, and marginal zone morphologies. Similar gene expression profiles between control ('Con') and experimental ('Exp') samples indicated comparable tissue conditions. tdTomato mRNA was observed exclusively in the 'Exp' sample, predominantly localized in the red pulp, aligning with the expected LNP delivery pathway via blood circulation. Spatial correlation analysis in the 'Exp' sample revealed that hemoglobin genes were highly correlated with tdTomato mRNA, while ribosome-related genes showed the lowest correlation. RNA degradation analysis demonstrated intact tdTomato mRNA in the medulla, whereas significant degradation was observed in the cortex. Compared to fluorescence imaging, the platform used provides distinct advantages, such as absence of autofluorescence, offering PCR-level sensitivity, and enabling absolute quantification, thereby enhancing the precision of these findings.
Conclusion: Using spatial transcriptomics, the study successfully mapped the distribution of externally delivered tdTomato mRNA within tissue and analyzed its spatial interactions with the surrounding microenvironment. RNA degradation patterns revealed distinct microenvironments affecting mRNA stability. These findings provide insights into the pharmacokinetics of mRNA-loaded LNPs and support the development of optimized nucleic acid delivery systems.

#5076 Unravelling melanoma brain metastasis tumor microenvironment characteristics using spatial transcriptomics.

Clemence J. Belle[1], Sandra Brosda[1], Vanessa F. Bonazzi[1], Victor Bulteau[1], Thomas Stuart[1], Zherui Xiong[2], Duncan Lambie[3], Peter A. Johansson[2], Lauren G. Aoude[1], Kalpana Patel[1], Samantha J. Stehbens[4], Mitchell S. Stark[1], Nikolas K. Haass[1], Wen Xu[3], Mark B. Pinkham[3], Matthew C. Foote[3], Sarah Olson[3], Victoria Atkinson[3], Arutha Kulasinghe[1], Quan H. Nguyen[2], Andrew Barbour[1]

[1]Frazer Institute, The University of Queensland, Woolloongabba, Australia,[2]QIMR Berghofer Medical Research Institute, Herston, Australia,[3]Princess Alexandra Hospital, Woolloongabba, Australia,[4]Australian Institute for Bioengineering and Nanotechnology, The University of Queensland, St Lucia, Australia

Background: Advanced melanoma is an aggressive cancer with a high metastatic potential often resulting in melanoma brain metastases (MBM). The complexity of the MBM tumor microenvironment (TME) impacts tumor progression and therapy response, leading to poor outcomes. Our study integrates spatial transcriptomics profiles with tissue morphology annotations of MBM and clinical data to investigate the TME landscape in relation to treatment and patient outcomes.
Methods: We performed spatial transcriptomics on 21 MBM samples collected after various treatment strategies. All samples were preserved in formalin-fixed paraffin-embedded (FFPE) blocks and profiled using the Visium Spatial Gene Expression kit (10X Genomics) with a 6.5x6.5mm Visium Capture slide. All sequencing was performed on a NovaSeq6000 platform (Illumina) with an average of 71,391 reads per spots. H&E slides were annotated by our study pathologist (DL) to enable pathology-guided cluster analysis. Spatial transcriptomics data analysis was conducted using Seurat R pipeline which involved data quality check, normalization, integration, cell type annotation and deconvolution, and clustering. Further differential gene expression analyses were performed between different identified tumor clusters or between clinical groups, leading to the identification of enriched pathways and cell-cell interaction patterns.
Results: Our phenotyping of 25,208 spots revealed the presence of diverse cell populations, including neurons, melanoma, plasma, endothelial, stromal, and myeloid cells. We identified 8 distinct functional clusters characterized by specific gene expression and activated pathways. These include 5 tumor clusters with different immune infiltration or expression profiles, identifying differences in cell metabolism and heterogeneity in the TME. Importantly, we found MBM from patients exposed to radiation were significantly enriched for epithelial-to-mesenchymal transition pathway and genes related to cell adhesion. We further showed a reduced immune response in patients received radiation compared those who did not, and we noted that an active immune response was generally positively correlated with survival.
Conclusions: Our study is the largest spatial analysis of MBM reported to date. Advances in spatial technologies provide novel insights into the structure and composition of MBM TME. Our findings highlight the importance of spatial context in understanding MBM biology and the potential of spatial transcriptomics in advancing precision oncology.

#5077 Single-cell and bulk RNA sequencing reveal SPINK1 and TIMP1 as epithelial cell marker genes linked to colorectal cancer survival.

N. N. Al-Bzour[1], Z. N. Abu-Rjai'[2], A. N. Al-Bzour[1], A. Qasaymeh[1], L. Chen[3], A. Saeed[4], A. Saeed[5];
[1]Jordan University of Science & Technology, Irbid, Jordan, [2]Yarmouk University, Irbid, Jordan, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Vermont Medical Center, Burlington, VT, [5]UPMC Hillman Cancer Center, Pittsburgh, PA

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-related mortality, with tumor microenvironment and gene expression playing critical roles in disease progression and prognosis. Identifying specific epithelial cell marker genes linked to survival may enhance prognosis and guide targeted therapies.
Methods: Single-cell RNA (scRNA) data for CRC patients was obtained from TISCH database (n=23176 cells), in which we identified EMGs using differential expression clustering analysis. Bulk RNA data was downloaded from The Cancer Genome Atlas (TCGA-COAD, n = 375). Using TCGA-CRC data, EMGs were analyzed using univariate Cox model, followed by Least Absolute Shrinkage and Selection Operator (LASSO) to reduce overfitting. Significant genes from LASSO were then fitted in a multivariate Cox model to screen independent predictors of survival. A survival-related EMG signature was developed to calculate a risk score, classifying patients into low- and high-risk groups based on the median risk score. We validated the risk score using GSE17536 CRC dataset (n=177). xCELL was used to perform immune deconvolution analysis.
Results: 142 EMGs were obtained from scRNA and analyzed for prognostic significance in the TCGA bulk-RNA dataset. Univariate Cox analysis retrieved 34 survival-associated genes and was screened using LASSO-cox resulting in 6 genes: *CA2, CLCA1, ITLN1, SPINK1, SPINK4,* and *TIMP1.* Multivariate Cox analysis showed that SPINK1 and TIMP1 were independent predictors of survival with SPINK1 associated with better outcomes (HR: 0.87, p-value: 0.009), and TIMP1 with worse outcomes (HR: 1.81, p-value <0.001). The 2 survival-related EMG risk score was calculated, and patients were grouped into high (n = 187) and low-risk (n = 188) groups. The low-risk group showed significantly higher (overall survival) OS and (disease free survival) DFS compared to the high-risk group (Median OS: 23 vs. 21.8 months, p-value = 0.0027; Median DFS: 20.5 vs. 20.3 months, p-value = 0.044). The immune microenvironment analysis showed significant enrichment of dendritic cells, CD8+ central-memory T-cells, class-switched memory B-cells, and macrophages in the high-risk group, while the low-risk group was significantly enriched in gamma delta T-cells, T-helper 1 and T-helper 2 cells, plasma cells, and natural killer cells. In a validation cohort, the low-risk group (n=89) showed better survival outcomes compared to the high-risk group (n=88) (Median OS: 50.2 vs. 35.2 months, Median DFS: 43.8 vs. 24.5 months, p-value = <0.001).
Conclusion: Our results showed a significant role of EMGs in CRC prognosis. Among them, SPINK1 and TIMP1 emerged as independent predictors of survival. Differential immune enrichment patterns between risk groups show the potential of integrating EMGs with immune landscape analysis to refine risk stratification and inform personalized therapeutic strategies.

#5078 Single-cell characterization of a carcinosarcoma patient-derived xenograft model.

Alida Palmisano[1], Yuri Kotliarov[2], Parimal Kumar[3], Ting-Chia Chang[3], Li Chen[3], Brandie Fullmer[3], Alyssa Chapman[3], Amanda Peach[3], Biswajit Das[3], Tomas Vilimas[3], Thomas Forbes[3], Shahanawaz Jiwani[3], Melinda G. Hollingshead[4], Yvonne A. Evrard[5], Sarah Shin[6], Hari Sankaran[2], Julia Krushkal[2], Alice Chen[6], Yingdong Zhao[2], Chris A. Karlovich[3], Mickey Williams[3], Lisa M. McShane[2], James H. Doroshow[6]

[1]General Dynamics Information Technology, Falls Church, VA,[2]Biometric Research Program, Division of Cancer Treatment and Diagnosis, National Cancer Institute, Rockville, MD,[3]Molecular Characterization Laboratory, Frederick National Laboratory for Cancer Research, Frederick, MD,[4]Biological Testing Branch, Developmental Therapeutics Program, National Cancer Institute at Frederick, Frederick, MD,[5]Advanced Development Research Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD,[6]Division of Cancer Treatment and Diagnosis, National Cancer Institute, Bethesda, MD

Carcinosarcoma (CS) is a rare aggressive biphasic tumor characterized by the presence of both carcinomatous (epithelial) and sarcomatous (mesenchymal) components. It can occur in various organs, including uterus and ovaries, and often exhibits rapid progression. The biphasic nature of CS makes it challenging to treat. In this study, we characterized a patient-derived xenograft (PDX) model developed from a 27 year-old female with CS of unknown primary origin in the NCI Patient-Derived Models Repository (https://pdmr.cancer.gov) to understand the transcriptomic features of these different components.

PDX samples of the tumor were iteratively passaged in separate NSG mice, and samples from different lineages across passages P0-P2 were collected for analysis. Twenty-five separate carcinoma/sarcoma regions from 7 samples through laser capture microdissection were obtained for bulk RNA-seq. Fourteen samples were sequenced through single-cell RNA-seq using 10x Genomics Single Cell Chromium, including 2 samples in P0, 8 in P1 and 4 in P2. Mouse reads were excluded using XenoCell. Human-only reads were processed through standard QC filtering, integration and annotation with Cell Ranger, Seurat and other R packages.

After quality-based filtering, we obtained 24,648 single cells from the integrated tumor samples. Through unsupervised clustering, cells separated into 16 Seurat-identified clusters, with consistent percentages of carcinoma and sarcoma components in P0, P1 and P2. Based on gene expression signature scores, each cluster was given a label descriptive of the cluster status. Five clusters had more epithelial/carcinoma characteristics (including one with a distinct ciliated signature), 2 clusters displayed a clear mesenchymal/sarcoma phenotype, 4 had low reads or gene counts, 2 had high cell cycle signature score and 3 clusters did not have a distinct carcinoma or sarcoma status.

We identified differentially expressed genes in each annotated cluster relative to the other clusters and performed gene set enrichment analysis. Individual carcinoma clusters demonstrated upregulation of pathways related to apoptosis, hypoxia and inflammation (p-value < 0.05), while sarcoma clusters demonstrated upregulation of WNT signaling, EMT and angiogenesis (p-value < 0.05). Clusters with unclear carcinoma/sarcoma phenotype showed patterns of expression similar to carcinoma clusters, with the additional activation of oxidative phosphorylation and DNA repair pathways.

Single cell data for a CS PDX model show that the biphasic nature of this histology is stable through passaging. Using single cell data, we identified the presence of clusters that are not fully committed to either the carcinoma or sarcoma phenotype. These clusters could represent transitional cell populations which may provide insight into biological drivers of cell plasticity in this tumor histology.

#5079 Spatial transcriptomics analysis of early-stage ER+/HER2- breast cancer reveals unique prognostic immune-fibroblastic subtypes.

Hannah N. Nyarko[1], Zak Kinsella[1], Daria Kalinska-Lysiak[1], Niamh M.C. Connoly[2], Jochen Prehn[2], John Crown[3], Catherine Kelly[4], William Gallagher[5], Darran O'Connor[1]

[1]Pharmacy and Biomolecular Sciences, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[2]Physiology and Medical Physics, Royal College of Surgeons in Ireland (RCSI), Dublin, Ireland,[3]St. Vincent's Private Hospital, Dublin, Ireland,[4]Mater Private Network, Dublin, Ireland,[5]Conway Institute, University Colege Dublin, Dublin, Ireland

Introduction: ER+ breast cancers have the best prognosis among all known breast cancer subtypes. Nonetheless, a substantial proportion of these patients, approximately 41%, experience late recurrence after at least 10 years after diagnosis. Numerous studies have highlighted the pivotal role of the tumor microenvironment (TME) in ER- breast cancer prognosis. However, this has not been thoroughly explored in the ER+ breast cancer subtype. In this study, we investigated immune and stromal cell diversity in the tumor microenvironment in hormone-dependent breast cancers and their association with survival.
Methods: Using NanoString GeoMx Digital Spatial Profiling (DSP) with the Whole Transcriptome Atlas (WTA), we conducted spatial transcriptomics profiling on formalin-fixed, paraffin-embedded tissue samples (FFPE). Regions of interest (ROIs) were selected from a cohort of 410 early-stage ER+/HER2- patients' tissue microarray (TMA). Guided by Pan-cytokeratin immunostaining (panCK), ROIs were segmented into neoplastic epithelial cells (panCK+) and TME (panCK-). Cell deconvolution was performed to elucidate immune and stromal cell abundances, using Nanostring's Spatialdecon and CIBERSORT tools.
Results: Cell abundances dichotomized into high and low groups were assessed for their association with survival. While the overall lymphocyte abundance and its subpopulations (TCD4 and TCD8 abundances) were not significantly associated with survival, they were associated with increasing Oncotype risk score. On the other hand, high fibroblast abundance was significantly associated with decreasing Oncotype risk score and a better survival outcome as a categorical and continuous variable. Based on an unsupervised clustering of patients by their immune and stromal cell proportions two distinct subgroups of patients were identified; lymphocyte-rich and lymphocyte-deficient. The lymphocyte-deficient group was characterized by high infiltration of fibroblasts and endothelial cells. Survival analysis in the subgroups yielded a significant result with the lymphocyte-rich group being associated with poorer outcomes ($HR = 1.87$, $p = 0.04$). Pathway analyses of differentially expressed genes in the lymphocyte-rich subgroup showed increased activity in immune activation, while the lymphocyte-deficient group was associated with increased activity in the extracellular matrix organization and angiogenesis.
Conclusion: While this finding challenges the conventional understanding of the role of lymphocytes and fibroblasts in cancer research, this complexity throws light on the heterogeneity of the tumor microenvironment in ER+ breast cancers, and can be harnessed to improve risk stratification, for more accurate, individualized therapies.

#5080 Investigation of exome-wide tumor heterogeneity on colorectal tissue-based single cells.

N. Szakallas[1], A. Kalmar[2], B. Bartak[2], B. Molnar[2], I. Takacs[2];
[1]Eotvos Lorand Tudomanyegyetem, Budapest, Hungary, [2]Semmelweis University, Budapest, Hungary

The progression of colorectal cancer is highly influenced by various environmental and genetic conditions, however, we can highlight tumor heterogeneity presenting serious resistance to targeted therapies and having crucial effects on disease outcomes. Motivated by this issue, we aimed to develop an end-to-end single-cell sequencing workflow starting from morphology-derived sample isolation from different regions of a tissue slide continue with exome sequencing to investigate the patterns of tumor heterogeneity.
Colonic biopsy specimens were collected during the endoscopic procedure, then cryosections (15 µm) were prepared and mounted on MMI MembraneSlides. Hematoxylin-eosin staining was applied to visualize the tissue morphology. Single-cell samples were obtained from 12 individual regions of negative control (NEG), tumor-associated normal (NAT), and colorectal cancer (CRC) tissues. Each sample had a diameter of 30-40 µm and a height of approximately 10-20 µm and was cut from a membrane frame slide by laser microdissection method. Following the single-cell DNA extraction and library preparation (Qiagen GmbH, CA, US), we performed paired-end next generation sequencing using NextSeq High Output kit on a NextSeq 500/550 instrument (IIllumina Inc., San Diego, CA, USA). Finally, we implemented bioinformatics analysis focusing on the patterns of tissue heterogeneity in the samples illustrated by CRC-specific mutated genes.
We obtained sequencing data with an average of 30X coverage. We investigated the mutually exclusive and co-occurring gene pairs and found that the co-occurrence of genes corresponding to near-tumor tissues was more significantly detected (such as *TTN-ADGRE1* in CRC with $p<0.05$). Our observations on single-cell tumor heterogeneity revealed that the different regions associated with the tumor - including negative control tissues - displayed altered mutation and heterogeneity profiles. Eventually, we presented the onco-mutation motifs of tissue regions which showed that the occurrence of mutations in genes BRAF (4/12), FBXW7 (2/12), and PCDH17 (1/12) in CRC samples are linked to resistance to EGFR inhibitor therapy. Additionally, the non-zero mutation rate of COL5A1 (1/12) gene in NAT indicates poorer survival outcome of patients. Supplementary, we aimed to present additional therapy resistant mutations characteristic to antiangiogenic, 5-fluorouracil (5-FU), chemo- and cetuximab therapies.
In our study, we identified region-specific heterogeneity motifs and demonstrated the individual and cumulative heterogeneity patterns of CRC and NAT single-cell-like samples. Additionally, we successfully detected high impact actionable mutations that influence therapy response and survival chances.

#5082 Deep learning model for cancer diagnosis in frozen section sentinel lymph nodes with limited annotations.

Joonho Lee, Joonyoung Cho, DoKyung Kim, Yoon-La Choi, Kyungsoo Jung, **Tae-Yeong Kwak**, Sun Woo Kim, Hyeyoon Chang

Deep Bio Inc., Seoul, Korea, Republic of

Introduction: Frozen section (FS) rapidly examines suspected tumor tissue microscopically during surgery, aiding diagnosis and surgical decisions. However, when applying AI or digital pathology to FS examination, stain and scanner variations pose significant challenges in developing robust deep learning-based diagnostic models. This study proposes a method that reduces stain variation to detect cancer in H&E-stained FS images of breast sentinel lymph nodes.
Design: We utilized 19,881 FS WSIs and 11,985 FFPE WSIs. The dataset included FS and FFPE WSIs from 33 organs collected from The Cancer Genome Atlas (TCGA), additional FS and FFPE WSIs from a domestic hospital and the Camelyon16 dataset. We reserved 20% of the FS dataset for evaluation; the remaining data were split into training (75%) and validation (25%). We employed instance-based Multiple Instance Learning (MIL) to identify cancerous patches (512×512 pixels at 10× magnification) in each WSI. After achieving sufficient feature discrimination, we fixed the backbone network. We obtained rough annotations from pathologists on 12 lymph node FS WSIs and trained a classifier with various data augmentation.
Result: Our method shows that the MIL plus classifier-only approach consistently outperforms MIL with full fine-tuning across diverse datasets (Camelyon16 FFPE and domestic FS). By reducing scanner variation, we significantly improved the model's generalization, which is a primary contribution of this study.
Conclusion: These findings suggest that mitigating stain and scanner variations with limited annotations can substantially enhance the performance and generalizability of deep learning models in cancer diagnosis.

Method	Dataset	Scanner	AUC/ROC	Sensitivity	Specificity	F1-score
MIL + Full fine-tuned	Domestic (FS)	Pannoramic 1000(3DHISTECH)	0.9546	0.9337	0.8043	0.9415
	Camelyon 16 (FFPE)	Pannoramic 250 Flash II(3DHISTECH)	0.9223	0.9286	0.7000	0.7879
	Camelyon 16 (FFPE)	NanoZoomer-XR C12000-1(Hamamatsu)	0.9482	0.9400	0.6875	0.7705
MIL + classifier only	Domestic (FS)	Pannoramic 1000(3DHISTECH)	0.9536	0.9337	0.8696	0.9494
	Camelyon 16 (FFPE)	Pannoramic 250 Flash II(3DHISTECH)	0.9241	0.8929	0.8000	0.8197
	Camelyon 16 (FFPE)	NanoZoomer-XR C12000-1(Hamamatsu)	0.9380	0.8800	0.8875	0.8544

#5083 Investigating the impact of T cell receptor repertoire diversity on cancer outcome.

Naja Lange, Asbjorn Kjar, Randi Istrup Juul, Iver Nordentoft, Lars Dyrskjot, Nicolai Juul Birkbak

Department of Molecular Medicine (MOMA), Aarhus University Hospital, Aarhus, Denmark

T cells are key effector cells in the adaptive immune system, playing a central role in the defense against pathogens. However, as we age, T cells undergo functional decline due to immunosenescence, the gradual decay of the immune system with age. This decline negatively affects the function and composition of immune cells, leading to an increased susceptibility to age-related diseases, such as cancer. We hypothesized that characterization of the peripheral blood T cell receptor (TCR) repertoire has the potential to provide insights into the current state of the immune system and serve as a biomarker for cancer progression. To investigate this, we analyzed the peripheral blood TCR repertoire in 5441 non-cancer patients and 450 cancer patients, utilizing sequencing data of the TCR-β chain from multiple cohorts obtained locally and from public sources. In both cancer and non-cancer patients, we observed a decline in the percentage of non-expanded clones, averaging approximately 4.6% ($P = 2.15 \times 10^{-8}$) and 3.5% ($P < 2 \times 10^{-16}$) for every 10-year increase in age, respectively. This decline was accompanied by a proportional increase in the expanded T cell clones with advancing age. Analyses of TCR-β diversity across age groups revealed that, among older individuals, males exhibited lower diversity than females in both non-cancer ($P = 4.9 \times 10^{-5}$) and cancer patients ($P = 5.3 \times 10^{-5}$). Additionally, investigating the relationship between tumor stage and TCR-β diversity showed that lower diversity correlates with more advanced tumor stages. Our results suggest that low TCR diversity represents reduced immune competency and a limited ability to prevent cancer progression.

#5084 Evaluation of single-cell foundation models for cancer outcome predictions.

Haitham Elmarakeby, Ahmed Roman, Shreya Johri, Eliezer M. Van Allen

Dana-Farber Cancer Institute, Boston, MA

Introduction: Tumor single-cell data provide unique insights into the cellular dynamics of cancer progression and therapeutic outcomes. Inspired by advancements in natural language processing (NLP), foundation models are increasingly used in single-cell analyses to uncover biological insights and identify clinical biomarkers. However, the performance of these models on cancer-specific tasks remains underexplored. We present an extensive evaluation of foundation models trained on millions of single-cell profiles for cancer-focused investigations.

Methods: We evaluated nine predictive models-three traditional methods and six foundation models (four Geneformer and two scGPT models), across various downstream tasks. Traditional models used embeddings from high variable genes (HVG), principal components (PCA), and generative model embedding (scVI), each paired with a random forest classifier for downstream classification. The evaluated foundation models varied in architecture sizes, pretraining dataset sizes (30M to 95M cell profiles), and training datasets, which were either generic or cancer-specific. We assessed the quality of representations by measuring their predictive performance on lung cancer treatment status (TKI treated vs. treatment-naive patients) and breast cancer subtypes (ER+ vs. TNBC). We examined how model characteristics influenced their performance in these domains for all tasks.

Results: Zero-shot evaluations of the foundation models showed superior single-cell data clustering, measured by average silhouette width (ASW), compared to traditional methods (HVG, PCA, scVI), suggesting that pre-trained embeddings from millions of single-cell profiles may offer enhanced representations. We thus evaluated the learned representation on downstream predictive tasks, showing that foundation models with a larger pretraining dataset (95M cells), cancer-specific training, larger input size (4096 genes), and deeper model (12 layers) achieved the best performance among foundation models (F1=0.97) for predicting treatment status in lung cancer. In contrast, smaller and generic foundation models had significantly lower performance, however, additional self-supervised training on task-specific data rescued their performance to match larger foundation models. Similar trends were observed in predicting breast cancer subtypes. Notably, the best foundation model's performance was not significantly different from the best traditional method (PCA) in predicting breast cancer subtypes.

Conclusions: These results highlight key factors driving foundation model performance on cancer-specific tasks. While current foundation models show inconsistent contributions to cancer-specific questions, observed performance trends highlight their potential to enhance single-cell data representation and drive significant advancements in cancer research and precision medicine.

#5085 Network toxicology and single-cell RNA sequencing to reveal the mechanism of ethylene oxide inducing blood cancers.

Bitian Zhang[1], **William C. Cho**[2], Dongjie Wang[1]

[1]ICM & State Key Lab of Research on Bioactivities & Clinical Applications of Medicinal Plants, The Chinese University of Hong Kong, Hong Kong SAR, China,[2]Department of Clinical Oncology, Queen Elizabeth Hospital, Hong Kong SAR, China

Introduction: During the COVID-19 pandemic, ethylene oxide (EO) was extensively utilized for mask disinfection to curb viral transmission. Despite its efficacy as a disinfectant, EO is a recognized carcinogen associated with an increased risk of leukemia and lymphoma. Understanding the carcinogenic dangers of EO exposure, especially in large-scale mask sterilization, is crucial for public health.
Methods: This study investigated the molecular mechanisms linking EO exposure to the development of leukemia and lymphoma. We employed RNA sequencing data from The Cancer Genomes Atlas to construct prognostic models using LASSO Cox regression, Kaplan-Meier survival analysis, and multivariate survival regression. Key genes associated with each type of cancer were identified. Single-cell RNA sequencing was also utilized to examine gene expression within the tumor microenvironment. Enrichment analyses were conducted to identify the biological pathways involved, and cell-cell interactions, along with transcription factors, were analyzed to elucidate EO-induced oncogenic processes.
Results: Our prognostic models identified two key genes for leukemia - ACKR3 and CCZ1B, and one for lymphoma - DECR2. Survival analysis revealed that high expression levels of ACKR3 (HR = 5.9, p = 1.5e-4) and CCZ1B (HR 0.15, p = 6.1e-5) are significantly associated with prognosis in leukemia patients. For lymphoma, DECR2 (HR = 19.85, p = 1.7e-4) similarly correlated with poorer survival rates. Single-cell RNA sequencing data demonstrated that ACKR3 and CCZ1B are predominantly expressed in monocytes/macrophages within the leukemia microenvironment, while DECR2 is highly expressed in advanced-stage lymphoma. Enrichment analyses indicated that apoptosis and cell cycle regulation pathways were significantly disrupted in both malignancies. Furthermore, critical cell-cell interactions involving ligand-receptor pairs (e.g., CXCL12-CXCR4) and transcription factors SPI1 (p = 0.001) and STAT1 (p = 0.003) were identified as potential mediators of EO-induced oncogenic processes.
Conclusions: Prolonged EO exposure is associated with significant alterations in immune cell function and apoptotic mechanisms, thereby increasing the risk of developing leukemia and lymphoma. The identified prognostic genes and disrupted pathways provide insights into the molecular underpinnings of EO-induced carcinogenesis. These findings highlight the necessity for alternative disinfection methods and the implementation of stricter regulatory measures to mitigate the long-term carcinogenic risks posed by EO.

#5086 Machine learning prediction and single-cell landscape of distant organ metastasis in non-small cell lung cancer.

Zaid Nassar Abu Rjai'[1], Ahmad Majid Bani-Ata[2], Ayah N. AL-Bzour[2]

Introduction: Management of non-small cell lung cancer (NSCLC) depends on the presence and site of distant metastasis. Machine learning (ML) models have shown promise in analyzing clinical and molecular data to predict cancer outcomes and prognosis. Advancements in single-cell RNA sequencing (scRNA) provide deeper understanding of the tumor microenvironment (TME) and in metastasis. We aim to analyze NSCLC metastasis across different organs, investigate the clinical and molecular predictors of distant organ metastasis, and the single-cell landscape driving tumor metastasis.

Methods: We used the cBioportal and the Gene Expression Omnibus (GEO) databases to retrieve clinical and scRNA data from the MSKCC Metastasis Cohort and GSE131907. The MSKCC dataset included 4,601 NSCLC patients with distant organ metastasis to adrenal, bone, CNS/brain, liver, lung, mediastinum, and pleura. Seven random forest classifiers (RFC) were built for each organ metastasis and trained on clinical and genomic features like age, sex, race, histology, overall survival, fraction genome altered (FGA), microsatellite instability (MSI), mutation count, tumor mutational burden (TMB), and tumor purity. Models were evaluated using area under the receiver operating characteristics curve (AUC/ROC), 10-fold cross-validation (CV), accuracy score, and feature importance. Single-cell RNA data was filtered to include primary tumor samples (n=65,702) and brain metastasis (n=28,429) for cell distribution analysis.

Results: Distant metastasis occurred in 3,784 (82%) patients. The most common metastatic sites were lung (41%), bone (38%), pleura (35%), CNS (26%), liver (18%), adrenal gland (12%), and mediastinum (8.7%). The RFC-Mediastinum model showed the highest accuracy (0.89), AUC (0.61), and 10-fold CV (0.90), followed by RFC-Adrenal (0.86, AUC=0.62, 10-fold CV=0.86). The lowest performance was seen in RFC-Lung (0.57, AUC=0.56, 10-fold CV=0.52). The most important predictive features across all models were FGA, MSI, TMB, and mutation count, while histology was the least important. Single-cell analysis revealed that brain metastasis had a predominance of stromal cells, particularly epithelial, compared to primary tumor samples. Primary tumor samples consisted mostly of CD8+ T-cells and macrophages. COL1A1/2 genes were significantly expressed in brain metastatic stromal cells, suggesting extracellular matrix remodeling in the TME.

Conclusion: Our study highlights the potential of ML models in accurately predicting distant organ metastasis in NSCLC. Variations in TME cellular compositions may be driven by complex intercellular communications in metastatic disease.

#5087 Single cell AI-prediction of protein biomarker on novel whole slide unstained blood smear images.
